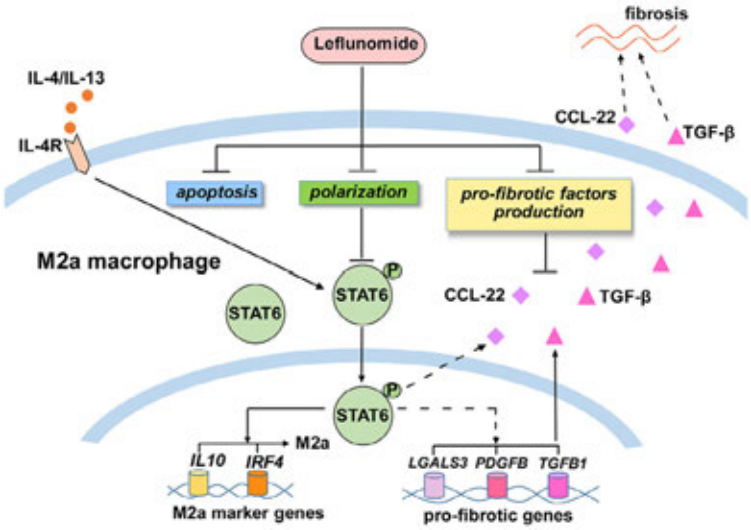
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the efficacy and safety of leflunomide (LEF) for active Chinese Takayasu Arteritis (TA) patients in induction therapy compared with cyclophosphamide (CYC) and in long-term treatment with comparison between new-onset patients and refractory patients who were ineffective or recurrent after CYC treatment. The mechanism of LEF on improving the inflammatory fibrosis in TA by regulating M2 macrophages were also explored.

Methods: Based on the East China TA cohort, a total of 131 patients with active TA who were treated with LEF or CYC were enrolled. The patients were all followed up for 6 months. Their epidemiological data, clinical performance, laboratory data and imaging data at baseline and follow-up were collected for comparison of the efficacy and safety of LEF and CYC. Multivariate analysis was used to compare the response rate of the two groups of patients after 6 months of treatment. Propensity-score matching (PSM) was used to correct the baseline data of the two groups. Fifty-six of patients treated with LEF were further analyzed for their response to treatment after 6 months and 12 months. Among them, 41 patients were treated with LEF since initial visit, and 15 patients were replaced with leflunomide after treatment with CYC. Peripheral blood monocytes of sixteen TA patients were treated with LEF. The ratio of M1/M2 and the apoptosis of M2 were detected by Flow cytometry. The supernatant level of cytokines and chemok-



Leflunomide could regulate the number and function of M2a cells in Takayasu's arteritis through multiple targets, including restriction of M2a polarization by inhibiting STAT6 phosphorylation and reducing expression of IL-10 and IRF4, promotion of apoptosis, inhibition of profibrotic genes expression, as well as reduction of production of profibrotic chemokines. Through these functions, leflunomide could prohibit the involvement of M2a in vascular remodeling.

ines secreted by M2a macrophages were detected by ELISA. The relative expression of profibrotic cytokines mRNA in M2a were detected by real-time PCR. Western Blot was used to measure the phosphorylation of Stat6.

Results: Patients in the LEF group were younger and had higher erythrocyte sedimentation rate (ESR) compared with CYC group. After 6 months of treatment, the clinical remission rate of LEF group was not inferior to CYC group. The overall clinical remission rate of patients treatment with LEF was 67.9% after 6 months of treatment, and 55.4% after 12 months. The level of ESR, C-reactive protein (CRP) and NIH scores decreased significantly after 12 months of LEF treatment. Patients who reacted as resistance to CYC achieved clinical remission in more than half of them after 6 and 12 months of LEF therapy. In addition, during the 12-month follow-up, most patients treated with LEF had well drug tolerance and a low incidence of adverse reactions. LEF could inhibite M2 polarization by curtailing STAT6 phosphorylation. LEF could also promote apoptosis of M2 and reduce the release of M2-derived CCL22 as well as the expression of profibrotic cytokines including CCL22 and TGF-β in M2.

Conclusion: LEF has comparable efficacy to CYC for induction of remission in active TA. Treatment with LEF in TA can achieve clinical remission in a short period of time, and maintain long-term stability of the disease, especially for refractory patients. LEF presents safety for women of childbearing age, and can be used for long-term treatment of patients with TA. LEF could reduce vascular fibrosis potential by down-regulating number and function of M2, which, eventually, could alleviate inflammatory fibrosis of aortic lesions in TA patients.

The Clinical and Angiographic Features of Chinese Takayasu's Arteritis Patients: A Cohort Study of 591 Patients in 6 Years

Yunjiao Yang,[1] Jing Li,[2] Xinping Tian,[1] and Xiaofeng Zeng[1], [1]Peking Union Medical College Hospital, Beijing, China (People's Republic), [2]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Sciences & Peking Medical College, Beijing

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the clinical and angiographic features of 591 Chinese Takayasu's arteritis (TAK) patients

Methods: Clinical and angiographic findings of 591 Chinese TAK patients enrolled in the Chinese Registry for Systemic Vasculitis (CRSV) from 2013 to October 31 of 2018 were collected. The vascular involvement were analyzed by Dendrogram using Ward Linkage.

Results: Clinical manifestations included Systemic manifestation in 66.2%, mucocutaneous abnormalities in 15.2% , sign and symptoms of peripheral vessels in 92.9%(as showed in Figure 1), abnormalities of central nervous system in 57.2%(56 patients suffered from stroke), vision loss in 11.2%,hypertension in 46.1% and abnormalities of renal

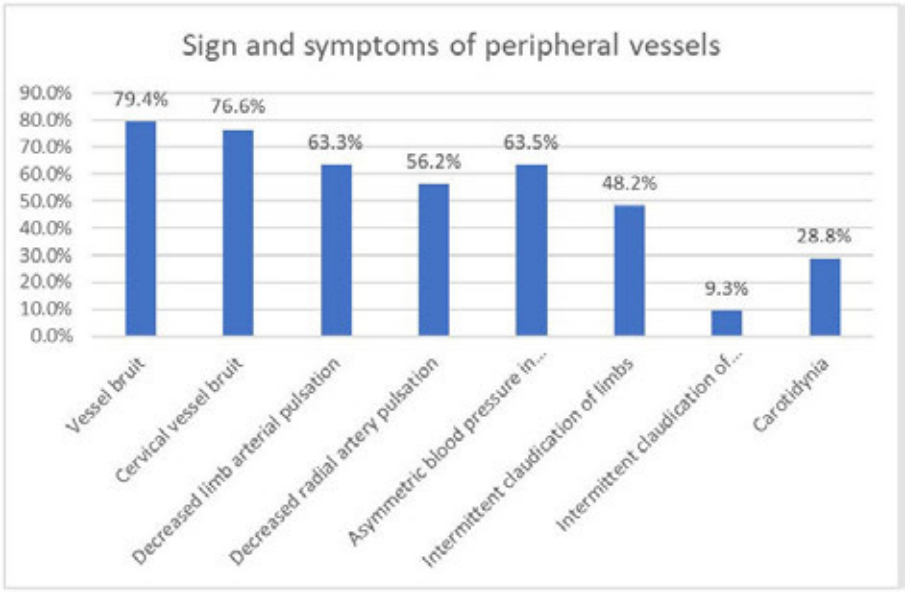

Figure 1. Sign and symptoms of peripheral vessels.

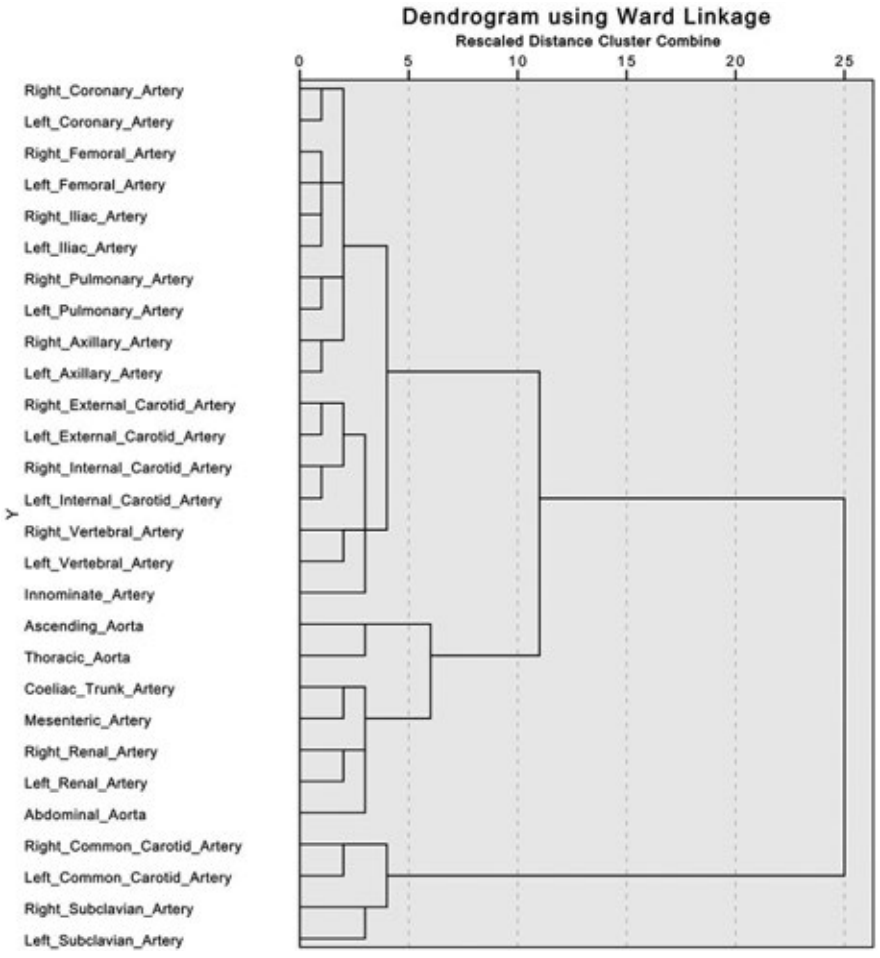

Figure 2. The clustering analysis of arterial involvement.

arteries in 35.5% of the patients. Meanwhile,28.1% of patients underwent angioplasty during the course of disease. The clustering analysis of arterial involvement was showed in figure 2.

Conclusion: The clinical and angiographic findings of TAK patients in China were different to those reported from other countries. We should pay more attention to the uniqueness of Chinese patients with Takayasu arteritis.

Application of Different Sets of Classification/diagnostic Criteria for Polymyalgia Rheumatica: Single Center Study of 100 Patients

Diana Prieto-Pena,[1] Mónica Calderón-Goercke,[2] Iñigo Gonzalez-Mazon,[1] Jose Luis Martín-Varillas,[3] Lara Sanchez-Bilbao,[3] Belén Atienza-Mateo,[3] Miguel Angel González-Gay,[4] and Ricardo Blanco[3], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [2]Hospital Marqués de Valdecilla, Santander, Cantabria, Spain, [3]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [4]Universidad de Cantabria and IDIVAL, Hospital Universitario Marqués de Valdecilla, Santander, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) diagnosis is based on clinical and analytical features characterized by shoulder and pelvic girdle pain associated with elevated acute phase reactants. Traditionally, Bird et al. and Chuang et al. criteria have been used for establishing PMR diagnosis. In 2012 an international working group developed new European League Against Rheumatism (EULAR)/American Collegue of Rheumatology (ACR) classification criteria for PMR. Purpose: a) To compare the performance of Bird et al., Chuang et al. and 2012 EULAR/ACR classification criteria for PMR in a single-center study. b) To describe the characteristics of the patients excluded by these criteria.

Methods: We included 100 patients with new-onset PMR who were consecutively diagnosed over a 7-year period in a referral center by experienced rheumatologists. PMR diagnosis was confirmed during a prospective 24-month follow-up after excluding other mimicking conditions. Rheumatoid factor (RF) and anticitrullinated protein antibodies (ACPA) were determined in all patients. Subjects were classified by each of the three different criteria.

Results: We studied 100 patients (61 women/39 men); mean age 67.1 ± 10.2 years. 96% of the patients fulfilled Bird et. al criteria, 94% fulfilled Chuang et al. criteria and 84% of the patients fulfilled 2012 EULAR/ACR criteria (TABLE 1, 2 and 3). We assessed the characteristics of the 16 patients who did not fulfilled 2012 EULAR/ACR criteria: 6 of them were under 50 years of age (range age 43-48 years). Another 10 patients did not complain of pain/stiffness in the shoulder girdle at any time. However, they presented a predominance of inflammatory pelvic girdle pain and elevated acute phase reactants.

Conclusion: In our single-center experience we found that 2012 EULAR/ACR criteria classified most of our patients. However, patients who presented predominant pelvic girdle affection and those who were under 50 years old despite showing all the rest of clinical and analytical required items were excluded. Some of these patients fulfilled Bird and/or Chuang criteria.

TABLE 1. 2012 ACR/EULAR CLASSIFICATION CRITERIA

Age at onset ≥ 50 years (required)	94/100	94%
Bilateral shoulder aching (required)	89/100	89%
Abnormal CRP and/or ESR (required)	96/100	96%
Morning stiffness duration > 45 min (2 points)	54/100	54%
Hip pain or limited range of motion (1 point)	90/100	90%
Absence of RF or ACPA (2 points)	100/100	100%
Absence of other joint involvement (1 point)	95/100	95%
Required for classification: score of 4 or more	**84/100**	**84%**

TABLE 2. CHUANG ET AL. CRITERIA (1982)

Age at onset ≥ 50 years (required)	94/100	94%
ESR ≥ 40 mm/hr	96/100	96%
Bilateral aching for ≥ 1 month involving two of the following areas:		
- Neck	47/100	47%
- Shoulders or proximal regions of the arms	89/100	89%
- Hips or proximal aspects of the thighs	90/100	90%
Exclusion of all other diagnosis of mimicking entities	100/100	100%
All criteria are required for classification	**94/100**	**94%**

TABLE 3. BIRD/WOOD CRITERIA (1979)

Age at onset > 65 years	59/100	59%
ESR > 40 mm/hr	96/100	96%
Bilateral shoulder pain/stiffness	89/100	89%
Duration onset < 2 weeks	77/100	77%
Stiffness > 1 h	54/100	54%
Depression and/or weight loss	16/100	16%
Bilateral upper arm tenderness	89/100	89%
Probable: 3 or more	**96/100**	**96%**

Predictors of Long-term Therapy with Glucocorticoid in Polymyalgia Rheumatica

Akiko Aoki,[1] Hiroshi Kobayashi,[1] and Hiroshi Oka[1], [1]Tokyo Medical University Hachioji Medical Center, Hachioji, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical symptoms of polymyalgia rheumatica (PMR) are improved by low-dose glucocorticoids (GC), but relapses and long-term GC therapy are common. 2015 EULAR/ACR recommendations suggest early introduction of methotrexate (MTX) in addition to GC, particularly in patients at a high risk for relapse and/or prolonged therapy. However, risk factors for prolonged therapy are not clear yet. We investigated predictive factors which corresponded to the long-term GC therapy.

Methods: This was a retrospective study in a single general hospital in Japan. We reviewed the medical records of 96 Japanese patients with PMR between April 2011 and May 2019. Diagnosis of PMR was based on Bird's criteria or 2012 EULAR/ACR Classification Criteria. All patients were treated with prednisolone (PSL) according to the BSR and BHPR guidelines. Patients treated with MTX and accompanied by the giant cell arteritis were excluded from this study. Relapse was defined as the reappearance of symptoms associated with elevated C-reactive protein (CRP) levels in patients receiving GC. Remission was defined as the absence of clinical symptoms and normal CRP with discontinuation of GC. We compared the clinical findings, laboratory data at baseline and clinical course between those who achieved remission within 2 years (early-remission group; n=38) and those who required GC therapy for more than 2 years (long-therapy group; n=16). Comparisons between groups was made using Student's t-test and chi-square test (IBM SSPE statistics version 25).

Results: 54/96 (56%) were women. The mean age at diagnosis was 75 (SD 16.0). As of May 2019, 46 patients have achieved a remission, 32 were undergoing treatment, and 18 have transferred to other hospitals or died (Table 1). The median duration of GC therapy of patients who have achieved remission was 18.5 months. Remission was achieved

Table 1 Summary of patients with diagnosis with PMR

		Duration of GC therapy	
		less than 2 years	more than 2 years
Remission	n=46	38	8
Under treatment	n=32	26	6
Changing hospital or death	n=18	16	2

Relapse: times	mean (SD)	0.4	(0.72	)	2.9	(1.86	)	<0.01
Relapse till 6 months	n (%)	3	(7.9	)	7	(73.8	)	<0.01

PSL, predonisolone; GC, glucocorticoid; SD, standard deviation

Table 2. Clinical findings in patients of 2 groups

in 16% (11/69) after one-year GC therapy, and 70% (38/54) after two-year GC therapy. There were no differences in sex, age, and or clinical features at diagnosis. Body-mass index and lymphocyte% were lower, and CRP was significantly higher in the long-therapy group (Table 2). Multivariate logistic regression analysis showed that history of relapse till 6 months was a significant predictor of long-term GC therapy (odds ratio, 9.07; 95%CI 1.949-42.248).

Conclusion: According to GCs therapy guidelines, the remission rate in our hospital is not low. However, some patients need the long-term therapy for more than 2 years. We might consider additional MTX therapy in patients who experience a relapse during the first six months.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Large-vessel vasculitis (LVV) is characterized by inflammation of the aorta and its major branches. The most common forms of LVV include giant cell arteritis (GCA) and Takayasu's arteritis (TAK). No standardized set of outcome measures currently exist to evaluate treatment response in patients with LVV. Various outcome domains have been proposed for LVV, including patient-reported outcomes (PROs), physician assessment of disease activity, vascular imaging, and laboratory assessment. However, data examining the relationships between these domains is limited. The objective of the current study was to assess the relationship structure between patient, physician, imaging, and laboratory-based outcome measure domains in patients with LVV.

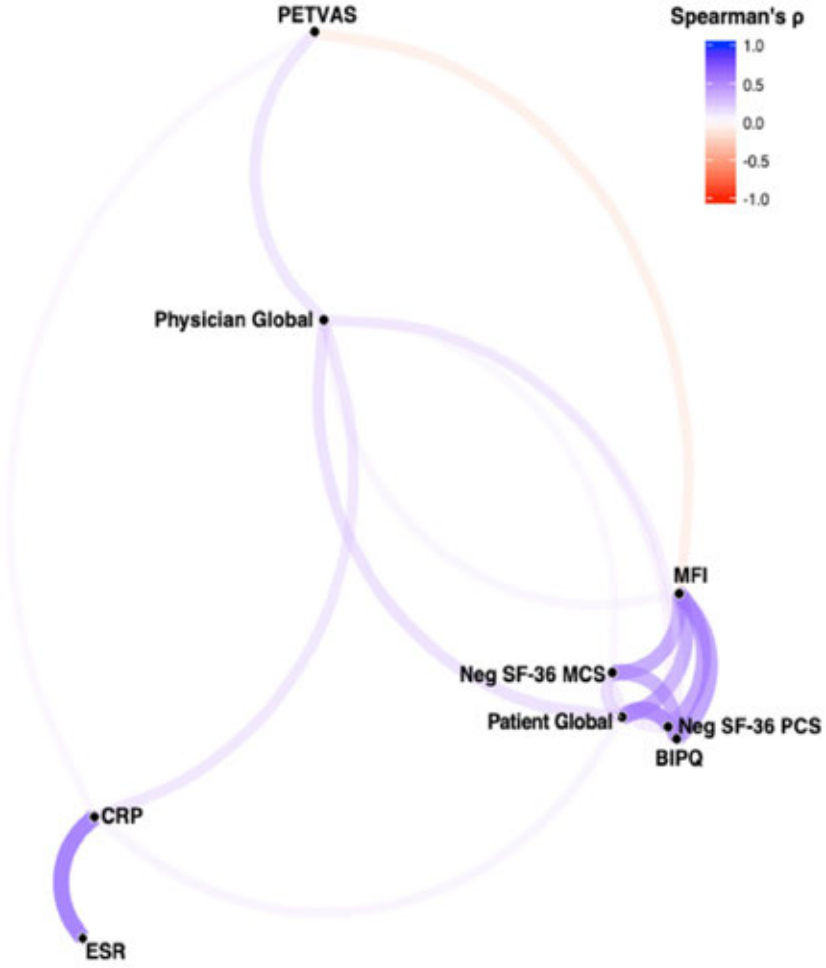

Figure. Correlation network of outcome measure domains in patients with LVV. Correlation network of the significant Spearman ρ correlation coefficients ($p<0.05$) between outcome measures created using the R package corrr. Color and thickness of the edges between nodes indicates the strength of the correlation. Nodes for each outcome measure are clustered in space using multidimensional scaling of the absolute values of the correlations, such that outcome measures with the highest overall magnitude of correlation with each other are closer in space. For ease of visualization, the SF-36 PCS and MCS measures were multiplied by -1 so that a higher score would indicate a worse outcome. MFI= Multidimensional fatigue inventory; BIPQ= brief illness perception questionnaire; Neg SF-36 PCS= negatively transformed 36-item short form health survey physical component summary score; Neg SF-36 MCS= negatively transformed 36-item short form health survey mental component summary score; CRP= c-reactive protein; ESR= erythrocyte sedimentation rate; PETVAS= qualitative score of vascular FDG-PET activity.

Methods: Patients fulfilling the ACR 1990 criteria for the classification of TAK or the modified ACR 1990 criteria for the classification of GCA were recruited into a prospective, observational cohort. Assessments within the following domains were independently recorded: patient-reported outcomes [multi-dimensional fatigue inventory (MFI); patient global assessment (PtGlobal); 36-item short form health survey (SF-36); brief-illness perception questionnaire (BIPQ)], physician global assessment (PhGlobal), acute-phase reactants (CRP, ESR), and imaging assessment (PET-VAS, a qualitative score of vascular FDG-PET activity). To visualize the relationship between domains, Spearman's correlation network analysis was performed. This analysis enables visualization of the strength and directionality of correlations and clusters variables most correlated to one another. Change over time in outcome measures was compared using the Wilcoxon signed rank test in patients with a change in clinical status from active disease (PhGlobal >0) to remission (PhGlobal=0) or from remission to active disease. Multivariable nominal logistic regression was performed to determine the outcome measures associated with clinically active disease.

Results: Analyses were performed on 112 patients (GCA=56, TAK=56), over 296 visits, with a median follow-up interval of 6 months. Correlation network analysis revealed outcome measures clustered independently and by specific domain (**Figure**). PhGlobal was centrally linked to all other domains, but correlations were modest (ρ=0.12 – 0.31, $p < 0.05$). All four PROs strongly correlated with each other (ρ=0.35-0.60, $p < 0.0001$). PROs were not correlated with PETVAS and only PtGlobal correlated with CRP (ρ=0.16, $p< 0.01$). Patients whose clinical assessment changed from active disease to remission (n=29) had corresponding significant decrease in ESR, CRP, and PETVAS at the remission visit. Patients whose clinical assessment changed from remission to active disease (n=11) had corresponding significant increase in CRP and PtGlobal at the active visit. PETVAS, CRP, and PtGlobal were independently associated with clinically active disease in regression analyses.

Conclusion: Measures of disease assessment in large-vessel vasculitis consist of independent, yet complementary domains, supporting the need to develop multidimensional and/or composite outcome measures, or a standard set of measures covering all domains.

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

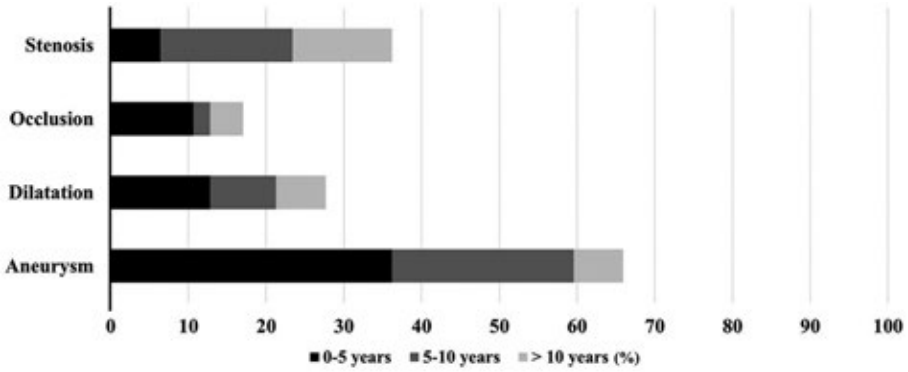

Figure 1. Pattern of arterial lesions in BD patients according to the symptom onset (n = 47).

Background/Purpose: Arterial involvement is a manifestation of systemic vasculitis in Behçet's disease (BD). Changes to BD arterial lesions over time can help predict patient prognosis. Few reports have been published, however, on arterial lesion during time courses in BD patients. We evaluated the angiographic patterns and changes to arterial lesions in BD patients.

Methods: We retrospectively reviewed BD patients with arterial lesions from January 1995 to December 2015. Arterial lesion patterns were categorized as stenosis, occlusion, dilatation, or aneurysm. Patients were divided into three groups by length of time (0-5 years, 5-10 years, and >10 years) of symptom duration before BD with arterial involvement diagnosis. Progression of arterial lesions was assessed by follow-up imaging. The Cox proportional hazards model was used to evaluate hazard ratios (HR) with a 95% confidence interval (CI) for arterial lesion progression.

Results: For 45 BD patients with arterial involvement, 99 total arterial lesions were observed as follows: stenosis (n = 27), occlusion (n = 9), dilatation (n = 19), and aneurysm (n = 44). Aneurysm was the most common angiographic lesion in 17 patients (36.2%), whereas only 3 patients (6.4%) had stenosis within five years of symptom onset (Figure 1). In patients with a symptom duration of 10 years or more, however, stenosis (n = 6, 12.8%) was most frequently observed, followed by aneurysm (n = 3, 6.4%). In 23 patients who underwent follow-up imaging (median 5.7 [IQR 2.8-7.5] years), 11 new lesions were detected in 8 patients (8/23; 34.8%) as follows: stenosis (n = 5), occlusion (n = 0), dilatation (n = 1), and aneurysm (n = 5). One of the 14 stenoses progressed to occlusion, and 2 of the 12 dilated lesions progressed to aneurysm. In multivariable analyses, arterial lesion progression was significantly associated with hypertension (HR 4.26, 95% CI 1.08-16.87, p = 0.039) and arterial involvement in a lower extremity (HR 5.44, 95% CI 1.09-27.10, p = 0.039).

Conclusion: In BD with arterial involvement, aneurysm was most often observed in early stages (symptom duration ≤ 5 years), while stenosis was more often observed during later stages (symptom duration > 10 years). Hypertension and arterial involvement in a lower extremity were found to be risk factors for arterial lesion progression.

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: As a large-vessel vasculitis of young-age group, Takayasu's arteritis (TAK) have a high morbidity and mortality caused by the disease or treatments such as corticosteroids. In this study we aimed to evaluate the damage in our Takayasu's arteritis patients by using Vasculitis Damage Index (VDI) and Takayasu's Arteritis Damage Score (TADS).

Methods: Takayasu arteritis patients fullfilling the ACR 1990 criteria and had >6 months follow-up were enrolled in this single-center study retrospectively. Data was collected from patients charts. TADS and VDI scores at diagnosis and at the end of the follow-up were evaluated and compared with baseline damage. Variables associated with damage scores were evaluated.

Any relapse	1.11 (0.52-2.37)	0.77	-	-
Number of relapses	0.98(0.65-1.49)	0.95	-	-

**Only variables with a p value of 0.2 in univariable analysis were involved in multivariable analysis*

Results: One-hundred fourteen patients (F/M: 101/13) were included in the study. The mean age at diagnosis, median symptom duration at baseline visit and mean follow-up duration were 35.3±13.3 years, 12 (0-360) months and 76.9 ± 51.4 months, respectively. Median VDI score was 4 (1-8) and median TADS score was 7 (1-15) at baseline assessment. At the end of the follow-up median VDI score was 5.0 (1-17) and median TADS score was 8.0 (1-19). Median ΔTADS was 1 (0-9) and ΔVDI was 1 (0-11). The median number of disease-related items were higher in TADS scoring (8 items vs 4 items). At least 1 new corticosteroid-related damage item occured in 35 patients (31%) (Figure 1). Age at symptom onset and cumulative CS doses were predictor factors for higher VDI score (≥5) in multivariate logistic regression analysis. Also age at symptom onset and disease duration were associated with increase in TADS (≥8). Gender and any relapse or number of relapses were not found to be associated with damage scores (Table 1).

Conclusion: In Takayasu arteritis, detecting the disease- and treatment-related part of damage must be considered while monitoring the disease. VDI seems to be predominantly evaluating the treatment-related damage, whereas TADS provides more detailed information on disease-related damage. Older age at symptom onset, disease duration and cumulative CS dose were associated with higher damage scores. Interestingly, the relapse frequency did not influence the damage level in our routine-follow-up of TAK patients.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

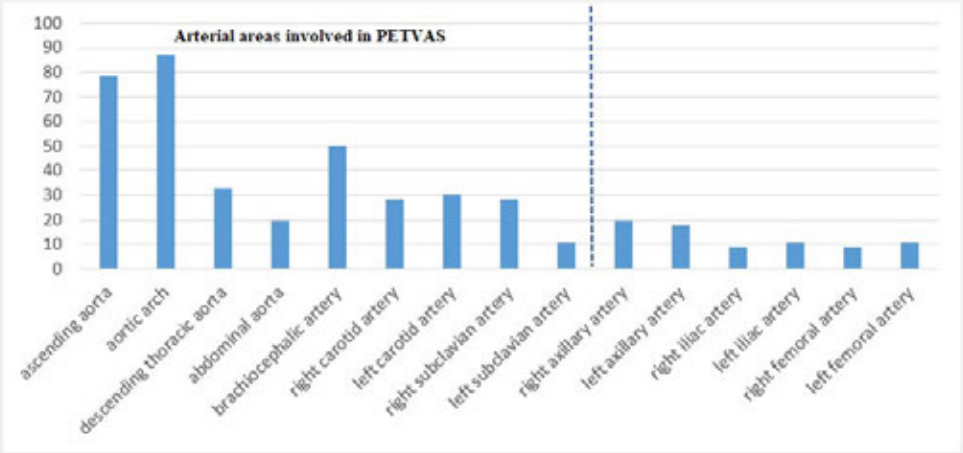
Background/Purpose: FDG-PET-CT is recommended as one of the imaging modalities for the diagnosis and monitoring of primary large-vessel vasculitis (LVV), such as Takayasu's arteritis (TAK). Interpretation of FDG uptake is based on the principle of determining the inflammatory metabolic activity in the vessel wall in LVV. However, vascular uptake due to atherosclerosis may be a contributing factor in PET-CT assessment. In this study we aimed to evaluate the characteristics of patients with and without involvement of arteries other than the 9 arteries used for assessing PET Vascular Activity Score (PETVAS), which is developed to determine LVV activity in most-commonly involved arterial areas.

Methods: Patients fulfilling ACR1990 classification criteria for TAK and underwent PET-CT imaging were evaluated retrospectively. Demographic and clinical data were collected from patients' charts. Traditional cardiovascular risk factors: diabetes, hypertension, hyperlipidemia, smoking history and body mass index (BMI) were evaluated. Nine arterial areas used for assessing PETVAS were ascending aorta, aortic arch, descending aorta, abdominal aorta, right and left carotid arteries, innominate artery, right and left subclavian arteries, as originally suggested. Bilateral axillary arteries and iliofemoral arteries were evaluated as atypical (extra-PETVAS) involvement.

Table1. Cardiovascular risk factors in patients with and without atypical arterial involvement

	Patients with involvement in only PETVAS arteries (n=21)	Patients with atypical arterial involvement (n=10)	p value
Age, years	33.8±9.6	51.3±16.6	**0.008**
Diabetes, n (%)	1 (5)	1 (10)	0.57
Hypertension, n (%)	7 (35)	6 (60)	0.25
Hyperlipidemia, n (%)	3 (15)	5 (50)	0.07
Smoking, n (%)	5 (25)	6 (60)	0.10
BMI, kg/m²	22.8±3.6	23.1±3.9	0.72

Figure 1. Distribution of vascular FDG uptake in Takayasu's arteritis patients



Results: 46 imagings of 34 patients (F/M:28/6) were evaluated. Mean disease duration was 9.3 ±6.5 years and mean age was 40.5± 15.1 years. In the majority of patients aortic arch (87%) was involved followed by ascending aorta (78%) and brachiocephalic artery (50%)(Figure 1). At least one arterial area was involved in 43 images. In 28% of these imagings (12/43), a PET involvement of an artery other than the arteries used for assessing PETVAS, were observed. The mean age of this group was higher than the rest of the group (51.0±16.6 vs 35.8±11.9 years, p=0.01). The number of involved arterial areas (8.5±4.0 vs 3.2±1.5, p=0.000) and total PETVAS scores (10 (2-27) vs 4 (1-17), p=0.013) were higher in atypical arterial involvement group. These patients were also more likely to have the cardiovascular risk factors (Table 1). Patients who had at least 2 cardiovascular risk factors had atypical arterial involvement more frequently (60% (6/10) vs 19% (4/21), p=0.03).

Conclusion: Patients with atypical arterial involvements in PET-CT may have increased atherosclerotic risk factors. These patients had more extended arterial involvement, implying that chronic vascular inflammation may be enhanced by atherosclerosis. Our results suggest that anti-atherosclerotic approaches should be implemented more vigourously in TAK patients.

Von Willebrand Factor Is Localized in the Extravascular Tissue of Patients with Juvenile Scleroderma

Natalia Vasquez-Canizares,[1] Beamon Agarwal,[2] Tamar Rubinstein,[3] Dawn Wahezi,[4] and Morayma Reyes Gil[5], [1]Children's Hospital at Montefiore, Bronx, NY, [2]GenomeRxUS LLC, Providence, PA, [3]Children's Hospital at Montefiore/Albert Einstein College of Medicine, Bronx, NY, [4]Children's Hospital at Montefiore, New York, [5]Montefiore Medical Center/Albert Einstein College of Medicine, Bronx

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Von Willebrand Factor (VWF) is a glycoprotein synthesized in endothelial cells and megakaryocytes that has an essential role in primary hemostasis. There is increasing evidence indicating that VWF is involved in inflammation and may play a role in the pathogenesis of fibrosing and cutaneous inflammatory conditions. Our objective was to study the role of VWF in the pathogenesis of skin manifestations of patients with Juvenile Scleroderma (JScl) compared to those with Juvenile Dermatomyositis (JDM). We hypothesize that patients with JScl have increased VWF expression in the extravascular tissue as compared to those with JDM. Since JScl patients have increased collagen deposition in the subcutaneous matrix, and VWF binds collagen, we also hypothesize that VWF colocalize with collagen in the subcutaneous matrix

Methods: We examined 11 skin biopsies from 4 patients with systemic sclerosis (SSc), 3 with localized scleroderma (LS) and 4 with JDM. Double immunofluorescence staining was performed in each tissue with antibodies against vWF and collagens type I and III. DAPI (4′, 6-diamidino-2-phenylindole) was also used for counterstaining of inflammatory cells. Tissue staining patterns were compared between groups

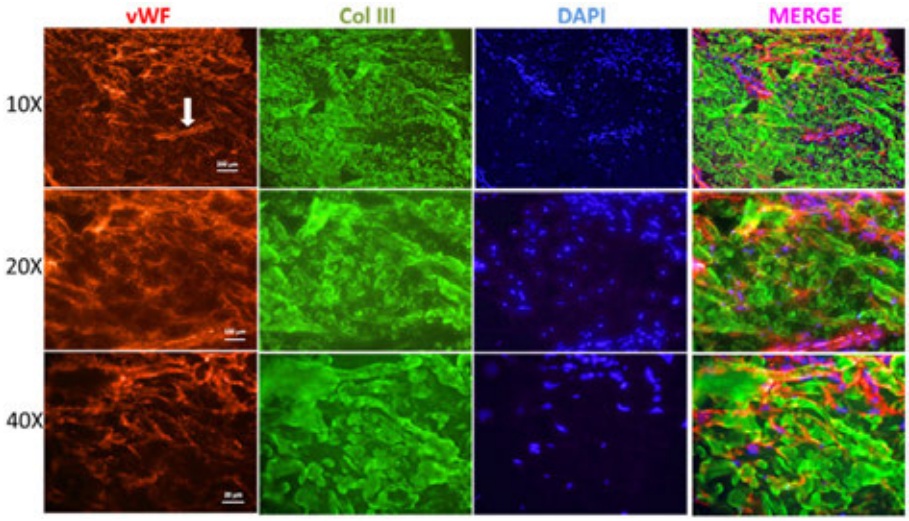

Figure 1. Double Immunofluorescence staining for VWF and collagen III in the skin of a patient with diffuse SSc. Cuts of the reticular dermis are shown at different magnifications. There is evidence of increased collagen expression (green) throughout the reticular dermis that diffusely co-localize with increased expression of VWF (red). Vessels (arrow) stain at higher intensity due to the presence of VWF in the subendothelium. There is also a superficial and deep perivascular inflammatory cell infiltrate (blue) co-localizing with VWF in areas of higher VWF expression.

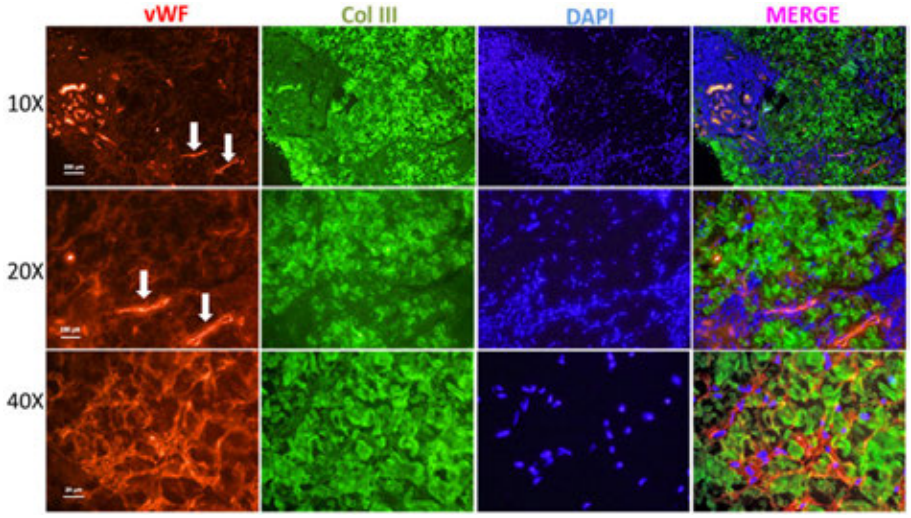

Figure 2. Double Immunofluorescence staining for VWF and collagen III in the skin of a patient with LS. Cuts of the reticular dermis are shown at different magnifications. There is increased collagen expression (green) that co-localizes with VWF (red). Vessels (arrow) stain at higher intensity due to the presence of VWF in the subendothelium. Superficial and deep perivascular, and interstitial inflammatory cell infiltrate is also found (blue) co-localizing with VWF in areas of higher VWF expression.

Results: Biopsies were obtained from the upper extremity of 10 females and the lower extremity of 1 male. Mean age and median disease duration from the first presenting symptom at time of biopsy was 8.8 years (SD 4.5) and 7 months (IQR 3-8), respectively. Seven patients had elevated levels of VWF in serum around time of biopsy (median 221%, IQR 101-282). All but 1 biopsy was performed prior to initiation of immunosuppressive therapy. Immunofluorescence staining showed a superficial and deep perivascular inflammatory cell infiltrate that co-localized with VWF in all tissues. There was expression of VWF in the extravascular tissue of patients with JScl co-localizing with collagen III in the reticular dermis (Figures 1 and 2). In comparison, VWF expression did not co-localize with collagen in the dermis of patients with JDM (Figure 3). Patients with SSc had higher expression of VWF as compared to patients with LS

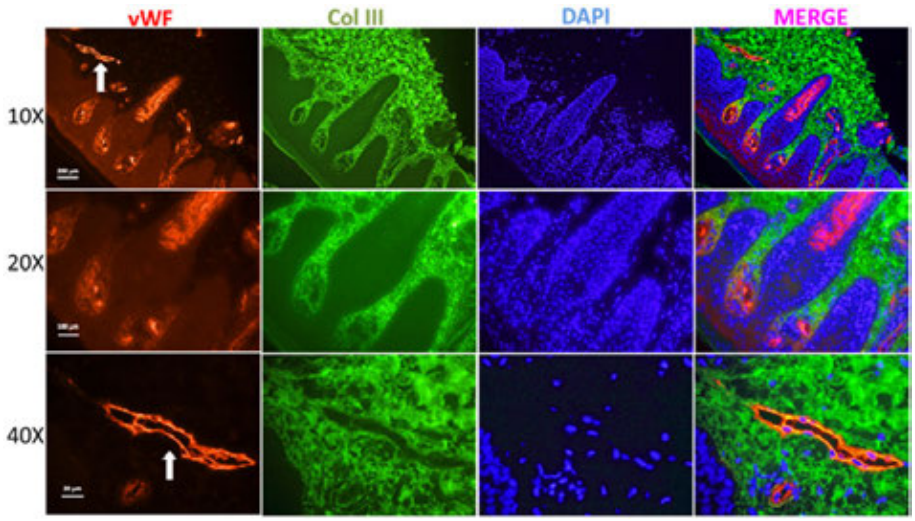

Figure 3. Double Immunofluorescence staining for VWF and collagen III in the skin of a patient with JDM. Cuts of the reticular and papillary dermis are shown at different magnifications. Expression of collagen III (green) is seen in the reticular dermis without co-localizing with VWF (red). Vessels (arrow) stain at higher intensity due to the presence of VWF in the subendothelium. There is an inflammatory infiltrate at the dermal papillae and at the periphery of the vessels that co-localizes with VWF.

Conclusion: VWF may participate in the pathogenesis of cutaneous inflammatory conditions. We have demonstrated that VWF co-localizes with cellular inflammatory infiltrates in the perivascular areas and in the dermis of patients with JScl and JDM. We additionally speculate that VWF may participate in the pathogenesis of fibrosing skin diseases based on evidence of increased extravascular expression in the tissue of patients with JScl (vs. JDM), and its co-localization with collagen. VWF expression intensity in the dermis of JScl patients may relate to extent of disease (SSc vs. LS)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: TNF Receptor-Associated Periodic Syndrome (TRAPS) is one of the autoinflammatory diseases. TRAPS is caused by heterozygous mutations in *the TNFRSF1A* gene. Although more than 100 *TNFRSF1A* mutations have been reported, only a few mutations such as T79M have been shown as TRAPS mutations. Previous studies suggested that mutant TNFR1 accumulates in the endoplasmic reticulum (ER), resulting in inflammatory responses owing to excessive ER stress. Reflecting the mechanism, the cell surface expression of T79M TNFR1 has been previously shown to be decreased. Recently, we have identified two TRAPS patients with a novel G87V mutation. In this study, we examined the effects of the novel G87V mutation using a cell model by comparing with the T79M mutation and low-penetrant mutations (R121Q, T90I).

Methods: Wild-type (WT) or mutant *TNFRSF1A* (G87V, T79M, R121Q, T90I) constructs were transfected into HEK-293 cells. The cell surface and intracellular expression levels were determined by flow cytometry. To examine the effect of G87V mutation in the patients, we measured the mitochondrial reactive oxygen species (ROS) in the peripheral blood mononuclear cells (PBMCs) of the patients and healthy donors. To evaluate the susceptibility to various inflammatory stimuli, PBMCs from TRAPS patients and healthy donors were treated with Toll-like receptor (TLR) ligands. Cytokine and chemokine profiles in the supernatant were determined by the Milliplex Human Cytokine/chemokine magnetic bead premixed 29-plex kit.

Results: The cell surface expression of TNFR1 was decreased in the G87V and T79M mutant cells compared to WT TNFR1-transfected cells. In contrast, the R92Q and T90I mutations did not suppress the cell surface expression of TNFR1. Mitochondrial ROS levels were increased in both monocytes and lymphocytes from TRAPS patients compared to those in cells from healthy individuals. In cytokine assay, PBMCs from the TRAPS patients tended to produce a larger amount of IL-6 in response to a low concentration (0.1 ng/ml) of LPS (TRAPS patient 1973.0 ± 923.4 pg/ml vs. healthy individual 46.9 ± 25.2 pg/ml). FSL-1 (TLR2/6 ligand) stimulation enhanced IL-8 production in the TRAPS PBMCs compared to that in control PBMCs (TRAPS patient 6604.8 ± 1325.0 pg/ml vs. healthy individual 3777.2 ± 2104.2 pg/ml, $p< 0.05$). Additionally, we found increased production of GM-CSF in response to LPS in the TRAPS PBMCs (TRAPS patient 45.6 ± 21.4 pg/ml vs. healthy individual 17.4 ± 10.9 pg/ml, $p< 0.05$). However, the secretion of IL-1α, IL-1β, and TNF in the TRAPS PBMCs was not increased.

Conclusion: The G87V TNFR1 was not expressed on the cell surface, similar to the pathogenic T79M mutation. The TLR2/6 ligand and cytokines (IL-8 and GM-CSF) are suggested to be involved in the pathophysiological mechanism underlying TRAPS. Our findings obtained from patients harboring unique mutations provide novel insight for better understanding of the inflammatory responses of TRAPS.

Chondrocytes Influence Fibroblast-like Synoviocytes from Patients with Juvenile Idiopathic Arthritis, Through the Abrogation of TGFβ Signaling, to Delay Cell Differentiation and Maturation

Megan Simonds,[1] Amanda Schlefman,[1] Suzanne McCahan,[1] Kathleen Sullivan,[2] Carlos Rose,[3] and **AnneMarie Brescia**[3], [1]Nemours Biomedical Research, Wilmington, DE, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Nemours/ Alfred I DuPont Hospital for Children, Wilmington, DE

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Progression of Juvenile Idiopathic Arthritis (JIA) can lead to growth disturbances in affected joints. Fibroblast-like synoviocytes (FLS) play a key role in the pathogenesis of JIA; however, the mechanisms of communication between FLS and growth plate chondrocytes is not well described. We have previously shown that JIA FLS overexpress BMP4, which promotes chondrocyte hypertrophy during endochondral bone formation (EBF) [1,2]. We examined the influence of chondrocytes (Ch) on diseased FLS to establish a possible mechanism for the bony overgrowth seen in JIA.

Methods: RNA was collected from three control FLS (CFLS) and JIA FLS (JFLS) cell lines cultured in their respective media at 6 and 24 hours. Concurrently, RNA was collected from three CFLS and JFLS cell lines cultured in conditioned media from Ch (CFLS-Ch and JFLS-Ch). Clariom S microarray was performed and log ratios of fold change over time calculated using linear expression.

Results: JFLS favor TGFβ signaling via an increase in Smad2 expression over BMP related genes (BMPR1a and BMP2) when compared to CFLS (Fig 1A). When exposed to chondrocyte-conditioned media, CFLS-Ch downregulate BMP-related genes (Smad5, Smad7, BMPR1b, BMP2, and GDF5) compared to untreated CFLS (Fig 1B). TGFβ-induced gene is significantly downregulated in JFLS-Ch compared to untreated JFLS (Fig 1C). Untreated JFLS overexpress genes related to proliferating/prehypertrophic chondrocytes (MMP9, MMP12, PCNA) than genes expressed during hypertrophy (VEGFA and SPP1) (Fig 2A). Both CFLS-Ch and JFLS-Ch express genes of chondroprogenitor

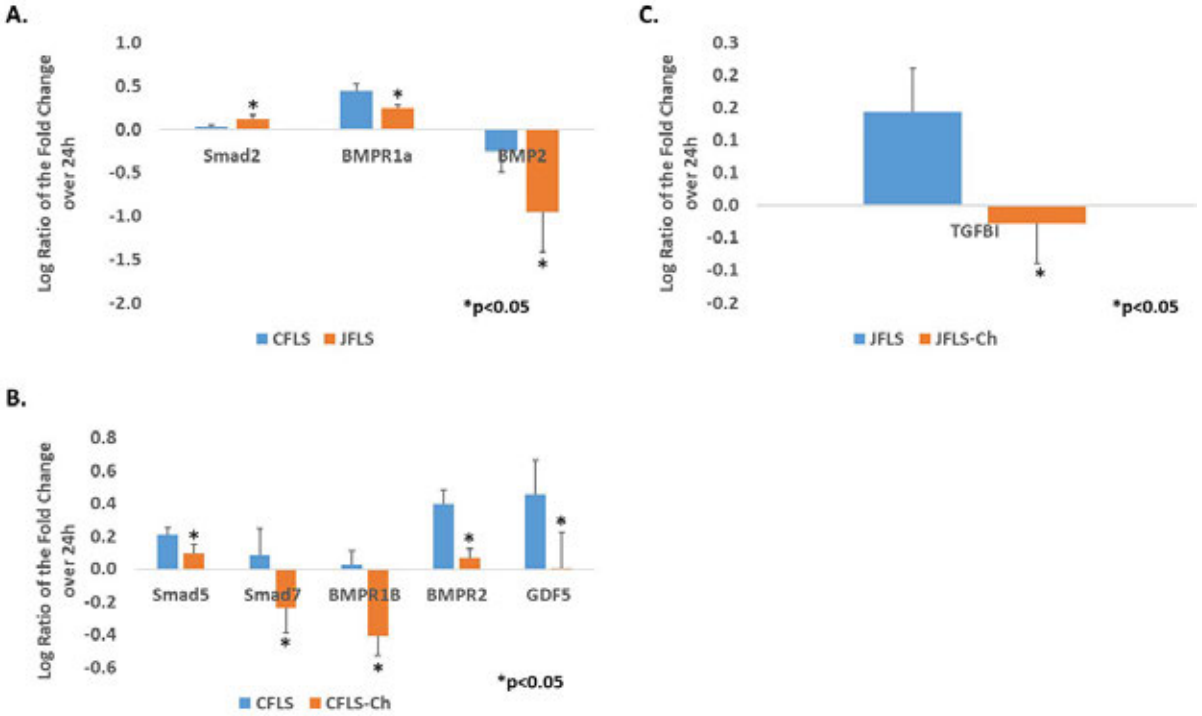

Figure 1. Log ratio of fold change in gene expression of TGFbeta/BMP genes over 24 hours. A. untreated control FLS (CFLS) and JIA FLS (JFLS). B. untreated CFLS compared to CFLS exposed to chondrocyte conditioned media (CFLS-Ch). C. untreated JFLS compared to JFLS exposed to chondrocyte conditioned media (JFLS-Ch) (*p-value<0.05)

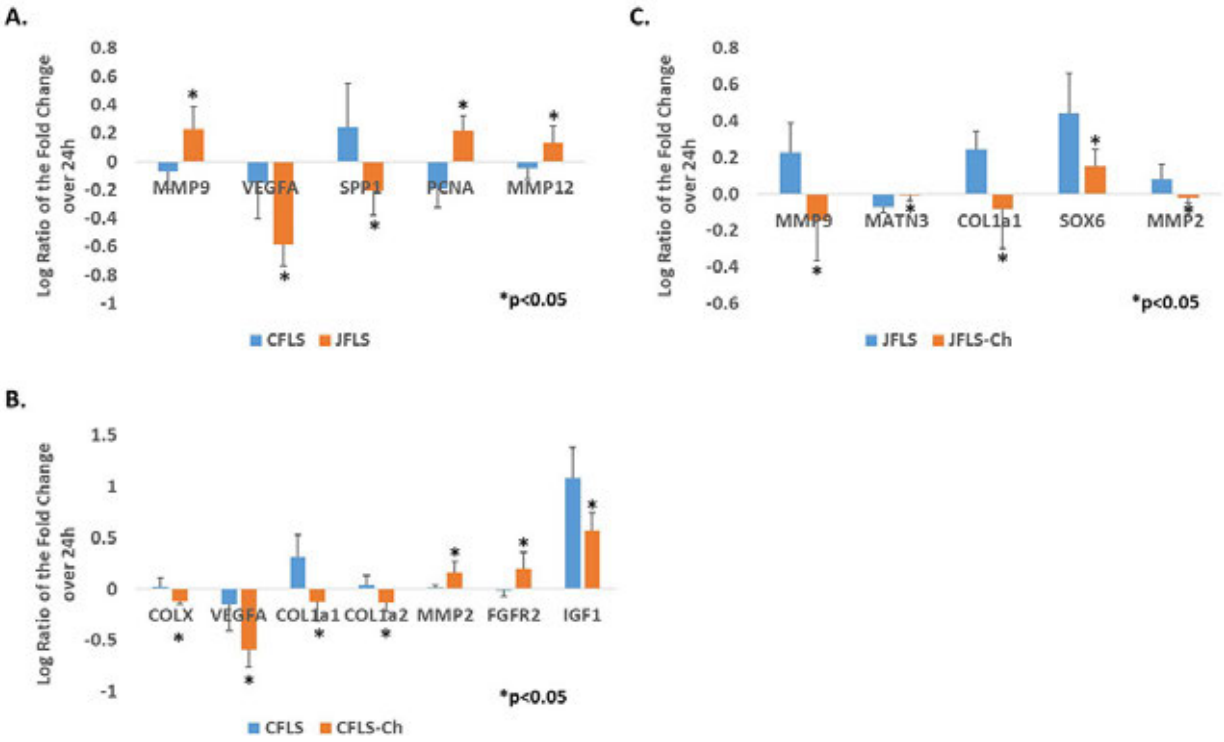

Figure 2. Log ratio of fold change in gene expression of cell differentiation/maturation over 24 hours. A. untreated control FLS (CFLS) and JIA FLS (JFLS). B. untreated CFLS compared to CFLS exposed to chondrocyte conditioned media (CFLS-Ch). C. untreated JFLS compared to JFLS exposed to chondrocyte conditioned media (JFLS-Ch) (*p-value<0.05)

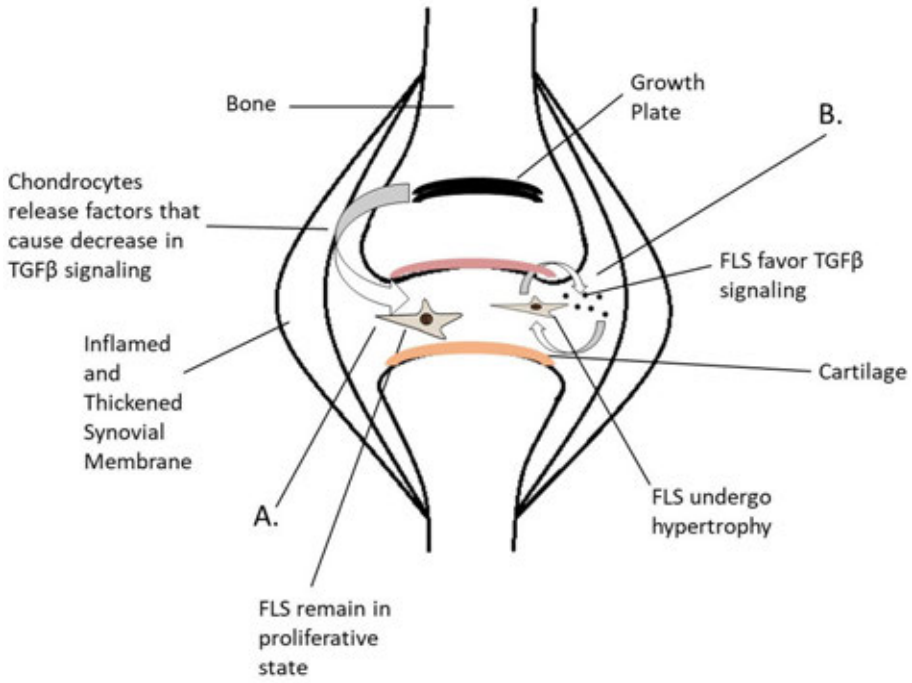

Figure 3. Ch delay JFLS maturation. A. Ch influence JFLS to downregulate TGFβ-related gene expression, causing these cells to remain in an undifferentiated, proliferative state. B. JFLS, without the influence of Ch, favor TGFβ signaling and express genes related to hypertrophy, suggesting these cells play a central role in bony overgrowth.

cells (MMP2, FGFR2 in CFLS and MATN3 in JFLS) as opposed to genes of prehypertrophic/hypertrophic Ch (COLX, VEGFA, COL1, IGF1 in CFLS and MMP9, COL1, SOX6, MMP2 in JFLS) (Fig 2B and 2C).

Conclusion: While untreated JFLS favor TGFβ signaling via increases in Smad2 expression, JFLS-Ch have a reduction in TGFβ signaling through TGFBI, a gene induced by TGFβ ligands with a role in EBF and Ch maturation [3]. Ch influencing JFLS to abrogate TGFβ signaling leads JFLS-Ch to express markers of chondroprogenitor cells as opposed to markers that promote chondrocyte hypertrophy. Ch may have mechanisms to prevent JFLS from influencing the growth plate Ch to undergo EBF. Untreated JFLS express genes related to chondrocyte hypertrophy and proliferation, suggesting that JFLS may play a direct role in the growth discrepancies seen in JIA (Fig 3).

Identical T Cell Clones Identified over Time in the Joints of Oligoarticular Juvenile Idiopathic Arthritis Patients

Amelie Jule,[1] Kacie Hoyt,[2] Margaret Chang,[3] Fatma Dedeoglu,[2] Melissa Hazen,[1] Peter Nigrovic,[4] and Lauren Henderson[1], [1]Boston Children's Hospital, Boston, MA, [2]Boston Children's Hospital, Boston, [3]Division of Immunology, Boston Children's Hospital, Boston, [4]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA; Department of Medicine, Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Oligoarticular juvenile idiopathic arthritis (oligo JIA) is characterized by arthritis in a few joints (fewer than 5) with recurrent flares of inflammation, often in the same joint distribution. The mechanisms driving site-specific inflammation in oligo JIA remain unknown. Previous evaluations of the T cell receptor beta (TCRB) repertoire in oligo JIA patients revealed clonotypic expansion among $CD4^+$ effector and regulatory T cell populations obtained from the synovial fluid (SF). We aimed to further delineate the dynamics of the T cell repertoire in the arthritic joints of oligo JIA patients longitudinally.

Methods: SF samples were collected from 3 oligo JIA patients, defined by ILAR criteria, at 2 timepoints. Serial samples were taken from the same affected joint in a given patient. Peripheral blood (PB) from 7 healthy donors was also collected. DNA was extracted from sorted regulatory ($CD4^+CD25^+CD127^{lo}$, Treg), effector ($CD4^+CD25^-$, Teff), and $CD8^+$ T cells. The TCRB complementarity determining region 3 (CDR3) was amplified by multiplex PCR and sequenced using the Illumina HiSeq platform (Adaptive Biotechnologies). Data was analyzed with VDJtools 1.2.1 and R 3.5.1.

Results: 3 oligo JIA patients (1 male and 2 females) with an average age of 6.4 years were studied. SF was collected from the knee joint in all cases. At baseline (T1), no patient was treated with immunosuppressive medications; however, at the second timepoint (T2), all were taking disease-modifying antirheumatic drugs. The SF sample at T2 was on average 17.3 months after the sample at T1. The SF Treg, Teff, and $CD8^+$ TCRB repertoires were more clonal than those of the respective T cell population in the PB of controls. There was no substantial variation over time in the clonality of Treg, Teff, and $CD8^+$ T cell populations from serial SF samples. In an individual patient, there was overlap in the amino acid sequences of the TCRB CDR3 at T1 and T2: on average, 18%, 19% and 8% of the clonotypes were the same at T1 and T2, respectively for Treg, Teff, and $CD8^+$ T cell repertoires. TCR clones that reoccurred over time tended to be more clonally expanded than TCR clones that occurred at only one timepoint, with frequencies of shared clones being 2-, 3-, and 5-fold larger on average, respectively in Treg, Teff and CD8+ T cells. Sharing of clones across patients was identified more frequently in Treg and $CD8^+$ T cell than Teff cells.

Conclusion: Flares of arthritis in oligo JIA were characterized by resurgence of the same TCR clones longitudinally. There was also sharing of TCR clonotypes in Treg and $CD8^+$ T cells across oligo JIA patients. These findings suggest that pathogenic clones, potentially recognizing similar antigens, may persist in the joints of oligo JIA patients and drive disease over time. While recurring clones may be recruited to the joint with each flare, the extent of repertoire overlap suggests a resident phenotype. Further work is ongoing to characterize the physicochemical properties of shared and clonally expanded clones, and to determine whether they are resident in the affected joints.

Cutaneous Gene Expression Signatures in Juvenile Myositis Reveal a Prominent IFN Signature in Lesional Skin

Jessica Turnier,[1] Celine Berthier,[1] Lam Tsoi,[1] Lori Lowe,[1] Gabrielle Morgan,[2] Johann Gudjonsson,[1] Lauren Pachman,[2] and J. Michelle Kahlenberg[1], [1]University of Michigan, Ann Arbor, MI, [2]Northwestern University, Chicago

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Skin inflammation can herald systemic disease manifestations and disease chronicity in juvenile myositis (JM), yet we lack an understanding of the pathogenic mechanisms driving skin inflammation in JM. The objectives of this study were to 1) define transcriptional signatures and biological networks in JM lesional skin, and 2) identify key genes and pathways that differentiate skin disease in JM from childhood-onset SLE (cSLE).

Methods: With IRB approval, we identified JM and cSLE patients who had a skin biopsy performed at either the University of Michigan or Lurie Children's Hospital of Chicago and verified diagnosis through chart review of clinical

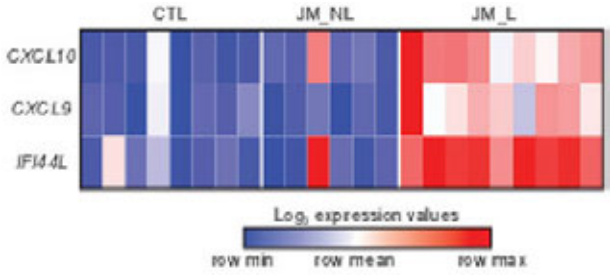

Figure 1. Top three differentially expressed genes in JM lesional skin compared to control and JM non-lesional skin

findings, labs, imaging and histopathology. We then isolated RNA from formalin-fixed, paraffin-embedded (FFPE) skin biopsy samples of 15 JM (9 lesional, 6 non-lesional), 7 cSLE and 8 control patients (CTL; samples from uninvolved skin removed with nevi excision). Following RNA isolation, we performed microarray analysis using Affymetrix ST 2.1 arrays and significance analysis of microarrays (SAM) to determine differentially expressed genes (DEGs; q-value ≤ 5%) between patient groups, comparing JM lesional (JM_L), JM non-lesional (JM_NL), cSLE and CTL. We utilized Ingenuity Pathway Analysis (IPA) to highlight enriched biological pathways and Genomatix Pathway System (GePS) to characterize regulated genes within biological networks.

Results: In the JM cohort, 2 patients had amyopathic disease, and 2 lacked characteristic skin findings of Gottron's papules, with the remaining patients having a classical JDM presentation. Principal component analysis demonstrated that the 2 patients without characteristic skin findings of JDM clustered with other JM_L patients. Comparison of JM_L to CTL skin revealed 221 DEGs, with all but one upregulated in JM_L. The majority of upregulated genes in JM_L were IFN-sensitive, with *CXCL10*, *CXCL9* and *IFI44L* representing the top three DEGs (FC = 23.2, 13.3, 13.0, q-value = < 0.0001) **(Figure 1)**. IPA revealed IFN signaling as the top canonical pathway and also showed upregulation of antigen presentation, pattern recognition receptors, communication between innate and adaptive immune cells, T cell signaling, the complement system and dendritic cell maturation. The top predicted upstream regulator was IFN alpha (p-value = 7.91×10^{-88}). JM_NL skin had a strikingly different transcriptional signature, both lacking a prominent IFN signal and with downregulation of multiple genes and pathways, including oxidative phosphorylation and protein ubiquitination. JM_L skin shared a highly similar gene expression pattern with cSLE. There were only 28 unique DEGs in JM_L compared to cSLE, whereas cSLE skin had 722 unique DEGs compared to JM_L. Of note, cSLE skin uniquely demonstrated increased expression of IFN gamma relative to CTL.

Conclusion: JM lesional skin demonstrates a striking IFN signature similar to that previously reported in muscle and peripheral blood. Although JM skin has few unique DEGs when compared to cSLE, a lack of upregulated genes specific to cSLE skin may distinguish JM. The origin of the IFN signature in JM skin and its association with clinical phenotype and response to therapy remains to be established.

Genetic Signatures Support Inflammation Driven Fibrosis in Localized Scleroderma

Christina Schutt,[1] Emily Mirizio,[2] Claudia Salgado,[3] Miguel Reyes-Mugica,[3] Kaila L. Schollaert,[2] and Kathryn Torok[3], [1]UPMC Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, [3]UPMC Children's Hospital of Pittsburgh, Pittsburgh

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Localized scleroderma (LS) is a progressive autoimmune disease of the skin and underlying tissue that is characterized by an initial inflammatory infiltration which is followed by fibrosis and collagen deposition. When left unchecked LS causes significant functional disability and disfigurement, especially in developing children. Histopathologic review of LS skin biopsies typically shows a stronger inflammatory or fibrotic pattern depending on disease stage. Our goal was to determine the transcriptome within inflammatory vs. fibrotic tissue to identify potential molecular targets using RNA sequencing (RNAseq) compared to histology scoring of inflammatory infiltrates vs. collagen deposition/fibrosis. Differentially expressed genes (DEGs) in LS patients were compared to skin histopathological features to determine correlation.

Methods: RNAseq was performed on paraffin-embedded skin (n=15 LS, n=2 pediatric healthy) using the Illumina HTS and TrueSeq Access library preparation. Paired-end RNAseq data was aligned using STAR and analyzed for DEGs using DESeq2. Genes were analyzed using DEG cutoffs of log fold change > ±2.0, adjusted $p < 0.05$, and a false discovery rate (FDR) cutoff of < 0.05 for Ingenuity Pathway Analysis (IPA) and enrichment software (GSEA©). Skin biopsies were reviewed by 2 blinded pathologists who determined 3 areas of inflammatory infiltrate per skin layer (papillary dermis, upper and lower reticular dermis) and counted total inflammatory cells (lymphocytes and plasma cells) per infiltrate, which determined a categorical inflammation score. Similar scoring was also developed for fibrosis, where 3 areas were chosen per skin layer and 3 measurements of collagen bundle thickness were taken. The average of these measurements was used for fibrotic scoring. Spearman's correlation between genes of interest and histology scoring was performed using GraphPad Prism.

Results: The degree of inflammatory cell infiltrate significantly correlated with both inflammatory (IFNγ, immunoglobulin, and T-cell activation, rs > ±0.5, $p < 0.01$) and fibrotic (IL-12 mediated signaling, and DNA damage response) (rs > ±0.5, $p < 0.05$) genes (Table 1). Collagen thickness did not correlate with typical fibrotic genes, but did correlate (rs > ±0.4, $p < 0.05$) with upregulated inflammatory genes, such as those associated with interferon signaling and T-cell activation (Table 1). Further support of IFN-related signaling, T lymphocyte activation, and cytokine production was demonstrated with IPA.

Conclusion: The identified immune pathways and genes corresponding with the LS skin inflammatory infiltrate indicate a unique genetic signature present during active disease with moderate-severe lymphoplasmacytic infiltrate and collagen thickness. This may indicate that fibrosis occurring in later stages of LS is an inflammation-driven process. Further investigation into the relationship and functions of these genes is underway and will aid in advancing treatment options for LS patients.

Interferon Response Gene Expression Differs in Whole Blood, Peripheral Blood Mononuclear Cells, Monocytes, Dendritic Cells, Neutrophils, and Skin Tissue in Patients with the Autoinflammatory Interferonopathies, CANDLE and SAVI

Jacob Mitchell,[1] Sara Alehashemi,[2] Bernadette Marrero,[3] Yan Huang,[4] Lena Bichell,[5] Gina Montealegre Sanchez,[1] Raphaela Goldbach-Mansky,[2] and Adriana de Jesus[1], [1]Translational Autoinflammatory Disease Section/NIAID/NIH, Bethesda, [2]Translational Autoinflammatory Diseases Section/NIAID/NIH, Bethesda, MD, [3]Computational Systems Biology Section/NIAID/NIH, Bethesda, [4]Translational Autoinflammatory Disease Section/NIAID/NIH, Bethesda, MD, [5]Translational Autoinflammatory Diseases Section/NIAID/NIH, Bethesda

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The disease progression of patients (pts.) with type-I interferon (IFN)-mediated diseases undergoing treatment with JAK1 and JAK2 inhibitors is monitored in part by measuring the transcription of a 28 IFN response gene (IRG) signature in whole blood with Nanostring technology, a 28-gene standardized IFN score is calculated. We sought to determine differences in 28-gene standardized IFN scores and in the patterns of IRG signatures among peripheral blood mononuclear cells (PBMCs), isolated monocytes, dendritic cells, neutrophils, and skin biopsies in the Type-I IFN-mediated diseases CANDLE (chronic atypical neutrophilic dermatosis with lipodystrophy and elevated temperatures) and SAVI (STING-associated vasculopathy with onset in infancy) compared to whole blood IRG signatures.

Methods: RNA was extracted from pt. and healthy control whole blood, PBMCs, monocytes, neutrophils, dendritic cells (DC), and skin biopsies. After cells isolation by Ficoll (PBMC), CD14 (monocytes) or CD123 (DC) magnetic bead isolation and density gradient separation with red blood cell lysis (neutrophils), RNA was extracted. Transcript counts for 28 IRGs and 4 additional genes were measured with a NanoString instrument, normalized based on the expression of 4 housekeeping genes in the sample, and scored as the sum of the 28-genes' z-scores compared to expression in the same cells or tissues in a cohort of healthy controls.

Results: Both CANDLE (n=4) and SAVI (n=5) patients have significantly greater 28-gene standardized IFN scores in whole blood, PBMCs than healthy controls (n=10). Higher IFN scores were seen in SAVI PBMCs as compared to SAVI whole blood, while CANDLE PBMC IFN scores were not different compared to CANDLE whole blood.SAVI PBMCs had significantly higher 28-gene IFN scores than CANDLE PBMCs (2003 ±2301 vs. 352.3 ±285.5, p=0.0082). In addition, SAVI PBMCs transcribed higher levels of *IFNA2* (7068 ±14434 vs. 3.158 ±0.657) and *IFNB1*(8452±16468 vs. 2.119 ±0.619) than PBMCs from CANDLE pts., corroborating RNAseq data that demonstrates highest Type-I IFN expression in the monocytes followed by dendritic cells of SAVI pts. One family of 3 patients with SAVI who had a novel STING missense variant had very elevated IFN scores in their PBMCs, while their whole blood IFN score was not considered to be elevated. Nanostring performed on RNA from skin tissue from 3 CANDLE and 3 SAVI pts. demonstrated a distinct distribution of the 28 IRGs in comparison with whole blood, with a relatively higher contribution of *CXCL10*to the 28-gene IFN score.

Conclusion: High expression of Type-I IFNs and IRGs in the PBMCs of SAVI pts. may demonstrate the role of myeloid cells in the amplification of constitutive IFN signaling in SAVI. In addition, pts. with a SAVI phenotype but a negative IRG signature in whole blood may only have an IRG signature in the PBMC fraction. Differences in IRG transcription profiles demonstrate that responses to IFN signaling are not uniform among cell subsets in different Type-I IFN-mediated diseases.

Multiple Genetic Diagnoses in a Cohort of Patients with Cryopyrin Associated Periodic Syndrome (CAPS)

Sofia Torreggiani,[1] Megha Garg,[2] Sara Alehashemi,[3] Kim johnson,[1] Jenna Wade,[4] Lena Bichell,[4] Magdalena Walkiewicz,[5] Adriana de Jesus,[6] and Raphaela Goldbach-Mansky[3], [1]Translational and Autoinflammatory Diseases Section/NIAID/NIH, Bethesda, MD, [2]Rochester Regional Health, Rochester, NY, [3]Translational Autoinflammatory Diseases Section/NIAID/NIH, Bethesda, MD, [4]Translational Autoinflammatory Diseases Section/NIAID/NIH, Bethesda, [5]Division of Intramural Research (DIR)/NIAID/NIH, Bethesda, MD, [6]Translation Autoinflammatory Diseases Section/NIAID/NIH, Silver Spring, MD

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cryopyrin associated periodic syndrome (CAPS) is an autosomal dominant autoinflammatory disease caused by mutations in *NLRP3*. CAPS comprises 3 clinical phenotypes of increasing severity: familial cold autoinflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), neonatal onset multisystem inflammatory disease (NOMID). CAPS is characterized by early onset systemic inflammation and neutrophilic urticaria (NOMID, MWS, FCAS), cochlear inflammation with hearing loss (NOMID, MWS), and central nervous system inflammation (NOMID). Although all patients had clinical features of CAPS, we aimed to identify additional Mendelian diagnoses that may explain phenotypic variability not attributable to CAPS.

Methods: CAPS patients and their parents, when available, had whole exome sequencing (WES) performed at the NIAID Centralized Sequencing Initiative (CENSEQ). Chromosomal microarray analysis (CMA) was performed in selected cases. Patients were evaluated for investigation of clinical phenotypic features not associated with CAPS.

Results: Of the 11 CAPS patients analyzed, 4 (36.4%) had a Mendelian genetic diagnosis in addition to CAPS. **Patient 1** is a 10-year-old female with a somatic mutation in *NLRP3* (p.G307C, ~15% mosaicism) and classic NOMID manifestations responsive to anti-IL-1 therapy. She was noted to have developmental delay, upslanting palpebral fissures and sparse eyebrows, which were explained by CMA findings compatible with 12q21.2q22 deletion syndrome (1). **Patient 2** is a 10-year-old female with a germline *NLRP3* mutation (p.E304K), clinical features of FCAS/MWS and response to anti IL-1. She presented clinodactyly, scoliosis, and broad great toes. Height was between the 5th and 10th percentile. WES revealed a novel heterozygous variant in *NPR2* (p.M1?), gene associated with autosomal dominant epiphyseal chondrodysplasia (OMIM#615923). **Patient 3** is an 8-year-old female with a

germline *NLRP3* mutation (p.N479K) and a NOMID phenotype, treated with anakinra with resolution of inflammation but no benefit on growth. She presented brachydactyly, a round face and a broad nasal bridge. WES showed a novel heterozygous variant in *FBN1* (p.L2626V), gene associated with several musculoskeletal syndromes, including Marfan syndrome (OMIM#154700), geleophysic dysplasia 2 (OMIM#614185) and Weill-Marchesani syndrome (OMIM#608328). **Patient 4** is a 19-year-old male with a germline mutation in *NLRP3* (p.G326E) and a clinical picture of NOMID, requiring high doses of canakinumab. WES showed a novel heterozygous variant (p.M274R) in *NLRC4* (OMIM#616050).

Conclusion: Of 11 CAPS patients with pathogenic *NLRP3* mutation, 4 had a secondary genetic diagnosis, which explained clinical features that were not attributable to CAPS. Our data suggest that further genetic testing should be considered to explain "phenotypic variability".

The Juvenile Idiopathic Arthritis-Associated IL2RA Haplotype Contains an Intronic Enhancer Whose Function Is Diminished by JIA-Associated Genetic Variants

Kaiyu Jiang,[1] Yungki Park,[1] Tarbell Evan,[1] Tao Liu,[2] and **James N. Jarvis**[3], [1]University at Buffalo Jacobs School of Medicine, Buffalo, NY, [2]Roswell Park Cancer Instiyute, Buffalo, NY, [3]University at Buffalo, Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: *IL2RA* has been identified as a JIA-associated risk locus using both candidate gene and genetic fine mapping approaches. However, numerous gene expression studies comparing children with active JIA to healthy control children have failed to identify *IL2RA* as a differentially expressed gene. Furthermore, the SNPs used to identify *IL2RA* lie within the first intron of the *IL2RA* gene, not its promoter or coding regions. The risk haplotype is marked by prominent H3K4me1/H3K27ac histone marks, suggesting that genetic risk may be mediated through enhancer function. We therefore sought to confirm whether this region is a functional enhancer and whether the enhancer operates in lymphoid cells, myeloid cells, or both. We also examined the effects of genetic variants on enhancer function at the *IL2RA* locus.

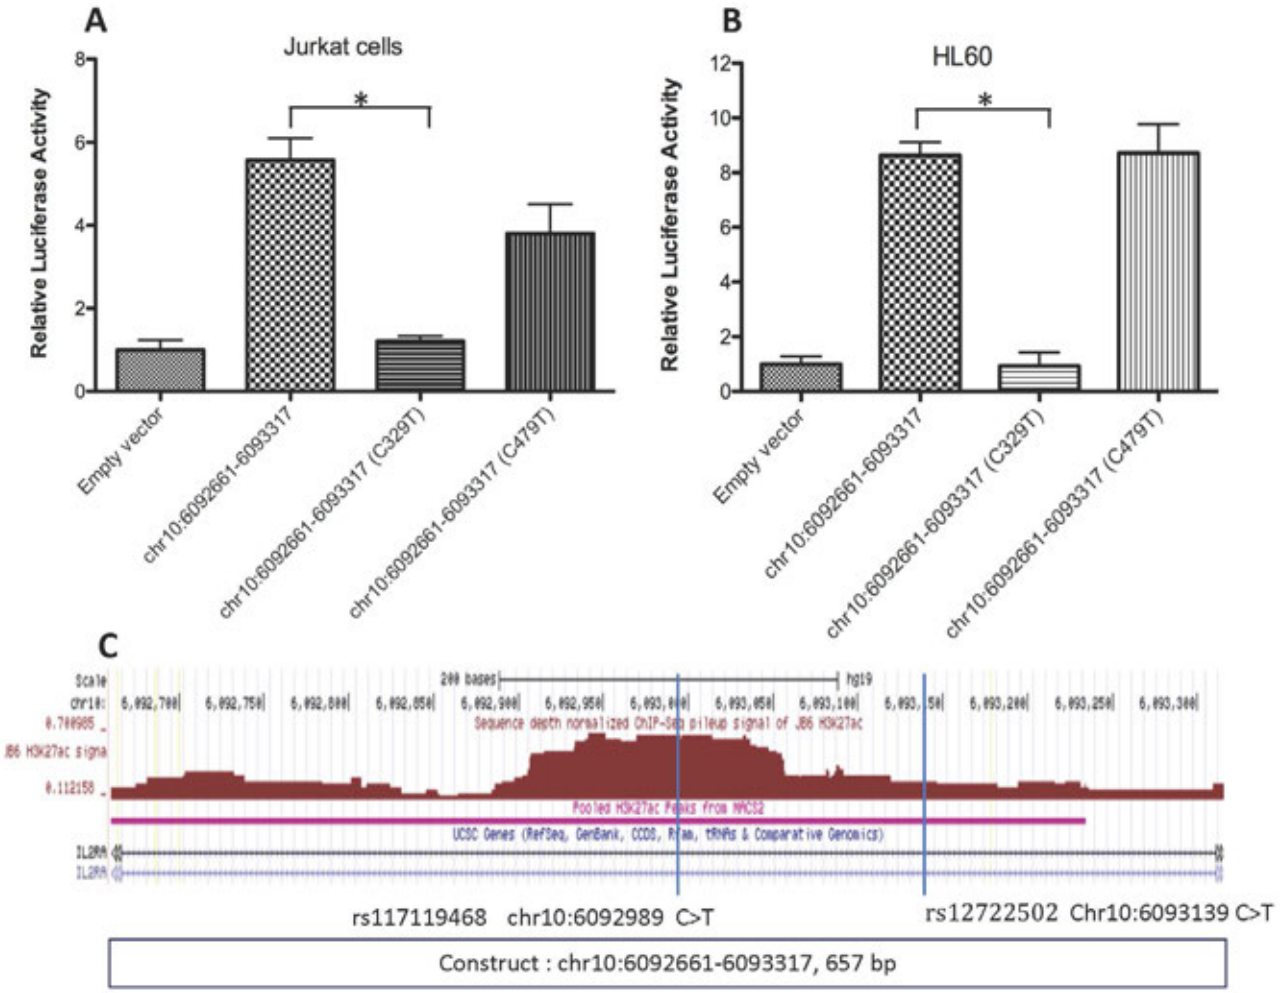

Figure 1. Effects of genetic variants

Methods: We used the pGL4 reporter system to query enhancer effects across a 1,000 bp region within the first intron of the IL2RA gene marked by H3K4me1 and H3K27ac histone marks in both CD4+ T cells and neutrophils. This region is within the linkage disequilbrium block that includes the SNPs used on both candidate gene and genetic fine mapping studies that identified IL2RA as a JIA risk locus. The pGL3 vector contains a minimal SV40 promoter that is, by itself, inefficient at driving luciferase function. We tiled three 500 bp constructs across the region of interest and cloned these constructs into pGL3 vectors, which were then transfected into Jurkat T cells and myeloid HL60. Cells were incubated for 24 hr, after which luciferase production was assessed using standard methods. We repeated these same experiments using constructs containing genetic variants (rs117119468 C- >T and rs12722502 C- >T) that we identified in children with JIA using whole genome sequencing.

Results: Within the H3K4me1/H3K27ac-marked region within the first intron of IL2RA, we observed enhancer activity across a 657 bp region from chr10:6092661 to chr10:6093317 in both Jurkat T cells and HL60 myeloid cells. The reporter constructs enhanced luciferase activity by 5-8 fold in Jurkat T cells (compared with a control vector that contained only the minimal SV40 promoter and the luciferase gene) and 4-6 fold in HL60 cells. A construct carrying a sequence within the first intron of the IL2R Agene that was not marked by the H3K4me1/H23K27ac histone

signature showed no enhancement of luciferase expression compared to background. Constructs containing the JIA-associated rs117119468 C- >T allele abolished the enhancer activity within the IL2R Alocus, while the construct containing the rs12722502 C- >T allele reduced luciferase activity by 30%.

Conclusion: The JIA-associated risk locus, *IL2RA*, contains an intronic enhancer that is active in both lymphoid and myeloid cells. JIA-associated genetic variants identified by WGS attenuate or abolish enhancer activity at this locus. These findings demonstrate the importance of assessing the non-coding functions of JIA risk loci, even where the coding function a specific gene might be plausibly implicated. Our findings also underline the potential importance of rare genetic variants, which may have stronger biological effects than GWAS SNPs, in complex traits like JIA.

Changes in MiR-17-92 Cluster Expression Link Systemic Juvenile Idiopathic Arthritis, Monocyte-to-Macrophage Differentiation, and Interferon Regulation

Divya Takellapti,[1] Xiaoling Niu,[2] Thuy Do,[3] and Grant Schulert[3], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Fudan University, Shanghai, Shanghai, China (People's Republic), [3]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: MicroRNAs (miRNAs) are small noncoding RNAs which post-transcriptionally regulate gene expression. The miR-17-92 cluster is well characterized; its overexpression has been found to serve a major oncogenic role in the targeting and downregulation of tumor-suppressive pathways. Our previous work identified several members of the cluster with significantly higher levels in monocytes from patients with active Systemic Juvenile Idiopathic Arthritis (SJIA), a chronic inflammatory disease of childhood. Children with SJIA are at risk for life-threatening complications including Macrophage Activation Syndrome (MAS), an episode of overwhelming inflammation driven by IFNɣ. The objectives of this study were to characterize the regulation of the miR-17-92 cluster, define key targets, and determine the cluster's role in inflammation and SJIA.

Methods: MiRNA levels were examined in THP-1 cells and primary human monocytes over the course of the monocyte to monocyte-derived macrophage (MDM) transition. MiR-17, miR-19a, and miR-20a were overexpressed in CD14+ monocytes for 2 days. Transcriptional profiles were performed using Ampliseq Transcriptome and the Ion Torrent S5 system and analyzed using AltAnalyze. Potential targets of the miR-17-92 cluster were then validated via dual-luciferase reporter assay.

Results: Neither blood monocytes nor fully differentiated THP-1 cells showed significant changes in miR-17-92 levels under standard polarization conditions, including M1, M2a, and M2b conditions, or IL-6 and IL-10 stimulation. The most sizable changes in miR-17-92 levels were found during monocyte to macrophage transition. Interestingly, primary monocytes showed increases in miR-17-92 levels within the first 48 hours of differentiation towards MDM similar to that seen in SJIA monocytes. In contrast, both PMA-differentiated THP1 cells and fully differentiated MDMs showed decreased miR-17-92 compared to undifferentiated monocytic cells. MiR-17-92 was overexpressed

in primary monocytes to model these early transition changes. Genome-wide transcriptional profiling showed an upregulation of genes involved in Type I and II Interferon pathways, including response to interferon-alpha (adjusted p=2.71x10-12) and interferon-gamma (adjusted p=7.81x10-9). Analysis of genes significantly downregulated by miR-17, miR-19a, or miR-20a identified several putative and previously validated miR-17-92 cluster targets, including ATG5, IFRD2, JAK1, PPARG, and PTPN2 which have interferon-regulatory functions. Dual-luciferase reporter assay experiments support that these genes are direct targets of miR-17, miR-19a, and/or miR-20a.

Conclusion: MiR-17-92 demonstrates initial increase followed by subsequent decrease in human monocyte to macrophage differentiation. Overexpression of miR-17-92 upregulates Type I and II interferon pathway genes, and these miRNAs target multiple genes involved in regulating interferon signaling and/or inflammatory response. Taken together, miR-17-92 overexpression in SJIA monocytes may suggest a more differentiated phenotype, and contribute to IFNɣ sensitivity and risk for MAS.

Is down Syndrome Associated Arthritis (DA) a Distinct Disease from Juvenile Idiopathic Arthritis (JIA)?

Charlene Foley,[1] Achilleas Floudas,[2] Sharon Ansboro,[2] Mary Canavan,[2] Monika Biniecka,[2] Emma Jane MacDermott,[3] Ronan Mullan,[4] Gerry Wilson,[5] Ursula Fearon,[6] and Orla Killeen[7], [1]Great Ormond Street Hospital, London, Ireland, [2]TBSI, Dublin, Ireland, [3]OLCHC, Dublin, Ireland, [4]Tallaght Hospital, Dublin, Ireland, [5]UCD, Dublin, Ireland, [6]TBSI, Dublin, [7]National Centre for Paediatric Rheumatology (NCPR), Our Lady's Children's Hospital Crumlin (OLCHC), Dublin, Ireland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Down syndrome associated Arthritis (DA) is 20 times more common than JIA. It is an erosive, polyarticular RF negative arthritis with predominance in the small joints of the hands and wrists. Little is known about the underlying mechanisms that drive DA pathogenesis. We hypothesise that it is a distinct disease from its closest ILAR subtype, polyarticular RF negative JIA (pRF-JIA) given the differences observed in the clinical phenotypes.

Our aims were to compare B cell subsets and T cell cytokine profiles in peripheral blood mononuclear cells (PBMCs); and synovial membrane immunohistochemistry and synovial fibroblast cell (SFC) functionality in children with DA and the ILAR subtype pRF-JIA. We also looked to see if known pRF-JIA susceptibility loci, *HLA-DQB1/HLA-DQA2* (rs7775055) and *PTPN22* (rs6679677) were present in children with DA.

Methods: Multicolour flow cytometry and FlowJo and SPICE software were used to analyse B cell subsets and T cell cytokine expression (IL17a, GMCSF, IFNγ, TNFα) in PBMCs from children with pRF-JIA, DA, T21 and HC, (n = 10 / gp).

Synovial tissue was obtained through ultrasound guided biopsy (DA n = 3; pRF-JIA n = 4) and analysed by immunohistochemistry for CD3 (T cells), CD20 (B cells) and CD68 (macrophages). Vascularity and lining layer hyperplasia were also scored.

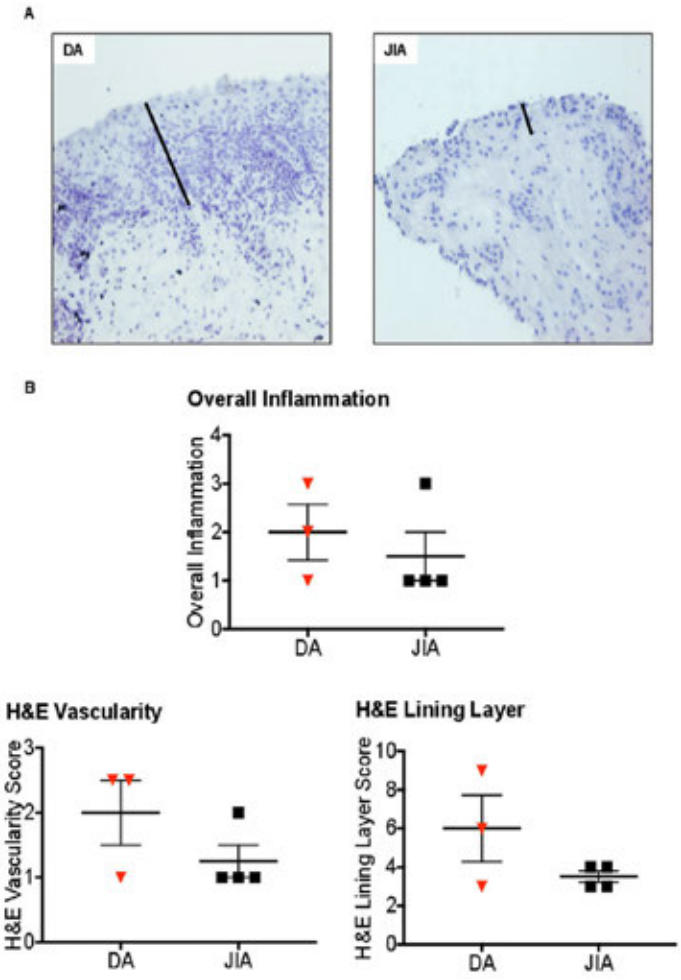

Figure 1. H&E staining of synovial tissue from children with DA and JIA, scored for global inflammation, vascularity and lining layer thickness A. Representative images of synovial tissue from the knee joint of a child with DA and JIA. The black line denotes lining layer. B. Two independent observers performed scoring. Graphs depict results for global inflammation and vascularity, with a score range of 0-3. Lining layer thickness was scored by number of cells thick. Sample size was DA n = 3 and JIA n = 4. Original magnification used was 20 X. Data are presented as mean ± SEM.

DA-SFC and pRF-JIA-SFC migration was assessed by wound repair scratch assays; invasion by Biocoat Matrigel™ Invasion Chambers; and bioenergetic activity using the XFe96-Flux-analyser where oxidative phosphorylation and glycolysis were quantified. Real-time PCR assessed glycolytic gene expression.

The team at the Arthritis Research UK Centre for Genetics and Genomics (Manchester) performed genotyping and analysis of rs7775055 and rs6679677 in DNA from children with pRF-JIA (n = 732), DA (n = 42), T21 (n = 31) and HC (n = 9196).

Results: Flow cytometry analysis revealed that children with DA had a significantly lower number of circulating CD19+CD20+ B cells when compared to children with pRF-JIA and HC. However, they had a greater proportion of memory B cells (CD27+) when compared to children with T21. T cell IFNγ and TNFα production was significantly greater in DA compared to pRF-JIA and HC. Greater T cell polyfunctionality was also observed in children with DA compared to all three comparison groups.

	HLA-DQB1/DQA2	PTPN22
JIA MAF	0.09085	0.1557
HC MAF	0.02251	0.1013
DA MAF	0	0.07143
T21 MAF	0.01613	0.06452

Figure 2. Comparison of MAF for HLA-DQB1/HLA-DQA2 (rs7775055) and PTPN22 (rs6679677) Comparable to the literature, the MAF for HLA-DQB1/HLA-DQA2 (rs7775055) in JIA is significantly greater than HC (p=2.4 x 10-53, OR 4.3). When compared to HC, both T21 and DA have a lower MAF. Results for these cohorts are significantly lower when compared to JIA MAF (p=0.04174 and p=0.00386 respectively). Similarly, for PTPN22 (rs6679677), MAF in JIA is significantly greater than HC (p=6.5 x 10-11, OR 1.6). Again, in both the T21 and DA cohort, MAF is lower compared to HC. DA MAF is significantly lower than JIA MAF (p=0.03592, OR 2.4) for this JIA susceptibility locus.

DA synovial tissue demonstrated greater lining layer hyperplasia (**figure 1**). Median cell thickness in DA was 6 (3-9 cells), compared to 2 (2-4 cells) in pRF-JIA. There was also increased vascularity and inflammatory cell infiltration in DA compared to pRF-JIA.

DA-SFC showed greater migratory and invasive capacity, and increased basal metabolic activity and metabolic gene expression when compared to pRF-JIA-SFC.

The MAF (minor allele frequency) for the pRF-JIA associated variants rs7775055 and rs6679677 were not similar in DA. The minor allele of rs7775055 was absent in DA (p = 0.004). The rs6679677 MAF was significantly different between DA and pRF-JIA, p = 0.036 (**figure 2**).

Conclusion: Significant differences were observed in the immune, histological and genetic profiles of DA and its closest ILAR subtype, pRF-JIA. These differences may help explain the erosive phenotype observed in DA and suggest it may be a distinct disease from JIA.

Oligoarticular Juvenile Idiopathic Arthritis Displayed Increased Expression of Co-Inhibitory Receptors Without Signs of T-Cell Exhaustion

Erdal Sag,[1] Selcan Demir,[2] Morten A. Nielsen,[3] Malene Hvid,[4] Egemen Turhan,[5] Yelda Bilginer,[2] Seza Ozen,[6] and Bent Deleuran[7], [1]Hacettepe University, Ankara, Turkey, [2]Division of Pediatric Rheumatology, Department of Pediatrics, Hacettepe University, Ankara, Turkey, [3]Department of Biomedicine, Aarhus University, Aarhus, Denmark, [4]Department of Biomedicine; Department of Clinical Medicine, Aarhus University, Aarhus, Denmark, [5]Department of Orthopedics and Traumatology, Hacettepe University, Ankara, Turkey, [6]Hacettepe University Hospital, Ankara, Turkey, [7]Department of Biomedicine; Department of Rheumatology, Aarhus University, Aarhus, Denmark

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Activated T cells are involved in the pathogenesis of the synovitis in oligoarticular Juvenile Idiopathic Arthritis (o-JIA). T cell activation is counter-balanced via co-inhibitory receptors (co-IRs) such as CTLA-4, PD-1, LAG-3, and TIM-3. Here we identify the role of co-IRs in the pathogenesis of o-JIA.

Methods: Paired synovial fluid (SF) and plasma, PBMCs and SFMCs, were obtained from o-JIA patients together with clinical data (n=14). Plasma from healthy controls (HC, n=14) and paired SF and plasma from 5 children requiring arthroscopy for non-inflammatory orthopaedic problems (OC, n=5) served as controls. Soluble levels of co-IRs were measured by ELISA and their cellular expression by flow cytometry. Spontaneously differentiated fibroblast-like synoviocytes (FLS) from SFMCs were co-cultured with autologous PBMCs/SFMCs and used as an *ex-vivo* disease models. Functional effects of co-IRs were evaluated via blocking them with checkpoint inhibitors in these *ex-vivo* disease models.

Results: o-JIA patients had increased soluble levels (Figure 1A) and CD3+CD4+CD45RO+ T cell surface expressions of sPD-1, sLAG-3, sTIM-3, but not sCTLA-4 in SF compared with plasma (Figure 1B). Plasma and SF levels of sLAG-3 and TIM-3, but not sPD-1 levels were higher in o-JIA patients compared with controls. (Figure 1A) None of the soluble co-IR levels correlated with disease activity. As CD4 T cell exhaustion is an outcome of continued antigen presentation, we examined if MHC-class II expression was present on these FLS. FLS expressed nearly no MHC-class II molecules in monocultures, but this was readily detected when co-cultured with PBMCs and SFMCs together with an increased Monocyte Chemoattractant Protein-1 (MCP-1) production. (Figure 2A) Only anti-LAG3 antibodies significantly increased the MCP-1 production in PBMC monocultures and FLS+PBMC co-cultures. (Figure 2B) PBMCs and SFMCs produced significantly higher levels of IFN-ɣ after CD3/CD28 activation ($p < 0.001$), but they were not affected by the addition of antibody towards the other checkpoint inhibitors.

Conclusion: This is the first report studying the effects of different co-IRs in o-JIA. Both the soluble levels and the surface expressions of co-IRs were higher at the site of inflammation in o-JIA. SFMCs and PBMCs of o-JIA patients are not exhausted, based on their ability to respond to CD3/CD28 activation. This is opposite to what has been shown in adult inflammatory arthritis. Co-cultures of autologous FLSs and PBMCs/SFMCs may serve as an *ex-vivo* arthritis model to perform functional analysis. LAG-3 might play a role in o-JIA pathogenesis and maybe a potential therapeutic option.

Differences in Chromatin Architecture in Treatment Naïve Pediatric Lupus Patients

Joyce Hui-Yuen,[1] Frank Jenkins,[2] Kaiyu Jiang,[3] Susan Malkiel,[2] Betty Diamond,[4] and James N. Jarvis[5], [1]Cohen Children's Medical Center, Northwell Health, New Hyde Park, NY, [2]Feinstein Institute for Medical Research, Manhasset, [3]University at Buffalo Jacobs School of Medicine, Buffalo, NY, [4]Feinstein Institutes for Medical Research, Manhasset, [5]University at Buffalo, Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex disease likely triggered by gene-environment interactions. We have shown that most of the SLE-associated haplotypes encompass genomic regions enriched for epigenetic marks associated with enhancer function in neutrophils, and T/B cells, suggesting that genetic risk is exerted through altered gene regulation. Data remain scarce on how epigenetic variance contributes to disease risk in pediatric SLE. We aim to identify differences in epigenetically-regulated chromatin architecture in treatment-naïve pediatric lupus (pSLE) patients compared to healthy children.

Methods: We used the assay for transposase-accessible chromatin-sequencing (ATACseq) to survey open chromatin in 8 treatment-naïve pSLE patients and 5 healthy children (HC). We investigated whether regions of open chromatin unique to pSLE patients might demonstrate enrichment for specific transcriptional regulators, using standard computational approaches to identify unique peaks and a false discovery rate of < 0.05.

Results: The mean age of onset was 13.75 (range 7-17) years in pSLE patients; 3 out of 8 patients were male. pSLE patients were 50% African American, 38% Caucasian, and 12% Asian, with all but 1 patient identifying Hispanic. The mean SLEDAI was 12.8 (range 6-24). Differential peak analysis identified 30139 uniquely accessible sites in pSLE patients. Further analyses of these open regions revealed that 46-60% of the peaks seen only in pSLE patients are located more than 100kb from the nearest transcription start site, implying that many transcription factors (TFs) may be acting on distal enhancers to regulate transcription. Differentially accessible regions (DARs) were enriched for enhancer marks H3K4me2, H3K4me3, and H3K27ac, and contained 42 TFs that may be accessible in pSLE patients but not HC. Variant calling within DARs found 3864 genes belonging to 129 different biologic processes, most notably cellular activation in immune response, regulation of cell proliferation, and cellular responses to external stimuli (e.g., interferon).

Conclusion: Over 50% of DARs identified in pSLE patients are located far from their nearest transcription start sites, and appear to be enriched for several enhancer histone marks, implying that TF binding sites are poised for activation. Pathways of significance analyses identified immunologic pathways important in the pro-inflammatory response. Thus, patterns of chromatin accessibility suggest important roles for chromatin regulators in treatment-naïve pSLE.

Application of Systems Biology-Based *In Silico* Tools for Optimal Treatment Strategy Identification in Still's Disease

Cristina Segu-Verges,[1] Mireia Coma,[1] Christoph Kessel,[2] Serge Smeets,[3] Dirk Foell,[2] and Anna Aldea[4], [1]Anaxomics, Barcelona, Catalonia, Spain, [2]University Hospital Muenster, Muenster, Germany, [3]Novartis, Amsterdam, Netherlands, [4]Novartis, Barcelona, Catalonia, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic JIA (sJIA) and Adult Onset Still's Disease may represent a disease continuum[1] of the same autoinflammatory disorder, Still's Disease. Current challenges in its management include the complex disease clinical phenotypes (systemic/rheumatic symptoms) and the absence of optimal treatment guidelines. Several efforts are being made to identify the best targeted strategy to take advantage of the "window of opportunity" and prevent complications and damage[2]. Systems biology-based methods are becoming reliable tools to understand the molecular effects of drugs in complex clinical settings. In this study, we constructed *in silico* models to explore and compare the mode of action (MoA) in Still's Disease of current biologicals, anakinra (ANA), canakinumab (CAN) and tocilizumab (TCZ), in addition to non-biological drugs such as corticosteroids and methotrexate, aiming to advance towards an optimal treatment approach.

Methods: Therapeutic Performance Mapping System was used to create Still's Disease pathophysiology and drug MoA models. Drugs' efficacies were compared using artificial neuronal networks, and detailed MoA of IL-1β and IL-6 blockers was modeled using sampling methods. Available expression data in sJIA patients was used for model validation (GSE80060, GSE21521, GSE8361, GSE7753, GSE76492).

Results: The models reflected human physiology (>90% accuracy) and Still's Disease pathophysiology (Figure 1A). Biologicals were found more efficient than non-biologicals (Table 1). IL-1 blockers behaved similarly (CAN as IL-1β-specific blocker was used for further analyses) and presented an innate immune system-centered mechanism, while TCZ acted over the adaptive immune system. A detailed evaluation of the MoA of CAN and TCZ on the innate immune system showed some well-known proteins (Figure 1B) differentially modulated. While CAN inhibits NF-κB, CXCL8 and S100A9 more effectively, CD64 (FCGR1A) is preferentially inhibited by TCZ. The CAN and TCZ MoA models reproduced 67% of the information obtained from expression data (Figure 2).

Conclusion: The created *in silico* Still's Disease models reproduce known clinical and molecular findings, which render them a good tool for future patient profiling, biomarker identification and treatment strategy designing. According to the models, the biologicals tested for proof-of-concept purposes provide a more pathophysiology-directed MoA than non-biological drugs, and are similarly effective on both systemic and rheumatic disease features. IL-1 blockers, specifically CAN, might be more efficient than TCZ in initial autoinflammatory/systemic phases of Still's Disease that is dominated by innate immune dysregulation. Key innate immune mediators are hereby proposed to explain the differences observed between CAN and TCZ MoA. Our systems biology data may thus support the development of therapeutic strategies fostering early intervention with CAN during the window of opportunity to prevent the development of destructive chronic arthritis and treatment- or disease-associated complications long-term.

Predictors of Response to Tumour Necrosis Factor - α Inhibitors (TNFi) in Juvenile Idiopathic Arthritis (JIA): A Single-center Experience

Muhammad Shipa,[1] Anastasia-vasiliki Madenidou,[2] vera Choida,[1] Anna Radziszewska,[3] corinne fisher,[4] coziana ciurtin,[1] maria Leandro,[1] and Debajit Sen[1], [1]Centre for Adolescent Rheumatology versus Arthritis at UCL, UCLH and GOSH, London, UK, [2]Centre for Adolescent Rheumatology, University College London London, UK, University College London, London, United Kingdom, [4]Centre for Adolescent Rheumatology versus Arthritis at UCL, UCLH and GOSH, London, UK

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologics have transformed the treatment of Juvenile idiopathic arthritis (JIA) and escalation to Tumour Necrosis Factor - α inhibitors (TNFi) after failure of methotrexate (MTX) was enshrined as NHS standard practice in National Institute of Clinical Excellence guidelines in 2002. The aim of our study was to explore the clinical response to first TNFi including duration on treatment before discontinuation due to loss of efficacy (secondary failure), clinical remission or side-effects. We looked at six sub-types of JIA. Group A consisted of subtypes of JIA with polyarticular course of disease encompassing Seropositive and Seronegative polyarticular JIA (SPPJIA, SNPJIA) and Extended oligoarticular JIA (EOJIA). The other groups were Persistent oligoarticular JIA (PO JIA), Psoriatic arthritis (Ps JIA) and Enthesitis-related arthritis (ERA). We excluded Systemic and undifferentiated JIA as we wanted to focus on the response to TNFi.

Methods: This was a retrospective, single centered, observational real-life study of the cohort of patients with JIA at UCLH (University College London Hospitals). We took a single data extract from our clinical database in January 2019. We included patients diagnosed with JIA (fulfilling International League of Associations for Rheumatology criteria) starting on TNFi from October 2012 (database inception) to December 2018. All had at least six months of follow-up since the introduction of the TNFi to 2018. The patients remaining on TNFi 6 months after initiation were defined as responders in accordance with national guidelines (NHS England stipulate that TNFi must be stopped if there is a failure to respond after 6 months). IBM statistics 2017 SPSS and Prism 8 for macOS was used for data analysis.

Results: We initially included a total of 328 JIA patients. Ten were excluded (5 missing data, 3 with treatment duration < 6 month, 2 malignancies). The baseline characteristics of the 318 patients are presented in **table 1**. Overall, the

response rate was 61% (195/318) (**Graph 1 a**). Of the 195 responders, 77 (39.5%) eventually stopped their treatment (**Graph 1 b**).Of these 45 (60%) had secondary failure due to inefficacy, 21 (27%) were in remission and 10 (13%) due to an adverse reaction.

Unlike other studies, there was no significant correlation between age of disease onset and treatment response (**graph 2 a**). Group A showed significantly better response if treatment was started earlier (**graph 2 b**). However, this was not demonstrated in other subtypes. Group A only demonstrated a better response if on MTX (**graph 2 c**). There was no significant difference among the other subtypes. A higher basal metabolic index (BMI) was associated with poorer response to TNFi in Ps JIA group (**graph 2 d**). A higher baseline C-reactive protein (CRP) was associated with better response to TNFi for ERA (**graph 2 e**). In Ps JIA a good response to TNFi was associated with a significantly lower Erythrocyte sedimentation rate (ESR) (**graph 2 f**) at initial presentation.

Conclusion: We found that a good response to TNFi treatment in patients with JIA was associated with

1. Polyarticular course disease (group A) - Early start of treatment, concomitant use of MTX.
2. Ps JIA: Lower BMI, Lower ESR.
3. ERA: Higher CRP.

Characteristics	Group A			Persistent oligo articular JIA (n=17)	Psoriatic arthritis (n=30)	Enthesitis-related arthritis (n=99)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis occurs in 10-20% of children with Juvenile Idiopathic Arthritis (JIA) and is typically asymptomatic. Ocular complications occur in 50% of children, (i.e. cataracts, vision loss). Even after uveitis is controlled, risk of disease exacerbation still exists. Therefore, frequent ophthalmic screening and monitoring is important for detection and management of JIA-associated uveitis (JIA-U). Potential objective measures of ocular inflammation are S100 proteins, cytokines, and chemokines that have been identified as biomarkers in aqueous humor. However, aqueous humor collection is invasive. Measuring the same biomarkers in tears, would be a less invasive approach. Our objective is to determine whether S100 proteins, cytokines, and chemokine levels differ in tears of JIA-U children with active or inactive uveitis.

Methods: Tears were collected using Schirmer strips from children ≥5 years old with JIA-U (n=20) and pediatric healthy controls (n=20) during routine clinic visit. S100A8, A9, and A12 were measured by ELISA, and IL-18, IL-8, IP-10, MCP-1, RANTES, and sICAM-1 by Luminex assays. Levels were compared between JIA-U children and healthy controls and between JIA-U children with active and inactive uveitis.

Results: S100 proteins, cytokines and most chemokines levels were similar in JIA-U compared to controls. However, differences were observed between JIA-U patients with active and inactive uveitis. Patients with active uveitis had significantly higher levels of tear S100A12 as compared to inactive uveitis (mean 27,722 pg/ML [SE

1.3] vs. 5,937pg/ML [SE 1.3], p=0.0001). Similar increased levels in active uveitis as compared to inactive uveitis for IL-8 (73 pg/ML [SE 1.3] vs. 37 pg/ML [SE 1.1], p = 0.026) and sICAM-1 (15,823 pg/ML [SE 1.2] vs. 8,778 pg/ML [SE 1.6], p=0.004)

Conclusion: Identifying uveitis biomarkers using tears would provide a noninvasive and objective method of detecting and monitoring uveitis. Our results indicate that S100A12, IL-8 and sICAM-1 from tears could be utilized as potential biomarkers for distinguishing inactive and active uveitis. This suggests that neutrophils may play a role in the pathogenesis of anterior uveitis which has been reported in an animal model of acute anterior uveitis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is an increasing body of evidence that inadequately controlled activation of complement factors leading to either overactivity or deficiency may be involved in the pathogenesis of some autoimmune diseases. However, the role of the complement system in juvenile idiopathic arthritis (JIA)is still not fully elucidated. The aims of this study were to determine the serum levels of the lectin pathway proteins early in the disease course and 17 years after disease onset and to correlate the protein levels to markers of disease activity in participants from a population-based Nordic JIA cohort. Additionally, we aimed to assess the predictive value of lectin pathway proteins with respect to remission status.

Methods: A population-based cohort study of consecutive cases of JIA with a disease onset from 1997-2000 from defined geographical areas of Finland, Sweden, Norway and Denmark with 17 years of follow-up was performed. Clinical characteristics were registered and H-ficolin, M-ficolin, MASP-1, MASP-3, MBL and CL-K1 levels in serum were analyzed.

Results: In total, 293 patients with JIA and available blood samples were included (mean age 23.7 ± 4.4 years; mean follow-up 17.2 ± 1.7 years). Further clinical characteristics of the participants at the 17-year follow-up are reported in Table 1.Concentrations of the lectin proteins in serum were higher at baseline compared to the levels 17 years after disease onset ($p \leq 0.006$, n=164). At baseline, the highest level of M-ficolin was observed in systemic JIA, which was significantly higher than in the oligoarticular persistent (p=0.024), polyarticular RF neg (p=0.048), ERA (p=0.02) and the undifferentiated categories (p=0.014) (Figure 1). Conversely, MASP-1 levels at baseline were significantly lower for the systemic group compared to the oligoarticular persistent (p=0.03) and the undifferentiated categories (p=0.019).

Further, high M-ficolin levels at baseline and at 17-year follow-up were correlated to high levels of ESR (Table 2). In contrast, high MASP-1 and MASP-3 tended to correlate to low ESR. CL-K1 showed a negative correlation to JADAS71 at baseline.

None of the protein levels had prognostic abilities with respect to remission or inactive disease status 17 years after disease onset.

Table 1 Clinical characteristics of participants in the Nordic JIA cohort at the 17-year follow-up visit.

Table 2 Correlation between disease activity and lectin levels at baseline and 17-years of follow-up.

	BASELINE#(n=238)			17-YEAR FOLLOW-UP (n=293)		
	ESR	JADAS71	Cum joints	ESR	JADAS71	Cum joints
MBL	N.S.	N.S.	N.S.	N.S.	N.S.	N.S.
H-ficolin	N.S.	N.S.	N.S.	N.S.	N.S.	N.S.
M-ficolin	r=0.23 p<0.01	N.S.	N.S.	r=0.20 p<0.01	N.S.	N.S.
CL-K1	N.S.	r=−0.16 p=0.05	N.S.	r=−0.13 p=0.05	N.S.	N.S.
MASP-1	N.S.	N.S.	N.S.	N.S.	N.S.	N.S.
MASP3	N.S.	N.S.	r=−0.13 p=0.04	N.S.	N.S.	N.S.

Only results with a p≤0.05 are listed. N.S= non-significant. #: Baseline was 6 months (-1/+2 months) after disease onset. ESR= erythrocytes sedimentation rate at baseline, JADAS71= juvenile arthritis disease activity score of 71 joints; cum joints= cumulative joint count; MASP= MBL-associated serine proteases; MBL= mannan-binding lectin; CL-K1= collectin kidney, r= Spearman's rho.

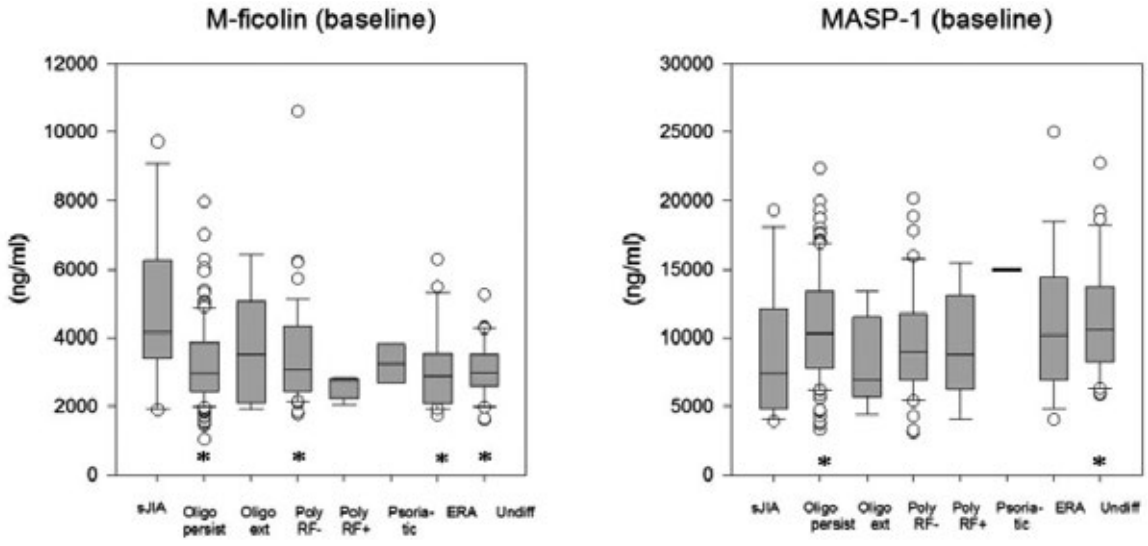

Figure 1 Distribution of M-ficolin (a) and MASP-1 (b) levels at baseline among the different JIA categories. * indicate p<0.05 when comparing to the level of systemic JIA (sJIA). Boxes indicate 25–75 percentile (IQR); a line in all boxes indicate medians; whiskers indicate upper adjacent values; small circles are outliers.

Conclusion: We hypothesize that increased serum M-ficolin levels are associated with higher disease activity in JIA and further, the results indicate that MASP-1, MASP-3 and CL-K1 negatively correlated to markers of inflammation.

Type I Interferon Score and Interferon Induced Mediators CXCL10 and Neopterin Are Correlated with Disease Activity in Juvenile Dermatomyositis

Rebecca Nicolai,[1] Ivan Caiello,[2] Rava' Lucilla,[3] Silvia Rosina,[4] Francesco Licciardi,[5] Luisa Bracci Laudiero,[2] Angelo Ravelli,[6] Fabrizio De Benedetti,[7] and Gian Marco Moneta[2], [1]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, [2]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, [3]Clinical Epidemiology Unit, Ospedale Pediatrico Bambino Gesù, Roma, Italy, Rome, Italy, [4]Giannina Gaslini Institute, IRCCS Clinica Pediatrica e Reumatologia, Genoa, Italy, [5]Division of Pediatric Immunology and Rheumatology, Regina Margherita Children Hospital, Turin, Italy, [6]IRCCS Istituto Giannina Gaslini, Università degli Studi di Genova, Genova, Italy, [7]Bambino Gesù Children's Hospital, Rome, Italy

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interferons (IFNs) seem to play an important role in the pathogenesis of juvenile dermatomyositis (JDM). Our group previously reported that expression of both type I and type II IFN related genes is increased in muscle biopsies of JDM patients and correlates with histological and clinical features of the disease. The aim of this study was to investigate expression of interferon regulated genes (IRGs), as well as serum levels of two type I and type II IFN induced chemokines (CXCL9, CXCL10) and neopterin in peripheral blood of JDM patients and to assess their correlations with clinical and laboratory findings.

Methods: We collected 189 blood samples from 39 JDM patients at different time points during follow-up. In 11 patients we obtained the first blood sample at time of muscle biopsy. We measured expression of type I IRGs (IFI27, IFI44L, IFIT1, ISG15, RSAD2, SIGLEC1), IFNg and type II IRGs (CXCL9, CIITA, IDO1) by quantitative PCR (qPCR) and calculated a type I and type II IFN score for muscle and blood samples; serum levels of CXCL9, CXCL10 and neopterin were analyzed by ELISA. Ten healthy subjects were used as controls (HC). At each visit, the following clinical data were recorded: physician's global assessment (PGA) of disease activity VAS (Visual Analogue Scale), cutaneous VAS, Cutaneous Assessment Tool (CAT) activity score, Childhood Myositis Assessment Score (CMAS), serum levels of creatine phosphokinase (CK, IU/l), presence of myositis specific or myositis associated antibodies (MSA/MAA), prednisone (or equivalent) dose (mg/kg/daily), ongoing immunosuppressive medications.

Results: Serum levels of CXCL9 where significantly correlated with muscle expression of IFNg and type II IFN score. The correlation of CXCL10 levels with muscle type I and type II IFN score was weaker. Muscle expression of CXCL9 and CXCL10 correlated with serum levels of these chemokines. Type I IFN score in blood of JDM patients was increased compared to HC and significantly correlated with PGA, cutaneous VAS, CAT activity score. Serum levels of CXCL9 and CXCL10 were significantly higher in JDM patients compared to HC. MSA positive JDM patients showed higher levels of CXCL9 and CXCL10 compared to MSA negative patients. CXCL10 levels were correlated with PGA

and CMAS, but not with cutaneous disease activity. CXCL9 showed no significant association with the evaluated clinical features. Neopterin levels were significantly correlated with PGA, cutaneous VAS, CAT activity score and CMAS.

Conclusion: Our findings indicate that expression of IRGs, measured as type I IFN score, and serum levels of CXCL10 and neopterin reflect specific features of disease activity in JDM, supporting their role as valuable disease biomarkers.

DNASE1L3 Variant in Hypocomplementemic Urticarial Vasculitis Syndrome Identifies a Different Clinical Phenotype

Marco Ranalli,[1] Chiara Passarelli,[2] Virginia Messia,[3] Manuela Pardeo,[3] Emanuela Sacco,[4] Antonella Insalaco,[3] Marina Vivarelli,[5] Fabrizio De Benedetti,[6] and **Claudia Bracaglia**[7], [1]Pediatric Department, La Sapienza University of Rome, Rome, Italy, [2]Unit of Laboratory of Medical Genetics, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, [3]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy, [4]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, [5]Division of Nephrology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy, Rome, Italy, [6]Bambino Gesù Children's Hospital, Rome, Italy, [7]Division of Rheumatology, IRCCS Ospedale Pediatrico Bambino Gesù, Rome, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypocomplementemic urticarial vasculitis syndrome (HUVS) is a rare disease characterized by persistent urticarial lesions and hypocomplementemia associated with systemic features involving musculoskeletal, pulmonary, renal and gastrointestinal systems. Systemic lupus erythematosus (SLE) develops in >50% of patients with HUVS, although the pathogenesis is unknown.

Methods: We describe 6 paediatric patients with HUVS, three of whom carry a homozygous variant of *DNASE1L3* and present a peculiar clinical phenotype. A Targeted Resequencing using a panel including genes already known to be mainly associated to Interferonopathies Lupus-like (*DNASE1*, *DNASE2*, *DNASE1L3*, *TREX1*) on the Illumina NextSeq® platform was performed. All variants identified were confirmed by Sanger sequencing and, when possible, family members were tested to study the segregation of identified variants. We applied in silico studies only to variants with an allelic frequency ≤1%.

Results: All patients described are Caucasian and 3 of them are female. Two patients presented at onset with extended cutaneous manifestation, joints and abdominal involvement with cholecystitis. They did not develop renal or pulmonary involvement. In contrast, the other four patients presented a more severe disease. All of them developed renal involvement (from microhaematuria up to nephrotic syndrome) with renal biopsy showing mesangial glomerulonephritis in three patients and pauci-immune glomerulonephritis (ANCA negative) in one. Moreover, two of them developed also pulmonary vasculitis (Table 1). A homozygous *DNASE1L3* variant (c.290_291delCA) was identified

Table 1. Patients' clinical characteristics

	Pt 1	Pt 2	Pt 3	Pt 4	Pt 5	Pt 6
Age at onset	9 y 6/12	3 y 10/12	9y 5/12	14y 3/12	3y 6/12	3y 1/12
Joints	Yes	Yes	Yes	No	Yes	Yes
Ocular	No	Yes	No	No	No	No
Abdominal	Yes	Yes	Yes	No	Yes	Yes
Pulmonary	No	Yes	Yes	No	No	No
Renal	Yes	Yes	Yes	Yes	No	No
Antibody anti-C1q	+	+	+	+	+	+
Anti-dsDNA	absent	absent	absent	absent	absent	absent
C3 (nv 90-180 mg/dl)	57	63	52	57	19	57
C4 (nv 10-40 mg/dl)	7	6	2	7	1	1
DNASE1L3 variant	+	+	Ongoing	+	-	-

in three of these patients. All of them were treated with glucocorticoid and dapsone at onset. Cyclophosphamide, mycophenolate mofetil and azathioprine were used in patients with renal involvement. None of them developed SLE.

Conclusion: HUVS is very rare disease in childhood. Approximately 50% of HUVS patients develop SLE. Genetic susceptibility to SLE is recognized and *DNASE1L3*-related SLE have been reported. Özçakar et al. have described 5 children from two families with HUVS who carry the same variant on *DNASE1L3* that we report here (1). Our patients confirm that variant in *DNASE1L3* can cause HUVS and support the hypothesis that this variant is responsible of a more severe phenotype with major organ involvement (renal and pulmonary). Patients with HUVS need to be followed very strictly for the risk to develop SLE. Presence of variant in *DNASE1L3* can identify patients with more severe disease and high risk to develop major organ involvement. These patients need more aggressive and possibly life-long immunosuppressive treatment.

Can High ANA Titre Combined with Clinical Features Predict Developing Autoimmune Conditions in Children?

Ovgu Kul Cinar,[1] Charlene Foley,[2] Ali Al-Hussain,[3] Kimberly Gilmour,[4] Matthew Buckland,[4] and Muthana Al-Obaidi[5], [1]Great Ormond Street Hospital, Lonodn, United Kingdom, [2]Great Ormond Street Hospital, London, Ireland, [3]Great Ormond Street Hospital, London, United Kingdom, [4]Great Ormond Street Hospital NHS Trust, Camelia Botnar Laboratories, London, United Kingdom, [5]Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Antinuclear antibodies (ANA) are autoantibodies that recognise cellular antigens found predominantly in the cell nucleus. They are associated with numerous autoimmune diseases such as systemic lupus erythematosus (SLE), but may also be found in infectious diseases, malignancies and apparently healthy individuals.

ANA is routinely requested as part of an initial work-up for autoimmune conditions. The titre of ANA required before a sample is considered "positive" varies between laboratories and is dependent on factors such as the technique used. In healthy children (5-18%), ANA titres of 1/80 to 1/320 have been reported. Over time a proportion will decrease in titre or disappear. However, some may persist raising concerns about the possibility of autoimmune disease in evolution. A prospective study of healthy children with positive ANA found that children who developed autoimmune disease had clinical features at presentation that were suspicious for such an outcome. Therefore, the usefulness of a positive ANA result for diagnosing autoimmune conditions is limited without clinical correlation.

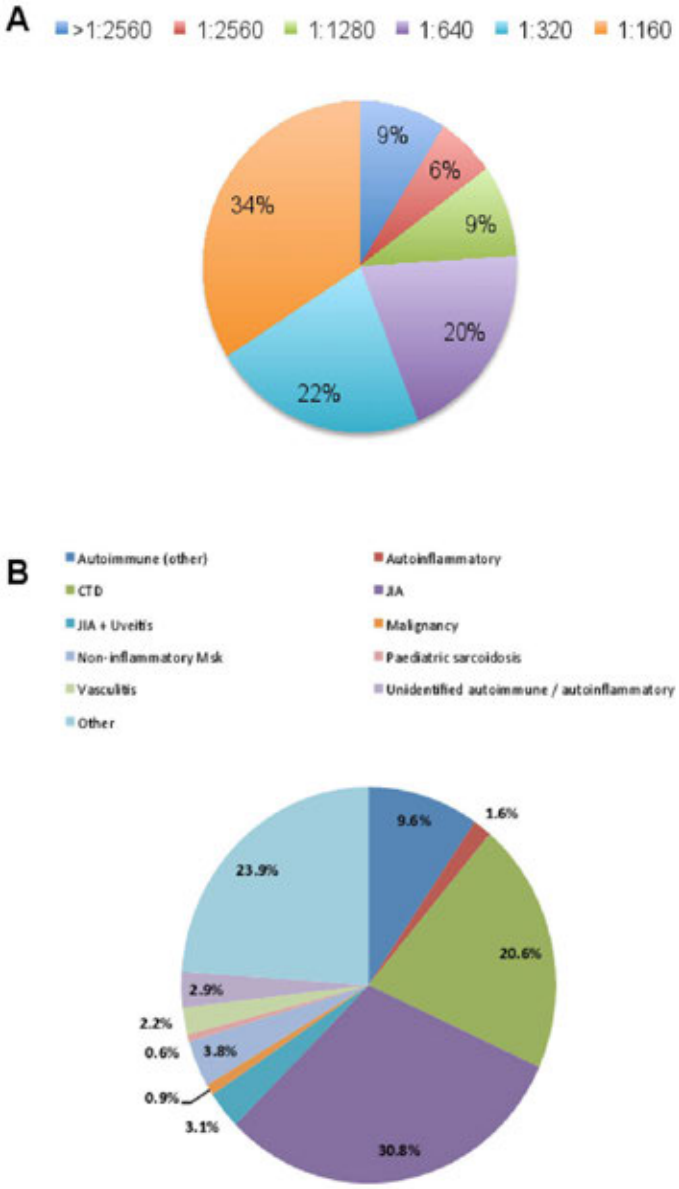

Figure 1. Percentage of each ANA titre observed in our cohort. B. Range of diagnoses observed in children with positive ANA results at presentation.

Our aim was to assess whether high ANA titre and clinical features at first presentation could predict final diagnosis

Methods: Single centre (Great Ormond Street Hospital for Children GOSH), retrospective study. The immunology laboratory at GOSH provided a list of positive ANA results (using indirect immunofluorescence) reported by their laboratory from January 2013 to July 2018. Results were filtered to exclude duplicate results for the same patient, creating a list of patients with ANA titre results from their first contact with our hospital. A retrospective chart review

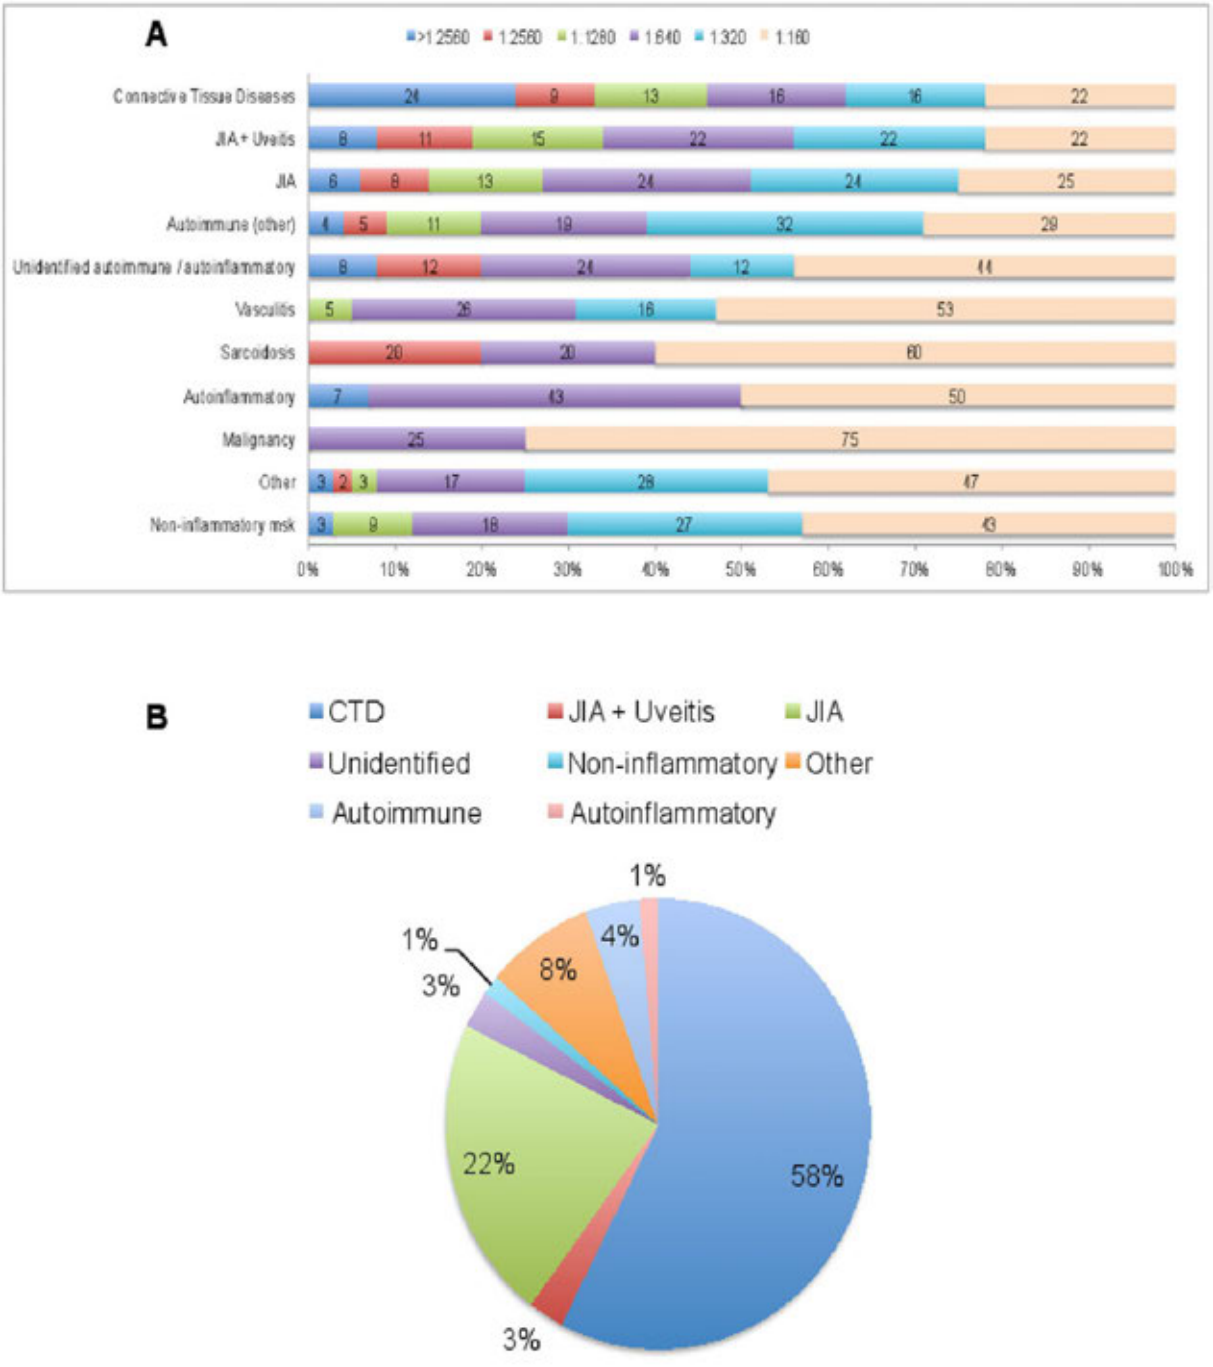

Figure 2. Bar chart displays the percentage of each diagnostic cohort that had each ANA titre. B. Pie chart for ANA titre >1:2560 showing the percentage of each diagnostic cohort that had this high titre. Over 50% of those with an ANA titre >1:2560 at presentation were diagnosed with a connective tissue disease (CTD)

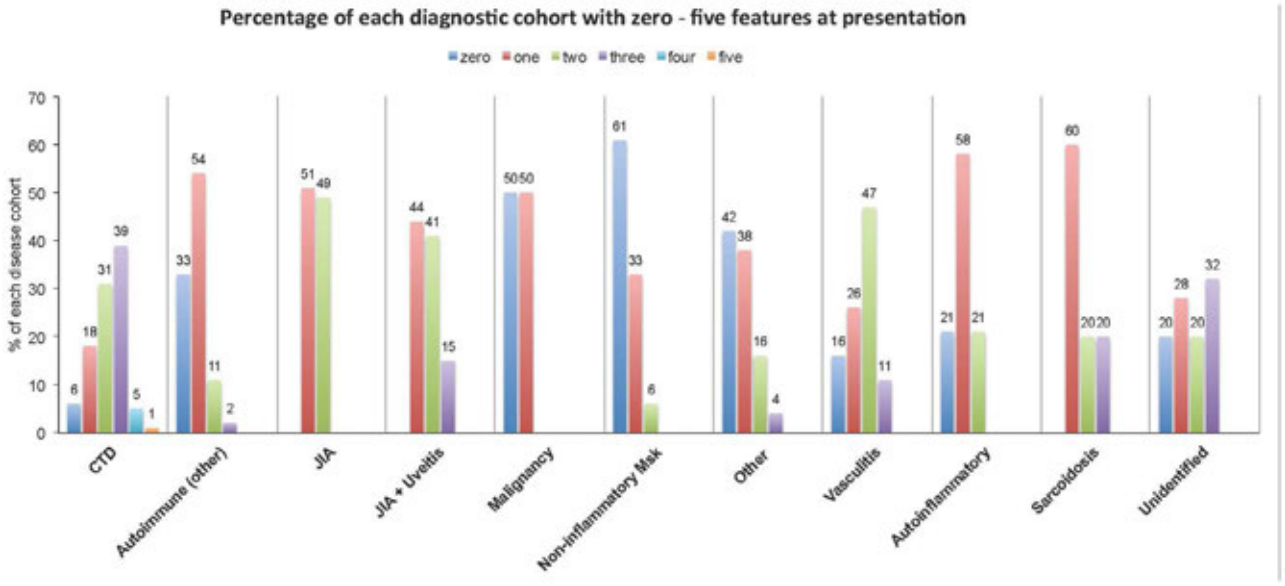

Figure 3. Bar chart depicting the number of clinical features children presented with depending on final diagnosis. Children diagnosed with a connective tissue disease (CTD) presented with 2 or more clinical features in 76% of cases, compared to only 6% of the non-inflammatory cohort.

was performed to ascertain presence or absence of clinical features at presentation under the following titles, arthritis, skin involvement, eyes, CNS involvement and raynaud's. We then reviewed the last clinical contact to document confirmed diagnosis and grouped these into 11 categories such as Connective Tissue Disease (CTD), JIA and so on.

Results: We performed a retrospective chart review on 1354 children (67% female; median age 7.5 years (0.1-17.5); median follow-up 4.8 years (0-18)) with positive ANA results (titres 1/160, 1/320, 1/640, 1/1280, 1/2560 and >1/2560). Figure 1A summarises the ANA titres observed in our cohort, and 1B the range of final diagnoses made. Figure 2A reports ANA titres at first presentation in relation to final diagnosis. A titre of 1/640 or above was most commonly seen (>50%) in children with an autoimmune rheumatology condition (JIA, JIA and uveitis or a CTD). In fact, children with the highest titre (>1:2560) were significantly more likely to be diagnosed with one of these conditions (figure 2B). Finally, we looked at the number of presenting features and correlated with final diagnosis (figure 3). Those diagnosed with a CTD were most likely to present with 2-5 clinical features (chi square $p< 0.0001$).

Conclusion: This study suggests that, patients presenting with higher ANA titres and a combination of clinical features at presentation should be assessed systemically and followed-up as they may have increased risk of an autoimmune rheumatological diagnosis.

Closing the Seronegative Gap in Pediatric Localized Scleroderma and Systemic Sclerosis

May Choi,[1] Emily Mirizio,[2] Fernanda Quinteros,[3] Katherine Buhler,[4] Marvin Fritzler,[1] and Kathryn Torok[5], [1]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [2]University of Pittsburgh, Pittsburgh, [3]University of Calgary, Calgary, [4]University of Calgary, Calgary, Canada, [5]UPMC Children's Hospital of Pittsburgh, Pittsburgh

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: It has become increasingly recognized that extra-cutaneous manifestations, such as musculoskeletal and neurologic involvement, are common in pediatric patients with localized scleroderma (LS). We previously demonstrated that the presence of certain autoantibodies (Aab) is associated with deep tissue and internal

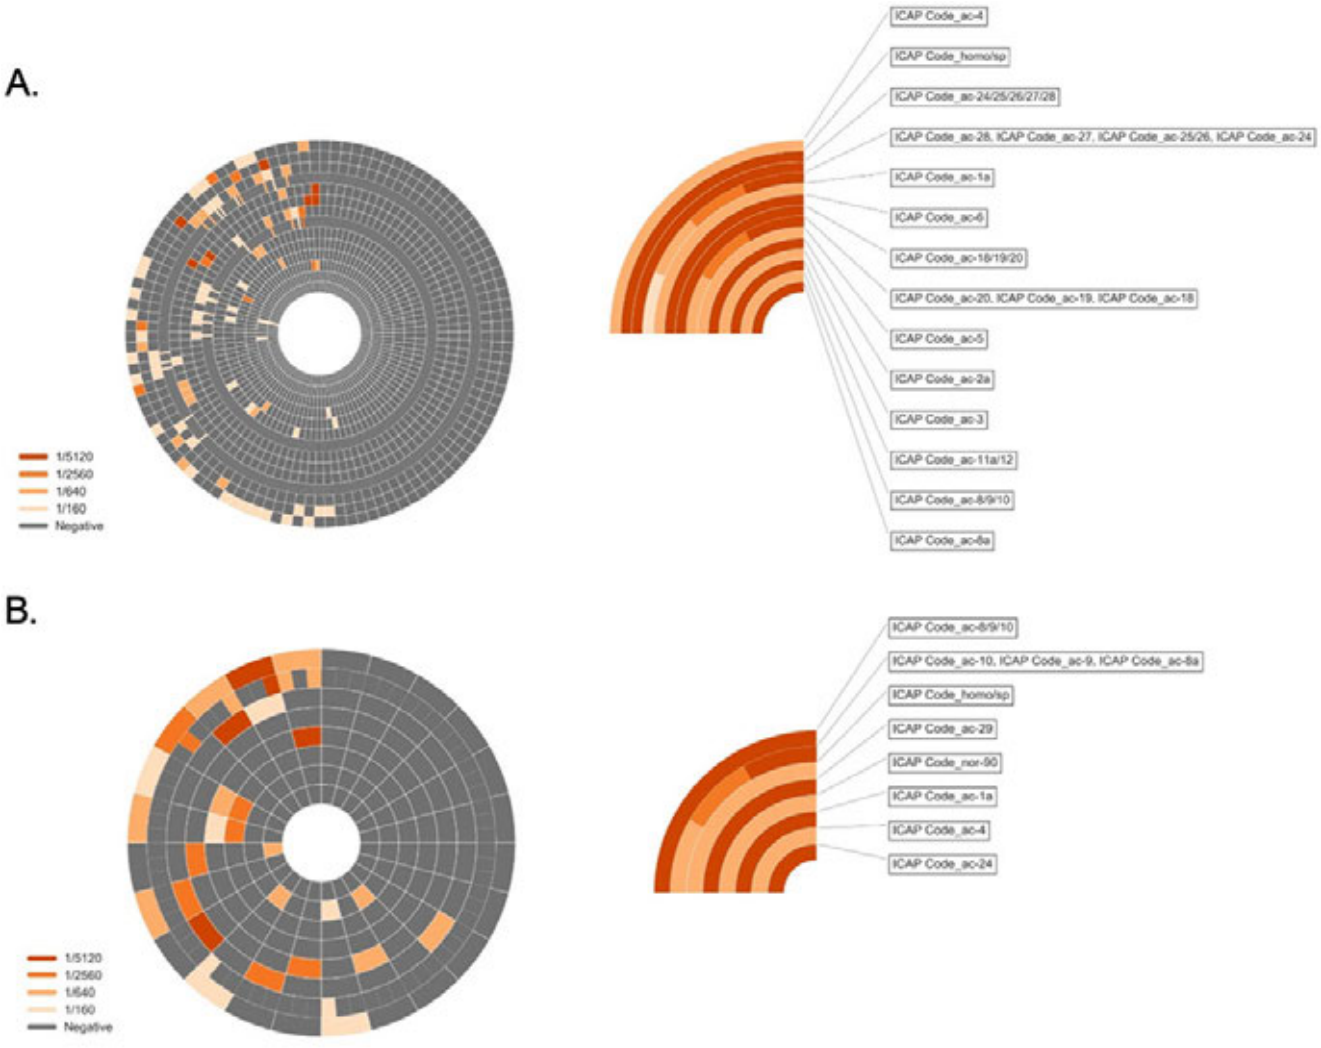

Figure 1. Circular heat maps for anti-nuclear antibody indirect immunofluorescence patterns in localized scleroderma (A) and systemic sclerosis (B) pediatric patients using the international consensus on ANA patterns (ICAP) nomenclature (www.anapatterns.org).

organ involvement compared to pediatric healthy controls. In this study, a wider screening Aab array was used in a study to compare pediatric LS to pediatric systemic sclerosis (SSc).

Methods: A total of 133 pediatric patients (n=109 LS and 24 SSc) were included. Sera was tested for antinuclear antibodies (ANA) using indirect immunofluorescence (IIF) on HEp-2 cells (Inova Diagnostics, San Diego, CA) where a titre of equal to or greater than 1/80 was considered to be positive. Circular heat maps were generated to compare the frequency of ANA patterns in each group. The international consensus on ANA patterns (ICAP, www.anapatterns.org) nomenclature was used to denote ANA IIF pattern nomenclature.

Results: A total of 59/109 (54%) LS patients and 16/24 (67%) SSc patients were ANA positive. LS had the greatest number of distinct ANA patterns (n=11) compared to SSc (n=7) (Figure 1). AC-4 (nuclear speckled) was the most common pattern (23/109, 21%) while AC-8/9/10 (nucleolar) was the least common in LS (2/109, 2%). The opposite was true for SSc where AC-8/9/10 (9/24, 38%) was the most common and AC-4 was uncommon (3/24, 13%). Other ANA IIF patterns such as AC-2 (dense fine speckles) (4/109, 4%) and AC-24 (centrosome) (8/109, 7%) were seen in LS, but was absent or rare in SSc.

Conclusion: Pediatric SSc had higher frequency of ANA positivity compared to pediatric LS, as clinically expected, but not by a high margin. Interestingly, patients with LS had more heterogeneous expression of ANA patterns, including patterns that are rarely seen in SSc such as AC-24 (centrosome). Furthermore, since the centrosome is in the cytoplasm, the centrosome pattern would not be reported by laboratories that only report nuclear IIF patterns as a positive ANA. Therefore, an ANA test that includes nuclear, cytoplasmic, and mitotic patterns should be considered as the screening test in patients with scleroderma, especially LS.

Speckle Tracking Echocardiography, a Sensitive Tool to Detect Early Cardiac Dysfunctions in Juvenile Systemic Sclerosis

Giovanni Civieri,[1] Biagio Castaldi,[1] Giorgia Martini,[1] Alessandra Meneghel,[1] Ornella Milanesi,[1] and **Francesco Zulian**[2], [1]Dept. of Woman's and Child's Health, university of Padua, Italy, Padua, Italy, [2]Department of Woman and Child Health, University of Padua, Italy, Padova, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Systemic Sclerosis (JSSc) is a rare connective tissue disease in which cardiac involvement is burdened by high morbidity and mortality. The traditional cardiac imaging techniques seem to be partially appropriate to assess the subclinical course of the disease. In adult-onset SSc, the Speckle Tracking Echocardiography (STE), was shown to be able to identify regional ventricular dysfunctions also in early stages of [1,2]. Aim of our study was to assess the role of STE of the right and left ventricle in order to identify early ventricular dysfunctions in JSSc.

Methods: Consecutive patients with JSSc [3], followed at our Pediatric Rheumatology Center, were periodically evaluated by the cardiology team. For each patient, information on demographic and clinical data, autoantibody profile and treatment were collected. Cardiac investigations, performed at least three times, at baseline (T0), 18 months (T18) and 36 months (T36) included: electrocardiography, conventional echocardiography, STE with assessment of left ventricular global longitudinal strain (GLS) (n.v. < -19%) and right ventricular longitudinal strain (RVLS) (n.v. < -25 %). The course of cardiac involvement during the follow-up was correlated with the overall disease severity, measured by the Juvenile Systemic Sclerosis Severity Score (J4S)[4].

Results: 18 JSSc patients, 12 (67%) females, entered the study (Table 1). ANA were positive in 17 patients (94%), 6 (33%) were anti Scl-70+. At T0, EKG was abnormal in 3 patients, EF was reduced in one survivor to cardiopulmonary arrest (EF=53.8%), the GLS was abnormal in 3 patients, only one with concomitant reduced EF and clinical history of cardiac involvement. A significant correlation between GLS and J4S at T0 was found (r=0.595; p=0.012) (Figure 1). The RVLS resulted abnormal in 5 patients with significant correlation with GLS (r=0.693; p=0.002). At T18, EF remained relatively stable while at T36 it decreased in 7/9 patients, with a mean value of 62.2% (p=0.09). GLS also worsened (from -21.6% to -18.2%; p=0.01). As for treatment, at baseline, none of the patients with pathological GLS was assuming calcium channel blockers (CCB), while all of those taking CCB during follow up had normal GLS. GLS

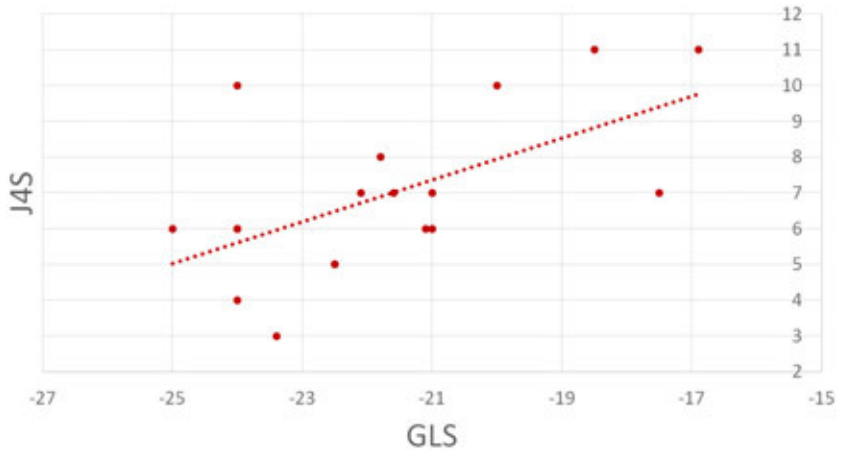

Figure 1. Correlation between J4S and GLS

Table 1 Clinical characteristics of the patients	T0 no.18	T18 no.9	T36 no.9
Sex F (%)	12 (67%)	5 (55%)	5 (55%)
Age (years)	12.3 ± 4.2	13.9 ± 3.4	15.1 ± 4.3
Age at onset (years)	7.8 ± 3	9.5 ± 2.7	9.5 ± 2.7
Disease duration (years)	4.5 ± 3.7	4.4 ± 1.5	5.8 ± 1.2
J4S	6.9 ± 2.3	6.4 ± 2.5	5.8 ± 3.7
mRSS	10.4 ± 9	8.3 ± 6.2	6.5 ± 4.8
Raynaud Phenomenon (% positive)	11 (61.1%)	7 (77.7%)	4 (44.4%)
Lung Involvement (% positive)	9 (50%)	3 (33.3%)	2 (22.2%)
GI Involvement (% positive)	15 (83%)	9 (100%)	7 (77.7%)
Musculoskeletal Symptoms (% positive)	10 (55%)	3 (33.3%)	3 (33.3%)

at baseline showed a significant correlation with the disease severity, measured by J4S (p=0.012). The same was observed for the RVLS (p=0.02).

Conclusion: STE is more sensitive than standard echo to evaluate the cardiac involvement in JSSc. Over time, we observed a gradual worsening of GLS, sign of a progressive left ventricular dysfunction, that was not identified by EF. It is possible that the coronary microvascular damage compromises the subendocardial fibers function which are more sensitive to ischemia and whose contractility is well assessed by GLS [5].

Rituximab for Rapidly Progressive Juvenile Systemic Sclerosis: A Proof-of-concept Study in Four Patients

Roberto Dal Pozzolo,[1] Alessandra Meneghel,[1] Biagio Castaldi,[1] Giorgia Martini,[1] Renzo Marcolongo,[2] and **Francesco Zulian**[3], [1]Dept. of Woman's and Child's Health, University of Padua, Padua, Italy, [2]Clinical Immunology, Dept. of Medicine, University of Padua, Padua, Italy, [3]Department of Woman and Child Health, University of Padua, Padova, Italy

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Systemic Sclerosis (JSSc) is a rare multi-systemic disease characterized by fibrous changes of the skin and internal organs [1]. Patients with "rapidly progressive" SSc present with rapid development of skin induration and life threatening organ involvement, leading to poor prognosis [2, 3]. Recently, Rituximab (RTX), a monoclonal antibody against the CD20 antigen on B cells, has shown to be a promising therapy for adult patients with SSc [4, 5]. We present our experience with four pediatric patients with rapidly progressive JSSc treated with RTX.

Methods: Data on clinical, laboratory and instrumental parameters were collected from four patients with rapidly progressive JSSc treated with RTX for at least one year. Data were recorded at baseline and every 6 months after initiation of therapy. All patients underwent i.v. RTX therapy with four cycles (375 mg/m^2 every 2 weeks), at 3 months intervals. Low dose oral prednisone and mycophenolate mofetil (MMF, 500 mg/m^2/day) were administered between RTX pulses. Skin changes were assessed by mRSS, changes on muscles involvement by CMAS. Variations on BMI, pulmonary function tests (FVC, FEV1, DLCO) and cardiac involvement (LVEF, LVEDV, GLS) were expressed as % change from baseline. J4S was used to assess the overall disease severity [6].

Results: Four JSSc patients (3M, 1F), aged 8-17 years, entered the study (Table 1). Three patients presented with prevalent cardiac involvement. One patient (no.3) presented with severe pulmonary involvement. After one year RTX treatment, all patients showed significant decreased of number/duration of Raynaud Phenomenon attacks and cutaneous involvement. Prior RTX treatment, 2 patients needed an implantable cardioverter defibrillator (ICD) because of episodes of severe ventricular tachycardia (VT). After 12 months of therapy one patient presented improvement LVEF (+19%) and J4S, the other showed a global cardiac improvement (LVEF +37%, LVEDV -18%) and J4S. Both underwent a second year-long treatment with RTX with stabilization of internal organs' involvement. Case 3 showed a significant improvement of the respiratory function (FVC +46%, FEV1 +33%, DLCO +30%) with decreased J4S. Case 4 improved her arrhythmia and muscle strength (CMAS +17%). No major RTX-related side effects were reported.

Conclusion: Rapidly progressive JSSc still carries a high mortality rate. To the best of our knowledge this is the first series of patients with JSSc successfully treated with RTX. Our experience, although in a small cohort, confirms the beneficial effect of this therapy on the life-threatening internal organ involvement, particularly on cardiac function.

Abstract Number: 0794

Mycophenolate Mofetil for the Treatment of Severe or Methotrexate-refractory Juvenile Localized Scleroderma

Laura Saggioro,[1] Giorgia Martini,[1] Roberta Culpo,[1] Alessandra Meneghel,[1] and **Francesco Zulian**[2], [1]Dept. of Woman's and Child's Health, University of Padua, Padua, Italy, [2]Department of Woman and Child Health, University of Padua, Padua Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Localized Scleroderma (JLS), includes a number of conditions characterized by skin thickening with varying degree of severity. Many patients, particularly those with the linear subtype, develop deformities and joint limitation or, as in scleroderma of head/face, functional and cosmetic problems as well as involvement of eyes and brain [1]. Although represents the first-line treatment for JLS [2], for some patients Methotrexate (MTX) is ineffective or not well tolerated. We investigated the safety and efficacy of mycophenolate mofetil (MMF) in a cohort of patients with severe or MTX-refractory JLS.

Methods: Consecutive JLS patients with severe or MTX-refractory followed at our Pediatric Rheumatology Unit were treated with MMF at doses varying from 600-1200 mg/m2/day bid. The disease was defined as active by the appearance of new lesions or increasing size of pre-existing ones, clinical signs of active inflammation, such as erythema, and/or by detection of disease activity by thermography when the affected area was more than 0.5°C warmer than the contralateral side or the surrounding skin depending on the site of the lesion itself. Outcome was defined as active disease (A), clinical remission on medication (CRM) (inactive disease for at least 6 consecutive months ON treatment) and Clinical Remission (CR) (inactive disease for at least 24 consecutive months OFF treatment).

Results: Twenty one patients (9M, 12F) entered the study. The JLS clinical subtypes [3] were circumscribed (C) morphea (2 pts), generalized morphea (GM) (1), linear scleroderma limbs (LSL) (5), linear scleroderma head/face (LSHF) (4), pansclerotic morphea (PM) (3), mixed subtype (MiX) (6). The age at onset of the disease was 8.2 yrs (range 0–14), disease duration at diagnosis was 10 months (range 0–3 years). Before starting MMF, 19 patients have been treated with MTX and low dose corticosteroids oral in 13 pts, IV pulse in 6. In this group, MMF was started because of MTX lost efficacy (10) or relapse after MTX withdrawal (9). In one patient MMF was started because of MTX-related anaphylaxis and one patient with linear head/face congenital scleroderma with cerebral involvement. After 7.4 year follow up (range 2-14.7) CRM was present in 8 patients (38%) and sustained CR in 8 (38%). Five patients (24%) (1 PM, 2 LSHF, 2 MiX) have still active disease despite MMF.

Conclusion: MMF is effective in severe and/or MTX-refractory JLS and generally well tolerated. Our study, although with the limits of being small-sized and retrospective, confirms that MMF represents a valid alternative to MTX, particularly in severe cases, when extracutaneous manifestations are present, or as complementary to MTX, when it loses efficacy. Further controlled studies are needed to confirm these data or to proof its efficacy as first line treatment of JLS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic scleroderma (jSSc) is an orphan disease with an estimated prevalence of 1 in 1 000 000 children. In the adult systemic scleroderma population there are large differences regarding organ pattern and severity between diffuse and limited subtypes.

Methods: We reviewed all patients of juvenile scleroderma inception cohort (jSScC) at the time of inclusion till 15th May 2019. The jSScC is a cohort, where patients, who fulfill the adult 2013 classification criteria , are age under 18 at the time of inclusion and developed the first non-Raynaud before the age of 16 years are included.

Results: 131 patients were included, 72.5% with diffuse subtype. 75% females in the diffuse (djSSc) and 71% in the limited subtype(ljSSc). 86% of patients were Caucasian. Mean age of onset of Raynauds was 9.7 years in the djSSc and 10.7 years in the ljSSc (p=0.8). Mean age of onset of the non-Raynauds was 9.9 years in the djSSc and 11.2 years in the ljSSc (p=0.7). Mean disease duration at time of inclusion was 3.4 years in the djSSc and 2.4 years in the ljSSc There was no significant difference in the ANA, anti-Scl-70 and anticentromere positivity. The mean modified skin score was significantly higher in the djSSc (17.3 compared 7.1, (p=0.3)). They were significantly more teleangiectasia in the djSSc group (39% compared to 19% (p=0.003)). Cardiac involvement was significantly higher in the ljSSc group (19% compared to 3% (p=0.005) There was no significant difference in the proportion of ILD, pulmonary hypertension, gastrointestinal involvement and renal involvement. No renal hypertension was observed. There was significantly more muscle weakness observed in the ljSSc group (38% compared to 17% (p=0.029)). There was no significant difference regarding number of joints with contractions. Physician rated disease activity (40 compared to 29, on 100 mm VAS scale (p=0.013)) and disease damage (37 compared 18, on a 100 mm VAS scale (p< 0.001)) was significantly higher in the djSSc. This significant difference was not found in rating of patients of disease damage and activity.

Conclusion: ljSSc and djSSc seems to be more similar than in adult patient with these subtypes, although physician rating of disease activity and damage found the djSSc more severe.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile systemic sclerosis(jSSc) is an orphan disease with a prevalence in around 3 in a million children [1]. Pulmonary involvement in jSSc occurs in approximately 40 % in the inception cohort [2]. Traditionally in jSSc, pulmonary function testing (PFT) with FVC and DLCO are used for screening and computed tomography (HRCT) was more reserved for those with abnormal PFTs. More recently, it has become apparent that PFTs might not be sensitive enough for detecting ILD in children.

Methods: Utilizing a prospective international juvenile systemic scleroderma cohort (JSScC) [2], to determine if pulmonary screening with FVC and DLCO is sufficient enough to assess the presence of interstitial lung disease in comparison to CT evaluation.

The JSScC cohort database was queried for available patients with recorded PFT parameters and HRCT performed to determine sensitivity of PFTs detecting disease process.

Table 1. Diagnostic test properties of FVC as a test for ILD detection.

	Disease + (ILD Yes on HRCT)	Disease – (ILD No on HRCT)	Total
Test + (FVC <80%)	a) True positive = 13	c) False positive = 7	a+c =20 (+Test)
Test – (FVC>80%)	b) False negative = 20	d) True negative = 27	b+d =47 (-Test)
Total	a +b = 33 (+Disease)	c+d = 34 (- Disease)	

Results: Of 129 patients in the jSScC, 67 patients had both CT imaging and an FVC reading from PFTs for direct comparison. DLCO readings were also captured but not in as many patients with tandem HRCT (n =55 DCLO and HRCT scan). Therefore, initial analyses focused on the sensitivity, specificity and accuracy of the FVC value from the PFTs to capture the diagnosis of interstitial lung disease as determined by HRCT. Table 1 presents these diagnostic test evaluations for the FVC. Overall, 49% of the patients had ILD determined by HRCT, with 60% of patients having normal FVC (>80%) with positive HRCT findings, and 24% of patients having normal DLCO (> 80%) with positive HRCT findings. Fourteen percent (n = 3/21) of patients with both FVC and DLCO values within the normal range had a positive HRCT finding.

Conclusion: The sensitivity of the FVC in the JSScC cohort in detecting ILD was only 39%. Relying on PFTs alone for screening for ILD in juvenile systemic sclerosis would have missed the detection of ILD in almost 2/3 of the sample cohort, supporting the use of HRCT for detection of ILD in children with SSc. In addition, the cut off utilized, of less than 80% of predicted FVC or DLCO could be too low for pediatric patients to exclude beginning ILD. This pilot data needs confirmation in a larger patient population.

Abstract Number: 0797

Characteristics of Coexisting Localized Scleroderma and Juvenile Idiopathic Arthritis

Daniel Reiff,[1] Courtney Crayne,[2] Melissa Mannion,[3] and Randy Cron[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]University of Alabama at Birmingham, Alabama

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Localized scleroderma (LS), including morphea and linear scleroderma, is an autoimmune disease where excessive collagen deposits underneath the skin lead to thickening, scarring, and fibrosis. Often limited to the skin, affecting only the outer layer and subcutaneous tissues, this disease may be one manifestation of a diffuse systemic inflammatory process. LS coexisting with juvenile idiopathic arthritis (JIA) is less well-described but has been reported in as many as 20% in a recent cohort of 53 LS patients. Herein, we describe a cohort of 8 children with both LS and JIA. The objective of this study is to determine the characteristics of JIA in children with LS and response to treatment regimens.

Methods: A retrospective chart review was completed on patients less than 19 years of age who were diagnosed with either morphea or linear scleroderma at a single institution from 2004-2018. Patients were identified using ICD-9 and ICD-10 diagnostic codes. Records were reviewed for additional diagnostic codes, exams, and laboratory findings confirming coexisting JIA.

Results: A total of 87 patients with a diagnosis of either morphea or linear or circumscribed scleroderma were identified. Eight (9%) also had coexisting JIA per diagnostic codes with active arthritis as documented by a pediatric rheumatologist. Median age of initial rheumatic disease diagnosis was 7.5 years. A majority of patients with both LS and JIA were female (62.5%). Half of the patients (n=4, 50%) had LS lesions over arthritic joints. JIA subtype varied widely with 3 (37.5%) patients with rheumatoid factor (RF) negative polyarticular JIA, 2 (25%) patients with oligoarticular JIA, 2 (25%) patients with psoriatic JIA, and 1 (12.5%) with enthesitis-related JIA. The timing of onset of LS and JIA also varied widely. Three (37.5%) patients had LS lesions preceding the appearance of clinical arthritis on exam, and three (37.5%) patients had arthritis before the appearance of LS. Two (25%) patients had both LS and arthritis at time of diagnosis. Two (25%) of the 8 patients had a positive ANA screen, both less than or equal to 1:320 with negative extractable nuclear antigen panels. All patients received methotrexate (MTX) during their disease course with only three (37.5%) receiving systemic steroids during treatment. All 8 patients had resolution of LS lesions. With respect to active joint count, 1 patient achieved remission on MTX alone, and 1 patient achieved remission on MTX and a tumor-necrosis factor inhibitor (TNFi). Six of the 8 patients had active arthritis on combination MTX and TNFi therapy.

Conclusion: In this cohort of pediatric patients with LS, 9% had coexisting JIA, which is lower than the 20% reported in previous studies. The characteristics of this cohort who had both LS and JIA varied widely. Presence of autoantibodies, including ANA titer, was inconsistent. All patients received MTX initially with resolution of LS lesions. However, the majority failed to respond to MTX and TNFi combination therapy and continued to have active arthritis. These results suggest that JIA coexisting with LS may be less likely to respond to traditional JIA therapies.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Deficiency of interleukin-1-receptor antagonist (DIRA) is a rare autoinflammatory disease caused by autosomal recessive loss of function mutations in *IL1RN* and characterized by early-onset generalized pustulosis, aseptic multifocal osteomyelitis, and elevation of acute-phase reactants. In a DIRA mouse model, aortitis can develop in a TNF-α dependent manner, no DIRA patients with large vessel vasculitis have previously been reported.

Methods: We performed clinical, genetic and radiographic evaluation of a patient with DIRA who developed an intra-cranial hemorrhage on anakinra treatment and had persistent low-grade elevation of acute phase reactants. We performed including whole exome sequencing and PET CT.

Results: A Puerto Rican patient previously reported with a homozygous 175-kb deletion and multiple comorbidities including severe bone deformities, developmental delay, generalized hypotonia at birth, pyoderma gangrenosum, developed a left intra-cranial hemorrhage at age 12. Follow-up work up of potential pathogenic causes revealed right-sided carotiditis and aortitis on PET CT images. Vascular findings were associated with carotid stenosis and an ascending aortic aneurism. Vascular abnormalities occurred while on optimal doses of anakinra (3.33 ±1.82 mg/kg/day) but persistently elevated inflammatory markers(CRP 5.41 ±3.08 mg/L and ESR 21.40 ±13.99 mm/hr). No other patient with DIRA was diagnosed with large vessel. vasculitis. While IL-1 receptor antagonist (*Il-1ra)* knock out (KO) murine models are prone to the development of vascular diseases, different genetic backgrounds modify vascular inflammation and injury. *Il1ra* KO on a C57BL/6J background is associated with intima damage and the development of atherosclerosis and *Il1ra* KO BALB/c mice develop aortitis that is responsive to TNF inhibition. Insights into the murine model suggested addition of TNF inhibitor after failure of increased doses of anakinra and steroids in achieving disease control. Acute phase reactants normalized after treatment with infliximab. Genetic analyses of rare variants that may contribute to the development af large vessel vasculitis are ongoing.

Conclusion: The development of large vessel vasculitis including carotitis and aortitis in a patient with DIRA who responds to combination therapy of IL-1 and TNF inhibition suggests a role of TNF in the development of large vessel vasculitis and may provide insights into pathways that may shed light on the pathogenesis of other forms of large vessel vasculitis. Strict monitoring of adverse events is required given the increased risk for opportunistic infections.

Abstract Number: 0799

Application of the Autoinflammatory Disease Activity Index (ADDI) to a Cohort of Patients in a Tertiary Hospital

Mireia Lopez-corbeto,[1] and Estefania Moreno Ruzafa[1], [1]Hospital Universitari Vall d'Hebron, Barcelona, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoinflammatory diseases (AIDs) cause chronic systemic inflammation that can damage multiple organs. Recently, the ADDI index has been developed and validated in the four most common monogenic AIDs, Cryopyrin-associated Periodic Syndrome (CAPS), Familial Mediterranean Fever (FMF), Mevalonate Kinase Deficiency (MKD) and Tumor Necrosis Factor Receptor-associated Periodic Fever Syndrome (TRAPS). The use of ADDI index could also be of great value in other AIDs. We sought to assess the application of ADDI in patients with the four most common monogenic diseases and other AIDs. To accomplish this objective a detailed cohort of patients with different AIDs is presented.

Methods: All patients with AIDs followed in the Pediatric Rheumatology Unit from Hospital Universitari Vall d'Hebron were identified. A cross- sectional, descriptive study was performed applying ADDI by two pediatric rheumatologists (EM, ML). CRP mg/dl, amyloid protein (AP) mg/L, ESR mm/h and protein/creatinine rate (mg/g Cr) were performed at the moment ADDI was applied. Disease duration and current treatment were assessed. The continuous variables are presented as mean and standard deviation (mean ± SD) and categorical variables are presented by percentages. Kappa (k) coefficient was calculated. Differences between two groups (sex and GC intake) was compared using Student's t-test and a significance level of < 0.05 was considered.

Results: A total of 41 patients with AIDs were included, 61% were female, with a median age of 20 ± 11.9 years at inclusion. Disease duration was 11 ± 8.2 years. AIDs included were 11 patients with FMF (26.8%), TRAPS n=4 (9.8%), MKD n=3 (7.3%), CAPS n= 2 (4,9%), Blau syndrome n= 7 (17.1%), SAVI syndrome n=3 (7.3%), CRMO n=4 (9.8%), PFAPA n=2 (4.9%), APLAID n=1 (2.4%), Stickler syndrome n=1 (2.4%), and 3 unknown AIDs with genetic test negative n=3 (7.3%). Current treatment is variable among patients, 6 (15.8%) are taking DMARDs, 9 (23.7%) Colchicine, 8 (21.1%) Anakinra, 13 anti-TNF therapy (34.2%), 1 (2.6%) Ruxolitinib and 1 (2.6%) Abatacept. Only 6 patients were receiving steroids with mean prednisone dose of 7.5 mg/day. The global ADDI mean score was 2.3 ± 2.2. No differences were found between gender and ADDI (male 2.19, female 1.9, P= 0.68). Musculoskeletal domain (MSK) shown the highest score with 1.02, followed by the ocular domain with 0.42. The patient with APLAID syndrome had the highest score of 6 followed by Blau syndrome with 4.71. FMF has the lowest score with 0.83. Patients with GC intake had a highest ADDI score than patients without GC treatment (3.7 vs 1.63 P=0.0018). Laboratory test results were mean ESR 27.2 ± 26.7mm/h, CRP 0.7 ± 1.3 mg/dl, AP 13.9 ± 18.6mg/L. Proteinuria was present in 2 patients with mean 286.5 ± 246.1mg/g. The k statistic showed an excellent agreement between two rheumatologist (k=0.98, P< 0.001). EM and ML applied ADDI in 5-10 minutes average.

Conclusion: ADDI is a feasible index suitable to measure damage in a single patient. In our cohort the mean ADDI index was low and MSK has the highest score. GC intake was associated with a higher ADDI score. Knowing the difficulties of applying an unified index for all diseases, ADDI may be supportive in other AIDs and longitudinal cohorts.

Cryopyrin-Associated Periodic Syndrome in Korea: 19 Years of Experience

Young Ho Kim,[1] Bongjik Kim,[2] Byung Yoon Choi,[2] Haeng Jin Lee,[3] Dae-Chul Jeong,[4] Jinhee Han,[2] Hye-Rim Park,[2] Jayoung Oh,[2] Seungmin Lee,[2] Dooyi Oh,[5] and Soyoung Lee[1], [1]Department of Pediatrics, Seoul National University Children's Hospital, Seoul, Seoul-t'ukpyolsi, Republic of Korea, [2]Department of Otorhinolaryngology-Head and Neck Surgery, Seoul National University Bundang Hospital, Seongnam, Kyonggi-do, Republic of Korea, [3]Department of Ophthalmology, Seoul National University Hospital, Seoul, Republic of Korea, [4]Department of Pediatrics, The Catholic University of Korea, Seoul, Seoul-t'ukpyolsi, Republic of Korea, [5]Department of Otorhinolaryngology-Head and Neck Surgery, Seoul National University Bundang Hospital, Seoul, Kyonggi-do, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cryopyrin-associated periodic syndrome (CAPS) is rare auto-inflammatory disorder characterized by recurrent episodes fever with variable manifestation of systemic inflammation such as urticarial skin rash, joint destruction, sensorineural hearing loss (SNHL) and neurologic problems. It includes familial cold auto-inflammatory syndrome (FCAS), Muckle-Wells syndrome (MWS), and neonatal onset multisystem inflammatory disease (NOMID). Pathogenic variants in NLRP3 are thought to be responsible for most cases of CAPS by excessive production of interleukin (IL)-1β.

Methods: Patients with diagnosis of CAPS who visited Seoul National University Children's Hospital from January 2000 to December 2018 were eligible for inclusion. Retrospective analysis was performed by review of medical records. Clinical information on symptoms and signs, inflammatory markers, pure tone audiometries, simple radiographs of joints, ophthalmoscopies, and other relevant data were collected. Molecular analysis for NLRP3 was performed by Sanger sequencing. Finally, clinical response to recombinant non-glycosylated human IL-1 receptor antagonist (anakinra) was determined by comparing symptoms and signs and changes in test results before and after the treatment.

Results: Sixteen patients were identified (11 NOMID, 3 FCAS, 2 MWS). Total of 112 person years were followed. Most consistent symptoms were fever and rash, present in all cases followed by joint symptoms (n=15), SNHL (n=9). Screening pure tone audiometry revealed high frequency hearing loss in 67% (4/6) of patients with normal hearing, including one FCAS patient. Eleven patients had onset within 1 week after birth, three patients within 3 months. Most common initial diagnoses were milk allergy (n=5), juvenile idiopathic arthritis (n=4), and neonatal sepsis (n=3). Diagnostic delay was common, ranging from 1 month to 17 years (median = 22 months). Pathogenic variation in NLRP3 gene was confirmed in fifteen patients. Anakinra was started for fifteen patients. All patients on anakinra had marked reduction of fever and rash, and 57.5% (5/8) of patients with SNHL had improved or maintained stable hearing. Three of five patients with high frequency hearing loss had improved or maintained stable hearing threshold at 8KHz. Five of eight patients with joint destruction restored normal joint anatomy. Mean initial anakinra dose was 1.19mg/kg/day,

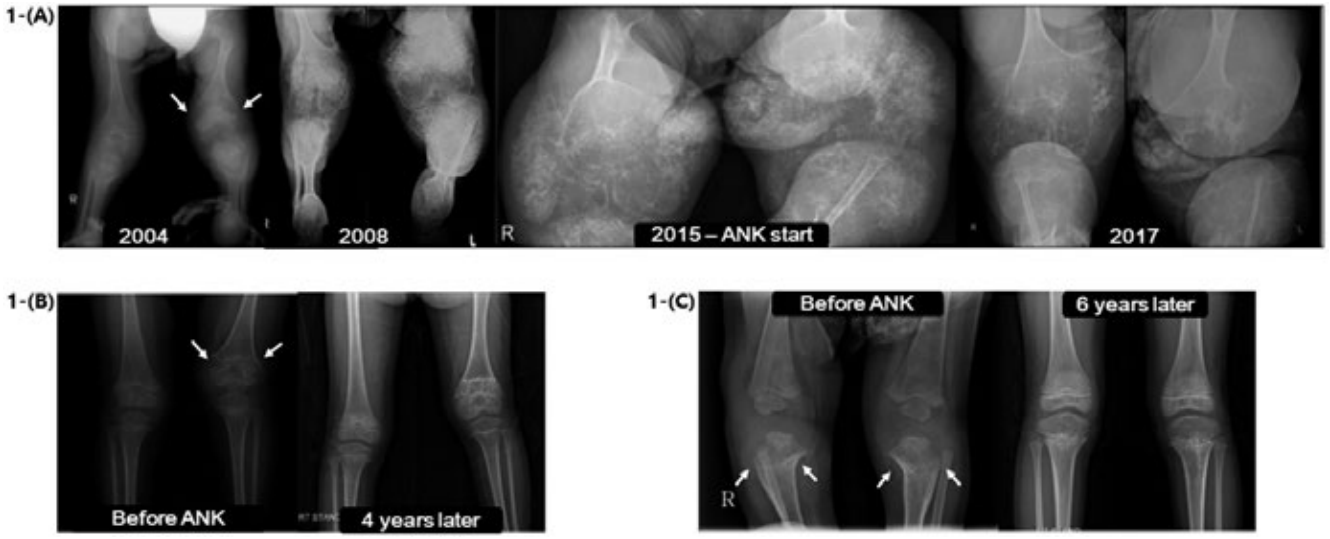

Figure 1. Simple radiographs of knee joint. White arrows indicate metaphyseal fraying and cupping and widening of the growth plate. 1-(a). Patient 2 with irreversible hip, knee, and ankle joint destruction. This patient started treatment with Anakinra (ANK) 14 years after diagnosis. 1-(b). Patient 10 with asymmetric distal femur involvement. This patient developed limb length discrepancy despite treatment. 1-(c). Patient 6 who restored normal joint anatomy after use of anakinra 10 months after diagnosis.

and mean final anakinra dose was 2.02mg/kg/day. Most common reason for dose escalation was relapsing clinical symptoms such as fever and rash. One patient with SNHL and one patient with high frequency hearing loss experienced improvement of hearing only after dose escalation. The most common adverse events were injection site erythema and infection.

Conclusion: This study represents the largest cohort of CAPS patients in Korea. High index of suspicion and early intervention with anakinra is crucial to prevent potentially devastating outcomes. In addition this study suggest regular audiometry is necessary and hearing problem maybe the most sensitive factor to determine anakinra dose.

	Cochlear enhancement on MRI (%)	16 (41)

Table 1. Patient characteristics CRP (0-4.99 mg/L), ESR (0-42 mm/h) *6 patients had disease flare, with high CRP/normal ESR in follow up

Background/Purpose: Neonatal-onset multisystem inflammatory disease (NOMID), caused by gain-of-function mutation in the NLRP3 inflammasome, presents with systemic inflammation, rash, eye inflammation, aseptic meningitis and sensorineural hearing loss. We assessed hearing loss progression in NOMID patients on anakinra treatment over median of 10 years.

Methods: 39 patients (23 female, median age at baseline 7y) were followed (median 10y) after starting therapy with IL-1 blocker Anakinra (table 1). All patients were on continuous therapy with dose adjustment for weight gain and disease flare (1). First audiograms obtained at the time of treatment initiation (or when able to cooperate) were compared to an audiogram obtained after a median of 10 (4 to 17) years on treatment. Pure-tone averages at 500, 1000, 2000, 4000 Hz (4F-PTA) and high frequency air conduction averages for 6000, 8000 Hz (HF-PTA) were calculated. For the current analysis, the first and last audiograms were compared. Normal hearing is defined as hearing threshold < 20 dB, mild hearing loss 20 to 40 dB, moderate loss 40 to 70 dB and severe loss is hearing threshold greater than 70 dB, 4F-PTA and HF-PTA were separately assessed. A change from one category to another (using 4F-PTA) was consideredPresence of cochlear enhancement was obtained from reports of 1.8 mm sections, contrast-enhanced FLAIR-MRI through the inner ear. The association between hearing loss progression and age at start of treatment, as well as presence of cochlear enhancement in last MRI was assessed using Fisher's exact test.

Results: Inflammatory markers normalized in 33 (85%) but cochlear enhancement persisted in 16 patients (41%) on treatment. At baseline, 34 (44%) ears had normal hearing on the 4F-PTA, only 28 (36%) ears had normal hearing on HF-PTA (figure 1).

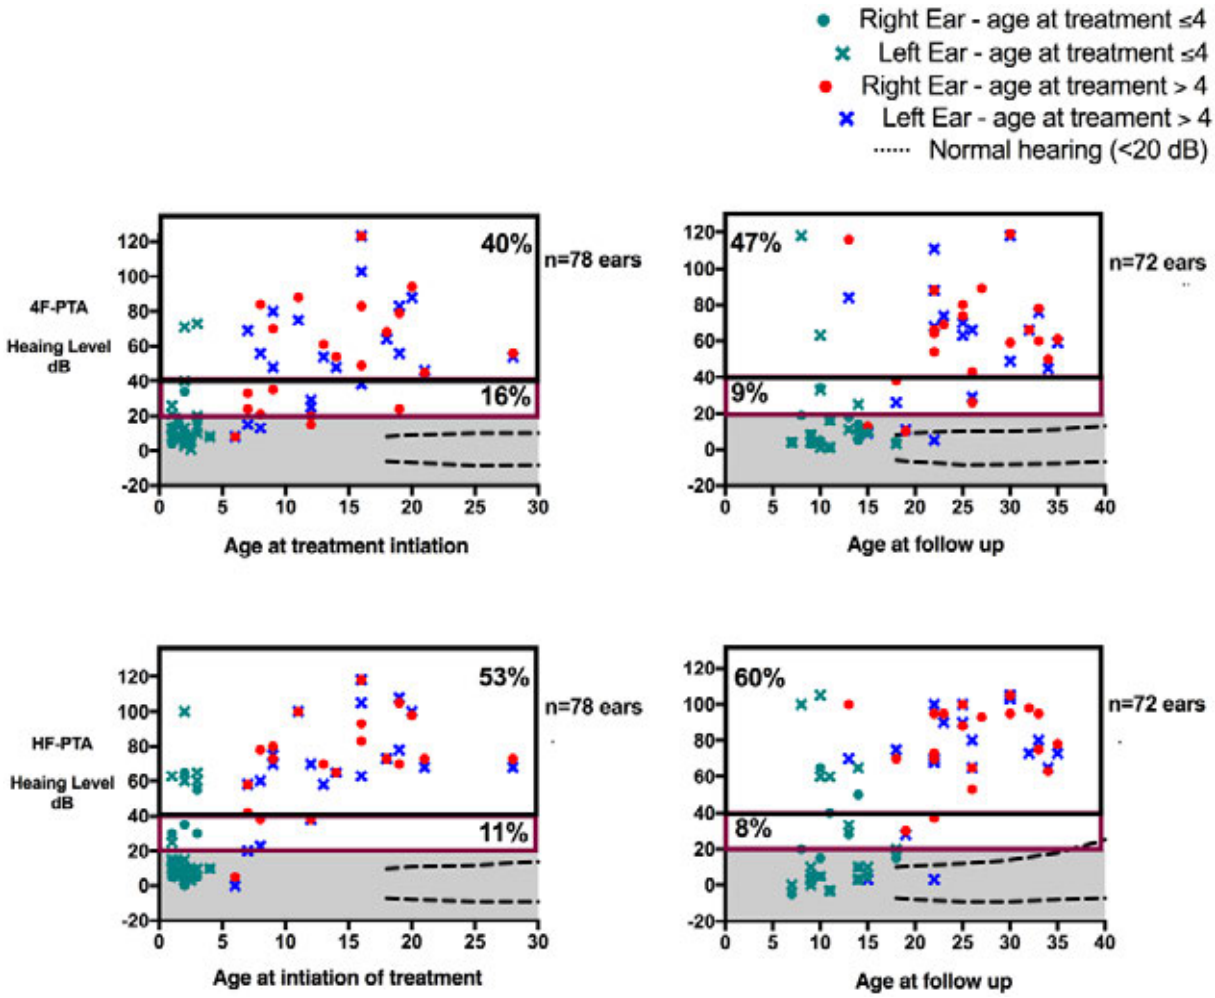

Figure 1. Ears with normal, mild and moderate to severe hearing loss at baseline and 10-year follow up are graphed separately based on values of 4F-PTA (500, 1000, 2000, 4000 Hz) (upper panels) and high frequency HF- PTA (6000, 8000 Hz) (lower panels). Normal hearing is defined as thresholds <20 dB, mild hearing loss is defined as 20 to 40 dB, and moderate to severe hearing loss is defined as hearing thresholds greater than 40 dB. From 14 patients who had normal hearing at baseline in both ears and were treated age 4 or younger, 13 retained hearing in follow up (green color). Dashed lines denote the 5th and 95th-percentile of age-matched normative thresholds from the International Organization for Standardization ISO 7029. As typically seen in sensorineural hearing loss progression of hearing loss is first seen in the HF-PTA before present in 4FT-PTA.

14 patients had normal hearing at baseline (36%); 13 (93%) started treatment at age 4y or younger, eleven of these retained normal hearing at follow up (median follow up 8y, range 4 to 15). Hearing worsened over time in 18 of 56 ears (32%) from 13 patients who had hearing loss at baseline. At last follow up, 2 patients had received cochlear implants for the past 5 and 10 years and 2 years respectively. All patients with progressive hearing loss were treated after age 4 (p = 0.0002). More ears with progressive hearing loss had cochlear enhancement at the time of the last MRI (p = 0.001) (Figure 2).

Conclusion: Progression of hearing loss was prevented in patients starting IL-1 blocking treatment at age of 4 or younger and had normal hearing at baseline. Hearing loss, when present at baseline, typically progressed over time on treatment and was first detected with the HF-PTA. Persistent inner ear enhancement on FLAIR MRI was associated with progressive hearing and suggest the use of FLAIR MRI to monitor inner ear inflammation. Our data points to the need of early treatment in maintaining normal hearing in patients with NOMID.

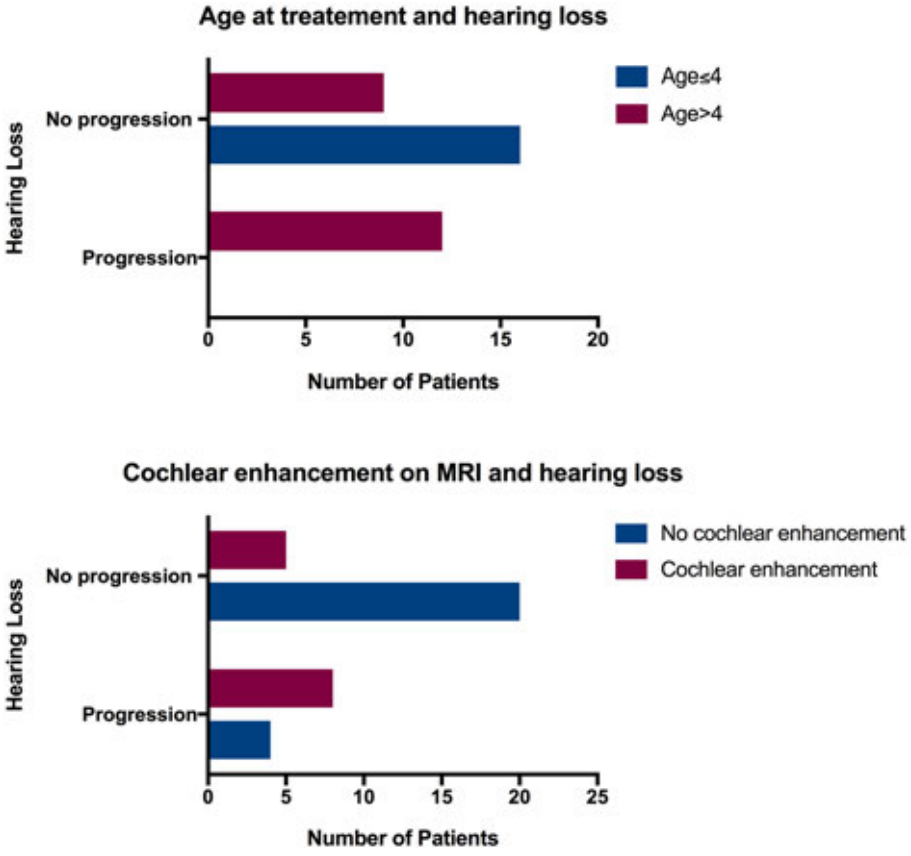

Figure 2. 37 patients had audiogram in follow up: Hearing loss was not observed in patients who started treatment at age <4y who had normal hearing at baseline. Hearing loss progressed in 13 patients who had hearing loss at baseline. All were treated after age 4 (upper panel). In ears with progressive hearing loss, cochlear enhancement was present in 66.8% of ears compared to 20% of hear that had no progressive hearing loss (p = 0.001).

Canakinumab Improves Patient-Reported Outcomes in Patients with Recurrent Fever Syndromes: Results from a Phase 3 Trial

Helen Lachmann,[1] Bernard Lauwerys,[2] Paivi Miettunen,[3] Tilmann Kallinich,[4] Annette Jansson,[5] Itzhak Rosner,[6] Raffaele Manna,[7] Saramaria Murias,[8] Sinisa Savic,[9] Serge Smeets,[10] Fabrizio De Benedetti,[11] and Anna Simon[12], [1]The Royal Free Hospital & University College London, London, United Kingdom, [2]Université catholique de Louvain, Brussels, Brussels Hoofdstedelijk Gewest, Belgium, [3]Alberta Children's Hospital, Calgary, ON, Canada, [4]Charite, Berlin, Germany, [5]Dr. von Hauner Children's Hospital, Ludwig-Maximilians-University, Munich, Germany, [6]Bnei Tzion, Haifa, Israel, [7]Università Cattolica del Sacro Cuore, Rome, Lazio, Italy, [8]University Hospital La Paz, Madrid, Madrid, Spain, [9]St James's University Hospital, Leeds, England, United Kingdom, [10]Novartis, Amsterdam, Netherlands, [11]Bambino Gesù Children's Hospital, Rome, Italy, [12]Radboud University Medical Centre, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Recurrent fever syndromes have a significant impact on health-related quality of life (HRQoL).[1] Canakinumab (CAN) has demonstrated efficacy and safety in patients with colchicine-resistant familial Mediterranean fever (crFMF), hyper-immunoglobulin D syndrome/mevalonate kinase deficiency (HIDS/MKD) and tumor necrosis factor receptor-associated periodic syndrome (TRAPS) in the pivotal phase 3, CLUSTER trial (NCT02059291).[2] However, the published data on impact of CAN on the HRQoL, work/school and social life of these patients are limited. To evaluate the effect of CAN on HRQoL, work/school and social life of patients in the 3 disease cohorts (crFMF, HIDS/MKD, and TRAPS) in a double blinded randomized Phase 3 trial (CLUSTER).

Methods: The detailed study design was reported previously.[2] The HRQoL of patients treated with CAN who met the primary endpoint of the CLUSTER trial2 was assessed at Baseline (BL), Week 17 (Wk17) and Week 41 (Wk41). HRQoL was also assessed in all patients (those initially randomized to CAN, those randomized to placebo who subsequently switched to CAN and those who did not switch to CAN). Outcomes measures were the Child Health Questionnaire (CHQ)-PF50 psychosocial (PsS) and physical (PhS) component summary scores (children >5–< 18 years), Short-Form health survey (SF-12) physical component summary (PCS) and mental component summary (MCS; adults ≥18 years) scores. An increase from baseline of 2, 5, and 8 points in the CHQ-PF50 PsS and PhS corresponds to a small, moderate and large treatment effect, respectively. Functional impairment related to work/school, social life and family life/home responsibilities was assessed by Sheehan Disability Scale (SDS) with a score of 5 or higher being associated with significant impairment.

HRQoL outcomes in patients who met the primary endpoint

BL, baseline; CHQ, Child Health Questionnaire; GFI, global functional impairment; HRQoL, health-related quality of life; MCS, mental component summary; PCS, physical component summary; PhS, physical summary score; PsS, psychosocial component summary; SF-12, Short form health survey; SDS, Sheehan Disability Scale. n= number of patients evaluated for HRQoL

Table 2

Results: Out of 181 patients, 90 (31 crFMF, 37 HIDS/MKD, and 22 TRAPS) were randomized to CAN treatment and 91 to placebo. Patients in all 3 cohorts showed a high impairment of HRQoL at baseline. In patients who met the primary endpoint, CAN was shown to improve CHQ-PF50 PsS and PhS; SF-12 MCS and PCS; and SDS scores, from baseline to Wk 17, which was maintained at Wk 41 **(Table 1)**. The improvement in HRQoL was also observed in all patients treated with CAN, and was sustained through Wk 41 **(Table 2)**.

Conclusion: Treatment with canakinumab led to sustained improvement of HRQoL, work/school and social life in patients with crFMF, HIDS/MKD and TRAPS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune, autoinflammatory mechanism and drugs used in treatment increase the risk of liver disease in patients with chronic rheumatic diseases. Hepatitis A vaccine is a highly effective vaccine that prevents both the formation and spread of clinical hepatitis. In childhood chronic rheumatic diseases, vaccination is of great importance. The risk of various infections increases with the immunosuppressive effect of both the disease and the drugs.Therefore, vaccination of these diseases is of high importance for the prevention of infectious diseases. Studies on the efficacy and safety of vaccines in autoimmune and autoinflammatory diseases are limited. The aim of this study was to investigate the efficacy and safety of hepatitis A vaccine in patients with autoinflammatory disease on anti-interleukin 1 and 6 treatment.

Methods: This study was carried out in Pediatric Rheumatology outpatient clinic and general paediatric outpatient clinic. A total of 39 patients with autoinflammatory diseases on anti IL-1 and IL-6 therapy were initially evaluated but 25 of them were excluded due to anti-HAV IgG positivity. At the end, 24 patients with autoinflammatory diseases on anti IL-1, anti IL-6 therapy and 39 healthy participants who were seronegative for hepatitis A received two doses of the hepatitis A vaccine in a 0 and 6 month schedule. Hepatitis A virus (HAV) IgG antibodies were measured before vaccination and one month after last dose of the vaccine. Anti-HAV IgG titer as S/ CO;1.1, IU/L was considered positive and protective.

Results: Total 24 patients with autoinflammatory condition and 39 healthy controls were included in the study. Among patients with diagnosis of autoinflammatory disease, 19 were Systemic juvenile idiopathic arthritis (SJİA) and 5 were Cryopyrin-associated periodic syndromes (CAPS) patients. The mean age was 14.1±3.7 and 12.2±3.3 years respectively. Canakinumab was used in 15 (62.5%) and tocilizumab in 9 (37.5%) all patients. Among all SJİA patients, 10 (52.6%) were treated with canakinumab and 9(47.4%) were treated with tocilizumab. All patients with CAPS (n: 5) were using canakinumab. Among SJIA cases, 15(75%) were also using methotrexate and 14(70%) prednisolone. Anti-HAV IgG concentrations were measured one month after the last dose of hepatitis A vaccine. There was statistically significant difference between patients with autoinflammatory condition and healthy controls regarding the anti-HAV IgG titer (mean 5.3±1.5 IU/L) versus (10.5±7 IU/L) $p< 0.05$. The rate of anti-HAV IgG seropositivity (cut-off 1.1 IU/L) in autoinflammatory disease (24/24 (100%) was significantly different comparing to healthy controls (33/39, 84.6%) ($p=0.04$). There was no disease flare of disease nor the adverse event detected in any patients after vaccination.

Conclusion: Anti-HAV IgG seroconversion was detected in patients with autoinflammatory disease on anti-IL1 and anti - IL6 therapy 1 month after the last dose of hepatitis A vaccine. The response to vaccine did not differ between healthy children and patients with autoinflammatory disease under canakinumab and tocilizumab. In this study hepatitis A vaccine was found to be safe in autoinflammatory diseases with canakinumab and tocilizumab treatment.

STING-associated Vasculopathy with Onset in Infancy (SAVI Syndrome) Can Mimic Juvenile Idiopathic Arthritis

Jose Luis Tandaipan,[1] Mireia Lopez Corbeto,[2] and Estefania Moreno Ruzafa[3], [1]Hospital Universitari Mutua Terrassa, Terrassa, Spain, [2]Hospital Universitari Vall d'Hebron, Barcelona, Catalonia, Spain, [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – ePoster I: Basic Science, Biomarkers, & Sclerodermic Fever – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gain-of-function mutations in TMEM173 encoding STING (Stimulator of Interferon Genes) underlie a novel type I INF termed SAVI syndrome. It is characterized by a vasculopathy that can affect skin, lungs and joints and can simulate Juvenile Idiopathic Arthritis (JIA).

Objectives: To describe a detailed cohort of patients with SAVI syndrome and highlight the similarity of the phenotype with JIA.

Methods: 3 patients diagnosed with SAVI syndrome from the Hospital Universitari Vall d'Hebron were recruited. Written informed parental consent was obtained for the use of clinical data and pictures reported. Detailed clinical data is described.

Results: Patient 1, an 11-year-old boy, was identified to carry a de novo c.461A >G mutation in TMEM173. He presented at 1st month of life with bronchial infection and skin vasculitis lesions in acral zones and arthritis. Fever was not reported. High-resolution computed tomography (HRCT) of the lungs identified a nonspecific interstitial pneumonia (NSIP) and a lung biopsy (LB) showed lymphoid hyperplasia. Rheumatoid factor (RF), ACPA antibodies and antinuclear antibodies (ANA) were also positive. Immunosuppressive (IS) treatments were given without any response (table 1). At the age of 6 years Ruxolitinib (RX) with an improvement of skin disease and lung function and the arthritis was well controlled. Patient 2, a 17-year-old girl, was identified to carry a de novo c.463G >A mutation in TMEM173. She presented at the age of 3 with a severe polyarthritis. No fever, skin or respiratory symptoms were reported at the beginning of the disease. Lab tests were positive for RF and ACPA antibodies. She was diagnosed with pJIA and few months later she reported dyspnoea. HRCT showed NSIP and lymphoid interstitial pneumopathy was found at the LB. RX was initiated at the age of 17 years but fibrosis was established and she has been included to lung transplant (LT). Patient 3, a 29-year-old man, was recently diagnosed with a de novo c.463G >A mutation in TMEM173. He presented at the age of 7 years with polyarthritis. Lab test was positive for RF, ACPA, and ANA. With the diagnosis of pJIA he received IS treatments with no response. Due to

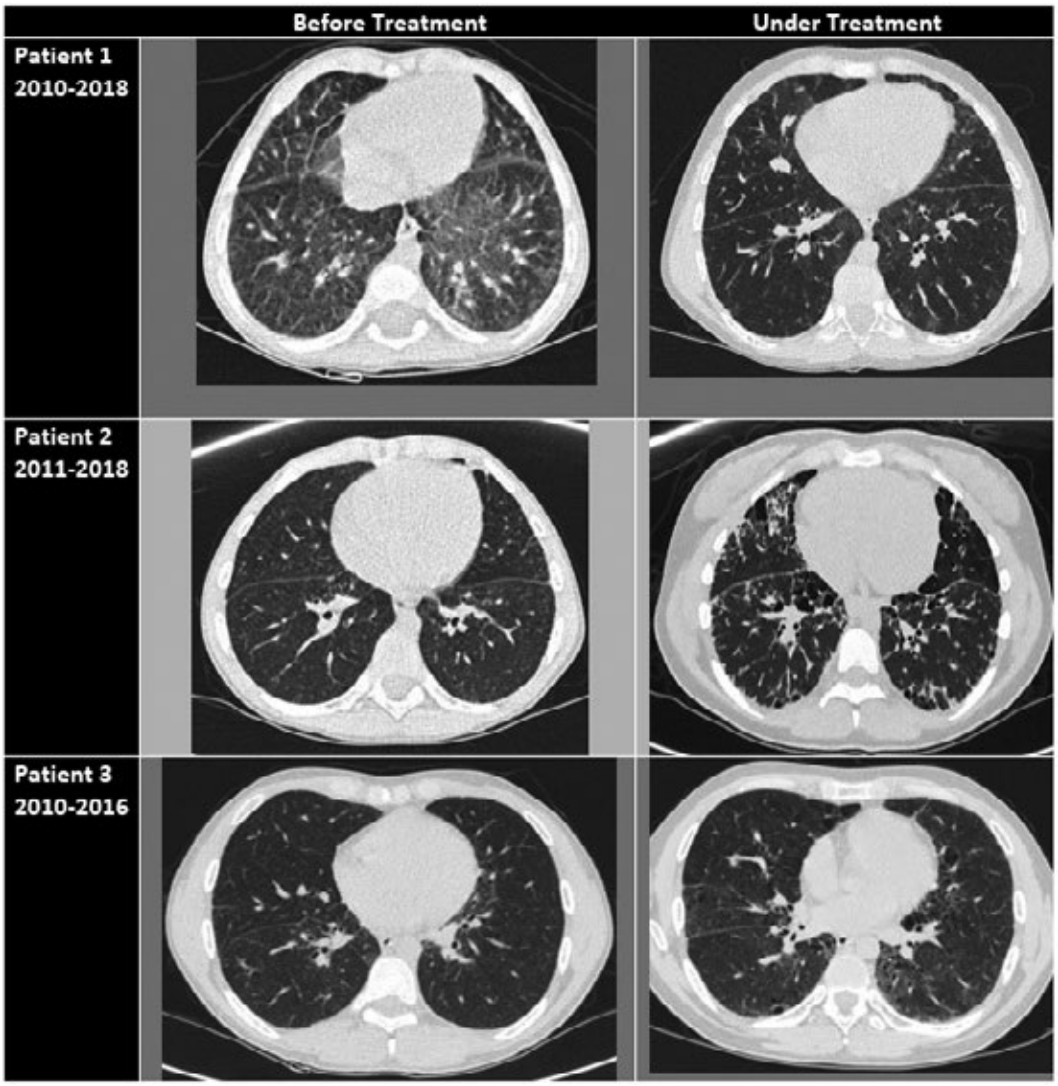
TABLE 1
Demographic, clinical, analytical, lung function and previous and current treatment



HRCT- Evolution of the Interstitial Lung Disease

recurrent bronchial infections a HRCT was performed showing an ILD and NSIP. SAVI syndrome was suspected and genetic test was performed with positive result. RX was initiated but compliance was not good. He is also being evaluated for LT.

Conclusion: SAVI syndrome is a rare monogenic autoinflammatory disease with few cases reported in the literature. Patient 2 and 3, in contrast with patient 1, had a different mutation (table 1), also severe articular and lung manifestations with no skin involvement. Furthermore, lab tests were positive for RF and ACPA and were misdiagnosed as JIA so genetic test was performed later in the follow-up. Being aware of the distinct phenotype of the disease could help the clinicians reassess the patients with these presentations that not respond well to conventional treatments.

Risk of Cardiovascular Disease in SLE Is Significant Early and Highlights Racial Disparities

Shivani Garg,[1] Christie Bartels,[1] Cristina Drenkard,[2] Gaobin Bao,[2] and S Sam Lim[2], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Plenary I
Session Type: Plenary Session I
Session Time: 11:00AM–12:30PM

Background/Purpose: SLE is an independent risk factor for premature cardiovascular disease (CVD) and afflicts African Americans (AA's) 3 times more than whites. Two predominantly white cohorts have challenged the paradigm that CVD is a predominantly late complication of SLE. This study measured the risk of CVD events and predictors in a population-based incident cohort comprised mostly of AA's over a 14-year period, starting from 2 years before diagnosis.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry of SLE patients from Atlanta, Georgia. Incident SLE patients in 2002-04 met ≥4 ACR SLE criteria or 3 criteria with a final diagnosis of SLE by their board-certified rheumatologist. CVD events or CVD deaths included ischemic heart disease, cerebrovascular accident, transient ischemic attack and peripheral vascular disease as adjudicated using published guidelines. Patients were matched to the Georgia Hospital Discharge Database and National Death Index from 2000-13. CVD-related hospitalizations and deaths were classified by the first three admission or cause of death codes. Predictors of CVD events during this period were examined using Cox proportional hazards model.

Figure 1. Cardiovascular Disease Events 2 Years Before SLE Diagnosis up to 14 Years After SLE Diagnosis

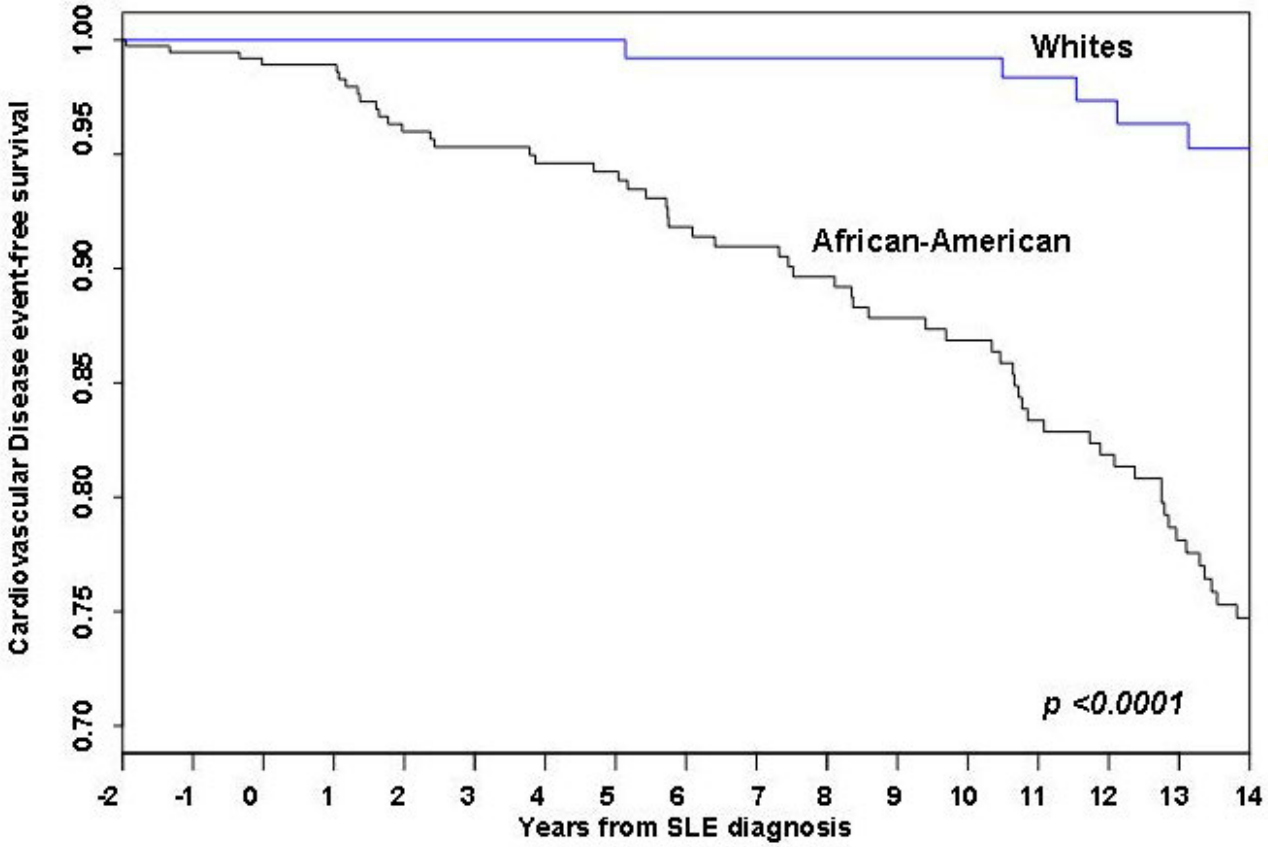
Results: Among 336 incident SLE patients, 87% were females, 75% were AA and mean age at SLE diagnosis was 40 ± 17 years. Overall, we found 31 CVD-related events and 5 CVD-related deaths from 2 years before until 10 years after SLE diagnosis and 26 CVD-related events and 1 CVD-related death from 10-14 years after SLE diagnosis. There

Figure 2. Cardiovascular Disease Event-Free Survival Stratified By Race in SLE cohort



were two CVD events which occurred >14 years after SLE diagnosis. The mean ages at SLE diagnosis and the first CVD event during 12-years of follow up starting 2 years before SLE diagnosis were 46 and 48 years, respectively, with 91% of events in females and 75% in AA. The mean ages of SLE diagnosis and first CVD event in the period 10-14 years after diagnosis were 38 and 52 years, respectively, with 70% of events in females and 76% in AA. CVD event probability is shown in Figure 1 with 22% experiencing any CVD event and the highest number of events occurring 1-2 years after SLE diagnosis. AA race predicted a 6-fold higher risk of a CVD event during the follow-up period (Adjusted HR 6.4, 95% CI 2.4-17.5; Table 1). CVD event rates in AA's were 18-fold higher during the initial 10 years starting 2 years before SLE diagnosis (Adjusted HR 18, 95% CI 2.2-141; data not shown). Other predictors were discoid lupus (Adjusted HR 3.2, 95% CI 1.5-6.8), age >65 years (Adjusted HR 7.9, 95% CI 2.2-29), and presence of immunological criteria (Adjusted HR 2.1, 95% CI 1.01-4.4) (Table 1). The stratified Cox proportional hazard model show significantly accelerated CVD events in AA compared to whites ($p< 0.0001$) (Figure 2).

Conclusion: We found significant CVD events peaking 1-2 years after SLE diagnosis, supporting other observations but now in a predominantly AA population-based cohort. AA race was the strongest predictor of CVD events in SLE. Future CVD prevention efforts should target such populations to reduce racial disparities, particularly around the period of SLE diagnosis.

A Randomized, Controlled Trial of Rituximab versus Azathioprine After Induction of Remission with Rituximab for Patients with ANCA-associated Vasculitis and Relapsing Disease

Rona Smith,[1] David Jayne,[2] and Peter Merkel[3], [1]University of Cambridge, Cambridge, England, United Kingdom, [2]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, University of Cambridge, UK, Cambridge, United Kingdom, [3]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Plenary I
Session Type: Plenary Session I
Session Time: 11:00AM–12:30PM

Background/Purpose: Rituximab is an effective therapy for induction of remission in ANCA-associated vasculitis (AAV). However, the effect of rituximab is not sustained, and relapse rates are high, especially in patients with a history of relapse. The RITAZAREM trial (ClinicalTrials.gov identifier: NCT01697267) is an international, multi-center, open-labelled, randomized, controlled trial of patients with AAV with relapsing disease comparing the efficacy, after induction of remission with rituximab, of two relapse-prevention strategies: repeat dose rituximab or daily oral azathioprine.

Methods: Patients with AAV were recruited at time of relapse and received induction therapy with rituximab and glucocorticoids. If remission was achieved by month 4, patients were randomized in a 1:1 ratio to receive either rituximab (1000 mg every 4 months for 5 doses) or azathioprine (2 mg/kg/day) as maintenance therapy. Patients were followed for a minimum of 36 months, with the primary outcome being time to disease relapse. The formal hypothesis testing plan initially considers the hazard ratio for relapse across all time periods. If, and only if this global test is significant at a 5% level then the hazard ratios during the treatment period and the follow-up periods are considered separately.

Results: 190 patients were enrolled and 170 randomized at 4 months (85 to rituximab; 85 to azathioprine). The data are complete on all patients up to at least month 24. Median age was 59 years (range 19-89), with a prior disease duration of 5.3 years (0.4-38.5). 123/170 (72%) patients had a history of testing positive for anti-proteinase 3 ANCA; 47/170 (28%) for myeloperoxidase ANCA; 104/170 (61%) were enrolled having suffered a major relapse, and 48/170 (28%) received a pre-specified higher dose glucocorticoid induction regimen (Table 1). Rituximab was superior to azathioprine in preventing disease relapse with a preliminary overall hazard ratio (HR) estimate of 0.36 (95% CI 0.23-0.57, $p < 0.001$) and a during-treatment HR estimate of 0.30 (95% CI 0.15-0.60, $p< 0.001$) (Figure 1). After adjustment, none of the randomization stratification covariates (ANCA type, glucocorticoid induction regimen, or relapse severity) had a significant differential effect on the primary outcome. By 24 months after entry, 20 months after randomization, 11/85 (13%) patients in the rituximab group had experienced a relapse compared to 32/85 (38%) patients in the azathioprine group. In the rituximab group 2/11 (18%) relapses were classified as major, compared to 12/32 (38%) in the azathioprine group. 19/85 (22%) patients in the rituximab group and 31/85 (36%) patients in the azathioprine group experienced at least one severe adverse event (SAE). 25/85 (29%) and 42/85 (49%) patients in the rituximab group developed hypogammaglobulinaemia (IgG < 5g/l) and non-severe infections respectively, compared to 21/85 (25%) and 41/85 (48%) in the azathioprine group.

Conclusion: In the RITAZAREM trial, following induction of remission with rituximab, rituximab was superior to azathioprine for preventing disease relapse in patients with AAV with a prior history of relapse. There were no new major safety signals for use of these medications in this population.

Table 1: Baseline characteristics of patients enrolled in RITAZAREM trial

Guselkumab, an Anti-interleukin-23p19 Monoclonal Antibody, in Patients with Active Psoriatic Arthritis Who Were Biologic-Naïve or Prior TNFα Inhibitor-Treated: Week 24 Results of a Phase 3, Randomized, Double-blind, Placebo-controlled Study

Atul Deodhar,[1] Philip Helliwell,[2] Wolf-Henning Boencke,[3] Elizabeth Hsia,[4] Alexa Kollmeier,[5] Ramanand Subramanian,[5] Xie Xu,[5] Shihong Sheng,[5] Bei Zhou,[5] and Christopher Ritchlin[6], [1]Oregon Health & Science University, Portland, OR, [2]University of Leeds, Leeds, United Kingdom, [3]Geneva Univ Hospitals, Geneva, Switzerland, [4]Janssen Research & Development, LLC/University of Pennsylvania, Spring House/Philadelphia, PA, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Plenary I
Session Type: Plenary Session I
Session Time: 11:00AM–12:30PM

Background/Purpose: Guselkumab (GUS), an anti-interleukin-23p19 monoclonal antibody, is approved to treat PsO. We evaluated GUS efficacy and safety in a Phase 3, double-blind, PBO-controlled trial in pts with active PsA who were biologic-naïve or prior TNFα inhibitor (TNFi)-treated (DISCOVER-1).

Methods: Adults with active PsA (≥3 swollen+≥3 tender joints; CRP ≥0.3mg/dL) despite standard therapies (eg, non-biologic DMARDs, apremilast, or NSAIDs) were eligible. Approx. 30% of pts previously could have received or have had inadequate response to 1-2 TNFi. Pts were randomized 1:1:1, stratified by Week [W] 0 DMARD use [Y/N] and prior TNFi use (Y/N), to GUS 100mg Q4W; GUS 100mg at W0, W4, Q8W (Q8W); or PBO. Concomitant stable use of select non-biologic DMARDs, oral corticosteroids, and NSAIDs was allowed. At W16, pts with < 5% improvement in tender+swollen joints could initiate or increase the dose of permitted medications while continuing study treatment. The primary endpoint was ACR20 at W24. Major secondary endpoints included: Investigator's Global Assessment (IGA) PsO response (IGA=0/1 + ≥2-grade reduction) at W24 in pts with ≥3% BSA PsO & IGA ≥2 at W0; changes in DAS28-CRP, HAQ-DI and SF-36 PCS scores and ACR50/70 response at W24; and ACR20/50 response at W16. As preplanned, enthesitis or dactylitis data were pooled with those from the companion Phase 3 GUS in PsA study (DISCOVER-2; to be reported elsewhere). Due to regional health authority differences in regulatory requirements for multiplicity control, two multiplicity control procedures were prespecified (Global and US). Results of statistical testing via US procedures are presented. Unadjusted (nominal) p-values are provided for other endpoints (Table). Adverse events (AEs) through W24 are reported.

Results: 381 pts were treated and analyzed; baseline characteristics were consistent with moderate-to-severe disease (mean BSA involved with PsO: 13.4%, pts with IGA=3-4: 42.5%; mean swollen/tender joint counts: 9.8/19.3). Significantly more pts receiving GUS Q4W (58.6%) and Q8W (52.8%) vs PBO (22.2%, both p< 0.001) achieved ACR20 response at W24 (Figure). Consistent response rates were observed in the subgroups of pts with or without prior TNFi use (Table). Significantly greater improvements in HAQ-DI and SF-36 PCS scores were seen in GUS- vs PBO-treated pts from W0 to W24. Among 249 pts with ≥3% BSA PsO and IGA ≥2 at W0, significantly more GUS- vs PBO-treated pts achieved IGA response. Higher proportions of pts achieved ACR20 response at W16, ACR50 response at W16/24, ACR70 response at W24, and PASI75/90/100 responses at W24. More GUS Q4W- or Q8W- vs PBO-treated pts achieved MDA response at W24 (Table). Serious AEs, serious infections, and death occurred in 9/381 (2.4%), 2/381 (0.5%), and 1/381 (0.3%) pts, respectively.

Table. Clinical Efficacy for DISCOVER-1, a Randomized, Placebo-controlled, Phase 3 Study of GUS in Pts with Active PsA Who Were Biologic-Naïve or Prior TNFi-Treated

Pts meeting treatment-failure criteria were considered nonresponders for binary endpoints and as having no improvement from baseline for continuous endpoints. Missing data were imputed as nonresponders for binary endpoints; multiple imputation was used to impute missing data for continuous endpoints. Treatment difference for binary endpoints was assessed via Cochran-Mantel-Haenszel test stratified by baseline use of non-biologic DMARDs (yes/no) and prior exposure to anti-TNFα agents (yes/no). Treatment difference for continuous endpoints was assessed via an analysis of covariance model.

[1] In the US procedure, the overall Type I error of the treatment comparisons of both doses versus placebo for the primary and the 3 selected major secondary endpoints, representing a total of 8 hypotheses, was controlled at a significance level of ≤0.05.

[2] Assessed in pts with ≥3% BSA PsO and IGA score ≥2 at W0.

[3] Unadjusted (nominal) p values are not controlled for multiplicity and descriptive/supportive only; no statistical significance should be implied.

