Results: By DEXA, 8/31 (25.8%) had OP and 12 (38.7%) had LBD. History of lymphopenia (75.0% vs. 31.8%, p=0.049) and lower concurrent HCQ dose (340 vs. 400 mg, p=0.006) associated with DEXA OP, while older age (48.3 vs. 36.3 y, p=0.024) associated with LBD. Higher ESR was inversely correlated with favorable bone structure (PW r(22) = -.49, p=0.025, PRR rs = -.51, p=0.018, PVF rs = -.51, p=0.018, RVF rs = .51, p=0.018, Tb.Th rs = -.58, p=0.005, Tb.Sp rs = .44, p=0.046, TNA rs = -.50, p=0.022). Higher CRP was likewise inversely correlated with favorable bone structure (PW r(20) = -.61, p=0.004, PRR rs = -.57, p=0.009, PVF rs = -.57, p=0.009, RVF rs =.57, p=0.009, Tb.Th rs = -.56, p=.011, Tb.Sp rs =.67, p=0.001, TNA rs = -.64, p=0.002). A history of lupus nephritis was associated with unfavorable bone structure (PW 705.3 vs. 833.3 μm, p=0.048, PRR 6.6 vs. 8.1, p=0.024, PVF 0.83 vs. 0.89, p=0.024, RVF 0.17 vs. 0.11, p=0.024, Tb.Th 178.1 vs. 193.4 mm, p=0.012, Tb.Sp 358.6 vs. 296.5 mm, p=0.056, TNA 0.41 vs. 0.54 (1/mm), p=0.009). ESR, CRP and history of lupus nephritis were not significantly associated with DEXA hip BMD, OP or LBD. MRI parameters for favorable bone structure were inversely correlated with DEXA hip BMD (PW r(28) = -.47, p=0.011, Tb.Th rs = -.53, p=0.003) and BMI (PW r(28) = -.54, p=0.003, TbTh rs = -.72, p< 0.001, TNA rs = -.44, p=0.017).

Conclusion: Higher ESR and CRP and a history of lupus nephritis associated with MRI parameters of unfavorable bone structure, but did not associate with DEXA abnormalities in SLE patients. MRI may be a more sensitive tool than DEXA to measure inflammatory effects on bone and potentially cumulative dose of steroid exposure. There were inverse correlations of MRI parameters with traditional osteoporosis risk factors and BMD measures on DEXA, and it

is possible that each tool evaluates different aspects of bone health. Further evaluation of MRI screening for fracture risk in SLE and GC exposed individuals is warranted to better quantify risk and guide treatment.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) patients show an increased risk of low bone mass as a result of multifactorial events: physical inactivity, persistent inflammation, low vitamin D levels (protection to avoid photosensitivity) and glucocorticoid treatment. Trabecular Bone Score (TBS) is an index extracted from the dual-energy X-ray absorptiometry (DXA) that provides an indirect measurement of bone axial microarchitecture and allows to get information about bone quality in several rheumatic diseases (1-4).

The aims of this study was to examine the prevalence and risk factors for low bone mineral density (BMD) (osteoporosis or osteopenia) in female patients affected by SLE in comparison with matched healthy subjects (HS).

Methods: 60 female patients (mean age 45±16 years) affected by SLE and 60 age- matched CNT (mean age 47±5 years) were enrolled. Bone Mineral Density (BMD, g/cm2) of the lumbar spine (L1-L4) was analyzed using a DXA scan (GE, Lunar Prodigy). Lumbar spine TBS was derived for each spine DXA examination using the TBS index (TBS iNsight Medimaps).

Results: The mean BMD was 0.49±0.41 SD g/cm^2 at the lumbar spine and 0.59±0.62 g/cm^2 at the hip in SLE patients. The prevalence of osteopenia and osteoporosis in SLE patients was 39.0% and 16.4% respectively. Most of SLE patients (70%) presented a bone loss that was significantly lower when compared with control group ($p< 0.001$). Likewise, lumbar spine TBS score was found significantly lower in SLE patients compared with HS (0.797±0.825 vs

1.398±0.207, p< 0.001, respectively). An history of high-dose oral glucocorticoids (> 10 mg/day) was found associated with the preservation of BMD at the lumbar spine but not in spinal trabecular bone as observed by TBS analysis.

Conclusion: SLE is associated with significant trabecular bone loss, which might not be caused by glucocorticoid therapy. This study underlines the role of TBS as new and safe diagnostic tool for the quantification of the bone quality in chronic and systemic inflammatory rheumatic diseases, such as SLE.

Modeling-Based Bone Formation Persists in the Femoral Neck Despite Remodeling Inhibition in Subjects Treated with Denosumab

David Dempster,[1] Peter Butler,[2] Mathias Bostrom,[3] Jeri Nieves,[1] Hua Zhou,[4] Li Chen,[2] Nicola Pannacciulli,[2] Rachel Wagman,[2] and Felicia Cosman[1], [1]Columbia University, New York, NY, [2]Amgen Inc., Thousand Oaks, CA, [3]Hospital for Special Surgery, New York, NY, [4]Helen Hayes Hospital, West Haverstraw, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Denosumab (DMAb) is a potent antiresorptive agent, but findings in non-human primates suggest that modeling-based bone formation (MBBF) may persist despite DMAb treatment (Ominsky *JBMR* 2015). This study assessed whether MBBF in the femoral neck (FN) is preserved in the context of inhibited remodeling-based bone formation (RBBF) in subjects receiving DMAb (NCT02576652).

Methods: This open-label study enrolled ambulatory postmenopausal women and men with osteoporosis (OP) who had received ≥2 doses of DMAb (60 mg subcutaneously Q6M) per standard of care and were planning to undergo elective total hip replacement (THR) due to osteoarthritis of the hip. Transverse sections of the FN were obtained after THR surgery and analyzed histomorphometrically. The primary endpoint was the subject incidence of MBBF, based on fluorochrome labeling and the presence of smooth cement lines, in cancellous, endocortical, and periosteal surfaces of the FN. Secondary and exploratory analyses used histomorphometric parameters to characterize rates of MBBF and RBBF in the 3 envelopes in enrolled subjects and historical controls. Controls were from the placebo group of a prior study and were not treated with DMAb. All analyses were descriptive.

Results: Four of the 6 subjects enrolled were included in the analyses (all women, mean age 73.5 y, mean duration of DMAb use 1.8 y); one subject withdrew consent due to an allergic reaction to the tetracycline label, and one subject did not undergo THR. The 17 historical controls had a mean age of 68.3 y; 71% were women, and 47% had received OP treatment that did not include DMAb. All subjects in both groups exhibited MBBF in periosteal bone surfaces; in cancellous and endocortical surfaces, all DMAb-treated subjects and 88% and 82% of historical controls, respectively, showed evidence of MBBF (Table). Compared with historical controls, DMAb-treated subjects showed 792%

Table. Descriptive histomorphometric analysis of modeling- and remodeling-based bone formation in study subjects and historical controls.

	Historical Controls (N = 17)	Study Subjects (N = 4)
Modeling-based fluorochrome labeling at the femoral neck, n (%)		
Cancellous	15 (88.2)	4 (100.0)
Endocortical	14 (82.4)	4 (100.0)
Periosteal	17 (100.0)	4 (100.0)
Specialized histomorphometric parameters		
Cancellous, mean±SD		
Modeling-based formation unit (/mm)	0.013 ± 0.014	0.146 ± 0.210
Overfilled remodeling-based formation unit (/mm)	0.012 ± 0.013	0.004 ± 0.006
Remodeling-based formation unit including overfilled units (/mm)	0.135 ± 0.108	0.029 ± 0.017
Endocortical, mean±SD		
Modeling-based formation unit (/mm)	0.065 ± 0.063	0.222 ± 0.231
Overfilled remodeling-based formation unit (/mm)	0.018 ± 0.025	0.011 ± 0.014
Remodeling-based formation unit including overfilled units (/mm)	0.178 ± 0.091	0.032 ± 0.032
Periosteal, mean±SD		
Modeling-based formation unit (/mm)	0.250 ± 0.084	0.199 ± 0.141
Overfilled remodeling-based formation unit (/mm)	0.000 ± 0.000	0.000 ± 0.000
Remodeling-based formation unit including overfilled units (/mm)	0.004 ± 0.007	0.003 ± 0.007

SD: Standard deviation

and 242% higher values of MBBF in the cancellous and endocortical surfaces, respectively, while RBBF values were 79% and 82% lower. In the periosteal surface, MBBF and RBBF rates were similar between subjects and controls.

Conclusion: These results demonstrate the occurrence of MBBF in the adult human FN and suggest that DMAb preserves MBBF while inhibiting RBBF, consistent with previous findings. This effect may contribute to the continued increases in bone mineral density demonstrated with up to 10 y of DMAb treatment (Bone *Lancet Diabetes Endocrinol* 2017).

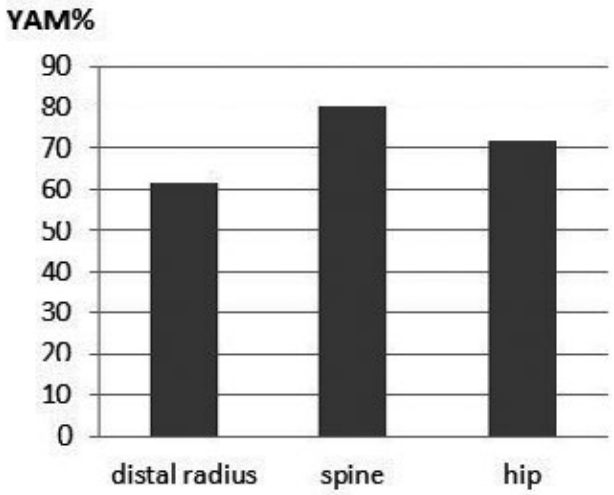
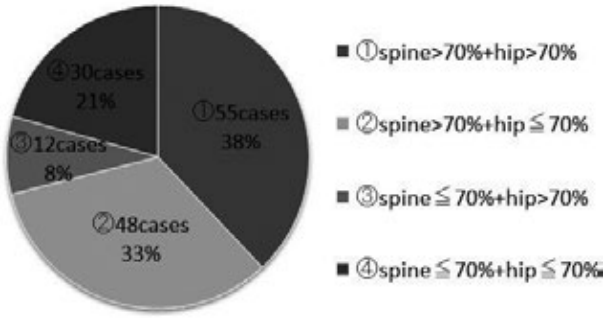
Abstract Number: 2216

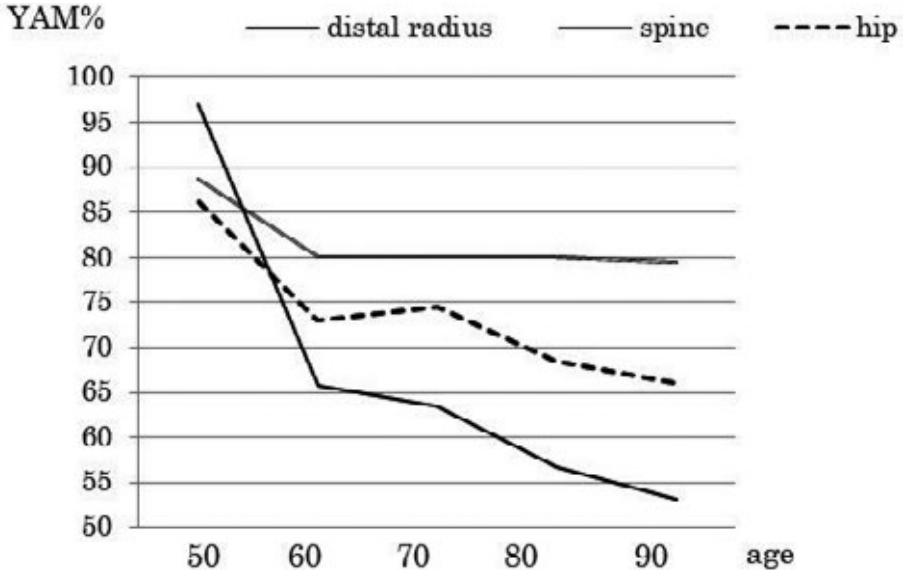
Bone Mineral Density of the Spine, Hip, and Distal Radius in Patients with Postmenopausal Osteoporosis

Ken Nakaseko[1], [1]Department of Orthopaedic Surgery and Rheumatology Kuwana City Medical Center, kuwana mie, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM







Background/Purpose: Bone mineral density (BMD) is used for the diagnosis of osteoporosis, predicting future fracture risk, and monitoring osteoporosis treatment. Osteoporosis is defined as BMD of at least 2.5 standard deviations below the young adult mean (YAM) (T-score ≦2.5) according to World Health Organization (WHO) criteria or a BMD of 70% or lower of YAM (YAM% ≦70) according to the Japanese Society for Bone and Mineral Research (JSBMR)

criteria in Japan. As is often the case, T-score or YAM% values of different skeletal sites are discordant. This means that making a diagnosis of osteoporosis may depend on measured sites. BMD of the spine and hip is usually measured for the diagnosis of osteoporosis; however, that of the distal radius is not always measured. The purpose of the present study was to clarify correlations of BMD among the three skeletal sites and evaluate whether measuring BMD of the distal radius is essential. In addition, BMD of the three skeletal sites based on patients' age was investigated.

Methods: Two hundred and one patients between the ages of 52 and 93 with postmenopausal osteoporosis were enrolled.

BMD of the spine, hip, and distal radius was measured using dual energy X-ray absorptiometry (DXA) (Prodigy, GE Healthcare UK Ltd.). The cut-off values for the diagnosis of osteoporosis according to JSBMR criteria were used. Analyses of correlations between BMD of two skeletal sites (i.e., hip and distal radius, spine and distal radius, and hip and spine) were assessed using the t-test.

Results: YAM% of the distal radius was 61.7%, being lower than that of the spine, 80.4%, and hip, 71.9% ($p > 0.001$) (Table 1). Correlation coefficients of BMD between the hip and distal radius, spine and distal radius, and hip and spine were 0.475965, 0.406596, and 0.415697, respectively. Among the 145 patients diagnosed as osteoporotic at the distal radius, 55 were not osteoporotic at either the spine or hip, 48 (33%) were osteoporotic at the hip but not spine, 12 (8%) were osteoporotic at the spine but not hip, and 30 (21%) were osteoporotic at both the spine and hip (Table 2). Among the 56 patients without osteoporosis at the distal radius, only one patient (1.8%) was osteoporotic at the spine and 12 (21%) were osteoporotic at the hip. YAM% of the three skeletal sites according to the patients' age is shown in Table 3.

Conclusion: BMD of the distal radius is significantly lower than those of the spine and hip. Sontag reported that the radius was frequently recognized as the site of initial osteoporotic fractures among women with osteoporosis. This report might support the present study and suggest the possible susceptibility of the radius to osteoporosis as the initial site compared with the spine and hip, especially in early osteoporotic generations. Among 145 patients diagnosed with osteoporosis at the distal radius, 55 (38%) were not osteoporotic at either the spine or hip. This means that a diagnosis of osteoporosis might not be made for some patients if only BMD of the spine and hip and not the distal radius is measured. Therefore, measuring BMD of the distal radius in addition to that of both the spine and hip is highly recommended to avoid underestimating the actual value of BMD for the diagnosis of osteoporosis, especially in early osteoporotic generations.

DEXA Does Not Accurately Reflect FRAX Score in Patients with Autoimmune Disease on Corticosteroids

Sima Terebelo,[1] Madina Abduraimova,[1] Latoya Freeman-Beman,[1] Naureen Kabani,[2] Joshy Pathiparampil,[1] Olga Dvorkina,[2] and Ellen M Ginzler[3], [1]SUNY Downstate Medical Center, Brooklyn, NY, [2]SUNY Downstate Medical Center, Brooklyn, [3]State University of New York Downstate Medical Center, Brooklyn, NY

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis (OP) is a problem in the aging population. Patients with autoimmune disease are at increased risk for OP given their history of steroid use.

Methods: As part of a QI project on bone health, we reviewed female patients age ≥50 and male patients age ≥60. If the last DEXA scan was done prior to 2 years ago, a recommendation was made to order a new study. We collected data on risk factors for secondary OP and steroid doses within the past year, including most recent dose and average dose over one year. FRAX scores were calculated for all patients regardless of DEXA score, accounting for all of the standard risks for OP. We adjusted FRAX scores for steroid use based on the NEJM article recommendation to multiply the FRAX score by 15% for major OP fractures and by 20% for risk of hip fractures in patients who currently take >7.5mg of prednisone daily (1).

Results: 55 patients with autoimmune disease were studied, of whom 48 received prednisone at some time. 20/55 were on prednisone during the past year, average dose 14.6mg/d (range 2.8-30mg/d), 18/55 are currently on prednisone. Of the 20 patients on prednisone over the past year, mean age was 64.3y (range 50-83), 19 female (95%), 18 Black (90%), (full demographics in Table 1). Prednisone use was classified as low (< 2.5mg/d) n=0, medium (2.5-7.5mg/d) n=11, high (>7.5mg/d) n=9. DEXA results were not available in 7 patients. 5 patients had normal bone density, 6 were classified as osteopenia, and 2 were osteoporotic. Calculated FRAX scores were different from those anticipated by DEXA score (Table 2). FRAX ≥ 20% risk for major OP fractures was found in 5/20pts; of those, 2 had no DEXA available, 1 had normal BMD on DEXA, 1 was osteopenic and one had osteoporosis. Calculated FRAX of ≥3% risk for hip fractures was found in 7/20 pts, of whom 2 had no DEXA avail, 2 had normal BMD on DEXA, 2 were osteopenic and 1 was osteoporotic. Further adjustment for high dose prednisone use resulted in 2 additional patients at risk, 1 with FRAX ≥ 20% risk for major OP fractures and 1 with FRAX ≥ 3% risk for hip fracture.

Demographics	N= 20 pts
Mean age	64.3y (range 50-83)
Gender	19F (95%)
Race	18 Black (90%)
Ethnicity	1 Hispanic (5%)
Weight	177.8 (range 101-258)
BMI	30.6 (range 17.1-45.2)
RA	9 pts (45%)
SLE	9 pts (45%)
Other autoimmune disease	6 (30%) [vasculitis 2 (EGPA, GCA), MCTD (2), UCTD (1)]
Current smokers	3/20 (15%)
h/o nontraumatic fracture	4/19 (21%)
Premature menopause (<45y)	4/15 (26.7%)
PPI	3/19 (15.7%)
calcium suppl	7/19 (36.8%)
vit D suppl	7/19 (36.8%)
bisphosphonates	9 prior use/ 3 currently
Other antiresorptive agents	Prolia-2 pts, miacalcin-1 pt
Prednisone daily dose	Medium (2.5-7.5mg/d) 11pts (55%) High (>7.5mg/d) 9pts (45%)
DEXA results	No DEXA- 7 pts Normal BMD- 5 pts Osteopenia- 6 pts Osteoporosis- 2 pts

Table 1. Demographics

	DEXA unavailable	DEXA normal	Osteopenia	Osteoporosis
FRAX major OP ≥20	2	1	1	1
FRAX hip ≥3	2	2	2	1

Table 2. DEXA scores versus Calculated FRAX scores

Conclusion: There is a discordance between DEXA measured osteopenia/osteoporosis and FRAX risk. This is of particular concern in our demographically unique, largely Afro-Caribbean population with a high proportion of obesity, calcium-poor diets and comorbidities that can impact bone health. We recommend that FRAX scores be calculated on all patients even if no DEXA is available. We encourage smoking cessation and calcium/vitamin D supplementation for all. Just as weight gives only a partial glimpse of a patient's burden of adiposity and BMI is needed to fully understand the issue, so too DEXA parameters only provide a partial glimpse of bone health.

1,25D3 Promotes Mineralization of Osteoblasts by Activating C/EBPβ-DKK1 Axis

Sungsin Jo,[1] Subin Yoon,[1] Seoung Wan Nam,[2] Jae-Hyuk Yang,[3] Il-hoon Sung,[4] and Tae-Hwan Kim[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [3]Department of Orthopedic Surgery, Hanyang University Medical Center, Guri Hospital,, Guri, Republic of Korea, [4]Division of Orthopedics, Hanyang University Hospital for Rheumatic Diseases, Seoul, Seoul-t'ukpyolsi, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 1,25-Dihydroxyvitamin D3 (1,25D3) has a positive therapeutic effect on osteoporosis by activating osteoblasts. Bone formation is a dynamic and sequential process that comprises osteoblasts proliferation, increased ALP activity, collagen synthesis, and mineralization. In addition, the tight regulation between Wnt/β-catenin signaling and Dickkopf-1 (Dkk-1), Wnt antagonist, is critical for these series of steps to induce osteoblast differentiation and bone formation. Therefore, it is possible that 1,25D3 promote osteoblastic differentiation through Wnt activation; however, the potential role of Dkk1 in 1,25D3-induced osteoblastic differentiation is not fully elucidated.

Methods: Bone tissues were obtained from knee replacement surgery and primary preosteoblasts were isolated using outgrowth method. Preosteoblasts cultures underwent microarray analysis on day 14 either with stimuli for differentiation or without. The microarray data was verified using qPCR and ELISA. Also, the effect of 1,25D3 during preosteoblasts differentiation to osteoblasts was assessed by intracellular alkaline phosphatase (ALP) activity analysis, alizarin red (ARS) staining for calcium deposit, and hydroxyapatite staining. To investigate the indirect regulation of genes by 1,25D3 in unmineralized osteoblasts, preosteoblasts were incubated with ascorbic acid (AA) for 3 days and then exposed to 1,25D3 for 1 day. Subsequently, what happened at the molecular level by 1,25D3 was investigated using qPCR, Dkk1 promoter assay, immunostaining, immunoblotting, and Chromatin Immunoprecipitation (ChIP) assay.

Results: Gene expression microarrays revealed upregulation of DKK1 expression in differentiated osteoblasts. Increase in DKK1 expression and secretion in differentiated osteoblasts were confirmed by qPCR and ELISA, respec-

tively. 1,25D3 promoted osteoblast maturation of preosteoblasts and obviously induced the expression of C/EBPβ and DKK1 at day 7 during differentiation. Interestingly, mRNA and protein levels of C/EBPβ and DKK1 were markedly increased by 1,25D3 treatment following AA stimuli. To demonstrate the relationship between the two genes, we performed knockdown of C/EBPβ with siRNA, which reduced the up-regulation of DKK1 induced by 1,25D3. In contrast, overexpression of C/EBPβ boosted enhancement of DKK1 by 1,25D3. Furthermore, we also found that C/EBPβ bind to human DKK1 promoter in response to 1,25D3. Intriguingly, blocking DKK1 attenuated calcified nodule of mineralized osteoblasts, but not ALP activity and collagen synthesis.

Conclusion: Taken together, these observations suggest that 1,25D3 promotes the mineralization of osteoblasts through activation of DKK1 followed by an increase in C/EBPβ.

Randomized Control Study in Glucocorticoid-Induced Osteoporosis Treated with Bisphosphonate or Denosumab (GOBID)

Ikuko Tanaka,[1] Mari Ushikubo,[2] Misako Konishi,[2] Yutaro Hayashi,[2] Satoshi Hama,[3] Keisuke Izumi,[2] Yutaka Okano,[2] Shigenori Tamaki,[4] and Hisaji Ohshima[2], [1]Nagoya Rheumatology Clinic, Ngoya, Japan, [2]National Tokyo Medical Center, Tokyo, Japan, [3]tokyo medical center, tokyo, Japan, [4]Nagoya Rheumatology Clinic, Nagoya, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has not been established which therapy, bisphosphonates or denosumab, is more effective for glucocorticoid-induced osteoporosis (GIO). The purpose of this study was to compare the therapeutic efficacy to GIO between bisphosphonate and denosumab on the basis of randomized control study (GIBID Study, UMIN000014341).

Methods: The inclusion criteria were as follows, glucocorticoids on, bone mineral density (BMD) < 80% in %YAM at the lumbar spine/femoral neck or fragile fracture at the spine, ≥1 year without bisphoshonates, ≥18 years old. The BMD was measured at the lumbar spine and femoral neck with GE Lunar iDXA. Incident fractures were evaluated with the semiquantative method (Genant) at the thoracic and lumbar spine. Medications, risedronate (17.5mg/W or 75mg/M, group B) or denosmab (60mg/6M, group P), were randomly assigned to the patients. The primary outcome was the changes in lumbar BMD (l-BMD) at 2 years.

Results: The included individuals were 28 rheumatoid arthritis (RA), 22 systemic lupus erythematosus (SLE), 17 polymyalgia rheumatic (PMR), other connective tissue diseases (CTDs) in total 89. The demographics of the group B and the group P were as follow, the number: 48/41 (B/P); female: 42/31; Age (mean): 66.0/70.6; prednisolone: 6.1/7.3mg/day; l-BMD; 0.959/0.928g/cm2; prevalent deformity at spine: 52/49%. No significant differences was observed between the groups. The change at 2 years in lBMD in group P (0.063+/-0.069 (mean+/-SD)) was significantly higher than that in group B (0.017+/-0.043) ($p< 0.001$). The numbers (rates) of incident fracture at 2 year were 6 (15%) in group B and 0 (0%) in group P ($p< 0.01$). Any serious adverse events due to the study drugs were not seen in the both groups.

Conclusion: These results suggest that denosmab is effective and safe for treatment of glucocorticoid-induced osteoporosis.

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis (OP) and osteoarthritis (OA) are often comorbid conditions in the elderly, with prevalence of OP in patients with OA reported as high as 30%. Previous studies have found significantly higher baseline BMD in OA patients than their non-OA counterparts, despite an increased risk for fracture, potentially contributing to delayed diagnosis and treatment in this population. In the ACTIVE phase 3 study of postmenopausal OP women, 18 months (M) of abaloparatide (ABL) treatment significantly increased bone mineral density (BMD) and reduced the risk of new vertebral, nonvertebral, clinical, and major OP fractures vs placebo (PBO) (NCT01343004). Women receiving ABL or PBO in ACTIVE were offered enrollment in the ACTIVExtend extension study in which both groups received 24M open-label alendronate (ALN) 70 mg weekly for a total of 43M (18M ABL or PBO, 1M for reconsent, and 24M ALN) (NCT01657162). The objective of this post hoc analysis was to evaluate efficacy and safety of ABL followed by ALN (ABL/ALN) vs PBO/ALN in the subgroup of patients with OA.

Methods: ACTIVExtend enrolled postmenopausal women with OP between the ages of 50 and 85; 558 were from the original ABL group and 581 from the PBO group of the ACTIVE study. Patients with the following terms in their medical history were included: “ongoing osteoarthritis” (including spine, knee, hand, foot, shoulder, and other sites), “spinal osteoarthritis”, “nodal/ hand osteoarthritis”, or “intervertebral disc degeneration”. New vertebral fracture incidence was evaluated using the modified intent-to-treat (mITT) population, other efficacy endpoints were evaluated using the ITT population. The percent mean changes in BMD from baseline to 43 months were calculated for the total hip (TH), femoral neck (FN), and lumbar spine (LS).

Results: A total of 395 ACTIVExtend patients with ongoing OA were identified (ABL/ALN, 190; PBO/ALN, 205). Most common sites of OA were at the knee (39.2%), and spine (38.5%). At baseline, 78 (19.7%) had a prevalent VF, 94 (23.8%) reported ≥1 prior NVF within the last 5 years, and 175 (44.3%) had no prior fractures. At 43M, 1.1% (2/186) ABL/ALN and 7.0% (14/201) PBO/ALN patients experienced ≥ 1 new vertebral fracture (P=0.004). Kaplan-Meier estimated cumulative incidence for other fracture endpoints was similar across treatment groups. Mean percent change in BMD were all significantly greater with ABL/ALN vs PBO/ALN at all timepoints assessed ($P < 0.001$). At 43M, BMD mean percent change from baseline was 6.0% ABL/ALN vs 2.3% PBO/ALN at the total hip, 4.9% ABL/ALN vs 1.4%

PBO/ALN femoral neck, and 14.3% ABL/ALN vs 6.7% PBO/ALN lumbar spine. Most common TEAEs overall were upper respiratory tract infection (9.0% vs 8.3%), arthralgia (7.9% vs 8.8%), worsening osteoarthritis (8.5% vs 6.4%), and back pain (7.9% vs 4.4%), for ABL/ALN vs PBO/ALN arms, respectively.

Conclusion: Improvements in vertebral fracture risk as well as significant gains in BMD were maintained through 43M with ABL/ALN vs PBO/ALN. This post hoc analysis suggests that ABL/ALN was effective in a subgroup of patients with OP and OA, with no new safety signals identified.

Bone Metabolism Impairment in Heart Transplant: Results from a Prospective Cohort Study

Luis Seguro,[1] Rosa Pereira,[2] Luciana Seguro,[3] Valeria Caparbo,[3] Monica Avila,[1] Sandrigo Mangini,[1] Iascara Campos,[1] Fabio Gaiotto,[1] Fabiana Marcondes-Braga,[1] and Fernando Bacal[1], [1]Instituto do Coracao (InCor), HCFMUSP, Sao Paulo, [2]Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Data on prevention of fractures after heart transplant (HTx) are controversial in the literature. Understanding the effects of HTx on bone may guide appropriate treatment in this high-risk population.

Methods: Seventy adult patients submitted to HTx were followed for 12 months. Clinical and laboratory parameters, bone mineral density (BMD), body composition, microarchitecture and vertebral fractures were assessed at baseline (intensive care unit discharge), 6 and 12 months. Patients received recommendations regarding calcium intake (1,000mg/day) and vitamin D supplementation (50,000U/week for 3 months, followed by 7,000U/week) after HTx.

Results: At baseline, 27.1% of patients had osteoporosis (T-score ≤-2.5), associated with the length of hospitalization before HTx (p=0.001). BMD decreased in the first 6 months, with partial recovery later. Bone microarchitecture deteriorated, mainly trabecular bone in the first 6 months and cortical bone in the subsequent 6 months. At baseline, 92.9% of patients had vitamin D level < 30ng/mL and 20.0% < 10ng/mL. Patients also had calcium at the lower limit of normal, high alkaline phosphatase, associated with low levels of vitamin D (15.5±9.1 ng/ml). These abnormalities were suggestive of impaired bone mineralization and normalized at 6 months with correction of calcium and vitamin D deficiency. The majority of vertebral fractures were identified at baseline (23.5% of patients). After multivariate analyses, only lower fat mass persisted as a risk factor for vertebral fractures (OR 1.23, 95% CI 1.04-1.47, p=0.012).

Conclusion: Present study showed a high frequency of densitometric osteoporosis, vitamin D deficiency, bone markers abnormalities sugestives of bone mineral defect and vertebral fractures shortly after HTx. Calcium and vitamin D supplementation should be the first step in correcting bone mineralization impairment, before specific osteoporosis treatment. Special attention should be given to patients with long length of hospitalization and low fat mass.

Table 2. CAD risk by FRAX and T scores (2) CAD risk by FRAX and T scores

genesis pathway. Bone health parameters are not yet incorporated in the cardiovascular risk assessment scale. The objective of our study was to look for an association between standard bone health scores and coronary artery disease (CAD) in our patient population.

Methods: A retrospective chart review of 1,134 patients who underwent cardiac catheterization between 2011 and 2017 at Jacobi Medical Center was performed. Patients between the age of 40 and 90 years who had a bone densitometry done within three years of the cardiac catheterization were included in the study. 106 patients met the inclusion criteria. Their baseline demographics, cardiac risks, and bone mineral density data were analyzed. Patients were categorized to have CAD if any of the epicardial coronary artery had ≥50% stenosis. Bone density levels were categorized by standard WHO classification. FRAX (Fracture risk assessment tool) scores were calculated using a validated online tool. Standard 10-year risk of hip fracture cut-off of 3% was used. Multivariate Logistic regression modeling was used to quantify the association between FRAX score and occlusive CAD. Variables were included in a multivariate model if they modified the association between the two by greater than 10%.

Results: Median age of the patients was 66.3 +/- 8.5 years and 91% were female. Thirteen percent of patients had a FRAX score ≥3%. Both groups were identical with respect to their demographic, metabolic, and cardiovascular risk profiles (Table 1). Standard secondary causes of osteoporosis were not different between the groups. Patients with FRAX score of ≥3% were 5.76 times more likely to have occlusive CAD in at least one of the coronaries than those with score of < 3% (OR 5.76; 95%CI 1.16-28.5, p< 0.032) after adjusting for age which is incorporated in the calculation of FRAX score. There was no association between bone densitometric T score and occlusive CAD (Table 2).

Conclusion: Bone health has shown to be an independent risk factor for angiographic CAD when adjusted for age in our patient population. Although the T score was not found to be significant, FRAX score adjusted for age of ≥3% was found to be strongly associated with significant angiographic coronary artery disease based on our data. Patients with FRAX score of ≥3% should be screened for CAD. Our observation warrants further research in this field.

Abstract Number: 2223

Attenuated Association Between Proton Pump Inhibitor Use and Fracture Risk After Consideration of Chronic Comorbidities

Liwei Wang,[1] Elizabeth Atkinson,[1] Hongfang Liu,[1] and **Shreyasee Amin**[1], [1]Mayo Clinic Rochester, Rochester, MN

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Proton pump inhibitors (PPI), which are often recommended in patients with rheumatic diseases due to frequent use of high risk medications such as NSAIDs or high dose steroids, have been associated with an increased risk for fractures. However, it is unknown whether associated chronic comorbidities contribute to the fracture risk observed from PPI use.

Methods: Using a unique medical records linkage system available in our community to undertake population-based studies, we identified 3433 community residents age ≥ 50 yrs (2269 [66%] women; 1164 men; mean age 70 yrs) who had any fracture during a 3-year period (2009-2011) and an equal number of age- and sex- matched controls from the same population who had no fractures in this time period. All fractures were validated and their antecedent cause determined by trained nurse abstractors through review of complete (inpatient and outpatient) community medical records. Using our unique resources enabling access to all medical records in the community, we identified PPI use as well as the Elixhauser Comorbidity Index (ECI) and its components in the 5 yrs prior to fracture/index date for both cases and controls. To determine whether the use of PPIs was higher among fracture cases than non-fracture controls after accounting for comorbidity differences, propensity score methodology was used to estimate inverse probability weights (IPW). The IPW were used with a weighted logistic regression model, further adjusted for age and ECI, to examine the association between PPI use (of at least 2 yrs) and fracture risk.

Results: PPI use was more common among fracture cases than non-fracture controls (35% vs 27%). Comorbidities were not only more common among fracture cases than controls (45% vs 33%, with at least 5 Elixhauser comorbidities), they were also more frequent among those who had used a PPI compared with those who had not (63% vs 34% in fracture cases, 51% vs 26% in controls). While the association between PPI use and increased fracture risk was attenuated in adjusted analyses, when compared with unadjusted analyses, it remained persistent but modestly elevated (unadjusted vs adjusted odds ratios (OR), respectively: OR: 1.50 [95% CI: 1.33-1.69] vs 1.18 [95% CI: 1.02-1.37] for any fracture; OR: 1.72 [95% CI: 1.44-2.05] vs 1.25 [95% CI: 1.01-1.55] for any major osteoporotic site [hip, spine, wrist, shoulder] fracture). We found similar results when considering only moderate trauma fractures (i.e. fractures due to a fall from a standing height or less) or any PPI use (data not shown). Using similar methods, we found no association between H2-blocker use and fracture risk (data not shown).

Conclusion: While we found an association between PPI use and increased fractures, this risk was more modest after accounting for associated chronic comorbidities, which is relevant when weighing the risks vs benefits of continuing PPI use.

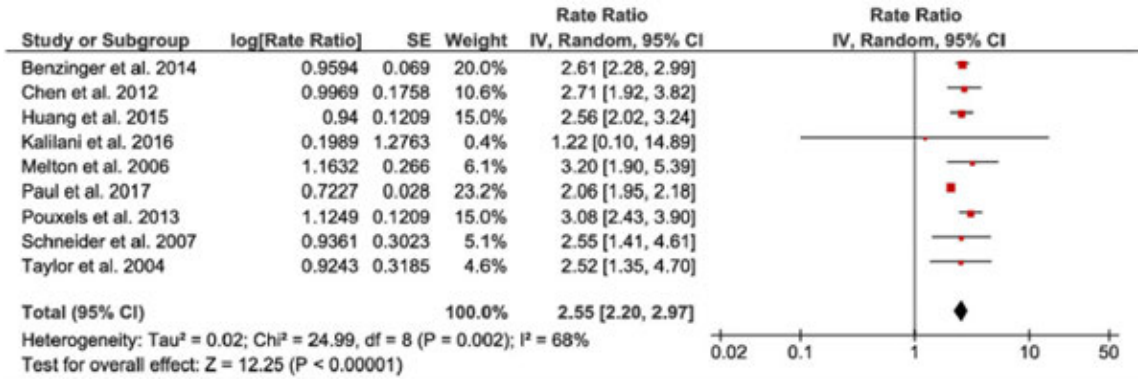
Parkinson's Disease and Risk of Fractures : A Meta Analysis of Cohort Studies

marion louvois,[1] stéphanie Ferrero,[1] Thomas Barnetche,[2] Christian Roux,[1] and Véronique Breuil[1], [1]university of nice, nice, France, [2]university of bordeaux, bordeaux, France

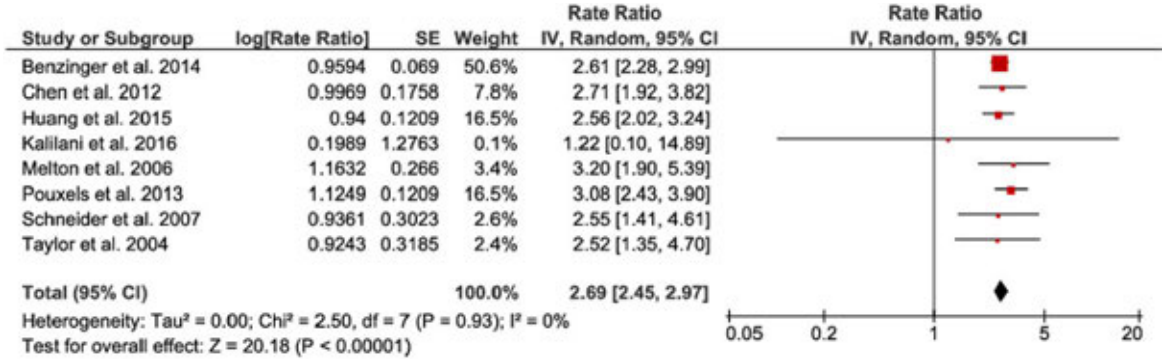
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Parkinson's disease is a common neurodegenerative disorder in older adults. Parkinson's patients have an increase risk of falls. More over, previous studies have shown a reduced bone mineral density related to multifactorial factors. A meta-analysis performed in 2014 suggested an increased risk of fracture in Parkinson's disease. The aim of this study is to update this previous meta-analysis to evaluate the association between Parkinson's disease and fracture's risk.



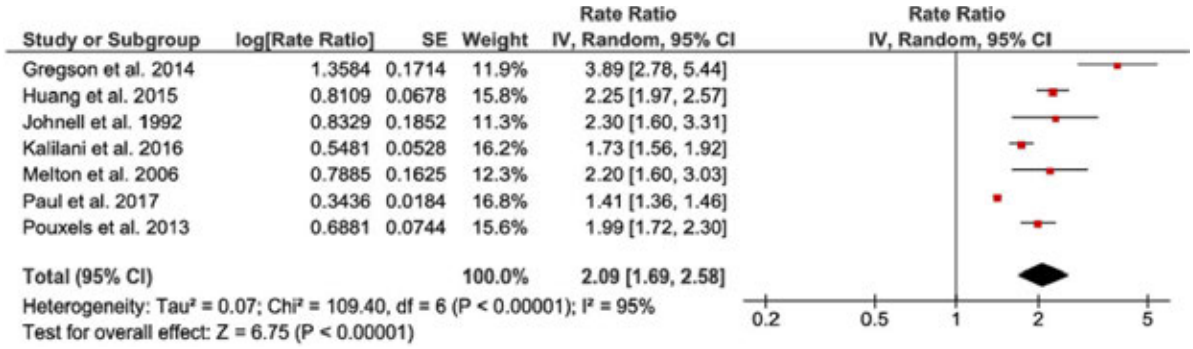
total fracture's risk

A Forest Plut of the association between Parkinson's disease and risk of fractures. The diamond represents the pooled RR and, the squares and the horizontal lines respectively represent the RR and 95% CI of each individual study.



sensitivity analysis hip's fractures

A Forest Plut of a sensitivity analysis of the the association between Parkinson's disease and hip fractures. The diamond represents the pooled RR and, the squares and the horizontal lines respectively represent the RR and 95% CI of each individual study.



total fracture's risk

A Forest Plut of the association between Parkinson's disease and risk of fractures. The diamond represents the pooled RR and, the squares and the horizontal lines respectively represent the RR and 95% CI of each individual study.

Methods: Eligible studies were search on PubMed, and Embase databases up to February, 2, 2019. Cohort studies, controlled or not, were selected. For each study, the authors extracted the risk of fracture for each anatomic site, or estimated it based on sample size and number of patients with fracture. Single risk ratios were then pooled to estimate a global risk ratio of fracture within a meta-analysis procedure using the inverse variance approach. Heterogeneity analysis was also performed with Cochran's Q-test and I^2value. RevMan software was used and p-value less than 5% was defined as significant.

Results: We included 13 retrospectives and propsectives cohort studies from the litterature's review. They involved 975646 participants. Parkinson's disease patients showed an increase fracture risk (RR globales fractures 2,09 $(1,69\text{-}2,58)_{95\%}$; I^2=95%). Especially hip fracture seems to be more frequent in Parkinson's disease population (RR hip fracture 3,13 $(2,36\text{-}3,15)_{95\%}$; I^2=68%). A sensitivity analysis was performed, excluding the study of Paul et al. which enrolled exclusively patients having fallen. This sub-analysis confirmed the increase of hip fracture risk with a negligible level of heterogeneity (RR 2.49 (2.45-2.97) $IC_{95\%}$; I^2=0%).

Conclusion: Our results confirmed the previous meta-analysis of an increased risk of fracture in Parkinson's disease, especially hip fracture recognized as a severe fracture associated with an increased morbidity and mortality. Currently, assessment of fracture's risk is not included in guidelines for Parkinson's disease patients care. Taking into account the increase risk of fracture, fracture's risk assessment should be recommended in Parkinson's disease adults.

Abstract Number: 2225

Systematic Osteoporosis Screening in Chronic Obtructive Pulmonary Disease (Study of Correlation Between Pulmonary Functions Tests and Bone Parameters): Emphysematous Status Is Linked to Low Bone Density and Osteoporosis

Olivier Malaise,[1] Cécile André,[1] Laurence Seidel,[2] Florence Schleich,[3] Renaud Louis,[3] and Michel Malaise[1], [1]Rheumatology department, CHU and University of Liège, Liège, Belgium, [2]Biostatistics department, CHU and University of Liège, Liège, Belgium, [3]Pneumology department, CHU and University of Liège, Liège, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic obstructive pulmonary disease (COPD) is usually considered as a risk factor for osteoporosis. However, COPD is an heterogeneous disease with different phenotypes, based on clinical and/or pulmonary function test classification. Our objectives are (1) to analyze the efficiency of a systematic osteoporosis screening in a COPD population (2) to analyze the clinical risk factor for OP in this population and (3) to correlate pulmonary function tests with bone parameters.

Methods: 90 consecutive COPD patients followed in pneumology ambulatory care were systematically included to have DEXA, VFA, blood analysis and pulmonary functiontests.

Results: 62% of the COPD patients were male, with a median BMI of 24.1kg/m2(14.5-44). 69% had a frequent use of glucocorticoids (maintenance inhaled or systemic and > 2 courses of systemic). 44% were active smokers. 26% of the COPD patients were identified as osteoporotic and VFA demonstrated an unknown vertebral fracture in 9%. Anti-osteoporotic drug was prescribed (or modified) in 32% after bone status investigation.

A low BMI was strongly associated with a low bone mineral density (BMD) and osteoporotic condition in lumbar spine, femoral neck and total hip (p< 0.0001). Active smokershad significant lower BMD and were more osteoporotic than ex-smokers at the three sites studied (p< 0.01). Female gender was associated to lower BMD for total hip and femoral neck only. Biologic bone turnover and D-vitamin levels were not associated with BMD, while glucocorticoid use (as defined by the FRAX) was only associated to total hip osteoporosis.

COPD severity based on FEV1 and FEV1/FVC ratio were not associated with bone weakness, with no link between FEV1 stratification and BMD. However, COPD phenotype modulated the bone strength: patients with complete emphysematous status (DLCO< 70%, DLCO/VA< 80% and CPT >115%) had significant lower BMD at lumbar spine, femoral neck and total hip (p< 0.05), with more osteoporosis at the hip (p< 0.01) and less normal condition (versus osteopenic and osteoporotic) at the lumbar spine and the femoral neck (p< 0.01). Of interest, there were more vertebral fracture on VFA and more history of hip fracture when DLCO was < 70%.

Conclusion: (1) Systematic screening for osteoporosis in COPD patients is efficient, with osteoporosis detection in 1/4, new vertebral fracture in 1/10 and a therapeutic intervention with anti-osteoporotic drug prescription in 1/3.

(2) Low BMI and active smoking were associated to osteoporosis in COPD patients. (3) COPD severity was not associated with bone loss, while the emphysematous status (association of 3 functional emphysematous characteristics: DLCO< 70%, DLCO/VA< 80% and CPT >115%) was correlated to bone weakness and osteoporosis. The “pink puffer” phenotype in COPD is at high risk for osteoporosis and should be particularly screened.

Factors Contributing to Fracture in Pernicious Anemia Patients Presenting with Symptomatic Subacute Vertebral Compression Fractures

Michael Lovy,[1] Nir Ben-Shlomo,[2] and Jacob Hattenbach[3], [1]Desert Oasis Healthcare, Palm Springs, CA, [2]Ben-Gurion Medical School, Beer Sheva, Israel, [3]College of Osteopathic Medicine of the Pacific, Pomona

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pernicious anemia (PA) has been associated with both low spine BMD and increased fracture risk in retrospective cohort studies. The cause of these observations is obscure. The purpose of this study is to describe and compare the clinical details of a cohort of PA patients who presented with subacute vertebral compression fractures (SVCF) to one without PA.

Methods: A retrospective cohort study was conducted from a population of 165 patients presenting with SVCF to an outpatient fracture clinic. The clinical characteristics of 30 PA patients diagnosed at the time of presentation, based on low vitamin B12 levels and the presence of either intrinsic factor (IF) or anti-parietal cell antibodies (APCA), was compared to the remaining 135 without PA. A complete history and physical exam including review of past medical records and current and past radiographs was performed. CBC, sedimentation rate, chemistry profile, TSH, urinalysis, vitamin B12, PTH, 25-OH vitamin D, and serum protein electrophoresis was done in all patients.

Results: There were 23 female and 7 male PA patients, ranging in age from 66-96 (mean 79.8 years) with a BMI of 15-31 (mean 25.3). 15 patients were taking thyroid hormone and 10 were on protein pump inhibitors (PPI). 16 patients had previous fractures. Fractures occurred after falling in 22, lifting in 3, and were spontaneous in 5. The location of the fracture was between T-11 and L-2 in 65% of the cases and 8 patients presented with multiple fractures. 25 out of the 30 patients with PA had evidence of peripheral neuropathy. IF was present in 17 patients, APCA in 5, and 8 had both. 25-OH vitamin D was < 20 ng/ml in 8 patients and PTH was >65 pg/ml in 6. A monoclonal gammopathy of undetermined significance (MGUS) was found in 6 PA patients. There was an increased incidence of peripheral neuropathy (p=0.002), 25-OH vitamin D < 20 ng/dl (p=0.01), use of PPI (p=0.006), thyroid disease (p=0.01), and MGUS (p=0.05) in the patients with PA. Age, gender, diabetes, previous fractures, BMI, PTH, fracture location, occurrence of multiple fractures, spontaneous fractures and those occurring with falling or lifting did not differ between the two cohorts.

Conclusion: This cohort of SVCF patients with PA had a higher incidence of peripheral neuropathy, vitamin D deficiency, PPI use, thyroid disease, and MGUS than SVCF patients without PA. These observations may explain the higher incidence of fractures and low BMD found in previous studies of PA patients.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hypophosphatasia (HPP) is caused by mutations in *ALPL,* resulting in low alkaline phosphatase (ALP) levels. The determination of ALPL mutation may not be accessible in clinical practice. In this case, an alternative simple method to predict the presence or absence of the mutation would be very useful. This study aimed to characterize the main clinical and laboratory features associated with the presence (HPP + GT) or absence (HPP – GT) of mutations in the *ALPL* gene among subjects with persistently low ALP levels.

Table 1. Demographic characteristics of study participants in each genetic group.

	HPP+ GT (N = 38)	HPP– GT (N = 45)	Total (N = 83)	*p* value
Age, Mean (SD) years	50.1 (14.9)	44.5 (10.5)	47.1 (13.0)	0.049
Female sex, No. (%)	22 (57.9%)	38 (84.4%)	60 (72.3%)	0.007
Race, No. (%)				
Caucasian	37 (97.1%)	45 (100.0%)	82 (98.8%)	0.274
Hispanoamerican	1 (2.6%)	0	1 (1.2%)	
Black	1 (2.6%)	0	1 (1.2%)	
BMI, kg/m^2 (SD)	25.9 (4.4)	22.7 (3.1)	24.2 (4.0)	0.0004

Methods: During this cross-sectional study, the laboratory reports from 386,353 people attending a Tertiary University Hospital from 2009 to 2015 were screened. 109 adult subjects with persistently low ALP values (≥2 measurements below or equal to 35 IU/L and none above 45 IU/L) were enrolled and 85 gave their consent for genetic testing. During one visit, a systematized questionnaire was performed to retrieve demographic, clinical and laboratory data and a genetic test to detect HPP was performed. Comparisons between groups were performed using the Student's *t*-test for unpaired data, if normally distributed; or Mann-Whitney U test, if not normally distributed. Logistic regression models adjusted for confounders were employed to investigate the association between clinical and laboratory characteristics and the presence/absence or ALPL mutation.

Results: Forty-seven percent (40/85) of subjects showed mutations in ALPL: 75% (30/40) were heterozygous for a pathogenic variant, 17.5% (7/40) for a likely pathogenic variant, 5% (2/40) for a variant of unknown significance (VUS) and one patient diagnosed of infantile HPP harbored compound heterozygous mutations. Demographic characteristics are shown in table 1. The presence of mutation was significantly associated with the presence of musculoskeletal pain (OR: 5.9; 95% IC: 1.7-20.5) and orthopedic surgery (OR: 4.8; 95% IC: 0.7-33.3). Metatarsal stress fractures were also more frequent in the HPP + GT group (4 vs 0, p=0.007). In terms of laboratory paramethers, ALP levels were lower in the HPP + GT group compared with HPP –GT group (24.2 vs 29.1 IU/L, $p < 0.0001$; respectively). Interestingly, levels below 25 UI/L showed a specificity of 97.8% and a positive predictive value of 94.4% to detect a positive genetic test.

Conclusion: In our cohort, ALP levels below 25 IU/L were identified as a very good predictor for the presence of mutations in ALPL. Furthermore, the presence of musculoskeletal pain and previous orthopedic surgery were also associated to a positive genetic test.

Association between clinical manifestations and genetic status.

Clinical feature	OR	95% IC	*p* value
Musculoskeletal pain	5.9	1.7 - 20.9	0.005
Fractures			
Peripheral fractures	1.5	0.5 - 4.2	0.444

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Table 1. Multivariable linear regression model evaluating the association of mean RA disease activity (DAS28ESR) on the outcome of femoral neck bone mineral density (gm/cm^2). (n=166, r^2=0.32).

Variable	β	95% CI	p-value
RA Disease Activity (DAS28ESR)			
Remission/Low	ref	--	--
Moderate	-0.054	-0.107 to -0.001	0.047
High	-0.052	-0.124 to 0.019	0.151

-95% CI = 95% confidence interval, RA = rheumatoid arthritis, DAS28ESR = Mean Disease Activity Score 28 Joints with Erythrocyte Sedimentation Rate.
-DAS28SER cut points: Remission/Low (<3.2), Moderate (3.2-5.1), High (>5.1).
-Analysis included the following covariates: age, sex, race/ethnicity, RA disease duration, high positive anti-CCP (defined as >60 units), weight, osteoporosis medication use (ever), mean prednisone dose, and use of biologic medications (proportion of visits where biologics were noted). Biologics include: TNF inhibitors, anti-IL6 agents, anti-CD20 agents as well as CTLA-4Ig.

Background/Purpose: Rheumatoid arthritis (RA) is an independent risk factor for osteoporosis (OP) and fracture. Although several OP risk factors are well-described in RA, many mechanisms by which the disease impacts bone mineral density (BMD) remain unknown. Measuring the direct contribution of RA disease activity on BMD is complicated by concomitant risk factors for BMD loss such as glucocorticoid treatment, inactivity and systemic inflammation. We evaluated the association of RA disease activity as measured by the Disease Activity Score 28 Joints with Erythrocyte Sedimentation Rate (DAS28ESR) and femoral neck BMD by dual energy x-ray absorptiometry (DXA), after controlling for known osteoporosis (OP) risk factors.

Methods: Data were from the University of California, San Francisco RA Cohort, an observational cohort established in 2006. In this cross-sectional analysis, all participants with femoral neck BMD and at least 1 DAS28ESR measurement were included. Mean DAS28ESR from study entry to date of DXA was calculated, and participants were placed into disease activity categories, based on validated cut-points (Remission/Low, Moderate and High). Mean values for other time-varying exposures from enrollment to DXA date were also calculated. Multivariable linear regression was performed to identify the independent association of DAS28ESR with BMD, controlling for age, race/ethnicity, RA duration, body weight, RA and OP medications, and high positive anticyclic citrullinated peptide (CCP) status (previously identified as an independent predictor of low BMD in RA).

Results: 166 participants with a mean age of 63±10.3 years; 87% female; 46% Latino and 35% Asian; and mean RA duration of 15±8 years were included. The majority were rheumatoid factor (RF) (n=145, 87%) and high anti-CCP positive (n= 109, 65%). The mean prednisone dose was 3.9±3.6 mg/day, 58% (n=97) were exposed to biologics and 57% (n=95) were exposed to OP medications over the course of the study. BMD categories based on femoral neck BMD were: 45% Normal BMD (n=76), 45% Low BMD (n=75), 10% OP (n=16). The distribution of DAS28ESR categories was: 20% low/remission (n=37), 60% moderate (n=100) and 18% high (n=30). In the multivariable model, moderate and high disease activity were both independently negatively associated with femoral neck BMD (β=-0.054 and -0.052 g/cm2 respectively), but only moderate disease activity achieved statistical significance ($p< 0.05$).

Conclusion: Controlling for known OP risk factors, higher RA disease activity is independently associated with lower BMD. These results suggest that treating RA patients to achieve the target of low disease activity or remission may improve BMD. Longitudinal studies are needed, however, to further explore these associations.

Differences in Fracture Risk Assessment (FRAX) and Osteoporosis Treatment Cutoffs with and Without Bone Mineral Density Are Greater in Anti-Cyclic Citrullinated Peptide Positive Rheumatoid Arthritis

Katherine Wysham,[1] Jonathan Graf,[2] Mary Margaretten,[2] Laura Trupin,[2] James Andrews,[3] Dolores Shoback,[2] and Patricia Katz[2], [1]Veterans Health Administration Puget Sound, Seattle WA, Seattle, [2]University of California, San Francisco, San Francisco, CA, [3]University of Washington, Seattle, WA

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: FRAX (Fracture Risk Assessment Tool) is the most commonly used tool to estimate 10-year fracture risk. FRAX estimates are performed with and without bone mineral density (BMD) measures; the BMD-adjusted FRAX (BMD-FRAX) provides a more sensitive estimate. In the United States, if FRAX major osteoporotic fracture (MOF) risk is ≥20% or the hip fracture risk is ≥3% or the T-score is ≤-2.5, then osteoporosis (OP) treatment is recommended. Rheumatoid arthritis (RA) is a risk factor for fracture in FRAX; however, RA is a heterogenous disease so it is important to identify which disease characteristics influence fracture risk. Anti-cyclic citrullinated peptide (CCP) positivity is thought to be a risk factor for lower BMD in RA. Our aim was to evaluate the difference in FRAX and BMD-FRAX estimates and OP treatment categories based on anti-CCP status.

Methods: Data were from the University of California San Francisco RA Cohort. All participants who had complete FRAX variable data and a DXA with a femoral neck BMD measure were included. Because OP medications improve BMD, thereby altering the risk of fracture, only OP medication naïve patients were included in the analysis. Participants were stratified by high positive anti-CCP status (dichotomized at >60 units to minimize heterogeneity of this group). Differences between FRAX and BMD-FRAX risk estimates were calculated for MOF and hip fracture. FRAX and BMD-FRAX based OP treatment categories were also compared.

Table 1: Average 10-year fracture risk assessment (FRAX) for major osteoporotic fracture (MOF) or hip fracture by anti-cyclic citrullinated peptide (CCP) status. FRAX calculations made with and without femoral neck bone mineral density (BMD). Osteoporosis (OP) treatment discordance and concordance comparing FRAX cutoffs[c] with and without BMD in the entire cohort as well as by anti-CCP status.

		High Positive anti-CCP[a]		
	All (N=56)	Yes (N=37)	No (N=19)	p-value[d]
10-year Fracture Risk by FRAX (%)				
MOF	8.0±5.9	7.9±6.2	8.2±5.4	0.83
MOF with BMD	8.6±9.2	9.4±10.8	7.2±4.3	0.42
Difference (MOF)[b]	0.6±5.2	1.5±6.1	-1.0±2.3	0.09
Hip	1.8±2.2	1.6±2.2	2.1±2.2	0.43
HIP with BMD	2.1±5.9	2.6±7.2	1.2±1.6	0.41
Difference (Hip)[b]	0.3±4.7	0.9±5.6	-0.9±1.6	0.16
Treatment threshold based on FRAX[c]:				
No Treatment Indicated for either	39 (69%)	26 (70%)	13 (68%)	--
No Treatment Indicated only with BMD-FRAX	3 (5%)	1 (3%)	2 (10%)	--
Treatment indicated only with BMD-FRAX	7 (13%)	6 (16%)	1 (5%)	--
Treatment Indicated for either	7 (13%)	4 (11%)	3 (16%)	--

CCP: cyclic citrullinated peptide; FRAX: Fracture Risk Assessment; MOF: Major Osteoporotic Fracture, BMD: Bone mineral density.
[a]- Anti-CCP positivity set at >60 units (3 times the upper limit of normal) to minimize heterogeneity in this group.
[b]- FRAX risk (%) with BMD minus FRAX risk (%) without BMD.
[c]- Osteoporosis treatment indications based on World Health Organization (WHO)- based FRAX 10-year risk cutoffs of ≥3% for hip fracture and ≥20% for MOF or a T-Score of ≤-2.5.
[d]-p-values derived from t-tests comparing groups with and without high positive anti-CCP.

Results: 56 OP medication naïve RA patients were included in this analysis. Subjects were 61.5±8.5years of age, 79% (n=44) were female and the majority were Hispanic (48%, n=27) or Asian (23%, n=13). Average disease duration was 11.9±8.9 years and mean Disease Activity Score 28 Joints with Erythrocyte Sedimentation Rate (DAS28ESR) was 3.9±1.2. The average prednisone dose was 3.3±4.5 mg/day. 66% (n=37) were categorized as high positive anti-CCP. No significant differences in RA disease characteristics were noted based on anti-CCP status. Individuals with high positive anti-CCP had a greater estimated fracture risk (MOF: +1.5±6.1%, Hip: +0.9±5.6%; See table) when FRAX was adjusted with BMD. Conversely, the group with lower anti-CCP values had decreased estimated fracture risk when BMD was added to FRAX (MOF: -1.0±2.3%, Hip: -0.9±1.6%), although these differences did not reach statistical significance. Changes in treatment category based on BMD-FRAX was supported in 18% (n=10) individuals; escalation of therapy was supported in 16% (n=6) of high positive anti-CCP individuals compared to 5% (n=1) in those with lower anti-CCP levels.

Conclusion: Adding BMD adjustment to FRAX scores increases the risk estimate in persons with high-positive anti-CCP levels but decreases the risk estimate in others. BMD-adjusted FRAX supports changes in OP treatment recommendations in nearly 1/5 of RA patients. Our data suggest that high positive anti-CCP individuals may represent a subset of the RA population who have an elevated risk for fracture that is not accurately captured in FRAX scores without BMD adjustment. Further studies in larger populations of OP medication naïve RA patients are needed to confirm these findings.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Applicability of FRAX in Clinical Practice. Results at 10 years

To evaluate the applicability of: 1) the fracture risk thresholds that we proposed in 2013 and 2) a new decision algorithm based on fracture risk calculated by FRAX.

Methods: In 2008, 853 women between 40 and 90 years old referred from Primary Care to the Bone Densitometry Unit were asked to complete a fracture risk factor questionnaire and underwent a bone density scanning (DXA). With FRAX, their absolute risk in the following 10 years of major fracture (MFR) and hip fracture (HFR) was calculated in the following 10 years.

In 2013, we published a proposal of thresholds of high (MFR ≥ 10%) and low (MFR ≤ 3.6%) fracture risk to identify the patients with medium fracture risk in whom a DXA would be indicated.

In 2018, the clinical course of the computerized history of Primary Care was reviewed to identify all bone fractures that occurred in 10 years. In case of doubts about the existence of a fragility fracture, its location or its mechanism of production, the emergency report and/or the bone X-ray was checked.

Results: The final sample is 837 patients; in 10, the follow-up is incomplete and 58 died. In 2008, the mean age of the patients was 61.95 (8.61) years. Eighty percent had at least one fracture risk factor. Twenty percent had normal BMD, 55% osteopenia and 25% osteoporosis. The mean MFR was 6.21% (5.39) and the HFR, 2.08% (3.20).

We identified 243 fractures (168 fragility and 75 traumatic fractures) in 153 patients. 124 patients had a MF (66 vertebral, 39 distal forearm, 10 hip and 9 humerus). Expected MF: 52. 64% of the patients who had MF did not have osteoporosis. 12 patients had a HF. Expected HF: 17.

The area under the ROC curve for MF prediction was 0.643 (95% CI: 0.592-0.694), low prediction capacity. For HR, 0.740 (95% CI: 0.632-0.849), moderate prediction capacity. For BMD in the three locations evaluated, the area was < 0.500, null predictive capacity.

The application of the proposed thresholds classifies appropriately the population with **low** (331 patients, 40% of the sample, incidence of fracture: 9.36%, 95% CI: 6.22-12.5), **medium** (357 patients, there would be recommended to perform a DXA in 42% of the sample; incidence of fracture: 16.25%, IC 95%: 12.42-20.07) and **high** (149, 18%, incidence of fracture: 23.49%, 95% CI: 16.68-30.30) fracture risk defined according to CAROC (< 10%, 10-20%, > 20%).

In patients with medium risk, reclassification to high risk was performed if they had osteoporosis or if the recalculated MFR including the BMD in FRAX calculation algorithm was ≥ 7%.

The result of the application of the algorithm was the classification of 574 patients (69%) as low risk (incidence of fracture: 10.98%, 95% CI: 8.42-13.53) and 263 (31%) as high risk (incidence of fracture: 23.19%, 95% CI: 18.09-28.29). The negative predictive value of fracture in patients classified as low risk is 89%.

Conclusion: The Spanish version of FRAX predicts adequately the HFR and can be used in clinical practice. On the contrary, it underestimates the MFR and should not be used to calculate it. However, in our series, the application of the proposed decision algorithm identifies properly the population with low, medium and high risk of fracture and could be used in clinical practice.

Abstract Number: 2231

Improving Compliance with Screening for Osteoporosis in Elderly Women

Asad Ullah,[1] Shaza Khalid,[1] Nagadarshini Vinod,[1] Asghar Marwat,[1] Ali Hussain,[1] Tom Simunich,[1] Medha Joshi,[1] and Lavanya Vuppu[1], [1]Conemaugh Memorial Medical Center, Johnstown

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: US Preventive Task Force (USPSTF) recommends screening for osteoporosis in women ≥ 65 years of age with dual-energy X-ray absorptiometry (DEXA) scan. There was inconsistent pattern of ordering DEXA scans for screening of osteoporosis at our internal medicine clinic (IMC) at Conemaugh Memorial Medical Center. The main aim of this study was to improve the compliance with screening for osteoporosis with DEXA scan at our IMC as per recommendations by USPSTF.

Methods:

- This is a quasi-experimental study with a pre and post intervention observational periods.
- Patients' medical charts from IMC at Conemaugh Memorial Medical Center were reviewed before an intervention period during which residents and clinic staff were educated regarding the importance of screening for osteoporosis and role of DEXA scans.
- Resident education sessions emphasizing the importance of screening for osteoporosis with DEXA scan were conducted twice a month for a period of 3 months. The need of DEXA screening in women ≥ 65 years, the correct interpretation of DEXA scans and the medication options for women diagnosed with osteoporosis or those with osteopenia who qualify for treatment were emphasized.
- Post intervention data was collected by reviewing patients' medical charts. Pre and post intervention data was compared to see if the above interventions resulted in improvement in compliance with screening for osteoporosis.

Results

- Data from our pre intervention phase showed that 72 women met criteria for osteoporosis screening. Based on our analysis, 32% (23/72) women appropriately received osteoporosis screening with DEXA scan.
- Post intervention data revealed that 58% (134/229) of patients that qualified for screening received DEXA scans.
- This observed 26% increase was statistically significant (P = .0002, z-test for significant difference between two independent proportions).

Conclusion: DEXA scans have been identified as the most sensitive screening test for osteoporosis. Based on the results of DEXA scans, patients can be started on medications like bisphosphonates which have been associated with a decreased incidence of fragility fractures. Our post intervention data has demonstrated a significant improvement in the osteoporosis screening practices of the IMC residents. The intervention measures used by us were simple, proved to be effective, and can be readily implemented in other primary care settings.

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster

Session Type: Poster Session (Tuesday)

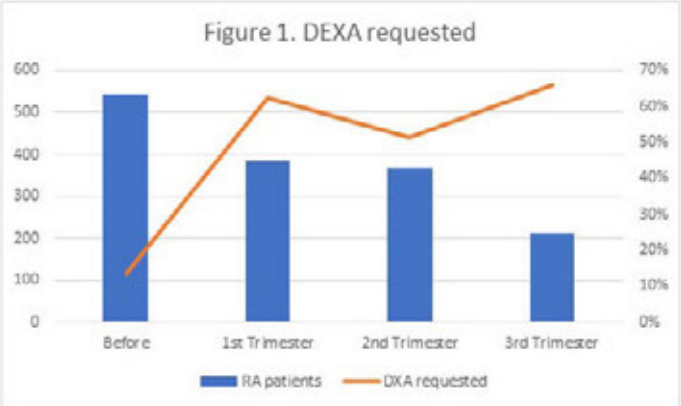
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a generalized skeletal disorder characterized by compromised bone strength and deterioration of quality, often leading to fragility fractures (1). People with rheumatoid arthritis (RA) are at increased risk of osteoporosis for many reasons (inflammation, use of glucocorticoids, inactivity, etc.) (2). Dual-energy x-ray absorptiometry (DEXA) is the recommended test for osteoporosis screening among patients with RA (3). As part of the "Integral Attention Program in Rheumatologic Patients" a program of "Bone Health" was developed. The purpose of this study is to describe the screening strategies implemented as part of this program and the results after implementation.

Methods: An algorithm was developed for the diagnosis and treatment of patients with risk factors for osteoporosis and was distributed among all the rheumatology fellows in the rheumatology clinic of the University Hospital "Dr. José Eleuterio González" in Monterrey, Mexico. To evaluate the diagnosis implementation of these algorithm among

Table 1. DEXA requested and reported among RA patients

	Before	1st Trimester	2nd Trimester	3rd Trimester
RA patients, N	543	384	369	211
DEXA requested, n (%)	73 (13.4)	240 (62.5)	190 (51.5)	139 (65.8)
DEXA reported, n (%)	-	44 (60.2)	146 (60.8)	114 (60)



RA patients, the electronic medical record (EMR) was consulted from February 2018 to January 2019 and data was grouped in trimesters (one trimester before the implementation and the next three afterwards) to get the number of DEXA requested among RA patients. To evaluate the accomplishment of requested DEXA, we obtained the number of reported DEXA registered in the EMR and divided between the number of requested DEXA the last trimester. From the total of RA patients every trimester, we subtracted the number of DEXA requested the last trimester. The results are reported as frequency and percentage.

Results: Before the Bone Health program was applied, of the 543 RA patients consulted, only 73 (13.5%) DEXA studies were requested. During the first trimester of the program from 384 RA patients, 240 (62.5%) DEXA were requested and 44 (60.2%) were reported. During the second trimester among 369 RA patients, 190 (51.5%) DEXA were requested and 146 (60.8%) were reported. Finally, during the third trimester among 211 RA patients, 139 (65.8%) DEXA were requested and 114 (60%) were reported. (Table and Figure 1).

Conclusion: The development and implementation of a bone health program with a systematic methodology and the diffusion of these strategies among the rheumatology fellows improved three-fold osteoporosis screening. We should continue working to guarantee that all the patients with risk factors for osteoporosis get a complete evaluation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Since March 2009, every patient who was admitted in the Orthopaedic Surgery Department for a hip fracture (HF) was evaluated during the admission period by a Hip Fracture Unit (HFU). The assessment included the risk of fracture and diseases related to bone fragility other than osteoporosis. In the discharge report, a mention of the risk of fracture and the previous treatments as well as a treatment recommendation were done. An electronic prescription was made for the advised treatment. An appointment in the next 3 months in the HFU outpatient clinics was set to monitor treatment adherence.

Purpose: To evaluate the incidence of HF in an 18 year period and the efficacy of the intervention made by the HFU in the incidence of second hip fracture (SHF).

Methods: From the area hospital discharge database of a teaching hospital between 1st of January of 2000 and 31st of December of 2017, the admissions for HF and SHF from the patients that lived in the reference area of the hospital were analyzed. A SHF was defined as the contralateral HF to a previous HF. SHF were only included if data from the previous HF was available. Two periods of study about 9 years long each were defined: a control period and an intervention period, before and after 1st of March 2009, the date when HFU started working. The rest of the items of the study were: sex, age, age at the time of HF and time of follow-up until SHF or the end of the study. Data about the reference population were accessible in the website of IDESCAT (Catalonian Institute of Statistics: http://www.idescat.cat/pub/). During the period of study, the subjects older than 65 years increased a 33%, from 48,606 to 64,396 inhabitants (31% women, 35% men).

Results: During the 18 years of the study, there were 2,625 patients > 65 years old admitted because of a HF (1,952 women and 673 men, ratio 2.9:1). The annual incidence of HF in this period was 257 fractures for 100,000 inhabitants and year (x 100 K/y) (333 x 100 K/y in women and 154 x 100 K/y in men).

The absolute number of hip fractures increased during the study period in women and in men with significant statistical difference ($p < 0.05$ women, $p < 0.001$ men). The incidence of HF has been stable in women and has increased in men ($p < 0.05$).

The patients included in both study periods were different in age and sex: in the intervention period there were more men (29% vs. 26%, $p < 0.05$) and they were older (83 ± 7 years, $p < 0.001$).

In the study period, 133 SHF were admitted (5.06% of fractures). There were 87 SHF which took place in the 1,143 patients who presented a HF during the control period (7.61%) and 46 in the 1,313 (3.50%) during the intervention period (p: ns). There were 244 patients who died during the admission and were excluded from the SHF study.

There were no differences in sex between patients who presented a SHF or those who did not. Patients with SHF were older than patients without SHF (86 ± 7 years vs. 83 ± 7 years, $p < 0.001$).

Conclusion: In a teaching hospital, the incidence of HF has remained stable in the last 18 years in women and has increased in men. After 9 years of a HFU intervention, we could not demonstrate a reduction in the incidence of SHF.

Osteoporosis Screening in a Resident-Driven Clinic of a Large Academic Hospital

Anam Umar,[1] Titilope Olanipenkun,[1] Hiu Sze Kwong,[1] Chelsy Harris,[1] Amber Faquih,[2] Muhammad Bilal,[1] and Chinedu Ivonye[1], [1]Morehouse School Of Medicine, Atlanta, [2]Emory University School Of Medicine, atlanta

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is associated with fragility fractures and represents a significant public health problem. The United States Preventive Services Task Forces (USPSTF) recommend dual-energy x-ray absorptiometry (DEXA Scan) of the hip and lumbar spine for osteoporosis screening in females aged 65 years and older. However, despite these recommendations, studies show that the screening rate remains suboptimal. Additionally, African-American females relative to other ethnic groups have been shown to have lower screening rates despite the higher risk of mortality following hip fractures. In teaching hospitals, internal medicine resident form an integral component of patient care and provide consultations to a significant proportion of patients in the primary care clinic. Hence, the objective of this study was to determine the screening rate for osteoporosis and identify factors that affect screening in a resident-driven clinic.

Methods: We selected through simple random sampling, 1,118 female patients aged 65 and older that visited one of the out-patient departments of Grady Memorial Hospital, Atlanta between July 1, 2017, and June 30th, 2018. Data was extracted from the electronic medical record (EMR) system. Osteoporosis screening rate was determined. Patients were asked to complete a questionnaire on reasons for not getting screened. We surveyed 20 internal medicine residents regarding their knowledge of osteoporosis screening and factors that influence their decisions. Two-sided P-value < 0.05 was considered statistically significant.

Results: Osteoporosis screening rate using DEXA scan was 37%(n=402). However, there was a disparity in screening rates by ethnic groups; African Americans (33%), Asians(78%), Caucasians(69%) and Hispanics(80%). Patients aged 65-75 years were more likely to have screening compared with age >75 (AOR 1.47 CI 1.04-3.16, P value< 0.005). Caucasians, Asians, and Hispanics were more likely to have screening compared to African Americans (AOR 1.29, CI 1.16-4.23, P value < 0.005). 81% (n=583/716) of the patients without screening did not have a scan ordered by their physicians. In cases where the scan was ordered but not done, identified reasons included lack of patients' knowledge regarding importance of screening (43%), scheduling and transportation issues(52%), and inability to afford the test (3%). More than 50% of surveyed residents cited inadequate knowledge of the screening recommendations and not remembering to discuss screening with patients and subsequently placing the order.

Conclusion: Our study provides information on the osteoporosis screening rate in a resident-driven clinic of a large academic hospital. We found the presence of racial disparities consistent with what has been previously reported in the literature. Interestingly, it appears that resident physician provider-related factors primarily drive the sub-optimal osteoporosis screening rates. We propose that education on the screening guidelines should be consistently provided to resident physicians involved in the care of these patients. Also, incorporating reminder alerts and patient education materials in the EMR system might improve the screening uptake and rate.

Osteoporosis Screening in African American Patients of Rheumatoid Arthritis Patients: Are We Doing Enough?

Anam Umar,[1] Eric Chang,[1] Martin Campbell,[1] Hiu Sze Kwong,[1] Elyse Steven,[1] Amber Faquih,[2] Muhammad Bilal,[1] and Ivonye Chinedu[1], [1]Morehouse School Of Medicine, Atlanta, [2]Emory University School Of Medicine, atlanta

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Osteoporosis & Metabolic Bone Disease – Basic & Clinical Science Poster – ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoporosis is a well-known extra-articular complication in rheumatoid arthritis (RA) patients It is more common in patients with RA than in the general population, due to active systemic inflammation, the use of corticosteroids, and lack of mobility. The prevalence of concurrent osteoporosis in RA patients is 50% The International Society for Clinical Densitometry (ISCD) and National Osteoporosis Foundation (NOF) has recommended dual-energy x-ray absorptiometry (DEXA) testing for all adult RA patients due to their high-risk status. However, a significant percentage of RA patients do not undergo DEXA scan despite these recommendations. Our aim was to assess osteoporosis screening rates in African American patients with RA.

Methods: Patients with a diagnosis of RA who visited a primary care clinic of Grady Memorial Hospital between July 1, 2017, and June 30th, 2018 were included (n=132) Data were extracted from the electronic medical record (EMR) system. We obtained data regarding the diagnosis of low bone marrow density in terms of osteoporosis and osteopenia through dual-energy x-ray absorptiometry (DEXA Scan) of the hip and lumbar spine. Medication use included steroids, methotrexate, leflunomide, azathioprine, hydroxychloroquine, adalimumab, and any other disease-modifying antirheumatic drugs. STATA software was used and two-sided P-value < 0.05 was considered statistically significant.

Results: Out of 132 patients (74% females, 98% African American, median age 55), only 60 patients had a DEXA scan on file. Of these 60 patients, 50% had low bone marrow density. Osteoporosis and osteopenia prevalence were 40% (24/60) and 10% (n= 6/60) respectively. 43% (N =57 people) were on steroids at the time of data collection and had indications for osteoporosis screening based on the American College of Rheumatology's guidelines but only 30% had a DEXA scan on file. Out of 24 patients, who had osteoporosis, 50% (n=12/24) were on bisphosphonates and 33% of them had repeat DEXA scan in 2 years. The patients who were on steroids were more likely to have screening done as compared to patients who were not on steroids. (OR=2.29 CI 1.1-4., p=0.0234). The patients' age 50-60 were less likely to have DEXA scan on file compared to patients age > 60 (OR=0.29 CI 0.1-0.7 P = 0.01). There was no statistically significant difference in DEXA screening rates between patients with multiple comorbidities versus patients with RA only or patients with low vitamin D versus normal vitamin D.

Conclusion: Our study provides information on osteoporosis screening in predominantly African American RA patients. About half of RA patients for whom treatment was indicated never received an Osteoporosis medication. Our study shows the improper implementation of guidelines in our high-risk patient population which is consistent with previous studies. The results of this audit will make us more vigilant to identify those patients who need DEXA scanning to ensure that treatment is efficacious. Future goals are to set up a resident-driven intervention to not only educate providers about the increased risk of osteoporosis in RA patients but to also increase guideline compliance rates.

Strength Training for People with Rheumatoid Arthritis: Barriers, Facilitators, and Tailoring Considerations

Jasmin Ma,[1] Jon Collins,[2] Eileen Davidson,[2] Kelly English,[3] Alison Hoens,[4] Karen Tsui,[5] Shanon McQuitty,[2] Louella Sequeira,[3] and Linda Li[4], [1]Arthritis Research Canada/University of British Columbia, Vancouver, Canada, [2]Arthritis Research Canada, Richmond, Canada, [3]Arthritis Research Canada, Richmond, [4]University of British Columbia, Vancouver, BC, Canada, [5]Arthritis Patient Advisory Board, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Strength training (ST) rates in people with rheumatoid arthritis (RA) are remarkably low (1-14%), reducing the potential health benefits of ST for this population (e.g., decreased fatigue, pain, muscle wasting, and inflammation). Compared to studies of factors that affect physical activity more broadly, studies on factors that affect ST in the general population are sparse; these studies are non-existent in RA. The purpose of this study was to examine patient-identified barriers, facilitators, and tailoring considerations for designing interventions to improve ST participation among people with RA.

Methods: Purposive sampling was used to include people with varying age (< /=40 vs >40), gender (male vs female), geographic location (rural vs urban), ST experience (none, less than the general population guidelines, meeting or exceeding the guidelines), and perceived RA severity (well-controlled/mild, moderate, severe). Semi-structured interview questions were co-developed with nine patient partners. Questions were iteratively modified to reflect new knowledge gleaned from interviews that were coded at mid-way points throughout data collection. Interviews were recorded and transcribed verbatim. We performed inductive thematic coding with the de-identified interview transcripts. Peer checking amongst researchers and patient partners was conducted to ensure credibility. We continued the interviews until content saturation was reached in the analysis.

Results: 13 participants were recruited through social media and email advertising across Canada (age range=25-70, male=3, rural=2, no ST experience=5, moderate-severe self-reported RA severity=6). Participants identified two barriers that were unique to the RA population. First, cognitive demand was an important barrier that was exacerbated by both disease/medication side-effects (e.g., 'brain fog' and poor memory) and increased focus required to perform ST compared to aerobic exercise (e.g., counting sets, reps, remembering the individual exercises and their techniques). Second, participants identified a knowledge gap in how much ST can be safely performed given their disease and how to distinguish between ST pain and RA pain. Several participants suggested the use of memory aids (e.g., videos, written programs) could assist in clarifying the steps to performing ST. Many also felt that RA-specific ST guidelines would be useful to improve understanding of how much ST is appropriate. When developing tailored programs, participants highlighted the need to understand their unique situation by probing for goals, motivators, barriers, available time and resources, abilities and limitations, and preferred environment, activities and communication style.

Conclusion: Our results revealed challenges to ST that were unique to people with RA. Participants also identified potential opportunities for developing tailored interventions for supporting ST participation. These findings have also provided a foundation for testing hypotheses that explore the mechanisms for improving ST behaviour in this population.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

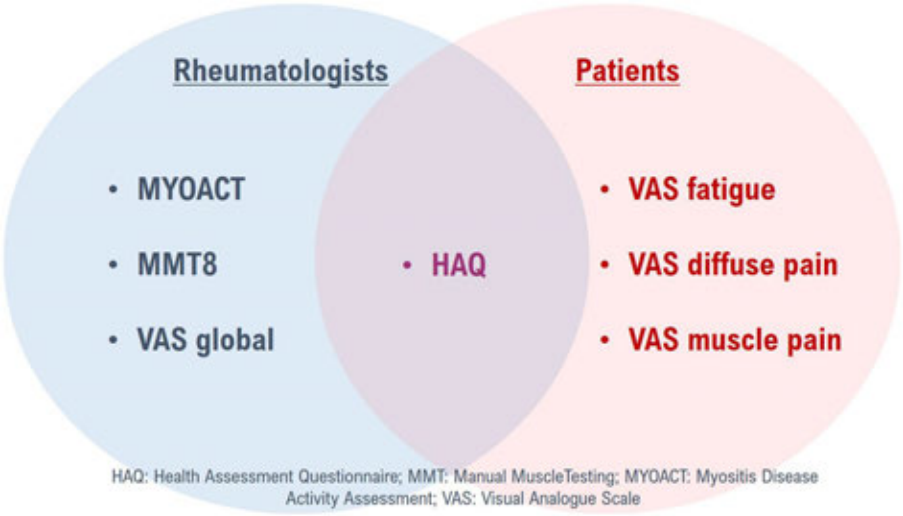
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Treat-to-target (T2T) strategy has become the best approach to treat several rheumatic disorders. However, most targets are only based on specialists' opinions, which may not reflect exactly the main patients' concerns during treatment. There is evidence that switching to a more patient-centered healthcare system seems to enhance treatment adherence and improve outcomes. Therefore, the purposes of this research were: a) to assess the concerns of the patients with systemic autoimmune myopathies (SAMs) during follow-up and compare to the rheumatologists' concerns; b) to gather patients' and physicians' concerns to develop a SAMs outcome standard set.

Methods: From 2018 to 2019, total of the 93 consecutive adult patients with SAMs (49 dermatomyositis and 11 polymyositis - EULAR/ACR 2017, and 33 anti-synthetase syndrome - Connors et al., 2010) and 51 rheumatologists from a tertiary center were invited to answer a standardized questionnaire. Initially, an open questionnaire was applied in order to assess unbiased concerns of both groups. Thereby, the top 10 answers were selected and applied a multiple-choice questionnaire, inquiring the top 3 major concerns. Answers of each group were plotted into charts



and frequencies were compared. The agreement rate was calculated by the sum of lowest frequency of each concern. Concerns were gathered in a SAMs outcome standard set, following the methodology proposed by the International Consortium for Health Outcomes Measurement (ICHOM). We also evaluated if the patients' concerns were associated with any current clinical features, previous manifestations or comorbidities.

Results: The top three concerns raised among the patients were: to avoid side effect of medication (51%), to improve muscle weakness (49%) and to prevent loss of functionality (35%). The top three concerns among rheumatologists were: prevent loss of functionality (71%), ensure quality of life (63%) and achieve disease remission (63%). The agreement rate between both groups was 41%.The patients' concerns that rheumatologists did not mention were respectively the improvement of: muscle pain (33% vs. 0%, P=0.001), diffuse pain (25% vs. 0%, P=0.001), skin lesions (23% vs. 0%, P=0.001) and fatigue (18% vs. 0%, P=0.001) - all symptoms related worries. The rheumatologists' concerns that patients did not mention were respectively the: achievement of disease remission (63% vs. 0%, P=0.001) and prednisone dose (0% vs. 22%, P=0.001). The concerns of pain and fatigue were not associated with other diagnosis such as fibromyalgia or depression/anxiety. Gathering both point of view, we developed a SAMs outcome standard set **(Figure 1)**.

Conclusion: Even though functionality and muscle weakness are still major concerns for physicians and patients, there are additional patients' concerns that should be assessed routinely during SAMs treatment and follow-up. Patients consider that controlling pain and fatigue are important outcomes to be pursued in SAMs and rheumatologists should be aware of these to provide a better assistance and ensure treatment adherence.

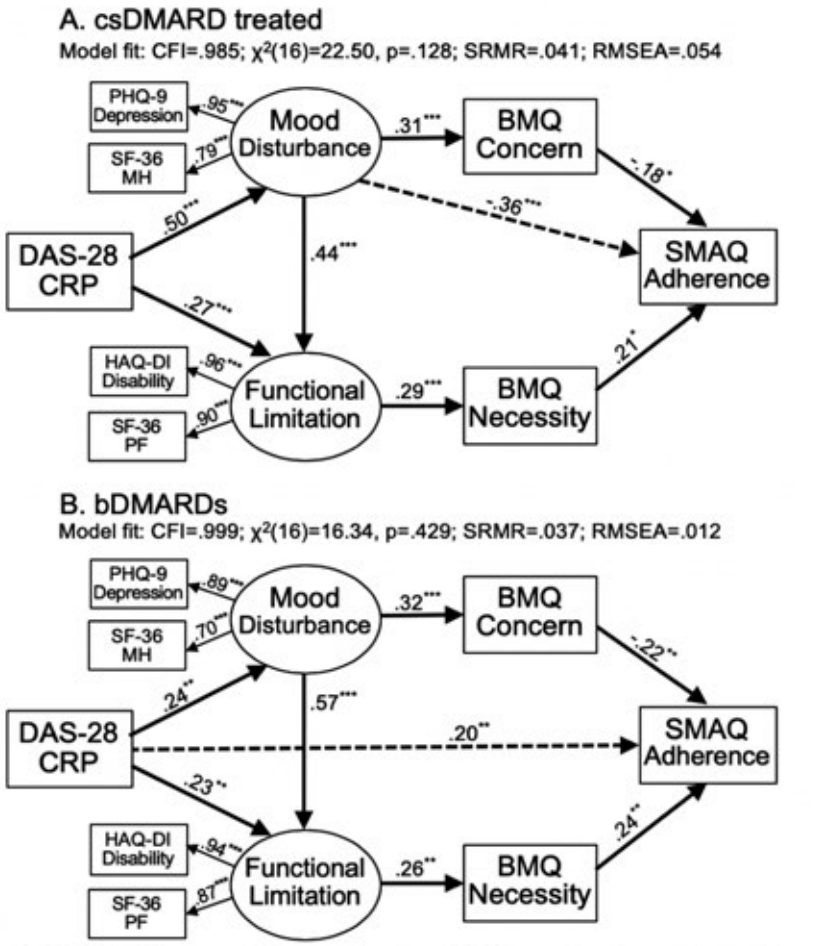
Role of Clinical Impact, Disease-specific Knowledge and Beliefs About Medication on Therapeutic Adherence in Rheumatoid Arthritis: An Integrative Structural Equation Modeling Approach

George Karpouzas,[1] Elizabeth Hernandez,[2] Lorena Ruiz,[3] Vibeke Strand,[4] and Sarah Ormseth[1], [1]Harbor-UCLA Medical Center and Los Angeles Biomedical Institute, Torrance, CA, [2]Harbor-UCLA and Los Angeles Biomedical Institute, Torrance, CA, [3]Harbor-UCLA andLos Angeles Biomedical Research Institute, Torrance, [4]Division of Immunology/Rheumatology, Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of rheumatoid arthritis (RA) to remission optimally ensures control of symptoms, prevention of structural damage, optimization of function and quality of life. Adherence to medical treatment is, therefore, critical for a comprehensive and successful management of RA. We interrogated the influence of distinct domains of RA clinical impact (disease activity, functional limitation, mood disturbance), RA-specific knowledge and patients' beliefs about medications on treatment adherence.

Figure 1: Contributions of clinical RA impact and beliefs about medication on therapeutic adherence.



DAS28-CRP: Disease activity score based on 28-joint count and c-reactive protein, PHQ-9: 9-item patient health questionnaire, SF-36 MH: Short Form 36 Health Survey mental health scale, HAQ-DI: health assessment questionnaire-disability index, SF-36 PF: Short Form 36 Health Survey physical function scale, BMQ: beliefs about medication questionnaire, SMAQ: Short medication adherence questionnaire.
*p<0.05, **p<0.01, ***p<0.001.

Methods: We evaluated 285 patients from a single center. In the proposed model, disease activity (DAS28CRP),mood disturbance (Patient Health Questionnaire-9 depression scale and SF-36 Mental Health domain), functional limitations (Health Assessment Questionnaire Disability Index and SF-36 Physical Function domain) and RA-specific knowledge (Patient Knowledge Questionnaire) were expected to predict beliefs about the necessity of RA medications and concerns about them (Beliefs about Medicines Questionnaire); in turn, those would impact adherence (Simplified Medication Adherence Questionnaire). Cross-sectional multi-group structural equation modeling evaluated the model separately in patients on bDMARDs on csDMARDs.

Results: RA-knowledge was not associated with medication beliefs or adherence and therefore dropped from the model. Addition of two supplementary paths (dashed lines) improved the model fit for both treatment groups (Figure 1). RA activity, functional limitations and mood disturbance influenced adherence via multiple, often competing pathways, directly or indirectly through a necessity/ concerns evaluation by the patient. RA activity directly promoted adherence in patients on bDMARDs ($p< 0.01$). In contrast, in patients on csDMARDs, RA activity had an indirect, net negative effect on adherence ($p< 0.01$), mainly through worsening mood disturbance ($p< 0.01$). Therefore, the experience of disease activity in patients on bDMARDs may be sufficiently impactful to independently promote med-

ication adherence.In contrast, RA activity may be largely experienced as depressed mood in patients on csDMARDs, overwhelming their capacity to adhere. Mood disturbance adversely influenced adherence directly in patients on csDMARDs ($p< 0.01$); yet there was no significant direct or net indirect effect of mood disturbance on adherence to biologics. Functional limitations fostered adherence through enhanced awareness of medication necessity ($p< 0.05$).

Conclusion: Distinct domains of clinical RA impact influence treatment adherence directly or indirectly through a necessity/ concerns framework. Mood disturbance and medication concerns may represent complementary yet salient intervention targets of RA management promoting adherence; the former may be more relevant in patients on csDMARDs whereas the latter in those on bDMARDs.

Reproductive Health Awareness and Needs: Assessment of Parents, Female Adolescents, and Young Adults with Pediatric Rheumatic Diseases

Veronica Mruk,[1] Kristine Carandang,[2] Megan Clowse,[3] Stacy Ardoin,[4] Elise Berlan,[5] and Cuoghi Edens[6], [1]Nationwide Children's Hospital / The Ohio State University, Columbus, OH, [2]University of California/Child and Adolescent Services Research Center, San Diego, CA, [3]Duke University, Durham, [4]Nationwide Children's Hospital/ The Ohio State University, Columbus, OH, [5]Nationwide Children's Hosptial / The Ohio State University, Columbus, OH, [6]University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The diagnosis of a pediatric rheumatic disease comes with worries for both parents and patient; one that may be overlooked is the impact on long- and short- term reproductive health, including the impact of the disease and treatment on fertility, pregnancy, and contraception. Little exploration has been done to assess the reproductive health needs and concerns of this population. We sought to identify areas of concern regarding reproductive health, topics in which pediatric patients/parents need more information, barriers to current knowledge, current sources of knowledge, and suggestions for ways to distribute information.

Methods: Females 15-20 years old diagnosed with any rheumatic condition and their parents were recruited from a children's hospital rheumatology clinic. Participants completed a survey collecting demographics, diagnosis, rheumatic medications, sexual activity, and contraception use and engaged in one of three focus groups: two age-specific patient groups and one parent group. Each audio-recorded focus group was professionally transcribed and coded using constant comparative analysis.

Results: A total of 9 patients and 7 parents participated. The majority of patients were Caucasian (n=7; 78%) and carried the diagnosis of JIA (n=6; 67%), with a small representation of systemic lupus (n=2; 22%) and vasculitis (n=1; 11%). Two-thirds of participants were on teratogenic medications. 11% of patients were sexually active, 55% of total subjects were using contraception. In the parent group, over 50% had some level of college education and household incomes over the median national average.

All focus groups expressed concerns about the interaction of rheumatic medications with contraception and fertility. Worry surrounding the effect of rheumatic conditions and medications on fertility, repercussions of future pregnancy on patients' and potential offspring's health, and motherhood was widespread. Participants reported varied levels of reproductive health education, ranging from none to in-depth discussions with fertility specialists, with a general agreement of dissatisfaction with currently available resources and the attention to rheumatic disease and reproductive health. Overall, rheumatology providers were not named by any of the focus groups as a consistent resource for reproductive health information.

Conclusion: Reproductive health is an important topic to female adolescents and young adults with rheumatic diseases, and their parents. The most prominent concern for all groups was medications' impact on many aspects of reproductive health. Young women and their parents were dissatisfied with the availability, quantity, and quality of reproductive health information related to pediatric rheumatic disease. Rheumatologists should re-consider our role in the reproductive health discussion, and seize the opportunity to improve the communication and education of this issue in our clinical practice.

Abstract Number: 2240

Mining Social Media Data to Investigate Patient Perceptions Regarding DMARD Pharmacotherapy for Rheumatoid Arthritis

Chanakya Sharma,[1] Samuel Whittle,[2] Pari Delir Haghighi,[3] Frada Burstein,[3] Roee Sa'adon,[4] and Helen Keen[1], [1]Fiona Stanley Hospital, Perth, Australia, [2]The Queen Elizabeth Hospital, Adelaide, Australia, [3]Monash University, Melbourne, Australia, [4]Treato, Or Yehuda, Israel

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our hypothesis is that patients have a positive opinion regarding the newer, biologic DMARDs and a negative sentiment towards the conventional synthetic agents. We sought to analyse discussions on social media platforms regarding DMARDs so understand the collective sentiment expressed towards these medications.

Methods: Treato data analytics were utilised to download all available discussions on social media about DMARDs in the context of Rheumatoid arthritis. Strict filters were used to ensure that only user (patient) generated content was downloaded. The sentiment (positive or negative) expressed in these posts was analysed for each DMARD using the Natural Language Processing technique of Sentiment Analysis. We then further analysed the reason for this sentiment for each DMARD, looking specifically at the categories of efficacy and side effects.

Results: Sophisticated computer generated algorithms analysed hundreds of millions of posts and finally included 54,742 social media discussion about csDMARDs and bDMARDs. The overall ratio of positive comments to negative comments was higher for bDMARDs (1.296) than for csDMARDs (1.079). Tofacitinib had the highest ratio of positive to negative comments (1.71) whereas sulfasalazine had the lowest (.97). Methotrexate was the only other agent with an overall negative ratio (0.995), primarily due to concerns regarding side effects. Efficacy was the main reason for a positive sentiment and lack of efficacy was the most common reason for a negative sentiment. Side effects however also played a significant role in generating a negative sentiment especially about the csDMARDs. Most common emotions associated with a negative sentiment were a sense of hopelessness along with fear and uncertainty.

Conclusion: Public opinion as expressed on social media is generally positive about the bDMARDs. Lack of efficacy is the biggest reason for a negative sentiment towards a medication, which often leads to a sense of hopelessness. A sense of fear and uncertainty play a role in generating this sense of hopelessness. Clinicians should be aware of this when dealing with patients who have failed a DMARD and provide cognitive reassurance to mitigate the pessimistic feelings that the patient might be experiencing.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: While juvenile myositis (JM) can negatively affect quality of life, studies of the emotional health needs of youth with JM are limited. We examined parent perspectives on emotional health needs and interventions for youth with JM.

Methods: Six focus groups (60 minutes each, audio-recorded, transcribed verbatim) of parents of youth ages 6-21 years old with JM were conducted at the 2018 CureJM National Family Conference. Parents were grouped by their child's age (6-12yo, 13-17yo, 18-21yo), with 2 focus groups per age range. Note takers in each focus group assisted with documentation of nonverbal cues by participants. At the start of each focus group, parents listed 3 words/phrases encapsulating JM-related emotional health challenges, which were then discussed in detail. Screening approaches and desired interventions were discussed. Using an a priori coding scheme, interview transcripts were independently coded using the constant comparison method and Dedoose software, with subanalysis by age group. Preference for emotional health interventions was also assessed via Likert scale (1 = very undesirable, 5 = very desirable). The study was approved by Children's Hospital of Philadelphia Institutional Review Board (IRB 18-015225).

Table 1: Parent demographics and reported child characteristics

Parents (n = 45)*	
Female, n (%)	38 (84%)
Race/Ethnicity, n (%)	
• White	43 (96%)
• Non-White**	2 (4%)
• Hispanic/Latino	4 (9%)
Child (n = 39)**	
Female, n(%)	29 (74%)
Mean age, years (SD)	13.7 (4.6)
Age group, n (%)	
• 6 to 12 years old	17 (44%)
• 13 to 17 years old	13 (33%)
• 18 to 21 years old	9 (23%)
Mean age disease onset, years (SD)	7.9 (4.6)
Mean disease duration, years (SD)	5.8 (4.7)
*Six parent couples participated total **non-white included: Asian (n = 1), other (n = 1); youth Asian (n = 1), other (n = 4)	

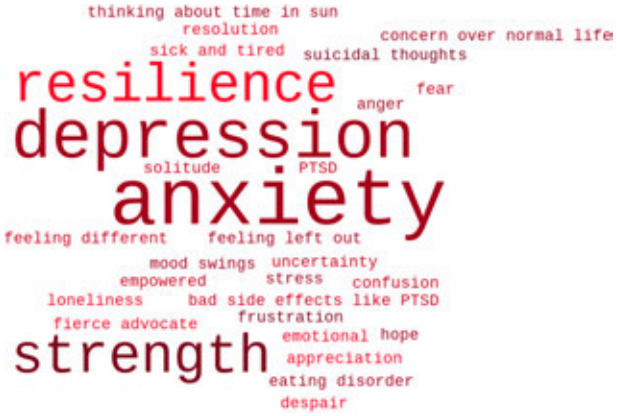

Figure 1. Parent-reported emotional health experiences of youth with juvenile myositis (word cloud, with size of word/phrase corresponding to listed frequency)

Results: Demographics are shown in Table 1. Parents commonly reported depression/anxiety as challenges, though strength/resiliency also emerged especially in older groups (Figure 1). Themes from the focus groups related to emotional challenges included impact of JM diagnosis, impact of JM on siblings/family dynamic, resiliency, and parental emotional health. Themes related to screening/intervention included perceptions that youth with JM may not always openly report distress, barriers to treatment (e.g. lack of access), desired interventions (e.g. technological modalities, peer support), and the role providers play in eliciting a history of emotional distress and providing access to emotional health resources. Parents strongly desired counseling and peer support groups for their children with JM (Figure 2).

Conclusion: Youth with JM and their family members experience substantial emotional challenges, with limited access to interventions. Resiliency in older age groups suggests coping may occur over time. Further studies should assess youth perspectives on emotional health in JM, as well as preferences for and efficacy of interventions.

Evaluating Important Change in Cutaneous Disease Activity as an Efficacy Measure for Clinical Trials in Dermatomyositis

Sarah Ahmed,[1] Srita Chakka,[2] Rebecca Krain,[3] Rui Feng,[4] and Victoria Werth[5], [1]Department of Dermatology, University of Pennsylvania, Philadelphia, PA, Philadelphia, PA, [2]Department of Dermatology, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Pennsylvania, Philadelphia, [5]Corporal Michael J. Crescenz VAMC, Philadelphia, PA, USA and Department of Dermatology, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The FDA uses near or total clearance in cutaneous disease in inflammatory skin conditions as an endpoint in clinical trials. However, patients may experience improvement in their quality of life (QoL) without achieving complete clearance of their skin disease. A previous study has shown that the Cutaneous Dermatomyositis Disease Area and Severity Index-Activity (CDASI-A) score correlates with the Symptoms and Emotions subscales of the Skindex-29, a skin specific measure of QoL, down to CDASI-A scores of 7 and 10, respectively. Our goal is to define an important change in disease activity, as measured by CDASI-A, that results in meaningful change in QoL in patients with dermatomyositis (DM).

Methods: In 103 patients seen in the outpatient Autoimmune Disease Clinic at the University of Pennsylvania, we assessed the percent change and actual change in CDASI-A needed to achieve a meaningful improvement in QoL using linear regression models.

Results: Comparing the Skindex-29 to the Dermatology Life Quality Index (DLQI), we found that meaningful improvement in the Symptoms and Emotions subscales of the Skindex-29 is 7.86 (P< .0001) and 10.29 (P< .0001) points, respectively. For patients with initial CDASI-A scores >14, a 40% change in CDASI-A between the first two visits suggests a meaningful change in the Skindex-29. In patients with moderate initial CDASI-A (15-26), the change in CDASI-A score needed to achieve a meaningful change in Symptoms and Emotions was 6 (P=.0002) and 7 (P=.0007), respectively. For initial CDASI-A scores in the severe range of 27-35, an improvement in CDASI-A by 11 (P=.0301) and 9 (P=.0212) points is needed to result in meaningful change in Symptoms and Emotions, respectively.

Conclusion: In patients with an initial CDASI-A of >14, a 40% change in CDASI-A can be used to indicate meaningful change in QoL in future DM trials.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disease characterized by multi-organ involvement and a complex clinical picture, with a wide range of manifestations with and unpredictable relapsing and remitting course. Evidence suggests that discordance between patients and physicians could negatively affect patient care, adherence to treatment and outcomes of the disease. In particular, physicians' and patients' assessments of disease activity and health status in SLE are shown to differ considerably, suggesting the need to better understand patients' perspective to bridge the gap in information and communication.

The aim of the present study is to assess knowledge, needs and expectations among SLE patients to shine a light on patients' perspectives. The research was part of the INTEGRATE Pilot project assessing patients' and clinicians' perspectives to develop a strategy for the monitoring and treatment of chronic diseases aligning the integration of patient driven data with the traditional clinical evaluation.

Methods: A web survey was designed to assess knowledge, needs and expectations among SLE patients. LUPUS EUROPE and partner clinicians were invited patients to participate in the survey. Furthermore, two focus groups involving 15 patients from 12 European countries were then organized into two-hour sessions to delve deeper into survey's results.

Results: Overall 554 SLE patients (mean age 44.3±13.1 years; 94.2% female) participated to the survey. Responders were mainly from Italy (28.7%) and UK (30.9%), but answers came from almost all European countries.

Data from the survey suggested that about 50% of the patients had good to very good knowledge of disease related issues. The main needs highlighted from responders were related to the involvement in decisions about treatment and disease management (74.2% reported high to extreme need), improvement of participation in social activities (77.3% declared moderate to extreme need) and maintenance of relationship with friends (64.8% reported high to extreme need). During the focus groups many patients reported that they were not adequately informed about treatment, side effects and lifestyle choices. All patients reported problems of communication about their disease with others including loved ones, friends, the wider community and in some cases specialists and GPs. There was a particular emphasis on improving their relationship with their specialists and other healthcare professionals. Patients highlighted the need to receive more "understandable" and personalized information, even suggesting the possible role of a specialized nurse in providing practical support.

Conclusion: Patients inputs collected from both the survey and focus groups suggested specific areas of unmet needs and also provided ideas in relation to the practical strategies to adopt in order to fill existing gaps. These results, combined with the assessment of clinicians' perspectives, could serve to design an integrated strategy for disease management.

What Are the Prescribing Trends and Satisfaction Levels with Analgesics for Osteoarthritis as Reported by US Rheumatogists, Orthopaedic Surgeons, and Primary Care Physicians?

Thomas Schnitzer,[1] Rebecca Robinson,[2] Lars Viktrup,[2] Joseph Cappelleri,[3] Andrew Bushmakin,[3] Leslie Tive,[4] Jennifer Mellor,[5] Nathan Williams,[5] Pavlina Hubanova,[5] and James Jackson[5], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Eli Lilly and Company, Indianapolis, IN, [3]Pfizer Inc, Groton, CT, [4]Pfizer, Inc, New york, NY, [5]Adelphi Real World, Bollington, England, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To describe patterns of care and physician satisfaction with prescribed treatments for osteoarthritis (OA).

Methods: Data were collected from February-May 2017 using US Adelphi Disease Specific Programme, a cross-sectional survey of 81 (52.9%) primary care physicians (PCP), 35 (22.9%) rheumatologists (RHEUM), and 37 (24.2%) orthopedic surgeons (ORTHO). Specialties were compared based on reported use and satisfaction with prescribed treatments using Likert-type scales: -2 (not satisfied) to +2 (very satisfied) for overall satisfaction; and -3 (performs very badly) to 3 (performs very well) for drug class attributes of efficacy, safety, quality of life (QoL), costs, and convenience. Specialties were compared using Fisher-Freeman-Halton exact tests and analysis of variance tests.

Results: Physicians were mostly male (72.5%), with private (84.7%) and office/outpatient (87.2%) practices and had been in practice over 15 years (77.8%). All specialty comparisons are listed as PCP, RHEUM, ORTHO, respectively. First-line treatment included predominantly lifestyle changes and NSAIDs (Figure 1), and rates for each treatment did not differ by specialty. Second and third-line medication use only differed by specialty for injectable corticosteroids and surgery, prescribed more frequently by ORTHOs. Affirmation from physicians that any guidelines were routinely followed differed by specialty (28.4%, 51.4%, 48.6%; $p< 0.05$). Slightly less than one-third of physicians had ever recommended cannabinoids (28.4% 28.6%, 27.0%). Among those physicians, the frequency of cannabinoid recommendations was reported as rare (60.4%), sometimes (34.9%), and frequent (4.7%). Physicians' satisfaction across all medications was mostly positive for mild patients (71.6%, 65.7%, 62.2%), but lower for moderate to severe patients (56.8%, 34.3% 51.4%) with mean satisfaction rated lowest among RHEUMs ($p< 0.05$, Table 1). When assessing performance across all 5 drug attributes evaluated, efficacy, cost considerations, and QoL differed by specialty (all $p< 0.05$; Table 2). Efficacy rating for overall medications, opioids, and other non-opioid analgesics were rated highest by PCPs and lowest by ORTHOs. Cost considerations differed for injectable corticosteroids which were most favorable among RHEUMs, and QoL was rated lowest among ORTHOs for opioids. Ratings for each medication by safety and convenience were similar across specialties. Opioids had the lowest mean performance ratings for efficacy (weak only), safety, and QoL.

Conclusion: Few differences by physician specialty were found in reported rates of first, second, and third line use of therapies for OA. Physicians rated satisfaction with overall medications as positive when treating patients with mild OA, but ratings were lower for moderate to severe patients. Variability by specialty was most pronounced in the performance ratings for efficacy and QoL; most noteworthy, opioids were reported highest by PCPs and lowest by ORTHOs. These data indicate more similarities than differences in OA treatment among physician specialties despite potential variations in physician specialty training and populations served.

Polymyositis (PM) and Dermatomyositis (DM) Symptom Flares and Associated Impact from the Patient Perspective

Lisa Christopher-Stine,[1] William Kelly,[2] George Wan,[3] Linda Kobert,[4] and Michael Reed[5], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins Myositis Center, Baltimore, MD, [3]Mallinckrodt Pharmaceuticals, Bedminster, NJ, [4]The Myositis Association, Alexandria, VA, [5]Vedanta Research, Chapel Hill, NC

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Flare activity or worsening symptoms are not well defined for myositis. This analysis characterizes PM and DM flares from the patient perspective and reports the corresponding disability and rates for emergency department or urgent care visits and hospitalizations.

Methods: An online survey was conducted with volunteer patients recruited from The Myositis Association and Johns Hopkins Myositis Center. Survey questions included sociodemographics, flare symptoms, Health Assessment Questionnaire Disability Index (HAQ-DI) and HAQ-Pain index, Work Productivity and Activity Impairment (WPAI), myositis related emergency department and urgent care (ED/UC) visits and hospital admissions during the past year. Flare frequency was assessed with two sequential questions, "Have you ever had a flare or worsening myositis symptoms?" if yes, "How many times in the past 12 months?".

Results: A total of 564 patients with self-reported diagnoses of PM (n=243) or DM (n=321) completed the survey between December 2017 and May 2018 (86.3% Caucasian, 78.2% female, 42.9% employed, mean age 56). There were 524 who recalled periods with or without worsening symptoms or flares (demographic profile similar to total sample) and those individuals are reported on here. There were 33 (6.3%) that reported never experiencing a flare, 113 (21.6%) reported 0 flares in the past year, 244 (46.6%) reported 1-3 flares, and 134 (25.6%) reported 4 or more

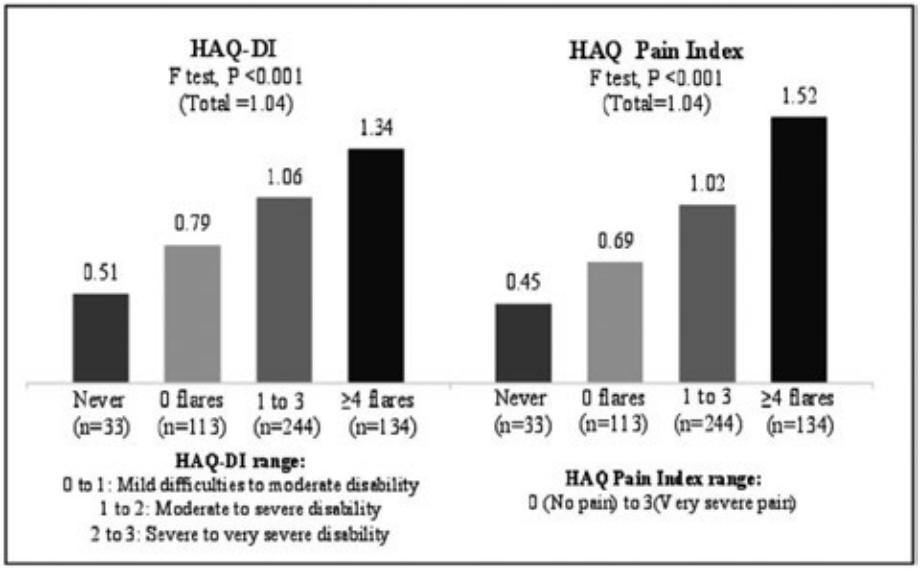

Figure 1. Mean HAQ-DI and HAQ Pain Index Scores for Never and Past Year Flare Groups.

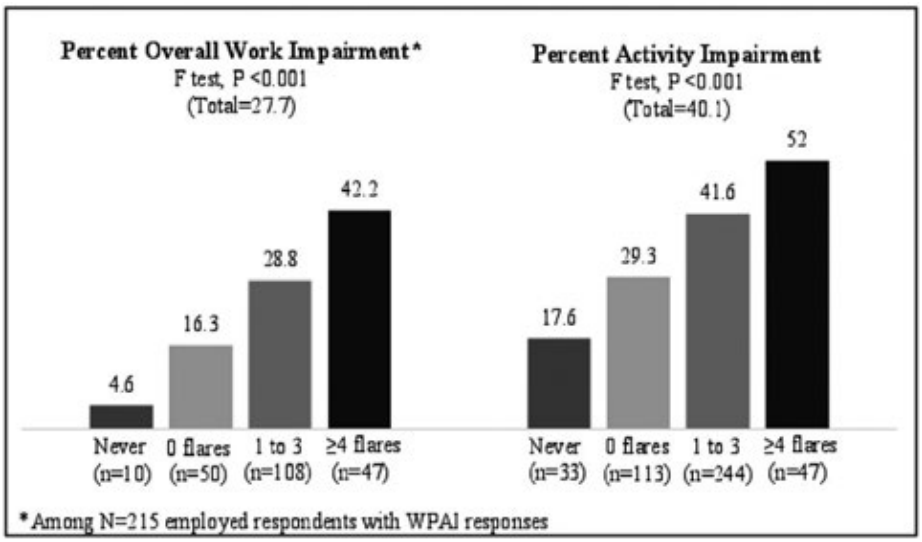

Figure 2 . Mean WPAI Work and Activity Impairment Percents for Never and Past Year Flare Groups.

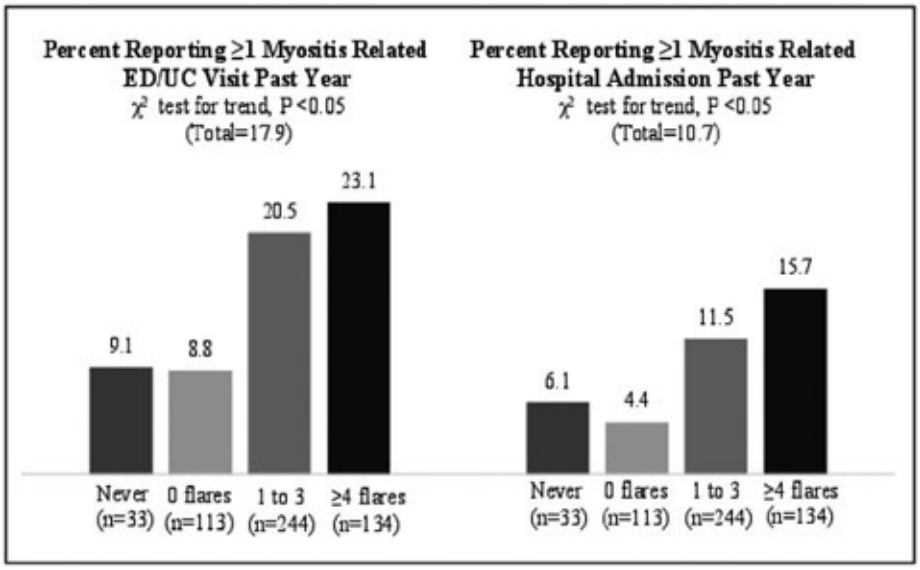

Figure 3. Myositis Related ED/UC Visits and Hospital Admissions for Never and Past Year Flare Groups.

flares in the past year. The pattern of flare frequency was similar for PM and DM respondents. Among those with past year flares or periods of worsening symptoms (n=378) the most common symptoms were muscle weakness (83%), extreme fatigue or exhaustion (78%), muscle pain/discomfort (64%), trouble climbing stairs (62%), trouble standing from a seated position (50%), and skin rash (45%). Dysphagia occurred for 27%. Increasing flare frequency was associated with greater mean HAQ-DI ($F=17.653$, $P < .001$), HAQ-Pain ($F=28.291$, $P < .001$) (**Figure 1**), greater mean percent of WPAI activity impairment ($F=20.109$, $P < .001$) and for the employed, greater mean percent of missed work time ($F=2.716$, $P < .05$), as well as greater impairment at work ($F=8.242$, $P < .001$), and overall work impairment ($F=9.933$, $P < .001$) (**Figure 2**). Percent with one or more past year myositis related ED/UC visits were found to be related to flare frequency ($\chi^2=11.634$, $P < .05$). The percent with one or more myositis related hospital admissions was also associated with flare frequency ($\chi^2=9.03$, $P < .05$) (**Figure 3**).

Conclusion: PM/DM-related flares or worsening symptoms are common, with 72% of respondents reporting one or more flare occurrence in the past year. Exacerbations of muscle weakness and fatigue were the most common flare symptoms, and flare frequency was associated with greater disability, more pain, more overall work impairment,

and more activity impairment. Past year ED/UC visits and hospital admissions were also more likely to occur as flare frequency increased. Higher frequency of patient-reported flares may serve as a marker of worsening physical functioning and intensifying health care needs, and therefore suggests their importance in the clinical assessment of patients with PM/DM.

Symptoms and Impacts in Psoriatic Arthritis: Findings from Qualitative Patient Interviews

Kaleb Michaud,[1] Evo Alemao,[2] Miroslawa Nowak,[3] Rachel Bruce,[4] Sarah Cantor,[4] Carlijn Hintzen,[5] Philip Mease,[6] **Kendra DeBusk**,[2] and Alexis Ogdie[7], [1]University of Nebraska Medical Center, Omaha, NE, [2]Bristol-Myers Squibb, Princeton, [3]Bristol-Myers Squibb, Princeton, NJ, [4]IQVIA, New York, [5]IQVIA, Amsterdam, Netherlands, [6]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA, [7]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease resulting in significant symptom burden.[1] Over time and without adequate treatment, PsA can lead to disability and reduced patient quality of life.[2] Fatigue is among the most common symptoms,[1] but is complex and difficult to measure. The most burdensome symptoms that impact PsA patients need to be better understood in order to select patient reported outcomes (PRO) tools that adequately capture these concepts.

Objectives

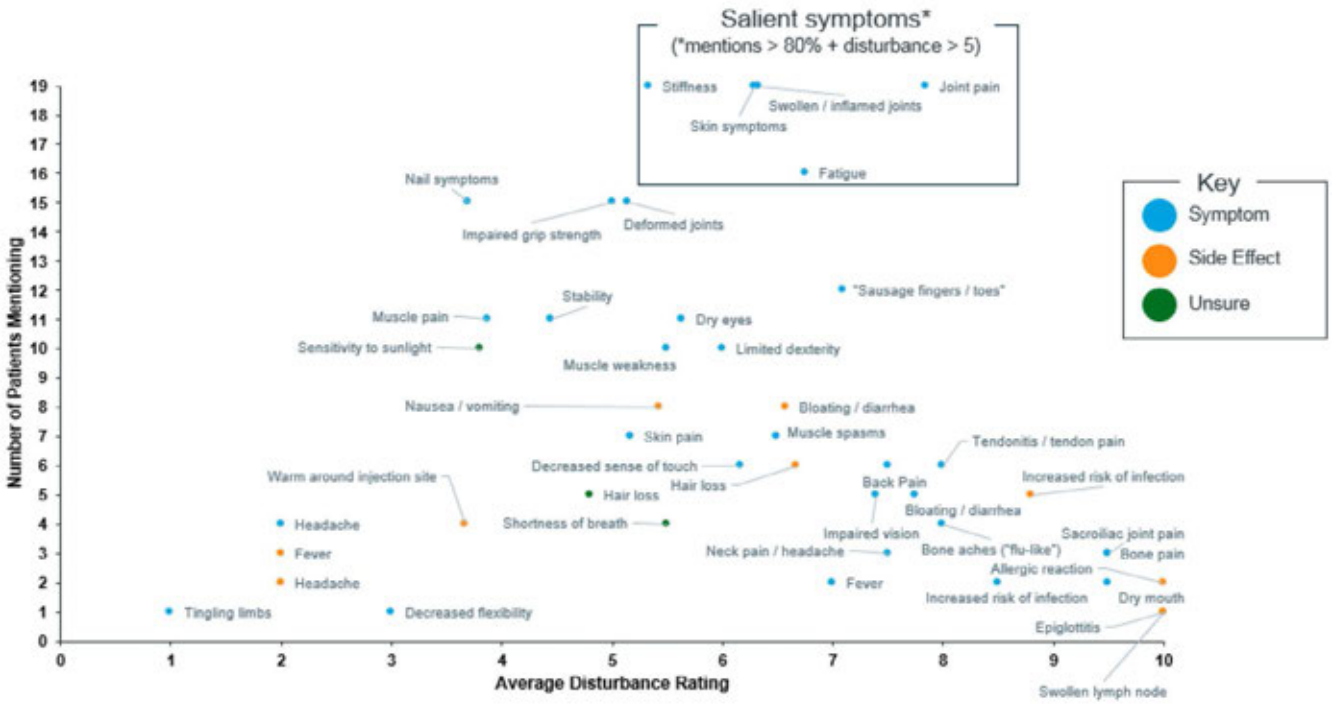
1. Identify the signs and symptoms of PsA experienced by patients, with a focus on fatigue, and how the disease and its treatment(s) impact patients' lives.

2. Assess the content validity of select PRO instruments and items to measure fatigue.

Methods: Qualitative interviews were conducted among patients with PsA recruited through the FORWARD databank, all of which satisfy the ACR classification for PsA. The most frequently experienced symptoms and impacts of PsA and the degree to which they disturbed patients' lives, were tabulated. Disturbance was evaluated on a scale from 0 (not at all) to 10 (greatly disturbs). Patients reporting fatigue were probed to describe the experience in their own words, and descriptors were recorded. Interviews were conducted and assessed on a rolling basis and recruitment continued until concept saturation was achieved.

Results: Nineteen PsA patients were interviewed for this study. A core set of PsA symptoms were identified by nearly all patients and with moderate to high average disturbance ratings (Figure 1): joint pain, skin symptoms, stiffness,

Figure 1. Salient Symptoms Reported by Patients in Qualitative Interviews (n=19)



swollen/inflamed joints, and fatigue. The most salient impacts (Figure 2) were sleep disturbance, physical disability, effects on daily activities, and feelings of frustration. Most common descriptors of fatigue included “fatigue,” “tiredness,” “lack of energy,” “mental fatigue,” and “exhaustion.”

Conclusion: Salient symptoms were consistent with those previously reported, along with a broader range of symptoms and impacts, which included fatigue. In addition to physical disability, others such as sleep disturbance, frustration, and effect of daily activities were common high impact themes that emerged.

Figure 2. Salient Impacts Reported by Patients in Qualitative Interviews (n=19)

Abstract Number: 2247

Patient Factors Associated with Willingness to Change Rheumatoid Arthritis Medications

Raj Vachhani,[1] Lang Chen,[1] Ronan O'Beirne,[2] Joshua Melnick,[3] Eric Ruderman,[4] Jeffrey Curtis,[1] and Maria Danila[2], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]University of Alabama at Birmingham, Birmimgham, AL, [4]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Evanston, IL

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence-based guidelines recommend escalation of therapy in patients with rheumatoid arthritis (RA) with inadequately controlled disease. However, some patients are hesitant to change therapies despite significant symptom burden. Understanding the patient factors that are associated with willingness to change therapy may inform the design of behavioral interventions to improve appropriate escalation of treatment in patients with RA.

Methods: Adult patients with self-reported RA who were enrolled in the ArthritisPower patient registry with a RAPID3 > 4 (range 0-10), treated with DMARDs in the past 6 months, and without potentially confounding conditions (e.g. fibromyalgia) were eligible to participate in the Confident Treatment Decisions for Living with Rheumatoid Arthritis (CONTROL RA) clinical trial. Patients were recruited by email to complete a compensated online survey. Participants' willingness to change RA treatment was determined at enrollment using the validated choice predisposition scale that reflects preference for changing RA therapies. Patients were asked "If at your next visit, your rheumatologist recommends that you change RA medication(s), would you be willing to do so?" This item was coded on an 11-point scale anchored by "Not willing at all" and "Extremely willing". Patients who answered 7-10 were categorized in the "more willing to change treatment" group, while those with a score of 0 - 6 were classified in the "less willing to change treatment" group. Bivariate tests and multivariable logistic regression evaluated the following characteristics associated with these two levels of willingness to change treatment: sociodemographic characteristics, biologic DMARD or conventional DMARD use, patient global assessment of disease activity (PGA), patient satisfaction with RA control, (yes vs no) personal attitudes favoring RA medications (calculated by surveying participants' agreement with 5 positive and 5 negative statements about use of medications in RA. Higher score represents more favorable attitude towards RA medications), patient-physician discussion on RA treatment goals occurring in the past year, subjective characterization of general health (5 point scale anchored by "excellent" and "poor"), and subjective readiness to change (Precaution Adoption Process Model). Subjective health literacy calculated by asking patients about their confidence in filling out medical forms.

Results: A total of 208 U.S. patients were recruited. Study participants were 90% Caucasian, 90% women, with high subjective health literacy and a mean (SD) age of 50 (11) years. In adjusted models, we found that compared to the less willing group, participants in the more willing to change group were more likely to have a higher PGA (OR 1.4 p = 0.0006, CI 1.1 – 1.6), and more likely to have a favorable attitude towards RA medication than those in the less willing group (95.1% vs 81.4%, p = 0.0042; OR 7.0, p = 0.0008, CI 2.2 – 21.8).

Table 1. Characteristics of patients with RA by willingness to change treatment status

Patient factors		Less willing to change (n = 86)	More willing to change (n = 122)	p value
Favorable attitude towards RA medication (higher score = more favorable attitude)		70 (81.4%)	116 (95.1%)	0.0042
Patient global assessment of present condition (0 = very well, 10 = very poorly)		4.9 (2.25)	6.0 (2.23)	0.0005
Age		48.8 (12.6)	50.1 (9.99)	0.67
Sex	Male	8 (9.4%)	13 (10.7%)	0.77
Race	White	76 (88.4%)	112 (91.8%)	0.41
Ever used biologics or conventional DMARDs		39 (45.3%)	57 (46.7%)	0.85
Patient satisfied with RA control	Yes	36 (41.9%)	45 (36.9%)	0.47
Treatment goals discussed in past year		64 (74.4%)	94 (77.0%)	0.66
General health	Excellent/Very good/Good	49 (57.0%)	58 (47.5%)	0.18
Readiness to change	Change not needed/haven't considered change	24 (27.9%)	23 (18.9%)	0.13

Table 2. Likelihood of willingness to change treatment status by associated patient factors

Patient factors	Variables	Odds Ratio	p value
Attitudes favor RA medication use	More agree vs More disagree/Neutral	6.986 (2.241 - 21.773)	0.0008
Patient global assessment of present condition	Continuous: 0 = very well, 10 = very poorly	1.362 (1.143 - 1.623)	0.0006
Age	Continuous	1.017 (0.988 - 1.048)	0.25
Sex	Female vs Male	0.913 (0.312 - 2.675)	0.87
Race	White vs Other	1.017 (0.343 - 3.014)	0.98
Ever used biologics or conventional DMARDs	Yes vs No	0.911 (0.490 - 1.695)	0.77
Patient satisfied with RA control	Yes vs No	2.141 (0.934 - 4.910)	0.07
Treatment goals discussed in past year	Yes vs No	0.895 (0.389 - 2.060)	0.79
General health	Excellent/Very good/Good vs Other	0.869 (0.422 - 1.790)	0.70
Readiness to change	Have considered/Not decided/Am changing/Already changed vs Change not needed/haven't considered change	1.843 (0.884 - 3.843)	0.10

Conclusion: Our study suggests that among patients with self –reported RA, having attitudes that favored RA medications and a higher patient global assessment of disease activity were independently associated with an increased willingness to change RA medications.

Legal Matters: Attitudes Regarding Marijuana for Medical Use Among Patients with Rheumatic and Musculoskeletal Disease

Kelly Gavigan,[1] Shilpa Venkatachalam,[1] Jeffrey Curtis,[2] Carole Wiedmeyer,[1] Tien Sydnor-Campbell,[1] Christine Stake,[1] Terri Robinson,[1] and W. Benjamin Nowell[1], [1]Global Healthy Living Foundation, Upper Nyack, NY, [2]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While there have been significant improvements in quality of life among people living with rheumatic and musculoskeletal disease (RMD) with the introduction of biologics and targeted therapies, patients often seek non-pharmacological alternative and complementary treatments, such as marijuana for medical use (MMU), to help manage their condition and symptoms. An understanding of patient use and perceptions of MMU is necessary to inform future research and care.

Methods: A 77-item cross-sectional survey was developed in partnership with RMD patient partners and administered online via CreakyJoints and the ArthritisPower research registry. Participants (pts) were eligible if they were ≥19 years of age, resided in the US and reported physician-diagnosed RMD. Pts reported on their current health status (NIH PROMIS Global Health), use and perceptions of MMU, and related information needs.

Results: A total of 1,059 pts completed the survey. A majority of pts were female (88%) and white (92%), with mean (SD) age of 57 (11) (Table 1). Of the total pts, 37% (n=387) reported use of MMU, either currently or in the past. Of those, a majority (93%) used it to manage a specific condition: 51% for rheumatoid arthritis, 46% for osteoarthritis, and 35% for fibromyalgia. Nearly two-thirds (62%) of current MMU users report using it at least once a day. Most current or past MMU users live in a state where marijuana is legal for medical reasons (77%), but only 40% have used a medical marijuana card to purchase it, with 60% citing the desire for use to be legal as a reason for using the card (Table 2). Top reasons for not using a medical marijuana card were marijuana not being legal for medical use where pt lives (42%), cost being more expensive through a medical dispensary (19%) and difficulty getting a card (18%). Among the 63% of all pts who had never used MMU, illegality (40%), potential impairment (24%), and not knowing where (21%) or how (20%) to obtain MMU were cited as top reasons for not using it. When asked about the likelihood of using MMU if it were legal where the pt lives, half of pts responded that they were likely to use it. The majority of pts (84%) living in states where marijuana is medically legal correctly identified their state as legal, whereas 66% of pts living in a state where medical marijuana is illegal knew that this was so. Overall, two-thirds of current or past MMU users informed their HCP about using MMU, but only 42% perceived that their HCP integrated it into their care (e.g. considering MMU part of pts' treatment regimen and advising on dosage). Of pts who live in states where marijuana is medically legal, 68% had informed their health care provider (HCP) of using MMU, whereas only 54% (p=0.02) informed their HCP in non-legal states.

A majority (62%) of participants expressed interest in participating in a trial on MMU treatment of RMD. Pts' top concern about a trial was ensuring participation would be legal (36%) (Table 3).

Table 1. Participant Characteristics, by Marijuana (MMU) Use

	Non-MMU Users (N=672)	Current and Past MMU Users (N=387)	p-value
Age, mean (SD)	57.8 (10.5)	56.0 (10.9)	0.007*
Female, n (%)	592 (88.1)	341 (88.1)	0.993

Corticosteroids only	29 (4.3)	19 (4.9)	0.655
No treatment or NSAIDS only	232 (34.5)	159 (41.1)	0.033*
Greater than a year on current therapy, n (%)	473 (70.4)	240 (62.0)	0.056
Satisfied with current therapy, n (%)	485 (72.2)	230 (59.4)	<0.001*
Living in state with legalized medical marijuana, n (%)	393 (58.5)	297 (76.7)	<0.001
PROMIS Global Physical Health, mean (SD)[1]	38.6 (7.6)	37.2 (7.1)	0.002*
PROMIS Global Mental Health, mean (SD)[1]	43.5 (8.8)	42.0 (8.6)	0.008*

*Statistically significant, p=0.05

+Not mutually exclusive

[1]Continuous scale from 20 (poor) to 80 (excellent)

Table 2. Reasons for medical marijuana card use among those currently using it (N=154)*

	n (%)
I want my marijuana use to be legal	93 (60.4)
It's the only way to access marijuana for medical use in my state	90 (58.4)
I want to know the chemical composition of what I'm receiving	65 (42.2)
I want to know that the chemical composition of what I'm receiving is the same each time	48 (31.2)
The medical dispensary has the chemical compositions that I want to try	41 (26.6)
The cost of purchasing marijuana is cheaper through a medical dispensary	23 (14.9)
Other	15 (9.7)

+Not mutually exclusive

Table 3. Concerns about clinical trial participation to examine marijuana for rheumatic and musculoskeletal disease treatment (N=1,059)[+]

	n (%)
I would want to be sure it is legal for me to be part of a marijuana trial	384 (36.3)
It might cost me money to participate	265 (25.0)
A trial might disrupt the prescribed treatment of my disease (not marijuana use)	250 (23.6)
I don't have concerns [exclusive choice]	244 (23.0)
I might receive a placebo drug	243 (23.0)
There might be side effects of the treatment	193 (18.2)
The treatment might not work	116 (11.0)
Other	110 (10.4)
A trial might take up too much of my time	97 (9.2)
A trial might disrupt my marijuana use	75 (7.1)
Participating in medical trials makes me uncomfortable	53 (5.0)

[+]Not mutually exclusive

Conclusion: Despite the lack of quality evidence to guide MMU, and regardless of its legality, many patients are using MMU to manage their RMD. Trials to inform MMU for RMD are urgently needed and patients are interested in participating in such studies.

Abstract Number: 2249

Evaluation of Rheumatoid Arthritis Patients' Preferences Using Discrete Choice Experiment

Aniket Kawatkar[1], [1]Kaiser Permanente Southern California, Pasadena, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) exerts multifaceted burden through medical expenditures, productivity losses, disability, and intangible costs of pain, fatigue, and loss of functional capacity. Patient preference measures how they value a health outcome and it can be elicited by the trade-offs they place on different levels of the health outcomes. The study objective was to evaluate patients' preferences for pain/fatigue, functional capacity, disability and joint replacement surgery, employment losses, and out-of-pocket cost using a discrete choice experiment (DCE).

Table 1. Average Importance of Outcomes

Attribute	Importance	Lower 95% CI	Upper 95% CI
Chances of being disabled and require joint replacement surgery	23	21	24
Out of pocket treatment cost	23	21	25
Limitations in daily activities	20	19	21
Number of days missed work due to RA	19	18	20
Joint pain, swelling and tiredness	16	14	17

Table 2. Average Patient Preferences

Attribute	Attribute Level	Preference	Lower 95% CI	Upper 95% CI
Joint pain, swelling and tiredness	None	78	76	80
	Moderate	77	75	79
	Severe	Reference Level		
Limitations in daily activities	None	99	97	101
	Moderate	81	79	84
	Severe	Reference Level		
Chance of being disabled and require joint replacement surgery	Low (5%) or 5 in 100 chance	114	111	117
	Medium (40%) or 40 in 100 chance	88	86	91
	High (90%) or 90 in 100 chance	Reference Level		
Number of days missed work due to RA	1 day each month	95	92	97
	8 days each month	63	61	65
	24 days each month	Reference Level		
Out of pocket treatment cost	$20 per Month	114	110	118
	$500 per Month	81	79	82
	$2,500 per Month	Reference Level		

Methods: A DCE was conducted in a prospective cohort of adult (18+ years) RA patients on methotrexate treatment, identified from the member population of Kaiser Permanente Southern California health plan. The web-based DCE survey varied the following 5 conjoint attributes with 3 levels in each: (1) Joint pain, swelling and tiredness (None, Moderate, Severe) (2) Limitations in daily activities (None, Moderate, Severe) (3) Chances of being disabled and require joint replacement surgery (Low (5%); Medium (40%), High (90%)) (4) Number of days missed work due to RA (1 day/month, 8 days/month, 24 days/month) (5) Out of pocket treatment cost ($20/Month, $500/Month, $2,500/Month). After initial pilot testing, graphical representation of levels was used to convey magnitude to patients. The choice profiles for each respondent were randomly sampled from the full-choice design ensuring level balance and near-orthogonality within each respondent's profile. After completing 2 training tasks (not

analyzed), each respondent completed 12 random choice tasks that provided trade-offs to varying levels of the 5 outcomes. Hierarchical Bayesian models were used to evaluate individual patient preferences accounting for inter-patient heterogeneity.

Results: The DCE completion rate was 53% (237/448) and the mean age of the sample was 53 (±16) years with the majority (84%) of female. Of the 5 attributes, chance of disability and joint replacement surgery was tied with out-of-pocket treatment cost as the most important attributes (Table 1) and loss in functional capacity was deemed more important compared to missing work and pain/tiredness. The average preference was 114 (95% CI 111-117) higher for low (5%) vs. high (90%) chance of being disabled and require joint replacement surgery (Table 2). In contrast, the average preference of moderate vs. no joint pain, swelling and tiredness was just one-unit difference (Table 2).

Conclusion: Treat-to-target approach based on swelling/tenderness/pain activity indices can be made more effective by shared decision making to incorporate patient preferences which value functional capacity and treatment cost higher. Better understanding of patient preferences can inform gaps in the existing evidence-base to inform practice guidelines.

Contribution of Personality Traits, Psychological Factors and Health Related Quality of Life on Medication Adherence in Patients with RA

Kyung Min Ko,[1] Su-Jin Moon,[2] Jung Hee Koh,[1] and Jun-Ki Min[1], [1]Division of Rheumatology, Department of Internal Medicine, Bucheon St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Bucheon, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Uijeongbu St. Mary's Hospital, College of Medicine, the Catholic University of Korea, Uijeongbu, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-adherence to long-term treatment is important in Rheumatoid arthritis (RA), as it can result in inadequate disease control and make rheumatologist to change the treatment strategy. Personality refers to individual differences in characteristic pattern of thinking, feeling and behaving. However, it is not clear that personality could predict medication non-adherence in patients with RA. The aim of this study is to investigate the association between personality traits and medication adherence and to identify the predictors of good medication adherence in RA patients including personality traits, psychosocial factors, disease activity, pain and health related quality of life (HRQoL).

Methods: Total 207 RA patients using disease-modifying antirheumatic drugs (DMARDs) was invited for an interview and questionnaire study from rheumatology outpatient clinics in Bucheon St. Mary's hospital in Korea. Medication adherence was measured with the Compliance Questionnaire of Rheumatology (CQR). Personality traits was analyzed with the five-factor model (neuroticism, extraversion, openness to experience, agreeableness, and conscientiousness) with Korean version of Big Five Inventory 10 (K-BFI-10). A high level of each personality trait represents high scores (≧4 average score) of each personality item of five factor models. Psychological factors were also assessed

Table 1. Multivariate logistic regression on medication adherence

	OR	95% C.I.	
		Lower	Upper
Diabetes Mellitus	2.57	1.03	6.42
The number of prescribed medication	1.21	0.98	1.51
Total glucocorticoid dose (mg/month)	1.00	1.00	1.01
High conscientiousness	2.37	1.24	4.53

OR; odds ratio, C.I.; confidential Interval

with Patient Health Questionnaire (PHQ-9), General Anxiety Disorder 7(GAD-7) and the British Columbia Cognitive Inventory (BC-CCI), respectively. HRQoL and functional disability were evaluated with EuroQoL dimension (EQ5D) and health associated quality (HAQ). Multivariate logistic regression analyses were performed to investigate predictors of good medication adherence.

Results: A total of 207 RA patients (Female 83.1%, mean age 57 years, mean RA duration, 8.0 years) were participated. Non adherence to their DMARD prescription (CQR < 80) was reported in 66.2%. The number of daily prescribed pills was higher in the medication adherence group (P = 0.03). Concomitant oral glucocorticoids use and the dose was significantly associated with medication adherence. The personality trait, high level of conscientiousness and comorbid with diabetes mellitus were associated with better medication adherence (odds ratio [OR], 2.37; 95% confidence interval [CI, 1.24-4.53 and OR,2.57; 95% CI, 1.03-6.42, respectively) (Table 1). There were no significant differences in psychological factors and HRQoL between medication adherence and nonadherence group.

Conclusion: The personality traits were associated with medication adherence; conscientiousness was a predictor of medication adherence, among the five personality traits. Patients with diabetes mellitus showed higher medication adherence.

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) poses complex diagnostic and management challenges, which may differ depending on whether SLE was diagnosed in childhood (cSLE) or in adulthood. We used qualitative methods to explore these issues with participants with childhood and adult-onset SLE to identify modifiable influences and coping strategies that could be leveraged to reduce areas of vulnerability and improve care.

Methods: Participants were recruited from two large academic medical centers, one with a Lupus Registry of individuals ≥18 years old with ≥4 1997 ACR classification criteria for SLE, and the other with a pediatric centralized data repository of cSLE patients. Three focus groups were held to explore potential vulnerabilities in SLE diagnosis and care including psychosocial aspects, medication use, the doctor-patient relationship, and the transition from pediatric to adult care. Focus groups were led by a trained moderator using a guide developed a priori, and were recorded and transcribed verbatim. A pediatric and adult rheumatologist reviewed transcripts and agreed upon preliminary concepts for coding. Codes were clustered into themes and transcripts were re-reviewed. A five-person study team adjudicated discrepant themes and chose key quotes. Qualitative software (Dedoose) was used for coding and thematic analysis of deidentified transcripts.

Results: Thirteen adults, 6 (46%) with cSLE, participated in three focus groups. The mean age was 35 (range 18-66); 5 participants identified as White, 5 Black, 2 Asian and 1 Hispanic. Themes were categorized into two domains: (1) challenges with SLE diagnosis and management and (2) patient coping strategies and modifiable factors of the SLE experience (**Table**). Participants identified five primary challenges: diagnostic odyssey, public versus private face of SLE ((discrepancy between the way one feels and the way one appears to others), SLE-related stresses, medication adherence, and transitioning from pediatric to adult care. Participants also offered specific strategies to address challenges, such as reducing stress and increasing sleep, and recognized modifiable factors in managing SLE and transitioning from pediatric to adult care including social support, open communication about SLE, and strong patient-provider relationships (**Figure**). Several participants with cSLE highlighted positive lessons learned through their experiences with SLE as part of their coping strategies, including empathy, resilience, and self-care skills.

Conclusion: Patients with childhood and adult-onset SLE identified common challenges, modifying influences and coping strategies based on their personal experiences. A strong patient-provider relationship emerged as a key modifiable factor improving the patient experience of living with SLE. Participants highlighted the importance of the human connection and trust in their medical team. The focus on optimism and empathy derived from their experience

Table: Description of themes and selected quotes		
Theme	**Description**	**Selected Participant Quotes**
Challenges in SLE		
Diagnostic Odyssey	The journey from onset of symptoms to diagnosis with SLE, including trauma of diagnosis	"I kept goin' back to the hospital, back to the hospital, back to the hospital.....When I say my chest was in excruciating pain, they was taking x-rays and everything. Then I finally had saw a different doctor, and the doctor saw that my lungs were completely dark. I'm like, I been comin' to you people for weeks.'"
Public vs. Private Face of SLE	Impact of SLE on life and identity, process of acceptance and sharing publicly, and coping with external changes in appearance and stigma and shame around SLE	"I kept the lupus hidden for a long time or as long as I could because I didn't wanna be thought of the lupus girl."
Medication Adherence	Side effects, system issues (ex: refills), changes in routine, forgetfulness, gap between knowing and doing	"Patients lie, and I think most patients overestimate when they answer to their doctor, "Have you been taking your medication?" "Yeah." "What percent?" "Like half the time," when it's not true. I do that ...sometimes, too, and I catch myself."
Transition from Pediatric to Adult Care	Logistics (ex: records transfer), difference in environment, patient responsibility, fear of losing relationship with first provider	"It's really all about the connection with your doctor. Cuz yeah, switching your medical records and things like that is—there's the whole logistics of it. I think it's just the relationship that you have with your doctor and then they haven't known you for such a long time. Having to switch to a new doctor who doesn't necessarily know you or know your medical record, but know you as a person."
SLE-Related Stress	Triggering disease flares, contributing to medication non-adherence	"I know sleep definitely affects me. My freshmen and sophomore years at university were really difficult with just stress. I would stress then I wouldn't eat well. I would just feel like I can't eat. Then I lost a lot of weight because of that, and then because of that I couldn't sleep. It's just like a cycle of stressing about my work, getting my work done, stressing about not being able to sleep, then not being able to sleep more. I would just walk in like a zombie and my professors would be like, 'Oh, you look really tired.' I'm like, 'I know.'"
Patient Strategies/Modifiable Factors		
Patient-Provider Relationship	Trust, two-way communication, role of research, bond with first rheumatologist	"I think it might be hard to stay motivated to take your prescription every day if you have a doctor you don't trust because then you might question whether or not they have your best interest in mind, or you may think that they're not aware of what the side effects are or compromises you need to make in order to keep taking this particular prescription. I think the doctor/patient relationship's very important."
Social Support	The role of parents, friends, social support networks, and technology	"I think my family has been real good about it and they just know—can kinda predict ahead what situations will bother me, so they try to help me with that. My brother was moving, my job was to watch the truck, so I didn't actually move anything. ... My mom is really supportive about taking me to doctor's appointments. She worries so much, so it can be—I know having lupus is hard, but sometimes I have to tell her, "You gotta keep it together."

with SLE was unique to several patients with cSLE. Leveraging factors that have improved the participants' experiences living with SLE may be used in future studies to address vulnerabilities in care.

The #Worldlupusday 2019 Across Twitter: An Explorative Analysis of Spreading Concepts and Sentiment Perceptions on Social Media

Salvatore Pirri,[1] Valentina Lorenzoni,[2] Leopoldo Trieste,[3] Rosaria Talarico,[4] Ilaria Palla,[3] Chiara Tani,[5] Elena Elefante,[5] Sara Cannizzo,[1] Isotta Triulzi,[3] Simone Ticciati,[6] Giuseppe Turchetti,[3] and Marta Mosca[5], [1]Institute of Management, Scuola Superiore Sant'Anna, Pisa, Toscana, Italy, [2]Institute of Management , Scuola Superiore Sant'Anna, Pisa, Italy, [3]Institute of Management, Scuola Superiore Sant'Anna, Pisa, Italy, [4]Università di Pisa, Pisa, Italy, [5]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [6]Rheumatology Unit, Azienda Ospedaliero Universitaria Pisana, Italy, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Social media nowadays has the capacity to disclose sentiments and opinions difficult to obtain elsewhere. This is of valuable importance in the healthcare sector as social networks mechanism can offer clues for health professionals coming from patients communities who reveal and express their needs, sentiments, as well indicators of self-reported quality of life [1]. The present study aims at illustrating the potential of using data from social media to unlock feelings and social network dynamics related to Systemic Lupus Erythematosus (SLE). SLE is still challenging because of the variety and complexity of symptoms, its impact on patients' quality of life. This study aimed at (1) collecting and analyzing tweets content using the (#) WorldLupusDay or #Lupus or #SLE released

Figure 1: Words cloud of tweeter frequency hashtags.

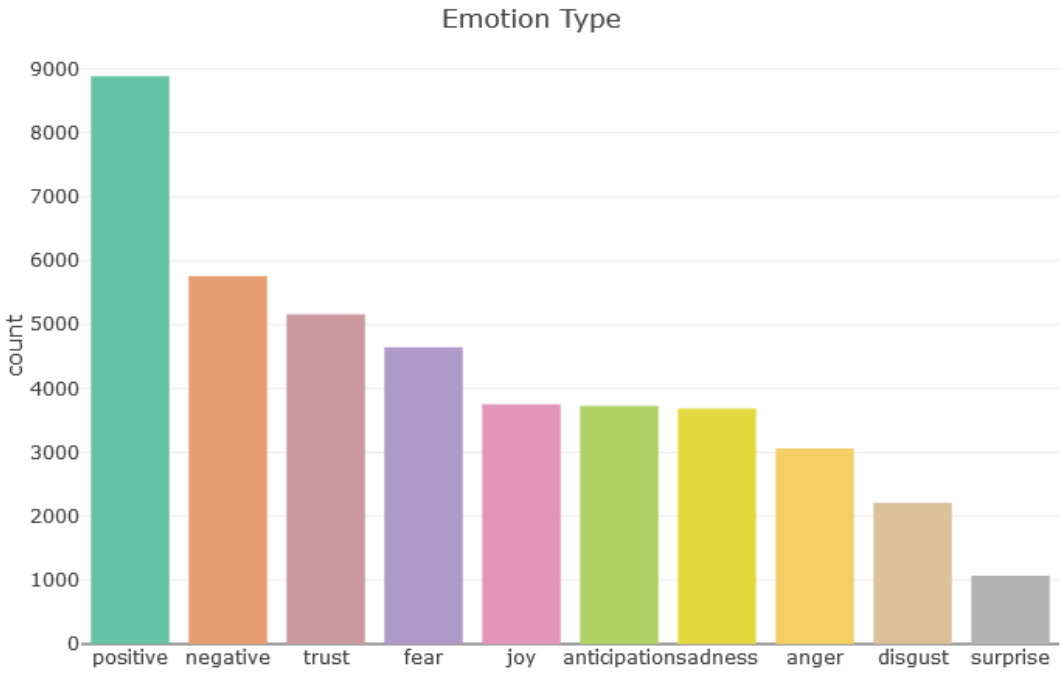

Figure 2: Tweets emotion distribution.

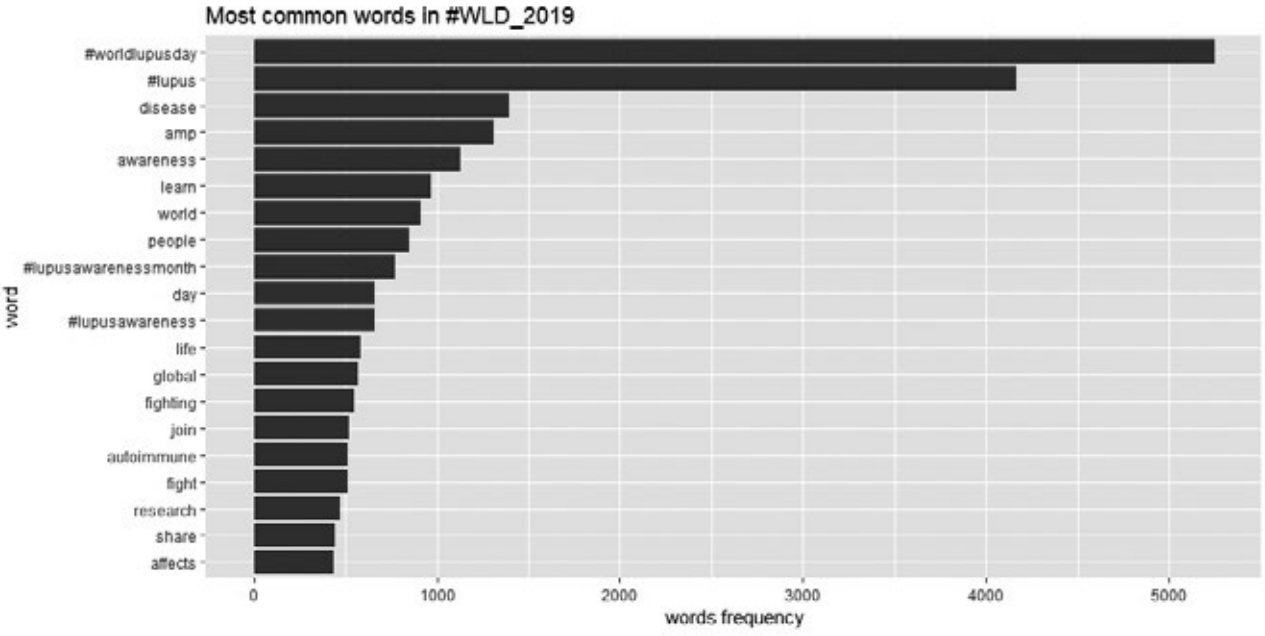

Figure 3: Top 20 most common words.

the 10th of May 2019; and at (2) using tweets text to compute sentiment score, explore main concepts and emotions, look at the most influencers' sentiment score and the trends shared about SLE disease.

Methods: As hashtags are the way that Twitter users categorize messages, promote ideas, and follow topics, using Twitter's public streaming API, all tweets released on the 10th of May 2019 worldwide and contain the hashtags #WorldLupusDay, #lupus and #SLE were used for the present analysis. Overall 6.162 tweets texts and account information (such as time, location, sources, followers count, friends count) created by 2.903 unique users account were extracted and used to perform a quantitative and qualitative analysis. The unique anonymous users' id identification number was used to gather the tweets text for each user and sentiment score values (anger, anticipation, disgust, fear, joy, sadness, surprise, trust, negative, positive) for each user were calculated using the NRC Emotion Lexicon[2] analysis. R software was used to analyze the retrieved tweets data.

Results: The most frequently words were Worldlupusday (*n* = 5247) lupus (*n* = 4165), disease (*n* = 1398) and amp (Accelerating Medicine Partnership; *n* = 773). The content analysis based on tweets text detected *awareness*, *research/share* and *more than my SLE* as frequently mentioned concepts in lupus world day tweets. Computed emotions values for all the tweets text collected revealed higher score in *positive* emotion (total score 8883; mean score = 1.4), and the lowers score in *surprise* emotion (total score 1068; mean score = 0.17). The overall distribution of the sentiment score tended to be more positive than negative with an average score of 0.57.

Conclusion: This study explored the potentiality of the social media network, in this case twitter, as a tool to identify users unmet needs and insights for sharing experience and feelings. Analyzing the emotions and sentiments score value evoked by terms identified in the users tweets text, a valuable picture of how users expressing themselves openly about their illness and perceptions on social media emerges, offering a possibility for gaining valuable insights of information missed using traditional tools for data collection.

Abstract Number: 2253

Comparing Patient and Provider Perspectives on Long Term Biologic Use and Tapering in Stable, Well-Controlled Rheumatoid Arthritis

Patrick Webster,[1] Nicole Wilson,[2] Christina Payne,[1] Kelly Shields,[3] and Tarun Sharma[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Medicine Institute Research, Bioinformatics, Pittsburgh, PA, [3]Highmark Data Science, Pittsburgh

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2015 American College of Rheumatology (ACR) and 2013 European League Against Rheumatology (EULAR) guidelines for management of rheumatoid arthritis (RA) conditionally recommend consider-

Table 1: Patient Demographic (n=30)	
Age, years	60(47-66)
Sex, females	21(70%)
Race, Caucasian	26(87%)
Seropositive (RF and/or ACPA)	15(52%)
Erosive disease on imaging	10(33.3%)

Table 2: Comparison of top concerns between well-controlled RA patients and their providers

Question	Patient Responses (n=20*)	Provider Responses (n=11)
Likelihood of considering tapering biologic (yes, %)	12 (60%)	4 (36%) [Always 1, Very likely 3]
Top concern about continuing biologic therapy long term	No concerns [10]	Clinical risk of long term biologic therapy [7]
	Infection [7]	Patient's coverage/affordability [3]
	Cancer [3]	Patient preference [1]
		Cost to healthcare system [0]
Top concern about reducing or stopping biologic therapy	Worsening Pain [9]	Flare [6]
	Loss of functional capacity/status [5]	Failed multiple therapies previously [2]
	Flare [4]	Patient preference [2]
	Medications less effective when restarting [1]	Risk of radiographic progression [1]
	No concerns [1]	Recapturing remission would be difficult [0]

ation of tapering biologic regimen in stable RA patients in remission with due consideration of patients' values and preferences. Given the paucity of data on perspectives, in this study we sought to explore and compare the patient and providers' perspectives on long term biologic use and biologic tapering.

Methods: Our study was performed using a survey instrument of adult patients with RA who were being followed at Allegheny Health Network Rheumatology between 01/01/2018 and 12/01/2018. The study included patients who have been on a biologic >6 months and clinically stable per review of their medical record (i.e. had no more than 1 RA flare in last 6 months, no change in DMARD or biologic dose in last 6 months). These patients were contacted to complete a questionnaire via a telephone survey designed to gather qualitative data on their perspectives about long term biologic therapy. A similar questionnaire was administered to their providers. Aggregate responses to each question were analyzed to compare patients and providers' perspectives, and to identify and predict patients' likelihood of considering tapering.

Table 3: Comparison of patients interested and not interest in biologic tapering			
	Patients interested in taper (n=13)	Patients not interested in taper (n=16)	p-value
Age, years	59(44-61)	61(55-68)	0.21
Duration of years	7.5(3-9)	16(8.5-27)	0.022
Duration on biologic, years	4(2-6)	4.5(2-8)	0.29
patient global assessment, at time of diagnosis (scale of 0-10; 10=worst)	9.5(8-10)	9.5(8-11)	0.88
patient global assessment, current (scale of 0-10; 10=worst)	3.5(2-4)	6.0(4.5-8.0)	0.005
On daily glucocorticoid, # patients	2(14%)	7(47%)	0.11
On DMARD therapy, # patients	10(77%)	11(79%)	0.9
Erosive Disease, # patients	4(29%)	6(38%)	0.71
RF/CCP positive, # patients	4(31%)	11(69%)	0.066
Well controlled RA per patient, yes	13(93%)	7(44%)	0.007
Previous biologic taper trial, yes	1(7.1%)	0	0.5
Previously failed biologics, yes	6(43%)	6(38%)	0.77
Concerns about long term biologic therapy, yes	9(64%)	7(44%)	0.26

Results: A total of 122 patients met our inclusion criteria. Of these, manual EHR review validated stable RA in 65 patients who were contacted for the telephone survey. 30 patient questionnaires were completed in entirety. Our cohort had the following characteristics: mean age of 55 years, 70% female, 86.7% Caucasian, 53.3% seropositive and 33.3% erosive disease (table 1). 20 of these 30 patients felt their RA was well controlled. 60% of the well controlled patients and 36% of the providers responded that they would consider biologic tapering as an option (table 2). Patients that would consider biologic tapering felt their RA was well controlled with lower patient global assessment scores and had a shorter duration of RA compared to those who did not consider tapering (table 3). The top concern of stable RA patients and their providers about long term biologic therapy was risk of infection and malignancy. Top concern of tapering biologics among both groups was risk of worsening RA (flare, function, pain). Of note, 10 patients (50%) had no concern about being on long term biologic therapy (table 2).

Conclusion: Patients on long term biologic therapy and stable, well-controlled RA were found to be more likely to consider tapering biologic therapy compared to their providers (60% versus 36%) in our survey-based study. Patients and providers shared the same top concerns about continuing or tapering biologic therapy. Patients with well-controlled and a shorter duration of RA were more likely to consider tapering as an option. This information is paramount in designing and implementing our divisional RA Biologic Tapering Initiative (RABTAP), but also to have a more effective and informed shared-decision with patients regarding continuing or tapering long-term biologic therapy in well-controlled RA.

The Urge for Mobile Apps in Rheumatology – a German Patient Perspective

Johannes Knitza,[1] Christina Raab,[1] Antonia Lambrecht,[1] David Simon,[2] Melanie Hagen,[1] Sara Bayat,[1] Georg Schett,[3] Arnd Kleyer,[1] and Axel Hueber[4], [1]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg, University Hospital Erlangen, Erlangen, Germany, Erlangen, Germany, [2]Department of Internal Medicine 3, Friedrich-Alexander-University Erlangen-Nuremberg (FAU) and Universitätsklinikum Erlangen, Erlangen, Bayern, Germany, [3]Department of Internal Medicine 3, Friedrich Alexander University Erlangen-Nuremberg, Erlangen, Germany, [4]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg, University Hospital Erlangen, Erlangen, Germany; Sektion Rheumatologie, Sozialstiftung Bamberg, Klinikum Bamberg, Bamberg, Germany, Erlangen, Germany

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mobile health applications have the potential of saving costs, empowering patients and improving treatment outcomes. Furthermore, the use of medical apps in routine care is increasing among rheumatologists[1]. In order to turn digitalization and all its benefits into practice it is crucial to include the main stakeholders. We therefore wanted to explore the needs and attitudes of patients with rheumatic diseases concerning mobile apps.

Methods: Between December 2018 and January 2019, 224 consecutive patients with rheumatoid arthritis, psoriatic arthritis and spondyloarthritis were seen at one rheumatology outpatients clinic and asked to complete a paper-

Table 1: patient demographic information

Factor		n (total = 224)	Mean, %
Age			
	<30	14	6
	30-39	35	16
	40-49	37	17
	50-59	65	29
	60-70	61	27
	>70	12	5
Gender			
	Male	90	40
	Female	134	60
Diagnosis			
	RA	127	57
	SpA	40	18
	PsA	57	25
Years since diagnosis		224	18
Patient global disease activity (VAS 0-10)		220	4

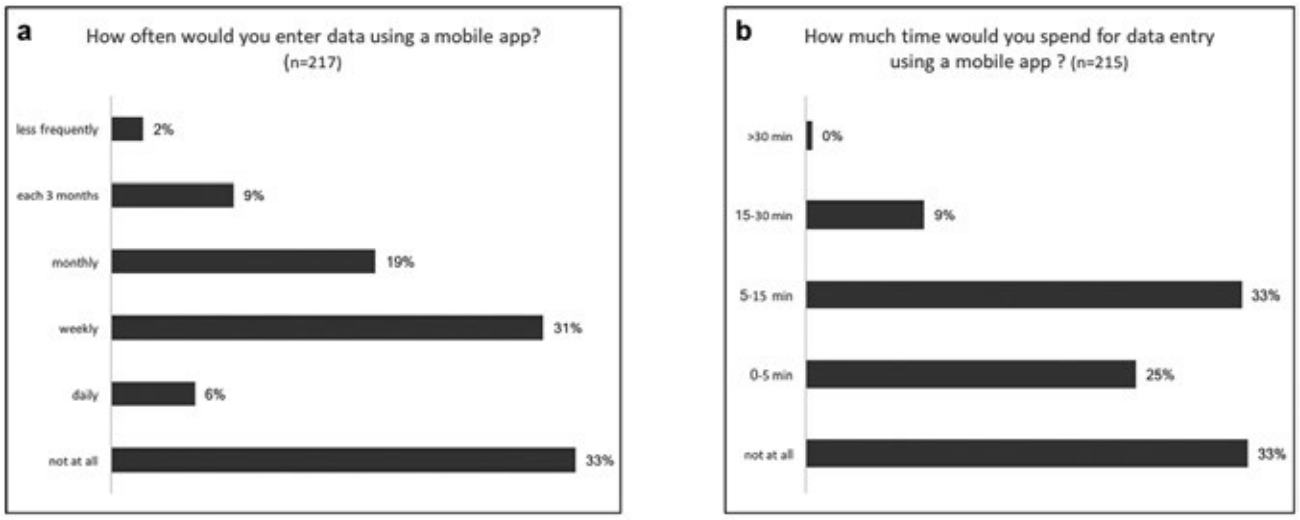

Figure 1

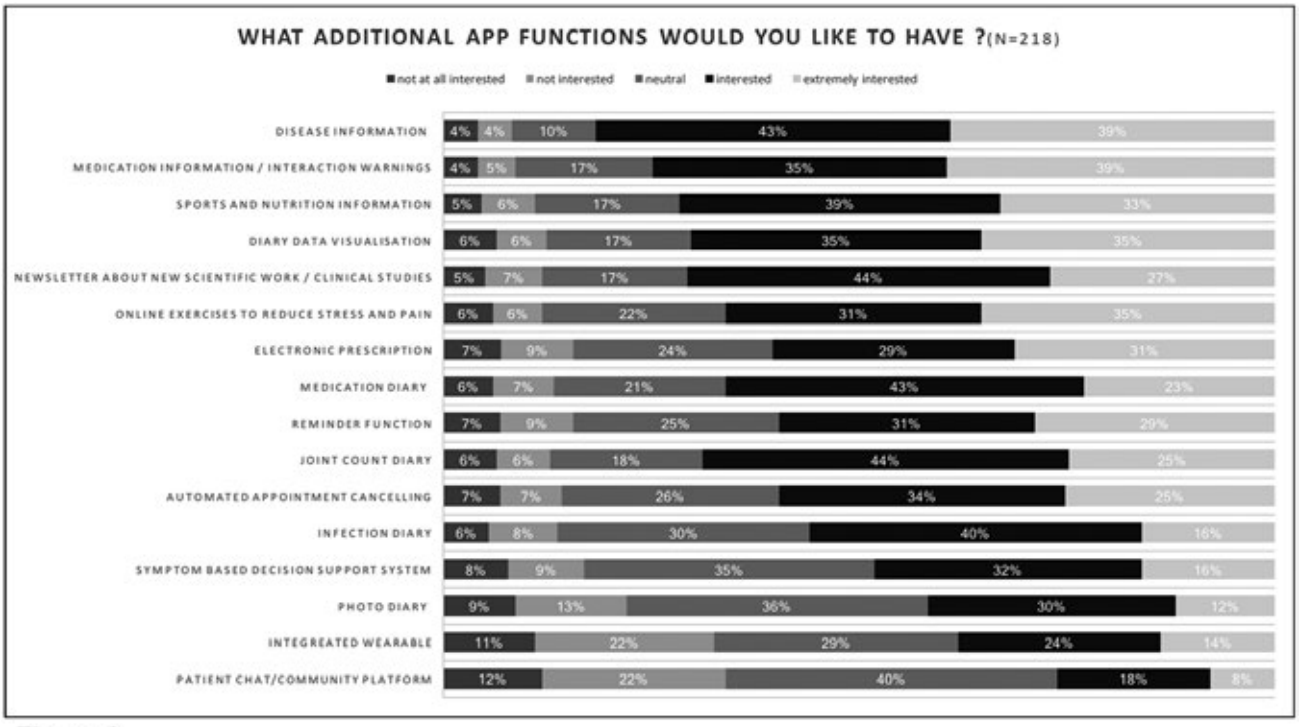

Figure 2

based survey. This survey evaluated the individual mobile app experiences, preferences and attitudes. This study was approved by the Ethics committee (No. 418-18B) and all patients consented to the study.

Results: Patient demographics are displayed in Table 1. 198 patients (90%) regularly used a smartphone, 103 patients (46%) regularly used social media. 144 (65%) patients believed that using medical apps could be beneficial for their health. Only 9 patients (4%) were currently using medical apps and only 24 patients (11%) stated that they knew useful rheumatology websites / mobile apps. 211 patients (96%) would agree to share their mobile app data

for research purposes if data was transferred by a secure and anonymized / pseudonymized method. 166 patients (76%) would welcome official mobile app recommendations from the national rheumatology society. Only 33% would not consent to future data entry (Figure 1), whereas average time for entry should not exceed more than 5 minutes. The most popular three app features desired were information about the disease, medication and sports and nutrition (Figure 2).

Conclusion: Most patients possessed smartphones and believed that using medical apps could be beneficial for their health. They were also willing to share data for research purposes. However only a small minority were currently using medical apps or knew useful apps. Patients stated that they would welcome app recommendations and information provided by apps. We could successfully identify unmet needs and patient priorities to accelerate and guide the way of mobile apps into routine rheumatology care.

Abstract Number: 2255

Adherence to Subcutaneous Anti-tnf Therapies in Chronic Inflammatory Rheumatism and Therapeutic Education

Francoise Fayet,[1] Angelique Fan,[1] Malory Rodere,[1] CARINE SAVEL,[2] Bruno Pereira,[1] and Martin SOUBRIER[3], [1]CHU Clermont-Ferrand, Clermont-ferrand, France, [2]CHU Gabriel Montpied, Clermont-Ferrand, Auvergne, France, [3]CHU Gabriel Montpied, Clermont Ferrand, Auvergne, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment options for chronic inflammatory rheumatism (CIR) have grown over the last few years with the emergence of anti-tumor necrosis factor (anti-TNF) agents. Patients' adherence to this treatment, however, appears suboptimal (Smolen et al, 2019). Given that therapeutic patient education (TPE) is now a recognized factor for improving treatment compliance, we sought to evaluate adherence to subcutaneous anti-TNF therapies by means of the Morisky Medication-Taking Adherence Scale-4 items (MMAS-4©) (Morisky and al, 1986; Morisky and al, 1990; Morisky & DiMatteo, 2011) among patients with CIR (rheumatoid arthritis [RA], ankylosing spondyloarthritis [AS], and psoriatic arthritis [PsA]) benefiting from different models of TPE.

Methods: This is a retrospective, observational monocentric study of current care practices. We evaluated patients receiving subcutaneous anti-TNF agents and benefitting from TPE from 2009 to 2013, categorized according to educational model (M1:individual informative consultation; M2: individual TPE; M3: individual and group TPE sessions). For all educational models, the patients were informed of the potential benefits and risks of the treatments. Adher-

ence was assessed by means of the MMAS-4© as follows: good adherence (MMAS-4© = 4), moderate adherence (MMAS-4© = 2-3), and poor adherence (MMAS-4© = 0-1).

Results: In total, 193 patients were included, comprising 124 women. The mean population age was 53.3 ± 14.8 years old; the mean CIR duration was 10 years [5; 18], with 113 patients suffering from RA, 73 from AS, and seven from PsA. Of the 193 patients, 107 (55.4%) received etanercept, 58 (30.1%) adalimumab, 11 (5.7%) certolizumab, and 17 (8.8%) golimumab. A total of 146 (75.7%) patients presented good adherence, 34 (17.6%) moderate adherence, and 13 (6.7%) poor adherence. The M1 model was followed by 92 patients, M2 by 80, and M3 by 21, with lower adherence observed in the M3 group compared to M1 and M2 (p=0.04). Old age was the only factor correlating with good adherence (p = 0.005). Level of knowledge had no significant impact on adherence (p=0.91). In this study, a similar rate of good adherence (70.6% - 74.1%) was found to that of the European-wide study by Smolen involving 3,390 CIR patients using the MMAS-4©. We found that the older subjects of our study presented the best treatment adherence, as was also observed by Smolen. As regards the specific educational model, we demonstrated that adherence dropped in patients receiving both individual and group TPE compared to those attending only individual TPE sessions or simple informative consultations. We were unable, however, to refer to other works from the literature, and it is possible that the group TPE analyzed in our study generated false beliefs introduced by certain patients. Actually, fear of treatment was shown to be inversely correlated to treatment compliance in CIR.

Conclusion: Our study demonstrated good adherence to anti-TNF treatment in patients receiving treatment education, particularly when it took the form of individual sessions.

Abstract Number: 2256

Patient Beliefs and Perceptions of Methotrexate for the Treatment of Rheumatoid Arthritis and Psoriatic Arthritis

W. Benjamin Nowell,[1] Elaine Karis,[2] Kelly Gavigan,[1] Laura Stradford,[1] Scott Stryker,[3] Shilpa Venkatachalam,[1] Gregory Kricorian,[3] and Jeffrey Curtis[4], [1]Global Healthy Living Foundation, Upper Nyack, NY, [2]Amgen Inc, Thousand Oaks, CA, [3]Amgen Inc., Thousand Oaks, CA, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is a frequently used therapy in both Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) due to its beneficial effects in both populations. Despite the well-known benefits of MTX, it is associated with a number of potential side effects and tolerability issues including nausea and fatigue, gastrointestinal toxicity, skin reactions, headaches, mouth sores and more serious, though rare, side effects such as liver toxicity and bone marrow suppression. The combined risks of rare but potential adverse events along with frequently reported side effects such as nausea and fatigue may add to patient burden of dealing with a chronic disease. Furthermore, many RA and PsA patients discontinue MTX with or without their physicians' knowledge (Mease, 2013). Currently, there is a gap in patient-centered studies focusing on patients' experience with MTX and how this relates to adherence and consequently patient outcomes. The purpose of this ongoing study is to examine patient beliefs and perceptions relating to methotrexate therapy for the treatment of RA and PsA.

Table 1: Participant Characteristics by Current or Previous Methotrexate (MTX) Treatment (N=121)

Characteristics	Participants (N=121)	Currently on MTX (n=49)	Previously on MTX (n=72)
Female, n (%)	108 (89.3)	42 (85.7)	66 (91.7)
Age, years, mean (SD)	57.2 (8.8)	56.5 (8.5)	57.8 (9.0)
White, n (%)	113 (93.4)	45 (91.8)	68 (94.4)
Bachelor's degree or higher, n (%)	58 (47.9)	30 (61.2)	28 (38.9)
Employment Status, n (%)			
Employed (full-time, part-time, self-employed	41 (33.9)	23 (46.9)	18 (25.0)
Not employed (unemployed, student, disabled, retired)	80 (66.1)	26 (53.1)	54 (75.0)
Current RA/PsA therapy, n (%)			
No treatment or NSAIDS only	3 (2.5)	0 (0.0)	3 (4.17)
Corticosteroids only	1 (0.8)	0 (0.0)	1 (1.4)
Non-biologic DMARDs only	46 (38.0)	21 (42.9)	25 (34.7)
Biologic DMARDs	72 (59.5)	28 (57.1)	44 (61.1)
Duration of current methotrexate use, years, mean (SD)	6.2 (5.9)	6.2 (5.9)	-
Current folic acid use, n (%)	52 (98.1)	48 (98.0)	-
BMI, mean, (SD)	31.2 (7.7)	32.7 (8.6)	30.1 (6.8)

Table 2: Side Effects Related to Methotrexate (MTX) (N=121), n (%)

Side Effect	Participants (N=121)	Currently on MTX (n=49)	Previously on MTX (n=72)
Any	83 (68.6)	26 (53.1)	57 (79.2)
Fatigue/tiredness	51 (42.1)	21 (42.9)	30 (41.7)

Abdominal pain	21 (17.4)	1 (2.0)	20 (27.8)
Diarrhea	21 (17.4)	6 (12.2)	15 (20.8)
Loss of appetite	20 (16.5)	6 (12.2)	14 (19.4)
Difficulty sleeping	16 (13.2)	3 (6.1)	13 (18.1)

Methods: Adult US patients in the ArthritisPower registry with self-reported rheumatoid arthritis RA or PsA taking or previously taking MTX were invited to participate in the survey via email invitation. Participants (pts) were either current or past users of MTX who completed a brief online survey. Recruitment for this study is ongoing. Descriptive statistics were conducted on data collected to date.

Results: As of May 2019, the survey had been completed by 121 pts of whom 88.4% were living with RA and 22.3% with PsA, not mutually exclusive. Mean age was 57.2 (8.8) years, 89.3% female, 93.4% White, with mean BMI 31.2 (7.7) (Table 1). Mean duration of MTX treatment among current users was 6.2 (5.9) years. Among respondents, 49

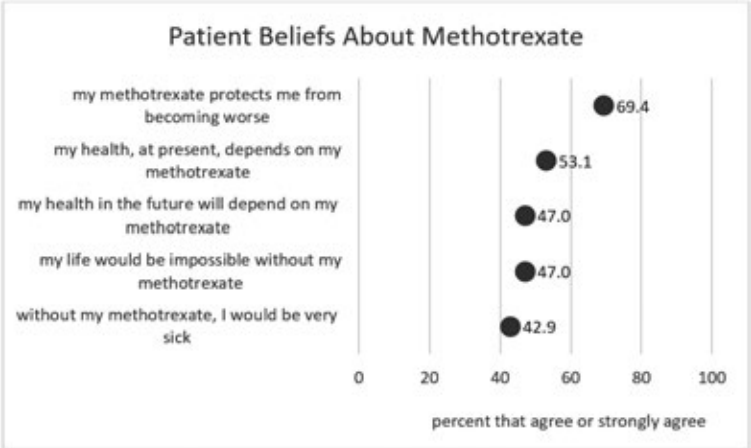

Figure 1: Patient Beliefs Among Current Users of Methotrexate (n=49)

(40.5%) were currently taking oral MTX and 72 (59.5%) had taken it previously but stopped. The majority of pts reported experiencing side effects on MTX: 26 (53.1%) among current users of MTX, 57 (79.2%) among those who previously discontinued MTX (Table 2). Fatigue was the most common symptom among current users, while nausea, abdominal pain, hair thinning, and difficulty sleeping were more common among discontinuers. When asked specifically, 57.1% of current users and 69.4% of discontinuers stated that they experienced fatigue within a day of their MTX dose. Nevertheless, among those currently taking MTX, most (69.4%) felt that MTX protects them from becoming worse and 47.0% agreed that their life would be impossible without MTX (Figure).

Conclusion: A majority of patients experience side effects such as fatigue, nausea and brain fog that they attribute to MTX. Importantly, people living with RA or PsA acknowledge the importance of taking MTX to manage their condition.

Patient and Clinical Characteristics Associated with Increased Willingness to Adopt RA Treatment After an Educational Intervention: An Analysis of the Confident Treatment Decisions for Living with Rheumatoid Arthritis (CONTROL-RA) Trial

Adam Taylor,[1] Lang Chen,[1] Ronan O'Beirne,[2] Joshua Melnick,[3] Eric Ruderman,[4] Jeffrey Curtis,[1] and Maria Danila[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]University of Alabama at Birmingham, Birmimgham, AL, [4]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Evanston, IL

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The treat to target (T2T) treatment strategy is associated with better clinical outcomes in patients with rheumatoid arthritis (RA). We have previously found that a direct-to-patient video intervention aimed to increase knowledge about T2T was associated with increased willingness to adopt RA treatment. The goal of this study was to evaluate patient and clinical characteristics associated with improved willingness to adopt treatment.

Methods: The CONTROL-RA trial, as previously reported, enrolled participants with self-reported RA, with RAPID 3 >4 (range 0-10) and without potentially confounding conditions or who had been using disease modifying anti-rheumatic drugs (DMARDs) in the past 6 months. Outcomes were collected using compensated surveys. Participants completed a baseline survey, viewed the educational intervention and completed the follow up survey immediately after. Intervention group participants viewed up to 6 videos (minimum of 2, mean duration 2 min) on topics relevant to T2T. We performed a multivariate analysis, where the primary outcome was pre-post difference in patient-reported

Table 1: Patient characteristics by level of engagement with the intervention videos

	High Engagement (N=80)	Low Engagement (N=24)	p
Age, mean (SD), years	50.4 (10.09)	45.8 (12.26)	0.06
Race, white, N (%)	71 (88.8%)	21 (87.5%)	0.88
Sex, female, N (%)	72 (90.0%)	20 (83.3%)	0.37
Biologic disease modifying antirheumatic drug (DMARD) use, ever, N (%)	23 (28.8%)	6 (25.0%)	0.72
Conventional DMARD use, ever, N (%)	26 (32.5%)	7 (29.2%)	0.76
General health, good or better, N (%)	40 (50.0%)	13 (54.2%)	0.72
Health literacy, excellent, N (%)	78 (97.5%)	24 (100.0%)	0.44
Familiar with T2T, N (%)	40 (50.0%)	14 (59.3%)	0.48
Baseline willingness to adopt treatment, mean (SD)	7.1 (2.26)	5.5 (2.62)	0.01
Change in willingness to adopt treatment after intervention, mean (SD)	0.6 (1.83)	0.3 (1.37)	0.57
Baseline decision conflict, mean (SD)	33.6 (17.06)	29.4 (15.85)	0.25

Table 2: Characteristics associated with improved willingness to adopt RA treatment

Variable	β	p	95% CI
Baseline willingness to adopt treatment	-0.49	<0.0001	-0.63 , -0.35
High engagement with intervention	0.53	0.14	-0.17 , 1.24
Age	0.03	0.04	0.00 , 0.06
Female sex	-0.62	0.16	-1.49 , 0.25
Biologic DMARD use, ever, yes	0.64	0.08	-0.08 , 1.37
Conventional DMARD use, ever, yes	0.11	0.76	-0.59 , 0.81
General health, good or better	0.20	0.57	-0.49 , 0.88
Health literacy, excellent	-1.49	0.14	-3.48 , 0.49
Familiarity with T2T, yes	0.30	0.32	-0.30 , 0.90
Patient global assessment	0.07	0.42	-0.10 , 0.25
Patient acceptable symptom state, yes	-0.75	0.07	-1.57 , 0.07
Decision conflict about treatment change	0.02	0.09	0.00 , 0.04
Readiness for treatment change	0.28	0.48	-0.52 , 1.08
Personal attitudes favoring medications	0.08	0.05	0.00 , 0.16

willingness to adopt treatment. The following factors were considered: extent of engagement (e.g. high engagement group watched >80% of each of the 6 videos vs low engagement group watched less), age, sex, race, prior biologic/DMARD use, general health, health literacy, familiarity with T2T, patient global assessment, patient acceptable symptom state (PASS), decision conflict about treatment change (decision conflict scale, lower score is better), readiness for treatment change (precaution adoption process model) and personal attitudes favoring medications (10 items surveying patient attitudes regarding acceptable medication risks vs benefits; higher score is more favorable).

Results: Responses of 104 participants in the intervention group were analyzed (Table 1). Participants were 92% white, 92% women, with a mean age of 49 years. A total of 80 (77%) participants were classified in the high engagement group. Participants classified in the high engagement group had higher baseline willingness to adopt treatment than those in the low engagement group (7.1 vs 5.5, p=0.006). The pre-post difference in willingness to adopt treatment was 0.6 in the high engagement group and 0.3 in the low engagement group (p = 0.57). In multivariable models the level of engagement with the intervention was not associated with improved willingness to adopt treatment (p=0.14). Lower baseline level of willingness to change RA treatment, older age and personal attitudes favoring medications were associated with improved willingness to adopt RA treatment (Table 2).

Conclusion: We observed a high level of engagement and were thus not able to discern a dose-response relationship between our intervention and improved willingness after the intervention. Interestingly, those with higher willingness to change treatment were more likely to view the educational intervention, suggesting that those who are less open to treatment change may need additional support to get involved with this type of educational program.

Causes of Influenza Vaccine Hesitancy in Rheumatoid Arthritis and Adults with Juvenile Idiopathic Arthritis

Sandra Pelaez,[1] Vincent Gosselin Boucher,[2] Valeria Valerio,[3] Elizabeth M. Hazel,[4] Kim Lavoie,[5] Brian Ward,[6] and **Ines Colmegna** [6], [1]Research Centre of the Sainte-Justine University Hospital, Montreal, Canada, [2]Montreal Behavioural Medicine Centre, Centre Intégré Universitaire de santé et services sociaux du Nord-de-l'Ile-de-Montréal (CIUSSS-NIM), Hôpital du Sacré-Cœur de Montréal & Department of Psychology, Université du Québec à Montréal, Montreal, QC, Canada, [3]The Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [4]McGill University Health Centre, Montreal, Canada, [5]Montreal Behavioural Medicine Centre, Centre Intégré Universitaire de santé et services sociaux du Nord-de-l'Ile-de-Montréal (CIUSSS-NIM), Hôpital du Sacré-Cœur de Montréal & Department of Psychology, Université du Québec à Montréal, Montreal, Canada, [6]McGill University Health Center, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vaccine hesitancy -the reluctance or refusal to vaccinate despite the availability of vaccines- is one of the threats to global health set by the World Health Organization in 2019. Adults with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) have a greater risk of influenza-related morbidity and mortality, however in this population, vaccine uptake remains suboptimal. This study evaluated the underlying reasons for influenza vaccine hesitancy among RA and JIA patients.

Methods: Between 2016 and 2018, 4 focus groups (FG) of RA and JIA patients were conducted at a large Canadian teaching university hospital. In addition, 8 individual telephone-based semi-structured interviews were done with patients who refused to both get the influenza vaccine and participate in the FG. Barriers of influenza vaccination were discussed. All encounters were transcribed verbatim, uploaded into MAXQDA 12, and thematically analyzed.The analytic strategy was guided by an existing theoretical hesitancy model proposed by the Strategic Advisory Group of Experts (SAGE) on immunization.

Results: Participants wereRA (n=23) and adult JIA (n=5) patients, 48±17.3 years-old (mean ± SD, age range= 20-74), English speakers, and mostly women (82%). Identified barriers to vaccination pertained to three main levels, namely: patients, health care-providers and health-care system. At the patient level, limited knowledge about the value and mechanisms of action of inactivated vaccines and the increased risk of infection associated with RA/JIA, as well as poor overall health literacy, were identified as causes of concerns, misconceptions or fears about influenza vaccination. Negative influence from relatives, peers and media, and in some cases the perception that vaccines are promoted to benefit the pharmaceutical industry were also reasons of hesitancy. At the level of health care provider, RA/JIA patients indicated that the limited time to discuss about vaccines is a key cause of vaccine hesitancy. Aspects related to the health-care system mainly revolved around organization, including waiting time and accessibility to vaccines as causes of vaccine hesitancy.

Conclusion: The causes of influenza vaccine hesitancy among RA/JIA patients are multiple. Vaccine specific issues, contextual and individual influences affect RA/JIA patients' vaccination decisions. Specific multi-level approaches

enhancing knowledge-awareness and facilitating communication with health care providers could reduce vaccine hesitancy.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) face a number of challenges which adversely affect their quality of life. The objective was to qualitatively evaluate content of online discussions on their perceived physical challenges posted by patients with RA.

Methods: Participants were adults 18 years or older, living the United States or Canada, diagnosed with RA and enrolled in a trial assessing the effects of social networking on chronic disease management in RA, using a private patient support group on Facebook. Different topics for discussion were posted weekly by a moderator. We collected the discussions posted by the participants on their perceived physical challenges and compiled them into a database. The data was coded using Dedoose, an online application for qualitative data analysis. We used a grounded theory approach and thematic content analysis to synthetize and categorized the codes into major themes.

Results: The group had 92 registered members. Sixty-four members comprising 60 females and 4 males participated actively by contributing to the discussion. They ranged in age from 24 to 71 years, 93.8% were non-Hispanic white, 68.8% were married or living with a significant other or partner and 61% had a Bachelor's degree or higher educational level. Participants had been diagnosed with RA between 1 and 9 years prior to the study. A total of 356 posts were found including 25 by the moderator. Number of posts per active participant ranged between 1 and 60. The major themes identified included: i) Perceived physical challenges, ii) Psychological manifestations, iii) Social effects of living with RA, and iv) Coping mechanisms.

Specific physical challenges commonly identified by participants included fatigue, pain, stiffness and inability or difficulty in carrying out simple daily tasks. Psychological manifestations included insomnia, brain fog, frustrations particularly from being misunderstood, and depression. Social effects included disruptions in their social engagements, family lives, difficulty in keeping up with friends and demands of work life. Coping mechanisms included use of medical therapies including pharmacotherapy and surgery, attitudinal changes, lifestyle modifications such as

going slowly in the mornings, getting up a bit early and not scheduling appointments before 10 am, and using social support.

Conclusion: Patients with RA face a myriad of physical challenges which may take a toll on their social lives and mental states. Our evidence suggests a beneficial effect for interventions designed to increase education or conversation between patients and their health care providers to address the identified issues.

Abstract Number: 2260

Patients' Journeys Through Giant Cell Arteritis: A Qualitative Study

Jennie Best,[1] Ivan Nunez,[2] Kristina Woodburn,[2] Abby Breyer,[2] Mike Conway,[2] and Margaret Michalska[1], [1]Genentech, Inc., South San Francisco, CA, [2]Azul Seven, Minneapolis, MN

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosis of giant cell arteritis (GCA) is difficult due to multiple presenting symptoms, and access to care may be delayed because often multiple providers are involved in the diagnosis of GCA and disease management. Treatment with high-dose glucocorticoids (GCs) can relieve symptoms and prevent vision loss, but GC-related adverse events are common; GCA often relapses once GCs are tapered. The purpose of this study was to understand the GCA patient care pathway and unmet needs in GCA through in-depth patient interviews.

Methods: US patients with GCA were recruited through outreach to physicians and The Vasculitis Foundation. Extensive individual interviews with patients were conducted by qualitative researchers by phone or in person and explored patients' perspectives and experiences from the onset of GCA symptoms to diagnosis and disease management. The qualitative data collected were analyzed using human-centered design methodology, including patient typologies (personas: optimist, fearful, stoic or despondent), forced temporal zoom (journey maps), forced semantic zoom (stakeholder system mapping) and affinity mapping for pattern recognition of unmet needs.

Results: A total of 28 patients were interviewed; 23 (82%) were women and mean age was 69 years (**Table**). The number of patients in each persona category is shown in the **Table**. Stoic and optimist personas had medium to high levels of self-advocacy and a positive/engaged attitude about their condition, while fearful and despondent personas had low levels of self-advocacy with disengaged/negative attitudes toward their condition. Patients often ascribed their milder GCA symptoms to causes such as stress and did not consult a physician until they developed moderate to severe symptoms. After diagnosis of GCA, all patients received GCs with little information on the chronicity of GCA or treatment alternatives to GCs. Overall, patients managed their GCA independently, and sought to balance relief of GCA symptoms with the adverse effects of GCs. Patients concentrated on tapering and discontinuing GCs, with less concern about relapse. Furthermore, patients who were most uncomfortable with the adverse effects of GCs often waited until their GCA symptoms became debilitating before telling their physician. Almost all patients reported searching for a support group after the diagnosis.

Table. Demographics of Patients With GCA Who Participated in Interviews and Personas Based on Analysis of Qualitative Interview Data

	Patients N = 28
Age, mean, years	69
Women, n (%)	23 (82)
Interview type, n (%)	
Phone	15 (54)
In person	13 (46)
US region, n (%)	
Midwest	10 (36)
Northeast	6 (21)
South	5 (18)
Mid-Atlantic	4 (14)
West	3 (11)
Persona, n (%)*	
Optimist	9 (32)
Despondent	9 (32)
Fearful	8 (29)
Stoic	6 (21)

* Some interviewees fit into multiple personas.

Conclusion: Patients with GCA experience adverse effects from GCs and want a clearer understanding of treatment options; they remain focused on reducing their GC dose and need access to support groups. For those with inflammatory comorbidities, GCA diagnosis is another burden in a debilitating journey resulitng in a sense of disempowerment and resignation toward their condition and limited treatment options. Patients' attitudes and self-advocacy vary depending on their personas; recognizing these personas may help HCPs coordinate patient care. Increased awareness of GCA among patients and HCPs may accelerate the path to diagnosis and treatment, and emerging therapies may help reduce GC burden.

Abstract Number: 2261

Post Traumatic Stress Disorder in Patients with Rheumatoid Arthritis

Marisel Vanesa Bejarano,[1] Anastasia Secco,[2] Marta mamani,[2] Felix Romanini,[2] and Natalia Tamborenea[3], [1]Hospital Bernardino Rivadavia, Caba, Buenos Aires, Argentina, [2]Hospital Rivadavia, Caba, Buenos Aires, Argentina, [3]Hospital Rivadavia, Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is growing evidence that complex interactions between individual's genetic susceptibility, immunological processes, and environmental factors such as stress , increase the risk of developing Rheumatoid Arthritis (RA). For this reason, disorders associated with severe stress such as post-traumatic stress disorder (PTSD) have been implicated in various autoimmune pathologies.

Objectives: To estimate the frequency of traumatic events prior to the diagnosis of RA. To determine the frequency of PTSD in patients with traumatic events prior to the diagnosis of RA. To compare demographic, clinical, serological characteristics, existence of depression and anxiety, according to the presence or absence of PTSD.

Methods: Observational, analytical, cross-sectional study. Patients with a diagnosis of RA according to ACR (1987) and ACR EULAR (2010) criteria were included, from the Rheumatology Service of a public hospital in Buenos Aires, Argentina. They were recruited between October 2016 and August 2018. All Patients with another rheumatic or chronic disease were excluded. To determine the presence of PTSD, the Traumatic Experiences Questionnaire was used in its version validated in Spanish. To assess the severity of PTSD, the Davidson Trauma Scale was used in its Spanish version validated for Argentina. The continuous variables were described as mean and standard deviation (SD) or median and interquartile range (IQR), according to distribution and sample size. The categorical variables were expressed in percentages.In the bivariate analysis we used, for the continuous variables, the Student or Mann Whitney test, according to distribution and sample size. The categorical variables were analyzed using Chi square or Fisher's exact test, according to the expected frequency distribution table. A logistic regression model was performed taking PTSD as a dependent variable.