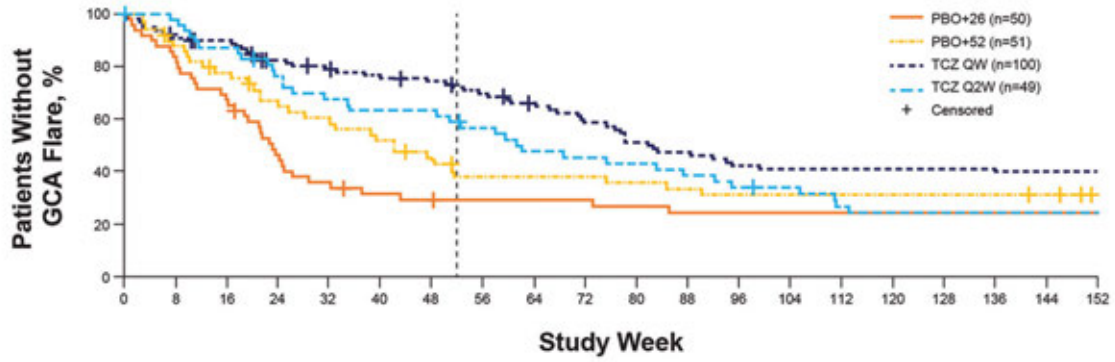
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Plenary I
Session Type: Plenary Session I
Session Time: 11:00AM–12:30PM

Background/Purpose: Tocilizumab (TCZ) 162 mg administered subcutaneously weekly (QW) or every-other-week (Q2W) plus 26-wk prednisone tapering resulted in higher rates of sustained glucocorticoid (GC)–free remission in patients with giant cell arteritis (GCA) than placebo plus 26-wk (PBO+26) or 52-wk (PBO+52) prednisone tapering in the 52-wk, double-blind, randomized controlled GiACTA trial.[1] The objective of this analysis was to determine long-term safety and explore maintenance of efficacy in GCA patients in a 2-year long-term extension (part 2) of this trial.

Methods: At the end of the double-blind period, patients in clinical remission (CR) were instructed to stop double-blind TCZ treatment upon entering part 2. CR was defined as absence of flare per investigator assessment without requirement for normalization of CRP < 1 mg/dL. GCA therapy, which could include initiation/termination of open-label TCZ and/or GC, was administered at investigator's discretion per disease status. Outcomes included maintenance of CR (no flare during part 2), flare, time to first flare, treatments received, cumulative GC dose, and safety. Treatment groups refer to originally assigned treatment (PBO or TCZ).

Results: Among 250 patients treated in the double-blind period, 215 entered part 2 and 197 (92%) completed 3 years in the trial. Among the 81 TCZ QW and 36 TCZ Q2W patients in CR at wk 52, 38 (47%) and 13 (36%) patients, respectively, maintained CR during part 2. Of these 51 original TCZ patients, 33 (65%) were treatment-free (no TCZ or GC treatment), which was higher than the treatment-free proportion of original PBO patients who maintained CR in part 2 (17/38; 45%). Median time to first flare while not receiving TCZ was longer for patients in the original TCZ groups (TCZ QW, 575 days; TCZ Q2W, 428 days) than for patients in the original PBO groups (PBO+26, 162 days; PBO+52, 295 days); TCZ QW patients remained flare-free the longest (Figure 1). Retreatment with TCZ (with or without GC) for flare was effective for restoring CR in part 2. Cumulative GC dose over the 3 years was lowest in the TCZ QW group (median dose [mg/day]: TCZ QW, 2647; TCZ Q2W, 3782; PBO+26, 5248; PBO+52, 5323). Rates of serious adverse events per 100 patient-years over 3 years (double-blind period + part 2) were comparable for patients who never received TCZ (23.2) and those who did receive ≥1 dose of TCZ (25.4), and rates of serious infections were 4.6 and 3.5 per 100 patient-years, respectively. Additional results will be presented for original PBO patients.

Figure 1. Kaplan-Meier plot of time to first flare over 3 years (double-blind and part 2 periods; ITT population).



No. of Patients

PBO+26	50	45	41	35	33	28	22	18	17	15	14	13	13	12	12	12	12	12	12	11	11	11	10	10	10	10	10	10	10	10	10	10	10	10	10
PBO+52	50	47	43	40	37	34	31	29	28	26	24	21	20	16	16	16	16	16	16	15	15	15	14	13	13	13	13	13	13	13	13	13	13	13	12	11	9
TCZ QW	100	93	88	85	85	79	75	72	70	68	66	65	64	60	58	55	53	50	47	46	41	38	38	36	34	33	33	33	33	33	33	33	33	33	32	32	32	32
TCZ Q2W	49	47	46	41	41	39	35	32	31	29	29	29	29	27	25	23	21	21	20	19	19	18	17	17	15	14	14	13	11	10	10	10	10	10	10	10	10	10

Patients never in remission were censored at day 1. Patients who withdrew were censored from the time of withdrawal. Dashed line indicates start of part 2.

Conclusion: Nearly half of patients treated with TCZ QW maintained CR for the entirety of part 2, but flares still occurred in the remaining patients once they discontinued TCZ treatment. Among patients who maintained CR in part 2, higher proportions of those originally assigned to TCZ were treatment-free compared with those originally assigned to PBO. Retreatment with TCZ restored CR in patients who experienced flare. Cumulative GC dose over 3 years was lower in patients originally assigned to TCZ than in those originally assigned to PBO. No new safety signals were observed with TCZ exposure in GCA patients during the 3-year study.

Abstract Number: 0809

TNF-α Drives Progressive Obliterative Pulmonary Vascular Disease and Represents a Novel Model of Connective-Tissue Disease Associated Pulmonary Arterial Hypertension (CTD-PAH)

Benjamin Korman,[1] Richard Bell,[1] R James White,[2] Maria de la luz Garcia-Hernandez,[3] Emily Wu,[2] Pamela Slattery,[2] Nelson Huertas,[2] Stacey Duemmel,[2] Marc Nuzzo,[2] Homaira Rahimi,[4] Craig Morrell,[2] Christopher Ritchlin,[3] and Edward Schwarz[2], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester, Rochester, NY, [3]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY, [4]University of Rochester Medical Center, Rochester

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Plenary I
Session Type: Plenary Session I
Session Time: 11:00AM–12:30PM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a severe cardiopulmonary disease characterized by an obliterative vasculopathy and vascular remodeling, right heart hypertrophy, and premature death. Connective tissue disease associated PAH (CTD-PAH) is common in scleroderma, and other autoimmune diseases, which have poor clinical outcomes. Recently, it has been shown that female human TNF-transgenic (TNF-Tg) mice die by 6-months from cardiopulmonary disease. Thus, we aimed to formally characterize this pathophysiology and assess its potential as a model of CTD-PAH.

Methods: Histologic analysis and immunofluorescent (IF) staining was performed on female TNF-Tg (3647 line) and wild type (WT) mice to characterize the pulmonary vascular and right ventricular pathology. Mice ($n \geq 4$) underwent: right heart catheterization to assess hemodynamics, or barium-perfused micro-CT to assess vascular morphology, or gas chromatography. Lungs from TNF-Tg/WT bone marrow chimeric mice, and anti-TNF vs. placebo treated TNF-Tg mice were assessed ($n \geq 3$). RNA sequencing was performed on lung tissue, and bioinformatic techniques were applied to compare TNF-Tg mouse lungs to publicly available human normal and CTD-PAH transcriptomic data.

Results: Female TNF-Tg mice display a progressive pulmonary vasculopathy beginning at 3 months of age manifested by vascular collagen deposition, enlarged pulmonary arteries, attenuation of distal arterioles, and vascular occlusion, which closely resemble CTD-PAH pathologically (Fig 1A-C). Hemodynamic assessment demonstrated a significantly increased right ventricular systolic pressure of 83.7± 10.3 mmHg vs. 25.7 ± 0.4 mmHg in TNF-Tg vs. WT mice (Fig 1D), making this one of the most robust models of murine PAH ever reported. μCT analysis confirmed pruning of the vascular tree (Fig 1H), and TNF-Tg mice had reduced gas exchange (Fig 1G). Increased aSMA IF staining in TNF-Tg lungs corresponded to proliferation (Ki-67+), and loss of von Willebrand factor positive (vWF+) vessels over time. We also observed an increase in $aSMA^{+}vWF^{+}$ cells (Fig 1, E, F, I), implicating endothelial-mesenchymal transition in this process. By 4 months of age, TNF-Tg mice display remarkable right ventricular hypertrophy, and transcriptional evidence of RV dysregulation (Fig 2A-G). Bone marrow chimera experiments revealed that mesenchymal cells, and not bone-marrow derived cells, are necessary to drive this process (Fig 2H), while anti-TNF therapy halted the progression of PAH pathology (Fig 2I). Human SSc-PAH lungs display increased TNF-a staining (Fig 3A), and human microarray data demonstrated a prominent TNF signature that can distinguish PAH from control lungs (Fig 3B). Comparison of gene expression between TNF-Tg lungs and CTD-PAH lungs showed significant similarities in expression patterns and clustering (Fig 3C) with enrichment in pathway overlaps including angiogenesis, Notch signaling, apoptosis, and VEGF signaling (Fig 3D).

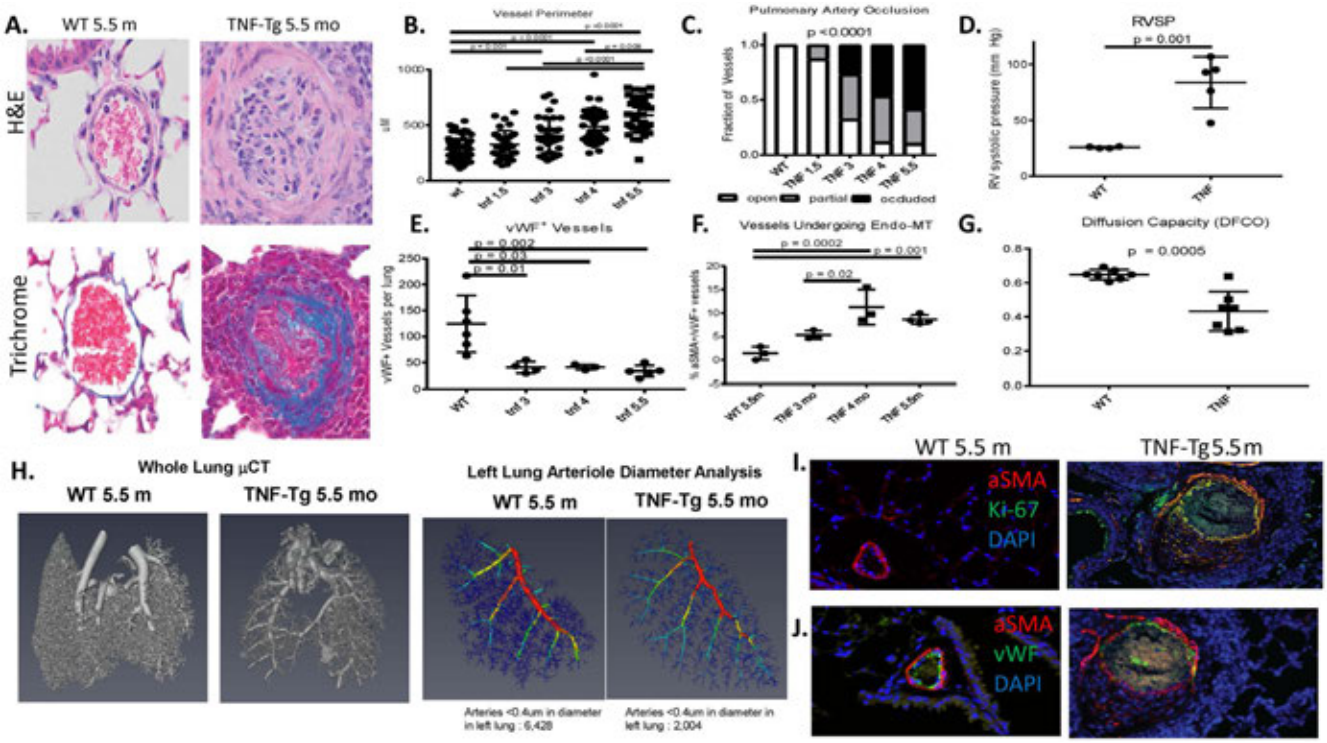

Figure 1. Characterization of pulmonary vascular abnormalities in TNF-transgenic (TNF-Tg) mice. A. Histologic evaluation of TNF-Tg pulmonary arterioles revealed intimal proliferation and vascular occlusion associated with vascular collagen deposition (Top, H&E, Bottom, Masson's Trichrome, 20x). B. Pulmonary arteriole size begins to increase at 3 months of age and becomes progressively larger over time. WT indicates 5.5 month old WT mice for this and all subsequent figures. C. Pulmonary arteries were progressively occluded in the TNF-Tg mice with over 90% of vessels showing at least partial occlusion by 4 months of age. D. Right heart catheterization of TNF-Tg mice demonstrate evidence of severe pulmonary arterial hypertension with increased right ventricular systolic pressure (RVSP) of 83.7± 10.3 mmHg vs. 25.7 ± 0.4 mmHg in TNF-Tg vs. WT mice. E. Number of arterioles in each mouse lung was counted on sections stained for von Willebrand factor (vWF) and there was substantial vessel loss by 3 months of age. F. Quantification of vessels immunofluorescently labeled double positive for both vWF and aSMA indicated that there is a progressive increase in endothelial-mesenchymal transition in TNF-Tg mice. G. TNF-Tg mice have impaired gas exchange as shown by gas chromatography for diffusion of carbon monoxide (DFCO). H. 3D reconstruction of micro-CT scans of barium perfused TNF-Tg and WT lungs demonstrates substantial pruning of the vascular tree with loss of distal arterioles in the TNF-Tg mouse (left, whole lung reconstruction, right, tree structure diagram used for quantification of arteriole size in left lung). I. Double immunostaining for aSMA and proliferation marker Ki-67 demonstrate co-localization in TNF-Tg mice indicating smooth cell proliferation not seen in WT mice. J. Double immunostaining for aSMA and vWF demonstrates co-localization of a subset of cells indicative of the presence of endo-MT in these lesions.

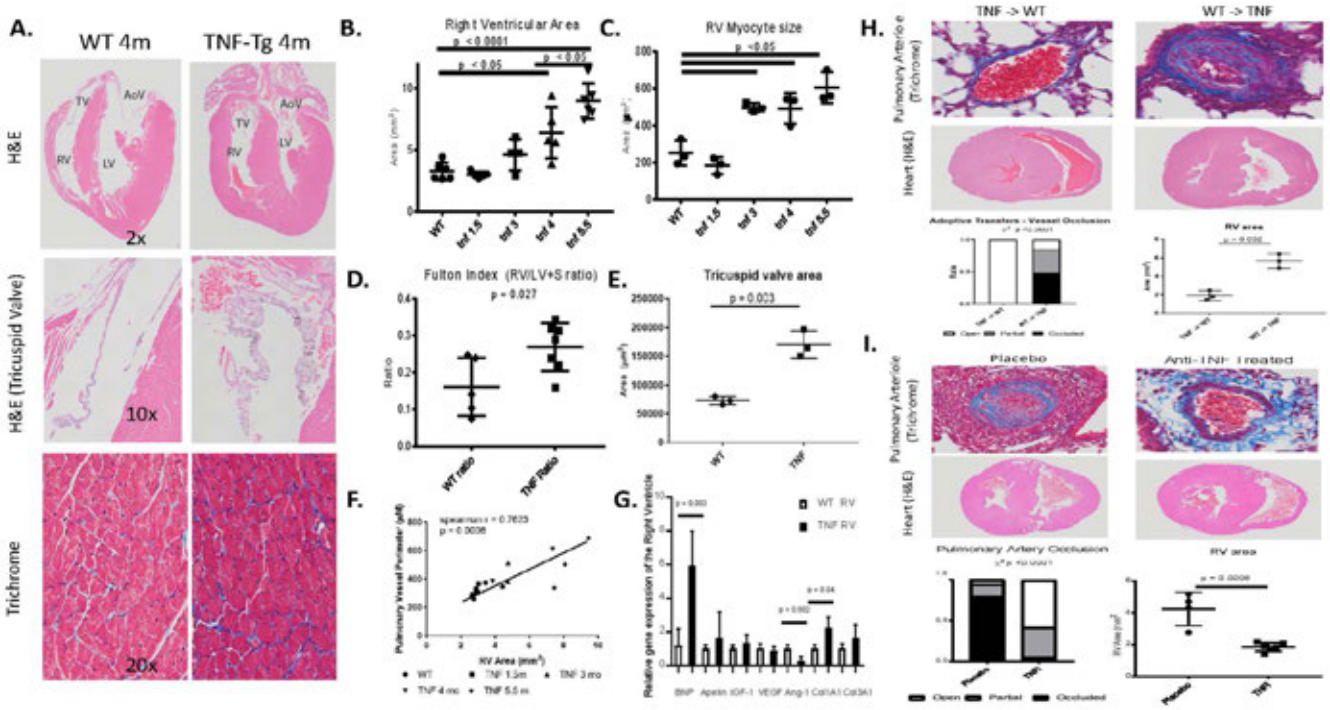

Figure 2. Right ventricular dysfunction in TNF-Tg mice. A. Right ventricular hypertrophy (top, H&E, 2x), tricuspid valve enlargement (middle, H&E, 10x) and myocyte hypertrophy and collagen deposition (bottom, Masson's trichrome, 20x) seen in 4 mo old TNF-Tg hearts compared to WT. B. Histomorphometry revealed progressive increase in RV size over time. C. Histomorphometry revealed progressive increase in RV myocyte size over time. D. Assessment of cardiac weight as measured by the Fulton index (RV/RV+LV+septum) demonstrates abnormal RV weight indicative of RV pathology in 4 mo old TNF-Tg and WT mice. E. Increase in tricuspid valve area in 4 month old TNF-Tg mice. F. RV area is significantly positively associated with pulmonary artery size. G. qPCR of RVs for genes previously shown to be abnormal in RV dysfunction demonstrate significant increases in B natriuretic peptide (BNP) and collagen 1A1 and decrease in angiopoietin-1 in TNF-Tg mice compared to WT, all genes relative expression were normalized to GAPDH. H. Bone marrow chimera experiments revealed that WT mice given TNF-Tg bone marrow at 6 weeks of age did not develop pulmonary or cardiac evidence of PAH at 5 months of age while TNF-Tg mice given WT bone marrow still developed the pathology indicating that mesenchymal rather than bone-marrow derived cells are responsible for the pathology. I. Treatment of TNF-Tg mice with anti-TNF therapy or placebo (CNTO12 and CNTO151, respectively, 10 mg/kg given weekly intraperitoneally from 3 months to 4.5 months of age) demonstrated a lack of progression of pulmonary vascular lesions and no significant right heart pathology after treatment with anti-TNF therapy while placebo animals developed severe PAH.

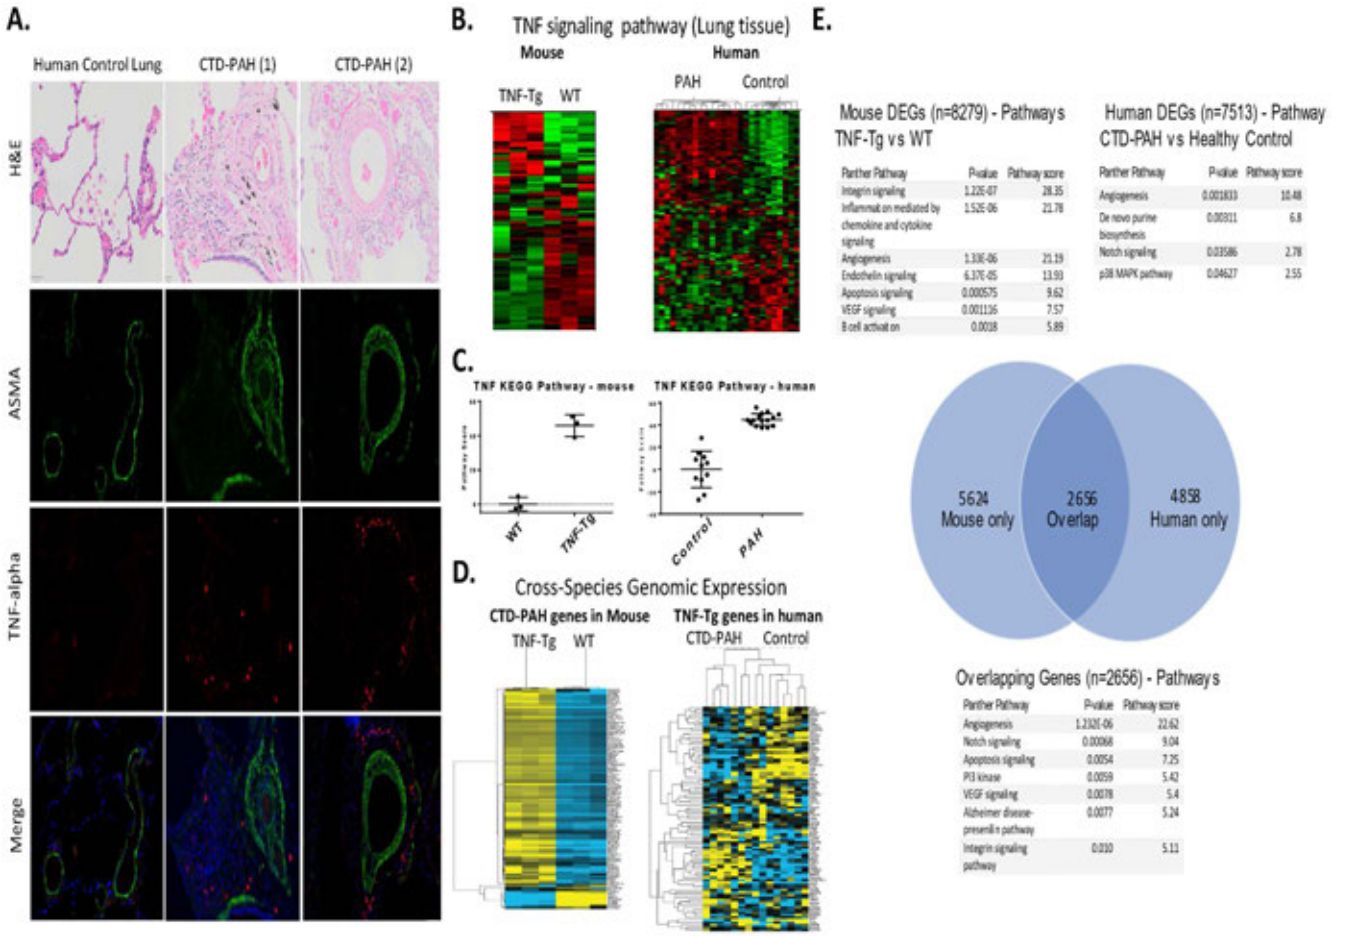

pah acr abstract figures korman et al 3

Figure 3. TNF expression and other relevant pathways overlap in human CTD-PAH and TNF-Tg mice. A. Immunostaining for aSMA and TNF-alpha in lung biopsies from CTD-PAH patients (n=2, representative of n=5) and normal lung (n=1 representative of n=2) demonstrate that CTD-PAH patients have a significant TNF+ infiltrate in the area surrounding vessels with aSMA proliferation not seen in control individuals. B. RNA sequencing of mouse lungs reveals that the TNF KEGG pathway can distinguish TNF-Tg and WT mice (n=3 per group) by hierarchical clustering (left heatmap, red = increased expression, green = decreased expression) and that the same TNF KEGG pathway in human lungs was able to distinguish patients with PAH of multiple etiologies (n=15) from control lungs (n=11) in publicly available microarray data (GSE113439, right heatmap), C. Condensed TNF pathway scores show significant differences between cases and controls (left, mouse, right, human). D. Top 100 differentially expressed genes from mouse and human PAH lungs are sufficient to distinguish PAH across species (left, top 100 CTD-PAH genes in mouse lung samples, right, top 100 TNF-Tg genes in human lung samples). E. Pathway analysis of human and mouse PAH show substantial overlaps. Over one third (n = 2656) of genes differentially expressed ($p<0.05$ in one species) showed overlap between species. Top pathways in overlapping genes included angiogenesis, notch signaling, apoptosis, and PI3 kinase signaling.

Conclusion: The TNF-Tg mouse represents a novel model of CTD-PAH which recapitulates nearly all key features of the disease and can serve as a valuable tool to better study and test potential CTD-PAH therapeutics.

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Lyn kinase is a member of the Src family of non-receptor tyrosine-protein kinases that modifies signals from various cell surface receptors and regulates innate and adaptive immune responses in myeloid cells, B cells and non-hematopoietic cells. We describe two unrelated patients, with de novo Lyn kinase (LYN) mutations, whose disease sheds light on the pathogenesis of neutrophilic small vessel vasculitis.

Methods: The patients were assessed clinically, immunological parameters, trio whole exome sequencing (WES) and pathogenic studies of the disease-causing *LYN* mutations were investigated in transfection studies and in patients' cells. Cytokine and chemokine panels were measured in patient's serum and monocyte culture supernatants; neutrophil function was assessed.

Results: Both patients presented with perinatal onset of neutrophilic small vessel vasculitis and systemic inflammation including hepatosplenomegaly, periorbital erythema, colitis and epididymitis. Low titer autoantibodies (ANA, anti-Sm, anti-SSA, anti-phospholipids and anti-mitochondrial) and vanishing bile duct disease and liver fibrosis were present in one patient. Both patients had a de novo mutation in Lyn kinase (LYN) (c.1524C >G, p.Y508* and c.1523A >T, p.Y508F). One patient responded to a TNF inhibitor alone, the other patient required combination with the src kinase inhibitor, dasatinib. Patients B cells had constitutive phosphorylation of LYN and downstream kinases (CD19, BTK, CD22, PLCg2) by flow cytometry. Skin biopsy sowed capillaritis with myeloperoxidase (MPO)+ neutrophils attached to small vessel walls. LYN was expressed neutrophils and upregulated in endothelial cells of capillaries with and without vasculitis, but not in endothelial cells of larger vessels. Markers of patient neutrophils had constitutively and stimulated increased expression of activated CD11b (granulocyte adhesion marker), CD64 (FC-receptor), and CD63 (marker of primary granule release) compared to normal controls. However, response to higher doses of chemoattractants was blunted in patient compared to control neutrophils. On dasatinib, bridging fibrosis and FibroScan measurements improved and RNA-seq from 3 liver biopsies showed progressive decrease in gene expression pathways related to wound healing and fibrosis. On dasatinib monotherapy, patient monocytes exhibited constitutive

activation of proinflammatory cytokines including TNF-a, G-CSF, IL-6, MIP-1a and MIP-1b, which was mitigated with combination therapy with src-kinase and TNF inhibitors.

Conclusion: Lyn tyrosine kinase mutations at Tyr508 lead to GOF and an autoinflammatory syndrome characterized by skin vasculitis, colitis, variable liver fibrosis and autoantibody production that sheds light on the role of neutrophil and endothelial cell activation in the pathogenesis of small vessel vasculitis and illustrates a therapeutic role for TNF inhibition alone or in combination with dasatinib.

Funding for this study was provided in part by the Division of Intramural Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health.

Abstract Number: 0811

Monomethyl Fumarate as a Novel Therapy for Macrophage Activation Syndrome: Mechanism of Action in an Animal Model

Chhanda Biswas,[1] Thomas Burn,[1] Niansheng Chu,[1] and **Edward Behrens**[1], [1]The Children's Hospital of Philadelphia, Philadelphia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Macrophage activation syndrome (MAS) is a deadly systemic inflammatory condition marked by an increase in enzymes of iron metabolism including ferritin and heme-oxygenase 1 (HO-1). Since HO-1 has been implicated in anti-inflammatory pathways, we reasoned that drugs that increase HO-1 activity may work to decrease disease activity in MAS. Dimethyl fumarate is an FDA approved drug for the treatment of inflammatory lesions in multiple sclerosis; its active metabolite monomethyl fumarate (MmF) has been shown to increase HO-1 activity. We therefore tested whether MMF could ameliorate MAS in a murine a model of the disease, and to determine its mechanism of action.

Methods: MAS was induced in mice using the well standardized TLR9-MAS protocol. MmF was injected i.p. at a dose of 45 mg/kg twice daily, DMSO injections were used as control. Organs were measured for weight, serum cytokines were measured by ELISA, cellular populations by flow cytometry, and complete blood counts were performed to assess disease activity. C57BL/6 mice were used for all experiments, HO-1 floxed mice bred to LysM-Cre mice (HO-$1^{\Delta Mac}$) were used in experiments to test the role of HO-1. HO-1 levels were examined by western blotting. Statistical testing was performed using Student's T-test or by 2-way ANOVA as appropriate.

Results: HO-1 is upregulated by TLR9 stimulation and is required for the majority of IL-10 induced by TLR9 in vitro and in vivo. Loss of HO-1 by monocytes and macrophages in the HO-$1^{\Delta Mac}$ mouse did result in lower IL-10 in TLR9-MAS, but did not significantly affect any of the disease parameters. Treatment with MmF increased HO-1 expression in splenic and peritoneal macrophages. Treatment with MmF during TLR9-MAS significantly improved anemia and

splenomegaly, and increased serum IL-10 levels while decreasing IFNγ and IL-12 levels. This improvement was significantly, but only partially dependent on HO-1 expression in the monocyte/macrophage compartment as HO-1$^{\Delta Mac}$ mice were not as protected by MmF therapy as wild type mice during TLR9-MAS.

Conclusion: MmF was effective in reducing a number of disease activity parameters of TLR9-MAS. Furthermore, decreases of the known disease driving cytokines IL-12 and IFNγ were profound. These changes were accompanied an increase in IL-10. We also show that HO-1 plays an important role in regulating IL-10 levels in inflammation, that MmF can increase HO-1 levels, and that the beneficial effects of MmF are partially dependent on HO-1 in the monocyte/macrophage compartment. These results suggest that the parent compound, the FDA approved drug dimethyl fumarate, should be considered in future investigations of MAS therapy, and that pharmacologic manipulation of the HO-1/IL-10 axis may be an important target for future MAS therapies.

Sex Differences in Autoimmunity and Cardiovascular Risk Could Be Associated with Altered Treg Phenotype and Lipoprotein Metabolism

George Robinson,[1] Kirsty Waddington,[1] Anna Radziszewska,[1] Hannah Peckham,[1] David A Isenberg,[2] Yiannis Ioannou,[1] Coziana Ciurtin,[3] Ines Pineda-Torra,[1] and Elizabeth Jury[1], [1]University College London, London, United Kingdom, [2]Centre for Rheumatology, London, United Kingdom, [3]Centre for Adolescent Rheumatology, University College London London, UK, Londond, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Males and females have altered immune responses resulting in variation in autoimmune risk. Sex differences exist in the frequency and activity of immune-cell subsets but mechanisms underlying sexual dimorphism remain unknown. Our previous work identified a link between immune cell function and lipid metabolism. We hypothesised that sex hormones could influence immune cell differentiation via changes in lipid metabolism and this could be altered in autoimmune diseases such as juvenile-onset systemic lupus erythematosus (JSLE) that emerges during puberty and has a strong female prevalence.

Methods: Flow cytometry and qPCR were used to measure metabolic marker expression on 44 immune cell subsets from 39 teenage healthy controls (HCs, 17 male, 22 female, mean age 19), 35 age matched JSLE patients (12 male, 23 female, mean age 19), pre puberty HCs (10 males and 10 females, mean age 8) and individuals with gender dysphoria undergoing cross-sex hormone therapy (10 biologic males and 10 biologic females). Analysis of metabolic biomarkers including lipoprotein composition was performed on matching serum using nuclear magnetic resonance.

Results: HC responder (Tresp) and regulatory (Treg) T-cell subsets displayed the strongest immune profile differences by sex with significantly increased Tregs (p= 0.036) and reduced Tresp (p= 0.001) frequencies in males compared to females. HC Male Tregs had an increased suppressive capacity, IL-4 production (p= 0.019) (supported by increased GATA-3 expression) and plasma membrane glycosphingolipid (GSL) expression (p= 0.038) compared to Tregs from HC females. GSL changes were mirrored by increased expression of GSL synthesis enzyme UGCG (p= 0.042) in male Tregs, suggesting a sex-specific alteration in lipid metabolism related to Treg function.

Metabolomic lipoprotein analysis of matching serum revealed that teenage HC males had significantly reduced atheroprotective high density lipoprotein subsets and increased atherogenic very low density lipoprotein (VLDL) subsets compared to HC females. These differences were not observed pre-puberty but were induced appropriately by sex hormone treatment in gender dysphoria individuals; suggesting that sex hormones regulate lipid metabolism in vivo.

VLDL subsets from HC males were preferentially enriched with triglycerides and correlated positively with activated Treg subsets compared to VLDL from HC females where no such relationship was seen. Furthermore, Tregs cultured with VLDL isolated from either HC males or females recapitulated the male and female Treg phenotype respectively. Strikingly, sex differences in Treg frequency, phenotype, lipid metabolism and serum lipoproteins were lost in patients with JSLE. This loss of sexual dimorphism in JSLE patients involved the development of a more atherogenic metabolomic profile and pro-inflammatory T-cell phenotype in females.

Conclusion: Potential defects in sex hormone signalling in patients with JSLE may lead to a loss of differential male/female lipid taxonomy. Defective lipoprotein metabolism in JSLE could alter immune cell plasma membrane lipids and immune cell function and contribute to increased cardiovascular risk in female JSLE patients.

Monocyte and Macrophage Transcriptional Phenotypes in Systemic Juvenile Idiopathic Arthritis Reveal TRIM8 as a Mediator of IFNγ Hyperresponsiveness and Risk for Macrophage Activation Syndrome

Grant Schulert,[1] Thuy Do,[1] Sanjeev Dhakal,[1] Ndate Fall,[2] Mario Medvedovich,[3] Sherry Thornton,[1] Nathan salomonis,[2] and Alexei A. Grom[1], [1]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]University of Cincinnati College of Medicine, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Systemic juvenile idiopathic arthritis (SJIA) is a severe and distinct subtype of childhood arthritis. Children with SJIA are at risk for macrophage activation syndrome (MAS), a life-threatening episode of hyperinflammation driven by interferon-gamma (IFNγ). Previous work has suggested that monocytes in SJIA display hyperresponsiveness to IFNγ, but the molecular basis of this remains unclear. The objective of this study is to identify monocyte and macrophage polarization phenotypes including features of interferon response.

Methods: Bulk RNA-sequencing (RNA-seq) was performed on purified monocytes from 26 patients with SJIA without overt MAS. In addition, single-cell RNA-seq was performed on isolated bone marrow macrophages (BMM). THP-1 monocytic cells were transfected with TRIM8-specific small-interfering RNA (siRNA) prior to stimulation with IFNγ.

Results: Bulk RNA-seq of purified SJIA monocytes revealed marked transcriptional changes between cells from patients with high vs low serum ferritin levels including upregulated gene pathways Response to External Stimulus ($p=2.73x10^{-17}$) Defense Response ($p=2.66x10^{-14}$), and Inflammatory Response ($p=1.95x10^{-11}$). When comparing the

SJIA monocyte signature to well-characterized polarization phenotypes, we identified little evidence of IFNγ-induced signature but substantial overlap with multiple polarization states, reflecting either a mixed phenotype or multiple distinct cell populations. Interestingly, among the most highly upregulated genes in SJIA monocytes was tripartite motif containing 8 (TRIM8), an E3 ubiquitin-ligase involved in activation of IFNγ through promoting degradation of the suppressor of cytokine signaling 1 (SOCS1). Elevated TRIM8 expression was found in monocytes from both active and inactive SJIA patients, with the highest levels in those with subclinical MAS (n=3). Furthermore, we utilized scRNA-seq to determine gene expression profiles of BMM from a patient with subclinical MAS. This single cell approach identified a distinct subpopulation of BMM which exhibited markedly altered transcriptional profiles, with the most significantly upregulated pathways being cellular response to IFNγ (p=1.35e-14), endocytic vesicle membranes (p=8.44E-14), and phagosome (p=2.98e-9). These BMM also showed significantly increased expression of TRIM8 (6.4-fold), IFNAR1 (10.5-fold), and IFNGR2 (13.8-fold). To confirm the role of TRIM8 in augmenting macrophage responses to IFNγ, TRIM8 expression was knocked-down in THP-1 using siRNA. TRIM8 knock-down macrophages showed significant reductions in both early (4 hour) and late (24-48 hours) response to IFNγ, as determined by production of CXCL9, a biomarker for MAS activity in both mouse models and patients.

Conclusion: Peripheral monocytes in SJIA display markers of multiple polarization states, while during MAS BMM demonstrate a clear IFNγ response phenotype. TRIM8 is highly expressed in both monocytes and macrophages in SJIA, and in vitro knockdown of TRIM8 reduces macrophage IFNγ response. These data provide a molecular mechanism for monocyte hyperresponsiveness to IFNγ in SJIA, as well as a novel therapeutic target for MAS.

Interferon Signature and Cytokine Patterns Define Novel Autoinflammatory Diseases

Adriana de **Jesus**,[1] Yangfeng Hou,[2] Stephen Brooks,[3] Louise Malle,[4] Angelique Biancotto,[5] Yan Huang,[6] Katherine Calvo,[7] Bernadette Marrero,[8] Susan Moir,[9] Andrew Oler,[10] Zuoming Deng,[3] Gina Montealegre Sanchez,[1] Scott Canna,[11] and Raphaela Goldbach-Mansky[12], [1]Translational Autoinflammatory Disease Section/NIAID/NIH, Bethesda, [2]Department of Rheumatology, Shandong Provincial Qianfoshan Hospital, Shandong University, Shandong, China (People's Republic), [3]Biomining and Discovery Section/NIAMS/NIH, Bethesda, MD, [4]Translational Autoinflammatory Diseases Section [TADS], NIAID/NIH, Bethesda, [5]NIH/CHI, Bethesda, [6]Translational Autoinflammatory Disease Section/NIAID/NIH, Bethesda, MD, [7]Hematology Service/Department of Laboratory Medicine/NIH, Bethesda, MD, [8]Computational Systems Biology Section/NIAID/NIH, Bethesda, [9]Immunopathogenesis Section/NIAID/NIH, Bethesda, MD, [10]NIH/NIAID, Bethesda, [11]UPMC Children's Hospital of Pittsburgh, Pittsburgh, [12]Translational Autoinflammatory Diseases Section/NIAID/NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Undifferentiated systemic autoinflammatory diseases (USAID) present diagnostic and therapeutic challenges. Cytokine dysregulation may identify disease groups that respond to targeted treatments. IFN-signaling blocking treatments in patients with high IFN signature and novel treatments for macrophage activation syndrome (MAS) may benefit patients without a genetic diagnosis. An integrated screening approach of patients with USAIDs that included assessment of an IFN signature and serum cytokines followed by genomic evaluation led to the identification of novel disease subsets that present with an IFN signature.

Methods: We evaluated 66 patients with USAID. Using a Nanostring assay, a 28-gene IFN score of selected interferon response genes (IRGs) was calculated. RNA-seq of matched samples was used for the correlation between RNA-seq and Nanostring for the validation of a 4-gene NF-kB Nanostring subscore. Serum levels of 48 analytes were determined by a multiplex cytokine assay and high IL-18 levels were reanalyzed by ELISA. Whole exome sequencing (WES) and/or whole genome sequencing (WGS) was performed in 61 of the 66 patients.

Results: Of the 66 patients, 36 (55%) had elevated interferon response gene signatures (IRS). Neutrophilic panniculitis (40% vs 0%) basal ganglia calcifications (46% vs. 0%), interstitial lung disease (47% vs 5%) and myositis (60% vs 10%) were significantly higher in pts with elevated IRS. Eight pts with pulmonary alveolar proteinosis (PAP) had highly-elevated IL-18 serum levels and recurrent macrophage activation syndrome (MAS). Of 11 patients with low IFN score elevation, CANDLE-like panniculitis and progressive cytopenias 2 were compound heterozygous for novel *LRBA* mutations, 3 males harbor novel splice variants in *IKBKG*/NEMO, and 6 patients have de novo frameshift mutations in *SAMD9L.* Of 13 patients with highly elevated IRS and CANDLE-, SAVI- or Aicardi-Goutières-Syndrome (AGS)-like phenotypes, 5 pts had each a mutation in either *SAMHD1, TREX1, PSMB8 or PSMG2*. Two patients had anti-MDA5-positive juvenile dermatomyositis, and 7 could not be further characterized. Different patterns of interferon-response-gene (IRG) elevation with a higher relative expression of 4 IRGs with NF-kB binding sites assessed referred to as 4- NF-kB/24-STAT1 ratio distinguished patients with *LRBA, IKBKG*/*NEMO* and *SAMD9L* mutations from the autoinflammatory interferonopathies CANDLE, SAVI and AGS and suggested proportionally increased concomitant NF-kB signaling in LRBA deficiency and NEMO-NDAS.

Conclusion: IRS elevation, characteristic cytokine elevations and clinical features identified 3 novel diseases, IL-18-mediated PAP and recurrent MAS (IL-18PAP-MAS), NEMOD5-associated autoinflammatory syndrome (NDAS), and SAMD9L-associated autoinflammatory disease (SAAD), thus expanding the diagnostic armamentarium in assessing patients with USAIDs, and pointing to novel pathways regulating interferon-response-gene-expression.

Expression Profiling of Genes in Rheumatoid Fibroblast-like Synoviocytes Regulated by Fas Ligand Using cDNA Microarray Analysis

Koji Fukuda,[1] Yasushi Miura,[2] Shinya Hayashi,[1] Toshihisa Maeda,[3] and Ryosuke Kuroda[1], [1]Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, [2]Division of Orthopedic Science, Department Of Rehabilitation Science, Kobe University Graduate School of Health Sciences, Kobe, Japan, [3]Matsubara Mayflower Hospital, Kobe, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Fas ligand (FasL) is a member of tumor necrosis factor superfamily (TNFSF6) and reported to contribute to synovial hyperplasia of rheumatoid arthritis (RA). Apoptosis through Fas/FasL pathway of RA synovial cells was inhibited by pro-inflammatory cytokines present within the synovium. We previously reported that decoy receptor 3 overexpressed in rheumatoid synovial fibroblasts (RA-FLS) stimulated by TNFα protects the cells from Fas-induced apoptosis. In this study, we investigated the gene expression profiles regulated by FasL in RA-FLS to reveal how FasL is involved in the pathogenesis of RA.

Methods: Primary cultured RA-FLS were incubated with either 1000 ng/ml of recombinant human FasL protein or phosphate buffered saline as unstimulated control diluted with Opti-MEM reduced serum medium for 12h. Gene expressions were detected by microarray assay (Human Genome U133 Plus 2.0, GeneChip® 3' Expression Array; Thermo Fisher Scientific).

Results: Microarray data analysis revealed that FasL up-regulated or down-regulated the expression of various genes in RA-FLS. The most up-regulated 3 genes by FasL were dual specificity phosphatase 6 (DUSP6; fold change, 34.6), epiregulin (EREG; fold change, 29.2) and interleukin11 (IL-11; fold change, 25.3). DUSP6 regulates CD4+ T-cell activation and differentiation by inhibiting the T-cell receptor-dependent extracellular signal-regulated kinases 1 and 2 activations. EREG is increased in patients with RA and associated with the development of cytokine-induced arthritis. IL-11 regulates the growth and development of hematopoietic stem cells and decreases the pro-inflammatory cytokines and nitric oxide productions. The most down-regulated 3 genes by FasL were angiopoietin-like 7 (ANGPTL7; fold change, 11.6), protein inhibitor of activated STAT2 (PIAS2; fold change, 11.3) and growth differentiation factor 5 (GDF5; fold change, 11.1). ANGPTL7 is pro-angiogenic factor and promotes pro-inflammatory responses through the P38 signaling pathway. PIAS proteins inhibit the activated STAT and are involved in the pathogenesis of RA. GDF5 is associated with joint destruction of patients with OA and RA. The function of regulated genes included transcriptional activator activity, positive regulation of metabolic process, positive regulation of cellular metabolic process, positive regulation of macromolecule metabolic process, positive regulation of nitrogen compound metabolic process, regulation of phosphorylation, positive regulation of biological process, regulation of phosphate metabolic process, regulation of MAPK cascade, and regulation of multicellular organismal process.

Conclusion: FasL regulates the expression of various genes in RA-FLS. FasL may affect the pathogenesis of RA by regulating gene expression of RA-FLS.

Disclosure: K. Fukuda, None; **Y. Miura**, None; **S. Hayashi**, None; **T. Maeda**, None; **R. Kuroda**, None.

The Long Non-coding RNA HOTAIR Regulates BMP2 and Wnt Pathways in Synovial Fibroblasts

Muriel Elhai,[1] Raphael Micheroli,[1] Mojca Frank-Bertoncelj,[2] Kerstin Klein,[1] Oliver Distler,[3] and Caroline Ospelt[2], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Switzerland., Zürich, Switzerland, [2]University Hospital Zürich, Zürich, Switzerland, [3]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Etiology & Pathogenesis I

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Mechanisms involved in joint patterning of rheumatic diseases remain unknown. The long non-coding RNA HOTAIR is exclusively expressed in synovial fibroblasts (SF) from lower extremity joints. HOTAIR is known to be an important regulator of the epigenetic landscape by modulating H3K27me3 and H3K4me1 marks. Here, we analysed the function of HOTAIR in SF.

Methods: HOTAIR was silenced in knee SF from osteoarthritis (OA) patients by GapmeRs. ChIP-sequencing of H3K27me3 marks (Illumina HiSeq 2500) and RNA-sequencing (NovaSeq 6000) were performed in GapHOTAIR- and control-transfected SF at 48h after transfection (n=3). Enriched pathways and protein interactions were analyzed using DAVID and STRING networks, respectively. Regulated genes were confirmed by real-time PCR in SF from OA and rheumatoid arthritis (RA) patients (n=8) and changes after cycloheximide adjunction (10ug/ml 6h and 24h) were evaluated (n=3). Signaling pathways were studied by Western blotting (n=5). Effect of HOTAIR silencing on the canonical Wnt pathway was assessed using TOP/FOP reporter system (n=4). The expression of HOTAIR was studied after stimulation with TNF-α in SF (n=17) and correlated with TNF-α-expression in synovial tissues from RA patients (knee and ankle) (n=7).

Results: ChIP-sequencing showed 3225 loci, which lost H3K27me3 marks in HOTAIR silenced SF. Transcription of the genes at 492 of these loci was up-regulated in SF transfected with GapHOTAIR. Pathway enrichment showed that these transcripts were mainly involved in cancer, apoptosis and Wnt signaling. Among them, we confirmed the overexpression of BMP2 (1.7±0.5-fold; $p< 0.01$) and CTNNB1 (beta-catenin) (1.5±0.5-fold; $p< 0.01$) and showed a down-regulation of other genes belonging to the Wnt pathway (LGR5 ($p=0.02$), GSK3β ($p=0.03$) and a trend for LRP6 ($p=0.06$)). Blocking translation by adding cycloheximide did not change BMP2 and CTNNB1 expression, confirming a direct effect of HOTAIR on these genes, whereas the effect on other Wnt genes was indirect. The repressor of Wnt pathway SFRP1 was significantly enriched for H3K27me3 marks in controls as compared to GapHOTAIR SF, but its transcription was not changed in GapHOTAIR SF. The regulation of the canonical-Wnt pathway was confirmed by the TOP/FOP system by 1.8±0.2-fold decrease in Wnt activation after HOTAIR silencing ($p=0.01$). BMP2 regulation was mediated by non-canonical pathway through ERK1/2 phosphorylation ($p=0.01$). TNF-α stimulation led to a 2.1±0.3 decrease in HOTAIR expression in SF ($p< 0.0001$) and was inversely correlated with HOTAIR in the RA synovium ($r=-0.79$; $p< 0.05$).

Conclusion: HOTAIR regulates the non-canonical BMP2 and the canonical Wnt pathway by epigenetic and transcriptional mechanisms. Downregulation of HOTAIR during inflammation might influence the phenotype of chronic arthritis in joints of the lower extremities with implications for disease severity and therapy.

Enhanced Expression of mRNA for TAK1 in CD34+ Cells of the Bone Marrow in Rheumatoid Arthritis

Shunsei Hirohata,[1] Tatsuo Nagai,[2] Tetsuya Tomita,[3] and Hideki Yoshikawa[3], [1]Department of Rheumatology and Infectious Diseases, Kitasato University School of Medicine, Tatsuno, Japan, [2]Kitasato University School of Medicine, Sagamihara, Japan, [3]Osaka University Graduate School of Medicine, Osaka, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory disease characterized by synovial hyperplasia, consisting of type A macrophage-like synoviocytes and type B fibroblast-like synoviocytes (FLS). We have previously demonstrated that bone marrow (BM) CD34+ cells from RA patients have abnormal capacities to respond to tumor necrosis factor-α (TNF-α) and to differentiate into FLS, playing an important role in the pathogenesis of RA. However, the mechanism of the abnormal responses to TNF-α of BM CD34+ cells has been unclear. Of note, transforming growth factor β activated kinase 1 (TAK1) has been shown to be activated in the inflammatory signal transduction pathways in response to IL-1β, TNF-α or toll-like receptor stimulation. Moreover, it has been disclosed that intraarticular administration of siRNA for TAK1 inhibited the development of collagen-induced arthritis in mice. It

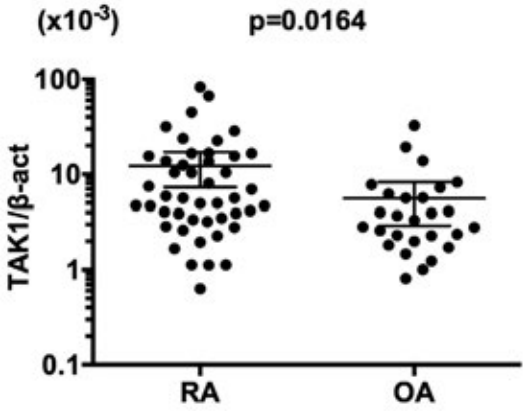

Figure 1. The expression of mRNA for TAK1 in bone marrow CD34+ cells in RA patients and in OA patients

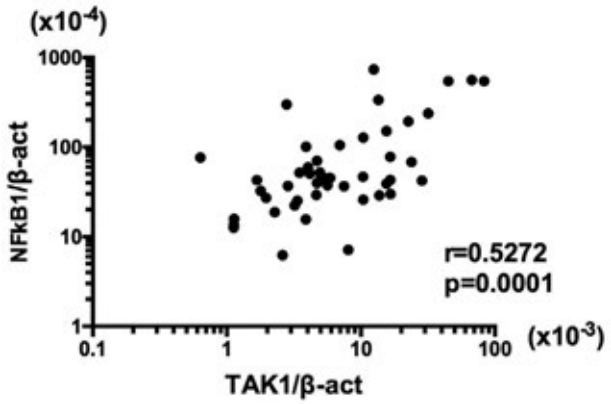

Figure 2. The correlation of the expression of TAK1 mRNA with that of NFκB1 (p50) mRNA in bone marrow CD34+ cells in RA patients

is thus possible that aberrant expression of TAK1 in BM CD34+ cells might lead to their abnormal responses to TNF-α resulting in enhanced differentiation into FLS. The current study therefore examined the mRNA expression of TAK1 in BM CD34+ cells from RA patients.

Methods: BM samples were obtained from 47 patients with RA (6 males and 41 females: mean age 58.8 years) and 27 patients with OA (2 males and 25 females: mean age 70.4 years), who gave informed consent, during joint operations via aspiration from iliac crest. CD34+ cells were purified from the BM mononuclear cells by positive selection with magnetic beads. The expression of mRNA for TAK1 was examined by quantitative reverse transcription PCR. The results are shown as the ratio of the copy numbers to those of β-actin mRNA.

Results: The expression of mRNA for TAK1 was significantly higher in RA BM CD34+ cells than OA BM CD34+ cells (Figure 1). The mRNA expression levels of TAK1 were not correlated with serum C-reactive protein (r=0.08316, p=0.5784) or with treatment regimens with or without methotrexate or glucocorticoids. TAK1 mRNA expression was significantly correlated with NFκB1 mRNA expression in RA BM CD34+ cells (Figure 2). Finally, TNF-α enhanced NFκB1 mRNA expression, but not TAK1 mRNA expression, in BM CD34+ cells from normal individuals.

Conclusion: These results indicate that the enhanced expression of TAK1 mRNA in BM CD34+ cells plays a pivotal role in the pathogenesis of RA through upregulation of differentiation of FLS. Moreover, the data have also disclosed that the upregulation of TAK1 mRNA expression might lead to the increased expression of NFκB1 mRNA in BM CD34+ cells, but not vice versa, consistently with the position of TAK1 upstream of mitogen-activated protein kinases and the IkB kinase complex in signaling cascades. It is thus confirmed that TAK1 might be a good therapeutic target in RA.

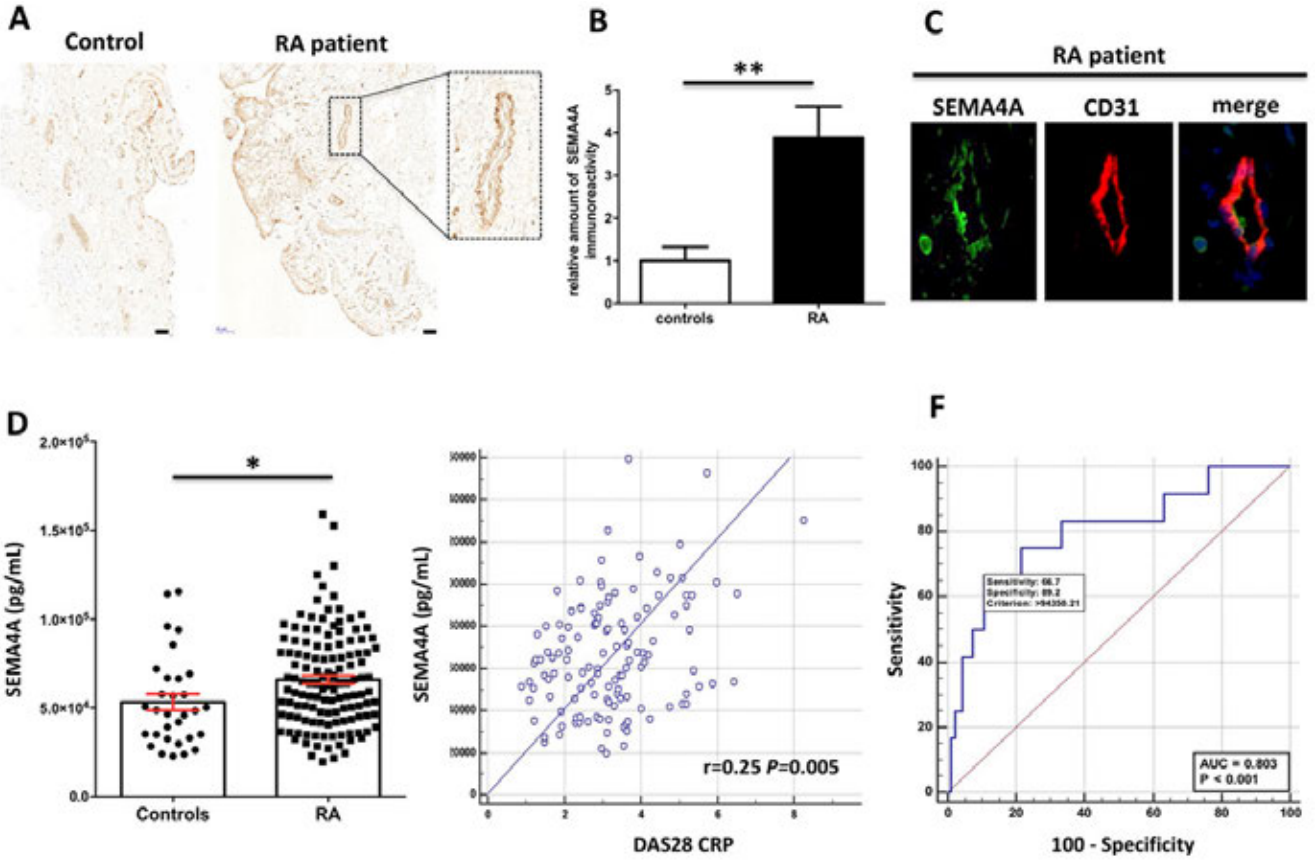
Semaphorins: From Angiogenesis to Inflammation in Rheumatoid Arthritis

Jerome Avouac,[1] Sonia Pezet,[2] Eloïse Vandebeuque,[1] and Yannick Allanore[1], [1]Paris Descartes University, Cochin Hospital, Rheumatology department, Paris, France, [2]INSERM U1016, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Synovial neoangiogenesis is an early and crucial event to promote the development of the hyperplasic proliferative pathologic synovium in rheumatoid arthritis (RA). A recent microarray analysis revealed a differential expression of semaphorin family in RA endothelial cells (ECs), which is known to contribute to angiogenesis and inflammation. Our aim was to study the potential implication of semaphorins in RA pathogenesis.

Methods: mRNA levels of class 3 and 4 Semaphorins (SEMA) SEMA3A, SEMA3E, SEMA4A and SEMA4E, as well as their receptors PlexinD1 (PLXND1) and Neuropillin-1 (NRP1), were measured by real-time quantitative PCR in RA (n=15) and control (n=15) ECs. Protein expression of these 4 semaphorins and their receptors was evaluated in ECs of 10 RA patients and controls by western blot, and in the synovial tissue of 10 RA patients and 5 controls by immunohistochemistry and immunofluorescence. Serum concentrations of these 4 semaphorins were measured by sandwich ELISA in a cohort of 130 patients with RA (85% women, mean age: 58 ± 12 years and mean disease duration: 11 ± 12 years) and 30 age- (56 ± 10 years) and sex- (82% women) matched controls.



A-C, Overexpression of SEMA4A in the synovial tissue of patients with rheumatoid arthritis (RA) compred to healthy controls. A, Representative images synovial sections stained for SEMA4A (scale bar 100μm). B, amount of immunoreactivity quantified with the image J software (n=5 for each). C, D Double labeling for SEMA4A and CD31 showing the expression of SEMA4A in synovial vessels. D, Increased circulating SEMA4A levels in the serum of patients with RA (n=130) as compared to healthy controls (n=30). E, correlation between SEMA4A serum levels and the disease activity score (DAS)-28 CRP. F, ROC curve illustrating the diagnostic value of SEMA4A to identify patients patients with high disease activity. *p<0.05, ** p<0.01.

Results: ResultsSEMA4A, PLXND1 and NRP1 mRNA and protein levels were markedly increased in RA ECs. The expression of SEMA4A (Figure 1A-B), SEMA3A, SEMA3E, PLXND1 and NRP1 was strikingly increased in the synovial tissue of RA patients. Confocal microscopy with double labeling for CD31 confirmed the prominent endothelial expression of these class 3 and 4 semaphorins and their receptors (Figure 1C). Serum levels of SEMA4A (Figure 1D) and SEMA3E were significantly increased in patients with RA compared to controls. Conversely, SEMA3A serum levels were strikingly lower in patients with RA compared to controls. SEMA4A (Figure 1E), SEMA3A, SEMA3E and SEMA4D serum levels correlated with markers of joint and systemic inflammation (swollen joint count, ESR, CRP, synovial vascularization assessed by power Doppler), validated composite score measuring disease activity (DAS28 and DAS28-CRP) as well as circulating proangiogenic markers (VEGF, Tie2, VCAM-1, IL-8). The diagnostic value of SEMA4A to identify patients with an "inflammatory profile" (DAS28 >3.2, CRP >10 mg/L and increased power Doppler global arthritis score) was defined by an area under curve (AUC) of 0.80 (P< 0.001) (Figure 1F). In the 52/130 patients (40%) in remission or with low disease activity defined by a DAS28< 3.2, defined by the persistence of synovial hyperemia detected on at least one joint, SEMA4A and SEMA4D detected residual infraclinical disease activity with an AUC of 0.70 (P=0.008 and P=0.012, respectively).

Conclusion: Gene expression profiling of ECs identified semaphorins as potential biomarkers and therapeutic candidates in RA. Class 3 and 4 semaphorins are overexpressed in ECs, synovial vessels and the serum of patients with RA. They also correlated with validated markers of inflammation and angiogenesis. Thus, semaphorins might be novel and appealing EC-derived inflammatory and proangiogenic targets in RA.

The Long Noncoding RNA HOTTIP Regulates Cell Cycle and Inflammatory Response in Hand Synovial Fibroblasts

Mojca Frank-Bertoncelj,[1] **Tadeja Kuret**,[2] Ana Županič,[3] Snezna Sodin-Semrl,[4] Oliver Distler,[5] and Caroline Ospelt[1], [1]University Hospital Zürich, Zürich, Switzerland, [2]University Hospital Zürich, Zurich, Tajikistan, [3]University Hospital Zürich, Zurich, Switzerland, [4]University Medical Center Ljubljana, Ljubljana, Slovenia, [5]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Etiology & Pathogenesis I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Previously we showed that the long noncoding RNA (lncRNA) HOTTIP is exclusively expressed in synovial fibroblasts (SF) from distal joints, such as small joints of hands and feet, which exhibit prominent proliferative and chemotactic activities (Frank-Bertoncelj, *et al*. Nat Commun, 2017). Our objective was to explore the role of HOTTIP in shaping the function of hand SF in arthritis.

Methods: We silenced the lncRNA HOTTIP in hand SF using LNA GapmeRs (100 nM, 48h). We conducted RNA-sequencing (n=2) and confirmed RNA-sequencing data with qPCR in a larger cohort of hand SF from RA patients (n=6). Protein-protein interaction analysis of RNA-sequencing data was performed using STRING. Protein levels of IL8 (n=4) and MMP3 (n=6) in cell supernatants were measured by ELISA. Cyclin dependent kinase inhibitor p21 (n=4) was detected by Western blot. Proliferation (n=3) was measured in vitro using the BrdU assay. Apoptosis and necro-

sis (n=6) were determined with Real time-Glo annexin V apoptosis and necrosis assay. Significance was defined as $p< 0.05$ measured by one-sample t-test or paired t-test.

Results: STRING analysis of RNA sequencing data showed changes in cell cycle, inflammatory response and integrin pathways after silencing of HOTTIP in hand SF. We confirmed the significant downregulation of transcripts involved in mitotic cell cycle (NCAPG, TUBGCP5, TADA3, ASPM, ZWILCH, CDC27, BUB1, GPSM2 and CDK6), significantly increased transcript and protein expression of the cyclin-dependent kinase inhibitor p21 and significantly less proliferation in HOTTIP silenced hand SF. No difference in apoptosis and necrosis was observed between HOTTIP and control silenced hand SF. Furthermore, silencing of HOTTIP resulted in significant upregulation of transcripts involved in inflammatory and immune response pathways (IL8, IL12A, IL17C, CXCL3, MMP3 and TNFAIP3) and significantly increased protein levels of IL8 and MMP3. Silencing of HOTTIP also significantly altered gene expression of different types of integrins (ITGA3, ITGB1, ITGB5, ITGB7 and ITGA2B) that play a role in adhesion and organization of newly synthesized extracellular matrix. Stimulation of hand SF with TNFα and IL6/IL6R resulted in significant decrease of HOTTIP expression.

Conclusion: Distal-specific expression of HOTTIP could support enhanced proliferative properties in hand SF. In inflammatory conditions, reduced levels of HOTTIP might shape a location-specific inflammatory response with joint-specific changes in cytokine and chemokine expression, cell adhesion and cell-to-extracellular matrix interactions.

Session Date: Sunday, November 10, 2019

Session Title: RA – Etiology & Pathogenesis I

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Our understanding of disease pathogenesis in Rheumatoid Arthritis (RA) is rapidly expanding with the advent of 'Omics' techniques. Importantly, current analysis takes into account many clinical covariates such as gender and age, however there are no studies to date that have systematically examined the impact that the timing of sample acquisition has on transcriptional profiles. This is a fundamental covariate given the real-world clinical setting of samples acquisition. Moreover, within day variation in RA symptoms are characteristic of disease (e.g. early morning stiffness). Herein, we evaluated the diurnal variation in transcriptomic profiles in 10 RA patients.

Methods: Whole blood was drawn into Paxgene tubes from 10 RA patients over the course of one day (8am, 9am, 11am, 1pm and 3pm), and stored at -80°C. RNA was extracted using the Paxgene Blood miRNA kit and libraries prepared for RNA-Seq using the Illumina TruSeq Stranded Total RNA Ribo-Zero H/M/R Gold kit. RNA-seq was performed and data analysed using the likelihood ratio test in the DESeq2 R package to identify any genes that showed a change in expression across the different time points. The genes identified as being differentially expressed and having a fold change greater than 1.5 between any two time points in the RNA-Seq analysis were clustered to identify patterns of expression. Gene ontology enrichment analysis as well as pathway over-representation analysis using the Reactome database was performed.

Results: RNA-Seq analysis identified 395 genes with a fold change of 1.5 or greater that were differentially expressed between the timepoints. Cluster analysis of these genes identified four patterns of expression. Two of the expression clusters (utilising 86 or 149 genes respectively) showed a decrease in transcripts throughout the day, figure 1. Notably, the gene ontology terms associated with the clusters were; neutrophil activation, myeloid and leucocyte migration, neutrophil degranulation, figure 2a. Furthermore, Reactome Pathways Analysis highlighted; interleukin-33 signalling, interleukin-10 signalling, and interleukin-1 family signalling as over-represented in the clusters. All of which are commensurate with increased immune activation in the morning. In comparison, the other two expression

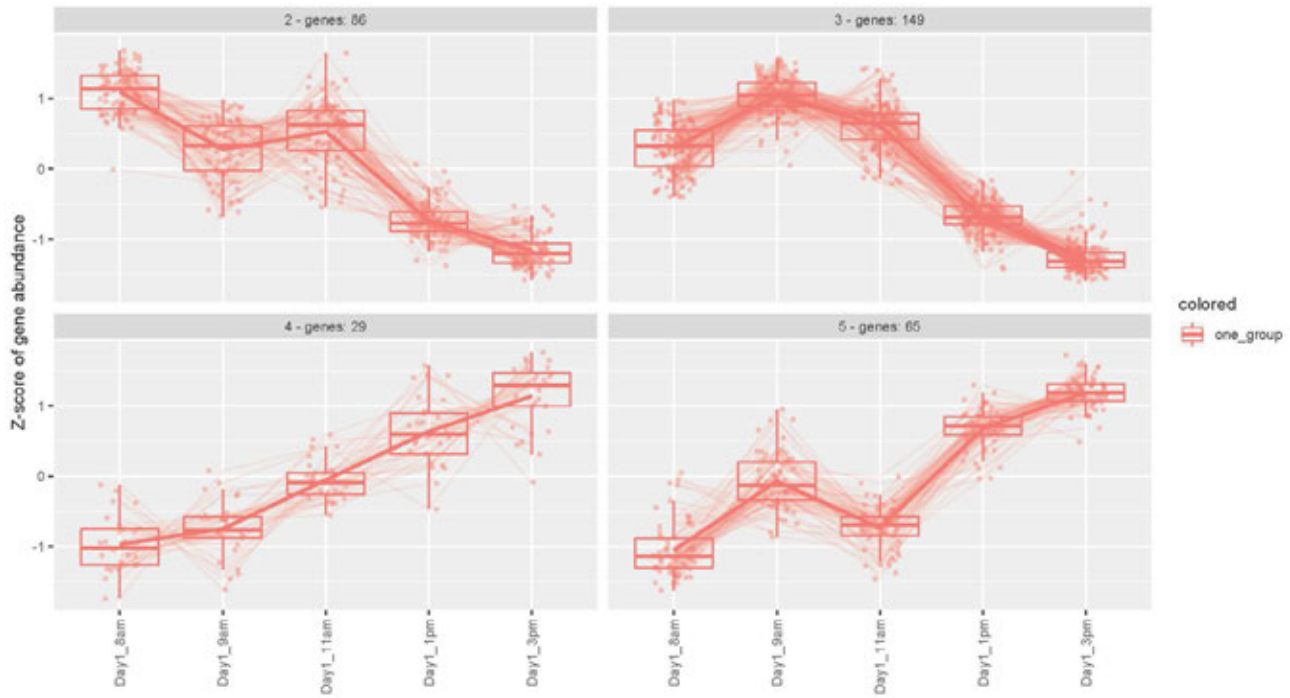

Figure 1. Clustering of genes with similar expressions patterns – The figure shows the detected patterns of expression within the differentially expressed genes having a fold change greater than 1.5. The z-score of gene abundance represents the number of standard deviations the expression at a time point is away from the overall mean.

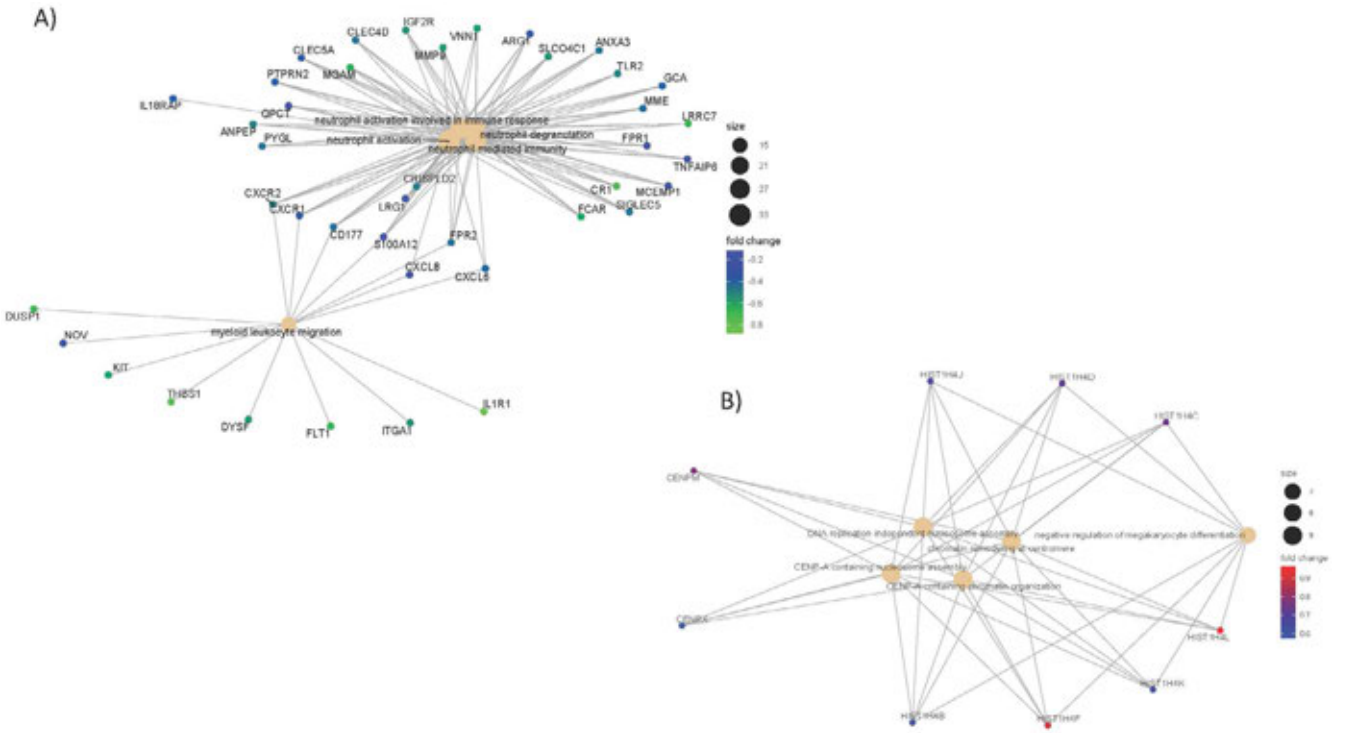

Figures 2a and 2b show the relationships between the genes from the cluster analysis and the enriched categories from the gene ontology analysis. Figure 2a show the genes from clusters 2 and 3 where there is an association with immune system function, and figure 2b, containing the genes from clusters 4 and 5, which were associated with DNA replication and processing. The fold changes displayed are log2 transformed and are between the 8am and 3pm time points.

clusters (utilising 29 and 65 gene respectively) increased during the day, figure 1. These clusters were associated with DNA replication and processing pathways and gene ontology terms, figure 2b.

Conclusion: Our results clearly demonstrate that timing of sample collection has a significant impact on the transcription profile of circulating cells and should therefore be accommodated within biomarker studies. Moreover, alterations were observed across rather fundamental biological pathways that may inform disease pathogenesis studies in future.

Session Title: Epidemiology & Public Health I: Risk Factors & Outcomes for Rheumatic Diseases

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Osteoarthritis (OA) is by far the most common arthritis.(1) However, its chronological trend in the United Kingdom (UK) is not known. We aimed to explore the trend in both incidence and prevalence of OA among adults aged 20 years or more in the UK during the period 1997-2017 using a large nationally representative primary care database.

Methods: The UK Clinical Practice Research Datalink (CPRD), comprising data on 17 million patients, was used for this study (2). We estimated the incidence and prevalence of general practitioner (GP) diagnosed OA (both overall

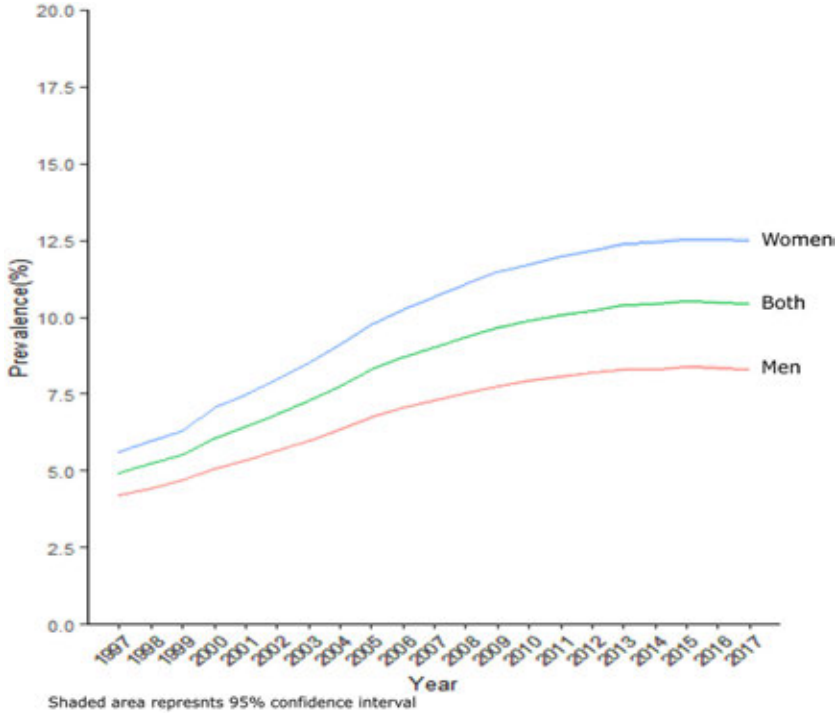

Figure 1. Trends of standardized prevalence of GP diagnosed OA in the UK 1997-2017 For men and women- Age standardized; Both- Age and sex standardized

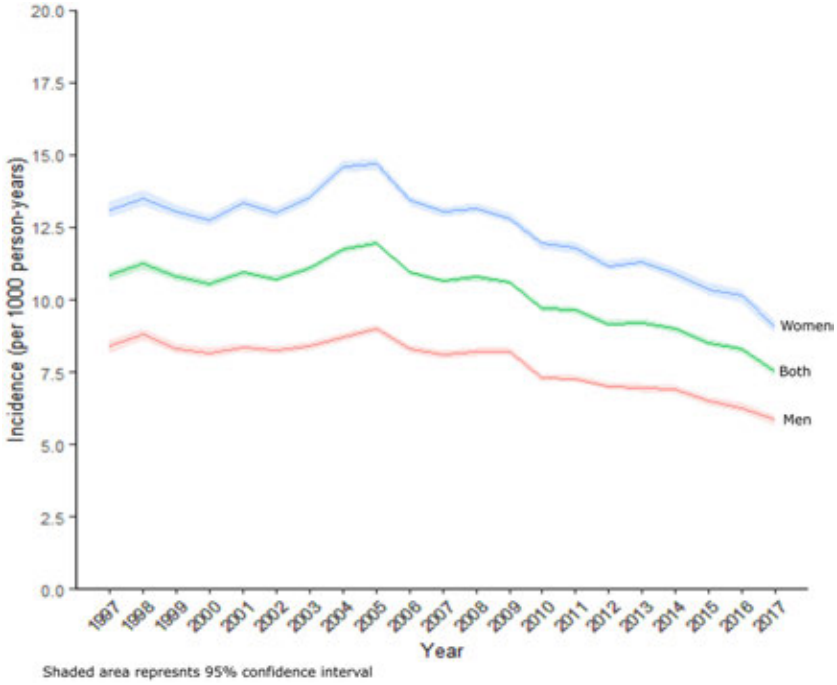

Figure 2. Trends in standardized incidence of GP diagnosed OA in the UK (1997-2017) For men and women- Age standardized; Both- Age and sex standardized

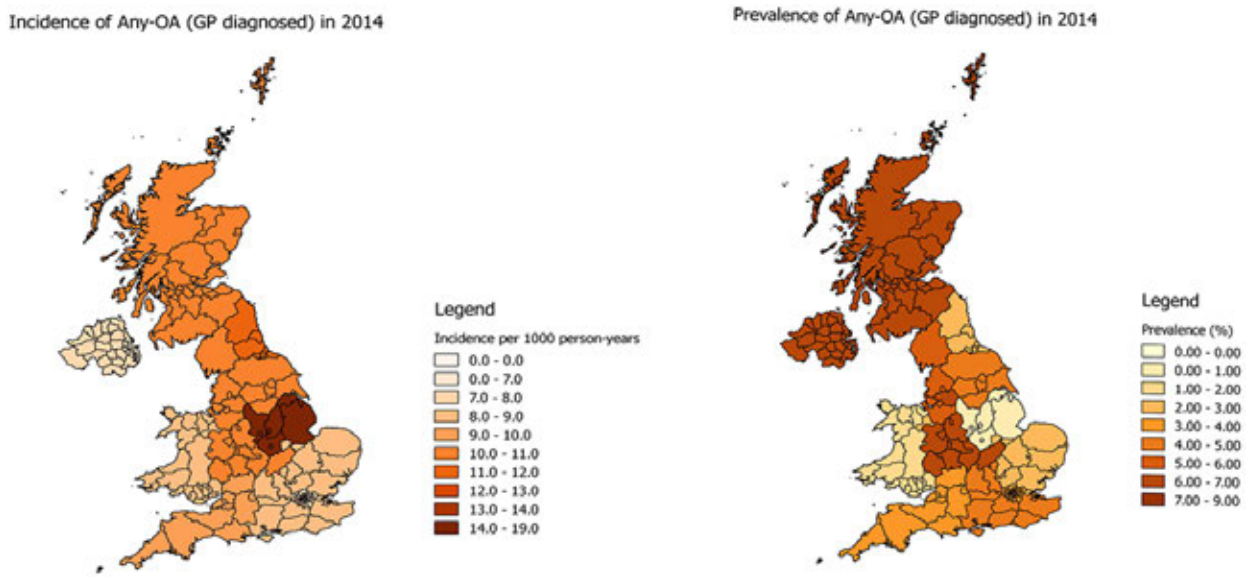

Figure 3. Prevalence and incidence of GP-diagnosed OA in different regions of the UK in 2014 The contribution from East Midlands region to the CPRD-GOLD database used in the study was nearly zero, which did not allow to have whole country representation for the year 2017.

and joint-specific: hip, knee, ankle/foot, wrist/hand and unspecified site) which was age-sex standardized using 2017 UK mid-year population. Joinpoint analysis was performed to identify the trend points. Geographical distribution was mapped according to the different regions in the UK. The data used for the study is recorded by the GPs in UK, and nearly 100% patients would have met the ACR classification criteria.

Results: During the year 1997-2017, 608,350 incident OA cases aged ≥20 years were recorded. In 2017, the standardized prevalence of GP-diagnosed OA for any joint in both sexes was 10.44% (95% CI 10.39%-10.49%), 12.49%; 95% CI 12.41%-12.56%) in women and 8.28% (95%CI 8.22%-8.35%) in men. The prevalence recorded according to body site was unspecified joint (7.32%), knee (2.76%), hip (1.17%), wrist/hand (0.52%) and foot/ankle (0.29%). The prevalence of any-OA increased from 4.9% in 1997 to 10.4% in 2017 with average annual percentage increase of 3.9% (95% CI 3.5-4.2%). (Figure-1) The standardised incidence of any OA in both sexes in 2017 was 7.5 per 1000 person-years (95% CI 7.4-7.6 per 1000 person-years), 9.0 per 1000 person-years (95% CI 8.8-9.2 per 1000 person-years) in women and 5.8 per 1000 person-years (95% CI 5.7-6.0 per 1000 person-years) in men. In 2017, the incidence recorded in joints was: unspecified site OA (5.2 per 1000 person-years), followed by knee (2.3 per 1000 person-years), hip (1.1 per 1000 person-years), wrist/hand (0.68 per 1000 person-years) and foot/ankle (0.19 per 1000 person-years) OA. The incidence of any OA decreased from 10.8 per 1000 person-years (95% CI 10.7-11.0 per 1000 person-years) in 1997 to 7.5 per 1000 person-years (95% CI 7.4-7.6 1000 person-years) in 2017 with an average annual percentage reduction of -1.7% (95%CI -2.6 to -0.8). (Figure-2) The prevalence and incidence varied across the UK, with the northern region had higher OA prevalence and incidence compared to the rest of the UK in 2014 with few exceptions. (Figure-3)

Conclusion: In the UK approximately one in 10 adults have clinically diagnosed OA. The knee is the commonest recorded site for OA that results in GP consultation. While the prevalence has increased, incidence has decreased in this population in the past 20 years. Further research is needed to understand these changes.

Cigarette Smoking Is a Risk Factor for ANCA-Associated Vasculitis

Greg McDermott,[1] Xiaoqing Fu,[1] John Stone,[2] Yuqing Zhang,[3] Hyon K. Choi,[3] and Zachary Wallace[1], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health I: Risk Factors & Outcomes for Rheumatic Diseases
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: ANCA-associated vasculitis (AAV) is a systemic small vessel vasculitis of unclear etiology associated with excess morbidity and mortality compared to the general population. Environmental exposures (e.g.

asbestos) have been associated with AAV but the effect of cigarette smoking on disease risk is unclear. Previous studies suggest that smoking is associated with an increased risk of AAV relapse and its effect may vary according to age and disease manifestation. However, these findings were based on studies with relatively small sample size. We performed a large case-control study to examine the association of cigarette smoking, a potentially modifiable factor, with the risk of AAV.

Methods: The Partners AAV (PAAV) Cohort is a consecutive inception cohort established at Partners HealthCare, a large hospital system in New England. All cases are PR3- or MPO-ANCA+. Eosinophilic granulomatosis with polyangiitis cases were excluded. For each AAV case, we randomly selected 3 controls from participants in the Partners HealthCare Biobank who completed a smoking questionnaire (N=30,536) and with no diagnosis of AAV and matched

by sex, race, and age (± 2 years) at the index date (i.e., treatment initiation). Smoking status at the index date was extracted from the electronic medical record and categorized into three groups: never, former, current. We examined the association between cigarette smoking and the odds of AAV using conditional logistic regression. We performed stratified analyses to verify the robustness of the findings.

Results: We identified 473 AAV cases and 1,419 controls whose data on smoking status were available (mean age: 59 (±16) years; women: 59%, white: 84%). The majority (65%) of cases were MPO-ANCA+ and 64% had any baseline renal involvement. There was a greater proportion of current and former smokers among AAV cases (Current=43 [9%], Former=211 [45%]) than in the control group (Current=63 [4%], Former=533 [38%]). The multivariable adjusted odds ratios for AAV were 1.58 (95% CI: 1.25-2.00) for former cigarette smoking and 2.70 (95% CI 1.76-4.14) for current cigarette smoking as compared with non-smoking (Table 1). When the proportion of ever-smokers was compared with that of never smokers, we found a similar association (1.72 [95% CI: 1.37-2.15]). These associations persisted in stratified analyses by sex, ANCA type, and organ involvement though they did not reach statistical significance in the PR3-ANCA+ subgroup. When we further matched cases and controls by education level, our findings were unchanged. When we stratified by index date and whether or not a case had established care in Partners ≥ 1 year prior to the index date, our findings were unchanged.

Conclusion: In this large case-control study, being a current or former smoker was strongly associated with an increased risk of AAV, especially MPO-ANCA+ AAV. The precise biological mechanism underlying this association remains to be elucidated but may be related to cell apoptosis and necrosis, and/or oxidative endothelial stress. These findings suggest that cigarette smoking may be a modifiable risk factor for AAV. Additional studies are warranted to confirm these findings.

The Association of Cigarette Smoking with the Risk of ANCA-Associated Vasculitis

risk of VTE in patients with psoriatic disease (PsD, which includes psoriasis and psoriatic arthritis) and rheumatoid arthritis (RA), two of the most prevalent inflammatory arthritis. However, population-based data using incident cohorts of PsD and RA are limited. Our objective was to estimate the risk of VTE, PE and DVT among patients with newly diagnosed PsD and RA compared with the general population.

Methods: We conducted a matched cohort analysis for PsD and RA separately. Our data included all outpatient and inpatient visits from Jan 1990 until Mar 2015 and all dispensed medication from Sept 1995 to Mar 2015 in the province of British Columbia. Incident PsD and RA patients were identified using previously validated algorithms and were matched with non-PsD (1:1) and non-RA (1:2) individuals randomly selected from the general population based on age, sex and entry cohort time. Patients should have at least a 7-year run-in period in order to consider the case as incident. Incident VTE was defined using ICD codes plus a dispensation of an oral anticoagulant. We calculated incidence rate ratio (IRRs), as well as age-, sex-, and entry-time-matched and multivariable hazard ratios (HRs) for the

<5 years	1.28 (1.12-1.47)	1.31 (1.08-1.58)	1.28 (1.09-1.52)	1.65 (1.51-1.80)	1.57 (1.36-1.81)	1.62 (1.45-1.80)

Table2 Age- and sex-adjusted relative risk for VTE, PE, and DVT in PSD and RA according to follow up period. Values are HR (95% CI).

risk of VTE, PE, and DVT adjusting for potential confounders. To test the robustness of our results, we performed two sensitivity analyses. First, to estimate the effect of unmeasured confounders, we included a simulated unmeasured confounder into our model. Second, we accounted for the competing risk of death via the subdistribution proportional hazards model.

Results: Cohorts included 110,323 individuals with incident PsD (51% female, mean age 47 yrs) and 89,346 individuals with incident RA (66% female, mean age 59 yrs). Of those at risk of incident events, 1,091 and 3,555 developed VTE, 547 and 1412 developed PE, 734 and 2,575 developed DVT, respectively (incidence rates= 1.19 and 3.95 for VTE, 0.59 and 1.55 for PE, 0.80 and 2.85 for DVT per 1000 person-years, respectively). Compared with the corresponding non-PsD and non-RA cohorts the age-, sex-, and entry-time-matched HRs for VTE, PE and DVT were 1.25 and 1.76, 1.22 and 1.81, 1.27 and 1.73, respectively ($P< 0.05$ for all). After further adjustment for baseline characteristics, the HRs remained significant except for PE in the PsD cohort. The risks were greatest within the first year after diagnosis and progressively attenuated with time except for PE in the PsD cohort. HRs remained significant after accounting for the competing risk of death for all outcomes in both PsD and RA cohorts. The results also remained significant at values of 20% prevalence in the RA cohort and OR of 1.3 for the association between the unmeasured confounder and all outcomes, but not in the PsD cohort.

Conclusion: Patients with PsD and RA have an increased risk of VTE (12% and 46%), PE (12% and 48%) and DVT (13% and 45%). The risk of VTE peaked in the first year after diagnosis and decreased with time thereafter. These findings support the need of increased monitoring of VTE complications in patients with PsD or RA.

Results from a Randomized Controlled Trial of the Safety of the Live Varicella Vaccine in TNF-Treated Patients

Jeffrey Curtis,[1] S Louis Bridges,[2] Stacey S Cofield,[2] John Bassler,[1] Theresa Ford,[3] Stephen Lindsey,[4] Alan Kivitz,[5] Ilhem Messaoudi,[6] Kaleb Michaud,[7] Joseph Huffstutter,[8] Ted Mikuls,[9] David Ridley,[10] William Shergy,[11] Sarah Siegel,[12] and Kevin Winthrop[13], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]North Georgia Rheumatology Group, PC, Lawrenceville, GA, [4]Ochsner Clinic Foundation, Baton Rouge, LA, [5]Altoona Center for Clinical Research, Duncansville, PA, [6]University of California Irvine, Irvine, CA, [7]University of Nebraska Medical Center, Omaha, NE, [8]Arthritis Associates, Hixon, TN, [9]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE, [10]St. Paul Rheumatology, Eagan, MN, [11]Rheumatology Associates of North Alabama, Huntsville, AL, [12]Oregon Health Science University, Portland, OR, [13]Oregon Health and Science University, Portland, OR

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Epidemiology & Public Health I: Risk Factors & Outcomes for Rheumatic Diseases

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: There has been minimal evaluation of the safety of live virus vaccines in patients receiving biologic therapies who may be immunocompromised. The Varicella Zoster Vaccine (VERVE) study is a blinded, 1:1 randomized placebo-controlled trial of the live attenuated zoster vaccine (ZV) in patients receiving TNF inhibitors (TNFi) to evaluate safety and immunogenicity.

Methods: Eligible participants: at least 50 years of age, current users of TNFi for any indication, and no prior ZV. Safety follow-up occurred over 6 weeks (the FDA-specified risk window for vaccine-related infection, were it to occur). Suspected cases of varicella infection or shingles had clinical assessment, PCR collection (with subtyping to differentiate wild-type vs. vaccine [Oka]-related infection), and digital photographs. Review was conducted under oversight of an NIH-appointed Data Safety Monitoring Board. Serum and PBMCs were collected at baseline and week 6 to assess ZV-related immunity, with safety follow-up through 6 months, at which time participants were unmasked to treatment arm.

Results: Recruitment closed in December 2018, with 617 randomized participants recruited at 33 centers: mean (SD) age 62.4 (7.5) years, 66.9% female, 87.2% white, 8.8% AA, 4.4% Hispanic. Most common TNFi indications: rheumatoid arthritis (59.6%), psoriatic arthritis (24.5%); TNFi medication at baseline: adalimumab (32.7%), infliximab (31.3%), etanercept (21.2%), golimumab (9.1%), certolizumab (5.7%). Concomitant therapies included background methotrexate (48.0%), and oral glucocorticoids (10.5%). Through week 6, there were zero cases of confirmed disseminated or local varicella infection, either wild type or vaccine strain, yielding an upper bound of the 95% confidence interval for vaccine-related varicella infection of < 1%. A total of 8 rashes were swabbed for varicella PCR; none were positive, and no clinically adjudicated varicella or shingles reactivation cases were observed through week 6. VERVE will close to blinded follow up in Summer 2019 and immunologic effectiveness of ZV will be reported in the full cohort in November 2019.

Conclusion: The randomized VERVE trial comprised of more than 600 patients receiving TNFi for multiple indications observed no cases of vaccine-related varicella infection or reactivation in the 6-week risk period following live zoster vaccination. This trial informs safety concerns of use of live virus vaccines in this population.

Abstract Number: 0825

Systemic Sclerosis Deaths at Younger Ages Have Decreased over the past Five Decades

Eric Yen,[1] Devanshu Singh,[2] and Ram Raj Singh[1], [1]UCLA, Los Angeles, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health I: Risk Factors & Outcomes for Rheumatic Diseases
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Patients with systemic sclerosis (SSc) can die prematurely of disease-associated complications. Over the past 2 decades, several advances in the treatment of SSc-associated complications may have affected SSc outcomes. For example, the two-year survival of patients with SSc-associated pulmonary arterial hypertension has improved from 47% to 71% with the availability of prostanoids. The influence of these advances on long-term SSc mortality in the general population remains unknown. Here, we tested the hypothesis that death from SSc is decreasing at younger ages over time.

Methods: This is a population-based study using a national mortality database of all U.S. residents, 1968 through 2015. First, we calculated the proportions of deaths for SSc and for all other causes (non-SSc) by age groups for each year from 1968 through 2015 and performed joinpoint trend analysis to estimate annual percent change (APC) and average APC (AAPC) in the proportion of deaths by age. Second, we calculated age-standardized mortality rate (ASMR) for SSc and non-SSc causes and ratio of SSc-ASMR to non-SSc-ASMR by age groups for each year from 1968 through 2015 and performed joinpoint trend analysis to estimate APC and AAPC for these measures by age groups.

Results: From 1968 through 2015, SSc was recorded as the underlying cause of death in 46,798 deaths. In 1968, 23.4% of all SSc deaths as compared to 13.5% of non-SSc deaths occurred at a younger (≤44 years) age group ($p< 0.001$, Chi-square test). In this age group, the proportion of annual deaths decreased more for SSc than for non-SSc causes: from 23.4% in 1968 to 5.7% in 2015 at an AAPC of -2.2% (95% CI, -2.4% to -2.0%) for SSc, and from 13.5% to 6.9% at an AAPC of -1.5% (95% CI, -1.9% to -1.1%) for non-SSc. Thus, in 2015, the proportion of SSc and non-

SSc deaths in ≤44 year age group was no longer significantly different. The percent of deaths in the 45-54 year age group also decreased more for SSc than for non-SSc over the 48-year period, but no statistical change was noted in the 55-64 year age group. However, in ≥65 year age group, the proportion of SSc deaths increased more for SSc than for non-SSc causes, indicating that SSc patients were dying later in life. Consistent with this observation, ASMR for SSc decreased from 1.0 (95% CI, 0.8-1.2) in 1968 to 0.4 (95% CI, 0.3-0.5) per million persons in 2015, a cumulative decrease of 60% at an AAPC of -1.9% (95% CI, -2.5% to -1.2%) in ≤44 year age group. The ratio of SSc-ASMR to non-SSc-ASMR also decreased in this age group (cumulative, -20%; AAPC -0.3%).

Conclusion: Mortality for SSc has steadily decreased in younger ages. Young individuals with SSc now make up the same proportion of deaths as those without SSc.

Abstract Number: 0826

Immune-Mediated Inflammatory Diseases (IMID) Collectively Rank Among the Leading Causes of Death

Meifang Wu,[1] Eric Yen,[2] and Ram Raj Singh[2], [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]UCLA, Los Angeles

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health I: Risk Factors & Outcomes for Rheumatic Diseases
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Almost every organ system can be affected by primary immune-mediated diseases characterized by inflammation and therapeutic response to immune-suppressive or anti-inflammatory drugs. These diseases can be collectively referred to as immune-mediated inflammatory diseases (IMID). Many rheumatic diseases can be categorized as IMIDs. Since IMIDs are purported to have shared pathogenic mechanisms, it would be important to understand their burden of disease together. Our goals are to determine 1) the burden of IMID deaths relative to the leading causes of death published by the Centers for Disease Control and Prevention (CDC) and 2) the mortality trends of top 15 individual IMIDs.

Methods: We compiled 43 IMIDs with a reported prevalence of >1 per 100,000 population, and obtained death counts for each of them using the CDC-WONDER database. We then calculated their crude death rates, pooled death counts of the 15 IMIDs with the highest crude death rates, and ranked the pooled IMID death counts among the CDC's official leading-causes-of-death ranklist for eleven age groups. Next, we calculated the annual age-standardized mortality rate (ASMR) for the top 15 individual IMIDs from 1999 to 2017. Lastly, we performed joinpoint trend analysis of the annual ASMRs for these 15 IMIDs.

Results: 371,154 deaths were attributed to the top 15 IMIDs in 5 years from 2013 to 2017. Of these deaths, IMIDs were recorded as the underlying cause in 202,430 deaths and as the contributing cause in 168,724 deaths. These IMID deaths (underlying + contributing) ranked 6th to 9th for all age groups among the leading causes of death. When only the underlying cause of death was considered, IMID ranked among the top 15 for all age groups and 7th to 9th in 15 to 64 year age groups. Among IMIDs, primary interstitial lung disease, multiple sclerosis, and type 1 diabe-

tes had the highest ASMRs in 2017 followed by rheumatic diseases including rheumatoid arthritis, lupus, systemic sclerosis, and systemic vasculitis, which ranked in the top 10. Joinpoint trend analysis showed that annual mortality rates for most IMIDs including rheumatoid arthritis, lupus, systemic sclerosis, systemic vasculitis, type 1 diabetes, myocarditis, primary biliary cirrhosis, and idiopathic thrombocytopenic purpura have decreased from 1999 to 2017, but have increased or unchanged for a few IMIDs including primary interstitial lung disease, multiple sclerosis, and myasthenia gravis.

Conclusion: Ranking of IMID among the top ten leading causes of death emphasizes the high burden of diseases characterized by inflammation. These data further highlight that IMID is a major public health problem. Similar to various forms of cancer, various IMIDs should be considered as a collective disease entity. The recognition of IMID as a leading cause of death may influence healthcare prioritization and research funding, which may help to reduce their disease burden.

A Phase 3 Randomized, Double-Blind, Placebo-Controlled Trial of Bedtime Sublingual Cyclobenzaprine (TNX-102 SL) for the Treatment of Fibromyalgia (FM): Evidence for a Broad Spectrum of Activity on the FM Syndrome

Gregory Sullivan,[1] R. Michael Gendreau,[2] Judith Gendreau,[3] Ashild Peters,[4] Perry Peters,[5] and Seth Lederman[6], [1]Tonix Pharmaceuticals Inc., New York, [2]Gendreau Consulting, Poway, CA, [3]Tonix Pharmaceuticals Inc, Poway, CA, [4]Tonix Pharmaceuticals Inc., San Diego, CA, [5]Tonix Pharmaceuticals Inc, San Diego, CA, [6]Tonix Pharmaceuticals Inc, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Fibromyalgia (FM) is characterized by chronic widespread pain, unrefreshing sleep, fatigue, and cognitive complaints. TNX-102 SL* is a sublingual (SL) formulation of cyclobenzaprine (CBP) that is rapidly absorbed and bypasses first-pass metabolism, providing for unique pharmacokinetics of the parent CBP and long-lived metabolite norcyclobenzaprine that previous studies have suggested lead to improvements in overall sleep quality. This may lead to improvements in pain and other somatic complaints by a mechanism distinct from existing FM therapies. This Phase 3 double-blind, randomized, placebo-controlled, multicenter trial (AFFIRM Study) evaluated safety and efficacy of a 2.8 mg dose of TNX-102 SL 2.8 mg in FM.

Methods: A total of 519 patients meeting ACR 2010 FM criteria were enrolled across 35 centers in a 12-week trial. Patients were randomized 1:1 to receive TNX-102 SL 2.8 mg (N=262) or placebo (N=257). Primary efficacy endpoint was a responder analysis of patients who reported ≥30% reduction in daily diary pain from baseline to endpoint. Secondary outcome measures included analyses of diary mean pain and sleep ratings, Fibromyalgia Impact Questionnaire (FIQ-R), Patient Global Impression of Change (PGIC), and PROMIS Sleep Disturbance (SD) scales.

Results: The study did not achieve statistical significance on the primary efficacy endpoint (TNX-102 SL, 28.6% responders v. placebo 22.6% responders; OR 1.41 [0.94-2.10], P=0.095). TNX-102 SL did show significant effects on pain over placebo when analyzed by other standard approaches including: 30% responder analysis with BOCF/LOCF imputation (P=0.012); 50% responder analysis with BOCF alone (P=0.035); and MMRM of mean change from baseline (P< 0.001). TNX-102 SL 2.8 mg improved FIQ-R total score: -13.7 compared to -7.5 for placebo (P< 0.001). PGIC responder rate v. placebo: 23.7% v. 16.3% (P=0.038). Measures of sleep quality improved including PROMIS SD: -8.0 v. -4.7 (P< 0.001); daily diary: 1.8 v. -1.0 (P< 0.001). Systemic adverse events (AEs) were infrequent, with the only AE reported in ≥5% of TNX-102 SL-treated patients of fatigue (5.7% v. 2.3% in placebo).The most common AEs were local oral events: transient oral hypoaesthesia (40.1% v. 0.8% in placebo), glossodynia (9.2% v. 1.6% in placebo), paresthesia oral (7.6% v. 1.2% in placebo), product taste abnormal (6.1% v. 0.8% in placebo). A total of 77.5% of TNX-102 SL-treated patients completed the study compared with 86.4% on placebo.

Conclusion: Bedtime TNX-102 SL 2.8 mg, although failing to achieve statistical significance on the 30% pain responder analysis primary outcome, had clinically meaningful effects on pain and sleep by several other measures. Moreover, there were robust effects of TNX-102 SL at 2.8 mg on the broad array of measures of FM symptoms and function, fatigue, and particularly on measures of sleep quality, the hypothesized mechanism of TNX-102 SL in FM. Post-study analyses suggest that a higher dose of TNX-102 SL may be needed to meaningfully improve pain symptoms in a greater percentage of treated patients.

*TNX-102 SL is an Investigational New Drug and has not been approved for any indication.

Abstract Number: 0828

A Path Model Analysis of the Cognitive Determinants of Physical Activity Among Patients with Fibromyalgia (FM)

Dennis Ang,[1] Anthony Kaleth,[2] and **William Bush**[3], [1]Wake Forest School of Medicine, Winston Salem, [2]Indiana University-Purdue University Indianapolis, IN, Indianapolis, IN, [3]Wake Forest Baptist Medical Center, Winston-Salem, NC

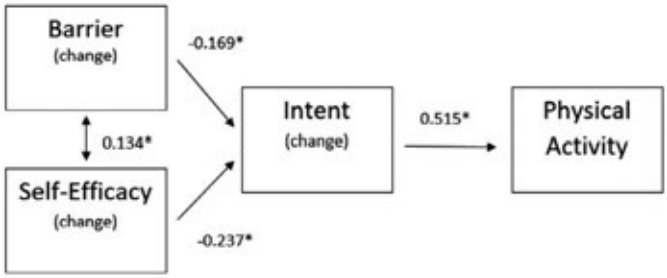
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: In individuals with FM, regular participation in physical activity (PA) is associated with improvement of symptoms, daily physical functioning, and overall well-being. Given the importance but also the challenges associated with the initiation and maintenance of physical activity, it is imperative that therapeutic targets are identified to increase and maintain moderate level of PA.

Methods: This is a secondary data analysis of a 36-week randomized clinical trial to promote PA among patients with FM. Participants were randomized to 1 of 2 treatment arms: 6 phone-based motivational interviewing (MI) sessions or an equal number of FM self-management instructions.

Table 1. Bivariate associations between changes in cognitive variables and physical activity groups

	Group 1 ≥10 MET hours/week increment and maintained (n=27)	Group 2 ≥10 MET hours/week increment followed by decline (n=68)	Group 3 Did not achieve ≥10 MET hours/week increment (n=75)	adjusted p-values
Exercise self-efficacy	-0.79 (0.34)	-0.06 (0.21)	0.68 (0.21)	0.0009
Perceived benefits	0.27 (1.44)	0.40 (0.91)	2.66 (0.89)	0.2654
Perceived barriers	0.91 (0.80)	1.65 (0.51)	-0.81 (0.49)	0.0022
Intention	-1.06 (0.26)	-0.40 (0.16)	0.52 (0.16)	< 0.0001



Changes in CHAMPS, a validated self-report measure of PA, were analyzed at each assessment period (baseline to week 12; week 12 to week 24; and week 24 to week 36). Based on CHAMPS, sustained PA was defined as an increase in moderate-vigorous PA (MVPA) of at least 10 MET h/week for ≥ 12 weeks. Using this threshold, three PA groups were defined based on subjects who: (Group 1) achieved a minimum increase of 10 metabolic equivalent (MET) hours/week that was subsequently sustained for at least 12 weeks; (Group 2) achieved a minimum increase of 10 MET hours/week that was not sustained for at least 12 weeks; and (Group 3) did not achieve an increase of at least 10 MET hour/week from baseline. Primary independent variables were baseline to week 36 changes in exercise self-efficacy, perceived benefits of PA, perceived barriers of PA, and intention to engage in MVPA. Initial analyses were performed using ANCOVA models to determine the association between cognitive variables and physical activity groups, adjusted for baseline values, and were performed using SAS v9.4. Controlling for treatment group assignment, path analyses were performed using M plus v7.31.

Results: For exercise self-efficacy, group 1 reported the largest improvement in exercise self-efficacy followed by group 2, and no improvement in group 3. For perceived barriers, groups 1 and 2 reported reductions in perceived barriers, while group 3 reported increased perceived barriers. For intention, groups 1 and 2 reported greater intention to engage in MVPA, while group 3 reported less intention. Change in perceived benefits were not significantly different among the 3 PA groups.

As shown in Figure 1 below, changes in perceived barriers and exercise self-efficacy influence intention to engage in PA, which in turn impacts changes in in the volume of PA. Perceived benefits of PA was not associated with either intention nor with physical activity. About 77% of the variance related to PA is explained by the model below.

Conclusion: When designing programs to promote PA in persons with FM, improving self-efficacy and resolving perceived barriers to exercise should be considered important therapeutic goals. Increasing awareness on the benefits of PA; however, may not elicit the desired PA behavior change.

Dietary Intake Does Not Explain Microbiome Alterations or Symptom Severity in Fibromyalgia

Amir minerbi,[1] Stéphanie Chevalier,[2] Abraham Anjarkouchian,[2] Audrey Moyen,[2] Yoram Shir,[1] and Mary-Ann Fitzcharles[1], [1]Alan Edwards Pain Management Unit, McGill University Health Centre, Montreal, Canada, [2]School of Human Nutrition, McGill University, Montreal, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: We have recently reported significant alterations in gut microbiome compositionin women with fibromyalgia (FM). As gut microbiome is affected by diet, differences in nutritional intake may have accounted for these alterations. Furthermore, there are some reports of selected dietary interventions impacting symptoms of FM. FM patients also frequently try various dietary regimens for symptom relief. The aim of this study was to examine the diet of women with FM compared to healthy controls, and to explore possible associations between the intake of certain nutrients, symptoms severity and gut microbiome composition.

Methods: The study population comprised 77 women with FM (by validated 2016 FM criteria) and 79 controls (household contacts, 1st degree relatives, other controls) Measures included: demographics, comorbidities, polysymptomatic distress scale and quality of life (FIQ). Dietary intake was assessed using the NIH Automated Self-Administered 24-hour recall, following dietician instruction and completion of three-day dietary recall. Datasets with at least two complete days were retained (n=146) and daily nutrient averages were calculated. Under-reporters were excluded from analysis. The Healthy Eating Index (HEI-2015) was calculated to assess diet quality. Intake of micro- and macro-nutrients was correlated with clinical measures of FM using Spearman's coefficient, and significance was adjusted for multiple comparisons. The gut microbiome was assessed by 16S and whole genome sequencing of stool samples.

Results: There were no differences in demographic and anthropometric characteristics among groups. Significant differences were observed in the abundance of 72 bacterial taxa of the gut microbiome between individuals with FM and controls. Energy and macronutrient intake (total and relative) and overall diet quality score were not different among patients and controls (Table 1). In addition, vitamin, mineral, different fatty acids, alcohol, caffeine, sugar and fiber intakes did not differ among groups; Normalised daily intake of micro- and macro-nutrients showed no significant correlation with demographic and anthropometric measures, disease specific measures, or with the quantities of gut microbiome bacterial taxa differentially abundant in FM.

Conclusion: The gut microbiome of FM patients differed significantly from controls, but without differences in dietary intake. Furthermore macro- and micro-nutrient intake was not correlated with clinical indices of FM, including pain intensity, fatigue, cognitive symptoms and sleep problems. Objective measures of nutrient status, when applicable, would be required to confirm these observations. These data suggest that reported dietary differences between patients and controls are unlikely to explain the differences in gut microbiome or the clinical phenotype of of FM, and add to the emerging body of evidence of a gut-brain axis.

FIQ: Fibromyalgia Impact Questionnaire, HOT: Hyperbaric Oxygen Therapy, MDT: Multidisciplinary Treatment, S: Supplement, T: Treatment, tDCS: Transcranial direct current stimulation, WBV: Whole Body Vibration

*: showing studies comparing with placebo. Text in bold shows significant values. Negative SMD favours treatment group.

Table 1. Effect size – Intervention versus non-intervention (usual care or placebo*): FIQ, pain, fatigue, sleep, depression

Background/Purpose: Non-pharmacological interventions are recommended as first-line treatment for fibromyalgia (FM)1. However, the evidence base supporting this has not been updated comprehensively, and the recent EULAR guideline was only based on a review of systematic reviews. The objective of this study was to assess the efficacy of non-pharmacological interventions on disease specific quality of life (FM Impact Questionnaire (FIQ)), pain, fatigue, sleep and depression in fibromyalgia.

Methods: MEDLINE, EMBASE, AMED, PsychINFO, CINAHL, Web of Science were systematically searched from their dates of inception until September 2018. In addition, the first 100 articles on Google Scholar were included. Randomised controlled trials (RCTs) comparing any non-pharmacological intervention versus usual care, no treatment, waiting list or placebo in patients with FM aged >16 years were included without language restriction. FIQ was the primary outcome of interest. Standardised mean difference (SMD) and 95% confidence interval (CI) were calculated using random effects model. The risk of bias was evaluated using modified Cochrane's tool.

Results: 16,251 studies were identified, and 148 RCTs (n=9,598) met all inclusion criteria. 89% patients in the included studies met ACR's 1990, 2010 or 2016 diagnostic criteria for FM. 109 studies (n=7,677) compared active treatment to usual care, waiting list or no treatment; and 39 (n=1,921) compared treatment with placebo or sham treatment. In total, 20 non-pharmacological interventions were evaluated. 52% trials had sample size < 50, and were at high risk of bias, especially on blinding (Fig 1).

Exercise (pooled for any type of exercise) was the only intervention associated with significant improvements for all five outcomes [FIQ (SMD=-0.67; 95% CI -0.89, -0.45), pain (-0.84; 95% CI -1.13, -0.55), fatigue (-0.88; 95%

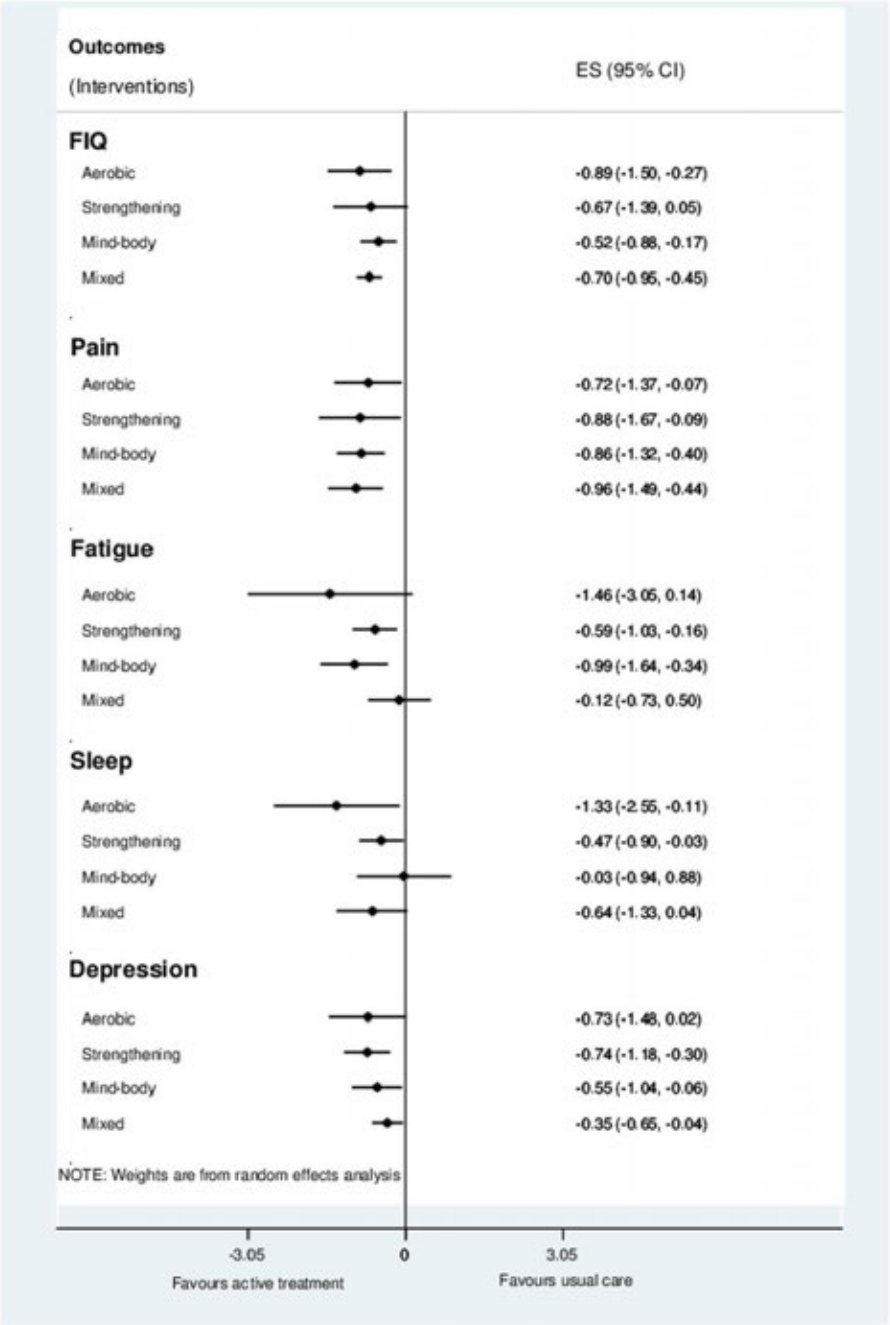

Figure 2. Effect size – Exercise types versus usual care: FIQ, pain, fatigue, sleep, depression

CI -1.39, -0.37), sleep (-0.55; 95% CI -1.04, -0.06) and depression (-0.55; 95% CI -0.82, -0.28)]. Psychological treatments including cognitive behavioural therapy and mindfulness were significantly more efficacious than usual care for FIQ, pain and depression but showed no improvement for fatigue and sleep (Table 1). All exercise types were effective at relieving pain (Fig 2). Mind body and strengthening exercises were effective at improving fatigue, while aerobic and strengthening exercises were effective at improving sleep. However, aerobic exercise had greater magnitude of effect on sleep than strengthening exercise. All exercise types except for aerobic exercise improved depression.

Conclusion: Non-pharmacological interventions are beneficial for FM. Exercise appears to be the most promising non-pharmacological intervention for relieving FM symptoms, although different exercise types benefit different outcomes. This suggests that different types of exercise should be prescribed to patients depending on their predominant symptoms.

Maintaining Musculoskeletal Health: A Randomized Controlled Prevention Trial Amongst People at High Risk of Developing Chronic Widespread Pain

Gary Macfarlane,[1] Marcus Beasley,[1] Neil Scott,[1] Gordon Prescott,[2] Paul McNamee,[1] John McBeth,[3] Gareth Jones,[1] Neil Basu,[4] Phil Hannaford,[1] Phil Keeley,[5] and Karina Lovell[6], [1]University of Aberdeen, Aberdeen, United Kingdom, [2]University of Central Lancashire, Preston, United Kingdom, [3]Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom, Manchester, United Kingdom, [4]University of Glasgow, Glasgow, United Kingdom, [5]University of Huddersfield, Huddersfield, United Kingdom, [6]University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Cognitive behaviour therapy (CBT) is effective in the management of fibromyalgia (and its characteristic feature Chronic Widespread Pain (CWP). CBT is recommended in all recent major fibromyalgia management guidelines. From large-scale epidemiological studies prediction models are available which identify groups at high-risk of developing CWP. We now test whether it is possible to prevent onset of CWP and/or change factors associated with its onset.

Methods: A randomized controlled trial of CBT delivered by telephone plus usual care (tCBT) was tested against usual care alone (UC). Eligible adults aged at least 25 years were identified by a survey of persons registered with sixteen general practices across Scotland. Respondents reporting regional pain (not CWP) for which they had recently consulted their GP and at least 2 items from a previously validated “high risk” profile (Somatic Symptom Scale, Sleep Problem Scale, Illness Behaviour Scale) were invited to participate. tCBT was delivered across 6 sessions over 8 weeks with booster sessions 3 and 6 months after treatment start. Primary outcome was CWP at 12 months. Secondary outcomes were risk profile measures: fatigue (Chalder Fatigue Scale), Patient Global Impression of Change (PGIC: 7 categories), psychological distress (General Health Questionnaire) and quality of life (EQ-5D-5L) also at 12

months. Analysis used logistic, ordinal logistic or linear regression depending on outcome variable type; expressed as an effect size with 95% confidence interval.

Results: 1002 people were randomized, with equal numbers assigned to each arm of the trial: 59% of participants were female, with a median age of 59 (range 25-91) years. 66% of tCBT participants completed treatment and 83% of all participants provided follow-up data at 12 months. There was no difference in the proportion with CWP at 12 months (tCBT 18.0% v. UC 17.5%). There were improvements (all favouring tCBT) in Illness Behaviour Score (mean difference (md) -0.83; -1.55,-0.11), Sleep Problem Scale (md -0.90; -1.45,-0.36), psychological distress (Odds Ratio (OR) $_{\text{per category}}$ 0.65; 0.50, 0.85), EQ-5D-5L (md 0.024; 0.009, 0.039), Chalder Fatigue Scale (md -1.05;-1.66,-0.44) and PGIC (OR $_{\text{per category}}$ 0.51;0.39,0.67). Specifically 30.2% of those receiving tCBT reported their health as much or very much better, compared to 17.3% of those receiving UC.

Conclusion: This first-ever large-scale trial of prevention, aimed at persons at high risk, has shown tCBT does not change the likelihood of CWP onset but does improve the underlying risk profile for developing the condition as well as improving distress , fatigue and quality of life. Those receiving tCBT were, 12 months later, significantly more like to consider their health was better. This trial provides evidence for extending the group of people considered to benefit from CBT.

Abstract Number: 0832

Diagnosis of Fibromyalgia: Comparison of AAPT and ACR Criteria

Marco Antivalle,[1] Federica Rigamonti,[1] Michele Agosti,[1] and Piercarlo Sarzi-Puttini[1], [1]L. Sacco University Hospital, Milano, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Fibromyalgia & Other Clinical Pain Syndromes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: In recent years, the diagnostic criteria for fibromyalgia (FM) have been reviewed multiple times, up to the publication of the provisional criteria of the ACR in their 2016 revision [1]. In 2018, a revised FM diagnosis was proposed by the ACTION-APS Pain Taxonomy (AAPT) [2], requiring for the diagnosis the presence of multisite pain (MSP), defined as 6 or more painful sites of a total of 9 possible sites, plus moderate to severe sleep poblems or fatigue.

The purpose of this work was to compare the diagnostic characteristics of the different sets of criteria.

Methods: The study population consisted of 530 patients (481 F, 49 M, mean age 47.9 ± 11.7 yrs) referred for fibromyalgia. All patients underwent a complete clinical workout, including the compilation of multiple questionnaires addressing the different domains of fibromyalgia. All patients were classified according to the newly proposed criteria and to the different sets of ACR criteria, including the 1990 criteria based only on tender points count, and the revised 2010 criteria with 2011 and 2016 revisions. Statistical analysis were performed with SPSS software, and parametric and non parametric methods were used as appropriate.

Results: Overall, FM was diagnosed in 95% of patients (503/530) by AAPT criteria; for ACR criteria, a diagnosis of FM was made in 79 % (420/530), 92% (488/539), 91% (482/530), and 71% (374/530) respectively by 2016, 2011, 2010 and 1990 criteria. The overall agreement (k statistics) between AAPT and the four sets of ACR criteria, although statistically significant $p < 0.001$ in all cases), was at best moderate (0.120, 0.472, 0.428, and 0.324 respectively). In particular, comparing AAPT and ACR2016 criteria, there were 89 discrepant cases, mostly diagnoses of FM by AAPT not confirmed by ACR2016 criteria (AAPT+/ACR2016-, N=83; AAPT-/ACR2016+, N=6). Overall, AAPT+/ACR2016- cases showed a moderate pain level (average 5.89±2.4 on a 0-10 NRS scale) and 82% was characterized by mild to moderate severity according to Polysymptomatic Distress Scale (value < 12).

Conclusion: Our results confirm that the diagnosis of fibromyalgia by the newly proposed AAPT diagnostic criteria is not completely coincident with ACR criteria. Fibromyalgia will be diagnosed more frequently by the new criteria. Further analysis is necessary to fully clarify the real extent of the proposed changes.

Effect of a Mobile App to Monitor Patient Reported Outcomes in Rheumatoid Arthritis: A Randomized Controlled Trial

Yvonne Lee,[1] Fengxin Lu,[2] Joshua Colls,[2] Meredith Murray,[2] Dong Suh,[2] Jing Song,[3] Julia Jungwha Lee,[4] Dorothy Dunlop,[4] and Daniel Solomon[5], [1]Northwestern University Feinberg School of Medicine, Chicago, [2]Brigham and Women's Hospital, Boston, MA, [3]Northwestern University Feinberg School of Medicine, Worthington, OH, [4]Northwestern University Feinberg School of Medicine, Chicago, IL, [5]Brigham and Women´s Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Treat to target (TTT) is an effective strategy to improve outcomes in rheumatoid arthritis (RA). However, barriers to TTT include frequent clinic visits, poor access to rheumatologists, and poor patient acceptance of treatment escalation. Mobile technology may provide a solution by enabling collection of patient-reported outcomes (PROs) between clinic visits. The objectives of this study were to examine the effects of a mobile application (app) to monitor PROs on: 1) patient satisfaction and 2) disease activity in RA.

Methods: We conducted a 6-month randomized controlled trial of an app + population manager vs. population manager alone in 191 RA patients. Participants in the app group were prompted to answer daily questionnaires on disease activity, function, pain, fatigue, sleep, and mood, using an app. Both groups were assigned a population manager who spoke with participants on the telephone at 6 and 18 weeks. Population managers also communicated with participants in the app group if responses to the daily assessments indicated a sustained increase in disease activity. The analysis followed an intent-to-treat principle. Missing data were imputed using last observation carried forward. To address the aim of improving patient satisfaction, the main outcomes were the global satisfaction score from the Treatment Satisfaction Questionnaire for Medication (TSQM) and the Perceived Efficacy in Patient-Physician Interactions (PEPPI) score. To address the aim of decreasing disease activity, the primary outcome was the Clinical Disease Activity Index (CDAI). Treatment effects were estimated with repeated measures analyses (baseline, 3-month, 6-month), using bootstrapped quantile regression models, adjusted for age, sex, and race.

Results: Of the 191 participants, 156 (82%) were women. 29% were at least 65 years old. Baseline global TSQM and PEPPI scores were high, with a median of 83.3 (interquartile range [IQR] 66.7-100) and 50 (IQR 47-50), respectively (Table). The median baseline CDAI was 8 (IQR 4-14), indicating low disease activity. After 6 months, median TSQM scores were 83.3 (IQR 66.7-100) in both groups, and median PEPPI scores were 50 (IQR 47-50) in the app group and 50 (IQR 48-50) in the no app group (Figure). Median 6-month CDAI scores were 8 (IQR 4-14) in the app group vs. 10 (IQR 3-16) in the no app group. Quantile regression analyses indicated no group (app vs. no app) differences at 6-months in medians of: TSQM β 0.00, 95% confidence interval [CI] -9.18, 9.18; PEPPI β 0.00, 95% CI -0.16, 0.16; and CDAI β -0.50, 95% CI -3.82, 2.82. Adherence with the app was over 75% during the 6-month follow-up.

Conclusion: A mobile app designed to collect PRO data on RA symptoms did not improve patient satisfaction or disease activity. However, baseline satisfaction scores were high and disease activity was low, suggesting ceiling and floor effects. Adherence with the app was strong. Future studies are needed to determine: a) if the app would be

Table. Baseline characteristics of trial participants.

Characteristic	Mobile app + Population Manager (N = 100)	Population Manager Alone (N = 91)	Overall Study Cohort (N = 191)
Sex, n (%)

Implementing Patient-Reported Outcome Measures in Clinical Care: Rheumatologist Perspectives on Opportunities and Challenges

Shanthini Kasturi,[1] John Wong,[1] Lisa Mandl,[2] Timothy McAlindon,[3] and Amy LeClair[1], [1]Tufts Medical Center, Boston, [2]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY, [3]Tufts Medical Center, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: There is growing interest in the implementation of patient-reported outcome measures (PROMs) in clinical rheumatology to promote patient-centered care and to meet the mandates of value-based health care initiatives. While studies suggest that patients support the routine measurement of patient-reported outcomes in clinical care, the views of rheumatologists are unknown. Understanding rheumatologists' perspectives on the potential utility and challenges of using PROMs at the point of care is critical to the successful clinical implementation of PROMs. The objective of this study was to investigate rheumatologists' views on the benefits of and barriers to utilizing PROMs in clinical care, with a specific focus on patients with systemic lupus erythematosus (SLE).

Methods: Structured interviews were conducted with academically affiliated clinical rheumatologists. Interviews were audio-recorded and transcribed verbatim. De-identified transcripts were uploaded into Dedoose™ Version

Table 1. Uses and Benefits of Patient-Reported Outcome Measures (PROMs) in Clinical Care

Contribute to Clinical Impression	
	"Do I use it clinically? I guess it becomes part of the equation in your brain. But do I specifically do something based on only that result? No... you talk to the patient, you examine the patient, you have a plan in your mind and that's high numbers over there that just supports what you are thinking if the patient is coming with a flare." [R3]
	"I use the information in combination with my clinical observation and impression of the patient because sometimes there's discrepancies." [R4]
	"You have to put it in the clinical context for sure but I think it's just another way to sort of fill that out. And I think it's just when somebody's really sick it's obvious. Quality of life is poor and all that stuff. Like that's a no brainer. But I think, you know, that maybe is only like ten to fifteen percent of the patients and the rest of the patients are a continuum of doing okay. Like doing okay well, and you know, actually not doing so well. And sometimes depending on people's coping mechanisms, you might have a misguided sense of really what their quality of life is." [R1]
- Identify Patient Perspective	"There are patients who have mild connective tissue disease or lupus but who really are suffering much more than other patients. I think that it's important to know that. That is some of the information that you get." [R2]
	"The other role it could play would be in a situation where you think the disease isn't that active and then there's enough things that are legitimately inflammatory that you realize you're just wrong about it. Because I think when a patient is upbeat and cheerful they sometimes don't seem that sick. But when you realize they're very fatigued; they can't get out of bed for two hours; they can't do this, that or the other thing. You're like hmm, maybe I'm not right about that or maybe they're not right about that." [R1]
- Identify Red Flags	"If I saw an outline or a number suddenly that was much lower or much higher, I'd probably ask them about it. So it would be a prompt for me to check into it." [R10]
	"I will glance at it when I go in. If I see something that I find surprising, I will raise it with a patient." [R2]
- "Biomarker"	"In some patients if you see a trend where some of these more subjective features tend to happen when their disease is more active. You can perhaps understand that in that patient that could be an actual marker of impending flare." [R12]
	"I think all of these things are useful in context. So if there is an idea that these – that a particular measure reflects disease activity in some kind of measurable standard way, then yeah, it would be really helpful to have some measure of that." [R5]
Set the Agenda	
	"It helps you focus because every patient's different. So when you go in the room, you're focusing on the things the patients care about because I think you don't always know what that is. And it's obvious sometimes when the patient still looks unhappy that you haven't hit on the right thing. So this way you can just get to the important stuff." [R1]
	"To have the information gathered for you, it just allows you to hone in on what seems to be most important for that particular patient." [R2]
- Save Time	"It would actually help you save time because it would show you some things that otherwise maybe wouldn't come out until the end of the visit." [R10]
	"I think that this kind of thing can save a little bit of time because we're all so constrained in terms of the amount of time we have for our encounters with patients. It provides you with an at-a-glance idea of how the patient perceives

Table 2. Challenges of Implementing Patient-Reported Outcome Measures (PROMs) in Clinical Care

No Added Value	
	"After 20 years of experience, you kind of know what's going on in five minutes ... Like many times we get the picture and we don't ask all the questions that we really need to ask if you are a resident." [R3]
	"I think I get to the same questions without doing it in a formal way... I think I get to the point, the questions that I need to ask for patient care and I think of [PROMs] more as for studies." [R15]
	"I don't feel like it adds to what I'm going to do for the patient beyond the things that I do." [R10]
	"I'm not always sure that it adds more to just asking people how they're doing and whether things are good or bad, or what their problems are. So I'm not always convinced there's an additive effect there." [R6]
Physician Culture Change	
	"I think sometimes people who are maybe a little skeptical about patient-reported outcomes think that the people who promulgate them are suggesting that they don't know how to talk to patients. They don't know how to get the right information and therefore this is fixing you not being a very good doctor." [R7]
	"If you're adding time, and you're adding logistical headaches, and you're adding all of these things to all the stuff that a physician has to do to get through a visit, then there has to be some good coming out of it. I think convincing people of the value of this stuff is sort of where you can get them to be interested in using it for patient care." [R15]
	"It's very difficult to change their culture or how physicians practice, or before practicing, just to bring something new to patient care." [R3]
	"I think the doctor has to be a believer as well because a lot of doctors may walk in the room thinking they know what to do, but they may not... some doctors may not think it's really that important and others may think, oh, this is really going to change what I offer the patient today." [R13]
Time Constraints/ Competing Priorities	
	"It doesn't mean that you don't think it's important, but you have to focus on what you think is medically the most important. I think that's why these other things, they just don't get addressed because of lack of time, lack of resources." [R2]
	"The doctor feels like they just barely have enough time to address all the other important issues, which the patient may not think that's important at the time; it's always the main issue here." [R14]
Score Interpretation	
	"I see it in the chart there in front of me. I have no clue what that means for a patient. So, to me asking them how are you doing is so much more than what those numbers say. And I have people that check nine every time and I don't – it's like all right. Well, for ten years they've been checking nine and it's fibromyalgia." [R10]
	"Unfortunately it's the people with lupus that's kind of not severe that you most want a score like this, where it works the least well because they're the people who you're like eh, is it all fibro-y stuff going on here?" [R6]
	"Absent context there's no kind of anchoring for it. It can be very high in that different people give very disparate answers based on – I don't know – all kinds of reasons." [R5]
Lack of Effective Interventions	

8.2.14 web application for qualitative data analysis. Two authors (SK and AL) reviewed a subset of transcripts to construct a preliminary codebook which was iteratively updated to include emergent themes as additional transcripts were coded. The final codebook was applied using a comparison and consensus approach. Thematic analysis was used to identify the main benefits and barriers of the use of PROMs in clinical care.

Results: Interviewees consisted of 15 attending rheumatologists affiliated with two academic medical centers in two states, and included 8 women (53%) and 7 men (47%). Subjects reported a median of 15 years in practice (range 5 to 43), with 53% reporting a specific interest in SLE. Rheumatologists identified several uses and benefits of implementing PROMs in clinical care (Table 1), including contributing to the clinical impression by providing the patient perspective, and promoting agenda setting by uncovering "the unspoken questions." Interviewees noted PROMs could support treatment planning by enabling longitudinal tracking, identifying avenues for intervention, and providing a mechanism for asynchronous care and population management. They noted significant benefits of PROMs in building patient-physician relationships and facilitating patient engagement. However, they also identified several barriers to integrating PROMs in clinical care (Table 2), highlighting physician buy-in and culture change as significant

challenges beyond logistical considerations. They further underscored the lack of effective interventions and resources for addressing the domains of most interest to patients.

Conclusion: Rheumatologists identified multiple mechanisms through which PROMs could augment the care of SLE, but also noted several obstacles to implementation in clinical settings, questioning the added value of PROMs and the limited availability of interventions to improve patient-centered outcomes. Programs seeking to successfully integrate PROMs to enhance patient-centered care and meet quality benchmarks must prioritize physician buy-in and training, and provide resources to address the outcomes that are measured.

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Discordance between baseline patient's and evaluator's global assessment of disease activity is common[1] and may reduce the likelihood of remission following tumor necrosis factor inhibitor (TNFi) treatment in patients with psoriatic arthritis (PsA).[2] However, the impact of such discordance on retention rates of TNFi in PsA patients remains unexplored. Hence, the aim of this study was to explore the impact of discordance, defined as patient's minus evaluator's global assessment (ΔPEG), on retention rates and remission rates (DAS28(3)CRP (without patient's global) and DAS28(4)CRP (including patient's global)) in PsA patients initiating their first TNFi treatment. We used pooled data from the European Spondyloarthritis Research Collaboration Network (EuroSpA).

Methods: TNFi naïve PsA patients from 11 European registries in EuroSpA were included. Kaplan-Meier analyses were used to estimate TNFi retention rates after 6/12/24 months, with comparison between baseline ΔPEG quartiles using the log rank test, stratified by gender. Remission rates were compared between different ΔPEG quartiles with Chi-square test, stratified by gender.

Results: A total of 5855 PsA patients were included. Mean (SD) age for women (n=2988) / men (n=2867) were 49.3 (12.5) / 47.4 (11.7) years, disease duration 6.6 (7.3) / 6.7 (7.2) years, median (25-75 percentiles) baseline ΔPEG 17 (0-38) / 10 (0-30) mm. Retention rates and DAS28(4)CRP but not DAS28(3)CRP remission rates were lower for higher quartiles of baseline ΔPEG (table, figure).

TNFi retention rates	TNFi retention rates (%, 95%CI) according to baseline patient's minus evaluator's global assessment (ΔPEG) quartiles									
	Women (n=2988)					Men (n=2867)				
	1st quartile (-100 to 0) (n=815)	2nd quartile (1 to 17) (n=694)	3rd quartile (18 to 38) (n=739)	4th quartile (39 to 100) (n=740)	p value	1st quartile (-100 to -1) (n=648)	2nd quartile (0 to 9) (n=683)	3rd quartile (10 to 30) (n=865)	4th quartile (31 to 100) (n=671)	p value
6 months	87% (85-90%)	85% (82-88%)	81% (78-84%)	74% (71-77%)	<0.001	93% (91-95%)	93% (91-95%)	92% (90-93%)	86% (83-89%)	<0.001
12 months	79% (76-82%)	76% (73-79%)	70% (67-74%)	61% (57-65%)	<0.001	88% (85-90%)	86% (84-89%)	83% (80-85%)	78% (75-81%)	<0.001

DAS28(3)CRP remission (<2.6)	Proportions, % (95%CI), of patients in DAS28(3)CRP remission according to baseline patient's minus evaluator's global assessment (ΔPEG) quartiles									
	Women					Men				
	1st quartile (-100 to 0)	2nd quartile (1 to 17)	3rd quartile (18 to 38)	4th quartile (39 to 100)	p value	1st quartile (-100 to -1)	2nd quartile (0 to 9)	3rd quartile (10 to 30)	4th quartile (31 to 100)	p value
6 months	52% (48-57%)	53% (48-57%)	47% (43-52%)	48% (43-52%)	0.19	65% (60-70%)	69% (64-73%)	64% (60-68%)	68% (64-73%)	0.28
12 months	54% (50-59%)	57% (52-61%)	53% (48-57%)	50% (45-55%)	0.30	70% (66-75%)	72% (67-76%)	69% (65-73%)	72% (68-76%)	0.77
24 months	61% (56-66%)	60% (55-65%)	55% (50-60%)	52% (46-57%)	0.04	74% (69-79%)	76% (71-80%)	70% (66-74%)	73% (69-78%)	0.32

Table. Retention and remission rates of first TNFi in PsA patients.

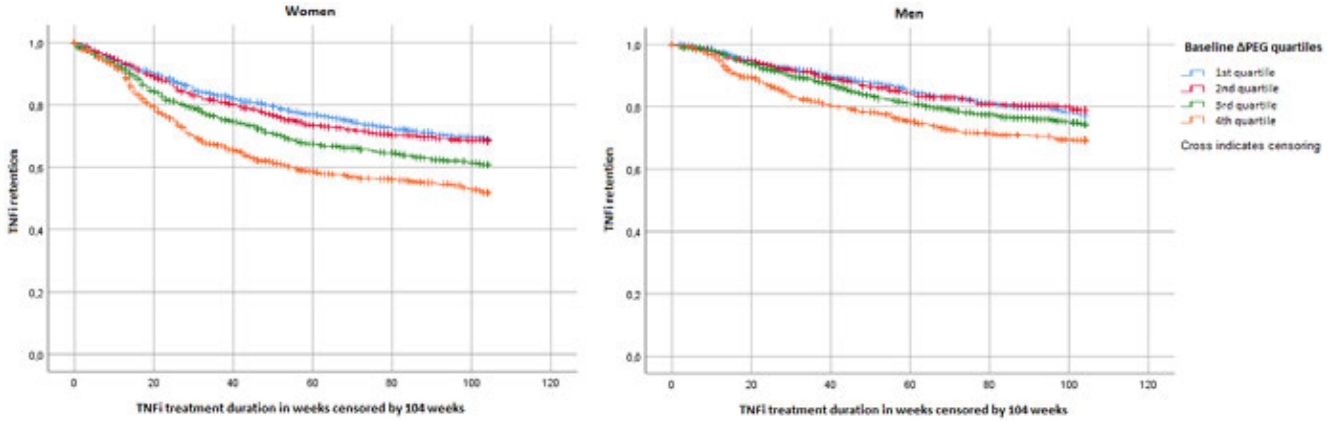

Figure 1. Retention rates of first TNFi across ΔPEG quartiles, censored by 104 weeks.

Conclusion: High baseline discordance (ΔPEG) was associated with lower TNFi retention rates and with lower DAS28(4)CRP remission rates, but not DAS28(3)CRP remission rates, after 6, 12 and 24 months' follow-up in both male and female PsA patients. The choice of remission criteria in the follow-up of PsA patients may affect important treatment decisions, and may be of particular impact in patients with high baseline ΔPEG.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Therapeutic options for patients with PsA are increasing but data directly comparing biologics are limited. The multicentre, open-label SPIRIT-H2H trial (NCT03151551) evaluated the efficacy and safety of ixekizumab (IXE) vs adalimumab (ADA) over a 52-week treatment period in biologic DMARD-naïve patients with active PsA. This analysis directly compared the effects of IXE vs ADA on patient-reported outcomes (PROs) and health-related quality of life (HRQoL) after 24 weeks' treatment in SPIRIT-H2H.

Methods: All patients fulfilled the Classification Criteria for Psoriatic Arthritis (CASPAR). Patients were randomised (1:1) to 52 weeks of IXE (160 mg week 0, then 80 mg every 2 weeks [Q2W] to week 12 and Q4W thereafter for patients with moderate-to-severe plaque psoriasis [PsO] or 160 mg week 0, then 80 mg Q4W for other patients) or ADA (80 mg week 0 then 40 mg Q2W from week 1 for patients with moderate-to-severe PsO or 40 mg week 0 then 40 mg Q2W for other patients). The primary objective was to assess the superiority of IXE vs ADA by comparing the proportion of patients achieving a simultaneous improvement of ≥50% in ACR criteria (ACR50) and 100% in Psoriasis Area Severity Index score (PASI100) at week 24. A number of PROs and HRQoL were evaluated (see Table). PRO changes from baseline to week 24 were analysed using analysis of covariance models with modified baseline observation carried forward imputation. Treatment satisfaction was assessed using the Treatment Satisfaction Questionnaire. Logistic regressions with non-responder imputation in the intent-to-treat population were used to evaluate results.

Results: A total of 566 patients were randomised to IXE or ADA; of these 82% of patients did not have moderate-to-severe PsO. Baseline characteristics were generally balanced between the two treatment groups. The percentage of patients simultaneously achieving ACR50 and PASI100 responses at week 24 was statistically superior for IXE vs ADA (36% vs 28%; $p< 0.05$). All PRO and HRQoL outcomes (Table) significantly improved from baseline in both treatment groups ($p< .001$ for all). Treatment with IXE was associated with a statistically significantly greater improvement in itch, Short form-36 Health Survey scores, Role-emotional and Dermatology Life Quality Index (DLQI) scores vs ADA (seen as early as week 4 for itch and DLQI improvement). For patients' overall satisfaction with treatment, 62.5% of IXE and 59.7% of ADA recipients were mostly satisfied. Both biologics had acceptable safety and tolerability.

Conclusion: In bDMARD-naïve patients with active PsA and PsO, IXE showed superior efficacy compared to ADA based on simultaneous achievement of ACR50 and PASI100 responses at week 24. Both biologics significantly improved HRQoL and other PROs. Greater improvements in PROs related to PsO were observed for IXE- compared to ADA-treated patients.

Table. PROs and HRQoL at baseline and least square mean change from baseline at week 24

Endpoint	IXE (N=283)		ADA (N=283)

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Discordance between baseline patient's and evaluator's global assessment of disease activity is common.[1] However, the impact of such discordance on retention and remission rates of TNF inhibitor (TNFi) therapy in axial spondyloarthritis (axSpA) patients remains unexplored. Hence, the aim of this study was to assess the impact of baseline discordance, defined as "patient's minus evaluator's global assessment of disease activity" (ΔPEG), on retention and remission rates of a first TNFi in axSpA patients across Europe.

TNFi retention rates	Retention rates (%, 95%CI) across different baseline patient's minus evaluator's global assessment (ΔPEG) quartiles									
	Women (n=3639)					Men (n=5374				
	1st quartile (-100 to 2) (n=908)	2nd quartile (3 to 20) (n=915)	3rd quartile (21 to 42) (n=907)	4th quartile (43 to 100) (n=909)	p value	1st quartile (-100 to -1) (n=1220)	2nd quartile (0 to 15) (n=1487)	3rd quartile (16 to 37) (n=1338)	4th quartile (38 to 100) (n=1329)	p value
6 months	88% (86-90%)	84% (82-87%)	78% (75-81%)	76% (73-79%)	<0.001	94% (92-95%)	91% (89-92%)	89% (88-91%)	87% (85-89%)	<0.001
12 months	81% (78-84%)	74% (71-77%)	67% (64-70%)	64% (61-68%)	<0.001	88% (86-90%)	86% (84-88%)	83% (81-85%)	79% (77-82%)	<0.001
24 months	75% (72-78%)	64% (61-67%)	60% (57-64%)	55% (52-59%)	<0.001	83% (81-86%)	80% (77-82%)	75% (72-77%)	72% (69-75%)	<0.001
ASDAS<1.3	Proportions, % (95%CI), of patients achieving ASDAS<1.3 at follow-up compared across different baseline ΔPEG quartiles									
	Women					Men				
	1st quartile (-100 to 2)	2nd quartile (3 to 20)	3rd quartile (21 to 42)	4th quartile (43 to 100)	p value	1st quartile (-100 to -1)	2nd quartile (0 to 15)	3rd quartile (16 to 37)	4th quartile (38 to 100)	p value
6 months	28% (23-33%)	24% (19-28%)	23% (18-27%)	17% (14-21%)	0.005	40% (36-45%)	41% (36-45%)	34% (30-38%)	31% (27-35%)	<0.001
12 months	27% (22-33%)	23% (18-29%)	23% (18-29%)	15% (12-19%)	0.002	41% (37-46%)	41% (37-46%)	33% (28-37%)	31% (27-35%)	<0.001
24 months	29% (23-35%)	24% (18-30%)	27% (21-33%)	16% (11-20%)	0.002	45% (40-50%)	41% (36-45%)	39% (33- 44%)	31% (27-35%)	<0.001
BASDAI≤2	Proportions, % (95%CI), of patients achieving BASDAI≤2 at follow-up compared across different baseline ΔPEG quartiles									
	Women					Men				
	1st quartile (-100 to 2)	2nd quartile (3 to 20)	3rd quartile (21 to 42)	4th quartile (43 to 100)	p value	1st quartile (-100 to -1)	2nd quartile (0 to 15)	3rd quartile (16 to 37)	4th quartile (38 to 100)	p value
6 months	45% (40-49%)	32% (28-36%)	28% (24-32%)	26% (23-30%)	<0.001	60% (56-63%)	51% (48-54%)	46% (42-49%)	42% (38-45%)	<0.001
12 months	47% (42-51%)	34% (30-38%)	30% (26-35%)	26% (23-30%)	<0.001	61% (57-64%)	53% (50-56%)	45% (41-48%)	43% (40-47%)	<0.001
24 months	49% (44-54%)	35% (31-40%)	31% (27-36%)	22% (18-26%)	<0.001	62% (58-66%)	56% (52-59%)	46% (42-50%)	42% (38-46%)	<0.001

Table. Retention and remission rates of first TNFi in axSpA patients.

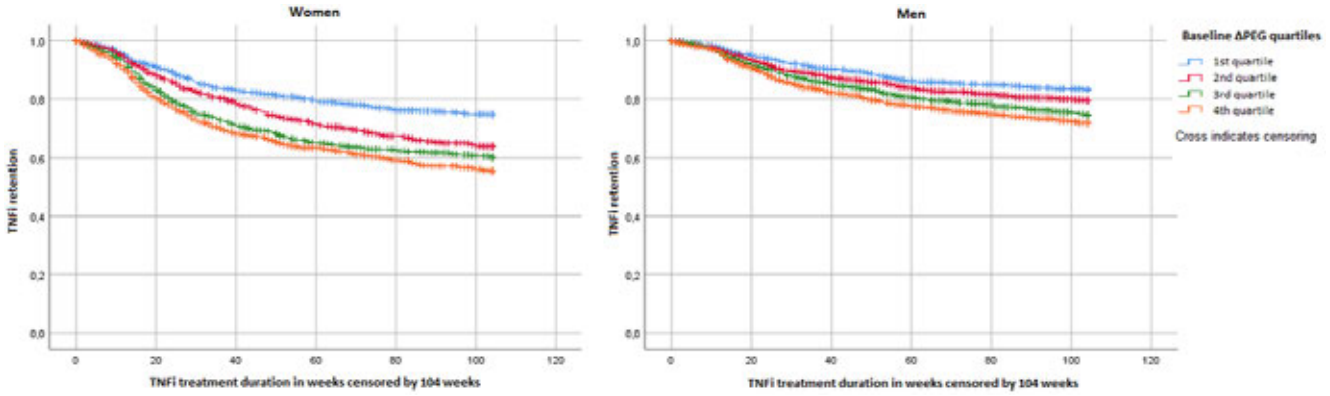

Figure. TNFi retention rate across ΔPEG quartiles, censored by 104 weeks.

Methods: AxSpA patients from 10 European registries participating in the European Spondyloarthritis Research Collaboration Network (EuroSpA) were included. Retention rates after 6/12/24 months' treatment with first TNFi were assessed with Kaplan-Meier analyses, with comparison between baseline ΔPEG quartiles with log rank test, stratified by gender. Proportions of patients in BASDAI remission (≤2) and ASDAS inactive disease (< 1.3) after 6/12/24 months for different ΔPEG quartiles were compared with Chi-square test, stratified by gender.

Results: A total of 9013 axSpA patients were included. Mean (SD) age for women (n=3639)/men (n=5374) were 42.7(12.0)/41.7(12.0) years, disease duration 5.1(7.4)/6.9(8.7) years, median (25-75 percentiles) baseline ΔPEG 20(3-42)/15(0-37) mm. TNFi retention rates and proportions of patients achieving BASDAI≤2 and ASDAS< 1.3 after 6/12/24 months were lower for higher quartiles of ΔPEG (table, figure).

Conclusion: In patients receiving their first TNFi, high baseline patient's compared with evaluator's global assessment is negatively associated with retention rates as well as proportions of patients achieving BASDAI remission and ASDAS inactive disease after 6, 12 as well as 24 months follow-up, both in female and male axSpA patients. TNFi retention rates were lower for women than for men at all timepoints.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes I: Patient Reported Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Patient-reported outcomes (PROs) are an important part of clinical decision making and are frequently used in combination with objective measures of disease activity and physicians' clinical assessment to help guide treatment decisions. Discrepancies between PROs and clinical measures of disease activity can lead to over-treated or under-treated disease and patient dissatisfaction. We sought to examine the correlation between minimal disease activity (MDA) with PROs as measured by the NIH Patient-Reported Outcomes Measurement Information System (PROMIS) Global Health (GH) questionnaire, and assess the effect of demographics, psoriatic arthritis related comorbidities, and number of comorbidities on PROMIS GH and MDA status.

Methods: A cross-sectional study was performed within Psoriatic Arthritis Research Consortium (PARC), a cohort of adult psoriatic arthritis patients meeting CASPAR criteria enrolled between 2016-2019. PARC is a longitudinal observational cohort study conducted at four institutions in the United States. The mean differences of PROMIS Physical, Mental and Fatigue T-scores between patients in MDA compared to those not in MDA were compared using the two sample t-tests. Correlations between MDA scores (0-7 criteria met) and PROMIS Physical, Mental and Fatigue T-scores were calculated using Spearman rank correlation. Higher T-scores on PROMIS measures mean 'more' of that concept for PROMIS Physical and Mental domains. Logistic regression model was used to evaluate contribution of additional covariates on MDA, including age, gender, hypertension, dyslipidemia, BMI, diabetes, smoking and number of comorbidities (Table 2). The odds ratios and 95% confidence intervals were presented. Multiple imputation was performed to impute missing data points. Data analysis was performed in SAS software (Version 9.4; Cary, NC).

		Non-remission (N=106)		Remission (N=129)		
Factor	Total (N=235)	N	Statistics	N	Statistics	p-value
PROMIS Physical Tscore	43.7 ± 9.0	106	38.2 ± 7.0	129	48.1 ± 8.0	*<0.001*[a]
PROMIS Mental Tscore	47.4 ± 10.5	106	42.7 ± 10.1	129	51.2 ± 9.3	*<0.001*[a]
PROMIS Fatigue Tscore	55.3 ± 10.3	105	59.8 ± 8.6	123	51.4 ± 10.1	*<0.001*[a]

Statistics presented as Mean± SD.
p-values: a=t-test.

Table 1. Comparison of PROMIS domains between MDA and non-MDA patients

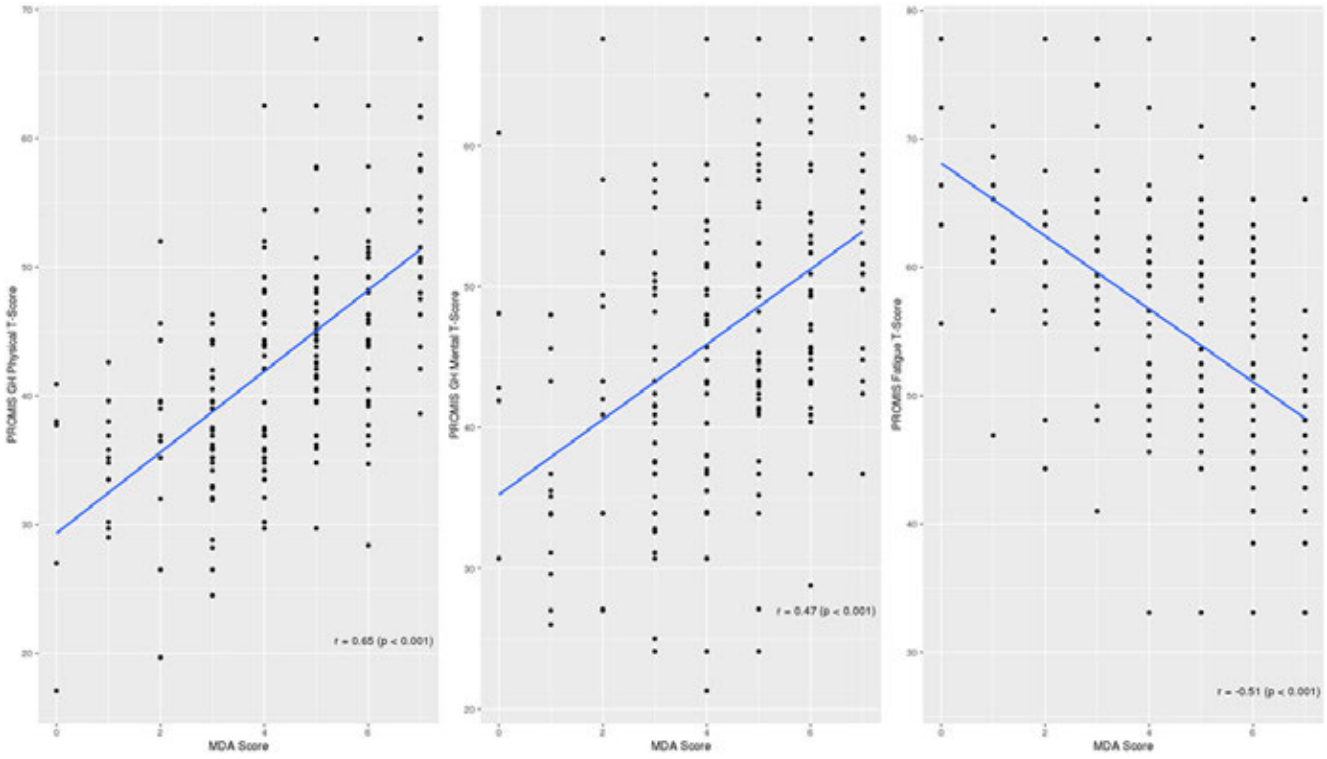

Figure 1. Scatterplot of MDA and PROMIS Physical, Mental and Fatigue Domains

Results: 235 patients (50% female, mean age 51±13.9) were included. 129 were in MDA and 106 were not in MDA. Patients in MDA had significantly higher PROMIS Physical, Mental and improved Fatigue T-scores compared to non-MDA patients (Table 1; $p< 0.001$). There was a positive correlation between MDA scores and PROMIS scores in Physical and Mental domains; correlation was strongest for PROMIS Physical T-score (Figure 1; $r=0.65$, $p< 0.001$). There was a moderate correlation between MDA and PROMIS Fatigue T-score (Figure 1; $r=-0.51$, $p< 0.001$). In the univariate analysis, there was a statistically significant association between hypertension and number of comorbidities with MDA status (Table 2). However, this effect was not observed in the multivariate analysis.

Conclusion: Achieving MDA was associated with a positive effect on patients' physical, mental and fatigue domains, irrespective of their demographics or PsA comorbidities. However, patients with a greater number of comorbidities were less likely to be in MDA. In this study, the PROMIS Physical domain had a higher correlation with MDA scores compared to the Mental domain and PROMIS Fatigue. PROMIS measures may be a useful tool in assessing disease activity from the patient's perspective.

Disease Activity, Cytokine Profiles, and the Risk of Incident Diabetes in Rheumatoid Arthritis

Joshua Baker,[1] Bryant England,[2] Michael George,[3] Grant Cannon,[4] and Ted Mikuls[5], [1]University of Pennsylvania, Philadelphia, PA, [2]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, [3]University of Pennsylvania, Philadelphia, [4]Salt Lake City VA Medical Center and Univeristy of Utah, Salt Lake City, UT, [5]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Rheumatoid arthritis is associated with a higher risk of diabetes mellitus (DM) and cardiovascular disease. While disproportional obesity and visceral fat accumulation may contribute to a higher incidence of DM, the systemic inflammatory disease may directly lead to insulin resistance and promote the development of cardiometabolic disease. Our aim was to evaluate associations between disease activity (including evaluation of specific cytokines and chemokines) among veterans with RA and determine independent associations with incident DM incidence in a longitudinal cohort.

Methods: Participants were enrollees in a multicenter, longitudinal observational cohort of US veterans with RA. Baseline demographics, comorbidities, body mass index (BMI), ACPA status, disease activity (DAS28-CRP), and active therapies were derived from query of the electronic medical record and registry data. Therapies and disease activity were assessed as time-varying covariates in initial models. Seventeen cytokines and chemokines were measured in banked serum obtained at the time of enrollment in a subset of partiipants using a bead-based multiplex

Table 2. Cox proportional hazards models assessing associations between quartile of MIP-1β and IL-8 and incident diabetes (2 separate models).

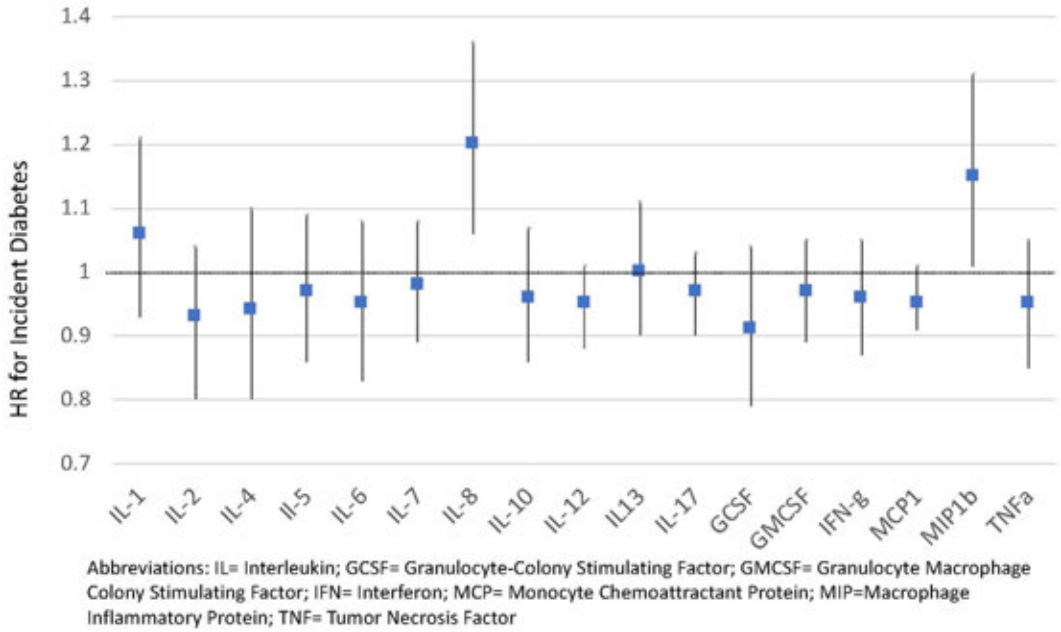

Figure. Hazard ratios for the risk of incident diabetes among rheumatoid arthritis patients by individual cytokine concentrations (per 1 SD) adjusting for age, sex, race, current smoking, baseline body mass index, and baseline medication use (each represents a separate model).

assay. Cytokine/chemokine values were log-adjusted and standardized (all values are per 1 SD). Incident DM was defined as the presence of a new diagnosis code at any time in follow-up (following at least 12 months of follow up without a code). Multivariable Cox proportional hazards models evaluated associations between clinical factors and incident DM. Independent associations between specific cytokines and chemokines were assessed adjusting for age, sex, race, smoking, and medication use at baseline.

Results: Among 1,918 RA patients without prevalent DM, there were 239 cases of incident DM over 9,055 person-years of follow-up. Patients with high disease activity, obese BMI, older age, male sex, and non-white race were at the greatest risk for incident DM (Table 1). Those using TNFi were at significantly lower risk. In models adjusting for demographics, smoking, and baseline medication use, two chemokines evaluated were significantly associated with the incidence of DM (per 1 SD). These were Macrophage Inhibitory Protein (MIP)-1b [HR 1.20 (95% CI 1.04, 1.39) p=0.01] and Interleukin(IL)-8 [HR 1.16 (95% CI 1.02, 1.33) p=0.02] (Figure). Higher quartiles of MIP-1b and IL-8 were associated with incident DM in a dose-dependent manner (Table 2). These associations were not attenuated with adjustment for DAS28-CRP.

Conclusion: Older age, male sex, higher disease activity, greater BMI, and elevated levels of the chemokines MIP-1b and IL-8 are associated with incident DM in veterans with RA. Notably, levels of IL-1, TNF-a, and IL-6 were not significantly associated with incident DM in this population although TNFi use was predictive of future DM. Future study may help to determine if other targeted treatments in at-risk individuals could help to prevent the development of DM in patients with RA.

Trajectory of Multimorbidity in Rheumatoid Arthritis in a U.S. Commercial Insurance Claims Database from 2006-2015

Bryant England,[1] Punyasha Roul,[2] Fang Yu,[2] Harlan Sayles,[2] Kaleb Michaud,[2] Fenglong Xie,[3] Jeffrey Curtis,[4] and Ted Mikuls[5], [1]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, [2]University of Nebraska Medical Center, Omaha, NE, [3]University of Alabama at Birmingham, Birmingham, [4]University of Alabama at Birmingham, Birmingham, AL, [5]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Multimorbidity, the presence of multiple chronic conditions, predisposes individuals to disability and premature mortality. RA is well known to be associated with select chronic conditions, but the timing of onset of multimorbidity and the rate of accruing additional conditions is not well established. We aimed to determine the trajectory of multimorbidity in RA compared to the general population.

Methods: We assembled RA cohorts within Truven MarketScan database from 1/2006-9/2015 using ≥2 ICD-9 codes for RA, a rheumatologist diagnosis, and DMARD use. Incident RA was identified using validated algorithms for claims data that required at least 12 months of observable time with medical and pharmacy coverage (observability) without RA diagnostic codes or DMARDs (Curtis et al. AC&R, 2018). RA subjects were matched 1:1 to non-RA subjects on age, sex, and calendar year. Chronic conditions were identified from observability to the end of follow-up (censoring at disenrollment or end of study period) using ICD-9 codes for 48 chronic conditions identified in systematic reviews of multimorbidity. Conditions occurring on or before the date fulfilling the RA algorithm (or equivalent date for non-RA) were considered prevalent. Multimorbidity was defined as having ≥2 chronic conditions (not including RA) and multimorbidity burden was defined by the number of conditions present. Cross-sectional prevalence and burden of

Table 1. Prevalence of chronic conditions in rheumatoid arthritis (RA) vs. non-RA subjects.

Condition	RA (n=139402) N (%)	Non-RA (n=139402) N (%)	Odds Ratio (95% CI)*
Most prevalent conditions in RA subjects*

Chronic back pain	20140 (14.5)	10266 (7.4)	2.24 (2.18, 2.30)
Osteoarthritis	19281 (13.8)	4754 (3.4)	5.17 (4.98, 5.36)
Non-inflammatory gynecologic disorders***	12954 (12.2)	11349 (10.6)	1.17 (1.13, 1.20)
Hyperlipidemia	15100 (10.8)	12183 (8.7)	1.30 (1.27, 1.34)
Diabetes, uncomplicated	10085 (7.2)	8268 (5.9)	1.25 (1.21, 1.29)
Hypothyroid	7305 (5.2)	4213 (3.0)	1.81 (1.74, 1.88)
Fibromyalgia	6595 (4.7)	1219 (0.9)	5.90 (5.53, 6.29)
Anemia	6154 (4.4)	2513 (1.8)	2.56 (2.44, 2.69)
Gastroesophageal reflux disease	5731 (4.1)	3058 (2.2)	1.94 (1.86, 2.03)

*Conditional odds ratios accounting for matching on age, sex, calendar year
**Ten most prevalent conditions in RA subjects are shown
***Among females only

multimorbidity in all RA vs. non-RA was determined using conditional logistic and negative binomial regression. The trajectory of multimorbidity over time in incident RA vs. non-RA was assessed using generalized estimating equations with an interaction term between RA status and year of follow-up.

Results: A total of 139,403 RA subjects (overall cohort) were matched to 139,403 non-RA subjects. This included a subcohort of 30,764 incident RA subjects. Mean (SD) age was 54.1 (13.4) years with 76.5% female. Time from observability to index date was 1.2 (1.8) years in the overall group and 3.2 (1.9) years in the incident subcohort. In the overall cohort, multimorbidity was present in 34.2% of RA subjects vs. 21.3% of non-RA (OR 2.30, 95% CI 2.26-2.35, $p< 0.001$). Multimorbidity burden was significantly higher in RA vs. non-RA (ratio of conditions 1.67, 95% CI 1.65-1.69, $p< 0.001$). Of the 48 chronic conditions examined, 42 were overrepresented (Table 1). In the incident subcohort, multimorbidity frequency was higher in RA subjects throughout follow-up (OR 2.75, 95% CI 2.66-2.84). Similarly, multimorbidity burden was higher in incident RA than non-RA at baseline and throughout follow-up (Figure 1; ratio of conditions 1.76, 95% CI 1.73-1.79). The rate of accruing chronic conditions was not higher in incident RA than non-RA (ratio of accruing conditions per year 0.99, 95% CI 0.98-1.00, $p=0.06$).

Conclusion: In a large, national, commercial claims database, we found the odds of multimorbidity were 2.3-fold higher in RA compared to the general population. Trajectory analyses in those with new onset disease suggest the heightened risk of multimorbidity in RA occurs early in the disease course or may even precede RA onset.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Elevation of anti-citrullinated protein antibodies (ACPA) precedes clinical rheumatoid arthritis (RA) diagnosis by years and may originate at inflamed mucosa, including airways. Damage from chronic inflammation may pre-dispose individuals with ACPA elevation to developing obstructive airway diseases, such as chronic obstructive pulmonary disease (COPD) and asthma, prior to or after clinical RA onset. Therefore, we investigated the association between elevated ACPA in blood banked prior to clinical RA diagnosis and risks for developing COPD or asthma.

Methods: We performed a cohort study among women who donated blood for research purposes in the Nurses' Health Studies to investigate whether pre-RA elevated ACPA was associated with development of COPD or asthma. RA cases met 1987 ACR or 2010 ACR/EULAR criteria and were each matched to 3 controls by age and menopausal factors at date of RA diagnosis (index date). Pre-RA ACPA elevation among RA cases was defined as: elevation (>5 units/mL) on 2nd generation commercial assay for cyclic citrullinated peptide or elevation (>99th percentile of the control distribution) of autoantibodies to ≥2 different citrullinated proteins on a research assay measuring autoantibodies targeting specific citrullinated protein epitopes. Incident COPD or asthma occurring after date of blood draw was determined using biennial questionnaires. Covariates, including smoking pack-years, were assessed by questionnaires. Cox regression estimated HRs for incident COPD and asthma in separate analyses. In all analyses (**Figure**), the date of blood draw was the baseline, and RA cases (by pre-RA ACPA status) were compared to their matched controls, excluding prevalent respiratory disease at blood draw. We performed a secondary analysis restricting follow-up to time between blood draw and index date to investigate the pre-RA/index period.

Results: We measured ACPA on a total of 1,125 women (283 pre-RA cases and 842 matched controls). Blood was banked mean 9.7 years (SD 5.8) prior to index date and mean age at blood draw was 51.4 years (SD 7.9). There were 59 RA cases (20.8%) with elevated ACPA in pre-RA blood. Pre-RA ACPA+ RA was associated with incident COPD occurring after blood draw (multivariable HR 3.06, 95%CI 1.34, 7.00) compared to their matched controls (**Table 1**). Pre-RA ACPA+ RA had a HR for asthma of 1.76 (95%CI 0.72, 4.26), similar to the association of Pre-RA ACPA- RA with asthma (HR 1.64, 95%CI 1.04, 2.58) (**Table 2**). When restricting follow-up to the pre-RA/index period, pre-RA ACPA+ RA was strongly associated with increased COPD risk (HR 10.84, 95%CI 1.13, 104.08), but asthma had similar results to the primary analysis (all RA: HR 1.69, 95%CI 1.00-2.86).

Conclusion: Women with elevated ACPA before RA diagnosis had increased risk for developing COPD, particularly just before RA presentation, suggesting lung damage accrues prior to clinical RA onset. Women who were later diagnosed with RA were more likely to report new-onset asthma than matched controls, regardless of pre-RA ACPA

Table 1. Hazard ratios for incident chronic obstructive pulmonary disease occurring after blood draw date, comparing RA cases by pre-RA ACPA status to their matched controls among women in the Nurses' Health Studies who donated blood and had ACPA tested for research purposes (n=1,125).

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: The frequency of pulmonary involvement in rheumatoid arthritis varies between 7-35%. The most important cause of death in RA patients is lung disease in UIP pattern. The aim of this study was to determine the mortality and associated factors in RA- related lung disease (RA-LD) patients followed up in a single tertiary center.

Table 1. Demographic,clinical characteristics and computed tomography findings of patients

	Death (+) (n=40)	Death (-) (n=116)	P	Multivariate
Sex (M/F)	23/27	35/81	0.78	1,18 (0,3-4,2)
Age at the diagnosis of RA ,years	61.4 (11,7)	53.5 (11,7)	<0.001	
Age at diagnosis of ILD ,years	66.0 (9.7)	61.6 (9.5)	0.014	
<3 years between RA and ILD diagnosis (%)	18/32(56,3)	26/101(25,7)	0.001	4.34 (1.27-14.8)
BMI (kg/m²)	26.4 (4)	28.5 (4,9)	0.03	
Smoking (ever) (%)	16/34 (47)	51/97 (52,5)	0.58	
RF + (%)	34/35 (97,1)	101/114 (88,5)	0.13	
RF titer ,IU/ml	1119 (1370)	471 (768)	0.01	
Anti-CCP + (%)	11/12 (91,6)	51/74 (68,9)	0.1	
Anti-CCP titer, ru/ml	335 (358)	273 (553)	0,7	
Anemia (%)	34/40 (%85)	80/116 (68,9)	0.1	0,6 (0,1-3,2)
Shortness of breath (%)	77	31	<0.001	
Crackles on physical examination (%)	92	51	<0.001	
Signs of ILD in lung x-ray (%)	96	70	0.005	
Pattern of lung involvement n (%)			<0.001	
UIP	35 (87)	54 (47)		10.33 (2.46-43.42)
NSIP	4 (10)	47 (41)		
AD	1 (3)	15 (12)		
Lung CT findings n (%)				
Ground glass appearance	35 (88)	84 (72)	0.053	
Bronchiectasis	36 (90)	60 (48)	<0.001	
Interseptal thickening	22 (55)	31(27)	0.001	
Reticular densities	38 (95)	89 (77)	0.01	
Honeycombing	32 (80)	42 (36)	<0.001	
Pleural effusion n (%)	9 (23)	9 (8)	0.02	14.4 (2.4-84.6)
Rheumatoid nodule n (%)	13 (33)	56 (49)	0.07	

Data was shown as mean (SD)

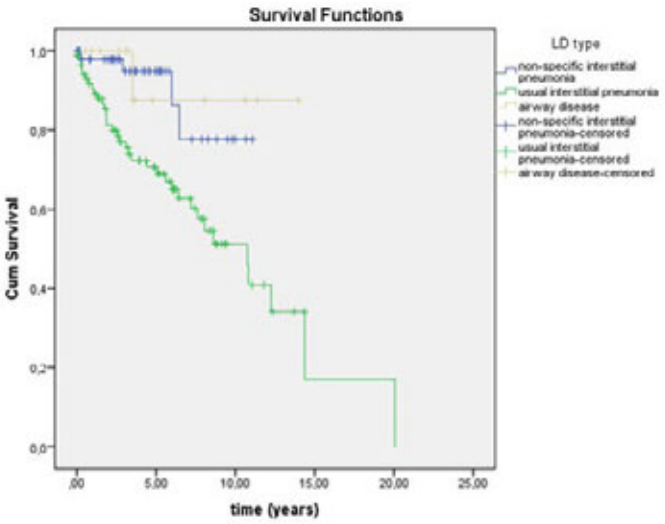

Figure 1. Kaplan-meier survival analysis of different RA-LD patterns

Methods: During January 2010 and March 2019, 826 RA patients had lung computerized tomography in Hacettepe University. Three radiologists re-evaluated lung CTs and 156/826 (18.8%) patients with RA-LD were included in the final analysis. Overall, 104 patients (%66.7) had at least one control lung CT. Lung CT findings were classified as UIP, NSIP and isolated airway disease (AD). Demographic, clinical, laboratory and therapeutic data was collected. Information on death of patients was obtained either by chart review of through the national death registration database. Factors related to mortality were analyzed with univariate and multivariate analysis; Kaplan-Meier plots were used for survival analysis.

Results: Totally, 156 patients (30.8% male) were included in the study. The mean (SD) follow-up duration was 129 (90) months for RA, and 53.8 (45) months for RA-ILD. Eighty-nine patients had UIP (57.0%), 51 (32.7%) had NSIP and 16 (10.2%) had AD pattern. 40/157 (25.6%) patients died during the follow-up period. The mean age of death was 70.7 years (10). The mean follow-up duration was 4.4 (4,4) years for the patient who had died, and 4.7 (3,5) years for the living patients. Presence of crackles was higher in the patients who died (34/37 [%92] vs 50/98 [51%], $p < 0.001$). Initial lung functions were similar (FVC: 85% (24.5) vs 82% (19), FEV1: 91% (22.4) vs 84% (20.5) however, patients who had died had lower lung volumes at last control visit (FVC: 57.1% (16.7) vs 91.0% (22.3), $p < 0.001$, FEV1: 61.0% (17.4) vs 87.0% (23.4), $p = 0.001$). Mortality was higher in patients with UIP (log-rank: 0.004) (figure 1). Among the treatments used, only the history of methotrexate and cyclophosphamide use were related with mortality (methotrexate 24 (60%) vs. 95 (81.9%) $p = 0.005$, steroid 39 (97.5%) vs 112 (96.6%) $p = 0.7$, leflunomide 29 (%) 72.5) vs 90 (77.6%) $p = 0.5$, sulfasalazine 18 (45%) vs 70 (60.3%) $p = 0.09$, hydroxychloroquine 30 (75%) vs 101 (87%, 1) $p = 0.07$, azathioprine 7 (17.5%) vs 10 (8.6%) $p = 0.14$, cyclophosphamide 10 (25%) vs 7 (6%) $p = 0.002$, pulse steroid 8 (20%) vs 3 (2.6%) $p = 0.001$, taking any biological treatment 16 (40%) vs 53 (45.7%) $p = 0.53$, Anti TNF 6 (15%) vs 32 (% 27.6) $p = 0.11$, abatacept 1 (2.5%) vs 11 (9.5%) $p=0.29$, rituximab 14 (35%) vs 24 (20.7%) $p=0.06$). Relationship between mortality and other parameters is shown in the table 1. UIP pattern, pleural effusion and the shorter time interval (< 3 years) between the diagnosis of RA and RA-LD were independent predictors of mortality in multivariate analysis (Table 1).

Conclusion: In our study, for RA-LD mortality, UIP pattern is usual suspected risk factor and pleural effusion, shorter time-interval between diagnosis RA and RA-LD are newly defined strong predictors. These risk factors may be used in the early risk stratification in the management of RA-LD routine practice.

High Lung Attenuation Measured with Quantitative Densitometry as a Surrogate Marker for Interstitial Lung Disease in RA: Association with Anti-CCP, Smoking, and Absence of Shared Epitope

Michail Alevizos,[1] Sonye Danoff,[2] Dimitrios Pappas,[1] David Lederer,[3] Cheilonda Johnson,[4] Elana Bernstein,[5] Joan Bathon,[5] and Jon Giles[5], [1]Division of Rheumatology, Columbia University, New York, [2]Division of Pulmonary & Critical Care Medicine, Johns Hopkins University, Baltimore, [3]Division of Pulmonary & Critical Care Medicine, Columbia University, New York, [4]Division of Pulmonary & Critical Care Medicine, University of Pennsylvania, Philadelphia, [5]Division of Rheumatology, Columbia University, New York, NY

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities

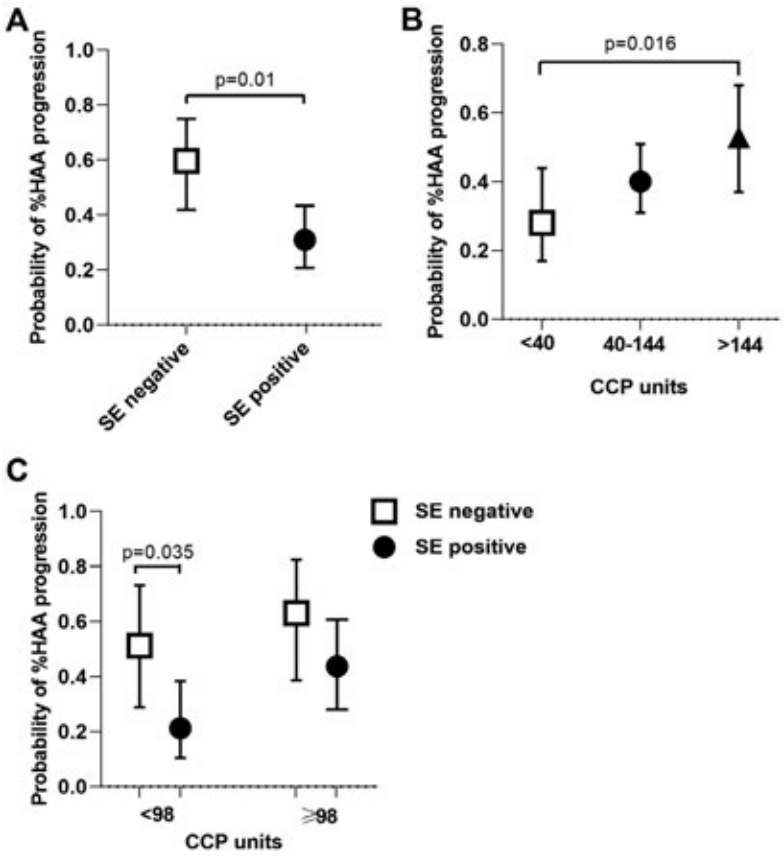
Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Risk factors for rheumatoid arthritis-associated interstitial lung disease (RA-ILD), a significant cause of morbidity and mortality, are poorly understood. RA-ILD detection is limited by the poor inter- and intra- observer variability on computed tomography (CT) scans, especially in early disease or when quantification of lung parenchyma involvement is attempted. Quantitative densitometry uses a computerized algorithm to measure the density of lung parenchyma, expressed as the proportion of the volume of high attenuation [percent high attenuation areas (%HAA)]. We sought to identify demographic and RA disease-specific risk factors for %HAA progression (increased by ≥ 10% from baseline %HAA).

Methods: RA patients enrolled in a prospective cohort study of cardiovascular disease underwent cardiac CT scans at baseline, pulmonary function testing and pulmonary symptom questionnaire at visit 2 (an average of 18 months post-baseline). A subset of patients underwent repeat cardiac CT scans at visit 3 (an average of 38 months post-baseline). Baseline scans were read by an expert pulmonary radiologist for ILD features. Baseline and V3 scans were assessed with quantitative densitometry, with %HAA calculated. Logistic regression was used to model the association of RA characteristics with strata of %HAA.

Results: A total of 193 patients had CT densitometry assessed at V1 [mean age=59 years; 61% female; median RA duration=8 years; %HAA=2.3-18.8 % of the lung parenchyma; 36% had evidence of ILD (predominantly mild) on expert read, 60% of whom were symptomatic]. Compared with subjects in the low %HAA stratum, subjects in the high %HAA stratum had a greater number of pack-years of smoking, a higher BMI, and a higher fibrosis score based on expert evaluation. A greater proportion were ever smokers, had shortness of breath on exertion on visit 2, a restrictive pattern on pulmonary function tests on visit 2, and a lower FVC on visit 2. After adjustment, higher BMI, anti-CCP ≥ 200 units, and a greater number of pack-years of smoking were each significantly associated with increased %HAA (≥10 % of the lung) at baseline visit, while male sex had a protective role against %HAA. For the subgroup of n=107 patients with repeat CT densitometry at V3, %HAA remained stable in 26%, decreased in 35%, and progressed in 39% of subjects. After adjustment, shared epitope was inversely associated with %HAA progression in the follow-up period (Figure A). Higher anti-CCP was significantly associated with %HAA progression in the follow-up period



(Figure B). The protective effect of shared epitope against HAA progression was statistically significant in patients in the low anti-CCP stratum (Figure C).

Conclusion: These prospective data provide evidence that anti-CCP, smoking, and absence of shared epitope are contributors to RA-ILD and could allow for early diagnosis and management of this serious complication of RA. Our findings on the negative effect of shared epitope are congruent with recently published data that have revealed strong association of a non-HLA gene (MUC5B promoter variant) with RA-ILD.

Adjusted means and 95% CIs depicted. Adjusted for pack-years of smoking, anti-CCP units, shared epitope, and baseline %HAA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes I: Pulmonary & Other Comorbidities
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

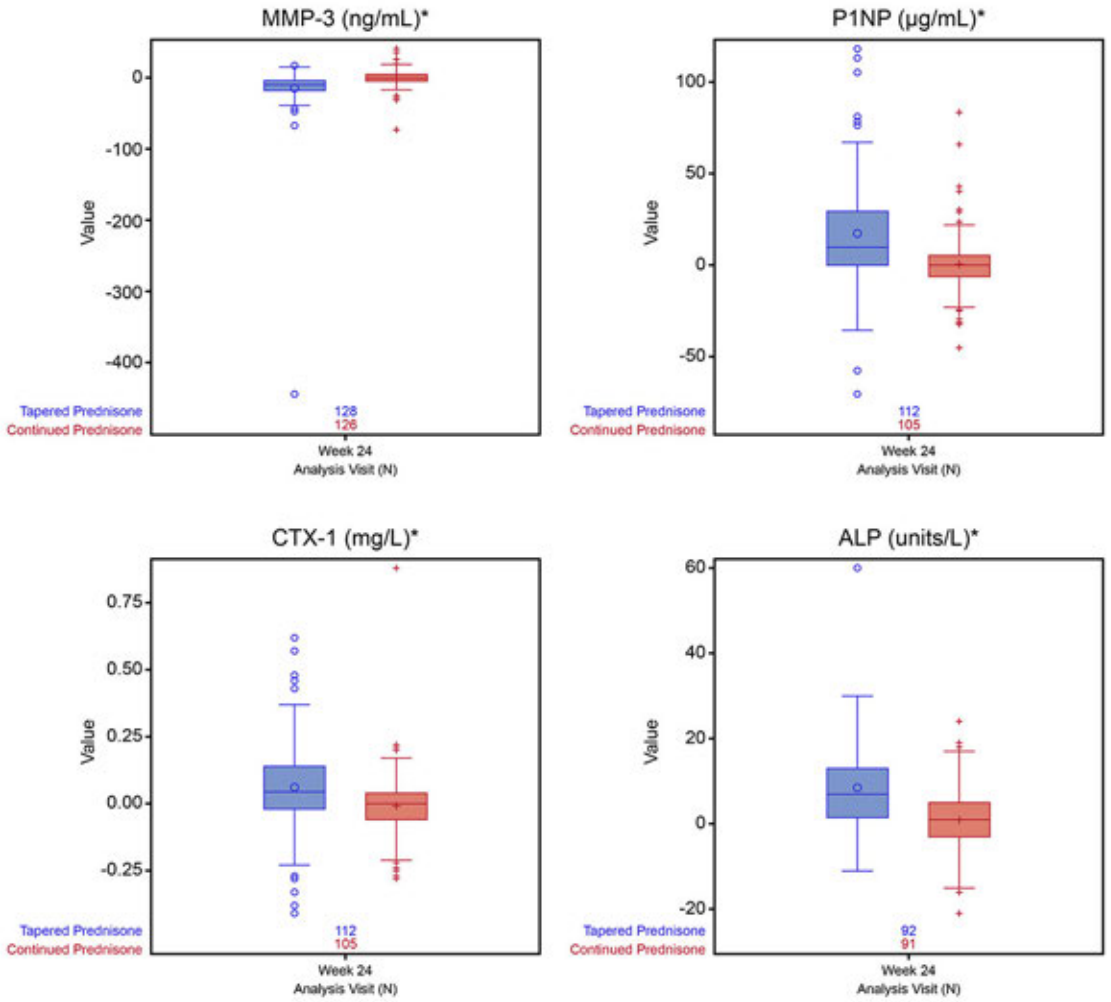
Background/Purpose: Glucocorticoids (GCs) directly impact bone metabolism via increased bone resorption and inhibited bone formation[1]; hence, systemic fracture risk increases with daily and cumulative GC doses.[2] However, many patients with established rheumatoid arthritis (RA) receive long-term treatment with GCs to suppress inflammation, which confers some benefit in delaying bone erosion.[3] This exploratory analysis of the SEMIRA (Steroid EliMination In RA) study[4] compared changes in markers of bone and cartilage metabolism in RA with low disease activity (LDA) or remission on tocilizumab (TCZ) + GC ± conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) who received either slow GC tapering (GC-taper) or continuation (5 mg; GC-5mg).

Methods: Patients (diagnosed per revised 1987 ACR criteria) had at least stable LDA (DAS28-ESR ≤3.2) for ≥4 weeks, were receiving a stable prednisone regimen (5 mg/day) + TCZ ± csDMARDs for ≥4 weeks, and received TCZ + GCs (prednisone equivalent 5-15 mg/day) for ≥6 months before randomization. Patients were randomly assigned to GC-5mg (n=128) or GC-taper (n=131; starting at 4 mg/day with 1-mg reduction every 4 weeks to 0 mg/day at weeks 16-24) for 24 weeks, during which TCZ ± csDMARDs remained stable. Change between baseline (BL) and week 24 in serum levels of markers of bone and cartilage metabolism—including N-terminal propeptide of type 1 collagen (P1NP), C-terminal telopeptide of type 1 collagen (CTX1), alkaline phosphatase (ALP), matrix metalloproteinase 3 (MMP3), calcium, phosphorus, and albumin—were exploratory outcomes. Within-group and between-group changes from baseline were evaluated by Wilcoxon paired rank test and Wilcoxon signed rank test, respectively.

Results: Figure 1 shows changes from BL to week 24 in bone and cartilage biomarkers. MMP3 (marker of cartilage degradation) was reduced at week 24 in the GC-taper group compared with GC-5mg. Change from BL at week 24 in P1NP (bone formation) and CTX1 (bone resorption) favored the GC-taper arm, with P1NP increasing relatively more than CTX1 (44% and 24%, respectively, compared with GC-5mg), indicating net anabolism. The increase in ALP from BL to week 24 was greater for the GC-taper arm than for the GC-5mg arm, suggesting neomineralization. There was no difference in the change from BL to week 24 in calcium, phosphorus, or albumin (not shown).

Conclusion: The findings of this biochemical marker analysis suggest that withdrawal from GC after achievement of LDA or remission with TCZ results in increased bone remodeling, with a trend toward an anabolic window and reduced cartilage degradation. Given that it could take a year to recover from increased fracture risk after cessation of GC therapy,[5] our results offer further insight on the reversible risk of systemic harm to noninflamed bone versus benefits for inflamed joints in the context of LDA or remission.

Figure 1. Box plots of change from baseline to week 24 in biomarkers of bone metabolism observed values



ALP, alkaline phosphatase; CTX-1, C-terminal telopeptide of type 1 collagen; MMP-3, matrix metalloproteinase 3; P1NP, N-terminal propeptide of type 1 collagen
*p<0.001 for tapered prednisone vs continued prednisone based on Wilcoxon signed rank test

Abstract Number: 0845

Comparison of Rituximab-Associated Hypogammaglobulinemia Rates in Patients with Systemic Rheumatologic Conditions

Stefanie Wade,[1] and Vasileios Kyttaris[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments I: Safety and Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Rituximab (RTX) is used in a wide variety of rheumatic disease. Emerging guidelines suggest measuring immunoglobulins (Ig) at pre-treatment screening and prior to repeat cycles of RTX. The association between hypogammaglobulinemia and infection post RTX has been evaluated in rheumatoid arthritis (RA) trials; however, there is limited data comparing total IgG levels across different diseases. We aim to compare the rate of hypogammaglobulinemia across RA, ANCA-associated vasculitis (AAV), and connective tissue disease (CTD) patients in a cohort at a tertiary university-based medical center. We hypothesized that baseline clinical and laboratory data will allow for risk prediction of hypogammaglobulinemia and infection rates in these patients.

Methods: Medical records of all RA, AAV, and CTD patients treated with RTX in an academic center from 2002 to 2019 were retrospectively reviewed. Baseline data at initiation of RTX, including clinical diagnosis, demographics, DMARD exposure, glucocorticoid (GC) dose, total serum IgG (normal range 0.7 to 1.6 g/dL) and disease activity were assessed. We defined GC exposure between the two Ig measurements, as an average daily prednisone dose: high (20mg or more), medium (11-19mg), or low (10mg or less). Analysis was performed using STATA. Group comparisons were done using chi square for categorical data and T-test for continuous variables.

Results: We screened 302 patients with rheumatologic conditions who were treated with RTX; of these, 165 patients received RTX for RA, AAV or a CTD. 58 of 165 patients had documented IgG levels pre and post treatment with RTX and 14/58 developed new onset hypogammaglobulinemia post RTX. Rates of hypogammaglobulinemia were significantly higher in AAV than in CTD patients (42.1% vs. 16.7%, p:0.014), despite similar cumulative exposure to RTX. The rate of hypogammaglobulinemia post RTX was trending higher in patients with AAV compared to RA (42.1% vs. 23.5%, p:0.24) despite AAV patients having lower cumulative exposure to RTX than RA patients (3.3+/-0.3g vs. 6.3+/-1.9g, p=0.1). GC exposure was greater in GPA versus RA ($p< 0.001$) and CTD (p=0.003) patients. Both RA and CTD patients were more likely to have prior exposure to conventional DMARD (cDMARD) versus AAV patients (p=0.005). RA patients had a higher likelihood of prior exposure to biologics versus AAV patients ($p< 0.001$). GPA patients were younger than CTD and RA groups. There was no observed difference in the infection rate among the groups.

Conclusion: AAV patients were more likely to develop hypogammaglobulinemia than RA and CTD patients. We identified high GC exposure as a potential risk factor for hypogammaglobulinemia. Age, cDMARD, and biologic exposure were not associated with increased risk of hypogammaglobulinemia. Reassuringly, infection rate was not increased in the AAV group, potentially reflecting use of prophylactic antibiotics. Limitations include low utilization of quantitative IgG measurements with repeat cycles of RTX in our center. Additional multicenter studies are needed to determine the true risk of low total IgG levels on rates of clinically significant infections, particularly in patients with AAV and high cumulative GC dose.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments I: Safety and Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Patients (pts) with RA have an approximate 2-fold increased risk of cardiovascular (CV) morbidity and mortality and of venous thromboembolic events (VTE)[1,2]. Among RA pts, the rates of major adverse CV events (MACE) and VTE were 0.3 – 0.7 incidences per 100 patient-years (PY)[3] and 0.3 – 0.8 events per 100 PY[4], respectively. Treatment of RA with Janus Kinase (JAK) inhibitors is known to increase lipid levels[5] along with mild, variable impacts on platelet counts[5,6], however these changes have not been linked to a CV[7] or VTE[8] risk, respectively.

Assess the rates of MACE and VTE from the integrated safety database of the Phase 3 clinical program of Upadacitinib (UPA), an oral, potent, reversible, JAK1-selective inhibitor, in pts with moderately to severely active RA.

Table. Adjudicated MACE and VTEs in patients treated with UPA, PBO and active controls

				UPA All Phase 3 Long-term

DVT and PE (Concurrent)	0.0 (0.0, 1.4)	0.3 (0.0 1.5)	0 (0.0, 0.8)	0.2 (0.0, 0.4)	<0.1 (0.0, 0.4)
Deaths due to DVT/PE	0.0 (0.0, 1.4)	0 (0.0, 1.0)	0 (0.0, 0.8)	<0.1 (0.0, 0.2)[c]	0 (0.0, 0.3)

[a]Includes patients on MTX monotherapy censored at time of rescue to combination therapy (either to UPA + MTX or addition of csDMARD); [b]Deaths are only treatment-emergent; [c]includes 1 fatal PE event: 55-year-old female with history of obesity, diabetes and hypertension developed PE after prolonged driving.
MACE was defined as CV death, non-fatal MI, and non-fatal stroke. VTE was defined as deep vein thrombosis and pulmonary embolism.
ADA, adalimumab, AE, adverse events; DVT, Deep Vein Thrombosis; E, events; EOW, every other week; MACE, major adverse cardiovascular events; MTX, methotrexate; PBO, placebo; PY, patient years; QD, once-daily; SAE, serious adverse events; TEAEs, treatment-emergent AEs; UPA, upadacitinib; VTE, venous thromboembolic events.

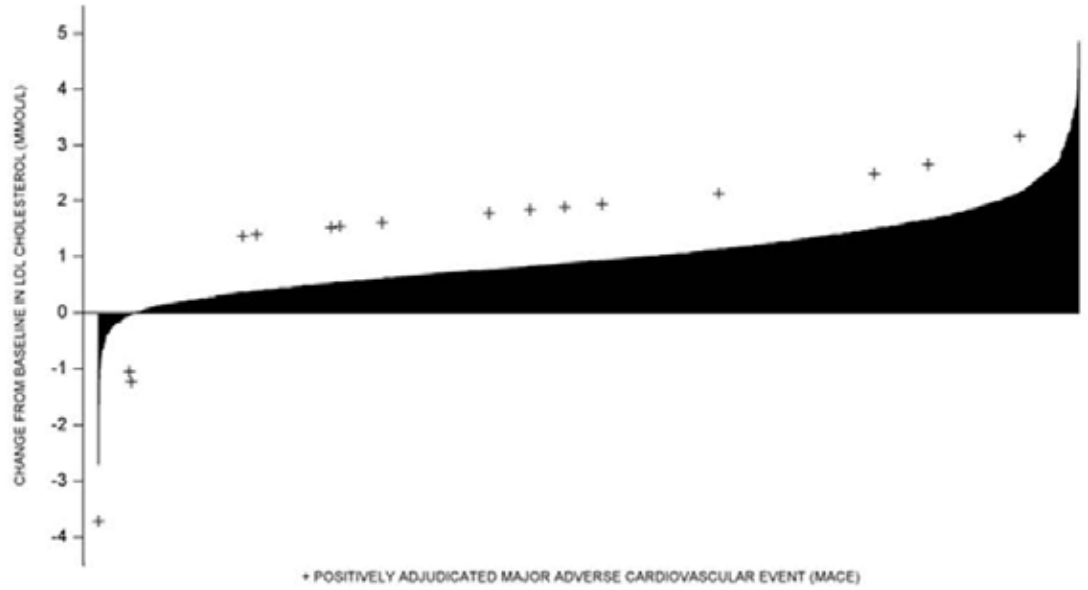
Methods: Treatment-emergent adverse events of MACE and VTE from 5 pivotal, randomized, blinded, Phase 3 trials of UPA 15 mg QD (all 5 trials) or 30 mg QD (4 trials) in RA pts were summarized into the integrated placebo (PBO), MTX, ADA 40 mg, UPA 15 mg and UPA 30 mg treatment groups. Data are presented as exposure adjusted event rates (EAERs, E/100 PY). All suspected MACE and VTEs were adjudicated by an external, independent, CV adjudication committee.

Results: Across trials, 3834 pts received ≥1 dose of UPA 15 mg (n=2630) or 30 mg (n=1204) with no option to switch doses (exposure =4020.1 PY), 1042 pts received PBO (256.8 PY), 530 pts received MTX (368.7 PY) and 579 pts received ADA 40 mg (467.8 PY). History of prior CV events (2-3%) and VTEs (4-7%) were comparable across groups.

The EAERs of MACE and VTE in the UPA groups were comparable to PBO, MTX and ADA **(Table).** Approximately 40% of MACE events and 1 pulmonary embolism event (UPA 15 mg) were fatal. All pts with a MACE or VTE event had ≥1 CV risk factor (hypertension, diabetes, dyslipidemia) or ≥1 VTE risk factor (prior history of thrombotic event, obesity, or hypertension) at baseline, respectively.

Though treatment with UPA increased the levels of low- and high-density lipoprotein cholesterol (LDL-C and HDL-C), their ratio remained constant over time. Analysis of data showed no association of LDL-C increases and MACE occurrences **(Figure)**. In both UPA groups, neither a dose-response nor a pattern of time-to-VTE-onset (23 to 1127 days of UPA) was observed. Slight decreases in mean platelet count from baseline were observed.

Figure: Adjudicated MACE events in patients with varying ΔBL in LDL-C



Note: the above plot of adjudicated MACE events is from the long-term exposure of the UPA 15 mg arm.
MACE is defined as CV death, non-fatal MI and non-fatal stroke;
CV, cardiovascular; LDL-C, Low density Lipid-Cholesterol, MACE, major adverse cardiovascular events; MI, myocardial infarction; UPA, upadacitinib; QD, once-daily.

Conclusion: EAERs of adjudicated MACE and VTE with UPA were comparable with MTX and ADA and consistent with reported background rates in the RA population. Similar to other JAK inhibitors, UPA increased the levels of lipids. However, no association between lipid levels and MACE could be established.

*$P<0.05$ Bari 4-mg vs placebo.
[a]No statistical comparisons were performed.
AE=adverse event; Bari=baricitinib; DVT=deep vein thrombosis; EAIR=exposure-adjusted incidence rate; IR=incidence rate; NMSC=non-melanoma skin cancer; PE=pulmonary embolism; TE=treatment-emergent.

Background/Purpose: Baricitinib (bari), an oral, selective inhibitor of Janus kinase (JAK) 1 and 2, is used to treat moderately to severely active RA in adults. The objective of the study was to update bari's safety profile with data from an additional Phase 3 trial and ongoing long-term extension (LTE) study.

Methods: Long-term safety of once-daily bari was evaluated in the All-Bari-RA dataset: all patients exposed to any bari dose from 9 randomized trials (5 Phase 3, 3 Phase 2, 1 Phase 1b) and 1 LTE (data to 13-Feb-2018). Placebo comparisons were evaluated to Week 24 from 7 Phase 2/3 trials: patients randomized to placebo, bari 2-mg, or 4-mg, with censoring at rescue/treatment switch. Dose responses were evaluated in the 2/4-mg extended dataset from 4 Phase 2/3 trials: patients randomized to 2- or 4-mg, LTE data included; data censored at rescue/dose change (as-treated

analysis) and, due to latent period for malignancy, analyzed without censoring (as-randomized analysis). Incidence rates (IRs) per 100 patient-years were calculated.

Results: A total of 3770 patients received bari (10,127 patient-years); maximum exposure was 7 years (Table). No significant differences were seen for bari 4-mg versus placebo in adverse events leading to permanent drug discontinuation, death, malignancy, serious infection, or major adverse cardiovascular events. Herpes zoster incidence rate (IR) was significantly higher for bari 4-mg versus placebo (3.8 vs 0.9) and numerically higher for bari 2-mg (3.1). IRs for deep vein thrombosis/pulmonary embolism were numerically higher in bari 4-mg versus placebo; IRs were similar in 2/4-mg-extended dataset. Malignancy (excluding non-melanoma skin cancer) IRs were 0.8 (2-mg) and 1.0 (4-mg; as-randomized analysis). Fewer than 1% of patients discontinued due to abnormal laboratory results.

Conclusion: In this updated integrated analysis of patients with active RA exposed to bari for up to 7 years, across safety topics, bari maintained a safety profile similar to that previously reported[1] and acceptable in the context of demonstrated efficacy.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments I: Safety and Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: As many as 30-40% of patients with RA remain on long term glucocorticoids. Infection risk with higher dose glucocorticoids is well known, but evidence on risk with low dose therapy is mixed. We aimed to assess infection risk with low-dose, long-term glucocorticoid use by studying patients on stable DMARD therapy.

Methods: Using Medicare claims data from 2006-2015, we evaluated RA patients (2 diagnoses ≥7 days apart) who initiated MTX or a biologic/targeted synthetic DMARD (tsDMARD) and remained on therapy for >180 days (no gaps > 90 days and no new biologic/tsDMARDs). Patients with other autoimmune rheumatic diseases, cancer, or HIV were excluded. The baseline period included the 180 days prior to the DMARD course initiation and the first 180 days of treatment (Figure 1). Average glucocorticoid dose in prednisone equivalents was calculated in the final 90 days of the baseline period and updated at each subsequent 90-day interval, categorizing as none, ≤5mg, 5-10mg, or >10mg/day. Cox models evaluated associations between glucocorticoid dose and time to the first serious infection (diagnoses from any position in hospital discharge diagnoses, positive predictive value >80%), clustering to account for patients contributing > 1 treatment episode. Patients were censored at end of the DMARD course, end of enrollment, 9/30/2015, death, or 90 days after a change in glucocorticoid dose category. Covariates were balanced across glucocorticoid dose categories using propensity score-based inverse probability weights. Predicted 1-year incidence of infection was calculated from weighted models.

Results: We identified 244,833 treatment episodes (56% methotrexate and 44% biologic/tsDMARD) among 170,357 unique patients meeting inclusion and exclusion criteria. At baseline 47% of patients were receiving glucocorticoids (Table 1). There were 20,630 serious infections with overall crude incidence of 11.0/100 person-years, most fre-

>10mg/day	7978	2702	894 (33.1)	3.47 (3.24-3.73)	2.78 (2.57-3.01)

Hazard ratios (HR) from Cox models. Propensity score adjusted analyses performed using stabilized inverse probability weights to balance covariates across treatment groups. Covariates included in propensity score models: age (categorized), female, race, year, disability, dual Medicare/Medicaid eligibility, quintiles of zip code based median household income, DMARD type, number previous biologics, diabetes, hypertension, COPD, asthma, cerebrovascular disease, obesity, congestive heart failure, coronary artery disease, myocardial infarction, peptic ulcer disease, extra-articular RA, anemia, chronic kidney disease, end-stage renal disease, depression, chronic pain, Charlson score, influenza vaccine past year, pneumococcal or zoster vaccine (ever), hospitalized infection past year, use of durable medical equipment, skilled nursing facility stay.

quently urinary infection, pneumonia, bacteremia/septicemia, and skin/soft tissue infection. Glucocorticoids were associated with an increased rate of serious infections with significant risk even at ≤5mg/day [HR 1.37 (1.32-1.41)] (Table 2). Predicted 1-year incidence of infection from propensity weighted models was 12.5% (95% CI 12.2-12.9) for ≤5mg, 17.2% (16.5-17.9) for 5-10mg, and 23.9% (22.3-25.6) for >10mg vs. 9.3% with no glucocorticoids. Results

were similar in sensitivity analyses requiring a primary diagnosis of infection, excluding patients with prior serious infection, and stratifying by MTX vs. biologic/tsDMARD use. Results remained significant in analyses that did not censor with glucocorticoid dose changes (37% of censoring events in the main analysis).

Conclusion: Among older RA patients stable on MTX or biologic/tsDMARDs, long term use of glucocorticoids is associated with a significant increase in the risk of serious infections even at doses ≤5mg/day. The magnitude of risk with ≤5mg/day is similar to that observed with biologics in other studies. Although the influence of disease activity could not be directly assessed, these results support recommendations to limit long term glucocorticoid use in RA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments I: Safety and Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Our objectives were to estimate and compare the incidence rate of malignancies between biologic and csDMARD-treated RA patients.

Methods: We conducted an historical cohort study within our national claim database that prospectively records individual health resource use of 86% of the French population (65 million inhabitants). RA adult patients were identified based on ICD-10 code (M05 or M06) between 2007-2016. Patients with previouscancer history were excluded.

Treatment exposures were incident first use of any treatment: csDMARD (methotrexate, leflunomide, sulfasalazine, azathioprine, hydroxychloroquine) or biologics (anti-TNF, rituximab, abatacept, tocilizumab, ustekinumab, anakinra). To identify incident treatment periods, a one year period prior our period of analysis was analysed; only patients that

Type of malignancies	HR csDMARD (ref) vs. all biologics	p value
All malignancies	0.92 [0.80;1.05]	p=0.224
Solid cancer (excluding non melanoma skin cancer)	0.90 [0.78;1.05]	p=0.182
Lymphoma	1.00 [0.55;1.835]	p=0.992
Other hematologic malignancies	0.85 [0.43;1.67]	p=0.636

Table 1. Risk of cancer of biologics compared to csDMARD in RA patients

did not receive any treatment during this period were included. .Exposure definition was considered with a 90-day latency after treatment initiation and a 180-day remanence period after drug discontinuation.

To compare the risk of malignancies between csDMARD and biologics treated patients, a dynamically propensity score (including age, sexe, year of first occurrence of RA code, date of treatment initiation, number of previous DMARDs, Charlson comorbidity index, diagnosis of tobacco and/or alcohol-associated disorders, number of hospitalisations for RA, cumulative corticosteroid dose) was constructed using pooled logistic regression. Hazard Ratios (HRs) for risk of cancer were estimated using Cox proportional hazards model after dynamically propensity score matching. Exposure was considered as a time-dependent variable. Sensitivity analyses are ongoing to assess the robustness of our results.

Results: Between 2007 and 2016, 83 706 RA patients exposed to csDMARD (n=63837) and/or biologics (n=19869) were identified. After propensity score matching, analyses were conducted on 19687 patients in each group (mean age: 51 ±14 yrs; female: 74.6%). Malignancies occurred in 435 patients exposed to biologics and 357 patients exposed to csDMARD,

The HR for overall risk of malignancies, risk of solid cancer (excluding non-melanoma skin cancer), lymphoma, and other hematologic malignancies did not differ significantly between csDMARD and all biologics analysed together (table). Regarding organ specific cancer, no difference was observed, except for risk of prostate cancer in men that occurred significantly less frequently in biologic treated patients (HR: 0.47 [0.29;0.76], p=0.003).

Conclusion: Using a large nationwide healthcare database, representative of the French population, the overall risk of malignancies and the risk of organ-specific cancers and hematologic malignancies in biologic treated RA patients did not differ from that of patients treated with csDMARD. Except for prostate cancer in men, which occurred less frequently in biologics treated patients. The reason of this difference remains unclear, but could be linked to a high frequency of screening before introducing biologic.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments I: Safety and Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: To assess the most recent safety-data of synthetic (s) and biological (b)DMARDs to inform the 2019 update of the EULAR recommendations for the management of RA.

Methods: Observational studies comparing any DMARD with another intervention for the management of patients with RA were identified by searches in MEDLINE, Embase and Cochrane (time-window: 2016-2019). Interventions included any bDMARD, csDMARD, tsDMARD or glucocorticoids. A comparator group was required for the study to be included. All safety outcomes were included. Observational studies were chosen because they better reflect routine clinical care. For treatments still without registry data, randomized controlled trials (RCTs) and long-term extensions (LTEs) thereof were used to extract safety data. Risk of bias was assessed according to the Hayden's tool for observational studies and Cochrane Collaboration's tool for RCTs.

Results: Of 3,886 articles screened, 42 observational studies fulfilled the inclusion criteria, with 16 focusing on the risk of infections, 8 on cancer, 10 on major cardiovascular events (MACE), 3 on lower intestinal perforations (LIP), 5 on withdrawals due to adverse events and 2 on immunological reactions. Studies were heterogeneous precluding meta-analysis. Two studies showed an increased risk of serious infections (SI) with bDMARDs compared to csDMARDs (aIRR: 3.1-3.9). In 9 studies, 4 at low risk of bias, the risk of SI was not different between bDMARDs, with one also showing no difference between tofacitinib and TNFi (Table 1). Two studies (high risk of bias) showed no difference in the risk of infection by herpes zoster across bDMARDs, but in one, an increased risk for tofacitinib compared to abatacept was reported. Five studies (4 at low risk of bias) showed no increased risk of cancer for bDMARDs compared to csDMARDs; and 2 (at low risk of bias) no difference between bDMARDs. The risk of MACE did not differ between bDMARDs and csDMARD (3 studies, 1 at low risk of bias) and also comparing different bDMARDs (4 studies, 1 at low risk of bias). An increased risk of LIP was found for tocilizumab compared to csDMARDs (1 study, low risk of bias) and to TNFi (2 studies, high risk of bias). In total, 57 manuscripts reported safety data from RCTs/LTEs, 21 evaluating biosimilars, 18 bDMARDs and 18 tsDMARDs. Overall, no unexpected safety outcomes were found, except for the possible increased risk of venous thromboembolism (VTE) with tsDMARDs (Table 2). This signal prompted FDA/EMA to issue warnings to avoid baricitinib 4mg (not 2mg) and tofacitinib 10 mg bid (not 5mg bid) in patients with risk factors for VTE.

		TCZ		**1.2 (1.0; 1.5)**	
		CZP		**0.8 (0.6; 1.0)**	
Silva-Fernández 2018 Rheumatology (Oxford)	BSRBR-RA	RTX	TNFi	1.0 (0.7; 1.4)	Low

Conclusion: Data obtained by this SLR are aligned with previous evidence; they show a slightly increased risk of SI with bDMARDs compared to csDMARDs and no difference between bDMARDs. The overall risk of cancer and MACE was not increased with bDMARDs compared with csDMARDs. The risk of LIP with tocilizumab and VTE with tsDMARDs needs further evaluation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: The overall presence of inflammation in the MRI-SIJ is associated with overall 5-year radiographic damage in patients with axSpA. But we do not know if a bone marrow edema (BME) lesion leads to a structural lesion at the same place (i.e. in the same quadrant). This study aims to investigate the association between BME and structural progression in the same quadrant of the SIJ, over time.

Methods: Patients from the DESIR cohort (early axSpA according to the rheumatologist) with ≥2 consecutive MRI-SIJ (out of baseline, 2 and 5 years), were included. Each image was independently scored by 3 trained central readers blinded to chronological order. BME was considered present in a time point if detected in ≥1/6 slices in each of the 8 quadrants. The prevalence of BME (yes/no) and structural lesions (sclerosis, erosions, fatty lesions and ankylosis;

[a]: Multilevel (reader, time, side, quadrant) with auto-regression and adjusted for the following variables: age, gender, ASDAS, treatment (NSAIDs, steroids, csDMARDs, and TNFi) and reader. ASDAS and treatment are time-lagged

all yes/no) defined, per quadrant, by the agreement of ≥2 out of 3 readers, was described at BL and at 5 years. The longitudinal association between BME and each of the structural lesions in the same quadrant was tested in time-lagged multilevel Generalized Estimating Equation (GEE) models with autoregression (i.e. adjusted for the structural lesion in the previous time point) and adjusting for clinical variables selected a priori on clinical grounds (age, gender, disease activity and treatment).

Results: In total, 197 patients were included (age 34 (SD 9) years, 48% male and 61% HLA-B27 positive). While BME and fatty lesions were evenly distributed across quadrants, erosions and sclerosis occurred preferably in the iliac side (i.e. Q1 and Q4) (Table 1). The prevalence of BME decreased over time (baseline range: 11%-16%; 5-year range: 7%-14%), while erosions (baseline: 2%-23%; 5-year: 3%-28%) and especially fatty lesions (baseline: 4%-14%; 5-year: 9%-21%) increased. Ankylosis and sclerosis were rare in this early axSpA cohort. In the multivariable models, BME was longitudinally associated with sclerosis (OR:1.7 (95% CI: 1.0;3.2)), erosions (2.0 (1.5;2.5)) and fatty lesions (1.7 (1.1;2.5)) (Table 2). The possible association with ankylosis could not be tested due to too low number of lesions.

Conclusion: In patients with early axSpA, inflammation in one SIJ quadrant leads to structural damage in the same quadrant. This finding reinforces the pathophysiological implications of inflammation in axSpA.

Ileal but Not Colonic Inflammation Is Linked to Fatty Lesions on MRI of the Sacroiliac Joints in Spondyloarthritis Patients

Ann-Sophie De Craemer,[1] Manouk de Hooge,[1] Thomas Renson,[1] Liselotte Deroo,[1] Triana Lobaton Ortega,[2] Anne Hoorens,[3] Philippe Carron,[1] Filip Van den Bosch,[1] and Dirk Elewaut[1], [1]Ghent University Hospital, Ghent, Belgium, [2]Ghent University Hospital, Gent, Oost-Vlaanderen, Belgium, [3]Ghent University Hospital, Gent

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Gut and joint inflammation in spondyloarthritis (SpA) are closely intertwined. About 50% of axial SpA patients display microscopic signs of inflammation in ileum and/or colon, a risk factor to develop Crohn's disease over time. It is currently not known if presence of microscopic gut inflammation in new onset SpA is associated with more structural lesions on magnetic resonance imaging of the sacroiliac joints (MRI-SIJ) and whether these lesions relate to the localization of gut inflammation. This study aims to assess whether structural lesions on MRI-SIJ (A) are associated with microscopic gut inflammation in SpA patients and (B) are preferably related to colon or ileum inflammation in case of gut involvement.

Methods: We analyzed baseline information from a patient cohort with a new diagnosis of SpA (expert opinion). Included patients fulfill the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axial or peripheral SpA. MRI-SIJ was scored by 3 readers, blinded for subject characteristics. Six consecutive slices were assessed for structural lesions: sclerosis, erosions, fatty lesions and (partial) ankylosis. MRI sum scores were analyzed as 2 out of 3 (median) scores. Colon and ileum biopsies were evaluated for microscopic signs of inflammation. The effect of gut inflammation (colon and/or ileum) on MRI-SIJ lesions was investigated by generalized linear models (GLM), adjusted for age and gender and stratified for the SpA phenotype.

Results: By January 2019, baseline data were available on 105 patients (95 axial and 10 peripheral SpA). Gut inflammation was present in 35 patients (17 ileum, 8 colon, 10 both). Table 1 shows the slope (β_1) of the GLMs for erosions, fatty lesions, sclerosis and (partial) ankylosis and the p-value for the SpA phenotype as an interaction term. Erosions, sclerosis, nor ankylosis show a significant association with gut inflammation in general. If present, colon inflammation has no significant relationship with each individual structural lesion. In contrast, presence of ileum inflammation was associated with an increase in the number of fatty lesions by 0,68 (95%CI 0,04 – 1,38). All results are independent of the SpA phenotype (p > 0,05).

Structural lesion	Gut inflammation	β_1	95% CI	p-value	p-value interaction term*
Erosions	Colon and/or ileum	0,02	(-0,39 – 0,45)	0,92	0,53
	Colon	-0,08	(-0,56 – 0,45)	0,75	0,50
	Ileum	-0,01	(-0,47 – 0,46)	0,94	0,66
Fatty lesions	Colon and/or ileum	0,38	(-0,23 – 1,04)	0,22	0,61
	Colon	-0,54	(-1,28 – 0,30)	0,16	0,94
	Ileum	**0,68**	**(0,04 – 1,38)**	**0,04**	0,88
Sclerosis	Colon and/or ileum	-0,19	(-0,60 – 0,23)	0,35	0,81
	Colon	0,05	(-0,45 – 0,60)	0,84	0,60
	Ileum	-0,27	(-0,68 – 0,17)	0,22	0,62
(Partial) Ankylosis	Colon and/or ileum	-0,38	(-1,14 – 0,44)	0,35	0,41
	Colon	-0,40	(-1,33 – 0,76)	0,45	0,60
	Ileum	-0,24	(-1,05 – 0,68)	0,58	0,40

Conclusion: Ileal but not colonic inflammatory gut lesions are linked to more fatty lesions on MRI-SIJ in newly diagnosed SpA patients. Baseline microscopic gut inflammation was not associated with erosions, sclerosis nor ankylosis. These data support the concept that microscopic gut inflammation, especially ileal inflammation, is associated with more severe axial inflammation in SpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Inflammation and new bone formation in the axial skeleton are characteristic features of radiographic axial spondyloarthritis (r-axSpA). Facet joints are frequently involved in r-axSpA but rather difficult to visualize on conventional radiography (CR). However, we have recently shown that low-dose CT (ldCT) can be used to assess facet joint ankylosis in the whole spine, except for the cervicothoracic junction, in patients with r-axSpA. We now aimed to study progression of facet joint ankylosis over two years in patients with r-axSpA.

Methods: In an observational cohort, r-axSpA patients with syndesmophytes on ≥1 but no more than 75% of spinal levels of the cervical and lumbar segments on CR and ≥1 inflammatory lesion on spinal MRI underwent whole spine ldCT (about 4 mSv) with repeated ldCT after 2 years. Paired ldCTs were independently assessed by 2 trained readers, blinded to chronology. Left and right facet joints of all levels between C2 and S1, with the exception of the levels between C5 and T2, were scored as ankylosis present (1) or absent (0). Interreader reliability was assessed with intraclass correlation coefficients (ICCs) (two-way average, absolute agreement) and smallest detectable change (SDC). Status scores were calculated for baseline and follow-up. Change scores of the whole spine and per segment were calculated if < 25% of the joint scores were missing. Remaining missing scores were imputed with the mean segment change score. For each reader, progression was calculated as the proportion of patients with change score >0. For the average score of the readers, progression was given as change score >0.5 and >SDC as well as net progression,

Table 2: Number of r-axSpA patients with progression of facet joint ankylosis over 2-year follow-up

		Reader 1 N(%)	**Reader 2 N(%)**
Whole spine change >0		15/50 (30%)	22/52 (42%)
Cervical segment change >0		2/44 (4%)	3/45 (7%)
Thoracic segment change >0		15/50 (30%)	17/52 (33%)
Lumbar segment change >0		3/51 (6%)	6/52 (12%)
	SDC	**Average of 2 readers N(%)**	
Whole spine			
Change >0.5	2	24/50 (54%)	
Change >SDC		13/50 (26%)	
Net progression		21/50 (42%)	
Cervical segment			
Change >0.5	0.2	1/40 (2.5%)	
Change >SDC		3/40 (7.5%)	
Net progression		0/40 (0%)	
Thoracic segment			
Change >0.5	2.7	23/50 (48%)	
Change >SDC		7/50 (14%)	
Net progression		21/50 (42%)	
Lumbar segment			
Change >0.5	1.1	5/51 (13.7%)	
Change >SDC		4/51 (7.8%)	
Net progression		3/51 (5.9%)	

Whole spine: N=50 (r1), N=52 (r2), N=50 (average 2 readers)
Cervical segment: N=44 (r1), N=45 (r2), N=40 (average 2 readers)
Thoracic segment: N=50 (r1), N=52 (r2), N=50 (average 2 readers)
Lumbar segment: N=51 (r1), N=52 (r2), N=51 (average 2 readers)

defined as the number of patients with change score >0.5 minus the number of patients with change score < -0.5 divided by the total number of patients.

Results: Baseline and 2-year follow up ldCT were available in 53 patients with r-axSpA (mean age 48.3, 85% male, 79% HLA-B27+). Interreader reliability for status scores was good to excellent. For change scores this was poor to excellent (table 1). SDCs were relatively low (tables 1 and 2). The proportion of patients with progression is given in table 2. Most changes were seen in the thoracic spine (tables 1 and 2).

Conclusion: Over two years, a fair number of patients had progression of facet joint ankylosis with most progression occurring in the thoracic spine. These results show that using whole spine ldCT, progression of facet joint ankylosis can provide useful information on new bone formation in r-axSpA patients.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Smoking and systemic inflammation have been shown to independently associate with radiographic spinal progression in patients with axSpA. Evidence suggests that certain socioeconomic (SE) factors (e.g. physically demanding jobs) may modify these associations.The study investigates the relationship between smoking and imaging outcomes (SI joints, spine, MRI and radiographs) over time in axSpA, to assess if SE factors first modify and if not, confound, such a relationship.

Methods: Patients with axSpA from the DESIR cohort who fulfil the ASAS axSpA classification criteria were included. Four imaging continuous outcomes (X-ray spine [mSASSS, range 0-72]; X-ray SIJs modified New York grading [mNY, 0-8]; MRI-Spine [SPARCC, range 0-414] and MRI-SIJ [SPARCC, range 0-72]) have been scored by 3 central readers independently (average score used) in one session, blinded for time order (baseline, 2 and 5 years). Smoking was tested as a binary variable: smoking status since last visit. SE variables were: age, gender, ethnicity (Caucasian vs other), job type based on 'collar' (blue [manual labour work] vs white [office-based work]); educational status (low vs high [university]); marital status (married vs not) and parental (number of children) status. Potential interactions between smoking and SE factors were first investigated and, if statistically ($p< 0.15$) and clinically relevant, models were stratified. The effect of smoking on imaging outcomes was assessed in multivariable time-varying models using generalized estimating equations adjusted for other possible confounders.

Results: In total, 425 axSpA patients were included: 225 [53%] male, 167 [40%] smokers and 287 [68%] blue collar. The mean baseline (SD) MRI-SIJ SPARCC was 4.67 (7.85), MRI-spine SPARCC: 2.73 (7.95)); mSASSS: 0.39(1.66); mNY: 1.70(1.84)). A significant interaction was found between smoking and job type with MRI-SIJ inflammation as the outcome ($p=0.031$) as well as with mNY grading ($p=0.096$). Similarly, educational status also proved to modify the association between smoking and MRI-SIJ inflammation ($p=0.026$). In the multivariable models, smoking was significantly associated with more MRI-SIJ inflammation over 5 years of follow-up but only in patients with a blue-collar job (β [95% CI]: 3.35 [0.54,6.17]) (table). Results were similar in the low education stratum (β [95% CI]: 2.69 [0.48, 4.91]. Smoking was not significantly associated with any of the other imaging outcomes over time. Male gender was positively associated with MRI-SIJ inflammation regardless of job type, and also with MRI-Spine inflammation and structural damage although only for blue-collar patients in the case of SIJ damage.

Conclusion: There is a strong association between smoking and MRI-SIJ inflammation over time in axSpA patients with blue collar job type or low education, irrespective of other socio-economic factors, systemic inflammation and

Table. (Time-varying) relationship between smoking and imaging outcomes across all patients or in strata according to type of job.

Other independent variables tested in models included HLA B27 status, all SE variables of interest, ASDAS or BASDAI, presence of psoriasis, inflammatory bowel disease and peripheral arthritis. ^Indicates confounding effect on the association between smoking and the outcome.

treatment. These findings suggest a possible role for mechanical stress (seen with manual jobs) amplifying the effect of smoking on axial inflammation in axSpA. No significant relationship was found between smoking and spinal inflammation or axial damage, possibly also due to the limited imaging changes in this cohort.

Abstract Number: 0855

Which Magnetic Resonance Imaging Lesions of the Sacroiliac Joints Are of Diagnostic Value for Axial Spondyloarthritis?

Xenofon Baraliakos,[1] Anna Ghadir,[2] Martin Fruth,[2] Uta Kiltz,[3] and Jürgen Braun[4], [1]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [2]Radiology Herne, Herne, Germany, [3]Rheumazentrum Ruhrgebiet/Ruhr University Bochum, Herne, Germany, Herne, Germany, [4]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Classification of patients as having axial spondyloarthritis (axSpA) by the imaging arm of the ASAS criteria relies partly on the detection of bone marrow edema (BME) suspicious of SpA on magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ). Fatty lesions (FL) and erosions on SIJ-MRI have been suggested to be genuinely related to SpA in the context of interpretation of a 'positive' MRI in case of doubtful BME cases (1). We evaluated the role of different SIJ-MRI lesions for diagnosing axSpA in daily routine practice.

Methods: Consecutive patients with chronic back pain (duration >3 months) starting before age 45 and clinical suspicion of axSpA underwent a complete diagnostic workup including SIJ-MRI. All clinical, laboratory and imaging data

Lesion type	Sensitivity	Specificity	OR	95% CI	p-value
BME	72.5%	63.3%	4.6	2.8-7.5	0.001
BME + any chronic lesion	71.8%	72.8%	16.0	7.5-34.0	0.001
FL	56.5%	89.3%	10.9	6.0-19.8	0.001
Erosion	59.5%	88.8%	11.6	6.4-21.0	0.001
Sclerosis	81.7%	43.2%	3.4	2.0-5.8	0.001
Ankylosis	12.2%	99.4%	23.4	3.1-178.7	0.002
BME+FL	36.6%	95.3%	11.6	5.3-25.7	0.001
BME+Erosion	48.9%	94.1%	15.2	7.4-31.4	0.001
BME+Sclerosis	64.1%	75.1%			0.001
BME+Ankylosis	5.3%	99.4%	9.5	1.2-78.1	0.036

Table 1. Odds ratios for MRI lesions and combinations used for diagnosing axSpA.

	Lesion type	axSpA	non-SpA	p-value
Mean±SD	Total score	14.8±10.8	2.7±3.4	p<0.001
	BME (0-24)	3.3±3.6	0.8±1.3	
	FL (0-24)	5.2±6.8	0.5±1.9	
	Erosions (0-24)	4.5±5.4	0.4±1.4	
Median	Sclerosis or Ankylosis (0-2)	0	0	--

Table 2. Mean/median Berlin SIJ scores ± standard deviation for inflammatory and chronic lesions.

were available to experienced rheumatologists for diagnosing axSpA or not (non-SpA). In parallel, two experienced readers, blinded to all patients´ information and diagnosis, evaluated the MRIs and made a 'diagnostic judgement' based only on imaging features. In addition, radiologists quantitatively assessed MRIs for BME (Berlin Score), FL, erosions, sclerosis and ankylosis.

Results: A total of 300 consecutive patients were recruited. AxSpA was diagnosed by the rheumatologists in 131 patients (43.7%) with mean age of 34.5±7.2 years, 73% HLA-B27+, mean symptom duration 58.6±69.5 months, vs. 169 non-SpA patients with mean age of 34.5±7.4 years, 21.3% HLA-B27+, mean symptom duration 33.9±45.1 months. The ASAS classification criteria were fulfilled by 99/131 patients diagnosed with axSpA (75.6%) vs. 70/169 patients diagnosed vs. non-SpA non-SpA (41.4%).

In 97/162 patients, rheumatologists and radiologists agreed on a diagnosis of axSpA and in the same number (97/162) there was agreement for non-SpA (overall agreement: 86.3%). However, 34/131 (28.1%) patients were diagnosed with axSpA by rheumatologists but not by radiologists.

According to radiologists, BME alone was critical for diagnosis in only 7/97 patients (7.2%) with axSpA as agreed by both, rheumatologists and radiologists, in contrast to chronic lesions alone (30/97, 30.9%) or the combination of both lesion types (60/97, 61.9%).

While the sensitivity of BME for diagnosing axSpA did not change, the specificity improved when chronic lesions were also present (Tab.1). In addition, based on rheumatologists´ diagnosis, the respective odds ratio (OR) for identifying axSpA by MRI was higher when chronic lesions were present (Tab.1). MRI scores were significantly higher in axSpA vs. non-SpA patients, indicating that axSpA is associated with deeper BME or chronic lesions (Tab.2).

Conclusion: The combination of structural changes and BME lesions as assessed by MRI performed best in the process of identifying axSpA in consecutive patients in a real-life setting. The discrepancy in diagnosis between rheumatologists and radiologists reflects the increasing insecurity of including only BME of SIJ as the major criterium for diagnosing axSpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical I: Imaging in Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Low grade bone marrow edema (BME) on magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) is challenging the discrimination between patients with early axial spondyloarthritis (SpA) and mechanical back pain. In our previous analysis, recreational and elite athletes had on average 3-4 SIJ quadrants with BME, and 30-41% met the Assessment of SpondyloArthritis international Society (ASAS) definition of active sacroiliitis [1]. Potential conditions simulating SIJ BME such as vascular partial volume effect or anatomical SIJ variants could not be explored due to standard semi-coronal MRI scans only. Our goals by assessing combined semi-axial and semi-coronal SIJ MRI scans in 2 cohorts of young athletes were to explore the frequency and topography of non-specific BME by 2 perpendicular MRI planes, its association with 4 constitutional SIJ features, and potential limitation of false positive assignments of ASAS-defined sacroiliitis by standard semi-coronal scans alone.

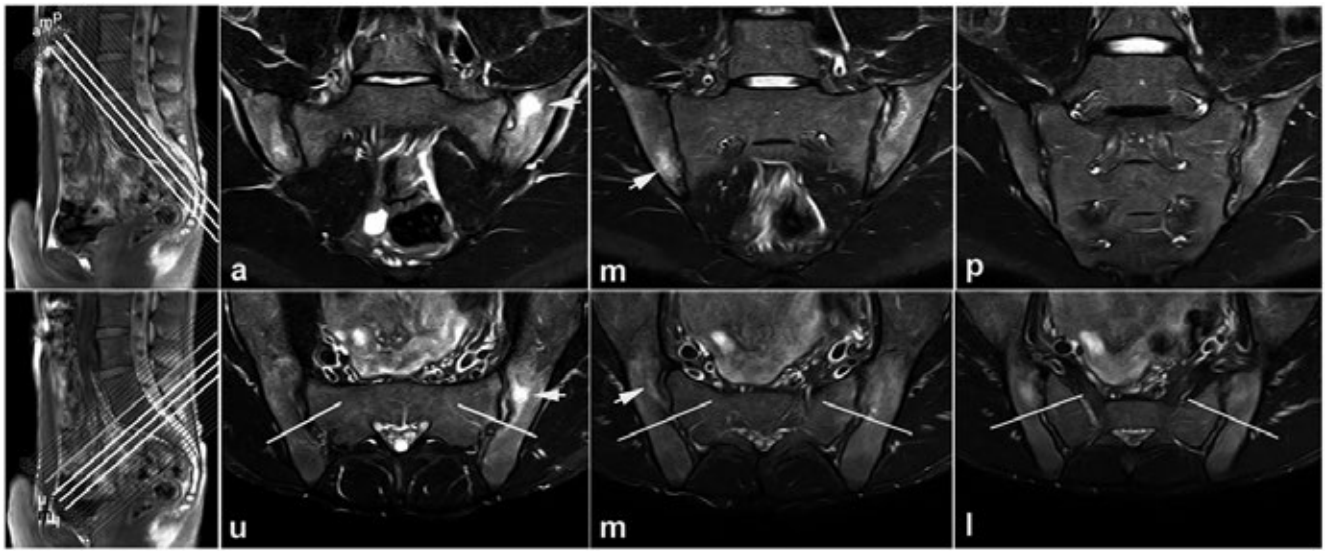

Figure 1. SIJ MRI with semi-coronal (upper row) and semi-axial (lower row) scans. Scout lines on the left panel visualize the orientation of the 2 perpendicular planes. Arrows indicate subchondral BME in corresponding anatomic location on both planes in a patient with axial SpA.

Table 1

	Runners before running (n=20)	Runners after running (n=20)	Ice-hockey players (n=22)
BME			
BME on 2 planes: n (%)	5 (25.0)	5 (25.0)	6 (27.3)
BME on semi-coronal plane[1]: n (%)	7 (35.0)	6 (30.0)	9 (40.9)
BME on 2 planes and BME on semi-coronal plane[1]: n (%)	4 (20.0)	4 (20.0)	4 (18.2)
BME on 2 planes but not on semi-coronal plane[1]: n (%)	1 (5.0)	1 (5.0)	2 (9.1)
BME on semi-coronal plane[1] but not on 2 planes: n (%)	3 (15.0)	2 (10.0)	5 (22.7)
Constitutional sacroiliac joint feature			
≥1 sacroiliac joint feature: n (%)	6 (30.0)	4 (20.0)	8 (36.4)
≥2 sacroiliac joint features: n (%)	0	0	1 (4.5)
Vascular partial volume effect: n (%)	2 (10.0)	1 (5.0)	4 (18.2)
Deep iliac ligament insertion: n (%)	3 (15.0)	2 (10.0)	2 (9.1)
Fluid-filled bone cyst: n (%)	0	0	2 (9.1)
Lumbosacral transitional anomaly: n (%)	1 (5.0)	1 (5.0)	1 (4.5)

Table 1. Frequency of sacroiliac joint BME on 2 perpendicular MRI planes versus on standard semi-coronal scans fulfilling the ASAS definition of active sacroiliitis, and frequency of BME associated with 4 constitutional sacroiliac joint features. n (%): number of subjects (percentage) showing a given feature as concordantly reported by ≥2/3 readers.

Methods: Combined semi-axial and semi-coronal SIJ MRI scans of 20 recreational runners before/after running and 22 elite ice-hockey players were evaluated by 3 blinded readers for BME and its association with 4 constitutional SIJ features: vascular partial volume effect, deep iliac ligament insertion, fluid-filled bone cyst, and lumbosacral transitional anomaly. Scans of TNF-treated SpA patients served to mask readers. Pre-test reader agreement for BME on semi-axial scans was calculated by single measure, absolute agreement intraclass correlation coefficient (ICC). We analysed distribution and topography of BME and associated constitutional SIJ features across 8 anatomical SIJ regions (upper/lower ilium/sacrum, subdivided in anterior/posterior slices) descriptively, as concordantly recorded by ≥2/3 readers on both MRI planes. BME confirmed on both scans was compared with previous evaluation of semi-coronal MRI alone which met the ASAS definition for active sacroiliitis.

Results: ICC agreement among 3 readers for semi-axial SIJ BME was 0.86 (0.72-0.95). Perpendicular semi-axial and semi-coronal MRI scans confirmed SIJ BME consistently in 25% and 27% of athletes, preferentially in the anterior upper sacrum. BME associated with 4 constitutional SIJ features was observed in 20-36% of athletes, clustering in the posterior lower ilium. The proportion of ASAS-positive sacroiliitis recorded on semi-coronal plane alone decreased by 30-50% upon amending semi-axial scans (from 30-35% to 20% in runners, from 41% to 18% in ice-hockey players).

Conclusion: Semi-axial combined with standard semi-coronal scans in MRI protocols for sacroiliitis facilitated recognition of non-specific BME, which clustered in the posterior lower ilium in association with constitutional SIJ features, and in the anterior upper sacrum. The proportion of false-positive ASAS assignments of sacroiliitis recorded on semi-coronal plane alone could be substantially reduced by amending semi-axial scans.

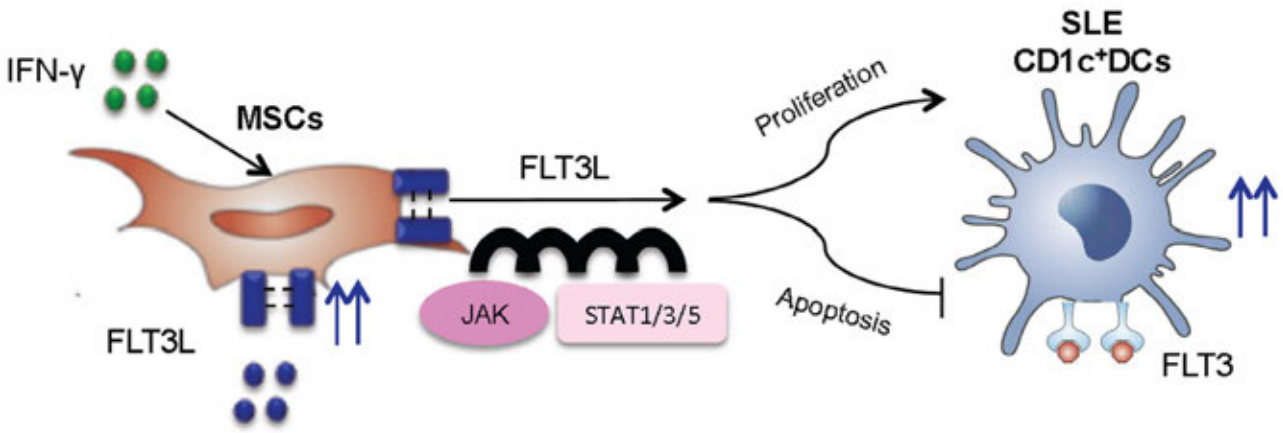
Mesenchymal Stem Cell Therapy Induces FLT3L and CD1c$^+$ Dendritic Cells in Systemic Lupus Erythematosus Patients

Xinran Yuan,[1] Dandan Wang,[1] and **Lingyun Sun**[2], [1]Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China (People's Republic), [2]The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, Jiangsu, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical I: Clinical Trials
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Allogeneic mesenchymal stem cells (MSCs) exhibit immunoregulatory function in human autoimmune diseases such as systemic lupus erythematosus (SLE), but the underlying mechanisms remain incompletely understood.



Methods: Totally, 166 SLE patients and 78 healthy subjects were included in this study. Tolerogenic DCs were isolated as Lin(CD3/19/56/14)$^-$ HLA DR$^+$CD11c$^+$CD1c$^+$ from peripheral blood mononuclear cells (PBMCs). Level of tolerogenic DCs was determined by flow cytometry, and serum concentration of FLT3L was assessed by ELISA from healthy controls and SLE patients. Twenty-one SLE patients were given MSCs infusions. We compared the number and function of tolerogenic DCs, as well as serum FLT3L before and after MSCs transplantation. PBMCs from SLE patients were collected and co-cultured with MSCs, to detect the number and function of tolerogenic DCs. The level of FLT3L in the supernatant solution was analyzed. FLT3L siRNA was added to the co-culture system, and the level of tolerogenic DCs was detected.

Results: Here we show that the number of peripheral tolerogenic CD1c$^+$ dendritic cells (DCs) and the levels of serum FLT3L are significantly decreased in SLE patients especially with lupus nephritis, compared to healthy controls. Transplantation of allogeneic umbilical cord-derived MSCs (UC-MSCs) significantly up-regulates peripheral blood CD1c$^+$DCs and serum FLT3L. Mechanistically, UC-MSCs express FLT3L that binds to FLT3 on CD1c$^+$DCs to promote the proliferation and inhibit the apoptosis of tolerogenic CD1c$^+$DCs. Conversely, reduction of FLT3L with small interfering RNA in MSCs abolishes the up-regulation of tolerogenic CD1c$^+$DCs in lupus patients treated with MSCs. Interferon-γ induces FLT3L expression in UC-MSCs through JAK/STAT signaling pathway.

Conclusion: In summary, allogeneic MSCs might suppress inflammation in lupus through up-regulating tolerogenic DCs.

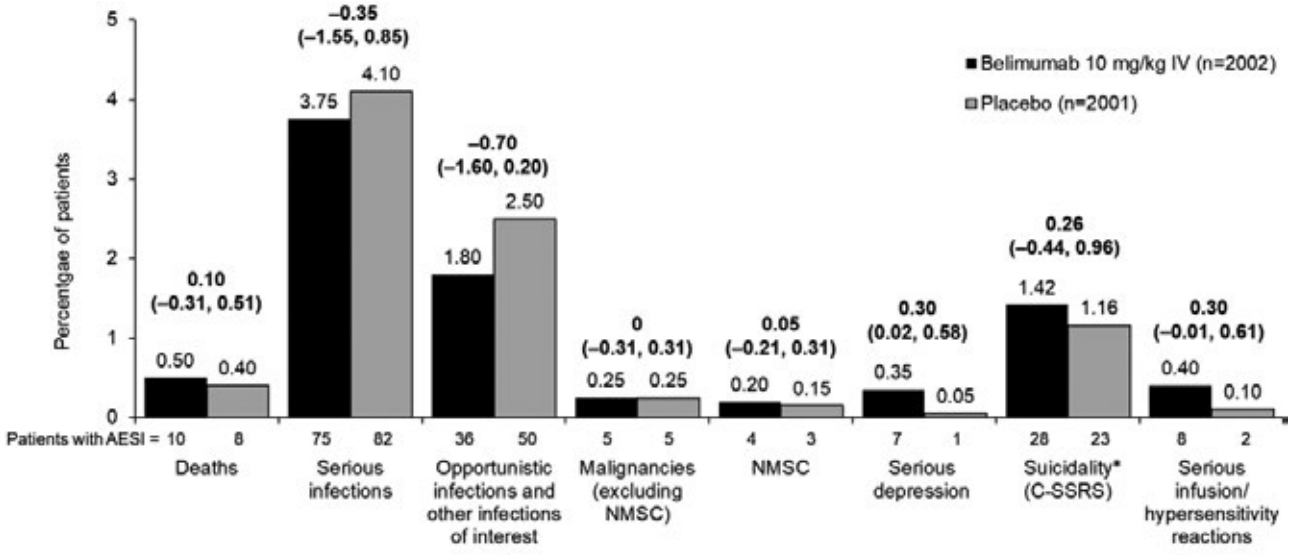
Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical I: Clinical Trials

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM



*Treatment-emergent suicidal ideation/behavior; belimumab: n=1972, placebo: n=1986.
Difference in % (95% CI) vs placebo displayed above bars. One patient was randomized to placebo but incorrectly received belimumab for >50% of doses, so is included in the belimumab arm for safety analyses (as-treated population).
CI, confidence interval; C-SSRS, Columbia-Suicide Severity Rating Scale; NMSC, non-melanoma skin cancer.

Figure. Prespecified AESI endpoints in the BASE study (on-treatment period: as-treated population)

Background/Purpose: Belimumab (BEL), approved in active, autoantibody-positive SLE, has demonstrated a positive efficacy/safety profile while suggesting potential for steroid sparing and reduced organ damage accrual. BASE, a placebo-controlled study, evaluated all-cause mortality and adverse events of special interest (AESIs), and limited efficacy endpoints.

Methods: Adults who met ACR SLE criteria were randomized (1:1) to monthly BEL 10 mg/kg IV or placebo (PBO) plus standard of care for 48 weeks. There was no minimum disease activity required or exclusions for psychiatric conditions, and no protocol mandated corticosteroid (CS) taper or assessment of change in disease activity. For primary endpoints of mortality and AESIs (reported previously), differences in rates (95% CI) were assessed vs PBO on-treatment (first to last dose +28 days). Serious suicidal ideation/behavior and self-injury events on-treatment, and C-SSRS suicidal ideation/behavior on-study (first dose to end of Week 52 follow up) were assessed (differences calculated *post hoc*). Percentages of patients with baseline CS dose >7.5 mg/day whose dose to treat SLE reduced by ≥25% to ≤7.5 mg/day (Weeks 40−52), SLE immunomodulator use (baseline vs treatment completion), study hospitalizations, and organ damage accrual (Week 52), were assessed.

Results: Baseline demographics and disease activity/characteristics were similar between groups. All-cause mortality was also similar (**Figure**); most deaths were due to infections (9 [0.45%] BEL, 3 [0.15%] PBO). On-study deaths occurred in 13 (0.65%) BEL and 22 (1.10%) PBO patients (difference [95% CI]: –0.45 [–1.03, 0.13]). Rates of on-treatment AESIs were similar, except for serious depression and serious infusion/hypersensitivity reactions (**Figure**).

On-treatment serious suicidal ideation/behavior and self-injury sponsor-adjudicated events occurred in 15 (0.75%) BEL and 5 (0.25%) PBO patients (difference [95% CI]: 0.50 [0.06, 0.94]); on-study suicidal ideation/behavior (C-SSRS) occurred in 48 (2.43%) BEL and 39 (1.96%) PBO patients (difference [95% CI]: 0.47 [–0.44, 1.38]). There were no suicide-related deaths.

Efficacy endpoints were assessed in those receiving ≥1 dose (intent-to-treat; 2001 BEL, 2002 PBO). More BEL vs PBO patients had a SLE CS dose reduction (**Table**). SLE immunomodulator use did not change vs baseline. Hospitalizations were similar between groups. BEL impact on organ damage, if any, was minimal.

Conclusion: In the largest, double-blind, placebo-controlled SLE study to date, on-treatment all-cause mortality, infection, and malignancy AESI rates were similar between BEL and PBO; imbalances were observed in serious depression, serious suicidal ideation/behavior and self-injury events, and serious infusion/hypersensitivity reactions. BEL reduced SLE CS use in high-dose patients; the effect was small and without supporting parallel disease activity measures. There was no change in SLE immunomodulator use, no differences in hospitalizations, and organ damage impact was minimal, as in other BEL studies.

n/N (%)	Placebo (n=2002)	Belimumab 10 mg/kg IV (n=2001)	Odds ratio vs PBO (95% CI)
Corticosteroid (to treat SLE) dose reduction of ≥25% to ≤7.5 mg/day during Weeks 40–52*	160/990 (16.2)	196/986 (19.9)	1.30 (1.03, 1.65); p=0.0284

Long-term Outcome of a Randomized Controlled Trial Comparing Tacrolimus with Mycophenolate Mofetil as Induction Therapy of Severe Lupus Nephritis

Chi Chiu Mok,[1] Ling Yin Ho,[2] Shirley Ying,[3] Woon Leung Ng,[4] and Man Chi Leung[4], [1]Department of Medicine, Tuen Mun Hospital, Hong Kong, China (People's Republic), [2]Tuen Mun Hospital, Hong Kong, Hong Kong, [3]Princess Margaret Hospital, Hong Kong, Hong Kong, [4]United Christian Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical I: Clinical Trials
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: To report the 10-year outcome of patients with lupus nephritis (LN) treated with combined prednisolone with mycophenolate mofetil (MMF) or tacrolimus (TAC) as induction in a randomized controlled trial (RCT).

Methods: Patients with active LN were randomized to receive MMF (2-3g/day) (N=76) or TAC (0.1-0.06mg/kg/day) (N=74) in combination with high-dose prednisolone (0.6mg/kg/day for 6-8 weeks and tapered) as induction therapy between 2005 and 2012. Complete renal (CR) or good partial renal responders were switched to azathioprine (AZA) (2mg/kg/day) for maintenance. We hereby report the 10-year outcomes of the patients in terms of renal flares (proteinuric/nephritic), renal function decline (drop in eGFR by ≥30% from baseline), development of chronic kidney disease (CKD) stage 4/5 (eGFR< 30ml/min) and mortality. Factors affecting renal prognosis were studied by Cox regression analysis. Renal parameters (urine P/Cr ratio [uPCr], eGFR) at different time points from 6 to 24 months were studied for their predictive value of a poor renal prognosis by ROC analysis.

Results: 150 patients (92% women) were studied (age 35.5±12.8 years, ISN/RPS class III±V 36%; IVG/S±V 46%; pure V 19%, activity and chronicity score 8.2±3.4 and 2.6±1.6, respectively). At entry, 67% patients had eGFR< 90ml/min. The rate of CR at 6m was 59% in MMF and 62% in the TAC group (p=0.71). Maintenance AZA was given to 79% patients. After a follow-up of 118.2±42 months, proteinuric and nephritic renal flares occurred in 34% and 37% of

patients treated with MMF and 53% and 30% in those treated with TAC, respectively. There was a total of 77 renal flares in 43 (57%) MMF-treated patients (0.11/patient-year) and 92 renal flares in 46 (62%) patients treated with TAC (0.12/patient-year; p=0.44). The cumulative risk of renal flare in patients treated with MMF/AZA was 28% at 3 years, 42% at 5 years and 58% at 10 years, whereas the corresponding figures for those treated with TAC/AZA was 32% at 3 years, 53% in 5 years and 66% in 10 years (p=0.43). Time to first renal flare was 70.4±47.1 months in MMF group and 65.2 ±50 months in the TAC group (p=0.61). The cumulative incidence of a composite outcome of eGFR decline by ≥30%, development of CKD stage 4/5 or death at 5 and 10 years was 24% and 33%, respectively, in patients treated with MMF, and 17% and 33%, respectively, in those treated with TAC (p=0.90). Factors significantly associated with this outcome were first time lupus nephritis (HR 0.26[0.11-0.59]; p=0.001), uPCR at 6m (HR 1.33[1.02-1.76]; p=0.04) and eGFR at 6m (HR 0.98[0.97-0.997]; p=0.02). ROC analysis demonstrated that an eGFR cut-off of 80ml/min (AUC 0.70; sensitivity 0.64, specificity 0.66) and uPCR cut-off of 0.75 (AUC 0.73; sensitivity 0.69, specificity 0.74) at month 18 best predicted CKD stage 4/5 or decline of eGFR by ≥30%.

Conclusion: Long-term data of our RCT showed that TAC remained non-inferior to MMF as induction therapy of LN in terms of renal flares, renal function decline and mortality. Relapsed renal disease, lower eGFR and more proteinuria post-induction therapy were associated with a poorer outcome. An uPCR ≤0.75 and eGFR of >80ml/min at 18 months best predicted a better outcome at 10 years, and should be considered as a target for induction/consolidation therapy.

Efficacy of Belimumab in Patients of Black Race with Systemic Lupus Erythematosus and High Disease Activity or Renal Manifestations

Luiz Sergio Guedes Barbosa,[1] Amit Saxena,[2] Ellen M Ginzler,[3] **Richard Furie**,[4] David D'Cruz,[5] Susan Burriss,[6] Jennifer Gilbride,[7] Michelle Miller,[6] James Groark,[6] David Roth,[6] and Beulah Ji[8], [1]NUTEC - Núcleo de Terapia Especializada em Cancerologia, Cuiaba, Brazil, [2]New York University School of Medicine, New York, NY, [3]State University of New York Downstate Medical Center, Brooklyn, NY, [4]Northwell Health, Great Neck, NY, [5]The Louise Coote Lupus Unit, Guy's Hospital, London, England, United Kingdom, [6]GSK, Collegeville, PA, [7]GSK, Stevenage, Hertfordshire, United Kingdom, [8]GSK, Uxbridge, Middlesex, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical I: Clinical Trials
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Black patients have more severe SLE and more frequent lupus nephritis vs other racial groups. Efficacy and safety of intravenous (IV) belimumab was demonstrated in three Phase 3 SLE studies; few black patients were included, limiting subgroup analyses. The EMBRACE study assessed efficacy and safety of IV belimumab plus standard of care (SoC) in black patients with SLE. Primary and key secondary endpoints have been presented;[1] here we focus on efficacy in patients with high disease activity (HDA) and renal manifestations.

Methods: EMBRACE (NCT01632241; GSK study 115471) is a multicenter, double-blind, placebo-controlled trial in patients of self-identified black race, ≥18 years, with active SLE by ACR criteria at screening. Patients were randomized (2:1) to receive monthly belimumab 10 mg/kg IV or placebo, plus SoC. The primary endpoint was the difference in modified SLE Responder Index (SRI-S2K) response rates between belimumab and placebo. SRI-S2K incorporates the SLEDAI-2K (S2K) proteinuria definition (>0.5 mg/24 h) rather than the SELENA-SLEDAI (SS) version (>0.5 mg/24-h

increase). A response is defined as ≥4-point reduction in S2K, no worsening [increase < 0.3] in Physician's Global Assessment, and no new BILAG A/2 B domain scores. SRI response (SS proteinuria scoring) at Week 52 was a key secondary endpoint. Subgroup analyses of SRI-S2K and SRI in patients with HDA (anti-dsDNA antibody positive, hypocomplementemia, or high SS-S2K scores [SS with S2K proteinuria scoring]) at baseline were performed. Other endpoints included time to renal flare, change from baseline in SS-S2K renal domain, and in proteinuria, over 52 weeks.

Results: No significant differences were seen in the mITT population (N=448) for SRI-S2K (**Table**). Among patients meeting HDA definitions at baseline, greater proportions were SRI-S2K responders at Week 52 with belimumab vs placebo; in the high anti-dsDNA group, the difference numerically favored belimumab. Similar results were observed with the SRI.

Belimumab patients (mITT) had a 46% lower risk of a renal flare vs placebo (hazard ratio [95% CI]: 0.54 [0.21, 1.36]; p=0.1880). Among those with baseline renal involvement measured by SS-S2K, numerically more belimumab patients experienced improvements in this domain at Week 52 vs placebo (23/55 [41.8%] vs 7/34 [20.6%]). Among those without baseline renal involvement measured by SS-S2K, the percentage worsening at Week 52 was low for both groups (placebo: 9/115 [7.8%], belimumab: 15/244 [6.1%]). In patients with baseline proteinuria >0.5 g/24 h, median (interquartile range) percentage reduction at Week 52 was numerically greater with belimumab (-65.3% [-81.1, -38.8%], n=38) vs placebo (-32.9% [-76.6, 36.3%], n=23; p=0.0558); more of these patients experienced proteinuria normalization (values ≤0.5 g/24 h) with belimumab (16/38 [42.1%]) vs placebo (6/23 [26.1%]) at Week 52. No new safety concerns were identified.

Conclusion: Black patients with SLE and HDA demonstrate benefits with belimumab vs placebo, with reductions in disease activity and SLEDAI renal domain scores.

Cutaneous Lupus Erythematosus Disease Area & Severity Index (CLASI) Demonstrates Thresholds for Detection of Treatment Response in a Phase-2, Placebo-Controlled Trial of Ustekinumab in SLE

Victoria Werth,[1] Bevra Hahn,[2] George Tsokos,[3] Shawn Rose,[4] Kaiyin Fei,[4] Yun Gregan,[4] Robert Gordon,[4] Kim Hung Lo,[4] and Ronald van Vollenhoven[5], [1]Hospital of the Univ of PA and Veteran's Administration Med Center, Philadelphia, PA, [2]University of California, Los Angeles, CA, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical I: Clinical Trials
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Ustekinumab (UST), an anti-IL-12/23 p40 monoclonal antibody, showed significantly greater improvement at week (wk) 24 compared with placebo (PBO) in Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) response (≥4-point improvement from baseline, BL) in a Phase 2 study.[1] Post hoc analysis revealed more UST than PBO patients (pts) achieving ≥50% improvement in total Cutaneous Lupus Erythematosus Disease Area & Severity Index (CLASI) activity score. Harmonization of measures of disease activity and improvement in SLE trials is important since the same clinical manifestations are defined differently among various assessment indices. Here, we examine the relationships of CLASI activity responses to SLEDAI-2K (S2K) mucocutaneous disease responses.

Methods: This phase 2 study enrolled adults with active SLE (S2K ≥6, ≥1 BILAG A and/or ≥2 BILAG B scores) despite standard of care therapy. Pts (n=102) were randomized (3:2) to UST IV ~6 mg/kg or PBO at wk 0, followed by SC injections of UST 90 mg or PBO every 8 wks beginning at wk 8, both added to standard of care. The S2K index, used in this analysis, measures complete improvement from BL. S2K Responder Index-50 (S2K RI-50) evaluates partial improvement and was used to assess partial (≥50%) improvement in S2K rash. CLASI rash was defined as the sum of erythema and scale/hypertrophy score. Independent adjudication of SLE assessments was performed to ensure medical plausibility and consistency of SLE disease activity scores in conjunction with all relevant pt data. In post hoc analysis, improvement in CLASI total activity score at wk 24 was calculated using increasing thresholds of BL disease activity and various cut points of improvement to define treatment response.

Results: Complete improvement from BL in rash was concordant between CLASI and S2K (correlation coefficients ≥0.997, Table 1). There was less agreement between CLASI and S2K RI-50 when assessing partial improvement

Table 1. CLASI Activity Scores Compared with SLEDAI-2K Activity

24-Week Improvement	Treatment	Activity Measure % (n/N*)		Correlation Coefficient **
		CLASI Rash†	SLEDAI-2K Rash‡	
100%	Placebo	30.8% (8/26)	30.8% (8/26)	1.0000
	Ustekinumab	28.9% (13/45)	31.1% (14/45)	0.9997
≥50%	Placebo	38.5% (10/26)	50.0% (13/26)	0.9996
	Ustekinumab	60.0% (27/45)	51.1% (23/45)	0.8693
		CLASI Mucosal Ulcer	SLEDAI-2K Mucosal Ulcer	
100%	Placebo	66.7% (8/12)	69.2% (9/13)	1.0000
	Ustekinumab	89.5% (17/19)	89.5% (17/19)	1.0000

*N=Evaluated populations with baseline SLEDAI rash present, total CLASI activity score >0, and CLASI rash or mucosal ulcer activity scores >0 in analyses of subcomponents;
**Correlation coefficients were calculated using tetrachoric correlation; †CLASI Rash = sum of erythema and scale/hypertrophy measure; ‡The SLEDAI-2K index was used to assess 100% improvement from baseline in SLEDAI-2K rash. SLEDAI-2K Responder Index-50 (S2K RI-50), was used to assess partial improvement (≥50% but less than 100% improvement) from baseline in SLEDAI-2K rash based on the percentage of body surface area involved.

in rash. A treatment difference (UST vs PBO) in the proportion of pts achieving partial improvement in rash was observed for CLASI (60% UST vs PBO 38.5%), but not S2K RI-50 (51.1% UST vs 50% PBO) (Table 1). Complete improvement from BL in mucosal ulceration was congruent between CLASI and S2K (correlation coefficient=1). Both instruments demonstrated greater proportions of responders to UST compared with PBO (Table 1). Treatment differences between UST and PBO in achievement of ≥20%, ≥35%, and ≥50% improvement from BL in total CLASI activity score were noteworthy at various thresholds of BL disease activity (Table 2).

Conclusion: CLASI was able to demonstrate partial improvement in active mucocutaneous disease that was not captured by S2K RI-50. A treatment effect favoring UST vs PBO was observed across a range of thresholds of BL CLASI activity and various cut points used to define improvement, which have previously been shown to be clinically meaningful.[2] While these findings are based on a limited sample size and duration of therapy, the results will be confirmed in an ongoing Phase 3 clinical trial of UST in SLE (NCT03517722).

First Use of Cenerimod, a Selective sphingosine-1-phosphate 1 ($S1P_1$) Receptor Modulator, for the Treatment of Systemic Lupus Erythematosus: A Double-Blind, Randomised, Placebo-Controlled, Phase II, Proof-of-Concept Study

Viktoria Hermann,[1] Anastas Batalov,[2] Svetlana Smakotina,[3] and Peter Cornelisse[1], [1]Idorsia, Allschwil, Switzerland, [2]Medical University of Plovdiv, University Hospital Kaspela, Plovdiv, Bulgaria, [3]Kemerovo Regional Clinical Hospital, Kemerovo, Russia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical I: Clinical Trials
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Aberrantly activated T- and B-lymphocytes play a major pathophysiological role in SLE. Cenerimod, a potent, selective sphingosine-1-phosphate 1 receptor modulator, blocks the egress of lymphocytes from lymphoid organs, thereby reducing their availability, thus providing rationale for development. The study investigated the effect of cenerimod on circulating lymphocytes, disease activity, safety and pharmacokinetics in SLE patients.

Methods: This study was conducted in two parts, separated by a safety review. Patients with SLEDAI-2K score ≥2 points for mucocutaneous or musculoskeletal manifestations and positive serum test for ANA or anti-dsDNA antibodies were randomised evenly in Part A to cenerimod 0.5, 1, or 2 mg or placebo once daily (QD) and 3:1 in Part B to cenerimod 4 mg or placebo QD and treated for 12 weeks. Predefined Day 1 safety assessments included heart rate (HR) monitoring and hourly 12-lead ECG monitoring (pre dose, to 6 hours post-dose). Endpoints included treatment-emergent adverse events (TEAEs), changes in total lymphocyte count, SLEDAI-2K score (modified [mSLEDAI] to exclude leucopoenia), biomarker anti-dsDNA antibody and pharmacokinetic assessments. All 67 patients (A: 49; B: 18) met at least 4 ACR criteria in the past, 70% had 4 to 11 ACR criteria ongoing at screening. Mean (SD) mSLEDAI-2K was 7.7 (±3.1) at baseline.

Table 2. Treatment Differences in Achievement of Partial Improvement in Total CLASI Activity Score at Various Thresholds of Baseline Disease Activity

Activity Measure	Improvement Threshold	Placebo % (n/N*)	Ustekinumab % (n/N*)	Difference % (UST vs PBO)
CLASI Total	≥20%	54.8 (17/31)	74.5 (38/51)	19.7
Activity Score	≥35%	41.9 (13/31)	60.8 (31/51)	18.9
Baseline >0	≥50%	41.9 (13/31)	54.9 (28/51)	13.0
CLASI Total	≥20%	58.8 (10/17)	71.9 (23/32)	13.1
Activity Score	≥35%	35.3 (6/17)	62.5 (20/32)	27.2
Baseline ≥4	≥50%	35.3 (6/17)	53.1 (17/32)	17.8
CLASI Total	≥20%	53.8 (7/13)	72.0 (18/25)	18.2
Activity Score	≥35%	30.8 (4/13)	60.0 (15/25)	29.2
Baseline ≥6	≥50%	30.8 (4/13)	52.0 (13/25)	21.2
CLASI Total	≥20%	58.3 (7/12)	70.6 (12/17)	12.3
Activity Score	≥35%	33.3 (4/12)	58.8 (10/17)	25.5
Baseline ≥8	≥50%	33.3 (4/12)	47.1 (8/17)	13.8

*N=Evaluated populations with baseline total CLASI activity score >0, ≥4, ≥6, ≥8 based on post hoc analyses. Values for subjects meeting treatment failure criteria were set to missing from the point of treatment failure forward

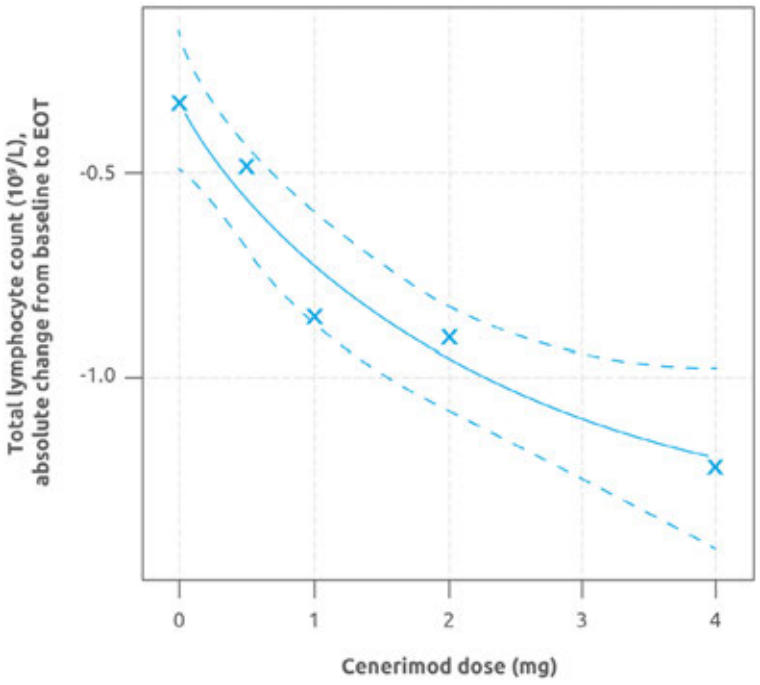

Figure 1. Estimation of dose-response relationship for absolute change from baseline to end of treatment. The MCP-Mod approach was performed for each of the five considered dose-response models. Plot shows the maximum effect (Emax) curve, with 95% CI (dashed lines), related to the model with the highest t-statistic. CI, confidence intervals; EOT, end of treatment; MCP-Mod, Multiple Comparison Procedure and Modelling.

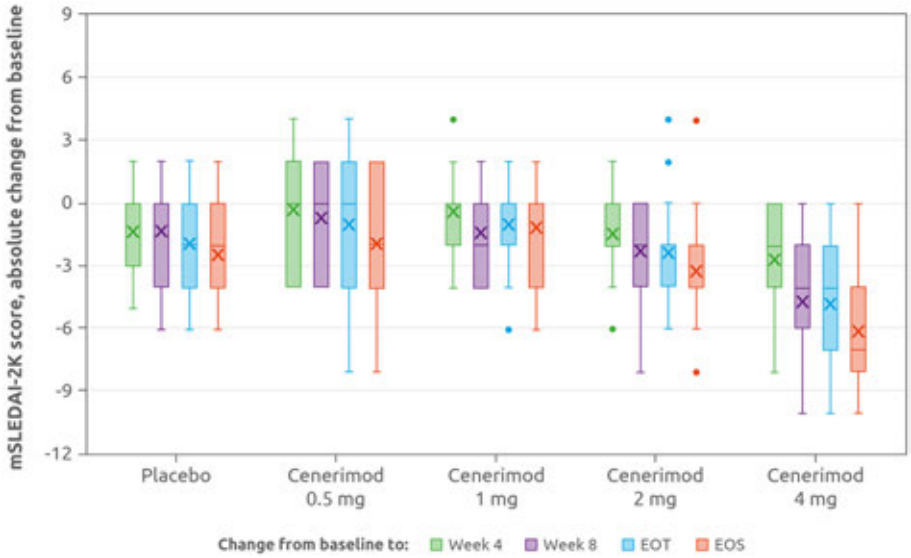

Figure 2. Absolute change from baseline in mSLEDAI-2K score. Box and whisker plot indicates the interquartile range (box), upper and lower 1.5 interquartile range (whiskers), mean and median (cross and horizontal line, respectively, within the box), and outliers at least above or below 1.5 times the interquartile range (dots). mSLEDAI-2K modified to exclude leucopoenia. EOS, end of study; EOT, end of treatment; mSLEDAI-2K, modified SLE Disease Activity Index-2000.

Results: Part A included 49 patients (12:12:13:12 receiving cenerimod 0.5, 1, 2 mg or placebo); Part B included 18 (13 cenerimod 4 mg; 5 placebo). Cenerimod dose-dependently reduced total lymphocyte count from baseline to end of treatment (EOT; $p< 0.001$; Figure 1). In pairwise comparisons, cenerimod 1, 2, and 4 mg significantly decreased lymphocytes versus placebo (all $p< 0.001$). Exploratory analyses indicated clinical and biological improvement with

cenerimod 4 mg with an estimated mean treatment effect on change from baseline to EOT in mSLEDAI-2K score of –2.420 (p=0.0306; Figure 2), and a decrease in anti-dsDNA of –28.80 U/mL (p=0.0146) compared with placebo. All treatment groups reported similar and non-dose-related rates of TEAEs (cenerimod 0.5: 41.7%; 1: 41.7%; 2: 46.2%; 4 mg: 38.5%; and placebo: 58.8%). After the first dose, cenerimod induced minimal, transient and dose-dependent decreases in HR; no patient had an HR < 40 bpm at any time post baseline. Small decreases in pulmonary function, not dose-related, were observed in cenerimod-treated patients at EOT. Cenerimod did not increase blood pressure or show any effects on laboratory variables. Trough plasma concentrations revealed steady-state conditions were reached after 4–8 weeks of QD dosing and dose-proportionality was observed.

Conclusion: Cenerimod has the potential to be a new therapeutic approach for patients with SLE and has shown to date an acceptable efficacy and safety profile with minimal, non-clinically relevant cardiovascular effects. These results warrant further evaluation in a larger study over a longer treatment duration. A Phase IIb, randomised dose-finding study was initiated in December 2018 to evaluate efficacy and safety of cenerimod in addition to background therapy in moderate-to-severe SLE (NCT03742037).

Tofacitinib in Early Diffuse Cutaneous Systemic Sclerosis— Results of Phase I/II Investigator-Initiated, Double-Blind Randomized Placebo-Controlled Trial

Dinesh Khanna,[1] Erica Bush,[2] Vivek Nagaraja,[2] Andrew Koenig,[3] Puja Khanna,[4] Amber Young,[5] Jeffrey Moore,[6] David Fox,[6] and Robert Lafyatis[7], [1]Scleroderma Program, Division of Rheumatology, Department of Internal Medicine, Autoimmunity Center of Excellence, University of Michigan, Ann Arbor, [2]University of Michigan, Ann Arbor, MI, [3]Rheumatology, Collegeville, [4]University of Michigan Medical School, Ann Arbor, [5]University of Michigan, Ann Arbot, [6]University of Michigan, Ann Arbor, [7]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Tofacitinib (TOFA) is a potent pan inhibitor of the Janus Kinase (JAK) family of kinases with a high degree of selectivity against JAK1 and JAK3 more than TYK2 or JAK2. This Phase I/II trial assessed the safety of TOFA 5 mg twice a day versus placebo (PLA) in diffuse cutaneous systemic sclerosis (dcSSc; clinicaltrials.gov NCT03274076).

Methods: A 6-month, 2 center, double-blind, randomized placebo-controlled trial was conducted between November 2017 and August 2018. Participants were randomized to either TOFA or matching PLA. Key inclusion criteria included dcSSc with disease duration of ≤ 60 months (defined as first non–Raynaud phenomenon) and modified Rodnan skin score (mRSS) ≥ 10 and ≤ 45 units. Background stable immunosuppressive therapies were allowed and varicella-zoster vaccine was required (unless previously received). Open label therapy was offered at Month 6. Primary outcome included the proportion of participants who experience Grade 3 or higher adverse events (AEs) using the

NIH guidance: Common Terminology Criteria for Adverse Events (CTCAE v4.03[1]) that occur at or before Month 6. Efficacy end points include mRSS, Health Assessment Questionnaire-Disability Index (HAQ-DI), patient and physician global assessments, and the ACR composite measure: Combined Response Index in Systemic Sclerosis (CRISS) [2]. The current abstract provides results from the double blind phase of the trial.

Results: 15 participants were randomized (2:1; 10 to TOFA and 5 to PLA) and formed the mITT group; 10 (100%) and 4 (80%) completed the 6-month treatment period in TOFA and PLA groups, respectively. Thirteen (13) of 15 participants were on stable daily doses of mycophenolate mofetil (mean dose=1700 mg; N=12) or weekly methotrexate (dose = 25 mg, N=1). Both the active and placebo group had 1 participant on methotrexate, leaving 8 of the TOFA participants on background mycophenolate as well as 3 in the PLA group. At baseline, mean/median age was 50.3/50.0 years, 66.7% were female, mean/median disease duration was 2.1/ 2.0 years, mean/median mRSS was 23.3/23.0, and mean/median HAQ-DI was 0.98/0.88. TOFA was well tolerated with no Grade 3 or higher AE's before or at month 6. There were comparable AEs and AEs of special interest between treatments with no serious AEs or deaths in the trial. There were trends in efficacy favoring TOFA vs. PLA at month 6, including mRSS and ACR CRISS.

Outcome at or before Month 6	Tofacitinib N=10	Placebo N=5
Number of Grade 3 of higher AE's	0	0
Number of Grade 2[1] of higher AE's	14	10
Number of treatment emergent AE's	21	12
Infections and Infestations	4	1
Gastrointestinal Disorders	4	1
General Disorders	1	4
Musculoskeletal and Connective Tissue Disorders	1	3
Skin and subcutaneous Disorder	3	0
Investigations	2	1
Respiratory, Thoracic, and Mediastinal Disorders	2	0
Nervous System Disorders	2	0
Cardiac Disorders	1	1
Renal and Urinary Disorders	0	1

Table 1. Safety outcomes during the double blind phase of the trial

Outcome at Month 6	Tofacitinib N=10	Placebo N=5	P-value
*ΔmRSS, 0-51, mean/median**	-5.8, -6.0	-2.3, -3.0	0.42
*ΔPatient Global Assessment, 0-10, mean/median **	0.0, 0.0	-2.8, -1.5	0.06
*ΔPhysician Global Assessment, 0-10, mean/median **	-1.6, -1.5	0.5, 0.5	0.04
*ΔHAQ-DI, mean/median **	-0.11, -0.06	0.06, 0.13	0.35
*ACR CRISS index, median**	0.30	0.10	0.68

*Two-sample t-tests (Kruskal-Wallis Test), Δ= change

Table 2. Efficacy measures during the double blind phase of the trial

Conclusion: In participants with dcSSc, TOFA was well tolerated with manageable AEs, with no Grade 3 or higher AEs, no SAEs and there were trends in improvement of clinical outcome measures. This study supports further evaluation of TOFA in dcSSc.

Change in Scleroderma Skin Histology Correlates with the Combined Response Index in Systemic Sclerosis (CRISS) in Patients with Early, Diffuse Cutaneous Systemic Sclerosis

Kimberly Showalter,[1] Robert Spiera,[1] Dana Orange,[2] Cynthia Magro,[3] Yaxia Zhang,[4] Jackie Finik,[5] and Jessica Gordon[1], [1]Hospital for Special Surgery, New York, NY, [2]Rockefeller University, New York, [3]Weill Cornell Medicine, New York, [4]Hospital for Special Surgery, New York, [5]Hospital for Special Surgery, New York, NY, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The Combined Response Index in Systemic Sclerosis (CRISS) is a composite outcome measure provisionally endorsed by the American College of Rheumatology for use in systemic sclerosis (SSc) clinical trials. In two early, diffuse SSc trials, skin histologic change within patients was evaluated at baseline and 52-weeks. The purpose of this study is to determine if change in skin histologic severity correlates with CRISS.

Methods: Paired baseline and 52-week post-treatment clinical data and forearm skin histology were examined from patient specimens in the Nilotinib (n=6) and Belimumab (n=18) trials. During these trials, a dermatopathologist (CM), blinded to clinical response, evaluated global histologic severity (pathologist overall impression on hematoxylin and eosin stain), infiltrate intensity, collagen density, and alpha-smooth muscle actin (aSMA) and CD34 staining intensity on a semi-quantitative scale (0-3), and measured thickness (epidermis to subcutis) and follicle count. The validation of these methods is presented separately. CRISS was calculated using 52-week change in physician and patient global assessment (0-10), % predicted forced vital capacity (FVC), health assessment questionnaire disability index (HAQ-DI), and modified Rodnan skin score (MRSS). Patients were assessed for criteria that renders CRISS score zero (scleroderma renal crisis, FVC decline >15% predicted, new heart failure, or new pulmonary arterial hypertension treatment). Wilcoxon rank sum or Kruskal-Wallis tests were performed to evaluate differences in CRISS according to histologic change. Spearman correlation was used to evaluate the correlation between histologic change and CRISS.

Results: 24 diffuse SSc patients contributed baseline and 52-week biopsies. Most were female (79%) and Caucasian (75%) with median [IQR] disease duration of 0.9 [0.6, 1.2] years. 54% were RNA polymerase III positive. Baseline

Table 1. Histologic change and Composite Response Index in Systemic Sclerosis (CRISS) at 52-weeks in 24 patients with diffuse cutaneous systemic sclerosis

Histologic Variable	Median [IQR] CRISS	p-value
Global Histologic Severity		0.02
Worse (n=6)	0.34 [0.00, 0.82]

Improved (n=15)	1.00 [0.84, 1.00]	
CD34 Staining Intensity		0.01
Decreased or Stable* (n=4)	0.34 [0.00, 0.69]	
Increased (n=20)	1.00 [0.83, 1.00]	
aSMA Staining Intensity		0.08
Decreased (n=13)	0.55 [0.27, 0.96]	
Stable (n=4)	0.55 [0.21, 0.84]	
Increased (n=7)	0.77 [0.00, 0.90]	
Collagen Density		0.08
Decreased (n=15)	0.77 [0.27, 0.97]	
Stable (n=4)	0.51 [0.05, 0.96]	
Increased (n=5)	0.00 [0.00, 0.68]	
Follicle Count		0.83
Decreased (n=7)	0.90 [0.68, 0.99]	
Stable (n=9)	0.55 [0.09, 0.91]	
Increased (n=8)	0.02 [0.01, 0.66]	
Infiltrate Intensity		0.47
Decreased (n=11)	0.55 [0.02, 0.92]	
Stable (n=8)	0.76 [0.22, 0.95]	
Increased (n=5)	0.00 [0.00, 0.96]	
Thickness		0.54
Decreased (n=9)	0.89 [0.42, 0.96]	
Stable (n=3)	0.55 [0.00, 0.68]	
Increased (n=12)	0.29 [0.01, 0.93]	

Legend: aSMA=alpha-smooth muscle actin. *Only 1 paired sample demonstrated decreased CD34 staining intensity; therefore, decreased and stable CD34 pairs were combined for analysis.

Table 2. Correlation between 52-week histologic change and the Composite Response Index in Systemic Sclerosis (CRISS) in 24 patients with diffuse cutaneous systemic sclerosis		
Histology Response Score and CRISS	**Spearman's Correlation Coefficient**	**p-value**
Global Histologic Severity	-0.52	0.01
CD34 Staining Intensity	0.53	0.01
Alpha-Smooth Muscle Actin Staining Intensity	-0.44	0.03
Collagen Density	-0.44	0.03
Follicle Count	-0.09	0.66
Infiltrate Intensity	-0.09	0.69
Thickness (μm, epidermis to subcutis)	-0.20	0.35

median [IQR] MRSS was 24 [22, 29] and physician global assessment was 5.8 [5.0, 6.8]. Mean (SD) patient global assessment was 3.2 (2.53) and HAQ-DI was 0.85 (0.59). Interstitial lung disease was present in 7 of 24 (29%). Mean (SD) baseline % predicted FVC was 86 (16). Median [IQR] CRISS was 0.93 [0.47, 1.00].

Treatment response, measured by median CRISS, was higher (improved) in those with decreased global histologic severity (p=0.02) and increased CD34 staining intensity (p=0.01) (Table 1). CRISS correlated negatively with change (decreased, stable, or increased) in global histologic severity (r=-0.52, p=0.01), aSMA staining intensity (r=-0.44, p=0.03), and collagen density (r=-0.44, p=0.03), and correlated positively with change in CD34 staining intensity (r=0.53, p=0.01) (Table 2).

Conclusion: Improved CRISS is associated with decreased global histologic severity, aSMA staining intensity, and collagen density, and increased CD34 staining intensity, suggesting these histologic features are treatment responsive and provide clinically meaningful information. Median CRISS in those with global histologic worsening was below the threshold of 0.6 that defines CRISS improvement in SSc trials. Future work may determine if baseline histologic features predict clinical response, measured by CRISS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Lenabasum is a synthetic, non-immunosuppressive, selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses and limits fibrosis in animal models of SSc. Lenabasum had acceptable safety and tolerability, and improved efficacy outcomes in the 16-week, double-blinded, randomized, placebo-controlled Part A of Phase 2 trial JBT101-SSc-001 (NCT02465437) in dcSSc subjects. The purpose of this study is to provide long-term open-label safety and efficacy data in study JBT101-SSc-001.

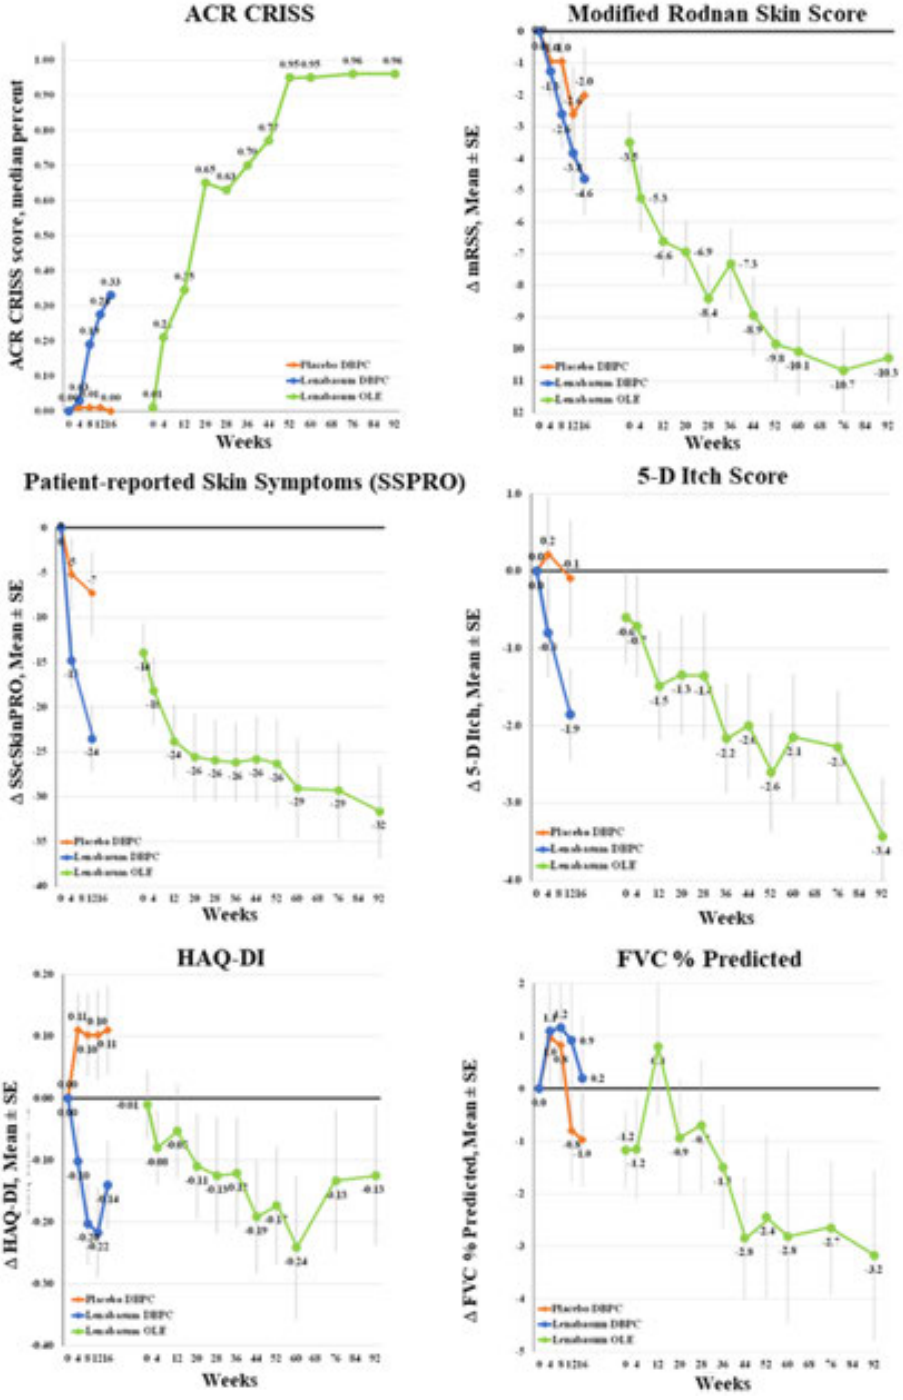
Methods: Subjects who completed Part A were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) that assessed safety and efficacy at 4 weeks, then every 8 weeks.

Results: 36/38 (95%) eligible subjects enrolled in the OLE. At data cut in March 2019, 29/36 (81%) patients remained in the OLE and had completed at least Week 92 in the study. Four subjects withdrew consent, 2 subjects withdrew due to AEs unrelated to lenabasum (tendonitis and scleroderma renal crisis), and 1 subject withdrew for other reasons. At Week 92, 35 (97%) subjects experienced at least 1 AE, with 249 total AEs. Seven (19%) subjects had ≥ 1 AE considered related to lenabasum in the OLE and 3 had AEs judged to be probably or definitely related to lenabasum: 1 had mild fatigue, 1 had a moderate skin ulcer and moderate lymph node pain, and 1 had mild disturbance in attention and mild lethargy and moderate feeling abnormal. Most subjects experienced AEs that were mild (n = 6, 17%) to moderate (n = 23, 64%) in maximum severity. Six (17%) had severe AEs and 1 (3%) had a life-threating AE of renal crisis associated with high-dose steroids. AEs in ≥ 10% of subjects were: upper respiratory tract infection (n = 11, 31%); skin ulcer, urinary tract infection, and arthralgia (each n = 6, 17%); and diarrhea, nasopharyngitis, and cough (each n = 4, 11%). Dizziness and fatigue occurred in 3 (8.3%) subjects each.

Improvement was seen in multiple physician- and patient-reported efficacy outcomes; selected outcomes are shown in Figure 1. Compared to study start, the CRISS median score (primary efficacy outcome) was 0.96 (0.43 IQR) at Week 92 and mRSS declined by mean (SD) = -10.3 (7.2) points. Health Assessment Questionnaire-Disability Index, Physician Global Assessment, Patient Global Assessment, skin symptoms, itch, and multiple PROMIS-29 domains also improved. FVC % predicted decreased 3.2% from study start.

Conclusion: Lenabasum continues to have a favorable safety and tolerability profile in the OLE of the Phase 2 trial JBT101-SSc-001 with no serious AEs or study discontinuations related to lenabasum. Efficacy out-

Figure 1. Change from Baseline in Selected Efficacy Outcomes in OLE



comes show stable improvement from about 1 year in the OLE or continued improvement in some cases. Background therapy, natural history of the disease, and open-label dosing limit what can be definitely contributed to lenabasum.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Systemic sclerosis (SSc) causes scleroderma renal crisis (SRC) and chronic kidney disease (CKD). A previous open label trial of bosentan suggested possible benefit for CKD following SRC [1]. Here we report the results of a placebo-controlled trial of zibotentan, a highly selective endothelin A receptor antagonist, in SSc associated CKD.

Methods: ZEBRA-1 was a double-blind randomised placebo-controlled trial in SSc with CKD (eGFR 45-60 ml/min) comparing oral zibotentan 10 mg/day and placebo over 26 weeks with final safety assessment at 52 weeks (Clinical Trials NCT02047708). Efficacy was assessed by eGFR with safety a key secondary endpoint. Candidate urinary molecular markers of SSc-associated CKD were measured. Variables were compared by non-parametric Mann-Whitney U test. Pharmacokinetics (PK) were explored in ZEBRA-1 and an additional single escalating dose PK substudy (ZEBRA-2) undertaken in patients (n=8) on haemodialysis.

Results: 16 patients consented to enter ZEBRA-1. There were 3 screen failures due to renal function being ineligible on re-testing. 7 patients received placebo and 6 zibotentan. Baseline renal function was well matched between treatment groups (median eGFR in placebo 51 (44-58); zibotentan 50.5 (49-59)). Renal function was equal at 26 weeks

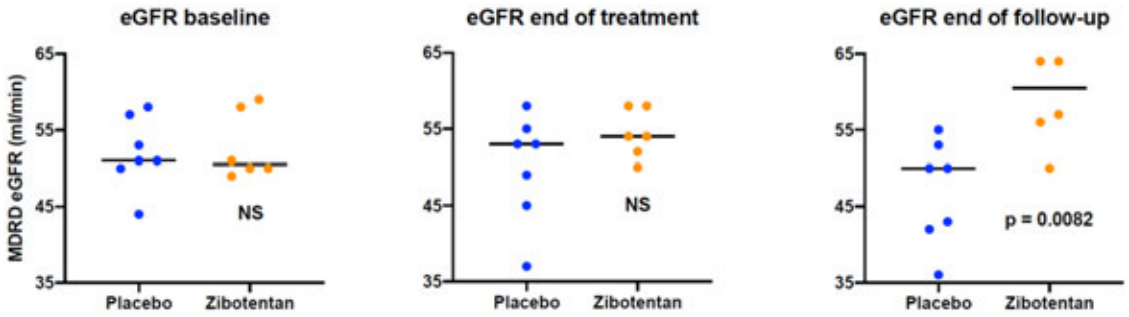

Figure 1. Impact of zibotentan or placebo on eGFR at baseline, 26 and 52 weeks

(placebo 53 (37-58); zibotentan 54 (50-58)) but eGFR significantly improved in the active treatment group at 52 weeks (placebo 50 (36-55) zibotentan 60.5 (50-74), p=0.0082) (see **Figure 1**).

Our previous work identified elevated urinary MCP-1: creatinine ratio as a marker of SSc-CKD [2]. Interestingly, levels declined on zibotentan but not in placebo. Thus, median baseline urinary MCP1/creatinine (pg/mg/L) was 7.1 (5.2-21.9) in placebo arm and 5.4 (3.1-28.9) for zibotentan, increased to 8.8 (6.3-33.5) at 26 weeks on placebo and reduced to 4.4 (2.9-11.2) on zibotentan. At 52 weeks MCP-1/creatinine for placebo arm was 7.5 (6.4-15.8) and was significantly lower at 4.5 (4.1-6.0; p=0.0095) after zibotentan.

There were 46 reported adverse events (AE) (26 placebo and 20 active treatment) in ZEBRA-1 in 11 patients (6 placebo and 5 zibotentan). Of the 46 reported AE, 6 were serious (3 in each arm). PK confirmed zibotentan levels within therapeutic range in ZEBRA-1 and suggested feasible dose regimen for dialysis patients (ZEBRA-2).

Conclusion: This is the first placebo-controlled interventional trial in renal SSc. Zibotentan was generally well tolerated. Compared with placebo, zibotentan treatment over 26 weeks was associated with improved eGFR at 52 weeks and fall in urinary MCP1:creatinine, a candidate marker for SSc kidney disease. Whilst preliminary, these results suggest targeting endothelin A in SSc associated CKD may be beneficial.

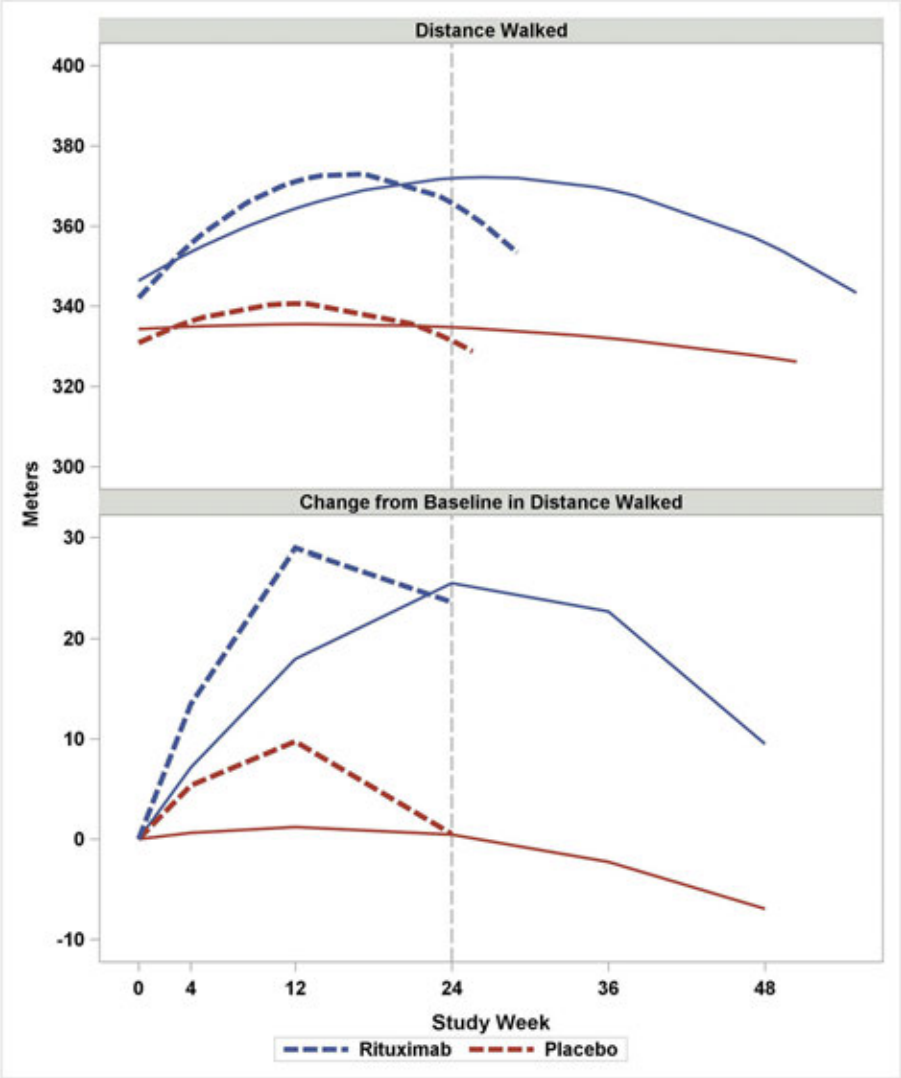
SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM



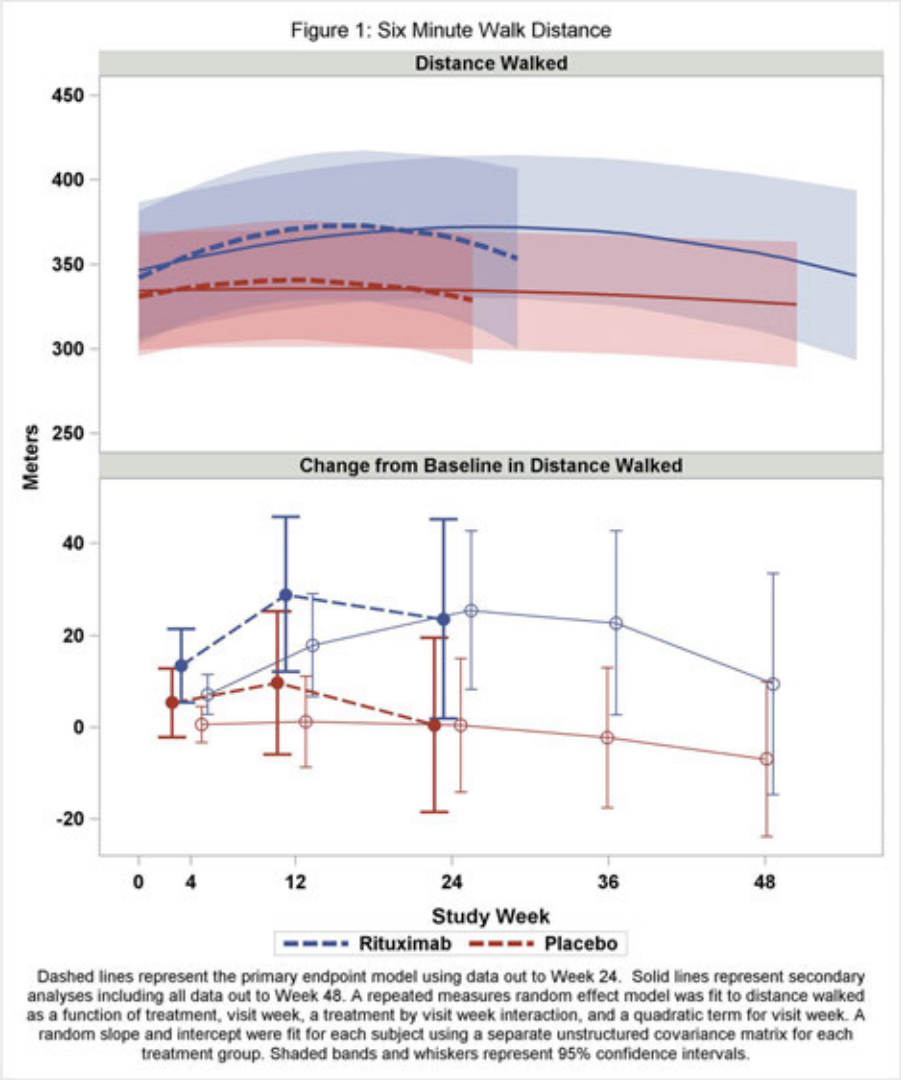


FIGURE 1. 6MWD Secondary Analysis Results. Top panel shows model-based longitudinal trends total distance walked in meters over time for both treatment groups. Lower panel shows the change in distance walked compared to baseline estimated from the model.

Background/Purpose: Pulmonary arterial hypertension (PAH) is a life-threatening complication of systemic sclerosis (SSc). Pre-clinical and clinical data have strongly implicated immune dysregulation and B cell activation in the pathogenesis of both SSc and PAH. While standard PAH therapies are approved for SSc-PAH, ongoing immune injury to the pulmonary vasculature is not routinely addressed. Consequently, we sought to determine whether B cell depletion with rituximab (Rx) could be effective in SSc-PAH.

Methods: We conducted a Phase II, randomized, double-blind, placebo-controlled multi-center clinical trial sponsored by the Autoimmunity Centers of Excellence, NIH. SSc-PAH patients on a stable standard PAH therapy without significant interstitial lung or renal disease were eligible. Dosing was two 1000 mg Rx infusions, 14 days apart. In this under-powered proof-of-concept study, multiple endpoints were evaluated to explore the potential for clinical benefit. The primary endpoint was change in 6-minute walk distance (6MWD) at 24 weeks. Key secondary efficacy endpoints included change in 6MWD at other time points, pulmonary vascular resistance (PVR), and time to change or addition of PAH medications, which were expected to remain unchanged until week 24 per protocol. A secondary objective of the study was to evaluate the safety profile of Rx in this population.

Table 1: Primary and Secondary Endpoints
Population: Modified Intention-to-Treat[1]

	Rituximab (n=27)	Placebo (n=27)	p-value
Primary Endpoint			
Change from Baseline in SMWT (meters)[2], mean (SE)			
Week 24	23.6 (11.05)	0.5 (9.71)	0.12
Secondary Endpoints:			
Change from Baseline in SMWT (meters)[3], mean (SE)			
Week 24	25.5 (8.79)	0.4 (7.43)	*
Week 48	9.5 (12.35)	-7.0 (8.63)	
Change from Baseline in PVR at Week 24 (dyes/sec/cm^5), mean (SD)	-39.0 (28.85)	7.2 (48.51)	
Change or Addition of PAH Medications, % Probability[4]			
By Week 12	11%	0%	
By Week 24	11%	15%	
By Week 36	28%	41%	
By Week 48	28%	41%	

* The p-value = 0.03 for this treatment group comparison. For all other secondary endpoints, the p-values for treatment group comparisons were >0.05.

1. The modified intention-to-treat population includes all eligible subjects who initiated treatment.
2. Model uses all data through Week 24 for estimates.
3. Model uses all data through Week 48 for estimates.
4. The probabilities are estimated from Kaplan-Meier curves for time-to-change or addition of PAH medications.

TABLE 2. Summary of Adverse Events

Results: Between 2010-2018, 57 participants (29 Rx, 28 placebo (Pc)) were randomized; 91% female, mean age = 58(SD 9.1) years, 90% limited SSc, mean duration of SSc-PAH = 1.8(SD 1.2) years. In the primary longitudinal analysis using data through week 24, 6MWD trended towards improvement after Rx relative to Pc but did not reach statistical significance (23.6±11.1m Rx, 0.5±9.7m Pc, p=0.12, Fig 1). A pre-specified secondary analysis, which included 6MWD data through week 48, demonstrated improvement at week 24 (25.5±8.8m Rx, 0.4±7.4m Pc, p=0.03, Figure 1), that was lost by week 48(9.5±12.4m Rx, -7.0±8.6m Pc, p=0.28). The probability of change or addition of PAH therapies after week 24 was lower in the Rx group (28% Rx, 41% Pc at weeks 38 and 48, Table 1). Changes in PVR at Week 24 were highly variable, but on average Rx fared better (mean(SD): -39 (28.9) Rx, 7.2(48.5) Pc, Table 1). Rx was well-tolerated with no unexpected adverse events or hypersensitivity reactions (Table 2). The number of adverse events, including infections, was similar in both treatment groups. A total of 4 deaths occurred in this at-risk cohort (3 in Rx, 1 in Pc); none of these deaths were directly attributed to Rx.

Conclusion: This is the first controlled trial examining the role of immunotherapy for SSc-PAH. Adjuvant B cell depletion therapy is a potentially effective and safe treatment for SSc-PAH. Our analyses uncovered potential benefits, despite being under-powered, and offer hope that targeted immunotherapy may be a promising approach. These results suggest repeat dosing of Rx after 24 weeks in responsive SSc-PAH patients. These results suggest that B cell-mediated injury contributes to ongoing pulmonary vascular disease in SSc-PAH and warrants further st udy.

The Effect of Atorvastatin on Microvascular Endothelial Function and Raynaud Phenomenon in Early Diffuse Scleroderma: Results of the "Tamer"' Study

Robyn Domsic,[1] Maureen Laffoon,[1] Balasubramani Goundappa,[2] Thomas Medsger,[1] Robert Lafyatis,[1] and Steven Wisniewski[1], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh Epidemiology Data Center, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical I: Therapeutics & Outcomes
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Statins have pleiotropic effects felt to influence in their beneficial cardiovascular effects. These include increased nitric oxide production and improved endothelial function, modulation of inflammation, and inhibition of overproduction of matrix components. Prior studies have been conflicting regarding the efficacy of statin therapy for Raynaud phenomenon (RP) in systemic sclerosis (SSc). However, these studies enrolled patients of wide disease duration and likely advanced vasculopathy. We hypothesized that there may be a window of opportunity; statin use in the early disease stages may benefit microvascular endothelial function and improve RP symptoms.

Methods: We performed an investigator-initiated, double-blind, randomized, placebo-controlled trial of atorvastatin 40 mg once daily vs placebo x 16 weeks (1:1 randomization). Patients were 18-70 years with early diffuse SSc, defined as < 3 years of SSc symptoms and RP. RP medications were stable ≥4 weeks. Patients were excluded if they had: diabetes, cardiovascular disease, were current smokers or used phosphodiesterase-5 inhibitors, recent prostacyclin therapy or prior sympathectomy. The primary outcome was improvement in microvascular endothelial function measured by reactive hyperemia index (RHI) using the EndoPAT™ system. Secondary outcomes included change in macrovascular endothelial function by brachial flow-mediated (FMD) dilation, and RP severity using the Raynaud condition score (RCS) and visual analog scale (RP-VAS). Given the sample size non-parametric analysis was performed to compare outcome measures between therapy groups.

Results: Twenty-four patients were randomized. One patient was diagnosed with pulmonary hypertension and withdrawn before 16 weeks. Baseline characteristics are in Table 1. Although randomized, the atorvastatin group had significantly lower RHI scores (worse endothelial function) and higher RCS and RP-VAS scores,

Table 1: Baseline characteristics of the TAMER study population			
	Atorvastatin n=10	Placebo n=14	p-value
Age at enrollment (years)	50±13.9	55.7 ± 7.3	0.27
Female	9 (90%)	10 (71%)	0.27
Ethnicity			0.41
Caucasian, non-Hispanic	7 (78%)	13 (93%)	
African-American	1 (11%)	1 (7%)	
Asian	1 (11%)	0	
History of hyperlipidemia	4 (40%)	2 (14%)	0.19
History of hypertension	1 (10%)	7 (60%)	**0.04**
Family History of early CVD	1 (10%)	1 (7%)	0.80
Obesity (BMI > 30)	2 (20%)	6 (43%	0.24
DISEASE CHARACTERISTICS			
Disease Duration (years)	1.54 ± 0.60	2.20 ± 0.76	**0.04**
Mean modified Rodnan skin score	18.9 ±9.6	22.8 ± 8.9	0.33
Digital pitting scar	4 (40%)	4 (29%)	0.31
Digital ulcers	0	1 (7%)	--
Fibrosis on chest imaging	3 (30%)	5 (36%	0.77
Gastrointestinal involvement	6 (60%)	8 (57%)	0.89
VASCULAR MEASURES			
Raynaud Condition Score (median, IQR)	5.0 (3.0, 7.5)	2.0 (1.0, 4.0)	0.49
RP VAS (median, IQR)	4.5 (2.0, 7.5)	1.5 (0.5, 3.0)	0.08
Mean EndoPAT RHI score (SD)	1.36 ± 0.36	1.85 ± 1.2)	**0.05**
Median % Peak Flow Mediated Dilation (IQR)	6.27 (6.75)	5.26 (5.19)	0.53

Table 2: Change in Raynaud phenomenon symptoms at 16 weeks			
	Atorvastatin	Placebo	p-value
Median change (IQR) in RCS	-2.0 (-2.0, 0)	0.0 (-1.0, 1.0)	0.12
Median change (IQR) in RP VAS	0.5 (-1.5, 6.0)	0.0 (-1.0, 1.5)	0.38

suggesting overall worse peripheral vascular disease. In those treated with atorvastatin, 60% (6/10) improved their RHI, compared to 29% (4/14) in the placebo group (p=0.12). There was no difference in change in peak FMD% between groups. The RCS decreased 2 points in the statin group compared to no change in the placebo (p=0.12; Table 2).

Conclusion: The results show a non-significant improvement in microvascular endothelial function measured by EndoPAT and RCS scores with the treatment of atorvastatin. This is encouraging given the small number of patients enrolled into the trial (original power calculations based on 30 patients) and the random assignment of a statin therapy group with significantly worse endothelial function and RP activity at baseline. Future studies of statins in early disease should be considered

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – ANCA-Associated I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare, systemic necrotizing small-vessel vasculitis, with only a few published North American series. This project aimed to describe main clinical characteristics, treatment patterns, and outcomes of patients with EGPA enrolled in the Vasculitis Clinical Research Consortium (VCRC).

Methods: Retrospective analysis of patients with EGPA participating in the VCRC Longitudinal Study (LS) or One-Time DNA (OT) collection from 2003-2019. Patients were at least 18 years old at enrollment and fulfilled the modified American College of Rheumatology 1990 criteria. Main demographics, time of onset of asthma to diagnosis, main organ involvement, ANCA status, type of treatments received since diagnosis, relapses, and deaths were analyzed. Patient subsets were compared according to ANCA status and use of cyclophosphamide (CYC).

Results: 354 patients (277 LS; 77 OT) were included; 309 (87.3%) were white, 20 (5.7%) Asian, and 7 (2%) Black or African American; male/female ratio was 145/209. Mean age at diagnosis and enrollment was 50.0 (±14.2) and 53.5 (±13.6) years, respectively; 246 (69.5%) had a diagnosis of asthma prior to the diagnosis of EGPA, for a mean of 8.6 (±12.2) years; 329 (92.9%) were eventually diagnosed with asthma. Of those tested for ANCA, 38.9% were positive, mostly with MPO-ANCA (86.2%). Main manifestations at diagnosis, and over the entire course of the disease (until last study visit), are listed in **Table 1**. With a mean follow-up from diagnosis of 7.0 (±6.2) years, 49.4% of patients had at least one relapse, with 35.7% of the 277 VCRC-LS patients relapsing post-enrollment. Characteristics of these first relapses post-enrollment included active asthma (35%), other lung disease (46%), ear/nose/throat (39%), cardiac (9%), skin manifestations (8%), and/or neuropathy (18%). Eleven (4%) of the VCRC-LS patients died after a mean of 4.7 (±2.5) years post-diagnosis (2 myocardial infarctions, 1 intestinal perforation, 1 metastatic cancer, 7 unknown). In the VCRC-LS, 115 (41.5%) patients received CYC at some point in their disease, 29 (10.5%) rituximab, 25 (9.0%) mepolizumab, 145 (52.4%) azathioprine, 109 (39.4%) methotrexate, and 25 (9%) mycophenolate mofetil. ANCA-positive patients had more kidney and neurologic involvement and a higher mortality, but less lung or cardiac manifestations (**Table 2**). Patients who received CYC had more cardiac and neurologic manifestations. At last study visit, 221 (79.8%) patients were off glucocorticoids (GC), but only 8 (2.9%) have been off systemic GC and immunosuppressant medications for >2 years during their follow-up.

Clinical manifestation	At diagnosis	Cumulative manifestations
Constitutional symptoms	207 (58.5%)	290 (81.9%)
Weight loss	83 (23.7%)	106 (29.9%)
Fatigue	178 (50.7%)	256 (72.3%)

Off oral glucocorticoid and immunosuppressant	5 (1.6%)	3 (2.4%)	2 (1.04%)	0.33	8 (2.6%)	3 (2.6%)	5 (3.1%)	0.82

*Data from patients within Vasculitis Clinical Research Consortium Longitudinal Study only.
ANCA: Anti-neutrophil cytoplasmic antibody; CYC: cyclophosphamide

Table 2. Main clinical manifestations at any point in disease course of 354 patients with eosinophilic granulomatosis with polyangiitis, according to ANCA status and use of cyclophosphamide

Conclusion: This first detailed analysis of the large VCRC cohort of patients with EGPA highlights the broad range of clinical manifestations seen in this disease and confirms that some clinical manifestations differ based on ANCA status, and that relapse rates are high. The extremely low number of patients able to stop GC and other immunosuppressant medications strongly supports the need for more effective treatments and identification of disease subsets to better tailor treatments.

Abstract Number: 0870

Off-Label Use of Biotherapies to Treat Relapsing And/or Refractory Eosinophilic Granulomatosis with Polyangiitis (Churg–Strauss)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – ANCA-Associated I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA; formerly Churg–Strauss syndrome), is characterized by small-vessel necrotizing vasculitis, and blood and tissue eosinophilia in asthmatic individuals. Glucocorticoids (GCs) usually control EGPA, but vasculitis relapses and GC-dependent asthma are frequent, as are long-term adverse events, leading to potential biotherapy use. We examined off-label biological therapy use for relapsing/refractory EGPA.

Methods: This retrospective European collaborative study included patients with EGPA, meeting the ACR criteria and/or Chapel Hill Consensus Conference definitions. Treatment efficacy and safety were recorded. Remission was defined as the absence of asthma, sinonasal and vasculitis manifestations with ≤5 mg/day of prednisone, and partial response as the absence of manifestations but requiring 6–10 mg/day of prednisone.

Results: Among the147 patients (74 men, 73 women; median age 52 years) included, 63 (43%) received rituximab (RTX), 51 (35%) mepolizumab (MEPO), at monthly respective doses of 100 mg or 300 mg for 29 (57%) and 22 (43%), and 33 (22%) omalizumab (OMA). Previous treatments were: GCs for all, azathioprine (68%), cyclophosphamide (40%), methotrexate (29%) or mycophenolate mofetil (15%).

At inclusion, median (interquartile range) BVAS in the RTX, OMA and MEPO groups, respectively, were 8.5 (5-13), 2 (2-5) and 2 (2-6). In the RTX-treated patients, median BVAS fell to 1 (0-4.5) at 6 and 0 (0-2) ay 12 months.A Median GCs dose decreased to 7.5 (5-10) at 6 months and 12 months. Overall, remissions, partial responses, therapeutic failure and stop for adverse event, respectively, were noted in 49%, 24%, 24% and 3% for RTX recipients. Remission was observed in 57% of ANCA-positive patients compared to 42% in ANCA-negative patients.

To treat GC-dependent asthma, MEPO had a much better GCs-sparing effect than OMA, and a better overall response. Remissions, partial responses, therapeutic failure and stop for adverse event, respectively, were noted in 15%, 33%, 48% and 4% for OMA recipients and 78%, 10%, 8% and 4% for MEPO recipients.Finally, no obvious difference was noted between patients receiving MEPO 100 mg and those 300 mg monthly, in terms of GC-sparing effect and overall response.

Sixteen (25%) patients stopped RTX: 2 for adverse events, and 14 for refractory disease. Also, 17 (27%) experienced adverse events, mainly severe infections. Seventeen (52%) stopped OMA: 1 for severe infusion reaction, and 16 for refractory disease. Four (12%) patients receiving OMA experienced mild to moderate adverse events. Three (6%) patients stopped MEPO: 2 for adverse events (one severe infusion reaction and one because of paraesthesia), and 1 for pregnancy. Eleven (22%) patients receiving MEPO experienced mild to moderate adverse events, mainly asthenia.

Conclusion: These results suggest that RTX could be effective for 50% of patients with EGPA vasculitis relapses, with an acceptable safety profile. MEPO is highly effective with a good GCs-sparing effect and safety profile in patients with GCs-dependant asthma, and 100 mg monthly seems to be an acceptable dose at first-line.

ANCA-Associated Vasculitis Management in the United States: Data from the RISE Registry

Zachary Wallace,[1] Huifeng Yun,[2] Jeffrey Curtis,[2] Shuo Yang,[2] Lang Chen,[2] John Stone,[3] and Hyon K. Choi[4], [1]Massachusetts General Hospital, Boston, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – ANCA-Associated I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The management of ANCA-associated vasculitis (AAV) evolved substantially in recent years because of evidence supporting the efficacy of various treatment regimens. As such, treatment approaches may vary across physicians. Understanding current practice can guide the design of pragmatic trials, inform cost-effectiveness research, and establish benchmarks. We sought to identify AAV treatment patterns in the US, especially outside of referral centers.

Methods: AAV patients seen in practices participating in the Rheumatology Informatics System for Efficacy (RISE) registry between January 1st, 2015 and December 31st, 2017 were included. AAV was defined as ≥ physician visit-associated 2 ICD-10 codes for AAV (M31.1, M31.31, M31.7, M30.1) ≥ 3 months apart and prescription/administration for rituximab (RTX), cyclophosphamide (CYC), azathioprine (AZA), methotrexate (MTX), mycophenolate mofetil (MMF), or glucocorticoids 3 months before or up to 6 months after the first ICD-10 code. New or flaring AAV cases were identified based on encounter codes for New/Consult visit; medications prescribed within 3 months of the 1st ICD-10 diagnosis code were assumed to be for "induction therapy." Demographic and prescription trends were assessed overall and across US regions. This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Results: 1,462 patients fulfilled the AAV case definition; 259 (18%) were new cases (**Table 1**). GPA was more common (1,097, 75%) than MPA (235, 16%) or EGPA (139, 10%). The mean age at the initial visit was 59.8 (±15.3) and 864 (59%) were female. Most visits occurred in the South (658, 45%) followed by the Mid-West (470, 32%), West (174, 12%), and Northeast (122, 8%). During the study period, patients had a median of 3 (IQR 0, 9) rheumatology clinician visits and an average follow-up of 579 days (IQR 328, 715). Among new patients, the most common induction regimens (**Table 2**) were RTX (80, 31%) followed by MTX (48, 19%). CYC was used in 11 (4%) cases. Among all patients (new and follow-up), the most common initially prescribed medication was a glucocorticoid (531, 36%), followed by MTX (290, 20%), RTX (286, 20%), and/or AZA (242, 17%); the most commonly prescribed medication at the end of follow-up was a glucocorticoid (684, 46.8%), followed by RTX (434, 30%), MTX (345, 24%), AZA (315, 22%), and/or MMF (170, 12%). Prescription trends were similar across regions.

Conclusion: This is among the first US studies to evaluate demographic and management patterns of AAV outside of major referral centers. The demographics of AAV patients in RISE are similar to those of other AAV cohorts. There was wide variation in management at different time points in care but these variations were similar across regions. Though RTX and CYC are considered non-inferior to one another, there was minimal CYC use. Glucocorticoids, RTX, and MTX were the most commonly prescribed medication throughout AAV care. Despite the superiority of RTX over

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – ANCA-Associated I

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Data on granulomatosis with polyangiitis (GPA) sustained remission off-therapy (SROT) are limited and it is unknown whether disease characteristics or treatment regimen may affect it. This study aimed to assess SROT of GPA patients from the French Vasculitis Study Group registry, and identify factors associated with its occurrence and durability during follow-up.

Methods: GPA had to satisfy the 1990 ACR classification criteria and/or revised Chapel Hill Nomenclature for study inclusion. SROT was defined as remission (BVAS=0) without glucocorticoids (GC) or immunosuppressants (IS), the latter for ≥6 months (ie 2 consecutive visits). SROT and its duration were extracted from the database. Data from patients with 3-, 5- and 10-year SROT were analyzed. Baseline characteristics of patients with 3-year GPA SROT were compared to those of registry GPA patients with available data at 3 years but not in SROT (controls), and 3-year SROT achieving 5-year SROT vs those who relapsed between 3 & 5 years. Patients with 3-year GPA SROT follow-up +7 years were analyzed according to maintained SROT or not.

Results: Among 795 database patients with new-onset GPA, 259 achieved at least 1 SROT at some time during their disease, after a median [IQR] of 36 [28–63] months post-diagnosis. The first SROT lasted a median of 14 [I8-32] months. Among 202 of those patients who had follow-up, 73 (36%) remained in SROT for a median follow-up of 34 [14-45] months post-SROT. Among 434 (54%) patients followed for ≥3 years post-diagnosis, 82% had received GC and cyclophosphamide induction therapy. At 3 years post-diagnosis, 92 (21%) patients in SROT were compared to 342 (79%) controls who had relapsed or were still taking GC or IS. Patients achieving 3-year SROT vs controls, respectively, had more frequently received intravenous cyclophosphamide as induction therapy (89% vs 77%, P=0.01), with a higher median number of infusions (7.5 vs 6; P=0.05); no other clinical or biological baseline difference was found. Among those 92 3-year SROT patients, 74 had ≥2 years of additional follow-up: 46 (62%) attained 5-year SROT and 28 (38%) had relapsed after a mean follow-up of 13 months. Baseline clinical and biological characteristics of patients achieving 5-year SROT did not differ from those of 3-year SROT patients who relapsed. Among those 92 3-year SROT patients, 16 had ≥7 additional years of follow-up: 6 (38%) achieved 10-year SROT, ie 8% of 75 GPA with available data at 10 years, and 10 (63%) had relapsed a mean 35 ± 28 months after achieving 3-year SROT.

Conclusion: Only 8% of GPA patients achieved 10-year SROT after conventional induction and maintenance therapies. No baseline clinical or biological characteristics helped distinguish patients achieving or maintaining SROT and

those who relapsed. However, patients achieving 3-year SROT had received more intensive induction therapy than those who relapsed or were still on GC or IS at 3 years.

Survival After Lung Transplantation in Adults with Primary Systemic Vasculitides: Analysis of the United Network of Organ Sharing (UNOS) Database

Sebastian E. Sattui,[1] Zafir Abutalib,[2] Jackie Finik,[2] and Robert Spiera[3], [1]Hospital for Special Surgery, New York, [2]Hospital for Special Surgery, New York, NY, New York, NY, [3]Hospital for Special Surgery, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – ANCA-Associated I
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Pulmonary involvement, including pulmonary vascular disease and interstitial lung disease can be an important cause of morbidity and even mortality in patients with primary systemic vasculitides (PSV). Outcomes of lung transplantation (LTx), a potentially life-saving intervention for patients with advanced pulmonary disease in patients with underlying autoimmune conditions including systemic sclerosis (SSc) and connective tissue disease-related ILD (CTD-ILD) are comparable to those of patients without underlying autoimmune conditions. Outcomes of LTx in patients with PSV have not been reported other than descriptively in scattered case reports. The aim of this study is to describe survival after transplantation in patients with PSV undergoing LTx and compare that to survival in LTx patients with SSc and non-CTD-ILD.

Methods: We conducted a retrospective cohort study of adult who underwent LTx in the United States between January 1996 and May 2018. Data was provided by UNOS, a non-profit organization that records data on all solid organ transplants performed in the US. Subjects from the thoracic transplant databases were included if they were at least 18 years of age and had diagnostic codes for PSV. Diagnosis of PSV included: Takayasu's arteritis (TAK), Granulomatosis with Polyangiitis (GPA), Eosinophilic Granulomatosis with Polyangiitis (EGPA) and Microscopic Polyangiitis (MPA). Age (within a 5-year range) and sex-matched controls undergoing LTx were identified for 2 other groups of transplanted patients: 1) Patients with a primary diagnosis of SSc and 2) Patients with a diagnosis of ILD (not CTD-ILD) and selected in a 1:1:1 ratio. We compared patient survival using Kaplan-Meier estimates and a Kruskal-Wallis test.

Results: 23 patients with PSV were identified in the thoracic transplant database. Of these, 2 patients underwent heart transplant (1 EGPA, 1 TAK) and 1 patient with diagnosis of GPA had a lung and heart transplant. 20 patients with a diagnosis of PSV were listed only for LTx, of those only 15 underwent LTx. 73% were male, with a median age 43 years and 73% were white (Table 1). GPA was the most common diagnosis (73%) (Table 2). Except for 1 patient with a diagnosis of TAK, all patients underwent LTx after May 4, 2005 (implementation of Lung Allocation Score). Patients with a diagnosis of PSV and SSc had a longer duration on waiting list compared to ILD patients ($p = 0.04$). Otherwise, there were no significant differences among baseline recipient characteristics between groups. Patients with PSV and

BMI = Body mass index; FVC = Forced vital capacity; ECMO = Extracorporeal Membrane Oxygenation; O2 = oxygen.

SSc had a longer survival time compared to ILD (p = .040) (Figure 1). There were no differences in survival or cause of death between PSV diagnoses.

Conclusion: To our knowledge, this is the first analysis reporting outcomes of patients with PSV undergoing LTx. PSV remains a rare context for LTx. There were no significant differences in patient survival time between PSV and SSc. Although this study has limitations, in particular small sample size, our data suggest that lung transplantation in patients with PSV achieved comparable outcomes to those in patients with SSc and better than ILD patients and should be considered a therapeutic option in this patient population.

[1]ANA positivity defined as ANA IF assay ≥80 titer; [2]Antibody positivity defined as ≥20 U; [3]Rheumatoid factor positivity defined as ≥14 IU/ mL; [4]Anti-ds-DNA positivity defined as ≥10 titer; [5]Anti-Scl-70 positivity defined as ≥1U.
[6]Pulmonary functional tests percentage of predicted value for age, gender, race/ethnicity, height, and weight.
[7]Body mass index, kg/m^2

Background/Purpose: Anti-neutrophil cytoplasmic antibodies (ANCA) have been identified in patients who have pneumonia without a diagnosis of ANCA-associated vasculitis (AAV). These patients are presently categorized as having idiopathic pulmonary fibrosis (IPF). Recent criteria categorize patients with features of autoimmunity but without a defined connective tissue disease as having interstitial pneumonitis with autoimmune features (IPAF). However, these criteria do not include ANCA. Growing evidence suggests that patients with ILD and ANCA may present differently from those with ILD in the setting of AAV or IPF.

Methods: We performed a retrospective case-cohort study of ANCA-associated ILD and randomly selected age and gender-matched controls with IPAF. Both groups were followed at the University of Chicago (1/2005 - 10/2018). Data on autoimmune serologies, baseline high-resolution CT scan using CALIPER (Computer-Aided Lung Informatics for Pathology Evaluation and Rating) parameters, baseline and longitudinal pulmonary functional tests (PFTs), vital status and lung transplant were collected from the electronic medical records. Variable comparisons utilized the Student's t-test or chi-squared, while panel data was evaluated with mixed-effect modeling. Survival analysis was computed using Cox regression models and the Kaplan-Meier estimator. (IRB#18-03349; #14163-A).

Results: In the study population (ANCA-associated ILD, n=52; IPAF, n=101), the mean age at ILD diagnosis was 63yrs, and 59% were women. Compared to white subjects, racial/ethnic minorities had lower TLC%, FVC%, FEV1%, and DLCO% (P=0.004, 0.003, 0.011, and 0.08 respectively). Groups were otherwise comparable with respect to race (Table 1). The prevalence of other autoimmune antibodies appeared greater in ANCA-associated ILD compared to IPAF, however these differences were not statistically significant (Table 1). Baseline and longitudinal PFTs were similar between both groups. Patients with ANCA-associated ILD had greater honeycombing in central portions of the lower lobes, and the central region of the left middle lobe (Table 2). ANCA positivity was not predictive of mortality (Figure 1), whereas total lung vessel volume, older age, non-White race, and lower DLCO% (P=0.043, < 0.001, 0.008, 0.054 respectively) were associated with mortality.

Table 2: Comparison between ANCA-associated ILD and IPAF groups with respect to CALIPER-derived parameters.

	ANCA (n=40)	IPAF (n=82)	P-value
CALIPER, mean (SD)[1]

Honeycombing	1.0 (2.7)	0.3 (0.7)	0.033

[1]CALIPER data described in the volumetric unit voxel.

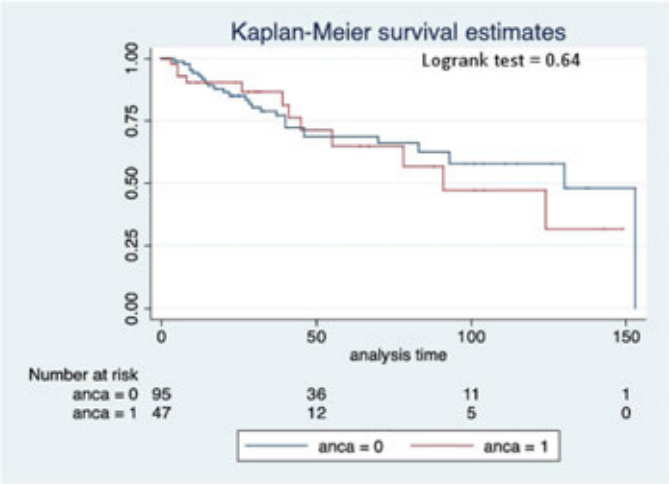

Figure 1: Kaplan-Meyer estimator of survival functions of ANCA- associated ILD and IPAF groups.

Conclusion: This is the largest US study comparing ANCA-associated ILD to IPAF. Our results suggest that these groups are similar, and these findings may argue in favor of adding ANCA to the IPAF criteria. Our radiographic data also suggests that ANCA-associated ILD may be driven by inhaled antigens and airway inflammation, leading to centrilobular fibrosis.

Effect of the Dr. Bart Application on Healthcare Use and Clinical Outcomes in People with Osteoarthritis of the Knee And/or Hip in the Netherlands; A Randomized Controlled Trial

Tim Pelle,[1] Karen Bevers,[1] Job van der Palen,[2] Frank van den Hoogen,[3] and Cornelia van den Ende[1], [1]Sint Maartenskliniek Nijmegen, Nijmegen, Netherlands, [2]Department of research methodology, Univeristy of Twente, Enschede, Netherlands, [3]Sint Maartenskliniek, Nijmegen, Netherlands

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: New Approaches to Old Diseases
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Self-management is of paramount importance in non-surgical treatment of knee/hip osteoarthritis (OA). Modern technologies offer the possibility to support self-management 24/7. We developed an e-self-management application (dr. Bart app) for people with knee/hip OA. A central element of the dr. Bart app is that the app proposes a selection of 72 preformulated goals to induce health behaviors based on the 'tiny habits method'[1]. The primary objective of this RCT was to evaluate the short term effects (3 & 6 months) of the use of the dr. Bart app (ad libitum), compared to usual care, on the number of secondary health care consultations in people with knee/hip

OA in the Netherlands. Secondary objectives were to study the effectiveness on clinical outcomes attributable to dr. Bart app.

Methods: A randomized controlled design involving participants ≥50 years with self-reported knee and/or hip OA, randomly allocated to the dr. Bart app or usual care. Participants were recruited from the community through advertisements in local newspapers and social media campaigns. In Figure 1 the theoretical framework of the dr. Bart app is presented. Participants received online questionnaires at baseline and after 3 and 6 months of follow-up. The primary outcome was the number of consultations in secondary health care due to OA in the knee/hip in the past six months. Secondary outcome measures were self-management behavior, pain, symptoms, functional limitations, physical activity, quality of life, and illness perceptions. Data were analyzed using negative binomial regression or linear mixed models, as appropriate, corrected for baseline, main OA-location (knee or hip), and interaction between treatment group and time.

Results: In total 427 eligible participants were allocated to either the dr. Bart group (n=214) or usual care (n=213). Mean age of the participants was 62.1 (SD 7.3) years, with the majority being female (72%) and having symptoms predominantly in their knee(s) (73%). Response rates for the follow-up questionnaires were 75.4% and 69.3% at 3 and 6 months, respectively. With respect to the number of consultations in secondary health care we found a non-significant incidence rate ratio (1.20 (95% CI: 0.67; 2.19)) between the dr. Bart app group and the usual care group. We found a positive overall treatment effect of the dr. Bart app on symptoms (2.6 (95% CI: 0.4; 4.9)), pain (3.5 (95% CI: 0.9; 6.0)) and, activities of daily living (2.9 (95% CI: 0.2; 5.6)), see Table 1. We found non-significant differences between groups for self-management behavior, physical activity, health-related quality of life and illness perceptions.

Conclusion: The dr. Bart app did not reduce the number of secondary health care consultations compared to usual care. However, we found positive effects attributable to the dr. Bart app on pain, symptoms, activities of daily living and functioning in sport and recreation in people with knee/hip OA, suggesting that the dr. Bart app has potential to positively influence health in people with knee/hip OA.

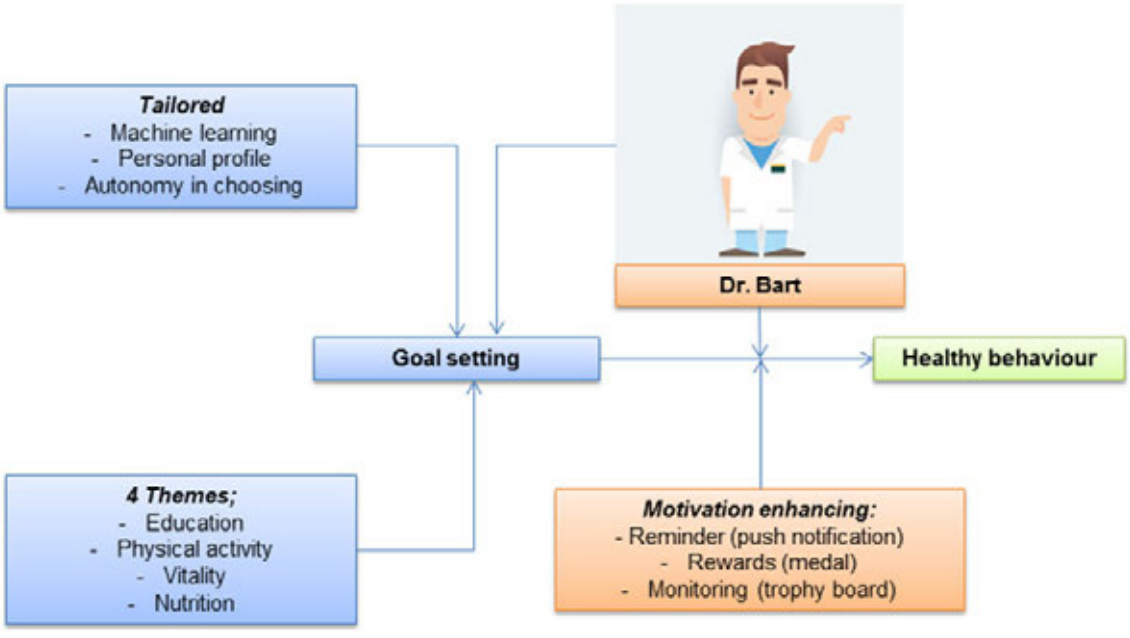

Figure 1. Theoretical framework of the dr. Bart app.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: New Approaches to Old Diseases
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Although patient-reported outcome measures (PROMs) are extensively used in clinical practice and research, it is unclear whether the most commonly used instruments adequately cover the perspective of young people with chronic inflammatory arthritis. This study was undertaken to investigate whether the aspects important to young people with inflammatory arthritis are sufficiently covered by the PROMs that are widely used in clinical practice and research.

Methods: A qualitative, multicentre focus group interview study was conducted in Austria, Croatia, Italy and the Netherlands in order to inform a EULAR-funded taskforce. Three groups of young people (aged 18-35 years) with either (1) rheumatoid arthritis (RA), juvenile idiopathic arthritis (JIA) and Still's disease, (2) psoriatic arthritis (PsA), or (3) axial spondyloarthritis (SpA) were interviewed at each centre. The interview guide was based on the WHO International Classification of Functioning, Disability and Health (ICF) to comprehensively cover all aspects of functioning in daily life [1]. It also included questions on the perspectives and views of the participants on selected PROMs (Pain scales, Patient Global Assessment [PGA], FACIT Fatigue Scale, The Health Assessment Questionnaire [HAQ]/Bath Ankylosing Spondylitis Functional Index [BASFI], and The 36-Item Short Form Health Survey [SF-36]). All interviews

Table. Overview of higher-level concepts and related quotes

Higher-level concepts	Quotes
Relevant issues for young people are not covered by widely used PROMs	*My appearance has never been brought up for discussion, but it impacts my teaching, my sex life, [...].* (male, 30, PsA)
Information, transparency and clarity regarding the purpose of PROMs are often missing	*Honestly, I have often thought that we should fill all those questionnaires to keep us quiet and to avoid that we will freak out!* (female, 27, PsA) *I do not understand the meaning. Why does the doctor care if I can wash my hair? Who will wash it instead? It is a stupid question!* (female, 27, PsA)
The individual life situation of a patient adds essential importance to the results of PROMs	*In my opinion it is problematic to estimate disease activity for today. With my medication, or without? At the moment, I am feeling fine, but it won't be like that without any medication, I guess. And that makes scoring a bit difficult.* (female, 27, PsA)
The scoring on a rating scale sometimes differs from the current health situation	*I am just putting my line anywhere and think – that's fine. (female, 27, PsA)* *I always score very low, like a 1, 2, or 3. which might look very harmless to the doctor. I often ask myself whether I should score worse, to get recognized.* (male, 30, PsA)
Certain PROMs were seen as outdated	*When you read this, you really feel old! (female, 21, RA)* *I think 'working on your computer' or 'typing' or something could be included. I mean how often do we still use a pen and pencil all day long? It should be a little more up to date.* (female, 25, PsA)
PROMs focusing on symptoms and physical function only, do not comprehensively cover patients' experiences	*I think it is also important what you [as an individual] need. Not only the physical part, but also the mental part, so how are you feeling. I think that is important too.* (male, 22, SpA)
The use of new technologies for data acquisition was suggested by some young patients	*Sometimes I do not want to answer with a whole story. [...] but I can also do that questionnaire [HAQ] digitally at my hospital. That is nice!* (female, 25, PsA)

were conducted by trained local investigators, audio-recorded, transcribed verbatim, and analysed using a modified form of 'meaning condensation' [2]. During a face-to-face meeting of the task-force members, the concepts were reformulated and organized into a scheme of higher and lower-level concepts.

Results: Thematic saturation was reached after 12 focus groups with 53 participants (21 with RA/JIA/Still's, 15 with SpA, 17 with PsA; 72% female, mean age 28, SD±5), resulting in 18 hours and 22 minutes of recorded time and 269 pages of transcript. The analysis revealed aspects of functioning in daily life important to young people with inflammatory arthritis which were mentioned in all countries. Furthermore, 55 concepts emerged with regard to PROMs and were summarized into seven higher-level concepts. The table depicts these higher-level concepts including quotes from the interviews.

Conclusion: The evaluation of young patients' perspectives should probably reach beyond the topics/aspects covered in the most commonly used PROMs. Accordingly, tailoring the assessments to specific needs of young people should be considered.

Abstract Number: 0877

Rheumatoid Arthritis Patients' Perspectives on Tapering of Biologics: A Qualitative Study

Jack Chan,[1] **Lisa Stamp**,[2] Nicola Liebergreen,[1] Henry Ndukwe,[1] Carlo Marra,[1] and Gareth Treharne[1], [1]University of Otago, Dunedin, New Zealand, [2]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: New Approaches to Old Diseases
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Tapering of biologics is now recommended in the management of people with RA in sustained remission.[1] Clinical studies have shown some RA patients can successfully taper their biologic without significant increases in disease activity or radiographic progression. However, little is known of RA patients' perspectives about the possibility of tapering their biologic. This study sought to identify factors that may influence RA patients' decision to taper their biologic.

Methods: Patients meeting the 2010 ACR/EULAR classification criteria for RA and currently taking biologics were eligible to participate in focus groups or individual interviews. Patients with any level of disease activity were included to allow exploration of a wide range of perspectives and to avoid exclusion of potentially valuable insights. All interviews and focus group discussions were audio recorded and transcribed verbatim. Transcripts were coded using an established approach to thematic analysis[2] to determine themes relating to patients' decision about tapering biologics.

Results: 128 eligible patients were invited, 76 declined or did not respond and 7 were unavailable. 45 participants were involved in either 1 of 6 focus groups (n=43) or an in-depth individual interview (n=2). Around two-thirds of participants were receiving biologics via infusion and the remaining were self-injecting. Five themes were identified: fear of the uncertainty of outcomes, prioritizing quality of life over the risk of adverse effects, relief from medication burden, healthcare system support, and preference for involvement in decision-making. Participants had strong concerns that tapering their biologic might lead to periods of uncontrolled disease activity leading to joint damage. Their desire for better quality of life outweighed the concern of adverse effects associated with long-term biologic use. Nevertheless, participants recognized a lower frequency of administration would provide convenience in some aspects of daily life. Prompt reinitiation of biologics and consultation with the rheumatology team if flares occur when tapering are crucial from the perspective of the participants. Furthermore, participants would prefer to make the decision to taper biologics together with their rheumatologist.

Conclusion: Concerns of uncontrolled disease and receiving access to treatment when disease flares are among the key issues that need to be addressed when planning tapering protocols. Tool to aid shared decision making may facilitate the exchange of information, improve patients' knowledge and understanding of the benefits and risks involved in tapering their biologic leading to greater acceptance of tapering.

Table: Cross-sectional and Longitudinal association of serum magnesium level with radiographic and symptomatic chondrocalcinosis and osteoarthritis	
Cross-sectional	**Adjusted** OR (95% CI)**
	Prevalent Radiographic chondrocalcinosis (N=985)
Serum Magnesium (mEq/L)	0.70 (0.52, 0.95)
	Prevalent Symptomatic chondrocalcinosis (N=985)
Serum Magnesium (mEq/L)	0.63 (0.35, 1.15)
	Prevalent Radiographic osteoarthritis (N=985)
Serum Magnesium (mEq/L)	0.94 (0.82, 1.08)
Longitudinal	**Adjusted** HR (95% CI)**
	Incident Radiographic chondrocalcinosis (N=772)
Serum Magnesium (mEq/L)	0.87 (0.66, 1.17)
	Incident Symptomatic chondrocalcinosis N=(830)
Serum Magnesium (mEq/L)	0.60 (0.43, 0.84)
	Incident Radiographic osteoarthritis (N=606)
Serum Magnesium (mEq/L)	0.99 (0.87, 1.16)
	Incident Symptomatic osteoarthritis (N=893)
Serum Magnesium (mEq/L)	0.95 (0.84, 1.07)
Adjusted for age, sex, BMI Odds and Hazard ratios are per SD increase in Magnesium	

Background/Purpose: High serum magnesium (Mg) may have anti-inflammatory effects and prevents the release of extracellular pyrophosphate, inhibiting CPP deposition. Cross-sectional data has linked low serum Mg levels with radiographic chondrocalcinosis (CC) but there is a paucity of longitudinal studies and an absence of studies of symptomatic CC. Since osteoarthritis (OA) and CC often co-exist and have other common risk factors, we evaluated the relation of serum Mg levels to prevalence and risk of 4 outcomes, radiographic CC, symptomatic CC, radiographic knee OA, and symptomatic knee OA in a large cohort of community dwelling older adults.

Methods: For each of the 4 outcomes we performed a nested case-control study within the Multicenter Osteoarthritis (MOST) study, a NIH-funded longitudinal cohort of persons with or at risk of knee OA. Serum Mg level (mEq/L) was measured (AU480, Beckman Coulter Inc., Brea CA 92821) at baseline. For each outcome, we excluded those who, at baseline had the outcome. Our outcomes from baseline through 60 month follow-up were incident (new onset) radiographic OA (KL-grade ≥2 in either or both knees), symptomatic OA (radiographic OA with frequent knee pain in the same knee), radiographic CC (presence of CC in either or both knees) and symptomatic CC (radiographic CC with frequent knee pain in the same knee). To examine cross sectional baseline associations for each outcome, we took subjects selected for Mg assessment for the other outcomes and evaluated the association of serum Mg (per SD increase) to prevalent radiographic OA, radiographic and symptomatic CC using logistic regression. Using each case control sample, we then examined the longitudinal association of baseline serum Mg to incident radiographic

OA, symptomatic OA, radiographic and symptomatic CC using Cox proportional hazards regression. All analyses were adjusted for age, sex, and BMI.

Results: Among 985 participants (mean age 62 yrs, 59% women and mean BMI 29.9 kg/, mean Mg levels 1.89 mEq/L) , the prevalence was 324 radiographic OA, 47 radiographic CC and 11 symptomatic CC. In **cross-sectional analyses (see table)**, serum Mg was not associated with prevalence of radiographic OA (per standard deviation of Mg, OR=0.94, 95% CI 0.82, 1.08) but was modestly associated with radiographic CC (OR=0.70, 95% CI 0.52, 0.95) and symptomatic CC (OR= 0.63, 95% CI 0.35, 1.15).

Incidence of radiographic OA occurred in 250 of 606 persons; 336 of 893 had incident symptomatic OA; 46 of 772 had incident radiographic CC; 33 of 830 had incident symptomatic CC. In **longitudinal analyses**, higher baseline serum Mg levels were not associated with risk of incident radiographic OA (HR=0.99, 95% CI 0.87, 1.16), symptomatic OA (HR 0.95, 95% CI 0.84, 1.07) or radiographic CC (HR=0.87, 95%CI 0.66, 1.17) but were associated with risk of symptomatic CC (HR= 0.60, 95% CI 0.43, 0.84).

Conclusion: Higher serum magnesium levels were associated with a lower risk of symptomatic CC but not with radiographic CC, radiographic OA, or symptomatic OA. The association of Mg with incident symptomatic CC has important clinical implications and is consistent with cross sectional studies but is based on small numbers and needs replication.

Abstract Number: 0879

Evaluation of Marijuana and Cannabidiol Use in the Rheumatologic Population from a Patient and Clinician Perspective: A Survey-Based Study

Heather Goodwin,[1] **Ali Porter**,[1] Melinda Edwards,[1] and Bonita Libman[1], [1]The University of Vermont Medical Center, Burlington, VT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: New Approaches to Old Diseases
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: To evaluate use of marijuana (MJ) and cannabidiol (CBD) as described by rheumatology patients at an academic medical center in Vermont, and to describe beliefs and practices of rheumatology clinicians regarding patient use of MJ and CBD in the United States.

Methods: A paper survey was distributed to adult patients during routine rheumatology clinic visits at the University of Vermont Medical Center between November 2018 and February 2019. A second survey was developed using Research Electronic Data Capture (RedCap) software and was disseminated via email to clinicians identified from the American College of Rheumatology membership list. Descriptive statistics were used to assess responses.

Results: A total of 419 patient surveys were collected with 148 (35.3%) reporting current use of MJ and/or CBD. Of those 148 patients, 42% were using both MJ and CBD, 36% only CBD, and 22% only MJ. RAPID3 scores of users

were collected; 52% as high severity, 40% moderate, 36% low, and 21% near remission. Worsening disease severity influenced patient use (Wald $\chi 2$ (3) =15.3, p =0.0165). Over half (51%) agreed they were able to decrease use of pain medication when MJ or CBD was used. The average self-reported pain on a 0-10 scale before and after use of MJ and/or CBD was 6.9 and 4.4 respectively.

Nearly half of clinician respondents disagreed that MJ (45.2%; n = 106) or CBD (37.4%; n = 105) should be recommended as medical therapy for patients with rheumatologic disorders. Of those practicing in states where MJ is legal for medical and recreational use, 52.9% agreed that they were comfortable addressing questions surrounding use vs. 33.3% in states where MJ is illegal, although this was not statistically significant. Many disagreed that opioid and NSAID use decreases with marijuana use (33.9% and 40.9% respectively), this was similar for CBD (32.2% and 34.8% respectively).

Conclusion: Patient and clinician perceptions are dissimilar regarding benefits of MJ and CBD use, especially around pain medication requirements. Worsening disease severity influences probability of use. Surrounding laws likely impact clinician perception and comfort with medical use. Additional research is needed to better understand the benefits and risks of MJ and CBD use in the rheumatologic patient population.

Abstract Number: 0880

Diseased Lupus Nephritis Kidneys Serve as a Primary Site of Systemic Autoimmune Development

Matthew Woodruff,[1] Christopher Tipton,[1] Jennifer Hom,[1] and Iñaki Sanz[1], [1]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Lupus nephritis (LN) is an autoimmune destruction of the kidney glomeruli and loss of kidney function affecting almost half of lupus patients. Although the disease is classified and treated based on accumulated glomerular damage and proliferative lesions, it has been shown that tubulointerstitial inflammation deeper in the organ is a better predictor of long-term renal viability. Autoimmune B cells have been identified as an important mediator of this inflammation, and recent work has identified interesting transcriptional maturation of these cells upon tissue engraftment. Here, we examine other critical properties of these cells that remain yet unexplored.

Methods: Kidney biopsies and matched blood from patients with Class II, III, or IV (+/- V) LN were obtained and processed for next-generation B cell receptor sequencing. The resulting B cell repertoire was analyzed to understand the properties of kidney B cells (KBCs), and their relationship to established compartments in the blood.

Results: Through repertoire sequencing and analysis, we report a highly dynamic B cell environment hallmarked by *in situ* development of kidney-derived B cell (KBC) lineages from naive-like precursors. These KBC lineages are capable of class switching, undergo extensive division, and display levels of somatic hypermutation not seen even in the memory autoimmune B cell compartment in the blood. Importantly, these highly selected B cell lineages are not restricted to the kidney following maturation, and can be identified in the blood of patients years after initial expansion in the kidney. Finally, biopsies of patients during acute onset of LN versus patients with a longer LN history

reveal distinct phases of humoral development within the renal environment that is not captured by current disease classification systems, and may be relevant to disease treatment.

Conclusion: Through these data we draw the surprising conclusion that rather than serving as a target of autoimmune attack, the renal environment serves as a primary site of humoral autoimmune development. This development is progressive by nature, and the early phase of disease onset may represent a distinct therapeutic opportunity for aggressive B cell directed intervention. Additionally, these data may help explain mixed results when applying B cell directed therapies towards these patients. In all, this study reveals a dynamic, progressive, and pervasive humoral immune component in the renal environment in every LN patient assessed to-date, and highlights a surprising gap between traditional histological classification of the disease and the underlying immune status.

Auto-antibodies Targeting Components of Sarcolemma Repair: A Pathogenic Mechanism in Human Inflammatory Myopathies

Kevin McElhanon,[1] Ana Capati,[2] Nicholas Young,[3] Brian Paleo,[2] Eric Beck,[2] Zarife Sahenk,[4] Rohit Aggarwal,[5] Chester Oddis,[5] Noah Weisleder,[1] and Wael Jarjour[6], [1]Dorothy M. Davis Heart and Lung Research Institute & Dept. of Physiology & Cell Biology, The Ohio State University Wexner Medical Center, Columbus, OH, [2]The Ohio State University Wexner Medical Center, Columbus, OH, [3]The Ohio State University Wexner Medical Center, Division of Immunology and Rheumatology, Columbus, OH, [4]Nationwide Children's Hospital, Columbus, OH, [5]University of Pittsburgh Medical Center, Pittsburgh, PA, [6]Ohio State College of Medicine, Columbus, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) represent a group of disorders causing chronic inflammation and significant damage to skeletal muscle due to an unchecked autoimmune response. Two mouse models of IIM have recently provided new insights into the pathogenesis of the disease. The synaptotagmin VII null (Syt VII$^{-/-}$) mouse is characterized by defects in membrane resealing and presents with a mild form of myositis at 2 months of age. A more robust model of IIM combines knock-out of Syt VII with a FoxP3 mutation resulting in a mouse with impaired membrane resealing and regulatory T-cell deficiency. Tripartite motif (TRIM) proteins are another family that has a critical role in membrane repair. Here, we explore the presence of a pathogenic mechanism involving sarcolemma repair that is responsible for initiation and/or propagation of muscle inflammation.

Methods: Autoantibodies directed to TRIM family protein members were examined by immunoblotting and/or ELISA. Membrane repair was monitored *ex vivo* using an established assay where the membrane of individual muscle fibers of intact skeletal muscle bundles were injured using an infrared multi-photon laser. Confocal live cell imaging was used to record entry of FM4-64 dye, which only fluoresces once it enters the cell. To examine membrane fragility, mouse skeletal muscle was collected from wild type mice or RAG1$^{-/-}$ mice adoptively transferred with lymph node preparations from either Syt VII$^{-/-}$/FoxP3$^{-/Y}$ mice or FoxP3$^{-/Y}$. Tissue was analyzed by immunohistochemistry for evidence of inflammation and tissue injury.

Results: We have established by direct ELISA that auto-antibodies against TRIM72, a critical protein involved in sarcolemmal membrane repair, is elevated in IIM patient sera. We show, for the first time, that a deficiency in T-regulatory

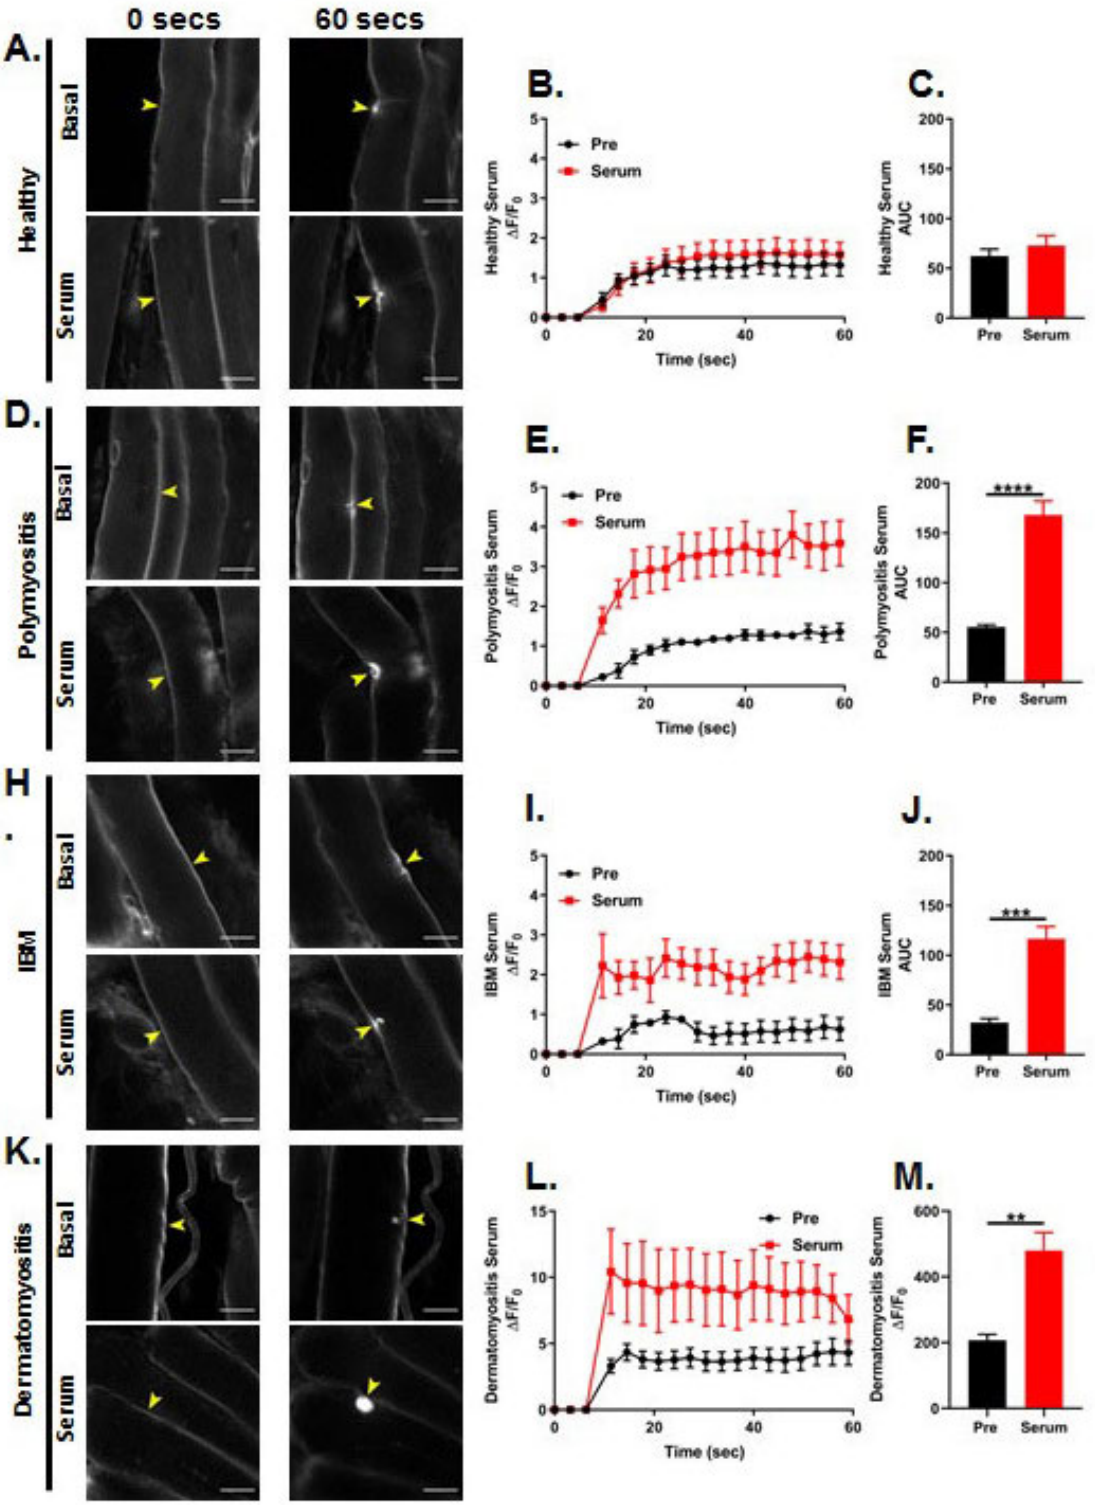

Figure. Myositis patient sera positive for TRIM72 autoantibodies compromises sarcolemmal repair in healthy skeletal muscle.

cells is not sufficient to induce sarcolemma fragility, however, purified antibodies against critical proteins that facilitate the sarcolemma repair process are sufficient to reduce membrane repair capacity. We also demonstrate that sarcolemma integrity is reduced in distal skeletal muscle in the absence of inflammation in our novel murine model of IIM. Moreover, we find that exogenous delivery of IIM (dermatomyositis, inclusion body myositis and polymyositis) patient

serum containing antibodies to TRIM72 can compromise sarcolemma resealing in healthy skeletal muscle in an *ex vivo* laser injury assay (see figure).

Conclusion: These findings represent a novel mechanism in IIM whereby decreased sarcolemma integrity induces a vicious cycle of aberrant antigen presentation that directly contributes to the pathophysiology of idiopathic immune myopathies.

Myositis patient sera positive for TRIM72 autoantibodies compromises sarcolemmal repair in healthy skeletal muscle.

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Tubulointerstitial inflammation (TII) in lupus nephritis (LN) is associated with a worse prognosis. Vimentin, a cytoplasmic antigen, is commonly targeted by *in situ* activated B-cells in TII. The prognostic im-

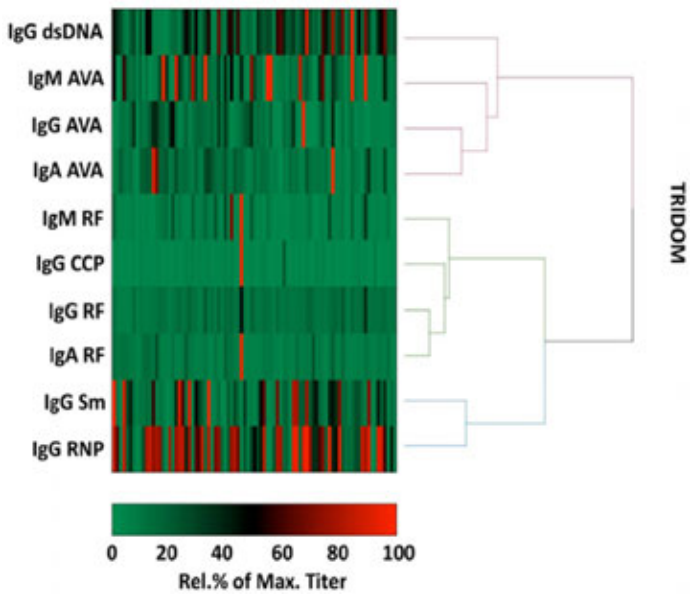

Figure 1. Heat Map and Hierarchical Clustering of autoantibody titers in serum samples from the cross-sectional mixed lupus cohort "TRIDOM"

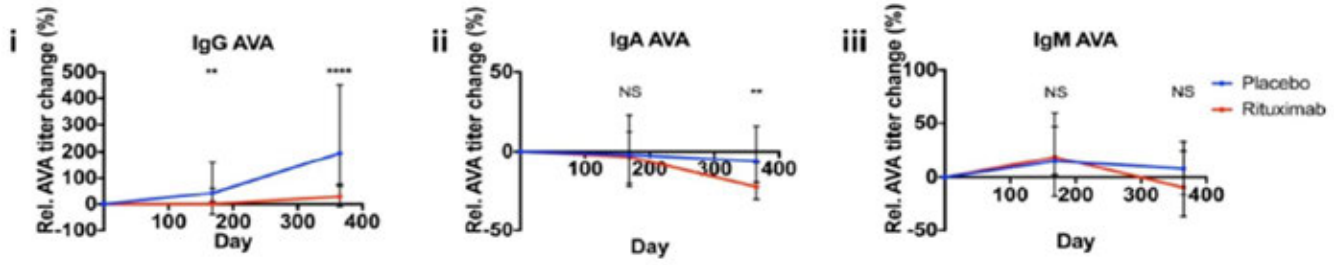

Figure 2. Difference between (i) IgG-, (ii) IgA- and (iii) IgM AVA by median relative titer change (as a percentage of serum titer at trial baseline) in LUNAR trial enrolled proliferative nephritis patients receiving MMF in the presence of rituximab or placebo

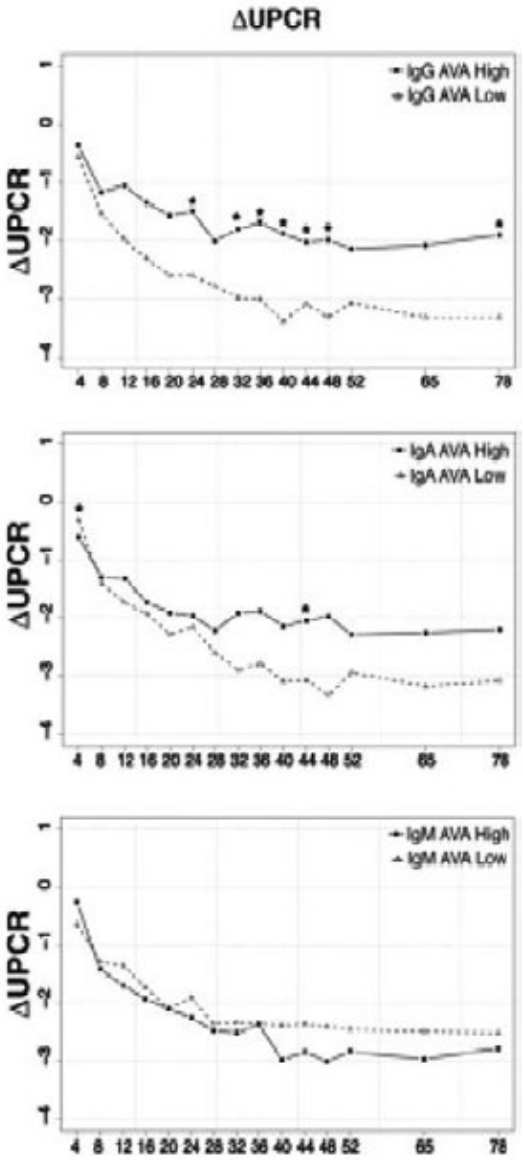

Figure 3. Change in Urine Protein to Creatinine Ratio from baseline in LUNAR patients. Patients from both treatment groups were pooled and subsequently stratified by having the indicated AVA isotype titer above or below total patient median titer at trial baseline.

portance of high serum anti-vimentin antibodies (AVAs) in LN and their relationship with common lupus autoantibody specificities is unknown. We investigated associations between AVA isotypes, other autoantibodies, and response to mycophenolate mofetil in the presence or absence of rituximab.

Methods: An inhouse AVA ELISA was developed using human vimentin as substrate (over expressed in, and purified from the inclusion bodies of, E.coli). Serum from a cross-sectional cohort of 99 lupus patients (22% LN, from the Translational Research Inititative in the Department of Medicine, "TRIDOM") was titrated for IgG-, IgA- and IgM-AVAs, lupus- associated, and RA-associated autoantibodies, and titers subjected to hierarchical clustering. Serum from baseline, 26 and 52 weeks from 131 proliferative LN patients enrolled in the LUNAR trial was analysed for a more exhaustive range of lupus associated antibodies and evaluated for associations with longitudinal laboratory parameters up to week 78.

Results: In TRIDOM, hierarchical clustering analysis revealed AVAs and IgG anti-dsDNA clustered together, whereas AVAs clustered away from anti-Sm, anti-RNP, and RA-associated autoantibodies. In LUNAR at baseline, AVAs correlated weakly with anti-dsDNA and more strongly with anti-cardiolipin titers. IgG anti-dsDNA titers were reduced in both treatment groups, but more profoundly in patients receiving rituximab. In contrast, IgG AVAs increased in both treatment groups from baseline to week 52 (median fold increase of 195% in the absence vs 28% in the presence of rituximab) while titers of IgM and IgA AVAs did not increase over time. Over 78 weeks a reduction in proteinuria was observed for each treatment group, as reported previously at 52 weeks. However, less reduction in proteinuria was observed for patients with baseline high titers of IgG AVA ($p< 0.0001$ for overall effect; mean difference in change of UPCR between high and low groups at week 78 = 1.42 g/g) and IgA AVA ($p=0.0069$; mean difference: 0.88 g/g). In comparison, baseline IgM AVA status was not associated with subsequent difference in change of UPCR ($p=0.75$).

Conclusion: AVAs, especially IgG AVAs, are unique in distribution and response to therapy compared to other commonly measured autoantibody specificities in lupus. Furthermore, high-titer IgG AVAs identify LN patients resistant to conventional therapies. AVAs may represent a new class of prognostic autoantibodies.

Abstract Number: 0883

B Cell-specific MyD88 Regulates Pathology After Disease Onset in Murine Lupus

Jeremy Tilstra,[1] Minjung Kim,[1] Claire Leibler,[1] and Mark Shlomchik[1], [1]University of Pittsburgh, Pittsburgh, PA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex autoimmune disease defined by immune dysregulation, antibody formation, followed by end-organ damage. MyD88 is a central immune adaptor protein that regulates disease pathogenesis in SLE that acts downstream of the Toll-like receptors, well known mediators of disease in SLE. Several components of the MyD88/TLR signaling pathway have been identified as risk alleles in SLE patients, including TLR7, TLR8, TLR9, IRAK1, IRAK4, OPN, and ACP1. Previously, we showed that global and B

cell-specific MyD88-deficient mice exhibited ameliorated disease, including reduced organ damage and suppressed autoantibody formation. Whether MyD88 regulates only disease initiation or contributes to disease perpetuation after onset of symptoms is unclear. By defining the role of MyD88 in SLE pathogenesis, we will be able to determine if MyD88 is a potential therapeutic target for SLE patients.

Methods: Lupus prone (MRL.*Fas*^{lpr}) mice develop autoantibodies, proteinuria, dermatitis, and glomerulonephritis, with disease onset occurring between 9-11 weeks of age. In order to study the therapeutic potential of MyD88 suppression, we used lupus prone (MRL.*Fas*^{lpr}) mice in which B cell-specific depletion of MyD88 is induced by tamoxifen (hCD20-Tam Cre, Myd88^{floxed}) while both Cre negative littermates and hCD20-Tam Cre^{+} Myd88 sufficient mice were used as a comparator groups. For all groups, tamoxifen was orally administered biweekly starting after disease onset (12 weeks of age). Cell specific deletion was assessed using cell sorting and qPCR of genomic DNA. Mice were analyzed for disease pathology at 19 and 21 weeks of age for females and males respectively. Analysis included proteinuria, renal histology for both interstitial and histologic disease, dermatitis, autoantibody production, and immune cell activation. Survival analysis was performed on female mice.

Results: MRL.*Fas*^{lpr} mice with induced B cell-specific deletion of MyD88 (Tam,B-MyD88$^{fl/fl}$) exhibited a significant survival advantage over control mice ($p< 0.05$) with reduced kidney histologic disease, including both glomerulonephritis ($p< 0.01$) and interstitial inflammation ($p< 0.01$). Additionally, Tam,B-MyD88$^{fl/fl}$ mice had reduced autoantibody formation as assessed by ANA immunofluorescence and ELISA. The B cell compartment was altered in these mice with no change in the percentage of total B cells, but vastly reduced ABC formation (defined as CD19^{+},CD11c^{+}, CD11b^{+}) ($p< 0.005$) and reduced total number of plasmablasts (CD19^{int}, CD138^{+}, CD44^{+})

Conclusion: These experiments suggest that there is a continued role for MyD88 signaling in B cells throughout the course of disease in MRL.*Fas*^{lpr} lupus prone mice, rather than simply disease initiation. Numerous genetic deletions have resulted in suppressed disease onset in lupus models, but herein, we observed disease amelioration after disease onset. This portends that targeting MyD88 or its upstream activators may be a viable therapeutic option in SLE.

Interferon-Alpha Disrupts Multiple B Cell Tolerance Mechanisms in 3H9 Mice

Dario Ferri,[1] Yuriy Baglaenko,[2] Kieran Manion,[3] Carolina Munoz-Grajales,[4] and **Joan Wither**[5], [1]University Health Network, Toronto, ON, Canada, [2]Brigham Woman's Hospital, Boston, [3]Krembil Research Institute, Toronto, ON, Canada, [4]University Health Network, Toronto, Canada, [5]University Health Network, Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Interferon-alpha (IFNα) is elevated in Systemic Lupus Erythematosus (SLE) and is thought to play a central role in its pathogenesis. Amongst IFNα's many effects on the immune system are direct effects on B cells, leading to enhanced B cell signaling and survival. It also plays a major role in the induction of B cell activating factor (BAFF). While past studies have explored the effects BAFF on B cell tolerance, little work has focused on how

IFNα directly affects this process. We hypothesize that elevated levels of IFNα directly contribute to the breach of B cell tolerance in SLE. To address this question, we used an adenoviral vector that expresses mouse IFNα (mDEF201) to induce sustained elevations of serum IFNα in the 3H9 mouse model of B cell tolerance.

Methods: 6-8 week old 3H9 mice, which contain a knock-in Ig heavy chain derived from a DNA-specific hybridoma, were injected IV with 10^7 PFU of Ad-mIFNα (mDEF201) or Ad-dl70-3 (empty vector). At 2 weeks post-treatment immune cell populations in the spleen and bone marrow were examined by flow cytometry, and anti-DNA antibody production was measured by ELISA. Serum levels of IFNα were quantified by ELISA and IFN-induced gene expression was assessed by qRT-PCR.

Results: Mice administered mDEF201 had elevated serum levels of IFNα and increased mRNA expression of several IFN-inducible genes. Elevated IFNα was associated with a marked increase in the levels of anti-ss/dsDNA autoantibodies, signifying a breach of B cell tolerance. Consistent with this idea, mDEF201 infected mice displayed several abnormalities suggestive of altered B cell homeostasis, including increased numbers of mature follicular/marginal zone B cells, increased frequencies of activated B cells, age-associated B cells (ABC), germinal center B cells, and $CD138^+$ plasma cells. These changes occurred in the setting of minimal changes to the T cell compartment. In the bone marrow, infected mice demonstrated reduced receptor editing, consistent with impaired tolerance induction. To assess the effect of IFNα on B cell anergy, the fate of $Ig\lambda1^+$ expressing B cells, a well-characterized dsDNA-reactive anergic B cell population, was examined. $Ig\lambda1^+$ B cells demonstrated several features of impaired anergy such as enhanced selection in to the mature B cell follicular compartment, increased levels of activation markers, and increased germinal center recruitment; however, anti-dsDNA $Ig\lambda1^+$ levels were not increased, suggesting only a partial breach of anergy. To determine whether altered B cell tolerance in infected mice was due to a direct effect of IFNα on B cells, 3H9 mice with B cell-specific knockout of IFNAR were produced. In these mice several of the IFNα-induced changes were reversed, such as enhanced B cell selection into the follicular, marginal zone, and ABC populations, enhanced B cell activation, and elevated levels of anti-dsDNA antibodies, highlighting the important role of IFNα-B cell interactions in these results.

Conclusion: These data indicate that IFNα may be a major contributing factor to the breach B cell tolerance in SLE through direct effects on autoreactive B cells that impact multiple mechanisms of tolerance, leading to enhanced B cell activation, generation of ABCs and autoantibody production.

TLR9 Signaling in HCV-Associated Atypical Memory B Cells Triggers Th1 and Rheumatoid Factor Autoantibody Responses

Chloé Comarmond,[1] Valerie Lorin,[2] Cindy Marques,[1] Anna Maciejewski-Duval,[1] Nizar Joher,[2] Cyril Planchais,[2] Maxime Touzot,[3] Thierry Hieu,[2] Valentin Quiniou,[1] Anne Desbois,[4] Michelle Rosenzwajg,[1] David Klatzmann,[1] Patrice Cacoub,[5] Hugo Mouquet,[2] and David Saadoun[5], [1]Assistance Publique des Hopitaux de Paris, PARIS, France, [2]Institut Pasteur, PARIS, France, [3]Institut Curie, Paris, France, [4]GHPS, Paris, France, [5]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: B Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Hepatitis C virus (HCV) infection contributes to the development of autoimmune disorders such as cryoglobulinemia vasculitis (CV). However, it remains unclear why only some HCV-infected individuals develop CV. HCV-CV is characterized by expansions of anergic $CD19^{+}CD27^{+}CD21^{low/-}$ atypical memory B cells (AtM). Here, we report the mechanisms by which AtM participate to HCV-associated autoimmunity.

Methods: Phenotype and function of peripheral AtM were studied by multi-color flow cytometry and co-culture assays with effector T cells and regulatory T cells in twenty chronically HCV-CV patients, 10 chronically HCV-infected patients without CV and 8 healthy donors. We performed gene expression profile analysis of AtM stimulated or not by TLR9. Immunoglobulin gene repertoire of AtM were analyzed after single B cell FACS sorting and expression-cloning of antibodies. Antibody reactivities of AtM were studied by ELISA.

Results: We show $Tbet^{+}CD11c^{+}CD27^{+}CD21^{-}$ AtM B-cell expansions in HCV-CV patients as compared to HCV controls without CV. TLR9 activation of AtM induces a specific transcriptional signature centered on TNFα overexpression, and an enhanced secretion of TNFα and rheumatoid factor-type IgMs in HCV-CV patients. AtM stimulated through TLR9 promote type 1 effector T-cell activation and reduce the proliferation of $CD4^{+}CD25^{hi}CD127^{-/low}FoxP3^{+}$ regulatory T cells. AtM expansions display intraclonal diversity with immunoglogulin features of antigen-driven maturation. AtM-derived IgM monoclonal antibodies do not react against ubiquitous autoantigens or HCV antigens including NS3 and E2 proteins. Rather, AtM-derived antibodies target unique epitopes on the human IgG Fc region and possess rheumatoid factor activity.

Conclusion: Our data strongly suggest a central role for TLR9 activation of AtM in driving HCV-CV autoimmunity through rheumatoid factors production and type 1 T-cell response.

Background/Purpose: Tissue accumulation of $p16^{INK4A}$-positive senescent cells is associated with age-related disorders such as osteoarthritis (OA). These senescent cells induce a tissue loss of function through a particular secretory phenotype called SASP (senescence-associated secretory phenotype). Links between OA onset and cellular

senescence remain poorly detailed. We wanted to determine the presence of articular senescent cells in *in vivo* OA mouse models and study the involvement of mesenchymal stem cells (MSC) senescence in OA pathogenesis.

Methods: Wild-type mice C57BL/6, SAMP8/R1 (senescence accelerated mouse-prone and resistant), transgenic *p16*$^{INK4A\ +/Luc}$and *p16*$^{INK4ALuc/Luc}$were used. Experimental OA was induced by intraarticular injections of collagenase (CIOA).

Results: (1) CIOA was induced in senescence-driven luciferase transgenic mice. Under CCD camera, a peak in luminescence was detected revealing the presence of senescent cells in the joint. Remarkably, articular senescence also contributes to OA: mice deficient in p16INK4a, a main senescence-driving known cell cycle inhibitor, were partially protected against CIOA. These results were confirmed in C57Bl/6 mice after CIOA by showing an increase in gene expression for senescence in the synovial tissue. (2) MSCs found in synovial, cartilage, fat pad and bone marrow participate in joint homeostasis. Because MSC are at the root of OA development, we hypothesize that cellular senescence onset in these progenitors would be a possible etiological factor for OA. We stablished an in vitro p16^{INK4A}-induced senescence model on human MSC: their intrinsic properties (self-renewing and chondrogenesis) are altered when senescent. In co-culture conditions with chondrocytes from OA patients, senescent MSC lost their extrinsic chondroprotective properties. (3) To in vivo challenge these findings, we rely on the mouse model of accelerated senescence SAMP8, which develop spontaneous OA at the age of 6 months with cartilage degradation, synovial hypertrophy, osteophytosis and subchondral bone remodelingassociated to meniscal calcification (micro-tomography). Isolated MSC from these mice express senescence (p16^{INK4a}, p21^{waf1}, MMP13, TGF-β1). Intra-articular injection of these isolated SAMP8-derived MSC compared to SAMR1-derived control MSC, in young wid-type C57Bl/6 mice, was suffisant by its own, to induce significant articular cartilage degradation (OA score of 12.2 ± 1.5 vs 6.1 ± 3.5 for SAMP8 and SAMR1 MSC respectively. $p < 0.05$).

Conclusion: p16^{INK4A}-induced cellular senescence in MSC played a causative role in cartilage loss of function and OA pathogeny. *In vitro*, senescent MSC show altered intrinsic and extrinsic supportive tissue functions.*In vivo*, intra-articular injection of senescent MSC induced cartilage degradation. Specific targeting of such deleterious senescent cells could be an innovating and promising treatment in OA.

Critical Role of the Cholinergic System Involvement in Osteoarthritis

Alice Courties,[1] Ariane Do,[1] Sarah Leite,[2] Audrey Pigenet,[2] Morgane Belle,[3] Geoffroy Nourissat,[4] Alain Sautet,[5] Alain Chedotal,[3] Uwe Maskos,[6] Francis Berenbaum,[7] and Jérémie Sellam[1], [1]Service de Rhumatologie, AP-HP Hôpital Saint-Antoine, Sorbonne Université, INSERM, Centre de Recherche Saint-Antoine, Paris, France, Paris, France, [2]Sorbonne Université, INSERM, Centre de Recherche Saint-Antoine, Paris, France, Paris, France, [3]Sorbonne Université, INSERM, CNRS, Institut de la Vision, Paris, France, Paris, France, [4]Chirurgie orthopédique, Clinique Maussins, Groupe Ramsay générale de santé, 67 rue de Romainville, 75019, Paris, Paris, France, [5]Chirurgie orthopédique, AP-HP Hôpital Saint-Antoine, Paris, Paris, France, [6]Unité de neurobiologie intégrative des systèmes cholinergiques, CNRS UMR 3571, Institut Pasteur, Paris, Paris, France, [7]Sorbonne Université-Inserm CDR Saint-Antoine, AP-HP, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The efferent vagus nerve can regulate inflammation via its principal neurotransmitter acetylcholine (ACh), a concept referred as the 'cholinergic anti-inflammatory pathway'. ACh interacts with members of the nicotinic acetylcholine receptor (Chrna) family, in particular with the alpha7 subunit (Chrna7), which is expressed not only by neurons but also by other cells involved in inflammation.

We aimed to decipher the roles of the non-neuronal and neuronal cholinergic systems in osteoarthritis (OA).

Methods: To explore the presence of neuronal cholinergic fibers in the joints, we used a whole joint immunolabeling protocol after 3Disco clearing. We evaluated the coexpression of peripherin (nerve marker) and choline acetyltransferase (cholinergic marker) in human bone-cartilage samples, from OA patients undergoing knee arthroplasty.

To explore the role of the non-neuronal cholinergic pathway, primary cultures of human OA chondrocytes and of WT and KO Chrna7$^{-/-}$ murine osteoblasts (OB) and chondrocytes were performed. The expressions of the molecular partners of Ach metabolism and of the cholinergic nicotinic receptors were assessed. *In vitro*, WT and Chrna7$^{-/-}$ chondrocytes and OB were treated with IL1b for 24h. In order to study the role of nicotinic receptors in cell activation, chondrocytes and OB were pretreated with nicotine at 1; 10 or 100 μM. We quantified the production of interleukin-6 (IL6) and metalloproteinase (MMP) along with RANK-ligand for OB by ELISA.

To induce OA, medial meniscus destabilization (DMM) of the knee was performed on 12-week-old WT and Chrna7 $^{-/-}$ mice and histological OARSI scoring was compared after 8 weeks between both genotypes.

Results: Cholinergic fibers were present in subchondral bone of all 3 OA joints explants analyzed coming from 3 different patients (Fig 1). Human OA and murine chondrocytes as well as murine OB express the whole machinery needed for the synthesis, transport and degradation of Ach. All these cells express nicotinic subunits a 4, 5, 6, 7 and β4. IL1β stimulation induced a significant increased production of IL6 and MMPs by WT and Chrna7-/- chondrocytes. Nicotine pretreatment counteracted this effect (decrease of 65% for IL6, 64% for MMP3 with nicotine 10μM, n=5; $p < 0.05$). Conversely to what happened in WT, nicotine had no effect on Chrna7-/- chondrocytes supporting a predominant role of this receptor in chondrocyte activation. In OB, stimulation of nicotinic receptors decreased the production of IL6, MMP3 and RANK-L induced by IL1β in the same manner in WT and Chrna7-/- OB, meaning that other subunits

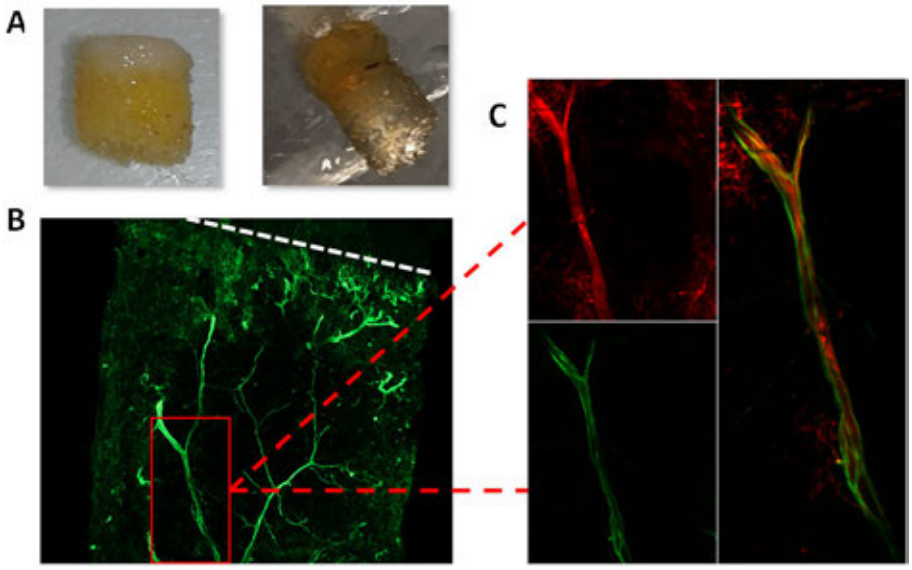

Figure 1. A: Osteoarthritic human bone and cartilage sample before and after 3DISCO clearing protocol, B and C: 3D in toto immunofluorescence of peripherin (nerve marker) in green and of ChAT (cholinergic nerve fiber) in red with colocalization of their expressions.

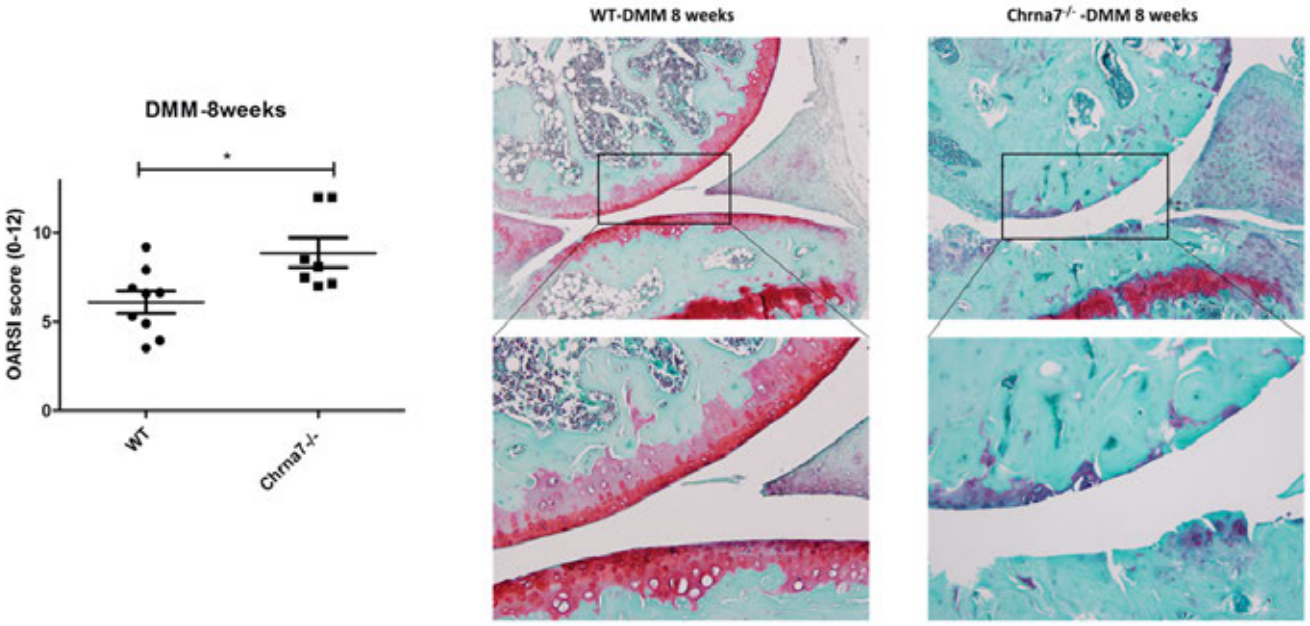

Figure 2. Chrna7 gene deletion is associated with more severe post-traumatic murine OA Left : OARSI score of the sum of femoral condyle and tibial plateau (0-12, 12 being the worst) between WT (n=9) and Chrna7 -/- (n=7) mice 8 weeks after the DMM,*p<0.05; Right : Representative SafraninO/fast green stained sections of the right knee 8 weeks after DMM in WT and Chnra7 -/- mice

than a7 are involved in OB activation. After DMM, Chrna7 -/- mice displayed significantly more OA lesions than their WT counterparts with a mean±SD OARSI score of 8.9±0.82 for Chrna7 -/- and 6.1±0.6 for WT (Fig 2).

Conclusion: Neuronal and non-neuronal cholinergic systems are present in murine and human joints. The activation of nicotinic receptors displays anti-inflammatory, anti-catabolic and antiresorptive properties on bone and cartilage. In chondrocytes this protective effect is mediated by the Chrna7 suggesting that activating the cholinergic system could be a new therapeutic target in OA.

Session Title: Osteoarthritis & Joint Biology – Basic Science

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Accumulated data indicated that osteoarthritis has a strong genetic component with a prevalent role of mitochondria and mtDNA variations. In the present work, we aimed to study the influence of the mtDNA variation in the joint deterioration in aging-related and surgically-induced OA in mice with the same nuclear genome but different mtDNA variants (named conplastic mice).

Methods: Conplastic mice (BL/6^{NZB}) strain was developed with the C57BL/6JOlaHsd nuclear genome and the NZB/OlaHsd mtDNA to compare with the original C57BL/6JOlaHsd strain (BL/6^{C57}).

In the spontaneous aging-related OA model, mice were kept under normal conditions and sacrificed at 25, 75 and 90 weeks of age. Hind knee joints from BL/6^{NZB} mice as well as from BL/6^{C57} mice were processed and cut into coronal sections for histological analysis. All sections were stained with Hematoxylin-Eosine and Safranin O-fast green and graded using a Mankin scoring system. Cartilage expression of markers of autophagy like LC3 and metalloproteinases like MMP-13 were also analyzed by immunohistochemistry. The surgical OA model was induced in 17 months old BL/6^{C57} and BL/6^{NZB} mice by transection of the medial meniscotibial ligament (DMM model) of the hind left knee joint. The right knee joint was used as sham surgery. The animals were euthanized 8 weeks later. Both hind knees were processed and cut into sagittal sections and examined for histopathological changes (OARSI scoring system, subchondral bone changes).

Results: In the aging model, conplastic mice BL/6^{NZB} presented reduced cartilage Mankin score at 25 (p=0.0317), 75 (p=0.0087) and 90 (p=0.0484) weeks compared with mice of the original strain BL/6^{C57} at the same age. Specifically, we showed a reduced score in both femoral condyle (FC) and tibial plateau (TP) of BL/6^{NZB} mice that reached the statistical significance at 25 (FC: p=0.0317; TP: p=0.0079) and 75 weeks (FC: p=0.0411; TP: p=0.0238). These results were accompanied with more expression of LC3 in cartilage from BL/6^{NZB} mice at 75 and 90 weeks when compared with cartilage from BL/6^{C57} at the same age. Difference in MMP13 cartilage expression between the two mice strains were also found. In the surgical OA model, we found that joints from BL/6^{NZB} mice presented a reduced OARSI score compared with BL/6^{C57} (p=0.018) in both femoral condyle and tibial plateau. We also observed less subchondral bone changes in BL/6^{NZB} mice compared with BL/6^{C57} mice (p=0.035).

Conclusion: This study demonstrates that mtDNA genetic manipulation improve both spontaneous joint aging and joint degradation in a conplastic aging animal model and in a surgically-induced OA conplastic mice respectively. BL/6^{NZB} conplastic mice develop less severe spontaneous joint aging and OA compared with the original strain BL/6^{C57}. These results support the hypothesis that mtDNA background has a role in the process of joint damage, suggesting a potential role of mtDNA as a novel therapeutic target in OA.

Identification of Genetic Variants Associated with Erosive Hand Osteoarthritis Using Pedigrees from a State-Wide Population-Based Cohort

Nikolas Kazmers,[1] Kendra Novak,[1] Zhe Yu,[2] Tyler Barker,[3] Tyler Abraham,[4] Robin Romero,[4] and Michael Jurynec[1], [1]University of Utah, Department of Orthopaedics, Salt Lake City, UT, [2]Huntsman Cancer Institute - Utah Population Database Resource, Salt Lake City, UT, [3]Intermountain Healthcare, Precision Genomics, Murray, UT, [4]Intermountain Healthcare, Precision Genomics, St. George, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Erosive osteoarthritis (EOA) of the hand is a characterized radiographically with centrally-located interphalangeal joint erosions, and clinically by its rapid onset, rapid rate of progression, and potential for substantial disability and deformity. Although an association between a single nucleotide polymorphism in the interleukin-1β gene has been demonstrated for EOA in a small case-control study, it remains unclear whether this condition has a genetic basis and there remains a lack of understanding of the underlying pathophysiology. Our purpose was to determine whether EOA clusters in families, which would suggest a genetic etiologic contribution. Secondarily, we performed genomic analyses on one high-risk family with EOA to identify candidate genes that have a significant contribution to the onset and progression of EOA.

Methods: EOA patients were identified by ICD-10 code (M15.4), then mapped to pedigrees using methods developed by the Utah Population Database (UPDB). The UPDB is a collection of >10 million individuals in multigenerational pedigrees dating back to the late 1700's which are linked to >30 million medical records. High-risk families with excess clustering of EOA were identified using the Familial Standardized Incidence Ratio (FSIR) threshold of ≥ 2.0. The magnitude of familial risk was calculated using relative risk from Cox regression models to determine the relative risk of EOA in related individuals using a ratio of 1:10 affected individuals to controls. Genomic analyses were performed as previously reported.

Results: We identified 231 unrelated high-risk pedigrees with an FSIR ≥ 2.0 (top pedigrees illustrated in Table 1). Of the 580 affected individuals within these pedigrees, mean age at diagnosis was 66 ± 11.0 years and 80.1% were female. The relative risk of developing EOA was significantly elevated in first-degree relatives (RR 30.51; 95% confidence interval 3.3 – 282.4; p = 0.0026). Genomic analyses in one EOA family consisting of two distantly related affected individuals and one unaffected sibling (Figure 1) identified a rare coding variant in the procollagen galactosyltransferase *COLGALT1* (Arg326Cys, AF - 0.00009) (Figure 2).

Conclusion: Our finding of excess familial clustering of hand EOA patients indicates a significant genetic contribution to the etiology of the disease. Although functional testing is still underway, we have identified a coding variant

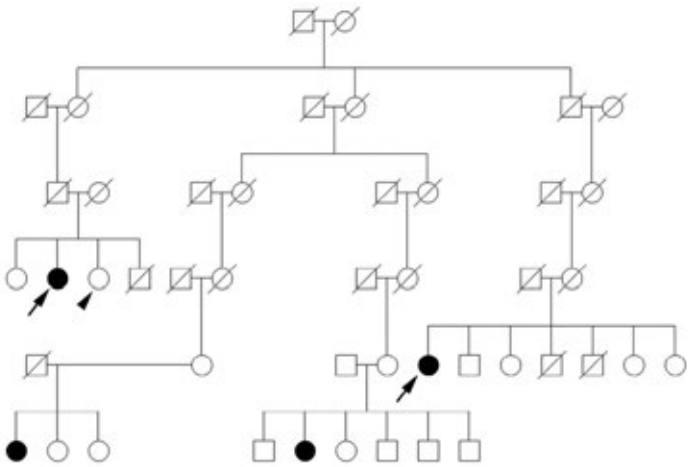

Figure 1 - EOA family #1 pedigree. EOA segregates as an apparent autosomal dominant trait. Arrows marks the affected individuals used for genomic analyses. Arrowhead marks the unaffected individual used for genomic analyses.

Table 1 - High-Risk Pedigrees with Excess Familial Clustering of Erosive Osteoarthritis of the Hand

Adenosine A2A Receptor Signaling Activates FoxO1 and FoxO3 and Promotes Cartilage Autophagy

Benjamin Friedman,[1] Carmen Corciulo,[2] Cristina Castro-Rivera,[2] and Bruce Cronstein[2], [1]Department of Medicine, Division of Rheumatology NYUSoM, NYC, [2]NYU Langone, New York

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Osteoarthritis (OA) is a debilitating and costly condition caused by loss of articular cartilage secondary to chondrocyte dysfunction. Autophagy is a homeostatic pathway that is upregulated in cellular stress and it is decreased in OA. Recent work demonstrates that the Forkhead transcription factors FoxO1 and FoxO3 regulate chondrocyte autophagy and their deficiency leads to the development of OA. We have previously reported that A2ARKO mice develop severe OA and rats with post-traumatic OA (PTOA) have lower OARSI scores when treated with liposomal preparations of adenosine by activating A2AR (Corciulo, et al NComms, 2017).

Methods: Active (non-phos FoxO) and inactive (Akt-phos FoxO) levels were evaluated in the human TC28α2 chondrocyte cell line by IF and WB after stimulation with the A2AR agonist CGS21680 (CGS, 1mM) +/- A2AR antagonist ZM241385 (ZM, 1mM) at 30 min. Autophagy proteins p62/SQTSM1, Gabarapl1, Beclin-1 and apoptosis proteins p53 and caspase 3 were analyzed by IF and WB at 1h. An *in vivo* obesity OA mouse model treated with joint injections of liposomal-CGS or lipo-adenosine was assessed by IHC for FoxO1/3 or phos-FoxO1/3, p62, Gabarapl1, and Beclin-1.

Results: FoxO1/3 both translocated to the nucleus in TC28α2 cells 30m post-CGS, while phos-FoxO1/3 translocated to the cytoplasm; these changes were all reversed with ZM pre-treatment. Total cellular FoxO1 increased significantly after A2AR activation by WB (1.6±0.08 vs 1.0±0.08, p< 0.001, n=4) and FoxO3 levels trended up (2.0±0.7 vs 1.0±0.3, p=0.11, n=3). There was p62 reduction in TC28α2 cells over a 3-hour time course (0.74±0.17 vs 1.0±0.24, p=0.01, n=3), which indicates active autophagy as p62 is degraded with the cargo. However, in the presence of 25μM hydroxychloroquine (HCQ) to inhibit autophagosome-lysosome fusion, there was a clear increase in p62 levels in A2AR-stimulated chondrocytes (78±7% vs 9±1.4% cells, p=0.003, n=3) consistent with increased autophagic flux. Similarly, autophagosome-associated Gabarapl1 and upstream regulator Beclin-1 formed punctate autophagy nucleation complexes after CGS treatment. While autophagy is generally pro-survival, it can be associated with apoptosis. We found that A2AR-stimulated autophagy was associated with decreased p53 level by WB at 1h (0.66±0.12 vs 1.0±0.11, p=0.02, n=3) and a visible reduction of p53 and caspase 3 by IF. The in vitro results were reflected by in vivo experiments from obese mouse knee joints, in which we observed an increase in cellular levels and nuclear localization of FoxO1/3 with a concomitant decrease in phos-FoxO1 in mice treated with the A2AR agonist. Similar to our in vitro results, the treated obese mice joints displayed decreased p62 and increase in Gabarapl1 and Beclin-1.

Conclusion: These results demonstrate that A2AR stimulation increases activation and nuclear localization of FoxO1 and FoxO3 and promotes an increase in autophagic flux without increasing apoptosis *in vitro*. More importantly, similar changes were observed *in vivo* in a murine model of obesity-induced OA. These findings provide a mechanism by which A2AR stimulation maintains chondrocyte homeostasis and reduces OA.

Lorecivivint (SM04690), a Potential Disease-Modifying Osteoarthritis Drug, Inhibits CLK2 and DYRK1A, Novel Molecular Regulators of Wnt Signaling, Chondrogenesis, and Inflammation

Vishal Deshmukh,[1] Alyssa O'Green,[1] Carine Bossard,[1] Tim Seo,[1] Lisa Lamangan,[1] Maureen Ibanez,[1] Abdullah Ghias,[1] Carolyn Lai,[1] Long Do,[1] Shawn Cho,[1] Joseph Cahiwat,[1] Kevin Chiu,[1] Melinda Pedraza,[1] and Yusuf Yazici[1], [1]Samumed, LLC, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis & Joint Biology – Basic Science
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In the synovial joint, Wnt pathway upregulation contributes to osteoarthritis (OA) by increasing osteocyte differentiation, cartilage thinning, and inflammation. Lorecivivint (LOR; SM04690), a novel small molecule, has previously demonstrated potential OA disease-modifying effects through Wnt pathway inhibition *in vitro*

and *in vivo*. These studies sought to elucidate the novel mechanism of action for LOR on Wnt pathway inhibition, chondrocyte differentiation, and anti-inflammation.

Methods: Wnt pathway activity was measured using a cell-based TCF/LEF luciferase reporter in SW480 colon cancer cells. A kinome screen (318 kinases) was performed. The effects of LOR on protein phosphorylation of serine and arginine rich splicing factors (SRSF proteins), Sirt1, and FoxO1 in hMSCs, chondrocytes, and synovial fibroblasts were measured by Western blot. The effects of LOR and siRNA knockdown (KD) on chondrogenic and Wnt pathway gene expression were measured by NanoString gene expression panels and effects on LPS-induced inflammatory cytokines (IL-6, IL-8, TNF-α) in BEAS-2B cells were measured by qPCR and ELISA. *In vivo*, the pharmacodynamic effects of LOR were evaluated in monosodium iodoacetate injection-induced and anterior cruciate ligament transection with partial medial meniscectomy rat knee OA models in which a single intra-articular LOR (0.1 µg, 0.3 µg, 1.0 µg) or vehicle injection was administered. Cartilage was isolated at Day 10 and 35; phosphorylation and expression of SRSF proteins, Sirt1, FoxO1, STAT3, and NF-κB were measured by Western blot.

Results: LOR was a potent (EC50=11nM) inhibitor of Wnt signaling. CDC-like kinases (CLKs) and dual-specificity tyrosine kinase (DYRK1A) were identified as molecular targets of LOR. In hMSCs and chondrocytes, compared to DMSO, LOR potently inhibited CLK-mediated phosphorylation of SRSF proteins. LOR also inhibited DYRK1A-mediated Sirt1 and FoxO1 phosphorylation, thus increasing total and nuclear FoxO1 levels. Compared to siRNA control, DYRK1A/CLK2 dual KD increased expression of chondrogenic genes (COL2A1, ACAN, COMP, CD44 [all $P < 0.05$]). Compared to siRNA control, CLK2 and DYRK1A KDs each inhibited Wnt pathway genes (AXIN2, TCF7, TCF4, LRP5, FZD6, FZD7, PITX2 [all $P < 0.05$]) with no effects on β-catenin levels. In synovial fibroblasts, compared to DMSO, LOR decreased phosphorylation of NF-kB and STAT3. In BEAS-2B cells, compared to siRNA control, DYRK1A KD inhibited inflammatory cytokine production (IL-6, IL-8, TNF-α [all $P < 0.05$]) while DYRK1A/CLK2 dual KD enhanced anti-inflammatory effects of DYRK1A KD. In cartilage from rat OA models, compared to vehicle, LOR inhibited phosphorylation of SRSF proteins, Sirt1, FoxO1, and STAT3 as well as expression of NF-κB.

Conclusion: Inhibition of nuclear kinases CLK2 and DYRK1A leads to effects on the Wnt pathway, chondrocytes, and inflammation **(Image)**. This dual mechanism of LOR potentially modifies OA through increased chondrocyte differentiation and function and benefits symptoms through anti-inflammatory activity. Human trials are ongoing.

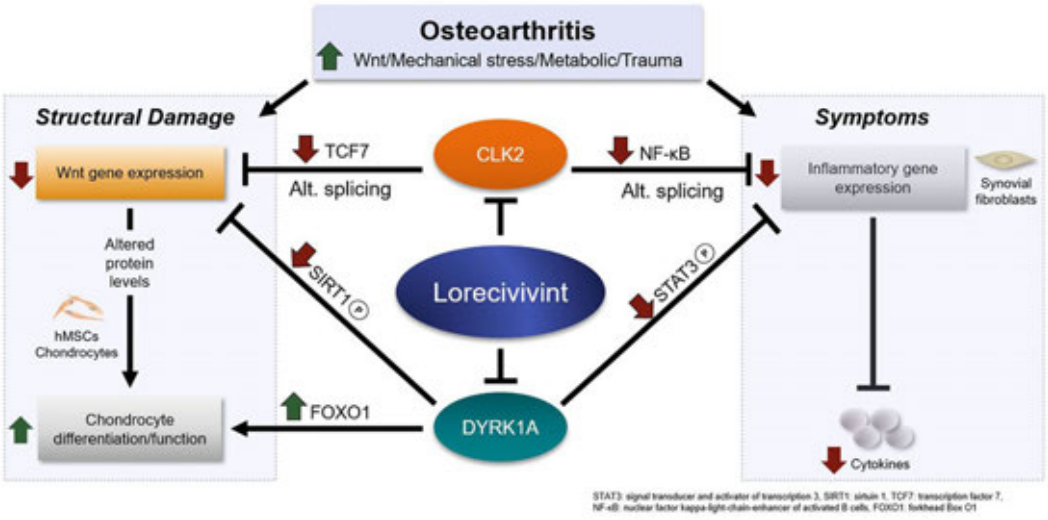

Image: Schematic representation of lorecivivint's proposed mechanism of action via CLK2 and DYRK1A inhibition in OA

Adverse Childhood Experiences Are Associated with Systemic Lupus Erythematosus in a Clinical Population from Bronx, New York

Roberto Valdovinos,[1] Nicole Brown,[2] Miguelina Germán,[2] Qi Gao,[3] Kaye Brathwaite,[2] Kimberly Reidy,[2] Dawn Wahezi,[4] Chaim Putterman,[5] Ruth E. Stein,[2] and Tamar Rubinstein[6], [1]Albert Einstein College of Medicine, Philadelphia, PA, [2]Children's Hospital at Montefiore/Albert Einstein College of Medicine, Bronx, [3]Albert Einstein College of Medicine, Bronx, [4]Children's Hospital at Montefiore, New York, [5]Albert Einstein College of Medicine, New York, NY, [6]Children's Hospital at Montefiore/Albert Einstein College of Medicine, Bronx, NY

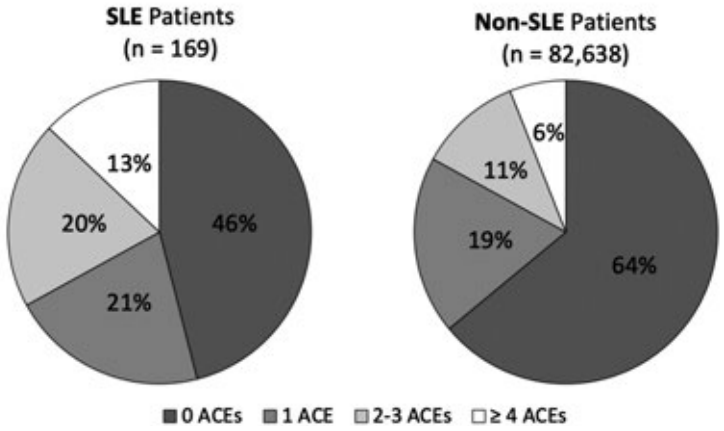
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Adverse Childhood Experiences (ACEs), which can result in chronic stress, are associated with autoimmune diseases in adulthood and arthritis in childhood. Recently ACEs were found to be associated with worse health outcomes as reported by adults with SLE in a dose-dependent manner. However, an association between ACEs and the diagnosis of SLE has not yet been demonstrated in either adult-onset or childhood-onset SLE. We aimed to determine whether ACEs are associated with SLE by examining ACE screens from patients with childhood- and adult-onset SLE compared to patients without SLE from Bronx, New York. We hypothesized that ACEs would be more common among patients with childhood-onset SLE and adult-onset SLE than those without SLE.

Methods: Using Clinical Looking Glass, a web-based software tool developed at a large, urban medical center in the Bronx, NY that allows for the extraction of patient data, we examined cross-sectional data on SLE diagnoses and ACE screenings administered at outpatient primary care and subspecialty clinics. Patients with SLE diagnoses were initially identified by billing diagnosis codes and validated by chart review to determine that they met either ACR or SLICC SLE classification criteria. We compared demographics using Pearson's chi-square for categorical variables and the Kruskal-Wallis test for nonparametric data. We examined ACE score as a categorical variable (0, 1, 2-3, $\geq$4) between patients with and without SLE. Multinomial logistic regression models were constructed to assess for associations between categorical ACE score and the presence of childhood-onset SLE or adult-onset SLE compared to no SLE, while adjusting for potential confounders (age, sex, race/ethnicity, and socioeconomic status).

Results: Our study included 169 SLE and 82,638 non-SLE patients. Age, sex, and race/ethnicity were significantly different between the two groups ($p< 0.001$), while socioeconomic status was not ($p=0.39$). The prevalence of any ACE in the SLE group was 54% vs 36% in non-SLE patients ($p< 0.001$). Overall, patients with SLE had higher ACE scores than patients without (Figure 1). Adjusted multinomial logistic regression revealed that ACEs at the levels of 2-3 and >4 were significantly associated with both childhood-onset and adult-onset SLE when compared to non-SLE patients. Further, there was a graded dose-response within the childhood-onset SLE group as the degree of ACE burden increased from 1 ACE, to 2-3 ACEs, and to >4 ACEs (Table 1).

Figure 1. ACE Burden in SLE vs non-SLE from Bronx, New York



Conclusion: Similar to prior studies of arthritis and other autoimmune diseases, this study found an association

Table 1. Multinomial Regression Model for Adverse Childhood Experience (ACE) Burden Among Patients with and without Childhood-onset Systemic Lupus Erythematosus (cSLE)

	Unadjusted model			Adjusted model*

between ACEs and SLE. This relationship is evident in both childhood-onset SLE and adult-onset SLE in this cohort from Bronx, NY, where social and economic disadvantage may place patients at a higher risk of developing ACEs. Understanding an association between ACEs and SLE development may elucidate biopsychosocial mechanisms for the disease. Further prospective studies should examine how ACEs impact disease development, activity, and damage.

Abstract Number: 0893

The Presence of Extractable Nuclear Antigens (ENA) Antibodies in a Large Population-based Cohort from the Netherlands and Their Association with Known Risk Factors for Systemic Lupus Erythematosus and Primary Sjögren Syndrome

Petra Yntema-Eckenhaussen,[1] Suzanne Arends,[1] Elisabeth Brouwer,[2] Caroline Roozendaal,[3] Hendrika Bootsma,[4] Johanna Westra,[1] and **Karina de Leeuw**[1], [1]Dept. of Rheumatology and Clinical Immunology - University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands, [2]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands, [3]Dept. of Laboratory Medicine - University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands, [4]University of Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Previous studies have demonstrated that years before clinical onset of auto-immune diseases, auto-antibodies can already be present. However, it is also known that some individuals can have these auto-antibodies and will never develop an auto-immune disease. So far, little information is available on the presence of antibodies to extractable nuclear antigens (anti-ENA) in the general population in relation to the risk of developing an auto-immune disease, with special interest for Systemic Lupus Erythematosus (SLE) and primary Sjögren Syndrome (pSS).

Objectives: To estimate the prevalence of anti-ENA and their association with the presence of known risk factors for SLE and pSS in the general Dutch population.

Methods: Lifelines is a prospective population-based cohort study in the Netherlands. Cross-sectional data from 40,135 participants were analyzed. The detection of anti-ENA was performed using the ENA-CTD (connective tissue disease) screen on the Phadia-250 analyzer with a ratio >1.0 considered positive. An extensive questionnaire was taken on demographic and clinical information (e.g. early musculoskeletal symptoms). Furthermore, some general blood parameters were available. SLE and pSS were defined by a combination of self-reported SLE or pSS, specific medication use and visiting a medical specialist within the last year. Characteristics were compared between 3 groups: SLE/pSS patients, anti-ENA positive, and anti-ENA negative participants.

Results: Of the total 40,135 consecutive individuals, 41 were detected as having defined SLE or pSS of whom 49% were anti-ENA positive. SLE/pSS patients were older and more often female. Of the remaining individuals (40,094), 1089 (2.7%) were found anti-ENA positive. Anti-ENA positivity was significantly associated with older age, female gender and joint stiffness compared to anti-ENA-negative participants. Interestingly, levels of haemoglobin, leucocytes and lymphocytes were significantly decreased in anti-ENA-positive participants compared to anti-ENA-negative participants. SLE/pSS participants had even significantly lower haemoglobin and reported even more joint stiffness then anti-ENA positive individuals. Lower lymphocyte levels, gender and older age appear as significantly independent predictors of anti-ENA positivity and also for being defined SLE/pSS. Of the anti-ENA positive individuals, 2.3% were positive for anti-dsDNA as well as anti-SSA. These individuals showed significantly lower lymphocyte-, leukocyte-, neutrophilic granulocyte- and monocyte levels compared to other anti-ENA positive participants.

Conclusion: In this large population-based study, the prevalence of anti-ENA-positivity was 2.8% for the total group and 2.7% when excluding patients with SLE or pSS. Older age, female gender, joint complaints and lower levels of hemoglobin, leucocytes and lymphocytes were more frequently present in anti-ENA-positive participants. Longitudinal studies are performed up to 15 years to investigate which individuals might develop SLE or pSS to be able to develop prediction models.

Abstract Number: 0894

Frequency, Severity and Costs of Flares Increase with Disease Severity in Newly Diagnosed Systematic Lupus Erythematous: A Real-World Cohort Study, United States, 2004–2015

Miao Jiang,[1] Barnabas Desta,[1] Aimee Near,[2] Xia Wang,[1] and **Edward Hammond**[1], [1]AstraZeneca, Gaithersburg, MD, [2]IQVIA, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: We evaluated the real-world frequency and severity of flares and associated costs 1 year post diagnosis in a US cohort with newly diagnosed SLE.

Methods: Adult patients with newly diagnosed SLE were identified using linked Truven Health MarketScan® commercial claims data and IQVIA's GE Centricity electronic medical record (EMR) database between January 1, 2005 and December 31, 2014. Patients were required to have no prior SLE or lupus nephritis diagnosis during 1 year prior to index date (diagnosis) and ≥1 year of continuous enrollment pre- and post-index date.

Disease severity and flare severity were classified as mild, moderate, or severe during 1 year post diagnosis using a claims-based algorithm, which combined SLE diagnosis, disease activity/SLE-related conditions (eg, end-stage renal disease as severe), medications (eg, oral corticosteroids [CS] ≥60 mg/day as severe), and health service use (eg, hospitalizations, emergency department visits), supplemented with EMRs (1). We evaluated the frequency and severity of flares by SLE severity during the first year post diagnosis. Annualized flare rates and all-cause costs 30, 60, and 90 days after a SLE flare were calculated using 2017 US dollars.

Results: Of 2,227 patients included in this analysis, the average age was 50.2 years; 90.6% were female and 54.4% white. In total, 26.3% (586) of patients were categorized as having mild, 51.0% (1,135) moderate, and 22.7% (506) severe SLE. Prescribed treatments included CS (76.1%), hydroxychloroquine (59.7%), methotrexate (14.7%), and biologics (2.7%).

The annualized flare rate among all SLE patients during the year post diagnosis was 3.45 (SD 1.90) flares. Annualized flare rates increased with disease severity: mild SLE, 2.23 (1.63); moderate SLE, 3.74 (1.73); severe SLE, 4.19 (1.89); $P < 0.0001$ (**Figure 1**). Patients with mild SLE did not experience severe flares. A total of 95.1% of all patients with

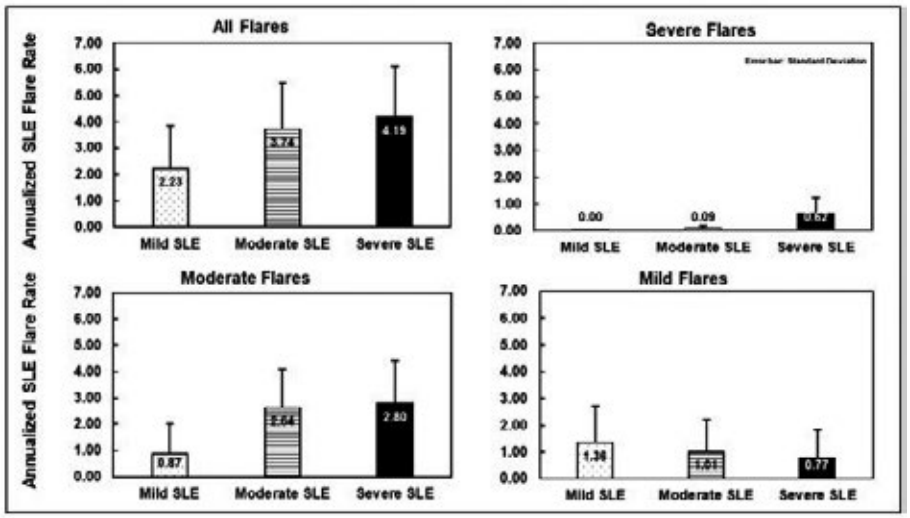

Figure 1. Annualized SLE Flare Rates (Mild, Moderate, and Severe) by SLE Disease Severity among Newly Diagnosed Patients During First Year of Diagnosis, United States 2005–2014

SLE had ≥1 flare, whereas 67.0% experienced 3 or more flares. The proportion of patients who experienced ≥3 flares increased with disease severity (42.0% mild, 74.5% moderate, and 79.6% severe SLE; $P< 0.0001$).

During the initial 30 days after a flare, the total mean all-cause cost of care was $3,884 (SD $12,178), and by flare severity was mild flare $1,672 ($4,566), moderate flare $3,831 ($11,552), and severe flare $16,856 ($29,001); $P< 0.0001$ (**Figure 2**). Health care costs following severe flares was 10.1-fold higher compared with mild flares and 4.4-fold higher for moderate flares compared with mild flares. Health care costs continued to increase 60 and 90 days after a flare with increasing flare severity. Inpatient costs were the primary driver of health care cost after a severe flare.

Conclusion: The frequency and severity of flares in patients with SLE increases with disease severity and with an associated significant increase in health care costs. Health care costs continue to increase substantially well into 90 days after a flare. Preventing the occurrence of flares, or reducing the rate and duration of flares, has potential to reduce SLE health care costs and reduce disease progression.

Abstract Number: 0895

A Spatial-temporal Analysis of Organ-specific Lupus Flares in Relation to Fine Particulate Matter Pollution and Temperature

George Stojan,[1] Anton Kvit,[2] Frank Curriero,[2] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: We performed a spatial-time cluster analysis of the Hopkins Lupus Cohort with the goal of identifying potential clusters of SLE organ specific flares and their relation to temperature changes and fine particulate matter pollution (PM2.5).

Methods: 1628 patients who fulfilled the SLICC classification criteria for SLE and who had recorded home addresses were included in the analysis. Disease activity was expressed as the Lupus Activity Index. Assessment of rash, joint involvement, serositis, neurologic, pulmonary, renal, and hematologic activity was quantified on a 0-3 VAS. An organ specific flare was defined as an increase in visual analogue scale (VAS) of 1 point or more compared to the previous visit. Daily fine particulate matter pollution (PM2.5) data measured in micrograms per cubic meter and temperature measured in degrees Fahrenheit were collected at various monitoring stations in the eastern United States and obtained from the Environmental Protection Agency. The nearest monitoring station for each patient at each visit date was determined, and the average PM2.5 concentration and temperature ten days prior to clinic visit was calculated. Both univariate and multivariate Generalized Estimating Equations (GEE) logistic regression models with an exchangeable correlation structure were built to study the association of individual (age, sex, ethnicity) and environmental (PM2.5, temperature) variables with the seven different outlined types of lupus disease activity. Spatiotemporal cluster detection was conducted using the SaTScan software. One month long minimum time intervals were considered for this analysis, and spatially overlapping clusters were allowed as long as the overlapping cluster did not contain the centroid of the cluster that was already there. Regression models were used for adjustment and included age, sex, and race, as well as PM2.5 and temperature.

Results: Three statistically significant ($p< 0.05$) unadjusted clusters were identified for joint flares, four rash flare clusters, one hematologic flare cluster, four neurologic flare clusters, three serositis flare clusters, four renal flare clusters, and five pulmonary flare clusters. Most of the identified clusters changed in significance, temporal, or spatial extent after adjusting for temperature, PM2.5 concentration, and individual covariates.

Conclusion: We describe the first space-time clusters of lupus organ-specific disease activity. Seasonal, as well as multi-year cluster patterns were identified, differing in extent and location for the various organ-specific flare types.

Many of the identified clusters changed in significance, temporal, or spatial extent after adjusting for environmental or individual covariates. Further study focusing on each individual lupus organ-specific activity will be required to better understand the driving forces behind these observed changes. The proposed spatial temporal analytical methods could lay the foundation for a new approach in the discovery of potential environmental and atmospheric factors and their role in the etiopathogenesis of lupus

Hydroxychloroquine Use and Cardiovascular Events Among Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis

April Jorge,[1] Na Lu,[2] Hyon K. Choi,[1] John Esdaile,[3] Diane Lacaille,[4] and J. Antonio Avina-Zubieta[5], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hosptial, Boston, MA, [3]Arthritis Research Canada and the University of British Columbia, Richmond, BC, Canada, [4]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada, [5]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Hydroxychloroquine (HCQ) is near-universally recommended for patients with SLE and is often used in the treatment of RA. Use of HCQ has been associated with reductions in hyperlipidemia, hyperglycemia, and hypercoagulability, which are established risk factors for cardiovascular-metabolic endpoints. We aimed to determine the potential temporal association between HCQ use and cardiovascular (CV) events among patients with SLE or RA.

Methods: We conducted a nested case-control study within a combined inception cohort of SLE and RA using an administrative health database including the entire population in the province of British Columbia, Canada. We identified cases with incident CV events, including non-fatal or fatal myocardial infarction (MI), stroke/transient ischemic attack (TIA), or venous thromboembolism (VTE) (e.g., deep vein thrombosis and pulmonary embolism), as defined by ICD codes. For each case, we identified up to three controls with SLE or RA matched on age, sex, and disease. HCQ exposure was categorized by the time between the last HCQ prescription date covered and the index date as remote (>365 days), recent (30-365 days) current (< 30 days), or never used.We used conditional logistic regression to assess the association between current use of HCQ or recent discontinuation of HCQ and the risks of incident combined CV events, MI, stroke/TIA, and VTE relative to remote HCQ use. Fully adjusted models included age, sex, SLE vs. RA, Charlson comorbidity index, chronic kidney disease, glucocorticoids, other DMARDs, cardiovascular medication use, and healthcare utilization assessed at the time of SLE or RA diagnosis.

Results: We identified 532 SLE cases matched with 1,249 SLE controls and 9,736 RA cases matched with 28,720 RA controls. The mean age at index date was 74 years. The majority were female (64% of cases and controls) (**Table 1**). Adjusted odd ratios (ORs) for combined CV events relative to the remote users were 0.83 (95% CI: 0.73, 0.93) for current users and 1.08 (95% CI: 0.91, 1.29) for subjects who recently discontinued HCQ (**Table 2**). HCQ non-users had the same risk of combined CV events as remote users (OR 0.99 [95% CI: 0.90, 1.08]).

Table 1. Characteristics of SLE and RA Cases with Cardiovascular Events and Matched Controls

Variable	Cases (n=10,268)	Controls (n=29,969)
Age (mean, SD)	74 (13)	74 (13)
Sex (% female)	63.6	63.7
Systemic Lupus Erythematosus (n)	532	1249
Rheumatoid Arthritis (n)	9736	28720
Charlson comorbidity index, mean (SD)	1.20 (1.21)	1.04 (1.03)
Chronic Kidney Disease (%)	14.3	11.8
Medications (%)		
Glucocorticoids	32.0	27.0
Cardiovascular medications	53.6	42.9
Other DMARDs	15.9	14.3
Healthcare Utilization, mean (SD)		
Number of hospitalizations	0.6 (1.1)	0.4 (0.8)
Number of outpatient visits	27.2 (19.7)	22.4 (15.5)

DMARDs, disease-modifying anti-rheumatic drugs. Includes azathioprine, methotrexate, mycophenolate, leflunomide, cyclosporine, cyclophosphamide, penicillamine, chlorambucil, minocycline, and gold.
Cardiovascular medications include anti-hypertensives, cardiac glycosides, diuretics, anti-arrhythmics, nitrates, and anticoagulants.

Table 2. Hydroxychloroquine Use and Cardiovascular Events According to Hydroxychloroquine Exposure Status

	Cases, N	Controls, N	Odds Ratio (95% CI)	Adjusted* Odds Ratio (95% CI)
Combined CV Events				
Remote HCQ Users	784	2097	1.0 (reference)	1.0 (reference)
Recent HCQ users	228	543	1.10 (0.93-1.30)	1.08 (0.91-1.29)
Current HCQ users	715	2101	0.88 (0.79-0.99)	0.83 (0.73-0.93)
HCQ non-users	8461	25197	0.88 (0.81-0.96)	0.99 (0.90-1.08)
Myocardial Infarction				
Remote HCQ Users	351	909	1.0 (reference)	1.0 (reference)
Recent HCQ users	103	242	1.09 (0.84-1.42)	1.09 (0.84-1.43)
Current HCQ users	333	927	0.92 (0.77-1.10)	0.86 (0.72-1.04)
HCQ non-users	3742	11227	0.86 (0.75-0.98)	0.95 (0.83-1.09)
Stroke/TIA				
Remote HCQ Users	314	881	1.0 (reference)	1.0 (reference)
Recent HCQ users	86	217	1.11 (0.83-1.46)	1.09 (0.82-1.45)
Current HCQ users	273	856	0.91 (0.75-1.10)	0.84 (0.69-1.02)
HCQ non-users	3636	10707	0.97 (0.84-1.11)	1.03 (0.89-1.18)
Venous Thromboembolism				
Remote HCQ Users	119	307	1.0 (reference)	1.0 (reference)
Recent HCQ users	39	84	1.21 (0.78-1.88)	1.06 (0.68-1.67)
Current HCQ users	109	318	0.89 (0.65-1.21)	0.73 (0.53-1.00)
HCQ non-users	1083	3263	0.86 (0.68-1.08)	0.92 (0.73-1.17)

*Additionally adjusted for Charlson comorbidity index, chronic kidney disease, glucocorticoid use, DMARD use, and cardiovascular medication use.

Conclusion: In this nested case-control study within an incident SLE/RA cohort, we found a 17% reduced risk of incident CV events overall associated with current HCQ use. We also identified trends towards reduced risks of MI, Stroke/TIA, and VTE associated with current HCQ use. By leveraging remote users as the comparison group, we reduced the potential for confounding by indication. These findings suggest a preventative benefit of HCQ use in reducing CV disease among patients with SLE and RA.

Abstract Number: 0897

Mortality Rates After Coronary Revascularization Procedures Among Systemic Lupus Erythematosus Compared to Diabetes Mellitus and General Population Medicaid Patients

Medha Barbhaiya,[1] Sarah Chen,[2] Candace Feldman,[3] Hongshu Guan,[3] Brendan Everett,[4] and Karen Costenbader[4], [1]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, [3]Brigham and Women's Hospital, Boston, [4]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Epidemiology & Public Health II: SLE
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Despite similar myocardial infarction risks in SLE and diabetes mellitus (DM) patients, individuals with SLE enrolled in Medicaid had substantially higher rates of coronary artery bypass grafting (CABG) and percutaneous coronary intervention (PCI) compared to age- and sex-matched DM patients. However, little is known about mortality after coronary revascularization procedures in SLE versus DM and general population patients and we hypothesized that SLE patients would have poorer outcomes. We evaluated 30-day mortality rates following coronary revascularization procedures among SLE compared to DM and general population patients enrolled in Medicaid.

Methods: We utilized Medicaid Analytic eXtract (MAX) data, containing billing claims from 29 most populated U.S. states (2007-2010) and identified adults aged ≥18-65 years with prevalent SLE or DM (≥3 ICD-9 codes, each ≥30 days apart) and >6 months enrollment prior to 3rd code, and patients without SLE or DM ("general population"). Among those in each cohort undergoing first CABG or PCI, we calculated post-procedure 30-day mortality rates (MRs) and mortality rate ratios (MRRs) per 1,000 person-years, with 95% confidence intervals (95% CIs) com-

Table. 30-day Mortality Rates and Adjusted Risks following Coronary Revascularization Procedures (Coronary Artery Bypass Graft and/or Percutaneous Coronary Intervention) in Systemic Lupus Erythematosus (SLE), Diabetes Mellitus (DM), and General Population (Non-SLE/Non-DM) Medicaid patients (2007-2010)

OR for death***[B] (95% CI)	**2.13 (1.09-4.13)**	1.0 (ref)	1.10 (0.50-2.50)

*MR = mortality rate, per 1,000 person years, **MRR= unadjusted mortality rate ratio
***OR=odds ratio for death within 30 days of coronary revascularization, adjusted for age (continuous), sex, race/ethnicity, Charlson score
[A]General population reference group
[B]Diabetes mellitus reference group
SD= standard deviation
---event cell sizes and follow-up suppressed given Federal reporting guidelines

pared to the DM and general populations separately. We used multivariable logistic regression models, adjusting for age, sex, race/ethnicity and Charlson index, to calculate odds ratios (OR) and 95% CIs, for 30-day mortality post-coronary revascularization procedures in the SLE compared to the DM and general population cohorts separately.

Results: Among 40,212 SLE patients, we identified 608 (1.51%) coronary revascularization procedures; among 80,424 prevalent DM, we identified 1185 (1.47%), and among 160,848 general population patients, there were 628 (0.39%) over similar follow-up periods in each group (approximately 1.7 years). Demographics and deaths within 30 days are shown in **Table**. Mean age at procedure was youngest in SLE patients and proportion of Black patients was highest in SLE. SLE patients had the highest 30-day post-revascularization mortality rate (351.35 [95% CI 221.36-557.67]) per 1,000 person years of observation, compared to DM (MRR 1.67 [95%CI 1.25-2.21]) and the general population (MRR 1.85 [1.31-2.63]). After multivariable adjustment, the odds of death within 30 days of coronary revascularization procedure were doubled in SLE compared to DM (OR 2.13 [95%CI 1.09-4.13]); a similar but non-significant trend was seen for SLE compared to general population (OR 1.93 [95%CI 0.85-4.42]).

Conclusion: SLE patients had 1.7 times higher 30-day mortality rates post-coronary revascularization compared to DM and general population patients, despite being on average much younger at procedure. After adjusting for demographics and comorbid index, SLE patients were twice as likely to die within 30-days of coronary revascularization procedure as DM patients. Future studies accounting for healthcare utilization, the complexity and indications of the procedures performed, SLE and cardiac disease severity, and investigating causes of post-procedure deaths are required.

definitions for elementary lesions in gout including the double contour (DC) sign (depositions of crystals on the surface of cartilage), tophus (larger hypo-echoic aggregation of crystals, usually well delineated) and aggregates (small hyper-echoic deposits). The present objective was to explore by ultrasound the longitudinal change of MSU depositions during a treat-to-target (T2T) approach with urate lowering therapy (ULT) in patients with gout.

Methods: In a prospective observational study, patients with crystal-proven gout were included if they presented after a recent gout flare and had increased serum urate levels (>360 μmol/L). The T2T approach focused on ULT and increasing drug doses with monthly follow-up until the treatment target was met (< 360 μmol/L, or < 300 μmol/L if clinical tophi), and no scheduled visits between 12 and 24 months. An extensive ultrasound assessment was performed (GE E9 machine, grey scale 15MHz) at baseline and after 3, 6, 12 and 24 months to assess MSU depositons (DC, tophi and aggregates) with bilateral assessment of radiocarpal joint, MCP 2, insertion of triceps and quadriceps, proximal and distal patellar and the Achilles tendon, cartilage of distal femur (maximal flexed knee), the talar cartilage of tibiotalar joint and MTP 1 joint. The degree of elementary lesions was semi-quantitatively scored 0-3 (0=none, 1=possible, 2=certain, 3=major deposits). Total sum scores of DC, tophi and aggregates separately as well as all lesions combined were calculated at each visit. Changes from baseline were explored by paired samples T-test.

Results: 207 patients were included at baseline (94.3% men, mean (SD) age 56.3 (13.7) years, disease duration 7.9 (7.7) years). The mean (SD) serum urate level decreased from 496 (81) μmol/L at baseline to 332 (75) μmol/L at 24 months. The treatment target was met in 87% at 12 months and in 76% at 24 months. Sum scores of MSU depositions decreased over 24 months (table) and the numeric decrease was most pronounced for DC (figure). At baseline/24 months the percentages of patients with no presence of DC sign was 7%/70%, no tophi; 7%/27% and no aggregates 1%/7%. Of patients having DC at baseline, 62% had no detected DC at 24 months, for tophi the corresponding percentages was 20, and for aggregates 6.

Conclusion: This study shows that most of the patients reached the target during T2T lowering therapy, and that this was followed by a major reduction of the ultrasound detected MSU depositions, especially DC.

Lack of Effect of Tart Cherry Concentrate Dose on Serum Urate in People with Gout

Lisa Stamp,[1] Yuqing Zhang,[2] Christopher Frampton,[3] Jill Drake,[3] Peter Chapman,[4] Stephen Duffull,[5] and Tuhina Neogi[6], [1]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand, [2]Massachusetts General Hospital, Boston, MA, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]Christchurch Hospital, Christchurch, New Zealand, [5]University of Otago, Dunedin, New Zealand, [6]Boston University School of Medicine, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies I: Clinical
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In small studies, cherries and cherry concentrate have been suggested to reduce serum urate and gout flares. The aims of this study were to determine the magnitude of the effect of tart cherry concentrate on serum urate in people with gout, the most effective dose of tart cherry concentrate in lowering serum urate, and adverse effects with tart cherry concentrate.

Methods: Fifty people with gout as defined by ARA preliminary classification criteria for gout AND a serum urate >6mg/dl (0.36mmol/l) were recruited. People with type 2 diabetes and those receiving diuretics were excluded. Half the participants were already receiving allopurinol and half were on no urate lowering therapy at the time of recruitment, and participants in each of these blocks were randomised into 5 Cherryvite montmorency tart cherry juice concentrate groups: placebo, 7.5mls twice daily, 15mls twice daily, 22.5mls twice daily and 30mls twice daily for 28 days. Participants were commenced on tart cherry concentrate and blood samples were taken at baseline, the 1, 3, and 5 hours post cherry and then day 1, 3, 7, 14, 21 and 28. Urine anthocyanin concentrations were determined by HPLC as a measure of compliance at before any cherry concentrate day 0 and 28. AUC for serum urate was calculated over the 28-day study period.

Table: Effect of cherry concentrate

	Placebo			7.5mls			15mls			22.5mls			30mls		
	Day 0	Day 28	Change	Day 0	Day 28	Change	Day 0	Day 28	Change	Day 0	Day 28	Change	Day 0	Day 28	Change

HBA1C	37.6 (9.1)	36.5 (8.2)	-1.1 (4.0)	36.1 (7.3)	36.5 (9.4)	0.5 (4.0)	40.3 (13.5)	39.7 (12.4)	-0.6 (5.0)	33.6 (4.4)	34.2 (5.3)	0.7 (3.3)	33.3 (4.6)	34.5 (4.5)	1.2 (2.9)
Urine anthocyanins	2482 (2441)	10039 (12662)	7557 (11443)	3899 (5085)	17018 (20696)	12631 (22431)	1213 (1866)	17509 (26534)	16417 (26254)	1258 (2723)	11266 (10002)	10008 (10916)	2217 (2445)	15619 (15668)	13662 (15303)
Gout flares	0.5 (0.5)	0.4 (0.5)	-0.1 (0.6)	0.4 (0.5)	0.6 (0.5)	0.1 (0.8)	0.2 (0.4)	0.4 (0.5)	0.2 (0.6)	0.4 (0.5)	0.6 (0.5)	0.1 (0.6)	0.0 (0.0)	0.4 (0.5)	0.4 (0.5)

Data are mean (SD)

Results: Cherry concentrate dose had no significant effect on reduction in serum urate AUC over the 28-day study period. There was no influence of cherry concentrate on the urate lowering effect of allopurinol. There was no effect of cherry concentrate dose on change in urinary anthocyanin between day 0 and day 28 (table). However, those receiving allopurinol had significantly greater increases in urinary anthocyanins (p< 001). Cherry concentrate dose had no significant effect on urinary urate excretion as measured by Simkin Index (p=0.53) or fractional excretion of urate (p=0.32). There were 24 adverse events over the 28 day period with only one (hyperglycaemia) considered possibly related to cherry concentrate. There was no significant effect of cherry concentrate on change in HbA1c (p=0.68) or weight (p=0.80) over the 28 days. There was no effect of cherry concentrate on the frequency of gout flares over the 28-day study period p=0.76) (table).

Conclusion: Tart cherry concentrate had no effect on serum urate or urine urate excretion over 28 days. Reassuringly there were few adverse events. If there is an effect of cherry concentrate on gout flares over a longer time period it is not likely to be mediated by reduction in serum urate.