Results: 128 patients were included, 86.72% were female, with a mean age of 52.23 years (± 12.39). The mean time of evolution of RA was 12.96 years (± 9.66). 55.47% of the patients reported having experienced at least 1 traumatic event prior to the diagnosis of RA. The most frequently reported traumatic events were: unexpected death of a family member or close friend (39.5%). 32.39% of the patients who had experienced a traumatic event presented PTSD. 43.48% of patients with PTSD experienced a severe disorder.63.49% had some degree of depression and 55.56% of anxiety.

Statistically significant differences were found between the patients who presented PTSD vs those without PTSD in: female sex (100% vs 83.81%, $p = 0.04$), anxiety (median 12, IQR: 4-18 vs 6, IQR: 0-11 $p < 0.01$) depression (median 14, IQR: 6-19 vs 6, IQR: 0-12 $p < 0.01$). The main variable that showed an independent association with PTSD was depression (OR: 1.13, 95% CI: 1.05-1.20, $p < 0.01$).

Conclusion: We observed that more than half of the patients had experienced at least 1 traumatic event prior to the diagnosis of RA and 32.39% of them presented PTSD. PTSD was found associated with the female sex, the presence of anxiety and, independently, with depression. RA is probably product of the influence of various factors, with stress being one more determinant, within many existing ones.

of SSc, we decided to focus on SSc patients with pulmonary involvement to determine their perception about the disease and correlate with quality of life, degree of disability and symptoms, as well as expectations.

Methods: This cross-sectional study included SSc patients with symptomatic lung involvement who signed an informed consent. Demographic, clinical and laboratory information were collected from an electronic register database. Revised Illness Perception Questionnaire (IPQR), 36-Item Short Form Health Survey (SF-36), Health Assessment Questionnaire Disability index (HAQDI), COPD Assessment Test (CAT) and three direct questions regarding quality of life, expectations about treatment and survival were applied to patients. IPQR score have negative domains (higher score means negative perception) and positive domains (higher score means positive perception). Correlations between questionnaires were made to evaluate patient perception measured by IPQR and if those perceptions would affect their opinion.

Results: 130 consecutive SSc patients were included, 55 (42%) with limited SSc, 64 (49%) diffuse and 11 (8%) sine scleroderma. Mean age was 54±12.5 years and mean disease duration 12±9 years. All domains of IPQR statistically correlated with SF36, HAQ and CAT, except the perception of chronicity. The Pearson linear correlation was negative between SF36 and negative IPQR domains (meaning worse quality of life and higher negative perception); and positive between SF36 and positive domains (meaning higher quality of life and higher positive perception). Higher HAQ and CAT indicated higher disability and dyspnea, presenting a linear positive Pearson correlation ($p < 0.0001$) (Table 1). A higher perception score was found comparing patients with moderate to severe disability (HAQ >1.25) or advanced dyspnea scores (CAT > 20) to patients with lower grade of disability or pulmonary symptoms. (Table 2). The relation between age, disease duration and IPQR had no statistical significance. Regarding the subjective opinion of the patients, established by direct questions, they presented optimistic answers as such 86.9% classified their quality of life as good, 45% expected cure or improvement with treatment in progress, and 85% believed that they would live more than 5 years. But no correlation between the IPQR domains and their opinion was found.

Conclusion: SSc patients with impaired quality of life, disability and major symptoms of dyspnea have higher perception of their disease by IPQR. However, the degree of perception does not appear to influence their opinion, suggesting an optimistic psychological profile with more positive attitude and effective coping strategies.

A Qualitative Study Evaluating Near-Patient Tools Including a Mobile Application for Earlier RA Referral; Potential to Reduce Chronic Disease Burden

Norma Biln,[1] **Simran Chahal**,[1] Bruce Clarke,[2] and Alison Warner[2], [1]Augurex Life Sciences Corp, Vancouver, Canada, [2]B2 Consulting, Kelowna, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, debilitative autoimmune disease. Patients who are treated with disease modifying therapy within 6-12 weeks of symptom onset have better outcomes which leads to a reduced economic burden of disease.[1] Technology that enables near-patient blood testing coupled with digital health

applications may increase the proportion of patients treated within this window. This study aimed to assess the perceived unmet need for early treatment amongst clinicians and patients as well as their perceptions of a near-patient blood test and digital health mobile application.

Methods: 74 participants, approximately half from each of Canada (n=18) and the US (n=20) participated in a combination of in-depth interviews and surveys for 40-50 minutes. 38 of the 74 subjects, consisted of 16 rheumatologists, 14 primary care physicians (PCPs) and 8 RA patients. To supplement the patient study-sample, 36 additional patients completed an online survey of quantitative and open-ended questions focused on diagnosis and perspectives of a described near-patient blood test and mobile application. Rheumatologists who were in full-time practice and PCPs who see at least 15 RA patients a month were included. Patients were between 18 and 60 years old, had an RA diagnosis and experience using apps for health management.

Results: Almost all Rheumatologists and PCPs indicated that the time between symptom onset and treatment initiation (currently 6-18 months) could be improved and agreed that difficulty diagnosing is still one of the biggest unmet needs. Referrals to a Rheumatologist range from 6 weeks to 3 months. Patients indicated that it took 8 months to 2 years before treatment initiation. Most Rheumatologists said the longest delay is due to inconclusive PCP clinical exams and blood work, leading to repeated visits before patients are referred. Most clinicians and patients welcomed new tools with 33% of patients willing to pay for the near-patient blood test and mobile application. Clinicians had few concerns about a near-patient blood test and indicated that it should be available in the clinic, not the pharmacy. Patients reported the appeal of an easy to use near-patient blood test that could have meant an earlier diagnosis over a traditional laboratory blood test.

Conclusion: RA is difficult for PCPs to identify for early referral and treatment within 6-12 weeks of symptom onset. The clinicians and patients we surveyed reported positive perspectives regarding near-patient blood tests and mobile applications and welcome their use to assist with earlier referral and treatment. With the emergence of innovative near-patient technologies, opportunities exist to intervene earlier and potentially reduce the social and economic burden of chronic diseases.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical Activity (PA) is beneficial for people with inflammatory arthritis (IA). In 2018, EULAR published the first recommendations for guiding PA in patients with IA.[1]These endorsed the American College of Sports Medicine-American Heart Association Public Health Recommendations, which encourage participation in four domains of PA: Aerobic, Resistance, Flexibility, and Balance. They also included provider recommendations

for PA promotion and delivery to patients with IA. Objectives of our study were to 1) Describe levels of participation in the four PA domains in an IA population; 2) Identify barriers/facilitators to PA; 3) Explore patient views on importance of PA; and 4) Investigate if EULAR recommendations for promotion/delivery of PA are being incorporated into care.

Methods: Patients with IA from a university rheumatology practice were invited in person or via the medical record to take an 81-question, 15-minute survey. The survey asked in which PA domains they participated, about facilitators/barriers to PA, and whether the recommendations for PA promotion had been addressed during their care. Respondents reporting minimum aerobic exercise for 20 minutes three times weekly plus at least one other domain were categorized into an "Active" group, others were categorized as "Inactive." Patient characteristics and survey responses were compared between groups using t-test for continuous and Chi-squared or Fisher's-Exact Test for categorical variables.

Results: Of 1,113 patients invited, 108 participated. Sixty (43%) reported aerobic exercise, 44 (41%) flexibility, 42 (39%) resistance, and 18 (17%) balance. Forty-three (40%) were categorized as active and 65 (60%) as inactive. The

Table 3: Utilization of EULAR PA Promotion/Delivery Recommendations by Providers				
EULAR PA Promotion/Delivery Recommendation[1]	**Pertinent Survey Question**	**Active N (%)**	**Inactive N (%)**	**p-val**
1: Promoting PA should be an integral part of standard care.	Has your rheumatologist emphasized the importance of PA?	32 (76)	53 (84)	0.31
2: All HCPs should take responsibility for and cooperate to promote PA, including making necessary referrals, to ensure that people receive appropriate PA interventions.	Has another physician emphasized the importance of PA?	33 (79)	49 (78)	0.92
3: Competent providers should deliver PA interventions.	Have you received a referral for help with PA?	17 (43)	28 (44)	0.90
4: HCPs should evaluate PA to identify which of the four domains of exercise can be targeted for improvement.	Has a HCP explained the four recommended domains of PA to you?	8 (19)	12 (19)	1.0
5: General and disease-specific contraindications should be identified and taken into account.	Has a HCP /specialist discussed types of PA you should NOT do due to arthritis?	11 (26)	18 (28)	0.83
6: PA interventions should have clear, personalised aims.	Has a HCP/specialist worked with you to develop aims and goals for PA?	14 (33)	23 (37)	0.74
7: General and disease-specific barriers and facilitators related to performing PA should be identified and addressed.	Has a HCP/specialist helped you to identify barriers to PA related to your general life?	7 (17)	14 (22)	0.51
	Has a HCP/specialist helped you to identify barriers to PA related to your arthritis?	17 (41)	20 (31)	0.33
8: Necessary adaptations to general PA should be based on a comprehensive assessment of patient factors.	Has a HCP/specialist helped you create an exercise program tailored to your health-related and personal needs?	17 (40)	20 (31)	0.33
9: HCPs should plan and deliver interventions that include behavioural change techniques, self-monitoring, goal setting, action planning, feedback and problem solving.	Has a HCP/specialist helped you to monitor or self-monitor your PA?	12 (29)	16 (25)	0.68
	Has a HCP/specialist discussed with you techniques to overcome barriers to PA?	11 (26)	18 (28)	0.33
10: Healthcare providers should consider different modes of delivery of PA in line with people's preferences.	Has a HCP/specialist discussed with you different PA options based on your preferences /needs?	14 (33)	18 (28)	0.57

Abbreviations: HCP = Healthcare Provider; PA = Physical Activity
1: Rausch Osthoff A-K, et al. 2018 EULAR recommendations for PA in people with Inflammatory Arthritis and Osteoarthritis. Ann Rheum Dis. 2018:1251–60.

active group had lower BMI and lower RAPID3 Scores, and fewer people with diabetes, sleep apnea, and tobacco use (Table 1). A larger proportion of the active group reported self-efficacy for exercise ($p< 0.001$), prioritizing exercise ($p=0.01$), exercising for weight control ($p< 0.001$) and improved energy with exercise ($p=0.04$). A larger proportion of the active group (86%) also reported PA engagement prior to arthritis diagnosis ($p=0.01$). More patients in the inactive group compared to the active group cited finances ($p=0.01$), pain ($p=0.03$), fatigue ($p< 0.001$), and concern that PA worsens arthritis ($p >0.001$) as barriers . Most patients (in both groups) understood the health-related benefits of PA (Table 2). A minority of patients in both groups perceived recommendations about PA were addressed in clinical care (Table 3).

Conclusion: While about half of patients with IA reported aerobic exercise, most do not engage in resistance, flexibility, or balance training despite recommendations. Overall, patients acknowledge the benefits of PA, but do not perceive that they receive advice regarding PA from doctors and most habits are formed without instruction from rheumatologists. With new EULAR guidelines, there is an opportunity for providers to have more prescriptive discussions about exercise.

Abstract Number: 2265

The Effects of Message Framing on Patients' Perceptions and Willingness to Switch to a Biosimilar

Chiara Gasteiger,[1] Annie Jones,[1] Maria Kleinstauber,[1] Maria Lobo,[2] Robert Horne,[3] Keith Petrie,[1] and **Nicola Dalbeth** [1], [1]University of Auckland, Auckland, New Zealand, [2]Auckland District Health Board, Auckland, New Zealand, [3]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients may hold negative perceptions towards biosimilars which can create barriers to their uptake. Physicians also report uncertainty in how best to explain biosimilars. The aim of this study was to measure the effect of differently framed explanations on patients' perceptions of and willingness to switch to a biosimilar.

Methods: Ninety-six patients with rheumatic diseases taking an originator biologic were randomised to receive one of four biosimilar explanations delivered by video- positive framing with and without an analogy, and negative framing with and without an analogy. The same physician was featured in each video explanation to ensure consistency.. The positive explanation employed a positive valence attribute frame, whereby the *similarities* between the biologic and biosimilar were emphasised. The physician featured in the video used positive body language and verbal cues (e.g. nodding and smiling) to promote a positive interaction. Comparatively, the negatively framed explanation focused on the *differences* between biologics and biosimilars, and the physician used negative body language and verbal cues (e.g. less confident vocal tone) to imply uncertainty regarding efficacy and safety. The analogy used focused on the concept of baking bread, using a cheaper yeast from a different brand. Willingness to switch to a biosimilar, perceptions about biosimilars, and the effectiveness of the explanation were measured after the information delivery.

Results: Positive framing led to more participants being willing to switch (67%) than negative framing (46%). Framing significantly predicted willingness to switch to a biosimilar, with participants in the positive framing group being 2.36 times more willing to switch ($P = 0.041$). The positive framing group also reported significantly greater perceived efficacy of biosimilars ($P = 0.046$), and thought the explanation was more convincing ($P = 0.030$). The analogy did not enhance willingness to switch or understanding ($P > 0.05$).

Conclusion: Positive framing can improve perceptions of and willingness to switch to a biosimilar in patients currently taking biologic medications.

Treatment Preferences in Patients with Axial Spondyloarthritis

Dafne Capelusnik,[1] Emilce Schneeberger,[2] Leonela Lysseth Macias Oviedo,[1] Juan Manuel Sevillano Gutierrez,[3] and Gustavo Citera[4], [1]Instituto de Rehabilitacion Psicofisica, CABA, Ciudad Autonoma de Buenos Aires, Argentina, [2]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [3]Instituto de Rehabilitacion Psicofisica, CABA, Argentina, [4]Instituto de Rehabilitación Psicofísica, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster II: Patient Preferences, Beliefs, & Experiences – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to the increasing tendency of involving patients in decisions regarding their health care and knowing the need for further research on patients' preferences about treatment and adherence, the aim of this study was to evaluate the treatment preferences of patients with Axial Spondyloarthritis (axSpA) and to identify the factors associated with their choice.

Methods: Patients diagnosed with axSpA (ASAS 2009 criteria) were included. Sociodemographic data, disease characteristics, disease activity and treatments received were recorded. A specially designed questionnaire was administered to evaluate patient preference for the drug administration, doses frequency, the favorite site and the person chosen for the drug administration. Also the attributes and disadvantages of the chosen rout were assessed, as well as the characteristics and compliance with the current treatment. Statistical analysis: Student's T-test, Chi2 test and multiple logistic regression analysis.

Results: Seventy patients were included with a median age (*m*) of 46.5 years (IQR 38-57), 55 males (78.6%) and a median disease duration of 13.5 years (7.75-23.25).

According to the patients, the relevant aspects in decreasing order of frequency for choosing a treatment were: the ability to improve quality of life (32.9%), improvement in joint inflammation (22.9%), pain (21.4%) and physical function (14.3%). Sixty-three patients (90%) chose to receive the medication at home, and 55 (78.6%) chose to self-administrate the drug. The most chosen mode of administration was oral (51.4%), following by subcutaneous (SC) (41.4%), intramuscular (IM) 4.3% and intravenous (IV) 2.9%. The preferred frequency of oral administration was one tablet per week (61.1%) and SC administration, once a month (34.5%). The main advantages of oral administration were: the easy administration (58.3%), no need for a special skill (33.3%) and no requirement of refrigeration (16.7%), and in the case of SC: the easy application (44.8%), the efficacy (27.6%) and the safety (13.8%). The choice of oral route was associated with: preference for self-administration (88.9% vs 11.2%, p = 0.05), preference for receiving the medication at home (97.2% vs 2.8%, p = 0.02) and higher level of education (14.5 ± 4.2 years vs 11.5 ± 4.7 years, p = 0.009). These last two variables remained significant in the multivariate analysis.

The choice of the SC route was independently associated with the type of axSpA (46.7% in ankylosing spondylitis (AS) vs 10% in non-radiographic axSpA (nr), p = 0.038).

The patients with greater adherence to treatment were receiving more frequent biological SC treatment (52.7% vs. 13.3%, p = 0.008), and had lower disease activity, higher functional capacity and better quality of life. In the multiple logistic regression model, being receiving biological SC treatment and having lower disease activity remained significantly associated with the treatment compliance according to the patient.

Conclusion: The most preferred way of administration by patients with axSpA was the oral route, with a weekly frequency and self-administration at home, followed by the subcutaneous route, with monthly infusion.

The Association Between Non-restorative Sleep and Diurnal Patterns of Cognitive Function and Fatigue in People with Fibromyalgia and Matched Controls

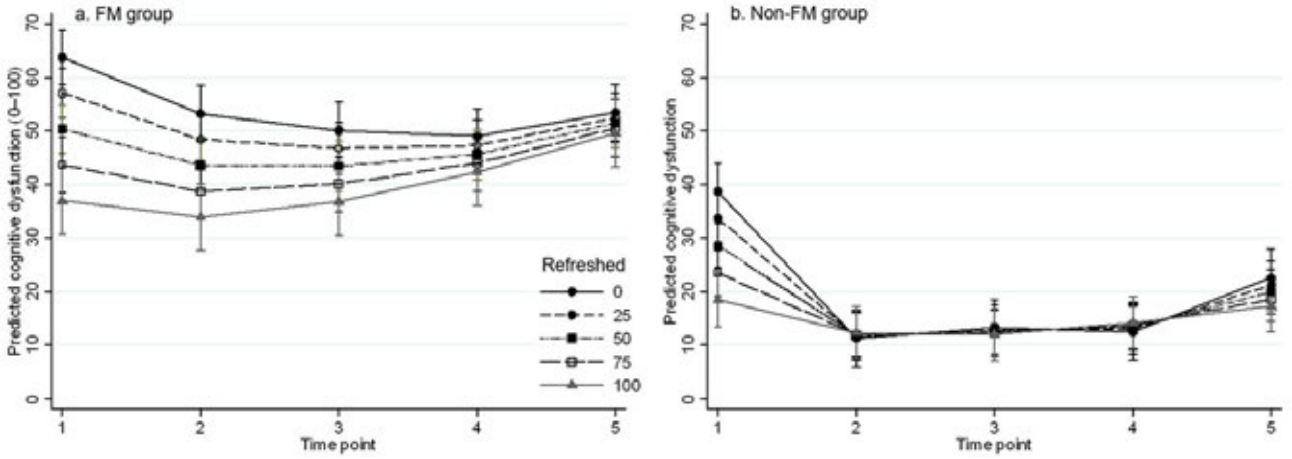
Daniel Whibley,[1] David Williams,[2] Daniel Clauw,[3] and Anna Kratz[4], [1]University of Aberdeen; University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]Division of Rheumatology, Department of Internal Medicine and Division of Anesthesia, Michigan Medicine, Ann Arbor, MI, [4]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Psychology/Social Science Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

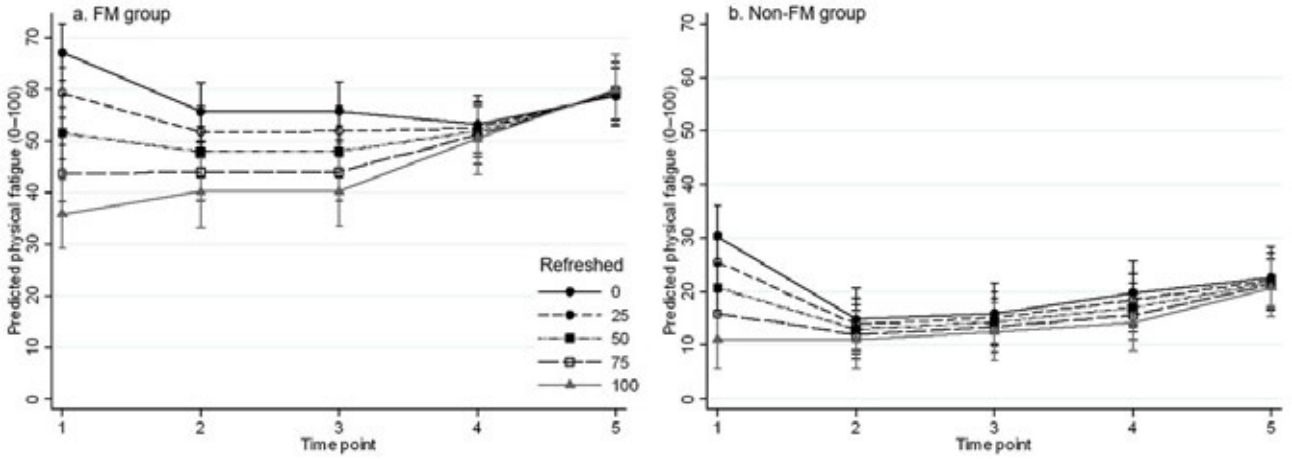
Background/Purpose: Non-restorative sleep is associated with poorer cognitive function and greater fatigue, not only in people living with fibromyalgia (FM), but also in the general population. Whether the extent of non-restorative sleep impacts on diurnal patterns of cognitive function and fatigue, and whether this differs based on FM status, has yet to be established.

Methods: This secondary analysis used data collected from 100 participants recruited to an ambulatory study conducted in real-world settings (50 participants who met 2016 ACR FM diagnostic criteria and 50 age-, sex- and education-matched non-FM controls). Participants reported the degree to which they felt refreshed upon awakening (0–100 scale, higher scores representing more restorative sleep). Ecological momentary assessments of self-reported cognitive function (perceived clarity and speed) and mental and physical fatigue (all measured using 0–100 numeric rating scales) were administered five times per day for eight days using a smartphone app. Multilevel linear regression models were used to investigate whether perceived level of refreshment on awakening was associated with diurnal symptom patterns of cognitive function and physical and mental fatigue.

Results: Mean age of the sample was 45.1 years (SD 13.9); 88% were female. A total of 756 days of data were available for analysis. Compared to the non-FM group, the FM group reported higher aggregate levels of cognitive dysfunction (mean difference: 31.5, 95%CI 25.2–37.8), physical fatigue (mean difference: 36.3, 95%CI 29.6–43.0), and mental fatigue (mean difference: 32.0, 95%CI 24.8–39.2). For both groups, non-restorative sleep was associated with greater cognitive dysfunction and fatigue (both mental and physical) on awakening. For the FM group, the effects of non-restorative sleep were sustained across the course of the day; for the non-FM group, recov-



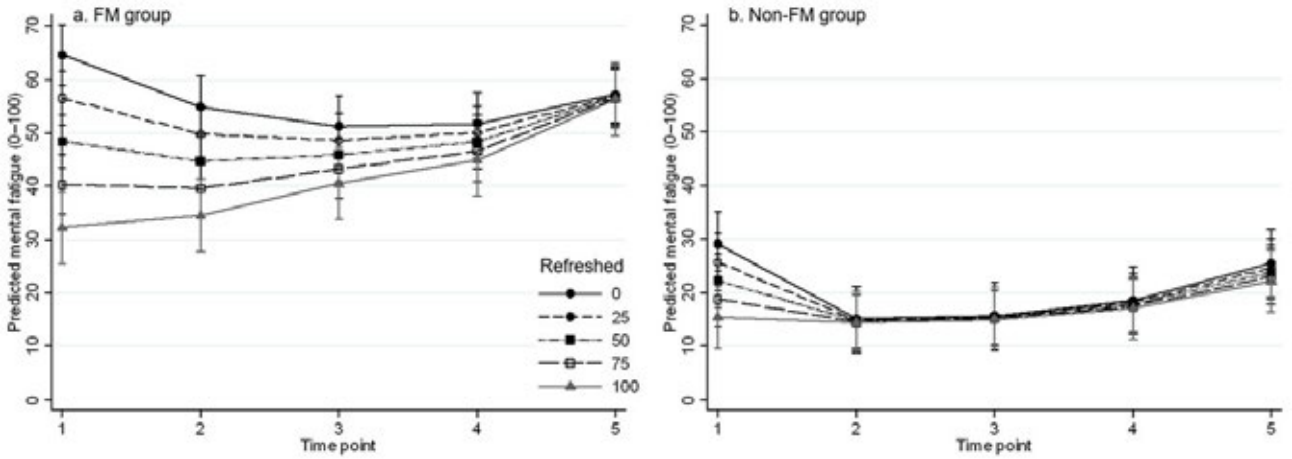
The impact of non-restorative sleep on diurnal pattern of cognitive function



The impact of non-restorative sleep on diurnal pattern of physical fatigue

ery was swift (Figures 1–3). There was a significant interaction between Group membership and impact of non-restorative sleep on diurnal symptom patterns for both physical and mental fatigue ($p < 0.01$), but not cognitive function ($p=0.07$).

Conclusion: Nights of non-restorative sleep exert negative effects on cognitive function and fatigue that persist longer into the day for those with FM compared to non-FM controls. If supported by further investigation, the diurnal patterns observed in the FM group may indicate optimal times for task planning and therapeutic engagement in response to subjective feelings of refreshment on morning awakening.



The impact of non-restorative sleep on diurnal pattern of mental fatigue

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Psychology/Social Science Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA) development, autoantibodies to citrullinated protein antigens (ACPA) are elevated in the blood before clinically-apparent synovitis develops. These findings underpin the development of several prevention trials in RA where individuals with elevated ACPA are studied to prevent or delay the development of clinically-apparent synovitis. Understanding the decision-making processes of individuals with such autoantibodies who are offered enrollment in a clinical prevention trial could provide important insights into optimizing participation in such trials. To address this, the Research Participation Influences (RPI) Study is an IRB-approved project that examines factors that influence the decision to participate in an ongoing RA clinical prevention trial.

Methods: Individuals with elevated serum levels of ACPA in absence of synovitis were notified of their ACPA results indicating risk for future RA development. Following this, subjects were provided a description of an interventional clinical trial and what their participation would entail. After each individual agreed to or refused participation, they were given a survey that gathered limited demographic information, first-degree relative (FDR) status, and 11 influences on trial participation which were rated on a Likert scale. In addition, 2 open response questions asked why individuals initially had their ACPA tested and to list any additional influencing factors. The responses were statistically compared between groups, and the qualitative data from open response questions were transcribed and sectioned by relevant meaning units. These units were used to build common themes using a language processing application.

Results: 62 surveys were collected; 37 'Yes' responses (agreed to trial) and 25 'No' responses (refused trial). Key findings in both the Likert and open response questions were that 'Yes' respondents expressed higher perceived risk for RA and higher perception of benefit to themselves or others (Table 1). 'No' respondents expressed more concern about adverse effects of the medication and had less personal or family experience with RA. There was a higher rate of FDRs agreeing to the trial (56.8%) than non-FDRs. Furthermore, 7 codes of high frequency were derived from the

Q5: In your own words, why did you decide to come here today to be screened and have your blood tested?
Q7a: Is there a reason not listed in the chart above that most influenced your decision to decline/participate in the clinical trial?

open response questions, revealing a general theme of support for research among the 'Yes' group and a negative perception of study medication among the 'No' group (Table 2).

Conclusion: 'Yes' respondents were more likely to be FDRs and exhibited a stronger concern for personal risk for RA than 'No' respondents. Given that all subjects were provided similar estimates of risk based on ACPA levels, further exploration is needed to determine why these differences in perception of risk were present, and whether these were due to other factors such as the presence of symptoms or an individual's interpretation of their risk for RA given family history. Understanding these and other underlying issues that influence participation, including perceptions of medications, will better inform researchers and individuals who are candidates for prevention.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Psychology/Social Science Poster – ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Although many RA patients attribute their disease onset to recent life events, results from retrospective studies remain unclear. We compared characteristics of newly diagnosed RA patients who did and did not report significant stressful life events (+*stress*) in year prior to diagnosis at baseline and 12 months.

Methods: Data were from early RA patients (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) from 01-2007 to 03-2017 with ≥ 12 months of follow-up. Patients were asked about major psychological (death, divorce/separation, family, financial, other) and physical (motor vehicle accident, surgery, major illness/infection, other) stressors in previous year. We used independent t-tests and chi square to compare characteristics by sex and stress classification and multivariable regression to examine the impact of stress on disease activity and patient reported outcomes (PROs) at 1 year after adjusting for age, sex, education, and baseline fibromyalgia diagnosis and swollen joint count.

Results: The 1933 adults were mostly female (72%), with a mean (SD) age of 55 (15) years. At baseline, 52% reported one or more stressors in previous year; family (48%), financial stress (36%), death (35%), surgery (28%), and major illness (26%) were the most common stressors. Patients with +*stress* were more likely to be women, were significantly younger, had more comorbidities, slightly higher mean DAS28, and were more likely to have fibromyalgia (Table 1). Patients with +*stress* also reported significantly baseline higher pain, fatigue, depression, sleep disturbance, patient global, and HAQ-DI scores.

At 1 year, swollen joint counts and the proportion of patients in DAS28 REM was similar between groups. However, PROs remained higher in those with a history of +*stress*, with some evidence of a dose-response relationship (Table 2). The greatest impacts were on mood, sleep disturbance, and fatigue.

Conclusion: In this pan-Canadian early RA cohort, stressful life events were common in the year prior to diagnosis and were associated with significantly worse depression, fatigue, sleep disturbance, pain, patient global and disability scores at diagnosis; 1 year later effects on PROs persisted even though disease activity was similar between groups. Newly diagnosed RA patients with a history of recent stressors may benefit from emotional support to optimize how they feel and function.

Abstract Number: 2270

A Pilot Study of the Psychosocial Impact of Undifferentiated Connective Tissue Disease

Juliette Kleinman,[1] Ecem Sevim,[2] Medha Barbhaiya,[3] Joann Vega,[1] Carol Mancuso,[2] Michael Lockshin,[4] and Lisa Sammaritano[5], [1]Hosptial for Special Surgery, New York, NY, [2]Hospital for Special Surgery, New York, NY, [3]Hospital for Special Surgery, Weill Cornell Medicine, New York, NY, [4]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY, [5]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Psychology/Social Science Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite increased awareness related to the diagnosis and treatment of Undifferentiated Connective Tissue Disease (UCTD), there is a dearth of research on the psychosocial impact of the disease. The objective of this qualitative pilot study was to better understand the psychosocial impact of UCTD on patient well-being.

Methods: We identified UCTD patients using the newly established Undifferentiated Connective Tissue Disease (UCTD) and Overlap Registry and the electronic medical record (EMR) clinic schedule of our specialty hospital. We recruited, consented and assembled for participation a convenience sample of patients diagnosed with UCTD, based on the presence of persistent antinuclear antibodies and CTD symptoms not meeting other classification criteria (*Mosca et al, Clin Exp Rheumatol 1999;17:615*). Baseline data on race and ethnicity, education level and disease duration were collected. A licensed clinical social worker administered a 30-minute structured interview by telephone. The standardized questionnaire consisted of demographic and 14 open-ended questions related to understanding and experiences related to UCTD. Grounded Theory was utilized to analyze the qualitative data and identify themes with a team of physicians, research coordinators and a social worker.

Table: Emerging Themes, Categories, and Illustrative Quotes Obtained from Structured Interviews by the Clinical Social Worker with Undifferentiated Connective Tissue Disease (UCTD) Patients (October 2018 – March 2019, n= 14)

Emerging Psychosocial Themes	Categories and Selective Illustrative Quotes
1. Acceptance of the disease	Validation by doctor and self • "I was in limbo, but they finally found out what was wrong with me, I wasn't crazy" • "I found a doctor who took me seriously" • "I may have to face the rest of my life with this, but it won't kill me" • "I don't accept that I have this"
2. Experience many symptoms	Extreme fatigue, loss of muscle strength and mobility, inflammation, joint and body pain and aches, skin changes and rashes: • "a disease that has no boundaries"
3. Uncertainty about future	Unknown future: • "My future is hard to predict. I'm not incapacitated now, but I know that one day I will be" • "I'm conflicted about my future" • "I don't want to be a burden on my family"
4. Importance of Self-management	Find ways to help yourself: positive attitude, exercise, good nutrition, rest, mindfulness, spirituality and prayer, gain knowledge: • "I exercise every day and eat right" • "I've learned to be strong; I focus on today" • "Make yourself a priority" • "Find a good rheumatologist you can talk to" • "Keep a positive attitude"
5. Value of professional support	Psychotherapy, social workers, counseling: • "Therapy helps me and my family cope" • "My family and friends don't always understand" • "Social workers should meet with patients in order to process a new diagnosis or for ongoing support" • A desire for support groups "help patients feel connected... meet each other...hear what someone else is going through"
6. Need to make accommodations	Work:

Results: We contacted 20 UCTD patients, of whom 14 participated (100% female, mean age 58 ± 13y [age range 27-74]). All patients had at least a Bachelor's degree and were predominantly white (64%), with other races included (21% African American, 7% Hispanic/Latina, and 7% Asian). Patients tended to have relatively long mean disease duration (12 ± 14yrs), and over half (64%) were currently engaged in counseling or mindfulness training. Nine specific psychosocial themes and categories emerged (Table), guided by data saturation. Patients expressed that profession-

al guidance and support for themselves, peers and family are necessary to increase awareness, reduce isolation and promote self-efficacy. They voiced a desire to “create support groups to connect to others”, with “patient education material” and to “have caregivers involved.”

Conclusion: This pilot study describes nine psychosocial themes expressed in structural interviews by women with UCTD at a major academic center, reflecting issues that may not be currently appreciated by health-care providers. Future studies will aim to recruit a larger, more diverse UCTD patient population, including those with recently diagnosed disease, to explore themes that may inform best practices for psychosocial interventions (e.g. patient support groups, educational materials, peer counselors) to support UCTD patients in better managing and coping with their illness.

Sexual Health, Intimacy and Rheumatology Practices

Julie Schwartzman-Morris,[1] Arianna Leo,[2] and Preeya Nandkumar[2], [1]Division of Rheumatology, Northwell Health, Great Neck, NY, [2]Division of Rheumatology, Northwell Health, Great Neck

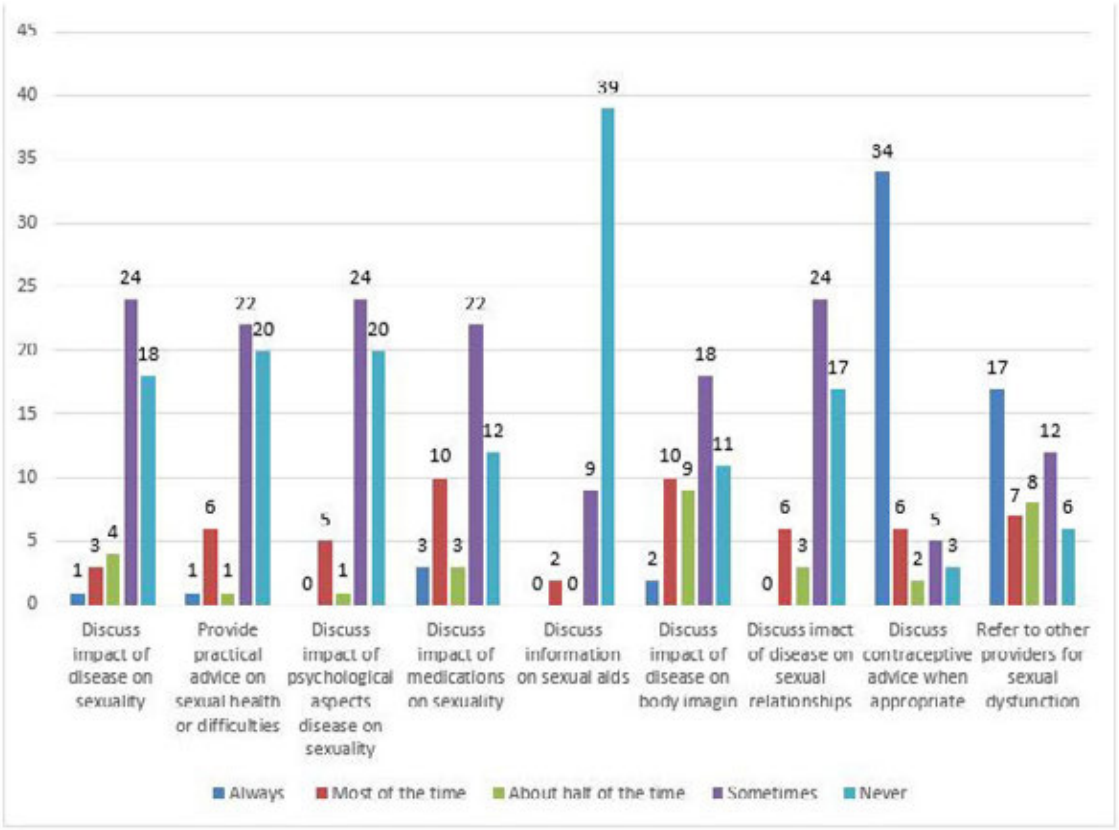

Figure 1. Rheumatology Provider Practices

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Psychology/Social Science Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with chronic illness often face challenges with their sexual health and intimacy. The issues can be inherent to the disease state, self-image, or physiologic function. Sexual health, function and intimacy issues are rarely included in the health assessment questionnaires and disability indices used by Rheumatologists. In addition, Rheumatologists may be ill equipped to ask and respond to patients' inquiries about sexual function. Most providers acknowledge the impact of a patient's disease on their sexual health, but admitted this area is often neglected. The purpose of this study was to learn about rheumatology care providers' practices when speaking to patients about sexual health and intimacy. Despite the extensive data suggesting the widespread, negative impact of chronic illness on sexual health, we hypothesize that there is a lack of training for providers about how to address sexual health and intimacy issues. We intend to use this information to develop a provider education program so they may provide better care for patients.

Methods: Rheumatology Health Care Providers (HCPs), including Rheumatologists, Nurse Practitioners, and RNs, were asked to complete a 31 item questionnaire (N=50). The survey was designed to understand current practices and potential reasons why providers fail to address sexual health with patients. Ten questions addressed provider awareness of the effects of rheumatologic disease on sexual health, discussion of these topics, and if patients were

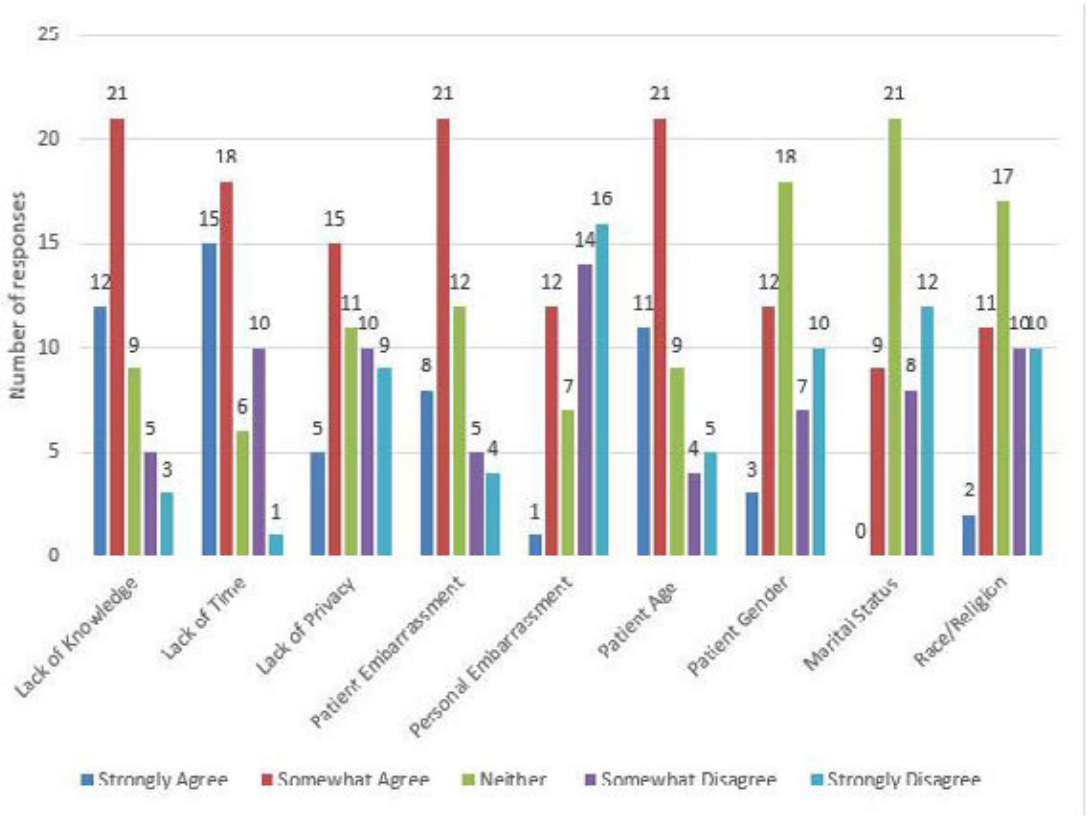

Figure 2. Issues that Influence the Decision to Discuss Sexual Health

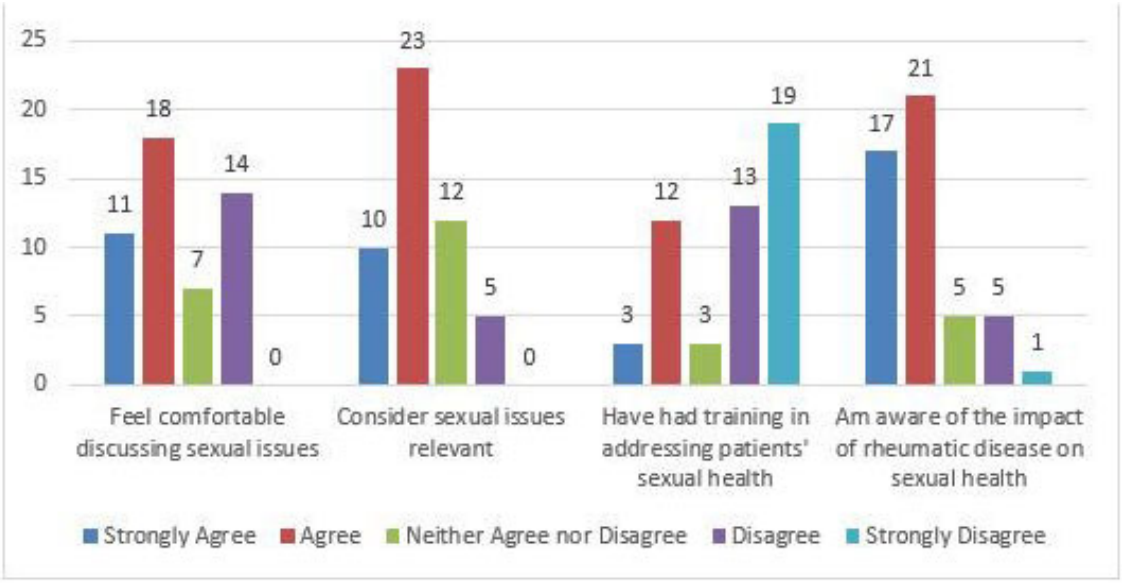

Figure 3. Care Provider Impressions

referred to other providers for assistance. Survey questions also assessed the effect of lack of time, and lack of training or experience in addressing sexual health issues. Each response was that of a five point Likert scale.

Results: Of the 50 HCPs who completed the survey, 48% reported that they discuss the impact of a patient's disease on their sexuality, and the impact of psychological aspects of disease on sexuality "sometimes." However, 36% and 40% of responders report that they "never" discuss either of the two topics, respectively. Additionally, 48% "sometimes" and 34% "never" discuss the impact of disease on patients' sexual relationships. Notably, 78% of HCPs never provide information about sexual aids. The majority of responders reported lack of skills/knowledge about sexual health, patient embarrassment, and patient age as barriers, while lack of time and privacy were noted to significantly interfere with providers' discussion of sexual health. Finally, 66% of HCPs agree or strongly agree that sexual health issues are relevant to rheumatology practice.

Conclusion: The impact of rheumatologic disease on sexual health cannot be underestimated. The results of this study highlight the barriers to discussing sexual health with patients, most significantly, a lack of knowledge about the topic. Additionally, more than half of survey responders agree that sexual health issues should be addressed, indicating an interest in the topic. We intend to use this information to develop a training program for rheumatology HCPs with the goal of educating providers about how to address and guide patients about their sexual health and intimacy issues.

Abstract Number: 2272

Self-reported Anxiety, Depression and Levels of Physical Activity in Patients with Adult Idiopathic Inflammatory Myopathies

Kristofer Andreasson,[1] Helene Alexanderson,[1] and Heléne Sandlund[2], [1]Karolinska Institutet, Stockholm, Sweden, [2]Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Psychology/Social Science Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The adult idiopathic inflammatory myopathies (IIM) comprise dermatomyositis (DM), necrotizing myopathy (NM), antisynthetase syndrome (ASS), overlap myositis and inclusion body myositis (IBM). Impaired muscle endurance and strength, low aerobic capacity, and self-reported fatigue and pain are common features in patients with IIM. Quality of life is reduced compared to population-based reference values. To our knowledge self-reported levels of physical activity have not been studied within patients with IIM's. Further, anxiety and depression are common in other rheumatic diseases, such as systemic lupus erythematosus, but is less studied in myositis, and not previously in relation to levels of physical activity. Although, there is evidence for symptom reducing effects of exercise for depression and anxiety (Craft & Perna, 2004). The purpose of this study is to assess the levels of self-reported physical activity, depression and anxiety amongst adult patients with adult IIM and to and analyze possible relationships between physical activity and anxiety/depression.

Methods: All patients visiting the Rheumatology clinic at Karolinska University Hospital in Solna between February and May 2019 where asked to fill in questionnaires about their levels of physical activity, anxiety and depression using the International Physical Activities Questionnaire – short form (IPAQ) and Hospital Anxiety and Depression Scale (HADS) which is used for screening, not diagnosis. The questionnaires were distributed by the myositis team nurse. Spearman's rho was used for correlation analysis. HADS is scored in two separate scales, one for depression (HADS-D) and one for anxiety (HADS-A). The cut-off value for probable depression or anxiety is ≥8 of a maximum of 21 per scale. Physical activity was scored as 1 (low, < 150 min/w), 2 (moderate, ≥ 150 min/w) and 3 (high intensity, ≥ 300 min/w).

Results: So far, a total of 34 patients answered the questionnaires. 28 (82%) of the patients reported to be physically active on a health-enhancing level (HEPA) according to WHO's guidelines of 150 minutes of moderate physical activity every week. 12 of these patients reported to be active on a high level the last seven days. A total of seven patients

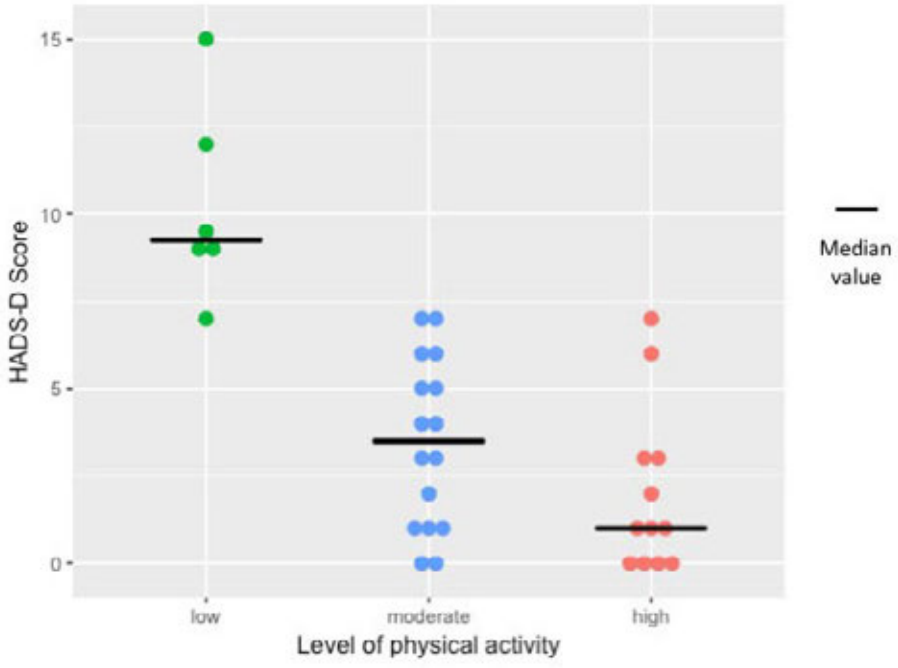

Figure 1. HADS-Depression score grouped by levels of physical activity by IPAQ

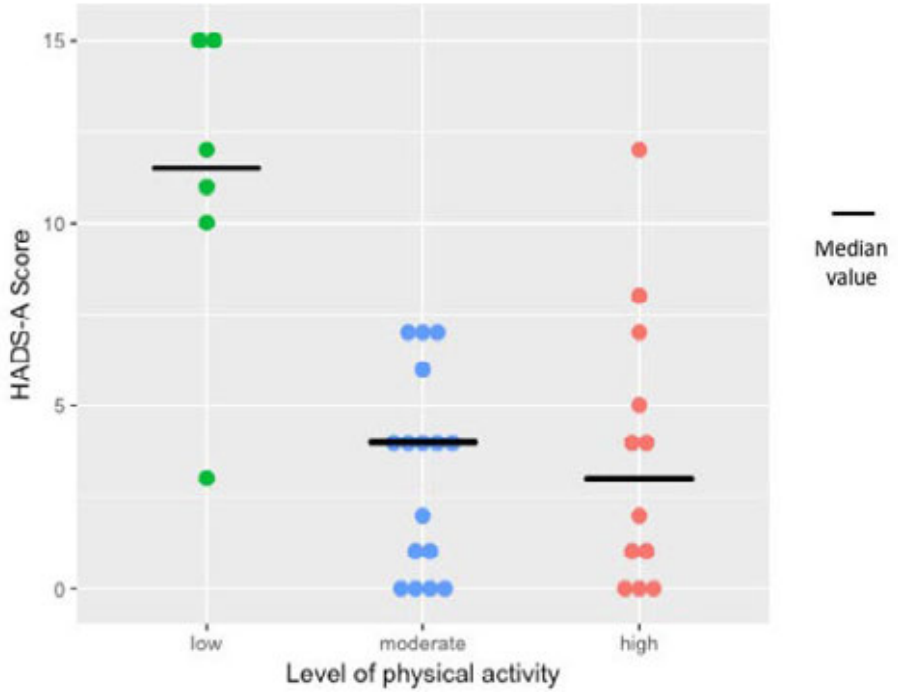

Figure 2. HADS-Anxiety score grouped by levels of physical activity by IPAQ

(21%) scored probable anxiety and/or depression, with five scoring ≥8 for both depression and anxiety. There was a moderate to strong negative correlation between Physical Activity and Depression (Fig. 1), rs=-0.63 (-0.8; -0.37) and a weak negative correlation between Physical Activity and Anxiety (Fig. 2), rs=-0.36 (-0.62; -0.02).

Conclusion: Self-reported data shows that most patients with IIM are physically active on a health-enhancing level and that higher levels of physical activity correlates well with less depression. However, anxiety showed a weaker correlation with physical activity. 82 % of the patients reported to reach HEPA which is a very high number. This can be due to frequent visits to physical therapists early in the disease and then yearly visits with focus on exercise and physical activity. This is preliminary data. Data collection will be ongoing throughout 2019 to confirm these results.

Risk of Serious Infections in Offspring According to TNFi Subtypes

Evelyne Vinet,[1] Yvan St-Pierre,[1] Cristiano S. Moura,[1] Jeffrey Curtis,[2] and Sasha Bernatsky[3], [1]McGill University Health Centre, Montreal, QC, Canada, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TNFi subtypes have differential placental transfer, with some reaching higher fetal than maternal blood levels. Thus, certain TNFi subtypes could cause immunosuppression in the offspring. However, to date,

there is no data on the risk of serious infections according to TNFi subtypes. We evaluated serious infections in a large group of children born to mothers with chronic inflammatory diseases who used TNFi during pregnancy. Our comparators were unexposed offspring born to affected and unaffected mothers. We determined if the risk of serious infections differed according to TNFi subtypes.

Methods: We identified all women with ≥1 hospitalization for delivery after a diagnosis of rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriasis (PsO), psoriatic arthritis (PsA), or inflammatory bowel diseases (IBD), and a randomly selected group of unaffected mothers, matched ≥4:1 for age, year of delivery, and state of residence, using MarketScan database (2011-2016). We defined TNFi exposure based on ≥1 filled prescription and/or infusion procedure code during pregnancy and/or the preconception period. We further refined TNFi exposure based on potential for high (infliximab, adalimumab, golimumab) vs low (certolizumab, etanercept) placental transfer. We ascertained serious infections in offspring based on ≥1 hospitalization with infection in the 1st year of life. We performed multivariable analyses, adjusting for maternal demographics, disease type, co-morbidities, pregnancy complications, and drugs.

Results: We identified 16,490 offspring of mothers with RA (4,142), AS (381), PsO/PsA (5,743), and IBD (6,731), as well as 164,553 children born to unaffected mothers. Among offspring whose mothers had inflammatory diseases, 1,611 (9.8%) were exposed to TNFi during pregnancy, 338 (2.0%) were unexposed during pregnancy but exposed in the preconception period, and 14,541 (88.2%) were unexposed both during the pregnancy and preconception periods. The percent of serious infections in offspring of inflammatory disease mothers with no TNFi exposure (2.1%; 95% CI 1.9, 2.3) was similar to those with TNFi exposure (2.3%; 95% CI 1.6, 3.0), while the percent of serious infections in children born to unaffected mothers was 1.6% (95% CI 1.6, 1.7). In offspring exposed to TNFi with high placental transfer, the percent of serious infections was 2.3% (95% CI 1.6, 3.3), while for TNFi with low transfer, it was 1.7% (95% CI 1.0, 3.1). In multivariable analyses, we did not observe an increased risk of serious infections in TNFi-exposed offspring vs unexposed offspring of mothers with inflammatory diseases (OR 1.0; 95% CI 0.7, 1.5). Results were similar when we restricted TNFi exposure to the 3rd trimester (OR 1.1; 95% CI 0.7, 1.7). In multivariable analyses of children exposed to TNFi with high vs low placental transfer, our point estimate was consistent with increased risk, but the CI was wide, including the null value (OR 1.43; 95% CI 0.66, 3.08).

Conclusion: When we compared the risk of serious infections in offspring exposed to TNFi with high vs low placental transfer, we observed a potential trend for an increased risk, although the CI was wide and included the null value. Our findings stress the need to further study this issue.

Targeted Education Improves Awareness of Reproductive Health Issues Among Women with Rheumatologic Diseases

Sonya Selvaraj,[1] Tanya Allawh,[2] Meagan Clark,[1] Sneha Patel,[3] Christina Payne,[4] and Arundathi Jayatilleke[1], [1]Drexel, Philadelphia, PA, [2]Hahnemann, Philadelphia, PA, [3]Einstein Montefiore, Bronx, NY, [4]Allegheny General, Philadelphia, PA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Reproductive Issues In Rheumatic Disorders Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Managing rheumatologic conditions in women of childbearing age necessitates consideration of reproductive health issues. We studied reproductive health awareness in women with rheumatic disease by surveying them on the effectiveness of audiovisual (AV) and written educational interventions in improving their knowledge regarding pregnancy, fertility, lactation, and contraception.

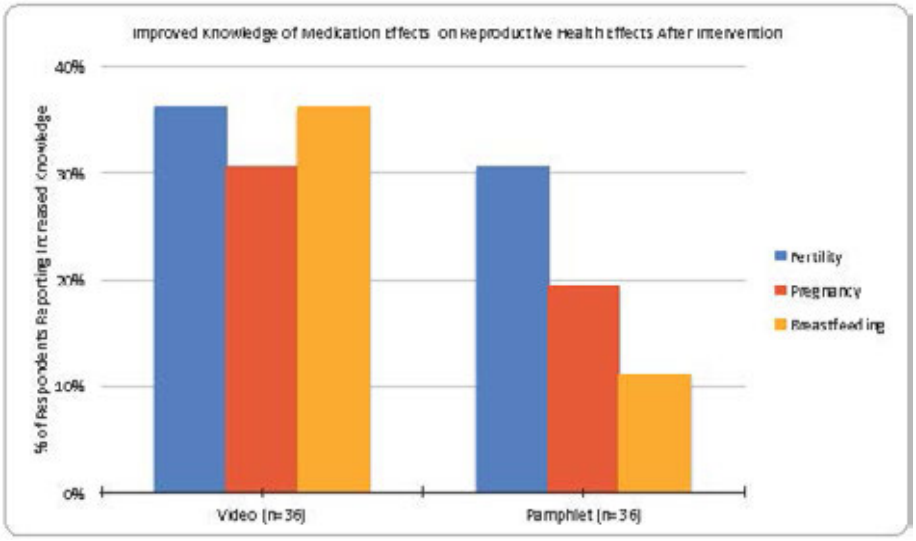

Figure 1 Survey respondents reported improved understanding of reproductive health issues after educational intervention.

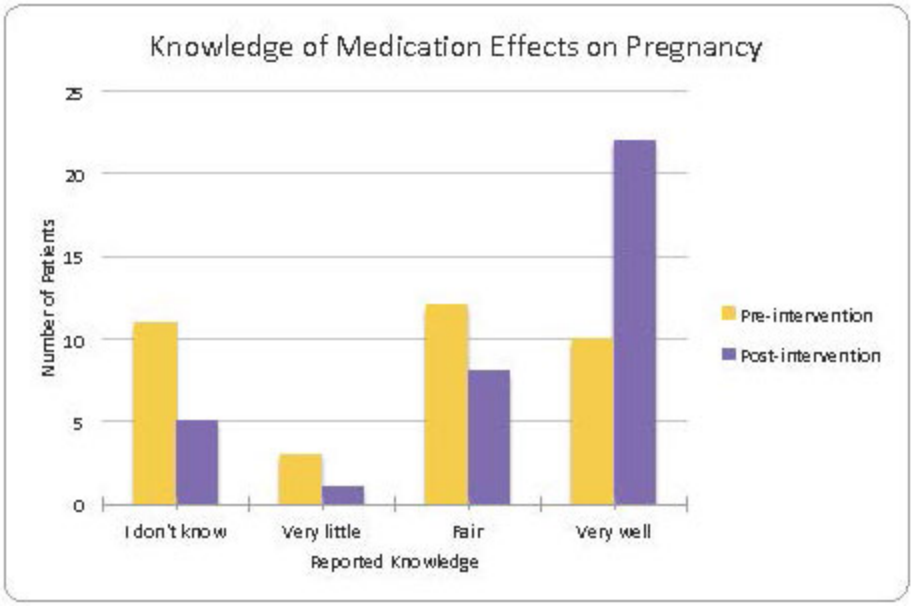

Figure 2 More women reported understanding the issue of medication effects on pregnancy after the intervention (n=36).

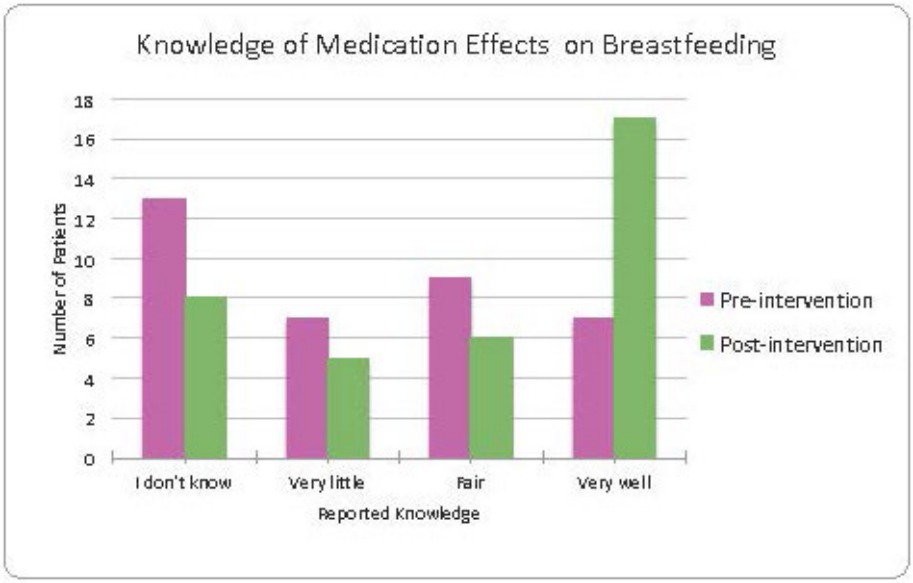

Figure 3 More women reported understanding the issue of medication effects on breastfeeding after the intervention (n=36).

Methods: We enrolled 101 women (ages 18-45) with rheumatic disease at our clinic and surveyed them on awareness of reproductive health issues as well as contraceptive practices. Respondents were randomized to view a video or receive a pamphlet with information on reproductive health issues and were surveyed again at a subsequent office visit.

Results: Pre-intervention surveys showed that of the 26 women who reported being sexually active with men and not using contraception (at risk of becoming pregnant), 19 (73%) were using teratogenic medications and thus at risk of adverse pregnancy outcomes. Furthermore, 32% of all participants reported not receiving any counseling previously regarding reproductive health.

74 (72%) received the intervention after an average of 6 months: 35 women (47%) watched the video and 39 (52%) received a pamphlet. 53 women (72%) returned a post-survey after an average of 9 months from time of intervention. 5 surveys were excluded from the final analysis due to not answering any post-survey questions.

Of the women who completed the post-intervention survey, 67% felt more knowledgeable about medication effects on fertility, 50% on pregnancy, and 47% on breastfeeding. 36%, 30%, and 36% reported improved awareness about fertility, pregnancy, and breastfeeding issues after the AV intervention compared to 30%, 19%, and 11% who received the pamphlet, although the difference did not reach statistical significance (see figure 1). After intervention, more women reported understanding these issues “very well” (see figures 2 and 3). In addition, fewer women (14/53; 26%) reported unprotected sex with men though many (11/14; 79%) were using teratogenic medications.

Conclusion: We previously reported that women with autoimmune diseases are not adequately counseled regarding reproductive health. Here, we show that women who received targeted education reported an increase in birth control use and knowledge about reproductive health, with a trend to better results in the AV arm. Women with rheumatic disease welcomed more information and conversation with providers regarding their reproductive health.

Effect of Race and Lupus Nephritis on Pregnancy Outcomes in Systemic Lupus Erythematosus: An Individual Participant Meta-analysis

Ravyn Njagu,[1] Amanda Eudy,[2] Stephen Balevic,[3] Michelle Petri,[4] Dafna Gladman,[5] Murray Urowitz,[6] and Megan Clowse[2], [1]Duke University, Durham, NC, [2]Duke University, Durham, [3]Duke University, Hillsborough, NC, [4]Johns Hopkins University School of Medicine, Baltimore, MD, [5]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [6]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Reproductive Issues In Rheumatic Disorders Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Individual cohort studies have found that Black and Hispanic women have worse pregnancy outcomes compared to their white counterparts. Additionally, this population of women has a higher prevalence of lupus nephritis. Therefore, this individual participant meta-analysis pooled data from multiple lupus pregnancy cohorts to assess the effect of maternal race and nephritis on pregnancy outcomes.

Methods: PubMed, Embase, and the Cochrane Database of Systematic Reviews were searched for prospective cohorts of pregnancies among women with lupus. Data from each cohort was collected and analyzed individually. Race was classified as white or non-white. Outcomes of interest included fetal loss, preterm birth (< 37 weeks gestation), preeclampsia, and high disease activity (PGA ever >1 or SLEDAI ever >4 during pregnancy). Pooled ORs were calculated in Review Manager. The analysis included one pregnancy per patient in women with a first trimester visit.

Results: The analysis included 312 pregnancies across three cohorts in the United States and Canada, of which 46% were to non-white mothers and 22% were to women with history of nephritis. Overall, there was an increased risk of fetal loss among non-white patients compared to white patients (OR: 1.96; 95% CI: 1.02,3.77). History of nephritis did not have an association with fetal loss. In patients with no nephritis history, non-white women had a higher rate of fetal loss (OR: 2.16; 95% CI: 1.03,4.52). There was no significant effect of race on preterm birth overall, nor when stratified by history of nephritis . Overall, there was no significant effect of race on preeclampsia. Among white women, a history of nephritis increased the risk of preeclampsia (OR: 3.57; 95% CI: 0.92, 13.92). Overall, non-white patients were at increased risk of high disease activity during pregnancy (OR: 1.74; 95% CI: 0.99, 3.05). Among non-

Association of Maternal Race with Poor Pregnancy Outcomes				
	Fetal Loss Pooled OR (95% CI)	Preterm Birth Pooled OR (95% CI)	Preeclampsia Pooled OR (95% CI)	High Disease Activity Pooled OR (95% CI)
Overall	1.96 (1.02, 3.77)	1.60 (0.90, 2.85)	1.57 (0.73, 3.37)	1.74 (0.99, 3.05)
LN History	1.06 (0.23, 4.84)	1.18 (0.34, 4.12)	0.69 (0.15, 3.11)	2.22 (0.71, 6.97)
No LN History	2.16 (1.03, 4.52)	1.61 (0.82, 3.18)	1.60 (0.65, 3.94)	1.26 (0.64, 2.48)

Table 1. Summary of pooled odds ratios for the association of maternal race with pregnancy outcomes

Association of Lupus Nephritis History with Poor Pregnancy Outcomes				
	Fetal Loss Pooled OR (95% CI)	Preterm Birth Pooled OR (95% CI)	Preeclampsia Pooled OR (95% CI)	High Disease Activity Pooled OR (95% CI)
Overall	1.01 (0.47, 2.22)	1.67 (0.87, 3.18)	2.20 (1.02, 4.75)	2.63 (1.43, 4.85)
White Women	1.29 (0.36, 4.58)	1.80 (0.60, 5.43)	3.57 (0.92, 13.92)	1.73 (0.66, 4.54)
Non-White Women	0.83 (0.31, 2.27)	1.37 (0.59, 3.17)	1.55 (0.50, 4.77)	3.22 (1.40, 7.43)

Table 2. Summary of pooled odds ratios for the association of maternal with pregnancy outcomes

white women, history of nephritis increased the risk of high disease activity during pregnancy (OR: 3.22; 95% CI: 1.40-7.43).

Conclusion: Race is not the only factor driving health disparities in pregnancy outcomes among women with lupus. Additionally, these differences are not entirely explained by the increased prevalence of nephritis in non-white women. When managing lupus in pregnancy, race and history of nephritis are important considerations. However, additional studies are needed to further elucidate why non-white women continue to have disproportionately worse outcomes.

Abstract Number: 2276

Impact of the Healthy Outcomes in Pregnancy with SLE Through Education of Providers (HOP-STEP) Program: A Mixed Methods Approach

Ravyn Njagu,[1] Amanda Eudy,[2] Amanda Snyderman,[1] Lisa Criscione-Schreiber,[2] and Megan Clowse[2], [1]Duke University, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While centers have worked to optimize lupus pregnancy outcomes, additional efforts are required to have a broader impact on lupus pregnancy outcomes. The goal of this educational initiative was to create a multi-dimensional intervention to equip community rheumatologists with the needed skills, attitudes, and confidence to effectively manage contraceptive decisions and improve pregnancy outcomes.

Methods: Design of the HOP-STEP program included a needs assessment followed by development of a comprehensive program using mixed modalities to create lasting practice change. The program included an in-person di-

dactic, a simulated clinical experience, training in use of a comprehensive handout to guide open contraception and pregnancy conversations, and access to a website with additional resources including certified medical education. We assessed program impact using a mixed methods approach. A survey was emailed to 149 individuals before and after workshop completion. All attendees were invited to be interviewed about their experience integrating HOP-STEP resources into practice.

Results: We analyzed 68 pre-surveys (response rate 46%, 93% women, 66% attending-level rheumatologists) and 55 post-surveys (response rate 37%, 96% women, 64% attending-level rheumatologists). For qualitative analysis, 8 interviews were completed until thematic saturation was achieved. At program completion, the percentage of providers reporting a systematic approach to preparing a woman with lupus for pregnancy increased from 45.6% to 94.6%; $p< 0.0001$. When assessed using confidence scale (0=no confidence, 100=high confidence), median provider confidence in helping women with lupus choose appropriate contraception increased from 59 to 89; $p< 0.0001$ and confidence in choosing pregnancy compatible medications increased from 66 to 91; $p< 0.0001$. While participants demonstrated limited change in contraceptive knowledge, an emerging theme was use of the HOP-STEP contraception handout: "I'm not really comfortable recommending birth control method[s], but it was interesting to see that whole [contraception] chart…it did increase my confidence because I could just cheat and look at it and show [patients] visually." After the program more providers correctly identified azathioprine (74% to 98%, $p < 0.0001$) and tacrolimus (46% to 91%, $p < 0.0001$) as pregnancy compatible and mycophenolate as teratogenic (84% to 96%, $p=0.04$). Regarding comparative teratogenicity, a common theme was elucidated by the following quote: "That Cellcept is as high as it is on the list of drugs that are very bad for fetuses…I didn't realize that quite as much as I should've, everybody knows about methotrexate, but the fact that Cellcept is probably even worse than methotrexate I was not aware of…"

Conclusion: We have demonstrated successful creation and delivery of a new multi-modal educational program, HOP-STEP, that has improved provider confidence, skills, and knowledge in managing women with lupus who desire pregnancy. Providers may now access a unique curriculum and resources that encourage providers and patients to have open and accurate conversations about pregnancy, creating lasting clinical change.

Abstract Number: 2277

Perspectives of Female Patients with Rheumatic Diseases Regarding Pregnancy Planning with Rheumatologists

Tierney Wolgemuth,[1] Mehret Birru Talabi,[1] Alaina Chodoff,[2] Sonya Borrero,[3] and **Mehret Talabi** [1], [1]University of Pittsburgh, Pittsburgh, PA, [2]UPMC, Pittsburgh, [3]University of Pittsburgh, Pittsburgh

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: Women with rheumatic diseases may be at greater risk for adverse maternal, perinatal, and pregnancy outcomes. The American College of Rheumatology recommends that female patients who are contemplating pregnancy should discuss their individual pregnancy risks with rheumatologists. Little is known about patients' information priorities and preferences for such information, or their general attitudes about pregnancy planning in the rheumatology outpatient setting.

Table 1: Themes and Representative Quotations

Theme	Illustrative Quote
Rheumatologist Awareness of Reproductive Plans	*I think an initial conversation and opening the door to conversations about sexual and reproductive health on the initial visit is really helpful in building that relationship and that line of communication with the rheumatologist. (34 years old, Spondyloarthritis)*
	I would just say they should bring it up. I know with my doctor, they didn't bring it up, I brought it up. It made it even more uncomfortable when I brought it up because of my age and stuff I was still kind of shy... I think if they would bring it up once in a while it would make it open more. (29 years old, Systemic Lupus Erythematosus)
Rheumatologist Provides Clear Pregnancy and Family Planning Information	*I want doctors to be honest with me. I don't want them to sugarcoat it... I just want them to be honest with me and tell me what to expect and everything. Because some doctors, they try to make it sound better than what it is. (29 years old, Systemic Lupus Erythematosus)*
	What do I expect? Honestly, I just expect honest answers... You know, lupus is not a good disease; it's a really brutal, ugly disease that manifests in a lot of ways, this being one of them, and I want to be prepared for the future, so I appreciate that he's able to tell me what this is really going to look like, and what's going to help me have the smoothest pregnancy. (29 years old, Systemic Lupus Erythematosus)
Rheumatologist Provides Holistic Care	*I think people [rheumatologists] get so focused on their specialty, sometimes they're not thinking about how that can affect other aspects of someone's life... I think thinking holistically about their approach to an individual's care, they need to consider other parts of their life, mental, physical, and what your plans are, what your life is about. (34 years old, Rheumatoid Arthritis)*
Discontinuation of DMARDs in Pregnancy†	*I probably wouldn't want to take it. I don't know- I'd have to talk to the doctor. I know with my other pregnancies I did not take any type of medication while I was pregnant so it'd definitely be something I'd have to discuss with them. I'm kind of a person that errs on the side of caution that I would sacrifice, I guess, more of how I'm feeling for if the baby was safe. (43 years old, Systemic Lupus Erythematosus)*
Enhanced Communication Between Rheumatologist & ObGyn	*I expect her [rheumatologist] to advise my OBGYN when it comes time. To tell them what I have and what to watch out for. For instance, to watch out for lupus in the infant or in the womb... not all OBGYNs I've seen know about that. (35 years old, Systemic Lupus Erythematosus)*
	I think providers should be able to collaborate amongst themselves, so if I'm needing my gynecologist to communicate with my rheumatologist, I shouldn't be a middle person for that, but right now, how it's set up, I am the mediator for that plan of care. (34 years old, Rheumatoid Arthritis)

†DMARDs, Disease-Modifying Anti-Rheumatic Drugs.

Methods: Female patients ages 18-45 with at least one rheumatic disease were recruited to participate in semi-structured qualitative interviews that explored their priorities and preferences related to reproductive health care. Recruitment occurred in outpatient rheumatology clinics in Pittsburgh, PA. Interviews were conducted via telephone, and were audio-recorded and transcribed verbatim. A code book was inductively developed based on transcript

content. Two coders applied the code book to all transcripts (Cohen's Kappa= 0.69), and coding differences were adjudicated to full agreement. The finalized coding was used to conduct a thematic analysis.

Results: Interviews were conducted among 30 women, who were 35.1 years old on average (S.D. 5.84); 52% were married, 53% had children, and 73% were white. The most common diagnoses included rheumatoid arthritis (23% of sample), systemic lupus erythematosus (23%), Sjogren's syndrome (17%), undifferentiated connective tissue disorder (10%), and spondyloarthritis (7%). Five themes emerged: 1) Women wanted rheumatologists to initiate conversations about family planning repeatedly over time; 2) Women desired clear and complete information from rheumatologists regarding fetal, pregnancy, and infertility risks associated with their diseases and disease-modifying anti-rheumatic drugs (DMARDs); 3) Women wanted to be treated holistically, with family planning issues addressed in the context of their life circumstances and personal values as well as their diseases; 4) Women were reluctant to continue any DMARDs during pregnancy, even if compatible with pregnancy; 5) Women felt that they were often intermediaries between their rheumatologists and obstetrician-gynecologists (ObGyns), but preferred for their rheumatologists to communicate directly with their ObGyns in advance of and during pregnancy. Illustrative quotations are presented in Table 1.

Conclusion: Patients strongly desired for rheumatologists to play an active and continuous role in their family planning care. Patients specifically want for their rheumatologists to provide education, review DMARD- and disease-related risks related to pregnancy, and communicate directly with ObGyns before and during pregnancy to optimize a woman's chances for a healthy pregnancy. Prior studies indicate that family planning rarely occurs in the rheumatology outpatient setting; our results further suggest that some women with rheumatic diseases do not receive the family planning care that they desire. Further work is needed to clarify the role of rheumatologists in family planning, and how to enhance communication between rheumatologists and other women's healthcare professionals.

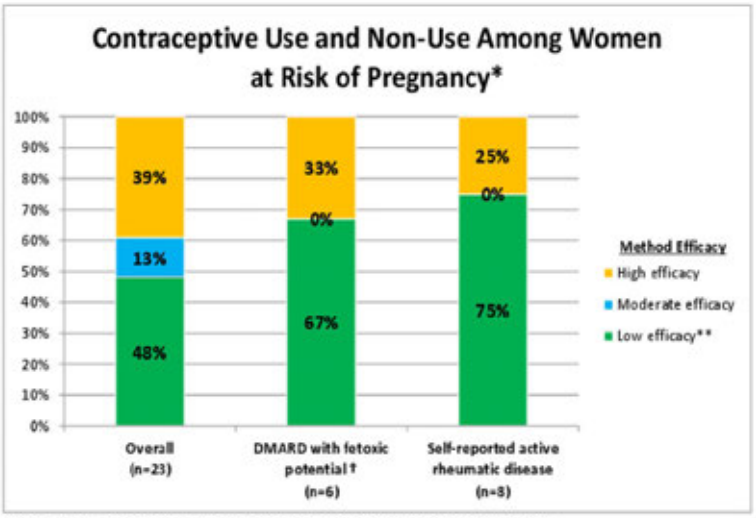
Perspectives About Contraception Among Reproductive-Aged Women with Rheumatic Diseases

Olivia Stransky,[1] Tierney Wolgemuth,[1] Alaina Chodoff,[2] and **Mehret Birru Talabi** [1], [1]University of Pittsburgh, Pittsburgh, PA, [2]UPMC, Pittsburgh

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior work suggests that women with rheumatic diseases are rarely prescribed contraception. However, in addition to preventing undesired pregnancy, contraception may help these women to delay pregnancy until their diseases are well-controlled on pregnancy-compatible anti-rheumatic drugs— thus, optimizing their chances for healthy maternal and fetal outcomes. While hormonal contraception may augment thrombotic risks in diseases such as systemic lupus erythematosus and antiphospholipid antibody syndrome, most women with rheumatic diseases are able to use contraception safely. This qualitative study explored women's perspectives about contraception use in the context of their diseases, and their preferences for contraception care from their health care providers.

Figure 1. Contraception use and non-use among women with rheumatic diseases at risk of pregnancy (N=23).



*Not currently pregnant or trying to become pregnant and has not had a hysterectomy.

** High efficacy: tubal ligation, vasectomy, IUD, or implant. Moderate efficacy: oral contraceptive. Low efficacy: condom, withdrawal, abstinence, or no method.

† DMARD with fetotoxic potential: Methotrexate (n=4) and mycophenolate mofetil (n=2) (Gotestam Skorpen C, Hoeltzenbein M, Tincani A, Fischer-Betz R, Elefant E, Chambers C, et al. The EULAR points to consider for use of antirheumatic drugs before pregnancy, and during pregnancy and lactation. Ann Rheum Dis. 2016;75(5):795-810.)

Table 1. Distribution of Rheumatic Diagnoses and Disease-Modifying Anti-Rheumatic Drugs (DMARDs)

Five most common diagnoses	**N**	**%**
Rheumatoid Arthritis	7	23%
Systemic Lupus Erythematosus	7	23%
Sjogren's Syndrome	5	17%
Undifferentiated Connective Tissue Disease	3	10%
Spondyloarthritis	2	7%
DMARD use in the sample*		
Hydroxychloroquine	11	26%
Prednisone	8	19%
Azathioprine	4	9%
Methotrexate	4	9%
Leflunomide	3	7%
Mycophenolate	3	7%
Etanercept	2	5%
Intravenous immunoglobulin	2	5%
Sulfasalazine	2	5%
Abatacept	1	2%
Infliximab	1	2%
Ustekinumab	1	2%
Tocilizumab	1	2%

*Some patients used more than one DMARD.

Table 2. Major Themes and Illustrative Quotations

Theme	Illustrative Quotation
Women feared that hormonal contraception could exacerbate their diseases, irrespective of the disease	*"I used [combined estrogen-progestin oral contraceptive pill] for about three years. And after I was diagnosed with lupus, I didn't take any birth control whatsoever."* (Patient with systemic lupus erythematosus, uses withdrawal method) *"I was put on an oral contraceptive before I got diagnosed with my autoimmune disease, and then after just talking to the rheumatologist it seemed the risks outweighed the benefits of it, so we just switched to using condoms."* (Patient with mixed connective tissue disease, uses condoms)
Women were more concerned about theoretical risks of hormones than the efficacy of the contraceptive method	*"I've been nervous about taking hormonal contraception because I didn't have a provider that could guide me through the process who had an understanding of hormones and autoimmune disease, so I didn't really use any birth control for the past few years."* (Patient with spondyloarthritis, currently pregnant) *"With lupus there's a higher risk of blood clots... you don't want to compound that with a pill."* (Patient with systemic lupus erythematosus, uses condoms)
Women who used fetotoxic DMARDs or self-reported that they had active disease were not more likely to select a contraceptive method based on its efficacy than other women	*"On occasion it makes me a little uneasy... however, given my hormonal issues, odds are incredibly low that I would conceive even without the condom."* (Patient with rheumatoid arthritis, prescribed methotrexate and abatacept, uses condoms) *"My PCP... asks what I'm on and reiterates that, 'you should not become pregnant', that we should be using some type of birth control to prevent pregnancy with being on this medication."* (Patient with psoriatic arthritis, prescribed methotrexate and ustekinumab, uses condoms)
Patients rarely sought information on contraception from their rheumatologists but some women lacked access to a gynecologist or primary care provider	*"[My rheumatologist] seems like he's pretty conservative. It just seems it would make him uncomfortable to talk about it."* (Patient with granulomatosis with polyangiitis, uses condoms) *"I see my rheumatologist for the rheumatology... I would only get my rheumatologist involved if I wanted to get pregnant."* (Patient with spondyloarthritis, uses oral contraceptive pill)

Methods: Semi-structured interviews were conducted among women ages 18-45 diagnosed with at least one rheumatic disease, who were recruited from two outpatient rheumatology clinics in Pittsburgh, PA. Interviews were transcribed verbatim, and a code book was inductively developed based on transcript content. Two independent coders applied the code book to all transcripts, and coding differences were adjudicated to full agreement. The finalized coding was used to conduct a thematic analysis.

Results: Thirty women participated in interviews; the average age of the sample was 35.1 years (S.D. 5.8), and most women were white (73%), married (52%), and had at least one child (53%). Twenty-three women were at risk for preg-

nancy; others had a hysterectomy, were pregnant (n=2), or attempting to conceive (n=1). Table 1 presents the disease diagnoses and DMARDs used by women in the sample. Four major themes about contraception emerged from the interviews (Table 2): 1) Women feared that hormonal contraception could exacerbate their rheumatic diseases, irrespective of the disease; 2) Women were more concerned about theoretical risks of hormones than the efficacy of the contraceptive method; 3) Women who used fetotoxic DMARDs or reported that they had active rheumatic disease were not more likely to select a contraceptive method by its efficacy than other women; and 4) Patients rarely sought information about contraception from their rheumatologists but some women lacked access to a gynecologist or primary care provider. Figure 1 presents contraception methods used by women at risk of pregnancy and by women who used potentially fetotoxic DMARDs or who had active disease— i.e., elevated risk of adverse pregnancy outcomes.

Conclusion: Many women prioritized limiting their exposure to hormones rather than preventing pregnancy with hormonal contraception, including women who did not wish to become pregnant or had elevated risk of adverse pregnancy-related outcomes. Most women did not perceive that their rheumatologists were the appropriate providers to manage their contraception care, but some women lacked access to contraception providers. Our study suggests that women with rheumatic diseases may require counseling about the effects of exogenous hormones on their diseases, education about safe and efficacious contraception methods, and consistent access to contraception care.

Pregnancy in Rheumatoid Arthritis: Continue, Reduce or Stop TNF Inhibitors? A Prospective Observational Study

Isabell Haase,[1] Susanna Spaethling-Mestekemper,[2] Ralph Brinks,[1] Matthias Schneider,[3] and Rebecca Fischer-Betz[3], [1]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Duesseldorf, Germany, [2]Rheumapraxis, Munich, Germany, [3]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with active Rheumatoid Arthritis (RA) are more prone to relapses and complications during pregnancy. The potential risks of disease activation and treatment during gestation have to be weighed in a shared decision prior to conception. An increasing number of women who wish to conceive are being treated with TNF inhibitors (TNFi). Some want to discontinue or at least reduce therapy during pregnancy and require information on opportunities and risks. Therefore, we sought to explore the outcome of pregnancies in women with RA who either discontinued, reduced or maintained TNFi treatment after conception.

Methods:: Pregnancies of women from an outpatient pregnancy clinic were evaluated before conception, during each trimester and postpartum. Clinical characteristics, disease activity (DAS28-CRP), medication use and pregnancy outcome were analysed. A flare was defined as increase in DAS28 > 1.2 or an increase in DAS28 > 0.6 and DAS28 ≥ 3.2. All women received extensive counselling before pregnancy based on current knowledge and subsequently decided to continue or stop TNFi at conception. If they stayed on TNFi and were in remission, women received the suggestion to stretch the therapy intervals in a disease activity guided manner.

	TNFi exposure until conception (N=41)	Pregnancies with ongoing TNFi exposure (N=29)	
		Successful reduction (N=17)	No reduction possible (N=12)
Patient characteristics at conception			
Age (years), median (IQR)	32 (29-34)	34 (32-36)	36 (34.75-37.25)
Disease duration (months), median (IQR)	92 (48-216)	96 (84-168)	82 (58-121.5)
Seropositivity, n (%)	21 (51.2%)	11 (68.8%)	10 (83.3%)
DAS28, median (IQR)	2.9 (2.5-3.1)	2.5 (2.175-2.75)	2.8 (2.6-2.9)
Prednisolone (mg/day), (median, IQR)	5.0 (5.0-7.0)	5.0 (3.0-5.0)	5.0 (3.0-5.0)
Sulfasalazine, n (%)	2 (4.9%)	5 (29.4%)	1 (8.3%)
HCQ, n (%)	1 (2.4%)	4 (23.5%)	3 (25.0%)
Pregnancy outcomes			
DAS28-CRP ≤ 3.2, n (%)			
1st trimester	24 (58.5%)	17 (100%)	9 (75.0%)

Flare postpartum, n (%)	13 (32.5%)	2 (12.5%)	1 (9.1%)
Odds ratio	1	0.27, 95% CI 0.07-0.95, p=0.04	0.29, 95% CI 0.07-1.22, p=0.09
Preterm birth[*1], n (%)	11 (26.8%)	1 (5.9%)	1 (8.3%)
Low birth weight[*2], n (%)	7 (17.0%)	-	1 (8%)
Breastfeeding, n (%)	28 (68.3%)	15 (88.2%)	10 (90.9%)
Glucocorticoid use during pregnancy			
Prednisolone (mg/day), (median, IQR)			
1st trimester	10.0 (5.0-10.0)	5.0 (5.0-6.0)	5.0 (3.0-5.75)
2nd trimester	10.0 (10.0-15.0)	5.0 (5.0-6.0)	5.0 (3.0-7.75)
3rd trimester	10.0 (7.0-12.75)	5.0 (4.25-6.375)	5.0 (4.0-7.25)
Of those taking prednisolone – taking ≥ 10mg/d, n (%)			
1st trimester	17 (65.4%)	1 (11.1%)	2 (16.7%)
2nd trimester	24 (82.8%)	1 (10.0%)	3 (25.0%)
3rd trimester	19 (70.4%)	-	2 (18.2%)
Intraarticular steroid therapy, n (%)			
1st trimester	8 (19.5%)	-	2 (16.7%)
2nd trimester	12 (30.0%)	3 (17.6%)	2 (16.7%)
3rd trimester	3 (7.5%)	2 (11.8%)	2 (18.2%)

[*1]≤ 36+6 weeks of gestation, [*2] birth weight < 2500g, HCQ = hydroxychloroquine

Table 1

We applied a multivariate logistic regression model to assess the association between the use of TNFi throughout pregnancy and the occurrence of flares during pregnancy. Adjustment for potential confounders (age, disease duration, DAS28 at conception, sero-positivity, HAQ, previous therapy with methotrexate, previous joint surgery) was performed using logistic regression.

	No TNFi	Adalimumab	Certolizumab	Etanercept
Women on therapy at preconception				
All Groups, n (%)	10 (14.3%)	9 (12.9%)	22 (31.4%)	29 (41.1%)
Group 1, n (%)	10 (24.4%)	4 (9.8%)	7 (17.1%)	20 (48.8%)
Group 2a, n (%)	-	2 (11.8%)	8 (47.1%)	7 (41.2%)
Group 2b, n (%)	-	3 (25.0%)	7 (58.3%)	2 (16.7%)
Women of group 2a during pregnancy				
Therapy interval (weeks), median (min-max)	-	3.5 (3.0-4.0)	4.0 (4.0-5.0)	2.0 (1.5-6.0)

Table 2

Results: After exclusion of two miscarriages, 70 completed pregnancies were enrolled and grouped according to their decision to stop (group 1) or continue (group 2) TNFi therapy during pregnancy. The latter were subdivided into those who could stretch the therapy intervals (group 2a) and those who could not (group 2b). A significantly lower flare rate during pregnancy was observed in women who continued their TNFi, whether they could or could not stretch application intervals (OR 0.06 and 0.12, respectively). Postpartum, again both groups with continued TNFi showed a lower flare rate, but significance was only reached in those who were able to reduce TNFi with an OR of 0.27. In addition, a higher dose of oral prednisolone was reported in group 1 (Table 1).

About 59% of the women who chose to stay on therapy during gestation were able to stretch the injection interval of their TNFi, which was either Adalimumab (median every 3.5 [min 3.0, max 4.0] wks), Certolizumab (median every 4.0 [min 4.0, max 5.0] wks) or Etanercept (median every 3.0 [min 1.5, max 6.0] wks) (Table 2).

Conclusion: Women with RA who discontinue TNFi at conception face a higher risk of flares during pregnancy and often have an increased demand for steroids to control disease activity. When in remission under ongoing TNFi therapy during pregnancy, it seems possible and safe for women to reduce the frequency of injections in a disease activity guided manner. These real-world data will help to provide women with comprehensive advice on treatment options and risks regarding TNFi therapy at pregnancy counselling.

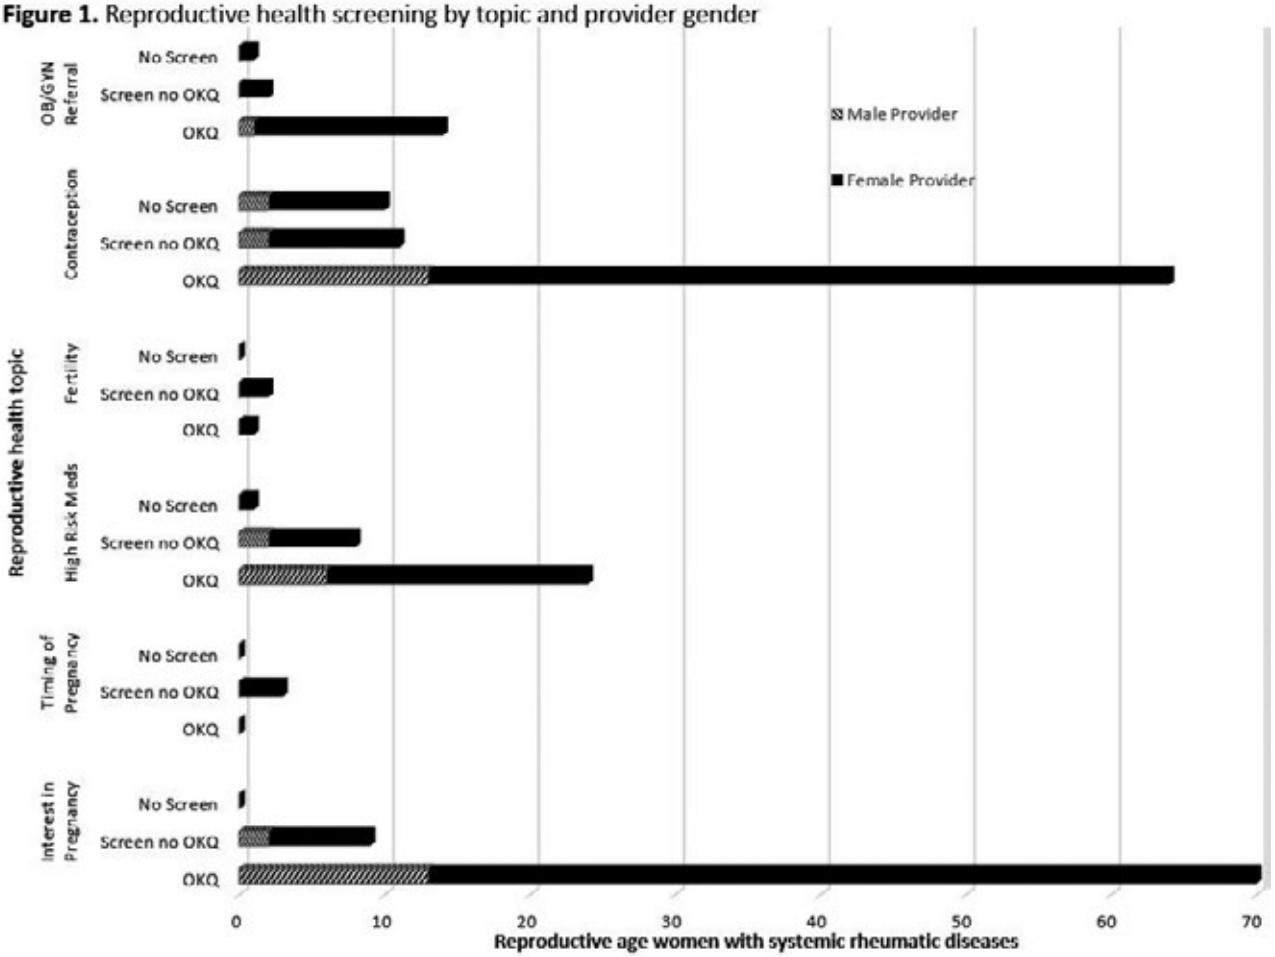
Background/Purpose: Reproductive health intention screening is critical in women with systemic rheumatic diseases, as both disease activity and medication use can impact pregnancy outcomes. However, studies report that < 50% of patients with rheumatic diseases receive contraception counseling. We introduced a simple reproductive

Figure 1. Reproductive health screening by topic and provider gender



health intention screen, One Key Question ® (OKQ), to our academic rheumatology practice and examined subsequent practice patterns.

Methods: We developed an electronic medical record (EMR) smart phrase with OKQ ("Would you like to become pregnant in the next year?") with responses that would prompt documentation of contraception, teratogenic medication use and referrals for OB/GYN care when appropriate. Reproductive age (18-50 year-old), female patients with a systemic rheumatic disease were flagged in the EMR for screening before appointments. We introduced OKQ at Rheumatology Grand Rounds, in email notifications, and with exam room reminder cards. Documentation of OKQ was at the rheumatologists' discretion. We measured reproductive health intention screening over 6 months following introduction of OKQ, conducted chart reviews, and used descriptive statistics and a logistic regression model to compare patients who were screened (with OKQ or other documentation) vs. a randomly selected subset of patients who had been flagged for screening but did not have OKQ documented.

Results: Over the 6-month pilot with 43 rheumatologists (56% female), among 1092 reproductive age women with rheumatic diseases, 11 providers (82% female) used OKQ to document reproductive health preferences for 83 women (8%). In the subset of 96 charts flagged for screening but without OKQ documented, 15 providers (67% female) documented reproductive health screening (without OKQ) for 18/96 women (19%). Patients had 2.4 times higher odds of being screened if they saw a female vs. male rheumatologist (95% CI 1.21-4.85). OKQ use resulted in documentation of a broader range of reproductive health topics by rheumatologists of both gen-

ders (Figure 1). Adjusting for provider gender, a 1-year increase in patient age was associated with 5% lower odds of screening (95% CI 0.02-0.09). Highly effective contraception was associated with reproductive health screening (p< 0.0001). Although use of a high-risk medication was not associated with screening (p=0.22) (Table 1), rheumatologists who screened their patients were more likely to document risks of teratogenic medications (p< 0.0001).

Conclusion: Despite introducing a simple, standardized intervention, < 10% of reproductive age women with rheumatic diseases were comprehensively screened using OKQ, < 20% of an eligible subset were asked selected reproductive health-related questions, and >50% of unscreened patients had no documented contraception. Younger age and seeing a female rheumatologist resulted in higher odds of screening. While some providers may have screened patients without documenting the response, the data suggest that a high proportion of patients are not being screened. While uptake was suboptimal, this intervention improved the depth and breadth of reproductive health documentation among those who were screened.

The Vasculitis Pregnancy Registry (V-PREG): Information from the First 3 Years

Jon Golenbiewski,[1] Kalen Young,[2] Cristina Burroughs,[3] Joyce Kullman,[2] Peter Merkel,[4] and Megan Clowse[5], [1]Duke University Medical Center, Durham, NC, [2]Vasculitis Foundation, Kansas City, MO, [3]University of South Florida, Tampa, FL, [4]University of Pennsylvania, Philadelphia, PA, [5]Duke University, Durham

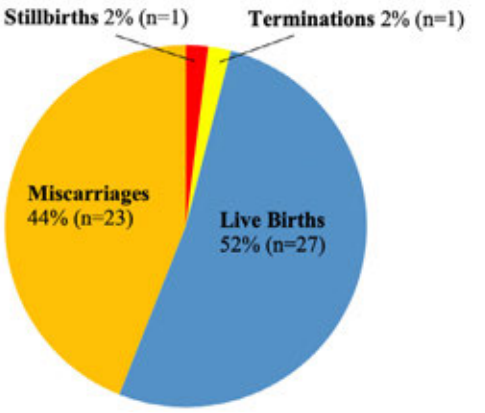
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: As outcomes for patients with vasculitis improve and treatments become less ovarian-toxic, more women with these diseases will become pregnant. How best to manage these pregnancies remains unclear

Table 1: Enrollment in V-PREG

Type of Vasculitis	Number of Patients
Granulomatosis with Polyangiitis	19
Microscopic Polyangiitis	2
Eosinophilic Granulomatosis with Polyangiitis	3
Takayasu's Arteritis	15
Behçet's Disease	5
IgA Vasculitis	4
Central Nervous System Vasculitis	3
Urticarial Vasculitis	3
Polyarteritis Nodosa	1
Other/Suspected	7

Figure 1: Outcomes of Pregnancies Prior to a Diagnosis of Vasculitis



and, given the rarity of these pregnancies, challenging to study. The Vasculitis Pregnancy Registry (V-PREG) is an online, patient-driven prospective pregnancy registry designed to collect observational data to increase our understanding of pregnancies in women with vasculitis [www.vpprn.org/VPREG].

Methods: V-PREG is imbedded within the online Vasculitis Patient-Powered Research Network (VPPRN), where members are asked to participate in this specific registry during pregnancy. Women with any form of vasculitis are eligible. All women indicate informed consent and are invited to complete online surveys at study entry, in each trimester, and post-partum. Women report pain, overall health, and vasculitis disease activity on a 0-10 visual analog scale (scores < 3 indicated minimal pain, vasculitis activity, or good health). Reminders to complete study surveys are sent to patients via repeated emails and phone calls.

Results: Between 11/2015-12/2018 62 pregnant women with one of several vasculitides enrolled in V-PREG (**Table 1**). Almost all women (95%) were diagnosed with vasculitis prior to conception and 67% (41/61) had been hospitalized for vasculitis at least once.

Twenty-one women reported 52 prior pregnancies **(Figure 1).** Of these, 44% (n=23) resulted in a miscarriage, with losses reported among several vasculitides. Additionally, 1 stillbirth and 1 elective termination were reported.

Of 36 pregnancies with data about the 3 months prior to conception, no women were hospitalized, 60% were taking immunosuppressive medications, 33% received glucocorticoids, and only one woman was taking a teratogenic medication (methotrexate). Self-reported vasculitis activity was generally low prior to conception with 83% reporting minimal pain, 75% good overall health, and 81% minimal vasculitis disease activity.

Of 32 pregnancies with first trimester data, 2 were hospitalized, 60% were taking immunosuppressive medications, and 40% received glucocorticoids. Self-reported vasculitis activity remained generally low with 78% reporting minimal pain, 72% good overall health, and 75% minimal or no vasculitis disease activity. There were no 1st trimester miscarriages.

Conclusion: V-PREG has successfully collected data on pregnancies among women with vasculitis. Women with vasculitis report an unusually high rate of prior miscarriage (>40%) compared to the average rate of approximately 15% for all pregnancies. The majority of current pregnancies occurred in women with minimal vasculitis activity and

off of teratogenic medications, suggesting they were well-timed for success. Given the small sample size and method of enrollment it is not yet clear if these findings are a result of disease itself, treatment, or possibly reporting bias. Future directions include continued patient enrollment, enhancing data return, and launch of planned translations of V-PREG to substantially increase the number of patients enrolled in the registry.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women of reproductive age with rheumatic diseases are often prescribed teratogenic medications; thus, reproductive counseling is important. A prior study demonstrated improvement in counseling documentation from 30% to 45% after a quality improvement (QI) initiative [1]. In this study, we aimed (1) to determine the rate of reproductive counseling documentation within an urban, academic teaching clinic and (2) to determine patient factors associated with a lack of reproductive counseling documentation in female patients with rheumatic disease who are prescribed teratogenic medications.

Methods: Patients were identified from the Rheumatology Fellows' Teaching Clinic at the Hospital for Special Surgery, which serves individuals enrolled in Medicaid or Medicare. All patients who were female, 18 – 45 years-old, and prescribed mycophenolate mofetil, mycophenolic acid, methotrexate, leflunomide, or cyclophosphamide were included. The electronic medical record (EMR) was reviewed for age at last visit, self-reported race/ethnicity, rheumatic disease, duration of patient-physician relationship, marital status, and antiphospholipid (APL) antibody status. The outcome was reproductive counseling as documented in the EMR, defined as present if the physician referenced reproductive counseling in any encounter when the teratogen was prescribed. Patient characteristics were compared using Fisher's exact, Chi-squared, Wilcoxon rank-sum, and t- tests where appropriate. Logistic regression was used to determine if age, teratogen prescribed, or disease type were independent predictors of counseling documentation status.

Results: 45 women (mean (SD) age 34 (6.76) years old) met inclusion criteria (Table 1). 47% were Hispanic, 30% were Black, and 40% were diagnosed with systemic lupus erythematosus. Reproductive counseling was documented in 73% of patients over a median [IQR] physician-patient relationship of 1.3 years [0.44, 1.74]. Of 12 patients with-

Table 1. Patient Characteristics by Reproductive Counseling Documentation Status.

Patient Characteristic	Total (N=45)	Counseling Not Documented (N= 12)	Counseling Documented (N= 33)	p-value
Age (years), mean (SD)	34 (6.76)	37 (6.4)	33 (6.7)	0.11
Race/Ethnicity				0.70
White, not Hispanic	2 (4%)	1 (8%)	1 (3%)	
Black or African American	14 (31%)	4 (33%)	10 (30%)	
Hispanic	21 (47%)	6 (50%)	15 (45%)

Married (%)	14 (31%)	6 (50%)	8 (24%)	0.10
Disease duration (years), mean (SD)	12 (7.8)	13.5 (2.5)	11.8 (1.3)	0.52
Patient-physician relationship duration (years), median (IQR)	1.3 (0.44, 1.74)	0.48 (0.41, 1.47)	1.45 (0.55, 2.02)	0.17
APL antibody, positive* (among N=31 evaluated)	3 (7%)	0 (0%)	3 (9%)	0.42
Contraception use status				0.06
No current use	13 (29%)	5 (42%)	8 (24%)	
Current use	24 (53%)	3 (25%)	21 (64%)	
Not documented	8 (18%)	4 (33%)	4 (12%)	
Contraception Type (N= 24)				0.76
IUD (Copper or levonorgestrel)	7 (16%)	2 (17%)	5 (15%)	
Condoms alone	11 (24%)	1 (8%)	10 (30%)	
Combined oral contraceptive pill	2 (4%)	0 (0%)	2 (6%)	
Depo-Provera injection	2 (4%)	0 (0%)	2 (6%)	
Tubal ligation	1 (2%)	0 (0%)	1 (3%)	
Implant (Estrogen/Progesterone)	1 (2%)	0 (0%)	1 (3%)	
Medication Prescribed				0.49
Mycophenolate/Mycophenolic Acid	23 (51%)	5 (42%)	18 (54%)	
Methotrexate	18 (40%)	5 (42%)	13 (39%)	
Leflunomide	4 (9%)	2 (17%)	2 (6%)	
Cyclophosphamide	0 (0%)	0 (0%)	0 (0%)	

Legend. JRA= juvenile rheumatoid arthritis; APL=antiphospholipid.
*Positive APL status defined as anticardiolipin IgG or IgM >40, beta-2-glycoprotein IgG or IgM >40, or positive lupus anticoagulant on at least two occasions >12 weeks apart.

out reproductive counseling documented, 5 (42%) were not using contraception. There was no statistically significant difference in race/ethnicity, language, disease, marital status, teratogen prescribed, APL status, disease duration, or age between those with or without documented counseling. By univariate analysis, disease type, teratogen prescribed, and age were not independent predictors of reproductive counseling documentation status (Table 2).

Table 2. Predictors of Reproductive Counseling Documentation

Predictor Variable	Odds Ratio (95% CI)	p-value
Disease		0.43
Systemic Lupus Erythematosus	1.00 (Reference)	
Rheumatoid Arthritis or Juvenile Rheumatoid Arthritis	1.26 (0.24, 6.35)	
Other	1.69 (0.71, 4.05)	
Medication Prescribed		0.52
Leflunomide	1.00 (Reference)	
Mycophenolate/Mycophenolic Acid	3.60 (0.40, 32.40)	
Methotrexate	1.61 (0.53, 4.88)	
Age (years)	0.91 (0.81, 1.02)	0.10

Legend. Logistic regression was used to predict the odds of reproductive counseling documentation. Odds ratios and 95% confidence intervals are reported.

Conclusion: Reproductive counseling was documented in 73% of reproductive-aged women prescribed teratogenic medications. We identified no patient factors to predict the absence of counseling documentation in the remaining 27%. This underscores the need for additional work in larger samples to identify potential patient- and/or physician-related factors associated with a lack of reproductive counseling documentation as well as QI initiatives to improve documentation and counseling rates.

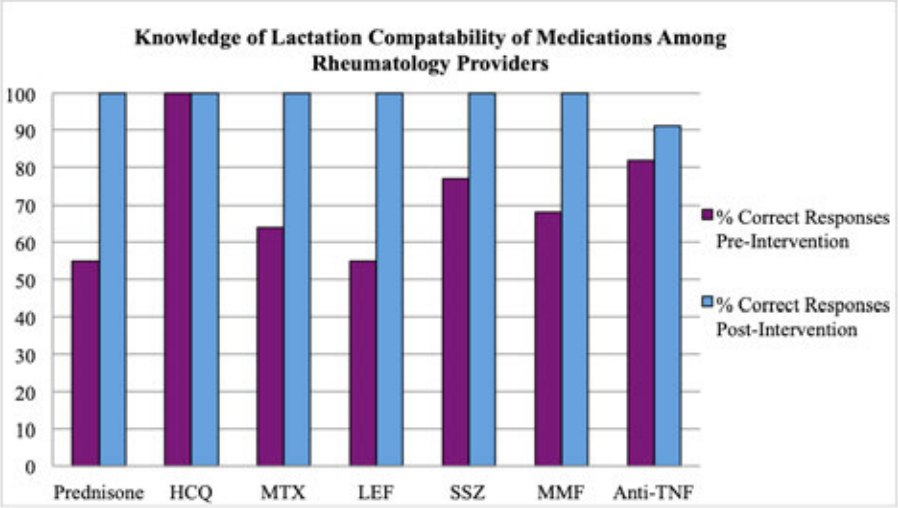
Abstract Number: 2283

Improving Lactation Knowledge Among Providers Caring for Rheumatology Patients

Brooke Mills,[1] and Bonnie Bermas[1], [1]UT Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While the benefits of breastfeeding for both the mother and her infant are well established, available resources regarding medication compatibility with lactation are limited. Thus, providers may feel ill equipped to encourage breast-feeding amongst patients on anti-rheumatic drugs. We sought to improve knowledge of the lactation compatibility of medications used to treat rheumatic diseases amongst obstetric and rheumatology providers at an academic medical center that includes a safety net hospital.



Rheumatic Diseases and Lactation

- Women should be encouraged to breastfeed if desired
- There are no data to suggest that lactation worsens disease activity
- Risks/benefits should be reviewed with each patient for her particular situation

Medical therapy during lactation+

Compatible

- NSAIDs, ASA (81mg)
- Prednisone <20mg
- Hydroxychloroquine
- Sulfasalazine
- Colchicine
- Azathioprine
- Cyclosporine
- Tacrolimus
- TNF inhibitors
  - Infliximab
  - Etanercept
  - Adalimumab
  - Golimumab
  - Certolizumab
- Anakinra*
- Belimumab
- Abatacept*
- Tocilizumab
- Sekukinumab*
- Ustekinumab*
- Rituximab

"Pump & Dump"

- Prednisone > 20mg/day: delay breastfeeding or discard breast milk for the first four hours following steroid administration

Contraindicated

- Methotrexate
- Leflunomide
- Mycophenolate mofetil
- Thalidomide
- ASA (325mg)
- Apremilast **
- Tofacitinib**

+ Patient/provider resources: **MotherToBaby**; **LactMed**

*Medications unlikely to pass into breast milk in significant quantities due to molecule size but have not been studied

**Medications are likely to pass into breast milk due to molecule size but have not been studied

Methods: Baseline lactation knowledge was obtained via a multiple-choice survey. The survey was developed based on a literature review of rheumatology patients' concerns and knowledge gaps with regards to the lactation process. Providers were then given a laminated "lactation and rheumatic diseases" information card and asked to take the survey again. Improvement in knowledge was assessed. The survey will be re-administered three months after the initial survey date to test the sustainability of the intervention.

Results: Twenty-two rheumatology providers were surveyed, including fellows, attendings, nurse practitioners and physician assistants. All of the providers recommended women with rheumatic diseases breastfeed their children. Twenty-two of 22 providers responded that hydroxychloroquine (HCQ) was compatible with lactation. In contrast, 10/22 (45%), 8/22 (36%), 10/22 (45%), 5/22 (23%), 7/22 (32%), and 4/22 (18%) of providers were unsure or unaware of the lactation compatibility of prednisone, methotrexate (MTX), leflunomide (LEF), sulfasalazine (SSZ), mycophenolate (MMF), and anti-TNF medications, respectively. After administration of the information card, 100% of providers correctly answered questions regarding the compatibility of MTX, LEF, SSZ, and MMF with lactation. Ninety-one percent of providers correctly answered questions regarding the compatibility of TNF therapy with lactation.

Conclusion: There are knowledge gaps among rheumatology providers with regards to medication compatibility with lactation. Creating a simple structured information card helped to address these deficiencies. The sustainability of this intervention will be measured.

Knowledge of medication compatibility with lactation improved after administration of the "lactation and rheumatic diseases" information card.

This "Rheumatic Diseases and Lactation" information card was developed to assist providers in determining the compatibility of medications with lactation.

The Titer of Anti-Double Stranded DNA Antibody Could Affect the Apgar Score of Newborns, Which Is Considered as the Predictive Clinical Index for Neurological or Physical Development

Hiromi Shimada,[1] Risa Wakiya,[2] Mai Mahmoud Fahmy Mansour,[2] Shusaku Nakashima,[2] Mikiya Kato,[2] Taichi Miyagi,[2] Tomohiro Kameda,[2] and Hiroaki Dobashi[1], [1]Kagawa University, Kagawa, Japan, [2]Kagawa University, Kagawa

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, the progression of treatment strategy enabled many systemic lupus erythematosus (SLE) women to become mothers. On the other hand, some reports have revealed another important problem about the associations between maternal SLE and neurological abnormalities including learning disorders and autism spectrum disorders among the children born to SLE mothers. However, it is unknown which factors influence neurological disorders on these children.

Table 1. Univariate analysis of risk factors for Apgar score

	Apgar score at 1 minute		Apgar score at 5 minutes	
Variable	Correlation Coefficient (r)	P-value	Correlation Coefficient (r)	P-value
SLEDAI				
First trimester	-0.288	0.09	-0.134	0.44
Third trimester	-0.624	<0.01*	-0.291	0.07
Positivity for autoantibody				
Anti SS-A antibody		0.99		0.34
Antiphospholopid antibody		0.54		0.20
Laboratory finding at the conception				
C3	0.281	0.10	0.220	0.20
C4	0.340	<0.05*	0.227	0.20
CH50	0.306	0.08	0.278	0.11
anti-dsDNA antibody	-0.808	<0.01*	-0.694	<0.01*
Mean dose of corticosteroid	-0.184	0.25	-0.014	0.93

Apgar scores is widely used as a common clinical index for assessing neonatal health status after birth. Especially, Apgar score at five minutes is demonstrated as a predictive index for neurological, cognitive, and psychological abnormalities of newborns. There is no report about the association between maternal SLE and Apgar score of newborns. The aim of this study is to identify risk factors for low Apgar scores of newborns from SLE mothers.

Methods: We investigated the data of 41 newborns who were delivered from SLE mothers from May 2006 to May 2019. SLE mothers were treated at Kagawa University Hospital from preconception counseling to pregnancy and delivery. We analyzed the association between SLE disease activities, autoantibody profiles, laboratory findings, treatment agents, and Apgar scores of newborns.

Results: In 41 newborns, the mean gestational weeks of delivery was 37.9 ± 2.8 weeks, and preterm birth occurred in nine cases (23.1%). The mean birth weight of newborns was 2754.0 ± 626.4 grams. Five newborns (12.8%) were light-for-date (less than the 10th percentile).

Table 1 showed univariate analysis of Apgar scores, which revealed that Apgar scores at one minute were related with SLEDAI score during the third trimester ($P< 0.01$), complement level of C3 ($P< 0.05$) and the titer of anti-double stranded DNA (ds-DNA) antibodies at the conception ($P< 0.01$). Additionally, Apgar scores at five minutes were associated with the titer of anti-dsDNA antibodies ($P< 0.01$). In multivariate analysis, there was a significant association between low Apgar scores at five minutes and high titer of anti-dsDNA antibodies ($P< 0.01$, Table 2).Other parameters including autoantibodies and corticosteroid dose were not associated with low Apgar score in either the univariate or the multivariate analysis.

Conclusion: In our retrospective study, high titer of anti-dsDNA antibodies at conception was a risk factor for low Apgar scores at both one minute and five minutes of newborns who were delivered from SLE mothers.

Table 2. Multivariate analysis of risk factors for Apgar score at 5 minutes

Variable	Standard β	P-value
SLEDAI at third trimester	0.340	0.06
C3 at conception	0.057	0.67
Anti-dsDNA antibody at conception	-0.913	<0.01*
		(R^2=0.538, P<0.001)

Variable	Standard β	P-value
SLEDAI at third trimester	0.356	0.06
C4 at conception	0.058	0.68
Anti-dsDNA antibody at conception	-0.922	<0.01*
		(R^2=0.540, P<0.001)

Variable	Standard β	P-value
SLEDAI at third trimester	0.410	0.03*
CH50 at conception	0.164	0.22
Anti-dsDNA antibody at conception	-0.941	<0.01*
		(R^2=0.566, P<0.001)

Variable	Standard β	P-value
SLEDAI at third trimester	0.306	0.09
Anti SS-A antibody	-0.056	0.66
Anti-dsDNA antibody at conception	-0.913	<0.01*
		(R^2=0.538, P<0.001)

Variable	Standard β	P-value
SLEDAI at third trimester	0.315	0.07
Antiphospholipid antibody	-0.072	0.57
Anti-dsDNA antibody at conception	-0.997	<0.01*
		(R^2=0.623, P<0.001)

Therefore, we speculate that high titer of anti-dsDNA antibodies might be a risk factor for children's physical or neurological development.

There is a need for long-term follow-up studies focusing on the neurological development of children born to SLE mothers.

* shows p-value of < 0.05 which is considered significant. SLEDAI: Systemic Lupus Erythematosus Disease Activity Index, C3,C4,CH50: complement, anti-dsDNA antibody; anti-double-stranded DNA antibody

* shows p-value of < 0.05 which is considered significant. SLEDAI: Systemic Lupus Erythematosus Disease Activity Index, C3,C4,CH50: complement, anti-dsDNA antibody; anti-double-stranded DNA antibody

C-section	74 (54%) of 138	20 (44%)	22 (56%)	32 (52%)

*Includes 3 twin and 1 triplet deliveries

Background/Purpose: Prospective cohort studies of pregnancies managed by experts demonstrate that up to 30% of systemic lupus erythematosus (SLE) pregnancies result in preterm birth. We assembled a real-world, multi-center, electronic health record (EHR)-based cohort of SLE births from three tertiary care centers in the Southeastern United States to assess the impact of race on adverse pregnancy outcomes.

Methods: Centers 1 and 2 selected subjects with at least 1 count of the SLE ICD-9 (710.0) or ICD-10 codes (M32.1*, M32.8, M32.9) and at least 1 ICD-9 or ICD-10 code for pregnancy-related diagnoses from 2013-2018. These subjects were reviewed by a rheumatologist to determine if the subject had SLE. Pregnancy outcomes were extracted as discrete variables through the EHR. Center 3 subjects had at least 4 counts of the SLE ICD-9 code or ICD-10 codes and at least 1 ICD-9 or ICD-10 code for pregnancy-related diagnoses. A subject was defined as a case if diagnosed with SLE by a rheumatologist, nephrologist, or dermatologist. Pregnancy outcomes were assessed through chart review for deliveries from 1993-2017. Only pregnancies that delivered at the academic center, had available pregnancy outcomes, and occurred after SLE diagnosis were included. Age-adjusted logistic regression models measured the association of maternal race with preterm birth and preeclampsia.

Results: Across the 3 centers, there were 131 women with SLE with 146 pregnancies. The mean age at delivery of 29 years was similar across the 3 centers (Table 1). The demographics were different between centers with more Black women at Center 1 (71%) and 2 (66%) compared to Center 3 (38%); there were very few Hispanic women. Overall, the rate of preterm birth was 42% with a mean gestational age of 35.7 weeks, which was similar in each center. More than half (54%) of all pregnancies were delivered surgically. Preeclampsia complicated 24% of all pregnancies, with the rate of preeclampsia twice as high in Center 1 (38%) compared to Centers 2 and 3 (17%). The large majority of preeclamptic deliveries occurred preterm (79%). When adjusting for maternal age, Black race was not significantly associated with preterm birth (OR = 1.28, 95% CI 0.62 – 2.62, p = 0.5) or preeclampsia (OR = 1.66, 95% CI 0.65 – 4.26, p = 0.3).

Conclusion: We observed higher than previously reported rates of preeclampsia, preterm birth, and Caesarean section at all 3 centers. Only slightly more than half of the deliveries were term and without preeclampsia. In the general population, preeclampsia is most common at term, whereas in this cohort 79% of preeclampsia occurred preterm. These findings likely reflect the severity of disease seen at large tertiary care referral centers in the Southeastern US. While the proportion of pregnancies to Black women was higher in this cohort than others, multivariate analysis demonstrated that race was not associated with adverse outcomes. We hypothesize that these findings reflect referral bias of the sickest SLE patients of all races to deliver at a tertiary care center. Our findings demonstrate that even at specialized, tertiary care centers, there is an unmet need for management guidelines that reduce adverse pregnancy outcomes in SLE.

Abstract Number: 2286

Mobile Responsive App – Useful Additional Tool for Data Collection in the German Pregnancy Register Rhekiss?

Jutta Richter,[1] Christina Bungartz,[2] Anja Weiß,[3] Rebecca Fischer-Betz,[4] Angela Zink,[5] Matthias Schneider,[1] and Anja Strangfeld[3], [1]Department and Hiller Research Unit of Rheumatology, Heinrich-Heine University Duesseldorf, Duesseldorf, Nordrhein-Westfalen, Germany, [2]German Rheumatism Research Center (DRFZ), Berlin, Berlin, Germany, [3]German Rheumatism Research Center (DRFZ), Berlin, Germany, [4]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany, [5]German Rheumatism Research Centre and Charité University medicine, Berlin, Germany

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Reproductive Issues In Rheumatic Disorders Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The German pregnancy register Rhekiss is designed as a nationwide, web-based longitudinal observational register established in 2015. The register follows women with inflammatory rheumatic disease prospectively from child wish through pregnancy until two years postpartum. During the observation, information on clinical and laboratory parameters, disease activity, comorbidities, flares, drug treatment, and (adverse) pregnancy outcomes are documented in pre-specified intervals. Physicians and patients (pts) report data for the same time periods via separated accounts and questionnaires (Qs) into a web-based application on personal computers, laptops, and notebooks. Due to the increasing use of mobile devices, a responsive App as a further documentation option and for facilitated patient-reported data entry was developed. We examined whether pts use an App for data entry in the pregnancy register.

Methods: The Rhekiss-App is available in German and can be downloaded for self-reported data retrieval since 08/2017 from App stores (Android and iOS). For the current analysis, Rhekiss register data were used from the time period October 2018 until April 2019 to ensure valid data on the applications modes.

Results: Within the analyzed period Rhekiss expected answers from 2207 Qs of 889 pts. Overall, 71.2% of the Qs were filled in. 49.9% of the Qs were sent from a browser installed on a desktop computer, ranging from 56% (January 2019) to 46% (April 2019), see table 1. Desktop users were on average 34±3.8 years old; the proportion of desktop users was highest in women after delivery (52%). The App installed on mobile devices was used for data entry of 760

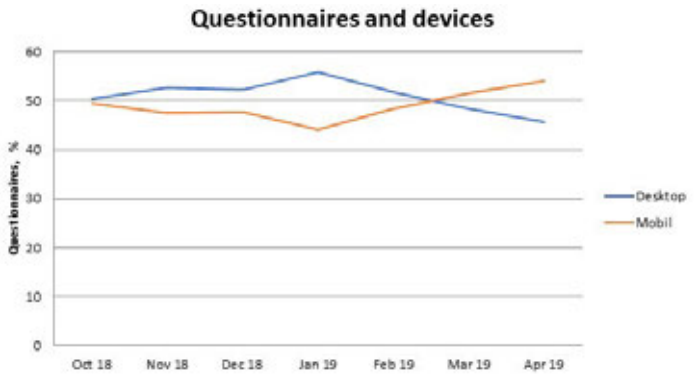

Figure 1 Progress of desktop and mobile documented questionnaires

	Desktop	Smartphone	Tablet/Phablet	Total
Number of questionnaires (%)	758 (49.9)	657 (43.3)	103 (6.8)	1518 (100)
Age of respondents years (SD)	33.9 (3.8)	33.1 (4.2)	33.8 (4.0)	33.5 (4.0)
Month				
October 2018	99 (50.5)	88 (44.9)	9 (4.6)	196 (100)
November 2018	102 (52.6)	81 (41.8)	11 (5.7)	194 (100)
December 2018	95 (52.2)	70 (38.5)	17 (9.3)	182 (100)
January 2019	85 (55.9)	56 (36.8)	11 (7.2)	152 (100)
February 2019	124 (51.7)	95 (39.6)	21 (8.8)	240 (100)
March 2019	73 (48.3)	66 (43.7)	12 (7.9)	151 (100)
April 2019	137 (45.8)	146 (48.8)	16 (5.4)	299 (100)

Table 1 Utilization of the various documentation routes over time

Qs (50.1%): Smartphone use ranged between 37% and 49%, tablet use was less frequent (up to 9%), and phablet use was neglectable, see table 1. Women with child wish had the highest smartphone App use (51%). Figure 1 depicts the progress of desktop and mobile documented Qs.

Conclusion: The responsive App is a useful additional tool for data collection in Rhekiss. It was used for data acquisition from approximately 50% of the questionnaires. While the use of the App on a smartphone was of high interest, the use of tablets/phablets for data collection seems negligible. Apart from desktop/browser developments, technological adoptions within observational cohorts and/or future (joined) registries need to take smartphone requirements and developments into account, especially when patient-reported data in young, mobile patients are collected.

Acknowledgement: The register's mobile App was implemented with software development from the IT partners Serrala, Berlin (Germany) and Questback, Köln (Germany)

Combined First-Trimester Serum BAFF and sFlt-1 Levels as an Early Biomarker of Spontaneous Abortion

Hindi Stohl,[1] Ning Yu,[2] and **William Stohl** [2], [1]Harbor-UCLA Medical Center, David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]University of Southern California Keck School of Medicine, Los Angeles, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunologic, angiogenic, and anti-angiogenic factors have been associated with spontaneous abortion (SAB), yet early identification of those pregnant women who ultimately undergo SAB remains very limited. B-cell activating factor (BAFF; a vital B cell survival factor), a proliferation-inducing ligand (APRIL; a vital plasma cell survival factor), placental growth factor (PlGF; a vital angiogenic factor), and soluble fms-like tyrosine kinase-1 (sFlt-1; a vital anti-angiogenic factor) may play a role in the development of SAB and, hence, may serve singly or in

combination as an early biomarker of SAB. The present study was performed to evaluate serum levels of sFlt-1, PIGF, BAFF, and APRIL in the first trimester of pregnancy and to assess associations and predictive values of first-trimester levels of these factors with SAB.

Methods: In this prospective observational study, serum sFlt-1, PIGF, BAFF, and APRIL levels were measured in the first trimester of pregnancy in a medically-diverse group of women and in non-pregnant controls. Associations and predictive values of first-trimester sFlt-1, PIGF, BAFF, and APRIL levels with development of SAB were tested.

Results: Serum samples from 286 women (48 non-pregnant controls and 238 pregnant women) were evaluated. Median serum BAFF levels were significantly lower and median serum sFlt-1 levels were significantly higher in the first trimester of pregnancy than in non-pregnant controls (0.900 ng/ml versus 1.000 ng/ml, $p = 0.007$, for BAFF; 0.454 ng/ml versus 0.103 ng/ml, $p < 0.001$ for sFlt-1). No differences in serum APRIL or PlGF levels were appreciated. SAB developed in 27 of the pregnant women (11.3%). While first-trimester levels of APRIL and PIGF were not associated with SAB, first-trimester serum BAFF was significantly elevated and first-trimester serum sFlt-1 was significantly reduced in women with SAB compared to those who maintained their pregnancies ($p = 0.005$ and $p < 0.001$, respectively). Using the optimal cut-offs generated through receiver operating characteristics curves for BAFF and sFlt-1, respectively, the positive predictive values for SAB when taking serum levels of both BAFF and sFlt-1 into consideration were 0.3529 ($p < 0.0001$) for all subjects (N = 236), 0.4667 ($p < 0.001$) for subjects without an underlying chronic medical disorder (N = 131), and 0.3750 ($p = 0.0045$) for subjects with an underlying chronic medical disorder (N = 105; including 20 subjects with systemic rheumatic diseases). The corresponding negative predictive values for SAB were 0.9808 ($p = 0.0009$) for all subjects, 0.9706 ($p = 0.0140$) for subjects without an underlying chronic medical disorder, and 1.0000 ($p = 0.0362$) for subjects with an underlying chronic medical disorder.

Conclusion: The combination of serum first-trimester levels of BAFF and sFlt-1 greatly increases the ability to positively and negatively predict SAB. Identification of pregnant women at high risk for SAB through testing of serum BAFF and sFlt-1 levels could assist in their counseling and ultimately facilitate clinical trials that test candidate therapeutic interventions.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologic disorders and inflammatory bowel disease can affect women of childbearing potential. Golimumab (GLM) is approved for rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis, nonradiographic axial spondyloarthritis, polyarticular juvenile idiopathic arthritis and ulcerative colitis (UC). To characterize pregnancy outcomes in patients treated with GLM, data obtained from maternal exposure to GLM are presented.

Methods: This dataset includes individual patient cases reported to the manufacturer through 06 April 2019. Cases included in the analysis were medically confirmed cases of maternal exposures to GLM during pregnancy or within 3 months prior to conception, and a reported pregnancy outcome. Both prospectively reported (ie, pregnancy outcome not known when first reported) and retrospectively reported cases (ie, pregnancy outcome known when first reported) were included. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries.

Results: Two hundred eight pregnancy cases[1] (131 rheumatological[2]; 43 UC; and 34 other) with 211 reported birth outcomes were identified. Of these 208 pregnancy cases, 119 were prospective and 89 were retrospective (Table 1). Average maternal age was 31.9 years. Of the 119 prospectively reported pregnancy cases, 89 (74.8%) resulted in live births, 19 (16.0%) resulted in spontaneous abortion (of these, 42.1% (8/19) received GLM in combination with methotrexate [MTX]), 10 (8.4%) resulted in induced/elective abortion, and 1 (0.8%) resulted in ectopic pregnancy. Overall, 9 congenital anomalies were reported (2 prospective/7 retrospective cases).

Table 1: Summary of Pregnancy Outcomes in Patients Treated With GLM

Pregnancy Outcome	Count (%)	Rheum	UC	Other	Congenital Anomaly (CA)	MTX Use[a]

Key: AE= Adverse Event; CA= Congenital Anomaly; GLM= Golimumab; MTX= Methotrexate

a: 0, 1st, 2nd, 3rd= trimester 0 (<3 months before conception), first, second, third trimester, respectively.

b: Patient received MTX at the time of conception/during pregnancy.

c: Count includes 1 live birth without AE/CA, 2 live births with AE, 2 spontaneous abortions and 1 elective/induced abortion.

d: Count includes 4 live births without AE/CA, 1 live birth with AE, 6 spontaneous abortions and 2 elective/induced abortions.

d: Count includes 1 live birth with AE.

f: Count includes 1 live birth without AE/CA, 1 live birth with CA, 3 spontaneous abortions and 2 ectopic pregnancy cases.

For 183 of the 208 pregnancy cases with reported outcomes, the trimester of exposure to GLM was known (Table 2). Among the 110 prospectively reported cases, 82 (74.5%) were exposed during trimester 0 or 1. Of these, 19 had concomitant exposure to MTX, with the following birth outcomes: 8 live births, 8 spontaneous abortions, 3 elective/induced abortions. Eighteen of the prospectively reported cases (16.4%) were exposed to GLM throughout pregnancy (1st, 2nd and 3rd trimester) and all resulted in live births.

References:

1. Three cases reported twin pregnancies.
2. Rheumatological includes rheumatoid arthritis, psoriatic arthritis, and ankylosing spondylitis.

Conclusion: The rates of congenital malformations and spontaneous abortions were consistent with published background rates for the general population. Persistent exposure throughout pregnancy was rare, but not associated with apparent clinical sequelae. Limitations of this analysis include the lack of a direct comparison group, the

variable amount of data available in the reports, and the possible bias towards reporting more negative outcomes in retrospective cases.

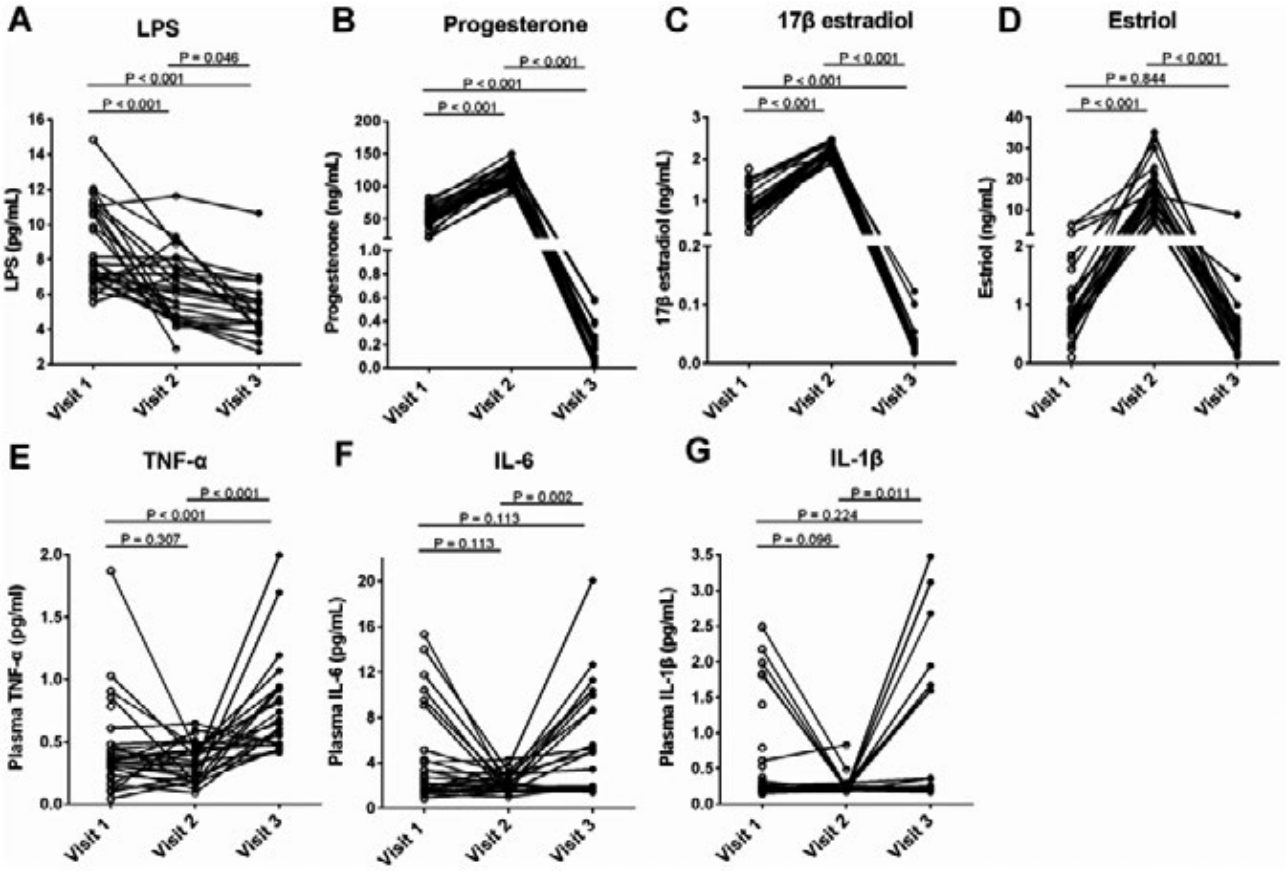
SESSION INFORMATION

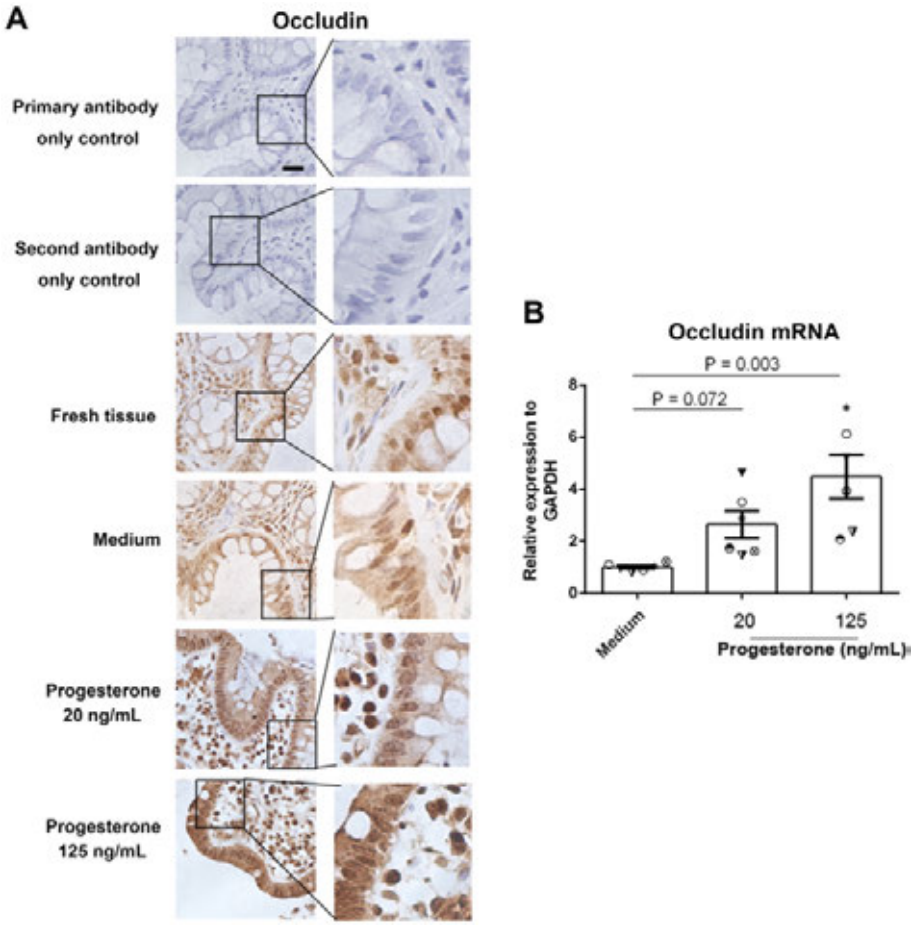
Session Date: Tuesday, November 12, 2019

Session Title: Reproductive Issues In Rheumatic Disorders Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

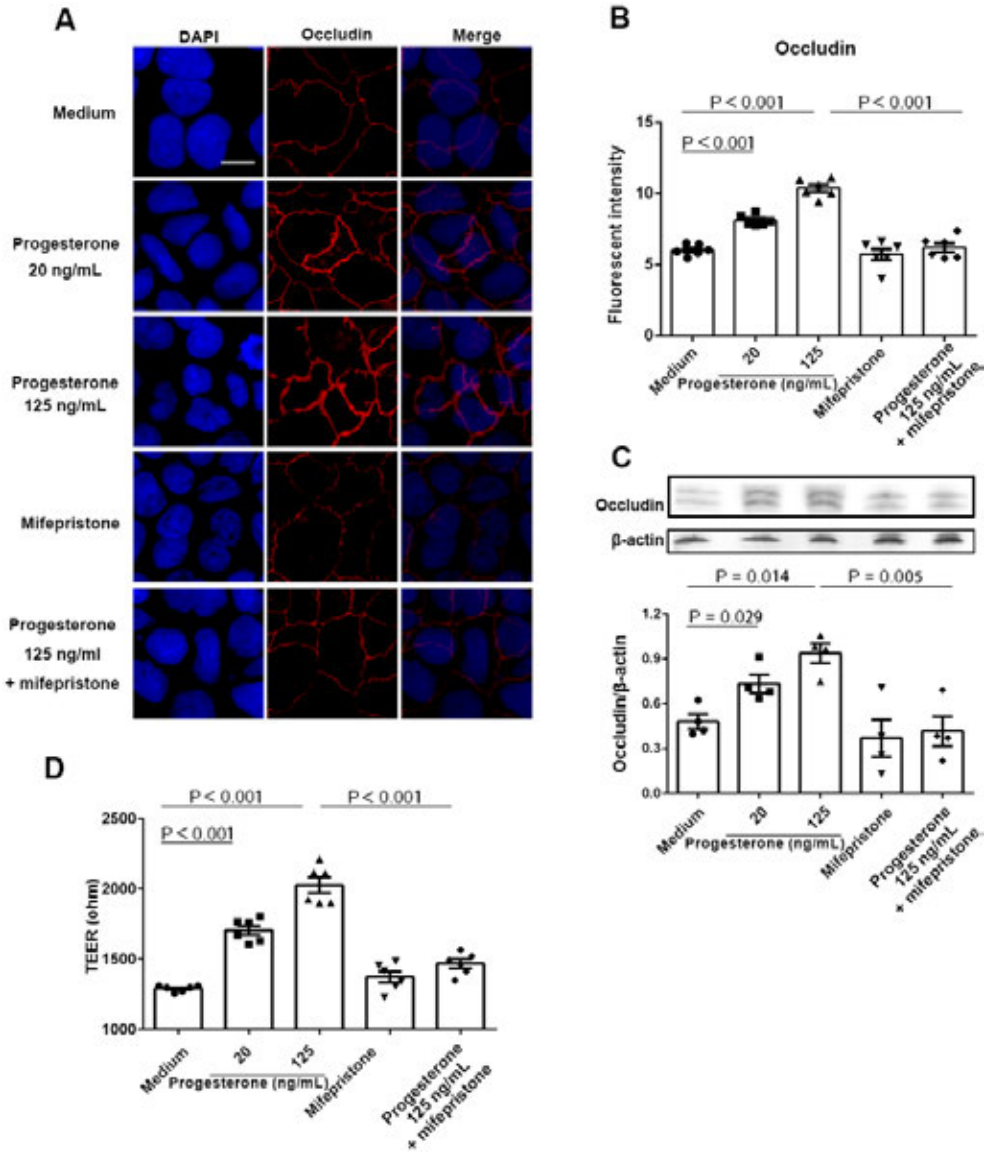




Background/Purpose: Progesterone plays a protective role in preventing inflammation and preterm delivery during pregnancy. However, the mechanism involved is unknown. Microbial product translocation from a permeable mucosa is demonstrated as a driver of inflammation.

Methods: To study the mechanism of the protective role of progesterone during pregnancy, we investigated the effect of physiologic concentrations of progesterone on tight junction protein occludin expression and human gut permeability *in vitro* and systemic microbial translocation in pregnant women *in vivo*. Plasma bacterial lipopolysaccharide (LPS), a representative marker of *in vivo* systemic microbial translocation was measured. Increased microbial translocation from a "leaky" gut has been shown to play a role in autoimmune diseases and pre-term delivery.

Results: We found that plasma LPS levels were significantly decreased from 24 to 28 weeks of gestation compared to 8 to 12 weeks of gestation ($P < 0.05$, ANOVA). The median plasma levels of LPS (pg/mL) were 7.76 (6.86 - 11.04) and 6.25 (4.53 - 7.55) and 4.88 (4.10 - 5.66) for 8-12 (visit 1), 24-28 weeks (visit 2) of gestation, and 6 to 8 weeks postpartum (visit 3), respectively. Plasma estriol and progesterone levels were increased at visit 2 compared to visit 1 but decreased at visit 3 ($P < 0.05$, non-parametric Mann-Whitney test). Moreover, plasma LPS levels were negatively correlated with plasma progesterone levels but positively correlated with plasma tumor necrosis factor-alpha (TNF-α) levels at visit 1 (Spearman correlation test) but not at visit 2. Progesterone treatment increased intestinal trans-epithelial electrical resistance (TEER) in primary human colon tissues and Caco-2 cells *in vitro* through upregulating tight junction protein occludin expression using IHC, qPCR, and TEER assays ($P < 0.05$, non-parametric Mann-



Whitney test). Furthermore, progesterone exhibited an inhibitory effect on nuclear factor kappa B (NF-κB) activation following LPS stimulation in Caco-2 cells by IHC, western blot and qPCR ($P < 0.05$, non-parametric Mann-Whitney test).

Conclusion: These results reveal a novel mechanism that progesterone may play an important role in decreasing mucosal permeability, systemic microbial translocation, and inflammation during pregnancy.

Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Undifferentiated connective tissue disease(UCTD) represents a common autoimmune condition in clinical practice, however, therapeutic strategies and follow-up are mostly based on clinician expertise. Little is known about the fetal and maternal pregnancy outcomes of women with UCTD. In this study, we aimed to investigate fetal/perinatal and maternal outcomes from a large multicentre cohort of women diagnosed with UCTD.

Methods: This multicenter study included patients diagnosed with UCTD ever pregnant, positive for antinuclear auto-antibodies and aged < 45 years old at study inclusion. Clinical data was collected retrospectively and complete laboratory profiles were assessed before conception, according to local standard of care adopted by all centers involved in the study.

Results: The study included a total of 133 women diagnosed with UCTD. Of the 224 pregnancies analysed,177 (79%) resulted in live births, 45 (20.1%) in miscarriages (defined as pregnancy loss before 12 weeks' gestation), 2 (0.9%) in stillbirths (pregnancy loss after 20 weeks' gestation) and six (2.7%) cases presented intrauterine growth restriction. Miscarriages and stillbirths were strongly associated with the presence of antiphospholipid antibodies (aPL) and extractable nuclear antigen antibodies (ENA).Maternal pregnancy complications were as follows: 5(2.2%) cases developed pre-eclampsia, 11 (4.9%) patients experienced gestational hypertension, and 12 (5.4%) women were diagnosed with gestational diabetes.

Joint involvement represented the most frequent clinical manifestation (57.9%), followed by Raynaud's phenomenon (10.6%), photosensitivity (32.3%) and haematological manifestations (27.1%).

The rate of disease evolution of our cohort from a diagnosis of UCTD to a diagnosis of definite connective tissue disease (CTD) was 12% within a mean time of 5.3 years (S.D. ±2.8). With a total follow-up after first pregnancy of

Session Title: Reproductive Issues In Rheumatic Disorders Poster

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pregnancies in women with systemic lupus erythematosus (SLE) often result in preterm birth. Active disease during pregnancy significantly increases the risks for these poor outcomes. Hydroxychloroquine (HCQ) reduces disease activity and flares in SLE, however, low serum levels may lead to treatment failure. Therefore, our objective is to evaluate HCQ levels during pregnancy and determine target serum levels to reduce maternal disease activity and preterm birth.

Methods: We performed a single-center observational study of women with SLE who were taking HCQ during pregnancy between 2013 and 2019. Serum samples were analyzed using validated high-performance liquid chromatography/mass spectrometry. Based on prior publications, we analyzed average HCQ exposure both continuously and

categorically: ≤ 100 ng/ml (low), 101-500 ng/mL (moderate), and > 500 ng/ml (high). The primary maternal outcome was disease activity, measured using the Physician Global Assessment (PGA) throughout pregnancy. The primary neonatal outcome was gestational age at birth. We excluded pregnancies in which the woman had lupus nephritis within the prior 3 years due to potential confounding between drug levels and preterm birth. We analyzed categorical outcomes using Fisher's exact test and continuous outcomes using linear regression models, Wilcoxon signed-rank test, Kruskal-Wallis test, t test, and ANOVA.

Results: We analyzed 172 samples from 52 pregnancies in 46 women (Table 1). HCQ concentration varied widely among individuals at each trimester. In addition, there was a non-statistically significant decline in HCQ concentrations throughout pregnancy, with a nadir in the 3rd trimester. Of live births (n=38), preterm birth was significantly more common in mothers whose average HCQ level was low (62.5%), compared to those with moderate levels (8.3%), and high levels (33.3%, p=0.005), Table 2. In addition, disease activity in these mothers was significantly higher in those with low HCQ levels (median [IQR]) PGA 0.67 [0.36-1.16], compared to those with moderate levels (0.06 [0-0.37]), and high levels (0.38 [0.25-0.5], p=0.006). The association between PGA and HCQ levels as a continuous variable was best characterized using a generalized linear model with a log function (figure 1, p=0.002).

*Comparing Low vs Moderate vs High HCQ
** Comparing Low vs Moderate and High HCQ combined

Table 2. Maternal and Neonatal Outcomes by Categorical HCQ Exposure (excluding lupus nephritis)

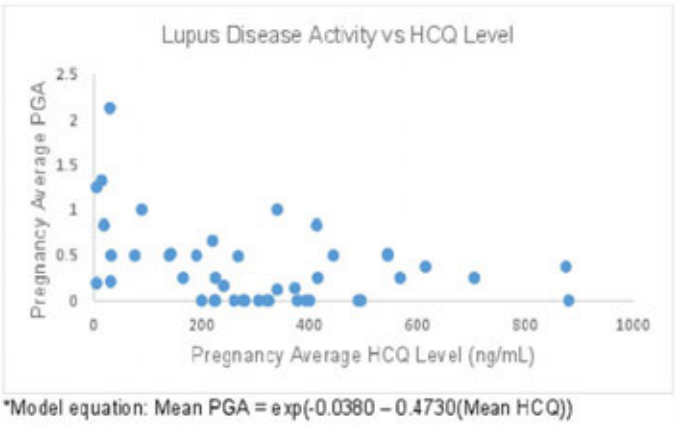

Figure 1: Lupus Disease Activity vs HCQ Level (all pregnancies, excluding lupus nephritis)*

Conclusion: Our data suggests that the optimal serum HCQ level in this cohort appears to be in the moderate range (101-500 ng/ml), with this group having the lowest maternal disease activity and the fewest preterm births. Women with the lowest HCQ levels, in the range concerning for medication non-adherence, had the highest lupus activity and rates of preterm birth. However, the relationship between HCQ drug levels and neonatal outcomes are complex and not linear, and some women with high exposure (levels >500 ng/mL) continue to experience SLE activity and preterm birth. Due to low sample sizes within subgroups, ongoing data collection and analyses will clarify the role of monitoring HCQ levels in lupus pregnancies, characterize the relationship between drug levels and medication adherence, and determine the need for HCQ dose adjustment through PK/PD modeling.

Disease Activity, frequency of RA flares and changes in medications upon different time points.

Background/Purpose: During pregnancy, patients with rheumatoid arthritis (RA) can experience flares that might influence pregnancy outcomes. We aimed at assessing disease course during pregnancy and identifying possible risk factors of disease flares.

Methods: Data about RA patients prospectively followed in a pregnancy clinic were retrospectively collected before conception and during each trimester (T). Clinical characteristics, disease activity (DAS28-CRP3), medication use, and pregnancy outcomes were analysed. Flare was defined by an increase of DAS28-CRP3 >0.6 if the DAS28-CRP3 was >3.2 and by an increase of DAS28-CRP3 >1.2 if the DAS28-CRP3 was ≤3.2.

Results: Among 83 pregnancies (median age 35-IQR 30-38; median disease duration 66 months, IQR 36-156; ACPA+ 62.3%%, RF+ 60.2%) in 64 RA patients enrolled between 2010 and 2018, 8 pregnancies ended with early miscarriages, 1 with intrauterine foetal death and 1 with ectopic pregnancy. The remaining 73 pregnancies in 63 patients were analysed. Before conception, 54(74%) patients were in remission, 10 (14%) had low disease activity and 9 (12%) moderate disease activity (Fig.1). During pregnancy, a flare occurred in 27 (37%) patients (13 in T1, 10 in T2, 6 in T3; 2 patients had >1 flare). Flares during pregnancy were associated with the discontinuation of bDMARDs at positive pregnancy test (55% of patients with flare vs 30% of patients with no flare, p=0.034 OR 2.857, 95%CI 1.112-8.323). Flares during the course of pregnancy were also associated with a previous use of >1 bDMARDs (33% of patients with flare vs 10% of patients with no flare, p=0.019, OR 4.1, 95%CI 1.204-13.966). Fig.1 reports the use of drugs during each trimester and post-partum period (presented as overall use and start/resume of single drugs). Particularly, patients who stopped bDMARDs at the beginning of pregnancy resumed it during 2nd-3rd trimester (12/29, 41.4%) or after delivery (13/29, 44.8%). Twenty-four live births (33%) were complicated (9 preterm deliveries,

of which 3 < 34weeks; 12 premature rupture of membranes (PROM), 5 at term and 7 preterm; 10 "small for gestational age" newborns). Preterm pregnancies were characterised by higher values of CRP and DAS28-CRP3 at T1 compared with pregnancies at term (10 (5-11) vs 3 (2.5-5) p=0.01 and 4.2 (1.9-4.5) vs 1.9 (1.7-2.6) p=0.01, respectively). Preterm deliveries were associated with the occurrence of flare (flare 27% vs no-flare 7%, p=0.034, OR 4.625, 95%CI 1.027-20.829).

Conclusion: In a cohort of prospectively-followed pregnancies, 37% of RA patients experienced at least one flare during pregnancy despite the majority of the patients were in remission prior to conception. There was a 3-fold-increased chance of flare in patients who were on bDMARDs (and stopped the treatment early in pregnancy) as compared with bDMARDs-naïve patients. Patients with more aggressive RA (use of bDMARDs, especially if >1) may get benefit from continuing treatment beyond conception to ensure control of maternal disease and better pregnancy outcomes.

Pregnancy in Patients with Systemic Lupus Erythematosus After Cyclophosphamide Therapy

Mitali Sen,[1] Anu Kurl,[1] Tejal Vashi,[2] and Arezou Khosroshahi[1], [1]Emory University, Atlanta, GA, [2]Emory University School of Medicine, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) predominantly affects females of reproductive age. Cyclophosphamide, an alkylating agent, labelled category D for pregnancy, is used for induction in treatment of severe manifestations of lupus. Previous studies have shown increased rate of primary ovarian insufficiency causing infertility in patients who have received cyclophosphamide. But recent studies with cancer treatment suggest fair pregnancy outcomes in such patients. Now, with an earlier age at lupus diagnosis, increasing maternal age for pregnancy, and with treatment protocols using lower doses of medication, we have an increasing population of lupus patients who plan to conceive after having received cyclophosphamide. The objective of our study was to add to the available data in identifying the impact of cyclophosphamide exposure on fertility and pregnancy outcomes.

Methods: Using diagnostic codes, we searched for female patients fulfilling ACR criteria for SLE who received cyclophosphamide in the time period from 2000-2018 in our academic institution. We have identified about 400 such patients and as a pilot project of an ongoing study, we performed a retrospective chart review on 100 of those patients. Each patient was evaluated for demographic and serological profile, age of patient at the time of cyclophosphamide infusion and pregnancy and subsequent maternal and fetal outcomes or infertility. We compared these variables using two sample T-test. This is part of an ongoing study and more patients are expected to be added to our final analysis.

TABLE 1

	Patients with successful pregnancy (n=10)	Patients with spontaneous pregnancy loss (n=4)	Premature ovarian failure (n=7)
Mean age at SLE diagnosis (years)	22.3	27.7	23.7
Race			
African American (%)	8 (80%)	3(75%)	5 (71.4%)
Caucasian (%)	0	0	1 (14.3%)
Hispanic (%)	1 (10%)	0	0
Asian (%)	0	0	1 (14.3%)
Undisclosed (%)	1 (10%)	1 (25%)	0
SSA/SSB positive	5 (50%)	2 (50%)	1 (14.3%)
Antiphospholipid Antibody positive	4 (40%)	2 (50%)	4 (57.1%)
No of patients on mycophenolate mofetil prior to pregnancy	10 (100%)	2(50%)	2 (71.4%)
Maternal co-morbidities: CKD 4/5, ESRD	2 (20%)	0	4 (57.1%)
No of patients on an average steroid dose > 10 mg daily (%)	6 (60%)	3 (75%)	3 (42.8%)

Results: Of the 100 female SLE patients reviewed in this study, 82 were given cyclophosphamide for biopsy proven nephritis, 12 for cerebritis, 3 for vasculitis and 1 each for diffuse alveolar hemorrhage and severe cutaneous disease. Fertility counselling was documented in 54% of the patients at the time of medication initiation. 19 patients had subsequent pregnancies; 10 with healthy maternal and fetal outcomes, 5 underwent elective termination within first trimester and 4 had spontaneous miscarriages. Only 7 out of 100 females were identified to have premature ovarian failure which included 4 who also had end stage renal disease. (Table 1)

Average age (in years) at the time of cyclophosphamide administration was 24.9 in patients with successful pregnancy; 33.4 with spontaneous miscarriage and 32 with premature ovarian failure. Average duration (in months) between the last cyclophosphamide infusion and subsequent pregnancy was 53.5 in patients with successful pregnancy vs 19.3 in patients with a spontaneous miscarriage (p 0.144). Average cumulative dose of cyclophosphamide (in mg)

was 3733 in patients with successful pregnancy compared to 2000 with spontaneous miscarriage (p 0.1529) and 4375 with ovarian insufficiency (p 0.0403).

Conclusion: Our findings suggest that a longer time interval between the last cyclophosphamide infusion and pregnancy was more favorable for a successful pregnancy outcome. However, a higher cumulative dose is more likely to be associated with premature ovarian failure.

Abstract Number: 2294

Contraception Documentation Rates in Women with Rheumatic Diseases on Teratogenic Medications in an Academic Rheumatology Clinic

Josna Haritha,[1] Cuoghi Edens,[2] and Iazsmin Ventura[2], [1]University of Chicago, Chicago, IL, [2]University of Chicago, Chicago

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases are prevalent among women of childbearing age; their treatment often requires medications that potentially affect a woman's fertility and are teratogenic. Prior studies have shown minimal contraception counseling in women receiving high-risk medications and decreased contraception utilization. Our study explores rates of contraception counseling and documentation of contraception use, as well as their type of contraception.

Methods: A retrospective chart review was performed in a university-based Rheumatology clinic. Women ages of 18–50 years who were prescribed mycophenolate mofetil (MMF), methotrexate (MTX), and/or cyclophosphamide (CYC) over a 6-year period with any rheumatic disease were included. 372 of 485 charts reviewed met inclusion criteria. Subject demographics, documentation of contraception type, and counseling were recorded (Table 1). Contraception method was categorized as highly effective (permanent [hysterectomy, tubal ligation] or reversible [IUD, implants, female partners]), effective (OCPs, patch, ring, injection) and ineffective (none, abstinence, condoms). Categorical variables were compared using Fisher's exact test and ordered logit models were calculated.

Results: The most common teratogenic medication prescribed was MTX (56%), followed by MMF (39%), CYC (0.5%); 4% were taking a combination of these. Median age was 41 years, and majority were African American (51%). Lupus and other related connective tissue diseases (50%) were most represented. Across all rheumatic diseases, documentation of any contraception was 39% and the rate of counseling was 36%. There was a statistically significant relationship between age and race with respect to effectiveness of contraception ($p< 0.001$ and $p=0.010$, respectively) (Table 2). Multiple ordered logistic models demonstrated that for patients with contraception counseling, the odds of being on highly effective or effective contraception versus ineffective contraception compared to those without counseling documentation were increased (OR: 1.28, 95% CI: 0.86-1.93). For patients with a documented contraception method, they were more likely to be on highly effective

Table 1: Subject Demographics

	General
N	372 (%)
Age (years)	
18-25	39 (10)
26-35	85 (23)
36-45	153 (41)
46-50	95 (26)
Race	
African American	190 (51)
White	159 (43)
Other (Hispanic, Asian)	23 (6)
Teratogenic Medication(s)	
MTX	209 (56)
MTX/MMF	10 (3)
MMF	145 (39)
CYC	2 (<1)
CYC/MMF	6 (2)
Contraception Type	
Highly effective (permanent) -Hysterectomy, tubal ligation, vasectomy	58 (16)
Highly effective (reversible) -IUD, Implants, female partners	37 (10)
Effective -OCPs, Patch, Ring, Depo-Provera	72 (19)
Ineffective -None, abstinence, condoms, spermicide	205 (55)
Contraception Documented	
Yes	144 (39)
No	228 (61)
Contraception Counselling	
Yes	134 (36)
No	238 (64)

or effective contraception versus ineffective (OR: 5.83, CI: 3.72-9.13). Any reference to contraception (either type or counseling) were more likely to use highly effective or effective contraception (OR: 3.84, CI 2.44-6.04) (Table 3).

Conclusion: Our results demonstrate that a rheumatologist's recognition of a patient's need for contraception and clinical documentation of such while on teratogenic medications is the most important predictor of effective contraception method use; the magnitude of its impact is maintained after adjusting for age and race. This study reinforces the importance of increasing both provider and patient education surrounding awareness of contraception needs. Future QI measures to implement interventions that focus on these topics are needed to help improve contraceptive use in young females and increase use of more effective contraceptives in women of all ages on teratogenic medications.

Table 2: Contraceptive Effectiveness Stratified by Age, Race and Teratogenic Medication in all Rheumatic Diseases

	Highly Effective	Effective	Ineffective	P-value

Burden of Systemic Lupus Erythematosus Among Korean Women in Childbearing Years Based on the National Health Insurance Service Data

Min Kyung Chung,[1] Jin Su Park,[2] Hyun Sun Lim,[2] Chan Hee Lee,[2] and **Jisoo Lee** [1], [1]Division of Rheumatology, Department of Internal Medicine, Ewha Womans University School of Medicine, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang, Republic of Korea

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Most women with systemic lupus erythematosus (SLE) are diagnosed with the disease in their reproductive ages, but the burden of SLE among women in childbearing years remains incompletely understood. We aimed to investigate the burden of SLE among Korean women in childbearing years in terms of prevalence and incidence of disease, prevalence of comorbidity, medication dispensing, and pregnancy and delivery rate.

Methods: From National Health Insurance Service data during 2009-2016, women between 20-44 years of childbearing years were identified. Among these women, the prevalence and incidence of SLE were estimated. Women without chronic diseases (CD) or rheumatic diseases including SLE, rheumatoid arthritis, and ankylosing spondylitis were defined as controls. Prevalence of CD including cancer (Ca), diabetes mellitus (DM), hypertension (HTN), and hyperlipidemia (HLD) was compared in SLE women and controls. Medication uses including NSAIDs, corticosteroids (CSs), and conventional (c) disease-modifying anti-rheumatic drugs (DMARDs), pregnancy and delivery rates in women with SLE were compared with controls.

Results: Total 12,756 women with SLE and 208,941 controls were identified. The overall prevalence of SLE during 2009-2016 was 138.5 (95% CI 136.1-140.9) per 100,000 and overall incidence of SLE was 49.1 (95% CI 47.7-50.5) per 100,000 females in childbearing years during 2011-2016. SLE women had significantly increased prevalence of CD compared with the controls in the same age group (60.4% vs 25.6%, odds ratio (OR) 5.4, p< 0.0001). Each chronic disease including Ca (6.3% vs 4.2%, OR 4.2), DM (9.7% vs 6.0%, OR 1.9), HTN (35.2% vs 8.2%, OR 8.0), and HLD (38.3% vs 16.6%, OR 3.6) were all more prevalent in SLE women compared with the controls (p< 0.001). The use of any rheumatic diseases related medications including NSAIDs, CSs, cDMARDs were more frequent in women with SLE than controls (NSAIDs; 53.6% vs 21.8%, CSs; 81.0% vs 4.3%, cDMARDs; 89.0% vs 0.4%, all p< 0.001). Although pregnancy rate showed no difference between SLE women and controls (22.1% vs 19.3%, OR=0.97, p=0.38), delivery rate was significantly lower in SLE women compared with controls (18.7% vs 20.3%, OR 0.8, p< 0.001).

Table 1. Prevalence of chronic diseases among women with SLE in childbearing age between 20-44 years during 2009-2016

	With SLE (12,756)		Without RD (n=208,941)		p-value	OR*	95% CI
	n	(%)	n	(%)			
Any CD	7,699	(60.36)	53,423	(25.57)	<.0001	5.43	5.22-5.65
Ca	808	(6.33)	8,845	(4.23)	<.0001	1.73	1.60-1.87
DM	1,232	(9.66)	12,606	(6.03)	<.0001	1.85	1.74-1.98
HTN	4,488	(36.18)	17,052	(8.16)	<.0001	8.03	7.69-8.40
HLD	4,884	(38.29)	34,672	(16.60)	<.0001	3.59	3.45-3.73

SLE, systemic lupus erythematosus; RD, rheumatic diseases; CD, chronic diseases; Ca, cancer; DM, diabetes mellitus; HTN, hypertension; HLD, hyperlipidemia; OR, odds ratio; CI, confidence interval

*Adjusted for age, income level, and habitation

Conclusion: High prevalence and incidence, increased rates of comorbidities and medication use, and decreased odds to have successful delivery are causes of a significant burden in Korean women with SLE during their childbearing years.

Abstract Number: 2296

Assisted Reproductive Technology in Patients with Inflammatory and Autoimmune Rheumatic Disease

Elisa Trujillo,[1] and Erika Padrón[1], [1]Hospital Universitario de Canarias, Santa Cruz de Tenerife, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with chronic inflammatory and autoimmune diseases increasingly solicit assisted reproductive techniques (ART) due to infertility, but there is little information about success rates of these techniques in such patients.

Objective: To analyze pregnancy rates after artificial insemination (AI) and *in vitro* fertilization-intracytoplasmic sperm injection (IVF-ICSI) in patients with inflammatory rheumatic disease.

Methods: Prospective study of 41 women with inflammatory rheumatic disease: 15 rheumatoid arthritis, 7 spondyloarthritis, 10 systemic lupus erythematosus, 4 Sjögren´s disease, 2 undifferentiated connective tissue disease, 1, dermatomyositis, 2 Behcet disease, monitored by our department. Mean age 33 years (range 24-41) and 5 ± 7 years from diagnosis of disease, currently inactive or with low clinical activity. Due to infertility, these patients underwent ART: 8 with AI and 33 with IVF-ICSI.

We analyzed pregnancy rate and live-birth rate per cycle in all women and by age.

Results: Pregnancy rate per cycle of AI was 14.9% with a cumulative rate of 33% after four cycles. In patients over 35 years the pregnancy rate per cycle was reduced to 7%.

The pregnancy rate per attempt using IVF-ICSI was 23.9% with a cumulative rate of 37% after three attempts. In women over 35 years the success rate was 23.2%.

The live-birth rate per-cycle was 74.9%; 73.3% in woman over 35.

Conclusion: The pregnancy rates of both AI and IVF-ICSI were a little lower in this series of patients with inflammatory rheumatic disease than those reported for the general population. However, the live birth rate per cycle was similar to the general population.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Reproductive Issues In Rheumatic Disorders Poster
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to half of pregnant patients with rheumatic diseases experience disease activity which can increase the risk of pregnancy complications and poor disease outcomes. Treatment with anti-tumor necrosis factor-alpha (anti-TNF-α) is extendedly used in these patients to control disease activity. Placental drug barrier cross has been described for all anti-TNF-α, except for certolizumab. It occurs mainly during the third trimester of pregnancy. Few studies have evaluated the changes of newborn's immune system upon this exposure. The aim of this study was to evaluate the impact of anti-TNF-α exposure during pregnancy on the newborn's immune system, especially on lymphocyte subpopulations and innate immunity (IL-12 / IFN-γ pathway).

Methods: Prospective multicenter study which included newborns born to mothers with rheumatic diseases (including rheumatoid arthritis, spondyloarthropaties (ankylosing, psoriatic), juvenile idiopathic arthritis) , treated during pregnancy with anti-TNF-α. A control group of newborns not exposed to anti-TNF-α during pregnancy was included. All neonates underwent: a) clinical follow-up by a pediatric immunologist in search for infections, allergies or autoimmune disease; b) Umbilical cord (UC) and peripheral blood analysis at birth, 3, 6 and 12 months to record lymphocyte T and B subpopulations, analyze lymphocytes' proliferation capacity, as well as vaccine responses and innate immunity against mycobacteria. All patients signed informed consent.

Results: Fourteen newborns have been included, 10 exposed to anti-TNF-α (Certolizumab: 6, throughout pregnancy; Etanercept: 4, of which 3 during throughout pregnancy) and 4 not exposed. Cohort features are summarized in table 1.

One child developed atopic dermatitis in the non-exposed group; no other allergies or autoimmune diseases have been reported. 7 infections (anti-TNF-α exposed: 3 vs non-exposed: 4) were diagnosed during follow-up. In 3 cases, the patient required hospitalization (1 pyelonephritis, 2 bronchiolitis).

Conclusion: The preliminary results do not show an increase in the risk of infections or immune dysregulation in the anti-TNF-α exposed group.

Patient code	Mother rheumatic disease	Assisted reproductive techniques	Anti-TNF-α therapy	Anti-TNF-α exposure during third trimester	Prednisone during pregnancy (mean daily dose)	DMARDs during pregnancy	Active disease during pregnancy	Gestational age at birth (weeks)	Lactation	Weight at birth (Kg)
1	SAPHO syndrome	No	**Certolizumab**	**Yes**	5mg	None	No	38.4	Mixed	2,64

11	Rheumatoid arthritis	No	**Etanercept**	**Yes**	7,5mg	None	Yes	39.2	Breast milk	2,83
12	Juvenile idiopathic arthritis	No	**Etanercept**	**Yes**	No	None	Yes	40.3	Formula	3,56
13		In vitro fertilization	**Etanercept**	**Yes**	none	Hydroxychloroquine	No	39.1	Breast milk	3,01
14	Ankylosing spondylitis	No	**Etanercept**	**No**	none	None	No	40.2	Infant formula	2,67

Table 1

No significant quantitative differences are observed in the lymphogenesis, but a more immature B population and a predominantly T memory population was found in newborns exposed to anti-TNF-α. These differences are attenuated at 3 and 6 months. Functional capacity of the IL-12 / IFN-γ pathway seems intact. The ongoing recruitment will give consistency to these results.

Background/Purpose: Interstitial lung disease (ILD) is a common and severe complication of rheumatoid arthritis (RA). It has been associated with the presence of ACPA. Anti-carbamylated peptides/proteins (anti-CarP) is a new family of RA autoantibodies associated with poor outcomes including an increased mortality due to respiratory disease (1). We aimed to analyze the prevalence of distinct anti-CarP fine specificities in an established RA cohort and determined whether anti-CarP are associated with ILD.

Methods: Cross sectional study. Patients with RA according to ACR/EULAR 2010 criteria with a disease duration of ≤ 10 years, and those with an associated ILD independently of the disease duration were included. ILD was diagnosed with a high-resolution CT according the American Thoracic Society/European Respiratory Society 2013 criteria, diagnosis confirmed by a multi-disciplinary committee. Demographic, clinical and radiological features were analyzed. Auto-antibody status (RF and ACPA) were also assessed. Three anti-CarP IgG autoantibodies were determined (anti-CarP fetal calf serum (FCS), anti-CarP fibrinogen (anti-Fib) and anti-CarP fibrine/filagrine homocitrulinated peptide (anti-CFFHP)) by home-made ELISA tests using as antigens either carbamylated proteins or a synthetic chimeric fibrin-filaggrin homocitrullinated peptide. Cut-off values were determined using ROC curves, with a specificity of 96% compared with a healthy population.

Results: 179 patients were included, 21% had an ILD. The mean age at ILD diagnosis was 64.2 (±9.7) years, the mean time from RA diagnosis until ILD diagnosis was 9.3 (IQR: 11.4) years. A significantly greater tobacco exposure (30.7 ±11.1 vs 21.8 ±12) and higher frequency of erosive disease (70% vs 44%) and disability (HAQ-DI >1: 27% vs 12%) was observed in patients with ILD. Total cohort demographic, clinical and radiological features are presented in *Table 1*.

Anti-CarPs prevalence in the total cohort was 49%, 56%, and 29% for anti-FCS, anti-Fib and anti-CFFHP peptide respectively. Positive Anti-FCS anti-Fib and anti-CFFHP peptide were found in 22%, 29% and 8% of ACPA negative patients respectively.

All anti-CarP fine specificities were significantly more prevalent in patients with ILD (anti-FCS 70% vs 43%; anti-Fib 73% vs 51%; anti-CFFHP 49% vs 23%), and significantly higher titers of Anti-FCS and anti-CFFCHP were observed in these patients.

A logistic regression model adjusted for age, disease duration, sex, smoking, erosive disease, RF and ACPA demonstrated that Anti-FCS (OR: 3.49; CI 95%: 1.16-10.50) and anti-CFFHP (OR: 4.82; CI 95%: 1.56-14.9) were independently associated with ILD.

Conclusion: In our cohort, the presence of anti-CarP ranges between 29-56% according to the antigenic specificity used. These autoantibodies were associated with ILD. Anti-CarP could be considered a more specific biomarker of ILD in patients with RA rather than ACPA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are known to have increased risk of disability. The aim of this study was to investigate the course of disability in early RA, and compare it to age- and sex specific reference values, overall and by sex.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in Malmö 1995-2005, was followed in a structured program for 10 years. Patients were managed according to usual care, with no pre-specified protocol for pharmacotherapy or rehabilitation. Disability was assessed using the validated Swedish version of the Health Assessment Questionnaire (HAQ) and compared to expected age- and sex specific values from the literature (Krishnan et al. A&R 2004; 50: 953-60). Changes in HAQ disability index (HAQ-DI) between different time points were assessed using the paired t-test. Differences between observed and expected HAQ-DI over time after ≥6 months were investigated using linear mixed-effects models.

Table 1. HAQ-DI in the early RA cohort compared to the expected, based on age- and sex-specific reference values, at inclusion and each follow-up

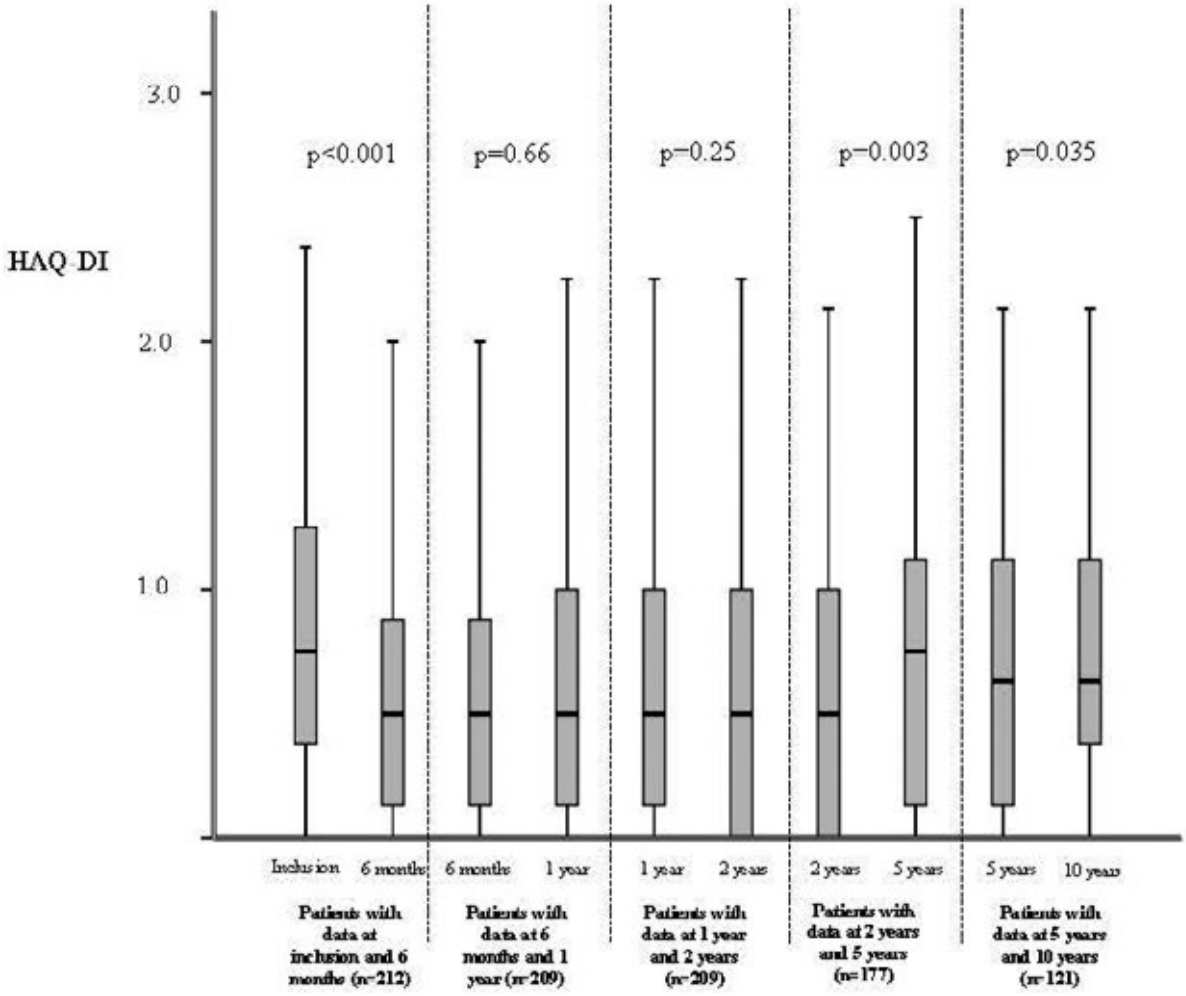
Figure 1. Changes in HAQ-DI between visits, in patients with data at both time points



Results: A total of 232 patients with early RA (70 % women, mean age 60.5 years, median symptom duration 7 months) were investigated. The HAQ-DI scores for all patients are reported in Table 1 together with the corresponding expected values. In paired analysis of those with available data at both time points, there was a significant decrease in HAQ-DI from inclusion to the 6 month follow-up (Figure 1). This was followed by a stable HAQ-DI through 24 months after diagnosis. Between 24 months and 60 months, and between 60 months and 120 months, there were significant increases in HAQ-DI. (Figure 1) The median HAQ-DI was higher for women than for men at every visit, both the observed and expected values (Table 1).

In linear mixed effect models, the estimated mean difference (EMD) over time from the 6 month follow-up through 10 years between observed and expected values was 0.29 [95% confidence interval (CI) 0.26 ; 0.33] for HAQ-DI. Estimated HAQ-DI values at 6 months, based on the intercept in the model, were higher than the expected (Table 2). Observed and expected values both increased significantly after the 6 month follow-up (Table 2), with no significant difference in the change per year (EMD0.004 (95% CI -0.008; 0.016). The EMD over time between observed and expected HAQ-DI scores were greater in women (mean 0.35; 95% CI 0.31; 0.39) than in men (mean 0.15; 95% CI 0.09; 0.22). In women, observed and expected HAQ-DI values increased over time (Table 2), with a trend towards a lesser increase in observed values (EMD for change over time 0.004/year (95% CI -0.01; 0.017). In men, there was a signif-

Table 2. HAQ-DI over time after ≥6 months of follow-up; linear mixed effect models

		Intercept		Change/year	
		Estimate	95% CI	Estimate	95% CI
HAQ-DI overall	Observed	0.64	0.56 ; 0.71	0.023	0.016 ; 0.030
	Expected	0.33	0.28 ; 0.38	0.032	0.029 ; 0.035
HAQ-DI women	Observed	0.69	0.60 ; 0.79	0.028	0.020 ; 0.037
	Expected	0.33	0.27 ; 0.39	0.034	0.030 ; 0.038
HAQ-DI men	Observed	0.50	0.38 ; 0.61	0.011	- 0.0030 ; 0.024
	Expected	0.32	0.23 ; 0.41	0.027	0.022 ; 0.033

Table 2

icant increase in expected, but not in observed values (Table 2). This difference did not reach statistical significance (EMD for change over time 0.006/year (95% CI -0.015; 0.028)).

Conclusion: Disability decreased during the first 6 months after diagnosis in patients with early RA. This was followed by a stable level of disability through 2 years, and a gradual increase after 2-10 years. The change in HAQ-DI after ≥ 6 months was similar to the expected based on data from the general population, suggesting that increasing disability over time in early RA is mainly explained by increasing age.

Risk Factors for Transfusion and Use of Tranexemic Acid in Patients with Rheumatoid Arthritis Undergoing Total Hip Arthroplasty and Total Knee Arthroplasty

Kyle Morse,[1] Jeremy Abolade,[1] Nicole Heinz,[1] Meng Zhang,[2] Linda Russell,[1] Serene Mirza,[1] Dana Orange,[3] Joshua Wright-Chisem,[1] Mark Figgie,[4] Peter Sculco,[1] and **Susan Goodman** [5], [1]Hospital for Special Surgery, New York, [2]The Feinstein Institute for Medical Research, Northwell Health, Manhasset, [3]Rockefeller University, New York, [4]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY, [5]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Utilization of total hip (THA) and total knee arthroplasty (THA) remains high for patients with RA, and most patients have moderate to high disease activity at the time of surgery. Risk of infection and transfusion are higher compared to OA, and transfusion at the time of surgery increases the risk of perioperative infection. Tranexamic acid (TXA), an anti-fibrinolytic, has gained widespread use in total joint arthroplasty to decrease transfusions, but benefits in RA has not been established. We aimed to determine the risk factors for transfusion for patients with RA undergoing THA/TKA, and assess the use of TXA in decreasing transfusions.

Methods: We retrospectively reviewed data from a prospectively collected cohort of 233 patients with RA and a convenience sample of 35 OA controls undergoing THA/TKA. Demographics, RA characteristics, and disease activity were systematically collected and hemoglobin and TXA use obtained by chart review. Disease activity was measured utilizing the DAS28 and CDAI, PROMs included HOOS/KOOS, and MDHAQ, and ESR, and CRP, and serologies

Table 2. Multivariate logistic regression to determine the risk of transfusion in 266 THA/TKA patients

Multivariate variable	Level	Odds ratio (95% CI)	p-value
TXA	No vs. Yes	0.585 (0.068, 5.06)	0.63
CDAI at baseline		1.079 (1.001, 1.162)	0.04
DAS28 – ESR at baseline		0.666 (0.313, 1.416)	0.29
Hemoglobin at baseline		0.394 (0.232, 0.669)	0.001
Duration of Surgery		1.022 (1.008, 1.037)	0.003

were drawn pre-op. Baseline characteristics were summarized using descriptive statistics and compared using Chi-squared, Fisher's exact test or two-sample t-test or Wilcoxon rank-sum test as appropriate. Logistic Regression analysis was performed to explore the relationship between transfusion (Yes or No) and predictors (including CDAI, DAS28, TXA received or not). Predictors that were found statistically significant ($p < 0.05$) in the univariate analysis were included in the multivariate analysis.

Results: RA cases were predominantly women (83%), with prolonged disease duration(14.1 +/-12 years), and active disease (mean DAS28= 3.7, CDAI=18.4±10.9), (TABLE 1). Transfusions were received by 26 RA(11.2%). TXA was given in 193 patients (67.3%, OA 83% vs RA 67%).There was no difference in blood loss or transfusion for those undergoing TKA vs THA (p=.32). Patients who received TXA required more transfusions than those who did not (11.9% vs. 4.1%, $p > 0.05$). In the univariate analysis, baseline hemoglobin, estimated blood loss, duration of surgery, baseline CDAI and baseline ESR increased the risk of transfusion. In the multivariate analysis to determine independent risk factors for transfusion (Table 2), a one g/dl decrease in baseline hemoglobin (OR=0.394, 95% CI (0.232, 0.669), p=0.001) , one-minute increase in surgical duration (OR=1.022, 95% CI (1.008, 1.037), p=0.003) and a one-point increase in CDAI (OR=1.079, 95% CI (1.001, 1.162) were significant. TXA was not associated with post-operative transfusion in either the univariate or multivariate analysis.

Conclusion: Pre-surgical optimization should include assessment and treatment of anemia in patients with RA who undergo total joint arthroplasty. This is important, as TXA was not associated with a lower transfusion rate as reported for patients with OA. Decreased pre-operative hemoglobin may be a modifiable risk factor, while increased disease activity as measured by CDAI and increased surgical time were risk factors for post-operative transfusion but may be more difficult to change in these patients with long standing RA.

Profile of Renal Function in Patient Suffering from Rheumatoid Arthritis

Denis Choquette,[1] Louis Bessette,[2] Loïc Choquette Sauvageau,[3] Isabelle Ferdinand,[3] Boulos Haraoui,[3] Frédéric Massicotte,[3] Jean-Pierre Pelletier,[4] Jean-Pierre Raynauld,[5] Marie-Anaïs Rémillard,[3] Diane Sauvageau,[3] Edith Villeneuve,[6] and Louis Coupal[3], [1]Institut de Recherche en Rhumatologie de Montréal, University of Montreal, Québec, Canada., Montreal, QC, Canada, [2]Centre de l'Ostéoporose et de Rhumatologie de Québec, Québec, QC, Canada, [3]Institut de Recherche en Rhumatologie de Montréal, Montréal, QC, Canada, [4]University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, Canada, [5]Institut de Rhumatologie de Montréal, Montreal, QC, Canada, [6]Institut de Recherche en Rhumatologie de Montréal, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Many medications used in the treatment of rheumatoid arthritis (RA) impact renal function. Some of these may be contraindicated in the presence of a certain degree of renal failure or may require dosage adjustment. Product monograph of different molecules such as hydroxychloroquine (HCQ), methotrexate (MTX), sulfasalazine (SSZ), tofacitinib (TOFA) address the issue with different nomenclature. A glomerular filtration rate (GFR) cut-off point of 60 mL/min/1.73 m^2 is often mentioned for dose adjustment or contraindication. The objective of this work is to evaluate the proportion of patients with impaired renal function at the moment of initiation of RA treatment.

Methods: The data of all patients affected by RA starting a csDMARD, bDMARD or tsDMARDS were extracted from the Rhumadata® registry. For those patients, the estimated GFR (eGFR) was assessed using the CKD-EPI equation and the MDRD formula. eGFR are presented in five years age groups for both men and women. Results are expressed as mean ± standard deviation, range, percentiles (5, 25, 50, 75 and 95) and the proportion of patients an impaired renal function (IRF) (i.e. an eGFR below 60 ml/min/1.73 m^2). Potential predictors of IRF include age at diagnosis, gender, disease duration, exposure to csDMARDS or b or ts DMARDs, hypertension, CVD, Charlson comorbidity index. The use of "contraindicated" molecules is explored.

Results: Overall eGFR was obtained for 609 men and 1853 women. In men, mean eGFR in the 25-29, 55-59 and 75-79-years age groups are 125±10, 92±15 and 69±16 ml/min/1.73 m^2. In women, these estimates are 115±14, 87±16 and 70±17 ml/min/1.73 m^2. No patients below 45 years of age has an IRF. After this age, the proportion of men with an IRF increases from 5.1% in the 45-49-years age group to 21.2% in the 75-79-years age group. In women, these same proportions are 2.3 and 24.2%. The results of a stepwise forward selection logistic regression predicting IRF retained age at diagnosis (OR and 95% confidence interval=1.093 (1.073, 1.112)), gender ((women vs. men) 1.929 (1.278, 2.913)), disease duration (1.111 (1.087,1.136)) and hypertension (3.271 (2.116, 5.056)). The CKD-EPI equation and the MDRD formula identically classified 99% of patients as having (6%) or not having (93.0%) IRF. MTX, SSZ, HCQ and Tofacitinib are respectively prescribed for 78%, 10%, 62% and 6% of patients without IRF. These proportions are 63%, 9%, 52% and 4% among patients with IRF, the differences being statistically significant for MTX and HCQ.

Conclusion: As expected, eGFR decreases with age in both groups. Patients in all age groups after 45 years old may have an eGFR inferior to 60 ml/min/1.73 m^2. Below 55 years old, less than 5% of our population has less than 60 ml/

min/1.73 m² of GFR as measure by CKD-EPI equation. Physicians prescribe less MTX, SSZ, HCQ and Tofacitinib to patients with IRF.

Comparison Between Fibromyalgia and Neuropathic Pain in Patients with Established Rheumatoid Arthritis

Yong Gil Hwang,[1] Lei Zhu,[1] and Larry Moreland[1], [1]University of Pittsburgh, PITTSBURGH, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our objectives were (1) to identify similarities and differences of pain symptoms identified by fibromyalgia (FM) and neuropathic pain (NP) screening tool (2) to compare pain qualities and their relationship with rheumatoid arthritis (RA) disease activity.

Methods: 169 RA patients enrolled in the University of Pittsburgh Rheumatoid Arthritis Comparative Effectiveness Registry (RACER) underwent a clinical evaluation and fulfilled 3 self-report questionnaires (PainDETECT, Patient-

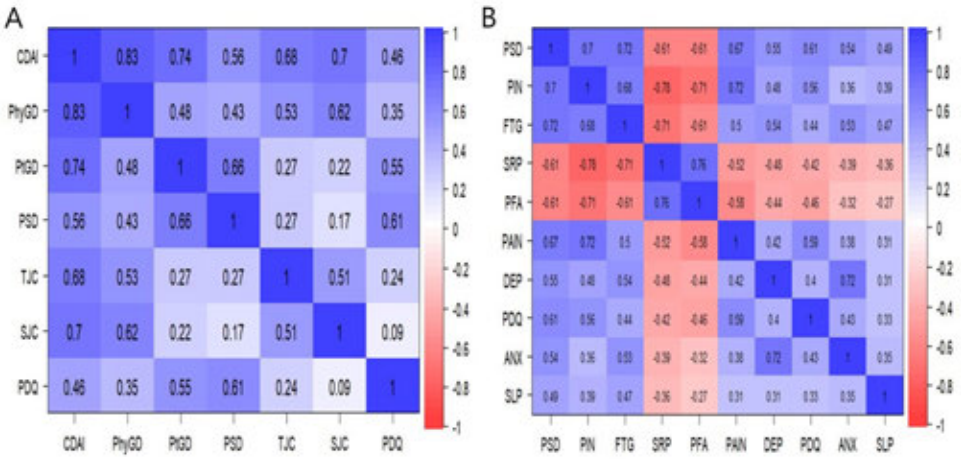

Table 1 Demographics and comparison of clinical characteristics of subgroups based on the fibromyalgia and PainDETECT categories (Mean (SD))

* Mean (SD) / % of sensory disturbances that were regarded as clinically relevant (i.e. score of >= 3), BMI: body mass index, PDQ: PainDETECT questionnaire, PSD: polysomatic distress score, SJC: swollen joint count, TJC: tender joint count, PhyGD: physician global disease assessment, PtGD: patient global disease assessment, CDAI: clinical disease activity index, Discrepancy: absolute value for discrepancy between PhyGD and PtGD, RA: rheumatoid arthritis, PROMIS: Patient-reported outcomes measurement information system

Reported Outcomes Measurement Information System (PROMIS) 29, Widespread Pain Index/Symptom Severity Scale). The results of the clinical evaluation and questionnaires were then compared.

Results: 20 patients (11.8%) met the fibromyalgia criteria, whereas 16 patients (9.6%) were found to have neuropathic pain. However, only three patients were categorized as FM among those patients who were classified as NP. PainDETECT and polysomatic distress score were significantly correlated with pain levels, RA disease activity, and all PROMIS domains. (Figure 1) No significant difference in the swollen joint count was found regardless of the presence or absence of FM or NP. Tender joint count, patient & physician global disease assessment (PtGD, PhyGD), and clinical disease activity index (CDAI) were significantly higher in patients with NP vs those without NP, whereas only PtGD was higher in patients with FM vs those without FM. (Table 1) Significantly higher scores were found for all PROMIS domains and sensory profiles in patients with NP, while anxiety, depression, fatigue, pain interference, and slight pressure-associated pain were increased in patients with FM. (Table 2)

Conclusion: This study highlights the differences between FM and NP in association with RA disease activity and PROMIS29 domains and demonstrates the PainDETECT can be a useful tool in identifying clinical phenotypes of RA patients.

A. Correlation matrix among painDEDECT, polysomatic distress score, and clinical disease activity index B. Emotional and Social Determinants of Health Increase Office Communication for Patients with Rheumatoid Arthritis

Dana DiRenzo,[1] Michael Wu,[2] Thomas Grader-Beck,[2] Susan J. Bartlett,[3] and Clifton Bingham[1], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore, [3]McGill University, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In RA patients, anxiety and depression are associated with higher disease activity and worse outcomes. We hypothesized that in RA patients, poorer mental health would also be associated with more frequent office communication.

Methods: Charts of RA patients who received care at a university arthritis center for at least 1 year between April and September 2018 were identified from 530 records consecutively ordered by MRN (any arthritis type). Patients completed Patient Reported Outcome Measurement Information System (PROMIS) 29-item profiles (depression, anxiety, fatigue, physical function, pain interference, sleep disturbance, participation in social roles and activities) at an index care visit and phone calls and patient portal messages to rheumatologists and other providers were summed from the preceding 12 months. Patients were stratified by telephone call volume (none vs >=1). Demographics, clinical char-

Table 1. Patient characteristics stratified by RA patients who called any provider in past year vs RA patients without telephone communication.

	>=1 Telephone Call N=62	No Telephone Calls N=92	p-value
Age, mean (SD)	60 (13)	56 (14)	0.078
Female sex (n, %)	72 (78)	38 (61)	0.022
White (n, %)	64 (70)	45 (73)	0.69
Disease Duration, (years) median (IQR)	9 (5, 16)	7 (4, 14)	0.29
CDAI, median (IQR)	8.3 (5, 21.25)	6.5 (3.5, 12.5)	0.082
Current Medications (n, %)			
Biologic	49 (53)	28 (45)	0.32
Methotrexate	47 (51)	40 (65)	0.099
Prednisone	21 (23)	13 (21)	0.79
Anti-Depressant	24 (26)	9 (15)	0.086
Benzodiazepine	15 (16)	15 (16)	0.24
Patient Portal Activated (% yes)	73 (79)	56 (90)	0.070
Patient Portal Messages, median (IQR)			
To Arthritis Center	0 (0, 6)	1 (0, 6)	.25
To Any Provider	2 (0, 10.5)	2 (0, 7)	0.98
Telephone Calls, median (IQR)			
To Arthritis Center	1 (0, 1)	0 (0, 0)	**<0.001**
To Any Provider	3 (1, 7)	0 (0, 0)	**<0.001**

acteristics, and frequency of communication were compared between groups using t-tests or chi-square; Poisson regression was used to evaluate the relationship between emotional distress and telephone frequency, controlling for age, sex, race, RA disease duration, clinical disease activity index (CDAI), and PROMIS physical function, social participation, sleep disturbance, pain interference, and fatigue. A sensitivity analysis was performed controlling for use of anti-depressants (AD) and benzodiazepines (BZD).

Results: 154 out of 185 RA patients met 2010 ACR criteria, completed PROMIS profiles, and had a complete CDAI; 1,452 office communications were accrued. Patients were mostly female (n=110, 71%) and white (n=109, 71%) with a mean age (SD) of 59 (14). The median RA disease duration (IQR) was 8 years (5, 16), and median CDAI (IQR) was low at 7.5 (4, 19). High anxiety was present in 24% of RA patients, and high depression symptoms in 18%. RA patients with >=1 versus no telephone calls were mostly female, tended to be older, have more disease activity, and take ADs (Table 1). In multivariable Poisson regression, age (IRR=1.04, p< 0.01), race (IRR=1.75, p=< 0.01), social participation (IRR=0.95, p< 0.01), sleep disturbance (IRR=1.02, p=0.01), and anxiety (IRR=1.03, p< 0.01) were significantly associated with telephone call volume (any provider) (Table 2). Depression was associated with call volume in univariate analysis (IRR=1.04, p< 0.01) with a trend in multivariable analysis (IRR=0.98, p=0.06). In sensitivity analysis when controlling for use of AD and BZD, anxiety and depression continued to significantly impact call volume.

Conclusion: Office communication is driven by emotional and social determinants of health and not RA disease activity, duration, or disability. Patients with high anxiety or depression symptoms telephoned significantly more often than those with low symptoms, although this was not necessarily directed towards the rheumatologist. Early identification of anxiety and depression symptoms may prompt implementation of multi-modal strate-

Table 2. Determinants of Telephone Call Volume.

Bone Microstructure of Patients with Rheumatoid Arthritis: A HR-pQCT Study

Ikuko Tanaka,[1] Takashi Kato,[2] Hiroaki Mizuno,[3] Ryosuke Hibi,[3] Motoaki Kai,[4] Kunikazu Ogawa,[4] Hisaji Ohshima,[5] and Shigenori Tamaki[3], [1]Nagoya Rheumatology Clinic, Ngoya, Japan, [2]National Center for Geriatrics and Gerontology, Obu, Japan, [3]Nagoya Rheumatology Clinic, Nagoya, Japan, [4]Mie Rheumatology Clinic, Suzuka, Japan, [5]National Tokyo Medical Center, Tokyo, Japan

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), it has been reported that osteoclast are activated by immune complexes, anti-CCP antibodies (ACPAs), and inflammatory cytokines. The purpose of this study was to investigate the relationship between bone microstructure and joint involvement by imaging the distal radius using HR-pQCT.

Methods: Subjects were 127 female patients with RA, who were examined with X-ray and HR-pQCT. The patients were divided into the group with no RA change (erosion) in the wrist joint (E(-), Steinbrocker Stage I, N=80, 58+/-12 years old) and the group with RA change in the wrist joint (E(+), Steinbrocker Stage II and III, N=47, 59+/-15 years old). Seventy nine patients with APCA negative unclassified arthritis (UCA) (57+/-10 years old) was used as a disease control group. The distal radius, 9mm away from the distal end of the radius, was scanned with HR-pQCT. Parameters representing bone microstructure were measured separately in the cortical bone, trabecular bone, and the total bone. Statistical significant level was set at $p< 0.05$.

Results: The total volumetric bone mineral density (vBMD) and trabecular vBMD were significantly lower in E(-) and E(+) than in UCA. The cortical vBMD was significantly lower in E(+) than in E(-) and UCA. The cortical porosity and cortical pore diameter, measures of cortical microstructures, were significantly larger in E(+) than in E(-) and UCA. The trabecular measures such as trabecular bone volume fraction and trabecular number were lower in E(-) and E(+) than in UCA, while they were lower in E(+) than in E(-). Trabecular separation was larger in E(-) and E(+) than in UCA. There was no significant difference in trabecular thickness among the three groups.

Conclusion: In E(+) the porosity of the cortical bone was increased, and the cause of this was considered to be the effect of hand arthritis. In E(-) bone loss was observed in the trabecular bone but not in the cortical bone, suggesting the elevation of non-arthritic bone resorption.

Multimorbidity May Worsen Fatigue in Patients with Rheumatoid Arthritis

John Davis,[1] Elena Myasoedova,[1] Tina Gunderson,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a pervasive problem for many patients with rheumatoid arthritis (RA) that often persists despite treatment with effective disease-modifying therapies. Recent studies have suggested that patients with RA have a high burden of multimorbidity, which could affect their disease experiences and treatment outcomes. We sought to determine whether multimorbidity is associated with fatigue in patients with RA.

Methods: This cross-sectional, prospective study of a population-based cohort from a geographically well-defined area included patients with prevalent RA who completed a questionnaire. Fatigue was assessed using the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ, V1 27.08.10). Patients' medical records were reviewed for 25 chronic comorbidities from a combination of the Charlson Comorbidity Index, Elixhauser Comorbidity Index, and Rheumatic Disease Comorbidity Index prior to the date of BRAF-MDQ. Rheumatic comorbidities were not included. Linear regression models were used to estimate the change in fatigue outcome with multimorbidity adjusting for age, duration of RA, sex, obesity (body mass index ≥30 kg/m^2), current smoking status, C-reactive protein and RF/CCP positivity. Models were fit for the Total MDQ score and each subscore.

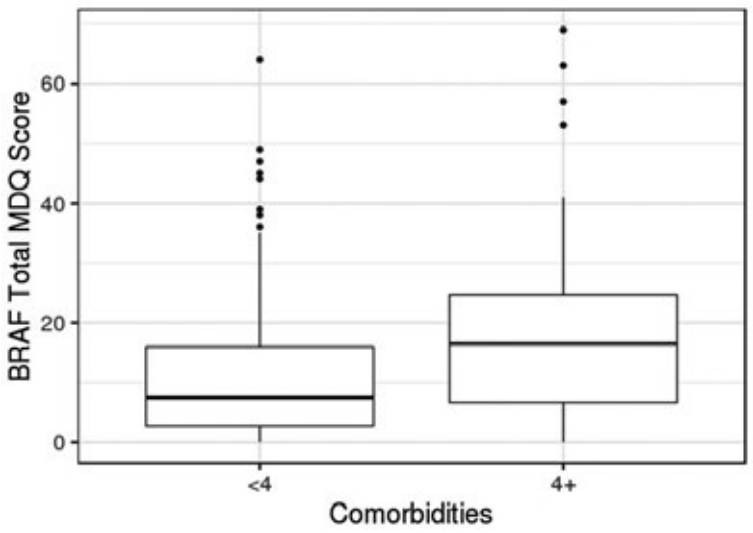

Figure. Total BRAF-MDQ score for patients with less than 4 versus 4 or more comorbidities

Results: The cohort included 192 patients (median age: 62 years, median RA duration: 13 years, 75% female, 46% obese, 6% current smokers, 69% RF/CCP positive). Multimorbidity was common with 93 (48%) patients having 2 or more comorbidities, and 27 (14%) having 4 or more comorbidities. Total BRAF-MDQ scores ranged from 0-69 (median [interquartile range (IQR)] 9 [3, 18]), with higher scores indicating greater fatigue. Patients with 4 or more comorbidities had higher total BRAF-MDQ scores (mean: 21.2; SD 20.2) than patients with less than 4 comorbidities (mean 11.2; SD 11.6; p=0.014; figure) Adjusted linear regression models revealed each additional comorbidity was associated with a 2.4 unit (95% confidence interval [CI]:1.0-3.7) increase in total BRAF-MDQ level (p< 0.001), and the presence of 4 or more comorbidities was associated with an 10.1 (95% CI: 4.3-15.9) unit increase in total BRAF score. Comorbidities were significantly associated with all 4 subscores in adjusted models. An association of this magnitude is likely to be clinically meaningful.

Conclusion: High levels of multimorbidity are associated with increased fatigue in patients with RA. The findings suggest that interventions targeting multimorbidity could help alleviate treatment-refractory fatigue in patients with RA and other rheumatic diseases.

Prevalent and Incident Multimorbidity in Rheumatoid Arthritis: A Population-Based Cohort Study

Tina Gunderson,[1] Elena Myasoedova,[1] John Davis,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Multimorbidity is associated with increased risk of adverse outcomes in patients with rheumatoid arthritis (RA). Multiple studies have suggested increased burden of multimorbidity in patients with RA, but the extent of this increase and whether this excess in multimorbidity changes over time has not been well characterized.

Methods: In this retrospective, population-based cohort study, residents of a geographically well-defined area who met 1987 ACR criteria for incident RA in 1999-2013 were identified from a comprehensive medical record linkage system. Age and sex-matched non-RA comparators were selected from the same underlying population. Index date for each non-RA comparator corresponded to an incidence date of a matching patient with RA. Their medical records were then reviewed for 25 chronic comorbidities from a combination of the Charlson Comorbidity Index, Elixhauser Comorbidity Index, and Rheumatic Disease Comorbidity Index at index date and after index date. Rheumatic comorbidities were not included. Aalen-Johansen methods were used to estimate the cumulative incidence of multimorbidity (presence of 2 or more chronic comorbidities) or severe multimorbidity (5 or more) adjusted for the competing risk of death. Cox proportional hazards models with adjustment for age, sex, obesity (body mass index ≥30 kg/m^2) at index date, and calendar year were used to compare the rate of development of multimorbidity or severe multimorbidity between the RA and non-RA cohorts.

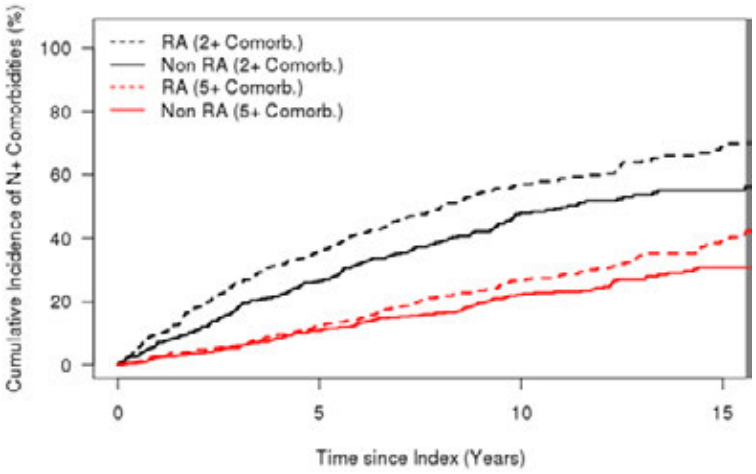

Figure. Cumulative incidence of multimorbidity in patients with and without rheumatoid arthritis.

Results: A total of 597 patients with incident RA (70% female; 90% Caucasian, 3% African-American; mean age 55.5 years) and 594 non-RA (70% female; 91% Caucasian, 3% African-American; mean age 55.4 years) were studied. By incidence/index date, RA patients had an increased prevalence of multimorbidity compared to non-RA subjects (38% RA vs. 32% non-RA, p=0.021) while prevalence of severe multimorbidity was similar (5% RA vs. 4% non-RA, p=0.68). The mean number of comorbidities (excluding rheumatic) by index date were 1.4 in RA patients and 1.2 in non-RA subjects. During follow-up (median 10.2 years RA patients, 10.3 years non-RA), RA subjects also showed an increased incidence of multimorbidity (214 RA vs. 188 non-RA; adjusted hazard ratio (HR): 1.41; 95% confidence interval (CI): 1.16–1.72). By 10 years after RA incidence/index, the cumulative incidence of multimorbidity among those without multimorbidity at index was 56% among the RA patients (95% CI: 51-62%) compared with 48% among the non-RA (95% CI: 43-54%; see figure). RA patients showed some increase in incidence of severe multimorbidity (167 RA vs. 139 non-RA; adjusted HR: 1.21; 95%CI: 0.96-1.51).

Conclusion: Patients with RA have both a higher prevalence of multimorbidity by the time of RA incidence as well as increased incidence thereafter. Studies investigating the underpinnings and implications of these findings are underway.

Intermetatarsal Bursitis Is Prevalent in Patients with Established Rheumatoid Arthritis and Is Associated with Anti-CCP and RF

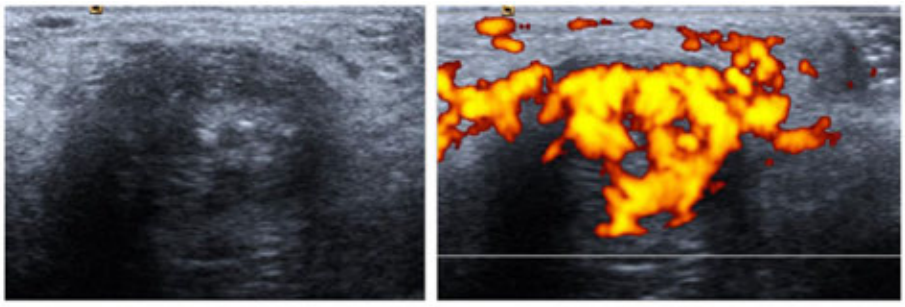
Hilde Hammer,[1] Tore Kvien,[2] and Lene Terslev[3], [1]Diakonhjemmet Hospital, Oslo, Norway, [2]Diakonhjemmet Hospital, Dept. of Rheumatology / University of Oslo, Faculty of Medicine, Oslo, Norway, [3]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

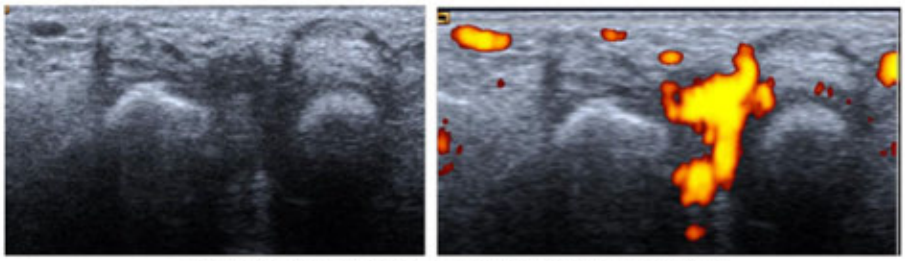
Background/Purpose: Ultrasound is sensitive for detection of inflammatory changes in patients with rheumatoid arthritis (RA). Intermetatarsal bursitis (IMB) may be detected by use of longitudinal dorsal scans between the metatarsophalangeal joints. The present objective was to explore the prevalence of IMB and its associations with subjective, clinical and laboratory assessments in established RA patients.

Methods: A total of 209 patients with RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were included when initiating biological disease modifying antirheumatic drugs (bDMARD). The patients were assessed at baseline and after 1, 2, 3, 6 and 12 months with patient's global disease activity VAS, clinical examination (assessor's disease activity VAS, tender and swollen joint counts performed by a study nurse) and laboratory variables (ESR, CRP, anti-CCP and rheumatoid factor (RF)). Composite clinical scores (DAS28(ESR), CDAI and SDAI) were calculated. The presence of patient reported joint pain (PRJP) was assessed at joint level by use of a manikin (bilateral wrist, MCP1-5, PIP2-3, elbow, knee, ankle, MTP1-5). Each joint was scored 0-3 reflecting the level of spontaneous joint pain the last day. All ultrasound examinations (semi-quantitative scoring (0-3)) of grey scale synovitis (GS) and power Doppler (PD) (PIP 2-3, MCP 1-5, wrist, elbow, knee, talocrural, MTP 1-5 and extensor carpi ulnaris (ECU)/tibialis posterior (TP) tendons bilaterally) were performed by one rheumatologist (HBH) with high intra-reader reliability (Siemens Acuson Antares, excellence version, 5-13 MHz probe). In addition, both feet were at each examination assessed by dorsal longitudinal scan of all spaces between the MTP joints for IMB. Baseline GS and PD ultrasound and PRJP sum scores of MTP 1-5 bilaterally were calculated. Associations were explored by use of Mann-Whitney test and Odds Ratios (OR).

Results: A total of 43 patients (20.6%) had uni- or bilaterally IMB (27.8% right side, 41.9% left side and 23.3% bilaterally, while 7.0%.had no description of side). The patients had up to 4 IMB (n=1 in 72.1%, n=2 in 14.0%, n=3



Longitudinal, bursitis between MTP 3 and 4 joints



Transverse, bursitis between MTP 3 and 4 joints

UL av IMB for abstrakt

in 7.0% or n=4 in 7.0%. The figure shows a typical GS and PD ultrasound of an IMB. The locations of IMB (n=64) were: 4.7% between MTP1 and 2, 32.8% between MTP 2 and 3, 57.8% between MTP 3 and 4, 4.7% between MTP 4 and 5. The presence of IMB was not associated with sum score of baseline GS, PD or PRJP, and not with any of the clinical assessments. However, patients with versus without IMB had significantly higher MTP scores of GS and PD (p=0.05 and p=0.002, respectively), but no difference in PRJP. In addition, presence of IMB was associated with anti-CCP (OR (95% CI) 4.1 (1.2-14.0) and RF (3.7 (1.4-10.1), where 93% of patients with IMB were anti-CCP positive and 87% RF positive.

Conclusion: Intermetatarsal bursitis is quite common in established RA patients and was primarily found between MTP 2-3 and 3-4. It was associated with higher levels of ultrasound MTP joint inflammation and presence of anti-CCP and RF. Thus, ultrasound examination of forefeet should include exploring for this pathology which may indicate more severe disease.

The Interaction Between Human Leukocyte Antigen Class II Alleles and Seroprotection to Seasonal Influenza Vaccination in Patients with Rheumatoid Arthritis: A *post-hoc* Analysis

Miriam Kim,[1] Jin Kyun Park,[2] Eun Bong Lee,[3] and **Kichul Shin** [4], [1]Seoul National University College of Medicine, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, seoul, [4]Department of Internal Medicine, Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Seoul, Korea., seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There are few studies that have looked into the role of human leukocyte antigen (HLA) class II alleles in seroprotection to influenza, especially in subjects with rheumatoid arthritis (RA). We aimed to investigate the correlation between HLA class II polymorphism and the serologic response following seasonal influenza vaccination in patients with RA.

Methods: A total of 314 patients with RA were randomized to continue MTX (MTX-CONT) or to hold MTX (MTX-HOLD) for 2 weeks after vaccination with 2016–2017 seasonal quadrivalent influenza vaccine that contained H1N1, H3N2, B-Yamagata and Victoria (Clinicaltrials.gov NCT02897011). Positive vaccine response was defined as a ≥ 4-fold increase in the hemagglutination inhibition antibody titer, and a satisfactory vaccine response was defined to have a positive response in ≥ 2 of four vaccine antigens. Patients were typed for HLA-DRB1, -DQB1, -DQA1, and -DPB1 using the PCR sequence-based typing method, and its allele profiles were analyzed with the SBTengine soft-

ware. Antigen frequencies in percentage (AgF%) were compared in responder and non-responder groups using the Chi-square test.

Results: Baseline characteristics of both MTX-CONT (n= 155) and MTX-HOLD (n= 159) groups were comparable, as well as the AgF% of four HLA class II genes. In the MTX-HOLD patients, two alleles were associated with a satisfactory vaccine response: the HLA-DRB1*11:01 allele was detected at significantly higher frequencies in responders to H1N1 (p= 0.046, odds ratio, OR 6.33), H3N2 (p= 0.031, OR 9.87), and Victoria (p= 0.043, OR 8.29). The HLA-DQB1*03:02 allele frequency was significantly higher in responders to H3N2 (p= 0.017, OR 3.69) and Victoria (p= 0.047, OR 2.29). These AgF%-responder associations were nonexistent in the MTX-CONT group. There was no HLA class II antigen frequency associated with responders to B-Yamagata in both groups.

Conclusion: Our data indicate that holding MTX after influenza vaccination could lead to better seroprotection in RA patients with HLA-DRB1*11:01 or -DQB1*03:02. Further study is needed to elucidate the mechanisms of higher antibody response to influenza antigens in this subset of patients.

Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis(RA) is an autoimmune disease mainly manifested by aggressive polyarthritis.The incidence of osteoporosis(OP) has risen and the risk of fracture has further increased in parallel with the prolongation of the disease course,which seriously affects the prognosis and the quality of patients'lives.The purpose of this study is to investigate the incidence of OP in patients with RA and the status of peripheral lymphocyte subsets.

Methods: A total of 734 patients with RA and 81 healthy controls (HC) were enrolled in this study. All peripheral lymphocyte subsets of these participants were assessed by flow cytometry. Patients were divided to pure RA group and RA-OP group according to their bone mineral density (BMD) of lumbar or bilateral hip and the history of fragility

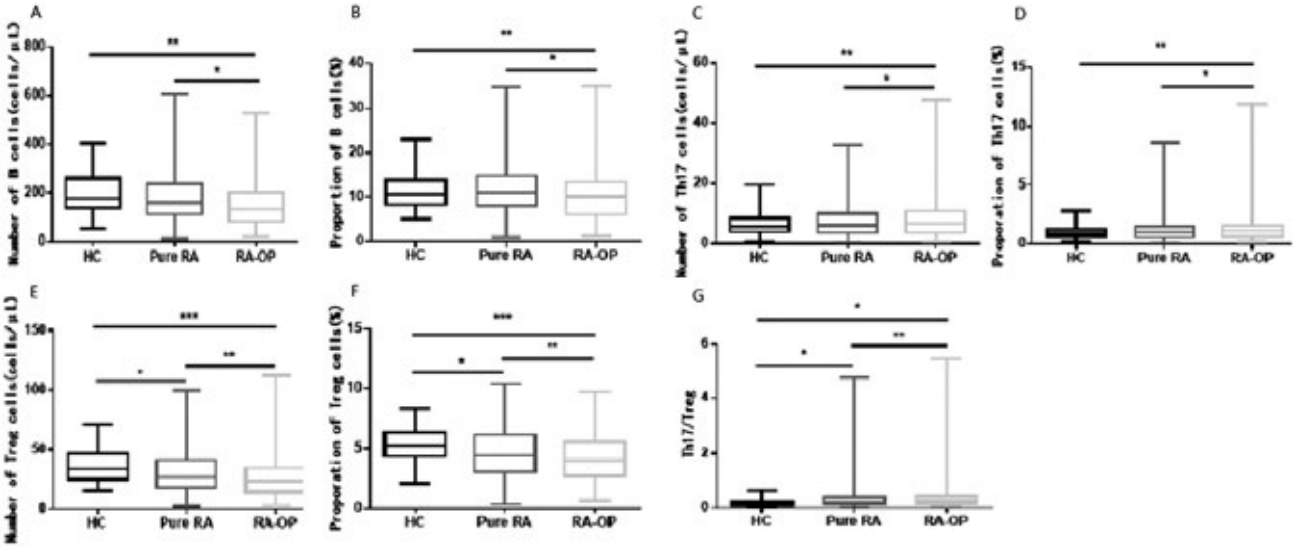

Figure1: The levels of B、Th17、Treg cells and the ratio of Th17/Treg among HC, pure RA and RA-OP group.(*P<0.05;**P<0.01;***P<0.001).

Table 1 The clinical characteristics of patients with or without osteoporosis in RA suffers (Mean±SD)

Treg(%)	5.33±1.41	4.69±2.08[a]	4.24±1.82[ab]
Th17/Treg	0.19±0.11	0.33±0.44[a]	0.41±0.58[ab]

([a] means $P<0.05$ compared with healthy control group, [b] means $P<0.05$ compared with pure RA group)

tion(P< 0.001) but also a higher disease activity was observed in RA-OP patients. Moreover, RA-OP patients suffered more joints swelling and pain (P< 0.05) as well as ESR(P< 0.001) and CRP(P=0.014) (Table 1). Compared with those of HC and RA group, the number of Th17 in RA-OP patients was significantly increased (P< 0.05), while Treg cells decreased (p< 0.05), leading to a higher ratio of Th17/Tregs (P< 0.05) (Table 2). In addition, the level of B cells in the pure RA or RA-OP group was significantly reduced, and this alteration was more obvious in patients with OP.

Conclusion: RA patients have a high incidence of OP, which was related to gender, age,disease duration and disease activity. Notably, immune disorder caused by Th17/Treg imbalance may also contribute to OP in RA patients. In addition, total B cells trended to decrease. Anti-osteoporosis treatment and immune regulation might be considered at the early stage of disease.

Abbreviations: RADAI - RA Disease Activity Index; VAS - Visual Analog Scale; HAQ - Health Assessment Questionnaire; PDQ - Perceived Deficits Questionnaire, SF-6D - Medical Outcomes Study 6-Item Short Form, PSQI - Pittsburgh Sleep Quality Index.

Table 2: Results of multivariable regression model of log-transformed cognitive function.

Significant Predictors*	Multivariable Model Regression Coefficient (p-value)
Depression: PDQ	0.03430 (<.0001)
Physical Function: HAQ	-0.08653 (0.0659)
Quality of Life: SF-6D	0.02033 (0.0282)
Fibromyalgia as a comorbidity	0.11423 (0.1106)

*Alpha=0.15. Cognitive Function assessed with the global EMQ score, with higher scores associated with poorer cognitive function. Abbreviations: PDQ - Perceived Deficits Questionnaire; SF-6D - Medical Outcomes Study 6-Item Short Form; HAQ - Health Assessment Questionnaire.

Background/Purpose: Cognitive impairment (CI), or "brain fog" as rheumatoid arthritis (RA) patients often describe it, is prevalent in persons with RA and can significantly impact daily life1. Despite this, the cause of CI remains poorly understood in persons with RA. This study aimed to identify the determinants of cognitive function in RA to help gain a better understanding of what might contribute to CI in some individuals.

Methods: A cross-sectional study was conducted using 2018 data from an annual survey administered to an RA cohort, derived from a population-based cohort identified using administrative health data. Participants completed self-report questionnaires assessing sociodemographics, and RA-specific information (duration, disease activity, pain, fatigue, physical function), comorbidities including depression, lifestyle factors (alcohol, smoking, physical activity, sleep), BMI, and quality of life. Cognitive function was measured with the Everyday Memory Questionnaire (EMQ), 13 Item Version. Descriptive statistics were performed to characterize all the parameters. Associations between cognitive function and potential determinants were first explored using univariable linear models. Multivariable linear regression analyses were then performed with variables found to be associated with cognitive function in the univariable models, using a stepwise selection at alpha=0.15. Models were natural log-transformed to normalize residuals.

Results: The sample was comprised of 145 RA patients (all women, mean age = 73.7 years; RA duration; 31.3 years). The mean global EMQ score was 21.9, with 43 (30% of the sample) classified as having some level of CI (score above 25). Of these 43, 34 (79%) showed moderate impairment (score 26-38), and 9 (19%) showed severe impairment (score at or above 39). Significant predictors identified in univariable analyses are listed in Table 1. In the multivariable model, physical function, quality of life, depression, and having fibromyalgia as a comorbidity remained independently associated with impaired cognitive function, model R2 is 0.3758 (Table 2).

Conclusion: CI was prevalent among our sample of patients with RA. Our findings suggest that measures of RA severity, such as poor physical function, and comorbidities, such as depression and having fibromyalgia, are associated with impaired memory in RA. Interventions that target CI, as well as pain and depression, require evaluation to help improve how CI is managed in RA.

Association of Sexual Dysfunction and Depression in Rheumatoid Arthritis Female Patients

Bruna Piola,[1] Pedro Santos,[2] Flávia Barros,[2] Hugo Lima,[2] Paulo Cerquinho,[2] Rafael Caminha,[2] Dennys Fagundes,[2] Leia Andrade,[2] Felipe Torres,[2] Mariana Luna,[2] and **Laurindo Rocha** Jr[2], [1]Instituto de Medicina Integral Professor Fernando Figueira -IMIP, Recife, Pernambuco, Brazil, [2]Instituto de Medicina Integral Professor Fernando Figueira - IMIP, Recife, Pernambuco, Brazil

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic disease that affects joints and is associated with many aspects of the patients´ lives, including sexual function and psychiatric comorbidity, such as depression. This study aimed to assess sexual function and its association with depression in female RA patients and to analyze the factors associated with these conditions.

Methods: We conducted a cross-sectional study with 64 RA female patients. For clinical diagnosis of depression, the DSM-5 (Diagnostic and Statistical Manual of Mental Disorders - 5th edition) was used and the BDI-II (Beck Depression Inventory II) was applied to evaluate the intensity of depression symptoms. Sexual dysfunction (SD) was evaluated using Female Sexual Function Index (FSFI) questionnaire. Clinical and sociodemographic data was collected. Thirty healthy women were included as controls.

Results: The mean age of patients was 52.6 years ($\pm$11.7) compared to a mean 52 years ($\pm$13) of the controls. None of the controls had SD associated with depression. Fifty-one patients had SD, in which 18 (28%) had depression associated with SD. Depression in patients with SD was associated with higher scores of the Health Assessment Questionnaire (p=0.05) and of visual analogue scale for fatigue (p=0.039). Of note, these patients correlated the prednisone dose negatively with domains of FSFI such as arousal (r= -0.5374; p= 0.043), lubrication (r= -0.5032; p= 0.048), orgasm (r= -0.5374; p= 0.043) and satisfaction (r= -0.6197; p=0,03). Patients with SD and no depression (n=33) showed positive correlation of height with arousal (r= 0.3480; p=0.047), lubrication (r= 0.3524; p= 0.044), orgasm (r= 0.3655; p= 0.036) and pain (r=0.3809; p=0.029). Overall, there were no associations of the domains of FSFI with presence of depression or intensity of depression symptoms.

Conclusion: There was high prevalence of sexual dysfunction and depresson in RA patients. Sexual dysfunction and depression might be present concomitantly in RA patients and are suggested to be associated with worse clinical aspects. There is no association of the aspects of sexual function with depression or with the intensity of depression symptoms.

Lymphoproliferative Disorders in Patients with Rheumatoid Arthritis: Results from Japanese Multi-institutional Study Using Research Electronic Data Capture

Suguru Honda,[1] Ryoko Sakai,[2] Masako Majima,[1] Naoko Konda,[1] Hideto Takada,[1] Kazuhiko Yamamoto,[3] Tsutomu Takeuchi,[4] and Masayoshi Harigai[1], [1]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Department of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan, [3]Riken Center for Integrative Medical Sciences, Kanagawa, Japan, [4]Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of lymphoma is higher among patients with rheumatoid arthritis (RA) compared to general populations [1]. Methotrexate (MTX), the anchor drug for RA, is considered to be associated with development of lymphoproliferative disorders (LPD) [2]. Although a substantial proportion of the cases are reported from Japan, a large-scale epidemiological study on LPD in patients with RA has not been conducted. Thus, the purpose of this study is to investigate epidemiological and clinical characteristics, and risk factors of LPD in Japanese patients with RA.

Methods: This is a multi-institutional retrospective observational study. We enrolled patients who were aged 20 or older, met the 1987 American College of Rheumatology / European League against Rheumatism classification criteria

Figure 1 Histopathological type (n=73)

for RA, and visited the registered hospitals for rheumatology training program of Japan College of Rheumatology at least once between 1st April 2011 and 31st July 2011. We excluded patients who had been diagnosed as having lymphoma before the enrollment. The first visit of each patient during the above 4 months was defined as the start of the observation with a follow-up period of 3 years onward. A patient who fulfilled the definition of LPD during the observation were followed for up to 5 years from the onset of LPD. LPD of this study included lymphoma with pathological diagnosis, LPD other than lymphoma with pathological diagnosis, and clinical LPD without pathological diagnosis. We calculated proportion of patients with LPD, and investigated risk factors for LPD using a logistic regression model, and described pathological features, vital prognosis, and cause of death in patients with LPD. We used a REDCap toll for collecting data.

Table 2 Risk factors of LPD

	Standard error	Odds ratio	Confidence interval of odds ratio†		P value
			Lower limit	Upper limit	
Age by decade	0.010	1.553	1.293	1.877	<0.001
Sex (female vs. male)	0.001	1.003	1.001	1.005	0.008
Sjogren's syndrome	0.589	0.457	0.144	1.451	0.184
Methotrexate use	0.275	3.402	1.983	5.836	<0.001
Tacrolimus use	0.333	1.552	0.809	2.979	0.186
At least any one of Biologic DMARDs use	0.252	0.960	0.586	1.573	0.870
Corticosteroids use	0.195	1.162	0.792	1.704	0.443

LPD : lymphoproliferative disorder, DMARDs : disease modifying anti-rheumatic drugs
† : multivariate logistic regression model

Results: Of 11100 patients enrolled, 10812 were analyzed. At baseline, the mean age was 63 years old and 79.3% were female. The mean disease duration was 9.8 years, 6.8% of the patients had Sjogren's syndrome, and mean DAS28-CRP (3) was 3.22. Prevalence of MTX use and biological agent use was 58.6% and 22.8 %, respectively. The mean dose of MTX at baseline was 7.4 mg/week. Ninety-six patients (0.89%) developed LPD during the observation period. There were significant differences in patients' characteristics such as age, sex, disease duration, and use of MTX between those who did and did not develop LPD (Table 1). Multivariable logistic regression analysis showed that age by decade (odds ratio [OR] 1.55 [95% CI 1.29-1.88]) and MTX use at baseline (3.40 [1.98-5.84] were significant independent risk factors of developing LPD (Table 2). Of 73 cases with pathological diagnosis, diffuse large B cell lymphoma (DLBCL) was the most frequent (n = 41, 54%), followed by Hodgkin lymphoma (n=12, 16%) (Figure 1). Mortality rate was 20% (n=23/92). The major cause of death was lymphoma (n=18, 78.3%), followed by cardiovascular diseases (n=2, 8.7 %).

Conclusion: Conclusions: This nationwide study revealed risk factors and pathological subtypes of LPD, and vital prognosis in Japanese patients with RA for the first time.

Patients with Rheumatoid Arthritis Have a Higher Risk of Bipolar Disorder: A Systematic Review and Meta-analysis

Patompong Ungprasert,[1] Nipith Charoenngam,[2] and Ben Ponvilawan[2], [1]Cleveland Clinic, Cleveland, OH, Bangkok, Thailand, [2]Mahidol University, Bangkok, Thailand

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with chronic autoimmune diseases may have a higher risk of psychiatric illness as a result of chronic neuro-inflammation and immune dysregulation. The current study was conducted with the aim to investigate the relationship between rheumatoid arthritis (RA) and bipolar disorder by identifying all available studies and summarizing their results together.

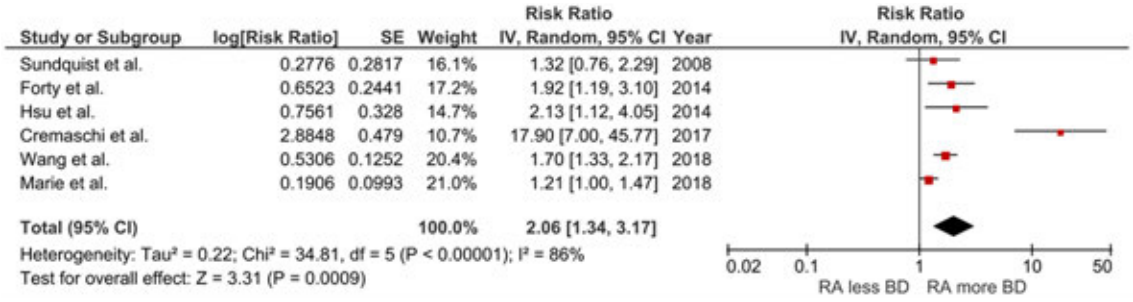

Figure 1: Forest plot of the current meta-analysis

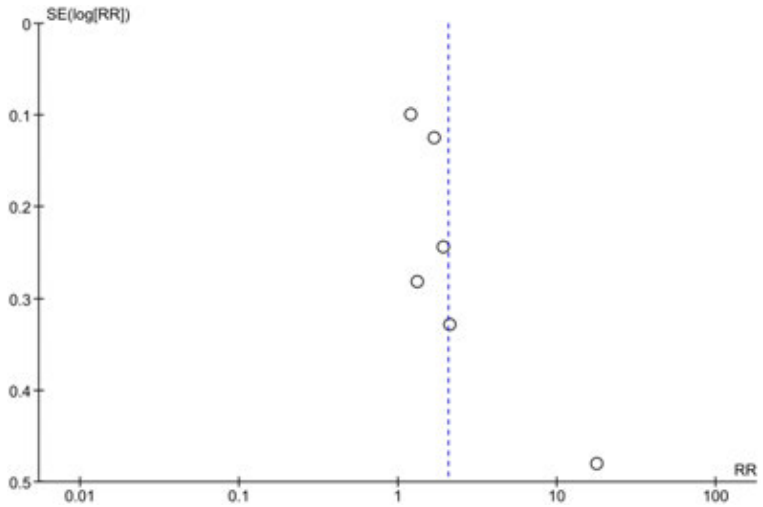

Figure 2: Funnel plot of the current meta-analysis

Methods: Potentially eligible studies that compared the risk of developing bipolar disorder between patients with RA and individuals without RA were identified from Medline and EMBASE databases from inception to May 2019 using search strategy that comprised of terms for "rheumatoid arthritis" and "bipolar disorder". Eligible studies could be either cohort studies or case-control studies. For cohort studies, they must recruit two groups of participants, patients with RA and individuals without RA. Then, the studies must follow their participants for incident bipolar disorder and report relative risk between the two groups. For case-control studies, they must recruit cases with bipolar disorder and controls without bipolar disorder. Then, the studies must explore their prior history of RA and report odds ratio comparing the two groups. Relative risk and standard error from each study were extracted and combined together using the random effect, generic inverse variance technique of DerSimonian and Laird. Odds ratio of case-control study was used as an estimate for relative risk to calculate the pooled effect estimate along with relative risk of cohort study.

Results: A total of 1,542 articles were identified using the aforementioned search strategy. After two rounds of independent review by two investigators, six studies with 420,458 participants fulfilled the inclusion criteria and were included into the meta-analysis. The risk of developing bipolar disorder was significantly higher among patients with RA than individuals without RA with the pooled relative risk of 2.06 (95% CI, 1.34 – 3.17; I^2 86%) (figure 1). Funnel plot was relatively symmetric and was not suggestive of presence of publication bias (figure 2).

Conclusion: A significantly higher risk of developing bipolar disorder among patients with RA was demonstrated in this study.

Improved Anxiety, Depression, and Emotional Distress for Rheumatoid Arthritis Patients Following the Completion of an Online Mental Health Intervention

Caitlin Blaney,[1] Carol Hitchon,[1] Ruth Ann Marrie,[2] Corey Mackenzie,[1] Pamela Holens,[1] and Renée El-Gabalawy[2],
[1]University of Manitoba, Winnipeg, Canada, [2]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anxiety and depression are common in people with rheumatoid arthritis (RA). These comorbidities are associated with worse disease outcomes including pain and functional disability. Thus, treating mental health comorbidity is an important component of RA care. Given access to clinical mental health resources are limited, we evaluated the potential benefit of an online mental health intervention (i.e., self-directed cognitive behavioral therapy/CBT) for reducing mental health symptoms and improving quality of life in individuals with RA.

Methods: RA participants with self-reported clinically significant anxiety (n=38, 89% female) were enrolled. Participants completed The Worry and Sadness program, a validated, 6-module course including psychoeducation and strategies for self-management developed by an Australian research group. The program was completed, at home, over 12 weeks. Mental health outcomes were assessed using the Patient-Reported Outcomes Measurement Information System (PROMIS) scales for anxiety and depression, the Kessler Psychological Distress Scale (K-10) for emo-

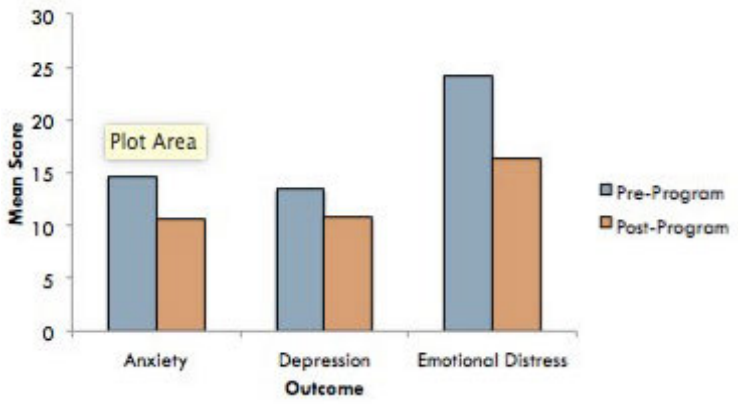

Figure: Pre-post comparisons of anxiety, depression, and emotional distress using the PROMIS Anxiety, PROMIS Depression, and Kessler Psychological Distress Scale (K-10).

tional distress, and the PROMIS scale for physical-health related quality of life. Arthritis outcomes were assessed with the modified health assessment questionnaire (mHAQ) for physical function, PROMIS scales for pain and fatigue, and a patient-reported verbal assessment for disease activity. Measures obtained before and after completing the program were compared using paired Student t-tests. Participants also rated the usefulness of the program.

Results: Participants who have completed the program (n=23) were predominantly female (mean age=59.4 years, standard deviation/SD=11.36). Immediately after completing the program, anxiety (mean difference pre-program versus post-program=4.13, SD=3.53, t(22)=5.61, p< 0.001), depression (mean difference pre-program versus post-program=2.57, SD=2.71, t(22)=4.54, p< 0.001), and emotional distress (mean difference pre-program versus post-program=7.81, SD=7.15, t(20)=5.01, p< 0.001) scores were all significantly reduced (Figure). Quality of life was unchanged, as were arthritis outcomes. Components of the program endorsed as useful to participants included identifying problematic thoughts, whereas reducing behavioural avoidance was considered less helpful.

Conclusion: Mental health symptoms experienced by RA patients improved after completing the Worry and Sadness online program, however, the program might benefit from adaptation to meet the needs of persons living with RA. Online tools are one feasible strategy to address the mental health needs of persons with RA, particularly in regions with limited clinical mental services.

Abstract Number: 2315

Association of Rheumatic Autoimmune Disease, Including Rheumatoid Arthritis, with Post-Traumatic Stress Disorder but Not Traumatic Brain Injury in Veterans

Biji Kurien,[1] Calin Prodan,[2] and **Robert Scofield** [1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Department of Neurology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmune diseases, including rheumatoid arthritis (RA) and systemic lupus erythematosus, are 2- to 3-fold more common among those with post-traumatic stress disorder (PTSD) than among matched controls. In US Armed Service personnel, PTSD is more prevalent among individuals with mild traumatic brain injury (TBI). For both PTSD and TBI there are immune changes that might predispose to autoimmune disease. We undertook this study in US veterans to investigate potential differences in risk of autoimmune rheumatic illness for TBI patients with versus PTSD those without PTSD.

Methods: We studied a cohort of 229 subjects (137 with PTSD) followed in a US Department of Veterans Affairs TBI clinic. Diagnoses were gathered from the electronic medical record. Clinical diagnosis of a rheumatic autoimmune disease was confirmed by chart review. Each subject with RA was evaluated for the 2010 ACR/EULAR RA Classification Criteria. We determined anti-CCP and rheumatoid factor by ELISA, anti-ENA by BioPlex and ANA by indirect immnofluorescence in a randomly selected subgroup of 40 veterans with TBI (20 with PTSD and 20 without PTSD), and without a prior diagnosis of RA, SLE, APL, or myositis.

Results: We found 11 of 137 (8%) TBI/PTSD subjects had RA. Each of these 11 met the 2010 ACR/EULAR criteria. Meanwhile, only 2 of 92 (2.1%) of those with TBI without PTSD had RA. Other rheumatic autoimmune disease in the PTSD/TBI group included polymyositis (3), SLE (1), undifferentiated connective tissue disease (1), and primary APL (1). Thus, a total of 17/137 (12.5%) in the PTSD/TBI group had a rheumatic autoimmune disease. Among those with only TBI, there were only 4/92 (4.3%) patients with a rheumatic autoimmune disease. This difference (17/137 versus 4/92) was statistically significant (p=0.02, Fisher's exact test). In the subgroup with serology, 6/20 sera from PTSD/TBI were ANA positive, while only 1/20 from TBI alone was ANA positive. Concerning anti-ENA, among PTSD/TBI subjects 1 had anti-Ro/SSA, one had anti-RNP and one had anti-RNP and anti-dsDNA. No TBI alone subjects had anti-ENA. Low positive RF was common but increased among those in the PTSD/TBI subgroup as compared to TBI alone (16/20 versus 10/20, p=0.04, Fisher's exact test).

Conclusion: There is an increased prevalence of autoimmune rheumatic disease, in particular rheumatoid arthritis, and positive rheumatic autoantibodies in TBI subjects with PTSD compared to those without PTSD. We conclude that TBI and autoimmunity are not associated, while autoimmunity – both clinically manifest and silent – is associated with PTSD. Studies investigating causality and mechanism are indicated in this at-risk population.

Length of Stay (in days)	4.61	4.78	4.49	4.67	4.72

Background/Purpose: Rheumatoid arthritis (RA) has been associated with increased cardiovascular mortality. More intensive treatment with a focus on "treat to target" strategies are being developed, resulting in improved control of inflammation and lower levels of disability. Our literature review suggested that most of the studies were done to assess incident acute myocardial infarction (AMI) before 2010.

Our goal with this study was to evaluate recent (2010-2014) temporal trends of prevalence and mortality in AMI hospitalizations, with underlying RA in a nationally representative sample.

Methods: We reviewed the National Inpatient Sample (NIS) data over five years from 2010-2014 and identified adult AMI hospitalizations using validated ICD9-CM codes. These hospitalizations were stratified based on the secondary diagnosis of RA. Descriptive statistics were represented as means/medians for continuous and as frequencies and percentages for categorical variables. Using survey data-analysis, we calculated prevalence and in-hospital mortality.

Results: We identified 297192 hospitalizations with AMI from 2010 to 2014. Around 44557 patients had a secondary diagnosis of RA. Mean age of these patients was 70.41± 0.13 years (significantly higher than those without RA, p-value < 0.05), and 63.11% were females. There were 2315 estimated inpatient deaths from 2010-2014, with no significant difference in odds of mortality when compared to patients without RA (p value=0.75).

Conclusion: Trends in hospitalizations and inpatient mortality in RA patients hospitalized for AMI seems to have plateaued in recent years. RA patients were older and mostly females, as noted in previous studies as well. These findings are likely related to early disease recognition, improved disease control, as well as the implementation of cardiovascular risk factor modifications for patients with underlying RA. Further trends in mortality from other cardiovascular causes, such as stroke and congestive heart failure, will provide insight into other cardiovascular events.

Gut Dysbiosis Is Associated with Measures of Early Vascular Dysfunction in Patients with Rheumatoid Arthritis

Michelle Ormseth,[1] Joseph Solus,[1] Annette Oeser,[1] and C. Michael Stein[1], [1]Vanderbilt University Medical Center, Nashville

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

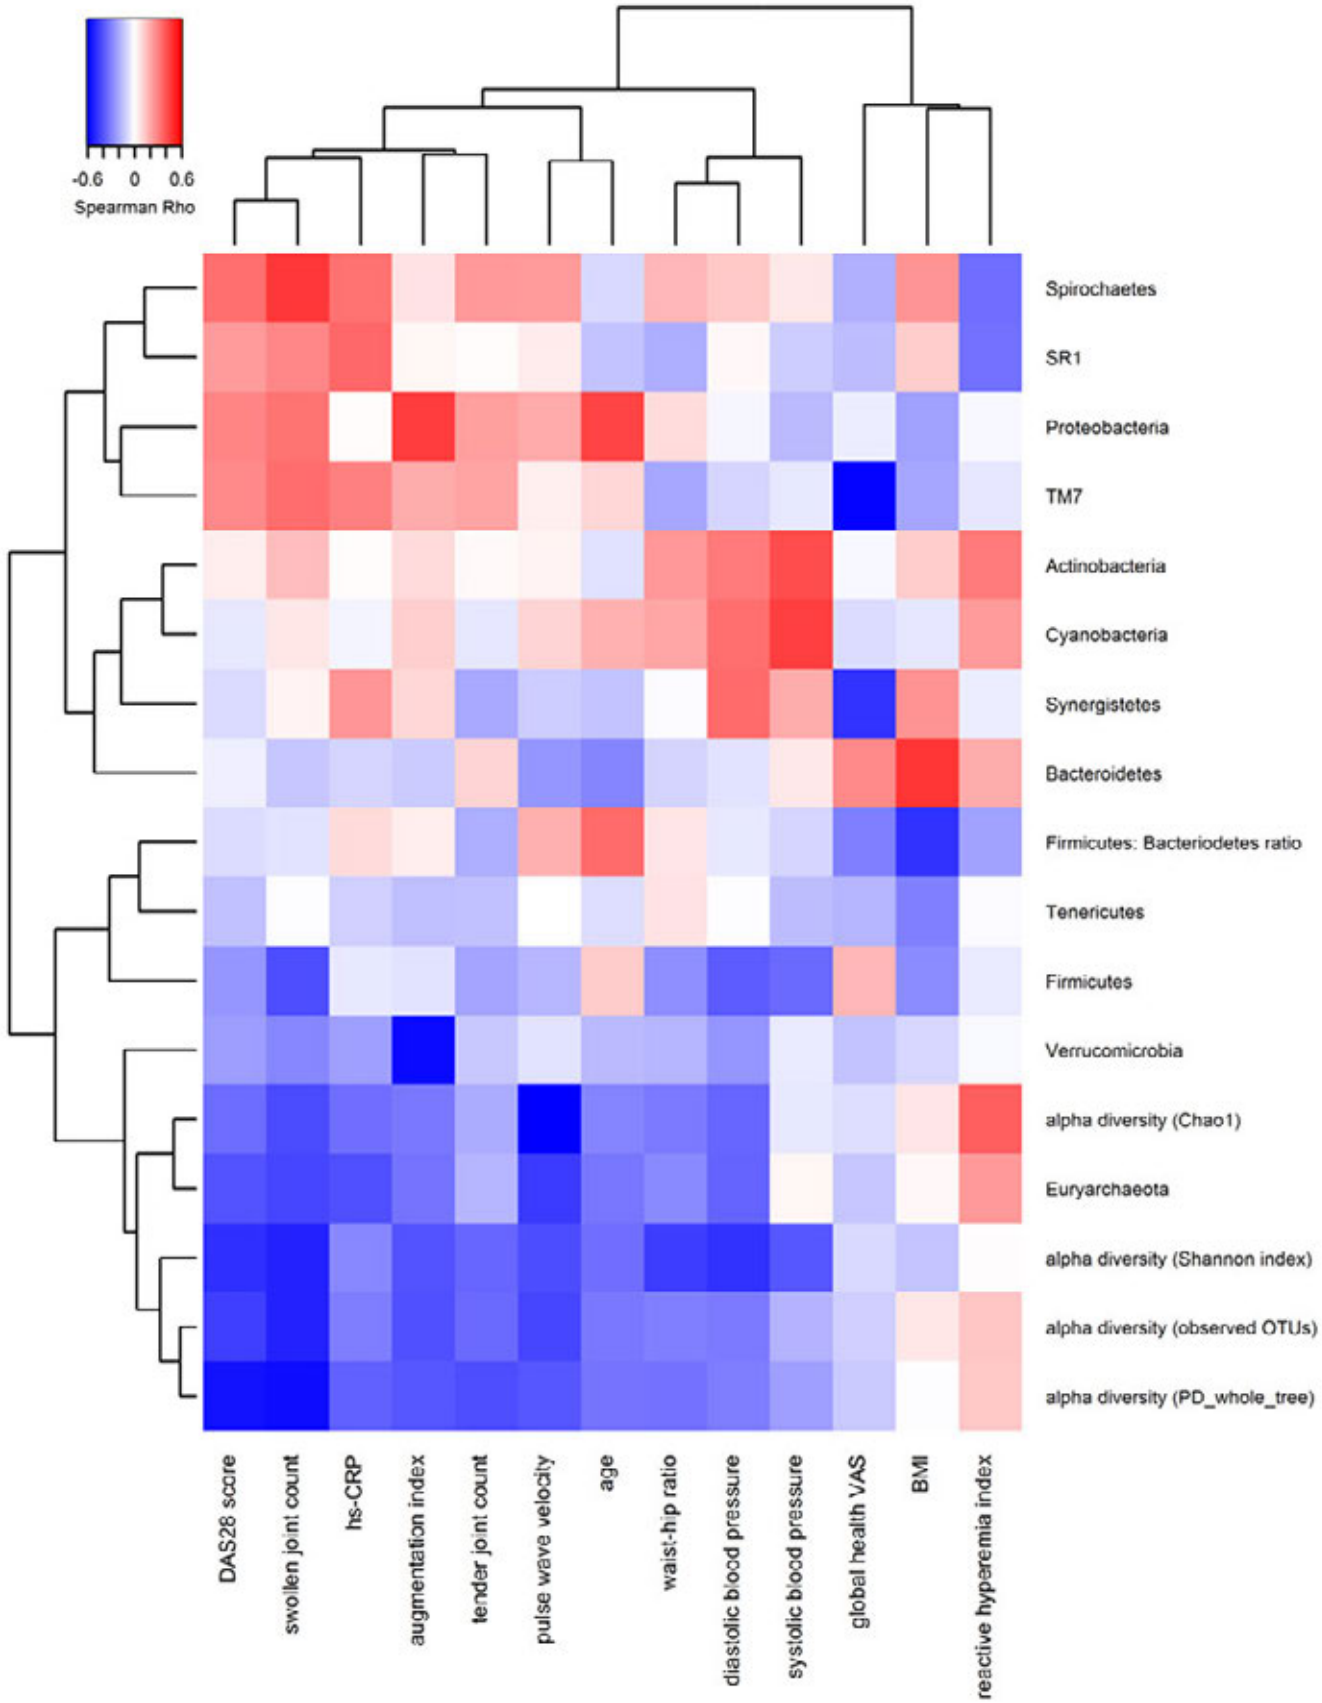

Figure 1 Heatmap with hierarchical clustering of gut microbiome alpha diversity and relative abundance of different phyla with measures of vascular function and clinical features in patients with rheumatoid arthritis.

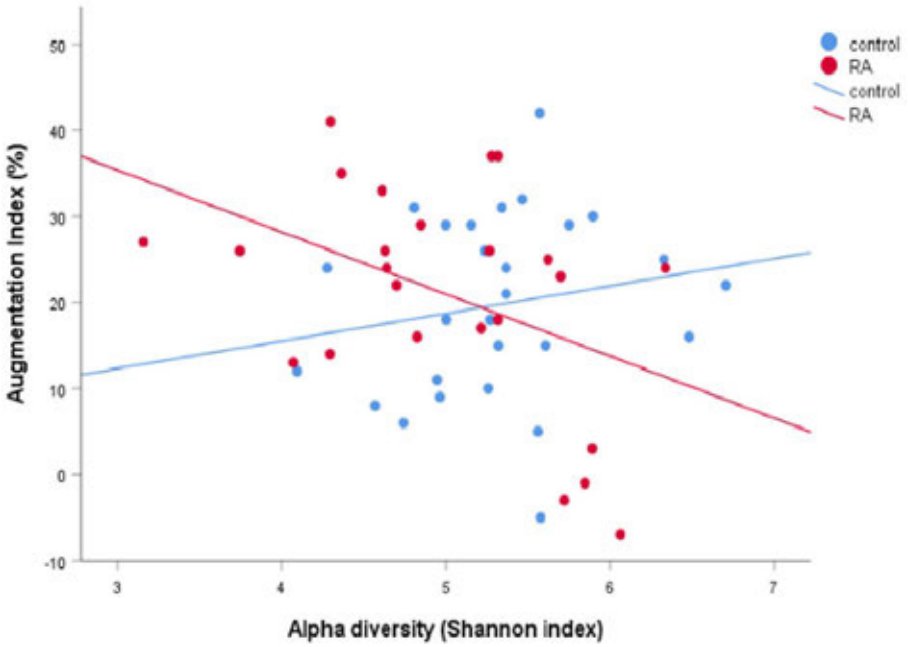

Figure 2. Rheumatoid arthritis modifies the association between Alpha diversity (assessed by Shannon index) and augmentation index. P=0.03 for interaction.

Background/Purpose: Patients with rheumatoid arthritis (RA) have accelerated cardiovascular disease independent of traditional risk factors. Previous studies demonstrate that the gut microbiome is altered in patients with RA and that the gut microbiota may play a role in development of cardiovascular disease in the general population. We tested the hypothesis that gut dysbiosis is associated with early vascular dysfunction in patients with RA.

Methods: Patients with RA (N=30) and control subjects (N=30), frequency matched for age, race and sex were recruited from the Nashville VA hospital and Vanderbilt University Medical Center. Measures of early vascular function including augmentation index, carotid-radial pulse wave velocity, and reactive hyperemia index as well as clinical data were obtained. Stool 16S rRNA gene sequencing was performed by Corebiome. The gut microbiome composition was compared in RA and control subjects with adjustment for false discovery rate. The primary analyses were determination of the association between alpha diversity (as a summary statistic of dysbiosis) and vascular measures in RA. Exploratory analyses included the association of phylum level relative abundance of microbes with vascular measures in RA.

Results: After adjustment for false discovery rate, there was no significant difference in gut microbiome composition, and a non-significant decrease in alpha diversity in RA versus control subjects. Among patients with RA, higher augmentation index and pulse wave velocity (both indicating increased vascular stiffness) were associated with lower alpha diversity (indicating increased dysbiosis) (Figure 1). However, these associations were not present among control subjects; and disease status (RA versus control) modified the association between Shannon index and augmentation index (P=0.03 for interaction, Figure 2). Among patients with RA higher augmentation index was associated with significantly greater proportion of gut Proteobacteria and lower proportion of Verrucomicrobia; and higher PVW was associated with less Euryarchaeota (Figure 1). Similarly, higher RA disease activity was associated with lower alpha diversity, significantly lower proportion of Euryarchaeota and more Fusobacteria in the gut (Figure 1).

Conclusion: Among patients with RA, but not control subjects, reduced gut microbiome alpha diversity was associated with increased vascular stiffness. Gut microbiome dysbiosis may be a contributor to accelerated atherosclerosis in RA.

Background/Purpose: Paraoxonase 1 (PON1) is a high density lipoprotein (HDL)-associated enzyme, which promotes the anti-oxidant and anti-inflammatory properties of HDL. We previously associated low PON1 activity with increased atherosclerotic risk in patients with rheumatoid arthritis (RA). The current work investigates the relationship of PON1 activity to a lipidomics panel of pro-inflammatory bioactive lipid mediators (BLM) in patients with RA and arthritic K/BxN mice.

Methods: Group A included 16 RA patients with carotid atherosclerosis (RA-ATH), 16 RA patients without carotid ATH (RA), and 16 healthy controls (HC). Group B included 29 arthritic K/BxN mice, (9 weeks (n=10), 14 weeks (n=12), 21 weeks (n=7)), and 21 non-arthritic control mice, (14 weeks, KRN (n=10), Ag7 (n= 11)). Circulating PON1 activity was measured using 3 different substrates: phenylacetate (arylesterase assay), dihydrocoumarin (lactonase assay), and paraoxon (paraoxonase assay). Liquid chromatography–electrospray ionization, tandem mass spectroscopy was performed for a panel of 10 circulating BLM including TXB2, 13 HODE, 9 HODE, 17S-HDHA, 15 HETE, 14 S-HDHA, 11 HETE, 12 HETE, 5 HETE, and 5-oxoETE.

Results: PON1 activity was lower in patients with RA compared to HC and was significantly lower in the RA-ATH group compared to the RA group by both paraoxonase and lactonase assays. Similarly, PON1 activity was lower in arthritic K/BxN mice compared to KRN/Ag7 non-arthritic controls. Multiple BLMs were elevated in RA patients and K/BxN mice compared to controls, with trends for highest levels in the RA-ATH group compared to RA and HC groups (Table 1). Lower PON1 activity by arylesterase and lactonase assays correlated with higher levels of several BLMs in both humans and mice (Table 2).

Conclusion: Low circulating activity of the HDL-associated enzyme PON1 associates with higher pro-inflammatory BLMs in both RA patients and arthritic K/BxN mice. This work suggests a potential mechanism for increase atherosclerotic risk in patients with active RA via suppression of PON1 activity and elevation in pro-inflammatory lipid mediators. Further work is warranted to determine if PON1 represents a potential "dual" therapeutic target in patients with RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease is highly prevalent in Rheumatoid Arthritis (RA) and in non-RA subjects with low vitamin D levels. The aim of the present study was to evaluate the long-term risk of serious cardiovascular events (SCVE) RA patients having low vitamin D at time of diagnosis, compared to patients with normal vitamin D levels at RA diagnosis.

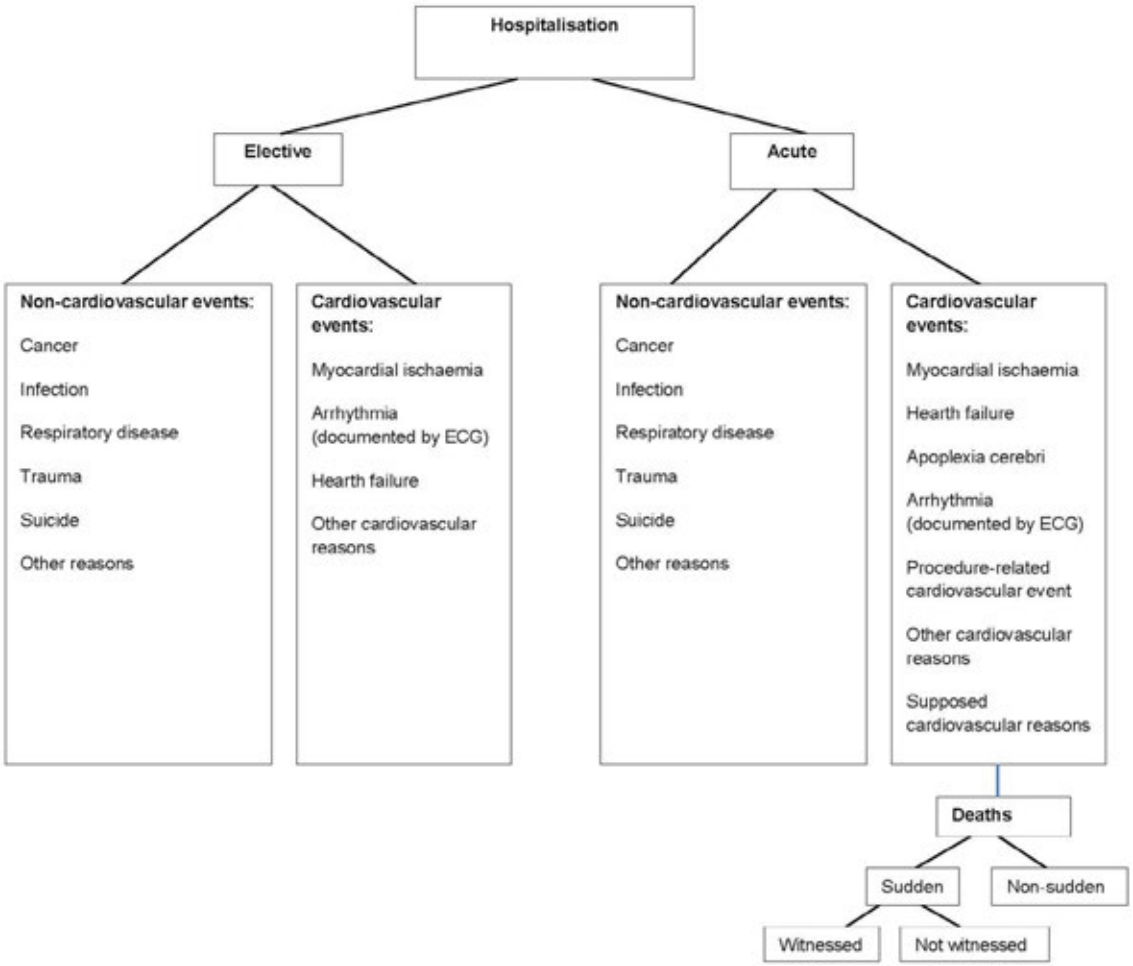

Figure 1 - SCVE adjudication CIMESTRA CVD
Figure 1 - Adjudication-strategy for SCVEs

Methods: The study is a longitudinal observational study with retrospective evaluation of outcomes using patient record adjudication, based on post-hoc evaluation of an Investigator-Initiated, Multicenter, Randomized, Double-Blind, Parallel-Group, Placebo-Controlled Study: The CIMESTRA Study (NCT00209859). Patients were recruited at 4 Danish University Clinics from October 1999 to October 2002**:** 160 early diagnosed, DMARD- and steroid RA-patients, fulfilling ACR 1987 criteria for RA were included in the original CIMESTRA study (NCT00209859). Eligibility criteria excluded most co-morbidities. The original CIMESTRA study treated all patients with methotrexate and intra-articular steroid, aiming at remission. Patients were further randomized to ciclosporine or placebo. Self-reported vitamin D intake was evaluated, and vitamin D supplemented according to national Danish Guidelines.

One-hundred-fifty-eight patients had vitamin D metabolites measured at time of diagnosis, prior to initiation of treatment and eventual vitamin D supplementation, and were included in the current study: Patients were allocated according to serum D_{total} (the sum of $25OHD_2$ and $25OHD_3$) at time of diagnosis, comparing "low" = $D_{total} < 50$ nmol/l to "normal" = $D_{total} \geq 50$ nmol/l. One-hundred-forty-two patients were alive without missing data for journal-adjudications after 10 years of follow-up. Primary outcome was a composite of fatal and non-fatal SCVEs. Secondary outcomes

(%)	5 (7.5%)	7 (7.7 %)	Crude analysis[a]: OR=0.95, 95% CI (0.29; 3.13), p=0.93 Logistic regression[b]: OR=0.86, 95% CI (0.25; 2.93), p=0.81.*** Adjusted logistic regression[c]: OR=0.61, 95% CI (0.11; 3.34), p=0.57**** Adjusted logistic regression[d]:OR=0.41, 95%CI (0.05; 3.23), p=0.4

SCVE: Serious Cardiovascular Event, defined as hospitalisation or death owing to any cardiovascular event.
[a] Crude logistic regression; D_{total} as independent variable, no other covariates.
[b] Simple logistic regression, further containing Trial Center and ciclosporine group as fixed effects.
[c] Multiple logistic regression, further adjusted for age, sex, smoking, BMI-status and ACPA-status.
[d] Multiple regression analyses, further adjusted for baseline variables statistically associated with vitamin D_{total} levels at baseline.
Adjusting for Centre and ciclosporine in evaluation of SCVE death, two centers were omitted, leaving 88 observations for analyses.
** Adjusting for sex, smoking, adipositas and ACPA-positivity at time of diagnosis omitted women, non-smokers, ACPA-positive and patients not adipose, leaving no observations for comparison, and no further adjustments were performed.
*** Adjusting for Centre end ciclosporine, omitted patients from one centre, where no Deaths occurred, leaving 125 observations for the analysis
**** Further adjusting for age, gender, smoking, BMI and ACPA-status, omitted the 45 remaining non-smokes, as no deaths ccurred among them, and the final model comprised of 81 subjects.

Table 1 - Results of logistic regression
Table 1: Evaluation of outcomes after 10 years depending on baseline Dtotal level dichotomised at 50 nmol/l, in RA patients followed in the CIMESTRA trial (data as observed based on the ITT population).

were cardiovascular mortality and all-cause mortality. All events were evaluated through patient-record adjudication, using a validated adjudication process (See figure 1).

Odds for SCVE were evaluated using multiple logistic regression, adjusted for original trial group-allocation (ciclosporine or placebo), Trial Center, and the pre-specified, potential confounding variables sex, age at time of diagnosis, smoking, adipositas and ACPA-status, whereas the fully adjusted model further included weight and $1,25(OH)_2D$, both being statistical significant associated with D_{total}-status at time of diagnosis.

Results: Overall 10-year SCVE incidence was lower than expected (13.9% in patients with low D_{total}, 14.3% in patients with normal D_{total}) (See figure 2). There were no difference in SCVE between D_{total} groups in crude analysis OR=0.91, 95%CI (0.4; 2.3), or in fully adjusted model: OR=0.86, 95%CI (0.2; 3.2) (See table 1) Survival analyses showed no difference in SCVE according to baseline D_{total}, HR=1.15, 95 % CI (0.6; 2.3).

Conclusion: The 10-year SCVE incidence of 13.9% was unexpectedly low. Low vitamin D status at time of RA diagnosis was not associated with long-term SCVE in early diagnosed, aggressively controlled and DMARD treated RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a significantly higher risk of cardiovascular disease (CVD) than general population. The Heart Disease Fact Questionnaire (HDFQ-RA 1 and 2) is a self-reported questionnaire that assesses the knowledge of general CVD risk and more specifically the related with RA and its treatment. The aim of this study was to validate the Spanish version of this questionnaire; and to assess the level of knowledge regarding CVD risk in a cohort of patients with RA.

Methods: Multicenter, observational, cross-sectional study. Translation and cross-cultural adaptation of the HDFQ-RA was performed according to the Beaton et al. guidelines. Consecutive patients ≥ 18 years old with RA (ACR/EULAR 2010) were included. Socio-demographic data, RA characteristics and traditional cardiovascular risk factors were recorded. All patients answered the questionnaire; a subgroup of them attended previously an informative meeting about CVD. A subgroup of patients completed the questionnaire again 10-15 days later. Statistical analysis: Demographic and disease characteristics were described. Internal consistency was assessed with Cronbach's alpha coefficient and inter-item correlation. Correlation of disease characteristics and questionnaire scores was evaluated with Student's T test, Chi^2 test and Fisher's exact test or Spearman correlation. Test-retest reliability was determined.

Results: A total of 787 patients from 25 centers across the country were included: 87.7% women, mean age 45 years (±12.7). Cronbach's alpha test was 0.83 and 0.93 for HDFQ-RA1 and HDFQ-RA2, respectively. There were no redundant questions. Test-retest reliability were 0.48 for HDFQ-RA1 and 0.42 for HDFQ-RA2. Median proportion for correct answers were 53.8% in HDFQ-RA1 and 62.7% in HDFQ-RA2; for incorrect answers 13.8% in HDFQ-RA1 and 0% in HDFQ-RA2; and for unknown responses 21.1% in HDFQ-RA1 and 22.1% in HDFQ-RA2. Sixty-six percent of patients did not know that RA increases the CVD risk, and a high percentage were unaware that NSAIDs and glucocorticoids magnify this risk even more. A higher level of instruction was associated with a higher number of correct answers ($p < 0.0001$). The subgroup of patients who attended the informative meeting about CVD had higher scores in both questionnaires ($p < 0.001$ for HDFQ-RA1 and $p = 0.001$ for HDFQ-RA2). Patients with a history of CVD had

higher scores (p = 0.01195 for HDFQ-R1 and p = 0.0114 for HDFQ-RA2) as well as those suffering from hypertension and those who were physically active.

Conclusion: HDFQ-RA1 and HDFQ-RA2 showed good internal consistency. Patients with a history of CVD and those who received previous instruction on CVD had higher scores, proving the construct validity of the questionnaire. This study demonstrates that a high percentage of RA patients neither know the higher risk of CVD caused by the disease nor the negative impact of NSAIDs and glucocorticoids on this risk. We consider that the use of these types of questionnaires would allow the implementation of targeted CVD prevention strategies as well as the ongoing assessment of their effectiveness over time.

Subclinical Myocardial Dysfunction Assessed by Strain Imaging in Patients with Rheumatoid Arthritis and Spondyloarthritis

Guillaume CLERFOND,[1] Marc VILLEDON DE NAIDE,[2] Clara ALLEMAND,[3] Lucie ULMANN,[3] Romain ESCHALIER,[3] Martin SOUBRIER,[4] Bruno Pereira,[5] and **Anne TOURNADRE** [6], [1]CHU de Clermont Ferrand, Clermont Ferrand, [2]CHU de Clermont Ferrand, Clermont -Ferrand, France, [3]CHU de Clermont Ferrand, Clermont Ferrand, France, [4]CHU Gabriel Montpied, Clermont Ferrand, Auvergne, France, [5]CHU CLERMONT-FERRAND, CLERMONT-FERRAND, France, [6]CHU de Clermont-Ferrand, Clermont-Ferrand, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although cardiovascular (CV) risk and mortality are increased in rheumatoid arthritis (RA) and spondyloarthritis (SpA), mechanisms resulting in CV risk excess and stratification are still unclear. Myocardial deformation imaging (expressed as myocardial strain) allows early detection of CV disease (CVD). The objective of the study was to assess subclinical myocardial dysfunction by 2D speckle tracking imaging in patients without known CVD and to compare to controls.

Methods: Two-dimensional and Doppler echocardiography with strain analysis was performed before initiating first biologic DMARD in patients with RA and SpA, and without CVD and CV risk factors (arterial hypertension, diabetes and known atherosclerosis). Myocardial strain measured by 2D speckle tracking echocardiography provides reliable

information about regional and global ventricular function. The strain is described as the deformation of an object normalized to its original shape and size. The strain can be analyzed in the longitudinal, circumferential and radial displacements of the left ventricle. Global Longitudinal Strain (GLS), used in this study, is negative due to left ventricular shortening in the course of contraction. The more the contraction is significant, the more the strain is negative. Abnormal GLS was defined by a value > -18.5 %. RA and SpA patients were compared to age- and sex-matched controls with normal echocardiography and no CVD or risk factors. Associations between GLS and disease characteristics were analyzed.

Results: 22 RA patients (mean age 55.9 ± 10.1 years, 77 % women, median disease duration 5.8 years, mean DAS28 4.4 ± 1.3) and 25 axial SpA (mean age 43.3 ± 0.3, 44 % men, mean disease duration 9 years, mean BASDAI 57 ± 12) were analyzed. At baseline, RA patients had worse GLS compared to controls (-20.1 ± 2.2 vs -21.5 ± 1.4, p=0.01). Moreover, GLS was not in the normal range in 5 RA (22.8%), while none of the controls had altered GLS (p=0.02). In SpA patients, mean GLS was not different from controls (-21.7 ± 0.68 vs -20.8 ± 1.7, p=0.60). However, 8 SpA patients (32 %) and 4 controls (16 %) had an abnormal GLS (p=0.01). Among these 8 patients, treatment with TNF inhibitor during 1 year improved GLS (-17.8 ± 1 vs -21.7 ± 1.9 p=0.002) and normalized the value in 6 of the 8 patients. For RA and SpA, no significant associations were found between baseline GLS and disease duration, activity (DAS28, BASDAI, ASDAS-CRP), disability (BASFI, HAQ), systemic inflammation (CRP). Patients with SpA and radiographic sacroiliitis (-19.9 ± 1 vs -22.6 ± 0.68 p=0.05) or HLA B27 positivity (-20.8 ± 0.67 vs -24.5 ± 1.34 p=0.05) had worse GLS.

Conclusion: This study confirms a subclinical myocardial dysfunction in active RA and SpA patients without known CVD and CV risk factors compared to controls. In SpA patients, strain abnormalities seem to be improved with anti-TNF treatment.

Toward Cardiovascular Risk Stratification in Rheumatoid Arthritis: Use of Regression Tree Analyses to Evaluate Impact of Serum Biomarkers and Cardiovascular Risk Factors on Carotid Intima Media Thickness

Kimberly Liang,[1] Yaming Li,[1] Suresh Mulukutla,[1] Steven Reis,[1] Marc Levesque,[1] Donald Jones,[1] Rachel Gartland,[1] Jennifer Avolio,[1] Ali Hakim Shoushtari,[1] Flordeliza Villanueva,[1] Larry Moreland,[1] and Douglas Landsittel[2], [1]University of Pittsburgh, Pittsburgh, PA, [2]University of Pittsburgh, Pittsburgh, RI

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

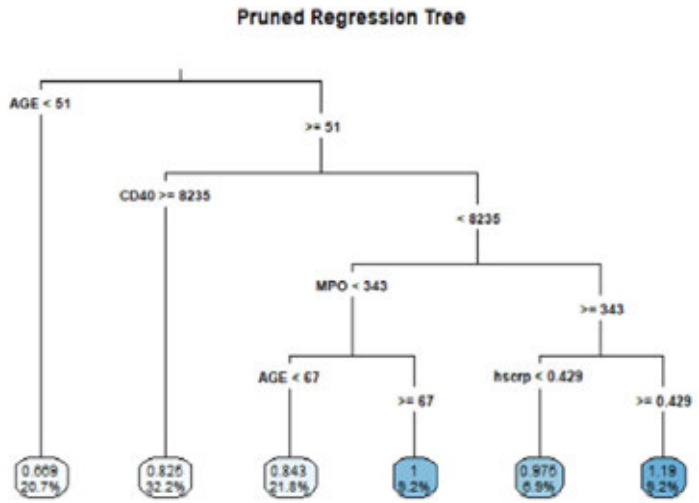
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Both traditional cardiovascular (CV) risk factors and disease-related factors contribute to the increased risk of cardiovascular disease (CVD) in rheumatoid arthritis (RA). Mechanisms of atherosclerosis include (1) Endothelial dysfunction/activation mediated by intercellular adhesion molecules (e.g., ICAM-1, VCAM-1, E-selectin), nitrite (NO), and oxidative stress (e.g., via MPO activity); (2) Inflammation mediated by cytokines (e.g., IL-6); (3) Plaque

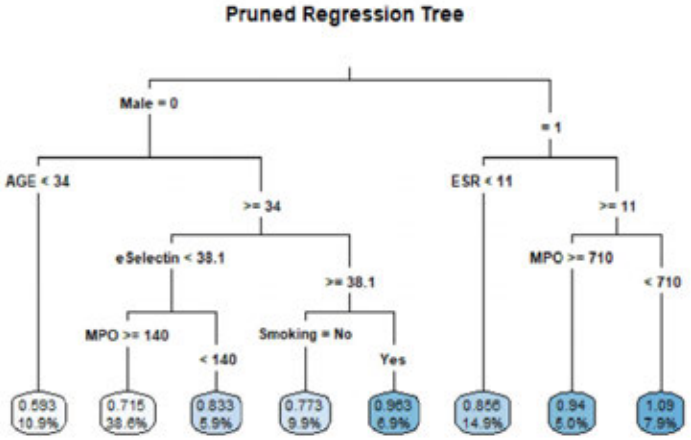
Figure 1 – Pruned Regression Tree for the RA Group



stability mediated by CD40-CD40L interactions; and (4) Proteolysis/Plaque rupture mediated by proteolytic enzymes (e.g. MMP-9). Inflammatory and immune biomarkers important in RA pathogenesis include erythrocyte sedimentation rate (ESR), C-reactive protein (hsCRP), and IL-17. This study seeks to develop easy to visualize decision rules for the differential effects of these serum biomarkers and CV risk factors on carotid intima-media thickness (cIMT) in RA vs. control subjects.

Methods: Carotid ultrasounds measured maximum cIMT and plaque presence, and serum biomarkers (ICAM-1, VCAM-1, E-selectin, NO, MPO, IL-6, CD40L, MMP-9, ESR, hsCRP, IL-17) were measured on 87 RA cases and 101 controls. All RA subjects met 2010 ACR classification criteria. CV risk factors (age, gender, race, obesity, hyperten-

Figure 2 – Pruned Regression Tree for the Control Group



sion (HTN), diabetes (DM), hyperlipidemia (HL), smoking (ever), personal and family history of CVD) were collected on all subjects. Regression tree models were applied with cIMT as the outcome measure, and all the serum biomarkers and significant (based on an unadjusted linear model) CV risk factors (age, gender, DM, smoking, personal history of CVD) as potential splits in the tree model. Tree models are built by identifying the best split across all values of all variables and partitioning the data into the two resulting subgroups (or nodes); within each subgroup the process is repeated until the nodes are too small (n< 10) to split further. The trees were also pruned by eliminating nodes (beginning with the lowest branches of the tree) that did not contribute significantly to model fit.

Results: Demographics were similar between RA and controls except for age (mean 59.6+/-12.0 in RA vs. 54.0+/-14.7 years in controls; p=0.005), as were CVD risk factors except for hypertension (46.4% in RA vs. 23.3% in controls). The tree models (Figures 1-2) display the mean cIMT (with the percent in that group) for each terminal node (e.g. final subgroups). For RA cases, Figure 1 shows that RA patients age 51 or older with CD40 < 8235 had the highest mean cIMT, especially for MPO ≥ 343 or for age 67 or older with MPO < 343 (0.98-1.19). In controls, males with ESR ≥ 11 and female smokers age 34 or older with eSelectin ≥ 38.1 had the highest mean cIMT (0.86-1.09).

Conclusion: This study reveals that RA and control subjects have differential contributing effects of various serum inflammatory and vascular biomarkers and traditional CV risk factors on subclinical atherosclerosis risk, as measured by cIMT. Results may inform future studies to develop additional CVD risk stratification algorithms in RA patients.

The Association Between Disease Activity with Coronary Microvascular Dysfunction in Rheumatoid Arthritis

Sicong Huang,[1] Zeling He,[1] Daniel Solomon,[2] Elena Massarotti,[3] Charlotte Golnik,[1] Thany Seyok,[1] Seth Brownmiller,[4] Tianrun Cai,[3] Nicole Yang,[3] Laurel Campbell,[3] Leanne Barrett,[3] Courtney Bibbo,[3] Kenneth Pariser,[3] Derrick Todd,[3] Marcy Bolster,[4] Marcelo Di Carli,[3] and **Katherine Liao**[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women´s Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA, [3]Brigham and Women's Hospital, Boston, [4]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation accounts for much of the excess cardiovascular disease (CVD) in patients with rheumatoid arthritis (RA). We hypothesize that increased systemic inflammation leads to vascular endothelial dysfunction and coronary microvascular dysfunction (CMD). CMD in the general population is associated with increased risk for cardiac mortality, however, there are limited data on CMD in RA. The objective of this study was to study the associations between RA clinical factors with CMD.

Methods: We used interim baseline data from the first 53 subjects enrolled in the Lipids, Inflammation, and CV Risk (LiiRA, ClinicalTrials.gov: NCT02714881) study. Briefly, the LiiRA study enrolls RA patients, age >35, about to

Table. Baseline clinical characteristics of LiiRA subjects

Clinical characteristics	All, n= 53
Age, years mean (SD)	54.9 (11.1)
Female, n (%)	83.0
RA disease duration, years mean (SD)	9.1 (9)
Seropositive, n (%)	70
CDAI*, mean (SD)	22.2 (13.6)
Low (%)	22.6
Moderate (%)	34.0
High (%)	43.4
ESR mm/h, mean (SD)	29.3 (44)
Baseline RA treatment (%)	
Methotrexate	67.9
Sulfasalazine	1.9
Hydroxychloroquine	22.6
Leflunomide	13.2
No DMARD	17.0
Prednisone (%)	37.7
Prednisone, mean dose (SD)	8.7 (6.8)
Comorbidities (%)	
Hypertension	26.4
Coronary artery disease	0
Diabetes mellitus	0
BMI, mean (SD)	29.4 (6.7)
Family history of CVD, n (%)	60.4
Ever smoker (%)	43.4
Abnormal stress test, n (%)	3 (5.6)

initiate tumor necrosis factor inhibitor (TNFi) therapy. Exclusion criteria include statin use, prednisone dose or equivalent >10mg, or biologic DMARD use in the past 6 months. Demographics, RA clinical factors, and clinical disease activity index (CDAI) were collected. All subjects underwent a stress myocardial perfusion PET scan (cardiac PET), a routine clinical stress test at our institution. The cardiac PET quantifies myocardial blood flow (MBF) at rest and during maximal hyperemia in response to a stress agent, regadenoson. Coronary flow reserve (CFR) is a ratio of MBF during maximal hyperemia over that at rest. A lower CFR in the absence of obstructive coronary artery disease (CAD) is indicative of CMD. We tested correlations between RA clinical factors with CFR. Our primary analysis tested the association between CDAI and CFR adjusted by age, gender, and smoking status.

Results: The mean age of subjects in LiiRA was 55 years, 83% were female, 70% seropositive, with a mean RA disease duration of 9.1 years (Table). No patients had history of CAD or DM, and 26% had a history of hypertension. Three patients (5.3%) had mildly abnormal perfusion scans at baseline. Higher CDAI was correlated with a lower CFR, r=-0.37, p=0.007 (Figure); this association remained significant after adjusting for age, gender, and smoking status (p=0.004). Other clinical factors associated with a significantly lower CFR were older age, r=-2.8, p=0.04, and a higher tender joint count, r=-0.34, p=0.01. We observed no correlation between DMARD or prednisone use at baseline with CFR.

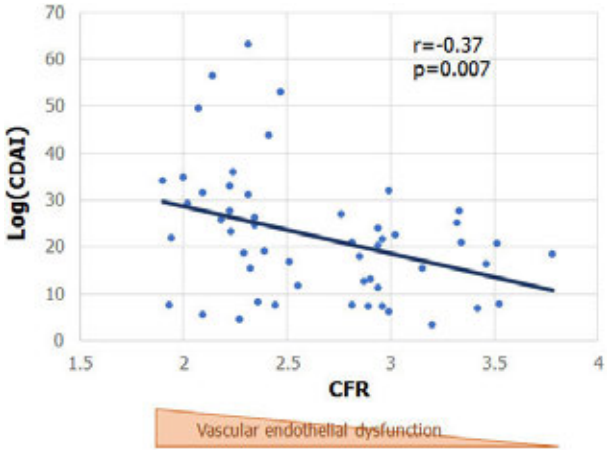

Figure. Correlation between RA disease activity as measured by CDAI with coronary flow reserve (CFR); a lower CFR indicates higher degree of vascular endothelial dysfunction and coronary microvascular disease (CMD).

Conclusion: Among RA patients with no history of overt CAD and low prevalence of CV risk factors, higher RA disease activity was associated with a higher degree of CMD. These findings support a mechanistic pathway whereby inflammation may lead to increased CV risk through microvascular dysfunction. Studies are underway to determine whether CMD is modifiable with RA treatments.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The Metabolic Syndrome (MetS) is an independent factor of cardiovascular morbidity and mortality and most studies show that its prevalence is higher in established Rheumatoid Arthritis (RA) than in the general population, which would be associated with systemic inflammatory activity. Few studies have evaluated this association in patients with Early Arthritis (EA) with different results. Objective: To study the frequency of MetS in patients with EA and its association with disease activity and antibodies profile.

Methods: We studied all the patients with diagnosis of EA who consecutively attended to Rheumatology Unit at Cordoba Hospital from August 2016 to February of 2018. EA was diagnosed by the presence of inflammation in 3 or more joints of less than 12 months duration. A non-RA population was a control group, matched by age and gender.

Table 1. Demographic and clinical characteristics of the 124 cases and controls

	Early Arthritis n=62	Controls n=62	P
Female sex	51 (82.3)	51 (82.3)	1.00

IDF	21 (33.9)	9 (14.5)	**0.012**

Table 3. Comparison of the 62 patients with EA according to the presence of metabolic syndrome using the IDF and/or ATP and/or WHO criteria

	EA/MetS+ n=25	EA/MetS- n=37	*p*
Age (years)	46.7 (10.2)	37.9 (12.2)	**0.004**
RF (IU/mL)	273.6 (558.3)	155.8 (256.6)	0.362*
RF >=14 IU/mL	16 (64.0)	20 (54.1)	0.436
ACPA (U/mL)	163.1 (192.5)	145.7 (217.6)	0.748
ACPA >=30 U/mL	15 (60.0)	22 (59.5)	0.966
ESR (mm/hour)	43.1 (29.2)	48.8 (35.5)	0.511
CRP (mg/dL)	1.1 (2.6)/24	1.4 (2.2)/36	0.609
DAS28-ESR	5.0 (1.5)	5.3 (1.0)	0.070*

Clinical and laboratory data were collected. The activity of the disease was evaluated by DAS28-ESR. The presence of MetS was evaluated according to 3 different international classification: World Health Organization 1998-1999 (WHO), Adult Treatment Panel III 2004 (ATPIII) e International Diabetes Federation 2005 (IDF). EA cases were analysed in to two groups according to MetS or not diagnosis (MetS+/MetS-). A chi-squared test and T-test or Mann–Whitney U test were applied for comparison of categorical and continuous variables as appropriate. $P < 0.05$ was considered statistically significant.

Results: Sixty-two EA patients were included. Demographic and clinical data are shown in table 1. Diagnosis criteria of MetS was more frequent in EA patients than in the control group according to the 3 definitions used (Table 2). In addition, EA patients with and without presence of MetS did not show statistically significant differences in ESR neither in CRP level. There was also no significant difference in level of RF and ACCP antibodies. On the other hand, there was no difference in DAS 28-ESR between EA patients with and without MetS. These results are shown in Table 3.

Conclusion: MetS seems to be more frequent in EA and its presence is not associated with disease activity and the presence of RF or ACCP antibodies. MetS is a known risk factor for cardiovascular disease, morbidity and mortality in systemic autoimmune diseases. A tight control of this condition in the early stages of disease should be recommended.

Note: all variables are expressed as mean and standard deviation (±SD) and compared using the T-test or Mann–Whitney U (*) except for females that are expressed in frequency and percentage (n (%)) and compared using the chi-squared test.

Note: all variables are expressed in frequency and percentage (n (%)) and compared using chi-squared test. ATP III: Adult Treatment Panel III. WHO: World Health Organization. IDF: International Diabetes Federation.

Note: continuous variables are expressed as mean and standard deviation and compared using the T-test or Mann–Whitney U (*). Categorical are expressed in frequency and percentage and compared using chi-squared test. MetS: Metabolic syndrome. RF: Rheumatoid Factor. ACPA: Anti-citrullinated cyclic peptide antibodies. ESR: Erythrocyte sedimentation rate. CRP: C Reactive Protein. DAS28-ESR: Disease Activity Score of 28 joints with ESR.

High Intensity Interval Training Improves Rheumatoid Arthritis Cardiorespiratory Fitness and Systemic Inflammation in Association with Alterations in Skeletal Muscle Metabolomic Profiles

Brian Andonian,[1] David Bartlett,[1] Deborah Muoio,[1] Timothy Koves,[1] Olga Ilkayeva,[1] Andrew Hoselton,[1] Megan Reaves,[1] William Kraus,[1] and Kim Huffman[1], [1]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

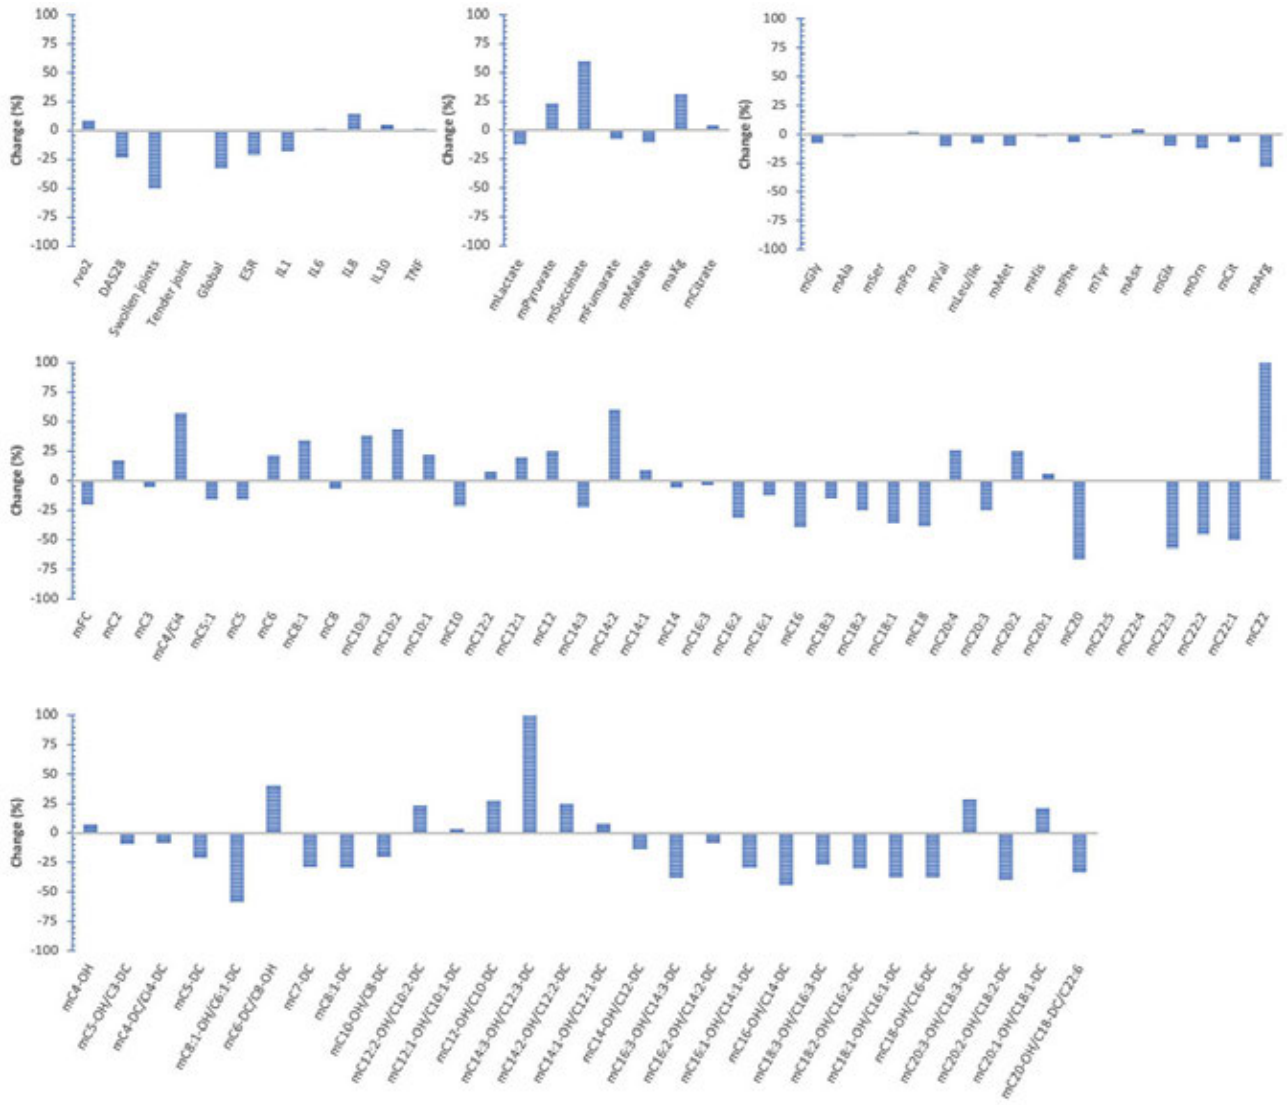

Figure 1. Change in cardiorespiratory fitness, disease activity, systemic inflammation, and skeletal muscle metabolites in RA following high intensity interval training. Bars represent median percent change from baseline for each variable for subjects with RA (n=11).
rVO_2 (relative maximal oxygen consumption), DAS28 (disease activity score-28), ESR (erythrocyte sedimentation rate), IL (interleukin), TNF (tumor necrosis factor), m (skeletal muscle), FC (free carnitine), C (acylcarnitine), OH (hydroxyl), DC (dicarboxyl)

Background/Purpose: Patients with rheumatoid arthritis (RA) are at greater risk for cardiometabolic disease and early death. It is unclear if current anti-inflammatory pharmacotherapies alone are enough to prevent RA comorbidities. In our previous work, in persons with established RA on stable medications, a high intensity interval training (HIIT) program improved both cardiorespiratory fitness and disease activity (Bartlett DB et al. Arthritis Res Ther. 2018; 20:127). To better understand the mechanisms by which exercise training improves RA inflammation and cardiometabolic risk, we evaluated relationships of HIIT-mediated changes in skeletal muscle metabolic profiles with improvements in cardiorespiratory fitness, disease activity, and systemic inflammation.

Methods: RA participants (n=11; mean age=64.0±7.5), who all satisfied 1987 ACR criteria, underwent clinical, physiologic, and biologic assessments before and after 10 weeks of supervised HIIT. Disease activity was assessed via Disease Activity Score-28 with ESR (DAS28). Cardiorespiratory fitness (relative VO_2 peak, mL/kg/min) was assessed via cardiopulmonary exercise testing. Plasma concentrations of cytokines (IL-1β, IL-6, IL-8, IL-10, and TNF-α) were quantified via immunoassay. Using *vastus lateralis*

biopsies, skeletal muscle (m) concentrations of metabolites (organic acids, amino acids, and acylcarnitines) were quantified via targeted mass spectrometry. Percent changes for clinical and metabolic intermediate data were calculated as follows: ([post-intervention variable minus pre-intervention variable]/pre-intervention variable) × 100. Correlations were evaluated with Spearman's rho.

Results: In RA participants, 10 weeks of HIIT improved peak VO_2 (median 8.2%) and DAS28 (median -23.8%). Changes in concentrations of plasma inflammatory cytokines and skeletal muscle organic acids, amino acids, and acylcarnitines are shown [Figure 1]. Among participants, improved peak VO_2 was associated with reduced muscle concentrations of leucine/isoleucine (r=-0.65, p=0.029) and phenylalanine (r=-0.61, p=0.047). Systemic inflammation improvements were inversely related to several muscle metabolic intermediates. Improved ESR, but not DAS-28, was associated with increased muscle pyruvate (r=-0.61, p=0.046). Plasma IL-8 reductions associated with increased muscle succinate (r=-0.61, p=0.047). Plasma IL-6 reductions associated with increases in muscle citrate (r=-0.65, p=0.028) and multiple muscle acylcarnitines, including mC2 (acetylcarnitine), mC12:1, mC12, mC20:1, mC6-DC/C8-OH and mC20:1-OH/C18:1-DC (r< -0.60, p< 0.05 for all).

Conclusion: In RA, HIIT-mediated improvements in fitness and inflammation were associated with muscle metabolic changes. Cardiorespiratory fitness improvement was associated with muscle amino acid reductions. RA systemic inflammation improvements were associated with greater muscle concentrations of multiple components of oxidative metabolic machinery. Thus, RA immune and metabolic function are likely improved with exercise training through systemic enhancement of protein synthesis and fat oxidation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an elevated cardiovascular (CV) disease risk, explained both by an increased prevalence of traditional CV risk factors and the presence of chronic systemic inflammation that leads to (1) increased arterial stiffness, (2) thickening of the arterial wall and (3) impairs vascular function.

In this study we investigated the effect of anti-inflammatory treatment on prognostic markers for preclinical cardiovascular disease (arterial wall thickening and arterial stiffness) and the correlation of these markers with RA disease parameters.

Methods: Carotid ultrasound (using Artlab echotracking system) was used to determine far wall carotid intima media thickness (IMT) and pulse wave analysis was done with SphygmoCor tonometry to calculate carotid-femoral pulse

	n	Baseline	6 months	Mean difference (95% CI)
PWV (m/s)	39	8.0	7.3	0.7 (-0.2;1.5)
AIx (%)	45	27.4	26.6	0.8 (-6.4;7.9)
IMT (mm)	44	0.68	0.68	-0.007 (-0.03;0.02)

Table 1. Prognostic markers of atherosclerosis prior and after 6 months of anti-inflammatory therapy

wave velocity (PWV) and augmentation index (AIx). Paired t-test was used to compare PWV, AIx and IMT prior and after 6 months of therapy. Pearson correlation was calculated to investigated the correlation of PWV, AIx and IMT with (natural logarithm of) C-reactive protein (CRP), (natural logarithm of) erythrocyte sedimentation rate (ESR) and disease activity score-28 (DAS28). For correlations, data from both time points were pooled.

Results: In total 61 consecutive RA patients (50% early arthritis starting with csDMARD and 50% established RA starting with adalimumab) were asked to undergo arterial analysis just prior to start of therapy and after 6 months. PWV was performed in 45 patients at baseline and 39 at follow-up, IMT in 56 and 45 patients respectively and AIx in 51 and 44 patients respectively. Both signs of arterial stiffness (PWV and AIx) decreased after 6 months of therapy (mean difference 0.7 and 0.8 respectively; table 1), although this did not reach statistical significance. IMT remained stable during 6 months of therapy.

PWV (n=84) showed a significant correlation with ESR (0.262, $p< 0.02$) and DAS28 (0.269, $p< 0.02$). Both AIx (n=95) and IMT (n=101) showed a significant correlation with CRP (-0.223, $p< 0.05$ and 0.244, $p< 0.02$, respectively). Other correlation coefficients were not statistically significant (data not shown, $p >0.05$).

Conclusion: Arterial stiffness as measured with PWV tended to decrease after 6 months of anti-inflammatory treatment. Arterial stiffness and arterial intima media thickness correlated with serological inflammatory parameters. Altogether, these changes might suggest that effective anti-rheumatic therapy has favorable cardiovascular effects. Whether or not this ultimately leads to a significant reduction of clinical cardiovascular endpoints remains to be established in prospective studies.

Cardiovascular Disease in Rheumatoid Arthritis: Risk Factors and the Role of Auto-antibodies

Leticia Ferri,[1] Grace Crocket,[2] Yuting Kuang,[3] Boris Breznen,[4] and Mir Sohail Fazeli[4], [1]Bristol-Myers Squibb Company, Princeton, NJ, [2]Bristol-Myers Squibb; Rutgers University, New York City, NY, [3]Doctor Evidence, Doctor Evidence, CA, [4]Doctor Evidence, Santa Monica, CA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

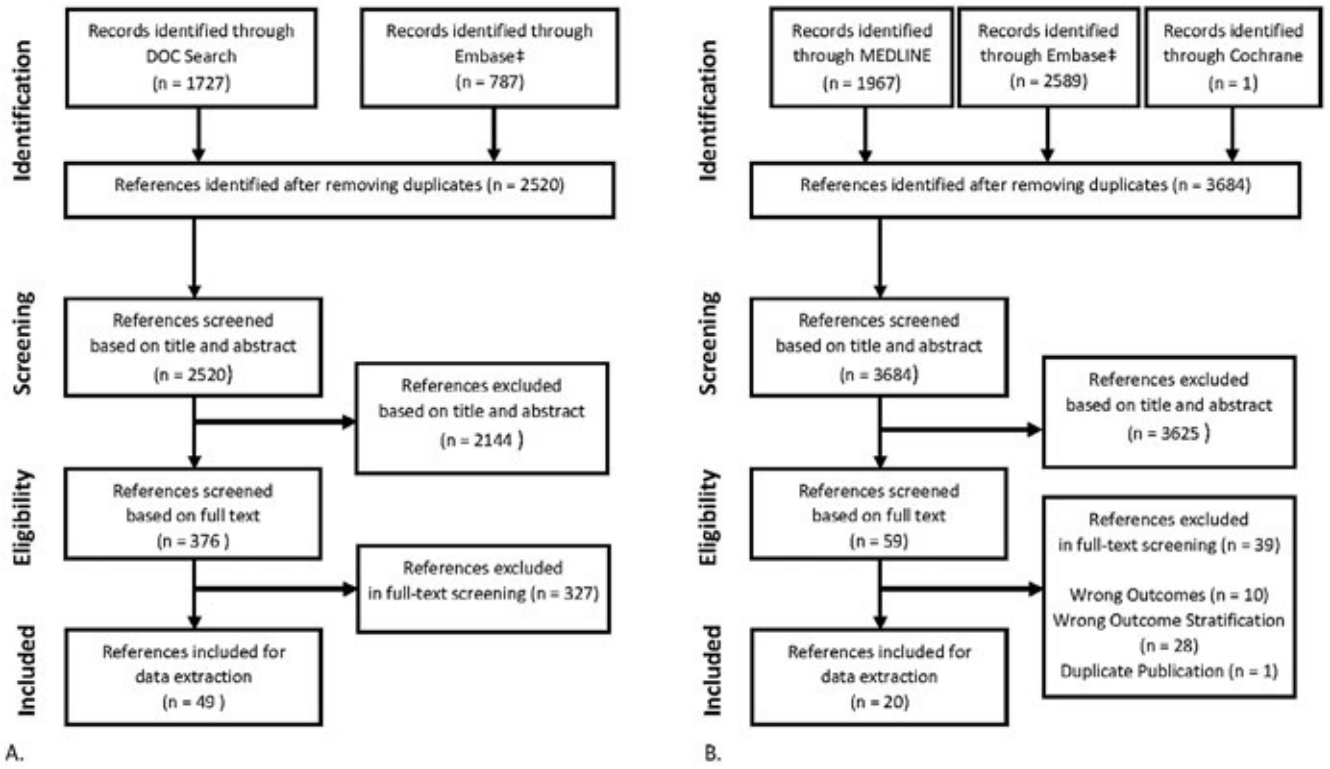

Figure: 1A PRISMA diagram for review on epidemiology and risk factors; 1B PRISMA diagram for review on auto-antibodies* ‡ For ACR and EULAR conferences, all proceedings were available through the Embase database, and were therefore included in the main Embase search results. * No additional record was idendified from the US and European clinical trials registries.

Background/Purpose: Shorter life expectancy in RA patients has in part been associated with an increased incidence of cardiovascular disease (CVD). This literature review summarizes the current understanding of CVD in the RA population, focusing on the role of risk factors and auto-antibodies.

Methods: A systematic literature review was conducted by searching MEDLINE, Embase, and Cochrane CENTRAL (inception-Jan 15, 2019) supplemented by a search in ACR, EULAR, and US and European clinical trial registries (2017 to 2019). Eligible studies included literature reviews, meta-analyses, clinical trials, and observational studies that investigated auto-antibody status related to CVD in the context of RA. This was supplemented by a comprehensive search using Doctor Evidence LLC's proprietary search platform (DOC Search) containing MEDLINE, clinicaltrials.gov, WHO-ICTRP, EPAR, Daily Med, and RSS feeds, targeting literature on epidemiology and risk factors associated with development of CVD in RA.

Results: The results of search and screening yielded 69 publications: 49 on CVD epidemiology and risk factors in RA, and 20 on cardiovascular outcomes stratified by auto-antibody status (Figure 1).

Eligible epidemiological studies reported higher risk of developing CVD and an increased burden of CVD comorbidities in RA patients compared to the general population, with a 48% increased CVD incidence, a 60% increased risk of cardiovascular death, and reduced life expectancy of 3 to 10 years or more in RA vs. non-RA. The reported prevalence of CVD in RA patients varied across countries. Eastern European populations report-

Traditional Risk Factors for CVD in RA	Novel Risk Factors for CVD in RA
Hypertension	Inflammation
Insulin resistance and diabetes	Atherosclerosis
Hyperhomocysteinemia	Neutrophil extracellular traps
Body weight	Phospholipids
RA treatment history (Non-steroidal anti-inflammatory drugs and corticosteroids)	Anti-citrullinated peptide antibodies and rheumatoid factors
Hyperlipdemia	Anti-apolipoprotein A1 antibodies
	Psychological risk factors including depression and anxiety

Table 1: Traditional and novel risk factors for CVD in RA

ed more than twice the prevalence of CVD in RA vs. US populations (21.3% vs. 8.5%); while India had a lower prevalence (5.6%). The risk of developing CVD was also significantly different between sexes, with men having a higher 10-year cumulative incidence of CVD compared to women (20.9% vs. 11.1%). However, the risk of CVD in women with RA increased following menopause. Specifically, women that underwent early menopause (< 45 yrs) were shown to be at significantly higher risk of CVD events compared to women who did not (HR 1.56, 95% CI 1.08-2.26).

The risk factors for CVD in RA can be separated into the traditional CVD risk factors as observed in the general population, and RA-specific risk factors (Table 1). Several studies noted that the risk factors for CVD often predate the onset of RA, suggesting that subclinical inflammatory processes facilitating both RA and atherosclerosis may be developing before patients become RA symptomatic.

Four types of auto-antibodies were identified showing association with cardiovascular events –RF, anti-CCP, aPL, and anti-lipoprotein auto-antibodies – with risk profiles varying across different types of auto-antibodies (Table 2).

Conclusion: Review of the current published literature suggests that a higher risk of CVD in RA populations is in part the result of shared inflammatory processes between the two, and that the presence of auto-antibodies could potentially be associated with increased risk of specific cardiovascular outcomes.

In Rheumatoid Arthritis, New-onset Prednisone Use Is Associated with a Daily Dose, Cumulative Dose, and Duration-dependent Risk for Cardiovascular Events at 6 Months and 1 Year of Use

Anthony Ocon,[1] George Reed,[2] and Joel Kremer[3], [1]University of Rochester Medical Center, Rochester, NY, [2]Corrona Research Foundation, Waltham, MA, [3]Albany Medical College and The Center for Rheumatology; Corrona, LLC, Albany, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory joint disease but also affects the cardiovascular (CV) system. Many patients are treated with corticosteroids. Corticosteroid use is associated with increased risk for cardiovascular events (CVE). We hypothesized that patients with RA who initiate corticosteroid therapy would have an increased risk for CVE related to dose and duration of corticosteroid use.

Methods: We investigated all RA patients enrolled in the Corrona registry between 10/2001-3/2018 who were not using prednisone at the time of enrollment and with at least one follow-up entry. Incident CVE were defined as physician-reported CVE captured in Corrona registry protocol (see Table 1). The enrollment visit date was the index date for estimating time to CVE. Survival analysis using Cox proportional hazard regression models were used to estimate adjusted hazard ratios (HR). Baseline covariables in the model adjusted for gender, age, race, duration of RA, history of CV disease, history of prednisone use, diabetes, hyperlipidemia, and/or hypertension, statin use, tobacco use, year of enrollment, the modified health assessment questionnaire score, and the clinical disease activity index (CDAI) for RA. Prednisone use and CDAI were included as time varying covariates. Several measures of prednisone use were considered: current dose; cumulative dose, and duration over the prior year and over the prior 6 months; weighted dose over 1 year and 6 months, with higher weights for more recent use. Data ranges for total dose and duration analyses were based on quartiles of prednisone use.

Results: 24,752 patients were eligible. 80,501 patient years of follow-up were analyzed. The overall rate of CVE was 1.75/100 person years (95% CI 1.66-1.84/100 person years). Table 1 shows HR and 95% confidence intervals (CI) for the various models. Current prednisone dose showed an increased risk at 5-9mg (HR=1.47) and ≥10mg (HR=1.56). Cumulative prednisone dose at 6 months showed increased risk at 811-1100mg (HR=1.42) and >1100mg (HR=1.55); weighted dose showed increased risk at 811-1100mg (HR=1.49) and >1100mg (HR=1.52). Cumulative prednisone duration at 6 months showed increased risk at >181 days (HR=1.48). Cumulative prednisone dose at 1 year showed increased risk at 1101-2100mg (HR=1.30) and >2100mg (HR=1.54); weighted dose shows increased risk for >2100mg (HR=1.69). Cumulative prednisone duration at 1 year showed increased risk for >360 days (HR=1.70).

101-220 days	1.27 [0.97, 1.65]		86-175 days	1.20 [0.81. 1.77]
221-360 days	0.87 [0.59, 1.29]		176-181 days	1.28 [0.84, 1.93]
>360 days	1.70 [1.33, 2.18]		>181 days	1.48 [1.20, 1.84]

Conclusion: For patients with RA who initiate corticosteroid use, there is an increased CVE risk associated with daily dose, cumulative dose over the last six months and one year, and duration of use. Physicians should counsel patients on the increased CVE risk and consider interventions to minimize risk.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

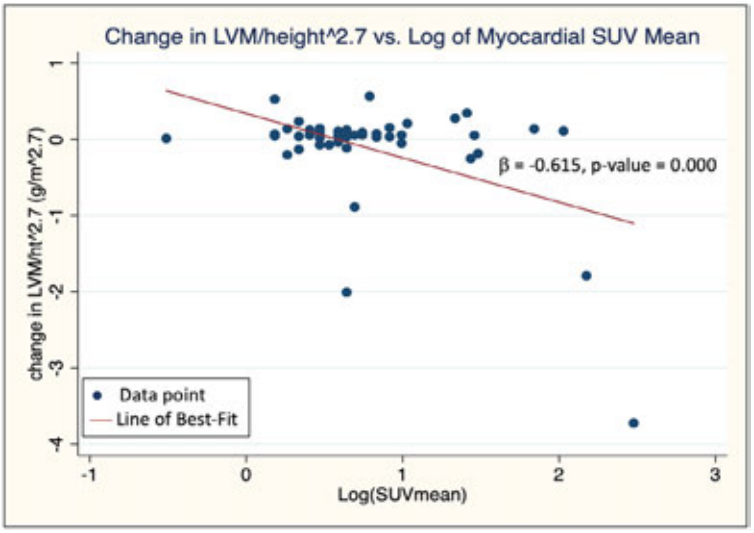
Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of developing heart failure (HF) in RA patients as compared with non-RA subjects is significantly higher even when adjusted for traditional cardiovascular (CV) risk and presence of ischemic heart disease. HF in RA patients is characterized by preserved ejection fraction and diastolic dysfunction. A recent prospective study demonstrated more rapid declines in diastolic function and left ventricular mass (LVM) over time in RA patients compared with control subjects. In RA participants in the RHYTHM (RHeumatoid arthritis: studY of THe Myocardium) study, we observed a high prevalence of subclinical myocarditis (39% with visualized uptake on 18-Fluorodeoxyglucose Positron Emission Tomography-Computed Tomography [18-FDG PET-CT]) as well as microvascular dysfunction (myocardial flow reserve reduced [MFR] in 29%). We hypothesized that RA patients with subclinical myocarditis and/or microvascular dysfunction would have greater decline in LV structure and function over time compared to RA patients without these features.

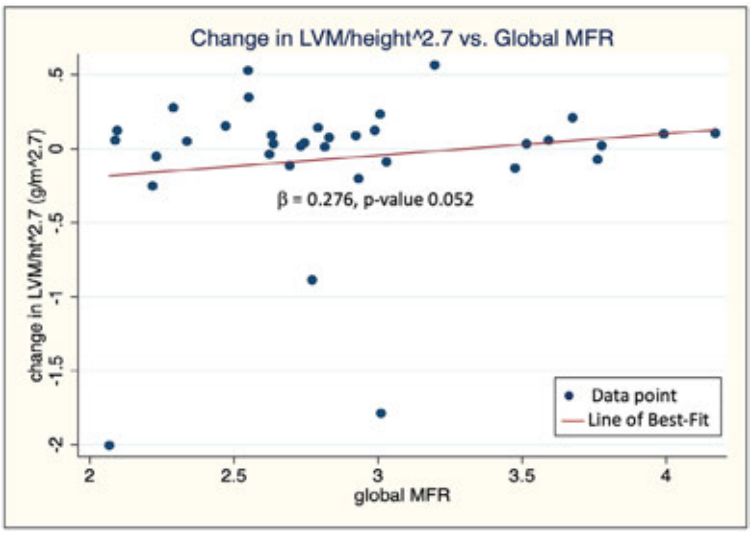
Methods: One hundred nineteen RA patients without clinical CV disease who were enrolled in RHYTHM underwent baseline 18-FDG PET-CT to measure myocardial FDG uptake as a measure of myocardial inflammation (assessed as standardized uptake value [SUV]), and MFR as a measure of microvascular function; in addition, 3-dimensional (3D) echocardiography was performed to assess LV structure and function. Forty-nine patients returned for a follow-up

Parameters	Mean (SD)	95% CI	Paired t-test p-value	Wilcoxon sign-rank test z-value
ΔLVMI, g/ht^2.7 (in $m^{2.7}$)	-0.11 (0.69)	[-0.31, 0.09]	0.14 (Δ<0)	0.12 (Δ<0)
ΔLVMI, g/BSA (in m)	-0.34 (1.48)	[-0.70, 0.09]	0.06 (Δ<0)	0.42 (Δ<0)
ΔLVEF	-0.001 (0.01)	[-0.005, 0.002]	0.19 (Δ<0)	0.31 (Δ<0)
ΔE/A	-0.02 (0.07)	[-0.04, 0.001]	0.03 (Δ<0)	0.06 (Δ<0)
ΔE/E'	0.06 (0.59)	[-0.10, 0.23]	0.22 (Δ>0)	0.79 (Δ>0)
ΔGLS, s^{-1}	0.32 (0.34)	[0.22, 0.42]	0.00 (Δ>0)	0.00 (Δ>0)

Table 1. Changes in selected echocardiographic parameters after 3-6-year time period, including left ventricular mass index (LVMI) adjusted for height^2.7 or body surface area (BSA), systolic function parameters including left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS), and diastolic function parameters including E/A and E/E' ratios



Graph 1. Left ventricular mass (LVM) adjusted by height^2.7 decreases significantly with increasing myocardial inflammation represented by the log transformed mean standardized uptake value (SUV) on 18-FDG-PET scan.



Graph 2. Left ventricular mass (LVM) adjusted by height^2.7 decreases significantly with lower (less favorable) myocardial flow reserve (MFR) obtained with nuclear stress studies.

visit at 3-6-years post-baseline and underwent repeat 3D echocardiography. The mean changes in echo parameters were calculated and Wilcoxon sign-rank tests performed to assess statistical differences between groups. Multivariable regression models were created to assess associations between log transformed mean SUV and global MFR with change in selected echocardiographic parameters.

Results: Although in the overall group there was no significant change in the LVM index (LVMI) over time (Table 1), both higher baseline myocardial SUV (i.e., myocarditis) and lower (less favorable) MFR were associated with a greater decline in LVMI (Figures 1 and 2). In the overall group, although there was no decline in ejection fraction (EF) over

time, a significant decline in global longitudinal strain (GLS), a more sensitive measure of systolic dysfunction than EF, was observed. With regard to diastolic function, a decline in the E/A ratio, but not in the E/E' ratio, was observed over time. However, there were no statistically significant relationships in changes in systolic or diastolic function with baseline SUV or MFR.

Conclusion: These results suggest that subclinical myocardial inflammation and myocardial microvascular dysfunction may be risk factors for myocardial remodeling and decline in systolic and diastolic function in individuals with RA. Whether these subclinical features lead to clinical HF in RA is, as yet, unknown.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For patients with rheumatoid arthritis (RA), heart failure (HF) is a significant cause of morbidity and mortality. HF is further classified into 2 subtypes to guide management; HF with preserved ejection fraction (HFpEF) and HF with reduced ejection fraction (HFrEF). HFrEF is commonly observed after myocardial ischemia due to myocyte loss. Chronic inflammation is proposed to play a major role in HFpEF even in the absence of a chronic inflammatory condition. These HF subtypes have been traditionally difficult to study in RA due to the need for a large RA cohort with ejection fraction (EF) data. The objective of this study was to test existing approaches using natural language processing (NLP) to characterize HF subtypes in an electronic medical record (EMR) based RA cohort, and to study differences in clinical risk factors between the two HF subtypes in RA.

Methods: We used data from an EMR-based RA cohort from 2 tertiary care centers. Within this cohort we applied a published protocol using machine learning and natural language processing (NLP) to identify patients with HF. Among RA patients with HF, we further applied an NLP tool to extract EF data from cardiology reports. Incident HF cases (RA-HF) were identified and matched 1:3 by age, sex, and healthcare utilization to RA patients without HF. HF was classified using the EF data into HFrEF (EF< 40%) and HFpEF (EF >50%). The index date for HF patients was the date of the first EF measurement; thus, this study was limited to HF patients with EF in their records. For controls, the index date was the closest healthcare utilization date within a 6-month window for the EF date. We assessed covariates including RA clinical factors and traditional HF risk factors over the 3-year period prior to the index date.

Table 1. Clinical characteristics of RA patients with HF* compared to age, sex, and healthcare utilization-matched RA controls without evidence of HF.

Clinical characteristics	HF* (n=544)	Controls (n=1632)	p-value

Charlson's comorbidity index	1.17 (1.09-1.26)	<0.001	1.20 (1.11-1.31)	<0.001	1.25 (1.02-1.54)	0.034

*Only variables with significant associations shown. Conditional logistic regression adjusted by variables in Table 1.

TNFi, tumor necrosis factor alpha inhibitor; CAD, coronary artery disease; HF, heart failure; HFpEF, heart failure with preserved ejection fraction; HFrEF, heart failure with reduced ejection fraction; MI, myocardial infarction; OR, odds ratio; RA, rheumatoid arthritis.

Using a case-control design, conditional logistic regression was performed to identify risk factors associated with the development of unclassified HF, HFpEF, and HFrEF.

Results: We identified 544 RA subjects with incident HF and EF data. Compared to age and sex matched controls, the RA-HF subjects were less likely to be seropositive or on methotrexate or TNF-α inhibitor (TNFi), and have more comorbid conditions (Table 1). Among RA clinical factors, methotrexate was associated with a lower

risk of any HF and HFpEF, and not HFrEF. TNFi use was also associated with reduced risk of any HF, with a stronger trend for reduction in HFpEF (Table 2). Traditional HF risk factors such as myocardial infarction (MI) and coronary artery disease (CAD) were associated with increased risk of any type of HF, with stronger association with HFrEF; valvular disease and atrial fibrillation were more strongly associated with increased risk for HFpEF, consistent with prior literature.

Conclusion: In this preliminary study, we observed that RA factors such as MTX and TNFi use was associated with reduced risk of HF, specifically HFpEF in the former. These differences may provide guidance on understanding the role of inflammation and HFpEF in RA, where anti-inflammatory therapies may provide benefit. Future work is needed to validate incident HF and EF definitions and to take into account the time-varying effect of DMARDs and disease activity on the risk of HF and its subtypes in RA.

Association of Rheumatoid Arthritis-related Autoantibodies with Pulmonary Function Test Abnormalities in a Prospective Rheumatoid Arthritis Registry

Sicong Huang,[1] Xintong He,[1] Tracy J. Doyle,[2] Alessandra Zaccardelli,[1] Allison Marshall,[1] H. Maura Friedlander,[3] Rachel Blaustein,[3] Elisabeth Smith,[3] Christine Iannaccone,[1] Taysir Mahmoud,[3] Michael Weinblatt,[1] Paul Dellaripa,[1] Nancy Shadick,[1] and Jeffrey Sparks[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, [3]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary involvement in rheumatoid arthritis (RA), such as bronchiectasis, bronchiolitis, pleuritis, or interstitial lung disease (ILD), is associated with high morbidity and mortality. Pulmonary function testing (PFT) assesses for a wide range of pulmonary abnormalities, broadly characterized as restrictive or obstructive. Seropositive RA patients may be more likely to have restriction, commonly present in ILD. Obstruction may also be more common in seropositive RA related to smoking and airway mucosa as a possible initiating site for RA-related autoantibody development. Therefore, we aimed to determine whether RA-related autoantibodies were associated with abnormalities on PFTs.

Methods: We investigated RA serostatus and PFT abnormalities using a single center prospective RA registry. RA serostatus was assessed by commercial assays for cyclic citrullinated peptide (CCP) and rheumatoid factor (RF) obtained at baseline for research purposes. We used standard cutpoints to define presence and level of positivity for each autoantibody. Outcomes were abnormalities on clinically-indicated PFTs: restriction (% predicted

forced vital capacity [FVC] < 80), obstruction (ratio of forced expiratory volume in one second to FVC [FEV1/FVC] < 0.7), diffusion abnormality (% predicted diffusing capacity of the lungs for carbon monoxide [DLCO] < 70), and a composite of any abnormality. Logistic regression estimated ORs and 95%CIs for types of PFT abnormalities by RA-related autoantibody status, adjusted for possible confounders. We also analyzed only those who had PFTs performed.

Results: Among 1,272 analyzed subjects, mean age was 56.3 years (SD 14.1), 82.2% were female, 69.5% were seropositive (CCP+ or RF+), and 6.8% had ILD. There were 100 subjects with abnormal PFTs. Seropositivity was associated with increased odds of any PFT abnormality (multivariable OR 2.29, 95%CI 1.30-4.03, Table 1) compared to seronegativity. When analyzing by type of PFT abnormality, seropositivity was associated with restriction, obstruction, and diffusion abnormality; multivariable ORs were 2.48 (95%CI 1.26-4.87), 3.12 (95%CI 1.28-7.61), and 2.30 (95%CI 1.09-4.83), respectively. When analyzing by CCP and RF status, the associations were stronger for RF+ than for CCP+ (any PFT abnormality: OR 1.99, 95%CI 1.21-3.27 for RF+ vs. RF-; OR 1.67, 95%CI 1.03-2.69 for CCP+ vs. CCP-), with a dose effect of higher RF levels increasing odds for each PFT abnormality (p for trend< 0.05). Results were similar when only analyzing subjects who had PFTs performed (seropositivity: OR 2.40 (95%CI 1.07-5.35 vs. seronegativity, Table 2).

Conclusion: Seropositive RA patients had 2-fold increased risk for abnormalities on PFTs performed for clinical indications compared to seronegative RA. This association was present for all types of PFT abnormalities and was

not explained by smoking. Patients with seropositivity may be at risk for obstructive lung diseases, in addition to the previously known association of seropositivity with restrictive lung diseases, such as ILD. Future studies should assess the value of screening for PFT abnormalities in seropositive RA patients, particularly those with high-titer RF+.

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis(RA) patients have increased cardiovascular(CV) risk with no data on CV risk scores in Indian patients.The primary objective was to study prevalence of traditional CV risk factors in RA. Secondary objectives were to assess performances of various CV risk scores with respect to each other and against subclinical atherosclerosis as measured by carotid intima media thickness(CIMT).

Table1. Demographics, Disease characteristics and prevalence of Traditional risk factors *	
Male:Female	49:285
Age, in years	47.16+12.57
Disease duration, in years	7.25+5.92

EAM: Extraarticular manifestation, BMI:Body Mass Index, TCh:Total Cholesterol, HDL: High density lipoproteins, LDL: Low density lipoproteins

Methods: Patients fulfilling 2010 ACR/EULAR criteria for RA were included. Presence of traditional CV risk factors were recorded. 10-year-CV risks were predicted using Framingham Risk scoring using lipids (FRS-Lipids) and body mass index (FRS- BMI), QRISK-3, SCORE and the algorithm recommended by 2013-ACC/AHA guidelines(ASCVD) in patients who were 40 years or older. CIMT was measured on the far-wall of the common carotid artery at least 5 mm below its end. CIMT value greater than 0.90 mm or presence of plaque was chosen as marker of subclinical atherosclerosis.

Results: Table 1 highlights clinical profile and risk factors in 334 enrolled patients. Friedman's test for global variance of various showed significant difference among various risk predicting algorithms. Post-hoc analysis done with Wilcoxon-signed-rank test showed significant variability between each of them. When subclinical atherosclerosis assessed by CIMT was taken as reference, ASCVD and QRISK-3 showed maximum sensitivity **Fig:1**. Differences in disease characteristics and risk factors between patients with and without subclinical atherosclerosis and are underlined in **Table 2**.

Conclusion: There is considerable variablity between various risk scores and cannot be used indiscriminately in Indian RA patients. ASCVD and QRISK-3 scores had the maximum sensitivity in predicting subclinical atherosclerosis.

Risk of Incident Myocardial Infarction Among Disabled Patients with Rheumatoid Arthritis Who Were Beneficiaries of the Social Security Disability Insurance

Iris Navarro-Millan,[1] Mangala Rajan,[1] Geyanne Lui,[1] Lisa Kern,[1] Laura Pinheiro,[1] Sebastian E. Sattui,[2] Lisa Mandl,[3] Fenglong Xie,[4] Jeffrey Curtis,[5] and Monika Safford[1], [1]Weill Cornell Medicine, New York, [2]Hospital for Special Surgery, New York, [3]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY, [4]University of Alabama at Birmingham, Birmingham, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA have high risk for myocardial infarction (MI). A meta-analysis showed that the age and sex adjusted pooled relative risk of MI among patients with RA was 1.69, 95% confidence interval (CI) 1.50 - 1.90. There is limited understanding about the prevalence and incidence of MI events among individuals younger than 65 years of age disabled (defined as beneficiaries of the social security disability insurance (SSDI)) with RA.

Table 2: Three-Year Incidence of Myocardial Infarction among Patients with Rheumatoid Arthritis <65 Years of Age Receiving Social Security Disability Insurance Benefits and Free of Cardiovascular Disease at Baseline

Methods: We analyzed claims data of the SSDI beneficiaries aged 18-64 years of age with RA, defined as ≥2 ICD-9 CM codes (714.xx) from a rheumatologist > 7 and < 365 days apart, OR 1 ICD-9-CM code from a rheumatologist AND a DMARD in 2011 in a period > 7 and < 365 days. Prevalent CVD was defined by ICD-9-CM code from heart failure, stroke, or CVD procedures (coronary artery bypass grafting, percutaneous coronary intervention, or carotid endartherectomy) in 2011. We used the chronic conditions data warehouse to identify CVD risk factors (ICD-9-CM codes for diabetes, hyperlipidemia, hypertension, obesity) in 2011. We followed subjects without prevalent CVD in 2011, through 2014 to determine incident MI, defined as the first hospitalization for MI (discharge diagnosis ICD-9-CM codes 410.xx). Age adjusted incidence rates were estimated using Poisson models. Age- and sex-adjusted Cox proportional hazard model was used to compare the risk for incident MI between patients with and without CVD factors at baseline.

Results: There were 48,905 patients in the study sample; 78.9% were female, 72.2% were ≤60 years of age, and 69% had at least one CVD risk factor, with hypertension being the most prevalent (52.7%) (Table 1). The prevalence of CVD was 9.3% (N = 4,528). Among the 44,377 without CVD at baseline, 28,538 (64%) had baseline CVD risk factors; 433 MI events occurred among those with CVD risk factors and 143 among those without over 35.9 median months of follow-up (Table 2). The age-adjusted incident rate of MI was 5.02 (95% CI 4.52 – 5.58) per 1000 person-years for those with CVD risk factors and 3.42 (95% CI 2.90 – 4.03) per 1000 person-years for those without CVD risk factors. The age- and sex-adjusted hazard ratio (HR) for incident MI for those with CVD risk factors compared to those without was 1.47 (95% CI 1.22-1.78).

Conclusion: The prevalence of CVD and CVD risk factors was high in this population of disabled individuals younger than 65 years of age with RA. The incident rate for MI was high in the subgroup of patients without CVD risk factors considering that 80% of those patients were 60 year of age or younger (3.42 per 1000 person-year). As expected, patients with CVD risk factors were 47% more likely to experience an MI compare to patients without CVD risk factors.

Abstract Number: 2334

Is Cardiovascular Risk and Mortality in Rheumatoid Arthritis Compared to Diabetes Mellitus and the General Population Overestimated?

Brian Løgstrup,[1] Torkell Ellingsen,[2] Alma Pedersen,[3] Bianka Darvalics,[3] Kevin Olesen,[4] Hans Erik Bøtker,[4] and Michael Mæng[4], [1]Department of Cardiology, Aarhus University Hospital, Denmark, Aarhus, Syddanmark, Denmark, [2]Department of Rheumatology, Odense University Hospital, Denmark, Odense, Syddanmark, Denmark, [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, Aarhus, Denmark, [4]Department of Cardiology, Aarhus University Hospital, Denmark, Aarhus, Denmark

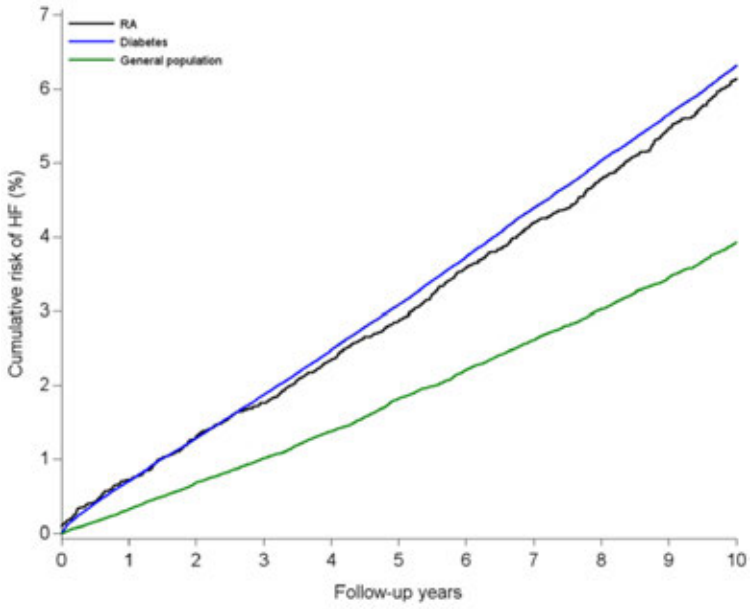

Figure 1. Cumulative risk of heart failure during the 10 year follow-up period.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the risk of cardiovascular disease (CVD) and mortality in patients with rheumatoid arthritis (RA), diabetes mellitus (DM), and the general population.

Methods: Patients diagnosed with RA were matched 1:5 by age, sex, and year of RA diagnosis with the general population. In the same period, patients with incident DM were included. Outcomes were heart failure (HF), myocardial infarction (MI), coronary revascularization, and death up to 10 years after diagnosis.

Results: We included 15,491 patients with RA, 309,698 patients with DM, and 77,455 persons from the general population. Patients with RA had an increased risk of HF (HR 1.46, 95% CI 1.34-1.59), MI (HR 1.48, 95% CI 1.34-1.63), percutaneous coronary intervention (PCI) (HR 1.37, 95% CI 1.22-1.54), and coronary artery bypass grafting (CABG) (HR 1.20, 95% CI 0.98-1.49) compared to the general population. When comparing RA and DM, RA patients had a lower adjusted risk of HF (HR 0.79, 95% CI 0.73-0.85) and CABG (HR 0.61, 95% CI 0.50-0.74) and similar risk of MI and PCI. The mortality risk among patients with RA and the general population was similar, but lower than in patients with DM (RA vs DM: HR 0.65, 95% CI 0.63-0.68).

Conclusion: This study demonstrates that RA is associated with an increased risk of CVD compared to the general population but without reaching the risk levels observed in patients with DM. Among patients with RA, we observed comparable mortality at 10-year follow-up compared to the general population and significantly lower mortality than patients with DM.

Abstract Number: 2335

Prediction of Myocardial Fibrosis in Rheumatoid Arthritis Assessed by Cardiac Magnetic Resonance Imaging Using Artificial Neural Networks Models

Hitomi Kobayashi,[1] Isamu Yokoe,[2] Yasuyuki Kobayashi,[3] Eichi Takaya,[4] Atsuma Nishiwaki,[1] Kaita Sugiyama,[1] Noboru Kitamura,[1] Masaki Haraoka,[3] and Masami Takei[1], [1]Nihon University School of Medicine, Tokyo, Japan, [2]Kyoundo Hospital, Tokyo, Japan, [3]St.Marianna University School of Medicine, Kawasaki, Japan, [4]Graduate School, Keio University, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac involvements cause of morbidity and mortality globally in rheumatoid arthritis (RA). Myocardial dysfunction may arise from a number of distinct processes, including myocardial inflammation and myocardial fibrosis, any of which may be active in RA. Global longitudinal strain (GLS), using non-contrast feature tracking cardiac magnetic resonance (FT-CMR), has been reported to be significantly associated with the extent of myocardial fibrosis. Late gadolinium enhancement (LGE) corresponds to histopathologic zones of myocardial fibrosis and necrosis. In the last few years, it has been suggested that artificial neural networks (ANNs) approaches are an established method for analyzing large datasets. ANNs could be a useful tool for prediction in medical scenarios. We aimed to predict myocardial fibrosis in RA assessed by FT-CMR and LGE using ANNs models.

Methods: RA patients and controls with no known heart disease or risk factors were enrolled. The normal threshold was defined based on the statistical±2SD limits on healthy controls in FT-CMR. In this study, a three-layered feed-forward neural network model was structured to detect a myocardial abnormality from GLS and LGE, respectively. Inputs for the network were totally 22 variables including attributes (e.g., Age, Sex, BMI, Duration, RF, SDAI, MMP-3, CRP, ESR, TC, TG, HDL, LDL, sBP/dBP, HbA1c, NTproBNP, MTX, PSL, biologics used) and observed values (e.g., DAS28, ACPA). The network's output was existence or non-existence (1 or 0) of abnormity in each target index. The back-propagation learning algorithm was used to train the ANNs structure. As the hyper parameters of ANNs, the number of neurons (10, 50, 100, 200) in the hidden layer, optimization method (Stochastic Gradient Descent, Adaptive Moment Estimation), initial learning rate (0.001, 0.005, 0.05) in the optimization method and the number of iterations (10, 50, 100, 200, 400) were determined to get the best performance using leave-one-out cross-validation. We calculated accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) to evaluate the performance of the ANNs model.

Results: We evaluated 88 patients with RA (95% women; mean age, 59.5±9. 0 years) and 30 healthy controls (100% women; mean age, 55.7±4.5 years). All 118 subjects underwent FT-CMR and 51 patients underwent LGE. Abnormal GLS values and LGE were seen in 67/88 subjects (76.1%) and 19/51 subjects (37.3%), respectively. We created a mathematical model with an AUC value of 0.73 and 0.71, respectively, able to predict abnormal GLS and LGE. The accuracy, sensitivity, specificity, PPV and NPV for prediction of abnormal GLS values and LGE were 80.7%, 88.1%, 57.1%, 86.8%, 60.0% and 74.5%, 73.7%, 70.6%, 58.3%, 82.8%, respectively.

Conclusion: We applied ANNs to identify a prediction model for myocardial fibrosis in RA assessed by CMR. We could construct a mathematical model with laboratory and clinical items, and treatment, to potentially identify asymptomatic RA patients with myocardial fibrosis. This prediction tool could be used potentially in a clinical practice setting to stratify RA patients according to myocardial fibrosis.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA have an augmented cardiovascular mortality up to 50% compared to controls. Chronic inflammation of the disease causes endothelial dysfunction and accelerated atherosclerosis. Key molecular pathways in this process are dependent on cytokines like TNF-α, IL-1, IL-6, among others, which are shared with RA. Increased disease activity could contribute to atherosclerosis. Carotid ultrasound (US) has recently been recommended as a screening tool for early detection of subclinical atherosclerosis. Thus, the aim of this study was to compare different cytokines between Mexican-mestizo RA-subjects with/without carotid plaque (CP).

Table 1. Clinical characteristics.

Variable	CP (n= 37)	No CP (n=34)	*P*

*-variable reported as: median (q25-q75), **-variable reported as: n (%), ***-variable reported as: media ± SD

Table 2. Cytokines levels	
	Median (q25-q75)
IL1, pg/ml	8.1 (6.6-9.6)
TNF-a, pg/ml	76 (61-101)
IL6, pg/ml	4.4 (4.1-4.8)
ICAM, ng/ml	91 (61-141)
VCAM, ng/ml	56.5 (41.3-65.1)
MMP9, pg/ml	811 (721-931)

Methods: An observational cross-sectional trial was designed. Inclusion criteria: age between 40-75 years old, fulfillment of the 2010 ACR/EULAR classification criteria, and detection of a CP during a carotid US. Subjects with a prior diagnosis of cardiovascular disease or a poor US window were excluded. RA subjects were matched to controls (RA patients without CP) by age and cardiovascular (CV) comorbidities. Every subject had a carotid US performed; reviewed by two board-certified radiologists. Cytokines measured were IL-1, IL-6, TNF-α, VCAM-1, ICAM-1 and MMP-9, using an ELISA reader (Glomax E9032). Descriptive analysis was done with frequencies (%), median (q25-q75), and comparisons between groups with Chi square and Mann-Whitney U tests.

Results: 71 subjects were included, 95.8% were females, with a median age of 58 years (54-65). Comparisons between groups are in Table 1 and levels of cytokines in Table 2. Groups were well balanced, with no differences in CV comorbidities ($p > 0.05$). No significant differences among cytokine levels regarding CP were found. Subjects in remission (n=12, 33%) had a lower prevalence of CP ($p < 0.05$, OR: 0.3; 95% CI: 0.1-0.9) and a lower median IL-1 level than those with higher disease activity ($p < 0.05$). No significant differences were found among any other of the compared cytokines.

Conclusion: In our cohort subjects in remission had a lower prevalence of CP. No difference was found between cytokines regarding CP. Subjects with active disease had a higher level of IL-1 than subjects in remission. To our best knowledge, this is the first study to evaluate levels of cytokines in Mexican RA-subjects.

Treat to Target Is Not Linked to Best Myocardial Strain Indices: Is There Really a Myocardial Dysfunction Directly Associated with Disease Activity?

Alisson Pugliesi,[1] Hugo Nourani,[1] José Roberto Matos Souza,[1] and Manoel Bertolo[2], [1]University of Campinas, Campinas, Sao Paulo, Brazil, [2]University of Campinas, Campinas, Brazil

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of developing heart failure (HF) is twice as high in the RA population. It is hypothesized that, in addition to the atherosclerotic ischemic component and the traditional risk factors, there is a mechanism of cardiotoxicity related to the inflammatory pathways. A few previous studies indicate an association between disease activity and myocardial dysfunction, but they involved elderly population with comorbidities and in use of TNF-α inhibitors. Our main objective is to evaluate the correlation between clinical disease activity index (CDAI) and global longitudinal strain (GLS) — the most sensitive echocardiographic method to detect changes in ventricular contractility — in a RA population without cardiovascular risk factors and using only conventional synthetic DMARDs.

Methods: From June 2016 to January 2019, RA patients were selected to perform transthoracic speckle tracking echocardiography for GLS evaluation. Patients aged 18-60 years and classified according to ACR 2010 criteria were included. Patients with diabetes mellitus, uncontrolled hypertension, smokers, BMI >35, atherosclerotic disease history, and in use of biological medication were excluded. Patients underwent a clinical evaluation in which a single physician measured the CDAI and, within a period of one month, an echocardiographer blinded to the patient's clinical data assessed the GLS. Student's t-test and Spearman correlation were used for statistical evaluation.

Results: Thirty-six patients (91.7% female, with ages ranging from 16 to 56 years) participated in the study. No correlation was found between CDAI and GLS values (Graphic 1). There was no adequate accuracy between values of CDAI≤10 and GLS< -18% and GLS< -20% (values considered normal), according to Table 1. The presence of RF, anti-CCP and the disease duration were also not associated with CDAI values.

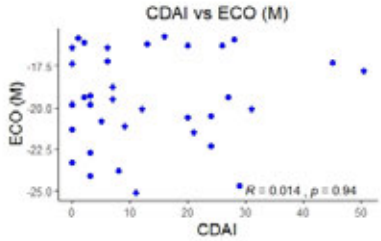
Conclusion: Data from this study (small but with highly selected population) do not corroborate the association of CDAI with myocardial dysfunction and question whether there is a cardiotoxicity factor linked to the disease. Traditional risk factors, subclinical atherosclerotic disease, and cardiotoxic drug effects should be the subject of studies designed to explain the higher prevalence of HF in the RA population.

Table 1 – Acuracy of CDAI≤10 to predict GLS < - 18% and GLS < -20%

GLS	Sensitivity	Specificity	PPV	NPV	Acuracy	p-value
≤-18%	53,8	60,9	43,8	70,0	58,3	0,393
≤-20%	38,1	46,7	50,0	35,0	41,7	0,364

GLS: Global Longitudinal Strain; PPV: Positive Predictive Value; NPV: Negative Predictive Value

GRAPHIC 1: CORRELATION OF CDAI WITH ECOCHARDIOGRAPHY FINDINGS (GLS)



CDAI: Clinical Disease Activity Index

ECO (M): Values of Global Longitudinal Strain

Validation of a Claims Algorithm to Identify Interstitial Lung Disease in Patients with Rheumatoid Arthritis

Margaret Guthrie,[1] Ankoor Shah,[2] Leonard Lobo,[3] Jim Oates,[4] Cassie Clinton,[1] Narender Annapureddy,[5] Fenglong Xie,[6] Bryant England,[7] and Jeffrey Curtis[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Duke University, Durham, NC, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC, [4]Division of Rheumatology & Immunology/Medical University of South Carolina, Charleston, SC, [5]Vanderbilt University, Nashville, TN, [6]University of Alabama at Birmingham, Birmingham, [7]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is an increasingly important problem for patients with Rheumatoid Arthritis (RA). However, current approaches to ILD case finding are suboptimal or have been evaluated only in limited settings. Our objective was to develop, refine, and validate a claims-based algorithm to identify both prevalent and incident ILD in a cohort of RA patients enrolled in Medicare compared to the gold standard of medical record review.

Methods: We used Medicare administrative claims data 2006-2015 to derive a cohort of RA patients and then identified suspected ILD using variations on several features of the data. These included various ILD diagnosis codes using ICD9/10 coding, evaluation by pulmonologists and rheumatologists, occurrence of chest CT, lung biopsy results, and pulmonary function tests. Suspected ILD cases were evaluated at five participating medical centers: Duke, Medical University of South Carolina, University of Alabama at Birmingham, University of North Carolina, and Vanderbilt. The centers identified patients in their medical systems using either a search tool run against a central data warehouse or repository (e.g. i2b2) or a local ILD registry. Medical record reviewers abstracted the clinical data, including physician notes, CT scan and imaging results, lung pathology reports, and pulmonary Function tests (PFTs), into a case report form which was then adjudicated by two ILD experts (pulmonology and rheumatology). Discordance in adjudication was resolved by consensus. The positive predictive value (PPV), the primary outcome of the study, was calculated for each ILD algorithm for both prevalent and incident ILD and 95% confidence interval (CI) using a binomial distribution.

Results: We identified 264 linkable RA patients with sufficient data to evaluate for ILD. Overall, 115 (44.6%) of suspected cases (based on a highly sensitive case finding approach) were classified as ILD. The most common diagnosis codes identified in this initial search were 515 (Postinflammatory pulmonary fibrosis, 33%), 518.89 (Other disorders of lung, 24%), 714.81 (rheumatoid lung, 9%), 793.19 (Other nonspecific abnormal finding of lung field, 8%), and J84 (Other interstitial pulmonary diseases with fibrosis, 6%). 516 (Other alveolar and parietoalveolar pneumonopathy, 3%). A total of 36.0% of cases were hospitalized (4.9% primary diagnosis code, 31.1% non-primary diagnosis code), and the remainder were outpatient. The best performing algorithm for prevalent ILD had a PPV of 77% (95% CI 67%-85%) and for incident ILD was 74.2% (95% CI 58.9-89.6%).

Conclusion: ILD case finding in RA patients using administrative claims data is feasible and has reasonable accuracy. Both prevalent and incident ILD can be identified.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis associated interstitial lung disease (RA-ILD) is an extra-articular manifestation with a poor prognosis. In clinical practice, to establish such a diagnosis requires to rule out other causes of ILD.

Usual interstitial pneumonia is the most common high-resolution computed tomography pattern found in RA-ILD and is indistinguishable from that of chronic hypersensitivity pneumonitis, an immune-mediated ILD that can result from the exposure to several widely recognized antigens.[1] To date, it is not known whether the determination of exposure to environmental factors known to cause lung fibrosis, such is the case of avian or fungi antigens, by measuring their antibodies (Ab) plays a role both in diagnosis and further management of patients with RA-ILD.

Our aim was to describe the frequency of significant levels of AA and AF Ab in a cohort of patients with RA-ILD.

Methods: We performed a cross-sectional study including all patients with RA according to the ACR 2010 classification criteria diagnosed with ILD from June 2014 to March 2019 on an ILD multidisciplinary committee of a tertiary referral centre.

Age (Mean ± SD, years)	67.3 ± 11
Sex (female)	26 (74.3%)
RA duration, (median (IQR), years)	9.91 (16.3)
Presence of erosions	24 (68.6%)
Ever-smokers	20 (57.1%)
Antibody status	
ACPA positive	30 (85.7%)
ACPA titres (median (IQR), CU)	873.6 (2020.4)
RF positive	27 (77.1%)
RF titres (median (IQR), IU)	200 (520)
ENA positive	3 (8.6%)
Anti-Ro (SSA)	3
Anti-La (SSB)	1
Type of ILD	
UIP	12 (34.3%)
NSIP	16 (45.7%)
COP	4 (11.4%)
RB-ILD	3 (8.6%)
ILD duration	1.95 (1.3)
Bronchiectasis	25 (71.4%)
Emphysema	14 (40%)
Current treatment	
GC	24 (68.6%)
csDMARD	23 (65.7%)
MTX	14 (40%)
LEF	10 (28.6%)
HCQ	5 (14.3%)
bDMARD	8 (22.9%)
ABA	5 (62.5%)
TCZ	3 (37.5%)
tsDMARD (Tofacitinib)	1 (2.9%)

Table 1. Main demographic and clinical features of included patients expressed as n (%). IQR: Interquartile range; CU: Chemiluminescence Units; IU: International Units; UIP: Usual Interstitial Pneumonia; NSIP: Non-specific Interstitial Pneumonia; COP: Cryptogenic Organising Pneumonia; RB-ILD: Respiratory Bronchiolitis associated ILD; MTX: Methotrexate; LEF: Leflunomide; HCQ: Hydroxychloroquine; ABA: Abatacept; TCZ: Tocilizumab.

All patients were evaluated using a standardized laboratory protocol including: red and white blood cell count, kidney and liver function tests, c-reactive protein, eritrosedimentation rate, rheumatoid factor (RF), antinuclear Ab, extractable nuclear antigens (ENA), ACPA (CCP2), anti-avian (AA) and anti-fungi (AF) Ab.

AA included specific IgG Ab against parakeet and parrot feathers and pigeon droppings and serum proteins. AF included Micropolyspora faeni, Thermoactinomyces vulgaris, Stachybotrys atra, Penicillium sp, Cladosporium herbarum, Aspergillus fumigatus, Candida albicans and Alternaria alternata Ab. Both groups were assessed by ImmunoCAP® IgG Specific (Thermo Fisher Diagnostics). Since there are no validated cut-off levels, we defined significant (positive) levels when above the p90 of the cohort's distribution for the AA or AF Ab with the highest frequency.

Results: 35 patients were included; their main demographic and clinical features are shown in table 1. 3 ENA-positive cases were found; 2 of them had high levels of RF and ACPA titers and the remaining had erosive disease.

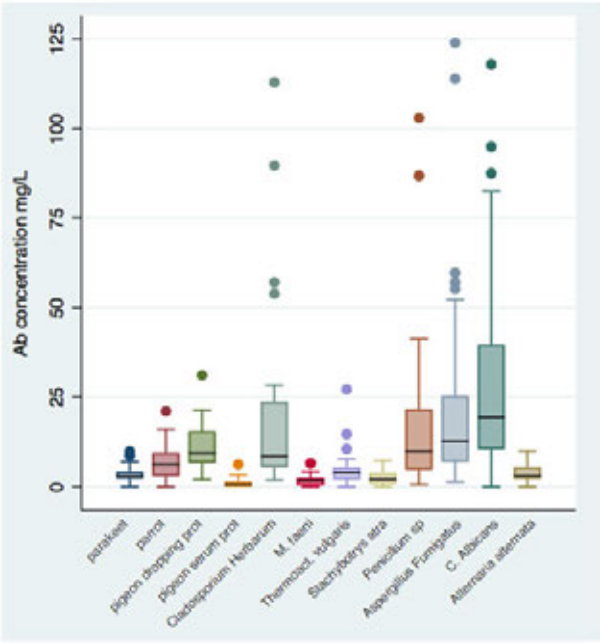

Figure 1. Summary of the distributions of AA and AF antibodies within the cohort M. faeni: Mycropolyspora faeni; Thermoact. vulgaris: Thermoactinomyces vulgaris

Antibodies against C. albicans, A. fumigatus, Penicillium spp, C. herbarum, and pigeon droppings proteins presented the highest levels within the cohort. A summary of the distribution of all Ab is shown in Figure 1.

Overall, 14 (40%) of patients had significant (positive) levels either AA or AF Ab according to our definition. 2 patients had double positivity, 2 had triple and 1 presented quadruple positivity; frequencies of each of the most represent-

Antibodies	n(%)	p90 (mg/L)
Anti-avian		
pigeon dropping proteins	7 (20%)	18
Anti-fungi		
Cladosporium Herbarum	4 (11.4%)	53.9
Penicilium spp	4 (11.4%)	36.1
Aspergillus Fumigatus	4 (11.4%)	57.1
Candida Albicans	4 (11.4%)	82.5
Total positive	14 (40%)	

Table 2. Frequency of patients having significant (positive) levels of antibodies. (Antibodies against parakeet, parrot, pigeon serum proteins, M faeni, St atra, T. vulgaris and A. Alternata antigens were excluded because of the low levels found).

atives Ab are shown in table 2. Of note, 5 out of 14 patients with reported positive Ab levels were not aware of any environmental exposure on anamnesis.

Conclusion: 40% of patients within our cohort presented significant levels of either AA or AF antibodies according to our strict definition. Adding these measurements to the routine work-up of RA-ILD could help the multidisciplinary team's diagnostic decisions. Further research is needed to determine their role in RA-ILD outcomes.

Treatment of Interstitial Lung Disease and Airway Disease Complicated with Rheumatoid Arthritis

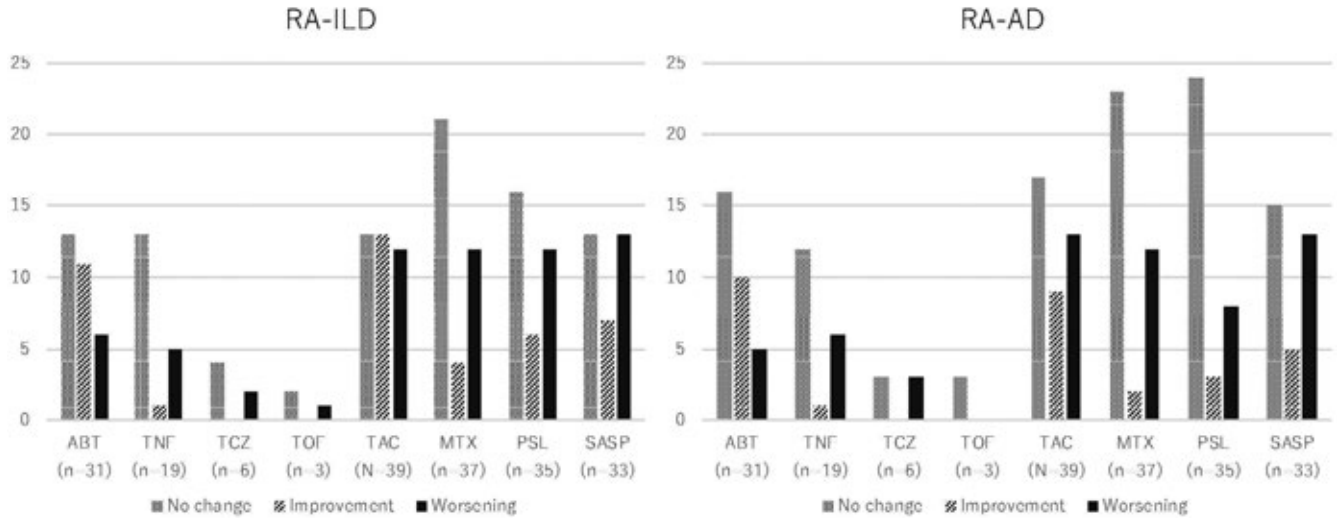
Takeshi Shoda,[1] Tohru Takeuchi,[2] Takuya Kotani,[2] Koji Nagai,[2] Kennichiro Hata,[2] Shigeki Makino,[2] and Shigeki Arawaka[2], [1]Yodogawa christian hospital / Osaka medical college, Osaka, Japan, [2]Osaka medical college, Osaka, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) complicated with rheumatoid arthritis (RA) is detected in 27 to 67% of patients on high-resolution computed tomography (HRCT), and airway disease (AD) are detected in 39 to 60%. These contribute to an increase in the mortality rate in comparison with RA without respiratory complications. However, the most appropriate treatment for RA-ILD or AD has not been established. In this study, we examined the effectiveness of treatments for these disorders.

Methods: The subjects were consecutive RA patients with ILD and/or AD who were registered in the RA registry in our department between January 2015 and September 2017, and could be followed-up for ≥1 year after the start of intensified treatment. We investigated the clinical data, contents of treatment, imaging findings, and

Figure 1



prognosis after 1 year. HRCT assessment was blindly performed by two pulmonologists specializing in interstitial pneumonia.

Results: The subjects were 95 patients with RA-ILD and/or AD complicated with RA (36 males, 59 females, mean age: 70.0 ± 9.9 years). 87 patients had RA-ILD, 65 had AD, and 57 (60%) had both. 80 patients (84.2%) were positive for RF, and 77 (81%) were positive for ACPA. The mean KL-6 level was 332 U/mL[223-602]. The HRCT pattern was evaluated as UIP in 49 patients (51.6%), NSIP in 27 (28.4%), and others in 11 (11.6%). Concerning treatment, MTX was selected in 37 patients (38%), with a mean dose of 6.9 ± 2.4 mg. PSL was selected in 35 (36%), with a mean dose of 5.6 ± 3.1 mg. TAC was selected in 36 (37%), with a mean dose of 2.1 ± 0.8 mg. IGU, SASP, and BUC were selected in 2 (0.02%), 33 (34%), and 6 (0.06%) patients, respectively. bDMARDs and TOF were used in 61 patients (64%): INF, 3 patients (3%); ETN, 6 (6%); ADA, 5 (5%); GLM, 5 (5%); CTZ, 0 (0%); ABT, 29 (30%); TCZ, 5 (5%); and TOF, 3 (3%). Many patients received ABT. With respect to the prognosis after 1 year, ILD exacerbation on HRCT was correlated with the KL-6 level (p=0.054), but there was no correlation between the exacerbation of AD and KL-6 level (p=0.408). As shown in Figure 1, the improvement ratings of ABT and TAC were higher than that of PSL when investigating the treatment response on HRCT. However, those of TNF and MTX were extremely low.

Conclusion: To treat RA-ILD, biologics were used in 64% of the subjects, suggesting their safety. ABT and TAC may be useful for the treatment of RA-ILD or AD.

Findings of Pulmonary Abnormalities on High Resolution Computed Tomography in a Cohort of Rheumatoid Arthritis Patients Without Known Lung Disease

Scott Matson,[1] Kevin Deane,[2] Christopher Collora,[1] Xi Zheng,[1] Marie Fester,[1] Joyce Lee,[1] and M. Kristen Demoruelle[3], [1]University of Colorado, Denver, [2]University of Colorado Denver, Division of Rheumatology, Aurora, CO, USA, Aurora, CO, [3]University of Colorado Denver, Division of Rheumatology, Aurora, CO, USA, Aurora

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary manifestations of rheumatoid arthritis (RA) lead to significant morbidity and mortality. Lung manifestations in RA are myriad, however little is known about how to predict those patients at highest risk for development of clinically significant disease.

Methods: In this study we performed a screen for lung disease by high resolution computed tomography (HRCT) scan in a population of patients with RA without known interstitial lung disease. We also collected baseline demographics, clinical information and blood was tested for RA associated antibodies including anti-CCP3 (IgG), CCP3.1 (IgG/IgA), and RF. Chest imaging was reviewed and interpreted by two radiologists with expertise in thoracic radiology who independently reviewed all HRCT scans using a scoring algorithm supplied by the research investigators. For those interpretations which were discriminant between readers, the radiologists discussed the case and came to consensus. We compared demographics (gender, age, duration of RA) and antibody profiles between RA patients with abnormal imaging on HRCT and those who did not have pulmonary disease.

Results: We screened 55 patients from the rheumatology clinic at the University of Colorado, who denied having any lung disease, with HRCT. We found that 31% (n=17) of the patients had findings of pulmonary fibrosis (as defined by abnormal reticulations, evidence of traction bronchiectasis or honeycombing). These 17 patients were determined to have fibrosis in “possible” or “probable” usual interstitial pneumonia (UIP) pattern. We found that those patients with pulmonary fibrosis were older (65.3 vs 54.9 years, p=.007). There was no statistically significant difference in gender, smoking status, duration of RA or antibody profile between those with and without fibrosis. Of the 55 patients scanned, we also found that 62% (n=34) had airways disease as determined by consensus findings of air trapping and bronchial wall thickening without findings of emphysema. In this small cohort, there was no association between presence of airways disease and age, smoking status, duration of RA or antibody positivity.

Conclusion: In this at-risk population for lung disease, we found 31% of RA patients without known lung disease to have findings of pulmonary fibrosis and 62% to have HRCT findings of airways disease. Prospective study of an at risk population for development of lung disease may help inform screening methods.

TABLE 1			
	Fibrosis	No fibrosis	
	n=17, 31%	n=38

Association of Serum KL-6 Level and Change of Pulmonary Function in Interstitial Lung Disease of Rheumatoid Arthritis - Data from Prospective KOrean Rheumatoid Arthritis Interstitial Lung Disease (KORAIL) Study

Jeong Seok Lee,[1] Young Im Yoon,[2] Eun Young Lee,[3] Jung Yoon Choe,[4] Hwa Jung Lee,[5] Yong-Beom Park,[6] Eun Ha Kang,[7] You-Jung Ha,[7] Yeon-Ah Lee,[8] and Seong Hye Jang[9], [1]Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea, [2]Seoul National University Hospital, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Seoul, Republic of Korea, [4]Division of Rheumatology, Daegu Catholic University Medical Center, Daegu, Republic of Korea, [5]DAEGU CATHOLIC UNIVERSITY, Daegu, Republic of Korea, [6]Yonsei university college of medicine, severance hospital, Seodaemun-gu, Seoul-t'ukpyolsi, Republic of Korea, [7]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea, [8]School of Medicine, Kyung Hee University, Seoul, Republic of Korea, [9]Soonchunhyang University, Cheonan, Republic of Korea

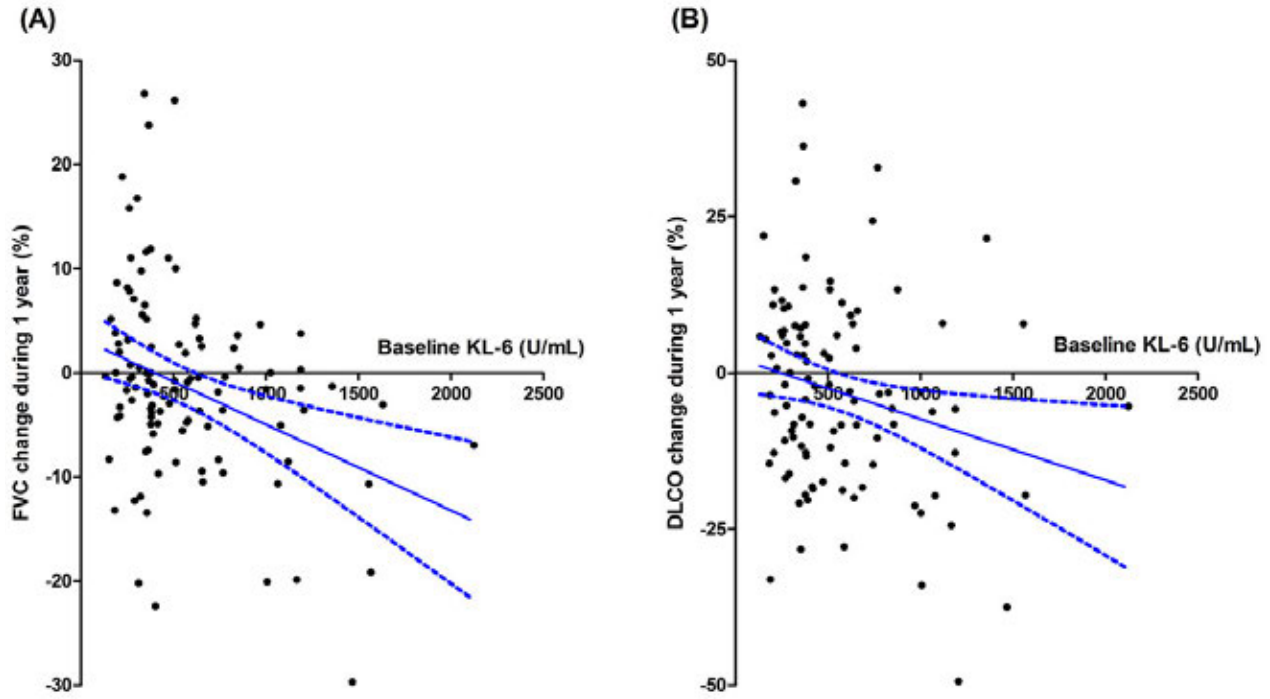
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the most common lung disease among rheumatoid arthritis (RA) patients. Although the overall mortality rates for RA have decreased in general, ILD is associated with increased morbidity and mortality of RA patients, especially in older age groups. We have launched a multicenter prospective cohort of RA-ILD named as KOrean Rheumatoid Arthritis Interstitial Lung disease (KORAIL) cohort, to explore clinical prognosis using biomarkers and imaging modalities. This is the first disclosure of results originated from KORAIL cohort.

To describe general clinical characteristics of KORAIL cohort. To elucidate the role of serum concentration of Krebs von den Lungen-6 (KL-6), a potential biomarker of ILD, in evaluation of current status and prediction of functional change during first 1 year after enrollment. The association between KL-6 concentration and inflammatory cytokines were also investigated.

Methods: Entering clinical information to e-case report form, chest CT, pulmonary function test, and blood samples were conducted at baseline and followed every year. Serum KL-6 concentration (U/mL) was measured through the Nanopia KL-6 assay latex-enhanced immunoturbidimetric assay method. Multiplex ELISA was used to measure serum concentration of TNF-alpha, IL-6, GM-CSF, and IL-17.

Results: One hundred and sixty eight patients with RA-ILD have been enrolled from six university hospitals in Korea. Till January 2019, 129 patients (76.8%) were followed for 1 year, 71 patients (42.3%) for 2 years, and 21 patients



Higher baseline KL-6 could predict functional deterioration of RA-ILD in next 1 year

(12.5%) for 3 years. RA was diagnosed at 58.7±11.3 (mean±SD, years old), ILD at 63.7±8.6, and enrolled at 66.4±8.0. Baseline KL-6 was significantly associated with baseline DLCO (r=-0.196, p=0.029), 1 year change(%) of FVC (r=-0.319, p=0.001) (figure A) and DLCO (r=-0.191, p=0.048)(figure B). TNF-alpha, IL-6, GM-CSF, and IL-17 had no association with functional deterioration or KL-6.

Conclusion: KL-6 could predict functional deterioration of RA-ILD in next 1 year.

Treatment with Biologic DMARDs Does Not Increase Risk of Severe Pulmonary Events in Patients with Rheumatoid Arthritis and Pre-existing Lung Disease

Shinji Watanabe,[1] Takahisa Gono,[1] Ryosuke Fukue,[1] Seiji Kobayashi,[1] Yuichiro Shirai,[2] Mitsuhiro Takeno,[3] and Masataka Kuwana[2], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Tokyo, Japan, [2]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan, [3]Nippon Medical School, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary complication is one of the leading causes of mortality in patients with rheumatoid arthritis (RA). Pre-existing lung disease is known as a risk factor for development of severe pulmonary events during treatment with synthetic and biologic disease-modifying anti-rheumatic drugs (DMARDs). However, it remains unknown whether risk of severe pulmonary events is higher in patients treated with biologic DMARDs (bDMARDs) than those without, in the setting of pre-existing lung disease. This study is aimed to clarify this clinical question by using single-center cohort data.

Methods: This study used RA patients registered in a cohort enrolling consecutive patients with RA at Nippon Medical School Hospital, based on the following criteria: satisfaction of 2010 ACR/EULAR classification criteria; pre-existing lung disease, including interstitial lung disease (ILD), chronic obstructive pulmonary disease (COPD), bronchial asthma, airway disease such as bronchiectasisand bronchiolitis, and lung infection such as pulmonary non-tuberculosis mycobacteria (NTM)confirmed by chest CT; and follow-up of at least 52 weeks after chest CT imaging. Severe pulmonary event was defined by newly onset or reactivation pulmonary infection, newly onset or exacerbation of ILD, and drug-induced lung injury that require therapeutic intervention. Baseline characteristics and concomitant treatmentwere compared between patients treated with and without bDMARDs, Then, baseline characteristics and concomitant treatment were matched using the propensity score method. Cumulative rates for severe pulmonary events were compared using Kalan-Meier method, and statistical difference between 2 groups was tested by log-rank test.

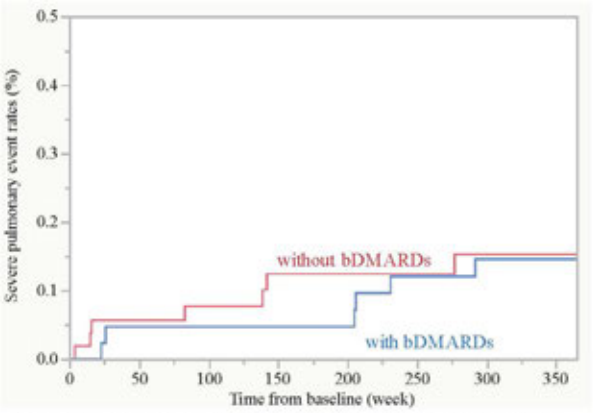

Figure 1A. Severe pulmonary event rates between patients treated with and without bDMARDs in a crude analysis.

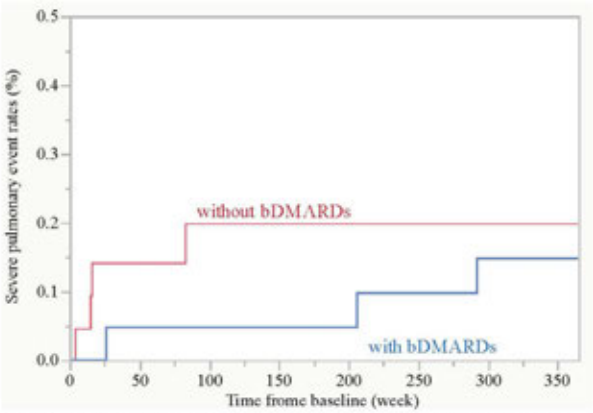

Figure 1B. Severe pulmonary event rates between patients treated with and without bDMARDs by matching baseline characteristics and concomitant treatment using the propensity score method.

Results: This study analyzed 99 patients with RA and pre-existing lung disease. The median age at enrollment was 73 years, and 59% were female. Pre-existing lung diseases included airway disease in 61, ILD in 44, COPD in 22, pulmonary NTM in 4, and bronchial asthma in one.During the follow-up of 52 weeks, 45 patients received 1 or 2 bDMARDs (TNF inhibitors in 15, abatacept in 19, and tocilizumab in 13), while the remaining 54 patients did not. A total of 17 severe pulmonary events occurred in 14 patients (9 pneumonia, 5 worsening of ILD, 2 drug-induced lung injury, and one *Pneumocystis jiroveci*pneumonia). In a crude analysis, there was no difference of cumulative severe pulmonary event rates between patients treated with and without bDMARD (15% versus 15% at 52 weeks, P = 0.81; Figure 1A). Younger age, higher KL-6, and higher anti-CCP antibody titer were significantly associated with use of bDMARDs, but methotrexate and corticosteroids were used similarly between the 2 groups. After propensity score matching by employing age, KL-6, and anti-CCP antibody titer, severe pulmonary event rates were still comparable between patients treated with and without bDMARDs (15% and 20% at 52 weeks, P = 0.54; Figure 1B).

Conclusion: Use of bDMARDs was not associated with increased risk of severe pulmonary events in RA patients with pre-existing lung disease, while this finding should be validated by independent multicenter cohorts.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) as an extra-articular manifestation of rheumatoid arthritis (RA) leads to significant morbidity and mortality. As data is limited, this study aims to investigate the efficacy of mycophenolate mofetil (MMF) in the treatment of RA associated ILD.

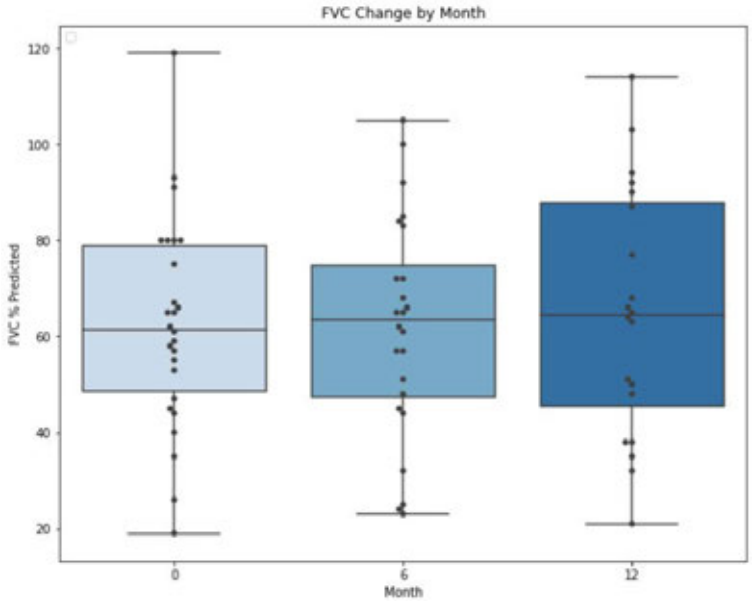
Methods: This retrospective chart review identified patients with a clinical diagnosis of RA and ILD at a single tertiary academic medical center who were treated with MMF for at least 3 months between 1/01/2005 and 12/31/2018. Patients were identified by diagnosis codes, then reviewed to confirm clinical diagnoses and to collect data on concurrent therapies, pulmonary function, infections and hospitalizations.

Results: Twenty six patients were identified; 17 female (65.4%) and 23 Caucasian (88.5%) with a mean age of 57.8 at the time of diagnosis of RA. RF was positive in 20 (76.9%), ACPA in 16 (61.5%) and 10 (38.5%) were seropositive for both, while 3 (11.5%) patients were seronegative. The mean time to diagnosis of ILD after diagnosis of RA was 40.6 months with a range of -50 to 504 months. Seven (26.9%) patients had an ILD diagnosis prior to RA.

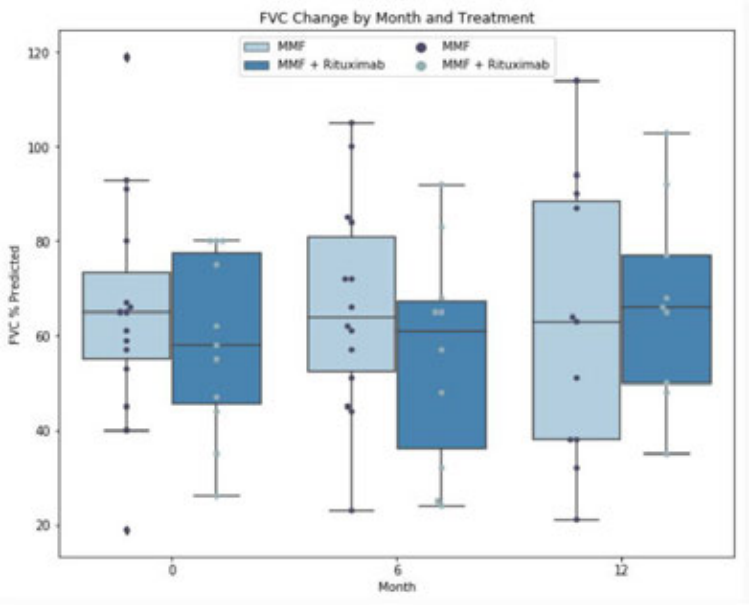
Fourteen (53.8%) patients had usual interstitial pneumonia (UIP), 5 (19.2%) nonspecific interstitial pneumonia (NSIP), 3 (11.5%) organizing pneumonia (OP), and 4 (15.4%) had other forms such as mixed UIP and NSIP. The average duration of MMF therapy was 24.9 months with an average maximum daily dose of 2163.5mg. Eleven (42.3%) patients were concurrently on rituximab (RTX), 1 (3.85%) on methotrexate, 1 (3.85%) on certolizumab, and 1 (3.85%) on sulfasalazine. Fifteen (57.7%) patients were on prednisone ≥10mg daily and 6 (23.1%) were on < 10mg daily for at least one month.

Average FVC for all patients was 62.4 ± 21.9% predicted at the time of initiation of MMF, 61.9% ± 23.0 predicted at 6 months (p=0.95), and 64.8% ± 25.9 predicted at 12 months (p=0.67). In aggregate, 13 (50%) patients on MMF had stable or improved FVC over the 12-month period, of whom 6/13 (46.2%) were on concurrent RTX. Six of 11 (54.5%) patients on combination MMF and RTX had stable or improved FVC over the 12-month period.

There were 26 hospitalizations in 8 (30.8%) patients; 17 (65.4%) for infections, 3 (11.5%) for respiratory failure, and 6 (23.1%) for cardiovascular events. Twenty four (92.3%) hospitalizations were in the combination MMF and RTX treatment group, including all infection related admissions. There were 10 outpatient infections treat-



Boxplot diagram showing the FVC percent predicted for all patients at the time of initiation of mycophenolate mofetil, at 6 months, and at 12 months



Boxplot diagram showing the comparison of the FVC percent predicted for patients on MMF without rituximab, compared to patients on combination therapy with mycophenolate mofetil and rituximab, at the time of initiation of mycophenolate mofetil, at 6 months, and at 12 months.

ed with antimicrobials. There were 8 (30.8%) deaths; 6 were in the MMF and RTX combination group. Two deaths were from infection and ILD, 2 from infection, 2 from cardiac disease, 1 from ILD, and 1 from myasthenia gravis crisis.

Conclusion: In this cohort of 26 RA patients with ILD, treatment with MMF as mono or combination therapy with RTX was associated with a stable or improved FVC in 50% of patients at 12-month. About 55% of patients on combination MMF and RTX showed stability or improvement in FVC. Patients treated with MMF compared to combination MMF and RTX had similar FVC values at the end of the study period, however, the combination therapy had more hospital admissions and infections. Further studies are needed to better understand the efficacy and safety of MMF or combination therapy with RTX in RA associated ILD.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) is a severe extraarticular manifestation of rheumatoid arthritis (RA).

Interstitial lung disease (ILD) associated with Rheumatoid Arthritis (RA) has a poor prognosis. Effectives treatments in RA such as anti-TNF have been implicated in the exacerbation of ILD.

Our objective was see the efficacy of Abatacept in ILD associated with RA.

Methods: Retrospective multicenter study of RA patients with ILD treated with ABA atleast for 3 doses. The ILD was diagnosed by HRCT. We have analyzed the following variables: **a)** 1-point change the Modified Medical Research Council (MMRC); **b)** FVC improvement or decline ≥10%; improvement or decrline ≥10% in DLCO **c)** radiological improvement in HRCT scan, **d)** changes in DAS28 score. **e)** prednisone dose. Values were compared with baseline.

Results: We studied 263 patients (150 women /113 men) with ILD associated to RA. The patients were smokers or exsmoker in a 53%. APCC was positive in 88.6%. The follow-up mean was 22.66±19.66 months.

Figure 1	
MMRC, Available data 230	
-Stable	73,4%
-Improvement	20,9%
-Worsening	5,7%
FVC, Available data 162	
-Stable	75,3%
-Improvement	12.3%
-Worsening	12,3%
DLCO, Available data 140	
-Stable	75,7%
-Improvement	15%
-Worsening	9,3%
HRCT, avalaible data 128	
-Stable	57,8%
-Improvement	18,8%
-Worsening	23,4%

The mean age was 64.64 ± 10 years. The median to progression of ILD was 12 [3-41.25] months. The mean DLCO at onset was 65,68±18.33 and the FVC at onset was 85.88±21.77 111 patients were treated in monotherapy.

The most frequent pattern was UIP 41,6% 32,7% NSIP 24,7% “others” thats include mixed patterns BONO or BO.

The Figure1 expresses the evolution of the avalible data.

DAS28 also improved from 4.501±1.486 to 3.107±1.333 and we also appreciate a decrease in the dose of prednisone from the initial mean 7.5 [5-10] to the final mean 5mg [5-7.5]. The global mean of FVC at the end of follow up was 85.3±20.69 the global mean of DLCO at the end of follow up was 65.35±19.88 both similar to the onset mean.

Conclusion: Abatacept could be a relatively safe and effective treatment for patients with interstitial lung involvement associated with rheumatoid arthritis. However, should be verified in prospective and randomized studies.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A wide spectrum of interstitial lung abnormalities (ILA) occurs in patients with rheumatoid arthritis (RA). This study characterized ILA in large single-center cohort, including identification of risk factors and parameters that may influence ILA´s progression.

Methods: All clinically-indicated computed tomography (CT) chest scans performed in adult RA patients from 2014-16 were evaluated for the presence of ILA using a sequential reading method. ILA were defined as nondependent changes affecting more than 5% of any lung zone and included nondependent ground-glass or reticular opacities, diffuse centrilobular nodularity, nonemphysematous cysts, honeycombing or traction bronchiectasis. Scans were classified as (a) no ILA, (b) indeterminate (focal alterations with less than 5% involvement of the lung) or (c) ILA; ILA were further subdivided into subpleural, centrilobular, mixed, and extensive distributions.The progression of ILA was determined visually and subsequently quantified by two independent observers blinded to clinical information. Univariate analyses were conducted with Fisher exact test and two-tailed t-tests or Wilcoxon rank-sum tests where appropriate. For multivariate analyses, unadjusted and adjusted logistic regression models were used to assess the strength of the association between RA-ILA and variables of interest. P-values < 0.05 were considered statistically significant.

Results: 293 patients were scored for the presence of ILA. Chest CT were mostly indicated due to respiratory signs and/or symptoms (n = 131), but also not related to pulmonary indications (n = 115), and reasons not identified (n = 44). Twenty -five patients (9%) that presented indeterminate ILA were excluded from the analysis, remaining 268 patients. Sixty-four (22%) presented ILA, predominantly older male smokers, and less likely on biologics/small molecule disease-modifying anti-rheumatic drugs **(table 1)**. The most common pattern of distribution observed was subpleural **(table 2).** Among ILA, 15 (43%) had usual interstitial pneumonia (UIP) or probable UIP on CT, 5 (14%) had

[b] infliximab, etanercept, adalimumab, golimumab, certolizumab

Missing data (Progressor / Non-progressor): RF (n=3 / n=8), ACPA (n=4 / n=7)

Abbreviations: ILA: interstitial lung abnormalities; RA: rheumatoid arthritis; DAS: disease activity score; ERS: erythrocyte sedimentation rate; RF: rheumatoid factor; ACPA: anti-citrullinated protein antibodies; DMARD: disease modifying anti-rheumatic drugs; CT: computed tomography.

nonspecific interstitial pneumonia (NSIP), and 15 (43%) had an unclassifiable pattern. Of the 56 ILA patients with sequential CTs, 38% had evidence of radiologic progression over 4.4 years.

Comparing “progressors group” with “non-progressors group”, the only statistically significant difference among the two groups was a higher median baseline ILA involvement in “progressors”. **(table 3)**

Conclusion: We identified that ILA in RA patients is characterized predominantly by UIP in a subpleural pattern, with an impressive high rate of progression in approximately four years. A lower frequency of biological/small molecules drugs in the non-ILA group is probably explained by a bias of indication due to pulmonary comorbidities. Greater baseline ILA extent, but not RA treatment (even methotrexate and anti TNF), was the most important risk factor for progression. Active surveillance is therefore recommended for these patients.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a leading cause of death in patients with rheumatoid arthritis (RA). In end-stage RA-ILD, lung transplant becomes the only option for these patients. However, there are concerns about worse outcomes and a higher risk of allograft dysfunction in patients with RA after lung transplantation due to the underlying immune dysregulation in this population. The main aim was to assess post-transplant survival in patients with RA-ILD compared with patients with idiopathic pulmonary fibrosis (IPF). Secondary outcomes included rate of acute rejection and chronic rejection.

Methods: Single center study in a referral center for lung transplant of all patients with RA-ILD who underwent lung transplantation from 2008 to 2017 compared with a control group of patients with IPF matched for age, transplant year and basiliximab induction. Cumulative survival rates after lung transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test. Distributions of categorical variables were compared by Pearson Chi2 or Fisher exact test as appropriate.

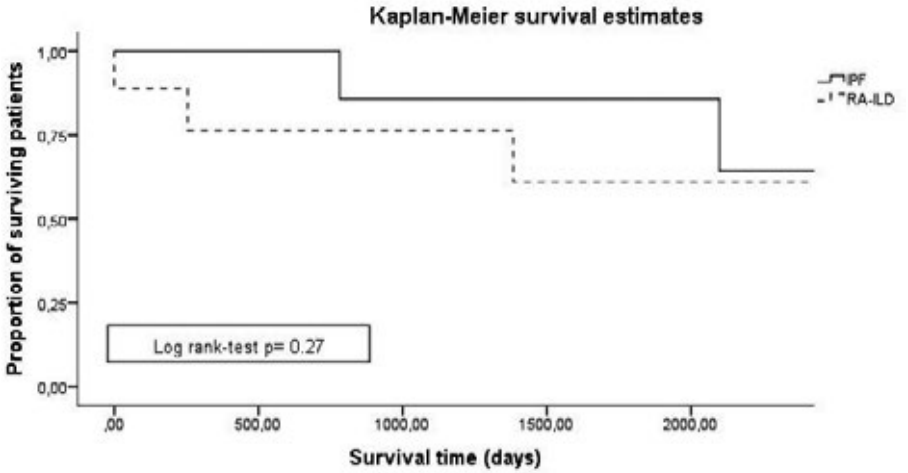
Results: Patients with RA-ILD (n=9) had similar baseline characteristics than IPF patients (n=9) which are shown in the **TABLE**. All patients with RA showed the histological subtype of usual interstitial pneumonia. RA-ILD patients

TABLE

	IPF (n=9)	RA-ILD (n=9)	P
Age *(years)*, mean ± SD	60.9 ± 5.1	58.2 ± 10.2	0.86
Sex *(women)*, *n (%)*	4 (44.4)	6 (66.7)	0.64
Time on waiting list (*days*), median [IQR]	99.0 [14.5-345.0]	90.0 [35.0-161.3]	0.92
Smokers, n (%)	5 (55.6)	6 (66.7)	0.99
Type of transplant (*bilateral*), n (%)	3 (33.3)	4 (44.4)	0.99
Donor CMV + and recipient CMV -, n (%)	2 (22.2)	1 (11.1)	0.45
Basiliximab induction, n (%)	2 (22.2)	2 (22.2)	0.99
Variables at transplant			
FEV 1 (%), median [IQR]	55 [34.0-82.6]	52 [41.8-66.3]	0.97
FVC (%), median [IQR]	53 [36.0-72.3]	57 [44.7-71.8]	0.36
FEV1/FVC, median [IQR]	82 [79.0-84.0]	78 [72.0-96.0]	0.74
DLCO	34 [23.0-40.0]	39 [32.0-64.5]	0.17
KCO	65 [52.0-70.0]	74 [63.0-100.0]	0.09
Serum creatinine (*mg/dL*), mean ± SD	0.79 ± 0.16	0.73 ± 0.28	0.37
Right catheterization, n (%)	4 (44.4)	6 (66.7)	0.64
mPAP (*mm Hg*), mean ± SD	21.0 ± 2.7	30.8 ± 8.9	0.15
PCP (*mm Hg*), mean ± SD	11.7 ± 1.5	13.7 ± 3.6	0.60
Treatment pre-transplant			
Glucocorticoids, n (%)	6 (66.7)	8 (88.9)	0.58
Immunosuppressive drugs, n (%)	2 (22.2)	9 (100.0)	0.002
Allograft dysfunction			
Acute rejection	7 (77.8)	4 (44.4)	0.34
Chronic rejection	1 (11.1)	2 (22.2)	0.45

DLCO: diffusing capacity of lung for carbon monoxide; IFP: idiopathic pulmonary fibrosis; ILD: associated interstitial lung disease; KCO: transfer coefficient of the lung for carbon monoxide; RA-ILD: rheumatoid arthritis-ILD; mPAP: mean pulmonary arterial pressure; PCP: pulmonary capillary pressure.

tended to experience acute graft rejection less commonly than those with IPF (77.8% vs 44.4%; p=0.34). However, a non-statistically significant increased frequency of chronic graft rejection was observed in the group of RA-ILD (11.1% vs 22.2%; p=0.45). Cumulative survival rates at 5 year post-transplant did no differ significantly between RA-ILD and IFP [61.0% vs 85.7% (p=0.27)] **(FIGURE 1)**.



Conclusion: Patients who underwent lung transplantation for RA-ILD in our center showed a trend to lower long-term post-transplant survival than in those with IPF. This could be explained by an increased frequency of chronic graft rejection. However, in selected candidates, RA-ILD should not be considered a contraindication for lung transplantation.