Serum Urate Lowering with Allopurinol Improves Endothelial Function in Young Adults

Angelo Gaffo,[1] David Calhoun,[2] Elizabeth Rahn,[1] Suzanne Oparil,[2] Peng Li,[2] Tanja Dudenbostel,[2] David Redden,[2] Amy Mudano,[2] Jeffrey Foster,[1] Daniel Feig,[2] Stephanie Biggers,[2] and Kenneth Saag[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies I: Clinical
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: An effect of serum urate on vascular endothelium has been postulated as a mechanism for its association with hypertension and cardiovascular disease. Prior studies in this area have produced conflicting

	Mean or frequency
Age (years)	27.7± 7.0
Gender Male Female	 49 (64%) 28 (36%)
Race/Ethnicity African American Not African American	 30 (39%) 47 (61%)
Serum urate at baseline Male Female	 6.3 ± 0.9 mg/dL 4.9 ± 0.9 mg/dL
Blood pressure at enrollment Mean Systolic (mmHg) Mean Diastolic (mmHg)	 133.8 ± 10.2 84.1 ± 9.2
FMD at baseline (%)	9.9 ± 4.1
Highly sensitive C-reactive protein at baseline (mg/L) (n=79)	3.8 ± 4.7

Table 1. Baseline characteristics of participants who completed FMD testing (n =77)

Outcomes	Placebo			Allopurinol			p for change in FMD
	Pretreatment	End of Placebo phase	p	Pretreatment	End of Allopurinol phase	p	
FMD (%)	9.9 (4.3)	9.8 (4.3)	0.76	9.9 (5.1)	12.9 (5.4)	<0.0001	
Change in FMD (%)		-0.1 (3.6)			2.9 (4.5)		<0.0001

Table 2. Endothelial function measured as flow mediated dilation (FMD) percent change during placebo and allopurinol administration phases

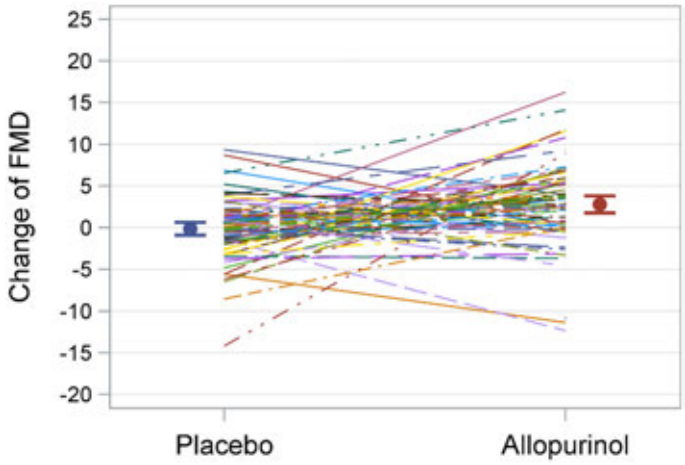

Figure. Change in endothelial function measured as flow mediated dilation (FMD) percent change during placebo and allopurinol administration phases

results. We sought to test the hypothesis that serum urate reduction with allopurinol would lead to improvements in endothelial function in young adults with pre-hypertension.

Methods: Single center, double-blinded, crossover trial in which participants were randomly assigned to allopurinol (300 daily mg) and placebo for a period of 4 weeks, separated by a 2-4 week washout. Adults ages 18-40 with base-

line systolic blood pressure (SBP) ≥ 120 and < 160 mm Hg or diastolic blood pressure ≥ 80 and < 100 mm Hg, and serum urate ≥ 5.0 mg/dL for men or ≥ 4.0 mg/dL for women were enrolled. Key exclusion criteria included chronic kidney disease, gout, or use of urate-lowering therapies. Endothelial function was assessed with flow-mediated dilation (FMD) testing of the brachial artery using high-resolution ultrasound at four study time points: 1) first baseline, 2) post-allopurinol or placebo treatment, 3) second baseline post-washout, and 4) post-placebo or allopurinol treatment. High-sensitive C-reactive protein (hs-CRP) was measured at the same study points as FMD. Safety assessments were conducted as part of the study.

Results: Of the 99 randomized main study participants, 77 completed all FMD testing (Table 1). Among these 77 participants, serum urate decreased by 1.40 + 1.19 mg/dL during the allopurinol period ($p< 0.0001$) and by a (non-significant) 0.06 + 0.76 mg/dL while taking placebo. The percent change in FMD was highly significant ($p< 0.001$) during the period assigned to allopurinol (2.9 ± 4.5) versus during the period assigned to placebo (-0.1 ± 3.6)(Table 2 and Figure). Changes in serum urate and FMD were highly correlated (Pearson r = -0.31, p =0.005). Improvements in FMD measurements while taking allopurinol were seen across all studied participant subgroups (younger and older, men and women, African-American and non-African-American, higher categories of serum urate, higher blood pressure at baseline visits). There were no changes from baseline in hs-CRP levels after the allopurinol or placebo phases. No allopurinol hypersensitivity events or other serious adverse events were observed.

Conclusion: Urate-lowering therapy with allopurinol in young adults led to significant improvements in endothelial function when compared with placebo while there was no observed effect on hs-CRP levels.

Sensitivity of Dual-Energy CT, Ultrasound, and X-Ray for Pseudogout: A Pilot Study

Sara K. Tedeschi,[1] Daniel Solomon,[2] Kathleen Vanni,[3] Dong Suh,[3] and Stacy Smith[4], [1]Brigham and Women's Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA, [2]Brigham and Women´s Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA, [3]Brigham and Women's Hospital, Boston, MA, [4]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies I: Clinical
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Advanced imaging modalities such as ultrasound (US) and dual-energy CT (DECT) can help diagnose crystalline arthritis. DECT is a highly sensitive and specific modality to detect gout and has not been well studied in pseudogout. We compared the sensitivity of DECT, US, and x-ray (XR) in pseudogout.

Table 1. Performance of DECT, ultrasound and x-ray in pseudogout

	DECT volume >0.40 cm^3	DECT volume >0.01 cm^3	Ultrasound	X-ray
Sensitivity (95% CI) in the aspirated joint	90% (62-100%)	100% (74-100%)	100% (74-100%)	70% (41-92%)
Prevalence (95% CI) in the standardized joint	20% (4-49%)	90% (62-100%)	80% (51-96%)	30% (9-59%)

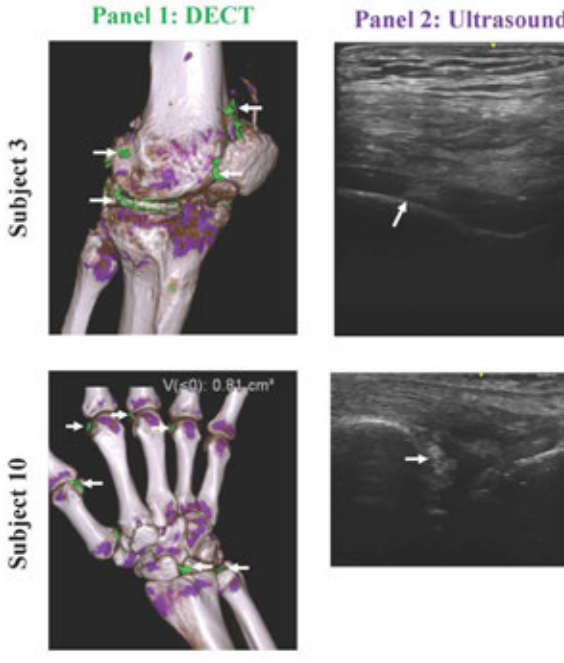

Figure 1. DECT, ultrasound, and x-ray images of an aspirated knee (top row) and wrist (bottom row), each with synovial fluid CPP crystals. Imaging abnormalities are indicated with white arrows.

Panel 1: DECT. 3D volume-rendered technique reconstructed DECT images using Siemens CT *syngo.*via CPPD software package. CPP deposits are shown in green.

Panel 2: Ultrasound. Calcific deposits in the femoral hyaline cartilage (top row) and TFCC (bottom row)

Panel 3: X-ray. Chondrocalcinosis in the meniscus and intercondylar notch (top row) and in the intercarpal joints, radiocarpal joint, and TFCC (bottom row)

Methods: We prospectively enrolled patients with crystal-proven pseudogout in a pilot study at a tertiary care center, 3/2018-11/2018. Eligible patients were 18 years old with acute monoarthritis, joint aspiration, and synovial fluid calcium pyrophosphate (CPP) crystals identified via polarized microscopy. Patients with both monosodium urate and CPP crystals were excluded. Subjects underwent DECT, US, and XR of the aspirated joint and a standardized joint (right wrist). A musculoskeletal radiologist interpreted all images; a rheumatologist trained in US additionally interpreted US images and consensus was reached for each scan. DECT images were post-processed using Siemens syngo. via software, applying color-coded overlay indicating volume and location of CPP deposits. DECT was defined as positive if color-coded overlay consistent with CPP was present. We excluded artifacts in nail beds, skin, motion or beam hardening, and deposits < 1 mm. We considered two volume thresholds (cm^3) for a positive DECT scan after inspecting the data: >0.40 cm^3 and >0.01 cm^3. Ultrasound was defined as positive if hyperechoic deposits in hyaline cartilage, fibrocartilage, or tendon were observed. X-ray was defined as positive if chondrocalcinosis was observed in hyaline cartilage or fibrocartilage. We calculated the sensitivity of a positive scan in the aspirated joint (reference standard: synovial fluid CPP crystals) and prevalence in the standardized joint.

Results: Ten patients enrolled a mean (SD) of 17 (9) days after joint aspiration. Mean age was 73 (10) years and 40% were female. The knee was aspirated in 8/10 and the wrist was aspirated in 2/10. Six subjects received intra-articular

steroids before enrollment. In the aspirated joint, sensitivity (95% confidence interval) was 90% (62-100%) for DECT volume >0.40 cm^3, and 100% (74-100%) for DECT volume >0.01 cm^3; 100% (74-100%) for US; and 70% (41-92%) for XR (**Table 1**). In the standardized joint, DECT was positive in 20% (4-49%) for volume >0.40 cm^3, and 90% (62-100%) for volume >0.01 cm^3. XR chondrocalcinosis was present in 30% (9-59%) and US was positive in 80% (51-96%) of wrists. Representative images from an aspirated knee and wrist are presented in **Figure1**.

Conclusion: DECT and US had high sensitivity for pseudogout using synovial fluid CPP crystal analysis as the reference standard. Larger studies testing the sensitivity and specificity of DECT in pseudogout vs. other types of arthritis and establishing a volume threshold are needed.

The Effects of a Low-Fat, Mediterranean, or Low-Carbohydrate Diet on Serum Urate

Chio Yokose,[1] Sharan Rai,[2] Na Lu,[3] Natalie McCormick,[4] Gary Curhan,[5] and Hyon K. Choi[1], [1]Massachusetts General Hospital, Boston, MA, [2]Department of Nutrition, Harvard T.H. Chan School of Public Health, Boston, MA, [3]Massachusetts General Hosptial, Boston, MA, [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [5]Channing Laboratory and Renal Division, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Metabolic & Crystal Arthropathies I: Clinical
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Gout and hyperuricemia are associated with cardiometabolic comorbidities and increased risk of premature mortality. Often, low-purine (i.e., low-protein) diets are recommended for patients with gout, based on epidemiologic studies linking purine intake and risk of incident gout and gout flares. However, such a diet could potentially lead to higher intake of foods rich in refined carbohydrates and trans fat, which could worsen the cardiometabolic comorbidities of gout. Conversely, diets that promote weight loss, such as Mediterranean and low-carbohydrate diets, could improve cardiovascular risk factors and may also reduce serum urate (SU) by improving insulin resistance, thereby enhancing urate excretion. However, clinical trial data on the effect of dietary interventions on SU are scarce. Thus, the objective of this study was to determine the effects of three established weight loss diets (i. low-fat restricted calorie; ii. Mediterranean restricted calorie; iii. low-carbohydrate non-restricted calorie) on SU levels by conducting a post-hoc analysis of the Dietary Intervention Randomized Controlled Trial (DIRECT) study.

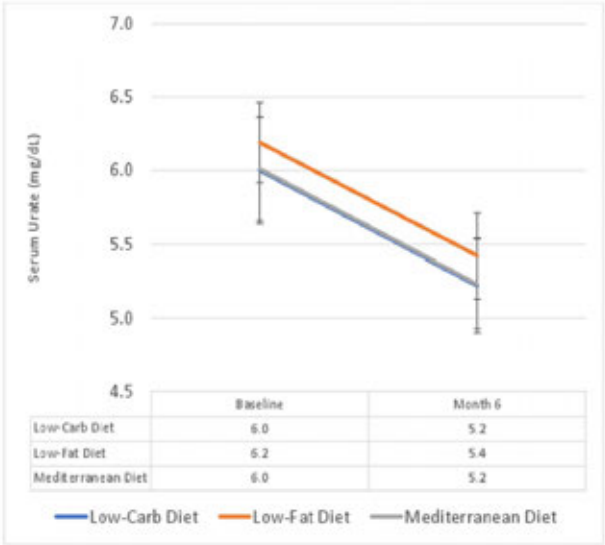
Methods: The DIRECT study included men and women age 40-65 with a body mass index (BMI) of at least 27 kg/m^2 or a diagnosis of either type 2 diabetes or coronary heart disease (regardless of BMI). Participants were randomly assigned to one of three weight loss diets: i. low-fat restricted calorie; ii. Mediterranean restricted calorie; iii. low-carbohydrate non-restricted calorie. We measured SU levels at baseline and 6 months using stored samples from the study from 232 trial participants. The primary outcome of this ancillary analysis was the change in SU from baseline among the three diet groups.

Table 1: Baseline Characteristics of Study Participants

Baseline Characteristics*	Low-Fat Diet (n=84)	Mediterranean Diet (n=75)	Low-Carbohydrate Diet (n=73)
Age, years	50.8 ± 6.5	52.6 ± 6.2	51.2 ± 6.2
Male, N (%)	72 (85.7)	65 (86.7)	66 (90.4)
SUA, mg/dL	6.2 ± 1.3	6.0 ± 1.5	6.0 ± 1.5
SU ≥ 7 mg/dL, N (%)	22 (26.2)	17 (22.7)	18 (24.7)
BMI, kg/m^2	30.5 ± 3.1	30.1 ± 3.3	30.7 ± 3.5
Weight, kg	90.8 ± 12.2	87.7 ± 12.1	91.3 ± 14.6
Diabetes, N (%)	10 (11.9)	11 (14.7)	12 (16.4)
Coronary heart disease, N (%)	27 (32.1)	36 (48.0)	20 (27.8)
Blood pressure, mm Hg			
Systolic	129.8 ± 12.6	131.3 ± 16.4	129.3 ± 14.3
Diastolic	79.0 ± 8.8	80.0 ± 10.2	77.5 ± 8.1
Lipid profile			
HDL, mg/dL	38.4 ± 9.7	40.2 ± 9.8	37.2 ± 8.8
Triglycerides, mg/dL	155.9 ± 62.5	168.5 ± 65.1	171.9 ± 84.8
Total cholesterol : HDL ratio	5.2 ± 1.4	5.3 ± 1.4	5.6 ± 1.5
GFR, ml/minute/1.73 m^2	96.4 ± 23.6	92.6 ± 18.7	99.2 ± 21.8
HOMA-IR	2.8 ± 1.9	3.4 ± 2.7	3.4 ± 3.2

*Unless indicated otherwise, values are the mean ± standard deviation.
Abbreviations: SU – serum urate; BMI – body mass index; HDL – high-density lipoprotein; GFR – glomerular filtration rate; HOMA-IR – homeostasis model assessment of insulin resistance.

Figure 1: Overall Serum Urate Response According to Diet Group

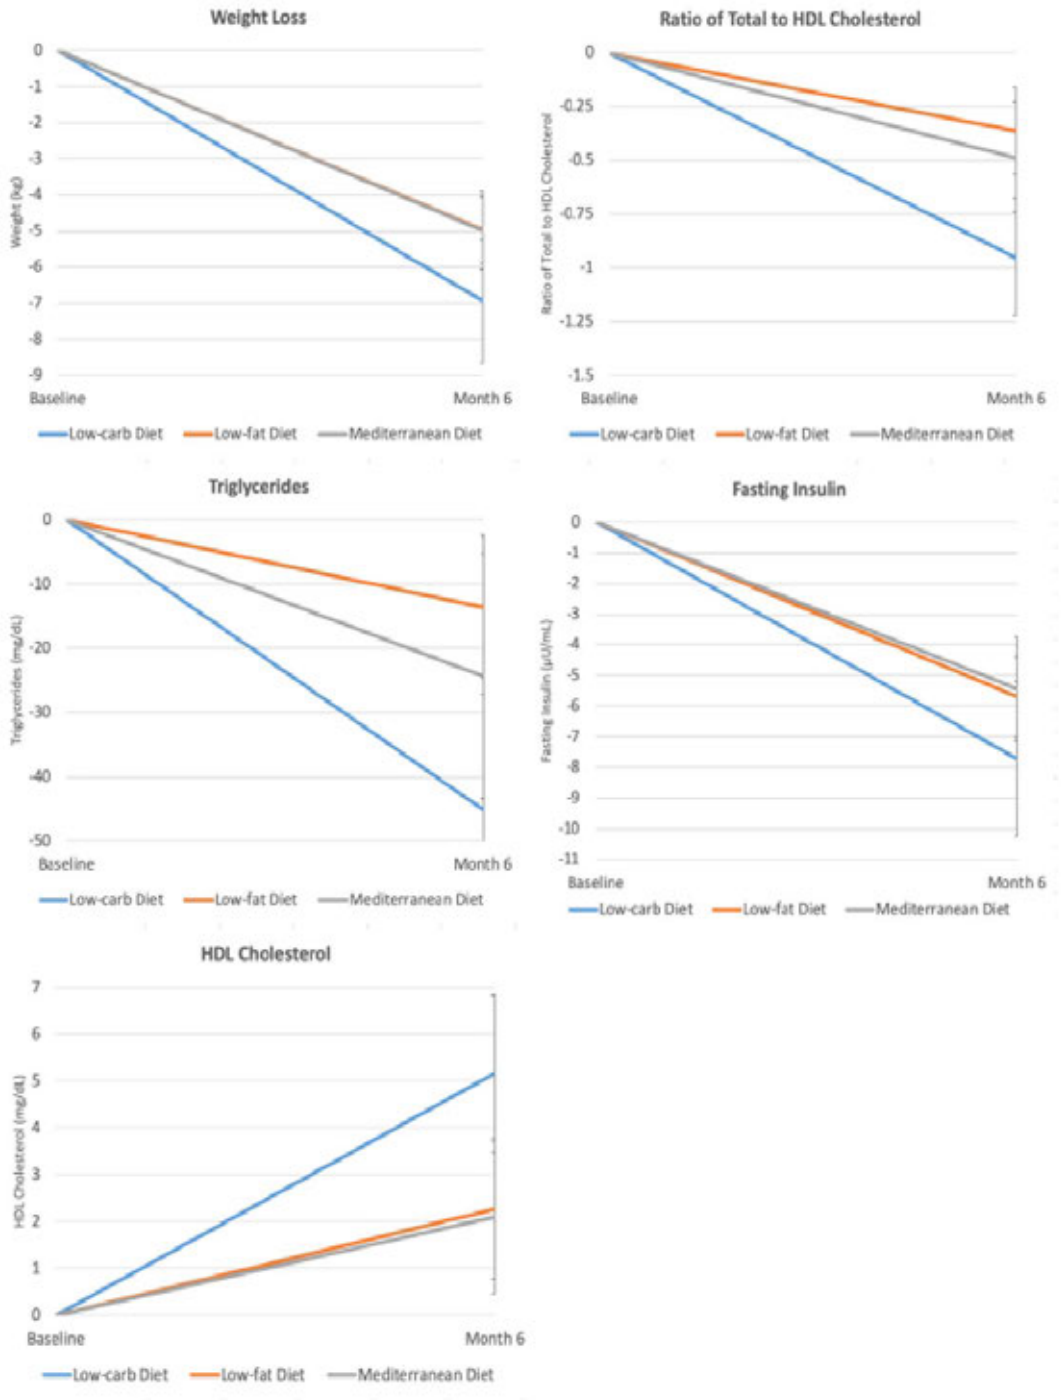


Results: Baseline characteristics were well-balanced between the three groups (Table 1). All three diets significantly reduced SU levels by 0.8 mg/dL each over 6 months (all p for within-group comparison < 0.001 and p >0.98 for between-group comparisons) (Figure 1). This urate-lowering effect was most pronounced among those with baseline hyperuricemia (i.e., SU 7mg/dL). The mean SU decrease was 1.9 mg/dL for the low-fat group, 2.0 mg/dL for the Mediterranean group, and 2.5 mg/dL for the low-carbohydrate group. The relative reduction in the ratio of total cholesterol to high-density lipoprotein cholesterol was 16.9% in the low-carbohydrate group and 7.0% in the low-fat

group (p=0.01). BMI, blood pressure, cholesterol profile, triglycerides, and insulin levels also improved significantly in all three groups (Figure 2), with more prominent improvement in the low-carbohydrate group, particularly lipid profiles.

Conclusion: Low-fat restricted calorie, Mediterranean restricted calorie, and low-carbohydrate non-restricted calorie diets can all lower SU levels, although the effect size is smaller than that of a typical urate-lowering drug. Cardio-

Figure 2: Weight Loss and Cardiovascular Risk Factors Among Those with Baseline Hyperuricemia



vascular risk factors improved consistently across all three diets, whereas it remains unclear whether urate-lowering drugs have similar benefits. Thus, dietary interventions aimed at weight loss could be a useful adjunctive tool to modestly lower SU levels and improve the cardiovascular risk factors associated with hyperuricemia.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Autoinflammatory diseases (AIDs), often caused by single gene mutations, are disorders in which aberrant activation of innate immune cells causes uncontrolled systemic inflammation. Because many autoinflammatory mediators negatively regulate of allergic/atopic cytokines, patients with AIDs are thought to be at low risk of developing atopy. However, the prevalence of atopy in the AIDs is not established.

Methods: We conducted a retrospective chart review of patients enrolled on protocol 94-HG-0105 “Genetics and Pathophysiology of Familial Mediterranean Fever and Related Disorders”. All patients had a molecular diagnosis (Sanger sequencing) of familial Mediterranean fever (FMF); cryopyrin-associated periodic syndrome (CAPS); tumor necrosis factor-associated periodic syndrome (TRAPS); deficiency of adenosine deaminase 2 (DADA2), hyper-IgD syndrome (HIDS); pyogenic arthritis, pyoderma gangrenosum, and acne (PAPA); or haploinsufficiency of A20 (HA20). Atopic features were defined as serum IgE > 100 kU/L, absolute eosinophil count (AEC) > 500, true (non-neutrophilic) urticaria, asthma, atopic dermatitis, or food allergy. Severe atopic features were defined as serum IgE > 500, AEC > 1500, anaphylaxis (excluding medication-induced), recurrent angioedema, multiple food allergies, or eosinophilic gastrointestinal disease (EGID). Comparator laboratory data (IgE, AEC) were obtained from theNational Health and Nutrition Examination Survey (NHANES). Comparator data on food allergy, asthma, atopic dermatitis, angioedema, anaphylaxis, and EGID were obtained from US population-based studies (National Health Interview Survey, Behavioral Risk Factor Surveillance System, National Opinion Research Center, US commercial healthcare databases). Comparator data on urticaria and angioedema, which had not been studied in US populations, were obtained from European population-based studies (surveys and national registries).

Results: Atopic features are shown in Table 1, and severe atopic features are shown in Table 2. Clinical features of atopy were less prevalent in AIDs than in the general population except for asthma, which was observed in CAPS, PAPA, and HA20. Of the AIDs, FMF, TRAPS, and HIDS had the lowest prevalence of atopy. With regards to lab features of atopy, AIDs had a low prevalence of elevated IgE, whereas mild eosinophilia was highly prevalent in CAPS, PAPA, and HA20. Severe atopy was rare in all the AIDs, with rates lower than those seen in the general population for all features except eosinophilia. Severe eosinophilia (AEC > 1500) was seen in CAPS and PAPA, and EGID was a prominent component of intestinal inflammation in one HA20 patient.

Disease (total patients)	IgE>500	AEC>1500	Recurrent angioedema	Anaphylaxis	EGID	Multiple food allergies
FMF (99)	0.0%	1.0%	0.0%	0.0%	0.0%	0.0%
CAPS (76)	7.9%	7.9%	0.0%	3.9%	0.0%	2.6%
HIDS (33)	0.0%	0.0%	0.0%	3.0%	0.0%	0.0%
PAPA (15)	0.0%	6.7%	0.0%	0.0%	0.0%	0.0%
TRAPS (44)	0.0%	0.0%	0.0%	2.3%	0.0%	2.3%
HA20 (12)	0.0%	0.0%	0.0%	0.0%	8.3%	0.0%
DADA2 (38)	0.0%	0.0%	0.0%	2.6%	0.0%	0.0%
Adult general population (prevalence)	7.3%	0.2%	<0.1%(*8*)	0.05-2%(*9*)	<0.1%(*10*)	4.9%(*2*)
Pediatric general population (prevalence)	8.1%	0.4%	<0.1%(*8*)	0.05-0.5%(*9*)	<0.1%(*10*)	2.4%(*6*)

Table 2. Prevalence of severe atopic features in patients with autoinflammatory disease confirmed by genetic testing, and comparison data in the general population. IgE= total serum IgE (international units/mL); AEC= absolute eosinophil count (103/μL); EGID= eosinophilic gastrointestinal disease; FMF= familial Mediterranean fever; CAPS= cryopyrin-associated periodic syndrome; TRAPS= tumor necrosis factor-associated periodic syndrome; DADA2= deficiency of adenosine deaminase 2; HIDS= hyper-IgD syndrome; PAPA= pyogenic arthritis, pyoderma gangrenosum, and acne; HA20= haploinsufficiency of A20.

Conclusion: Most clinical features associated with atopy are rare in AIDs, as is elevated IgE, and the presence of severe atopy in an AID should prompt further investigation. However, both mild and severe eosinophilia are seen at a higher prevalence in CAPS, PAPA, and HA20, suggesting that *NLRP3*, *PSTPIP1*, and *TNFAIP3*mutations may alter eosinophil biology. Further studies are needed to determine the significance, disease associations, and treatment associations of eosinophilia in these diseases.

Bone Manifestations in Gaucher Disease: A Monocentric Study of 128 Patients

Yann Nguyen,[1] Jérôme Stirnemann,[2] Monia Bengherbia,[1] Karima Yousfi,[1] Dalil Hamroun,[3] Wassim Allaham,[4] Bruno Fantin,[4] and Nadia Belmatoug[1], [1]Centre de reference des maladies lysosomales, Hôpital Beaujon, AP-HP, Clichy, France, [2]Hôpitaux Universitaires de Genève, Genève, Switzerland, [3]CHRU de Montpellier, Montpellier, France, [4]Hôpital Beaujon, AP-HP, Clichy, France

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Gaucher disease (GD) is a rare lysosomal storage disorder caused by mutations in the glucocerebrosidase gene, leading to defective lysosomal acid β-glucosidase. Its incidence ranges between 0.4 and 5.8 for 100,000 inhabitants. GD patients may present splenomegaly, hepatomegaly, cytopenia, and/or skeletal disease. Bone manifestations (BM) include acute or chronic bone pain, risk of pathologic fractures (PF), epiphyseal avascular necrosis (AVN), bone infarcts and/or decreased bone mineral density. We aimed to describe BM at baseline and during follow-up in a large cohort of GD patients.

Methods: We conducted a monocentric retrospective study of GD patients followed in a French referral center for lysosomal disorders and enrolled in the French Gaucher Disease Registry. Their demographical and clinical characteristics at diagnosis, and their treatments, clinical bone manifestations and imaging during follow-up were collected.

Results: A total of 128 GD patients (123 GD type 1 and 5 GD type 3) were followed up for a median [interquartile range] of 24.7 [12.9–34.3] years. Male/female ratio was 0.9. Genotype was N370S/N370S for 22 (17.1%), N370S/other for 77 (60.2%), and other/unknown for 29 (22.7%) patients. Median age at GD diagnosis was 19.2 [9.1–29.2] years. BM were the first GD symptom for 11 (8.6%) patients. At GD diagnosis, 31 (28.2%) had chronic bone pain, and 16 (12.5%) had acute bone crisis. During follow-up, 98 (76.6%) had clinical BM. Thirty (23.5%) patients had had at least one episode of epiphyseal AVN, including 14 (10.9%) with multiple AVN. Of the 52 AVN episodes, 33 (63.5%) involved femoral head, 6 (11.5%) humeral head, 6 (11.5%) knees, and 8 (15.4%) other joints. Diaphyseal or metaphyseal bone infarcts occurred in 32 (25.0%) patients, including 12 (9.4%) with multiple bone infarcts. Of the 50 episodes of bone infarcts, femoral diaphysis was involved in 18 (36%) cases, tibia in 13 (26%), pelvis in 6 (12%) and humerus in 3 (6%). PF occurred in 38 (29.7%) patients: 25 had a unique PF, whereas 13 had ≥2 PFs. On the 66 PF, 25 (37.9%) were located on upper limbs, 19 (28.8%) on lower limbs, and 15 (22.7%) were vertebral fractures. Of the 77 patients with available bone X-rays, 48 (62.3%) were pathologic, showing Erlenmeyer flask deformity in 28 (36.4%) cases, osteopenia in 18 (23.4%) and/or osteolytic lesions in18 (23.4%). Evidence of bone marrow infiltration was present for at least 62 (52.1%) of the 119 patients with available magnetic resonance imaging. Of the 66 patients with available bone densitometry during follow-up, 29 (43.9%) had osteopenia with T-score between -1 and -2.5, and 11 (16.7%) had osteoporosis with T-score < -2.5. In 2019, 118 (92.2%) were alive. Among them, 106 (89.8%) are currently treated with imiglucerase (n=54), velaglucerase (n=31), or eliglustat (n=21).

Conclusion: This retrospective monocentric study of 128 patients followed up in a GD referal center during a median of 25 years provides useful information on bone involvement in GD, which occurs in a large majority of GD patients.

A Third of Relapsing Polychondritis Patients with Ear Involvement at Presentation Had Airway Involvement at the Last Follow-up with a High Mortality Rate

Jun Shimizu,[1] Yoshihisa Yamano,[1] Kimito Kawahata,[2] and Noboru Suzuki[1], [1]St. Marianna University School of Medicine, Kawasaki, Japan[2]Rheumatology and Allergology, St. Marianna University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: We have reported that 239 patients with relapsing polychondritis (RP) were divided into three subgroups, namely patients with airway involvement (A subgroup, 20% of 239 patients), patients with ear involvement (E subgroup, 49%), and patients with both airway and ear involvement (B subgroup, 29%) (Medicine. 2018; 97(42): e12837.). Each subgroup exhibited characteristic clinical features. Patients in A subgroup and patients in E subgroup were characterized by saddle nose deformity and central nervous system (CNS) disorders, respectively. Patients in B subgroup had clinical characteristics of progressive and long disease course. We suggested that the disease progressed from A and E subgroups to B subgroup.

Methods: In the current study, we compared organ involvement at disease onset with that at the last follow-up to assess whether the disease progressed from A and E subgroups to B subgroup in patients with RP. We measured serum matrix metalloproteinase-3 (MMP3) concentrations of 32 samples obtained from newly recruited RP patients.

Results: At the first visit, patients had airway involvement (namely A subgroup at disease onset, 18% of 239 patients), ear involvement (E subgroup at disease onset, 56%), both airway and ear involvement (B subgroup at disease onset, 1.7%), eye involvement (7.1%), inner ear dysfunction (3.8%), arthritis (2.9%), CNS involvement (2.5%), nasal chondritis (1.3%), and skin involvement (0.84%). 34% of RP patients in E subgroup at disease onset developed airway involvement by the last follow-up (mean follow-up, 6.0 years) with a significantly higher mortality rate (13%) compared with those without airway involvement (2.3%). Cumulative incidence of CNS involvement was 12% (28 patients) in this study and encephalitis and meningitis were the most frequent manifestations (12 patients, 5.0%). Encephalitis/meningitis occurred before the onset of obvious chondritis in 6 patients (2.5%). In another cohort of RP patients, serum MMP3 concentrations were significantly higher in B subgroup (n=13) than those in A subgroup (n=7) and E subgroup (n=12).

Conclusion: RP patients with disease progression from E subgroup to B subgroup had higher mortality than those remaining in E subgroup at the last follow-up. Caution should be exercised in the diagnosis of CNS involvement in RP patients because of the varying clinical course at disease onset. Although the further study is necessary, MMP3 in RP patients may aggravate the inflammatory response of chondrocytes and promote overlapping organ involvement.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: To characterize the main epidemiological, clinical and radiological features at presentation of sarcoidosis in a large multicenter cohort from Southern Europe.

Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the American Thoracic Society/European Respiratory Society/World Association of Sarcoidosis and Other Granulomatous Disorders (WASOG) 1999 statement on sarcoidosis. Organ involvement was retrospectively determined in each patient at the time of diagnosis using the 2014 WASOG organ assessment instrument. Ethnicity was defined according to the FDA classification.

Results: The cohort consisted of 1521 patients (81% biopsy-proven), including 877 (58%) women and 644 (42%) men, with a mean age at diagnosis of 47.4 ± 15.2 years; 234 (15%) patients were born outside Spain. With respect to the FDA ethnic classification, 1370 (90%) patients were classified as White, 80 (5%) as Hispanic, 47 (3%) as Black/African American and 24 (2%) as Asian. Thoracic involvement was present at diagnosis in 1409 (92%) patients,

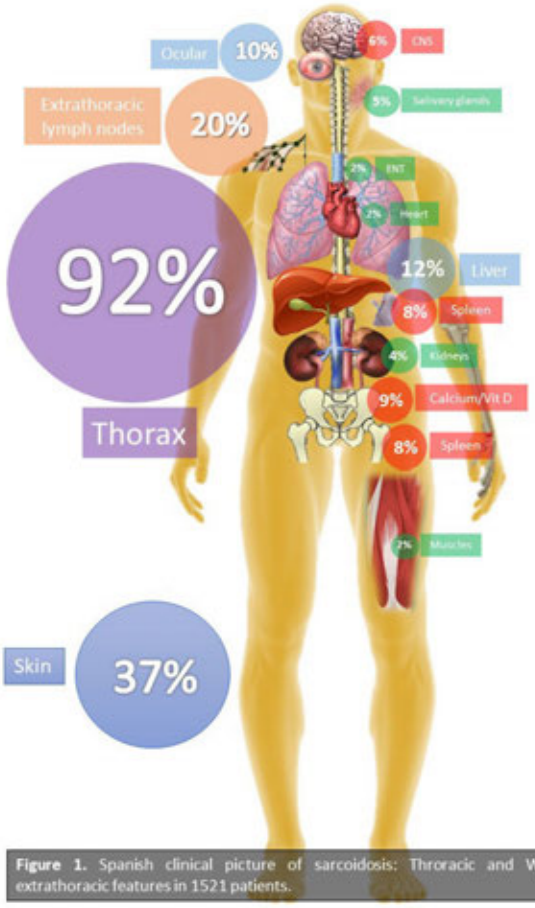

Figure 1. Spanish clinical picture of sarcoidosis: Thoracic and WASOG extrathoracic features in 1521 patients.

including 427 (29%) patients presenting with stage I, 619 (41%) with stage II, 288 (19%) with stage III and 53 (3%) presenting with stage IV. Extrathoracic disease was reported in 1096 (72%), and systemic disease (defined as at least 2 extrathoracic organs involved) in 523 (34%). According to the WASOG classification, the most frequently reported extrathoracic involvements at diagnosis were cutaneous in 558 (37%) patients, extrathoracic lymph nodes in 309 (20%), liver involvement in 189 (12%) and ocular involvement in 156 (10%) (**Figure**). Potentially life-threatening WASOG involvements were reported in frequencies less than 10%, including neurological involvement in 98 (6%) patients, kidney involvement in 58 (4%) or cardiac involvement in 30 (2%). Need for systemic therapy was required in 756 (50%) and aggressiveness of therapy in 124 (8%). Therapeutic approaches at diagnosis included the use of oral glucocorticosteroids in 731 (49%) patients, immunosuppressive agents in 118 (8%) and biological agents in 22 (1.5%).

Conclusion: This is one of the largest series of sarcoidosis reported out of the US, predominantly composed by White patients in nearly 90% of cases. Clinical presentation is dominated by adenopathies (both thoracic and extrathoracic) and cutaneous features (erythema nodosum), with lower frequencies in the main extrathoracic involvements. However, extrathoracic disease was reported in 3 out of 4 patients, and one third of patients presented with at least 2 different extrathoracic organs involved. These findings underline the systemic clinical expression of sarcoidosis, being mandatory a multidisciplinary management of the disease.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: To analyze the prevalence and characteristics of musculoskeletal sarcoidosis in a large nationwide multicenter cohort.

Methods: In January 2016, the Autoimmune Diseases Study Group (GEAS-SEMI) created a national registry (SARCOGEAS) of patients with sarcoidosis. Sarcoidosis was diagnosed in agreement with the criteria proposed by the American Thoracic Society/European Respiratory Society/World Association of Sarcoidosis and Other Granulomatous Disorders (WASOG) 1999 statement on sarcoidosis. Musculoskeletal involvement was characterized according to the 2014 WASOG organ assessment instrument, which is defined as the direct infiltrative granulomatous involvement affecting joints, bones, tendons and/or muscles (demonstrated either by imaging techniques or biopsy).

Results: Among 1521 patients included in the Registry at May 31, 2019, there were 129 (8.5%) that fulfilled the WASOG criteria for musculoskeletal sarcoidosis (72 women and 53 men, mean age at diagnosis of 45.4 years): 108 (7.1%) presented with osseous involvement and 21 (1.4%) presented with muscular sarcoidosis. Among patients presenting with osseous sarcoidosis, 24 presented typical radiological features of osseous granulomatous infiltration, 6 presented dactylitis, 25 nodular tenosynovitis and 56 asymptomatic osseous involvement demonstrated by PET/MRI: Among patients with muscular sarcoidosis, 5 presented with asymptomatic muscular involvement demonstrated by PET/MRI, 2 with palpable muscle masses, and the remaining 14 with biological/histopathological evidence of muscular involvement. In comparison with patients without musculoskeletal infiltrative involvement, those presenting with musculoskeletal sarcoidosis were predominantly White patients (96% vs 89%, p=0.025), had more frequently an acute onset of the disease (28% vs 18%, p=0.02), a higher frequency of systemic sarcoidosis (defined as the involvement of at least 2 different extrathoracic organs, 82% vs 30%, p< 0.001), a higher frequency of skin involvement (60% vs 35%, p< 0.001) and a higher frequency of need for therapy (64% vs 48%, p=0.001), including both glucocorticosteroids (61% vs 48%, p=0.007) and immunosuppressive agents (16% vs 7%, p=0.003).

Conclusion: Sarcoid musculoskeletal infiltration affects around 9% of patients with sarcoidosis, in most cases presenting as asymptomatic bone/muscular involvement demonstrated by PET, MRI and/or biopsy. These patients present with a very active systemic phenotypic profile, especially including cutaneous features, and required a more intensive systemic therapeutic approach.

Epidemiology and Presentation of Sarcoidosis with and Without HIV Infection

Jennifer Hanberg,[1] Liana Fraenkel,[2] and Amy Justice[3], [1]Yale School of Medicine; West Haven Veteran's Administration, New Haven, CT, [2]Yale School of Medicine and VA Connecticut Healthcare System, New Haven, [3]Yale School of Medicine; West Haven Veteran's Administration, West Haven, CT

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease I: Expanding the Spectrum of Clinical Features in Rheumatological Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Sarcoidosis and HIV are thought of as antithetical, one driven by excess, the other by deficiency, of CD4+ T-cells. However, case reports and series describe comorbid sarcoidosis and HIV. To date, there has been no controlled comparison of the incidence and presentation of sarcoidosis in persons with and without HIV infection.

Methods: Patients were selected from the Veterans Administration Cohort Study, a longitudinal cohort of veterans with HIV and age, sex and race-matched uninfected comparators. Among those with at least one ICD code for sarcoidosis, chart review was conducted to confirm incident or prevalent sarcoidosis. Cases where sarcoidosis developed before HIV were excluded from analysis. Incident cases (other than Stage I pulmonary sarcoidosis) were required to have tissue diagnosis and compatible clinical presentation with exclusion of reasonable alternative diagnoses; prevalent cases required documentation of diagnosis only. Organ involvement and immunosuppressive therapy were recorded for one year following the date of biopsy.

Results: Among 1,610 patients with at least one ICD code for sarcoidosis, 875 (54%) had prevalent sarcoidosis and 332 (21%) had incident sarcoidosis. After excluding 9 cases in which sarcoidosis developed before HIV and all prevalent cases, incidence of sarcoidosis among patients living with (N=56,470) and without (N=116,130) HIV was 0.9 (95% CI: 0.7-1.2), versus 1.5 (95% CI: 1.3-1.7) per 10,000 person-years. Uninfected individuals developed sarcoidosis more frequently than those with HIV (rate ratio 1.6 (95% CI: 1.2-2.1)). In those with HIV, sarcoidosis was diagnosed

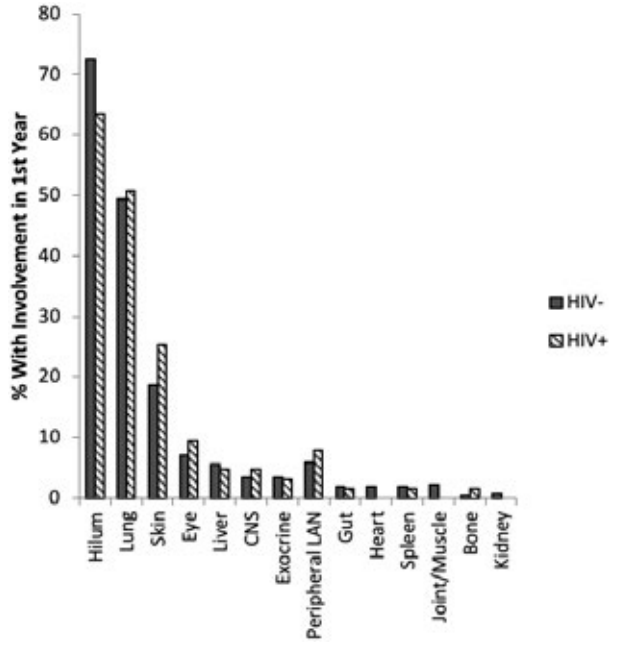

Figure 1 Frequency of Organ Involvement in First Year of Sarcoidosis, in Patients With or Without HIV. CNS=central nervous system. LAN=lymphadenopathy.

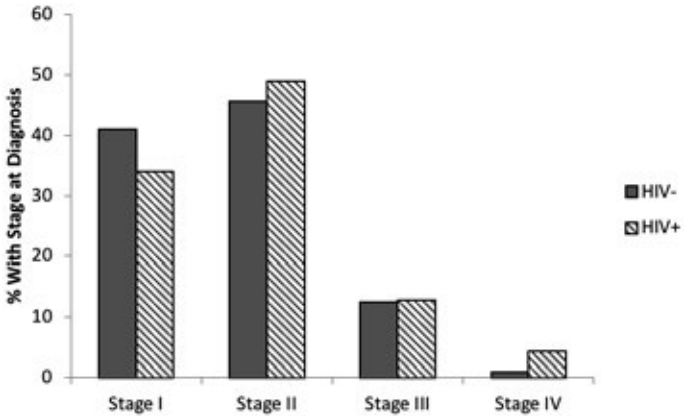

Figure 2. Stage of Pulmonary Sarcoidosis at Diagnosis

a median of 8.0 years after HIV diagnosis (3.3-15.4). At diagnosis, median CD4 count was 420 cells/mm^3 (268-530) and 56% of patients had a viral load < 500 copies/mL. Organ involvement and stage of pulmonary involvement (Figure 1, Figure 2), treatment with systemic glucocorticoids (37% vs 36%, p=0.93) and total dose of prednisone over one year (2195 vs 1800 mg, p=0.97) were all similar by HIV status. Use of steroid-sparing immunosuppressants (methotrexate, hydroxychloroquine, azathioprine and calcineurin inhibitors) tended to be less common in those with HIV (4.8% vs 10.4%, p=0.17).

Conclusion: Compared to those with HIV, those without were 60% more likely to develop sarcoidosis. Most patients with HIV and incident sarcoidosis had CD4 counts over 200, while just over half were virally suppressed. While presentation was similar, as was the use and total dose of oral glucocorticoids, use of steroid-sparing regimens tended to be less common among those with HIV.

Is Long-term High-intensity Strength Training Beneficial or Harmful for Knee Osteoarthritis Patients? The Strength Training and Arthritis Trial (START)

Stephen Messier,[1] Shannon Mihalko,[2] Daniel Beavers,[3] Barbara Nicklas,[3] Paul DeVita,[4] J Carr,[5] David Hunter,[6] Kimberly Bennell,[7] Ali Guermazi,[8] Mary Lyles,[3] and Richard Loeser[9], [1]Wake Forest University, Winston Salem, [2]Wake Forest University, Winston Salem, NC, [3]Wake Forest School of Medicine, Winston Salem, NC, [4]East Carolina University, Greenville, NC, [5]Vanderbilt University School of Medicine, Nashville, TN, [6]University of Sydney, Sydney, Australia, [7]Centre for Health, Exercise and Sports Medicine, Department of Physiotherapy, School of Health Sciences, Faculty of Medicine Dentistry & Health Sciences, The University of Melbourne, Melbourne, VIC, Australia., Parkville, Victoria, Australia, [8]Boston University School of Medicine, Boston, MA, [9]UNC, Chapel Hill, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis – Clinical I: Innovations
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Few have studied long-term high-intensity strength training in knee osteoarthritis (OA) patients due to the unsubstantiated belief that it might exacerbate OA symptoms. Our purpose was to determine whether high-intensity strength training would improve mechanistic and clinical outcomes compared to low-intensity strength training and attention control.

Methods: Single-blind, 18-month, 3-arm randomized clinical trial conducted between September 2011 and August 2017. The strength training interventions were center-based. Participants were 377 community-dwelling adults (age ≥ 55 years) with a body mass index of 20-45 kg/m^2 (mean = 31.4 kg/m^2) with pain and mild to moderate radiographic

START outcome table ACR Table 1. Mean (95% CI) baseline and 18-month follow-up data for the high and low intensity strength training and control groups.

knee OA. Randomization was to either high-intensity strength training (75-90% 1RM), low-intensity strength training (30-40% 1RM), or attention control (healthy living classes). Primary outcomes were knee pain and knee-joint compressive forces during walking. Secondary outcomes included additional clinical measures of disease severity (e.g., function, mobility), radiographic progression by joint space narrowing, thigh muscle volume, knee extensor and knee flexor strength, inflammatory biomarkers, and self-efficacy. All primary statistical analyses used an intention-to-treat method.

Results: At 18 months, 320 (85%) participants completed the study. Knee pain and knee compressive forces were similar between the groups. Knee extension and flexion strength were significantly greater in the two strength-training groups (Figures 1 and 2). Self-reported function, 6-minute walk distance, BMI, IL-6, thigh muscle volume, and joint space width were similar across groups. Self-efficacy was greater in the two strength-training groups compared to the control group (Table 1). The two strength-training groups and the attention control group met the OARSI responder criteria of clinically important reductions in pain (between 27-39%) and improvements in function (between 31-44%) with no statistical differences between groups.

Conclusion: The significant improvements in knee strength in the two strength-training groups relative to the control group did not result in significantly better reductions in pain and knee joint loads, or improvements in function. This was due, in part, to the clinically important improvements in pain and function in the control group of between 33-35%. These results indicate that long-term high-intensity strength training for knee OA patients is a well-tolerated non-pharmacologic intervention that increases knee extensor and flexor strength, significantly improves self-efficacy, and does not exacerbate knee pain or disease progression relative to low-intensity strength training or attention control. An attention control with a focus on healthy living and living with OA, however, is just as effective as high- and low-intensity strength training in improving most clinical and mechanistic outcomes.

Is There Any Role for Opioids in the Management of OA?

Mikala Osani,[1] Stefan Lohmander,[2] and **Raveendhara Bannuru**[1], [1]Tufts Medical Center, Boston, MA, [2]Department of Clinical Sciences Lund, Faculty of Medicine, Lund University, Lund, Sweden, Lund, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis – Clinical I: Innovations
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Opioids have long been prescribed for chronic pain conditions, including osteoarthritis (OA). Although the safety of opioids has been questioned, there is little information about their temporal efficacy. Additionally, differences in overall efficacy and safety between strong versus weak opioid classes have not been clearly delineated. We conducted meta-analyses of pain and function at 2, 4, 8, and 12 weeks and analyzed relevant safety outcomes for all opioids, as well as strong versus weak opioids.

Methods: We searched MEDLINE and the Cochrane Database from inception to April 2019 and actively sought unpublished data. Placebo-controlled RCTs assessing the efficacy and/or safety of FDA-approved opioids in patients with knee and/or hip OA were included. We excluded studies using enriched enrollment or double-dummy design involving non-oral treatments. Screening and data extraction were undertaken by two reviewers. We calculated standardized mean differences and risk ratios with 95% confidence intervals. Study quality was assessed using Cochrane risk of bias tool. Random effects meta-analyses were performed, and heterogeneity assessed using the I^2 statistic. Subgroup analyses of strong and weak opioids were conducted for pain at every time point, and for safety outcomes. Meta-regression was performed to assess the impact of dosage (morphine equivalency) on pain relief.

Results: The included 23 RCTs comprised 11,402 participants. 64% were female. The mean age ranged from 54 to 67 years; mean BMI from 28 to 34 kg/m^2. All trials were of moderate quality with potential attrition bias being the primary methodological concern. Overall, opioids demonstrated small, statistically significant benefits on pain at each time point ranging from -0.28 to -0.19 (Figure 1); similarly small, statistically significant effects were observed with respect to function at 2, 4, and 12 weeks ranging from -0.26 to -0.16. Opioids had no impact on quality of life or depression; participants who received opioids reported significantly higher quality of sleep. We found that strong opioids had consistently smaller benefits on pain than weak opioids (Figure 1). Meta-regression revealed that opioid dosage (morphine equivalency) has no impact on pain relief (p=0.09) (Figure 2). Methodological bias (selection, attrition) may contribute to the poor performance of strong opioids, or perhaps a pharmacodynamic classification of “strong” has been incorrectly equated with the clinical efficacy of these drugs. Strong opioids showed a safety profile consistently worse than weak opioids, particularly with respect to drug withdrawal symptoms (2.78 [1.41, 5.49] versus 1.06 [0.19, 5.80]) and discontinuations due to adverse events (5.47 [4.63, 6.47] versus 2.77 [2.26, 3.39]).

Conclusion: Overall, opioids demonstrate only small benefits on pain and function from 2 to 12 weeks of treatment and contribute no measurable benefit to QOL or depression versus placebo. Strong opioids demonstrated consistently worse pain relief, with greater risk of any safety outcome than weak opioids. In light of this evidence, clinicians and policy makers should reconsider the utility of strong opioids in the management of OA.

Abstract Number: 0911

Perfusion in Bone Marrow Lesions Assessed on Dynamic Contrast-enhanced MRI and Its Association with Pain in Knee Osteoarthritis: A Cross-sectional Study

Cecilie Daugaard,[1] Robert Riis,[2] Elisabeth Bandak,[3] Janus Nybing,[4] Stine Hangaard,[3] Henrik Gudbergsen,[3] Marius Henriksen,[3] Henning Bliddal,[3] and Mikael Boesen[4], [1]The Parker Institute, Copenhagen University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark, Frederiksberg, Sjelland, Denmark, [2]Dept. of Radiology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark, Copenhagen, Denmark, [3]The Parker Institute, Copenhagen University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark, Copenhagen, Denmark, [4]Dept. of Radiology, Copenhagen University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis – Clinical I: Innovations
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In osteoarthritis (OA) structural changes are only weakly associated with pain. The reason for this discrepancy remains unknown and the exact cause of knee pain in OA is still unclear which makes the target of treatment difficult. Bone marrow lesions (BMLs) and cysts are hallmarks of knee OA changes on MRI but studies investigating the association between BML and pain show conflicting results. Our objective was to evaluate the association between pain and perfusion in BMLs assessed on static- and dynamic contrast enhanced (DCE)-MRI in patients with knee OA in a cross-sectional setting.

Methods: MRI was performed at enrolment in the LOSEIT trial (ClinicalTrials.gov NCT02905864) studying persons with overweight/obesity and knee OA. BMLs with and without subchondral cystes were assessed across the whole knee using both DCE-MRI analysed with DYNAMIKA® (Image Analysis Group, LTD, London) and non-CE-MRI scored according to the MRI Osteoarthritis Knee Score (MOAKS) and correlated to pain using the Knee injury and Osteoarthritis Outcome Score (KOOS).

Results: Data were available from 107 participants, 64% women, 89% had radiologically verified OA (KLG 2 or 3). The participants had a mean age of 60.8 years, a mean BMI of 34.5 kg/m2, a mean KOOS pain of 63.7 (0-100 scale),

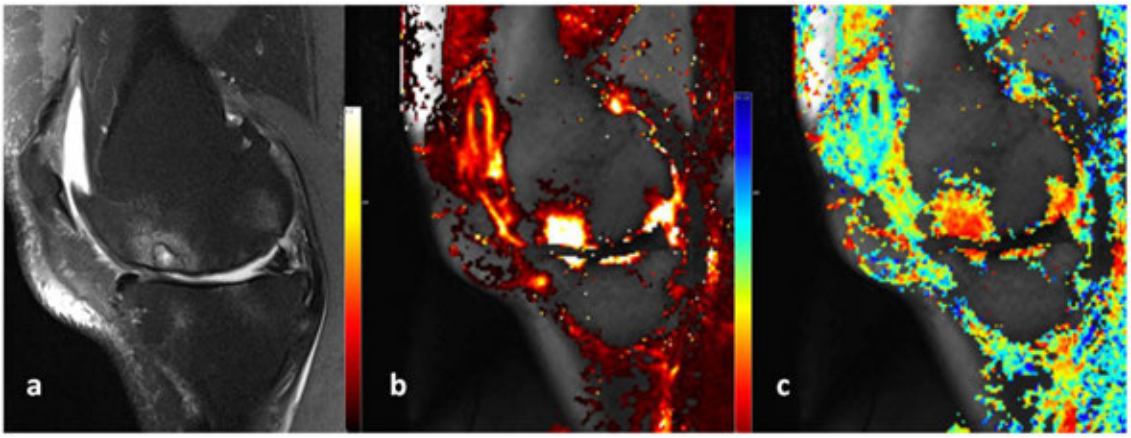

Figure. 1 Bone marrow lesion with cyst in knee with OA. a) non-CE-MRI b) DCE-MRI Initial rate of enhancement (IRE) c) DCE-MRI Time To Peak (TTP).

and a mean BML sum score of 6.5 (0-45 scale). For BMLs containing subchondral cysts the heuristic perfusion variable Time To Peak (TTP) showed a statistically significant correlation with KOOS Pain (r=0.40; p=0.002) meaning that higher and faster perfusion leading to earlier TTP in BMLs containing subchondral cysts is correlated to more knee pain. DCE-MRI parameters in BMLs without cysts and MOAKS BML scores were not correlated to KOOS pain.

Conclusion: In this study, we found that the perfusion variable TTP from DYNAMIKA® on DCE-MRI data in BMLs containing subchondral cysts was associated with the severity of knee pain in patients with knee OA. Thus DCE-MRI has the potential to separate and study different pain phenotypes of knee OA.

Co-morbidities Associated with Discordance Between Structural Severity and Pain in Osteoarthritis: Implications for Clinical Trial Design in OA – a Post-Hoc Analysis of Data from Two Randomized Controlled Trials

Jonathan Bjerre-Bastos,[1] Inger Byrjalsen,[2] Morten Karsdal,[3] Jeppe Andersen,[1] and Asger Bihlet[1], [1]Nordic Bioscience Clinical Development, Herlev, Denmark, [2]Nordic Bioscience, Herlev, Denmark, [3]Nordic Bioscience, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis – Clinical I: Innovations
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Development of new disease-modifying drugs in osteoarthritis (DMOADs) has proven difficult and is complicated by heterogeneous study populations and insensitive endpoints of structural change, symptomatic benefit, and discordances between structural disease severity and reported symptoms. In such trials, counterintuitively, mild structural disease may be associated with severe symptoms and vice versa. The reasons for this discordance are unknown, and research to uncover factors potentially distorting the perceived severity of symptoms is needed to better characterize the clinical relevance of structural improvement, if any, in DMOAD trials. Psychological conditions including anxiety and depressive disorders (ADD) as well as concurrent pain conditions are known to affect pain sensitivity and perception, and as common co-morbidities of osteoarthritis (OA), these conditions may partly explain the observed discordance between structure and symptoms, and if established, exclusion of patients with such co-morbidities in DMOAD trials could potentially improve the understanding of structural benefit in a clinical context.

	Spearman's r	P-value
Anxiety-depression group	-0.05	0.55
Anxiety-depression controls	-0.21	0.01*
Back pain group	-0.01	0.93
Back pain controls	-0.13	0.02*

Table 1. Associations between WOMAC pain JSW (in red) and other baseline covariates

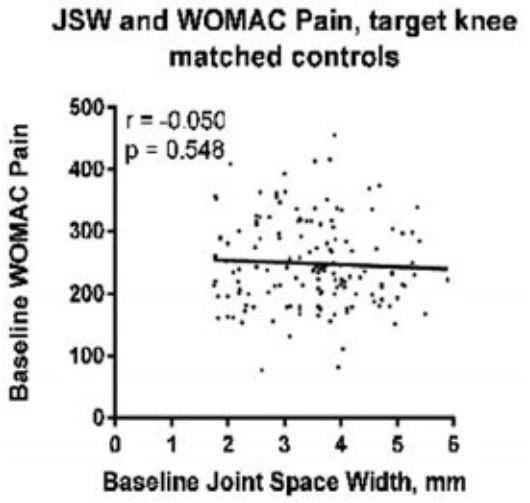

Figure 1. Linear correlations between WOMAC pain and JSW in ADD group, with Spearman's R reported

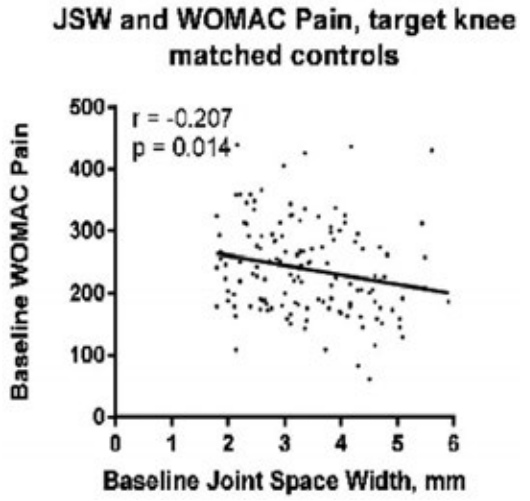

Figure 2. Linear correlations between WOMAC pain and JSW in ADD controls, with Spearman's R reported

The purpose of this analysis was to investigate the impact of ADD and back pain (BP) on the association between structural features of OA and the patient-reported pain.

Methods: Baseline data from two phase 3 clinical trials investigating oral salmon calcitonin in OA, NCT00486434 and NCT00704847 (total N=2206), was analyzed in a post-hoc cross-sectional analysis. Patients with self-reported depression, anxiety, post-traumatic stress syndrome (PTSD), either present or previous, were selected and compared with a control group, matched by sex, age, BMI and Kellgren Lawrence (KL) grade. The correlations between Joint-Space Width (JSW), and the WOMAC Pain Score were plotted for the ADD group and ADD controls, and Spearman's correlation analysis was performed for both ADD and BP groups.

Results: In the ADD group, 149 patients had AD in medical history of which 123 were ongoing at baseline. In the BP group, 333 patients had BP in medical history of which 322 were ongoing at baseline. The study groups of ADD, BP and respective matched controls (MC) were highly similar in terms of age, sex, BMI, JSW, KL-grade and WOMAC pain.

Associations between pain and JSW

Referring to table 1, no correlation was found in the ADD and BP group between JSW and WOMAC pain. In the respective MC groups, statistically significant correlations (MC for ADD: R= -0.21, p = 0.01, and MC for BP: R=-0.13, p=0.02) was found between JSW and pain indicating that lower JSW was associated with higher pain in the control groups but not in the ADD or BP groups. The univariate linear relationship between JSW and pain in the ADD and MC groups are illustrated in Figure 1 and 2.

Conclusion: A marked structure-symptoms discordance was found in OA patients with ADD and BP, while a statistically significant correlation was seen in matched controls without ADD or BP. The results suggest that exclusion of trial patients with anxiety and depression and/or back pain in medical history may improve the accuracy of pain reporting in clinical OA trials.

Depression as a Moderator of Analgesic Effectiveness in Knee Osteoarthritis

Alan Rathbun,[1] Michelle Shardell,[2] Joseph Gallo,[3] Alice Ryan,[1] Elizabeth Stuart,[3] Megan Schuler,[4] Michelle Yau,[5] and Marc C. Hochberg[1], [1]University of Maryland School of Medicine, Baltimore, MD, [2]National Institute on Aging, Baltimore, MD, [3]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]RAND Corporation, Boston, MA, [5]Hebrew SeniorLife Institute for Aging Research, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Osteoarthritis – Clinical I: Innovations
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Depression often accompanies knee osteoarthritis (OA), exacerbating the severity and persistence of pain, and may negatively affect clinical outcomes associated with analgesic treatment. This study evaluated whether depression moderates (Figure 1) the effectiveness of analgesics on knee pain severity in knee OA.

Methods: Eligible participants (n=1,477) were identified from the Osteoarthritis Initiative and were not using analgesics (acetaminophen, non-steroidal anti-inflammatory drugs, or opioids) at baseline (time *t*) and had radiographic disease (Kellgren-Lawrence [K-L] grade 2, 3, or 4) at the first annual follow-up visit (time *t*+1). Analgesic initiation and utilization was assessed at the first three annual follow-up visits (time *t*+1, time *t*+2, time *t*+3), and depression was evaluated concurrent to analgesic use with the Center for Epidemiological Studies Depression (CES-D) scale and corresponding screening threshold (CES-D score ≥ 16). Knee pain severity from the second to the fourth annual follow-up visit (time *t*+2, time *t*+3, time *t*+4) was measured with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain scale (rescaled range = 0-100). Time-invariant and time-varying confounders measured at time *t* and time *t*+1, time *t*+2, and time *t+3* were age, sex, race, education, marital status, employment, health insurance, smoking, alcohol consumption, Charlson comorbidity index, and symptomatic knee OA status; and K-L grade, body mass index, physical performance, knee injuries, knee injections, and WOMAC pain score, respectively. Structural nested mean models appropriate for evaluating time-varying effect moderation were implemented using an inverse-probability-of-treatment-weighting regression-with-residuals approach.

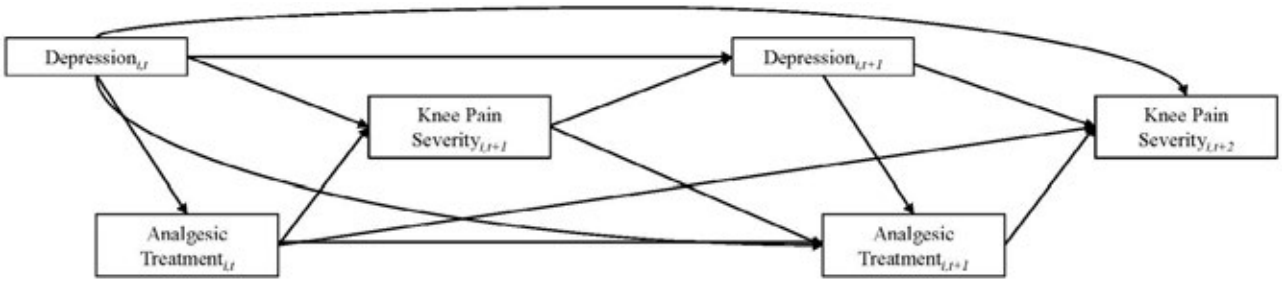

Figure 1. Directed acyclic graph illustrating the hypothesized causal relationships between analgesic treatment, depression, and knee pain severity. Subscripts *i* and *t* refer to the ith participant at time point t, respectively.

Table 1. Moderated intermediate causal effects (treated versus untreated) of analgesic treatment on knee pain severity in depressed and non-depressed participants with radiographic knee OA.

Treatment Interval	Pain Assessment	Depressed (β, 95% CI)		Non-Depressed (β, 95% CI)		Difference (β, 95% CI)	
Y1	Y2-Y4	-0.42	(-7.56, 6.72)	0.12	(-2.11, 2.34)	-0.54	(-8.04, 6.98)
Y2	Y3-Y4	-1.57	(-12.89, 9.74)	-1.16	(-3.48, 1.16)	-0.41	(-11.96, 11.14)
Y3	Y4	**-15.51**	**(-26.13, -4.89)**	0.76	(-1.67, 3.18)	**-16.27**	**(-27.12, -5.42)**
Y1-Y2	Y2-Y4	-1.99	(-16.74, 12.76)	-1.05	(-4.18, 2.09)	-0.94	(-16.03, 14.14)
Y1-Y3	Y2-Y4	-17.50	(-36.33, 1.33)	-0.29	(-4.03, 3.45)	-17.21	(-36.50, 2.07)

Y1: Year 1; Y2: Year 2; Y3: Year 3; Y4: Year 4; Y1-Y2: Year 1 to Year 2; Y1-Y3: Year 1 to Year 3; Y2-Y4: Year 2 to Year 4; Y3-Y4: Year 3 to Year 4.

Results: In non-depressed participants, analgesic treatment at years one, two, and three had minimal effect (Table 1) on knee pain severity at years two, three, and four, respectively, and time-specific associations ranged from -1.16 (95% CI: -3.48, 1.16) to 0.76 (95% CI: -1.67, 3.18). Moreover, persistent use of analgesics did not increase the magnitude of the treatment effect in non-depressed participants. By contrast, time-specific treatment effects in depressed participants increased during follow-up from -0.42 (95% CI: -7.56, 6.72) to -15.51 (95% CI: -26.13, -4.89), and the association between year three analgesic use and year four knee pain severity was statistically significant. The magnitude of the associations increased with persistent analgesic use in depressed participants, primarily due to significant effect moderation concerning year three analgesic use, where the subsequent difference in treatment effect between depressed and non-depressed participants was -16.27 (95% CI: -27.12, -5.42).

Conclusion: Findings indicate a statistically and clinically significant greater one-year treatment effect of analgesic use that lowered knee pain severity in persons with knee OA and depression. Thus, OA patients with depression may derive more benefit from analgesic treatment for chronic knee pain than non-depressed patients, perhaps because their pain is undertreated.

Iversen,[3] Julie Buring,[1] Jeffrey Katz,[1] JoAnn Manson,[1] and Karen Costenbader[4], [1]Brigham and Women's Hospital/Harvard Medical School, Boston, [2]Brigham and Women's Hospital, Boston, [3]Northeastern University, Boston, [4]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Osteoarthritis – Clinical I: Innovations

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

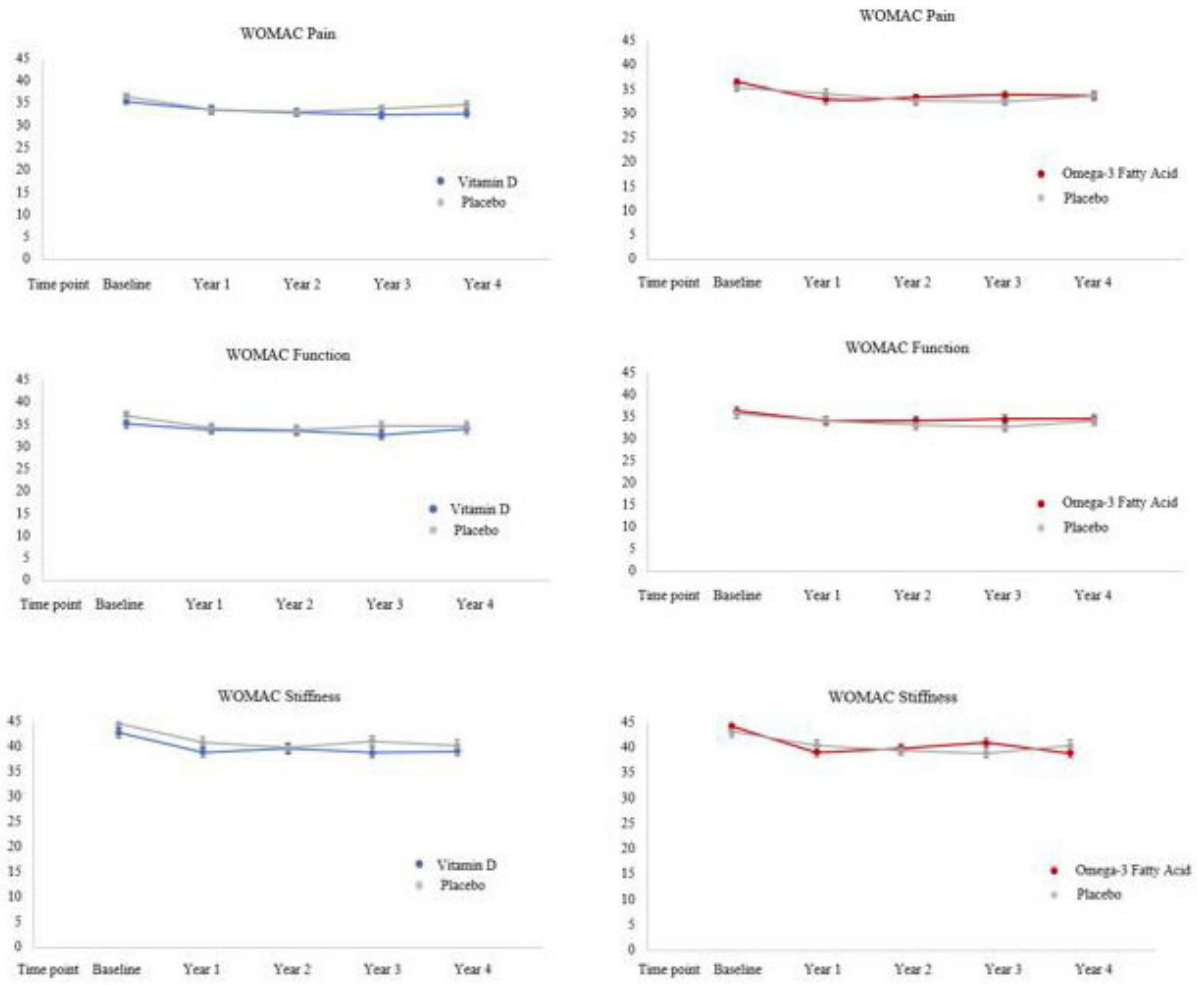

Figure 1. Repeated measure analyses of WOMAC scores over time for Vitamin D and Omega- 3 Fatty acid versus placebo with censoring for total knee replacement adjusted for age, sex, and other treatment group respectively, among subjects followed in the Knee Pain Subcohort of the VITAL trial (n=1398)

Background/Purpose: Chronic knee pain from osteoarthritis (OA) is frequent in the older adult population. Prior trials have had conflicting results concerning vitamin D's therapeutic effects, and no large trials have investigated the potential benefits of marine omega-3 fatty acids (n-3 FA) for chronic knee pain. We investigated the effects of vitamin D and n-3 FA supplementation on knee pain in a large clinical trial of older adults.

Methods: The double-blind, placebo-controlled VITamin D and OmegA-3 TriaL (VITAL) randomized 25,871 U.S. adults (women ≥ age 55, men ≥ age 50) in a 2-by-2 factorial design to supplementation with vitamin D (2000 IU/day) and/or n-3 FA (1 gm/day). Prior to randomization, we identified a subgroup of 1430 eligible participants reporting frequent, chronic knee pain and provided additional annual knee pain questionnaires. Analyses included 1398 participants who returned ≥ 1 questionnaire. Questionnaires assessed self-reported pain and functional status with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at baseline and annually over 5-years of follow-up. For the primary intention-to-treat analysis, we used a repeated measures model to assess the effect of treatment on measures of WOMAC over follow-up, after adjustment for age, sex, and the other treatment arm. Analyses were censored for total knee replacement (TKR). The time by treatment interaction term was used to assess change in WOMAC between randomized groups. In secondary analyses, differences in rates of TKR between treatment groups and placebo were assessed using Cox regression. Reduction in use of daily pain medications (non-steroidal anti-inflammatory and stronger pain medications such as opiates) comparing treatment groups and placebo was ascertained using chi square analysis.

Results: Participants' mean age was 68 years (SD= 7) and 66% were female. Baseline characteristics were well balanced. In a validation study, 400 participants were randomly selected for record review; of the 226 records received, 92% were confirmed to have knee OA. Over 5-years of follow-up, WOMAC Pain did not differ between vitamin D and placebo or n-3 FA and placebo at any time point. The time by treatment interactions were not statistically significant for either treatment arm (p interaction vitamin D = 0.41, p interaction n-3 FA = 0.77). Similarly, we did not observe clinically or statistically significant differences in WOMAC Function and Stiffness between randomized groups at any time point or over time. (Figure 1) TKR was reported by 140 participants in the vitamin D arm and 156 in placebo; 146 reported TKR in the n-3 FA and 150 in placebo. The hazard ratios for incident TKR in the vitamin D and n-3 FA arms were 0. 97 (95% CI 0.77, 1.22) and 0.99 (95% CI 0.79, 1.24) respectively in comparison to placebo after adjustment for age and sex. Among the daily pain medication users at baseline, there were no significant differences in frequency of pain medication use at last available follow-up between vitamin D and placebo and n-3 FA and placebo.

Conclusion: Neither Vitamin D nor n-3 FA supplementation for up to 5 years improved knee pain, stiffness or function, rate of TKR, or pain medication use in older adults with frequent, chronic knee pain.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: The Juvenile Arthritis Disease Activity Score (JADAS) has gained increasing popularity for the measurement of the level of disease activity in patients with juvenile idiopathic arthritis (JIA). However, so far the JADAS has been validated only in children with the non-systemic categories of JIA. The objective of our study has been to develop and validate the systemic JADAS (sJADAS), a new version of the JADAS specific to systemic JIA (sJIA).

Methods: The sJADAS is made up by adding a fifth item, named Systemic Manifestation Score (SMS), to the four items included in the original tool (physician global assessment of disease activity, parent/patient global assessment of well-being, active joint count and erythrocyte sedimentation rate). The SMS ranges from 0 to 10 and is aimed to quantify the activity of systemic features. The sJADAS score ranges from 0 to 50. The validation sample included patients with definite and possible/probable sJIA with active systemic manifestations, which should comprise fever, who were assessed at baseline and then at a subsequent visit, 2 weeks to 3 months after initial evaluation. Validation procedures included assessment of concurrent, construct and discriminant validity, internal consistency and responsiveness to clinical change.

Main disease activity features and values of composite disease activity scores of patients with systemic juvenile idiopathic arthritis at study entry and at second visit.

	Baseline (No.)		Second visit	
	No		No	
Physician global assessment	160	7.5 (6 - 9)	157	1 (0 - 3.5)
No swollen joints	161	3 (0-7)	157	0 (0 - 1)
No tender joints	158	4 (1 - 11)	154	0 (0 - 1)
No joints with limited range of motion	158	3 (1 - 8)	157	0 (0 - 0)
No active joints	161	4 (1 - 10)	157	0 (0 – 2)
White blood cell count, $\times 10^9$/liter	161	15 (9.64 - 20)	161	11.255 (7840 - 15000)
Neutrophil count, $\times 10^9$/liter	159	8770 (4895 - 14200)	159	6186 (3995 - 8960)
Hemoglobin, g/dl	162	10.1 (8.9 - 11.1)	162	11.8 (10.6 - 12.8)
Platelet count, $\times 10^9$/liter	161	468 (349 - 575)	161	354500 (271 - 450)
Ferritin, ng/ml	152	874 (284 - 2956)	152	161 (60 - 330)
Erythrocyte sedimentation rate, mm/hour	160	65 (40 - 95)	160	18 (7 - 36)
C-reactive protein, mg/dl	153	13.9 (7.9 - 24.3)	153	1 (0.3 - 4.8)
Fibrinogen, gm/liter	98	518 (350 - 637)	98	264.5 (199 - 374)
sJADAS10	160	28.2 (22.6 - 34.9)	156	6.5 (1.8 - 12.3)
JADAS10	160	23.3 (17.3 - 28.5)	157	6 (1 - 10.5)
cJADAS10	160	18.5 (13.3 - 24.3)	157	4 (0.5 - 9)
DAS28	157	5 (3.9 – 6.1)	151	2.4 (1.7 – 3.3)
CDAI	157	18.5 (14.0 – 28.0)	156	4.0 (0.5 – 9.5)
Systemic Manifestation Score	158	5 (4 - 7)	156	0 (0 - 2)

Data are the median (interquartile range)

Results: A total of 163 patients, 86.9% (n=139) with definite sJIA and 13.1% (n=21) with possible/probable sJIA, assessed at disease onset (n=91; 55.8%) or at time of a disease flare (n=72; 44.2%) were enrolled in 57 centers in 10 countries from February 2017 to December 2018. Median age at disease onset was 4.9 years (interquartile range, IQR 2.6–7.9) and median age at study entry was 6.4 years (IQR 3.7–10.8). Median disease duration from onset to study entry was 0.2 years (IQR 0.1–1.9). Median sJADAS at baseline visit was 28.2 (IQR 22.8–34.9), while median JADAS10 and clinical JADAS10 (cJADAS10) were respectively 23.3 (IQR 17.3–28.5) and 18.5 (IQR 13.3-24.3). sJADAS correlated strongly with JADAS10 (rs=0.98), cJADAS10 (rs=0.91), DAS28 (rs=0.83) and CDAI (rs=0.83); moderately with functional ability scales (JAFS and CHAQ) (rs=0.69; rs=0.62) and total score (rs=0.56) and physical (rs=0.59) and psychosocial (rs=0.38) subscale scores of the health-related quality of life tool (PRQL) and with pain VAS (rs=0.58); mildly with CRP (rs=0.40). sJADAS discriminated well between patients with or without morning stiffness ($p< 0.0001$), with different levels of disease activity defined by the physician ($p< 0.0001$) and with different degrees of pain ($p< 0.0001$). Internal consistency was good (Cronbach's alpha=0.635) and comparable to that of JADAS10 (Cronbach's alpha=0.595). Responsiveness to change, measured on all patients (SRM=2.21) and on patients classified as improved at second visit (SRM=2.59) was strong and superior to that of JADAS10 (SRM=1.97 and 2.28, respectively).

Conclusion: The sJADAS was found to be a valid instrument for the assessment of disease activity in sJIA. This score is feasible and easily applicable in standard clinical practice, which should result in its widespread acceptance and use. The good responsiveness to clinical change indicates that the sJADAS is suitable to assess therapeutic response in sJIA clinical trials.

Concurrent validity (baseline values).

Correlation between sJADAS and:	Spearman' r [N]
JADAS10	0.98 [n=160]
cJADAS	0.91 [n=160]
DAS 28	0.83 [n=155]
CDAI	0.83 [n=157]

Convergent validity (baseline values).

Correlation between sJADAS and:	Spearman' r [N]
CRP	0.40 [n=151]
JAFS	0.69 [n=157]
Parent Pain VAS	0.58 [n=158]
HRQL	0.56 [n=150]
Physical sub-score HRQL	0.59 [n=150]
Psychosocial sub-score HRQL	0.38 [n=150]
CHAQ	0.62 [n=119]

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Macrophage activation syndrome (MAS) is the most severe complication of systemic juvenile idiopathic arthritis (sJIA) and its adult equivalent, adult-onset Still's disease (AOSD). Because MAS can follow a rapidly fatal course, its prompt recognition and immediate therapeutic intervention are critical. An international collaborative effort has recently led to the publication of the 2016 classification criteria for MAS in sJIA. However these criteria are intended to serve for classification purposes and not as diagnostic tool. The aim of this study was to develop and validate a diagnostic score for timely detection of MAS in patients with sJIA

Table 1.

	β-coefficient	95% Confidence Interval
Central nervous system (CNS) involvement	2.44	1.26; 3.65
Hemorrhagic manifestations	1.54	0.00; 3.05
Active arthritis	-1.30	-2.05; 0.00
Platelet count (PLT), x 10^9/liter	-0.003	-0.005; -0.001
Lactic dehydrogenase (LDH), U/liter	0.001	0.0002; 0.002
Fibrinogen, mg/dl	-0.004	-0.006; -0.002
Ferritin, ng/ml	0.0001	0.00; 0.0002

Calculation of the MS score = CNS involvement*2.44 + hemorrhagic manifestations*1.54 + arthritis*(-1.30) + PLT count*(-0.003) + LDH*0.001 + fibrinogen*(-0.004) + ferritin*0.0001

In a febrile patient with known or suspected systemic juvenile idiopathic arthritis, the diagnosis of MAS should be considered if the MS score is ≥ -2.1

The area under the curve of the model is 0.95. For clinical variables (CNS involvement, hemorrhagic manifestations, active arthritis), a score of 1 or 0 is placed in the formula, depending on whether the variable is present or absent, respectively. For laboratory variables, the observed value in the above-mentioned unit are included.

Methods: The clinical and laboratory features of 362 patients with sJIA-associated MAS and 404 patients with active sJIA without evidence of MAS were collected in a multinational collaborative project. Eighty percent of the study population was used to develop the score and the remaining 20% constituted the validation sample. A Bayesian Model Averaging approach was used to assess the role of each clinical and laboratory variable in the diagnosis of MAS and to obtain the coefficients of selected variables. Variables with an inclusion probability greater than 0.80 composed the final score, named MAS/sJIA (MS) score, which resulted from the linear combination of the values of each variable multiplied by their coefficients. The cutoff that best discriminated MAS from active sJIA was calculated by means of receiver operating characteristic (ROC) curve analysis. Score performance was evaluated in both developmental and validation samples

Results: The 7 variables included in the MS score (central nervous system dysfunction, hemorrhagic manifestations, active arthritis, platelet count, fibrinogen, lactate dehydrogenase and ferritin) are presented in Table 1 together with their coefficients and with the MS score calculation formula. The final score ranges from -8.4 to 41.8. A cut-off value > -2.1 revealed the best performance in discriminating MAS from active sJIA, with a sensitivity (SE) of 0.85, a specificity (SP) of 0.95, area under the curve of 0.95 and a kappa value of 0.80. The good performance of the MS score was confirmed in the validation sample (SE 0.89, SP 0.99, AUC 0.97, kappa 0.87)

Conclusion: The MS score is a powerful and feasible tool that may assist practitioners inmaking a timely diagnosis of MAS in patients with sJIA. Future assessments at the bedside could be enhanced and made easier by developing a phone/web application. Considering that sJIA and AOSD are nowadays thought to be part of the same disease spectrum, the MS score might be also useful in timely recognition of MAS in patients with AOSD. The MS score deserves validation in a prospective cohort of patients with sJIA-associated MAS

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic Juvenile Idiopathic Arthritis (SJIA) is associated with a recently recognized albeit poorly defined and characterized lung disease (LD). Our objective is to describe clinical characteristics, risk factors, histopathologic and immunologic features of SJIA-associated LD (SJIA-LD).

Methods: This was a prospective cohort study; patients were identified upon lung disease detection or referral to Cincinnati Children's Hospital for consultation or second opinion. This study was approved by the Institutional Review Board, and written informed consent was obtained from all patients and/or their legal guardians. Clinical data was abstracted from medical records, and epidemiologic, cellular, biochemical, genomic analysis, and transcriptional profiling analyses were performed.

Results: Twenty-two patients with SJIA-LD have been evaluated since 2010. Typical radiographic findings included diffuse ground-glass opacities, subpleural reticulation, peribronchovascular and/or septal thickening, and lymphadenopathy. Pathologic findings included patchy but extensive lymphoplasmacytic infiltrates and mixed features of pulmonary alveolar proteinosis (PAP) and endogenous lipoid pneumonia (ELP). Compared to SJIA patients without LD, children with SJIA-LD were younger at SJIA diagnosis, had prior episodes of macrophage activation syndrome (MAS), have had adverse reactions to biologic therapy, and have higher serum IL-18. PAP is classically associated with primary or secondary dysfunction of alveolar macrophages leading to accumulation of pulmonary surfactant in alveolar spaces. However, SJIA-LD patients lacked genetic, serologic, or functional evidence of GM-CSF pathway dysfunction typical of primary familial or autoimmune PAP. Additionally, bronchoalveolar lavage (BAL) rarely demonstrated proteinaceous material and had less lipid-laden macrophages than seen in primary PAP. Instead, SJIA-LD BAL fluid contained elevated levels of IL-18 and IFNγ-induced chemokines CXCL9-10. Finally, multiplex transcriptional profiling of SJIA-LD lung tissue identified upregulated type II interferon and T-cell activation networks, including a STAT1 transcriptional network. Two of the most highly upregulated non-HLA genes were *CXCL10* (9-fold increase) and *CXCL9* (7-fold increase), IFN-induced chemokines whose serum levels are strongly associated with MAS. This signature was also present in SJIA-LD lung tissue sections lacking substantial histopathological findings, suggesting it may precede and may even drive lung pathology. Taken together, this gene expression analysis supports significant IFNγ-induced pulmonary inflammation in children with SJIA-LD.

Conclusion: Pulmonary disease in SJIA has distinct clinical and immunologic features and represents an uncharacterized inflammatory lung disease. MAS may constitute a risk factor for SJIA-LD development. Both BAL cytokine analysis and gene expression profiling of lung tissue revealed substantial inflammation including elevated IL-18, IFNγ pathway activation and T cell function.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Recent experiences suggest a disturbing epidemic of digital clubbing and insidious, Pulmonary Alveolar Proteinosis (PAP)-like lung disease occurring in patients with Systemic Juvenile Idiopathic Arthritis (SJIA-PAP). Many SJIA-PAP patients also suffer from prior and/or concomitant Macrophage Activation Syndrome (MAS) and most have been exposed to IL-1 and/or IL-6 inhibition. Though variable, many SJIA-PAP patients progress to pulmonary hypertension, respiratory failure, and death. To improve diagnostic screening and pathogenic understanding of SJIA-PAP, we undertook a near-proteomic serum analysis in SJIA-PAP and related controls.

Methods: We measured 1311 distinct analytes in 162 serum samples from a cohort of patients with SJIA-PAP (n=11), inactive sJIA/MAS (30, including two NLRC4-MAS), active SJIA (24), active MAS (12, including two NLRC4-MAS), autoimmune/genetic PAP (14), Neonatal-Onset Multisystem Inflammatory Disease (5), STING-associated Vasculopathy of Infancy with interstitial lung disease (4), and healthy controls (21). Targets were measured using Slow Off-rate Modified Aptamers (SOMAmers), augmented by selected Luminex-based measurements. We used a linear regression model (Limma) to identify relationships with individual diseases.

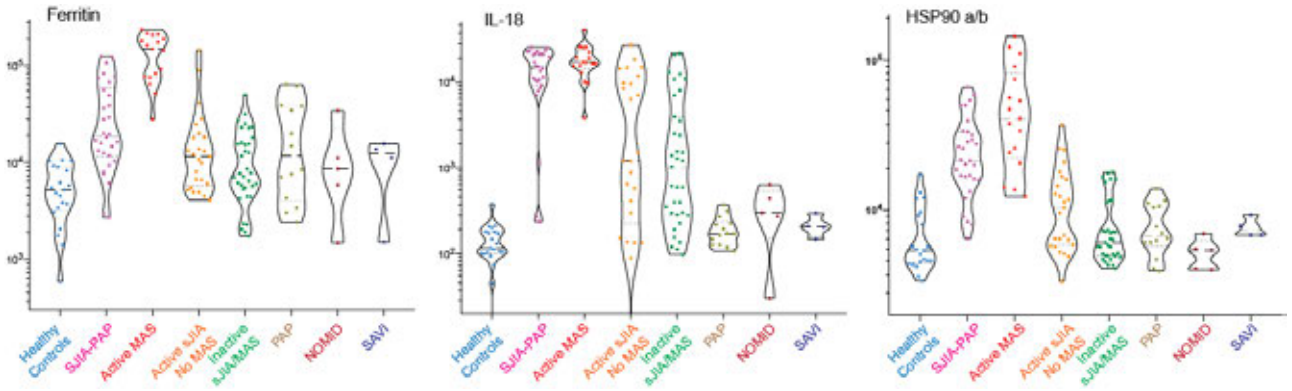

Figure 1. Violin plots of MAS-associated protein targets in the indicated patient groups.

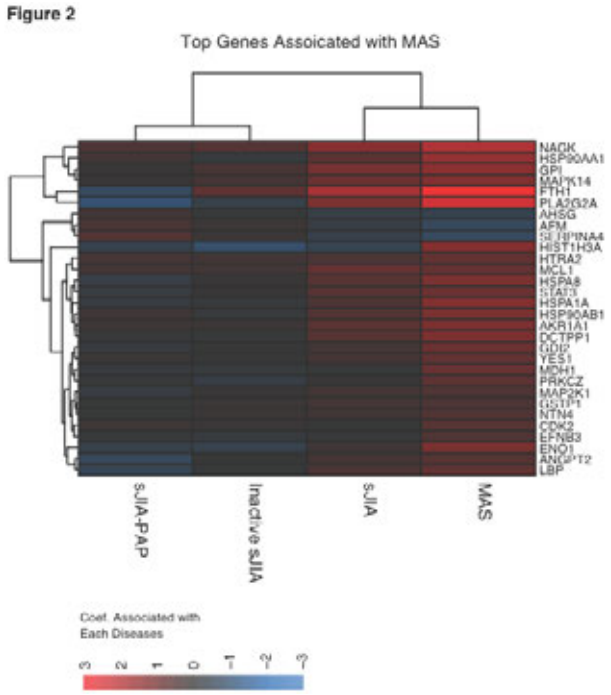

Figure 2. Top 30 targets (FDR<0.05) associated with MAS. Color represents the coefficients for each target under each condition, as determined by limma.

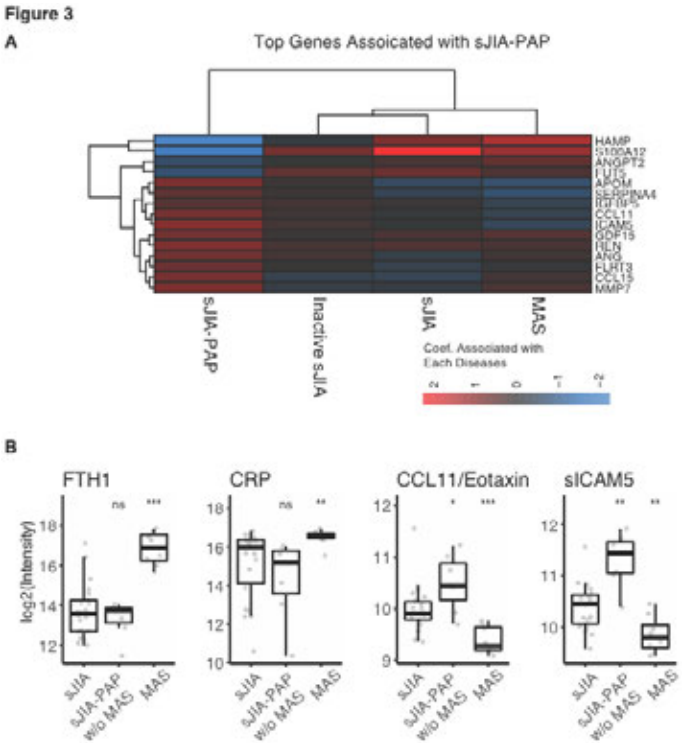

Figure 3. An SJIA-PAP signature is independent of the MAS signature. A) Top 15 targets (FDR < 0.2) associated with lung disease. B) Expression of four targets in SJIA, SJIA-PAP w/o MAS (those SJIA-PAP patients without CRP and ferritin elevation), and active MAS.

Results: Biomarkers canonically associated with SJIA and MAS (e.g. CRP, S100 proteins, ferritin, IL-18) supported the validity of pre-analysis groupings (Fig. 1). Novel, MAS-specific biomarkers suggested targetable cell death (heat-shock proteins) and metabolic (glycolytic enzyme) pathways (Fig. 2). Analytes elevated in SJIA-PAP but not inactive

SJIA, active SJIA, or active MAS (e.g. sICAM-5 & MMP7) suggest lung-intrinsic macrophage activity and may aid in screening or monitoring SJIA-PAP. About half the SJIA-PAP samples demonstrated MAS-like features despite the absence of overt MAS, while the other half displayed relatively low CRP and ferritin levels (Fig 3B), lacked prominent elements of the sJIA/MAS signature (e.g., S100, heat-shock proteins), but had elevated IL-18. Lung disease in these patients was not resolved, and they expressed an sJIA-PAP signature (Fig 3B) that did not correlate with the MAS signature, suggesting distinct regulation of MAS and SJIA-PAP.

Conclusion: This massively-multiplexed serum analysis identified novel targets and pathways in MAS, and suggested an eosinophilic feature in SJIA-PAP patients. High MAS activity was frequently observed despite the absence of overt MAS, but was not required to maintain SJIA-PAP inflammation. Though these data require prospective validation, they provide mechanistic insights into SJIA, MAS, and the development of SJIA-PAP and may provide candidate biomarkers with which to better diagnose and monitor these disorders.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) is a childhood arthritis with features of autoinflammation, and is associated with high risk of macrophage activation syndrome (MAS). IL-18 has been increasingly shown to have key roles in linking sJIA and MAS, in particular due to an imbalance between IL-18 and its natural inhibitor IL-18 binding protein (IL-18 BP). Therefore, we hypothesized that free(unbound) IL-18, rather than total IL-18, might be a more accurate biomarker for sJIA disease activity and emerging MAS.

Methods: Serum samples were obtained from 43 established sJIA patients, free and total IL-18 (pg/ml), CXCL9, and S100 protein levels were determined. Free IL-18 levels were compared between patients with regards to clinical and laboratory features, including disease activity, history of MAS, and other emerging biomarkers for sJIA and MAS.

Results: Median free IL-18 level for the cohort was 2.03 pg/ml (IQR: 0-35.68). Free IL-18 levels were significantly higher in patients with active disease (median 25.96, IQR 16.89-66.52) compared to those with clinically inactive disease (CID) (0, IQR -1.29-7.79; p=0.0002). Likewise, those with history of MAS had significantly higher free IL-18

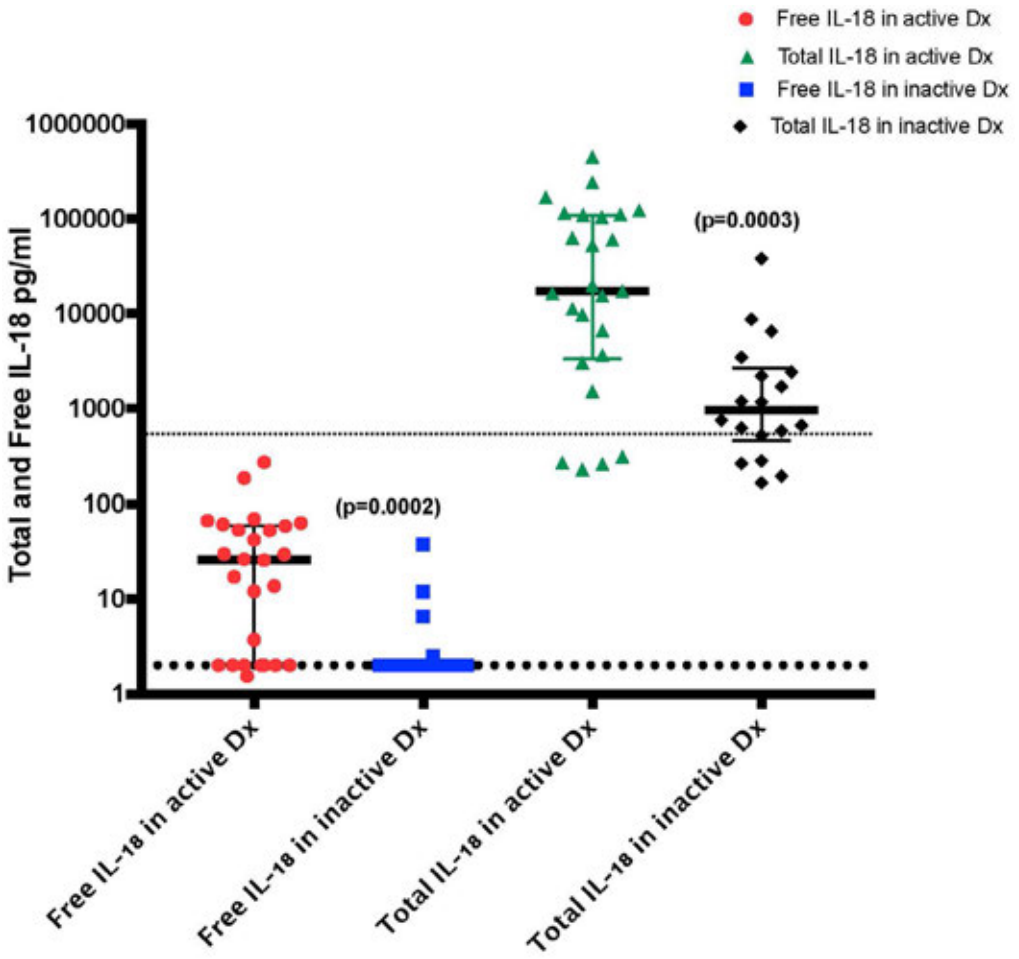

Figure (1). Free and total IL-18 levels in patients with active and inactive disease. Horizontal Lines represent upper limit normal for free (0 pg/ml) and total IL-18 (540 pg/ml).

levels (29.55, IQR 16.14-67.51) when compared to those without MAS history (0, IQR -0.29-15.07; p=< 0.0001).Of note, Patients with active disease and history of MAS had higher free IL-18 than in patients with active disease and no history of MAS (0=0.01). Patients with fever, arthritis, systemic features or elevated inflammatory markers (ESR/CRP) had significantly higher free IL-18 levels (p= 0.001, 0.318,0.0003 and < 0.0001, respectively). Notably, free IL-18 levels were undetectable in the majority (78%) of patients with CID. This is in marked contrast to total IL-18, where a majority (83%) of CID still had high levels (median 956.5, IQR 458-2682, upper limit normal 540 pg/ml) (Figure 1).

Free IL-18 performed well as a biomarker for disease activity with AUC of 81% (p=0.0006). There was a strong correlation between free and total IL-18 levels (r=0.87, p< 0.0001)), with sustained significance when restricted to patients with only active disease or CID (r=0.81 and 0.73 respectively). Correlation was moderate with CXCL9 (r=0.57, p< 0.0001)), S100A8/9 (r=0.50, p=0.0022)) and S100 A12 (r=0.38, p=0.0228)). Interestingly, correlations between free IL-18 and S100 A8/9 and A12 were stronger in patients with active disease (r=0.68 and 0.58), but weak and statistically insignificant for patients in CID.

Conclusion: Free IL-18 levels were significantly higher in sJIA patients with active disease, fever, systemic features and arthritis. Levels were undetectable in the majority of patients with CID. Free IL-18 correlated well with other disease biomarkers particularly when disease was active, indicating that free IL-18 is a promising new sensitive biomarker for sJIA disease activity. It also supports the role of IL-18/IL-18 BP imbalance in the pathogenesis of sJIA and MAS.

Adenosine Deaminase 2 as a Circulating Biomarker of Macrophage Activation Syndrome

Pui Lee,[1] Grant Schulert,[2] Scott Canna,[3] Yuelong Huang,[4] Jacob Sundel,[4] Mary Beth Son,[1] Lauren Henderson,[1] Peter Nigrovic,[5] Jane Newburger,[6] Fatma Dedeoglu,[6] Mindy Lo,[6] Esra Meidan,[6] Ying Li,[4] Olha Halyabar,[6] Margaret Chang,[7] Kacie Hoyt,[6] Thuy Do,[2] Robert Sundel,[8] and Rachel Blaustein[4], [1]Boston Children's Hospital, Boston, MA, [2]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]UPMC Children's Hospital of Pittsburgh, Pittsburgh, [4]Brigham and Women's Hospital, Boston, [5]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA ; Department of Medicine, Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA., Boston, [6]Boston Children's Hospital, Boston, [7]Division of Immunology, Boston Children's Hospital, Boston, [8]Boston Children's Hospital, Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Pediatric Rheumatology – Clinical I: Systemic JIA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Macrophage activation syndrome (MAS) is a life-threatening complication of systemic juvenile idiopathic arthritis (sJIA) characterized by a vicious cycle of immune cell activation and dysregulated cytokine production that can result in multi-organ failure. Unambiguous biomarkers of MAS are needed to facilitate prompt diagnosis and treatment, as well as to inform the understanding of disease pathogenesis.

Methods: Adenosine deaminase 2 (ADA2) activity was quantified in peripheral blood using an established spectrophotometric assay in healthy children and in children with a range of inflammatory diseases. Sources of ADA2 and triggers for its release were explored using cytokine stimulation of peripheral blood mononuclear cells, flow cytometry, and confocal microscopy of MAS bone marrow.

Results: We established normal levels of peripheral blood ADA2 levels in 175 healthy children and compared these values with Kawasaki disease (KD; n = 25), systemic lupus erythematosus (SLE; n = 13), juvenile dermatomyositis (JDM; n = 13) and multiple forms of juvenile idiopathic arthritis (JIA; n = 120). Aside from mild elevation in some patients with SLE and JDM, levels of ADA2 levels above the upper limit of normal were largely restricted to sJIA patients with clinically diagnosed MAS (**Figure 1**). In two independent sJIA cohorts, ADA2 activity beyond the upper limit of normal effectively distinguished MAS from active sJIA without MAS, with combined sensitivity = 86% and specificity = 93%. Longitudinal analysis of several patients with sJIA/MAS showed normalization of ADA2 levels with resolution of MAS. In sJIA patients, ADA2 levels correlated closely with other biomarkers of MAS including ferritin, interleukin (IL)-18, and the interferon (IFN)-γ-inducible chemokine CXCL9. In peripheral blood mononuclear cells, ADA2 was strongly induced by IL-12, IL-18 and IFN-γ. Monocytes were the primary ADA2 source in peripheral blood, with hemophagocytes a prominent source of ADA2 in MAS bone marrow as assessed by confocal microscopy.

Conclusion: ADA2 in the peripheral blood is a sensitive and specific biomarker of MAS, reflecting the activation status of monocytes, macrophages, and potentially hemophagocytes. In patients with active sJIA, ADA2 activity

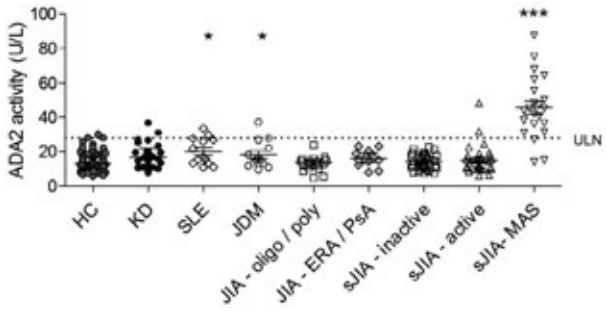

Figure 1. Peripheral ADA2 activity in healthy children and patients with childhood inflammatory diseases. HC, healthy control; KD, Kawasaki disease; SLE, systemic lupus erythematosus; JDM, juvenile dermatomyositis; JIA, juvenile idiopathic arthritis; ERA, enthesitis-related arthritis; PsA, psoriatic arthritis; MAS, macrophage activation syndrome; ULN, upper limit of normal; * $p < 0.01$, *** $p < 0.0001$

beyond the upper limit of normal represents strong evidence for concomitant MAS and could potentially help guide clinical care.

Indicators of Actionable Levels of Atherosclerosis in RA Patients Who Appear to Have Low or Intermediate Atherosclerotic Cardiovascular Risk Based on Standard Risk Algorithms

Jon Giles,[1] Cecilia Chung,[2] Mary Chester Wasko,[3] Amy Kao,[3] Annette Oeser,[2] C. Michael Stein,[2] and Joan Bathon[4], [1]Columbia University, Vagelos College of Physicians & Surgeons, New York, NY, [2]Vanderbilt University, Nashville, TN, [3]Allegheny Health Network-West Penn Hospital, Pittsburgh, PA, [4]Division of Rheumatology, Columbia University, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In the general population, statins reduces atherosclerotic cardiovascular disease (ASCVD) events in those with a computed tomography (CT)-assessed coronary artery calcium (CAC) score ≥100 units, regardless of background level of predicted ASCVD risk. Since general ASCVD risk models underperform in RA, we sought to identify RA-specific clinical indicators of an actionable level of CAC [i.e. CAC ≥100 (aICAC)] to distinguish those seemingly at lower ASCVD risk who would benefit from CAC screening and/or ASCVD prevention.

Methods: Data were pooled from 4 cohorts of RA patients and a cohort of non-RA controls who all underwent CT-assessed CAC calculated using the Agatston method. Those on statins or with prior known CVD were excluded. Predictors of aICAC were modeled using logistic regression for those with low (< 5%) and intermediate (5-15%) ASCVD risk based on the ACC/AHA 10-year risk equation. The number needed to screen (NNS) with CT to identify an individual with aICAC was assessed before and after classifying patients according to ASCVD strata-specific predicted probabilities.

Table. Actionable Level of CAC (alCAC) and Number Needed to Screen (NNS) with Computed Tomography (CT) to Detect alCAC According to Strata of the American College of Cardiology/American Heart Association (ACC/AHA) 10-year Hard ASCVD Event Risk Score*

ASCVD Score	Number of RA patients	% with alCAC	OR_{adj} RA vs. Control**	p-value	RA-NNS	Control-NNS
All	546	24.2%	2.50	<0.001	n=4	n=8
< 5%	310	8.7%	2.51	0.001	n=12	n=36
5 – 14.99%	148	33.1%	2.19	<0.001	n=3	n=7
≥ 15%	88	63.6%	3.51	<0.001	n=2	n=3

* alCAC = Agatston CAC Score ≥ 100 units

** Adjusted for age, gender, race/ethnicity, body mass index, traditional CVD risk factors, NSAID use, and aspirin use

Results: A total of 546 RA patients and 5,279 non-RA controls were studied. The majority (57%) of the RA group had an ASCVD risk score< 5% and 27% had risk between 5-15%. alCAC was observed in n=132 (24%) of the RA group, and 58% of the total alCAC for the RA cohort was contained within the two lower ASCVD risk groups, including 20% in the group with an ASCVD score < 5%. The adjusted odds of alCAC was greater in the RA vs. control groups for all strata of ASCVD risk (Table), and the NNS was lower in RA for each stratum. In the low ASCVD risk RA group, alCAC was associated significantly and independently with higher age, ever smoking, lower BMI (particularly among ever smokers), antihypertensive use, very low and high LDL-C, aspirin use, RA duration (particularly among those not treated with biologics), and higher DAS28 score. The AUC-ROC for these indicators was 0.921 (95% CI 0.858, 0.984) and was significantly higher than modeling the ASCVD score alone (AUC=0.657; p-value for model comparison< 0.001). A different set of indicators of alCAC was present for those with ASCVD risk between 5-15% [male gender, waist circumference, current smoking (particularly among those with a normal BMI), antihypertensive use, and non-use of methotrexate]. The AUC-ROC for these indicators was 0.776 (95% CI 0.694, 0.857) and was significantly higher than modeling the ASCVD score alone (AUC=0.605; p-value for model comparison=0.004). Taking only those in the 4th quartile of predicted probability from each ASCVD risk stratum identified 67% of the seemingly low/intermediate ASCVD risk RA patients with alCAC (NNS=3), including all but n=4 in the low risk group. Taking the 3rd and 4th quartiles identified 80% with an alCAC (NNS=3), including all in the low risk group.

Conclusion: Using ASCVD strata-specific prediction models, clinical characteristics that included RA features were able to distinguish a large proportion of the seemingly lower ASCVD risk RA patients with alCAC who would benefit from additional screening and/or aggressive preventive treatment. External validation is warranted in order to apply this approach to clinical practice.

Improved Incidence of Cardiovascular Disease in Patients with Incident Rheumatoid Arthritis in 2000s: A Population-Based Cohort Study

Elena Myasoedova,[1] John Davis,[1] Veronique Roger,[1] Sara Achenbach,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

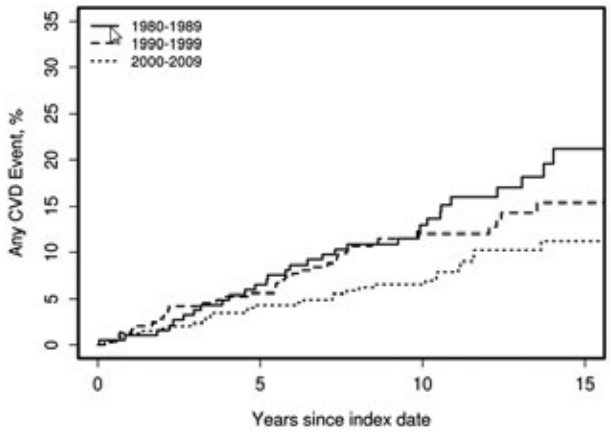

Figure. Cumulative incidence of any CVD event in patients with RA by decade of RA incidence

Background/Purpose: Increased burden of cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA) as compared to the general population is well recognized. Several studies suggested reduced CVD mortality in RA in recent decades. Longitudinal studies on trends in occurrence of CVD events in RA patients over time are lacking. To address this gap in knowledge, we evaluated trends in incidence of CVD in patients with incident RA in 1980-2009.

Methods: We studied patients with incident RA (age ≥18 years, 1987 ACR criteria met in 1980-2009) followed until death, migration out of the region, or 12/31/2016. Follow-up of each decade was truncated to make the length of follow-up comparable (i.e., the 1980–89 cohort was truncated at December 31, 1996, the 1990–99 cohort was truncated at December 31, 2006 and the 2000–09 cohort was truncated at December 31, 2016). Incident CVD events included myocardial infarction (MI), stroke (ischemic or hemorrhagic), coronary heart disease (CHD) death and first occurrence of any of these. Patients with CVD events prior to RA incidence date were excluded. Cox proportional hazards models were used to compare incident CVD events by decade, adjusting for age and sex. Cumulative incidence of CVD events adjusted for death from other causes was calculated.

Results: The study included 906 patients with incident RA (mean age 55.9 years; 69% female). There were 201, 299 and 406 patients in 1980-89, 1990-99 and 2000-09, respectively. During median follow-up of 10.6, 10.4 and 10.2 years per decade of RA incidence, CVD events occurred in 31, 38, and 31 patients. Patients with incident RA in 2000–09 had markedly lower cumulative incidence of any CVD events than patients diagnosed in 1990s and 1980s (Figure). Hazard ratios (HR) for any CVD events demonstrated a temporal reduction in CVD events among patients with incident RA in 2000s compared with incident RA in 1980s (HR: 0.52; 95% confidence interval (CI): 0.32-0.86) and a reduction compared with incident RA in 1990s (HR: 0.65; 95% CI: 0.40-1.05).

Conclusion: The incidence of major CVD events in RA declined markedly over time. These findings may reflect increased awareness, improved primary CVD prevention and better RA disease management in recent years. More studies are needed to understand the determinants and implications of these data.

First Cardiovascular Event in Rheumatoid Arthritis: Do Patients with Venous Thromboembolism Have a Different Risk Profile Than Patients with Atherosclerotic Cardiovascular Disease?

Gulsen Ozen,[1] Sofia Pedro,[2] Rebecca Schumacher,[2] Teresa Simon,[3] and Kaleb Michaud[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]Bristol-Myers Squibb*, Princeton, NJ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Chronic inflammation is linked to increased risk of cardiovascular disease (CVD) in RA that may manifest as venous thromboembolism (VTE) or atherosclerotic CVD (ASCVD). VTE is a potentially fatal condition that has been an increasing concern due to recent associations with the use of JAK inhibitors. However, our knowledge is limited about what factors determine VTE development in patients with RA, and if these risk factors are different than the ones for atherosclerotic CVD (ASCVD). We performed a cohort study aiming to assess risk factors favoring VTE over ASCVD in patients with RA.

Methods: RA patients participating in FORWARD, The National Databank for Rheumatic Diseases, from 1998 through 2018 were assessed for incident nonfatal or fatal unprovoked VTE (deep venous thrombosis and pulmonary emboli not associated with active cancer, recent surgery, hospitalization, fracture, pregnancy) and ASCVD (myocardial infarction and stroke) validated from hospital/death records. Patients with prior VTE/ASCVD and active cancer were excluded. Event rates were calculated, and the risk factors for VTE and ASCVD were determined separately using Cox proportional hazards compared to patients who had no history of VTE and ASCVD.

Results: Of 31,366 RA patients, we identified 539 first unprovoked VTE and 1,648 first ASCVD events during median (IQR) 4 (1.5-7) years of follow-up. The crude incidence rates per 1,000 patient-years (95% CI) were 0.34 (0.31-0.37) for VTE and 1.57 (1.51-1.63) for ASCVD. Baseline characteristics of patients by the CVD type are presented in *Table 1*. Patients with VTE were significantly more obese than patients with ASCVD but not different in terms of the history of prior cancer, fracture and traditional CV risk factors (diabetes [DM], hypertension [HT], and smoking). The multivariable models showed that older age, being male, having more comorbidities, history of fracture, worse HAQ scores, moderate/high disease activity and glucocorticoid use were associated with both increased VTE and ASCVD risks (*Table 2*). However, age and gender were stronger risk factors for ASCVD than for VTE and history of prior fracture and glucocorticoid use were stronger risk factors for VTE than for ASCVD. Traditional CV risk factors, DM and HT increased only ASCVD risk. Obesity had opposite effects on VTE and ASCVD risks: increased VTE risk (HR [95% CI], 1.46 [1.13-1.87]) and decreased ASCVD risk (HR [95% CI], 0.58 [0.50-0.68]) while underweight (HR [95% CI], 1.51 [1.13-2.02]) increased ASCVD risk. Hydroxycholoroquine use was found to be associated with a lower risk of VTE and ASCVD (*Table 2*).

Conclusion: With different risk magnitudes, VTE and ASCVD share common risk factors representing RA disease severity including disability, high disease activity and glucocorticoid use. The main difference in risk factors for these CV events is the traditional CV risk factors; DM and HT increase ASCVD risk and obesity increases VTE risk with a paradoxical effect on ASCVD. Being obese and having a prior fracture may be promoting immobilization and hence

Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: We recently reported that highly-sensitive cardiac troponin-I (hs-cTnI) associates with occult coronary atherosclerosis burden and cardiovascular event (CVE) risk in rheumatoid arthritis (RA). We further showed that IgA antibodies against beta2-glycoprotein-1 (a-b2GPI-IgA) contribute to higher coronary artery calcium (CAC) and accelerated plaque and CAC progression in RA. It is unclear when to proceed with coronary atherosclerosis evaluation in asymptomatic RA patients and whether such an assessment should be repeated in the future. We here explored whether either biomarker alone or their combination best predicted plaque or CAC presence on an initial coronary CT angiogram (CCTA); we then interrogated whether either biomarker predicted progression to extensive or obstructive plaque on a follow-up evaluation

Methods: One hundred fifty RA patients underwent a baseline CCTA; 101 had repeat evaluation within 83±3.6 months. Hs-cTnI and a-b2GPI IgAwere assessed at baseline; the latter were confirmed 12 weeks later, if positive. Extensive plaque was defined as >5 coronary segments withplaque, or stenosis score >5, or CAC >100.The diagnostic accuracy of Framingham D'Agostino cardiac risk score (FRSDA) alone vs. hs-cTnI or a-b2GPI-IgA sequentially

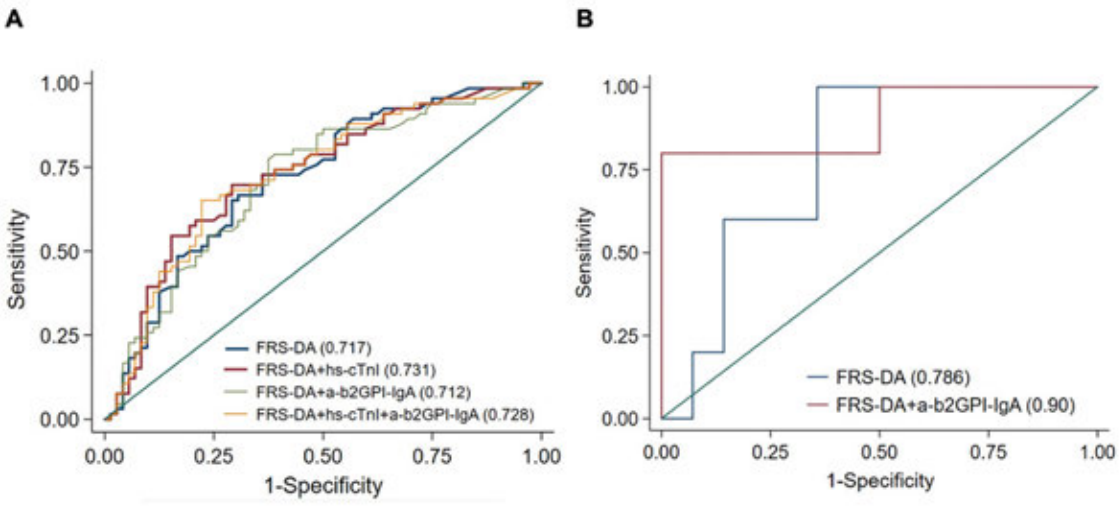

Figure 1. (A) Diagnostic accuracy for prediction of occult coronary plaque at baseline. Framingham D'Agostino (FRSDA) alone is the baseline model followed by addition of hs-cTnI or a-b2GPI-IgA individually or combined. **(B)** Diagnostic accuracy for progression from non-obstructive and non-extensive plaque at baseline to obstructive or extensive atherosclerosis at follow-up.

or combined for plaque or CAC at baseline was evaluated as area under the curve (AUC). Improvement in prediction accuracy between constructs was further assessed as integrated discrimination improvement (IDI). Similar AUC and IDI constructs were evaluated for transition to obstructive or extensive atherosclerosis at follow-up in patients with baseline plaque.

Results: High hs-cTnI added to FRSDA increased AUC from 0.717 to 0.731 (Figure 1A) and improved prediction for baseline plaque [IDI=0.041 (SE)=0.017, p=0.015]. In contrast, a-b2GPI-IgA did not [0.005 (0.006), p=0.47] and the combination offered no added benefit to the hs-cTnI model alone. Similar observations were made for baseline CAC. Hs-cTnI alone did not independently predict CAC change (β=0.084, p=0.215) whereas a-b2GPI-IgA presence did (β=0.235, p=0.001). High hs-cTnI predicted greater CAC change in a-b2GPI-IgA positive patients but not in negative ones [p-interaction= 0.034, estimated marginal mean difference (IQR)=0.36 (0.12-0.59), p=0.003]. Addition of a-b2GPI-IgA to FRSDA in patients with prevalent non-extensive non-obstructive plaque increased AUC from 0.785 to 0.900 (Figure 1B) and significantly improved the prediction for development of obstructive or extensive atherosclerosis at follow-up [0.387, (0.13), p=0.003].

Conclusion: High hs-cTnI significantly and independently improved the risk of baseline plaque presence and may trigger an initial non-invasive coronary atherosclerosis evaluation. A-b2GPI-IgA presence may justify a follow-up evaluation in patients with non-extensive, non-obstructive plaque at baseline.

Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Inflammation has been thought to be a risk factor for cognitive impairment and dementia. RA, an autoimmune inflammatory disorder is associated with a high risk of cardiovascular disease (CVD) as a result of underlying inflammation, However, it is unknown if RA patients at risk of CVD are similarly at higher risk of developing dementia. The objective of this study was to describe the incidence of dementia among patients with RA older than 40 years, and to compare the risk of incident dementia between those with known CVD and those without CVD, with and without traditional CVD risk factors.

Methods: We conducted a longitudinal analysis, using Centers for Medicare and Medicaid claims (CMS) data from 2006-2014. To be included, patients had to be continuously enrolled throughout 2006 (12 months calendar year of fee for service), > 40 years old, eligible for Medicare parts A, B and D, and without a diagnosis of dementia in 2006. RA

Table 1. Characteristics of Patients with RA Older than 40 Years of Age without Dementia Stratified by History of Cardiovascular Disease (CVD) and Traditional CVD Risk Factors

CVD = cardiovascular disease; Prevalent CVD as defined by ICD-9-CM codes for myocardial infarction, heart failure, stroke, or CVD procedures (coronary artery bypass grafting, percutaneous coronary intervention, or carotid endarterectomy); CVD risk factors included diabetes, hyperlipidemia, hypertension, and obesity in 2006 defined by ICD-9-CM codes.

was defined as: two RA diagnoses (ICD-9-CM 714.xx) by a rheumatologist > 7 and < 365 days apart and or at least one diagnosis of RA and least 1 prescription for a DMARD. Incident dementia was defined as: 2 outpatient claims for dementia (ICD-9-CM codes for 290.xx, 294.1x, or 331.xx) at least 40 days apart in 2007 or later. Prevalent CVD was defined by ICD-9-CM codes for myocardial infarction, heart failure, stroke, or CVD procedures (coronary artery bypass grafting, percutaneous coronary intervention, or carotid endarterectomy) in 2006. CVD risk factors were defined by ICD-9-CM codes for diabetes, hyperlipidemia, hypertension, and obesity in 2006. Age-adjusted incidence rates (IR) were estimated using Poisson models. Age- and sex-adjusted Cox proportional hazard models (HR) were used to compare risk of incident dementia in 3 groups of RA patients; 1) with prevalent CVD 2) without CVD but with CVD risk factors, and 3) no prevalent CVD events nor CVD risk factors.

Results: There were 79,957 RA patients in the study sample; 80.8% were female, and 79.6% were white (Table 1). The prevalence of dementia was 2.36% (n = 1,887). After removing RA patients with prevalent dementia in 2006, 75,634 remained. Between 2007-2014, there were 9,835 (13%) cases of incident dementia (Table 1). The age-adjusted IR of dementia was 25.6 (95% CI 24.3 – 26.9) per 1000 person-years for those with prevalent CVD, 17.5 (95% CI 17.1 – 18.1) per 1000 person-years for those with CVD risk factors, and 15.2 (95% CI 14.59-16.00) in patients with neither (Table 2). The age- and sex-adjusted HR for incident dementia was 2.1 (95% CI 1.9 - 2.2) in those with prevalent CVD and 1.2 (95% CI 1.1 - 1.2) in those without prevalent CVD with presence of any CVD risk factor compared to those without CVD and or CVD risk factors.

Table 2. Incident Rates of Dementia Between Year 2007-2014 in Patients with RA Stratified by History of Cardiovascular Disease (CVD) and Presence of CVD Risk Factor during Calendar Year 2006 (Baseline)

	N	Number of patients with incident dementia	Mean number of years of followup	Crude Rate per 1000 person years	Age Adjusted Incident rate per 1000	Age and Gender Adjusted Hazard Ratios (95% CI)
Prevalent CVD	9,487	1,717	4.78	37.86	25.60 (24.32 - 26.93)	2.08 (1.94 - 2.21)
No prevalent CVD, but with CVD risk factor	47,096	6,218	5.94	22.22	17.55 (17.05 - 18.06)	1.18 (1.12 - 1.24)
No prevalent CVD or CVD risk factors	19,051	1,900	6.13	16.26	15.28 (14.59 - 16.00)	Reference

CVD = cardiovascular disease; Prevalent CVD as defined by ICD-9-CM codes for myocardial infarction, heart failure, stroke, or CVD procedures (coronary artery bypass grafting, percutaneous coronary intervention, or carotid endarterectomy); CVD risk factors included diabetes, hyperlipidemia, hypertension, and obesity in 2006 defined by ICD-9-CM codes.

Conclusion: The incidence of dementia in patients with RA was as high or higher than previous reports from the general population. The presence of CVD in patients with RA increases the risk for incident dementia 2-fold when compared to patients with RA without CVD or CVD risk factors. Our study suggests that in patients with RA, increasing risk for CVD may also be associated with an increased risk for dementia. Further studies comparing patients with and without RA are needed to clarify this association.

Session Title: RA – Diagnosis, Manifestations, & Outcomes II: Cardiovascular Comorbidities

Session Type: ACR Abstract Session

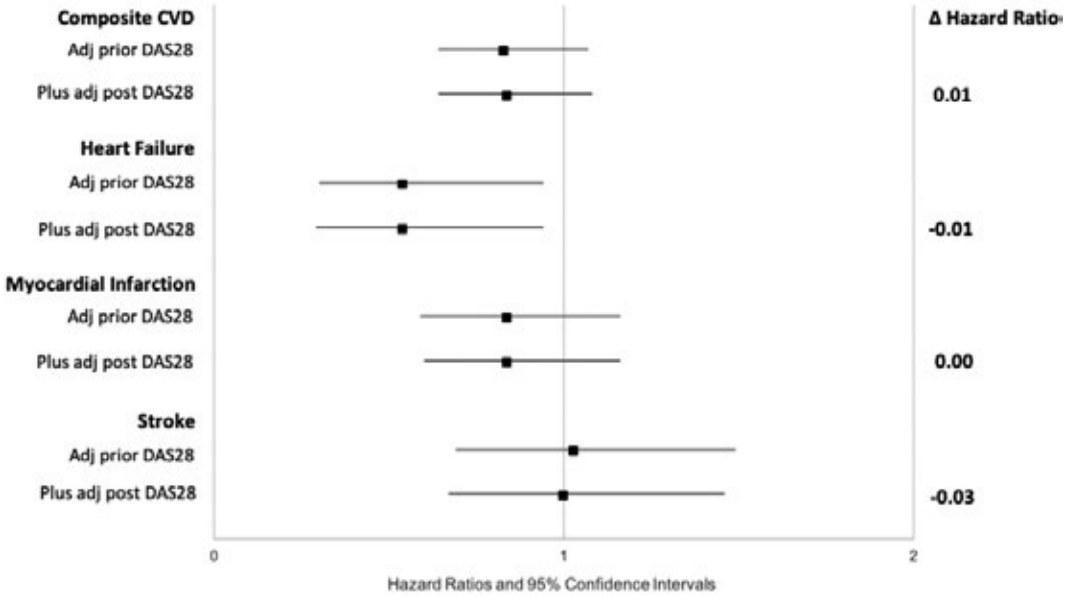
Session Time: 4:30PM–6:00PM

Table. Marginal structural models examining associations of time-varying methotrexate use with incident cardiovascular events in rheumatoid arthritis‡

Event category	HR (95% CI)	p-value
Composite CVD	**0.72 (0.56-0.91)**	**0.006**
Heart failure	0.40 (0.23-0.67)	0.001
Myocardial infarction*	0.78 (0.53-1.13)	0.19
Stroke	0.76 (0.41-1.43)	0.40

‡ Marginal structural models included baseline sex, race, smoking status, hypertension, hyperlipidemia, diabetes, chronic kidney disease, liver disease, previous CVD, statin use, and RA duration. Age, BMI, aspirin and NSAID use, DMARD exposure (non-methotrexate conventional DMARDs, biologic DMARDs, and prednisone), and DAS28 were used from the current and prior visit.
* Myocardial infarction includes coronary revascularization (percutaneous coronary intervention, coronary bypass)
Abbreviations: CI, confidence interval; CVD, cardiovascular disease; HR, hazard ratio

Figure. Effect of Rheumatoid Arthritis Disease Activity Modulation as a Mediator of Cardiovascular Risk Reduction with Methotrexate use in Rheumatoid Arthritis



Forest plots illustrating the association of time-varying MTX use with incident cardiovascular events in rheumatoid arthritis patients. Sequential multivariable cox models include pre-MTX disease activity (Adj prior DAS28) and post-MTX disease activity (Plus adj post DAS28).

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk of cardiovascular disease (CVD). Methotrexate (MTX), a mainstay in the treatment of RA, appears to mitigate this risk. However, prior studies have been limited in their ability to account for the effects of disease activity and examine the mechanisms that account for CVD risk reduction. We aimed to determine whether the association of MTX with reduced CVD risk was related to modulation of disease activity or direct effects.

Methods: We observed participants in a prospective, multicenter cohort of US Veterans with RA for incident CVD events from 4/2005 to 4/2015. CVD events were defined as a composite of acute myocardial infarction (AMI), coronary revascularization, stroke, and hospitalization for heart failure (CHF). These were identified using diagnostic and procedure codes from inpatient and outpatient encounters (validated by medical record review) and the National Death Index. Demographics, traditional CVD risk factors, comorbidities (including hypertension, hyperlipidemia, diabetes, chronic kidney disease, liver disease, and prior CVD), as well as aspirin, statin, and NSAID use were assessed using registry and administrative data. MTX (and other DMARD/prednisone) exposure was defined at each visit by linking to pharmacy dispensing data,

including a 90-day grace period upon discontinuation. To reduce confounding by disease activity, we used marginal structural models incorporating disease activity from the prior visit into the propensity to receive MTX to determine the overall association of MTX with CVD events. To examine whether the association of MTX use with CVD was mediated through disease activity, we used sequential Cox models including post-MTX disease activity.

Results: RA patients (n=2168) were predominantly older (mean age 64 years), male (90%), frequent smokers (80% current/former), seropositive (79% RF, 78% anti-CCP), with moderate baseline disease activity (mean DAS28 3.7). The incidence of composite CVD events (n=401) was lower in MTX exposed patients (33.8/1000 person-years) vs. MTX non-exposed patients (40.7/1000 person-years). Using marginal structural models to account for disease activity at the prior visit, MTX use was associated with reduced risk of composite CVD events (HR 0.72, 95% CI 0.55-0.89) and CHF (HR 0.40, 95% CI 0.23-0.67), with a trend toward reduced risk of AMI and stroke (**Table**). In sequential multivariable Cox models to assess direct and indirect effects, adjustment for post-MTX disease activity did not significantly alter the association of MTX use with composite or individual CVD events (range ΔHR -0.03 to 0.01, **Figure**).

Conclusion: In a multicenter RA cohort, MTX use was associated with a 30% reduced risk of composite CVD events and a 60% reduced risk of CHF hospitalizations. The protective effect of MTX was independent of other factors including treatment-related changes in disease activity, suggesting that additional mechanisms mediate CVD risk reduction with MTX in RA. This should be considered when selecting DMARD therapy regimens in RA patients.

Session Title: RA – Treatments II: Novel Treatments for RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Filgotinib (FIL), an orally administered, potent, selective inhibitor of Janus kinase 1 (JAK1), has shown good efficacy and was well tolerated for treatment of rheumatoid arthritis (RA). The objective of this study is to compare efficacy and safety of FIL with and without methotrexate (MTX) in patients with RA who were naïve to MTX therapy.

Methods: This phase 3, double-blind, active-controlled study randomized patients with moderately to severely active RA (2:1:1:2) to FIL 200mg daily + MTX weekly (up to 20mg), FIL 100mg + MTX, FIL 200mg (+placebo [PBO]), or MTX (+PBO) for up to 52 weeks; results through week 24 are presented. Primary efficacy endpoint was proportion of patients achieving ACR20 response at week 24; additional assessments included ACR50 and ACR70 responses;

Table 2. Safety Events of Interest through Week 24

Patients with event, n (%)	FIL 200 mg + MTX (N = 416)	FIL 100 mg + MTX (N = 207)	FIL 200 mg Monotherapy (N = 210)	MTX Monotherapy (N = 416)
Serious AEs	17 (4.1)	5 (2.4)	10 (4.8)	12 (2.9)
Serious infections	4 (1.0)	2 (1.0)	3 (1.4)	4 (1.0)
Herpes zoster	2 (0.5)	1 (0.5)	1 (0.5)	2 (0.5)
Adjudicated MACEs	2 (0.5)	0	1 (0.5)	2 (0.5)
Venous thrombotic events	0	0	0	1 (0.2)
Malignancies	0	0	0	1 (0.2)
Deaths	1 (0.2)[a]	0	0	0

[a]Cause of death was lupus myocardiopathy.
AE, adverse event; MACE, major adverse cardiovascular event

DAS28-CRP score ≤3.2 and < 2.6, and changes in van der Heijde mTSS, HAQ-DI, SF-36 PCS, and FACIT-Fatigue. Safety endpoints included types and rates of adverse events (AEs). Logistic regression adjusting for stratification factors with nonresponder imputation was used for treatment comparisons for ACR response and other binary endpoints. Mixed-effect model adjusting for baseline value, stratification factors, treatment, visit, and treatment by visit interaction as fixed effects with observed cases was used for continuous endpoints.

Results: Of 1,252 randomized patients, 1,249 received study drug (416 FIL 200mg+MTX; 207 FIL 100mg+MTX; 210 FIL 200mg monotherapy; 416 MTX monotherapy) and were analyzed; 1,130 completed week 24. Most (76.9%) were female; mean time since RA diagnosis was 2.2 years (median 0.4 years); mean (standard deviation [SD]) DAS28-CRP was 5.7 (1.0); and 35.9% were using oral steroids at baseline. At week 24, significantly more patients in the FIL 200mg+MTX (81.0%; P< 0.001) and FIL 100mg+MTX (80.2%; P< 0.05) arms achieved an ACR20 response compared to MTX monotherapy (71.4%)(Table 1). Compared to MTX monotherapy, more patients receiving FIL with or without MTX achieved ACR50 and ACR70 responses, DAS28-CRP < 2.6 and ≤3.2, and reported improvements in SF-36 PCS (Table 1). The onset of activity was rapid, with significantly more patients achieving ACR50 and DAS28-CRP < 2.6 with FIL than MTX at week 2. The FIL safety profile was consistent with prior studies through week 24 (Table 2).

Conclusion: The JAK1 inhibitor FIL in combination with MTX led to significant improvements in RA signs and symptoms, physical function, and patient-reported outcomes compared to MTX alone and was well tolerated in patients with early active RA naïve to MTX. Clinically meaningful response to FIL occurred as early as 2 weeks after treatment initiation.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments II: Novel Treatments for RA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Upadacitinib (UPA), a JAK1-selective inhibitor, was efficacious as monotherapy upto 24 weeks (wks) in MTX-naive patients (pts) with active RA.[1]

To assess safety and efficacy of UPA through 48 wks in an ongoing extension of the ph 3 SELECT-EARLY RCT.

Methods: SELECT-EARLY had a 48-wk double-blind active comparator-controlled period. Pts were initially randomized to monotherapy (mono) with UPA 15 or 30 mg or MTX (titrated up to Wk8). Rescue therapy was offered if pts met the following: (1) From Wk 12-24, pts without ≥20% improvement from BL (Δ) in both TJC and SJC at 2 consecutive visits continued blinded study drug with optimized background RA medications. (2) At Wk26, pts with CDAI ≤2.8 continued their original study drug; in pts with CDAI >2.8 and < 20% Δ in TJC and SJC, for those on MTX, UPA15/30mg was added; for those on UPA15/30mg, MTX was added. For pts with CDAI >2.8 but ≥20%Δ in TJC and SJC, background medications were optimized. Background csDMARDs could be initiated after Wk26. After Wk48, pts could continue in a long-term extension. Efficacy data up to the Wk48 visit are reported based on initial randomized treatment. For binary non-radiographic endpoints, NRI was used for missing data and rescue handling; for continuous non- radiographic endpoints, LOCF was used for rescue handling. Radiographic analyses are based on linear extrapolation for missing data imputation and rescue handling. Adverse events (AE) per 100 pt yrs (PY) are summarized up to a cut-off date of Aug 16 2018.

Table 1. Efficacy Endpoints at Week 48

	MTX N=314	UPA 15 MG N=317	UPA 30 MG N=314
ACR20, %	57	74***	75***

§mTSS from 2nd reading session of radiographs at Wk48

Table 2. Treatment emergent adverse event (AE) summary; E/100PY in Patients on monotherapy (censored at time of change to combination exposure of UPA+MTX/csDMARD)

	MTX MONO N=314, PYS=314.4	UPA 15 MONO N=317 PY=343.1	UPA 30 MONO N=314 PY=336.7
Any Adverse Event	303.1	345.4	358.2
Serious AE	11.8	14.3	15.4
AE Leading To D/C Of Study Drug	8.9	11.4	10.7
Serious Infection	2.9	4.1	5.0
Herpes Zoster[ǂ]	1.3	6.4	4.8
Hepatic disorder[¥]	19.7	18.7	15.7
Any Malignancy (excluding NMSC)[γ]	1.0	1.2	0.6
MACE (adjudicated)[δ]	0.6	0.9	1.2
VTE (adjudicated)[§]	0.6	0	0.3
Deaths[†]	0.3	1.2	1.8

[ǂ]Herpes zoster: most involved a single dermatome and were non-serious. No cases of CNS involvement.
[¥]Hepatic disorders: majority were asymptomatic transaminase elevations,
[γ]Malignancies excl NMSC: MTX: 1 malignant neoplasm of ovary, 1 pt with gall bladder adenocarcinoma and hepatic cancer;
UPA15: 1 malignant neoplasm progression, 1 metastatic malignant melanoma, 1 squamous cell carcinoma of lung, 1 uterine carcinoma in situ;
UPA30: 1 cervix cell carcinoma, 1 uterine cancer
[δ]MACE (includes cardiovascular [CV] death, non-fatal Myocardial infarction [MI], non-fatal stroke): MTX:1 CV death, 1 non-fatal stroke; UPA15: 1 CV death, 1 pt had 2 adjudicated events: a non-fatal MI, followed by CV death (due to hypoxic encephalopathy, not MI); UPA30:3 CV deaths, 1 non-fatal MI
[§]VTE: MTX: 1 pt with PE, 1 pt with DVT and PE; UPA30: 1 DVT
[†]Deaths (includes non-treatment emergent [NTE] deaths): MTX: 1 due to acute MI; UPA15: 2 due to MI (1 was NTE), 1 due to malignant melanoma and malignant neoplasm (NTE), 1 non-CV death; UPA30: 1 due to pneumonia /sepsis, 1 fatal MI, 2 CV deaths, 1 due to peritonitis, 1 CV death due to other causes (NTE); 1 death due to meningitis was reported on combination of UPA30+csDMARDs

References:

1. van Vollenhoven R et al. Arthritis Rheumatol. 2018;70 (supp10):

Results: Of 945 pts randomized and treated, 747(79%) completed Wk48 treatment, 163 (17.2%) discontinued (D/C) study drug prior to Wk48, 35 pts (4%) had not completed the Wk48 treatment as of this analysis. Primary reasons for D/C were AEs for 62 pts (6.5%), and lack of efficacy in 20 pts (2.1%). At Wk26, UPA15/30 was added for 37 (12%) of pts on MTX; MTX was added for 19 (6%) and 9 (3%) of pts on UPA15 and UPA30, respectively. Cumulative exposures to MTX mono, UPA15 mono and UPA30 mono were 314.4, 343.1 and 336.7 PYs, respectively. Through Wk48, pts on UPA15 and 30 vs MTX continued to have significantly greater improvements in clinical, functional and pt-reported outcomes (except FACIT-F for UPA15, p=.058 vs MTX) (Table 1). At Wk 48, CDAI Remission (REM) was achieved by 33% and 40% of pts on UPA15 and 30 respectively vs 17% on MTX; 28% and 33% vs 13% achieved Boolean REM. At Wk48, ΔmTSS were significantly less on UPA15 and UPA30 vs MTX. The safety profile of UPA15 and UPA30 mono was generally similar to MTX, except for total AEs and herpes zoster, which were higher with UPA15 and 30 vs MTX (Table 2). There were 11 deaths (including 3 non-treatment emergent deaths) due to varied causes.

Conclusion: UPA15 and 30 monotherapy continued to show significant improvements in RA signs and symptoms and inhibition of structural damage vs MTX through 48 wks. Only a small proportion of pts required MTX addition to UPA mono at Wk26 to achieve and maintain response. The safety profile based on all exposure remained consistent with ph 2 and 3 RCTs in RA, although an integrated safety analysis of UPA across the full ph 3 RA program will provide a more comprehensive understanding of the benefit:risk profile of UPA in RA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments II: Novel Treatments for RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Fenebrutinib (GDC-0853, FEN) is an orally administered, highly selective, non-covalent, and reversible small molecule inhibitor of Bruton's Tyrosine Kinase (BTK).[1] We report the efficacy and safety of FEN compared with placebo (PBO) in combination with background methotrexate (MTX) in patients with rheumatoid arthritis (RA) and an inadequate response to tumor necrosis factor (TNF-IR), identified as a population with existing unmet medical need.

Methods: This multicenter, randomized, double-blind Phase 2 study included two cohorts of patients with moderate-to-severe RA: cohort 1 (MTX-IR patients) and cohort 2 (TNF-IR patients). Primary (cohort 1) and key secondary (cohorts 1 and 2) endpoints were a 50% improvement in the American College of Rheumatology scores (ACR50) at Week

Table 1. Efficacy endpoints for TNF-IR patients

*Intent-to-treat population **Pre-specified alpha = 0.2

12, with pre-specified alpha of 0.2. Patients in cohort 2 (TNF-IR) were randomized to PBO and to FEN 200 mg BID arms for 12 weeks with the continuation of background MTX dose; the safety and efficacy results for this cohort are reported here (cohort 1 data has been reported previously[2]).

Results: Demographics and disease characteristics for the TNF-IR cohort were balanced in the PBO (*n*=49) and FEN (*n*=49) arms with mean age of 55 and 51 years, respectively, and 76% female patients/arm. Median duration of RA disease was 8.7 years (PBO) and 7.2 years (FEN). The mean baseline doses for MTX were 16.6 mg (PBO) and 15.7 mg (FEN). Corticosteroid mean doses were 8.3 and 7.5 mg prednisone-equivalents in the 33% and 39% of patients using corticosteroids in the PBO and FEN arms at baseline, respectively. Baseline mean values for DAS28-CRP and HAQ-DI were similar (6.0 and 5.9, and 1.76 and 1.45, respectively) for PBO and FEN arms. The majority of patients in the PBO (90%) and FEN (98%) arms completed the 12-week study. ACR20/50/70 responses (**Table 1**) were greater for FEN versus PBO and generally increased over time, with plateau of ACR50 after W8 for all patients. ACR50 response at W12 was greater for FEN (25% vs 12%, *p*-value=0.07 [pre-specified type-1 error rate=0.20 two sided]). At W12, DAS28-CRP decreased by -1.43 (PBO) and -2.26 (FEN) from baseline. More patients in the PBO arm (45%) than in the FEN arm (22%) reported at least one AE; no serious AEs were reported. There were 37 AEs in the PBO arm and 22 AEs in the FEN arm (including one case of herpes zoster), with one AE (worsening RA) leading to treatment

withdrawal in the PBO group. No deaths or malignancies were reported. There were no clinically significant changes in hematology or immunoglobulin parameters. In two patients treated with FEN, Grade 3 chemistry abnormalities were observed (low phosphorous, high uric acid). No Grade 4 or 5 abnormalities were reported. Although no Grade 3 creatinine elevations were observed, there was an increased mean change from baseline in creatinine in the FEN arm (5.1 µmol/L) in comparison to PBO arm (-0.4 µmol/L) at W12.

Conclusion: FEN demonstrated higher efficacy rates across disease activity measures vs. PBO at W12 in the TNF-IR population. The safety profile of FEN in this population is acceptable.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments II: Novel Treatments for RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The inflammatory reflex is an endogenous neuroimmune circuit that helps regulate innate and adaptive immunity (Annu. Rev. Immunol. 2012; 30:313). Activation of this reflex by electrical vagus nerve stimulation (VNS) reduced systemic inflammation and disease activity in a 17 patient rheumatoid arthritis (RA) proof-of-concept study using a reprogrammed epilepsy stimulator (PNAS 2016; 113(29):8284). Here we report on the safety and efficacy of a novel miniaturized neurostimulator, the "MicroRegulator" (MR), in a first-in-human, double-blind pilot study of VNS in multi-drug refractory RA patients.

Methods: The MR was implanted on the left vagus nerve in 14 patients with active RA and prior insufficient response to ≥2 bDMARDS or JAK inhibitors with ≥2 different modes of action; all patients remained on a stable background of MTX (n=12) or HCQ. Three weeks after implantation, the first 3 subjects were stimulated 1 min QD and, following safety review board approval, the remaining 11 patients were implanted with the MR and ran-

domized to 1 min: sham, QD, or QID VNS for 12 weeks (primary endpoint; PE). Patients, rheumatologists, joint assessors and monitors were fully blinded to treatment arm. Patients randomized to sham had their devices activated after the PE was reached. The pharmacodynamic response to VNS was assessed in blood using cytokine production in an ex-vivo bioassay (TruCulture). Clinical efficacy was measured by DAS28-CRP and CDAI responses and by wrist MRI (RAMRIS OMERACT). Vagus nerve activity (tone) was extracted from heart rate variability assessments of Holter-captured ECG.

Results: 14 patients were enrolled (mean prior bDMARDs = 4.8, mean DAS28-CRP= 5.94). Implantation and stimulation were generally well tolerated. There were no device or treatment-related SAEs and 2 notable surgery related adverse events (left vocal cord paralysis, Horner's syndrome) that resolved without clinically significant sequelae. Confirming activation of the inflammatory reflex, the pharmacodynamic response of VNS was observed in both actively stimulated groups with >30% decrease from baseline in bioassay levels of IL-1β, IL-6, and TNF-α at PE, with minimal change in the sham group. Mean DAS28-CRP change at PE was: combined QD= -1.34, QID= 0.38, Sham= 0.16. Of QD stimulated patients, 4/6 had a EULAR good or moderate response vs. 1/4 QID and 0/4 shams. Both DAS28 and CDAI response was achieved by 5/10 actively stimulated patients at PE, with 2 in DAS28 remission. MRI inflammation measures did not change by PE. RAMRIS erosion scores correlated with EULAR response (change in responders = -2.2 vs. 2.4 in non-responders). Mean vagal tone in the stimulated patients was increased 2.75-fold relative to sham stimulated patients.

Conclusion: The novel MR device and stimulation was well tolerated independent of the two surgery-related events. MR associated VNS reduced signs and symptoms of RA in a meaningful number of highly drug-refractory patients. No clinical improvement was observed in the sham group. These initial pilot data support the use of the MR for QD VNS in a larger blinded sham-controlled study in patients who have failed biologics or targeted oral therapies as a novel approach for treatment of RA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments II: Novel Treatments for RA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

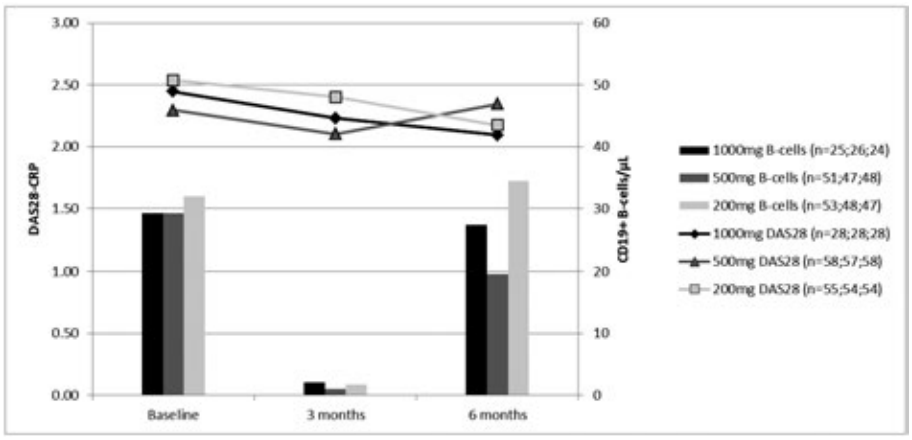
Background/Purpose: Rituximab is an effective treatment for patients with RA. 1000mg (1×1000mg or 2×500mg) has similar six-month efficacy as the registered dose of 2×1000mg.(1) Based on several case reports and a case series even lower doses might be sufficient for maintenance treatment, potentially improving safety and decreasing costs.(2) The objective of this study was to compare effectiveness of rituximab retreatment with ultra-low doses (1×500mg or 1×200mg) to standard low dose (1×1000mg).

Methods: A six-month double-blind randomized controlled non-inferiority trial (REDO study (3)) was performed in five centers in the Netherlands. Patients with rheumatoid arthritis responding well to rituximab (based on DAS28-CRP< 2.9 or clinical judgement) were randomized (1:2:2) to 1×1000mg, 1×500mg or 1×200mg rituximab respectively. DAS28-CRP and peripheral CD19+ B-cells were measured at baseline, three and six months. Primary analysis (per protocol with last observation carried forward (LOCF)) consisted of a hierarchical testing procedure comparing ultra-low doses (1×500mg at three and six months, then 1×200mg at three and six months) to 1×1000mg using a non-inferiority margin of 0.6 (on DAS28-CRP). DAS28-CRP change of study groups was compared using linear regression,

1a. Baseline characteristics (mean (sd) or n (%))				
	1000mg (n=29)	500mg (n=58)	200mg (n=55)	Total (n=142)
Age	63.8 (9.0)	64.0 (10.9)	64.2 (12.2)	64.0 (11.0)
Female	18 (62%)	37 (64%)	40 (73%)	95 (67%)
ACR1987/2010 positive	27 (93%)	57 (98%)	52 (95%)	136 (96%)
Disease duration in years	17.1 (11.1)	14.9 (10.7)	13.5 (7.2)	14.8 (9.6)
RF/ACPA positive	27 (93%)	54 (93%)	49 (89%)	130 (92%)
Duration of RTX use (years)	4.0 (2.8)	3.3 (2.7)	4.0 (2.4)	3.7 (2.6)
Concomitant csDMARD	20 (69%)	35 (60%)	32 (58%)	87 (61%)
Concomitant oral prednisone	4 (14%)	9 (16%)	9 (19%)	22 (15%)
1b. Flares, co-medication and (S)AEs during follow-up (n (%))				
Patients with flare(s)	3 (10%)	14 (24%)	10 (18%)	27 (19%)
Extra 1000mg RTX received*	0 (0%)	2 (3%)	2 (4%)	4 (3%)
Patients with ia gc injection(s)	2 (7%)	1 (2%)	4 (7%)	7 (5%)
Patients with im gc injection(s)	4 (14%)	7 (12%)	16 (29%)	27 (19%)
Patients with SAE(s)	3 (10%)	6 (10%)	4 (7%)	13 (9%)
Infections/patient years	1.24 (18/14.57)	0.52 (15/28.95)	0.55 (15/27.49)	0.68 (48/71.01)

*2 patients with regular RTX accidently given a few days before study end (protocol violation) not included
ia: intra-articular; im: intramuscular; gc: glucocorticoid; RTX: rituximab; SAE: serious adverse event.

Table 1



adjusted for baseline DAS28-CRP, RF/ACPA status and concomitant csDMARD use. Intention-to-treat (ITT) analyses were done similarly (including all cases without LOCF).

Results: The projected inclusion was met (n=142, table 1a). In both ultra-low dose groups two patients received an extra dose of 1000mg rituximab due to a flare. The 500mg dose was non-inferior to 1000mg at three months (-0.07 (95% CI -0.41 to 0.27)), but not at six months (0.29 (95% CI -0.08 to 0.65). The 200mg dose was non-inferior to 1000mg at both time points. Because of our pre-defined hierarchical testing, non-inferiority could not formally be inferred for the 200mg dose. ITT analyses showed non-inferiority for all comparisons. Mean DAS28-CRP scores remained low in all groups throughout the study, and B-cell counts decreased similarly at three months (figure 1). The incidence density of infections was lower in the 500mg group (rate ratio 0.42 (95% CI 0.21 to 0.83, p=0.01)) and in the 200mg group (rate ratio 0.44 (95% CI 0.22 to 0.88, p=0.02)) compared to the 1000mg group (table 1b).

Conclusion: Non-inferiority of retreatment with 1×500mg or 1×200mg rituximab versus 1×1000mg after 6 months could not formally be established. However, ultra-low doses appear similarly effective in the majority of RA patients, judged by non-inferiority of ITT analyses, DAS28-CRP course over time and B-cell results, with a better safety profile and possibly slightly more co-medication.

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments II: Novel Treatments for RA

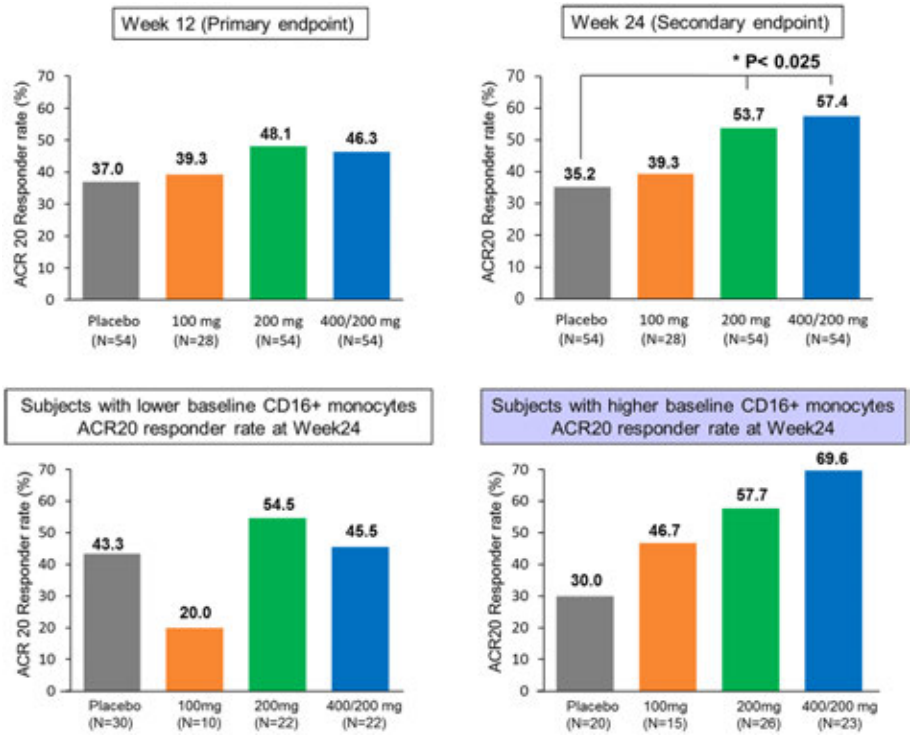
Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1. We have conducted clinical trials of E6011, a novel humanized anti-FKN monoclonal antibody, for patients with rheumatoid arthritis (RA) in Japan[1]. This is the report of efficacy and safety results of E6011 from a Phase 2, multicenter, randomized, double-blind, placebo-controlled, parallel-group comparison study in RA patients inadequately responding to MTX (NCT02960438)

Methods: During the 24-week double-blind period, patients with moderately to severely active RA of inadequate response to MTX were randomly assigned to E6011 100 mg, 200 mg, 400/200 mg, or placebo groups at a 1:2:2:2 ratio. In the E6011 100 mg, 200 mg, and placebo groups, subjects received 100 mg, 200 mg, or placebo at Weeks 0, 1, 2, and every 2 weeks subsequently. In the E6011 400/200 mg group, subjects received 400 mg at Weeks 0, 1, 2, 4, 6, 8, 10 and then 200 mg every 2 weeks subsequently.

Results: A total of 190 subjects (54 in the placebo group, 28 in the 100 mg group, 54 in the 200 mg group, 54 in the 400/200 mg group) received study drug. Of the 190 subjects, 169 completed and 21 discontinued study treatment prematurely during the 24-week double-blind period. The ACR20 response rate at Week 12 (non-responder imputation), the primary endpoint, was 37.0% in the placebo group, 39.3% in the 100 mg group, 48.1% in the 200 mg group, and 46.3% in the 400/200 mg group (not statistically significant), and statistically significant difference from placebo in ACR20 response rate was found in the 200 mg and 400/200 mg groups at Week 24 (35.2% for placebo, 39.3% for 100 mg, 53.7% for 200 mg, 57.4% for 400/200 mg). In addition, we focused on CD16+ monocytes which highly expressing FKN receptor/CX3CR1 as a blood biomarker that linked to the clinical response to E6011. The whole patient population was divided into 2 groups according to the median value of baseline CD16+ monocyte percentage (Median: 10.35%). Much clearer ACR20 response was observed in a dose dependent manner in the subjects who showed higher baseline CD16+ monocytes over the median at Week 24 (NRI) (30.0% for placebo, 46.7% for 100 mg, 57.7% for 200 mg, and 69.6% for 400/200 mg) although such fashion was obscure in the subjects below the median value. This study explored the effect on progression of joint destruction by mTSS, a clear signal that E6011 suppressed the progression of joint destruction was not detected. Adverse events that occurred in ≥5% of subjects in any E6011 group were nasopharyngitis, upper respiratory tract infection, stomatitis, bronchitis, back pain, pharyngitis, and dental caries. As a results, E6011 was well tolerated with no notable safety concerns at doses of 100, 200, and 400/200 mg when administered subcutaneously for 24 weeks.



Conclusion: E6011 provided clinical improvements with a good safety profile in RA patients with inadequately responding to MTX. Especially, a higher efficacy of E6011 was suggested in patients with higher baseline CD16+ monocytes (%). This is the world-first evidence suggesting that a novel approach to target FKN/CX3CR1 interaction could be beneficial for RA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: Axial Spondyloarthritis Treatment
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: It is difficult to evaluate the role of TNF inhibitor therapy in slowing the radiologic progression in patients with ankylosing spondylitis (AS) because of frequent changes in disease activity and medication. In addition, the role of TNF inhibitors in slowing the radiologic progression was underestimated because most patients starting TNF inhibitors were in a high inflammatory state. Therefore, an analysis of time varying compounders such as disease activity is essential. The aim of this study was to investigate whether long-term treatment with TNF inhibitors can reduce radiographic progression in patients with AS using an 18-year longitudinal cohort data.

Methods: Of the 1,280 patients who followed for 18 years in single center cohort, data of 328 patients treated with TNF inhibitors were included. For each patient who received TNF inhibitors, the time interval was categorized based on the patient's TNF inhibitor status ('on the TNF inhibitors' and 'off the TNF inhibitors' intervals). The data were analyzed using the Modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS), erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and imputed at each time point by linear interpolation. We obtained 2315 intervals (1,063 intervals 'on the TNF inhibitors' and 1,252 intervals 'off the TNF inhibitors') from 328 patients with computable intervals. A multivariable linear regression with compound symmetry correlation structure within each patient was performed using a generalized estimating equation for rate of change in mSASSS (per year) as the outcome, and with ESR, CRP, and BASDAI as the time-varying covariate. A marginal structural model for inverse probability of treatment weighting (MSM with IPTW) was constructed to evaluate the underestimated effect of TNF inhibitors.

Results: The rate of mSASSS significantly decreased with the use of TNF inhibitors (b=-0.054, p=0.023 in the multivariable model) (Table 1). The adjusted rate of mSASSS with multivariable analysis was 0.916 per year during 'on the TNF inhibitors' and 0.970 per year during 'off the TNF inhibitors' period when the other covariates were fixed at their

BASDAI at start (sqrt, mean(sd))	2.90 (1.92)	3.90 (2.69)	0.429	3.35 (2.28)	3.86 (2.77)	0.199
Previous mSASSS rate (mean(sd))	20.03 (20.08)	19.46 (19.97)	0.028	20.97 (20.15)	20.18 (20.33)	0.039

*standardized mean difference

mean values. However, the role of TNF inhibitors was underestimated on the rate of mSASSS because ESR and CRP at the start of interval were significantly higher in 'on the TNF inhibitors intervals (b=-5.946, $p< 0.001$ and b=0.412, $p< 0.001$, respectively). To eliminate the effects of confounding variables such as ESR and CRP on the mSASSS, we

created a pseudo-population using an IPTW. (Table 2) The rate of mSASSS showed a greater decrease with the use of TNF inhibitors (b=-0.111, p< 0.001) than in the multivariable regression model. The adjusted rate of mSASSS was 0.848 per year during 'on the TNF inhibitors' and 0.959 per year during 'off the TNF inhibitors' intervals.

Conclusion: TNF inhibitor treatment significantly slowed radiologic progression when compared to other therapies. In addition, the effect of TNF inhibitors on radiological progress has been previously underestimated.

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: Axial Spondyloarthritis Treatment

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Secukinumab (SEC) is an interleukin-17 inhibitor used to treat patients with axial spondylarthritis (axSpA) and psoriatic arthritis (PsA). Drug survival is often used as a proxy for treatment effectiveness and safety. We aim to assess SEC survival in routine clinical practice and to identify survival predictors associated.

Methods: We conducted a retrospective, longitudinal, observational, multicentric study including all patients with axSpA or PsA who received at least 1 injection of SEC between July 2016 and April 2019. We collected demographic and clinical characteristics, onset date, initial dosage and dosage modification of SEC, previous biologic Disease-modifying antirheumatic drugs (bDMARDs) and concomitant treatments. We classified the reason of discontinua-

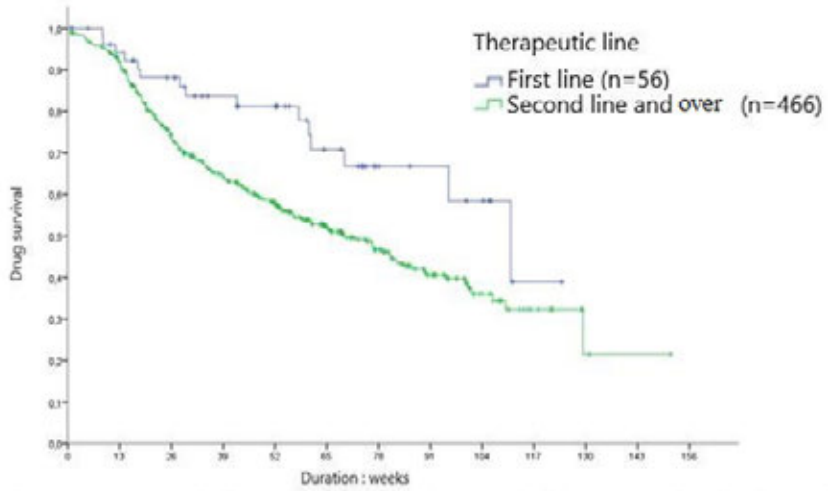

Figure 1 : Drug survival according to the therapeutic line among the whole population

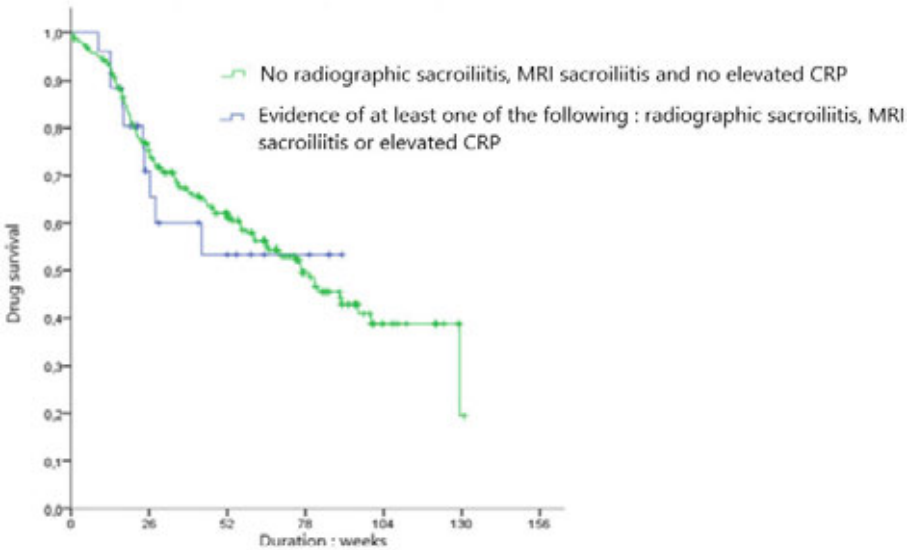

Figure 2 : Drug survival according to imaging and CRP status among the axSpA population

tion in lack of effectiveness, adverse events and others. Potential predictors evaluated were baseline age, gender, smoking status, previous bDMARDs and concomitant treatment. Among the axSpA cohort, evidence of radiographic sacroiliitis, MRI sacroiliitis or elevated CRP were also assessed as potential predictors. Drug survival was analyzed by the Kaplan-Meier method and differences of survival between groups was assessed by log-rank test.

Results: The main characteristics of the 556 patients (pts) included were the following: 338 (61%) axSpA , 183 (33%) PsA, 324 (58%) female, mean age 47 +/- 12 years, 221 (40%) smokers,160 (29%) radiographic sacroiliitis, 238 (43%) MRI sacroiliitis, 206 (37%) elevated CRP, 239 (43%) HLA B27 positive, mean BASDAI 48,9 +/-27%. SEC was associated to methotrexate (MTX) in 140 pts (25%) and was the first line bDMARD in 56 patients (10%).

The median drug survival (MDS) of SEC was 76 weeks (w) (interquartile range [65-88]). At 52w, 245 pts (60%) SpA were still treated with SEC. Among reasons of discontinuation, 172 (68%) pts discontinued SEC for lack of effectiveness, 46 (18%) for adverse events and 13 (5.1%) for others.

First line SEC administration was associated with a longer survival versus second line and more: 111w [83-138] vs 69w [57-81] (p=0.01) (figure 1). MDS was not significantly different according to gender, disease, MTX combo, elevated CRP, axSpA vs PsA and smoking status.

Among the axSpA pts, absence of radiographic or MRI sacroiliitis and normal CRP did not modify significantly SEC survival (p=0.85) (figure2).

Conclusion: In routine clinical practice, SEC median survival was 76 weeks. Fist line administration was associated with improved SEC retention. Lack of effectiveness was the most common reason of discontinuation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: Axial Spondyloarthritis Treatment

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Acute anterior uveitis (AAU), inflammation of the anterior uveal tract, is the most common extraarticular manifestation in patients (pts) with axial spondyloarthritis (axSpA), reported by up to 40% of pts.[1]

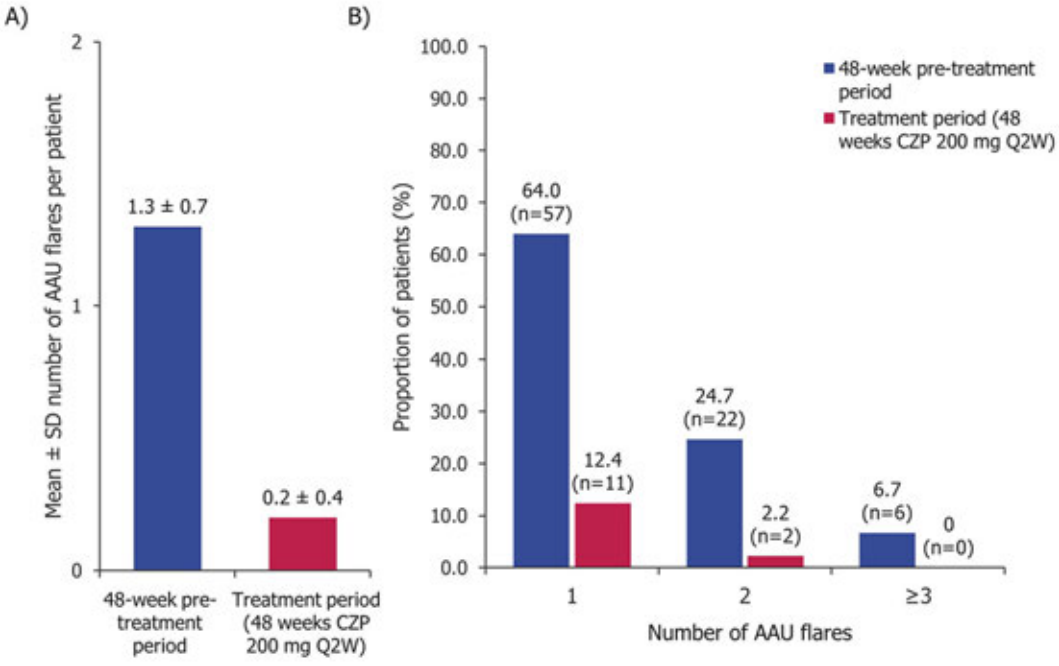
Uveitis is associated with a significant clinical burden; common symptoms include blurred vision, photophobia and pain.[2] Previous studies have shown that anti-TNFs can reduce the incidence of AAU flares in pts with radiographic axSpA (ankylosing spondylitis),[3,4,5] but few have focused on pts across the full axSpA spectrum. The aim of the C-VIEW study was to analyze the impact of certolizumab pegol (CZP) treatment on AAU flares in pts with active axSpA (radiographic and non-radiographic) and a recent history of AAU.

Table: Baseline characteristics of patients in C-VIEW

	CZP 200 mg Q2W (N=89)
Age (years), mean ± SD	46.5 ± 11.2
Male, n (%)	56 (62.9)
Racial group, n (%)	
Caucasian	87 (97.8)
Other	2 (2.2)
Diagnosis, n (%)	
Radiographic axSpA	75 (84.3)
Non-radiographic axSpA	14 (15.7)
Duration of axSpA (years), mean ± SD	8.6 ± 8.4
Time since onset of first uveitis flare (years), mean ± SD	9.9 ± 9.0
ASDAS, mean ± SD	3.5 ± 0.9
BASDAI, mean ± SD	6.5 ± 1.5

ASDAS: Ankylosing Spondylitis Disease Activity Score; axSpA: axial spondyloarthritis; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CZP: certolizumab pegol; Q2W: every 2 weeks; SD: standard deviation.

Figure: (A) Mean number of AAU flares experienced by patients in C-VIEW and (B) proportion of patients experiencing 1, 2 or ≥3 AAU flares



AAU: acute anterior uveitis; CZP: certolizumab pegol; Q2W: every 2 weeks; SD: standard deviation.

Methods: C-VIEW (NCT03020992) is an ongoing multicenter, open-label, phase 4 study. Pts had active axSpA according to the Assessment of SpondyloArthritis international Society (ASAS) classification criteria, a history of recurrent AAU (≥2 AAU flares in total and ≥1 AAU flare in the year prior to study entry), were HLA-B27 positive, and were eligible for anti-TNF treatment (active axSpA, previous failure of ≥2 NSAIDs, biologic naïve or had failed at most one anti-TNF). Pts received CZP 400 mg at Weeks (Wks) 0/2/4, then 200 mg every 2 wks through 96 wks. The primary variable was the incidence of AAU flares compared to historic rates. A pre-specified interim analysis compared AAU incidence in the 48 wks prior to CZP treatment initiation with the 48 wks of treatment, using Poisson regression adjusted for possible within-patient correlations, with period (pre- and post-baseline) and axSpA disease duration as covariates. Incidence rates (IR) were calculated based on the number of cases per pts at risk over 48 weeks. Observed data are reported.

Results: Of 115 enrolled pts, 89 initiated CZP treatment and 85 completed Wk 48. Baseline characteristics are shown in the **Table**. The 48-wk interim analysis revealed significantly fewer AAU flares per pt during CZP treatment compared to before treatment (**Figure**; Poisson-adjusted IR: 0.2 vs 1.5, $p< 0.001$). The number of pts experiencing 1 and ≥2 AAU flares (64.0% and 31.5%, respectively) was substantially reduced during CZP treatment (12.4% and 2.2%). In the 13 patients who had AAU flares both pre- and post-baseline, the mean duration of AAU flares was also reduced during CZP treatment from 97.4 to 58.4 days. After 48 wks CZP, pts' disease activity had improved substantially (mean ± SD Ankylosing Spondylitis Disease Activity Score [ASDAS]: 2.0 ± 0.9; BASDAI: 3.3 ± 2.1), with 31.4% of pts achieving ASAS partial remission and 29.1% ASDAS major improvement. No new safety signals were identified.

Conclusion: In this open-label study, we found a significant reduction in the AAU flare rate in axSpA pts with a history of recurrent AAU during the first 48 wks of CZP treatment. Pts also experienced significant improvement in axSpA disease activity during CZP treatment.

Missing values were imputed using double-blind last observation carried forward or, for ASDAS-MI and ASAS40, considered to be non-response. [a] BASDAI Q1; [b] Average of BASDAI Q5 and Q6. ASAS40: Assessment in SpondyloArthritis international Society 40% response; ASDAS-MI: Ankylosing Spondylitis Disease Activity Score – Major Improvement; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CZP: certolizumab pegol; MCS: mental component summary; PBO: placebo; PCS: physical component summary; SD: standard deviation; SF-36: 36-Item Short Form Survey (SF-36); wk: week; yrs: years.

Background/Purpose: Patients (pts) with axial spondyloarthritis (axSpA) often experience delayed diagnosis, which can lead to treatment delay. However, there are indications that earlier treatment with anti-TNFs can lead to a greater clinical response. Certolizumab pegol (CZP) has been shown to improve the signs and symptoms of non-radiographic (nr)-axSpA.[1] However, it is not known if earlier CZP treatment has a greater impact on efficacy in nr-axSpA. Here we report clinical and pt-reported outcomes in pts with active nr-axSpA treated with CZP or placebo (PBO) over 52 weeks (wks) stratified by their symptom duration.

Methods: C-axSpAnd (NCT02552212) is a 3-year, phase 3, multicenter study including a 52-wk double-blind, PBO-controlled period (completed).1 Pts had previous inadequate response to ≥ 2 NSAIDs and were randomized 1:1 to PBO or CZP (400 mg at Wks 0/2/4, then 200 mg every 2 wks). This post-hoc analysis reports outcomes at Wk 12 and Wk 52 in pts stratified by their baseline symptom duration (< 5 and ≥ 5 years; key clinical outcomes also reported for < 3 and ≥ 3 years). Outcomes included: Ankylosing Spondylitis Disease Activity Score – Major Improvement (ASDAS-MI), Assessment in SpondyloArthritis international Society 40% response (ASAS40), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), nocturnal spinal pain, fatigue (BASDAI Q1), morning stiffness (average of BASDAI Q5 and Q6), and the 36-Item Short Form Survey (SF-36) physical and mental component summary (PCS/MCS). Subjects with missing values or values observed after discontinuing double-blind study treatment were considered as non-responders for binary measures or, for quantitative measures, had the last observation from double-blind treatment carried forward.

Results: Of 317 recruited pts, 159 were randomized to CZP, and 158 to PBO. The median (range) baseline (BL) symptom duration was 4.9 (1.0–41.9) years for CZP-treated pts and 5.2 (1.1–38.2) years for PBO pts. 50.3% (80/159) CZP pts and 48.7% (77/158) PBO pts had a symptom duration < 5 years. At Wks 12 and 52, ASDAS-MI and ASAS40 responder rates, and improvements in BASDAI, nocturnal spinal pain, fatigue, morning stiffness and SF-36 PCS were substantially better among CZP-treated pts with shorter symptom duration (< 5 years at BL) vs longer symptom duration (**Table**). Amongst PBO pts, responses were low and there was no consistent trend in outcomes by symptom duration (**Table**). Similarly, using a cut-off of 3 years, responder rates for ASDAS-MI and ASAS40 were greater in CZP-treated pts with shorter symptom duration: at Wk 52, 56.4% (31/55) and 42.3% (44/104) of pts with < 3 and ≥ 3 years symptom duration achieved ASDAS-MI, respectively, while 65.5% (36/55) and 51.9% (54/104) achieved ASAS40.

Conclusion: In this post-hoc analysis, CZP-treated nr-axSpA pts with shorter symptom duration (< 5 vs ≥ 5 years) showed greater improvements across signs and symptoms of disease and in quality of life. To our knowledge, this is the first report indicating that early CZP treatment for nr-axSpA may be beneficial to pts.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: Axial Spondyloarthritis Treatment

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: The monoclonal antibody bimekizumab potently and selectively neutralizes both IL-17A and IL-17F. We report the 48-week efficacy and safety of bimekizumab in patients (pts) with active ankylosing spondylitis (AS; NCT02963506). The positive primary endpoint (Assessment in SpondyloArthritis International Society [ASAS] 40 response rate at Week 12) was previously reported.[1]

Methods: Eligible pts with active AS (Bath AS Disease Activity Index [BASDAI] ≥4; spinal pain ≥4 [0–10]) who fulfilled the modified New York criteria (central reading) with inadequate response/intolerance to NSAIDs were randomized 1:1:1:1:1 to subcutaneous (sc) bimekizumab 16 mg, 64 mg, 160 mg, 320 mg, or placebo every 4 weeks, for 12 weeks

(double-blind period). Subsequently, pts in the 16 mg, 64 mg, and placebo groups were re-randomized 1:1 to sc bimekizumab 160 mg or 320 mg every 4 weeks through Week 48; dosing in the original 160 mg and 320 mg groups was unchanged through Week 48 (dose-blind period). Efficacy endpoints included ASAS20, ASAS40, ASAS5/6, ASAS partial remission, and AS Disease Activity Score with C-reactive Protein (ASDAS-CRP) to Week 48; data presented for all pts who began the dose-blind period and received ≥1 dose of study drug. Non-responder imputation accounted for missing binary scores; multiple imputation accounted for missing continuous values.

Results: Of 303 randomized pts, 265 (87.5%) completed the 48-week treatment period. Pts (mean [SD] age 42.2 [11.8] years; males 84.5%; median [range] time from first symptoms 12.3 [0.2–47.2] years; mean [SD] BASDAI 6.5 [1.4]; mean [SD] total spinal pain 7.1 [1.7]; HLA-B27 positive 89.1%; prior anti-TNF therapy 11.2%) had similar baseline characteristics across treatment groups.

At Week 12, significantly more bimekizumab-treated pts vs placebo achieved ASAS40 (16 mg 29.5%; 64 mg 42.6%; 160 mg 46.7%; 320 mg 45.9%; placebo 13.3%; $p< 0.05$, all doses). ASAS40 response rates increased to Week 24 and were maintained to Week 48 (35.5–64.0%; Table 1). Improvements observed at Week 12 in other efficacy endpoints were sustained to Week 48: ASAS20 51.9–80.0%, ASAS5/6 41.9–80.0%, ASAS partial remission 20.6–34.4% (Table 1). At Week 12, mean improvement from baseline in ASDAS-CRP scores were from –0.3 to –1.7; scores improved further from baseline and were maintained to Week 48: from –1.6 to –2.0 (Table 1).

During the 48-week treatment period, treatment-emergent adverse events (TEAEs) were reported by 235/303 (77.6%) pts; 20/303 (6.6%) discontinued due to TEAEs (safety set; Table 2). One death (cardiac arrest, 160 mg group, double-blind period) was judged unrelated to study drug by the investigator. Most commonly reported TEAEs were nasopharyngitis, bronchitis, and pharyngitis. Irritable bowel disease was reported by 4/303 (1.3%) pts; no TEAEs of suicidal ideation were reported. Serious infections were reported by 4/303 (1.3%) pts (Table 2). $p< 0.05$

Table 1. Efficacy results at Week 48, presented by treatment groups during the dose-blind period (dose-blind set[a])

	Placebo→ BKZ 160 mg n=24	Placebo→ BKZ 320 mg n=34	BKZ 16→ 160 mg n=31	BKZ 16→ 320 mg n=27	BKZ 64→ 160 mg n=34	BKZ 64→ 320 mg n=25	BKZ 160→ 160 mg n=58	BKZ 320→ 320 mg n=61

Oral fungal infection	8 (5.4)	6 (4.0)	14 (4.6)
TEAEs of interest, n (%)			
IBD[c]	1 (0.7)	2 (1.3)	4 (1.3)[d]
Opportunistic infections	0	0	1 (0.3)[e]
Depressive disorders	0	0	1 (0.3)
Serious TEAEs of infection	3 (2.0)	1 (0.7)	4 (1.3)
Suicidal ideation and behavior[f]	0	0	0

[a]Safety set: all randomized patients who received at least 1 dose of study drug

[b]The all BKZ group included 5 patients who received BKZ in the double-blind period but did not receive BKZ 160 mg or 320 mg: 2 patients in the 16 mg group and 2 patients in the 64 mg group discontinued before re-randomization; 1 patient in the 16 mg group did not start the dose-blind period. In addition, 1 patient received doses of 160 mg and 320 mg in error and was therefore included in both the 160 mg and 320 mg groups, but only once in the all-BKZ group

[c]IBD was defined as the higher-level MedDRA term of non-infective colitis; including both incident cases and disease flares

[d]One patient reported IBD while receiving bimekizumab 16 mg during the double-blind period

[e]This patient reported an opportunistic infection of Herpes zoster while receiving bimekizumab 16 mg during the double-blind period

[f]Suicidal ideation as measured by the electronic Columbia Suicide Severity Rating Scale (eCSSRS) was reported by 2 patients at baseline, 3 patients at Week 1, 1 patient at Week 8, and by no patients for the remainder of the 48-week treatment period (dose-blind set). No suicidal behavior as measured by the eCSSRS was reported throughout the 48-week treatment period

BKZ, bimekizumab; IBD, irritable bowel disease; MedDRA, Medical Dictionary for Regulatory Activities; TEAE, treatment-emergent adverse event

Table 2. Overview of incidence of treatment-emergent adverse events, most frequently reported treatment-emergent adverse events, and TEAEs of interest during the treatment period (safety set) BKZ 160 mg

Conclusion: Following positive results at Week 12,[1] this Phase 2b study demonstrated the sustained efficacy of bimekizumab in pts with active AS to Week 48. Bimekizumab was generally well tolerated and no new or unexpected safety findings were identified.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical II: Axial Spondyloarthritis Treatment

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

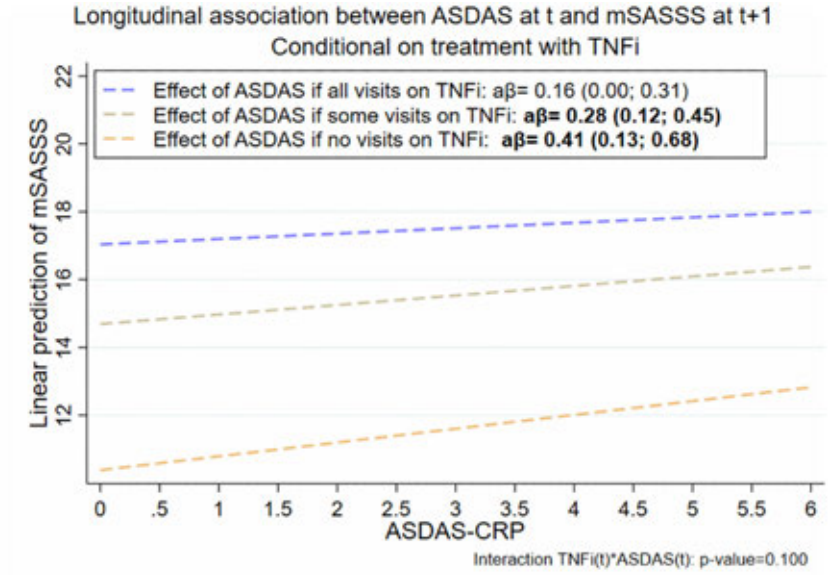

Figure. Longitudinal effect of ASDAS at the beginning of each 2-year interval on mSASSS 2 years later conditional on TNFi treatment group (multivariable linear GEE model with autoregression adjusted for symptom duration, gender, HLA-B27 and number of previous TNFi).

Background/Purpose: Recent observational data suggest that TNFi reduce spinal radiographic progression in radiographic axial spondyloarthritis (r-axSpA) mostly by inhibiting disease activity[1]. Yet, resolution on the controversial effect of TNFi on structural progression is yet to be achieved. We aimed to investigate whether in r-axSpA TNFi have an indirect (through ASDAS) and/or direct effect on spinal radiographic progression.

Methods: Patients (pts) with axial spondyloarthritis (axSpA) fulfilling the modified New York criteria (mNY) were included in this prospective, observational cohort (ALBERTA FORCAST). Clinical and imaging data were collected at baseline and every 2 years up to 10 years of follow-up. Radiographs of the spine were independently scored by 2 central readers and one adjudicator (if disagreement), with known chronological order but blinded to clinical data, using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). The indirect effect of TNFi on mSASSS progression was evaluated by testing the interaction between TNFi and ASDAS at the start of each 2-year interval (t). If significant ($p< 0.15$) the association between ASDAS at t and mSASSS at the end of the interval (t+1) was assessed in 3 groups of exposure to TNFi: i. treatment in all visits; ii. treatment in some visits and iii. Never treated. The direct effect of TNFi on mSASSS progression was evaluated by testing the association between TNFi at t and mSASSS at t+1 (adjusting for ASDAS at t). Multivariable GEE models adjusted for mSASSS at t (autoregression) and for a set of potential confounders defined a priori on clinical grounds (Figure). In a sensitivity analysis, the direct effect of TNFi was also tested after adjusting for a propensity score (PS), to take confounding by indication into account.

Results: In total, 314 pts were included [74% males, mean symptom duration 17.8 (SD 11.7) years, 83% HLA-B27 positive and 7% previously treated with ≥1 TNFi]. The interaction between ASDAS and TNFi at t was significant (p=0.10). A gradient was seen for the effect of ASDAS at t on mSASSS at t+1, which was more than 2 times higher in patients never treated with TNFi (β (95% CI): 0.41 (0.13; 0.68) compared to those always treated [β (95% CI): 0.16 (0.00; 0.31)] (Figure), showing that treatment with TNFi diminishes the effect of ASDAS on mSASSS. In addition to the indirect effect, TNFi also directly associated with less mSASSS progression: Pts receiving TNFi at t had on average 0.87 mSASSS-units less on t+1 compared to those not treated [β (95% CI): -0.85 (-1.35; -0.35)] and this was noted independently of ASDAS. Importantly, this effect remained significant after PS-adjustment [β (95% CI): -0.80 (-1.37; -0.22)].

Conclusion: This data indicates that treatment with TNFi limits spinal radiographic progression in pts with r-axSpA only partially by decreasing disease activity. A direct effect of TNFi in reducing mSASSS progression, and independent of ASDAS inflammation, is also seen suggesting that other mechanisms also contribute to structural modification by TNFi.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical III: Clinical Trials II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Randomized trials in lupus nephritis (LN) of type I anti-CD20 monoclonal antibodies failed to demonstrate superiority over standard of care alone. NOBILITY (NCT02550652) is a Phase II, randomized, double-

Table 1. Response Rates at Week 52

	Obinutuzumab + MMF N = 63	Placebo + MMF N = 62	Difference, % (80% CI)	*P* Value
CRR, n (%)	22 (34.9)	14 (22.6)	12.3 (2.1 to 22.6)	0.1145
Overall response (CRR or PRR), n (%)	35 (55.6)	22 (35.5)	20.1 (8.9 to 31.3)	0.0246
mCRR, n (%)	25 (39.7)	16 (25.8)	13.9 (3.2 to 24.5)	0.0900

CRR, complete renal response; mCRR, modified CRR, which excluded the urinary sediment criterion; MMF, mycophenolate mofetil; PRR, partial renal response.

Table 2. Adverse Events Through Week 52

	Obinutuzumab + MMF N = 63	Placebo + MMF N = 62
AEs, n (%)	55 (87.3)	52 (83.9)
Serious AEs, n (%)	9 (14.3)	13 (21.0)
Deaths, n (%)	0	2 (3.2)
Serious infection, n (%)	1 (1.6)	8 (12.9)
Infusion-related reaction, n (%)	10 (15.9)	6 (9.7)

AE, adverse event; MMF, mycophenolate mofetil.

blind, placebo (PBO)-controlled study designed to test the hypothesis that enhanced B-cell depletion with the type II anti-CD20 monoclonal antibody obinutuzumab (OBI) will result in improved responses in proliferative LN.

Methods: 125 patients with biopsy-proven ISN/RPS 2003 Class III or IV LN within 6 months and urine protein to creatinine ratio (UPCR) > 1 on a 24-hour collection were randomized to receive OBI 1000 mg or PBO infusions on days 1, 15, 168, and 182 with safety and efficacy assessments through week 104. All patients received mycophenolate mofetil (MMF) and corticosteroids; a corticosteroid taper was mandatory. The primary endpoint was complete renal response (CRR) at week 52, defined as achievement of UPCR < 0.5, normal serum creatinine not increased by > 15% from baseline, and urine RBCs < 10/hpf without RBC casts. Key secondary endpoints were achievement of overall (complete or partial) renal response (ORR), modified CRR without urinary sediment, and improvements in serologic markers of activity. Peripheral B cells were measured using high sensitivity flow cytometry (HSFC). The prespecified alpha level was 0.2.

Results: At baseline, mean UPCR was 3.1 g/g and mean serum creatinine was 0.84 mg/dL. The primary endpoint, CRR at week 52, was achieved by 34.9% of patients in the OBI group and 22.6% in the PBO group (12.3% delta; 80% CI 2.1% to 22.6%; $P = 0.115$). 55.6% of patients in the OBI group and 35.5% in the PBO group achieved ORR at week 52 (20.1% delta; 80% CI 8.9% to 31.3%; $P = 0.025$). 91% of patients in the OBI group had no detectable peripheral B cells by HSFC at day 28. Significant improvements in anti-dsDNA titers and C3 and C4 levels were observed with OBI compared with PBO. There were no unexpected safety findings. OBI was not associated with increased rates of serious adverse events (14.3% vs. 21.0%) or serious infections (1.6% vs. 12.9%) compared with PBO. Infusion-related reactions were more common with OBI (15.9% vs. 9.7%) and were generally mild. Two deaths occurred prior to week 52, both in the PBO group.

Conclusion: NOBILITY met its primary and key secondary efficacy endpoints. At one year, OBI resulted in increased complete and partial renal responses compared with placebo when added to MMF and corticosteroids for the treatment of proliferative LN. OBI was not associated with increases in rates of serious adverse events or serious infections. Forthcoming data through week 104 will permit further assessment of the longer term safety and efficacy of OBI in proliferative LN.

Response to Placebo in Randomized Clinical Trials with Biologics in Non-renal, Non-neuropsychiatric Systemic Lupus Erythematosus: A Systematic Review and Pooled Analysis

Konstantinos Tselios,[1] Laura Wakani,[2] Dafna Gladman,[3] Jiandong Su,[4] and Murray Urowitz[4], [1]University Health Network, University of Toronto, Toronto, Canada, [2]University Health Network, Toronto, Canada, [3]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [4]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical III: Clinical Trials II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Most randomized controlled trials (RCTs) with biologic medicines in systemic lupus erythematosus (SLE) failed to reach their respective end-points with the rates of the response to placebo (plus standard of care treatment) being unexpectedly high. The aim of this systematic review was to quantify the response to placebo for different end-points in the RCTs in non-renal, non-neuropsychiatric lupus patients.

Response rates at 48-52 weeks for placebo-treated patients from 12 RCTs in non-renal, non-neuropsychiatric SLE

Outcome	Patients (responders/all)	Response rate (%)	Range of response (%)
Primary end-point*	940/2621	33.5	17.5-48.6
SRI-4	910/2319	39.2	32.3-48.4
SRI-5	345/1240	27.8	20.4-39.3
SRI-6	334/1240	26.9	18.9-37.4
BICLA	238/722	33	25.7-36.1
Patients reducing prednisone to ≤7.5mg/day	141/919	15.3	12-26.6
Normalization of anti-dsDNA antibodies	142/1829	7.8	6-9.7
Normalization of C3	375/1829	20.5	14-22
Normalization of C4	177/1074	16.5	7.7-21.9

*As defined by each study
SRI-4: SLE Responder Index 4 (reduction of ≥4 in SLEDAI-2K, no worsening in PGA, no new A or two new B scores in the British Isles Lupus Assessment Group, BILAG)
SRI-5: as above with ≥5 reduction in SLEDAI-2K
SRI-6: as above with ≥6 reduction in SLEDAI-2K
BICLA: (BILAG-based Combined Lupus Assessment) improvement from baseline in the BILAG-2004 score, no worsening in SLEDAI-2K and PGA, no unpermitted changes in concomitant medications

Methods: The Pubmed database was searched from 2000 to April 2019 for phase II/III RCTs that assessed the efficacy and safety of biologic drugs in human non-renal, non-neuropsychiatric SLE at 48 or 52 weeks after randomization. Data on efficacy (primary and secondary end-points) and safety (serious adverse events, serious infections, malignancies and deaths) of the placebo-treated patients were collected in a pre-established data retrieval form. Descriptive statistics were used.

Results: Twelve RCTs (n=7940 in total) were included. Patients who received placebo (n=2621) were mostly females (2460, 93.9%) and Caucasians (1621, 61.8%) with a mean age of 39.7±12.2 years and mean disease duration of 6.5±6.8 years. Their initial SLE Disease Activity Index 2000 (SLEDAI-2K) was 10.3±3.7 whereas 1278/2096 (61%) were positive for anti-dsDNA antibodies, 881/2039 (43.2%) had low C3 and 772/2039 (37.9%) low C4 at randomization. Their standard of care (SOC) treatment included glucocorticosteroids in 2128/2464 (86.4%) [mean dose 11.5±7.9mg/day, prednisone >7.5mg/day in 1062/1917, 55.4%], antimalarials in 1619/2376 (68.1%) and immunosuppressives in 1067/2376 (44.9%) (509 azathioprine, 369 methotrexate, 270 mycophenolate). There were no significant differences regarding demographics, clinical manifestations and treatment between placebo-treated patients and individuals in the active arms of most RCTs. The response rates of the placebo-treated patients for the different end-points are shown in the table.

The mean reduction in SLEDAI-2K (n=1267) was 4.05 (range 3.3-4.8) and in the Physician Global Assessment (PGA, 0-100 scale, n=1554) 19.9 (range 11.7-23.8). The sample size in 10 studies was calculated with an expectation of an average 15% difference between the active drug and placebo (range 12-20%) in achieving the primary end-point; the actual difference was 9% on average (range 1.2-17.9%). Regarding safety, there were 449/2621 (17.1%) serious adverse events with 105/1899 (5.5%) serious infections, 6/1310 (0.5%) malignancies and 17/2621 (0.65%) deaths.

Conclusion: One third of the patients treated with placebo plus SOC achieved their respective primary end-points in RCTs with biologics in non-renal, non-neuropsychiatric SLE. The response rate was even higher for certain end-points, such as the SRI-4, while it decreased with more stringent end-points. It is possible that certain patient characteristics (prevalent cases with a long disease duration at enrollment and unspecified phase of the disease course i.e. recent or chronic, persistent flare at randomization) and study design (use of glucocorticosteroids and immunosuppressives, stringency of the outcomes) influence the response to placebo.

Abstract Number: 0941

Treatment of Lupus Nephritis with anti-CD20 Followed by Anti-BAFF: Impact on B Cell Reconstitution, B Cell Subsets, and Autoreactivity

Yemil Atisha Fregoso,[1] Susan Malkiel,[2] Kristina Harris,[3] Sai Kanaparthi,[3] Margie Byron,[4] Linna Ding,[5] Dawn Smilek,[6] David Wofsy,[7] Maria Dall'Era,[8] Cynthia Aranow,[1] and Betty Diamond[9], [1]Feinstein Institute for Medical Research, Manhasset, NY, [2]Feinstein Institute for Medical Research, Manhasset, [3]Immune Tolerance Network, Bethesda, [4]Rho Federal Systems, Inc., Chapel Hill, NC, [5]National Institute of Allergy and Infectious Diseases, Bethesda, MD, [6]Immune Tolerance Network, San Francisco, CA, [7]UCSF, San Francisco, [8]University of California, San Francisco, San Francisco, CA, [9]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical III: Clinical Trials II

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

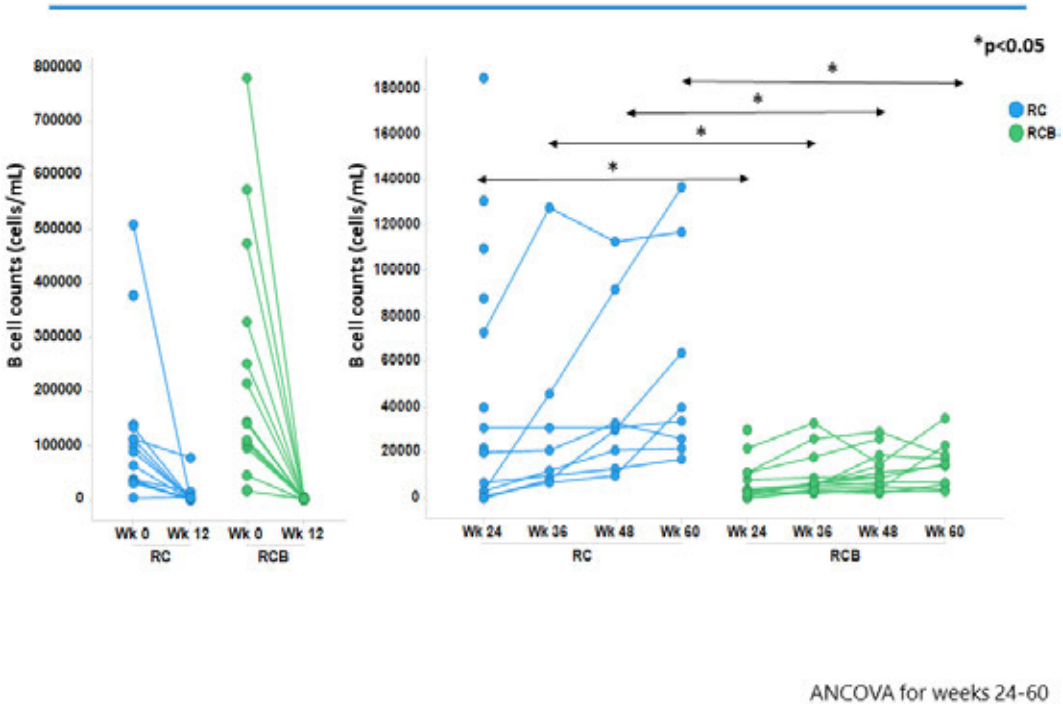

Figure 1. B cell counts in Per Protocol Sample

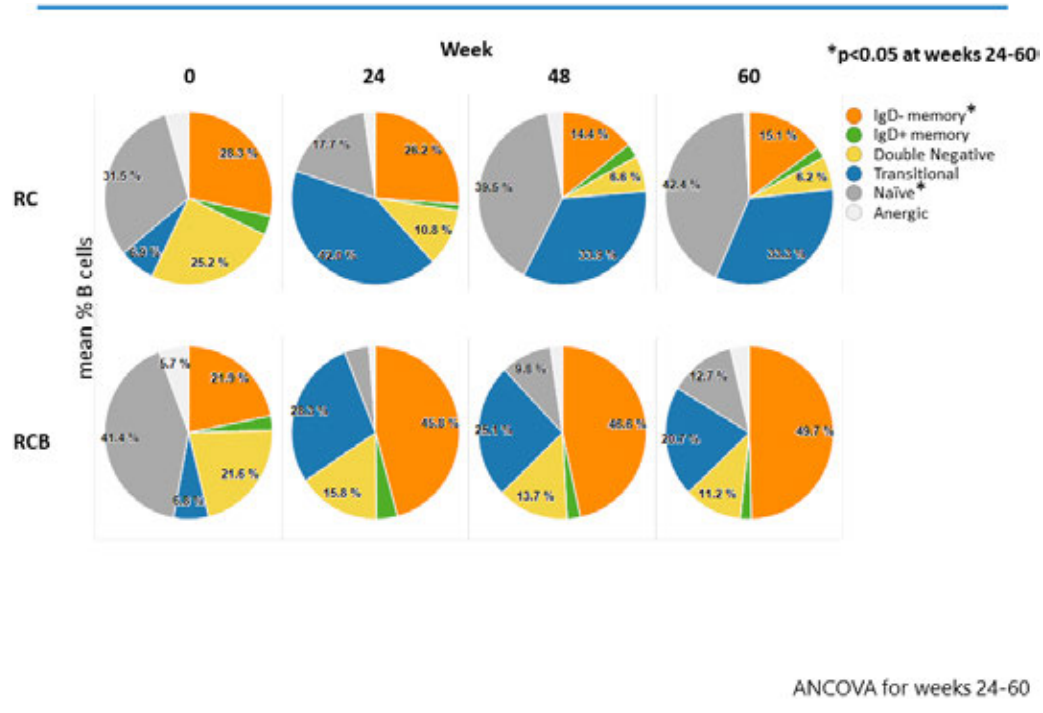

Figure 2. Relative Proportions of B Cell Subpopulations Differ Between RC v. RCB Subjects in Per Protocol Sample

Background/Purpose: Despite the relevance of B cells in lupus, two clinical trials of anti-CD20 failed to meet primary endpoints in patients with lupus and lupus nephritis (LN). One explanation is that after treatment with anti-CD20, BAFF levels are elevated, which may favor survival and expansion of pathogenic autoreactive B cells. The CALIBRATE study (NCT 02260934) was designed to determine whether addition of anti-BAFF (belimumab) could enhance the clinical and biological effects of anti-CD20 (rituximab), and to assess safety of the combination.

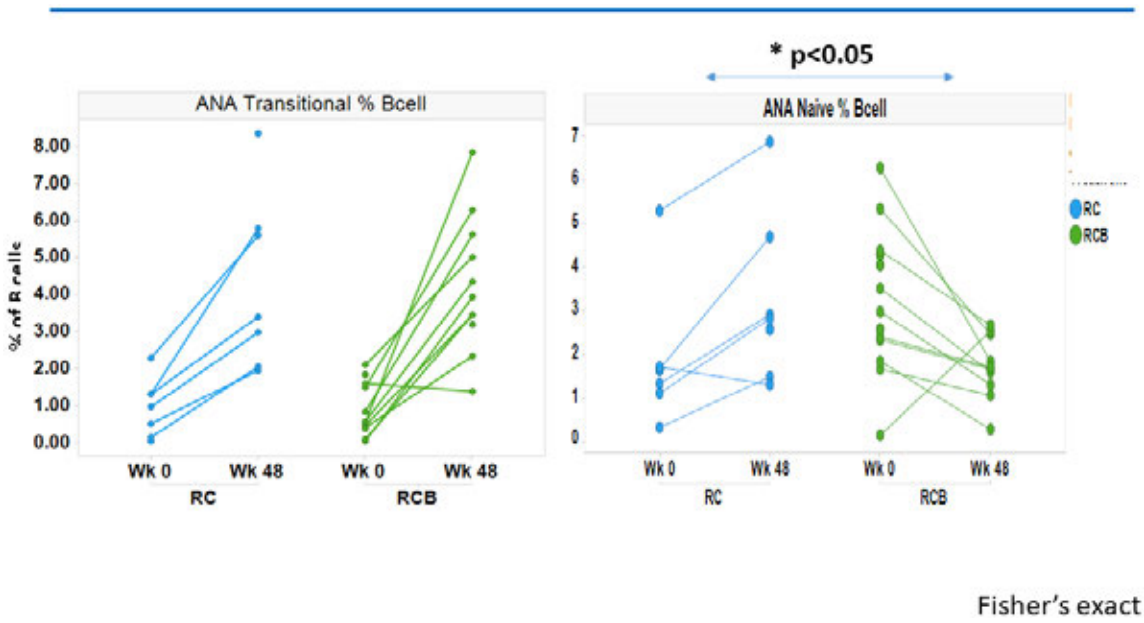

Figure 3. Proportions of ANA+ transitional and Naïve B cells in RC v. RCB Subjects in Per Protocol Sample

Methods: Forty-three patients with active LN despite conventional treatment were enrolled in a prospective randomized open-label trial that compared two regimens. All subjects received iv rituximab (1000 mg), CYC (750 mg), and methylprednisolone (100 mg) at wks 0 and 2, followed by 40 mg/d prednisone with taper to 10 mg/d by wk 12. At wk 4, subjects were randomized to belimumab (10 mg/kg iv at wks 4, 6, 8 and then every 4 wks) plus prednisone (RCB, n=21) or prednisone alone (RC, n=22) to wk 48. After wk 48, patients received only prednisone. Complete response (CR) was defined as: (i) urine protein:creatinine ratio (UPCR) < 0.5; (ii) eGFR ≥ 120 or, if < 120, eGFR >80% of screening; and (iii) prednisone dose of 10 mg/d. Partial response (PR) differed only in the UPCR criterion (>50% reduction). B cell populations and autoreactive B cells (ANA+ B cells) from peripheral blood were analyzed in Per Protocol (PP) samples as previously described (Arthritis Rheum 2016;68:2210) at wk 0, 24, 48 and 60

Results: B cell depletion occurred in both groups by wk 12. Partial reconstitution was observed in the RC group by wk 24 compared to the RCB group. B cells counts in the RCB group remained lower at wk 60, 12 wks after belimumab was discontinued (Figure 1). In both groups, the proportion of transitional B cells was increased compared to baseline at all time points. Proportions of naïve B cells decreased and switched memory B cells increased in the RCB group compared to the RC group, and these differences persisted after belimumab was discontinued (Figure 2). In both groups, the proportion of ANA^+ transitional cells in the B cell compartment was increased at wk 48. In contrast, the proportion of ANA^+ naive cells was increased in the RC group and decreased in the RCB group (Figure 3).

At wk 48, CR was 38% in the RCB group and 32% in the RC group; overall response (CR+PR) was 52% in the RCB group compared to 41% in the RC group (*p*-ns). Five subjects in the RC group and 2 in the RCB group experienced grade 3 or higher infectious adverse events, and all resolved. At wk 48, in PP patients, median IgG levels remained within the normal range in both groups. Resolution of hypocomplementemia and positive anti-DNA antibody status was not statistically different between groups.

Conclusion: Treatment with anti-BAFF following anti-CD20 was not associated with increased risk of infections or adverse events. The sequential treatment impaired B cell reconstitution, altered proportions of B cell subpopulations, and decreased the relative proportion of autoreactive ANA^+ naïve cells in circulating B cells. In this phase 2a study, addition of anti-BAFF did not significantly improve clinical outcome.

A Randomized Prospective Trial to Assess the Clinical Utility of Multianalyte Assay with Complement Activation Products in Diagnosing Systemic Lupus Erythematosus

Daniel Wallace,[1] Roberta Alexander,[2] Tyler O'Malley,[3] Arezou Khosroshahi,[4] Mehrnaz Hojjati,[5] Konstantinos Loupasakis,[6] Jeffrey Alper,[7] Yvonne Sherrer,[7] Maria Fondal,[7] Rajesh Kataria,[8] Tami Powell,[2] Claudia Ibarra,[2] Sonali Narain,[9] Elena Massarotti,[10] Arthur Weinstein,[2] and Thierry Dervieux[2], [1]Cedars Sinai Medical Center/UCLA, Los Angeles, CA, [2]Exagen, Vista, CA, [3]Exagen, Oceanside, CA, [4]Emory University, Atlanta, GA, [5]Department of Rheumatology, Loma Linda University, Loma Linda, CA, [6]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [7]BendCare Rheumatology, Naples, FL, [8]Southern Ohio Rheumatology, Wheelersburg, OH, [9]Northwell Health, Great Neck, Long Island, NY, [10]Brigham and Women's Hospital/Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical III: Clinical Trials II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Cell-Bound Complement Activation Products (CB-CAPs) in multianalyte assay panel (MAP) is a diagnostic immunology laboratory test with established clinical validity in distinguishing systemic lupus erythematosus (SLE) from other rheumatic diseases. The Clinical Laboratory Assessment and Recommendation (CARE) for Lupus study was designed to evaluate the clinical utility of this testing method in diagnosing SLE.

Methods: CARE for Lupus was a multicentered, randomized, and prospective study that enrolled patients evaluated for a suspicion of SLE by board certified rheumatologists (within three months of referral). At baseline, all patients presented with an history of antinuclear antibody positivity and were randomized (1:1) to standard diagnostic laboratory testing (SDLT, all ordered at the discretion of the rheumatologist) or to CB-CAPs/MAP testing, which reports a two-tiered index test result and has 80% sensitivity and 86% specificity for SLE. The primary end-point was based on the change in the physician likelihood of SLE on a 5-point Likert scale collected before and after testing (at 4 and 12-weeks). Changes in pharmacological treatment based on laboratory results were assessed in both arms. Statistical analysis consisted of Wilcoxon and Fisher's Exact tests.

Results: A total of 145 subjects were enrolled at 32 sites and randomized to SDLT arm (n=73 subjects, mean [SEM] age=48±2 years, 94% females) and CB-CAPs/MAP arm (n=72 subjects, 50±2 years, 93% females). Positivity rate for CB-CAPs/MAP was similar in the 2 groups (15.1% in SDLT arm vs. 12.5% in CB-CAPs/MAP arm, p=0.65). At enrollment (pre-test), likelihood of SLE in SDLT and CB-CAPs/MAP arms was similar (**Table**). At the 4 weeks follow-up visit, patients randomized to the CB-CAPs/MAP testing arm presented with greater decrease in the likelihood of SLE than those randomized to the SDLT arm (p=0.027) and these differences remained significant at the 12-week follow-up visit (p=0.025) (**Table**). We observed a significantly greater decrease in the likelihood of SLE (decrease ≥1 point from enrollment) in the group of patients randomized to CB-CAPs/MAP testing arm (40/72, 56%) compared to the SDLT

Table. Physician reported likelihood of SLE pre-test and post-test.
Results are expressed as mean ± SEM at each study visit and change from enrollment (in brackets).

	Pre-test (enrollment)	Post-test at 4-weeks	Post-test at 12-weeks
SDLT arm N=73	1.46±0.06	1.23±0.08 [-0.19±0.07]	1.11±0.10 [-0.31±0.10]
CB-CAPs/MAP testing arm N=72	1.42±0.05	1.01±0.10 [-0.44±0.10]	0.84±0.10 [-0.61±0.10]

Table. Physician reported likelihood of SLE pre-test and post-test. Results are expressed as mean ± SEM at each study visit and change from enrollment (in brackets).

arm (27/73, 37%) (difference= 19%; p=0.031) at 12 weeks. In the group of patients randomized to the CB-CAPs/MAP testing, two-tiered test results associated significantly with initiation of prednisone (50% Tier-1 positive and 14% Tier-2 positive vs. 3% Tier-2 negative, p=0.034) and a similar trend was observed in the initiation of hydroxychloroquine (HCQ) (50% Tier-1 positive and 29% Tier-2 positive vs. 11% Tier-2 negative, p=0.112). Initiation of prednisone and HCQ also associated with two-tiered positive test results in the group of patients randomized to SDLT (blinded group) (p=0.020 and p=0.054, respectively).

Conclusion: The decrease in the likelihood of SLE in both study arms following testing is consistent with the low prevalence of the disease. CB-CAPs/MAP was more effective than SDLT in allowing the physician to determine that SLE is an unlikely diagnosis. In addition, positive CB-CAPs/MAP test results impacted treatment management.

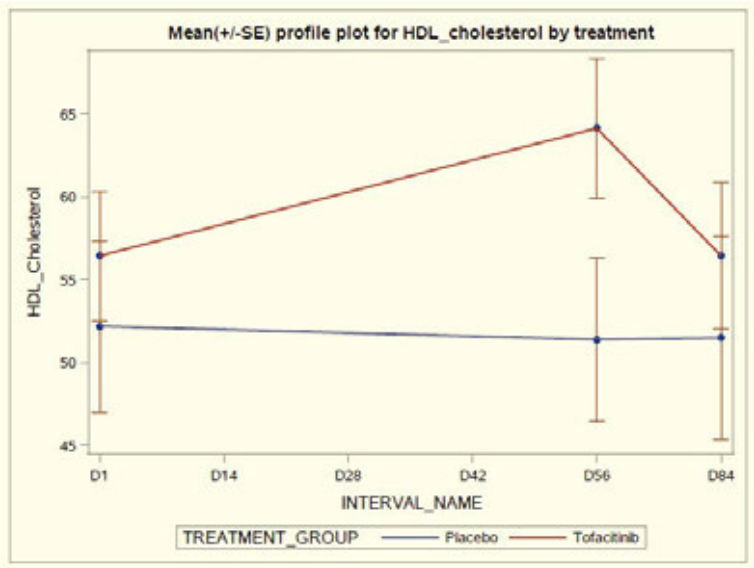
Severe	0(0%)	2(7.1%)	2(2.8%)

Adverse Events



Significant Increase(p=0.0006) in HDLc Number and Particle Size in Treatment group at Day 56

Background/Purpose: A pharmacologic intervention that modulates JAK/STAT signaling pathways represents a novel approach for the treatment of Systemic Lupus Erythematosus (SLE). In animal models of SLE, tofacitinib improved clinical features, immune dysregulation and vascular dysfunction. The *STAT4* risk allele is associated with higher risk of severe manifestations in SLE. We hypothesized that immune modulation in response to JAK/STAT inhibition would differ between SLE subjects that carry or not carry the *STAT4* risk allele.

Methods: We conducted a phase 1b/2a randomized, double-blind, placebo-controlled clinical trial of oral tofacitinib, 5 mg twice daily, in 30 SLE subjects (2:1 drug to placebo ratio) with mild to moderate disease activity, stratified by

the presence or absence of *STAT4* risk allele. Study duration was 84 days, with 56 days of active treatment followed by 28 days of off drug period. In addition to recording adverse events (AEs), lipoprotein profile, non-invasive vascular function studies, immuno-phenotyping, and gene expression studies were performed at various time points.

Results: Tofacitinib was well tolerated with no worsening of SLE disease activity, and no severe AEs, opportunistic infections or liver function abnormalities. No thromboembolic events were observed in this short duration trial. A total of 43 AEs (mostly mild respiratory infections) occurred in the treated group compared to 28 AEs in placebo. There was a significant increase in HDL-C and HDL particle size in tofacitinib-treated patients at day 56 accompanied by significant improvements in plasma protein lecithin: cholesterol acyltransferase (LCAT) concentration and cholesterol efflux capacity. Arterial stiffness decreased in the tofacitinib-treated group but not in the placebo-treated group. The type I Interferon gene signature, circulating levels of low- density granulocytes and neutrophil extracellular traps significantly decreased in the tofacitinib treated group compared to the placebo group by the end of treatment, accompanied by significant decreases in pSTAT phosphorylation of different immune cells. Various T cell activation and checkpoint markers significantly decreased in tofacitinib treated individuals and this was modulated by presence or absence of *STAT4* risk allele.

Conclusion: In a short-term trial, tofacitinib was well tolerated in SLE subjects with mild-moderate disease activity. Use of tofacitinib resulted in improvements in innate and adaptive immune dysregulation and lipoprotein phenotype and function. This study also points to the potential utility of including genetic data in clinical trials to advance precision medicine. Long-term studies are needed to determine the efficacy of tofacitinib in the various manifestations of SLE including cardiovascular risk.

[a] SLEDAI-2K total score calculated using anti-dsDNA positive if >10 iU. ANA: antinuclear antibody; BILAG: British Isles Lupus Assessment Group; BMI: body mass index; C3/4: complement C3/C4; DZP: dapirolizumab pegol; PBO: placebo; SLEDAI-2K: Systemic Lupus Erythematosus Disease Activity Index 2000; SOC: standard of care.

Background/Purpose: Dapirolizumab pegol (DZP) is a polyethylene glycol-conjugated Fab' fragment, which targets CD40 ligand and is in development for the treatment of systemic lupus erythematosus (SLE). The primary objective was to establish a dose-response relationship for DZP using prespecified models. Other objectives were to compare the safety and efficacy of DZP to standard of care (SOC) treatment, and to assess the durability of response after study drug withdrawal.