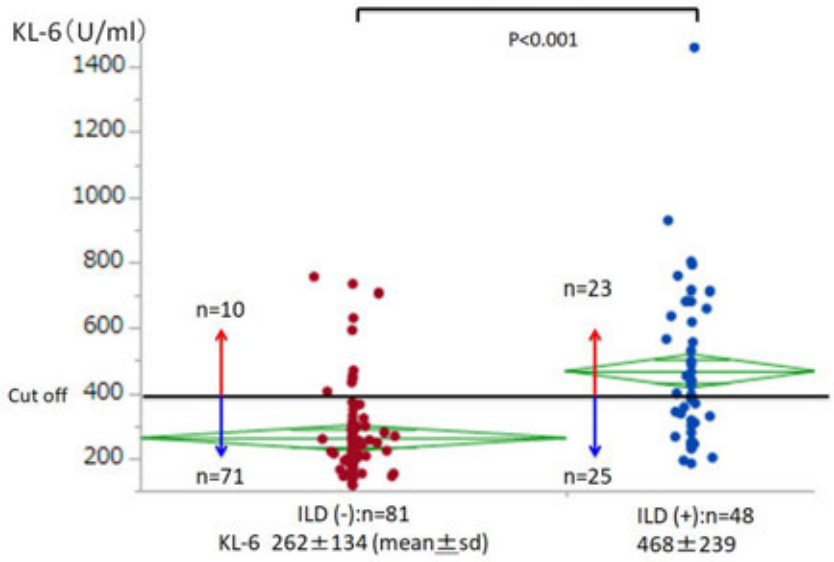
Abstract Number: 2348

KL-6 Is a Useful Marker to Monitor the Progression of RA-ILD, but Not to Diagnose or Predict the Development of ILD

Yuta Takamura,[1] Ayae Tanaka,[1] Kazuhiro Kurasawa,[1] Anna Hasegawa,[2] Chika Hiyama,[2] Toshiyuki Miyao,[1] Ryutaro Yamazaki,[1] Satoko Arai,[1] Takayoshi Owada,[1] Reika Maezawa,[1] and Masafumi Arima[2], [1]Dokkyo Medical University, Mibu-machi, Shimotsuga-gun, Tochigi, Japan, [2]Dokkyo Medical University, Mibu, Tochigi, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a critical comorbidity in RA. To manage RA-ILD, early diagnosis and monitoring disease progression are important. KL-6 is a marker of disease activity of ILD including CTD-ILD such as scleroderma. However, clinical values of KL-6 in the management of RA remain to be elucidated. The purpose of this study is to determine whether KL-6 elevation is useful to diagnose ILD, whether KL-6 elevation predicts newly developing/worsening ILD, and to whether KL-6 increase is associated with developing/worsening ILD.



Serum KL-6 levels in RA patients with/ without ILD

Methods:: A retrospective cohort study. Subjects were consecutive RA patients who started first biologic at Dokkyo Medical University Hospital and received HR-CT examination before and during biologics therapy and serum KL-6 levels were measured before the therapy. Medical records were reviewed retrospectively. Chest radiography was taken before biologics. When KL-6 levels were above 400 U/ml, KL-6 was judged as elevated. CT findings were accepted gold standard for the existence of ILD.

Results: Subjects were 129 patients, M/F; 44/85, mean age; 51.6year old, disease duration; 7.9 years, and RF-positivity; 83%. Chest radiography was taken in 107 cases. A sequential KL-6 examination was carried out in 86 cases. ILD was found in 48 patients (37%). At the entry, KL-6 levels were 468±239 U/ml in ILD group and 262±134 U/ml in non-ILD one (Fig.1). KL-6 elevation was found in 10/81 (11.3%) of non-ILD patients and in 23/48 (48%) of ILD ones.

The sensitivity, specificity, PPV and NPV of KL-6 to detect ILD were 0.47 0.70, 0.70 and 0.73, respectively, while the specificity, specificity, PPV and NPV of chest radiography were 0.6, 0.87, 0.67 and 0.65, respectively.

KL-6 at the entry failed to predict development/worsening of ILD. Newly emerging/ worsening ILD was found in 31/129 (24%) in whole. Newly emerging ILD was found similarly in 3/10 (30%) of patients with KL-6 elevation and 10/71 (14%) of those without elevation in non-ILD group (p=0.20). Worsening ILD was observed in 6/23 (26%) of patients with KL-6 elevation and 11/25 (44%) of those without the elevation in ILD group (p=0.23).

Increasing KL-6 levels during the observation period was associated with development/ worsening of ILD, which were observed in 23/50 (46%) of patients with KL-6 increase and 3/36 (8%) of those without the increase (p=0.0002). Similarly, development of ILD was found in 12/29 (41%) of non-ILD patients with KL-6 increase and 2/23 (9%) of those without the increase (P=0.009), and worsening of ILD was observed in 11/21 (52%) of ILD patients with KL-6 increase and 1/13(8%) of those without the increase (P=0.008).

Conclusion: KL-6 levels were increased in RA with ILD. However, KL-6 elevation was found in non-ILD patients, and there were ILD patients without KL-6 elevation. The ability of KL-6 to detect ILD is low like chest radiography. KL-6 elevation failed to predict development/worsening of ILD. However, the increase in KL-6 level is associated with development/worsening of ILD. Thus, KL-6 is a useful marker to monitor activity of ILD, but not to diagnose and predict it.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the most common lung manifestation of RA and the 2nd leading cause of death in RA patients.[1,2] The purpose of this literature review was to characterize the epidemiology, risk/prognostic factors, and treatment landscape of rheumatoid arthritis-associated interstitial lung disease (RA-ILD).

Methods: A systematic literature review was conducted by searching MEDLINE, Embase, and Cochrane CENTRAL (inception-Dec 26, 2018) supplemented by conference proceedings from ACR and EULAR, and US and European clinical trial registries (2016 to 2018). Randomized controlled trials (RCTs), non-randomized clinical trials, and observational studies that investigated therapies for adults with RA-ILD and reported efficacy and safety outcomes were

Table 1: Breakdown of study count per intervention

included. This was supplemented by a comprehensive search using Doctor Evidence LLC's proprietary search platform (DOC Search) containing MEDLINE, clinicaltrials.gov, WHO-ICTRP, EPAR, Daily Med, and RSS feeds, targeting the most relevant literature on the epidemiology and risk/prognostic factors associated with RA-ILD.

Results: The results of search and screening yielded 42 publications eligible for evidence synthesis; 22 studies reporting on the epidemiology and risk/prognostic factors and 20 studies (1 non-randomized clinical trial and 19 observational studies) on treatments for RA-ILD (Figure 1).

Unadjusted incidence of ILD in RA patients ranged from 1.3/1,000 person-years for interstitial pneumonia-type ILD to 5.0/1,000 person-years for "probable or definite ILD." RA-ILD prevalence ranged widely from 1.8% to 67%. This variation is more likely attributable to the difference in sample sizes, definitions of ILD, and how ILD was diagnosed across the eligible studies. Comorbidities among patients with RA-ILD included ischemic heart disease (13%), congestive heart failure (8.5%), and diabetes (9.9%). Advanced age was the strongest predictor of developing ILD with

pre-existing RA and poorer prognosis once RA-ILD was present. Male gender, RA disease duration, and anti-CCP/CCP2 positivity were also reported as important potential risk factors for ILD. Of the 6 studies that included RA drug treatments in their multivariate models assessing risk factors for ILD among RA patients, only one identified drug use (steroids) as an independent risk factor for developing ILD.

A variety of therapies were used across studies with some studies reporting classes of medication, while others were focused on specific combinations of individual therapies (Table 1). The included studies showed moderate to good effect for all therapies used in RA-ILD for DAS28, dyspnea, diffusing capacity for carbon monoxide, forced vital capacity (FVC), forced expiratory volume (FEV1), FEV1/FVC, and exacerbation of ILD. Few safety outcomes of interest were reported.

Conclusion: This review highlights epidemiology and potential risk factors (male gender, RA duration, and anti-CCP positivity) for ILD development in RA patients. Well-designed RCTs and meta-analyses are warranted to fully assess optimal treatment efficacy and safety of RA-ILD therapies.

Derivation and Validation of a Biomarker-Based Cardiovascular Risk Prediction Score in Rheumatoid Arthritis

Jeffrey Curtis,[1] Fenglong Xie,[2] Cynthia Crowson,[3] Brent Mabey,[4] Darl Flake,[4] Richard Bamford,[4] Cheryl Chin,[4] Eric Sasso,[5] Elena Hitraya,[5] Alexander Gutin,[4] and Jerry Lanchbury[4], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Alabama at Birmingham, Birmingham, [3]Mayo Clinic Rochester, Rochester, [4]Myriad Genetics, Inc, South San Francisco, CA, [5]Crescendo Bioscience, South San Francisco, CA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster III: Comorbidities

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are at elevated risk for cardiovascular (CV) events, but efficient risk stratification based on CV prediction models is not part of routine clinical practice. We constructed and validated a biomarker-based CV risk prediction model and compared it to alternative risk prediction approaches.

Methods: Using Medicare administrative data 2006-2016, we constructed a cohort of RA patients age ≥40 with ≥1 RA diagnosis from a rheumatologist, excluding patients with malignancy, past myocardial infarction (MI) or stroke. Patients were linked to multi-biomarker disease activity (MBDA) test results obtained as part of routine care. The composite CV outcome consisted of MI, stroke, and CV death occurring within 3 years, using validated algorithms.

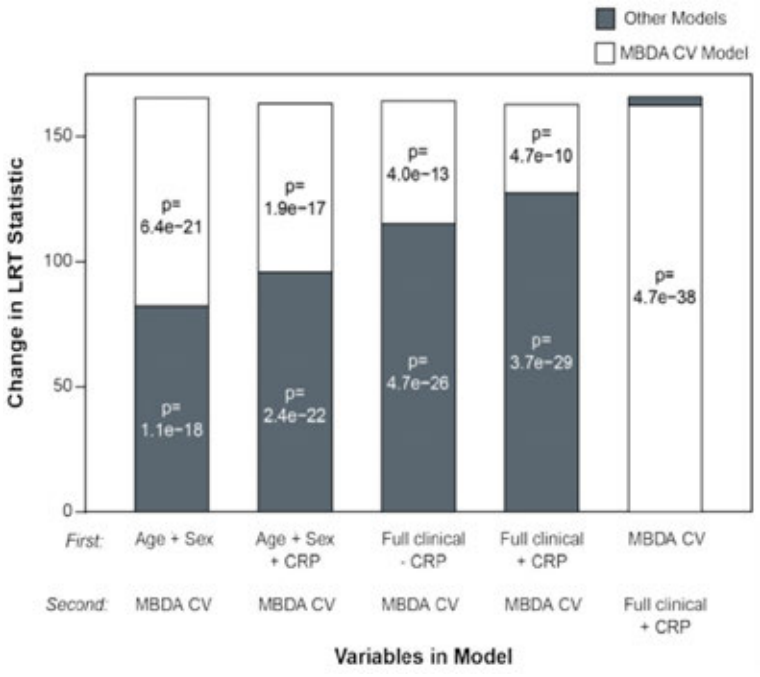

Figure 1: Incremental improvement of MBDA-based RA-CVScore compared to other CV Risk Prediction Models

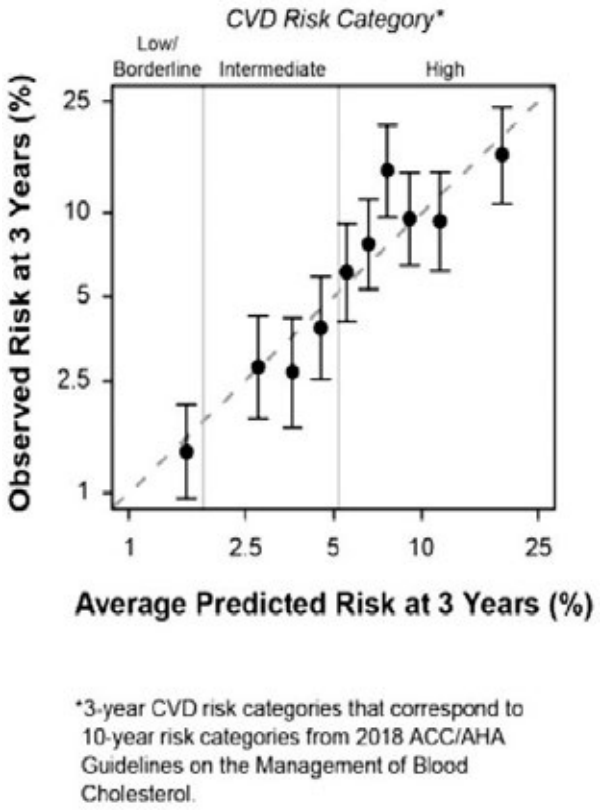

Figure 2: MBDA-Based RA-CVScore Calibration for Composite CV Outcome at 3 years

The cohort was split 2:1 to create a training dataset and an internal validation dataset. Clinical predictors were examined based on subject matter expertise, informed by existing risk prediction scores: age, sex, race, traditional CV risk factors (e.g. diabetes, hypertension, hyperlipidemia, high-risk CV conditions [e.g. ischemic heart disease]), RA-related factors (e.g. glucocorticoid use, methotrexate, number of prior biologics), MBDA score, and its 12 biomarkers, log-transformed. Backward elimination was used to remove predictors with $p \geq 0.05$. The resulting MBDA-based CV risk score was applied to the validation dataset to compare it to four different prediction models (age+sex; age+sex-+CRP; age+sex+diabetes+hypertension+smoking+high risk CV [±CRP]). We evaluated: 1) the incremental improvement in the likelihood ratio (LR) statistic, 2) discrimination (AUROC), and 3) calibration (predicted vs. observed, based on Kaplan-Meier estimates with 95% CI) in CV event-based deciles. Validation followed a pre-specified analysis plan.

Results: 30,751 RA patients were linked to MBDA test results and eligible for analysis. Patient characteristics were mean (SD) age of 68.7 (9.5) years, 23.4% age < 65, 82% women. Comorbidities included diabetes (39%), hypertension (78%), smoking (24%), and history of high-risk CV condition (37%). RA-related features included use of glucocorticoids (58%), methotrexate (60%), TNFi (33%) and other biologics (16%). Mean (SD) MBDA score was 41 (14). The final features included in the MBDA-based CV risk score were age, diabetes, hypertension, smoking, history of high-risk CV conditions, the MBDA score, leptin, TNFRI and MMP-3. Median (IQR) of predicted 3-year CV risk was 3.4% (2.1%, 5.6%). Based on extrapolation to 10-year risk, 19.6% of patients would be considered low/borderline, 52.2% intermediate, and 28.2% high risk per ACC/AHA 2018 guidelines.

Compared to all four simpler CV prediction models, significant improvement in the LR statistic was observed with the addition of the MBDA-based CV risk score (Figure 1). Model accuracy (calibration) was good across deciles (Figure 2). The AUROC was 0.70.

Conclusion: A simple, biomarker-based prediction score incorporating a few clinical risk factors appears to have good accuracy to predict CV risk in RA. Additional validation in independent cohorts will be helpful to verify its performance characteristics.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

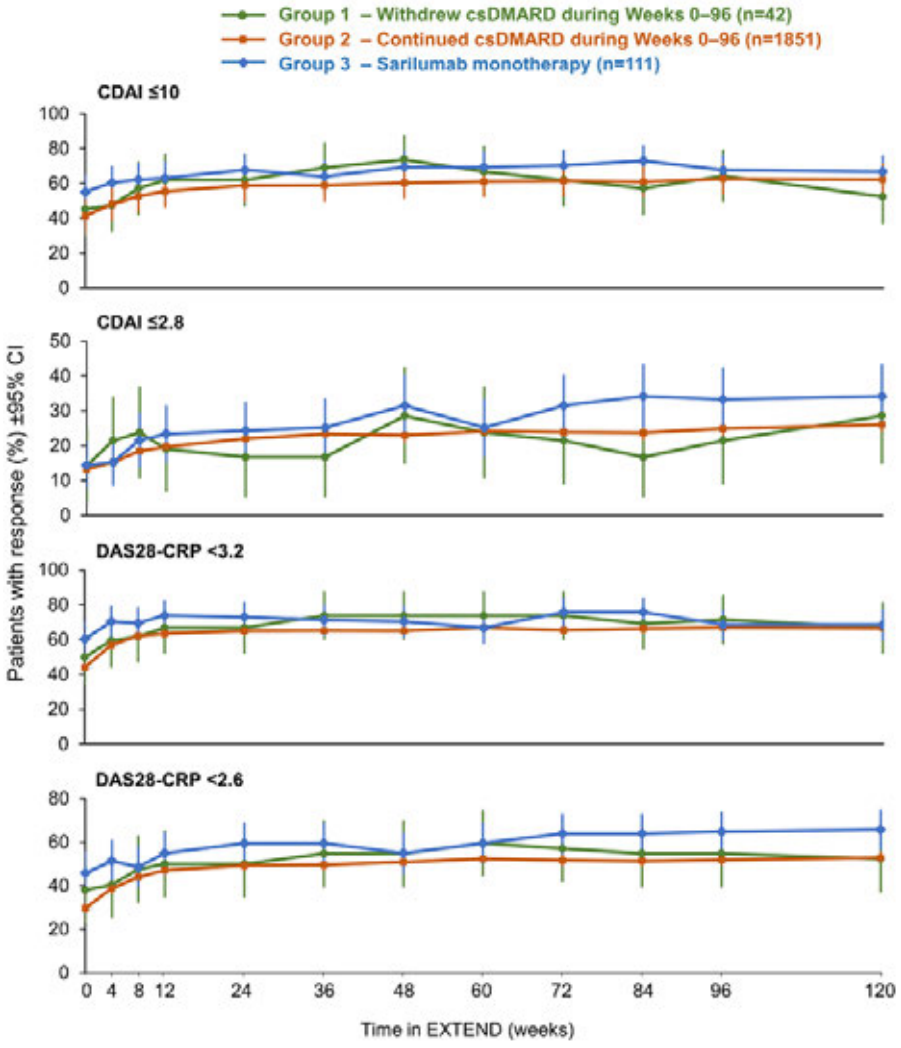
Background/Purpose: The EXTEND open-label extension study (NCT01146652) is collecting data on long-term treatment of RA with sarilumab as monotherapy and in combination with conventional synthetic disease-modifying antirheumatic drugs (csDMARDs), predominantly methotrexate. We conducted a post hoc analysis to compare outcomes between patients who received sarilumab monotherapy, sarilumab +csDMARDs, or discontinued csDMARDs during sarilumab treatment.

Methods: Patients enrolled in four trials of sarilumab SC 150 or 200 mg q2w +csDMARDs (MOBILITY, NCT01061736; TARGET, NCT01709578; ASCERTAIN, NCT01768572; and NCT01217814) and a sarilumab monotherapy study (ONE, NCT02121210) were eligible to receive open-label sarilumab SC 200 mg q2w in EXTEND, +csDMARDs if given in the parent trial. In EXTEND, csDMARDs could be stopped at the investigator's discretion (reasons not recorded). Post hoc analyses were conducted on three groups: Group 1 permanently discontinued csDMARDs at any time during Weeks 0–96 of EXTEND and then received sarilumab monotherapy; Group 2 continued csDMARDs; and Group 3 enrolled from the monotherapy study and never received csDMARDs. A subgroup of Group 1, patients who received csDMARDs during Weeks 0–12 and discontinued csDMARDs during Weeks >12–96, was used for sensitivity analysis.

Table. Summary of treatment-emergent AEs			
n (%) [number of events per 100 PYs]	**Group 1 Withdrew csDMARD during Weeks 0–96 (N=42) [PYs=104]**	**Group 2 Continued csDMARD during Weeks 0–96 (N=1851) [PYs=5870]**	**Group 3 Sarilumab monotherapy (N=111) [PYs=230]**
Any AE	41 (97.6) [225]	1626 (87.8) [184]	83 (74.8) [138]
Serious AE	17 (40.5) [17]	475 (25.7) [13]	16 (14.4) [10]
AEs leading to sarilumab discontinuation	15 (35.7) [16]	382 (20.6) [7]	8 (7.2) [3]

Results: There were 42 patients in Group 1, 1851 in Group 2, and 111 in Group 3, with minor differences between groups in demographics and disease characteristics at entry into EXTEND. At 96 weeks, 69%, 80%, and 83% of patients remained on study in Groups 1, 2, and 3, respectively. Similar substantial and durable response rates (Clinical Disease Activity Index [CDAI] ≤2.8 or ≤10, Disease Activity Score (28 joints)-C-reactive protein [DAS28-CRP] < 2.6 or < 3.2) were observed between patients who discontinued csDMARDs, patients who continued csDMARDs, and patients who never received csDMARDs (Figure). Results of the sensitivity analysis subgroup (n=27) were consistent with Group 1. The adverse event (AE) profile was as expected. AE incidence was greater in Group 1 than in Groups 2

Figure. Percentage of patients achieving CDAI ≤10 (low disease activity), CDAI ≤2.8 (remission), DAS28-CRP <3.2 (low disease activity), and DAS28-CRP <2.6 (remission); Last observation carried forward (LOCF) was used to impute missing values and/or for patients who discontinued treatment



and 3 (Table), including hepatic disorders (21, 7, 3 per 100 patient-years [PYs], respectively) and leukopenia (43, 13, 20 per 100 PYs, respectively). Rates of infection and serious infection were lowest in Group 3.

Conclusion: During the 120-week study, patients initially on sarilumab +csDMARDs who subsequently discontinued csDMARDs maintained similar clinical responses to patients who continued sarilumab +csDMARDs or received sarilumab monotherapy throughout. The AE profile was as expected, with no new safety signals.

Real-World Distribution of Anti-Cyclic Citrullinated Peptide Concentrations and Impact on Treatment Patterns of Patients with Rheumatoid Arthritis

Andrew J. Klink,[1] Bela Bapat,[1] Jill Kaufman,[2] Francis Lobo,[3] **Xue Han**,[3] Leticia Ferri,[3] Rick Szymialis,[3] Tayla Poretta,[3] and Bruce Feinberg[1], [1]Cardinal Health Specialty Solutions, Dublin, OH, [2]Cardinal Health Specialty Solutions, Dublin, [3]Bristol-Myers Squibb Company, Princeton, NJ

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Distinct subgroups of RA are being identified by clinical, biochemical, and genomic markers. ACPA positivity is one such biomarker associated with a clinical profile of early rapidly progressing RA. This study aimed to understand the distribution of anti-cyclic citrullinated peptide (anti-CCP2) concentration and its impact on treatment patterns among RA patients in the real-world community practice setting.

Methods: A retrospective cohort study using chart review methodology was used to abstract data of adult RA patients treated in US community rheumatology clinics with biologic disease modifying antirheumatic drug (bDMARD) within 1 year of data collection launch (April 2019). Rheumatologists provided patient-level data from medical records including demographics, biomarkers, treatment sequencing, and clinical outcomes. Patient characteristics and outcomes were summarized descriptively.

Results: The majority (77.6%; n=706) of 910 RA patients meeting eligibility were tested for ACPA at the time of RA diagnosis. Among the 75.9% (n=536) who were ACPA positive (anti-CCP2 >19 AU/mL), the anti-CCP2 quartiles observed were: 20-64 AU/mL, 65-142 AU/mL, 143-246 AU/mL, and 250-19,000 AU/mL. Gender distribution was similar (70%-75% female) across anti-CCP2 quartiles, while median ages were: 45.5, 42.0, 53.0, and 48.0 years, across increasing quartiles. The proportion of patients with rheumatoid factor positivity increased with each anti-CCP2 quartile (79.8%, 90.5%, 91.1%, and 93.1%, respectively). Prior bDMARD use was: 34.6%, 29.5%, 36.7%, and 40.5% in quartiles 1-4, respectively. Among the experienced bDMARD users, higher proportions of patients had ≥2 prior bDMARD use in higher quartiles (25.0%, 19.4%, 34.5%, and 32.1%, respectively). Current bDMARD use was similar across quartiles of anti-CCP2; 25.2% with ACPA positivity were treated with adalimumab, followed by 19.8% etanercept, 17.4% abatacept, 10.4% certolizumab, 10.4% tocilizumab, 6.5% infliximab, 5.4% golimumab, and 4.9% rituximab.

Conclusion: Results of this real-world evidence research demonstrate that while ACPA testing has achieved good adoption in US community rheumatology practice, anti-CCP titers do not appear to be correlated with bDMARD selection. Further research of the prognostic value of ACPA-positivity/titers may further aid in the clinical identification of the most appropriate bDMARD for each patient.

Klink,[1] Jill Kaufman,[2] Francis Lobo,[3] **Xue Han**,[3] Leticia Ferri,[3] Rick Szymialis,[3] Tayla Poretta,[3] and Bruce Feinberg[1], [1]Cardinal Health Specialty Solutions, Dublin, OH, [2]Cardinal Health Specialty Solutions, Dublin, [3]Bristol-Myers Squibb Company, Princeton, NJ

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Research is redefining RA as a heterogeneous group of diseases distinguished by clinical, biochemical, and genomic markers. ACPA positivity is one such biomarker associated with a clinical profile of early rapidly progressing RA (ERPRA). This study aimed to understand patterns of biomarker testing including ACPA and their impact on treatment patterns in RA patients in the real-world practice setting.

Current bDMARD	ACPA+ (n=536), n (%)	ACPA- (n=170), n (%)
Adalimumab	135 (25.2)	48 (28.2)
Etanercept	106 (19.8)	28 (16.5)
Certolizumab	56 (10.4)	14 (8.2)
Tocilizumab	56 (10.4)	19 (11.2)

Methods: A retrospective cohort study using chart review methodology was used to abstract data of adult RA patients treated in US community rheumatology clinics with bDMARD therapy ≤1 year of data collection launch (April 2019). Rheumatologists provided patient-level data from medical records including demographics, biomarker assessments, treatment sequencing, and clinical outcomes. Patient characteristics and outcomes were summarized descriptively.

Results: There were 910 RA patients meeting eligibility criteria and abstracted between March 2018 and February 2019. Most patients were tested for ACPA status at RA diagnosis (77.6%). Of the ACPA tested patients, 75.9% were ACPA+ (anti-CCP2 concentration >19 AU/mL) and 24.1% were ACPA-. The proportion of patients retested for ACPA status was similar between the 2 cohorts (22.6% ACPA+ vs. 25.9% ACPA-, P=0.67). The majority of RA patients were female (73.7% ACPA+ vs. 75.9% ACPA-, P=0.57), Caucasian (74.3% ACPA+ vs. 80.6% ACPA-, P=0.09), and were covered by commercial health insurance (68.8% ACPA+ vs. 63.5% ACPA-, P=0.20). Although racial distribution was similar among ACPA+ and ACPA- cohorts, ACPA positivity was more prevalent in ACPA tested African Americans compared to ACPA tested Caucasians (87.1% vs. 74.4%, P< 0.01). ACPA+ patients were younger on average compared to ACPA- patients (48 years vs. 52 years, P< 0.01). There were no regional differences by ACPA status. The rate of testing of traditional biomarkers at the time of current bDMARD use: erythrocyte sedimentation rate 92.7%, C-reactive protein 79.1%, RF 98.9%; these rates did not differ by ACPA status (all P >0.05). Higher proportion of ACPA+ patients were RF+ compared to ACPA- patients (90.1% vs. 50.0%, P< 0.01). The treatment with bDMARD had similar distribution regardless of ACPA status as presented in the table.

Conclusion: These retrospective real-world data demonstrate that ACPA testing has attained good adoption among RA patients in US community rheumatology practices. ACPA positivity significantly varies from other biomarkers but does not appear to influence treatment choice. Additional research is needed to affirm published data that ACPA levels may differentiate disease that may be more effectively treated by non-TNF inhibitor bDMARDs.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) constitutes first-line therapy in rheumatoid arthritis (RA). However, up to 40% of RA patients do not benefit from MTX therapy. To restrain joint damage, prediction of insufficient response to MTX prior to treatment is desirable to initiate alternative treatment options. Previously, we developed a prognostic multivariable prediction model for insufficient clinical response to MTX at 3 months in the "treatment in the Rotterdam early arthritis cohort" (tREACH, ISRCTN26791028). This model was replicated in another Rotterdam cohort (MTX-R), however, information on two predictors: smoking and BMI was absent. The purpose of the current study was to replicate the complete prediction model in an independent, non-Rotterdam early RA cohort (U-Act early), which included data on smoking and BMI.

Methods: Clinical, laboratory and life style parameters were assessed from 91 early RA patients of the MTX treatment arm of the U-Act early cohort (NCT01034137). 92% of the subjects met the 2010 ACR/EULAR classification criteria for RA. Insufficient response was defined as DAS28-ESR >3.2 after 3 months of MTX treatment. The following predictors and the corresponding cut-off values were defined in the prediction model for insufficient response: baseline DAS28 >5.1, baseline HAQ >0.6, baseline erythrocyte-folate < 750 nmol/L, Adenosine triphosphate Binding Cassette transporter (ABC) family B member 1 (ABCB1) rs1045642 genotype, ABCC3 rs4793665 genotype, current smoking and BMI >25kg/m2. Univariable and multivariable logistic regression models were used to assess the associations between the predictors and insufficient response to MTX in the current cohort, which was reported as odds ratio (OR) and 95% confidence intervals (CI). To assess the predictive power of the model, a receiver operating characteristic (ROC) curve was constructed from the predicted probabilities, with its corresponding area under the curve (AUC) and 95% CI. The model in the current study (U-Act early) was considered to be replicated when the 95% CI overlapped with that of the tREACH model (AUC: 0.80, 95% CI: 0.73 – 0.86).

Results: In the U-Act early, the AUC of the complete prediction model was 0.75 (95% CI: 0.64 – 0.85), which resembles the 95% CI of the tREACH (P >0.05). The strongest predictors were baseline DAS28 >5.1 (univariable OR=4.5, 95% CI: 1.7 – 11.6) and baseline HAQ >0.6 (univariate OR=3.0, 95% CI: 1.2 – 7.5), which together constructed a ROC with an AUC of 0.70 (95% CI: 0.59 – 0.80). With the exception of current smoking, all predictors contributed to the improvement of the prediction model in this study. For these predictors the AUC was also 0.75 (95% CI: 0.64 – 0.85).

Conclusion: We successfully replicated our previously published prognostic prediction model of insufficient MTX response constructed of genetic, clinical and life style variables in an independent cohort, where 75% of insufficient responders were correctly classified. A cost-benefit analysis will be decisive on which predictors to use when implementing the model in a clinical setting.

Abstract Number: 2355

Antirheumatic Therapy Is Associated with Reduced Complement Activation in Rheumatoid Arthritis

Thao Nguyen,[1] Ingrid Hokstad,[2] Gia Deyab,[3] Tom Eirik Mollnes,[4] Stefan Agewall,[4] Morten Fagerland,[4] Gro Eilertsen,[5] Mark Feinberg,[6] Knut Mikkelsen,[2] Øystein Førre,[4] and Ivana Hollan[7], [1]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [2]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Oppland, Norway, [3]Innlandet Hospital Trust, Bærum, Akershus, Norway, [4]Oslo University Hospital, Oslo, Norway, [5]The Artic University of Norway, Tromsø, Norway, [6]Harvard Medical School and Brigham and Women´s Hospital, Boston, Boston, MA, [7]Lillehammer Hospital for Rheumatic Diseases and Brigham and Women's Hospital, Boston, Lillehammer, Oppland, Norway

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammation and immune dysregulation appear to significantly contribute to increased risk of cardiovascular disease (CVD) in rheumatoid arthritis (RA). The complement system is a key component of the innate immune system, and recent research suggests that it might be involved in pathophysiology of CVD in the general population. However, information regarding complement activation in response to treatment and its importance in the development of premature CVD in RA is limited.

We will examine effects of methotrexate (MTX) and tumor necrosis factor inhibitors (anti-TNF) on complement activation using soluble C5b-9 (sC5b-9) levels in RA; and assess associations between sC5b-9 levels and established inflammatory biomarkers.

Methods: From the observational PSARA study, we assessed 64 RA patients starting with MTX monotherapy (n=34) or anti-TNF with MTX co-medication (n=30) due to active disease. The median age was 57 years, median RA duration was 5.5 years, and 73% were women. All patients starting with anti-TNF had previously been unsuccessfully treated with MTX. ELISA was used to measure sC5b-9 complexes in EDTA plasma immediately prepared and stored at minus 80^0C. The patients were examined at baseline and after 6 weeks and 6 months of treatment.

Results: At baseline, the median sC5b-9 level was 1.10 CAU/ml [IQR 0.70], and 57 (89%) patients had sC5b-9 above the upper limit of the estimated reference range (< 0.7). sC5b-9 levels were significantly lower at 6-week (median 0.85 CAU/ml [IQR 0.55]) and 6-month (median 0.80 CAU/ml [IQR 0.58]) visits compared to baseline (p< 0.0005 and p=0.014, respectively). There were no significant differences in sC5b-9 levels between patients treated with MTX monotherapy and those treated with MTX combined with anti-TNF treatment from baseline to 6 weeks (p=0.689) and from baseline to 6 months (p=0.901). The changes in sC5b-9 from baseline to 6 weeks and from baseline to 6 months positively correlated with changes in erythrocyte sedimentation rate (ESR; rs= 0.364, p=0.003 and rs= 0.372; p=0.002, respectively), and C-reactive protein (CRP; rs=0.411; p=0.001 and rs= 0.348; p=0.005, respectively). Similarly, baseline sC5b-9 levels were significantly related to baseline ESR and CRP levels.

Conclusion: Patients with active RA had elevated sC5b-9, indicating increased complement activation. sC5b-9 decreased with antirheumatic treatment during the 6-month treatment period. There were no differences between MTX monotherapy and anti-TNF regimens. Further studies are warranted to determine if the well-known cardioprotective effects of antirheumatic drugs might be partly due to their ameliorating actions on complement activation, and whether the complement system might be a target for therapy in RA.

Antirheumatic Therapy Is Not Associated with Changes in Circulating N-terminal Pro-brain Natriuretic Peptide Levels in Patients with Active Rheumatoid Arthritis

Thao Nguyen,[1] Gia Deyab,[2] Morten Fagerland,[3] Stefan Agewall,[3] Gro Eilertsen,[4] Mark Feinberg,[5] Knut Mikkelsen,[6] Øystein Førre,[3] and Ivana Hollan[7], [1]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway, [2]Innlandet Hospital Trust, Bærum, Akershus, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]The Artic University of Norway, Tromsø, Norway, [5]Harvard Medical School and Brigham and Women´s Hospital, Boston, Boston, MA, [6]Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Oppland, Norway, [7]Lillehammer Hospital for Rheumatic Diseases and Brigham and Women's Hospital, Boston, Lillehammer, Oppland, Norway

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) are predisposed to impaired cardiac function and heart failure (HF). While the pathophysiology has not been fully elucidated yet, inflammation is suspected to play an important role. However, the impact of disease-modifying antirheumatic drugs on cardiac dysfunction in RA remains controversial. Although anti-inflammatory drugs might have protective effects, some of them, i.e. tumour necrosis factor inhibitors (anti-TNF), might also negatively influence cardiac function. Serum N-terminal pro-brain natriuretic peptide (s-NT-proBNP) is used as a biomarker of cardiac function, and levels ≤125 ng/L with high probability exclude HF[1].

To examine effects of methotrexate (MTX) and anti-TNF regimens on s-NT-proBNP in patients with active RA, and to assess associations between s-NT-proBNP and endothelial function (EndoF).

Methods: From the observational PSARA study, we examined 64 RA patients starting with MTX monotherapy (n=34) or anti-TNF with MTX co-medication (n=30) due to active disease. All patients starting with anti-TNF regimens had

Table 1 Baseline characteristics

	All patients (n=64)	MTX monotherapy (n=34)	Anti-TNF regimens (n=30)
Age (years)	57 (28-79)	56 (28-79)	58 (39-75)
Women, n (%)	47 (73)	25 (73)	22 (73)
RA duration, years	5.5 (0-30)	3 (0-25)	8 (0-30)
Hypertension, n (%)	17 (26.6)	7 (20.6)	10 (33)
CVD (history of angina, MI, heart surgery, PTA, cerebrovascular disease, thromboembolism, aortic aneurysm, peripheral artery disease), n (%)	17 (26.6)	6 (17.6)	11 (36.7)

Unless indicated otherwise, values are given as mean (range)

been previously unsuccessfully treated with MTX. s-NT-proBNP (ELISA), EndoF (measured by finger plethysmography), and other laboratory and clinical parameters were evaluated at baseline and after 6 weeks and 6 months of treatment.

Results: Median age was 57 years (range 28-79), and 73% were women. 17 (27%) patients had CVD (history of angina, MI, heart surgery, PTA, cerebrovascular disease, thromboembolism, aortic aneurysm, peripheral artery disease). None of the patients had known/symptomatic HF. There were no statistically significant differences between s-NT-proBNP levels at baseline (median 2241 ng/L [IQR 9002]) and after 6 weeks (median 2300 ng/L, [IQR 8960]) and 6 months (median 2358 ng/L [IQR 7772]) of antirheumatic therapy (p=0.992 and p=0.528, respectively). There were no significant differences in the effects of MTX monotherapy and anti-TNF regimens on s-NT-proBNP levels (pbaseline-6weeks=0.779; pbaseline-6months=0.421). At baseline, 57 (89%) patients had s-NT-proBNP >125 ng/L, and 44 (69%) had high s-NT-proBNP levels (s-NT-proBNP >450 ng/L in patients < 50 years old and >900 ng/L in patients ≥50 years old), and these frequencies did not significantly change with antirheumatic treatment. s-NT-proBNP was not related to EndoF.

Conclusion: A large proportion of RA patients without known HF had elevated s-NT-proBNP levels, which might indicate subclinical impairment of cardiac function. s-NT-proBNP levels were not influenced by six-month MTX and/or anti-TNF treatment. Thus, in contrast to some previous studies, our data does not support the notion that anti-inflammatory treatment protects against HF, and that anti-TNF treatment has negative effect on cardiac function in RA. Nevertheless, definitive conclusions cannot be drawn by our study, e.g. due to limitations of s-NT-proBNP as surrogate marker of HF. Cardiac function in terms of s-NT-proBNP levels was not related to EndoF.

Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Liver test abnormalities are known to predict liver pathology in patients using methotrexate (MTX). Monitoring guidelines for MTX suggest frequent assessment of liver tests (AST and ALT). The frequency of liver test abnormalities and liver pathology (liver AEs) in patients using MTX varies substantially in prior studies and there are sparse placebo-controlled data on these issues. We examined liver AEs reported during follow-up in the

Table 1: Risk of Liver Adverse Events Reported Among Patients in CIRT Trial			
	MTX	Placebo	
	N = 2,391	N = 2,395	HR (95% CI)
Any AST or ALT abnormality	937 (39%)	511 (21%)	2.1 (1.9, 2.4)
Mild (>1-2x ULN)	906 (38%)	495 (21%)	2.1 (1.9, 2.4)
Moderate (>2-3x ULN)	152 (6%)	46 (2%)	3.4 (2.4, 4.7)

Table 2: Predictors of AST or ALT Abnormalities Among 2,391 Patients Taking MTX in the CIRT Trial	
Baseline variables	HR (95% CI)
Age, per year	0.99 (0.98 – 0.99)
Gender, male	1.07 (0.90 – 1.26)
Diabetes (vs no diabetes)*	0.93 (0.81 – 1.06)
Statin use, yes	1.17 (0.96 – 1.42)
Alcohol, per drink per week	1.17 (1.08 – 1.28)
*Inclusion for CIRT trial required diabetes or metabolic syndrome.	

Cardiovascular Inflammation Reduction Trial (CIRT), a randomized double-blind placebo-controlled trial of MTX for the prevention of cardiovascular disease.

Methods: The current analyses were pre-defined as secondary analyses of the CIRT trial (Ridker et al, NEJM 2019). AST and ALT were collected every 8-10 weeks during CIRT, dosages were adjusted by rheumatologists if liver tests were found to be abnormal, and work-up was recommended for patients with persistently elevated liver tests. Patients were randomized to receive MTX (target dose 15 to 20mg weekly) or placebo. Median trial follow-up was 2.3 years; maximum 5 years. All reports of liver AEs at routine visits or as hospitalized serious AEs were followed up with a request for medical records. These events were adjudicated using a standardized assessment by an internist (DHS) and liver specialist (AR). We examined the frequency in all patients of AST and ALT abnormalities (>upper limits of normal, ULN) and liver pathology, defined as cirrhosis, non-alcoholic steatohepatitis (NASH), and other. AST and ALT abnormalities were also categorized as mild (>1- 2 x ULN), moderate (>2-3 x ULN), or severe (>3 x ULN). The relative rates of these outcomes were estimated using hazard ratios (HR) in adjusted Cox regression. Adjusted Cox regression was also used to examine risk factors for first liver test abnormalities among patients in the MTX arm.

Results: 2,391 patients were randomized to MTX (median dosage of 16mg weekly) and 2,395 to placebo. During follow-up, in the MTX arm, 937 (39%) experienced an AST or ALT abnormality with a rate of abnormal tests (first or recurrent) of 11.5 per 100 tests (95% CI 11.1-11.9). In the placebo arm, 511 (21%) experienced an abnormal test with a rate (first or recurrent abnormality) of 5.1 per 100 tests (95% CI 4.8-5.3). The hazard ratio (HR) for first abnormal liver tests was 2.1 (95% CI 1.9-2.4) in MTX versus placebo. The risk for abnormal liver tests of different severity are shown in **Table 1**. There were 14 (0.6%) patients in the MTX arm and 9 (0.4%) in the placebo arm that were diagnosed with liver pathology during follow-up; the HR for these events was 1.6 (95% CI 0.7-3.6). These events were categorized as cirrhosis (n=6, 0.3% in MTX vs n=1, 0.04% in placebo) and NASH (n=8, 0.3% in MTX vs n = 8, 0.3% in placebo) (see **Table 1**). Predictors of ALT or AST abnormalities in the MTX arm included younger age and more alcohol intake at baseline (see **Table 2**).

Conclusion: Compared to placebo, the risk of abnormal AST or ALT was increased two to three-fold with MTX use; most abnormal values were only mildly elevated. More alcohol intake and younger age were the only clear risk factors for abnormal liver tests among patients randomized to MTX. We found few cases of cirrhosis during follow-up in either arm, but more in the MTX arm.

Abstract Number: 2358

Short-term Risk of Major Adverse Cardiovascular Events or Venous Thrombo-embolic Events in Patients with Rheumatoid Arthritis Initiating a Janus Kinase Inhibitor: A Meta-analysis of Randomised Controlled Trials

Margaux MALAURIE,[1] Arnaud Constantin,[2] Yannick Degboé,[1] Adeline Ruyssen-Witrand,[3] and Thomas Barnetche[4], [1]CHU TOULOUSE, TOULOUSE, France, [2]CHU TOUOUSE, TOULOUSE, France, [3]Rheumatology Unit, Toulouse university Hospital, UMR 1027, Inserm, Université Paul Sabatier Toulouse III, Toulouse, France, [4]FHU ACRONIM, Department of Rheumatology, Centre Hospitalier Universitaire, Bordeaux, France, Bordeaux, France

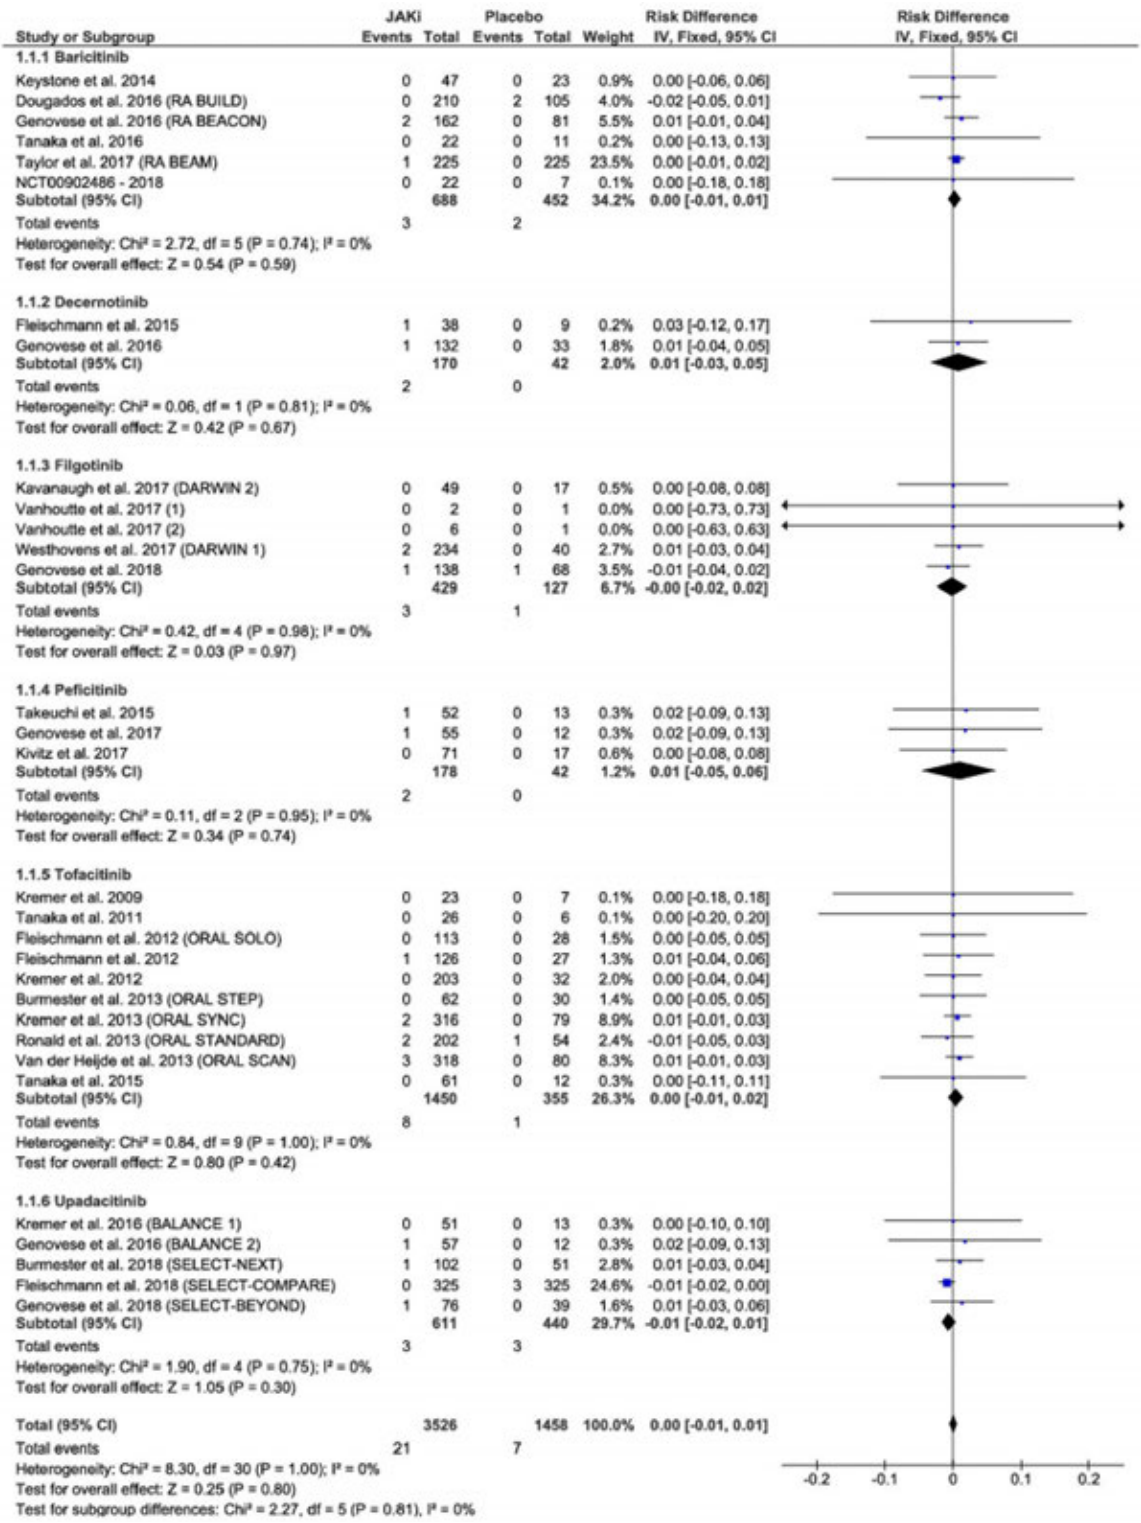
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The objective was to investigate the short-term risk of major adverse cardiovascular events (MACEs) or venous thromboembolic events (VTEs) in patients with rheumatoid arhthritis (RA) initiating a Janus kinase inhibitor (JAKi).

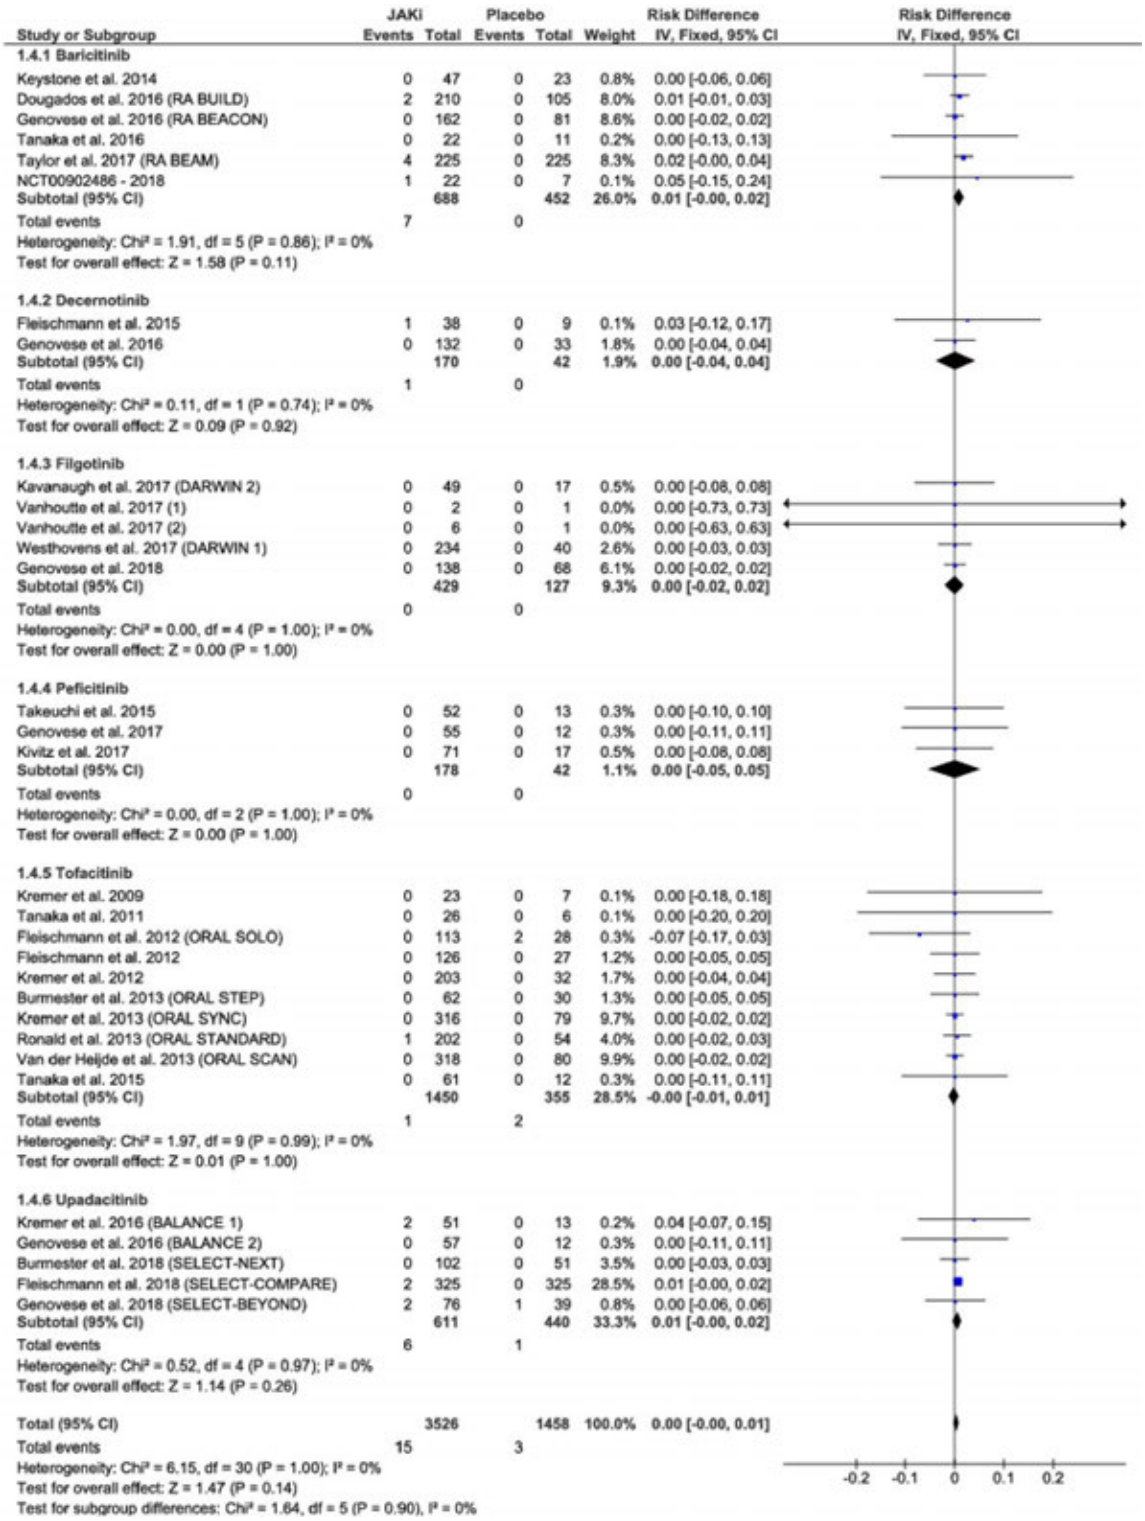
Methods: Screening for the study was carried out using MEDLINE, Cochrane and Embase, from the inception of the database to February 2019. Randomised controlled trials (RCTs) of JAKi for the treatment of rheumatoid arthritis were included. Two investigators independently extracted MACEs or VTEs reported during the placebo-controlled phase. The primary outcome measures were the incidence of MACEs or VTEs.

Results: From 205 references screened, 26 articles were selected, and 3 articles were added by manual searches. Accordingly 30 RCTs were included in the meta-analysis. No statistically significant difference was observed in MACE (Figure 1) or VTE incidences (Figure 2) in patients receiving any of the JAKi compared to the placebo group. A numeric imbalance was observed in the baricitinib group with 7 VTEs (688 P-Y) compared with none in the placebo group (452 P-Y), with 0,01 -0,00 to 0,02 risk difference, which is not statistically significant. A numeric imbalance was also observed in the upadacitinib group with 6 VTEs (611 P-Y) compared to 1 VTE in the placebo group (440 P-Y), with 0,01 -0,00 to 0,02 risk difference, which is not statistically significant neither.

Conclusion: This MA of 30 RCTs did not reveal any statistically significant change in the short-term risk of MACEs or VTEs in patients with RA initiating a JAKi. Data from the long-term extension phases of these RCTs, from studies designed to compare JAKi to bDMARDs with respect to MACEs or VTEs and from the long-term follow-up of patients included in JAKi registries are required to further characterise the risk of MACEs or VTEs in patients with RA treated with JAKi.



Difference in the risk of MACEs in RA patients treated with JAKi compared with the placebo in RCTs.



Difference in the risk of VTEs in RA patients treated with JAKi compared with the placebo in RCTs.

BMI and drug retention

Background/Purpose: The primary objective was to evaluate the effect of body mass index (BMI) on tumor necrosis factor α (TNF-α) blockers (including etanercept, infliximab, adalimumab and golimumab) retention in patients with RA.

Methods: This prospective cohort study contains data from the Israeli registry of inflammatory diseases, status May 2019. Patients were grouped by BMI: normal (BMI < 24.9 kg/m2), overweight (BMI 25-29.9 kg/m2), obese (BMI 30-34.9 kg/m2) and morbid obese (BMI ≥35 kg/m2). Event-free survival was calculated using Cox regression with a Hazard Ratio and Confidence Interval of 95%. Kaplan-Meier Analysis was used to describe drug survival. Statistical significance was defined as p< 0.05.

Results: The registry included 521 RA patients (80% females) treated with etanercept, infliximab, adalimumab or golimumab. 818 treatment initiations were included in the final analysis, 334 in the normal weight group, 261 in the overweight, 144 in the obese and 79 in the morbid obesity group. 326 treatment episodes were with etanercept, 215 with adalimumab 197 with infliximab, and 80 with golimumab. Negative correlation of elevated BMI with lower drug survival was significant when comparing the morbid obese group to the other patients HR 2.06 (95% CI 1.55-2.73, p< 0.01), indicating a higher rate of treatment switches with BMI >35, the difference was significant in all the drugs, except golimumab that showed insignificant trend. Adalimumab switch rate was higher compared to etanercept with HR =1.51 (95% CI 1.20-1.91, p< 0.01), no other significant differences were noted between the other drugs.

Conclusion: Morbid obese RA patients have lower TNF-α blocker retention compared to normal weight patients.

Abstract Number: 2360

Safety of Biological DMARD in Patients with Interstitial Lung Disease from a Chilean Cohort of Patients with Rheumatoid Arthritis

Silvana Saavedra,[1] Karen Vergara,[2] Claudia Hernandez,[2] Pedro Zamorano,[2] Annelise Goecke,[2] Luis Toro,[2] and FELIPE REYES[1], [1]HOSPITAL CLINICO UNIVERSIDAD DE CHILE, Santiago, Chile, [2]HOSPITAL CLINICO UNIVERSIDAD DE CHILE, Santiago, Region Metropolitana, Chile

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common pulmonary manifestation of rheumatoid arthritis (RA) that may be related to the inflammatory process itself, to infectious complications, and/or to the therapy. Biological disease-modifying antirheumatic drugs (bDMARD) have dramatically improved the outcome of RA, but an increasing number of reports have described the potential lung toxicity of this group of drugs.

Methods: Retrospective cohort study using data from RA patients beneficiaries of the “Ley Ricarte Soto program”, at the Hospital Clínico Universidad de Chile, was conducted to assess ILD prevalence and exacerbations , among users of abatacept (ABA), rituximab (RTX), and anti-TNFα agents. Clinical findings and laboratory data were collected

from medical records. The presence or progression of ILD on HRCT was evaluated by a rheumatologist, a pneumonologist and a radiologists who have expertise in assessing ILD, all part of the Rheumatic Lung Group at our Hospital.

Results: 126 RA patients were included; 85% female, mean (SD) age 55 (13.4) years, mean disease duration 11 (8.7 years). RA was seropositive in 108 patients (85.7%). DAS28 ESR was 6.1 (1.2) previously to initiate bDMARDs. A total of 30 patients (23.8%) had been previously diagnosed with ILD, most common patterns on HRCT were UIP (n=10[33%]) and bronchiolar abnormalities (n=4[13.3%]). Patients with as compared to without ILD at baseline were more frequently males (53 vs 15%, $p < 0.05$), had an older age (62.6 $\pm$ 11.9 vs 55 $\pm$ 13.4, $p < 0.005$), a higher positivity of anti-CCP (73 vs 47.6% $p < 0.005$) and a more frequent history of smoking (43 vs 21%, $p < 0.005$). The patients with a history of ILD were also, significantly more likely to receive ABA (n=24 [82.8] % versus n=35 [36.1%] without ILD; $p < 0.001$) and significantly less likely to receive anti-TNF therapy (n=3 [10.3%] versus n=57 [58.7 %] without ILD; $p < 0.001$). Only 6 patients received RTX, two of them with history of ILD. All patients with RA-associated ILD remained stable at 28 month follow-up. In the group of patients without a history of ILD, only one developed an organizing pneumonia that responded well to corticosteroids and was not related to the biological therapy.

Conclusion: Our data show that, in a real-world setting, there were no significant differences in the risk of complications between patients with or without a baseline history of ILD receiving different biologic agents. In our Cohort, bDMARDs were not associated with new ILD either. These data may be affected by the short follow-up window and the preference for the use of ABA, over anti-TNFα agents, as initial biological therapy in RA-ILD.

Abstract Number: 2361

Early Treatment of Rheumatoid Arthritis with Disease-Modifying Anti-Rheumatic Drugs at < 3 versus 3-6 Months from Onset of Symptoms: Results from a Cohort of Hispanics from Puerto Rico

Mariangelí Arroyo-Ávila,[1] Ruth Fred-Jiménez,[1] Naydi Pérez-Ríos,[1] Noelia Rodríguez,[1] Grissel Ríos,[1] and Luis Vilá[1],
[1]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is no doubt that early treatment of rheumatoid arthritis (RA) with disease-modifying anti-rheumatic drugs (DMARDs) is associated with better long-term outcomes. However, the time frame of early treatment has not been clearly established. Previously, we reported in our cohort of RA patients that those treated with DMARDs within 6 months of disease onset had less physical damage and functional impairment than those treated ≥6 months. Now, we sought to determine if a narrower therapeutic window (< 3 months) would be even more effective.

Methods: A cohort of Hispanics from Puerto Rico with RA (per 1987 American College of Rheumatology classification criteria) was studied. Demographic features, lifestyle behaviors, RA clinical manifestations, disease activity (per Disease Activity Score 28 [DAS-28]), functional status (per Health Assessment Questionnaire [HAQ]), patient's and physician's global assessments (by visual analogue scales), infections, hospitalizations, and RA pharmacotherapy

were determined. Very early treatment (VET) was defined as the initiation of DMARDs (synthetic and/or biological) < 3 months of symptoms attributable to RA, whereas early treatment (EA) was defined as DMARDs treatment ≥3 but < 6 months from RA onset. Study groups were compared using chi-squared, Fisher's exact, Mann Whitney or Student's t tests, as appropriate.

Results: The cohort comprised 394 RA patients, but for this analysis, only those who received VET (n=75) and ET (n=43) were included, for a total of 118 patients. The mean age and disease duration of the study population were 53.7 ± 13.6 and 7.5 ± 7.1 years, respectively. The majority of patients were women (87.3%). Both groups were comparable regarding age, sex, socioeconomic status, disease duration, and health-related behaviors (cigarette smoking, alcohol consumption, and exercise). During the disease course, no significant differences were observed for joint deformities (33.3% vs. 37.2%, p=0.670), requirement of intra-articular joint injections (37.3% vs. 41.9%, p=0.627), joint replacement surgeries (10.7% vs. 4.65%, p=0.259), extra-articular manifestations (38.7% vs. 48.8%, p=0.282), infections (any cause) (46.7% vs. 53.5%, p=0.476), and mean hospitalizations (any cause) (0.1 ± 0.5, p=0.635) between VET and ET groups. Also, at last study visit no differences were seen for mean DAS-28 (3.6 ± 1.3 vs. 3.5 ± 1.5, p=0.534), HAQ (1.0 ± 0.7 vs. 0.8 ± 0.7, p= 0.07), patient's global assessment (43.9 ± 28.9 vs. 38.5 ± 25.7, p=0.376) and physician's global assessment (17.0 ± 18.4 vs. 17.4 ± 19.3, p=0.888) scores. Initial and cumulative treatment with synthetic and biological DMARDs was similar for both groups.

Conclusion: In this group of Puerto Ricans with RA, we found no differences in the clinical outcomes of patients treated with DMARDs < 3 months vs. 3-6 months from onset of RA symptoms. Thus, the therapeutic window of < 6 months seems reasonable for this group of patients. This information is valuable when designing strategies of early intervention for patients with inflammatory arthritis.

Associations of Disease-Modifying Anti-Rheumatic Drug (DMARD) Adherence with Time to First Biologic and Cycle Time on DMARDs, and Healthcare Utilization/Cost in a New RA Patient Cohort

Stephanie Saeli,[1] Joseph Roots,[2] Kelly Shields,[2] and Tarun Sharma[1], [1]Allegheny Health Network, Pittsburgh, PA, [2]Highmark Data Science, Pittsburgh

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lack of adherence to medications is a well-known problem with chronic conditions, RA included. Nonadherence is associated with decreased quality of life and poorer outcomes. This study explores the effect of adherence to DMARDs on the time to biologic initiation, cycle time on each DMARD, and on healthcare utilization and cost in patients with new-onset RA utilizing a large claims-based database.

Methods: A cohort of adult patients with new-onset RA within Allegheny Health Network Rheumatology was created utilizing our administrative database. Incident RA was defined using a previously validated algorithm: ICD9 code 714 or ICD10 codes M05.XX and M06.XX with no DMARD use for at least 6 months prior, no RA diagnosis visits or biolog-

Table 1: Comparison of non-adherent and adherent groups

ic use for at least 1 year prior, and with continuous enrollment during the study period (01/01/2015-07/31/2018 with a 9 month follow up period to account for adherence until 04/01/2019). Demographics (age/sex), socio-economic status, insurance, medications (non-biologic DMARDs, tofacitinib, biologics, glucocorticoids, other daily oral medications) were recorded. Proportion of days covered (PDC) ≥80% was counted as adherence. Time to biologic initiation

(primary outcome) was defined as number of days from first DMARD prescription until the first biologic prescription. Cycle time on DMARD was defined as number of days on a DMARD before switching to or adding another DMARD. We compared non-adherent vs adherent group characteristics to examine if certain factors correlate with adherence using SAS Enterprise Guide 7.11 HF3.

Results: A total of 132 patients with new-onset RA met our criteria. Ninety patients (68%) were found to be adherent to their non-biologic DMARDs prior to biologic initiation. Our cohort had a mean age of 52 years and 62% female. Patients in the non-adherent group were younger (49 vs 55 years, p-value 0.011) and had lower estimated income (p-value 0.0015). Median time to biologic was longer in the non-adherent group (287 vs 191 days, p-value 0.076). Cycle times on the first and second DMARDs were found to be longer in the adherent vs non-adherent group (501 vs 115 days, p-value < 0.0001, and 314 vs 99 days, p-value 0.02 respectively). Total cost of DMARD medications prior to biologics was higher in the adherent group. The most common first DMARD prescription in both groups was methotrexate, but higher in adherent vs non-adherent (74% vs 48%, respectively, p-value 0.011). In both groups, approximately half of patients were prescribed a biologic as their second medication. Comparison of the groups can be found in Table 1.

Conclusion: Our study found that overall DMARD medication adherence is low and the time to biologic initiation may be longer in the non-adherent patients. Non-adherent patients tended to be younger, have lower household income, and spend less time on each DMARD prior to initiating a biologic. We plan to implement a team-based care approach focusing on medication education and integrating pharmacists and social workers at point of care, especially for those patients with unfavorable social determinants of health.

Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) produces joint destruction, functional deterioration, comorbidity and premature death. The best results are achieved with an early start of a treat-to-target and tight control strategy that allow to quickly and effectively control the inflammatory process. Methotrexate is the *DMARDs* of first choice, but only half of patients (pts) respond satisfactorily in monotherapy and often produces side effects. Studies exploring the contribution of genetic variability to the variability of the efficacy to MTX in RA and its toxicity show highly variable results. The aim was to explore the combined effect of the clinical characteristics related to the patient, the disease and the treatment, and of different genetic polymorphisms linked to the transport and metabolic pathways of MTX, on the therapeutic response of this drug, in terms of efficacy and safety, in a cohort of RA patients treated with MTX in monotherapy.

Methods: Case-control study nested in a cohort of patients with RA of the Hospital de Mérida, Spain, (2012-2015), followed-up by protocol in the monographic consultation of RA of the Rheumatology Service and treated with MTX monotherapy (since 1990). Efficacy was defined as a maintained response (low activity) and remission during follow-up, according to DAS28-PCR, and toxicity, as any adverse event related to MTX at any time during treatment. The SNPs *ABCB1*_C3435T, *GGH*_T16C, *FPG*_G2782A, *MTHFR*_C677T, *MTHFR*_A1298C, *AMPD1*_C34T, *ITPA*_C94A and *ADA*_A534G, and variables related to the pts, the disease and the treatment were studied.

Results: A total of 301 pts were included (mean age at diagnosis 50 years, 67% women, mean baseline value of DAS28-PCR of 4.5, baseline deterioration of physical function in 75%, early bone erosions in 55% and extraarticular involvement in 24%), representative of a severe RA. MTX monotherapy failed in half of the pts, generally due to lack of efficacy, and half had adverse events related to MTX, most frequently gastrointestinal, neurological and hepatic, which caused the suspension of MTX in a third of the cases and an 18 % of the total. The probability of MTX response was lower in women, active smokers and patients with more severe disease (higher baseline activity, early erosions and extra-articular manifestations), and independently of the clinical determinants, in homozygotes for the mutated allele (C/C genotype) of the *MTHFR*_A1298C SNP and in the carriers of the CC haplotype of C677T-A1298C of *MTHFR* (28.2%). T/T genotype of MTHFR_677CTc was associated with a higher probability of remission (OR = 4.07). The overall toxicity was more frequent in women and younger pts and C/T genotype of *MTHFR*_C677T. Hepatic toxicity was more frequent with positive Mantoux, G/G genotype of *ADA*_A534G and males, but no fe-

Haplotype *MTHFR* C677T–A1298C	Folate regeneration and DNA synthesis	↑ effectiveness ↑ toxicity			Haplotype C-C (male) ↑ global and hepatic	Haplotypes C-A and C-C ↓effectiveness (LA and Remission)

males, with C/C genotype of MTHFR_A1298C. Some SNPs showed a protective effect for toxicity. Sex behaved as a modifying factor.

Conclusion: Most of the SNPs studied have been associated with some measure of outcome, although the size of the effect is small. Genetic association studies should take into account the sex of patients and other clinical variables. Young patients and women had a worse response. Smoking is the main modifiable risk factor of poor response to MTX in RA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Lymphoproliferative disorders (LPD) remains as a major problem to resolve among the patients with rheumatoid arthritis (RA). During few decades, rheumatic therapy has dramatically changed with the ad-

vent of new disease modifying anti-rheumatic drugs (DMARDs). However, it is unclear whether these drugs relate to LPD developing in the patients withRA.

Methods: The current study included 518 RA-LPD patients in a Japanese multi-center collaborative study in order to characterize the current clinicopathological feature of RA-LPD and influence of methotrexate (MTX), tacrolimus (TAC) and biologic agents.

Results: Patient age at RA-LPD diagnosis ranged from 16 to 90 (median 69) years (1:2.43, men:women). Diffuse large B cell lymphoma was most frequent (51.3%), with 225 cases (81.5%) regressing only upon immunosuppressive agent withdrawal. Among these, 63 (27.0%) exhibited regrowth. The 5-year survival rate was 86.9%. Multivariate analysis revealed that sex (male), advanced clinical stage, TAC medication, T cell phenotype, and > 70 years of age upon LPD development constituted unfavorable prognostic factors.Additionally, the current clinicopathological profiles indicated that RA-LPD could be categorized into four groups depending on the use of DMARDs. Naïve, MTX, TAC and Bio (anti-tumor necrosis factor (TNF)). Naïve group consisted of the patients (45 cases) who had not received had MTX, TAC and anti-TNF agents. The positivity of EBER-1 of this group was lower than those of other groups. But it was a poorer prognostic factor. MTX group (461 cases), in which MTX had been administered with or without other DMARDs, showed increase of Hodgkin lymphoma (HL) and pharynx origin and decrease of B cell phenotype, stomach and breast origin. TAC group (78 cases), in which TAC had been used with or without other DMARDs, had a feature of older age, prolonged duration from the time of MTX initial medication to LPD development, the increase of polymorphic-LPD, elevated CRP at the onset of LPD and poorer prognosis. Bio (anti-TNF) group (110 cases), in which biologic agents (anti-TNF) had been given with/without other GMARDs, had a feature of younger age at the onset of LPD, the elongated duration from the time of MTX initial medication to LPD development, increase the frequency of HL, HL-like lesion, EBER-1 positivity, and decrease of Follicular lymphoma.

Conclusion: In conclusion, the current analyses showed the prognostic factors of RA-LPD and the distinctive characteristics in relation to the use of anti-rheumatic drugs.

Risk of Diabetes Treatment Switching or Intensification Associated with Use of Abatacept versus Other Biologic Drugs in Patients with Rheumatoid Arthritis and Diabetes Mellitus

Sarah Chen,[1] Hemin Lee,[2] Yinzhu Jin,[2] Jun Liu,[2] and Seoyoung C. Kim[2], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, [2]Brigham and Women's Hospital and Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients have a high prevalence of cardiovascular comorbidities including diabetes mellitus (DM). Past studies have suggested a potential beneficial effect of abatacept on insulin sensitivity, but the effect of biologic therapy on DM severity in RA patients with DM is generally unknown. The objective of this study was to compare the rates of DM treatment switching or intensification among patients with RA and DM (type 1 or 2), newly initiating abatacept versus other disease-modifying antirheumatic drugs (DMARD).

Methods: We identified RA patients aged ≥18 years with ≥2 RA diagnoses separated by 7-365 days using claims data from Truven MarketScan database (2005-2016). We included new users of abatacept, tumor necrosis factor inhibitors (TNFi) (adalimumab, etanercept, certolizumab, golimumab, and infliximab), rituximab, tocilizumab, and tofacitinib. The date of their 1st drug dispensing was defined as the index date. We required ≥365 days of continuous enrollment prior to the index date, defined as the baseline period. We excluded patients with history of malignancy. Among these RA patients, we identified patients with DM by using ≥1 diagnosis for either type 1 or type 2 DM and ≥1 anti-diabetic drug prescription during baseline. The primary outcome was 'DM treatment switching or intensification' defined as adding or switching to a different oral antidiabetic medication or insulin. We calculated incidence rates (IR) and hazard ratio (HR) of DM treatment switching or intensification in patients initiating abatacept versus other biologic DMARDs or tofacitinib.

Results: We included 10,019 patients with both RA and DM initiating abatacept (mean age 58.5 years, female 78%), TNFi (56.7, 71%), rituximab (58.1, 76%), tocilizumab (57.6, 79%), or tofacitinib (58.0, 77%) (**Table 1**). Cardiovascular comorbidities were prevalent; hypertension was present in up to 74% and hyperlipidemia was present in up to 67% of patients. Baseline insulin use was highest in the rituximab group (44%) and lowest in the tofacitinib group (35%). Over the 7,396 total person-years of follow up, there were 1,643 total DM treatment switching or intensification events (**Table 2**). The crude IR of DM treatment switching or intensification per 1,000 person-years was highest in abatacept initiators (IR 236.7) and lowest in tofacitinib initiators (IR 203.3). After adjusting for 15 baseline covariates, the risk of DM treatment switching or intensification was similar between abatacept and TNFi (HR 0.94, 95% confidence interval [CI] 0.81-1.10), rituximab (HR 0.95, 95% CI 0.78-1.17), and tocilizumab (HR 0.86, 95% CI 0.68-1.07) and lower for tofacitinib (HR 0.78, 95% CI 0.60-1.01).

Conclusion: In patients with both RA and DM, we found no difference in the risk of DM treatment switching or intensification after initiating abatacept versus TNFi, rituximab, and tocilizumab, while the risk appeared to be lower for tofacitinib initiators compared to abatacept.

Table 1. Baseline characteristics of patients with rheumatoid arthritis and diabetes mellitus initiating DMARD therapy

	Abatacept (n=1,785)	TNF inhibitors (n=5,953)	Rituximab (n=888)	Tocilizumab (n=759)	Tofacitinib (n=634)

Comparison of Healthcare Resource Utilization (HCRU) and Costs of Type 2 Diabetes Mellitus (T2DM)-Related Complications in TNFi-Experienced Medicare Beneficiaries with Rheumatoid Arthritis (RA) and T2DM Who Switch to Abatacept or Other Targeted Disease-Modifying Anti-Rheumatic Drugs

Vardhaman Patel,[1] Zulkarnain Pulungan,[2] Anne Shah,[2] Barton Jones,[2] Allison Petrilla,[2] Leticia Ferri,[3] Xue Han,[3] and Kaleb Michaud[4], [1]Bristol-Myers Squibb, New York City, NY, [2]Avalere, washington, DC, [3]Bristol-Myers Squibb Company, Princeton, NJ, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with RA experienced an increase in the whole-body insulin sensitivity and a reduction in HbA1c levels from treatment with abatacept, which is a type of targeted DMARD (tDMARD).[1] Abatacept is often used in tumor necrosis factor inhibitor (TNFi)-experienced patients; however, comparative impact of tDMARDs on type 2 diabetes mellitus (T2DM) related outcomes is lacking. This study examined healthcare resource utilization (HCRU) and costs associated with T2DM in TNFi-experienced patients with RA and T2DM who switched to another tDMARD.

Methods: In this retrospective cohort study, 100% Medicare fee-for-service (FFS) claims (Parts A/B/D) were used to identify TNFi-experienced RA patients who initiated abatacept, another TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, infliximab) or non-TNFi (anakinra, rituximab, sarilumab, tocilizumab, tofacitinib) from 2010 through 2017. Patients ≥65 years of age were included if they had ≥2 diagnosis of RA, ≥1 diagnoses of T2DM or ≥1 T2DM medications, no recent history of cancer, and were continuously enrolled for 12 months pre-index date or date of tDMARD initiation. Patients were followed from tDMARD initiation until discontinuation of the index treatment, disenrollment, death, or end of study period, whichever occurred first. Patients who switched to abatacept were propensity score (PS) matched to TNFi and non-TNFi users separately on a wide range of confounders. T2DM-related complications for which HCRU and costs were estimated were from the validated Diabetes Severity Complication Index (DCSI)[2] - neuropathy, nephropathy, cerebrovascular, cardiovascular, retinopathy, peripheral vascular disease and metabolic. The HCRU of T2DM-related complications was estimated per 1,000 patients per month using counts of inpatient stay, ER visits and outpatient visits whereas Medicare costs or payments (2019 USD) were estimated as per-patient per month (PPPM).

Results: A total of 1,987 PS-matched pairs of abatacept and TNFi initiators, and 1,697 PS-matched pairs of abatacept and non-TNFi initiators were identified. During follow-up, the rate of hospitalizations with T2DM-related complications per 1,000 patients per month was the lowest in abatacept compared to both TNFi (20.6 vs. 24.2) and other non-TNFi groups (21.6 vs. 22.7). PPPM T2DM-related complication costs were lower in abatacept than in TNFI's and non-TNFI users by $141 and $11 respectively. The major driver of healthcare costs for each group was the utilization of inpatient services. PPPM T2DM-related costs decreased following initiation of the new line of treatment for both abatacept (12%-21%) and non-TNFI (14%) initiators, but it was the opposite for initiators of TNFis (10% increase).

Table. Rates and costs of T2DM-related complications in TNFi-experienced patients

Measures	PS Matched Cohort 1		PS Matched Cohort 2	
	Abatacept (N = 1,987)	TNFi (N = 1,987)	Abatacept (N = 1,697)	Other Non-TNFi (N = 1,697)
Mean Age	73.0	72.9	72.4	72.6
Mean CCI Score	4.4	4.4	4.4	4.5
Mean Duration of Follow-up (days)	377.5	364.3	346.9	334.0
T2DM-related HCRU by setting of care during follow-up, Per 1000 Patients Per Month				
Hospitalizations	20.6*	24.2	21.6	22.7
Cardiovascular	16.8	20.3	18.1	18.8
Cerebrovascular	1.8	2.1	2.0	1.5
Metabolic	0.7	0.4	0.7	0.5
Nephropathy	6.6*	8.9	7.3	8.2
Neuropathy	3.3	2.8	4.0	3.8
Peripheral Vascular Disease	1.8	3.1	2.0	3.2
Retinopathy	0.5	0.7	0.5	0.4
ER Visits	14.6	14.2	14.8	13.7
Hospital Outpatient Visits	115.2	118.2	118.2	113.2
Physician Office Visits	506.0	552.6	525.6	531.9
T2DM-related complication costs, PPPM				
Total Medical	$482*	$623	$504	$515
Inpatient	$254*	$350	$260	$270
ER	$13	$15	$14	$14
Hospital Outpatient	$74	$56	$86	$64
Physician Office	$76	$86	$81	$85
Other Medical (includes costs related to skilled nursing facility, home health and DME, and hospice utilization)	$63*	$116	$62	$81
Follow-up T2DM Medication Costs, PPPM	$64	$67	$71	$75

*P<0.05

T2DM = Type 2 diabetes mellitus, DME = durable medical equipment, PPPM = per-patient per month

Conclusion: These findings suggest that TNFi-experienced Medicare patients with RA and T2DM who switch to abatacept had a reduction in the rate and cost of hospitalizations associated with T2DM-related complications in comparison to patients who switch to other tDMARDs.

The Effect of DMARDs on Cardiovascular Outcomes in Rheumatoid Arthritis: A Systematic Literature Review

Vardhaman Patel,[1] Leticia Ferri,[2] Xue Han,[2] Lauren Mintzer,[3] and Mir Sohail Fazeli[3], [1]Bristol-Myers Squibb, New York City, NY, [2]Bristol-Myers Squibb Company, Princeton, NJ, [3]Doctor Evidence, Santa Monica, CA

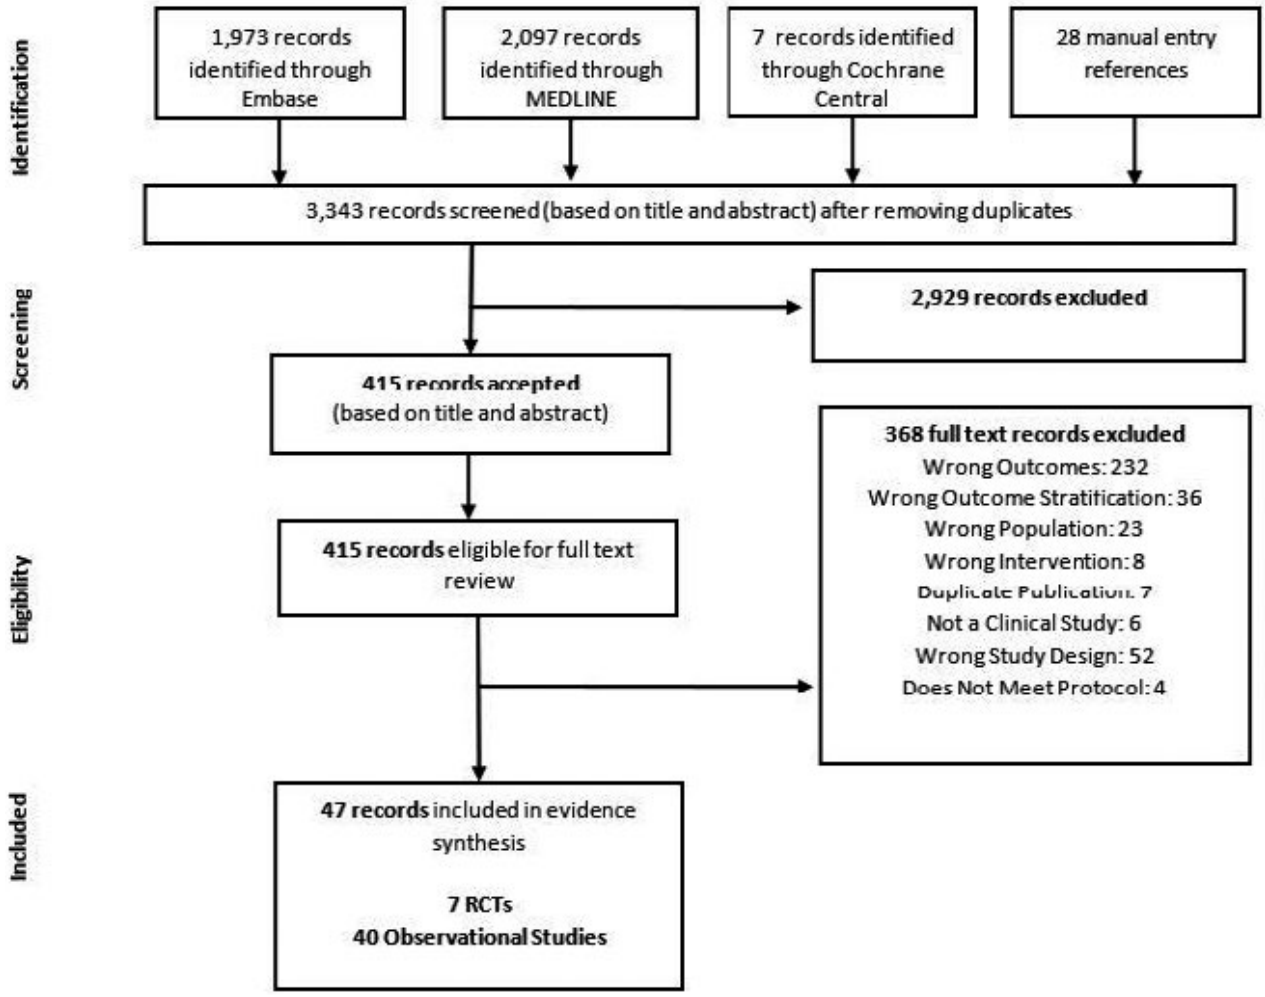
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies and chronic systemic inflammation experienced in rheumatoid arthritis (RA) increases the risk of cardiovascular disease (CVD). This systematic literature review (SLR) aimed to characterize the available evidence with respect to the effect of DMARDs on cardiovascular outcomes in patients with RA with and without history of CVD.

Methods: A SLR was conducted by searching MEDLINE, Embase, and Cochrane CENTRAL databases (inception to Jan. 2019) supplemented by a search in conference proceedings from ACR and EULAR (2017 to 2019), and US and European clinical trial registries (Jan. 2005 to Jan. 2018). Studies eligible for inclusion were observational studies and randomized controlled trials (RCTs) investigating adult patients with RA treated with biologic and non-biologic DMARDs and reporting cardiovascular events including major adverse cardiac events (MACE), other cardiovascular event composites, myocardial infarction (MI), stroke, and heart failure.

Results: As described in Figure 1, the SLR yielded 47 eligible publications, including 7 RCTs, 6 prospective observational, and 34 retrospective observational studies. Baseline rates of CVD (0%-83%) or history of cardiovascular events (0%-80.1%) varied between studies with six studies entirely excluding patients with cardiovascular comorbidities.

The most commonly reported outcomes were cardiovascular event composites (MACE or other) and MI (Table 1). Incidence rates (per 1000 person-years) for any cardiovascular event composite ranged from 3.1-30.7 for csDMARDs,



DMARDFig1
Figure 1: PRISMA diagram

2.93-35.8 for TNF inhibitors (TNFi) and 3.7-23.8 for non-TNFi. The rate of MI ranged from 2.38-10.4 for csDMARDs, 0.51-9.3 for TNFi and 2-8.43 for non-TNFi. Rates were heterogenous across studies, likely due to differences in cardiovascular characteristics. One study found a five-fold increase in cardiovascular outcomes for patients with a history of CVD, HR 5.302.

Twenty studies reported statistically significant differences between DMARDs for a variety of cardiovascular outcomes (Table 2). Compared to unexposed patients, hydroxychloroquine, TNFi, sulfasalazine, leflunomide, and methotrexate significantly lowered risk of cardiovascular outcomes with HRs ranging from 0.32 (95% CI 0.18-0.56) to 0.89 (0.82-0.98). Head-to-head comparisons of DMARDs found abatacept to significantly lower cardiovascular outcomes compared to TNFi [0.71 (0.55-0.93) to 0.841 (0.75-0.94)]. Another non-TNFi biologic, rituximab, also significantly lowered risk of CV events [0.78 (0.63-0.98)]. TNFi significantly lowered outcome rates compared to non-biologic DMARDs [0.24 (0.06-0.95) to 0.39 (0.19-0.82)] and csDMARDs [0.45 (0.21-0.96) to 0.83 (0.704-0.98)], although a single study found TNFi inferior to MTX for heart failure requiring hospitalization [1.7 (1.07-2.69)].

DMARDTable1

Table 1: Incidence Rates of MACE or CV Composite and Myocardial Infarction

Conclusion: This review found the rate of cardiovascular outcomes to vary widely across studies. We found DMARDs to consistently lower the rate of cardiovascular events compared to unexposed patients. Although data is still limited, multiple studies reported that non-TNFi significantly lower cardiovascular event rates compared to TNFi.

DMARD	Comparator	Study	Outcome	HR (95% CI)

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Several studies have reported an increased risk of gastro-intestinal perforation (GIP) in rheumatoid arthritis (RA) patients treated with tocilizumab (TCZ) compared to conventional synthetic disease modifying anti rheumatic drugs (csDMARDs) or TNF inhibitors (TNFis) (1–3). However, a recent study did not find an increased risk of GIP with TCZ compared to TNFis and even compared to others biologic-DMARDs (bDMARDs), namely rituximab (RTX) and abatacept (ABA) (4). The aim of our study was to compare the risk of diverticulitis and GIP in RA patients treated with TCZ compared to RTX and ABA using a propensity-matched analysis.

	TCZ registry (n=1492)	RTX registry (n=1986)	ABA registry (n=1019)	All patients (n=4501)

Table 1: Characteristics of patients including in the French registries TCZ=tocilizumab ; RTX=rituximab ; ABA=abatacept ; DM=diabetes mellitus ; RA=rheumatoid arthritis ; RF=rheumatoid factor ; ACPA= anti-citrullinated protein antibodies ; csDMARDs=conventional synthetic disease modifying anti rheumatic drugs ; CS=corticosteroids; SD=standard deviation

Methods: We conducted a study of patients with TNFis refractory RA, prospectively followed in 3 observational French registries evaluating the effectiveness and safety of RTX (Autoimmunity and Rituximab (AIR)), ABA (Orencia and Rheumatoid Arthritis (ORA)), and TCZ (REGistry–RoAcTEmra (REGATE)). Adult patients with RA according to the 1987 ACR criteria, initiating intravenous treatment with RTX, ABA, or TCZ were enrolled from 107 clinical centers between September 2005 and August 2013 (5). Using a propensity score approach, we compared the risk of diverticulitis or GIP during treatment with TCZ vs RTX and ABA. Pearson Chi-squared analysis and multivariable logistic regression were used to evaluate correlation between different risk factors and the onset of diverticulitis or GIP among TCZ, RTX or ABA (the latter 2 pooled). We also retrospectively collected the outcome of these specific adverse events and compared the clinical presentation by treatment.

Results: Forty-one diverticulitis and 19 GIP occurred in 4501 RA patients (patient's characteristics are shown in table 1) (corresponding incidences of 0.027 and 0.012 per 1000 person-years). Based on inverse probability weighting, there was an increased risk of GIP due to diverticulitis (5.66 [2.63-12.18], p< 0.0001) in the TCZ group vs RTX and ABA. There was also an increased risk of diverticulitis and GIP but not GIP due to another etiology. In multivariate analysis, age was associated with an increased risk of diverticulitis (1.03/year [1.01-1.06], p=0.03) in all patients, and history of neoplasia was associated with an increased risk of GIP in patients treated with TCZ (5.04 [1.03-24.65], p=0.04). Compared to RTX and ABA, diverticulitis and GIP during TCZ occurred earlier after the last perfusion (24.5+/-18.4 vs 58.6+/-49.2 days, p=0.01), with usually atypical clinical presentation (slow transit in 30% vs 0, p=0.04) and milder biological inflammatory markers at the time of the event (hemoglobin: 13.9+/-1.8 vs 10.6+/-2.8 g/dL, p=0.01; platelets: 251583+/-85976 vs 371500+/-68066/mm3, p=0.04; and C-reactive protein: 31.2+/- 58.4 vs 88.2+/-89.6 mg/L, p=0.005).

Conclusion: TCZ was associated with an increased risk of diverticulitis, GIP and GIP due to diverticulitis, but not those caused by another etiology, compared to RTX and ABA. Our study confirms an increased risk of GIP in RA patients treated with TCZ and could be explained by an increased risk of diverticulitis with misleading clinical presentation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Delays in treatment for inflammatory arthritis (IA) are associated with unfavorable outcomes, including impaired quality of life, irreversible joint damage, and disability. Our objective of this study was to characterize treatment initiation patterns in Veterans with newly diagnosed rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).

Table 1. Baseline demographics and characteristics

	All IA (n=12,118)	RA (n= 9,711)	PsA (n=1,472)	AS (n= 935)
	No./Mean (%/SD) [95% CI]	No./Mean (%/SD) [95% CI]	No./Mean (%/SD) [95% CI]	No./Mean (%/SD) [95% CI]
Age	63.7 (13.3) [63.4, 63.9]	65.2 (12.6) [64.9, 65.4]	57.8 (13.1) [57.1, 58.5]	57.6 (16.1) [56.5, 58.6]

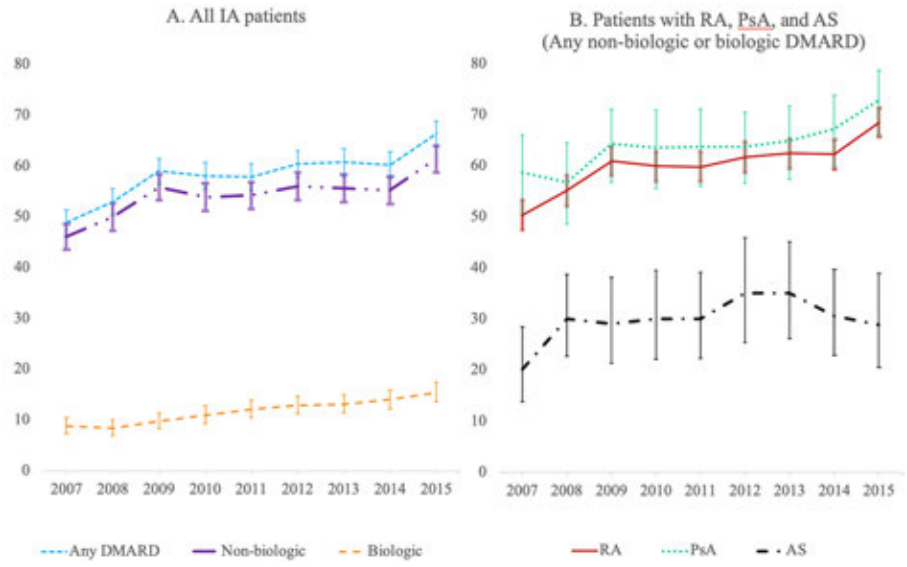
Figure 2. Percentage of veterans treated with ≥1 DMARD within 12 months after the initial IA diagnosis in A. All Veterans with inflammatory arthritis and B. Veterans with RA, PsA, and AS



Methods: International Classification of Diseases codes and natural language processing were used to identify incident cases of RA, PsA, or AS, between January 1, 2007 and December 31, 2015, in patients enrolled in the Veteran Health Administration. Patterns of treatment initiation and non-treatment with disease modifying anti-rheumatic drugs (DMARDs) were assessed in the 12-month follow-up period after the incident diagnosis (Figure 1). Confidence intervals were used to statistically evaluate differences between comparison groups.

Results: The population consisted of 12,118 IA patients (9,711 RA, 1,472 PsA, 935 AS), with 91.3% males and a mean age of 63.7 (Table 1). The percentage of Veterans treated with ≥1 DMARD during the 12-month follow-up period increased from 48.8% in 2007 to 66.4% in 2015. Amongst Veterans diagnosed with IA in 2015, DMARD treatment was more common for PsA patients (72.9%) and RA patients (68.6%) than AS patients (28.9%). The mean time to the initial DMARD after diagnosis did not change over the observation period (35.5 days for RA, 43.9 days for PsA, 59.5 days for AS). In Veterans diagnosed with IA in 2015, a DMARD was dispensed ≤30 days after diagnosis in 45.8%, 31-90 days in 10.1%, and 91- 365 days for 10.5%; the remaining 33.6% were not treated with a DMARD within the 365-day follow-up period (Figure 2). Rheumatology specialty care was accessed by 87.4% of Veterans treated with a non-biologic DMARD and 92.2% treated with a biologic DMARD, in patients diagnosed in 2015.

Conclusion: DMARD treatment rates during the initial 12 months after diagnosis increased between 2007 and 2015, but non-treatment remained common, particularly in Veterans with AS. Time to treatment after the initial IA diagnosis did not change throughout the study period, and DMARDs were dispensed within 30 days of diagnosis for most Veterans who were treated within the 1-year follow-up period. DMARD treatment was uncommon in patients without rheumatology specialty care.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of Rheumatoid Arthritis (RA) has undergone a big change in the last two decades in strategies, objectives and therapeutic options, especially with the use of the Disease Modifying Drugs (DMARDs), both synthetic and biological. We have little information about the management of these drugs in real life conditions so it is necessary to expand our knowledge about discontinuations and their reasons. Purpose: to describe the discontinuations of DMARDs as well as their causes in patients with incident RA.

Methods: We conducted an observational longitudinal study. Patients: all recent onset RA diagnosed between January 1st 2007 and December 31st 2015 followed in outpatient clinic at Hospital Clínico San Carlos until January 1st 2017, which used any DMARD (synthetic and biologic) during at least 3 months. Primary outcome: discontinuation of the DMARD and cause of discontinuation (adverse event, inefficacy, patient decision, remission, doctor decision, others). Covariables: sociodemographic, clinical and treatment. Incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI].

Results: We included 2388 courses of DMARD treatment in 814 patients (3706.14 patient-years). 77.52% were women with a mean age at diagnosis of 57.53±15.50 years. 72.85% of patients were diagnosed at first visit. From the courses of DMARD, 13.74% were biologicals (72.04% anti-TNF) and 60% were used in monotherapy. 55% of patients were RF positive, 44% ACPA positive and the mean DAS28 was 5.26±1.4. The most commonly prescribed drugs were Methotrexate (MTX) and Antimalarials (AM) among csDMARDs, and Etanercept (ETN) and Adalimumab (ADA) among bDMARDs. There were 1094 DMARDs discontinuations of the 2388 courses (45.81%) in 438 patients with an IR of 29.5[27.8-31.3]. 52% were due to adverse event (IR:15.95), 13.5% to inefficacy (IR: 3.99), 11.6% to doctor decision, 11.2% to patient decision, 5.8% to remission and 5.2% due to other causes. IR was higher in combined therapies, especially in triple therapy (IR: 78.19). It was higher in biologic therapy (IR: 48.8) compared to classical DMARDs. Regarding specific drugs, MTX had the lowest crude incidence (IR: 13.38). All IRs by variables are shown in table 1.

Conclusion: Global discontinuation rate was estimated in 29*patient-years, with 53.8% of treatments discontinued during follow-up. The major cause of suspension was adverse event appearance, followed by inefficacy. It seems that discontinuations are more common in combined therapies (especially in triple therapy) and in therapies including biologic drugs. Methotrexate was the most frequently prescribed drug and also the one with the lowest incidence rate of discontinuations.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Our objectives were to estimate and compare the incidence rate of malignancies associated with the different classes of biologics in RA patients.

Methods: We conducted an historical cohort study within the Frenchour national claim database, named SNIIRAM. Thisthat database prospectively records individual health resource use healthcare data of 86% of the entire French population (65 million inhabitants) since 2007. RA adult patients were identified based on ICD-10 code (M05 or M06) recorded from long-term chronic disease status allowing for full medical reimbursement and/or hospital discharge summaries discharge between 2007-2016. Patients with cancer history before biologic introduction were excluded.

Treatment exposures focused on incident first use of biologics including all anti-TNF, rituximab, abatacept, tocilizumab, ustekinumab, anakinra. To identify incident treatment periods, a one year period prior our period of analysis was analyzed; only patients that did not receive any biologics during this period were included. Patients having previously

Type of malignancies	HR [95% CI] Anti-TNF (ref) vs. other biologics	p-value
All malignancies	0.93 [0.77;1.14]	p=0.499
Solid cancer (excluding non-melanoma skin cancer)	0.92 [0.74;1.14]	p=0. 431
Lymphoma	0.59 [0.26;1.34]	p=0.209
	HR [95% CI] Anti-TNF (ref) vs. Abatacept	p-value
All malignancies	1.21 [0.84;1.73]	p=0. 346
Solid cancer (excluding non-melanoma skin cancer)	1.21 [0.82;1.80]	p=0. 381
Lymphoma	0.95 [0.35;2.53]	p=0. 909
	HR [95% CI] Monoclonal anti-TNF (ref) vs. Etanercept	p-value
All malignancies	1.11 [0.94;1.32]	p=0. 225
Solid cancer (excluding non-melanoma skin cancer)	1.11 [0.92;1.33]	p=0. 293
Lymphoma	1.00 [0.55;1.835]	p=0.992
Other hematologic malignancies	0.83 [0.45;1.52]	p=0. 530

receivedused only csDMARDs during observation period were included. For each individual, the index date was the first prescription of biologic to identify incident treatment periods. In the base case analysis, eExposure definition was considered with a 90-day latency after treatment initiation and a 180-day remanence period after drug discontinuation.

To compare the risk of malignancies between biologics, a propensity score (including age, sexe, year of first occurrence of RA code, date of treatment initiation, number of previous DMARDs, Charlson comorbidity index, diagnosis of tobacco and/or alcohol-associated disorders, number of hospitalisations for RA, cumulative corticosteroid dose) was constructed for each comparison. Hazard Ratios (HRs) for risk of cancer were estimated using Cox proportional hazards model with using propensity score inverse probability of treatment weighting (IPTW)weighting with stabilized weight. Since patients could have been exposed to different biologics, exposure was considered as a time-dependent variables and propensity score was estimated dynamically using pooled logistic regressionreassessed for each new exposure. Sensitivity analyses are ongoing to assess the robustness of our results.

Results: Between 2007 and 2016, 31792 patients (112802 patient-years)- were exposed to biologics. The annual incidence rate of overall malignancies was 0.865 per 100 patients. Malignancies occurred in 712 patients exposed to anti-TNF and 240 patients exposed to another biologic. The overall risk of malignancies and risk of lymphoma did not differ between anti-TNF and other biologics (analysed all together), or abatacept. Within the anti-TNF class, the overall risk of malignancies and risk of lymphoma did not differ between etanercept and monoclonal anti-TNF.

Conclusion: Using a large nationwide healthcare database, representative of the French population, the overall risk of malignancies did not seem to differ across the different classes of biologic. Also, among anti-TNF, etanercept and monoclonal antibodies did not differ regarding the risk of malignancies including the risk of lymphoma.

Comparision of risk of malignancies between biologics in RA patients

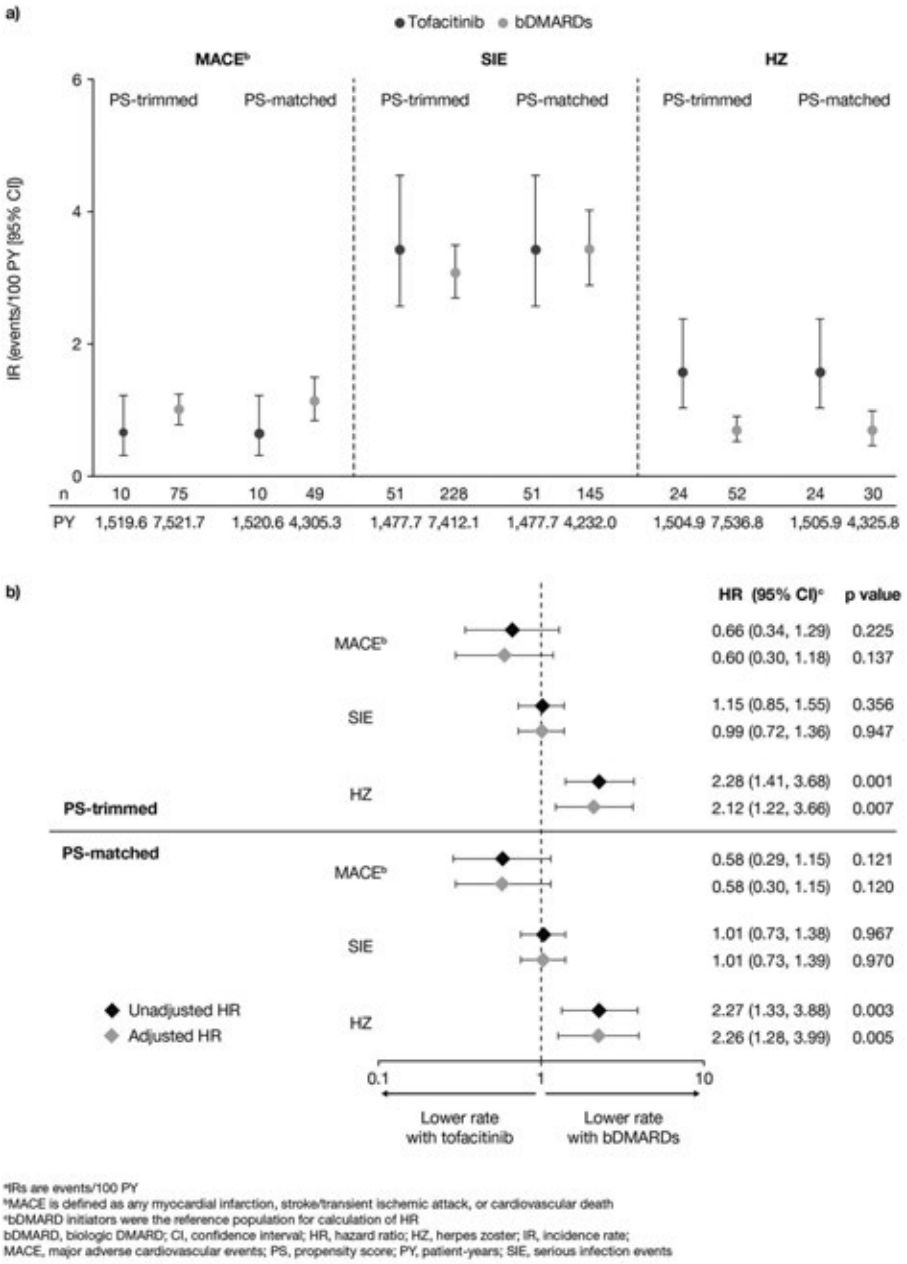
SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Figure 1. a) Crude IRs[a] for MACE, SIE, and HZ; and b) HR for MACE, SIE, and HZ

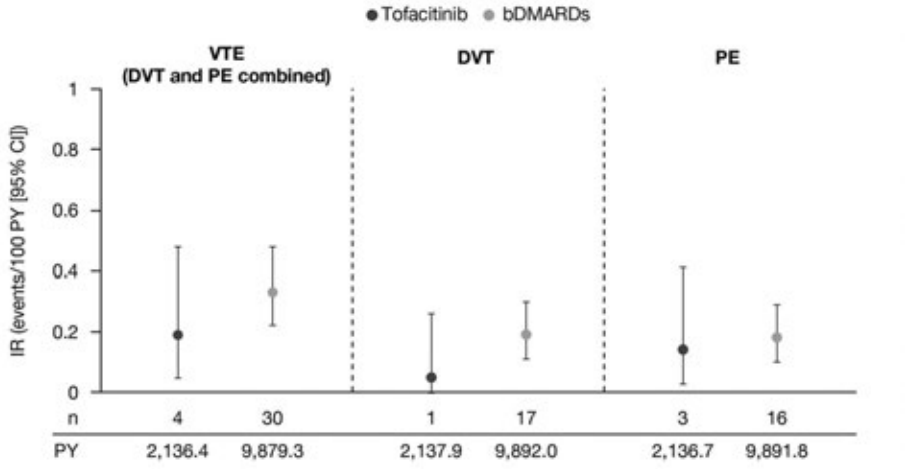


[a]IRs are events/100 PY
[b]MACE is defined as any myocardial infarction, stroke/transient ischemic attack, or cardiovascular death
[c]bDMARD initiators were the reference population for calculation of HR
bDMARD, biologic DMARD; CI, confidence interval; HR, hazard ratio; HZ, herpes zoster; IR, incidence rate; MACE, major adverse cardiovascular events; PS, propensity score; PY, patient-years; SIE, serious infection events

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Real-world data (RWD) complement clinical trial data in assessing long-term safety. We evaluated 5-year adverse event (AE) incidence rates (IRs) in new starters of tofacitinib vs biologic (b)DMARDs using cohorts from the US Corrona RA registry.

Figure 2. Age- and gender-standardized IRs[a] for VTE[b]



[a]IRs are events/100 PY
[b]VTE data did not have >80% power to detect a hazard ratio of <2.25 at this data cut, and PS were not calculated; data presented are age- and gender-standardized IRs, estimated using direct standardization (tofacitinib population used as the standard population)
bDMARD, biological DMARD; CI, confidence interval; DVT, deep vein thrombosis; IR, incidence rate; PE, pulmonary embolism; PS, propensity scores; PY, patient-years; VTE, venous thromboembolism

Methods: This prospective, observational 5-year study in the ongoing US Corrona RA registry routinely collected 9 predefined AE categories from participating physicians. Major cardiovascular adverse events (MACE), serious infectious events (SIE), and herpes zoster (HZ) were *a priori* identified as having ≥ 80% power to detect a hazard ratio (HR) of 2.0 (MACE, SIE) or 2.25 (HZ) between patients (pts) starting tofacitinib or bDMARDs between 6 Nov 2012 (US FDA approval) and 30 Jun 2017 (follow-up to 31 Dec 2017). A safety signal for pulmonary embolism and mortality was seen in the tofacitinib 10 mg twice daily arm of an FDA post-marketing study in RA designed to evaluate the long-term risk of MACE and malignancy. Pts in that ongoing, open-label, endpoint-driven study had to be ≥ 50 years of age, have ≥ 1 cardiovascular risk factor, and be on a stable dose of methotrexate to be eligible for enrollment. For MACE, SIE, and HZ analyses, baseline variables with a standardized difference > |0.10| between cohorts, and *a priori*-selected-covariates (gender, age, line of therapy, history of AE of interest) were used to construct propensity scores (PS) to derive PS-trimmed (primary) and PS-matched (sensitivity) populations (ratio: max. 4 bDMARD:1 tofacitinib; caliper=0.05). Pts were followed from start until AE of interest, discontinuation and/or start of new therapy +90 days, death, or end of follow-up, whichever came first. IRs (no. of events/100 pt-years [PY]) were estimated, and multivariable-adjusted Cox regression was used to estimate HRs comparing rates of first events between cohorts.

Results: In total, 1,544 tofacitinib (2,138.2 PY) and 7,083 bDMARD (9,904.9 PY) starters were included. PS-trimming led to 1,117 tofacitinib and 5,542 bDMARD starters. MACE and SIE rates were similar in both cohorts (Figure 1a); adjusted HRs (95% confidence interval) were: MACE 0.60 (0.30, 1.18); SIEs 0.99 (0.72, 1.36; Figure 1b). Compared with bDMARDs, the HZ IR was higher with tofacitinib (Figure 1a) and the HZ HR was significantly increased (adjusted HR 2.12 [1.22, 3.66]; Figure 1b); all HZ events were non-serious with tofacitinib. Similar results were seen in PS-matched populations. Venous thromboembolic event (VTE) IRs were similar in both cohorts (Figure 2).

Conclusion: This is the first comparative analysis of RWD for tofacitinib and bDMARDs to use PS-trimmed and PS-matched analyses to adjust for channeling/prescribing patterns for newly approved therapies. Pts starting tofacitinib or bDMARDs had similar MACE, SIE, and VTE rates. Tofacitinib starters had higher HZ IRs vs bDMARD starters.

Two Decades of Changes in RA Treatment and Disease Outcomes from the United States

Sofia Pedro,[1] Alyssa Dominique,[2] Rebecca Schumacher,[1] Yomei Shaw,[1] Kristin Wipfler,[1] Teresa Simon,[3] and Kaleb Michaud[4], [1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb*, Princeton, NJ, [4]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: RA causes significant morbidity and mortality. Over the last two decades, several new medications and strategies for treating RA earlier and more aggressively have become available. The objective of this study was to describe changes in RA treatment and the impact on disease outcomes over the last two decades by comparing medication use and patient-reported outcomes in a large, US-wide registry.

Methods: Patients with physician-diagnosed RA in FORWARD, The National Databank for Rheumatic Diseases, were included. Patients observed from 2008–2018 were matched 1:1 at study entry by age, sex and HAQ score to non-overlapping patients observed from 1998–2007. A random observation from each decade group was selected for demographics, disease characteristics, comorbidities, health outcomes and medications using t-test and chi-squared tests as appropriate to describe differences.

Results: We matched 8772 patients in the decade 2008–2018 with 8772 patients from the prior decade. At study entry, the time of the matching (mean [SD] calendar years 2000 [2.8] and 2012 [2.6] for respective decades), average age was 58 years, 83% were female, and mean (SD) HAQ score was 1.1 (0.7). Characterizing these decades with a random observation (Table 1), we observed slightly worse disease activity measures including pain visual analog scale, patient global score, Short Form-36 mental component summary score, quality of life and more comorbidities in the later decade, even when matching for HAQ. For individual HAQ items, better scores were observed in 2008–2018 vs 1998–2007 for items describing the performance of daily activities. There was a higher use of aids (such as canes and wheelchairs) reported in the later decade, resulting in worsened HAQ scores. MTX was the most commonly used conventional synthetic (cs)DMARD over both decades; use of other non-MTX csDMARDs was lower and

Table 1. Patient Demographics and Clinical Characteristics in a Random Matched Observation for Each Decade

Random observations within each decade	1998–2007 (n=8772)	2008–2018 (n=8772)	p value

VAS for QOL (0–100)	65.45 (21.25)	63.73 (21.15)	<0.001
HAQ and use of aids (not exhaustive)			
Dress yourself (0–3)	0.59 (0.68)	0.52 (0.65)	<0.001
Climb up five steps (0–3)	0.80 (0.83)	0.65 (0.80)	<0.001
Chores such as vacuuming or yard work (0–3)	1.19 (0.97)	1.08 (0.95)	<0.001
Uses cane, %	17.3	29.4	<0.001
Uses wheelchair, %	4.6	7.1	<0.001
Needs help with dressing and grooming, %	12.8	9.6	<0.001
Medications			
Current csDMARD or bDMARD use, %	78.9	82.1	<0.001
Current csDMARD use, %	72.5	69.4	<0.001
Number of csDMARDs	2.23 (1.65)	1.84 (1.43)	<0.001
Current bDMARD use, %	25.8	44.8	<0.001
Number of bDMARDs	0.44 (0.74)	1.19 (1.35)	<0.001
Current TNFi use, %	25.2	33.3	<0.001
No csDMARD/bDMARD or prednisone use, %	16.2	12.6	<0.001

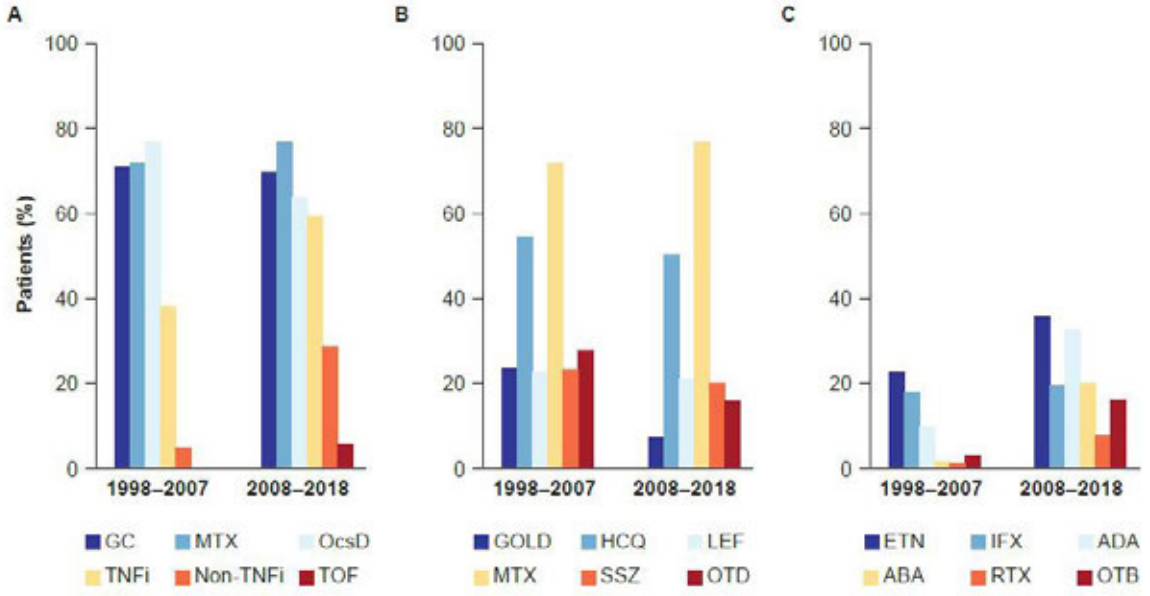
Values are mean (SD) unless indicated otherwise

bDMARD=biologic DMARD; csDMARD=conventional synthetic DMARD; QOL=quality of life; SF-36=Short Form 36; TNFi=TNF inhibitor; VAS=visual analog scale

use of biologic (b)DMARDs was higher in 2008–2018 vs 1998–2007 (Figure 1). Additionally, the use of combined (≥2) csDMARDs was less frequent in 2008–2018 vs 1998–2007, whereas the use of bDMARDs, either as monotherapy or in combination with ≥1 csDMARD, was higher in 2008–2018 vs 1998–2007 (Figure 2).

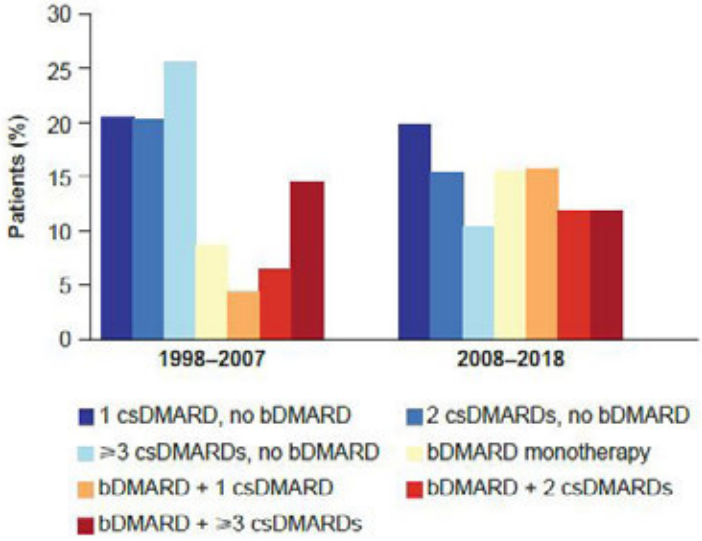
Conclusion: Over the last 20 years, there was a differential pattern of DMARD use between the two time periods (1998–2007 and 2008–2018), with a shift from use of non-MTX csDMARDs toward greater bDMARD use. Although

Figure 1. Comparison of the Proportion of Patients Who Had Ever Used csDMARDs or bDMARDs by Matched Decade (1998–2007 and 2008–2018): (A) Overall, (B) for Individual csDMARDs and (C) for Individual bDMARDs



ABA=abatacept; ADA=adalimumab; bDMARD=biologic DMARD; csDMARD=conventional synthetic DMARD; ETN=etanercept; GC=glucocorticoids; GOLD=injectable gold; HCQ=hydroxychloroquine; IFX=infliximab; LEF=leflunomide; non-TNFi=non-TNF inhibitors; OcsD=other csDMARDs no MTX; OTB=other bDMARDs (anakinra, certolizumab pegol, golimumab and tocilizumab); OTD=other csDMARDs (cyclosporine, doxycycline, azathioprine and cyclophosphamide); RTX=rituximab; SSZ=sulfasalazine; TNFi=TNF inhibitor; TOF=tofacitinib

Figure 2. The Proportion of Patients Using Combined Therapy With csDMARDs and/or bDMARDs at a Random Observation by Matched Decade (1998–2007 and 2008–2018)



bDMARD=biologic DMARD; csDMARD=conventional synthetic DMARD

matching did not allow for differences in functional disability between the two decades, patients in the latter decade had lower scores for performing daily activities and required less assistance from others but had greater use of aids such as a cane or a wheelchair. These results may contribute to a better understanding and management of disease for patients with RA.

MRI of the Wrist in Early Rheumatoid Arthritis After 1-year Treat-to-target Strategy

Fan Xiao,[1] Jacky Ka Ko,[1] Jiang Yue,[1] James Griffith,[1] and Lai-Shan Tam[1], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background: There are two types of remission in rheumatoid arthritis. The first, and most commonly applied, is clinical remission. Imaging remission is another aspect to consider given that (a) the correlation between clinical and imaging at presentation is only modest, (b) imaging can show subclinical inflammation not evident clinically and (c) imaging evidence of inflammation can predict structural damage. In this study, we compared clinical and imaging remission in early rheumatoid arthritis (ERA) patients after one year of standard treatment.

Objective: To semi-quantitatively and quantitatively measure the degree of inflammation (synovitis, tenosynovitis, bone marrow oedema) and structural change (erosions, joint space narrowing) on MRI in early RA patients following treat-to-target strategy treatment for one year and to compare this with change in clinical parameters.

Methods: Prospective cross-sectional study of 70 ERA patients underwent treat-to-target strategy treatment for one year. DAS28-ESR remission (DAS28-ESR score < 2.6), 2011 ACR/EULAR definition of remission, SDAI remission (SDAI ≤ 3.3) and Boolean remission was measured before and after treatment. High resolution MRI of the most symptomatic wrist was performed before and after treatment. MRI parameters including RAMRS subscores, synovial volume (synovitis and tenosynovitis), synovial perfusion (max enhancement, enhancement slope) were measured.

Results: 55 (79%) out of 70 ERA patients completed baseline and one-year clinical and MRI assessments. Remission rates for DAS28-ESR, SDAI and Boolean were 60% (33), 44% (24) and 33% (18) respectively. Eight (24%) out of 33 patients with DAS28-ESR remission, showed progression in bone erosion. Four (17%) of 24 patients with SDAI remission showed progression in bone erosion while 1 (5 %) of 18 patients with Boolean remission showed progression in bone erosion. Patients who achieved remission after treatment had a greater reduction in MRI-

evident inflammation as well as bone erosion. At month 12, MRI-evident joint synovitis, tenosynovitis and bone marrow oedema was still frequently seen in ERA patients with clinical remission though patients who achieved Boolean remission had the lowest levels of joint synovitis, bone marrow oedema as well as bone erosion for all patients at one year.

Conclusion: MRI detected inflammation is common even in patients with clinical remission. Patients with Boolean remission had less residual inflammation than DAS28-ESR or SDAI remission patients. Treat to target protocols should ideally target Boolean remission.

Safety of Baricitinib Under Clinical Settings in Patients with Rheumatoid Arthritis, Using Data from All-Case Post-marketing Surveillance and Spontaneous Reports

Hiroaki Matsuno,[1] Tatsuya Atsumi,[2] Shuji Takei,[3] Naoto Tamura,[4] Masayoshi Harigai,[5] Takao Fujii,[6] Shigeki Momohara,[7] Yuko Takahashi,[8] Nobuhiro Narii,[8] Naoto Tsujimoto,[8] **Atsushi Nishikawa**,[8] **Taeko Ishii**,[8] Kazuhiko Yamamoto,[9] Masataka Kuwana,[10] and Michiaki Takagi[11], [1]Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, [2]Hokkaido University, Sapporo, Japan, [3]Kagoshima University, Kagoshima, Japan, [4]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan, [5]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [6]Wakayama Medical University, Wakayama, Japan, [7]Hakkeikai Incorporated Medical Institution, Shizuoka, Japan, [8]Eli Lilly Japan K.K., Kobe, Japan, [9]Riken Center for Integrative Medical Sciences, Kanagawa, Japan, [10]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan, [11]Yamagata University Faculty of Medicine, Yamagata-shi, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib (bari), is an oral, selective inhibitor of Janus kinase (JAK) 1/ and JAK 2, is used to treat moderately to severely active RA in adults. The objective of the study was to evaluate Bari's safety under clinical settings in RA patients.

Methods: All-case post-marketing surveillance of Bari (except patients in clinical studies) collects safety and efficacy data for the first 24 weeks starting in September 2017; collection of safety data like serious adverse events (SAEs) continues for 3 years. This interim report summarizes registration data including pretreatment test rates and adverse events (AEs) collected in the surveillance and spontaneous reports.

Results: As of August 2018, 1288 patients had been enrolled. Registration data are as follows: women, 81%; mean age, 64 years old; mean RA duration, 12 years; Steinbrocker stage II, 32%; stage III or IV, 52%; Bari 4 mg, 68%; Bari 2 mg 32%; methotrexate (MTX) use, 57%; corticosteroid use, 51%; pretreatment test for tuberculosis (TB), 93%; HBV, 95%; HCV, 93%; and estimated glomerular filtration rate (eGFR), 96%. Of 299 AEs collected, 53 were SAEs. SAEs reported in 2 or more patients were pneumonia (8), fall (4), osteonecrosis (3), Herpes zoster (2) and interstitial lung disease (2). Pulmonary TB (1), lymph node TB (1) and deep vein thrombosis (1) were also reported as SAEs.

Conclusion: Care is needed to ensure that all pretreatment tests be conducted in all patients; although most patients underwent all tests, some tests were not conducted in some patients. In these preliminary data, consistently with bari's known safety profile, SAEs including infections were reported. Careful monitoring of patients receiving bari is recommended.

* Global p-value

Background/Purpose: Among the potentially modifiable prognostic factors in RA, there is evidence for associations with smoking history, BMI and dietary fish oil supplementation. An integrated examination of these lifestyle factors as predictors of RA outcomes was undertaken in a single early RA cohort receiving standardised algorithm-directed treat-to-target DMARD therapy.

Methods: Consecutive patients attending the Early Arthritis Clinic at the Royal Adelaide Hospital with recent-onset RA according to the 1987 revised American College of Rheumatology criteria and with disease duration < 12 months were eligible. All patients commenced 'triple therapy' with methotrexate, sulfasalazine and hydroxychloroquine and received advice to take fish oil supplements at anti-inflammatory doses, except for 139 patients within this cohort of 339 who participated in a randomised placebo controlled trial (RCT) of fish oil supplementation. Prognostic variables for DAS28 remission and DAS28 low disease activity (LDA) at the 12 month visit (+/- 6 weeks window was allowed) were identified using multivariable logistic regression models, correcting for potential confounders (age, sex, RF and CCP status and shared epitope). Omega-3 status was assessed as plasma eicosapentaenoic acid (EPA) levels.

Results: Of 311 participants with complete data, 57.6% reached DAS28 LDA and 43.7% were in DAS28 remission at one year. Increase in plasma EPA was associated with an increase in the odds of being in DAS28 LDA (OR=1.28; p< 0.0001) and DAS28 remission (OR=1.22; p< 0.001). There was a statistically significant interaction between smoking status and BMI on DAS28 LDA. Increase in BMI was associated with a decrease in the odds of being in DAS28 LDA in current and former smokers, but had no impact on LDA in patients who had never smoked. There were no statistically significant associations with BMI or smoking history and DAS28 remission. While a 1kg/m2 increase in BMI was associated with a decrease in the odds of having DAS28 low disease activity at 1 year in current and former smokers, it had no impact in patients who had never smoked.

Conclusion: Among all prognostic factors, fish oil supplementation in early RA patients receiving T2T therapy is significantly associated with the greatest increased odds of achieving DAS28 LDA at one year. The effect modification by smoking status on the association of BMI with treatment outcomes in early RA strongly supports counselling for lifestyle modification in patients who have a smoking history, particularly if they are overweight.

Methotrexate Discontinuation and Dose Decreases After Therapy with Tocilizumab: Results from the Corrona Rheumatoid Arthritis Registry

Dimitrios Pappas,[1] Taylor Blachley,[2] Steve Zlotnick,[3] Jennie Best,[3] Kelechi Emeanuru,[2] and Joel Kremer[4], [1]Columbia University, New York, NY, [2]Corrona, LLC, Waltham, MA, [3]Genentech, Inc., South San Francisco, CA, [4]Albany Medical College and The Center for Rheumatology; Corrona, LLC, Albany, NY

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is frequently prescribed with biologic disease-modifying antirheumatic drugs. Evidence has shown that tocilizumab (TCZ) monotherapy is effective in the treatment of patients with rheumatoid arthritis (RA).[1,2] Similar outcomes have been shown in patients responding to TCZ combination therapy who discontinued MTX or remained on combination therapy.[3] The purpose of this study was to examine MTX discontinuation and dose decreases in patients with RA initiating TCZ and to describe disease activity outcomes in a real-world setting.

Table 1. Change in Disease Activity and PROs* at 6 Months in Patients With RA

	All Patients (N = 444)	Discontinued MTX (n = 72)	Decreased MTX Dose (n = 67)	No Change in MTX Dose (n = 269)	Increased MTX Dose (n = 36)
CDAI	−7.8 (14.3)	−5.5 (13.1)	−7.1 (13.6)	−8.4 (14.7)	−9.8 (15.2)
DAS28	−1.2 (1.7)	−1.0 (1.7)	−1.1 (1.5)	−1.3 (1.6)	−0.9 (2.4)
Tender joint count	−3.2 (7.9)	−1.3 (7.1)	−1.8 (7.5)	−3.8 (8.1)	−4.2 (7.6)
Swollen joint count	−2.6 (5.6)	−2.2 (5.2)	−2.2 (5.1)	−2.7 (5.8)	−3.1 (6.1)
Physician global assessment	−13.1 (23.1)	−13.3 (23.4)	−17.0 (20.7)	−11.8 (23.4)	−16.2 (24.0)
Patient global assessment	−7.6 (25.9)	−6.4 (25.9)	−13.5 (28.5)	−6.4 (25.0)	−7.3 (26.4)
mHAQ	−0.1 (0.4)	−0.1 (0.4)	−0.1 (0.4)	0 (0.4)	−0.2 (0.5)
Patient pain	−7.3 (24.4)	−6.2 (23.7)	−8.2 (24.8)	−7.0 (24.3)	−10.8 (26.2)
Patient fatigue	−6.3 (26.6)	−7.3 (26.5)	−8.6 (30.7)	−5.0 (26.3)	−10.3 (20.2)
Morning stiffness present, n (%)	−29 (7.1)	−6 (9.4)	−5 (8.2)	−17 (6.8)	−1 (3.0)
Morning stiffness time, h	−0.1 (3.7)	−0.7 (2.8)	0 (2.1)	−0.1 (3.8)	0.3 (6.1)

CDAI, Clinical Disease Activity Index; DAS28, Disease Activity Score in 28 joints; mHAQ, modified Health Assessment Questionnaire; MTX, methotrexate; PRO, patient-reported outcome; RA, rheumatoid arthritis.
* Changes in disease activity and PRO measures are presented as mean (SD) unless otherwise indicated.

Methods: TCZ-naïve patients enrolled in the Corrona RA Registry who initiated TCZ and had a 6-month follow-up visit without discontinuation of TCZ were included. Patients were grouped by MTX dose at the time of TCZ initiation (≤ 10 mg, > 10 to ≤ 15 mg, > 15 to ≤ 20 mg, > 20 mg). The primary outcome was the proportion of patients with changes in MTX use at 6 months. Changes in disease activity (Clinical Disease Activity Index [CDAI]) and patient-reported outcomes (PROs) over the follow-up period are described.

Results: Of 444 eligible patients, 82.7% were female, and 83.7% were white, with a mean (SD) disease duration of 11.6 (9.3) years and a baseline CDAI score of 24.0 (15.4). The mean (SD) MTX dose at baseline was 17.7 (5.8) mg. Overall, a total of 139 patients (31.3%) discontinued or decreased MTX at 6 months (overall mean [SD] dose change, –3.0 [7.5] mg); across baseline MTX dose groups, the proportion of patients who discontinued or decreased MTX at 6 months ranged from 28.2% to 38.2%. Improvements in CDAI scores and PROs were observed at 6 months in all baseline MTX dose groups and in patients who discontinued, decreased, maintained, or increased MTX doses at 6 months (**Table 1**). Similar patterns and results were observed at 12 months (not shown).

Conclusion: A considerable proportion of patients initiating TCZ were able to discontinue or decrease the dose of MTX after TCZ initiation. Patients who were able to discontinue or decrease MTX experienced similar improvements in disease activity and functionality. Discontinuing or decreasing MTX may be an effective treatment strategy for patients initiating TCZ combination therapy.

Table 1 Comparison of the Demographic, Clinical and Laboratory Characteristics of Rhupus, RA, and SLE patients

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rhupus is the overlap of SLE and RA. While a few studies have been conducted among Rhupus patients, no studies have focused on Black population with Rhupus. Our aim was to describe the clinical, laboratory, radiographic and therapeutic profiles of predominantly Black patients with Rhupus and to compare this group with age and sex-matched patients with SLE and with RA.

Methods: Retrospective chart review of SLE and RA overlap patients followed at 2 large urban hospitals. Rhupus patients were identified by ICD codes and compared to age and sex matched cohort of SLE only and RA only groups. Descriptive statistics using SPSS® version 24 were applied to analyze the differences between the three cohorts.

Results: 38 patients met the ACR criteria for both RA and SLE (Rhupus) with 94.7% being women, mean age of 50.9±14.4 (SEM). Blacks represented 81.6% with a BMI of 28.6±7.3Kg/m^2. 50% had hypertension, 71.1% had at least one cardiovascular (CV) risk factor and 26.3% had 3 or more CV risk factors. Mean ESR = 58.28 ± 5.45 and

Table 3 Comparison of Clinical, Laboratory, Radiographic, and Therapeutic Profiles of Rhupus and SLE only patients

CRP = 28.94 ± 8.8. There were no significant differences in CV risk factors, CV outcomes and inflammatory markers between the three cohorts. The rate of leukopenia and CRP levels were significantly higher in the Rhupus compared to the SLE and RA groups.

Compared to RA only group there were higher rates of smoking and ANA positivity among Rhupus populations. Leukopenia and positive RF and ACPA rates were frequent among Rhupus patients compared to RA only cohort.

Corticosteroids, MTX, and biologic DMARDs use did not differ between Rhupus and RA cohorts. Rate of utilization of other-than-MTX DMARDs and the combination of steroid with DMARDs was higher among the Rhupus compared to the RA only cohort.

When comparing Rhupus and SLE patients, the rates of mucocutaneous lesions, serositis, neurologic manifestations, and laboratory values including autoantibodies were no different between the groups. Smoking, arthritis, hand XR abnormalities, erosions, seropositive RA were more frequent among the Rhupus vs. SLE patients. However, lupus nephritis and RNP antibodies were less frequent in Rhupus compared to SLE only group. Corticosteroids, MTX, conventional and biologic DMARDs and combination therapy were more frequently used in Rhupus compared to SLE population.

Conclusion: In our predominantly Black population, Rhupus patients had higher rates of smoking and ANA positivity compared to RA patients. It also had lower rate of positivity for RF or ACPA. Rates of smoking, arthritis, erosions, positivity for RF, ACPA and aCL antibodies were higher among Rhupus compared to SLE patients. These results suggest smoking to be a potential risk factor for Rhupus and might play a role in the underlying pathophysiology of this overlap syndrome. Further studies are needed to confirm our findings and elucidate risk factors and predictors of Rhupus to help develop preventive and therapeutic strategies for this important disease entity.

High Initial Methotrexate Dose Is Not Associated with an Increased Risk of Liver Toxicity in Korean Patients with Rheumatoid Arthritis

Se Rim Choi,[1] Yeong-Wook Song,[2] Eun Bong Lee,[3] and Jin Kyun Park[1], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Seoul, Republic of Korea, [2]Seoul National University Hospital, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, seoul

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is the most commonly prescribed disease modifying anti-rheumatic drugs (DMARDs) for the treatment of RA due to its high efficacy and favorable safety profile. However, a higher incidence of MTX toxicity at dose >7.5mg/week has been reported in East Asia, especially in Japan, possibly due to a different genetic background in regard to MTX metabolism. Therefore, it is common to start MTX in a lower dose and to titrate it up slowly to target of 15-20 mg/ week. This approach can be associated with a significant delay in reaching a “therapeutic MTX dose” in RA patients. The aim of this study is to investigate as to whether a certain starting dose of MTX is associated with an increased MTX-toxicity in Korean patients with RA.

Methods: In this retrospective cohort study 2361 MTX-naïve RA patients, in whom MTX was initiated between 2009 and 2018, were included. Patients were divided into a low (≤7.5mg/week), moderate (10-12.5 mg/week) and high (≥15 mg/week) dosing groups. A MTX toxicity is defined as an increase of post-MTX AST or ALT >80 mg/dL. Groups were compared using chi-square and one-way analysis of variance. Factors associated with toxicity on liver were examined using logistic regression analyses. All analyses were performed by using SPSS (IBM SPSS statistics version 25).

Results: The mean age was 54.1 +/- 13.9 year. Women were dominant (79.6%). 31 (1.3%) and 5 (0.2%) patients had hepatitis B and C virus infection, respectively. There was no significant difference in age, sex, underlying liver disease between the three dosing groups. 1756 (74.4%) patients were taking glucocorticoids (prednisolone equivalent 7.7 +/- 4.8 mg/day) and 321 (13.6%) patients were taking leflunomide or sulfasalazine. The mean starting MTX dose was 11.1 +/- 3.0 mg/week. 522 (22.1%) patients, 1162 (49.2%) and 677 (28. 7%) patients started MTX ≤7.5mg/ week, 10-12.5 mg/week and ≥15 mg/week, respectively. All patients received folate supplementation. Liver toxicity was observed in 30 (1.3 %) patients. The rate of liver toxicity did not differ among the groups (1.5% in the low vs. 0.9% in the moderate vs. 1.6% in the high dosing group, P = 0.38). In logistic regression analyses, clinical parameters including age, sex, body mass index and initial MTX dose were not associated with an increased risk of a hepatotoxicity either.

Conclusion: This study demonstrated clearly that the initial MTX dose up to 15 mg /week was not associated with an increased toxicity on liver in Korean patients with RA. Therefore, MTX can be started at 15 mg/week in Korean patients with RA without a safety concern on liver toxicity.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Total management including reconstructive joint surgery and rehabilitation should be needed for further improvements of physical function for long-standing RA patients. In these days, it is very important to evaluate the effectiveness of joint surgery as well as drug therapy based on patient-reported outcome (PRO) The purpose of this study is to explore the relationship among depression, clinical variables and other PROs including physical function.

Methods: Multicenter prospective observational cohort study was conducted among patients who underwent elective joint surgery for RA from April 2012 to March 2016 (Study registration: UMIN000012649). In this study, we collected data at baseline and at 6 or 12 months after the surgery. These data were as follow; age, sex, disease duration, drug therapies, and disease activity (DAS), TUG, and patient-reported outcome [HAQ-DI, EQ-5D (QOL), pain and BDI-II (depression)]. Correlation between BDI-II and other variables were determined using multiple liner regression analysis.

Results: Totally, 346 patients before elective joint surgery were analyzed cross-sectionally. Mean age, disease duration, pain(VAS), DAS28, HAQ-DI, EQ-5D and BDI-II were 64.2 years, 17.0 years, 36.2 mm, 3.02, 1.11, 0.641 and 13.0, respectively. 52.6% of elective joint surgeries were in upper limbs and 47.4% were in lower limbs. Multiple liner regression analysis showed that HAQ-DI [B:-0.099 (95%CI:-0.117- -0.08) β:-0.48] pain VAS [B:-0.002 (95%CI:-0.002- -0.001) β:-0.26] and BDI-II [B:-0.003 (95%CI:-0.005- -0.002) β:-0.19] were independent factors for EQ-5D. Furthermore, HAQ-DI [B:3.78 (95%CI:2.54- 5.06) β: 0.33] and pain VAS [B: 0.062 (95%CI: 0.023- 0.101) β 0.17] were significant impact on BDI-II. Especially, walking and eating were independent factors for BDI-II in HAQ-DI categories.

We confirmed these BDI-relating factors above in longitudinal analyses, at last observation (6 or 12 months) after joint surgery in lower limbs (n=138). BDI-II was remarkably improved from 12.1 (mean) to 10.5. Change in HAQ-DI had significant impact on that in BDI-II [B:3.183 (95%CI:0.301- 6.065) β:0.229] while that in painVAS did not. The improving in walking was a relevant factor for improving of BDI-II after the surgery [B:2.898(95%CI:0.641- 5.155) β:0.213].

Conclusion: Depression is an important patient-reported outcome for QOL in established RA patients. Improving of physical function with joint surgery in lower limbs caused improving of depression status. Rheumatologists should take the joint surgery into consideration as effective intervention for treatment of established RA patients.

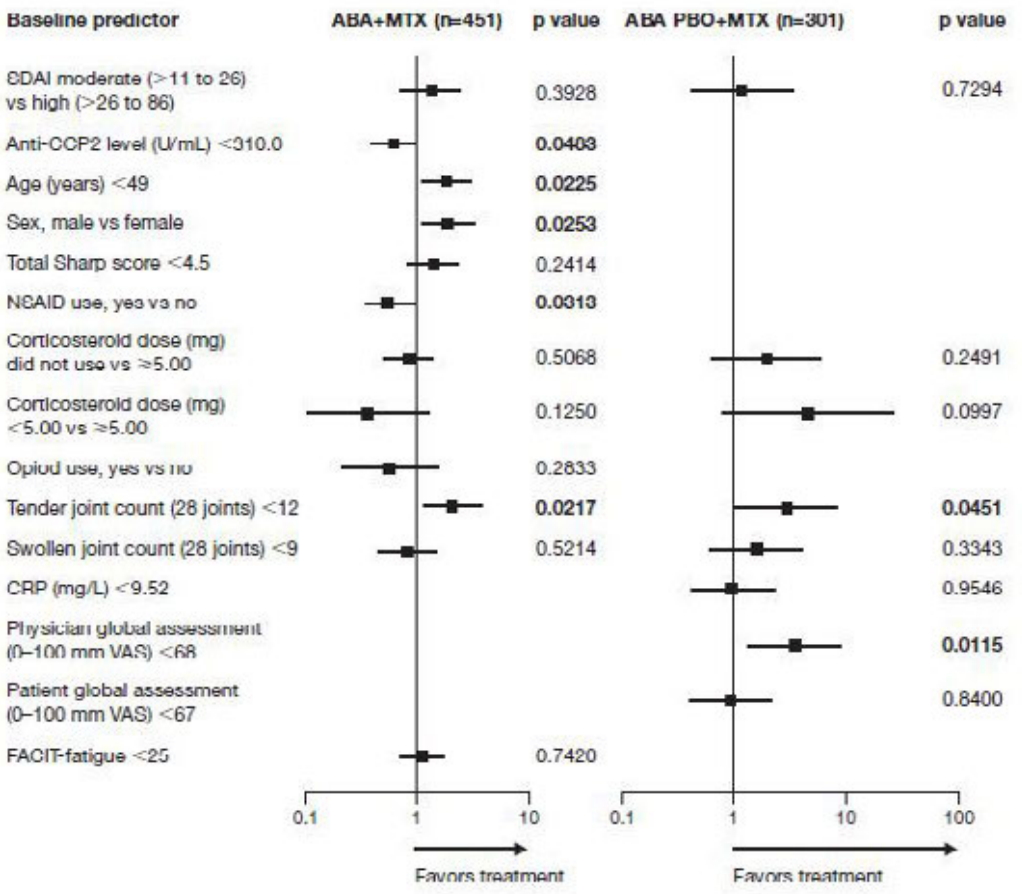
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Phase IIIb Assessing Very Early Rheumatoid arthritis Treatment (AVERT)-2 trial (NCT02504268) is evaluating SC abatacept (ABA) + MTX versus ABA placebo (PBO) + MTX in adults with early RA.[1] AVERT-2 was designed to demonstrate that ABA + MTX could achieve higher rates of SDAI remission versus ABA PBO + MTX and to test a clinically meaningful withdrawal strategy. Identifying factors associated with response may help guide treatment decisions, including initial treatment choice and de-escalation of therapy. We investigated baseline characteristics that were associated with sustained SDAI remission (≤3.3 at Weeks 40 and 52), therefore allowing patients to enter the de-escalation period, in AVERT-2.

Methods: For the induction period (IP), patients were randomized 3:2 to SC ABA (125 mg weekly) + MTX or ABA PBO + MTX for 56 weeks. Following the IP, patients entered a 48-week de-escalation period. Key inclusion criteria:

Figure 2. Dichotomized Characteristics Associated With Sustained SDAI Remission in Multivariate Analyses



Sustained SDAI remission: patients in remission at Weeks 40 and 52. As corticosteroid dose (mg) <5.00 vs ≥5.00 had a p value <0.2 in the univariate model, corticosteroid dose (mg) did not use vs ≥5.00 was also included in the multivariate model for completeness, despite having a p value >0.2
Data are odds ratios (95% CI)
FACIT=Functional Assessment of Chronic Illness Therapy; VAS=visual analog scale

age ≥18 years; RA diagnosis ≤6 months (ACR/EULAR 2010 criteria); ACPA+; CRP >3 mg/L or ESR ≥28 mm/h; TJC ≥3 and SJC ≥3; DMARD naive. Logistic models were used to explore potential factors associated with sustained SDAI remission by treatment arm in the cohort 1 analysis population (all randomized patients treated in the IP). Continuous variables were dichotomized based on median values before introduction to the models. A total of 30 baseline characteristics (demographics, disease/clinical endpoints, co-medication use, serum markers, patient-reported outcomes) were tested individually by logistic regression in a univariate analysis, and variables with $p< 0.2$ were entered into a multivariate model.

Results: Overall, 752 patients were randomized and treated in cohort 1 during the IP: 451 with ABA + MTX and 301 with ABA PBO + MTX. Baseline characteristics were similar across treatment arms. A total of 11 and 8 baseline characteristics, respectively, were identified as independently associated with sustained remission with ABA + MTX and ABA PBO + MTX (Fig. 1). Baseline characteristics associated with sustained remission by multivariate analysis (Fig. 2) with ABA + MTX were anti-CCP ≥310 U/mL, age < 49 years, male sex, NSAID naïve and TJC < 12. Baseline characteristics associated with sustained remission by multivariate analysis with ABA PBO + MTX were physician global assessment (PGA) < 68 and TJC < 12 (Fig. 2).

Conclusion: In this population of ACPA+ patients with early RA, several baseline characteristics were found to be associated with sustained SDAI remission in patients treated with abatacept + MTX: anti-CCP2 levels ≥310 U/mL, age < 49 years, TJC < 12, being NSAID naïve and/or being male. In patients treated with abatacept PBO + MTX, having PGA < 68 and/or TJC < 12 were associated with sustained SDAI remission. The identification of baseline characteristics associated with treatment response in patients with very early RA may provide additional insight into which patients may be suitable for de-escalation of therapy.

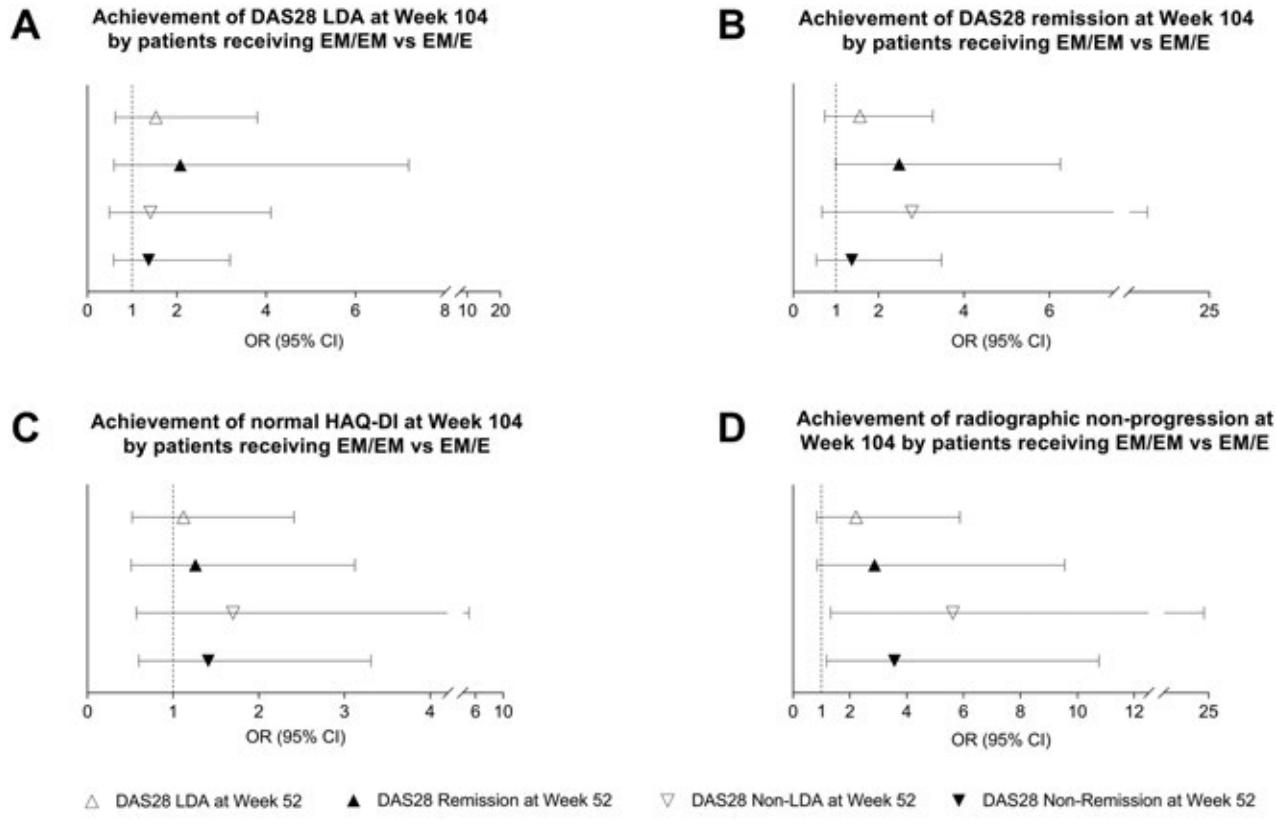
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For patients with rheumatoid arthritis (RA) who are treated with etanercept (ETN) plus methotrexate (MTX), dosing down of ETN or withdrawal of MTX are options once treat-to-target has been achieved. In the COMET study[1] (NCT00195494), patients with RA received combination therapy (50 mg/week ETN+MTX) for 52 weeks in Period (P) 1, and were then randomized to either continue combination therapy or discontinue MTX and receive ETN monotherapy for a further 52 weeks (P2). The purpose of this analysis was to compare Week 104 clinical, functional, and radiographic outcomes between treatment arms for each patient subgroup, classified by disease activity score in 28 joints (DAS28) response (achievement or not of DAS28 low disease activity [LDA; DAS28 score ≤3.2] or remission [DAS28 score < 2.6]).

Methods: Odds ratios (ORs) comparing the ETN+MTX and ETN P2 treatment arms for each Week 52 DAS28 status were calculated from logistic regression models with treatment, Week 52 DAS28 status, and their interaction as predictors of achieving DAS28 LDA, DAS28 remission, normal Health Assessment Questionnaire-Disability Index (HAQ-DI) score (score ≤0.5), and radiographic non-progression (change from Year 2 baseline in modified Total Sharp Score [mTSS] of ≤0.5) at Week 104.

Results: A total of 208 patients (105 in the ETN+MTX and 103 in the ETN monotherapy P2 treatment arms, respectively) were included in this analysis. The odds of achieving DAS28 LDA, DAS28 remission, or normal HAQ-DI at Week 104 in patients who did or did not achieve a DAS28 response at Week 52 did not generally differ significantly between the treatment groups (Figure, Panels A-C), which could be attributed, at least in part, to lack of power to detect treatment differences due to small sample sizes (36 [ETN+MTX] and 28 [ETN] patients were in the Week 52 LDA



CI, confidence interval; DAS28, disease activity score in 28 joints; E, etanercept; EM, etanercept + methotrexate; HAQ-DI, health assessment questionnaire-disability index; LDA, low disease activity; OR, odds ratio

non-response category while 51 [ETN+MTX] and 40 [ETN] patients were in the remission non-responder category). The only exception was the significantly higher odds of achieving radiographic non-progression in patients treated with ETN+MTX vs ETN monotherapy who did not achieve a DAS28 response at Week 52 (Figure, Panel D). Although the overall lack of significant ORs suggests that there were almost no differences between the two treatment arms, the ETN+MTX treatment arm had ~5-15% higher rates of response compared with ETN monotherapy for the DAS28 and HAQ outcomes (regardless of Week 52 DAS28 subgroup), and for radiographic outcomes for Week 52 DAS28 responders. A ~25% higher rate of response for the ETN+MTX vs the ETN monotherapy treatment arm was seen for radiographic outcomes in the Week 52 DAS28 non-response categories (Table). Week 52 DAS28 status did not modify treatment effect on outcomes, but did increase the ETN treatment effect on radiological efficacy from ~10% for Week 52 DAS28 responders to ~25% for Week 52 DAS28 non-responder.

Conclusion: For patients with RA receiving ETN+MTX who achieved DAS28 LDA or remission after 52 weeks, discontinuation of MTX at Week 52 may result in minimal loss of clinical, functional, and radiological efficacy after an additional 52 weeks of treatment with ETN monotherapy.

Proportion of patients who achieved Week 104 outcomes, stratified by achievement/non-achievement of DAS28 response (LDA/Remission) at Week 52, n/N (%)								
Week 104 outcome	Achieved DAS28 LDA at Week 52 (response)		Did not achieve DAS28 LDA at Week 52 (non-response)		Achieved DAS28 Remission at Week 52 (response)		Did not achieve DAS28 Remission at Week 52 (non-response)	
	EM+EM	EM+E	EM+EM	EM+E	EM+EM	EM+E	EM+EM	EM+E
DAS28 LDA	60/69 (87.0)	61/75 (81.3)	13/36 (36.1)	8/28 (28.6)	50/54 (92.6)	54/63 (85.7)	23/51 (45.1)	15/40 (37.5)
DAS28 Remission	53/69 (76.8)	51/75 (68.0)	9/36 (25.0)	3/28 (10.7)	46/54 (85.2)	44/63 (69.8)	16/51 (31.4)	10/40 (25.0)
Normal HAQ-DI	53/69 (76.8)	56/75 (74.7)	13/36 (36.1)	7/28 (25.0)	44/54 (81.5)	49/63 (77.8)	22/51 (43.1)	14/40 (35.0)
Non-progression in annualized mTSS	56/63 (88.9)	54/69 (78.3)	30/33 (90.9)	16/25 (64.0)	45/49 (91.8)	47/59 (79.7)	41/47 (87.2)	23/35 (65.7)

DAS28 LDA = DAS28 ≤3.2

DAS28 Remission = DAS28 <2.6

Normal HAQ-DI = HAQ ≤ 0.5

Non-progression in annualized mTSS = change from Year 2 baseline mTSS ≤ 0.5

DAS28, disease activity score in 28 joints; E, etanercept; EM, etanercept + methotrexate; HAQ-DI, health assessment questionnaire-disability index; LDA, low disease activity; mTSS, modified Total Sharp Score

Treatment for Rheumatoid Arthritis After Methotrexate-associated Lymphoproliferative Disorder Developed

Yuji Yoshioka,[1] Shouhei Nagaoka,[2] and Hiroyuki Hagiyama[3], [1]Saiseikai Yokohamashi Nanbu Hospital, Yokohama, Japan, [2]Yokohama Minami Kyousai Hospital, Yokohama, Kanagawa, Japan, [3]Yokohama City Minato Red Cross Hospital, Yokohama

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate-associated lymphoproliferative disorder (MTX-LPD) is important complication in the rheumatoid arthritis (RA) treatment. There were few reports about clinical features of MTX-LPD and RA treatment after MTX-LPD.

Methods: We retrospectively extracted RA patients diagnosed as MTX-LPD in 3 rheumatology centers between March 2019 and January 2008 from medical record.

Results: 39 patients were included. We classified MTX-LPD disease course after withdrawal of MTX in three; not improved group (group A; 8 patients) , completely improved group (group B; 19 patients) , improved once but relapse after few years group (group C; 12 patients).There was significant difference in EBER-ISH positivity between improved after withdrawal of MTX group (group B + group C) and group A (11/17 vs 1/7 p=0.00247). Significant difference was seen in morbidity rate of Sjogren's syndrome (SS) between group B and C (0/19 vs 4/12 p=0.00701). Histopathological examples were obtained 32 patients; 12 of 32 were diagnosed as diffuse large B-cell lymphoma (DLBCL), 8 as Hodgkin's lymphoma(HL), 7 as hyperplasia, 2 as Follicular lymphoma (FL), 1 as peripheral T-cell lymphoma (PTCL), 1 as Angioimmunoblastic T-cell lymphoma (AITL), 1 as Lymphomatoid granulomatosis (LYG). All patients discontinued MTX after diagnosed as MTX-LPD. In improved after withdrawal of MTX group (group B + group C), 25 of 31 patients showed relapse of RA in average 9.61 months after discontinuation of MTX. In group A, all patients received chemotherapy and RA flare was not seen during chemotherapy but three of 8 showed relapse of RA in average 26.5 months. After RA flare following drugs were administered including overlap; Iguratimod(IGU) in 10 cases, Salazosulfapyridine(SSZ) , Abatacept(ABT), and Tacrolimus(TAC) in 8, Bucillamine(BUC) in 6, Mizoribine(MZB) in 5, Tocilizmab(TCZ) in 2, Auranofin(AUR), D penicillamine and Etanercept(ETN) in 1. Recurrence of LPD was seen in 4 cases after additional administration of DMARDs; IGU in 2cases, SSZ and TAC in one.

Conclusion: EBER-ISH positivity was associated with spontaneous improvement of MTX-LPD and absence of SS was associated with completely improvement of MTX-LPD. Relapse of RA after withdrawal of MTX is common and LPD might recur after additional treatment of RA flare, but there was no specific drug to recur LPD.

Yoga Improves Fatigue and Mental Health in Rheumatoid Arthritis: Preliminary Results of a Randomized Controlled Trial

Silva Pukšić,[1] Joško Mitrović,[2] Melanie-Ivana Čulo,[2] Marcela Živković,[3] Biserka Orehovec,[4] Dubravka Bobek,[5] Marko Lucijanić,[6] and Jadranka Morović-Vergles[7], [1]Department of Clinical Immunology, Rheumatology and Allergology, University Hospital Dubrava, Zagreb, Croatia, Zagreb, Croatia, [2]Department of Clinical Immunology, Rheumatology and Allergology, University Hospital Dubrava, Zagreb, Croatia, [3]Department of Laboratory Diagnostics, University Hospital Dubrava, Zagreb, Croatia, Zagreb, Croatia, [4]Department of Laboratory Diagnostics, University Hospital Dubrava, Zagreb, Croatia, [5]Department of Physical Medicine and Rehabilitation with Rheumatology, University Hospital Dubrava, Zagreb, Croatia, Zagreb, Croatia, [6]Department of Hematology, University Hospital Dubrava, Zagreb, Croatia, Zagreb, Croatia, [7]Department of Clinical Immunology, Rheumatology and Allergology, University Hospital Dubrava, School of Medicine,Zagreb, Croatia, Zagreb, Croatia

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients perceive reduced health-related quality of life (HRQOL) through functional disability, pain, increased fatigue and impaired psychological functioning. Previous trials demonstrated that Yoga, a mind-body therapy, can enhance both physical and mental health in various chronic conditions including RA. The primary objective of the study was to explore the efficacy of yoga program in improving HRQOL. Secondary objectives included improvement in fatigue, anxiety, depression and disease activity.

Methods: 43 RA patients (2010 ACR/EULAR criteria), ≥ 18 years, stable on standard pharmacological treatment with disease activity according to DAS28CRP < 5.1 were randomly assigned to 12 weeks yoga intervention (2x/week 90 min; n=22) or arthritis-education control (1x/week 60 min; n=21). Yoga intervention according to „Yoga in daily life system" included asanas, relaxation, pranayama and meditation. Control group had educational lectures on arthritis-related topics delivered by rheumatologist followed by group discussion. Participants completed study evaluations at baseline and post-intervention. Evaluations included The Short Form-36 (SF-36) scores for Physical Component Summary (PCS) and Mental Component Summary (MCS), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), Hospital Anxiety and Depression scale (HADS) and Disease Activity Score-28CRP (DAS28CRP) questionnaires. Data were analyzed as differences in post and pre-intervention scores. Between group differences were analyzed using the t-test for independent samples. To assess effects of intervention we used per-protocol analysis. P values < 0.05 were considered statistically significant.

Results: Of the 43 patients included 37 (18 = intervention group, 19 = control group) completed the trial period. Groups did not significantly differ in baseline characteristics (P >0.05 for all analyses). Mean (SD) age was 55 (10.4) years, median (IQR) disease duration 5 (2.5,8) years, 93 % were female. There was no significant difference found between groups for SF-36 MCS (p=0.366), PCS (p=0.511) and DAS28CRP (p=0.724). Yoga group showed statistically significant improvements compared to control in FACIT-F (p=0.013), HADS anxiety (p=0.047) and HADS depression (p=0.004). Results are shown in the Table. No serious adverse events were observed during trial period.

Conclusion: Although Yoga was not associated with change in SF-36 scores and disease activity it led to significant improvement in fatigue, depression and anxiety which are principal contributors to decreased life quality of RA patients. Our findings are limited by small sample sizes and lack of statistical power to obtain significance for some

Table 1. Changes in outcomes from baseline
N= 37

Variables	Baseline mean (SD)	Change from baseline (95%CI) at 12 weeks	95% CI and P-value for difference between groups

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, the combination therapies of conventional synthetic disease-modifying anti-rheumatic drugs (cDMARDs) with Chinses medicine has prevailed for the treatment of rheumatoid arthritis (RA) in China. The objective of this pilot study was to assess the efficacy and safety of Biqi capsule, a Chinses herbal medicine combined with methotrexate (MTX) against patients with rheumatoid arthritis (RA) comparing with the combination therapy of MTX with Leflunomide (LEF).

Methods: This was a multicenter, open-label, randomized, parallel controlled trial with 24-week course on the treatment of RA. Total of 70 participates with RA were randomly assigned at a ratio of 1:1 to received Biqi capsule at a dose of 1.2g twice daily, or LEF at a dose of 20mg once daily in addition to MTX treatment. The primary outcome was the rate of achievement of 20% improvement in the American College of Rheumatology criteria (ACR 20) at 24 weeks. Secondary outcomes included the ACR50 and ACR70 responses, EULAR response, the side effects of the medications, 28-tender joint count (TJC28), 28-swollen joint count (SJC28), patient's assessment of pain (VAS), patient's and physician's global assessment of disease activity (PaGADA/PhGADA), erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor(RF) and health assessment questionnaire (HAQ) score. Efficacy and safety were assessed after 4, 12 and 24 weeks of follow-up.

Results: 59/70 (84.3%) patients completed 24 weeks of the study. In an intention-to-treat analysis (ITT), ACR20 response was attained in 27 (77.1%) of 35 patients with MTX+Biqi treatment and 29 (82.9%) of 35 patients with MTX+LEF treatment at 24 weeks ($p=0.550$). Importantly, fewer adverse events were found in patients treated with Biqi+MTX compared to patients with MTX+LEF ($p< 0.05$).

Conclusion: With a beneficial clinical response and acceptable tolerability, our study suggested that Biqi capsule appeared to be a promising alternative option in combination with MTX in RA treatment.

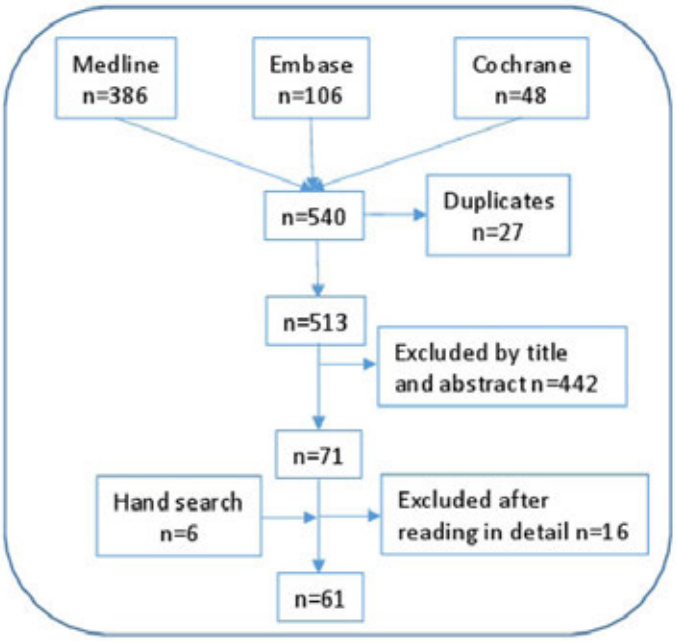
Consensus Statement and Recommendations on Methotrexate Use in Combined Therapy with Biological or Targeted Synthetic Disease Modifying Drugs in Patients with Rheumatoid Arthritis

Jesus Tornero,[1] Mercedes Alperi-López,[2] Ivan Castellvi,[3] Juan José de Agustín de Oro,[4] Alejandro Escudero,[5] Rosario Garcia-Vicuña,[6] Miguel Angel González-Gay,[7] Cristina Hidalgo,[8] Esteban Rubio,[9] Raimon Sanmarti,[10] Núria Casamira,[11] and Jaime Calvo-Alen[12], [1]Hospital de Guadalajara, Guadalajara, Spain, [2]Hospital Universitario Central de Asturias, Oviedo, Spain, [3]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain, [5]IMIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain, [6]Hospital Universitario de La Princesa, Madrid, Spain, [7]Universidad de Cantabria and IDIVAL, Hospital Universitario Marqués de Valdecilla, Santander, Spain, [8]Hospital Clínico Universitario de Salamanca, Salamanca, Castilla y Leon, Spain, [9]Rheumatology Department, University Hospital Virgen del Rocío, Sevilla, Spain, [10]Department of Rheumatology, Hospital Clínic, Barcelona, Barcelona, Spain, [11]Medical Department, Gebro Pharma S.A., Barcelona, Spain, [12]Hospital Universitario Araba, Vitoria-Gasteiz, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our aim was to develop recommendations for the management of methotrexate (MTX) when considering the combination with biological (b) or targeted synthetic (ts) disease modifying drugs (DMARDs) in rheumatoid arthritis (RA).

Methods: Methodological procedures included nominal discussion group, systematic literature review, and Delphi survey for agreement. A panel of 11 expert rheumatologists, including two coordinators, was selected. The coordinators defined the goals, scope and users of the document and delivered a set of 11 relevant clinical questions regarding the use of MTX in combination with b or tsDMARDs, including the indication, dose, route of administration, dose-adjustments, efficacy and safety. To address them, an extensive systematic literature review was performed. The following PICO queries and inclusion criteria were defined, 1) RA patients (population); 2) on, or considering the start of combined therapy with MTX and b or tsDMARDs (intervention); reporting efficacy and/or safety variables like composite activity indexes, radiographic progression, serious adverse events, etc. (outcomes); 3) searches restricted to systematic literature reviews and meta-analysis, humans, English and Spanish articles. Then, an expert documentalist designed the search strategies (Medline, Embase and the Cochrane Library up to January 2019), using Mesh ant text word terms. Two reviewers selected the articles and collected data, independently. Subsequently, a manual search of the bibliography of the articles that were finally included was performed. Evidence tables were produced. The quality was evaluated with the Oxford Center for Evidence Based Medicine recommendations. Simultaneously, EULAR and ACR abstracts (2017 and 2018) were evaluated, along with national and international consensus and guidelines. This information was used by the coordinators to generate preliminary



Firuge 1. Studies flow-chart.

recommendations. Then, all the experts, in a nominal discussion group, agreed on the proposed objectives, scope and users, and analyzed the results of the review and preliminary recommendations. Recommendations were reformulated as considered, and voted in a Delphi process (yes/no). Agreement was considered if at least 80% of experts voted yes. The level of evidence and grade or recommendation were assigned using the Oxford Centre for Evidence-Based Medicine guidance. The full document was critically appraised by the experts and the project was supervised at all steps by a methodologist.

Results: The systematic literature search retrieved 513 citations of which 61 were finally included. A total of 9 preliminary recommendations were proposed, 2 were not voted and were explained in the main text of the document, 3 new ones were proposed and 10 were finally voted and accepted (depicted in table 1 with their level of evidence, grade of recommendation and grade of agreement). The level of agreement was very high in all of them and was achieved in the first Delphi round.

Conclusion: This document is intended to help clinicians solve usual clinical questions and facilitate decision making when treating RA patients with MTX in combination with bDMARDs or tsDMARDs.

#	RECOMMENDATION	LE	GR	LA
1	In patients with active RA and inadequate response to MTX, this drug should be continued when starting a TNF inhibitor (LE 1a; GR A), ABT (LE 2a; GR B), RTX (LE 1b-2a; GR B)	-	-	100%
2	MTX should not be discontinued in patients with active RA and inadequate response to MTX who start IL-6 inhibitors	1a	A	91%
3	MTX should not be discontinued in patients with active RA and inadequate response to MTX who start JAKs inhibitors	1b	A	91%
4	When starting a combined therapy with MTX and bDMARD in MTX-inadequate responders RA patients, it is recommended to continue with the same MTX doses	1b	A	100%
5	When combining MTX with TNF-inhibitors, the dose of MTX should be at least 10 mg/w	1b	A	100%
6	When starting a combined therapy with MTX and JAKs inhibitors in MTX-inadequate responders RA patients, it is recommended to continue with the same MTX doses	1b	A	100%
7	In RA patients who have achieved and sustained the treatment goal, the panel recommends, as treatment strategy, to give priority to the de-escalation of the bDMARDs, which does not exclude MTX dose adjustments or even MTX withdrawal in some intolerant patients on IL-6 inhibitors	5	D	100%
8	bDMARDs should be combined with MTX as the first csDMARD choice, although other csDMARDs could be considered if MTX intolerance/contraindication	1b	A	100%
9	JAKs inhibitors should be combined with MTX as the first csDMARD choice, although other csDMARDs could be considered if MTX intolerance/contraindication	1b	A	100%
10	Combined therapy of MTX with bDMARDs and tsDMARDs does not imply a different management of the standard of care for routine patient safety monitoring	5	D	100%

Abbreviations: MTX=methotrexate; RA=rheumatoid arthritis; TNF= tumour necrosis factor; ABT=abatacept; RTX=rituximab; mg=milligram; w=week; IL-6=interleukin 6; JAKs=Janus kinases; bDMARD=biológical disease modifying drugs; tsDMARDs=targeted synthetic disease modifying drugs (DMARDs).

Background/Purpose: Treatment of Rheumatoid Arthritis (RA) has changed drastically in the last two decades in strategies and objectives, as well as in therapeutic options, especially with the use of the disease modifying drugs (DMARD), both synthetic and biological. The data on the management of these patients under clinical trial conditions are abundant but it is necessary to expand our knowledge on how to use them in daily clinical practice. Purpose: to describe the clinical management and treatment in a cohort of patients with incident RA on daily clinical practice.

Methods: We conducted an observational longitudinal study. Patients: all recent onset RA diagnosed between January 1st 2007 and December 31st 2015 followed in outpatient clinic at Hospital Clinico San Carlos until January 1st 2017, which used any DMARD (synthetic and biologic) during at least 3 months. Variables: sociodemographic (age and gender), clinical (comorbidities, smoking status, date of diagnosis), quality of life (Rosser index), laboratory test (ESR, Rheumatoid Factor, ACPA), disease activity (HAQ and DAS28), treatments during follow-up (NAIDs, corticoids, DMARD (type, dates of start and discontinuation)) and treatment course (first or subsequent). Descriptive techniques were used of sociodemographic, clinical and treatment characteristics.

Results: We included 2388 courses of DMARD treatment in 814 patients. 77.52% were women with a mean age at diagnosis of 57.53±15.50 years. 63% of them were married and 85% lived with family. 44% had primary studies and 50% were in an active employment situation. The mean time to diagnosis was 8.8±226.3 months with a diagnosis in first visit in 72.9% of patients. 16% of patients were active smokers. The most frequent basal comorbidities were: hypertension (34%), dyslipidemia (30%), diabetes mellitus (13%) and depression (8.7%). The mean quality of life at the beginning of the disease measured by the Rosser index was 0.97 ± 0.04. 55% of patients were Rheumatoid Factor positive, 44% ACPA positive with a high mean DAS28 at the beginning of the disease (5.26±1.4). In table 1 we present all treatments globally and by treatment course. The mean time to the first treatment course was 21 [0-43] days.

Conclusion: Our patients have a poor quality of life at the beginning of the disease and present a severe activity. The management we do is aggressive and early with a diagnosis at first visit in 72.9% of patients. In 25% of patients treatment is prescribed from the moment of diagnosis and at least 50% of our patients are treated before a month from first visit. Most patients start with monotherapy, the frequency of combined treatment increases later on and it is more frequent after the second course of treatment. Methotrexate alone or in combination is the most frequently prescribed treatment. The use of biological DMARD increases throughout the follow-up, the most frequent being Adalimumab. The preferred combinations by our rheumatologists are Methotrexate - Antimalarial, Methotrexate - Leflunomide and Methotrexate - Adalimumab.

table 2 optum modeling abstract

Table 2: Adjusted hazard ratio (HR) of filling a) ≥90 days' supply of glucocorticoid prescriptions, b) ≥900mg prednisone equivalents' worth of glucocorticoid prescriptions, within 1 year of RA diagnosis

long term GC use, defined as 90 days' GC supply filled within 1 year of first RA claim (study period), adjusted for patient demographics, comorbidity, and overall and RA-related healthcare utilization. We assessed demographics, comorbidity, and overall healthcare utilization over a washout year before first RA claim. We performed a sensitivity

analysis using a dose-based definition, 900mg prednisone equivalent filled during study period (representing 10mg/day for 3 months).

Results: During the study period, 2933 (31%) patients filled 90 days' GC supply, and 3000 (31%) filled 900mg. Baseline patient characteristics are presented in Table 1. Characteristics independently associated with 90 days' GC supply include male sex (adjusted hazard ratio [HR] 1.4, p< 0.001), age >60 years (HR 1.2, p=0.005), having ≥6 Elixhauser comorbidities (HR 1.3, p< 0.001), taking GC prior to RA diagnosis (HR 2.0, p=0.001), use of biologic DMARD (HR 1.3, p< 0.001), and seeing a rheumatologist ≤3 months from RA diagnosis, relative to >3 months (HR 1.3, p=0.006) (Table 2). Age groups 18-40 (HR 0.8, p< 0.001) and 41-50 (HR 0.9, p=0.002) were associated with lower risk of the outcome. Race, year of RA diagnosis, number of pre-diagnosis office visits and prescription fills, and time to first DMARD fill (if ≤12 months) were not significantly associated with the outcome. Findings were similar for the dose-based outcome; association with ≤3 months to rheumatologist was attenuated but significant (HR 1.10, p=0.006) (Table 2).

Conclusion: In this commercially insured incident RA cohort, seeing a rheumatologist within 3 months of diagnosis was independently associated with long term GC utilization, while time to first DMARD (within 12 months) was not. This association, suggested by our prior descriptive work[1], held after controlling for claims-based measures of RA severity like DMARD use, biologic use, and GC use prior to diagnosis. Prior work supports the other factors associated with GC use in this cohort (i.e. male sex, older age, comorbidity)[2]. Further work to evaluate potential associations between rheumatologist access and long term GC utilization is warranted.

Abstract Number: 2389

Treat to Target by Specific Cytokine Interdiction: Multiple Biomarker Disease Activity Test Deconstructed

L Douglas Graham,[1] and **Lee Graham** [1], [1]Du Page Medical Group, Westmont, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatologists have been encouraged to achieve low disease activity state when treating rheumatoid arthritis (RA). If it cannot be achieved with initial therapy, experts recommend changing to a different mechanism of action. There is no established means of selecting among the mechanisms of action.

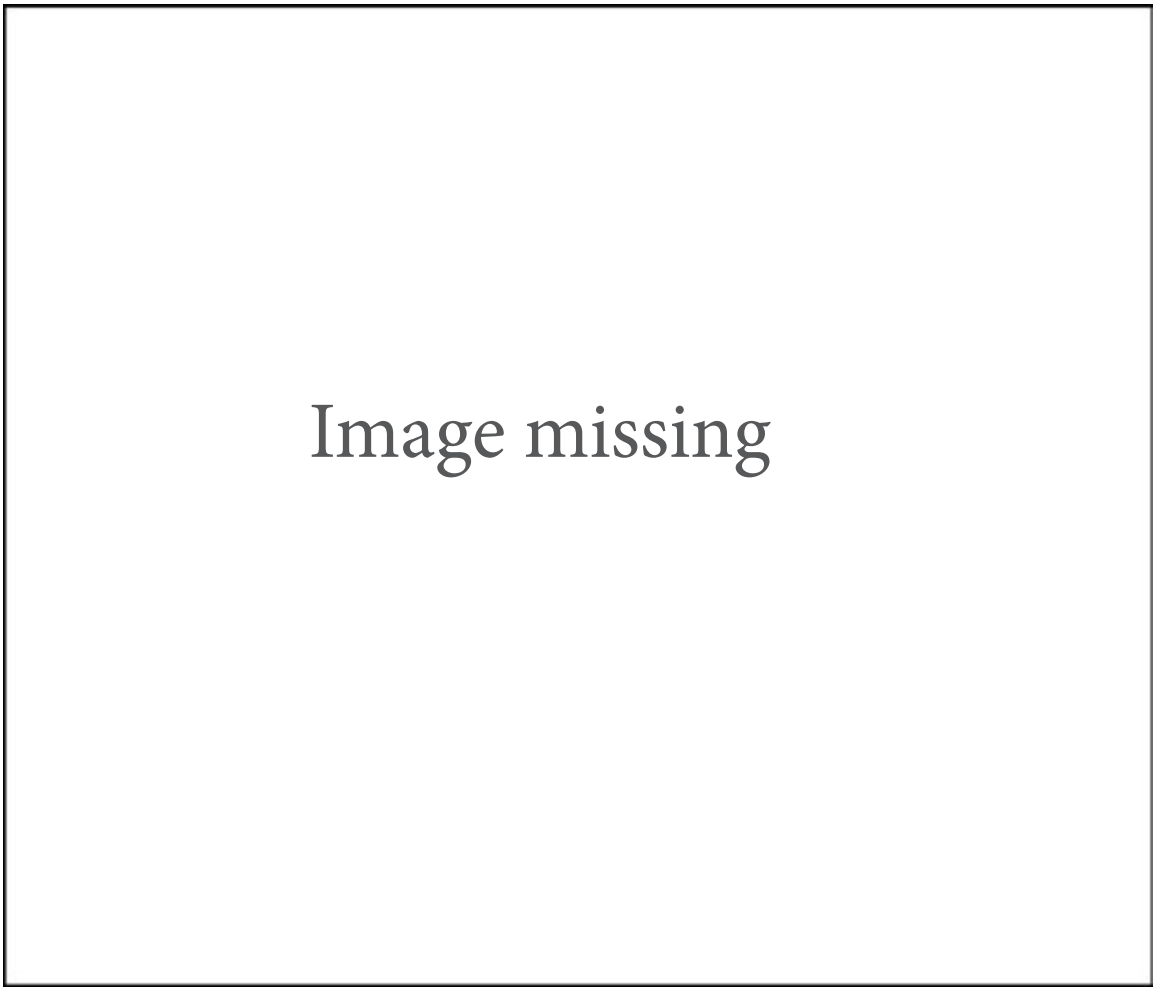
RA is a heterogeneous disease with variations in presentation, extra-articular features, and response to treatment. No single biomarker has been identified to predict response to treatment. Many cytokines have been identified in RA. 12 have become available in one test (MBDA). This study attempted to determine if the patterns of cytokine elevations could be used for treatment selection.

Methods: A literature search was performed, identifying clinical trials on RA which measured responses to the cytokines included in the MBDA: VCAM-1, VEGF-A, IL-G, TNF, MMP-1, MMP-3, YKL-40, Leptin, Resistin, SSA, and CRP. The trials included hydroxychloroquine (HCQ), sulfasalazine (SSZ), methotrexate (MTX), leflunomide (LEF), abatacept (ABA), tocilizumab (TCZ), rituximab (RTX) and tofacitinib (TOFA). A table(Table1) was constructed of cytokines versus treatment. Patients seen in the practice with RA were given the MBDA, and treatment was selected based on

TABLE 1

	HCQ	SSZ	MTX	LEF	TNF	ABA	TCZ	RTX	TOFA
VCAM-1	N	N	N	Y	Y	Y	N	N	N
VEGF-A	N	Y	Y	N	Y	N	Y	N	N
IL-6	Y	Y	Y	Y	N	Y	Y	Y	Y
TNF	N	Y	N	Y	Y	N	N	N	N
MMP-1	N	N	N	Y	Y	N	Y	N	Y
MMP-3	N	Y	Y	Y	Y	Y	Y	N	Y
YKL-40	N	N	N	N	Y	N	Y	N	N
LEPTIN	N	N	N	N	N	Y	N	N	N
RESISTIN	N	N	N	N	Y	N	N	N	N
SSA	Y	Y	Y	Y	Y	N	Y	N	Y
CRP	Y	Y	Y	N	Y	Y	Y	Y	N

Y = published clinical trial data
N = no published clinical trial data



MBDA score distribution using selective cytokine interdiction compared to conventional treat to target strategies

the agents with efficacy on highest number of cytokines elevated or past the 40th percentile reported on the MBDA, excluding EGF (elevated in remission) and leptin, which is affected by body composition, whenever pre-existing conditions, insurance coverage, and patient preference allowed. 263 patients were tested, 2 to 4 times over a 14 month period during routine visits.

Example: 83 year old patient with 6 year history RA: rheumatoid factor 169.6, CCP > 250, Larsen II radiographic changes. Past treatment: prednisone and MTX. MBDA score 09/06/2013: 69 high arthritis activity. VCAM-1 97%, VEGF-A 52%, IL-6 >99%, MMP-1 80%, MMP-3 96%, YKL-40 66%, Resistin 54%, SSA 82%, CRP 98 % percentiles. TOFA prescribed. Post treatment MBDA score 10/14/2016: 31 VCAM-1 67%, IL-6 30%, MMP-1 56%,MMP-3 29%, YLK-40 51%, Resistin 56%, SSA 19%, CRP 43%

Results: The MBDA scores in the physician's practice were graphed against the national average MBDA scores in practices using conventional treat to target strategies (Figure 1). Differences within the distribution of scores, and in the heights of the high, medium, and low MBDA scores can be observed between the two groups

Conclusion: This study is not meant to be a proof of concept achieved though a randomized controlled trial which demonstrated statistical significance. The data from the clinical trials utilized in Table 1 and the practices contain

heterogeneous populations of patients of unknown disease duration and dissimilar prior treatments. This study is observational, without the structure of a clinical trial, generated during routine clinical practice, and could qualify as real world data. Figure 1 may demonstrate an advantage to treatment selection based on the unique cytokine profiles of patient. With the increasing numbers of mechanisms of action, rising costs of treatment, and the shift to value-based care, it may be of value to explore the utility of multiple biomarker arrays in achieving low disease activity states in a directed manner.

Clinical trials that included responses to cytokines contained in the MBDA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

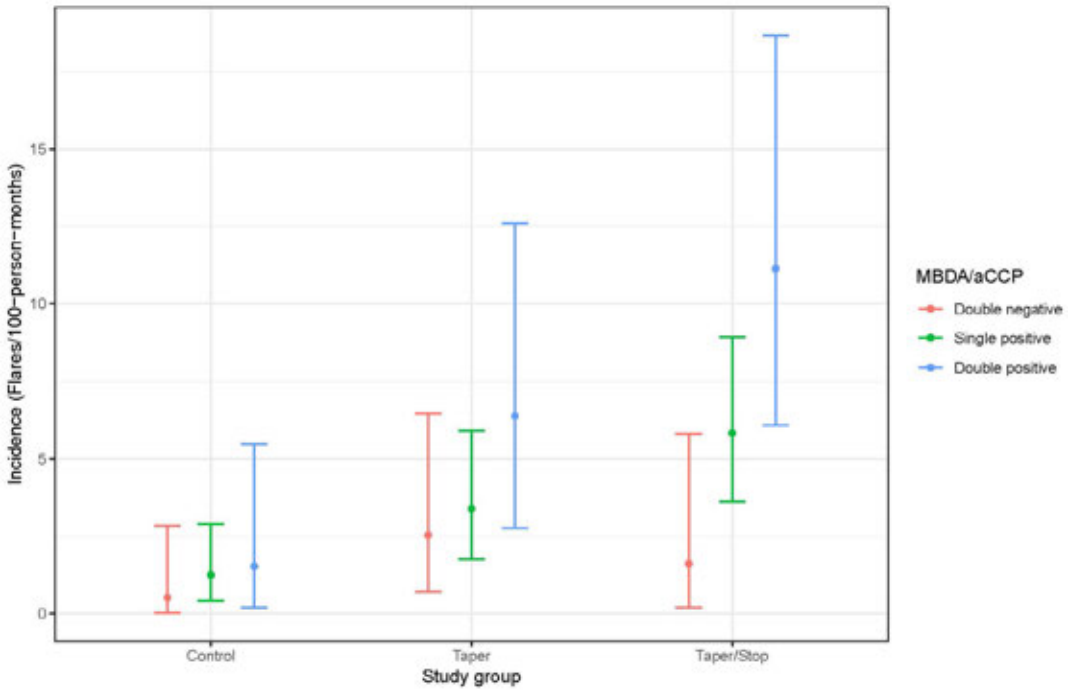
Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Achieving remission is the ultimate treatment goal in patients with rheumatoid arthritis (RA). With the development and wider use of highly effective disease modifying anti-rheumatic drugs (DMARD) about half of RA patients reach the disease remission state, raising the question about tapering or stopping anti-rheumatic treatment and appropriate predictors. The purpose was to analyze the effect of multi-biomarker disease activity (MBDA) score and anti-citrullinated protein (ACPA) on relapse rates in RA patients in sustained remission enrolled in the prospective randomized controlled RETRO study.

Methods: MBDA scores and ACPA status were determined in the baseline samples of patients in sustained DAS28-ESR remission fulfilling RETRO inclusion criteria. Patients were unblended and either continued DMARDs (Control),



incidenceplot

tapered dose by 50% (Taper) or stopped DMARDs after tapering (Taper/Stop) for one year according to the RETRO study protocol. MBDA and ACPA status were used as relapse predictors. Relapse was defined as the loss of a DAS28-ESR remission. We calculated incidence of flares and 95% Poisson confidence intervals by baseline ACPA and MBDA status in each study group (double negative, single positive, double positive). We compared the risk of flare in the treatment arms with a Cox regression model and calculated hazard ratios (HR) and 95% confidence interval (CI) for relapses.

Results: Serum samples and follow-up data of 203 patients included in the RETRO trial were analyzed. A flare was observed in 8/59 patients (13.6%) in the Control group, 24/60 (40.0%) patients in the Taper group and 37/68 (54.4%) patients in the Taper/Stop group among the 187 patients that completed their 1-year follow-up. HR (95%CI) for a relapse was 3.43 (1.54-7.66) in the taper group and 5.32 (2.47-11.46) for the control group. HR of flare of a positive MBDA and ACPA was 4.00 (1.72-9.31) compared to a negative MBDA and ACPA. Flare incidence did not differ with baseline MBDA/ACPA status in the control group, whereas in the taper/stop group, number of positive biomarkers could identify three distinct subgroups with a graded incidence of flare (Figure).

Conclusion: Tapering or stopping DMARDs after stable remission was associated with an increased risk of RA flares. Incidence of flares in MBDA/ACPA double-negative patients after tapering and stopping RA treatment was comparable to those that continued treatment within the precision limits of our subgroups.

Effect of Biologics on the Hemoglobin A1c in a Population of Rheumatoid Arthritis Patients

Ana Goico,[1] **Anoka Martis**,[1] Chistopher Kabir,[1] David Mael,[1] and Shoeb Mohammed[1], [1]Advocate Illinois Masonic Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor (TNF), a pathogenic inflammatory mediator in Rheumatoid Arthritis (RA), has been shown to play an essential role in the pathophysiology of insulin resistance. Studies have demonstrated the effects of TNF on glucose metabolism, the most important of which is the promising reduction in blood sugar levels. Consequently, TNF inhibitors (TNFi) should have a clinically important impact on glucose control and confer benefits to patients with Type 2 Diabetes Mellitus (DM). More research is needed to fully understand the impact of biologics on glucose control. The objective of this study was to examine the effect of initiating biologic therapy on hemoglobin A1c (HbA1c) among RA patients.

Methods: This retrospective cohort study included adult RA patients who were prescribed one or two disease-modifying antirheumatic drugs, had at least two recorded HbA1c measurements, and were initiated on biologic therapy. RA patients with DM were included if they had an HbA1c $\geq$ 6.5% in the 6 months prior to initiation of biologics. Glucose control was defined as HbA1c $\leq$ 7.0% at their last test result following the initiation of biologics. Medians (interquartile ranges) and numbers (percentages) are reported for descriptive statistics. Stratified by DM diagnosis, change in HbA1c is represented by Kaplan-Meier plots between TNFi and non-TNFi groups and the hazard ratios reported.

Results: Among the 266 RA patients, median age in years was 61 (15) and 48 (18.1%) were males. Biologic therapy distribution was: 93 (35.6%) Adalimumab, 78 (29.9%) Etanercept, 19 (7.3%) Infliximab, and 71 (27.2%) non-TNFi. Sixty-two (60.2%) of non-DM patients and 116 (71.2%) of the DM group were obese, and 23 (14.1%) of DM were on insulin. The median change in HbA1c in the DM group was -0.3 (1.6) and non-DM 0.2 (1.0). Among the DM group, at 1 year, 13% reached glucose control with TNFi and 12% with non-TNFi; no difference was found over the observed time (HR= 0.94; 95% CI = 0.53, 1.67). In the non-DM group, at 1 year, 2% had a final uncontrolled glucose result with TNFi and 3% with non-TNFi; no statistically significant differences in HbA1c was observed over time (HR = 0.65; 95% CI = 0.21, 2.05).