Methods: This phase 2b study (NCT02804763) consisted of a 24-week double-blind (DB), placebo (PBO)-controlled period (study drug plus SOC), followed by a 24-week observational period (SOC only). Patients were randomized 1:1:1:1 to SOC+PBO or SOC+intravenous DZP (6/24/45 mg/kg) every 4 weeks to Week 24. The primary objective was measured at Week 24, and other objectives throughout the study.

Adults with SLE (SLICC classification criteria) and moderate to severe disease activity (SLEDAI-2K score ≥6 and ≥1 BILAG A or ≥2 BILAG B domain scores), receiving stable doses of corticosteroids (CS; ≤40 mg/day prednisone-equivalent) and/or antimalarials and/or immunosuppressants, were eligible. Patients receiving CS ≥10 mg/day were required to start tapering within 4 weeks of first study drug infusion. Patients with stable lupus nephritis were permitted entry.

Table B: Immunologic and clinical outcomes

Mean change from baseline, unless otherwise stated	SOC + PBO (N=43)		SOC + DZP 6 mg/kg (N=43)		SOC + DZP 24 mg/kg (N=44)		SOC + DZP 45 mg/kg (N=46)

SLEDAI-2K	-4.2	**-4.1**	-5.0	**-5.6**	-5.1	**-5.3**	-5.3	**-5.4**
Cumulative no. BILAG severe flares [f]	7	**12**	4	**12**	0	**5**	1	**5**

Observed case data, unless otherwise specified. [a] In patients with anti-dsDNA >10 iU at baseline, measured using the Farr assay; [b] In patients with C3 or C4 below the lower limit of normal at baseline; [c] In patients who tested positive for each antibody at baseline; [d] Decreases at Week 48 are due to intervention with escape treatment; [e] Defined as all Grade As improved to B, C, or D, and all Grade Bs improved to C or D, and no worsening in other organ systems with Grade C, D, or E at baseline (worsening is defined as ≥1 new A or ≥2 new Bs); [f] BILAG severe flare: a new BILAG 2004 Grade A since the previous visit in any system, due to individual items that are new or worse qualifying for the Grade A. Δ: difference vs placebo; mNRI: modified non-responder imputation; OR: odds ratio vs placebo; PGA: physician's global assessment; SRI: SLE Responder Index.

Clinical outcomes were analyzed in patients who received ≥1 full dose of study medication and had ≥1 post-baseline efficacy measurement. Safety and immunologic outcomes were analyzed in patients who received ≥1 dose of study medication (any dose).

Results: Of 182 randomized patients, 178 (97.8%) completed the DB period to Week 24 (including 167 [91.8%] on study drug), and 164 (90.1%) completed the observational period to Week 48. Baseline demographics were similar across groups **(Table A)**. At Week 24, all DZP groups showed numerically greater improvements in immunological and clinical outcomes vs PBO **(Table B)**. Following study drug withdrawal, immunologic parameters generally worsened and returned towards baseline. Whereas SLEDAI and PGA stabilized across treatment groups after study drug withdrawal **(Table B)**, BICLA and SRI-4 response rates declined, mostly due to interventions with escape medicines during this period, which automatically led to non-responder status. As none of the prespecified dose-response models fit the Week 24 BICLA responder rates with statistical significance ($p< 0.05$), the primary objective was not met. Rates of treatment-emergent adverse events (TEAEs) and serious TEAEs were generally balanced across treatment groups **(Table C)**. Four thromboembolic TEAEs were observed during the DB period: one in the 24 mg/kg DZP group and three in PBO.

Table C: Safety outcomes

n (%) [ER per 100 patient-years]	SOC + PBO (N=45)	SOC + DZP 6 mg/kg (N=45)	SOC + DZP 24 mg/kg (N=45)	SOC + DZP 45 mg/kg (N=47)
Mean duration of exposure (days)	***216.7***	***224.0***	***215.6***	***212.1***
Any TEAE	28 (62.2) [90]	29 (64.4) [130]	35 (77.8) [116]	34 (72.3) [84]
Infections and Infestations	15 (33.3) [21]	21 (46.7) [43]	26 (57.8) [40]	22 (46.8) [29]
Infusion reactions	0	0	0	1 (2.1) [1]
Thromboembolic events	3 (6.7)	0	1 (2.2)	0
Serious TEAEs	5 (11.1) [6]	2 (4.4) [2]	4 (8.9) [4]	5 (10.6) [6]
Study discontinuation due to TEAEs	1 (2.2) [1]	0	0	0
Permanent withdrawal of study drug due to TEAEs	4 (8.9) [4]	0	2 (4.4) [2]	2 (4.3) [2]
Severe TEAEs	3 (6.7) [4]	1 (2.2) [1]	3 (6.7) [3]	7 (14.9) [8]
Deaths	0	0	0	0

TEAEs were those with onset at the time of, or after, the first dose of study drug, until 12 weeks after the last dose. Patients who withdrew from the study early (during the DB Treatment Period) entered a Safety Follow-Up Period, which ended 12 weeks after the final dose of study drug. DZP: dapirolizumab pegol; ER: event rate; PBO: placebo; TEAE: treatment-emergent adverse event; SOC: standard of care.

Conclusion: DZP-treated patients showed consistent improvements in disease activity across all doses. Upon study drug withdrawal, immunologic parameters returned to baseline levels, whilst clinical outcomes such as SLEDAI and PGA stabilized. None of the prespecified dose-response models could be selected; thus, the primary endpoint was not met. DZP was generally well-tolerated. The potential clinical benefit of DZP warrants investigation in a larger stu dy.

Comparison of Clinical Manifestations in IgG4 Related Disease Patients with/without Aortitis/Periaortitis and Periarteritis: A Prospective Cohort Study of 587 Patients with IgG4-RD Disease

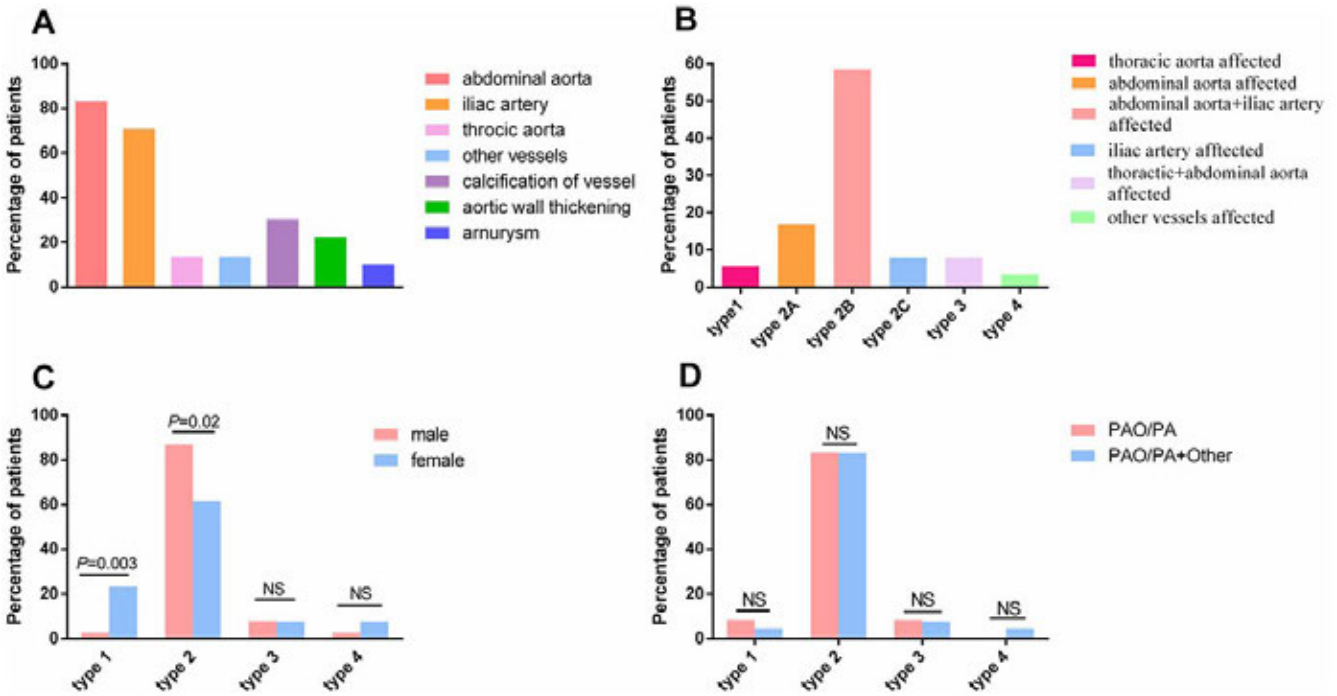
Linyi Peng,[1] Wen Zhang,[2] and **Panpan Zhang**[1], [1]Department of Rheumatology, Peking Union Medical College Hospital, Chinese Academy of Medical Science & Peking Union Medical College, Beijing, China (People's Republic), [2]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: We aimed to clarify the clinical features of IgG4-related disease (IgG4-RD) with/without aortitis/periaortitis and periarteritis (PAO/PA), and evaluate the treatment efficacy of patients with PAO/PA.

Methods: A total of 587 IgG4-RD patients with a follow up time of more than 6 months were enrolled in this study. The distribution of IgG4 related PAO/PA was classified into four types: type 1, thoracic aorta affected; type 2a, abdominal aorta affected, type 2b, abdominal aorta and iliac artery affected, type 2c, iliac artery affected; type 3, thoracic and abdominal aorta affected; type 4, other artery affected. The demographic data, clinical characteristics, laboratory parameters and treatment efficacy of enrolled patients were analyzed.

Results: Of 587 IgG4-RD patients, 89 (15.2%) had PAO/PA. The age of PAO/PA patients was 58.3 ± 11.1 years, and there was a male dominance(85.4%, 76 male patients). The percentage of vessels affected in IgG4 related PAO/PA was as follows: the abdominal aorta affected was 83.1%, the iliac artery affected was 70.8%, the thoracic aorta affected was 13.5% and the other vessels were affected. The most prevalent type of PAO/PA was type 2B, with 74 (83.1%) patients, followed by type 2A, type 2C, type 3 and type 1. Compared with patients without PAO/PA, patients with PAO/PA had higher percentage of back pain, and abdominal pain, the percentage of dacryoadenitis/ sialadenitis and paranasal sinus affected was lower. ESR and hsCRP was higher in patients with PAO/PA, whereas serum IgG4 and T-IgE levels were lower compared with patients without PAO/PA. After treatment with glucocorticoid and immunosuppressants, patients IgG4-RD RI, ESR, hsCRP, serum IgG4 and T-IgE levels decreased significantly. 44 (38.2%) patients achieved a remission with the reduction of abnormal soft tissues more than 70%, 39 (43.8%) with a reduction of 31%-70%, and 16 (18.0%) patients with a reduction of less than 30%.



Vessels affected of IgG4-RD patients with PAO/PA Figure 1A represented vessels affected of patients with PAO/PA. Figure 1B represented the distribution of IgG4 related PAO/PA. figure 1C and 1D represented the comparison of vessel distribution between male and female patients, PAO/PA merely and PAO/PA respectively

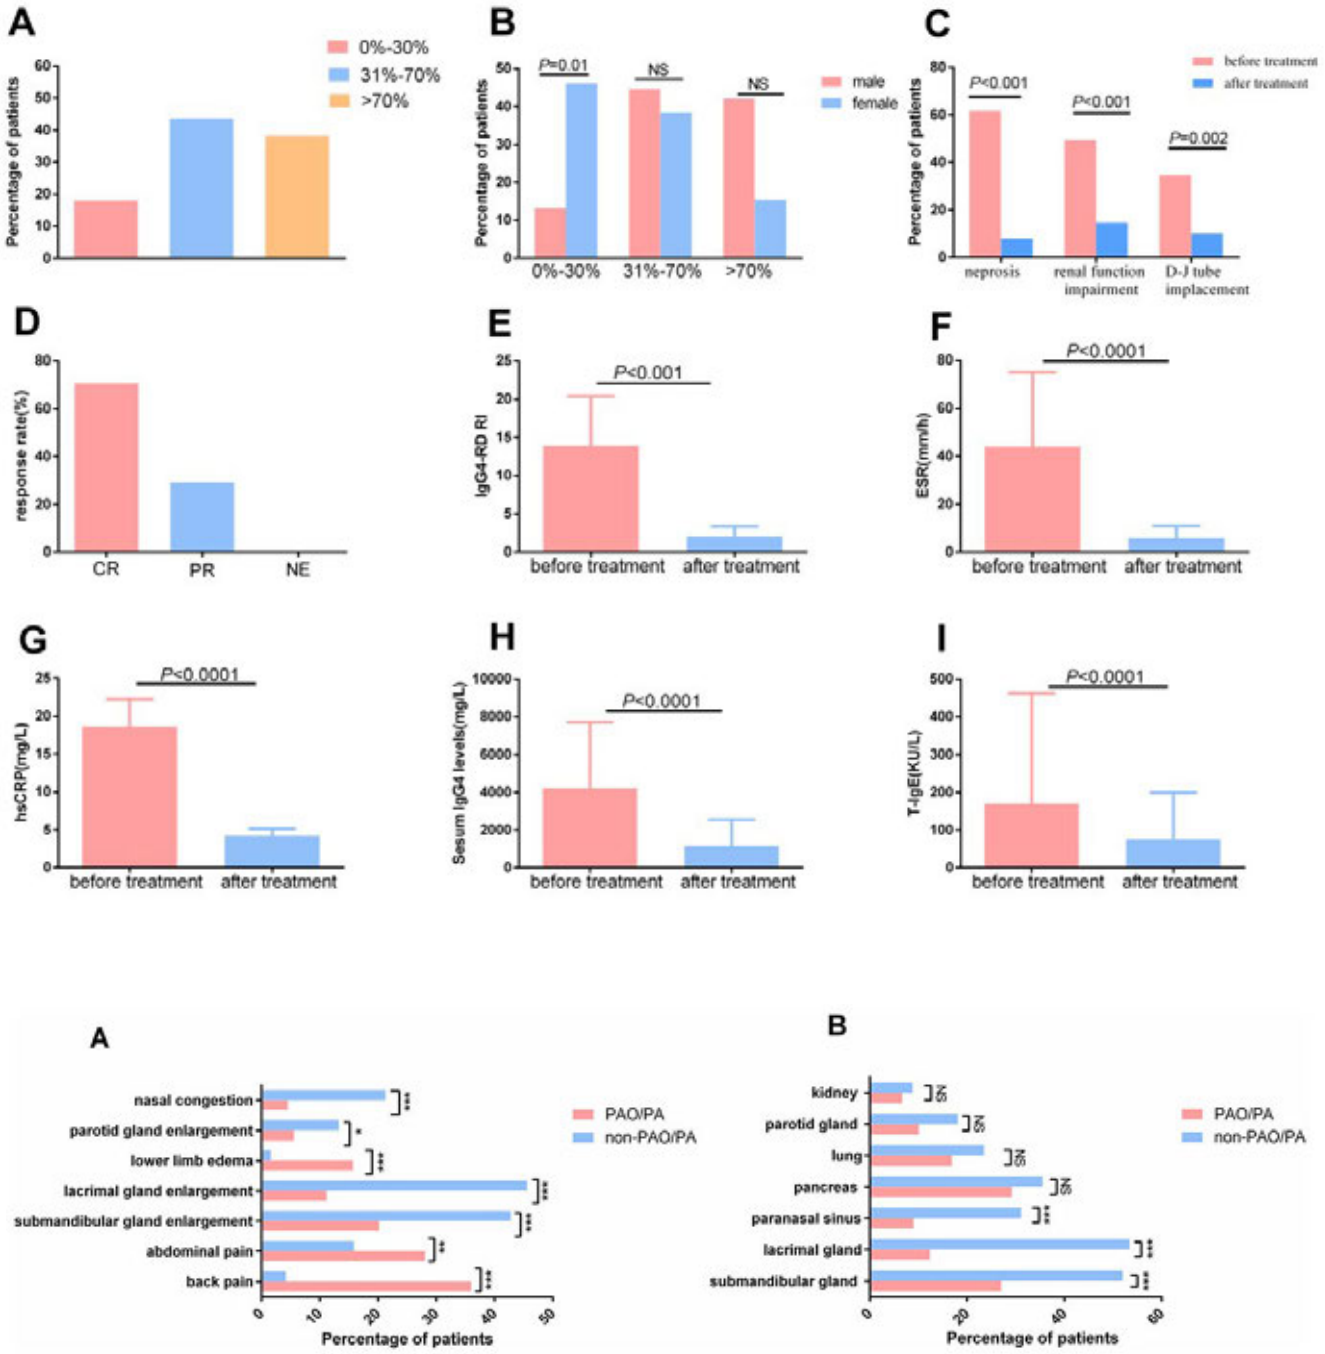


Figure 3 Onset symptoms and organs affected of patients with/without PAO/PA Figure 3A and figure 3B represented onset symptoms and organs affected of IgG4-RD with PAO/PA. * represented P<0.05, *** represented P<0.001.

and without active major organ involvement. The primary efficacy endpoint was area under the curve for the number of OU over 12 weeks (AUC_{Wk0-12}). Clinical improvement of OU was evaluated by assessments of OU pain (100 mm visual analogue scale) and measures of disease activity and QoL. Disease activity measures included the Behçet's Syndrome Activity Score (BSAS) and Behçet's Disease Current Activity Index Form (BDCAF; including 3 components: Behçet's Disease Current Activity Index, Patient's Perception of Disease Activity, Clinician's Overall Perception of Disease Activity). QoL assessments included the Behçet's Disease QoL (BDQoL) score and the 36-item Short-Form Health Survey version 2 (SF-36v2), consisting of the Physical and Mental Component Summary (PCS and MCS) scores and Physical Functioning domain (PF) score. An analysis of covariance model was used to analyze the prima-

Conclusion: The most common affected vessel in patients with PAO/PA was abdominal aorta, and type 2b was the predominant distribution of PAO/PA. Patients with PAO/PA had lower percentage of allergy history, dacryoadenitis/sialadenitis and paranasal sinus affected, lower serum IgG4 levels, T-IgE, higher IgG4-RD RI, ESR and hsCRP than patients without PAO/PA.

Improvements in Disease Activity and Quality of Life for up to 64 Weeks in Patients with Behçet's Syndrome: Results from a Phase III Study

Gulen Hatemi,[1] Alfred Mahr,[2] Mitsuhiro Takeno,[3] Doyoung Kim,[4] Melike Melikoglu,[5] Sue Cheng,[6] Shannon McCue,[7] Maria Paris,[6] Mindy Chen,[8] and Yusuf Yazici[9], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul University-Cerrahpasa, Behcet's Disease Research Center, Istanbul, Turkey, Istanbul, Turkey, [2]Hospital Saint-Louis, University Paris Diderot, Paris, France, [3]Nippon Medical School, Tokyo, Japan, [4]Yonsei University College of Medicine and Severance Hospital, Seoul, Republic of Korea, [5]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul University – Cerrahpasa, Behçet's Disease Research Center, Istanbul, Turkey, Istanbul, Turkey, [6]Celgene Corporation, Summit, [7]Celgene Corporation, Summit, NJ, [8]Celgene Corporation, Berkeley Heights, NJ, [9]New York University School of Medicine, New York

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Behçet's syndrome is a chronic, multi-system inflammatory disorder characterized by painful, recurrent oral ulcers (OU) that can impair quality of life (QoL). Apremilast (APR), an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in the treatment of OU of Behçet's syndrome in a phase III, multicenter, randomized, double-blind, placebo (PBO)-controlled study (RELIEF). We report short- and long-term results from RELIEF for the efficacy of APR treatment on QoL and physical function for up to 64 weeks.

Methods: A total of 207 patients were randomized (1:1) to APR 30 mg twice daily (APR 30 BID) or PBO twice daily for a 12-week PBO-controlled phase, followed by a 52-week active treatment extension. Eligible patients were ≥18 years old, had active Behçet's syndrome, with ≥3 OU at randomization or ≥2 OU at screening and randomization

Changes From Baseline at Week 12 and Week 64

	Week 12*			Week 64†	
	PBO	APR 30 BID	*P* Value	PBO/ APR 30 BID	APR 30 BID
BDQoL, mean change (SD)	−0.5 (0.7)	−3.5 (0.7)	0.0003	−3.41 (6.6)	−3.57 (6.6)
SF-36v2 PCS, mean change (SD)	0.9 (0.8)	3.1 (0.8)	0.0204	3.3 (9.1)	3.4 (7.9)
SF-36v2 MCS, mean change (SD)	−0.7 (0.9)	4.6 (0.9)	<0.0001	1.9 (10.5)	5.4 (11.1)
SF-36v2 PF, mean change (SD)	0.04 (0.9)	2.9 (0.9)	0.0060	2.5 (10.1)	3.4 (10.2)

Intent-to-treat population.

*Last-observation-carried-forward analysis; least-squares mean is shown for Week 12. †Data as observed. For SF-36v2, a higher score indicates better functioning and a positive change from baseline indicates improvement. For BDQoL, a lower BDQoL score indicates better QoL and a negative change from baseline indicates improvement.

ry endpoint and change from baseline in BDQoL score and SF-36v2 PCS, MCS and PF scores at Week 12. Data at Week 64 are as observed.

Results: The primary efficacy endpoint of AUCWk0-12 for the number of OU was significantly lower in APR 30 BID vs PBO patients ($P< 0.0001$); improvement in the number of OU and OU pain was sustained in patients continuing APR 30 BID treatment for up to 64 weeks and emerged in patients switched from PBO to APR 30 BID for Weeks 12 to 64. Significant improvements were observed with APR 30 BID vs PBO in mean change from baseline at Week 12 in BSAS ($P< 0.0001$), BDCAF components ($P\leq0.0335$), and BDQoL score ($P=0.0003$). The improvements in BSAS, BDCAF, and BDQoL outcomes were maintained in patients continuing APR 30 BID treatment for up to 64 weeks, and comparable effects were observed at Week 64 among patients who switched from PBO to APR 30 BID. Significant improvements were also observed in mean change from baseline at Week 12 in SF-36v2 PCS ($P=0.0204$), MCS ($P< 0.0001$), and PF ($P=0.0060$) scores in APR 30 BID vs PBO patients. These effects in SF-36v2 scores were also maintained at Week 64 among patients initially randomized to APR 30 BID, and the improvements were generally similar among patients who switched from PBO to APR 30 BID (Table).

Conclusion: Patients with active Behçet's syndrome treated with APR 30 BID vs PBO experienced significant reductions in OU and clinically meaningful improvements at Week 12 in disease activity and QoL. Improvements were sustained at Week 64 in patients continuing APR treatment.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Deficiency of adenosine deaminase 2 (DADA2) is an autosomal recessive disease caused by biallelic loss-of-function mutations in the *ADA2* gene . Over 60 pathogenic mutations have been identified in all domains of the resultant protein, adenosine deaminase 2 (ADA2). ADA2 is an endothelial cell growth factor and promotes M2 macrophage differentiation, leading to a chronic inflammatory state. Known manifestations of ADA2 deficiency include recurrent fevers, immunodeficiency, livedo racemosa, polyarteritis nodosa, and early-onset stroke – many of which may worsen with acute or recurrent disease flares. An earlier study by our group demonstrated a reduced risk of recurrent strokes in 15 patients with DADA2 secondary to anti-tumor necrosis factor (TNF) treatment. The purpose of this abstract is to provide additional stroke data before and after initiation of anti-TNF treatment on a larger cohort since the initial publication.

Methods: A single center study evaluated 49 patients with molecularly diagnosed pathogenic mutations in ADA2. Medical records were manually reviewed. Stroke incidences were only included if reported as confirmed by imaging. Patients were subdivided by past incidence of stroke and initiation of anti-TNF treatment such as etanercept, adalimumab, golimumab, or infliximab. Cumulative duration of the disease was calculated for each patient before and after initiation of anti-TNF treatment, i.e. time since birth and time to present record, respectively.

Results: Of the 49 patient cohort, 24 had documented histories of strokes, all of which are currently on anti-TNF treatment. The median age of first stroke was 5.0 years (range, 0.48 to 21) with a median of 2 strokes per patient (range, 1 to 10). Before initialization of anti-TNF treatment, the patients had a cumulative disease duration of 8,997

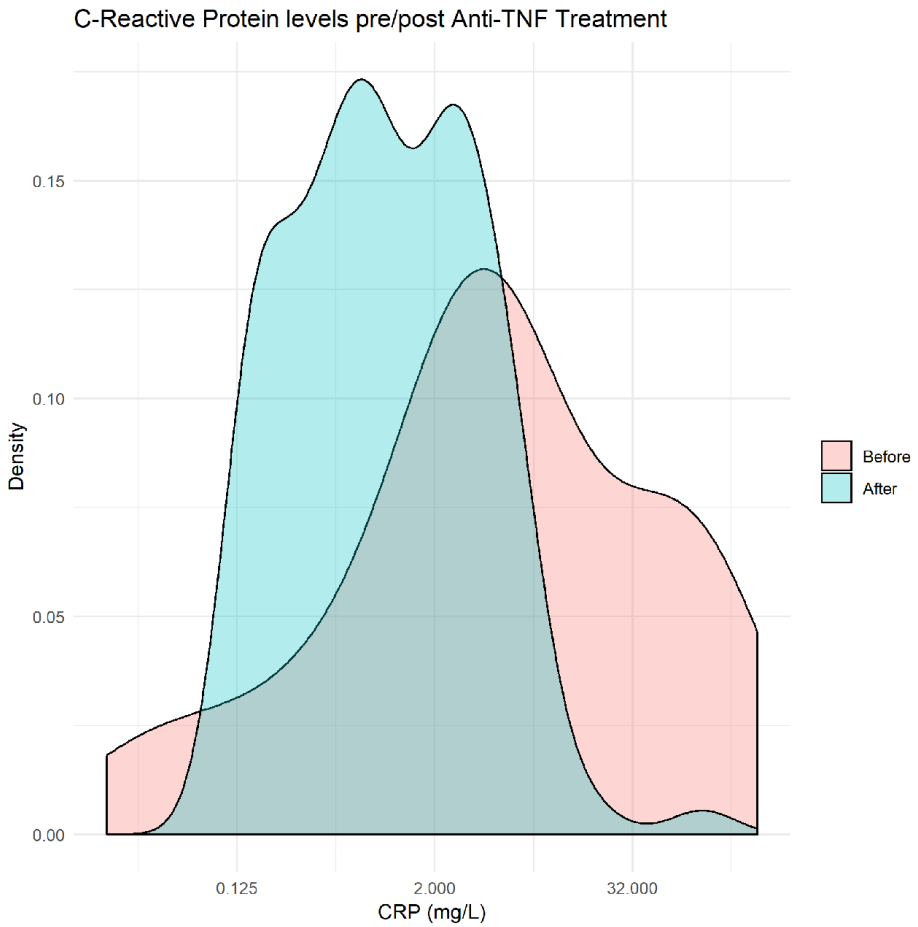

Figure 1: CRP level in patients with history of early-onset stroke before and after starting anti-tnf treatment, n = 24. Before treatment the average CRP level was 24.7 mg/L (median, 4.72) with a standard deviation of 42.7 mg/L. After starting anti-tnf treatment average CRP was 2.72 mg/ (median, 1.00) with a standard deviation of 8.36 mg/L.

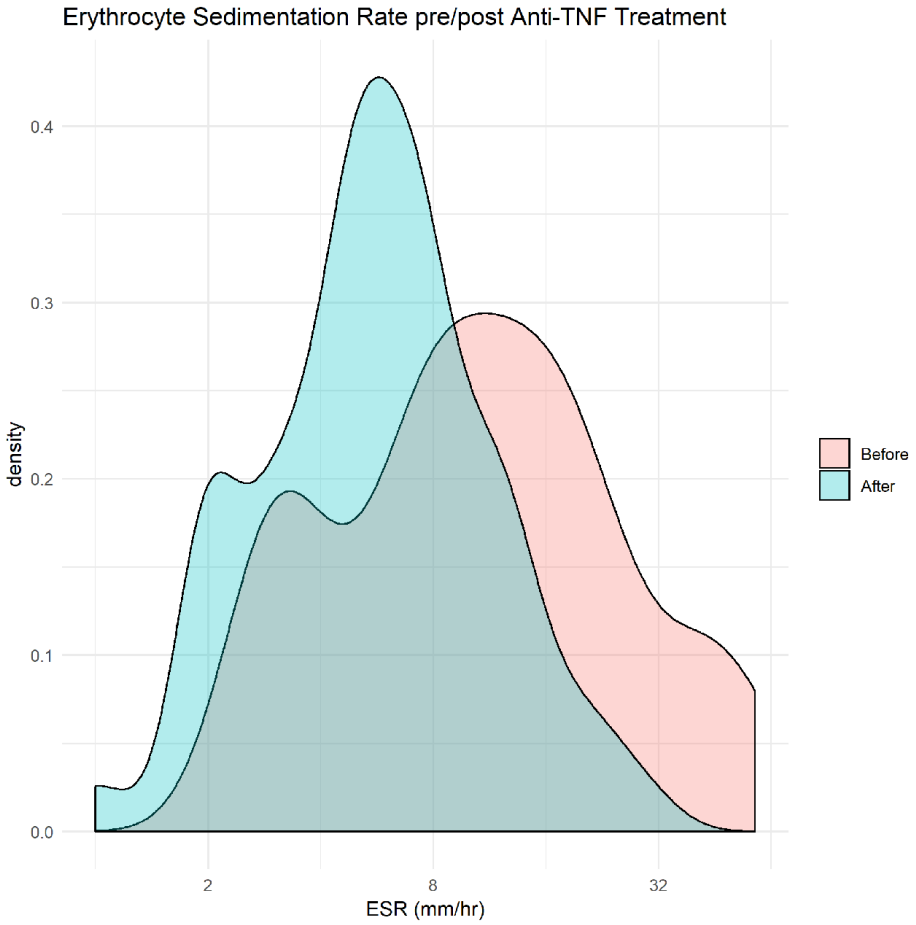

Figure 2: ESR level in patients with history of early-onset stroke before and after starting anti-tnf treatment, n = 24. Before treatment the average ESR was 15.1 mm/hr (median, 11.0) with a standard deviation of 13.8 mg/L. After anti-tnf treatment average ESR was 7.06 mm/hr (median, 5.50) with a standard deviation of 5.31 mm/hr.

patient months and a cumulative total of 69 strokes. After the initiation of anti-TNF treatment there have been no reported strokes over a period of 2,024 patient-months with a median duration of 56 months (range, 1.7 to 153) ($p < 0.001$).

Conclusion: Patients with DADA2 have a high risk for early-onset strokes. In a cohort of 49 patients with DADA2, 24 patients with history of stroke have all began anti-TNF treatment. Thus far these patients have experienced no recurrent strokes over a cumulative period of 2,024 patient months. This suggests anti-TNF treatment plays a key role in the reduction of strokes in patients with DADA2. Aside from stroke reduction, we have seen a normalization in key lab values such as CRP (Figure 1), ESR (Figure 2), Hgb and HCT which indicates an overall decrease in inflammation. Other lab indicators such as neutropenia and red cell aplasia remain variable or unchanged, suggesting additional targeted therapy may further benefit DADA2 patients.

Relapsing Cryoglobulinemic Vasculitis Following Successful HCV Eradication by Interferon-Free Direct Acting Antivirals, an International Multicenter Study

Mohamed Tharwat Hegazy,[1] Ahmed Fayed,[1] Tarek El Shabony,[1] Marcella Visentini,[2] David Saadoun,[3] Patrice Cacoub,[3] and Gaafar Ragab[1], [1]Cairo University, Cairo, Egypt, Cairo, Egypt, [2]Sapienza University of Rome, Rome, Italy, Rome, Italy, [3]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Paris, France

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Interferon-free Direct Acting Antiviral (DAA) combinations proved to be effective for the treatment of HCV induced Cryoglobulinemic Vasculitis (HCV-Cryovas). Some reports showed relapses of HCV-Cryovas despite a sustained viral response (SVR) after DAA. Possible explanations for such relapses included the persistence of few copies of HCV-RNA in liver cells, macrophages, or lymphocytes, or the persistence of pathogenic B-cell clones. The scale and features of these relapses are not fully appreciated. Our aim was to follow HCV-Cryovas patients treated with DAAs for a longer period and to assess Cryovas relapsers clinically and serologically

Methods: We studied a total of 1019 HCV-Cryovas patients who fulfilled the validated 2014 classification criteria. All cases received DAA treatment protocols. They represented the collective registries of the following 4 centers: 1- Nephrology unit, Internal Medicine Department, Cairo University, Egypt, 2- Rheumatology and clinical Immunology unit, Internal Medicine Department, Cairo University, Egypt, 3- Department of Internal Medicine and Clinical Immunology, National Reference Center for Autoimmune Systemic Rare Diseases, Hopital La Pitié Salpêtrière, Paris, France, 4- Referral Centre for Mixed Cryoglobulinemia, Department of Translational and Precision Medicine, Sapienza University of Rome, Rome, Italy. We excluded cases with hepatitis B or HIV, as well as cases that received IFN-based protocols. From 2015 to 2019, patients received the following DAA protocols: Sofosbuvir + either Simeprevir, Daclatasvir, Ledipasvir or Ribavirin. They all achieved a sustained viral response (SVR). They were followed over 24 months after viral eradication. Cases with cutaneous or renal relapses were additionally assessed by skin and/ or renal biopsies. Clinical relapse was reported when there was purpura, arthralgia/arthritis, neuropathy, or nephropathy. Serological relapses were considered if Cryoglobulins >1.5%, elevated rheumatoid factor (RF) or consumed complement 4 (C4) are detected. Acute interstitial nephritis in renal biopsy means lymphocytic or mononuclear inflammatory interstitial infiltrate. Vasculitis in renal biopsy would be either cryoglobulinemic-type or polyarteritisnodosa-type

Results: All 1019 HCV-Cryovas patients achieved SVR and showed partial or complete clinical and serological responses of Cryovas at the end of DAA treatment (EOT). A total of 116/1019 (11.38%) cases showed evidence of both clinical and serological Cryovas relapses **(Table 1)**, while 7/1019 (0.7%) cases only showed evidence of serological Cryovas relapse. All 123/1019 (12.07%) Cryovas relapsers remained negative for HCV by PCR. Overall, 98 cases of the relapsers had renal manifestations and 95 cases had a renal biopsy **(Table 2)**; 102 patients had purpura and 95 of them had a skin biopsy **(Table 3)**.

Conclusion: In our multicenter international study, after a follow-up period of 24 months and despite a SVR post-DAA, we report a 12.07% relapse rate of HCV-Cryovas. Close observation and longer follow-up studies, as well as,

Clinical Manifestations of the HCV Cryovas Relapsers	Number (%)
Purpura	102/116 (87.9%)
Renal	98/116 (84.4%)
Peripheral neuropathy	88/116 (75.8%)
Arthralgia/arthritis	8/116 (6.9%)
Lymphoma	3/116 (2.5%)
Skin ulcers	3/116 (2.5%)

Table 1: Clinical Manifestations of HCV Cryovas Relapsers.

Renal Pathology of HCV-Cryovas Relapsers	Number (%)
Membrano-Proliferative glomerulonephritis (GN)	43/95 (45.3%)
Membranous nephropathy	17/95 (17.9%)
Focal segmental glomerulosclerosis (FSGS)	2/95 (2.1%)
Crescentic GN	33/95 (34.7%)
Acute interstitial nephritis	56/95 (58.9%)
Thrombotic microangiopathy	37//95 (38.9%)
Vasculitis	40/95 (42.1%)
Arterial intimal fibrosis	25/95 (26.3%)

Table 2: Renal pathology.

Skin Pathology	Number (%)
Fibrinoid necrosis	95/95 (100%)
Endothelial cell swelling and thickening of the blood vessel wall	95/95 (100%)
Infiltration of the blood vessel wall with neutrophils and nuclear dust	77/95 (81.1%)
Extravasation of erythrocytes	89/95 (93.7%)
Intracapillary hyaline thrombi	51/95 (53.7%)

Table 3: Skin pathology.

deeper investigations of the immune system are needed to better understand the underlying mechanism of Cryovas relapse after HCV viral eradication

Assessment of Femoral Vein Wall Thickness with Doppler Ultrasound Can Be a Diagnostic Tool for Behcet's Disease

Fatma Alibaz-Oner,[1] Rabia Ergelen,[2] Yasin Yildiz,[3] Ayten Yazici,[4] Aydan Mutis,[5] Zeynep Erturk,[3] Mustafa Aldag,[6] Ayşe Cefle,[7] Bahar Artim-Esen,[8] Gonca Mumcu,[9] Tulin Ergun,[10] And Haner Direskeneli[11], [1]Marmara University Faculty Of Medicine,Department Of Rheumatology,Istanbul,Turkey, Istanbul, Turkey, [2]Marmara University, School of Medicine, Radiology, Istanbul, Turkey, [3]Marmara University, School Of Medicine, Rheumatology, Istanbul, Turkey, [4]Kocaeli University, Faculty Of Medicine, Division Of Rheumatology, Kocaeli, Kocaeli, Turkey, [5]Marmara University, School of Medicine, Rheumatology, Istanbul, Tuvalu, [6]Bahcesehir University, School Of Medicine, Department Of Cardiovascular Surgery, Istanbul, Turkey, [7]Division Of Rheumatology, Kocaeli University School Of Medicine, Kocaeli, Turkey, Kocaeli, Turkey, [8]Istanbul University, Istanbul Faculty Of Medicine, Department Of Internal Medicine, Division Of Rheumatology, Istanbul, Turkey, [9]Marmara, University, Department Of Health Management, Marmara University School Of Health Sciences, Istanbul, Turkey, Istanbul, Turkey, [10]Marmara University, School Of Medicine, Dermatology, Istanbul, Istanbul, Turkey, [11]Marmara University, School Of Medicine, Division Of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Behcet's disease(BD) is a uniqe systemic vasculitis mainly involving venous vessels in contrast to other systemic vasculitides. Diagnosing BD is a challenge, especially in countries with a low prevalence. International Study Group Criteria, accepted to as diagnostic, has low sensitivity, especially in early cases when major organ involvement such as uveitis or deep vein thrombosis(DVT) presents alone. Pathergy (skin prick) test, the only specific diagnostic tool, has quite a low positivity. We recently published a controlled study of assessing venous wall thickness(VWT) as a surrogate marker of venous disease in BD with doppler ultrasound (US) and observed a very sensitive and specific VWT in male BD patients. The common femoral vein(CFV) thickness measurement, as the primary site of US with the cut-off values > 0.48-0.49 mm, had a high area under the receiver operating characteristic curve(>0.8) with sensitivity and specificity of around 80% (1). In this study, we aimed to investigate the diagnostic performance of CVF thickness measurement in BD including females comparing with multiple control disease groups.

Table 1: Venous Wall Measurements of Lower Extremity in Study Groups

	Behcet's Disease (n=110)	Healthy Controls (n=47)	Systemic Vasculitis (n=21)	Venous Insufficiency (n=28)	Anti-phospholipid Syndrome with DVT (n=29)
Age (years)	33.5 ± 6	30.1 ± 5	33.3 ± 7	36.7 ± 6	38.3± 9
Gender, male n (%)	89 (81)	40 (85)	12 (58)	13 (46)	9 (65)
Body Mass Index, kg/m2	25.5 ± 4	24 ± 2	23.8 ± 3.5	27.7 ± 4	27.2 ± 7
Right CFV Thickness (mm)	0.79 ± 0.3	0.34 ± 0.1	0.34 ± 0.15	0.38± 0.1	0.48 ± 0.15
Left CFV Thickness (mm)	0.78 ± 0.3	0.3 ± 0.1	0.36 ± 0.14	0.38 ± 0.2	0.48 ± 0.15

CFV: Common Femoral vein, DVT:Deep Venous Thrombosis

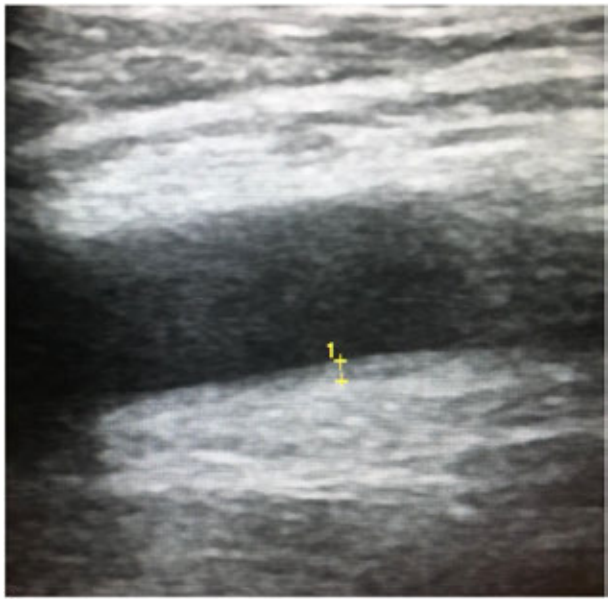

Figure 1. Measurement of common femoral vein thickness

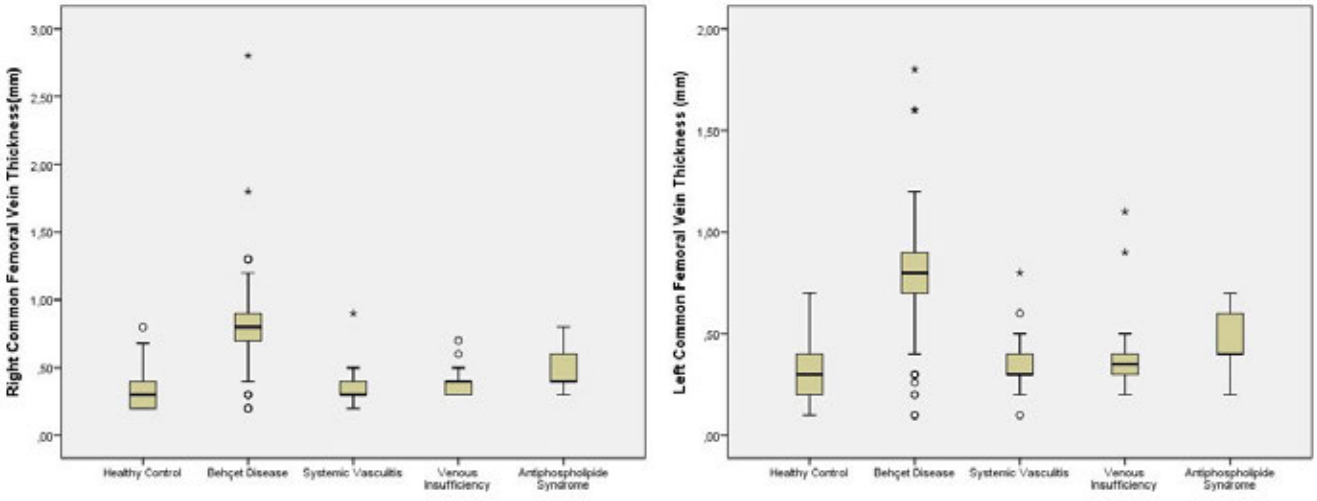

Figure 2. Distribution of common femoral vein thickness in study groups

Methods: One hundred-ten patients with BD, 47 healthy controls (HC), 21 patients with systemic vasculitides, 28 patients with venous insufficiency, 29 patients with antiphospholipid syndrome(APS) having DVT history, were included the study. Behcet's Syndrome Activity Score(BSAS) was used to assess disease activity. Bilateral CFV thickness was measured with US by an experienced radiologist blinded to cases(Figure 1).

Results: Bilateral CFV thickness was significantly higher in BD compared to all comparative groups ($p< 0.001$ for all)(Table 1 and Figure 2). No correlations were present between CFV thickness and both BSAS and CRP levels ($p >0.05$ for all). In only 2 (8%) patients with venous insufficiency and 2 (10%) patients with systemic vasculitis, bilateral CVF thickness was higher than the cut- off values. Interestingly, APS was the only control group with positivity, in 12 (41%) patients with APS, bilateral CFV thickness was higher than the cut-offs. There was no difference between male vs female BD patients regarding CVF thickness (right CFV:0.78±0.3 mm vs 0.79±0.1 mm,$p=0.96$, left CFV:0.78±0.3 vs 0.81±0.1, $p=0.80$). Although a higher CVF thickness tendency was observed in VBD, no statistically significant

difference was present between BD patients with (n=40) and without (n=58) vascular involvement (right CFV:0.82±0.3 mm vs 0.75±0.3 mm, p=0.122, left CFV:0.84 ± 0.3 vs 0.76±0.3, p=0.165).

Conclusion: Increased CFV thickness is present in BD patients, independent of vascular involvement. We also found that CFV thickness is a distinctive feature of BD, rarely present in other inflammatory/vascular diseases such as ankylosing spondylitis (previously shown), systemic vasculitides and venous insufficiency (except APS with DVT). CFV thicknesses are easily and reliably measured by Doppler US. We, therefore, suggest that assessment of CFV can be a diagnostic tool for Behcet's disease with a good sensitivity and specificity to differentiate BD from similar disorders.

Low-Dose IL-2 Effectively Restored Decreased Regulatory T Cells in Patients with Behcet's Disease

Xiao-qing Liu,[1] Xiaojie Liu,[2] Nalin Lai,[3] Ting Cheng,[1] Chong Gao,[4] and Xiao-feng Li[1], [1]The Second Hospital of Shanxi Medical University, Taiyuan, China (People's Republic), [2]Taiyuan University of Technology, Taiyuan, China (People's Republic), [3]Shanxi Medical University, Taiyuan, China (People's Republic), [4]Brigham and Women's Hospital, Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders I: Miscellaneous Disorders
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Behcet's disease (BD) is a chronic multisystemic disease characterized by muco-cutaneous and ocular manifestations, with central nervous system, vascular and/or gastro-intestinal involvement. Several studies have shown that immune mechanisms play an important role in the development of the disease and limited options of therapeutic medicines for BD. Low dose IL-2 has been reported to selectively promote the expansion of Treg. This study aimed to investigate the significance of Treg cells in the pathogenesis and the effect of low dose IL-2 on BD.

Methods: Absolute number of CD4+CD25+FOXP3+Treg, CD4+IL17+T (Th17) and other subsets in peripheral blood (PB) from 173 patients with BD and 90 healthy donors were characterized by flow cytometry combined with an internal microsphere counting standard. Thirty-nine patients were treated with daily subcutaneous injections of 0.5 million IU of human IL-2 for five consecutive days, and then its effects on lymphocyte subpopulations in PB were analyzed.

Results: There was a significant disturbance in lymphocyte subpopulations mainly manifested as the decreased level of Tregs compared with the health controls (median:22.32 cells/ul VS median:33.12 cells/ul, $P< 0.001$) and it was correlated negatively with BDCAF, ESR and CRP ($P < 0.01$), suggesting an important role of Tregs in sustained high disease activity. While no major difference in the absolute counts of circulating Th17 cells between patients with BD and health control. Accordingly, the ratios of Th17/Treg in patients with BD (median:0.38) were significantly higher

than those of health control (median:0.21). Moreover, low dose IL-2 effectively increased the number of Tregs ($P < 0.001$) and re-balance the ratio of Th17 and Tregs, leading to clinic symptom partly remission in a rapid way without observed side effects.There was a significant disturbance in lymphocyte subpopulations mainly manifested as the decreased level of Tregs compared with the health controls (median:22.32 cells/ul VS median:33.12 cells/ul, $P< 0.001$) and it was correlated negatively with BDCAF, ESR and CRP ($P < 0.01$), suggesting an important role of Tregs in sustained high disease activity. While no major difference in the absolute counts of circulating Th17 cells between patients with BD and health control. Accordingly, the ratios of Th17/Treg in patients with BD (median:0.38) were significantly higher than those of health control (median:0.21). Moreover, low dose IL-2 effectively increased the number of Tregs ($P < 0.001$) and re-balance the ratio of Th17 and Tregs, leading to clinic symptom partly remission in a rapid way without observed side effects.

Conclusion: Absolute decrease of PB Tregs in patients with BD was associated with disease activity ,which might be the major reason for imbalance of Th17/Tregs. It is speculated that BD is an autoimmune disease triggered by the defect of immunotolerance. More importantly, low-dose IL-2 proposes a selective biological treatment strategy by restoring immune tolerance and promoting rapidly remission.

Abstract Number: 0951

Avoidable Acute Care Use for Vaccine-Preventable Illnesses Among Medicaid Beneficiaries with Lupus: Demographic and Healthcare Utilization Differences

Candace Feldman,[1] Chang Xu,[1] and Karen Costenbader[1], [1]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research I: Clinical Perspectives
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Nearly 25% of patients with SLE are hospitalized each year often for outcomes that may have been avoided if patients had received sustained, high quality outpatient care. A recent Delphi panel defined SLE-specific adverse outcomes that may result in avoidable acute care use (emergency department [ED] visits or hospitalizations) and included 7 vaccine-preventable illnesses. We used U.S. nationwide data from a vulnerable SLE population to describe the burden of acute care use for these illnesses and to examine demographic and healthcare utilization predictors.

Methods: Using claims data from Medicaid (public insurance for low income individuals) from 29 U.S. states (2000-2010), we identified adults (18-65 years) with prevalent SLE (≥3 ICD-9 codes 710.0 separated by ≥30 days). We required 12 months of enrollment prior to the first code (index date) to identify baseline comorbidities, vaccine uptake, and healthcare utilization. We defined avoidable acute care use for vaccine-preventable illnesses as discharge diagnosis codes from ED visits or hospitalizations for influenza, pneumococcal disease, meningococcal disease, herpes zoster, high-grade cervical dysplasia/cervical cancer, and hepatitis B, after the index date. We estimated the incidence rate (IR) of acute care use for vaccine-preventable illnesses and used Cox regression to assess risk (HR, 95% CI) of first acute care visit for vaccine-preventable illnesses by baseline demographics and healthcare use, adjusting for vaccinations, SLE-related comorbidities and medications.

Table 1: Incidence rates of acute care use* for vaccine-preventable illnesses among Medicaid beneficiaries with SLE (N=46,075)				
	Number of patients	Person-years	Incidence Rate per 1,000 person-years (95% CI)	Percent of events in patients without vaccine claims**
Composite of vaccine-preventable illnesses†	1340	195,960	6.8 (6.5-7.2)	93%
Herpes zoster	490	199,382	2.5 (2.2-2.7)	97%
Influenza	412	199,669	2.1 (1.9-2.3)	95%
Pneumococcal disease	325	200,283	1.6 (1.4-1.8)	NR
Hepatitis B	91	201,340	0.5 (0.4-0.5)	100%
High-grade cervical dysplasia/Cervical cancer	58	190,321	0.3 (0.2-0.4)	100%
Meningococcal disease	26	201,444	0.1 (0-0.1)	100%
*Acute care use includes emergency department visits or hospitalizations †31 SLE patients had more than one vaccine-preventable illness but were included once in the composite measure **Vaccine claims during the 12-month baseline period NR= In accordance with CMS policies, cell sizes >0 and <11 are not reported; percent of events among patients who received pneumococcal vaccine is within this range				

Table 1 Vaccine Prevent Illness ACR

Results: We identified 46,075 Medicaid beneficiaries with SLE with mean follow-up of 4 (SD 3) years. The mean age was 39 (SD 12) and 93% were female, 40% were black, 38% white, 13% Hispanic, 2% Asian. Vaccine uptake during the 12-month baseline period included: 3,331 (7.2%) receiving the influenza vaccine, 1,020 (2.2%) shingles, 551 (1.2%) pneumococcal, 290 (0.63%) hepatitis B, 91 (0.2%) human papillomavirus, and 17 (0.04%) meningitis. The incidence rate of acute care use for vaccine-preventable illnesses was 6.8 per 1,000 person-years; most were herpes zoster, influenza or pneumococcal disease (**Table 1**). 93% of events occurred in patients who had not received baseline vaccinations. In adjusted analyses, we observed a higher risk of acute care use for vaccine-preventable illnesses among black patients, in the Midwest and South, and among patients with more baseline ED visits and hospitalizations (**Table 2**). Greater outpatient visits were associated with a dose-response reduction in acute care use, with >30% reduced risk (HR 0.69, 95% CI 0.56-0.74) comparing >10 visits to none.

Conclusion: Claims for vaccinations in this nationwide, vulnerable population of SLE patients were rare, likely reflecting a combination of underreporting and low uptake. As expected, patients with vaccine claims had minimal acute care use for vaccine-preventable illnesses. Greater outpatient use was associated with significantly reduced risk of ED visits and hospitalizations for vaccine-preventable illnesses suggesting that established, consistent outpatient care with optimal SLE monitoring and management, and access to preventive care, can reduce avoidable acute care use.

Table 2: Multivariable Cox regression model for first episode of acute care use for vaccine-preventable illnesses by demographic factors and baseline healthcare utilization among Medicaid beneficiaries with SLE (N=46,075)	
Variables	**Hazard ratio (95% Confidence Interval)**

Abbreviations: ESRD = end-stage renal disease, CHF = chronic heart failure, COPD= chronic obstructive pulmonary disease, ADI = Area Deprivation Index

Background/Purpose: Medicare measures readmissions within 30 days of hospitalization across several conditions as a marker of care quality. While not currently a reporting condition, in systemic lupus erythematosus (SLE) observed 30-day readmission rates range from 17-27%, rivaling reportable conditions such as congestive heart failure (CHF). No controlled studies thus far have performed such between-condition comparisons. Using a nationwide

Medicare cohort, we compared adjusted readmission rates among SLE, CHF, and the general Medicare population, and assessed relationships between patient and hospital factors and 30-day readmissions in SLE with the goal of identifying targets for readmission prevention measures.

Methods: Using claims data from a 20% random US national Medicare sample, we identified all patients with inpatient hospitalizations in 2014 to compare risk of 30-day readmission among patients with SLE to those with CHF and the general Medicare population. Inclusion required age of at least 18 years old, live discharge, and at least 12 months of continuous Medicare part A and B coverage prior to index admission. Baseline patient and hospital covariates included age, sex, race, ethnicity, Medicaid, baseline year comorbidity, prior hospitalization, hospital volume, medical school affiliation, and area deprivation index (ADI)–a measure of neighborhood disadvantage from patients' census block group. Analysis used multivariable Cox proportional-hazards regression clustered by patient to find adjusted hazard ratios (HRs) of 30-day readmission among patients with SLE compared to those with CHF and the general Medicare population.

Results: The SLE cohort (n=10,868) was younger by nearly 20 years and predominantly female. They were twice as likely to be Black, on Medicaid or disabled, and had nearly four-fold higher ESRD as compared to CHF or general Medicare (Table 1). The 30-day readmission rate of 24% was identical for SLE and CHF, and significantly higher than the general Medicare cohort rate of 18%. Patients with CHF and SLE had similarly elevated hazard ratios for readmission (HR 1.190, 95% CI 1.190, 1.191 and HR 1.192, 95% CI 1.192, 1.192, respectively; Table 2), compared to patients without either condition. Among patients with SLE, readmission risk was highest in the 18-33 age group (Table 3). Higher readmission risk was also observed in SLE patients who were Black, Native American, hospitalized within the past year, and who had comorbidities including CHF, COPD, and ESRD. Dual Medicaid status predicted slightly increased risk, and hospital factors were more modestly predictive. Overall, primary diagnoses for readmissions did not significantly differ between groups.

Conclusion: 30-day readmission rates in SLE are as high as those in CHF, with readmissions impacting one in four hospitalized SLE patients. Transitional care programs, Medicare policies, and other efforts designed to reduce readmissions should consider focusing on SLE, a high risk group for readmissions that is currently not widely recognized as such. Existing interventions should particularly target SLE patients who are younger, with ESRD or prior hospitalization.

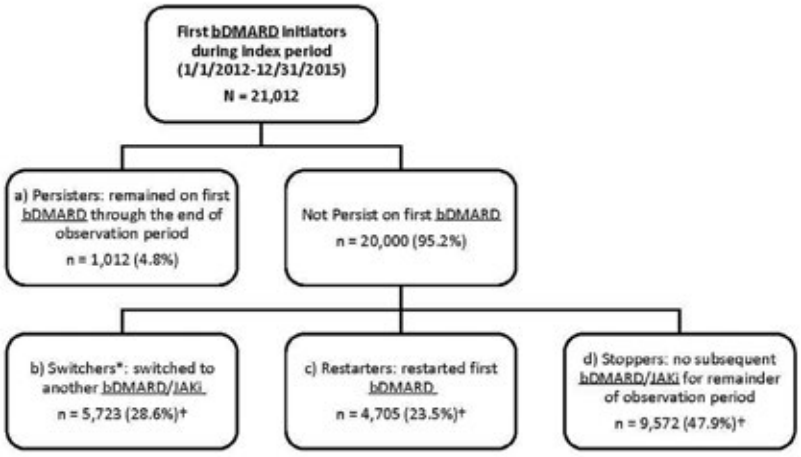
bDMARD, biologic DMARD; IQR, interquartile range; SD, standard deviation.

Background/Purpose: In RA patients not meeting treat-to-target goals despite treatment with a biologic (b)DMARD, ACR guidelines[1] recommend using other targeted immunomodulators (TIM): TNF-α inhibitor (TNFi), non-TNFi biologic (b)DMARDs, or a Janus kinase inhibitor (JAKi). Understanding treatment disposition and persistency can help optimize next treatment selection among Medicare recipients who initiated first bDMARD. We described treatment patterns and persistency in Medicare RA patients on first bDMARD.

Methods: In 20% sample of Medicare fee-for-service beneficiaries, the study population comprised RA patients (≥1 RA claims + ≥1 DMARD claims) who initiated (index date) their first bDMARD between 01/2012 and 12/2015 (no bDMARD use ≥12 months pre-index), without cancer or non-RA autoimmune disease. Subsequent treatment patterns were described during a follow-up period ending 12/2016, with censoring at death or end of Medicare coverage. Patients were grouped as Persisters (persisted on their first bDMARD) or Non-Persisters (did not persist), the latter being divided into Switchers (switched to another TIM), Restarters (restarted the first bDMARD after a gap), and Stoppers (stopped TIMs altogether). Persistency loss was estimated through Kaplan-Meier time-to-event analysis, with the event being discontinuation or first gap in initial bDMARD coverage exceeding 60 days past next-refill due date. Persistency was estimated for all patients and stratified by Non-Persisters, and then further by Switchers, Restarters, Stoppers.

Figure 1. Patient Disposition



*Switchers: 1291 patients switched to another bDMARD/JAKi before completing all prescribed days of their first bDMARD (medication possession), with 762 switching within 30 days prior to end of first bDMARD medication possession
†Percentages shown are within the 20,000 Non-Persisters. The estimates as a percent of N=21,012 first bDMARD initiators: Switchers 27.2%, Restarters 22.4%, and Stoppers 45.6%
bDMARD, biologic DMARD; JAKi, Janus kinase inhibitor.

Results: The sample of 10,314,539 enrollees contained 154,311 RA patients, including 21,012 patients initiating bDMARD (52% intravenous, 48% subcutaneous): 79% female with mean age 66 years (Table). The sample consisted of 1,012 (4.8%) Persisters, 5,723 (27.2%) Switchers, 4,705 (22.4%) Restarters, and 9,572 (45.6%) Stoppers (Figure 1). Among all bDMARD initiators, 22.0% lost persistency by month 2 and 56.0% by month 12 (Figure 2a). Within Non-Persisters, the probability of losing persistency at month 12 was 58.9% overall, 72.4% for Switchers, 73.0% for Restarters, and 43.8% for Stoppers (Figure 2b). Among Non-Persisters, incident events peaked at months 1, 3, 6, 9, 12, 24, 36, 48, and 60; with contributions to persistency loss similar for all groups until month 12, after which Stoppers largely drove ongoing loss of persistency (Figure 2b, c).

Conclusion: After initiating their first bDMARD, Medicare beneficiaries with RA experienced substantial treatment interruptions, demonstrating deviations from the standard treatment-escalation approach described in the ACR guidelines. Over half the patients lost persistency on first bDMARD by year 1. Moreover, almost half of those who lost persistency on first bDMARD remained off TIM therapy altogether, suggesting a substantial unmet need for treatment in this patient population that warrants further investigation.

Physical Therapy and Opioid Use in Knee Osteoarthritis

Deepak Kumar,[1] Christine Peloquin,[2] Andrew Stokes,[3] Lee Marinko,[4] James Camarinos,[4] David Felson,[5] and Maureen Dubreuil[2], [1]Boston University, Boston, MA, [2]Boston University School of Medicine, Boston, [3]Boston University School of Public Health, Boston, [4]Boston University, Boston, [5]Boston University School of Medicine, Department of Rheumatology, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research I: Clinical Perspectives
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Knee osteoarthritis (OA) is a leading cause of chronic pain in older adults. Physical therapy (PT) decreases OA pain and consequently may reduce burden of opioid use in this population. The purpose of this study was to investigate the associations of type, dose, and timing of PT with utilization of opioids following PT in individuals with incident knee OA who had used opioids in the past or were opioid naïve, using data from a large claims database.

Methods: We conducted a cohort study using 2000-2014 data from the OptumLabs® Data Warehouse (OLDW), a longitudinal, real-world dataset with de-identified administrative claims and electronic health record (EHR) data. We included adults between the ages of 40-89, who after ≥ 6 months of claims data, had a knee OA diagnosis using ICD9 codes, the date of which we defined as the index date. We excluded individuals with OA-related surgeries, knee injuries, PT, cancer, or rheumatoid arthritis within 6 months prior to index date. Only persons who received PT within 12 months of the index date and who had at least 1 year of follow-up after the first PT episode of care were included. The first PT episode of care was considered to start with an initial PT evaluation followed by at least one treatment session, and was considered to end if there was a 4-week period with no PT claim or if a second evaluation was recorded. We studied several PT exposures including dose (number of sessions), timing and active versus passive modality (Table 1). The outcome was any opioid use in the 12 months after the end of the PT episode of care. Opioid use was defined as at least 2 filled prescriptions of opioids commonly used for musculoskeletal pain. Combinations of opioids with medications commonly used for cough, nasal congestion, and headache were excluded. We conducted the analyses in individuals who had used opioids prior to PT ("opioid experienced") and those who had not used opioids prior to PT ("opioid naïve"). Covariates included age, hyperlipidemia, diabetes, and overweight/obesity. Adjusted odds (aOR) of receiving opioids were assessed (Table 1) using logistic regression.

Exposure	Definition	Modeling	Reference category
Dose of PT	Number of PT sessions on unique dates within the first PT episode of care	1-5 sessions, 6-12 sessions, > 12 sessions	1-5 sessions
Timing of PT	Time between knee OA diagnosis and start of first PT episode of care	<3 months, 3-<6 months, 6-<9 months, 9-<12 months	<3 months
Active vs. passive PT	Active PT defined as only active PT treatment codes (e.g. therapeutic exercise, gait retraining, etc.); passive PT = passive treatment codes (e.g. ultrasound, hot pack, manual therapy, etc.).	Active (only active or active ≥ passive), passive (only passive or passive > active)	Passive

Table 1. Exposure definitions

Variables		Opioid Experienced			Opioid Naïve		
		Subjects	Opioid Use	aOR	Subjects	Opioid Use	aOR
Total		32,324	18,901 (58.5%)		39,302	6,092 (15.5%)

	6-12	30.1%	55.3%	0.65 (0.62, 0.69)	31.6%	13.8%	0.79 (0.74, 0.84)
	>12	23.0%	48.1%	0.49 (0.47, 0.52	12.5%	13.6%	0.77 (0.70, 0.84)
Physical Therapy Timing (Months)	<3	49.5%	57.8%	REF	72.0%	14.9%	REF
	3-<6	25.1%	57.3%	0.98 (0.93, 1.04)	13.3%	18.0%	1.26 (1.17, 1.37)
	6-<9	14.5%	60.2%	1.10 (1.03, 1.17)	8.3%	16.5%	1.14 (1.03, 1.26)
	9-<12	10.9%	62.1%	1.20 (1.11, 1.29)	6.3%	16.2%	1.11 (1.00, 1.25)
Active vs. Passive Physical Therapy	Passive	25.8%	61.2%	REF	26.5%	15.6%	REF
	Active	74.2%	57.5%	0.86 (0.82, 0.91)	73.5%	15.5%	1.00 (0.94, 1.06)

Table 2. Prevalence of exposure and outcomes among opioid experienced and naïve individuals

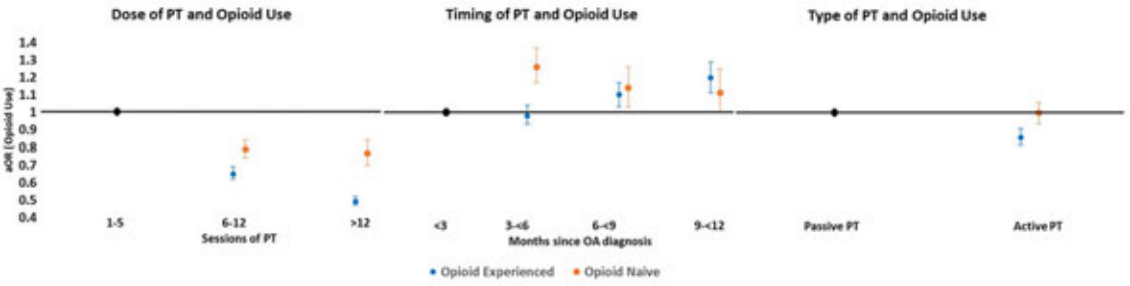

Figure 1. Adjusted odds ratios of opioid use among opioid experienced and naïve individuals

Results: We included 32,324 opioid experienced (age=60.9±10.3 years; 61.5% female) and 39,302 opioid naïve individuals (age=62.6±11.2 years; 66.0% female) (Table 2). Among both opioid experienced and opioid naïve individuals, more than 5 sessions of PT and early PT after knee OA diagnosis (vs. > 6 months) were associated with reduced odds of opioid use (Table 2, Figure 1). Among opioid naïve individuals, receiving PT >3 months after diagnosis vs. earlier was related with increase odds of opioid use (Table 2, Figure 1). Receiving active PT (vs. passive PT) was associated with reduced odds of further opioid use in opioid experienced individuals but not in the opioid naïve group (Table 2, Figure 1).

Conclusion: PT provided earlier after OA diagnosis, more than 5 sessions of PT, and use of active PT interventions may reduce opioid use in people with knee OA. These results provide guidance on optimal dosage, timing, and type of PT interventions that might be effective at reducing opioid use in this population.

Adherence to Statin Therapy in Rheumatoid Arthritis Patients: A Population-Based Cohort Study

Tom Hahn,[1] Eric Sayre,[2] Maria Victoria Goycochea-Robles,[3] and **Diane Lacaille**[4], [1]Department of Medicine, University of British Columbia, Vancouver, Canada, [2]Arthritis Research Canada, Vancouver, BC, Canada, [3]Unidad de Investigación en Epidemiologia HGR 1, Mexican Institute of Social Security -, Mexico City, Mexico, [4]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research I: Clinical Perspectives
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Cardiovascular diseases (CVD) are increased in RA and lead to premature mortality. Statins are effective at preventing incidence of, and mortality from, CVD; yet, adherence can be problematic. The objective of this study was to assess adherence to statin therapy in a population-based cohort of rheumatoid arthritis (RA) patients compared to the general population, and to identify the predictors of statin discontinuation in the RA cohort.

Methods: A population-based cohort study using administrative health data was conducted on all incident RA patients in the Province, identified using physician billing data and previously published criteria, and general population controls matched (2:1) on age, sex and calendar year. The study included all individuals who initiated a statin for the first time between January 1997 and December 2009, with follow-up until December 2014. Statin discontinuation was defined as a gap in medication dispensing of ≥4 months. The primary outcome was survival time from statin initiation until first discontinuation , and the secondary outcome was the proportion of days covered (PDC) of medication, calculated only during courses of active statin use (i.e., excluding periods of statin discontinuation), which represents the percentage of the time when a medication is taken as prescribed. A multivariable Cox proportional hazards models was used to identify the predictors of statin discontinuation in the RA sample only.

Results: The sample includes 4845 incident RA patients who were incident statin users, and 9204 individuals from the general population, providing 16728 and 34351 PY of follow-up, resp. 82.4% of the RA and 80.2% of the general population cohorts had at least one discontinuation; and 42.2% of RA and 40.2% of the general population permanently discontinued statin therapy during follow-up. Figure 1 shows that survival on statin (time to first statin discontinuation) was slightly lower for RA than general population ($p < 0.001$). Median survival was 2.29 years for RA patients and 2.64 years (for controls. Incidence rate of discontinuation was 23.87 per 100PY for RA and 21.48 per 100PY for the general population, yielding an incidence rate ratio (IRR) of 1.11; 95% CI, 1.07 – 1.16. Adherence [Mean (SD) PDC] during treatment courses was 92.9 (9.3)% in RA patients and 92.7 (9.4)% among controls. Significant pre-

[1] *Adjusted HR's from a combined multivariable model. HR = hazard ratio; 95% CI = 95% confidence interval; RA = rheumatoid arthritis; MI = myocardial infarction; CVA = cerebrovascular accident; CVD = cardiovascular disease; DMARD = disease-modifying antirheumatic drug.*

[2] *DMARD categories: 1 = no DMARD use; 2 = antimalarial drugs, sulfasalazine; 3 = methotrexate, intramuscular gold; 4 = leflunomide, cyclosporine A, azathioprine, cyclophosphamide, chlorambucil, or mycophenolate mofetil; and 5 = biologics.*

[3] *Evaluated over the 1 year preceding statin initiation.*

[4] *Evaluated prior to statin initiation since 1990 (earliest available data).*

[5] *P value for Chi-square test.*

dictors of statin discontinuation in RA included number of daily medications; use of CVD medications; previous MI; higher income; and depression (Table 1).

Conclusion: Findings from our population-based study indicate that RA patients and the general population both frequently discontinue statin therapy, but have high adherence during periods of statin use. Rates of statin discontinuation were slightly higher in RA patients, despite an increased risk of CVD. Risk of discontinuation was lower in RA patients with a higher number of daily meds, use of cardiovascular meds, prior MI, and higher income, and was higher in patients with depression. These results emphasize the importance of discussing adherence.

The Impact of Psychiatric Comorbidity on Health Care Utilization and Preventive Health Care in Rheumatoid Arthritis: A Population Based Study

Carol Hitchon,[1] Charles Bernstein,[1] James Bolton,[1] Renée El-Gabalawy,[1] John Fisk,[2] Alan Katz,[1] Lisa Lix,[3] James Marriott,[1] Scott Patten,[4] Christine Peschken,[3] Jitender Sareen,[1] Alexander Singer,[1] Randy Walld,[1] and Ruth Ann Marrie[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Dalhousie University, Halifax, NS, Canada, [3]University of Manitoba, Winnipeg, Canada, [4]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Health Services Research I: Clinical Perspectives
Session Type: ACR/ARP Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Psychiatric comorbidity is increased in rheumatoid arthritis (RA) and may complicate medical care, increasing the risk of adverse health outcomes and health care utilization (HCU). We describe the impact of psychiatric comorbidity in RA on HCU (ambulatory care visits, hospitalizations, number of hospital days, prescription drugs) including recommended preventive health care (influenza vaccination, pap and mammogram tests).

Methods: We accessed administrative health data (1984-2016) from a region with near universal health coverage and identified a prevalent cohort with diagnosed RA (n=16975). We matched each RA case on age and sex with up to 5 controls (CNT) with no RA diagnosis (n= 84756). Psychiatric morbidities including depression, anxiety and bipolar disorder (PsyMb) were identified in RA cases and CNT. Annual rates of ambulatory care visits [mean visits (SD)/person], all-cause hospitalization (%), days of hospitalization [(mean days (SD)/hospitalization], total prescribed drugs (mean (SD)/person), influenza vaccination (%), pap tests (%), and mammograms (%), were age and sex-standardized to the 2010 Canadian population. Ambulatory care visits were categorized by provider (family physician [FP], rheumatologist, mental health specialist, other specialist). We compared rates of HCU and preventive care amongst four groups (CNT, CNT+PsyMb, RA, RA+PsyMb) using generalized linear models adjusted for age, sex, rural vs urban residence, income quintile, total comorbidities (assessed by John Hopkins Aggregated Diagnostic Groups), DMARD prescription, and RA-specific procedures (e.g. arthroplasty). Rates and percentages are reported with 95% confidence intervals (CI). We tested whether PsyMB and RA had additive or synergistic effects on HCU or preventive care.

Results: Most RA patients were female (72%) and urban residents (59%). Mean age at diagnosis was 54(SD:16) years. Mean follow-up duration was 13(SD:9) years. After adjustment, compared to RA without PsyMb, those RA with PsyMb had an additional 3.7 (95%CI: 3.5-3.9, p< 0.0001) ambulatory visits/year, 2.3% (95%CI: 1.8-2.8; p< 0.0001) increased hospitalization, 0.7 (95%CI: 0.5-0.95 p< 0.0001) more hospital days/admission and were prescribed 2.3 (95%CI 2.2-2.5; p< 0.0001) more drugs (Table). RA+PsyMb had increased ambulatory care visits for all providers particularly FPs [additional 2.9 FP visits/year (2.8, 3.0); interaction between RA, Psych and provider p< 0.0001] (Figure). Overall rates of preventive care in RA were 34% for influenza vaccination, 38.3% for mammograms and 43.3% for pap tests when indicated. RA+PsyMb had increased influenza vaccinations (5.5%; 4.8-6.2%, p< 0.0001) and screening mammograms (4.7%; 3.7-5.7%, p< 0.0001) but not pap tests (0.2%; -1-0.06%, p=0.6). No interactive effects were significant for influenza vaccination or mammogram preventive measures between RA and RA+PsyMb (Table).

Conclusion: Psychiatric comorbidity increases health care utilization among those with RA, particularly for FP visits. Increased contact with care providers may contribute to higher rates of some preventative care such as vaccination, but overall preventive care rates remained suboptimal.

Group	Ambulatory visits Mean (95% CI)	Number drugs Mean (95% CI)	Hospitalization % (95%CI)	Hospital days Mean (95% CI)	Influenza vaccine % (95%CI)	Pap test % (95%CI)	Mammogram % (95%CI)

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Age-associated B cells (ABCs) are a novel B cell subset, which expands with age in non-autoimmune mice but accumulates prematurely in autoimmune-prone strains. ABCs exhibit unique phenotypic and functional characteristics. In addition to classical B cell markers, ABCs also express myeloid markers such as CD11c. ABC differentiation depends on T-bet and is promoted by TLR7 stimulation and cytokines like IFN-g and IL-21. While ABCs have been proposed to play a key role in the development of autoimmune diseases, the mechanisms regulating ABC formation and function are poorly understood. The SWEF proteins are a small family of proteins that includes SWAP-70 and its homolog DEF6, a recently identified risk variant for human SLE. The lack of SWEF proteins leads to the spontaneous development of a lupus-like syndrome, which, similarly to human SLE, preferentially occurs in females. We have recently shown that ABC formation is enhanced in SWEF-deficient mice (=DKO mice). Given that alterations in cholesterol homeostasis can promote autoimmunity, here we have investigated whether the accumulation and/or function of ABCs in SWEF-deficient mice could be affected by changes in the expression of the LDL receptor (LDLR) and/or a High Cholesterol Diet (HCD).

Methods: We have generated DKO mice, which also lack the LDLR (LDLRKO-DKOs), to assess the effects of metabolic dysregulation on the development of autoimmunity in DKO mice. Mice were fed either chow or a HCD. T_{FH} cells, ABCs, germinal center B cells (GCBs), and plasma cells (PCs), were analyzed in the spleens of DKO females and males, LDLRKO-DKO females and males and control mice (WT, LDLRKO females and males) by FACS. To monitor the severity of the lupus phenotype, autoantibody levels were tested by ELISAs and end-organ inflammation was assessed by histology.

Results: As compared to wt mice, DKO mice exhibit an accumulation of T_{FH} cells, ABCs, GCBs, and PCs (F >M). DKO female mice with a concomitant deletion of the LDLR (LDLRKO-DKOs) fed a chow diet displayed a similar expansion of ABCs, GCBs, and PCs to DKO female mice. As compared to DKO females, LDLRKO-DKO females on a chow diet however displayed increased focal chronic inflammation of skeletal muscles and joints. Feeding a HCD to LDLRKO-DKO female mice did not substantially affect the expansion of ABCs, GCBs, and PCs. Interestingly, as compared to DKO males on a chow diet, DKO males fed a HCD exhibited a marked increase in ABCs, GCBs, and PCs, which was associated with an increased production of autoantibodies. LDLRKO-DKO males on either a chow or a HCD exhibited an increase in PCs and a more variable increase in ABCs and GCBs.

Conclusion: ABCs accumulate to a similar manner in female DKO mice irrespective of the concomitant absence of the LDLR. Lack of the LDLR in DKO female mice, however, leads to increased tissue inflammation. A HCD can pro-

mote marked expansion of ABCs in DKO male mice and promote the production of autoantibodies. Thus, alterations in cholesterol homeostasis can affect ABC accumulation and other autoimmune parameters in a sex-specific manner.

Identification of IFN-γ-producing Effector B Cells in Humans: Their Relevance to the Pathogenesis of Systemic Lupus Erythematosus

Kazuhiko Higashioka,[1] Masahiro Ayano,[2] Yasutaka Kimoto,[3] Hiroki Mitoma,[2] Mitsuteru Akahoshi,[2] Yojiro Arinobu,[2] Koichi Akashi,[1] Takahiko Horiuchi,[4] and Hiroaki Niiro[5], [1]Department of Medicine and Biosystemic Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan, [2]Department of Medicine and Biosystemic Science, Graduate School of Medical Sciences, Fukuoka, Japan, Fukuoka, Japan, [3]Department of Internal Medicine, Kyushu University Beppu Hospital, Beppu, Japan, [4]Department of Internal Medicine, Kyushu University Beppu Hospital, Beppu, Japan, Beppu, Japan, [5]Clinical Education Centre, Kyushu University Hospital, Fukuoka, Japan, Fukuoka, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune, multi-systemic disease that potentially affects any organ in the body. Clinical efficacy of B cell-targeting therapy underscores a crucial role of the antibody (Ab)-independent functions of B cells in the pathogenesis of SLE. Among such functions, cytokine production by B cells has recently gained much attention. The type 2 interferon IFN-γ is a key cytokine involved in SLE and produced by a variety of immune cells, however it remains somewhat elusive whether human B cells have potential to produce this cytokine. Here, we have sought to identify IFN-γ-producing B cells in humans and investigate their role in the pathogenesis of SLE.

Methods: B cell subsets from peripheral blood (PB) from healthy controls (HC) and patients with SLE were enriched by cell sorting, stimulated with $CD4^+$ T cell-related cytokines and subjected to the analysis of IFN-γ expression at both mRNA and protein levels. To check whether IFN-γ-producing B cells can be induced by $CD4^+$ T cells, we co-cultured B cells with $CD4^+$ T cell subsets. To determine the functional impacts of IFN-γ-producing B cells on $CD4^+$ T cells, B cells from patients with SLE were co-cultured with $CD4^+$ T cells. In addition, we thoroughly analyzed the surface markers of IFN-γ-producing B cells in HCPB and investigated whether this unique B cell subset coexists with $CD4^+$ T cell subsets in the effusion of SLE patients with pleuritis.

Results: Among a panel of $CD4^+$ T cell-related cytokines, IFN-γ and IL-21 significantly facilitated the generation of IFN-γ-producing B cells particularly from switched-memory (IgD^-CD27^+) B cells.In the presence of anti-BCR/CD40L with IFN-γ and IL-21 which mimics stimulation of B cells by follicular helper $CD4^+$ type 1 cells (Tfh1 cells), the $CXCR3^+$ fraction of switched-memory B cells strongly produced IFN-γ. Consistent with this, circulating Tfh1 cells from HCPB induced IFN-γ production from $CXCR3^+$ switched-memory B cells. IFN-γ-producing B cells were enriched in the $CD226^+PD\text{-}1^+$ fraction. The frequency of $CXCR3^+$ switched-memory B cells was higher in patients with SLE than HC. Intriguingly, under Tfh1 conditions $CXCR3^+$ switched-memory B cells from patients with SLE further accelerated IFN-γ production from $CD4^+$ T cells. In the effusion of SLE patients with pleuritis, Tfh1 cells were the predominant Tfh subset and $CD226^+PD\text{-}1^+CXCR3^+$ switched-memory B cells produced high amounts of IFN-γ.

Conclusion: Together, these findings clearly suggest the existence of IFN-γ-producing effector B cells in humans that are involved in the pathogenesis of SLE via closely interacting with $CD4^+$ T cells.

A Novel Image Analysis Program, "CytoSkaler", Demonstrates That Anti-Vimentin Antibody Affinity Maturation in Lupus Tubulointerstitial Nephritis Also Results in More Selective Antigen Targeting

Andrew Kinloch,[1] Aazam Mohsin,[1] Yuta Asano,[1] Carole Henry,[1] Nirit Mor Vaknin,[2] Maureen Legendre,[2] Patrick Wilson,[1] David Markovitz,[2] and Marcus Clark[1], [1]University of Chicago, Chicago, IL, [2]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vimentin is a dominant target of B-cells selected in lupus tubulointerstial inflammation (TII), a predictor of renal failure. The origins of anti-vimentin antibodies (AVA) are unknown. Technologies quantifying specific antigenic targeting do not exist. **Objectives**:$_1$ Characterize reactivities of germline BCR precursors of TII AVAs; $_2$ Develop software to quantify mAb reactivity with subcellular regions of cultured cells and tissue; $_3$ Quantify selectivity of mAbs for vimentin vs other cellular antigens; $_4$ Determine somatic hypermutations (SHMs) influential in Vimentin selectivity.

Methods: 10 human IgG1 AVA mAbs (from 6 TII patients) in selected (sel) and germ-line reverted (rev) forms, and 21 mAbs from naïve healthy B-cells were generated. Recombinant human vimentin (native and citrullinated) reactivity was assayed by ELISA. HEp-2 cells were co-stained with TII AVAs (sel and rev) and subcellular markers (nuclear [Hoechst], vimentin [mAb V9] and cytoplasm [mAb eno-1]), and imaged by multicolor immunofluorescence laser scanning confocal microscopy. Single amino acid variants of TII mAbs "PB4" (n=16) and "PB5" (n=11), representing single SHM reversions were also assayed. Lupus TII tissue was co-stained with novel FLAG-tagged variants of PB4 and PB5 (sel and rev). Mean pixel intensity (MPI) was a measure of magnitude of human mAb reactivity. Vimentin selectivity was quantified by co-variance of binding (Pearson Correlation coefficient of MPI with anti-vimentin channel), or ratio of MPI of vimentin positive : other respective subcellular region. A machine learned software ("CytoSkaler") was developed to identify individual cultured cells, and subcellular areas, allowing measurement of human mAb reactivities (MPIs) with subcellular regions. CytoSkaler was also used for quantifying reactivity with subcellular regions of TII tissue.

Results: 9/10 reverted TII AVA mAbs had reduced vimentin reactivities by ELISA, comparable to those of naïve healthy B-cell derived mAbs. All TII mAbs had lower reactivities with citrullinated antigen. CytoSkaler yielded highly accurate cell segmentation estimations (accuracy =0.97, intersection of union =0.96), allowing high throughput quantification of human mAb reactivities with subcellular regions. Typically, CytoSkaler demonstrated progression from low magnitude, broad cellular reactivity at germline, to high preference, and magnitude of reactivity, for vimentin positive regions following affinity maturation (i.e "PB4"). MAb PB5 was unique, maturing from a germline precursor with a speckled nuclear pattern and purified histone reactivity. Staining patterns observed with TII tissue using Flag-

PB4 and -PB5 matched those generated with HEp-2 cells. Reactivity of PB4 with vimentin was due to a combination of multiple SHMs. In PB5, S36D reversion was responsible for nuclear (Histone) reactivity and G55D lost vimentin reactivity.

Conclusion: From low reactivities comparable to naïve healthy B-cells, or Histone reactivity, TII AVAs gain both affinity and selectivity for vimentin. We have developed image analysis software for quantifying mAb selectivity for candidate antigens, and a flag human IgG1 mAb construct enabling analysis of human tissue rich in IgG.

Autoantibodies in Rheumatoid Arthritis Target Citrulline-Containing and Native Epitopes from Conformationally Disordered Regions of Proteins

Zihao Zheng,[1] Lauren Fahmy,[1] Alan Bridges,[2] Michael Newton,[1] and **Miriam Shelef**[1], [1]University of Wisconsin - Madison, Madison, [2]William S. Middleton Memorial Veterans Hospital, Madison

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPAs) and rheumatoid factor (RF) are the main diagnostic and pathologic autoantibodies in rheumatoid arthritis. However, autoantibodies develop against proteins with other post-translational modifications, such as homocitrullination, as well as against various native proteins without obvious unifying characteristics of the antigens. Moreover, some rheumatoid arthritis patients generate only RF or only ACPAs (as detected by the anti-cyclic citrullinated peptide (CCP) test) and some produce neither. We have a poor understanding of the autoantibody repertoire in these patients. Our objective was to broadly evaluate autoantibody binding in seronegative and seropositive rheumatoid arthritis to identify general and novel features of autoantibody reactivity.

Methods: An array was created with 172,828 overlapping peptides derived from 122 proteins citrullinated in the rheumatoid joint including variants with arginines or lysines replaced with citrullines or homocitrullines, respectively. IgG and IgM binding to peptides was compared for CCP+RF+, CCP+RF-, CCP-RF+, and CCP-RF- rheumatoid arthritis versus controls. Highly bound peptides were analyzed for amino acid patterns and predictors of structural disorder. Published synovial fluid citrullinomes were also analyzed for amino acid patterns.

Results: Broadly, CCP+RF+ subjects had very high and CCP+RF- and CCP-RF+ subjects had modest citrulline-specific IgG binding. All rheumatoid arthritis groups had low homocitrulline-specific IgG binding and CCP+RF+ subjects had high IgG binding to native peptides. CCP-RF- subjects had very little antibody binding in general. By far, the highest IgG binding in rheumatoid arthritis was to citrulline-containing peptides, irrespective of protein identity, especially if the citrulline was adjacent to glycine or serine. Citrullinated arginines in the rheumatoid joint were also frequently next to glycine and serine. The most highly bound citrulline-containing and native peptides had multiple features predictive of conformational disorder.

Conclusion: In general, we observed a continuum of autoantibody binding in rheumatoid arthritis with a very high amount of binding in CCP+RF+ subjects, modest binding in CCP+RF- and CCP-RF+ subjects, and very little binding in CCP-RF- subjects. Further, citrulline, particularly next to serine or glycine, is a major driver of autoantibody reactivity in rheumatoid arthritis, likely due in part to frequent *in vivo* citrullination of arginine next to serine or glycine. Finally, structural disorder may be a newly discovered feature that drives rheumatoid arthritis autoantibodies.

Microenvironment in Systemic Sclerosis Provides a Protective Niche for Tissue-resident B Cells During B Cell Depletion Therapy with Anti-CD20 Antibody

Ai Kuzumi,[1] Ayumi Yoshizaki,[1] Takemichi Fukasawa,[1] Satoshi Ebata,[1] Yoshihide Asano,[1] and Shinichi Sato[1], [1]University of Tokyo Graduate School of Medicine, Department of Dermatology, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: B cell depletion therapy with anti-CD20 antibody rituximab has emerged as a potential treatment for systemic sclerosis (SSc). Rituximab, which has been used to treat B cell malignancies and some autoimmune diseases, efficiently depletes circulating B cells. Tissue-resident B cells, on the other hand, have been shown to be more difficult to deplete, posing a therapeutic challenge. Resistance of tissue-resident B cells to rituximab has been associated with the inflammatory microenvironment in malignancy and autoimmunity, where B cell survival is promoted by various cytokines and chemokines. Among these survival factors, the following two have received much attention: CXCL12, a chemokine essential for the B cell niche in bone marrow, and B cell activating factor (BAFF), a cytokine promoting the survival of autoreactive B cells. In this study, we investigated the role of microenvironment on tissue-resident B cells during B cell depletion therapy with anti-CD20 antibody in SSc.

Methods: Bleomycin (BLM)-induced SSc model mice were treated with anti-CD20 antibody. AMD 3100, an antagonist of the CXCL12 receptor CXCR4, was used to block CXCL12. Anti-BAFF antibody was used to block BAFF. B cell depletion was assessed by flow cytometry in bone marrow, spleen, lymph nodes, lungs, and peripheral blood. Skin and lung fibrosis was evaluated histopathologically. CXCL12 and BAFF expression was quantified by qRT-PCR and immunofluorescence staining.

Results: While anti-CD20 antibody efficiently depleted circulating B cells and attenuated skin and lung fibrosis, a fraction of $CD20^+$ B cells persisted in spleen, lymph nodes, and lungs of BLM-induced SSc model mice, contrasting with efficient depletion of tissue-resident B cells in control mice. Residual B cells showed increased expression of CXCR4. CXCL12 and BAFF expression was increased in skin and lungs of BLM-induced SSc model mice. Co-administration of anti-CD20 antibody with AMD3100 or anti-BAFF antibody enhanced the depletion of tissue-resident B cells. Furthermore, these combination therapies achieved greater attenuation of fibrosis in BLM-induced SSc model mice compared with anti-CD20 monotherapy.

Conclusion: SSc microenvironment provides a protective niche for tissue-resident B cells against anti-CD20 antibody. B cell survival factors like CXCL12 and BAFF are potential therapeutic targets that enhance the efficacy of B cell depletion therapy in SSc.

Non-cytotoxic therapy	10 (25%)	
No therapy	18 (45%)	
Meets 2013 Classification Criteria	40 (100%)	

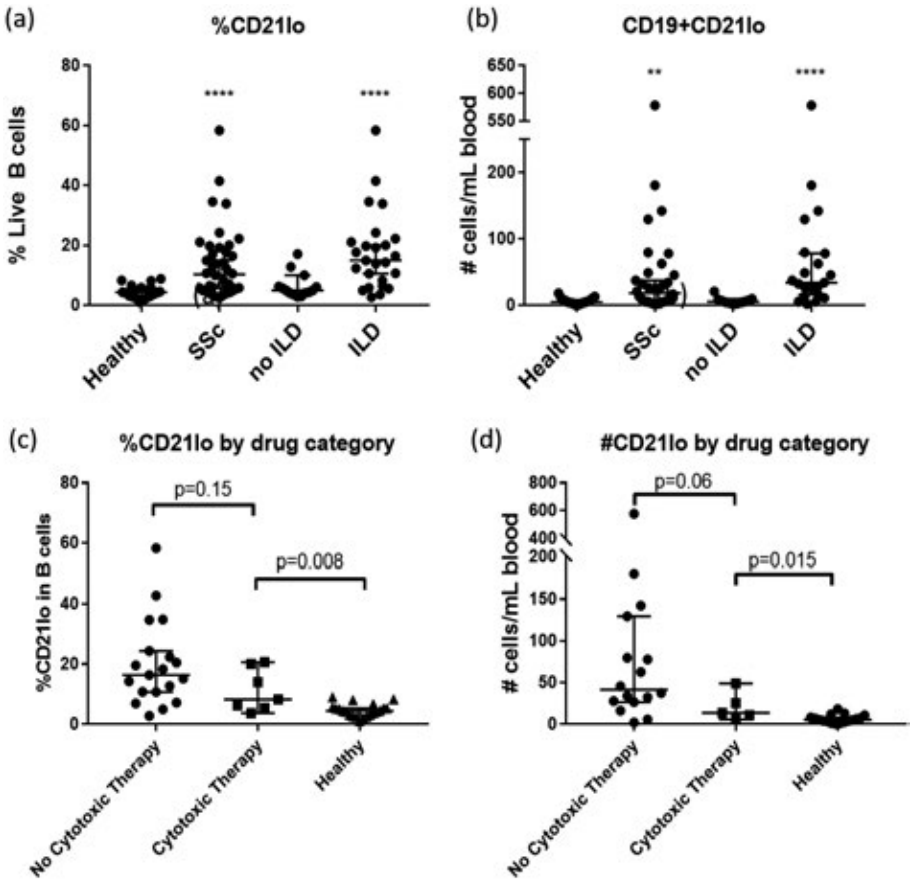

Figure 1. Only patients with SSc-ILD have an increase frequency (a) and absolute number (b) circulating $CD19^{+}CD21^{lo}$ cells; SSc patents without ILD have no difference in $CD19^{=}CD21^{lo}$ cells compared to healthy controls. (C-D) Patients who are treated with cytotoxic therapy (e.g. MMF/AZA) have a trend towards normalization for this cell population. ** p<0.01, ****p<0.0001

Background/Purpose: Systemic sclerosis (SSc) is a severe systemic disease characterized by fibrosis of the skin and visceral organs. While protein biomarkers of lung damage, e.g. krebs von den lungen-6 and surfactant protein D (SPD) have been reported in SSc-ILD, no immunologic predictors of SSc-ILD have been reported. CD21lo B lymphocytes have been implicated as autoimmune-prone cells. We evaluated the relationship of these cells to clinical phenotype in patients with SSc.

Methods: Cryopreserved peripheral blood mononuclear cells (PBMCs) were stored as part of the MYSTIC cohort (VUMC IRB 141415). Detailed clinical phenotyping, including extent of cutaneous involvement and serologic status, was performed at the time of patient enrollment. All patients met the 2013 ACR classification criteria for SSc. The presence of interstitial lung disease was defined as FVC< 79% predicted, isolated DLCO< 79% predicted in the absence of pulmonary hypertension, or radiographic fibrosis on CT scan. PBMCs were thawed and subjected to mass cytometry to investigate B cell phenotypes in patients with SSc (n=40) versus healthy controls (n=21). Data was analyzed with biaxial gating and correlated to clinical phenotypes. Statistical significance was determined using Mann-Whitney U-tests.

Results: Basic demographics are shown in table 1. Patients with SSc-ILD have a higher percentage of CD19+CD-21lo cells compared to patients without interstitial lung disease (15.0% versus 5.0%, p=0.0004); there is no increased

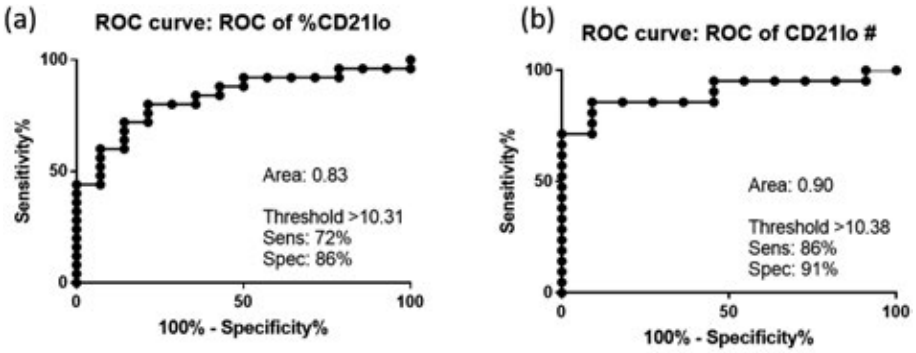

Figure 2. ROC curves showing the correlation of (a) percent and (b) absolute number of circulating $CD19^{+}CD21^{lo}$ cells with SSc-ILD

CD19+CD21lo frequency for patients with SSc without ILD compared to healthy controls (5.0% v. 4.4%, p=0.22). Similarly, the absolute number of circulating CD19+CD21lo cells is increased for SSc-ILD compared to SSc without ILD or healthy controls (34.0 v. 5.59 v. 5.09 cells/mL, p< 0.0001) (Figure 1A-B). There was no correlation between CD19+CD21lo cells and extent of cutaneous involvement of serologic status. For the subset of patients with ILD treated with mycophenolate mofetil or azathioprine (n=7), there was a trend towards normalization of their CD19+CD-21lo frequency (8.2% v. 16.4%, p=0.15) compared to those not treated with these medications (n=19). This trend was even stronger when considering the absolute number of circulating CD19+CD21lo cells for treated versus untreated patients (13.6 v. 41.4 cells/mL, p=0.06) (Figure 1C-D). An ROC curve was generated to predict the presence of ILD. A threshold of 10.3% circulating CD19+CD21lo cells had sensitivity of 76%, specificity of 86%, and AUC 0.87. A threshold of 10.4 cells/mL had a sensitivity of 86%, specificity of 91%, and AUC of 0.90 (Figure 2).

Conclusion: This single center study demonstrated the presence of circulating $CD19^{+}CD21^{lo}$ cells is highly predictive of SSc-ILD. The frequency and absolute number of circulating cells seems to decrease with treatment of ILD. These findings will need to be confirmed in a second large cohort.

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Loss of systemic self-tolerance leading to anti-nuclear autoantibody (ANAs) by B cells is a hallmark of SLE. However, up to 20% of healthy female individuals are also ANA+, and most will never develop clin-

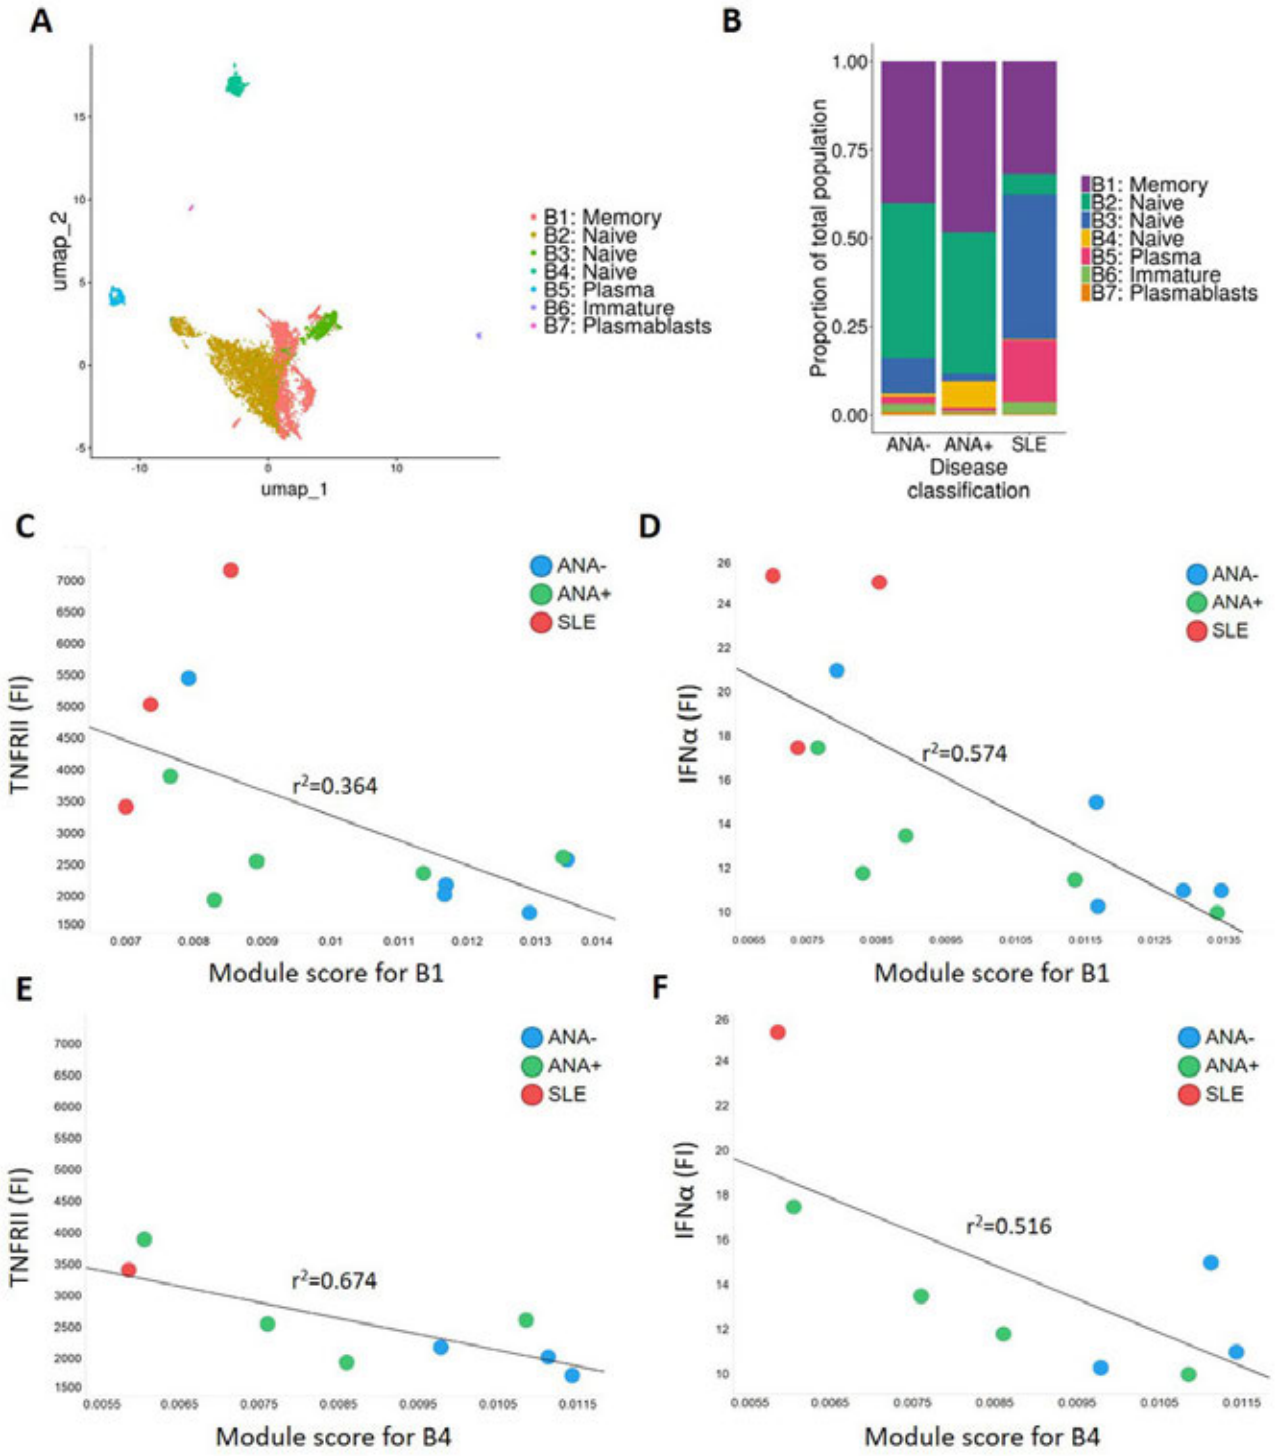

Figure 1. African American ANA+ B cell populations negatively correlate with pro-inflammatory cytokines. A. Visualization of B cell subpopulations by UMAP of scRNA-seq data. B. Proportion of cells from each disease classification in each B cell cluster reveals differences is constituent subpopulations. C. Linear regression of plasma TNFRII fluorescent intensity (FI) with TNFRII/p53/apoptosis/death-receptor signaling - related gene module score for memory B cells (cluster B1). D. Linear regression of plasma IFNα fluorescent intensity (FI) with TNFRII/p53/apoptosis/death-receptor signaling - related gene module score for memory B cells (cluster B1). E. Linear regression of plasma TNFRII fluorescent intensity (FI) with TNFRII/p53/apoptosis/death-receptor signaling - related gene module score for naive B cells (cluster B4). F. Linear regression of plasma IFNα fluorescent intensity (FI) with TNFRII/p53/apoptosis/death-receptor signaling - related gene module score for naive B cells (cluster B4).

ical autoimmune disease. The B cell pathways involved in autoimmune progression and regulation of healthy ANA+ individuals is unknown.

Methods: Peripheral blood mononuclear cells (PBMCs) from African American ANA- (n=6), ANA+ healthy individuals (n=6) and SLE (n=6) subjects were sorted for CD3-CD19+ B cells by flow cytometry and RNA was isolated for next-generation sequencing. Differential gene expression, Weighted Gene Correlation Network Analysis and pathway analysis were used to identify differences in pathways and upstream regulators. scRNA-sequencing of B cells from PBMCs were used to determine frequencies and identify differential gene signatures in specific B cells subsets. Plasma soluble mediators were assessed by xMAP multiplex arrays and used for linear regression analyses.

Results: Pathway analysis of total B cells in ANA+ healthy individuals revealed unique pathway modules with elevated eigengene scores associated with p53 signaling (p=0.000275), TNFRII signaling (p=0.0000699), apoptosis (p=0.00399) and death receptor signaling (p=0.00902) compared to ANA- controls and SLE patients. Using scRNA-seq analysis, seven distinct B cell populations among all subjects were identified using a community detection algorithm and visualized using Uniform Manifold Approximation Projection. The proportion of total B cells within each cluster varied by disease status. A unique cluster of $CD69^{low}$ naïve B cells was more prevalent in ANA+ healthy subjects, memory B cells also trended higher in ANA+ healthy individuals, while SLE patients were characterized by higher frequencies of plasma cells and $CD69^{high}$ naïve B cells. Gene expression signatures of p53/TNFRII, apoptosis, and death receptor signaling were elevated in all B cell subsets of ANA+ healthy individuals (Figure 1A-B). In ANA+ healthy individuals, the elevated gene expression signatures in memory B cells correlated negatively with plasma IFNα (p=0.0027), IL-15 (p=0.011), IP-10 (p=0.027), IL-10 (0.025), TNFRII (p=0.029), and IL-23 (p=0.038) levels, and negatively in $CD69^{low}$ naïve B cells with IFNα (p=0.012) and TNFRII (p=0.045) levels (Figure 1C-F). SLE patients exhibited higher plasma levels of multiple cytokines including IFNα and associated mediators, TNFRII, IL-10, BLyS and Th1/2/17 associated mediators ($p< 0.05$).

Conclusion: ANA+ healthy individuals have enhanced gene expression in B cell pathways that drive apoptosis and cell cycle suppression, which may regulate autoreactive T cell activation, and proliferation, and subsequent clinical autoimmune pathogenesis. This provides clues into potential targets for prevention of clinical autoimmunity.

-- Inpatient	--	1 (25)	1 (10)
-- ICU		0 (0)	2 (20)

Table 1. Demographics of patients and healthy volunteers included in study. Four healthy controls, 4 patients with non-Jo-1 inflammatory myopathy patients (one each with anti-Tif1-gamma, anti-Mi-2, anti-EJ, and anti-PL-7 antibodies), and 10 patients with anti-Jo-1 antibodies as determined by clinical testing. Demographics and clinical information were collected from the electronic medical record at the time of enrollment. Disease severity was defined as stable if the patient's primary rheumatologist or pulmonologist did not discuss changing medications at the time of enrollment and "active" if immunosuppression was increased. Disease activity was determined to be "life threatening" if the patient was admitted to the hospital due to their rheumatologic illness, was receiving pulse steroids, and was receiving an increase in immunosuppression.

Figure 1

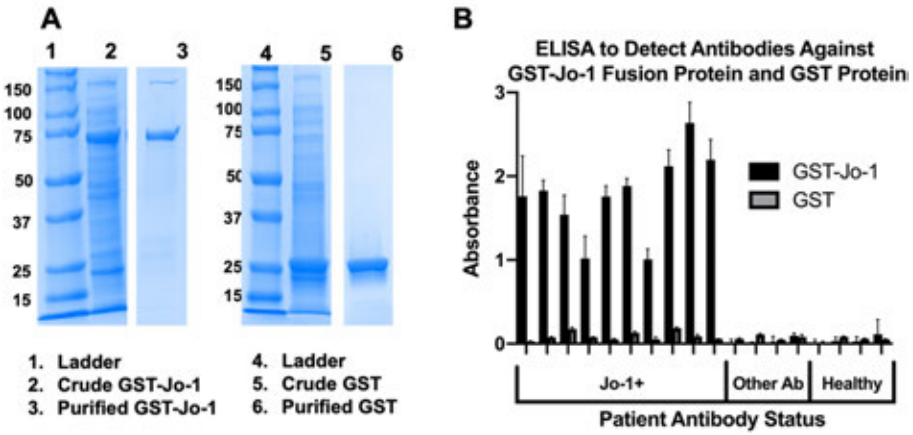

Figure 1. ELISA detects anti-Jo-1 specific antibody in the sera of patients with clinical laboratory confirmed cases of Jo-1 associated disease. (A) Glutathione S-transferase (GST) and GST-Jo-1 were expressed in bacteria and purified. Samples were run on SDS-page gels and Coomassie blue staining confirmed purity of protein samples. (B) ELISA performed against purified GST-Jo-1 fusion protein (black) and purified GST protein (gray). Patient sera were diluted 1:1000 and applied to plates coated with purified GST-Jo-1 or GST proteins. Our ELISA successfully discriminates between Jo-1-positive and Jo-1-negative sera. The Jo-1-positive patient sera react against GST-Jo-1 fusion protein but not against GST alone, demonstrating that the antibodies are specific for the Jo-1 protein.

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are systemic autoimmune diseases traditionally classified as dermatomyositis or polymyositis, but these disorders are increasingly defined by the presence of myositis-specific and myositis-associated antibodies. Anti-Jo-1 autoantibodies recognize histidyl tRNA synthetase

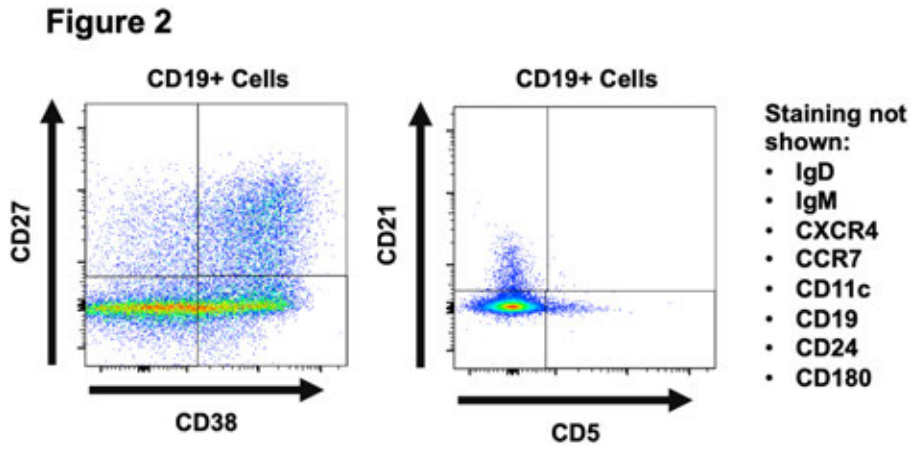

Figure 2. Representative flow cytometry data. Cryopreserved PBMCs from a known Jo-1 positive patient were thawed and stimulated in vitro. After 6 days of stimulation, cell culture supernatants were screened for the presence of anti-Jo-1 antibodies. Equal numbers of Jo-1 positive and Jo-1 negative screened wells were phenotyped using flow cytometry. Representative data for a Jo-1 positive well are shown above amongst CD19+ cells.

and are frequently found in these patients. In addition to producing antibody, B cells present antigen to T cells, a function that is independent of antibody production. Jo-1-specific B cells have not been previously characterized. To develop targeted therapies for IIM, we must first understand the etiology of autoreactive B cells in this disease. We hypothesize that anti-Jo-1 B cells will exhibit features of memory B cells and show evidence of somatic hypermutation and antigen-driven selection.

Methods: We enrolled 10 patients that were anti-Jo-1 autoantibody positive by clinical testing at our university medical center (Table 1). Antigen-specific B lymphocytes are typically rare in the repertoire and the B cell receptor is not automatically secreted as antibody, making detection of specificity difficult. To overcome these challenges, we polyclonally stimulated peripheral blood mononuclear cells (PBMCs) from IIM patients to drive *in vitro* B cell differentiation into antibody-secreting cells and developed a high throughput ELISA to screen and identify wells containing Jo-1 antibody-secreting cells. We applied flow cytometry phenotyping of wells that were positive or negative for anti-Jo-1 B to investigate their expression of twelve B cell phenotypic markers.

Results: Using recombinant Jo-1 protein, our ELISA successfully distinguished the presence or absence of anti-Jo-1 antibodies in clinically validated patient sera (Figure 1). Stimulation of human PBMC resulted in detection of IgG in the supernatants of all wells. A proportion of these wells were positive for anti-Jo-1 IgG autoantibody with an estimated frequency of approximately 0.01% of the total B cell repertoire, a frequency that is comparable to previously reported tetanus toxoid B cells in vaccinated individuals. We also detected a residual population of anti-Jo-1 B cells in a patient who previously received rituximab. B cell subsets differentially expressed CD24, CD27, CD38, IgM, and IgD following polyclonal stimulation. Differences in CXCR4 and CCR7 expression were also observed in different B cell subsets identified in these cultures.

Conclusion: This is the first demonstration of anti-Jo-1 B cells in the primary immune repertoire of patients with IIM, including those who have previously received rituximab. Flow phenotypic analysis suggests that differences in B cell subset distribution of anti-Jo-1 B cells can be assessed using our methods. These data provide the first critical steps towards understanding anti-Jo-1 B cell biology in patients with IIM to enable their future tracking as clinical disease and therapeutic response biomarkers.

Discovery of DWP212525, a Potent JAK3 and BTK Dual Target Inhibitor for the Treatment of Autoimmune Diseases

Yong Dae Shin,[1] Jae-Hun Jung,[1] Eun Kyung Kim,[1] SOHEE IM,[1] Sunah Jun,[1] NamYoun Kim,[1] SeungHwarn Jeong,[1] Hyaejung Hyun,[1] and Joon Seok Park[1], [1]Daewoong Life science research institute, Yongin-si, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Janus Kinase (JAK) and Bruton's tyrosine kinase (BTK) play critical roles in activation and function of T cells and B cells. Dysregulation of this process has been known to cause various immune-related diseases. Tofacitinib, a JAK inhibitor, was originally developed as a JAK3 inhibitor but it showed limited selectivity against JAK1 and JAK2. Although Tofacitinib has proved therapeutic effects in RA, serious side effects such as anemia and neutropenia have been frequently reported. Meanwhile, existing BTK inhibitors have insufficient clinical efficacy, which creates higher demands for treatment with improved efficacy. DWP212525 is a novel and selective JAK3 and BTK inhibitor which may have synergistic effects for the treatment of rheumatoid arthritis and other inflammatory diseases such as pemphigus vulgaris (PV).

Methods: Inhibition of JAK3 and BTK enzyme activity and selectivity against Cys-family kinase group were evaluated by a series of biochemical assays. Cellular activity for target phosphorylation in human T and B cells were measured by Phospho-STAT5 or phospho-BTK cellular kit. BCR dependent CD69 expressions were determined in hPBMC. To measure BTK occupancy, mouse spleen was extracted at several time points up to 24 hours after receiving an oral administration of DWP212525. Occupancy was quantified by the number of unbound BTK in ELISA-based assay using biotinylated-DWP212525, which binds to free active site of target after oral administration of DWP212525. Furthermore, the efficacy of DWP212525 was investigated in the mouse collagen-induced arthritis (CIA) model and mouse PV model, in comparison with selective BTK inhibitor.

Results: We developed a novel and potent dual target inhibitor, DWP212525, with JAK3 IC_{50} value of 0.2 nM and BTK IC_{50} value of 1.5 nM. More importantly, DWP212525 is highly selective against JAK3 and BTK, yet has low affinity toward JAK1, JAK2 and EGFR. DWP212525 shows successful inhibition of BCR-dependent CD69 expression in B cells (IC_{50} value of 132nM). *In vivo*, oral administration of low-dose DWP212525 (1mg/kg) showed more than 80% BTK occupancy in mouse splenocytes. Interestingly, the plasma concentration of DWP212525 rapidly decreased, but high rate of BTK occupancy was maintained for up to 24 hours. In mouse CIA model, we observed a dose-dependent improvement of arthritis symptoms in the group treated with DWP212525. The ED_{50} value of DWP212525 is 0.8 mg/kg. In mouse PV model, DWP212525 alleviated the severity of disease index score prevented body weight loss and confirmed that the survival rate was higher than the positive control group treated with a BTK inhibitor and the vehicle group at the end of the 32-day oral administration after the induction of the disease.

Conclusion: We developed a novel, highly potent, and selective covalent inhibitor of JAK3 and BTK, DWP212525. We demonstrated that DWP212525 has potent *in vitro* and *in vivo* pharmacological activities compared to Tofacitinib and existing selective BTK inhibitor. These results suggest that DWP212525 can be more effective due to the addition of JAK3 inhibition than selective BTK inhibitor for the treatment of various autoimmune diseases, including RA and PV.

Minimal Residual Autoimmunity After Rituximab in ANCA-associated Vasculitis Patients

Laura van **Dam**,[1] Jelle Oskam,[2] Sylvia Kamerling,[2] Eline Arends,[2] Edwin Bredewold,[2] Magda Berkowska,[2] Jacques van Dongen,[2] Ton Rabelink,[2] Cees van Kooten,[2] and Onno Teng[2], [1]LUMC, Leiden, Zuid-Holland, Netherlands, [2]LUMC, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: B-cell depletion with rituximab (RTX) is an effective treatment for ANCA-associated vasculitis (AAV) patients. Repeated RTX upon B-cell repopulation or return of ANCAs improved therapeutic efficacy, which indicates the presence of minimal residual autoimmunity (MRA) after RTX. Therefore, this study aimed to perform in-depth phenotypic and functional analyses of B and plasma cells after RTX in AAV.

Methods: EuroFlow-based highly sensitive flow cytometry (HSFC) was used during longitudinal follow-up of RTX-treated AAV patients (n=12). To investigate MRA in the memory B-cell compartment after RTX, peripheral blood mononuclear cells (PBMCs) were stimulated with CpG, IL-2 and IL-21 *in vitro* to induce plasma cells (PCs) and ANCA-IgG and -IgM were measured in these supernatants and in paired serum samples by ELISA.

Results: By employing HSFC we demonstrated that 12 weeks after RTX, low but significant numbers of circulating $CD19^+$ B cells ($0.21*10^6$ cells/L) could still be detected (reduction of -99.7%). While naïve B-cells, memory B-cells and $CD20^+$ plasmablasts (PB) were rapidly depleted, $CD20^-$ PCs were reduced slower and depleted incompletely. Residual $CD20^-$ PCs were $0.05*10^6$ cells/L (-95.8% from baseline), whereof 57% were mature $CD138^+$ PCs. Early repopulation at 12 weeks was dominated by $CD20^-CD138^-$ PCs, followed by $CD20^+$ PBs at 24 weeks while memory and naïve B cells remained suppressed. Simultaneously, serum ANCA IgG, IgM and IgA, produced by autoreactive PCs, decreased but did not disappear after RTX. Interestingly, 24 weeks after RTX, serum anti-MPO IgM increased in 3/4 patients, which associated with repopulating $CD20^+$ PBs. This suggested remaining autoreactive B cells despite RTX treatment, which was further studied by *in vitro* PBMC cultures. In these supernatants both anti-MPO-IgG and -IgM were detected at baseline, whereas anti-MPO IgG disappeared after RTX, in contrast to anti-MPO IgM, which was detected 24 weeks after RTX.

Conclusion: RTX results in a strong but not complete B cell depletion. In-depth analysis demonstrated that both ANCA-producing PCs and ANCA-memory B cells can be detected after RTX, indicating residual B-cell autoimmunity in AAV patients. Further identification of MRA could be worthwhile for guiding personalized treatment in AAV patients.

Bruton's Tyrosine Kinase (BTK) Pathway Is Active in Synovium at Various Stages of Rheumatoid Arthritis Disease Progression

Sunil Nagpal,[1] Qingxuan Song,[2] Matthew Loza,[3] Yanqing Chen,[4] Xuefeng Yin,[2] Leon Cheng,[4] Michael Huber,[4] Frédéric Baribaud,[3] Fang Shen,[1] and Navin Rao[1], [1]Janssen R&D, Spring House, PA, [2]Janssen R&D, Spring House, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Janssen Research, La Jolla

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bruton's tyrosine kinase (BTK), a TEC family non-receptor kinase, is expressed in B cells and myeloid cells. BTK relays signaling downstream of B cell receptor (BCR) and toll-like receptors (TLR) in B cells, whereas in myeloid cells, it mediates activating Fcg receptor and TLR signal transduction. Given the importance of these cell types in autoimmune pathogenesis, inhibition of BTK pathway is expected to provide an effective strategy for the treatment of rheumatoid arthritis (RA). However, the activity status of the BTK pathway in RA synovium and at various stages of RA disease progression has not been addressed.

Methods: RNA-Seq expression profiling was used to examine the expression of *BTK* in synovial tissue samples from healthy, osteoarthritis (OA), seropositive arthralgia, early RA and established RA subjects. Immunohistochemistry was performed to determine the expression of BTK protein in healthy, OA and RA synovial tissue biopsies. BTK-responsive gene signatures were generated from vehicle or BTK inhibitor-treated and activated human B cells and monocytes. Gene Set Variation Analysis (GSVA) was employed to assess the status of BTK signaling by interrogating BTK in vitro B cell and monocyte gene signatures against expression profiles of synovial tissues from various stages of RA disease progression.

Results: We demonstrate that the expression of *BTK* was significantly increased in arthralgia, early RA and established RA, compared to healthy and OA synovial tissue samples. In addition, RA patients showed increased cytoplasmic BTK protein expression in the synovium when compared to their healthy and OA counterparts, and the protein was restricted to synovial immune cell infiltrates. GSVA revealed that anti-IgM-responsive genes in naïve B cells were significantly enriched in synovial tissues from various stages of RA disease progression, whereas immune complex (HSA and anti-HSA complex)-responsive genes in monocytes showed enrichment only in established RA synovial tissue samples, demonstrating differential involvement of B cells and monocytes in arthralgia and early disease vs., established RA. In accordance with these observations, BTK gene signatures from activated B cells showed enrichment in synovial tissue samples during RA disease progression, while BTK monocyte gene signatures showed enrichment only in established RA synovium.

Conclusion: Taken together, these data suggest that BTK pathway is active in synovium during RA disease progression, and BTK inhibitors may show efficacy not only for the treatment of RA but also in halting the progression of the disease to established RA.

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

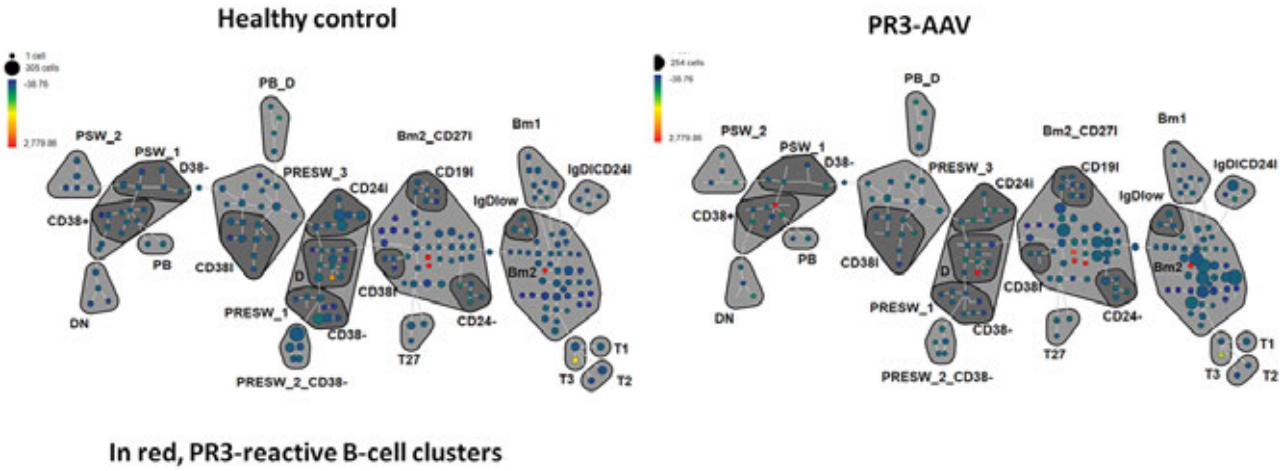
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: We previously developed a method to recognize proteinase 3 (PR3)-specific B cells by flow cytometry. We reported that, in a small number of subjects, the proportion of PR3-specific B cells was higher in patients with PR3-ANCA-associated vasculitis (AAV) compared to healthy controls (HCs) (Cornec et al, J Autoimmunity 2017). The objectives of this study were to replicate our previous findings on a larger number of subjects, including anti-myeloperoxidase (MPO)-AAV patients as disease controls, and to study the association of PR3-specific B cell proportions with clinical and biological features in patients with PR3-AAV.

Methods: We analyzed samples from 161 patients who participated in the RAVE trial, including 110 patients with PR3-AAV and 51patients with MPO-AAV, as well as 27 HCs. We measured the proportion of PR3-specific B cells and subsets among cryopreserved PBMCs using a multi-color flow cytometry panel including CD19, IgD, CD27, CD38, CD24, and biotinylated PR3. SPADE (Spanning-tree Progression Analysis of Density-normalized Events) algorithm was used for the unsupervised clustering of flow cytometry data, based on the level of expression of each of the 6 markers on each cell.

Results: The proportion of PR3-specific B cells was higher in patients with PR3-AAV and MPO-AAV (median [25-75% interquartile range]: 2.82% [2.35-3.74] and 2.87 [2.15-3.84], respectively) compared to HCs (1.51 [1.25-1.73], both $p< 0.001$), while they did not differ substantially between PR3-AAV and MPO-AAV ($p=0.517$). We observed a significant shift towards a more mature phenotype of these PR3-specific B cells in patients with PR3-AAV compared to MPO-AAV and HCs, as represented by a higher proportion of PR3-specific B cells among the unswitched memory B-cell subsets (IgD+CD27+; 6.14% [4.27-8.74] versus 4.47% [3.11-6.87] versus 2.89% [2.19-4.23], $p< 0.01$ for all comparisons), switched memory B-cell subsets (IgD-CD27+; 2.98% [1.67-5.00] versus 2.1% [1.38-3.09] versus 1.19% [0.96-1.60], $p< 0.001$ for all comparisons), and double negative B-cell subsets (IgD-CD27-; 2.23% [1.54-3.76] versus 1.44% [0.83-2.53] versus 0.80% [0.00-1.34], $p< 0.01$ for all comparisons). In patients with PR3-AAV, no associations between PR3-specific B cell proportion and age, sex, new diagnosis vs relapsing disease, or disease activity (BVAS/WG) was observed. The SPADE clustering resulted in the definition of 200 distinct subsets detectable in each sample with variable proportions, and showed a strong segregation of patients and HCs, and PR3-AAV and MPO-AAV patients. A cluster belonging to the switched memory subset was PR3-reactive only in PR3-AAV (figure).



SPADE analysis of B-cell subsets. PR3-reactive subsets are represented in red. One post-switch memory B-cell subset is PR3-reactive only in PR3-AAV patients.

Conclusion: Circulating PR3-specific B cells can be detected in the peripheral blood. The proportion of PR3-specific B cells was higher in patients than in HCs. Interestingly, PR3-specific B cell repartition is shifted towards a memory phenotype in PR3-AAV patients. Further studies are ongoing to characterize the dynamics of the PR3-specific B cells after therapy, and to understand the differences of these autoreactive B cells between patients with PR3-AAV and HCs.

ß-adrenergic Receptor Activation: A Way to Enhance CD4 T Cell Suppression by Improving Regulatory B Cell Function

Nadine Honke,[1] Birgit Opgenoorth,[1] Matthias Schneider,[2] and Georg Pongratz[3], [1]Department of Rheumatology, Hiller Research Center of Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [2]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany, [3]Policlinic and Hiller Research Unit of Rheumatology, UKD, Heinrich Heine University, Düsseldorf, Germany

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: 1. Rheumatoid arthritis (RA) is an autoimmune disease in which next to other cell populations CD4 T cells play a crucial role. It has been shown that catecholamines provided by the sympathetic nervous system (SNS) ameliorate the development and course of arthritis by increasing the production of the anti-inflammatory cytokine IL-10 in regulatory B cells (Bregs). In the current study, we investigated whether Bregs have the ability to produce catecholamines and how such a production is regulated. Moreover, we tested which adrenergic receptor activation is important to improve the Bregs function to evaluate if an additional adrenergic receptor stimulus can enhance the suppression of CD4 T cells.

Methods: In *in vitro* experiments on activated murine B cells or B cells and splenocytes from collagen-induced arthritis (CIA) mice, modulation of Bregs and their effect on CD4 T cells proliferation were investigated. The production and release of catecholamines were analyzed in naïve, IgM, CpG or IgM/CpG activated B cells after 4h and 24h by FACS. For analysis of CD4 T cell suppression pre-inactivated or pre-activated B cells and CD3/CD28 activated splenocytes from immunized mice were cocultured for 48h and 72 h. CD4 T cell proliferation as well as the expression of PDL-1 and Fas-L on B cells was monitored by FACS. The IL-10 production from B cells was directly measured in the cells by intracellular FACS staining or in the supernatant of B cell cultures by ELISA.

Results: Catecholamines are not only provided by the SNS but are produced by the B cells themselves. Analysis of B cells by FACS showed a raised production of catecholamines after short time exposure to different B cell activation stimuli (Control vs. IgM, n=6, n.s.; Control vs. CpG, n=6, p***< 0,0002; Control vs. IgM/CpG, n= 6, p****< 0,0001). Long time activation of B cells, on the other hand, leads to release of produced catecholamines (Control vs. IgM, n=4, p**< 0,0029; Control vs. CpG, n=4, p****< 0,0001; Control vs. IgM/CpG, n= 4, p****< 0,0001). This hints to a time and context dependent production and release of catecholamines. Furthermore, FACS analysis showed that CpG-activated Bregs have the ability to suppress CD4 T cells (Control vs. CpG, n= 11, p****< 0,0001). Increased suppression of CD4 T cells was observed after addition of norepinephrine or isoproterenol, ADR beta agonists, to CpG-activated Bregs (CpG vs. CpG/NE, n=11, p*=0,0343; CpG vs. CpG/Iso, n=11, p***=0,0009). This higher suppression of CD4 T cells correlates with enhanced IL-10 production by Bregs (CpG vs. CpG+Iso, n=8, % rel. to control ~40%, p**=0,0045; CpG vs. CpG+NE, n=8, % rel. to control ~16%, p**=0,0012).

Conclusion: In conclusion, our data suggest that ß-adrenergic receptor activation by catecholamines or synthethic receptor agonists in addition to a BCR/TLR9 stimulus is associated with an increase of the anti-inflammatory potential of regulatory B cells to suppress CD4 T cells. This could be a strategy to modulate Bregs for therapeutic purposes in RA.

New-onset ANCA-associated Vasculitis Is Associated with Significant Phenotypic B Cell Dysfunction

Emilie Chan,[1] Susan Hartzell,[2] Lisa Anderson,[2] Chiara Cantarelli,[2] Chiara Guglielmo,[2] Ioannis Tassiulas,[3] Sofia Andrighetto,[2] Andrea Angeletti,[4] Joaquin Manrique Escola,[5] and Paolo Cravedi[2], [1]Mount Sinai Hospital, New York, NY, [2]Mount Sinai Hospital, New York, [3]Icahn School of Medicine, New York, [4]Sant'Orsola-Malpighi Hospital, Bologna, Italy, [5]Complejo Hospital de Navarra, Pamplona, Spain

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Figure 1. B cell phenotype in ANCA-associated vasculitis compared to healthy controls

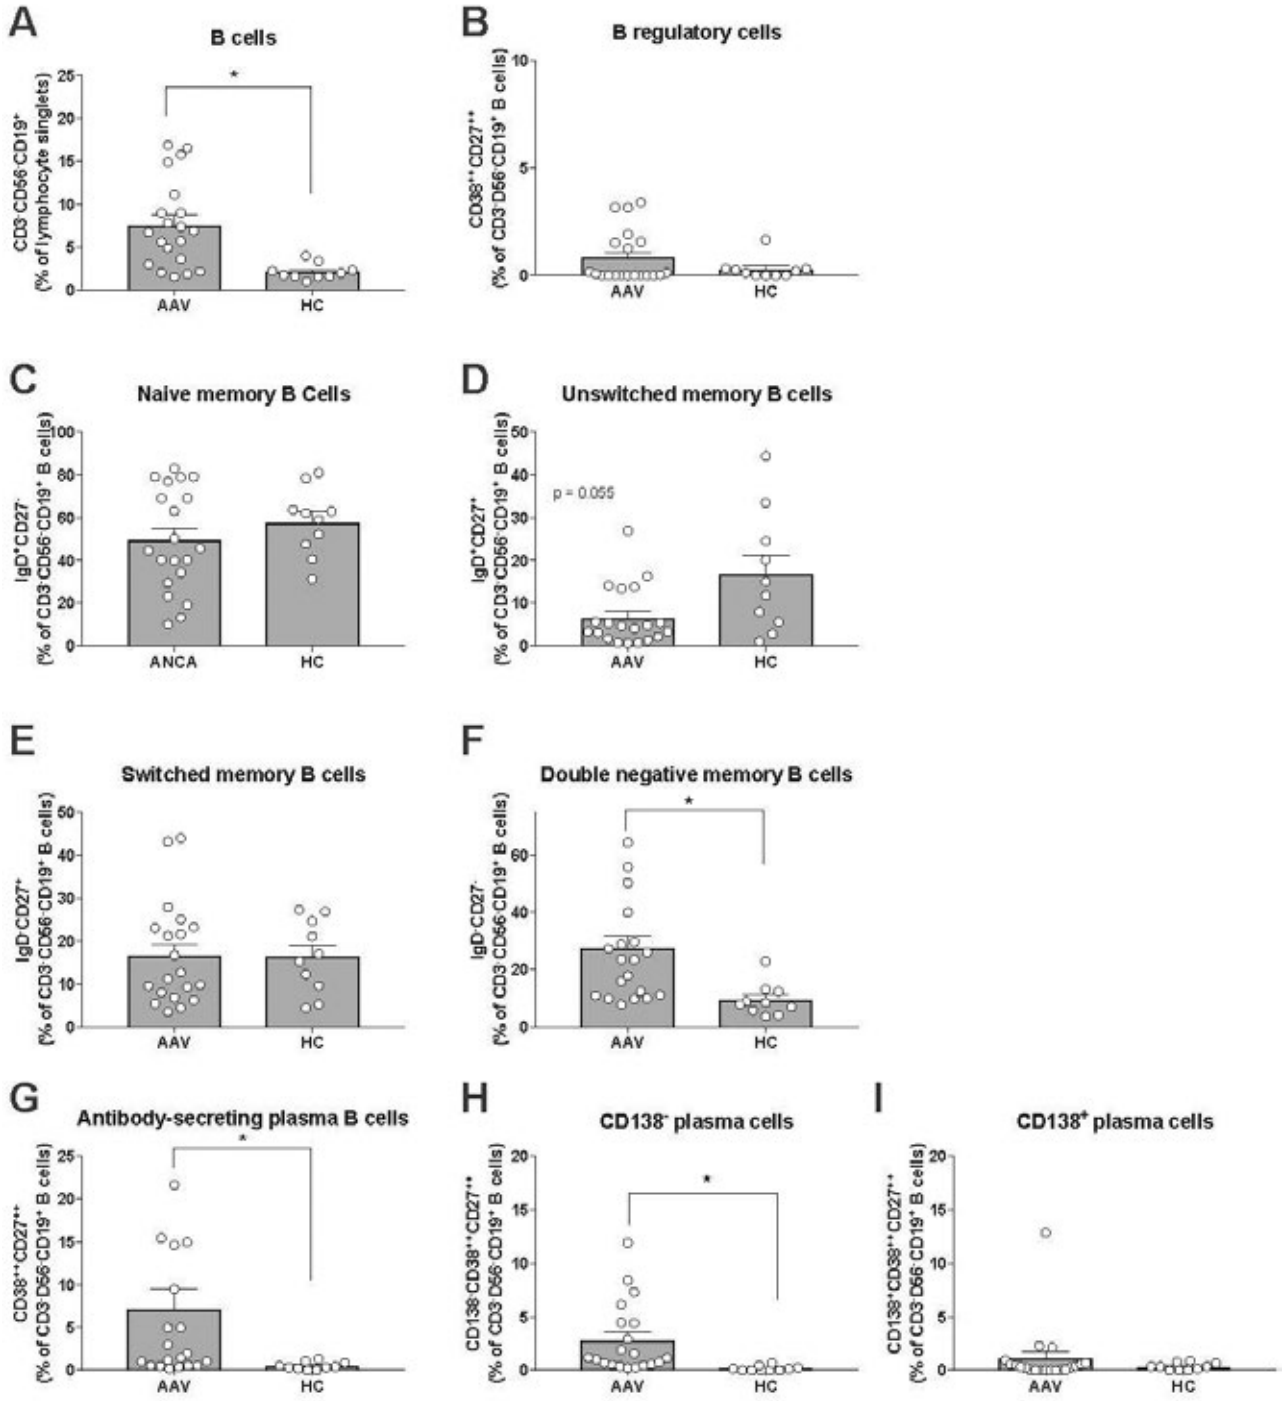

Figure 1. Percentages of CD3-CD56-CD19+ B cells (A) and CD25 hi CD71hi B regulatory cells (B) in ANCA-associated vasculitis patients (AAV, n=20) and healthy controls (HC, n=10). Percentages of B memory cell subpopulations: IgD+CD27- naive, IgD+CD27+ unswitched, IgD-CD27+ switched, and IgD-CD27- double negative (C-F). Percentages of CD38hiCD27hi plasma cells with expression of CD138- and CD138+ (G-I). *p<0.05.

Background/Purpose: ANCA-associated vasculitis (AAV) is characterized by the production of auto-antibodies and can be treated with rituximab, a B cell-depleting agent. Despite this, limited data are available characterizing the B cell dysfunction associated with AAV.

Methods: We performed comprehensive flow-cytometric analyses of major cell markers of B cell function in 20 patients with new diagnosis of AAV with renal involvement and 10 healthy controls (HC). Peripheral blood samples were taken at clinical onset prior to treatment initiation for AAV patients. We measured CD25 ^{hi} CD71^{hi} B regulatory cells; subpopulations of memory B cells, including IgD^{+}CD27^{-} naive, IgD^{+}CD27^{+} unswitched, IgD^{-}CD27^{+} switched, and IgD^{-} CD27^{-} double negative; and CD38^{hi}CD27^{hi} plasma cells and their expression of CD138.

Results: We found significantly increased percentages of of CD3^{-}CD56^{-}CD19^{+} B cells in AAV patients compared to HC (**Fig. 1A**). We did not find a significant difference in CD25 ^{hi} CD71^{hi} B regulatory cells between AAV and HC (**Fig. 1B**). AAV patients had increased frequency of double negative IgD^{-}CD27^{-} memory B cells but no difference in the naïve, switched, or unswitched memory B cell subpopulations (**Fig. 1C-F**). We found significantly higher levels of CD38^{hi}CD27^{hi} plasma cells in AAV patients, with greater CD138^{-} but no difference in CD138^{+} expression between groups (**Fig. G-I**).

Conclusion: Patients with new diagnosis AAV display a unique phenotype of B cell dysfunction that is characterized by an increase in the double negative (DN) memory B cell population, which has been implicated in other autoimmune diseases, and an increase in plasma cells, suggesting persistent antibody production. We did not demonstrate a difference in B regulatory cells, a departure from previously published results that may be explained by our study of early disease activity.

Session Date: Monday, November 11, 2019

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rho GTPases, such as RhoA, have emerged as important regulators of lymphocyte biology owing to their ability to be rapidly activated downstream of a broad range of signals. Two of the major effectors of RhoA signaling are the Rho Kinases (ROCKs), ROCK1 and ROCK2, a pair of serine-threonine kinases that have been previously implicated in the control of cell adhesion, migration, proliferation/survival, and gene expression. Despite the fundamental reliance of T and B cells on these processes, the precise involvement of the ROCKs in lymphocyte

biology is yet to be elucidated. Here, we investigate the contribution of ROCK1 to B cell development and differentiation following immunization with a T-dependent antigen.

Methods: To assess the roles of B cell ROCK1 in T cell-dependent responses, mice with B cell-specific deletions of ROCK1 (CD23-Cre.*Rock1*$^{flox/flox}$ and Cγ-Cre.*Rock1*$^{flox/flox}$ mice) were immunized with a T-dependent antigen. *Rock-1*$^{flox/flox}$ mice were also immunized as a control for this study. The differentiation of germinal center (GC) B cells and plasmablast/plasma cells (PB/PCs) was monitored by FACS at various timepoints following immunization. Total and antigen-specific antibody responses were also assessed by ELISA. The molecular mechanisms employed by ROCK1 to promote B cell differentiation were further examined by FACS-sorting B cell populations from spleens of immunized mice followed by RNA-sequencing analyses.

Results: We found that ROCK1 is expressed and activated in splenic B cells. Mice with B cell-specific deletion of ROCK1 showed marked reductions in total and antigen-specific antibody responses following immunization. These decreased humoral responses corresponded with impaired formation and maintenance of antigen-specific GC B cells and PB/PCs following immunization in the ROCK1-deficient mice. Through next generation sequencing, we have furthermore identified a ROCK1-regulated transcriptional program that supports the phenotype of GC B cells.

Conclusion: Our study demonstrates that ROCK1 is activated in B cells and is required for the optimal development of mature B cell populations at baseline and for efficient GC responses following immunization. These findings thus uncover previously unknown B cell-specific roles for ROCK1 in promoting humoral responses and suggests that targeting ROCK1 activity may provide therapeutic benefit for the treatment of diseases marked by aberrant B cell responses.

Disease Severity Is Linked to an Increase in Autoantibody Diversity in IgG4-related Disease

Hang Liu,[1] Cory Perugino,[2] Musie Ghebremichael,[1] Zachary Wallace,[2] Sydney Montesi,[3] John Stone,[4] and Shiv Pillai[5], [1]Ragon Institute of MGH, MTI and Harvard, Cambridge, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital, Boston, MA, [4]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [5]Ragon Institude of MGH, MIT and Harvard, Charlestown, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The oligoclonal expansion in IgG4-related disease (IgG4-RD) of both plasmablasts and tissue-infiltrating CD4+ cytotoxic T lymphocytes, the identification of specific auto-antigens as B cell targets, and the consistent clinical responsiveness to B cell depletion all support the possibility that this disorder is an autoimmune disease in which adaptive immune responses contribute to the associated tissue fibrosis. Since 2015, four different auto-antigens have been described as potential triggers for IgG4-RD: prohibitin, annexin A11, laminin 511-E8 and galectin-3. However, validation of these findings using external patient cohorts and characterization of the relationship between these specific auto-antigens has yet to be achieved.

Methods: Autoantibody responses against prohibitin, annexin A11 and laminin 511-E8 were measured by ELISA among a clinically diverse cohort of IgG4-RD patients (n = 100). Idiopathic pulmonary fibrosis (IPF) plasma samples (n = 50) were used as a disease control and age- and sex-matched healthy donor plasma samples (n = 50) as healthy controls. We clustered our cohort into subsets of patients according to their number of autoantibody responses (no responses, 1 response, and ≥ 2 responses) and compared clinical parameters among these groups.

Results: The frequencies of IgG4 autoantibody responses against prohibitin (10%), annexin A11 (12%), and laminin 511-E8 (7%) were not significantly different from those of controls. Patients with pancreatobiliary disease did not enrich for annexin A11 or laminin 511-E8 autoantibodies. A portion of the cohort (n = 86) had been analyzed previously at our center for anti-galectin-3 antibody responses with 25 (29%) having IgG4 anti-galectin-3 antibodies. Among these 86 subjects, 32 (37%) had IgG4 antibodies to at least one of the 4 auto-antigens and 12 (14%) showed reactivity to ≥ 2 of the tested antigens. The subset of patients with ≥ 2 autoantibodies had higher total IgG1, IgG2, IgG4, and C-reactive protein levels; were more commonly hypocomplementemic; and were more likely to have visceral organ involvement.

Conclusion: Antibodies against prohibitin, annexin A11, and laminin 511-E8 were found in only a small portion of patients with IgG4-RD. A subset of IgG4-RD patients, however, had IgG4 antibodies against ≥ 2 autoantigens. Patients with antibodies against ≥ 2 autoantigens present with robust IgG subclass elevations, complement consumption, and visceral organ involvement. This broader break in immunological tolerance in IgG4-RD was associated with more severe disease. (Supported by NIH U19 AI 110495 and UM1 AI144295)

Serum IgG4 Concentrations Differ According to Race and Sex

Tyler Harkness,[1] Xiaoqing Fu,[1] Yuqing Zhang,[2] Hyon K. Choi,[2] John Stone,[3] Kimberly Blumenthal,[1] and Zachary Wallace[1], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated IgG4 concentrations are used to support a diagnosis of IgG4-related disease (IgG4-RD). IgG4 concentrations are reported to be higher in male IgG4-RD patients than in female patients and higher in Asian patients than in non-Asian patients. Similar observations have been made in studies of other immunoglobulin concentrations but were limited by relying on small cohorts with similar conditions/exposures or by excluding certain races. There are scarce data on demographic differences in IgG4 concentrations. We assessed IgG4 concentration differences according to sex and race in a large cohort with demographic diversity.

Methods: The Partners Research Patient Data Registry (RPDR) was queried to identify patients who had ≥ one IgG subclass concentrations measured between January 1, 1989 and March 15, 2018 within the Partners HealthCare Network. Immunoglobulin (Ig) concentration test results, sex, date of birth, self-reported race, billing ZIP code (to

* $p < 0.05$

Multivariate-Adjusted Differences in IgG, IgA, IgE, and IgM Concentrations According to Sex and Race

estimate socioeconomic status [SES]), and diagnostic billing codes (to determine clinical indication for testing) were extracted. The distributions of IgG4 concentrations were compared across race and sex categories using t-tests and ANOVA tests, as appropriate. Multivariate-adjusted differences in IgG4 concentrations and the proportion of subjects with results above the reference range across race and sex subgroups were estimated using linear and logistic regression, respectively.

Results: Of the 12,851 subjects, the mean age was 54.7 (±18.3) years, 7,917 (62%) were female, 11,673 (91%) were White, 611 (5%) were Black, and 302 (2%) were Asian (Table 1). Asian and Black subjects, compared to White subjects, had higher IgG4 concentrations (mean 140.4 and 53.6 vs. 41.6 mg/dL, $p< 0.001$) and more often had IgG4

concentrations above the ULN (24.8% and 12.0% vs. 7.0%; p< 0.001). In age- and sex-adjusted analyses, Asian subjects had over a 4-fold higher odds (aOR 4.3, 95% CI 3.3-5.7) and Black subjects had a2-fold higher odds (aOR 1.9, 95% CI 1.4-2.4) of having an IgG4 above the ULN than White subjects. Males had higher IgG4 concentrations than females (mean 56.3 vs. 37.4 mg/dL, p< 0.001) and more often had IgG4 concentrations above the upper limit of normal (ULN) than females (10.5% vs 6.1%, p< 0.001; Table 2). In age- and race-adjusted analyses, females were 40% less likely than males to have an IgG4 above the ULN (aOR 0.6, 95% CI 0.5-0.6). These differences persisted but were attenuated after adjustment for SES (Table 2). Our findings were similar when we stratified according to clinical indication. Similar observations were made when evaluating IgG, IgG1, IgG2, IgG3, IgA, and IgE concentrations (Table 3).

Conclusion: IgG4 concentrations differ according to race and sex and reflect similar differences observed in other Ig concentrations. These similarities suggest that a non-specific activation of Ig-producing B cells by environmental or genetic factors is responsible for these observations. These results have implications both for the interpretation of IgG4 concentration testing for the diagnosis of IgG4-RD and for the use of Ig concentrations in other clinical settings and research.

Bruton's Tyrosine Kinase (BTK) Inhibitors and Autoimmune Disease: Making Sense of BTK Inhibitor Specificity Profiles and Recent Clinical Trial Successes and Failures

Garth Ringheim,[1] Matthew Wampole,[1] and Kinsi Oberoi[1], [1]Clarivate Analytics, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical development of BTK/Tec family kinase inhibitors for treating autoimmune diseases has lagged that of their successful application in oncology. The lack of selective BTK inhibitors to date has partly limited progress in developing drugs that target BTK for autoimmune diseases, where the tenant is held that long term therapy in nonlife threatening diseases necessitates minimizing off-target effects. Autoimmune diseases, however, often demonstrate alterations in multiple immune cell types and signaling pathways, making it difficult to decipher which of these factors are causal and to what degree. The objective of this study was to perform a meta-analysis on available BTK inhibitor pre-clinical and clinical data to develop guidelines and predictors of successful therapeutic applications in autoimmune diseases.

Methods: Biochemical and functional data were collected and analyzed for BTK inhibitors in clinical development from public data sources and Clarivate Analytics database content using a repertoire of programs and services including PubMed, Web of Science, Cortellis Intelligence, Cortellis Integrity, Metacore, Metabase, OFF-X, and CBDD. Development candidates were assessed and categorized for their target specificity profiles, signaling pathways, immunocyte functions, biomarkers, and their reported biological activities in clinical trials.

Results: BTK inhibitor profiles showed remarkably similar specificity profiles within the Tec family kinase group of enzymes. Some differences, however, were observed in T-, B-, and macrophage cell associated enzymes across development candidates that were inconsistent with functional effects, suggesting additional mechanism of action participation. Clinical trial failures in rheumatoid arthritis despite BTK inhibition and effects on B cell biomarkers suggest insufficiency of BTK inhibition as well as off-target pathways associated with those drugs. In contrast, enzymes involved in pathways targeting antibody and T cell activities showed correlation with clinical trial success in diseases where these processes are implicated, including multiple sclerosis and pemphigus vulgarus. Overlap of these disease mechanisms and additional biological pathways associated with lupus strongly suggest a future therapeutic application in this yet to be validate clinical indication.

Conclusion: Current BTK inhibitors in development for autoimmune diseases demonstrate significant lack of specificity with similar patterns of off-target enzyme activities. Some specificity differences, however, were evident. Overall, similarities and differences in specificity showed strong correlation with most reported immunocyte functions, but inconsistencies were evident in some activities that challenge current ascribed functional assumptions for BTK inhibitors. Meta-analysis of BTK inhibitor specificity profiles validated by current clinical trials demonstrate the potential for the collective use of data to understand autoimmune disease pathology and to enhance efficiency in disease indication selection for drugs in clinical development.

Functional Impairment of Mitf and the MiT Transcription Factor Family Dysregulates B Cell Activation and Function

Abhimanyu Amarnani,[1] Ramile Dilshat,[2] Nikita Malakhov,[3] Brian Ghezelaiagh,[4] Chongmin Huan,[1] Erna Magnusdottir,[2] Eirikur Steingrimsson,[2] and Christopher Roman[1], [1]SUNY Downstate Medical Center, Brooklyn, [2]University of Iceland Biomedical Center, Reykjavik, Iceland, [3]SUNY Downstate Medical Center, New York Presbyterian-Weill Cornell Medical Center, Brooklyn, [4]SUNY Downstate Medical Center, Stony Brook University, Brooklyn

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoreactive B cells are central in the development of many autoimmune diseases, such as systemic lupus erythematosus (SLE), and are normally eliminated or inactivated by B cell tolerance mechanisms. Our lab developed a mouse model, called TDN-B, whereby inhibition of the *microphthalmia* transcription factor (MITF) and its family members, TFE3, TFEB, and TFEC occurs specifically in B cells. Prior work showed that B cell homeostasis and tolerance were compromised in this model, as evidenced by splenomegaly, elevated autoantibody titers, and altered B cell compartments. Further, this model worsened SLE-like disease when superimposed on an SLE-susceptible genetic background (B6.lpr), driving accelerated mortality, production of pathologic autoantibodies, and hastened renal disease. To define the signaling pathways regulated by Mitf and the MiT family that could explain their involvement in B cell tolerance, the presented work evaluated the TDN-B model, and a genetic model in which Mitf was not expressed in any cell type ($Mitf^{mi\text{-}vga9}$).

Methods: B cell and T cell subsets were characterized by flow cytometry of bone marrow and spleen, serum immunoglobulin and autoantibody serum titers were quantified by ELISA, in-vitro isolated B cell cytokine secretion was

quantified by Luminex, B cell and T cell organization within splenic follicles was visualized through wide-field and confocal microscopy, and comprehensive investigation of mRNA expression in ex-vivo B cells was defined through RNA sequencing. All experiments compared TDN-B, Mitf$^{mi\text{-}vga9}$, and wildtype mice.

Results: Both TDN-B and Mitf$^{mi\text{-}vga9}$ mice showed increased serum rheumatoid factor, splenomegaly, increased numbers of splenocytes, and disorganization of splenic follicles. Uniquely, Mitf$^{mi\text{-}vga9}$ mice, with Mitf absent in all cells, showed increased serum levels of IgG anti-dsDNA, increased splenic germinal center (GC) B cells, and increased splenic plasma cells (PCs). While increased splenic GC B cells and PCs were not observed in TDN-B mice, increased numbers of pre-B/immature B cells and PCs were observed in the bone marrow. RNA sequencing of ex-vivo B cells showed that in both models, upregulated mRNA pools were significantly enriched for genes with roles in GC growth and/or regulation. Further, pathways related to regulation of cell cycle, MHCII antigen presentation, and cytokine signaling were all significantly enriched for in mRNA from both Mitf$^{mi\text{-}vga9}$ and TDN-B B cells. Additional experiments in Mitf$^{mi\text{-}vga9}$ mice uniquely demonstrated increased numbers of B cells with surface expression of activation markers (CD69, CD25) and antigen presentation molecules (MHCII, CD86), and that B cells in culture had increased secretion of TNF-alpha after LPS stimulation.

Conclusion: These data demonstrate that the functional impairment of Mitf and the MiT transcription factor family results in a breach of B cell tolerance that is coincident with cellular and molecular changes, which lead to dysregulation of B cell activation, antigen presentation, cytokine secretion, germinal center organization, plasma cell differentiation, and autoantibody production. The underlying mechanisms responsible for these effects are under investigation.

Session Date: Monday, November 11, 2019

Session Title: B Cell Biology & Targets In Autoimmune & Inflammatory Disease Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Dysregulation of B cells play a critical role in the pathogenesis of primary Sjögren's syndrome (pSS). Long non-coding RNAs (lncRNAs), which have become the focus of studies on autoimmune diseases, may contribute to the pathogenesis of pSS through multiple signal transduction pathways. However, no study focuses on the effects of dysregulation of the transcriptomes, including lncRNAs, of B cells on the pathogenesis of pSS. The aim of this study was to identify the molecular mechanism of dysregulation of B cell subpopulations of pSS at the transcriptome level.

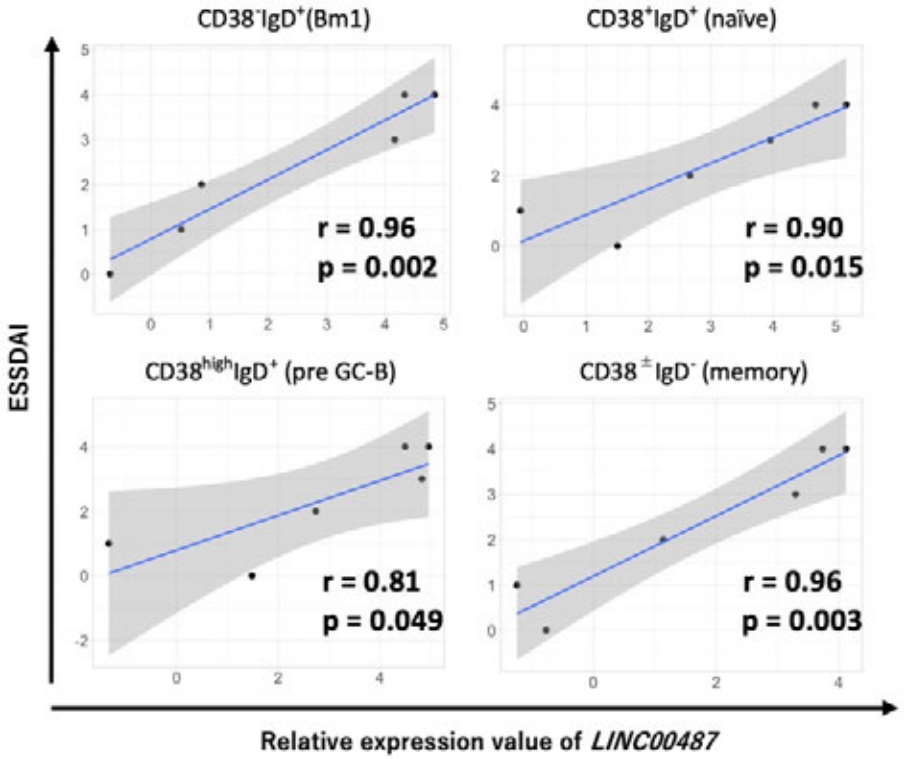

Figure 1. Scatter plot of disease activity score and relative expression level of LINC00487 in CD38-IgD+ (Bm1), CD38+IgD+ (naïve), CD38highIgD+ (pre GC-B) and CD38±IgD- (memory) subset of patients with primary Sjögren's syndrome.

Methods: We enrolled patients with pSS (n=6) and healthy controls (HC) (n=6). Peripheral B cells acquired from these subjects were separated by cell sorting into four subsets: $CD38^{-}IgD^{+}$ (Bm1), $CD38^{+}IgD^{+}$ (naïve B cells), $CD38^{high}IgD^{+}$ (pre-germinal centre B cells), and $CD38^{\pm l}gD^{-}$ (memory B cells). Total RNA was extracted, and gene expression was measured using microarrays. We conducted a bioinformatics analysis to identify differentially expressed genes (DEGs) and weighted gene co-expression network analysis (WGCNA) to identify pSS-associated signalling pathways. We validated gene expression levels in $CD19^{+}$ B cells of patients with pSS (n=7) and HC (n=7) in other cohorts by quantitative PCR (qPCR).

Results: Using principal component and clustering analyses, we found that transcript expression patterns depended on cell type rather than clinical condition (pSS or HC). DEGs analysis identified *LINC00487* as significantly upregulated in all B cell subsets as well as HLA and interferon signature genes. Moreover, the normalized intensity value of *LINC00487* significantly correlated with the disease activity score in all pSS B cell subsets (Figure 1). An in vitro study using human B cell lines revealed that the expression of *LINC00487* was strongly induced by IFNα. In validation cohort using qPCR, expression of *LINC00487* in $CD19^{+}$ B cells of patients with pSS tended to upregulate compared with HC, although it was not significant (relative expression levels of *LINC00487*/GDH; 0.00227 vs 0.00025, p = 0.12). Further, expression of *LINC00487* was significantly correlated with interferon stimulated gene, *interferon induced protein 44 like* (*IFI44L*). WGCNA revealed six clusters associated with the B cell subpopulation of pSS. Further, genes that encode components of the B cell receptor (BCR) signaling pathway were identified as intramodule hub genes such as *IKZF3* and *HRK*. *SOX4*, which may be targeted by several microRNAs identified in upstream analysis, was identified as an inter-module hub gene (Figure 2).

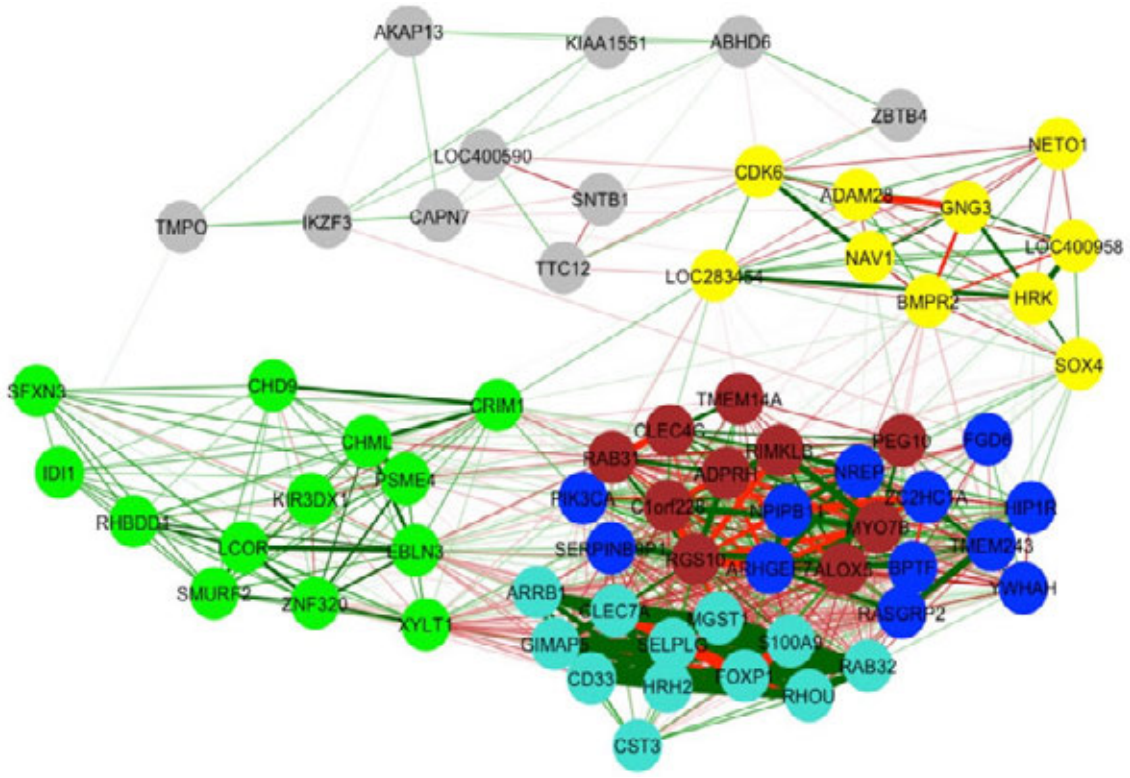

Figure 2. Associativity of intra- and inter-modular hub genes in B cells of pSS. Node-color corresponds with module-color. Green-coded edge means positive correlation and red-coded edge means negative correlation, respectively. The width of edge reflects absolute weight of correlation.

Conclusion: Our transcriptome analysis revealed key genes involved in the molecular dysregulation of B cell subpopulations associated with pSS. This knowledge contributes to our understandings of the pathogenesis of pSS.

Conditional Deletion of MKL1 Inhibits Osteoclast Formation and Bone Erosions in Collagen Induced Arthritis Mice

Wenfeng Tan,[1] Aishu Luo,[1] Yong Xu,[2] Shiyu Lin,[3] Miaojia Zhang,[4] and Fang Wang[3], [1]the First Affiliated Hospital of Nanjing Medical University, Nanjing, China (People's Republic), [2]Nanjing Medical University, NANJING, China (People's Republic), [3]the First Affiliated Hospital of Nanjing Medical University, Nanjing, [4]the First Affiliated Hospital of Nanjing Medical University, Najing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Excessively osteoclasts (OCs) activation play an essential role in bone erosions in rheumatoid arthritis (RA). Thus, controlling OCs would be an effective strategy to prevent pathological bone resorption. OCs originate from the hematopoietic monocyte-macrophage lineage. We previously showed that MKL1 is high expressed in macrophages and is indispensable for TNFα induced proinflammatory transcription in macrophages. Here, we explored the effect of MKL1 on OCs differentiation and function and examined its role on bone resorption during inflammatory arthritis.

Methods: OCs differenation and function were assayed by TRAP staining and pit formation assay. Bone erosions in collagen induced arthritis mice (CIA) was analyzed by histopathology and MicroCT. RNA-seq was used to detect the potential mechanism that involved in OCs formation after conditional deletion of MKL1 in macrophages.

Results: The multinucleated osteoclast formation in vitro was impaired in bone marrow cells isolated from the KO mice compared with those from wild-type mice (WT). OCs related genes expression included TRAP and CTSK were significantly down-regulated in KO mice. Targeted ablation of MKL1 in macrophages resulted in decreased OCs numbers in bone marrow and increased bone mass in KO mice. In contrast, no effect on T cells, B cells and monocyte numbers in bone marrow. Deletion of MKL1 mice showed the mild bone resorption after subcutaneously injecting of LPS on calvariae compared with WT mice. In a CIA model , KO mice exhibited the delayed arthritis onset, mild arthritis score, lower synovial inflammatory cell infiltration and decreased bone erosion, as compared with WT mice. RNA-seq indicated that OCs derived from mice with macrophage MKL1-deficient mice had an increased Rho kinase and IFN signaling pathway.

Conclusion: Our data suggested that MKL1 plays an important role in regulation osteoclast formation and bone erosions in CIA mice.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) therapies are constrained by the failure to deliver sufficient quantities of drug to the inflamed site, systemic side effects, and the inability for the patient to self-direct therapeutics in a site-targeted fashion. To address this, we have conjugated anti-inflammatory drugs to the light-responsive fluorophore Cy5, anchored to vitamin B12. These photocleavable drug-conjugates can be loaded into red blood cells (RBCs) and released only after laser light activation. *In vitro* studies have shown RBC-B12-Cy5-dexamethasone successfully induced nuclear migration of the glucocorticoid receptor after laser light photocleavage. We believe this system can be used in the treatment of RA, where externally and selectively applied laser to joints can trigger photocleavage of anti-inflammatories internally loaded into RBCs to the targeted site.

Methods: Collagen Antibody Induced Arthritis (CAIA) was induced in 45 DBA1J mice. Arthritis was measured by a blinded observer with a clinical disease score index, and mice were randomized to 3 groups after symptom onset: RBC-B12-Cy5-dexamethasone (RBC-DEX), RBC-Cy5 (negative control), intraperitoneal dexamethasone (IP-DEX; positive control). Hypotonic solution was used to create a porous membrane in murine RBCs for drug uptake, followed by isotonic solution to close the pores and trap the phototherapeutic inside until photo-release. The RBC-DEX group received RBCs (90% hematocrit, 100μL) loaded with B12-Cy5-dexamethasone (approx. 0.0065 mg) intravenously. The RBC-Cy5 control group received RBCs internally loaded with only B12-Cy5. Intravenous injections were given one time at symptom onset for both RBC-DEX and RBC-Cy5. The IP-DEX group received 0.5mg/kg daily until a clinical score of 0 in the arthritic paw receiving laser. Laser (635 nm, 3 mW) was applied to one affected joint for 5 minutes immediately following i.v. or i.p. injection (based on group assignment) and each day until termination. There were no adverse reactions from laser application.

Results: RBC-DEX and IP-DEX produce significant improvement in clinical arthritis compared to the control RBC-Cy5 (p=0.0007, p=0.0002 respectively), but do not significantly differ from each other (p=0.6) (Fig. 1). The RBC-DEX

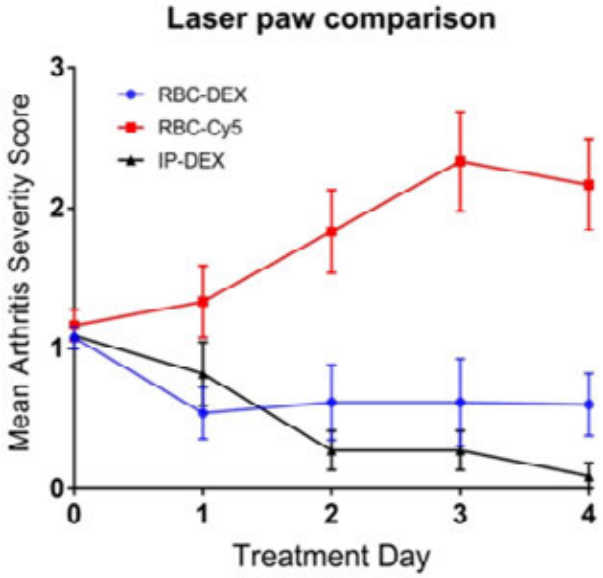

Figure 1. Assessment of mean arthritis severity score after treatment. Across 3 groups: p<0.0001*. RBC-Cy5 vs. IP-DEX: p=0.0002* RBC-DEX vs. IP-DEX: p=0.6 RBC-DEX vs. RBC-Cy5: p=0.0007*

group received on average 80% less dexamethasone as compared to the IP-DEX treatment group, without significantly different results.

Conclusion: RBC-DEX is an effective CAIA treatment compared to negative control and is as effective as the positive drug control using a substantially lower dose of dexamethasone. This warrants further study into the parameters that are required for selective release of RBC-DEX in arthritis treatment.

Platelet Derived Growth Factor Receptor Alpha (PDGFRα) Blockade Inhibits Arthritis in Mice

Bhanupriya Madarampalli,[1] Paul Panipinto,[1] Erica Chow,[1] Kendahl Sugai,[1] Fanqi Shi,[1] and Erika Noss[1], [1]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The interplay between infiltrating immune cells and activated joint stromal cells drives inflammation, cartilage destruction, and bone erosion in rheumatoid arthritis (RA). Among joint cells, fibroblasts amplify inflammation and erode cartilage. Identifying anti-fibroblast therapies to combine with approved drugs targeting the systemic immune response has the potential to improve clinical efficacy without substantially increasing immunosuppressive risk. Based on prior studies showing PDGFRα expression is upregulated in RA synovium and stimulates fibroblast proliferation and matrix invasion *in vitro, w*e propose that targeting platelet-derived growth factor receptor-alpha (PDGFRα) will block synovial fibroblast-mediated inflammation and cartilage erosion, promoting translation of a new anti-PDGFRα biologic for sarcoma treatment to autoimmune arthritis.

Methods: PDGFR expression in human primary synovial fibroblasts was determined by quantitative reverse transcription-polymerase chain reaction (qRT-PCR) and flow cytometry analysis. Matrix metalloproteinase (MMP)-3 release was quantified by ELISA. Role of PDGFRα *in vivo* was tested using the serum transfer arthritis model. PDGFRα-expressing cell populations in arthritic KxB/N mice synovium were analyzed by flow cytometry after *ex vivo* enzymatic digestion. Since PDGFRα genetic silencing is embryonically lethal, PDGFRα conditional knock out (KO) mice were developed by breeding floxed PDGFRα (*B6.Cg-PDGFRatm8SorEiJ*) mice with a strain expressing tamoxifen-inducible cre-recombinase under control of the ubiquitin promoter (*B6.Cg-Tg(UBC-cre/ERT2)1Ejb/1J)*. Commercially available anti-PDGFRα antibodies were used to prevent arthritis.

Results: *In vitro* cultured human synovial fibroblasts expressed higher levels of PDGFRα, compared to the related receptor, PDGFRβ, by qPCR analysis. Although both PDGFRα and PDGFRβ activation increased synovial fibroblast proliferation *in vitro*, only PDGFRα activation through its specific ligand, PDGF-AA, acted synergistically with TNF-α to increase production of MMP-3, a known biomarker of RA joint damage. PDGFRα KO mice developed less arthritis and histologic damage compared to littermate controls in the serum transfer arthritis model. A pilot antibody treatment experiment also showed that antibodies directed against PDGFRα prevented arthritis development. By flow cytometry, most synovial CD45-CD31- mesenchymal (fibroblast) cells in inflamed KxB/N mice synovium strongly

expressed PDGFRα and PDGFRβ. However, PDGFRα was more selectively expressed by fibroblasts, with PDGFRβ also expressed on populations of immune and endothelial cells.

Conclusion: These *in vitro* and *in vivo* studies support a role of PDGFRα in regulating synovial fibroblast-mediated pathology, indicating that blocking PDGFRα may be a new treatment strategy in inflammatory arthritis. Further investigation of the role of PDGFRα in arthritis development is expected to support translation of a new anti-PDGFRα cancer monoclonal antibody into arthritis treatment.

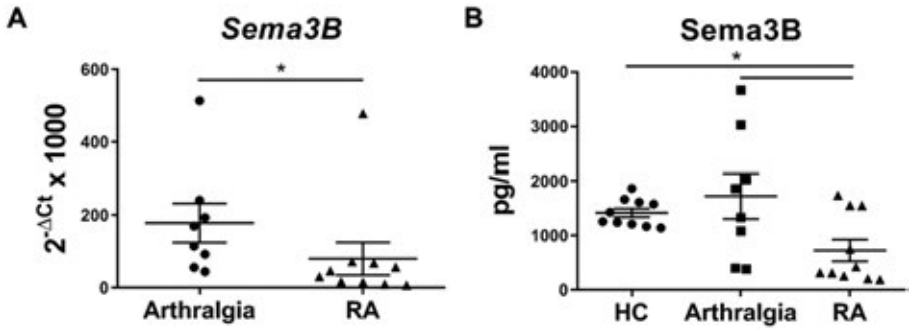
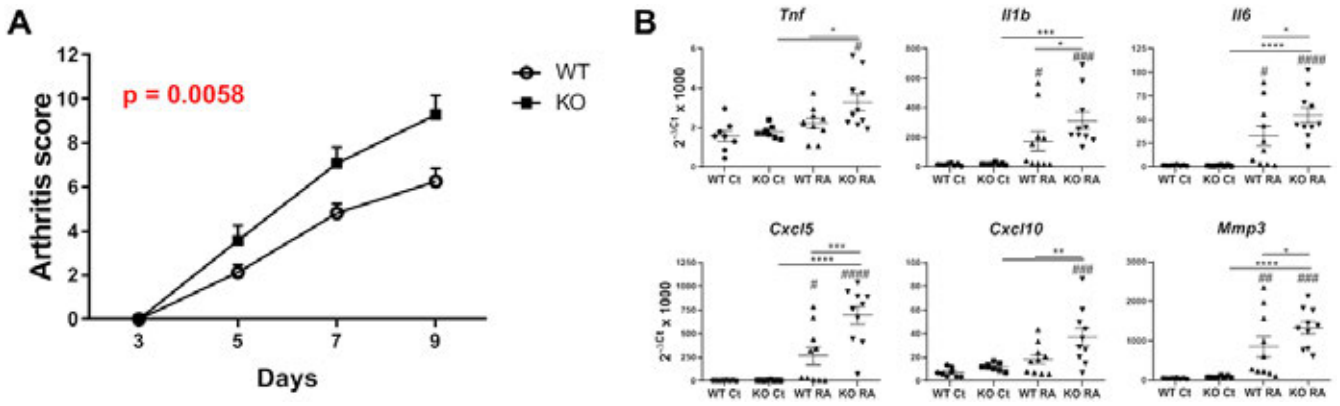
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

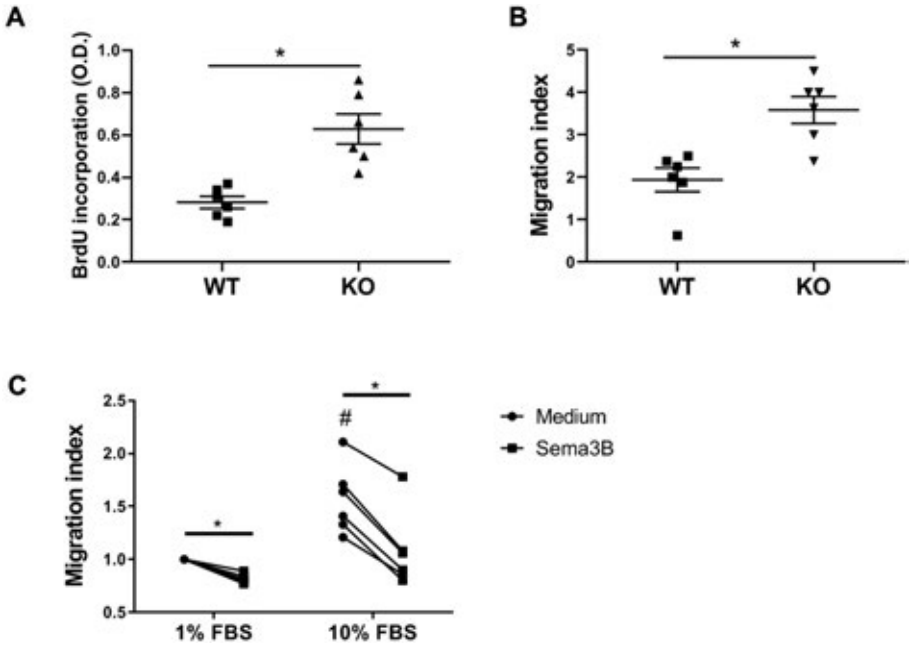
Background/Purpose: The semaphorin family is a large group of proteins initially described in axon guidance. However, semaphorins also play a role in other processes involved in rheumatoid arthritis (RA) such as the regulation of



A-B. Sema3B mRNA and protein levels in the synovial tissue (A) and serum (B) of RA and arthralgia patients. Data is presented as a scatter plot, where each point represents an individual patient. * $p<0.05$.



(A) Daily global arthritic scores of WT and Sema3B deficient (KO) mice. (B) mRNA expression of inflammatory mediators in the forepaws of control and arthritic WT or Sema3B KO mice. Data is presented as a scatter plot, where each point represents an individual mouse. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$ and **** $p < 0.0001$. # $p < 0.05$, ## $p < 0.01$, ### $p < 0.001$ and #### $p < 0.0001$ compared to WT control mice.



A-B. Proliferation (A) and migration (B) of mFLS from WT and Sema3B-deficient (KO) mice in the presence or absence of 10% FBS for 24 h. Data is shown as BrdU incorporation (A) or migration index (B) and presented as a scatter plot, where each point represents an individual mouse. C. Migration of mFLS stimulated with Sema3B (100 ng/ml) in the presence or absence of 10% FBS for24 h. Data is shown as migration index and presented as connected dots. * $p < 0.05$ compared to medium 1% FBS.

immunity, angiogenesis, apoptosis and cell migration and invasion. Previously we demonstrated that semaphorin 3B (Sema3B) expression is reduced in the synovial tissue and synovial fluid of RA compared to undifferentiated arthritis patients and reduces the invasive capacity of RA fibroblast like synoviocytes (FLS). Here, we validated initial findings in an independent cohort of patients and determined the role of Sema3B in an *in vivo* model of arthritis

Methods: Sema3B expression in healthy control (HC, n=10), RA (n=10) and arthralgia patient (n=8) synovial tissue and serum was determined by qPCR and ELISA. Arthritis was induced in wild type (WT) and Sema3B-deficient mice (Sema3B KO) mice (n=10 for both) by intraperitoneal injection of 100 ml of K/BxN serum on day 0 and day 2. Mice were sacrificed on day 9 after serum transfer. mRNA expression in total joints and murine fibroblast-like synociocytes

(mFLS) was determined by qPCR. mFLS proliferation and migration were determined using BrdU and wound closure assays, respectively.

Results: mRNA levels of Sema3B were significantly lower in the synovial tissue of RA patients compared to arthralgia patient (p=0.0205). Importantly, serum levels of Sema3B were also reduced in RA patients compared to HC and arthralgia patients (p=0.034 and p=0.0241, respectively) The clinical severity of serum-induced arthritis was significantly higher in Sema3B KO mice compared to WT mice (p=0.0015). This was associated with a higher joint and mFLS expression of the inflammatory mediators IL-1β, TNF, IL-6, CXCL-5 and CXCL-10 and the matrix metalloproteinases MMP-2 and MMP-3 (p-values ranging between $p< 0.05$ and $p< 0.001$). Functional experiments demonstrated a significantly higher proliferation and migration capacity (p=0.034 and p=0.0313, respectively) in the mFLS from Sema3B KO compared to WT mice. Importantly, the administration of recombinant mouse Sema3B abrogated the enhanced migratory capacity of Sema3B KO mFLS (p=0.044).

Conclusion: Our data confirm our previous results demonstrating that Sema3B expression is reduced early in RA onset and provide evidence that Sema3B has a protective role in a mouse model of arthritis. Therefore, Sema3B administration could be a novel therapeutic strategy for the treatment of RA.

Adipocytokines and Obesity in the Context of Rheumatoid and Osteoarthritis Mouse Models

Hani Manfred Sauermilch,[1] Marie-Lisa Hülser,[1] Carina Schreiyäck,[1] Yubin Luo,[2] Aline Bozec,[2] Georg Schett,[3] Ulf Müller-Ladner,[4] and Elena Neumann[5], [1]Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University Giessen, Germany, Giessen, Germany, [2]Department Clinic of Medicine 3 - Immunology and Rheumatology, University of Erlangen-Nürnberg, Erlangen, Germany, Erlangen, Germany, [3]Department of Internal Medicine 3, Friedrich Alexander University Erlangen-Nuremberg, Erlangen, Germany, [4]Justus Liebig University Gießen, Department of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Germany, Gießen, Hessen, Germany, [5]Justus Liebig University Gießen, Department of Rheumatology and Clinical Immunology, Campus Kerckhoff, Bad Nauheim, Germany, Giessen, Hessen, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adipocytokines are bioactive factors mainly produced by adipose tissue and exert many important effects on energy homeostasis as well as immune responses. Osteoarthritis (OA) is one of the most common degenerative joint diseases whereas rheumatoid arthritis (RA) is a chronic autoimmune joint disease. To evaluate the role of adipokines and obesity in the setting of both diseases at different time points, we combined an obesity model (high-fat diet, HFD) with a model for OA (DMM, destabilization of the medial meniscus) and RA (collagen induced arthritis, CIA).

Methods: The DMM model was performed in C57Bl/6 mice fed with HFD or ND (normal diet) prior to OA induction. In the CIA model, DBA/1Rj mice were fed with the same diets for 12 (DMM) and 6 (CIA) weeks prior to CIA induction.

Mice were sacrificed to collect histological as well as serological data after 4, 6 and 8 weeks (DMM model) or after 4, 5.5 and 7 weeks (CIA model) after arthritis induction. Histological scoring for arthritis induction (both models) and assessment of a clinical score for the CIA model was performed. Serum concentrations of CRP, the adipokines adiponectin, leptin and visfatin were measured. Immunohistochemical stainings were performed to evaluate local adipokine distribution in the joints. Diet-induced systemic changes were analyzed using a fatty liver score and evaluation of crown-like structures (CLS) in adipose tissue.

Results: Induction of OA/ RA was successfully established in an HFD setting, shown by the histological joint destruction and the increased fatty liver score and bodyweight, respectively. In DMM, the number of CLS were significantly higher in the HFD group (0.2 ± 0.16, n=7) compared to the ND group (5.2 ± 0.98, n=8). However, CIA induction increased the number of CLS in HFD (2.77 ± 1.07, n=6) and especially in ND animals (8.14 ± 0.23, n=5) compared to healthy ND mice (0.45 ± 0.03, n=4) and healthy HFD mice (2.57 ± 0.53, n=4) without CIA induction. With regard to healthy animals, CRP serum levels were significantly increased in mice after CIA induction. Interestingly, CIA and DMM induction decreased systemic leptin levels significantly which could not be observed in the local leptin distribution in the joints (CIA).

Conclusion: Our data show that OA is deteriorated by HFD, similar to observations in humans. Histological CIA scoring showed no significant difference in CIA severity under HFD or ND. The high numbers of CLS in CIA animals with ND and the strong reduction of serum leptin levels in CIA animals with HFD indicates that CIA onset and severity are mainly obesity independent while OA (DMM) appears to be influenced by obesity. Interestingly, systemic and local adipokine concentrations did not match in DMM as well as the CIA model. This data suggests a time-dependent adipokine expression and segregation of local and systemic adipokine effects in the context of RA and OA.

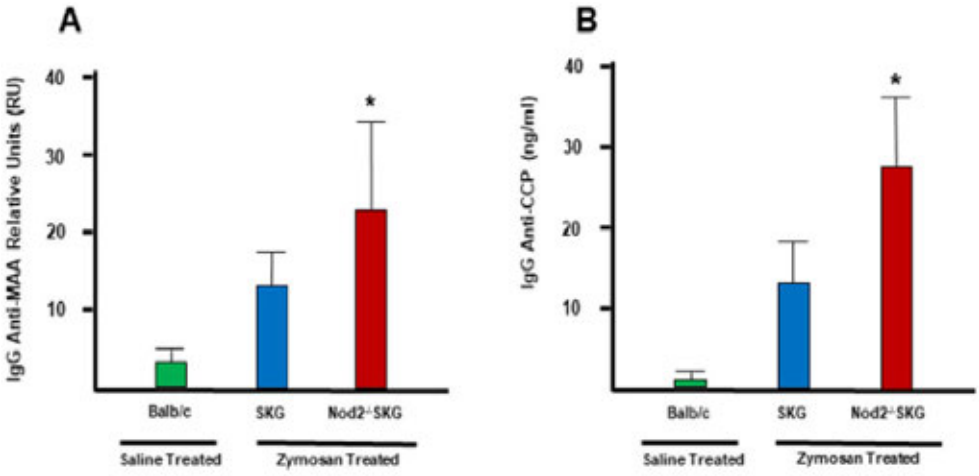
A Novel Role for Nod2 in Controlling Autoantibody Production and Arthritis in SKG Mice

Ruth Napier,[1] Emily Vance,[1] James O'Dell,[2] Jill Poole,[3] Bryant England,[4] Michael Duryee,[3] Ted Mikuls,[2] Holly Rosenzweig,[5] and Geoffrey Thiele[2], [1]Oregon Health & Science University and Portland VA Hospital, Portland, OR, [2]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE, [3]University of Nebraska Medical Center, Omaha, NE, [4]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, [5]Oregon Health & Science University and Portland VA Hospital, Oregon

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory disease that manifests in a chronic and debilitating polyarthritis. Although the etiology of RA is unknown pathogenic autoreactive T cells and autoantibodies including anti-CCP and anti- malondialdehyde-acetaldehyde (MAA) are thought to contribute to disease pathogenesis. Our recent studies identified the microbial sensor Nod2 as a critical genetic determinant in controlling the Th17-response and arthritis severity in SKG mice (Napier RJ et al. J Immunol 2018). However, whether Nod2 also contrib-



Increased concentrations of serum anti-CCP and anti-MAA autoantibodies at 8 weeks post zymosan exposure in Nod2-/-SKG, zymosan-exposed SKG and saline treated Balb/c mice. IgG anti-MAA (A) and IgG anti-CCP (B) antibody concentrations were significantly elevated in Nod2-/-SKG zymosan treated mice as compared to SKG zymosan treated mice ($p = 0.0111$ for CCP; and, $p = 0.0223$ for MAA) and sham treated Balb/c mice ($p = 0.0371$ for CCP; and, $p = 0.0430$ for MAA). No significant differences were observed in the concentrations of anti-CCP or anti-MAA antibodies between the SKG zymosan treated mice and the saline treated Balb/c mice.

utes to autoantibody production in SKG mice is unknown. The purpose of this study was to extend our understanding of the protective mechanisms by which Nod2 controls arthritis in SKG mice to humoral immunity.

Methods: Balb/c, SKG and Nod2$^{-/-}$SKG mice (6-8 wk age) were housed under specific pathogen-free conditions. Arthritis was induced by i.p. injection of 1.5 mg zymosan (Sigma-Aldrich) vs. saline (sham control). Serum IgG anti-CCP and anti-MAA antibodies were measured by ELISA 8 weeks later. Clinical arthritis for each paw was graded (0–4) in masked fashion. T cells (CD4$^+$ and CD8$^+$) were isolated from joint synovial fluid and evaluated (#T cells/ml) by flow cytometry.

Results: Nod2$^{-/-}$SKG mice had significantly increased concentrations of serum anti-CCP and anti-MAA autoantibodies at 8 weeks post zymosan exposure compared to zymosan-exposed SKG ($p = 0.0111$ for CCP; and, $p = 0.0223$ for MAA) and sham treated Balb/c mice ($p = 0.0371$ for CCP; and, $p = 0.0430$ for MAA), the latter group demonstrating only negligible autoantibody reactivity. While there were increased concentrations of anti-CCP and anti-MAA antibodies in SKG mice exposed to zymosan compared to saline exposed Balb/c mice, they were not significantly higher ($p = 0.080$ for CCP; and, $p = 0.111$ for MAA). Comparisons with previously reported data (Napier et al.) showed serum anti-CCP and anti-MAA concentrations were increased in conjunction with arthritis scores in SKG and Nod2$^{-/-}$SKG mice stimulated with zymosan. Likewise, we observed similar increases anti-CCP and anti-MAA concentrations that were associated with the total number of CD4$^+$ T cells present in the synovial fluid collected from SKG and Nod2$^{-/-}$ SKG mice stimulated with zymosan.

Conclusion: These data suggest a previously unprecedented role for Nod2 in suppressing autoreactive B cell responses in the SKG arthritis model. Increased autoantibody concentrations correlated with increased synovial T cell responses and more severe arthritis. Understanding the mechanisms and consequences of enhanced autoantibody production in Nod2-deficient SKG mice will contribute to our understanding of the pathophysiology of RA. Moreover, arthritis resulting from Nod2 deficiency in SKG mice renders a disease model that is characterized by enhancements in both T cell responses and humoral immunity, suggesting that the Nod2$^{-/-}$SKG mice might provide a highly relevant system for modeling RA.

Increased concentrations of serum anti-CCP and anti-MAA autoantibodies at 8 weeks post zymosan exposure in Nod2-/-SKG, zymosan-exposed SKG and saline treated Balb/c mice. IgG anti-MAA (A) and IgG anti-CCP (B) anti-

body concentrations were significantly elevated in Nod2-/-SKG zymosan treated mice as compared to SKG zymosan treated mice (p = 0.0111 for CCP; and, p = 0.0223 for MAA) and sham treated Balb/c mice (p = 0.0371 for CCP; and, p = 0.0430 for MAA). No significant differences were observed in the concentrations of anti-CCP or anti-MAA antibodies between the SKG zymosan treated mice and the saline treated Balb/c mice.

Abstract Number: 0983

Fecal Transfer from Mice on High or Low Magnesium Diets Confers Arthritis Protection

Teresina Laragione,[1] Carolyn Harris,[1] and Percio Gulko[1], [1]Icahn School of Medicine at Mount Sinai, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Magnesium (Mg) plays a key role in the immune response. We have previously demonstrated that alterations in the Mg balance by increasing or decreasing the Mg daily intake significantly protected mice in Collagen Induced Arthritis and KRN serum-induced arthritis. The effect correlated with reduced number of Th17 T cells and increased number of FoxP3$^+$ Treg cells, as well as with a significant reduction in the amounts of Segmented filamentous bacteria (SFB) and a significant increase in the amounts of *Bacteroides fragilis (*BFR). In this study, we hypothesized that the gut microbiota changes induced by dietary Mg modifications could account for the arthritis protective effect induced by the diet.

Methods: Donor mice (C57BL/6; Taconic) were placed on a low (50 ppm), regular (500 ppm) or high Mg diet (2800 ppm) for 14 days. Fecal samples were obtained on days 14 and 15, homogenized in water (30 mg of fecal pellet in 400 ml) and filtered. Recipient mice (C57BL/6; Taconic) were treated with an antibiotic cocktail containing Metronidazol (140 mg/Kg), Neomycin (140 mg/Kg) and Vancomycin (10 mg/Kg) for 5 days and allowed to recover for 2 days. Recipient mice receiving a regular 500ppm diet were then gavaged daily from day 0 to day 5 with fecal material from the donor mice and arthritis was induced by injecting 100 ml of arthritogenic serum from KRN mice on days 3 and 5. The animals were scored daily for

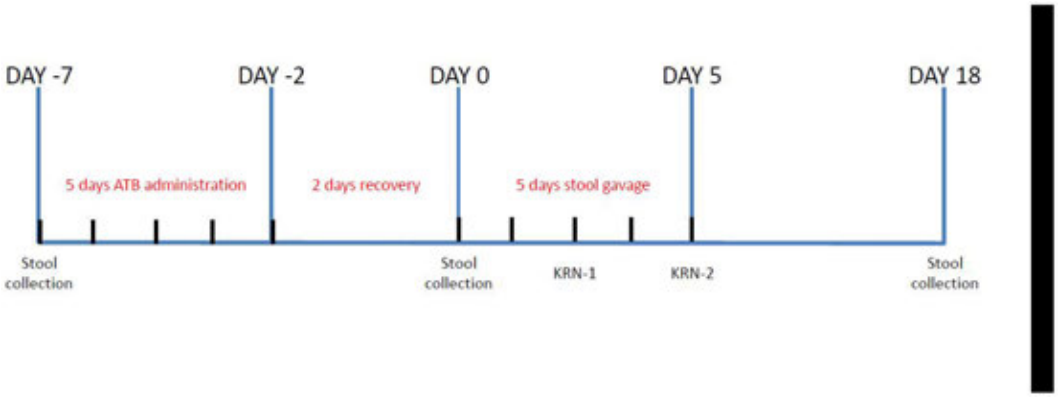

Figure 1. Timing of the stool collection, antibiotic (ATB) administration, stool collection and arthritis induction with KRN serum transfer (KRN-1= first dose; KRN-2=second dose) from day -7 to day 18.

15 days. Fecal samples were collected before antibiotics treatment (day -7), after antibiotic treatment but before the fecal transfer (day 0) and at endpoint (day 18). Genomic DNA was extracted and the levels of the commensal bacteria BFR and SFB determined by qPCR. Tissues were also collected for histology and flow cytometry analysis.

Results: Antibiotic treatment for 5 days eliminated SFB and BFR content in all groups (stool qPCR day 0). Fecal transfers were completed without problems. Recipient groups receiving fecal transfer from either the low or high Mg diet donor mice had a significant 50% reduction in maximum arthritis severity scores ($p< 0.05$) and a nearly 30% increase in FoxP3+ Treg and Tr1+ compared with recipients of fecal transfer from the regular Mg diet mice.

Conclusion: This study provides evidence suggesting that the high and low Mg diets reduce arthritis severity and increase numbers of FoxP3+ Tregs via the modulation of the intestinal microbiome and that stools from these mice can transfer these protective phenotypes into recipient mice. Therefore, targeting Mg homeostasis with dietary modifications has the potential to become a new tool to modify the intestinal microbiome to treat autoimmune disorders such as arthritis.

Important Role of CD11c^{+} Cells in Inflammatory Arthritis

Antonia Puchner,[1] Elisabeth Simader,[1] Victoria Saferding,[2] Gerhard Kroenke,[3] Rene Pfeifle,[4] Daniel Aletaha,[1] Josef Smolen,[1] and Stephan Blueml[1], [1]Medical University of Vienna, Vienna, Austria, [2]Division of Rheumatology, Department of Internal Medicine III, Medical University of Vienna, Vienna, Austria, [3]Department of Internal Medicine 3, Friedrich-Alexander-University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Austria, [4]University Hospital Erlangen, Erlangen, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different subsets with specific functions. As powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the active role of DCs in joint inflammation is not known yet.

Methods: We analyzed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We used CD11c-diphteria toxin receptor (DTR) transgenic mice. K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

Results: Both CD8+CD11c+ and CD11b+CD11c+, can be found in synovial tissue in TNF driven arthritis. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthritis were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of CD11c+ cells in K/BxN arthritis. In addition, local bone destruction and the number of osteoclasts was also significantly reduced. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of CD11c+ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.

Conclusion: These data show that in addition to initiating an adaptive immune response, CD11c+ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially CD11b+CD11c+ and monocyte derived inflammatory seem to play a role in inflammatory arthritis, suggesting that they could be an important therapeutic target.

Inhibition of Calcium/calmodulin-dependent Protein Kinase IV in Rheumatoid Arthritis: Dual Effect on Th17 Cell Activation and Osteoclastogenesis

Tomohiro Koga,[1] Tomohito Sato,[2] Yushiro Endo,[1] Sosuke Tsuji,[1] Ayuko Takatani,[1] Toshimasa Shimizu,[1] Remi Sumiyoshi,[1] Takashi Igawa,[1] Shin-ya Kawashiri,[1] Naoki Iwamoto,[1] Kunihiro Ichinose,[1] Mami Tamai,[1] Hideki Nakamura,[1] Tomoki Origuchi,[3] Nobuya Yoshida,[4] Masataka Umeda,[5] George Tsokos,[4] and Atsushi Kawakami[6], [1]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki, Japan, [2]Nagasaki University, Nagasaki, Japan, [3]Nagasaki University School of health sciences, Division of physical therapy, Nagasaki, Japan, [4]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [5]Beth Israel Deaconess Medical Center, Boston, MA, [6]Nagasaki University Graduate School of Biomedical Sciences, Department of Immunology and Rheumatology, Division of Advanced Preventive Medical Sciences, Nagasaki

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CD4 $^{+}$ T cells are important in the pathogenesis of rheumatoid arthritis (RA), and therapies targeting the differentiation of osteoclasts are attracting attention. Calcium/calmodulin-dependent protein kinase IV (CaMK4) is a molecule involved in T cell activation and osteoclast differentiation, but the role of CaMK4 in T cells and osteoclasts in RA remains unclear.

Objective: We investigated the role of calcium/calmodulin-dependent protein kinase IV (CaMK4) in the expression of joint injury in rheumatoid arthritis (RA).

Methods: Mice subjected to collagen-induced arthritis (CIA) were treated with KN-93, a CaMK4 inhibitor, and the clinical score was evaluated by micro-computed tomography (μ-CT) and histology. The effect of CaMK4 inhibition on inflammatory cytokines and humoral immune response was also examined. *CAMK4* gene expression was measured in $CD4^{+}$ T cells from healthy controls and patients with active RA. $CD4^{+}$ cells were isolated from RA patients to determine the effect of KN-93 on T cell differentiation. We also isolated $CD14^{+}$ cells from RA patients to investigate osteoclast differentiation.

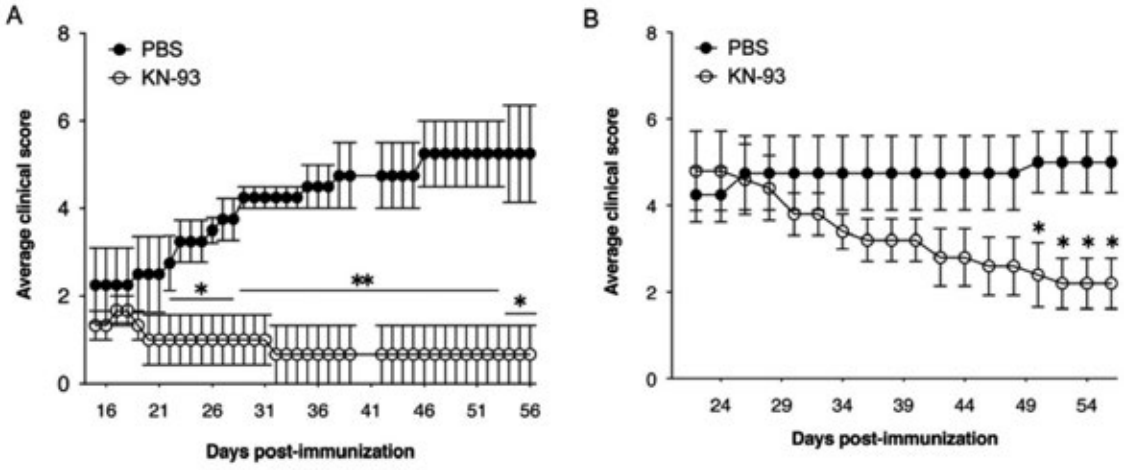

Figure 1. Administration of CaMK4 inhibitor, KN-93, attenuates the development of CIA in mice. Mean clinical scores of CIA in mice treated with KN-93 or PBS prior to the onset of disease (n = 5 per group) (A) and after established disease (n = 5 per group) (B) *p < 0.05; mean ± SEM.

Results: Treatment of CIA mice with KN-93 reduced significantly the arthritis clinical score and joint destruction as evaluated by μ-CT and histology. Further analysis revealed that CaMK4 inhibition in CIA mice suppressed the production of inflammatory cytokines including IL-6, IL-17, G-CSF, and MCP-1. Expression of *CAMK4* was significantly higher in $CD4^+$ T cells from patients with RA compared with cells from healthy controls. CaMK4 inhibition mitigated IL-17 production by $CD4^+$ cells from patients with RA. The number of *in vitro* differentiated osteoclasts from $CD14^+$ cells from RA patients was significantly decreased in the presence of the CaMK4 inhibitor.

Conclusion: The present study provides evidence that CaMK4 inhibition ameliorates CIA by suppressing the production of Th17 cell-related cytokines. At the translational level, we demonstrate that CaMK4 is increased in $CD4^+$ T cells from patients with active RA and that CaMK4 inhibition results in the decreased levels of osteoclast differentiation. Taken together, our findings indicate that CaMK4 inhibitors represent potential therapeutic agents in the treatment of patients with RA.

Session Title: RA – Animal Models Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

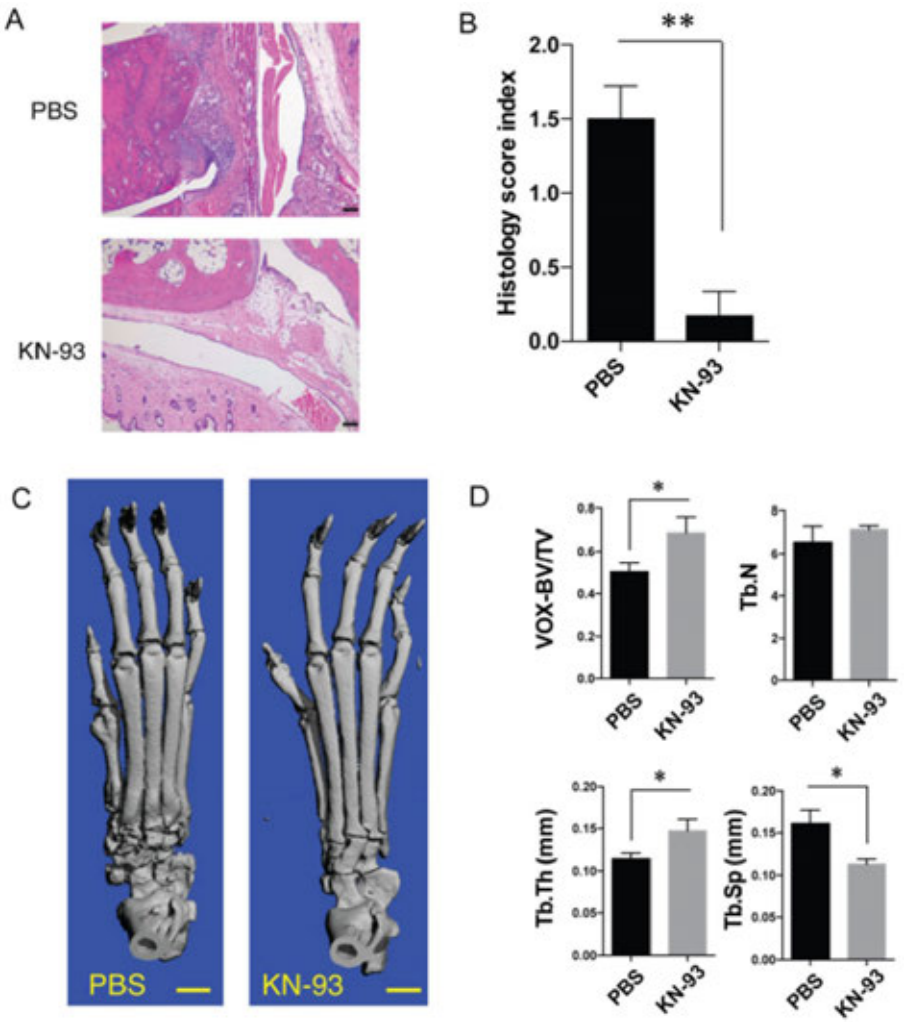

Figure 2. Preventive effect of KN-93 on joint damage in CIA mice. (A) Representative hematoxylin and eosin staining of the ankle joints of KN-93 or PBS-treated mice with CIA. Scale bars represent 100 μm. (B) Pathology scores of each group were calculated and expressed as mean ± SEM (n=4). * p< 0.05. (C) Microfocal computed tomographic images showing the dorsal surface reconstruction of the hind paws of PBS-treated (left) and KN-93 treated (right) mice. (D) Bone volume fraction (BV/TV), trabecular number (Tb.N), trabecular thickness (Tb.Th), and trabecular spacing (Tb.Sp) in mice treated with PBS or KN-93. Data represent mean and SEM, *p < 0.05.

Background/Purpose: Cognitive dysfunction including depression-like symptoms is a frequent comorbidity of rheumatoid arthritis (RA). Recently, rats with adjuvant-induced arthritis (AIA) were found to exhibit reduced levels of brain-derived neurotrophic factor (BDNF), a neurotrophin largely involved in neuroplasticity, learning, memory and cognitive abilities, in cognition-related brain regions[1]. Tofacitinib, an inhibitor of JAK3 and JAK1, has a great effect on RA activity, but whether it might improve cognition is unknown. To answer this question, the present study investigated the effect of Tofacitinib on brain BDNF levels and depression-like symptoms in AIA rats.

Methods: AIA was induced by injection of *Mycobacterium butyricum* in the tail of male Lewis rats. A group of rats without arthritis served as controls. At the first signs of arthritis, AIA received Tofacitinib (10 mg/kg twice daily, s.c.) or saline (Vehicle). Arthritis score was daily evaluated and a radiographic score was attributed to hind paws at the end of the treatment period. After 21 days of treatment, BDNF levels were measured in two brain regions involved in cog-

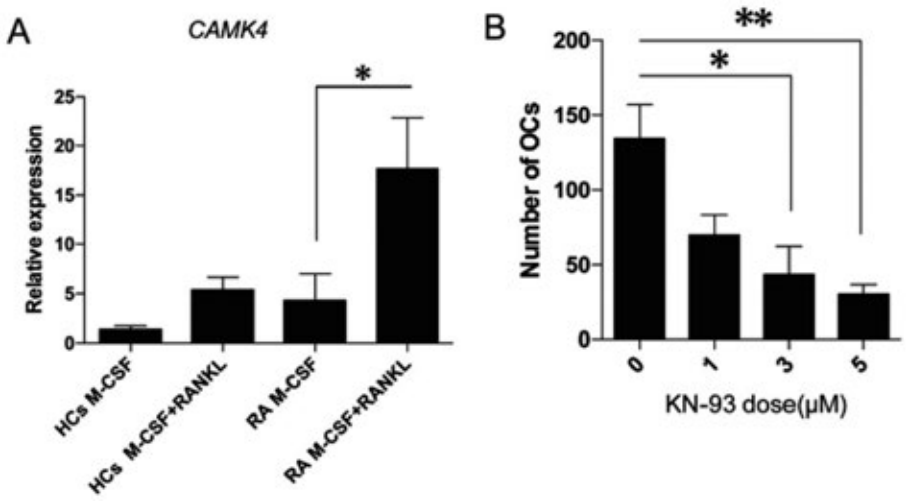

Figure 3. CaMK4 expression is involved in the osteoclastogenesis of RA (A) CAMK4 mRNA expression in CD14+ monocytes from patients with RA or HCs determined by qPCR. (* p< 0.05; median with interquartile range). (B) Active RA patients had significantly lower numbers of osteoclasts in the presence of KN-93 (* p< 0.05, ** p < 0.01; mean ± SD; n = 4). (C)

nition (prefrontal cortex and hippocampus) using western blot analysis. Anhedonia as a core symptom of depression was assessed from the sugar preference test before and during (3 times) treatment.

Results: As compared to controls, AIA resulted in depression-like symptoms from day 6 to 28 post-immunization. These symptoms coincided with a significant decrease in BDNF levels in the prefrontal cortex (-46%, p< 0.001) but not in the hippocampus (-5%, n.s.). BDNF levels were higher in Tofacitinib-AIA rats than vehicle-AIA rats either in the prefrontal cortex (+20%, p< 0.05) or hippocampus (+132%, p< 0.001). By contrast, anhedonia did not differ between Vehicle- and Tofacitinib-AIA rats.

Conclusion: The present data showed that Tofacitinib increased cerebral BDNF levels in AIA rats whatever the cognition-related structure considered, but with a stronger effect in the hippocampus than in the prefrontal cortex. However, the positive effect of Tofacitinib on BDNF did not translate into reduced anhedonia. Further studies are needed to identify the BDNF-dependent cognitive functions that are improved by Tofacitinib in RA.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies against citrullinated proteins (ACPAs) could be associated with bone loss, pain and tenosynovitis prior to disease onset in human rheumatoid arthritis (RA) and induce bone loss and pain when injected in mice. We aimed to investigate if transfer of human ACPAs into mice could induce tenosynovitis and/or subclinical inflammation.

Methods: Monoclonal ACPA (1325:04C03 and 1325:01B09) and control (1362:01E02) antibodies (mAbs) were generated from synovial plasma or memory B cells of RA patients. 2mg of combination of monoclonal ACPAs or control antibody were injected in BALB/c female mice (12-16 Weeks). Pain-like behavior was monitored by measuring mechanical hypersensitivity using von Frey filaments every 3 days and estimation by up-down Dixon method. Bone mineral density was measured by micro-CT. Using specially designed mobilization casts, dedicated mouse MRI coils, and gadolinium enhanced contrast medium, the hind limbs of these mice were scanned and evaluated for any signs of soft tissue joint inflammation. The MRI images were scored for the presence of synovial thickening, effusion and tendon inflammatory changes by 3 readers in a blinded manner.

Results: ACPAs (1325:04C03 and 1325:01B09) induced significantly more pronounced pain-like behavior (lasting for at least 4 weeks) and reduction of the trabecular bone thickness in the hind limbs, whereas no such effect was seen with the control monclonals generated in the same way as the monoclonal ACPAs. While no macroscopic sign of joint inflammation could be detected, MRI data shows sub-clinical joint inflammatory changes (such as perfusion of contrast in tendons, soft tissues and joints) in mice injected with ACPAs but not in those injected with control mAb. Using a semiquantitative score for the degree of inflammatory changes (0- Within normal range, 1-Mild, 2- Moderate and 3- Severe) we were able to show that ACPA induced mild to moderate inflammatory changes affecting tendon thickness, joint effusion and soft tissue enhancements, in contrast to control antibody or Saline injected mice which was within normal range (figure 1 below).

Conclusion: We show that ACPA induces pain-like behavior, bone loss and sub-clinical inflammation in mice, a model that mimics the pre-clinical state of ACPA positive RA

Session Title: RA – Animal Models Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory joint disease of autoimmune etiology. If insufficiently treated, RA leads to joint damage and irreversible disability. Although there is no cure, remission is possible with biological and synthetic disease-modifying antirheumatic drugs (DMARDs). Steroid treatment is highly efficacious in many autoimmune diseases, but significant side effects prevent their chronic use. With current treatment options many patients still do not achieve remission, thus prompting the need for improved therapeutics. An antibody drug conjugate (ADC) has been developed that combines TNF inhibition via the antibody with selective delivery of glucocorticoid into inflammatory cells, allowing disease inhibition while preventing the steroid side effects. In this study we evaluated longitudinal *in vivo* treatment effects of this anti-TNF-steroid ADC in the rat collagen-induced arthritis (CIA) model by multimodal translational imaging.

Methods: Inflammatory arthritis was induced in female Lewis rats by immunization with bovine type II collagen in incomplete Freund's adjuvant (IFA) on days 0 and 6. Rats were treated starting at peak inflammation on day 17 with either 10 mg/kg anti-TNF-steroid ADC, ip, qw; 10 mg/kg unconjugated anti-TNF mAb, ip, qw; or 3 mg/kg of the steroid payload po, qd; for three weeks. Paw swelling was assessed by measuring hindlimb volumes with a plethysmometer. Longitudinal *in vivo* magnetic resonance (MR) and X-ray micro-computed tomography (μCT) imaging of the hindlimb were used to monitor pathological changes in soft tissues and in bones, respectively, from day 0 before treatment to day 42. Rats were sacrificed on day 42 for histopathological assessment of hindlimb pathology including pannus and bone remodeling. In addition, *ex vivo* μCT was performed on hindlimb samples collected at the study endpoint (day 42).

Results: T2-weighted (T2W) images revealed that treatment with anti-TNF-steroid ADC for one week reduced joint tissue edema, while anti-TNF mAb elicited only a modest reduction. To further explore these changes in T2W contrast, we employed a histogram-based approach to divide the tibia-talus-tarsal hindlimb region into two compartments based on the T2W images. Anti-TNF-steroid ADC displayed superior treatment effects in both compartments as compared to anti-TNF mAb. Treatment effects in preserving bone integrity were evaluated by quantifying bone density, roughness, volume, and surface area with μCT. Three weeks of treatment with anti-TNF-steroid ADC significantly protected bone from damage indicated by an increased high-density bone volume and reduced surface area and roughness relative to the control. Both *in vivo* MRI and μCT and *ex vivo* μCT metrics corresponded well with histologic evaluation at the study endpoint (day 42).

Conclusion: These results demonstrate improved treatment efficacy of the anti-TNF-steroid ADC showing both resolution of inflammation as well as preservation of bone integrity when compared to anti-TNF mAb treatment alone. The quantitative imaging metrics were sensitive to treatment effects and may serve as biomarkers in a clinical trial.

Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dysfunction of lymphatic vessel contraction has been implicated in inflammatory arthritis progression and arthritic flare in murine models. Previous studies have demonstrated that tumor necrosis factor transgenic (TNF-Tg) mouse models of rheumatoid arthritis (RA) have notable ultrastructural damage to lymphatic smooth muscle cells (LSMCs).[1] As inflammatory arthritis progresses, LSMC contractions initially increase in frequency and the lymph node expands followed by a complete loss of LSMC contractions and lymph node collapse in severe disease states.[2] Effective treatment of inflammatory arthritis in TNF-Tg mice is associated with recovery of LSMCs and lymphatic vessel contractions.[1] As this regenerative process is critical for joint homeostasis and RA remission, elusive information on LSMC progenitors is needed. To address this, we tested the hypothesis that LSMCs are derived from the same stem cell pathway as vascular smooth muscle cells (VSMCs), which includes early mesenchymal expression of Paired Related Homeobox 1 (Prrx1) and subsequently differentiated Neural-Glial Antigen 2 (NG2) cell markers.[3,4,5]

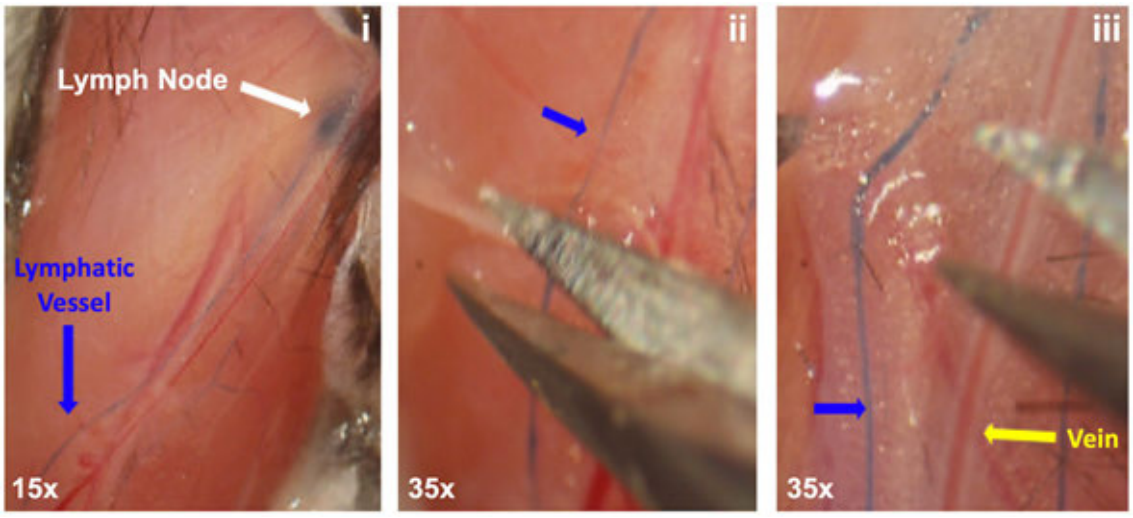
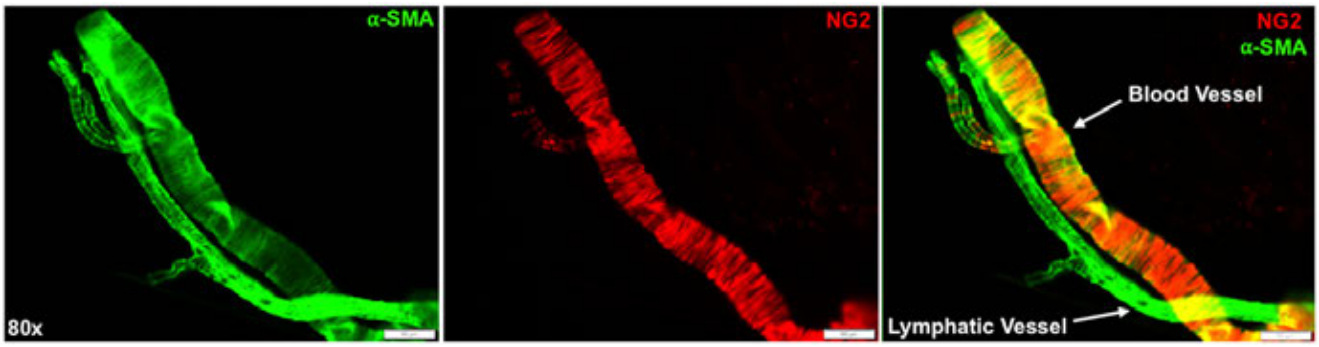
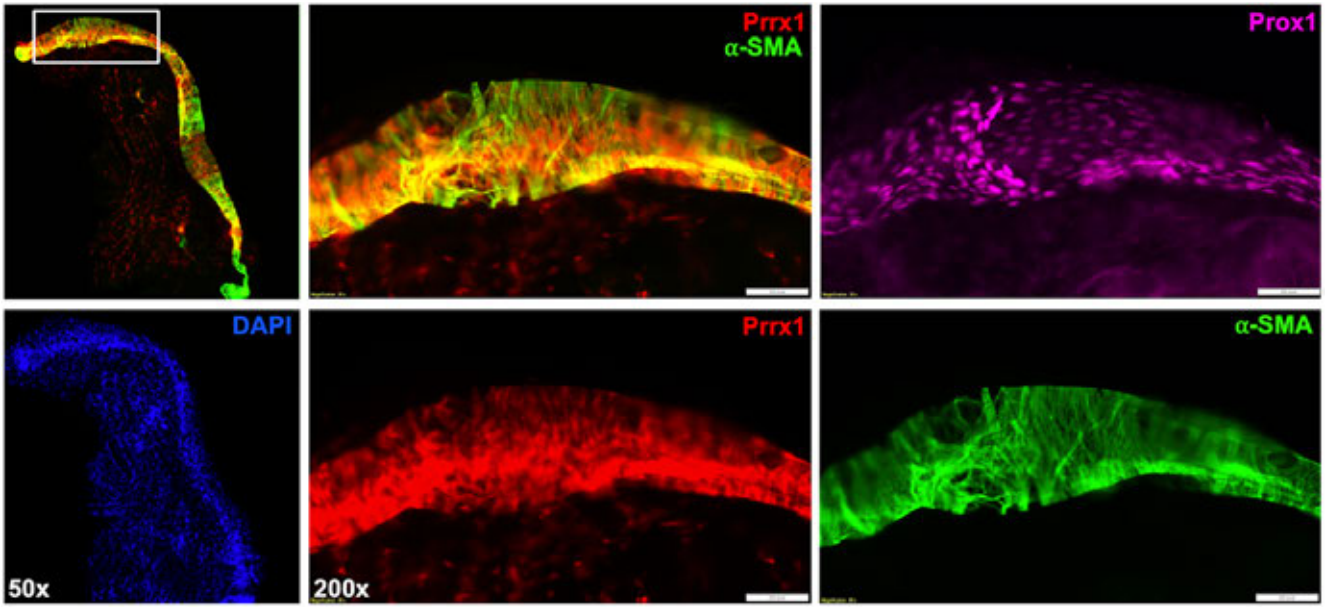
Methods: All animal studies were performed on IACUC approved protocols. We harvested the popliteal lymphatic vessels and saphenous vein from Prrx1-Cre and NG2-CreER^{T2} x Rosa26-Ai9 mice via micro-dissection of the sura. For the procedure, the mice were anesthetized, and 2% Evan's Blue dye was injected into their footpads to locate the lymphatic vessels. Induction of the NG2-CreER^{T2} was achieved with 0.1 mg/g of tamoxifen administered intraperitoneal on 4 consecutive days starting at post-natal day 10. All cohorts were sacrificed at post-natal day 20. To



Micro-dissection of popliteal lymphatic vessels from the sura. Mice were anesthetized and injected with 2% Evan's Blue dye into their footpad. With the dye, micro-dissections of the popliteal lymphatic vessels can be performed after opening the sural surface of the leg. (i) The length of the lymphatic vessel can be seen in blue (blue arrow in all panels) traveling to the popliteal lymph node (white arrow). (ii) Incisions were made on the anterolateral border of the lymphatic vessel to release it from the fat pad. (iii) The lymphatic vessel was then cut away from the saphenous vein (yellow arrow) and removed.



Post-natal lymphatic smooth muscle cells are not NG2 derived. The vessels were dissected from Ai9+/- x NG2-CreERT2 +/- (NG2-Cre+) mice at post-natal day 20. The NG2-Cre+ mice were all administered 0.1 mg/g of tamoxifen intraperitoneal for 4 days starting at post-natal day 10 to induce the Cre system in NG2+ cells. The NG2-Cre+ LSMCs have no red fluorescent protein unlike the VSMCs, which show notable red fluorescence of NG2+ VSMCs that co-localizes with α-SMA.



Post-natal lymphatic smooth muscle cells have Prrx1 heritage. The vessels were dissected from Ai9+/- x Prrx1-Cre +/- (Prrx1-Cre+) mice at post-natal day 20. The Prrx1-Cre+ mice constitutively expressed tdTomato via the Cre system in Prrx1+ cells without induction with tamoxifen. The Prrx1-Cre+ LSMCs have notable red fluorescent protein just as VSMCs (not shown) that co-localizes with the α-SMA. This novel finding demonstrates that LSMCs are of Prrx1 origin, similar to VSMCs, but the LSMC lineage diverges prior to the expression of NG2.

identify the lymphatic vessel, we used immunofluorescent staining for Prospero Homeobox Protein 1 (Prox1) – a lymphatic endothelial cell specific transcription factor. We visualized the LSMCs and VSMCs through immunofluorescent staining for Alpha-Smooth Muscle Actin (αSMA) to determine if Prrx1+ or NG2+ SMCs co-localized with αSMA via multicolor immunofluorescent microscopy.

Results: Our findings demonstrate that Prox1+/αSMA+ LSMCs are Prrx1 derived, but are NG2 negative. The LSMCs from NG2-CreER^{T2} x Rosa26-Ai9 mice were devoid of red fluorescence, while the LSMCs from Prrx1-Cre x Rosa26-Ai9 mice showed notable red fluorescence that co-localized with αSMA. Thus, LSMCs originate from an unknown progenitor cell pathway that is similar to, yet importantly unique from, that of the vascular system.

Conclusion: LSMCs are derived from Prrx1+ mesenchyme similar to VSMCs, but diverge before expression of NG2. They are also not derived from Paired Box Protein 7 (Pax7)+ satellite cells (data not shown). Future work elucidating the LSMC lineage could yield insights for targeted therapies for diseases with lymphatic involvement, such as inflammatory arthritis.

Micro-dissection of popliteal lymphatic vessels from the sura. Mice were anesthetized and injected with 2% Evan's Blue dye into their footpad. With the dye, micro-dissections of the popliteal lymphatic vessels can be performed after opening the sural surface of the leg. (i) The length of the lymphatic vessel can be seen in blue (blue arrow in all panels) traveling to the popliteal lymph node (white arrow). Development of a Novel Anti TNF-Steroid Antibody Drug Conjugate That Shows Promising Efficacy at Doses That Avoid Steroid Side Effects in a Mouse Model of Rheumatoid Arthritis

Wendy Waegell,[1] Christian Goess,[2] Robert Stoffel,[1] Michael McPherson,[1] Adrian Hobson,[1] Suzanne Mathieu,[2] Lucy Phillips,[1] and Shaughn Bryant[1], [1]AbbVie, Worcester, [2]Abbvie bioresearch Center, Worcester, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TNF-inhibitors are a well established therapy for autoimmune diseases including rheumatoid arthritis, Crohn's disease, psoriasis and ankylosing spondylitis but they have limited efficacy in some patients. Corticosteroid treatment is highly effective in autoimmunity but prolonged use at efficacious doses is contraindicated by significant side effects. We have developed a plasma stable antibody drug conjugate (ADC) that has steroid molecules linked to an anti-TNF a mAb. This ADC is targeted to TNF-a expressing inflammatory cells and internalized to cellular lysosomes. Once in the lysosome the ADC is digested and delivers steroid molecules into the cell. This significantly reduces the efficacious steroid dose to below levels that induce undesired side effects. In an acute in vivo model, contact hypersensitivity in C57BL/6 mice, we have shown that an anti-TNF-steroid ADC can significantly

inhibit the inflammatory response with a minimal effect on the steroid biomarkers, corticosterone and P1NP. Additionally, in a mouse model of rheumatoid arthritis, collagen induced arthritis (mCIA), we have demonstrated that a single therapeutic treatment with an anti-TNF-steroid ADC is able to completely inhibit disease for a greater than 30 days, while anti-TNF mAb only partially inhibits disease.

Methods: To evaluate whether the anti-TNF-ADC can reverse joint damage in mCIA we modified the mCIA model so that treatment was initiated 7 days after disease onset.

Results: To evaluate whether the anti-TNF-ADC can reverse joint damage in mCIA we modified the model so that treatment was initiated 7 days after disease onset. At this time there is significant pannus invasion as well as bone and cartilage destruction in the tarsal region of the ankle joint in these mice. We demonstrate that anti-TNF-steroid ADC treatment, after established disease, appears to heal the joints of previously arthritic mice when compared to a group of satellite animals sacrificed 7 days after disease onset. The tarsal joints from these mice were evaluated using micro computed tomography and by histologic evaluation. Restoration of normal joint architecture was seen in at least 40% of mice with TNF-steroid ADC treatment that was not seen with either an isotype control ADC or with the anti-TNF mAb alone.

Conclusion: These promising results suggest that a steroid targeted to cells involved in joint destruction via TNF binding has the potential to achieve not only lasting remission but also repair of the arthritic joints in RA patients, while sparing patients from steroid induced side effects.

Identification of Citrullinated Peptide Specific T-cells in Humanized Mice Immunized with Citrullinated Peptides

Matthew McElwee,[1] Thamotharampillai Dileepan,[1] and Marc Jenkins[1], [1]University of Minnesota, Minneapolis, MN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositive rheumatoid arthritis (RA) is a T-cell mediated disease that is characterized by the presence of antibodies to proteins that have undergone the post-translational conversion of arginine to citrulline. Certain HLA-DR major histocompatibility complex class II (MHCII) molecules, for example HLA-DRB1*0401 are closely associated with the development of seropositive RA. These molecules prefer to bind peptides with citrulline not arginine in the P4 position. Thus, citrullination of arginine can create peptides that bind to HLA-DRB1*0401 molecules better than the un-citrullinated versions. These citrullinated peptide:HLA-DRB1*0401 complexes may form neoantigens that activate T-cells with specific T-cell receptors. Indeed, such cells have been identified in patients with RA. In this study, we investigated the correlation between the reported binding affinity of citrullinated peptides to HLA-DRB1*0401 molecules (Ting et al.) and the number of T-cells that recognize these complexes after immunization with citrullinated peptide in transgenic mice expressing HLA-DRB1*0401 molecules.

Methods: Mice expressing HLA-DRB*0401 were immunized with 100 mg of one of eleven citrullinated peptides. The citrullinated peptides tested all had a citrulline at the P4 position and were from human proteins known to have citrullinated antibodies raised against them in RA. These proteins were: collagen intermediate layer protein (2 peptides), fibrinogen (2 peptides), vimentin (3 peptides), LL37 (1 peptide), a-enolase (1 peptide), and aggrecan (2 peptides). Ten days after immunization, citrullinated peptide:HLA-DRB1*0401 tetramers were used to identify specific T-cells in secondary lymphoid organs by flow cytometry.

Results: There was a wide range in the number of citrullinated peptide:HLA-DRB1*0401 tetramer-binding cells isolated from immunized mice (43-5557). The peptide that generated the lowest number of tetramer-binding cells was from human aggrecan 89-103 (Cit95) and the highest number was from human fibrinogen 69-81 (Cit74). When analyzing all peptides, there was a significant correlation between the affinity of the peptide for HLA-DRB1*0401 and the log10 number of citrullinated peptide:MHC tetramer positive cells identified after immunization (R squared 0.454, $p< 0.03$)

Conclusion: Immunization with citrullinated peptides with higher binding affinity to an RA-associated MHCII molecule stimulated a greater number of specific T-cells. These results provide further evidence that citrullination enhances T cell immunogenicity by improving the capacity of peptides to bind MHCII molecules.

Identification of CJ-15314, a Novel Highly Selective JAK1 Inhibitor, for the Treatment of Rheumatoid Arthritis

So Young Ki,[1] Dongkyu Kim,[1] Juhyun Lee,[1] Byoung Seok Moon,[1] and Shin-Young Ryu[1], [1]CJ Healthcare, Icheon-si, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Janus kinases (JAKs) play critical roles in mediating various cytokine signaling. First-generation non-selective JAK inhibitors such as tofacitinib and baricitinib are widely used for rheumatoid arthritis (RA). However, safety concerns such as anemia, thrombosis, and infection are raised for these therapeutics primarily linked with insufficient selectivity for JAK subfamily. The second-generation selective JAK1 inhibitor, filgotinib, exhibits a better safety profile, but testicular toxicity issue remains to be resolved. In the present study, we demonstrate that CJ-15314, a novel highly selective JAK1 inhibitor, exhibits robust efficacy in RA animal models with a preferable safety profile.

Methods: Biochemical, cell-based, human whole blood assay were performed to determine the inhibition potency and selectivity for JAK subfamily kinases. In vivo efficacy was evaluated in rat adjuvant-induced arthritis (rAIA) and collagen-induced arthritis (rCIA) models following oral administration (q.d.) for 2 weeks. A 2-weeks rat repeated dose toxicity study was performed to directly compare the toxicity between CJ-15314 and filgotinib.

Results: In biochemical analysis, CJ-15314 inhibited the JAK kinase family in a concentration - dependent manner, and the IC_{50} value of JAK1 was 3.8 nM, showing 18 fold more highly selectivity over JAK2 and 83 fold over JAK 3.

Accordingly, in human whole blood assays, CJ-15314 is 11 fold more potent against IL6-induced pSTAT1 inhibition through JAK1 (IC_{50} value: 70 nM) than GM-CSF-induced pSTAT5 inhibition (JAK2) whereas bricitinib and filgotinib exhibited only 2-fold and 7 fold respectively. In an in vivo efficacy model, CJ-15314 inhibited disease severity scores in a dose dependent manner. In the rAIA model, relative to vehicle-treated animals, CJ-15314 at 30 mg/kg showed 95.3% decrease in disease activity score, 51.2% in figotinib at 30 mg/kg, baricitinib at 10 mg/kg showed 97.7%. CJ-15314 showed superior anti-arthritic efficacy than filgotinib and similar efficacy to baricitinib. Although baricitinib induced a significant decrease in hematocrit, RBC, and reticulocyte count, CJ-15314 minimally affected anemia-related parameters at end of the 2-week treatment. In the rats CIA model, like 10 mg/kg of bricitinib, 30 mg/kg of CJ-15314 also had a similar effect, with a significant reduction in histopathological scores and plasma IL-1 beta level. In an acute 5-day repeated dose study in mice, CJ-15314 demonstrates relatively low responses to drug-induced platelet counts increase in 10, 30, 90 mg/kg treated groups compared with that of other JAK inhibitors, suggesting a low risk of thrombosis due to inhibition of peripheral thrombopoietin signal. In a rat 2 weeks repeated dose toxicity study, CJ-15314 exhibited a preferable safety profile, whereas tubular atrophy and luminal cell debris were observed testis and epididymis for filgotinib-treated groups.

Conclusion: CJ-15314 is a highly selective JAK1 inhibitor, demonstrates robust efficacy in RA animal models, exhibits differentiated toxicity profiles.

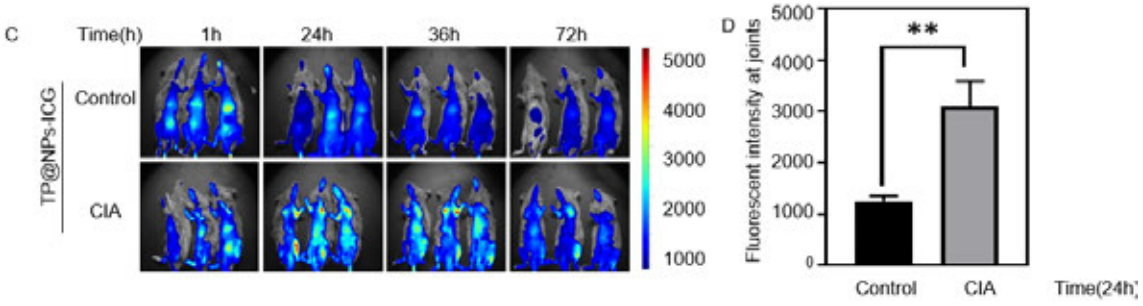
Session Date: Monday, November 11, 2019

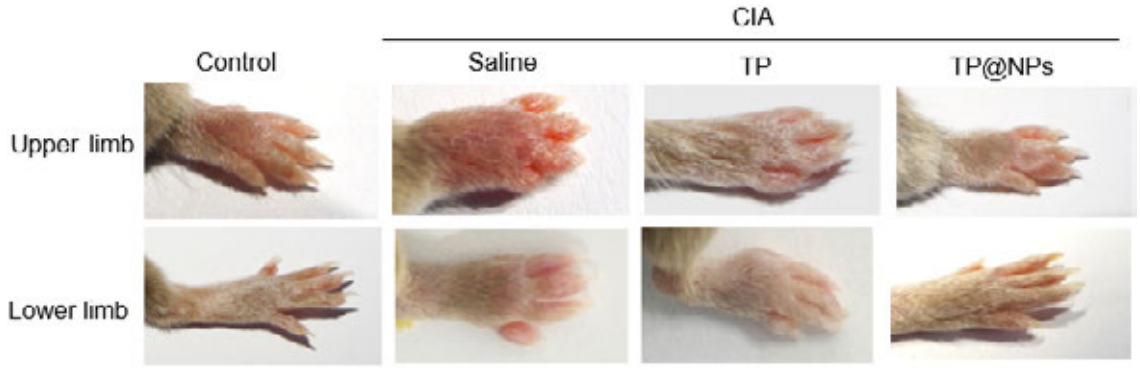
Session Title: RA – Animal Models Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM



To observe drug targeting and release in vivo, we applied small animal in vivo imaging technology to detect the enrichment efficiency and retention time of TP@NPs in arthritis mice. After injection of TP@ NPs-ICG, the fluorescence intensity in the joint of CIA mice was higher, which was the most obvious at 24 hours. The fluorescence of normal mice was not enriched in the joints.



The results suggested that the Model+TP@NPs group, as well as the control group had no obvious swelling and deformity of the claws on the mices. In addition, compared with Model+Saline group, free TP group was improved, but its curative effect was far less than that of Model+TP@NPs group.

Background/Purpose: The best packaging of holistic therapy for Rheumatoid arthritis (RA) will involve two components: a potent anti-inflammatory therapeutic and a rationally designed drug delivery vehicle to enrich the target site concentration and sustained release of the drug. The natural product, triptolide (TP), which is an effective anti-inflammatory compound, has been used for RA in clinical. However, the potential clinical application of triptolide is limited due to its poor solubility and high toxicity. Drug delivery systems responding to inflammatory acidic pH environment can be constructed by using nanomaterials as carriers combined with TP. Through targeting and nano-drug sustained release, the toxic and side effects of drugs can be reduced and therapeutic effects can be improved.

Methods: The effects of TP@NPs on cell survival, apoptosis and ROS production were detected in RAW264.7 cells. NPs group and saline group were used as control group, TP@NPs group and free TP component of the same amount of TP were given high and low doses (0.15mg/kg/3 days and 0.075mg/kg/3 days) to treat collagen induced arthritis mice for 30 days. ABOG staining,TRAP staining and micro-CT were used to observe bone destruction. HE staining and biochemical indexes of liver and kidney (ALT, AST, CRE, BUN) were used to observe drug toxicity.

Results: Compared with TP, TP@NPs could effectively improve the survival rate of RAW264.7 cells($P< 0.05$).The apoptosis rate of TP was 26.6±8.052, while that of TP@NPs was 1.693 ±0.1617 ($P< 0.01$).The proportion of ROS produced by TP was 10.97±0.5774, which was reduced to 3.68±0.51 by TP @NPs ($P< 0.01$). Q-PCR showed that TP@NPs and TP had the similar effect on inhibiting inflammation in vitro ($P >0.05$). In vivo study, the serum AST ($n=5$, $P=0.0083$), ALT ($n=5$, $P=0.0013$), CRE ($n=5$, $P=0.0069$) and BUN ($n=5$, $P=0.0312$) in TP@NPs (containing high dose TP) treated CIA mice were significantly lower than those in high dose TP group. HE staining showed histomorphological abnormalities of liver, kidney and spleen in high dose TP treated CIA mice, while the structure of those organs in TP@NPs (containing high dose TP) group maintained normal. Furthermore, the score of CIA mice ($n=10$, $P< 0.05$), and the serum level of IL-1β, IL-6 and TNF-α($n=5$, $P< 0.05$) of TP@NPs (containing low dose TP) group were lower than low dose TP group. ABOG and TRAP staining and micro-CT showed that TP@NPs (containing low dose TP) effectively reduce the destruction of articular cartilage, synovial hyperplasia and osteoclast production ($n=10$, $P< 0.05$), and the loss of talus bone mass (0.95±0.1108 VS 1.133 ±0.09074 $n=9$, $P=0.007$). In vivo imaging showed that TP@NPs was able to target inflammatory joints of CIA mice, but not normal mice (the fluorescence intensity was 1247 ± 108.2, $n=3$, 12 limbs VS 3093 ± 496.4, $n=3$, 12 limbs) at 24 h.

Conclusion: The nano-drug can achieve the sustained release of TP, maintain a good blood concentration, improve water solubility, improve the efficacy, reduce toxic side effects, and can be candidate therapy for RA.

To observe drug targeting and release in vivo, we applied small animal in vivo imaging technology to detect the enrichment efficiency and retention time of TP@NPs in arthritis mice. After injection of TP@ NPs-ICG, the fluorescence intensity in the joint of CIA mice was higher, which was the most obvious at 24 hours. The fluorescence of normal mice was not enriched in the joints.

The results suggested that the Model+TP@NPs group, as well as the control group had no obvious swelling and deformity of the claws on the mices. In addition, compared with Model+Saline group, free TP group was improved, but its curative effect was far less than that of Model+TP@NPs group.

Increased Antibody and T-cell Responses Following Treatment of Collagen-Induced Arthritis in C57Bl/6 Mice with Organic Dust Inhalants

Michael Duryee,[1] Jill Poole,[1] Amy Nelson,[1] Katherine Janike,[1] Kathryn Rentfro,[1] Lynell Klassen,[1] James O'Dell,[2] Bryant England,[3] Geoffrey Thiele,[2] and Ted Mikuls[2], [1]University of Nebraska Medical Center, Omaha, NE, [2]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha, NE, [3]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Increasing evidence suggests that inhalant exposures, such as tobacco smoke or silica, are implicated in the initiation of autoimmunity leading to rheumatoid arthritis (RA). To further study the relationship between inhalant lung injury and RA-related autoimmunity, a mouse model of collagen induced arthritis was subjected to inhalation of organic dust extract (ODE) and disease-specific autoantibody and T cell responses were measured.

Methods: Male C57BL/6 mice were injected with chicken collagen type II plus Freund's complete adjuvant (CIA) or saline on day 1 and 21. ODE or saline was instilled by intranasal inhalation daily for 5 weeks. Groups are identified as: 1) Sham (saline injection + saline inhalation), 2) ODE, 3) CIA, and 4) ODE + CIA. At 5 weeks, IgG antibody to malondialdehyde-acetaldehyde (MAA) and anti-citrullinated protein antibody (ACPA) were measured in serum. T-cell proliferation assays were performed by IFN-γ ELISPOT using human serum albumin (HSA) that was either MAA modified or citrullinated (CIT) as the stimulating antigen.

Results: Serum IgG anti-MAA antibody concentrations were significantly increased ($p < 0.0001$) in ODE + CIA mice compared to all other groups Figure (A). In contrast, ACPA concentrations were significantly lower ($p < 0.0001$) in CIA + ODE mice compared to CIA alone with the former group demonstrating autoantibody concentrations similar to sham and ODE mice (B). T-cell proliferations against HSA-MAA were significantly increased in both CIA ($p < 0.0001$) and CIA + ODE ($p < 0.01$) mice compared to sham and ODE, yet neither of these differed significantly from each other (C). In contrast, T cell proliferations were significantly decreased ($p < 0.01$) in the CIA + ODE group compared to CIA alone when HSA-CIT was used as the stimulating antigen (D).

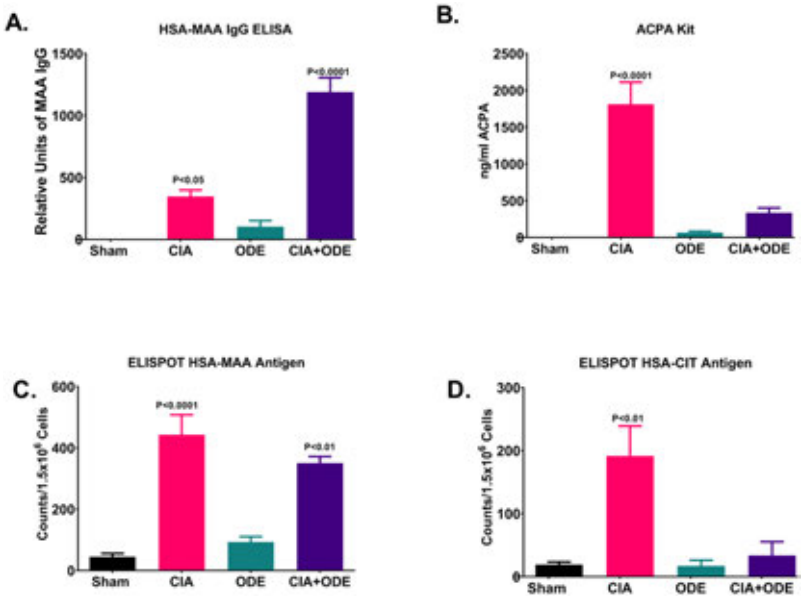

Figure 1. Increased Antibody and T-cells Response to MAA Modified Antigens in C57bl/6 Treated with Sham, CIA, ODE, or ODE+CIA. (A) Serum anti-MAA antibody (CIA p<0.05 vs. sham or ODE; CIA+ODE p<0.0001 vs. all other groups). (B) Serum ACPA (CIA p<0.0001 vs. all other groups; p=NS for all other comparisons). (C) T-cell proliferation to HSA-MAA (CIA p<0.0001 vs. sham or ODE; CIA+ODE p<0.01 vs. sham or ODE; p=NS for CIA vs. CIA+ODE). (D) T-cell proliferation to HSA-CIT (CIA p<0.01 vs. all other groups). N=10 mice per group.

Conclusion: Increased anti-MAA antibody and decreased ACPA concentrations in the ODE + CIA treated group compared to CIA alone suggests a shift in autoimmune response when arthritis prone mice are exposed to inhalant injury. Although mechanisms underpinning these "shifts" require further investigation, an increase in proliferating T-cells to MAA and a simultaneous decrease to citrullinated antigen suggests that inhalant injury may reduce immune responses to disease-specific antigen (citrullinated antigen) at the expense of enhanced responses to a more ubiquitous autoantigen (MAA-modified antigen). This novel animal model that incorporates CIA and inhalant injury, has the potential of providing much needed insight into the complex interplay between mucosal injury and autoimmunity that characterizes RA.

Inhibition of Endoplasmic Reticulum Stress Using 4-phenylbutyric Acid Ameliorates the Severity of Collagen-induced Arthritis in Mice via Attenuation of Proliferation and Inflammatory Responses of Synovial Fibroblasts

Wan-Hee Yoo,[1] Yunjung Choi,[2] Eun-gyeong Lee,[2] Chang-hoon Lee,[3] and Myeung-Su Lee[3], [1]Department of Internal Medicine, Chonbuk National University Medical School, Research Institute of Clinical Medicine of Chonbuk National University-Biomedical, Research Institute of Chonbuk National University Hospital, Jeonju, Korea, JeonJu, Republic of Korea, [2]Research Institute of Clinical Medicine of Chonbuk National University-Biomedical Research Institute of Chonbuk National University Hospital, JeonJu, Republic of Korea, [3]Wonkwang University College of Medicine, Iksan, Republic of Korea

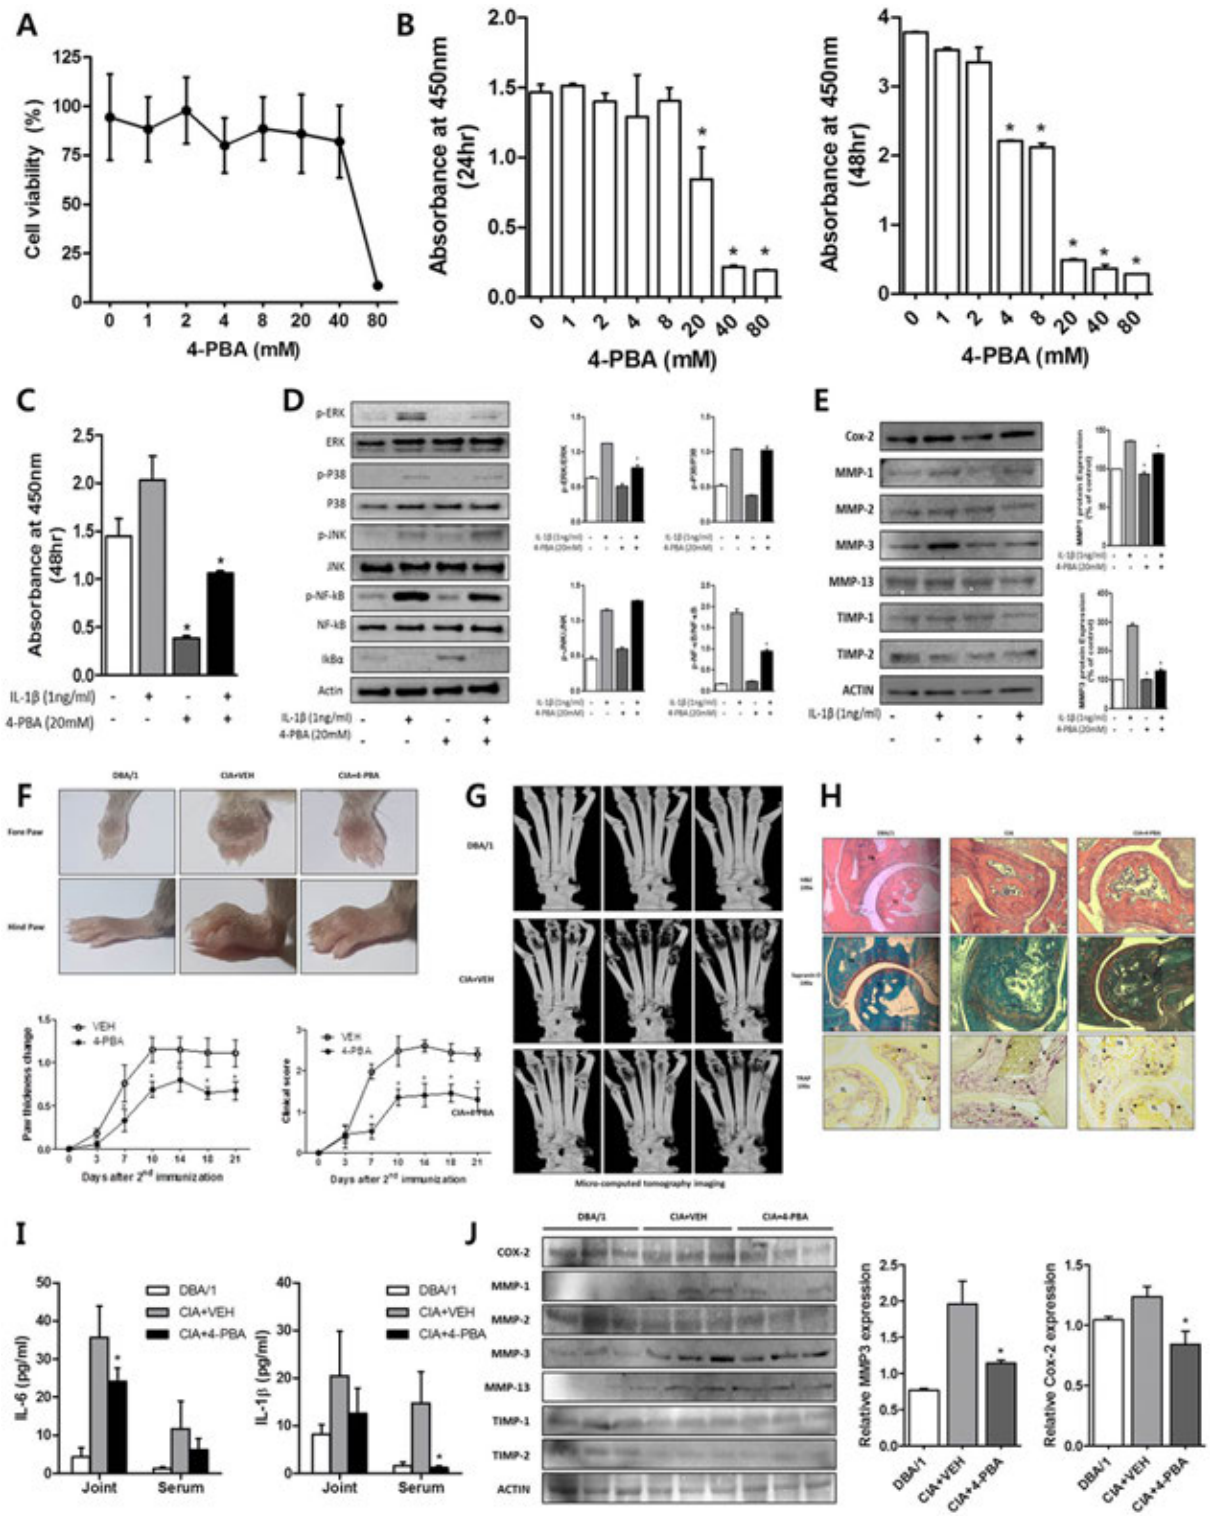
SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Animal Models Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM



Background/Purpose: Several studies have recently revealed the pathological role of endoplasmic reticulum (ER) stress in the pathogenesis of inflammatory diseases. In addition, 4-phenylbutyric acid (4-PBA) was shown to exert potent pharmacological effects, including anti-inflammatory properties, via inhibition of ER stress. However, it is not known whether 4-PBA attenuates the severity of rheumatoid arthritis, which is most the common inflammatory arthritis.

The purpose of the present study was to investigate the effect of ER stress inhibition by 4-PBA on interleukin-1β-induced proliferation and the inflammatory response of rheumatoid synovial fibroblasts (RASFs) and determine whether the inhibition of ER stress by 4-PBA ameliorated experimentally induced arthritis. The potential underlying mechanisms of the therapeutic efficacy of 4-PBA were also investigated.

Methods: The proliferation of RASFs and expression of matrix metalloproteinases were evaluated in the presence of IL-1β with or without 4-PBA. The effect of 4-PBA on the phosphorylation of MAPK and the activation of NF-kB in IL-1β-stimulated RASFs was assessed. In an in vivo study, the effects of 4-PBA were investigated using DBA/1 mice with collagen-induced arthritis (CIA). Assessments of paw thickness, clinical score, micro-computed tomography imaging, histology of tibiotalar joints, and the inflammatory cytokine levels of joints extracts and serum were used to determine the therapeutic effect of 4-PBA.

Results: In vitro, 4-PBA inhibited the proliferation and expression of IL-1β-stimulated RASFs and matrix metalloproteinases (MMP-1 and MMP-3) through the suppression of both the phosphorylation of MAPKs and NF-kB in IL-1β-stimulated RASFs. The intraperitoneal administration of 4-PBA markedly attenuated the severity of arthritis in CIA mice. 4-PBA treatment ameliorated joint swelling, the degree of bone erosion and destruction, and decreased the level of inflammatory cytokines (IL-6 and IL-1β) and matrix metalloproteinases (MMP-3 and Cox-2). Furthermore, remarkable improvements in histopathological findings occurred in 4-PBA-treated mice.

Conclusion: These findings suggested that 4-PBA could attenuate the severity of arthritis in CIA mice through partially blocking the phosphorylation of MAPKs and the activation of NF-κB in RASFs. Thus, through the inhibition of ER stress, 4-PBA may be a potent agent for the treatment of RA.

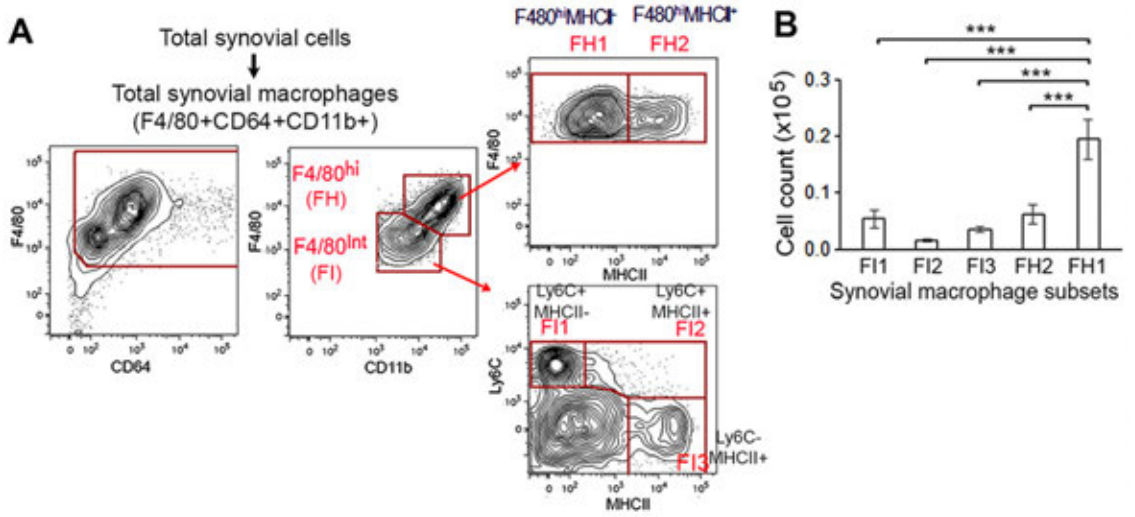
[1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, [3]Northwestern University Feinberg School of Medicine, chicago, [4]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, [5]Northwestern University Feinberg School of Medicine, Division of Rheumatology, chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously identified that under homeostatic conditions Flip was necessary for macrophage (MΦ) survival. The mechanisms responsible for the differentiation of monocyte-derived MΦs into anti-

Figure 1.



Synovial tissue macrophage subsets during homeostasis

inflammatory tissue-resident MΦs (TRMs), under chronic inflammatory conditions, is not known. Earlier studies demonstrated that under homeostatic conditions, efferocytosis is important in maintaining MΦ tissue residency. The purpose of this study was to define synovial TRMs and the role of Flip in MΦ differentiation during chronic inflammation.

Methods: The HUPO arthritis model was established employing mice with *Flip* depleted in CD11c^{+} cells. HUPO arthritis, which begins spontaneously after 4 weeks of age, was evaluated by clinical scoring and histology. Synovial tissue MΦ subsets were defined by flow cytometry and proliferation by BrdU incorporation. Transcriptional profiles for each subset was documented by RNAseq. Monocyte-derived MΦs in joint tissue were identified following bone marrow reconstitution and parabiosis.

Results: We identified the F4/80^{hi}MHCII^{-}Ly6C^{-} subset (FH1) as the population of TRMs, dominant among the 5 subsets of synovial MΦs during homeostasis (Fig 1). Genes that are upregulated in the TRMs have tissue-specific functions such as for MΦ maturation and maintenance of homeostasis. The wild type FH1 and FH2 (F4/80^{hi} MHCII^{+}Ly6C^{-}) subsets are maintained at a slow self-renewing rate and not replenished by circulating monocytes. The *cflar* (Flip) expression is high in F4/80^{hi} MΦs, and targeted deletion of *Flip* in the *Flip$^{f/f}$ CD11c^{cre}* HUPO mice results in a marked reduction of the FH1 population, while the FH2 subset is greatly increased. The percent of the FH1 subset inversely correlated with arthritis severity and granulocyte infiltration. Parabiosis experiments demonstrated both HUPO and control monocytes differentiated into FH2 MΦs in HUPO recipients, while only the control MΦs were able to differentiate into FH1 cells. This inability of HUPO monocytes to differentiate from FH2 to FH1 MΦs was not due to increased MΦ apoptosis. The reduced Flip did not result in increased apoptosis was associated with a reduction of pro-apoptotic, and an increase of anti-apoptotic signaling molecules. Further, the HUPO FH2 MΦs demonstrated a reduction of genes and their coding proteins such as Cfs1r (CD115), Tgfbr2, and Mrc1 (CD206), which are associated with tissue residency and efferocytosis. In addition, genes important for MΦ functions and phagocytic clearance of apoptotic cells, such as *Timd4* and *CD163* were reduced in the HUPO FH1 and FH2 subsets.

Conclusion: These observations suggest that under homeostatic conditions, efferocytosis maintains the dominance of the FH1 population as TRMs. In contrast, apoptosis is reduced, and all populations of MΦs, except FH1, are increased under HUPO chronic inflammatory conditions. FH2 MΦs deficient in Flip survive, but are not capable of

differentiation into anti-inflammatory TRMs. These observations provide novel insights into the role of MΦs in the initiation and progression rheumatoid arthritis.

Stromal Cell-derived DCSTAMP Coordinates Cell Migration and Osteoclast Activation in TNF-driven Murine Arthritis

Maria de la luz **Garcia-Hernandez**,[1] Javier Rangel-Moreno,[2] Benjamin Korman,[2] Ananta Paine,[1] Nelson Huertas,[3] and Christopher T. Ritchlin[3], [1]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY, [2]University of Rochester Medical center, Rochester, NY, [3]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: DC-STAMP is a transmembrane protein involved in the fusion of mononuclear osteoclasts and essential for the formation of fully functional multinucleated osteoclasts (OCs). Recently we found impaired accumulation of macrophages in the inflamed synovium, and a correlation between reduced bone resorption and the area occupied by $TRAP^+$OCs in bones of $DCSTAMP^{+/+}$TNF Tg mice. Interestingly, serum concentration of murine TNF and MCP-1, a macrophage attracting chemokine, was lower in DCS-$STAMP^{-/-}$TNF Tg mice than TNF Tg mice. These results suggested that impaired bone erosion in DC-$STAMP^{-/-}$TNF Tg mice may result from defective attraction of immune cells to the joints. Thus, we examined both the mechanism and type of cells involved in the progression of TNF-driven inflammatory arthritis in the presence or absence of DCSTAMP.

Methods: C57BL/6 mice were irradiated and reconstituted with $1X10^7CD45.2^+$TNF Tg and $1X10^7CD45.1^+DCSTAMP^{-/-}$ bone marrow cells. Six weeks after bone marrow transfer, mice were i.p injected, at days 0 and 3, with 150 ml of serum from NOD.KRN mice. $CD45.2^+$and $CD45.1^+$cells were enumerated by flow cytometry or immunofluorescence. To elucidate whether DCSTAMP on stromal cells participates in bone resorption, we generated reciprocal chimeric mice, using WT, $DCSTAMP^{-/-}$, TNF Tg, $DCSTAMP^{-/-}$TNF Tg mice as recipients or donors of BM cells, and measured bone density by mCT scan. Migration of bone marrow cells isolated from WT, $DCSTAMP^{-/-}$, TNF Tg and $DCSTAMP^{-/-}$ TNF Tg mice was tested by chemotaxis assays using conditioned media from stromal cells activated with TNF. mRNA expression of inflammatory cytokines by macrophages activated with IL-4 or LPS/IFNgwas quantitated with qPCR.

Results: Enumeration of congenic cells by flow cytometry in 50:50 bone marrow chimeras showedthat 77% ±1.5 and 70% ±1 of $CD45.1^+$DC-$STAMP^{-/-}$cells accumulated in popliteallymph nodes and spleen, respectively; but they were absent in the inflamed synovium. In contrast, $CD45.2^+$ TNF-producing cells were significantly increased in the synovium of mice with acute arthritis. Moreover, polarized macrophages of DC-$STAMP^{-/-}$and DC-$STAMP^{-/-}$ TNF Tg mice had a significantly lower expression of TNF ($p = 0.004$), IL1b ($p = 0.02$) and iNOS ($p = 0.001$) and higher IL10 expression ($p = 0.04$). We also found that bone volume in mice expressing DC-STAMP on the stromal or hematopoietic cells increased 2-fold in femur ($p = 0.05$) and 2.5-fold in tibia ($p=0.04$), compared with mice expressing TNF in both stromal and hematopoietic cells. Interestingly, $DCSTAMP^{-/-}$stromal cells activated with mouse or human TNF had lower expression of MCP1 ($p = 0.002$), CX3CL1 ($p = 0.001$), IL-1b ($p = 0.03$) and MMP9 than WT stromal cells. *In vitro* chemotaxis assay using supernatant collected from WT stromal cells showed a 28-fold decrease in migration

of monocytes from DCSTAMP$^{-/-}$(p = 0.02) and DCSTAMP$^{-/-}$ TNF mice (p = 0.01). These monocytes also had 4-fold decrease (p = 0.01) in the migration towards supernatant from DC-STAMP$^{-/-}$stromal cells.

Conclusion: Our data reveal an unexpected role for stromal cell-derived DC-STAMP in the modulation of migration and pathogenic polarization of monocytes into inflamed arthritic joints.

Stimulation of Splenic Neurovascular Bundle Protect Mice from Developing Collagen-induced Arthritis

Thomas Simon,[1] Clara Panzolini,[2] Julien Lavergne,[2] Arun Srihar,[3] Margriet Vervoordeldonk,[3] nicolas Glaichenhaus,[2] and Philippe Blancou[2], [1]CNRS/IPMC, Valbonne, France, [2]IPMC/CNRS, VALBONNE, France, [3]Galvani Bioelectronics, Stevenage, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vagus nerve (VN) stimulation has shown the potential to improve the disease development in animal models of arthritis and in patients with RA. However, the VN can affect respiratory, cardiovascular, and gastro-intestinal physiology. The splenic nerve (SpN) has been confirmed to be the principal effector nerve for the VN-mediated immune control. Here we tested efficiency of stimulating the nerve plexus around the splenic artery on acute LPS-induced inflammation and collagen-induced arthritis (CIA) in mice and compared it to VN stimulation (VNS) and anti-TNF treatment.

Methods: In an acute LPS mouse model, mice were implanted on the SpN or VN. After recovery from surgery, LPS was injected and splenic nerve stimulation (SNS) or VNS was applied in conscious mice. TNF and norepinephrine (NE) were measured after 90 min. Next, SNS was evaluated in CIA. CIA was induced in DBA1/J mice by immunization with bovine type II collagen at days 0 and 21. At day 11, mice were implanted with micro-cuff electrode (CorTec) onto the SpN or VN. From day 16 to day 45, VNS and SNS were applied as rectangular charged-balanced biphasic pulses with 650 μA pulse amplitude, 200 μs pulse width at 10 Hz frequency for 2 min 1 or 6 times a day using a Plexon stimulator. Alternatively, mice were treated 3 times/week from day 16 to 45 with 10mg/kg anti-TNF (etanercept) i.p. In curative settings, SNS was applied 6 times a day when mice scored positive for 3 consecutive days. Clinical arthritis was determined by visual examination of swelling and redness of the paws and measurement of paw thickness. Sham mice were undergoing the same procedure but did not receive stimulation.

Results: Stimulating the splenic nerve resulted in an increase of NE (by >100%) in the spleen, as well as a significant reduction in LPS-induced TNF (~50%). This effect was comparable to VNS. In CIA in mice all sham animals developed arthritis, compared to 14% following 6 times per day SNS ($p < 0.001$). In contrast, 85% of the animals developed arthritis ($p = 0.35$) when SNS was applied only once a day. However, in both stimulated groups a significant decrease in clinical scores and paw thickness was observed compared to unstimulated group ($p < 0.01$ and $p < 0.05$, respectively). Interestingly, SNS treatment inhibited CIA to the same extend as VNS. Moreover, the same electrical parameters dramatically decreased arterial blood pressure during VNS stimulation, which was not the case for

SNS. While etanercept treatment reduced clinical scores ($p < 0.001$) an immediate rebound in clinical score was seen following cessation of treatment, while mice with SNS were still partially protected 35 days after treatment discontinuation ($p = 0.013$, compared to sham). Finally, when SNS was applied as a therapeutic treatment, clinical scores were significantly reduced ($p < 0.001$). Analysis of the cells within the spleen after SNS demonstrated a reduction of inflammatory monocytes that correlated with an improvement in clinical scores.

Conclusion: These studies demonstrate that SNS affect the immune cells in the spleen, suppresses pro-inflammatory cytokine production, and reduces clinical symptoms in CIA providing compelling scientific rationale and pre-clinical evidence for the use of splenic neuromodulation in treating RA.

Targeted Drug Delivery Using a Novel Joint-homing Peptide for Arthritis Therapy

Rakeshchandra Meka,[1] Shivaprasad Venkatesha,[1] Bodhraj Acharya,[1] and Kamal Moudgil[1], [1]University of Maryland School of Medicine and Baltimore VA Medical Center, Baltimore, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic debilitating autoimmune disease characterized by inflammation of the synovial tissue of the joints, which if not controlled early and adequately, may cause severe joint damage and deformity. There are many potent anti-arthritic drugs, which are given orally or by injection, and their prolonged use is associated with many adverse reactions. This is attributable in part to the widespread distribution of the drugs, exposing healthy organs to those drugs. Thus, there is a need for targeted drug delivery methods to direct the drugs primarily to the inflamed joints.

Methods: We developed a peptide-directed liposomal drug delivery system to deliver dexamethasone (DEX) to arthritic joints of rats with adjuvant-induced (AA) arthritis. The peptide ART-2 shows preferential homing to inflamed joints when injected intravenously. Therefore, we exploited this attribute of peptide ART-2 to guide the DEX-entrapping liposomes to arthritic joints. Arthritic rats were treated with test or control liposomes, or free drug after the onset of disease and the severity of arthritis was monitored regularly thereafter. Sera of these rats were tested for assessment of toxicity to liver, kidney, and pancreas.

Results: ART-2-DEX liposomes, when injected intravenously into arthritic rats after the onset of arthritis, were more effective in suppressing disease progression than control-DEX liposomes lacking ART-2 or free DEX at an equivalent dose of this drug. Furthermore, despite increased efficacy, the toxicity profile of ART-2-DEX liposomes was comparable to that of control liposomes or free DEX, thereby resulting in enhanced therapeutic index of DEX therapy.

Conclusion: Our results furnish a proof-of concept for the use of a novel joint-homing peptide for targeted delivery of drugs including biologics or small molecule compounds to arthritic joints with enhanced efficacy and reduced

systemic exposure. This targeted therapy platform may be suitable for use in RA patients. (Supported by VA Merit Review I01 BX002424, NIH R01AT004321, and RRF.)

RKIP, as an Upstream Regulator of Intracellular Signaling, Exerts Anti-arthritic Effect in Fibroblast-like Synoviocyte and Collagen-induced Arthritis

Sang-Il Lee,[1] Hae Sook Noh,[2] and Yun-Hong Cheon[1], [1]Divison of Rheumatology, Gyeongsang National University Hospital, Jin-Ju, Republic of Korea, [2]Gyeongsang University Hospital, Jinju, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Nuclear factor-kappaB (NF-kappaB) and extracellular-signal-regulated kinase (ERK) have been implicated as a therapeutic target for the treatment of rheumatoid arthritis (RA). Raf kinase inhibitory protein (RKIP), as an upstream regulator for NF-kB and ERK pathways, has been widely explored in the field of cancer. However, the effect of RKIP in RA have not yet been elucidated. Thus, the purpose of this study was to investigate whether RKIP might have anti-arthritic effects.

Methods: The adenovirus containing RKIP complementary DNA (Ad-RKIP) or RKIP shRNA (Ad-shRKIP) were used in fibroblast-like synoviocytes (FLS) of RA patients and mouse models of collagen-induced arthritis (CIA) and K/BxN serum transfer arthritis. Quantitative real-time PCR, phospho-protein array analysis, immunohistochemistry, ELISA, western blotting, TRAP and safranin-O staining, migration and invasion assay were used.

Results: The expression of RKIP were significantly decreased in synovial tissue and FLS of RA compared to osteoarthritis (OA). Ad-RKIP suppressed invasion and migration, chemokine production, and matrix metalloproteinase secretion induced by cytokines (IL 1ß, LPS, TNF α, and TGF ß) in RA FLS. Additionally, RKIP negatively regulated the Raf/MEK/ERK and NF-κB pathway in RA FLS. CIA and K/BxN serum transfer arthritic mice, which were injected with Ad-shRKIP, showed earlier development and exacerbation of arthritis. However, Ad-RKIP treated CIA mice had a lower cumulative incidence and less severe arthritis, based on radiologic and histopathologic findings, and inflammatory cytokine levels, than control virus-injected mice.

Conclusion: These results suggest that using RKIP to block the NF-kappaB and the Raf/MEK/ERK pathway in RA reduce both the inflammatory response and the joint destruction. Thus, RKIP may have therapeutic potential in the prevention and treatment of RA.

Oral Collagen Type V Supplementation Inhibits Cartilage Degeneration in Experimental Arthritis

Lizandre Keren Silveira,[1] José Eduardo Rodrigues,[1] Silvana Atayde,[1] Sergio Catanozi,[1] Antonio dos Santos Filho,[2] Vera Luiza Capelozzi,[1] Ricardo Fuller,[2] Ana Paula Velosa,[2] and **Walcy Teodoro**[1], [1]Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, BR, Sao Paulo, Sao Paulo, Brazil, [2]Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, BR, Sao Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It is known that collagen V (col V) can generate autoimmunity when exposed. In contrast, induction of tolerance with col V supplementation is able to protect affected tissues in autoimmune diseases. In an earlier study, we found that Col V oral supplementation reduced synovial inflammation in experimental arthritis but its action in cartilage is not known. To verify the action of oral Col V supplementation on cartilage in an experimental model of induced arthritis (IA).

Methods: Thirty 3 months-old male *Lewis* rats with weight of 220–240g were used. Arthritis was induced by intra-articular infiltration of 500μg of mBSA emulsified in complete Freund's adjuvant (10μl) at days zero, 7 and 14. Oral Col V (isolated from bovine placenta) supplementation (500μg/300μl / day / 30 days) was daily performed until 30 days' euthanasia in 10 animals (IA-Col V group). The other 10 did not receive oral Col V (IA group). Five rats received intra-articular saline (Sal group) and 5 received only oral Col V (Col V). Morphological and histomorphometric analyses were performed after Safranin-O/Fast Green, immunofluorescence and immunohistochemistry staining with *Image-Pro Plus6.0 software*. Serum IL-1β, TNFα, IL-17, IL-10 and anti-Col V were measured. All the animals received human care in compliance with the *Guide for the Care and Use of Laboratory Animals*, published by the US National Institutes of Health. Ethics in Committee Research for Animal Studies approval number 295/12.

Results: In the IA-Col V group, cartilage showed neither cracks, nor chondrocyte organization, and the growth line was preserved compared to the IA group. There was no reduction in chondrocytes number in the IA-col V group (39.86±1.79 vs 25.35±4.62, p< 0.009), cartilage thickness (78.73±7.27 vs 52.52±5.74, p< 0.03), proteoglycans content (76.82±9.31 vs 25.45±1.23%, p< 0.0036), type II collagen content (76.99±1,339 vs 39.13±5,618 p< 0.0001) and apoptosis (21.85±6.92 vs 71.69±10.46) compared to the IA group. In addition, there was lower serum expression in the IA-col V group of IL-1β (4.28±4.75 vs 21.96±2.29, p< 0.0001), TNFα (1.70 ± 0.51 vs 1.76 ± 0.39, p< 0.0001), IL-17 (2.19±0.50 vs 27.24±10.65, p< 0.0001) and IL-10 (0.13±0.03 vs 27.95±17.11, p< 0.0001) compared to the IA group. Furthermore, the IA group presented serum anti-collagen V. The results of the Sal and Col V groups were similar to those of the IA-Col V group for every parameter.

Conclusion: The oral collagen V supplementation avoided the degradation of cartilage in an experimental arthritis model and may represent a new therapeutic option for this condition.

Beneficial Effect of Angiotensin Receptor Blocker in a Spondyloarthritis Animal Model

Seung-Cheol Shim,[1] Jin-Sun Choi,[2] Ji-Young Kim,[2] and Chan-Geol Park[2], [1]Division of Rheumatology, Department of Internal Medicine, School of Medicine, Chungnam National University, Chungnam National University Hospital, Daejeon, Republic of Korea, [2]Chungnam National University Hospital, Daejeon, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) have been shown to be efficacious in the treatment of the signs and symptoms of spondyloarthritis (SpA). However, NSAIDs have a variety of side effects on gastrointestinal tract, kidney, and cardiovascular system. Angiotensin II (AT II) mediates several pro-inflammatory responses by signaling through AT type I receptor (AT1R). The recruitment of circulating inflammatory cells to the endothelium and subendothelial space is an early step in the inflammatory response. Ang II can also trigger Toll-like receptor 4 activation in various cell types, which stimulates the innate immunity. In addition, it has been reported that Ang II drives colonic mucosal inflammation by promoting intestinal epithelial cell apoptosis and mucosal TH17 responses in colitis development.

The purpose of this study is to investigate the benefits of angiotensin receptor blocker (ARB) on the bony overgrowth and the bowel inflammation in a SpA animal model.

Methods: ZAP-70W163C–mutant (SKG) mice were housed under specific pathogen free conditions. All of the mice were injected intraperitoneally with 1,3-glucan (curdlan). Mice were treated with ARB and/or naproxen (NXN). Clini-

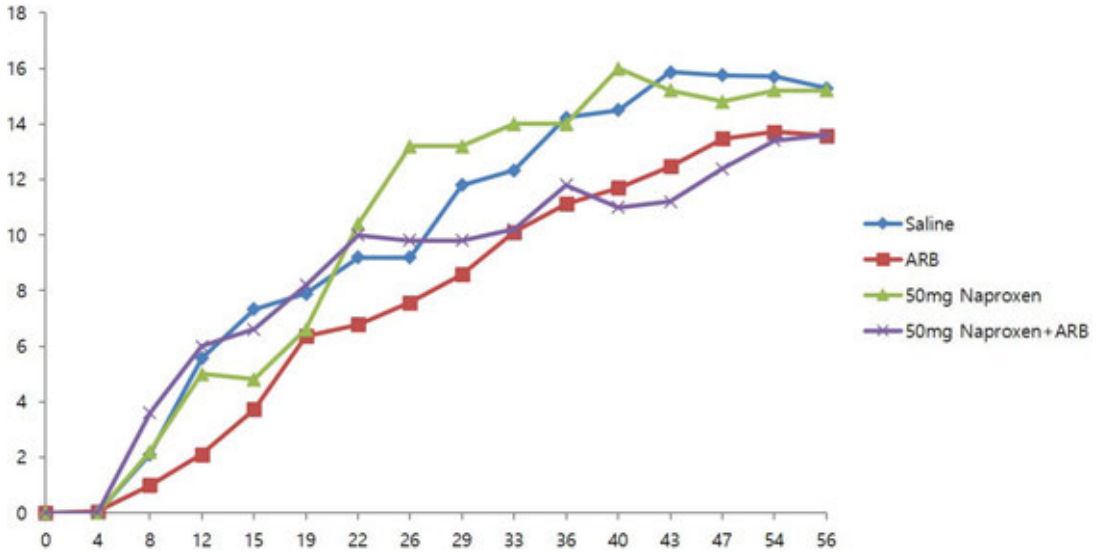

Figure 1. Peripheral Arthritis in SKG.

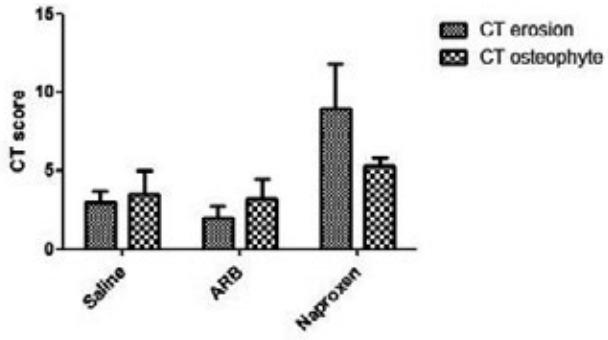

Figure 2. Bone morphology in SKG.

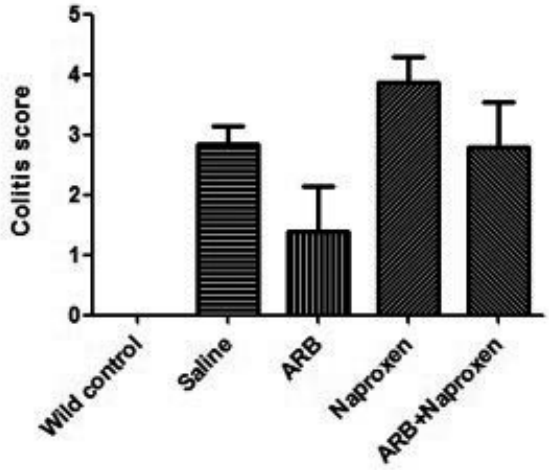

Figure 3. Intestinal inflammation in SKG.

cal manifestations were scored and the expression of inflammatory molecules were examined. Arthritis, spondylitis, and ileitis were assessed histologically at 8-week experimental end points. A bone mineral density tests (BMD) were conducted as well.

Results: ARB treatments lowered the morphology scores (MS), but NXN did not (Fig 1). The expression of myeloperoxidase was decreased in peripheral and axial joints by ARB but not by NXN, which might be caused by decreased expression of TNF-α, IL-17, IL-22, and IL-23.

The development of erosion and osteophyte was inhibited by ARB, while increased by NXN in bone CTs (Fig 2). ARB decreased the expression of BMP2, RUNX2, and osterix.

Next, we investigated the effect of ARB and NXN on ileitis of the SKG mice. ARB improved ileitis, but NXN significantly aggravated the ileitis which was partially restored on the combination therapy with ARB (Fig 3). In addition, we analyzed the results on BMDs in SKG mice depending on the treatment groups. Both ARB and NXN improved BMDs.

Conclusion: These results indicate that ARB has beneficial effects on the arthritis, ileitis, and osteoporosis in a SpA mice model. Further clinical studies are warranted.

TNF Inhibitors Improves Arterial Stiffness with Cs DMARDs-resistant Active Psoriatic Arthritis: A Cohort Extended Study

Kensuke Kume,[1] kanzo amano,[1] toshikatsu kanazawa,[1] susumu yamada,[1] and kazuhiko hatta[1], [1]Department of Rheumatology/Hiroshima Clinic, Hiroshima, Hiroshima, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background/ Patients with psoriatic arthritis (PsA) have an increased cardiovascular (CV) risk. We should have strategies for primary cardiovascular prevention in PsA[1)]. But there is no evidence of CV risk management and arterial stiffness about Tumor necrotic factor (TNF) inhibitors in patients with PsA.

Objective/ To examine the effect of TNF inhibitors on arterial stiffness in conventional synthetic (cs) DMARDs resistant PsA patients in a cohort study design.

Methods: Sixty eight PSA and patients with moderate to severe active disease despite cs DMARDs treatment (disease activity score: DAPSA2) score >14) were received TNF inhibitors plus cs DMARDs. All patients have no previous history of CV. Arterial stiffness was assessed with cardio-ankle vascular index (CAVI, modified pulse wave velocity(PWV)) and augmentation index corrected for a heart rate of 75 beats per minute (AIx@75) at baseline and 24 weeks follow-up. Clinical data were collected at regular visits. CAVI is very similar to pulse wave velocity (PWV), and CAVI measures arterial wall stiffness independent of blood pressure and it is superior to brachial ankle PWV as an index of arterial stiffness.

Results: 58 PsA patients(28 patients adalimumab, and 30 patients infliximabrespectively) were completed this study, Treatment with TNF inhibitors(10.88 ± 1.86 and 9.46 ± 1.14 %; p = 0.006), attenuated the CAVI significantly from baseline to 24 weeks follow up. Treatment with TNF inhibitors (36.4 ± 8.6, 32.1 ± 3.8 %; p = 0.008) attenuated the Aix@75 significantly from baseline to 24 weeks follow up. DAPSA score improved significantly from baseline to 24 weeks(17.45 ± 6.33, 5.44 ± 3.43: p=0.01). There are no significant differences among biologics about CAVI and Aix@75. Surprisingly, improvement of CAVI and AIx@75 were not correlated disease activity at 24 weeks of biologics treatment (CAVI: p=0.91, AIx@75: p=0.88). TNF inhibitors improves arterial stiffness independently of its effects on disease activity, since even in high disease activity (8 cases; DAPSA score >28) is halted.

Conclusion: These findings suggest that combination therapy, TNF inhibitors with cs DMARDs not only reduced PsA disease activity but also limited vascular damage in patients with cs DMARDS resistant active PsA.

Genetic Ablation of γδTCR Inhibits IL-23-induced Neutrophilia and Attenuates Epidermal Hyperplasia, Synovitis, Onycholysis and Enthesitis Associated with Psoriatic Arthritis

Cuong Nguyen,[1] Trevor Chan,[2] Ilias Tagkopoulos,[2] Matthias Eberl,[3] and Iannis Adamopoulos[1], [1]Division of Rheumatology, Allergy and Clinical Immunology, University of California at Davis, Sacramento, CA, [2]University of California, Davis, Department of Computer Science, California, USA, Davis, CA, [3]Division of Infection and Immunity, School of Medicine and Systems Immunity Research Institute, Cardiff University, Cardiff CF14 4XN, United Kingdom, Cardiff, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: γδ T cells are non-conventional lymphocytes that straddle between innate and adaptive immunity. Although γδ T cells have been implicated in psoriatic arthritis, the exact mechanisms that govern pathogenicity remain elusive.

Methods: To investigate the roles of γδ T cells in eliciting psoriatic arthritis-like pathology, we performed *in vivo* gene transfer of IL-23 (minicircle DNA) in B10.RIII (WT) and/or $TCR^{\delta-/-}$ mice. qRT-PCR, RNAseq, Western blot, flow cytometry, ELISA, H&E and immunofluorescence staining were used to analyze the phenotype of WT and transgenic mice in this study.

Results: Herein, we show that IL-23 MC gene transfer induces SCART scavenger receptors 1/2 surface marker of adult γδ T cells and a population of $CD11b^{+}LY6G^{+}$ associated with synovitis and epidermal hyperplasia in joint and skin tissues respectively which is accompanied with onycholysis and enthesitis hallmark pathologic features of human PsA. We observed a profound neutrophil inflammatory infiltrate in the synovium, epidermis, nail bed, and enthesis in IL-23 gene transfer WT mice, which were absent in $TCR^{\delta-/-}$ mice. Furthermore, our data demonstrate that absence of γδ T cells was associated with an attenuation of inflammatory gene expression as well as expression of neutrophil markers which mechanistically correlated with a reduction of IL-17A and a marked increase of the anti-inflammatory cytokine IL-27.

Conclusion: Collectively, our data demonstrate that γδ T cells are critical components in pathogenesis of IL-23-induced psoriatic arthritis like disease, suggesting that γδ T cells could be potentially targeted for treatment of the rheumatic diseases.

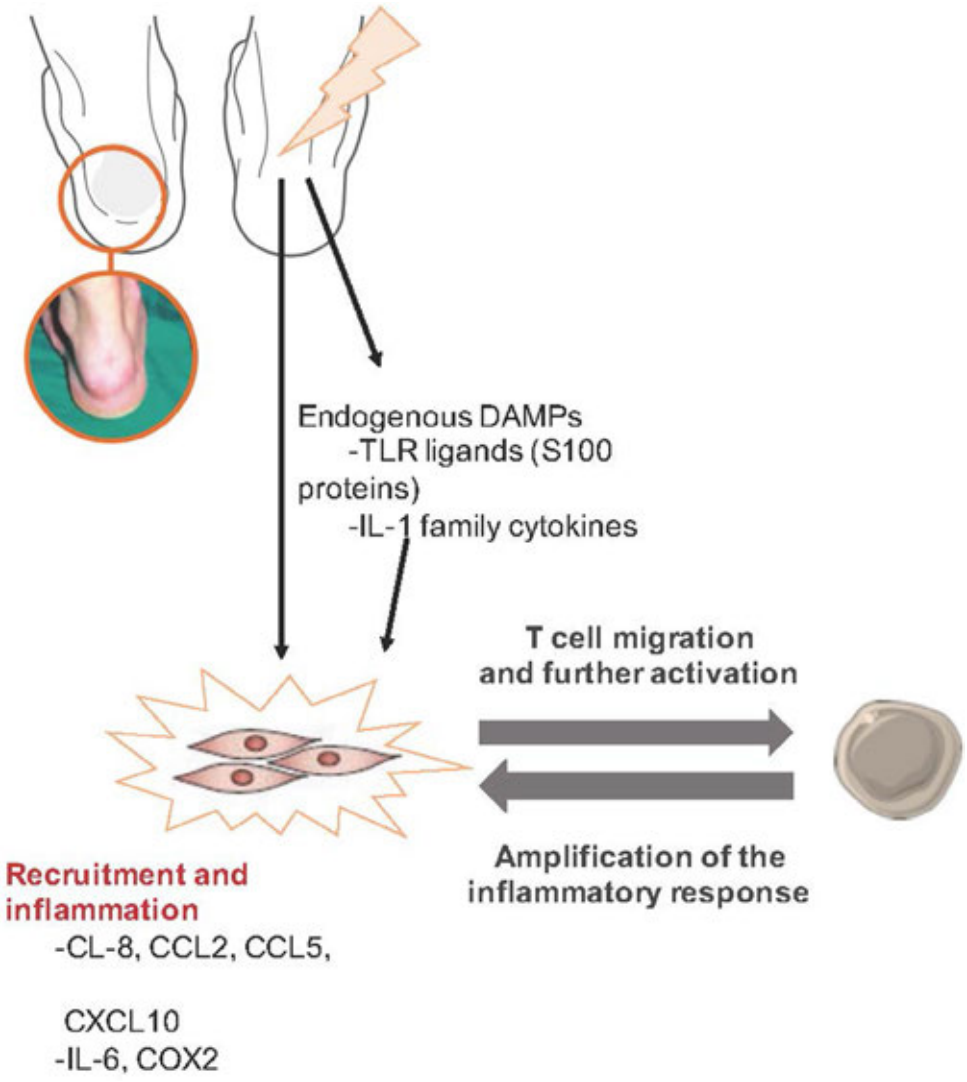
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Emerging evidence supports the concept that stromal cell functions extend beyond maintenance of tissue architecture, exerting a key role in choreographing immune responses and thereby defining disease persistence. Accordingly, as enthesitis is a hallmark of spondyloarthropaties (SpA), we propose an interplay between tendon stromal cells (tenocytes) and the adaptive immune system (T cells) in the development of a chronic inflammatory response in SpA.

We aimed to assess the effect of tendon stromal cells (tenocytes) on T cell migration and activation and the impact of these activated T cells on the stroma.

Methods: Tenocytes were explanted from tissue obtained from anterior cruciate ligament (ACL) reconstructions. The effect of damage on tenocytes after stimulation with conditioned media from tendon explants or IL-1ß was evaluated



Proposed mechanisms driving T cell/stromal tendon activation in SpA.

by qPCR. A transwell membrane system was used to test the impact of conditioned media from tenocytes on T cell migration. T cells and tenocytes were co-cultured with or without the presence of a transwell membrane to quantify T cell activation (CD69 by FACS and IFN-γ by ELISA). Changes in gene expression on tenocytes after co-culture with activated T cells were analysed by qPCR.

Results: In the presence of damage, tenocytes upregulated inflammatory mediators (IL-6, COX2), chemokines (CCL2, CCL5, CXCL10, CXCL12) and adhesion molecules (ICAM-1). Conditioned media, particularly after stimulation with IL-1ß, from tenocytes induced T cell migration. Co-cultures of tenocytes and T cells resulted in activation of T cells that was contact dependant. In turn, these activated T cells upregulated the production of inflammatory mediators in tenocytes and increased the COL3/COL1 ratio.

Conclusion: Our results support a role of the tendon stromal compartment in the development and maintenance of an inflammatory response in SpA. Following damage, tendon stromal cells are able to induce the recruitment of T cells, that once enter the tissue interact with the stroma and get further activated. These activated T cells promote an upregulation of inflammatory cytokines and chemokines from the stromal compartment, creating a positive feedback loop that amplifies and maintains this inflammatory response.

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Table 1. Association between vaspin rs35262691 polymorphism and presence/absence of carotid plaques in patients with axSpA.

Genotype/Allele	Presence of carotid plaques (%)	Absence of carotid plaques (%)	OR [95% CI]	p
TT	23.1	35.8	1 (Reference)	-
TC	51.9	47.1	**1.92 [0.99-3.71]**	**0.052**
CC	25.0	17.1	**4.90 [2.12-11.37]**	**<0.001**
T	49.1	59.3	1 (Reference)	-
C	50.9	40.7	**2.08 [1.40-3.09]**	**<0.001**

p values adjusted by sex, age at the time of the study and traditional cardiovascular risk factors (hypertension, dyslipidemia, obesity, smoking habit).
CI: Confidence interval; OR: odds ratio.

Background/Purpose: Vaspin is a novel adipokine with insulin-sensitizing functions that exerts anti-inflammatory actions[1,2]. It has been associated with cardiovascular (CV) disease, CV risk factors and inflammation in the general population and in chronic inflammatory conditions different from axial SpA (axSpA)[2-4]. In particular, it has been suggested that vaspin may act as a compensatory mechanism for inflammation and CV disease[1,3]. This could be relevant for axSpA, given the high incidence of CV disease (mainly due to accelerated atherosclerosis) exhibited by these patients[5,6], which turns this comorbidity into a matter of major concern among rheumatologists. However, data on the role of vaspin regarding surrogate markers of atherosclerosis in the context of axSpA is scarce. For this reason, we aimed to evaluate the implication of vaspin in subclinical atherosclerosis in axSpA at the genetic and protein level.

Methods: This study included 385 patients that fulfilled the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA[7]. Clinical data was retrieved from medical records. Carotid US was performed to evaluate the presence of subclinical atherosclerosis (carotid plaques and abnormal carotid intima-media thickness [cIMT] values). 3 polymorphisms of *vaspin* (rs2236242, rs35262691 and rs7159023), previously associated with CV risk factors and/or reported as functional gene variants, were genotyped by TaqMan probes. Serum vaspin levels were assessed by ELISA. Statistical analysis was performed using STATA® v. 11.1, adjusting the results by potential confounding factors.

Results: We disclosed that the C allele of rs35262691 conferred a higher risk of developing carotid plaques in axSpA ($p< 0.05$)(Table 1). Regarding serum vaspin levels, even if they showed no statistically significant association with carotid plaques or cIMT values, these values positively correlated with factors associated with high CV risk such as systolic blood pressure ($p=0.02$) and waist circumference ($p=0.03$). Furthermore, serum vaspin levels were significantly higher in female patients than in males ($p< 0.001$).

Conclusion: Our results show for the first time that *vaspin* rs35262691 polymorphism is associated with carotid plaques in axSpA. The relevance of this molecule in the atherosclerotic process is further demonstrated by the relationship between serum levels and CV risk factors. All these data support a key role of vaspin in atherosclerosis in axSpA.

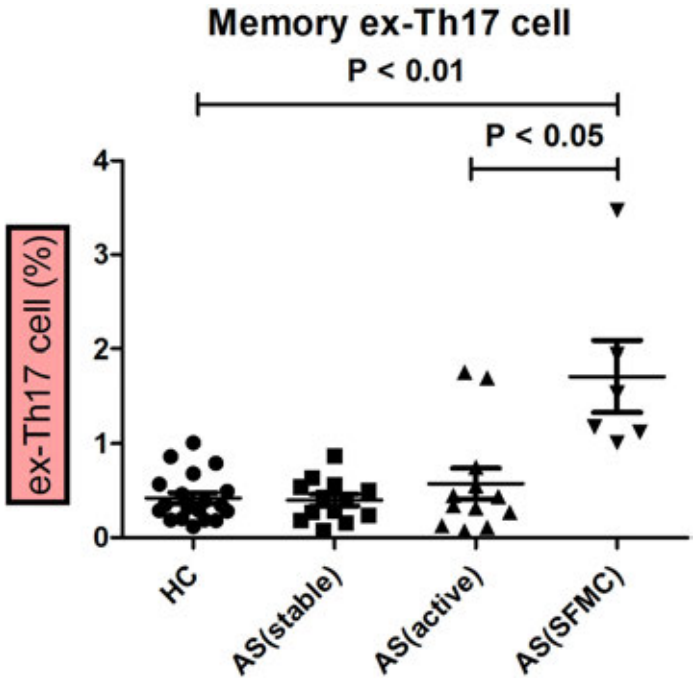
Memory ex-Th17 Cells Contribute to Synovial Inflammation in Spondyloarthritis

SO-HEE JIN,[1] Pu-Reum PARK,[1] Ji Hyun KANG,[1] DONG-JIN PARK,[1] and **TAE-JONG KIM** [1], [1]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (SpA) is characterized by inflammation of the synovium. An increase in the number of Th17cells in SpA has been reported. However, it is known that Th17 cells exhibit considerable plasticity, at sites of autoimmune inflammation. Th17 cells can switch to become IL-17 and IFN-r producing ex-Th17 cells. The aim of this study was to investigate the human ex-Th17 cells in synovial fluid at the site of the inflammation in SpA.

Methods: The samples of peripheral blood mononuclear cells (PBMC) and synovial fluid mononuclear cells (SFMC) samples were obtained from SpA patients, and age- and sex-matched Healthy controls(HCs). Cells were surface stained with anti–CD4-Pacific Blue, anti-Fixable Viability Dye-eFluor780, anti-CD45RO-PE. Cells were intracellular stained with antibodies against IFN-r (FITC) / IL-17 (APC) and analyzed. Intracellular cytokine staining, samples were pre-stimulated with 100 ng/ml PMA and 1UM ionomycin in the presence of Golgi-plug for 4 h. For STAT3 Phosflow, Cells were harvested, fixed, and permeabilized using appropriate buffers (Cytofix Fixation Buffer and Phosflow Perm Buffer III) at the time points indicated. The anti-phospho-STAT3 Tyr705-PE Abs were used. The Levels of cytokines in the serum or synovial fluid were assessed using Magnetic Luminex Assay. Statistical analysis was performed using Prism 5.0 Software (GraphPad Software, San Diego, USA). A $p < 0.05$ was considered statistically significant.



Results: Memory CD4 T cells present in the PBMC and SFMC of patients with SpA, as well as in the PBMC of HCs, were analyzed for the production of IFN-r and IL-17A. We observed a increase of ex-Th17 cells in the synovium from patients with SpA compared to the PBMC from HCs. The proportion of memory ex-Th17 was higher in SpA arthritis patients (mean±SD, 1.70±0.92 %) than in healthy controls (0.42±0.25 %) (*P< 0.01)* (Figure 1). Because the cytokine milieu regulates the immune cells function, we measured the inflammatory cytokines in the synovial fluid. Among the cytokines, synovial IL-6 levels were significantly higher in SpA patients(13357±4984 pg/ml) than those in Osteoarthritis (207±146 pg/ml) or serum in HCs (37.87±56.11 pg/ml) ($P < 0.001$).

We next evaluated IL-6 and pSTAT3 expression. Significantly higher levels of IL-6 and pSTAT3 transcripts were detected in arthritis patients when compared with SpA without arthritis, or normal controls. PBMC from AS patients were cultured in the presence of different concentrations of IL-6 (10, 20, 50, 100, or 500ng/ml), in the absence of exogenous IL-23 and TGF. IL-6 was sufficiently inducing significant ex-Th17 expansion. Ex vivo targeting of ex-Th17 cells with the IL-6 inhibitor significantly decreased the production of IL-17 as well as IFN-r cytokines in synovial cells.

Conclusion: We showed that pathogenic ex-Th17 cells accumulated in the joints of SpA patients. Ex-Th17 cell is dependent on the cytokine milieu with IL-6. They may play a pathogenic role at sites of inflammation, suggesting that the IL-6/STAT-3 axis is functioning in arthritis patients with SpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously identified CXCL10, NOTCH2NL, HAT1, and SETD2 as differentially expressed between psoriasis arthritis (PsA) and psoriasis patients without arthritis (PsC). This study aimed to validate these findings and determine their expression in leukocyte subsets in psoriatic disease.

Methods: Prospectively followed psoriasis patients without arthritis (PsC) were assessed yearly by rheumatologists for the presence of PsA. *CXCL10, CXCR3, NOTCH2NL, HAT1,* and *SETD2* mRNA levels were measured in whole blood from 39 patients with early PsA (< 2 years disease duration), 38 PsC (>10 years disease duration) and 39 healthy controls (HCs) as well as in T-cells (CD3+), monocytes (CD14+), and NK cells (CD56+) from PsA (n=25), PsC (n=23) and HCs (n=15). Gene expression was compared between groups using Mann-Whitney U tests.

Results: *CXCL10* expression was elevated in PsA compared to PsC (2.4-fold, p=0.071) and HC (1.9-fold, p=0.407), although this was not statistically significant. Within T cells, *CXCL10* was increased in PsA patients compared to HC (Figure 1; 4.9-fold, p< 0.01). *CXCL10* expression was higher in monocytes as compared to T-cells (6.7-fold, p< 0.001) and NK cells (5.0-fold, p< 0.001) in all study subjects combined. *CXCR3, HAT1* and *SETD2* were higher in T cells (233.7-fold, 3.2-fold and 2.9-fold, respectively) and NK cells (168.2-fold, 2.3-fold and 2.6-fold, respectively) compared to monocytes (p< 0.001). Expression of *NOTCH2NL* was increased in T cells compared to monocytes (1.9-fold; p< 0.001).

Conclusion: Gene expression differences were identified in psoriatic disease that could provide insight into their role in driving the development of PsA and aid in developing targeted treatments.

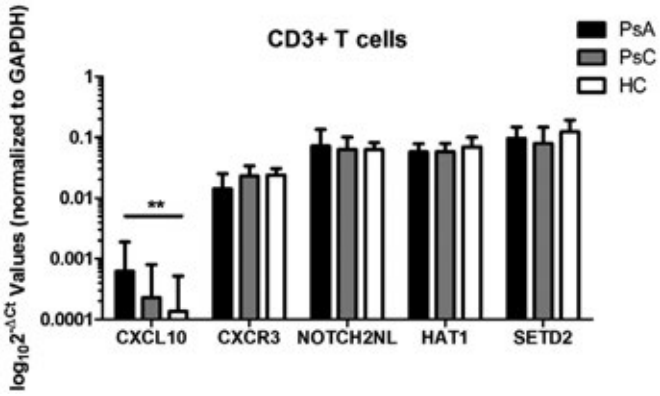

Figure 1. Bar graph depicting gene expression of CXCL10, CXCR3, NOTCH2NL, HAT1 and SETD2 in PsA (n=25), PsC (n=23) and HC (n=15) in CD3+ T cells from human whole blood. CXCL10 expression in T cells was significantly higher in PsA patients compared to HC. ** indicates p<0.01.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is the rheumatic disease most associated with metabolic disorders, including obesity and metabolic syndrome, where inflammation is a determinant key factor, increasing the risk of cardiovascular disease. Thus, searching a therapeutic strategy that could target both inflammation and metabolic complications is of great interest to reduce cardiovascular risk in these patients. **Objectives:** 1) To analyze the effect of Apremilast in the adipocytokine pattern, metabolic syndrome components and endothelial dysfunction in patients with PsA and metabolic syndrome (MetSyn). 2) To explore the *in vitro* effects of PDE4 inhibition in the endothelial function and adipocyte biology in the PsA context.

Methods: Human study: Twelve PsA patients diagnosed with MetSyn were given apremilast 30 mg twice daily for 6 months. Microvascular endothelial function was measured through post occlusive hyperemia using Laser-Doppler. The levels of cytokines, inflammatory and oxidative stress markers, endothelial adhesion molecules and adipokines were analyzed on serum and peripheral mononuclear blood cells (PMBCs) by ELISA and RT-PCR. **Treatment of adipocytes and endothelial cells with serum from PsA patients and apremilast:** 3T3L1-differentiated adipocytes and HUVECs were treated with serum 10% of PsA patients and HDs alone or with apremilast (10 mM) for 24h. The expression of adipokines (leptin, adiponectin, visfatin and resistin), adhesion molecules (e-Selectin, VCAM, ICAM), genes involved in inflammation (TNF-a, IL-1b, IL-8 and IL-6), lipid metabolism (DGAT, PLIN, HSL, GLP-1 and PPAR-g), insulin signalling (IRS-1, IRS-2 and GLUT-4) and oxidative stress (SOD-1) was analysed by RT-PCR and western blot.

Results: After 6 months of treatment, Apremilast significantly reduced BMI index, insulin resistance state and levels of complement C3, inflammation, and levels of ApoB. Microvascular endothelial dysfunction was significantly restored shown by an increase of the peak flow and hyperaemia area and decreased adhesion and inflammatory molecules in serum. Altered serum adipokines profile was minimized. mRNA expression levels of inflammatory, adhesion and migration molecules and adipokines were modulated in PMBCs from PsA patients after 6 months with apremilast.

In vitro treatment of endothelial cells with apremilast significantly reduced the expression of adhesion molecules, genes involved in proliferation, adipocytokines and oxidative molecules induced by the serum of PsA patients.

In vitro treatment of adipocytes with apremilast decreased the high levels of leptin, visfatin and resistin induced by PsA serum. In addition, levels of genes involved in lypolisis, adipogenesis and insulin signalling were modulated, favoring an improvement of the insulin resistance induced by PsA serum.

Conclusions: Our *in vivo* and *in vitro* studies suggest that apremilast might reduce IR, inflammation and endothelial dysfunction, parameters strongly involved in cardiovascular disease, by directly targeting adipose tissue and endothelial cells.

Supported by the Minister of Health (ISCIII, PI17/01316, RIER RD16/0012/0015) cofinanced with FEDER funds.

IL-17A Induces Distinct Functional Differences Between Two Novel Mesenchymal Stem Cell Populations Identified at the Human Enthesis

Tobias Russell,[1] Abdulla Watad,[2] Charlie Bridgewood,[3] Almas Khan,[4] Abhay S Rao,[4] Peter Loughenbury,[4] Peter Milner,[4] Robert Dunsmuir,[4] Thomas Baboolal,[3] Elena Jones,[5] Richard Cuthbert,[1] and Dennis McGonagle[6], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM)University of Leeds, Leeds, England, United Kingdom, [2]Department of Medicine "B", Zabludowicz Center for Autoimmune Diseases Sheba Medical Center, Ramat-Gan, Israel, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine (LIRMM)University of Leeds, Leeds, United Kingdom, [4]Leeds Teaching Hospitals NHS Trust, Leeds, [5]University of Leeds, Leeds, England, United Kingdom, [6]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is associated with entheseal inflammation and new bone formation. Resident populations of lymphocytes have been identified at the enthesis that on stimulation with IL-23 produce pro-inflammatory cytokines including IL-17A and IL-22 (1) which drive inflammation and may also influence osteogenesis. Surprisingly, enthesis resident mesenchymal stem cells (MSCs) have not been phenotypically or functionally characterised.

To determine if human entheseal tissue harbours a population of MSCs and to investigate the effect of spondyloarthritis associated pro-inflammatory cytokines on MSC osteogenesis and adipogenesis.

Methods: Samples from healthy spinous process and interspinous ligament (10 male, 10 female, median age = 49) were divided into entheseal soft tissue (EST) and peri-entheseal bone (PEB) (1) and enzymatically digested. MSCs content was assessed using a CFU-F assay. Flow cytometry was used to examine expression of MSCs specific markers in plastic adherent cultures. Following osteogenic, chondrogenic and adipogenic inductions, osteogenesis was qualitatively assessed by alkaline phosphatase and alizarin red staining and quantitatively by measurement of calcium accumulation. Chondrogenesis and adipogenesis were assessed using glycosaminoglycan assay and Oil

Red O staining respectively. Osteogenic and adipogenic cultures were also supplemented with IL-17A (50ng/ml), IL-22 (10ng/ml) or TNF-α (1ng/ml) to determine the effect of these cytokines on adipogenesis and osteogenesis.

Results: As a proportion of total cellularity EST developed approximately 5 fold more CFU-F than matched PEB ($p< 0.0001$). Cultured cells were overwhelmingly positive for expression of MSC markers CD73, CD90, CD105 (median 98.66% range: 87.69-98.7%) and negative for CD14, CD19, CD45 and HLA-DR (median 0.34% range: 0-2.53%) however some CD34 expression was noted particularly in EST cultures (median 3.74% range: 0-29%). Both populations were capable of tri-lineage differentiation, although PEB MSCs had 2.75-fold greater osteogenic ($p< 0.05$) and -4.4-fold adipogenic ($p< 0.05$) potential than matched EST MSCs. Calcium accumulation was significantly lower for PEB MSCs when exposed to any cytokine ($p< 0.05$), though addition of IL-17A to EST MSCs significantly increased calcium accumulation by 1.5-fold ($p< 0.05$). Addition of IL-17A or TNF-α significantly decreased lipid accumulation for EST MSCs ($p< 0.05$).

Conclusion: Both the EST and PEB contain cells that meet the ISCT criteria defining MSCs. However, MSCs from these sources are functionally distinct in terms of their differentiation potential and response to inflammatory cytokines. IL-17A is capable of enhancing osteogenesis and impairing lipid accumulation in entheseal soft tissue MSCs. These findings are potentially important in explaining the altered bone and fat phenotype observed in AS as the aberrant new bone formation arises in this tissue.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Delayed diagnosis of psoriatic arthritis (PsA) can lead to poor clinical outcomes. A large proportion of PsA patients remain undiagnosed due to a lack of robust biomarkers. Gene expression analysis at single peripheral blood mononuclear cell (PBMC) resolution may help to identify novel cells and RNA signatures present in PsA compared to psoriasis patients without arthritis (PsC).

Methods: PBMCs were isolated from 3 patients with early PsA (< 2 years) and 3 PsC patients matched for age, sex, and psoriasis duration. All patients were treatment naïve. Single cells were isolated using the droplet-based Chromium platform (10X Genomics) and cDNA libraries were sequenced on an Illumina HiSeq 4000. Data were processed in CELLRANGER and secondary analysis performed using R packages. Poor quality cells were filtered out based on high percentage of mitochondrial content, number of genes expressed and library size. Data were normalized by

scran normalization and unsupervised graph-based clustering of cells was performed using a K-nearest neighbor algorithm. Cell types were inferred using immune marker genes and computed cluster markers.

Results: PsA patients were 2/3 male, median age 65 (range 53-75) years, median active joint count 3 (0-7), and median psoriasis area and severity index (PASI) score of 1.4 (0.4-3.1). PsC patients were 2/3 male, age 64 (56-75) years, PASI score 2.8 (0.3-8.7). After quality control and filtering, high quality expression profiles were obtained from 7350 and 7022 cells from PsA and PsC patients, respectively. The number of clusters identified in each sample is shown in Table 1. Sample PsA2 had unique clusters of monocytes and CD34+ cells, whereas PsC2 had a unique cluster of plasmacytoid dendritic cells. The remaining clusters were evident in all patients and consisted of T cells, B cells, macrophages, NK cells and myeloid dendritic cells. Differential expression analysis of PsA compared to PsC patients revealed several differences (shown in Table 2). In myeloid dendritic cells significant upregulation of genes such as *JUP* (junction plakoglobin/gamma catenin, fold change[FC]=1.36, adj.p=$6.8x10^{-47}$) and *LYZ* (lysozyme, FC=1.23, adj.p=$2.9x10^{-39}$) was found. T cells showed significant downregulation of *IL32* (interleukin 32, FC=0.66, adj.p=$5.0x10^{-35}$), *ERAP2* (endoplasmic reticulum aminopeptidase 2, FC=0.77, adj.p=$3.0x10^{-16}$), and upregulation of *HLA-C* (human leukocyte antigen C, FC=1.28, adj.p=$3.2x10^{-33}$). FCGR3A+ monocytes showed a significant upregulation of *IFITM3* (interferon induced transmembrane protein 3, FC=1.56, adj.p=$3.5x10^{-11}$) and *LILRA6* (leukocyte immunoglobulin-like receptor A6, FC=1.23, adj.p=$1.8x10^{-5}$). Cytotoxic T cells showed upregulation of *TRBV4-2* (T cell receptor beta variable 4-2, FC=3.02, adj.p=$7.3x10^{-29}$) and *TNFAIP3* (TNF alpha induced protein 3, FC=1.35, adj.p=$3.8x10^{-6}$). Natural killer cells and naïve T helper cells showed significant downregulation of several ribosomal proteins in PsA compared to PsC patients.

Conclusion: The data show novel insights into gene expression differences in different cell populations that might help in differentiating PsA from PsC.

Apremilast Inhibits Immune Cells Support of Inflammatory Osteoclastogenesis

Yannick Degboe,[1] Flavia Sunzini,[1] Iain McInnes,[2] and **Carl Goodyear** [1], [1]University of Glasgow, Glasgow, United Kingdom, [2]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is associated with bone erosion and inflammation-induced bone loss. This process is mediated by osteoclasts, and modulated by inflammatory cytokines (*i.e.* TNF, IL-1, IL-6, IL-17, and GM-CSF) from immune and stromal cells. Apremilast (APR; a selective phosphodiesterase 4 inhibitor) has known efficacy in PsA, and decreases pro-inflammatory mediators. Although published data indirectly suggest a positive impact of APR on inflammatory-driven bone loss in PsA, data is lacking with regard to the impact on osteoclast generation and activity.

Methods: Osteoclasts were differentiated from primary human $CD14^+$ blood monocytes (derived from PsA patients and healthy controls (HC)) with M-CSF, sub-optimal level of RANKL, plus additional inflammatory-associated stimuli. In brief, osteoclastogenesis was undertaken in the presence of: *(i)* TNF, *(ii)* Supernatants from activated Peripheral

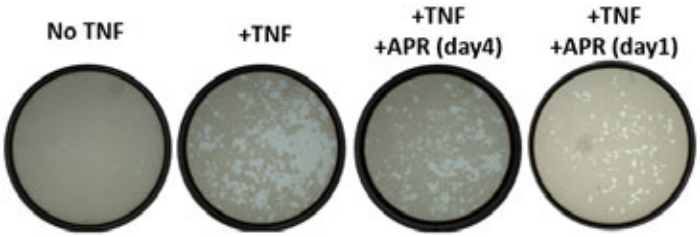

Figure 1. Impact of apremilast on osteoclast resorptive activity. Osteoclastogenesis was driven by TNF. CD14+ precursor where treated at monocyte stage (day1) or pre-osteoclast stage (day4). Resorption plates from a PsA patient representative of 5 experiments in PsA patients and HC.

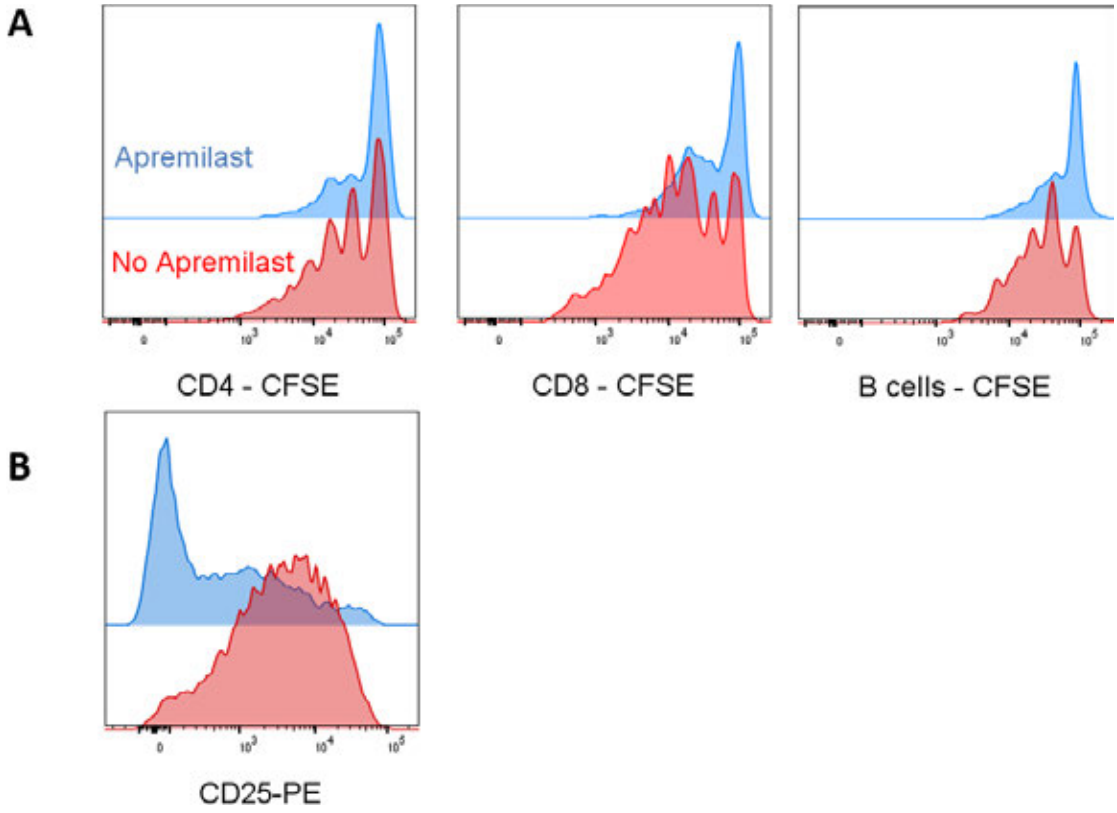

Figure 2. Impact of apremilast on PBMC proliferation and activation. PBMC were activated for 3 days with anti-CD3/CD28/CD2 beads +/- apremilast. (A) Proliferation of T cells and B cells (CFSE uptake) and (B) lymphocytes activation (CD25 membrane expression) were assessed by flow cytometry. FACS plots representative of 3 experiments in HC.

Blood Mononuclear Cells (PBMC) treated with or without APR, *(iii)* Co-culture with activated PBMC, pre-treated with or without APR. Mature osteoclasts were enumerated (Tartrate-Resistant Acid Phosphatase staining/microscopy) and assessed for resorptive activity (Osteo Assay Surface/microscopy). The direct impact of APR on lymphocytes proliferation and activation was also assessed via flow cytometry and cytokines assay.

Results: APR significantly decreased TNF-enhanced osteoclastogenesis and osteolytic activity in both PsA and HC samples *(Figure 1)*. Notably, APR had a dramatic impact on the ability of monocytic precursors to respond to osteoclastogenic signals, but was also able to substantially modulate the capacity of pre-osteoclast to respond to the same signals.

The treatment of activated PBMCs with APR markedly reduced lymphocytes proliferation (CD4, CD8, B cells), and activation (CD25 membrane expression; TNF, IL-17A, M-CSF, IL-2 production in supernatants) *(Figure 2)*. This mod-

ulation resulted in a decrease in the capacity of either PBMC condition media or PBMC coculture-driven osteoclastogenesis.

Conclusion: Phosphodiesterase 4 targeting by APR inhibits *in vitro* inflammation-driven osteoclastogenesis. Our study supports the hypothesis that this therapeutic approach can modulate bone integrity in inflammatory condition such as PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TNFα inhibitors are an effective treatment for many inflammatory diseases. However, their mechanism of action is more complicated than just blocking the targeted cytokine. MicroRNAs are important post-translational regulators of gene expression and their expression has been found deregulated in rheumatic diseases such as rheumatoid arthritis or spondyloarthritis. The general goal of this work is to investigate changes in miR expression in monocytes and CD4+ T-lymphocytes from patients with axial spondyloarthritis during anti-TNF treatment.

Methods: Sixty-eight patients with axial spondyloarthritis were enrolled in the study. Among these patients, 63 fulfilled the 2009 ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays (n= 47) or objective signs of inflammation on MRI (n=16) and 72% were HLA-B27 positive. All patients were naïve for biologic treatments at baseline and had an active disease (mean BASDAI score of 49 +/- 19 and mean ASDAS score of 3+/-1) requiring the initiation of a TNFα inhibitor (Etanercept 41, Adalimumab 17, Golimumab 10). Mean CRP at baseline was 12.5 +/-18. At 3 months, the BASDAI response rate was 59%. Blood sample were collected at baseline (M0) and 3 months (M3) after the initiation of the treatment. Monocytes and CD4$^+$ T-lymphocytes were isolated from peripheral blood mononuclear cells and 372 miR were investigated by qPCR. A paired Wilcoxon signed-rank test was used to explore differential expression of miRs between M0 and M3.

Results: Pair-wise comparison of miR level before and 3 months after anti-TNF treatment identified 35 differentially expressed (DE) miRs in circulating CD4+ T lymphocytes and 53 DE miRs in monocytes (false discovery rate < 5%). Eighteen miRs were commonly deregulated in both cell types, among which 12 were upregulated and 6 were down-regulated after treatment. Strikingly, we found DE miRs before and after treatment in patients with good response

to TNF inhibitors while there was little or no DE miRs in non-responders according to BASDAI response criteria. Differentially expressed miRs were not correlated to the CRP levels or to the variation of the CRP between 0 and 3 months. Also, in patients with negative CRP at baseline, we found DE miRs (nominal p-value < 5%) suggesting that the modulation of miRs was not only reflecting a better inflammation control.

Conclusion: This work demonstrates that TNF inhibitors might at least partially act by modulating miR expression, especially in patients who respond well to treatment.

Regulatory Role of IL-23 and Its Receptor System in Spondyloarthritis and Its Therapeutic Relevance in anti-IL-17 Failure Patients

Siba Raychaudhuri,[1] and Smritikana Raychaudhuri[2], [1]UC Davis School of Medicine, Sacramento, CA, [2]UC Davis School of Medicine, Davis, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Here we hypothesized that (i) IL-23/IL-23R system more specifically the specific IL-23p19 subunit mediated signaling system regulates expansion/maintenance and functional maturation in respect to production of the signature cytokines of Th17 cells (IL-17 and IL-22) in psoriatic arthritis (PsA) and ankylosing spondylitis (AS) and that (ii) a high affinity humanized IgG1/j monoclonal antibody that binds to the p19 subunit of IL-23 such as tildrakizumab will block IL-23 induced JAK/STAT signaling system and inhibit expansion/maintenance and functional maturation of the effector Th17 cells in PsA and AS.

Methods: PsA and AS patients with an active disease not on DMARDS/biologics were recruited in this study. Mononuclear cells from peripheral blood (PBMC) and synovial fluid (SFMC) of age/sex matched PsA patients (n=10), PBMCs from AS patients (n=10) and normal individuals (n=10) were isolated. Magnetically selected $CD3^+$ T cells (10^6 cells/ml) were activated with anti-human CD3/CD28 cocktail+rIL-23. Activated $CD3^+$ T cells were cultured with and without tildrakizumab (120 pM). To identify the activated memory $CD4^+CD11a^+CD45RO^+IL\text{-}17^+$ T cells and $CD4^+CD11a^+CD45RO^+IL\text{-}22^+$ T cells Hi-D FACS studies were performed (FACSFusion Aria); the % of cell population and the MFI were analyzed by using Flow Jo software. Anti-proliferative effect of tildrakizumab on PBMCs and SFMCs was assessed by MTT and CFSE dilution assays. Immunoblot assays were done on lysates of the cultured $CD3^+$T cells to identify Jak2/p-Jak2, Tyk2/p-Tyk2, stat3/p-stat3, and RORγt.

Results: (i). In PBMCs/SFMCs of PsA and AS patients rIL-23 induced marked upregulation of IL-17A and IL-22 in the memory T cells (CD11a+CD45RO+); tildrakizumab inhibited rIL-23 induced IL-17 and IL-22 expression in CD4+ memory T cells, more specifically we noticed with tildrakizumab there was marked reduction of CD4+CD11a+CD45RO+IL-17+

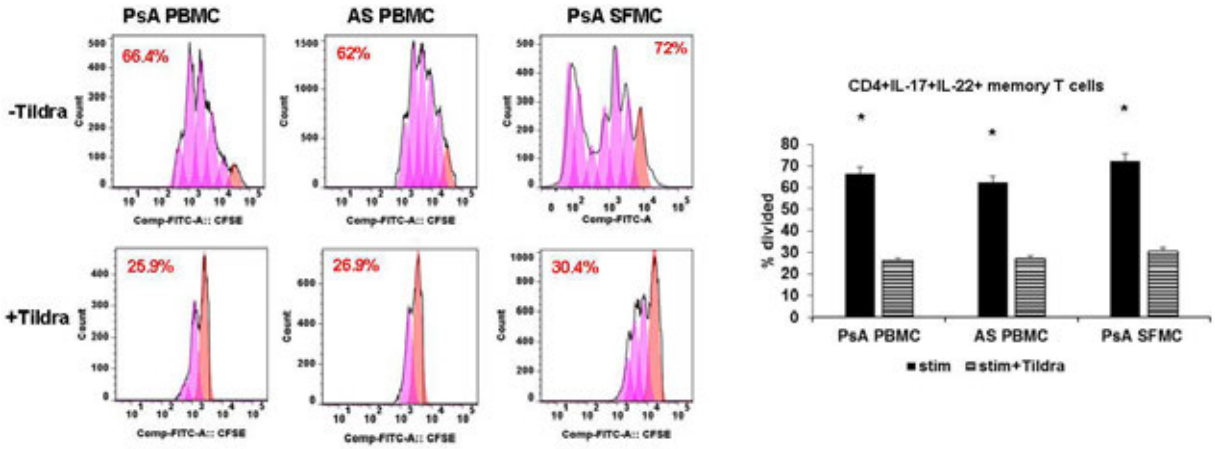

Figure 1. Recombinant IL-23 induces proliferation of CD4+IL-17+IL-22 memory T cells and that can be blocked by tildrakizumab, a monoclonal antibody that binds to the p19 subunit of IL-23. PBMCs of PsA (n=10), AS (n=10), OA (n=10) and SFMCs of PsA (n=5), OA (n=5) were stained with 5μM CFSE and then incubated in the presence or absence of tildrakizumab prior to stimulation with CD3/CD28+rIL-23. HI-D FACS studies were performed to identify live CD3+CD4+CD11a+CD45RO+IL-17+IL-22+ T cells. Cells pre-treated with tildrakizumab had significant reduction of proliferation of IL-17+IL-22+ memory T cells (p<.01).

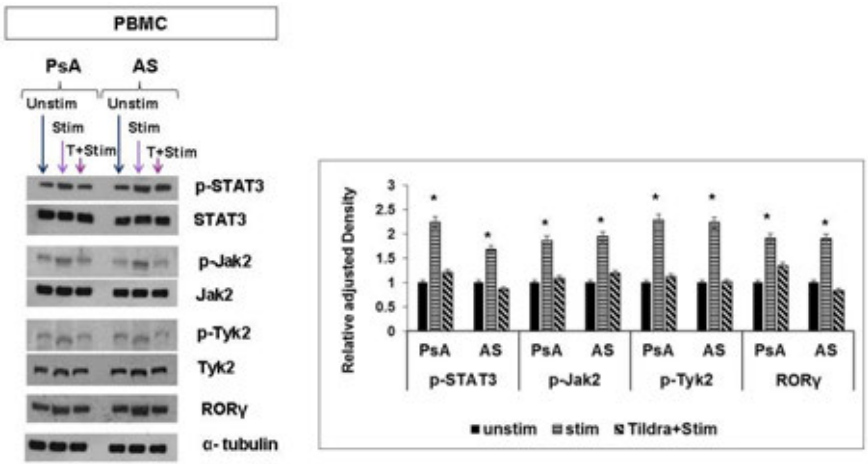

Figure 2. In activated PBMC T cells of psoriatic arthritis (PsA) and ankylosing spondylitis (AS) rIL-23 induced JAK/STAT signaling system and activation of RORγt the master transcription factor for IL-17 and IL-22; and these phosphorylation events could be inhibited by tildrakizumab (p<0.001). Unstim= Unstimulated; Stim= Stimulated, T+ Stim= tildrakizumab + Stimulated.

T cells and CD4+CD11a+CD45RO+IL-22+ T cells (p< .01)) (ii) tildrakizumab significantly inhibited proliferation of these CD4+IL-17+ memory T cells and CD4+IL-22+ (Fig 1) (iii) Immunoblot assays demonstrated PsA/AS activated CD3+ T cells treated with tildrakizumab had decreased expression of phospho-STAT3/Jak2/Tyk2/RORgt by two-folds (p< 0.001) compared to CD3+ T cells not treated with tildrakizumab (Fig 2).

Conclusion: Marked upregulation of IL-23 at the disease sites of PsA and AS is well established. rIL-23 activated sorted pathological $CD3^{+}$ T cells in PsA and AS induced proliferation of CD4+IL-17+IL-22+ memory T cells and up-regulations of IL-17A and IL-22 (by ELISA) and tildrakizumab inhibited all these outcomes significantly. We noticed in secukinumab treated PsA patients (n=10) those who had pretreatment higher levels of IL-22 did not respond to secukinumab. This suggests that by blocking the IL-23R an additional therapeutic advantage can happen because of its inhibition of both IL-17 and Il-22. Putting together here we have provided the (i) proof of concept about IL-23p19 induced immune dysregulations in PsA and AS (ii) the potentials of p19 targeted therapy for PsA and AS (iii) a prospect for a choice of anti-IL23p19 therapy in anti-IL-17 resistant patients.

Session Title: SLE – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic autoimmune rheumatic diseases (SARD) including Sjogren's Disease (SjD), Systemic Sclerosis (SSc) and Systemic Lupus Erythematosus (SLE) are characterized by the production of anti-nuclear antibodies (ANA) and are associated with considerable morbidity and/or mortality. ANA production can also be seen in ~20% healthy women, only a small subset of which will eventually progress to a SARD diagnosis. Although pro-inflammatory cytokines including TNFα and IL-6 are only increased in symptomatic patients, some of the cellular immune changes associated with SARD are also seen in ANA^+ non-symptomatic (ANA^+ NS) individuals. In order to better understand the immunologic changes that lead to SARD progression, we used flow cytometry to investigate a variety of innate and adaptive immune populations in ANA^+ NS as compared to healthy controls (HC) and SARD patients.

Methods: Consenting ANA^+ (IF ≥ 1:160) participants were recruited through the clinic and classified as ANA^+ NS (n = 38), ANA^+ with symptoms but lacking sufficient criteria for SARD diagnosis (UCTD, n=42) or early SARD (SLE, n=5, SSc, n=2). SARD diagnosis and classification was assessed according to the 1997 ACR criteria for SLE and the 2013 ACR-EULAR criteria for SSc. All SARD patients were within 2 years of diagnosis and not taking DMARDs (hydroxychloroquine allowed) or prednisone. ANA^- HC (n= 14) were also recruited. Peripheral blood mononuclear cells (PMBCs) were isolated and stained with fluorochrome labeled antibodies to identify immune cell populations via flow cytometry.

Results: Several of the immunologic changes previously reported for SARD patients were also seen in ANA^+ NS and UCTD. These included: increased proportions of plasma cells and plasmablasts; a trend to increased transitional B cells, activated class-switch memory B cells, activated memory Tfh and Tph cells; and a trend towards decreased proportions class-switched memory B cells. Contrary to initial reports that T regulatory (T_{reg}) cells are decreased in SARD, these cells were increased in ANA^+ NS and UCTD groups with similar changes seen for the SARD patients. However, a subset of regulatory cells, CD8 T_{reg} were markedly decreased in ANA^+ NS and UCTD patients, suggesting a potential functional role for these cells in regulating autoimmunity. Monocytes and myeloid dendritic cells are increased in SARD patients and have been shown to produce pro-inflammatory cytokines. These populations were also significantly increased in ANA^+ NS and to a lesser extent in UCTD patients, as compared to HC. In contrast, no changes were seen in the proportion of plasmacytoid dendritic cells in ANA^+ NS and UCTD patients.

Conclusion: Several of the immune changes in ANA$^+$ NS individuals appear to parallel those seen in SARD patients, indicating that there is substantial immune activation even in asymptomatic ANA$^+$ individuals. These findings argue that the differences between ANA$^+$ NS and SARD patients may result from altered function rather than altered proportions of these populations.

Abstract Number: 1016

Identification of Differentially Expressed Genes and Signaling Pathways in Systemic Lupus Erythematosus by Integrated Bioinformatics Analysis

Wei Liu,[1] Yuanhao Wu,[1] and Wenjia Zhao[1], [1]First Teaching Hospital of Tianjin University of Traditional Chinese Medicine, Tianjin, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a common autoimmune disease. The occurrence and development of SLE is a result of multiple factors, but its exact pathogenesis has not been fully elucidated.

Methods: Here, we used bioinformatics to analyze and identify the key pathogenic genes of SLE and to reveal the underlying pathogenic molecular mechanism.

Results: The expression profiles of GDS4185, GDS4888, GDS4889 and GDS4890 were downloaded from the Gene Expression Omnibus (GEO) database, which contained 99 samples, including 42 cases of SLE samples and 57 cases of normal samples. The four microarray datasets were integrated to get differentially expressed genes (DEGs). The gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichments of DEGs were operated by DAVID and KOBAS online calculuses, respectively. The protein–protein interaction (PPI) networks of the DEGs were created from the STRING database. A total of 839 DEGs were extracted from the four GEO datasets, of which 289 genes were upregulated and 550 genes were downregulated. GO analysis indicated that the biological functions of DEGs focused primarily on response to virus, type I interferon signaling pathway and cellular protein metabolic process. The main cellular components include perinuclear region of cytoplasm, focal adhesion and cell-cell adherens junction. The molecular functions include protein binding, double-stranded RNA binding and actin filament binding. KEGG pathway analysis showed that these DEGs were mainly involved in the Osteoclast differentiation, HTLV-I infection, Measles, FoxO signaling pathway, Herpes simplex infection, Primary immunodeficiency and Jak-STAT signaling pathway. The 14 most closely related genes among DEGs were identified from the PPI network.The 14 genes are: HERC5, TP53, CDC20, GNB2, GNB4, PPP2R1A, GNAI2, PMCH, SOCS3, HERC6, STAT1, SOCS1, ISG15, IFIT3.

Conclusion: This research suggests that screening for DEGs and pathways in SLE using integrated bioinformatics methods could help us realize the molecular mechanism underlying the development of SLE, be of clinical implication for the early diagnosis and prevention of SLE, and afford reliable targets for the treatment of SLE.

The Integration of Genetic Data, Molecular Pathway Analysis and Differential Expression to Delineate the Impact of Ancestral Differences on Lupus

Katherine Owen,[1] Bryce Aidukaitis,[1] Adam Labonte,[1] Michelle Catalina,[1] Prathyusha Bachali,[1] Nicholas Geraci,[2] Miranda Marion,[3] Hannah Ainsworth,[4] kip Zimmerman,[3] Timothy Howard,[4] Carl Langefeld,[4] Peter Lipsky,[2] and Amrie Grammer[5], [1]AMPEL Biosolutions and the RILITE research institute, Charlottesville, VA, [2]AMPEL BioSolutions, LLC, Charlottesville, VA, [3]Wake Forest School of Medicine, Winston-Salem, NC, [4]Wake Forest School of Medicine, Winston-Salem, [5]AMPEL BioSolutions and RILITE Research Institute, Charlottesville, VA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a multi-organ autoimmune disorder with a prominent genetic component. Evidence has shown that individuals of African-Ancestry (AA) experience the disease more severely and with an increased co-morbidity burden compared to European-Ancestry (EA) populations. However, the relationship between genetics, molecular pathways, and disease severity has not been fully delineated. Here, we examined AA and EA SLE-associated single nucleotide polymorphisms (SNPs) and linked them via expression quantitative trait loci (eQTL) across multiple tissues to genes with altered expression (E-Genes). Putative EA and AA E-Gene signatures were coupled with SLE differential expression (DE) datasets and upstream regulators to map candidate molecular pathways. Together, these genetic and gene expression analyses enable a better understanding of how the identified SNPs could contribute to aberrant immune function as well as the influence of ancestry on the genetic basis of SLE.

Methods: A previous SLE Immunochip study (Langefeld et al., 2017) identified SNPs significantly associated with SLE in AA (2,970 cases; 2,452 controls) and EA (6,748 cases; 11,516 controls) cohorts. eQTL mapping identified E-Genes from SLE SNPs and their ancestry-specific SNP proxies (based on linkage disequilibrium) via the GTEx database. For both ancestral groups, E-Gene lists were examined for the significant enrichment of gene ontogeny (GO) terms, canonical IPA® (Qiagen) pathways and BIG-C™ categories. Next, we analyzed the gene expression profiles of predicted E-Genes across multiple SLE DE datasets, including those from blood and multiple tissues. Differential expressed genes (DEGs) were identified and subjected to pathway analysis with IPA®, clustering using MCODE and visualization in Cytoscape with the ClusterMaker2 plugin. Drug candidates targeting E-Genes, DEGs and upstream regulators (UPRs) were identified using CLUE, IPA® and STITCH.

Results: A total of 908 Immunochip SNPs were mapped to 252 eQTLs and coupled to 760 E-Genes (207 in EAs, 30 in AAs, 523 shared; Figure 1A). Shared E-Genes were highly enriched in interferon signaling, whereas EA E-Genes were associated with nucleotide degradation and AA E-Genes were linked to multiple biosynthesis and intracellular signaling pathways (e.g., retinol biosynthesis and AMPK signaling). Protein-protein interaction (PPI) networks of clustered EA, AA and shared E-Genes illustrate the high degree of ancestral overlap evident within each E-Gene set (Figure 1B). Clustering analysis of all DE E-Genes and IPA-predicted UPRs highlight disease-associated pathways that are both shared and ancestry-specific. Drug candidate comparison identified a total of 115 drugs targeting EA, AA and shared E-Genes and their molecular pathways.

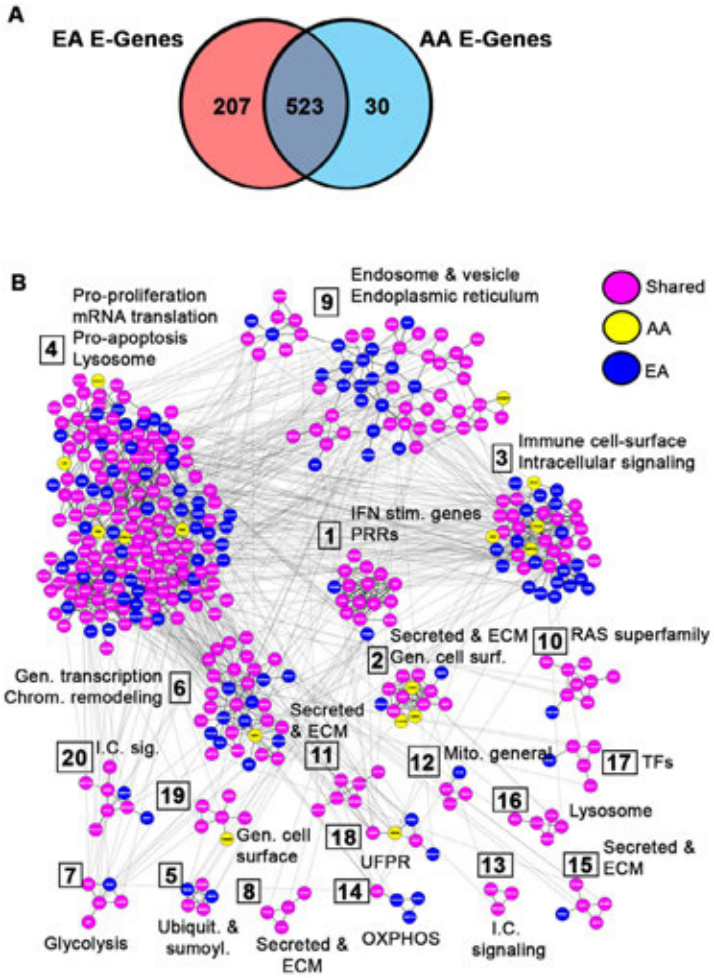

Figure 1. (A) Venn of E-Gene overlap. (B) Cytoscape visualization of E-Gene PPI networks using MCODE clustering. Significant BIG-C functional categories for individual modules are listed.

Conclusion: Using a bioinformatics-based approach that utilizes pathway analysis and gene expression data, we were able to discover novel ancestry-dependent and ancestry-agnostic candidate causal targets in SLE and couple those with drug discovery tools to identify new therapies with the potential to impact disease processes within and across specific populations.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Compared to Caucasian, African-American ethnicity is associated with a higher risk of developing systemic lupus erythematosus, lupus nephritis, high-risk histological features, resistance to treatment, and mortality. In phase 1 of the Accelerating Medicines Partnership (AMP), we used single-cell genomics to identify ethnicity associated features.

Methods: Single cell RNA sequencing was performed on renal biopsies obtained for clinical purpose; one pipeline applying CEL-Seq2 in a leukocyte enriched sample and the other Fluidigm C1 800 in an agnostic approach to dissociated renal cells. Differential abundance of cell populations was determined using a logistic mixed model. Then, the differential expression profile was determined for each cell cluster and interpreted using pathway enrichment analysis.

Results: Samples from 19 African-American and 20 Caucasian patients were obtained. We identified 30 cell clusters. Type I and II interferon inducible genes were upregulated in most cell populations. A cluster of T cells with exceptionally high interferon signature was found to be increased in African-Americans (OR 4.8). Macrophages and DC4-like dendritic cells were instead less abundant (OR 0.3). In African-Americans, type I and II interferon response pathways were enriched in several cell types including T cells, B cells, plasma cells, and activated monocytes. The majority of the differentially expressed genes was specifically inducible by type II interferon. In addition, while there was no local expression of type I interferons, interferon gamma was abundantly expressed by infiltrating NK and CD8 T cells.

Conclusion: African-American patients with lupus nephritis have a stronger interferon response pathway activation, especially type II. Our findings suggest an intrinsic biological factor underlying the outcome gap and highlight the role of interferon gamma in lupus nephritis, implicating this pathway as a potential therapeutic target in SLE. Further work in Phase 2 of AMP is being pursued to validate and extend these findings.

Session Date: Monday, November 11, 2019

Session Title: SLE – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Type I interferon (IFN) is an important mediator in the pathogenesis of systemic lupus erythematosus. Serum type I IFN levels clearly vary between SLE patients of different continental ancestral backgrounds, with levels being highest in African-American SLE patients. It is not known whether this diversity is also present within continental ancestral groups. In this study, we examine regional differences between European populations and use ancestry informative markers (AIMs) to assess for Northern versus Southern European admixture in a European-American cohort, and to correlate proportional regional European ancestry with serum type I IFN activity.

Methods: We studied type I IFN levels in European ancestry SLE patient cohorts from Sweden, Crete and the United States. Patients all met the ACR classification criteria for SLE. Serum IFN-a activity was determined using a WISH cell reporter assay. In the United States cohort, a validated set of European American ancestry informative markers (AIMs) designed to distinguish northwest and southeast European ancestry was used to assess for proportional Northern versus Southern European ancestry. Principal component analysis (PCA) was performed to infer population structure.

Results: The Swedish cohort had the highest type I IFN levels, while the US cohort was intermediate, and the lowest IFN levels were detected in the Crete cohort. The US subjects are a mix of Northern and Southern European ancestry by self-report, so we genotyped 297 ancestry informative markers in the 366 US SLE patients with self-reported European American ancestry. In this group, circulating type I IFN levels were correlated with three of the top five principal components derived from the AIMs considered in aggregate using Fisher's method for the combination of p-values across the three components ($p = 0.024$). Given that these components segregate northern versus southern European ancestry, this finding in the US cohort supports the concept that type I IFN levels vary according to regional genetic ancestry within Europe.

Conclusion: In this study, we demonstrate that variations in type I IFN levels correlate with regional ancestry within Europe in European-derived cohorts of SLE patients, further supporting the heterogeneity in type I IFN pathway activation in SLE patients of different ancestral backgrounds.

NLRP12 Regulates Interferon-α Expression and Is a Biomarker for Disease Activity of Systemic Lupus Erythematosus

Ming-Han Chen,[1] Yen-Po Tsao,[1] and Szu-Ting Chen[2], [1]Division of Allergy, Immunology & Rheumatology/Taipei Veterans General Hospital, Taipei, Taiwan (Republic of China), [2]Institutes of Clinical Medicine, National Yang-Ming University, Taipei, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematous (SLE) is a systemic autoimmune disease with diverse etiological factors. It was well recognized that interferon (IFN) signature did the perpetration on the progress of this disease. NLRP12 (NOD-like receptor family (NLR) pyrin domain containing 12) is a pyrin containing NLR protein that we had linked its new biological function to the cross-regulation of Toll like receptor (TLRs) and Rig-I like receptor (RIG-I) pathways. NLPR12 acts as an innate immune check-point in regulating type I IFNs expression during TLRs and RIG-I activation. Therefore, we aimed to investigate the underline molecular mechanism of NLRP12 regulation and its significance in SLE patients.

Methods: PBMCs were collected from 60 SLE patients and 20 healthy donors for analysis of *NLRP12* and IFN-α (*IFNA)* gene expression by RT-QPCR. PBMCs were applied for Chromatin immuneprecipitation (ChIP) assay and electrical mobility shift assay (EMSA) to determine the putative transcription factor that regulates *NLRP12* expression. An involvement of epigenetic regulation of *NLRP12* expression in SLE patients was also analyzed.

Results: We found that *NLRP12* expression was significantly lower in PBMC isolated from SLE patients compared to healthy donors. The inverse correlation was observed in *NLRP12* and *IFNA* gene expression as well as *NLRP12* expression and amount of double-stranded DNA autoantibody in SLE patients. Interestingly, *NLRP12* expression was gradually restored to the normal level after treatments in the patients. Results from Chlp and EMSA analysis indicated potential transcription factors (TFs) regulating *NLRP12* promoter activity, thus lead to transcriptional suppression of *NLRP12* in SLE PBMC.

Conclusion: In this study, expression level of *NLRP12* has been demonstrated to be a biomarker of disease activity in SLE patients. Mechanistically, a specific transcription factor regulating *NLRP12* expression in SLE PBMC is in accord with the same TF that suppresses *NLRP12* expression in type I IFN treated-monocyte. This finding may offer clues and an explanation for SLE patients with type I IFN signature.

Anti-IFNAR Treatment Does Not Reverse Neuropsychiatric Disease in MRL/*lpr* Lupus Mice

Michelle Huang,[1] Ariel Stock,[2] Elise Mike,[2] Roland Kolbeck,[3] and Chaim Putterman[4], [1]Albert Einstein College of Medicine, Bronx, [2]Albert Einstein College of Medicine, Bronx, NY, [3]MedImmune, Gaithersburg, MD, [4]Albert Einstein College of Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Many systemic lupus erythematosus patients display a type I interferon (IFN) signature, and IFNα levels and gene signatures have been positively correlated with disease severity. Previous studies blocking the type I IFN pathway systemically in lupus models have seen some beneficial effects in attenuating both systemic and renal disease. However, its effects on the neuropsychiatric manifestations have yet to be assessed, even though therapeutic administration of IFNα has been associated with induction of depression, a common manifestation in NPSLE patients. Our aim was to investigate whether disrupting the type I IFN pathway systemically would attenuate the development of murine neuropsychiatric lupus.

Methods: Female MRL/*lpr* mice were administered an anti-IFNAR antibody (MAR1-5A3; MedImmune, Gaithersburg, MD) or an IgG isotype control antibody (1A7, IgG1) intraperitoneally 3 times weekly for 12 weeks starting at 4-5 weeks of age. Depression-like behavior was assessed at 8-9 weeks of age using the Porsolt swim test. Cognitive dysfunction was assessed at the end of treatment at 16-17 weeks of age, using the object placement (OP) and object recognition (OR) tests, which evaluates spatial and recognition memory, respectively. Brain tissue was analyzed by histology and by immunofluorescent staining for $B220^+$ and $CD3^+$ cells, as well as albumin and IgG deposition in the brain parenchyma to determine brain barrier integrity.

Results: No significant differences were seen between the anti-IFNAR and control treated mice when assessing for depression-like behavior (p=0.32) or cognitive dysfunction (OP: $x^2(1) = 0.54$, $p = 0.46$; OR: $x^2(1) = 0.002$, $p = 0.96$). Anti-IFNAR treatment also did not significantly improve cellular infiltration, as evident by hematoxylin and eosin staining and infiltrate composition comparing $B220^+$ and $CD3^+$ cell counts. Staining for albumin and IgG leakage in the brain parenchyma also showed similar brain barrier integrity between the groups. RNA expression level of CXCL10, a known interferon-stimulated gene, were significantly different in the spleen ($p = 0.023$) and the choroid plexus ($p = 0.0088$), suggesting that the pathway was inhibited in the choroid plexus with systemic delivery of the antibody.

Conclusion: Surprisingly, our results showed no improvement in neuropsychiatric disease in the MRL/*lpr* mouse model and suggest that the role of IFNAR signaling in the pathogenesis of neuropsychiatric lupus continues to need to be carefully assessed.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Both plasmacytoid dendritic cells (pDCs) and switched memory B cells (SMBCs) are considered to be key effector cells in systemic lupus erythematosus. It seems likely that within these classical cell lineages, additional diversity of function will exist that will contribute to disease pathogenesis. To explore this question, we performed single-cell RNA sequencing in pDCs and SMBCs from SLE patients and controls to assess gene expression patterns and cellular sub-groupings within these lineages.

Methods: pDCs and SMBCs from SLE patients (n=10) and Healthy controls (n=5) were purified by magnetic separation. For deep sequencing, we used the Fluidigm C1 HT system with 800 capture site chips to capture single cells. Single cell capture was verified by direct visualization using the Array Scan system, allowing us to remove empty wells and wells with multiple cells. After quality control and adaptor trimming, the data was analyzed using SeqGeq software. pDCs and SMBCs were clustered using UMAP and pseudo-time analysis was performed using the Monocle program. Type I IFN activity in SLE plasma was measured using reporter cell assay.

Results: A total of 2774 pDCs and 2578 SMBCs from SLE and healthy controls passed the quality control and were used for further analysis. In pDCs, we observed unique clusters for patients with high interferon, low interferon, and controls, indicating that the IFN response is a major determinant of overall gene expression patterns in SLE patient pDCs. IFN signature in pDCs correlated with circulating type I IFN activity in the SLE patients measured at the same time. Other genes upregulated in pDCs included the type I interferon regulator AXL and MACC1. The SMBCs were heterogeneous in patients and controls, and in contrast to the pDCs, the overall clustering pattern was independent of the IFN score. SMBC clusters were predominantly defined by genes indicating cellular activation or proliferation such as HLA-DRs and CREB1, or genes associated with nucleic acid processing such as DNASE1 and SNORD3B-1.

Conclusion: We find distinct clusters of cells defined transcriptionally within the pDC and SMBC lineages, and the transcripts which define these subgroups differ between cell lineages. Type I IFN induced transcripts are important to pDC diversity, while in SMBCs transcripts related to cellular activation and nucleic acid processing are critical markers of transcriptional heterogeneity.

Neutrophils Are an Important Source of Microparticles in Lupus and Asymptomatic ANA$^+$ Individuals

Carolina Muñoz-Grajales,[1] Dennisse Bonilla,[2] Earl D. Silverman,[3] Sindhu Johnson,[4] Arthur Bookman,[5] Zahi Touma,[2] Zareen Ahmad,[6] Linda Hiraki,[7] and Joan Wither[8], [1]University of Toronto, Toronto, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Translational Medicine, Research Institute, The Hospital for Sick Children, Toronto, Canada, [4]Toronto Scleroderma Program, Department of Medicine, Toronto Western and Mount Sinai Hospitals, University of Toronto, Toronto, Canada, Toronto, Canada, [5]University Health Network - Toronto Western Hospital, Toronto, Canada, [6]Mount Sinai Hospital, Toronto, Canada, [7]The Hospital for Sick Children, Toronto, Canada, [8]University Health Network, Krembil Research Institute, Toronto, ON, Canada

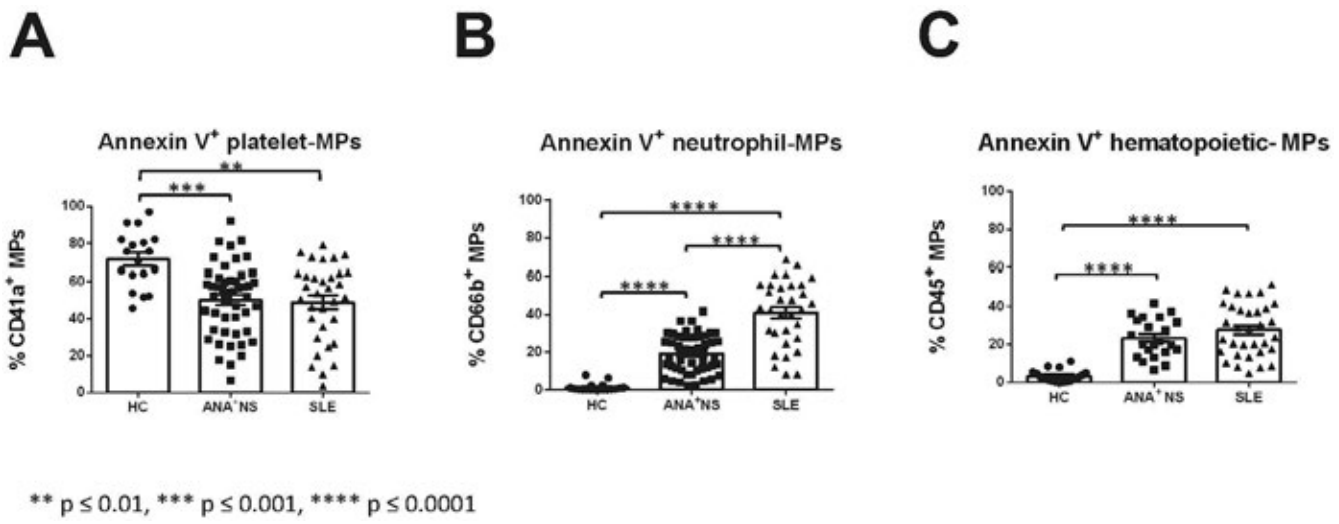
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Apoptotic microparticles (MPs) in the circulation of systemic lupus erythematosus (SLE) patients are enriched for nucleic acids and complexed with IgG (MP-IC), as compared with those from healthy controls (HC). These MPs have been shown to activate monocytes, suggesting that they are an important stimulus for production of pro-inflammatory factors in SLE. We previously presented data showing that nucleic acid-enriched IgG-complexed MPs are also increased in asymptomatic anti-nuclear antibody (ANA) positive individuals (ANA^+NS), in the absence of elevated levels of pro-inflammatory factors. Although platelets represent the main source of MPs in healthy individuals, endothelial- and neutrophil-derived MPs are also found in SLE. In this study, we examined the origin of MPs in ANA^+NS.

Methods: Flow cytometry was used to examine the number, origin, nucleic acid content, and IgG binding of peripheral blood Annexin V^+MPs in ANA^-HC (n=18), ANA^+NS (≥1:160 by IF, n=48), and SLE patients (n=33). MP nucleic acid content was determined by staining with Syto13 and the MP cell source by staining with antibodies against CD41a (Platelets), CD105 (endothelium), CD45 (hematopoietic cells), CD14 (monocytes), CD66b (neutrophils), CD19 (B cells), CD3 (T cells), and CD235a (erythrocytes).

Results: Consistent with published work and with our previous data, SLE patients had increased levels of MPs and MP-ICs that contained higher levels of nucleic acids, as compared to ANA^- HC. A subset of ANA^+NS had similar elevations in the amount of IgG coating their MPs and nucleic acid content to those seen in SLE. As expected, the majority of the MPs obtained from HC exhibited platelet markers (**Figure A**). Notably, in ANA^+NS individuals and SLE patients the proportion of Annexin V^+ platelet-MPs was reduced compared to HC (**Figure A**) and there were increased proportions of Annexin V^+ $CD66b^+$MPs (apoptotic neutrophils-MPs) and $CD45^+$MPs (hematopoietic) **(Figure B and**



C). However, the proportion of neutrophil-MPs was significantly higher in SLE than in ANA$^+$NS (**Figure B)**. There were non-statistically significant trends to higher CD14$^+$MPs (monocytes-MPs) and endothelial MPs in ANA$^+$ NS. There were no CD19, CD3, or CD235a positive MPs detected.

Conclusion: Apoptotic and/or activated neutrophils and hematopoietic cells are a significant source of auto-antigenic MPs in both ANA$^+$NS individuals and SLE patients. However, neutrophil apoptosis/activation appears to be more prominent in SLE patients, raising the possibility that it contributes to the pro-inflammatory process that discriminates symptomatic and asymptomatic ANA$^+$individuals.

Lysosome Defects in SLE Promote the Accumulation of Nuclear Antigens on the Surface of Hematopoietic Cells

Sun Ah Kang,[1] Jennifer Rogers,[2] Saira Sheikh,[3] Megan Clowse,[2] Lisa Criscione-Schreiber,[2] and Barb Vilen[4], [1]University of NOrth Carolina at Chapel Hlil, Chapel Hill, NC, [2]Duke University, Durham, [3]University of North Carolina, Chapel Hill, NC, [4]University of North Carolina CHapel Hill, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Impaired clearance of cell debris allows nuclear self-antigens such as DNA to accumulate, bind autoreactive IgG and form immune complexes (IgG-ICs) in SLE. We recently reported that multiple models of lupus-prone mice harbor defects in lysosome acidification. Reduced acidification diminishes the degradation of IgG-ICs and induces their recycling back to the plasma membrane. This perpetuates FcγR signal transduction which in turn further impairs lysosome function, and promotes BAFF secretion. The sustained presence of IgG-ICs in the endocytic pathway causes phagolysosome membrane permeability allowing IgG-ICs to enter the cytosol, activating Type I IFN and inducing pyroptosis. In this study, we translate our murine findings and assess whether lysosomal defects and surface accumulation of DNA-containing ICs are evident in active vs inactive SLE patients.

Methods: We enrolled ANA positive active or inactive SLE patients (SLEDAI ≥ 6, or ≤ 5 meeting 2012 SLICC criteria) and seropositive (RF/CCP) active rheumatoid arthritis (RA) patients (2010 ACR criteria and DAS28 >5.1). Healthy controls (HCs) were enrolled from a platelet donation center.

The levels of surface-bound antigen (DNA or CCP) from circulating hematopoietic cells (monocytes, dendritic cells, T and B cells), in SLE, RA and HC were analyzed by flow cytometry. Lysosomal pH was measured using ratiometric flow cytometry from whole blood cells treated with exogenous IgG-ICs. Lysosomal pH changes were normalized to cells treated with Concanamycin A, an inhibitor of lysosome acidification.

Results: We measured relative lysosome pH in blood monocytes and B cells from 18 active and 16 inactive SLE patients with 16 HCs. Among active SLE patients, 67% of monocytes and 50% of B cells showed defective pH changes

Table 1. Lysosomal pH Changes in SLE patients.

	Time points			Healthy Mean +SD	# of patients	Total # of Patients analyzed	%
CD14+	T30			0.84			
		Active patients	above Healthy Mean+SD		16	18	88.89
			below Healthy Mean+SD		2	18	11.11

			below Healthy Mean+SD		14	16	87.50

Table 2. Crosssectional study of the level of surface bound DNA on hematopoietic cells from lupus patients.

		SLE				RA	
		Active SLEDAI ≥ 6	Inactive SLEDAI ≤ 5	HC	*p* compared to HC	RA patients	HC
CD19+	N	57	52	109		8	5
	Surface DNA (MFI)	22.94	11.53	4.99	0.000000161	1.47	1.08
	Surface DNA (Fold over HC)	4.60	2.31	1.00		1.36	1.00
CD3+		51.00	47.00	98.00		8.00	5.00
	Surface DNA (MFI)	4.57	2.70	3.00	0.0490	1.10	1.00
	Surface DNA (Fold over HC)	1.52	0.90	1.00		1.10	1.00
CD14+		57.00	51.00	109.00		8.00	5.00
	Surface DNA (MFI)	13.49	12.99	9.64	0.0217	6.31	3.45
	Surface DNA (Fold over HC)	1.40	1.35	1.00		1.83	1.00
CD14-CD19-CD11chi		29.00	19.00	46.00		8.00	5.00
	Surface DNA (MFI)	24.99	17.17	12.65	0.0273	12.97	17.95
	Surface DNA (Fold over HC)	1.98	1.36	1.00		0.72	1.00

at 60 min (relative pH greater than mean+SD of HC). Of inactive SLE patients, only 6% of monocytes and 13% of B cells showed defective lysosomal acidification (Table 1).

To define whether altered lysosome function promoted accumulation of IgG-ICs, we measured surface DNA levels in 57 active and 51 inactive patients and 109 HCs. We found a significant increase in surface DNA on B cells (4.6 fold) and dendritic cells (2.0 fold), but not on T cells (1.5 fold) or monocytes (1.4 fold) in active SLE vs. HC. Levels of surface DNA on B cells were significantly higher in active versus inactive patients (Table 2). Conversely, 14 active RA patients did not show elevated surface DNA or CCP on any cell type.

Conclusion: We show that monocytes and B cells from active, but not inactive, SLE patients exhibit significantly diminished lysosome function, and that B cells and DCs accumulate surface DNA. The lower level of antigen on monocytes may reflect migration of activated monocytes from blood, because in mice, we also observed that blood monocytes do not exhibit high levels of surface nuclear antigens unlike splenic macrophages from the same animal. The mechanisms underlying accumulation of nuclear antigen on T cells remain unclear. Last, elevated levels of nuclear antigens were not present on active RA controls, suggesting that the defect is driven by mechanisms unique to lupus.

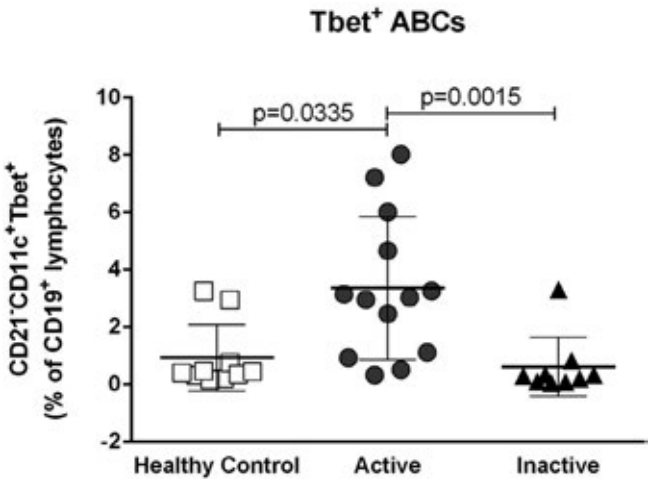
Dynamic Changes During SLE Flare Implicate Age-Associated B Cells and Altered T Follicular and Peripheral Helper Cell Responses in Disease Activity

Kieran Manion,[1] Zahi Touma,[2] Dennisse Bonilla,[2] Dafna Gladman,[3] Murray Urowitz,[2] and Joan Wither[4], [1]Krembil Research Institute, Toronto, ON, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]Krembil Research Institute, U of Toronto, Toronto, ON, Canada, [4]University Health Network, Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic autoimmune disorder in which periods of relative disease inactivity are punctuated by flares that present with increased inflammation and tissue damage. The current literature suggests that this enhanced disease activity is linked to immune cell subsets involved in ANA production, including T follicular (T_{fh}) and peripheral helper (T_{ph}) cells, plasma cells, and age-associated B cells (ABCs); however, it is largely unknown how these and other immune subsets differ between flare and inactive disease, particularly in individual patients followed longitudinally.

Methods: 12 healthy controls (HC), 23 SLE patients with flare (Active) and 9 inactive SLE patients (Inactive) were recruited. All patients had a diagnosis of SLE based on the 1997 ACR criteria. Active patients had to be within 1 month of flare onset (defined as a clinical SLEDAI-2K≥0 requiring a change in therapy) and agree to follow-up assessments at 6 and 12 months. Inactive patients had to be inactive for ≥1 year (clinical SLEDAI-2K=0) and be on ≤10mg prednisone at recruitment. Peripheral blood mononuclear cells (PBMCs) were isolated over a Ficoll gradient within 3 hrs of collection, stained with fluorescent antibodies for immune cell subsets, and examined by flow cytometry. Statisti-

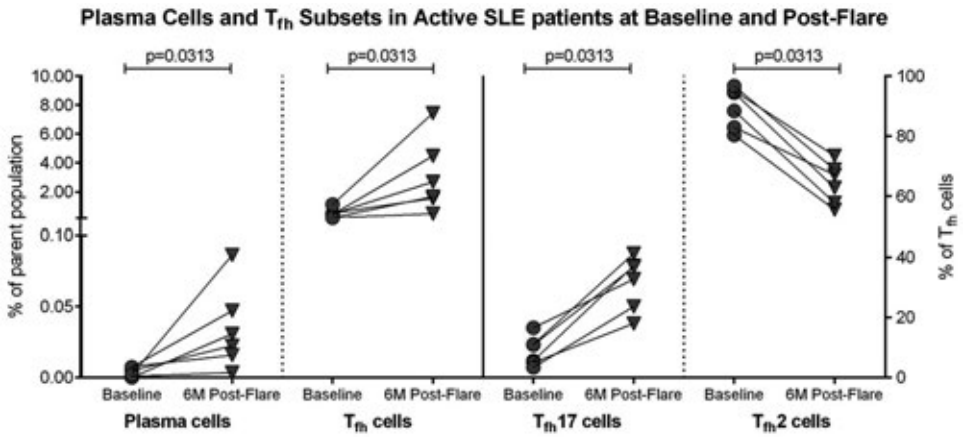


Tbet+ age-associated B cells (ABCs; CD19+CD21-CD11c+Tbet+) are significantly elevated in SLE patients experiencing a flare as compared to healthy controls or inactive SLE patients.

cal significance was determined using Kruskal-Wallis tests to compare HC, active and inactive SLE groups, Wilcoxon matched-pairs signed rank tests to compare baseline and follow-up visits, and Spearman tests for correlation.

Results: While active and inactive patients had increased proportions of T_{ph} cells ($CD4^+PD1^{hi}CXCR5^-$) compared to HC, only a small subset of patients in either group had elevated levels of plasma cells ($CD19^{lo}CD27^{hi}CD38^+CD138^+$), plasmablasts ($CD19^{lo}CD27^{hi}CD38^+CD138^-$) and activated memory T_{fh} cells ($CD4^+PD1^{hi}CXCR5^{hi}$), with no differences between the two groups. In contrast, active patients had significantly more ABCs ($CD19^+CD21^-CD11c^+Tbet^+$) than inactive patients or HC and this correlated significantly with T_{ph} cells (r=0.6909, p=0.0226). Interestingly, at their 6-month follow-up visit, active patients showed significant increases in T_{fh} and plasma cells, and trends to increased $CD86^+$ B and T_{ph} cells, despite improvements in their SLEDAI-2K. These findings suggest that activated T and B cells may be depleted from the blood during flares, possibly as a result of tissue recruitment. Notably, increases in activated memory T_{fh} cells post-flare were predominantly due to increases in the $T_{fh}17$ subset, while the $T_{fh}2$ subset was significantly decreased.

Conclusion: Our results show that while T_{ph} cells and ABCs are elevated in active SLE, plasma cells and activated T_{fh} cells may be depleted from the peripheral blood during acute flare and return to the blood post-flare, reflecting



Left Y-axis: Plasma cells (CD19loCD27hiCD38+CD138+) and T follicular helper cells (Tfh; CD4+PD1hiCXCR5hi) are significantly elevated in the blood of SLE patients at 6-months post-flare compared with baseline. Right Y-axis: Tfh17 cells (CD4+PD1hiCXCR5hiCXCR3-CCR6+) are significantly elevated in SLE patients 6-months post-flare compared with baseline, while Tfh2 cells (CD4+PD1hiCXCR5hiCXCR3-CCR6-) show a significant decrease.

recruitment to and subsequent release from tissues. These findings highlight the importance of longitudinal studies in individuals with active SLE.

Interferon Lambda Promotes Age-Associated B Cells

Jennifer Barnas,[1] Nida Meednu,[1] Andrew McDavid,[1] Jennifer Albrecht,[1] Christopher Richardson,[1] R. John Looney,[2] and Jennifer Anolik[1], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester Medical Center, Rochester

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Age-associated B cells (ABC), defined as CD11c+ T-bet+ or CD11c+CD21-, represent a subset of B lymphocytes that are increased in systemic lupus erythematosus (SLE) patients. ABC are posited to differentiate into autoreactive plasma cells in autoimmune disease. We and others reported that this population is found within the naïve and memory B cell compartments, but are most expanded in the IgD- CD27- CD24- CD21- (DN2) B cell subset. Using flow cytometry, we have previously shown that DN2, T-bet+, and CD11c+CD21- peripheral blood B cells correlate with interferon lambda (IFN-λ) serum levels, and numbers of ABC increase with SLE disease activity. An interferon stimulated gene (ISG) expression profile is found in many cell types in SLE, including B cells, and interferon is thought to be important to lupus pathogenesis. IFN-λ is known to generate an IFN signature similar to that of IFN alpha in epithelial cells, but few studies address IFN-λ effects on B cells. We hypothesized IFN-λ contributes to the gene expression profile seen in SLE and impacts B lymphocytes.

Methods: Human peripheral blood from healthy donors (n=6) or SLE (n=8) patients meeting ACR criteria were stained for CD11c, CD19, CD14, CD27 and IgD then flow sorted into CD14+ (monocytes), CD27- IgD- CD19+ (DN B cells), or CD27-IgD+ CD19+ (naïve B cells) populations and their RNA isolated for RNA-Seq transcriptomic analysis. B cells were cultured with IL-21, anti-Ig, R848 and BAFF to generate ABC-like cells *in vitro* with no IFN, interferon gamma (IFN-γ), IFN-λ1 or both for RNA isolation (4 hours) or flow cytometry (7 days). TBX21 (T-bet) and IFIT1 (an ISG) expression was measured by qRT-PCR. Cells were stained for CD3, CD11c, CD19, CD21, CD27, CD38, IgD and T-bet.

Results: Of the CD19+ cells used for transcriptional analysis, 5.2±3.0% of healthy donors and 9.6±7.9% of SLE B cells were CD11c+ as detected during the flow cytometry sort. Using RNA-Seq transcriptional analysis, IFN-λ receptor (IFNLR1) was expressed in B cells but was absent from monocytes. Expression in naïve B cells was 40 counts/million reads for healthy and 53 counts/million in SLE. The DN compartment had higher IFNLR1 expression with 66 counts/million in healthy and 131 counts/million in SLE. IFN-λ1 induced expression of IFIT1 *in vitro* suggesting that the IFN-λ receptor is indeed functional in B cells. When B cells were cultured in the presence of IFN-γ, TBX21 expression was strongly induced. IFN- λ1 could not be substituted for IFN-γ for the generation of CD11c+ CD21- cells as measured by flow cytometry or TBX21 expression at the RNA level. However, the combination of IFN-γ and IFN-λ1 resulted in an increased percentage of CD11c+ CD21- B cells at 7 days.

Conclusion: ABC are most represented in the DN2 B cell compartment. The DN2 B cells have the highest level of expression of IFNLR1. IFNLR1 is functional on B cells as ISG expression is increased when stimulated with IFN-λ1.

Studies are ongoing to determine if IFN-λ1 has differential effects on different B cell compartments, alters B cell differentiation pathways including generation of autoreactive plasma cells (PC), or enhances ABC and PC survival, thus potentiating SLE disease pathogenesis.

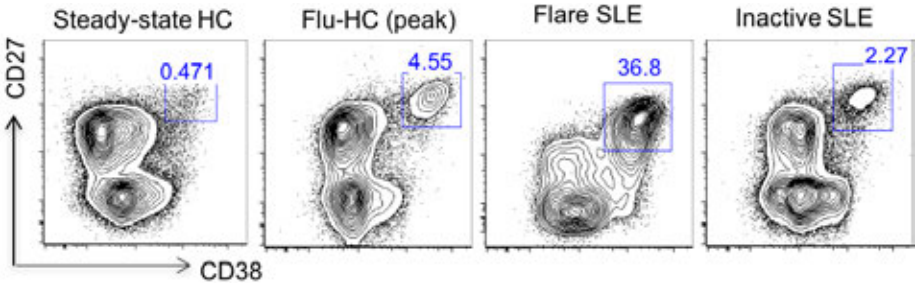
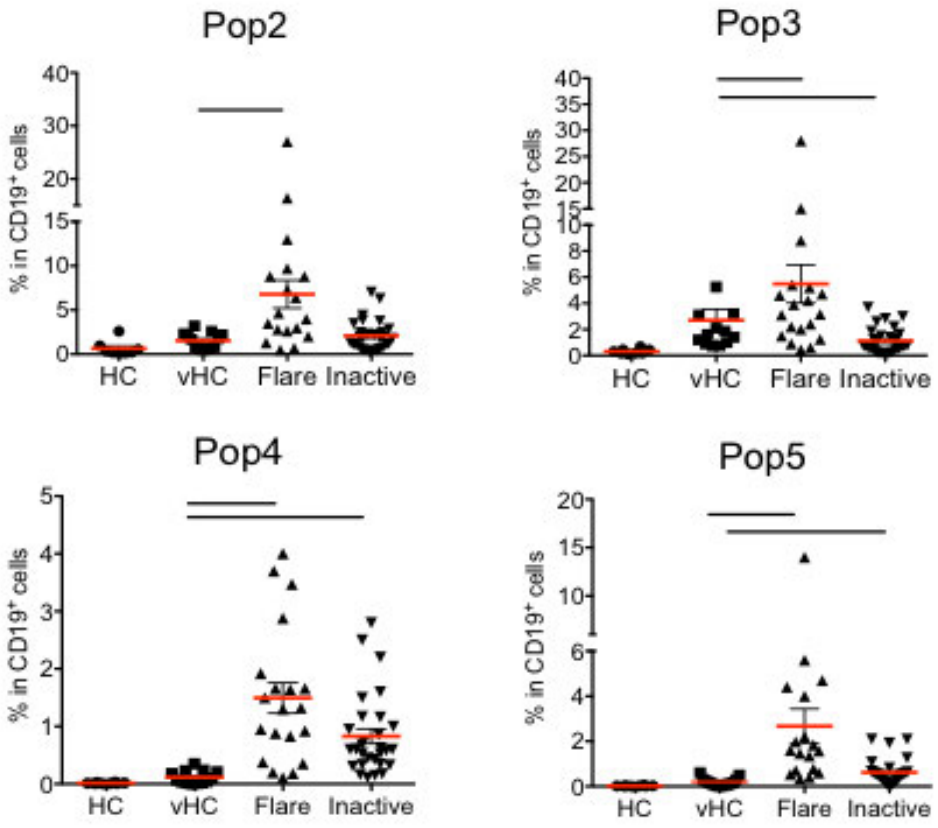
Abstract Number: 1027

Characterization of Antibody Secreting Cells in Patients with Active Systemic Lupus Erythematosus

Weirong Chen,[1] Sohee Hong,[2] Christopher Tipton,[1] Jennifer Hom,[1] Fabliha Anam,[3] Eun-Hyung Lee,[1] and Iñaki Sanz[1], [1]Emory University, Atlanta, GA, [2]Emory Univeristy, Atlanta, [3]Emory University, Atlanta



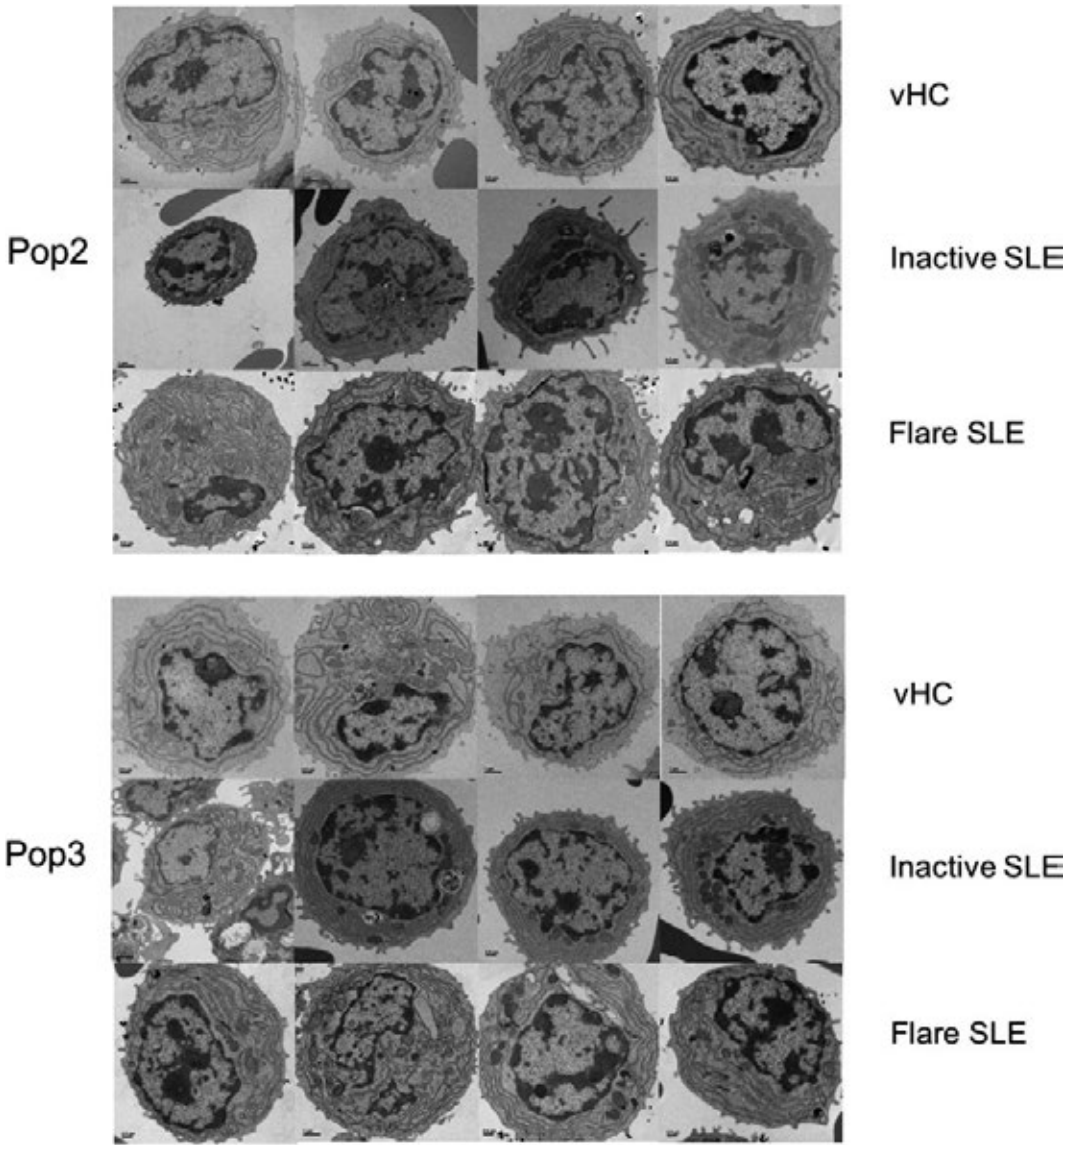
Rise of the circulating antibody-secreting cells in SLE patients during flare.



All ASC subsets are markedly increased in flaring SLE patients.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a severe systemic autoimmune disease in which multiple autoantibodies against nuclear, cytoplasmic and cell surface auto-antigens are produced by antibody secreting cells (ASCs). In the non-disease state, the frequency of circulating ASCs in total B cells is extremely low, and increases in a tightly regulated manner following immunization or infection. However, during active SLE, ASCs are dysregulated and exhibit a dramatic increase in the circulation. Indeed, the frequency of ASCs in the peripheral blood is correlated with disease activity, as measured by the SLEDAI scoring system. Despite their clinical significance, the subsets, morphology, and molecular phenotypes of circulating ASCs in SLE remain largely unknown.



Ultra structural morphology of ASC subsets from SLE patients and healthy subjects.

Methods: Healthy subjects received the vaccination against influenza virus were recruited and peripheral blood from healthy controls was obtained at the steady state or at the peak of antibody secreting response after vaccination (day

6-7). Patients with SLE fulfilled four or more criteria of the modified American College of Rheumatology classification were recruited and evaluated by expert rheumatologists for disease status.

Results: In this study, peripheral ASC were divided into 4 subsets based on the surface expression of the CD19 and CD138: CD19+CD138- (pop2), CD19+CD138+ (pop3), CD19-CD138- (pop4), and CD19-CD138+ (pop5). CD19+ subsets, and to a larger extent, CD19- subsets, were markedly increased in active SLE patients compared to healthy controls post flu-vaccination. Besides, electron microscopy showed ultrastructural changes in the circulating ASCs subsets from active SLE patients relative to those from vaccinated healthy controls, including a condensed nucleus, enhanced endoplasmic reticulum volume, increased numbers of mitochondria, and presence of autophagosomes, features resembling those of bone marrow plasma cells. Interestingly, phenotypic characterization of circulating ASCs suggested that those from active SLE patients had significantly elevated expression of CXCR4, receptors for homing and survival in the bone marrow, compared to healthy controls post vaccination. Furthermore, next generation sequencing was used to analyze the clonality and connectivity between circulating ASC subsets from active SLE patients. In most flare SLE patients, we observed highly polyclonal repertoire and clonal relatedness in all ASC subsets.

Conclusion: Together, these data show that, during flare SLE, ASCs dramatically increase and undergo morphological changes and CXCR4 upregulation, indicating their potential of bone marrow homing and becoming long-lived plasma cells.

Lupus Auto-antibodies Act as Positive Allosteric Modulators at GluN2A-containing NMDA Receptors to Induce Excitotoxicity and Spatial Memory Deficits

Kelvin Chan,[1] Jacquelyn Nestor,[2] Tomas Huerta,[2] Czeslawa Kowal,[2] Patricio Huerta,[2] Bruce Volpe,[2] Betty Diamond,[3] and Lonnie Wollmuth[1], [1]Stony Brook University School of Medicine, Stony Brook, NY, [2]Feinstein Institutes for Medical Research, Manhasset, NY, [3]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Systemic lupus erythematosus (SLE) experience various peripheral and central nervous system manifestations including spatial memory impairment. A subset of auto-antibodies (DNRAbs) cross-react with the GluN2A and GluN2B subunits of the NMDA receptor (NMDAR). The underlying subunit specificity for DNRAbs to mediate SLE neuropathological effects are currently unknown. Here, we characterize the specific subunit effects of DNRAbs on NMDA receptors.

Methods: We employ whole-cell and single-channel patch clamp electrophysiology to study the mechanism of potentiating NMDAR currents by DNRAbs. We employ primary neuronal cell cultures, pharmacology, and ICC to test for subunit-specific NMDAR antagonists to block DNRAb-mediated cell death. We employ transgenic animals to selectively knock out NMDAR subunits for immunohistochemistry, microglia assessment, *in vivo* place field recordings, and spatial memory behavior testing.

Results: We find that these DNRAbs act as positive allosteric modulators on NMDARs with GluN2A-containing NMDARs, even those containing a single GluN2A subunit, exhibiting a much greater sensitivity to DNRAbs than those with exclusively GluN2B. Accordingly, GluN2A-specific antagonists provide greater protection from DNRAb-mediated neuronal cell death than GluN2B antagonists. Using transgenic mice to perturb expression of either GluN2A or GluN2B in vivo, we find that DNRAb-mediated disruption of spatial memory characterized by early neuronal cell death and subsequent microglia-dependent pathologies requires GluN2A-containing NMDARs. Finally, spatial memory defects resulting from aberrant hippocampal place fields affected by DNRAbs require GluN2A-containing NMDARs as well.

Conclusion: Our results indicate that GluN2A is the primary subunit that drives DNRAb-mediated NMDAR potentiation, and SLE cognitive/spatial memory defects. Thus, GluN2A-specific antagonists or negative allosteric modulators are strong candidates to treat SLE patients with nervous system dysfunction.

Epstein-Barr Virus Interleukin 10 in SLE Pathogenesis

Neelakshi R. Jog,[1] Wade DeJager,[1] Joel Guthridge,[2] and Judith James[2], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a systemic autoimmune disease characterized by periods of elevated and suppressed disease activity. Epstein Barr Virus (EBV) has been associated with SLE. EBV maintains latency in infected B cells and shows intermittent reactivation. Response to EBV can lead to loss of tolerance to lupus autoantigen Ro/SS-A by molecular mimicry and epitope spreading. Elevated levels of EBV Viral capsid antigen (VCA) and Early Antigen (EA) IgG, which are indirect measures of viral reactivation, increase the probability of transitioning to SLE in unaffected family members, which underscores the importance of EBV reactivation in SLE autoimmune responses. Viral IL10 (vIL10), an EBV lytic protein, is a homolog of interleukin 10, and we showed increased plasma vIL-10 in SLE patients compared to controls. In this study we aimed to understand the importance of vIL-10 in SLE clinical disease progression.

Methods: Plasma from 28 SLE patients with varying disease activity and 19 matched healthy unrelated controls were concentrated and vIL10 detected by western blotting and normalized to pooled control sera. Plasma cytokines were measured by xMAP assays. EBV EA IgG were measured by ELISA. Transcriptional co-expression signature module scores were calculated from Illumina Beadchip Microarray gene expression data for 29 immune pathway related modules.

Results: The levels of vIL-10 correlated with EA IgG ($r=0.4468$, $p=0.0044$). vIL-10 and EA IgG correlated with IFN gene expression module score ($r=0.604$, $p=0.006$, $r=0.588$, $p=0.003$, respectively). vIL10 levels additionally correlated with IFNβ, IFNg, and B cell modules. vIL-10 levels were independent of steroid, hydroxychloroquine, or immunosuppressant use or SLE disease activity. vIL-10 levels were significantly higher in patients that were Ro positive compared to Ro negative patients ($p=0.0365$). We did not observe any differences in vIL-10 levels between patients based

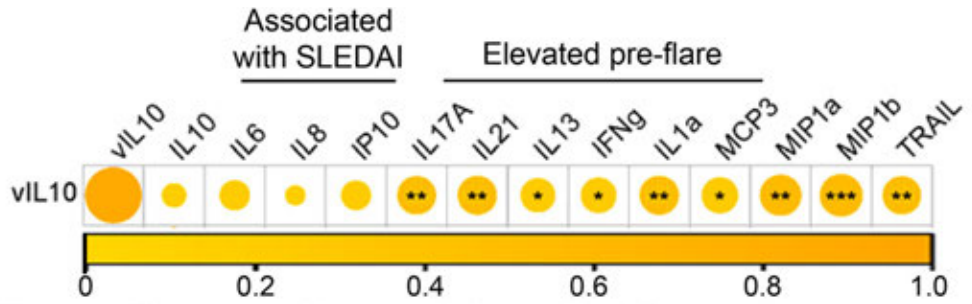

Figure 1. Plasma cytokine correlations with vIL10. Plasma cytokines were measured by xMAP assays. vIL10 measured as in Fig 1. Spearman rho were calculated and correlogram was generated in R. Color represents direction and size represents strength of correlation. *p<0.05, **p<0.01, *** p<0.001. IL-6, IL-8 and IP10 correlate with disease activity scores, while IL-17, IL-21, IL-13, IFNγ, IL1α, MCP3 are elevated pre-flare.

on dsDNA or RNP antibody positivity, nor based upon clinical ACR classification criteria. There was significant positive correlation between vIL10 levels and plasma cytokines, including: MIP1 α (r=0.5264, p=0.0020), MIP1β (r=0.5620, p=0.0008), TRAIL (r=0.4501, p=0.0097), and IL-17A (r=0.4543, p= 0.009), IL-21 (r=0.4659, p=0.0072), IFNg (r=0.3834, p=0.0303), IL-1 α (r=0.4710, p=0.0065), MCP3 (r=0.3994, p=0.0235), and IL-13 (r=0.3604, p=0.0427), which are cytokines that are elevated in SLE patient plasma prior to a flare (Figure 1). The levels of vIL-10 did not correlate with IL-6, IL-8, or IP-10 that are associated with disease activity.

Conclusion: The correlation of vIL-10 levels with B cell and anti-viral and gene expression modules supports increased EBV reactivation. The correlation of vIL-10 with cytokines elevated pre-flare suggests that increased reactivation followed by increased vIL-10 preceding a flare may initiate an inflammatory cascade that culminates in a flare. An increased vIL-10 level in Ro+ patients suggests that distinct pathways may regulate autoimmune response in patients based on autoantibody specificities.

es in methylation have been associated with auto-antibody and lupus nephritis status. A prior study showed that closer residential proximity to highways was associated with hypomethylation of 3 CpG sites in the *UBE2U* gene in SLE patients.

Methods: In this study, we examine the association of particular matter 2.5 ($PM_{2.5}$) levels on the day of blood draw with DNA methylation in a cohort of SLE patients from the California Lupus Epidemiology Study (CLUES). All subjects satisfy the ACR criteria for SLE. $PM_{2.5}$ levels were estimated by Sonoma Technology from air pollution concentrations based on geocoded residential locations. DNA methylation was measured using the Illumina HumanMethylationEPIC BeadChip for 271 unique subjects of White, Hispanic, African American, and Asian ethnicities. Noob background subtraction with dye-bias correction as well as quantile normalization were conducted in *minfi*. CpG sites with high detection p-values, cross-reactive probes, and CpG sites potentially measuring SNPs were removed for a total of 748,793 CpG sites for analysis. We first conducted an analysis for differentially methylated position (DMPs) using *limma* linear models with empirical Bayes variance shrinkage, adjusting for age, sex, current smoking status, current medication use, estimated cell-type proportions from *ReFACTor*, and genetic ancestry. We then conducted an analysis of differentially methylated regions (DMRs) using *bumphunter*. Given the previous findings in the *UBE2U* gene, we also conducted a candidate DMP analysis for the 21 CpG sites on the EPIC chip which map to *UBE2U.*

Results: Concentrations of $PM_{2.5}$ fell between 1.8 and 25.9 μg/m3 (SD = 3.3) with all subjects' exposure classified as either "Good" or "Moderate" according to the Air Quality Index (AQI). Preliminary results showed 17 DMPs (after FDR correction) associated with $PM_{2.5}$ exposure, 16 of which were hypomethylated. These CpG sites mapped to genes including *TTC17, SGCB, CCDC26, AFF3, KCP, VGLL4, CNTN2, NPHP4, and GAPVD1.* One region located 900bp upstream of *KLRC3* was significantly differentially methylated after FDR correction. No CpG sites in *UBE2U* reached statistical significance.

Conclusion: These results suggest for the first time that there is differential methylation with increased $PM_{2.5}$ exposure in SLE patients.

Expanded Circulating Peripheral Helper T Cells Are Associated with B Cell Differentiation in Systemic Lupus Erythematosus

Ayako Makiyama,[1] Asako Chiba,[2] Daisuke Noto,[1] Goh Murayama,[3] Tomohiro Mizuno,[4] Taiga Kuga,[5] Ken Yamaji,[5] Naoto Tamura,[5] and Sachiko Miyake[2], [1]Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan, [3]Department of Internal Medicine and Rhumatology, Juntendo University School of Medicine, Tokyo, Japan, [4]Department of Immunlogy, Juntendo University School of Medicine, Tokyo, Japan, [5]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoreactive T-B cell interactions in lymphoid tissue have been thought to play a crucial role in the autoantibody production in systemic lupus erythematosus (SLE). These $CD4^+$T cells are known as follicular helper T (T_{FH}) cells expressing CXCR5, a chemokine receptor promoting cell migration to B cell follicles. Recently, a new population of 'peripheral helper' T (T_{PH}) cells that help B cell responses has been discovered in synovium of patients with rheumatoid arthritis. Like T_{FH} cells, T_{PH} cells express ICOS and PD-1, but these cells lack CXCR5. Previously we reported that circulating T_{PH} cells are increased in SLE and their activated status was associated with the disease activity. Here we assessed whether T_{PH} cells contribute to autoantibody production by B cells in SLE.

Methods: Peripheral blood mononuclear cells collected from SLE patients and healthy individuals were analyzed for T and B cell subsets by flow cytometry. T_{PH} cells were identified as $CD3^+CD4^+CD45RA^-CXCR5^-$ cells with a high expression of PD-1. The production of IL-21 by T_{PH} cells stimulated with phorbol 12-myristate 13-acetate (PMA) and ionomycin was assessed by intracellular cytokine staining and flow cytometry. To assess functional roles of T_{PH} cells in B cell maturation and antibody production, T cell populations (T_{PH}, T_{FH}, and $CXCR5^-PD\text{-}1^-$memory $CD4^+$T cells)and switched memory B ($CD19^+CD27^+IgD^-$) cells were sorted from PBMC using magnetic bead selection and a FACS Aria sorter. Sorted T cell populations and autologous B cells were co-cultured and stimulated with lipopolysaccharide (LPS) and staphylococcus enterotoxin B (SEB) for 7 days. Plasmablast differentiation was assessed by flow cytometry. Antibody levels in culture supernatants were measured by ELISA.

Results: Activated T_{PH} cells were positively correlated with SLEDAI and anti-DNA antibody titers, and were negatively correlated with serum complement levels and lymphocyte counts. The frequency of activated T_{PH} cells was correlated with that of plasmablasts and activated switched memory B cells. Lupus T_{PH} cells had the capacity to produce IL-21, a pivotal cytokine for B cell and plasma cell differentiation, as much as T_{FH} cells. T_{PH} cells from lupus patients induced B cell differentiation into plasmablasts and promoted antibody production in T-B cell co-cultures.

Conclusion: Our data demonstrate that the increased frequency and activated status of T_{PH} cells are associated with the disease activity as well as enhanced B cell responses in SLE, and T_{PH} cells provide B cell help. $CD4^+ICOS^+PD\text{-}1^+$cells and plasma cells were reported to be present in the nephritic kidneys and associated with active disease in SLE. These data indicate the contribution of T_{PH} cells to autoantibody production in aberrant lymphoid organs and the involvement of extra-follicular T-B cell interactions in the pathogenesis of SLE.

Lipocalin-2 Exacerbates Lupus Nephritis by Promoting Th1 Cell Differentiation

Weiwei Chen,[1] and **Lingyun Sun**[1], [1]Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Kidney involvement is a major concern in systemic lupus erythematosus (SLE). Lipocalin-2 (LCN2) has been indicated as a potential marker of the presence and severity of lupus nephritis (LN), but the role of increased LCN2 in LN and the underlying molecular mechanisms remain unclear.

Methods: LCN2 expression in naïve $CD4^+$ T cells of SLE patients was evaluated by real-time PCR (RT-PCR). LCN2 expression in renal biopsy samples from patients with lupus nephritis was detected by immunohistochemical staining. To investigate the production of LCN2 in lupus mice during progression of LN, LCN2 expression in PBMCs and naïve $CD4^+$ T cells were measured by RT-PCR, mRNA and protein levels of LCN2 in kidneys were measured by qPCR and western blot respectively at different stages of disease. To investigate whether increased LCN2 levels contribute to the development of LN, the MRL/*lpr* mice received intraperitoneal injection of anti-LCN2 antibody or recombinant LCN2. Pristane was injected to induce lupus in WT and *LCN2*-/- mice. At the end of the experiment, the renal pathology, proteinuria, spleen index were evaluated. The frequency of T lymphocyte subpopulations in spleen, lymph node and kidney was analyzed by flow cytometry. To further investigate whether LCN2 regulates Th1 differentiation, MACS-sorted WT and *LCN2*-/- naïve $CD4^+$ T cells were differentiated into Th1 cells under specific skewing condition.

Results: Here we report that the levels of LCN2 in peripheral blood and renal tissue are highly increased in LN patients and mouse models. Elevated LCN2 in $CD4^+$ T cells promote IFN-γ overexpression through upregulating

STAT4 phosphorylation. Both genetic depletion of LCN2 in pristane-induced mice or inhibition of LCN2 by injection of anti-LCN2 antibody in MRL/*lpr* mice greatly improve nephritis. The frequency of splenic or renal Th1 cells reduces in proportion to LN disease acitivity. Furthermore, administration of LCN2 exacerbates the disease with significantly higher renal activity scores accompanied by increased Th1 cells. Importantly, circulating Th1 cells and IFN-γ levels are markedly increased in LN patients, and these changes are associated with increased LCN2 levels.

Conclusion: Collectively, our findings demonstrate LCN2 is a regulator of Th1 which could be a therapeutic target for the treatment of LN.

Mass Cytometric Immunophenotyping Highlights a Dysregulated T cell-B Cell Axis in Patients with New-onset Lupus

Ye Cao,[1] Stephen Alves,[2] Corine Sinnette,[3] Cameron Speyer,[3] Gregory Keras,[1] Yujie Qu,[2] Joshua Keegan,[4] James Lederer,[4] Deepak Rao,[3] and Karen Costenbader[3], [1]Brigham and Women's Hospital, Boston, [2]Merck, boston, [3]Brigham and Women's Hospital, Boston, MA, [4]BWH, Boston

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The immune cell subsets most altered early in SLE disease course remain unclear. Defining abnormalities in lymphocyte populations in patients with new-onset SLE may reveal pathways that are fundamental drivers of the autoimmune response in SLE. Mass cytometry provides a powerful method to broadly assess immune cell phenotypes in samples from patients and may reveal immune cell subsets that are most prominently altered in SLE patients compared to controls.

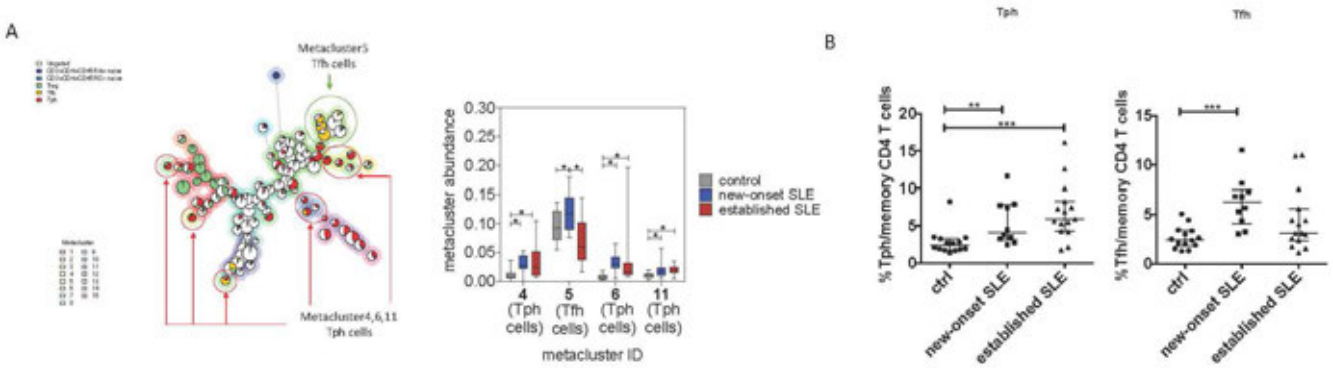

Figure 1. Expanded PD-1hi CXCR5- Tph cells and PD-1hi CXCR5+ Tfh cells in blood of new-onset SLE patients. A. FlowSOM analysis of CD45RO+ CD4+ T cells shows an increased abundance of T cell metaclusters 4,5,6,11. Metaclusters 4,6,11 are PD-1hi CXCR5- cells. Metacluster 5 is PD-1hi CXCR5+ cells. *Student's t-test p<0.05. B. Quantification of Tph cells (PD-1hi CXCR5-) and Tfh cells (PD-1hi CXCR5+) cells by biaxial gating. * p<0.05, ** p<0.01, *** p<0.001 by Mann-Whitney U test.

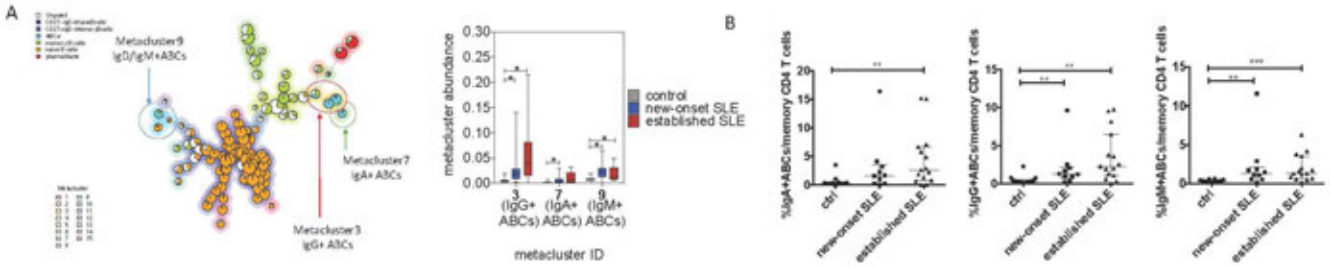

Figure 2. Expanded CD11c+ ABCs in the blood of new-onset and established SLE patients. A. FlowSOM analysis of total B cells shows an increased abundance of B cell metaclusters 3,7 and 9. Metacluster 3 is IgG+ ABCs. Metacluster 7 is IgA+ ABCs. Metacluster 9 is IgM+ ABCs. *Student's t-test p<0.05. B. Quantification of IgG+, IgA+, and IgM+ ABCs by biaxial gating. * p<0.05, ** p<0.01, *** p<0.001 by by Mann-Whitney U test.

Methods: We used two 39-marker mass cytometry panels (a T cell panel and B cell panel) to evaluate CD4+ T cells and B cells in cryopreserved peripheral blood mononuclear cells from patients with new-onset SLE (diagnosis within 6 months, n=10), compared to patients with established SLE (n=15), and non-inflammatory controls (n=14). All SLE patients met the 1997 ACR classification criteria for SLE. New-onset SLE patients were naïve to immunosuppressive therapy; hydroxychloroquine and prednisone ≤ 10mg/day were permitted. Established SLE patients were on a range of treatments. We used FlowSOM to define and quantify metaclusters of memory CD4+ T cells and B cells based on their 39-parameter characterization. We used Student's t-test to identify significantly altered metaclusters in SLE patients ($p< 0.05$). Expanded cell populations were confirmed by biaxial gating.

Results: We identified 15 metaclusters (i.e. cell populations) of memory CD4+ T cells by FlowSOM. Of these, 4 T cell metaclusters were significantly increased in new-onset SLE patients compared to healthy controls (Figure 1). Three of these 4 metaclusters were also increased in established SLE patients. Analysis of marker expression on these cell populations revealed that all 4 populations displayed high expression of PD-1 and ICOS. One of the populations also expressed CXCR5, consistent T follicular helper (Tfh) cells, while the other 3 lacked CXCR5, consistent with T peripheral helper (Tph) cells, a CXCR5- B cell-helper T cell population initially identified in RA joints. Biaxial gating confirmed a significant expansion of both Tph cells (2.0-fold, p=0.034) and Tfh cells (2.4-fold, p=0.001) in new-onset SLE patients. In the analysis of B cells by FlowSOM, we identified 3/15 B cell metaclusters significantly expanded in new-onset SLE patients (Figure 2). Cells in all 3 of these metaclusters showed a CD11c+ Tbet+ CD21- phenotype consistent with age-associated B cells (ABCs). The 3 metaclusters were distinguished by expression of distinct immunoglobulin isotypes representing IgM+, IgG+, and IgA+ ABCs. Across all patient groups, the frequency of Tph cells was positively correlated with the frequency of ABCs (r=0.34,p=0.036), including both IgG+ and IgM+ ABCs, and with the frequency of Tfh cells (r=0.44,p=0.005). Tph cells, but not Tfh cells, also showed a negative association with serum complement C3 levels (r=-0.51,p=0.017), a marker of disease activity in SLE.

Conclusion: Broad immunophenotyping analyses highlight marked expansion of Tph cells, Tfh cells, and ABCs are prominent features of the immune dysregulation in patients with new-onset, immunosuppressant-naïve SLE. These cells may be involved in the early phases of the pathologic autoimmune response in SLE.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have highlighted the potential role of microRNAs (miRNAs) as diagnostic and prognostic biomarkers in Systemic Lupus Erythematosus (SLE). While Rituximab (RTX) represents an important therapeutic option, identifying those patients who might benefit from this approach is still an unmet clinical need. This study aimed to analyze the circulating miRNAs profile in SLE patients' serum and the modulatory effect of RTX.

Methods: Twenty-seven healthy donors (HDs) and 25 SLE patients were recruited. SLE patients were clinically and serologically evaluated at baseline and after 3-month RTX treatment (375 mg/sq weekly / 4 weeks). Clinical assessment included changes in disease activity, using the SLE Disease Activity Index 2000 (SLEDAI-2K) and complete serological evaluation. Whole miRNome profile of serum samples was performed in an exploratory cohort of HDs and SLE patients before and after RTX therapy. The functional classification and target gene prediction of altered miRNAs was interrogated by Ingenuity Pathway Analysis software (IPA), which allowed us to select a set of miRNAs whose expression was validated by qPCR in the whole cohorts of patients and HDs. Changes in the levels of potential inflammatory mediators modulated by these miRNAs was also evaluated by multiplex assay.

Results: After 3-month RTX therapy, active SLE patients (SLEDAI-2K=9,5) showed a significant reduction in disease activity (SLEDAI-2K=1,5) along with reduced acute phase reactants (CRP and ESR) levels, and anti-dsDNA titers. miRNome profile showed altered expression of 153 miRNAs in SLE at baseline when compared to HDs (cut-off: 2-fold change): 142 increased and 11 reduced. Among those, the expression of 121 out of 153 (79%) miRNAs were reverted by *in vivo* treatment with RTX. The functional classification of these miRNAs revealed their association with clinical features of the SLE physiopathology such as inflammatory response, renal and haematological disease, connective tissue disorders and neurological, cardiovascular and dermatological disease, among others.

By using IPA analysis, we identified a panel of 5 microRNAs (miR-149-3p, 125b-5p, 199a-5p, 106b-3p 124-3p) that showed potential targets molecules comprising key pro-inflammatory cytokines and immune receptors, along with a high number of molecules that control intracellular pathways associated with inflammatory and autoimmune pro-

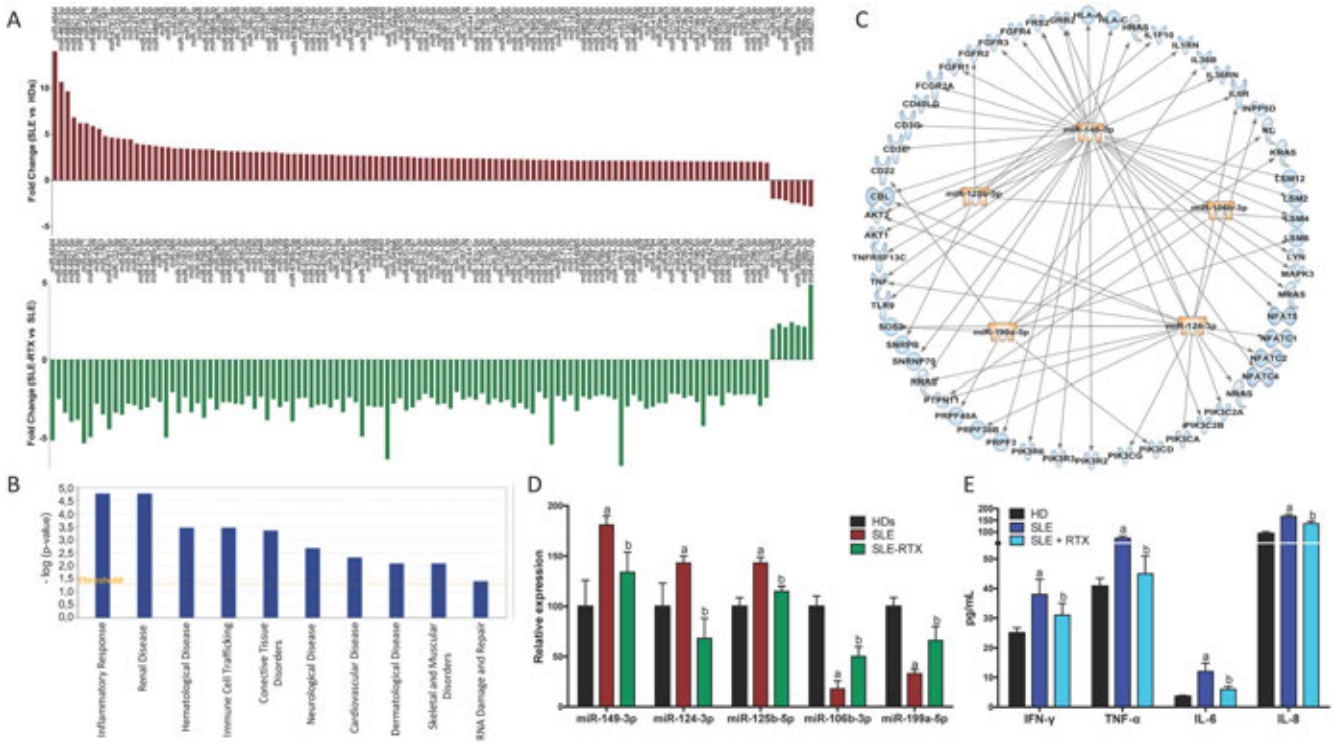

Figure 1. Autoimmunity Review-v1.

cesses. The altered expression of these selected miRNAs in SLE patients' serum vs HD was further validated in the entire cohort, along with the effect of RTX in the reversion of those levels.

Accordingly, the reestablishment of the altered circulating miRNA profile of SLE patients was accompanied by the downregulation of a set of pro-inflammatory cytokines found elevated in SLE serum, including IFNg, TNFa, IL6 and IL8.

Conclusion: Our overall data support the role of specific miRNAs as biomarkers for monitoring the response to B-depletion treatment in SLE, allowing an early identification of those patients who could benefit more from this therapy, and ultimately leading to a more tailored approach.

Session Title: SLE – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) disproportionally affects females (9:1) over males. Despite significant research effort, the exact mechanisms behind this compelling sex bias are undefined. Our prior studies demonstrate a significant role for estrogen receptor alpha (ERα) mediated inflammation in the pathogenesis of disease. NZM2410 lupus prone mice, expressing a truncated ERα functional knockout, survived longer and had significantly reduced renal disease. Yet, a complete knockout of ERα was not protective, suggesting the truncated isoform may be protective with the full-length gene necessary for disease.

Methods: Our goal is to identify the molecular mechanisms utilized by liganded ERα in regulating the inflammatory milieu. To understand ERα function, transient transfections of full length ERα and a shortened isoform ERα46 (lacking the AF-1 activation domain and similar to the functional knockout) were performed in MDA-MB-231 cells, which lack ERα and mRNA of inflammatory cytokines and cellular proliferation markers examined. Additionally, we identified ERα associated target genes and determined differences in their expression in B cells isolated from female African American (AA) lupus patients with an average age of 45.5 years and matched healthy controls.

Results: Transfection results indicate that both ERα46 reduces ERα66 driven mRNA expression of IL-1β one hour after stimulation with a TLR4 agonist. Similar results were also obtained for the cellular proliferation and survival markers MAPK14 and KLF4. Interestingly, an additive increase in expression was seen for TFF1, another cellular proliferation marker one hour after stimulation. RNA-seq analysis indicates that 60% of ERα associated target genes were differentially expressed between patients and controls. The majority of these genes (82%) were upregulated in lupus patients compared to controls. Genes with increased expression were included TLRs, NFκB related transcription factors and IL-1β.

Conclusion: These results further support a role for ERα in the pathogenesis of SLE. Future goals include utilizing high throughput sequencing technology to examine the transcriptional impact of liganded ERα in B cells of African American pediatric lupus patients.

Session Title: SLE – Etiology & Pathogenesis Poster I

Session Type: Poster Session (Monday)

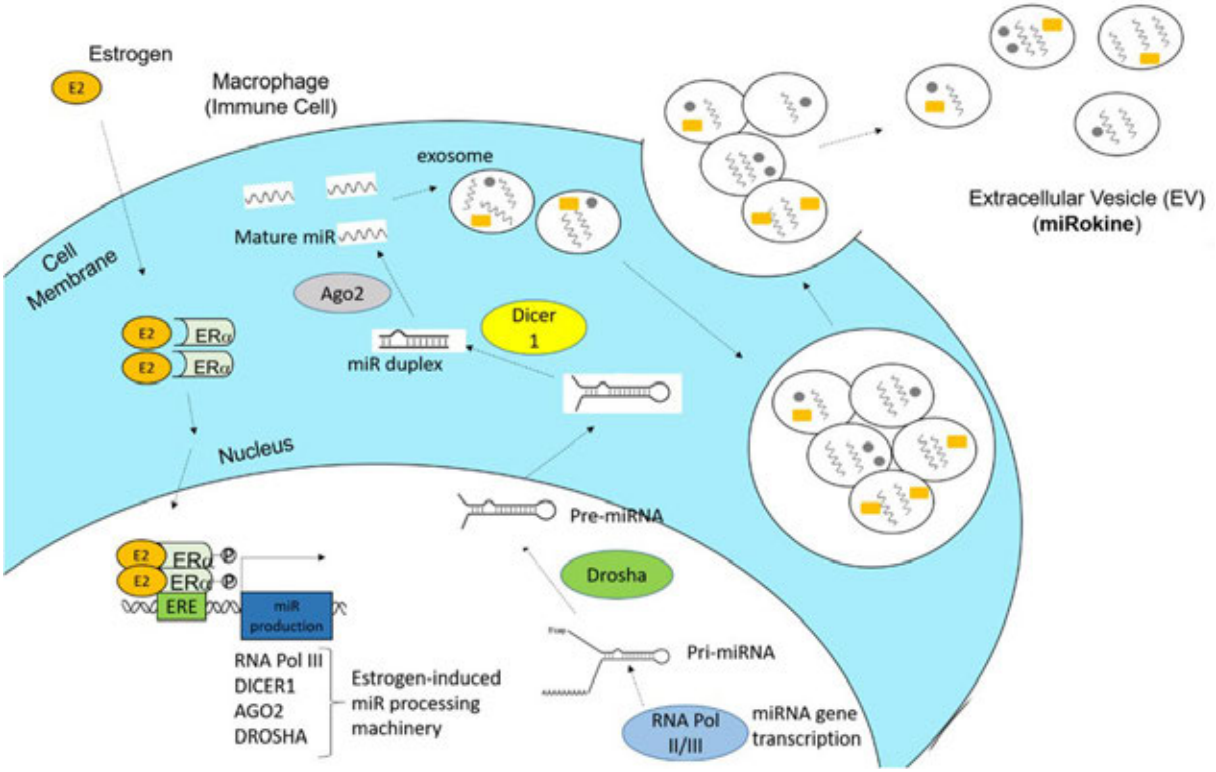
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies examining intracellular micro-RNA (miR) expression in PBMCs of patients with Systemic Lupus Erythematous (SLE) have identified distinct disease-associated changes in expression. We have previously demonstrated that estrogen lowers the threshold of immune cell activation to a greater extent in females and leads to significantly enhanced toll-like receptor (TLR)7 and TLR8 expression. Moreover, our studies have also shown enhanced estrogenic responses in PBMCs from SLE patients compared to healthy controls. Furthermore, our recent data demonstrates estrogen-mediated upregulation of extracellular vesicle (EV) production via enhanced TLR8 expression in THP-1 cell lines and unique miR signatures in EVs isolated from SLE patient plasma and urine. The overall objective of the current study is to identify novel estrogen-regulated mRNAs and miRs that may be responsible, in part, for the unique miR signatures observed in EVs from SLE patients.

Methods: Our cohort for this study consisted of five post-adolescent, premenopausal, female donors. Human PBMCs were isolated from whole blood and cultured in hormone free conditions before stimulation with 10 nM of 17β-estradiol (estrogen; E2) for 24 hr. E2-treated samples were compared to untreated controls for each donor. RNA was isolated from cell lysates and RNA libraries were prepared for RNA-sequencing (RNAseq). Global RNA reads were analyzed and cross-referenced with a sequencing database (miRBase) of known miRs and mRNAs. Results for mRNA and miR data were analyzed collectively on Ingenuity Pathway Analysis (IPA) software.

Results: Analysis of our RNAseq data by IPA revealed the predicted upregulation of estrogen-dependent breast cancer signaling by canonical pathway overlay and estrogen receptor upregulation by overlap upstream analysis. Additionally, further analysis identified upregulated pathways that included several involved in miR transcription and processing. Specifically, argonaute-2 (AGO2) had an IPA overlap p-value of 0.006, which resulted from upregulation of AGO2 expression by 1.3-fold ($p < 0.01$) with E2 treatment and significant downregulation of FOS, miR-127, miR-34, and miR-27. Moreover, Dicer1 (Ribonuclease III) was also stimulated 1.3-fold ($p < 0.01$) with E2 and an IPA overlap p-value of 0.001 was observed that resulted from miR-34, miR-196, and miR-218 suppression. Also, RNA polymerase III ($p < 0.01$) and Drosha RNase III ($p < 0.01$) were found to be signafigantly induced with estrogen treatment.

Conclusion: Our data reveal a potential mechanism of estrogen-mediated miR production and pathogenic inflammation via EV signaling in SLE. In this model, estrogen would enter an immune cell, dimerize with estrogen receptor (ER) α, translocate to the nucleus, and promote the expression of miR processing machinery, including RNA polymerase III, Dicer1, AGO2, and Drosha. The resulting miRs can then be packaged along with other proteins and secreted in EVs as



Schematic of our proposed mechanism of estrogen-mediated micro-RNA production and inflammation via extracellular vesicle signaling in lupus.

extracellular signaling regulators (miRokines) that can be taken up by recipient immune cells to induce an inflammatory cascade.

Urinary C3d Is a Good Marker for Monitoring Treatment Response After 3 Months of Induction Treatment in Patients with Biopsy Proven Lupus Nephritis

Sujata Ganguly,[1] Sanjukta Majumder,[2] Hafis Muhammed,[3] Amita Aggarwal,[4] and Ramnath Misra[2], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, India, [2]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, Uttar Pradesh, India, [3]SGPGI, Lucknow, Uttar Pradesh, India, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Complement activation is one of the important pathogenic features of lupus nephritis and low serum complements are conventionally used to monitor disease activity in lupus Earlier we have shown that urinary C3d correlates with renal disease activity in a cross sectional study(1). In this study we sought to explore whether urine C3d correates with renal disease activity after 3 months of immunosuppressive therapy.

Methods: 37 consecutive patients of SLE who fulfilled SLE SLICC 2012 classification criteria seen between – through – month and year were included in the study of which 18 (M:F-1:17) patients were biopsy proven active nephritis (AN) (defined if there was urinary protein 1 g/day or 0.5g/day and sediment abnormalities (urine RBC or WBC count >5/hpf) or increased serum creatinine), 4(M:F-1:3) were inactive nephritis(IN), 5(All females) were non nephritis(NN) and 10(all females) were age and sex matched healthy controls . Plasma and urine samples were collected for all the patients and stored at -80. Repeat samples were taken for active nephritis patients on 3 months follow up. Clinical parameters were noted and serum C3,C4 and antiDsdna was obtained. SLEDAI and renal SLEDAI was calculated. Urine C3d was analysed using commercially available ELISA Kit and the values were normalized to creatinine excretion(pg/mg).

All statistical analysis was done using SPSS ver 23.

Results: Twelve patients achieved remission or low disease activity at 3 months. In these 12 patients the median Urinary C3d significantly decreased from 800.43 pg/mg(IQR- 115.32-1517.52) to 50.34 pg/mg, (28.43-756.17) after 3 months of treatment(p-0.01). This could be due to increase in C3d values on follow up in 6 patients in whom proteinuria was persistent and there was no response to treatment. The Area under curve(AUC) for differentiating active nephritis from inactive nephritis was 0.926 (SE- SE-0.064, 95%CI- O.8012-0.99, p- 0.009). The AUC for differentiating active nephritis from extra renal lupus was 0.647 (SE-0.117 95%CI-0.419-0.875, p -0.009) and from healthy controls was 0.906 (SE-0.061, 95%CI- 0.7872-0.99, p-0.001). There was a significant correlation of Urine C3d values with Urine protein to creatinine ratio(r-0.458, p-0.002) but no correlation was seen with serum C3, C4, antidsdna , SLEDAI and rSLEDAI.

Conclusion: Urinary C3d levels can be used to differentiate active renal from inactive renal disease and extra renal involvement. Decrease in urinary levels on follow up makes it a useful biomarker to monitor treatment. Lack of correlation with serum C3 points towards renal generation of C3d and hence an added biomarker in our current repertoire.

Distinct Cell-bound Complement Activation Signatures Are Observed in Patients with Systemic Lupus Erythematosus

Rebecca Schriefer,[1] Gabriel Arguelles,[1] John Atkinson,[1] Dennis Hourcade,[1] and **Alfred Kim** [1], [1]Washington University School of Medicine, Saint Louis, MO

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cell-bound complement activation products (CB-CAPs) have previously been shown to associate with SLE disease activity, but only a small fraction of total CB-CAPs has been examined. Leveraging mass cytometry, we have developed and validated a panel capable of comprehensively characterizing the types and quantities of CB-CAPs and complement receptors on human PBMCs. In this pilot study, we sought to characterize the types and amounts of CB-CAPs observed in flaring and inactive SLE and identify SLE patient stratifications based on CB-CAPs signatures.

Methods: Six paired PBMC samples from flaring and remission consented patients with 1997 ACR or 2012 SLICC classified SLE were obtained from the Washington University Lupus Clinic. Mass-tag barcoded PBMCs were stained using a validated set of 30 antibodies to cell surface markers, various CB-CAPs, and complement receptors. Stained PBMCs were run on a Helios-upgraded CyTOF2 mass cytometer, and data analyzed in Cytobank (viSNE, FlowSOM).

Results: We found that in flaring subjects, B cells possessed the greatest load of CB-CAPs compared to T cell and macrophages. Most CB-CAPs markers were absent in the paired remission samples. Evidence of classical, alternative, and common pathway activation was observed on these SLE B cells and can be categorized into six broad metaclusters. Five of the metaclusters possessed both classical and alternative pathway activation markers but differed in how completely the common pathway was activated, including 25% of B cells that did not activate C5 at all despite C3 activation. The fifth metacluster possessed only alternative and common pathway activation markers. B cell subsets of virtually every type could be found in each metacluster, with the exception of plasma cells which were devoid of any complement activation markers.

Conclusion: These data represent the first attempt to stratify SLE patients based off of CB-CAP signatures. B cells from flaring subjects broadly possess CB-CAPs, and all B cell subsets with exception of plasma cells are subject to complement activation. Subjects in remission were essentially devoid of CB-CAPs. We observed six distinct CB-CAPs signatures, with differences in the extent of classical, alternative, and common pathway activation defining these signatures. Our data may have important implications for how CB-CAPs biomarkers are best used in the clinic and clinical trials. Additionally, identification of CAPS signatures may inform investigators about which complement targets are best suited for specific individuals.

Molecular Profiling Identifies Immunologic Subgroups and Informs Mechanism of Action of Baricitinib in SLE

Thomas Dörner,[1] Yoshiya Tanaka,[2] Michelle Petri,[3] Josef Smolen,[4] Daniel Wallace,[5] Ernst Dow,[6] Damiano Fantini,[6] Richard Higgs,[6] Guilherme Rocha,[6] Brenda Crowe,[6] Robert Benschop,[6] Adam Abel,[6] Nicole Byers,[6] Maria Silk,[6] Stephanie de Bono,[6] and Robert Hoffman[6], [1]Charite Universitätsmedizin Berlin and DRFZ, Berlin, Germany, [2]University of Occupational and Environmental Health Japan, Kitakyushu, Japan, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]Medical University of Vienna, Vienna, Austria, [5]Cedars-Sinai Medical Center/University California at Los Angeles, Los Angeles, CA, [6]Eli Lilly and Company, Indianapolis, IN

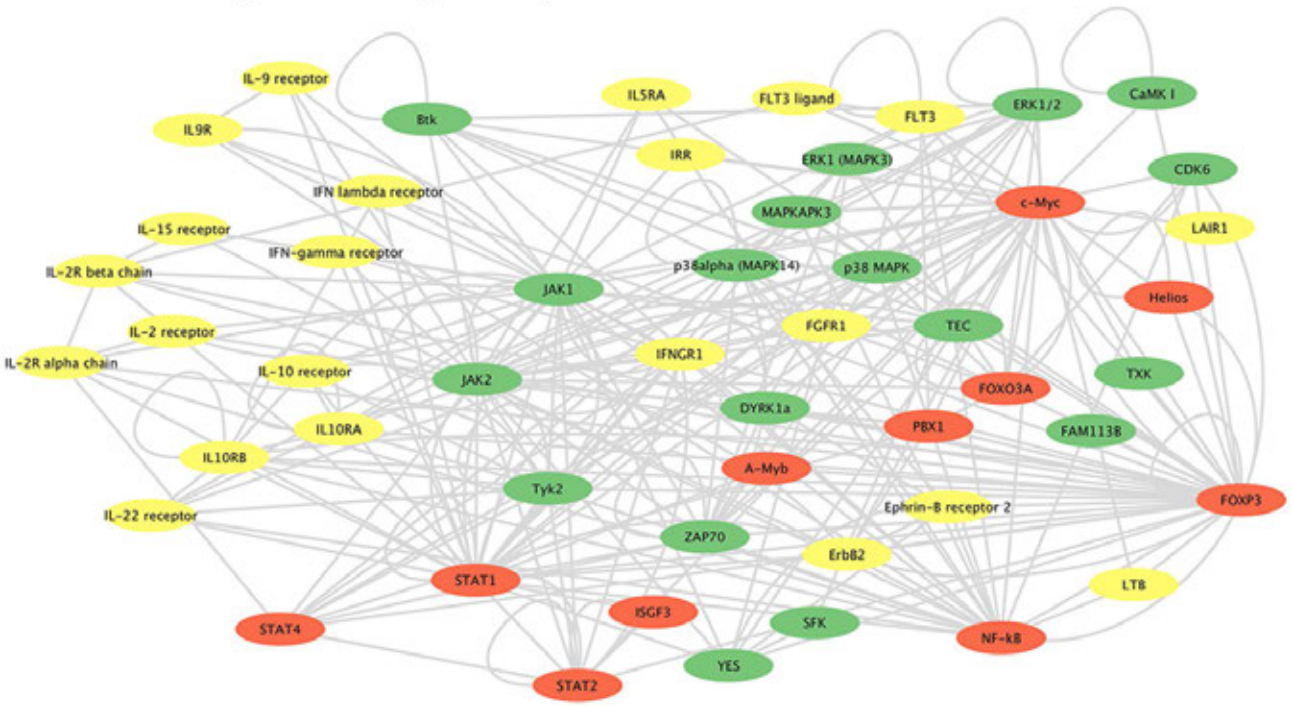
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Etiology & Pathogenesis Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib is an oral selective Janus kinase (JAK) 1 and JAK2 inhibitor. In the Phase II, 24-week, randomized, placebo-controlled, double-blind study JAHH (NCT02708095), once-daily baricitinib resulted in significant clinical improvements in patients with active SLE receiving standard background therapy, compared with placebo.[1] We characterized the molecular and cellular immune pathways impacted by baricitinib in SLE.

Methods: A total of 314 patients were randomized 1:1:1 to receive once-daily placebo, baricitinib 2-mg, or baricitinib 4-mg for 24 weeks in study JAHH. Patients were 18 years of age or older, had a diagnosis of SLE, and had active disease involving skin or joints. Whole blood samples were obtained from patients in JAHH at baseline and weeks 2, 4, 12, and 24, and cellular and serologic immune biomarkers were measured using flow cytometry and immunochemistry assays. RNA was isolated from whole blood and analyzed using Affymetrix HTA2.0 array and quantitative PCR. Data were summarized to transcript level and analyzed using a mixed effects model on a log2 transformed response with multiplicity correction. Clinical and immunologic characteristics were compared between subgroups defined using molecular profiling.

Results: At baseline, the IFN signature negatively correlated with complement (C) 3 and C4, and positively correlated with serum immunoglobulin (Ig) G, anti-dsDNA, anti-Sm, anti-RNP, anti-Ro 52/SSA, anti-Ro 60/SSA, and anti-La/SSB in patients with active SLE. These correlations constituted a distinctive subgroup, or endotype. Serum autoantibodies and complement were not altered by baricitinib treatment, suggesting that the mechanism of action of baricitinib in SLE may be primarily through an anti-inflammatory effect. Gene expression profiling demon-

Figure. Gene network analysis of pharmacologically-induced changes in gene expression in response to treatment with baricitinib 4-mg at week 12 compared with placebo



strated that there was an elevation of *STAT1, STAT2,* and multiple IFN responsive genes at baseline in patients with SLE. Statistical and gene network analysis demonstrated that baricitinib treatment reduced the expression of functionally interconnected genes involved in SLE including *STAT1*, *STAT2*, and *STAT4*, and multiple IFN responsive genes (Figure).

Conclusion: Baricitinib treatment reduced the expression of *STAT1*, *STAT2*, and IFN responsive genes in patients with SLE. Gene network analysis revealed that baricitinib treatment reduced the expression of a network of genes associated with JAK/STAT pathways, cytokine signaling, and SLE pathogenesis, suggesting that baricitinib effects may be mediated through pharmacologic impact on multiple immune pathways.

Gene network analysis of genes changed based on baricitinib's inhibition of JAK1 and JAK2 signaling and the most significantly baricitinib-induced changed genes, regardless of mechanism. The analysis includes genes changed with baricitinib 4-mg at week 12 compared with placebo. The genes included were identified by two Methods 1) the 50 genes most significantly changed with baricitinib-treatment and 2) genes that interact with JAK1 or JAK2 via transcriptional regulation or phosphorylation as defined by the curated MetaBase (www.clarivate.com) database and had an adjusted P value < 0.05. In order to graphically show the interactions, these genes, along with STAT1, STAT2, JAK1, JAK2, and TYK2 were queried against the known interactions in MetaBase, and kinases (green), ligands/receptors (yellow), and transcription factors (red) with known interactions were connected and displayed using cytoscape (cytoscape.org); genes that were not directly connected to this network or were in other categories are not shown.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: A better knowledge of the mechanisms and biomarkers of skin and lung damage in systemic sclerosis (SSc) related fibrosis remain a challenge. Our aim was to characterize serological and vascular manifestations, functional and histopathological features of skin and lung in the purpose of establishing a novel SSc murine model induced by Collagen V immunization.

Methods: Female C57BL/6 mice (n=19, IMU-COLV) were subcutaneously immunized with two doses of Col V (150μg) emulsified in complete Freund adjuvant, followed by two intramuscular boosters. The control group (n=19) did not receive Col V. After 120 days, respiratory mechanics, serum autoantibodies and vascular manifestations were examined. The skin and lung inflammatory process and the collagen gene/protein expression were analyzed.

Results: After immunization, the skin of the animals presented increased thickness (28.59±1.79 vs. 22.84±0.82; p=0.0132), epidermal rectification, decreased papillary dermis, and appendages atrophy, also showing increased deposition of collagen III (20.05±2.20 vs. 11.65±1.29; p=0.0147) and collagen V (3.65±0.47 vs. 1.05±0.18; p=0.011) fibers, and increased gene expression of COL5A1 (3,15±0,80 vs. 0,90±0,32; p=0,0316) and COL5A2 (2,10±0,24 vs. 0,56±0,24; p=0,0401). Vascular changes included endothelial cell activity and apoptosis by increased expression of VEGF (21.1±1.55 vs. 6.88±0.19; p< 0,004), endothelin-1 (10.20±0.81 vs. 2.35±0.44, p< 0,0022) and caspase-3 (21.21±1.34 vs. 8.26±0.29, p=0,0007), coinciding with increased gene expression of endothelin-1 (2,02±0,32 vs. 0,78±0,07; p=0,0351), VEGF (2.26±0.37 vs. 0.97±0.11; p=0.0019) and caspase-3 (1.99±0.17 vs. 0.92±0.10; p< 001). Immunized animals presented lung dysfunction characterized by increased tissue elastance and remodeling of parenchyma by non-specific interstitial pneumonia and vascular sclerosis. Compared to controls, immunization promoted increase of total collagen (6.95±0.42 vs. 5.33±0.31, p=0,0071), collagen I (25.90±3.31 vs. 5.57±0.59; p=0.003) and V (18.53±1.05 vs. 7.53±0.41; p< 0.0001) fibers in lung parenchyma, coinciding with COL1A1 (2.34±0.40 vs. 0.85±0.12; p=0.0070), COL1A2 (2.39±0.23 vs. 1.30±0.06; p=0.0016), COL5A1 (1.80±0.32 vs. 0.97±0.13; p=0.0379) and COL5A2 (1.56±0.18 vs. 0.93±0.10; p=0.014) gene expression. Anti-collagen III (0,15±0,006 vs. 0,09±0,005; p=0,0001) and IV (1,369±0,005 vs. 0,15±0,044; p< 0,0001) and antinuclear antibodies (ANA) (p=0,001) were detected in sera from IMU-COLV.

Conclusion: We demonstrated that cutaneous, vascular and pulmonary remodeling are mimicked by type V collagen-induced SSc mice model, thus representing a suitable preclinical model to study the mechanisms and therapeutic approaches in SSc.

Computational Methods for Drug Repositioning of Systemic Sclerosis Using Gene Fold-Change and Network Analyses

Dillon Popovich,[1] Michael Whitfield,[2] Yue Wang,[3] Guoshuai Cai,[4] and Mengqi Huang[5], [1]Geisel School of Medicine at Dartmouth College, Hanover, [2]Geisel School of Medicine at Dartmouth College, Biomedical Data Science at Dartmouth College, Hanover, [3]Geisel School of Medicine at Dartmouth, Hanover, NH, [4]Arnold school of Public Health, University of South Carolina, Columbia, SC, [5]Geisel School of Medicine at Dartmouth College, Hanover, NH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical trials with systemic sclerosis (SSc) patients have yet to lead to an FDA approved treatment. We have adopted a gene fold-change analysis called "IDEA" to compare cell lines from the CMAP 2.0 database with biopsies of SSc patients. Using IDEA, we can identify perturbagens that induce a genetic signature in cell lines to be more comparable with healthy controls than SSc patients. We have also created correlation networks with patient cohort gene expression data. Head nodes within these networks may be targetable via perturbagens, disrupting genes highly correlated with the SSc disease phenotype. Here, we use this method to identify several potential perturbagens that may modulate the SSc phenotype.

Methods: Raw .cel files were downloaded from CMAP 2.0, processed with RMA, quantile normalized and fit to a multichip linear model. Probes are collapsed at average intensity while gene fold-change is the ratio of treatment to control intensities followed by a $\log_2$-transformation. The data is then processed for use with the BASE algorithm. A t-test (Bonferroni corrected) is calculated to determine which perturbagens have a gene signature most similar to healthy controls when compared to either the Inflammatory or Fibroproliferative SSc patient subsets. Patient cohort data is run through WGCNA using a signed network. Modules that correlate highly with patient subsets are chosen to create their respective correlation networks.

Results: Using two independent microarray datasets, we found four overlapping perturbagens that affect the inflammatory subset and fourteen that affect the fibroproliferative subset. Using drug set enrichment analysis (DSEA), we were able to classify which drugs are more highly enriched in cell signaling pathways and immune system pathways. PI3K-inhibitors and an immunosuppressive highly regulate these pathways. WGCNA was used to create correlation networks based on genes most associated with patient gene expression subtypes. The top hub nodes for the inflammatory network were MS4A6A, CD93 and HLA-DMA, while the fibroproliferative network had IKBKG (fig. 1). These hubs and their associated genes may be key gene expression hubs to target with for intervention.

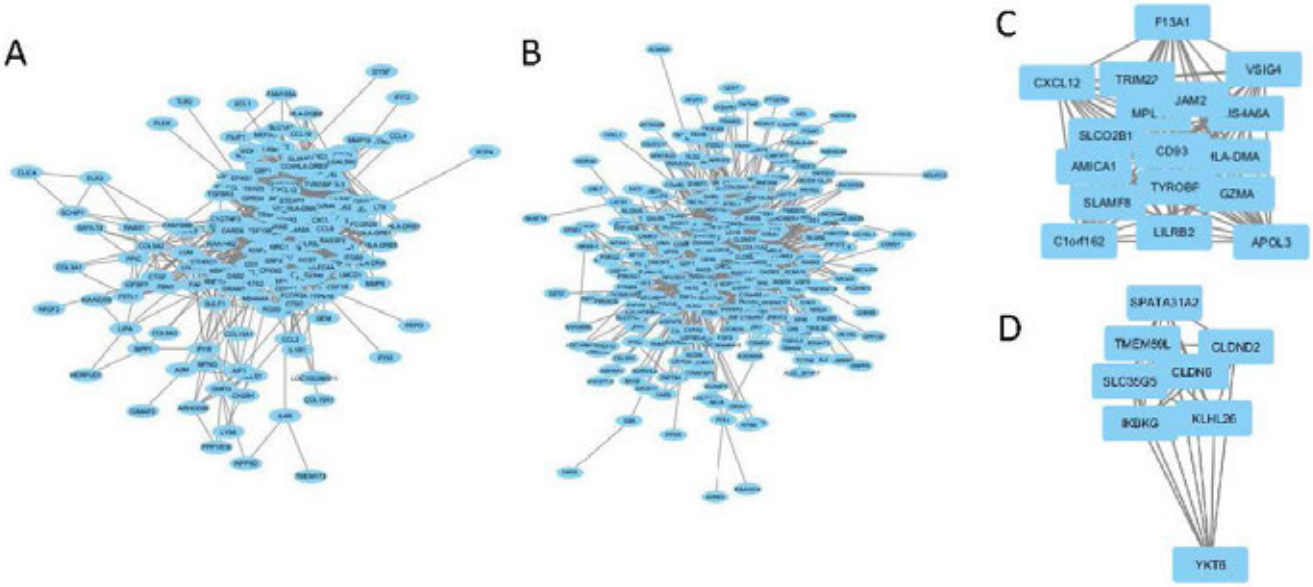

Figure 1. A) Left – Highest correlated modules with the Inflammatory subset of patients as a correlation network. B) Highest correlated modules with the Fibroproliferative subset of patients as a correlation network. C) Nodes with the highest degrees from the inflammatory network. D) Nodes with the highest degrees from the Fibroproliferative network.

Conclusion: We have identified a wide range of perturbagens ranging in mechanism of action, from anti-inflammatories to anti-psychotics and anti-biotics as potential therapeutic perturbagens of interest to further test. These perturbagens have been shown to genetically modulate the molecular pathways dysregulated in SSc, opening a different avenue towards treating the disease.

Thy-1 (CD90) as a Novel Marker for Tracking *in Vivo* Skin Fibrosis

Benjamin Korman,[1] Ananta Paine,[2] Stacey Duemmel,[3] Marc Nuzzo,[3] and Christopher Ritchlin[2], [1]University of Rochester Medical Center, Rochester, NY, [2]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY, [3]University of Rochester, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Thy-1 (CD90) is a cell surface marker which is found primarily on fibroblasts and whose expression has previously been shown to correlate with pathologic subsets of fibroblasts. SSc patients have been shown to have increased circulating levels of Thy-1 and increased Thy-1 staining in skin. Assessment of fibrosis in animal models is usually limited by the need for histologic and biochemical assays to determine the course of collagen dep-

osition, ASMA expression, and other characteristic findings. We used a Thy-1-YFP reporter mouse to assess whether expression of Thy-1 can serve as a surrogate for fibrosis in vivo using the bleomycin induced skin fibrosis model.

Methods: Thy-1-YFP mice were injected with intradermal bleomycin over a time-course with 0 to 10 injections and were imaged on an IVIS spectrum in vivo fluorescent imaging system three times per week for up to 35 days. 3 mice per time point were assessed histologically and biochemically at 0, 3, 8, 14, 16, 21, 28, and 35 day time points. Skin was assessed for presence of YFP+ cells using fluorescent microscopy, for dermal thickness, for biochemical assessments of fibrosis, and for fibrogenic gene expression.

Results: SSc patients have increased Thy-1 expression in skin and this correlates with collagen and other fibrogenic gene expression and the modified Rodnan skin score (MRSS). Thy-1-YFP mice had no baseline skin Thy-1 fluorescence and began to display epi-fluorescence which was localized to the areas surrounding intradermal bleomycin injections. This was statistically increased by IVIS at day 10 and then progressively increased until 21 days at which point it began to dissipate. This pattern correlated closely with both dermal thickness and expression of fibrotic genes. Fluorescence microscopy confirmed that YFP positive cells were restricted to dermal cells with spindle-shaped fibroblast morphology.

Conclusion: Thy-1 is differentially expressed in SSc skin and correlates with extent of skin disease. In bleomycin-induced fibrosis, Thy-1-YFP mice demonstrated inducible expression with bleomycin and were useful for quantitatively tracking fibrosis progression using in vivo fluorescent imaging. Fluorescent intensity measured in vivo correlated with histologic and biochemical outcomes of fibrosis measured terminally. This system is able to track fibrosis in vivo and will allow for dynamic assessment of fibrosis over time in treatment trials to assess onset and resolution of fibrosis without requiring large numbers of experimental animals. Further studies should further assess the pathophysiologic role of Thy-1 in SSc skin fibrosis.

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Metabolic perturbations are emerging as drivers of fibroblast activation in fibrosis. Transcriptomic analyses have shown the enrichment of glycolysis and suppression of tricarboxylic acid (TCA) cycle in fibrotic human skin, which could favor the development of skin fibrosis (Zhao et.al Nat Metab 2019). Here we explored, whether TGFβ can induce metabolic alterations in dermal fibroblasts (DF) and whether dimethyl alpha-ketoglutarate (αKG), the key TCA metabolite, can influence the TGFβ-driven profibrotic responses in DF.

Methods: Human DF from healthy controls (HC, n=3-7) and patients with systemic sclerosis (SSc, n=4-8) were treated with TGFβ and/or αKG (6 mM). Apoptosis was measured with flow cytometry using Annexin V assay. Overall metabolic activity was assessed by the Alamar blue assay. Gene expression was analyzed by qPCR. Protein amounts (fibronectin, αSMA) were measured with Western blot. Contractile properties of DF were assessed by gel contraction assay. Significance ($p< 0.05$) was determined by one sample t test or ANOVA with Tukey's correction for multiple comparisons.

Results: The basal mRNA expression of genes involved in metabolism, e.g. *GPI*, *ACO1* and *SUCLA*, differed between DF from HC and SSc patients ($p< 0.05$). TGFβ increased the overall metabolic activity of DF (p=0.01, mean x-fold±SD 1.22±1.2 above background) as assessed by the Alamar blue assay and significantly ($p< 0.05$) upregulated mRNA levels of the core components of glucose uptake and glycolysis (*GLUT1, PGK1, PGAM1, ENO*), the TCA cycle (*SUCLA, MDH*) and glutaminolysis (*SLC1A5, GLS1, GOT2*). The mRNA expression of *HIF1α*, a major inducer of metabolic reprogramming, was enhanced (Fig. 1, p=0.0001, x-fold 3.2±1.6), whereas the mRNA expression of *PGC1α*, the central regulator of mitochondrial biogenesis and cellular energy metabolism, was strongly suppressed (Fig. 1, $p< 0.0001$, x-fold 0.2±0.2). αKG reversed the TGFβ-driven upregulation of HIF1α (Fig. 1, p=0.06, x-fold 1.4±0.3) but had no effect on the TGFβ-driven suppression of PGC1α mRNA (Fig. 1). Furthermore, αKG significantly repressed the TGFβ-driven secretion of fibronectin into cell culture supernatants (p=0.047, normalized O.D. TGFβ+αKG 0.5±0.1 vs. TGFβ 1.2±0.6) and diminished the TGFβ-induced production of *αSMA* mRNA (p=0.07, x-fold TGFβ+αKG 2.1±1.2 vs. TGFβ 8.2±4.7) and protein (p=0.02, normalized O.D. TGFβ+αKG 0.34±0.38 vs. TGFβ 3.1±2.3). αKG reduced the contractile capacity of TGFβ-stimulated DF (p=0.003, no contraction in TGFβ+αKG–treated DF vs. 67.1±5.4% in TGFβ-stimulated DF). Apoptosis was not enhanced in TGFβ ± αKG–treated DF.

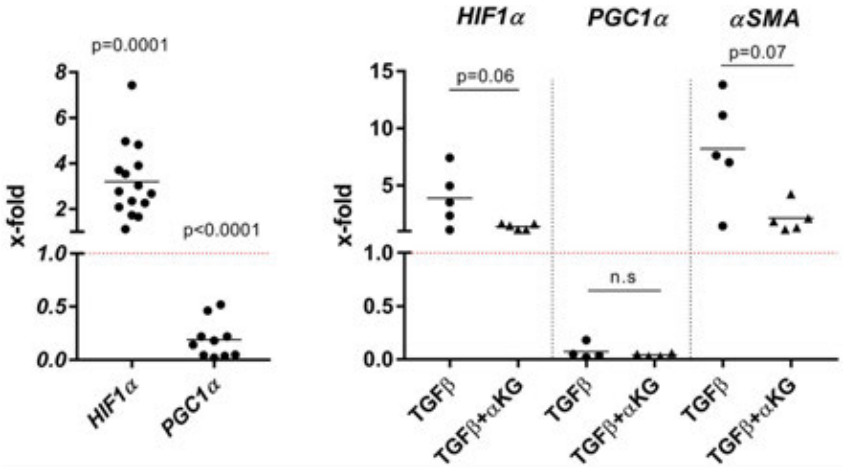

Figure 1. Gene expression analysis of HIF1a, PGC1a and aSMA in dermal fibroblasts stimulated with TGFb in the presence or absence of alpha-ketoglutarate (aKG). The results are shown as x-fold change of normalized gene expression vs. untreated cells (set to 1, as denoted with red line).

Conclusion: TGFβ alters the expression of central metabolic regulators and increases the overall metabolic rate in DF, whereas αKG suppresses the TGFβ-driven profibrotic responses in DF. This suggests that metabolism is intimately linked to the fibrotic processes in skin. Targeting perturbed metabolism could offer novel anti-fibrotic strategies in SSc.

TGF-β Isoforms Modulate the RNA Cargo of Extracellular Vesicles (Exosomes) Isolated from Cultured Normal Human Lung Microvascular Endothelial Cells: A Mechanistic Link Between Endothelial Cell Dysfunction and the Establishment of a Profibrotic Phenotype in SSc?

Peter Wermuth,[1] and Sergio Jimenez[1], [1]Jefferson Institute of Molecular Medicine and Division of Connective Tissue Diseases, Thomas Jefferson University, Philadelphia, PA, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Extracellular vesicles (EV) are a diverse assortment of lipid bilayer-bound vesicles of various sizes and origin. Exosomes are a subset of EV arising from multivesicular bodies released into the extracellular space and into the circulation that contain various macromolecules including numerous microRNA (miRNA) and proteins. EV can mediate intercellular communication by fusing and releasing their macromolecular contents into target cells. The mechanism of the establishment and progression of a profibrotic phenotype in Systemic Sclerosis (SSc) is not currently well understood. Microvascular damage is considered an early event in SSc pathogenesis and EV produced by damaged microvascular endothelial cells may represent an important component in the initiation and progression of SSc. Here, we characterized the miRNA content of EV isolated from cultured normal human lung microvascular endothelial cells (HLMVEC) treated with TGF-β1, TGF-β2, or TGF-β3 to determine the specific influence of the TGF-β isoforms on the RNA content of HLMVEC.

Methods: Commercially obtained normal HLMVEC were treated with 10 ng/ml of TGF-β1, TGF-β2, or TGF-β3 in FBS-free media. Culture media was isolated from duplicate wells after 72h and EV were isolated by resin-based purification. Total EV RNA was isolated and RNA sequencing (RNA-seq) was performed by 50bp paired-end RNA-seq at 10-20 million reads per sample and aligned to the reference genome (hg19). Differential analysis of RNA content was performed by comparing each treatment group to untreated cells using OASIS 2.0. Gene set enrichment and pathway analysis of miRNA targets was performed employing the MirPath v3.0. Differential expression of selected EV RNA was verified by qPCR.

Results: Treatment of cultured normal HLMVEC with TGF-β isoforms altered the RNA contents of EV isolated from these cells. In addition to changes in miRNA content, marked differences in the amounts and identity of other classes of small RNA such as piRNA were induced upon treatment with the TGF-β isoforms. Analysis of EV miRNA targets indicated extracellular matrix (ECM)-receptor interactions, proteoglycans, ECM components and TGF-β signaling were among the most significantly targeted pathways.

Conclusion: Despite similarities in structure and sequence, TGF-β protein isoforms result in distinct populations of HLMVEC-derived EV. The pattern of upregulated and downregulated EV miRNA from TGF-β1- and TGF-β3-treated HLMVEC show considerable overlap compared with TGF-β2-treated HLMVEC. However, each TGF-β isoform mediated distinct patterns and levels of EV small RNA species. Pathway analysis revealed that numerous pathways are regulated by all three isoforms although the individual genes affected and the magnitude of the changes produced differed for each specific TGF-β isoform. The pathways targeted indicate that EV miRNA could affect target cells by altering the pathways involved in extracellular matrix synthesis, potentially inducing a profibrotic phenotype in target cells. This mechanism may explain the extension of SSc-associated pathological alterations from afftected to normal tissues.

Myocardial Involvement in SSc: Key Role of $Lin^{-}gp38^{+}$ Stromal Cells in the Onset of Fibrosis and Defects of the Conduction System

Mara Stellato,[1] Michal Rudnik,[2] Florian Renoux,[3] Przemyslaw Blyszczuk,[4] Elena Osto,[5] Matthias Dewenter,[6] Petra Seebeck,[7] Elena Pachera,[2] Oliver Distler,[8] and Gabriela Kania[4], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Zurich, Switzerland, [3]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, [4]Centre of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [5]Institute of Clinical Chemistry, University Hospital Zurich, Switzerland, Zurich, Zurich, Switzerland, [6]Department of Molecular Cardiology and Epigenetics, University Hospital, Heidelberg, Germany, Heidelberg, Germany, [7]Zurich integrative Rodent Physiology, University of Zurich, Switzerland, Zurich, Switzerland, [8]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac fibrosis is a known complication of SSc, associated with increased mortality. During fibrogenesis, fibroblasts differentiate into myofibroblasts and secrete excessive extracellular matrix proteins. Here,

we aim to identify the role of a specific fibroblast subset in fibrogenesis and defects of the cardiac electrophysiology in the Fra2 transgenic (tg) mouse model.

Methods: Cardiac function of Fra2 tg and Rag2$^{-/-}$ Fra2 tg mice was assessed by echocardiography, ECG and radiotelemetry. Hearts were analysed by immunohistochemistry (IHC) and IF. The myocardial fibroblast subset represented by stromal (Ter119$^-$CD45$^-$CD31$^-$, hereafter Lin$^-$) gp38$^+$ cells, was sorted and cultured. The phenotype was evaluated by qPCR, α-smooth muscle actin (αSMA) and stress fibre IF, secreted collagens and contraction assay. Proliferation and apoptosis were measured by BrdU incorporation and Caspase 3/7 activity.

Results: Fra2 tg mice displayed increased ejection fraction (p=0.02) and fractional shortening (p=0.02) with decreased left ventricle end-diameter and end-volume in systole (p=0.006, p=0.008) and in diastole (p=0.007, p=0.008) in echocardiography. ECG in conscious mice revealed lower heart rate (HR) (WT 741 ± 33 BPM, tg 644 ± 37 BPM, p< 0.0001) and prolonged QRS, ST and QTc parameters (p=0.001, p=0.01, p=0.01), which may predispose to arrhythmias. Continuous ECG measured by radiotelemetry showed the presence of atrioventricular (AV) blocks that correlated with phenotype severity score (R=0.9, p=0.02). Fibrosis might be responsible for these changes by separating myocardial bundles, causing improper conduction. Indeed, the myocardium of Fra2 tg mice uncovered mild inflammation and interstitial fibrosis with higher expression of collagen- (p=0.03, n=7) and periostin-expressing cells (p=0.001, n=7), increased number of αSMA+ myofibroblasts as well as Lin-gp38+ cells compared to WT mice (1.4% ± 1.4, n=15 and Fra-2 tg: 6% ± 4.5, n=14, p=0.001). Importantly, the majority of myocardial Fra-2 tg gp38+ cells co-expressed αSMA, collagen, ADAM12 and periostin, indicating a myofibroblast-like phenotype. Finally, gp38 expression correlated with collagen deposition (R=0.9, p< 0.0001) measured by Sirius Red staining. In vitro, sorted Lin-gp38+ cells isolated from Fra2 tg mice showed increased αSMA total protein and αSMA fibres that co-localized with stress fibres, resulting in a faster and stronger contraction capability of Fra2 tg cells (p< 0.0001, n=3). Proliferation of Fra2 tg cells was increased compared to WT cells (p=0.007, n=5), while apoptosis was unchanged (p=0.335, n=5). Rag2-/-Fra2 tg mice showed no myocardial fibrosis or Lin-gp38+ cell expansion. ECG parameters of Rag2-/-Fra2 tg mice did not differ from control mice, indicating that inflammation is necessary to acquire the Fra2-driven fibrotic phenotype and defects in the conduction system.

Conclusion: Fra2 overexpression and inflammation drive the differentiation of fibroblasts into myofibroblasts, leading to cardiac fibrosis and defects of the conduction system. This mechanism might be a therapeutic target for SSc patients with disorders of the cardiac conduction system.

The Effect of Nintedanib versus Mycopheolate Mofetil in the FRA2 Mouse Model of Systemic Sclerosis Associated Interstitial Lung Disease

Thuong Trin-Minh,[1] Yun Zhang,[2] Jörg Distler,[3] and Lutz Wollin[4], [1]University Erlangen-Nuremberg, Erlangen-Nuremburg, Germany, [2]University Erlangen-Nuremberg, Erlangen, Germany, [3]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany, Erlangen, Germany, [4]oehringer Ingelheim, Biberach, Germany

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a key driver of mortality in patients with systemic sclerosis (SSc). In lack of approved treatment it constitutes a high unmet medical need. Nintedanib is approved for the treatment of idiopathic pulmonary fibrosis. A recently completed Phase III clinical trial including patients with SSc-ILD (SENSCIS®) showed that nintedanib slows the loss of pulmonary function by 44% in patients with SSc-ILD relative to placebo, as measured by annual rate of decline in FVC over 52 weeks. Mycophenolate mofetil (MMF), an immunosuppressant acting on T and B lymphocytes is used in the clinical practice to treat patients with SSc.

Aim: To compare the activity of nintedanib and MMF in transgenic (tg) FRA2 mice a model of SSc-ILD

Methods: FRA2 mice at an age of 9 weeks were treated with MMF at 100 or 150 mg/kg qd or nintedanib 50 mg/kg bid and were sacrificed at an age of 16 weeks. Histological changes of pulmonary fibrosis were quantified by Ashcroft Scoring. In addition, whole lung sections were stained with Sirius Red and fibrotic area was determined using ImageJ. The amount of collagen protein in skin samples was determined via hydroxyproline assay. The degree of luminal occlusion of pulmonary arteries was examined histologically. The percentage of proliferating vascular smooth muscle cells was evaluated by triple staining for DAPI (nuclear staining), Ki67 (proliferation marker) and SM22. The percentage of apoptotic endothelial cells in the skin of mice was determined by double staining for CD31 (endothelial cells) and caspase 3 (apoptosis).

Results: Nintedanib effectively ameliorated pulmonary fibrosis in FRA2 tg mice and reduced the fibrotic area, the Ashcroft scores and the hydroxyproline content as compared to vehicle-treated FRA2 tg mice. In contrast, treatment of FRA2 tg mice with MMF at doses of 100 mg/kg or 150 mg/kg qd had only mild antifibrotic effects that did not yield statistically significant effects across the three different outcomes.

Treatment with nintedanib also ameliorated remodeling of the pulmonary arteries and significantly reduced the number of occluded pulmonary vessels, the number of proliferating vascular smooth muscle cells and the number of apoptotic endothelial cells. No effect on the remodeling of pulmonary arteries was observed with MMF.

Conclusion: In the FRA2 mouse model of SSc-ILD nintedanib ameliorates pulmonary fibrosis, proliferation of pulmonary vascular smooth muscle cells and apoptosis of microvascular endothelial cells. In contrast, MMF has minor effects on pulmonary fibrosis and no effects on vascular manifestations.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent findings have implicated CXCL4 in the pathogenesis of systemic sclerosis (SSc), while also indicating a potential role of this chemokine as a biomarker in SSc. Herein, we examined whether plasma levels of CXCL4-L1, a non-allelic variant of CXCL4, which displays a constitutive pathway of secretion by platelets and smooth muscle cells and is a stronger inhibitor of angiogenesis compared to CXCL4, differ between SSc patients and healthy controls. Furthermore, we investigated if CXCL4-L1 levels correlate with clinical and capillaroscopy features of SSc patients.

Methods: CXCL4 plasma levels were measured by ELISA in 94 SSc patients, 5 patients with very early diagnosis of SSc (VEDOSS) and 74 healthy controls. CXCL4-L1 plasma levels were measured by ELISA in 68 of 94 SSc patients, 9 VEDOSS patients and 58 of 74 healthy controls. Nailfold Video Capillaroscopy (NVC) and clinical data were collected from all patients. To compare levels of expression of CXCL4-L1 mRNA in peripheral blood mononuclear cells (PBMCs) between SSc patients with and without pulmonary arterial hypertension (PAH) and healthy controls we used information from the publicly available online microaray dataset GSE33463. Comparisons were performed using the Mann-Whitney U-test.

Results: Plasma levels of CXCL4 were significantly higher in SSc patients (mean±SD= 62.84 ± 82.32ng/ml) compared to controls (mean±SD= 32.67 ± 33.48ng/ml, p=0.0004) and correlated significantly with smocking (B=51.74, p=0.024) and presence of interstitial lung disease on high resolution computed tomography of the chest (B=33.47, p=0.042), after adjustment for age and gender. CXCL4-L1 plasma levels were increased in SSc patients (mean±SD=205.54±199.39pg/ml), compared to both VEDOSS patients (mean±SD=75.67±51.00 pg/ml, p=0.0158) and controls (mean±SD=82.29±114.88pg/ml, p< 0.0001) and correlated significantly with capillaroscopic parameters [dilatation score, (B=116.3, p=0.007), micohemorrhages score, (B=185.87, p=0.012)]. After correction for age and gender correlation with microhemorrhages score remained marginally significant (B=146.26, p=0.063). In terms of

mRNA expression CXCL4-L1 was increased in PBMCs of SSc patients compared to controls, as well as in PBMCs of SSc patients with PAH compared to SSc patients without PAH.

Conclusion: CXCL4-L1, an angiogenesis inhibitor, is increased in the peripheral blood of SSc patients both at the mRNA and protein levels. Correlation of CXCL4-L1 levels with capillaroscopic indices and PAH in these patients suggest that further prospective studies should examine whether CXCL4-L1 may serve as biomarker for vascular damage in SSc.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The CD4+ T cell subset driving the pathogenesis of systemic sclerosis (SSc) remains poorly understood. Many different CD4+ T cell subsets have been implicated, but previous studies on SSc have typically not used quantitative multi-color approaches on tissue biopsies. We have previously reported on the expansion of CD4+ cytotoxic T lymphocytes (CD4+CTLs) in the blood of SSc patients. Furthermore, CD4+CTLs are implicated in the pathogenesis of another autoimmune fibrotic disease, IgG4-related disease. We sought to quantify CD4+CTLs and other CD4+ T cell subsets in untreated SSc tissues from patients with diffuse cutaneous SSc (dcSSc).

Methods: Multi-color immunofluorescence was used to quantify CD4+ T cell subsets in 350 skin sections of thirty-five patients with early dcSSc enrolled in the ASSET trial (placebo-controlled trial of abatacept vs. placebo in early dcSSc, clinicaltrials.gov NCT02161406). Paired blood samples from 18 of these patients, along with 9 additional SSc blood samples recruited through the Massachusetts General Hospital (MGH), were used to quantify frequencies of, examine the TCR repertoire and explore the transcriptomes of circulating CD4+CTLs. All patient samples from the ASSET trial and 6 of 9 of the subjects recruited through the MGH were untreated at the time of collection. Twenty age-matched healthy donors and 19 non-fibrotic sarcoidosis patient samples were used as blood controls, while 10 skin samples from healthy donors were used as tissue controls.

Results: CD4+CTLs were expanded in the blood of SSc patients, showed marked clonal-restriction by TCR repertoire analysis and the magnitude of expansion correlated with the degree of tissue fibrosis. The transcriptomes of CD4+ CTLs from SSc patients enriched for gene sets suggesting enhanced metabolic activity, cell survival, and

conditioning by both type 1 and type 2 interferons. Quantitative multi-color immunofluorescence revealed that T_{H1}, T_{H2}, and T_{FH} cells are relatively rare populations in SSc tissues, comparable to those observed in normal skin, whereas CD4+CTLs are prominent and represent the most abundant CD4+ T cell subset in most dcSSc skin biopsies. Many of these cells synthesized IL-1β suggesting that they have been reactivated in tissues. We observed and quantified prominent activated caspase-3 staining, particularly in endothelial cells, and many endothelial cells upregulated MHC class II molecules in dcSSc skin biopsies.

Conclusion: The low abundance of infiltrating T_{H1}, T_{H2}, and T_{FH} cells in the skin of SSc subjects suggests that these CD4+ T cells are unlikely to be of pathogenic significance in this disease. In contrast, activated, clonally-expanded and tissue infiltrating CD4+CTLs likely drive the pathogenesis of SSc. The prominent accumulation of apoptotic HLA class II expressing endothelial cells in the lesions of these patients suggests that recurring immune mediated endothelial cell apoptosis may contribute to tissue damage and remodeling in this fibrotic disease. (Supported by Autoimmune Centers of Excellence awards from the NIAID to SP, DK, DF and JS)

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is an urgent unmet need for effective therapeutic approaches for Systemic Sclerosis (SSc), a systemic autoimmune disease characterized by progressive fibrosis of skin and multiple internal organs and

severe microvascular alterations. The molecular mechanisms responsible for the fibrotic process in SSc have not been fully identified, although numerous recent studies have demonstrated a crucial role of various protein kinases in the development of tissue fibrotic reactions. Here we examined the role of a novel group of kinases in the activation of fibrotic phenotype in SSc dermal fibroblasts.

PIM (Proviral Integration Moloney virus) family of serine/threonine protein kinases consists of three members PIM1, PIM2 and PIM3 that promote growth factor-independent proliferation of numerous cell types by phosphorylating a range of cellular proteins. Both PIM1 and PIM2 kinase are involved in the control of cell growth, differentiation and apoptosis. PIM kinases do not have an identified regulatory domain, therefore once transcribed they are constitutively active. Recent crystallography studies revealed that, unlike other kinases, PIM1 and PIM2 possess a hinge region which creates a unique binding pocket for ATP, thus offering a target for an increasing number of potent small-molecule PIM kinase inhibitors such as the novel PIM1/2 Kinase inhibitor VI we studied here.

Methods: PIM1 levels were assessed by Western blot analysis of cell lysates from confluent dermal fibroblasts obtained from skin biopsies from the leading edge of forearm lesions of patients with diffuse SSc of recent onset and from healthy donors. SSc dermal fibroblasts were grown in culture and treated with the PIM1/2 kinase inhibitor. Western blot analysis of cell lysates were performed to examine the effects of the PIM1/2 inhibitor employing specific antibodies for PIM1, αSMA, and housekeeping protein. Media from cell cultures were collected and Western blots for collagen type I and fibronectin were performed. Activation of PIM1 endogenous gene expression in normal fibroblasts was performed employing lentiviral CRISPR activation plasmid particles. Control cells were transduced with control lentiviral particles.

Results: SSc dermal fibroblasts displayed marked elevation of PIM1 levels in comparison with normal fibroblasts (>2-Fold). PIM1/2 kinase inhibitor treatment of cultured SSc dermal fibroblasts did not cause morphological changes or detectable cytotoxicity at the concentrations employed, however, the levels of type I collagen and fibronectin production were markedly decreased as a result of PIM1/2 activity inhibition. Lentiviral overexpression of PIM1 in normal dermal fibroblasts resulted in a remarkable upregulation of the expression and production of numerous profibrotic proteins including collagen type I, αSMA and fibronectin.

Conclusion: The results indicate that PIM1 plays an important role in the molecular mechanisms responsible for the exaggerated fibrotic process in SSc. Thus, inhibition of PIM kinases provides a novel therapeutic target for the development of potent antifibrotic drugs for SSc and other fibrotic disorders.

Genome-Wide DNA Methylation Signatures in Classical Monocytes from African Ancestry Patients with Systemic Sclerosis

Peter Allen,[1] Jena Wirth,[2] Nathan Wilson,[2] Jim Oates,[3] Melissa Cunningham,[2] Devin Absher,[4] and Paula Ramos[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Medical University of South Carolina, Charleston, [3]Division of Rheumatology & Immunology/Medical University of South Carolina, Charleston, SC, [4]HudsonAlpha Institute for Biotechnology, Huntsville, AL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare, fibrotic autoimmune disorder characterized by cutaneous and visceral fibrosis, immune dysregulation, and vasculopathy. It disproportionately affects individuals of African ancestry (AA) who, despite the higher disease severity, are dramatically underrepresented in research. Monocytes show heightened activation in SSc, and in AA relative to European ancestry individuals. Monocytes are thus a good target tissue for elucidating disease mechanisms. In this study, we sought to identify differentially methylated loci associated with SSc in classical monocytes from AA patients.

Methods: We profiled DNA methylation patterns on FACS-isolated classical monocytes (CD14++CD16-) from 12 female AA SSc cases and 12 female AA controls using Illumina's MethylationEPIC BeadChip. All patients met the 2013 ACR/EULAR classification criteria for SSc. After QC and data normalization, a linear mixed model analysis was computed to examine DNA methylation differences between patients and controls, including disease status as a random effect and the first two principal components as fixed effects. The best model was selected based off on the QQ plot. Associated CpGs identified as significant were used to identify the closest gene and then those genes were analyzed for common pathways and functions.

Results: In addition to CpGs near several pseudogenes, top differentially methylated CpGs (P< 10E-05) included those near the cilia and flagellar motility *CFAP44* gene, the T-cell surface glycoprotein *CD5*, the ubiquitin ligase *TRIM4*, the angiopoietin *ANGPTL4*, the DNA repair *FANCC*, the synthetase *OAS3*, and the transporter *SLC41A2*. The top genes have known immune, angiogenic, and transcription regulation roles.

Conclusion: These data support a role for DNA methylation differences in mediating sustained monocyte activation and susceptibility to SSc in AA. Many of the differentially methylated genes comprise pseudogenes and non-coding RNA genes, supporting a contribution of dysregulated regulatory elements to disease. Although DNA methylation studies in skin fibroblasts revealed an enrichment of extracellular matrix and focal adhesion genes, our results in monocytes support a dysregulation of genes involved in immune processes, which is consistent with gene expression studies in different peripheral blood subsets. Collectively, these results support the need to understand the regulatory architecture of SSc in different cell types and in individuals of different ancestries.

Identification of Differential Chromatin Accessibility Using ATAC-seq in a Novel 3D Tissue Culture System of Systemic Sclerosis

Tamar Wheeler,[1] Ji-Qing Chen,[1] Diana Toledo,[1] Bhaven Mehta,[2] Yue Wang,[2] Meredith Brown,[1] Rajan Bhandari,[3] and Mengqi Huang[4], [1]Dartmouth College, Hanover, [2]Geisel School of Medicine at Dartmouth, Hanover, NH, [3]Dartmouth College, Lebanon, [4]Geisel School of Medicine at Dartmouth College, Hanover, NH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although the majority of SSc research has focused on differential gene expression, recent studies havedemonstrated that non-coding epigenetic changes in chromatin accessibility are likely play a key role

in SSc biology. In this study we developed a system for analyzing differentially accessible regulatory regions in SSc-derived cell lines using Assay for Transposase Accessible Chromatin with sequencing (ATAC-seq) in a novel 3D *in vitro* skin-like tissue model.

Methods: SSc and healthy control (HC) dermal fibroblast (FB) lines were isolated and expanded from skin biopsies. All patients met 2013 ACR/EULAR criteria for SSc.FBs were seeded in transwell chambers and cultured for 5 weeks to obtain self-assembled stromal (SAS) tissues in a simple 3D tissue model that recapitulates SSc biology. ATAC-seq was performed on both monolayer/2D fibroblast cultures and 3D tissues following tissue dissociation. ATAC-seq libraries were sequenced. Paired end reads were aligned to the hg19 reference genome and 300bp peaks were called in ZINBA. Data underwent quality control analyses and unsupervised hierarchal clustering. Genomic location of peaks was determined using ChIPseeker. The integrative genomics viewer (IGV) was used to analyze the genomic context of specific differentially accessible regions.

Results: ATAC-seq libraries contained a large number of reads (~30 million) and had comparable accessibility profiles to standard data sets (Fig. 1A-D). SSc FBs contained significantly more open chromatin (Fig. 1E) and the percentage of peaks within distal/intergenic regions was significantly higher than in HC FBs (Fig. 1F). In unsupervised hierarchal clustering of the top 50 differential 300bp peaks in both 2D and 3D tissues, SSc and HC tissues clustered by disease state. A differentially accessible region of significant interest was identified in both 2D and 3D individual heatmaps as well as a combined 2D/3D heatmap in which it was the only genomic peak which distinguished between SSc and HC samples (Fig. 1G). This region falls within an intron of a gene on chromosome 8 and contains a putative enhancer predicted to contain a binding site for the transcription factor STAT3.

Conclusion: We were able to produce high quality data from both 2D and 3D cultures. Preliminary analysis of ATAC-seq data demonstrates that SSc fibroblasts maintain a distinct chromatin accessibility profile as compared to HC fibroblasts, characterized by increased global accessibility. The majority of these differentially accessibility peaks reside in genomic regions commonly associated with regulatory elements. Additionally, we were able to identify a region of significant interest containing a putative enhancer region and predicted binding site for STAT3, a transcription factor known to be dysregulated in SSc.

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The TβRIIΔk-fib transgenic mouse model of systemic sclerosis (SSc) develops constitutive structural vasculopathy with vessel wall fibrosis and is susceptible to pulmonary hypertension (PH) induced by the VEGF receptor inhibitor SU5416. This model of SSc-PH results from pulmonary endothelial cell (EC) injury leading to endoluminal EC proliferation. The pan-peroxisome proliferator-activated receptor (PPAR) agonist Lanifibranor has recently been tested in a phase II clinical trial in SSc, and PPAR nuclear receptors are reported to have beneficial effects on haemodynamics in human PH. We have explored the effect of lanifibranor on TβRIIΔk-fib mice receiving SU5416 to trigger PH.

Methods: 8-12 week old TβRIIΔk-fib mice (n=33) and littermate sex-matched WT mice (n=29) were administered one of two doses of lanifibranor (30 mg/kg- low dose- or 100 mg/kg- high dose) or vehicle administered by daily oral gavage for 23 days. On day 2 a single 50mg/kg dose of SU5416 in carboxymethylcellulose vehicle was administered by intraperitoneal injection. Right (RVSP) and left ventricular (MABP) pressures and Fulton index were measured on terminally anaesthetised mice according to local protocols. Histological and immunohistochemical assessment of pulmonary and cardiac tissue was performed.

Results: As expected, no significant differences in MABP were seen across groups. All mice had some elevation of RVSP compared to published baseline pressures in this model due to administration of SU5416 in all groups. TG mice treated with vehicle developed elevated RVSP compared to WT mice in the vehicle groups consistent with previous studies [1]. TG mice treated with high dose lanifibranor demonstrated generally higher RVSP than those treated with vehicle or low dose lanifibranor, for instance: mean RVSP TG-SU-100 35.89 ±4.1; TG-SU vehicle 29.0±2.7; $p < 0.05$) with some values exceptionally high (54 mmHg; 49 mmHg; figure 1). Increased endothelial cell proliferation within pulmonary vessels for mice receiving lanifibranor was identified as the likely cause using Ki-67 immunohistochemistry staining. Despite the elevation in RVSP in those mice treated with lanifibranor at high dose, there was no significant increase in RV mass when compared to other groups (for instance, RV/LV+S in TG-SU-100 0.24±0.007; WT-SU-100 0.24±0.005; not significant; figure 2).

Conclusion: Treatment with high dose lanifibranor exacerbated SU5416-induced pulmonary hypertension in the TβRIIΔk-fib mouse model of SSc without resultant increases in RV mass according to Fulton index. Mechanistically, we propose that agonism of different PPAR isoforms in the pulmonary circulation results in exaggerated EC proliferation after SU5416 leading to paradoxical worsening of PH, but protection from the right ventricular hypertrophy that occurred

Figure 1: Right ventricular systolic pressure following Lanifibranor administration

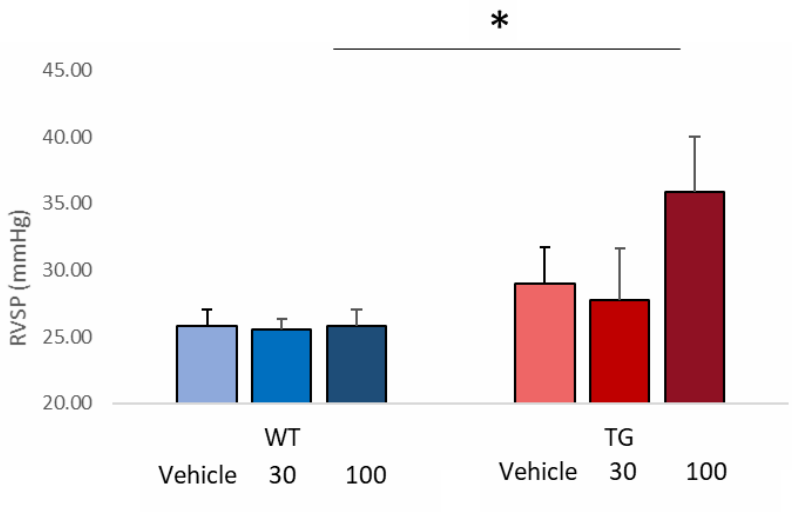

Figure 2: Fulton index following Lanifibranor administration

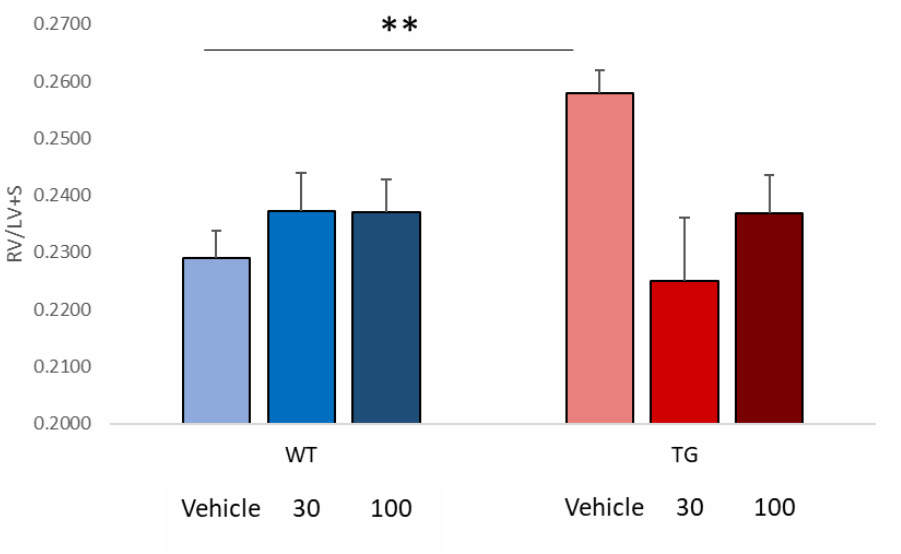

*p<0.05, **p<0.01

in control mice. Thus, the right ventricular outcomes in our study suggest that there might be protection against RV dilatation and hypertrophy in other forms of murine PH and in human PAH that may positively impact on clinical outcome.

WIF1	86.87	0.36	0.27	0.01	<0.001

Background/Purpose: We have examined whole skin biopsy gene expression by RNAseq in a rare subgroup of scleroderma with both systemic sclerosis (SSc) and concurrent keloidal morphea (KM). We hypothesised that this subtype of localised scleroderma would provide exceptional insight into fibroblast activation in vivo relevant to skin fibrosis in systemic sclerosis and suggest new potential molecular markers for classification.

Methods: 4mm skin biopsies were taken from forearm skin of SSc cases classified as limited (lcSSc) (n=5) or diffuse (dcSSc) (n=7). All patients met ACR/EULAR criteria for classification of SSc. In 4 cases there was concurrent KM and

4mm skin were also taken from these lesions. Control biopsies were taken from forearm skin of healthy individuals (HC) (n=4). Whole genome expression analysis was performed by RNAseq. Data were normalised and scaled. Gene expression analysis was undertaken and differentially expressed genes were compared across the clinical subgroups using ANOVA with Benjamini-Hochberg post-hoc correction. The 500 most differentially expressed genes were identified, and unsupervised clustering was performed using CIMminer (Bethesda, Maryland, USA). Integration of the candidate genes from ANOVA, and principal component analysis (PCA) was carried out to identify instructive genes for a molecular classifier.

Results: RNAseq identified over 13000 expressed genes. PCA discriminated 4 unique clusters, with keloidal morphea and HCs being the most distinct. PC1 accounted for 33% and PC2 for 22% of variation. Initial analysis identified over 3000 significantly different genes expressed by paired analysis. The 500 most significantly differentially expressed genes (all with $p < 0.001$) were selected. Unsupervised hierarchical clustering of gene expression based on these results, showed clear clustering of the keloidal morphea group, and the HCs. The majority of lcSSc and dcSSc patients clustered to their patient subgroups (Figure 1). Correlation between ANOVA and PCA results highlighted 100 key genes shared across both analysis results. These included genes upregulated in SSc: SFRP4, THY1, COMP, ADAM12, THBS4, ADAMTS12 (table 1) and others with lower expression than in HC: WIF1, KLF5. These include several implicated in pathogenesis or included in recent candidate biomarkers for skin disease in SSc.

Conclusion: We show the high value of RNAseq and the unique strength using skin biopsies from SSc with concurrent keloidal morphea, histologically characterised by dense fibro-proliferation, to define profibrotic genes relevant to SSc. This provides powerful insight into pathogenesis and candidate molecular markers for classification across the scleroderma spectrum.

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is characterised by autoimmunity, fibrosis and vasculopathy. There is striking heterogeneity in skin fibrosis that is likely to reflect the balance between pro- and anti-fibrotic pathways underlying spontaneous regression of skin fibrosis in late stage diffuse SSc. We have studied potential serum markers

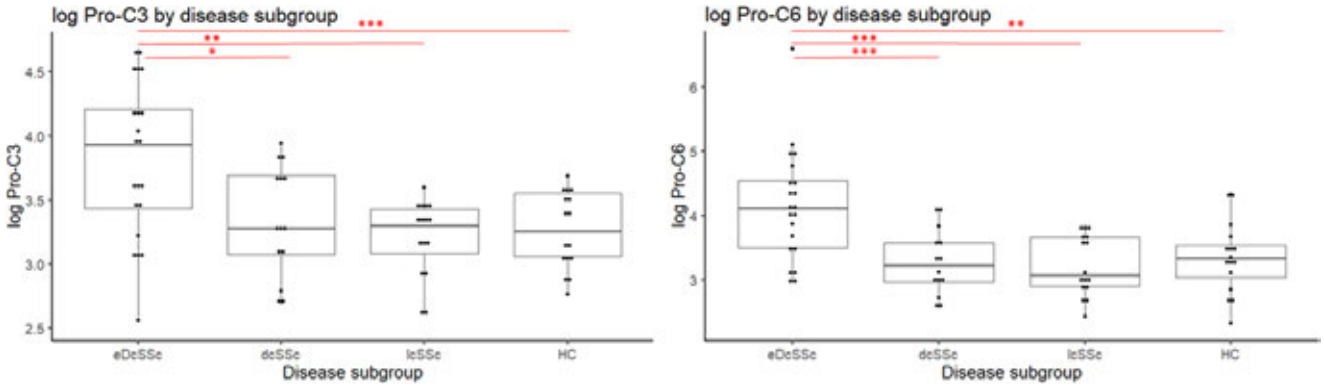

Figure 1. Box plots to show the difference in expression of a) logPro-C3, and b) logPro- C6 in different subgroups in SSc and healthy controls. Significance on subgroup analysis indicated by * p<0.05, **p<0.01, ***p<0.001.

of profibrotic activity in SSc, with a view to understanding their relationship with progression of fibrosis as measured by the modified Rodnan skin score (MRSS) to better define cases likely to respond to fibrosis-targeted therapies.

Methods: We prospectively recruited a cohort of well characterised patients (the BIOPSY cohort) from across the scleroderma spectrum. In total 67 patients had adequate serum and plasma samples to be included in the analysis (21 early diffuse disease (dcSSc) (< 5 years disease duration), 14 established dcSSc, 16 limited SSc (lcSSc), 16 healthy controls (HC)). MRSS was recorded at the time of sample collection. Standard and novel measures of serum

or plasma markers were undertaken by immunoassay (20 in total) reflecting extracellular matrix (ECM) turnover or cytokine drivers of fibrosis, and analysed at the same time point to reduce any batch effect.

Results: Our results confirmed that 13 analytes showed significant differences in concentration by subgroup using one-way ANOVA. Markers of collagen synthesis were significantly different between the subgroups (Pro-C6, Pro-C3, PIIINP) (Figure 1), while markers of collagen degradation were not significantly altered (C3M, C6M, C4M2, C7M) (Table 1). This difference was most significant between the early dcSSc subgroup compared with the other subgroups (Student t-test with Bonferroni correction). There was significant upregulation of IL-6, MCP-1, and oncostatin M in SSc compared to HC. Consistent with other reports the ELF score, originally validated in liver fibrosis, was significantly higher in the SSc patient cohort. There were significant correlations between several candidate profibrotic serum markers and MRSS: Pro-C3, Pro C6, PIIINP, and IL6 (all $p< 0.01$) (Figure 2).

Conclusion: Our results show the utility of extended patient cohorts to delineate fundamental biology in SSc. We identify key pro-fibrotic molecular markers upregulated in SSc and correlated these to extent of skin fibrosis. Markers of collagen III and collagen VI synthesis are particularly raised, especially in the early stages of the disease. We did not find any significant difference between SSc subgroups and healthy controls for markers of collagen degradation. These promising cross-sectional data suggest that therapies targeting drivers of fibrosis are most likely to show benefit for skin in early dcSSc. This will be further explored longitudinally in the BIOPSY cohort.

Proteomic and Transcriptomic Analysis of Human Eosinophilic Fasciitis Fibroblasts

Benjamin Chaigne,[1] Claire Fernandez,[2] Morgane Le Gall,[2] Philippe Chafey,[2] Benjamin Saintpierre,[2] Virginie Salnot,[2] Francois Guillonneau,[2] Claire Le Jeunne,[3] and Luc Mouthon[4], [1]Cochin University Hospital, Paris, France, [2]Cochin Institute, Paris, France, [3]Paris Descartes University, Cochin Hospital, Internal Medicine department, Paris, France, [4]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic fasciitis (EF) is a rare scleroderma-like disorder with less than 200 cases reported. Due to the rarity of the disease, data regarding its pathophysiology are lacking. Herein we aimed at studying the transcriptome and the proteome of EF fibroblasts.

Methods: Skin fibroblasts from EF patients (n=4), systemic sclerosis (SSc) patients (n=4), and healthy controls (HC) (n=4), were cultured and harvested for transcriptomic and proteomic analysis. Analyses were performed using next

generation sequencing and label-free quantification, respectfully. Functional analyses were performed using Ingenuity Pathway Analysis and Panther softwares.

Results: Five hundred and nine genes involved in 14 biological processes (BP) and 199 pathways were differentially expressed between EF and control groups. Among them, the circadian clock system (CCS) ($p=1.70\ 10^{-9}$), the plasminogen-activating cascade (PAC) ($p=3.82\ 10^{-5}$), the FGF signalling pathway ($p=1.15\ 10^{-4}$), and the integrin signalling pathway ($p=1.33\ 10^{-3}$) were overrepresented. When comparing EF to HC genes, Panther showed overrepresented down-regulated pathway including CCS ($p=1.71\ 10^{-12}$), and overrepresented up-regulated pathways such as flavin biosynthesis, ($p=9.22\ 10^{-4}$), PAC ($p=1.19\ 10^{-6}$), de novo purine biosynthesis ($p=1.63\ 10^{-3}$), FGF signalling pathway ($p=1.47\ 10^{-3}$) and integrin signalling pathway ($p=9.14\ 10^{-4}$). When comparing EF to SSc genes Panther showed overrepresented down-regulated CCS ($p=2.51\ 10^{-4}$).

Two hundred and twenty four proteins involved in 10 BP and 126 pathways were differentially expressed between EF and control groups. When comparing EF to HC proteins, Panther showed specific overrepresented up-regulated biological processes such as vesicle-mediated transport ($p=4.66\ 10^{-5}$) and intracellular protein transport ($p=1.24\ 10^{-4}$), and overrepresented up-regulated pathways such as 5-hydroxytryptamine degradation (5-HTD) ($p=1.56\ 10^{-4}$) and overrepresented down-regulated pathways such as heterotrimeric G-protein signalling pathways-rod outer segment photo-transduction (HTGSP) ($p=1.24\ 10^{-4}$). When comparing EF to SSc proteins, Panther showed specific overrepresented down-regulated biological processes such as 5-HTD ($p=4.48\ 10^{-4}$), and overrepresented down-regulated pathways such as HTGSP ($p=1.98\ 10^{-4}$), and ubiquitin proteasome pathway ($p=1.05\ 10^{-3}$).

Conclusion: This work described the transcriptome and the proteome of EF fibroblasts and highlighted significant specificities of EF fibroblasts when compared to HC and SSc.

Profibrotic Macrophage Activation in Systemic Sclerosis Is Dependent on the Mechanosensing MRTF-A Pathway

Tricia Lim,[1] Kristina Krogmannova,[1] Shiwen Xu,[1] Bahja Ahmed Abdi,[2] David Abraham,[1] Christopher Denton,[3] and Richard Stratton[1], [1]University College London, London, United Kingdom, [2]University College London, London, [3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An M2-like alternative activation state of macrophages has been linked to the pathogenesis of several fibrotic disorders, including systemic sclerosis (SSc). MRTF-A is an essential mechanosensing transcription factor involved in cellular responses to stiff fibrotic tissue, but its role in controlling macrophage polarisation is unknown. However, genome database profiling identifies the promoter region of the interleukin 13 receptor gene, IL13Rα1, critical to M2 polarisation, as a target of MRTF-A.

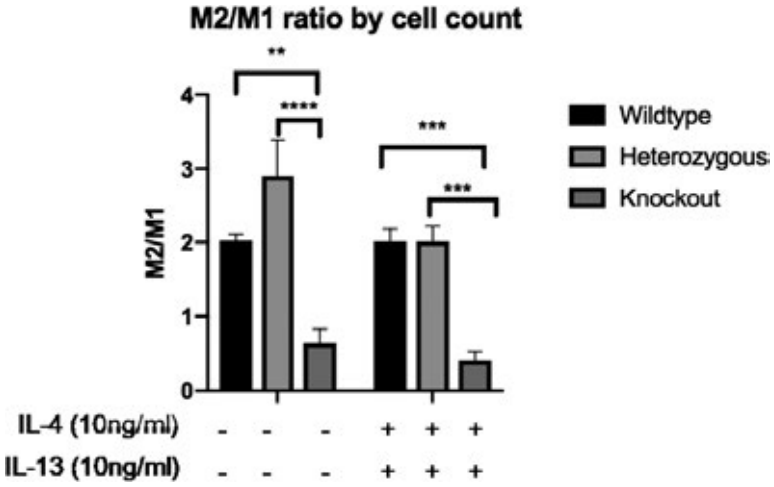

Figure 1. Bone marrow derived macrophages from MRTF-A knockout, heterozygous and wild type mice were cultured on 50kPa Softwell gels with or without cytokine stimulation with IL-4 and IL-13 combined, used to polarise the cells. Morphologic analysis was used to identify M2-like elongated cells or else more rounded M1-like morphology. In the KO cells cytokine treatment failed to induce the M2-like morphology (**p=0.0011, ***p=0.0008, ****p<0.0001).

Methods: MRTF-A knockout (KO) and wild type (WT) control mice, were subject to excisional wound healing and *ex vivo* polarisation of bone marrow-derived macrophages, in order to model M2-responses. Peripheral blood mononuclear cells from SSc patients (N=9) were cultured in M-CSF (4ng/ml) for 7 days to derive M2-like human macrophages. 50kPa Softwell gels were used to reproduce the effect of stiff tissue microenvironments. Morphology (elongated M2-like, round M1-like), and gene expression by qPCR were used to profile the macrophage activation state (IFNγ for M1-like, Arg1 and CD206 M2-like, IL13Rα1 predicted MRTF-A responsive, and IL-4R, predicted non-responsive). Secreted TGFb was assayed by ELISA. CCG-257081 (CCG) (10μM), an MRTF-A pathway inhibitor, was used to block MRTF-A.

Results: In mice, MRTF-A WT (2.02±0.086, mean±SEM) and MRTF-A Het macrophages (2.24±0.716) exhibited significantly higher M2/M1 cell morphology ratio compared to MRTF-A KO macrophages (0.640±0.193) (p=0.0373 and p=0.0165 respectively)(see figure below). Excisional wound repair was also delayed (day 7, WT 47.7±13.9, KO 98.6±19.3, p< 0.037; day 11, WT 3.3 ±1.1, KO 27.4 ± 4.1 p< 0.011, % basal wound area). SSc macrophages showed M2-like activation signature under basal conditions (high Arg1, CD206, M2-morphology), partially reversed by CCG, reducing CD206 (basal 9.16 ± 4.26, CCG treated 1.79±0.98, p=0.0039), supressing the elongated M2-like morphology (SSc basal 4.04, ±0.74, cells per field, CCG treated 0.46±0.18, P=0.0017), and inhibiting the secretion of TGFβ (SSc basal 7.0± 4.9 pg/ml, CCG treated 0.0±1.7 P=0.039). The M1-like inflammatory marker IFNγ was increased by CCG treatment consistent with repolarisation (SSc basal 2.02±0.54, CCG treated 10.4±3.6, p=0.0039). As a direct target of MRTF-A, IL13Rα, was decreased by CCG (21.5±3.39) compared to control (83.2±19.9, p=0.0252), and in mice KO macrophages showed decreased IL13Rα1:IL4R ratio, indicating a pathway selective effect. However, paradoxical elevation of Arg1 in some SSc cells following CCG treatment (SSc basal 7.11±2.89, CCG treated 19.19±8.31, p=0.027), and induction of Arg1 in KO mouse macrophages by polarising cytokines, indicates that not all M2-like responses were affected.

Conclusion: Additional to a pivotal role in myofibroblast function, loss of MRTF-A results in reduced IL-13Rα1 and attenuated cytoskeletal changes associated with M2-like polarisation. Experiments using the CCG-257081 inhibitor in human macrophages support this model, and indicate possible therapeutic potential in inhibiting the MRTF-A mechanosensing pathway by targeting IL4/13.

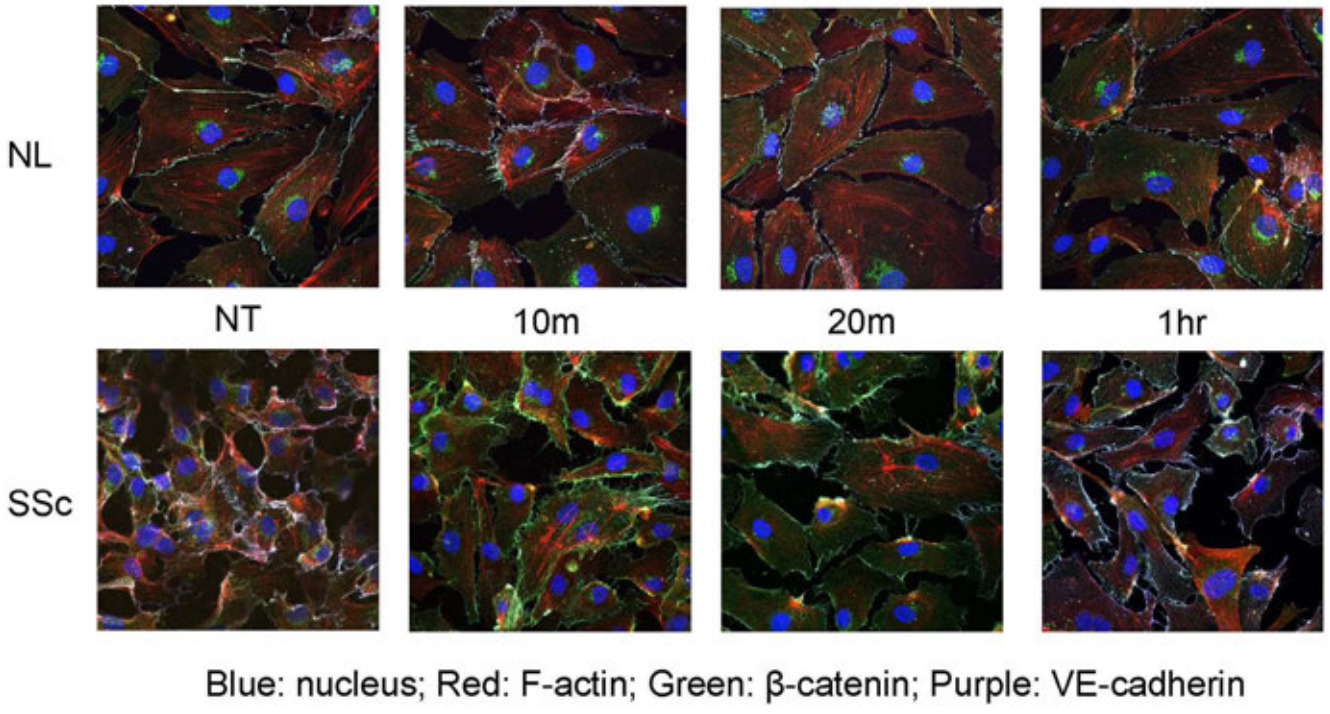
Dissecting the Cellular Mechanism of Prostacyclin Analog Iloprost in Reversing Vascular Dysfunction in Scleroderma

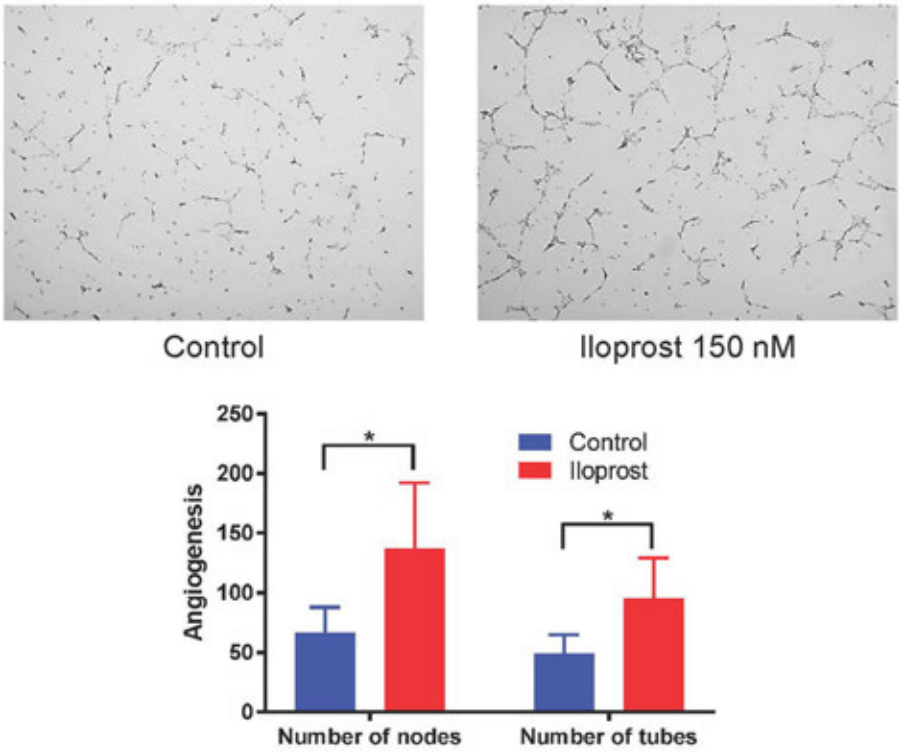
Pei-Suen Tsou,[1] Nicholas Flavahan,[2] and Dinesh Khanna[3], [1]University of Michigan, Ann Arbor, MI, [2]The Johns Hopkins University School of Medicine, Baltimore, MD, [3]Scleroderma Program, Division of Rheumatology, Department of Internal Medicine, Autoimmunity Center of Excellence, University of Michigan, Ann Arbor

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Iloprost improves Raynaud's phenomenon and digital ulcers in scleroderma (SSc) patients. This is hypothesized to reflect anti-platelet and vasodilatory effects. Different trials and cohorts have reported efficacy of Iloprost for 4-8 weeks [1] despite a short half-life (0.57hr; [2]). Adherens junctions, which are formed by clustering of VE-cadherin on neighboring endothelial cells (ECs), regulate numerous endothelial properties, including cell morphology, signaling and phenotype [3]. When junctions are disrupted, VE-cadherin and β-catenin are disengaged from



Immunofluorescence staining of VE-Cadherin (purple), beta-catenin (green), F-actin (red) after Iloprost incubation in normal and SSc endothelial cells.



Iloprost significantly increased tubulogenesis in SSc endothelial cells.

the cell membrane and can contribute to vascular dysfunction and endothelial to mesenchymal transition (Endo-MT). We hypothesized that vascular dysfunction in SSc reflects disruption of EC adherens junctions and that the vascular protective effect of Iloprost is mediated by strengthening of these junctions in SSc ECs.

Methods: Dermal ECs were isolated from biopsies of healthy subjects and SSc patients. ECs were treated with Iloprost (150nM) for various times. Visualization of cellular localization of VE-cadherin, β-catenin, and F-actin was done by immunofluorescence. Tubulogenesis was examined using Matrigel in vitro tube formation assay. Inhibition of VE-cadherin clustering was achieved by a function blocking antibody. Cell proliferation was assessed by BrdU incorporation. Cell migration was examined using Incucyte imaging. Endo-MT was induced by treating healthy ECs with TGFβ for 72 hrs. Gene expression was determined by qPCR. Plasma VE-cadherin was determined using ELISA. T-tests were used to compare differences between groups, and $P < 0.05$ considered significant.

Results: Cell staining demonstrated disruption of adherens junctions and disorganized F-actin filaments in SSc compared to normal ECs. When stimulated with Iloprost, there was a significant increase in VE-cadherin and β-catenin clustering at cell junctions up to 1 hour of incubation in both normal and SSc ECs. However, F-actin organization in SSc ECs was still distorted (Fig 1). Iloprost treatment increased EC tubulogenesis in both normal and SSc ECs (Fig 2). This effect was inhibited by a neutralizing antibody to VE-cadherin. Iloprost had minimal effect on EC proliferation. In normal ECs, TGFβ induced Endo-MT with upregulation of *ACTA2*, *S100A4*, and *SNAI1*, and downregulation of *PECAM1*, *CDH5*, and *FLI1*. This process was blocked by Iloprost co-incubation; Iloprost normalized the expression of all genes except for *FLI1*. Similar results were observed in SSc ECs treated with Iloprost for 72 hrs (Table 1). Plasma level of VE-cadherin was significantly elevated in SSc compared to healthy controls.

Table 1. Gene expression after Iloprost treatment in SSc ECs (mean ± S.D.)	
Gene	**Expression fold change (n=2 patient pairs)**
COL1A1	0.22 ± 0.30
ACTA2	0.36 ± 0.16
S100A4	0.29 ± 0.07
CDH5	2.32 ± 1.34
PECAM1	6.08 ± 2.95
SNAI1	0.18 ± 0.26
FLI1	0.79 ± 0.50

Conclusion: Our data suggests that long lasting beneficial effects of Iloprost may stem from its ability to stabilize endothelial adherens junctions, increasing EC tubulogenesis, and inhibiting Endo-MT. These results provide a mechanistic basis that supports the use of Iloprost in treating SSc patients with Raynaud's phenomenon and digital ulcers.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Epigenetic regulation, including histone acetylation, plays an important role in scleroderma (SSc) fibrosis. The binding of the bromodomain and extra-terminal domain proteins (BRDs) to acetylated histone residues is critical for gene transcription. It has been shown that BRD inhibitor JQ1 prevents fibrosis in various tissues. However, the involvement of BRDs in SSc fibrosis has not been examined. This study sought to determine the expression and functions of BRDs in SSc fibroblasts. We hypothesize that modulating BRDs by JQ1 will alleviate SSc fibrosis.

Methods: Dermal fibroblasts were isolated from biopsies from healthy subjects or patients with diffuse cutaneous SSc (dcSSc). Fibroblasts were treated with JQ1 (0.01-22μM) for 48 hours. Knockdown of BRD2, BRD3, or BRD4 was achieved by siRNA transfection. Gene expression was determined by qPCR. A scratch wound assay and gel contraction assay were used to evaluate fibroblast function. Cell proliferation was assessed by ki67 immunofluorescence, BrdU incorporation, as well as Incucyte imaging. The *in vivo* anti-fibrotic efficacy of JQ1 was determined in a bleomycin-induced skin fibrosis mouse model. A t-test was used to compare differences between groups, and a p-value of < 0.05 was considered significant.

Results: BRD inhibitor JQ1 dose-dependently downregulated pro-fibrotic genes including *ACTA2*, *COL1A1, and CTGF* in dcSSc fibroblasts. It also downregulated *BRD4* but upregulated *BRD2*. In addition, JQ1 treatment inhibited cell migration, proliferation, and gel contraction mediated by dcSSc fibroblasts. Daily administration of JQ1 (50mg/kg) in mice prevented bleomycin-induced skin fibrosis. The expression of *BRD2*, *BRD3*, and *BRD4* were similar in fibroblasts from healthy controls and dcSSc patients. To determine which BRD is involved in the anti-fibrotic effect of JQ1, we knocked down BRD2, BRD3, or BRD4 in dcSSc fibroblasts. Surprisingly, knockdown of BRD2, 3, or 4 had minimal effect on cell proliferation. BRD4 knockdown in dcSSc fibroblasts resulted in down-regulation of *ACTA2* and *COL1A1* and relaxed gel contraction. In contrast, BRD2 knockdown led to upregulation of *COL1A1* while it had no effect on gel contraction.

Conclusion: BRD modulation by JQ1 showed promising anti-fibrotic effects both *in vitro* and *in vivo*. JQ1 decreased profibrotic gene expression in dcSSc fibroblasts, and inhibited cell migration, proliferation, and gel contraction, which are the three manifestations of dcSSc fibroblasts. Our results suggested that BRD4 is pro-fibrotic while BRD2 might be anti-fibrotic. We believe that BRD modulators have the potential of becoming therapeutics for SSc patients in the future. These results also revealed the specific involvement of BRD2 and BRD4 in SSc fibrosis.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Human plasmacytoid dendritic cells (pDCs) have been implicated in the pathogenesis of Systemic Sclerosis (SSc) through their ability to infiltrate the skin and secrete interferons (IFN), interleukin-6 (IL-6) and other proinflammatory chemokines directly, or through type-I IFN response of resident cells. Blood dendritic cell antigen 2 (BDCA-2) is a human-specific pDC-type II C-type lectin that potently inhibits IFN secretion. Here we determined the effects of CBS004, a novel monoclonal antibody against BDCA-2, on Toll-like receptor (TLR)-induced transcriptome and IFN secretion in pDCs from healthy volunteers (HV) or patients with SSc in vitro, and tested its effect on two different xeno-transplant mouse models of human pDC dependent tissue inflammation and fibrosis.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from 26 SSc patients and 16 HV. IFN secretion were evaluated by ELISA. TLR7-9 stimulation was induced by Imiquimod or ODN. pDCs were isolated by magnetic cell sorting. Full transcriptome was analysed by RNA-sequencing. For the xenotransplant models, NOD/SCID mice were injected in the tail vein with $25x10^4$human pDCs, 12 h after topical application of Imiquimod for the inflammation model, and along bleomycin skin injections in the fibrotic model. CBS004 was delivered by intraperitoneal injection at 5 mg/kg. Harvested skin was analysed by FACS for human pDC infiltration, by real-time PCR using a mouse type-I IFN response array (Qiagen) and by histology for dermal thickness.

Results: PBMCs from SSc patients spontaneously produced higher levels of IFN-I compared to HV ex vivo (206.7±23.4 vs. 43.4±6.8 pg/ml, P< 0.0001). CBS004 significantly inhibited basal levels of IFN-I in 83% of SSc samples. TLR9 stimulation of SSc PBMCs induced >30-fold increase in IFN-I secretion (7167±4377 pg/ml), which was completely abrogated by treatment with CBS004 (209±40.5 pg/ml, P< 0.001). RNA-seq analysis of human pDCs stimulated with TLR-9 agonist revealed 168 Differentially Expressed Genes (DEGs, FDR < 1%) mapping to IFN, JAK/STAT, IL-6, NF-kB and angiogenesis pathways. Pretreatment with CBS004 prevented upregulation of most DEGs, which drove an expression profile similar to non-stimulated pDCs. In the xenotransplant model, tail vein injection of pDC resulted in detection of human pDCs in the skin (0.3%) with at least 2-fold upregulation of 35/74 mouse type-I IFN response genes including Ccl2, 4, 5 and Cxcl10, Ifit1, 2 and 3, Mx1 and 2, Oas1, Tlr7, 8 and 9 compared to imiquimod treatment alone (P< 0.005). Mice receiving IP injection of CBS004 had a 3-fold reduction in infiltrating pDCs (0.1%) and suppression of 85% of the type-I IFN response genes upregulated by pDC injection (Anova P< 0.01). In the bleomycin model, pDC injection significantly increased dermal thickness (30%, P< 0.01), which was completely prevented by CBS004 treatment.

Conclusion: Our study demonstrates that BDCA-2 targeting with CBS004 mAb may block both the spontaneous and TLR dependent pDC driven IFN activation in Scleroderma. Further, we show that BDCA2 targeting with CBS004 can revert human pDC driven tissue inflammation and fibrosis in two distinct human pDC xenotransplant mouse models.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is an autoimmune disease characterized by fibrosis and inflammation. Multiple organ systems are affected including the skin, gastrointestinal tract, vasculature, and lungs (Katsumoto, Whitfield, & Connolly, 2011). Gene expression analyses have identified four distinct molecular subtypes (inflammatory, fibroproliferative, normal-like, and limited) despite the heterogenous presentation of the disease. Microbial dysbiosis has been implicated previously in SSc skin and lower GI tract, (Arron et al., 2014; Volkmann, 2017), but

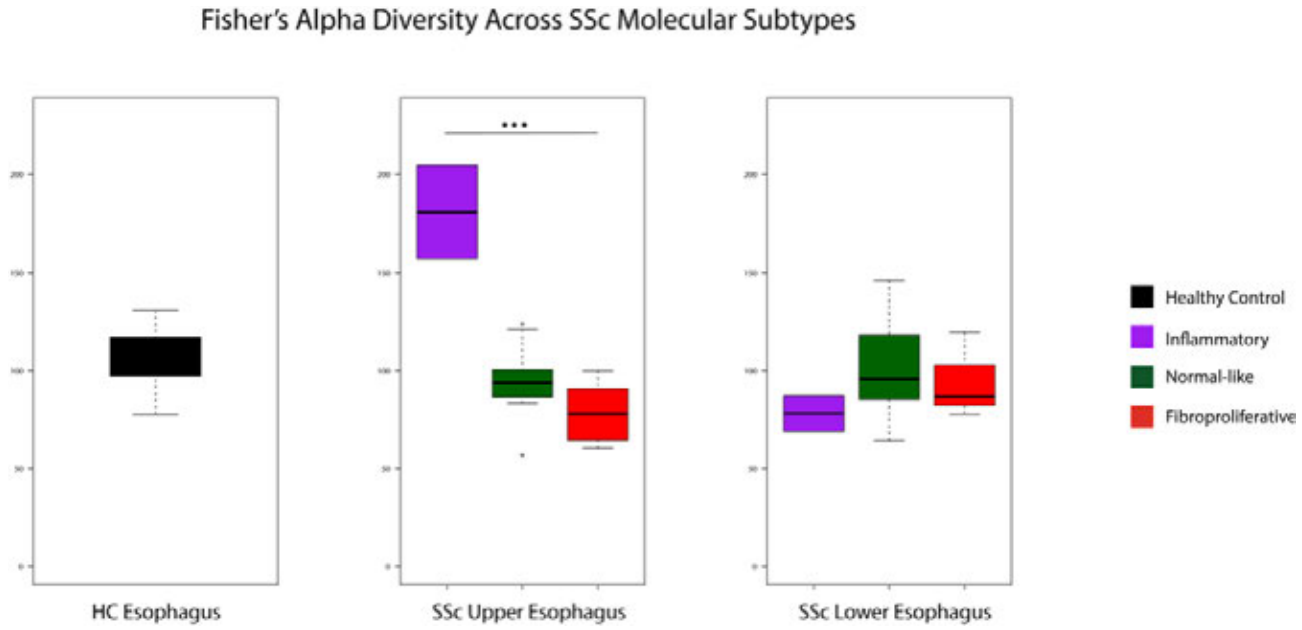

Figure 1. Alpha Diversities by molecular subtype across esophageal sites.

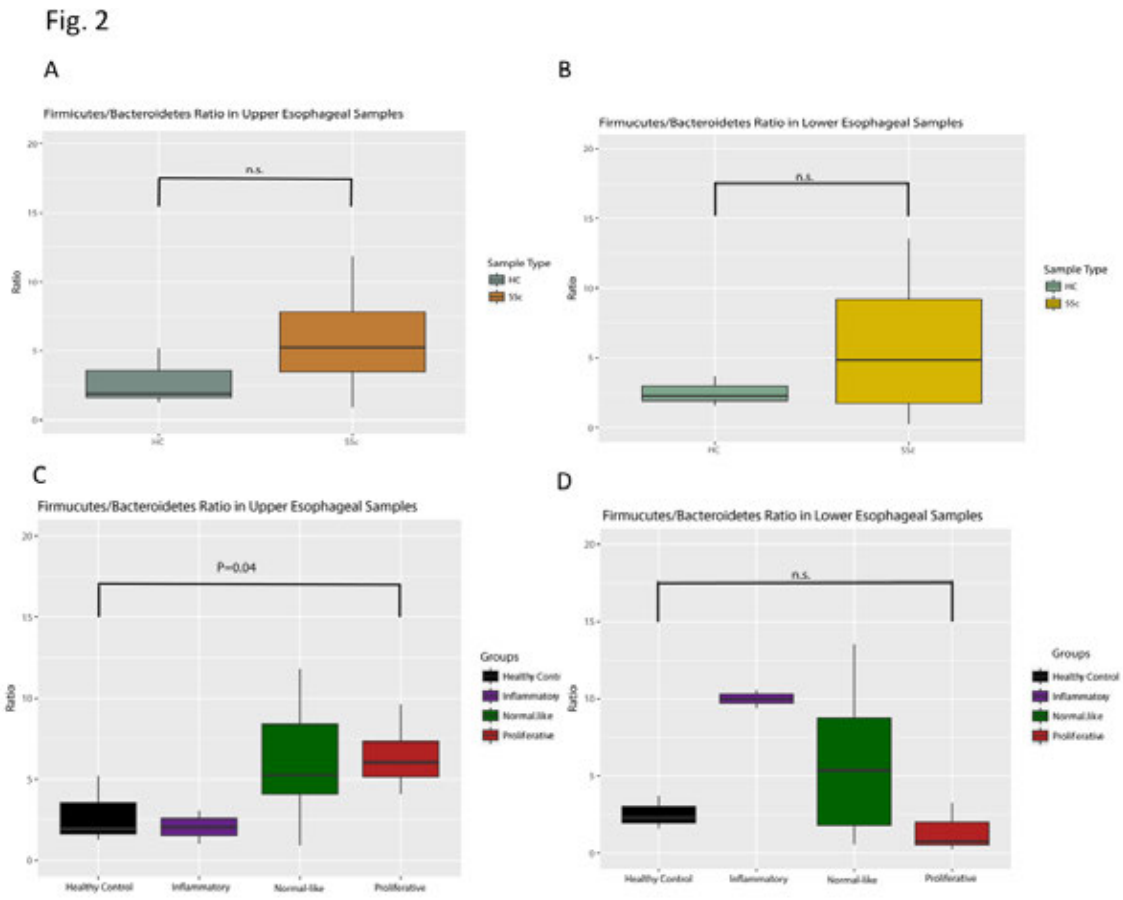

Figure 2. Firmicutes to Bacteroidetes ratios for healthy controls versus SSc patient samples in the upper esophagus, (A) the lower esophagus, (B), the upper esophagus stratified by molecular subtype (C), and the lower esophagus stratified by molecular subtype (D).

Fig.3

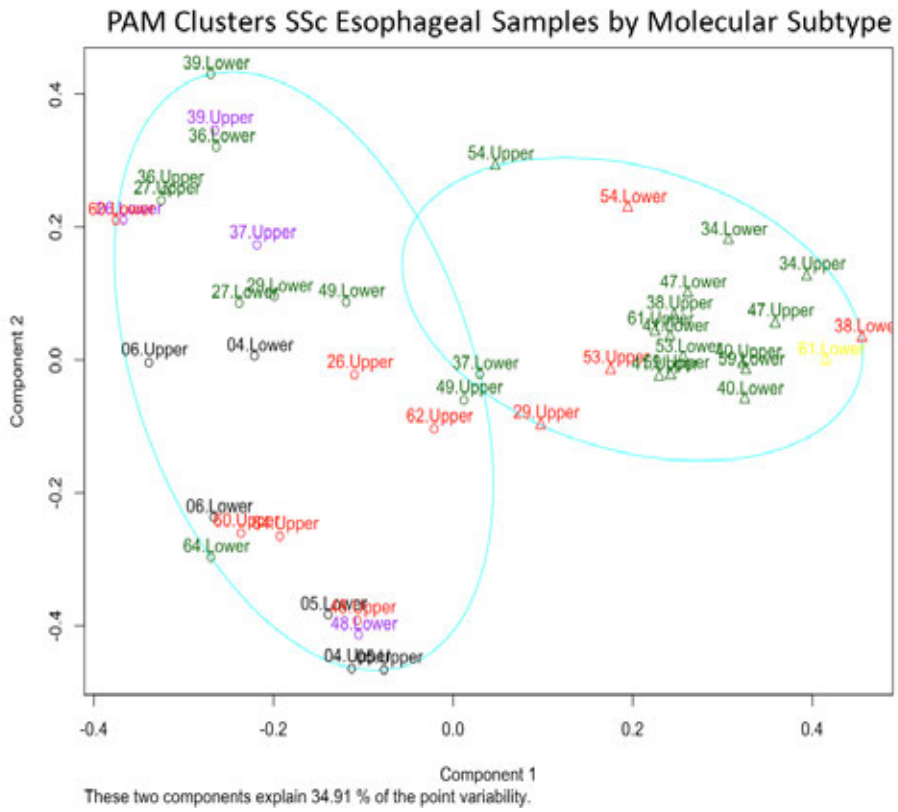

Figure 3. Partition Around Medoids (PAM) clustering of SSc patient esophageal samples based on metagenomic features remaining after filtration and normalization.

no esophageal characterization has been completed. This study characterizes the esophageal microbiome of SSc patients and explores patterns in microbial profiles.

Methods: RNA sequencing was completed on 20 SSc patient and 3 healthy control samples. Sequencing reads were run through Integrated Metagenomic Sequence Analysis (IMSA) to extract non-human microbial reads remaining after initial BLAST to the h19 NCBI human genome. Remaining reads were BLAST to the NCBI nt nucleotide database and taxonomic information was acquired using NCBI taxonomy lookup tool. Non-spurious hits were removed, and samples were rarefied to the lowest read count. Metrics such as the alpha diversity and Firmicutes/Bacteroidetes Ratio, which is associated with gut inflammatory diseases, were calculated. Partition Around Medoids (PAM) clustering based on k clusters was conducted on metagenomic features to group individuals into microbiome enterotypes.

Results: The alpha diversity of SSc samples was lower than that of control samples across the upper and lower esophagus (Wilcoxon Signed-Rank Test, n.s). When parsed by esophageal site and molecular subtype, the alpha diversity was higher in inflammatory samples of the upper esophagus (Kruskal-Wallis Test, $p < 0.05$) and slightly elevated in normal-like and fibroproliferative samples of the lower esophagus (Fig. 1). Concurrent with differences in alpha Diversity, the Firmicutes to Bacteroidetes ratio was elevated in patient samples when compared to healthy controls (Fig. 2A and 2B). When stratified by SSc molecular subtype, Firmicutes/Bacteroidetes ratios were higher in SSc upper esophageal samples which call to the normal-like and fibroproliferative subtypes, and higher in SSc lower esophageal inflammatory and normal-like samples (Fig. 2C and 2D; Kruskal-Wallis test $p < 0.05$ and n.s., respectively). Samples clustered to two groups irrespective of site, and there is a significant association between molecular subtype and cluster membership (Fig. 3; Fisher's Exact Test, $p < 0.05$).

Conclusion: There are patterns and differences in microbial diversity and membership that distinguish SSc and healthy controls, and SSc samples across molecular type. Several of these associations are statistically significant and affirm a potential association between the microbiome and SSc pathogenesis. Work investigating specific microbial membership and gene expression associations are motivated by these findings.

PI3K-Akt Pathway Plays a Crucial Role in Production of Collagen in Fli1 Deficient Condition and Its Inhibitor Has the Therapeutic Potential in Treating Fibrosis

Yuko Ota,[1] Atsushi Kitani,[2] and Warren Strober[2], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, [2]Mucosal Immunity Section, Laboratory of Clinical Immunology and Microbiology, NIAID, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease characterized by fibrosis of the skin and internal organs. Previous studies have shown that dermal fibroblast in patients with SSc frequently shows decreased levels of Fli1 due to hypermethylation. We aimed to clarify the mechanisms underlying the regulation of Fli1 gene of fibrosis using Fli1 deficient cells and mice generated by the CRISPR/Cas9-mediated gene edition.

Methods: Fli1-deficient fibroblast cell line (Fli1ΔNIH3T3 cells) and mice ($Fli1^{+/-}$ mice) were generated by CRISPR/Cas9 system using paired guide RNAs specific for mouse Fli1 and a nickase Cas9 that reduces off-target problem. NIH3T3 cells were transfected with a lentiCRISPR v2 vector and then selected by puromycin. We evaluated collagen and profibrotic cytokine production in the absence of Fli1 by mRNA level. To reveal the mechanism for induction of collagen in Fli1ΔNIH3T3 cells, we treated the cells with various antibodies and inhibitors and performed RNA-sequencing. In order to estimate in vivo efficacy of LY294002 derivative on fibrotic disease, we utilized bleomycin-induced lung fibrosis with $Fli1^{+/-}$ mice and treated with LY294002 derivative by intra-peritoneal injection 3 times and evaluated lung fibrosis by histology, collagen content, and Ashcraft scores. We also evaluated the ex vivo effect of candidate drug using skin fibroblasts from patients with SSc.

Results: Fli1ΔNIH3T3 cells were found to have pro-fibrotic characteristics such as increased expression of COL1A1, COL1A2 as well as increased expression of TGF-b1, CTGF, IL-6, FN, and ACTA2. Antibody neutralization of TGF-β1 and IL-6 didn't inhibited collagen synthesis in Fli1ΔNIH3T3 cells. In addition, whereas MAPK inhibitors of Erk U0126, JNK SP600125, p38 SB20358 failed to suppress the increased collagen production, Nintedanib, a triple kinase inhibitor of VEGFR, FGFR, and PDGFR partially inhibited collagen synthesis. Surprisingly, a phosphoinositide 3-kinases (PI3K) inhibitor, LY294002, which also has inhibitory activity against bromodomain-containing protein (BRD) 2, 3 and 4, had a major inhibitory effect on COL1A2 mRNA expression, suggesting the PI3K-Akt and bromodomain pathways have a major pro-fibrotic role in Fli1ΔNIH3T3 cells. This correlated with the fact that, p-Akt expression was increased in Fli1ΔNIH3T3 cells. In addition, a low toxicity LY294002 derivative also inhibited collagen synthesis in Fli1ΔNIH3T3, confirming PI3K and BRD4 dual inhibition was most effective to reduce COL1A2 production. Furthermore, analyses

of RNA-seq revealed several molecules to induce collagen via PI3K-Akt pathway. Finally, LY294002 derivative treatment significantly ameliorated lung fibrosis as evaluated by Masson Trichrome staining, decreased collagen accumulation in the lung and Ashcroft clinical scores. In both normal and SSc fibroblasts, COL1A2 mRNA were significantly inhibited by LY294002 derivative.

Conclusion: Lack of Fli1 expression activates the molecule that induces collagen accumulation through PI3K-Akt and bromodomain pathway. PI3K and BRD4 dual inhibitor showed therapeutic potential in treating fibrosis.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A variety of abnormalities in lymphocyte surface markers and functional subsets have been described in patients with systemic sclerosis (SSc), but conflicting results abound, and these studies often examined patients with heterogeneous disease duration, clinical phenotype, exposure to immunosuppressive agents, and degree of organ involvement. We studied a clinically homogeneous group of 88 early diffuse cutaneous SSc patients who had not received immunosuppressive drugs and 25 matched healthy controls.

Methods: The SSc patients were participants in the ASSET study, a placebo-controlled blinded trial of abatacept in SSc. Lymphocyte subsets were enumerated by multi-parameter flow cytometry of peripheral blood mononuclear cells at the baseline visit. Production of the cytokines IL-4 and IL-17 was measured by intracellular flow cytometry following T cell activation in overnight cultures.

Results: SSc patients had increased percentages of CD4+ T cells and B cells, but a lower percentage of CD8+ T cells compared to healthy control subjects. The CD4+CD28-negative population was expanded in SSc, in the CD4 subset. The number of CD40 ligand+ cells was expanded in the SSc patients ($p=0.003$), but another T cell activation marker CD69, did not show increased expression on SSc T cells. A notable expansion of CD319+ T cells was seen among the CD4+ cells, where they are barely detectable in healthy subjects (2.96% versus 0.8%, $p< 0.001$). These CD4+CD319+ (SLAM-F7+) cells are cytotoxic and oligoclonal, and were recently shown to be a dominant T cell population in perivascular lymphocytic infiltrates in SSc skin. Frequencies of IL-4+ cells did not differ between SSc and

controls, but expansion of IL-17 producing (2.38% versus 0.82%, p=0.007) and dual IL-4/IL-17 producing (1.16% versus 0.24%, p=0.023) cells was observed in SSc. Numbers of regulatory, and peripheral helper T cells were similar in SSc and control groups.

Conclusion: In this carefully selected group of early diffuse SSc patients, analysis of immune cell parameters has identified abnormalities that likely reflect disease pathogenesis and that are candidate biomarkers for sub-classification and targeted treatment of early diffuse SSc.

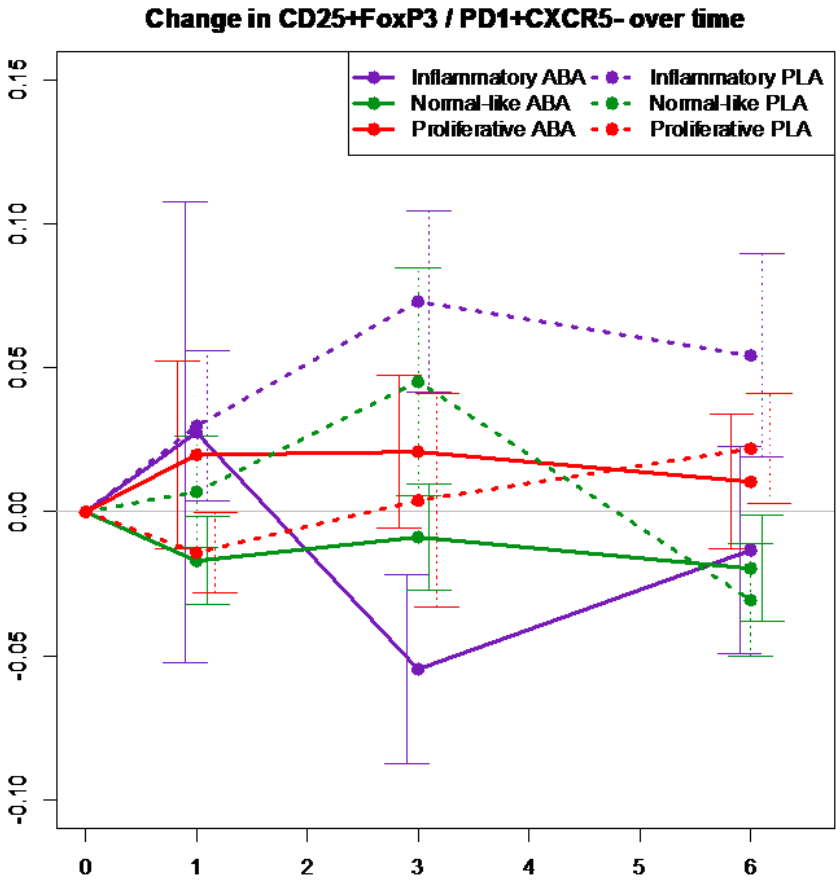
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: In a randomized controlled trial of abatacept in early diffuse systemic sclerosis (Khanna D, et al ACR 2018), we observed early clinical flares (< 2 months into treatment with study drug) in 5 of 88 patients, including 4 renal crisis and one early pulmonary deterioration. Four of these patients (3 renal crisis and pulmonary decline) were receiving abatacept. Early depletion of regulatory T cells (Tregs) was recently observed in a study of abatacept for multiple sclerosis (Glatigny et al, J Immunol, 2019:1373-82). We asked whether depletion of Tregs occurred early in SSc patients treated with abatacept, and whether this could be linked to concurrent clinical deterioration.

Methods: We used multi-parameter flow cytometry to enumerate Tregs and other lymphocyte subsets, such as T peripheral helper cells (Tph) at times 0, 1, 3 and 6 months of the ASSET study. We stratified patients, according to their



pattern of gene expression on baseline skin biopsies, into three predefined distinct subgroups, termed inflammatory, fibroproliferative and normal-like.

Results: The SSc patients who experienced serious early clinical deterioration were all in the inflammatory gene expression subgroup. The numbers of Tregs did not differ at baseline comparing SSc patients (4.7% of CD4+) versus controls (4.14%, p = 0.235), and was not lower in the inflammatory subgroup at baseline (5%), compared with fibro-proliferative (4.29%) or normal-like (4.78%) subgroups (p values not significant comparing these subgroups to each other). With abatacept treatment the Treg number progressively fell in the inflammatory subgroup from month 0 to 3 (p=0.02 at 1 month, 0.0009 at 3 months, 0.02 at 6 months). At 3 months placebo-treated inflammatory subgroup patients had a mean 6.42% Tregs within CD4+ cells compared to 2.49% in abatacept-treated patients. In the normal-like group there was a Treg reduction in the abatacept-treated patients at 3 months (p=0.03). In the fibro-proliferative group Tregs rose in both placebo and abatacept-treated patients (p not significant). We also noticed that changes of Tregs and Tph cells tended to correlate negatively with each other in the inflammatory group patients early during abatacept treatment (r = -0.38, month 0 to 1), compared to patients who received placebo (r = +0.52) and those who received abatacept in the other 2 gene expression subgroups. We created a novel parameter, the ratio of Treg/Tph cells, to further assess immune cell imbalance that might occur with abatacept treatment in early SSc. This ratio declined sharply early during abatacept treatment (p = 0.007 at 3 months)(Figure 1), and the change was primarily driven by patients in the inflammatory subgroup.

Conclusion: Stratification of SSc patients into predefined subgroups based on skin biopsy gene expression predicts which patients are at risk for early flares on abatacept. A proposed mechanism for such flares involves Treg depletion and early Treg/Teffector cell imbalance. Although clinical benefit appears in these patients by 6-12 months, initial treatment may require agents other than or in addition to abatacept. This needs to be further confirmed in other ongoing trials of abatacept.

CD123$^+$ Plasmacytoid Dendritic Cells from Systemic Sclerosis Patients Are Susceptible to the Cytotoxic Activity of Tagraxofusp, a CD123-Targeted Therapy

Ross Lindsay,[1] Janice Chen,[1] Robert Spiera,[2] Jessica Gordon,[2] Marie-Dominique Ah Kioon,[3] Franck Barrat,[3] and Christopher Brooks[1], [1]Stemline Therapeutics, New York, [2]Hospital for Special Surgery, New York, NY, [3]HSS Research Institute, Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tagraxofusp is a novel targeted therapy directed to the interleukin-3 receptor (CD123). Tagraxofusp is comprised of human IL-3 recombinantly fused to a truncated diphtheria toxin (DT) payload engineered such that IL-3 replaces the native DT receptor-binding domain. In this way, the IL-3 domain of tagraxofusp directs the cytotoxic DT payload to cells expressing CD123. Upon internalization, tagraxofusp irreversibly inhibits protein synthesis and induces apoptosis of the target cell.

Tagraxofusp was recently approved by the FDA for the treatment of patients with blastic plasmacytoid dendritic cell neoplasm (BPDCN), a malignancy derived from the plasmacytoid dendritic cell (pDC) precursor. pDCs are immune cells that express CD123, secrete IFN-α, and play a role in inflammation and disease pathogenesis observed in systemic sclerosis (SSc) patients[1,2]. Therapeutic depletion of pDCs or attenuation of pDC function may represent a novel approach to treating SSc patients.

Methods: Patients fulfilled the 2013 ACR/EULAR classification criteria for SSc[3]. PBMCs from either SSc patients or healthy volunteers (HV) were prepared using Ficoll-Paque density gradient from fresh blood. pDCs were isolated from PBMCs as previously described and used to enrich the frequency of pDCs in an additional draw of PBMCs[4]. pDC-enriched PBMCs (3-6% pDCs) were cultured at $2x10^5$ cells per well in the presence or absence of CpG-274 (0.5 μM) to activate pDCs and then incubated with tagraxofusp (0.01-100 ng/ml, 0.17 pM-1.7 nM) at 37°C, 5% CO_2, and 95% humidity. After 24 h of culture, pDC survival was assessed by flow cytometry (CD14-, CD3- BDCA4+ CD123+), and supernatants were collected for cytokine quantification by a multiplexed Luminex assay. Changes in gene expression were measured by PCR on 10 μg cDNA, and calculated based on relative threshold cycle and expression of a ubiquitin housekeeping gene.

Results: Tagraxofusp was cytotoxic towards pDCs from both HV (n=5) and SSc donors (n=5) to a similar extent. The ED_{50} of tagraxofusp in pDCs from HV and SSc was 4.3 and 3.2 ng/ml (74.4 and 55.4 pM), respectively; no effect was observed on B or T cells across the tagraxofusp dose range tested (Fig.1A). Tagraxofusp-mediated pDC depletion

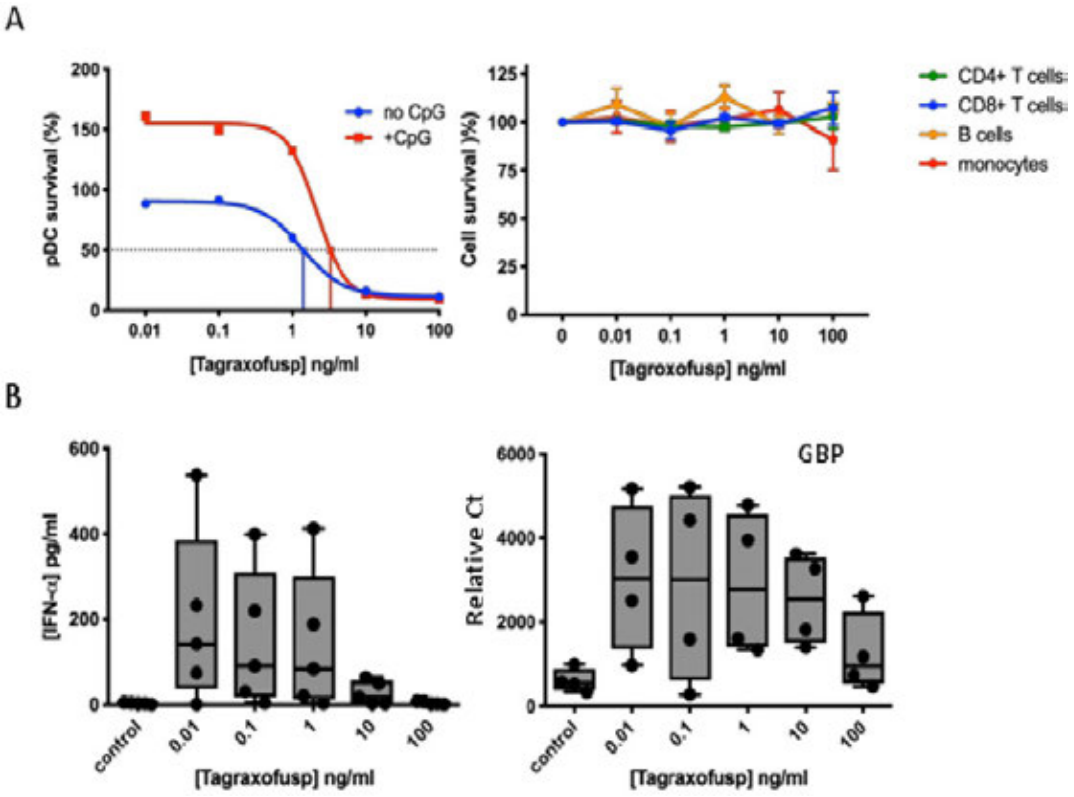

Figure 1. SSc pDC survival following 24 h incubation with tagraxofusp demonstrating a similar ED50 in both CpG-stimulated (red) and unstimulated (blue) pDCs (n=5) but no effect on B/T cells or monocytes (A). Concurrent with the decline in pDC survival, reductions in CpG-induced IFN-a production and expression of the IFN-a-induced gene, GBP, were observed (B).

was further accompanied by a 68-fold reduction in secreted IFN-α and a 3-fold downregulation of GBP, a type 1 IFN-induced gene (Fig. 1B).

Conclusion: Tagraxofusp is a novel CD123-targeted therapy that is cytotoxic towards pDCs from SSc patients. These data present a novel approach of targeting pDCs in the treatment of SSc, and a clinical trial is under design.

Aberrant Expression Levels of Soluble Co-inhibitory Receptors Linked to Disease Activity in Systemic Sclerosis

Voon Ong,[1] Svetlana Nihtyanova,[2] David Abraham,[2] Maithri Aspari,[3] Christopher Denton,[4] and Bent Deleuran[5], [1]UCL Medical School, Royal Free Campus, London, [2]University College London, London, United Kingdom, [3]Department of Biomedicine; Department of Rheumatology, Aarhus University, Arrhus, Denmark, [4]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom, [5]Department of Biomedicine; Department of Rheumatology, Aarhus University, Aarhus, Denmark

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Emerging evidence suggests dysregulated T cell activation in systemic sclerosis (SSc). Co-inhibitory-receptors such as TIM-3, PD-1 and LAG-3 are key factors in immune homeostasis and autoimmunity. These receptors regulate T-cell responses by inhibiting effector T-cell activation directly by affecting antigen presentation. Soluble forms of these molecules are generated by proteolytic cleavage of membrane-bound proteins. We evaluate the potential role of these soluble co-inhibitory markers in SSc and their impact on disease outcomes in diffuse SSc (dcSSc).

Methods: sPD-1, sLAG-3 and sTIM-3 were measured in sera from 35 patients with dcSSc and 26 healthy controls. All patients had disease duration of less than 5 years. Modified Rodnan skin sore (mRss) varied between 8-39, mean 22. Correlation with key clinical parameters including possible effect of disease modifying agents (DMARDs: methotrexate, mycophenolate mofetil and prednisolone) was determined. Patient characteristics are summarised in **Table 1**.

Results: For sPD-1, compared to healthy controls with below detection levels, the mean level was increased (136pg/ml) among dcSSc patients. There was no association between sPD-1 and organ involvement or autoantibodies. Comparison of sPD-1 levels in patients on DMARDs with those without treatment demonstrated significant effect of

immunosuppressive therapies, with mean sPD-1 95.1 pg/ml among patients on DMARD compared to 216.7 pg/ml among those on no treatment (p=0.02).sPD-1 demonstrated association with ESR (Spearman's rho=0.3505, p=0.03), but not CRP. There was association between sPD-1 and mRss (Spearman's rho=0.3759, p=0.04) and FVC (Spearman's rho=0.3722, p=0.04). Mean sLAG-3levels were significantly lower among dcSSc patients (394.6 pg/ml) vs healthy controls (740.8 pg/ml, p< 0.05). sLAG-3 was inversely associated with disease duration (Spearman's rho =-0.3438, p=0.04). There was a trend for association between sLAG-3and mRss, with higher levels of sLAG-3 seen in patients with higher skin score (Spearman's rho =0.3304, p=0.06),and between sLAG-3levels and presence of tendon friction rubs (TFR) (mean sLAG-3366.3 ng/ml among patient without TFR and 531.5 ng/ml among those with TFR, p=0.08). There was highly significant difference in the sTIM-3 levels between healthy controls (mean 4721.9 ng/ml) and dcSSc patients (8728.0 ng/ml, p< 0.05). There was a trend for association between anti-Scl70 (ATA) positivity and sTIM-3 levels (7579.5 ng/ml in ATA+ vs 9406.6 ng/ml in ATA- patients, p=0.09). Hb levels showed significant association with sTIM-3, with higher Hb levels associated with lower sTIM-3 levels (Spearman's rho =-0.4018, p=0.02). There was a weak association between platelet count and sTIM-3 (Spearman's rho =0.3267, p=0.06).

Conclusion: Our data show that soluble co-inhibitors are differentially expressed in early dcSSc and correlate with key clinical features. Although they may be selectively affected by some immunosuppressive therapies, this may reflect pathway dysregulation and may provide serological markers for evaluation of disease activity and severity in diffuse SSc.

Dysregulated IL-6 Dependent Dermal Adenosine Signaling via Adenosine A2A Receptor May Drive Fibrosis in Systemic Sclerosis

Christopher Denton,[1] Shiwen Xu,[2] Sue Verma,[3] and **Voon Ong** [4], [1]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom, [2]University College London, London, United Kingdom, [3]Leadiant Biosciences, London, United Kingdom, [4]UCL Medical School, Royal Free Campus, London

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Altered generation of adenosine from extracellular nucleotides by ectonucleotidases may orchestrate chronic injury responses and promote fibrosis via the adenosine A2A receptor (ADORA2A). We have explored perturbed adenosine signaling pathways and potential links with fibroblast activation in early stage diffuse scleroderma (SSc).

Methods: Dermal fibroblasts were cultured from diffuse SSc (n=15) and healthy controls (n=5). RNA-Seq explored expression of enzymes involved in degradation of adenosine (adenosine deaminase [ADA] and adenosine kinase [AK]), ectonucleotidases(CD39, CD73) and adenosine receptors.Production of key profibrotic mediators (collagen α1[Col1], alpha smooth muscle actin [αSMA] and connective tissue growth factor [CTGF]) was analysed by western

blot of cell lysates in response to adenosine receptor agonist 5'-N-ethylcarboxamidoadenosine (NECA), A2A adenosine agonist (CGS-21680), A2A adenosine antagonist (ZM241385) and polyethylene glycol conjugated recombinant bovine ADA[PEG-rADA] (EZN 2279- elapegademase). Cell migration was assessed at 48h using scratch wound assay and contraction of fibroblast populated 3D collagen gel lattices at 24h.

Results: ADA transcript was increased (1.85-fold, p=0.01, n=12) in SSc fibroblasts (SScF) compared to normal fibroblasts (NF, n=5). In contrast, no significant difference in AK expression (0.79-fold, p=0.19) was observed. ADORA2A was significantly lower in SScF compared to NF (0.33 fold, p=0.04) and CD73 expression reduced in SScF compared to NF (0.61-fold, p=0.004). SScF produced higher levels of Col1 than NF (11.54±2.66 vs 22.07±1.57, p=0.02, n=3). Whilst there was no significant increase in Col1 in response to EZN2279 (9.24±1.18, p=0.2) or ZM241385 (8.95±1.55, p=0.17) in NF, there was with CGS-21680 (1.86 fold, p=0.04). In contrast, there was a smaller induction in Col1 in SScF with CGS-21680 (1.34 fold, p=0.02). The increase in Col1 in SScF was attenuated with EZN2279 and ZM241385 to similar extent (0.56 fold and 0.55 fold respectively, p< 0.05). Analogous response was observed for both αSMA and CTGF. Migratory capacity was enhanced with CGS-21680 in NF (62.83±4.80 vs 45.73±4.86 p< 0.05, n=3) and in SScF (31.17±3.62 vs 25.06±2.01, p< 0.05, n=3). In SScF, this was abrogated with EZN2279 and ZM241385 (56.29±6.26 and 52.32±4.33 respectively, p< 0.05). Gel contraction was induced by CGS-21680 in SScF (120.56±21.19 vs 78.77±6.91, p< 0.05,n=3) compared to NF (196.01±20.87 vs 133.82±19.46, p=0.06,n=3). In SScF, induction of contractile activity was further attenuated with EZN2279 and ZM241385 (189.83±16.44 and 181.02±13.18 respectively, p< 0.05). When stimulated with NECA, increased IL-6 was detected in media of fibroblasts (NF, n=3) (3.09±1.04 vs 14.18±1.56, p< 0.05) and this was attenuated with both EZN2279 and ZM241385 (3.88±0.99 and 3.03±1.10 respectively, p< 0.05).

Conclusion: These data suggest adenosinergic signalling is profibrotic and altered in SSc and that an ADORA2A-IL6 dependent loop may contribute to fibrosis. This may have therapeutic relevance for SSc.

Identification of miRNAs in Systemic Sclerosis Based on Activity and Network Analysis

Yiwei Yuan,[1] Yue Wang,[2] Patricia Pioli,[3] and Michael Whitfield[4], [1]Geisel School of Medicine at Dartmouth, Hanover, [2]Geisel School of Medicine at Dartmouth, Hanover, NH, [3]Dartmouth College, Hanover, [4]Geisel School of Medicine at Dartmouth College, Biomedical Data Science at Dartmouth College, Hanover

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

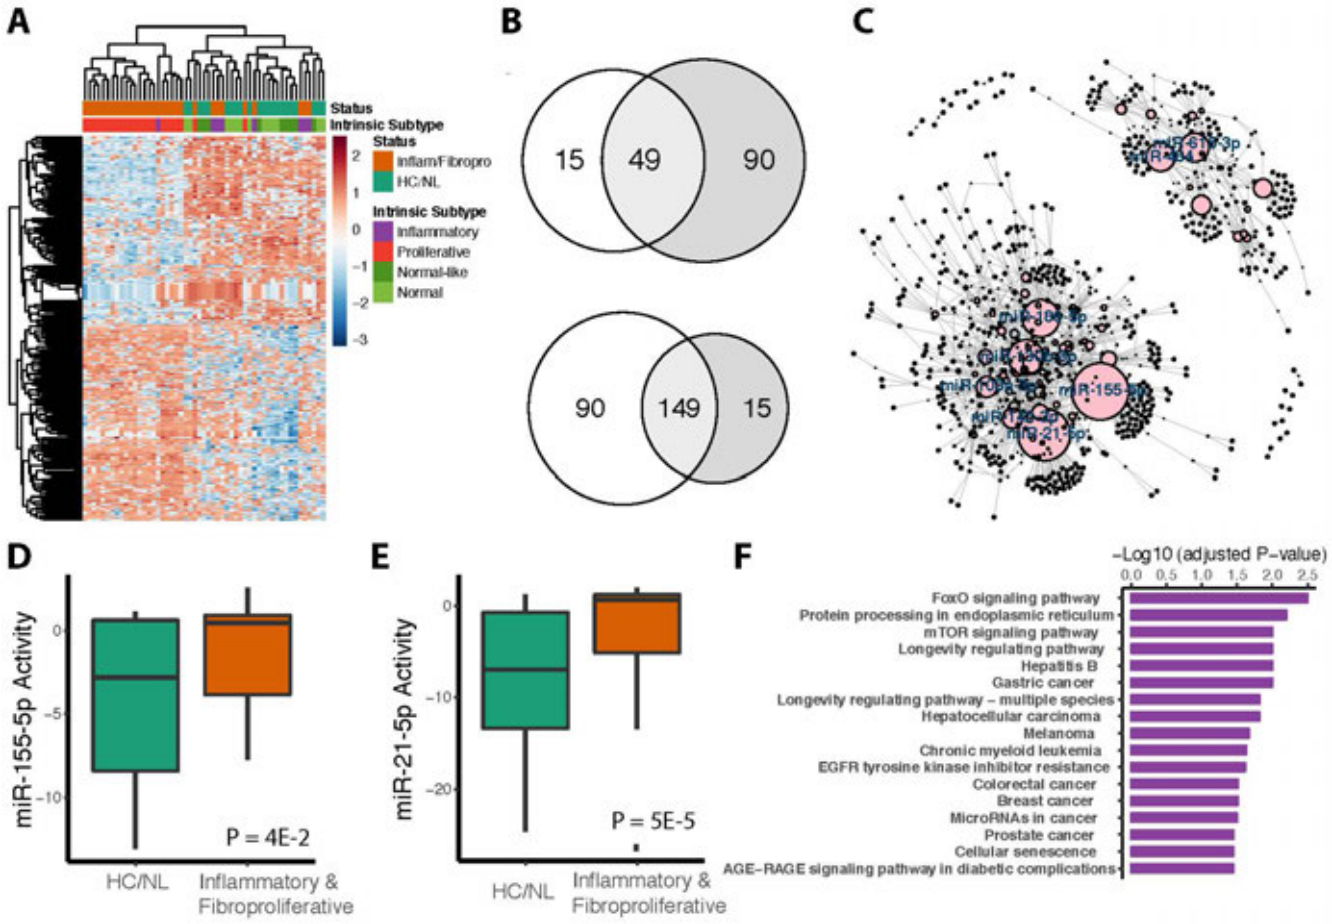

Figure 1. The identification of miRNA in SSc based on activity and network analysis. (A) Heatmap of miRNAs with differential activity in Milano dataset. (B) Venn diagram plot of miRNAs with the consistent direction within datasets. (C) miRNA-target network using miRNAs with differntial activity and targets. (D) and (E): Boxplot for miR-155-5p and miR-21-5p activity in Milano dataset. (F) Enriched pathways of miR-155-5p targets.

Background/Purpose: Systemic sclerosis (SSc; scleroderma) is a rare, heterogenous autoimmune disease characterized by skin fibrosis, vasculopathy and internal organ involvement. SSc patients can be divided into four intrinsic gene expression subtypes: inflammatory, fibroproliferative, limited and normal-like. The expression and activity of miRNAs, non-coding RNAs that post-transcriptionally regulate gene expression, have not been comprehensively characterized across the intrinsic gene expression subsets. We investigated the regulation and activity of miRNAs across the SSc subsets, developed a miRNA-target network, and experimentally validated a key hub of the network.

Methods: Gene expression profiles were downloaded for two patient cohorts, Milano et al. (GSE9285; 75 samples) and Assassi et al. (GSE58095; 102 samples). miRNA-target interactions (MTIs) were collected from miRTarBase; the activity of each miRNA is based on the expression of its target genes. The BASE algorithm was used to generate the miRNA regulatory activity scores for each miRNA in each sample. A Wilcoxon rank sum test was used to identify miRNAs with differential activity in inflammatory and fibroproliferative SSc samples. A miR-seq was performed on 8 SSc and 4 healthy control skin samples to validate findings. Targets strongly inhibited by cognate miRNAs were used to create the MTI network by calculating their negative correlation. The R package “igraph” was used for visualization and topological analysis of the network. Centrality measures

were used to determine the node importance. For the most essential miRNAs, target genes were ranked and functionally annotated by pathway enrichment analysis using g:Profiler. miRNAs knockdowns in primary human SSc-differentiated macrophages were used to validate *in-silico* analyses.

Results: We identified a total of 198 miRNAs that were consistently differentially activated in both datasets (149 miRNAs were upregulated, and 49 miRNAs were downregulated). 1534 target genes were connected to these miRNAs in the network. Topological measurements of the network revealed that miR-155-5p and miR-21-5p had the broadest influence throughout the network. Both miR-155-5p and miR-21-5p showed consistently high activity in inflammatory and fibroproliferative SSc samples, and were highly expressed by miR-seq. MiR-155-5p has 92 target genes in this network that are significantly enriched in pathways that regulate inflammation and macrophage activation including the FoxO signaling pathway, which has been shown to mediate the prevention of autoimmunity.

Conclusion: We identified a list of miRNAs that show differential activity in SSc samples. MiR-155-5p and miR-21-5p were the most central in the regulatory network topologically, and have significantly higher activity and expression in inflammatory and fibroproliferative SSc samples. Over-activation of miR-155-5p leads to the loss of pathways associated with inhibition of autoimmune disease and proliferation of muscle cells.

Classical Monocytes from African Ancestry Patients with Systemic Sclerosis Show Transcription and Energy Regulation Gene Expression Signatures

Paula Ramos,[1] Willian da Silveira,[2] Jena Wirth,[1] Nathan Wilson,[1] Robert Wilson,[1] Jin Hyun Nam,[1] E. Starr Hazard,[1] Jim Oates,[3] Melissa Cunningham,[1] Dongjun Chung,[1] and Gary Hardiman[2], [1]Medical University of South Carolina, Charleston, [2]Queen's University, Belfast, United Kingdom, [3]Division of Rheumatology & Immunology/Medical University of South Carolina, Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare autoimmune disorder characterized by immune dysregulation, cutaneous and visceral fibrosis, and vasculopathy. It disproportionately affects African ancestry (AA) individuals who, despite the higher disease severity, are dramatically underrepresented in research. Monocytes show heightened activation in SSc, and in AA relative to European ancestry individuals. Monocytes are thus a good target tissue for elucidating disease mechanisms. In this study, we sought to characterize differential gene expression of classical monocytes in SSc patients and unaffected controls of African ancestry.

Methods: Classical monocytes (CD14++CD16-) were FACS-isolated from 17 female AA SSc cases and 18 female AA controls. All patients met the 2013 ACR/EULAR classification criteria for SSc, most (72%) presenting with diffuse cutaneous SSc. Total RNA was used to prepare RNA-Seq libraries using Illumina's TruSeq RNA Exome kit. Upon sequencing on an Illumina HiSeq2500 instrument, data was analyzed by Rosalind, with a HyperScale architecture developed by OnRamp BioInformatics. Specifically, individual sample reads were aligned to the hg19 reference genome using STAR and quantified using HTseq. Differential expression analysis was implemented using DESeq2 and functional enrichment analysis was performed using Advaita iPathway Guide.

Results: A total of 743 genes showed differential expression (FDR P-value < 0.4). The top differentially expressed genes (P < E-04) include the collagen *COL9A2* gene, the protein phosphatase *PPP1R14B*, the tubulin *TUBB4B*, the kinase-binding *AKAP1*, the ubiquitin ligase *RNF146*, the heparanase *HPSE*, the nuclear factor NF-Kappa-B activator *TRAF3IP2*, and the chromatin regulator *SMARCA4.* The SSc monocyte transcriptome showed an enrichment of genes in the AMPK signaling pathway, genes involved in chromatin organization, transcription factor binding, and glycogen storage diseases. The top upstream regulator is the MAPK11 kinase.

Conclusion: Unlike what has been reported in different peripheral blood subsets in EA patients, our results show a weaker upregulation of genes involved in immune and inflammatory processes in monocytes from AA patients. Instead, our study reveals an upregulation of genes involved in cellular processes associated with transcription and energy regulation in SSc patients, consistent with an increased metabolic rate of these myeloid cells in SSc. These results support the increasing awareness that metabolic reprogramming has important roles in mediating immune and vascular responses. Collectively, these results support the need to understand the regulatory architecture of SSc in different cell types and in individuals of different ancestries.

$CD4^+$ T Helper Cell Populations with High PD-1 Expression Are Expanded in Systemic Sclerosis

Alisa Mueller,[1] Andrea Fava,[2] Deepak Rao,[1] and Francesco Boin[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]UCSF, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disease characterized by tissue fibrosis, vascular injury, and autoantibody production. $CXCR5^+$ $PD\text{-}1^+$ T follicular helper (Tfh) cells, which are T cells specialized to help B cells, are expanded in the circulation of SSc patients and may contribute to both immune activation and fibrotic organ damage. Emerging evidence supports the existence of a wider range of B cell-helper T cells characterized by high expression of PD-1 including $PD\text{-}1^{hi}$ $CXCR5^-$ T peripheral helper (Tph) cells, which are dramatically expanded in the joints of RA patients and in the circulation of SLE patients. Here, we have evaluated the frequency of $PD\text{-}1^{hi}$ $CD4^+$ T cell subsets in a well-characterized cohort of SSc patients.

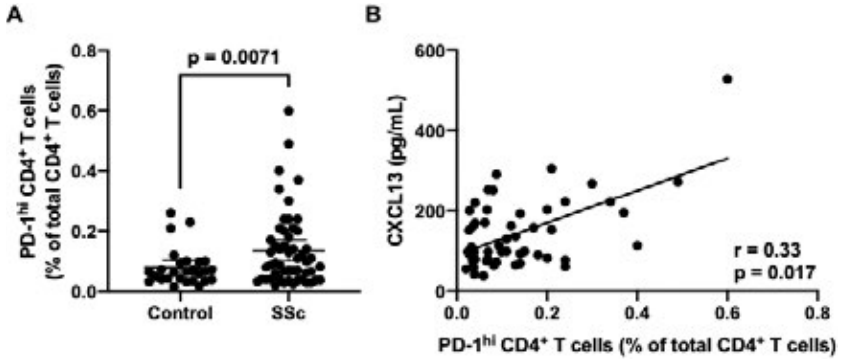

Figure 1. Expanded PD-1hi CD4+ T cell population in SSc patients. A) Percentage of PD-1hi CD4+ T cells among total CD4+ T cells in PBMCs from SSc and control patients by flow cytometry. B) Correlation between frequency of PD-1hi CD4+ T cells and CXCL13 levels as measured by ELISA with Spearman statistics.

Methods: Peripheral blood mononuclear cells (PBMCs) were collected from 101 SSc patients fulfilling the 2013 ACR/EULAR SSc classification criteria and 33 healthy controls. A comprehensive set of demographic and clinical characteristics was obtained at the time of enrollment including data on organ involvement, disease severity, autoantibody profile, pulmonary and cardiac functional status, and medications. Flow cytometry analysis was performed on PBMCs using an antibody panel designed to identify specific $CD4^+$ T cell subsets. Serum cytokine levels were measured by ELISA.

Results: Using strict gating on cells with very high PD-1 expression, we observed that the frequency of PD-1^{hi} $CD4^+$ T cells among total $CD4^+$ T cells was significantly increased in SSc patients compared to healthy controls (0.136% vs. 0.078%, p = 0.0071; Figure 1A). The PD-1^{hi} $CD4^+$ population contains two distinct B cell-helper T cell subsets: $CXCR5^+$ Tfh cells and $CXCR5^-$ Tph cells. Strict gating on $CXCR5^-$ cells indicated that PD-1^{hi} $CXCR5^-$ Tph cells were also increased in SSc samples (p = 0.011). PD-1^{hi} $CD4^+$ T cell populations are the major source of the B cell chemoattractant CXCL13, and we observed a positive correlation between PD-1^{hi} $CD4^+$ T cell frequency and serum CXCL13 concentration in SSc patients (Spearman r = 0.33, p=0.017; Figure 1B). To evaluate clinical associations with PD-1^{hi} $CD4^+$ T cell frequency, we stratified SSc patients based on high (≥ 0.20%) or low (≤ 0.05%) PD-1^{hi} $CD4^+$ T cell frequency. We found that 58% (7/12) of patients with high PD-1^{hi} $CD4^+$ T cell numbers had interstitial lung disease (ILD) compared to 27% (4/15) of patients with low PD-1^{hi} $CD4^+$ T cell numbers.

Conclusion: Our study shows that the frequency of PD-1^{hi} $CD4^+$ T cells, including PD-1^{hi} $CXCR5^-$ Tph cells, is significantly increased in SSc patients. Preliminary analyses suggest a relationship between PD-1^{hi} $CD4^+$ T cell frequency and SSc-ILD. These findings support a potential role for B cell-helper T cells including Tph cells in the autoimmune pathology of SSc.

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) affects approximately 10% of patients with systemic sclerosis (SSc) and is a leading cause of death. Screening algorithms using clinical parameters have been developed to identify patients at high risk for PAH who should undergo confirmatory right heart catheterization (RHC). We sought to identify serum cytokines that might be useful in risk stratification of SSc patients for this potentially fatal complication.

Table 1. Baseline demographics and clinical characteristics of patient groups.

	Healthy n=20	PAH n=81	High Risk n=71	Low Risk n=10
Age, mean (std) (n)	59.7 (8.9) (20)	58 (11.3) (79)	60.1 (10.8) (71)	52.3 (10.7) (10)
Sex				
Female	15 (75)	59 (74.68)	62 (87.32)	9 (90)
Male	5 (25)	20 (25.32)	9 (12.68)	1 (10)
Race				
Asian/Pacific Islander		1 (1.27)	1 (1.41)	3 (30)
Black		12 (15.19)	2 (2.82)	0
Caucasian		64 (81.01)	60 (84.51)	3 (30)
Hispanic		2 (2.53)	5 (7.04)	3 (30)
Native American		0	2 (2.82)	0
Other Ethnic Origin		0	1 (1.41)	1 (10)
SSc Subtype				
Diffuse		20 (25)	15 (21.13)	5 (50)
Limited		57 (71.25)	54 (76.06)	5 (50)
Unclassified		3 (3.75)	2 (2.82)	
Antibody				
Mixed or other		15 (18.99)	13 (18.57)	0
Scl 70		13 (16.46)	15 (21.43)	2 (20)
U1RNP		3 (3.8)	1 (1.43)	0
Anticentromere		20 (25.32)	15 (21.43)	6 (60)
Isolated Nucleolar		20 (25.32)	13 (18.57)	0
Negative		3 (3.8)	9 (12.86)	2 (20)
RNA polymerase II		5 (6.33)	4 (5.71)	0
FVC, median (range) (n)		71.2 (27.1 - 104.8) (69)	85.2 (32.5 - 130.6) (64)	96 (84 - 112) (10)
DLCO, median (range) (n)		37 (9.9 - 90.7) (67)	50.4 (10.1 - 94.2) (60)	98.5 (80 - 128) (10)
RVSP, median (range) (n)		50.5 (17 - 120) (68)	38.5 (23 - 80) (60)	28 (18 - 35) (7)

Table 1. Baseline demographics and clinical characteristics of patient groups. PAH=pulmonary arterial hypertension; std=standard deviation; FVC=forced vital capacity; DLCO=diffusion capacity for carbon monoxide; SSc=systemic sclerosis.

Methods: Subjects were enrolled in the Pulmonary Hypertension Assessment and Recognition of Outcomes in Scleroderma (PHAROS), a multi-center prospective registry that includes SSc patients with 1) incident PAH based on RHC; 2) at high risk for PAH. High risk patients had a diffusion capacity for carbon monoxide (DLCO) < 55% predicted with a forced vital capacity (FVC) of >70% predicted, FVC/DLCO ratio >1.6, or right ventricular systolic pressure (RVSP) ≥40 mmHg on echocardiography. Low risk patients were enrolled at Stanford and had a DLCO ≥ 80%, FVC ≥ 80%, and RVSP ≤35mmHg or normal echocardiogram if no measurable tricuspid regurgitant jet was observed. Serum was available from 71 high risk patients, 81 incident PAH patients, 10 low risk patients, and 20 healthy controls (HC). A custom 14-plex array was used for cytokine analysis. Samples were normalized by background correction and removed if correlation between technical replicates was < 0.8. Cytokine expression was compared between patient groups by principal component analysis and Tukey's test result. A multiple hypotheses corrected p-value < 0.05 was considered significant.

Results: Baseline characteristics of each patient group are described in Table 1. Two cytokines (sVCAM-1 and PDGF-BB) were removed from further analysis due to low correlation on replicate testing. Principle component analysis showed unique clustering for each patient group (Figure 1). We found that there was a significant difference in cytokine expression in at least one group comparison for every cytokine. Overall, there was very little difference in cytokine expression comparing high risk and PAH patient groups; however, these groups had substantially different cytokine profiles compared to low risk patients. In particular, low expression of PAI-1, EGF, BDNF, and sICAM-1 differentiated the low risk group from the high risk and PAH groups, as well as from HC. Higher levels of RANTES and IL-12p40 differentiated the three SSc groups from HC (Figure 2).

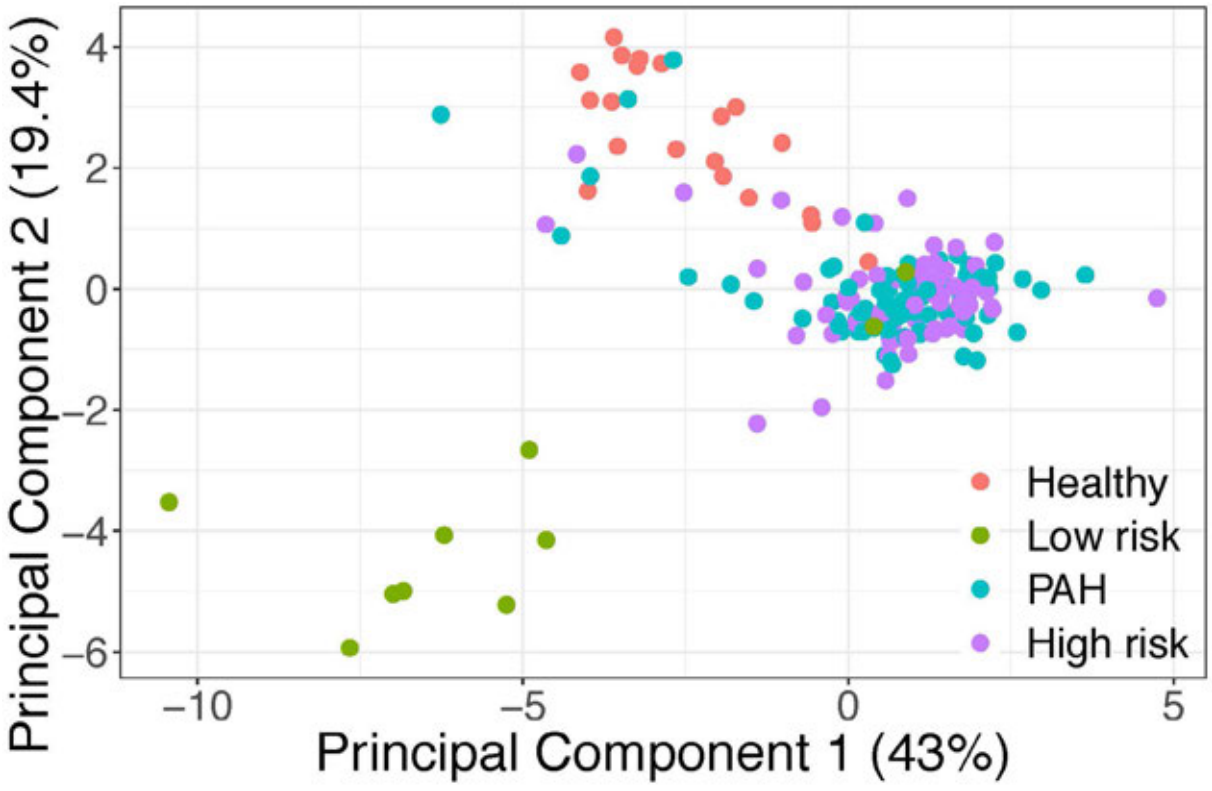

Figure 1. Principal component analysis of 14-plex cytokine array data distinguished different patient groups. Healthy controls and low risk SSC patients were different from SSc patients with PAH or at high risk of developing PAH.

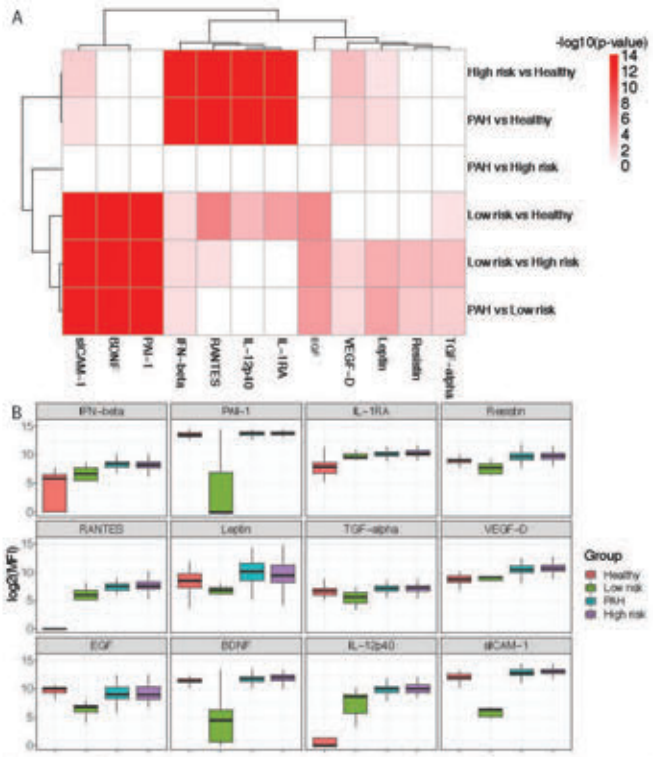

Figure 2. (A) Multiple hypotheses corrected p-values for each antigen in every pairwise comparison using Tukey's test. Every antigen was significantly different in at least one comparison. No antigen was significantly different between SSc patients at high risk of PAH or with PAH. (B) Boxplots of expression of each significant antigen in each of the four groups. Boxes represent inter-quartiles (25% and 75% percentile), and whiskers represent maximum and minimum values.

Conclusion: These data suggest that cytokine profiles can identify SSc patients who are at high risk for PAH. However, high risk and PAH patients had very similar cytokine profiles, suggesting that these patients are on a disease continuum. Our results need to be validated in an independent cohort of SSc patients.

A Common Transcriptional Signature Is Present in Circulating Classical Monocytes and Skin Macrophages in Systemic Sclerosis

Hadijat Makinde,[1] Salina Dominguez,[2] Gaurav Gadhvi,[3] Kathleen Aren,[4] Chang Zeng,[3] Garrett Eickelberg,[3] Dinesh Khanna,[5] Shervin Assassi,[6] Tracy Frech,[7] Monique Hinchcliff,[8] Carla Cuda,[9] Deborah Winter,[2] and Harris Perlman[2], [1]Northwestern University, Chicago, IL, [2]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, [3]Northwestern University, Chicago, [4]Northwestern.edu, Chicago, [5]Scleroderma Program, Division of Rheumatology, Department of Internal Medicine, Autoimmunity Center of Excellence, University of Michigan, Ann Arbor, [6]Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, Texas, USA, Houston, TX, [7]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT, [8]Yale University, Section of Rheumatology, Allergy and Immunology, New Haven, CT, [9]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago, IL

Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The etiology and pathogenesis of systemic sclerosis (SSc) are poorly understood; however, an increasing body of evidence supports an early inflammatory phase that precedes fibrosis. Circulating monocytes likely play a critical role in SSc progression through secretion of pro-inflammatory molecules and as precursors of macrophages that can reorganize the extracellular matrix (ECM) to leading to the development of end-organ fibrosis. Here we evaluate the transcriptional similarities between circulating classical monocytes and macrophages present in the skin of SSc patients.

Methods: Classical monocytes (CMo) were sorted using multiparameter fluorescence-activated cell sorting (FACS) from early diffuse cutaneous (dc) SSc sample blood obtained through the Prospective Registry of Early Systemic Sclerosis (PRESS) cohort. Bulk RNA-seq was performed, and transcriptional profiles were analyzed along with age-, sex-, and ethnicity-matched controls. Additionally, $CD45^+$ immune cells, as well as $CD31^+$ endothelial cells were FACS-sorted from skin biopsies of one SSc patient and one control patient and prepared for single-cell RNA-seq.

Results: There was an expansion in the skin macrophages from 36 cells in the control sample to 67 cells in the patient sample but no significant difference in the quantity (as a percent of total CD45+ cells) of circulating CMo ($p=0.134$) between controls and SSc patients. The differentially expressed genes in the circulating CMo were identified using DESeq2. Of the 152 significantly up-regulated genes (DESeq2, $p< 0.05$, Log2 Fold change in expression >1) observed in the circulating CMo population and the 290 up-regulated genes (Log2 Fold change in expression >1) found in the skin macrophage cluster compared to their respective controls, we find 23 genes in common ($p< 1.23x10\text{-}8$, hypergeometric distribution test). These shared genes are involved in processes that include 'inflammatory response' ($p< 6.56x10\text{-}4$, IL10, IL8, IL1B, CXCR4), 'regulation of mononuclear cell proliferation' ($p< 7.65x10\text{-}5$, IL1B, IL10, MNDA, PNP), 'dendritic cell migration' ($p< 5.07x10\text{-}4$, GPR183, CXCR4), 'cytokine-mediated signaling pathway' ($p< 1.68x10\text{-}5$, IL10, VEGF, CXCR4, IFI6), 'negative regulation of epithelial cell proliferation' ($p< 4.45x10\text{-}4$, RGCC, THBS1, EREG), 'regulation of endothelial cell proliferation' ($p< 4.02x10\text{-}5$, VEGFA, IL10, RGCC, THBS1).

Conclusion: These data indicate that a common transcriptional signature exists between circulating classical monocytes and macrophages present in the skin of SSc patients, potentially suggesting that macrophage-specific pathways that have gone awry at the site of fibrosis can be detected in a circulating precursor population. Future studies will focus on interrogating the penetrance of this gene signature by cross-referencing blood monocyte and skin

macrophage transcriptional profiles from the same patient to determine whether this signature in circulating classical monocytes correlates with the severity of skin fibrosis and/or serves as a predictive marker of disease.

CCR2^{+} Circulating Monocytes Contribute to the Survival of ADSC in Bleomycin-Induced Skin Fibrosis

Madhavi Latha Chalasani,[1] Liyoung Kim,[1] and Theresa Lu[2], [1]Hospital for Special Surgery, New York, NY, [2]Hospital for Special Surgery, Weill Cornell Medicine (Microbiology and Immunology), New York

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Monocytes and monocyte-derived cells play a crucial role during homeostasis and also during the development of various inflammatory diseases including skin fibrosis. Ly6C^{hi} inflammatory monocytes formed in the bone marrow enter the circulation as mature C-C Chemokine Receptor 2 (CCR2^{+}) cells and exert their function by their ability to differentiate into macrophages and other myeloid cell types in the peripheral tissues. Our lab previously showed upregulation of monocytes and monocyte derived macrophages followed by loss of adipose-derived stromal cells (ADSC) in bleomycin-induced skin fibrosis. CCR2 is implicated to have a pathogenic role in multiple fibrosis models. Here, we hypothesized that CCR2^{+} monocytes that infiltrate the skin following bleomycin treatment play an important role in modulating ADSC maintenance and bleomycin-induced skin fibrosis changes.

Methods: C57BL/6J wild type (WT) and CCR2 knockout (CCR2KO) mice were injected with either PBS (control) or 100ug of bleomycin subcutaneously on the lower back skin for indicated time periods. Skin was assessed for cellular changes by flow cytometry and for fibrotic changes by H&E staining followed by dermal and dermal white adipose tissue (DWAT) thickness measurements.

Results: Consistent with the idea that monocyte accumulation in skin is dependent on CCR2 and that the macrophages are monocyte-derived, we observed a robust increase in monocytes and monocyte-derived macrophages in WT but not CCR2KO mice at day 21 after bleomycin treatment. Contrary to expectations, however, while bleomycin-treated WT mice showed ~55% reduction in ADSC numbers compared to PBS control, CCR2KO mice under the same conditions showed further severity in ADSC loss (~80% reduction). CCR2 KO mice also showed increased dermal thickness without further loss of DWAT compared to bleomycin-treated WT mice. These results suggest a role for CCR2^{+} cells, potentially monocytes and monocyte-derived macrophages, in maintaining ADSC numbers and limiting fibrosis in bleomycin-induced skin fibrosis.

Conclusion: Our results thus far suggest a protective role for CCR2, potentially by mediating the accumulation of monocytes and macrophages and maintaining ADSC numbers during bleomycin-induced skin fibrosis. Further stud-

ies will focus on establishing the role of CCR2-dependent monocytes versus CCR2 on other cell populations as well as on understanding the mechanism by which CCR2 regulates ADSC populations. These results could thus help in better understanding and therapeutic targeting of the disease.

Identification of Distinct Pro-Fibrotic Monocyte and Macrophage Subsets in Systemic Sclerosis

Angela Tam,[1] Lauren Reinke-Breen,[2] Glenda Trujillo,[2] Shiwen Xu,[1] Christopher Denton,[3] David Abraham,[1] Gabor Jarai,[2] and Voon Ong[4], [1]University College London, London, United Kingdom, [2]Bristol-Myers Squibb, Pennington, [3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom, [4]UCL Medical School, Royal Free Campus, London

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammation may modulate the balance of classical, intermediate and non-classical monocyte subsets (defined by CD14/CD16 expression)[1]. Monocytes are heterogeneous and subsets can be further delineated by examining expression of other cellular markers such as CD163, a haemoglobin-scavenging receptor which is associated with resolving inflammation and fibrosis. Systemic sclerosis (SSc) is a chronic autoimmune disease and a prototype for studying how the immune system regulates fibrosis[2]. The aim of this study is to characterise monocyte/macrophage subsets, and their function in SSc.

Methods: Blood samples from healthy donors and SSc patients were collected for serum, leukocyte and monocyte isolation. Leukocytes were stained with CD14, CD16 and CD163 antibodies for FACS analysis. Monocytes were iso-

Table 1. Key demographic features of SSc cohort.

Experiment		Healthy control	SSc
FACS	n	9	10
	Age (years)	56.7±14.3	50.7±5.7
	No. of women	7	8
	No. of dcSSc	-	10

lated by negative selection and Ficoll separation of blood and cultured for 7 days into macrophages. Soluble CD163 levels were measured by ELISA. Macrophage supernatants were applied to scratch-wounded healthy skin fibroblast monolayers and fibroblast-populated collagen gels, to assess their effect on fibroblast migration and contraction, respectively. Mann-Whitney U tests, 2-tailed unpaired t-tests, Spearman's Rank and linear regression were used for statistical analysis.

Results: In our cohort of SSc patients (Table 1), we found two-fold more circulating $CD163^{+}CD14^{lo}CD16^{hi}$ non-classical monocytes (6.02±0.8 $x10^{3}$ cells/mL), than in healthy controls (2.69±1.0 $x10^{3}$ cells/mL), p=0.026. Accordingly, we observed significantly higher levels of soluble CD163 in SSc sera (682ng/mL) than in healthy control sera (587ng/mL), Mann Whitney U=413, p=0.010. Higher levels of soluble CD163/total protein were detected in supernatants of SSc macrophage cultures (9.96 $x10^{-3}$) compared to those of healthy controls (7.76 $x10^{-3}$), Mann Whitney U=77, p=0.005. There were no associations between sera or supernatant CD163 levels and clinical parameters such as disease duration, modified Rodnan skin score and lung fibrosis.

Fibroblasts treated with SSc macrophage media migrated faster (n=2, rate of closure 2.9% wound area/hour, R^2=0.90) into the scratch wound area of monolayers than those treated with healthy control media (n=2, rate of closure 1.7% wound area/hour, R^2=0.82), p=0.017. SSc macrophage supernatant promoted fibroblast contraction as indicated by the lower weight of fibroblast-populated collagen gels cultured in SSc macrophage supernatant (n=5, 110.7±8.6 mg) compared to those in healthy control supernatant (n=2, 153.6±6.8 mg), p=0.035.

Conclusion: Our data suggests that the increased frequency of systemic $CD163^{+}$ non-classical monocytes corresponds with upregulation of soluble CD163 in SSc. Parallel to this, the paracrine macrophage-fibroblast crosstalk is supportive of the micro-environment in promoting fibrosis. Thus, modulating both the systemic and local effects of non-classical monocytes mediated by CD163 may have therapeutic relevance in targeting fibrosis in SSc.

Epigenetic Regulation-Mediated Reduction in the Expression of Prostacyclin Receptor and Prostacyclin Synthase in Scleroderma Skin, Vascular Smooth Muscle Cells, and Microvascular Endothelial Cells

Yongqing Wang,[1] nezam Altorok,[2] and **Bashar Kahaleh** [2], [1]University of Toeldo, TOLEDO, OH, [2]University of Toledo, Toledo, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Basic Science Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Progressive functional and structural vascular disorder is one of the hallmark features of Systemic Sclerosis (Scleroderma, SSc). Vascular dysfunction lead to dysregulated vascular tone control and activation of vascular smooth muscle cells (vSMCs) resulting in enhanced vasospasm and intimal hyperplasia. It is believed that vascular dysfunction results from imbalance in endothelial signals with increase vasoconstrictors and defective release of vasodilators and vSMCs inhibitors. In this study, we examine the expression levels of prostacyclin synthase (PTGIS) and prostacyclin receptor (IP) in normal and SSc skin, microvascular endothelial cells (MVECs) and vSMCs. We also investigated the effects of the DNA methyltransferase inhibitor 5-Aza-2′-deoxycytidine (Aza), and the histone deacetylase inhibiter trichostatin (TSA) on PTGIS and IP gene expression in SSc and normal MVECs and vSMCs.

Methods: MVECs and vSMCs were isolated from SSc patients' skin and matched healthy subjects. The mRNA and protein expression levels of IP and PTGIS were measured by qPCR and Western blot analysis (WB). In addition, epigenetic inhibitors were added to cell cultures to assess the role of epigenetic regulation on IP and PTGIS expression levels. MVECs and VSMCs were treated with Aza at 5uM for 5 days and TSA at 100nM for 1 day, and mRNA and protein expression levels were measured.

Results: The mRNA expression levels of PTGIS and IP were significantly downregulated in SSc-skin to 0.183-fold ± 0.03 for PTGIS ($P< 0.01$) and to 0.54-fold ± 0.06 for IP ($P< 0.01$), compared to control skin. The mRNA expression levels of PTGIS and IP were also decreased in SSc-vSMCs, compared to control (to 0.29-fold ± 0.04, $P< 0.01$ for PTGIS; to 0.46-fold ± 0.06 for IP, $P< 0.01$). WB analysis demonstrated similar reduction on the protein levels in SSc -vSMCs. Addition of Aza and TSA resulted in increased expression of IP and PTGIS to almost normal levels in SSc-vSMCs. SSc-MVECs also exhibited lower expression levels of PTGIS than control MVECs at both mRNA level (0.214-fold ± 0.03, $P< 0.01$) and protein level (0.49-fold ± 0.05, $P< 0.05$). The addition of Aza and TSA corrected the reduced mRNA and protein expression levels of PTGIS in SSc-MVECs.

Conclusion: These data demonstrate a defective prostacyclin (PGI2)-IP pathway in MVECs and vSMCs from SSc patients. This defect may contribute to the vascular dysfunction observed in SSc by decreasing the vasodilatory PGI2/IP signaling pathway, resulting in enhanced vasospasm and vascular remodeling. The addition of Aza and TSA corrected the reduced PTGIS and IP expression levels, suggesting an epigenetic regulation. Augmenting IP and PTGIS expression, either independent of or combined with the use of PGI2 analogues, may be an important new therapeutic strategy for SSc.

The Impact of Race on Birth Outcomes Among Women with Autoimmune Rheumatic Diseases

Lena Sabih,[1] Jennifer Strouse,[1] Nichole Nidey,[2] Gretchen Bandoli,[3] Rebecca Baer,[4] Sky Feuer,[5] Laura Jelliffe-Pawlowski,[5] Christina Chambers,[6] Kelli Ryckman,[2] and Namrata Singh[7], [1]University of Iowa Hospitals and Clinics, Iowa City, [2]UIOWA, Iowa City, [3]University of California, San Diego, La Jolla, [4]UCSD, La Jolla, [5]UCSF, San Francisco, [6]UCSD, San Diego, [7]University of Iowa, Iowa City

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune rheumatic diseases (ARDs) are associated with adverse pregnancy outcomes (APOs). There are only a small number of studies that have looked at the association of race with APOs, especially in women of Asian race/ethnicity. Black race has been associated with worse APOs in women with ARDs when compared to Non-Hispanic White populations in a small number of studies. The aim of our study is to evaluate the impact of race and rheumatic disease on birth outcomes including preterm birth (PTB), congenital anomalies, low birth weight (LBW), and small for gestational age (SGA) in a large multiethnic cohort of women.

Table 1: Effect of race on pregnancy outcomes in singleton births of women 18 years and older with ARD in California from 2007 to 2012

Race	Asian		Black		Hispanic		White
	OR	95% CI	OR	95% CI	OR	95% CI

SLE	1.52	0.89-2.59	1.76*	1.02-3.05	1.37	0.89-2.11	REF
RA	0.40	0.14-1.12	1.50	0.73-3.08	0.89	0.57-1.37	REF

Models adjusted for maternal age, education, insurance and parity

ARD = autoimmune rheumatic disease, OR = odd's ratio, CI = confidence interval, SLE = systemic lupus erythematous, RA = rheumatoid arthritis, REF = reference

[A] SLE, RA, antiphospholipid syndrome, psoriatic arthritis, ankylosing spondylitis, JIA

* p≤0.05

Methods: Birth records linked to hospital discharge data of singleton births in California from 2007 to 2012 were leveraged for a retrospective cohort study including women at least 18 years old diagnosed with ARD. International classification of diseases, ninth revision codes were used to identify women with ARD, as well as PTB, LBW, SGA and congenital anomalies among infants. Race/ethnicity was abstracted from birth record data. The odds of PTB, LBW, SGA and congenital anomalies were estimated in separate logistic regression models and models were adjusted for maternal age, education, insurance and parity.

Results: Among women with an ARD diagnosis (rheumatoid arthritis, systemic lupus erythematosus, antiphospholipid syndrome, psoriatic arthritis, ankylosing spondylitis, juvenile idiopathic arthritis) who met our eligibility criteria, Black women had a two-fold increased odds of PTB when compared to Non-Hispanic White women (OR 2.09, 95% CI 1.72-2.53). Additionally, Asian (OR 1.63, 95% CI 1.35-1.96) and Hispanic (OR 1.33, 95% CI 1.16-1.52) women were also more likely to give birth preterm. In women with RA, increased OR of PTB was only significant in Black women compared to Non-Hispanic White women. The odds of SGA were significantly increased for Asian (OR 2.33, 95% CI 1.92-2.83), Black (OR 2.24, 95% CI 1.89-2.89) and Hispanic women with any ARD compared with Non-Hispanic White women and remained significant for those with RA and SLE. Among women with any diagnosis of an ARD, race was not significantly associated with premature rupture of membranes except for Black women (OR 1.53, 95% CI 1.04-2.24).

Conclusion: Our findings support previous work that among women with an ARD diagnosis, minority race is a risk factor for adverse pregnancy outcomes including PTB and SGA. Although the etiology of this increased risk is not fully understood socioeconomic and genetic contributions have been proposed in prior work. Our study is the first study with a large group of women with Asian race/ethnicity and found that this group, along with Hispanic and Black women, have an increased risk of adverse pregnancy outcomes when compared with Non-Hispanic White women. Asian, Black, and Hispanic women with ARDs should undergo increased monitoring during pregnancies.

Models adjusted for maternal age, education, insurance and parity

ARD = autoimmune rheumatic disease, OR = odd's ratio, CI = confidence interval, SLE = systemic lupus erythematous, RA = rheumatoid arthritis

[A] SLE, RA, antiphospholipid syndrome, psoriatic arthritis, ankylosing spondylitis, JIA

* p≤0.05

tion. Live born infants were followed by maternal interview and pediatric records to approximately one year of life. Any use in pregnancy, and gestational timing of biologic medication were examined as predictors of any non-serious infections reported by the mother or the pediatrician in the infant. Non-serious infections were defined as infections not requiring hospitalization, e.g., common cold, otitis media, influenza, or urinary tract infection. Odds ratios (OR) and adjusted odds ratios (aOR) accounting for maternal use of systemic corticosteroids and their 95% Confidence Intervals (CI) were computed using the generalized estimating equation (GEE) approach.

Results: Between 2004 and 2017, 1,513 live born infants were born to women enrolled in the study. Of these, 768 were born to mothers who had used a biologic medication anytime in pregnancy, 311 to mothers with autoimmune diseases who used no biologic medication in pregnancy, and 434 to women with no chronic health conditions. Overall, 423/768 (55.1%) of mothers who used a biologic anytime in pregnancy had an infant with at least one non-serious infection compared to 152/311 (48.9%) in the autoimmune-disease unexposed group (aOR 1.28, 95% CI 0.98, 1.68). 276/492 or 56.1% of infants born to women who used a biologic anytime in the third trimester had a non-serious infection compared to autoimmune-disease unexposed (aOR 1.32, 95% CI 0.99, 1.78). Similarly elevated but non-significant aORs were found regardless of how late in gestation the last dose of biologic medication was taken. In contrast, infants born to mothers who used biologics anytime in pregnancy were consistently more likely to have non-serious infections compared to infants born to women without autoimmune diseases (179/434 or 41.2%); ORs 1.73 to 2.32).

Conclusion: Use of biologic medications anytime during pregnancy or in the third trimester was not associated with a significant increased risk of non-serious infections in infants when compared to infants born to women with the same underlying diseases but no biologic treatment, after accounting for use of systemic steroids. In contrast, a ~2-fold increase in non-serious infections was seen with biologic use in comparison to infants born to women without autoimmune diseases. It is possible that there was bias in documentation of more mild infections in infants born to women with autoimmune diseases compared to those without. Nevertheless, these data are generally reassuring to women with autoimmune diseases who require treatment with biologics during any part or all of pregnancy.

Methods: We queried a retrospective California birth cohort created from linked birth certificates and hospital discharge summaries. From 2,963,888 births, we identified women with rheumatoid arthritis, systemic lupus erythematosus, psoriasis and inflammatory bowel disease. Pregnancy complications included preeclampsia/hypertension, gestational diabetes and infection in pregnancy. Adverse pregnancy outcomes were preterm birth, cesarean delivery and small for gestational age. We performed a causal mediation analysis to estimate the total effects of each autoimmune condition and adverse pregnancy outcome, and the indirect effects of each pregnancy complication.

Results: Each autoimmune condition was associated with an increased risk of all adverse pregnancy outcomes (Tables 1-3, inflammatory bowel disease not shown), except psoriasis and small for gestational age. The strongest mediator was preeclampsia/hypertension, accounting for 20-30% of the excess risk of preterm births and 10-15% of excess cesarean deliveries in all autoimmune conditions except IBD. Gestational diabetes and infections generally accounted for < 10% of excess adverse pregnancy outcomes. Of the four autoimmune conditions, selected pregnancy complications mediated the least amount of adverse pregnancy outcomes among women with inflammatory bowel disease (not shown).

Conclusion: We found evidence that some excess risk of adverse pregnancy outcomes is mediated through pregnancy complications, particularly preeclampsia/hypertension. Quantifying excess risk and associated pathways provides insight into the underlying etiologies of adverse pregnancy outcomes and can inform intervention strategies.

Table 3. Effect decomposition of the influence of psoriasis and potential mediators on adverse pregnancy outcomes in 3 million live births in the state of California

Cardiovascular Risk Awareness in Patients with Rheumatic Diseases: A Case-Control Study

Dionicio Angel Galarza-Delgado,[1] Iris Colunga-Pedraza,[2] Jose Azpiri-Lopez,[2] **Karla Paola Cuellar-Calderon**,[2] Ileana Cecilia Reynosa-Silva,[2] Marielva Castro-Gonzalez,[2] and Carolina Marlene Martinez-Flores[2], [1]Universidad Autonoma de Nuevo Leon "Dr. Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico, [2]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular diseases are among the most common comorbidities in patients with rheumatic diseases (RD) and leads them to an overall increase of mortality in comparison to the general population. Risk reduction can be reached through different strategies that control traditional cardiovascular risk (CVR) factors. In order to start lifestyle changes it is necessary an adequate knowledge of the disease and its consequences. Furthermore, patients who perceive themselves at a higher risk of developing CVD are more likely to make changes. The precaution adoption process model (PAPM) is a self-applied questionnaire useful to evaluate the knowledge of cardiovascular risk and outlines the actions that have been taken by each patient. Therefore, the objective was to assess the awareness of their CVR in patients with/without rheumatic diseases.Methods

A cross-sectional, observational, single center study was designed. Patients were recruited at a community educational healthcare conference. Population was divided into two groups; case group, with the following RD: RA, SLE, SS, AS, Scleroderma, PsA and DM, and a control group with subjects without RD. After clinical history, subjects were asked

Table 1. Demographic Characteristics

	Case (n=140)	Control (n=134)	*p*

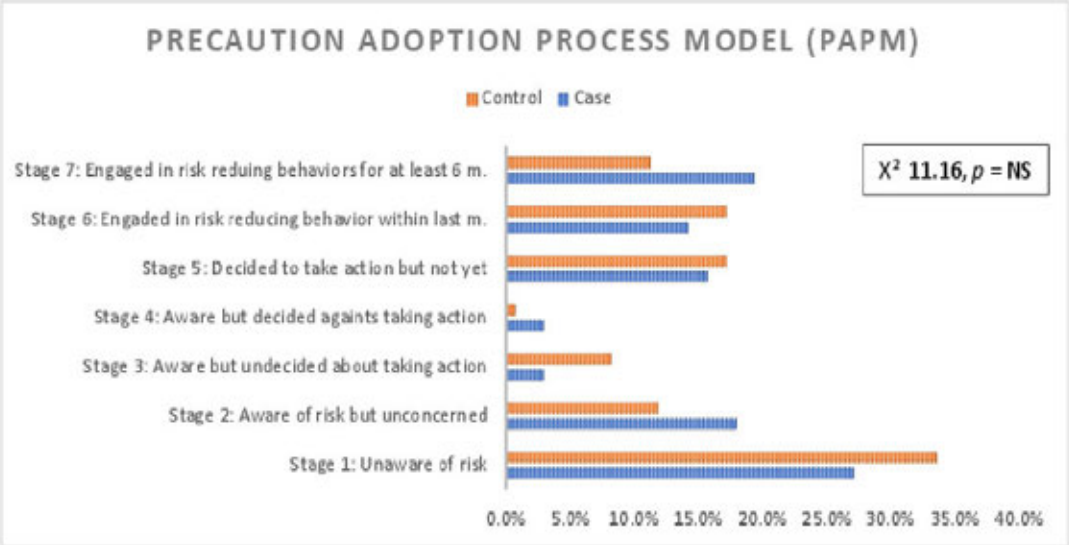
Table 3 Precaution Adoption Process Model (PAPM)



if they considered themselves at a higher risk of having CVD and PAPM was used to stratify the stage assigned. Frequencies (%) and median values (q25-q75) were used for descriptive analysis and Chi Square test for comparisons.

Results: A total of 274 patients were included. Demographic characteristics are in table 1. CVD risk perception as a binary variable was 56.1% and 47.8% in the case and the control groups, respectively (p= 0.167). Women and subjects with complete university education showed more awareness. According to PAPM scale, most of the patients located themselves in stage 1 (27.1% vs 33.6% in case vs control groups; p= NS), which means they are unaware of their augmented CVR (Figure 1). In the subjects with RD, 66.5% have not made any changes to reduce their risk while 71.6 % of the controls neither. In the control and case group having hypertension makes them prone to start actions to reduce their CVR with an OR of 2.9 (95% CI 1.3-6.6, p=0.007) and OR 2.4 (95% CI 1.0-5.6, p=0.029), respectively. Only 31.4% of the case group received CVR advice from physician, as compared to 26.1% in control group (table 2).

Conclusion: Even though patients with RD have an increased CVR due to the inflammatory condition and coexistence of traditional CVR factors, most of the individuals perceived it the same as control group. Therefore, these could explain the lack of initiative to start actions to reduce their CVR. According to EULAR recommendations the rheumatologist is the one responsible and they should commit to give a better education.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Figure 1. Frequency of First-Line Regimens Over Time

	2012	2013	2014	2015	2016	2017
TNF	41.08	37.01	34.58	29.85	29.46	28.98
IL	3.75	4.8	2.61	4.62	5.08	4.96
cDMARD	55.17	58.19	58.62	51.59	51.81	53.79
APR	0	0	4.2	13.95	13.66	12.27

Background/Purpose: Many new PsA treatments have emerged without clear guidelines on which therapy to use initially. We describe PsA treatment trends and patient journeys between 2012 and 2018.

Methods: Adult PsA patients were selected if they initiated any therapy (index date) with an oral conventional DMARD (cDMARD; cyclosporine, methotrexate, sulfasalazine, leflunomide, azathioprine, gold, hydroxychloroquine), apremilast (APR), TNF inhibitor (adalimumab, certolizumab, etanercept, golimumab, infliximab), or IL inhibitor (ixekizumab, secukinumab, ustekinumab) from January 1, 2012, to June 30, 2017. Selected patients had ≥12 months pre- and post-index continuous enrollment in the IBM Watson Health MarketScan® Commercial and Medicare Supplemental Database and no history of biologic-indicated autoimmune conditions (ie, diagnosis of rheumatoid arthritis or IBD) or cancer in the pre- or post-index period. Treatment patterns were assessed until end of follow-up. Concluding a line of therapy was defined as discontinuation (>90-day lapse in therapy) or switch to a new line of PsA therapy (cDMARD, APR, TNF, or IL), whichever occurred first. Patients switching to a new line of therapy or restarting the previous therapy after discontinuation were categorized. Initiating or switching to combination therapy was defined as ≥2 new agents within 14 days, or adding a new agent on current therapy with ≥60 days' supply overlap. Patient characteristics, first- and second-line PsA agent use, and frequency of treatment sequences were summarized by years and first-line drug categories.

Results: A total of 5,135 PsA patients (cDMARD: n=2,821 APR: n=341, TNF: n=1,756, IL: n=217) were included. Mean age was 48 (SD 11.9) years and 52.3% were female. Mean age was similar among treatment groups, whereas the cDMARD and APR groups had more female patients. Mean length of follow-up was 1,017 (SD 514) days. First-line oral cDMARD and IL use remained consistent from 2012 to 2017. First-line APR use increased

Figure 2. Frequency of Second-Line Regimens Over Time

	2012	2013	2014	2015	2016	2017	2018
TNF	38.76	43.76	44.24	37.93	36.08	34.07	31.13
IL	9.13	6.13	6.84	7.62	11.26	13.81	14.57
cDMARD + TNF	25.84	22.41	17.36	17.18	16.02	15.29	3.32
cDMARD + IL	0.48	1.27	0	0.49	0.72	0.75	1.32
cDMARD	26.79	26.43	25.88	20.58	22.08	22.65	26.49
APR + TNF	0	0	0.34	0.97	0.72	0.55	0
APR + IL	0	0	0	0.65	0.14	0.18	0
APR + cDMARD	0	0	1	1.78	1.88	2.76	1.32
APR	0	0	4.34	12.8	11.11	9.94	21.85

Table 1. Top 5 Patient Treatment Journeys Over Time

2012	%	2017	%
TNF → Still on Therapy	19.21	cDMARD → Discontinuation → None	14.36
cDMARD → Discontinuation → None	16.37	TNF → Still on Therapy	10.97
cDMARD → Still on Therapy	15.37	cDMARD → Still on Therapy	8.88
TNF → Discontinuation → None	11.52	TNF → Discontinuation → None	6.79
cDMARD → Switch → cDMARD, TNF → Still on Therapy	5.22	Apremilast → Still on Therapy	4.96

over time since its FDA approval in 2014, while TNF use decreased (Figure 1). At end of follow-up, a larger proportion of first-line APR patients remained on therapy (27.9%) vs cDMARD (11.8%), TNF (22.5%), and IL (23.5%). Among those who ended first-line therapy, treatment patterns were as follows: APR had the highest rate of sustainability as staying first line (not progressing to second-line therapy) after discontinuation (30.9%), followed by cDMARD (24.6%), TNF (19.3%), and IL (16.3%). Oral cDMARDs had the highest rate of switching (61.4%), followed by TNF (56.7%), APR (52.0%), and IL (44.0%). IL had the most restart after discontinuation (39.8%), followed by TNF (24.0%), APR (17.1%), and cDMARD (14.0%). Second-line cDMARD use was maintained throughout the study period. Second-line APR and IL use increased while TNF and cDMARD + TNF combination use decreased (Figure 2). Differences in the most frequent 12-month patient treatment journeys were observed during the study period (Table 1).

Conclusion: APR as first- and second-line treatment increased while TNF use decreased during the study period. cDMARD use remained consistent and IL therapy use increased second line. Introduction of newer PsA agents has impacted the treatment paradigm.

Sarilumab	0 (0.0)	1 (2.1)

CCI: Charlson comorbidity index; DAS28-ESR: Disease Activity Score - erythrocyte sedimentation rate.

Background/Purpose: Biosimilars hold the potential to improve access to needed therapies at a reduced cost. In Canada, biosimilar etanercept (bsETA-Brenzys® and Erelzi®) were recently approved for rheumatoid arthritis (RA) and other rheumatologic conditions; however, comparisons of patterns of use of biosimilar with its originator product (boETA-Enbrel®) are scarce. Our objective was to describe the recent use of bsETA and boETA in patients with RA, ankylosing spondylitis (AS), and psoriatic arthritis (PsA).

Methods: Data from patients initiating bsETA (either biologic-naïve users, patient transitioning from boETA, swappers and switchers from other biologic agents) were extracted from RHUMADATA®, a practice-based registry (14 Quebec rheumatologists) for the period of January 2015 to November 2018. For comparison purposes, we identified patients initiating/switching/swapping to the boETA product in the same period. We obtained baseline demographics and clinical data for all patients. Therapy persistence in bsETA versus boETA initiators was compared using Kaplan-Meier methods and adjusted hazard ratios (HR). Our hazard models adjusted for age, sex, disease duration, methotrexate (MTX) dose at baseline, and comorbidities (Charlson comorbidity index).

Results: We studied 48 patients initiating bsETA (including 37 etanercept-naïve patients) and 59 patients initiating boETA. Sex distribution, age, comorbidities and disease duration (at etanercept initiation) were similar between groups (Table 1). Use of MTX and/or other conventional synthetic DMARD (csDMARDs) at etanercept initiation was also similar between groups; however, patients in the boETA group started with a significant higher dose of MTX (22.0 ± 3.5mg) when compared to bsETA users (19.0 ± 5.2mg, p=0.011). Persistence on therapy was similar in both groups (Figure 1): after 12 months, 75% of originator etanercept versus 84% of biosimilar etanercept initiators remained on their initial treatment. Adjusting for baseline age, sex, disease duration, methotrexate dose at baseline, and comorbidities, the adjusted HR for therapy persistence in biosimilar etanercept versus originator etanercept group was 2.05 (95% CI 0.83, 5.04).

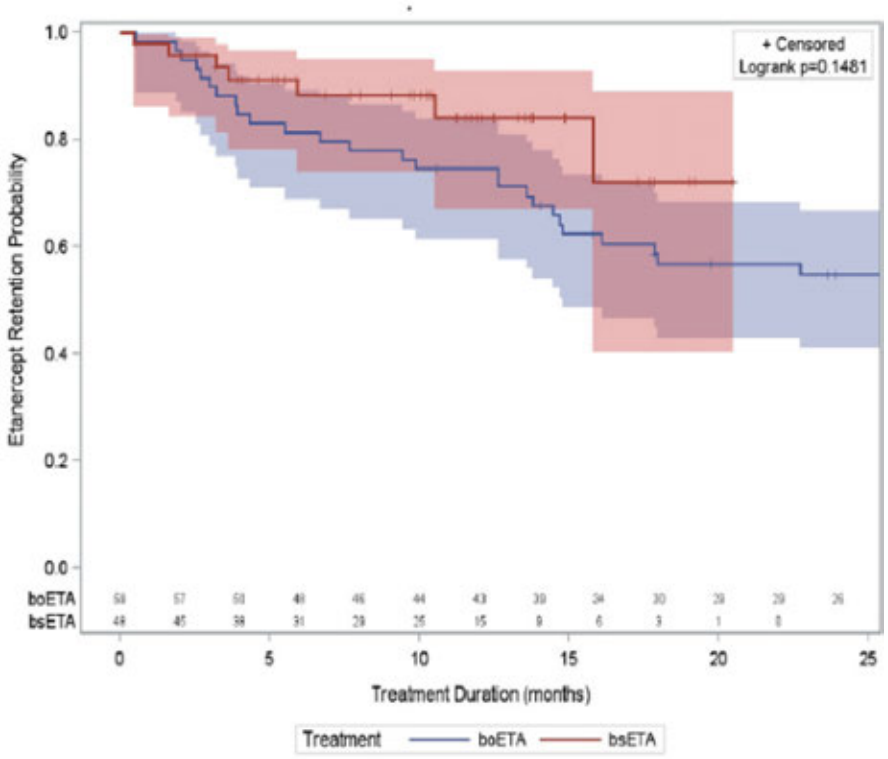

Figure 1. Kaplan Meier survival curves for therapy persistence per treatment group of a) boETA, and b bsETA.

Conclusion: Patients initiating bsETA or boETA were similar in terms of age, disease duration, disease activity, and comorbidities. We were unable to identify clear differences in treatment persistence between the two groups; a strong trend for greater persistence with biosimilar versus originator may be related to residual confounding (e.g.: disease activity). Further work is ongoing to study outcomes in a larger, multicentre group of patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA), psoriatic arthritis (PsA), and axial spondyloarthritis (axSpA) share many clinical features but are differentiated by key clinical and molecular characteristics. Patients with RA are often seropositive (S+) for rheumatoid factor (RF) or anti-cyclic citrullinated peptide (CCP) antibodies, whereas those with PsA or axSpA are usually seronegative (S–) for these antibodies. Limited data are available comparing patients with S+ and S– RA, and few studies have compared disease burden across patients with S+ RA, S– RA, PsA, and axSpA. We compared clinical and disease characteristics among these 4 groups in the Corrona RA and PsA/SpA Registries.

Methods: Adult patients with RA enrolled in the Corrona RA Registry and those with PsA or axSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and February 2019 were included. Patients with RA must have had nonmissing RF and anti-CCP values at enrollment and were classified as S+ (RF or anti-CCP $\geq$ 20 U/mL) or S– (RF and anti-CCP $<$ 20 U/mL). Patient demographics, clinical characteristics, and disease activity and patient-reported outcome (PRO) measures collected at registry enrollment were compared between patients with S+ RA vs S– RA, PsA, or axSpA using *t* or Wilcoxon rank-sum tests for continuous variables and χ^2 or Fisher exact tests for categorical variables.

Results: A total of 4827 patients with S+ RA, 1959 with S– RA, 3001 with PsA, and 512 with axSpA were included. Patients with S– RA had a higher prevalence of comorbidities than those with S+ RA, including fibromyalgia (13.1%

Table 1. Demographics and Clinical Characteristics of Patients With Seropositive RA, Seronegative RA, PsA, and AxSpA at Enrollment

AxSpA, axial spondyloarthritis; BMI, body mass index; NMSC, nonmelanoma skin cancer; PsA, psoriatic arthritis; RA, rheumatoid arthritis; S+, seropositive; S−, seronegative.
* $P < 0.05$ for comparison between patients with S− RA, PsA, and axSpA vs those with S+ RA.
† $P < 0.05$ for comparison of overall distribution across categories between patients with S− RA, PsA, and axSpA vs those with S+ RA.

vs 5.9%) and depression (22.7% vs 17.6%) (**Table 1**). Patients with axSpA had a lower prevalence of comorbidities than those with S+ RA; there was no clear trend in prevalence of comorbidities between patients with PsA and S+ RA. Overall biologic and prednisone use were comparable between patients with S+ and S− RA, whereas patients with PsA or axSpA had more biologic use and less prednisone use than those with S+ RA (**Table 2**). Prior csDMARD use was higher among patients with S− RA and lower among patients with axSpA than those with S+ RA; current csDMARD use was comparable between patients with S+ and S− RA but lower among those with PsA or axSpA. Patients with S+ RA had higher swollen joint counts, ESR, and CRP levels than those with S− RA, PsA, or axSpA,

AxSpA, axial spondyloarthritis; CDAI, Clinical Disease Activity Index; CRP, C-reactive protein; EQ-5D, EuroQol 5 dimensions; ESR, erythrocyte sedimentation rate; HAQ, Health Assessment Questionnaire; PsA, psoriatic arthritis; RA, rheumatoid arthritis; S+, seropositive; S−, seronegative; VAS, visual analog scale.
* Data are presented as mean (SD) unless otherwise indicated.
† $P < 0.05$ for comparison between patients with S− RA, PsA, and axSpA vs those with S+ RA.
‡ $P < 0.05$ for comparison of overall distribution across categories between patients with S− RA, PsA, and axSpA vs those with S+ RA.

and higher tender joint counts than those with PsA and axSpA (**Table 3**). Patients with S+ RA had a higher mean physician global assessment score than those with S– RA or PsA but lower than those with axSpA. Patients with S+ RA had a mean patient global assessment score comparable with that of patients with S– RA but lower than those with PsA or axSpA.

Conclusion: Patients with S– RA had a higher comorbidity burden but similar treatment profiles and PRO scores compared with those with S+ RA. Patients with PsA or axSpA had more biologic use and worse PRO scores than those with S+ RA. These results demonstrate the differences in disease manifestations of patients with these diseases. Further studies are needed to identify factors that differentiate these disease groups, particularly regarding therapeutic response.

Cancer Risk in Patients with Ankylosing Spondylitis: A Nationwide Population-based Dynamic Cohort Study from Korea

Eunyoung Lee,[1] Kyung-Do Han,[2] Yeong-Wook Song,[3] and Eun Young Lee[1], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Seoul, Republic of Korea, [2]Department of Biostatistics, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Seoul, Republic of Korea, [3]Seoul National University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

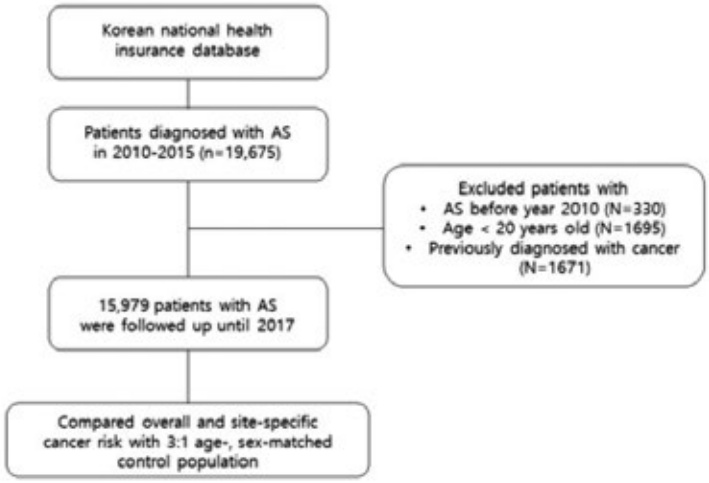
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study is to determine the risk of overall malignancy and site-specific cancer in ankylosing spondylitis (AS) patients compared with patients without AS in Korea.

Methods: The study utilized the National Health Information Database managed by National Health Insurance Service in Korea. The data from national health screening programs, data related to medical care institutions and a registry of cancer and rare/severe intractable diseases were also included. Patients diagnosed as AS (International Classification of Diseases, 10th revision codes M45.0 and code V140 used in Korea for severe intractable diseases) between 2010 and 2015 were extracted. Of these, patients with a history of cancer during the washout period from 2008 to 2009 were excluded. For the control cohort, an age- and sex-matched population without AS was randomly extracted at a control-to-case ratio of 3:1. The incidence rates for overall and specific cancers were calculated per

Figure 1. Flowchart of the study process



AS, ankylosing spondylitis

1000 person-years. Multivariate Cox regression model was used to evaluate the risk for malignancies. Results presented as hazard ratios (HRs) with 95% confidence intervals (CIs).

Results: A total of 15,979 patients with AS and 47,937 matched controls were included for analysis. The prevalence of diabetes mellitus, hypertension and dyslipidemia which are well known risk factors for cancer were statistically high in AS patients (5.76% vs 4.84%, 16.66% vs 12.34%, 11.3% vs 7.99%, respectively) [$p < 0.0001$, $p< 0.001$ and $p < 0.0001$. respectively]). Cancer was diagnosed in 311 patients (1.95%) and 931 patients (1.94%) in the AS group and age- and sex-matched control group, respectively. After adjusting age, sex, diabetes mellitus, hypertension, dyslipidemia, regions and income status, patients with AS showed higher risk for lymphoma (HR, 3.052; 95% CI, 1.446-6.446), leukemia (HR, 2.322; 95% CI, 0.911-5.914) and multiple myeloma (HR 2.829; 95% CI, 1.16-6.901). The risk of solid cancers was not different between the two groups.

Conclusion: In this nationwide population-based study in Korea, AS patients were associated with increased risk of hematologic malignancies. Further research is needed to determine the relationship between AS and these malignancies.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment effectiveness in patients with axial spondylarthritis (axSpA) is evaluated by a combination of objective markers of disease activity and patient reported outcomes (PROs), e.g. pain, physical function, fatigue and global scores. Development in PROs over time in patients, who initiate treatment with their 1st, 2nd or 3rd Tumour Necrosis Factor inhibitor (TNFi) in routine practice is limited. Hence, the aim of this study was to investigate PROs at baseline, 6 and 12 months in axSpA patients who initiate their 1st, 2nd or 3rd TNFi in clinical practice: their distribution, changes from baseline and heterogeneity across registries.

Table 2: PROs after 6, 12 and 24 months of TNFi treatment in the pooled AxSpA cohort

	1st TNFi			2nd TNFi			3rd TNFi

Data are as observed. Percentage of available data varied from 10-82%. Values are median (Inter Quartile Range (IQR)) unless otherwise stated. PRO: Patient reported outcome; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; TNFi: Tumour Necrosis Factor inhibitor.

*Crude value: the fraction of patients in PRO remission of those still on drug with available data at 6, 12 and 24 months. Percentage of available data varied from 35to 90%.

** LUNDEX-adjusted: Crude value adjusted for drug retention.

Methods: Pooled data on axSpA patients from 14 European registries participating in the EuroSpA Research Collaboration were analysed (1). Patients were included if they had been followed in the registry from initiation of the 1st TNFi. PROs included scores for pain, disease activity (global and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI)), physical function (Bath Ankylosing Spondylitis Functional Index (BASFI)) and fatigue, all captured with Visual Analogue Scales 0-100 mm (VAS). The distribution of PROs at 6, 12 and 24 months after TNFi start and the changes from baseline to 6, 12 and 24 months were investigated with descriptive statistics. PRO remission rates were defined as the proportion of patients achieving a state of pain score ≤20 mm, global score 20 mm, BASDAI ≤20 mm, BASFI ≤20 mm and fatigue score ≤20 mm. Crude and LUNDEX-adjusted (2) PRO remission rates were assessed for the pooled cohort and the individual countries.

Results: Of the 25,988 axSpA patients, who initiated 1st TNFi, 8,294 patients switched to a 2nd TNFi, while 2,842 patients subsequently switched to a 3rd TNFi. Baseline characteristics of the study cohort are shown in Table 1. The 6, 12 and 24 month PRO status and changes in PROs for 1st, 2nd and 3rd TNFi in the pooled cohort are summarized in Table 2. For the 1st, 2nd and 3rd TNFi, median PROs after 6 months ranged from 20mm to 30mm, 27mm to 40mm and 35mm to 50mm, respectively. Similarly, median decreases in PROs from baseline to 6 months ranged from 18 to 30mm, 8 to 18mm and 8 to 18mm for the 1st, 2nd and 3rd TNFi. In the overall cohort 6 month LUNDEX-adjusted PRO remission rates varied from 33% to 41%, 23% to 33% and 17% to 24% for the 1st, 2nd and 3rd TNFi, respectively (Table 2). In the individual registries, LUNDEX-adjusted 6 months PRO remission rates for the 1st TNFi ranged from 32% to 51%, 24% to 50%, 28% to 48%, 32% to 51% and 21% to 47% for pain, global, BASDAI, BASFI and fatigue scores, respectively.

Conclusion: Overall, one-third of patients in a very large observational cohort achieved a state of PRO remission after 6 months of treatment with their first TNFi with considerable variation in PRO remission rates between registries.

As expected, improvements in PROs and PRO remission rates were lower in those who received a 2nd or 3rd TNFi, reflecting confounding by indication (i.e. selection of non-responders and more severe cases).

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) have vastly improved prognosis in patients with axial spondyloarthritis (axSpA). However, many patients treated with TNFi still fail to achieve a treatment target of remission. Hence, the aim of this study was to construct and validate a prediction model for achievement of Ankylosing Spondylitis Disease Activity Score (ASDAS) inactive disease (< 1.3) in bio-naive axSpA patients after 6 months of TNFi treatment.

Methods: Of the 14 registries in the EuroSpA Collaboration (1), 10 collected data on ASDAS and patients with a 6 months follow-up visit (time window 3-9 months) with registration of variables needed for ASDAS calculation constituted the study cohort. The study cohort was split by dividing 50% of patients from each individual registry into a derivation and validation cohort. Logistic regression analyses were used to identify conventional clinical variables (marked with bold in Table 1) associated with ASDAS < 1.3 at follow-up in the derivation cohort. Missing covariate data were imputed with Multiple Imputation with Chained Equations. Variables with a p-value < 0.25 in univariate analyses were included in the initial multivariable model. A priori it was decided to adjust for age, gender and country. Purposeful selection guided removal of variables from the multivariable model. Model fit was tested in the validation cohort by area under the Receiver Operating Curve (ROC) and misclassification error.

Results: Of the 25,988 axSpA patients in the EuroSpA database who started their 1st TNFi 7,396 had a relevant follow-up visit with registration of variables needed for ASDAS calculation. The study cohort had slightly higher

Table 1: Baseline characteristics

	Patients with assessment of ASDAS at follow-up (n=7,396)		Patients without assessment of ASDAS at follow-up (n= 18,592)	
	No. of patients with available data, n	Median (IQR) or percentage	No. of patients with available data, n	Median (IQR) or percentage

ASDAS: Ankylosing Spondylitis Disease Activity Score; BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; BASFI: Bath Ankylosing Spondylitis Functional Index; VAS: Visual Analogue Scale

disease activity at baseline than the patients without follow-up ASDAS assessment (Table 1). At 6 months, 2,203 patients (29.8%) of patients were in ASDAS inactive disease. Based on univariate analyses, all tested variables except concomitant csDMARDs were included in the initial multivariate model. During model fitting, time since diagnosis, smoking, VAS pain, VAS Global and Physician global were excluded. The final model demonstrated that HLA-B27 positivity, treatment start after 2015, moderately elevated CRP, low baseline BASDAI, low BASFI and low fatigue scores increased the probability of ASDAS inactive disease at 6 months (Table 2). The regression coefficients of the model were used to derive a prediction index for each patient in the validation cohort, determining their predicted probability of ASDAS inactive disease at 6 months. The ability of the model to correctly predict ASDAS inactive disease using different cut-offs for predicted probability are shown with the ROC (see Figure 1). The fit was deemed reasonable (median area under the curve 0.74, misclassification error 0.26).

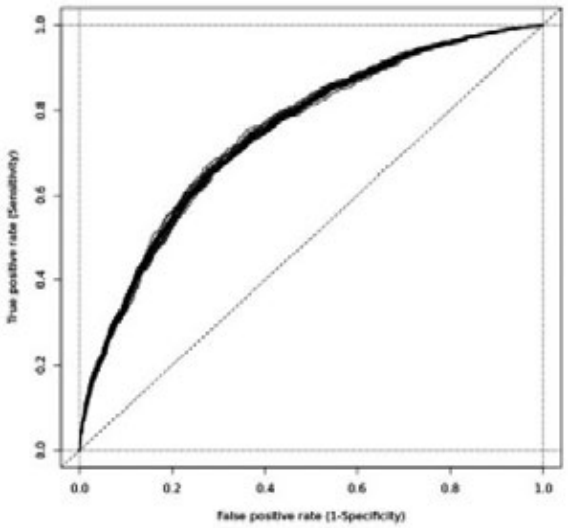

Figure 1: Receiver Operating Curves in the validation cohort (20 imputed datasets)

Conclusion: A clinical prediction model for ASDAS inactive disease after 6 months of TNFi treatment was constructed correctly identifying 3 out of 4 patients as responders/non-responders. Future studies should investigate the potential of improving the model by addition of imaging and soluble biomarkers.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Probiotics have been hypothesized to mediate inflammation through gut microbiome modulation, and growing evidence has suggested that our intestinal gut microbiome may play a role in the development

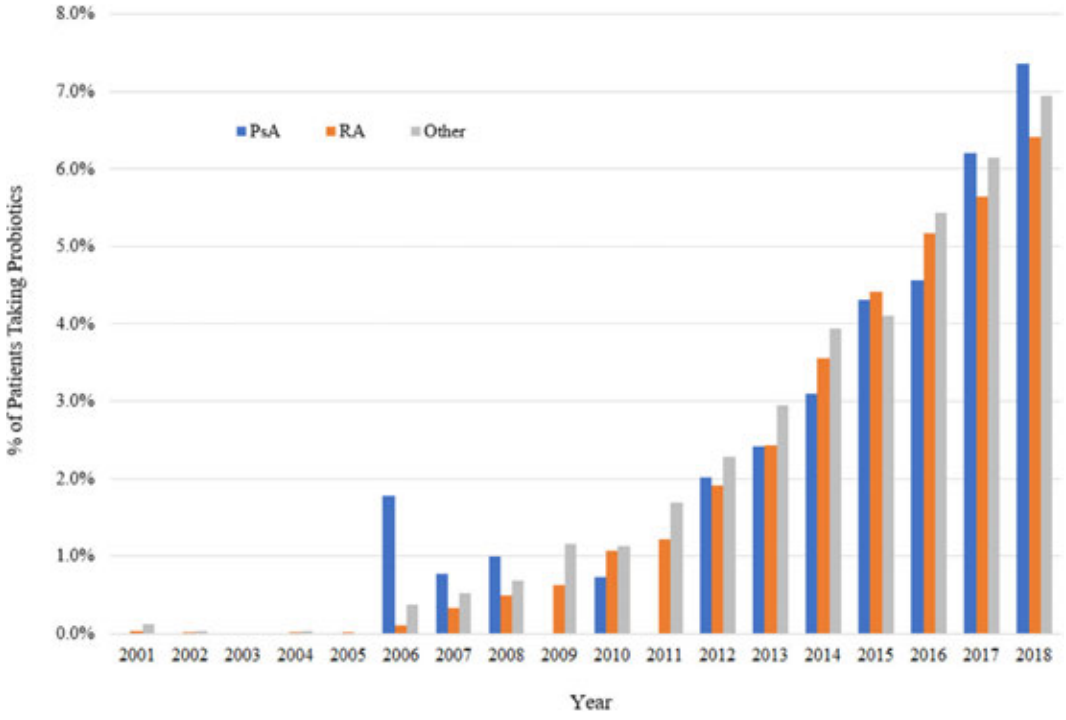

Figure 1. Probiotic use over time by primary rheumatic disease diagnosis in FORWARD. Average N per year was 5 for psoriatic arthritis, 137 for RA, and 81 for Other.

Table 1. Baseline demographic and clinical characteristics of patients by primary diagnosis at enrollment.

	PsA (n = 782)			RA (n = 34378)			
Characteristic	Probiotic user (n = 29)	Nonuser (n = 753)	*p*	Probiotic user (n = 1019)	Nonuser (n = 33091)	*p*	*p* (users, PsA vs RA)

or persistence of spondyloarthritis. This has become understood to some degree among patients who frequently ask about the possible role of probiotics in PsA. The objective of this study was to evaluate associations between probiotic use and patient-reported outcomes in patients with psoriatic arthritis (PsA).

Methods: We examined probiotic use among patients with PsA in FORWARD, The National Databank for Rheumatic Diseases. Patients with rheumatoid arthritis (RA) acted as a comparison group, and patients with dual diagnoses were excluded. The prevalence of probiotic use was determined for each calendar year since the earliest report on record in the databank. Patients who reported probiotic use in at least one encounter were classified as probiotic users. For comparisons made between probiotic users and nonusers, we used propensity score matching to balance confounders. Descriptive statistics were calculated for patient demographics, clinical characteristics, and five outcomes of interest (PAS-II, HAQ-II, pain VAS, SF-36 PCS, and SF-36 MCS). Significance was assessed with Student's t-tests and Fisher's exact tests as appropriate. Paired t-tests were utilized to assess differences in outcomes before and after probiotic use in the PsA cohort.

Results: Probiotic use has increased in recent years, from less than 1% prior to 2006 to approximately 7% of FORWARD patients reporting probiotic use in 2018 (Figure 1). Of the 782 PsA and 34,378 RA patients included in the study, 3.7% and 3.0% reported probiotic use at some point, respectively. In the RA cohort, probiotic users are more likely than nonusers to be female, be Caucasian, have more education, have a higher income, have a higher comorbidity index, use PPIs, and use other supplements in addition to probiotics. Probiotic users and nonusers in the PsA cohort generally follow these same trends, but the differences do not reach statistical significance except in the case of fish oil use (Table 1). After propensity score matching, probiotic users with PsA had significantly lower SF-36 PCS scores and significantly higher pain VAS scores than nonusers with PsA (Table 2). In the paired comparison of probiotic users with PsA before initiating probiotic use and after probiotic exposure, there were no statistically significant differences in any of the five outcomes.

Conclusion: We found increasing probiotic use reported by patients with PsA. In this observational study, we found no significant changes in patient function scores before and after initiation of a probiotic. Prospective studies are needed to examine whether probiotics affect disease activity and function in patients with PsA. Given the difference noted in pain scores between probiotic users and nonusers with PsA, patients who take probiotics may have higher baseline pain levels.

Psoriatic Arthritis - Epidemiology, Incidence Rate in Psoriasis Patients, Comorbidity Profiles and Risk Factor Analysis

Jürgen Rech,[1] Michael Sticherling,[2] Mona Biermann,[3] Benjamin Häberle,[3] and Maximilian Reinhardt[4], [1]Department of Internal Medicine 3, Friedrich-Alexander-University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Germany, [2]Department of Dermatology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, Erlangen, Bayern, Germany, [3]Medical Affairs, Novartis Pharma GmbH, Nürnberg, Germany, Nürnberg, Bayern, Germany, [4]Medical Affairs, Novartis Pharma GmbH, Nürnberg, Germany, Nürnberg, Germany

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis (PsO) is a systemic inflammatory disease accompanied by comorbidities such as depression, cardiovascular diseases or metabolic syndrome. Approximately 10 - 27% of PsO patients develop psoriatic arthritis (PsA), a rheumatologic comorbidity of PsO. Due to increased impairment of working ability and risk of a potential destructive disease course of PsA, early diagnosis and therapeutic intervention are crucial for optimal patient care. This analysis on German health claims data was conducted to determine the rate of development of PsA in PsO patients over 4 years. Furthermore, comorbidity profiles of PsO patients with and without concomitant PsA were compared as well as potential risk factors for the development of PsA were assessed.

Methods: This was a non-interventional retrospective analysis of anonymized insurance health claims data using a subset of the Institute of Applied Health Research Berlin (InGef) database, which was observable between 2012 and 2017. The database contained 2.9 million subjects stratified by age and gender based on the population structure of Germany as reported by the German Federal Statistical Office DeStatis. Continuously insured individuals were identified by ICD-10 GM version 2019 codes (L40.0: psoriasis vulgaris, L40.5: psoriatic arthritis). Risk factors for the development of PsA in Pso patients were determined by conditional logistic regression analysis in sex- and age-matched populations.

Results: The cumulative percentage of patients with incident PsO developing PsA (PsO-PsA) over 4 years was 3% with a mean time to diagnosis of PsA of 1.5 years. Patients developing PsA were on average approx. 5 years younger than patients not developing PsA within 4 years. Although both patient groups displayed a similar spectrum of comorbidities with a high frequency of diseases associated to metabolic syndrome, unspecific arthritic symptoms were distinctly more frequent in PsO-PsA patients. However, only 4% of patients with PsO and 43% of patients with concomitant PsA consulted ambulatory rheumatologists. PsO patients diagnosed with “acute rheumatism” (odds ratio: 2.93, 95% CI=1.01-2.99; p= < 0.001) or “pain in unspecific joints” (odds ratio: 1.74, 95% CI=1.76-4.86; p= 0.047) showed an increased risk to develop PsA later on. Specific arthritic symptoms such as “Bouchard’s nodes” and “Heberden’s nodes”, on the other hand, did not confer a higher risk for development of PsA

Conclusion: The lower mean age of PsO–PsA patients and the mean time to PsA diagnosis of only 1.5 years show that PsA development can already start early after PsO diagnosis reinforcing the need for early involvement of rheumatologists in the medical care of PsO patients. The small percentage of patients with or without concomitant PsA presented to rheumatologists suggests that the majority of PsO patients with concomitant PsA were not under specialized rheumatologic care and patients with existing PsO might profit from intensified rheumatologic screening. The identified risk factors for the development of PsA, "acute rheumatism" and "pain in unspecific joints", confirm previous findings that PsA diagnosis is preceded by unspecific arthritic symptoms.

Golimumab Improves Work Productivity and Activity and Quality of Life in Patients with Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA): Final Results from a Non-Interventional Study in Germany (GO-ART)

Klaus Krüger,[1] Sven Remstedt,[2] Astrid Thiele,[3] and Ines Klaudius[4], [1]Medical Centre of Rheumatology, Munich, Germany, [2]Rheuma Praxis Berlin, Berlin, Germany, [3]Krankenhaus St. Josef Wuppertal, Wuppertal, Germany, [4]MSD Sharp & Dohme GmbH, Haar, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Golimumab (GLM) has shown its efficacy and tolerability in various randomized clinical trials. Systemic data for GLM regarding health-economic parameters in daily clinical practice are essential not only for pharmaceutical companies but also for cost-benefit analyses in Germany.

This prospective NIS was designed to evaluate the impact of GLM therapy on work productivity and activity as well as Quality of Life (QoL) in patients with RA, AS or PsA in Germany under routine settings over an observation period of 12 months, plus an additional voluntary extension period of 12 months (total 24 months) to collect long-term data on health economic parameters.

Methods: GO-ART was an observational prospective study on patients with RA, AS or PsA (biologic-naïve and biologic-experienced) who started treatment with GLM at 63 sites of Germany.

The primary endpoint was the change in work productivity/activity impairment as measured by Work Productivity and Activity Impairment (WPAI) questionnaire from baseline, measured primarily at month 3 and secondarily at months 6, 12 and 24.

As secondary endpoint the change in quality of life (RAQoL for RA patients, ASQoL for AS patients and NAPPA-QoL for PsA patients) was assessed.

Table 1:

AS = Ankylosing Spondylitis; PsA = Psoriatic Arthritis; RA = Rheumatoid Arthritis
WPAI = Work Productivity and Activity Impairment
Total work productivity impairment = Overall impairment estimate calculated by an algorithm of absenteeism and presenteeism.
Absenteeism = Percentage of work time missed because of patient's health problem in the past 7 days.
Presenteeism = Percentage of impairment experienced while at work in the past 7 days because of patient's health problem.
Activity impairment = Percentage of impairment in daily activities because of patient's health problem in the past 7 days

[a] *t-test;* [b] *Wilcoxon Signed rank test*

Results: 748 patients (RA=250, PsA=249, AS=249) started GLM therapy. The primary efficacy endpoint was analyzed in the modified intention-to-treat (mITT) subset of 493 patients (RA=158, PsA=157, AS=178) with full-time or part-time employment at baseline (mITTe). A total of 348 patients entered the additional 12-month observation period, of which 303 completed the 24-month assessment.

By 3 months after initiation of Golimumab treatment, a marked improvement was seen in all 4 WPAI domain scores ("absenteeism" (time off work), "presenteeism" (on-the-job productivity), "total work productivity impairment" (TWPI), and "activity impairment") in daily living because of patient's health problems related to RA, PsA or AS, as shown in Table 1 (all p-values < 0.05).

The statistically significant improvements in the mean WPAI domain scores were maintained over the 24-month observation period in all 3 indications with a higher treatment effect regarding “activity impairment” and “presenteeism” compared to “absenteeism” (Table 1).

Quality of life improved significantly ($p< 0.0001$) from baseline at month 3, 6, 12 and 24 in patients with RA (RAQoL), AS (ASQoL) and PsA (NAPPA-QoL) based on questionnaire data of 237 RA patients (RA-miTT), 228 AS patients (AS-mITT) and 235 PsA patients (PsA-mITT) indicating a clinically relevant improvement.

Conclusion: Treatment with GLM provided sustained improvement in WPAI and QoL in patients with RA, PsA and AS over the observational period of 24 months.

All scores of the WPAI showed a significant ($p< 0.05$) reduction in mean score values in each indication.

GLM leads to an improvement of work productivity and daily activities in patients already within the first 3 months of treatment.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumour necrosis factor inhibitors (TNFi) are efficacious in patients with psoriatic arthritis (PsA), but some patients switch to a different TNFi because of adverse events (AE) or lack of effect (LOE). The EuroSpA Collaboration has previously demonstrated a 1-year retention rate of 77% and 6 months LUNDEX adjusted

Table: Baseline characteristics, retention and remission rates of PsA patients initiating 2nd and 3rd TNFi overall and stratified by reason for withdrawal from the previous TNFi (AE or LOE).

	2nd TNFi (n=4971)*		3rd TNFi (n=1768)**	
	Baseline characteristics			
Age, years	50(41-58)		51(42-59)	
Male	42%		38%	
Concomitant/prior csDMARD	54% / 82%		53% / 86%	
Disease duration, years	5(2-11)		7(4-13)	
First TNFi drug Infliximab/ Etanercept / Adalimumab / Certolizumab / Golimumab	12% / 38% / 34% / 4% / 13%		18% / 28% / 29% / 5% / 20%	
DAS28	4(3.1-4.9)		4.1(3.2-5)	
DAPSA28	24.6(15.2-37)		25.3(16.3-38.6)	
	Retention rates			
6 months (95% CI)	80% (78-81%)		78 % (76-80%)	
12 months (95% CI)	69% (67-70%)		66 % (64-68%)	
24 months (95% CI)	60% (59-61%)		56 % (53-58%)	
	Initiating 2nd TNFi because of AE on 1st TNFi	Initiating 2nd TNFi because of LOE on 1st TNFi	Initiating 3rd TNFi because of AE on 1st TNFi	Initiating 3rd TNFi because of LOE on 1st TNFi
6 months (95% CI)	76% (73-79%)	78% (77-80%)	75% (71-80%)	76% (73-79%)
12 months (95% CI)	66% (64-69%)	65% (64-67%)	65% (60-71%)	63% (59-66%)
24 months (95% CI)	58% (55-61)	56% (54-58%)	55% (50-61%)	51% (48-55%)
	Remission rates			
	LUNDEX adjusted ***		LUNDEX adjusted ***	
DAS28 remission at 6 / 12 / 24 months	35% / 29% / 23%		27% / 22% / 18%	
DAPSA28 remission at 6 / 12 / 24 months	14% / 11% / 9%		10% / 9% / 7%	
	Initiating 2nd TNFi because of AE on 1st TNFi	Initiating 2nd TNFi because of LOE on 1st TNFi	Initiating 3rd TNFi because of AE on 1st TNFi	Initiating 3rd TNFi because of LOE on 1st TNFi
	LUNDEX adjusted ***

DAPSA28 remission at 6 / 12 / 24 months	13% / 10% / 10%	11% / 9% / 8%	9% / 7% / 9%	9% / 8% / 6%

*Data are observed. median (IQR) or percentages; csDMARD: conventional synthetic Disease Modifying Anti Rheumatic Drug; TNFi: tumor necrosis factor inhibitor; DAS28: Disease Activity Score 28 joint-count; DAPSA28: Disease Activity index for Psoriatic Arthritis 28 joint-count; *number of patients with available data varied from n=2904-4971; **number of patients with available data varied from n=1035-1768; ***LUNDEX adjusted: crude rates adjusted for drug retention*

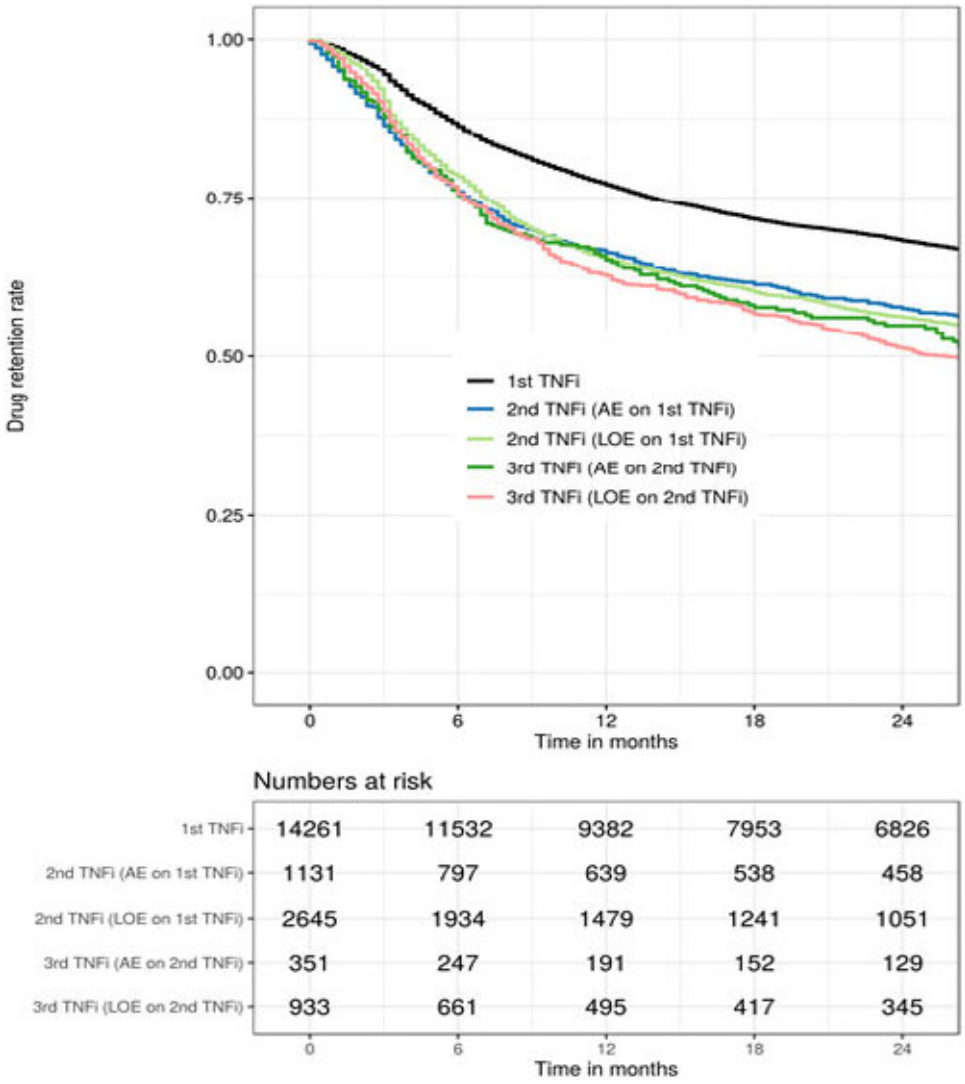

Figure: Kaplan-Meier curves (top) showing drug retention rates up to 24 months for 1st TNFi*, for 2nd (AE or LOE on 1st TNFi) and 3rd TNFi (AE or LOE on 2nd TNFi). The table (bottom) shows the number of patients who were still being treated at the corresponding time points
*previously reported

28-joint count Disease Activity Score (DAS28) remission rates of 45%[1] in patients with PsA initiating the first TNFi treatment. Little is known about the effectiveness of switching to a second and third TNFi in patients with PsA.

We aim to investigate retention and remission rates at 6, 12 and 24 months in patients with PsA initiating the 2nd and 3rd TNFi in clinical practice across Europe. Secondly, to investigate whether the outcomes are associated with the reason for withdrawal (AE or LOE) from the previous TNFi-treatment.

Methods: Prospectively collected data on PsA patients in routine care from 12 European registries were pooled. Kaplan-Meier estimation was used to investigate TNFi retention rates. LUNDEX adjusted[2] remission rates were calculated for DAS28< 2.6 and 28 joint Disease Activity index for Psoriatic Arthritis (DAPSA28) ≤4. Group comparisons were performed by Chi-square test.

Results: A total of 4971 patients initiating their 2nd TNFi and 1768 patients initiating their 3rd TNFi were included. Baseline characteristics are shown in the Table.

The overall retention rates for 2nd and 3rd TNFi at 12 months were 69% (67-70%) and 66% (64-68%), (2nd vs 3rd p=0.053), respectively (Figure). Corresponding retention rates for the individual registries ranged from 48-100% and 49-91%, respectively. If patients had stopped the 1st TNFi due to AE or LOE, 12-month retention rates for the 2nd TNFi treatment were 66% and 65%, respectively. In patients who stopped the 2nd TNFi due to AE or LOE, 12-month retention rates for the 3rd TNFi treatment were 65% and 63%, respectively.

For the 2nd and 3rd TNFi, 6 months LUNDEX adjusted DAS28 remission rates were 35% and 27% (p< 0.001), respectively, and for DAPSA28 remission 14% and 10% (p=0.008) (Table).

Conclusion: The EuroSpA Collaboration demonstrated decreasing retention and remission rates with increasing number of previous TNFi, although with only minor difference between 2nd and 3rd. Patients who had withdrawn from the previous TNFi due to LOE had retention rates and remission rates similar to those who had withdrawn due to AE.

Abstract Number: 1089

Causes of Death in ANCA-Associated Vasculitis According to ANCA Type

Zachary Wallace,[1] Xiaoqing Fu,[1] Tyler Harkness,[1] John Stone,[2] Yuqing Zhang,[3] and Hyon K. Choi[3], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Survival has improved in ANCA-associated vasculitis (AAV) with evolving management strategies, but patients remain at an increased risk of death compared to the general population. Contemporary data regarding cause of death in AAV remain scarce and although growing appreciation of differences between patients with different ANCA types exists, no analysis has evaluated causes of death among patients with ANCA directed against myeloperoxidase (i.e., MPO-ANCA) as opposed to proteinase-3 (PR3-ANCA). We evaluated overall causes of death in a contemporary inception cohort of AAV patients, stratifying the analysis according to ANCA type.

Methods: We identified a consecutive inception cohort of patients newly-diagnosed with AAV evaluated between 2002 and 2017 in the Partners HealthCare System in Boston and determined vital status through the National Death Index. Cause of death was extracted from death certificates and organized using a validated schema that clusters diagnoses into clinically meaningful categories, such as cardiovascular disease (CVD), infection, malignancy, renal disease, and non-infectious respiratory disease based on ICD-9 or ICD-10 codes. We determined cumulative incidence

Table 1. Baseline Characteristics of the Partners ANCA-Associated Vasculitis Cohort

	Overall	MPO-ANCA+	PR3-ANCA+
N	484	313	171
Demographics			
Age (Mean, SD)	58.2 (17.3)	61.9 (15.8)	51.5 (18.1)

Observed / Expected Deaths	12 / 1	10 / 1	2 / 0
Observed Mortality Rate (95% CI)	4.0 (1.8-6.1)	5.1 (1.9-8.3)	2.3 (0-4.9)
Standardized Mortality Ratio	13.9 (7.9-24.5)	16.4 (8.8-30.6)	6.5 (1.6-26.3)
Cancer Mortality†			
Observed / Expected Deaths	20 / 7	14 / 5	6 / 2
Observed Mortality Rate (95% CI)	6.7 (3.9-9.5)	7.7 (3.8-11.5)	5.3 (1.4-9.3)
Standardized Mortality Ratio	2.7 (1.8-4.2)	2.7 (1.6-4.6)	3.7 (1.5-9.5)
Respiratory Mortality			
Observed / Expected Deaths	7 / 4	6 / 3	1 / 1
Observed Mortality Rate (95% CI)	2.4 (0.8-4.1)	3.6 (0.9-6.2)	0.8 (0-2.3)
Standardized Mortality Ratio	2.0 (0.9-4.2)	2.4 (1.1-5.4)	0.9 (0.1-6.4)
Renal Mortality			
Observed / Expected Deaths	4 / 1	3 / 1	1 / 0
Observed Mortality Rate (95% CI)	1.5 (0.2-2.9)	2.0 (0.0-4.0)	0.8 (0-2.3)
Standardized Mortality Ratio	4.3 (1.6-11.3)	4.5 (1.4-13.9)	2.5 (0.3-17.6)

*Restricted to ages 15-85 years old to estimate expected deaths; †Most common cancers included bronchus/lung cancer (n=9) and gastrointestinal cancer (n=6)

of overall and cause-specific mortality and standardized mortality ratios (SMR) compared to the general population. We compared MPO-ANCA+ and PR3-ANCA+ cases using Cox regression models.

Results: The study population consisted of 484 patients with a mean age of 58 years at diagnosis (**Table 1**). 40% were male, 65% were MPO-ANCA+, and 65% had renal involvement. The median baseline BVAS/WG was 4.0. During 3,385 person-years (PY) of follow-up, 130 patients died, yielding a mortality rate of 38.4/1,000 PY and a SMR of 2.3 (95% CI: 1.9-2.8). The most common cause of death was CVD (10-year cumulative incidence 7.1%), followed by malignancy (5.9%) and infection (4.1%). Of the common causes of death, the SMR for death due to infection was greatest for both MPO- and PR3-ANCA cases (16.4 [95% CI: 8.8-30.6] and 6.5 [95% CI: 1.6-26.3], respectively). MPO-ANCA patients had a significantly elevated SMR for death due to CVD (3.0 [95% CI: 1.8-4.8]), respiratory disease (2.4 [95% CI: 1.1-5.4]), and renal disease (4.5 [95% CI: 1.4-13.9]); however, these causes were not significant among PR3-ANCA+ patients (**Table 2**). In contrast, PR3-ANCA+ subjects had a greater SMR for malignancy-associated mortality than MPO-ANCA+ subjects (3.7 [95% CI: 1.5-9.5] vs 2.7 [95% CI: 1.6-4.6]). MPO- and PR3-ANCA cases had similar risk of all-cause mortality (aHR 1.3 [95% CI: 0.8-1.9], p=0.2). However, MPO-ANCA+ cases had a higher risk of CV death (HR 4.52 [95% CI: 1.00-20.33], p=0.049) compared to those who were PR3-ANCA+ (**Figure 1**).

Conclusion: The premature mortality risk in AAV is explained by CVD, infection, malignancy, and renal death. CVD is the most common cause of death but the largest excess mortality risk in AAV is associated with infection. MPO-ANCA+ subjects are at higher risk of CVD death than PR3-ANCA+ subjects. Our findings highlight the importance

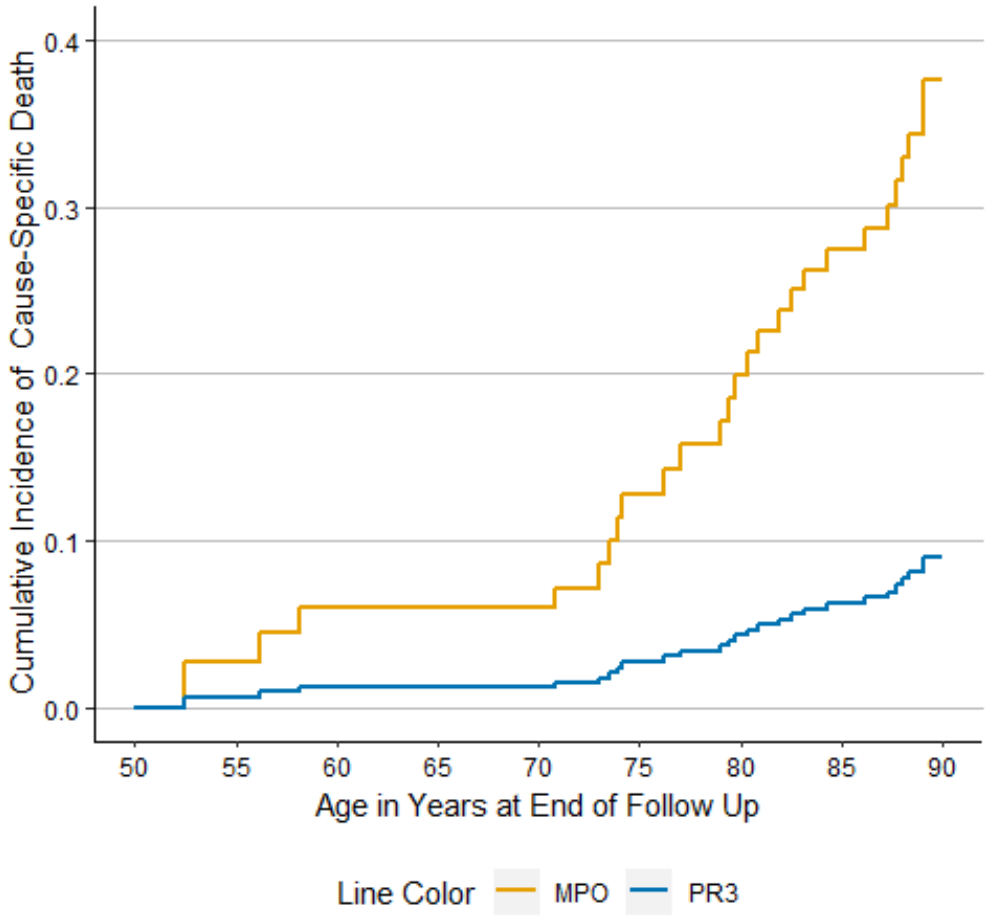

Figure 1. Cumulative Incidence of CVD-Specific Mortality in MPO- vs PR3-ANCA+ ANCA-Associated Vasculitis

of CVD as a cause of death, especially for MPO-ANCA+ subjects, but also emphasize the importance of infections, malignancies, renal failure, and respiratory issues to excess mortality in AAV.