Conclusion: No statistically significant difference in HbA1c levels or glucose control could be determined from initiating biologics in non DMARD-naïve RA patients with or without DM. Further large-scale, prospective studies on the impact of biologic therapy on non-articular outcomes are warranted to assess the need of preferentially starting these medications in the above-mentioned population.

Abstract Number: 2392

The Effectiveness of anti-IL-6 Therapy to Elderly-onset Rheumatoid Arthritis

Takayasu Ando,[1] Takeshi Suzuki,[2] Yutaka Gotou,[1] and Kimito Kawahata[3], [1]Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Kanagawa, Japan, [2]Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki, Japan, [3]Rheumatology and Allergology, St. Marianna University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In daily practice, our rheumatologist has experienced different clinical feature of elderly-onset rheumatoid arthritis (EORA) compared with younger-onset RA (YORA). In EORA patients, serological marker of inflammation, like C-reactive protein, tend to be higher than that of YORA. And previous report suggested that significantly higher level of serum interleukin-6 (IL-6) and lower level of serum of tumor necrosis factor -α were detected in EORA compared with YORA patients. Hence, in elderly patients, IL-6 might be more important for the pathogenesis of RA. However, the treatment for EORA remains uncertain. We hypothesize that anti-IL-6 therapy is more effective for EORA patients than YORA patients. The objective this study is to clarify that the efficacy of anti -IL-6 therapy to EORA patients.

Methods: Inclusion criteria were as follows: diagnosis of RA based on 2010 ACR/EULAR classification criteria; the patients treated by anti-IL-6 drugs (tocilizumab or sarilumab); the disease activity could be evaluated at baseline and week 24 from started anti-IL-6 treatments by using disease activity score 28 erythrocyte sedimentation rate (3) (DAS28-ESR (3)). These patients were classified 3 groups according to RA onset age; younger-onset(YO); under 60 years old), middle age onset (MO); 60-69 years old, and elderly-onset (EO); equal or over 70 years old). And we compared the baseline characteristics, disease activity between 3 groups.

Results: We examine 107 RA patients who treated with anti-IL-6 drugs. Sixty-seven patients were YO, 22 were MO, 18 were EO. The rate of female patients was higher in YO compared with EO (92.5% vs 66.7%). Disease duration tends to be longer according to age at disease onset (EO; 11.7 years, MO; 5.5 years, YO; 1.4 years, respectively). And rate of seronegative (rheumatoid factor and anti-cyclic citrullinated peptides antibodies were negative) patients were also higher in EO compared with the other groups. The mean change of DAS28-ESR(3) from baseline to week 24 was significantly greater with EO than MO or YO($p < 0.05$). In analysis of each component of DAS28-ESR (3), tenderness joint count and swollen joint count was tended to decrease in EO. However, only ESR was significantly decreased in EO (< 0.05).

Conclusion: In EORA patients, anit-IL-6 therapy could be more effective than YORA patients. And especially, ESR of EORA patients could be more decreased by anti-IL-6 therapy.

Risk of Thromboembolism with Janus Kinase Inhibitors: A Systematic Review and Meta-Analysis of Randomized Placebo Controlled Trials

Jawad Bilal,[1] Irbaz Bin Riaz,[2] Maryam Sadiq,[3] Muhammad Salick,[4] Yahya Nomaan,[5] Nusrum Iqbal,[6] Sandipan Bhattacharjee,[7] Lary Prokop,[8] and C. Kent Kwoh[7], [1]University of Arizona College of Medicine, Tucson, AZ, [2]Mayo Hospital Rochester, Rochester, MN, [3]Nishtar Medical College, University of Health Sciences, Lahore, Albany, NY, [4]Albany Medical Center, Albany, NY, [5]Phoenix Children's Hospital, Phoenix, AZ, [6]St Joseph's Hospital, Tucson AZ, Tucson, AZ, [7]University of Arizona, Tucson, AZ, [8]Mayo Clinic, Rochestor, MN

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments Poster III: Safety and Outcomes

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose:

Importance: The efficacy of Janus kinase (JAK) inhibitors is well established across a range of diseases. However, there is a major concern regarding the potential risk of an increased number of thromboembolic adverse events.

Objective: To assess the risk of thromboembolism in patients treated with JAK inhibitors.

Methods:

Data Sources: Ovid MEDLINE(R) and Epub Ahead of Print, In-Process & Other Non-Indexed Citations, and Daily, Ovid EMBASE, Ovid Cochrane Central Register of Controlled Trials, Ovid Cochrane Database of Systematic Reviews, and Scopus were searched (Inception to May 23, 2019).

Study Selection: Published randomized, placebo-controlled trials (Phase II and III) that evaluated JAK inhibitor therapies in any disease and had reported safety data.

Data Extraction and Synthesis: This systematic review is reported according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Two investigators independently extracted study data, and assessed risk of bias.

Main Outcomes and Measures: The outcome of interest was the number of thromboembolic events in individuals receiving JAK inhibitor therapies compared to placebo. We used the Peto fixed effects model to calculate the pooled odds ratios as this is the appropriate model for rare events.

Results: We included 9 eligible RCTs (9496 patients). Patients receiving JAK inhibitors had higher risk of thromboembolic events OR 4.09 (95% CI 1.91-8.48, P < 0.001, I2=0%;)(figure 1). The results remained consistent with continuity correction OR 3.56 (95% CI 1.74-7.30, P=0.001, I2=0%), and after excluding studies with cancer patients OR 2.98 (95% CI 1.48-6.00, P=0.002, I2=0%). Medications wise analysis showed OR 7.65 (95% CI 2.45-23.88, P=0.002, I2=0%) with bariticinib (3 trials), OR 1.75 (95% CI 0.74-4.13, P=0.19, I2=0%) with ruxolitinib (2 trials), and OR 2.21

Table 1

(95% CI 0.40-12.17, P=0.36, I2=0%) with upadacitinib (3 trials). There were 2 trials of tofacitinib and outcome of interest was reported in one trial only which is why drug wise analysis of tofacitinib was not performed.

Limitations: Short follow up duration

Conclusions: Risk of thromboembolism is increased in patients who are treated with JAK inhibitors as compared to placebo. The findings remained consistent even when studies with cancer patients were excluded. In subgroup analyses based on individual medications, only bariticinib showed statistically significant findings of increased thrombosis risk. This analysis provides toxicity estimates for thromboembolic events associated with the use of JAK inhibitors that can inform shared-decision making when patients and clinicians are contemplating the use of JAK inhibitors for various indications.

Abstract Number: 2394

Use and Influence of Biologic/Janus Kinase Monotherapy Among Recently Switched Rheumatoid Arthritis Patients: Results from an Annual National Patient Chart Audit

Lynn Price,[1] Phil Pouliot,[1] and Lauren Schmitt[1], [1]Spherix Global Insights, Exton, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: US rheumatologists have long agreed that methotrexate (MTX) is the backbone of rheumatoid arthritis (RA) treatment, and while comfort with biologic/JAK monotherapy is growing, the majority of RA patients remain on a combination regimen, either with MTX or another conventional DMARD. With IL-6 inhibiting biologics and JAKs touted for their efficacy as monotherapy treatment options, this research sought to understand physician's attitudes towards combination therapy and the role monotherapy plays as a driver behind brand choice when switching RA patients from one biologic/JAK to another.

Methods: An independent market analytics firm collaborated with US rheumatologists (n=320) to conduct a retrospective chart review of patients diagnosed with rheumatoid arthritis (RA) (n=1,312), who had switched from one biologic/JAK therapy to another in the prior twelve weeks. Rheumatologists were able to submit up to seven RA patient charts. Data were collected in September 2018 and included clinical and non-clinical patient demographics, as well as physician demographics and attitudinal survey responses. This study was a non-longitudinal trending analysis to 2016 and 2017 audits following the same methodology.

Results: Approximately two-thirds of collaborating US rheumatologists agree with the statements: "MTX is the backbone of RA treatment" and "I prefer to prescribe biologics in combination with MTX whenever possible;" however, three-quarters also agree, "my comfort in using biologics/JAK monotherapy is growing." Indeed, when examining the chart audits of recently switched RA patients, only 35% were on a true monotherapy regimen (no MTX, other conventional DMARDs, or steroids), a figure that has remained stable since 2016. Half of all recently switched, biologic/JAK-treated RA patients were on a combination regimen with MTX, and there were no significant differences in rates of combination MTX use by RA disease severity. The possibility of biologic/JAK monotherapy was significantly more of a driver behind the decision to switch patients to JAK and IL-6 inhibitors than it was for switches to TNF-α inhibitors, abatacept, or rituximab. However, patients recently switched to a TNF were just as likely as those switched to a JAK, and more likely than those switched to an IL-6, to be on a monotherapy regimen.

Conclusion: While US rheumatologists state they are becoming more comfortable with biologic/JAK monotherapy for the treatment of RA, use of biologic/JAK therapy in combination with a conventional DMARD (most commonly MTX), is common practice and has not changed since 2016. The possibility of monotherapy treatment is a factor in the decision to switch patients to JAK and IL-6 inhibitors more commonly than when switching to other biologic classes; however, there are no statistically significant differences in rates of monotherapy by mechanism of action among recently switched RA patients.

Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A study of patients with RA at their first visit to an academic rheumatology site indicated an unexpected observation that 75% of patients had a history of prior treatment with either glucocorticoids or disease modifying antirheumatic drug (DMARD) agents, while only 25% were DMARD-naïve (1). Therefore, we analyzed a hypothesis that DMARD-naïve RA patients would have greater improvement from first visit to 6-month follow-up visit than patients who had prior treatment, according to MDHAQ/RAPID3 (multidimensional health assessment questionnaire/routine assessment of patient index data3) scores.

Methods: The first visit of all RA patients (by ICD codes) to one site that occurred between 5/2011-2/2017 was identified by retrospective chart review. All patients with all diagnoses complete MDHAQ/RAPID3 at all visits. RAPID3 (0-30) is the sum of 3 0-10 scores for physical function, pain visual analog scale (VAS), and patient global assessment VAS; severity categories are ≥12=high, 6.1-12= moderate, 3.1-6= mild, ≤3= remission. Patients who had a complete MDHAQ/RAPID3 at first visit and 6-month follow-up visit were classified into 3 groups on the basis of prior DMARD therapy: 1)"DMARD-naïve" - no glucocorticoid or DMARD; 2) "active DMARD"- had DMARD therapy within previous month; 3)"DMARD-interrupted" - had prior DMARD therapy interrupted for > 1 month. Mean MDHAQ/RAPID3 and individual RAPID3 component scores within each of the 3 groups were compared at first and 6-month follow-up visits for possible change using paired t tests. Differences between the 3 groups in changes over 6 months were compared using analysis of variance (ANOVA).

Results: Demographic data for age, sex, ethnicity, level of formal education, as well as body mass index, did not differ significantly in the 3 RA groups. Median disease duration was 1 year in DMARD-naïve patients, 2 years in active-DMARD, and 5 years in DMARD-interrupted patients (p=0.006). Mean MDHAQ/RAPID3 scores were 15.5 in DMARD-naïve, 14.8 in active-DMARD, and 16.5 in DMARD-interrupted patients, all indicating high severity (≥12) - no clinically or statistically significant differences. At 6-months follow up, MDHAQ/RAPID3 was improved in all RA groups, -5.7 in the DMARD-naïve group vs -2.7 in the active DMARD group vs -3.6 in the DMARD-interrupted group (p=0.05), also reflected in the RAPID3 component scores (Table). The difference in the DMARD-naïve group, but not the other groups, exceeded the minimum clinically important improvement (MCII) criterion of 3.8 for MDHAQ/RAPID3, which was almost met in the DMARD-interrupted group, but not in the active-DMARD group.

Conclusion: Patients with RA improved with treatment from first visit to 6 months later, greatest in DMARD-naïve, less in DMARD-interrupted, and least in the active-DMARD group. The similarity of MDHAQ/RAPID3 scores at baseline of DMARD naïve to those of previously-treated patients suggests that "treat-to-target" appears poorly implemented in routine clinical care. The data appear to reinforce the importance of early treatment for optimal control of RA.

Variable(s)	All RA (n=201)	3 Groups according to treatment

ACR Abstract - Table 3

Background/Purpose: The Dual Specificity Phosphatase 22 (*DUSP22*) gene expression has been shown to be regulated via DNA methylation of its promoter. In addition, aberrant DNA methylation of *DUSP22* in lymphocytes has been observed in RA patients and it has been linked to erosive disease. Global DNA hypomethylation of lymphocyte cell subpopulations from RA patients was reversed after methotrexate (MTX) treatment, suggesting MTX has the ability to alter DNA methylation. However, no study to date has evaluated the effect of RA treatment on *DUSP22* DNA methylation. Here, we investigated whether plasma DNA methylation in the promoter region of *DUSP22* varies by treatment regime in RA and further, we determined *DUSP22* promoter DNA methylation changes after MTX exposure in lymphoblastoid cell lines.

Methods: We recruited 26 patients who satisfied the ACR criteria of RA. DNA was isolated from plasma, bisulfite converted, and pyrosequenced to determine DNA methylation levels in the promoter region of *DUSP22* at four different CpG sites. In addition, lymphoblastoid cell lines of healthy individuals were treated with increasing concentrations (0nM and 50nM) of MTX and DNA methylation of *DUSP22* was determined. Statistical non-parametric testing, Kruskall-Wallis for comparisons across groups and Mann-Whitney for differences between two groups, were conducted.

Results: Of the 26 RA patients included in this study, 20 were under MTX and/or Plaquenil regimens. DNA methylation of the CpG3 (-198bp from transcription start site(TSS)) of *DUSP22* was significantly lower in patients treated with MTX(MTX+) but not with Plaquenil(Plaq-) when compared to those on neither MTX(MTX-) nor Plaquenil(Plaq-) (21.46 ± 8.76% vs. 48.51±7.35%, p=0.034). However, no significant differences were found between the MTX+Plaq- and MTX+Plaq+ groups for this site (21.46 ± 8.76% vs. 42.25±16.40%, p=0.088). No other differences in *DUSP22* DNA methylation were observed for other CpG sites or the mean. In addition, subgroup analysis of MTX and Prednisone versus MTX- use did not yield any statistically significant differences. In *in-vitro* studies, exposure to

50nM MTX increased CpG4 (-192bp from TSS) DNA methylation (0.13±0.48% vs 0.59±0.45%, *p*=0.035) but not of CpG3 (2.25±1.34% vs. 3.09±1.21%, *p*-value=0.133). No other changes in DNA methylation were observed after MTX treatment in cell lines derived from healthy individuals.

Conclusion: Our findings suggest that RA treatment might have an effect on plasma *DUSP22* DNA methylation. These findings also highlight the possibility that different drugs, when used in combination (i.e. Plaquenil and MTX), may interact and affect DNA methylation. *In-vitro* findings mirror previous data in drug naïve patients in which MTX increases DNA methylation, in contrast we found MTX treatment increases plasma *DUSP22* DNA methylation. Our study has a small sample but it is the first one to investigate the effect of several RA drugs on DNA methylation of the *DUSP22* promoter, suggesting mechanisms of action for widely used DMARDs like MTX and Plaquenil. Future studies with larger sample size are needed to confirm our findings, and add to our understanding of the epigenetic effects of RA drugs.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Skin lesion as a side effect of Tocilizumab (TCZ) has not been paid much attention. In the drug information sheets, incidence of dermatological adverse reactions was only 1~2%. However, we experienced several RA cases with development of various skin lesions associated with neutrophil activation after TCZ therapy. Although the precise mechanism is still unclear, of particular interest is the decreased neutrophil counts in peripheral blood have been known after initiation of TCZ in clinical trials, which did not affect the rate of serious infections. On the other hand, we also experienced exacerbation of skin ulcer despite the inflammation, such as activity of rheumatoid arthritis, was absolutely under control. In this study, we try to detect the changes in transcriptome of peripheral blood after TCZ treatment.

Methods: As total of 23 RA cases (43.2 person-years) was completely followed in our single hospital from the initiation of TCZ, their medical records were checked to calculate the incidence of dermatological adverse reactions to TCZ from 2014 to 2018. Meanwhile, to explore the normal response to anti-IL6 therapy, peripheral whole blood at just before (pre) and 3 months after (post) TCZ treatment from 10 RA cases without any dermatological problems were subjected to gene expression study. Total RNAs were then extracted with PAXgene miRNA kit. After quantifying the transcripts, differentially expressed genes (DEGs) were selected by paired comparison (post vs. pre), setting

thresholds at 2-fold change up/down and less than P=0.05 in paired T-test. And then, enrichment analysis using gene ontology (GO) terms were performed.

Results: Among 23 patients, 4 cases (9.25/100 person-years) of Skin lesion including neutrophilic dermatosis and leukocytoclastic vasculitis were observed as side effects of TCZ. Although 2 of them required termination of the therapy, others were possible to continue TCZ treatment. We also experienced 2 cases of exacerbation of skin ulcer despite the inflammation was under favorable control. For transcriptome analysis, total of 57571 transcripts were identified and the 52/156 genes of up/down-regulated genes were selected as DEGs from the comparison of post vs. pre treatment of TCZ using paried T-test. Surprisingly, 8 out of the top 10 enriched GO terms in the up-regulated genes were relevant to leukocyte activation such as 'neutrophil chemotaxis'. On the other hand, 6 out of the top 10 enriched GO terms in the down-regulated genes were related to tissue repair, such as "platelet activation" and "wound healing".

Conclusion: As the cytokine network is very complicated and an exquisite balance presented in immune and homeostatic system is strictly maintained, inhibition of a multifunctional cytokine signaling such as IL-6 may cause unexpected adverse reactions. Our findings indicate a potential risk of the development of skin lesions associated with neutrophil activation by anti-IL6 therapy. The mechanism may also help the increased margination of neutrophils in normal situation, and it may be a hint for the secret behind the decreased neutrophil counts after TCZ treatment. Anyway, we will not recommend anti-IL6 therapy for the patients with skin ulcers from our experiences.

Abstract Number: 2398

Prevalence of Anxiety and Depression in a Cohort of Patients with Rheumatic Diseases on Biological Infusions

Alexander Peck,[1] Ella Starobinska,[2] Gilbert Ortega,[1] Jaclyn Leong,[1] Travis Maestas,[1] Phan Saligrama,[1] Jawad Bilal,[1] and Dominick Sudano[3], [1]University of Arizona College of Medicine, Tucson, AZ, [2]University of Arizona College of Medicine, Tucson, AL, [3]Banner University Medical Center Tucson, Tucson

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies have shown an increased prevalence of psychologic disorders in rheumatic diseases, such as rheumatoid arthritis, systemic lupus erythematosus, and psoriatic arthritis, compared to the general population. Of note, the coexistence of anxiety and depression with rheumatic diseases has been linked to worse outcomes and increased health care utilization. Our aim was to examine the prevalence of anxiety and depression in a cohort of patients with rheumatic diseases on biologic infusions.

Methods: We conducted a retrospective study between 2013 and 2017 at two infusion centers affiliated with the University of Arizona Arthritis Center. We identified patients with rheumatic diseases on biological infusions for the concurrent diagnosis of anxiety and/or depression and examined hospitalizations. Statistical analysis by Fisher's exact test using Baptista-Pike was performed with Prism Software and is represented using the odds ratio with the 95% confidence interval and p-value.

Results: Of the total 548 patients with rheumatologic diagnoses, 77% of the sample was female. The mean age was 63 years. 59.7% had rheumatoid arthritis , 12.9% had osteoporosis, 6% had systemic lupus erythematosus, 5% had psoriatic arthritis, 4% had ankylosing spondylitis, 1.2% had gout, 0.9% had mixed connective tissue disease, 1.2% had juvenile idiopathic arthritis, 1% had anti-neutrophil cytoplasmic antibodies vasculitis, 1.6% had osteoarthritis, 0.3% had Behcet's disease, 0.5% had dermatomyositis, 0.5% had polymyositis, 0.8% had adult-onset still's disease, and 0.3% had giant cell arteritis.

175 patients (31.9%) within the cohort had a diagnosis of anxiety and/or depression. 76 patients (13.8%) had depression, 99 (18%) had anxiety, and 42 (7.6%) had concurrent anxiety and depression. 90/332 (27.1%) with RA, SLE 15/34 (44.1%), osteoporosis 24/71 (33.8%), ankylosing spondylitis 10/29 (34.5%), psoriatic arthritis 7/25 (28%), vasculitis 4/9 (44.4%), others 24/51 (47%) had either depression or anxiety or both.

61/175 (34.9%) of patients with depression and/or anxiety had 1 or more hospitalization compared to 87/373 (23.3%) patients without any psychological diagnosis (**OR 1.76, 95% CI [1.19-2.60],** *P = 0.004*).

Conclusion: The findings of this study show a high prevalence of anxiety and depression in our cohort of patients with rheumatic diseases. Although, patients with one or both of these psychiatric diagnoses had significantly higher rates of hospitalizations but this association needs to be further investigated by regression analysis. Given the high prevalence of anxiety and depression in the rheumatology patient population, an interdisciplinary team approach with rheumatologists, primary care physicians, psychiatrists, and psychologists to manage a patient's mental health may play an important role in improving long-term rheumatic and psychiatric disease outcomes.

Background/Purpose: During the past 15 years, advancements in the understanding of the safety and effectiveness, as well as the expanding access and availability of biologic disease-modifying anti-rheumatic drugs (bDMARDs), have likely influenced the pattern of use of such compounds in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS). This analysis is aimed at assesing changes in the baseline characteristics of RA, PsA and AS patients who underwent biological therapy from 2007 to 2019 in a real world setting.

Methods: Data were obtained from BIOBADASER, the Spanish registry of biologics which compiles data from routine clinical practice. Patients diagnosed with RA, PsA and AS who started biological treatment from 2007 to 2019 were included. Sociodemographic and clinical variables, as well as first bDMARD use, were stratified by the starting year period (2007-2009; 2010-2012; 2013-2015; 2016-2019) and then compared using Anova. The therapeutic target chosen by physicians to manage these patients was also analyzed. Parametric values were compared using a general linear model for repeated measures with simple contrast considering the initial value (2007-2009) as the reference.

Results: 6197 patients (3266 RA patients, 1517 PsA and 1414 AS) were included in this analysis (Table 1). Patient age at the beginning of the first biologic was significantly higher during the period 2016-2019 than in 2007-2009 (50.1 vs 50.6). Disease duration until the use of biologics decreased significantly (8.6 vs 6.5). In RA patients, disease activity, as assessed by DAS28 at the start of the biological treatment, was significantly higher during the 2007-2009

period than in the last period analyzed (5.2 vs 4.7). The use of a TNF inhibitor as a first option also changed significantly (96.6% vs 59.8%). Regarding comorbidities, the number of rheumatic patients treated with biologics and who had a history of cancer (1.7% vs 3.9%), hypercholesterolemia (14.7% vs 26.8%), or hypertension (23.1% vs 25.1%) increased significantly. The Charlson index also increased (1.9 vs 2.2).

Conclusion: Our data show that during the last 12 years the usage pattern of biologics in patients with RA, PsA and EA has changed. Nowadays these compounds are used in patients with shorter disease evolution times, with less disease activity and with more comorbidities. The availability of greater pharmacological resources, as well as an increased knowledge of the safety and effectiveness of biologics could explain these findings.

Abstract Number: 2400

The Effect of Co-medication with Methotrexate and Other Conventional Synthetic Disease Modifying Anti-rheumatic Drugs on First Tumor Necrosis Inhibitor Drug Survival in Patients with Rheumatoid Arthritis: Results Form a Nationwide Registry

Herman Mann,[1] Lucie Nekvindová,[2] Jakub Závada,[3] Zlatuše Křístková,[2] Pavel Horák,[4] Jiří Vencovský,[1] and Karel Pavelka[1], [1]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2, Czech Republic, [2]Institute of Biostatistics and Analyses Ltd., spinoff company of Masaryk University, Brno, Czech Republic, [3]Institute of Rheumatology, Prague, Prague, Czech Republic, [4]Faculty of Medicine and Dentistry, Palacky University Olomouc, Olomouc, Czech Republic

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) should be used for the treatment of rheumatoid arthritis (RA) in combination with conventional synthetic disease modifying anti-rheumatic drugs (csDMARD), preferably with methotrexate (MTX). However a significant proportion of RA patients receive TNFi in combination with other csDMARD or in monotherapy. We aimed to assess the effect of co-medication with MTX or other csDMARDs on drug survival of the first TNFi in RA.

Methods: All adult patients with RA followed in the Czech national registry ATTRA who started TNFi therapy after January 1st 2012 were considered. Baseline demographic data of patients starting their first TNFi in combination with MTX, with other csDMARD or as a monotherapy were compared. Six-year drug survival was analyzed using Kaplan-Meier method, log rank test was used to compare differences between groups. ATTRA is a centralized prospective computerized registry collecting data on efficacy, safety and quality of life of patients treated with biologic disease modifying anti-rheumatic drugs (bDMARD) in the Czech Republic. TNFi therapy is usually indicated for patients with RA who have failed treatment with at least one csDMARD.

Results: A total of 1841 RA patients initiated first bDMARD treatment during the studied period, with 1724 patients receiving TNFi. 1307 patients (76%) started TNFi therapy in combination with MTX (median dose 15mg weekly),

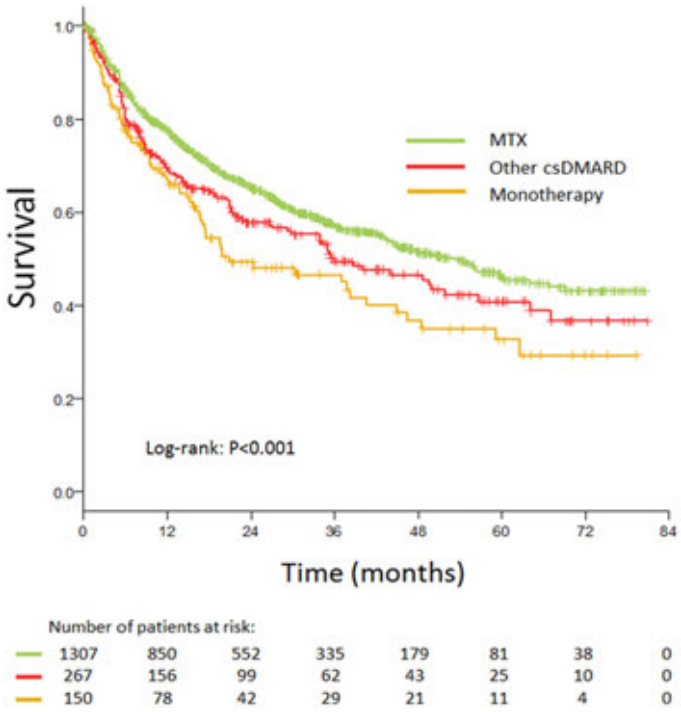

Figure 1: Kaplan–Meier curves of 6-year drug survival of the first TNFi based on co-medication

		MTX (N = 1307)	Other csDMARD (N = 267)	Monotherapy (N = 150)	P-value
Gender (female)	N (%)	993 (76.0%)	216 (80.9%)	114 (76.0%)	0.216
Age (years)	Median (5; 95 perc)	54.0 (29.0; 71.0)	55.0 (33.0; 74.0)	57.0 (33.0; 74.0)	0.007
Disease duration (years)	Median (5; 95 perc)	7.9 (1.4; 27.5)	8.2 (1.5; 27.3)	8.7 (1.0; 26.3)	0.629
Anti-CCP positivity	N (%)	918 (71.6%)	193 (73.7%)	101 (69.2%)	0.618
GC use in the past	N (%)	1157 (88.7%)	233 (87.3%)	132 (88.6%)	0.792
GC use currently	N (%)	923 (70.6%)	186 (69.7%)	90 (60.0%)	0.028
csDMARD use in the past	N (%)	1283 (99.6%)	264 (99.2%)	135 (90.6%)	<0.001
csDMARD number in the past	N (%)				
0		5 (0.4%)	2 (0.8%)	14 (9.4%)	<0.001
1		426 (33.1%)	45 (16.9%)	24 (16.1%)	
2		366 (28.4%)	73 (27.4%)	41 (27.5%)	
3		277 (21.5%)	79 (29.7%)	39 (26.2%)	
4 and more		214 (16.6%)	67 (25.2%)	31 (20.8%)	
CRP (mg/dl)	Median (5; 95 perc)	15.2 (1.4; 68.0)	16.7 (1.4; 75.8)	13.8 (1.4; 78.1)	0.232
Tender joint count (0-28)	Median (5; 95 perc)	13.0 (5.0; 24.0)	12.0 (5.0; 26.0)	13.0 (5.0; 26.0)	0.860
Swollen joint count (0-28)	Median (5; 95 perc)	9.0 (2.0; 18.0)	9.0 (2.0; 19.0)	9.0 (2.0; 20.0)	0.878
DAS28	Median (5; 95 perc)	6.1 (4.9; 7.5)	6.1 (4.6; 7.7)	6.2 (4.7; 7.8)	0.772
HAQ score	Median (5; 95 perc)	1.5 (0.6; 2.5)	1.6 (0.5; 2.5)	1.8 (0.8; 2.5)	0.004

Table 1: Baseline patient characteristics

267 patients (15%) with other csDMARD (most commonly leflunomide) and 150 patients (9%) as monotherapy. The baseline disease activity based on the number of tender/swollen joints, CRP levels and DAS-28 scores was comparable between the three groups. There was a significantly higher number of patients without history of csDMARD therapy prior to TNFi initiation in the monotherapy group (Table 1). Overall TNFi drug survival was significantly better

in patients receiving MTX co-medication (median survival 53 months) compared to those on monotherapy (median survival 21 months). Patients receiving TNFi in combination with other csDMARD had median survival worse than those on methotrexate and better than those on monotherapy (median survival 36 months), albeit the difference was not statistically significant (Figure 1). The most common reason for TNFi discontinuation was loss of efficacy (33%, 37% and 28% for MTX, other csDMARD combination and monotherapy respectively) followed by primary inefficacy (20%, 19% and 27%) and adverse effects (19%, 15% and 23%).

Conclusion: In this registry study of patients with RA, use of MTX co-medication was associated with significantly better first TNFi drug survival compared to monotherapy.

Enhanced Methotrexate Polyglutamation in Japanese as Compared to Caucasian Rheumatoid Arthritis Patients Starting Methotrexate

Thierry Dervieux,[1] Joel Kremer,[2] Kelley Brady,[1] Chihiro Takahashi,[3] Tsutomu Takeuchi,[4] and Yuko Kaneko[5], [1]Exagen, Vista, CA, [2]Albany Medical College and The Center for Rheumatology; Corrona, LLC, Albany, NY, [3]Division of Rheumatology, Department of Internal Medicine, Tokyo, Japan, [4]Keio University Hospital Division of Rheumatology, Tokyo, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is an anti-folate prodrug activated to MTX polyglutamates (MTXPGs). Japanese Rheumatoid Arthritis (RA) patients are thought to have heightened sensitivity to MTX and guidelines have recommended lower MTX doses in that group of patients as compared to Caucasians. We evaluated the impact of ancestry on the accumulation of MTXPG and the effect of these metabolites on disease control.

Methods: Two cohorts of consented adult RA patients naïve to MTX and scheduled to start oral MTX for their treatment were analyzed. All patients fulfilled the 1987 or 2010 ACR criteria for RA. The first cohort consisted of 48 Caucasians from New York State (73% females, mean age: 56±2 years, mean body mass index [BMI]: 28.6±0.1 kg/m^2). The second cohort consisted of 58 Japanese from the Tokyo metropolitan area (88% females, mean age 57±2 years, BMI=21.9±0.4 kg/m^2). MTX was started at 7.5-8 mg/weekly (with daily folic acid) and escalated every 4 weeks over 4 months, not to exceed 16 mg/week in Japanese RA. Accumulation of MTXPG metabolites was assessed using total red blood cells (RBCs) $MTXPG_{1-5}$ (1 to 5 order of glutamic residue) expressed as nmol/L packed RBCs. MTXPG were measured using liquid chromatography in a central laboratory. Serum transaminases were also collected. All clinicians were blinded to MTXPG levels during clinical assessments. Disease activity was assessed using Disease

	Estimate [SE]	P value
Intercept	-26.4±6.1	<0.001
Age per 10 years	2.9±1.0	0.004
MTX dose per mg weekly	5.4±0.2	<0.001
Per 100 days therapy	10.7±2.4	<0.001
Japanese Ancestry	**16.9±2.7**	**<0.001**

Table: Linear Mixed Effect models of RBC MTXPG1-5 accumulation (Marginal R^2= 0.71; N=467 visits collected in 106 patients)

Activity Score in 28 joints (DAS 28). Group comparisons used Wilcoxon's test. Linear mixed effect with random intercept and fixed slope were used to assess the impact of ancestry on MTXPG accumulation and the effect of these metabolites on disease control.

Results: After 3 months therapy similar MTX dosages were administered in the Japanese and Caucasian cohorts (mean 12±3 [SEM] and 12±2 mg/week, respectively; p=0.65). Japanese ancestry associated with higher RBC MTX-PG1-5 levels (mean 91±28 [SD] nmol/L) as compared to Caucasian ancestry (mean 61±24 nmol/L) (p< 0.01). This heightened RBC MTXPG1-5 accumulation among Japanese remained significant (estimate 16.9±2.7 nmol/L; p< 0.001) after adjusting for MTX dosage, age, duration of MTX therapy (Table) (Marginal R2=71%). Caucasian patients presented with higher DAS28 at baseline (5.1±0.1 points) than Japanese patients (3.5±0.1 points) (p< 0.001). Higher DAS28 at baseline associated with higher disease activity at follow-ups (estimate=0.66±0.04; Marginal R2=0.38). Heightened RBC MTXPG1-5 levels associated with lower DAS28 by univariate analysis (estimate=-1.6±0.1 point per 100 nmol/L; p< 0.001; Marginal R2=0.19) and the impact of the levels on disease control remained significant (estimate=-0.9±1.4 point per 100 nmol/L; p< 0.001) after adjusting for baseline DAS28 and duration of MTX therapy (Marginal R2=0.57). Higher RBC MTXPG1-5 accumulation also associated with elevated serum transaminases (estimate=4.8±0.1 and 10.0±1.9 units per 100 nmol/L MTXPG1-5 for AST and ALT, respectively) (Marginal R2=0.04 each) (p< 0.001).

Conclusion: MTXPG accumulation differs with ancestry. Japanese RA patients present with enhanced MTX polyglutamation as compared to Caucasians.

Table 1: Results of logistic regression to analyze potential factors influencing satisfaction with drug treatment

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The satisfaction of rheumatoid arthritis (RA) patients with their pharmacological therapy is a relevant patient reported outcome which influences treatment adherence and continuation. However, it has not been investigated frequently, and almost never in large studies. The aim of this study was to assess factors exerting a potential influence on the satisfaction with the pharmacological treatment and to quantify the strength of their association.

Methods: The German register RABBIT is a prospective longitudinally followed cohort of RA patients enrolled with a new start of a DMARD after at least one conventional synthetic (cs)DMARD failure. This analysis comprises patients who were enrolled with start of a DMARD between 01/2009 and 10/2018, who were observed for at least 12 months and had been on the therapy prescribed at enrolment for at least six months.

Satisfaction with the applied treatment was measured in four categories from “very satisfied” to “very unsatisfied”. Logistic regression combined with multiple imputation of missing values was performed to calculate odds ratios (ORs) for factors which might have an influence on treatment satisfaction.

Results: At treatment onset, 55% of the 8,677 patients were "very" or "rather" satisfied (in the following: "satisfied"), while the rest was "very" or "rather" unsatisfied (in the following: "unsatisfied") with their therapy. After one year of treatment, 86% of patients were satisfied with their treatment. Satisfaction at baseline, reduction of DAS28-ESR, pain and log glucocorticoid dose as well as the increase of physical function were positively associated with the achievement of treatment satisfaction after one year. Depression, obesity as well as a prior treatment failure of biologic (b) DMARDs were negatively associated with it (see Table 1). A prevalent fibromyalgia tends to have a negative effect as well. Regarding glucocorticoid therapy, being still treated with either 5 to 15 mg/d (OR: 0.69, 95% CI: 0.55; 0.85) or ≥ 15 mg/d glucocorticoids (OR: 0.27, 95% CI: 0.16; 0.44) was negatively associated with the achievement of therapy satisfaction (data not shown).

Conclusion: Reductions in disease activity, pain and glucocorticoid dosage as well as improvement of physical function present a positive association with the achievement of treatment satisfaction, while depression, obesity, and prior treatment failures with bDMARDs present a negative one. Our results show clearly that efforts to taper glucocorticoid doses are positively associated with the improvement of patients' satisfaction.

Adverse Events of Special Interest in Patients with Rheumatoid Arthritis Treated with Peficitinib in Asian Population: Pooled Safety Findings

Tsutomu Takeuchi,[1] Yoshiya Tanaka,[2] Mitsuhiro Rokuda,[3] Hiroyuki Izutsu,[3] Yuichiro Kaneko,[3] Musashi Fukuda,[3] and Daisuke Kato[3], [1]Keio University School of Medicine, Tokyo, Japan, [2]University of Occupational and Environmental Health Japan, Kitakyushu, Japan, [3]Astellas Pharma, Inc., Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Peficitinib, a novel oral Janus kinase (JAK) inhibitor, has demonstrated efficacy in studies of Japanese, Korean and Taiwanese patients with RA. This analysis of pooled safety data examines new safety findings and incidence rates for AEs of special interest in studies.

Methods: Safety data from 4 clinical studies of adult patients with active RA defined by 1987 ACR criteria or 2010 ACR/EULAR criteria were pooled. The pooled Phase (Ph) 3 studies included safety data from the Asian Ph 3 study (RAJ3) and Japanese Ph 3 study (RAJ4). The pooled Ph 2/3 studies included Ph 2b study (RAJ1), RAJ3, RAJ4 and extension study (RAJ2 [data cut-off, May 31, 2018]). RAJ1 included RA patients irrespective of RA treatment history including untreated state. RAJ3 included RA patients with inadequate response to conventional DMARDs including MTX. RAJ4 included RA patients who were inadequate responders to MTX. RAJ2 is an open-label extension study of patients completing these 3 studies.

Table 1. Patient demographics for pooled studies

Min–Max					
Treatment exposure (patient-years)	707.8	340.2	567.4	1615.3	2336.3

Safety was assessed by monitoring adverse events (AEs) and serious adverse events (SAEs), and summarized using MedDRA Preferred Terms. Two pooled datasets (Ph 3 studies pooled and Ph 2/3 studies pooled) were used for the analyses.

Results: A total of 1052 patients were included in the pooled Ph 2 and 3 studies; of those patients, 843 were enrolled into RAJ2 (**Table 1**). Patient characteristics were similar across all treatment groups. Overall exposure to peficitinib in Ph 2/3 studies was 2336.3 patient-years. Across the 4 studies, there were 3 deaths.

In the pooled Ph 3 studies, there were no deaths. The overall incidence of AEs was similar between the 2 peficitinib groups (**Table 2**): 88.5% in the peficitinib 100 mg/day group, 87.7% in the peficitinib 150 mg/day group, and 89.0%

Table 2. Adverse events in pooled Phase 3 studies

Event	Peficitinib			Etanercept
	100 mg (n=278)	150 mg (n=276)	Combined (n=554)	(n=200)

[1]Adverse Drug Reactions, defined as AEs considered possibly or probably related to study drug by the investigator

[2]National Cancer Institute grading: grade 3, severe or medically significant; grade 4, life threatening; grade 5, death related to AE

ADR, adverse drug reaction; AE, adverse event; SAE, serious adverse event

in the etanercept (ETN) group. The incidence of SAEs was 9.4%, 7.6%, and 9.0%, respectively. In the peficitinib 100 mg/day group, 9.4% of patients discontinued due to an AE. The most common AE in patients receiving peficitinib was nasopharyngitis, which occurred in 30.5% of patients (31.0% in the ETN group).

Table 3. Adverse events of special interest in pooled studies, overall period. Exposure-adjusted incidence rates (incidence per 100 patient-years, 95% confidence intervals)

	Pooled Phase 3 studies				Pooled Phase 2/3 studies
	Peficitinib			Etanercept	
	100 mg	150 mg	Total		
Serious infection	2.8 (1.3, 5.9)	3.2 (1.6, 6.3)	2.9 (1.9, 4.6)	2.0 (0.8, 5.5)	2.5 (1.9, 3.2)
Herpes zoster-related disease	7.4 (4.7, 11.8)	4.0 (2.1, 7.4)	5.7 (4.2, 7.9)	2.6 (1.1, 6.2)	6.5 (5.5, 7.7)
Malignancies	1.2 (4.0, 3.7)	0	0.6 (0.2, 1.6)	0.5 (0.1, 3.6)	0.9 (0.6, 1.3)
Dyslipidemia	5.8 (3.4, 9.7)	9.8 (6.6, 14.7)	8.5 (6.5, 11.1)	2.6 (1.1, 6.2)	5.6 (4.6, 6.7)
Cardiovascular and cerebrovascular AEs	0.4 (0.1, 2.8)	0.4 (0.1, 2.8)	0.3 (0.1, 1.2)	1.0 (0.3, 4.1)	0.5 (0.3, 0.9)
Gastrointestinal disorder	2.8 (1.4, 5.9)	6.1 (3.7, 10.1)	5.1 (3.6, 7.2)	2.6 (1.1, 6.2)	3.3 (2.7, 4.2)
Anemia	2.0 (0.8, 4.8)	1.6 (0.6, 4.2)	1.7 (0.9, 3.0)	2.6 (1.1, 6.2)	1.1 (0.8, 1.7)
Neutropenia and lymphopenia	8.3 (5.3, 12.9)	5.2 (3.0, 8.9)	6.4 (4.7,8.7)	3.1 (1.4, 6.9)	3.7 (3.0, 4.6)
Hepatic impairment	11.4 (7.8, 16.7)	18.7 (13.9, 25.2)	14.8 (12.1, 18.2)	14.1 (9.6, 20.8)	7.3 (6.2, 8.5)
Renal impairment	3.7 (1.9, 7.0)	1.2 (0.4, 3.7)	2.6 (1.6, 4.2)	2.0 (0.8, 5.5)	1.4 (1.0, 1.9)
Muscle disorder	13.1 (9.2, 18.7)	15.7 (11.4, 21.6)	14.5 (11.8, 17.8)	7.4 (4.4, 12.5)	8.5 (7.3, 9.9)
Interstitial lung disease	0.4 (0.1, 2.8)	0	0.5 (0.1, 1.4)	2.0 (0.8, 5.4)	0.3 (0.1, 0.6)

AEs of special interest were defined as serious infections, tuberculosis, *Pneumocystis jurovecii* pneumonia, herpes zoster-related disease, virus reactivation, malignancies, non-melanoma skin cancer, malignant lymphoma, cardio- and cerebrovascular AEs, dyslipidemia, changes to QT interval, hypertension, gastrointestinal events, anemia, neutro- and lymphopenia, thrombocytopenia, hepatic or renal impairment, muscle disorder, and interstitial lung disease
AE, adverse event

Among AEs of special interest in the pooled Ph 3 studies, the incidence (95% CI) of serious infections was 2.9 (1.9, 4.6) in patients receiving peficitinib and 2.0 (0.8, 5.5) in those receiving ETN (**Table 3**). The incidence of herpes zoster-related disease was greater in peficitinib groups (5.7 [4.2, 7.9]) than in placebo (2.3 [0.6, 9.4]) or ETN groups (2.6 [1.1, 6.2]), and the overall incidence of malignancies (0.6 [0.2, 1.6]) was similar to that in the placebo and ETN groups (1.2 [0.2, 8.3] and 0.5 [0.1, 3.6], respectively).

Conclusion: This analysis provides an overview of safety across peficitinib clinical studies in patients with RA, and shows it is well tolerated with no major specific concerns with longer term administration of peficitinib.

Does Combined Therapy Affects Adherence in Rheumatoid Arthritis?

Iván de Jesús Hernández-Galarza,[1] **Rita Pineda-Sic**,[1] Marielva Castro-Gonzalez,[1] Diana Elsa Flores-Alvarado,[1] Octavio Ilizaliturri-Guerra,[1] Rodolfo Uriarte-Botello,[1] and Dionicio Galarza-Delgado[1], [1]Universidad Autonoma de Nuevo Leon, Hospital Universitario "Dr Jose Eleuterio Gonzalez", Monterrey, Nuevo Leon, Mexico

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment adherence in Rheumatoid Arthritis (RA) patients vary from 30 to 80%. It is important to identify the associated factors to a low adherence, so clinicians can make interventions to obtain better therapeutic results. Adherence to treatment has been described to be affected by several factors, such as access to healthcare facilities, education, socioeconomic status, quality of communication between physician and patient, among others. REPAIR® is a software designed with the purpose of improve data collection and medical practice in our outpatient clinic. The aim of this study was to compare the adherence to synthetic Disease-Modifying Antirheumatic Drugs (DMARDs) among RA patients with monotherapy and combined therapy (two medications) in an open population.

Methods: Cross sectional, observational, comparative study. This study was conducted in rheumatology outpatient clinic of University Hospital in Monterrey, México. Consecutive patients with RA were approached during their rou-

Table No. 1

	Monotherapy (n=346)	Combined therapy (n=613)	p
Age (years), median (IQR)	54 (44-63)	53 (43-59)	0.018
Women, n (%)	317 (91.6)	575 (93.8)	0.362
Inadequate adherence to treatment, n (%)	52 (15)	102 (16.6)	0.514
Adequate adherence to treatment, n (%)	294 (85)	511 (83.4)	

Table No.2

	Monotherapy (n=346)	Combined therapy (n=613)
Medication used		
Methotrexate, n (%)	282 (81.5)	264 (43.1)
Leflunomide, n (%)	16 (4.6)	111 (18.1)
Sulfasalazine, n (%)	19 (5.5)	134 (21.9)
Hydroxychloroquine, n (%)	16 (4.6)	42 (6.9)
Chloroquine, n (%)	9 (2.6)	46 (7.5)
DMARDb, n (%)	2 (0.6)	11 (1.8)
Cyclophosphamide, n (%)	0 (0)	1 (0.2)
Mofetil mycophenolate, n (%)	0 (0)	1 (0.2)
Azathioprine, n (%)	0 (0)	2(0.3)
Inadequate Adherence Reasons		
Own Decision, n (%)	10 (20.4)	27 (29)
Economic, n (%)	17 (34.7)	22 (23.7)
Side Effects, n (%)	9 (18.4)	11 (11.8)
Lack of availability, n (%)	5 (10.2)	15 (16.1)
Forgetfulness of dose, n (%)	5 (10.2)	14 (15.1)
Other, n (%)	3 (6.1)	4 (4.3)

tine appointments, march 2018 to december 2018 period, were asked how many days of the last month they forgot or took their DMARDs (self-report). We classified the adherence rate in 2 categories based on the days of the last month they took the indicated medication; adequate: 75%-100% (> 21 days), inadequate < 75% (< 21 days). When adherence was inadequate we ask about the cause. Data was obtained from REPAIR ® (internal electronic patient record). The Kolmogorov-Smirnov test was used to determine normal distribution. Categorical variables are expressed as total number and percentage (%), and numerical variables as median and the 25th-75th percentiles (p25-p75). Chi square and Mann-Whitney U-test were used to compare groups and considered significant if $p< 0.05$. Data was analyzed with SPSS version 24.

Results: A total of 959 patients were included. When comparing adherence to treatment and gender between groups no statistically significant difference was found. The main cause of inadequate adherence in monotherapy group was economic (34.7%) and own decision in combined therapy group (29.1%).

Conclusion: Patients with combined therapy had the same percentage of adherence as patients with monotherapy. These results may indicate that number of drugs prescribed not necessarily affects adherence to treatment in RA patients. The principal causes for an inadequate adherence to treatment were: economic for monotherapy group and own decision for combined therapy group. However, long-term studies are needed to evaluate the persistence of treatment in these groups of patients.

Protein Biomarkers Predicting the Response to IFX+MTX+LEF Treatment in Patients with Rheumatoid Arthritis

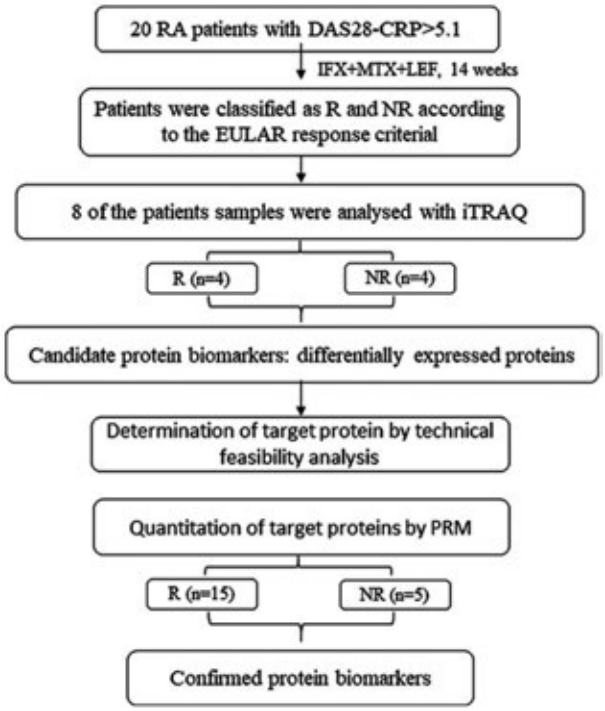
Jian Chen,[1] Meng-shi Tang,[2] Li-chang Xu,[3] Shu Li,[2] Yan Ge,[2] Jing Tian,[2] Xi Xie,[2] Jin-wei Chen,[2] Jin-feng Du,[2] and **Fen Li** [1], [1]Department of Rheumatology and Immunology, the Second Xiangya Hospital, Central South University, Changsha, Hunan, China, Changsha, [2]Department of Rheumatology and Immunology, The Second Xiangya Hospital, Central South University, Changsha, [3]International Department of YALI High School, Changsha

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

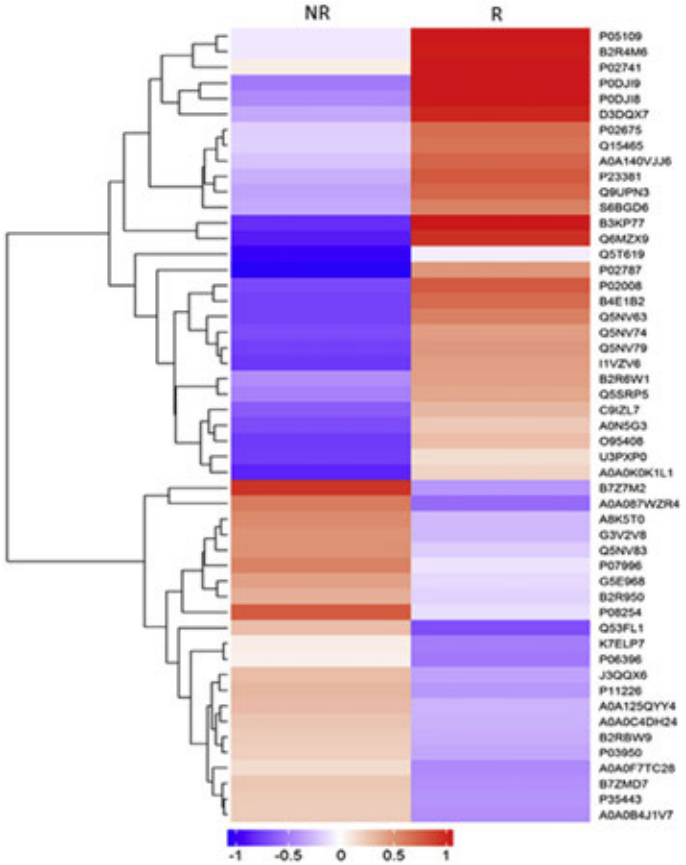
Background/Purpose: Patients with rheumatoid arthritis (RA) usually receive triple therapy with methotrexate (MTX), leflunomide (LEF) and infliximab (IFX), but nearly one-third of them do not respond to triple therapy. This study aimed to identify biomarkers for predicting the efficacy of triple therapy to optimize personalized treatment of RA.

Methods: All 20 enrolled patients met 2010 ACR/EULAR criteria for RA and were classified into good, moderate and non-responders (GR, MR, NR) for triple therapy. The Responders (R) were defined as the sum of GR and MR. Protein profiles of 4 responders and 4 non-responders were investigated via isobaric tags for relative and absolute quantification (iTRAQ), and differentially expressed proteins (DEPs) with high-confidence peptides were validated in 15 responders and 5 non-responders by parallel response monitoring (PRM).

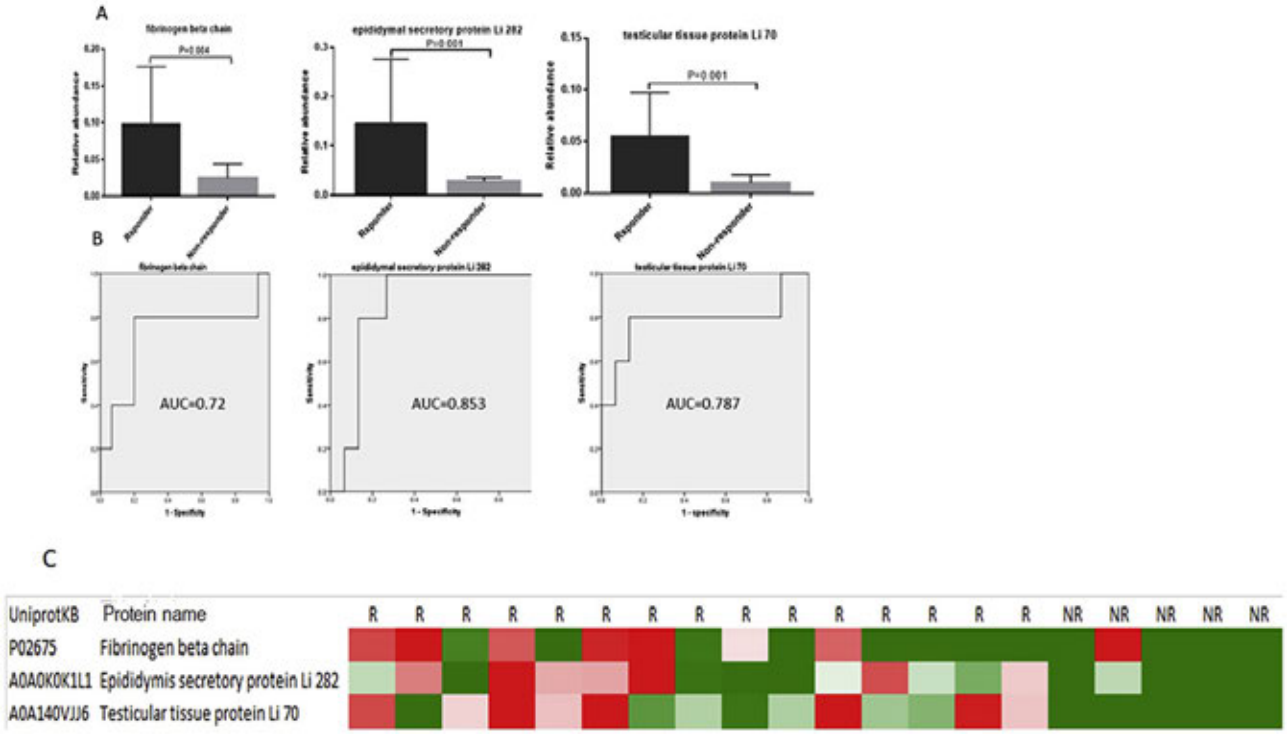
Results: iTRAQ identified 51 DEPs between responders and non-responders ($p < 0.05$, fold change $> \pm 1.2$).The top five up-regulated DEPs were B7Z7M2, A0A087WZR4, Q53FL1, P08254 and G3V2V8, while the top five down-regulated proteins were Q6MZX9, B3KP77, P0DJI9, P0DJI8 and P02787. Targeted mass spectrometry by PRM identified 10 candidate biomarkers, and 3 DEPs including fibrinogen beta chain, epididymal secretory protein Li 282 and testicular tissue protein Li 70 were confirmed as predictive biomarkers.



The workflow of proteomic analysis in this study. The study included candidate biomarkers discovering by iTRAQ and biomarkers confirmation by PRM. R, responders; NR, non-responders; iTRAQ, isobaric tags for relative and absolute quantification; PRM, parallel reaction monitoring



Hierarchical cluster of DEPs between R group and NR group, with folds > ±1.2 and P value <0.05. Rows represent the proteins and columns represent the group of patient. The relative expression level is indicated by the intensity of the color. Red, high expression; Blue, low expression. R, responder; NR, non-responder.



A) Comparison of 3 targeted DEPs. Fibrinogen beta chain, epididymal secretory protein Li 282 and testicular tissue protein Li 70 were up-regulated in R group as compared to NR group with $P < 0.05$. B) ROC curve of 3 targeted DEPs. AUC of the three predictive proteins was 0.720, 0.853 and 0.787, respectively. DEPs, Differentially expressed proteins; R, responder; NR, non-responder; ROC, relative operating characteristic. AUC, Area under the curve. C) Heatmap of 3 targeted DEPs in 15 responders (R) and 5 non-responders (NR). The color indicated the relative expression level. Green: 0.5; white: 1, and red: 2.

Conclusion: This study demonstrated the feasibility of exploring biomarkers by applying iTRAQ and PRM mass spectrometry techniques, and a panel of biomarkers were identified to predict clinical response of IFX+MTX+LEF treatment in active RA patients.

Hepatobiliary Events in >5000 Patients with Inflammatory Arthritis Treated with Biosimilar or Originator Etanercept in Routine Care, Results from the Danish Nationwide DANBIO Registry

Bente Glintborg,[1] Stylianos Georgiadis,[2] Mette Nørgaard,[3] Frank Mehnert,[3] Kathrine Lederballe Grøn,[1] Niels Steen Krogh,[4] and **Merete Lund Hetland** [1], [1]DANBIO and Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Centre of Head and Orthopaedics, Rigshospitalet, Copenhagen, Denmark, [2]DANBIO registry and Copenhagen Center for Arthritis Research, Centre for Rheumatology and Spine Diseases, Rigshospitalet, Copenhagen, Denmark, [3]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark, [4]Zitelab / DANBIO, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Marketing of biosimilar biological drugs may significantly reduce drug costs if comparable safety and efficacy of originator and the biosimilar can be documented. In a phase 3 randomized clinical trial, biosimilar SB4 treatment had a slightly higher occurrence of hepatobiliary adverse events compared with the originator etanercept (ETN) treatment (ref 1) - potentially explained by differences in patients' comorbid diseases and co-medication use (ref 2). In Denmark, biosimilars have high penetration due to a tender-based system with tax-paid biologics. Therefore, in April 2016, Danish patients with inflammatory rheumatic diseases were mandatorily switched from ETN to SB4 (=non-medical switch) (ref 3) and SB4 became the first choice for bio-naïve patients.

We aimed to explore the incidence rates (IRs) of hepatobiliary events during the first 6 months of routine care treatment with either ETN or SB4 among Danish adult patients with inflammatory rheumatic diseases.

Methods: Observational cohort study. Patients initiating treatment with ETN (Jan 2010-April 2016) or SB4 (April 2016-Feb 2018) were identified in the nationwide DANBIO registry. Among SB4 treated patients, the subgroup of non-medical switchers (i.e. had switched from ETN 0-90 days previously) was identified. Furthermore, patients could be either bDMARD-naïve or switchers from previous bDMARD treatment (other than ETN). Incident hospital contacts (hospitalizations or out-patient care) due to hepatobiliary events were identified through linkage to the national patient registry and included diseases of the liver, gallbladder and bile duct system. Age and gender standardized IRs per 100 person-years (PY) during 0-6 months since treatment start were assessed.

Results: A total of 5,738 patients (2,748 ETN/2,990 SB4) were included (Table 1). Among SB4-treated patients, 52% were non-medical switchers. Baseline characteristics were similar for bio-naïve patients who started SB4 or ETN and similarly for patients who had switched from other bDMARD. Non-medical switchers tended to have lower disease activity (Table 1).

During the first 6 months of treatment, 50 hepatobiliary events were identified, of which 23 were hospitalized (Table 2). IRs in all treatment groups were low with wide and overlapping confidence intervals. There was a tendency towards lover IR of hepatobiliary events among SB4 non-medical switchers.

Among the 50 patients with hepatobiliary events, 14 (28%) received concomitant methotrexate. Main events were gall-bladder stones (8 events), elevated transaminases (5 events), liver-cirrhosis (3 events) and pancreatitis (3 events).

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) is an oral reversible JAK inhibitor engineered for greater selectivity for JAK1 versus JAK2, JAK3, and TYK2, and is currently being assessed for the treatment of RA. Here we report on an integrated, long-term safety analysis of UPA in Japanese patients (pts) with RA from the UPA clinical development program.

Methods: Japanese pts were included from three studies: the Phase 2b/3 SELECT-SUNRISE study[1] (which only enrolled Japanese pts), and the Phase 3 SELECT-EARLY[2] and SELECT-MONOTHERAPY[3] studies (which included subsets of Japanese pts). In SELECT-SUNRISE, pts with an inadequate response (IR) to csDMARDs were randomized to receive UPA 7.5 mg, 15 mg, or 30 mg once daily (QD), or matching placebo (PBO), for 12 weeks in addition to background csDMARDs. In SELECT-EARLY, MTX-naïve pts received monotherapy with UPA 7.5 mg (Japan only), 15 mg, or 30 mg QD, or MTX, for 24 weeks. In SELECT-MONOTHERAPY, MTX-IR pts received monotherapy with UPA 15 mg or 30 mg QD, or continued with MTX monotherapy, for 14 weeks. Each study included the option to continue

Table. Safety profile of UPA in Japanese pts versus the global population

TEAE, events (E/100 PY)[a]	Japanese population			Global population	
	7.5 mg QD (n=121) (PY=171.2)	15 mg QD (n=126) (PY=176.3)	30 mg QD (n=124) (PY=154.7)	UPA 15 mg QD (n=2630) (PY=2655.1)	UPA 30 mg QD (n=1204) (PY=1365.0)
Any AE	645 (376.8)	627 (355.6)	797 (515.2)	7852 (295.7)	5033 (368.7)
Serious AE	28 (16.4)	29 (16.4)	38 (24.6)	399 (15.0)	291 (21.3)
AEs leading to discontinuation of study drug	14 (8.2)	16 (9.1)	24 (15.5)	224 (8.4)	182 (13.3)
Death	0	0	3 (1.9)	11 (0.4)	11 (0.8)
Infection	265 (154.8)	251 (142.4)	279 (180.3)	2487 (93.7)	1581 (115.8)
Serious infection	10 (5.8)	9 (5.1)	16 (10.3)	102 (3.8)	85 (6.2)
Opportunistic infection	2 (1.2)	4 (2.3)	17 (11.0)	17 (0.6)	24 (1.8)
Active/latent tuberculosis	0	1 (0.6)	1 (0.6)	58 (2.2)	21 (1.5)
Herpes zoster	14 (8.2)	25 (14.2)	33 (21.3)	99 (3.7)	96 (7.0)
NMSC	0	0	0	8 (0.3)	15 (1.1)
Malignancy other than NMSC	1 (0.6)	2 (1.1)	3 (1.9)	23 (0.9)	19 (1.4)
Lymphoma	0	0	1 (0.6)	1 (<0.1)	1 (<0.1)
Hepatic disorders	15 (8.8)	24 (13.6)	14 (9.0)	382 (14.4)	173 (12.7)
Gastrointestinal perforation	0	1 (0.6)	2 (1.3)	5 (0.2)	4 (0.3)
Anemia	4 (2.3)	3 (1.7)	13 (8.4)	121 (4.6)	79 (5.8)
Neutropenia	6 (3.5)	3 (1.7)	15 (9.7)	82 (3.1)	93 (6.8)
Lymphopenia	5 (2.9)	6 (3.4)	7 (4.5)	50 (1.9)	42 (3.1)
CPK elevation	8 (4.7)	17 (9.6)	29 (18.7)	163 (6.1)	170 (12.5)
Renal dysfunction	1 (0.6)	1 (0.6)	3 (1.9)	11 (0.4)	14 (1.0)
Adjudicated MACE[b]	1 (0.6)	0	2 (1.3)	17 (0.6)	13 (1.0)
Adjudicated VTE[c]	0	1 (0.6)	1 (0.6)	16 (0.6)	4 (0.3)

BID, twice daily; CPK, creatine phosphokinase MACE, major adverse cardiovascular events; NMSC, non-melanoma skin cancer PBO, placebo; PY, pt-years; QD, once daily;
TEAE, treatment-emergent adverse event; UPA, upadacitinib
[a]AESIs were identified by a Standardized MedDRA query or Company MedDRA query; TEAEs were defined as any AE with an onset date on or after the first dose of study drug and no more than 30 days after the last dose of study drug if subject discontinued study drug prematurely
[b]Defined as cardiovascular death, non-fatal myocardial infarction, and non-fatal stroke
[c]VTE, venous thromboembolism (pulmonary embolism or deep vein thrombosis)

into a long-term extension. The exposure adjusted event rates (EAERs) of adverse events (AEs) and AEs of special interest (AESI) per 100 pt-years (PY) are reported. Results in Japanese pts were compared with the global population in UPA Phase 3 studies.

Results: Japanese pts (n=371) received UPA 7.5 mg QD (n=121), 15 mg QD (n=126), or 30 mg QD (n=124). Exposure to UPA was 171.2, 176.3, and 154.7 PY in the 7.5 mg, 15 mg, and 30 mg groups, respectively, with mean exposures of 516.8, 511.0, and 455.5 days. The demographic characteristics of pts in all the treatment groups were generally well balanced; the majority of pts were female and aged between 40 and 64 years. Among the Japanese population, EAERs were consistently higher in the 30 mg group compared with the 15 mg and 7.5 mg groups (Table). EAERs in the 15 mg and 7.5 mg groups were comparable. In comparison with the global population, the EAER in the 15 mg

and 30 mg groups was higher in the Japanese population. The EAER of infections (including herpes zoster) was also higher in the Japanese population compared with the global population. The EAERs of AESI (including malignancies, cardiovascular disorders, hepatic disorders, and laboratory abnormalities) were comparable between the Japanese and global populations.

Conclusion: No new safety risks were identified with administration of UPA in Japanese pts. As reported with other JAK inhibitors, herpes zoster occurred at higher rates on UPA in Japanese pts versus the global population. The 7.5 mg and 15 mg doses had lower EAERs of overall AEs, infections and laboratory-related AEs compared to that observed with 30 mg.

Abstract Number: 2408

A Prospective Analysis of Factors Impacting Medication Decision-Making in Patients with Rheumatoid Arthritis

Elizabeth Salt,[1] Amanda Wiggins,[2] Kristine Lohr,[2] and Mary Kay Rayens[2], [1]University of Kentucky, Lexington, KY, [2]University of Kentucky, Lexington

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments Poster III: Safety and Outcomes – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prior research suggests that medication decision-making in rheumatoid arthritis (RA) patients is affected by disease activity, satisfaction with care, trust in their health care provider, and quality of patient-provider communication.(1-3) Because few studies have used quantitative methodologies to do such, we will describe changes in these key decision-making factors over time.

Methods: We collected data over 6 months (baseline, 1 week, 8 weeks, 16 weeks and 24 weeks) in a sample of 143 RA patient at one University health system. We measured medication adherence with the *Medication Adherence Report Scale-9RA*, a 9-item scale using a 5-point Likert scale (5 = *never* and 1 = *very often;* score range: 9 - 45; Cronbach's α =.77; test-retest reliability = .73).(4-6) Satisfaction with care was measured with the *Client Satisfaction Questionnaire-8,* an 8-item scale using a 4-point Likert-type scale where 4 indicates increased satisfaction (score range 8 – 32; Cronbach's α = .93). A significant correlation with client-reported symptoms supports scale validity.(7) Trust in provider was measured with the *Trust in Physician Scale* (TPS), an 11-item scale using a 5-point Likert scale (1 = *strongly disagree* – 5 *strongly agree;* Cronbach's α = .87).(8) The scale has significant negative correlations with measures of skepticism supporting scale validity.(8) Disease activity was measured with the *Routine Assessment of Patient Index Data 3* (RAPID3) on three domains: physical function, pain, and patient global assessment on a scale of 0 to 10 (range 0 - 30).(9, 10) The RAPID3 has been significantly correlated with other measures of disease activity.(9, 10) We used repeated measure mixed modeling and Friedman's test to describe the factors over time.

Table 1. Repeated measures modeling of key factors over time.

	Potential range	Baseline	1-week	8-weeks	16-weeks	24-weeks	p
Provider communication	20-80	76.58 (0.72)	75.46 (0.84)	73.70 (0.97)	73.69 (1.13)	73.52 (1.28)	**.034**
Trust in provider	0-100	87.43 (1.05)	85.50 (1.22)	82.97 (1.41)	84.13 (1.64)	80.74 (1.86)	**.012**
Satisfaction	8-32	30.13 (0.29)	29.67 (0.35)	29.06 (0.40)	29.25 (0.46)	28.03 (0.53)	**.008**
Medication adherence	9-45	43.18 (0.25)	43.02 (0.30)	43.82 (0.34)	43.81 (0.41)	42.80 (0.46)	.20
Perceived quality of patient communication							
Information verifying	1-7	6.48 (0.05)	6.41 (0.06)	6.40 (0.07)	6.47 (0.08)	6.40 (0.09)	.86
Information seeking	1-7	6.42 (0.07)	6.39 (0.08)	6.28 (0.09)	6.31 (0.11)	6.21 (0.12)	.50
Information giving	1-7	6.49 (0.05)	6.45 (0.06)	6.47 (0.07)	6.51 (0.08)	6.45 (0.09)	.97
Social-emotional	1-7	6.58 (0.06)	6.52 (0.66)	6.42 (0.08)	6.56 (0.09)	6.43 (0.10)	.44

Note: cells contains means and associated standard errors

Table 1. Prospective

Table 2. Disease activity over time.						
	Baseline (*n* = 133)	1 week (*n* = 96)	8 weeks (*n* = 72)	16 weeks (*n* = 53)	24 weeks (*n* = 42)	*P*
Remission	1 (1%)	1 (1%)	1 (1%)	0 (0%)	0 (0%)	.75
Low	2 (1%)	1 (1%)	2 (3%)	0 (0%)	2 (5%)	
Moderate	40 (30%)	30 (30%)	20 (28%)	18 (34%)	10 (24%)	
High	90 (68%)	64 (67%)	49 (68%)	35 (66%)	30 (71%)	

Note: Cells contain frequency and percent.

Table 2. Prospectivedocx

Results: We identified a significant decrease in the patient's perceived quality of provider communication (p=.034), trust in the provider (p=.012) and satisfaction with care over time (p=.008). We did not identify changes over time in medication adherence, any of the four subscales measuring the patient's perception of the quality of their communication with their health care provider, or disease activity overtime (Tables 1 and 2).

Conclusion: Despite stable medication adherence, disease activity did not change significantly over time. Although trust in the provider, satisfaction with care, and quality of provider communication scores were high, these values decreased over time suggesting that providers must make concerted efforts to maintain these key factors during the patient care experience.

24-hour Activity Profiling in People Living with Arthritis: Habits Matter

Lynne Feehan,[1] Linda Li,[1] Na Lu,[2] and Hui Xie[3], [1]Arthritis Research Canada and University of British Columbia, Vancouver, Canada, Vancouver, BC, Canada, [2]Arthritis Research Canada, Vancouver, Canada, Vancouver, BC, Canada, [3]Arthritis Research Canada and Simon Fraser University, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Research Methodology Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Current practices promoting change in physical activity classify individuals as being more or less active. However, across 24-hours people spend time in different types of activities including sleeping. Variations in 24-hour activity may have implications for a person's health and well-being and may influence how a person responds to interventions that promote physical activity. The purpose of this study was twofold. First, we aimed to identify distinct 24-hour activity profiles in people with arthritis. Second, we explored individual characteristics and factors associated with those profiles.

Methods: A secondary analysis of baseline data from two ongoing randomized clinical trials studying the effect of physical activity counselling for people with knee osteoarthritis (OA), rheumatoid arthritis (RA), or systemic lupus erythematosus (SLE). 24-hour activity was measured by a Sensewear Mini worn for seven days. Participants completed an online survey for measures of demographics, occupation, depression (PHQ-9 Depression scale), and habitual sitting and walking behaviors (Self-reported Habit Index: SRHI). Activity profiles were identified using latent class analysis (LCA) to 24-hour activity data from individuals with 4 to 6 days (20+ hours) of wear. Data were stratified by minutes off body, sleeping, resting, sitting, and walking intermittently (< 50 steps / min) or purposefully (> 50 steps / min). Multiple logistic regression with backward elimination were used to identify factors predictive of cluster allocation relative to a reference cluster with the highest sitting reported as an Odds Ratio (95%CI). Predictive variables included age, sex, type of arthritis, depression score, usual occupation and home leisure sitting habit, and outdoor walking habit scores.

Results: In 172 individuals [mean age 58.1 years; 86% female; OA (30%), RA (49%), SLE (21%), mean daily steps 5990 (SD: 3234)] we identified four distinct 24-hour activity profiles relative to the cohort (Figure 1). These included: 1) **Balanced Activity** (n=40) [on average 9.4 hours of sitting, 5.2 hours of walking, 7.4 hours of sleep], 2) **High Sitting** (n=35) [on average 13.2 hours of sitting, 1.9 hours walking, 6.9 hours of sleep], 3) **High Sleeping** (n=45) [on average 10.4 hours sitting, 2.8 hours walking, 8.4 hours of sleep], and 4) **Low Sleeping** (n=52) [on average 12.2 hours of sitting and 3.9 hours of walking, 6.5 hours of sleep] (Table1). Age and self-reported occupational sitting and walking outside habits predicted activity profile; showing that relative to the high sitting cluster, participants in the other clusters were younger (OR: 0.95 to 0.98), had lower occupational sitting (OR: 0.56 to 0.74) and higher walking outside habits (OR: 1.09 to 1.43) (Table2).

Conclusion: Using objectively measured physical activity data, we identified four 24-hour activity profiles. Our findings suggest that some profiles such as individuals with high sitting may be prime targets for future physical activity promotion initiatives, particularly in individuals with strong habitual activity behaviors.

	Balanced Activity	High Sleeping	Low Sleeping	High Sitting
Number (#)	40	45	52	35

Using External Data to Estimate Omitted Variables in Observational Data: A Plasmode Simulation Study Investigating the Relationship Between Osteoarthritis and Cardiovascular Diseases to Compare Alternative Approaches in Imputing the Body Mass Index Variable

Mohammad Atiquzzaman,[1] Mohammad Karim,[2] Jacek Kopec,[3] Hubert Wong,[4] Mary De Vera,[5] and Aslam Anis[2], [1]Faculty of Pharmaceutical Sciences, University of British Columbia, Surrey, BC, Canada, [2]School of Population and Public Health, University of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada, [4]University of British Columbia, Vancouver, BC, Canada, [5]Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Research Methodology Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: BMI is a well-known confounding factor in the association between osteoarthritis (OA) and cardiovascular diseases (CVD). However, BMI is not usually recorded in administrative databases. When BMI is imputed using the proportion-based imputation (PBI) method, a BMI category is assigned to an individual according to the proportions observed in external data based on a set of pre-defined variables (1). Alternatively, standard Multiple Imputation (MI) methods can also be employed in the same situations. We investigated the OA-CVD relationship as a

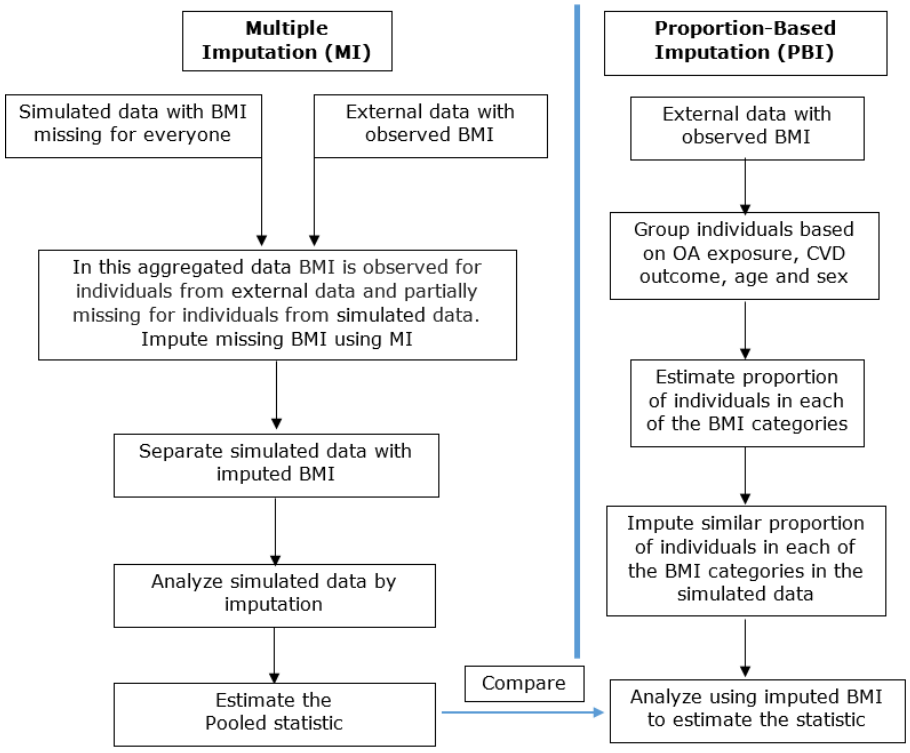

Figure 1: Conceptual framework to compare MI with PBI in imputing BMI variable missing for everyone in a study data using information from external database

Table 1: Description of various datasets used to compare multiple imputation approach with proportion-based imputation method in imputing BMI variable missing for everyone in a database

Dataset	Description	Number of individuals (N)	Comments
Data.1	Study dataset created from CCHS cycle 3.1 (2005)	84,452	All study variables are observed including BMI
Data.2	500 simulated datasets created from study dataset using plasmode simulation	75,000	All study variables are observed including BMI
Data.3	Copies of 500 simulated datasets	75,000	BMI is missing for everyone in the dataset. Other study variables are observed
Data.4	External data (compiled data from CCHS cycles 1.1 and 2.1)	149,810	All study variables are observed including BMI

demonstration to compare MI with PBI (figure 1). We hypothesized that BMI imputed using MI will minimize potential bias in the OA-CVD association compared to BMI categories imputed using PBI.

Methods: In this plasmode simulation study 500 simulated datasets were created using publicly available data from the Canadian Community Health Survey (CCHS) cycle 3.1. BMI was set missing for everyone in the simulated data. This mimics administrative data in which BMI is not recorded and missing for everyone in the database. A large dataset compiled from CCHS cycles 1.1 and 2.1 served as the external data in which BMI was observed for everyone. Table 1 summarizes the databases accessed. BMI missing in copies of simulated data was imputed using MI (with a number of imputations = 5) and PBI accessing observed BMI information in external data. To evaluate the performance of imputation methods, the distribution of the BMI variable and the adjusted odds ratio (aOR) estimated from the multivariable logistic regression model were compared. In this model, CVD outcome was regressed on OA exposure adjusting for age, sex, physical activity index, level of education, household income level, smoking status, diabetes, hypertension and BMI category. After analyzing the imputed datasets, the proportion of individuals in each of the four BMI categories and the ORs were averaged from the 500 simulated datasets. The 95% confidence interval (CI) of the averaged OR was calculated by the percentile method.

Results: Compared to PBI, MI produced proportions of individuals closer to the known proportions across the BMI categories except for the overweight category (Table 2). Considering the known aOR of 1.59 (1.36, 1.82), BMI imput-

Table 2: Comparison of proportion of individuals in each of the four BMI categories after imputing BMI for everyone in the simulated data with the BMI categories originally recorded by Statistics Canada in Canadian Community Health Survey cycle 3.1 (2005) data

BMI category	Data.1	Data.2	Data.3	
			BMI imputed using multiple imputation	BMI imputed using proportion-based imputation
Under weight	2.23	2.26	2.54	2.00
Normal weight	44.84	45.98	41.45	38.35
Over weight	35.12	34.93	38.66	34.77
Obese	17.81	16.83	17.34	24.87

ed using MI introduced less bias in OA-CVD association compared to PBI, the aOR was 1.62 (1.39, 1.86) and 1.66 (1.41, 1.90), respectively.

Conclusion: This is the first study to compare MI with PBI in the context of imputing BMI information that is not recorded at the database level. MI was superior to imputation method based on population-level proportions in imputing BMI missing for everyone in the simulated datasets. The generalizability of these methodological results will become more evident as more similar studies are undertaken in a variety of settings.

Casting a Wide Net: Comparing Strategies for Recruiting 18-35-year-olds with Rheumatic Disease as Study Participants

Arif Jetha,[1] Lori Tucker,[2] Julie Bowring,[3] Catherine L. Backman,[4] Laurie Proulx,[5] Vicki Kristman,[6] and Monique A.M. Gignac[3], [1]Institute for Work & Health, Toronto, ON, Canada, [2]British Columbia Children's Hospital, Vancouver, Canada, [3]Institute for Work & Health, Toronto, Canada, [4]University of British Columbia, Vancouver, Canada, [5]Canadian Arthritis Patient Alliance, Ottawa, Canada, [6]Lakehead University, Thunder Bay, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Research Methodology Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Young adulthood is a unique life phase that spans 18-35 years, and is characterized by healthcare, educational, vocational and social transitions. Experiences in young adulthood can shape long-term health and socioeconomic outcomes. Yet, young adults with rheumatic conditions are a challenging population to recruit, and as a result are underrepresented in population health research. The objective of this study is to examine and compare recruitment strategies utilized in the construction of a large cohort of young adult participants with rheumatic disease.

Methods: Young adult participants with rheumatic conditions (e.g., juvenile arthritis, systemic lupus erythematosus, rheumatoid arthritis) were recruited as part of a three-year longitudinal study of transitional work experiences in Canada. A multifaceted recruitment strategy was utilized to construct a representative cohort including 1) rheumatology clinics in three provinces; 2) national community-based patient organizations; and 3) a representative panel from a survey research firm. Efforts were taken to recruit participants who varied in terms of disease severity to capture a breadth of experiences. Bivariate analyses (i.e., Chi-Square analysis and analysis of variance) were conducted to examine if participants differed based on sociodemographic (e.g., age, gender and hours worked) and health factors (e.g., pain, fatigue and disease activity) across the three recruitment approaches.

Results: A total of 412 young adult participants (mean age = 29 years ± 4.2) with rheumatic disease were successfully recruited and completed the baseline survey. A majority of participants had rheumatoid arthritis (36%) and juvenile arthritis (20%). Most participants were recruited using the research firm (75%) and community-based organizations (19%). Fewer participants were recruited through clinics (6%). Participants recruited from rheumatology clinics were younger (27 years ± 5.1) when compared to those recruited through community-based organizations (28.5 years ± 4.3) or the research firm (29 years ± 4.0) ($p < .01$). A greater proportion of participants recruited through community-based organizations were female (84%) compared to participants from rheumatology clinics (58%) or the research firm (42%) ($p < .001$). Participants recruited through community-based organizations reported less disease severity (e.g., pain, fatigue, disease activity and depression) and indicated more work hours compared to participants recruited from rheumatology clinics or research firm ($p < .001$).

Conclusion: A multifaceted approach can be effective in recruiting a large cohort of young adults with rheumatic disease. The use of community-based organizations and research firms have the potential to recruit large samples of young adult study participants beyond rheumatology clinics. Participants recruited through different approaches may vary in terms of sociodemographic and health factors and enable researchers to capture a diversity of experiences. The increased inclusion of young adult participants in population health research will offer a better understanding of the impact of rheumatic disease during a critical transitional life phase.

Values and 95% CI based on 5000 bootstrap samples.

WOMAC Pain on 0-100 scale, MID used is 12 points. Risk of MID is the proportion of subjects in the group attaining MID and ranges from 0 to 1.

All values adjusted for WOMAC pain at randomization and sex.

Table for Evaluation of MID for RCT of pain in OA v3
Mean Difference, Risk of MID, and Risk Difference Values in RCT

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Research Methodology Poster – ARP
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Minimal important differences (MID), based on within-subject evaluation of attaining an improvement in a continuous outcome such as a pain scale, are important for evaluating the magnitude of treatment effects in randomized clinical trials (RCT) in OA. While designed to assess whether an individual's improvement achieved a meaningful threshold, MID has often been used to gauge the between treatment-group mean difference in change in the outcome. We propose an alternate analysis, where each subject is evaluated for reaching the MID (yes/no) preserving the subject specific meaning of the MID and then the risk of MID is compared between groups, while allowing for adjustment for baseline values. We examine whether this alternative analysis approach provides complementary information to the between group treatment difference in change in pain.

Methods: As our pain measure, we used WOMAC pain on a 0-100 scale. We evaluated mean differences, and risk differences in subject attainment of MID in 4 completed RCT in knee osteoarthritis with treatment effects ranging from negative/null, to moderate, to strong. The difference between the value at randomization and the value at the end of treatment was the change in WOMAC pain. Based on a systematic review, a reduction of 12 (Devji T. *BMJ Open* 2017) was used for the MID. Adjusted between treatment group mean differences in change were estimated by analysis of covariance with the outcome of WOMAC pain at the end, by treatment, adjusting for WOMAC pain at baseline and sex. Adjusted risk differences in subject attainment of MID, by treatment, came from marginalized predicted probabilities generated by logistic regression using attainment of MID as the outcome, with treatment, WOMAC pain at baseline, and sex as predictors. 95% confidence intervals were generated by nonparametric bootstrap methods.

Results: Treatment group mean differences ranged from -1.6 to 13.0, and the risk differences ranged from -0.11 to 0.33 (see table). Only 1 RCT had a mean difference above the MID, yet all studies had substantial percentages of subjects with MID improvement. The direction and significance of the mean difference and risk difference results were usually, but not always, concordant. The risk difference analysis made it clear that the control risk for MID varies across RCT in ways that relate to the trial conditions but not necessarily to the treatment effect.

Conclusion: Rather than use the MID to evaluate between treatment group mean differences, we propose using the proportion of subjects attaining MID as a secondary outcome in an RCT evaluating a continuous measure. This preserves the meaning of the MID for which it was validated and allows identifying important information about the subject response to treatment and control in RCT that is not readily apparent from the mean difference.

LOU064: A Highly Selective and Potent Covalent Oral BTK Inhibitor with Promising Pharmacodynamic Efficacy on B Cells for Sjoegren's Syndrome

Bruno Cenni,[1] Peter End,[1] Maciej Cabanski,[1] Annamaria Jakab,[1] Enrico Funhoff,[1] Magdalena Kistowska,[1] Arvind Kinhikar,[2] Alessio Maiolica,[1] Masaru Hirano,[3] Barbara Nuesslein-Hildesheim,[1] Amanda Littlewood-Evans,[1] Daniela Angst,[1] Robert Pulz,[4] and Martin Kaul[1], [1]Novartis Institutes for BioMedical Research, Basel, Switzerland, [2]Novartis Institutes for BioMedical Research, Cambridge, MA, [3]Novartis Institutes for BioMedical Research, Tokyo, Japan, [4]Novartis Institues for BioMedical Research, Basel, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bruton's Tyrosine Kinase (BTK) is a cytoplasmic tyrosine kinase selectively expressed in B cells, macrophages, mast cells and basophils. The essential role of BTK in B cell antigen receptor and Fc receptor signaling is validated by human and mouse genetics, as well as by preclinical pharmacological intervention. BTK inhibition is expected to positively impact autoimmune diseases driven by autoreactive B cells and inflammatory immune-complexes, such as Sjoegren's Syndrome (SjS).

We report preclinical characteristics and selected clinical data of the highly selective BTK inhibitor LOU064 with a potential best in class profile for the therapy of SjS.

Methods: LOU064 was profiled in a series of *in vitro* assays for its effect on BTK dependent signaling, as well as in *in vivo* models for systemic B cell response and inflammation.

LOU064 was assessed in studies with healthy volunteers and asymptomatic atopic subjects. Single doses from 0.5 to 600 mg and multiple doses from 10 to 600 mg/day over 12 days were assessed with regard to safety, pharmacokinetics and pharmacodynamics.

Results: LOU064 potently inhibited *in vitro* BTK activity (IC50 range 0.6 to 1.3 nM) and showed excellent selectivity against 456 other kinases. At the cellular level, LOU064 showed potent inhibition of BTK dependent *in vitro* signaling in human blood B cells (IC50 18.3 nM) and basophils (IC50 66.5 nM), both clinically relevant target cells.

Consistent with covalent target binding, brief systemic LOU064 exposures were sufficient for full and sustained BTK occupancy and PD effects in several animal models. In an *in vivo* model for the inhibition of B cell dependent antibody formation in female rats LOU064 inhibited the IgM antibody response to sheep red blood cells by 96 % at a dose of 3 mg/kg. In the rat collagen induced arthritis model LOU064 induced fast and complete reduction of paw swelling and inhibited histological bone/cartilage erosion and inflammatory infiltrates at a dose of 3 mg/kg. The efficacy of LOU064 was dose proportional and correlated to BTK occupancy.

In healthy volunteer studies, oral LOU064 administration showed rapid absorption, with fast onset of action and sustained blood BTK occupancy starting from 30 mg. The *ex vivo* blood B cell activation marker CD69 was inhibited by 50% or more at doses of 30 mg and higher 24hrs post dose. All doses tested up to 600 mg daily for 12 days were

well tolerated, and no safety stopping criteria were met at any time. No SAEs or AEs leading to study discontinuation or dosing interruption occurred.

Conclusion: LOU064 is a novel covalent BTK inhibitor that showed excellent in vitro selectivity against relevant kinases and very high potency and efficacy in preclinical models of inflammation and B cell function with a very fast onset of action.

In healthy volunteers, LOU064 administration of single and repeated doses up to 600 mg were well tolerated. Short systemic exposure of LOU064 enabled full and sustained BTK occupancy and blood B cell inhibition.

These data make LOU064 a strong candidate for the treatment of chronic diseases driven by B cell autoimmunity and immune-complex mediated macrophage inflammation including SjS.

*** Average of left and right eye. NA = Not applicable.

Background/Purpose: Abatacept (CTLA-4-Ig) targets the CD80/CD86:CD28 co-stimulatory pathway required for full T-cell activation and T-cell dependent activation of B-cells. The Abatacept Sjögren Active Patients phase III (ASAPIII) trial assessed the efficacy and safety of treatment with subcutaneous abatacept in patients with early active primary Sjögren's syndrome (pSS). In the double blind phase, no difference was found in the primary endpoint, EULAR Sjögren's syndrome disease activity score (ESSDAI) after 24 weeks, but a higher number of patients receiving abatacept reached the minimal clinically important change in EULAR Sjögren Syndrome Patient Reported Index (ESSPRI). B-cell hyperactivity was decreased by abatacept. The aim of the current analysis is to evaluate efficacy and safety of extended treatment with abatacept after 48 weeks.

Methods: The ASAP-III study is a monocenter, investigator-initiated, double-blind, placebo-controlled trial with an open label extension phase (NCT02067910). ASAP-III included 80 adult patients with biopsy-proven pSS, fulfilling the AECG and ACR/EULAR criteria, with a disease duration of ≤7 years and moderate to high (ESSDAI ≥5).

After receiving weekly subcutaneous injections with abatacept (125 mg) or placebo for 24 weeks, all patients were treated with abatacept for another 24 weeks (figure 1). Concomitant use of other DMARDs including hydroxychloroquine was not permitted, with the exception of a stable dose of prednisone (≤10mg), and rescue therapy with prednisone or cyclophosphamide. At each visit (see figure 1), participants were evaluated by a multidisciplinary team of rheumatologists, ophthalmologists, and oral and maxillofacial surgeons. The primary endpoint was ESSDAI at 24 weeks. Secondary outcomes at 24 and 48 weeks included clinical, patient reported, functional, histological, laboratory, ultrasound, and microbiome parameters, and the occurrence of (serious) adverse events and treatment discontinuation.

Results: Patient characteristics at baseline and in week 24 are shown in table 1. Of 80 included patients, 78 were included in the extension phase. Two patients from the placebo arm were lost to follow up before week 24. Database lock for the extension phase is planned in September 2019. Subsequently, the first analyses of the week 24-48 results will be performed, focusing on ESSDAI, ESSPRI, quality of life (EQ-5D-5L), unstimulated and stimulated whole salivary flow (UWS, SWS), Schirmer's test, Ocular Staining Score (OSS), serological parameters (rheumatoid factor, IgG), and safety parameters.

Conclusion: The ASAP-III trial was designed to assess the clinical efficacy and safety of subcutaneous abatacept in pSS patients with short disease duration and active disease. Results of week 24-48, the open-label extension phase, are available at the ACR 2019 annual meeting.

Evaluation of Pharmacokinetics and Immunogenicity Following Subcutaneous Administration of Abatacept in Primary Sjogren 's Syndrome (pSS) and RA Patients

Yash Gandhi,[1] Mehmooda Shaikh,[2] Blisse Vakkalagadda,[1] Grigor Abelian,[1] Neelanjana Ray,[1] Robert Wong,[1] and Bindu Murthy[1], [1]Bristol-Myers Squibb, Princeton, [2]Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (ABA) has proven efficacy in autoimmune diseases and is being evaluated in pSS. The purpose of this investigation was to evaluate the pharmacokinetics (PK) and immunogenicity (IM) of subcutaneous (SC) ABA in pSS and RA patients.

Methods: One hundred eighty eight subjects diagnosed with active, moderate to severe pSS who meet the 2016 ACR/EULAR Classification Criteria for pSS and have a ESSDAI disease activity score of at least 5 at screening and are refractory to symptomatic or local therapy (e.g., NSAIDs) were randomized 1:1 to 125 mg SC weekly ABA (95

Table 1. Abatacept Cmin (GM [%CV]) in pSS and RA patients

Disease	Day 15	Day 29	Day 43	Day 57	Day 85	Day 113	Day 141	Day 169
RA	11.2 (44)	15.6 (48)	18.1 (47)	21.7 (47)	20.4 (41)	23.7 (52)		
pSS	15.0 (31.3)	21.4 (36.0)		22.4 (43.0)	27.5 (38.4)	25.5 (42.1)	25.8 (40.8)	24.5 (42.7)

subjects) or placebo (92 subjects) in a double-blind, 24-week, placebo-controlled study (NCT02915159, IM101603) [Ref. 1].

ABA trough (Cmin) samples were collected in all subjects during the treatment window of 365 days and semi-intensive PK samples were collected in a subset of subjects during the first 85 days. Serum ABA concentrations and anti-drug antibodies (ADA) were measured using a validated enzyme immunoassay method and an electrochemiluminescence assay, respectively.

Graphical analyses evaluated the PK profile and Cmin of ABA in pSS and compared to the ACCOMPANY study (IM101173) in RA patients [Ref. 2]. IM101173 was a 4-month open-label Phase 3b study to evaluate the immunogenicity and safety of SC ABA administered 125 mg weekly in the absence of an IV loading dose, when given as monotherapy versus with concomitant MTX, and to assess whether the use of concomitant MTX influenced the development of immunogenicity in RA patients with inadequate response to MTX.

Immunogenicity incidence rates were also summarized in the pSS and RA populations.

Results: Geometric mean (GM) Cmin values in pSS patients of > 15 μg/mL were achieved by Day 15 and remain greater than the threshold of 10 μg/mL that is associated with near maximal efficacy response established in RA patients across all body weights who receive the weekly 125 mg SC dosing (Table 1). ABA GM (%CV) Cmin values at steady state (Day 85) were comparable in pSS (27.5 [38.4%] μg/mL) and RA (20.4 [41%] μg/mL) patients.

During the 168-day blinded period, 1 (1.1%, n=90) subject with pSS had a positive antibody response specific to CTLA4 and possibly Ig relative to baseline while on-treatment. During the 4-month open label period, the overall immunogenicity rate was 4.1% (2/49) in RA subjects.

Conclusion: Subcutaneous administration of ABA 125 mg weekly in pSS achieved consistent target steady state trough concentrations to that observed in RA and shown to be efficacious in RA [Ref 3]. SC abatacept elicited minimal immunogenicity and was associated with no effect on PK or safety in either pSS or RA patients.

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: ALPN-101 is an Fc fusion protein of a human inducible T cell costimulator ligand (ICOSL) variant immunoglobulin domain (vIgD™) designed to inhibit simultaneously the CD28 and ICOS costimulatory pathways. CD28 and ICOS each play a role in T cell activation and adaptive immunity which can contribute to autoimmune disease when dysregulated. ALPN-101 has previously been shown to have potent immunosuppressive activity in various *in vitro* and *in vivo* models of disease, including acute graft versus host disease, inflammatory arthritis, and multiple sclerosis. We report here *in vitro* assays using PBMC from healthy donors vs. patients to analyze human T cell and B cell activation and suppression of antibodies and inflammatory mediators thought to contribute

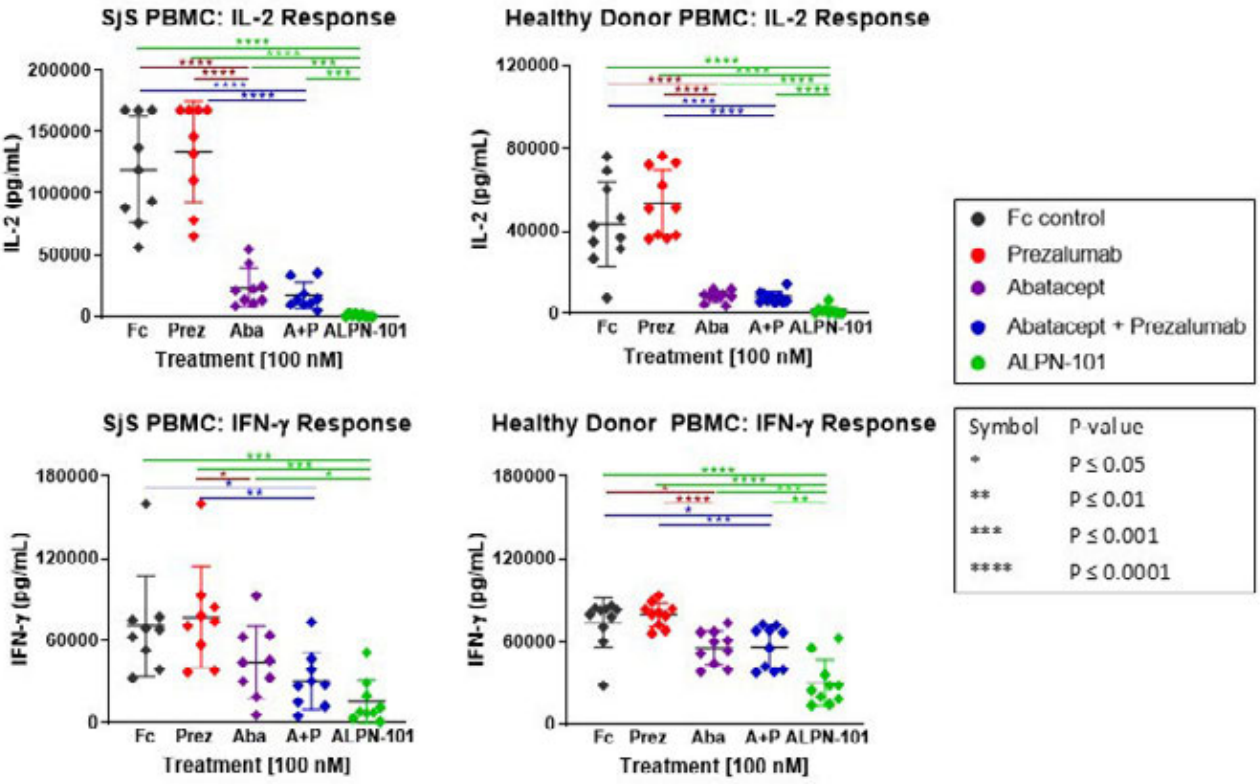

Figure 1: ALPN-101 Potently Inhibits T Cell Activation In Vitro in PBMC from Healthy Donors and Sjogren's Syndrome Patients. In vitro stimulation of healthy donor and Sjogren's syndrome (SjS) patient PBMC with artificial APC [fixed K562 expressing cell surface OKT3 (anti-CD3)/CD80/ CD86/ICOSL)] at a 20:1 ratio. Test articles were added at 100 nM and supernatants were collected and assayed for cytokine concentrations after a 48 hr incubation. ALPN-101 demonstrated statistically significant superiority to prezalumab, abatacept, or a combination of prezalumab+abatacept for the majority of donors and analytes tested.

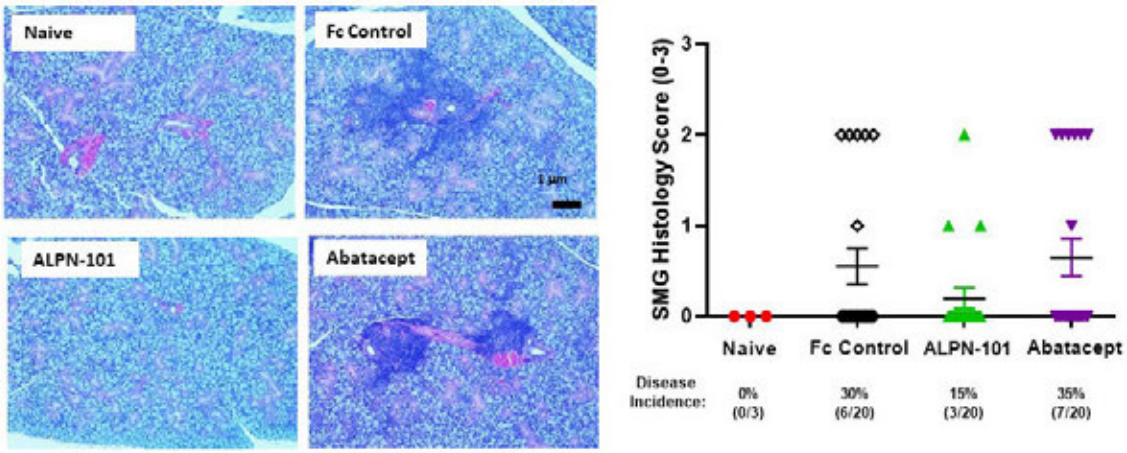

Figure 2: ALPN-101 Inhibits Sialadenitis in the NOD x Anti-PD-L1 Mouse Model of Sjogren's Syndrome. Six-week old female NOD/ShiLtJ mice were treated IP with a blocking anti-mouse PD-L1 antibody (to induce inflammation in the salivary glands, as described in Zhou et al., 2016, Sci. Rep. 6:39105) along with Fc control, abatacept, or ALPN-101 test articles on days 0, 2, 4, and 6. On Day 8, submandibular glands (SMG) were collected, sectioned, and stained with H&E and scored for inflammation on a scale of 0-3.

to the pathogenesis of Sjögren's syndrome (SjS) and other connective tissue diseases. Additionally, the efficacy of ALPN-101 was confirmed *in vivo* in mouse immunization models, and in a mouse model of SjS.

Methods: Primary cell assays were performed with healthy donor and SjS patient PBMC stimulated with K562 cells expressing CD80, CD86, ICOSL, and anti-CD3 (OKT3) to evaluate the potency of ALPN-101 to suppress cytokine production. The activity of dual pathway inhibition by ALPN-101 was compared to the CD28-only inhibitor abatacept (CTLA-4-Fc) and to the ICOS pathway inhibitor prezalumab (AMG-557; anti-ICOSL, Creative Biolabs). ALPN-101 was compared to abatacept *in vivo* in standard mouse immunization models (KLH, sheep RBC), and in a model of SjS involving anti-PD-L1 antibody-mediated acceleration of sialadenitis in NOD mice.

Results: Compared to abatacept, prezalumab, or combination abatacept + prezalumab, ALPN-101 demonstrated superior suppression of pro-inflammatory cytokine (i.e. TNF-α, IFN-γ, IL-1β, IL-2, IL-6, IL-17A, GM-CSF, etc.) release from stimulated healthy or SjS patient PBMCs (Fig. 1). ALPN-101 treatment inhibited antibody production *in vivo* in mouse immunization models, and suppressed proliferation and antibody production in human B cell/T cell co-cultures. In anti-PD-L1-treated NOD mice, ALPN-101 suppressed sialadenitis with activity superior to abatacept (Fig. 2); analyses of SjS-related autoantibodies are underway.

Conclusion: The efficacy of dual CD28/ICOS antagonist ALPN-101 is superior to CD28 or ICOS costimulatory pathway inhibitors, administered individually or in combination, in human *in vitro* and/or mouse *in vivo* translational studies. A Phase 1 clinical trial with ALPN-101 in healthy volunteers is underway, in preparation for future trials in multiple autoimmune diseases.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The interaction of inducible T cell costimulatory ligand (ICOSL) and the ICOS receptor is key in the pathogenesis of primary Sjögren's syndrome (pSS). MEDI5872 interferes with this pathway by binding to ICOSL. We evaluated the safety and efficacy of MEDI5872 in patients (pts) with pSS.

Methods: We conducted a Phase 2a, randomized, placebo (PBO)-controlled study (NCT02334306) in pts with active pSS (according to American-European Consensus Group criteria for pSS) and active disease defined by EULAR Sjögren's syndrome disease activity index (ESSDAI) ≥6 and markers of B-cell hyperactivity (target enrollment N=42). Pts were randomized (1:1) to MEDI5872 210 mg or PBO subcutaneously (SC) once weekly for 3 weeks, then every 2 weeks for 9 weeks. Beginning on Day 99, all pts received MEDI5872 210 mg for an additional 12 weeks "open-label period" (OLP). The primary endpoint was mean change in ESSDAI score from baseline to Day 99. Secondary endpoints at Day 99 included: proportion of ESSDAI responders (≥3 points decrease in ESSDAI, no discontinuation of investigational product and no use of prohibited medications); changes in ESS patient reported index (ESSPRI) score from baseline; and biomarker endpoints (including changes in plasma cells [PC] and T-follicular helper [Tfh] cells in the peripheral blood [PB] and minor salivary glands [MSG], and changes in MSG biopsy focus score). Duration of response was assessed during the OLP. P-values were not adjusted for multiplicity; P< 0.1 was considered statistically significant.

Results: Baseline characteristics were similar between the MEDI5872 (n=16) and PBO (n=16) arms (enrollment stopped early due to slow recruitment). Mean (SD) ESSDAI score was 11.8 (5.4) and 11.6 (4.5); and mean (SD) ESSPRI score was 6.5 (2.2) and 6.4 (1.8) for MEDI5872 and PBO, respectively. At Day 99 mean (SE) ESSDAI score decreased by 3.8 (0.9) and 2.3 (0.8) with MEDI5872 and PBO, respectively (adjusted mean difference (SE) of –1.4 (1.3), P=0.262). ESSDAI responder criteria were met by 7/16 and 4/16 patients in the MEDI5872 vs. PBO groups, respectively (P=0.458). Two patients in the PBO group had ≥3 points decrease in ESSDAI but were considered non-responders due to drop-out or use of prohibited medication. No other clinical efficacy measurement or PRO showed significant improvement at Day 99. No further improvement was noticed past Day 99 during the OLP.

On MSG biopsies at Day 99, CD4+/ICOS Tfh-like cells decreased from baseline with MEDI5872 and increased from baseline in the PBO group (geometric mean ratio to baseline (SE), MEDI5872 vs. PBO: 0.75 (0.18) vs. 1.76 (0.21), P=0.008). There was no difference in change from baseline in total PC or PD1/ICOS+ Tfh-like cells. No statistically significant differences were observed in PBPC and Tfh cell levels in the blood. IgA, IgG and IgM rheumatoid factor

(RF) levels decreased with MEDI5872 but not with PBO; the difference compared to PBO was statistically significant at Day 99. Adverse event rates were balanced: 11 pts (68.8%) with MEDI5872 vs. 14 pts (87.5%) with PBO experienced ≥1.

Conclusion: In patients with active pSS, despite decreasing the level of RF, MEDI5872 210 mg did not achieve consistent improvement of clinical or other biomarker measures of disease activity.

Tofacitinib Inhibits Increased Inflammatory Marker Expression in a Human Salivary Cell Line Deficient in Autophagy: A Model of Sjögren's Syndrome

María José Barrera,[1] **Sergio Aguilera**,[2] Patricia Carvajal,[3] Isabel Castro,[4] Sergio González,[5] Claudio Molina,[1] Soledad Matus,[6] Daniela Jara,[3] and María Julieta González[3], [1]Facultad de Odontología, Universidad San Sebastián, Santiago, Chile, [2]Clínica INDISA, Santiago, Chile, [3]ICBM, Facultad de Medicina, Universidad de Chile, Santiago, Chile, [4]Departamento Tecnología Médica, Universidad de Chile, Santiago, Chile, [5]Escuela de Odontología, Universidad Mayor, Santiago, Chile, [6]Fundación Ciencia & Vida, Santiago, Chile, Santiago, Chile

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an immune-mediated exocrinopathy, where defects in autophagy could contribute to the pathogenesis. Minor labial salivary glands (MLSG) of primary SS (pSS) patients show increased IL-6 levels, JAK/STAT activation and decreased expression of autophagy markers, such as ATG5 and Beclin-1. Additionally, autophagy activation has been related with a reduced inflammatory response, although this is a controversial topic. Interestingly, activation of the IL-6/JAK/STAT3 pathway inhibits autophagy through increased MCL-1 expression in human small airway epithelial cells[1]. The aim of this study was to determine inflammatory markers expression in autophagy-deficient salivary epithelial cells stimulated with or without IL-6. Finally, inflammatory markers expression relying on JAK/STAT signalling pathway was inhibited using tofacitinib.

Methods: Immortalized human submandibular gland (HSG) cell line were transduced with lentiviral ATG5 shRNA-expressing vector (*shATG5*), and with an empty lentiviral vector used as negative control. The protein levels of ATG5, p62 and LC3B were determined in shATG5 and control cells. The mRNA levels of IL-6, IL-1β, IL-8, MCL-1 and CCL2 were measured by qPCR in control and autophagy deficient HSG cells. Subsequently, 3D-acini were generated from shATG5 and control cells, incubated with 10 ng/mL recombinant IL-6 (with/without tofacitinib) for 24h to measure MCL-1 and IL-6 (both STAT3 target genes) mRNA levels by qPCR.

Results: Increased IL-6, IL-1β and IL-8 mRNA levels was observed in shATG5 cells compared to control cells. Upregulation of these mRNA was observed with IL-6 stimulation and reversed by tofacitinib. Moreover, p62 protein levels increased and LC3B decreased in shATG5 cells, confirming our previous findings in MLSG from pSS patients.

Interestingly, overexpression of mRNA levels of MCL-1, an autophagy inhibitor, was observed with IL-6 stimulation, but reversed in the presence of tofacitinib.

Conclusion: Our findings showed that decreased autophagy increases inflammatory markers expression in HSG cells. Tofacitinib inhibits the inflammatory effect of decreased autophagy, probably through the blocking of IL-6/JAK/STAT3 pathway, having a potential therapeutic effect in SS. More information is needed to establish the contribution of autophagy to SS pathogenesis and its role as a therapeutic target.

Abstract Number: 2419

An ex-vivo Assay to Evaluate the Efficacy of Different Treatments for Inhibiting B Lymphocytes Activation by Salivary Gland Epithelial Cells in Sjögren's Syndrome

Elodie Rivière,[1] Juliette Pascaud,[2] Audrey Paoletti,[3] Bineta Ly,[3] Gaetane Nocturne,[4] and Xavier Mariette[5], [1]IDMIT, CEA - Université Paris Sud - INSERM U1184, Le Kremlin Bicêtre ; Arthritis R&D, France, Paris, France, [2]IMVA - IDMIT, CEA - Université Paris Sud - INSERM U1184, Le Kremlin Bicêtre, Paris, France, [3]IDMIT, CEA - Université Paris Sud - INSERM U1184, Le Kremlin Bicêtre, Le Kremlin Bicetre, France, [4]Center for Immunology of Viral Infections and Autoimmune Diseases, Assistance Publique – Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, Université Paris Sud, INSERM, Paris, France., Paris, France, [5]Center for Immunology of Viral Infections and Autoimmune Diseases, Assistance Publique – Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, Université Paris Sud, INSERM, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is an auto-immune disorder characterized by a chronic hyperactivation of B lymphocytes. We previously showed that salivary gland epithelial cells (SGECs) could play a role in this B-cell activation (1). We developed a co-culture model of SGECs and B lymphocytes and showed that SGECs from pSS induced a higher survival and activation (when stimulated with Poly(I:C)) of B lymphocytes compared to SGECs from controls. The aims of this study were to identify the factors involved in the activation of B lymphocytes by pSS SGECs and to evaluate the efficacy of different treatments for inhibiting this interaction.

Methods: Patients with pSS according to 2016 EULAR/ACR criteria and controls were studied. Primary cultured SGECs from pSS and from controls were stimulated or not with Poly(I:C) and co-cultured with B lymphocytes sorted from healthy donors blood. Transwell assays were performed. Inhibition experiments with anti-BAFF antibody (belimumab) 10µg/mL, anti-JAK1/3 (tofacitinib) 50nM, anti-APRIL antibody 2µg/mL (kindly provided by P. Schneider) and anti-IL-6 receptor (tocilizumab) 50 µg/mL were performed. Survival and activation (CD38) of B lymphocytes were assessed by flow cytometry

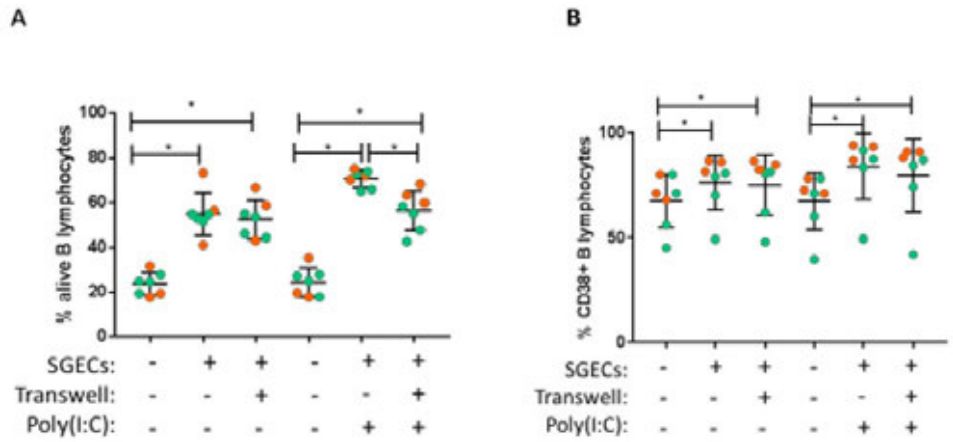

Figure 1: The increases of B lymphocytes viability and activation are mainly due to soluble factors. A: Percentage of alive B lymphocytes at day 5 with and without transwell, in presence or not of Poly(I:C) in co-culutures with SGECs from 3 pSS (in orange) and 4 controls (in green) B: Percentage of CD38+ B lymphocytes at day 5 with and without transwell, in presence or not of Poly(I:C).

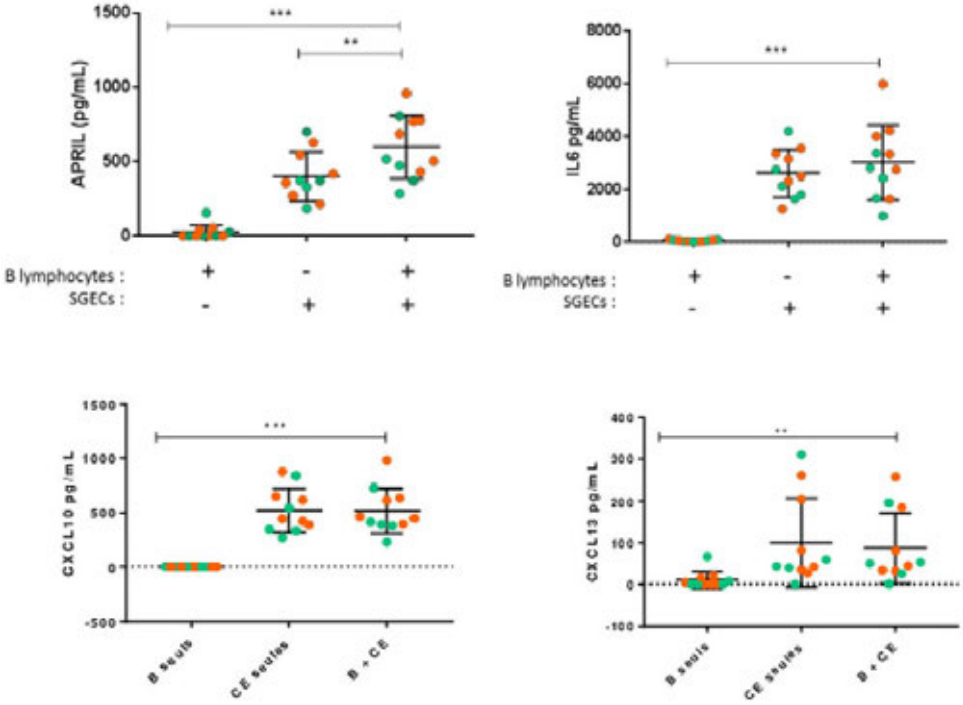

Figure 2: Assessment of soluble factors in the co-cultures supernatants from 6 pSS (in orange) and 5 controls (in green). Dosage of APRIL, IL-6, CXCL10 and CXCL13 in the supernatants of B lymphocytes cultured alone, SGECs cultured alone and B lymphocytes co-cultured with SGEC.

after 5 days of co-culture. Cytokines concentrations were assessed in supernatants (Luminex). Statistical analyses were performed with Prism using Mann-Whitney test (not paired data) and Wilcoxon (paired data) tests.

Results: The induction of B lymphocytes survival and activation was mostly dependent on soluble factors as assessed by transwell assays (Figure 1). Soluble factors were assessed in co-cultures supernatants. BAFF was detectable in co-cultures supernatants only with stimulation with poly(I:C), but adding belimumab to the co-culture did not inhibit the effect of SGECs on B lymphocytes survival and activation, even in the condition stimulated with Poly(I:C). SGECs were able to secrete APRIL and, interestingly, the co-culture of SGECs from pSS with B lymphocytes increased the secretion of APRIL by SGECs compared to SGECs cultured alone (Figure 2). However, inhibition

by an anti-APRIL antibody did not decrease survival of co-cultured B lymphocytes. IL-6 was secreted by SGECs in co-culture supernatants (Figure 2). However, addition of tocilizumab in the co-culture did not inhibit B lymphocytes survival and activation by SGECs. Similar results were obtained with tofacitinib. Lastly, chemokines such as CXCL10 and CXCL13 were also detected in SGECs supernatants (Figure 2).

Conclusion: Several soluble factors secreted by SGECs could play a role in the interactions between SGECs and B lymphocytes. However, targeting one by one the suspected cytokines did not allow identifying a single responsible factor suggesting that a combination of several factors could be required. In the context of the NECESSITY project, further inhibition experiments with the combination of leflunomide and hydroxychloroquine and with inhibitors of specific B-cell mediators as Btk and Pi3K are planned and will be presented at the congress.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a rare systemic autoimmune disease characterized by a dysregulation of cellular and humoral immunity, leading to a hyper-activation of B cells.

We looked if increase in T follicular helper cells (Tfh) (CD4+PD1+CXCR5+) or T peripheral helper (Tph) cells (CD4+PD1+CXCR5-), as well as cytokines involved in the cross-talk between T and B cells (CXCL-13, soluble CD40L (sCD40L)) could be involved in this B-cell activation.

Methods: We studied two cohorts of patients recruited in the Sjögren reference center of Paris-Sud university (23 controls/29 pSS and 14 controls/18 pSS, respectively). All patients had a diagnosis of pSS according to the ACR/EULAR 2016. Mass cytometry (CYTOF) and flow cytometry were used to quantify circulating cell populations. Cytokines were measured by MULTIPLEX.

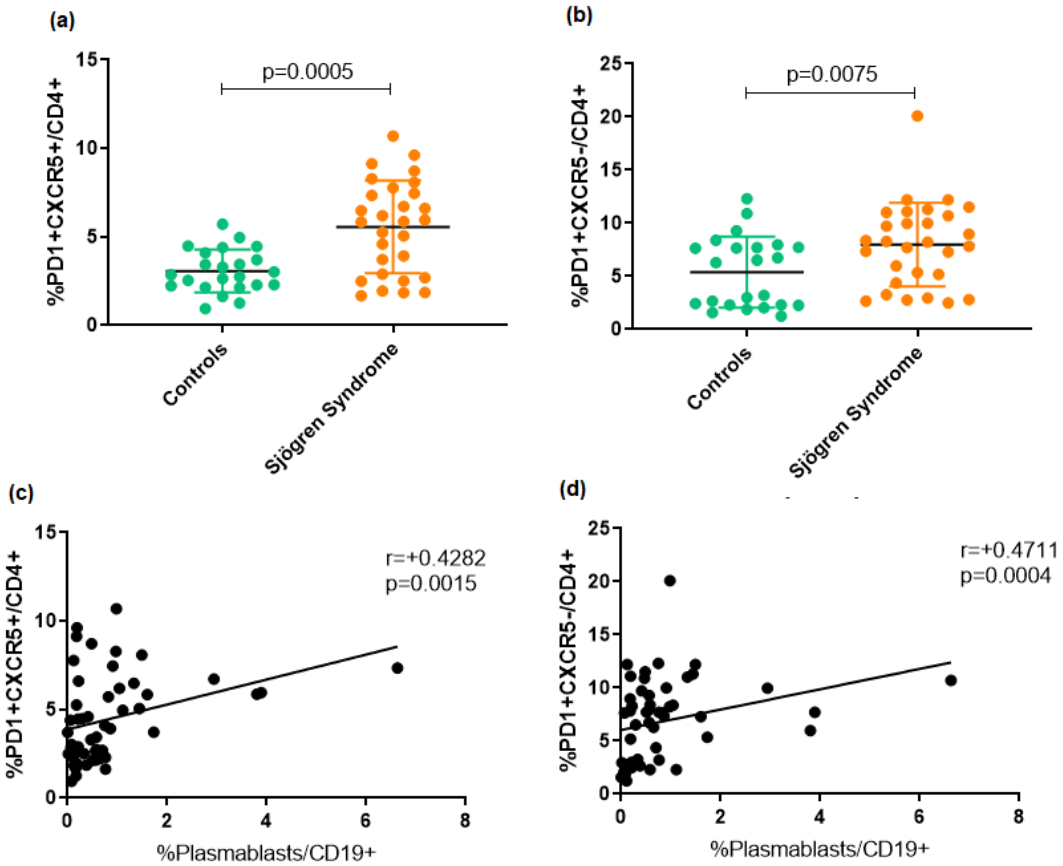

Figure 1: Expansion of circulating Tfh cells (a) and Tph cells (b) in patients with primary Sjögren Syndrome versus healthy controls, assessed by mass cytometry. Correlation between circulating Tfh and plasmablasts (c) and circulating Tph and plasmablasts (d).

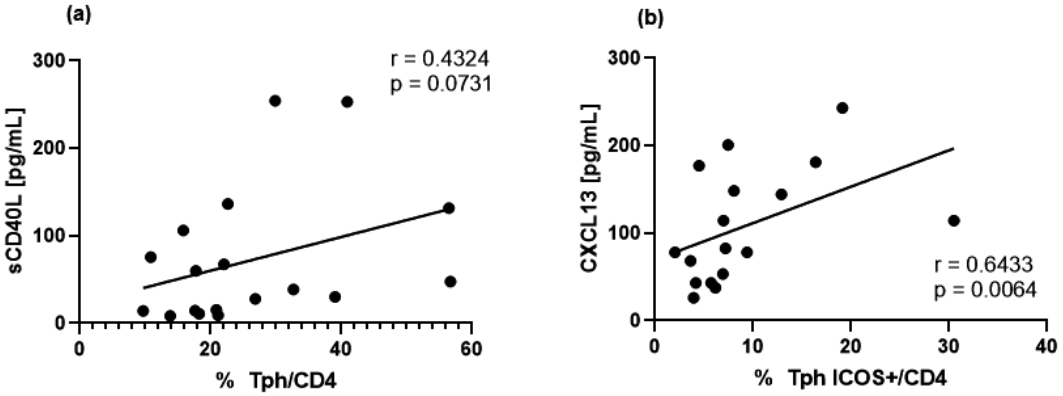

Figure 2: Correlation between plasmatic levels of sCD40L and circulating Tph (a) and between plasmatic levels of CXCL-13 and circulating Tph ICOS+ (b) in patients with primary Sjögren Syndrome.

Results: We showed a peripheral expansion of Tfh (CD4+PD1+CXCR5+) in patients with pSS compared to controls in flow cytometry and mass cytometry (CYTOF): 5.6 +/- 2.6% vs 3.1 +/- 1.2% (p=0.0005) and 10.2 +/- 5.8% vs 6.3 +/- 3.3% (p=0.0349), respectively. Similarly, patients with pSS had higher blood levels of Tph (CD4+PD1+CXCR5-) with both techniques: 8.0 +/- 4.0% vs 5.4 +/- 3.3% (p=0.0075) and 27.3 +/- 13.8% vs 14.9 +/- 9.3% (p=0.0045), respectively. Activated Tph assessed by ICOS expression (CD4+PD1+CXCR5-ICOS+) were also higher in pSS patients: 9.6 +/- 7.1% versus 4.4 +/- 3.3% (p=0.0037).

There was a positive correlation between plasmablasts (CD19+CD27+CD38hi) and Tfh levels (r=+0.43, p=0.0015) and Tph levels (r =+0.47, p=0.0004) in CYTOF.

Patients with pSS also had a trend in favor of a higher level of CXCL13 and soluble CD40L compared to controls: 148.8 +/- 186.2 pg / mL vs 130.5 +/- 207.2 pg / mL (p=0.0846) and 69.9 +/- 70.2 pg / mL mL vs 34.3 +/- 28.2 pg / mL (p=0.0802). There was a positive correlation between Tph and soluble CD40L (r=+0.43, p=0.07) and between activated Tph (CD4+PD1+CXCR5-ICOS+) and CXCL13 (r=+0.64, p< 0.05) in patients with pSS.

Conclusion: Circulating Tfh and Tph T-cell subsets play a role in the hyper-activation of B cells in pSS. Therefore, inhibition of Tfh/Tph function or of cytokines involved in their cross-talk with B cells (CXCL13, CD40L) seems promising therapeutic perspectives in pSS.

Abstract Number: 2421

Circulating CCR7^{lo}PD-1^{hi} Follicular Helper T Cells Indicate Disease Activity and Glandular Inflammation in Patients with Primary Sjögren's Syndrome

Ji-Won Kim,[1] Jaeseon Lee,[2] Ui Hong Jung,[1] Sung-Hoon Park,[1] Jennifer Lee,[3] Seung-Ki Kwok,[3] and Sung-Hwan Park[3], [1]Catholic University of Daegu School of Medicine, Daegu, Republic of Korea, [2]Catholic University of Korea, College of Medicine, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Since primary Sjögren's syndrome (pSS) is an autoummune disease of B cell hyperactivity and pathologic autoantibody response, follicular helper T (Tfh) cells and follicular regulatory T (Tfr) cells are suggested to be key players in pSS. We examined subsets of Tfh and Tfr cells from the blood in pSS patients, and whether these subsets represent disease activity, glandular inflammation, or autoantibody responses in pSS.

Methods: Circulating Tfh and Tfr cells, along with their specific subsets, were identified from the peripheral blood of 18 pSS patients and 14 age- and sex-matched healthy controls using flow cytometry analysis. Patients with pSS fulfilled the 2016 American College of Rheumatology/European League Against Rheumatism Classification Criteria for pSS. Serum interleukin (IL)-21 was measured using the enzyme-linked immunosorbent assay. We examined the correlation of blood Tfh and Tfr cells and their subsets with disease activity, blood B-cell subsets, serum autoantibody titers, serum immunoglobulin G (IgG) levels, and serum IL-21 levels in pSS.

Results: Blood Tfr and Tfh cell ratios were increased in pSS patients compared with healthy controls. The CCR7^{lo}PD-1^{hi} subset of circulating Tfh cells was increased in pSS patients with high degree of focal lymphocytic sialadenitis; whereas circulating Tfh cells did not differ between pSS patients and healthy controls. The frequency of CCR7^{lo}PD-1^{hi} Tfh cells was significantly correlated with disease activity scores (Spearman's rho = 0.552, p = 0.018) and differen-

tiated B cells. PD-1 expression on blood Tfh and Tfr cells showed positive correlations with IL-21 in pSS. Increasing trend of blood Tfr cells was observed in primary pSS patients, and blood Tfr cells (particularly Th1 and Th17 subsets) represented hypergammaglobulinemia in pSS.

Conclusion: Circulating $CCR7^{lo}PD\text{-}1^{hi}$ Tfh cells indicated disease activity and glandular inflammation in pSS. Circulating Tfr cells, shifted toward Th1 and Th17 subsets, indicated ongoing IgG production in pSS. Subsets of circulating Tfh or Tfr cells could be biomarkers for disease monitoring and patient stratification in pSS.

Abstract Number: 2422

Increased Apoptosis and Compromised Suppressive Capacity of Regulatory T Cells in Primary Sjögren's Syndrome

Min Feng,[1] Xiangcong Zhao,[1] and Jing Luo[1], [1]the second hospital of shanxi medical university, Taiyuan, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the apoptosis and suppressive function of regulatory T cells (Tregs) in primary Sjögren's syndrome (pSS), and the effect of low-dose IL-2 on apoptosis of Tregs.

Methods: Apoptosis of Tregs and effector T (Teff) cells were measured by staining with Annexin V and 7-amino-actinomycin D (7-AAD) in 54 female patients with pSS and 25 aged-matched female healthy controls (HCs) using flow cytometry. The function of Tregs was evaluated by the suppressive capacity to autologous $CD4^{+}CD25^{-}$ responder T (Tresp) cells expansion and was expressed as the proliferation of Tresp cells. The apoptosis degree of 13 pSS after the administration of low-dose IL-2 was also analyzed.

Results: Defect of number (P=0.030) and percentage (P=0.004) of Tregs was observed in pSS. Tregs was more sensitive to apoptosis than Teff cells, and apoptosis degree of Tregs was parallel to disease activity. Functional assay showed a compromised suppression for Tresp proliferation. The administration of low-dose IL-2 reduced the apoptitic rate of Tregs and Teff cells. Furthermore, serum concentrations of interleukin-6 (IL-6), IL-10, IL-17, interferon-γ (IFN-γ) and tumor necrosis factor-α (TNF-α) were positively associated with early apoptotic Tregs and Teff cells, but with late apoptotic Teff cells negatively. In addition, Cystatin C, α1 microglobulin and β2 microglobulin could contribute to the early apoptosis of Tregs (r=0.553, P=0.001; r=0.537, P=0.004; r=0.552, P=0.001) and Teff cells (r=0.534, P=0.001; r=0.560, P=0.002; r=0.401, P=0.019).

Conclusion: Aberrant increased apoptosis and impaired function of Tregs may partially contribute to the immune imbalance, leading to the onset of pSS. And multiple up-regulated cytokines, cystatin C, α1 microglobulin and β2

Table 1. Demographic and serological characteristics of patients and controls

Data are reported as mean±SD or median (Q_{25}, Q_{75}), and were analyzed by the independent-samples t test or the Mann-Whitney U test, respectively.

Abbreviation: WBC: white blood cell; RBC: red blood cell; Hb: hemoglobin; PLT: platelet; LYMP: lymphocyte; NEUT: neutrophile granulocyte; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; ALT: alanine aminotransferase; AST: aspartate aminotransferase; NK: natural killer; IL-2: interleukin-2; IL-4: interleukin-4; IL-6: interleukin-6; IL-10: interleukin-10; IL-17: interleukin-17; IFN-γ: interferon-γ; TNF-α: tumor necrosis factor-α

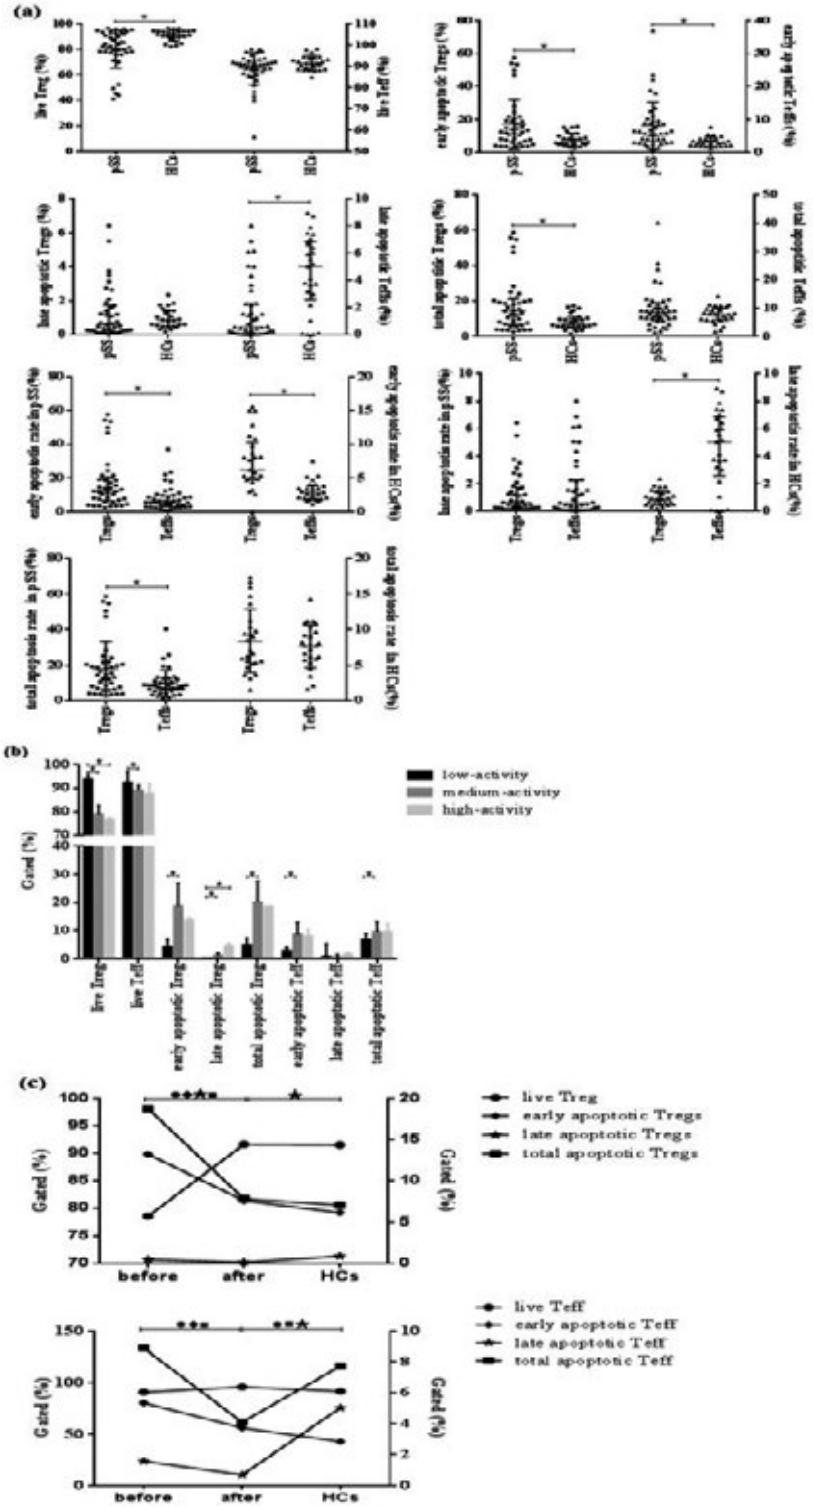

Figure 1: (a) Apoptosis of Tregs and effector T (Teff) cells in pSS and HCs. The left two scatter plots referred to the left Y-axis, and the right two scatter plots referred to the right Y-axis. Comparisons of live, early apoptotic, late apoptotic/necrotic, and total apoptotic Tregs and Teff cells between pSS and HCs. And comparisons of early apoptotic, late apoptotic, and total apoptotic Tregs and Teff cells in pSS and HCs, respectively. (b) Comparisons of rate of live, early apoptosis, late apoptotis, total apoptosis of Treg and Teff cells in low-activity (ESSDAI<5, n=22), medium-activity (5≤ESSDAI≤13, n=29) and high-activity (ESSDAI≥14, n=3) in pSS, respectively. (c) Apoptosis of Tregs and Teff cells in response to low-dose IL-2 administration in pSS was shown. Rate of live cells referred to the left Y-axis, and the proportions of early, late and total apoptotic cells referred to the right Y-axis.

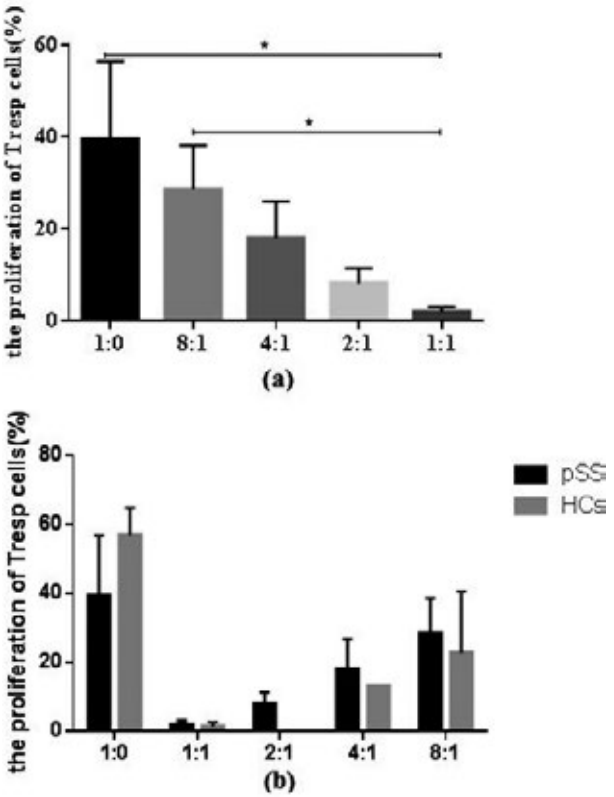

Figure 2. The suppressive function of Tregs for Tresp cells proliferation in different Tresp/Treg ratio (1:0, 1:1, 2:1, 4:1 and 8:1) was examined by flow cytometry. (a) Suppressive capacity of Tregs was in a Tresp/Treg ratio-dependent manner. Data were presented as median (Q25, Q75) and were analyzed by the Independent-samples Kruskal-Wallis test one-way ANOVA. (b) Suppressive capacity of Tregs and the proliferation of Tresp cells themselves were compromised in pSS compared with healthy controls (HCs). Data were presented as median (Q25, Q75) and were compared by Mann-Whitney U-test. *P<0.05.

microglobulin were responsible for the increased sensitivity to apoptosis of Tregs. Low-dose IL-2 could decrease the sensitivity to apoptosis of Tregs and alleviate disease activity.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: pSS is characterized by lymphocytic infiltration of salivary gland epithelial cells (SGEC). This infiltrate is made of T (TL) and B (BL) lymphocytes. SGEC are now known to be active players of the pathogenesis of the disease. Here we aimed to focus on the crosstalk between SGEC and TL in pSS and on the impact of IL7 on this process given the role of IL7 on TL biology.

Methods: IL-7 serum level was assessed in 372 pSS patients and 73 paired controls. Primary cultures of salivary gland epithelial cells (SGEC) from patients and controls were stimulated by Poly I:C 30 ng/ml, IFN-α 600UI/ml, IFN-γ 5ng/ml and IFN-λ (IL-28) 25ng/ml for 72 hours. IL-7 secretion was tested in culture supernatant (SN) by ELISA and by quantitative RT-PCR. Four-day and eight-day co-cultures (allogenic and then autologous) between LT and SGEC were performed in presence of Poly IC and anti-CD3/anti-CD28 and anti IL7-R (OSE-127, 10 µg/ml) or control isotype. TL survival and activation were assessed by FACS. Last, explants from minor salivary gland biopsies (MSGB) from 9 pSS patients and 3 controls were cultured for 4 days in presence of anti IL7-R (OSE-127, 10 µg/ml) or control isotype. Transcriptomic analysis from the biopsies (explants and cells in the SN) was studied by Nanostring (Immunology panel_v2).

Results: pSS patients had higher serum IL-7 levels than controls: 7.56 ng/ml ± 8.52 (mean ± SD) versus 4.86 ng/ml ± 5.59; p< 0.0001. SGEC stimulation with Poly I:C, IFN-α, -γ and -λ induced IL-7 protein secretion in the supernatant (p=0.002, p=0.004, p=0.007, p=0.004 respectively). IL-7 expression was confirmed by quantitative RT-PCR. Allogenic

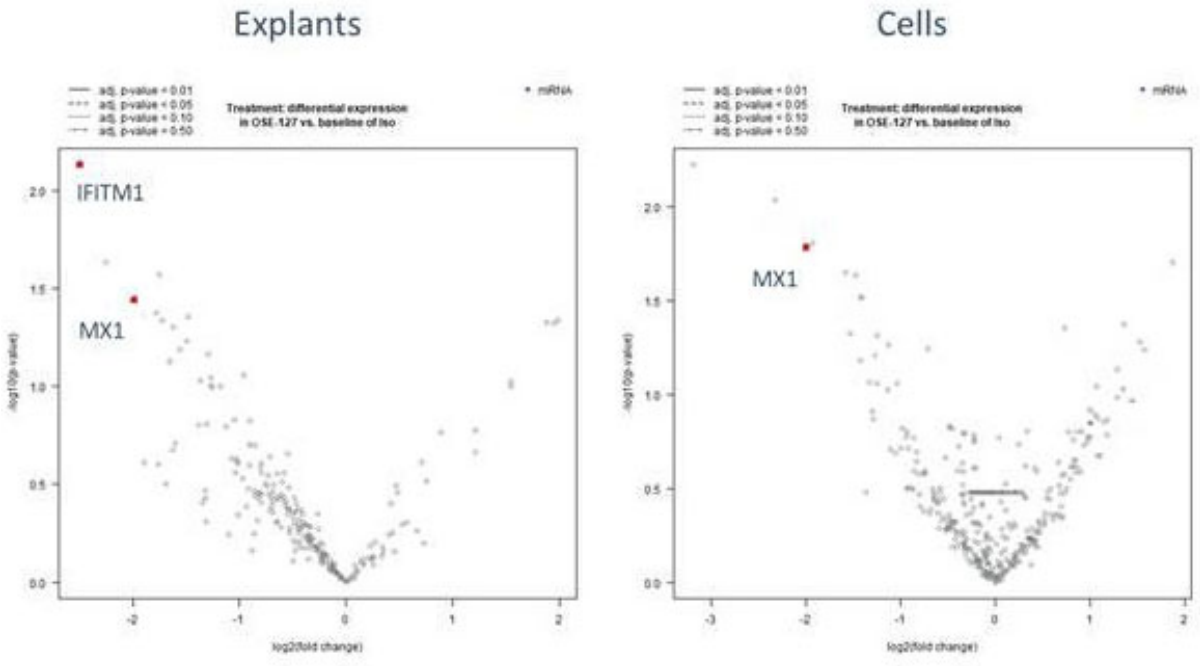

Figure: Volcano plots showing differential expression of the mRNA after exposure to OSE-127

co-culture lead to increased activation of TL as assessed by increased HLA-DR expression and this was partially inhibited by adding OSE-127 in the co-culture. This activation was not observed in autologous co-cultures. Co-cultures of SGECs with either allogenic or autologous TL showed that TL survival was increased by co-culture and this effect was not abolished by inhibiting IL7 signaling with OSE-127. Lastly, analysis of the mRNA signature from MSGB explants from pSS patients revealed that inhibition of IL7 signaling by OSE-127 lead to a decreased of IFN signature as assessed by decreased expression of IFITM1 and Mx-1 both in the explants and in the cells in the SN (Figure).

Conclusion: This study shows that IL7, a key TL cytokine, is increased in pSS and is locally produced by SGEC after PolyI:C and IFNs stimulation. SGEC are likely to have a feeder effect allowing survival of TL but it seems to be independent of IL7. However and interestingly, IL7 signaling may participate to the IFN signature observed in different glandular cellular sub-types in pSS, as demonstrated by decreased IFN signature after IL7-R inhibition both in the explant and in the cellular SN.

RORγt Antagonist Attenuates Experimental Sialadenitis Like Sjögren's Syndrome via Inhibition of CD25 Expression on $CD4^+$ T Cells

Yuko Ono,[1] Hiroto Tsuboi,[2] Masafumi Moriyama,[3] Hiroyuki Takahashi,[2] Fumika Honda,[2] Saori Abe,[2] Yuya Kondo,[2] Isao Matsumoto,[2] Seiji Nakamura,[4] and Takayuki Sumida[2], [1]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Science, Faculty of Dental Science, Kyushu University, Tsukuba, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [3]Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Science, Faculty of Dental Science, Kyusyu University, Fukuoka, Japan, [4]Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Science, Faculty of Dental Science, Kyusyu University, Fukuoka

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our previous study demonstrated that T cells specific RORγt transgenic-mice under human CD2 promoter (RORγt-Tg mice) developed severe spontaneous sialadenitis like Sjögren's syndrome (SS) in which RORγt overexpressed $CD4^+$T cells and reduced regulatory T cells (Tregs) contributed to the pathogenesis. The purpose of this study was to clarify the effectiveness and its mechanisms of RORγt antagonist (A213) for sialadenitis like SS in RORγt-Tg mice.

Methods: 1. *In vivo* **experiments**.

6 weeks aged RORγt-Tg mice were administered orally 300 mg/kg of A213 or phosphate buffered saline (PBS) every three days for two weeks. We compared 1) saliva volume, 2) histopathology of salivary glands, 3) proportion of $CD4^+CD25^+$T cells in spleen and cervical lymph nodes (cLNs), 4) percentages of $CD4^+CD25^+Foxp3^+$ and $CD4^+CD25^{+-}$ $Foxp3^-$cells in $CD4^+$T cells of cLNs, and 5) the protein expression levels of CD69 on $CD4^+CD25^+Foxp3^+$ and $CD4^+CD25^{+-}$ $Foxp3^-$cells, between A213 and PBS treated groups.

2. *In vitro* **experiments.**

Splenic $CD4^+$T cells derived from RORγt-Tg mice were cultured with different concentrations of A213 (0, 0.01, 0.1, 1 μM) *in vitro*, and we investigated 1) the expression of CD25 on $CD4^+$T cells, 2) the production of IL-2 from $CD4^+$T cells, and 3) the proportion of IL-$17^+IFN\gamma^-$, IL-$17^-IFN\gamma^+$, and IL-$17^+IFN\gamma^+$ cells in $CD4^+CD25^+$T cells.

Results: 1. *In vivo* **experiments.**

1) A213 significantly recovered the salivary secretion in RORγt-Tg mice compared with PBS (changes in saliva volume at day 14; 1.3±0.3 in PBS group, 3.1±1.4 in A213 group, $P< 0.05$). 2) Infiltration of mononuclear cells in salivary glands was dramatically improved in A213- compared with PBS-treated group. The focus score at day 14 was significantly lower in A213- than in PBS-treated group (2.5±0.6 in PBS-treated group, 0.3±0.3 in A213 treated-group, $P< 0.05$). 3) The proportion of $CD4^+CD25^+$cells in $CD4^+$T cells of spleen was comparable between A213-and PBS-treated group. On the other hand, the proportion of $CD4^+CD25^+$cells in $CD4^+$T cells of cLNs was significantly lower in A213- than PBS- treated group ($P=0.007$). 4) The proportions of both $CD4^+CD25^+Foxp3^+$ and $CD4^+CD25^+Foxp3^-$cells in $CD4^+$T cells of cLNs were significantly decreased in A213- than PBS-treated group ($P< 0.05$). 5) The mean fluorescence intensity (MFI) of CD69 on $CD4^+CD25^+Foxp3^-$cells in cLNs was significantly lower in A213- than PBS-treated group ($P< 0.05$), while no significant difference was detected in CD69 on $CD4^+CD25^+Foxp3^+$cells.

2. *In vitro* **experiments..**

1) A213 (0, 0.01, 0.1, 1 μM) significantly suppressed the expression of CD25 on $CD4^+$T cells derived from RORγt-Tg mice in a dose dependent manner. 2) A high concentration of A213 (1 μM) significantly suppressed the IL-2 production from $CD4^+$T cells derived from RORγt-Tg mice. 3) $IFN\gamma^-$IL-17^+cells were significantly decreased by A213 (0.1, 1 μM), while $IFN\gamma^+$IL-17^- and $IFN\gamma^+$IL-17^+cells were significantly decreased by only a high concentration of A213 (1 μM) in $CD4^+CD25^+$cells ($P< 0.001$).

Conclusion: RORγt antagonist could suppress the sialadenitis like SS via inhibition of $CD4^+CD25^+$cells in cLNs and have potential to be a new promising therapy for SS patients.

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren syndrome (SjS) is an autoimmune disorder characterized by inflammation and destruction of exocrine glands. The presence of autoantibodies (AA) against the Ro52/TRIM21, an RNP complex binding to the stem-loop structure of human cytoplasmic RNA, might be relevant in the SjS pathogeny. It has been suggested that distinguishing between antibody reactivity against Ro60 and Ro52/TRIM21 could be helpful in terms of evaluating clinical course, features and even pre-symptomatic stages of the disease. Objective: To evaluate the prevalence of anti-Ro52/TRIM21 antibodies in a cohort of patients diagnosed with primary SjS.

Methods: In this cross-sectional study we evaluated 179 patients with primary SjS according to the ACR classification criteria who had been admitted between December 2008 and December 2018 to our outpatient clinic. All patients had ANA titers higher than 1:320 in at least two positive determinations for any pattern. ANA, anti-Ro52/TRIM21, anti-Ro60, anti-La and rheumatoid factor (RF) were tested by immunoblot (Euroimmun, Lübeck, Germany).

Results: In our cohort the median age at diagnosis was 57 years (range: 20- 85 years) with a clear dominance of females (n=160, 89%). the most frequently reported ANA patterns were speckled (93%), while only few patients had a homogeneous (6%) pattern. 177/179 were positive for anti-Ro52/TRIM21 (98%), 159/179 (88%) for anti-Ro60, 127/179 for anti-La (79%) and 94/179 (52%) showed RF reactivity. 76/179 (42%) patients showed all four reactivities (anti-Ro52/TRIM21, anti-Ro60, anti-La and RF). Out of these 76 patients, 11 (6%) patients exhibited Raynaud's syndrome, 25 (13%) exhibited arthritis/arthralgia, 31 (17%) had hypergammaglobulinemia, 13 (7%) had hypocomplementemia and 26% had elevated free kappa/lambda chains, as typical clinical and laboratory features described in SjS.

Conclusion: Our results showed that anti-Ro52/TRIM21 but not anti-Ro60 is present in virtually all patients with SjS and had the most prevalent antibody reactivity. This finding needs to be considered in the current classification criteria of SjS (2), which include the presence of anti-Ro60, rather than anti-Ro52/TRIM21. Also, including the anti-Ro52/TRIM21 measurement in larger cohorts and longitudinal studies would also help us in improving the knowledge of its pathogenic role and to define of more focused diagnostic/therapeutic strategies.

Clinical features of 355 enrolled patients with primary Sjogren's syndrome

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate clinical characteristics of patients with primary Sjögren's syndrome (SS) who were negative for anti-Ro/SSA antibody but positive for minor salivary gland biopsy (MSGB) compared to patients who presented positivity for anti-Ro/SSA antibody.

	Total, n=354	Anti-Ro positive group, n=325	Anti-Ro negative group, n=29	P value

C4 (mg/dl)	22 (18-26)	22 (18-26)	22 (18-26)	0.956
Anti-La/SSB antibody positivity	186/354 (52.5)	186/325 (57.2)	0 (0)	<0.001
Anti-centromere antibody positivity	38/302 (12.6)	23/274 (8.4)	15/28 (53.6)	<0.001
Anti-topoisomerase antibody positivity	5/282 (1.8)	3/255 (1.2)	2/27 (7.4)	0.074
Anti-ribonucleoprotein antibody positivity	6/207 (2.9)	6/189 (3.2)	0 (0)	>0.999
Anti-Jo-1 antibody positivity	3/295 (1.0)	2/267 (0.7)	1/28 (3.6)	0.259
Anti-DNA antibody positivity	10/315 (3.2)	10/287 (3.5)	0 (0)	0.609

Serological features

Methods: Data of 355 patients from the Korean Initiative of primary Sjögren's Syndrome (KISS), a nationwide prospective cohort for primary SS in Korea, were analyzed. All patients fulfilled 2016 American College of Rheumatology/European League Against Rheumatism (EULAR) classification criteria. Of these patients, 326 were positive for anti-Ro/SSA antibody and 29 were antibody-negative, although they had positive findings in MSGB. Various clinical features including all kinds of tests for evaluating secretory function, disease-related clinical indices and serological values available in the cohort were compared between the two groups.

Results: The anti-Ro/SSA negative group showed less rheumatoid factor positivity ($p < 0.001$), leucopenia ($p = 0.003$), hypergammaglobulinemia ($p < 0.001$), lower serum β_2-microglobulin level ($p = 0.034$), more anti-centromere antibody positivity ($p < 0.001$), higher score in dryness domain of EULAR SS patient reported index ($p = 0.048$) and more positivity for peripheral nervous system domain in EULAR SS disease activity index and loss of teeth in SS disease damage index ($p = 0.021$ and 0.041, respectively) than patients who were positive for anti-Ro/SSA antibody.

Conclusion: Primary SS patients who are negative for anti-Ro/SSA antibody have different clinical characteristics compared to patients who are positive for such antibody in Korea. Therefore, clinicians should consider MSGB in patients with suspicious symptoms who are anti-Ro/SSA negative.

Serological features

Background/Purpose: To clarify clinical features of primary Sjogren's syndrome (SS) patients who show the positivity for anti-centromere antibody in Korea.

Methods: We assessed 318 patients who met 2016 American College of Rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for primary SS. All patients were selected from the Korean Initiative of Primary Sjogren Syndrome (KISS), a prospective cohort. Among them, 53 patients were positive for anti-centromere antibody, while other 265 patients were not. We compared two groups in various clinical data including demographic features, extraglandular manifestations, clinical indices and laboratory values available from KISS database.

Results: The anti-centromere-positive SS group showed higher median age ($p = 0.042$), xerostomia inventory scores ($p = 0.040$), anti-nuclear antibody and anti-topoisomerase antibody positivity ($p < 0.001$, $p = 0.006$, respectively), more frequent Raynaud's phenomenon and liver involvement ($p < 0.001$, $p = 0.002$, respectively). On the other hand, less frequency of leukopenia ($p = 0.021$), rheumatoid factor and anti-Ro/SSA antibody positivity ($p < 0.001$, both), and hypergammaglobulinemia ($p = 0.006$) were observed in this SS group.

Conclusion: Distinguishing clinical features were discerned in primary SS patients with the positivity for anti-centromere antibody compared to patients without the antibody. This primary SS subset should be investigated further in future studies.

Serum Myositis Specific/associate Autoantibodies Help Identify Early Connective Tissue Diseases Relevant Interstitial Lung Diseases: A Medical Center Experience

Chieh-Yu Cheng,[1] Wei-Han Ju,[1] Tony Szu-Hsien Lee,[2] En Chao,[1] Hsiang-Cheng Chen,[1] Feng-Cheng Liu,[1] Deh-Ming Chang,[3] and CHUN-CHI LU[4], [1]Tri-Service General Hospital, Taipei city, Taiwan (Republic of China), [2]National Taiwan Normal University, Taipei city, Taiwan (Republic of China), [3]Taipei Veteran General Hospital, Taipei city, Taiwan (Republic of China), [4]University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung diseases (ILD), a heterogeneous group of pulmonary disorders, originated from idiopathic causes or secondary to certain etiologies, such as infectious diseases, drugs, or connective tissue diseases (CTD). Common causes of CTD associated ILD (CTD-ILD) include rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), systemic sclerosis (SSc), polymyositis (PM), dermatomyositis (DM), and Sjogren's syndrome (SS). Specific autoantibodies in autoimmune rheumatic diseases (ARD) are clinically useful biomarkers associated with a particular disease and/or clinical manifestations. Myositis-specific autoantibodies (MSAs) and myositis associate autoantibodies (MAAs) have been applied for the diagnosis of PM/DM. MSAs were defined as autoantibodies relatively specific for PM/DM, while MAA could not only be identified in PM/DM but also could be noticed in other autoimmune rheumatic diseases. Some MSAs and MAAs have been detected in patients with ILD and PM/DM simultaneously or idiopathic ILD patients. However, the prevalence of MSAs and MAAs in CTD-ILD is lacking.

Purpose: This study aimed to define the prevalence of MSAs and MAAs in patients with clinical symptoms of ILD in the presence of a particular autoimmune rheumatic disease and to identify the correlation between the presence of MSA/MAAs and ARD specific autoantibodies (autoAb).

MAA				
Antibody	PM100	PM75	Ku	Ro52
Positive rate	3.22%	2.90%	4.35%	33.01%
MSA				
Antibody	oJ	EJ	PL-12	PL-7
Positive rate	0.16%	0.48%	1.45%	1.13%
Antibody	SRP	Jo-1	SAE1	NXP2
Positive rate	2.25%	3.38%	0.64%	1.29%
Antibody	MDA5	TIF1g	Mi-2b	Mi-2a
Positive rate	0.97%	1.45%	3.54%	0.64%

The prevalence of MSA and MAA in patients with CTD-ILD

ILD	ALL(n=58)	Percentage
MSA positivity		
Jo-1	11	18.97%
Mi-2	5	8.62%
SRP	2	3.45%
PL-7	0	0.00%
PL-12	3	5.17%
EJ	1	1.72%
OJ	0	0.00%
MDA5	3	5.17%
MAA positivity		
SSA/Ro-52	42	72.41%
Ku	1	1.72%
PM/Scl75	1	1.72%
PM/Scl100	4	6.90%
Disease positivity		
Polymyositis	12	20.68%
Dermatomyositis	12	20.68%
Sjogren's syndrome	38	65.51%
RA	6	10.34%
SLE	6	10.34%
Systemic sclerosis	1	1.72%

Sjogren's syndrome is the most common cause of CTD-ILD in the cohort.

Methods: 413 subjects who had been diagnosed with at least one of autoimmune rheumatic diseases, including RA, SLE, PM, DM, and SS were included in this prospective study at a single medical center between February 2018 and October 2018. All enrolled patients had experienced clinical evidences of pulmonary diseases and were suspicious of ILD, such as exertional dyspnea or abnormalities on the chest plain film. Serological immunotherapy strips were performed to detect MSA/MAAs. These patients received imaging examinations as well. Correlation analysis was performed among the different collected variables.

Results: The diagnosis of CTD-ILD were confirmed in 58 of 413 patients. The prevalence of MSAs and MAAs were 16.4% and 39.9%, respectively. The most frequently found autoantibody was anti-Ro-52 (33%), followed by anti-Ku (4.35%), anti-Mi-2 (4.1%) , anti-Jo-1 (3.38%), anti-PM/Scl100 (3.22%), anti-PM/Scl75 (2.9%), anti-SRP (2.3%), and anti-PL-12 (1.5%)(Table 1).

To our surprise, SS is the most common disease in these patients with CTD-ILD, followed by PM/DM. MSA/MAAs were identified in patients withRA and SLE relevant ILD (Table 2). Anti-SAE1 and anti-Ku autoAb are positively correlated with anti-RNP autoAb (Phi = 0.323 and 0.246, p = 0.012 and 0.045, respectively). Anti-MDA5 autoAb seems to be possibly associated with anti-La autoAb (p = 0.08)

Conclusion: Our data indicates that MSA/MAAs could be able to detected in CTD-ILD in addition to PM/DM-ILD. The diagnostic criteria of CTD-ILD is unavailable except patients have obvious clinical evidences and imaigings' manifestations. Define how the presence of serum MSA/MAAs are relevant to CTD-ILD could help contribute to early diagnosis and prevent poor prognosis and is warranted in the future.

Zipcode-Binding Protein 1 (ZBP1) Facilitates Ro60 Surface Translocation, Cellular Growth and Autoimmune Sequelae

Francis DiDonato,[1] Jill Buyon,[1] and Robert Clancy[1], [1]NYU School of Medicine, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the strong association of maternal anti-Ro60 autoantibodies in the development of SS, Neonatal Lupus (NL) and scLE, understanding causality is challenging given that the intracellular location of the target RNP antigen only becomes accessible to extracellular autoantibodies during cell death. While binding Y RNA is a property of Ro60 in dying cells, Ro60 contributes to events essential to proliferation including the degradation of non-coding RNAs. To define potentially targetable molecular events associated with Ro60 accessibility and their effects on proliferation, we evaluated two candidate chaperone Ro60 binding proteins, ZBP1 (also known as IGF2BP1, which has two RNA recognition domains and plays a role in nuclear export of protein) and PTBP1 (which binds RNA in heterogeneous nuclear complexes).

Methods: Short hairpin (sh)RNA knockdown (KD) of both ZPB1 and PTBP1 was accomplished by using MISSION pLKO.1 derived lentiviral vehicles for targeted shRNA to yield each of the specific depletions in human fetal fibroblasts. Affinity purified anti-Ro60 antibodies (AP60) isolated from the serum of 2 mothers of children with cardiac NL and control IgG isolated from a healthy donor were used to evaluate Ro60 surface translocation in intact and apoptotic cells by flow cytometry. Fibroblast proliferation was determined using 5-ethynyl-2′-deoxyuridine (EdU) incorporation.

Results: KD of targeted transcripts were confirmed by qPCR and western blot. Permeabilized KD and wildtype fibroblasts demonstrated equivalent intracellular expression of Ro60. As expected, flow cytometry with AP60 revealed no surface staining of non-permeabilized wildtype or KD fibroblasts. The next set of experiments addressed binding of AP60 to polyHEMA-apoptotic fibroblasts. Staining with annexin V (a proxy of apoptosis) was uniformly consistent between the wildtype and KD cells. As expected, compared to non-apoptotic fibroblasts, AP60 but not control donor IgG readily bound the surface of wildtype apoptotic fibroblasts, supporting that Ro60 was indeed translocated during apoptosis (MFI of 97 $\pm$ 5 vs 211 $\pm$ 14, respectively; $P < 0.05$; N=3). In contrast, binding of AP60 was significantly attenuated in the ZPB1 KD fibroblasts (81.5 $\pm$ 7; N = 3) vs anti-Ro binding of apoptotic wildtype fibroblasts

(P< 0.05). However, the binding of AP60 was equivalent in the apoptotic PTBP1 KD fibroblasts (MFI of 203 $\pm$ 6, N= 3, P=NS) compared to apoptotic wildtype fibroblasts. With regard to cell proliferation, the percent positive EdU cells of wildtype fetal fibroblasts, ZBP1 KD fibroblasts, and PTBP1 KD fibroblasts were 56%, 2% and 45%, respectively, a result suggesting that the loss of ZBP1 restrains cell cycle progression.

Conclusion: ZBP1 represents a novel and required chaperone for the translocation of Ro60 to the cell surface during apoptosis in addition to contributing to cell proliferation. Given that Ro60 antigen accessibility is essential, not only to the generation of anti-Ro60 responses but also to the formation of surface immune complexes and subsequent tissue injury, ZBP1 may represent a newly targetable candidate to forestall both the initiation and sequelae of auto-immunity.

Detection and Clinical Significance of Circulating M3 Muscarinic Acetylcholine Receptor Reactive Th17 Cells in Patients with Primary Sjögren's Syndrome

Saori Abe,[1] Hiroto Tsuboi,[1] Yuko Ono,[2] Fumika Honda,[1] Mizuki Yagishita,[1] Izumi Kurata,[1] Ayako Ohyama,[1] Hiroyuki Takahashi,[1] Yuya Kondo,[1] Isao Matsumoto,[1] and Takayuki Sumida[1], [1]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Section of Oral and Maxillofacial Oncology, Division of Maxillofacial Diagnostic and Surgical Science, Faculty of Dental Science, Kyushu University, Tsukuba, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SS) is an autoimmune disease which is characterized by lymphocytic infiltration including $CD4^+$ IL-17 producing helper T (Th17) cells to the lacrimal and salivary glands. We previously detected anti-M3 muscarinic acetylcholine receptor (M3R) antibodies and M3R reactive $CD4^+$ IFNγ producing helper T (Th1) cells in patients with SS. Moreover, we clarified that M3R reactive Th1 and Th17 cells had pathogenic roles in the development of auto-immune sialadenitis in SS mice model. The purpose of this study was to identify circulating M3R reactive Th17 cells, those T cell epitopes, and the relationship between these cells and clinical features in patients with primary SS (pSS).

Methods: 1. Peripheral blood mononuclear cells (PBMCs) were isolated from 10 pSS patients and age-gender matched 10 healthy controls (HCs). According to their HLA-DRB1 typing, top 10 ranked 20 mer peptides from the full length of M3R, which were highly predicted to bind to each HLA molecules by using the immune epitope database website, were selected for each case. PBMCs were stimulated with these selected M3R peptides mixture for 40 hours, and M3R reactive IL-17 producing cells were detected by IL-17 enzyme-linked immunospot assay (ELISpot).

2. Clinical features were compared between M3R reactive IL-17 producing cells positive and negative pSS patients.

3. PBMCs from 5 pSS patients positive for M3R reactive IL-17 producing cells, were stimulated with each selected 12-20 mer M3R peptide separately, to identify the dominant M3R peptides responsible for IL-17 secretion.

4. To confirm that detected IL-17 producing cells were Th17 cells, peripheral $CD4^+$ T cells from 3 pSS patients positive for M3R reactive IL-17 producing cells, were co-cultured with dendritic cells (DCs) generated from peripheral $CD14^+$ monocytes in each case, and stimulated with the dominant M3R peptides identified in Methods 3.

Results: 1. 5 of 10 (50%) pSS patients, while none of 10 (0%) HCs, showed significantly increased IL-17 positive spots against selected M3R peptides mixture stimulation compared with non-stimulation in ELISpot. M3R reactive IL-17 producing cells were detected significantly more frequently in pSS than in HCs (p=0.03).

2. 5 pSS patients positive for M3R reactive IL-17 producing cells had significantly higher ESSDAI score than 5 negative pSS patients (8.4±4.8 vs 2.0±0.0, p=0.031).

3. In all 5 pSS patients positive for M3R reactive IL-17 producing cells described in Results 1, IL-17 was produced against M3R AA76-95 stimulation, showing that the sequence might be the dominant M3R peptide responsible for IL-17 secretion.

4. Co-cultured $CD4^+$ T cells with DCs under stimulation with the dominant M3R peptide identified in Results 3, showed significantly increased IL-17 positive spots than non-stimulation, clarifying that M3R reactive Th17 cells were detected.

Conclusion: We detected circulating M3R reactive Th17 cells in pSS patients using ELISpot for the first time. Moreover, T cell epitope of these cells was shown to be M3R AA76-95 in all M3R reactive Th17 cells positive pSS patients. Interestingly, M3R reactive Th17 cells might associate with higher ESSDAI score.

Extracellular Vesicles in Primary Sjögren's Syndrome: A Promising Source for Novel Proteomic Biomarkers

Chiara Baldini,[1] Francesco Finamore,[2] Francesco Ferro,[1] Silvia Rocchiccioli,[2] Marta Mosca,[3] Letizia Mattii,[4] and Antonella Cecchettini[4], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy, [2]National Research Council – Clinical Institute of Physiology, PISA, Italy, [3]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [4]University of Pisa, Pisa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a complex autoimmune disorder characterized by the specific involvement of salivary and lachrymal glands. In the recent past several attempts have been made by using a

proteomic approach to identify valid biomarkers for pSS in whole saliva. Extracellular vesicle (EVs) include exosomes, microvesicles and apoptotic body. Little is known about the potential advantages of EVs proteomics compared to the overall traditional concept of analyzing the proteome of whole saliva nor to what extent their content may reflect the phenotypic state of pSS. In this study, we used a sequential window acquisition of all the theoretical fragment ion spectra (SWATH-MS) approach to monitor the dynamics of saliva EVs sub-proteome of pSS patients compared to healthy controls (HC)

Methods: We included patients with a diagnosis of pSS made according to the AECG 2002 criteria and healthy volunteers as controls. Saliva was collected under standardized conditions. EVs were enriched by sequential ultra-centrifugation steps from saliva samples. Peptide identification and quantitation was performed using a SWATH-MS approach using an assay spectral library for peptide matching. Protein-protein interaction network and pathway analysis were carried out to figure out the most representative biological paths in pSS.

Results: We enrolled 26 pSS patients (AECG 2002 criteria) and 13 healthy subjects. Quantitative data showed a distinct separation between pSS group and HC group, indicating that pSS may influence the phenotype of protein cargoes of salivary EVs. The majority of the differentially expressed proteins were found to be up-regulated in EVs pSS compared to controls. A highly interconnected sub-network of protein involved in several inflammatory processes was generated. Among several inflammatory pathways found in this study, a particular emphasis was given to proteins belonging to IL-12 signaling such as annexin A2, macrophage migration inhibitory factor (MIF), S100A8-A9 and plastin-2 proteins.

Conclusion: Our results highlight the key role of EVs S100 proteins and MIF as putative biomarkers for salivary gland dysfunction in pSS suggesting that the inflammatory phenotype observed in pSS whole saliva is also extended to salivary EVs.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Thymic stromal lymphopoietin (TSLP) has been implicated in primary Sjögren's syndrome (pSS) and related B-cell lymphoproliferation / lymphoma (NHL) by tissue studies on salivary glands (SG). It resulted significantly higher in the serum of pSS patients compared to non-pSS sicca and to healthy subjects, with the highest levels in NHL-pSS. The purpose of this work was to confirm that serum TSLP is elevated in pSS by the study of independent cohorts.

Methods: Serum TSLP levels were measured by ELISA in 91 pSS patients (F=86, 94.5%; mean age 57.2 years, 25-80) from the original cohort (cohort 1) of Udine (UD), Italy. In this study, one additional multicentre cohort (cohort 2) from the Italian SS Study Group (GRISS) was studied, including 125 pSS patients from the Universities of Roma (RO), L'Aquila (L'AQ), Pisa (PI) and Perugia (PG). pSS patients with active NHL (n=12 in cohort 1; n=1 in cohort 2) were excluded from comparative analyses to avoid bias. Secondly, additional serum samples from pSS-related NHL in stable and complete remission, from both cohort 1 and 2, were analysed in a separate subgroup (n = 12). Thirdly, a preliminary evaluation of serum TSLP was performed in pSS patients from a different geographical area (University of Athens, Greece; cohort 3).

Results: Cohort 2 included 125 pSS patients (F=114, 91.2%; mean age 58.1 years, 23-84): 124 benign, 1 with NHL. In this cohort, serum TSLP levels were confirmed to be high (mean 30.26 pg/mL, 0.41-95.21) and comparable to cohort 1 (mean 33.81 pg/mL, 0-140.8; p=ns). No difference was found by the separate analysis of pSS from single Centres between each other (RO n=49, mean 33.21, 1.4-95.21; L'AQ n=34, mean 38.6, 16.31-85.11; PI n=28, mean 20.23, 0.41-56.67; PG n=13, mean 19.39, 1.03-68.38; p=ns), and vs cohort 1 (p=ns). The only patient in cohort 2 with NHL showed serum TSLP of 160.91 pg/mL, comparable to the mean TSLP in the 12 UD pSS with NHL (151.96 pg/mL). Importantly, in pSS-related NHL in stable remission, serum TSLP resulted undetectable (7/13) or detectable at very low levels (6/13) (mean 10.46, 0-38.5), and significantly lower than in benign pSS patients from the two cohorts (n=203, mean 31.48, 0-140.8; p=0.0022). Metachronous samples from one patient, at the stage of NHL activity and then at NHL remission, showed a decrease in TSLP from 128.04 pg/mL to undetectable levels. Finally, TSLP levels were increased also in the Greek cohort (mean 54.9, 26.72-78.95), and significantly higher than the two Italian cohorts (p=0.0085 and p< 0.0001, vs cohort 1 and 2, respectively).

Conclusion: Serum TSLP levels are increased in pSS, as herein confirmed in independent cohorts. TSLP might be important in the disease pathophysiology, and mirrors the course of pSS-related B-cell lymphoproliferation. It may represent a novel important biomarker.

Abstract Number: 2433

Fatigue in Primary Sjögren's Syndrome as a Manifestation of Heavier Disease Activity of Mucosa-Associated Lymphoid Tissue (MALT)

Saviana Gandolfo,[1] Marco Binutti,[1] Elena Doriguzzi Breatta,[1] Cinzia Fabro,[1] and Salvatore De Vita[1], [1]Rheumatology Clinic, Udine University Hospital, Department of Medical Area, University of Udine, Udine, Italy, Udine, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is one of the most prevalent and impacting symptoms in primary Sjögren's syndrome (pSS), significantly impairing the patient quality of life. To date, even though available measures of fatigue and other patient-reported symptoms (PROs) poorly correlate with pSS disease activity assessed by ESSDAI, therapeutic interventions reducing the burden of pSS disease activity showed utility in improving fatigue in pSS. The purpose of this study was to investigate if fatigue correlates to pSS features reflecting disease activity, by evaluating if a) higher fatigue severity is associated with a heavier involvement of mucosa-associated lymphoid tissue (MALT) in salivary gland (SG) as documented by histopathology or by the clinical presence of SG swelling, and b) if fatigue correlates to other pSS-related somatic symptoms, such as dryness and arthralgias.

Methods: 86 consecutive unselected pSS patients, fulfilling the latest ACR/EULAR pSS classification criteria, reported their degree of fatigue, general dryness, ocular dryness, oral dryness and pain on 10-cm VAS (range 0-100), and completed ESSPRI (range 0-10), PROFAD-SSI-SF (range 0-28) and EQ-5D-scale (0-100) questionnaires. Four subgroups of fatigue severity were studied (1): no fatigue (VAS=0): 12.8% (n=11); low fatigue (VAS=1-24): 25.3% (n=19); moderate fatigue (VAS=25-74): 58.7% (n=44); high fatigue (VAS=75-100): 16% (n=12). As previously reported (1), no significant difference between the four subgroups was observed in age, sex and prevalence of potential contributors to fatigue, such as autoimmune thyroiditis, anemia and fibromyalgia. Frequencies of peculiar pSS manifestations related to a heavier activity of MALT, at any time in the clinical history of patients, such as SG swelling, and a biopsy-proven myoepithelial sialadenitis (MESA) or pSS-related MALT lymphoma, were evaluated for each subgroup. Correlations between VAS fatigue and other PROs were finally performed.

Results: pSS patients with moderate or high fatigue VAS showed significantly higher frequencies of SG swelling ($p=0.0274$), and of MESA or lymphoma histological diagnosis ($p=0.0397$) compared to pSS patients with no or low levels of fatigue. VAS fatigue scores did not correlate with ESSDAI. Patients with higher levels of fatigue showed significant ($p< 0.0001$) higher scores in total ESSPRI, dryness-ESSPRI, pain-ESSPRI, ocular dryness VAS, oral dryness VAS, pain VAS, somatic fatigue domain of PROFAD, arthralgia domain of PROFAD, total SSI and PROFAD-SSI-SF, and reported worst scores in quality of life EQ-5D-scale.

Conclusion: Fatigue severity in pSS appears to mirror the degree of MALT involvement, which is the biological substrate of pSS itself where key pathogenetic events take place. A better definition of the immunobiological basis of pSS fatigue, starting from the study of the MALT, is therefore crucial to identify novel target therapies to treat fatigue, besides symptomatic agents. Since fatigue may also correlate with pSS somatic symptoms, such as dryness and arthralgia, the development of dedicated pSS scoring tools integrating both disease activity, in the MALT perspective, and PROs is definitely worthwhile.

Risk of Lymphoma and Thyroid Cancer in Primary Sjögren's Syndrome Measured Using the Korean Health Insurance Claims Database

Joong Kyong Ahn,[1] **Jiwon Hwang**,[2] and Gi Hyeon Seo[3], [1]Division of Rheumatology, Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon-si, Republic of Korea, [3]Health Insurance Review and Assessment Service, Wonju, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The development of lymphomas is one of the most serious complications of SjS but the incidence, prevalence and estimated risk of lymphoma in primary SjS vary significantly worldwide. Meanwhile, studies from Taiwan and Spain, the estimated risk of thyroid cancer appears slightly increased in primary SjS compared with previous results. Although primary SjS is a very rare disease and many cases are required to determine the exact risk of malignancy in this condition, most epidemiological studies of primary SjS have been limited to a small number of cases such as case-control studies, leading to low-quality evidence. A large sample size with a significant number of cases is therefore required to analyse the risk of lymphoma and thyroid cancer in primary SjS. The aim of this study was to evaluate the incidence and risk of lymphoma and thyroid cancer in patients with primary Sjögren's syndrome (SjS) employing a large-scale assessment based on the Korean National Health Insurance Service (NHIS) claims database.

Methods: Primary SjS was identified using the Korean NHIS medical claims database between 2007 and 2017. The case definition required more than one visit based on the Sjögren's syndrome diagnostic code and the registration system for rare and incurable diseases. A 3-year washout period was applied in our study to exclude patients who were diagnosed before their information was entered into the national rare and incurable disease database. The presence of a connective tissue disease before the SjS diagnosis and within one year after the SjS diagnosis was ruled out in order to recruit primary SjS only. We included all admissions with a primary diagnosis of lymphoma and thyroid cancer.

Incidence and SIR and 95% CI for lymphoma and thyroid cancer in patients with primary Sjogren's syndrome

Results: The primary SjS incidence was 1.88 cases/100,000 inhabitants. Female patients had a higher incidence than male patients, with a female-to-male ratio of 7.65:1. For primary SjS, the standardised incidence ratios for lymphoma and thyroid cancer were 4.66 (95% confidence interval [CI] 2.69–7.55) and 1.23 (95% CI 0.88–1.68), respectively. The lymphoma risk was 4.66-fold higher among the patients with primary SjS than in the general population. Compared with the general population, female patients with primary SjS had a 5.32-fold higher risk of developing lymphoma, while the male patients did not. Patients with primary SjS did not have a higher risk of developing thyroid cancer.

Conclusion: Primary SjS is associated with a higher risk of developing lymphoma. The lymphoma risk appears to have decreased compared with that in previous studies. Our study suggests that the risk of lymphoma or thyroid cancer with SjS is not higher than that reported in previous studies.

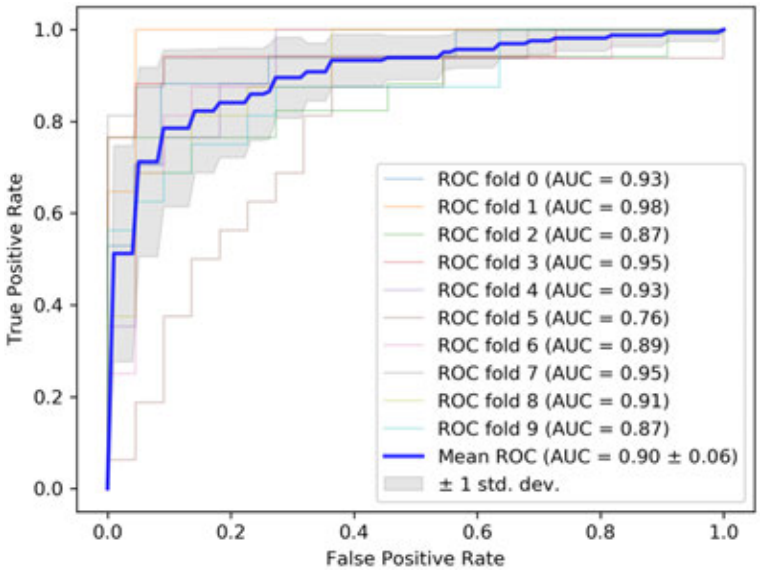
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

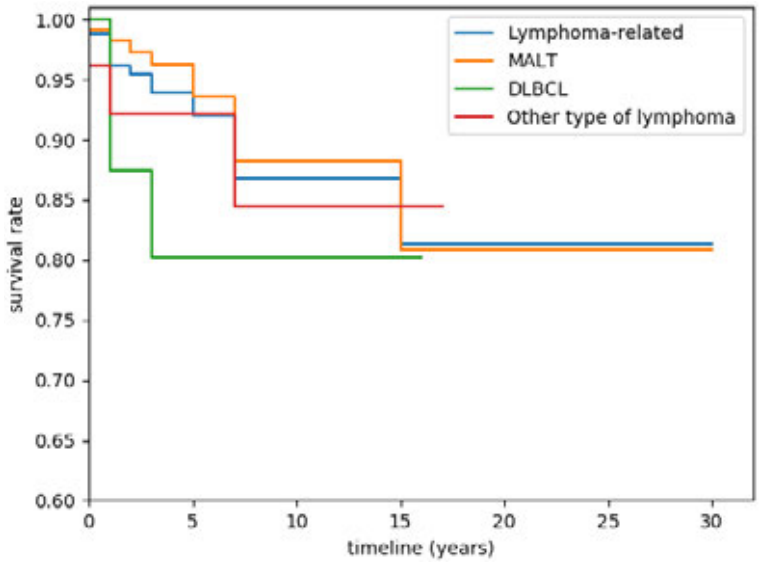
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-Hodgkin's lymphomas (NHLs) may complicate primary Sjögren's syndrome (pSS) with significant impact on morbidity and mortality among patients. A large cohort of SS associated lymphoma patients was constructed from 3 specializing (pSS) centers [Udine, Athens, Piza-(UPA]) aiming to a) identify predictors of lymphoma by applying innovative data driven analysis tools b) estimate outcome and survival curves of SS associated lymphoma patients.

Methods: One hundred and sixty-two patients with SS associated lymphomas who fulfilled the 2016 ACR/EULAR were included in the study. Clinical, histological and laboratory data were collected. For lymphoma prediction, a robust decision-making machine learning algorithm was applied on the harmonized dataset using the Extreme Gradient Boosting (XGBoost) framework. Weak decision tree ensembles were combined through the gradient boosting optimization approach which reduces the prediction errors yielding a high-performance supervised learning model for predicting binary lymphoma outcomes in pSS. Two hundred and seventy-eight SS patients without lymphoma were recruited as controls for the prediction model matched according to age, gender and SS disease suration. A conventional 10-fold cross validation approach was then applied on the harmonized dataset to evaluate the sensitivity, specificity, and accuracy of the robust classifier. Kaplan-Meir survival curves



The ROC curve depicting the performance of the proposed lymphoma prediction model.



Kaplan-Meier curves for overall survival (OS) of SS HNLs patients and SS NHL histologic subgroups

for the total lymphoma population as well as for patients with mucosal associated lymphoid tissue lymphomas (MALTL), diffuse large B cell lymphomas (DLBCL) and other lymphoma types were generated. Lymphoma features were compared between Greek and Italian SS lymphoma patients including gender, age at lymphoma diagnosis, time from SS to lymphoma diagnosis, time from SS onset to lymphoma diagnosis, lymphoma follow up time and histologic lymphoma subtypes.

Results: No differences were found among the main lymphoma features mentioned above between Greek and Italian SS associated lymphoma patients. The median age at lymphoma diagnosis, time from SS diagnosis to lymphoma and lymphoma follow up time of the total population was 58 years old (range: 25-82), 4 years (range: -5, 30) and 6 years (range: 0, 30) respectively. Preliminary data analysis, revealed parotid gland enlargement >2months, neutrophils count at diagnosis, palpable purpura due to cryoglobulinemia, salivary or lachrymal gland enlargement at SS onset and hypergammaglobulinemia as main contributors of the most prominent decision tree pathways, with average area under the curve (AUC) =0.90, sensitivity=0.76, accuracy=0.83, and precision=0.84 (Figure 1). The estimated 10-year overall survival rates (OS) were 87% for the total population, 88,2% for patients with MALTL and 80% for DLBCL group (Figure 2).

Conclusion: To our knowledge, this is the largest pSS associated lymphomacohort. Preliminary harmonized pooling data, after applying novel bioinformatics tools, confirmed classical features as lymphoma predictors, pointing out the dynamic perspective of the proposed lymphoma prediction model. In addition, SS patients with NHLs display a favorable prognosis, especially those with MALTL.

The Salivary Glands as the Key Site of Inflammation and Lymphoproliferation Leading to Lymphoma in Primary Sjögren's Syndrome: Relevance for Dedicated Scoring, Biomarker Development and Lymphoma Prevention

Salvatore De Vita,[1] Saviana Gandolfo,[1] Chiara Baldini,[2] Miriam Isola,[3] Michael Voulgarelis,[4] Andreas Goules,[4] Ginevra De Marchi,[5] Marco Binutti,[1] Sara Zandonella Callegher,[5] Francesco Ferro,[2] Claudio Battistella,[3] Loukas Chatzis,[4] and Athanasios Tzioufas[4], [1]Rheumatology Clinic, Udine University Hospital, Department of Medical Area, University of Udine, Udine, Italy, Udine, Italy, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy, [3]Department of Medical Area, University of Udine, Udine, Italy, Udine, Italy, [4]Department of Pathophysiology, Athens School of Medicine, National and Kapodistrian University of Athens, Athens, Greece, Athens, Greece, [5]Rheumatology Clinic, Udine University Hospital, Udine, Italy, Udine, Italy

Session Date: Tuesday, November 12, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Since the risk of B-cell non-Hodgkin's lymphoma (NHL) evolution is increased in primary Sjögren's syndrome (pSS), its prevention represents a relevant therapeutic end-point. A crucial preliminary step to this end is to determine the key site of inflammation and lymphoproliferation in pSS patients developing NHL.

We investigated the involvement of salivary gland (SG) mucosa-associated lymphoid tissue (MALT) in the development of NHL in pSS, based on: a) the history of major SG swelling (SGSW); b) the presence of geminal centres (GCs) in antedating salivary biopsies; and c) NHL localization itself, in particular salivary or lachrymal. The site of lymphoproliferation may be as relevant as the type of B-cells, given the role of microenvironment in B-cell expansion.

Methods: 165 cases pSS-related NHLs from the UPA Study Group (Udine, Pisa, Athens; 30, 27 and 108 cases respectively) were studied, with matched pSS controls with no lymphoma evolution. The history of SG and lachrymal swelling was evaluated in detail (both at pSS onset and in the follow-up before NHL development, episodical < or >2 months of duration, and chronic) together with the presence of GCs in SG biopsies well before NHL development, the different sites of NHL localization at its onset (salivary, lachrymal, gastric, lung, kidney, breast, skin, bone marrow, lymph nodes, spleen, others), and the NHL histotype.

Results: 165 pSS-related NHLs were studied (149 females: 90.3%; mean age: 56.3 years, range 25-82; mean time to NHL from pSS diagnosis: 5.8 years). Controls were 114, matched for sex, age and disease duration. By stepwise multivariate analyses, association with NHL was found for SGSW lasting > 2 months during follow-up (OR 16.41, 95%CI 5.97-45.08; p< 0.001) and SGSW at onset (OR 3.30, 95%CI 1.28-8.48; p< 0.013). In cases without SGSW at pSS onset, NHL evolution was higher only if SG swelling > 2 months occurred later (OR 114.29, 95%CI 14.05-929.80; p< 0.001). The SGs were then considered as the key site of inflammation and proliferation in pSS-related NHL if: 1) a history of SGSW (as above associated with NHL) was present, and/or 2) GCs were detectable in SG biopsy before NHL, and/or 3) NHL was indeed localized in the SG (n=105) or lachrymal glands (n=6) at its onset. 1 and/or 2 and/or 3 was detected in 85.4% of NHLs (140/165; 80,7% in Italy and 87.8% in Greece). Of note, this occurred more frequently than any lymphoma histotype (MALT NHL being, in any case, the largely most frequent histotype: 74.1%). No differences were noticed between the cohorts.

Conclusion: The SGs proved to be a key and early site of inflammation and lymphoproliferation in pSS-related lymphomagenesis, and the study of pSS-related NHL localization allowed a better understanding of the pathogenetic events implicated. NHL later develops in the SGs themselves or in other sites where MALT is accumulated, highlighting again the role of the local microenvironment. The SG MALT therefore represents a target to develop dedicated activity scoring and novel biomarker tools in pSS. Furthermore, a decrease in the amount and quality of SG MALT is a possible surrogate target for lymphoma prevention therapies in pSS, where long-term studies are poorly feasible.

Autoantibodies from Sjögren's Syndrome Enhance NLRP3 Inflammasome Activation and IL-18 Production in Human Salivary Gland Cell Line A-253

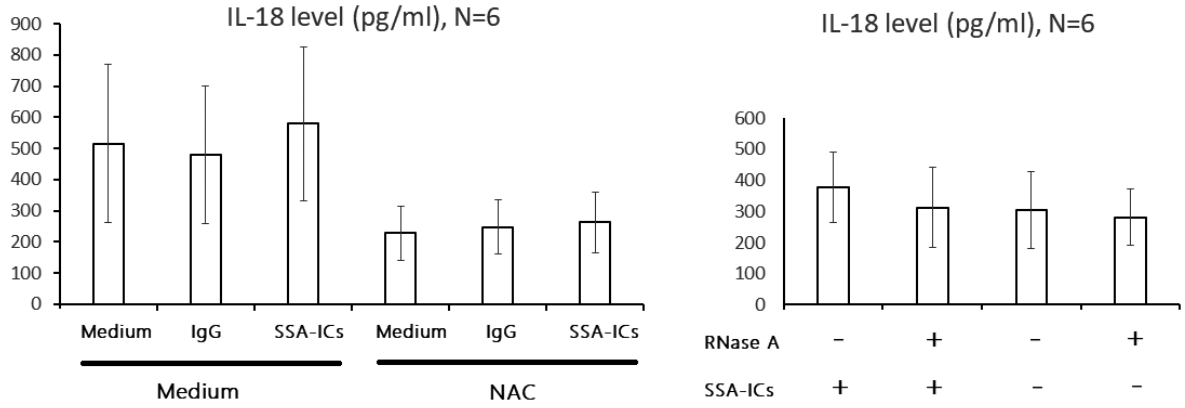
Cheng-Han Wu,[1] Ko Jen Li,[2] Chia-Li Yu,[3] and Song-Chou Hsieh[3], [1]Graduate Institute of Clinical Medicine, National Taiwan University College of Medicine, Taipei, Taiwan, Taipei, Taiwan (Republic of China), [2]National Taiwan University Hospital, Taipei, Taiwan (Republic of China), [3]Division of Immunology,Rheumatology and Allergy, Department of Internal Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan, Taipei, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

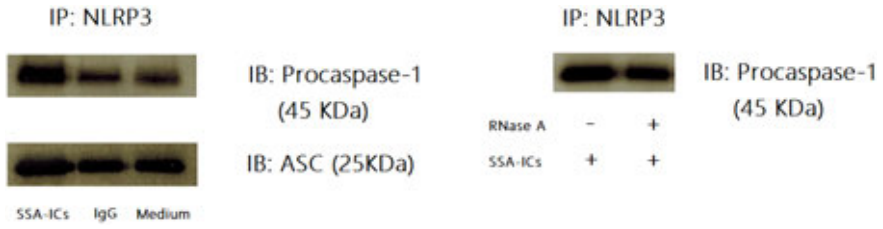
Background/Purpose: Primary Sjögren's syndrome (SS) is a chronic autoimmune epithelitis characterized by the presence of autoantibodies against SS-related antigen A (SSA) and lymphocytic infiltration of exocrine glands. The underlying mechanisms in the initiation and perpetuation of SS remain to be fully elucidated. Recently, the NOD-, LRR- and pyrin domain-containing protein 3 (NLRP3) inflammasome and pro-inflammatory cytokine Interleukin-18 (IL-18) have been implicated in the pathogenesis of SS. IL-18 serum concentrations were significantly higher in anti-SSA+ than in anti-SSA- SS patients and titers of anti-SSA antibodies were closely related with IL-18 protein levels. We hypothesized that immune complexes (ICs) containing anti-SSA antibodies (anti-SSA ICs) would lead to NLRP3 inflammasome activation and eventually to IL-18 production in an experimental model represented by the human salivary gland cell line A-253.

Methods: A-253 cells from human epidermoid carcinoma of the submaxillary gland were cultured. ICs were generated by incubation of cell culture supernatants (which contained released SSA autoantigens) with human anti-SSA antibody (OriGene Technologies, MD, USA), control human IgG and culture medium respectively for 1 hour and were stored at -80°C until used. A-253 cells were subjected to different stimulations for 4 hours. NLRP3, ASC, procaspase1 and IL-18 protein expression were measured by western blot and supernatant IL-18 level by enzyme-linked immunosorbent assay. Anti-SSA antibody and control human IgG were used at a final concentration of 80 ug/ml in all experiments. Results are presented as the mean ± S.D. The Student's t-test was used for comparisons between two groups.

Results: A253 cells spontaneously released IL-18 and supernatant levels of IL-18 were significantly increased after stimulation with anti-SSA ICs, compared with control human IgG (p=0.021). Reactive oxygen species (ROS) scav-



Effect of NAC and RNase A digestion of supernatants on anti-SSA ICs induced IL-18 production in A-253 cells.



Activation of the NLRP3 inflammasome by ICs containing anti-SSA antibodies.

engers, N-acetyl cysteine (NAC, 10mM), significantly decreased the secretion of IL-18 in each group ($p < 0.05$). More importantly, in the presence of NAC (10mM), anti-SSA ICs failed to induce IL-18 production from A-253 cells (p=0.19, compared to medium control). NLRP3 blockade by NAC were confirmed as NAC (25mM) treatment resulted in a marked decrease in the protein expression of the NLRP3 inflammasome and almost completely abolished the production of IL-18 from A-253 cells. Immunoprecipitation of NLRP3 was used to demonstrate that anti-SSA ICs potentiated coprecipitation of ASC and procaspase-1 proteins in A-253 cells. Furthermore, ICs containing anti-SSA antibodies and RNase A-digested cell culture supernatants (RNase A 100 ug/ml, incubation of 2 hours, for the removal of RNA from supernatants) decreased the amount of coprecipitated procaspase-1,secreted less IL-18 (p=0.02 compared to ICs containing no RNase A-digested supernatants) and lost the capacity to induce IL-18 production from A-253 cells (p=0.43, compared to medium control).

Conclusion: This novel study showed that ICs containing anti-SSA antibodies activated NLRP3 inflammasome and induced IL-18 secretion in A-253 cells. Endogenous RNA components of anti-SSA ICs and reactive oxygen species were responsible for this activation.

Autoantibody Mediated Salivary Gland Hypofunction in Sjögren's Syndrome Involves Activation of Innate Immunity and Endothelial Cells

Harini Bagavant,[1] Joanna Papinska,[1] Marta Trzeciak,[2] Indranil Biswas,[1] Nataliya Smith,[2] Debra Saunders,[2] Rheal Towner,[2] and **Umesh Deshmukh** [1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of autoantibodies reactive against the Ro52/TRIM21 protein is a hallmark of Sjögren's syndrome. We have reported that Ro52-immunized mice develop IgG deposits in their submandibular glands (SMG) and salivary gland dysfunction, which is facilitated by innate immune activation. This study was undertaken to investigate the mechanisms involved in anti-Ro52 mediated salivary gland hypofunction.

Methods: Female NZM2758 mice (12-14 wk old) were injected with alum on days 0 and 10, followed by passive transfer of immune sera from rabbits immunized either with Ro52 or the control protein, Maltose binding protein (MBP). Pilocarpine-induced saliva was measured to evaluate salivary gland function. Gene expression in SMG was analyzed by using the nCounter mouse inflammation panel (Nanostring Technologies Inc). Localization of IgG deposits in the SMG was investigated by immunofluorescence staining for anti-rabbit IgG and neuronal, and endothelial cell markers. Antibody penetration in the brain was studied by fMRI and immunostaining. To investigate the role of innate immunity, serum cytokines levels were measured by BioPlex mouse 23-plex assay in alum injected mice. Effects of cytokines on salivary epithelial cell tight junctions were evaluated by measuring trans-epithelial electrical resistance (TEER) *in vitro*.

Results: NZM2758 mice, pre-treated with alum, and injected with anti-Ro52 rabbit immune sera had significantly lower saliva production than mice receiving anti-MBP sera. The IgG deposits in SMG of anti-Ro52 recipient mice, co-localized with the endothelial cell marker CD31 in small blood vessels and were present in close proximity of the neurons. Compared to anti-MBP treated mice, the SMG from anti-Ro52 recipients showed significantly higher expression of *Ptgs2* that encodes for prostaglandin synthase (p=0.0043). Further, anti-Ro52 recipients showed IgG deposits along the cortical blood vessels in the brain and significant penetration of IgG into the brain parenchyma. IL1α, one of the cytokines induced by alum, induced a drop in TEER indicating disruption of tight junctional complexes.

Conclusion: Our data suggest that in Sjögren's syndrome, antibody deposition on endothelial cells in the vicinity of neurons in salivary glands induces localized inflammation that affects neuronal signaling and saliva production. The pathogenic effects of anti-Ro52 are further enhanced by inflammatory cytokines induced by innate immune activation. In addition, antibody penetration into the brain might contribute to the glandular hypofunction and neurological issues such as brain fog and cognitive dysfunction, a feature often seen in Sjögren's syndrome patients.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory joint diseases (IJD) such as psoriatic arthritis (PsA) have an increased risk of cardiovascular disease (CVD) since inflammation plays a pivotal role in the pathogenesis of coronary artery disease (CAD), heart failure (HF) and atrial fibrillation (Afib)[1]. Ischemic heart disease and HF are the main causes of the increased and premature mortality among patients with IJD[2].

Additionally, patients with PsA have a prevalence of hyperuricemia (HUC) of 32%, 3 times greater as compared with the general population, which may be related to increased cell turnover as well as the release of pro-inflammatory cytokines and tumor necrosis factor[3].

Prolonged exposure to high levels of uric acid (UA) has been shown to result in oxidative stress causing endothelial dysfunction, ionic channel changes, atrial and ventricular remodeling[4]. There is experimental evidence indicating that uric acid stimulates renin-angiotensin-aldosterone system (RAAS), and it is associated with an increase in cardiac tis-

sue xanthine oxidase activity, all of which induce cardiomyocyte hypertrophy, myocardial oxidative stress, interstitial fibrosis and impaired diastolic relaxation[5].

Methods: This is a retrospective cohort study using the 2016 National Inpatient Sample (NIS) of adults diagnosed with PsA based on ICD-10 codes, to detect the prevalence of cardiovascular (CV) conditions such as CAD, Afib, and HF with preserved ejection fraction (HFpEF) in patients with concomitant HUC or gout versus age matched controls. Chi square was used for point prevalence and multivariate linear regression adjustment was used for age, gender, race, CAD, diabetes mellitus, HTN, hyperlipidemia (HLD), smoking, chronic kidney disease (CKD) and Charlson comorbidity index to obtain prevalence odds ratio (POR). We used STATA-15 for statistical analysis.

Results: We identified 37,315 patients with PsA, of whom 2,165 had concomitant HUC or gout (5.80%). Mean age was 61 years, 57% were females. Our results showed that PsA with concomitant HUC or gout compared to PsA without HUC or gout was associated with a higher rate of Afib (17.8% vs 6.1%, $p < 0.001$), CAD (35.1% vs 19.4%, $p < 0.001$) and HFpEF (7.2% vs 3.1%, $p < 0.001$). Furthermore, patients with PsA and HUC/gout appeared to have more risk of developing Afib (POR 1.79; 95%-CI 1.31-2.45; $p < 0.001$) and HFpEF (POR 1.56; 95%-CI 1.08-2.26; p=0.018), compared to patients with normal uric acid after multivariate-adjustment for risk factors. No statistical difference in CAD was identified between the two groups (POR 1.21; 95%-CI 0.94-1.55; p=0.131) after multivariate linear regression adjustment for confounders.

Conclusion: This study showed that HUC is independently associated with CVD, mainly with Afib and HFpEF in patients with PsA. It remains to be seen if a treat-to-target approach with normalization of UA in patients with PsA will result in improved CV outcomes. We believe that our findings merit further investigation and that this study adds weight to the hypothesis of UA as a potential risk factor for CVD. Prospective studies are needed to establish the role of serum uric acid level as a biomarker or predictor for CVD, including CAD, Afib and HFpEF in patients with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence thus far on the effect of psoriatic arthritis (PsA) on bone mineral density (BMD) has been inconsistent. There is also insufficient guidance surrounding BMD testing in PsA patients. The purpose of this study was to determine BMD in the PsA population, factors associated with having BMD testing performed, and the effect of PsA clinical activity on BMD.

Methods: This retrospective cohort study was conducted at the Psoriatic Arthritis Clinic. Patients who had a BMD, irrespective of clinical indication were included. All patients in the cohort fulfilled the 2006 CASPAR criteria. Patients without T-scores reported, those with no visits prior to first BMD and those < 50 years old at the time of BMD were excluded. Descriptive statistics were used to summarize lumbar spine, femoral neck and total hip T-scores. Cox proportional hazard regression was performed on patients with BMDs with visits at the clinic within 2 years of their first BMD to determine covariates that predicted undergoing BMD testing. Subsequently, spearman correlation analysis was used to identify clinical features associated with low bone density. Linear regression analysis was used to model T-scores changes according to different clinical variables.

Results: Of the 214 patients with BMDs, 201 fulfilled inclusion criteria and were included for analysis. Higher age at initial visit (p< 0.001), menopause (p< 0.008), biologic therapy (p< 0.001) and disease-modifying antirheumatic drug (DMARD) use (p< 0.018) were associated with a higher chance of having a BMD when adjusted by age at baseline, PsA disease duration and gender (Table 1). The percentage of patients in the osteopenic and osteoporotic range of BMDs was 45.3% and 12.9% respectively. Mean T-scores at the lumbar spine, femoral neck and total hip were -0.3, -1.1 and -0.45 respectively. Higher body mass index (BMI) was significantly associated with a higher BMD across all measured sites (Table 2). Every unit increased in the Psoriasis Area Severity Index (PASI) was associated with a 0.084 decrease, whereas every unit increased in psoriasis body surface area (BSA) translated to a 0.804 decrease in lumbar spine T-score. For total hip T-scores, every additional damaged joint was associated with a 0.027 decrease in T-score.

BMD, bone mineral density; SF-36, short form health survey; PASDAS, psoriatic arthritis disease activity score; BSA, body surface area; BMI, body mass index, PASI, psoriasis area and severity index; HAQ, health assessment questionnaire

Conclusion: Higher age at initial visit, menopausal status, biologic therapy and DMARD use predicted undergoing BMD testing in our cohort. 45.3% and 12.9% of patients with PsA had osteopenia and osteoporosis respectively, with mean T-scores at the lumbar spine, femoral neck and total hip being -0.3, -1.1 and -0.45 respectively. High BMI was significantly associated with a higher BMD. More research is needed to identify risk factors associated with worsening BMD over time in the PsA population.

Rates of Treated Depression Among Patients with Psoriatic Arthritis Treated with Apremilast, Biologics, DMARDs, and Corticosteroids in the US MarketScan Database

Catherine Vasilakis-Scaramozza,[1] Rebecca Persson,[1] Katrina Wilcox Hagberg,[1] Steve Niemcryk,[2] Michael Peng,[2] Maria Paris,[2] Anders Lindholm,[2] and Susan Jick[3], [1]Boston Collaborative Drug Surveillance Program, Lexington, [2]Celgene Corporation, Summit, [3]Boston Collaborative Drug Surveillance Program and Boston University School of Public Health, Boston

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Depression is common among PsA patients, but rates may differ by PsA treatment. Our study compares rates of treated depression by PsA treatment type in patients with PsA.

Methods: We conducted a population-based cohort study of treated PsA patients in the MarketScan database in 2014-2018. Cohort entry was the date of first prescription for a study drug (apremilast, tumor necrosis factor inhibitor [TNF-i] biologics, interleukin-17 or -12/23 inhibitor [IL-i] biologics, conventional DMARDs, or systemic corticosteroids) after March 21, 2014, the date on which apremilast was approved. Patients with antidepressant treatment before cohort entry were considered prevalent cases and excluded. A patient was considered currently exposed to a study drug from the prescription date through the prescription duration + 30 days. Patients were followed from cohort entry through censor date, defined as the first of the following: index date (date patient became a case), end of record,

Table. IRs for Treated Depression Alone Among PsA Patients Treated With Apremilast, DMARDs, Biologics, and Corticosteroids, and With at Least 1 Year of Recorded History Before the Cohort Entry Date

Exposure at the Index Date	Cases N=643	Person-Years Total=62,380	IR per 1,000 PY (95% CI)
DMARDs only	67	7,276	9.2 (7.1, 11.7)
Apremilast only	18	2,085	8.6 (5.1, 13.6)
TNF-i biologics only	187	19,983	9.4 (8.1, 10.8)
IL-i biologics only	42	3,603	11.7 (8.4, 15.8)
Corticosteroids only	44	3,705	11.9 (8.6, 15.9)
Apremilast + any nonsteroid	6	576	10.4 (3.8, 22.7)
TNF-i with DMARDs	42	4,460	9.4 (6.8, 12.7)
IL-i with DMARDs	7	389	18.0 (7.2, 37.1)
Corticosteroids + any other	92	6,276	14.7 (11.8, 18.0)
Past use*	138	14,027	9.8 (8.3, 11.6)

*Defined as any days after the end of "current use" and before a new study drug prescription.

or end of study period (October 31, 2018). Cases were patients with a first diagnosis of treated depression (without concurrent anxiety), defined as a diagnosis of depression with a prescription for an antidepressant within 30 days, and at least 7 days after cohort entry. We calculated incidence rates (IRs) and 95% confidence intervals (CIs) for each outcome per 1,000 patient-years among patients with at least 1 year of recorded medical history before their cohort entry date. Past use is defined as any days after the end of "current use" and before a new study drug prescription.

Results: The study population included 31,720 patients (median age at cohort entry: 53 years; female: 44%; history of depression: 4.8%). The IRs were similar between treatments with somewhat higher rates of treated depression among patients exposed to corticosteroids alone or in combination with any other study drug and patients exposed to IL-i alone or with DMARDs. Among the 643 treated depression cases, IRs (95% CIs) were as follows: apremilast only, 8.6 (5.1, 13.6); DMARDs only, 9.2 (7.1, 11.7); TNF-i only, 9.4 (8.1, 10.8); IL-i only, 11.7 (8.4, 15.8); and corticosteroids only, 11.9 (8.6, 15.9). The IRs for combination treatments were: TNF-i with DMARDs, 9.4 (6.8, 12.7); past use, 9.8 (8.3, 11.6); apremilast + other non-steroid study drugs, 10.4 (3.8, 22.7); corticosteroid + any other study drug, 14.7 (11.8, 18.0); and IL-i with DMARDs, 18.0 (7.2, 37.1).

Conclusion: Rates of treated depression were similar across PsA treatments, with somewhat higher rates of treated depression among patients exposed to corticosteroids alone or in combination with any other study drug and among patients exposed to IL-i alone or in combination with DMARDs.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a substantial problem in patients with psoriatic arthritis (PsA) that needs to be considered in the core set of domains. This study aimed to evaluate the relationship between fatigue and disease activity levels as determined by various scales in patients with PsA.

Methods: A total of 1134 patients (726 females, 408 males) diagnosed with PsA according to the CASPAR criteria were included (Turkish League Against Rheumatism (TLAR) Network multi-center study). Demographic features and clinical conditions of the patients were recorded. The following parameters were assessed: Maastricht Ankylosing Spondylitis Enthesis Score (MASES), Psoriasis Area and Severity Index (PASI), VAS fatigue (0-10 points: 0 - < 2 absent or mild, 2 - < 5 moderate, and 5 - 10 severe fatigue), Hospital Anxiety and Depression Scale (HAD), Fibromyalgia Rapid Screening Tool (FIRST). Disease activity was evaluated using the scores of DAS28, DAPSA, BASDAI, minimal disease activity (MDA), and very low disease activity (VLDA). The Spearman correlation coefficient was used for correlations. The Mann-Whitney U and chi-squared tests were used for between-group comparisons. A P value of less than 0.05 was considered to be statistically significant.

Results: The mean age of the patients was 46.9 (SD:12.1) years, and the median disease duration was four years (range 0-44 years). The mean fatigue score was 4.9 (SD:2.8), being absent or mild, moderate, and severe fatigue in 14.8%, 24.9%, and 60% of the patients, respectively. The mean of women's fatigue VAS was 5.4 (SD:2.7) while the men's fatigue VAS mean was 4.01 (SD:2.7) ($p< 0.05$). Fatigue has good correlation with VAS-pain (rho: 0.595), FIRST (rho: 0.513), anxiety (rho: 0.436), depression (rho: 0.388), MASES (rho: 0.297) and it has poor correlation with PASI (rho: 0.073). DAS28 and DAPSA remission, MDA, and VLDA rates were 24.3%, 2.6%, 13.6%, and 2.3%, respectively. The fatigue score was significantly lower in patients with DAS28 remission, DAPSA remission, MDA and VLDA ($p< 0.05$) and fatigue has a significant correlation with disease activity levels on DAS28 and DAPSA ($p< 0.05$) (Table 1). The DAS28, DAPSA, and BASDAI scores showed significant between-group differences across the three severity groups of fatigue, being the highest disease activity among patients with severe fatigue ($p< 0.05$). Significantly higher FIRST, anxiety and depression scores were noted in patients with DAS28 remission and fatigue compared with patients in remission but no fatigue ($p< 0.05$).

Conclusion: Fatigue is common and associated with disease activity, depression, anxiety, and fibromyalgia in PsA. Patients with remission, according to DAS28, DAPSA, and patients with MDA and VLDA have already mild to moderate fatigue.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: This study sought to compare the disease activity and its relationship with anxiety, depression, fatigue, and fibromyalgia of patients with psoriatic arthritis (PsA) between female and male gender in a Turkish population.

Methods: This multi-center Turkish League Against Rheumatism (TLAR) Network study included 1134 patients (726 females, 408 males) diagnosed with PsA according to the CASPAR criteria. Demographic and clinic parameters of the patients were recorded. Disease activity was evaluated using the scores of DAS28, DAPSA, cDAPSA, MDA, VLDA, and BASDAI. Health Assessment Questionnaire (HAQ), SF-36, Hospital Anxiety and Depression Scale (HAD), fatigue VAS (0-10), and Fibromyalgia Rapid Screening Tool (FIRST) were assessed. Disease activity and remission rates were compared in male and female patients, and their relationship with fatigue, anxiety, depression, and fibromyalgia scores was analyzed. The Spearman correlation coefficient was used to assess correlations. Comparisons were made using the Mann-Whitney U and chi-squared tests. $p< 0.05$ was considered significant.

Results: The mean age of the patients was 47.4 years (SD:12.1) for females, 46 years (SD:12.2) for males (Table-1). Disease activity scores of DAS28, DAPSA, cDAPSA, and BASDAI were significantly higher in women than in men ($p< 0.05$) (Table-2), with men having both higher remission and low-activity rates. There was a significant difference in the rate of MDA in favor of men ($p< 0.05$), but not in the rate of VLDA. The frequencies of dactylitis, enthesitis, inflammatory bowel disease, and arthritis were similar in men and women, while men had a higher incidence of spondylitis ($p< 0.05$). Both men and women with MDA had significant improvements in the scores of fatigue, HAQ, FIRST, anxiety and depression as well as in SF-36 subscales as compared with their counterparts without MDA ($p< 0.05$). Overall, although there was no significant between-group difference in age, body mass index, and disease duration, women had significantly higher anxiety, depression, and FIRST scores (fibromyalgia) compared with men ($p< 0.05$) (Table-2). In both men and women, disease activity scores of DAPSA, DAS28, and BASDAI were significantly correlated with the scores of FIRST, anxiety, depression, fatigue, and HAQ ($p< 0.05$).

Conclusion: In patients with PsA, women seem to have lower levels of remission and higher levels of disease activity than men. In both women and men, disease activity scores are significantly correlated with fatigue, functional status, anxiety, depression, fibromyalgia, and quality of life.

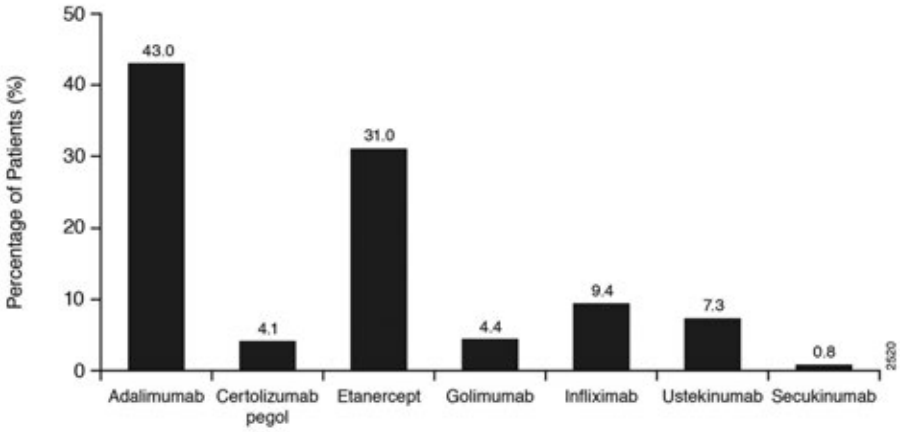
Real-world Treatment Patterns Among Patients with Psoriatic Arthritis Treated with Biologic Therapies

Jessica Walsh,[1] Qian Cai,[2] Timothy Fitzgerald,[3] Christopher Pericone,[2] Pankaj Shukla,[4] and Soumya Chakravarty[5],
[1]Division of Rheumatology, University of Utah, Salt Lake City, UT,[2]Janssen Scientific Affairs, LLC, Titusville, NJ, [3]Janssen Scientific Affairs, LLC, Horsham, PA, [4]Mu-Sigma, Chicago, IL, [5]Janssen Scientific Affairs, LLC; Drexel University College of Medicine, Horsham; Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Though biologic therapies have demonstrated long-term response in randomized clinical trials for psoriatic arthritis (PsA), such patient populations and settings may not reflect the general PsA population

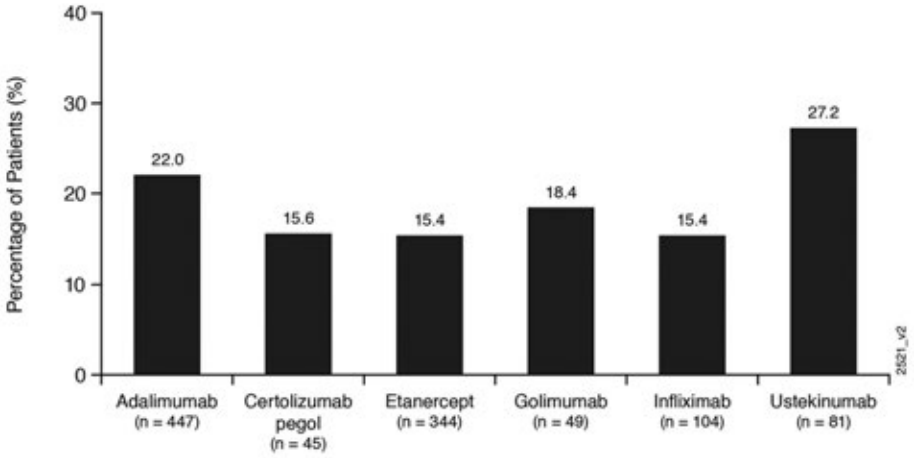
Figure 1. Index Biologic Among Study Patients (N = 1,109)



or real-life practice patterns, e.g., switching or adding therapies for patients with inadequately controlled symptoms. To better understand long-term patterns of biologic use for PsA treatment, this study aimed to describe 2-year adherence, persistence and switching among PsA patients initiated with adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, ustekinumab or secukinumab.

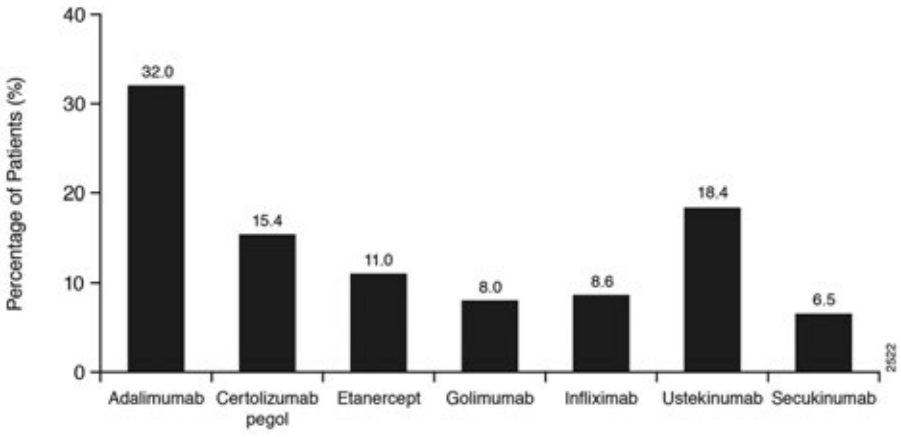
Methods: Adults with ≥ 1 medical or pharmacy claim for the above biologics during 1/1/2013 - 12/31/2016 were selected from Optum's de-identified Clinformatics® Data Mart Database. The date of the first claim was the index date. Patients were required to have ≥ 12 months pre-index and ≥ 24 months post-index continuous enrollment, with ≥2 PsA diagnoses ≥ 30 days apart during the 12-month pre-index through 12-month post-index period, and the first diagnosis occurring on or prior to the index date. Patients were excluded if they had ≥ 2 different biologics on the same day, a medical claim for rheumatoid arthritis, ankylosing spondylitis, other spondyloarthropathies, contraindications, or an index biologic filled during the 12-month pre-index period. Days' supply from medical claims (14.8% of all claims) was imputed based on the most frequently observed days' supply from pharmacy claims (84 days: ustekinumab; 28 or 30 days: other biologics). Baseline characteristics, adjunctive medication, number of patients who discontinued index biologic (ie, had a gap between fills of > 1.5 times the dispensed days' supply(135 days for ustekinumab; 45 days for other biologics), and number of patients who switched to a different biologic were reported by index biologic.

Figure 2. Percentage of Patients Who Persisted with Index Biologic for 24 Months (N = 1,100)



Note: No patients in the secukinumab cohort (n = 9) persisted for 24 months

Figure 3. Subsequent Biologic Among Patients Who Switched Biologic Therapies (N = 337)



Results: Of 1,109 patients included, mean (SD) age was 52.1 (12.8) years and 50.6% were female. The most common index biologics were adalimumab (43%) and etanercept (31%) [Fig 1]. During the 24-month follow-up period, 19.1% of patients persisted on their index biologic; ustekinumab had the highest persistence (27.2%) [Fig 2].The mean (SD) proportion of days covered (PDC) for index biologics was 0.47 (0.31). Of the 897 patients who discontinued their index biologic, 35.2% restarted the same biologic, 37.6% switched to a different biologic, and 33.6% discontinued without restarting or switching. The most common biologics that patients switched to were adalimumab (32%) and ustekinumab (18.4%) [Fig 3]. Of patients (n=864) who persisted with the index biologic for ≥ 90 days, 48.6% received ≥ 1 adjunctive medication during the period from 90 days post index to the end of persistence or 24 months, the most common were corticosteroids (27.7%), opioids (16.7%) and nonsteroidal anti-inflammatory drugs (13.4%).

Conclusion: In this real-world study of biologic PsA therapies, 24-month persistence ranged from 15.4%-27.2%, with ustekinumab having the highest persistence. Of patients who persisted on their index biologic for >90 days, nearly half used adjunctive therapy.

Enthesitis, Dactylitis, and Axial Disease in Psoriatic Arthritis (PsA): Impact on Patient Quality of Life and Work Productivity

Jessica Walsh,[1] Alexis Ogdie,[2] Kaleb Michaud,[3] Steve Peterson,[4] Elizabeth Holdsworth,[5] Chetan Karyekar,[4] Nicola Booth,[6] Jessalyn Kemp,[7] Soumya Chakravarty,[8] Shelly Kafka,[9] and Laure Gossec[10], [1]Division of Rheumatology, University of Utah, Salt Lake City, UT, [2]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [3]University of Nebraska Medical Center, Omaha, NE, [4]Janssen Global Services, LLC, Horsham, PA, [5]Adelphi Real World, Manchester, England, United Kingdom, [6]Adelphi Real World, Bollington, United Kingdom, [7]Adelphi Real World, Manchester, United Kingdom, [8]Janssen Scientific Affairs, LLC; Drexel University College of Medicine, Horsham; Philadelphia, PA, [9]Janssen Scientific Affairs, LLC, Horsham, PA, [10]Sorbonne Université and Hôpital Pitié-Salpêtrière, Paris, France

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: PsA is a chronic, inflammatory disease characterised by peripheral arthritis, axial disease, dactylitis, enthesitis and skin and nail psoriasis. The impact of skin and joint components of the disease on quality of life and work productivity has been studied (1,2) but the impact of other manifestations has not. This analysis assessed the impact of enthesitis, dactylitis, and axial disease on quality of life and work productivity in PsA patients.

Methods: Cross-sectional study among patients with PsA recruited by rheumatologists and dermatologists in France, Germany, Italy, Spain, UK, and US. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Physicians recorded (Yes/No) if patients currently presented with enthesitis, dactylitis, inflammatory back pain (IBP), and sacroiliitis (identified by x-ray or MRI). Multiple linear regression

Table 1: Impact of manifestations on PROs: Adjusted* regression coefficient and p-values

Outcome measure (N patients with data available)	Manifestation	Coef.	P value
EQ5D Index (N=771)	Enthesitis	-0.12	0.002
	Dactylitis	-0.07	0.010
	IBP	-0.07	0.001
	Sacroiliitis	-0.06	0.259
EQ5D VAS (N=784)	Enthesitis	-8.86	0.013
	Dactylitis	-4.31	0.123
	IBP	-4.10	0.073
	Sacroiliitis	-10.19	0.043
HAQ DI (N=744)	Enthesitis	0.17	0.096
	Dactylitis	0.17	0.024
	IBP	0.20	0.003
	Sacroiliitis	0.30	0.035
PsAID12 (N=750)	Enthesitis	1.32	0.002
	Dactylitis	1.09	0.003
	IBP	0.47	0.060
	Sacroiliitis	0.59	0.243
WPAI: Productivity (N=485)	Enthesitis	14.40	0.034
	Dactylitis	4.36	0.128
	IBP	4.07	0.185
	Sacroiliitis	-3.86	0.332

* Adjusted for age, gender, number of joints affected, time since diagnosis.

analyses were used to examine the impact of these manifestations on patient reported outcomes (PROs) including EQ5D index, EQ5D VAS, HAQ-DI, PsAID12, and WPAI. Models were adjusted for age, gender, number of joints affected, and time since diagnosis. There was no imputation of missing data.

Results: The sample included 1103 patients: mean age 47.6 [SD 13.2] years, 46% were female, 58% were working full time. Mean number of joints affected by PsA was 3.8 (SD 5.2), and 54.9% were receiving biologic treatment. Enthesitis (present in 6.3% of patients), dactylitis (8.0%) and IBP (12.6%) were associated with worse outcomes overall (Table 1); sacroiliitis (3.9%) was linked to worse physical function and quality of life.

Conclusion: In a multi-national, real-world PsA population, enthesitis, dactylitis, IBP, and sacroiliitis were significantly associated with worse patient quality of life and/or work productivity across a range of PROs independent of the number of joints affected. These manifestations should be considered alongside skin and joint components in order to optimize patient outcomes.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The impact of gender on tumor necrosis factor inhibitors (TNFi) effectiveness has been poorly studied in Psoriatic Arthritis (PsA) patients. The objective of this work was to study gender differences in persistence and response to a first TNFi in PsA patients.

Methods: PsA patients prospectively followed at the Rheumatic Diseases Portuguese Registry (Reuma.pt), treated with a first TNFi, between 2001 and 2017 were included. Drug retention was assessed by Kaplan-Meier survival analysis and Cox models adjusted for the year of starting a TNFi. Response rates measured by European League Against Rheumatism (EULAR) response, Disease Activity Index for Psoriatic Arthritis (DAPSA) remission, Minimal Disease Activity (MDA) and Ankylosing Spondylitis Disease Activity Score (ASDAS) response, applying the LUNDEX method, were compared between genders. Baseline predictors of discontinuation and response were identified (Cox and multivariable multinomial/logistic regression models).

Results: 750 PsA patients were included, mean age 47.6(±11.6) years and 50.3% (n=377) females .PsA females showed significantly different baseline PsA disease characteristics in comparison with males: were older, more of-

ten obese, had a longer delay between diagnosis and the start of the first TNFi, had more severe peripheral disease activity and required more often concomitant corticosteroids and conventional synthetic disease modifying anti-rheumatic drug. The overall TNFi survival rates for females were also significantly lower when compared with those from males. Additionally, PsA females experienced lower rates of response as assessed by good EULAR response, DAPSA remission and MDA at 3 and 6 months, and by ASDAS at 6 months. Female gender was further identified as an independent predictor factor of worse persistence and showed a lower chance of good EULAR response.

Conclusion: PsA female patients from Reuma.pt have distinct PsA features and worse persistence and response to a first TNFi in comparison with males. More successful therapeutic approaches will require considering the impact of gender on TNFi effectiveness.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis (Pso) is one of the most common chronic inflammatory skin diseases in Europe. Psoriatic arthritis (PsA) is closely associated to Pso whereas the skin manifestation appears usually years before PsA-related symptoms emerge. Up to 30% of Pso patients develop PsA, but there is no clear correlation between disease duration of Pso and PsA development. Therefore, biomarkers for its early detection are of major importance. In early PsA, changes in synovial vascularisation combined with increased expression of proangiogenic factors appear first. Therefore, imaging biomarkers for detection of changes in vascularisation can be useful for early detection of joint disease. Fluorescence-optical imaging (FOI) is a new method to detect changes in microvascularisation of the hands.

Methods: Sensitivity of FOI for detection of subclinical signs of inflammation as biomarker for early PsA was observed in a prospective, multicentre study (XCITING) including patients with dermatological confirmed skin psoriasis only. 411 patients were included from dermatology care units across Germany without diagnosis of PsA but potential risk factors for its development (nail psoriasis and/or joint pain or swelling within the last 6 months). Clinical exam-

Non-selective COX inhibitors (%)	20	12,9	35,7	25,9

*nail involvement was required for inclusion and cannot only be used with limitation within interpretation

ination (CE; swollen (66) and tender (68) joint count, enthesitis, dactylitis assessment) and standardised ultrasound (US) assessment was performed by a qualified rheumatologist to assess musculoskeletal inflammation. FOI was performed additionally. Data was analysed in focus on increased vascularisation of musculoskeletal structures of both hands as inflammatory marker. In cases of discrepant results (positive FOI and negative results for CE and US), MRI was performed to prove the findings.

Results: 83 of the 411 patients of the cohort were negative in all assessments (Pso only). 112 patients showed subclinical signs of musculoskeletal inflammation in the central reading of FOI, whereas CE and US were negative. In 37,5% of those patients, subclinical inflammation was confirmed by MRI assessment. Both groups (MRI pos and MRI neg) were well balanced in age, sex, BMI and CRP. In the MRI pos group, patients had more severe symptoms of Pso/musculoskeletal complains indicated by increased rates for use of topical or systemic treatments (e.g. MTX 16,7 % vs. 5,7% for Pso, Pso plaques at hands 35,7 vs 15,7%) and NSAID (NSAID 40,5% vs 18,8%) and showed an increased incidence for concomitant diseases (71,4% vs 45,7%). Compared to the PsA (n=143) and Pso (n=95) only group, the MRI pos group showed high similarities in age of onset of Pso (mean age 31,4 vs 31,5 years), in TJC (mean of 6,7 vs 6,2), NSAID use (40,5% vs 32,9%) and BSA (mean 8,9 vs 9,5%) to the diagnosed PsA group and in difference to the Pso only and MRI neg group (table 1).

Conclusion: Early detection of development of musculoskeletal symptoms in PsO patients seem to be associated to the severity of skin symptoms and its need for therapeutic intervention. The FOI and MRI pos group had high similarities in several domains with clinically evident active PsA but not to the Pso only group. Moreover, it seems that the use of systemic treatment with e.g. MTX for Pso has no preventive effect on the development of arthritis.

Factors Associated with Discordance Between Patient and Rheumatologist Assessment of Disease Activity in Psoriatic Arthritis Considered in Remission

Marie Moly,[1] Cédric Lukas,[2] Jacques Morel,[1] Bernard Combe,[3] and Gaël Mouterde[4], [1]CHU Montpellier, Montpellier, France, [2]Rheumatology department, CHU Montpellier, Univ Montpellier, Montpellier, France, [3]CHU Montpellier, Montpellier University, Montpellier, France, [4]CHU Montpellier and Univ Montpellier, Montpellier, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment of disease activity in psoriatic arthritis (PsA) requires evaluation of multiple aspects and can be difficult. Perception of disease activity by patient and physician is frequently discordant (1). The aim of our study was to evaluate factors associated with persistence of disease activity evaluated by patients yet considered in remission by their rheumatologist.

Methods: We performed a transversal monocentric study. PsA patients were included if they met the CASPAR criteria and if they were considered in remission by their rheumatologist. Demographic data, characteristics of the disease, treatments were collected. Disease activity was evaluated by several scores: Disease Activity Score (DAS28-CRP), Simple Disease Activity Index (SDAI), Clinical Disease Activity Index (CDAI), Disease Activity in Psoriatic Arthritis (DAPSA), Minimal Disease Activity (MDA), modified Boolean remission criteria for PsA. We collected multiple Patient's Reported Outcomes (PROs): Psoriatic Arthritis Impact of Disease (PsAID), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Health Assessment Questionnaire (HAQ), Dermatology Life Quality Index (DLQI), Beck Depression Inventory (BDI), Fibromyalgia Rapid Screening Tool (FiRST), Pain Catastrophizing Scale (PCS). Discordance was defined by a difference between patient's and rheumatologist's global assessment ≥30/100 on a Visual Analogue Scale (VAS). Univariate and multivariate analyses were performed to evaluate factors associated with the presence of discordance.

Results: 62 PsA patients were included. 40.3 % were women and the mean (SD) age was 55 (14) years (Table 1). 61% patients were in remission (rheumatologist definition) for more than 12 months and 19% for less than 3 months. 50% met MDA, 63% DAS28-CRP < 2,6, 39% SDAI and CDAI remission, 27% DAPSA remission, and 8% Booleans remission criteria. 39% had a discordant disease activity assessment from their rheumatologist. In univariate analysis, factors associated with discordance were a history of depression, an associated fibromyalgia, a history of

PsAID > median (2.1), n (%)	18 (75)	13 (34.2)	5.77 (1.84-18.06)	0.002

Table 2: Factors associated with discordance: Univariate analysis

clinical enthesitis and a history of corticosteroid use (Table 2). All disease activity scores and PROs were higher in discordant group and were associated with discordance in univariate analysis. In multivariate analysis, discordance was associated with no previous corticosteroid use (OR 24.5 (95%CI 2.9-203.7), p=0.003), a higher BDI scale (OR

1.4 (95%CI 1.1-1.8) by supplementary point, p=0.017) and a higher DAPSA score (OR 1.5 (95%CI 1.2-2), p< 0.001) by supplementary point.

Conclusion: In this PsA cohort, discordance between patient and rheumatologist is very common. Discordance in assessment of disease activity was associated with no previous corticosteroid use, probably reflecting a less severe disease, presence of depressive symptoms and an increase of DAPSA, reflecting a more active disease.

Table 1. Psoriasis phenotype in PsO vs PsA population.

environmental and clinical-demographic factors have been implicated, but are yet to be characterized in specialized, combined care centers. We aim to describe clinical phenotypes differentiating patients with PsO from those with PsA at a large, urban tertiary care PsO-PsA clinic.

Methods: Consecutive adult patients meeting CASPAR criteria for PsA (n= 448) or with dermatologist diagnosed skin psoriasis only (n=161) were prospectively recruited at the NYU Psoriatic Arthritis Center and the NYU Psoriasis and Psoriatic Arthritis Clinic. All data was collected utilizing clinical visit notes and additional on-site questionnaires. Type of psoriasis and body surface area (BSA) was determined by dermatologists or rheumatologists specializing in psoriatic disease. Data was analyzed using statistical software SPSS using chi squared test with Yates Continuity Correction for dichotomous/categorical variables and t-test for continuous variables.

Results: Patients with PsO were more likely to be older (52.7 vs. 48.9, p=.032) and have hypertension, obesity, diabetes, and history of myocardial infarction (Figure 1). Patients with PsO had a statistically higher BSA than those with PsA (5.8% vs 3.1%, p=.003). While the type of psoriasis was similar, the site of psoriasis involvement (specifically the scalp and nail) differentiated the populations (Table 1). In PsA compared to PsO, the odds ratio of scalp involvement was 2.96 (95% Confidence Interval [CI] 2.02, 4.34) and that of nail involvement was 14.66 (95% CI 8.21, 26.16). Inverse psoriasis was not different between groups. Additionally, those with PsA were much more likely to have a first degree relative (FDR) with psoriasis compared to those with cutaneous disease alone (31.9% vs. 12.0%, p=.007) (Figure 1).

Conclusion: We report for the first time the comorbidities and psoriasis features of PsA and PsO populations in a large, combined center. We found that scalp involvement and any nail involvement was more prevalent in the PsA as compared to PsO. Only one previous study has identified scalp psoriasis[1] as a possible risk factor for progression, while previous studies looking at nail psoriasis reported much lower odds ratios[1,2]. Patients with PsA also demonstrated a higher number of FDRs with skin psoriasis, reinforcing the notion of strong heritability in PsA. The identification of risk factors for progression is of critical importance to study natural history of psoriatic disease and to inform the adequate design of prevention trials in psoriasis patients who have enriched features associated with future transition to synovio-enthesial disease.

The Paradoxical Effect of Depression on Psoriatic Arthritis Outcomes in a Combined Psoriasis-Psoriatic Arthritis Center

Rebecca Haberman,[1] Samrachana Adhikari,[1] Deborah Ramirez,[2] Eileen Lydon,[1] Malavika Attur,[1] Andrea Neimann,[1] Soumya Reddy,[1] Andrea Troxel,[1] and Jose Scher[3], [1]NYU School of Medicine, New York City, [2]NYU School of Medicine, New York, [3]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogenous inflammatory disease affecting skin, joints, and other domains. While psychiatric diseases (i.e., depression and anxiety) are known comorbidities, little is known about their impact on disease severity and patient reported outcomes (PROs). The objective of this study was to characterize the prevalence of psychiatric comorbidities in an academic combined psoriasis-psoriatic arthritis center and determine their impact on PsA clinical and patient derived outcomes.

Methods: Consecutive adult patients meeting CASPAR criteria for PsA (n=436) were prospectively recruited at the NYU Psoriatic Arthritis Center. All data was collected from clinical visits utilizing a standardized EPIC template. Depression was defined by established diagnosis and/or use of anti-depressant medications. Objective measures of disease severity included swollen and tender joint counts (SJC/TJC) and PROs including RAPID3 scores. Data was analyzed using statistical software R.

BASELINE CHARACTERISTICS (n= 436)	
Age	47.5 (range 21-83)
Male	54% (237)
Race/Ethnicity	
White	74.1 % (323)
Black	1.4% (6)
Asian	5.7% (25)
Other/Unknown	19.3% (84)
Hispanic	4.8% (21)
Depression	19.5% (85)
Anxiety	15.6% (68)
ADHD	4.8 % (21)

Table 1. Baseline characteristics of our PsA population.

Outcomes at initial visit*	Depressed Mean	Non-Depressed Mean	p-values
TJC	3.5	2.9	.636
SJC	1.2	1.8	.086
RAPID3	12.7	10.4	**.035**
BSA	1.4	3.03	**.001**
Outcomes at subsequent visits	**Mean Difference** between Depressed and Non-Depressed	p-value	
TJC	0.6	.196	
SJC	-0.5	.134	
RAPID3	2.3	**.004**	
BSA	-1.38	**.015**	
Adjusted TJC**	0.7	.220	
Adjusted SJC**	-0.2	.470	
Adjusted RAPID3**	2.3	**.015**	
Adjusted BSA	-0.96	.293	

Table 2. Outcomes of tender and swollen joint counts and RAPID3 at baseline and over subsequent visits. *Outcomes at the initial visit were analyzed using t-test. Repeated measures were analyzed with Satterthwaite's approximations for the t test within mixed effects linear model with gaussian errors. P-values of equal to or less than .05 were considered significant. ** Adjusted using matching by propensity score that included age, sex, multiple comorbidities, and medication use.

Results: Our cohort was comprised of 436 patients: 54% male, mean age of 47 years, and mostly Caucasians (74.1%). Within our population, 19.5% had depression, 15.6% had anxiety, and 4.8% had ADHD (Table 1). Of those with depression, 71% were on anti-depressive medication. At the initial visit, patients with PsA and depression were more likely to be on medication(s) for PsA (80% vs 65%, p=.01) and had a trend towards higher rates of biologic use (47.5% vs 40.4%, p=.126). Those with depression had a similar TJC to their non-depressed counterparts, but had a trend towards fewer swollen joints and concomitant higher RAPID3 scores (Table 2). When analyzing repeated outcome measures over subsequent visits, individuals with depression were similarly more likely to have a higher TJC, a lower SJC, and a higher RAPID3 score (although only RAPID3 was found to be statistically significant, p=.004). Importantly, these findings persisted when analyzing participants that were matched with propensity scores to adjust for age, sex, comorbidities, and medication use. In addition to joint activity, psoriasis activity measured by body surface area (BSA) was lower in those who were depressed (1.4% vs 3.03%, p=.001) and these differences were maintained over subsequent visits.

Conclusion: Our results expand on prior reports of significantly elevated rates of depression in PsA. Notably, individuals with depression were more likely to be on medication(s) for their PsA, had fewer swollen joints, and a lower BSA but, paradoxically reported higher RAPID3 scores. This discrepancy is likely a manifestation of how depression could affect the way patients experience their PsA despite apparent improvement in skin and joint symptoms. Depression should, therefore, be considered a critical comorbidity when addressing PsA care in routine visits. Further work is needed to understand whether modulation of psychiatric comorbidities can lead to improved PsA outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with psoriatic arthritis (PsA) are at increased risk for cardiovascular (CV) events, but different treatment options may not have the same rates of CV events (Jamnitski et al. *Ann Rheum Dis.* 2013;72:211-6; Ogdie et al. *Curr Opin Rheumatol.* 2015;27:118-26). This study compared rates of myocardial infarction (MI), stroke, and revascularization by treatment type in patients with PsA.

Methods: We conducted a population-based cohort study of treated PsA patients in the MarketScan database from 2014 to 2016. The cohort entry was the date of the first prescription for a study drug (apremilast [APR] only or in combination with ≥1 other study drugs, anti-TNF-α biologics only, other biologics and DMARDs [OBDs] only, corticosteroids only, OBDs + corticosteroids, and anti-TNF-α biologics with OBDs and/or corticosteroids) after March 21, 2014, the date on which APR was approved. Patients were followed from cohort entry through the censor date, defined as the first of the following: the index date (date patient became a case), end of record, or end of study period (December 31, 2016). MI and stroke cases required 1 inpatient diagnosis plus 2 additional diagnoses on separate days; revascularization required a procedure code for revascularization without MI or stroke, all ≥7 days after cohort entry. A patient was considered currently exposed from the prescription date through the prescription duration + 30 days. We calculated incidence rates (IRs) and 95% CIs for each outcome per 100 patient-years among the entire population and in the subgroup of patients with no history of serious CV disease (CVD).

Results: The study population included 51,971 patients (median age: 52 years; female: 52%; serious CVD history: 4.0%). IRs were low for all outcomes, and between-treatment differences did not reach statistical significance (95% CIs for IRs were overlapping). Among the 187 MI cases, IRs (95% CIs) were as follows: for APR only, 0.10 (0.01, 0.35), or in combination, 0.49 (0.20, 1.02); anti-TNF-α biologics only, 0.13 (0.09, 0.19); anti-TNF-α biologics with OBDs and/or corticosteroids, 0.31 (0.22, 0.43); OBDs only, 0.32 (0.23, 0.44); corticosteroids only, 0.44 (0.27, 0.68); and OBDs + corticosteroids, 0.45 (0.24, 0.76). Among the 79 stroke cases, IRs (95% CIs) were as follows: for corticosteroids only, 0.08 (0.02, 0.22); anti-TNF-α biologics only, 0.09 (0.06, 0.13); for OBDs only, 0.10 (0.05, 0.17); anti-TNF-α biologics with OBDs and/or corticosteroids, 0.12 (0.06, 0.20); APR only, 0.15 (0.03, 0.43), or in combination, 0.14 (0.02, 0.51); and OBDs + corticosteroids, 0.21 (0.08, 0.45). Among the 292 revascularization cases, IRs (95% CIs) were as follows: for APR only, 0.25 (0.08, 0.57), or in combination, 0.42 (0.15, 0.92); anti-TNF-α biologics only, 0.36 (0.29, 0.44); anti-TNF-α biologics with OBDs and/or corticosteroids, 0.37 (0.27, 0.50); OBDs + corticosteroids, 0.38 (0.19, 0.68); OBDs only, 0.48 (0.36, 0.61); and corticosteroids only, 0.49 (0.31, 0.73). Among patients with no serious CVD history, IRs were generally lower but results were not materially different from the main analyses.

Conclusion: Rates of MI, stroke, and revascularization were low for treated PsA patients and were similar across treatments.

The Performance of a Multi-marker Genetic Test to Identify Patients with Psoriatic Arthritis Among Psoriasis Patients

Lihi Eder,[1] Quan Li,[2] Dana Jerome,[3] Chandra Farrer,[4] Proton Rahman,[5] and Tanya N. Burry[6], [1]Women's College Hospital and the Department of Medicine, University of Toronto, Toronto, Canada, [2]Toronto Western Hospital, Toronto, Canada, [3]University of Toronto, Toronto, [4]University of Toronto, Toronto, Canada, [5]Memorial University, Newfoundland, NL, Canada, [6]Memorial University, St. Johns, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Improved understanding of the complex genetic architecture of PsA along with the reduction in the cost of genetic testing provide an opportunity to assess the application of genetic testing for PsA diagnosis in clinical setting. The study aimed to assess the performance of the multi-SNP genetic test in predicting a clinical diagnosis of PsA by a rheumatologist among psoriasis patients with musculoskeletal symptoms.

Methods: 328 patients with psoriasis and musculoskeletal symptoms that were referred to a rapid access clinic for suspected PsA were enrolled. Patients with a prior diagnosis of PsA were excluded. A rheumatologist evaluated all patients and classified them as "PsA" or "not PsA". All patients who were classified as not PsA at baseline were reassessed 1 year later to determine whether they have developed PsA. We tested 2 outcomes: 1) diagnosis of PsA at baseline; and 2) diagnosis of PsA at baseline or at 1 year. A custom multi-SNP genetic assay was genotyped on a

Table 1 – The association between genetic markers and psoriatic arthritis (selected top markers)

Chrom	SNP	Gene	PsA diagnosis at baseline (N=78)			PsA diagnosis at 1 year (N=95)		
			OR	95% CI	P value	OR	95% CI	P value

MassARRAY system (Agena Biosciences). The custom PsA weighted genetic panel included 42 variants in or near 20 genes based on genome-wide significance in PsA studies. We tested the ability of each genetic maker individually to predict PsA using logistic regression models adjusted for age and sex. Machine-learning methods including logistic regression, naïve bayes and random forest were used to identify the optimal prediction model. Age and sex were included in the prediction models.

Results: 78 patients were classified as PsA (PsA-baseline) and the remaining 250 patients as not PsA. After 1 year, 17 additional patients developed PsA resulting in 95 patients with PsA at 1 year (PsA-1 year). The association between the tested SNPs and PsA is shown in Table 1. Five SNPs located at LCE3A (rs10888503), TNIP1 (rs146571698) and IL-23R (rs4655683, rs2201841 and rs12044149) were associated with PsA-baseline or PsA-1 year (all $p< 0.05$). Of the three machine-learning methods used, logistic regression was found to have the best prediction properties (highest AUC). Overall, the performance of prediction models to classify patients as PsA was modest (see Table 2). The AUC, sensitivity and specificity of the models to predict PsA at baseline were: 0.62, 0.15, 0.97, respectively and at 1 year: 0.62, 0.15, 0.94.

Conclusion: Despite the association of several genetic markers with PsA, genetic testing has only a marginal effect on predicting a diagnosis of PsA among patients with psoriasis and musculoskeletal symptoms.

Static and Longitudinal Construct Validity of PROMIS CAT and Profile29 for Assessing Pain Interference, Physical Function and Fatigue in Psoriatic Arthritis

Ana-Maria Orbai,[1] Jamie Perin,[2] Albert W Wu,[3] Katherine C. Smith,[4] and Clifton Bingham[5], [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Public Health, Department of International Health, Baltimore, [3]Johns Hopkins University Bloomberg School of Public Health, Department of Health Policy and Management, Baltimore, MD, [4]Johns Hopkins University Bloomberg School of Public Health, Department of Health, Behavior and Society, Baltimore, MD, [5]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, physical function and fatigue are outcomes reported as having the greatest importance to people with psoriatic arthritis (PsA)[1,2]. We assessed these outcomes in participants in a longitudinal PsA study using Patient Reported Outcomes Measurement Information System (PROMIS) measures, which have not been used before in PsA, concomitantly with measures of PsA-specific disease activity and patient reported outcomes. The objective was to assess construct validity of PROMIS measures in PsA.

PROMIS Instrument T-scores and VAS and HAQ-DI scores	*Visit 1*	*Visit2*	*Change v2-v1*
Mean (SD)	*(n=100)*	*(n=93)*	*(n=93)*
PROMIS29 Pain Interference	55.5 (9.2)	54.8 (9.9)	-0.97 (6.1)
PROMIS-CAT Pain Interference	55.9 (9.4)	55.1 (9.9)	-0.92 (6.8)
Pain VAS (0-100)	36.1 (28.7)	34.5 (28.9)	-2.3 (23.7)
PROMIS29 Physical Function	43.0 (9.4)	44.1 (9.7)	1.0 (4.8)
PROMIS-CAT Physical Function	43.8 (10.3)	45.0 (10.0)	1.1 (4.0)
PROMIS-CAT Mobility	44.2 (9.3)	44.9 (9.3)	0.4 (4.1)
HAQ-DI (0-3)	0.7 (0.8)	0.6 (0.7)	-0.06 (0.3)
PROMIS29 Fatigue	53.8 (10.7)	53.2 (10.7)	-0.9 (7.3)
PROMIS-CAT Fatigue	54.1 (10.7)	53.0 (11.0)	-1.1 (7.2)
Fatigue VAS	41.7 (32.2)	38.0 (30.1)	-5.4 (23.2)

Table 1. Consecutive visit scores and change scores for PROMIS and legacy measures

Spearman correlation coefficients	*Rho (v1)*	*Rho (v2)*	*Rho (v2-v1)*
T-scores		*Pain VAS (0-100mm)*	
PROMIS29 Pain Interference	0.79 (0.69, 0.90)	0.86 (0.80, 0.92)	0.64 (0.49, 0.78)
PROMIS-CAT Pain Interference	0.78 (0.68, 0.88)	0.88 (0.83, 0.93)	0.54 (0.37, 0.72)
T-scores		*HAQ-DI (0-3)*	
PROMIS29 Physical Function	-0.88 (-0.94, -.83)	-0.87 (-0.92, -0.81)	-0.56 (-0.71, -0.40)
PROMIS-CAT Physical Function	-0.87 (-0.92, -0.83)	-0.86 (-0.91, -0.81)	-0.30 (-0.51, -0.08)
PROMIS-CAT Mobility	-0.84 (-0.91, -0.77)	-0.85 (-0.91, -0.79)	-0.33 (-0.51, -0.15)
T-scores		*Fatigue VAS (0-100mm)*	
PROMIS29 Fatigue	0.89 (0.84, 0.94)	0.89 (0.85, 0.94)	0.66 (0.53, 0.80)
PROMIS-CAT Fatigue	0.83 (0.75, 0.91)	0.86 (0.80, 0.93)	0.34 (0.13, 0.54)

Table 2. Spearman correlations (rho) between PROMIS and legacy measure, for point scores at consecutive visits and change scores between the visits

Methods: Participants were followed quarterly in conjunction with rheumatology clinical care visits. Disease activity was assessed using the clinical Disease Activity Score in Psoriatic Arthritis (cDAPSA), Minimal Disease Activity (MDA) state, and their components: 68 tender joint counts, 66 swollen joint counts, Leeds Enthesitis Index (LEI), patient global assessment visual analog scales (VAS) of arthritis/psoriasis and PsA, pain VAS, and Health Assessment Questionnaire Disability Index (HAQ-DI). Pain interference, Physical function/Mobility, and Fatigue PROMIS-Profile29 short forms and computer adaptive test (CAT) were also collected. Spearman correlation coefficients (rho) were computed between PROMIS Pain Interference and Pain Visual Analog Scale (VAS), PROMIS Physical Function/Mobility and HAQ-DI, and PROMIS Fatigue and Fatigue VAS to assess construct validity of point scores (at both visits) and change scores (between the two visits). Approximate 95% confidence intervals for rho were constructed by bootstrapping. We hypothesized moderate to high correlations for point scores (>0.6) and due to measurement error, low to moderate correlations for change scores (>0.2).

Results: One hundred participants had a baseline visit and 93 a second study visit, all met CASPAR PsA classification criteria. Mean age (SD) was 52 (12) years, PsA disease duration 17.7 (13) years, 88% were white and 60% female. At baseline, mean (SD) 68 tender and 66 swollen joint counts were 3.2 (4.9) and 3.1 (3.7), 8% had enthesitis, 3% dactylitis; mean(SD) HAQ-DI was 0.7(0.8), PsAID 3.21 (2.4), pain VAS 36 (28.7)mm, and patient global PsA 37.7 (31.7)mm. MDA state was met by 50% and DAPSA treat-to-target by 55%. Participants were treated with biologicals alone or in DMARD combination (44% TNFi, 5% IL17i, 6% IL12/23i), and 45% with DMARD alone. Visit and change PROMIS scores are shown in Table 1 and were higher/worse than the general population (reference T-score of 50) for Pain interference and Fatigue and lower/worse for Physical Function/Mobility. As hypothesized, correlations between point scores of PROMIS and corresponding instruments were high at both visits (>0.8) and correlation between change scores were low to moderate (>0.3) (Table 2).

Conclusion: PROMIS Profile29 short forms and corresponding PROMIS CAT Pain interference, Physical Function/Mobility and Fatigue have good construct validity for assessing PsA symptoms and life impact in both cross-sectional and longitudinal analyses. PROMIS measures can be used in psoriatic arthritis clinical care and research.

PROMIS Profile29 Differentiates Active Disease from Treat-to-Target State in Psoriatic Arthritis

Ana-Maria Orbai,[1] Rebecca Manno,[2] Jamie Perin,[3] Noori Kim,[4] Katherine C. Smith,[5] Albert W Wu,[6] Clifton Bingham,[7] and Uzma Haque[2], [1]Division of Rheumatology, Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Division of Rheumatology, Baltimore, MD, [3]Johns Hopkins University School of Public Health, Department of International Health, Baltimore, [4]Johns Hopkins University School of Medicine, Department of Dermatology, Baltimore, MD, [5]Johns Hopkins University Bloomberg School of Public Health, Department of Health, Behavior and Society, Baltimore, MD, [6]Johns Hopkins University Bloomberg School of Public Health, Department of Health Policy and Management, Baltimore, MD, [7]Johns Hopkins University, Baltimore, MD

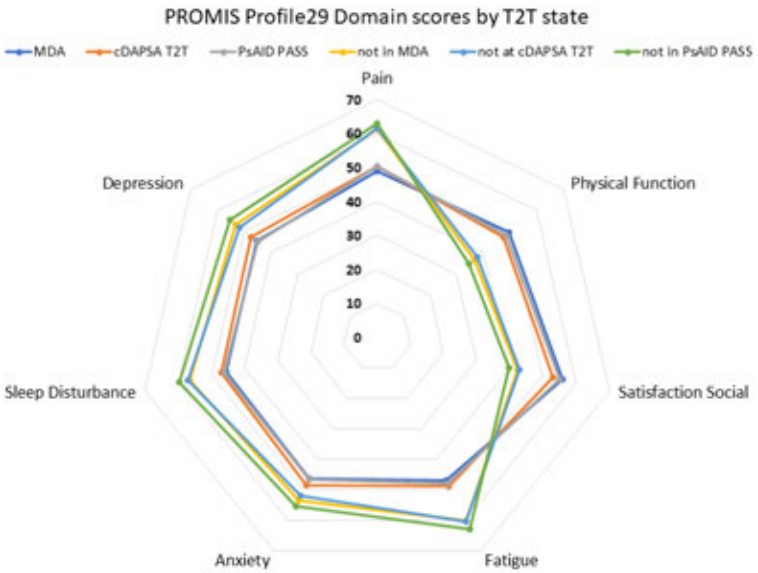

Figure 1. PROMIS Profile29 domain scores at visit1 in Psoriatic Arthritis treat-to-target (T2T) states defined by Minimal Disease Activity (MDA), clinical Disease Activity in Psoriatic Arthritis (cDAPSA) and Psoriatic Arthritis Impact of Disease (PsAID) patient acceptable symptom state (PASS). Mean domain scores in paired T2T states (T2T vs not T2T) are different with statistical significance p<0.001 for MDA; p<0.05 for CDAPSA except for anxiety (p=0.06); and p<0.0001 for PsAID PASS;

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

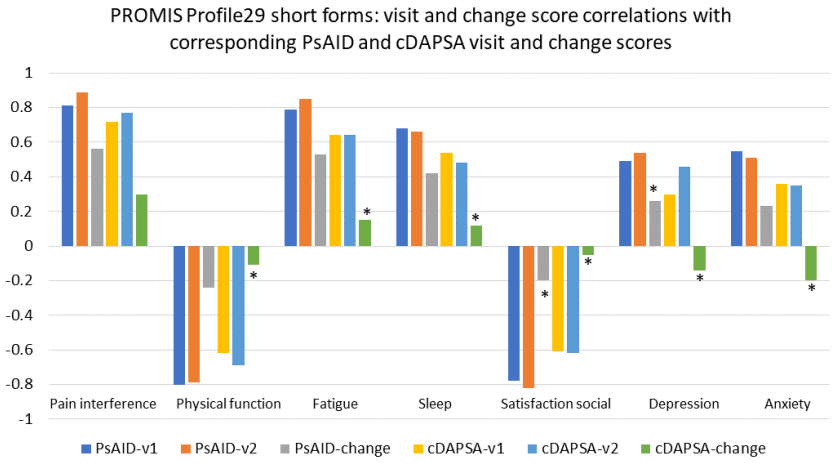

Figure 2. PROMIS Profile29 visit (v1 and v2) and change scores (v2-v1) correlations with corresponding PsAID and cDAPSA visit and change scores (all significant with p<0.05, except if marked with * correlation is not significant)

Background/Purpose: Psoriatic arthritis (PsA) symptoms and quality of life are core domains for PsA assessment[1]. The PROMIS Profile29 measures symptoms and quality of life using a T-score metric referenced to the general population, and has not been used in PsA before. The objective was to assess construct validity of the PROMIS Profile29 in PsA.

Methods: Participants with PsA were followed every 3-6 months in conjunction with rheumatology clinic visits. The PROMIS Profile29 was collected concomitantly with PsA specific measures: clinical Disease Activity Score in Psoriatic Arthritis (cDAPSA), Minimal Disease Activity (MDA), and the Psoriatic Arthritis Impact of Disease (PsAID)[2]. Multiple anchors were used to define treat-to-target (T2T) status: MDA vs not MDA[3], cDAPSA T2T (cDAPSA< 14) vs not[3], and the PsAID patient acceptable symptoms state (PsAID score< 4)[2]. We hypothesized mean PROMIS scores will be worse in patients not at T2T vs T2T, and that correlations with PsAID and cDAPSA will be moderate-high and low-moderate, respectively. We hypothesized lower correlations between change scores versus point scores due to measurement error.

Results: One hundred participants had a baseline visit and 93 a second study visit, all met CASPAR PsA classification criteria. Mean age (SD) was 52 (12) years, PsA disease duration 17.7 (13) years, 88% were white and 60% female. At baseline, mean (SD) tender (out of 68)/swollen (out of 66) joints were 3.2 (4.9)/3.1 (3.7), 8% had enthesitis, 3% dactylitis; mean(SD) HAQ-DI 0.7(0.8), PsAID 3.21 (2.4), pain VAS 36 (28.7)mm, patient global PsA 37.7 (31.7)mm. MDA state was met by 50% and DAPSA treat to target (T2T) by 55%. Treatment included biologicals alone/in DMARD combination in 55% and DMARD alone in 45%. PROMIS Profile29 T-scores (Figure 1) were significantly better across all domains for participants at T2T versus not, using MDA status and PsAID PASS. cDAPSA T2T status grouping yielded similar results, except for PROMIS Anxiety which was not significantly different. Results were consistent at both visits. Spearman correlations with PsAID were very high (>0.8) for PROMIS Profile29 Pain interference, Physical function, Fatigue and Satisfaction with social roles, high (>0.6) for Sleep, and moderate (>0.4) for Depression and Anxiety. Correlations with cDAPSA were high for Pain, Physical function, Fatigue and Satisfaction, moderate with Sleep, and low with Depression and Anxiety. Change score correlations were in the expected direction and lower than point correlations between Profile29 forms and PsAID, except for Depression (not significant). Change score correlations with cDAPSA were low and significant for Pain interference but not the other domains.

Conclusion: PROMIS Profile29 differentiated PsA T2T state from active disease using multiple anchors. Point PROMIS Profile 29 T-scores had moderate-high correlation with PsAID scores; and change scores had low-moderate correlation with PsAID change scores, meeting pre-specified hypotheses. The PROMIS Profile29 can be used to assess clinical status in PsA and it aligns with PsA specific disease activity and life impact measures.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis, a characteristic clinical feature of psoriatic arthritis (PsA) [1], is a core outcome for PsA clinical trials. While enthesitis is considered important when treating patients with PsA [2], there is limited evidence to show the impact of enthesitis on patient reported outcomes (PROs) and physician satisfaction with treatment in the real-world. The objective of this analysis is to describe the impact of enthesitis on PROs and physician satisfaction with treatment in a real-world setting.

Methods: Cross-sectional survey of rheumatologists, dermatologists, and their consulting PsA patients in Australia, Canada, EU5, and US, conducted by Adelphi from 2018-2019. Physicians assessed current presence and severity (mild, moderate, or severe) of enthesitis, overall PsA disease severity, symptoms experienced, and their satisfaction with disease control the current treatment provides (5-point Likert scale: very satisfied to very dissatisfied). Patient self-reported data included current level of pain (1-10 scale), EQ-5D, Psoriatic Arthritis Impact of Disease (*PsAID12*), Health Assessment Questionnaire Disability Index (HAQ-DI) and Work Productivity and Activity Impairment Index

	Overall (N=3157)	With enthesitis (N=205)	Without enthesitis (N=2952)	P-value

Table 2: Patient reported outcomes

(WPAI-SHP). Bivariate descriptive analyses were conducted to describe features and outcomes in patients with and without enthesitis.

Results: Rheumatologists (454) and dermatologists (238) provided information related to enthesitis for 3157 PsA patients with 653 patient self-completed questionnaires. Mean (SD) age was 49.2 (13.3) years, mean (SD) body mass index 26.9 (6.5), 45.9% were female and 57.4% were in full-time employment. Enthesitis was present in 6.5% (205) of PsA patients surveyed. Patients with current enthesitis had worse overall disease severity compared to patients without enthesitis (12.2% vs. 2.2% severe) [Table 1]. Patients with enthesitis had more extraarticular manifestations, including nail deformities, dactylitis, sacroiliitis and inflammatory back pain than patients without enthesitis [Table 1]. Enthesitis was associated with more pain, worse quality of life (QoL), more disability, and a greater impact on work [Table 2]. Patients with enthesitis had increase NSAID and opioid pain medication use, but similar biologic use (with enthesitis 58.5% vs. without enthesitis 58.5%, p=1.0000). Physicians were significantly less satisfied with the control the current treatment provided in patients with enthesitis vs without enthesitis (57.6% vs 84.3% satisfied, p< 0.0001).

Conclusion: PsA patients with enthesitis had more severe disease and experienced worse QoL than patients without enthesitis but were not more likely to receive advanced therapies. Physicians were significantly more dissatisfied with treatment for patients with enthesitis than those without.

Validity of Patient-reported Cardiovascular Events in a Large Longitudinal Cohort of Patients with Psoriatic Arthritis and Psoriasis

Keith Colaco,[1] Vinod Chandran,[2] Dafna Gladman,[3] and Lihi Eder[4], [1]University of Toronto, Women's College Hospital, University Health Network, Toronto, ON, Canada, [2]University Health Network, University of Toronto, Toronto, Canada, [3]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [4]Women's College Hospital and the Department of Medicine, University of Toronto, Toronto, Canada

Table 1. Performance of rheumatologist-assessed cardiovascular event ascertainment

Cardiovascular Outcome	Number of events	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Any cardiovascular event	402	87.2	99.1	90.6	98.8
Angina	99	82.1	83.3	75.3	88.2
MI	88	88.2	90.6	84.8	92.8
Revascularization	101	48.0	99.0	98.0	66.5
CHF	48	56.4	94.5	71.0	90.2
CVA	42	81.8	94.7	75.0	96.4
TIA	24	33.3	98.3	70.0	92.6
CHF, congestive heart failure; CVA, cerebrovascular accident; MI, myocardial infarction; NPV, negative predictive value; PPV, positive predictive value; TIA, transient ischemic attack					

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Valuable information on cardiovascular disease outcomes can be obtained from large cohort studies. Such studies often rely on self-reported events, which are best validated with linkage to administrative data or review of electronic medical records. Given the increased risk of cardiovascular disease in patients with inflammatory rheumatic diseases, we aimed to assess the validity of patient-reported and physician-recorded cardiovascular events in a large cohort of patients with psoriatic disease.

Methods: Patients enrolled in a prospective cohort study from 1978 to 2018 were included in the analysis. Participants are assessed by a rheumatologist at 6-12 month intervals according to a standardized protocol that includes information about co-morbidities. Typically, patients report their co-morbidities which are recorded by the physician. The information is stored in a computerized database. We searched the database for records of cardiovascular events recorded during the follow-up period. Cardiovascular outcomes included angina, myocardial infarction (MI), revascularization procedures, congestive heart failure (CHF), cerebrovascular accident (CVA) and transient ischemic attack (TIA). The accuracy of the outcomes was verified by linkage to hospital discharge databases and review of medical records, which was considered as the gold standard ascertainment method. The validity of cardiovascular events by rheumatologists was assessed by calculating sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV).

Results: 2,171 patients with psoriatic disease (1498 with psoriatic arthritis, 673 with psoriasis only) were followed in the cohort from 1978 to 2018. The mean duration of follow-up for patients with psoriatic arthritis and psoriasis only was 10.2 years and 4.1 years, respectively. During this period, 204 (9.4%) patients reported 402 events (Table 1). Sixty-three events from the lost-to-follow up period were excluded. Overall the accuracy of patient-reported cardiovascular events was good to excellent. The sensitivity, specificity, PPV, NPV for any cardiovascular event was 87%, 99%, 91%, 99%, respectively. A similar pattern of results was observed for angina, MI and CVA. Identification of TIA showed poor sensitivity (33%), followed by revascularization (48%) and CHF (56%). NPV of all outcomes were excellent, with the exception of revascularization.

Conclusion: Ascertainment of self-reported cardiovascular events by rheumatologists is fairly accurate for identifying incident occurrences of cardiovascular events. Additional methods, such as record linkage and chart review, could be used to identify events not captured by conventional methods.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with psoriasis and psoriatic arthritis (PsA) can develop a variety of comorbidities which may influence the therapeutic regimen and affect treatment results. Previous studies show a high incidence of coexistence of psoriasis and systemic lupus erythematosus (SLE). Unlike psoriasis, the coexistence of PsA and SLE has been reported only in case reports.

Objective: To assess the prevalence of SLE in a PsA patient cohort and to compare it to the general population using the database of a large health care provider.

Methods: A retrospective database study consisting of a PsA cohort matched for age and sex with randomly selected control patients was conducted on patient data from 2002-2017, including demographics, clinical and laboratory manifestations of SLE and dispensed medications including SLE-inducing drugs. Statistical analysis was conducted using Student's t-test or Chi square test, as appropriate. In the PsA group, incidence density sampling procedure (SAS v9.4) was performed matching PsA patients without co-existing SLE as controls to each case of PsA with co-existing SLE by age and follow-up time which was defined as date of SLE diagnosis. Univariable and multivariable conditional logistic regression analysis were used to assess the influence of drugs, age at PsA diagnosis, PsA duration on development of SLE. All tests were 2-sided; p values of < 0.05 were considered statistically significant.

Results: The PsA study group consisted of 4836 subjects, median age of 56+/-15, 2603 (53.8%) of whom were female. The control group consisted of 24180 subjects matched for age and sex. Eighteen patients (0.37%) in the PsA study group and 39 patients (0.16%) in the control group where diagnosed with SLE (p=0.002). SLE patients without co-existing PsA had higher anti-double stranded DNA positivity (92.3% vs 66.7%, p=0.022) and positive

anti-cardiolipin antibodies (46.2% vs 16.7%, p=0.041). No other significant differences were observed between the two groups in terms of SLE clinical and laboratory manifestations. PsA patients with concomitant SLE compared to PsA patients without SLE were more often female (100% vs 53.7%, p< 0.0001), had more osteoporosis (38.9% vs 12.8%, p=0.005) and were more likely to be treated with beta blockers (27.8% vs 9.8% p=0.027). Usage of drugs with known potential to induce SLE prior to diagnosis of SLE was higher in the PsA than in the control group (11 out of 18 patients), but there was no difference in SLE manifestations between the groups. Univariable and multivariable conditional logistic regression analysis showed that older age at PsA diagnosis (p=0.001, p=0.008, respectively), shorter PsA duration (p= 0.06, p=0.03) and statin treatment (p=0.01, p=0.012) were associated with SLE in PsA patients.

Conclusion: A 2.3 fold increase in the prevalence of SLE in PsA patients relative to control group was found in our study population. Risk factors for SLE development included older age at PsA diagnosis, shorter PsA duration, and statin treatment. The positive correlates between SLE and PsA may point to common underlying pathogenetic pathways and may affect treatment choices and medication development.

Predictors of Structural Progression in Psoriatic Arthritis: Clinical versus Systemic Inflammation

Carina Borst,[1] Farideh Alasti,[2] and Daniel Aletaha[3], [1]Division of Rheumatology, Department of Medicine III, Medical University of Vienna, Vienna, Austria, [2]Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria, [3]Medical University of Vienna, Vienna, Austria

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) belongs to the group of the spondylarthropathies. It is associated with psoriasis and typically seronegative for autoantibodies. PsA disease activity can be measured using the Disease Activity in Psoriatic Arthritis (DAPSA) score which is based on both clinical (e.g., swollen joint count, SJC) and systemic (e.g., C-reactive protein, CRP) markers of inflammation. However, the impact of clinical and systemic inflammation on structural progression is unclear. In this analysis, our aim was to determine the contribution of clinical and systemic inflammation to structural progression of patients with PsA.

Methods: In a secondary data analysis, we analyzed patient data from the IMPACT 2 trial of infliximab (INF) vs. placebo (PLC) in patients with established PsA (disease duration in years: INF: 7.5±7.8, PLC: 8.4±7.2). Concomitant methotrexate treatment was allowed but not mandatory in both treatment arms. We obtained modified Sharp-van-der-Heijde scores from X-rays performed at baseline and after one year to compute radiographic progression. We further extracted levels of SJC and CRP and calculated time-averaged SJC (taSJC) and CRP (taCRP) values to reflect the clinical and systemic inflammation, respectively. In a multivariable binary logistic regression model, we assessed the impact of taSJC, taCRP, and their interaction, on structural progression. Next, we divided patients into different subgroups depending on their taSJC and taCRP levels into active (+) or inactive (-). We tested whether radiographic progression was different in taSJC+ vs. taSJC- and taCRP+ vs. taCRP- using the Mann-Whitney-U-test.

Results: We analyzed available data of 151 patients (76 PLC, 75 INF). Patients in the INF arm showed no radiographic progression (-1.16±3.96), while patients in the PLC arm showed little progression (0.74±2.98). We therefore focused on the 76 PLC patients. Despite the small overall progression, taSJC, taCRP, and their interaction were associated with radiographic progression (OR for taSJC: 1.24, CI 95 %: 1.04-1.47, p=0.016; OR for taCRP: 6.08, CI 95%: 1.12-33.03, p=0.036; interaction term: p=0.097). Radiographic progression was higher in taSJC+ patients compared to taSJC- patients (1.05±3.21 and 0.56±2.30, respectively; p=0.016), as well as numerically higher without statistical significance in taCRP+ vs. taCRP- patients (1.14±3.23 and 0.05±2.37, respectively; p=0.532). Also, despite the limited power of subgroup analyses, there was evidence that SJC activity plays a role in CRP- patients (p=0.076), whereas CRP activity seems to be of less importance SJC- patients (p=0.643).

Conclusion: In patients with PsA, both clinical and systemic inflammation have impact on structural progression; in patients without systemic inflammation, clinical joint activity may still be considered as a risk factor for progression.

Effect of Obesity and Surgical Weight Loss on Joint Surgery Hospitalizations in Psoriatic Arthritis: Data from National Inpatient Sample

Rashmi Dhital,[1] Dilli Ram Poudel,[2] Anthony Donato,[3] Olubunmi Oladunjoye,[4] and Paras Karmacharya[5], [1]Reading Hospital ,PA, Shillington, PA, [2]University of Pennsylvania, Philadelphia, [3]Reading Hospital, PA, Reading, [4]Reading Hospital, PA, West Reading, PA, [5]Reading Hospital, Mayo Clinic, Rochester

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity is associated with higher disease activity and poor treatment response in patients with psoriatic arthritis (PsA). However, there is limited data as to how weight loss strategies affect outcomes in PsA. The aim of our study was to compare joint surgery hospitalizations (as a surrogate marker of significant radiographic damage and progression) among (1) obese and non-obese PsA patients; (2) obese PsA patients without and with a history of bariatric procedure and subsequent weight loss.

Methods: National Inpatient Sample (2001-2014) was used to identify patients ≥ 18 years with PsA using ICD-9 code 696.0. To increase the specificity, we excluded patients with RA (ICD-9 code 714.0) and AS (ICD-9 code 720.0) (Figure 1). For each patient with PsA, a matched control of the same age (± 1 year), sex, race/ethnicity and NIS stratum (based on hospital's census region or division, ownership/control, location/teaching, and bed size) was randomly selected. We compared hospitalizations for joint surgeries among obese and non-obese PsA patients. Joint surgeries related to trauma/fracture were excluded. Secondly, we performed univariate and multivariate regression to compare joint surgery hospitalizations among PsA patients with a history of bariatric procedure vs. those without bariatric procedure. For this analysis, hospitalizations prior to 2006 were excluded as the ICD-9 code for history of

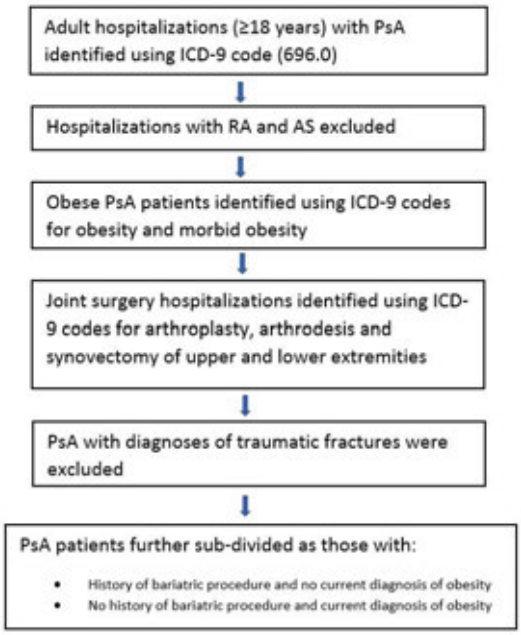

Figure 1. Flow chart showing the selection of PsA patients with joint surgery hospitalizations

bariatric procedure (V45.86) did not exist. Patients with current hospitalization for bariatric surgery were excluded to avoid confounding in the time gap between surgery and weight loss. Patients with a diagnosis of obesity were excluded from the group with a history of bariatric procedure in order to identify post-bypass patients who were no longer obese.

Results: In 2001-2014, there were 266,096 PsA hospitalizations. Among them, 44,055 (16.6 %) PsA patients had obesity or morbid obesity compared to 11.6% in the general population ($p < 0.001$). The overall hospitalization for joint surgeries in PsA was 7.42%. The rates of joint surgeries were significantly different among obese versus non-

	Overall PsA	PsA with obesity	PsA with no obesity	P value
Hospitalizations for joint surgery (%) (arthroplasty, arthrodesis or synovectomy)	7.42	9.55	7	<0.001
Female (%)	7.85	9.61	7.43	<0.001
Mean age for joint surgery hospitalizations (years)	61.61±10.59	59.68 ± 9.42	62.13± 10.83	<0.001

Table 1- Hospitalizations for joint surgery in obese and non-obese psoriatic arthritis patients (2001-2014)

	Univariate analysis	Multivariate analysis ***
History of bariatric surgery and no current obesity (ref: no history of bariatric surgery and current obesity diagnosis)	0.77 (0.51 – 1.18), p=0.24	0.84 (0.54 – 1.27), p =0.4

Table 2- Univariate and multivariate regression analyses of risk of joint surgery hospitalizations in patients with psoriatic arthritis treated with bariatric surgery (2006-2014) *** Multivariate analysis adjusted for age, gender, insurance status, hypertension, diabetes mellitus, dyslipidemia, current smoking status, hospitalization year and NIS stratum

obese PsA hospitalizations (9.55 % vs 7.0%, p< 0.001) (Table 1). Mean age of joint surgery was 59.68 ± 9.42 years vs. 62.13± 10.83 years (p< 0.001) in obese PsA compared to non-obese PsA patients (Table 1). In the years 2006-2014, a total of 1,640 (0.91%) PsA hospitalizations had a history of bariatric surgery with no current diagnosis of obesity. There was no significant difference in overall joint surgery hospitalizations among these surgically treated formerly obese patients compared to currently obese PsA patients with no history of bariatric surgery (OR 0.83, 95% CI 0.54 – 1.27, p=0.4)(Table 2).

Conclusion: Our study showed obese PsA patients had higher hospitalizations for joint surgeries compared to non-obese patients. However, no difference was noted in joint surgery hospitalizations among PsA patients without and with a history of bariatric procedure and not currently obese. While few studies have shown improvement in disease activity after weight loss, the benefit of weight loss might be more in early PsA. Further longitudinal studies should explore the short and long-term effect of weight loss on PsA disease outcomes.

Background/Purpose: Frailty, a state of decreased homeostatic reserve, is associated with increased disability and mortality, independent of age. Frailty has been evaluated in large datasets using validated algorithms in the elderly. Although frailty has been investigated in several rheumatic diseases, including RA, to our knowledge, frailty has not been investigated in AS and PsA, which often affect younger patients. In this study, we evaluated the prevalence of frailty among patients < 65 years old with AS and PsA compared to RA in a national claims database.

Methods: We performed a cross sectional study of Centers for Medicare and Medicaid Services (CMS) Medicare beneficiaries (Part A and B) from 2014 who were < 65 years old. Patients with an ICD-9-CM code for AS, PsA, or RA on 2 occasions ≥7 days apart within a year or 1 ICD-9-CM code and ≥1 DMARD prescription (from Part D) were included. Patients with SLE, IBD, cancer, human immunodeficiency virus, end stage renal disease, skin psoriasis, or organ transplantation were excluded. Sociodemographic characteristics, Charlson-Deyo score (CDS), and previously published frailty components [1] were compared between those with AS/PsA and RA. Frailty was defined as presence of ≥2 components [1] (Table 2). Logistic regression was used to determine the odds of being frail in AS/PsA and RA, adjusting for age, gender, race/ethnicity, and CDS.

Results: 6485 AS/PsA and 50744 RA beneficiaries were identified. AS/PsA patients were more often white (81.6% v. 68.4%, p< .0001), male (49.9% v. 21.6%, p< .0001), and younger (37.4% v. 23.3% ≤ 50 years old, p< .0001) as compared to those with RA (Table 1). Enrollees with AS/PsA had lower CDS than those with RA (p< .0001). Fewer patients with AS/PsA were frail (0.77%) compared to those with RA (1.16%) (p=.005) (Table 2). Several frailty components, including gait abnormality (p=.003), debility (p=.01), difficulty walking (p=.01), and decubitus ulcer (p=.006), were less common in those with AS/PsA. After adjustment for confounders, odds of frailty did not differ significantly between AS/PsA (OR 0.89, 95% CI 0.66-1.20) and RA.

Conclusion: The prevalence of frailty in AS/PsA was lower than that in RA; however, odds of frailty were similar in both groups after adjustment for confounders. The prevalence of frailty in RA was lower than in prior cohorts of young RA patients [2-3], possibly suggesting that this frailty definition may underestimate frailty prevalence. Data analysis is ongoing to compare these findings with models using other validated frailty algorithms. It will be important to have accurate frailty estimates to leverage the information in large administrative datasets to optimize patient outcomes.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Oligoarticular disease in patients with psoriatic arthritis (PsA) is often underdiagnosed and undertreated. The goal of this study is to understand and identify current practices and unmet needs in the treatment of patients with oligoarticular PsA in Canada.

Methods: Twenty-one rheumatologists took part in a 25-minute online survey, conducted in English and French, between December 2018 and January 2019 from multiple locations across Canada. The participating rheumatologists were required to have diagnosed at least 1 patient with PsA currently presenting with 1 to 4 active joints. In addition, the participants were required to review charts of patients with oligoarticular PsA who were at least 18 years of age and had never been treated with apremilast, tofacitinib, or biologics.

Results: Data from the clinical practices of the participating rheumatologists over the 4 weeks before the survey indicated that >50% of patients with PsA presented with oligoarticular disease. A review of 97 charts of patients with

Figure 1. Presentation of Active Joints in Patients With Oligoarticular PsA (N=97)

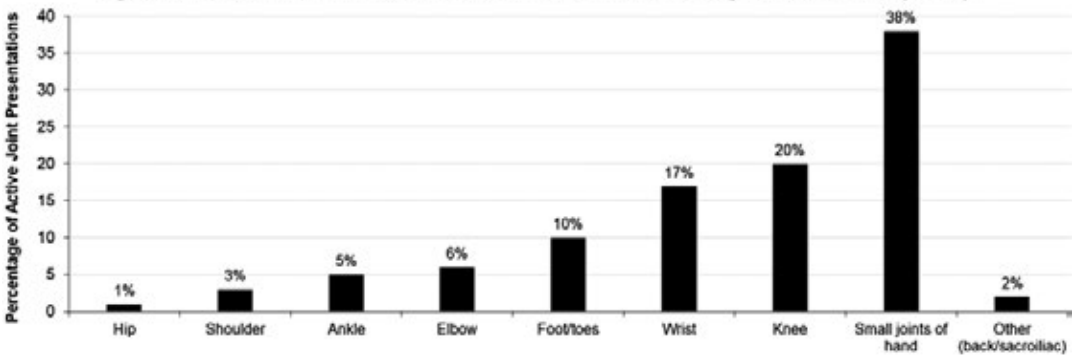

Figure 2. Current and Previous Treatments for the Management of PsA

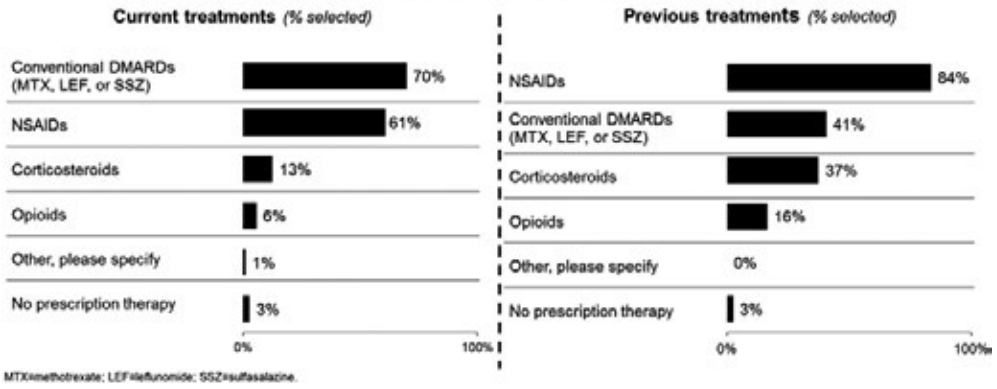

oligoarticular PsA revealed that most (66%) were of working age (25-64 years), had a mean disease diagnosis of 5 years, and presented with 3 active joints on average, the majority of which were swollen. The most frequently mentioned presentation of active joints in patients with oligoarticular PsA was small joints of the hand (38%), knee (20%), and wrist (17%) (**Figure 1**). Patients presented with other manifestations of the disease, particularly skin disease (79%), nail disease (35%), dactylitis (32%), and enthesitis (29%). With respect to treatment, 70% of patients were currently being treated with conventional DMARDs; despite this, non-steroidal anti-inflammatory drugs (NSAIDs), corticosteroids, and opioids continued to be utilized (**Figure 2**). Only 29% of physicians reported being extremely satisfied with their patients' current therapy in terms of overall disease management and were least satisfied with the management of their patients' enthesitis (only 14% extremely satisfied). Participating rheumatologists indicated a preference for switching therapies in 79% of the patients; however, 57% of the participants cited not doing so because of patient hesitation.

Conclusion: Patients with oligoarticular PsA present with manifestations across all disease domains. Despite commonly held beliefs that oligoarthritis predominantly affects large joints, our data suggest that smaller joints, including those of the hand and wrist, are important manifestations of the condition. Patients are not adequately controlled by conventional DMARDs, and physician satisfaction with current therapies remains low.

Use of Complementary and Alternative Medicine (CAM) in a Psoriatic Arthritis Cohort

John RobertsIV,[1] Lisa Mandl,[2] Zafir Abutalib,[1] and **Sergio Schwartzman** [2], [1]Hospital for Special Surgery, New York, NY, New York, NY, [2]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY

SESSION INFORMATION

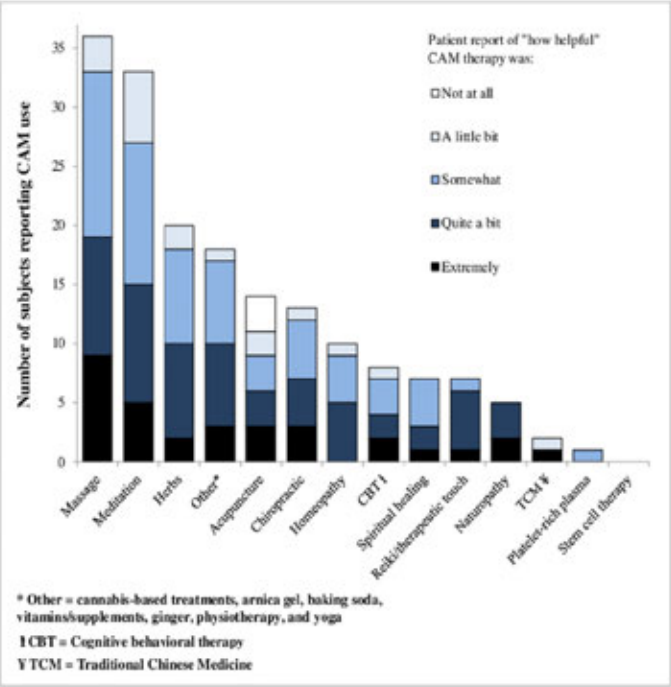
Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Figure 1. Frequency of CAM use (N=68).

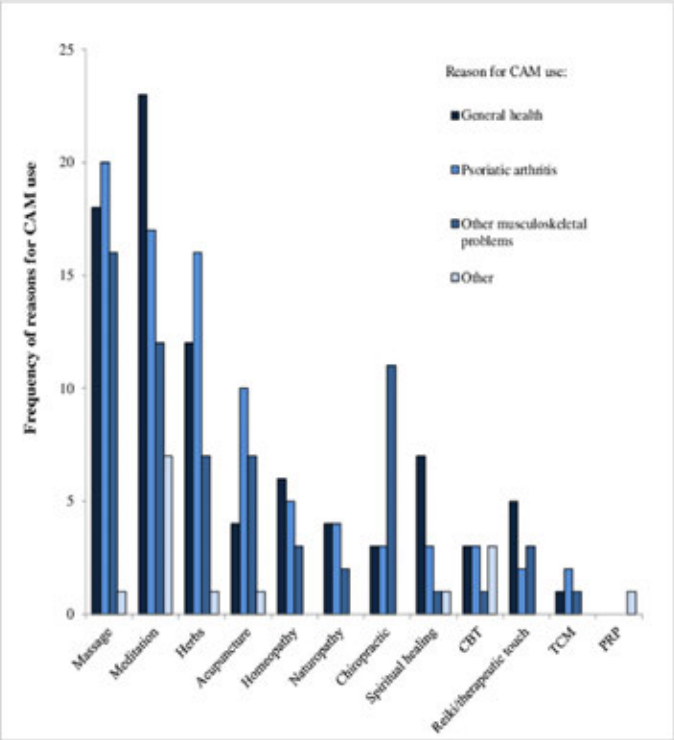


Background/Purpose: Approximately one third of people in the United States use complementary and alternative medicines. While there is published data on the use of CAM in the general population and some disease states, use in patients with psoriatic arthritis (PsA) has not been explored in detail. In this study we evaluated CAM use in an institutional cohort of validated PsA patients.

Methods: PsA patients seen at a single center between January 1, 2013 and December 31, 2017 were identified using ICD-9 and ICD-10 codes. Of those patients identified, patients who met CASPAR classification criteria were enrolled, and current biologic therapies and targeted synthetics were abstracted from chart review. All patients with available email addresses were surveyed regarding their use of CAM in the last 12 months, reason for CAM use, and helpfulness of CAM use. Patients were asked about specific commonly used complementary and alternative medicine treatments, based on literature review. A Wilcoxon rank-sum test was used to compare median age between CAM and non-CAM users. Pearson's chi-squared tests were used for sex and race, and a Fisher's exact test was used to compare biologic and/or targeted synthetic medication use among CAM and non-CAM users.

Results: 328 subjects were sent the questionnaire, and the response rate was 39.3% (129/328). 53% had used CAM in the last 12 months (Figure 1). CAM users were younger: 58 years vs. 63 years (p-value: 0.057), and more likely to be female: 64.7% vs 37.7% (p-value: 0.002). There was no association between race and CAM use (p-value: 0.74). The most popular CAMs used were massage, meditation, and herbs. Reasons for use of CAMs: 34.0% for PsA, 34.4% for general health, 25.6% for other musculoskeletal problems, and 6.0% for other reasons (Figure 2). 26.5% of patients reported using CAM not listed in the questionnaire. These included: cannabis-based treatments, arnica gel, baking soda, vitamins/supplements, ginger, physiotherapy, and yoga.

Figure 2. Patient-reported reason for CAM use.*



* For each CAM, subjects had the option of indicating multiple reasons for use.

Table 1. Biologic and/or targeted synthetic use among CAM and non-CAM users.

	CAM users (n=68) N (%)	Non-CAM users (n=61) N (%)
Biologics	**35 (51.5)**	**35 (57.4)**
Adalimumab	12 (17.6)	11 (18.0)
Etanercept	4 (5.9)	7 (11.5)
Secukinumab	10 (14.7)	10 (16.4)
Infliximab	1 (1.5)	5 (8.2)
Ustekinumab	1 (1.5)	2 (3.3)
Certolizumab	2 (2.9)	0 (0.0)
Golimumab	1 (1.5)	2 (3.3)
Ixekizumab	2 (2.9)	1 (1.6)
Rituximab	2 (2.9)	0 (0.0)
Guselkumab	0 (0.0)	1 (1.6)
Targeted Synthetics	**3 (4.4)**	**8 (13.1)**
Apremilast	2 (2.9)	8 (13.1)
Tofacitinib	1 (1.5)	0 (0.0)
Overall	**38 (55.9)**	**43 (70.5)**

Overall, 18.4% found CAM use to be extremely helpful; 33.9% quite a bit helpful; 35.6% somewhat helpful; 10.3% a little bit helpful; 1.7% not at all helpful. Although not statistically significant, CAM users were less likely to be on biologics and/or targeted synthetic medications than were non-CAM users (55.9% vs. 70.5%; p-value: 0.26) (Table 1).

Conclusion: CAM use is common in a validated PsA cohort, with more than half of respondents reporting use of at least one type of CAM in the last 12 months. CAM use is more common among those not on biologics/targeted synthetics. Further studies are needed to determine whether CAMs are being used in lieu of standard medications used to treat PsA and if CAM use impacts adherence to traditional therapy.

Body Composition and Fat Distribution in Patients with Psoriasis or Psoriatic Arthritis

Eric Toussirot,[1] Francois Aubin,[1] maxime Desmarets,[1] Daniel WENDLING,[2] benoit Augé,[3] jerome Gillard,[4] olivier messica,[4] Xavier Guillot,[1] caroline Laheurte,[5] elisabeth monnet,[1] and gilles dumoulin[1], [1]University Hospital, Besancon, France, [2]Rheumatology, University Teaching Hospital (CHRU), Besançon, France, [3]private office, besancon, France, [4]Centre Hospitalier, Lons le Saunier, France, [5]EFS, besancon, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity is a leading comorbidity in both psoriasis (Pso) and psoriatic arthritis (PsA) and is associated with common metabolic complications and increased cardiovascular (CV) risk. Obesity is also a risk factor for the onset of these diseases. Body composition and fat distribution have been rarely evaluated in Pso and PsA. In this study, we aimed to characterize the fat mass distribution in patients with Pso or PsA compared to a control group, with a special emphasis on the android/visceral region.

Methods: case-control study (NCT02849795). Patients with Pso (plaque psoriasis) or PsA (CASPAR criteria) were evaluated. Each patient was paired to a control subject, recruited in the same outpatient population, and matched for sex, age and body mass index (BMI) category. Clinical assessment included BMI, anthropometric measurements (waist circumference, waist /hip ratio), disease activity (PASI for Pso, CPDAI for PsA) and the SCORE CV risk score. Laboratory parameters of inflammation (ESR, CRP, IL-6), lipid parameters (total cholesterol, LDL and HDL cholesterol, triglycerides), metabolic parameters (glycemia, insulin, HOMA), serum adipokines (total and high molecular weight [HMW] adiponectin, leptin, resistin and retinol binding protein 4 [RBP4]) were measured. Body composition (lean mass, fat mass) and fat distribution (android/gynoid regions and visceral fat) were evaluated (DEXA, Lunar GE, CoreScan). Our primary criteria was the fat mass in the android/visceral region. Comparisons between patients and controls were performed with paired t tests, between all groups with ANCOVA (adjusted for age, sex, and BMI category) and Tukey post-hoc tests. Pearson correlations between CV risk and fat mass were calculated within groups.

	PsA	Controls	Pso	Controls
N	52	52	52	52
Age (years)	52.5 ± 11.7	52.8 ± 11.1	50.5 ± 12.8	50.7 ± 12.9

Table 1 ADIPSO

Table 1: clinical characteristics, laboratory parameters, serum adipokines, metabolic parameters and body composition measurements of patients with Pso and PsA and their respective control subjects (Quantitative variables are presented as mean ± standard deviation; Pso: psoriasis; PsA: psoriatic arthritis; * p <0.05; **p <0.01; ***p<0.005).

Results: 52 patients with Pso and 52 patients with PsA and their respective paired-control were evaluated (Table 1). Total fat mass was increased in Pso but not in PsA. Android fat and visceral fat were found higher in Pso ($p< 0.05$) while the fat mass measurements did not differ between the patients with PsA and their controls. Waist circumference was higher in patients with Pso compared to their controls. Leptin, leptin/fat mass ratio, and total adiponectin were

elevated in PsA while only the HMW/total adiponectin ratio was decreased in Pso. Insulin levels and HOMA were increased in both Pso and PsA groups. Finally, RBP4 was higher in both Pso and PsA patients compared to their respective controls. In patients with Pso, android and visceral fat were correlated with SCORE (r=0.3, p=0.02 and r= 0.6, p < 0.0001 respectively). In ANCOVA analysis, visceral fat was higher in Pso patients (p=0.0029), with a trend toward higher android fat (p=0.055), compared to PsA patients.

Conclusion: visceral fat is increased in patients with Pso but not in PsA. In parallel, both groups showed an elevation of circulating RBP4. Patients with Pso and PsA were also characterized by metabolic disturbances as showed by the increase in HOMA, and specific adipokine changes. In the Pso group, visceral fat is associated with CV risk evaluated by SCORE. Weight control and reduction of fat mass, especially visceral fat mass, may thus be an important concern in patients with Pso and appears less relevant in PsA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The multidisciplinary unit of psoriatic arthritis (PsA) are attractive to improve the early diagnosis and optimize the management of complex patients with PsA. There are published data about different models, activity data and patient satisfaction in this kind os unit. To evaluate its effectiveness, we also need to know the clinical results of patients with PsA who visit them.

The objective of this study is to evaluate the control of the cutaneous and articular activity of the patients with psoriatic arthritis in our multidisciplinary unit.

Methods: We reviewed 199 medical records and included 132 patients with peripheral, mixed or axial PsA, treated with DMARDs or biological therapy (TB), followed up for at least 6 months in our unit. Epidemiological, clinical and skin and joint activity data are collected, evaluating DAPSA, PASI, BSA, PGA and percentage of patients that reach MDA (minimal disease activity). The data is analyzed using SPSSv23.

Results: 132 patients, 65.2% males, with a mean age (SD) of 54.98 (13.99) years, and a time of evolution of 110.37 months (SD 89.77). Diagnosis: 65.9% peripheral PsA, 30.3% mixed and 3.8% pure axial involvement. 68.2% had one comorbidity and 27.3% two or more. 56.8% had a family history of psoriasis and 19.7% of PsA. The presentation of

	DAPSA	PASI	BSA
Nº of patients	121	122	123
Mean	5,6419	3,020	3,721
Median	3,5300	2,000	2,000
Standard Deviation	6,76648	2,9095	3,9312
Minimum	0,06	0,0	0,0
Maximum	54,50	13,00	18,00

Cutaneous and joint activity

			Minimal Disease Activity		Total
			No	Yes	
Remission	(DAPSA < 4) No	Nº of patients %	39 68.4%	18 31.6%	57 100.00%
	(DAPSA < 4) Yes	Nº of patients %	5 7.8%	59 92.2%	64 100.00%
Total		Nº of patients %	44 36.4%	77 63.6%	121 100.00%

Outcome measures

psoriasis was predominantly in plaques (81.8%) and 8.3% in folds. 36.4% had previous enthesitis, 39.4% previous dactylitis. 68.2% had received one DMARD, 37.1% two or more. 22% had received previous biological therapy and 10.6% had received at least two biological drugs. Current treatment: 57 patients (43.1%) received BT and 75 patients received DMARD (only 2.3% receive two DMARDs). BT: 30.3% anti-TNF, 6.1% Ustekinumab, 3.8% Secukinumab and 3.8% Apremilast. Time of current treatment in months: mean 59.79 (SD 58.87). Cutaneous and joint activity: median of DAPSA 3.53 (0.06-54.50), PASI 2 (0-13) and BSA 2 (0-18). PGA from very mild to mild 83.6%, mild PASI 79% and mild BSA 52%. DAPSA of low activity 90.1% and DAPSA of remission (< 4) 59.2%. 62.4% of the patients reached MDA criteria.

Conclusion: We consider that the clinical results of the patients visited in our multidisciplinary clinic are in general, good or very good, even in the subgroup of more complex patients. It would be necessary to carry out an additional cost study to assess its efficiency.

Reliability and Validity of the Self-Administered Comorbidity Questionnaire in Psoriatic Arthritis

Didem Erdem,[1] Halise Hande Gezer,[2] Sevtap Acer Kasman,[1] and Mehmet Tuncay Duruoz[1], [1]Marmara University School of Medicine, PMR Department, Rheumatology Division, İstanbul, Turkey, [2]Marmara University School of Medicine, PMR Department, Rheumatology Division, İstanbul, Istanbul, Turkey

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The Self-Administered Comorbidity Questionnaire (SCQ) is a self-report questionnaire. It assesses 13 common medical conditions and the impact of comorbidities on functional status (1). The aim of this study is to investigate the validity and reliability of the Turkish version of the SCQ in Psoriatic Arthritis (PsA).

	Rho	P value
Convergent validity		
The effect of comorbid diseases on QoL (VAS)	**0.723**	<0.005
Patient global assessment of general health (VAS)	**0.512**	<0.005
HAQ	**0.486**	<0.005
PsAQoL	**0.519**	<0.005
SF-36		
Physical functioning	**-0.611**	<0.005
Physical role	**-0.396**	0.001
Bodily pain	**-0.336**	0.006
General health	**-0.618**	<0.005
Vitality	**-0.423**	<0.005
Mental health	-0.199	0.111
Emotional role	-0.195	0.119
Social functioning	**-0.329**	0.008
Divergent validity		
Age	**0.463**	<0.005
Disease duration	0.164	0.192
Body mass index	**0.276**	0.026

Table 1. Construct validity of SCQ (Correlation coefficient with other parameters)

Methods: Patients with PsA, according to Classification Criteria for Psoriatic Arthritis (CASPAR), were included in the study. Data about age, sex, body mass index (BMI), disease duration (month) were noted. Psoriatic Arthritis Quality of Life (PsAQoL) scale and Short Form 36 (SF-36) were used to assess the quality of life. The Health Assessment Questionnaire (HAQ) was used to evaluate the physical disability. The effects of comorbid diseases on quality of life (QoL) and Patient Global Assessment of General Health (PGA) were assessed on the Visual Analogue Scale (VAS). The English version of SCQ was the original scale used for translation and adaptation. Translation, back translation, and cross-cultural adaptation of the SCQ into Turkish were done according to the standard procedure. The reliability of SCQ was determined by internal consistency (Cronbach's alpha coefficient). Face validity and construct validity (convergent and divergent validities) were evaluated. For the face validity, the final Turkish version of SCQ was tested by 15 patients to determine if they could understand the items. The correlations of the SCQ with the HAQ, SF-36, PsAQoL, the VAS scores of the effect of comorbid diseases on QoL and PGA were assessed for convergent validity. The relation of the SCQ with age, BMI, and disease duration were assessed for divergent validity. The construct validity of the SCQ scale was determined by Spearman's correlation coefficient. The descriptive analysis was done for demographic data. $P< 0.05$ accepted as significant.

Results: The mean age of 65 patients (46 female, 19 male) with PsA was 46.20 (SD: 13.05) years. The median (min-max) duration of disease was 24 (1-384) months. The mean BMI of patients was 29.06 (SD: 5.92). The Cronbach's alpha coefficient of the SCQ for internal consistency was 0.755. The SCQ score had moderate and significant positive correlations with HAQ, PsAQoL, the VAS scores of the effect of comorbidity on QoL and PGA ($p< 0.05$). The significant negative correlations were detected with physical function, physical role limitation, bodily pain, general health, vitality and social function subgroups of the SF-36 ($p< 0.05$). The SCQ score had positive correlations with age and BMI ($p< 0.05$). There was no correlation between SCQ score and duration of disease (rho: 0.164, p: 192). The correlations of SCQ with the clinical variables that show convergent and divergent validities were given in Table 1.

Conclusion: The Turkish version of the SCQ is a valid and reliable instrument in PsA. The SCQ is a simple, accurate and not time-consuming self-report instrument to assess comorbidities in patients with PsA.

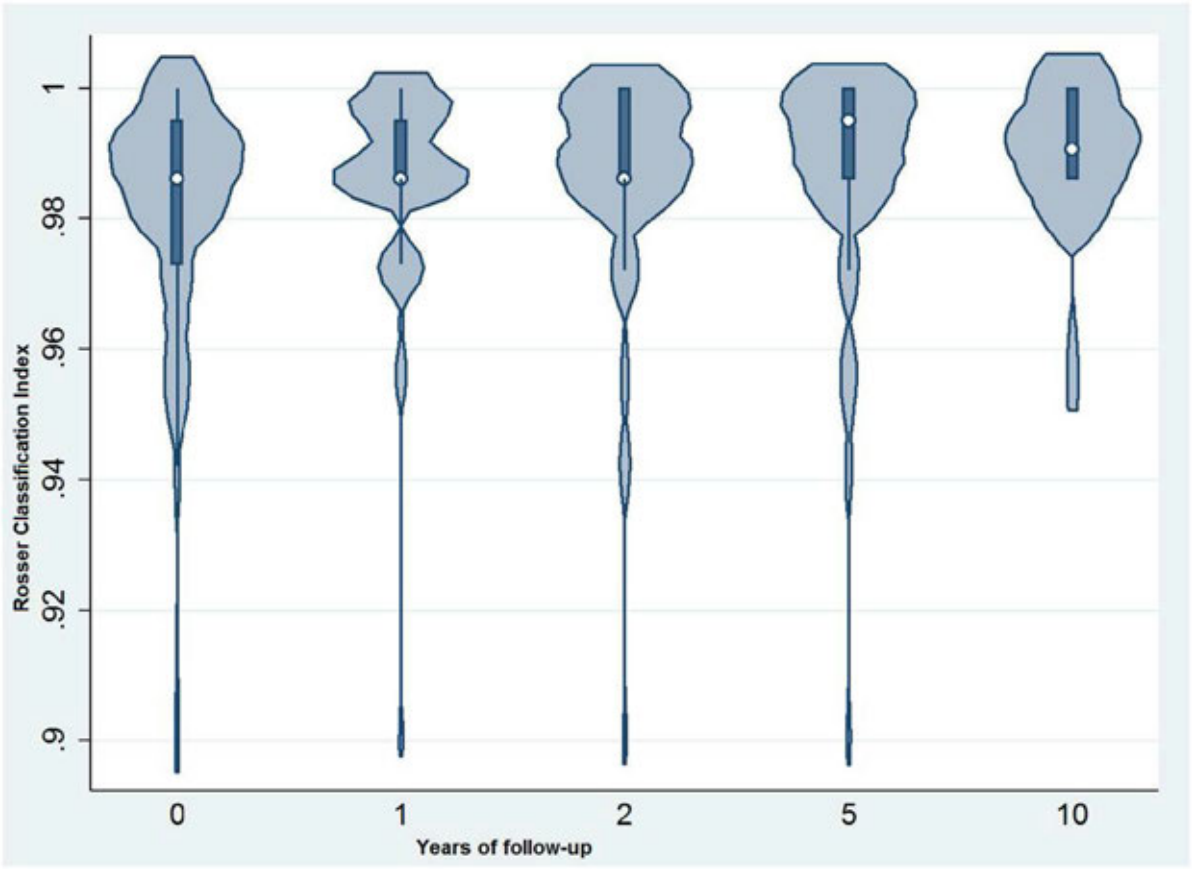
SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features



Graph 1. Rosser classification index throughout the follow-up.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is consider a multifaceted disease, with patients reporting lower health-related quality of life (HRQoL). Data of burden of disease is substantial and there exists a need for properly designed studies to learn more about the evolution of HRQoL in this condition. **Purpose:** To analyze the evolution on HRQoL in patients with PsA and to evaluate factors that may influence this evolution.

Methods: Retrospective longitudinal observational study including incident patients diagnosed with PsA from 2007 to 2016, and followed-up until loss of follow-up or December 2017; with at least two registered visits; PsA diagnosis according to The CASPAR criteria (ClASsification criteria for Psoriatic ARthritis) and symptoms onset after 16 years old. Patients were from the rheumatology outpatient clinic of Hospital Clínico San Carlos, Madrid, Spain. Clinical information was collected from a departmental electronic health record, including demographic, clinical, treatment, and HRQoL related variables (measured with the Rosser Classification Index), reported numerically on a scale between 0 and 1, as a result of the combination of two different categories disability and distress; The influence of these variables in repeated measures of HRQoL were analysed using bivariate and multivariate generalized estimating equations (GEE) models nested by patient. Those variables with a p-value < 0.20 (plus age, sex, follow-up time, and calendar year) were introduced in the multivariate analysis. Bonferroni p-value threshold adjustment was carried out.

Results: We included 248 patients, with a median follow-up of 4.3±3.3 years. 57.6% were male, with a median age at the onset of symptoms and diagnosis of 48 and 49 years, respectively. 88% of patients had a personal history of Psoriasis. Regarding clinical manifestations during the follow-up, 86%, 33%, 35%, and 30% of the patients presented with peripheral arthritis, inflammatory low back pain, enthesitis and dactylitis, respectively. In addition, they received treatment with nonsteroidal antiinflammatory medications (NSAIDs), oral glucocorticoids and disease-modifying antirheumatic drugs (DMARDs) 74%, 59% and 86%, respectively. 22% received biological agents. The Rosser mean value (SD) at the first visit was 0.98 (0.02), with a slight improvement after the first 2 years and worsening after 5 years of follow-up (Graph 1). Regarding to the variables independently associated with HRQoL during follow-up, obesity (p=0.018), osteoporosis (p=1.3e-03), osteoporotic fractures (p=5.7e-12) and chronic obstructive pulmonary disease (p=6.7e-06) were associated with a poorer HRQoL. Conversely, treatment with methotrexate (p=8.2e-05), and the use of bisphosphonates (p=4.9e-04) were associated with better HRQoL. Interestingly the presence of enthesitis was also associated to worse HRQoL, although not significantly after p-value adjustment.

Conclusion: We observed that the presence of certain comorbidities were independently associated with a worse HRQoL. In addition, regarding different treatments, the use of methotrexate and the concomitant use of treatment with bisphosphonates were independently associated with a better HRQoL.

CI, confidence interval; DAPSA, disease activity in psoriatic arthritis; TJC, tender joint count, SJC, swollen joint count; CRP, C reactive protein; bDMARD, biologic disease modifying antirheumatic drug; Psoriatic Arthritis Impact of Disease Questionnaire-version with 12 questions; HAQ, Health Assessment Questionnaire.

* Patient global evaluation had to be excluded from the model due to multicollinearity effect

** Physician opinion, in a 0-10 numerical rating scale, that the cause of the patient's current symptoms is other disease and NOT psoriatic arthritis (such as osteoarthritis, fibromyalgia, comorbidities, etc)

Background/Purpose: Sleep quality is diminished in patients with psoriatic arthritis (PsA) and close to 40% of PsA patients consider sleep impairment a priority domain.This work analyzed determinants of impaired sleep in patients with PsA.

Methods: This was a cross-sectional analysis of an observational study (ReFlap, NCT03119805), which included adult patients with definite PsA with ≥ 2 years disease duration from 14 countries (ref 1). Sleep was assessed using the patient self-reported evaluation of sleep on a 0-10 numerical scale, included in the Psoriatic Arthritis Impact of Disease questionnaire (PSAID-12) (ref 2). A score ≥ 4 was considered as sleep impairment. Demographic and clinical variables associated to sleep impairment were assessed through univariate analysis; prevalence ratios (PR)[95% CI] were reported. Variables independently associated to sleep impairment in the univariate analysis (with p-value < 0.05) were entered in the Poisson regression model.

Results: A total of 396 patients were analyzed: mean age 51.9 ± 12.6, 51% (N= 202) were females, 59.7% were receiving biologic therapy (N= 221), 53.3% (N=201) of participants had 1-5% of body surface area (BSA) affected by psoriasis, 74% (N=293) had mild disability (defined as a score ≤1 in the Health Assessment Questionnaire-HAQ); 23.7% (N=94) were in remission and 36.9% (N=146) in low disease activity according to the Disease Activity in Psoriatic Arthritis (DAPSA) score. Median (25th-75th) patient's self-evaluation of sleep difficulties was 2 (0-6), 39.9% (N=158) were considered as having sleep impairment. In the univariate analysis, factors independently associated to sleep impairment were: moderate (HAQ >1 to 2) and severe (HAQ >2 to 3) disability (PR: 1.55 [1.39-1.72] and 2.07 [1.97-2.18] respectively, p< 0.001), glucocorticoid use (PR: 1.52 [1.16-1.99], p=0.003), obesity (PR: 1.50 [1.06-2.11], p=0.021), psoriasis affecting >20% of BSA (PR: 1.12 [1.08-1.17], p< 0.001), moderate and high disease activity by DAPSA (PR: 7.01 [3.54-13.8] and 8.71 [4.46-17.9] respectively, p< 0.001) and self-reported levels of anxiety, depres-

sion and fatigue (PR: 1.22 [1.18-1.28], 1.16 [1.14-1.21] and 1.28 [1.23-1.33] respectively, p< 0.001). Poisson regression model showed only self-reported levels of anxiety (PR: 1.05 [1.02-1.08], p=0.003) and the pain component of DAPSA (PR: 1.06 [1.01-1.09], p< 0.001) contributing to sleep impairment (Table 1).

Conclusion: Sleep impairment was frequent in this population of PsA patients; pain and anxiety were independently associated to sleep impairment.

JAK-STAT Signaling System in Pannus Formation of Psoriatic Arthritis: A Therapeutic Target

Siba Raychaudhuri,[1] and Smritikana Raychaudhuri[2], [1]UC Davis School of Medicine, Sacramento, CA, [2]UC Davis School of Medicine, Davis, CA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) involves inflammation of the joint synovium where synovial cells (FLS) are the target for T cell activated cytokines for pannus formation. The T cell secreted cytokines (IL-17A, IL-22 and TNF-α) signal through the JAK family of tyrosine kinases. Activated JAKs recruit and activate STATs, which in turn drive gene transcription. IL-17A, IL-22 and TNF-α play leading roles in PsA but their regulatory role on JAK-STAT signaling for pannus formation remains largely unknown. Here we have addressed (A) whether these key regulatory cytokines induce phosphorylation of STAT3 and thus regulates (i) FLS proliferation and (ii) IL-6, IL-8 and MMP3

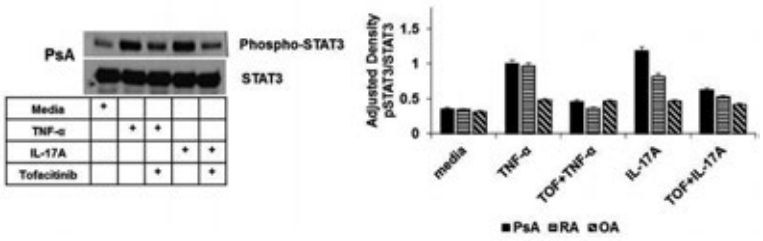

Fig 1. IL-17A and TNF-α activate JAK-STAT signaling pathway. STAT3 is a transcription factor that plays a significant role in the pathogenesis of PsA. IL-17A and TNF-α induced phosphorylation of STAT3 by a fold change of 2 compared to the untreated PsA FLS (p<.01). PsA FLS pre-treated with tofacitinib (TOF) inhibited IL-17A and TNF-α induced phosphorylation of STAT3 (p<.01). Similar results were also seen in RA FLS.

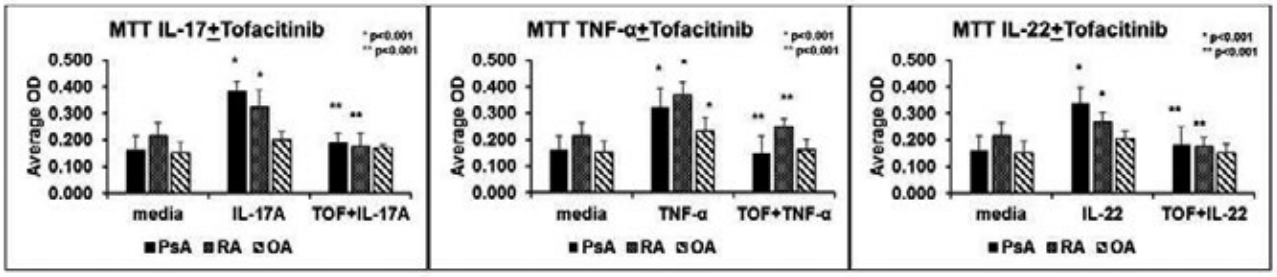

Fig 2 - Anti-Proliferative effect of pan-JAK inhibitor (Tofacitinib) on IL-17, TNF-α and IL-22 induced PsA FLS and RA FLS proliferation. * Compared with the media (<.001); ** Compared with IL-17A vs IL-17A+ Tofacitinib (<.001); ** Compared with TNF-α vs TNF-α + Tofacitinib (<.001); ** Compared with IL-22 vs IL-22+ Tofacitinib (<.001).

production by FLS. (B) Can a JAK-STAT inhibitor (Tofacitinib) inhibit this process and thus brakes pannus formation induced by TNF-α, IL-17 and IL-22.

Methods: FLS were isolated from synovial tissue biopsies of PsA, RA and OA (n=5, for each). They were cultured in presence or absence of tofacitinib (50nM) with TNF-α (20ng/mL), IL-17A (100ng/mL) or IL-22 (100ng/mL); supernatants were collected on the day 5. ELISAs were performed for IL-6, IL-8 and MMP-3 with ELISA kits (PeproTech). MTT assay was done for proliferation. Immunoblot studies of FLS lysates were done to identify for STAT3/ phospho-STAT3.

Results: 1. We observed that IL-17/IL-22/TNF-α induced phosphorylation of STAT3 by 2 fold change relative to the untreated PsA FLS. PsA FLS pre-treated with tofacitinib showed decreased levels of phospho-STAT3 compared to the FLS cells not treated with tofacitinib (p< 0.01) (Fig 1). 2. We observed IL-17, TNF-α and IL-22 induced significant proliferation of PsA and RA FLS compared to the media (p< 0.001); and cells that were pre-treated with tofacitinib had significantly lower proliferation (p< 0.001) (Fig 2). 3. PsA and RA FLS stimulated with IL-17A, TNF-α or IL-22 produced significantly more IL-6 IL-8 and MMP-3 compared to media (p< 0.001) and that could be significantly reduced when these FLS were pre-treated with tofacitinib (p< 0.001).

Conclusion: The two critical events of inflammatory/proliferative process for pannus formation are: (i) FLS proliferation; (ii) IL-6, IL-8 and MMP-3 production by FLS. Here we observed: (i) IL-17A, TNF-α and IL-22 the most critical cytokines for the disease process of PsA regulate these biological functions of FLS by activating JAK-STAT kinase system (ii) Further tofacitinib a pan jAK inhibitor effectively blocked these effects. These observations support a critical role for JAK-STAT signaling pathways in PsA and provide mechanisms of actions of tofacitinib for its efficacy.

Abstract Number: 2469

Diversity of Poly-Functional T Cells in Psoriatic Arthritis and Rheumatoid Arthritis and Its Therapeutic Significance

Siba Raychaudhuri,[1] and Smritikana Raychaudhuri[2], [1]UC Davis School of Medicine, Sacramento, CA, [2]UC Davis School of Medicine, Davis, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: Importance to specific T cell subpopulations has been attributed for specific diseases such as Th17 cells in psoriatic disease, Th1 cells in TB and Th2 response for intracellular parasite infections. However, there are evidences that immune response is not a watertight condition for a specific T cell sub population. As a clinician, we notice this diversity too; a patient of psoriatic arthritis (PsA) may respond to an anti-TNF agent whereas anti-IL-17A may not work; a patient may respond to anti-IL-23 but fails anti-IL-17A or anti-TNF agents. Considering this background here we have addressed poly-functionality of the activated effector memory T cells as well the difference of poly functionality in T cells between individual autoimmune disease such as in PsA and rheumatoid arthritis (RA).

Methods: Peripheral blood (PBMC) synovial fluid (SFMC) mononuclear cells were collected from untreated PsA and RA (n=15/each) patients with active disease. Magnetically sorted $CD3^+$ T cells were isolated from PBMCs and SFMCs; were activated (10^6 cells/ml) with anti-human CD3/CD28 cocktail and cultured in RPMI medium for 5 days (Fig 1). Hi-D FACS studies were performed to: (i) identify activated memory cells (CD3+CD4+CD45RO+) T cells (ii) identify the percentage of following Th1/Th17 cytokine profile: IL-17A, IL-22, TNFα, IFNy. The percentages of each cell population and the mean fluorescence intensity (MFI) were analyzed using Flow Jo software.

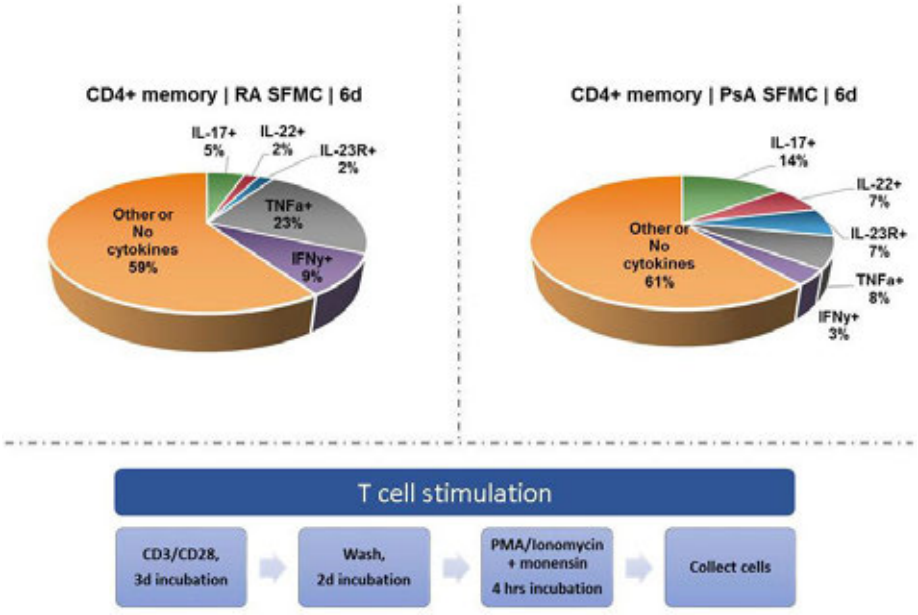

Figure 1. Poly-Functional synovial fluid mononuclear (SFMC) T cells and its variance in psoriatic arthritis (PsA) and rheumatoid arthritis (RA).

Results: We noticed a marked polyfunctionality in PBMC/SFMC T cells both in PsA and RA. SFMC T-cells exhibited greater cytokine polyfunctionality, compared with matched blood. In PsA SFMCs the number of IL-17A (7.5+0.4%), IL-22(6.4+0.3%) and IL-23R (6.5+0.%) secreting cells were significantly higher than the PsA PBMCs (3.8+0.3%, 1.1+0.5%, 1.2+0.7%, respectively; p< 0.001). Whereas % of TNFα T cells in PsA PBMCs (20.7+0.66) was higher than PsA SFMCs (8.16+0.11, p< 0.001); IFNy expressing cells in PBMCs and SFMCs were similar. RA SFMCs had significantly higher numbers of IL-17A (4.9+0.2%), IL-22 (2.5+0.1%), IL-23R (2.1+0.4%) and IFNy (24.3+0.2%) compared to RA PBMCs (1.8+0.%%, 0.8+0.2%, 1.0+0.5%, and 14.7+0.%% respectively, p< 0.001). RA PBMCs had higher numbers of TNFα secreting cells than RA SFMCs (15.8+0.5% vs 7.9+0.2%; p< 0.001).

Conclusion: Consistent to our and other reports we noticed activated CD4 memory T cells were the major source for these cytokines. Compared to RA (Fig 1), in PsA SFMCs significantly higher levels of IL-17A, IL-22 and IL-23R were noticed. In RA SFMCs the levels of TNFα and IFNγ were significantly higher- a trend towards a Th1 pattern. The study supports the common view that in PsA the T cells are more skewed towards Th17 cells. Probably that explains better efficacy for anti-IL-17A targeted therapy in PsA compared to RA. More intriguing result is that in both in PsA and RA the pathological T cells in the SF were vastly polyfunctional. It is expected the kinetics of the polyfunctionality and thus their cytokine profile would vary at different time point of the disease and this could be one possible explanation for variations for responsiveness or failure to a specific anti-cytokine therapy.

Abstract Number: 2470

Relationship Between Serum Calprotectin Level and Presence of Subclinical Atherosclerosis and Arterial Stiffness in Patient with Psoriatic Arthritis

Isaac T. Cheng,[1] Martin M Li,[1] Edmund K Li,[1] Alex P Lee,[1] and Lai-Shan Tam[1], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: Calprotectin is a member of S100 leukocyte. Serum calprotectin is a sensitive biomarker of disease activity in patients with psoriatic arthritis (PsA). While various CV risk score only shown modest correlation with augmented CV risk in patient with PsA, whether calprotectin could play an addition role remains uncertain. Therefore, the aim of this study is to elucidate the association between serum calprotectin and subclinical atherosclerosis and arterial stiffness in patient with PsA

Methods: Seventy-eight PsA patient (age: 53±11 years, 47(54%) male) without CV event was recruited into this cross-sectional study. High resolution carotid ultrasound was performed to assess the presence of carotid plaque and intima-media thickness (IMT). Arterial stiffness was measured by branchial-ankle pulse wave velocity (PWV) and augmentation index (AIx). Serum calprotectin level was measured by QUANTA Lite Calprotectin Extended Range ELISA kit from (INOVA Diagnostics, San Diego, CA, USA).

Multivariate analysis for factors associated with presence of carotid plaque.

	OR	95% CI	*p*
Disease duration (years)	1.10	1.02 to 1.19	0.018
Ln Calprotectin	3.25	1.22 to 8.69	0.019

*Factors included in the multivariate analysis: age, gender, disease duration, swollen joint count, hyperlipidemia, Framingham 10-year CVD risk >10%, current use of statins, and calprotectin level

Table 1 - Multivariate analysis for factors associated with presence of carotid plaque

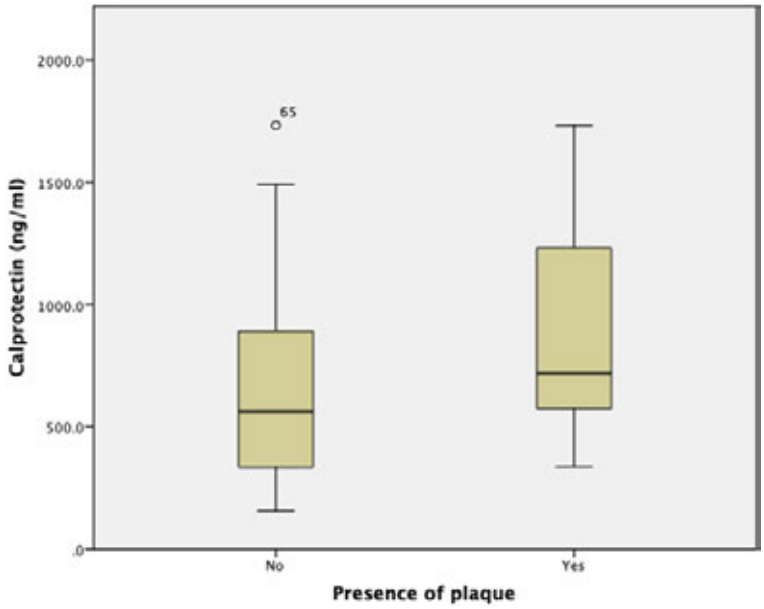

Figure 1 - Calprotectin level in subjects with or without carotid plaque

Results: 29/78 (38%) of patient had carotid plaque (CP+). Subjects in the CP+ group were older, had higher inflammatory burden in terms of higher number of swollen joint and longer disease duration. The prevalence of statins use was also higher in the CP+ group. Serum calprotectin level were significantly higher in the CP+ group (CP- group: 639.2 ±378.2 ng/ml,vs CP+ group: 911.8ng/ml ±429.4, p=0.005) (Figure 1). Using multivariate logistic regression analysis, higher level of ln calprotectin was an independent explanatory variable associated with the presence of carotid plaque (OR: 3.25, 95%CI: 1.22 to 8.69, p=0.019) after adjusting for baseline covariates. There was also significant correlation between calprotectin level and C-Reactive Protein (CRP) (r=0.237, p=0.037), mean IMT (r=0.301, p=0.021) and maximum IMT (r=0.265, p=0.043). However, no significant association were observed between calprotectin level and PWV or AIx.

Conclusion: Increased calprotectin level were associated with presence of plaque and increased IMT. Serum calprotectin may be a novel biomarker for assessing CV risk in patient with PsA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) has been defined as an inflammatory arthritis associated with psoriasis. The disease activity can be evaluated using many scales in patients with PsA. There is a great temperature difference between geographic region in Turkey. For example,the average annual air temperature in Erzurum (one of the Eastern Anatolian cities) is 5.7° C whereas in Antalya (one of the Mediterranean region cities) average temperature is 18.7° C. Furthermore, altitude of Eastern Anatolian cities is higher than Mediterranean cities.

The aim of this study was to assess whether there are regional differences in disease burden in patients with PsA.

Methods: Patients with PsA over the age of 18 who met the CASPAR classification criteria were enrolled consequently in this multicenter cross-sectional observational study. Turkish League Against Rheumatism (TLAR)- Network was formed with the participation of 25 different centers. Patients were grouped for 7 geographic regions (Marmara, Aegean, Mediterranean, Central Anatolia, Black Sea, Eastern Anatolia and southeastern Anatolia) in Turkey. Clinical and laboratory data were recorded. PsQoL; HAQ; BASFI, VAS-fatigue, VAS-pain, patient and physician GA; DAPSA,

Table 1 Comparison of crude disease activity, quality of life and disability measures between 7 geographic regions of Turkey in patients with PsA (mean ± SD)

DAS28, BASDAI, and PASI scores were assessed. Statistical analysis was performed using the SPSS v22 package program. One-way ANOVA test were used to compare 7 geographic regions. Regression analysis was used to calculate adjusted disease measures. $p<0.05$ was considered statistically significant.

Results: A total 1130 patients (36% male, 64% female) with PsA included in this study. The mean age was 46.96 ± 12.25 years. The mean symptom duration was 9.40 ± 8.88 years. Crude results related to disease activity, quality of life and disability were summarized in table 1. Statistically significant differences observed for age, sex and BMI between groups. Thus, adjusted values of disease activity, quality of life and disability were calculated (table 2). Eastern Anatolian patients were youngest whereas Mediterranean patient were oldest (40.03 ± 13.19 vs 50.42 ± 11.47, $p< 0.0001$). Diagnostic delay time similar between groups (p:0.096). Crude VAS-pain, fatigue, PtGA, PhGA were significantly different between groups whereas this difference disappeared when adjustment for age, sex and BMI were made in table 2. Disease activity score were highest in Mediterranean region and lowest in eastern Anatolia region according to adjusted DAPSA (17.72 ± 1.75 vs 16.35 ± 1.62, $p< 0.0001$), DAS28 (3.53 ± 0.29 vs 3.25 ± 0.28 $p< 0.0001$) and BASDAI (4.12 ± 0.48 vs 3.80 ± 0.49, p:0.080). Adjusted BASFI (2.83 ± 0.52 vs 2.28 ± 0.51, $p< 0.0001$), PsAQoL (7.54 ± 1.48 vs 6.07 ± 1.44, $p< 0.0001$) and HAQ (0.48 ± 0.11 vs 0.36 ± 0.13, $p< 0.0001$) score were highest in Mediterranean region and lowest in Eastern Anatolia region. Additionally, PASI score lowest in Mediterranean region and highest in Eastern Anatolia region.

HAQ	0.42±0.13	0.43±0.12	0.44±0.12	0.48±0.11	0.42±0.11	0.36±0.13	0.40±0.12	**<0.0001**	0.43±0.13

Table 2 Comparison of adjusted disease activity, quality of life and disability measures between 7 geographic regions of Turkey in patients with PsA [mean ± SD)(adjustment for age, sex and BMI)

Conclusion: This is the first study reporting that geographic region differences may affect disease activity as well as patient characteristic in patients with PsA. Regional weather conditions such as temperature, humidity and altitude may explain the regional differences in disease activities and other clinical characteristics.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis is a chronic inflammatory disease. More than 20% of patients with PsA patients suffer from fibromyalgia, a chronic pain syndrome characterized by widespread pain and tender points. PsA patients with concomitant fibromyalgia have high scores of disease activity, irrespective of underlying inflammatory process. Thus, assessment of clinical disease activity in those patients is challenging. Ultrasound (US) is a common imaging modality for disease activity evaluation. Hence, the aim of the current study is to examine whether US can be used as an objective tool for assessment of disease activity in PsA patients with fibromyalgia.

Methods: The study population included consecutive PsA patients that were recruited prospectively. All the patients fulfilled the CASPAR criteria. The assessment of the patients included complete medical history and physical examination, including assessment of 68 joints, enthesitis (Leeds and SPARCC) and fibromyalgia tender points. All the patients were assessed by the widespread pain index (WPI) and symptom severity score (SSS) for fibromyalgia. Patients were classified with fibromyalgia if they fulfilled the 1990 or 2010 classification criteria for fibromyalgia. All the patients underwent a detailed US evaluation including 40 joints, 40 tenosynovitis and 14 points of entheses (according to the MASES index plus bilateral lateral epicondyles). The score of the US was based on the summation of semi-quantitative score (0-3) for joints and tendons plus enthesitis score based on the MASEI score. Both clinical and sonographic evaluation occurred in the same day and the sonographer was blinded to the clinical data.

Results: Eighty-six patients completed the study. Overall, 3440 joints, 3440 tendons and 1204 entheses were scanned by the US. Thirty-three patients (38%) classified with both PsA and fibromyalgia were compared to 53 (62%) PsA patients without fibromyalgia. The demographic data were overall similar in PsA patients with and without fibromyalgia (Table 1). Patients with PsA and fibromyalgia had significantly increased scores for almost all the clinical measures, including not being in MDA (97% vs 56.6%, $p< 0.001$), CPDAI (11.5 vs. 7.3, $p< 0.001$) and DAPSA (33.6 vs. 15.5, $p< 0.001$). The total US score were similar between patients with and without fibromyalgia. Furthermore, the subcategories of US synovitis, tenosynovitis and enthesitis were comparable in both groups (Table 2).

Characteristics	PsA without Fibromyalgia N=53	PsA with Fibromyalgia N=33	P-Value
Age, mean (± s.d)	55.8 (12)	52.3 (14.4)	0.24
Gender, Female, n (%)	29 (54.7)	21 (63.6)	0.55

Table 1 Demographic and clinical data
Demographic and cinical characteristics

	PsA without Fibromyalgia N=53	PsA with Fibromyalgia N=33	P-Value
Total US Score, mean (± s.d)	29.2 (18.8)	26 (23.8)	0.5
Synovitis score, mean (± s.d)	11.9 (12)	11.1 (16.2)	0.8
Tenosynovitis score, mean (± s.d)	2.6 (3.4)	2.6 (3.7)	0.9
Enthesitis score, mean (± s.d)	14.4 (9.1)	12.1 (8.9)	0.3

Table 2. Sonographic comparison between PsA with to without fibromyalgia
Table 2. Sonographic comparison between PsA with and without fibromyalgia

Conclusion: While patients with PsA and fibromyalgia had increased scores of clinical measures of disease activity compared to those without fibromyalgia, US scores were similar between the groups. Hence, US can be used as a discriminative tool for objective assessment of disease activity in patients with PsA and concomitant fibromyalgia.

Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease, with involvement of at least five health domains: peripheral joint disease, enthesitis, dactylitis, axial involvement, and skin and nail psoriasis. Because of the heterogeneity of the disease, assessment of disease activity is challenging. One of the many single or composite outcome measures that has been developed is the Psoriatic Arthritis Disease Activity Score (PASDAS). The PASDAS is a comprehensive measure that takes arthritis (66/68 joint score), dactylitis, enthesitis, CRP, physician disease activity VAS score and patient-reported outcomes into account. Furthermore, it is a continuous outcome measure in contrast to the Minimal Disease Activity criteria (MDA), facilitating the longitudinal follow-up of disease activity. The PASDAS also has better parametric distribution and discriminative capacity compared to other outcome measures such as the Disease Activity for PSoriatic Arthritis score (DAPSA). However, feasibility of PASDAS use in routine clinical care has been questioned due to its complexity. It requires a CRP and filled-out SF36 form at time of assessment, does not include a formal skin assessment, is difficult to calculate and is time consuming for both patient and physician. Here we describe our efforts to mitigate these drawbacks and to implement routine measurement of the PASDAS for all 1200 PsA patients in our clinical practice.

Methods: The implementation consisted of the following stages: 1) assessment of patients' acceptability of measurement burden; 2) implementation of mathematical calculations of the PASDAS in our electronic health record; 3) PASDAS and skin assessment training of rheumatology nurses and rheumatologists; and 4) (logistic) adjustments to the outpatient visit.

Results: Our patient partners preferred comprehensive clinical assessment of skin and joints above a limited assessment, although the former would be more time consuming. For this reason, and to comply with international guidelines, we decided to also add assessment of skin disease, by using the Body Surface Area (BSA) and Physician Global Assessment score (PGA). Furthermore, research demonstrated that for the PASDAS calculation the physical component score (PCS) of the SF36 could be substituted by the SF12-PCS. As the SF12 is more concise, minimizing patient burden, we chose to implement the SF12 instead of the SF36. To enable hassle free calculation of the PASDAS, the scoring formulas including mannequins for joint, enthesitis and dactylitis scoring, and the SF12v1 together with the skin scores (BSA and PGA) were implemented in our electronic health record. Lastly, we set-up a three phase consultation that consists of laboratory tests and consultation with a rheumatology nurse who performs the physical measurements before each visit with the physician.

Conclusion: Standardized and routine measurement of the PASDAS and skin involvement at each outpatient visit of all our PsA patients before consultation with the treating rheumatologist was successfully implemented, underscoring the feasibility of this approach. In addition to improving clinical care, routine outcome measurements can be used for a variety of clinical studies.

Impact of Multidomain Disease Presentations on Overall Disease Burden Among Patients with Psoriatic Arthritis: Results from the Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) Registry

Alexis Ogdie,[1] Peter Hur,[2] Mei Liu,[3] Sabrina Rebello,[3] Robert McLean,[3] Blessing Dube,[3] Meghan Glynn,[4] and Philip Mease[5], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Corrona, LLC, Waltham, MA, [4]Corrona, LLC, Waltham, [5]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease with heterogeneous presentations that may involve peripheral arthritis, axial disease, enthesitis, dactylitis, and psoriatic skin and nail disease, either alone or in combination. Prior studies have characterized patients affected in one domain; however, there is limited evidence in understanding the differential impact of multidomain vs single-domain presentations on the overall disease burden in PsA. We aim to compare disease characteristics, quality of life, and work productivity at enrollment among patients with PsA who have multidomain vs single-domain presentations in the Corrona PsA/SpA Registry.

Methods: This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry between March 2013 and August 2018. Patients were evaluated for the presence of 6 disease domains at enrollment: enthesitis (SPARCC enthesitis count > 0), dactylitis (dactylitis count > 0), peripheral arthritis (PA; tender and/or swollen joint count > 0), nail psoriasis (global nail psoriasis VAS > 0), axial disease (physician-reported presence of spinal involvement, based on clinical judgment and/or radiographs or MRI showing sacroiliitis), and skin disease (BSA > 0%), and were further classified as having multidomain or single-domain disease presentations. Separate multivariable linear regression models evaluated the association of the presence of multidomain presentations with selected PsA disease characteristics, quality of life, and work productivity measures relative to single-domain presentations. Models were adjusted for age, sex, race, BMI, disease duration, and current and prior biologic, conventional synthetic disease-modifying antirheumatic drug, and prednisone use.

Results: Of 2315 patients with PsA enrolled in the Corrona PsA/SpA Registry who had ≥ 1 disease domain presentation, 1698 patients (73.3%) were classified as having multidomain disease presentations and 617 (26.7%) as single-domain presentations. The most common single-domain and multidomain presentations, respectively, were skin disease (12.7%) and PA + skin disease (11.7%). At enrollment, patients with multidomain presentations had higher BMI; shorter disease duration; were more likely to have fibromyalgia, depression, and anxiety; and were more likely

BMI, body mass index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; EQ-5D, EuroQol 5-Dimensions; HAQ-DI, Health Assessment Questionnaire Disability Index; PsA, psoriatic arthritis.
* Single-domain disease is the reference group. Adjusted for age, sex, race, BMI, disease duration, and current and prior biologic, csDMARD, and prednisone use.

Conclusion: In this US real-world cohort, nearly three-quarters of patients with PsA had multidomain disease presentations, which were associated with worse disease activity, quality of life, and work productivity measures compared with single-domain disease presentations. Assessing all PsA domains is critical for developing a comprehensive management plan and reducing the impact of PsA on patients' lives.

Abstract Number: 2475

Prevalence of Disease Domain Presentations Among Patients with Psoriatic Arthritis: Results from the Corrona Psoriatic Arthritis/ Spondyloarthritis (PsA/SpA) Registry

Alexis Ogdie,[1] Peter Hur,[2] Mei Liu,[3] Sabrina Rebello,[3] Robert McLean,[3] Blessing Dube,[3] Meghan Glynn,[4] and Philip Mease[5], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [3]Corrona, LLC, Waltham, MA, [4]Corrona, LLC, Waltham, [5]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous, chronic inflammatory disease of the skin and musculoskeletal system. Six key domains of PsA have been identified to help guide treatment: peripheral arthritis, axial disease, enthesitis, dactylitis, nail psoriasis, and skin disease.[1] Understanding the epidemiology of these different disease presentations is important for the management and treatment of PsA, yet there is limited evidence available. We aim to describe the prevalence of disease domain presentations among patients with PsA at enrollment in the Corrona PsA/SpA Registry.

Methods: This study included adult patients with PsA enrolled in the Corrona PsA/SpA Registry between March 2013 and August 2018. Patients were evaluated for the presence of 6 disease domains at enrollment: enthesitis (Spondyloarthritis Research Consortium of Canada enthesitis count > 0), dactylitis (dactylitis count > 0), peripheral arthritis (PA; tender and/or swollen joint count > 0), nail psoriasis (global nail psoriasis visual analog scale > 0), axial disease (physician-reported presence of spinal involvement, based on clinical judgment and/or radiographs or MRI showing sacroiliitis), and skin disease (BSA > 0%). The most common mutually exclusive disease presentations were summarized among all patients with PsA and those who initiated biologics using frequency counts and percentages.

Results: Of 2617 patients with PsA enrolled in the Corrona PsA/SpA Registry, 1698 patients (64.9%) had multidomain disease presentations, 617 (23.6%) had single-domain presentations, and 302 (11.5%) had no presentations. Overall, 1814 (69.3%) patients presented with skin disease, 1523 (58.2%) with PA, 1042 (39.8%) with nail psoriasis, 539 (20.6%) with enthesitis, 319 (12.2%) with axial disease, and 235 (9.0%) with dactylitis at enrollment. Among all patients with PsA, the most common disease presentations were skin disease (12.7%), PA + skin disease (11.7%), and PA + nail psoriasis + skin disease (10.3%) (**Figure 1**). A total of 354 patients initiated biologics at enrollment. Of these, 289 patients (81.6%) had multidomain disease presentations, 45 (12.7%) had single-domain presentations, and 20 (5.6%) had no presentations; 273 patients (77.1%) presented with PA, 267 (75.4%) with skin disease, 159 (44.9%) with nail psoriasis, 115 (32.5%) with enthesitis, 70 (19.8%) with dactylitis, and 64 (18.1%) with axial disease at enrollment. The most common disease presentations were PA + nail psoriasis + skin disease (11.6%), PA + skin disease (11.3%), enthesitis + PA + nail psoriasis + skin disease (8.8%), and enthesitis + PA + skin disease (5.9%) (**Figure 2**).

Conclusion: The majority of patients with PsA presented with multiple disease domains. Biologic initiators generally had a higher prevalence of all disease features. These results may increase the physician awareness of the heteroge-

Side Effects of Methotrexate and TNFi: Differences in Tolerability Among Patients with PsA and RA

Alexis Ogdie,[1] Ervant Maksabedian,[2] Bradley Stolshek,[2] Yomei Shaw,[3] and Kaleb Michaud[4], [1]University of Pennsylvania, Philadelphia, PA, [2]Amgen Inc., Thousand Oaks, CA, [3]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [4]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is generally well tolerated in rheumatoid arthritis (RA) but little is known about the tolerability of MTX in psoriatic arthritis (PsA). One recent study has identified shorter MTX persistence among patients with PsA compared to RA in the US,[1] while another study in Europe found similar persistence on MTX in RA and PsA.[2] In addition, tolerability to MTX may be lower than tumor necrosis factor inhibitors (TNFi) in both PsA and RA. We hypothesized that shorter MTX persistence in patients with PsA is due to lower tolerability relative to RA patients.

Objective: To examine the relative reporting of side effects to MTX and TNFi among patients with PsA compared to RA within one year of drug initiation.

Methods: Retrospective cohort study conducted using data from the Forward, The National Databank for Rheumatic Diseases, from 2000 through 2018. Patients enroll in the registry and complete questionnaires every 6 months. Patients with RA and PsA were included in this study if they had at least one questionnaire completed prior to initiating a target drug (MTX or a TNFi) and at least one questionnaire within 12 months after initiation (new user design). The

Obese (N, %)	628 (33%)	30 (56%)	1,202 (33%)	50 (48%)
Comorbidity Count (mean, SD)	1.5 (1.75)	1.61 (1.86)	1.4 (1.58)	1.54 (1.53)
Symptoms Reported (mean, SD)	8.64 (6.39)	10.65 (7.61)	8.11 (6.02)	8.84 (6.33)
Depression (N, %)	367 (19%)	18 (33%)	587 (16%)	26 (24%)
Fibromyalgia[c] (N, %)	65 (3%)	6 (11%)	95 (3%)	8 (7%)

Notes: [ab] The MTX and TNFi initiator groups for RA and PsA include both the mono and combo therapy initiators (e.g., the MTX initiator groups include MTX mono initiators and TNFi users who added MTX). [c] Physician-diagnosed fibromyalgia.

primary outcome of interest was the rate of reported side effects to the target drug. The prevalence of side effects over 1 year was reported among patients with RA and PsA, and stratified by use of MTX monotherapy, TNFi monotherapy, or MTX-TNFi combination therapy (starting either MTX or TNFi and adding second to regimen). In the primary analysis, patients could enter the TNFi cohort more than once if more than one drug was initiated. In a sensitivity analysis, we only allowed patients to enter the cohort for first TNFi.

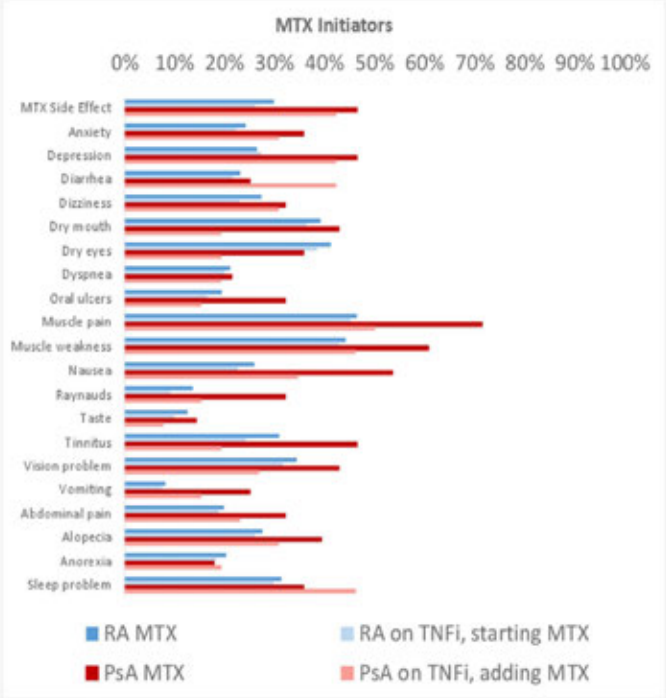

Figure 1. Patient-reported side effects among new initiators of MTX.

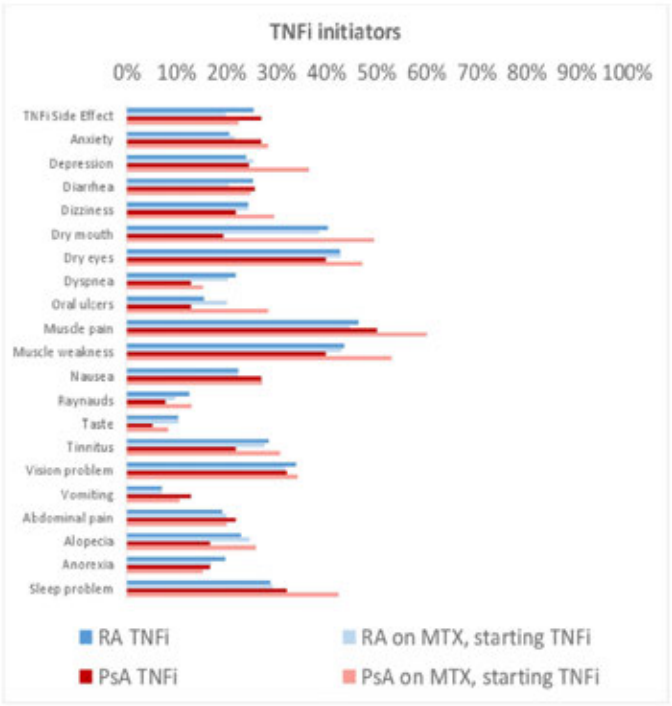

Figure 2. Patient-reported side effects among new initiators of TNFi.

Results: Use of MTX or TNFi was reported among 11,571 patients with RA and 598 patients with PsA. Of these, 2,047 RA and 54 PsA patients were new initiators of MTX, and 3,793 RA and 107 PsA patients were new initiators of a TNFi. Baseline characteristics are shown in Table 1. Among initiators of MTX, 26-30% of RA patients compared to 42-46% of PsA patients reported a side effect in the first year (Figure 1). Among initiators of TNFi, 20-25% of RA and 22-27% of PsA patients reported a side effect in the first year (Figure 2). PsA patients initiating MTX were more likely to report nausea, vomiting, abdominal pain, anxiety, depression, tinnitus, and alopecia compared to RA patients initiating MTX or PsA patients initiating a TNFi.

Conclusion: Patients with PsA, in general, reported more symptoms than patients with RA. In particular, patients with PsA patients reported more side effects to MTX compared to patients with RA or patients with PsA initiating a TNFi.

Burden of Disease at Treatment Initiation Among Biologic-Naïve Patients with Oligoarticular versus Polyarticular Psoriatic Arthritis in the Corrona Psoriatic Arthritis/Spondyloarthritis Registry

Alexis Ogdie,[1] Mei Liu,[2] Meghan Glynn,[3] Kelechi Emeanuru,[2] Leslie Harrold,[4] Sven Richter,[5] Benoit Guerette,[5] and Philip Mease[6], [1]Department of Medicine and Rheumatology and Department of Epidemiology and Biostatistics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA, [2]Corrona, LLC, Waltham, MA, [3]Corrona, LLC, Waltham, [4]Corrona, LLC and University of Massachusetts Medical School, Worcester, MA, [5]Celgene Corporation, Summit, [6]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Oligoarticular PsA accounts for ≈50% of PsA worldwide, but only a paucity of data describes disease burden among these patients. The Corrona PsA/SpA Registry, a prospective, US-based, observational cohort study, collects real-world data on PsA patient characteristics and treatment, including oligoarthritis. This analysis characterized patient demographics, clinical characteristics, and patient-reported outcomes (PROs) at treatment initiation in the Corrona PsA/SpA Registry in biologic-naïve patients with oligoarticular (≤4 swollen and ≤4 tender joints) vs polyarticular (>4 swollen or >4 tender joints) PsA.

Methods: Biologic-naïve patients ≥18 years of age diagnosed with PsA and enrolled in the registry who initiated apremilast, biologics, and/or csDMARDs for PsA from March 2013–December 2018 were included. Patient demographics, disease activity, treatment history, comorbidities, and PRO data were analyzed at treatment initiation; comparisons between oligoarticular and polyarticular PsA patients were performed using *t*-tests or Wilcoxon rank-sum tests for continuous variables and chi-square tests or Fisher's exact tests for categorical variables.

Results: 330 biologic-naïve PsA patients initiating apremilast, biologics, and/or csDMARDs were included (oligoarthritis: n=149; polyarthritis: n=181). Demographics and clinical characteristics were mostly similar for patients with oligoarthritis and polyarthritis, including mean age (51.6 vs 54.3 years; *P*=0.068), proportion of females (51.0% vs 59.7%; *P*=0.117), mean disease duration (3.0 vs 3.1 years; *P*=0.789), and prior use of csDMARDs (13.4% vs 21.0%; *P*=0.072). Comorbidity history was similar between the 2 groups, but the proportion of patients with fibromyalgia was higher in the polyarthritis group (2.0% vs 8.8%; *P*=0.008; Table 1). Patients with oligoarthritis had lower disease activity at treatment initiation vs those with polyarthritis based on SJC (0-66) and TJC (0-68), nail psoriasis VAS score, cDAPSA score, presence of enthesitis, SPARCC enthesitis score, presence of dactylitis, and dactylitis count. More patients with oligoarthritis were classified with minimal disease activity vs patients with polyarthritis (Table 2). Mean Pain VAS (42.6 vs 59.8), Fatigue VAS (41.9 vs 55.3), Patient's Global Assessment of Disease Activity VAS (38.6 vs 47.7), and HAQ-DI (0.7 vs 1.0) scores were significantly lower and the proportion of patients with HAQ-

Table 1. History of Comorbid Conditions Among Biologic-Naïve Patients With Oligoarticular vs. Polyarticular PsA*,§

History of Comorbidity, n (%)	Oligoarthritis n=149	Polyarthritis n=181	*P* Value
Cancer (any except NMSC)	15 (10.1)	19 (10.5)	0.898
Cardiovascular disease	17 (11.4)	23 (12.7)	0.719
Depression	20 (13.4)	36 (19.9)	0.119
Diabetes mellitus	20 (13.4)	33 (18.2)	0.236
Fibromyalgia	3 (2.0)	16 (8.8)	0.008
Hyperlipidemia	26 (17.4)	38 (21.0)	0.418
Hypertension	48 (32.2)	74 (40.9)	0.104
Metabolic syndrome	19 (12.8)	33 (18.2)	0.174
Nail psoriasis	65 (43.6)	97 (53.6)	0.071
Psoriasis	121 (81.2)	150 (82.9)	0.694

*Oligoarticular PsA (≤4 swollen and ≤4 tender joints) vs. polyarticular PsA (>4 swollen or >4 tender joints). §Includes patients initiated on apremilast, biologics and/or csDMARDs. NMSC=non-melanoma skin cancer.

Table 2. Disease Characteristics of Biologic-Naïve Patients With Oligoarticular vs. Polyarticular PsA*,§

Disease Characteristic	Oligoarthritis n=149	Polyarthritis n=181	*P* Value
Swollen joint count (0-66), mean (SD)	1.3 (1.5)	6.2 (5.3)	<0.001
Tender joint count (0-68), mean (SD)	1.6 (1.5)	13.9 (12.7)	<0.001
Nail psoriasis VAS, mean (SD)	11.4 (23.6)	15.7 (24.6)	0.037
cDAPSA score, mean (SD)	10.9 (5.6)	31.1 (15.8)	<0.001
High (>27) cDAPSA, n (%)	0 (0.0)	91 (52.0)	<0.001
Presence of enthesitis, n (%)	37 (24.8)	84 (46.4)	<0.001
SPARCC enthesitis score, mean (SD)	2.1 (1.3)	4.4 (3.4)	<0.001
Presence of dactylitis, n (%)	25 (16.8)	54 (29.8)	0.006
Dactylitis count, mean (SD)	1.9 (1.6)	2.4 (1.7)	0.060
Minimal disease activity, n (%)	40 (29.6)	6 (3.6)	<0.001

*Oligoarticular PsA (≤4 swollen and ≤4 tender joints) vs. polyarticular PsA (>4 swollen or >4 tender joints). §Includes patients initiated on apremilast, biologics and/or csDMARDs. SPARCC=Spondyloarthritis Research Consortium of Canada.

DI score < 0.5 was significantly greater for patients with oligoarthritis vs polyarthritis (39.7% vs 20.1%) (all $P \leq 0.001$). Presence of inflammatory back pain (8.7% vs 10.5%; $P=0.588$) and mean psoriasis-involved body surface area (8.0% vs 6.8%; $P=0.276$) were similar in the 2 groups.

Conclusion: This Corrona PsA/SpA Registry analysis showed similar overall disease and comorbidity burden in biologic-naïve patients with oligoarthritis and polyarthritis. However, patients with oligoarthritis vs polyarthritis had lower scores on disease activity and PRO measures at treatment initiation.

Enthesitis Frequency and Treatment Patterns in Patients with Psoriatic Arthritis in Europe and Japan

Daniel Aletaha,[1] Patrick Zueger,[2] Naijun Chen,[2] and Nicola Booth[3], [1]Medical University of Vienna, Vienna, Austria, [2]AbbVie Inc., North Chicago, IL, [3]Adelphi Real World, Bollington, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis, a symptom commonly associated with psoriatic arthritis (PsA), negatively affects quality of life. Although enthesitis is routinely reported in randomized clinical trials of new therapies for PsA, it has not been well characterized in real-world patient populations. The aim of this study is to determine the frequency and severity of enthesitis and describe treatment patterns in PsA patients with enthesitis in Europe and Japan.

Methods: Data were analysed from the Adelphi PsA Disease Specific Programme, a cross-sectional survey of 344 rheumatologists (and orthopedic surgeons and internists in Japan), 171 dermatologists and their consulting patients in France, Germany, Italy, Spain, UK (5EU) and Japan from 03/2018 to 11/2018. Participating physicians completed patient record forms capturing clinical and treatment information based on medical record data. Patients with a physician-confirmed diagnosis of PsA who were ≥18 years old and not participating in a clinical trial were eligible for inclusion. The proportion of patients with enthesitis was assessed overall and by country at several times during the PsA disease course. For patients currently experiencing enthesitis, data describing enthesitis severity and PsA-related treatments were collected.

Table 1. Frequency of Enthesitis in 5EU and Japan at Various Times in the PsA Disease Course

Region	N	Ever had enthesitis n (%)	Currently have enthesitis n (%)	Enthesitis at PsA diagnosis n (%)	Enthesitis at most recent treatment initiation n (%)
Overall	1945	522 (26.8)	233 (12.0)	406 (22.0)[a]	456 (23.8)[a]
5EU	1675	426 (25.4)	177 (10.6)	322 (20.3)[a]	368 (22.3)[a]
France	277	74 (26.7)	28 (10.1)	47 (18.4)[a]	59 (21.9)[a]
Germany	360	56 (15.6)	26 (7.2)	40 (11.5)[a]	49 (13.7)[a]
Italy	360	105 (29.2)	44 (12.2)	80 (23.7)[a]	87 (24.9)[a]
Spain	369	113 (30.6)	49 (13.3)	98 (27.6)[a]	100 (27.5)[a]
UK	309	78 (25.2)	30 (9.7)	57 (19.5)[a]	73 (23.8)[a]
Japan	270	96 (35.6)	56 (20.7)	84 (32.3)[a]	88 (32.6)

[a]Percentages calculated on non-missing values; missing values were <8%. 5EU, France, Germany, Italy, Spain, and UK; UK, United Kingdom.

Table 2. Treatments Used in Patients with PsA and Current Enthesitis

Treatments	Overall, N=233		5EU, N=177	
	Current Use n (%)	Ever Used n (%)	Current Use n (%)	Ever Used n (%)
NSAIDs	75 (32.2)	168 (72.1)	48 (27.1)	127 (71.8)
Corticosteroids	32 (13.7)	94 (40.3)	24 (13.6)	83 (46.9)
csDMARDs	110 (47.2)	167 (71.7)	96 (54.2)	145 (81.9)
tsDMARDs	28 (12.0)	34 (14.6)	14 (7.9)	19 (10.7)
bDMARDs	136 (58.4)	140 (60.1)	110 (62.2)	114 (64.4)

5EU, France, Germany, Italy, Spain, and United Kingdom; bDMARDs, biologic DMARDs; csDMARDs, conventional synthetic DMARDs; NSAIDs, nonsteroidal anti-inflammatory drugs; tsDMARDs, targeted synthetic DMARDs.

Results: 1945 patients with PsA were included. Mean age was 48.9 (SD 13.6) years, 54.2% were male, and mean time since diagnosis was 59.3 (SD 5.9) months (n=1595). Overall, 26.8% of patients ever had enthesitis, 12.0% of patients currently had enthesitis, 22.0% had enthesitis at the time of PsA diagnosis, and 23.8% had enthesitis at their most recent PsA-related treatment initiation (Table 1). At each time point assessed, the proportion of patients with enthesitis was greatest in Japan and lowest in Germany. Of patients with current enthesitis, 28.8% of cases were moderate or severe compared with 70.0% of cases at diagnosis and 61.8% of cases at initiation of patients' most recent PsA-related treatment regimen. The most frequently used medications among patient with current enthesitis were biologic DMARDs (58.4%), conventional synthetic DMARDs (47.2%), and NSAIDs (32.2%) (Table 2).

Conclusion: Enthesitis is a common disease manifestation in real-world PsA patients in Europe and Japan. The majority of patients with current enthesitis were treated with advanced therapies; physicians rated patients' enthesitis as moderate or severe in 28.8% of those who continued to have enthesitis despite treatment, suggesting an unmet need and target for future PsA therapies.

SF-36	Mean change in MCS score**	6 mo: 2.5–5.5[16, 18, 25, 29, 30]; 12 mo: 2.4–4.8[3, 16, 18]	12 mo: -0.1[17]
	Mean change in PCS score**	6 mo: 3.9–9.5[16, 18, 25, 27, 29, 30] 12 mo: 6.3–10.2[3, 4, 16, 18, 29]	12 mo: 7.3[17]

*MDA is assessed as five of the seven following criteria: ≤1 tender joint count, ≤1 swollen joint count, PASI≤1 or body surface area ≤3%, patient pain VAS≤15, patient global assessment of disease activity VAS≤20, HAQ-DI≤0.5, tender entheseal points≤1

**SF-36 summary scores (PCS-36 and MCS-36) range from 0 to 100, with higher scores representing better self-reported health

DAS=Disease Activity Score; FACIT-F=Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI=Health Assessment Questionnaire Disability Index; MCS=Mental Component Summary; MDA=Minimal Disease Activity; mo=Months; PCS=Physical Component Summary; PsA=Psoriatic Arthritis; SF-36=36-Item Short Form Health Survey; VAS=Visual Analog Scale

Table 1. Clinical and patient-reported outcomes 6- and 12-months post-advanced therapy initiation among patients with PsA

review is to establish unmet needs in PsA patients with respect to the clinical, patient-reported and economic outcomes associated with current treatments.

Methods: A review of the literature from January 2008 to May 2019 was conducted. EMBASE and MEDLINE databases were searched to identify full-text, English-language articles and rheumatology conference abstracts evaluating the clinical, patient-reported, and economic outcomes associated with currently available advanced therapies (biologic disease-modifying anti-rheumatic drugs [DMARDs] and targeted synthetic DMARDs) and conventional synthetic DMARDs (csDMARDs) for adults with PsA. Randomized-controlled trials (RCTs), non-interventional observational studies, and economic models evaluating the impact of treatment on at least one outcome from the above categories were eligible for inclusion.

Results: Among 1,026 records initially screened, 100 articles were selected for inclusion. Of these, 52, 74, and 20 studies reported on the impact of treatment on at least one clinical, patient-reported, and economic outcome, respectively. Across studies, treatment with advanced therapies resulted in greater clinical efficacy and effectiveness, improvements in patient-reported outcomes, and higher 12-month persistence rates compared with csDMARD treatment. Advanced therapies were generally found to be cost-effective. Long-term outcomes over four or more years

DV56686 PsA_UnmetNeedLitReview_Abstract_FINAL_TABLE2

were investigated in 15 studies, revealing improvements in clinical outcomes consistent with shorter-term studies. Clinical and patient-reported outcome data at six and 12 months post-treatment initiation among patients treated with advanced therapies are summarized in Table 1. The proportion of patients achieving minimal disease activity at 12 months post-treatment initiation ranged from 23.6%–64.0%. The impact of advanced therapies on pain and physical functioning varied considerably across RCTs and observational studies. Though commonly assessed in RCTs, little real-world data are available for fatigue, enthesitis, and quality of life in PsA patients initiating advanced therapies.

Conclusion: While more effective than csDMARDs, a substantial proportion of PsA patients still fail to achieve complete disease control or remission with advanced therapies. There remains a need for new treatment options to further improve treatment outcomes in this patient population.

Opioid Use Surrounding Diagnosis of Inflammatory Arthritis

Anna Sheahan,[1] Victor Sloan,[1] Jeffrey Stark,[2] and Robert Suruki[1], [1]UCB Pharma, Raleigh, NC, [2]UCB Pharma, Smyrna, GA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although treatment of inflammatory arthritis (IA) has improved, opioid use among patients remains common. A study from Finland showed increases in opioid use leading up to a diagnosis of IA, then a decrease after diagnosis, and that opioid use in axial spondyloarthritis was higher than in other IAs.[1] In a study of patients with AS, 44% of patients were using opioids, and 26% of these patients were using only opioids.[2] The timing of opioid use surrounding IA diagnosis in the USA is not known. The objective of this study was to describe opioid use in the year preceding and following diagnosis of AS, RA, and PsA.

Methods: This retrospective observational study analyzed USA commercial claims data (IBM® MarketScan®) from patients with an International Classification of Diseases (ICD) 9/10 code for AS, RA, or PsA (index date) between 2010–2017. Three controls, matched on year, age, sex, region, and insurance plan type, were selected for each disease case. Opioid pharmacy claims were examined in a 12-month baseline (BL) and 12-month follow-up (FU) period after index date with further division into 3-month periods. Chronic opioid use was defined as ≥90 cumulative days' supply in a 12-month period and was assessed separately in BL and FU. Long-term use was defined as ≥1 opioid claim in ≥3 of 4 quarters in FU. Prevalence ratios for long-term opioid use in the disease vs matched control cohorts were calculated for FU.

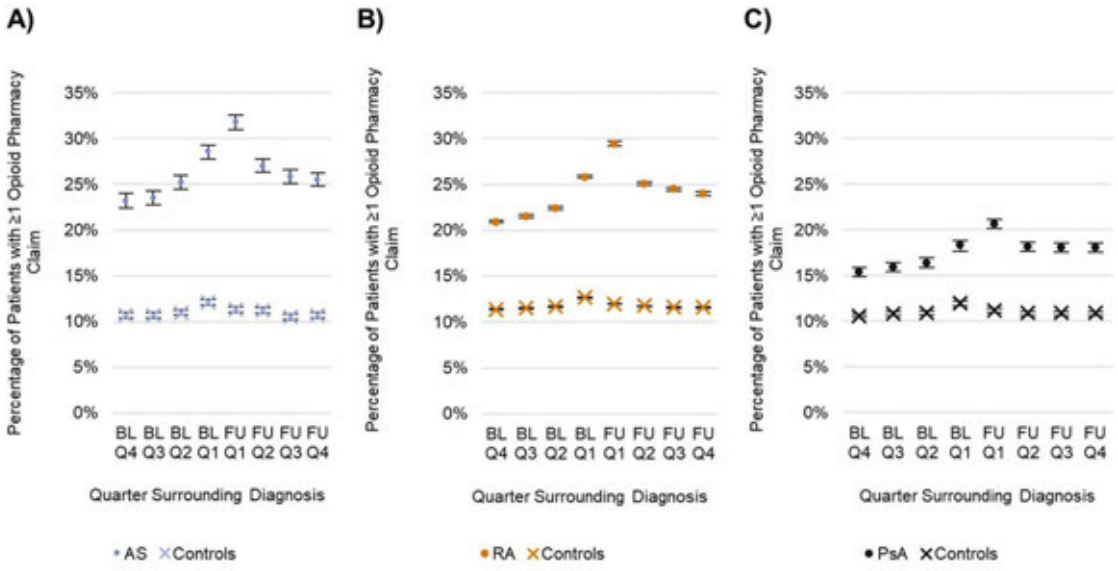
Results: The study included 12,377 AS, 215,286 RA, and 20,679 PsA patients (**Table**). In all 3 cohorts, prevalence of opioid exposure was highest in the quarter following (inclusive of) diagnosis, and prevalence of use was higher in all disease vs matched control cohorts for each quarter (**Figure 1**). Compared to matched controls, prevalence of chronic opioid use was higher in disease cohorts in BL and FU (**Table**), and prevalence of long-term use in FU was also higher (**Figure 2**).

Table 1: Characteristics of the AS, RA, and PsA cohorts and their matched controls

	Ankylosing spondylitis (AS)		Rheumatoid arthritis (RA)		Psoriatic arthritis (PsA)	
	AS cohort (n=12,377)	Matched controls (n=37,131)	RA cohort (n=215,286)	Matched controls (n=645,858)	PsA cohort (n=20,679)	Matched controls (n=62,037)
Age, mean years (SD)	51.1 (15.0)	51.1 (15.0)	55.3 (14.6)	55.3 (14.6)	51.5 (12.9)	51.5 (12.9)
Females (%)	48.5	48.5	71.5	71.5	52.5	52.5
Chronic opioid use in baseline (%)	16.6	5.0	13.5	5.5	8.7	4.9
Chronic opioid use in follow-up (%)	19.2	5.2	16.2	5.7	10.5	5.1

SD: standard deviation.

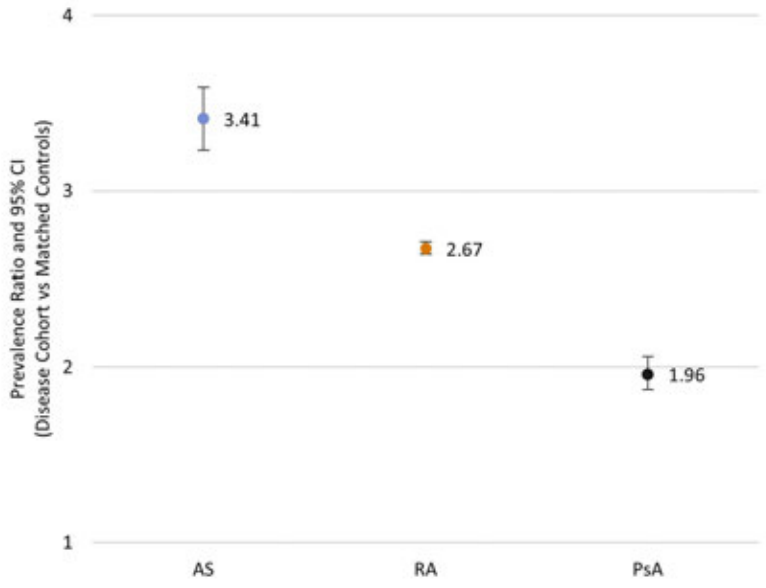
Figure 1: The percentage (and 95% confidence intervals) of patients with ≥1 opioid claim in the 4 quarters of BL preceding diagnosis and the 4 quarters of FU after diagnosis (inclusive) among A) AS patients and matched controls, B) RA patients and matched controls, and C) PsA patients and matched controls



BL: baseline; FU: follow-up; Q: quarter.

Conclusion: Opioid use is common among patients with IA in both the year preceding and the year following diagnosis, peaking at the time of diagnosis. For all IAs, prevalence of opioid claims and long-term opioid use were higher than in matched controls. Although patterns in these data are similar to those seen in Finland, the overall prevalence of any opioid use (in cases and controls) was higher in the USA. The prevalence of long-term opioid use was highest in AS patients compared to matched controls and highest among the 3 IAs, similar to the finding in Finland. The prev-

Figure 2: Prevalence ratios and 95% CIs for long-term opioid use in the 12 months following diagnosis (inclusive of the diagnosis date) among patients with AS, RA, or PsA compared to matched controls



CI: confidence interval

alence of opioid use in IA suggests the presence of uncontrolled pain in the period surrounding diagnosis. Given the ineffectiveness of opioids to address the underlying cause of IA, more comprehensive or appropriate treatments such as DMARDs and/or biologics to address the underlying disease should be considered, in accordance with relevant guidelines.

Background/Purpose: Uveitis is an extra articular manifestation of psoriatic arthritis (PsA). Uveitis may be more chronic Biological therapy, especially monoclonal TNF inhibitors, are useful to prevent and to treat refractory non-infectious uveitis. However, other biologics had been related to paradoxical uveitis. Our aim was to assess **a)** the epidemiological and clinical features of uveitis associated to PsA and **b)** its relationship with biological treatment used in PsA.

Methods: Observational study of unselected consecutive patients studied in a single reference University Hospital with**: a)** diagnosis of PsA by CASPAR criteria and **b)** diagnosis of uveitis by ophthalmologist exploration. Demographics features, clinical findings, complementary tests and treatment were recorded.

Results: We studied 320 (182 women/138 men) patients with PsA; mean age at PsA diagnosis of 41.7±15.79 years and with a delay of diagnosis from the onset of symptoms of 2.6±2.01 years.

Ten patients (4 men/6 women) out of 320 patients (prevalence 3.13%) with a mean age of 42.2 ± 16.8 years were diagnosed of uveitis after a mean follow-up of 10±7.9 years. In all cases, the uveitis had an anterior pattern. Only 1 (10%) of them had a bilateral affection, acute onset in 10 patients (100%), and 4 of them (40%) had a recurrent pattern. The diagnosis of uveitis preceded the one of PsA in 5 (50%) patients in 1.6±0.87 years. In those with a previous diagnosis of PsA, it was done 13.3±10.4 years before the uveitis onset. Only 1 patient (10%) with recurrent unilateral uveitis presented vitritis. In 10 patients the mean number of anterior chamber cells was 2±0.4. Comparison of baseline characteristics and clinical features between patients who developed uveitis and those who did not is shown in **table.**

Only 2 patients (20%) with uveitis received biological therapy. The first one developed its first episode of uveitis after 29 months with etanercept. After the episode, a switch to adalimumab was done, without any other episode of uveitis after 22 months of treatment. The second one was a patient with multiple episodes of recurrent uveitis, who developed new flares with adalimumab, certolizumab and golimumab.

Conclusion: Most of the uveitis had an anterior and unilateral pattern. The onset of uveitis in patients with PsA can either precede or go after the diagnosis of the PsA. HLA B27+ was more frequent in patients with uveitis. Biological therapy did not achieve good answer in patients with recurrent uveitis.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Growing evidence has pointed gender as a key variable influencing clinical response to biological drugs in psoriatic arthritis(PsA). Although the reasons remain unclear, it has been hypothesized that different clinical presentations could contribute to this gender-related contrast in treatment effectiveness.

Objective: to analyse the disease profile in male and female patients with PsA starting biological treatment.

Methods: Data from an observational prospective cohort including all patients with PsA initiating biological therapy from 2002-2018 in a university hospital was conducted. Demographic information, laboratory tests, disease presentation (axial presentation, including oligoarticular affection, and poliarticular presentation), disease activity indexes (ASDAS and DAPSA for axial and peripheral-only presentations, respectively) and concomitant treatment were collected before starting biological drug. Patients were stratified by gender to compare the characteristics of the populations. Chi-squared for categorical and t-student tests for continuous variables were used to analyse the differences between groups.

Results: Out of 109 included patients, 55 (51%) were males and 54 (49%) females. Baseline gender-stratified characteristics are shown in Table 1. Including the whole population of the study, mean age at diagnosis was 57 ± 14.6 years, mean PsA duration was 17.7 ± 9.2 years, and mean Body Mass Index (BMI) was 27.2 ± 4.9. Axial or oligoarticular presentation was shown in 57 patients (52%), whereas 52 patients (48%) had poliarticular manifestations. Mean

baseline ASDAS was 3.2 ± 1.0 and mean baseline DAPSA was 25.4 ± 13.6. Biological therapies initiated included etanercept in 42% of the cases, infliximab in 25%, adalimumab in 19%, golimumab in 7% and secukinumab in 6%. No significant differences were observed between genders for most of the characteristics including: age at starting biologic, disease duration, BMI, smoking habit, positive HLA B27 and rheumatoid factor, baseline activity, baseline ESR, baseline CRP, baseline sulfasalazine (SSZ), baseline prednisone (PRD), baseline patient global assessment and biological drug use. However, there was differences between gender in some other characteristics. While males had higher axial presentation of the disease (p=0.01), females had higher poliarticular disease (p=0.02) and used methotrexate more frequently (p=0.02). These differences in methotrexate use might be explained by the predominance of peripheral presentation in female patients.

Conclusion: In clinical practice, biological therapy (TNFi and IL-17i) is prescribed in a similar frequency in male and female patients with PsA. Nevertheless, the predominant articular manifestation behind the prescription of the biological therapy is different among genders: while men have predominant axial disease, women have predominant peripheral manifestations. These differences in clinical presentation in both genders may contribute to differences in therapeutic management, such as increased use of methotrexate in women with PsA who initiate biological therapy.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment of the disease in psoriatic arthritis (PsA) remains a clinical challenge. Hence, there is no agreement on which index best correlates with the actual disease state of patients.

Objective: to assess the performance of and agreement between composite activity indices of common use in clinical practice (DAPSA and DAS66) and the physician global assessment (PhGA) to evaluate disease activity in PsA patients under biological therapy.

Methods: Patients with peripheral-only PsA initiating a first biological therapy (TNFi and IL-17i) between 2002 and 2018 in a university hospital were included. Demographic information, laboratory tests, concomitant treatments, PhGA and disease activity indexes (DAPSA and DAS66) were collected at baseline and 6 months (6 m) after starting biological treatment. At 6 m, the patients were classified in the following disease activity status: remission (DAPSA PhGA was also determined at 6 months, and it was assorted by consensus of 3 expert rheumatologists in remis-

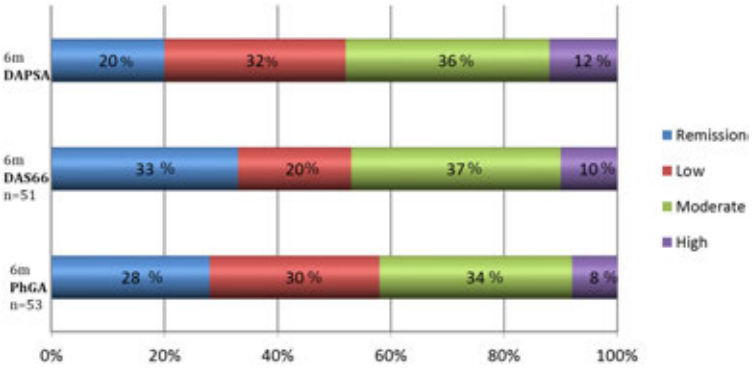

Figure 1. Clinical response after 6 months of biological therapy, shown as percentage of the total in each group.

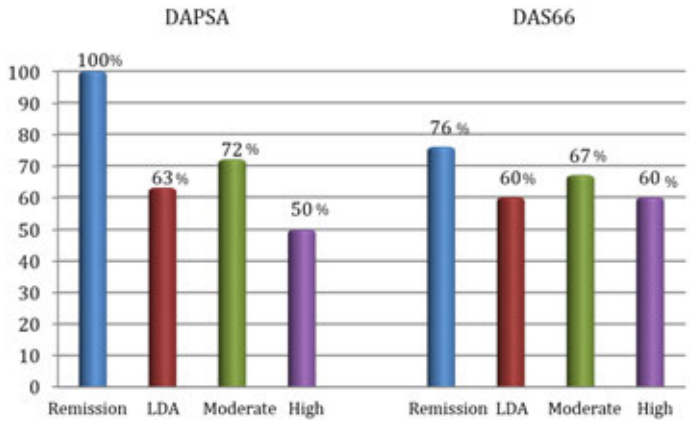

Figure 2. Agreement for disease activity status between disease activity indexes and PhGA.

sion (PhGA ≤ 10), LDA (PhGA >10-≤30), moderate activity (PhGA >30≤-60) and high activity (PhGA >60). The number (%) of patients achieving the different disease activity status by each of the different indexes at 6m and the agreement between PhGA scores and disease activity indices were determined.

Results: Out of 54 included patients, 20 (37%) were males, 37 (68%) were non-smokers, 34 (63%) had a BMI ≥25, with mean (SD) baseline disease activity indices of DAS 66: 4.8 (1.2) and DAPSA: 26 (14.9). Biological therapies initiated included etanercept in 37% of the cases, infliximab in 32%, adalimumab in 20%, golimumab in 4% and secukinumab in 7%. Clinical response at 6m according to different indexes and PhGA is depicted in Figure 1. More than half of the patients achieved at least LDA disease activity after 6 months of biological treatment, regardless of the index used. Thus, physician-perceived remission or LDA was frequent (58%). DAPSA index was the most stringent in terms of classifying patients in remission. Moderate to strong positive correlation was observed between DAS 66 and PhGA (Spearman $r = 0.729$, $p < 0.001$) and a strong correlation was observed between DAPSA and PhGA (Spearman $r = 0.852$, $p < 0.001$). The relative agreement between disease activity indexes and PhGA at 6 m for different disease activity states are shown in Figure 2. DAPSA classified better the patients in remission according to the PhGA.

Conclusion: In clinical practice, 50 % of the patients with PsA achieve at least a low activity state of the disease at 6 m after receiving a first biological therapy, and this is replicated by different indices. DAPSA based remission/LDA performed better than DAS66 to detect PhGA-defined remission or LDA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Gender has been lately suggested as influential in the response to treatment with biological drugs in spondyloarthritis. However, data about the association between gender and treatment response in axial PsA (axPsA) or peripheral PsA (pPsA) are scarce.

Objective: to analyze the association between gender and clinical response to biological therapy in patients with axPsA and pPsA.

Methods: An observational cohort study was conducted, prospectively collecting data from 108 patients treated with biological therapy (93% TNFi and 7% IL-17i) from 2002-2018. Patients were divided into two groups according to their clinical predominant manifestation: axPsA or pPsA. Disease activity indexes (ASDAS and BASDAI for axPsA and DAPSA and DAS28 for PsA) were collected before starting drug and 6 months later (baseline and 6m visit, respectively). Low disease activity (LDA) was defined as ASDAS < 2.1 or BASDAI < 4 (axPsA) and DAPSA ≤14 or DAS28 ≤ 3.2 (pPsA). Clinical improvement was defined as an improvement ≥ 1.1 points in ASDAS (dASDAS) or 50% in BASDAI (BASDAI50) for axPsA, and an improvement of 50 % in DAPSA (DAPSA50) or dDAS28 ≥ 1.2.

First, the frequency of male- and females - patients achieving LDA and clinical improvement at 6m were compared using Fisher test, separately for axPsA and pPsA. Second, the association between gender and each of the clinical outcomes was analyzed using logistic regression models adjusted for confounders (age, disease duration, previous biologics, smoking habit, body mass index (BMI), baseline DMARDs and baseline disease activity).

axPsA (n= 55)				pPsA (n= 54)			
	Males (n= 35)	Females (n= 20)	p-value		Males (n= 20)	Females (n=34)	p-value
LDA				LDA			
ASDAS <2.1	25 (74 %)	7 (37 %)	0.02	DAPSA ≤14	14 (74 %)	12 (39 %)	0.02
BASDAI < 4	24 (72 %)	5 (26 %)	0.02	DAS28 ≤ 3.2	13 (68 %)	6 (31%)	0.09
Clinical Improvement				Clinical Improvement			
dASDAS ≥ 1.1	20 (59 %)	7 (37 %)	0.15	DAPSA50	10 (53 %)	11 (36 %)	0.25
BASDAI50	16 (48 %)	3 (16 %)	0.04	dDAS28 ≥ 1.2	11 (57 %)	8 (42 %)	0.15

Table 1. Response rates after 6 months of biological therapy, stratified for PsA subtype and gender.