Identification of a Distinct Intestinal Behçet's Disease Cluster in Japan: A Nationwide Retrospective Observational Study

Yutaro Soejima,[1] Yohei Kirino,[1] Mitsuhiro Takeno,[2] Michiko Kurosawa,[3] Ryusuke Yoshimi,[1] Nobuhisa Mizuki,[4] and Hideaki Nakajima[1], [1]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Nippon Medical School, Tokyo, Japan, [3]Department of Epidemiology and Environmental Health, Juntendo University Faculty of Medicine, Tokyo, Japan, [4]Department of Ophthalmology and Visual Science, Yokohama City University Graduate School of Medicine, Yokohama, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

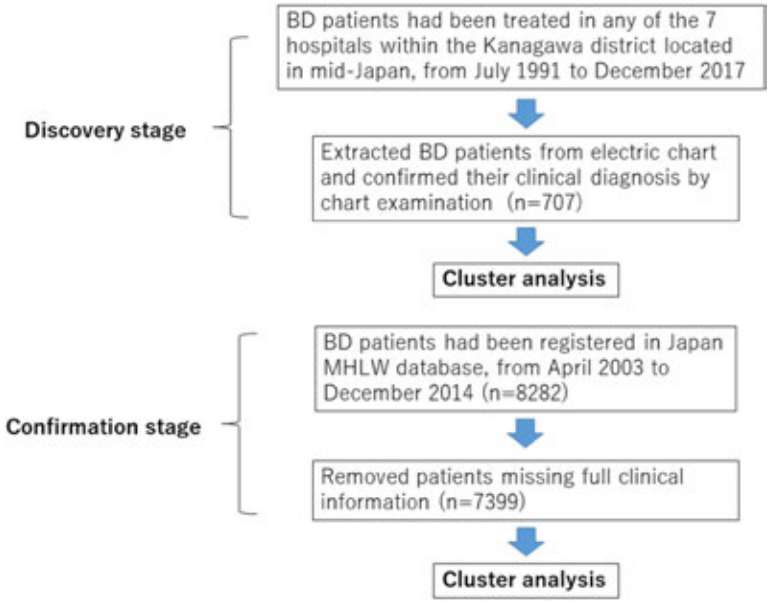
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Behçet's disease (BD) patients with poor prognoses must be identified to receive individualized care. This study aimed to identify a subgroup of BD patients with distinct clinical manifestations.

Methods: Design: This was a retrospective study of regional and nationwide registries.

Setting: This study was performed in Japan.



Flow diagram of BD patients participating in the study

Table 1. Characteristics of the cluster with BD patients in YCU registry

Characteristics	Total (n=707)	Cluster 1 (n=164)	Cluster 2 (n=168)	Cluster 3 (n=207)	Cluster 4 (n=168)	P

MHLW = Ministry of Health, Welfare, and Labour, Japan.
ISG = International Study Group for Behçet's Disease.
ITR-ICBD = International Team for the Revision of the International Criteria for Behçet's Disease.

Patients: A total of 707 patients registered to the Yokohama City University (YCU) regional BD registry between 1990 and 2017, and 7,399 newly registered BD patients to the Japanese MHLW database between 2003 and 2014, were included.

Measurements: For the discovery stage, YCU registry data on the clinical phenotype of BD, drug use, and HLA-B51 status were obtained. For the confirmation stage, a nationwide registry, including clinical phenotype of BD patients registered < 1 year after BD diagnosis, drug use, and HLA-B51 status, was used. Hierarchical cluster analysis of clinical phenotype and HLA-B51 positivity was independently performed on both populations.

Results: Four different clusters were identified from the YCU registry. Cluster 2 showed higher rates of gastrointestinal (GI) involvement, steroid use, and immunosuppressants, and lower rates of ocular disease, International Study Group criteria fulfillment, and HLA-B51 positivity. A similar GI cluster was identified in the Japan MHLW registry. The evolutional analysis revealed increased rates of the GI cluster in the last 30 years

Conclusion: Clustering analysis identified a distinct GI cluster associated with atypical and severe BD clinical symptoms that are increasing in Japan.

Abstract Number: 1091

Risk of Preterm Birth by Timing of Lupus Diagnosis Among Women in the Georgia Lupus Registry

Meghan Angley,[1] Penelope P. Howards,[1] Cristina Drenkard,[1] and S Sam Lim[1], [1]Emory University, Atlanta, GA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Women with systemic lupus erythematosus (SLE) are at a greater risk of having a preterm birth than the general population. Most studies examine preterm births in women with SLE only after they have been diagnosed with SLE, but it has been established that both symptoms and immune abnormalities can appear years before a clinical diagnosis of SLE is made.

Methods: The Georgia Lupus Registry (GLR) is a population-based registry of individuals with SLE in 2002-2004 in Atlanta, Georgia. The GLR was matched to Georgia Birth Certificates from 1994-2013. Births were categorized by timing before and after diagnosis (≥3 years before, 0-3 years before, 0-3 years after and ≥3 years after). Risks of pre-

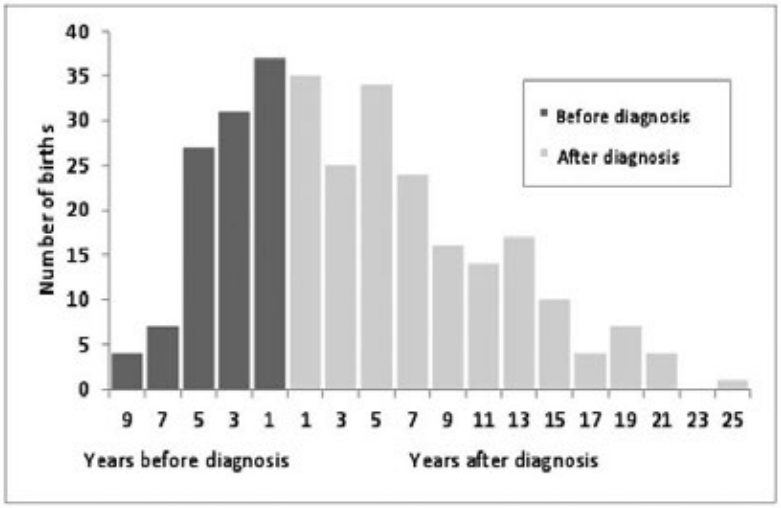

Figure 1. Distribution of births by timing of SLE diagnosis

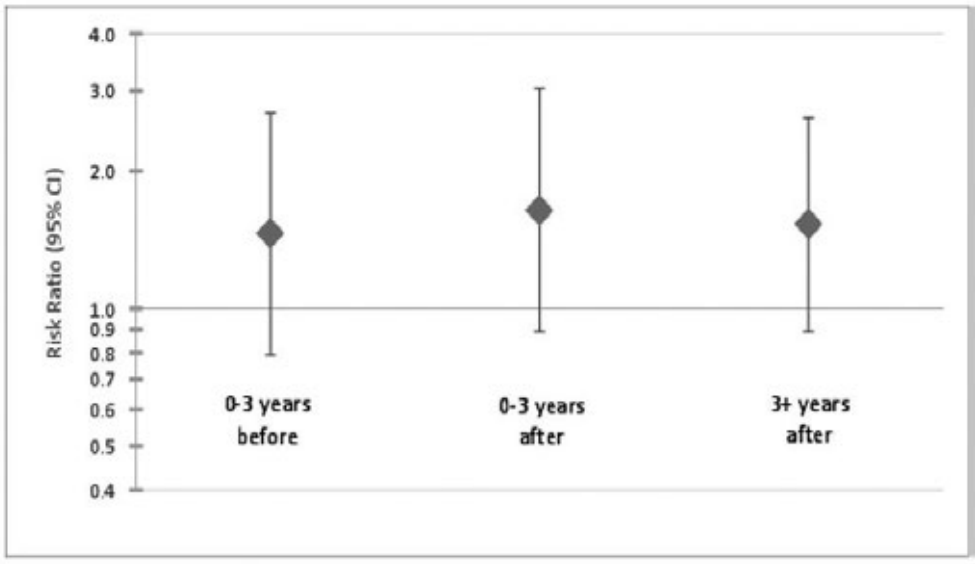

Figure 2. Adjusted risk ratio of preterm birth by timing of SLE diagnosis, compared to births occurring 3+ years before SLE diagnosis

term birth (delivery < 37 weeks of gestation) were calculated. Log-risk models with generalized estimating equations accounted for multiple deliveries in the same woman. Only singleton births were analyzed.

Results: In 189 women, 297 singleton births were identified; 80% were to African American and 18% to white women, and 125 births occurred before and 172 births occurred after diagnosis (see figure 1). For births occurring ≥3 years before, 0-3 years before, 0-3 years after and ≥3 years after, the risks of preterm birth were 19%, 29%, 34% and 33%, respectively. Compared to women who gave birth ≥3 years before, women who gave birth 0-3 years before had slightly elevated risk of preterm birth (risk ratio [RR]: 1.46, 95% confidence interval [CI]: 0.79, 2.68), as did women who gave birth 0-3 years after (RR: 1.64, 95% CI: 0.89, 3.04) and women who gave birth ≥3 years after (RR: 1.53, 95% CI: 0.89, 2.62) (see figure 2). Analyses controlled for parity, age and race.

Conclusion: The risk of preterm birth is also increased preceding SLE diagnosis, although lower than that after diagnosis. This suggests late diagnosis of SLE or that immunologic and other factors may impact birth outcomes years before clinical disease.

Efficacy and Safety of Dose Adjustment Based on Patients' Body Size in Low Dose Intravenous CYC Treatment for Rheumatic Diseases

Aiko Hirano,[1] Takashi Kida,[1] Akiko Kasahara,[1] Aki Sakashita,[1] Tomoya Sagawa,[1] Shunya Kaneshita,[1] Takuya Inoue,[1] Kazuki Fujioka,[1] Wataru Fujii,[1] Makoto Wada,[1] Masataka Kohno,[1] and Yutaka Kawahito[1], [1]Inflammation and Immunology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan, Kyoto, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Intravenous (IV) CYC in combination with glucocorticoids is a widely used induction therapy for severe cases of rheumatic diseases such as SLE, SSc, DM and ANCA-associated vasculitis. The dosage of Euro-lupus low dose regimen (six pulses of IV CYC biweekly at a fixed dose of 500 mg), which is one of the standard regimens, does not take account of body size. The fixed dose of 500 mg is equivalent to approximately 300 mg/m^2 or less per body surface area (BSA) for average sized European patients, but it can be more than 300 mg/m^2 per BSA for patients with smaller physiques. In this study, we evaluated the efficacy and safety of dose adjustment based on patients' body size in low dose IV CYC treatment for rheumatic diseases.

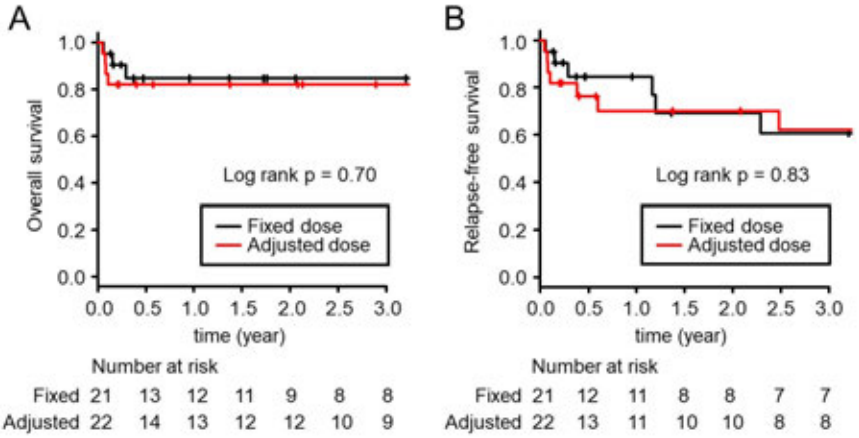
Methods: In this retrospective cohort study, we analyzed consecutive patients with rheumatic diseases, consisting of SLE, SSc, DM and ANCA-associated vasculitis, who received IV CYC therapy at the rheumatology department of the Kyoto Prefectural University of Medicine in Japan between 2008 and 2019. Patients with a creatinine clearance less than 10 mL/min were excluded. We compared clinical outcomes and adverse events in patients receiving doses above and below 300 mg/m^2 for BSA. All data were presented as median [interquartile range (IQR)] or absolute number (percentage). In comparing two groups, we used the Mann–Whitney U test (for continuous variables) or Fisher's exact test (for categorical variables). The Kaplan–Meier curves were compared using the log rank test. Any p value < .05 was considered statistically significant.

Table 1. Baseline characteristics and treatment details of patients

Factor	Adjusted dose group (n=22)	Fixed dose group (n=21)	p value
Rheumatic disease			**<0.001**
SLE	8	3	
SSc	1	2	
DM	4	15	
ANCA-associated vasculitis	9	1	
Age, years, median (IQR)	54.0 (43.5, 66.0)	61.0 (49.8, 66.8)	0.503
Sex, female, n (%)	13 (56)	13 (59)	1
Body height, cm, median (IQR)	159.8 (153.6, 167.5)	158.8 (154.3, 164.1)	0.928
Body weight, kg, median (IQR)	51.2 (46.5, 63.1)	52.8 (48.7, 54.3)	0.919
Body surface area (Du bois), median (IQR)	1.51 (1.47, 1.62)	1.52 (1.47, 1.61)	0.892
CCr			0.108
<10, n (%)	0 (0)	0 (0)	
10~50, n (%)	4 (17)	0 (0)	
50<, n (%)	18 (83)	21 (100)	
Initial prednisolone dose, mg/kg, median (IQR)	0.96 (0.83, 1.21)	0.91 (0.79, 1.05)	0.617
Glucocorticoid pulse therapy, n (%)	14 (61)	7 (32)	0.075
IV CYC dosage, mg/body, median (IQR)	300 (300, 345)	500 (500, 500)	**<0.001**
IV CYC dosage, mg/kg, median (IQR)	5.9 (5.5, 7.4)	10 (9.3, 11.2)	**<0.001**
IV CYC dosage, mg/m^2, median (IQR)	203 (195, 238)	340 (319, 355)	**<0.001**
Times of IV CYC, median (IQR)	4 (2, 6)	4.5 (2.3, 6.8)	0.714
Cumulative dose of CYC, mg, median (IQR)	1200 (810, 2100)	2500 (1413, 3695)	**0.017**

Adjusted dose group = patients who received IV CYC treatment less than 300mg/m2 for BSA (adjusted for body size).
Fixed dose group = patients who received IV CYC treatment more than 300 mg/m2 for BSA (fixed dose of 500mg).
IQR, interquartile range; CCr, creatinine clearance; IV, intravenous.

Figure 1. Kaplan-Meier curves for overall survival and relapse-free survival of patients



Results: We identified 43 patients (SLE = 11, SSc = 3, DM = 19, ANCA-associated vasculitis = 10), all of whom met the ACR classification criteria. Among them, 22 received IV CYC treatment less than 300mg/m^2 for BSA as "adjusted" low dose treatment considering body size, and 21 received more than 300mg/m^2 for BSA as "fixed" low dose treatment. There was no difference between the two groups as age, gender, height, weight and body surface area (Table 1). Although there were differences in underlying rheumatic diseases, the dosage of initial prednisolone was similar between the two groups. There was no difference in the frequency of IV CYC administration, but the median dose for IV CYC was lower in the adjusted dose group than in the fixed dose group (300 mg/body vs 500 mg/body, respectively, $p < 0.001$), and the median cumulative dose was also lower in the adjusted dose group (1200 mg vs

2500 mg, respectively, p = 0.017). Between the two groups, there was no difference in overall survival or relapse-free survival (Figure 1).

Conclusion: Our data indicates that adjusted low dose IV CYC biweekly treatment (less than 300 mg/m^2 for BSA) may have equal clinical efficacy and better safety compared to fixed low dose treatment. This dose adjustment of low dose IV CYC treatment based on patients' body size would be beneficial as an effective and safe remission induction therapy for rheumatic diseases.

Abbreviations: NHANES: National Health & Nutrition Examination Survey; IBD= Inflammatory Bowel Disease; UC= Ulcerative Colitis; SE=standard error; n.s.= non significant; ndc=no data collected; All IBD= Ulcerative Colitis and Crohn's Disease; UC Difference: significance value for t-test of Ulcerative Colitis prevalences NHANES 2009-10 vs. NHANES II.
Notes: Overall prevalence is for US adults ages 20-69 years; *variance estimate not reliable, SE not shown.

Background/Purpose: Associations between ulcerative colitis (UC) and Crohn's disease, known together as inflammatory bowel disease (IBD), with axial pain, inflammatory back pain (IBP) and spondyloarthritis (SpA) are well described but vary among studies. This study presents previously unreported nationally representative data from the US health surveys NHANES 2009-10 and NHANES II (1976-80) comparing axial pain rates in those with and without IBD.

Methods: NHANES 2009-10 and NHANES II questionnaires asked patients about history of clinician diagnosed UC (both) or Crohn's (NHANES 2009-10 only), gastrointestinal symptoms, medical care and IBD comorbidities. Both surveys asked questions about the timing and anatomical distribution of axial pain of at least 3 months and history of clinician-diagnosed arthritis. NHANES 2009-10 also asked questions about pain quality to estimate IBP prevalence (Calin, ESSG, Rudwaleit et al. criteria). Statistical analysis used SAS™ 9.4 using survey design variables and sample weights to produce nationally representative estimates.

Results: Data for 5105 participants in NHANES 2009-10 and 13,730 in NHANES II ages 20-69 was analyzed. Overall, IBD prevalence in NHANES 2009-10 was 1.2 % (95% CI 1.0-1.4%); UC prevalence was 1.0% (95% CI 0.8-1.2%). UC prevalence in NHANES II was 1.0% (95% CI 0.8-1.2%). In NHANES II, UC rates were higher at ages 50-69 than at ages 20-49 ($p< 0.01$), and higher among women than men ($p< 0.01$). (Table 1) In NHANES 2009-10, 69% of IBD cases (Crohn's or UC) had colonoscopy at diagnosis; 60% had recent gastrointestinal symptoms; 30% had been hospitalized in the previous year or had prior transfusions; and 21% had IBD comorbidities (uveitis, ankylosing spondylitis, colon cancer, osteoporosis).

Figure 1. illustrates NHANES 2009-2010 subjects with at least 3 months of back pain. IBD cases were more likely to have pain onset older than 45 years (40.0% vs 26.2%), rest or sleep pain (42.9% versus 27.3%), and pain on awakening (90.5% vs 58.0%).

Figure 2. reveals prevalence of axial pain in IBD patients from both surveys. Prevalence rates of axial pain for at least 3 months were non-significantly increased among IBD cases in NHANES 2009-10 (27.8% vs 19.2%), and increased among UC cases in NHANES II (22.3% vs. 7.8%; $p< 0.01$). Amor Criteria axial pain (axial pain plus pain at night or AM stiffness) was increased among UC cases in the NHANES II data (21.3% vs 7.4%, $p< 0.01$), as was clinician-diagnosed arthritis (38.5% vs 20.7%, $p< 0.01$). IBP and SpA analysis in NHANES 2009-2010 was limited due to

Figure 1. Inflammatory Back Pain Indicator Variable Frequencies in the NHANES 2009-10 Survey

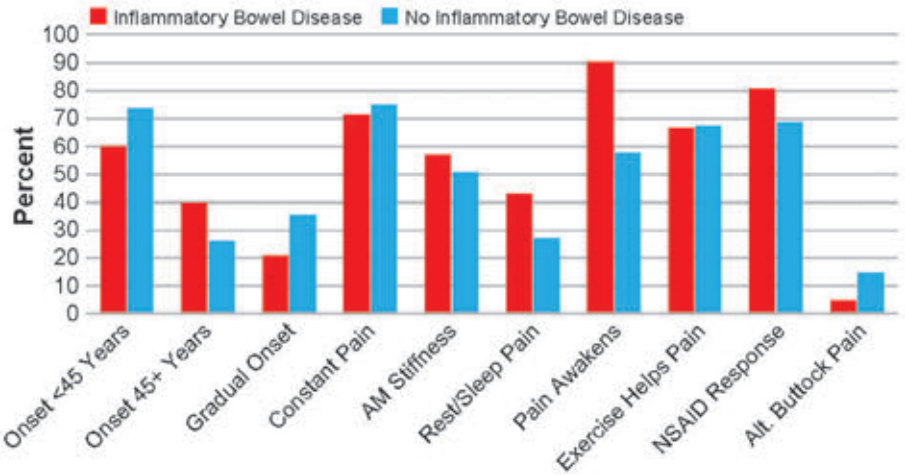

Figure 2. Prevalence of Axial Pain in Diagnosed Inflammatory Bowel Disease (IDB) & Ulcerative Colitis (UC)

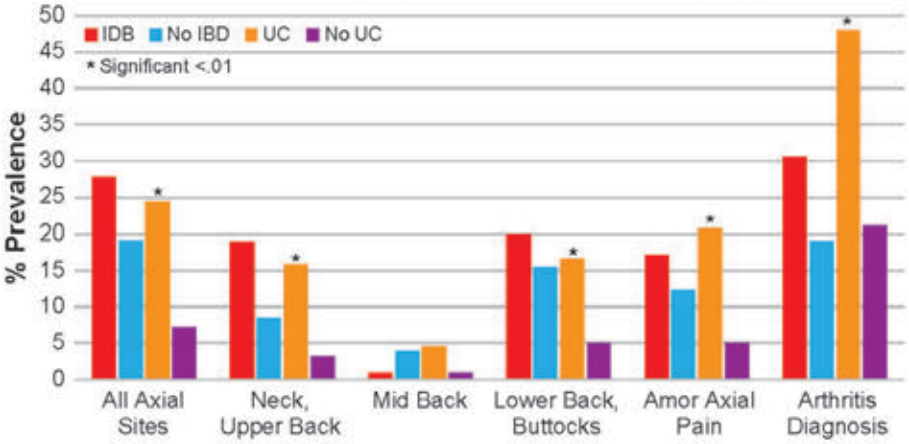

Axial Pain 3 or More Months by Site & Diagnosis of Arthritis
IBD Data: NHANES 2009-10; UC Data: NHANES 1976-80

sample size so statistical testing wasn't performed, however, the unadjusted overall IBP and SpA estimates for IBD cases was 9.7% and 10% respectively, vs. 7.2% and 1.8% of controls.

Conclusion: Prevalences of UC in these two nationally representative population surveys were consistent at 1% of the general population, similar to previous surveys. This suggests stable UC prevalence and recognition rates between the 2 survey time periods. Chronic axial pain history was seen in almost 25% of IBD and UC cases and arthritis diagnosis rates were increased. IBD-axial pain was more likely to have an older age at onset and to occur with sleep or rest. Studies with larger sample sizes are required to estimate IBP and SpA rates in IBD.

EULAR Points to Consider for the Development, Evaluation and Implementation of Mobile Health Applications for Self-management in Patients with Rheumatic and Musculoskeletal Diseases

Aurelie Najm,[1] Elena Nikiphorou,[2] Marie Kostine,[3] Christophe Richez,[4] John Pauling,[5] Axel Finckh,[6] Valentin Ritschl,[7] Petra Balazova,[8] Simon Stones,[9] zoltan Szekanecz,[10] Yeliz Prior,[11] Annamaria Iagnocco,[12] Sofia Ramiro,[13] Francisca Sivera,[14] Maxime Dougados,[15] Loreto Carmona,[16] Gerd Burmester,[17] Dieter Wiek,[18] Laure Gossec,[19] and Francis Berenbaum[20], [1]Nantes University Hospital, Nantes, France, [2]King's College London, London, United Kingdom, [3]Department of Rheumatology, Bordeaux, France, [4]Deprtament of Rheumatology, Bordeaux, France, [5]Department of Rheumatology, Royal National Hospital of Rheumatic Diseases, Royal United Hospitals NHS Foundation Trusts, Bath, England, United Kingdom, [6]Division of Rheumatology, Geneva University Hospital, Switzerland, Geneva, Switzerland, [7]Medical University of Vienna, Vienna, Austria, [8]EULAR Young PARE, Zurich, Switzerland, [9]University of Leeds, Leeds, United Kingdom, [10]University of Debrecen, Debrecen, Hungary, [11]Centre for Health Sciences Research, University of Salford, Salford and Mid Cheshire NHS Foundation Trust Hospitals, Crewe, UK, Salford, United Kingdom, [12]Academic Rheumatology Centre, Università degli Studi di Torino, TURIN, Italy, [13]Leiden University Medical Centre, Leiden, Netherlands, [14]Hospital General Universitario de Elda, Elda, Spain, [15]Cochin Hospital, Paris, France, [16]Instituto de Salud Musculoesquelética - Inmusc., Madrid, Spain, [17]Charité—University Medicine Berlin, Berlin, Germany, [18]patient research partner, Germany, Germany, Germany, [19]Sorbonne Université and Hôpital Pitié-Salpêtrière, Paris, France, [20]Sorbonne Université-Inserm CDR Saint-Antoine, AP-HP, Paris, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In the expanding era of e-health, a wide range of mobile health applications (apps) have become available to enable people with rheumatic and musculoskeletal diseases (RMDs) to better self-manage their health. However, guidance on the development and evaluation of such apps is lacking. The objective of this EULAR task force was to establish points to consider (PtC) for the development, evaluation and implementation of apps for self-management of RMDs.

Methods: A systematic literature review of app content and development strategies was conducted, followed by a qualitative study with six patients and an online survey of people living with RMDs (n=394). Based on these data and expert opinion, the PtC were formulated in a face-to-face meeting in November 2018 by a multidisciplinary TF panel of experts, including patients, from 10 countries. The level of agreement among the panel in regard to each PtC was established by anonymous online voting.

Results: Three overarching principles and 10 PtC were formulated (Table). Out of the 10 PtC, three were related to patient safety (1,5,6), considered as a critical issue by the panel, along with accuracy of information provided by apps. Three were related to relevance of the content and functionalities (2,7,9) and the importance of apps being tailored to the individual needs of people with RMDs. The requirement for transparency around app developers and funding sources (3,4), along with involvement of relevant health professionals were also raised. Ease of app access across ages and abilities was highlighted (8), in addition to considering the cost-benefit of apps from the outset (10). The level of agreement was high (Table).

Table. The 10 Points to Consider.

	Points to consider	Level of agreement mean (SD)
1.	The information content in self-management Apps should be up to date, scientifically justifiable, user-acceptable and evidence-based where applicable.	9.8 (0.4)
2.	Apps should be relevant and tailored to the individual needs of people with RMDs.	9.7 (0.5)
3.	The design, development and validation of a self-management App should involve people with RMDs and relevant health care providers.	9.8 (0.6)
4.	There should be transparency on an Apps' developer, funding source, content validation process, version updates and data ownership.	9.9 (0.3)
5.	Data collection as part of an App must adhere to all applicable regulatory frameworks, particularly data protection.	9.9 (0.3)
6.	Apps must not result in physical or emotional harm to people with RMDs.	9.3 (1)
7.	Apps could facilitate patient-health care provider communication and contribute to electronic health records or research.	9.4 (0.9)
8.	App design should consider accessibility of people with RMDs across ages and abilities.	9.4 (0.9)
9.	If a social network is an important component of an App, structures should be in place to ensure appropriate content moderation.	9.5 (0.6)
10.	The rheumatology community should consider the cost-benefit balance of Apps before its endorsement and/or its promotion.	8.9 (1.3)

Conclusion: These PtC provide guidance on important aspects that should be considered for the development of new apps, the quality assessment of existing apps, as well as for further development of existing apps.As part of the dissemination phase, these PtC will be shared with a larger group of health professionals, patients and app developers and for wider consensus.

Abstract Number: 1095

The Role of Immunosuppressive Therapy in the Development of Atherosclerotic Cardiovascular Disease in Patients with Psoriatic Arthritis

Linh Truong,[1] Nicole Ridolfi,[2] Eugenia Chen,[2] and Maida wong[3], [1]University of California, Irvine, San Diego, CA, [2]University of California, Irvine, Orange, [3]Tibor Rubin Veterans Affairs Medical Center, Long Beach

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is accumulating evidence demonstrating an increased prevalence of atherosclerotic cardiovascular disease (ASCVD) among the psoriatic arthritis (PsA) population. Yet, the relationship between immunosuppressive therapies and the development of ASCVD remains unclear. This study was undertaken to investigate the ASCVD risk among PsA patients and its relationship with systemic immunosuppressive therapies, including tumor necrosis factor alpha (TNF-α) inhibitors and methotrexate (MTX).

Methods: A multicenter retrospective cohort study involving the Veterans Affairs Hospitals in Long Beach (LBVA) and Greater Los Angeles (GLAVA) was performed. PsA patients from both sites (n=189) were evaluated against controls (n=99) without autoimmune diseases. The groups were matched on age, sex, race, BMI, smoking exposure, and ASCVD risk factors (hypertension, diabetes, and hyperlipidemia). Their ASCVD risk was evaluated using the American College of Cardiology/American Heart Association's (ACC/AHA) ASCVD risk score. The odds ratio (OR) for developing any ASCVD event, myocardial infarctions (MI), congestive heart failure (CHF), and cerebral vascular accidents (CVA) were calculated. Additionally, the OR for CHF in the PsA patients was analyzed in relation to their exposure to TNF-α inhibitors, MTX, and concomitant use of TNF-α inhibitors with MTX, with exposure defined as use of therapy ≥ 12 months.

Results: PsA and controls ACC/AHA ASCVD risk scores of 21.5% and 17.1% (p=0.005). PsA patients twice the risk for developing any ASCVD event (OR 1.9; 95% CI 1.10 to 3.35). CHF (OR 3.4; 95% CI 1.27 to 9.1) was the most likely event to develop when compared to CVA (OR 1.33; 95% CI 0.50 to 3.55) and MI (OR 1.28; 95% CI 0.69 to 2.23). The risk of developing CHF is increased in PsA patients exposed to MTX (OR 4.7; 95% CI 1.24 to 17.77) relative to TNF-α inhibitors (OR 3.42; 95% CI 1.00 to 11.05). Meanwhile, PsA patients exposed to concomitant TNF-α inhibitors with MTX had decreased risk for developing CHF (OR 1.91; 95% CI 1.26 to 12.10) when compared to the overall PsA cohort in this study, and the subgroups of PsA patients exposed to either TNF-α inhibitors or MTX alone.

Conclusion: PsA patients have an increased risk for developing ASCVD, in particular CHF. Exposure to either MTX or TNF-α inhibitor individually does not confer a protective role against CHF. However, combining the use of MTX with TNF-α inhibitor therapy decreases the risk of developing CHF relative to the overall PsA cohort and those receiving monotherapy with MTX or TNF-α inhibitor therapy alone. This suggests that the two therapies work together to attenuate adverse myocardial remodeling and offer a beneficial role against the development of CHF in PsA patients.

Learning the Relationships Between Psoriatic Arthritis and a Patient's History of Musculoskeletal Symptoms from Electronic Health Records Using Bayesian Networks

Amelia Green,[1] Theresa Smith,[1] and **Neil McHugh** [1], [1]University of Bath, Bath, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Electronic health records (EHRs) from large health care systems provide access to rich and comprehensive patient-specific information from many sources consisting of heterogeneous data types. The unique

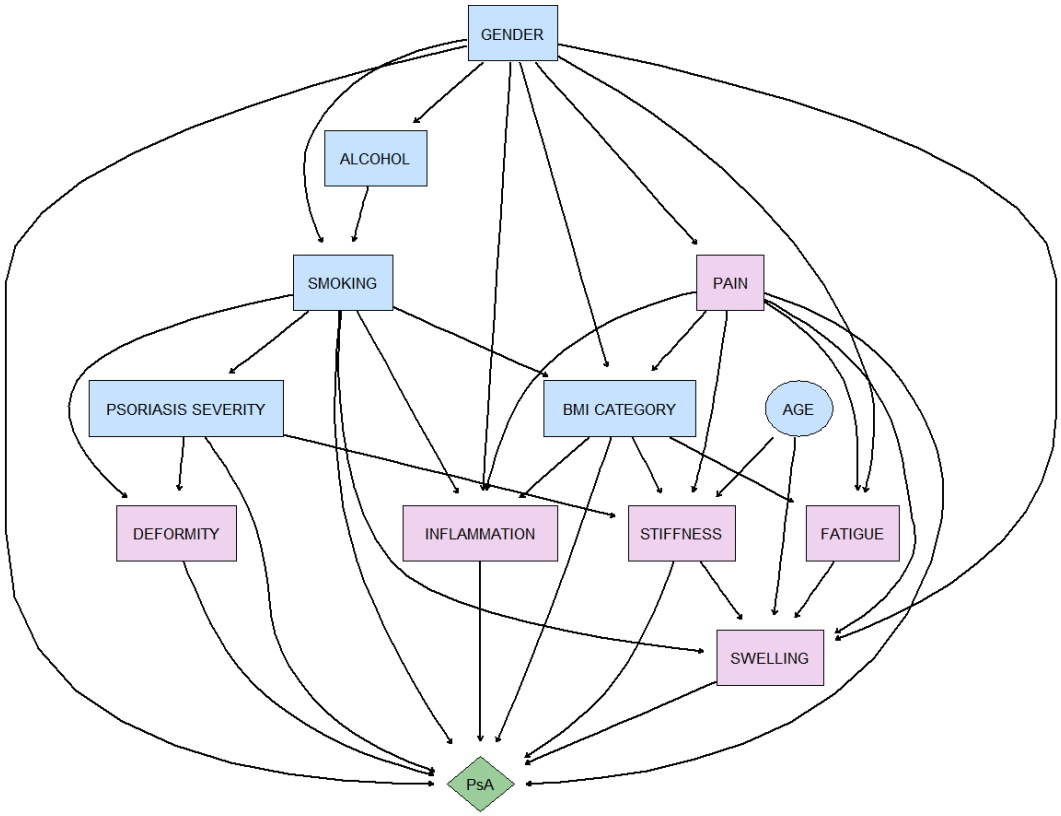

Figure. Graphical model of a Bayesian network built using EHR data to predict the development of PsA in people with psoriasis and to gain insight into the psoriasis population at increased risk of PsA. The figure includes the structure of MSK symptoms (coloured purple), grouped into one of six categories and defined in terms of counts over the study period, in addition to baseline demographic variables (coloured blue). In particular, nodes represent input variables and edges represent conditional dependencies between the variables. Continuous and discrete variables are indicated by elliptical and rectangular nodes, respectively. Nodes are defined as follows: GENDER sex of the patient (male or female); ALCOHOL baseline drinking status of the patient (non-drinker, ex-drinker or current drinker); SMOKING baseline smoking status of the patient (non-smoker, ex-smoker or current smoker); PSORIASIS SEVERITY severity of psoriasis (mild or severe); BMI baseline body mass index of patient; AGE baseline age of the patient (years); PAIN MSK symptoms associated with pain (143 medcodes); DEFORMITY MSK symptoms associated with a deformity or derangement (6 medcodes); INFLAMMATION MSK symptoms associated with inflammation (96 medcodes); STIFFNESS MSK symptoms associated with stiffness (64 medcodes); FATIGUE MSK symptoms associated with fatigue (34 medcodes); SWELLING MSK symptoms associated with swelling (36 medcodes).

features and challenges of EHR data, including missing information and non-linear interactions, require novel statistical approaches for analyses. Bayesian Networks (BNs) provide a relatively new method of representing uncertain relationships among variables and here we explore their ability to learn the structure of MSK symptoms related to the development of PsA in people with psoriasis.

Methods: Incident cases of psoriasis were identified between 1998 and 2015 from the UK Clinical Research Practice Datalink (CPRD). MSK symptoms occurring during the study period were identified based on medcodes and were checked by a physician to eliminate redundant MSK symptoms. Baseline demographics for gender, age, body mass index (BMI), psoriasis severity, alcohol use and smoking status were also extracted. The BN structure was composed using a combination of expert knowledge and data-oriented modeling with several methods compared to obtain a BN structure which best described the relationships between the variables. Bayesian inference was used to compute the posterior distribution of network weights, which quantify the strength of these relationships. The BN model was evaluated using well-established performance metrics.

Results: Over one million MSK symptoms were extracted for the 90,189 incident cases of psoriasis identified, of which 1409 developed PsA. These consisted of 379 unique medcodes which were concatenated into one of six categories (pain, deformity, inflammation, stiffness, swelling or fatigue). The graphical representation of the BN structure in Figure 1 shows widespread probabilistic associations between the 12 variables included in the modelling. Nine were identified as direct predecessors of PsA. While the remaining three variables did not influence the PsA directly, they did influence PsA through their respective child nodes. For example, age and fatigue influence PsA through their common child node, swelling. Our BN was 81% accurate in predicting the development of PsA in a validation set. The AUC for this predictive model was 0.85 (95% confidence interval (CI): 0.83-0.87), translating into 81% sensitivity and 89% specificity.

Conclusion: The presented BN model considers the demographics and MSK symptoms of people with psoriasis and can be used as a useful method to predict the development of PsA with reasonable accuracy. It provides useful information to clinicians, such as the probabilistic relations among variables of interests that associate with individuals at increased risk of developing PsA. In addition to offering both modelling flexibility and statistical validity, our technique seamlessly handles missing data and offers the opportunity to combine findings from the medical literature with clinical judgement to shape the model. Important improvements and future developments to the BN model would a) broaden the MSK symptom categories and b) extend the variable set by including addition EHR data such as tests, prescriptions and referrals.

Trends in NSAIDs and Opioids Among Patients with SLE: A Population-based Study

Lingyi Li,[1] Na Lu,[1] Jacek Kopec,[2] John Esdaile,[3] Hui Xie,[4] and J. Antonio Avina-Zubieta[2], [1]Arthritis Research Canada, Vancouver, BC, Canada, [2]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada and the University of British Columbia, Richmond, BC, Canada, [4]Arthritis Research Canada and Simon Fraser University, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

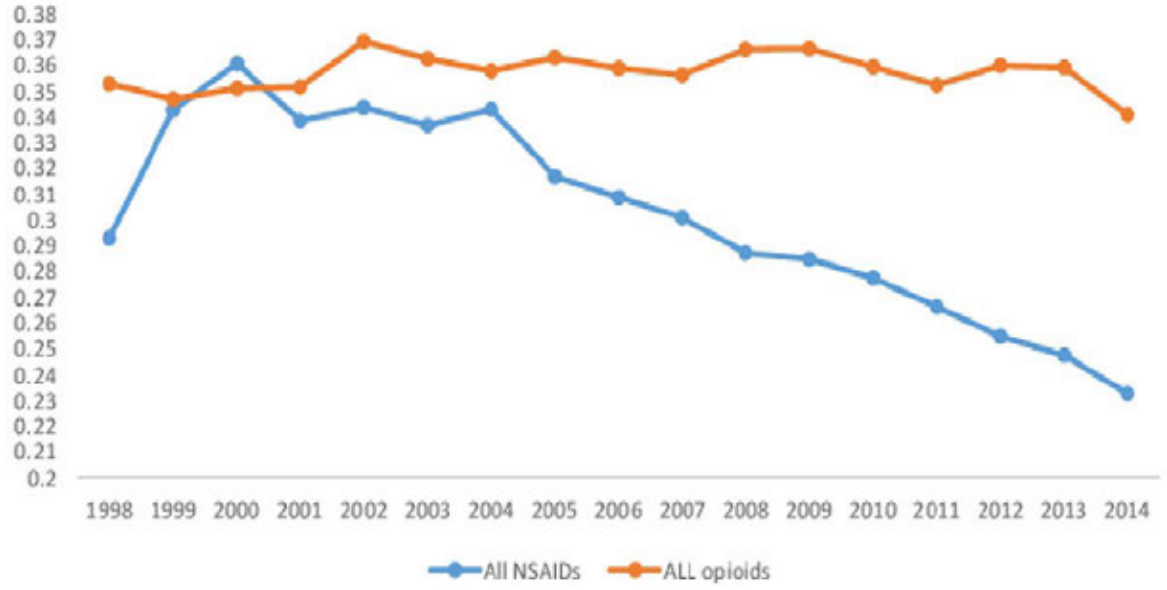

Figure 1. Trends of prescriptions for NSAIDs and opioids among patients with prevalent SLE in an entire province of Canada, 1998-2014

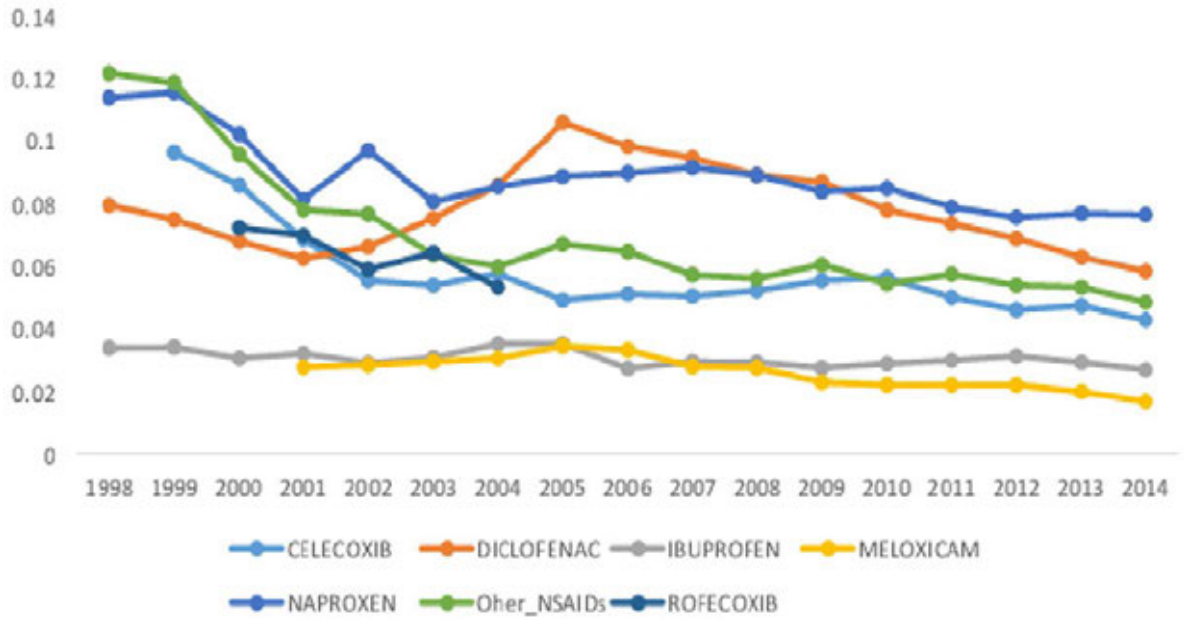

Figure 2. Prescriptions for NSAIDs in patients with prevalent SLE in an entire province of Canada, 1998-2014

Background/Purpose: Non-steroidal anti-inflammatory drugs (NSAIDs) and opioids are prescribed for the management of pain among patients with rheumatic diseases including systemic lupus erythematosus (SLE). However, both types of medication can be associated with serious side effects. For example, increased mortality has been reported among people who use opioids. Our purpose in this study was to describe the trends in prescribing of NSAIDs (including coxibs) and opioids among patients with SLE in the general population.

Methods: We use a population-based administrative database that included all prescriptions for persons aged 20+ processed by pharmacies in the entire province, between 1998 and 2014, linked to diagnostic codes for visits to phy-

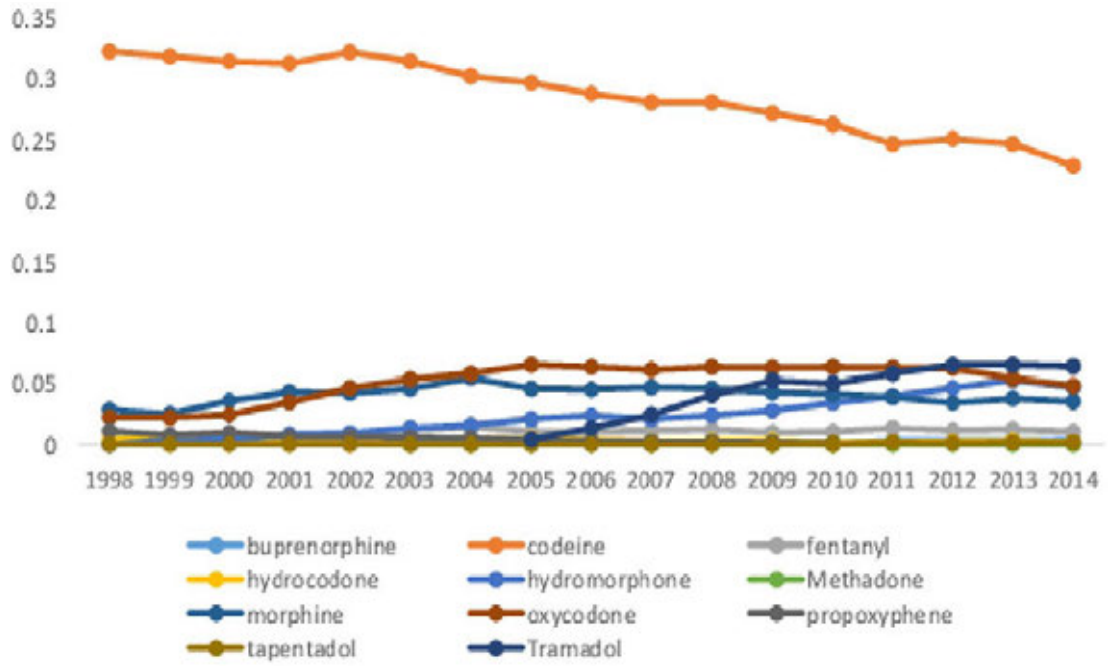

Figure 3. Prescriptions for opioids in patients with prevalent SLE in an entire province of Canada, 1998-2014

sicians and hospitalizations. We identified all prevalent cases of SLE, defined as at least 2 codes at least 2 months apart within 2 years. We identified all prevalent prescriptions for each NSAID and opioid available in the province and calculated the proportion of people receiving NSAID or opioid medication.

Results: Between 1998 and 2014, the proportion of SLE patients with an NSAID prescription declined from 29.2% to 23.2% (Figure 1). For most NSAIDs (Figure 2), prescriptions declined aggressively as of 2004 and were relatively stable until 2014, with the exception of diclofenac, which increased substantially from 2001 to 2005 and decreased afterwards. In 2014, the most common NSAID was naproxen (7.7%) followed by diclofenac (5.8%), celecoxib (4.3%), ibuprofen (2.7%) and meloxicam (1.7%). For opioids (Figure 1), the overall trend was relatively flat from 1998 to 2014, with 35.3% in 1998 to 34.1% in 2014. Codeine was by far the most commonly prescribed opioid throughout the study period, but declined from 32.2% of prevalent SLE patients in 1998 to 22.8% in 2014 (Figure 3). Tramadol increased steadily from its introduction in 2005 and has been the second most common opioid since 2012, reaching 6.4% in 2014. Prescriptions for oxycodone started to decline around 2011 and reached 4.8% in 2014, whereas those for hydromorphone steadily increased (4.7% in 2014). Morphine increased slightly from 1998, reaching 5.5% in 2004, then declined thereafter. Other opioids were rarely prescribed in patients with SLE.

Conclusion: There have been important changes in the pattern of prescribing analgesics in our province during the study period. Declines in NSAIDs may have been compensated by increased prescriptions for some opioids. This is likely to change as new guidelines discourage the long-term use of opioids as a consequence of the current opioid crisis.

Epidemiology and Mortality of SLE (Systemic Lupus Erythematosus) in Hungary Based on a Nationwide Retrospective Claims Database Study

Melinda Kedves,[1] Fruzsina Kósa,[2] Péter Takács,[2] Péter Kunovszki,[2] Jennifer Lofland,[3] and György Nagy[4], [1]Hospital of Bács-Kiskun County, Department of Rheumatology, Kecskemét, Bacs-Kiskun, Hungary, [2]Janssen, GCSO, Budapest, Budapest, Hungary, [3]Janssen Scientific Affairs, LLC, Spring House, PA, [4]Buda Hospital of the Hospitaller Order of Saint John of God, Department of Rheumatology, Budapest, Budapest, Hungary

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

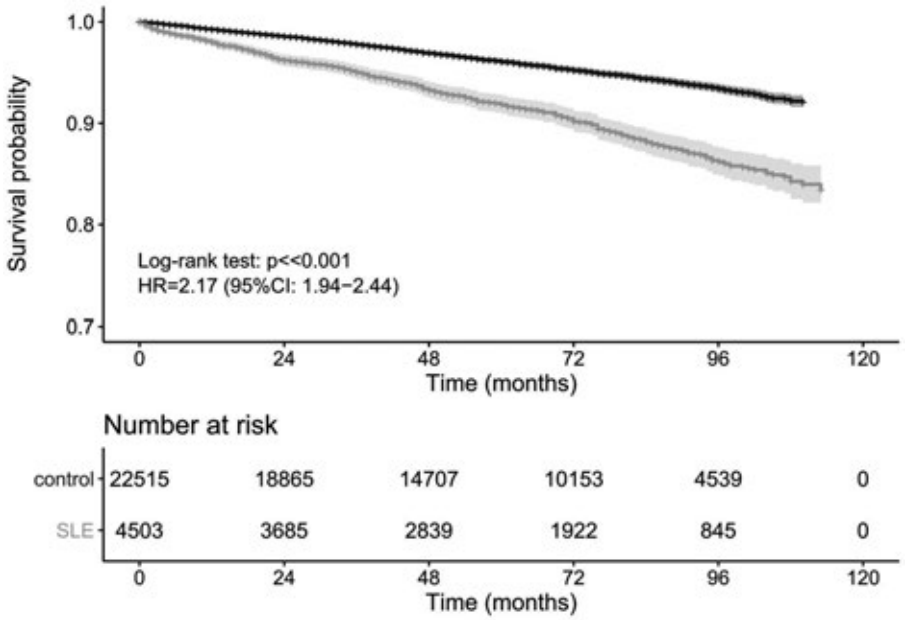
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is little evidence in Hungary on the real incidence, prevalence and mortality of systemic lupus erythematosus (SLE) that is based on a robust estimate from real world data. Claims data-based evidence on the SMR of SLE patients from other countries shows great variance.

Objectives: The aims of this study were to provide robust estimates on the incidence, prevalence and population-controlled mortality of patients with SLE in Hungary.

Methods: Study design and description of data source: This was a non-interventional, retrospective study based on historical real-world data from the database of the National Health Insurance Fund of Hungary (NHIF). This database provides detailed data on the inpatient and outpatient care and prescription purchases of SLE patients covering the full population of Hungary. The analysis will be limited to data collected between 1st January 2008 and 30th June 2017.



Kaplan-Meier estimation of overall survival of SLE patients and matched controls in Group A, comparison using log-rank test

Methods: Patients with minimum 2 SLE ICD codes were included from the database (prevalent patients). Two study groups were created. A wider one consisting of all incident SLE patients (group A) and a subgroup that only contains those who received some form of relevant therapy in the first 6 months from diagnosis (group B).

Baseline demographic characteristics and mortality were described. Mortality was analysed using standardized mortality ratio (SMR) compared to the general population of Hungary. The overall survival (OS) from SLE diagnosis date was estimated using the Kaplan-Meier method and was compared to the survival of a matched sample of the general population using a log-rank test.

Results: In total 7.888 prevalent patients were identified in the database. In group A 4.503 patients were included, 2.582 patients were in group B. Women had an overwhelming majority in both groups (85%). Median age of patients at the time of diagnosis were 46 and 47 years in group A and group B respectively. In group A the yearly incidence decreased from 624 patients in 2008 to 373 patients in 2016, whereas the incidence in group B was more stable, varying between 224 and 336 patients during the same period. In total 12% and 10% of patients had died in the study period in group A and group B respectively. SMR was 1,63 (95% CI 1,43 - 1,83) and 2,09 (95% CI 1,80 - 2,39) in group A and B respectively. Overall survival was significantly worse ($p< < 0,001$) in both groups compared to the general population, HR=2,17 (95% CI 1,94 - 2,44) in group A and HR=2,75 (95% CI 2,38 - 3,17) in group B.

Discussion: Definition of SLE prevalence and incidence are in line with literature for other claims data studies. Results on SLE prevalence and incidence are also similar to the published data. There is a significant excess mortality due to SLE; the level of excess mortality is underestimated.

Conclusion: This full-populational database study showed that despite that a wide range of therapeutic option are available for patients suffering for SLE, the mortality and survival compared to the general population is significantly worse for these patients. Therefore, new innovative therapies are needed to improve these aspects of SLE.

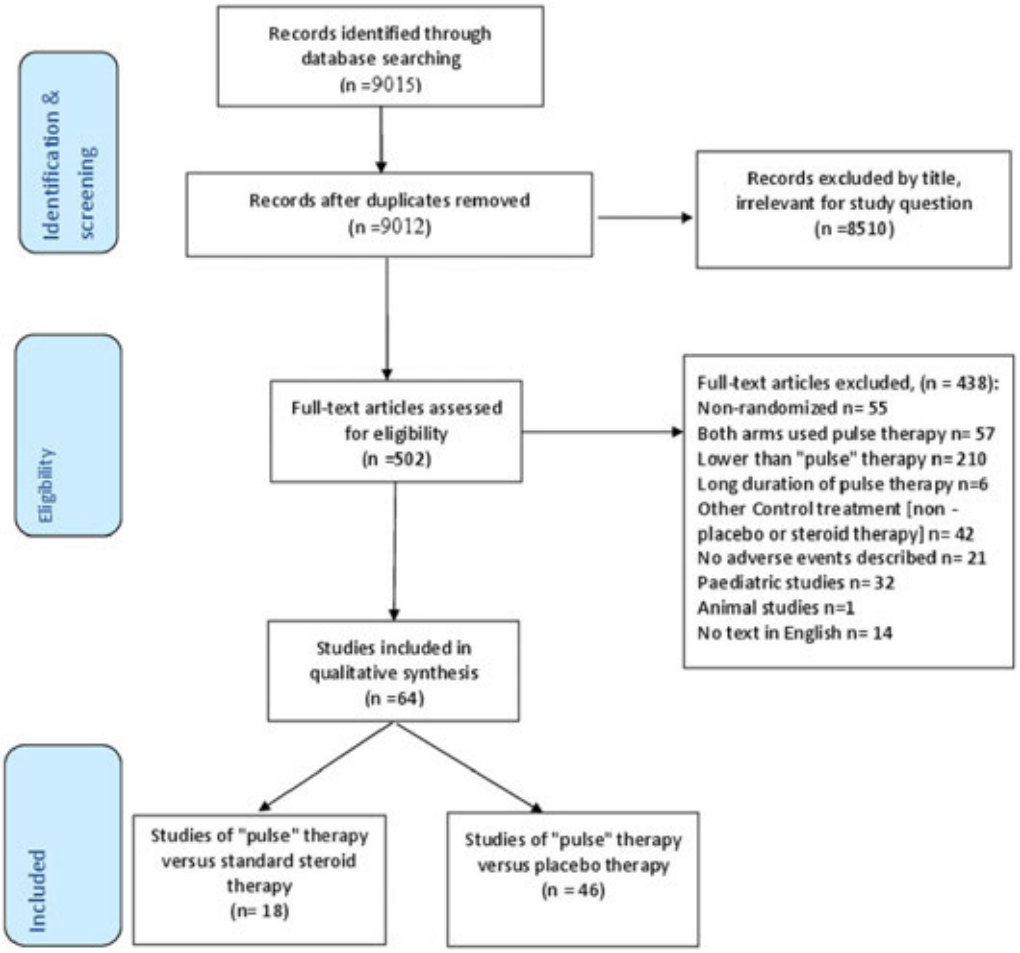
The Safety of Pulse Therapy- Systematic Review and Meta-analysis

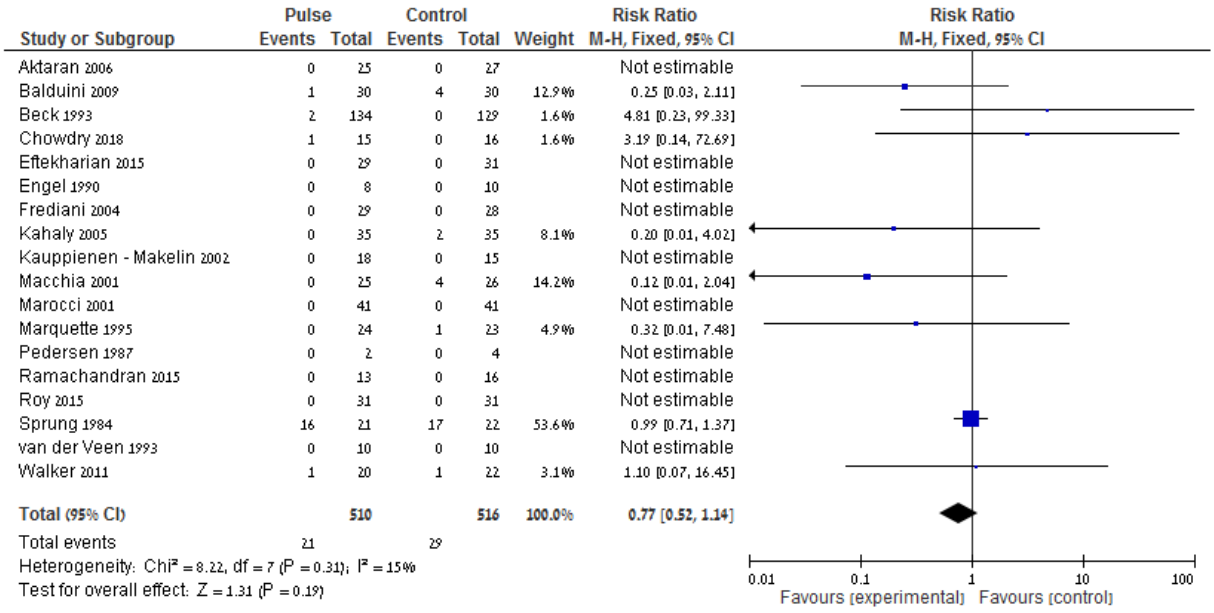
Yonatan Edel,[1] Tomer Avni,[1] Yair Molad,[2] daniel Shepshelovich,[1] Shelley Reich,[1] Benaya Rozen-zvi,[1] Michal elbaz,[3] leonard leibovici,[3] and Anat Gafter-Gvili[1], [1]Rabin Medical Center, petach tikva, HaMerkaz, Israel, [2]Rabin Medical Center, Beilinson Hospital, and Tel Aviv University, Petach Tikva, HaMerkaz, Israel, [3]rabin Medical Center, petach tikva, Israel

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

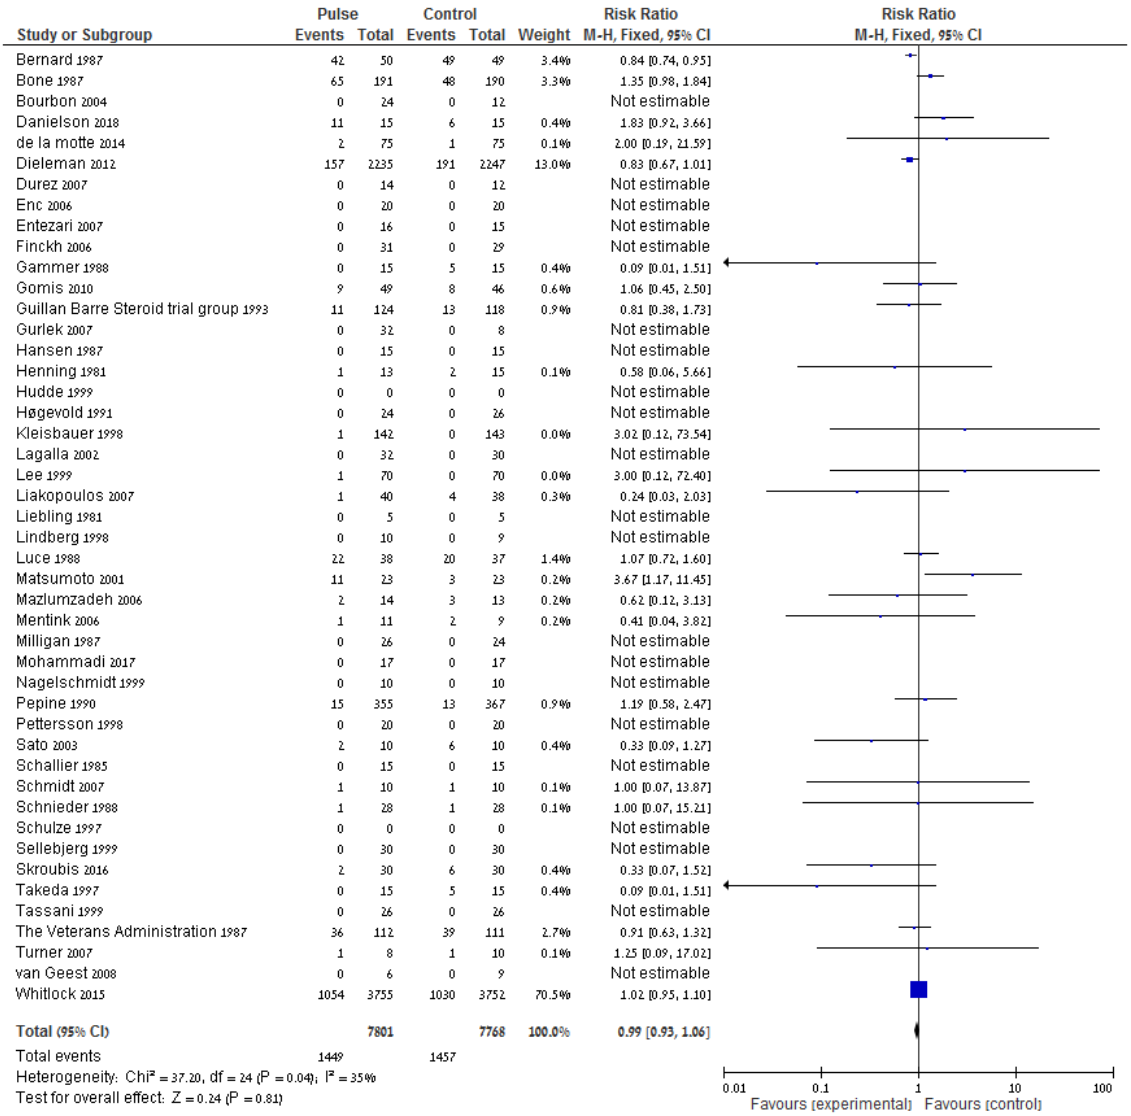
Background/Purpose: Very high dose (or pulse) glucocorticoid treatment is widely used for autoimmune, inflammatory, infectious and other conditions. We aimed to amass all available evidence from randomized controlled trials regarding the safety of pulse steroids therapy, in order to establish its safety

Figure 1: PRISMA study flow chart





Primary outcome: SAEs, pulse steroids vs. oral therapy



Primary outcome: SAEs, pulse steroids vs. placebo / no therapy.

Methods: Systematic review and meta-analysis of all randomized controlled trials comparing pulse steroids to oral steroids or to placebo/no treatment. All electronic databases up to 12/2018 were reviewed. Risk ratios (RR) with 95% (CI) for differences between pulse steroids and comparator were pooled (when RR < 1 denotes less risk with pulse steroids) using a fixed effect meta-analysis. The primary outcome was occurrence of severe adverse events (SAEs). Secondary outcomes included any adverse events (AEs), AEs requiring discontinuation, AEs per system involved and all-cause mortality. Sensitivity analysis was based on the methodology, design, and follow up time. Subgroup analysis was based on comparator, dosage of pulse steroids, treated condition and system involved

Results: A total of 64 trials were included: 18 trials which compared pulse steroids to oral steroids and 46 trials which compared pulse steroids to placebo / no intervention. Pulse steroids was not associated with increased risk for SAEs for both comparators: RR 0.77 (95% CI 0.52-1.14), and RR 0.99 (95% CI 0.93-1.06), respectively. Sensitivity analysis based on adequate allocation concealment and use of a valid AE grading did not alter the results. Subgroup analysis revealed no increased risk of specific SAEs or AEs with pulse steroids compared to oral steroids

Conclusion: Pulse steroids was not associated with an increase risk of SAEs and should be regarded as safe

Abstract Number: 1100

Opioid Overdose Hospitalizations in Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis

Christine Anastasiou,[1] Jing Li,[1] Laura Trupin,[2] Gabriela Schmajuk,[3] and Jinoos Yazdany[1], [1]UCSF Division of Rheumatology, San Francisco, CA, [2]University of California, San Francisco, San Francisco, CA, [3]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Individuals with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) often suffer from both acute and chronic pain, and the prevalence of opioid medication use among persons with RA has been estimated at 16%[1]. Because of the risk of overdose among opioid users, we sought to investigate opioid overdose-related hospitalizations among patients with SLE and RA in comparison to the rest of the population.

Methods: We used the National Inpatient Sample (NIS), which after weighting provides annual estimates for more than 35 million hospitalizations in the US. Analysis was limited to individuals without missing relevant variables hospitalized in 2016. Admissions with opioid overdose were identified based on these ICD-10-CM codes: T40.0-40.4, T40.6, X42.x, X62.x or Y12.x, which could be included as the primary reason for admission or one of up to 30 causes. SLE and RA were also captured in ICD-10-CM codes (M32.1x, M32.8, M32.9 and M05.x, M06.0x, M06.2x, M06.8x, M06.9, M08.x respectively); patients with codes for both conditions were classified as SLE. We compared the proportion of opioid overdose admissions among patients with SLE, RA, and neither condition using chi-squared tests. We used Poisson regression to model admissions due to opioid overdose as a function of disease (SLE, RA, or neither), controlling for demographics (age, sex, race) and socioeconomic status (SES) characteristics (health insurance and residence in a low-income ZIP code). All analyses accounted for the complex sampling design of the NIS.

Results: Among 33,207,455 hospitalizations in 2016 included in the analysis, 512,740 (1.5%) were of patients with RA and 147,480 (0.44%) with SLE. A higher proportion of hospitalizations were due to opioid overdose as a primary cause among patients with RA (0.23%) or SLE (0.34%), in comparison to patients with neither condition (0.17%; $p < 0.01$). Including all diagnoses of opioid overdose increased the proportions to 1.46% for patients with RA, 1.50% for SLE, and 0.85% for those with neither condition, and the differences were still significant ($p < 0.01$). After accounting

Table. Opioid overdose admissions among patients with RA or SLE compared to admissions among those with neither condition, adjusted for demographics and SES characteristics.* National Inpatient Survey 2016.

	Opioid overdose as primary diagnosis	Opioid overdose as any diagnosis
Disease group	Adjusted relative risk (95% CI)	Adjusted relative risk (95% CI)
SLE	2.44 (1.99, 2.98)	1.83 (1.67, 2.01)
RA	1.47 (1.30, 1.67)	1.44 (1.37, 1.52)
Neither condition	Ref	Ref

*Results from Poisson regression model, adjusting for age, sex, race, residence in a low-income ZIP code, and health insurance.

for demographic and SES characteristics of the hospitalized patients, both RA and SLE were associated with higher relative risks of opioid overdose hospitalizations compared to patients with neither condition, either as a primary diagnosis or any diagnosis. SLE was associated with a higher relative risk of opioid overdose hospitalization compared to RA (Table).

Conclusion: RA and SLE were associated with a 1.5 to 2-fold higher risk of opioid overdose hospitalization compared to the general population. Local and national overdose intervention programs should consider targeting RA and SLE individuals as at potentially increased risk for opioid overdose.

Abstract Number: 1101

Development of an Algorithm to Identify Sjögren's Syndrome Patients in the French National Healthcare Claims Database

Valérie Devauchelle Pensec,[1] Laurent Chiche,[2] Joe Zhuo,[3] Isabelle Lavrard,[4] Guillaume Desjeux,[5] and Raphaele Seror[6], [1]University Hospital of Brest, Brest, France, [2]Hôpital Européen, Marseille, France, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Bristol-Myers Squibb, Rueil-Malmaison, France, [5]E-health Services Sanoïa, Digital CRO, Gémenos, France, [6]Hopitaux universitaires Paris Sud, Kremlin-Bicetre, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's syndrome (SS) is a chronic autoimmune disease, consisting of primary SS (pSS) when it presents alone and secondary or associated SS when accompanied by other connective tissue diseases. Prevalence of primary SS ranges between 10 and 90 cases per 100,000 people in Europe. However, there is a lack of efficient algorithm that can be used in claim-based database to identify SS patients. Our objective was to establish an algorithm that can be used to identify SS patients by using a sub-sample of the French healthcare database claim.

Methods: Potential SS cases were identified based on ICD-10 codes (M35.0) when used for SS-related hospitalization or chronic disease status allowing full expenditure reimbursement codage, from 2005 to 2016. Reimbursements of at least one drug of interest, number of specialist prescriptions, reimbursement of Schirmer's test, procedures on salivary gland and research of antinuclear antibody were identified as variables of interest to build an algorithm. Patients having at least exclusion criteria of pSS ACR-EULAR classification criteria were excluded. Patients with associated code of rheumatoid arthritis, juvenile arthritis, ankylosing spondylitis, systemic lupus erythematosus, systemic sclerosis and other overlap syndromes, based on ICD-10 codes or biological therapy reimbursements, were classified as secondary SS. The onset of the disease was identified as the first occurrence of ICD-10 M35.0. A cross-validation was performed by using a logistic regression to estimate the accuracy of 15 different "diagnosis" algorithms.

Results: Among the 447 potential SS patients identified, 44 were excluded, 267 patients were classified as pSS and as 136 secondary SS. The most efficient algorithm to identify pSS (with an accuracy of 0.94) was: ICD code of SS + at least 2 prescriptions of at least one of the drugs of interest in 4 years before, or the 4 years after the first occurrence of the ICD code of SS. For secondary SS, the best algorithm (with an accuracy of 0.89) was: ICD code of SS + at least 2 prescriptions by a rheumatologist or an internal medicine physician both before and after the first occurrence of the ICD code of SS. With these algorithms, estimated prevalences were 29.5 per 100,000 for pSS and 8.30 per 100,000 for secondary SS in 2016.

Conclusion: Using a sub-sample of the French healthcare claims database, we developed, two algorithms to efficiently identify primary and secondary SS patients. Further analysis is planned to estimate at national-level prevalence and incidence of SS in France and analyze healthcare consumption. In addition, these algorithms can potentially be adapted for claims data in other countries.

Abstract Number: 1102

Estimate of Prevalence of Secondary Distal Renal Tubular Acidosis Among Patients with Sjogren's Syndrome and Systemic Lupus Erythematosus in a US Population with Employer-Sponsored Health Insurance

Gary Bryant,[1] Linda Law,[2] and Josephine Li-McLeod[3], [1]University of Minnesota Medical School, Minneapolis, MN, [2]Advicenne, Cincinnati, OH, [3]Stratevi, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Distal renal tubular acidosis (dRTA) involves impairment in the distal tubule, leading to insufficient renal acid secretion, which can result in metabolic acidosis, hypokalemia, nephrolithiasis, nephrocalcinosis and bone demineralization. While primary dRTA is caused by genetic factors, and additionally associated with poor growth and deafness, secondary dRTA may result from autoimmune disorders, such as Sjögren's syndrome or systemic lupus erythematosus (SLE), which also attack the distal tubule. Some medications are also associated with secondary dRTA. While secondary dRTA is a rare disease, US prevalence may be under-reported. This analysis utilizes administrative claims data to estimate the prevalence of secondary dRTA among patients with Sjogren's syndrome or SLE in a US employer-sponsored insurance (ESI) population.

Methods: Utilizing the Truven MarketScan® Commercial and Medicare Supplemental Databases from Jan 1, 2016–Dec 31, 2016, secondary dRTA patients were identified using the following criteria: at least 1 inpatient or ≥2 outpatient claims ≥30 days apart for Sjögren's syndrome (ICD-10-CM: M35.0x) or SLE (ICD-10-CM: M32.xx) or acidosis (ICD-10-CM: E87.2). To further delineate the sample, patients were also required either to have a claim for an alkalinizing agent or have a diagnosis of other disorders resulting from impaired renal tubular function (ICD-10-CM: N25.89). MarketScan Commercial Insurance Weights were then applied to project the sample to the total US ESI population.

Results: A total of 100,680 patients with ICD-10-CM diagnosis code of Sjögren's syndrome, SLE, or Acidosis were identified in the 2016 Marketscan database. Of these, 1,125 were prescribed an alkalinizing agent or had a diagnosis code of impaired renal tubular function. Applying the insurance weights to the 1,125 identified sample, this projected to an estimated 6,716 secondary dRTA patients, which extrapolates to an estimated secondary dRTA patient prevalence rate of 3.88 per 100,000 in the 2016 US ESI population.

Conclusion: The ability to unequivocally identify secondary dRTA patients based on a diagnostic code is limited. This approach used claims data to provisionally identify and estimate the prevalence of secondary dRTA patients in the US ESI population. According to the Kaiser Foundation, ESI represents 49% of the total US population. Further research is needed to validate this approach to effectively identify and characterize the treatment experiences of dRTA patients.

Abstract Number: 1103

Prevalence of Diagnosed Systemic Lupus Erythematosus (SLE), Patient Healthcare Utilization and Characteristics by Major Health Insurance Types in the US

Yiting Wang,[1] Laura Hester,[1] Jennifer Lofland,[2] Shawn Rose,[3] Chetan Karyekar,[4] Dave Kern,[5] Margaret Blacketer,[1] Kourtney Davis,[1] and Kimberly Shields-Tuttle[6], [1]Janssen Research & Development, LLC, Titusville, [2]Janssen Scientific Affairs, LLC, Spring House, PA, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Janssen Global Services, LLC, Horsham, PA, [5]Janssen Scientific Affairs, Titusville, [6]Janssen Research & Development, LLC, Spring House

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: One study estimated that between 161,000 and 322,000 people in the US had definite or probable SLE, based on data from the period of 1965-1973. We aimed to provide current US estimates of SLE prevalence by major health insurance types and describe patient healthcare utilization and characteristics.

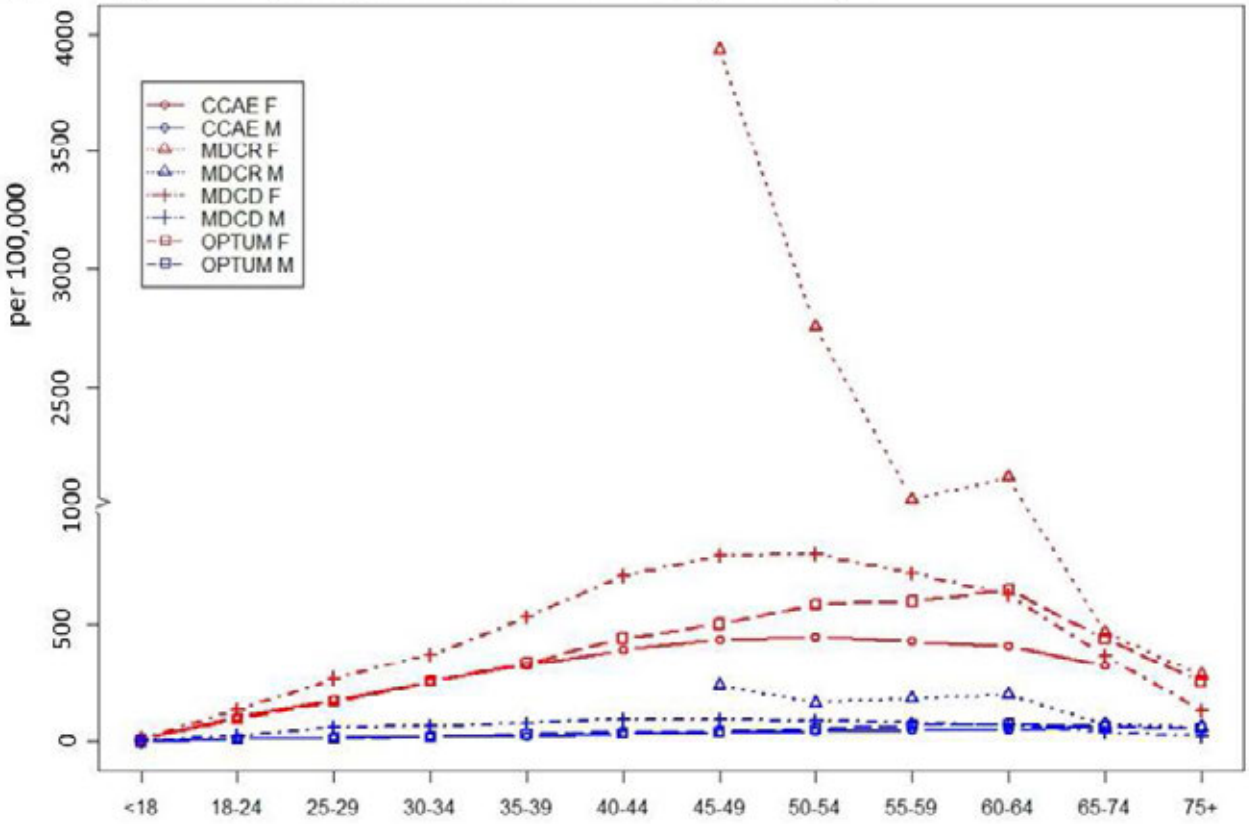
Methods: We used 4 large US health insurance claims databases converted to the OMOP Common Data Model: IBM MarketScan® Commercial (CCAE), IBM MarketScan® Medicare Supplemental (MDCR), IBM MarketScan® Multi-state Medicaid (MDCD), and Optum Clinformatics® Data Mart Databases. In each database, age and sex-specific SLE prevalence was estimated for calendar year 2016.

Numerator for prevalence estimates included individuals with ≥1 SLE diagnosis or ≥1 belimumab prescription in 2016, and met the following before or in 2016:

(1) ≥3 SLE diagnoses (ICD-10 M32.10, or ICD-9 710.0) spanning ≥ 60 days; or
(2) ≥1 belimumab infusion/injection and ≥2 SLE diagnoses; or
(3) ≥1 inpatient SLE diagnosis and ≥1 dispensed prescription for systemic corticosteroids, antimalarials, or immunomodulators commonly used in SLE treatment.

Denominator included individuals enrolled for the entire year of 2016.

Figure 1. Age-, and sex-specific prevalence of SLE in the 4 study databases, 2016



Projection of prevalent SLE cases (rounded in thousands) in the US was based on prevalence estimates from each database and US census data by insurance types.

Results: Figure 1 shows the prevalence in females was consistently higher than males across all age groups, ranging from 4- to 23-fold. The highest prevalence in women and men aged 45-64 was observed for those in Medicare who qualify based on disability status. The estimated number of prevalent SLE cases actively treated under commercial (including Medicare supplemental) or Medicaid plans is 450,000 (=285,000+66,000+99,000) to 521,000 (=422,000+99,000) (Table 1). Overall healthcare utilization including hospitalizations for infections appeared highest (despite lowest mean age) in Medicaid (Table 1). Comorbidities were common across multiple organ systems in SLE patients, including renal failure/dialysis. SLE medications most commonly dispensed were systemic corticosteroids and anti-malarial drugs; < 5% of the SLE patients had claims for anti-inflammatory biologic agents.

Conclusion: Estimates of both prevalence proportion and number of civilian SLE cases based on 2016 US data demonstrate a considerable increase over the last three decades, yet likely underestimate the true public health burden which would include persons undiagnosed or not actively seeking healthcare under the insurance plans contributing to our analysis.

Heritability and Familial Risk of Systemic Lupus Erythematosus in Sweden: A Population-based Case-control Study

Elizabeth Arkema,[1] Marios Rossides,[1] Christopher Sjöwall,[2] Elisabet Svenungsson,[3] and Julia Simard[4], [1]Clinical Epidemiology Division, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [2]Department of Clinical and Experimental Medicine, Rheumatology/Division of Neuro and Inflammation Sciences, Linköping University, Linköping, Sweden, [3]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [4]Stanford University School of Medicine, Palo Alto, CA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies examining the relative risk (RR) associated with having a first degree relative (FDR) with systemic lupus erythematosus (SLE) were small and few investigated different proband-relative relationships nor stratified by proband characteristics, which is likely important when studying a heterogenous disease such as SLE. Our goal was to estimate the familial RR and heritability of SLE stratified by age at onset, sex and kinship in a large population-based sample.

Methods: We conducted a case-control-family study using Swedish nationwide registers. Proband SLE cases were identified from the National Patient Register using ICD codes for SLE (≥2 visits, ≥1 in specialist care (internal medicine, pediatrics, rheumatology, dermatology, nephrology); 1971-2016; n=8801). Lupus nephritis was defined using ICD codes for lupus-related kidney disease (ICD-10 N00-N06, N16.2, N16.4, N16.8, N17-N19, N26, M32.1) Proband controls were matched to each case 5:1 on age, sex and residential location. FDRs and half siblings were identified from the Multi-Generation Register and SLE in relatives was identified the same way as for cases. Conditional logistic regression models estimated RRs for SLE associated with having an FDR with SLE. Models were stratified by age at onset, sex of the proband/relative, and lupus nephritis. Robust variance estimates were used to calculate 95% confidence intervals (95%CI) to account for correlated data. Heritability was estimated using tetrachoric correlations among first degree relatives and prevalence estimates for our population.

	Cases	Controls	RR (95%CI)
	N exposed/N total	N exposed/N total	
First degree relatives			
Number of relatives			
≥1 relative	442/8801	182/36208	11.1 (9.3, 13.3)
≥2 relatives	34/8801	4/36208	39.8 (14.1, 112.4)
Kinship*			
Parents	153/12144	73/53133	9.3 (6.1, 14.1)
Full Siblings	183/10082	50/44502	17.9 (3.1, 101.9)
Offspring	141/13918	62/61358	10.4 (4.6, 23.7)
Age at inclusion*			
<18 y	37/415	7/1870	23.7 (11.0, 53.6)
18-39 y	166/2375	49/10102	16.5 (11.8, 23.2)
40-64 y	174/3867	87/16298	9.2 (7.1, 12.0)
>64 y	65/2144	29/7938	7.2 (4.7, 10.8)
Sex of Proband/Relative*			
Female/Female	308/6775	126/28356	11.2 (9.0, 14.0)
Female/Male	51/6692	27/28143	9.0 (5.5, 14.7)
Male/Female	52/1309	24/5432	9.4 (5.8, 15.5)
Male/Male	32/1299	5/5383	32.0 (11.3, 90.8)
Lupus Nephritis*			
Yes	149/2965	60/12427	11.7 (8.6, 15.9)
No	293/5836	122/23770	10.9 (8.8, 13.5)
Second degree relatives*			
Half siblings	16/3466	7/3634	2.6 (0.5, 13.3)

* Probands can contribute more than one observation, therefore adjusted for autocorrelation from family clustering using robust variance estimates

Results: 5% of proband cases had ≥1 relative with SLE compared to 0.5% of controls. The RR for SLE associated with having ≥1 FDR with SLE was 11.1 (95%CI 9.3, 13.3; Table). The RR was higher if ≥2 FDRs had SLE (39.8; 95%CI 14.1, 112.4) and lower if a half sibling had SLE (RR 2.6; 95%CI 0.5, 13.3). RRs were higher for SLE diagnosed at a younger age (< 18y RR 23.7; 95%CI 11.0, 53.6) and in male proband/male relative kinships (RR 32.0; 95%CI 11.3, 90.8), although this was based on small numbers. There was no considerable difference in the association when stratified by lupus nephritis status. Heritability was 61% (95%CI 58, 64).

Conclusion: Having a first degree relative with SLE is associated with an 11-fold increased risk of SLE, making it a very strong risk factor for the disease. The risk is highest for pediatric SLE and decreases with increasing age at diagnosis. There were no large differences in risk by lupus nephritis phenotype, kinship, or sex. The male proband-male relative association was the highest, although this was based on small numbers. 61% of the phenotypic variance of SLE is attributable to genetic factors.

Relative risk of SLE associated with having relatives diagnosed with systemic lupus erythematosus (SLE) overall and stratified by age at inclusion, sex of the proband, sex of the relative and lupus nephritis phenotype.

Relationships Among Cognitive Emotion Regulation, Body Image, Family and Marital Function and Quality of Life in Chinese Female Patients with Systemic Lupus Erythematosus

Huilin Zhang,[1] Lezhi Li,[2] Mengyue Chen,[2] and **Qing Zhang**[3], [1]Clinical Nursing Teaching and Research Section, Second Xiangya Hospital, Central South University, Changsha, Hunan, China (People's Republic), [2]Xiangya Nursing School, Central South University, Changsha, Hunan, China (People's Republic), [3]Department of Dermatology, Second Xiangya Hospital, Central South University, Changsha, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: At present, there are few researches on cognitive emotional regulation, body image, family and marital function, and life quality of female patients with systemic lupus erythematosus (SLE) in China. The aim of this study is to explore the relationships of these factors, and to build a path equation model among these factors.

Methods: Participants in the study included 242 female patients with SLE from three hospitals of China. The questionnaires contained demographic information sheet, SLE Disease Activity Index (SLEDAI), Lupus Quality of Life (LupusQoL), Cognitive Emotion Regulation Questionnaire (CERQ), Body Image Lupus Scale (BILS), Family and Marital Functioning Measures (FFM and MFM). Statistical Methods included descriptive analysis, correlation analysis, one-way ANOVA, multiple linear regression, and path equation modeling analysis.

Results: We identified non-adaptive strategies score was negatively correlated with the total score of life quality (r=-0.589, P< 0.05). The score of body image (r=0.466, P< 0.05) and the total score of family and marital function (r=0.562, P< 0.05) were both positively correlated with the total score of life quality. Adaptive strategies score was positively correlated with the total score of family and marital function (r=0.149, P< 0.05), and non-adaptive strate-

gies score was negatively correlated with the body image score (r=-0.313, P< 0.05) and the total score of family and marital function (r=-0.476, P< 0.05). The body image score was positively correlated with the total score of family and marital function (r=0.285, P< 0.05). Moreover, path equation model showed that adaptive strategies had direct positive effect on family and marital function (β=0.227, P=0.000); non-adaptive strategies had direct negative effect on body image (β=-0.231, P=0.001), family and marital function (β=-0.494, P=0.000), and quality of life (β=-0.358, P=0.000); SLEDAI scores had direct negative effect on body image (β=-0.140, P=0.041), family and marital function (β=-0.263, P=0.000), and quality of life (β=-0.363, P=0.000); family and marital function had direct positive effect on body image (β=0.116, P=0.030) and quality of life (β=0.171, P=0.000); body image had direct positive effect on quality of life (β=0.201, P=0.000).

Conclusion: Our results prove that in female SLE patients, non-adaptive strategies lead to low quality of life; and the better the body image and family and marital function, the higher the quality of life. In addition, body image and family and marital function have direct positive effect on quality of life; cognitive emotion regulation styles have direct and/or indirect effect on quality of life. Body image and family and marital function, as mediated variables, can mediate the relationship between cognitive emotion regulation styles and quality of life.

Abstract Number: 1106

Systemic Lupus Erythematosus and Sjögren's Syndrome in the Agricultural Health Study: Lower Risk Associated with Childhood Farm Residence and Raising Livestock

Christine Parks,[1] Stuart Long,[2] Laura Beane-Freeman,[3] Hofmann Jonathan,[3] and Sandler Dale[1], [1]National Institute of Environmental Health Sciences, Research Triangle Park, [2]Westat, Research Triangle Park, NC, [3]National Cancer Institute, Bethesda

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior research suggests that growing up on a farm and contact with livestock may confer protection against developing systemic autoimmune diseases, such as rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE). We examined associations between SLE and a related disease, Sjögren's syndrome (SS), with childhood and adult farm experience and potential exposures to livestock for licensed pesticide applicators and their spouses in the Agricultural Health Study (AHS).

Methods: Cohort participants were enrolled in 1993-1997 in North Carolina and Iowa and followed through 2015; Lupus (mostly SLE) and SS cases were identified based on self-report and classified as "confirmed" by medical records or "clinical" based on reported use of disease-specific anti-rheumatic drugs. Our analysis sample included 214 participants with confirmed or clinical SLE/SS, with 107 incident cases (N=45 confirmed SLE or lupus with DMARD use, with or without SS, 34 primary SS, and 20 SS with RA), and a comparison group of participants (n=54,205) who did not report a systemic autoimmune disease. Farming exposures were self-reported at enrollment, while data on childhood farm animal contact were collected from 68% of the sample during follow-up. We estimated odds ratios (OR) and 95% Confidence Intervals (CI) using logistic regression models adjusted for age, sex and state for cases, overall and stratified by sex, and in sensitivity analyses excluding RA.

Results: Cases were more likely to be female (83% versus 48% of non-cases; age-adjusted OR=5.3; 95%CI 3.7, 7.6), especially for prevalent (88% female; OR=7.8; 95%CI 4.4, 13.9) and less so for incident cases (77% female; age-adj OR=3.9; 95%CI 2.5, 6.2). Childhood farm residence (at least half the time up to age 18) was inversely associated with risk of becoming a case, overall, (OR=0.46; 95%CI 0.31, 0.69) and in models limited to women (OR=0.59; 95%CI 0.39, 0.91). Incident cases were less likely to live or work on a farm that raised livestock as well as crops compared with those who only raised crops, though the association was not statistically significant (OR=0.72; 95%CI 0.48, 1.09, p=0.12). Among women, however, incident cases were significantly less likely to live or work on a farm that raised 500 or more livestock animals (OR=0.50;95%CI 0.27, 0.92), with inverse associations also seen for women on farms raising hogs, field corn, and hay (all with $p< 0.05$).

Conclusion: These preliminary results support the idea that exposures related to childhood farm residence and livestock farming may decrease susceptibility to developing SLE and SS. While our analyses are limited by the low frequency of SLE/SS in the cohort, especially in men, they are consistent with prior findings for RA in female spouses in the AHS. Further analyses will explore associations of SLE/SS with other agricultural exposures, including pesticides.

Are Rheumatologists Correctly Identifying and Controlling Traditional Cardiovascular Risk Factors?

Dionicio Galarza-Delgado,[1] Jose Azpiri-Lopez,[1] Iris Colunga-Pedraza,[1] Iván de Jesús Hernández-Galarza,[1] **Ileana Cecilia Reynosa-Silva**,[1] Karla Paola Cuellar-Calderon,[1] Marielva Castro-Gonzalez,[1] and and Carolina Marlene Martinez-Flores[1], [1]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Epidemiology & Public Health Poster II: Spondyloarthritis & Connective Tissue Disease
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic systemic inflammation generated by rheumatic diseases (RD) is related to the increased cardiovascular risk (CVR) in this population. However, the coexistence of traditional CVR factors such as diabetes, hypertension, obesity, smoking, and dyslipidemia, further increases CVR burden. Through an adequate control of this factors, CVR can be decreased. But to achieve this, primary care physicians and rheumatologists should be aware of how relevant it is to make frequent cardiovascular assessment to RD patients. Therefore, the aim of this study is to determine the prevalence of underdiagnosis and inefficient treatment of traditional cardiovascular risk factors in RD patients.

Methods: An observational, retrospective study of patients between 30 and 75 years with rheumatoid arthritis, psoriatic arthritis, systemic lupus erythematosus and ankylosing spondylitis. Patient information was obtained from March 2018 to April 2019 through the REPAIR® software, an electronic records database used at the rheumatology clinic at a University Hospital in northeastern Mexico. Exclusion criteria: previous atherosclerotic cardiovascular disease, overlap syndromes, diabetes, or pregnancy. Evaluation included history of lifestyle, comorbidities, use of corticoids, blood pressure, anthropometry and fasting glucose measures. Framingham-Body Mass Index (FRS-BMI) was used to calculate their predicted CVR to 10 years.

Results: A total of 451 patients were recruited, 90.2% were women, with a median age of 52 years (43-59). In this population, 80.2% of the patients had at least one CVR factor; the presence of traditional CVR factors according to

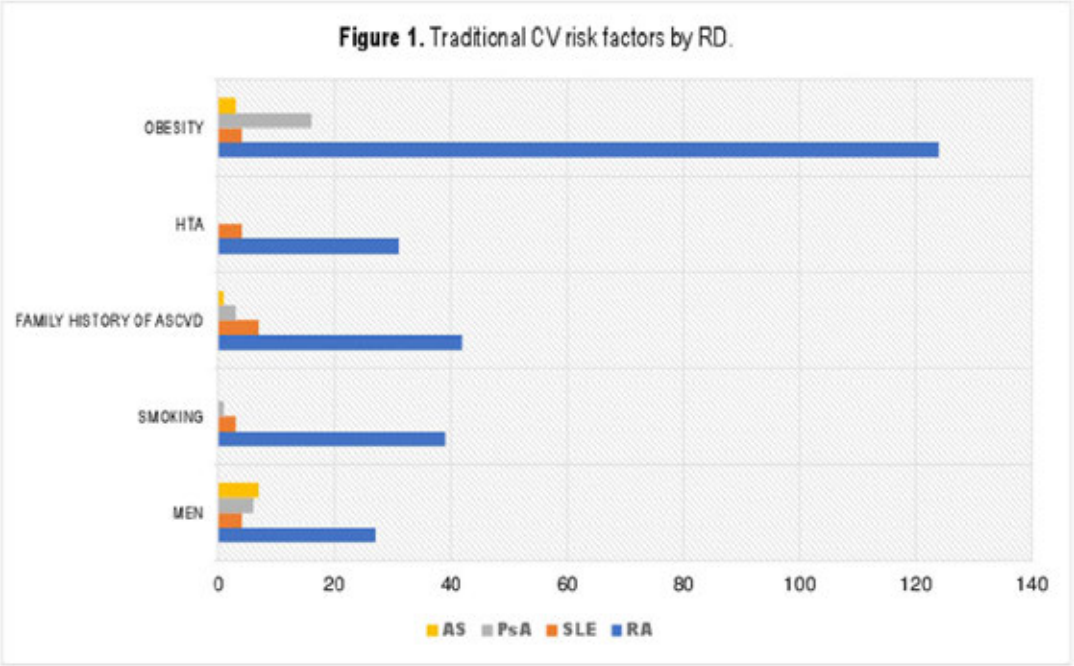

Table 1. Demographic characteristics.	
	n=451
Men, n (%)	44 (9.8)
Active smoking, n (%)	43 (9.5)
Hypertension, n (%)	35 (7.8)
Rheumatoid arthritis, n (%)	365 (80.9)
Psoriatic arthritis, n (%)	14 (3.1)
Systemic lupus erythematosus, n (%)	62 (13.7)
Ankylosing spondylitis, n (%)	10 (2.2)
Corticosteroid use, n (%)	136 (30.2)
Fasting glucose, mg/dL, median (p25-p75)	91 (84-99)
FRS-BMI score, median (p25-p75)	4.9 (2.8-8.1)

RD is shown in Figure 1. Other population characteristics are in Table 1. More than half of the patients were not in their ideal weight, 37.2% being diagnosed as overweight and 32.8% with obesity. Out of the patients with no previous diagnosis of hypertension (n=416, 92.2%), 25.96% had elevated or high blood pressure levels. From the patients that previously had hypertension, 65.7% did not have an adequate control of their blood pressure, even though they were on pharmacological treatment. History of dyslipidemia was found in 4.9% of patients. Half of them arrived at consultation with a recent lipid profile, having a median LDL of 133.5 (109-158) mg/dL, not meeting target levels. Even though no diabetic patients were included, 22.8% of the patients had hyperglycemia. According to FRS-BMI, 82% of the patients had a low CVR, 13.7% moderate risk, and 4.2% had a high CVR.

Conclusion: This study suggests that traditional CVR factors are underdiagnosed and insufficiently treated in RD patients. The previous is alarming, because 80.2% of the patients have at least one CVR factor, and they could highly benefit from its adequate control. Besides having a RD and at least one traditional CVR factor, 17.9% of the patients had a moderate or high CVR according to FRS-BMI. Rheumatologists should become more aware of the increased CVR in RD patients, and make CV assessment a part of their routine.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Health Services Research Poster II – ACR/ARP

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mobile applications promise to facilitate the life of patients as well as physicians. In routine practice, however, rheumatology apps are largely unknown and little is known about their quality and safety. The aim of this study was to provide an overview of the mobile rheumatology applications currently available in the German App Stores, to evaluate the app quality using the Mobile App Rating Scale (MARS) and compile brief, ready to-use descriptions for patients as well as rheumatologists.

Methods: The German Google Play and Apple App Stores were systematically searched to identify German Rheumatology mobile applications addressing patients as well as physicians. App quality was assessed independently using MARS by in total 8 physicians, 4 using Android and 4 using iOS smartphones. The MARS score is based on a 5-point Likert scale in four sections with multiple items: engagement (5 items), functionality (4 items), aesthetics (3 items), and information quality (7 items). In addition, there is a "subjective" section consisting of 4 items. Apps were randomly assigned so that 4 apps were rated by all raters and the remaining apps were rated by two Android and two iOS users. Furthermore, brief app descriptions including app developers, app categories and features were compiled to inform potential users and developers.

Table 1: MARS and App Store ratings of included apps

App	MARS[a] score, median (range)	iOS raters, N	Android raters, N	MARS[a] section scores, median (range)					Google Play Store ratings[b], mean (N)	iTunes Store ratings[b], mean (N)

[a]Mobile App Rating Scale

[b]App Store ratings retrieved on April 21st 2019

[c]No App Store ratings available

[d]App not found in App Store as of April 21st 2019

Results: In total 128 and 63 apps were identified in the German Google Play and Apple App Stores, respectively. After removing doublets and only including apps that were available in both stores 28 apps remained, of which 16 final apps met the inclusion criteria, which were: (1) German language; (2) availability in both app stores; (3) targeting patients or physicians as users, and (4) clearly including rheumatology or rheumatic diseases as subject matter. Exclusion criteria were: (1) congress apps (2) company apps with advertisements. 9 apps addressed patients, 7 apps addressed physicians. No clinical studies to support the effectiveness and safety of these apps could be found. Pharmaceutical companies were the main developers of two apps. Rheuma-Auszeit, was the only app mainly developed by a patient organization. This app, had the highest overall MARS score (4.19/5). 3/9 patient apps featured validated questionnaires. The median overall MARS score was 3.85/5 ranging from 2.81/5 to 4.19/5. One patient targeted app and one physician targeted app had a MARS score >4/5. No significant gender or platform (iOS/Android) differences could be observed.

Conclusion: This is the first study, which systematically identified and evaluated mobile applications in rheumatology for patients as well as physicians available in German App Stores. We found a lack of supporting clinical studies, use of validated questionnaires and involvement of academic developers. Overall app quality was very heterogeneous. To create high-quality apps a closer cooperation lead by patients and physicians is vital.

Development of Smart-phone Spondyloarthritis Management System and Real-world Study of Chinese Patients with Ankylosing Spondylitis

Xiaojian Ji,[1] Jian Zhu,[2] Jianglin Zhang,[2] and **Feng Huang**[3], [1]Department of Rheumatology, Chinese PLA GeneralHospital,, Beijing, Beijing, China (People's Republic), [2]Chinese People's Liberation Army General Hospital, Beijing, China (People's Republic), [3]Department of Rheumatology, Chinese PLA General Hospital, beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We developed a multipurpose digital platform, Smart-phone SpondyloArthritis Management System (SpAMS), based on two of the most important objectives: 1) for patients: to activate patient engagement and provide education about disease self-management and 2) for clinicians and researchers: to provide a new source of real-world data for the scientific community by collecting questionnaire data, physical measurements, and images with comprehensive clinical follow-ups.

Methods: SpAMS was designed for patients with axial SpA, including AS and nonradiographic axial SpA (nr-axSpA), and open to the public by being embedded in the WeChat social media application (Figure 1). The project was launched in August 2015, beta-tested in January 2016 with rheumatologist and a small group of patients, and finally released in April 2016. Patients diagnosed with axial SpA in the Chinese People's Liberation Army (PLA) General Hospital were recruited consecutively in the Chinese Ankylosing Spondylitis Prospective Imaging Cohort (CASPIC). Demographic and clinical data were collected through SpAMS. All data were pseudonymised for analysis and matched by generation time and unique anonymous identifiers.

Results: Between April 2016 and February 2019, 27,628 WeChat social media users all over China subscribed to our WeChat service account and received weekly notifications about SpA disease management strategies. In the last 30 days alone, a total of 50,028 users read those management strategies 85,261 times (Figure 2), and this figure has remained stable over the past 6 months. The most-read articles concern exercise and lifestyle. There were 7,158 subscribers who logged into our system and registered as patients with axial SpA. Of them, 1,684 had face-to-face clinic visits at the Chinese PLA General Hospital (Figure 3). In total, 1,426 patients with axial SpA were enrolled in the

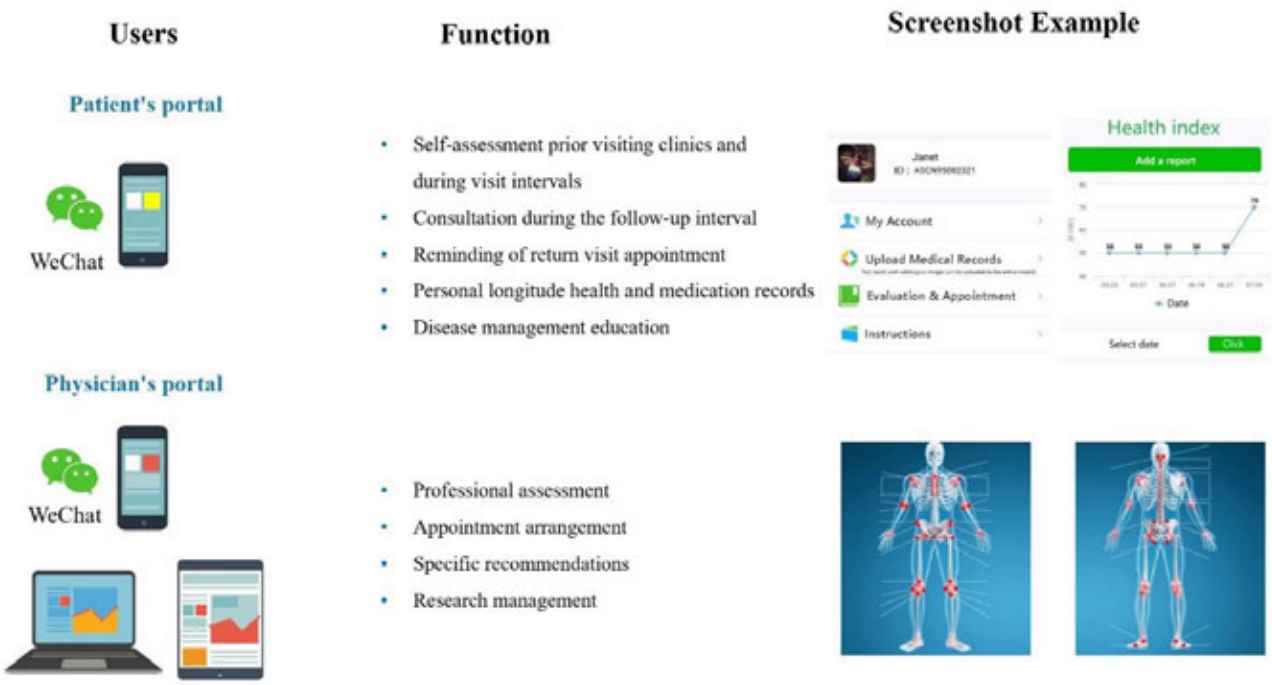

Figure 1. Patient's and Physician's portal in SpAMS.

Figure 2. Pageview of SpA disease management strategies in the last 30 days.

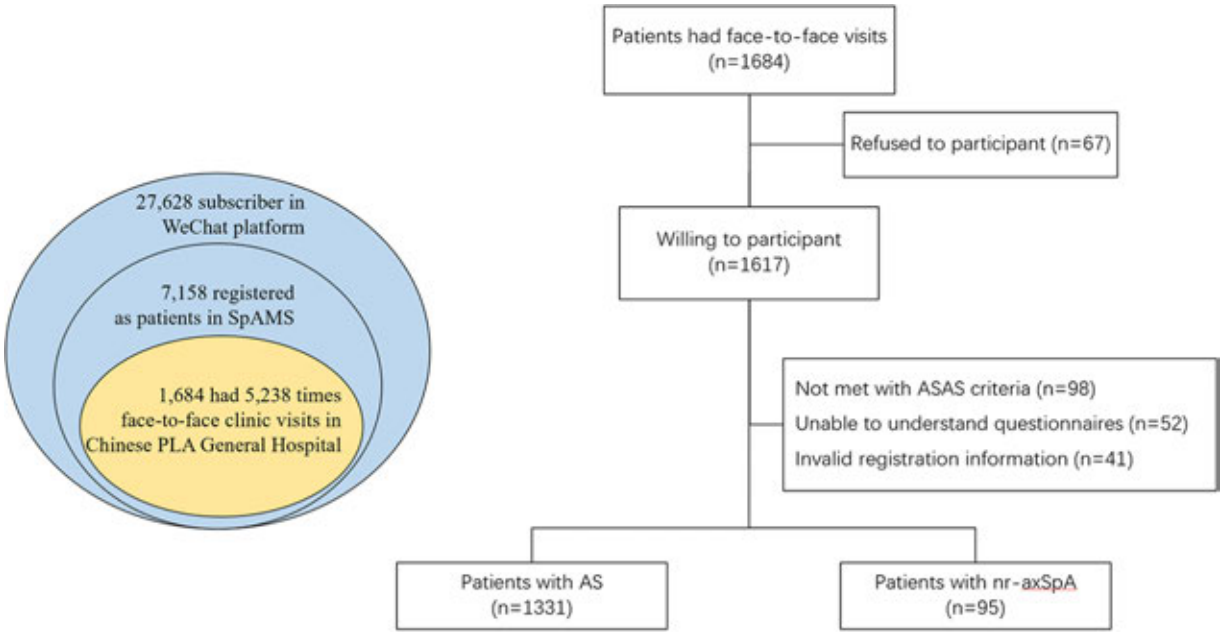

Figure 3. Defining the cohort samples.

cohort (AS = 1331 and nr-axSpA = 95). To date, 4,659 patient-reported assessments (mean 3.9, range 1 to 21) and 3,304 physician-reported assessments (mean 2.8, range 1 to 11) have been collected.

Conclusion: SpAMS is a disease management tool that can help patients with AS perform self-management and provide clinic data to clinicians.

Expanding Access to Research Using Tele-Health: Lupus and Informatics Feasibility Study

Trevor Faith,[1] Jihad Obeid,[1] Kit Simpson,[1] and Diane Kamen[2], [1]Medical University of South Carolina, Charleston, [2]Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, South Carolina, USA., Charleston, SC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Participating in clinical research can be burdensome for subjects due to time and travel barriers, particularly among underserved, rural, and/or chronic disease bearing populations such as systemic lupus erythematosus (SLE). Telemedicine offers one way to overcome these barriers by providing tele-research visits. Doxy.me is a platform which facilitates these types of visits with its tele-consent functionality. However, diverging from the traditional in-person informed consent methodology could unduly influence subjects' willingness to participate, reduce their comprehension of their study and associated risks or benefits. This poses an ethical concern that warrants exploration prior to widespread implementation. In this study, we examined the impact of tele-consent on measures of consent quality as compared to in-person consenting procedures.

Methods: Assessments of perceived decision-making control (Decision Making Control Index, DMCI), consent quality (Quality of Informed Consent, QuIC), and health literacy (Short Assessment of Health Literacy – English Version) were integrated into an ongoing observational study. This study enrolls African American patients with SLE and healthy controls over the age of 18, many of whom are of Gullah Geechee heritage. Subjects were invited to participate in tele-consent and associated assessments at their in-person observational study visit. Willing subjects were randomized to tele-consent or standard in-person consent, followed by consent assessments. An independent samples t-test was used to compare mean outcome scores and age, whereas the chi-squared test was used for categorical demographic variables.

Results: Twenty-five subjects have completed the study, 12 of whom were randomized to tele-consent. There were no significant differences in age (mean 49 ± 15.39), sex (96% female), or health literacy scores (mean 16.7 ± 2.14, out of 18). The study sample is entirely African American, possesses health insurance, and 52% are diagnosed with SLE. Two tele-consent subjects were unable to complete their tele-consent encounters. One failure was due to a software issue while the other failed due to subject usability problems. Outcome measures did not vary significantly between groups; for tele-consent and standard consent the QuIC part A scores were 95.0 and 92.9 respectively ($p = 6.83$) out of 100, whereas the Part B scores were 4.9 and 4.8 respectively ($p = 0.851$) out of 5. Similarly, scores on the DMCI were 51.2 and 50.8 ($p = 0.974$) out of 54.

Conclusion: The lack of statistically significant differences in outcome measures is promising for the validity of tele-consent. However, two tele-consent failures, one of which was due to the software, were encountered. A larger sample size will provide greater surety in these results and determine if failures may be a significant barrier to implementation. Tele-consenting is a novel methodology to increase recruitment and retention of under-served and hard to reach populations in minimally invasive studies. Trials may benefit from partnering with external laboratories or satellite clinics to facilitate more complex research visits while maintaining a reduction in travel burden for participants.

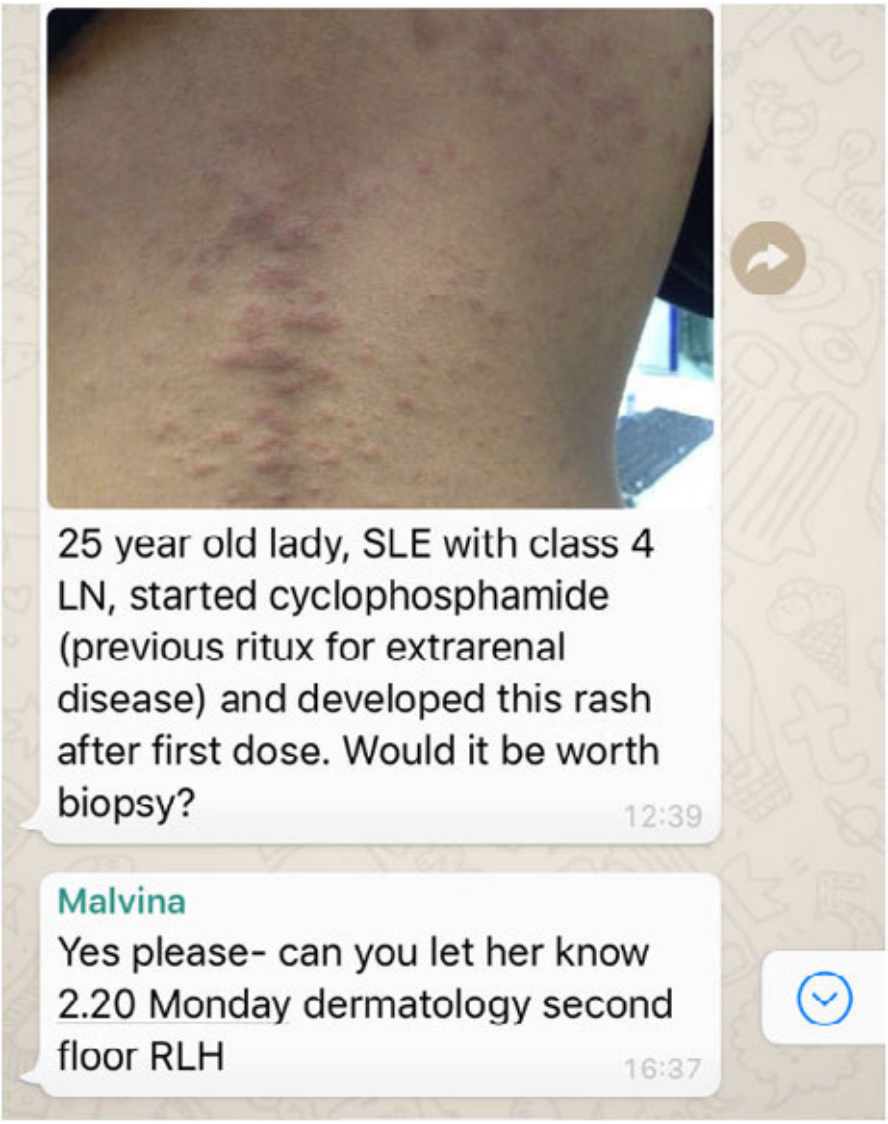
Session Title: Health Services Research Poster II – ACR/ARP

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Clinicians have been increasingly using social media sites professionally. Platforms such as WhatsApp ® could be a potentially effective tool in teledermatology for rapid diagnosis and/or triage.



Cutaneous disease is a common manifestation of lupus but patients may also develop rashes not directly attributable to the disease and hence the importance of accurate diagnosis and management. In this study we introduced and service evaluated a WhatsApp® lupus telederm platform for diagnosis and management of cutaneous lesions in lupus patients attending clinic at an inner city Lupus Centre.

Methods: A WhatsApp ® group was created comprising all clinicians involved in the running of lupus clinics within the centre and included 2 senior dermatologists. Lupus patients who presented with skin lesions which posed diagnostic or management uncertainty were consented for lesion photography. Images were uploaded to WhatsApp ® along with relevant but brief clinical history. Patient confidentiality was protected by avoiding upload of any patient identifiable data. Dermatologist responses were collated and effectiveness of the service for patients was analysed.

Results: 1-year retrospective data from WhatsApp ® was evaluated. Images from 27 lupus patients had been uploaded for advice. Dermatologist advice could be categorised as either 1. Diagnosis and treatment advice (18 patients) (*example - image1*) or 2. Advice to refer to emergency dermatology clinic for further clinical evaluation (*example*

– *image 2*) (9 patients). Patients in category 1 received a diagnosis and treatment institution within 48 hours. Those in category 2 were seen in dermatology clinic within 11 days where 7 underwent skin biopsy with subsequent diagnosis. The average time of a dermatologist to respond to queries was 1.1 days.

Conclusion: Our pilot project demonstrates that WhatsApp ® is an effective teledermatology platform for lupus patients with skin lesions allowing prompt evaluation and management.

Abstract Number: 1112

Rheumatologists' Opinions and Use of Telemedicine in the Southwestern U.S

Kimberly Reiter [1], [1]Albuquerque VA Medical Center, University of NM School of Medicine, Albuquerque, NM

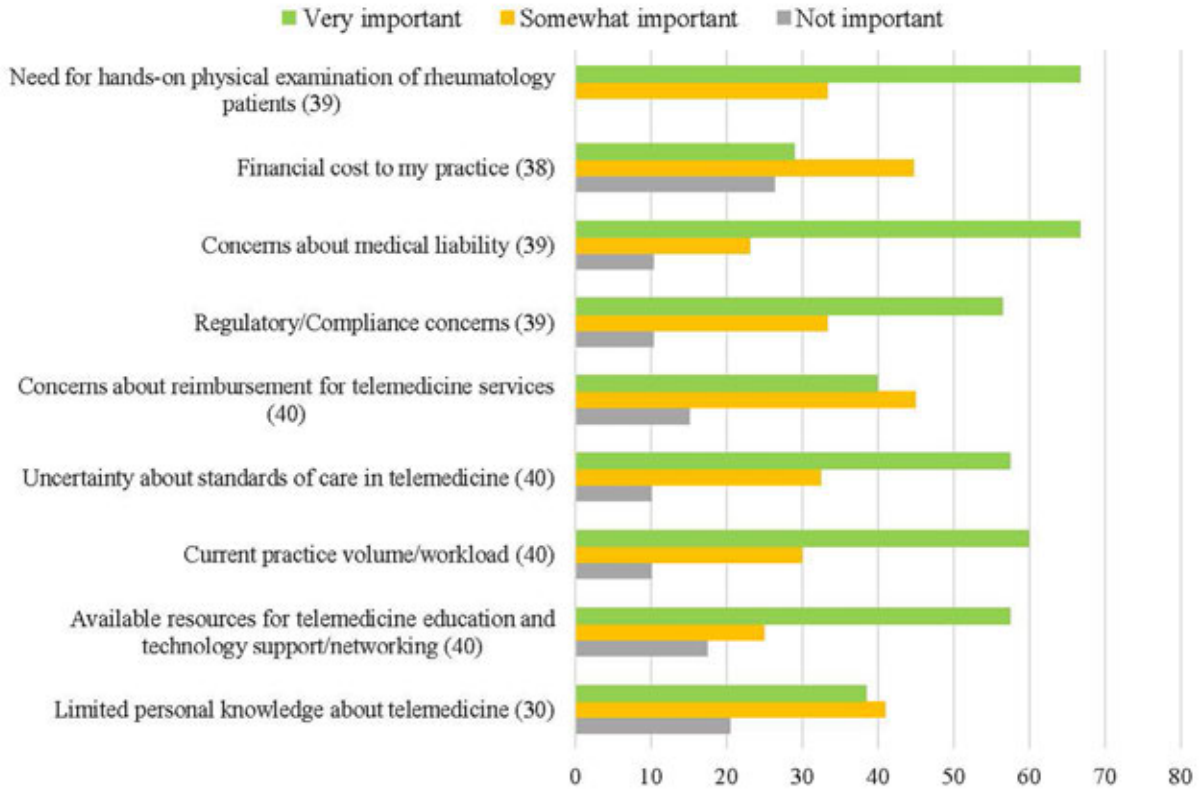
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Telemedicine (TM) is increasingly employed in chronic disease management and can reduce barriers in access to care. In the Southwestern U.S., where there is a disproportionate shortage of rheumatologists, TM may be one tool to improve access to rheumatology care. While use of TM in rheumatology is growing, the nature of rheumatology patient evaluations presents unique challenges to this modality of care. We sought to understand the attitudes of rheumatologists in the Southwestern U.S. towards the use of TM in caring for patients with rheumatic diseases.

Methods: We surveyed a convenience sample of rheumatology providers attending the 19th Annual Rheumatic Diseases Conference in Santa Fe, NM. Respondents completed paper questionnaires in which we collected general provider information, and assessed use of and familiarity with TM, general attitudes towards TM, and perceived barriers to its use. All respondents were anonymous. Simple counts of provider responses are reported here.

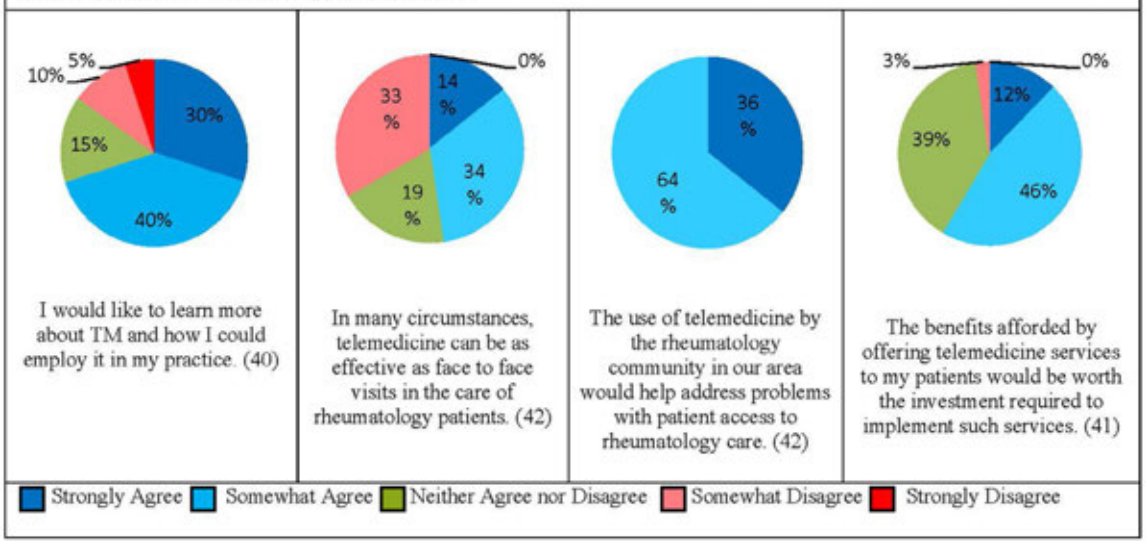
Results: A total of 42 participants completed our survey: 39 were actively practicing rheumatology (31 physicians and 8 physician assistants or nurse practitioners). 32.5% of providers were part of independent small group or solo practices, 37.5% were employed by multispecialty or hospital-affiliated groups, and 25% practiced in academic centers. 22 providers practiced in NM, followed by TX (9) and CO (5), and three were from non-Southwestern states. All but two providers (neither from NM) were practicing in underserved areas. Four providers from NM and CO reported practicing TM. Of those not using TM, 60.5% had considered providing TM services, while 17% had considered implementing TM services, but ultimately decided not to. Among possible barriers to TM, current practice volume/workload, concerns about medical liability, and the need for hands-on physical exam for rheumatology patients were rated as "very important" factors in provider willingness to use TM (60%, 66.7%, and 66.7% of providers, respectively). All respondents either somewhat (64.3%) or strongly (35%) agreed that TM use by rheumatologists would help address problems with access to rheumatology care. Over half of providers also cited the following factors as very important barriers to TM use: available resources for TM education and technology support/networking (57.5%); uncertainty about standards of care in TM (57.5%); and regulatory/compliance concerns (56.4%). Most providers were

Figure 1: Rheumatology Provider Rating of Importance of Potential Barriers to TM and Effects on Willingness to Provide TM Services.



X axis represents percentage of providers rating each barrier as "very important", "somewhat important", or "not important". Numbers of respondents to each item in parentheses.

Figure 2: Provider Agreement with Statements about Telemedicine.
Numbers of respondents to each statement in parentheses



either neutral toward (39%) or somewhat agreed (46.3%) with the statement that the benefits afforded to patients by offering TM would be worth the investments required to implement these services.

Conclusion: While a majority of surveyed rheumatology providers in our area have considered using TM and generally agree that it would improve access to care, few have employed it in their practices. Current provider workload, and uncertainties surrounding practice logistics and adequate patient assessment represent important barriers to TM use. Increased educational efforts in TM technology, regional support for TM infrastructure, and further study and dissemination of patient care tools and standards of care may increase rheumatologist use of TM.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

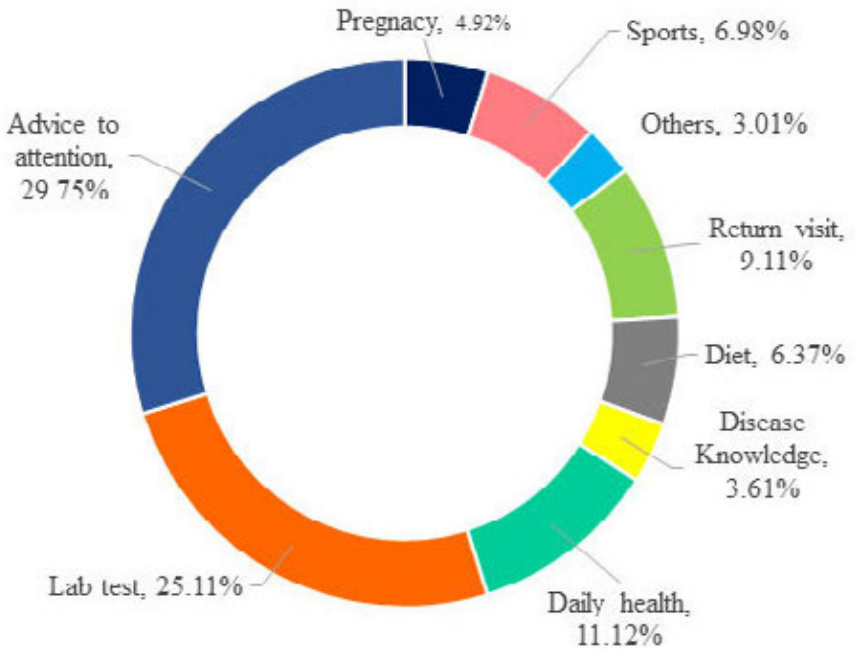
Session Title: Health Services Research Poster II – ACR/ARP

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Without efficient primary medical care and follow-up system in China, patients can choose any hospital or doctor they like in seeking medical care. As a result, most patients rush to large hospitals. Once patients left those clinics, no follow up data is available. Surveys show that over 40% of patients were unnecessary

Figure1. The distribution diagram of question type.

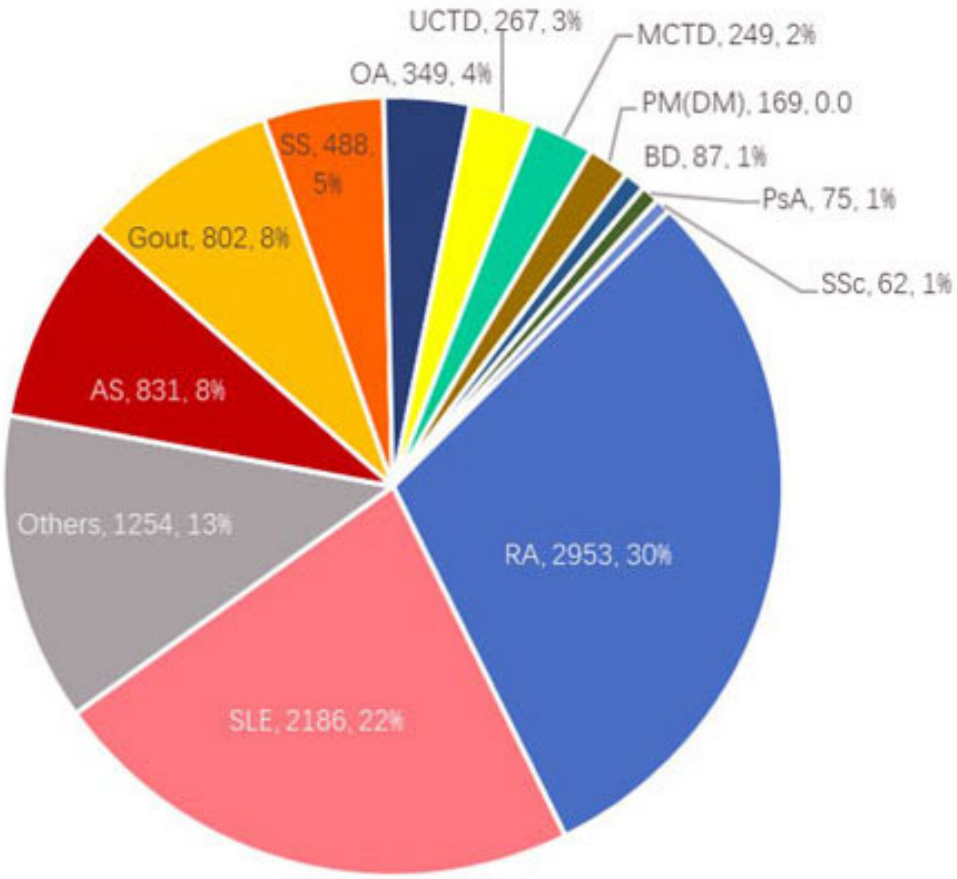


to go to hospital, only need advices from physician. SSDM is a series of APPs for diseases management, which strengthens the interaction between physicians and patients based on valuable data. Our previous study showed that patients could master the SSDM and perform self-management after training.The purpose of this study is to evaluate the feasibility and benefit of improving medical economics and disease activity outcomes in rheumatic patients through online consultation based on SSDM by rheumatologist.

Methods: The rheumatologists implemented the education and training programs on patients in clinic and assisted the patients in downloading the SSDM mobile application. The SSDM includes doctors' and patients' interfaces. The patients' terminal includes serial self-assessments (DAS28, SLEDAI, HAQ), medication management, adverse events and lab data records. After data entry, the data synchronizes to the mobile of the authorized doctor. On the basis of these data, the rheumatologists can accept the request from their follow-up patients and practice consultation through SSDM in the form of text or voice.

Results: From Feb 2015 to May 2019, 729 rheumatologists supplied 9,044 patients (RA 32.7%, SLE 23.7%, AS 9.2%, gout 8.9%, Sjogren syndrome 5.4%, OA 3.9% and other 16.3%) with 13,507 consultations. The diagrams of question type (Figure1) and disease profile (Figure2) were shown in figures. The consulting fee ranged from RMB 0 to 500 yuan (USD: RMB =1: 6.81) each in average of 78.10 ± 45.12 yuan, which matched the registration fee in hospital. The total fee for consultations was 958,584 RMB. 39% patients received online consultation are living in different cities from the rheumatologists. If the patients seek medical care in hospital, in addition to the registration fees and medical expenses, the mean opportunity cost of transportation, accommodation, and lost wages was 874.40 ± 505.21 (200 - 2,800) RMB. The total cost for all patients would have been 11,810,576 RMB, which is 12.3 times more compared with the cost of online consultation. Among 2,913 RA and 1,879 SLE patients with repeat self-evaluations who were followed up for over 90 days, the treat-to-target rate improved from 42.10% to 58.47% (DAS28< =3.2) and from 44.81% to 62.10% (SLEDAI< =4), respectively. Survey shows that satisfaction rate with the consultations is 100%.

Figure2. The diagrams of disease profile.



Conclusion: Through online disease management and consultations using SSDM, Chinese patients with rheumatic diseases enjoy good quality of medical care at lower cost with high satisfaction. Armed with data science, SSDM may supply the rest of world with an option for reshaping the healthcare system.

Survival and Cost of Biologic DMARDs in a Military Medical Center: A Quality Improvement Initiative

Sarah Smilow,[1] Caleb Anderson,[2] Victoria Sullivan,[3] Roger Stitt,[4] Patrick Mastin,[5] Angelique Collamer,[2] and Jess Edison[2], [1]Walter Reed National Military Medical Center, Silver Spring, [2]Walter Reed National Military Medical Center, Bethesda, MD, [3]Walter Reed National Military Medical Center, Bethesda, [4]US Army, Ft Eustis, [5]William Beaumont Army Medical Center, El Paso, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: High drug costs and lack of transparency of these costs is a major concern in the United States. Biologic therapy for rheumatoid arthritis (RA) is expensive, ranging from $7,000 to $203,000 per patient annually. At our institution, the Department of Defense (DoD) negotiated cost for biologic therapies is not readily available to prescribing physicians. Additionally, there is little guidance on the next best therapy in RA treatment if oral DMARD therapy and an initial TNF inhibitor fails. As a Quality Improvement initiative, we investigated the DoD costs of available biologic treatments for RA. We hypothesized that there would be a change in prescribing patterns and substantial cost reductions if rheumatologists had readily available information on biologic medication prices.

Methods: During phase I of this QI project, we conducted a chart review of RA patients on biologics between January 2015 and December 2016. We documented which biologics were used, assigned a monetary cost for each patient, and assessed the overall impact on cost for each biologic therapy switch. Phase II of the project started with a 'cost awareness curriculum.' We acquired and distributed the biologic price-list to Rheumatology clinic personnel. We reviewed the prices and phase I results on a quarterly basis. Fifteen months after implementing the curriculum, we performed a second chart review to document which biologic treatments were utilized.

Results: The Phase I data analysis identified a lower overall use of non-anti-TNF biologic therapies. Among these other biologic therapies, there was an increased use of rituximab ($21,887/4 doses) and abatacept ($29,785/year) over the less costly tofacitinib ($14,633/year). Fifteen months after instituting the 'cost awareness curriculum' we again analyzed the use of biologics. We found that there was increased used of tofacitinib and decreased use of both abatacept and rituximab. This change in practice habits represented a cost savings of $10,232/month or $122,794 over 15 months.

Conclusion: Biologic drugs are now commonly used in Rheumatology, Gastroenterology, Oncology, and many other specialties. In the United States, there is little competition for biologics, but some are less expensive, especially when comparing oral medications to those that require infusions or injections. Drug costs are not transparent and co-pays vary between insurance companies. Physicians often prescribe the drug that is deemed 'first-line' or 'on formulary' by insurance companies. However, as demonstrated here, once empowered with knowledge of drug costs, physicians are able to save the patient and institution money by practicing cost-conscious medical care and choosing the less costly medication. In our clinic, rheumatologists selected the lower cost medication more often following education on the costs of available biologics, saving $122,794 over the 15 month analysis period.

Abstract Number: 1115

Switching Patterns Among Patients with Chronic Inflammatory Diseases Switching to an Infliximab Biosimilar or Remaining on Originator Infliximab (REMICADE)

Bruno Emond,[1] Kay Sadik,[2] Marie-Hélène Lafeuille,[1] Willy Wynant,[1] Aurélie Côté-Sergent,[1] Patrick Lefebvre,[1] Kimberly Woodruff,[2] and **Timothy Fitzgerald** [3], [1]Analysis Group, Inc, Montreal, QC, Canada, [2]Janssen Scientific Affairs, LLC, Titusville, NJ, [3]Janssen Scientific Affairs, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammatory diseases (CIDs) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA), plaque psoriasis (PsO), ankylosing spondylitis (AS), Crohn's disease (CD), and ulcerative colitis (UC) can be managed effectively with biologic agents such as originator infliximab (IFX). Although IFX biosimilars have been approved in the US since April 2016 for the treatment of CIDs, *they* have yet to be designated as *interchangeable.* The impact of switching patients stable on originator IFX to a biosimilar in the US is not well documented. This study compares switching patterns of patients stable on originator IFX switching to an IFX biosimilar (switchers) versus those remaining on originator IFX (continuers).

Methods: Symphony Health Solutions' Patient Transactional Datasets, which includes comprehensive longitudinal US claims data, was used (10/2012–11/2018) to identify adults with ≥2 claims for either RA, PsA, PsO, AS, CD, or UC, and ≥1 claim for originator or biosimilar IFX (Figure 1). The index date (on or after 4/5/2016) was the first IFX biosimilar claim for switchers or a random originator IFX claim for continuers. Pre-index, patients had to be stable on originator IFX (i.e., ≥5 originator IFX claims in the 12 months pre-index). Switchers were matched 1:3 to continuers using propensity score matching adjusted for covariates such as age, gender, and type of CID (full list in Table 1). Post-index switching patterns were compared between switchers and continuers using hazard ratios (HRs), Kaplan Meier (KM) curves, and log-rank tests. Of note, the database didn't include reasons for switching/discontinuation or prescriptions/services received outside of the network.

Table 1. Demographic characteristics measured at the index date

	Unmatched sample			Matched sample[1]		
	Patients switching to an IFX biosimilar	Patients remaining on originator IFX	Standardized difference	Patients switching to an IFX biosimilar	Patients remaining on originator IFX	Standardized difference
	N=823	N=36,096		N=823	N=2,469	
Age in years, mean ± SD [median]	57.9 ± 16.2 [61.0]	51.0 ± 16.9 [53.0]	41.7%	57.9 ± 16.2 [61.0]	57.1 ± 16.3 [60.0]	4.9%
Age categories, n (%)						
<35	89 (10.8%)	7,410 (20.5%)	27.0%	89 (10.8%)	260 (10.5%)	0.9%
35-44	100 (12.2%)	5,228 (14.5%)	6.9%	100 (12.2%)	299 (12.1%)	0.1%

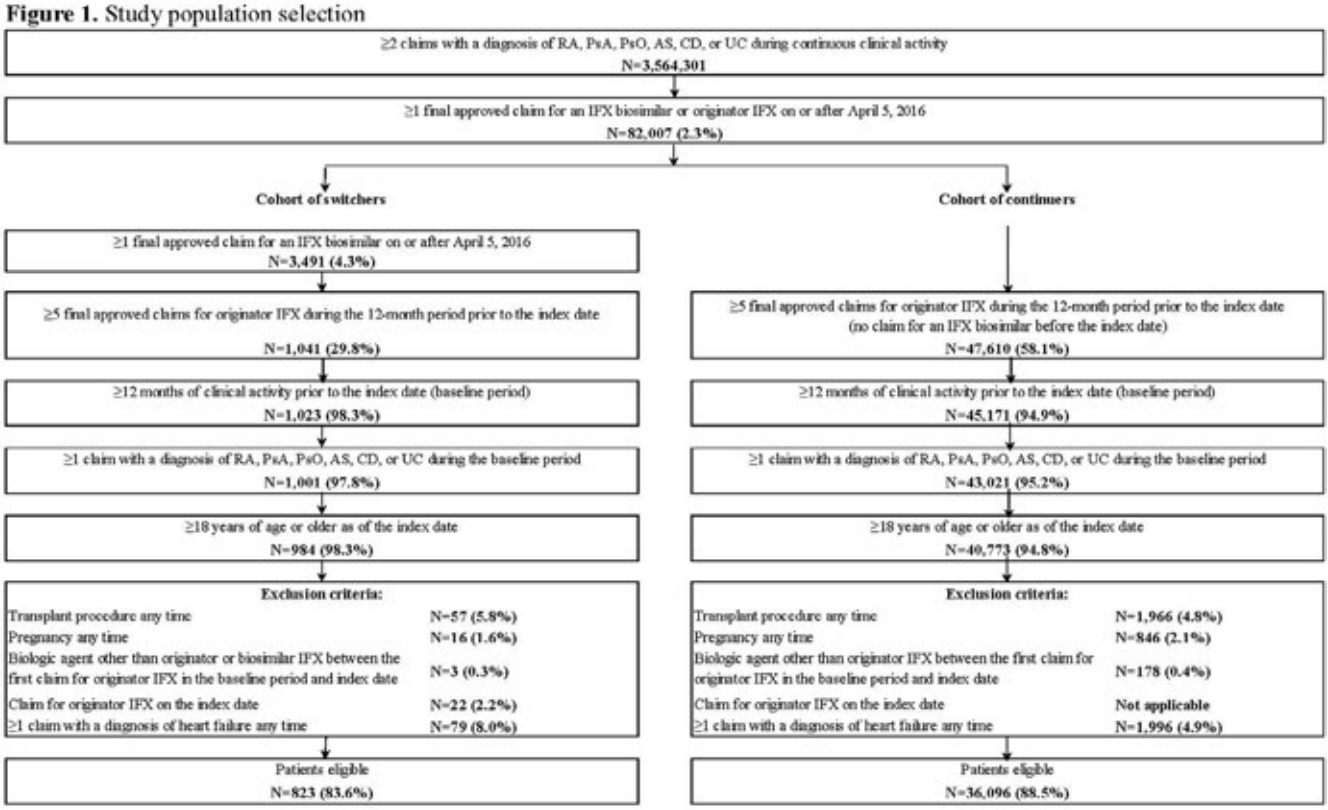
Midwest	270 (32.8%)	10,286 (28.5%)	9.4%	270 (32.8%)	805 (32.6%)	0.4%
Northeast	76 (9.2%)	8,558 (23.7%)	39.8%	76 (9.2%)	258 (10.4%)	4.1%
West	210 (25.5%)	5,340 (14.8%)	27.0%	210 (25.5%)	606 (24.5%)	2.2%
Unknown	7 (0.9%)	58 (0.2%)	9.7%	7 (0.9%)	19 (0.8%)	0.9%
Type of insurance plan, n (%)						
Commercial	338 (41.1%)	23,889 (66.2%)	52.0%	338 (41.1%)	1,002 (40.6%)	1.0%
Medicare	355 (43.1%)	8,281 (22.9%)	44.0%	355 (43.1%)	1,063 (43.1%)	0.2%
Medicaid	107 (13.0%)	3,161 (8.8%)	13.7%	107 (13.0%)	324 (13.1%)	0.4%
Other	23 (2.8%)	765 (2.1%)	4.4%	23 (2.8%)	80 (3.2%)	2.6%

Notes:

1. Switchers were matched 1:3 to eligible continuers based on the propensity score of switching to an IFX biosimilar. The propensity score was estimated using a multivariable logistic regression, and baseline covariates included age, gender, year of index date, region, type of insurance plan, presence of RA (as an exact match factor), PsA, PsO, AS, CD, UC, inflammatory bowel disease (as an exact match factor), Quan-Charlson comorbidity index, pharmacy and medical costs per month, number of outpatient visits per month, place of service for index claim, and specialty of physician prescribing IFX at index date.

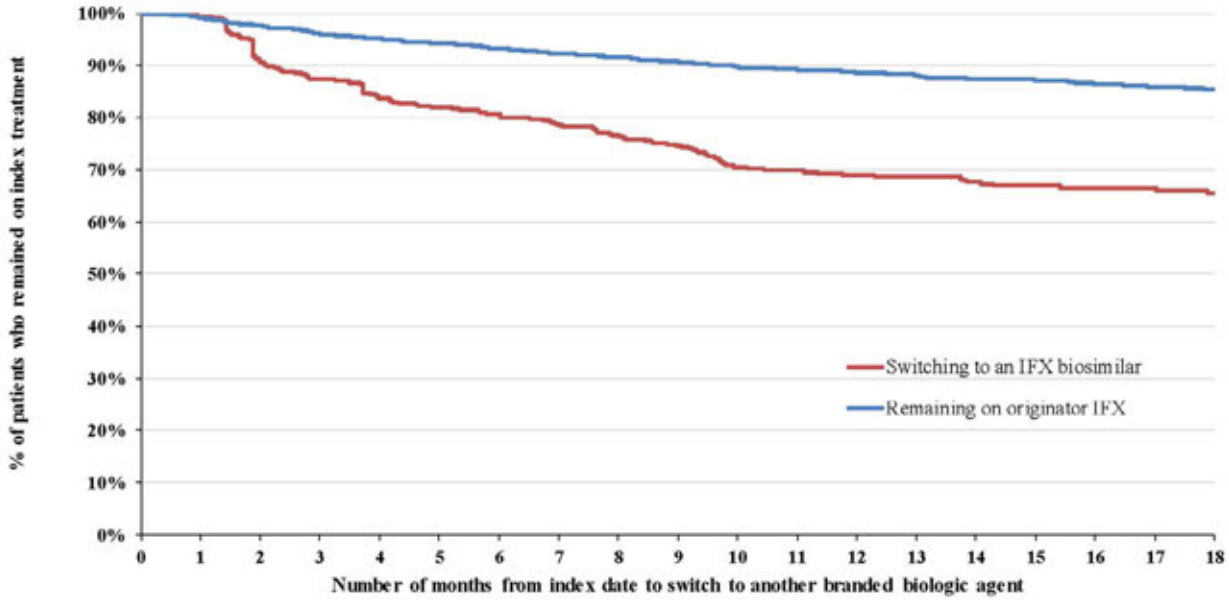
Figure 1. Study population selection



Results: After matching, 823 switchers and 2,469 continuers were included. Among switchers, 44.3%, 33.9%, and 17.4% had RA, CD, and UC, respectively, versus 44.3%, 32.8%, and 18.3% for continuers. Mean age was 57.9 (standard deviation [SD]=16.2) and 57.1 (SD=16.3) years among switchers and continuers, respectively; 66.3% were female in both cohorts (Table 1). Over a mean post-index period length of 350 (SD=197) and 321 (SD=214) days for switchers and continuers, respectively, 211 (25.6%) switchers and 225 (9.1%) continuers switched to another branded biologic agent (HR=2.92; P< 0.001). Of 211 switchers, 82.5% switched back to originator IFX and 17.5% switched to another branded biologic agent. The mean time to switch to another branded biologic agent was 142 (SD=110) days for switchers and 174 (SD=142) days for continuers. The KM rates of switchers and continuers remaining on index treatment were 87.3% and 96.2% at 3 months post-index, 80.8% and 93.4% at 6 months, and 68.9% and 88.7% at 12 months, respectively (all log-rank P< 0.001; Figure 2).

Conclusion: Patients with CIDs switching from originator to biosimilar IFX were almost 3 times more likely to switch to another branded biologic agent compared to patients remaining on originator IFX. Among those who switched to an IFX biosimilar and then to another branded biologic agent, >80% returned to originator IFX, on average within 5 months. Switching to IFX biosimilars should be carefully considered in light of the resulting risk of treatment instability and potential impact on clinical outcomes.

Figure 2. KM curve of time to switch to another biologic agent



KM rates (95% confidence interval)	3 months	6 months	9 months	12 months	18 months
Switching to an IFX biosimilar	87.3% (84.8, 89.5)	80.8% (77.7, 83.4)	74.9% (71.5, 78.1)	68.9% (65.0, 72.5)	66.1% (61.9, 70.0)
Remaining on originator IFX	96.2% (95.3, 96.9)	93.4% (92.2, 94.4)	90.8% (89.3, 92.0)	88.7% (87.1, 90.2)	85.7% (83.6, 87.6)
P-value of log rank test	<0.001	<0.001	<0.001	<0.001	<0.001

Non-medical Switching from Reference to Biosimilar Etanercept - No Evidence for Nocebo Effect – a Retrospective Analysis of Real-life Data

Uta Kiltz,[1] Styliani Tsiami,[1] Xenofon Baraliakos,[2] and Jürgen Braun[3], [1]Rheumazentrum Ruhrgebiet/Ruhr University Bochum, Herne, Germany, Herne, Germany, [2]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [3]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Real-world data about switching patients from originator product to a biosimilars are important to assess and to document the outcome of switches in clinical practice in order to confirm the low risk of major problems. It has been hypothesized that lack of efficacy and adverse drug events (ADEs) upon switching from reference biologics to biosimilar products are related to the nocebo effect [1]. To evaluate the effectiveness and safety of systematic non-medical switching from innovator etanercept (Enbrel®) to biosimilar etanercept (SB4 (Benepali®)) in adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) in a real-life setting based on different information strategies before switching.

Methods: Data of all adult patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or axial spondyloarthritis (axSpA) who had received innovator etanercept and were switched in our specialized center from innovator to biosimilar etanercept for economic reasons were retrospectively analysed. Whether or not patients were informed about the switch was left to the discretion of the treating physician. Disease activity and function were regularly assessed,

Table 1. Patient characteristics.

	Assessment	Baseline (n=84)	Follow-up 12 weeks (n=81)	Follow-up 24 weeks (n=74)
RA	DAS28	3,1 (1,4)	2,8 (1,0)	3,1 (1,3)
	HAQ	1,2 (0,7)	1,3 (0,7)	1,3 (0,7)
	CRP (mg/dl)	0,5 (0,6)	0,6 (0,8)	0,7 (0,9)
PsA	DAS28	2,9 (1,4)	1,9 (1,4)	2,8 (1,5)
	HAQ	0,8 (0,5))	0,9 (0,9)	0,9 (0,9)

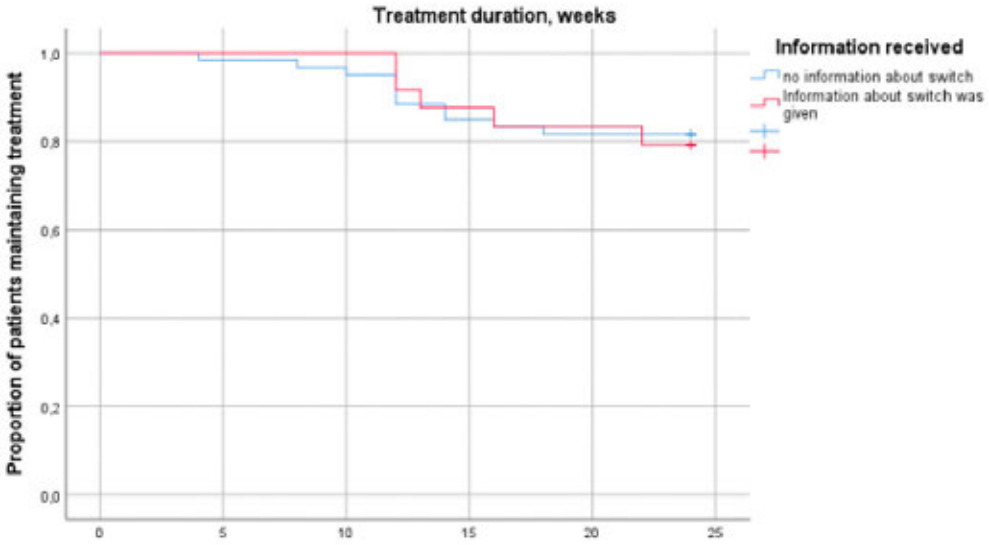

Figure 1. Retention of biosimilar stratified for patients with and without information.

and any changes were recorded in two consecutive visits at week 12 and 24. The scores documented at week 12 week after switching were taken as primary outcome. AEs were documented.

Results: A total of 84 patients were included (44 RA, 25 axSpA and 15 PsA patients), 24 of which had received information about switching (28.5%). The scores at week 12 of both, disease activity and function, remained rather unchanged (Table 1). Whether patients had been informed about switching or not did not influence outcomes or AE. The retention rate of the biosimilar was 96.4% (n=81) at week 12 and 87.6% (n=71) at week 24 (Figure 1). While 7 patients were lost to follow-up, 6 patients discontinued due to inefficacy or AE, including one malignant melanoma. Overall, 18 AEs were reported in 10 patients (12%). In 3 patients (3.6%) who had 5 AEs in the first 12 weeks the innovator was successfully re-administered.

Conclusion: Systematic switch from innovator to biosimilar etanercept was not associated with changes in disease activity or function in all three indications within 12 weeks. This was independent of information on the switch transmitted to the patients.

Government Subsidization of Biologic Therapy for Inflammatory Arthritis in a Co-Funded Healthcare Model: A Singapore Experience

Kai Ting Cheryl Chua,[1] Wai Yee Joanna Leong,[2] Kee Fong Phang,[1] Sajeewani Dissanayake,[1] Peter Cheung,[1] Warren Fong,[3] Keng Hong Leong,[4] Ying Ying Leung,[3] Anita Yee Nah Lim,[1] Nai Lee Lui,[5] Mona Manghani,[6] Amelia Santosa,[1] Melonie Kannamma Sriranganathan,[2] Ernest Suresh,[7] Teck Choon Tan,[8] Gim Gee Teng,[1] and Manjari Lahiri[1], [1]National University Health System, Singapore, Singapore, [2]Changi General Hospital, Singapore, Singapore, [3]Singapore General Hospital, Singapore, Singapore, [4]Leong Keng Hong Arthritis and Medical Clinic, Singapore, Singapore, [5]Lui Centre for Arthritis & Rheumatology, Gleneagles medical Centre, Singapore, Singapore, [6]Tan Tock Seng Hospital, Singapore, Singapore, [7]Ng Teng Fong Hospital, Singapore, Singapore, [8]Khoo Teck Puat Hospital, Singapore, Singapore

Table 1

Consensus statement on initiation and continuation of a biologic or targeted synthetic disease modifying anti-rheumatic drug for rheumatoid arthritis requiring government subsidization		
	Median agreement score on a 5 point Likert scale† (% with agreement)	Voting round‡
1. A uniform disease activity measure, the DAS28-ESR should be used as the disease activity measure to assess RA activity.	5 (100%)	1
2. The patient must have at least moderate disease activity, defined as DAS28-ESR ≥ 3.2.	5 (100%)	1
3. The patient must have failed 2 csDMARD strategies (including MTX unless contraindicated) at optimal dose; at least one strategy must be a combination.	5 (100%)	2
4. An optimal duration of a strategy should be a minimum of three months.	5 (100%)	2
5. An optimal trial of therapy should include MTX at target dose of 15-20mg/week, unless contraindicated.	5 (90.9%)	1
6. For the first line biologic, approved TNFi, non-TNFi (abatacept, tocilizumab, rituximab) or tsDMARD (JAKi) may be considered, in no particular order of preference.	5 (100%)	2
7. If first line TNFi fails, second line treatment may be another TNFi, non-TNFi or tsDMARD, in no particular order of preference.	5 (100%	2
8. If a first line non-TNFi or tsDMARD fails, second line treatment may be a TNFi or another non-TNFi or tsDMARD.	5 (100%)	2
9. Co-morbidities, pregnancy/lactation and drug safety should be considered when determining treatment strategies and selecting bDMARD/tsDMARDs.	5 (100%)	1
10. A biosimilar may be substituted for the originator drug for better cost-effectiveness.	4 (90.91%)	1
11. All patients on bDMARD/tsDMARDs must have DAS28-ESR documented every three months; bDMARD/tsDMARD therapy may be continued if the patient has at least a EULAR moderate response by six months from commencement.	5 (100%)	1

DAS28-ESR: disease activity score 28-erythrocyte sedimentation rate, csDMARD: conventional synthetic disease modifying anti-rheumatic drug, MTX: methotrexate, TNFi: tumor necrosis factor inhibitor, tsDMARD: targeted synthetic DMARD, JAKi: Janus Kinase inhibitor, bDMARD: biologic DMARD, EULAR: European League Against Rheumatism

† Likert scale of 5 unless otherwise stated, where 1 = strongly disagree, 5 = strongly agree.
‡ Due to the drop out of one respondent, there were 11 respondents in the first voting round and 10 in the second.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Real world utilization of biologic therapy for inflammatory arthritis often falls short of international best practice and is heavily influenced by affordability and national healthcare financing models. Healthcare in Singapore is delivered through a complex mix of regulated compulsory personal savings, limited hospitalization-focused personal and government aided medical insurance, and means-tested government subsidies for selected

Table 2

Consensus statement on initiation and continuation of a biologic disease modifying anti-rheumatic drug for psoriatic arthritis with peripheral joint involvement requiring government subsidization[§]		
	Median agreement score on a 5 point Likert scale[†] (% with agreement)	Voting round[‡]
1. Swollen and tender joint count should be used as the disease activity measure to assess PsA.	5 (100%)	1
2. Patient should have a minimum of three swollen AND tender joints/digits/entheses to be considered for biologic therapy.	N.A (73%)	1
3. Unless contraindicated, patient should have failed two csDMARD strategies at optimal doses for a minimum of three months each to be considered for biologic therapy.	5 (100%)	2
4. For dactylitis/enthesitis, failure of NSAIDs and/or local injection should be documented, if appropriate.	4 (91%)	1
5. For choice of first biologic, TNFi, IL17i, IL12/13i, tsDMARD (JAKi) may be considered.	5 for TNFi, IL17i, tsDMARD (100%) 4 for IL12/23i (100%)	2
6. If first line treatment with TNFi fails, second line may be another TNFi, IL17i, IL12/23i or tsDMARD.	5 (100% for TNFi, IL17i, tsDMARDs; 90% for IL12/23i)	2
7. If a first line treatment with a non-TNFi (IL17i, IL12/23i, tsDMARD) fails, second line treatment may be a TNFi or another non-TNFi.	5 (100%)	2
8. All patients on bDMARD/t1sDMARDs must have response to therapy measured and documented every three months.	5 (73%)	1
9. For continuation of therapy with bDMARD/1tsDMARDs, patient must achieve an adequate response by six months.[¶]	5 (100%)	1
10. Infliximab should be used in combination with methotrexate unless contraindicated.	5 (90%)	1
11. A biosimilar may be substituted for the originator drug for better cost-effectiveness.	4 (91%)	1

N.A: Not applicable, NSAID: nonsteroidal anti-inflammatory drug, IL12/23i: interleukin-12/23 inhibitor, IL17i: interleukin-17 inhibitor

§ For predominantly axial involvement, please refer to the AS/SpA recommendations. These recommendations are not intended to refer to children with PsA or patients with skin psoriasis alone.
¶ As there was no consensus on choice of response criteria (PsARC vs. 20% SJC & TJC improvement vs. either), recommendations from the previous chapter guidelines[1] to use PsARC as the response measure will be retained

Reference: [1]Lahiri M, Teng GG, Cheung PP, et al. (2015) Singapore Chapter of Rheumatologists consensus statement on the eligibility for government subsidy of biologic disease modifying anti-rheumatic agents for the treatment of psoriatic arthritis. Int J Rheum Dis.20:1527-40.

Table 3

Consensus statement on initiation and continuation of a biologic disease modifying anti-rheumatic drug for axial spondyloarthritis requiring government subsidization		
	Median agreement score on a 5 point Likert scale† (% with agreement)	Voting round‡
1. Patients should fulfil either ASAS criteria for spondyloarthritis or modified New York criteria for ankylosing spondylitis.	5 (91%)	1
2. Patients with active disease may be defined by either BASDI ≥4 or ASDAS ≥2.1.	4 (82%)	1
3. Patients should have failed two sequential NSAIDs at maximum tolerated doses for a total duration of at least four weeks and should be participants in an appropriate physiotherapy and exercise program.	5 (82%)	1
4. For patients with peripheral arthritis, sulfasalazine at optimal dose should have been used for at least 12 weeks unless contraindicated.	5 (91%)	1
5. Symptomatic enthesitis should have failed appropriate local treatment.	4 (73%)	1
6. If bDMARD is considered, either TNFi or IL17i may be considered as first line therapy.	5 (100% for TNFi; 70% for IL17i)	2
7. If first line bDMARD fails, switch to either another TNFi or IL17i.	5 (80% for TNFi; 100% for IL17i)	2 for TNFi, 1 for IL17i
8. The choice of bDMARD therapy should take into consideration patients' unique characteristics and the extra-articular manifestations of SpA such as uveitis and inflammatory bowel disease.	5 (82%)	1
9. All patients on bDMARD therapy should have response to therapy measured and documented every three months. For continuation of therapy with bDMARD, patients should achieve an adequate response at six months.	5 (100%)	1
10. Response should be monitored by the disease activity measure used to initiate biologic therapy, and is defined by ASDAS improvement ≥1.1 or BASDI improvement ≥2.0.	5 (100%)	1
11. A biosimilar may be substituted for the originator drug for better cost-effectiveness.	4 (91%)	1
ASAS: Assessment of SpondyloArthritis, BASDI: Bath Ankylosing Spondylitis Disease Activity Index, ASDAS: Ankylosing Spondylitis Disease Activity Score		

clinical indications. We describe our experience in translating current evidence into an applicable framework to guide government funding decisions to facilitate equitable access to biologic therapy.

Methods: A core working group (CWG) searched recently published guidelines of biologic agents in rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA) developed for best practice use (9 RA, 5 PsA and 4 AxSpA) or reimbursement (2 RA, 4 PsA and 2 AxSpA). Where appropriate, recent primary literature was reviewed and the evidence synthesized in the form of tables. A modified Delphi approach was used and statements were drafted for rating by an expert task force panel (TFP) comprising rheumatologists practicing in the public and

private sectors across Singapore. The TFP independently rated 3 separate sets of draft statements for RA, PsA and AxSpA after consideration of the synthesized evidence. Consensus was reached if there was at least 70% agreement (score of 4 or 5 on a five-point Likert scale). Statements not reaching consensus were discussed in a face to face meeting, and second round of independent voting was done, after rewording and/or editing statements if necessary. Next, government agencies were engaged to adopt the final statements to guide government funding. The guidelines will be disseminated to the relevant pharmaceutical companies to allow them to make informed decisions on drug pricing to be considered favourably in the government tender.

Results: Three sets of consensus statements were derived, pertaining to initiation, choice and continuation of biologic therapy for active RA, PsA or AxSpA (tables 1, 2, 3 respectively). These form an easily applicable framework to be used by practicing physicians and funding authorities.

Conclusion: We describe our experience in formulating evidence-based guidelines within the real-world practice which is heavily influenced by treatment affordability. Lessons learnt in engaging all relevant stakeholders may be applicable to guide nascent subsidization programs in healthcare economies worldwide.

Abstract Number: 1118

US Community Rheumatologists' Knowledge and Perceptions of Biosimilar Expanded Indication Approval by Extrapolation

Ting-Chun Yeh,[1] Yolaine Jeune-Smith,[1] Eli Phillips,[1] Ajeet Gajra,[1] and Bruce Feinberg[1], [1]Cardinal Health Specialty Solutions, Dublin, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To expand treatment options, increase access to life-saving medications, and lower healthcare costs through competition, the US Congress created an abbreviated licensure pathway for biosimilars.[1] Based upon scientific justification including: PK, PD, efficacy, safety, and immunogenicity data, two tumor necrosis factor inhibitor (TNFi) biosimilars were approved for all reference biologic indications (e.g., ankylosing spondylitis, psoriatic arthritis) despite clinical efficacy studies in just one indication (rheumatoid arthritis)[a]—a process known as extrapolation. Non-inferiority trial design for one approved indication and extrapolation based labeling for other indications represent potential barriers to physician adoption of biosimilars. This study aimed to assess community rheumatologists' perceptions and utilization patterns of the two TNFi biosimilars approved and commercialized in the US.

Methods: A live meeting in November 2018 surveyed US-based community rheumatologists regarding their perceptions and utilization patterns of biosimilars. Participants completed a web-based premeeting survey and live queries captured via an audience response system. Physician characteristics and responses were summarized using descriptive statistics.

Figure 1: Rheumatologists' Perceptions on Biosimilar Extrapolation

Would you prescribe a biosimilar in all indications that have been granted approval based on extrapolation?

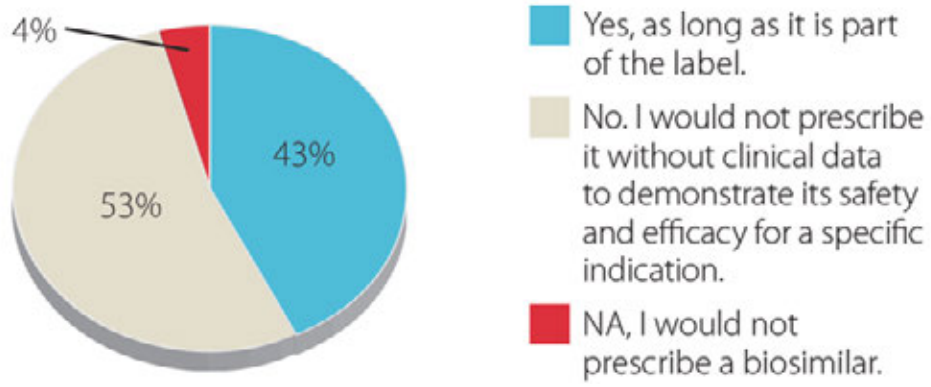

Figure 2: Real-Word Evidence (RWE) and Biosimilar Extrapolation

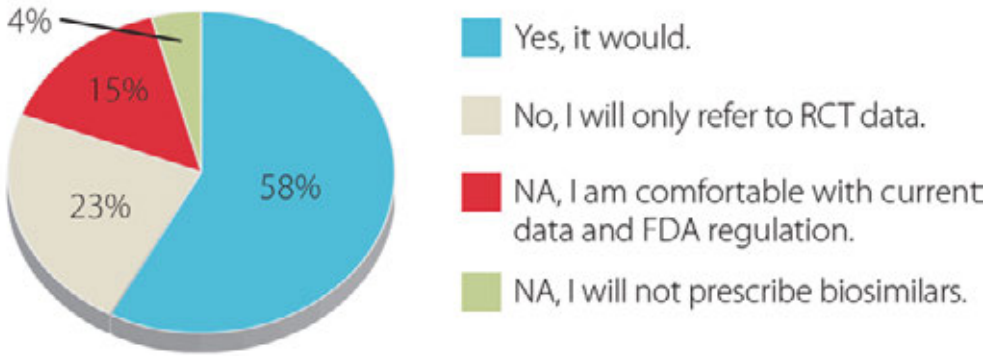
Would RWE data be sufficient for you to prescribe a biosimilar for an indication approved based on extrapolation?



Results: 54 rheumatologists participated describing their practices as: urban 48%, suburban 45%, and rural 7%. Median years in practice were 19 years (range 3-40). 67% have prescribed biosimilars since being commercially available in late 2016. Regarding their familiarity with biosimilars and the FDA approval process: 34% very familiar, 56% somewhat familiar, and 10% not. A minority of the rheumatologists (15%) expressed comfort with current biosimilar safety/efficacy data and FDA regulation. Regarding extrapolation-based labeling: 53% said they would not prescribe without data for a specific indication (Figure 1). Regarding additional data: 58% indicated that real-world evidence would suffice for an extrapolated indication, while 23% would only accept randomized controlled trials (Figure 2). Participants stated they are most likely to prescribe a biosimilar when it provides cost-savings to the patient or their practice with 48% requiring a 31-50% discount from the reference product for them to consider a biosimilar over the reference biologic. Various concerns remain regarding prescribing a biosimilar, including FDA evaluation process and payer coverage and/or reimbursement for a biosimilar.

Conclusion: The majority of the participating rheumatologists appear to be familiar with biosimilars and its FDA approval process, and they are open to prescribing them, especially when there are cost-savings. Further safety/efficacy data is needed for rheumatologists to willingly expand their use of biosimilars to the indications that were approved based on extrapolation.

[1]FDA.gov

[a]One of the TNFi biosimilars had an additional clinical study in Crohn's disease.

Patterns of Medication Use for Patients with Sarcoidosis: Data from the ACR's RISE Registry

Gabriela Schmajuk,[1] Julia Kay,[2] Jing Li,[2] Sonam Choden,[1] Esi Morgan,[3] Jinoos Yazdany,[2] and Andreas Reimold[4], [1]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA, [2]UCSF Division of Rheumatology, San Francisco, CA, [3]Cincinnati Children's Hospital, University of Cincinnati, Cinncinati, OH, [4]Dallas VA and Univ of Texas Southwestern Medical Centers, Dallas, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcoidosis results in significant morbidity and mortality but is a generally understudied disease. There are currently no FDA approved drugs for the treatment of extra-pulmonary sarcoidosis, but rheumatologists use a variety of treatment strategies in this patient population. We used the ACR's RISE registry to analyze the spectrum of drugs used to treat sarcoidosis in real-world practice.

Methods: RISE is a national, EHR-enabled registry that passively collects data on all patients seen by participating practices, reducing the selection bias present in single-insurer claims databases. As of December 2017, RISE held validated data from 1,257 providers in 236 practices, representing ~36% of the U.S. clinical rheumatology workforce. Patients included in this study were ≥18 years old, had medication data available, and had ≥ 1 code for sarcoidosis between January 1 2017 and December 31 2017. We identified sarcoid-related disease manifestations during the calendar year including eye, lung, and joint involvement according to validated ICD code definitions. We assessed medication use, including conventional synthetic DMARDs, biologic DMARDs, new synthetic DMARDs, and glucocorticoids during 2017; patients were considered treated if they received ≥ 1 prescription for a drug from a given category.

Results: We found 3791 unique patients with ≥ 1 diagnosis of sarcoidosis from 188 practices. 77% were female; 50% white, 29% black; with mean age 58.2 ± 12.4. Specific manifestations included eye disease (3.6%), lung disease (24.7%), and joint disease (29.9%). Overall, 2094 (55.2%) were treated with at least one DMARD of any type. 13.5% received a biologic or new synthetic DMARD, the most common of which were TNF inhibitors (76.4% of this category; top drugs infliximab and adalimumab), followed by rituximab (5.2%), tofacitinib (5.0%), and abatacept (4.6%). Biologics and new synthetic DMARDs were most often prescribed for patients with joint involvement (see Figure). However, overall, 579 patients (15.3%) were prescribed glucocorticoid monotherapy; 597 (15.7%) were prescribed prolonged glucocorticoid therapy (prednisone 10 mg or equivalent for longer than 90 days). No significant variation was identified according to race, insurance status or geographic region after controlling for specific disease manifestations.

Conclusion: To our knowledge this is the first study to assess patterns of medication use for patients with sarcoidosis seen in U.S. rheumatology practices. Given that there are no approved drugs for extra-pulmonary sarcoidosis, the

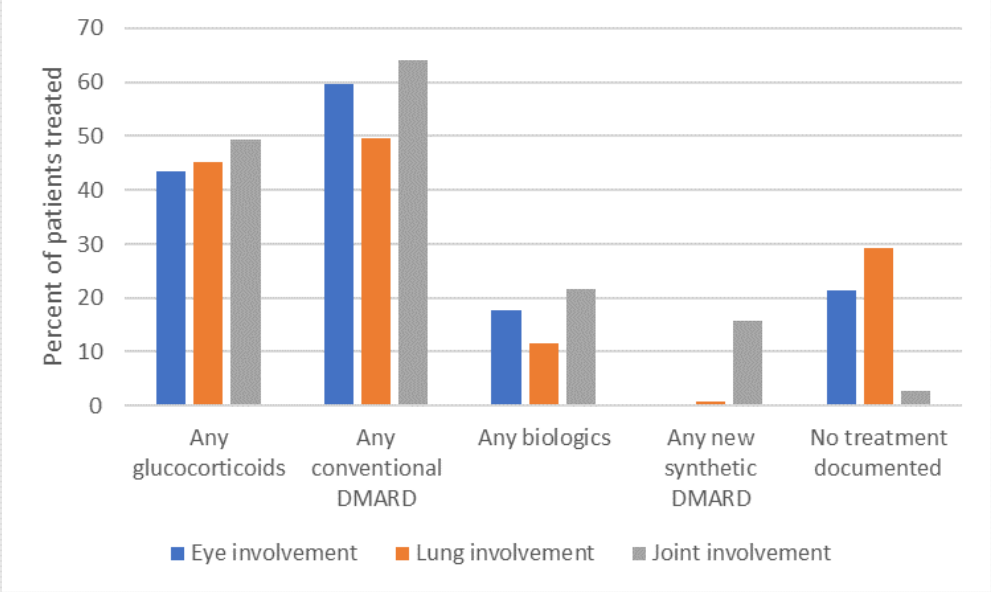

Figure. Percent of patients treated with each drug class, by sarcoid-related disease manifestation.

meaningful use of TNFi suggests that they have become standard of care, especially for the joint manifestations of this disease. Our finding that 15% of patients have prolonged use of moderate or high dose glucocorticoids suggests that there may be a significant need for new drug research and development in this area.

Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Abstract Number: 1120

Prevalence of Burnout in Rheumatology Professionals

Vivekanand Tiwari,[1] Arthur Kavanaugh,[2] George Martin,[3] and Martin Bergman[4], [1]Temple University, Philadelphia, PA, [2]University of California, San Diego School of Medicine, La Jolla, CA, [3]Dr. George Martin Dermatology Associates, Kihei, HI, [4]Drexel University College of Medicine, Stockholm, Sweden

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Burnout among physicians has major implications for health care. We measured prevalence of burnout in a large group of Rheumatology professionals attending a national Rheumatology meeting, using the Maslach Burnout Inventory (MBI)™, and assessed the association of burnout with various professional and personal factors.

Methods: The MBI™, a 22-item questionnaire that includes three domains, emotional exhaustion (EE), depersonalization (DP) and reduced personal accomplishment (PA), was administered to attendees at the Rheumatology Winter

Table: Frequency and percentage of MBI domains demonstrating burnout.

Domains	Freq.	Percent	Cum.
0	63	49.22	49.22
1	26	20.31	69.53
2	29	22.66	92.19
3	10	7.81	100.00
Total	128	100.00	100.00

Clinical Symposium, in February 2019. 128 attendees completed the MBI™ and a demographics questionnaire. Burnout for each domain was defined as EE≥27, DP≥10 and PA≤33**.** IRB waiver obtained from Mercy Hospital IRB. Statistical analysis was performed using Stata V 14 (Plano, TX).

Results: Of the 128 respondents, 51% demonstrated burnout in at least one MBI™ domain. 37.5% of all respondents reported EE burnout, 30.5% DP burnout and 21% PA burnout. 20% had burnout in 1 domain only, 22.7% had burnout in any 2 domains, and 7.8% had burnout in all 3 domains (Table). 34.6% of respondents reported not being happy with their EMR. Practitioners unhappy with their EMR were 2.86 times more likely to burnout (OR=2.86 p=0.015, 95% CI: 1.23-6.65). Compared to people who exercise at least once a week, lack of exercise was associated with a 5-fold increase in burnout. (OR=5.00 p= 0.016, 95% CI: 1.3 - 18.5). Work hours more than 60 hours per week was found to be positively associated with burnout (OR=2.6 p= 0.019, 95% CI: 1.16 -5.6) compared to work hours < 60 per week. Compared to other practice types, practitioners in group practice were 57% less likely to burnout (OR=0.43 p=0.029 95% CI: 0.20-0.92). Practitioners who spend > 20% of their time in work performing activities they find personally satisfying are 68% less likely to report burnout than people who spend less time (OR=0.32 p=0.005 95% CI: 0.15-0.71). Of note, sex, marital status, degree, income and years in clinical practice did not seem to have significant association with burnout in these respondents. There were too few smokers to have any effect. A trend was noted in taking more vacation time (< 3wks), but p-value was not significant (p=0.055). A similar trend toward less burnout in moderate drinkers vs. light drinkers was also noted (p=0.074)

Conclusion: This study confirms the reported high prevalence of physician burnout. The results are in line with the overall reported rate of 54.4% among US physicians showing the deeply pervasive nature of burnout syndrome, even in Rheumatology, which is traditionally considered a “low stress field”.

Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In contrast to historical trends, women now comprise more than half of rheumatology fellowship graduates in the United States (US). Differences in academic rank according to sex have been found in some medical specialties. Our objective was to determine the association between sex and academic rankings among US rheumatologists.

Methods: We identified all practicing US rheumatologists in 2015 using a comprehensive database of all licensed US physicians maintained by Doximity, an online physician networking service. This database contains several demographic and professional characteristics of U.S. physicians. Among academic rheumatologists, we determined the

Characteristics of Academic Rheumatologists in the United States

	Overall (N = 941)	Men (N = 551)	Women (N = 390)	P-value
Age (Mean, SD)	52.3 (12.3)	56.8 (11.9)	46.0 (9.7)	< 0.001
Faculty at Top 20 Med School (N, %)	320 (38.1)	184 (35.9)	136 (41.6)	0.096
Age groups, y (N, %)				< 0.001
Age <40	165 (18.4)	41 (7.8)	124 (33.5)	
Age 40-44	132 (14.7)	64 (12.1)	68 (18.4)	
Age 45-49	96 (10.7)	52 (9.9)	44 (11.9)	
Age 50-54	106 (11.8)	54 (10.2)	52 (14.1)	
Age 55-59	121 (13.5)	79 (15.0)	42 (11.4)	
Age 60-64	127 (14.1)	99 (18.8)	28 (7.6)	
Age 65+	151 (16.8)	139 (26.3)	12 (3.2)	
Year Since Residency (Mean, SD)	22.0 (12.9)	26.6 (13.0)	15.7 (9.8)	< 0.001
Faculty Rank (N, %)				< 0.001
Professor	249 (26.7)	200 (36.8)	49 (12.6)	
Associate	220 (23.6)	152 (28.0)	68 (17.5)	
Assistant	387 (41.5)	171 (31.5)	216 (55.5)

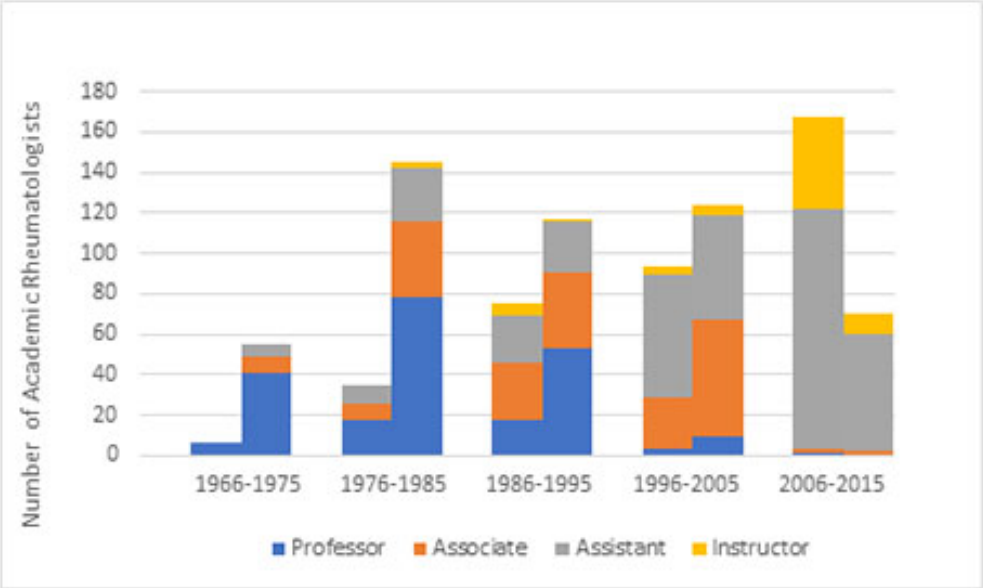
FACR, Fellow of the American College of Rheumatology
*Listed as principal investigator for registered studies on clinicaltrials.gov.



Academic Rank by Residency Graduation Period Among Women and Men

proportions of Professors, Associate Professors, Assistant Professors and Instructors among men and women. We compared sex differences in physician age, years since residency graduation, number of publications (from PubMed), number of National Institutes of Health (NIH) grants, registered clinical trials (from ClinicalTrials.gov), appointment at a top 20 medical school (as ranked by *U.S. News and World Report*), and total Medicare volume (obtained from Centers for Medicare and Medicaid Services). The primary outcome was the odds of being a Full Professor or Associate Professor, and the exposure of interest was sex. We used logistic regression to estimate the odds ratio (OR, 95% Confidence Interval) of Full or Associate professorship (vs Assistant Professor) by sex after adjusting for the above covariates. We also examined faculty rankings by 10-year period of residency graduation among men and women.

Results: Among 6,125 total practicing rheumatologists, 941 (15% overall) had academic faculty appointments in 2015, and 390 were women (41%). Women academic rheumatologists were younger (mean age 46.0 versus 56.8 years, $p< 0.001$) and completed residency more recently (mean 15.7 versus 26.6 years ago, $p< 0.001$) than men. Women had fewer total publications, first or last author publications, and NIH grants (Table 1; all $p< 0.001$). In unadjusted analyses, women academic rheumatologists were less likely to be Professor or Associate Professor than men (OR 0.52 [95% CI: 0.45-0.60]). These differences persisted within 10-year periods of residency graduation ($p=0.015$ for 1986-1995 and $p< 0.001$ for 1996-2005) (Figure 1). In fully-adjusted analyses, women were less likely to be Full or Associate Professors (vs. Assistant Professors) than men (aOR 0.76 [95% CI 0.59-0.99]. However, the adjusted odds of being a Full Professor (vs. Associate Professor or Assistant Professor) were similar among men and women (aOR 1.07 [95% CI 0.78-1.49].

Conclusion: Among academic rheumatologists, women are less likely than men to be Full or Associate Professors. While differences in workforce age explain some of these observations, they persisted within 10-year periods of training completion. To address these disparities, barriers to the advancement of women in academic rheumatology should be addressed, such as differences in research productivity, and how contributions to innovation, research, and education are assessed in academic promotion. As the workforce gender balance shifts in coming years, academic advancement of women in rheumatology should be fostered.

Session Date: Monday, November 11, 2019

Session Title: Health Services Research Poster II – ACR/ARP

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: JIA studies demonstrate that there is a "window of opportunity" early in the disease course during which appropriate management improves outcomes: prompt referral to pediatric rheumatology (PR) center is crucial for best results. There are no publications about patient's pathway until first PR visit from India. In this country, the number of JIA is huge: the estimated prevalence ranges from 350 000 to 1.3 million. Health-care costs are paid out of pocket by patients and there is a significant shortage of pediatric rheumatologists (PRsts) with approximately 15 PRst concentrated in urban centres. These parameters are likely to impact referral pathways. This study aimed to describe time from onset of symptoms to first PR visit of JIA patients to a tertiary center in India and to analyze predictive factors for time to referral.

Methods: This retrospective study is from data collected on JIA patients in the PR center, Institute of Child health, Sir Ganga Ram Hospital (SGRH) in New Delhi where both paid (private) and free (poor) patients are seen. JIA patients fulfilling ILAR 2004 criteria and seen at least twice from 01/10/2013 to 30/09/2018 were included. Data collected were: demographic details, history of the disease, referral practitioner, clinical and laboratory features, treatment. Patients

Median ESR (mm/h)	64 [34, 90]	40 [22.5, 71]	<0.001

Data are presented as frequencies (associated percentages) or as median [interquartile range]
PR: pediatric rheumatology, OPD: out patient department, AJC: active joint count, LROM: limitation of range of motion, MAS: macrophage activation syndrome, ESR: erythrocyte sedimentation rate

previously assessed by PRst or with missing data were excluded. Mann-Whitney U-test, Chi square and logistic regression (univariate and multivariate) were used as appropriate to study factors that determined time to first PR visit.

Results: In all 520 patients were included (45% girls, median age 10 years, 71% were systemic JIA patients and enthesitis related arthritis patients (table 1)): 396 children were diagnosed at our PR center (group A), 124 were previously diagnosed as JIA and managed by non PRst before first PR visit (group B). Median time of symptom onset to first assessment in PR was 4.1 months and median distance travelled 119.5 km. Despite ongoing treatment at first PR visit, group B patients had more aggressive disease (active joint count 4 versus 3, $p< 0.01$; cervical involvement 10.5% versus 5.3 %, $p< 0.05$; children non attending to school 16.1% versus 9.1%, $p< 0.05$) and resided further away (205 km versus 79.6 km, $p< 0.001$). For group B patients, predominant referral doctor was adult rheumatologist (66%), for group A- pediatrician (50%) (table 2). On univariate analysis, factors that predicted PRst visit within 3 months were private patients, short distance to travel, family history of inflammatory disease, history of fever, history of acute uveitis or high ESR. On multivariate analysis all factors remained except high ESR.

Conclusion: Time to first PR assessment at this center is comparable to western countries(1). Cost of care and long distance to travel were factors that delayed consultation ; acuity of complaints, short distance to travel, adequate financial resources and a family member with rheumatologic condition hastened referral.

Possible factors to improve referral to PR centres would be to increase the number of PRst and to provide free medical insurance countrywide. Indeed many families can ill afford the travel and cost of care for a child with JIA.

Healthcare Factors More Predictive of Smoking Cessation in Patients with Rheumatoid Arthritis Than Patient Characteristics

Maria Schletzbaum,[1] Xing Wang,[1] Robert Greenlee,[2] and Christie Bartels[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Marshfield Clinic Research Institute, Marshfield, WI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking doubles the risk of developing RA, and continuing to smoke after RA diagnosis is associated with worse disease control, treatment failure, and premature mortality. Further, smoking independently contributes to the top three causes of mortality in RA: cardiovascular disease, pulmonary disease, and cancer. Thus, smoking cessation is important for patients with RA. Many sociodemographic and socioeconomic factors are associ-

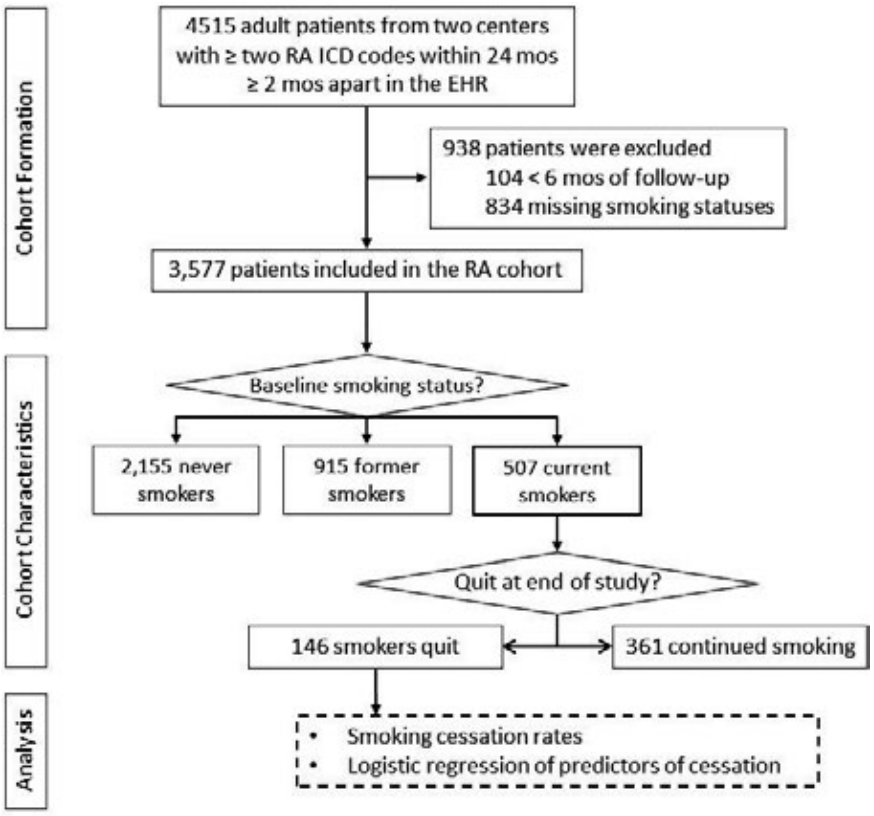

Figure 1. Rheumatoid Arthritis and Current Smokers Cohort Formation and Description.

ated with smoking, but factors that predict cessation, especially in patients with RA or chronic disease, are less clear. Identifying factors that predict likelihood of cessation, and populations that are less likely to quit, can help guide interventions. This study evaluated patient and healthcare factors as predictors of smoking cessation in patients with RA.

Methods: Electronic health record (EHR) data were abstracted for patients with at least one rheumatology and one primary care visit and at least two ICD diagnosis codes for RA at least two months apart from two Midwestern health systems (one rural community, one academic) in 2003-2016. Patients without baseline and end of cohort smoking statuses or without six months of follow-up were excluded. Logistic regression was used to determine predictors of smoking cessation.

Results: Overall, 3,577 patients with RA were included, with 14% (n=507) being current smokers at baseline (Figure 1). Among baseline smokers, 71% were seropositive (Table 1). Males and patients ages 40 to 59 were more likely to be current smokers. Current smokers were more likely to have a pulmonary comorbidity and to see primary care than never smokers (25% vs. 16% and 83% vs. 69% respectively; $p< 0.01$). Black patients were 2.77 times more likely to be current smokers (OR 2.77, CI 1.59, 4.82. $p< 0.01$) and patients who received Medicaid were over 4 times more likely to be smokers (OR 4.17, CI 3.37, 5.15, $p< 0.01$).

In this RA cohort, the overall smoking cessation rate was 5.7% per person year. Patients who were new to rheumatology care had 60% higher odds of quitting than patients already in rheumatology care (Adj. OR 1.60 CI 1.02, 2.50, $p=0.04$; Table 2). Patients in the rural community system were 1.66 times more likely to quit smoking (Adj. OR 1.66, CI 1.03, 2.69, $p = 0.04$). Odds of quitting increased 15% each year of follow-up (Adj. OR 1.15, CI 1.06, 1.25, $p< 0.01$).

Cardiopulmonary Comorbidity		0.84 (0.55, 1.26)		
Rural Community Health System		1.33 (0.89, 2.00)	1.66 (1.03, 2.69)	**0.039**
Length of Study Follow-up (years)		1.13 (1.05, 1.21)	1.15 (1.06, 1.25)	**<0.001**

Conversely, seropositive patients were significantly less likely to quit (Adj. OR 0.57, CI 0.35, 0.91; p=0.02). Age, sex, race, ethnicity, and ever receiving Medicaid were not significant predictors of smoking cessation.

Conclusion: Healthcare factors, including health system and being new to rheumatology care, were more predictive of smoking cessation in patients with RA than patient factors, illustrating the importance of healthcare system support in cessation. While all RA patients should receive cessation support, seropositive patients, who are at higher risk for RA progression and mortality, were less likely to quit and may benefit from targeted cessation efforts. Emphasizing smoking cessation after a new RA diagnosis and leveraging system cessation interventions, as done subsequently in the academic system, could improve smoking cessation and outcomes in patients with RA.

Abstract Number: 1124

The Direct and Indirect Costs of Illness Associated with Systemic Lupus Erythematosus in the USA, UK, France, and Germany: A Structured Review

Jennifer Lofland,[1] Pamela Berry,[2] Feng Pan,[2] Chetan Karyekar,[3] Hannah Guiang,[4] Rebecca McTavish,[4] and Melissa Thompson[4], [1]Janssen Scientific Affairs, LLC, Spring House, PA, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Janssen Global Services, LLC, Horsham, PA, [4]Cornerstone Research Group, Inc, Burlington, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease. SLE tends to peak during prime working years, resulting in a high economic burden due to treatment costs and productivity losses. With the emergence of biologics in the treatment landscape of SLE, there is a renewed interest in understanding the economic burden of SLE. Therefore, the objectives of this study were to: (1) review current evidence on the direct and indirect costs associated with SLE in the USA, UK, France, and Germany; (2) examine the relationship between costs and disease and flare severity; (3) identify gaps in the evidence to inform future research.

Methods: MEDLINE was searched using a combination of cost and SLE-related keywords on November 16, 2018. The search yielded 232 titles and abstracts for screening. The results of the search were cross-checked against an existing systematic review for validation purposes.[1] Only English-language studies published after 2008 with populations from the USA, UK, France, and Germany were included.

Results: Mean annual direct costs in Europe ranged from €3,067 to €4,003 (2011 Euro) compared to $15,000 (2008 USD) to $30,000 (2010 USD) in the USA. Mean annual indirect costs of absenteeism and short-term disability in the USA were reported to be $6,195 and $6,620 (2010 USD), respectively. In the USA studies, medical costs consistently accounted for a greater proportion of the cost burden compared with medication costs, ranging from 65% to 85% depending on disease severity. Within medical costs, inpatient hospitalizations tended to be the primary cost driver. This differed from the European findings where medication costs comprised the largest proportion of total annual costs (UK: 40%, France: 62%, Germany 68%). This difference may be a consequence of when the studies were conducted, as it is unclear whether the use of biologics was captured in the USA studies.

In the USA, higher Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI) scores were associated with increased costs. Direct medical costs were 2.2, 1.3, and 3.4 times higher in severe patients than non-severe patients in UK, France, and Germany, respectively. Each new severe flare increased the total annual direct costs (UK: €650, France: €1,330 [2011 Euro]).

Conclusion: At the time this study was undertaken, there was a limited number of studies examining indirect costs in European countries. Indirect cost data were only available from the USA and most research focused on income loss and work productivity impairment. Little research was found on daily activity loss and caregiver costs. Additional studies aimed at quantifying total costs in SLE are warranted.

Health Care Resource Utilization and Costs in Patients with Juvenile Idiopathic Arthritis Treated with Abatacept and Other Targeted Disease Modifying Anti-rheumatic Drugs

Joe Zhuo,[1] Ying Bao,[2] Qian Xia,[2] Aarti Rao,[3] Niyati Sharma,[3] Xue Han,[4] and Robert Wong[5], [1]Bristol-Myers Squibb, Princeton, NJ, [2]Bristol-Myers Squibb, Lawrenceville, NJ, [3]Mu Sigma, Bangalore, India, [4]Bristol-Myers Squibb Company, Princeton, NJ, [5]Bristol-Myers Squibb, Princeton

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is a common, chronic rheumatic disease of childhood that carries substantial economic impact on patients (pts) and families[1]. The objective of this study was to evaluate the healthcare resource utilization and costs of JIA pts treated with abatacept (ABA) vs. other biologics and targeted disease modifying anti-rheumatic drugs (tDMARDs).

Table1: Baseline Demographic and Clinical Patient Characteristics

	Abatacept Pts (n=26)	Other tDMARDs Pts (n=1,678)	p-value
Age (years) on index date, mean (SD)	13.46 (4.42)	12.09 (4.66)	0.3145
Female, n (%)	23 (88.46%)	1,160 (69.13%)	0.0337
Disease duration (days), mean (SD)	552.26 (576.71)	334.67 (526.23)	0.0108
Comorbidities, n (%)			
Asthma	4 (15.38%)	108 (6.44%)	0.0863
COPD	1 (3.85%)	15 (0.89%)	0.2189
Diabetes	1 (3.85%)	22 (1.31%)	0.2995
Lymphoma	0 (0.00%)	4 (0.24%)	1
Malignancy	0 (0.00%)	7 (0.42%)	1
Uveitis	3 (11.54%)	167 (9.95%)	-
Iridocyclitis *	2 (7.69%)	105 (6.26%)	0.7391
Prior medications, n (%)			
Biologic DMARDs	7 (26.92%)	228 (13.59%)	0.0765
Conventional DMARDs	21 (80.77%)	1,127 (67.16%)	0.142
Corticosteroids	14 (53.85%)	848 (50.54%)	0.7376
NSAIDs	17 (65.38%)	1,048 (62.46%)	0.7595

Table2: Change in HealthCare Resource Utilization Associated with the Initiation of Abatacept vs. Other-tDMARDs

	Abatacept pts (n=26)		Other tDMARDs Pts (n=1,678)		
	BL/FU Pts (N)	Change in number of healthcare service use* per patient, mean (SD)	BL/FU Pts (N)	Change in number of healthcare service use* per patient, mean (SD)	p-value
Inpatient admissions	0/1	0.04 (0.20)	84/54	-0.02 (0.38)	0.2915
Length of stay, days	0/1	0.08 (0.39)	84/54	-0.10 (2.43)	0.2939
Outpatient visits	26/25	-0.12 (7.13)	1,669/ 1,640	-1.60 (7.97)	0.1533
Emergency visits	8/6	-0.08 (1.67)	284/ 222	-0.05 (0.75)	0.1920
Urgent care visits	1/0	-0.04 (0.20)	65/57	0.00 (0.44)	0.5189
Pharmacy visits	25/25	-2.12 (9.48)	1,621/ 1,650	3.16 (5.98)	0.0018
All Cause Healthcare visits	26/26	-2.31 (14.29)	1,676/ 1,671	1.49 (11.19)	0.2426

*Change=(use in post-index period – use in pre-index period), positive difference means an increase in resource use in the follow-up period
BL/FU pts depicts the number of pts having visits in pre-index and post-index period respectively
Other DMARD (TNF and non-TNF) includes adalimumab, golimumab, infliximab, etanercept, certolizumab pegol, tocilizumab, rituximab and tofacitinib

Methods: Pts (age < 18 years) from Truven's MarketScan US Commercial Claims and Encounters claims database with ≥ 2 diagnoses of JIA (ICD-9: 714.3x or ICD-10: M08.xxx) separated by at least one day between 1 July 2006 till 31 March 2018 were split into 2 mutually exclusive cohorts of pts taking ABA vs. other tDMARDs as initial treatment on or after first JIA diagnosis. Index date was defined as the first prescription date for the drugs of interest. Healthcare resource use including inpatient, outpatient, emergency, urgent care visit and pharmacy visits and costs were calculated for the 6 months' pre-index period and post-index period (index date till date of treatment switching, discontinuation, enrollment end or 183 days, whichever is earliest). The other tDMARDs pts were also stratified by TNF vs. non TNF pts. Statistical differences were assessed using chi-square and Kruskal-Wallis tests with significance level of 0.05.

Results: A total of 1,704 pts (26 ABA and 1,678 biologics and other tDMARD pts) were included in the analysis. ABA pts are more likely to be female, have a longer disease duration and had more prior biologic use (Table 1). The num-

Table3: Change in medical costs among patients treated with abatacept and other tDMARDs

Change in medical cost from pre-index period to post-index period, per patient**							
Inpatient costs	$669.28 ($3,412.68)	-$5,941.52 ($18,118.95)	0.0858	-$362.13 ($11,551.95)	0.3015	-$511.76 ($11,802.25)	0.2937
Outpatient costs	$1,950.85 ($20,277.18)	$21,243.07 ($29,877.39)	0.0099	-$574.82 ($11,469.87)	0.0325	$10.28 ($12,801.55)	0.0461
Emergency costs	-$121.99 ($1,833.94)	-$325.04 ($1,336.97)	0.9559	-$36.65 ($1,002.66)	0.213	-$44.39 ($1,013.62)	0.2264
Urgent care costs	-$5.29 ($26.98)	-$8.14 ($31.19)	0.6542	-$0.35 ($112.80)	0.4933	-$0.56 ($111.41)	0.5139
Pharmacy costs	$2,836.41 ($5,628.26)	-$2,943.06 ($26,178.76)	0.0209	$11,935.02 ($10,079.60)	<.0001	$11,536.02 ($11,074.01)	<0.0001
All Cause costs	$5,329.25 ($21,047.22)	$12,025.31 ($43,753.22)	0.3836	$10,961.05 ($19,271.05)	0.2057	$10,989.59 ($20,289.53)	0.2072

* compared with abatacept patients.
**Change=(costs in post-index period –costs in pre-index period), positive difference means an increase in resource use in the follow-up period
Other DMARDs includes adalimumab, golimumab, infliximab, etanercept, certolizumab pegol, tocilizumab, rituximab and tofacitinib

ber of total healthcare visit decreased by 2.31 per pt in ABA pts but increased by 1.49 per pt in other tDMARD pts. (Table 2) The difference was primarily driven by the change of pharmacy visits (-2.12 per ABA pt vs. +3.16 per other tDMARDs pt) As a result, the increase in the pharmacy related costs for other tDMARDs pts was $5,660.3 more than that in ABA pts (Table 3). The increase of total cost over time was numerically greater in other tDMARD pts, TNF pts and non-TNF pts although the differences were not statistically significant.

Conclusion: Despite a longer disease duration, pts initiated with ABA had a greater decrease in pharmacy visit and related cost in comparison with other tDMARDs pts. Further analysis is warranted to understand the cause of the differences and its implications.

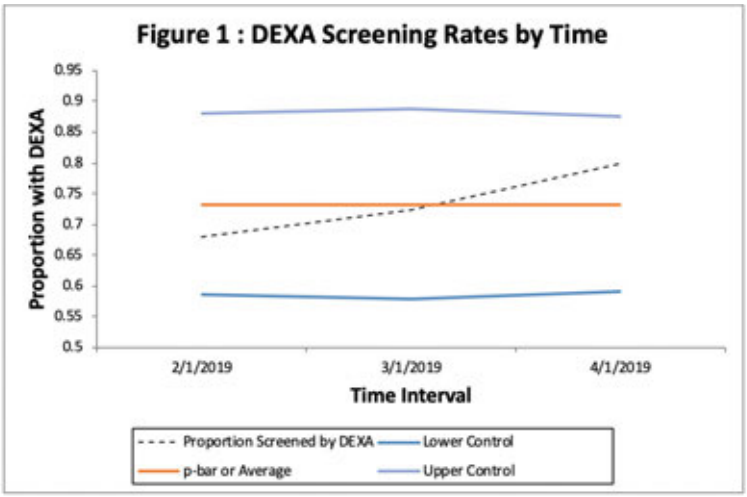
Abstract Number: 1126

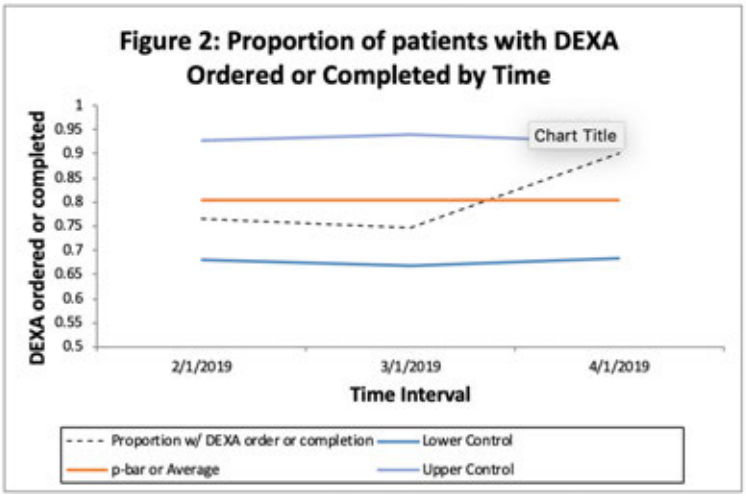
A Medical Assistant Driven Quality Improvement Intervention Increases Rates of DEXA Screening Among RA Patients

Sarah French,[1] Joshua Ng,[1] Darlene Young,[2] Michael Evans,[3] Tobias Schmelzinger,[1] Gabriela Schmajuk,[4] Jinoos Yazdany,[5] and Andrew Gross[1], [1]UCSF, San Francisco, CA, [2]UCSF, San Francisco, [3]University of California San Francisco, San Francisco, [4]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA, [5]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are at increased risk for developing osteoporosis as compared to the general population, even after controlling for glucocorticoid use[1]. Identification and treatment of osteoporosis are important quality measures for prevention of fragility fractures. The National Osteoporosis Foundation recommends bone mineral density (BMD) testing with dual-energy x-ray absorptiometry (DEXA) starting at age 50 in





patients with significant osteoporosis risk factors, including a history of RA[2]. We used the Institute for Healthcare Improvement (IHI) Model for Improvement to implement and assess osteoporosis screening among rheumatoid arthritis patients seen in our academic rheumatology clinic.

Methods: Performance on DEXA screening was calculated as the proportion of RA patients ≥ 50 years old who had ever received a DEXA since 2012. The proportion of patients with an active DEXA order or completion was also measured. Our multidisciplinary quality improvement team utilized a medical assistant led intervention of pending orders for DEXA in patients meeting the following qualification criteria: age ≥ 50 years, RA diagnosis, no prior DEXA or existing order for DEXA, and at least 2 visits in the rheumatology clinic including one within 6 months. We generated two automated electronic health record reports, one to identify BMD screening candidates and one to measure uptake of orders and DEXA completion. Control charts were used to examine performance of these measures over time.

Results: Our clinic provides care for over 500 patients with RA who are ≥ 50 years old. Prior to the intervention, our baseline osteoporosis screening rate was 70% and the proportion of patients with an active DEXA order and/or completion was 76.5%. After our first Plan-Do-Study-Act (PDSA) cycle intervention, our DEXA screening rate increased to 77.3% and the rate of DEXA ordered and/or completed increased to 90% (Figure 1).

Conclusion: Using an interprofessional quality improvement team we were able to improve performance on DEXA ordering and screening, an important measure of health care quality for patients with RA. We plan to pursue future PDSA cycles in order to achieve a target DEXA screening rate of ≥ 85%.

Interventions to Improve Time to Appointment and Outcome Variables in the Pediatric to Adult Transition of Care in Rheumatology

Nicole Bitencourt,[1] Una Makris,[2] Bonnie Bermas,[3] Tracey Wright,[4] and Elizabeth Solow[5], [1]UT Southwestern Medical Center, Dallas, [2]UT Southwestern Medical Center and Dallas VA Medical Center, Dallas, [3]UT Southwestern, Dallas, [4]University of Texas Southwestern, Texas Scottish Rite Hospital for Children, Children's Health, Dallas, TX, [5]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

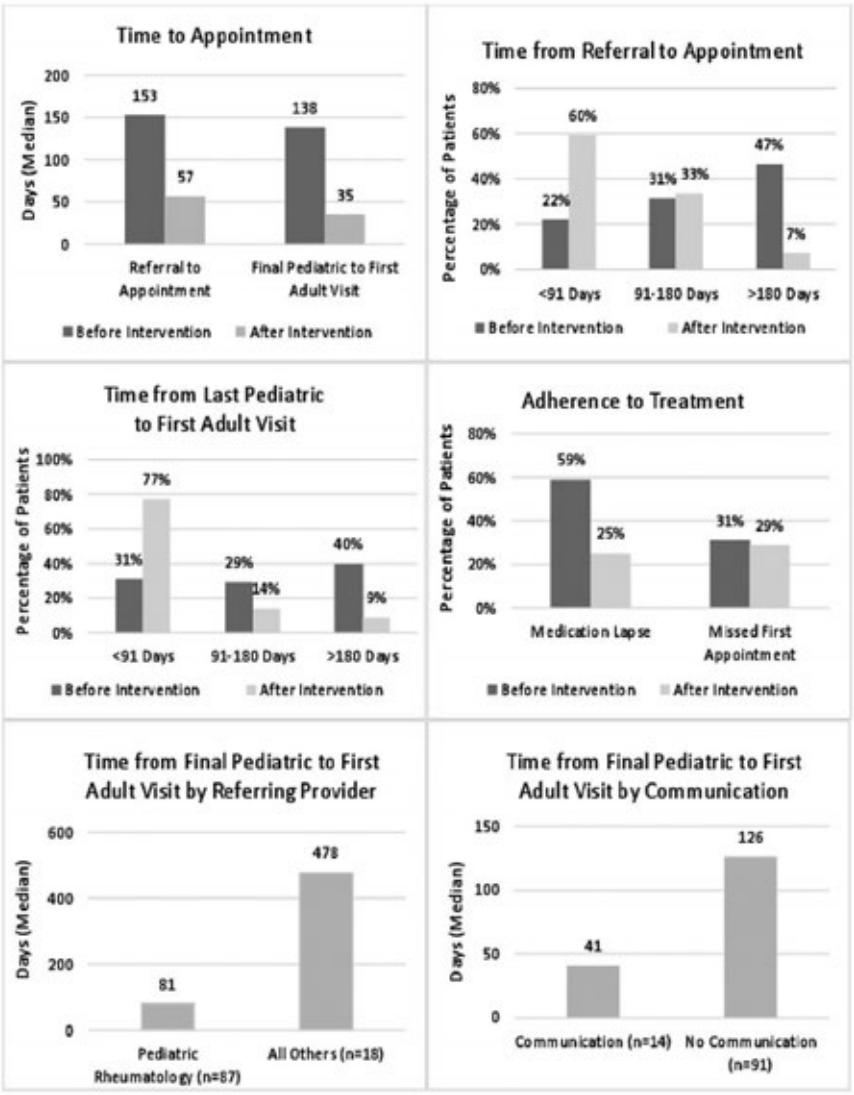
Background/Purpose: The transition from pediatric to adult care is a vulnerable period, in which poor health outcomes are reported amongst youth transferring to adult care. We sought to improve the efficiency of the referral process and established dedicated appointment slots for patients transferring from pediatric to adult care in our large safety-net hospital system.

Methods: A chart review was conducted from eight-six pediatric patients between ages 17 and 21 transitioning to a safety-net adult rheumatology clinic between March 2014 and February 2018 (pre-intervention) and 42 patients from March 2018 to April 2019 (post-intervention). Independent variables included demographic information, diagnoses, referring physician type (pediatric rheumatologist or other), communication between pediatric and adult physicians, and lapse in medical coverage of greater than 30 days between final pediatric and first adult visit. The relationship between these variables and outcomes of interest was analyzed including time between referral and first appointment, time between final pediatric and first adult visit, healthcare utilization between referral and first adult visit including hospitalizations and ED visits, and self-reported medication non-adherence at first visit. Comparisons were made using Chi-square and Mann-Whitney U tests.

Table 1. Demographics of Pediatric Patients Transitioning to Adult Rheumatology Clinic (n=128)

	Before Intervention Number (%)	After Intervention Number (%)	Comparison of Before vs After
Sex			
Female	62 (72)	35 (83)	p=0.16
Male	24 (28)	7 (17)	
Race/Ethnicity			
Hispanic	60 (70)	24 (57)	p=0.27
African-American/Black	14 (16)	11 (26)	
Caucasian	10 (12)	4 (10)	
Asian	2 (2)	3 (7)	
Diagnosis			
Connective Tissue Diseases	47 (55)	22 (52)	p=0.10
Juvenile Idiopathic Arthritis	34 (40)	12 (28)	
Other Rheumatic Diseases	5 (6)	7 (16)	
RDCI Comorbidity Index (Average)	0.95	1.1	p=0.31
Mean Age at Referral			
Referral by Pediatric Rheumatology	18.4 years	18.0 years	p<0.001
Referral by All Others	19.9 years	20.2 years	p=0.37
Referring Provider			
Pediatric Rheumatologist	63 (73)	34 (81)	p=0.34
All Other Providers	23 (27)	8 (19)	
Primary Coverage at Referral			
Coverage:	64 (74)	26 (62)	
Medicaid	11 (13)	1 (2)	p=0.21 (all types of insurance vs no insurance)
Title V Funding (CSHCN)	4 (5)	1 (2)	
Affordable Care Act Plan	2 (2)	7 (17)	
CHIP	1 (1)	3 (7)	
County Funding	4 (5)	4 (10)	
No Coverage			

CHIP: Children's Health Insurance Program; CSHCN: Children with Special Health Care Needs; RDCI (Rheumatic Disease Comorbidity Index)



Results: Pre-intervention, the interval between referral and appointment with adult rheumatology was a median of 158 days, which declined to a median of 35 days post intervention (average 80 days). Interval between final pediatric to first adult visit also declined from a median of 153 days to 57 days post-intervention ($p< 0.01$). As the intervention was based on identifying referrals from the main pediatric rheumatology clinics in the area, those who were not referred to adult care by pediatric rheumatologists continued to have prolonged time to first visit. Hospitalizations and emergency department visits during the interim period between pediatric and adult visits declined significantly, as did self-reported medication non-adherence at first adult visit (from 59% to 25%). Initial missed appointment with adult rheumatology remained unchanged by the intervention.

Conclusion: Youth transitioning into adult rheumatology experience significant delays to first adult rheumatology visit, but dedicated appointment slots and improving the referral process were effective in reducing time to first adult appointment, decreasing health care utilization during the transfer period, and decreasing self-reported medication non-adherence at first visit. It remains important that pediatric rheumatologists ensure they refer all appropriately-aged patients to adult care.

Abstract Number: 1128

Physician-Patient Interaction and Medication Adherence in Lupus Nephritis

Sofia Georgopoulou,[1] Louise Nel,[2] Shirish Sangle,[2] and David D'Cruz[3], [1]King's College London & The Royal Marsden Hospital NHS Foundation Trust, London, England, United Kingdom, [2]Guy's & St Thomas' Hospitals NHS Foundation Trust, London, England, United Kingdom, [3]The Louise Coote Lupus Unit, Guy's Hospital, London, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The quality of physician-patient interaction can have a significant impact on medication adherence. Little is known about this relationship in patients with lupus nephritis (LN).

Methods: Cross-sectional, quantitative study. Data collected included demographics, current medication, SLEDAI, medication adherence, beliefs about medicines, shared decision-making (SDM), patient-doctor depth of relationship (PDDR); patient-doctor quality of relationship (PRDQ9), interpersonal trust in a physician (ITP), and illness perceptions.

Results: 98 patients satisfying the American College of Rheumatology (ACR) classification criteria for LN completed the questionnaires. Binary logistic regression indicated that medication adherence was significantly predicted by: (a) ITP (B= 0.85; Wald= 3.94; 95%CI: 1.01, 5.44; p=0.05); (b) timeline cyclical (B= -0.89; Wald= 4.95; 95%CI: 0.19, 0.90 p< 0.05) and beliefs about necessity of medicines (B= 0.75; Wald= 4.14; 95%CI: 1.03, 4.38; p< 0.05). Mediation analysis showed that BMQ_N significantly mediated the relationship between trust and medication adherence when adjusted for age (B= 0.48, CI95%= 0.06, 1.08 p< 0.01). A further mediation analysis showed that PDDR (B= 0.05, CI95%= 0.01, 0.09 p< 0.001), SDM (B= 0.07, CI95%= 0.01, 0.13 p< 0.001) and PDRQ9 (B= 0.08, CI95%= 0.01, 0.16 p< 0.001) significantly mediated the relationship between illness coherence and ITP.

Conclusion: Findings highlighted two key elements: (a) the importance of patient trust in their physician in relation to medication adherence and (b) patients' good understanding of their illness is linked to a better relationship with their doctor and greater participation in shared-decision making which is associated with increased trust. Tailored psycho-educational interventions could contribute to improving the quality of patient-doctor relationship, increase trust and SDM which, in turn, might improve medication adherence in patients with LN.

Abstract Number: 1129

Direct Medical and Societal Cost of Opioid Use in Symptomatic Knee Osteoarthritis Patients in the United States

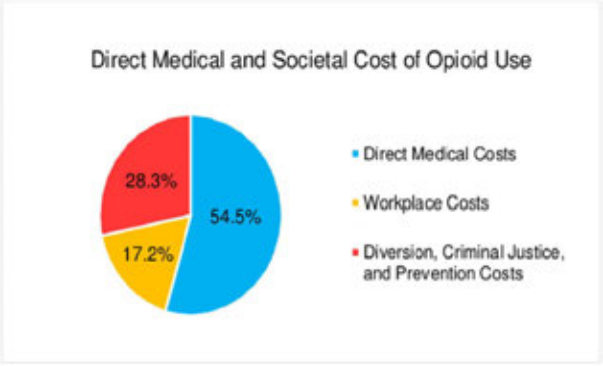
Jamie Huizinga,[1] Elizabeth Stanley,[1] Shuang Song,[1] James Sullivan,[2] Jeffrey Katz,[3] and Elena Losina[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital/Harvard Medical School, Boston, [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Symptomatic knee OA affects 14 million adults in the US. Recent estimates suggest that about 40% of people with knee OA are taking prescription opioids. Opioid use carries substantial societal costs associated with diverted opioid prescriptions and opioid use disorder (OUD), defined by the Diagnostic and Statistical Manual of Mental Disorders IV criteria for abuse and dependence. We sought to estimate the direct medical and societal cost associated with opioid consumption among patients with symptomatic knee osteoarthritis in the US.

Methods: We used a validated, widely published computer simulation model of knee OA (OAPol Model) to estimate lifetime direct medical costs associated with opioid use and the societal costs associated with opioid diversion and OUD in the US knee OA population. The direct medical costs of opioid use included the cost of medication, outpatient visits, and treatment complications including addiction and overdose. Medication, outpatient visit, and non-OUD related complication costs were derived from the 2017 Red Book, Healthcare Cost and Utilization Project, Medicare Physician Fee Schedule, and literature sources. The direct medical cost of opioid addiction and overdose was derived from published literature (Birnbaum 2011) at a per person annual cost of $16,600. Societal costs included diversion and OUD related impacts. The cost of diversion ($200/prescription) and OUD were derived from published literature (Birnbaum 2011). For those experiencing OUD, the per person cost was $17,200 for lost workplace productivity and $3,500 for criminal justice and prevention. Using data from Medicare Current Beneficiary Survey, we estimated the prevalence of opioid addiction, excluding those who overdose, among those with knee OA who had been prescribed opioids to be 0.93%. Using World Health Organization data, we estimated the prevalence of overdose to be 0.77%, resulting in a total estimated prevalence of addiction of 1.7% among knee OA opioid users. We discounted costs at 3% annually.

Results: We estimated 9 million persons have moderate or severe pain due to knee OA; the total lifetime direct medical and societal cost associated with opioid use was $14.8 billion. Direct medical costs of opioids were estimated at $897 per knee OA patient with moderate or severe pain. Societal costs per knee OA patient with moderate or severe pain were estimated at $283 for lost workplace productivity and $465 for diversion/criminal justice/prevention costs. Direct medical costs make up 55% ($8.1 billion) of the total direct medical and societal cost of opioid use in this population (Figure). The societal costs of opioid use due to lost workplace productivity costs make up 17 % ($2.6 billion) of the total cost of opioid use in this population, and diversion/criminal justice/prevention costs 28% ($4.2 billion).



Total cost of opioid use: $14.8 billion

Conclusion: The total direct medical and societal cost of strong opioid use in the US knee OA population is substantial. This could be due in part to the high prevalence of symptomatic knee OA in the US. Close to 50% of the total costs attributed to opioid use in this population is spent on diversion, criminal justice, prevention and work-related expenditures.

The Risk of Toxic Retinopathy Among Patients on Hydroxychloroquine

Abdulrahman Alrashid,[1] Millicent Anne Stone,[2] Nigel Davies,[2] and David D'Cruz[3], [1]King Abdulaziz Medical City - Riyadh, Riyadh, Saudi Arabia, [2]Guy's and St Thomas Foundation Trust, London, United Kingdom, [3]The Louise Coote Lupus Unit, Guy's Hospital, London, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is widely used in treatment of autoimmune rhuematological diseases. In particular, systemic lupus erythermatosus where it proved to prevent disease flare, reduce organ damage and decrease mortality. Although the drug has a favourable *safety profile however, it has been* associated with increased *risk of* severe retinal toxicity. Recent data has demonstrated that hydroxychloroquine retinopathy might be more common than previously recognized with an overall prevalence of 7.5%.

Table 1

Clinical characteristics of patients with HCQ Retinopathy

	Gender	Age, y	Diagnosis	Dose, mg	Duration, y	eGFR, ml/min	Steroid	Immunosuppression