Results: Out of 108 included patients, 55 (51%) had predominant axPsA and 54 (49%) pPsA.

In the group of axPsA, 35 (64%) were males, 33 (60%) were nonsmokers, 33 (60%) had a BMI ≥25, with mean (SD) baseline disease activity of ASDAS: 3.3 (1.0) and BASDAI: 5.4 (2.0). The frequency of patients achieving clinical response was higher in males than females (Table 1). After adjusting for confounders, male gender was significantly associated with higher probability of achieving LDA (ASDAS OR=4.4; p=0.03 and BASDAI OR=6.0; p=0.01), and clinical improvement (dASDAS: OR=4.8; p=0.04 and BASDAI50: OR=5.19; p=0.03).

In the group of pPsA, 20 (37%) were males, 37 (68%) were nonsmokers, 34 (63%) had a BMI ≥25, with mean (SD) baseline disease activity indexes of DAPSA: 26 (14.9) and DAS 28: 4.8 (1.2). The frequency of patients achieving LDA was higher in males than females (74% vs 39%; p=0.02, respectively). After adjusting for cofounders, male gender was independently associated with higher probability of achieving LDA by DAPSA (OR=4.0; p=0.03) and DAS28 (OR= 2.1; p=0.3). Finally, an association between male gender and clinical improvement was also observed but this was statistically significant only when using dDAS28 as the outcome: OR=2.9; p=0.1 for DAPSA50 and OR=5.8; p=0.02 dDAS28.

Conclusion: Male gender is associated with a higher rate of response to biological treatment (TNFi and IL-17i) in axPsA and pPsA. This association is robust despite using the new recommended disease activity indices and cut-off points for clinical practice. Further investigations of these gender-related differences are important for a better management of PsA and for the development of new therapies.

Red Cell Distribution Width Positively Correlates with Atherosclerotic Cardiovascular Disease Risk Score in Psoriatic Arthritis and Decreases with BDMARD Therapy

Angela Gupta,[1] Sofi Damjanovska,[2] David Zidar,[3] Donald Anthony,[4] and Maya Mattar[3], [1]Case Western Reserve University, Cleveland, [2]Case Western Reserve University, Cleveland Heights, OH, [3]Louis Stokes Cleveland VA Medical Center, Cleveland, OH, [4]Case Western Reserve University, Cleveland, OH

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Red blood cell distribution width (RDW) is a parameter that measures variation in red blood cell size and volume. It is elevated when there is variation in red cell size (anisocytosis). RDW has been found to be a predictor of cardiovascular disease (CVD), but is not commonly incorporated in current risk evaluation instruments. Research has linked an elevated RDW to disease activity in psoriasis, but limited data is available on the relationship between these parameters and psoriatic arthritis.

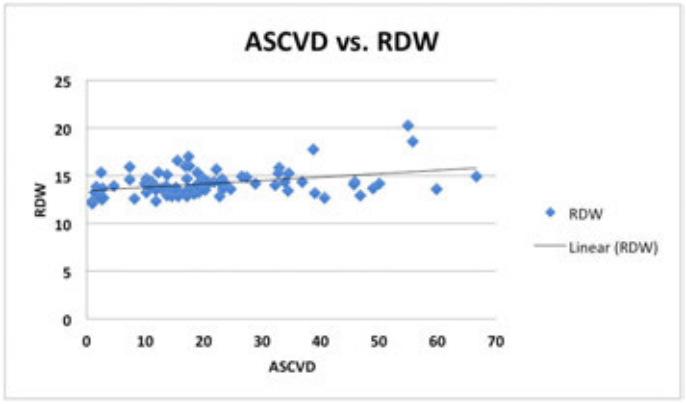

Figure 1 depicts the positive linear correlation between ASCVD score and RDW (r =.35, p-value = 0.001).

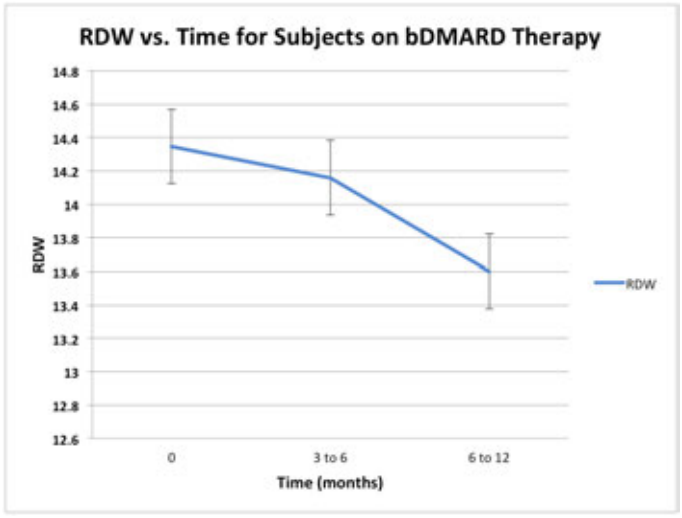

Figure 2 depicts the relationship between RDW over time for patients on bDMARD therapy alone. A trend towards a decline in RDW from 0 to 12 months was observed (p = 0.11).

Methods: We performed a retrospective chart review study examining the relationship between RDW, MPV, hemoglobin, absolute lymphocyte count (ALC), and atherosclerotic cardiovascular disease (ASCVD) 10 year risk score (incorporating age, hypertension status, diabetes mellitus (DM) status, lipid profile, and smoking status) in a cohort of patients with psoriatic arthritis, taking into account their HLA-B27 status, race, and treatment history.

Results: RDW was positively correlated with ASCVD score, and RDW was found to decrease over 12 months for all patients started on bDMARD therapy. As expected, we found positive correlations between ASCVD score, hemoglobin A1c, and age, and negative correlations between ASCVD score, hemoglobin, and albumin. Patients started on NSAID therapy had a statistically significant increase in RDW between time 0 and 6 months (p = 0.03), but this was not maintained at twelve months. Patients on csDMARD therapy did not experience a statistically significant change in RDW at 6 or 12 months, while patients on bDMARD and bDMARD + csDMARD therapy experienced a statistically significant decline in RDW from 0 to 6 months (p = 0.046) and from 0 to 12 months (p = 0.040). When patients on

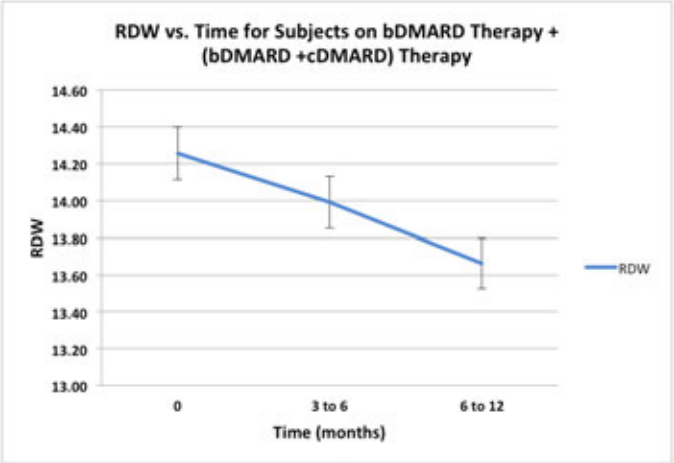

Figure 3 shows the relationship between RDW over time for patients on both bDMARD therapy and bDMARD and cDMARD therapy. A statistically significant decline in RDW from 0 to 6 months (p = 0.046) and from 0 to 12 months (p = 0.040) was observed.

bDMARD therapy were analyzed alone, a trend towards a decline in RDW from 0 to 12 months was also observed (p = 0.11).

Conclusion: This data shows that not only is there is a positive correlation between RDW and traditional cardiovascular risk factors, as represented by ASCVD score, in patients with psoriatic arthritis, but also that bDMARD therapy appears to be associated with decreasing RDW in these patients over time, the latter consistent with RDW in part reflecting disease activity. Whether RDW adds to cardiovascular risk assessment beyond traditional cardiovascular risk factor analysis is yet to be determined. Data here suggest it may be a viable candidate since it appears to reflect both disease activity and traditional risk factors. More investigation related to bDMARD therapy and other non-conventional parameters of disease activity in psoriatic arthritis as they relate to CVD is warranted. This could have powerful clinical implications, as having other approaches of monitoring disease activity (aside from ESR and CRP) would be beneficial for patients.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity of psoriatic arthritis (PsA) is affected by many parameters including joint, spinal and skin involvement, enthesitis, dactylitis and pain. According to disease activity indices such as DAPSA, DAS28 and MDA, some patients may not be in remission even though they do not have joint involvement and arthritis.

The aim of this study was to assess the clinical parameters that affect remission in patients with PsA

Methods: This study involved patients with PsA consistent with CASPAR criteria from Turkish League Against Rheumatism (TLAR) Network multi-centre study. The demographic and clinical parameters of patients (pain VAS, patient global VAS, doctor global VAS, tender and swollen joint) were recorded. Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Psoriasis Area and Severity Index (PASI), fatigue with the VAS (0-10), Hospital Anxiety and Depression Scale (HAD), Fibromyalgia Rapid Screening Tool (FIRST), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Health Assesment Questionnaire (HAQ) were evaluated. DAS28, DAPSA and minimally disease activity (MDA) were used to asses the disease activity and remission. The patients were classified into two groups, according to their remission status and swollen joint count. (group 1 are in remission and no swollen joint; group 2 patients are not in remission and no swollen joint). The Spearman correlation coefficient was used to evaluate the correlations between variables. The Mann-Whitney-U test and Chi-squared test were used for comparison between the groups. $P< 0.05$ was considered statistically significant. The SPSS22.0 statistic package was used for statistical analysis.

Results: Of 1134 patients diagnosed with PsA, 720 patients (471 female (%65.4), 249 male (%34.6) were found to have peripheral involvement. The mean age was 47,6 years (SD:12.03). The median disease duration was 6.47 years (min:0, max:44). DAPSA, DAS28 and MDA scores were obtained in 561, 687 and 553 patients (Table 1). The two groups were similar in terms of age, gender, educational status, disease duration ($P >0.05$). Group 1 and 2 differed significantly in terms of VAS pain, VAS global pain, VAS doctor global, tender joint count, fatigue, anxiety, depression, FIRST score, PASI, BASDAI, enthesitis and HAQ score ($p< 0.05$) (Table-2)

	DAS28	DAPSA	MDA
Swollen joint 0 and remission n (%)	108 (15)	10 (1.4)	62 (8.6)
Group-1			
Swollen joint 0 and not remission n (%)	242 (33.6)	269 (37.4)	220 (30.6)
Group-2			
Swollen joint ≥1 and not remission n (%)	305 (42.5)	279 (38.8)	258 (35.8)
Swollen joint ≥1 and remission n (%)	32 (4.4)	3 (0.4)	13 (1.8)

Table-1: Patients according to DAPSA remission, DAS28 remission and MDA DAS28 DAPSA MDA

	DAPSA remission			MDA

Enthesitis median (min-max)	1 (0-13)	2 (0-13)	*<0.05*	0 (0-13)	2 (0-13)	*<0.05*

Table-2: Comparison of the groups according to DAPSA remission and MDA

Conclusion: PSA may not be in remission even though joint involvement has been controlled. In these patients fatigue, pain, anxiety, depression, fibromyalgia, functional disorders, skin lesions, enthesitis, tender joint and spinal involvement more often than the patients in remission and no active joint involvement. In the evaluation of the disease activity, it is necessary to make evaluations by using composite scales.

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: MicroRNAs (miRNAs) are small non-coding RNAs which are regulating physiologic and pathological processes. In numerous diseases specific miRNA signatures have been identified and can potentially serve as biomarkers. In psoriatic arthritis (PsA) no specific biomarker is available so far. As previously shown, inflammation of peripheral joints in patients with psoriasis can be identified using MRI technique despite no clinical evidence for psoriatic arthritis. Therefore, specific biomarkers to capture these patients at an early time point is of clinical interest. The aim of this pilot study was to identify specific circulating miRNA signatures in patients with psoriasis and psoriatic arthritis and to investigate potential biomarkers for inflammatory involvement of joints.

Methods: 16 patients with (PsA) fulfilling CASPAR criteria and 16 patients with psoriasis (PsO) without any current or past clinical symptom of arthritis or enthesitis received high field MRI of the hand, demographic and clinical data including disease duration, activity scoring as well as demographic data were collected. MRI scans were scored according to PsAMRIS method. 187 miRNAs were quantified in serum of PsA and PsO patients and 16 age- and sex-matched controls (CO) using RT-qPCR (TAmiRNA Vienna).

Results: PsA patients, PsO patients and CO had a comparable age (median (IQR), years, 48.5 (13.0) vs 53.0 (10.0) vs 48.0 (15.0), p=0.547). In all 3 cohorts 50% were females. BMI was higher, but not significantly above the upper normal range in PsA and PsO patients compared to CO(p=0.177). The median (IQR) disease duration of PsA patients was 2.5 (10) years. Duration of skin disease was 14.0 (31) years in PsA patients vs. 12.0 (14) years in PsO patients. 60% of PsO patients reported unspecific arthralgias without clinical signs of arthritis. In PsA Minimal Disease Activity (MDA) was present in 46.7% of patients. Psoriasis Area and Severity Index (PASI) was 0 (0.1) in PsA vs. 1.7 (5.3) in PsO patients. In MRI osteitis was found in 18.8% of PsA patients vs. 12.5% of PsO patients. Synovitis was present in 37.5% of PsA patients and in 43.8% of PsO patients. 1 patient of each group showed periarticular inflammation and tenosynovitis was only detected in PsA patients (25%). In the first analysis significant differences in miRNA profiles of patients with PsA, PsO and controls have been revealed. We were able to identify 51 miRNAs in the PsO and 64 miRNAs in the PsA group significantly down or upregulated (BH-adjusted $p < 0.05$) compared to healthy CO. Between

these signatures, an overlap of 33 miRNAs, which were significantly changed in PsA and PsO compared to CO was detected (adjusted p< 0.05), while 18 (PsO) and 31 (PsA) miRNAs were specific to each group.

Conclusion: The results of miRNA analysis in this pilot study in patients with psoriasis and psoriatic arthritis suggest that serum microRNA levels are not identical between PsO and PsA compared to CO, and that miRNAs could serve as biomarkers to detect a joint involvement in psoriasis in the future.

MDA *Versus* DAPSA: Applicability in a Real World

rafaela Gonçalves,[1] Lays Martins,[2] henrique mariz,[1] marina brito,[3] georgia pereira,[3] andrea dantas,[3] and Angela Duarte[2], [1]clinical hospital of federal university of pernambuco, recife, Pernambuco, Brazil, [2]Universidade Federal de Pernambuco, Recife, Brazil, [3]clinical hospital of federal university of pernambuco, recife, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a progressive, chronic, and potentially irreversible inflammatory disorder. Systematic clinical follow-up of PsA patients is necessary to maintain and adjusting the proposed therapy. There are two different disease activity composite index suggested by Treat To Target (1). MDA (2) defines a state of illness and includes joint involvement, skin, enthesis and quality of life questionnaire, while DAPSA (3) stratifies disease activity in remission, low, moderate or high disease activity, and does not evaluate skin, enthesitis neither quality of life. Thus, our work aims to establish if these indexes are comparable and evaluates the feasibility of applying each one of them in the clinical practice of our outpatients.

Methods: Methodology: We used data of 124 outpatients of Clinicals Hospital of Federal University of Pernambuco (HC-UFPE), Brazil, between October 2016 and December 2018, who met the criteria of CASPAR (4) and aged ≥18 years. The study was approved by the local medical research ethics committee (CAAE 08028119.7.0000.8807). MDA was defined as having at least five of the seven items that compose it (painful joints ≤1, swollen joints ≤1, LEI ≤1, PASI ≤1, patient global visual analogue scale (VASptGlobal) ≤20mm, patient pain (VASptPain) ≤15mm and HAQ ≤0.5. DAPSA is calculated with the number of painful + swollen joints + VASptGlobal (0-10 cm) + VASptPain (0-10 cm) + PCR mg/dL and low disease activity or remission (DAPSA-LDA/REM) if ≤14. Average disease burden of patients in MDA and DAPSA-LDA/REM was compared. The agreement between the tested definitions was established using 2×2 tables and calculation of a *kappa*.

Results: Of the total population (124 patients), MDA was performed in 107 (86.3%), of which 40 (37.4%) reached MDA (minimum 5/7); and DAPSA could be done in 77 (62.1%) patients, of which 48 (62.3%) were in DAPSA LDA/REM. There was a moderate agreement between DAPSA LDA/REM and MDA (*kappa*=0.544) (95%IC: 0.371 to 0.717) as shown in table 1. All patients in MDA, except 2, were with DAPSA LDA/REM, however, some who achieve DAPSA

	DAPSA REM/LDA	DAPSA MDA/HDA	*kappa*
MDA	33	2	0.544
NOT-MDA	16	26	

table DAPSA REM

TABLE 1. Number of patients according disease status DAPSA LDA/REM (Low/Remission) or DAPSA MDA/HAD (Moderate/High), and achieving or not MDA

LDA / REM did not reach the MDA. Of the 14 patients in DAPSA LDA/REM, but not in MDA, did not fill at least 1/7 of the domains, as 6 for the (HAQ), 4 (PASI/BSA), 2 (joint pain and edema), and 2 (enthesitis). In addition, of the 48 patients who reached DAPSA LDA/REM, 6 (12.5%) patients had at least one enthesitis. With regard to the achievement of the disease activity composite indexes, it was not possible to perform the DAPSA in 47 (37.9%) patients, since 34 (27.4%) patients had no CRP result needed to perform calculation and the other 12 had chronic pain secondary to fibromyalgia. In the other hand, was not possible to perform the MDA in 17 (13.7%) because there was no record in the last consultation of the updated BSA/PASI skin or HAQ, or by associating fibromyalgia.

Conclusion: Because they have moderate agreement, both can be used in clinical practice. Though, we believe that MDA could be the more feasible in following-up our patients, noting that the difficulty of performing CRP was the main limitation for DAPSA. Besides, enthesitis was present in 12.5% even when in LDA/REM

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) prevalence is equal in men and women, though gender may play a role in driving mechanisms of PsA leading to differences in manifestations of clinical disease (1). This analysis assessed key differences in clinical characteristics, disability, quality of life, and work productivity by gender in real-world practice.

Methods: Cross-sectional survey of rheumatologists and dermatologists and their patients in France, Germany, Italy, Spain, UK, and US. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Data were analyzed by gender. Demographic characteristics, treatment use, and clinical characteristics (Tender Joint Count [TJC], Swollen Joint Count [SJC], Body Surface Area [BSA] psoriasis) were

Table 1: Demographic and clinical characteristics in women and men [mean (SD) or n (%)]

	Women	Men	P value
n (%)	1047 (46.1)	1223 (53.9)	-
Age, years	48.3 (13.7)	48.8 (12.8)	0.42
Working full time*, n (%)	206 (49.4)	350 (68.6)	<0.01
Charlson Comorbidity Index score	1.10 (0.51)	1.15 (0.58)	<0.01
Time from first symptoms to diagnosis, years	1.48 (3.53)	1.14 (2.48)	0.76
PsA duration, years	4.87 (6.15)	4.95 (5.79)	0.42
Currently receiving biologic treatment, n (%)	557 (53.2)	674 (55.1)	0.38
BSA psoriasis involvement, mean %	5.5 (8.4)	5.5 (8.1)	0.87

Table 2: Quality of life, disability, and work productivity in women and men [mean (SD)]

	Women	Men	P value
EQ5D utility score	0.80 (0.18)	0.82 (0.17)	0.02
HAQ-DI score	0.56 (0.60)	0.41 (0.52)	<0.01
PsAID12 score	2.66 (2.07)	2.27 (1.98)	<0.01
WPAI percentage of activity impairment	27.9 (22.0)	24.6 (22.4)	<0.01
WPAI percentage of work time missed	4.0 (14.0)	5.8 (19.2)	0.62

reported by physicians, while quality of life (EQ5D and PsAID12), disability (HAQ-DI), and work productivity (WPAI) were reported by patients. Men and women were compared using parametric tests and non-parametric tests where appropriate.

Results: Data were collected for 2270 patients (595 US, 1675 Europe). Demographic characteristics, time from first symptoms to diagnosis, biologic treatment, and clinical characteristics were comparable between women and men (Table 1). More women reported worse quality of life, disability, and work activity impairment than men (Table 2).

Conclusion: In women and men with similar PsA disease activity and treatment rates, women experienced worse quality of life, greater disability, and greater work impairment, despite a lower burden of comorbidities.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is an inflammatory skin disease. Psoriatic arthritis (PsA) is an inflammatory arthritis that affects 30% of psoriasis patients. The heterogeneity of psoriatic disease (PsD- psoriasis and PsA) is partly explained by genetic heterogeneity: human leukocyte antigen (*HLA)-C*06* is the strongest genetic risk factor for psoriasis without arthritis (PsC), while *HLA-B*27* and other *HLA-B* alleles are more strongly associated with PsA. Yet, PsD pathogenesis is not fully understood, inspiring an interest in the role of an important environmental factor: the microbiome. We aimed to characterize the cutaneous microbiome of psoriatic plaques and compare its diversity between PsC and PsA patients and between the major PsD-associated *HLA* alleles.

Methods: Skin swabs were obtained from a psoriatic lesion on the extensor aspect of the elbow or knee, and from unaffected skin on the contralateral joint in PsC patients (psoriasis diagnosed by a dermatologist, evaluated by a rheumatologist to exclude PsA) and PsA patients satisfying CASPAR criteria. Control samples were taken from matched sites in healthy subjects. PsA patients were evaluated by a rheumatologist using a standard protocol to determine the number of affected joints, peripheral and/or axial joint involvement. Subsequently, microbial DNA was isolated from the swab samples, and high-throughput 16S ribosomal DNA sequencing was utilized to characterize the cutaneous microbiota. Molecular HLA Class I typing was done from DNA obtained from peripheral blood, and subjects were classified as being *HLA-C*06* positive, *HLA-B*27* positive or *HLA-C*06* and *-B*27* negative (termed double negative). All study subjects were Caucasian. Dada2 pipeline was used in the bioinformatic analysis to infer unique amplicon sequences from raw reads and remove chimeric sequences. QIIME v.1.9.1 was used to assign taxonomy with reference to an internally-designed 16S database, and to compute alpha-diversity. Biostatistical analysis was performed in R.

Results: We recruited 34 healthy controls (59% male), 55 PsC patients (47% male), and 136 PsA patients (63% male). 38 PsC and 90 PsA patients were included in this analysis after excluding subjects with recent use of topical

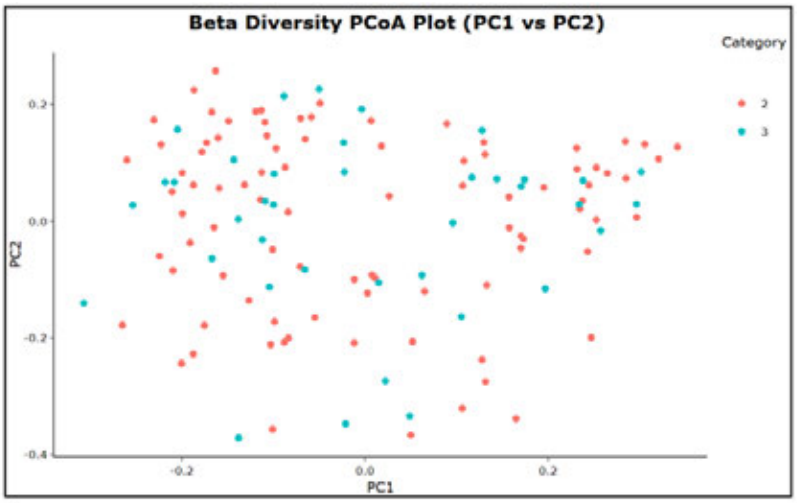

Figure 1: PsC vs PsA lesions demonstrate no distinct clustering of PsA (pink) and PsC (blue) on a beta-diversity principal coordinate analysis plot

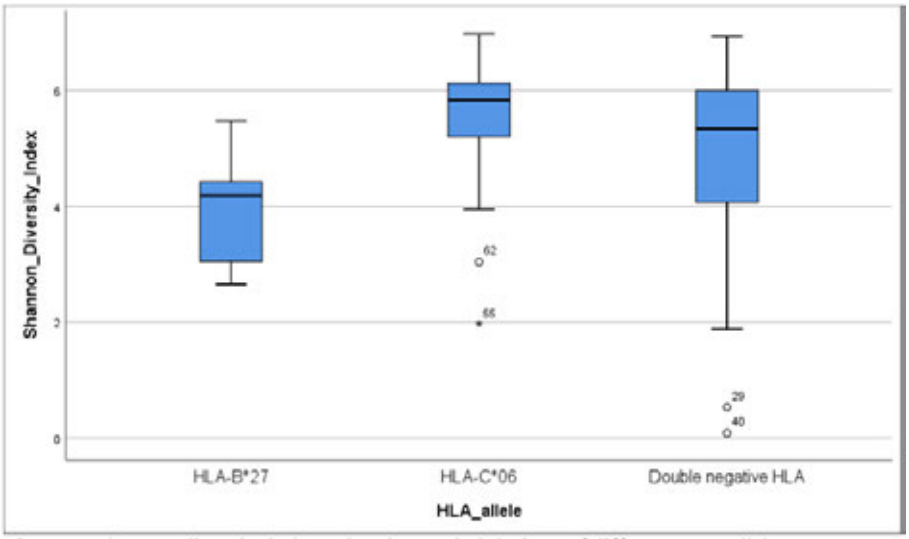

Figure 2: Shannon diversity index values in psoriatic lesions of different HLA alleles

ointments (≤7 days), antibiotics (≤3 months), and other related treatments. Linear model demonstrated that alpha diversity was significantly higher in lesional compared to unaffected samples in all PsD patients, as measured by Shannon diversity index (p=0.0106). However, there was no significant difference in lesional diversity between PsA and PsC patients (p=0.2244) (Figure 1). Interestingly, while there was no significant difference in alpha diversity between lesional swabs from *HLA-B*27*-positive compared to double negative patients (p=0.1401), it was shown to be significantly higher in lesional swabs from *HLA-C*06*-positive patients compared with both *HLA-B*27*-positive patients (p=0.0066) and double negative patients (p=0.0331) (Figure 2) by analysis of variance with Tukey's correction for multiple comparisons.

Conclusion: The cutaneous lesional microbial diversity of patients with psoriatic disease may be influenced by the *HLA-C*06* but not *–B*27* alleles.

Data are as observed, median (IQR) or percentage; csDMARD: conventional synthetic Disease Modifying Anti Rheumatic Drug; DAS28Disease Activity in 28 joints; DAPSA28: Disease Activity in Psoriatic Arthritis in 28 joints; SJC28:28 Swollen Joint Count; 28TJC: 28 Tender Joint Count; VAS: visual analogue scale; HAQ: Health Assessment Questionnaire.

Background/Purpose: Tumor necrosis factor inhibitors (TNFi) have contributed to improved prognosis in patients with psoriatic arthritis (PsA). However, many patients treated with TNFi fail to achieve a treatment target of remission. Hence, the aims of this study were to identify predictors of 6-month Disease Activity in Psoriatic Arthritis in 28 joints (DAPSA28)(1) remission (DAPSA28≤4) in bio-naive PsA patients starting TNFi in clinical practice and investigate the performance of the derived prediction model.

Methods: Pooled data from PsA patients in 13 European registries participating in the EuroSpA Research Collaboration were analyzed(2). Patients with a 6-month follow-up visit (time window 3-9 months) with data allowing for calculation of DAPSA28, were included. The study cohort was divided into a derivation and validation cohort (50% of patients from each registry in each sub-cohort). Logistic regression analyses were applied to identify conventional

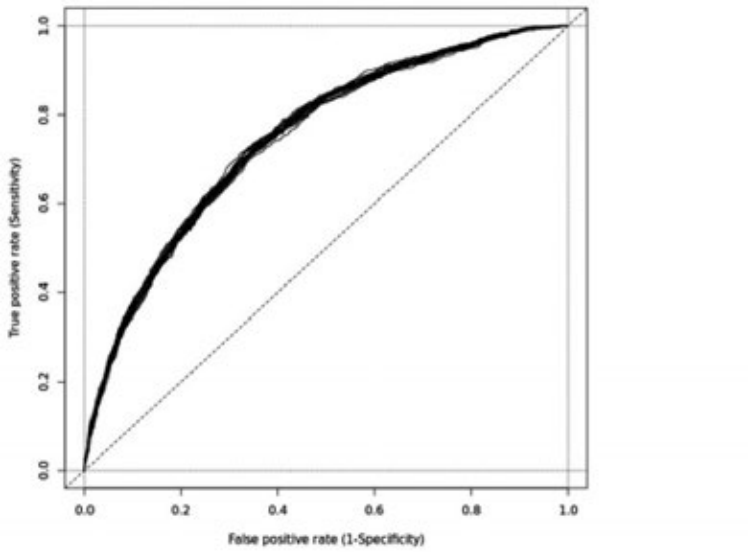

Figure 1: Receiver Operating Curves in the validation cohort (20 imputed datasets).

clinical variables (marked with bold in Table 1) associated with DAPSA28≤4 at 6 months in the derivation cohort. Missing covariate data were imputed with Multiple Imputation with Chained Equations. Variables with a p-value < 0.25 in univariate analyses were included in the initial multivariable model. A priori it was decided to adjust for age, gender and country. Purposeful selection guided removal of variables from the multivariable model. Model fit was tested in the validation cohort by area under the Receiver Operating Curve (ROC) and misclassification error.

Results: Of the 16,230 PsA patients in the EuroSpA database 7,975 patients initiating 1st TNFi had a registered follow-up visit with registered variables for DAPSA28 calculation and were included in the study. The study cohort had slightly higher baseline disease activity than the patients without DAPSA28 assessment at follow-up (Table 1). At 6 months, 1,956 (24.5%) patients were in DAPSA28 remission. Based on univariate analyses, all tested variables except concomitant csDMARD and time since diagnosis were included in the initial multivariate model. The final multivariate model identified that current or past smoking, treatment start prior to 2009, normal CRP, high 28TJC, high global, fatigue and HAQ scores decreased the probability of DAPSA28 remission at 6 months (Table 2). The regression coefficients of the model were used to derive a prediction index for each patient in the validation cohort, determining their predicted probability of DAPSA28 remission at 6 months. The ability of the model to correctly predict DAPSA28 remission using different cut-offs for predicted probability are shown with the ROC (Figure 1). The fit was deemed reasonable (median area under the curve 0.75, misclassification error 0.22).

Conclusion: A prediction model based on conventional clinical variables correctly predicted DAPSA28 remission status at 6 months in 3 out of 4 patients in a validation cohort. Future studies should investigate the potential of improving the model by addition of imaging and soluble biomarkers.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is now an increasing range of drug options in PsA. To inform the update of the EULAR PsA management recommendations (Ref 1), we performed a systematic literature review assessing the efficacy and safety of pharmacological agents in PsA.

Methods: Original articles published since the last EULAR literature review (2015) until 2018 in English were searched in Medline, Embase and Cochrane Library, as well as ACR/EULAR abstracts (2015-2018). For efficacy, randomised controlled trials (RCTs) investigating pharmacological interventions, defined as biological (b)DMARDs, targeted synthetic (ts)/conventional synthetic (cs)DMARDs were analysed. The main efficacy outcomes were ACR response criteria, PASI75, enthesitis, physical function and radiographic progression. For safety, also cohorts and case-control studies were analysed with a focus on adverse events, infections, cancer and cardio-vascular events.

Results: Of 6380 articles (efficacy: 2191, safety: 4189), 76 (68 original articles and 8 abstracts) were analysed. The drugs most investigated over the timeframe of this search were TNFi (5 trials) and IL17i (5 trials) (Table 1). Other drugs with mechanisms not previously published on in this indication were especially IL23-p19 inhibitors and JAK inhibitors (Table 1).

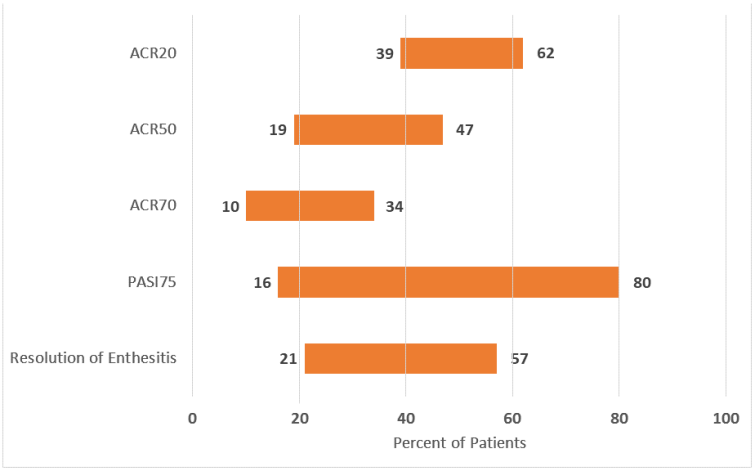

Figure 1. Chart showing range of efficacy across trials, in the active treatment arms, at the primary timepoint on different outcomes in PsA randomised controlled trials published 2015-2018.

All trials of original drugs, except one open-label study comparing Ustekinumab to TNFi, were placebo-compared trials and met their primary endpoint, ACR20 (Table 1). Figure 1 indicates the variety of responses across disease manifestations. Biosimilar comparison with bio-originator showed non-inferiority.

Safety was evaluated in 32 articles. One article, investigating patients in the ARTIS and DANBIO registries did not show an increased risk of cancer with TNFi compared to TNFi naïve PsA patients and the general population. There was an increased risk of Candida infections and inflammatory bowel disease with IL17 inhibiting agents. Two longitudinal cohorts showed an elevated risk for major adverse cardiac events in PsA. One longitudinal cohort study showed no association of cardiovascular events with any treatment.

Conclusion: New drugs targeting IL17A, IL23-p19, JAK, CD80/86, TNF/IL17A and IL6 demonstrated efficacy for the treatment of PsA with varying responses across different disease domains. Efficacy of TNFi agents and other bDMARDs was confirmed. Investigated biosimilars were non-inferior to their reference products. No new major safety signals were identified, though long-term studies and more registry data are needed. This literature review informed the EULAR updated recommendations for management of PsA.

IL-6 and TNF-α Influence on Clinical Manifestations, Activity and Comorbidity in Psoriatic Arthritis Patients

Maria Elisa Acosta,[1] Luis Gomez-Lechon,[1] Guadalupe Manzano Canabal,[1] Olga Compan,[2] Cristina Hidalgo,[3] Olga Martinez,[1] Ana Turrión,[1] Javier del Pino,[1] and Carlos Montilla[1], [1]Hospital Clínico Universitario de Salamanca, Salamanca, Spain, [2]Hospital Clinico Universitario de Salamanca, SALAMANCA, Spain, [3]Hospital Clínico Universitario de Salamanca, Salamanca, Castilla y Leon, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The activation of the Th-1 and Th-17 lymphocytes response seems to be one of the causes associated with PsA onset. During this process cytokines like TNF-α and Il-6 play an important role in chronic inflammatory response. However, their role in clinical manifestations and comorbidity is less known.

Purpose: To relate the IL-6 and TNF-α serum levels with clinical spectrum, presence of dactylitis, enthesitis, disease activity and comorbidity in a group of patients with PsA.

Methods: A Cross-sectional study with 194 PsA patients (diagnosed by the CASPAR criteria). IL-6 and TNF-α serum levels were determined by ELISA. The clinical variables measured were: clinical spectrum (peripheral, axial or mixed), presence of dactylitis, enthesitis, psoriasis (measured by PASI score) and HLA-B27. Disease activity was measured with the minimal disease activity criteria (MDA). In regards to comorbidity, we measured cardiovascular risk markers such as waist-to-hip ratio (WHR), Apolipoprotein A, Apolipoprotein B, Lipoprotein A, Insulin, Insulin resistance and microalbuminuria; hepatic steatosis was measured by ultrasound and fatigue by FACIT-F questionnaire.

Results: Of the 194 patients, 107 were men (55.2%) and 87 (44.8%) female. The mean of age was 53.33 years (SD: 10.86). 14.9% were receiving biological therapy. Eighteen patients had an exclusive axial affectation, 72 mixed and 104 peripheral only. 17.5% were HLA-B27 positive and 52.1% had a MDA. Regarding IL-6, we found no correlation

	Mean IL6 (SD)	P
Biological therapy (yes/no)	5,97(5,20)/ 5,68(4,24)	0,87
Dactylitis (yes/no)	7,35(4,63)/5,26(4,66)	0,24
MDA (yes/no)	5,15(4,65)/6,34(4,53)	0,38
Axial/mixed/peripheral	4,33(3,24)/ 6,87(5,31)/5,20(4,89)	0,34
HLA-B27 (+/-)	2,84(1,70)/6,29(4,76)	0,001
Axial+Mixed+HLA-B27(-)/Axial+Mixed+HLA-B27(+)	7,54(5,02)/2,91(1,89)	0,01
Hepatic steatosis (yes/no)	6,07(4,79)/3,82(2,87)	0,17

Table 1

	Mean TNF-α (SD)	p
Biological therapy (yes/no)	180,68(176,20)/12,57(10,12)	0,001
Dactylitis (yes/no)	24,75(18,75)/57,48(37,95)	0,29
MDA (yes/no)	74,86(62,66)/18,93(9,20)	0,009
Axial/mixed/ peripheral	50,70(37,32)/63,12(97,98)/28,86(18,79)	0,19
HLA-B27 (+/-)	72,68(67,24)/45,58(41,42)	0,23
Axial+Mixed+HLA-B27(-)/Axial+Mixed+HLA-B27(+)	46,02(40,83)/38,61(3,27)	0,70

Table 2

with the number of entheses affected, SJC, PASI, ESR, WHR, Apolipoprotein A, Apolipoprotein B, Lipoprotein A, Insulin, Insulin resistance, microalbuminuria, nor FACIT-F. We found a positive correlation between IL6 levels and CRP (R=0.41, p< 0.0001). The rest of the results are shown in Table1.

Regarding TNF-α, we found no correlation with number of entheses affected, SJC, PASI, ESR, CRP, WHR, Apolipoprotein A, Apolipoprotein B, Lipoprotein A, insulin, insulin resistance, microalbuminuria nor FACIT-F. The rest of the results are shown in Table2.

Due to the close correlation between the use of biologicals and TNF-α serum levels, we analyzed them between TNF-i and Ustekinumab/Secukinumab (242.18 SD: 207.71 vs. 32 SD: 27.32, p < 0.007). In the analysis excluding patients treated with biologicals, we only found a positive correlation with microalbuminuria (R:0.72, p< 0.001), even when excluding patients with a history of hypertension or diabetes (R: 0.37, p< 0.004). We found no correlation between IL-6 and TNF-α levels (R:-0.01, p< 0.85).

Conclusion: Excluding CRP, we found no correlation between IL-6 levels and clinical disease activity or comorbidity. In our results HLA-B27 influenced IL-6 levels, but it is unknown the pathogenesis on which this relationship is based, however findings that correlate IL-6 polymorphisms with HLA-B27 may indicate that the relationship obtained is not casual. On the other hand, blockade of TNF-α causes higher TNF-α serum levels. TNF-α was associated with subclinical kidney damage in PsA patients with or without diabetes. Even though this cytokine is known to be involved in kidney damage this correlation has not been documented in non-diabetic PsA patients.

Comparison of Comorbidity in Spondyloarthritis: Influence on Inflammatory Activity in Patients with Psoriatic Arthritis

Luis Gomez-Lechon,[1] Maria Elisa Acosta,[1] Guadalupe Manzano Canabal,[1] Olga Compan,[1] Cristina Hidalgo,[2] Olga Martinez,[1] Ana Turrión,[1] Javier del Pino,[1] and Carlos Montilla[1], [1]Hospital Clínico Universitario de Salamanca, Salamanca, Spain, [2]Hospital Clínico Universitario de Salamanca, Salamanca, Castilla y Leon, Spain

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous disease that is included in the group of spondyloarthritis. Although PsA has its own clinical characteristics, it has a relatively specific comorbidity in relation to the rest of the entities that make up the group. The most frequent comorbidities in PsA are emotional disorders (anxiety and depression) and obesity. Its presence implies a deterioration in the quality of life, an increase in mortality and constitutes a factor to be taken into account in the selection of treatment. However, the influence of these comorbidities on the activity of the disease is less known.

Purpose: To compare the presence of psycho-affective disorders and factors associated with obesity in patients with spondylitis and PsA. Relate them to the activity of the disease in patients with PsA.

Methods: Prospective longitudinal study that included 100 patients with ankylosing spondylitis (AE) and 160 patients with PsA who attended the outpatient clinics of a tertiary hospital. Patients with PsA who had at least four assessments of the activity in one year, measured by the minimum disease activity (MDA), were included in the study. We compared those patients who met MDA criteria in the four visits compared to the rest of the patients. The tendency to anxiety and depression was evaluated using the Hospital Anxiety and Depression Scale (HADS) questionnaire. Regarding cardiovascular comorbidity, the waist / hip ratio and the analytical variables were measured: apolipoprotein A, apolipoprotein B, A lipoprotein, C peptide, insulin, insulin resistance (HOMA) and leptin. CRP, ESR and IL-6 were also measured. The age, the disease duration and the treatment used were collected basally. Due to the circadian

Table 2

variation of these determinations, all were collected at the same time. Patients with diabetes mellitus, dyslipidemia in treatment or thyroid disease due to the influence on the parameters associated with cardiovascular comorbidity were excluded.

Results: The significant differences between the patients with ankylosing spondylitis and Aps are shown in Table 1. When comparing the patients with PsA that reached a MDA compared to the rest, the following significant differences were found Table 2. Among the variables that make up the MDA concept, only the number of swollen joints (r: 0.22, $p < 0.009$) and HAQ (r: 0.20, $p < 0.01$) were correlated with the concentration of leptin . There was no correlation between leptin levels and those of PCR, VSG or IL-6.

Conclusion: In our study, patients with PsA presented a higher concentration of several markers of vascular risk (insulin resistance, apoprotein A and leptin) compared to patients diagnosed with spondylitis. In the PsA, leptin influenced to a greater extent than the emotional factors (anxiety and depression) to reach a prolonged MDA. Leptin correlated with the number of swollen joints but not with acute phase reactants (ESR and CRP) or IL-6. These results could confirm that leptin would promote a low-grade inflammation not detected by the levels of ESR, CRP or IL-6.

Background/Purpose: Oligoarthritis, defined as ≤4 affected joints, was recognized as a pattern of psoriatic arthritis (PsA) by Moll and Wright. In some jurisdictions, patients with oligoarticular disease are not able to receive biologic therapy. It remains unclear whether patients with oligoarticular disease differ from those with polyarticular disease and what predicts progression from oligoarticular to polyarticular disease.

Oligoarthritis, defined as ≤4 affected joints, was recognized as a pattern of psoriatic arthritis (PsA) by Moll and Wright. In some jurisdictions, patients with oligoarticular disease are not able to receive biologic therapy. It remains unclear

whether patients with oligoarticular disease differ from those with polyarticular disease and what predicts progression from oligoarticular to polyarticular disease.

Methods: Patients followed at the PsA clinic within 1 year of diagnosis were included. Patients were followed according to a standard protocol at 6-12 month intervals. All information was tracked in a computerized database. Oligoarthritis was defined in two ways. First, based on the presence of ≤ 4 inflamed joints, and second based on ≤ 4 involved joints (including both inflammation and damage). Descriptive statistics are provided for patients presenting with oligoarthritis and polyarthritis at baseline. Multivariate Weibull regression models for handling interval- and right-censored data were developed with the outcome being progression to polyarticular disease. All models are adjusted for age at diagnosis of PsA and gender.

Results: 407 inception patients who had at least two visits were included. Of those 192 presented with oligoarthritis and 215 with polyarthritis. Demographic features were similar in the two groups. As expected, polyarticular involvement was associated with a higher number of actively inflamed joints. The distribution of joints involved was similar in the two group, with small joints of the hands and feet being most commonly involved (Table 1).

Of the 192 patients who presented with oligoarthritis 75 remained oligoarticular and 117 evolved into polyarticular. The only predictor for progressing to polyarthritis was the presence of small hand joint involvement. (Table 2). When we considered oligoarthritis definition based on inflamed and/or damaged joints the predictors for progression included small joints upper extremity as well as use of DMARDs.

Conclusion: Oligoarticular disease is similar to polyarticular disease. Most patients present with upper extremity small joint involvement. The majority of patients who present with oligoarticular disease progress to polyarticular involvement. Patients with oligoarticular disease should be treated aggressively to prevent polyarticular involvement.

Serum Metabolomic Analysis of Psoriatic Arthritis Using Solid Phase Microextraction – Liquid Chromatography – High-Resolution Mass Spectrometry Identifies Putative Disease Activity Markers

Vinod Chandran,[1] Nikita Looby,[2] Nathaly Reyes-Garces,[2] Rohan Machhar,[3] Miao Yu,[2] Anna Roszkowska,[2] Janusz Pawliszyn,[2] and Vathany Kulasingam[4], [1]University Health Network, University of Toronto, Toronto, Canada, [2]University of Waterloo, Waterloo, ON, Canada, [3]Krembil Research Institute, University Health Network, Toronto, Canada, [4]University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity in psoriatic arthritis (PsA) is often difficult to assess but drives treatment decisions, joint damage and long-term outcomes. We aimed to identify serum markers for PsA disease activity using metabolomics.

Figure 1a: PCA (PC1:25.4%, PC2:16.5%) plot of healthy controls and patients with PsA. Data obtained from positive mode acquisition. 1b: OPLS-DA (Comp1: 12.3%, Comp 2: 18.2%) plot of mild vs severe PsA patients. The model was found to have a goodness of fit of $R^2y = 0.73$ and predictability of $Q^2=0.44$. Although this predictability falls below the acceptable 0.5, validation via permutation revealed a significant model $p < 0.05$ for both model quality parameters.

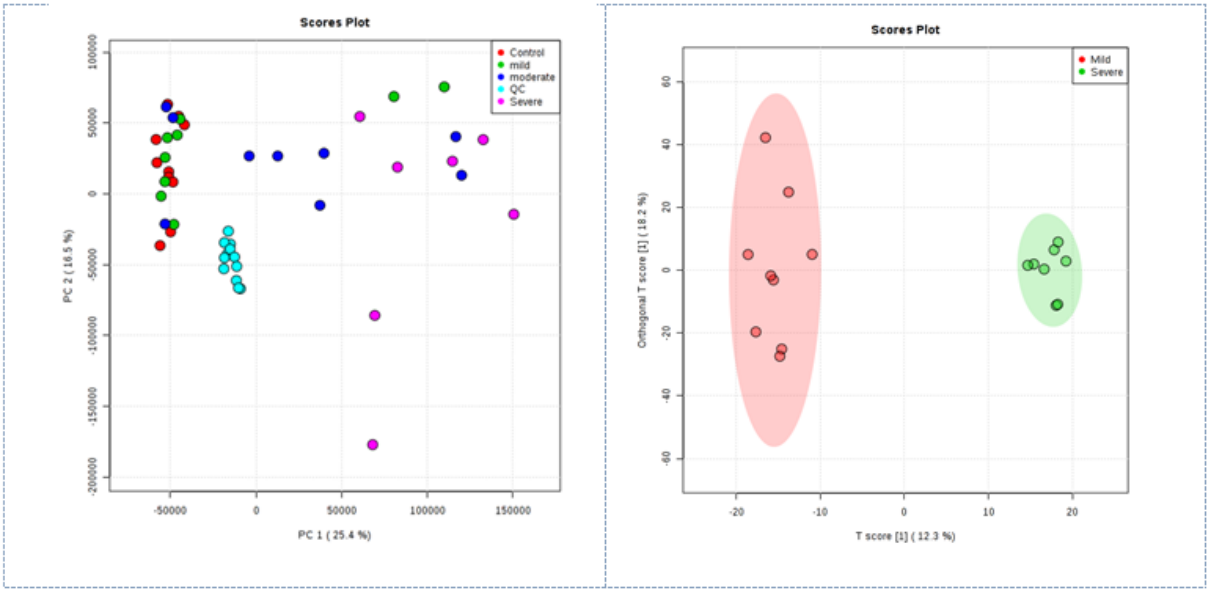

Table 1. Tentatively annotated features showing statistically significant differences across varying Degrees of psoriatic arthritis activity for negative mode data

Feature No.	Tentative ID	m/z	Retention time (s)	Adduct	P value	Q value
4448	2-Hydroxydecanedioic acid 3-Hydroxysebacic acid cis-4-Hydroxycyclohexylacetic acid	217.1077	707	$[M-H]^-$ $[M+CH3COO]^-$	0.001554	0.02996

2256	N1-(alpha-D-ribosyl)-5,6-dimethyl-benzimidazole L-phenylalanyl-l-hydroxyproline Prolyl-Tyrosine	313.0959	735	$[M+Cl]^-$ $[M+Cl]^-$ $[M+Cl]^-$	0.001482	0.02996

Methods: Serum samples were obtained from a cohort of carefully phenotyped patients with PsA satisfying CASPAR criteria (n=30, 15 males, mean age 48 years, disease duration 11 years) and healthy controls (n=10, mean age 43 years). Based on the number of actively inflamed (swollen or tender joints) patients were grouped as mild (< 4 actively inflamed and 0 swollen joints; n = 10), moderate (4-5 actively inflamed and < 3 swollen joints; n = 10) and severe (>5 actively inflamed and >3 swollen joints; n = 10). Serum samples were processed using thin film microextraction using an established protocol. For metabolite identification high performance liquid chromatography with high-resolution mass spectrometric detection was performed using a ThermoScientific Q-Exactive mass spectrometer. MS/MS validation was performed via parallel reaction monitoring. The MS/MS spectrum obtained was compared to the fragmentation patterns of metabolites in the m/z cloud of MS finder databases. Human metabolome database was used for annotation of extracted peak using XCMS online and METLIN. Statistical analysis was performed using Metabo-

Table 2. Tentatively annotated features showing statistically significant differences between healthy controls and severe psoriatic arthritis patients for positive mode data

Feature No.	Tentative ID	m/z	Adduct	Retention time (min)	P value	Q value
57	S-aminomethyldihydrolipoamide	237.1090	$[M+H]^+$	13.25	0.00008	0.018

549	Gamma-glutamyltyrosine	311.1238	$[M+H]^+$	13.45	0.001	0.03
715	Arginyl-glycine	254.1224	$[M+Na]^+$	13.33	0.002	0.04

analyst 4.0. For univariate analysis, a Kruskal Wallis with a false discovery rate (FDR) adjusted p-value of 0.05 was applied. For multivariate analysis, Principal Component Analysis (PCA), Partial Least Square – Discriminant Analysis (PLS-DA) and Orthogonal Projection to Latent Structures – Discriminant Analysis (OPLS-DA) were performed.

Results: PCA (figure 1a) revealed clear distinction between mild, moderate and severe PsA, but no difference between healthy controls and mild PsA. OPLS-DA (figure 1b) demonstrated a cross-validated significant separation between mild and severe PsA. Multivariate and univariate analysis yielded 10 statistically significant features across the three PsA groups, tentatively identified using xMSAnnotator for negative mode data (Table 1) while 7 statistically significant features were found to differentiate controls from patients with severe PsA and were tentatively identified using XCMS online for positive mode data (Table 2). Some of these tentatively identified compounds were found to be associated with the serine and threonine metabolism pathways and most if not all compounds presented a relative increase in concentration proportional to disease severity.

Conclusion: Untargeted metabolomics of serum via solid phase microextraction has the potential to identify markers for PsA disease activity.

Table 2

Background/Purpose: There is limited prospective data as to the frequency of axial spondyloarthritis (axSpA) in unselected patients referred to rheumatologists with undiagnosed back pain who have presented with acute anterior uveitis (AAU), psoriasis, or colitis to their respective specialists. It is also unclear which clinical features discriminate between axSpA and non-specific causes of back pain that might inform the development of a screening strategy to expedite referral of patients to rheumatologists. Our aims were: 1. To determine the prevalence of axSpA in unselected patients referred with undiagnosed back pain presenting with AAU, psoriasis, or colitis. 2. To determine which clinical characteristics define patients with axSpA.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at facilitating early detection of axial SpA. First and last patients were recruited on February 2013 and March 2018, respectively. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. Differences in clinical characteristics between those who were diagnosed as axSpA or non-specific back pain were analyzed using chi-squared and t-tests.

Results: A total of 246 patients were recruited, 47.6% were diagnosed with axSpA, and these included 68.5% of B27 positive patients. Symptom duration was 7-8 years and the majority had back pain severity >5 on a 0-10 scale (Table 1). Diagnosis of axSpA was established in 45.7%, 61.6%, and 40.2% of patients, while ASAS classification criteria were met by 26.1%, 71.2%, and 27.6% of patients with psoriasis, AAU, and IBD, respectively. Inflammatory back pain, male gender, lateral lumbar flexion, CRP, B27 positivity, and positive imaging discriminated axSpA from other causes of back pain (Table 2) and these remained significant in multivariate analysis adjusted for age, gender, and symptom duration.

Conclusion: Substantial diagnostic delay was evident in this prospective cohort of patients presenting with extra-articular manifestations despite a substantial burden of back pain. Referral to a rheumatologist should constitute standard of care, especially if B27 positive and presenting with psoriasis or AAU.

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Data about heart failure (HF) in patients with psoriatic disease (PsD) are sparse. The aims of the study were to: 1) determine the incidence and predictors for HF in patients with PsD and 2) describe their electrocardiographic (ECG) and echocardiographic (TTE) findings.

Methods: A cohort analysis was conducted on patients followed prospectively from 1978 to 2018 in the psoriatic disease program. Participants were assessed according to a standard protocol that included demographics, medications, measures of disease activity and comorbidities. The primary outcome was the first incident event of HF. HF events were further classified into ischemic and non-ischemic HF. Potential HF events were identified by searching the cohort database and linkage with provincial hospitalization and mortality databases. Patients with HF prior to study entry were excluded. The association between cardiovascular risk factors, measures of disease activity and occurrence of HF events was assessed using Cox proportional hazard models with time varying co-variates. Review of medical records identified ECG and TTE findings in patients with HF.

Results: A total of 1994 patients with PsD with 22,437 patient years were analyzed. During the follow-up period, 64 new HF events occurred (38 ischemic, 26 non-ischemic). The cumulative prevalence of HF by the age of 70 and 80 years was 1.4% and 3.7%, respectively. The incidence rate of first HF event during the study period was 2.85 per 1000 patient years. Of the 41 cases with available medical records, there were 19 cases of ischemic HF and 22 cases of non-ischemic HF (arrhythmias, cardiomyopathy and valvular dysfunction). In all events, the most common ECG findings were atrial fibrillation (22%), bundle branch blocks (29%) and pathological Q waves (33%). In all HF events, TTE revealed 37% reduced ejection fraction, 29% preserved ejection fraction, wall motion abnormalities (61%), left ventricular hypertrophy (41%) and valvular abnormalities (32%).

On multivariate analysis (Table 1), the following variables were independent predictors for all HF events: ischemic heart disease ($p< 0.001$), adjusted mean (AM)-tender joint count (TJC), AM-swollen joint count, AM-ESR, and HAQ (all $p< 0.05$). The strength of association of disease activity measures was higher when the analysis was restricted to non-ischemic HF as the outcome, with pain score, AM-TJC, AM-SJC, ESR and damaged joint count as independent predictors (all $p< 0.05$). The strongest predictor of ischemic HF was prior ischemic heart disease and additional independent predictors included: AM-ESR and HAQ ($p< 0.05$). Being in a minimal disease activity state was protective for all HF and ischemic HF ($p< 0.05$).

Conclusion: Increased risk of HF in PsD is associated with a combination of traditional cardiovascular risk factors and disease activity, particularly in patients with non-ischemic HF. The effect of inflammation on HF may be partially independent of atherosclerotic disease.

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Delay in diagnosis of psoriatic arthritis (PsA) has been shown to contribute to poor radiographic and functional outcome and less successful response to treatment (Haroon et al 2015). Disease interception models are now being proposed to identify siblings at risk of psoriasis (PsC) and PsA among PsA probands, to facilitate earlier management strategies. We set out to determine genetic variants that are likely to be associated with the risk of developing PsC and PsA among siblings of PsA patients.

Methods: A total of 195 probands were identified from well-established PsA cohorts. Family history and clinical assessment of siblings was systematically evaluated, and DNA of siblings was also collected. SNP genotyping was performed using 42 PsA-weighted SNPs on the probands and siblings. 308 siblings were collected (179 unaffected siblings and 129 affected of which 71 had psoriasis without PsA (PsC), and 56 had PsA). For analysis the concordance of genes from probands to sibling pairs (PsA -PsC , PsA-PsA and PsA-PsC or PsA) were compared with PsA-unaffected sibling pair. Probandwise concordance rates were determined using the formula 2C/(2C+D), in which C is the number of concordant pairs and D is the number of discordant pairs. The concordance difference between two groups were calculated using fisher exact test with an odds ratio (OR) > 1 indicating that the concordance rate in affected siblings was greater than unaffected sibling.

Table 1

PsA or PsC Siblings					
Gene	SNP	P-value	OR	95%. CI lower	95%. CI upper
PTPN22	rs2476601	0.0005	0.28	0.113	0.633
LCE3A	rs10888503	0.021	1.78	1.069	2.983
IL12B	rs2082412	0.016	1.98	1.111	3.600
HLA-C	rs12191877	0.0002	2.88	1.574	5.443
HLA-C*0602	rs2894207	0.009	2.05	1.174	3.661
PsA Siblings					
PTPN22	rs2476601	0.005	0.26	0.093	0.695
LCE3A	rs10888503	0.001	3.10	1.505	6.766
HLA-B*3906	rs2844603	0.023	0.48	0.238	0.944
HLA-C	rs12191877	0.029	2.33	1.079	5.394
PsC siblings					
PTPN22	rs2476601	0.008	0.30	0.108	0.795
HLA-C	rs12191877	0.0006	3.55	1.592	8.779
HLA-C*0602	rs2894207	0.039	2.09	1.029	4.445

Results: The mean age of the PsA probands at assessment was 48.1 yrs (±14.6) (age of onset of PsC 26.4 (±12.1) and PsA 34.4 (±10.9) yrs). The mean age of PsC siblings at assessment was 53.1 yrs (±14.3) (age onset of PsC at 27.5 (±15.7). The PsA siblings at assessment was 55.2 yrs (±13.4), with age of onset of PsC at 29.4 (±14.9) and PsA 36.1 (±12.9) yrs. Finally, the mean age of assessment of unaffected sibling was 50.2 yrs (±13.2). A differential concordance rate was noted for three genes with PsC, 4 genes with PsA, six genes for PsC or PsA, compared to the unaffected sibling (Table). In addition, when the concordance of PsA siblings were compared to PsC siblings, LCE3A was more likely (OR 2.6, p=0.015) in PsA and HLA-B*3906 was less likely (OR 0.43, p=0.038) to be shared in PsA .

Conclusion: There is greater concordance of known susceptibility genes among PsA siblings and PsC siblings of PsA probands. The genotype of the PsA probands along with the siblings is helpful in determining siblings at risk and should be considered as a potential biomarker for risk prediction.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking has been shown to be associated with an increased risk of psoriatic arthritis (PsA) in the general population, but there are controversies among patients with psoriasis. We hypothesize that smoking is a risk factor for axial PsA specifically, similar to axial spondyloarthritis, more than the other PsA phenotypes.

Axial Disease present vs absent			
	Multivariate analysis n=1528		
Variables	OR	95%CI for OR	P
Age	0.98	0.98-0.99	**0.001**
Gender (male vs female)	1.49	1.17-1.89	**0.001**
Smoking			**0.029**
Current vs never	1.42	1.07-1.88	**0.014**
Ex-smoker vs never	0.97	0.71-1.31	0.859
Nail involvement, ever (presence vs absence)	1.43	1.14-1.80	**0.002**
Polyarthritis, ever (presence vs absence)	0.71	0.56-0.89	**0.003**
DIP involvement, ever (presence vs absence)	0.56	0.40-0.80	**0.001**

CI: Confidence Interval, DIP: Distal Interphalangeal, OR: Odds Ratio.

Table 1. Multivariate analysis on factors associated with axial psoriatic arthritis

Methods: *PsArt-ID (Psoriatic Arthritis- International Database)*] is a multicenter, international database, investigating the disease characteristics in real life. From that registry, 1535 PsA patients with smoking data were included for this analysis. Smoking status was categorized as never, current smoker or ex-smoker. Axial PsA was based on the clinicians' judgement, requiring clinical features but not mandating any imaging. In addition grading of sacroiliitis was done by a central reader, whenever available. The effect of smoking, as well as other potential predictor factors on axial PsA and radiographic sacroiliitis, was assessed using a logistic regression analysis.

Results: Axial PsA was more common across current smokers compared to ex and non-smokers (38.9% vs 27.2% vs 26.8%, respectively; p< 0.001). Multivariate analysis to predict axial PsA showed that younger age [Odds ratio (OR)=0.98, 95% Confidence Interval (CI)= 0.97-0.99, p=0.014], male gender (OR=1.49, 95% CI=1.17-1.89, p=0.001), current smoking status (OR=1.42, 95% CI=1.07-1.88, p=0.014) and presence of nail disease (OR=1.43, 95% CI=1.14-1.80, p=0.002) were significant predictors for axPsA whereas polyarticular (OR=0.71, 95% CI=0.56-0.89, p=0.003) and distal joint involvement (OR=0.56, 95% CI=0.40-0.80 p=0.001) were protective (Table 1). Current smoking status was also found a significant predictor for radiographic sacroiliitis (OR=13.6, 95% CI= 2.87-64.6, p=0.001) (Table 2).

Conclusion: Current smoking is a significant risk factor for both axial PsA and radiographic sacroiliitis in patients with PsA, and not the peripheral phenotypes.

Radiographic sacroiliitis present vs absent			
	Multivariate analysis n=125		
Variables	OR	95%CI for OR	P

is associated with radiographic damage in patients with PsA, we aimed to determine the association between MetS and axial as well as peripheral radiographic abnormalities in PsA.

Methods: Data on clinical (including MetS) and radiographic features were obtained from a large PsA cohort. Patients were classified as having MetS at the last clinic visit if they satisfied the harmonized definition of MetS by Albert KG et al (1). Demographic, clinical and radiographic data were compared between groups using t-test, Wilcoxon test or chi square test as appropriate. Regression methods were used to adjust for differences in age, sex or PsA duration and treatment, as appropriate. We used multivariable logistic regression to identify features independently associated with MetS in PsA patients.

Results: 319 PsA patients with MetS were compared to 319 patients without MetS (Table 1). Patients with MetS were older at assessment, and had an older age at onset of psoriasis and PsA. As expected, they had a higher waist circumference, BMI, diabetes and cardiovascular comorbidities. Patients with MetS were also more likely to be treated with conventional DMARDs and biologics indicating more severe disease. Patients with MetS were more likely to have calcaneal spurs, DISH, cervical and lumbar degenerative disc disease, after accounting for sex, PsA duration and biologic therapy. There were no differences in the presence of sacroiliitis (NY criteria) or radiographic damage to peripheral joints. Patients with MetS also reported a higher HAQ, pain score and global disease activity score. Multivariate regression analyses identified calcaneal spurs, DISH, cervical and lumbar degenerative disc disease as features independently associated with MetS in patients with PsA.

Conclusion: PsA patients with MetS present at an older age, have higher prevalence of comorbidities and more severe disease when treatment and patient reported outcomes are considered. MetS is not associated with radiographic severity of PsA but is associated with osteoarthritic and metabolic changes in the spine and enthuses.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (ABA), a selective T-cell co-stimulation modulator, has been shown to improve disease activity in patients with psoriatic arthritis (PsA), but its effect on psoriatic inflammation at a molecular level has not been determined.

Methods: 40 patients received ABA and 38 received PBO in this substudy of a 24 week, Phase 3, randomized, double blind, placebo (PBO) controlled, multicenter study, followed by a 28 week open-label period in subjects with active PsA based on the Classification Criteria for Psoriatic Arthritis (CASPAR). 3mm punch skin biopsies were taken of lesional and non-lesional skin at Day 1 and of lesional skin at 24 weeks. Gene expression analysis was conducted using Affymetrix HGU133 2.0+ arrays. Differentially expressed genes (DEG) were evaluated with a cut-off of fold change >2.0 and FDR < 0.05. Results were validated with RT-PCR. To summarize per-patient differences across pathways, we also used gene set variation analysis (GSVA).

Results: Globally, gene expression of lesional skin (LS) in the ABA treatment group at week 24 more closely resembled non-lesional (NL) skin than did the placebo group at week 24. Comparing LS at week 24 to baseline NL skin, the placebo group had 38% more DEG (more transcriptionally abnormal). The ABA treated group had 48% fewer DEG (less transcriptionally abnormal). Improvement analysis showed significant normalization in curated gene sets representative of active psoriasis. Both the “PsA skin vs normal skin” gene set and the “PsA synovium vs normal synovium” gene set showed greater improvement in the ABA treated group than the placebo treated group. The improvement in many gene sets appeared to be amplified (50-90% improvement) for patients who achieved an ACR20, PASI75, and KRT16-75 responses vs those who did not regardless of treatment. Several cellular markers of epidermal growth and differentiation were reduced in both drug and PBO treated groups. This was significant in the ABA treated group for K16 and Ki67. There was a significantly greater % reduction in thickness, KRT16, Ki67, CD3 and CD11c in the ABA treated ACR20 and KRT16-75 responders group than in the ABA treatment group as a whole. In the ABA group, but not in PBO group, mRNA expression of IL22, IL17F, KRT16, CXCL1, CXCL8, IL1B, IL26, CCL18, iCOS, and CTLA4 was significantly decreased at Week 24 compared to Day 1 ($p < 0.05$). Changes in IL17A and IL23p19 mRNA in the skin were correlated with joint tenderness in all patients.

Conclusion: Abatacept modulates a wide range of inflammatory molecules in psoriasis skin lesions. At a molecular level, patients treated with ABA showed a reversion toward more transcriptionally normal gene patterns and markers of epidermal growth and differentiation. While the primary purpose of this study was to look at the effect of ABA on psoriatic inflammation, this was also an opportunity to evaluate any associations between the ACR20 components

and changes in the skin at a molecular level over time. IL17A and IL23p19 in the skin were correlated with joint tenderness. Cytokines produced in the skin might affect joints via diffusion through the blood.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a common feature of Spondyloarthritis (SpA)[1]. Enthesitis at the Achilles tendon is an important manifestation with impact on function which is often refractory to standard NSAID/corticosteroid treatment[1,2]. ACHILLES is a double blind, placebo-controlled, multicenter Phase 3 trial designed to investigate the efficacy of secukinumab on enthesitis by clinical as well as imaging assessments in patients (pts) with active psoriatic arthritis (PsA) and axial SpA (axSpA). Here we report the impact of enthesitis on the burden of disease based on the ACHILLES pts characteristics.

Methods: Pts (≥18 years) with active PsA [CASPAR criteria and ≥1 TJC and SJC] or axSpA [ASAS axSpA criteria and total BASDAI ≥ 4], and MRI-positive heel enthesitis (according to the investigator`s judgement) refractory to standard treatment were enrolled in the trial. Enrolment was completed in October 2018. Pts were randomized to receive subcutaneous secukinumab 150 or 300 mg or placebo at baseline (BL), Weeks (Wk) 1, 2, 3, and 4, followed by once every 4 wks. Starting at Wk 24, all pts received secukinumab 150 or 300 mg. The primary endpoint of ACHILLES is the proportion of pts achieving resolution of Achilles tendon enthesitis with secukinumab vs placebo at Wk 24. BL clinical characteristics were analyzed after the last pt was randomized. Summary statistics are presented separately for PsA and axSpA indications, irrespective of treatment arm in order to preserve the blinding of the trial. In addition, the BL characteristics of PsA pts, representing 62.7% of the total ACHILLES population, were compared to PsA pts without enthesitis from the FUTURE studies.

Results: Of the 304 pts screened, 204 (128 PsA and 76 axSpA) pts completed the screening phase and were randomized. BL and disease characteristics of enrolled pts are shown in **Table 1**. PsA pts presented with a higher weight/BMI compared to axSpA pts at BL. Time since diagnosis was shorter for axSpA pts while duration of enthesitis was comparable for both indications. Physician's (PhGA) and patient's global assessment (PtGA) of disease activity scores (0-100 VAS) in the PsA pts were 57.2 and 62.3, respectively, and 66.8 and 71.8, respectively, in the axSpA pts,

Table 1: Baseline characteristics of patients in the ACHILLES trial

Variables mean (SD) unless otherwise specified	**PsA N = 128**	**axSpA N = 76**
Age (years)	49.4 (11.1)	45.1 (10.9)
Male, n (%)	54 (42.2)	37 (48.7)
BMI (kg/m^2)	30.1 (6.1)	28.1 (6.4)
Time since diagnosis (months)	63.9 (77.8)	52.9 (70.1)
Duration of Enthesitis (months)	34.0 (57.2)	34.1 (63.1)
Number of LEI counts present	2.6 (1.6)	2.4 (1.6)
Tender joint total score (78 joints)	14.9 (14.8)	-
Swollen joint total score (76 joints)	6.8 (8.1)	-
hsCRP (mg/L)	9.7 (20.3)	11.0 (13.7)
Heel pain (NRS, 0-10)	5.8 (2.3)	7.1 (1.6)
Physician's global assessment of heel enthesiopathy activity (VAS, 0-100)	60.0 (18.6)	68.1 (15.9)
Patient's global assessment of heel enthesiopathy activity (VAS, 0-100)	62.8 (23.9)	71.5 (15.6)
Physician's global assessment of disease activity (VAS, 0-100)	57.2 (20.0)	66.8 (15.8)
Patient's global assessment of disease activity (VAS, 0-100)	62.3 (21.9)	71.8 (15.5)
Patient's assessment of PsA pain intensity (VAS, 0-100)	60.8 (21.4)	-

N, number of patients randomized
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BMI, body mass index; hsCRP, high-sensitivity C-reactive protein; LEI, Leeds Enthesitis Index; NRS, numerical rating scale; VAS, visual analogue scale

Table 2: Baseline demographics and disease characteristics of ACHILLES PsA patients compared to pooled FUTURE 2 and 3 patients without enthesitis		
Variables Values are mean (SD) unless otherwise specified	**Pooled FUTURE pts without enthesitis N = 246**	**ACHILLES PsA pts N = 128**
Age (years)	48.4 (12.9)	49.4 (11.1)
BMI (kg/m^2)	28.8 (5.1)	30.1 (6.1)
Male, n (%)	142 (57.7)	54 (42.2)
Tender joint total score (78 joints)	15.2 (11.5)	14.9 (14.8)
Swollen joint total score (76 joints)	9.3 (7.5)	6.8 (8.1)
Number of LEI counts present	0	2.6 (1.6)
Physician's global assessment of disease activity (VAS, 0-100)	51.5 (17.7)	57.2 (20.0)
Patient's global assessment of disease activity (VAS, 0-100)	56.4 (20.6)	62.3 (21.9)
Patient's assessment of PsA pain intensity (VAS, 0-100)	53.1 (21.9)	60.8 (21.4)

indicating a high disease burden. Interestingly, while patient's global assessment of heel enthesiopathy activity and PtGA were comparable in both indications, the physician's global assessment for enthesitis was rated higher than the PhGA. Comparison with BL data from pooled FUTURE 2 and 3 trials show that pts without enthesitis reported lower PsA pain and PhGA/PtGA scores at BL, although with a higher SJC but comparable clinical characteristics in terms of age and weight (**Table 2**).

Conclusion: In SpA patients suffering from enthesitis, axSpA pts present with a higher burden of disease compared to PsA pts. PsA pts report higher disease burden when compared to pts without enthesitis, suggesting that enthesitis may be an important factor contributing to the burden of disease in PsA.

Differential Expression of Human Endogenous Retroviruses in Psoriatic Disease

Remy Pollock,[1] Rohan Machhar,[1] Laila Zaman,[1] Dafna Gladman,[2] and Vinod Chandran[3], [1]Krembil Research Institute, University Health Network, Toronto, Canada, [2]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Human endogenous retroviruses (HERV) are the stably inherited remnants of ancient retroviruses that infected the ancestral germline. A growing body of research has associated the differential expression and regulation of HERVs with a number of diseases, including systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA). HERVs are thought to contribute to the pathogenesis of autoimmune diseases by modulating the expression of host immune-related genes, molecular mimicry, or cross reactivity of host proteins with HERV encoded products. We aimed to compare the expression of 4 HERVs previously associated with autoimmune disorders (HERV-K, HERV-K10, HERV-W, and HERV-H) in whole blood, CD3+ T cells, and CD14+ monocytes of patients with cutaneous psoriasis without arthritis (PsC), psoriatic arthritis (PsA), and healthy controls.

Methods: PsC, PsA patients satisfying the CASPAR criteria, and healthy controls were recruited for the study. RNA was extracted from whole blood collected in Tempus tubes and HERV expression was measured by quantitative real time PCR (qRT-PCR) or droplet digital (dd)PCR with normalization to *GAPDH*. HERV expression in whole blood RNA from 40 PsA patients was compared to 40 age and sex matched PsC patients and 40 age and sex matched healthy controls. Subsequently, HERV expression in 55 PsC patients who progressed to develop PsA (converters) was compared to 55 age and sex matched PsC patients who did not develop PsA over the same duration of follow-up (non-converters). Finally, HERV expression in RNA isolated from CD3+ T cells and CD14+ monocytes from 19 PsA patients was compared to 13 PsC and 8 healthy controls. Expression differences between groups were determined by one-way ANOVA, Kruskal-Wallis and Mann-Whitney tests where appropriate.

Results: In whole blood, HERV-K was significantly differentially expressed between 40 PsA and 40 PsC patients (fold change [FC]=1.57, p=0.008). HERV-K was also significantly differentially expressed in baseline samples from 55 converters compared to 55 non-converters (FC=1.93, p=0.03). No other HERV genes were differentially expressed between these groups in whole blood. Significant expression differences were more evident in purified cells (Table 1).

Conclusion: In whole blood, expression of HERV-K differentiates PsA and PsC patients, and its expression is significantly elevated in PsC patients prior to the development of PsA. HERV expression differences between the groups are also evident in purified T cells and monocytes. These data suggest a role for HERVs in the pathogenesis of psoriatic disease and their potential use as prognostic markers of arthritis in patients with psoriasis.

Table 1. Differential expression of HERVs in purified T cells and monocytes.

	PsA vs. PsC		PsA vs. Controls		PsC vs. Controls	
	CD3+ T cells FC, p value	CD14+ Monocytes FC, p value	CD3+ T cells FC, p value	CD14+ Monocytes FC, p value	CD3+ T cells FC, p value	CD14+ Monocytes FC, p value
HERV-K	0.43, p=0.02	0.30, p<0.01	ns	0.17, p<0.01	2.18, p=0.02	ns

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: As psoriasis (Pso) commonly precedes psoriatic arthritis (PsA), an important unanswered question is whether treatment of Pso might influence the development of PsA in patients with psoriasis.

The objective of this study was to analyze the incidence of PsA in a large cohort of patients with PsO according to different treatments, with the hypothesis that treatment with biologics might prevent the development of PsA.

Methods: Patients with PsO without PsA followed at a University Hospital were included in this retrospective cohort study. Data was obtained from the Hospital Electronic Medical Record (EMR). Patients were classified according to their treatment in topics group (topic and phototherapy), conventional DMARDs (cDMARDs) group (Methotrexate (MTX) and cyclosporine (Cyc)), and biologic DMARDs group (bDMARDs) (TNFi, IL17i, and IL12-23i). Patients contributed time since beginning of the corresponding treatment until diagnosis of PsA, lost of follow up, end of treatment or end of study. Incident cases of PsA were attributed to one treatment if developed during the administration of that treatment and up to 6 months after its discontinuation if no other treatment was started. Incident cases that developed more than one year after discontinuation of treatment were disregarded (3 cases). Incidence rate was calculated for the whole population and for each one of the treatment groups and compared with chi2test, and rate ratios were calculated as well. A multivariable logistic model for the development of PsA was analyzed by treatment groups, adjusting by other variables.

Results: 797 patients, contributed a total of 10017 patient/years. Patient's characteristics are shown in table 1. 599 (75%) patients were treated only with topics or phototherapy, 106 (13%) with cDMARDs (81% MTX and 19% Cyc) and 92 (11.5%) with biologics (TNFi: 64: etanercept: 44, adalimumab:23, infliximab:6 ; IL17i: 43: 14 Ixekizumab, 29 Secukinumab; IL12-23i: (Ustekinumab) 16; some patients received more than one biologic). During follow-up 72 patients developed PsA (68 under topics; 3 under cDMARDs (2 MTX and 1 Cyc) and 1 under biologics (1 Secukinumab): Global incidence rate: 7.2 per 1000 patient/years (table 1). Although numerically the incidence of PsA in PsO patients treated with biologics was lower, the difference was not statistically significant. In Cox regression analysis, after adjusting by sex, age, and BMI, treatment with biologics was significantly associated with a reduced risk of developing PsA: Hazard ratio (95% CI): 0.1 (0.013 – 0.7); p= 0.021.

	Topics, n= 599	cDMARDs, n=106	bDMARDs, n=92	Total group, n=797
Mean age at PsO diagnosis (SD)	43.6 (20.6)	46.2 (20.7)	35.1 (18.9)	42.9 (20.6)
Female, n (%)	314 (52)	53 (50)	36 (39)	403 (50.5)
Plaque PsO, n/N (%)	514/578 (89)	93/103 (90)	85/90 (94)	692/771 (90)
BMI, n; Mean (SD)	498; 27.6 (5.4)	80; 28.5 (5.6)	91; 30 (7)	659; 28 (5.7)
N Developed PsA (%)	68 (8.5)	3 (0.38)	1 (0.13)	72 (9)
Follow up (patient/years)	9153	316	548	10017
Incidence rate/1000 Patient/ years (95% CI)	7.4 (5.8-9.4)	9.5 (1.9-27.5)	1.81 (0.04-10)	7.2 (5.6-9)
Median years between PsO and PsA (IQR)	10 (2-21)	Patient 1: 23 Patient 2: 11.7 Patient 3: 24.7	Patient (1): 9.6	10.5 (2-20.8)

Conclusion: Treatment with biologics in patients with PsO seemed to reduce the risk of PsA and preventing its development in this retrospective single center cohort.

*This study was achieved with a grant from PANLAR (Pan-American League Against Rheumatism).

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Longitudinal assessment of psoriatic nail dystrophy and its response to treatment is limited outside of research settings due to the complexity of existing scoring tools. The 'Severity of Nail Psoriasis Score' (SNAPS; previously known as the Bath Nail Score) is a simple tool developed for use in the observational setting. It assesses for the presence of 4 features of fingernail psoriasis (pitting, onycholysis, hyperkeratosis, and severe nail deformity; score 0-40). We aimed to validate this tool in an observational cohort of patients with Psoriatic Arthritis (PsA).

Methods: Consenting consecutive patients enrolled in the Bath PsA longitudinal cohort underwent photography of their fingernails. Clinical assessments included 66/68 tender and swollen joint count, Psoriasis Area and Severity Index, Leeds Enthesitis Index, Leeds Dactylitis Index, and Physician Nail Visual Acuity Scale (PhNVAS). Participants completed the Health Assessment Questionnaire-Disability Index and a Patient Nail VAS (PtNVAS). Dorsal view photographs of each fingernail were acquired using a tripod-mounted DSLR camera with macro lens. An angled mirror was positioned distally to capture the presence of hyperkeratosis. Scoring was conducted by two assessors (WT and AA) using the modified Nail Psoriasis Severity Index (mNAPSI; range 0-130) and SNAPS tools (Table 1). Timed scoring was conducted in a third of patients to assess the feasibility of both tools. Five patients were scored by both assessors at two time points to assess for inter-rater and test-retest reliability using interclass correlation coefficients (ICCs) for absolute agreement of single measures. The correlation between outcome variables was assessed using Pearson's correlation (r) and Spearman's rho where appropriate.

Results: Nineteen consecutive patients with and 2 consecutive patients without nail involvement were included. Mean (SD) age was 55 (11.2) years and 42.9% were female. Mean (SD) mNAPSI and SNAPS scores were 24 (17.2) and 14 (8.8). Median (IQR) PhNVAS and PtNVAS were 20 (13.0-37.0) and 18 (9.5-29.3). A total of 210 nails were assessed. Nail disease was present in 90.5% of patients using either score, and in 79% of nails using SNAPS and 82.4% of nails using mNAPSI. The main nail feature contributing to this discrepancy was splinters. Mean time to score the nails per patient using the SNAPS and mNAPSI was 59 (13.0) and 136 (27.8) seconds respectively. The inter-rater and test-retest reliability of the SNAPS was 0.92-0.94 ($p< 0.001$) and 0.93-0.96 ($p< 0.005$). The inter-rater and test-retest reliability of the mNAPSI was 0.71-0.78 ($p< 0.03$) and 0.95-0.97 ($p=0.002$). There was a strong correlation between the SNAPS and mNAPSI ($r=0.95$, $p< 0.001$) (Figure 1), and a moderate correlation between the SNAPS and PhNVAS ($r=0.77$, $p< 0.001$) and PtNVAS ($r=0.63$, $p=0.002$), and the mNAPSI and PhNVAS ($r=0.84$, $p< 0.001$) and PtNVAS ($r=0.64$, $p=0.002$). The SNAPS scores did not demonstrate significant floor or ceiling effects (Figure 2).

Nail Scores *	Pitting	Onycholysis and Oil Drop Dyschromia	Crumbling	Severe nail deformity ᵃ	Leukonychia	Splinter Haemorrhages	Hyperkeratosis	Lunula Red spots
mNAPSI (0-13)	0-3	0-3	0-3		0-1	0-1	0-1	0-1
SNAPS (0-4)	0-1	0-1		0-1			0-1	

*Per nail

ᵃ Psoriatic nail dystrophy affecting both sides of the nail, i.e. across the longitudinal midline

Table 1. Nail Psoriasis Scoring Systems

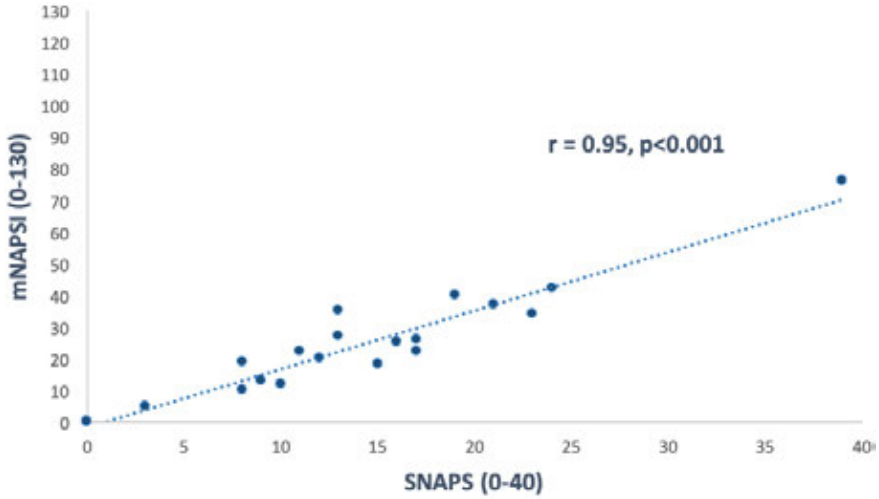

Figure 1. Correlation between the mNAPSI and SNAPS

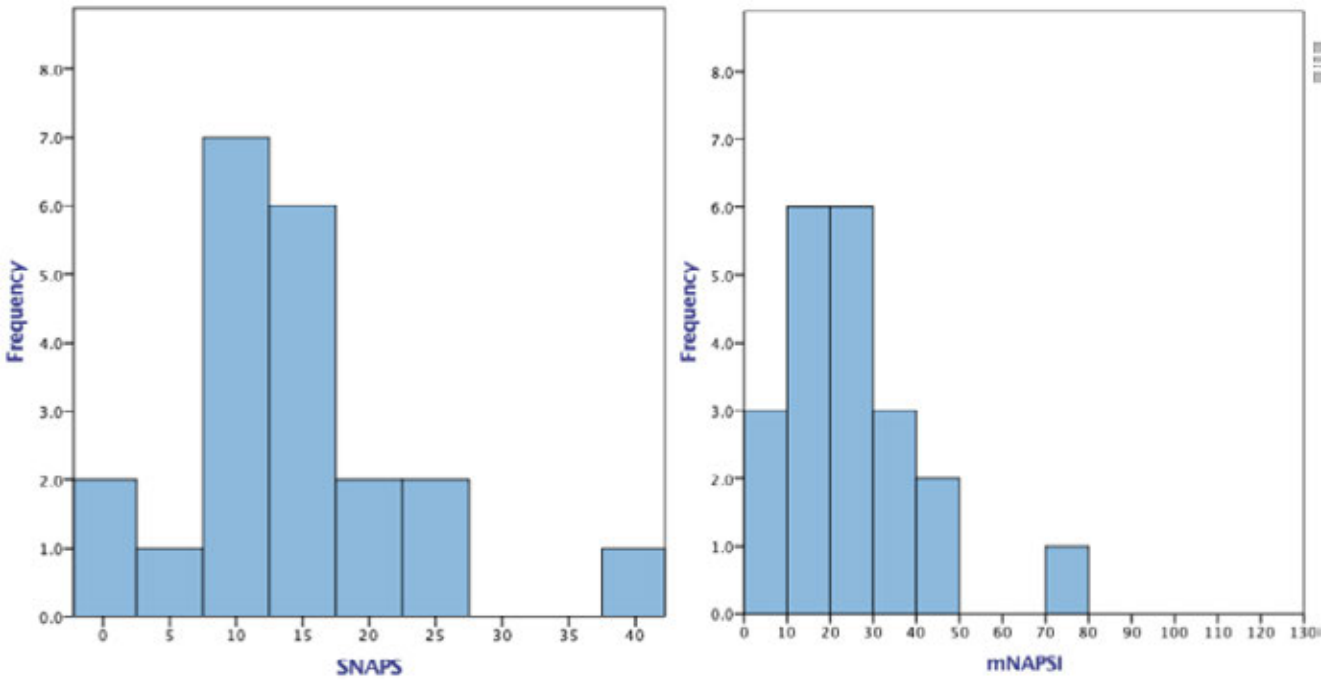

Figure 2. Histograms of Nail Scores

Conclusion: SNAPS is feasible, reliable and demonstrates construct validity against mNAPSI for assessing psoriatic nail dystrophy. Follow-up data is needed to assess longitudinal validity.

The Impact of Psoriasis Severity on Outcomes Among Psoriatic Arthritis Patients Receiving Adalimumab

Joseph Merola,[1] Laura Coates,[2] Elizabeth M Lesser,[3] Wendell C Valdecantos,[3] Yanna Song,[4] and Philip Mease[5],
[1]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [2]University of Oxford, Oxford, United Kingdom, [3]AbbVie Inc., North Chicago, [4]AbbVie Inc., North Chicago, IL, USA, North Chicago, [5]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a heterogeneous, chronic, immune mediated disease associated with psoriasis (PsO), with varying skin severity which can range from mild to severe involvement. It is not well understood how skin severity can impact treatment outcomes.

Here we evaluate the impact of PsO severity on clinical, functional, and structural outcomes among PsA pts treated with adalimumab (ADA) or placebo (PBO).

Methods: Pts with baseline PASI and BSA available from ADEPT, a phase 3, randomized, double-blind, PBO-controlled trial of ADA 40 mg every other week, were included in this post hoc analysis.2 Pts were sub-grouped based on baseline PsO severity (severe PsO: PASI ≥12 OR BSA ≥10%; mild-to-moderate PsO: PASI < 12 AND BSA < 10%), relative to overall study population. Clinical outcomes at wk 24 were assessed by attainment of minimal disease activity (MDA), remission and low disease activity (LDA) by disease activity index for psoriatic arthritis (DAPSA), and PASI50/75/90; function and structural progression were assessed by the % of pts experiencing HAQ-DI normative values (≤0.25) and improvement from baseline ≥0.22 (MCID), and the % of pts having change from baseline in mTSS ≤0 and ≤0.5 in the modified total Sharp score (mTSS) respectively. A logistic model with treatment group baseline PASI/BSA and PASI/BSA by treatment interaction was fit for each outcome variable. P-values for interaction term and baseline BSA/PASI were calculated. Non-responder imputation was used for missing clinical and functional endpoints. 75th percentiles were imputed for missing radiographic data. Treatment-emergent adverse events (TEAEs) were monitored throughout.

Results: Of the 163 pts enrolled in the study with baseline PASI and BSA, only 23% (n=37;ADA: 17; PBO: 20) were classified as having severe PsO and had similar characteristics to those with mild-to-moderate PsO, except for numerically higher physician's global assessment, dactylitis, and enthesitis scores. Following 24 wks of treatment, 41% of ADA-treated pts achieved MDA and 45% achieved DAPSA LDA or better, a finding consistent irrespective of baseline PsO severity (**Table**). 72% of ADA-treated pts with baseline PsO did not exhibit any structural progression by mTSS (≤0) through 24 wks as compared to 55% receiving PBO. Logistic regression analyses confirmed limited role that PsO severity played across examined outcomes. DAPSA remission was more likely at wk 24 among pts with higher baseline PASI scores, and this effect was less apparent with ADA treatment. TEAEs appeared comparable between ADA and PBO groups; fewer infectious AEs occurred in the ADA severe PsO group vs the mild-to-moderate PsO group.

Table. Clinical, Functional, and Structural Outcomes Through 24 Weeks Among Adalimumab- and Placebo-treated Patients Having Severe[a] or Mild-to-Moderate[b] Psoriasis at Baseline Relative to the Overall Study Population.

	ADA 40 mg eow				PBO eow			
n (%)	Severe Ps (N=17)	Mild-to-Moderate Ps (N=66)	Mild-to-Severe Ps (N=83)	Total study population (N=151)	Severe Ps (N=20)	Mild-to-Moderate Ps (N=60)	Mild-to-Severe Ps (N=80)	Total study population (N=162)
MDA	5 (29)	29 (44)	34 (41)	53 (35)	3 (15)	6 (10)	9 (11)	11 (7)
VLDA	3 (18)	10 (15)	13 (16)	13 (9)	0	1 (2)	1 (1)	1 (1)
DAPSA ≤4	4 (24)	19 (29)	23 (28)	33 (22)	1 (5)	1 (2)	2 (3)	4 (2)
DAPSA >4, ≤14	4 (24)	10 (15)	14 (17)	33 (22)	3 (15)	5 (8)	8 (10)	14 (9)
HAQ-DI ≤0.25	6 (35)	29 (44)	35 (42)	70 (46)	4 (20)	12 (20)	16 (20)	33 (20)
ΔHAQ-DI ≥0.22	12 (75)	43 (80)	55 (79)	99 (79)	5 (31)	16 (38)	21 (36)	52 (42)
PASI50[d]	14 (82)	42 (64)	56 (68)	N/A	3 (15)	8 (13)	11 (14)	N/A
PASI75[d]	8 (47)	35 (53)	43 (52)	N/A	1 (5)	3 (5)	4 (5)	N/A
PASI90[d]	7 (41)	24 (36)	31 (37)	N/A	1 (5)	2 (3)	3 (4)	N/A

All analyses are non-responder imputation, unless otherwise noted.
[a]Severe psoriasis defined as psoriasis activity and severity index (PASI) ≥12 OR body surface area (BSA) ≥10%; [b]mild-to-moderate psoriasis defined as PASI <12 AND BSA <10%; [c]imputation using ranks of total Sharp score and 75th percentile; [d]PASI responses were only collected for patients with mild-to-severe psoriasis at baseline; ADA: adalimumab; eow: every other week; PBO: placebo; Ps:psoriasis; MDA:minimal disease activity; DAPSA:disease activity index for psoriatic arthritis; HAQ-DI: health assessment questionnaire disability index; ΔHAQ-DI:change from baseline in HAQ-DI; ΔmTSS:change from baseline in modified total Sharp score.

Conclusion: Prevalence of severe PsO in this population of PsA pts was consistent with previous observations.[3] Treatment with ADA was associated with better PsA outcomes as compared to PBO irrespective of the degree of PsO severity at baseline.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Joints with different sizes (e.g. small and large joints) and anatomical locations (upper and lower extremities) can be affected in psoriatic arthritis (PsA). Our aim was to explore the effect of these different joint patterns on patient reported outcomes (PROs) in a patient population presenting with mono-oligoarthritis.

Methods: PsArt-ID (Psoriatic Arthritis- International Database) is a multicentre registry aiming to understand the disease characteristics of PsA in real life. From that registry, 387/1670 patients who had oligo-monoarthritis in cross sectional assessment were included. Mono-oligoarthritis was defined as having 1-4 joints that were tender and swollen in the same assessment. The joints were categorized according to their size (small and large) and location (upper and lower extremity). Patients who had combination of these joints were excluded. PROs (health assessment

Table 1. Disease outcomes and C-reactive protein levels based on the joint size

	1-2 Joints		p	3-4 Joints		p
	Small joints*	Large joints**		Small joints*	Large joints**	
HAQ (0-3), mean (SD)	0.72 (0.66)	0.70 (0.65)	0.749	0.95 (0.72)	1.1 (1.01)	0.986
Pain (0-100), mean (SD)	41.71 (22.54)	46.17 (26.37)	0.307	51.14 (24.16)	72.50 (16.87)	**0.007**
Patient Global Assessment (0-100), mean (SD)	34.84 (25.81)	35.77 (29.58)	0.901	38.93 (27.71)	60.00 (25.29)	**0.016**
Physician Global Assessment (0-100), mean (SD)	27.32 (20.62)	26.90 (24.05)	0.504	34.88 (24.79)	56.36 (25.30)	**0.010**
Fatigue (0-100)	36.26 (26.23)	36.46 (29.82)	0.895	40.64 (29.24)	60.91 (25.86)	**0.038**

CRP (mg/dl), mean (SD)	7.52 (12.11)	15.31 (25.56)	**0.005**	14.03 (18.23)	28.24 (38.05)	0.080

*" Small joints" are used to refer the distal interphalangeal joints, proximal interphalangeal joints, metacarpophalangeal joints, second through fifth metatarsophalangeal joints, thumb interphalangeal joints, and wrists.

**" Large joints" are used to define shoulders, elbows, hips, knees, and ankles.

HAQ= Health Assessment Questionnaire, CRP = C-reactive protein, SD= Standard deviation

questionnaire, pain score, patient global assessment (PGA), fatigue, morning stiffness), physician global assessment, C-reactive protein (CRP) were compared based on the joint patterns**.** Analysis was made by categorizing according to joint counts (1-2 joints and 3-4 joints).

Results: The mean age (SD) was 46.9 (14.24) with a mean (SD) PsA duration of 3.93 (6.03) years. For joint counts, 194 (50.1%) patients had 1, 108 (27.9%) had 2, 46 (11,9 %) had 3 and 39 (10.1%) patients had 4 joints involved. Within patients with 1-2 involved joints, size of the joints only had an impact on CRP values with large joints having higher CRP (p=0.005) (Table 1), similar to joints of the lower extremity (p= 0.004) (Table 2). None of the PROs were significant based on the size or the location, if 1-2 joints were inflamed. Within patients with 3-4 involved joints, PGA, pain, fatigue and physician global assessment were higher in patients with large joint involvement. Similarly, PGA, pain and physician global assessment was higher in patients with lower extremity involvement as well as higher CRP values.

Table 2. Disease outcomes and C-reactive protein levels based on the joint location

	1-2 Joints		p	3-4 Joints		p
	Upper extremity	Lower extremity		Upper extremity	Lower extremity	
HAQ (0-3), mean (SD)	0.77 (0.67)	0.66 (0.64)	0.131	0.97 (0.72)	0.95 (0.88)	0.649
Pain (0-100), mean (SD)	43.60 (23.63)	44.16 (25.52)	0.995	49.92 (24.87)	67.35 (18.03)	**0.009**
Patient Global Assessment (0-100), mean (SD)	35.86 (26.32)	34.79 (29.11)	0.638	38.20 (28.34)	54.44 (24.30)	**0.019**
Physician Global Assessment (0-100), mean (SD)	27.90 (20.40)	26.35 (24.16)	0.218	34.40 (24.99)	49.72 (25.63)	**0.025**
Fatigue (0-100)	37.31 (26.26)	35.47 (29.73)	0.444	40.25 (29.54)	54.44 (27.27)	0.076
Morning stiffness, (min), mean (SD)	30.32 (30.59)	35.47 (41.49)	0.849	52.87 (67.42)	63.33 (46.11)	0.094
CRP (mg/dl), mean (SD)	7.34 (12.01)	15.28 (25.33	**0.004**	13.33 (18.59)	25.34 (30.50)	**0.012**

HAQ= Health Assessment Questionnaire, CRP = C-reactive protein, SD= Standard deviation

Conclusion: For PsA patients with 3-4 joints involved, lower extremity and larger joints are associated with poorer outcomes with worse PROs, physician global assessment and higher CRP. The size and anatomical location of the joints are less important for patients with 1-2 joints in terms of the outcomes.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic progressive inflammatory arthropathy associated with psoriasis (PsO). PsA places a considerable burden, adversely affecting health-related quality of life (HRQoL).

So far, all studies evaluating effectiveness and outcomes of PsA management have focused on arthritis while the impact on the skin component has served as a secondary endpoint. Hence, there is a knowledge gap on how both components interact with each other and impact patient-perceived dermatology-specific HRQoL.

This study evaluates the patient-perceived burden of skin disease in a PsA cohort.

Methods: This was a multicenter, single-country, cross-sectional observational study primarily aiming to evaluate the importance of skin disease to Greek PsA patients adjusting for arthritis activity, in a routine clinical practice setting. Patients were classified into three groups according to their arthritis activity, which was defined using the DAS28 cut-off points: DAS28-CRP≤ 3.2 (low); DAS28-CRP >3.2 to ≤5.1 (moderate); and DAS28-CRP >5.1 (high). Within each arthritis group, patients were further sub-divided based on PsO severity, defined by the Body Surface Area (BSA) affected by PsO using a cutoff of 3% (Figure 1). PsO-dependent HRQoL was measured with the Dermatology Life Quality Index (DLQI). The primary endpoint was the mean difference in DLQI score between patients with BSA< 3% (mild PsO) versus patients with BSA ≥ 3% (moderate-to-severe PsO) within each of the defined PsA activity groups. A two-way factorial Analysis of Variance (ANOVA) was used to evaluate the difference of DLQI measurements between PsO severity levels in each PsA activity group.

Results: Overall, 222 patients with purely peripheral or predominantly peripheral joint involvement were enrolled. All patients were Caucasian with a mean (SD) age of 53.7 (13.4) years. The median BSA was 3.0% (IQR: 1.0-5.0), and the median DAS28-CRP score was 3.7 (IQR: 3.1-5.2). Psoriatic plaques affected high impact sites, i.e. hands, feet, face, neck, scalp, genitals/groin, and intertriginous areas in 74.3% (165/222) of patients (Table1). With regard to the primary endpoint, results showed that the interaction between PsO severity and PsA activity overall was not statistically significant (p=0.672). However, a statistically significant main effect of PsO severity on DLQI was identified (p< 0.001) showing that the mean DLQI difference between PsO levels is the same in each of the PsA activity groups. The

Figure 1. Patient groups in APOPSIS study

	BSA < 3%	BSA ≥3%
DAS28-CRP > 5.1	PsA: high activity PsO: mild	PsA: high activity PsO: moderate to severe
<3.2 DAS28-CRP ≤ 5,1	PsA: moderate activity PsO: mild	PsA: moderate activity PsO: moderate to severe
DAS28-CRP≤3,2	PsA: low activity PsO: mild	PsA: low activity PsO: moderate to severe

Enthesitis at enrollment present	79(35.6%)	7(18.9%)	7(18.9%)	15 (40.5%)	12 (32.4%)	20 (54.1%)	18 (48.6%)
Nail psoriasis at enrollment present	99 (44.6%)	13 (35.1%)	14 (37.8%)	15 (40.5%)	21 (56.8%)	14 (37.8%)	22 (59.5%)
Number of nails affected	N=97 6.0 (3.0-9.0)	N=13 3.0 (2.0-6.0)	N=14 4.5 (3.0-10.0)	N=15 4.0(4.0-6.0)	N=20 6.0(3.0-11.5)	N=14 7.0(4.0-10.0)	N=21 6.0(4.0-10.0)
Extraarticular manifestations present	97(43.7%)	10 (27.0%)	7(18.9%)	17(45.9%)	18 (48.6%)	28 (75.7%)	17(45.9%)

two-way factorial ANOVA mean difference in DLQI total scores between patients with 'moderate-to-severe' and patients with 'mild' PsO was estimated to be 4.7 (95% CI: 3.1-6.3; p< 0.001) across all three PsA activity levels (Table2). Moreover, patients with PsO plaques at high impact sites reported DLQI scores 2.4 points (95% CI: 0.4-4.3; p=0.019) higher than those for patients without plaques at such sites.

Table 2. Estimated total DLQI scores at enrollment per PsO severity level within each PsA activity level of the two-way factorial ANOVA with the main effect of PsO severity levels adjusted for PsA activity levels

Patient-rated total DLQI score estimates of patient-rated total DLQI score at enrollment per PsO severity level within each PsA activity level of the two-way factorial ANOVA with the main effect of PsO severity levels adjusted for PsA activity levels; Number of observations used: N=222

	DLQI score			
			95% CI	
PsO severity level &PsA activity level	Sample means	Estimates	Lower limit	Upper limit
BSA<3% & DAS28-CRP≤3.2	2.3	2.0	0.4	3.6
BSA≥3% & DAS28-CRP≤3.2	6.5	6.7	5.1	8.3
BSA<3% & 3.2<DAS28-CRP≤5.1	4.8	5.3	3.7	6.9
BSA≥3% & 3.2<DAS28-CRP≤5.1	10.5	9.9	8.3	11.5
BSA<3% &DAS28-CRP>5.1	5.5	5.3	3.7	6.9
BSA≥3% & DAS28-CRP>5.1	9.7	9.9	8.3	11.5

Conclusion: This study provides novel real-world evidence demonstrating that PsO severity negatively impacts the dermatology-specific HRQoL independent of the PsA disease activity. In addition, PsO localization at high impact sites (excluding nails) adversely affects dermatology-specific HRQoL.

Validation of the Modified Stokes Ankylosing Spondylitis Spinal Score (mSASSS) as a Tool to Assess Axial PsA

Daniel Pau,[1] Justine (Yang) Ye,[2] Sevket Tunc,[3] Antonio Wong,[3] Vinod Chandran,[3] Richard Cook,[4] and Dafna Gladman[5], [1]University of Toronto, Toronto, Canada, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, Canada, [4]University of Waterloo, Waterloo, Canada, [5]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Axial joint involvement commonly links psoriatic arthritis (PsA) to spondyloarthritis with widely variable prevalence (25-70%). Patients with axial PsA (AxPsA) are older than patients with ankylosing spondylitis (AS) and identifying radiographic changes related to the spondylitis may be more challenging leading to disagreement among readers. Currently, there is no universally accepted method to score AxPsA. In AS, the mSASSS system is the most widely used tool to assess the severity of spondylitis and define progression. Based on previous studies in AxPsA, the mSASSS had the highest sensitivity, specificity, and odd ratios of determining disease progression. We

aimed to assess the reliability of the mSASSS scoring system between two rheumatologists and various confounders using the PsA Scoring Module for Axial Radiograph Toronto (SMART) tool developed by Biagioni et al.

Methods: A retrospective study was conducted in which radiographs from 2015-2018 in our Psoriatic Arthritis Clinic database were retrieved by an assessor (DIP) via convenience sampling and scored with the SMART tool by two rheumatologists (SET, AW). According to the SMART tool, patients are scored for the presence of osteophytes, degenerative disc disease, osteopenia, and diffuse proliferative skeletal hyperostosis (DISH). We then removed patients who had DISH recorded in our database. Discordant radiographs were adjudicated by a third independent reader (DDG, N = 11). The intra-rater reliability was reported in Intraclass Correlation Coefficient (ICC) with the balanced one-fold random model in all patients as scored by two readers (N = 119), and after adjudication and removing the DISH patients (N = 109).

Results: Patients (N = 119) with well-established PsA with and without axial disease were included. The mean age was 58.19 ± 14.15 years, the mean age at PsA diagnosis was 36.74 ± 12.59 years. 17 patients had inflammatory back pain and 34 had mechanical back pain. The intra-rater ICC between readers of the total mSASSS, cervical mSASSS, and lumbar mSASSS were 0.25, 0.23, and 0.20 respectively. With DISH exclusion, the ICC were 0.89, 0.93, and 0.40 respectively.

Conclusion: Initial results demonstrated poor agreement between readers in the presence of DISH and other confounders. With removal of radiographs with DISH and adjudication of discordant readings, the total mSASSS demonstrated moderate intra-reader reliability. Therefore, the presence of DISH leads to misinterpretation of mSASSS scores and should be considered when reading radiographs in AxPsA.

Table 1. Multivariate analysis of factors associated with patients' opinion of remission and LDA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In psoriatic arthritis (PsA), the objective of treatment is remission or low disease activity (LDA), but there is little research into patients' perception of remission. The aim of this analysis was to identify which factors associate with patient-defined remission.

Methods: This is an analysis of ReFlap (NCT03119805), a cross-sectional international study of consecutive adult patients with PsA > 2 years of disease duration. Remission was defined by a positive response to the question "At this time, is your psoriatic arthritis in remission, if this means: you feel your disease is as good as gone?"; LDA by the question "At this time, are you in low disease activity, if this means: your disease is in low activity but it's not as good as gone?".

Potential variables that may associate with the opinion of remission/LDA were analysed using stepwise multivariable logistic regression. Variables were demographic (age, gender, disease duration, Groll comorbidity index), disease-related (joint counts, psoriasis body surface area (BSA), enthesitis, CRP), patient-reported outcomes (pain, PsAID, HAQ) and physician opinion of cause of symptoms (physician score for symptoms due to PsA, to joint damage or to other disease all scored 0-10). Due to high levels of correlation between variables, principal component analysis (PCA) was used to explore clustered components associated with remission/LDA. PCA was used to extract factors with orthogonal rotation. Factors with an eigenvalue of ≥1 were included.

Results: Among 466 recruited cases, 31 did not meet inclusion criteria and 11 had missing data leaving 424 for analysis. A total of 94 (22.2%) patients self-classified as remission and 285 (67.2%) as low disease activity or remission.

MEN			WOMEN		
Factor	Components	Variance	Factor	Components	Variance
1	Disease impact (pain, PsAID, HAQ) Arthritis (TJC/SJC)	27.5	1	Disease impact (pain, PsAID, HAQ)	22.2
2	Age/Chronicity (age, comorbidities and damage/other diseases causing symptoms)	17.2	2	MSK disease (TJC/SJC, enthesitis)	19.1
3	Psoriasis and enthesitis	10.6	3	Chronicity (age and comorbidities) with controlled psoriasis	11.6
4	TJC in shorter duration disease	9.99	4	Joint damage (disease duration and damage)	9.27
5	CRP	7.99	5	CRP and psoriasis	9.13
			6	Other diseases causing symptoms	9.11

Table 2. Principal component analysis of factors associated with patients' opinion of remission

When exploring factors associated with patients' opinion of remission in multivariate analysis, pain, psoriasis BSA, PsAID total score, NRS of physician score of symptoms related to joint damage and Groll comorbidity index were identified as independent predictors. For LDA, results were similar except for the addition of physician global and loss of psoriasis as significant predictors (table 1).

As PCA cannot include binary variables, PCA was performed separately by gender. For remission, variance explained by the key factors was 74% for men and 80% for women. Key factors (table 2) for remission were, for both genders, disease impact (PsAID, pain, HAQ). Other factors identified included MSK disease activity, chronicity/joint damage, psoriasis BSA, enthesitis and CRP. For women, physician's opinion of symptoms related to other disease was a separate factor. For LDA, similar factors were identified but the percentage variance explained was lower (64-68%).

Conclusion: When considering the patients' opinion of remission, a number of factors contribute to this perception dominated by disease impact measured by pain, PsAID and HAQ. In addition, disease activity in all domains, chronicity/age, comorbidities and other conditions contribute to a robust model highlighting how multifaceted "remission" can be for individuals.

Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: European League Against Rheumatism Treatment recommendations support implementing a treat-to-target (T2T) approach in psoriatic arthritis (PsA) based on the findings of the TICOPA trial. However, a UK survey estimated that ~90% of clinicians do not follow this. This study explored clinicians' views on implementing T2T in PsA.

Methods: Individual interviews and a focus group with clinicians, audio-recorded and analysed using thematic analysis. Datasets were compared and integrated for analysis.

Results: Eight rheumatologists and two healthcare professionals (5-26 years' experience) participated in telephone interviews (25-35 minutes). One consultant delivered PsA-specific clinics. Seven rheumatologists and two trainees (3-22 years' experience) participated in a focus group (102 minutes). Three clinicians delivered PsA-specific clinics. There were four main themes:

Individual motivation to change clinical practice: "We have set up weekly psoriatic arthritis clinics at our hospital and it took almost 2 ½ years." Typically, individual clinicians with a specialist interest developed care pathways for PsA patients. They sought external information, training and support to champion T2T in their local service.

A lack of consensus on what to measure: "There has to be a strong argument to get me to do any other type of assessment because PsARC is quicker and we've been trained appropriately." Views varied on the assessments

needed to inform disease management. A strong justification would be needed for measures that could increase appointment time and patient burden.

What is achievable with limited resources: "If it's a mixed clinic it isn't really that feasible"

Lack of nursing support and registrar training in skin/joint scores were barriers to T2T. Challenges were amplified when PsA patients attended general rheumatology clinics and there were no dedicated database systems to support data collection.

Mandatory versus voluntary pressures to change: "Actually knowing somebody's watching you… with an audit makes a hell of a difference to how you run your service." Changes in practice were more likely when mandated by service providers and linked to tariffs/funding. Sharing local guidelines and protocols could facilitate T2T implementation.

Conclusion: A driver of T2T implementation was clinicians with a specialist interest in PsA who set up dedicated clinics. Barriers included a lack of consensus about targets, and practical challenges (clinical time, collecting outcomes, insufficient training and database requirements). T2T implementation in PsA requires an integrated approach to address support and resource needs of individual clinicians, teams, local IT systems, and service providers.

Relationships Between Psoriatic Arthritis Disease Activity Score and Patient-Reported Outcomes in Patients with Psoriatic Arthritis: Post Hoc Analysis of Two Phase 3 Studies

Laura Coates,[1] Andrew Bushmakin,[2] Oliver FitzGerald,[3] Dafna Gladman,[4] Lara Fallon,[5] Joseph Cappelleri,[2] Ming-Ann Hsu,[6] and Philip Helliwell[7], [1]University of Oxford, Oxford, United Kingdom, [2]Pfizer Inc, Groton, CT, [3]University College Dublin, Dublin, Ireland, [4]University of Toronto, Toronto, ON, Canada, [5]Pfizer Inc, Montreal, QC, Canada, [6]Pfizer Inc, Collegeville, PA, [7]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a complex heterogeneous disease associated with multiple domains. Psoriatic Arthritis Disease Activity Score (PASDAS) is a composite disease activity measure for PsA, developed to assess improvements in multiple clinical outcomes in response to treatment using a single instrument.[1] The

objective of this post hoc analysis was to evaluate associations between PASDAS and a set of patient-reported outcomes (PROs).

Methods: All available data from two Phase 3 studies in patients with PsA (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439])[2,3] were analyzed. PASDAS (score range 0–10) is based on the following measures: Patient's Global Assessment of PsA Visual Analog Scale (VAS); Physician's Global Assessment of PsA VAS; tender and swollen joint counts; Leeds Enthesitis count; tender dactylitis count; Short-Form 36 Health Survey Physical Component Summary (SF-36 PCS); and C-reactive protein. PASDAS cut-offs for low and high disease activity are 3.2 and 5.4, respectively.[4] A set of PROs was analyzed (Table 1). A repeated measures regression model was used to evaluate the relationship between PASDAS and PROs. A sensitivity analysis to assess the linearity assumption was performed.

Results: An approximately linear relationship was observed between PASDAS and PROs, which was consistent across all PROs and both studies. For example, in OPAL Broaden, a 1-point difference in PASDAS was associated with a mean (95% CI) difference in Patient's Assessment of Arthritis Pain VAS (Pain) score of 9.9 mm (9.4, 10.4) (OPAL Beyond: 10.7 mm [10.1, 11.2]). Mean Pain scores (95% CI) corresponding to PASDAS low and high disease activity cut-offs, respectively, were 26.3 mm (25.0, 27.5) and 48.0 mm (46.7, 49.4) in OPAL Broaden (OPAL Beyond: 25.4 mm [23.7, 27.1] and 48.8 mm [47.4, 50.3], respectively) (Figure 1). In OPAL Broaden, a 1-point difference in PASDAS was associated with a mean (95% CI) difference in Patient's Global Joint and Skin assessment (PGJS)-VAS score of 12.0 mm (11.6, 12.4) (OPAL Beyond: 12.6 mm [12.1, 13.1]). Mean (95% CI) PGJS scores corresponding to PASDAS low and high disease activity cut-offs, respectively, were 28.2 mm (27.1, 29.3) and 54.7 mm (53.6, 55.8) in OPAL Broaden (OPAL Beyond: 27.8 mm [26.3, 29.2] and 55.4 mm [54.1, 56.7], respectively).

Conclusion: The approximately linear association observed here provides insight into the relationship between PASDAS and examined PROs, some of which were components of PASDAS, while others were independent outcomes. Results were similar in both studies, suggesting that findings are consistent across different populations.

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

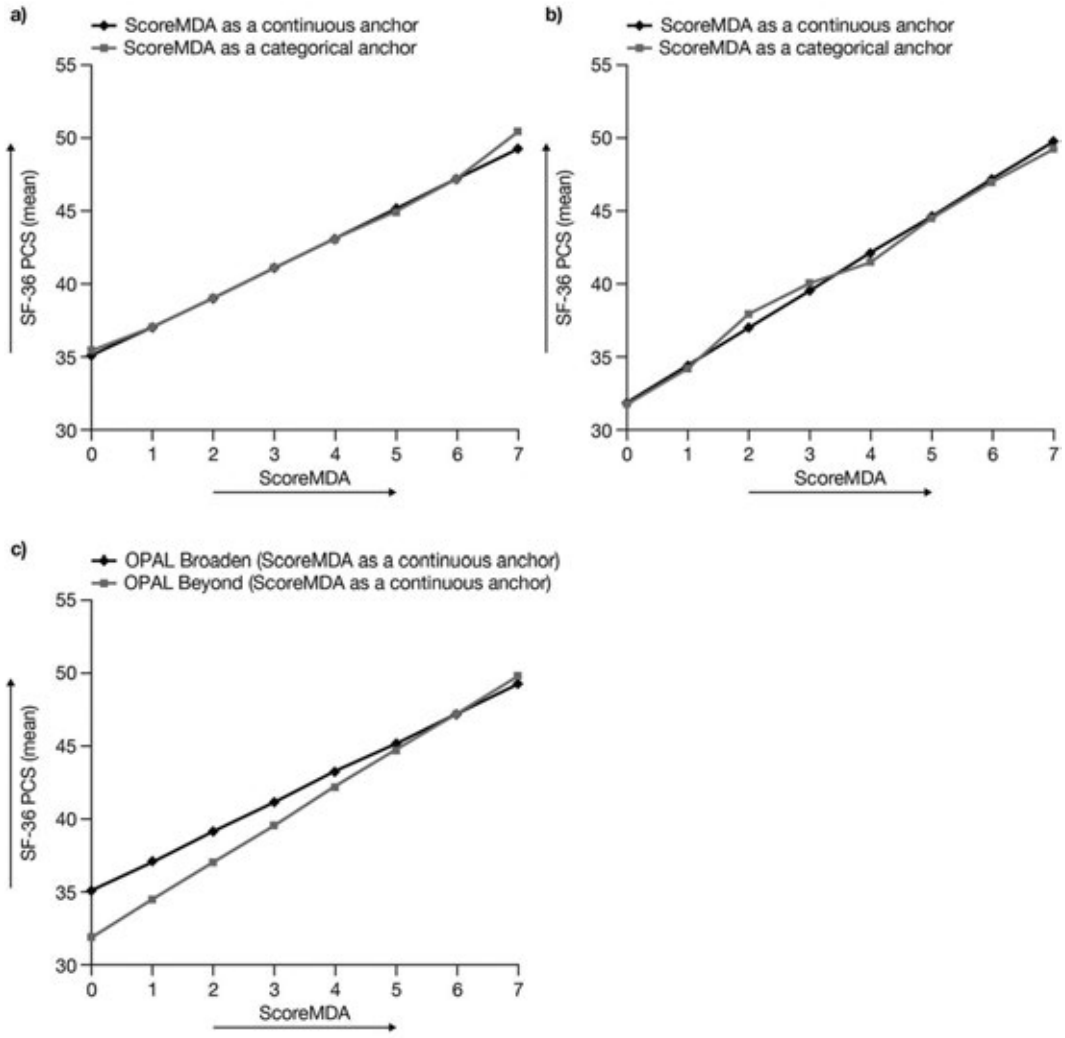
Background/Purpose: PsA is associated with multiple disease domains, requiring the use of different clinical measures and patient-reported outcomes (PROs) to assess improvements in disease activity following treatment. However, the relationship between clinical measures and PROs is not well understood. The objective of this post hoc analysis was to evaluate associations between Minimal Disease Activity (MDA) and a set of PROs.

Methods: All available data from two Phase 3 studies in patients with PsA (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439])[1,2] were analyzed. MDA in PsA, as a binary outcome, is defined as meeting ≥ 5/7 of the following criteria: tender joint count ≤ 1; swollen joint count ≤ 1; Psoriasis Activity and Severity Index ≤

Table 1. Patient Reported Outcomes included in analysis

Patient Reported Outcome	Description
SF-36v2 Physical Component Summary Physical Functioning Domain	36-Item Short-Form Health Survey, Version 2 acute
FACIT-F Total Score Experience Domain Impact Domain	Functional Assessment of Chronic Illness Therapy-Fatigue
PGJS-VAS	Patient's Global Joint and Skin assessment - Visual Analog Scale
PGJS-VAS-PsO	Patient's Global Joint and Skin Assessment-Visual Analog Scale - Psoriasis Question
EQ-5D Visual Analog Scale Utility Index	EuroQol Five Dimension 3 Level

Figure 1. Estimated relationships between SF-36 Physical Component Summary and ScoreMDA in a) OPAL Broaden, b) OPAL Beyond, and c) OPAL Broaden vs OPAL Beyond



SF-36 PCS: norm-based scores were used (a score of 50 representing the mean for the general population [Ware JE et al. Quality Metric 2000]), with higher scores indicating less impairment; ScoreMDA: continuous MDA with values from 0–7 (0–4, no MDA; 5–7, MDA) Arrows on the figure indicate the direction of improvement
MDA, Minimal Disease Activity; SF-36 PCS, 36-Item Short-Form Health Survey Physical Component Summary

1 or body surface area ≤ 3%; patient global disease activity Visual Analog Scale (VAS) ≤ 20; Patient's Assessment of Arthritis Pain VAS (Pain) ≤ 15; HAQ-Disability Index (DI) score ≤ 0.5; and tender entheseal points ≤ 1. For the purpose of this analysis, an alternative MDA outcome is proposed (ScoreMDA) by considering every criterion as an individual item (ie 1 if true and 0 if false, to give a score range of 0–7; scores ≥ 5 indicate the patient had MDA). A set of PROs was analyzed (Table 1). A repeated measures regression model was used to evaluate the relationship between ScoreMDA and PROs. A sensitivity analysis to assess the linearity assumption was performed using ScoreMDA as a categorical anchor (represented by integer values 0–7).

Results: Results indicated a linear relationship between ScoreMDA and PROs, which was similar across all PROs and in both Phase 3 studies. For example, in OPAL Broaden, a 1-point difference in ScoreMDA was associated with a mean (95% CI) difference in SF-36 Physical Component Summary (PCS) score of 2.0 points (1.9, 2.2) (OPAL Beyond: 2.5 points [2.3, 2.7]) (Figure 1). These results indicate that improvements in any one MDA criterion is associated with an improvement in SF-36 PCS score approaching clinical relevance (clinically important difference [CID] for SF-36

PCS is 3 points) and improvements in any two criteria in MDA is associated with an improvement in SF-36 PCS score that exceeds the CID. Results were closely aligned when ScoreMDA was used as a categorical or a continuous anchor, thus supporting a linear relationship between ScoreMDA and the PROs.

Conclusion: There was a robust linear relationship between ScoreMDA and selected PROs. Results were similar across studies, suggesting that they may be generalizable to different populations. This method provides insight into the relationships between clinical measures and PROs in PsA, which could aid their interpretation and facilitate the assessment of disease activity.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster III: Psoriatic Arthritis, Clinical Features

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: ***Objectives*****.** The addition of carotid ultrasound CU into composite cardiovascular risk (CVR) scores has been found useful in the identification of high CVR in patients with inflammatory arthritis. We aim to evaluated if the performance of CU in the CVR stratification of patients with psoriatic arthritis (PsA) would identify patients in the very-high SCORE risk category and if this reclassification could be explained through features related to disease activity.

Methods: A cross-sectional study including a set of 206 patients fulfilling CASPAR criteria for PsA and 179 controls was performed. The following data were assessed: lipid profile; Systematic Coronary Risk Evaluation SCORE risk stratification; disease activity indexes through Disease Activity in Psoriatic Arthritis -DAPSA-, Bath Ankylosing Spondylitis Disease Activity -BASDAI-, Bath Ankylosing Spondylitis Functional Index -BASFI., skin disease activity measurements by Psoriasis Area Severity Index -PASI-, Body Surface Area -BSA-, and Nail Psoriasis Severity Index -NAPSI- scores; and the presence of carotid plaques and carotid intima media thickness (cIMT) trough ultrasound. A multivariable regression analysis, adjusting for classic cardiovascular risk factors, was performed in order to evaluate if risk reclassification following (CU) could be explained by features related to the disease and independently of traditional CVR factors.

Results: 49% patients with PsA had carotid plaques compared to 26% in controls (p=0.000). Similarly, cIMT was found to be higher in patients in comparison with controls (0.606 ± 0.116 *vs.* 0.679 ± 0.165, p=0.000). 51% of the patients were reclassified into a very-high SCORE risk category after carotid ultrasound compared to controls (26%, p=0.000). Principally, patients in the low SCORE category risk were significantly more reclassified (14% vs. 30%, p=0.002). Age (p=0.000), hypertension (p=0.000), obesity (p0.011), the use of statins (p=0.000), disease duration (p=0.000), and DAPSA score (p=0.049) were the variables that positive and univariately were associated with reclassification in PsA patients. Interestingly, PsA patients being reclassified disclosed lower total cholesterol (197 ± 36 vs. 179 ± 40 mg/dl, p=0.001) and LDL cholesterol serum levels (116 ± 35 vs. 106 ± 34 mg/dl, p=0.032) compared to controls. When the association of disease relation data with reclassification was assessed through multivariable regression, DAPSA score was associated with a higher probability of being reclassified (beta coef. 1.09 [95%CI 1.01-1.18]), p=0.035) after adjusting for age and traditional (CVR) factors. This relation was also found using DAPSA score. In this sense, a moderate or high activity category disclosed an odds ratio of 13.09 (95%CI 1.44-1118.76), p=0.022, compared to those patients in the low activity

Conclusion: Patients with PsA are more frequently reclassified into the very-high SCORE risk category after carotid ultrasound performance compared to controls. This reclassification can be independently explained by the activity produced by the disease

Development of a Biomarker Panel for Prediction of Disease Flares in Systemic Lupus Erythematosus

Serena Fasano,[1] Luciana Pierro,[1] Alessia Borgia,[1] Melania Coscia,[1] Ranieri Formica,[1] Antonella Riccardi,[1] and Francesco Ciccia[1], [1]University of Campania L. Vanvitelli, Naples, Italy

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

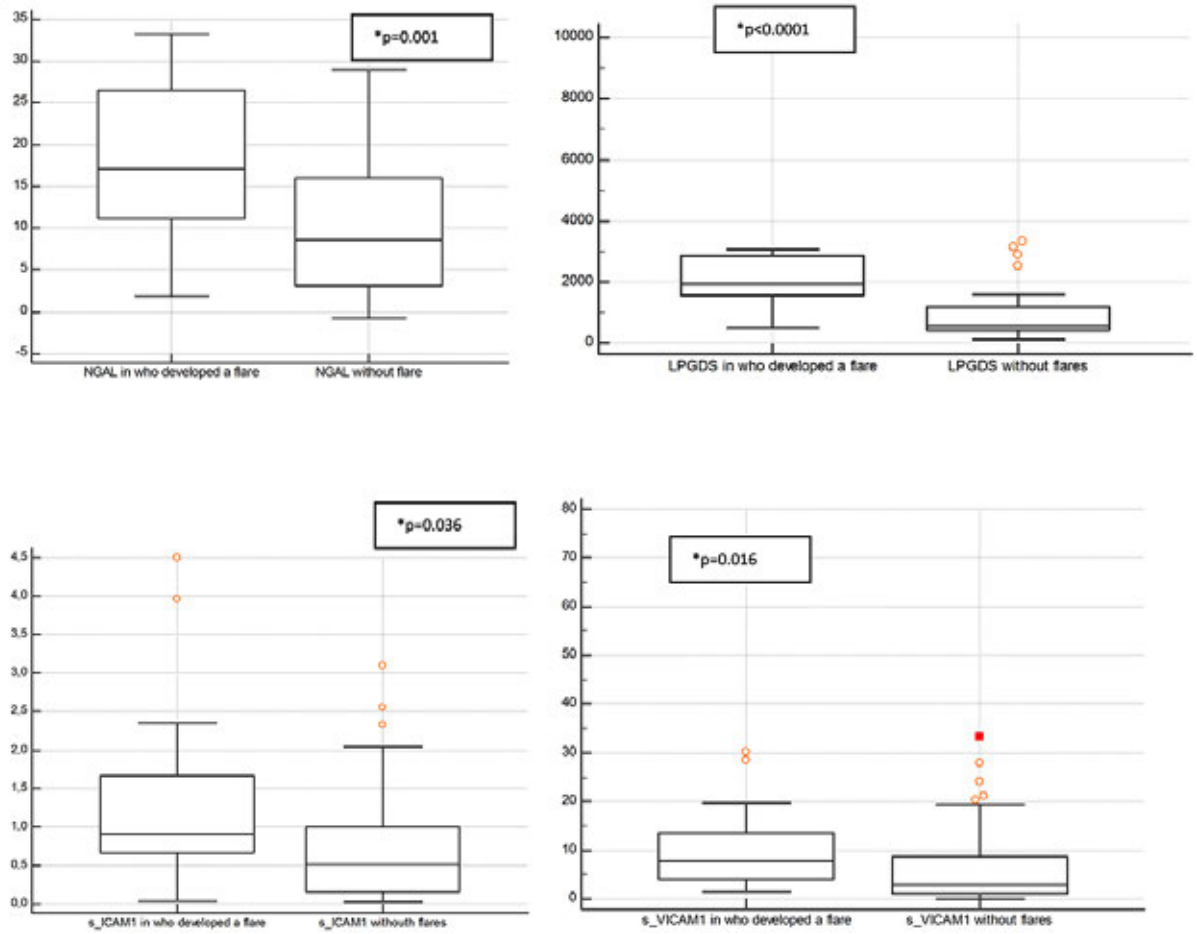
Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Fig 1

Comparison of urinary biomarkers levels between SLE patients who develop a flare after 12 weeks of urine collection and patients without flares.



Background/Purpose: Systemic Lupus Erythematosus (SLE) is an autoimmune disease with a relapsing-remitting course. Uncontrolled lupus flares might lead to organ damage. The routinely performed biomarkers (antidsDNA Ab and serum complement) have a limited predictive value for the prediction of flares. Recent evidence suggests that novel urinary biomarkers, namely vascular cell adhesion molecule-1 (VCAM-1), intercellular adhesion molecule-1 (ICAM-1), monocyte chemoattractant protein 1 (MCP-1), Urinary Neutrophil Gelatinase Associated Lipocalcin (NGAL) and Lipocalin-type Prostaglandin D-Synthetase (L-PGDS) are able to discriminate between SLE patients with ongoing renal activity and those without nephritis (1-3).

Objective. To assess the ability of novel urinary biomarkers in predicting flares in comparison to the conventional biomarkers and to derive a biomarker panel which may improve diagnostic accuracy.

Methods: Urine samples were collected from patients prospectively followed at our clinic who fulfilled ≥4 of the ACR 1997 revised criteria for the classification of SLE (4) and who were in stable disease at baseline visit (no new features of lupus disease activity compared with the previous assessment). Flares were identified by SELENA flare index (SFI) after 3 and 6 months of urine collection (5). Urinary biomarkers levels were measured in the second void urinary sample by ELISA assay. Data were compared by the unpaired student's t test or the Mann–Whitney U test as appropriate. Receiver operating characteristic (ROC) analysis was used to calculate the area under the curve (AUC) with associated 95% confidence interval (CI) to find the best cut-off values. Multiple regression was used to build models identifying independent predictors of disease flares.

Results: Urine specimen was collected from 71 patients, including 68 females and 3 males with a mean age of 44.4 years(±11.2) and a median SLEDAI2K of 2 (IQR 0-4). During 6 months-follow-up, 18 (25%) out of the 71 patients experienced a single disease flare. Among them, 8 episodes had renal involvement. Urinary L-PGDS, NGAL, ICAM-1 and VCAM-1 levels were significantly increased 12 weeks before a disease flare ($p< 0.05$; Figure1). Urinary MCP-1 levels were no significantly increased. Based on ROC analysis, urinary NGAL (AUC: 0.75) and L-PGDS (AUC: 0.82) outperformed conventional biomarkers (Table1). At univariate analysis(Table2), NGAL, L-PGDS, ICAM-1,VCAM-1, hypocomplementemia, anti dsDNA antibodies were predictors of lupus flares, while age at inclusion was protective. At multivariate analysis, antidsDNA antibodies and L-PGDS were independent predictors of lupus flares with OR=11.8 and 24.5, respectively. A combination of novel and conventional biomarkers demonstrated an excellent ability for accurately identifying a flare. (AUC >0.9; Table2)

Conclusion: This study has demonstrated the ability of a novel biomarker panel in predicting a lupus flare in its incipient phase. Further studies are needed to determine its clinical utility in everyday practice.

Table 1. Area under the curve (AUC), cut off values, sensitivity and specificity for novel and standard biomarkers for disease flares.

Hydroxychloroquine Is a Modifiable Predictor of Durable LLDAS

Hakan Babaoglu,[1] Jessica Li,[2] Daniel Goldman,[3] Laurence Magde,[4] and Michelle Petri[2], [1]Gazi University School of Medicine, Ankara, Turkey, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD, [4]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Lupus Low Disease Activity State (LLDAS), a potential treat to target goal in systemic lupus erythematosus (SLE), has been found to correlate with reduced damage accrual in SLE. In particular, SLE patients, in LLDAS for more than half of the observation time, have a lower risk of new damage. We identified predictors of being in LLDAS over 50% of the observation time.

Methods: This analysis was based on cohort data from its inception until May, 2019. A total of 2363 SLE patients, diagnosed according to the SLICC or ACR classification criteria and with at least two clinical visits, were included. We applied the definition of LLDAS and determined whether LLDAS was satisfied at each visit for each patient. Then, each observation for each patient was defined based on the status at the following visits throughout the whole follow

Table 2. Clinical manifestations of patients, grouped according to percentage of time in LLDAS

up. Follow up visits that occurred after a gap of more than 12 months (+/- 1 month) between clinic visits were excluded. Percentage of time in LLDAS was calculated. Durable LLDAS was defined as being in LLDAS for over 50% of the observation time. Patients were then classified into groups based on whether they had durable LLDAS or not. We analyzed the predictors of durable LLDAS from the stepwise selection procedure in logistic regression.

Results: Ninety-two percent of the patients were female, 40.2% African-American, and 51.9% Caucasian. 50% of the patients were diagnosed with SLE under the age of 30 years, 25% were between the age of 30 and 40, 14.5% were between 40 and 50, and 10.5% were diagnosed at age of 50 and over. 1198 (50.6%) patients overall, including 35.2% of African-Americans, achieved durable LLDAS. Patients with durable LLDAS, were significantly older at diagnosis, more educated, had longer disease duration, and were less likely to be African-American (Table 1,2). In the multivariable model, African-American ethnicity, ever having low C3, subacute cutaneous lupus erythematosus, alopecia, renal insufficiency, anti-RNP positivity, % of time with immunosuppressant use, and mean prednisone dose remained negative predictors, while age at diagnosis, disease duration, hemolytic anemia and higher % of time with hydroxychloroquine use remained positive predictors of durable LLDAS (Table 3).

Conclusion: A higher percentage of time with hydroxychloroquine use is a modifiable predictor of durable LLDAS, even after adjustment for clinical, demographic and other treatment variables. Only one third of African-American patients achieved durable LLDAS. Hydroxychloroquine use (and demonstration of adherence) remains essential in both clinical practice and in randomized clinical trials.

Median time to LLDAS was presented as years. There was no significant association between time to LLDAS and baseline age, sex, history of smoking, immunosuppressant use, musculoskeletal activity, hematological activity, serositis, and anticardiolipin antibody positivity. SELENA-SLEDAI and PGA were not included in the final multivariable model due to their collinearity with cutaneous and renal activity.
LLDAS=lupus low disease activity state, SLE=Systemic Lupus Erythematosus, C3=Complement 3, C4=Complement 4, Anti-dsDNA=anti double stranded DNA, PGA=Physician Global Assessment, SLICC/ACR= Systemic Lupus International Collaborating Clinics/ American College of Rheumatology, SELENA-SLEDAI= the Safety of Estrogens in Lupus Erythematosus National Assessment version of the SLE disease activity index, and *= baseline.

Table 1. Predictors of time to LLDAS

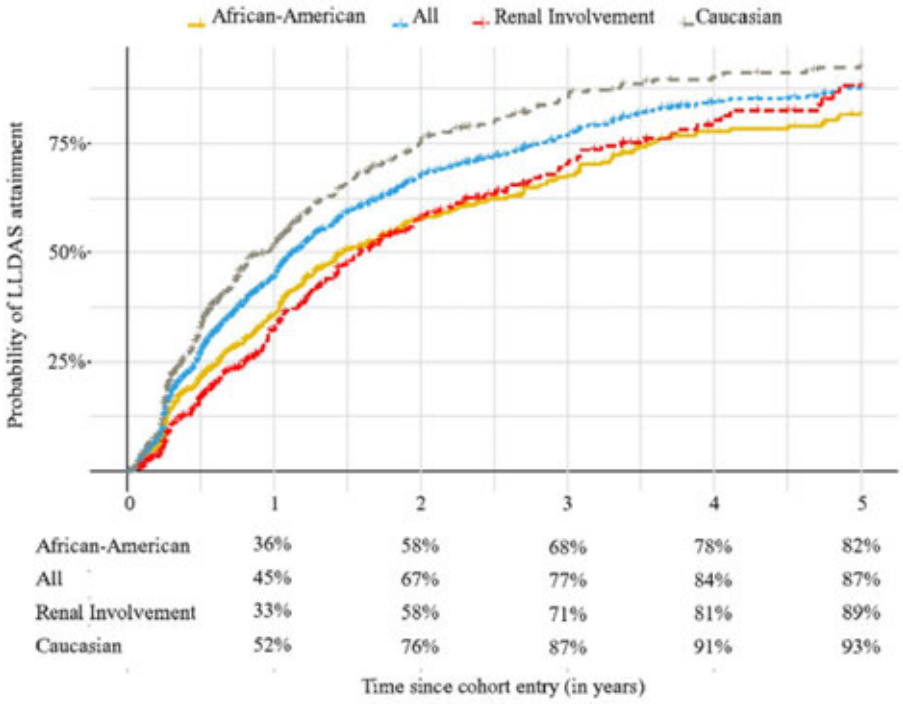

Figure 1. Probability of LLDAS attainment according to patients ethnicity and renal involvement at the stated time points

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus Low Disease Activity State (LLDAS) is a potential treat to target goal in systemic lupus erythematosus (SLE). It is well established that SLE patients who were in LLDAS for more than half of the observation period have a lower risk of new damage. The presentation and course of SLE is affected by ethnicity. African-American SLE patients are known to experience more severe SLE and, more chronic disease activity pattern. LLDAS in African-Americans has not been fully elucidated. In this study, we determined the time to LLDAS and predictors of time to LLDAS in a cohort with both Caucasian and African-American representation.

Methods: This analysis was based on cohort data from its inception until January, 2019. A total of 2,512 SLE patients, diagnosed according to the SLICC or ACR classification criteria, were included. We applied LLDAS (1), which was defined as a SELENA-SLEDAI score of ≤4 with no scores for the renal, central nervous system, cardiopulmonary, vasculitis, fever, no hemolytic anemia or gastrointestinal activity, no increase in any SELENA-SLEDAI component since the previous visit, a PGA of ≤1, and a prednisone dose of ≤7.5 mg/day. Immunosuppressant and hydroxychloroquine treatment were allowed for LLDAS. Patients were grouped according to LLDAS status at cohort entry. Those who did not satisfy LLDAS at cohort entry were analyzed prospectively. The Kaplan Meier approach was used to estimate the distribution of time to LLDAS and probability of patients achieving LLDAS after cohort entry, censoring patients who had a gap of 7 or more months in their follow-up time or who dropped out of the study before attaining LLDAS. Cox regression was used to identify patient characteristics that were associated with time to LLDAS.

Results: 1086 (43.2%) patients were in LLDAS at the first cohort visit. The probability of LLDAS attainment within one year was 52% for Caucasians, and 36% for African-Americans. Among those with renal involvement, the

estimated probability of achieving LLDAS within one year was 33% (Figure 1). The median time to LLDAS was 1.1 years. In multivariable models, African-American ethnicity, baseline prednisone >10 mg daily, baseline hypocomplementemia, baseline damage, and baseline renal activity remained significant predictors of longer time to attain LLDAS, while disease duration < 1 year and cutaneous activity were associated with earlier attainment (Table 1).

Conclusion: We demonstrated the achievability of LLDAS in both African-Americans and Caucasian patients, supporting the validity of LLDAS in multiple ethnicities. The time to LLDAS was longer in African-American SLE. Characteristics of African-American SLE such as renal activity and hypocomplementemia were also independent predictors of slower attainment of LLDAS. These findings point to the need to include African-American SLE patients in both clinical and pharmaceutical research, as we cannot generalize from studies from Europe and Asia.

Cenerimod, a Potent, Selective and Orally Active Sphingosine 1-phosphate Receptor 1 Modulator, Reduced Blood Antibody-secreting Cells in Patients with SLE

Daniel Strasser,[1] Virginie Sippel,[1] Ursula Grieder,[1] Andrea Kieninger-Graefitsch,[2] Gabin Pierlot,[1] Hervé Farine,[1] Paulina Kulig,[1] Geoffroy Bourquin,[1] Marcel Keller,[1] Peter Groenen,[1] Marten Trendelenburg,[2] and **Mark Murphy** [1], [1]Idorsia Pharmaceuticals Ltd, Allschwil, Switzerland, [2]University Hospital Basel, Basel, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is an autoimmune disease driven by autoreactive T and B lymphocytes. Lymphocytes infiltrate self-antigen expressing tissues, in which tertiary lymphoid structures are often observed, suggesting local generation of autoreactive effector cells. Autoreactive B lymphocytes produce autoantibodies leading to deposition of autoantibody immune complexes in tissues. The pathological process is amplified by secretion of inflammatory molecules. Reported here is the *in-vitro* and clinical characterization of cenerimod, a potent, selective, and orally active sphingosine 1-phosphate receptor 1 ($S1P_1$) receptor modulator **(1).**

Methods: All patients with SLE were classified according to ACR criteria. Primary lymphocytes from patients with SLE and healthy subjects were isolated from blood and characterized for $S1P_1$ receptor surface expression and cenerimod-induced $S1P_1$ receptor internalization by flow cytometry. In a phase 2 clinical trial in patients with SLE (NCT02472795) **(2)**, blood T and B lymphocyte populations were enumerated by flow cytometry before and after 12-weeks of treatment with different doses of cenerimod. Unbiased analysis of flow cytometry data was employed to identify novel cenerimod-responsive lymphocyte populations. Inflammatory biomarkers were measured by ELISA in plasma samples.

Results: Surface expression of $S1P_1$ receptor was demonstrated on primary blood lymphocytes both in healthy subjects and patients with SLE *in-vitro*. $S1P_1$ receptor expression levels were ~3-fold higher on B cells compared to T cells. Cenerimod was potent and efficacious at $S1P_1$ receptor internalization in T and B lymphocyte populations with an EC_{50} of ~15 nM in both healthy subjects and patients with SLE. In a cenerimod phase 2 clinical trial in patients with SLE, a dose-dependent reduction of blood T and B lymphocyte populations was evident, with a reduction of CD4+ T cells (up to 95%) and CD19+ B cells (up to 90%). Unbiased analysis discovered an ~85% cenerimod-induced reduction of blood antibody-secreting cells (CD45+/CD19+/CD27+/IgD-/CD20-/CD38++), which were demonstrated to be increased two-fold in patients with SLE compared to healthy subjects.

In the phase 2 clinical trial in patients with SLE, cenerimod reduced plasma IFN-a levels compared to placebo. IFN-a was shown to correlate with inflammatory molecules elevated in patients with SLE.

Conclusion: These data demonstrated for the first time $S1P_1$ receptor surface expression on blood T and B lymphocytes in patients with SLE, in which cenerimod was potent and efficacious in reducing $S1P_1$ receptor surface expression. In the phase 2 clinical trial in patients with SLE, cenerimod dose-dependently reduced blood T and B lymphocyte populations. Blood antibody-secreting cells, potentially involved in SLE pathogenesis, were increased in patients with SLE and reduced by cenerimod treatment in the phase 2 clinical trial.

The results warrant further investigation of the clinical efficacy of cenerimod and the impact on SLE biomarkers in the currently recruiting phase 2b clinical trial (NCT03742037).

Table 1. Treatment Emergent Adverse Events (TEAEs), Safety Population

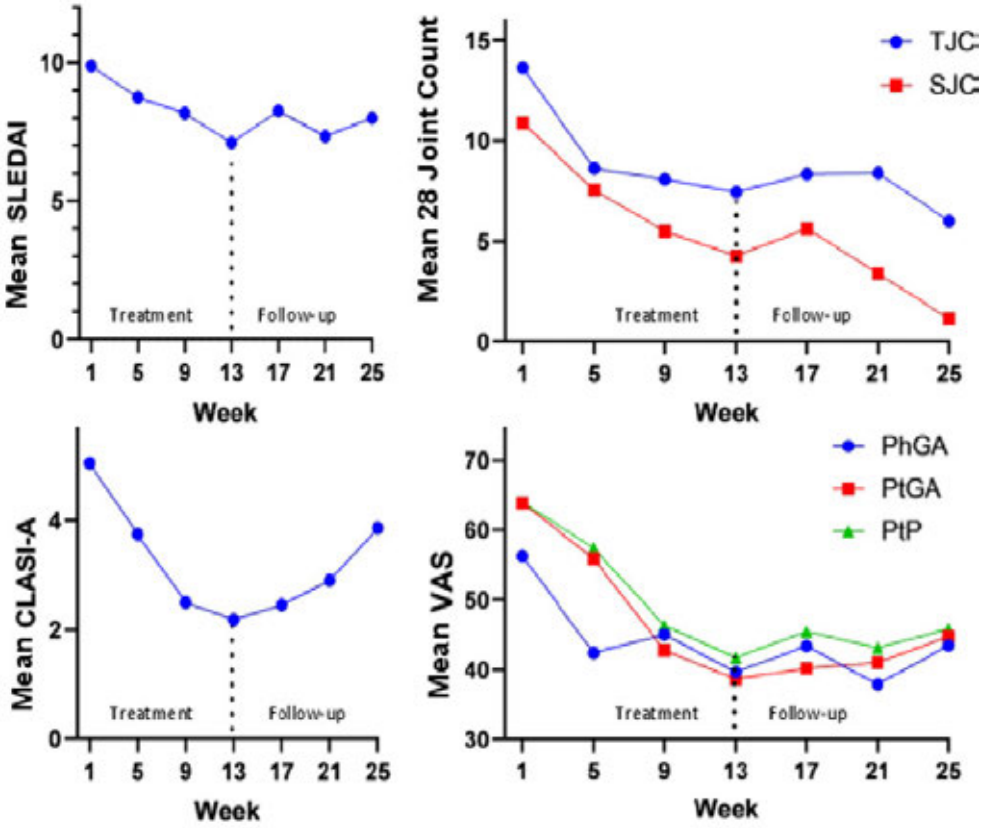

Figure 1. Efficacy Assessments in Evaluable Patients (N=16).

Background/Purpose: Nonspecific proteasome inhibitors, eg, bortezomib (BTZ), target both the constitutive and immuno- proteasome and are approved for the treatment of multiple myeloma. While BTZ has been used to treat refractory SLE and LN, it is associated with adverse events (AEs) that limit its use. KZR-616, a first-in-class selective immunoproteasome inhibitor, is highly active in murine SLE (Muchamuel et al. ARD 2018. 77:A685). In healthy vol-

unteers (HV), KZR-616 subcutaneously (SC) at 30 and 45 mg weekly (QW) was shown to be safe, be well tolerated, and achieve target levels of immunoproteasome inhibition (Lickliter et al. ARD 2018. 77:A1413). We report here the preliminary safety and efficacy of KZR-616 in the Phase (Ph) 1b portion of the MISSION Study KZR-616-002 in active SLE patients (pts) (NCT03393013).

Methods: This open-label multicenter dose escalation trial enrolled SLE pts with SLEDAI ≥4 despite stable background immunosuppressants, antimalarials, and/or corticosteroids (≤20 mg prednisone equivalent). The pts received KZR-616 at 45 mg (Cohort 1), 60 mg (Cohort 2), or 30 mg stepped up to 60 mg (Cohort 2a) SC QW through Week 13 (W13) with 12 weeks of follow up. Enrollment in Cohort 2a continued until ≥6 pts had ≥4 weeks of dosing with 60 mg. Safety data included AEs, vitals, ECGs, and laboratory tests. Pharmacokinetics (PK) and pharmacodynamics (PD) were assessed at baseline (BL) and W5. Efficacy measures included the SLEDAI, Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI), 28 tender (T) and swollen (S) joint counts (JC), Physician (Ph) and Patient (Pt) Global Assessments (GA), and Patient Pain (PtP) in evaluable pts (receive ≥1 month of KZR-616; non-evaluable pts were replaced). No corrections were made for missing data.

Results: Twenty-four pts were enrolled as of 6 May 2019 (Table 1): 91.7% were female; BL median SLEDAI was 10.0. All pts received ≥1 dose of KZR-616. In each cohort, 3 pts discontinued early: 3 due to withdrawn consent in Cohort 1; 1 due to AE and 2 due to withdrawn consent in Cohort 2; 1 due to loss to follow-up and 2 due to AEs in Cohort 2a. The majority of AEs were mild (85.8%) to moderate (12.8%) with no signs of peripheral neuropathy or clinically significant hematologic AEs. One pt in Cohort 2 had a serious AE (SAE) of thrombotic microangiopathy and withdrew from the study. In Cohort 2a, there was 1 SAE of localized herpes zoster; the pt resumed and completed dosing after SAE resolution. All pts in Cohort 2 vomited within ~8-24 hours (h) of their first dose (typically resolving within 24 h); 2 of the 5 pts completed the study at either 45 or 60 mg. Cohort 2a pts (30 to 60 mg step up) tolerated 60 mg without significant vomiting. The PK and PD at 45 and 60 mg were similar to that measured for the same doses in HV. Figure 1 shows mean evaluable pt efficacy data. Of 11 pts reaching W13 to date, 3 of 6 with low BL complement levels had resolution; 5 (45.5%) had a SLEDAI improvement of ≥4 points from BL.

Conclusion: KZR-616 at 45 mg SC QW or with step up dosing to 60 mg appears safe and well tolerated and showed evidence of improvement in disease activity at W13 in active SLE pts on stable background therapy. The Ph 2 doses in the first randomized placebo-controlled trial with KZR-616 in active LN pts on mycophenolate and prednisone are 30 and 45 mg.

Table 2. Demographic data in RTX-treated patients who suffered serious infection during follow-up.

Background/Purpose: Mortality in Systemic Lupus Erythematosus (SLE) is increased compared to the general population. We sought to investigate mortality rates and associated factors in a cohort of refractory SLE patients treated with Rituximab (RTX).

Methods: Patients recruited to a national biologics registry (first or repeat cycle of RTX-treated and standard of care-SOC) groups were included. Demographics, concurrent medication use, disease activity (BILAG 2004/SLEDAI-2K) and damage scores (SLICC/ACR-Damage Index -SDI) were recorded. Information regarding mortality and infection was collected from study centres and the national death registry. Serious infection events (SIEs) were defined as any infection resulting in treatment with intravenous antibiotics, hospitalization, disability or death. An infection occurring with 9 months of treatment was classified as associated with RTX. Logistic regression analysis was performed using Stata (v14).

Results: 830 patients were included (715 RTX and 115 SOC-treated) with 2693 person years of follow-up. 33 deaths were reported and there was no difference in mortality between RTX and SOC groups – 28 (3.9%) RTX-treated patients died vs 5 SOC (4.3%) (1.2 deaths vs 1.5 deaths/100 pt yrs follow up). Median cumulative RTX dose did not differ between deceased and alive groups.

The primary cause of death was identifiable in 24 RTX-treated patients and included infection (n=11, 45.83%), ischaemic heart disease (n=5, 20.83%) and malignancy (n=4, 16.67%). Factors associated with mortality in the RTX group included male sex, disease duration, older age at diagnosis, hypogammaglobulinaemia and higher SDI. There was also an excess of traditional cardiovascular risk factors including hypertension and diabetes in the deceased group (Table 1).

125 SIEs occurred in 56 patients (7.8%) and 18 SIEs occurred in 7 patients (6.1%) in the RTX and SOC groups respectively during 9 months follow-up. SIE rates did not differ between groups (5.29 in RTX vs 5.46 in SOC /100 pt. yrs. follow up). The commonest SIEs in the RTX group were respiratory (n= 35, 28%). Patients who suffered SIEs within the RTX group had significantly higher baseline steroid dosing (15mg vs 10mg, p= 0.01) and demonstrated a trend to older age at recruitment, renal involvement, hypogammaglobulinaemia and higher SDI (Table 2).

Logistic regression analysis of the RTX group identified previous myocardial infarction (OR= 12.33, 95% CI 1.57-97.48), hypogammaglobulinaemia (OR= 4.25, 95% CI 1.06-16.91), diabetes (OR= 4.30, 95% CI =1.55-11.86), malignancy (OR= 3.64, 95% CI 1.51-8.81), respiratory disease (OR 2.61, 95% CI 1.15-5.90), total previous immunosuppressant use (OR 1.27, 95% CI = 1.02-1.58), SDI (OR 1.26, 95% CI 1.05-1.51) and baseline steroid use (OR 1.02, 95% CI 1.00-1.05) as significant predictors of SIEs within 9 months of treatment.

Conclusion: Despite having refractory disease, RTX-treated patients did not exhibit increased mortality or SIE rates compared to patients receiving SOC. Mortality was instead associated with co-morbidities as well as some SLE severity markers. Monitoring higher risk individuals more closely and proactive management of these risk factors may further improve outcomes in this refractory population.

Abstract Number: 2522

Frequency and Early Prediction of Hydroxychloroquine Induced Retinopathy in SLE

Jessica Li,[1] Daniel Goldman,[2] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In 2016, the American Academy of Ophthalmology (AAO) published recommendations designed to reduce hydroxychloroquine induced retinopathy via early detection and reduction of hydroxychloroquine dosing from 6.5 mg/kg to less than 5 mg/kg. We prospectively determined the frequency and the predictive role of blood levels of hydroxychloroquine to identify those at greater future risk of retinopathy. Blood hydroxychloroquine levels are preferred over plasma levels, as they more accurately reflect exposure over the last month.

Methods: 382 SLE patients were examined by ophthalmologists with retina specialization, with a fundus examination and one or more of the newer retinal screening tests: Spectral-Domain Optical Coherence Tomography (OCT); Multifocal Electroretinogram (mfERG); Microperimetry (MP1); and Fundus Autofluorescence (FAF). Hydroxychloroquine blood levels were tested at every visit and quantified by liquid chromatography-tandem mass spectrometry.

Results: Twenty-three patients had confirmed hydroxychloroquine toxicity for an overall retinopathy frequency of 4.3%. The frequency of retinopathy was: 1% in the first 5 years, 1.8% from 6 to 10 years, 3.3% from 11 to 15 years, 11.5% from 16 to 20 years, and 8.0% after 21 years of use (Table 1). Higher hydroxychloroquine blood levels (both mean and maximum) predicted later hydroxychloroquine retinopathy (Table 2).

Conclusion: The frequency of retinopathy in our prospective study was much less than in the retrospective Kaiser Permanente study. Hydroxychloroquine blood levels in the upper tertile predicted retinopathy. Mean hydroxychloroquine levels likely better predict risk than the maximum level. Hydroxychloroquine blood levels would allow clinicians to either decrease the dose or increase monitoring in those with blood levels in the highest tertile. Currently, however, availability of hydroxychloroquine blood levels has been limited.

Duration of use (years)	Total	N	Percent	P-value	P-value for Trend
5 or less	103	1	0.97%	0.0006	0.0002
6 to 10	109	2	1.83%

Contemporary Prescription Opioid Use and Predictors Among Patients with Systemic Lupus Erythematosus

April Jorge,[1] Na Lu,[2] and Hyon K. Choi[1], [1]Massachusetts General Hospital, Boston, MA, [2]Massachusetts General Hosptial, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a complex illness that can be associated with chronic pain. In recent years, an international opioid epidemic has become a major public health concern and is attributed, in part, to prescription opioids. We assessed contemporary patterns of opioid prescribing among patients with SLE in a general population context and examined potential associations with prescription opioid use.

Methods: Using a United Kingdom general population database, we conducted a cohort study of adult SLE patients, identified by Read codes. The exposures of interest were opioid prescriptions between January 1, 2007 and December 31, 2016. We classified opioids as weak, including tramadol and codeine, and strong, including hydrocodone, morphine, fentanyl, oxycodone, hydromorphone, and methadone. We examined the proportion of patients receiving prescriptions for weak and strong opioids and performed logistic regression to assess whether prescription use of these medications varied by age, sex, duration of SLE, other medication use for SLE, comorbid conditions, lifestyle exposures, and socioeconomic status. We adjusted for age and sex.

Results: Of 10,784 SLE patients, (86% female, mean age 51.2 years), 32% were prescribed weak opioids and 10% were prescribed strong opioids during the study period. 21% and 7% received multiple prescriptions for weak and strong opioids, respectively. Concomitant diagnoses of fibromyalgia and OA each increased the odds of receiving prescription opioids (adjusted odds ratios [aOR] for strong opioids: 2.37 [96% CI 1.84-3.06] and 1.22 [95% CI 1.03-1.44] for fibromyalgia and OA, respectively) (**Table 1**). SLE patients who were also taking NSAIDs, DMARDs, or glucocorticoids each had increased odds of receiving prescription opioids. Current smokers were also more likely to be prescribed prescription opioids. There was a trend towards higher odds of prescription opioid use with increasing deprivation score, a measure of socioeconomic status; the aOR was 1.33 (95% CI 1.03-1.71) for weak opioid use among the highest deprivation quintile.

Conclusion: In this general population-based cohort study, nearly one-third of SLE patients were prescribed weak opioids and 10% were prescribed strong opioids. Prescription opioid use is higher among patients who are also taking NSAIDs, glucocorticoids, and DMARDs, among those with lower socioeconomic status, and in those with concomitant fibromyalgia or OA. These findings indicate the use of these potentially dangerous medications among a substantial portion of SLE patients. Future studies should assess the impact of opioid usage on mortality and other important outcomes among patients with SLE.

24-Month Outcomes Associated with Belimumab in Black/African-American Patients with Systemic Lupus Erythematosus in a Clinical Practice Setting in the United States

Christopher Collins,[1] Gail Kerr,[2] Joan Von Feldt,[3] Bernie Rubin,[4] Arie Katz,[3] Vanessa Castellano,[5] Jake Chung,[4] and **Christopher Bell** [5], [1]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [2]Washington DC VA Medical Center, Georgetown and Howard Universities, Washington DC, DC, [3]GSK, Philadelphia, PA, [4]GSK, Phildelphia, PA, [5]GSK, Research Triangle Park, NC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease characterized by diverse clinical manifestations and organ damage accrual. Black/African-American (B/AA) race is associated with higher SLE prevalence, disease activity, organ damage, and mortality than in Caucasian patients Although the efficacy and safety of belimumab (BEL) has been evaluated in adult patients of B/AA race with active SLE in a randomized clinical trial (EMBRACE; NCT01632241), real-world BEL effectiveness data in B/AA patients is limited. We report clinical outcomes in B/AA patients with SLE treated with BEL in a US clinical practice setting.

Methods: OBSErve US (evaluation **O**f use of **B**elimumab in clinical practice **SE**ttings in the US; GSK Study 117295) was an observational cohort study that randomly recruited non-academic rheumatologists from a national physician database. Data were collected on randomly selected adult patients with SLE who had received ≥8 BEL infusions as part of standard care. Patient demographics, disease characteristics, clinical outcomes, healthcare resource utilization, and oral corticosteroid (OCS) use were extracted from medical charts for 6 months prior to index date (1st BEL infusion), and then prospectively every 6 months up to Month 24. The primary outcome was physician-assessed overall clinical response relative to the previous 6-month time point. *Post hoc* analysis was performed (GSK Study 208439) on the B/AA subpopulation who completed the 24-month study period.

Results: OBSErve US enrolled 501 patients; 123 (24.5%) were B/AA and 69/123 (56.1%) B/AA patients continued to receive BEL at Month 24. Baseline (BL) characteristics of the Month 24 completers included: female 88.4%, mean age (standard deviation [SD]) 41.6 (12.5) years; severe SLE at BEL initiation (34.8%), and key clinical diagnoses: lupus nephritis (27.5%) and hypertension (26.1%). At Month 24, 33/69 (47.8%) B/AA patients had ≥50% improvement in physician-assessed overall clinical response between index and the previous 6 months, with further improvements observed in each subsequent 6-month period (**Figure 1**). By Month 24, 52/69 (75.4%) B/AA patients had mild SLE (severe SLE: 2.9%, **Figure 2**). Of the 69 B/AA patients with BL moderate/severe disease, 36/69 (52.2%) had consistent mild SLE at Month 6, 12, 18, and 24. At BEL initiation, 57/69 (82.6%) B/AA patients received OCS (mean [SD] dose: 19.7 [12.8] mg/day); and at Month 24, 40.4% had discontinued OCS with a mean (SD) OCS dose of 3.1 (3.2) mg/day.

Figure 1. Clinical responses in B/AA patients at Month 24 (n=69), according to physicians' impression of overall change in SLE manifestations relative to previous time point

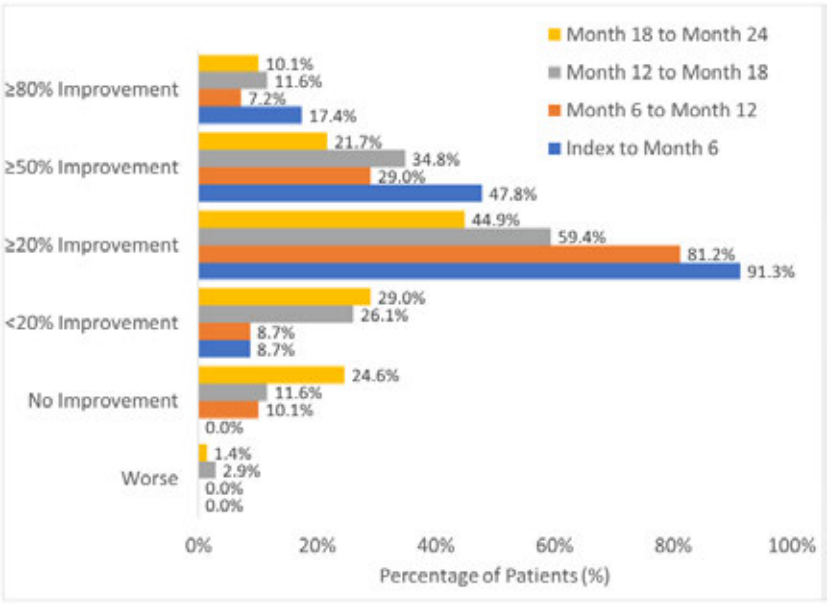

Figure 2. Disease severity according to physician assessment in B/AA patients at Month 24 (n=69 at each time point)

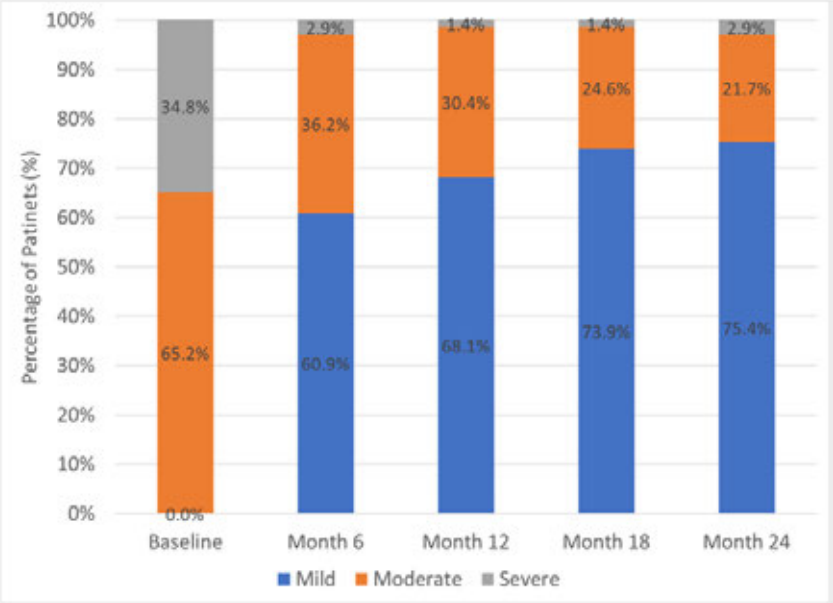

Conclusion: OBSErve US results from the B/AA SLE subpopulation who received BEL over 24 months in a clinical practice setting suggested substantial improvements in clinical outcomes (eg, reduced disease activity, severity, OCS utilization). While results may be limited with regards to sample size, subjective assessments, and analysis-by-responder bias, they demonstrated the effectiveness and durability of BEL in B/AA patients with SLE over 24 months. Results might inform decision-making when considering BEL for the treatment of B/AA patients with SLE, particularly in the context of published BEL efficacy and data from clinical trials.

Within-Trial Cost Analysis of Flares from a Phase 3 Clinical Trial Evaluating Subcutaneous Belimumab for the Treatment of Systemic Lupus Erythematosus

Tasneem Lokhandwala,[1] Binglin Yue,[1] Anna Coutinho,[1] and **Christopher Bell** [2], [1]Xcenda AmerisourceBergen, Palm Harbour, FL, [2]GSK, Research Triangle Park, NC

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic autoimmune disease characterized by diverse clinical manifestations and flares associated with organ damage, resulting in substantial short-term management costs. Results from the BLISS-SC trial demonstrated that subcutaneous (SC) belimumab plus standard of care (SoC) compared with placebo plus SoC was associated with significant reductions in flares.[1] This study evaluated whether reductions in flares were associated with lower healthcare costs when comparing belimumab and placebo in the United States (US).

Methods: This retrospective, observational, *post hoc* economic analysis (GSK study 207134) from the US payer perspective used data from BLISS-SC, a 52-week, Phase 3, randomized trial (NCT01484496), comparing weekly belimumab 200 mg SC plus SoC and placebo plus SoC in adults with active SLE. The primary endpoint was the cost of treating severe flares; the secondary endpoint was the cost of treating flares of any severity. The time horizon was 52 weeks. Unit cost per flare (2017 US$) was calculated from an analysis using an algorithm to identify flares in US claims data.[2] An event-based costing methodology was subsequently applied to flare events observed in BLISS-SC, allowing for a comparison of costs associated with treating flares in the belimumab group versus placebo. Generalized linear models with negative binominal distribution were used to predict adjusted rates of severe and mild/moder-

Figure 1. Adjusted costs associated with treating SLE flares

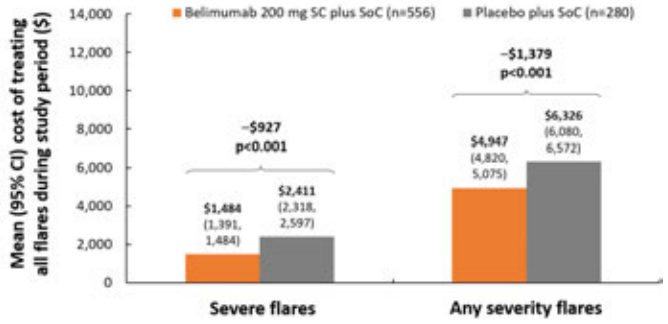

Figure 2. Adjusted rates of SLE flares per patient-year by severity

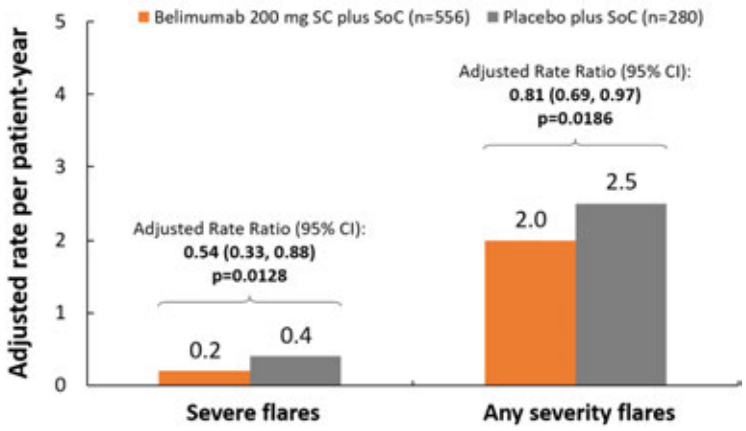

ate flares per patient. Adjusted rates of flares per patient were then multiplied by the flare unit cost (from claims data) to obtain adjusted costs associated with treatment of severe and mild/moderate flares. The mean (95% confidence interval [CI]) adjusted costs of any severity flares were computed by adding the estimated costs of severe and mild/moderate flares per patient.

Results: 836 patients from the intent-to-treat BLISS-SC population were included (belimumab plus SoC, n=556; placebo plus SoC, n=280); mean (standard deviation, SD) age was 38.6 (12.3) years; 94.4% were female. The mean (SD) unit cost was $9,273 ($38,800) per severe flare and $2,303 ($7,821) per mild/moderate flare. Mean adjusted predicted costs associated with treating flares during follow-up were significantly lower in the belimumab plus SoC group than in the placebo plus SoC group (severe flares, $927 lower, p< 0.001; flares of any severity, $1,379 lower, p< 0.001) (**Figure 1**). The adjusted rate of severe flares per patient-year was lower in the belimumab plus SoC versus the placebo plus SoC group (**Figure 2**).

Conclusion: This *post hoc* analysis of BLISS-SC data showed significantly lower costs of treating flares in patients with SLE treated with SC belimumab plus SoC compared with placebo plus SoC. Although the study is representative of a select clinical trial population and may differ from real-world patients with SLE, these results may help inform decision makers considering the introduction of SC belimumab to their healthcare system.

Study funding: GSK. Medical writing support: Gosia Carless, PhD, Fishawack Indicia Ltd, UK (funded by GSK).

[1]Stohl W, *et al. Arthritis Rheum.* 2017;69(5):1016–27
[2]Garris C, *et al. J Med Econ.* 2013;16(5):667–77

Adjusted cost estimates were obtained by multiplying the unit cost of flares by the adjusted rate of flares. The adjusted rate of flares was obtained using a generalized linear model with negative binominal distribution. Treatment arm (belimumab versus placebo) was used to predict the flare rate; other covariates included baseline complement levels (low C3 and/or low C4 versus no low C3 or C4), race (African-American versus other), and baseline Safety of Estrogens in Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index score (≤9 versus ≥10). Patient follow-up time as log10 (patient-years) was used as an offset variable in the model.

Antimalarial Agents Improve Physical Functioning in Patients with Systemic Lupus Erythematosus

Ioannis Parodis,[1] Sofia Soukka,[1] Alvaro Gomez,[1] Yvonne Enman,[1] Petter Johansson,[1] Sharzad Emamikia,[1] and Katerina Chatzidionysiou[1], [1]Division of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) suffer an impaired health-related quality of life (HRQoL), and the majority of them experience fatigue as a major problem. Traditionally, treatment of SLE has been symptomatic, and antimalarial agents (AMA) are considered a cornerstone of SLE treatment. In previous literature, results regarding the effect of antimalarial agents on HRQoL have been conflicting. In this study, we aimed at investigating the potential influence of AMA on SLE patients' self-perception of HRQoL aspects.

Methods: We utilised pooled baseline data from the BLISS-52 and BLISS-76 clinical trials of belimumab (n=1684). Access to data was granted by GlaxoSmithKline. The patients' HRQoL and fatigue were self-reported using the Medical Outcomes Study (MOS) short form 36 (SF-36) health survey, the functional assessment of chronic illness therapy (FACIT)-Fatigue scale and the three-level ^{EuroQol}-5 Dimension (EQ-5D) questionnaire. Minimal clinically important difference (MCID) was set to ≥5.0 points for SF-36 subscales, ≥2.5 points for SF-36 component summary scores, and ≥4 points for FACIT-Fatigue scores. High disease activity was defined as a SELENA-SLEDAI score ≥10. Organ damage was assessed using the SLICC/ACR Damage Index (SDI). The non-parametric Mann-Whitney *U* test was used for comparisons between AMA users and non-users. Linear regression models were next used in order to adjust for possible confounding factors; these included age, sex, ethnic origin, SLE disease activity, SLE duration, organ damage, corticosteroid use and use of other immunosuppressive agents.

Results: Results are presented as mean values ± standard devation. Patients receiving AMA (n=1098) performed better than patients who did not receive AMA (n=586) with regard to SF-36 physical component summary (PCS) scores (39.6 ± 9.5 versus 38.1 ± 9.9; P=0.001), physical functioning (61.1 ± 24.9 versus 55.0 ± 26.5; P< 0.001), role physical (53.2 ± 26.9 versus 50.3 ± 27.7; P=0.036), bodily pain (49.5 ± 23.8 versus 47.1 ± 25.3; P=0.016), FACIT-Fatigue scores (30.5 ± 11.8 versus 29.3 ± 11.9; P=0.046), EQ-5D scores (0.75 ± 0.18 versus 0.72 ± 0.19; P=0.004) and EQ-5D visual analogue scale (VAS) scores (64.6 ± 19.4 versus 61.7 ± 18.6; P=0.001). The difference in SF-36 physical functioning was the greatest among the SF-36 parameters, exceeding the corresponding MCID (≥5.0 points). The association between AMA use and better physical functioning was still significant after adjustment for confounding factors (standardised coefficient, β =0.08; P=0.001). In this analysis, Asian patients performed better in physical functioning (β =0.07; P=0.004) while African/African American patients performed worse (β =-0.07; P=0.003). High disease activity (β =-0.09; P< 0.001) and organ damage (β =-0.12; P< 0.001) were also independent factors of worse physical functioning, whereas corticosteroid use independently improved the outcome (β =0.06; P=0.022).

Conclusion: In the SLE populations of the BLISS-52 and BLISS-76 clinical trials, AMA use was associated with favourable HRQoL in terms of physical functioning independently of other factors.

Cytokine and Autoantibody Profiles During Treatment with Belimumab in Patients with Systemic Lupus Erythematosus

Ioannis Parodis,[1] Emil Åkerström,[1] Christopher Sjöwall,[2] Azita Sohrabian,[3] Andreas Jönsen,[4] Alvaro Gomez,[1] Martina Frodlund,[2] Agneta Zickert,[1] Anders Bengtsson,[4] Johan Rönnelid,[3] and Iva Gunnarsson[1], [1]Division of Rheumatology, Department of Medicine, Karolinska Institutet, Stockholm, Sweden, [2]Department of Clinical and Experimental Medicine, Rheumatology/Division of Neuro and Inflammation Sciences, Linköping University, Linköping, Sweden, [3]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden, [4]Lund University, Lund, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The anti-BAFF monoclonal belimumab is approved for the treatment of systemic lupus erythematosus (SLE) since 2011. Effects of belimumab on anti-double stranded (ds)DNA levels, as well as serum levels of B cell activating factor (BAFF) and a proliferation-inducing ligand (APRIL), both belonging to the tumour necrosis factor (TNF) ligand superfamily, have been demonstrated in previous studies. We investigated whether belimumab treatment impacts levels of other cytokines of interest in SLE (i.e. IFN-α2, IL-6, IL-10 and IL-17A), autoantibodies (i.e.anti-dsDNA, anti-TRIM21, anti-SSA (Ro60), anti-SSB, anti-Sm, anti-SmRNP, anti-U1-RNP, anti-histone, anti-ribosomal P, anti-PCNA antibodies), and circulating immune complexes (ICs).

Methods: Longitudinally collected serum samples for up to 24 months of treatment from 78 belimumab-treated patients with SLE from the Karolinska, Skåne and Linköping University hospitals were analysed. Serum cytokine levels were measured using Luminex xMAP technology (Milliplex Map kit HCYTOMAG-60K-04; EMD Millipore Corp., Billerica, USA). Nuclear antigen autoantibody specificities were determined by addressable laser bead immunoassay (ALBIA) using the Connective profile MX117 FIDIS kit (Theradiag, Paris, France). Circulating C1q-binding ICs were measured using enzyme-linked immunosorbent assay (ELISA) (Quanta Lite, Inova, San Diego, USA). P values < 0.05 derived from paired Wilcoxon signed rank tests between baseline and follow-up time points were considered statistically significant.

Results: In patients with detectable cytokine levels at baseline, serum levels of IFN-α2 were lower at month 6 (median: 8.9; IQR: 1.5–54.9 pg/mL) compared with baseline (median: 28.4; IQR: 20.9–100.3 pg/mL; P=0.043). Levels of IL-6 showed decreases from baseline (median: 7.1; IQR: 2.9–16.1 pg/mL) to month 6 (median: 0.5; IQR: 0.5–6.3 pg/mL; P=0.018) and throughout the 24-month follow-up. Levels of IL-10 (baseline median: 12.6; IQR: 2.8–29.7 pg/mL) showed more rapid decreases as soon as from month 3 (median: 1.8; IQR: 0.6–9.1 pg/mL; P=0.003) and remained significantly lower than baseline levels over the 24-month follow-up. Only one patient had detectable levels of IL-17A at baseline. In patients with positive autoantibody levels at baseline (>40 international or arbitrary U/mL), levels of anti-dsDNA (P< 0.001), anti-Sm (P=0.002), anti-SmRNP (P=0.028), anti-U1-RNP (P< 0.001) and anti-ribosomal P (P=0.012) antibodies decreased as soon as from month 3 and remained significantly lower than baseline levels over the study period. Anti-histone antibody levels showed decreases at month 3 (P=0.008) and month 6 (P=0.003) from treatment initiation, but were not significantly changed compared to baseline at later time points. In patients with

baseline circulating ICs 10.8 mg Eq/mL or higher (reference value), IC levels showed decreases at month 3 (P=0.028), month 6 (P=0.009) and month 12 (P=0.021), but not at month 24 (P=0.345).

Conclusion: In our cohort, belimumab treatment lowered IFN-α2, IL-6, IL-10 and circulating IC levels, as well as levels of multiple autoantibodies against nuclear components.

Effect of Additional Administration of HCQ on Pro-inflammatory Cytokine Expression, Especially in Lupus Nephritis

Risa Wakiya,[1] Kiyo Ueeda,[2] Hiromi Shimada,[2] Shusaku Nakashima,[1] Mai Mahmoud Fahmy Mansour,[1] Mikiya Kato,[1] Taichi Miyagi,[1] Tomohiro Kameda,[1] and Hiroaki Dobashi[2], [1]Kagawa University, Kagawa, [2]Kagawa University, Kagawa, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine(HCQ) is recommended for all patients with SLE in EULAR recommendation 2019, however, there are not enough data about the effect of additional HCQ treatment on the expression of pro-inflammatory cytokines, which plays an important role in SLE pathogenesis. The aim of this study is to clarify the effect of additional HCQ treatment on pro-inflammatory cytokines in SLE patients with low disease activity(LDA).

Methods: All patients with LDA enrolled in this study started HCQ treatment and had been receiving oral HCQ continuously for at least 3 months without using other immunosuppressive treatments or glucocorticoids. LDA was defined as SELENA-SLEDAI score of 8 or less with no activity in major organ systems and current prednisolone or equivalent dose of 10mg per day or less and well-tolerated maintenance doses of immunosuppressant. Serum levels of IFN-α, MRP8, MRP14, TNF-α, IL-2, IL-6, IL-8, VEGF-A, MCP-1, MIP-1α, IL-1β, IL-1ra, and G-CSF were measured at the time of HCQ administration and 3 months later using ELISA (CircuLex ELISA Kit, MBL)(Human IFN-alpha ELISA Kit, R&D) or a multiplex immunoassay (Luminex Assay, R&D). Data was analyzed using JMP® 13 software (SAS Institute Inc., Cary, NC, USA).

Results: 42 patients were enrolled in this study (M:F; 4:38, average age; 41.3±13.3; Table 1). 19 cases were in sustained remission of lupus nephritis(LN) patients. Serum levels of MRP8, MRP14 and IL-1ra at baseline were significantly higher in patients with a history of LN compared with those without LN (p=0.012, p=0.0043 and p=0.0092, respectively). Serum levels of MRP8, MRP14, TNF-α, IL-6, VEGF-A, IL-1ra, and IL-2 decreased significantly 3 months after additional HCQ treatment. The expressions of IFN-α didn't decrease significantly in 9 cases that could be detected.

Serum levels of IL-8 and MIP-1a decreased 3 months after additional HCQ treatment, but the difference was not statistically significant (p=0.211, p=0.109). However, serum levels of IL-8 same as VEGF-A significantly decreased in patients with a history of LN (with LN: IL-8, p=0.0026; VEGF-A, p=0.048; without LN: IL-8, p=0.370; VEGF-A, p=0.284).

Table 1. Characteristics of SLE patients enrolled in this study *1 Two patients received multiple immunosuppressants. *2 Four patients received antiplatelet agent and anticoagulant agent. *3 Anti-dsDNA positive means anti ds-DNA titer increases over 12 IU/ml. *4 Low complement means any of C3, C4 and CH50 decreases to less 68mg/dl, less 12mg/dl, less 30U/ml.

In addition, the magnitude of the changes in serum IL-8 levels in patients with a history of LN was significantly higher than in those without a history of LN (p=0.0039; Figure 1). The changes of IL-8 levels were correlated with those of serum MRP8 (r=0.32, p=0.049, Figure2).

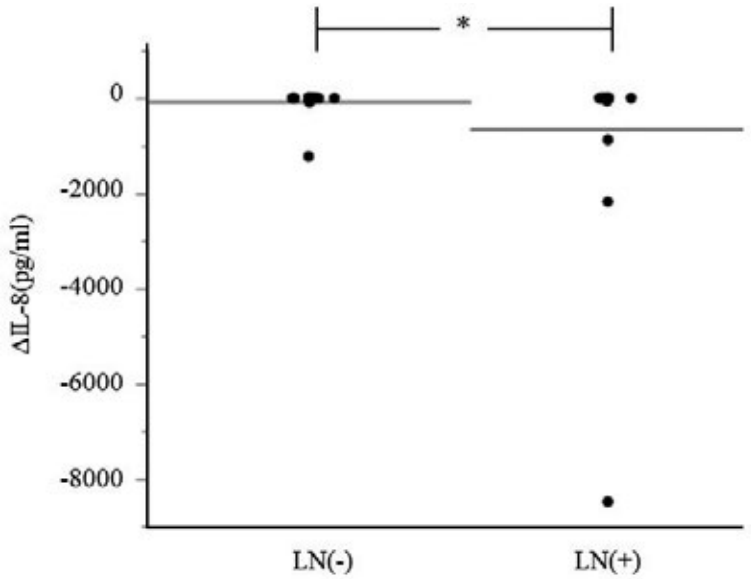

Figure 1. The magnitude of changes in serum IL-8 levels in patients with a history of LN were significantly higher than in patients without a history of LN. For statistical analyses * p<0.05, NS: Not significant, P value: Steel-Dwass test

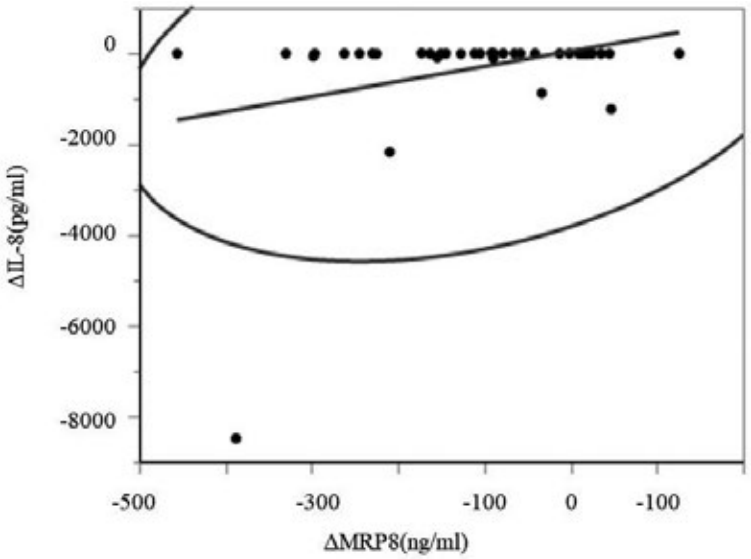

Figure 2. Correlation between the changes of IL-8 and those of MRP8 (r=0.32 p<0.05).

Conclusion: Additional HCQ treatment could decrease the several pro-inflammatory cytokines expression in SLE patients with LDA, especially in LN. Additionally, our data indicates that the effect of additional HCQ treatment could reduce the IL-8 expression in remission LN subjects significantly, which is reported to be associated with improvement of LN prognosis. HCQ use should be considered to be prescribed for all SLE patients as described in EULAR recommendation 2019.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

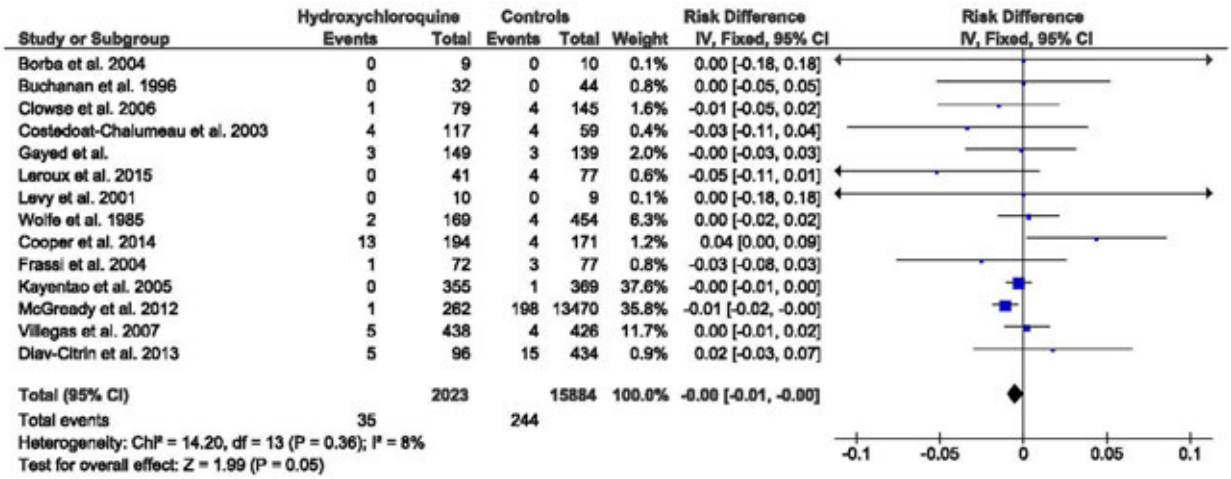
Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Chloroquine (CQ) and Hydroxychloroquine (HCQ) have been used for years during pregnancy for multiple indications (malaria prevention, autoimmune disorders, etc.…). Recently, some countries face restrictions to prescribe these drugs during pregnancy, due to report of ocular toxicity in animal models and potential genotoxicity. Change of the summary of product characteristics could significantly impact the adherence to this essential treatment for pregnancy in CQ/HCQ treated patients. The aim of this study was to perform a systematic review and a meta-analysis of fetal malformation rate under CQ and HCQ (all indications) during pregnancy. In the subgroup of patients suffering from an autoimmune disease, we performed an analysis of CQ and HCQ efficacy on maternal and pregnancy outcomes.

Methods: We systematically searched literature from inception to February 2 2019 (via Pubmed, Embase and abstracts from ACR and EULAR congresses) for studies that compare fetal malformation rate and pregnancy outcomes of CQ/HCQ versus placebo. Two independent reviewers carried out the review. A meta-analysis was performed, using the inverse variance approach, to estimate risk differences for malformation rate with its 95% confidence interval. Maternal and pregnancy outcomes will be analyzed with global odds-ratios and their 95% confidence interval.



Study or Subgroup	Hydroxychloroquine Events	Total	Controls Events	Total	Weight	Risk Difference IV, Fixed, 95% CI

Total (95% CI)		2023		15884	100.0%	-0.00 [-0.01, -0.00]
Total events	35		244			

Heterogeneity: Chi² = 14.20, df = 13 (P = 0.36); I² = 8%

Test for overall effect: Z = 1.99 (P = 0.05)

Heterogeneity was tested with Cochran's Q-test and I^2 value, and a random effect model was performed if needed. Revman software was used, considering a p-value threshold of 5%.

Results: From 2801 articles, the literature search revealed 90 articles and abstracts of potential interest, and further examination resulted in 14 studies fulfilling required criteria, with 12 cohort studies (7 prospective and 5 retrospective), and 2 randomized controlled trials. The selected articles include a total of 2023 exposed children of mothers treated by CQ/HCQ for an autoimmune disease (lupus, Sharp syndrome, Sjogren…) or malaria indication (treatment or prevention), compared to 15884 children in the control group.

The meta-analysis did not highlight any increase of malformation rate between the two groups (DR=0,00 $[-0.01, 0.00]_{95\%}$; p=0.05, I^2=8%).

In the secondary analysis on the maternofetal outcomes within studies on autoimmune diseases, the analyses did not reveal any difference between the two groups for occurrence of disease flare (OR=0.89 $[0.21, 3.77]_{95\%}$; p=0.88; I^2=79%), pre-eclampsia (OR=1.14 $[0.59, 2.23]_{95\%}$; p=0.69; I^2=5%), prematurity (OR=1.17 $[0.46, 2.97]_{95\%}$; p=0.75; I^2=81%), foetal growth restriction (OR=0.54 $[0.10, 2.82]_{95\%}$; p=0.46; I^2=89%), or congenital auriculo-ventricular block (OR=0.61 $[0.17, 2.1]_{95\%}$; p=0.43; I^2=0%). Conversely, the systematic literature reviews identified several cohort studies confirming the importance of HCQ in preventing lupus flares.

Conclusion: In our study, prenatal exposure to CQ or HCQ was not associated with any congenital abnormalities. HCQ should be continued in pregnancy for maintenance of remission or treatment of a disease flare.

Safety, Pharmacokinetics, and Pharmacodynamics of a Lyophilized Drug Product of KZR-616, a Selective Inhibitor of the Immunoproteasome

Ben Snyder,[1] Darrin Bomba,[2] Ken Harvey,[2] Janet Anderl,[2] Christopher Kirk,[2] Jinhai Wang,[2] R Andrea Fan,[2] and **Niti Goel** [3], [1]Nucleus Network Pty Ltd, Melbourne, Australia, [2]Kezar Life Sciences, SOUTH SAN FRANCISCO, CA, [3]Kezar Life Sciences, Duke University School of Medicine, South San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: KZR-616, a first-in-class selective inhibitor of the immunoproteasome, is being evaluated for the treatment of multiple autoimmune diseases, including LN and PM/DM. At 30 and 45 mg subcutaneously (SC) weekly (QW), KZR-616 is well tolerated and achieves target levels of immunoproteasome inhibition in healthy volunteers (HV) (Lickliter et al. ACR 2017). Initial doses of 60 mg or higher were associated with an adverse drug reaction including self-limited vomiting in both HV and SLE patients (pts) (Furie et al. EULAR 2019). Preliminary evidence from SLE pts suggests intrasubject dose escalation ('step-up dosing') may allow use of higher doses of KZR-616. Here we

n (%, # of TEAEs)	Cohort 1a 30→45→60 →75 mg N=7	Cohort 1b 30→60 mg N=9	Cohort 1c 30→75 mg N=6	All KZR-616 N=22	PBO N=7

Table 3. Mean (SEM) inhibition of immunoproteasome enzymatic activity following SC administration of KZR-616 in healthy volunteers. (a) Combined cohort data; (b) Day 1; (c) Day 8; (d) Day 15; (e) Day 22

report the preliminary results of a single-center, randomized, placebo (PBO)-controlled study evaluating the safety, tolerability, pharmacokinetics (PK), pharmacodynamics (PD) of a new lyophilized formulation of KZR-616 administered SC using step-up dosing (ACTRN12618002060224).

Methods: Female HV were enrolled because autoimmune diseases, eg, SLE, predominantly affect females who also have an apparent increased adverse drug reaction risk. There were 3 multiple ascending dose (MAD) SC cohorts (Table 1) and 3 single ascending dose intravenous (IV) cohorts at 15, 30, and 45 mg. Randomization of KZR-616:PBO

was 6:2 per cohort; HV who discontinued early could be replaced. Safety was assessed via adverse event (AE) monitoring, physical examinations, vital signs, electrocardiograms, and laboratory tests, with analyses both by cohort and by dose. Placebo data were pooled. Pharmacokinetics were measured by liquid chromatography tandem-mass spectrometry, and PD (immunoproteasome inhibition) was measured using enzymatic activity and active site binding (ProCISE) assays in peripheral blood mononuclear cells (PBMCs). Plasma cytokines/chemokines were measured by electrochemiluminescent detection (Meso Scale Diagnostics).

Results: Preliminary results from the SC cohorts are presented. There were 29 HV enrolled, 22 of whom received ≥1 dose of KZR-616. Average age was 22.6 years (PBO) and 27.9 years (KZR-616). In the SC cohorts, 95.5% of KZR-616 treated and 57.7% of PBO-treated HV experienced AEs (Table 1). All AEs were mild to moderate. The most common AEs were injection site reactions (ISRs), headache, and nausea, which were generally transient. The AE frequency or severity did not seem to increase with dose increase. There was one isolated Grade 3 laboratory value on KZR-616-treated: neutropenia in Cohort 1b at Day 4. The PK at 30, 45, and 60 mg were similar to data reported in the previous HV study (Table 2). Based on comparisons to the IV cohorts' PK, KZR-616 administered SC was 100% bioavailable. Inhibition of immunoproteasome enzymatic activity was also similar with SC administration of the new drug product as compared to previously reported data (Table 3).

Conclusion: No apparent dose limiting toxicities were observed in the MAD SC subjects at doses up to 75 mg when an initial dose of 30 mg was administered. The PK and PD in this study support the utilization of this lyophilized formulation of KZR-616 and administration of doses SC up to 75 mg in patients with rheumatic diseases.

Table 2. Association of 25(OH) vitamin D levels and pregnancy outcomes in those pregnancies in which level was measured in the first or second trimester (adjusted for lupus anticoagulant)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In the general population, low vitamin D has been associated with adverse pregnancy outcomes including preterm birth, pre-eclampsia and small for gestational age. In the general pregnancy population, replacement of vitamin D has been proven to reduce adverse pregnancy outcomes. We examined whether low vitamin D was also associated with adverse pregnancy outcomes in a large lupus pregnancy cohort.

Methods: A total of 268 patients (431 pregnancies) had blood levels of 25 hydroxy vitamin D (25(OH) vitamin D) measured as part of cohort follow-up. Pregnancies were followed with outcomes characterized as miscarriage or preterm birth < 37 weeks. A GEE model was used to estimate odds ratios (OR) and significance.

Results: There were 365 (84.7%) live births, 51 (11.8%) miscarriages, and 15 (3.5%) terminations. 34.7% of patients were African-American, 54.9% were Caucasian, and 10.4% were of other ethnicities. Compared to the reference vitamin D group of 40-50 ng/mL, patients with a first vitamin D below 30 ng/mL during cohort follow up had significantly higher odds of miscarriage (Table 1), but a U-shaped curve was found, with higher risk at high 25(OH) vitamin D levels, as well. The result did not change after adjustment for lupus anticoagulant. Similarly, patients with first vitamin D below 20 ng/mL had significantly higher odds of preterm birth. There were 180 pregnancies (122 patients) in which 25(OH) vitamin D had been measured in the first or second trimester. In those, there remained a significant association of preterm birth with 25(OH) vitamin D levels < 20 ng/mL (Table 2). The OR for miscarriage (2.79), although high, did not reach statistical significance in this smaller sample.

Conclusion: We found a U-shaped relationship, with miscarriage and preterm birth more common at both LOW and at HIGH levels of 25(OH) vitamin D (with the reference group at 40-50 ng/mL). The association at low vitamin D levels

mirrors what has been found in non-SLE pregnancies. The increase at high levels, though, cannot be explained, and has not been identified in the general pregnancy population. Although calcium supplements and prenatal vitamins are commonly prescribed in all pregnancies, particular monitoring of 25(OH) vitamin D levels (and replacement in those who are low) is not routine in SLE pregnancy management. Our data show, though, that there is a potential "therapeutic window", such that over-replacement must be avoided.

Effect of Treatment on Antiphospholipid Antibodies in SLE

Michelle Petri,[1] Laurence Magder,[2] and Daniel Goldman[3], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Unlike primary antiphospholipid syndrome patients, most SLE patients with antiphospholipid antibodies are on one or more treatments for their SLE that might affect levels of their antiphospholipid antibodies. We examined the effect of prednisone and hydroxychloroquine on antiphospholipid antibodies in an SLE longitudinal cohort.

Definition of Antiphospholipid	Number of informative strata	Current Prednisone Dose	Odds ratio of having APL on visits by Prednisone exposure	P-value[1]
aCL IgG>20	211	No Prednisone	1.0 (Ref)	
		Some but less than 10mg/d	0.61 (0.46, 0.80)	0.0004
		10+mg/day	0.39 (0.28, 0.54)	<0.0001
aCL IgG>40	84	No Prednisone	1.0 (Ref)

Any of the above	377	0.64 (0.55, 0.75)	<0.0001

[1] In each cell, individuals are informative if they have at least one visit with antiphospholipid positivity, at least one visit without antiphospholipid antibody, at least one visit with when treated with HCQ, and at least one visit when not treated with HCQ.

Table 2. Odds ratio of having antiphospholipid antibodies on visits with hydroxychloroquine compared to visits without hydroxychloroquine

Methods: 943 SLE patients, who were tested for each anticardiolipin isotype (aCL IgG, IgM and IgA; INOVA) and lupus anticoagulant (dRVVT with further confirmatory testing) for at least 10 quarterly clinic visits, were included. We compared visits positive for antiphospholipid antibodies to visits negative for antiphospholipid antibodies, with respect to treatment, using conditional logistic regression and conditioning on the patient.

Results: The effect of prednisone on anticardiolipin and dRVVT > 45 (with further confirmatory testing) is shown in Table 1. The effect of hydroxychloroquine is shown in Table 2.

Conclusion: Prednisone does not reduce IgM or IgA isotypes of anticardiolipin, or lupus anticoagulant. These results explain why prednisone does not reduce thrombosis in SLE. Hydroxychloroquine, on the other hand, significantly reduces all antiphospholipid types except for the IgA isotype of anticardiolipin. This may explain why IgA isotypes are more common in SLE. It may also explain why hydroxychloroquine leads to only a 50% reduction in thrombosis, as IgA isotypes do confer some risk of thrombosis.

Hydroxychloroquine Increases Low C3 in SLE

Michelle Petri,[1] and Jessica Li[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine is considered an immunomodulatory that does not affect serology. Hydroxychloroquine (HCQ) was recently introduced into Japan. In SLE patients who started hydroxychloroquine, there was improvement in hypocomplementemia (Y Ikeda, H Tamaki, M Okada. Abstract, Lupus 2019 Meeting, San Francisco, CA, April 6, 2019). We asked whether this was true in United States patients as well.

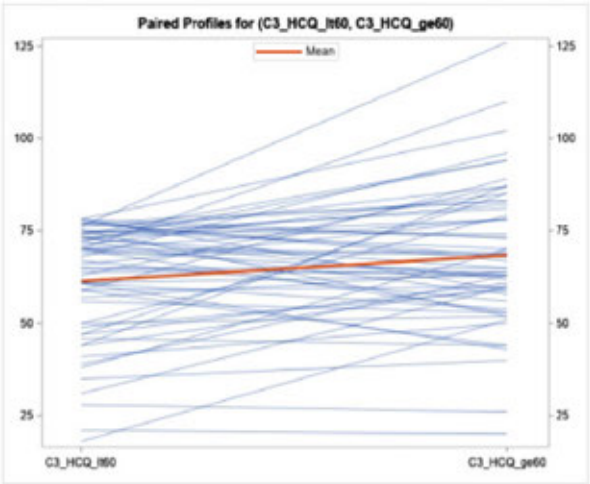

Figure 1. Improvement in C3 levels with HCQ

	Unadjusted		Adjusted[1]		Adjusted[2]	
	OR (95% CI)	p-value	OR (95% CI)	p-value	OR (95% CI)	p-value
HCQ blood level (per 100 unit increase)	0.27 (0.07, 0.47)	0.0081	0.26 (0.06, 0.46)	0.0101	0.26 (0.06, 0.46)	0.0100
Prednisone (per unit increase)			0.03 (-0.07, 0.13)	0.5307	0.02 (-0.08, 0.12)	0.6823
BMI (per unit increase)					0.21 (0.01, 0.42)	0.0397
[1]adjusted for prednisone [2]adjusted for prednisone and BMI						

Table 2. Within Patient Analysis: Patient had at Least One Visit with HCQ Negative and Low C3

Methods: A paired analysis of visits where HCQ level was 0 and a visit where it was higher was done. HCQ blood levels were quantified by liquid chromatography-tandem mass spectrometry. The visit with HCQ level of 0 must also have had low C3 (C3 < 79). There were 59 paired visits with HCQ blood level of 0 at first visit. We took the first visit in which the HCQ blood level was 0. We also did a "within patient" analysis of all visits in a patient who had at least one visit with a HCQ blood level of 0, using a linear mixed effects model.

Results: Figure 1 shows the C3 levels in ng/mL for the paired visits. The average difference in C3 level between the visit with HCQ less than 60 ng/mL (negative) and the visit with HCQ >=60 ng/mL (positive) is 7.08 (p = 0.0022). Table 2 shows the "within patient" analysis of ALL visits, with a p-value of 0.008. HCQ blood level remained significant after adjusting for prednisone, or prednisone and body mass index (BMI).

Conclusion: HCQ increases low C3, confirming the Japanese finding. This may explain multiple benefits of HCQ such as prevention of renal lupus and prevention of thrombosis, in which low C3 is an important risk factor. It also may affect SLEDAI improvement in clinical trials, if SLE patients become more compliant with hydroxychloroquine.

Abstract Number: 2534

Vitamin D Reduces Cardiovascular Risk Factors in SLE

Michelle Petri,[1] Jessica Li,[1] and Daniel Goldman[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D has effects on the cardiovascular system, including decreased renin-angiotensin, decreased insulin resistance, increased vascular relaxation and decreased vascular smooth muscle cell proliferation, that suggest it should have benefits for cardiovascular risk factors. It already has a role in the control of SLE disease activity, as it in particular reduces the urine protein/cr ratio. We explored this in a longitudinal SLE cohort.

Methods: This analysis included 1,503 patients, contributing 21,216 visits with 25(OH) vitamin D levels from May 2009 to March 2019. They were observed from 1 to 48 visits with a median of 12 visits per patient. 134 patients (9%) had 1 visit, 300 (20%) had 2-5 visits, 234 (16%) had 6-10 visits, and 835 (56%) had 11 or more visits in this analysis. 92% of the patients were female, 50% Caucasian, and 41% African American. At the first visit when

Range of mean Vitamin D level	Unadjusted		Adjusted (1)		Adjusted (2)	
	Slope (95% CI)	p-value	Slope (95% CI)	p-value	Slope (95% CI)	p-value
0 to 50 ng/mL	-4.9 (-6.6, -3.1)	<0.0001	-5.9 (-7.7, -4.0)	<0.0001	-5.0 (-7.0, -3.1)	<0.0001
50+ ng/mL	3.9 (-1.0, 8.7)	0.1163	3.6 (-1.2, 8.4)	0.1379	3.2 (-1.4, 7.9)	0.1754

	Unadjusted		Adjusted (1)		Adjusted (2)	
	Slope (95% CI)	p-value	Slope (95% CI)	p-value	Slope (95% CI)	p-value
Vitamin D level (Per 10 ng/mL difference)	-0.8 (-1.5, -0.03)	0.0422	-1.8 (-2.6, -1.1)	<0.0001	-1.0 (-1.7, -0.3)	0.0050

(1) adjusted for age, age-squared, sex, race

(2) adjusted for age, age-squared, sex, race, mean body mass index, mean prednisone dose, and proportion of time on hydroxychloroquine

Table 3. Estimated difference in person-specific mean glucose per 10 ng/mL difference in person-specific mean vitamin D

25(OH) vitamin D level was measured, mean age was 42.9 (SD=13.6) years. 20% were under the age of 30, 36% were between the age of 30 and 44, 33% between 45 and 59, and 12% were 60 or older. 77% had their first vitamin D level below 40 ng/mL and 26.5% had their first vitamin D level below 20 ng/mL. Longitudinal regression models between 25(OH) vitamin D levels and cholesterol levels, systolic blood pressure and glucose levels were constructed.

Results: We performed "between" person analyses: whether patients with higher levels of 25(OH) vitamin D had lower levels of the cardiovascular risk factors; serum cholesterol (Table 1), systolic blood pressure (Table 2) and glucose (Table 3). The reduction in serum cholesterol and systolic blood pressure was best fit by a two slope model, with the break point at 50 ng/mL and 40 ng/mL of 25(OH) vitamin D, respectively. Below the break point, the reduction was markedly greater. In a separate analysis, we demonstrated similar benefits in patients over time ("within patient"), with reduced cardiovascular risk factors at visits in which 25(OH) vitamin D levels were higher.

Conclusion: Higher 25(OH) vitamin D levels resulted in significantly lower total cholesterol, lower systolic blood pressure and lower glucose. No additional benefit was achieved above 50 ng/mL (for cholesterol) or 40 ng/mL (for systolic blood pressure). A similar break point of 40 ng/mL was found for the benefit of vitamin D supplementation on SLE disease activity. This "breakpoint" means that the target 25(OH) vitamin D is at a safe level, without risk of toxicity. Given the role of vitamin D in vascular repair and endothelial function, and its anti-inflammatory activity in blocking NF-kappa beta and reducing production of pro-inflammatory cytokines, replacement of vitamin D in SLE patients who are deficient or insufficient should be recommended, both for disease activity and also for long-term cardiovascular benefit.

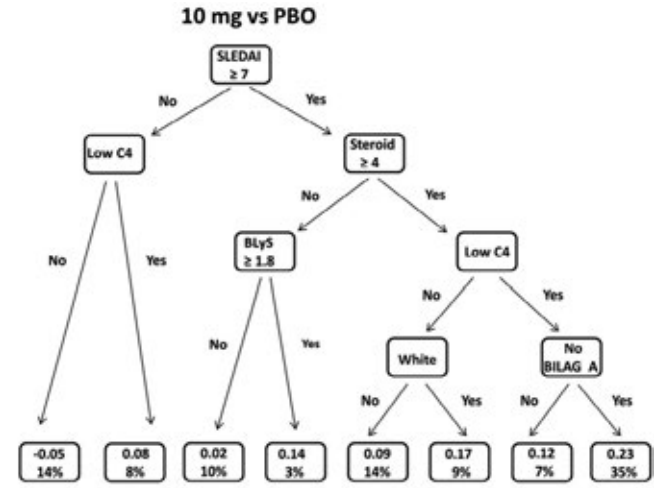
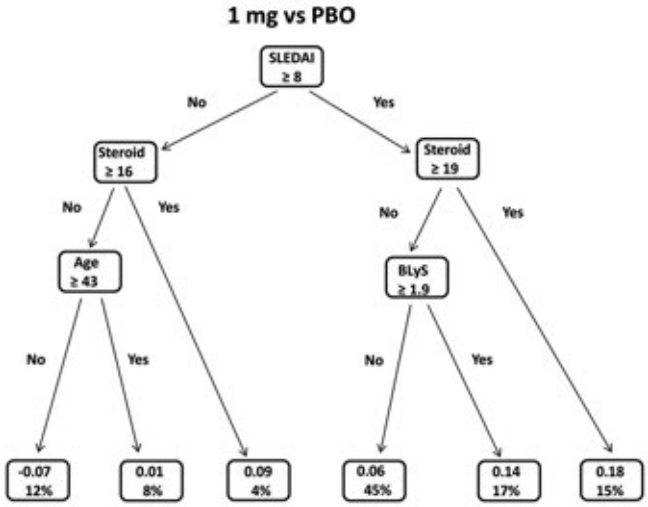
Identifying Subgroups of SLE Patients with Differential Responses to a BLyS Inhibitor: Application of a Machine Learning Algorithm to Clinical Trial Data

Mimi Kim,[1] Kith Pradhan,[1] Peter Izmirly,[2] Kenneth Kalunian,[3] Leslie Hanrahan,[4] and Joan Merrill[5], [1]Albert Einstein College of Medicine, Bronx, NY, [2]New York University School of Medicine, New York, [3]University of California at San Diego, San Diego, [4]Lupus Foundation of America, Washington DC, [5]Oklahoma Medical Research Foundation, Oklahoma City



Top number in terminal node: Expected difference in response rates (Belimumab – SoC)
Bottom number: % of subjects in that subgroup



SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Given the heterogeneity of systemic lupus erythematosus (SLE), the effect of any intervention is expected to vary. The ability to identify those most and least likely to benefit from a treatment would improve the interpretability of trial outcomes and advance medical care. Conventional subgroup analyses suffer from low power, can encompass only a few variables at a time, and require *a priori* specification of cut-points for continuous variables. We explored the utility of a machine learning-based algorithm for discovering in a SLE trial the subgroups in which adding experimental therapy to standard of care considerably enhances or diminishes response compared to placebo (PBO).

Methods: A two-step "virtual twin" (VT) method was applied to combined data from the BLISS-52 (N=865) and BLISS-76 (N=819) trials. A random forest algorithm was first used to estimate for each patient, given baseline char-

acteristics, the probabilities of SRI-4 response to belimumab and PBO. A regression tree was then constructed to partition the study population into distinct subgroups and identify those in which the estimated difference in these response probabilities is much greater or smaller than the treatment effect in the overall population. Two separate VT analyses were conducted of the 10 mg/kg and 1 mg/kg belimumab doses compared to PBO. Cross-validation was used to assess the method's performance.

Results: In the combined BLISS trials, response rates to the primary endpoint (SRI-4) were 51% in those receiving 10 mg/kg belimumab, 46% (1 mg/kg), and 39% (PBO). VT analysis of 10 mg/kg vs. PBO found a 23% belimumab response advantage over PBO in patients with *SLEDAI ≥ 7 & steroid dose ≥ 4 mg/d & low C4 & no BILAG A at baseline*, vs 12% in the total population. In contrast, the estimated response difference in those entering with *SLEDAI < 7 & normal C4* was 5% lower on 10 mg/kg than PBO. In analysis of 1 mg/kg vs. PBO, two subgroups showed enhanced belimumab effect: *SLEDAI ≥ 8 & steroid dose ≥ 19 mg/d* and *SLEDAI ≥ 8 & steroid dose < 19 mg/d & BLyS ≥ 1.9 ng/mL*; average estimated between-treatment response differences were 18% and 14%, respectively, compared to 7% in the overall population. But in patients with *SLEDAI < 8 & steroid dose < 16 mg/d & age < 43*, the 1 mg/kg belimumab response rate was estimated to be 7% lower. Cross-validation indicated the accuracy of the VT method to identify subgroups exceeded 70%.

Conclusion: Enhanced belimumab response was associated with low C4 and higher disease activity, steroid dose, and BLyS levels, as in prior studies. However, the VT method identified alternative cutpoints for continuous variables and additional features predicting non-response. SLEDAI ≥ 7 or 8 was most predictive of response to treatment. Thus, lower response difference is identified in patients who are potentially too ill (BILAG A severity) or not ill enough (minimal disease criteria) to benefit from adding belimumab. The 1 mg/kg belimumab effect was enhanced only in those on high baseline steroid doses. The VT and other machine learning techniques are promising for subgroup discovery in SLE trials as more sophisticated biomarkers, especially potent but less common indicators, become available.

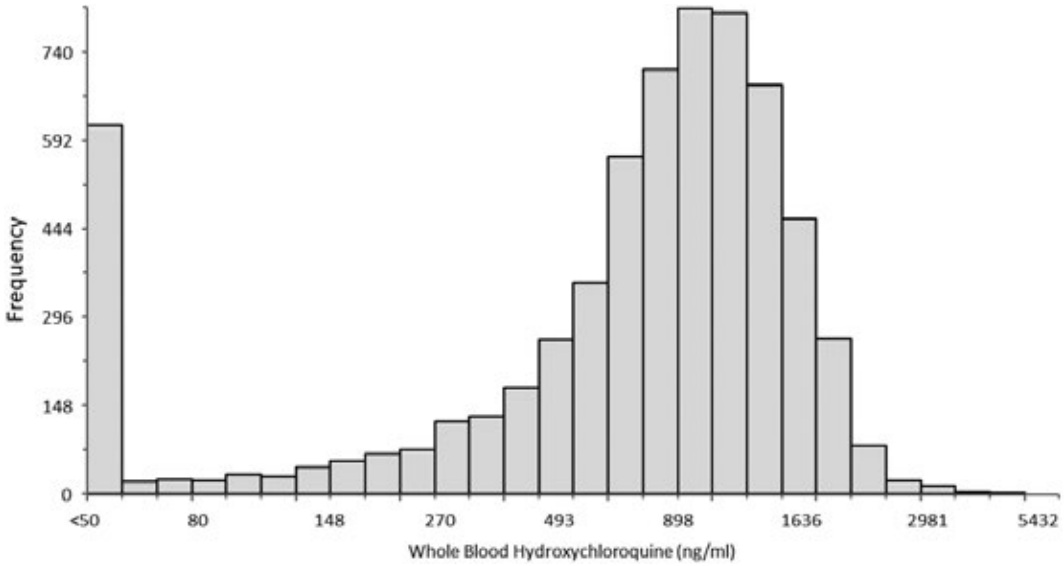
Abstract Number: 2536

Distribution and Predictors of Whole Blood Hydroxychloroquine Levels in Clinical Rheumatology Practices in the United States

Thierry Dervieux,[1] Kelley Brady,[1] Don Thomas,[2] John Conklin,[1] Eugene Fung,[3] Claudia Ibarra,[1] and Michelle Petri[4], [1]Exagen, Vista, CA, [2]Walter Reed National Military Medical Center, Bethesda, MD, [3]Arthritis & Osteoporosis Clinic, Waco, TX, [4]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Therapeutic drug monitoring of whole blood Hydroxychloroquine (HCQ) can help identify patients at risk of flares due to underexposure (e.g. severe non-adherence, < 200 ng/ml) or alternatively those with heightened risk of retinal toxicity due to overexposure (e.g. HCQ >1733 ng/ml) (Petri M et al. Arthritis Rheumatol.



2018). Our purpose was to report and evaluate factors associated with HCQ exposure in a large population of patients with rheumatic diseases.

Methods: The cohort of patients evaluated for this analysis originated from clinical rheumatology practices in the United States. Physicians (n=526) submitted specimens collected from patients under HCQ to reference clinical laboratory accredited by the College of American Pathologists. Levels were measured using venous blood collected in EDTA containing tubes or capillary blood collected on volumetric absorptive microsamplers. Recommendation was made to collect specimens after 6 months therapy (steady state). HCQ was measured using liquid chromatography coupled with tandem mass spectrometry and reported to clinicians within 5 days of specimen receipt. For each patient, mean HCQ blood level was calculated. Statistical analysis consisted of logistic regression analysis. Longitudinal changes were analyzed using linear mixed effect models.

Results: A total of 10523 specimens were collected from 6559 patients (mean [SD] age =52±15 years, 90% females). Average [SD] whole blood HCQ blood levels were 959±653 ng/ml (n=10523) and comparable between venous blood (946±6542 ng/ml, n=9391) and capillary blood (1063±654 ng/ml, n=1132). The distribution of mean HCQ levels per patient is highlighted in the Figure. The proportion of patients presenting with low HCQ blood levels (< 200 ng/ml) was 13.9% (912/6559), and these low levels associated with age (OR=0.71 CI95%:0.66-0.76 per 10 years) (p< 0.001), HCQ dose (OR=0.66 CI95%: 0.53-0.81 per 200 mg) (p< 0.001) and gender (OR=0.67 CI95%: 0.48-0.93 for females) (p< 0.001). HCQ levels greater than 500 ng/ml (indicative of compliance) were achieved in 74% patients (4901/6559) and 11% patients (716/6559) presented with potential overexposure to HCQ (>1733 ng/ml). Total non-adherence (HCQ< 50 ng/ml) in the presence of reported HCQ dose ≥200mg daily on test requisitions was 4.8% (223/4601 patients). In 4127 specimens collected from 2527 patients with HCQ dosing available (median 400 mg/daily), linear mixed effect models revealed that HCQ levels associated with HCQ dosage (estimate= 228±18 ng/ml per 200 mg HCQ, p< 0.001), patient age (93±7 ng/ml per 10-year, p< 0.001) and female gender (141±40 ng/ml, p< 0.001). This effect of age and gender on HCQ exposure was also significant in the subset of patients (n=2048, 3505 measurements) presenting with mean HCQ levels greater than 500 ng/ml and thus likely compliant to therapy (age: 65±7 ng/ml; gender: 123±41 ng/ml) (p< 0.001) after adjusting for HCQ dosing (206±20 ng/ml, p< 0.001).

Conclusion: Whole blood HCQ levels are significantly associated with gender, age, and HCQ dosing and remain essential in assessing adherence. As whole blood accurately reflects HCQ exposure (rather than plasma level), whole blood HCQ levels will have a future role in identifying overexposure as well.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treating to target is routine in rheumatoid arthritis, but no comparable standard has been defined for SLE. In 2015, the definition of Lupus Low Disease Activity State (LLDAS) was generated by Asia-Pacific

Baseline\Last follow-up	Number	%	SLEDAI≤4	%	SLEDAI≥5	%
SLEDAI≤4	737	53.17%	571	77.48%	166	22.52%
SLEDAI≥5	649	46.83%	362	55.78%	287	44.22%
Total	1386	100%	933	67.32%	453	32.68%

Table 1. The T2T results at baseline and in final follow up.

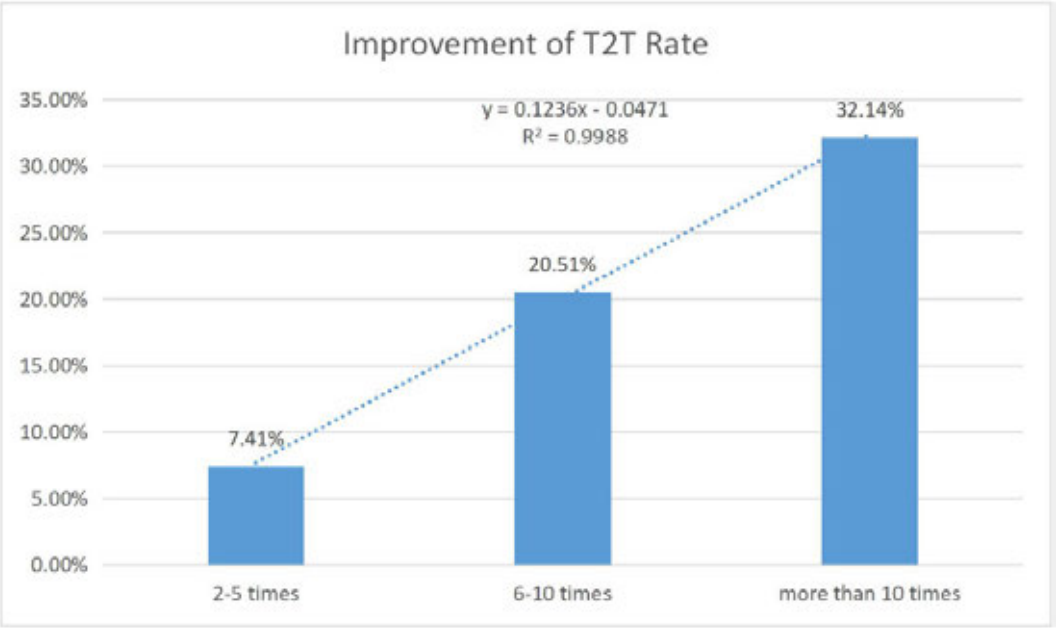

Figure 1. The improvement of T2T rate(y) was positively correlated with times of self-assessment for SLEDAI-2K(x) independently. The regression equation as "y = 0.1236x - 0.0471 R2 = 0.9988", p<0.01.

Lupus Collaboration, and the preliminary validation demonstrated its attainment to be associated with improved outcomes in SLE. A SLEDAI-2K score lower than 4 is the main criteria for LLDAS. SSDM is an interactive mobile disease management application, including application systems for both the doctors and patients. The patients can perform self-assessment, including SLEDAI-2K, 36-item short-form health survey (SF-36), and medical records entry (including medication and laboratory test results) through the mobile application. The data is synchronized to the SSDM of authorized rheumatologists and stored in cloud database. Based on the patients' data, rheumatologists will provide medical advices to the patients.

The objective of this study is to evaluate the patterns of T2T and related influential factors among SLE patients after applying SSDM in real world.

Methods: Patients were trained to master SSDM by rheumatologists or nurses in clinics. The first assessment for SLEDAI-2K was performed as the baseline. Patients were required to perform repeated assessments after leaving the clinics.

Results: From July 2015 to May 2019, 24,531 SLE patients enrolled in SSDM and mean age is 34.39±13.21(14-80) years old. And median disease duration is 3.29 years. The most commonly used drugs are hydroxychloroquine, glucocorticoids, leflunomide, mycophenolate mofetil, cyclophosphamide, methotrexate and cyclosporine A. Among them 1,386 SLE patients from 191 hospitals across China were followed up for more than 12 months through SSDM, and the results were summarized in Table 1.

The ratio of T2T achievers was 53.17% (737/1,386) at the baseline and improved significantly to 67.32% (933/1,386) after a 12-month follow-up, p< 0.01. Among T2T achievers at baseline, 77.48% (571/737) maintained T2T, and 22.52% (166/737) relapsed. Of patients who didn't achieve T2T at baseline, 55.78% (362/649) of the patients achieve T2T after 12-month follow-up.

The impact of the times of self-assessment for SLEDAI-2K on T2T has been analyzed. The more frequent of the self-assessments being conducted by patients, the higher improvement of T2T rate will be. We performed linear regression analysis of variables in statistics and parameter estimation by least square method. The improvement of T2T rate(y) was positively correlated with times of self-assessment for SLEDAI-2K(x) independently. The regression equation as "y = 0.1236x - 0.0471 R2 = 0.9988", $p < 0.01$. (Figure 1)

Conclusion: After proactive disease management via SSDM for more than 12 months, the rate of T2T in SLE patients increased significantly. Patients with SLEDAI-2K≤4 score at baseline had a significantly higher retention rate of disease activity. The patients who performed more self-assessments through SSDM had lower probability of relapse and higher rate of T2T maintaining and achievement. SSDM is a valuable tool for long term SLE follow-up through empowering patients.

Abstract Number: 2538

Importance of Serum Phosphatidylserine-Specific Phospholipase A_1 (PS-PLA_1) as a Novel Disease Activity Biomarker of Systemic Lupus Erythematous

Tetsuji Sawada,[1] Makoto Kurano,[2] Harumi Shirai,[3] Yukiko Iwasaki,[3] Koichiro Tahara,[1] Haeru Hayashi,[1] Koji Igarashi,[4] Keishi Fujio,[5] Junken Aoki,[6] and Yutaka Yatomi[7], [1]Department of Rheumatology, Tokyo Medical University Hospital, Tokyo, Japan, [2]Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [3]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, Japan, [4]Bioscience Division, Research and Development Management Department, TOSOH Corporation, Kanagawa, Japan, [5]Department of Allergy and Rheumatology, Graduate School of Medicine, The University of Tokyo, Tokyo, [6]Laboratory of Molecular and Cellular Biochemistry, Graduate School of Pharmaceutical Sciences, Tohoku University, Miyagi, Japan, [7]Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Phosphatidylserine-specific phospholipase A_1 (PS-PLA_1) is a secreted lipase that is proposed to be a producing enzyme for lysophosphatidylserine (LysoPS), which is an emerging lipid mediator with a number of immunomodulative effects. The aim of the present study was to assess the utility of serum levels of PS-PLA_1 in systemic lupus erythematosus (SLE).

Methods: Serum PS-PLA_1 was measured by enzyme-linked immunosorbent assay in 146 patients with SLE (including 43 untreated patients), 80 disease controls (35 active rheumatoid arthritis [RA], 23 Sjögren's syndrome [SS], and 22 systemic sclerosis [SSc]), and 237 healthy controls.

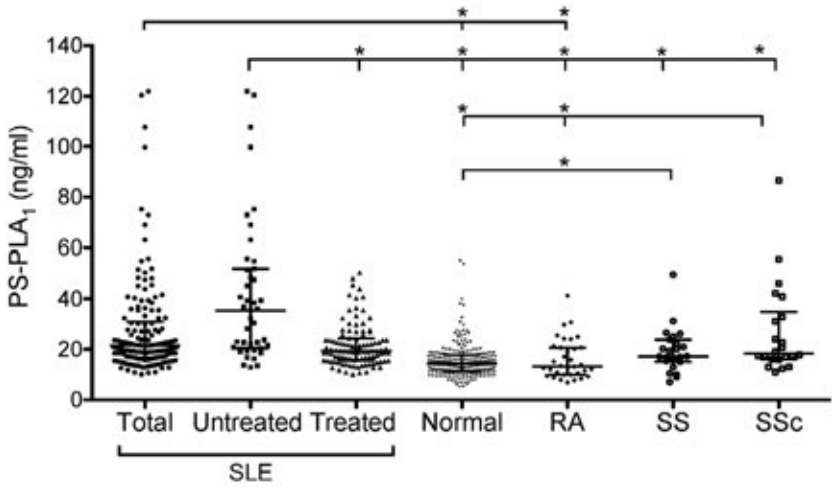

Figure 1. Distribution of the serum levels of phosphatidylserine phospholipase A1 (PS-PLA1) in patients with systemic lupus erythematosus (SLE), healthy controls (normal), and patients with rheumatoid arthritis (RA), systemic sclerosis (SSc), or Sjögren's syndrome (SS).

Results: Serum PS-PLA_1 was significantly higher in SLE patients than in healthy controls and RA patients. Although serum PS-PLA_1 was significantly elevated in SSc and SS patients compared with healthy controls, serum PS-PLA_1 was significantly higher in untreated SLE patients than in treated SLE patients and disease control patients. Receiver operating characteristic analysis revealed that a cut-off value of 17.9 ng/mL distinguished untreated SLE from disease control, with sensitivity and specificity of 88.4% and 57.0%, respectively. Serum PS-PLA_1 was significantly correlated with SLE Disease Activity Index (SLEDAI) and IgG with a correlation coefficient of 0.56 and 0.31, respectively, and inversely correlated with white blood cell counts, lymphocyte counts, total complement hemolytic activity (CH50), complement C3, and C4 with a correlation coefficient of -0.32, -0.26, -0.42, -0.39, and -0.18, respectively, in SLE patients overall. Stepwise multiple regression analysis identified SLEDAI, CH50, and IgG as significant parameters. In SLEDAI-based disease activity groups, serum PS-PLA_1 was significantly higher in SLE patients with high disease activity than in those with low disease activity. Serum PS-PLA_1 decreased significantly in parallel with SLEDAI in 25 SLE patients whose paired serum samples were available pre- and post-treatment.

Conclusion: Serum PS-PLA_1 was associated with disease activity of SLE, suggesting that serum PS-PLA_1 may be useful as a biomarker for monitoring disease activity of SLE.

Abstract Number: 2539

Patient Perception of Benefit and Risks Associated with Hydroxychloroquine Use in Systemic Lupus Erythematosus (SLE)

Sooyeon Kwon,[1] Jessica Farrell,[2] Sarfaraz Hasni,[3] and Shubhasree Banerjee[2], [1]The Center For Rheumatology, Loudonville, NY, [2]The Center for Rheumatology, LLC, Albany, NY, [3]NIAMS, National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is recommended in all patients with systemic lupus erythematosus (SLE). Studies suggest that a significant proportion of subjects are non-adherent to daily HCQ, leading to poor disease control, increasing morbidity and mortality. One of the main barriers to adherence is reported to be patients' fear of side effects most notably retinopathy. The objectives of this study were to assess SLE patients' (1) perception of the risk vs. benefit associated with the use of HCQ, (2) awareness of the risk factors of HCQ-induced retinopathy.

Methods: We administered an internet-based survey to SLE patients registered in the Lupus Alliance of Upstate New York (LAUNY) email listserv over 3 months. The survey included demographic information, such as age, gender, ethnicity, and education level, and their perception of the risks and benefits of HCQ therapy. Participation was voluntary, anonymous, and restricted to adults 18 years or older.

Results: A total of 94 subjects completed the survey. The mean age of responders was 48.4 ± 13.1 years; 98% (N=92) were women, 80% (N=75) Caucasian and 10% (N=9) African American. Fifty percent (N=47) had a bachelor's degree or higher education. The mean duration of SLE was 14 years with upper and lower quartiles of 21 and 5 years. Ninety five percent of patients (N=89) were either current or past users of HCQ (66 current use, 23 past use). Among them, 97% (N=86) of patients reported regular visits to eye doctors and 82% (N=73) had a baseline eye exam with HCQ initiation. The mean duration of HCQ use was 10 years with 15 years and 3 years of upper and lower quartiles. Twenty three percent of patients (N=22) with HCQ exposure were unaware of the potential ocular toxicity associated with HCQ use. More than 60% (N=57) reported that they will continue HCQ in view of its beneficial effects, despite potential risk of eye related-side effects. A significant proportion (37%, N=34) of patients were concerned about ocular toxicity associated with HCQ and expressed their desire to stop or discuss discontinuation of HCQ with their physician. Up to 60% of patients were not aware of predictors of retinal toxicity associated with HCQ.

Conclusion: Almost all of our patients on HCQ reported having regular eye check-ups for retinal toxicity. Many patients were concerned about potential retinal toxicity with HCQ use and were considering stopping the medication. In addition, a substantial number of patients were not aware of HCQ associated retinopathy. Our study identified a need for patient education regarding risks, benefits of HCQ therapy and awareness about potential predictors of HCQ retinal toxicity. Furthermore, educating healthcare providers to address HCQ toxicity on an ongoing basis will lead to better medication compliance and disease outcomes.

Abstract Number: 2540

Impact of IL34, IFN-α and IFN-λ1 on Disease Activity of SLE Patients in Egypt

Yasmin Hussein,[1] and Yousra Sadeq[1], [1]Mansoura University Hospital, Mansoura, Egypt

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a systemic inflammatory and autoimmune disease. IL-34 plays pivotal roles in the proliferation and differentiation of mononuclear phagocyte cells, osteoclastogenesis and inflammation. IFN-α play an important role in SLE pathogenesis and proportion of patients displays increased serum IFN-α and IFN-λ1. Interestingly, the gene signatures of IFN-λ1 and IFN-α overlap. Our objective was to assess IL34, IFN-λ1 and IFN-α in SLE with relationship to clinical, laboratory parameters, treatment response and disease progression. We hypothesized a subgroup of patient with a concordance of high level of these cytokines that could have a different disease behavior.

Methods: 82 newly diagnosed SLE Egyptian patients. History, examination and laboratory investigation with assessment of disease activity. Pretreatment assessment of IL34, IFN-α and IFN-λ1 level by ILIZA. Patients started treatment (antimalarial ±Steroid ±immunosuppressive drugs) with response evaluation after six months.

Results: 14 male (17.1%) and 68 female (82.9%), age mean±SD (48.6±8.2). Mean±SD of IL34, INFα and INF-λ1were 175.9±125.9 pg/mL, 109.3±32.5 pg/mL and 227.9±144.8 pg/mL respectively. 21 patients (25.6%) had lupus nephritis, 32 patients (39%) with SLAM >6 and 22 patients (26.8%) with SLEDAI >6. IL34 was positively correlated with anti-dsDNA (P= 0.002) but inversely correlated with C3 level (P = 0.009). IL34 was highly presented with lupus nephritis (P 0.005), SLAM >6 (P 0.03), SLEDAI >6 (P 0.007) and poor responder to treatment (P 0.02). IFNα was inversely correlated with C3 (P 0.001). IFNα was highly presented with lupus nephritis (P 0.02) and poor responders (P 0.01) however no relation with SLAM >6 nor SLEDAI >6. INF-λ1 was positively correlated with anti-dsDNA (P= 0.02) but inversely correlated with C3 (P = 0.01). INF-λ1 was highly presented with lupus nephritis (P 0.001), with SLAM >6 (P 0.04), with SLEDAI >6 (P 0.02). Accumulation of ≥3 clinical features during follow up was associated with high IL34 (P 0.001), high IFNα (P 0.001) and high INF-λ1 (P 0.001). We assigned high levels (i.e., ≥ 75% or third quartile)

	$IL34^{high}$, $IFN\alpha^{high}$ and $IFN\text{-}\lambda^{high}$	All others	p
Patients with Lupus Nephritis (21)	10 (47.6%)	11 (52.4%)	0.001
Patients without Lupus Nephritis (61)	7 (11.5%)	54 (88.5%)	
Patients with SLAM>6 (32)	11 (34.4%)	21 (65.6%)	0.02
Patients with SLAM≤6 (50)	6 (12%)	44 (88%)	
Patients with SLEDAI>6 (22)	8 (36.4%)	14 (63.6%)	0.03
Patients with SLEDAI≤6 (60)	9 (15%)	51 (85%)	
Patients with poor response (27)	10 (37%)	17 (63%)	0.01
Patients with good response (55)	7 (12.7%)	48 (87.3%)	

of each cytokine. Triple high (IL34high, IFNα high and IFN-λ1 high) found in 17 patients (20.7%) and were positively correlated with anti-dsDNA (P= 0.001) but inversely correlated with C3 (P = 0.001). Triple cytokines level was highly presented with lupus nephritis (P 0.001), SLAM >6 (P 0.02), SLEDAI >6 (P 0.03) and poor response to treatment (P 0.01) indicating these patients have aggressive disease. 28 patients developed (3 – 8) accumulated clinical features during the disease course, out of them 15 patients (53.5%) have high level of the triple cytokines indicating a poor prognosis of these subgroup.

Conclusion: High pretreatment serum IL-34 or IFN-λ1 has a prognostic significance in SLE patients. Patients with high IL-34 or IFNα or IFN-λ1 had more kidney affection and poor response to treatment. Triple cytokines elevation significantly associated with lupus disease activity, more kidney affection and poor response to treatment so, this aggressive phenotype of patients may be in need for combination of targets or a multicytokines targeted therapy.

Pharmacokinetics of Hydroxychloroquine in Systemic Lupus Erythematosus Patients with Renal Impairment

Naoto Yokogawa,[1] Masayuki Hashiguchi,[2] Yoshiki Nagai,[3] Kota Shimada,[4] Shoji Sugii,[1] Miho Oshima,[5] Keigo Setoguchi,[6] and Mikiko Shimizu[7], [1]Department of Rheumatic Diseases, Tokyo Metropoitan Tama Medica Center, Fuchu, Japan, [2]Division for Evaluation and Analysis of Drug Information, Faculty of Pharmacy, Keio University, Tokyo, Japan, [3]Department of Rheumatic Diseases, Tokyo Metropolitan Tama Medical Center, Fuchu, Japan, [4]Department of Rheumatic Diseases, Tokyo Metropoitan Tama Medica Center, Fuchu, [5]Division of Rheumatology, Mitsui Memorial Hospital, Tokyo, Japan, [6]Tokyo Metropolitan Cancer and Infectious Dease Center Komagome Hospital, Tokyo, Tokyo, Japan, [7]Department of Drug Metabolism and Pharmacokinetics, Faculty of Pharmaceutical Sciences, Aomori University, Aomori, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A low glomerular filtration rate (GFR: < 60 mL/min/1.73 m^2) is an established risk of hydroxychloroquine (HCQ) retinopathy and is presumably related to higher HCQ concentrations. However, the pharmacokinetics of HCQ in impaired renal function are not known. Herein, we evaluated the pharmacokinetics of HCQ in systemic lupus erythematosus (SLE) patients with renal insufficiency using single-dose and population pharmacokinetic analysis.

Methods: The present study was conducted in both the in-patient and out-patient settings at three hospitals and enrolled 20 SLE patients with various degrees of renal impairment. An HCQ dose of 300 mg/d (one 200 mg tablet and 100 mg of crushed HCQ) based on 6.5 mg/IBW was administered. Nine whole blood samples were collected from inpatients, and fewer samples were collected from outpatients from the pre-dose period up to 72 hours post-dose for single-dose pharmacokinetic analysis, and four to six blood samples after at least 16 weeks starting HCQ were collected from outpatients for population pharmacokinetics. The HCQ concentrations were measured using a validated LC/MS/MS. The pharmacokinetic parameters were estimated by the two-compartment model. The area under the blood concentration-time curve (AUC) was analyzed using moment analysis if five or more samples were collected for single-dose pharmacokinetic analysis. Population pharmacokinetics were analyzed by computer using a non-linear mixed-effects model.

Numbers represent the mean (SD).

*1: n=2, *2: n=4, *3: n=5

Table 2. Pharmacokinetic parameters

Results: One patient was excluded from analysis due to malabsorption syndrome. Six patients with GFR >60 mL/min/1.73 m^2, eight patients with GFR 45-59 mL/min/1.73 m^2, and five patients with GFR 15-44 mL/min/1.73 m^2 were included. The patient background is shown in Table 1. The dosage based on actual body weight and body habitus was similar between groups. The pharmacokinetic parameters are summarized in Table 2. In total, 185 HCQ concentration measurements were obtained from 19 patients.

There was a trend towards increased AUC, decreased renal elimination, and prolonged elimination half-life in patients with moderately impaired renal function. In population pharmacokinetics, HCQ clearance tended to be influenced by renal function.

Conclusion: Adjusting the HCQ dosage may be warranted in patients with moderately impaired renal function.

An Updated Meta-Analysis of the Efficacy and Safety of Mycophenolate Mofetil in the Induction Treatment of Chinese Patients with Lupus Nephritis

Minlin Zhou,[1] Yang yang,[2] Xiaoyan Han,[2] Xin Yu,[2] and Haitao zhang[1], [1]National Clinical Research Center of Kidney Diseases, Jinling Hospital, Nanjing University School of Medicine, Nanjing, China (People's Republic), [2]Shanghai Roche Pharmaceuticals Ltd, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Achieving clinical remission while reducing toxicity are primary objectives in the treatment of lupus nephritis (LN). Mycophenolate mofetil (MMF) has demonstrated efficacy benefits with good tolerance as the induction therapy in LN patients of Hispanic or mixed race. However, a comprehensive view is lacking in its usage among Chinese patients with LN. We conducted this meta-analysis based on most updated studies to review the efficacy and safety of MMF induction therapy in Chinese patients with LN.

Table 1. Basic clinical data for the 18 studies included

Reference	Sample size (T/C)	Age (years)*	Treatment regimen in MMF group	Treatment regimen in CYC group	Treatment duration (months)	Major outcome measures	Pathologic type of LN
Chan et al. 2005	33/31	T: 38.1 (10.2) C: 41.8 (8.9)	MMF: 2 g/day x 6 mos; mt with rd Pred: initially 0.8 mg/kg/day, then rd	CYC: oral 2.5 mg/kg/day x 6 mos; mt with AZA Pred: initially 0.8 mg/kg/day, then rd	24	CR, PR, TR, relapse	IV
Feng et al. 2014	30/30	T: 29.9 (1.8) C: 35.4 (2.1)	MMF: 2 g/day x 6 mos Pred: initially 0.5 mg/kg/day, then rd	CYC: IV drip 0.5 g every 2 wks x 6 mos Pred: initially 0.5 mg/kg/day, then rd	6	CR, PR, TR,	III/IV/V
Hu et al. 2002	23/23	T: 28.0 (8.8) C: 29.5 (10.2)	MMF: initially 1.0–1.5 g/day, then 0.5–1.0 g/day 3–6 mos later Pred: initially 10–30 mg/day, then rd to 10–15 mg/day	CYC: IV drip 0.75–1.00 g/m²/mo x 6, mt at ¼ dose for 1 yr MP: 0.5–1.0 g/day, then Pred 0.8 mg/kg/day, then rd	6	%UP ↓ by ⩾50%	IV
Wang et al. 2007	9/11	T: 32.2 (12.0) C: 30.8 (12.7)	MMF: 1.5–2.0 g/day x 6 mos MP: 0.5 g/day x 3 days; Pred: initially 0.6–0.8 mg/kg/day, then rd	CYC: IV drip 0.75–1.0 g/m² per mo x 6 mos MP: 0.5 g/day x 3 days; Pred: initially 0.6–0.8 mg/kg/day, then rd	6	CR, PR, TR	IV
Li et al. 2012	20/20	T: 26.5 (range 16–62) C: 33.0 (range 17–64)	MMF: 1.5–2.0 g/day x 6 mos Pred: initially 0.8–1.0 mg/kg/day, then rd	CYC: IV drip 0.5–0.75 g/m² per mo x 6 mos Pred: initially 0.8–1.0 mg/kg/day, then rd	6	CR, PR, TR	III/IV/V
He et al. 2010	30/30	NA	MMF: 1.5–2.0 g/day x 6 mos	CYC: IV drip 0.75 g/m² per mo x 6–9 mos	6	CR, PR, TR	III/IV/V

Table 2. Relative risks of adverse events with MMF versus cyclophosphamide induction therapy

Adverse event	No. of studies	MMF (n/N)	CYC (n/N)	RR (95% CI)	p value
Infection	11	47/296	87/287	0.52 (0.38, 0.71)	< 0.0001
Amenorrhoea	9	8/225	45/214	0.21 (0.11, 0.39)	< 0.0001
Leucopenia	11	10/262	26/256	0.44 (0.23, 0.83)	0.01
Alopecia	6	1/159	25/157	0.12 (0.04, 0.37)	0.0002
Gastrointestinal symptoms	11	27/282	59/279	0.48 (0.32, 0.71)	0.0002
Liver damage	6	4/109	12/114	0.44 (0.18, 1.12)	0.08

CI, confidence interval; CYC, cyclophosphamide; MMF, mycophenolate mofetil; RR, relative risk.

Methods: Relevant clinical trials were identified by searching PubMed, EMBASE, Cochrane Collaboration, Medline, National Guideline Clearinghouse, Best Evidence, China National Knowledge Infrastructure, Wangfang, SinoMed, China Science and Technology Journal Database, and WHO ICTRP (in February 2019). The search strategies consisted of (mycophenolate mofetil AND (cyclophosphamide OR azathioprine)) AND (lupus nephritis OR lupus glomerulonephritis OR proliferative glomerulonephritis OR membranous glomerulonephritis OR systemic lupus erythematosus) in English and in Chinese. Retrieved studies were assessed independently by two reviewers. Meta-analysis was conducted using RevMan5.3 software. This review was registered on PROSPERO (CRD42018086209).

Results: Eighteen randomized controlled trials (5 English and 13 Chinese articles; totalling 927 patients) were included in the analysis (Table 1). Complete remission (CR) and total remission (TR, CR + partial remission) were reported in 14 RCTs. MMF showed an efficacy advantage in terms of CR (44.7% vs 32.9%; relative risk [RR] 1.34; 95% confidence interval [CI]: 1.13, 1.58; p=0.0007) and TR (84.3% vs 70.9%; RR 1.16; 95% CI: 1.02, 1.33; p=0.03) compared to CYC (Figure 1). MMF was associated with lower risks of infection (RR 0.52; 95% CI: 0.38, 0.71; p< 0.0001), amenorrhea (RR 0.21; 95% CI: 0.11, 0.39; p< 0.00001), leukopenia (RR 0.44; 95% CI: 0.23, 0.83; p=0.01), alopecia (RR 0.12; 95% CI: 0.04, 0.37; p=0.0002), and gastrointestinal symptoms (RR 0.48; 95% CI: 0.32, 0.71; p=0.0002) than CYC (Table 2). Relapse rate seemed to be comparable between MMF and AZA groups (RR 1.16; 95% CI: 0.59, 2.28; p=0.68).

Conclusion: This meta-analysis of Chinese LN patient revealed that MMF is more effective than CYC in achieving CR and TR, and it is associated with lower incidences of infections, amenorrhea, leukopenia, alopecia, and gastrointestinal symptoms.

Abstract Number: 2543

Meta-Analysis Examining the Clinical Significance of Monitoring of Hydroxychloroquine Levels in SLE

Shivani Garg,[1] Rachna Unnithan,[2] Karen Hansen,[3] Nathalie Costedoat-Chalumeau,[4] and Christie Bartels[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]UW- Madison, Madison, [3]UW Madison, Madison, [4]Cochin University Hospital, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite the pivotal role hydroxychloroquine (HCQ) plays in treating SLE, less than 50% of patients take HCQ as prescribed. Nonadherence versus lack of effect to HCQ are difficult to distinguish, underscoring the importance of measuring HCQ blood levels to assess adherence. Despite this, information and consensus on the clinical impact of incorporating routine testing of HCQ blood levels is lacking. Therefore, we systematically reviewed publications examining the correlation between 1) HCQ levels and adherence, and 2) HCQ levels and SLEDAI scores, in SLE patients. *We hypothesized that low HCQ levels would correlate with nonadherence and higher SLEDAI scores*.

Figure 1. Forest Plot of correlation of measured HCQ blood levels with assessed adherence

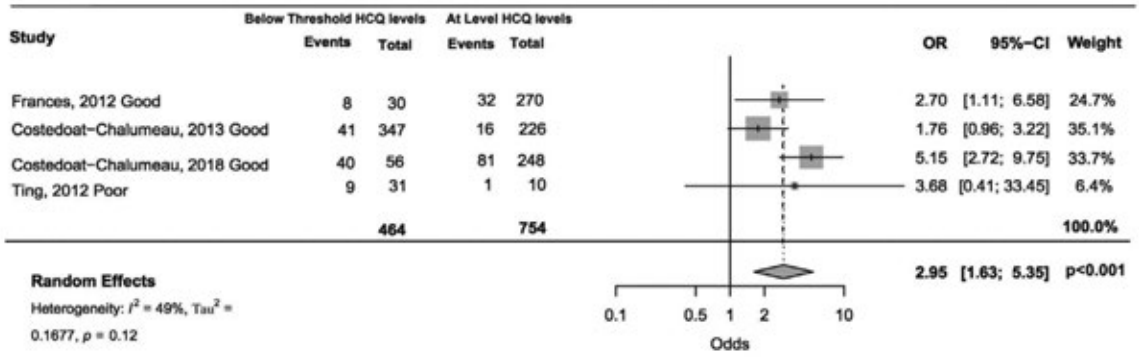

Figure 2. Forest Plot of correlation of measured HCQ levels with SLEDAI scores

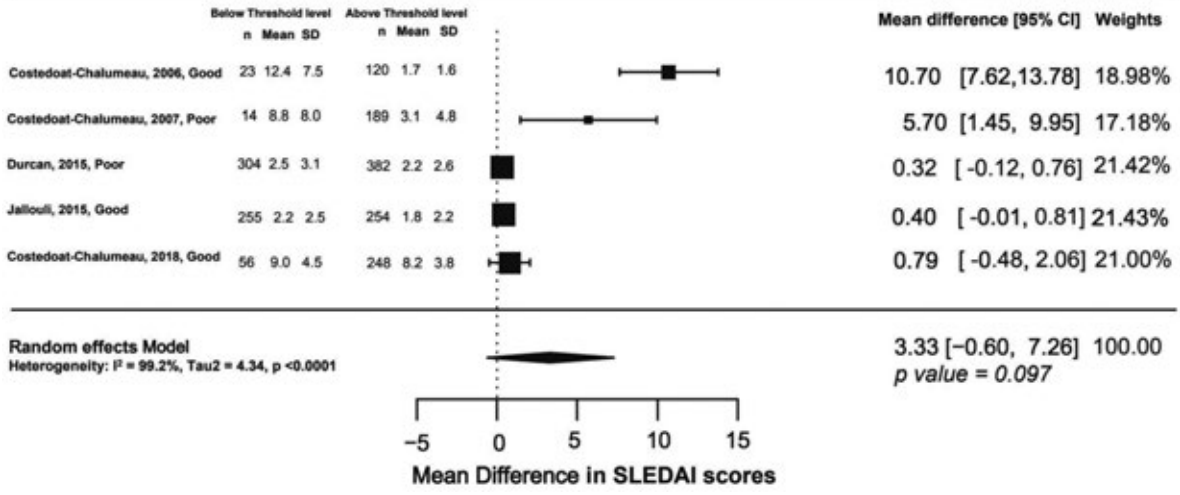

Methods: A comprehensive search was performed using MeSH heading and keywords in Medline, Embase, CINHL and Web of Science databases. We selected observational and interventional studies that measured HCQ levels and assessed adherence and/or SLEDAI scores in adults with SLE. Newcastle Ottawa Scale and Cochrane Collaboration Risk Assessment tools were used to rate the quality of observational and intervention studies, respectively. We used Forest plots to compare pooled estimates (95% CI) of correlations between HCQ levels and patient or physician reported nonadherence and SLEDAI scores. Heterogeneity was assessed using I^2.

Results: From 306 manually reviewed abstracts, four studies analyzing correlation between HCQ levels and adherence, and five studies examining the correlation between SLEDAI and HCQ blood levels, met inclusion criteria. The odds of nonadherence measured by physician or reported by the patient was 3 times higher in patients with below threshold HCQ blood levels, compared to those with higher HCQ blood levels (OR 2.95, 95% CI 1.63, 5.35, $p < 0.001$, I2 49%) (Figure 1). The mean SLEDAI score was 3.33 points higher in groups with HCQ levels below threshold levels, but this trend was not statistically significant (δ3.33, 95% CI -0.60, 7.26, p=0.097, I2 99%) (Figure 2). Risk of bias assessment revealed three poor quality studies which were excluded in sensitivity analysis; results remained unchanged. Limitations of our analysis include study heterogeneity and lack of consensus on optimal blood HCQ levels.

Conclusion: We found a good correlation between HCQ levels and non-adherence. While patients with low HCQ levels had higher SLEDAI scores, the p-value for this finding was not statistically significant. Future studies should clarify optimal blood HCQ levels to control lupus, and then investigate the value of measuring blood HCQ levels in clinical care.

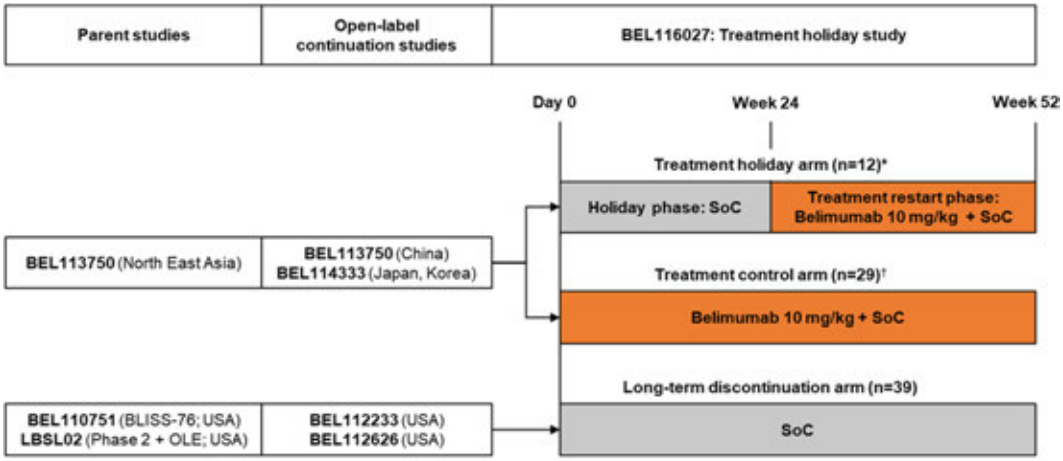
Results of the Open-label, Non-randomized 52-Week Study to Evaluate Treatment Holidays and Rebound Phenomenon After Treatment with Belimumab in Patients with SLE

Sang-Cheol Bae,[1] Richard Dimelow,[2] Beulah Ji,[3] Regina Kurrasch,[4] Saima Muzaffar,[5] Raj Punwaney,[4] David Roth,[4] Paul Stober,[4] Yeong-Wook Song,[6] Wendy Xie,[4] and Fengchun Zhang[7], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]GSK, Stevenage, United Kingdom, [3]GSK, Uxbridge, Middlesex, United Kingdom, [4]GSK, Collegeville, PA, [5]GSK, Stevenage, Hertfordshire, [6]Seoul National University Hospital, Seoul, Republic of Korea, [7]Peking Union Medical College Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab is approved as add-on therapy in active, autoantibody-positive SLE. Safety and efficacy up to 13 years has been reported in adults, but potential for rebound upon temporary discontinuation of belimumab has not been investigated. This study (BEL116027; NCT02119156) assessed the impact of temporary withdrawal of intravenous (IV) belimumab.

Methods: In this 52-week open-label study, adults with SLE who received belimumab 10 mg/kg IV for ≥6 months in open-label studies were recruited to three arms: treatment holiday (TH; 24-week belimumab withdrawal, reintroduction for 28 weeks); continuous belimumab (treatment control; TC), and long-term discontinuation (LTD) (**Figure**).



*†Key selection criteria for treatment holiday and treatment control ONLY: Low disease activity, defined by SELENA-SLEDAI score ≤3 after a minimum of 6 months of belimumab, C3 and C4 complement levels ≥ lower limit of normal, no mild-moderate or severe flare during screening, receiving stable SLE SoC with no new immunosuppressive/ immunomodulatory agent, anti-malarial, or NSAID (for >1 week) and prednisone (or equivalent) ≤20 mg/day within the 30 day screening period; SELENA-SLEDAI, Safety of Estrogens in Lupus National Assessment-Systemic Lupus Erythematosus Disease Activity Index; SoC, standard of care; NSAID, nonsteroidal anti-inflammatory drug; OLE, open-label extension

Number of SFI flares	5	2	17	74
Rate of SFI flares/patient-years	1.0	0.3	0.6	2.1
Baseline SELENA-SLEDAI score in parent study, mean (SD)	7.9 (4.19)	NA	9.2 (3.06)	10.2 (3.15)
Rebound (SELENA-SLEDAI exceeding parent study baseline, anytime up to Week 24), n	0	NA	2	2

ITT, intent-to-treat; NA, not applicable; SD, standard deviation; SFI, SELENA-SLEDAI flare index.

Table 1. Efficacy endpoints (ITT)

The primary endpoint was time to first SLE flare (SFI). Secondary endpoints included flare rates and evidence of rebound (SELENA-SLEDAI [SS] exceeding parent study baseline score, anytime post baseline to Week 24). Anti-drug antibodies (ADAs) and changes in immunoglobulins and B Cells were measured. Safety was monitored.

Due to slow enrollment the study was amended to reduce sample size; all analyses are descriptive.

Results: The ITT comprised 80 patients (TH: n=12, TC: n=29; LTD: n=39). The majority were female (88.8%), ≤45 years of age (71.3%), and had SS >3 at baseline in the parent study (97.5%). Day 0 disease activity, race and geographic distribution differed for LTD vs TC/TH. A higher proportion of LTD patients (8/39; 20.5%) had flares during screening for this study vs TH (1/12; 8.3%) or TC arms (0/29; 0%). Also, 41.0% of LTD patients were recruited from the US and 23.1% were White; TC and TH arms were recruited from China, Korea and Japan (100% Asian).

The majority in the holiday phase did not flare and flare rate during this time (1.0) was comparable to TC (0.6) (**Table 1**). Flare rate was highest in LTD (2.1). There were 9 severe and 4 renal flares in LTD and none in TH/TC.

n (%)	TH		TC	LTD
	Holiday phase (n=12)	Restart phase (n=11)	52 weeks (n=29)	52 weeks (n=39)
At least 1 AE	7 (58)	10 (91)	21 (72)	37 (95)
At least 1 SAE	0	1 (9)	2 (7)	6 (15)

Table 2. Summary of AEs (52-week study period)

No TH patients rebounded; two TC and two LTD patients rebounded (**Table 1**).

Adverse event (AE) and serious AE (SAE) rates were higher in LTD vs TC (**Table 2**). There were no withdrawals due to AEs and no SAEs in the holiday phase.

No ADAs were detected. In all arms, median levels of anti-dsDNA remained suppressed and complement C3/C4 levels remained above baseline over 52 weeks. At Day 0, median immunoglobulin levels were below baseline relative to the parent study and remained decreased throughout for all arms. B Cell levels remained depleted in TC throughout; in TH and LTD, CD19, CD20, and naïve B Cell counts started to recover after 16 weeks off-treatment but rapidly decreased to minimal levels following restart (TH). No Grade 3/4 laboratory abnormalities were noted in the TH arm. A small proportion of patients in the TC and LTD arms had Grade 3/4 laboratory abnormalities.

Conclusion: Temporary (24-week) discontinuation of belimumab in patients with low disease activity did not appear to increase risk of SLE flares or rebound. Across 52 weeks, no ADAs were identified in any arm and the belimumab safety profile was consistent with previous reports. Small sample size and differences in Day 0 characteristics between LTD and TC arms limit the ability to draw inferences.

Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN) ultimately requires renal replacement therapy (RRT) in 10-30% of LN patients. Thirty percent of these patients receive a kidney transplant. Belatacept is a second-generation, selective, T-cell co-stimulator blocker (inhibits CTLA-4) used as an alternative to calcineurin inhibitors (CNI) for maintenance regimens after kidney transplants. The pathogenic relevance of CTLA-4 inhibition and the favorable cardiovascular

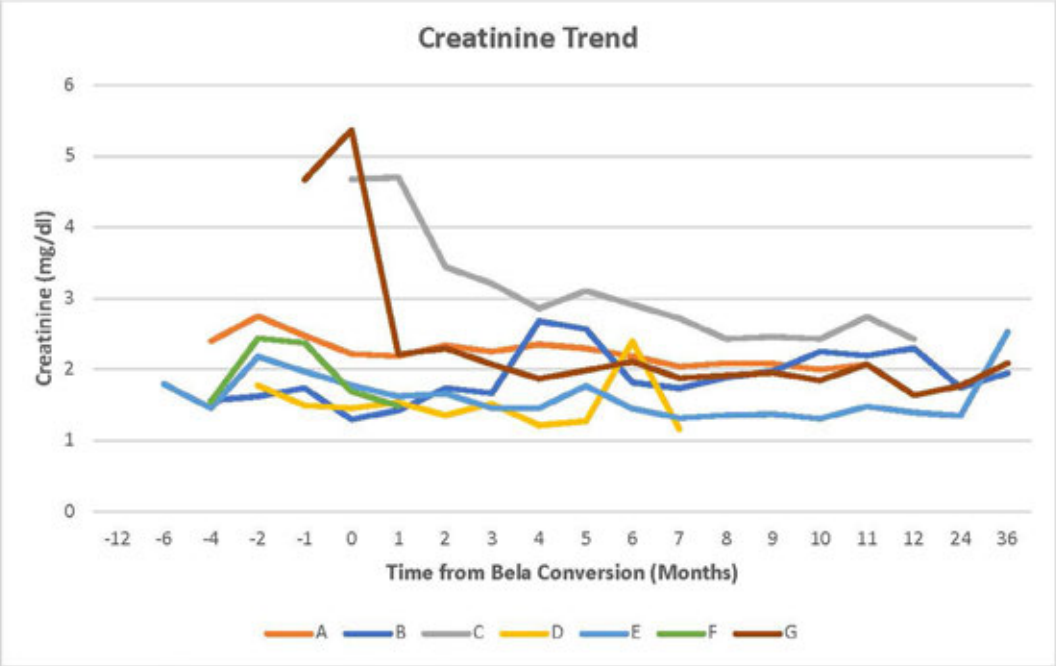

Figure 1: Trends in creatinine before and after belatacept conversion.

profile of belatacept make it an attractive therapeutic option in SLE. Additionally, intravenous administration of belatacept ensures therapeutic adherence.

Methods: This retrospective, single-center study evaluates the outcomes of LN kidney transplant recipients treated with belatacept from 2006 – 2018 at the Columbia University Lupus and Renal Transplant Cohorts. The treatment regimen consisted of 5mg/kg belatacept every 2 weeks for a total of 10 weeks (5 doses total), followed by monthly dosing. CNI weaning among the belatacept group was not standardized. Immunosuppressive regimen, kidney allograft function, and SLE activity were examined.The current study was initiated to evaluate the effect of belatacept on graft function and extrarenal SLE.

Results: Forty-eight patients with LN had undergone a kidney transplant between 2006 and 2018 with a mean follow-uptime of 72.2 ± 74.6 months. Belatacept was started in seven patients on CNI regimens (TAC n=6, cyclosporine n=1) at 15.5 ± 17.1 months following kidney transplantation. All patients were female with a mean age at SLE diagnosis of 21.1 ± 4.9 years. Five patients had undergone RRT prior to kidney transplantation (4 hemodialysis, 1 peritoneal

dialysis) for 38.7 ± 37.8 months. The mean interval between SLE diagnosis and KT was 13.1 ± 8.3 years. At the time of belatacept initiation, all patients were also treated with prednisone (7.1 ± 2.7 mg/day). Six were additionally treated with mycophenolate (1123 ± 625 mg/day), and one was additionally treated with azathioprine (25mg/day). CNIs were continued in five of seven patients at six months after belatacept. Two patients were on hydroxychloroquine, 2 took it only prior to KT. In five patients, creatinine levels stabilized six months after belatacept, one returned to hemodialysis due to CNI-toxicity and pyelonephritis and one is relisted for a kidney transplant due to ACR and cortical necrosis(Fig. 1). No allograft failure due to recurrent LN was noted in any of the patients. Five patients are currently followed for extrarenal lupus, and no extrarenal manifestations are documented in the other two patients. Data on SLE disease activity pre- and post- belatacept were available and scored in three of five patients using the SLEDAI-2KG which accounts for clinical and laboratory manifestations, as well as steroid use (Fig. 2). Mean ds-DNA pre and post belatacept was 133 ± 178 UI/mL and 58 ± 72 UI/mL, mean C3 89 ± 31mg/dL pre and 91 ± 21 mg/dL post, and mean C4 35 ± 15 mg/dL and 38 ± 7 mg/dL, respectively.

Conclusion: Belatacept in LN kidney transplant recipients may decrease extrarenal manifestations, attenuate CNI toxicity and stabilize allograft function, providing a better alternative to CNI regimens. Furthermore, these data suggest that belatacept may be a therapeutic option in SLE.

Abstract Number: 2546

Clinician's Simple Opinion of SLE Disease Progress: Used in a Clinical Trial

Anca Askanase,[1] Amit Saxena,[2] Aikaterini Thanou,[3] Cristina Arriens,[4] Debra J. Zack,[5] and Joan Merrill[6], [1]Columbia University, New York, [2]New York University Medical Center, New York, NY, [3]Oklahoma Medical Research Foundation, Oklahoma City, OK, [4]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [5]Xencor, Inc., San Diego, CA, [6]Oklahoma Medical Research Foundation, Oklahoma City

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Measuring improvement or worsening is problematic in lupus trials. The British Isles Lupus Assessment Group (BILAG) index often fails to capture sustained decrease in disease activity when the change levels off. The SLE Disease Activity Index (SLEDAI) is inflexible if improvement does not meet a low threshold definition. False positive or negative flares create additional problems. "Mild/moderate" worsening on the SLEDAI Flare Index (SFI) can be due to insignificant changes. According to an older BILAG flare definition (>/= 2 new B or 1 new A), which is still commonly used, a false flare occurs if previously improving disease stabilizes, while true worsening is frequently missed when organ scores remain unchanged. A newer BILAG flare definition addresses most of these issues, but fails to account for > 1 feature flaring in a single organ or to allow a moderately severe flare in only 1 organ to rate more than "mild." Given the pitfalls of glossary-based measures, we sought the advice of the clinician in determining changes in disease severity.

Methods: A simple algorithm for clinician's global impression of change (CGIC) was tested during a phase 2 trial of the B Cell modulator, Xmab5871. investigators were asked to rate disease progress at each visit as "no change or

TABLE 1: Disease Change in SLE Disease Activity Indices: Correlation to CGIC

(All p values: </= 0.0000002)

	Change in SLEDAI	Change in PGA	CGIC
Change in BILAG	0.423	0.664	0.684
Change in SLEDAI		0.353	0.412
Change in PGA			0.745

Spearman Rank Order Correlation (both improvements and worsening were assessed)

TABLE 2: Percent of 102 SLE Patients Reaching Day 225 (end of treatment period) Without Worsening

Flare Definition	All Patients %	Xmab5871 %	PBO %	p value (chi sq)
OLD BILAG	21.5	21.5	21.5	NS
NEW BILAG	24.5	25	23.5	NS
SFI	22.5	25	19.6	NS
CGIC	33.3	43	23.5	0.059

a n=12 nondiabetic healthy subjects. Data represent mean ± standard error of mean. Abbreviation: RCI, repository corticotropin injection.

insignificant change" (NC) "significant partial improvement" (PI), "major or complete improvement" (MI), "significant moderate worsening" (MW), or "severe worsening" (SW). Discrepancies between the CGIC and other instruments were brought to the investigators' attention, but it was emphasized that the clinician's opinion could conflict with the technical scoring. Results were collected in an online database along with the BILAG, SLEDAI, PGA and SFI results.

Results: Of 104 randomized patients, data from 102 were available from 2-11 visits. The results of the trial have been reported elsewhere; briefly, the primary endpoint, maintenance of improvement, was met by 42% of XmAb5871-treated patients vs 28.6% of the placebo (PBO) group (p=0.18) and time to flare was longer in the XmAb5871 group (p=0.025). Using the CGIC, clinicians rated 445 visits as NC, 148 PI, 64 MI, 84 MW and 8 SW. CGIC was tested as a gold standard for the comparison of other measures of change that are used in SLE trials. Results of this study are summarized in Tables 1 and 2.

Conclusion: Clinician's opinion, recorded using CGIC, is better reflected by changes of BILAG and PGA than it is by the SLEDAI, which offers fewer gradations of scoring. More patients were free of flare using the CGIC compared to other instruments. In the double-blind trial of Xmab5871 the increased CGIC threshold for defining worsening disease impacted results for patients receiving active treatment more than PBO, suggesting the utility of CGIC as a gold standard for clinical significance.

Abstract Number: 2547

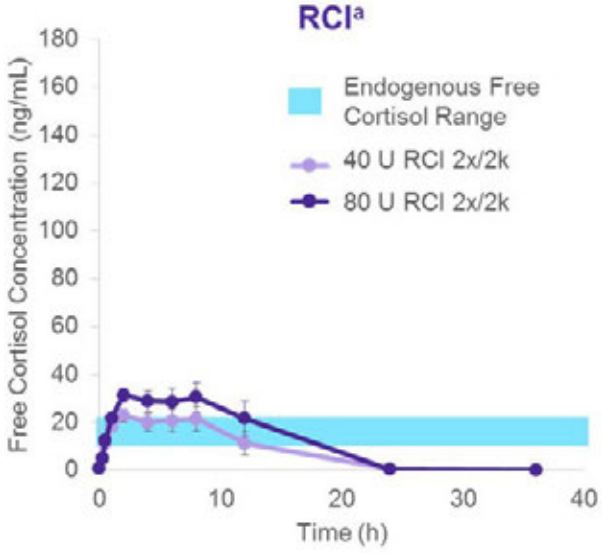
Safety Results of 50% Enrollment from a Multicenter, Randomized, Double-blind, Placebo-controlled Study to Assess the Efficacy and Safety of Repository Corticotropin Injection in Patients with Systemic Lupus Erythematosus Despite Moderate-dose Corticosteroid Use

Anca Askanase,[1] Dharani Munirathinam,[2] Enxu Zhao,[2] Julie Zhu,[2] Erin Connolly-Strong,[2] and Richard Furie[3], [1]Columbia University Medical Center, New York, NY, [2]Mallinckrodt Pharmaceuticals, ARD, LLC, Bedminster, NJ, [3]Northwell Health, Great Neck, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Repository corticotropin injection (RCI) is a naturally sourced complex mixture of adrenocorticotropic hormone ($ACTH_{1-39}$) analogues and other pituitary peptides that stimulates endogenous corticosteroid (CS) production and is an agonist for all 5 melanocortin receptors. RCI is approved by the US FDA for the treatment of acute exacerbations or as maintenance therapy in patients with systemic lupus erythematosus (SLE). In a pilot study,[1] RCI improved disease activity (vs placebo) and was well tolerated in patients with SLE. In a separate study, RCI increased endogenous cortisol levels to a similar extent as < 10 mg ofexogenous prednisone (**Figure 1**; data on file). The current trial was designed to assess the efficacy and safety of RCI in patients with persistently active SLE despite use of moderate-dose CSs (ClinicalTrials.gov ID: NCT02953821). This abstract describes the safety data from 50% of the expected enrolled subjects from the blinded and ongoing trial.

Methods: Patients enrolled in this multicenter, double-blind, randomized, placebo-controlled, 24-week trial are required to have SLE (≥4 of 11 ACR 1997 criteria) and active disease (moderate to severe rash and/or arthritis) despite stable doses of CSs ≥4 weeks before screening. Treatments are 1 mL RCI (80 U) or placebo subcutaneously every other day for 4 weeks, followed by twice per week for 20 weeks. Randomization is stratified by study site location (US



a n=12 nondiabetic healthy subjects. Data represent mean ± standard error of mean. Abbreviation: RCI, repository corticotropin injection.

Pyelonephritis	1 (1.3)
Metabolism and nutrition disorders	2 (2.5)
Hyperglycemia	2 (2.5)
Vascular disorders	2 (2.5)
Hypertension	2 (2.5)

*One patient had 2 TEAEs. Abbreviation: TEAE, treatment-emergent adverse event.

or outside of US) and prednisone or equivalent dose (≤20, >20 mg/d). Patients remain on stable doses of CSs through week 16, with tapering encouraged between weeks 16 and 24. The primary efficacy end point is the proportion of SLE Responder Index-4 (SRI-4) responders at week 16. Secondary and exploratory end points include measures of disease activity, prednisone dose, and serum biomarkers (ie, complements, autoantibodies, and inflammatory and bone turnover markers). Target enrollment is 270 patients; 162 are expected to be randomly assigned at ~60 global sites. Safety assessments include treatment-emergent AEs (TEAEs), physical examination, and vital signs and are summarized with descriptive statistics only.

Results: The 80 patients in this evaluation represent ~50% of the patients expected to be randomly assigned in the study. Data from these patients were blinded. Demographics and baseline characteristics show a racially diverse population (**Table 1**). A total 53 (66.3%) patients reported a TEAE, with the most common being headache (8.8%) and insomnia (6.3%). TEAEs of special interest are shown in **Table 2**. The reported serious AEs (pneumonia, hypertension) were deemed related to treatment and expected. No Suspected Unexpected Serious Adverse Reactions or deaths were reported.

Conclusion: In a study of RCI in patients with active SLE despite moderate-dose CS, blinded 50% enrollment data show disease characteristics consistent with those expected for patients with moderate/severe SLE. The safety profile suggests that RCI is well tolerated, consistent with a modest increase in cortisol production. The complete dataset will provide valuable information on the role of RCI in refractory SLE.

Abatacept Failed to Demonstrate Efficacy in an SLE Trial with Low Placebo Response Rates, Although Global Assessments Indicated Less Flare Severity

Aikaterini Thanou,[1] Cristina Arriens,[2] Teresa Aberle,[1] Heather Miller,[1] Lydia Mitchell,[3] Stan Kamp,[1] Anca Askanase,[4] Stavros Stavrakis,[5] Judith James,[2] and Joan T. Merrill[6], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, Oklahoma City, [4]Columbia University, New York, [5]University of Oklahoma Health Sciences Center, Oklahoma City, [6]Okalahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (ABA) is a fusion protein of the extracellular domain of CTLA4 and human IgG1-Fc, constructed to inhibit B/T cell co-stimulation. Previous studies of ABA in lupus failed to show benefit, but improvement in arthritis was suggested. Those studies included significant background medications and steroid rescue. The current 6-month randomized, double-blind, placebo (PBO)-controlled study of ABA in patients with SLE arthritis withdrew background medications to facilitate assessments.

Methods: Patients were entered with moderate to severe arthritis (BILAG A or B with ≥3 swollen and ≥3 tender joints). All SLE treatment except low dose prednisone was withdrawn and patients were randomized 1:1 to weekly sc ABA or PBO. DepoMedrol injections (≤320mg total) were allowed, if needed, until Month 2. At Month 3, additional steroids, immune suppressants or open-label ABA were allowed, but designated non-response. The primary endpoint was the BILAG-based Combined Lupus Assessment (BICLA) response at Month 6. The SELENA-SLEDAI PGA (SSPGA) and the LFA-Rapid Evaluation of Activity in Lupus (LFA-REAL) were used as exploratory endpoints. The SSPGA is a single visual analogue scale (VAS) assessing overall lupus activity, and the LFA-REAL derives a total VAS score by summing individual symptoms (1).

Results: 66 randomized patients received at least one dose of the study drug. Placebo response rates were lower than most SLE trials, but no primary or secondary endpoints were met (Table). The safety profile of ABA was consistent with its known effects. Additionally, a flare analysis was performed.

	ABA (n=31)	PBO (n=35)	p value
BICLA	8(26%)	8(23%)	>0.999
SRI4	9(29%)	8(23%)	0.587
SLEDAI 4 point improvement	9(29%)	8(23%)	0.587
SLEDAI arthritis improvement	9(29%)	8(23%)	0.587
BILAG A/B MSK improvement	9(29%)	8(23%)	0.587
SLEDAI 2	8(26%)	7(20%)	0.769
LLDAS	6(19%)	8(23%)	0.772

Table. Primary and secondary efficacy assessments at Month 6.

By Month 6, 13 (42%) patients on ABA vs. 15 (45%) PBO had a moderate/severe flare and 22 (71%) patients on ABA vs. 22 (67%) PBO experienced flare or treatment failure (dropout or added medications) (Log-Rank test, p=0.941 and p=0.539, respectively). Using the modified SELENA-SLEDAI Flare Index (mSSFI) (2) or BILAG flare index, global flare severity did not differ between groups, even after adjusting for rescue steroids, SLEDAI at screening and SLEDAI at visit prior to flare. Similarly, BILAG musculoskeletal (MSK) flares did not differ between groups.

Using the SSPGA and LFA-REAL, flare severity was greater in the PBO group vs. the ABA group. Adjusting for LFA-REAL MSK score at visit prior to flare and flare severity by BILAG MSK, increase in LFA-REAL MSK at flare visits was 8.7±1.5 for PBO and 3.0±1.5 for ABA (p=0.07). Adjusting for SSPGA at visit prior to flare and flare severity by mSSFI, increase in SSPGA at flare visits was 10.4±1.6 for PBO and 4.8±1.7 for the ABA group (p=0.017). The score difference for LFA-REAL was 15.5±2.7 for PBO vs. 5.1±2.8 for ABA-treated patients (p=0.008).

Conclusion: This protocol lowered PBO response rates to ≤23% by mandating withdrawal of background treatments. ABA did not demonstrate improvement in controlling disease activity. SSPGA and LFA-REAL scores suggested a decrease in flare severity in the ABA-treated patients.

Population Pharmacokinetics of Atacicept in Systemic Lupus Erythematosus (SLE) – an Analysis of Three Clinical Trials

Maria Pitsui,[1] **Orestis Papasouliotis**,[2] Colm Farrell,[1] Pascal Girard,[2] Oezkan Yalkinoglu,[3] and Cristina Vazquez-Mateo[4], [1]ICON Plc, Dublin, Ireland, [2]Merck Institute for Pharmacometrics, Lausanne, Switzerland, [3]Merck KGaA, Darmstadt, Germany, [4]EMD Serono Research and Development Institute, Inc., Billerica, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Atacicept targets the B-cell stimulating factors BLyS and APRIL and has been shown to reduce SLE disease activity. The aim of the analysis was to describe the pharmacokinetic (PK) profile of total (i.e. bound and unbound) atacicept after subcutaneous (sc) administration in healthy volunteers (HV) and SLE patients using a semi-mechanistic population PK model and to identify covariates explaining PK variability.

Methods: A total of 540 subjects, 37 from a Phase I study in Caucasian and Japanese HV where single 25, 75 or 150 mg sc doses of atacicept were administered, 298 from a Phase II study in SLE (NCT00624338) where 75 or 150 mg sc doses were administered weekly (QW) for 52 weeks (bi-weekly for the first 4 weeks of treatment), and 205 from

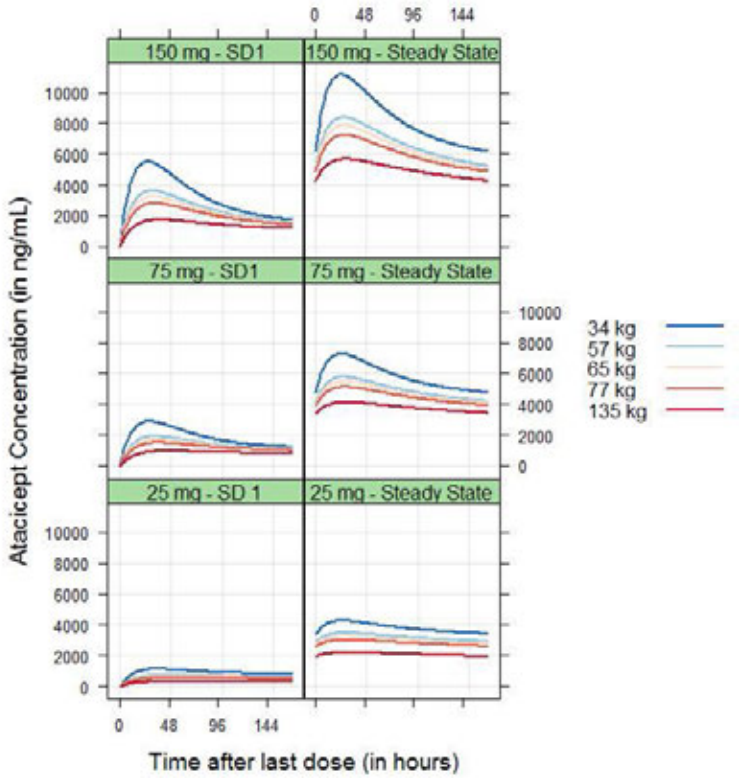

Figure 1. Simulated Typical Subject PK Profiles of total Atacicept for a Range (min, quartiles, max) of Baseline Weights – First Dose and Steady State – QW Dosing

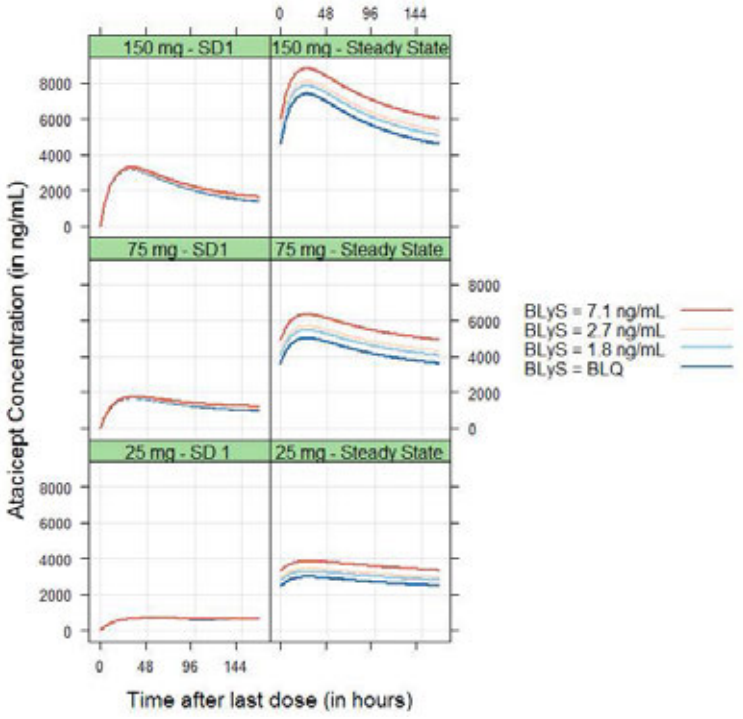

Figure 2. Simulated Typical Subject PK Profiles of total Atacicept for a Range of Baseline BLyS concentrations: BLQ (minimum and 1st quartile), 1.8 (median), 2.7 (3rd quartile) and 7.1 (97.5th percentile, as the maximum was a clear outlier) – First Dose and Steady State – QW Dosing

a second Phase II study in SLE (NCT01972568) with QW sc dosing of 75 or 150 mg for 24 weeks, contributed 3640 measurements of total atacicept in serum. Modeling was performed with the NONMEM software. A Quasi-Steady-State (QSS) approximation [1] of the target-mediated drug disposition (TMDD) [2] model was used to describe drug concentrations. Covariates tested in the model were weight, age, creatinine clearance, serum BLyS and APRIL (all at baseline), gender, race, dose and SLE vs HV population. Model-based exposure metrics (e.g. area under the concentration curve, AUC) were derived. Covariate effects were evaluated via simulations.

Results: A two-compartment QSS TMDD binding model with first-order absorption described total atacicept concentrations of the three trials, adequately capturing the central tendency and variability in the data. The model provided precise (relative standard errors < 20%) estimates of all parameters, including binding (K_{ss}=19.9 ng/mL), target turnover (R_{max}=715 ng/mL; K_{deg}=0.00362 h^{-1}), and drug-target complex elimination (K_{int}=0.000618 h^{-1}) parameters. The typical estimates of apparent linear clearances and volumes of distribution of the drug were: CL/F=0.324 L/h, Vc/F=36.3 L, Q/F=0.149 L/h and Vp/F=38.5 L. Residual variability was moderate, slightly higher in SLE patients (CV=25%) than in HV (CV=19%).

Drug CL/F and central volume Vc/F increased with body weight following allometric relationships (exponents of 0.75 and 1.00, respectively), while baseline target concentration (R_{max}) increased with baseline BLyS concentration (as R_{max} ~$(BLyS/2.56)^{0.176}$); however, resulting differences in exposure were small (Figure 1 and 2). No significant differences in PK between HV and SLE patients or racial groups were detected.

Conclusion: The developed population PK model allowed the description of the complete atacicept concentration time profile in SLE patients, a first step in the identification of exposure-response relationships for pharmacodynamic/clinical/safety endpoints that informed on Phase III study design.

Impact of Pathogenic and Protective Environmental Exposures on Autoimmune Disease—The Microbiome Effects on Lupus (MEL) Study

Hayley Walter,[1] Trevor Faith,[2] Alexander Alekseyenko,[3] Ali Bakhtiari,[3] Paula Ramos,[2] and Diane Kamen[4], [1]Division of Rheumatology/Medical University South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, [3]Medical University South Carolina, Charleston, SC, [4]Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, South Carolina, USA., Charleston, SC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic and often severe multi-organ autoimmune disease characterized by the production of autoantibodies and heterogeneous clinical manifestations. African Americans (AA) and young women are disproportionately affected by SLE, and AAs develop SLE at a younger age with a higher prevalence of kidney involvement (lupus nephritis, LN) compared to other racial/ethnic groups.

Little is known about the etiology of SLE. Genetic inheritance alone is insufficient for developing SLE, suggesting environmental triggers play a role in disease expression. Gut microbiota play a key role in setting the systemic immune tone and influences regulatory and inflammatory immunologic responses. Our study investigates gut microbiome characteristics that may lead to development, progression, and severity of disease in SLE. We hypothesize that gut microbial variation exists at the structural level between patients with SLE (either with or without LN), and healthy controls. Furthermore, we suspect higher microbiome diversity is protective against autoimmunity and a higher proportion of “pro-inflammatory” microbes is a risk factor for SLE and LN.

Methods: We characterized the microbial composition of fecal DNA from samples obtained from AA patients with SLE and from non-SLE AA controls. All participants provided informed consent for research participation and SLE/LN vs control status was confirmed during in-person interview, examination, lab evaluation, and record review. We performed genomic assessment of gut microbial communities using whole genome shotgun sequencing. Gut microbiota was quantified using a sequence-based profiling method. These metagenomes were analyzed against known microbial genome databases (NCBI-NR). Genus abundance profiles were constructed to evaluate microbial species distribution.

Results: 58 samples have been collected (28 SLE/LN and 30 controls) to date. Of these, 44 samples have been sequenced (27 patients and 17 unrelated controls) with the remaining pending at this time. Using metagenomic phylogenetic analysis, 371 species were identified. Principal coordinate analysis between female patients and female controls revealed no significant difference in organism abundance (p-value= 0.5914). In patients with lupus nephritis (n=9) compared to lupus patients without renal disease and controls (n=35), there was no significant difference in abundance at the phylum level (p-value= 0.3681).

Conclusion: Our preliminary studies show that among AA females with SLE and lupus nephritis, gut microbiome composition appears similar to that of unrelated controls. Other similar studies have shown significant differences in microbiome composition between SLE patients and controls, however patients included in our studies had low SLEDAI scores, indicating low disease activity at time of sample collection. We plan to perform multivariate modeling to determine if environmental factors (age, medications, diet, smoking, occupational exposures) in addition to SLE disease status affect microbial composition.

Validity and Reliability of Patient Reported Outcomes Measurement Information System (PROMIS) Computerized Adaptive Tests (CAT) in a Canadian Cohort of Patients with Systemic Lupus Erythematosus

Mitra Moazzami,[1] Lisa Engel,[2] Nicole Anderson,[3] Jiandong Su,[3] Dennisse Bonilla,[3] Pooneh Akhavan,[4] Patricia Katz,[5] Dorcas Beaton,[6] and Zahi Touma[7], [1]George Washington University, Washington, DC, [2]University of Manitoba, Winnipeg, MB, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada, [4]University of Toronto, Toronto, Canada, [5]University of California, San Francisco, san francisco, CA, [6]St. Michael's Hospital, Toronto, ON, Canada, [7]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcome measures are invaluable tools in clinical practice and are central in providing patient-centered care. There has been minimal research on the use of the Patient Reported Outcomes Measurement Information System (PROMIS) computerized adaptive test (CAT) in adults with systemic lupus erythematous (SLE). The present study aims to examine the construct validity and test-retest reliability of the PROMIS CAT in a Canadian cohort of patients with adult SLE.

Methods: All consecutive adult (≥18 years) patients with SLE visiting a Canadian Lupus Clinic between July-September 2018 were approached to participate. Patients completed PROMIS CAT during their clinical visit assessing 14 domains of health: physical function, mobility, pain behaviour, pain interference, ability to participate in social roles, satisfaction with social roles and activities, fatigue, sleep disturbance, sleep-related impairment, applied cognition-abilities, applied cognition-general concerns, anger, anxiety, and depression. C**onstruct validity** (using Spearman correlation, r) of PROMIS CAT scales was evaluated against commonly-used legacy instruments: SF-36, LupusQoL, the Perceived Deficits Questionnaire (PDQ-20), Beck Depression Scale - 2nd edition (BDI-II), Beck Anxiety Inventory (BAI), the Assessment of Chronic Illness Therapy Fatigue Scale (FACIT), and the Epworth Sleepiness

Table 1. PROMIS domains scores

Domain	Mean ± SD
Physical function	43.6 ± 9.2
Mobility	44.7 ± 9.6
Pain behaviour	53.7 ± 10.8
Pain Interference	55.2 ± 10.7
Ability to participate in social roles	48.2 ± 9.8
Satisfaction with social roles & activities	48.7 ± 11.4
Fatigue	57.3 ± 10.5
Sleep disturbance	55.4 ± 10.2
Sleep related impairment	56.0 ± 10.7
Anger	51.3 ± 9.8
Anxiety	55.6 ± 8.9
Depression	52.3 ± 9.8
Applied cognition-abilities	46.7 ± 9.3
Applied cognition-general concerns	46.4 ± 8.8

Domains highlighted in grey fell out of +/- 0.5 SD of population mean

Table 2. Test-retest reliability (Intraclass Correlation Coefficient (ICC [2;1]), n= 81

Domain	ICC (2, 1) and 95% CI
Physical function	0.90 (0.83, 0.94)
Mobility	0.91 (0.85, 0.95)
Pain behaviour	0.73 (0.50, 0.90)
Pain Interference	0.78 (0.63, 0.92)
Ability to participate in social roles	0.85 (0.75, 0.93)
Satisfaction with social roles & activities	0.70 (0.44, 0.88)
Fatigue	0.79 (0.65, 0.88)
Sleep disturbance	0.69 (0.49, 0.83)
Sleep related impairment	0.76 (0.64, 0.87)
Anger	0.71 (0.52, 0.85)
Anxiety	0.70 (0.51, 0.84)
Depression	0.82 (0.76, 0.90)
Applied cognition-abilities	0.64 (0.50, 0.78)
Applied cognition-general concerns	0.83 (0.72, 0.93)

Scale. **Test-retest reliability** (intraclass correlation coefficient (ICC [2;1]) was evaluated using baseline data and PROMIS CAT scores 7-10 days after baseline.

Results: 182 patients (91.2% females) with a mean age of 49.0± 14.1 years and mean disease duration of 18.5 ±12.2 years were enrolled. **Table 1** demonstrates the PROMIS sample mean with the population mean of 50±10 as reference. Half of domains' scores appeared to be within + /- 0.5 Standard Deviation (SD) of the population mean while Physical function and Mobility fell below 0.5 SD and Pain Interference, Fatigue, Sleep disturbance, Sleep related impairment, and Anxiety fell above 0.5 SD. Moderate-high correlations (r= 0.59-0.87) between PROMIS scores and relevant legacy instruments were demonstrated confirming a priori hypotheses regarding construct validity of the PROMIS CAT scales [e.g. r=0.85 for SF-36 Physical Functioning and PROMIS Physical Functioning; r=0.82 for FACIT-F and PROMIS Fatigue]. In 81 patients, good test-retest agreement was found for the majority of domains [ICC (2;1) range 0.64-0.93] (**table 2**). The lowest ICCs [2;1] were identified for applied cognitive abilities (ICC 0.64, 95% CI:0.50-0.78) and sleep disturbance (ICC 0.69, 95% CI:0.49-0.83).

Conclusion: This is the first study to examine the construct validity and the reliability of PROMIS CAT in a Canadian adult SLE cohort. Compared to legacy instruments (such as SF-36), PROMIS CAT has moderate-high correlation confirming its **construct validity** and good-excellent **reliability**. Considering the increasing use of the PROMIS across different health diagnoses, the PROMIS may be a promising non-diagnostic instrument to enhance SLE research and clinical practice.

Design and Development of an Online Intervention for Lupus Self-Management Based on the Transtheoretical Model of Change

Sarah Gilman,[1] Deborah Levesque,[2] Carol Cummins,[3] Daniel Wallace,[4] Victoria Werth,[5] and **Patricia Davidson** [6], [1]Wayfinder Health Strategies, Washington, DC, [2]Pro-Change Behavior Systems, Providence, RI, [3]Pro-Change Behavior Systems, Inc.,, Providence, [4]Cedars-Sinai Medical Center/University California at Los Angeles, Los Angeles, CA, [5]Corporal Michael J. Crescenz VAMC, Philadelphia, PA, USA and Department of Dermatology, University of Pennsylvania, Philadelphia, PA, USA, Philadelphia, PA, [6]Lupus Foundation of America, Washington, DC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Lupus Foundation of America is in Year 4 of a 6-year cooperative agreement with the Centers for Disease Control and Prevention to develop an online lupus self-management program based on the Transtheoretical Model of Change (the "stage model"). The program, *Strategies to Embrace Living with Lupus Fearlessly* (SELF), is a web-based intervention designed to help users adopt 4 key lupus self-management behaviors: 1) managing symptoms, 2) managing stress, 3) managing medications, and 4) working with a health care team. These behaviors were identified and operationally defined in year 3 of the cooperative agreement. We summarize the program design, as well as feedback from early users and engagement experts.

Methods: The intervention consists of 4 complementary components: 1) user assessments, 2) a web portal with stage-matched activities and information, 3) outbound text messages and emails to facilitate change and user engagement, and 4) a reporting tool to measure program utilization and outcomes.

The intake process consists of 4 modules, each focused on one of the 4 key behaviors. The modules provide feedback tailored to user responses to questions. After intake, users select a behavior to focus on, and a customized web portal becomes available. The portal includes stage-matched activities, a symptom tracker, a journal, information on the 4 key lupus self-management behaviors, and links to the Foundation's National Resource Center on Lupus, Health Educators, and LupusConnect™ messaging boards for peer support. Participants can sign up for emails or texts with stage-matched tips and links to the portal activities.

Every two weeks, the program delivers a mini assessment to track changes in self-efficacy, and asks users to select the behavior they would like to focus on next. Every 90 days, the program administers a comprehensive assessment and a printable report summarizing data on lupus symptoms, self-management behaviors, and stage of change that can be shared with a provider.

5 individuals with lupus with diverse demographic characteristics recruited by the Lupus Foundation of America served as early program testers. Engagement experts also reviewed the program design and structure.

Results: Feedback from early users and engagement experts was largely positive and used to refine the online program. Program development will be finalized by the Fall of 2019, at which time pilot testing will begin.

Conclusion: The SELF program is designed to provide a cohesive, tailored experience to help individuals with lupus manage their condition. This is the first program of its kind to deliver information and activities tailored to stage of change for four key behaviors for lupus self-management.

Prescription Opioid Use and Osteoporotic Fractures in Systemic Lupus Erythematosus: The Michigan Lupus Epidemiology & Surveillance (MILES) Cohort

Emily Somers,[1] Sioban Harlow,[1] Nina Zhou,[1] Lu Wang,[1] Kamil Barbour,[2] Charles Helmick,[3] Caroline Gordon,[4] Deeba Minhas,[1] Beth Wallace,[1] Afton Hassett,[1] Suzanna Zick,[1] W. Joseph McCune,[5] and Wendy Marder[1], [1]University of Michigan, Ann Arbor, [2]Centers for Disease Control and Prevention, Atlanta, [3]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [4]University of Birmingham, Birmingham, United Kingdom, [5]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We recently reported prescription opioid use in nearly one-third of systemic lupus erythematosus (SLE) patients in our population-based cohort. Data suggest that opioids may be associated with falls and decreased bone mineral density (postulated via impaired osteoblast activity and indirectly via hypothalamic-pituitary-adrenal axis dysfunction and hypogonadism), both of which increase fracture risk. Osteoporosis rates are elevated in SLE due to factors including use of glucocorticoids and gonadotoxic therapies (that can result in primary ovarian insufficiency). This analysis examines the association between opioid use and osteoporotic fractures in SLE.

Methods: The study included SLE patients from the population-based MILES Cohort. Sociodemographic, clinical and prescription data were obtained by structured interviews. Osteoporotic fracture history was ascertained from the validated Lupus Damage Index Questionnaire (LDIQ). Locally weighted scatterplot smoothing (Lowess) curve was fit to visualize the relationship between opioid duration and osteoporotic fracture, and determine the appropriate functional form for modelling. Multivariable logistic regression was then used to model the relationship between opioid usage and osteoporotic fracture, controlling for other variables specified *a priori* as relevant: age, sex, race, ethnicity, smoking history (daily cigarette smoking for ≥6 months), body mass index, SLE duration, high steroid exposure history (≥10 mg oral steroids for ≥1 month) and for females, cessation of menses prior to age 40 years, not due to surgery (indicator of primary ovarian insufficiency).

Results: Among the 458 SLE participants in this study, average age was 53.4 years (SD 12.3), 427 (93.2%) were female, and race was primarily self-reported as black (205; 44.8%) or white (233; 50.9%). Current prescription opioid use was reported by 141 participants (30.8%). History of osteoporotic fracture was reported in 16/141 participants with current prescription opioid use (11.4%) vs 17/317 not using opioids (5.4%); p=0.022. From multivariable regression, current opioid use (binary variable) was not associated with fractures; however, duration of opioid use was sig-

nificantly associated. Lowess curve indicated a piecewise linear relationship with an inflection at 15 years: for those with opioid use ≤15 years (n=120), odds of fracture were 16% more likely per year increase [OR 1.16 (95% CI 1.06, 1.26), p< 0.001], after adjusting for the covariates. Results were similar when restricting to females. Data were sparse beyond 15 years of opioid use (n=11) thus statistically unstable.

Conclusion: Duration of opioid use was associated with osteoporotic fracture in SLE patients. The odds of fracture increased by 16% for each year of use within 15 years of opioid initiation. Although a temporal association cannot be established from this study, and mitigating factors such as inactivity secondary to pain may be involved, our data suggest that chronic opioid therapy is an indicator for osteoporosis screening in the SLE. The potential for adverse effects on bone health further provides impetus for alternative pain management strategies.

Do All Patients Who Achieve Lupus Low Disease Activity State Have Similar Outcomes?

Konstantinos Tselios,[1] Dafna Gladman,[2] Jiandong Su,[3] and Murray Urowitz[1], [1]University Health Network, University of Toronto, Toronto, Canada, [2]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus Low Disease Activity State (LLDAS) has been associated with favourable outcomes in systemic lupus erythematosus (SLE). However, the complexity of its defining criteria (SLEDAI-2K≤4, no major organ involvement, no new clinical manifestation, no increase in Physician' s Global Assessment, daily prednisone dose≤7.5mg/day and stable doses of antimalarials, immunosuppressives and biologics) allows for considerable heterogeneity among these patients. The aim of the present study was to describe the major LLDAS phenotypes in inception patients first achieving LLDAS with emphasis on the likelihood of flare.

Methods: Inception patients from the Lupus Clinic (enrolled within 18 months since diagnosis) who achieved LLDAS for two consecutive visits from January 2000 to December 2016 were included. All patients were followed for at least two years and divided into major phenotypes as follows: glucocorticosteroid use (or not), clinical SLEDAI-2K≤2 on antimalarials only (or not) and serologically active clinically quiescent (SACQ) disease (or not). The likelihood of disease flare (any deviation from LLDAS) was assessed over the next 2 and then 5 years. SAS 9.4 was used for statistics; p< 0.05 was considered significant.

Results: Four hundred twenty one patients achieved LLDAS for two consecutive visits; 357 had at least two years and 295 had at least five years of follow-up. At two years, 149/357 (41.7%) patients flared after 1.1 years on average

Likelihood of lupus flare in the different subgroups of the patients who achieved LLDAS				
	At 2 years (n=357)		At 5 years (n=295)	
	Flares (n, %)	*p*	Flares (n, %)	*p*
No glucocorticosteroids	54/154 (35.1%)	0.026	79/127 (62.2%)	0.013
Treatment with glucocorticosteroids	95/203 (46.8%)		127/168 (75.6%)	
Clinical SLEDAI-2K≤2 on AM only	40/129 (30%)	0.002	64/107 (59.8%)	0.0047
Clinical SLEDAI-2K>2 on AM or glucocorticosteroids or immunosuppressives	109/228 (47.8%)		142/188 (75.5%)	
SACQ* only	69/149 (46.3%)	0.138	89/124 (71.8%)	0.536
Non-SACQ**	80/208 (38.5%)		117/171 (68.4%)	
*SACQ: serologically active clinically quiescent disease (LLDAS where the only SLEDAI-2K component is serology) ** LLDAS where SLEDAI-2K components must include clinical manifestations AM: antimalarials Flares were defined as any deviation from the LLDAS				

whereas at five years 206/295 (69.8%) patients flared after 1.9 years on average. The differences in the likelihood of flares are shown in the table.

Conclusion: Within the LLDAS population, patients who achieved a clinical SLEDAI-2K≤2 on antimalarials only as well as the patients who were not treated with glucocorticosteroids developed significantly less flares over 2 and 5 years. These findings suggest that the use of glucocorticosteroids or immunosuppressives and the nature of the clinical manifestations impact the ability of LLDAS to predict flares over the next 2 and 5 years.

Outcomes of structural, functional, conduction and biochemical abnormalities in AMIC		
Outcome	**At AMIC diagnosis**	**At last visit**
Death	N/A	1/10 (three months after diagnosis due to refractory heart failure)
Left ventricular hypertrophy (by echocardiogram)	Mild: 6 Moderate-to-severe: 4	Mild: 7 Moderate-to-severe: 3
Septal hypertrophy (by echocardiogram)	Mild (12-14mm): 7 Moderate-to-severe (≥15mm): 3	Mild (12-14mm): 8 Moderate-to-severe (≥15mm): 2
Left atrium	Mildly dilated or normal: 4 Moderate-to-severely dilated: 6	Mildly dilated or normal: 8 Moderate-to-severely dilated: 2
Systolic dysfunction (EF≤ 45%)	One patient	Full recovery
Diastolic dysfunction	Grade 1-2: 7 Grade 3: 3	Grade 1-2: 8 Grade 3-4: 2
Severe arrhythmias (requiring hospitalization)	One patient with permanent pacemaker due to complete AVB	One patient developed complete AVB and received a permanent pacemaker 18 months after drug withdrawal Two patients developed paroxysmal atrial fibrillation (12 months after drug withdrawal) and were managed with ablation
Troponin I	Abnormal in all patients	Serum levels reduced significantly in 7/10, unchanged in 2/10, increased in one patient Still abnormal in 8/10 at last visit
BNP	Abnormal in all patients	Reduced in 6/10 patients, still abnormal in 6/10 Normalized in 4/10

Background/Purpose: Antimalarial-induced cardiomyopathy (AMIC) is a hypertrophic cardiomyopathy with conduction system disorders, cardiac biomarker abnormalities and a short-term mortality of 45%. Data on the reversibility of the disease are sparse. The aim of this study is to assess the evolution of AMIC in the long term in patients with systemic lupus erythematosus (SLE).

Methods: Ten patients with SLE who developed AMIC were analyzed (mean age at diagnosis 63±8.7 years, mean disease duration 32.8±12.7 years, mean antimalarial treatment duration 22.4±9.4 years). Diagnosis was confirmed by myocardial biopsy in three patients (extensive cardiomyocyte vacuolation, intracytoplasmic myelinoid and curvilinear bodies) and considered probable in another seven cases based on a combination of abnormal cardiac biomarkers (high sensitivity troponin I and brain natriuretic peptide, BNP), hypertrophic cardiomyopathy (based on cardiac magnetic resonance, CMR) and the exclusion of other causes (coronary artery disease, uncontrolled hypertension). Other types of idiopathic hypertrophic cardiomyopathy and/or Anderson-Fabry cardiomyopathy were excluded by genetic testing.

Results: Mean follow-up after AMIC diagnosis was 23.7±10.7 months; antimalarials were discontinued in all patients, while diuretics were commenced or intensified in three. The evolution of structural, functional and conduction system abnormalities as well as the cardiac biomarkers are shown in the table.

All four patients with severe arrhythmias had a right bundle branch block and two of them had bifascicular block for years before the arrhythmia. The median reduction of troponin I (7/10 patients) was 29.7% at one year, 53.1% at two years and 74.1% at three years (compared to baseline). The median reduction of BNP (6/10 patients) was 49% at one year, 81.3% at two years and 68.8% at three years (compared to baseline).

Conclusion: Recovery of the structural (left ventricular and septal hypertrophy, left atrium enlargement), functional (systolic and diastolic dysfunction) and biochemical variables (troponin I, BNP) occurs in most patients with AMIC but this is slow and often incomplete even after two years. Conduction abnormalities may still develop many months after drug withdrawal.

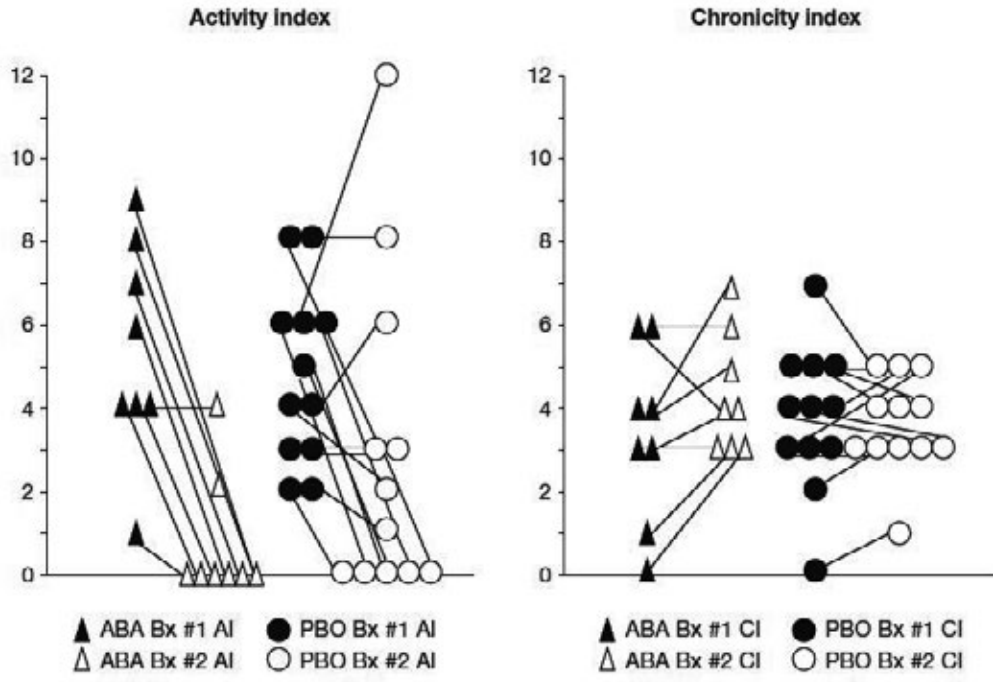
Background/Purpose: Current therapeutic management of active Class III or IV proliferative LN relies on the use of maintenance therapy following induction. The optimal method for determining the length of maintenance therapy remains a challenge. Most clinicians use a combination of clinical parameters and length of treatment. Unfortunately, there can be a disassociation between clinical parameters and renal biopsies, the gold standard for assessing dis-

Figure. National Institutes of Health Activity and Chronicity Indices



ABA=abatacept; AI=activity index; Bx=biopsy; CI=chronicity index; PBO=placebo

ease activity.[1] Here we present the findings of repeat renal biopsies and a *post hoc* analysis of their correlation with clinical outcomes from a single site in ALLURE (NCT01714817), a randomized, double-blind Phase III study comparing abatacept (ABA) with placebo (PBO) on background MMF and CS in patients with active Class III or IV LN.

Methods: We evaluated 20 patients from a single site who underwent repeat kidney biopsy (Bx) as part of standard practice. The first Bx was for diagnostic purpose and the second Bx was performed after study discontinuation for clinical decision making. Bx were processed using standard techniques and read, classified using International Society of Nephrology/Renal Pathology Society 2003 Classification and scored using the National Institute of Health activity and chronicity indices (AI/CI) by a single pathologist, blinded to clinical data.[2] Renal pathology findings were correlated with clinical outcomes collected during study participation.

Results: 20/25 patients randomized at the site had paired pre- and post-treatment Bx to be analyzed (ABA n=8; PBO n=12). Demographics and disease characteristics at baseline, duration of therapy and mean time between Bx were comparable (Table 1). 4 patients discontinued treatment, all due to lack of efficacy (ABA n=1; PBO n=3). Most patients achieved a urine protein to creatinine ratio (UPCR) ≤0.5 at least once during therapy (ABA 6/8; PBO 8/12) but mean UPCR at Year 1 was lower in the ABA arm (ABA 0.56; PBO 1.53). While the groups had comparable AI and CI scores at baseline, the ABA group had a lower mean score at the 2nd Bx (0.8 vs PBO 2.9; Table 1). 6/8 of the ABA group had an AI of 0 on repeat Bx vs 5/12 in PBO group (Fig. 1). 2 PBO patients had UPCR ≤0.5 but had some activity on 2nd Bx; 2 ABA patients without activity on 2nd Bx had UPCR >0.5 (0.6 and 0.8). After an average of >2 years of treatment, most responders were classified as III (C) on a repeat Bx (Table 2). Overall safety was comparable in both groups; 2 ABA patients had serious infections (pneumonia and gastroenteritis) that did not lead to discontinuation.

Conclusion: Repeat kidney Bx in patients with active LN after prolonged therapy can reveal discrepancies between clinical and histological responses. Most patients treated with abatacept showed lack of activity even with mild, residual proteinuria. Better methodologies are needed to detect renal activity and improve clinical decision making in patients with LN.

Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Drug induced subacute cutaneous lupus erythematosus has rarely been described. There is a growing literature reporting the association between proton pump inhibitor (PPI) use and subacute cutaneous lupus erythematosus (SCLE).

To compare the clinical characteristics of a cohort of patients with proton pump inhibitor induced subacute cutaneous lupus erythematosus, their clinical course and treatment with a control group of primary subacute cutaneous lupus erythematosus patients not exposed to proton pump inhibitors.

Methods: A matched case-control study in a tertiary referral setting at the Louise Coote Lupus Unit. There were 50 SCLE patients (25 patients with PPI induced SCLE and 25 patients with Primary SCLE). Clinical details recorded included underlying systemic lupus erythematosus (SLE) and SCLE, extent of cutaneous involvement, time to pres-

	PPI Group n= 25	Control Group n= 25	P value

Upper limbs	20 (80 %)	21 (84%)	
Lower limbs	19 (76%)	0 (0%)	< 0.0001

Table 1. Clinical and immunological details

entation, type of proton pump inhibitor and dosage, histological characteristics, immunological profiles, treatment and time to resolution.

Results: There were 25 patients in the PPI group and 25 patients in the Primary SCLE group. There was no significant gender difference, the mean age at diagnosis was 56.3 years for PPI group and 46 years for Primary SCLE group. Nineteen patients (76%) had underlying SLE in the PPI group. In this subgroup, only one patient had SCLE as part of their initial SLE presentation. Lower limb skin lesions were significantly more prevalent in the PPI group ($p< 0.0001$). No significant immunological profile difference was observed between the two groups in terms of anti-double stand DNA, anti Ro-60 antibody and Anti-Sm antibodies. The prevalence of anti Ro-52 antibodies was slightly higher in PPI group 66% compared with 42% in Primary SCLE group. Peripheral blood eosinophils were normal in all patients in the PPI group, supporting the hypothesis of drug induced SCLE rather than a true allergic reaction. Twelve patients underwent a skin biopsy in the PPI group and 11 patients had histology in keeping with SCLE. The median time to presentation was 12 months (range 3 weeks - 12 years) and median resolution period was 1 month (range 1 week- 5 months). Proton pump inhibitor was stopped in 23 patients while 2 patients could not stop it for another clinical indications. Ten patients (40%) received concurrent oral corticosteroid.

Conclusion: Proton pump inhibitor induced SCLE is more common in older patients and may be associated with anti-Ro 52 antibodies. Lower limb involvement is a pointer to PPI induced SCLE. Clinical resolution of the rash may take few days up to a few months. This is likely a class effect with all proton pump inhibitors.

Profiling of Gene Expression, Immune Cell Subtypes, and Circulating Protein Biomarkers in Systemic Lupus Erythematosus Patients Treated with the Selective Immunoproteasome Inhibitor, KZR-616

R Andrea Fan,[1] Janet Anderl,[1] Brian Tuch,[2] Darrin Bomba,[1] Niti Goel,[3] and Christopher Kirk[1], [1]Kezar Life Sciences, South San Francisco, CA, [2]Kezar Life Sciences, south san francisco, [3]Kezar Life Sciences, Duke University School of Medicine, South San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: KZR-616 is a selective inhibitor of the immunoproteasome, the form of proteasome found predominantly in immune cells. In nonclinical studies, KZR-616 blocks acute production of inflammatory cytokines, modulates T- and B-cell activation/differentiation *in vitro*, and is efficacious in murine SLE models[1]. Recently, we presented initial safety and efficacy data from the first 2 cohorts of an open-label study of KZR-616 in SLE patients (pts) [2]. Here we describe their baseline (BL) profile and post-treatment changes in transcriptomic and phenotypic analyses of circulating immune cells and plasma biomarker levels.

Methods: Pts (N=13) received KZR-616 subcutaneously at 45 or 60 mg weekly for 13 weeks with follow-up through Week (W) 25. Disease assessments were performed at BL and W5, 9, 13, 17, 21, and 25. Biomarker samples were

collected at BL and W5, 17, and 25 (~50% of pts had samples for all timepoints). Comparisons at BL were made to samples from 2 separate healthy volunteer (HV) studies. Proteasome activity was measured by enzymatic and active site binding assays[3]. RNA sequencing was performed using Illumina TruSeq® with whole blood collected in PAXgene® RNA tubes and isolated peripheral blood mononuclear cells (PBMCs). Expression of immune gene modules[4] was compared within and across pts. Cryopreserved PBMCs were analyzed by flow cytometry to profile immune cell subtypes. Plasma cytokines/proteins were quantified by electrochemiluminescent assays (Meso Scale Diagnostics) and colorimetric ELISAs.

Results: At BL, immunoproteasome enzymatic activity and subunit composition in SLE pts were not significantly different from that of HV. Whole blood gene expression, noted with treatment as early as W5, revealed a reduction in gene modules enriched for plasma cell, T-cell activation, inflammation, neutrophil, and IFNα response genes. Within individual pts, there was substantial heterogeneity in gene expression with the most marked changes in pts with greater clinical improvement. Consistent with the gene expression analyses, by flow cytometry, we detected reductions in double-negative B cells, class-switched memory B cells, plasmablasts, monocytes, and activated T cells in the 4 of 5 pts with available samples. Post-treatment, several SLE-related cytokines (eg, IL-6, BAFF, MIP-3β) were reduced in some pts and 3 chemokines (RANTES, MIP-3α, and MCP-4) were reduced in most pts (>3 of 6)

Conclusion: KZR-616 treatment was correlated with changes in gene expression, immune cell subtypes, and circulating protein biomarkers in SLE pts. Consistent with nonclinical data, we demonstrated a reduction in inflammatory activity across T, B, and innate immune effector cells at transcriptomic, cellular, and protein levels, supporting a broad mechanism of action for this first-in-class agent. Analyses of additional cohorts are underway to further elucidate these initial findings and may inform future study patient stratification based on molecular or cellular diagnostic criteria.

A Phase 2, Open-label Extension Study to Evaluate Long-term Safety of Anifrolumab in Adults with Systemic Lupus Erythematosus

W. Winn Chatham,[1] Richard Furie,[2] Amit Saxena,[3] Philip Brohawn,[4] **Erik Schwetje**,[5] Gabriel Abreu,[6] and Raj Tummala[5], [1]University of Alabama Medical Center, Birmingham, AL, [2]Zucker School of Medicine at Hofstra/Northwell, New York, NY, [3]NYU Langone Orthopedic Center, New York, [4]AstraZeneca, Gaithersburg, MD, [5]AstraZeneca, Gaithersburg, MD, USA, Gaithersburg, MD, [6]AstraZeneca, Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anifrolumab is a fully human, IgG1κ monoclonal antibody that binds to the type I IFN receptor and inhibits activity of all type I IFNs.[1] In the MUSE phase 2b randomized controlled trial (Study 1013, NCT01438489), anifrolumab demonstrated an acceptable safety profile and efficacy on a range of clinical endpoints in patients with moderate to severe SLE. An open-label extension (OLE) of Study 1013 (Study 1145, NCT01753193) evaluated long-term safety and tolerability of anifrolumab.

Methods: Study 1145 was a 3-year, multinational OLE in adults with moderate to severe SLE (per ACR classification criteria, assessed in Study 1013) who completed randomized treatment with anifrolumab 1000 or 300 mg or placebo in Study 1013 to Day 337 with follow-up to Day 422. All patients in Study 1145 initially received IV anifrolumab 1000 mg every 4 weeks (Q4W). After data from Study 1013 showed the 300-mg dose had a better benefit/risk profile, the dosage in Study 1145 was amended to 300 mg Q4W. Patients received anifrolumab Q4W over 156 weeks with 85 days of follow-up. The primary objective was to evaluate long-term safety/tolerability. Efficacy, pharmacodynamics, and health-related quality of life (HRQoL) were exploratory objectives. Safety was assessed at every visit; SLEDAI-2K and SLICC Damage Index were measured every 3 and 6 months, respectively.

Results: Of 305 randomized patients in Study 1013, 218 (71.5%) at 59 sites participated in Study 1145; 66/218 (30.3%) received placebo in Study 1013. Of 218 patients in Study 1145, 139 (63.8%) completed 3 years of treatment. The most common reason for treatment discontinuation was patient withdrawal (31/218, 14.2%). Treatment was discontinued due to adverse events (AEs) for 15/218 patients (6.9%). During Year 1, 152/218 patients (69.7%) had ≥1 AE (**Table**). Over the full study period, the rate of serious AEs was 8.56 per 100 patient-years (PY); the most common

Drug hypersensitivity	1 (0.17)
Hypersensitivity	2 (0.35)
Infusion-related reaction	4 (0.70)
Nausea (infusion-related)	1 (0.17)
Latent tuberculosis	5 (0.87)
Vasculitis	2 (0.35)

AE=adverse event; PY=patient years.
[a]Events occurred from the date of the first dose of Study 1145 anifrolumab until the last dose date plus 85 days.

Table. Percentages of patients with AEs during anifrolumab treatment in the first year of Study 1145 and exposure-adjusted rates of serious AEs and AEs of special interest per 100 PY throughout Study 1145

serious AEs were SLE flares and pneumonia (each 0.70 per 100 PY). The most common AE of special interest was herpes zoster (1.92 per 100 PY). There was 1 death due to pneumonia. Two of 218 patients were anti-drug antibody positive at any time during treatment (both persistently positive). Sustained improvement of the SLEDAI-2K was observed through the end of treatment (mean change –2.1 [SD=3.5] from baseline to Week 160; **Figure 1**). Short Form 36 Health Survey physical and mental component scores showed similar patterns of sustained improvement. SLICC Damage Index generally remained stable over time (mean change 0.1 [SD=0.6] from baseline to Week 168). Neutralization of type I IFN gene signature (IFNGS) expression was rapid and sustained in patients with high baseline IFNGS (**Figure 2**). C3, C4, and anti-dsDNA showed numeric trends toward sustained improvement.

Conclusion: Long-term anifrolumab treatment for up to 3 years was generally safe and well tolerated. The safety profile was consistent with the 52-week Study 1013. Disease activity, HRQoL, and SLE-related serology showed sustained improvement.

Factors Associated with Hydroxychloroquine Use in Systemic Lupus Erythematosus Patients with End Stage Renal Disease

Maria Salgado Guerrero,[1] Alejandra Londono Jimenez,[2] Chrisanna Dobrowolsky,[2] Shudan Wang,[2] Wenzhu B. Mowrey,[3] and Anna Broder[2], [1]Internal Medicine, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY, [2]Rheumatology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) use in SLE has been associated with a lower risk of end-organ damage, SLE flares, and thrombosis[1,2]. However the benefits of HCQ among SLE with end stage renal disease (ESRD) are less clear[3]. Despite HCQ benefits, fewer than 30% of SLE continue HCQ after ESRD onset[3]. On the other hand, there is an increased risk of HCQ toxicity among SLE-ESRD[4]. It has not been studied what factors are associated with HCQ use after ESRD. Understanding these factors may inform future studies assessing the safety and efficacy of HCQ in SLE-ESRD and address the "confounding by-indication" bias (i.e. different treatments are intentionally chosen for patients with different prognoses) when analyzing retrospective data regarding HCQ use in SLE patients with ESRD. Therefore, the objective of this study was to determine the factors associated with HCQ use among SLE patients with ESRD.

Methods: We performed a retrospective chart review of SLE patients with ESRD at a single tertiary care center between 2010-2017. All included patients met ACR and/or SLICC criteria for SLE and had at least one visit with rheumatology, nephrology, dermatology or primary care, before and after the development of ESRD. SLE-related symptoms, serologic markers of disease activity, and rheumatology visits were identified, both pre- and post-ESRD onset. Transplanted patients were excluded at the time of their first renal transplant.

Results: A total of 69 patients were included, 58 had pre-ESRD data. Of these patients, 33/58 (57%) were taking HCQ prior to ESRD onset. Following the diagnosis of ESRD, 40/69 (58%) were prescribed HCQ within six months after ESRD onset. Of these, six discontinued HCQ by the last documented visit, and one patient initiated HCQ six months after ESRD onset (prescribed by a rheumatologist). At the last documented visit, 35/69 patients (51%) had an active HCQ prescription. Patients taking HCQ were younger, more likely to be followed by a rheumatologist, had a higher frequency of documented arthritis, higher frequency of corticosteroid use and immunosuppressive medication use (Table 1). A history of oral ulcers, cytopenias, and elevated levels of dsDNA at any point (either pre or post-ESRD onset) was not significantly associated with HCQ use at the last visit.

Conclusion: HCQ is more likely to be continued among patients with signs of persistently active SLE. HCQ was more likely to be prescribed by a rheumatologist and was associated with the presence of arthritis. None of the se-

rology markers of disease activity were associated with HCQ prescription. Limited systemic evaluation and/or documentation by the different providers may have resulted in under-recognition and under-reporting of some of the SLE symptoms. However, these findings reflect the "real-world" experience with HCQ use after ESRD in a large tertiary care center.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: chievement of renal remission has been the target of the induction therapy in patients with active lupus nephritis (LN). Deep remission (DR) defined as the reduction of urine protein Cr ratio (UPCR) to 0.15 g/gCr was reported to reduce renal flare. However, the utility and associated factors of DR are not clearly evaluated enough. We herein evaluated the characteristics of the patients with DR.

Table.1 Clinical characteristics associated with achievement of deep remission within 12 months after starting induction therapy.

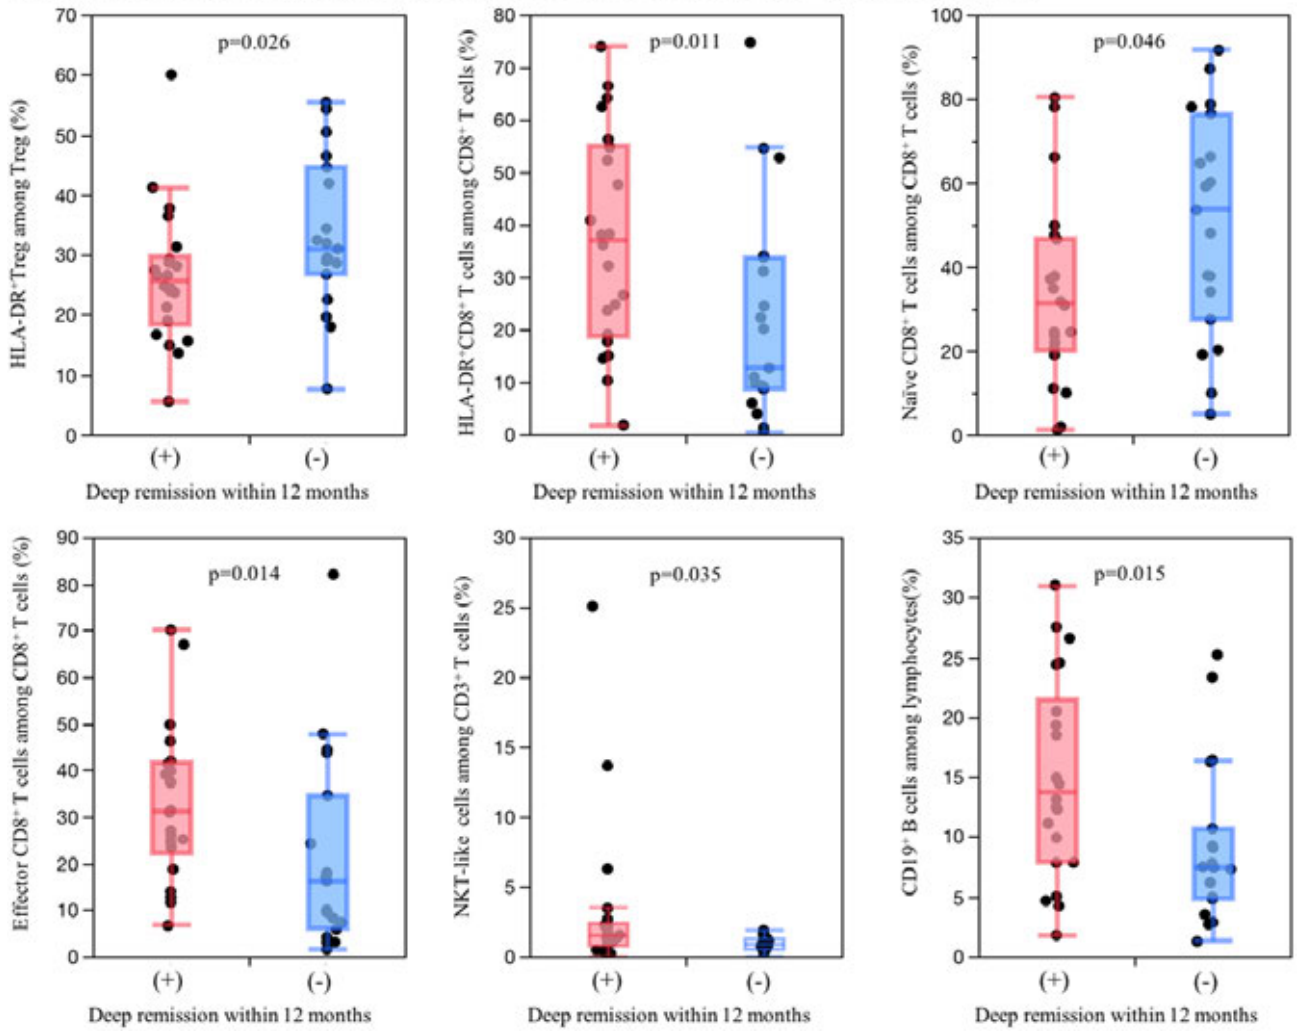
Cut-off for significance was p-value <0.05. Wilcoxon's test and Pearson's test were used for numerical and categorical analysis, respectively.

Figure 1. The significantly different proportions of peripheral immune cells between the patients achieving deep remission during 12 months after induction therapy and those without. Cut-off for significance was p-value <0.05 (Wilcoxon's test).



Methods: We enrolled the patients with active LN who started induction therapy from February 2015 to February 2018 in our hospital and were followed for more than 12 months. We prospectively assessed the achievement of complete renal response (CR), defined as stabilization (within 25%) in serum Cr with reduction of UPCR to 0.5 g/gCr, and DR. Standardized peripheral immunophenotyping by flowcytometry was analyzed with whole blood samples from all patients before starting induction therapy. Finally, we assessed a renal flare and the progression of damage accrual with SLICC-damage index (SDI) and the associations with achievement of DR.

Results: Forty-one patients were enrolled. Mean initial dose of prednisolone was 0.89 ± 0.24 mg/kg/day with 39.0% of intravenous cyclophosphamide, 41.5% of mycophenolate mofetil, and 17.1% of tacrolimus. Mean observational period was 31.3 ± 11.3 months. CR was achieved in 31 (75.6%) patients within 6 months and 33 (80.5%) within 12 months after starting induction therapy. DR was achieved in 15 (36.6%) and 22 (53.7%) within 6 and 12 months, respectively. Five (12.2%) patients had renal proteinuric flare, and no patient achieving DR had experienced it during observational periods. Increase in SDI was observed in 17.1% of patients. Especially, DR within 12 months was significantly associated with no progression of SDI (p=0.022). In addition, UPCR at final visit was significantly lower

in patients with DR ($p< 0.001$). Patients with DR within 12 months had a higher titer of SLEDAI score ($p=0.033$) and higher prevalence of co-existing musculoskeletal manifestation ($p< 0.001$) at baseline. The proportions of HLA-DR$^+$ Treg ($CD3^+CD4^+CD25^+CD127^{low}$) and naïve $CD8^+$ T cells ($CD3^+CD8^+CD45RA^+CCR7^+$) were lower and the proportions of $CD19^+$ B cells, HLA-DR$^+$ $CD8^+$ T cells, effector $CD8^+$ T cells ($CD3^+CD8^+CD45RA^+CCR7^-$), and NKT-like cells ($CD3^+CD19^-CD56^+\gamma\delta TCR^-$) were significantly higher in patients with DR than those without.

Conclusion: Achievement of DR within 12 months after induction therapy was associated with reduction in damage accrual in patients with active LN, which indicated DR can be a selected target of the treatment. Higher disease activity score and the proportions of peripheral Treg, $CD8^+$ T cells, and NKT-like cells at baseline might be surrogate markers for achievement of DR.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The impact of glucocorticoid (GC) use on major organ damage in SLE patients has not been formally studied by amalgamating the relevant data published in the literature over the past 40 years. We aimed to study the association between GC use and the occurrence of major organ damage in SLE patients by performing meta-analyses of observational studies published between 1970 and December 2018.

Methods: Literature search on PubMed (from 1966 to December 2018) for prevalence and longitudinal studies which reported GC exposure (proportion of GC users in the cohort [%GC use] and/or GC use in defined doses) and the occurrence (prevalence/incidence) of major organ damage in SLE patients using the keywords “cataract”, “cerebrovascular” (CVA), “stroke”, “cardiovascular” (CVS), “angina”, “myocardial infarction” (MI), “coronary artery bypass”, “osteoporosis”, “avascular necrosis” (AVN) and “osteonecrosis” in respective combinations with “lupus” was conducted. Studies with sample size < 50 and observation duration < 12 months were excluded. The logit of the proportion of patients with disease damage was modelled as a random effect in the meta-analysis, which was employed to study the association between the proportion of patients with organ damage and variables of GC use (mean daily [mg/day] and cumulative [gm] prednisone [PDN] doses and %GC use). A 2-stage estimation of the random-effects logistic

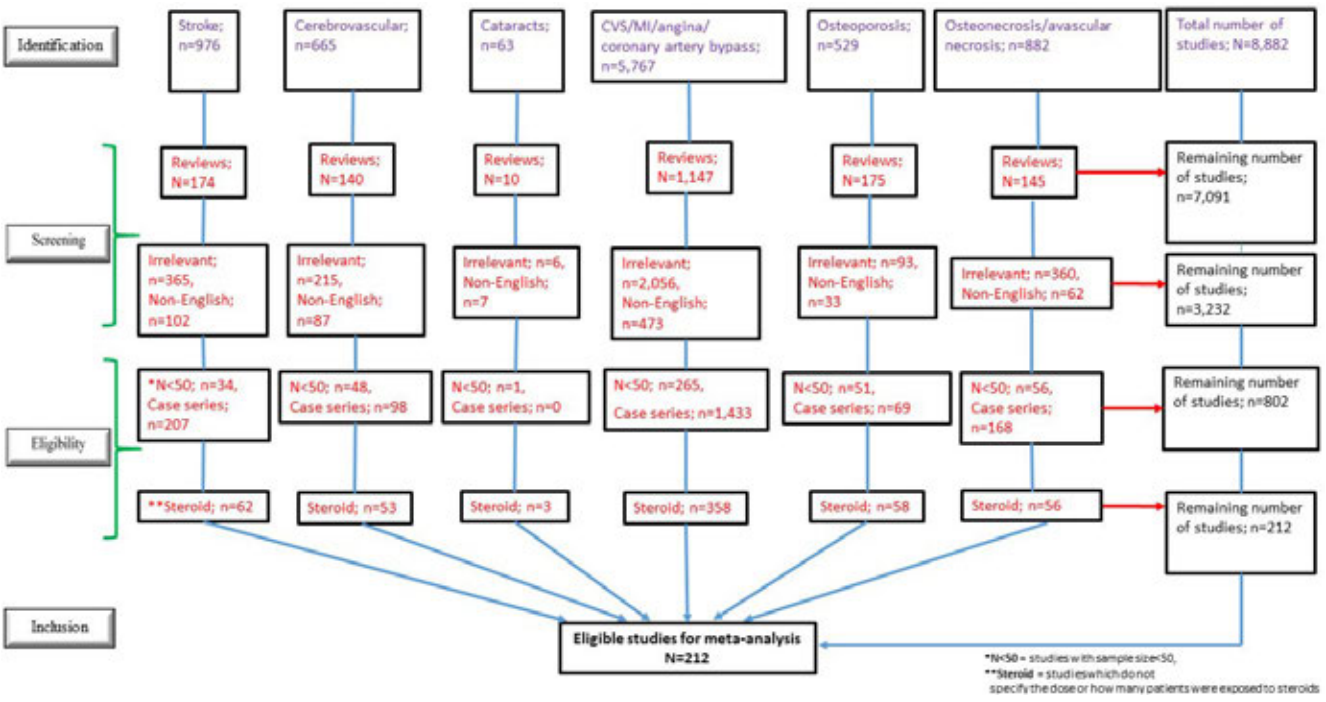

Figure 1. Result of literature search

regression models was used with restricted maximum likelihood estimation. Univariate associations between organ damage and moderators were examined for statistical significance, and variables related to GC use were adjusted for SLE disease duration in multivariate models if their univariate P values were < 0.2.

Results: Out of 8,882 publications screened, 212 articles involving 205,619 SLE patients were eligible for the meta-analyses (Figure 1), of which 97 were prevalence and 115 were longitudinal studies. Univariate analyses of prevalence studies revealed that mean daily PDN dose (odds ratio [OR]=1.10, p=0.007) and lower proportion of female in the cohort (OR=0.002, p=0.002) were associated with the prevalence of overall CVS events. Mean daily PDN dose (OR=1.52, p< 0.001) and %GC use (OR=2,255.2, p< 0.001) were associated with the prevalence of AVN. A significant association between cumulative PDN dose and prevalence of CVA was found after multivariate adjustment for SLE disease duration (OR=1.07, p=0.017). In longitudinal studies, a significant association was identified between cumulative PDN dose and incidence of cataracts after adjustment for SLE disease duration (OR=1.04, p=0.013). While the incidence of MI in SLE patients has dropped over the past 40 years (OR=0.94, p=0.002), it was associated with % GC use after adjustment for SLE disease duration (OR=8.18, p=0.012). Interestingly, significant univariate associations were found between antimalarial use and lower prevalence of MI (OR=0.05, p=0.002) and lower incidence of CVA (OR=0.20, p=0.032).

Conclusion: Independent of SLE disease duration, cumulative PDN dose was associated with higher prevalence of CVA and incidence of cataracts, and higher incidence of MI was associated with overall GC use.

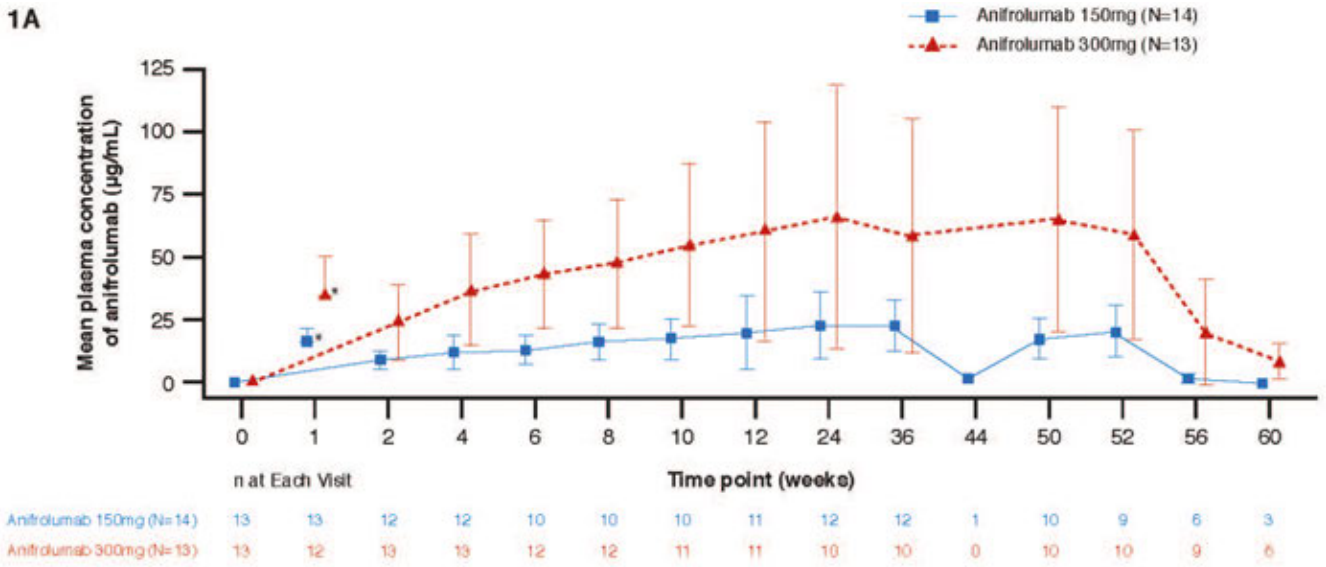
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anifrolumab, a fully human anti–IFN Type I receptor mAb, is under investigation for the treatment of SLE at a dose of 300 mg intravenously (IV) once every 4 weeks (Q4W), as added to Standard of Care (SOC) therapy. As subcutaneous (SC) administration may offer a greater treatment convenience and accessibility for patients, we evaluated the PK, PD, safety, tolerability, and efficacy of SC anifrolumab, when added to SOC in adults with Type I IFN test-high SLE and active skin disease.

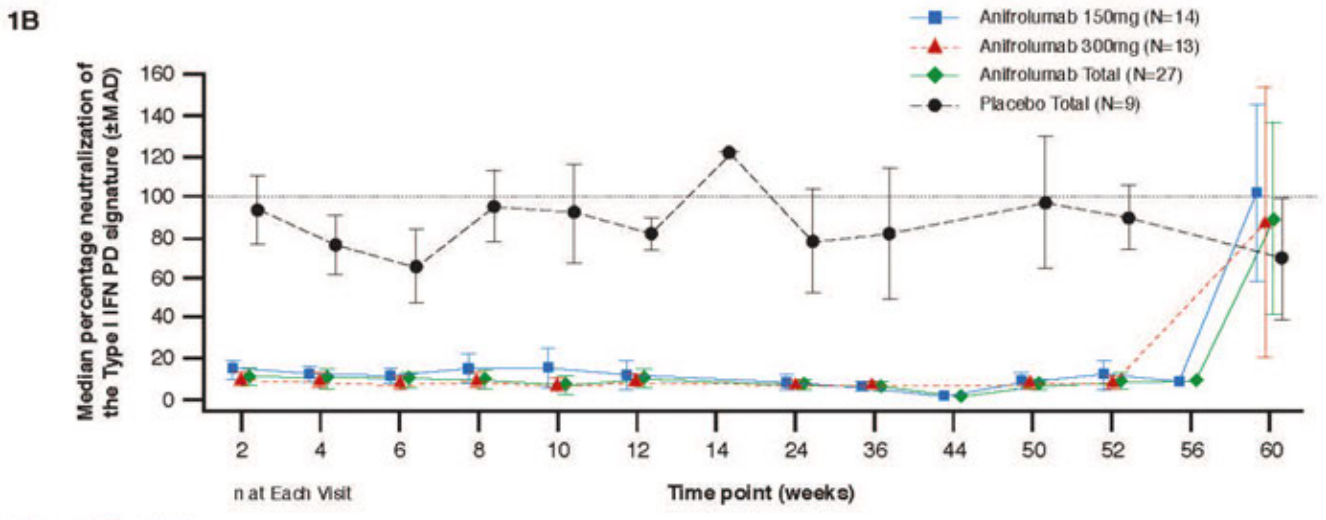
Methods: Patients (all fulfilling 1997 ACR SLE criteria) were randomized to the following, added to SOC, for up to 52 weeks (followed by an 8-week follow-up period): anifrolumab 150 mg, anifrolumab 300 mg or corresponding placebo, all SC Q2W (NCT02962960). Primary endpoints: PK (concentration of anifrolumab) and PD (Type I IFN gene suppression) at Week 12. Secondary endpoints: safety, tolerability and immunogenicity of anifrolumab over 52 weeks. Exploratory endpoint: efficacy of SC anifrolumab on active SLE skin disease using change from baseline in Cutaneous Lupus erythematosus disease Area and Severity Index (CLASI) activity score.

Results: Patients (anifrolumab 150 mg [n=14], 300 mg [n=13], placebo [n=9]), were Caucasian (77.8%) or Asian (22.2%); mean age 44.9 years; 89% female; 94% ANA positive; and 64% anti-dsDNA positive. Low C3 or C4 was observed in 53% and 36% of patients, respectively. Baseline mean CLASI and mean total SLEDAI-2K scores were 15.5 and 9.6, respectively. The baseline mean OCS dose differed between treatment groups: 8.2 mg/day prednisone or equivalent for combined anifrolumab groups and 10.3 mg/day for placebo group. The majority (75%) were on stable anti-malarial therapy.

Anifrolumab exhibited nonlinear PK where trough concentration increases were more than dose-proportional (Figure 1A). At Week 12, the median percentage neutralization of the Type I IFN PD signature was 88.0%, 90.7% and 18.5% in the anifrolumab 150 mg, 300 mg, and placebo groups, respectively; suppression was sustained over the 52-week treatment period (Figure 1B). At Week 12, a ≥75% neutralization of the Type I IFN PD signature was observed in 66.7%, 76.9%, and 11.1% of patients in the anifrolumab 150 mg, 300 mg and placebo groups, respectively. Over 52 weeks, 85.2% (combined anifrolumab) and 77.8% (placebo) of patients experienced ≥1 AE (Table 1). Ten SAEs were reported in 6 patients, all in anifrolumab groups (Table 1). The most commonly reported AEs across all treatment groups were upper respiratory tract infection, nasopharyngitis, bronchitis and headache. Anifrolumab exhibited low immunogenicity, with ADA detected post-baseline in only 2 patients and in low titers. No injection site reactions were reported. Greater reductions in CLASI activity score were observed at Week 52 in the anifrolumab 150 mg and 300 mg groups, vs. placebo (–10.2 and –13.2, vs. –6.3, respectively) (Figure 2).

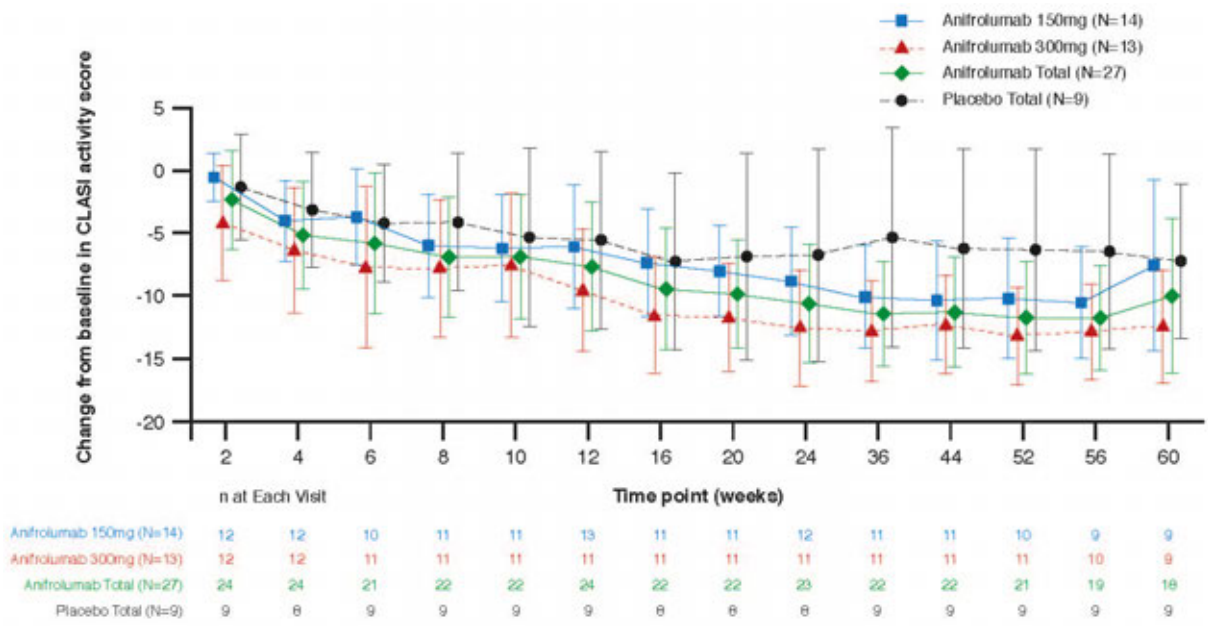


*Mean plasma concentration of anifrolumab was measured post-dose at Week 1. All other measurements were pre-dose.
N Number of patients in treatment group. n Number of patients at each visit. Number of patients with readings above the LLOQ was equal to n at each visit.
Serum concentrations below LLOQ prior to the first quantifiable concentration are set to a value of LLOQ/2.
Early discontinuation visits are mapped to the visit windows they were collected in.
LLOQ, lower limit of quantification.



N number of patients in treatment group. n number of patients at each visit.
The precision bars are ± MAD.
Median percentage neutralization represents the IFN21 PD signature score at post-dose time points relative to baseline values normalized to 100%.
MAD, median absolute deviation; IFN, interferon; % TM, percent target modulation.

Figure 1. A) Mean plasma concentration of anifrolumab versus time (Linear scale; PK analysis set); B) Median percent suppression of Type I IFN over time (PD analysis set)



N Number of patients in treatment group. n Number of patients at each visit.
The precision bars are ± SD.
CLASI, Cutaneous Lupus erythematosus disease Area and Severity Index; SD, standard deviation.

Figure 2. Mean change in CLASI Activity Score over time by treatment group (Full analysis set)

Conclusion: The observed PK/PD profile of SC anifrolumab was consistent with previous studies using IV administration. In addition, SC anifrolumab showed low immunogenicity and an acceptable safety and tolerability profile, similar to previous, larger IV studies in SLE. These findings support further development of SC anifrolumab as a treatment for SLE.

Adherence to Hydroxychloroquine Influences the Incidence of Organ Damage During Follow-up in Patients with Systemic Lupus Erythematosus

Ji-Hyoun Kang,[1] Seong-Eun Choi,[1] Haimuzi Xu,[1] Dong-Jin Park,[1] and Shin-Seok Lee[2], [1]Chonnam National University Medical School & Hospital, Gwangju, Republic of Korea, [2]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a cornerstone drug in patients with systemic lupus erythematosus (SLE), decreasing the risk of flares and comorbidities and improving survival. This study investigated the effects of HCQ adherence on clinical manifestations, disease activity, and organ damage in Korean patients with SLE.

Methods: Data on 299 SLE patients were obtained from the Korean Lupus Network registry. Demographic variables, clinical manifestations, laboratory findings, PGA, and SLEDAI-2000 and SLICC damage index scores were recorded at the time of enrollment and repeated annually for 4 consecutive years. Patients were divided into two groups according to the level of HCQ adherence. Adherence was defined by the medication possession ratio and dichotomized as ≤ 80% vs. > 80%. Univariate and multivariate analyses were performed to assess the impact of adherence to HCQ on clinical outcomes.

Results: Of the 299 patients, 31 (10.4%) showed poor drug adherence during the follow-up period. Patients with poor HCQ adherence were older (P=0.011), less insured (P=0.024), experienced lower employment (P=0.033), and had a higher rate of comorbidities such as hypertension (P=0.048) and depression (P< 0.001). The non-adherent group had higher mean and changed SLICC damage index scores than the adherent group across all 4 years. In the multivariate analysis, HCQ non-adherence was significantly associated with older age (OR, 1.043; 95% CI, 1.006–1.081; P=0.021), depression (OR, 11.98; 95% CI, 1.099–130.6; P=0.042), and an annual increase in the SLICC damage index score (OR, 2.275; 95% CI, 1.369–3.779; P=0.002).

Conclusion: HCQ adherence might be influenced by age and depressive mood. Additionally, the poor adherence to HCQ in SLE patients was correlated with higher cumulative organ damage. Therefore, patients with SLE should be educated to take HCQ appropriately to improve their clinical outcome in clinical practice.

Abstract Number: 2565

Pharmacokinetics and Exposure-response of Intravenous Belimumab in Children with Systemic Lupus Erythematosus

Richard Dimelow,[1] **Beulah Ji**,[2] and Herbert Struemper[3], [1]GSK, Stevenage, United Kingdom, [2]GSK, Uxbridge, Middlesex, United Kingdom, [3]GSK, Research Triangle Park

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab is approved in adults with active SLE and for childhood-onset SLE (cSLE). PLUTO, a Phase 2, placebo-controlled, double-blind trial (114055; NCT01649765), was the first study of belimumab in cSLE. Efficacy, safety, and pharmacokinetics (PK) of intravenous (IV) belimumab 10 mg/kg, plus standard therapy were evaluated. Pediatric and adult belimumab exposures were compared.

Methods: Patients with cSLE, 5–17 years of age, who were randomized to belimumab 10 mg/kg IV every 4 weeks, and for whom ≥1 PK sample was obtained, were included. Patients were required to have active SLE according to ACR classification criteria. A linear 2-compartment population PK model with first-order elimination described the pharmacokinetics of the population. An exploratory *post hoc* exposure-response analysis assessed the impact of between-patient exposure variability on clinical response (SLE Responder Index 4 [SRI4]) at Week 52, and the occurrence of a serious adverse event (SAE) at any time during the study.

Results: Data for 53 belimumab-treated patients were analyzed. Following three biweekly loading doses on Days 0, 14, and 28, belimumab pre-infusion (C_{min}) and post-infusion (C_{max}) concentrations reached steady-state levels over 8 weeks of treatment and were maintained over the 52-week treatment period for all cohorts. Week 24 C_{max} and Week 52 C_{min} values were consistent across cohorts, with a trend towards slightly higher exposure in the older versus younger age group (**Table**). The population PK model estimated a clearance of 158 mL/day, a steady-state volume of distribution of 3.5 L, a terminal half-life of 16.3 days, and a distribution half-life of 0.8 days in the overall population. Body size dependence was defined by the fat-free mass, a pharmacokinetically relevant covariate of clearance, and volume of distribution. Baseline white blood cell count on the central volume of distribution, and baseline IgG, proteinuria, and estimated glomerular filtration rate on central clearance, were also relevant covariates, although their relative influence on PK was smaller. After accounting for body size, age had no statistically significant effect on clearance. Individual and median steady-state pediatric PK profiles were similar to adult profiles[1] (**Figure**). At Week 52, SRI responders (n=28) had similar exposures to non-responders (n=25); median (interquartile range [IQR]) concentrations were 116 [96–140] µg/mL and 109 [88–134] µg/mL, respectively) and variability in exposures of both groups overlapped. Patients who experienced a SAE (n=9) had similar exposures to those who did not (n=44) (median [IQR] 128 [108–161] µg/mL and 110 [86–136] µg/mL, respectively).

Conclusion: Exposure estimates for belimumab 10 mg/kg IV in the pediatric population were consistent with adult exposures. No clinically meaningful correlations between exposure parameters and efficacy or safety were iden-

	Cohorts 1 and 3 (12–17 years of age) (n=43)	Cohort 2 (5–11 years of age) (n=10)

Polypharmacy and Potentially Inappropriate Medication Use in Young versus Older Adults with SLE

Dale Seguin,[1] Christine Peschken,[2] Casandra Dolovich,[1] Ruby Grymonpre,[1] Phil St. John,[1] and Annaliese Tisseverasinghe[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]University of Manitoba, Winnipeg, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polypharmacy, typically defined as ≥ 5 medications (meds), is a strong risk factor for adverse clinical outcomes, including delirium, falls, hospitalization, and death, especially in older adults. Previously, we presented novel data on the prevalence and risk factors for polypharmacy and potentially inappropriate medications (PIMs), such as benzodiazepines and other sedative-hypnotics (BZD/Z-drugs), in older adults with SLE. In this study we evaluate and compare polypharmacy and PIM use in all adults with SLE. Specific aims: 1. Compare prevalence of polypharmacy [a) ≥5 and b) ≥10 meds] and PIM use [a) opioids, b) BZD/Z-drugs] between age groups (< 40 vs. ≥65,

< 40 vs. ≥40, and < 65 vs. ≥65 years). 2. Assess any association between polypharmacy, PIM use, and their potential risk factors, including age, sex, SLE duration, and rural residence.

Methods: Population: Adults aged ≥18 years meeting ACR/SLICC SLE criteria and seen in our rheumatology clinic < 2 years ago. For age < 50 years, every 3rd patient included. Patients lacking data in the Manitoba Drug Program Information Network (DPIN) were excluded. Procedures: All demographic and clinical variables were determined using data from electronic medical records. For unadjusted bi-variate analyses, we chose alpha of 5%. Multivariable logistic regression models were constructed with inclusion of explanatory variables based on a priori clinical reasoning rather than stepwise selection.

Results: 271 patients included: 92% female, 13% < 3y SLE duration, 40% rural, 68% on ≥5 and 31% on ≥10 meds, 28% on BZD/Z-drugs, and 24% on opioids (Table 1). Prevalence of polypharmacy (≥5 meds) rose with age group (< 40 vs. 40-64 vs. ≥65 years), and was higher in women, rural residents, and SLE duration ≥3 years. Observations on ≥10 meds were similar except that sex difference was reversed (with fewer men). Prevalence of BZD/Z-drugs increased with age, whereas opioid use peaked in 40-64 year-olds. Prevalence of BZD/Z-drugs was higher in women, but opioid use higher in men. Rural residents had higher prevalence of PIMs compared to urban dwellers. The proportion of patients on BZD/Z-drugs was increased with SLE duration ≥3 years. However, the null hypotheses that these inter-group differences are due to chance were not rejected based on our alpha (i.e. $p > 0.05$). In multivariable models, polypharmacy was associated with older age (OR 2.27, 95% CI 1.16-6.31 for ≥40 vs. < 40 years for ≥5 meds). Opioids and BZD/Z-drugs were associated with polypharmacy (any definition) [OR 7.90 (95% CI 3.02-20.67) and 6.05 (2.63-13.96), respectively, for ≥5 meds].

Conclusion: This is the first study to investigate the prevalence and potential risk factors of polypharmacy and PIMs in SLE patients, including young adults. According to this study, polypharmacy and PIM use are highly prevalent in SLE, and the prevalence of polypharmacy and BZD/Z-drugs appears to increase with age. Moreover, PIM use is strongly associated with polypharmacy, independent of other patient characteristics.

Our future goals are to include all eligible clinic patients in these analyses and to evaluate impact of polypharmacy and PIM use on SLE clinical outcomes.

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is the most well established therapy for SLE, as it provides several beneficial properties, such as favorable effects on lipid profile, reduced cardiovascular (CV) risk and reduction in flares. However, one of the main concerns about HCQ use is retinopathy. In this regard, the American Academy

	Before AAO dose reduction	After AAO dose reduction	p
Total cholesterol (mg/dL)	165 (90-343)	163 (111-264)	0.471
> 200 mg/dL	9 (17)	10 (19)	0.800
HDL (mg/dL)	55 (23-95)	50 (16-102)	0.240
< 40 mg/dL	9 (17)	10 (19)	0.800
LDL (mg/dL)	88 (14-224)	89 (40-158)	0.992
> 130 mg/dL	4 (7)	8 (15)	0.359

Lipid-lowering drugs	9 (16)	10 (17)	0.802

Results are expressed in median (minimum-maximum) and n (%).

Table 1. Lipoprotein and glycemia levels, and frequencies of lipoprotein high cardiovascular risk in 53 patients with lupus nephritis before (retrospective evaluation) versus after hydroxychloroquine American Academy of Ophthalmology (AAO) dose reduction (end of prospective analysis)

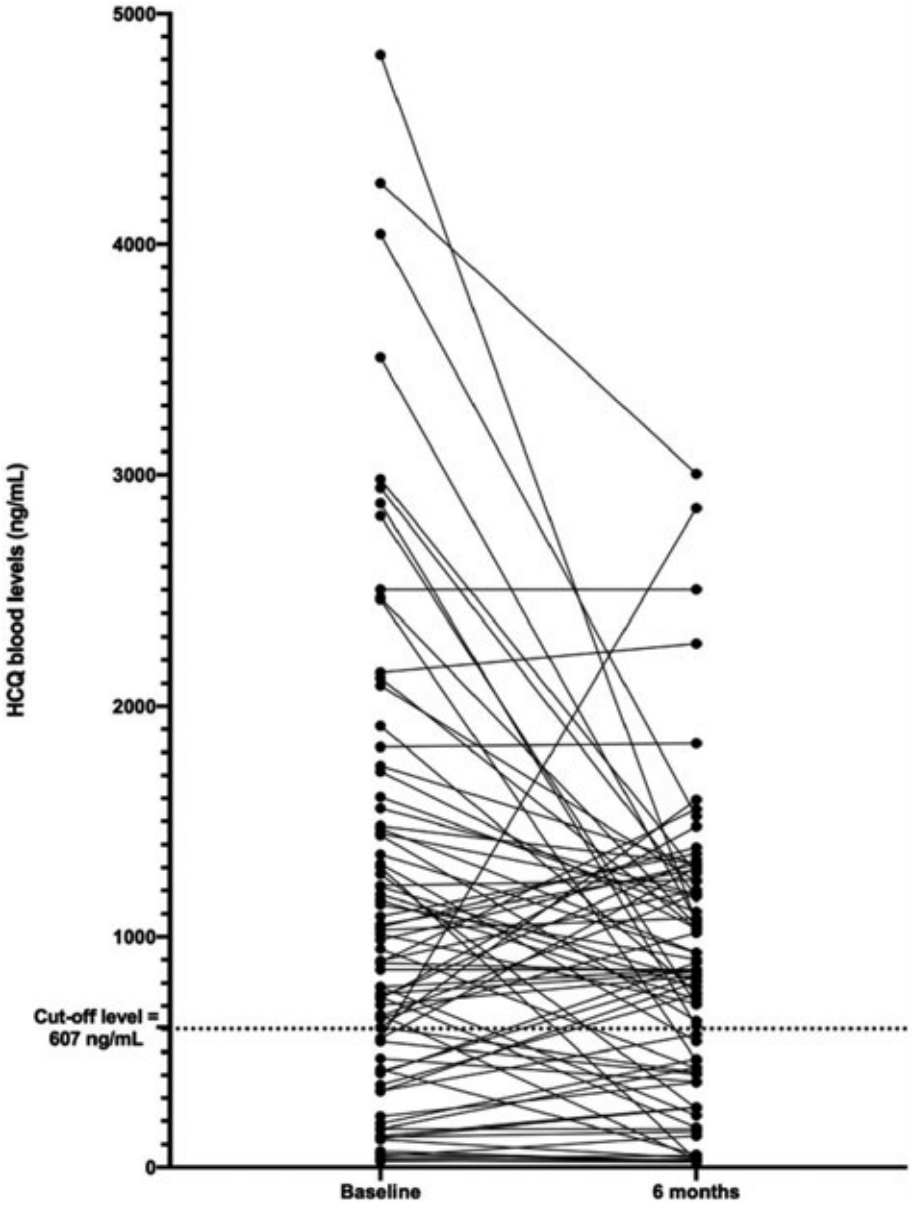

Figure 1. Prospective evaluation of hydroxychloroquine blood levels at baseline and after 6 months in lupus nephritis patients. The dotted line indicates blood HCQ cut-off level for disease flare.

of Ophthalmology (AAO) recently recommended the maximum daily dose of 5.0 mg/kg of real weight but this recommendation is only focused on retinal safety and there are no data evaluating if reduced doses would sustain the beneficial effects of this drug with regard to lipid profile and flare rates. Therefore, the aim of this study was to prospectively assess lipid profile and flare rate in high-risk retinopathy stable LN patients using low dose HCQ AAO recommendation.

Methods: Eighty-two stable LN patients (6-months before entry), ≥5 years of HCQ were evaluated at entry and after 6-months (6M). None of them had retinopathy (spectral-domain optical coherence tomography). HCQ blood levels were determined by liquid chromatography-mass spectrometry. Fasting lipoproteins/blood glucose levels were determined et entry and 6M. Flare was defined as increase in SLEDAI-2K≥3 and/or change in therapy. We also evaluated retrospectively lipid profile, high CV risk and flare rates before HCQ dose reduction according to AAO and compared to the same patients at the end of prospective analysis.

Results: Total/LDL/HDL cholesterol and triglyceride levels remained stable throughout the study (p >0.05) and no significant differences were observed in frequencies of high CV risk levels (p >0.05). Nine of 82 LN patients (10.97%) had flare during the 6-months follow-up. HCQ blood levels were significantly lower in patients with compared to those without flare [220.4(32.1-1471.7) vs. 986.6(26.1-4265.0)ng/mL, p=0.015]. Comparisons of other baseline characteristics demonstrated similar demographic data, disease parameters and concomitant treatment of LN patients with and without flare. An HCQ blood level cut-off of 607ng/ml was a predictor of 6-months flare [OR=5.67, 95%CI 1.34-24.03; sensitivity 78%, specificity 71%, p=0.002). Of note, retrospective analysis revealed comparable lipoprotein and glycemia levels as well as, frequencies of high CV risk and flare rates (9% vs. 10%, p=0.751) before and after AAO dose reduction (Table 1). HCQ blood levels were classified in low (< 607 ng/mL) or adequate (≥607 ng/mL) according to the cut-off level. At 6M evaluation, blood HCQ levels remained within the same range in 67 patients (82%), whereas it turned from low to adequate in six and from adequate to low in nine patients (McNemar's test, p= 0.606) (Figure 1).

Conclusion: We provide novel evidence that AAO HCQ low dose recommendation in stable LN patients with high-risk retinopathy is not associated with a deleterious effect on lipid profile or increased flare rates. This finding supports the notion that this new regimen retains the beneficial effect of HCQ with the advantage of a lower long-term cumulative dose and toxicity.

Iguratimod Is an Alternative Option for Refractory Lupus Nephritis: A Preliminary Observational Study

Qingran Yan,[1] Chunde Bao,[2] Yuening Kang,[1] Qiong Fu,[1] and Ran Wang[1], [1]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of medicine, Shanghai, China (People's Republic), [2]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of medicine, Shanghai, Shanghai, China (People's Republic)

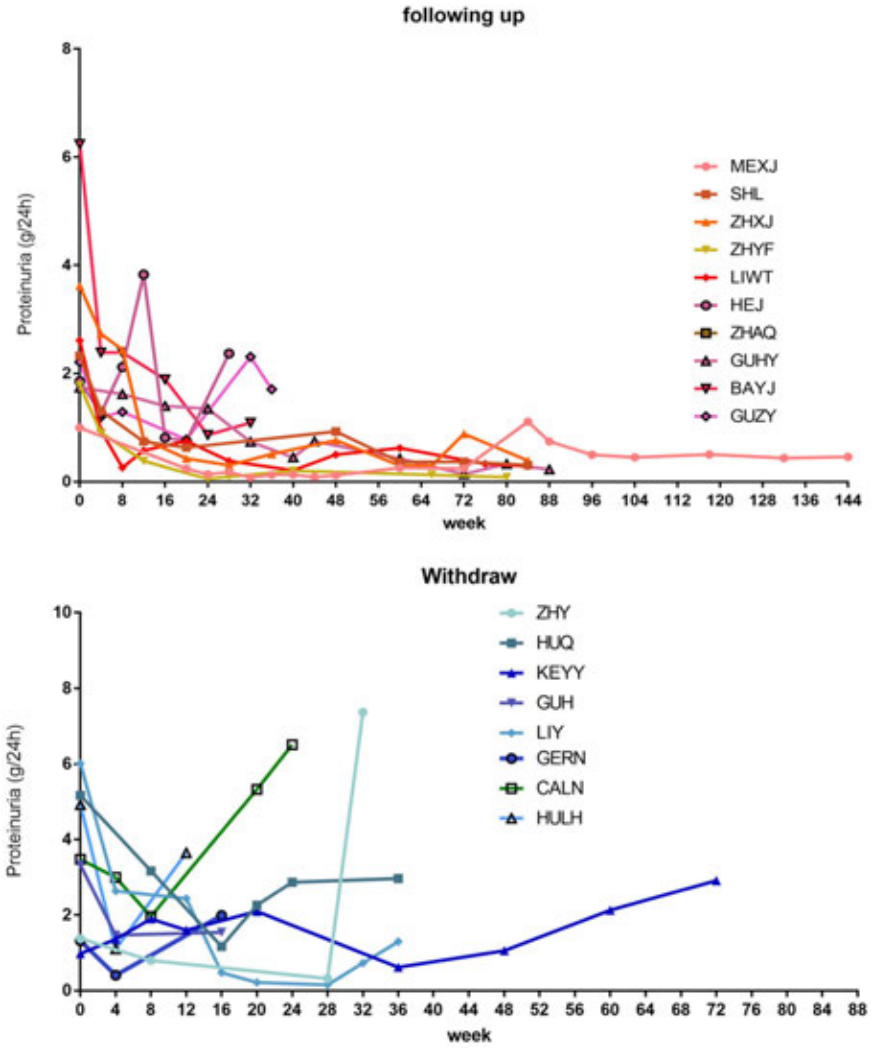
SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM



The 24h total proteinuria of each patient.

Background/Purpose: Despite significant advances in the management of patients with lupus nephritis (LN), a significant proportion of patients either do not respond to first-line immunosuppressive drugs, or relapse after initial remission. Iguratimod is a novel disease modifying anti-rheumatic drug that has been approved for treating rheumatoid arthritis in East Asia and has shown benefits in lupus animal model in our previous research. The aim of this study was to make a preliminary observation on the efficacy and safety of iguratimod in treating refractory LN patients.

Methods: We have enrolled adult refractory LN patients since 2015, who were eligible if they experienced at least two times of failure or relapse before enrollment. Failure was defined as no response to one certain immunosuppressive drug for at least six months. After enrollment, we simply switched their previous immunosuppressant to iguratimod (25 mg twice per day) and keeping all other medications. Complete/partial remission (PR/CR) at Week 24 was used as the primary outcome. An extended follow-up would continue once the patient achieved remission.

Results: A total of 20 refractory LN patients had been enrolled (18 female and 2 male patients) since 2015. At enrollment, the median proteinuria was 2.59g/24h (interquartile range, IQR: 1.52-4.92g/24h). None of them had observable

extra-renal symptoms. All of them had biopsy-proven LN (class III/IV/V) and two patients agreed repeated biopsy before switching to iguratimod. The median prednisone dosage was 10mg/d (IQR: 0-10mg/d). One withdrew the consents. Of the remaining 19 patients, the renal response rate was 84.2% at week 24. The median response duration (MRD) was 12 weeks and the IQR was 10-18 weeks. In follow-up of the 16 remitted patients, 25% (4/16) patients had renal relapse (median relapse duration: 32 weeks) and 4 patients exited the study for other reasons (one had extra-renal flare, one had severe adverse event, one lost of follow-up another was for incompliance). For the remaining 9 patients who were still in follow-up, the median follow-up was 84 weeks (IQR: 42-118 weeks), with 4 having CR and 5 PR.

Conclusion: Out study provided preliminary but promising clinical evidence for iguratimod in treating refractory LN patients. A large randomized clinical trial is needed to establish its safety and efficacy for refractory LN.

Guidelines/ Recommendations	Maximum HCQ and CQ doses	Frequency of Screening	Method of Screening
American Academy of Ophthalmology (2002)	HCQ: <6.5 mg/kg/day CQ: <3 mg/kg/day	• Baseline ophthalmology exam • Screening q2-4 years, annually after 5 years • Annual screening in patients with risk factors	• Visual acuity • Dilated cornea and retina exam • Amsler grid or Humphrey 10-2 VF • Optional: colour testing, fundus photography, mfERG
American Academy of Ophthalmology (2011)	HCQ: ≤400 mg/day or 6.5 mg/kg/day using ideal body weight (IBW) if short stature CQ: ≤250 mg/day or 3 mg/kg/day using IBW if short stature	• Baseline ophthalmology exam • Annual exam after 5 years • Annual screening in patients with risk factors	• Dilated retinal exam • VF with white 10-2 automated threshold testing • If available, one objective test: SD-OCT, mfERG or FAF
American Academy of Ophthalmology (2016)	**HCQ: ≤5.0 mg/kg/day using real weight CQ: ≤2.3 mg/kg/day using real weight**	**• Baseline ophthalmology exam • Annual exam after 5 years • Annual screening in patients with risk factors**	**• Fundus evaluation of macula • 10-2 automated VF • SD-OCT • Optional: mfERG and FAF**
Royal College of Ophthalmologists (1998)	HCQ: ≤6.5 mg/kg/day using lean body weight	• Baseline and annual assessment of vision during rheumatology clinic visit • Optometry and/or ophthalmology referral if concerns, with further visits at their discretion	• Visual acuity using a reading chart in rheumatology clinic • Colour vision • VF using red pin and red Amsler grid • Cornea and retina exam
Royal College of Ophthalmologists (2009)	HCQ: ≤6.5 mg/kg/day using lean body weight	• Baseline and annual assessment of vision during rheumatology clinic visit • No systematic screening program recommended • Optometry and/or ophthalmology referral if concerns, with further visits at their discretion	• Visual acuity using a reading chart in rheumatology clinic • Colour vision • Central VF using Amsler Chart or Humphrey 10-2 protocol • Cornea and retina exam • Consider retinal photography, SD-OCT, FAF, and other imaging
Royal College of Ophthalmologists (2018)	**HCQ: <5 mg/kg/day using absolute body weight**	**• Baseline ophthalmology exam • Annual screening from initiation of CQ or if on HCQ with risk factors • Annual exam after 5 years of HCQ**	**• 10-2 Humphrey VF testing using white stimulus • Pupillary dilation exam • Both SD-OCT and FAF if available • If abnormalities on FAF with normal 10-2 VF test results, 30-2 visual field testing is warranted • mfERG if VF deficits and no other imaging abnormality**

Table 1. International Ophthalmology Guidelines on Antimalarial Use. HCQ: Hydroxychloroquine; CQ: Chloroquine; VF: Visual Fields; SD-OCT: Spectral-Domain Optical Coherence Tomography; mfERG: Multifocal Electroretinography; FAF: Fundus Autofluorescence

Recommendations	Maximum HCQ dose	Frequency of Screening	Method of Screening
American College of Rheumatology (2016)	≤5 mg/kg/day using real body weight	• Baseline ophthalmology exam • Annual screening in patients with risk factors • Annual screening after 5 years if no risk factors	• Dilated retina exam • Humphrey 10-2 automated VF test • If available, mfERG, SD-OCT, or FAF also recommended
CRA Consensus Conference (1998)	≤6.5 mg/kg/day using ideal body weight or real body weight, whichever is less	• Baseline ophthalmology exam • Follow-up every 12-18 months, more frequently if risk factors	• Fundoscopic examination of macula • Central 10-degree VF testing using manual or automated methods • Visual acuity • Colour vision • Slit lamp dilated pupil examination

Table 2. Recommendations from Rheumatology Associations. HCQ: Hydroxychloroquine; VF: Visual Fields; SD-OCT: Spectral-Domain Optical Coherence Tomography; mfERG: Multifocal Electroretinography; FAF: Fundus Autofluorescence

Methods: A literature search was conducted using Embase and Medline to identify guidelines published from 1946 to September 2018. MeSH terms were employed for the search strategy with alternative spelling and related words entered as keywords and separated by 'OR' to broaden results (Figure 1). The Embase and Medline strategies both contained the same sub-searches for antimalarials and retinal disease, however they differed in the use of MeSH terms pertaining to guidelines. In addition to reviewing all English search results, references of all articles were reviewed to retrieve additional guidelines.

Results: A total of 243 results were reviewed, after accounting for duplicates, to obtain 11 recommendations. The American Academy of Ophthalmology, Royal College of Ophthalmologists and Canadian editorials summarize ophthalmology recommendations. (Table 1) Rheumatology sources include American College of Rheumatology and Canadian Rheumatology Association statements. (Table 2) American and British guidelines changed from suggesting hydroxychloroquine doses ≤6.5 mg/kg/day to ≤5 mg/kg/day more recently. American guidelines recommended baseline visual field testing and annual screening after five years. Visual field testing evolved from using Amsler grids to current recommendations of 10-2 automated visual fields and spectral-domain optical coherence tomography (SD-OCT). The 2012 Canadian recommendations suggested initial field testing every two years, with SD-OCT after 10 years. Older British guidelines advocated for baseline and annual assessment with Amsler grids during rheumatology clinic visits. The 2018 British guidelines support baseline and annual screening after five years with 10-2 visual fields, SD-OCT and fundus autofluorescence.

Conclusion: The newest recommendations suggest a hydroxychloroquine dose of ≤5 mg/kg/day. Retinal toxicity is irreversible; and the risk increases over time on antimalarial therapy. Annual screening after five years of treatment with automated visual fields and SD-OCT seems to be warranted to detect early changes and discontinue therapy if necessary. It is uncertain whether the magnitude of retinal toxicity is increasing due to early detection with more sensitive tests or if newer recommendations are based on best evidence.

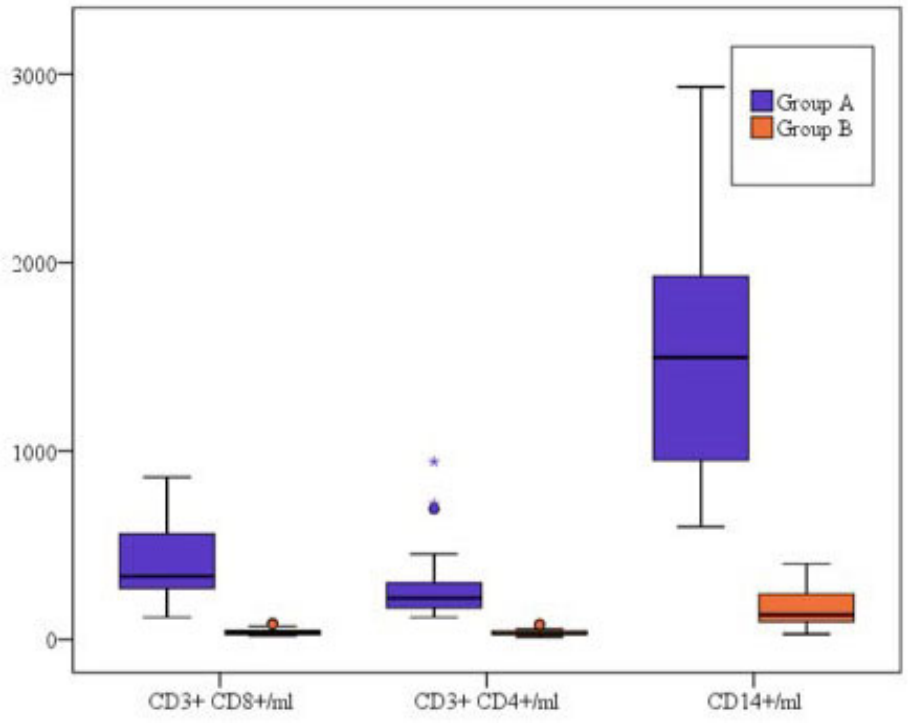
Urinary Cellular Profile as a Biomarker for Proliferative Lupus Nephritis

Amira El Gerby,[1] Abeer Abdelati,[2] Hanaa Donia,[3] and **Nouran Eshak** [4], [1]Rheumatology Department, Faculty of Medicine, Alexandria University, Egypt, Alexandria, Egypt, [2]alexandria university, alexandria, Egypt, [3]Clnical and Chemical Pathology Department, Faculty of Medicine, ALexandria University, Alexandria, Egypt, [4]Rheumatology Unit, Internal Medicine Department, Faculty of Medicine, Alexandria University, Lubbock, TX

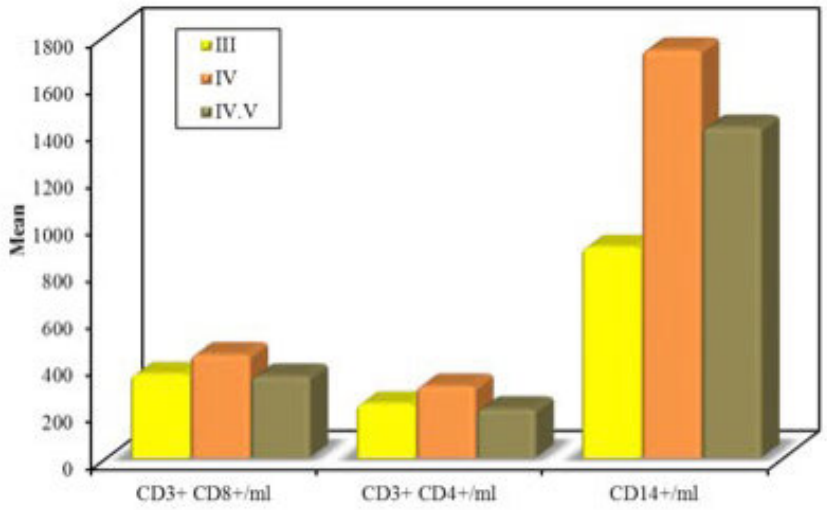
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Proliferative lupus nephritis (LN) is one of the most common and serious manifestations of SLE and is a major cause of morbidity. A search for the ideal biomarker for LN is still underway, one that can be used for early detection, and correlate with the class & activity of LN. Urine is normally devoid of leucocytes, however, it has been observed that macrophages and T-lymphocytes are routinely present in the urine of LN patients and those with other proliferative renal diseases.This provided the idea for their potential use as biomarkers for proliferative LN. The objective is to study the urinary CD4+, CD8+ T Lymphocytes, and CD14+ monocytes in patients with proliferative lupus nephritis, and explore their use as a biomarker for LN.

Methods: Our subjects included 30 patients with biopsy-proven proliferative LN (Group A) and 30 SLE patients without clinical or lab evidence of LN as controls (Group B). Laboratory investigations included serum creatinine, urine analysis, protein: creatinine ratio, anti-ds DNA Ab, C3 and C4. For the flow cytometric analysis, 100 ml of freshly voided urine in a sterile container were obtained from patients and controls. All samples were processed within 2-4 hours of collection to ensure viability of the cells. Urine mononuclear cell count was done using a hemocytometer. The urine



Comparison between the two groups according to CD3+ CD8+/ml, CD3+ CD4+/ml and CD14+/ml



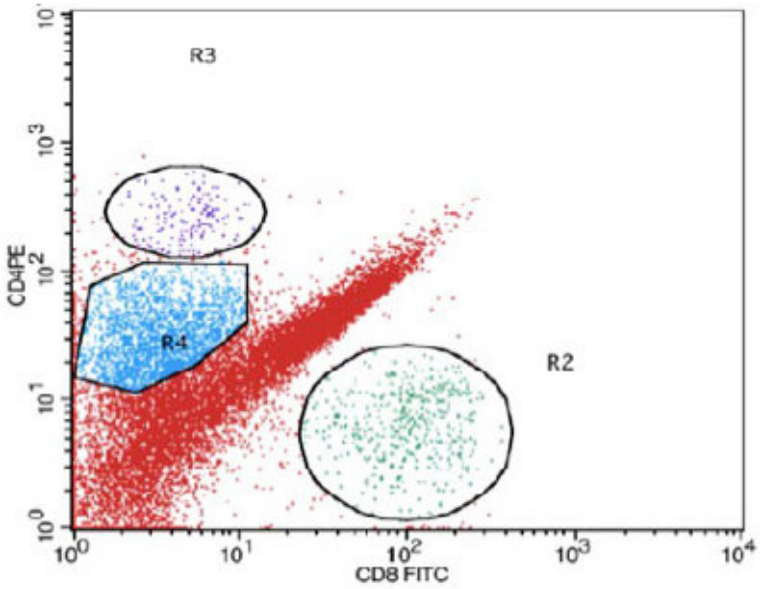
Comparison between the different classes of LN according to CD3+ CD8+/ml, CD3+ CD4+/ml and CD14+/ml.

samples were centrifuged then washed twice by phosphate-buffered saline/bovine serum albumin (PBS/BSA) & re-suspended in about 300 µls PBS. The cells were stained with anti CD8- FITC, anti CD4- PE, anti CD14-PERCP and anti- CD3-APC monoclonal antibodies. The flow cytometric analysis was done using Becton Dickinson, FACS Calibur multi-parameter flow cytometer equipped with BD CellQuest Pro software for data analysis.

Results: CD14 + cells were the most abundant cells in the urine of LN patients. The mean numbers of urinary CD8+, CD4+ and CD14+ cells/ml were significantly higher in patients with LN (405.6 ± 200.0, 281.1 ± 195.3, and 1554.7 ± 606.8 respectively) than in those without (39.30 ± 17.56, 34.33 ± 16.41, and 161.17 ± 90.91 respectively). AUC for ROC = 1.0 for all 3 markers with CD8+ >85 cells/ml, CD4+ >80 cells/ml, and CD14+ >400cells/ml being observed exclusively in LN.

The cell counts correlated significantly with the protein: creatinine ratio, but not with other markers of disease activity.

The CD4: CD8 ratio was significantly lower in LN patients (0.69 ± 0.21) than in those without (0.91 ± 0.31).



A dot plot of flow cytometric analysis of urinary T cells and monocytes in a patient with lupus nephritis showing increased both CD4+ and CD8+ T cells and macrophages (dim CD4 expression and CD14 positive (not shown))

Urinary CD14+ cells seem to occur in much higher counts in Class IV (1736.7 ± 522.0) than Class III LN (898.5 ± 17.68) p=0.084.

Conclusion: Urinary CD8+, CD4+, and CD14+ cells are highly sensitive and specific markers for detecting proliferative LN. A low CD4: CD8 ratio provides a further clue. The cell counts correlate with proteinuria. CD14 cell counts may be a potential biomarker to differentiate between the different classes of proliferative LN.

Early Improvement in SLEDAI-2K Responder Index-50 Predicts SRI-4 Response in a Randomized Placebo-Controlled Trial of Ustekinumab (UST) in Systemic Lupus Erythematosus

Zahi Touma,[1] Dafna Gladman,[2] Shawn Rose,[3] Kaiyin Fei,[3] Yun Gregan,[3] Robert Gordon,[3] Kim Hung Lo,[3] and Murray Urowitz[1], [1]University Health Network, University of Toronto, Toronto, ON, Canada, [2]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [3]Janssen Research & Development, LLC, Spring House, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While traditional Systemic Lupus Erythematosus (SLE) Disease Activity Index 2000 (SLEDAI-2K) scoring assesses complete SLE response for individual disease manifestations, the SLEDAI-2K Responder Index-50 (S2K RI-50) evaluates responses using partial improvement (≥50%) in each of the 9 organ systems of SLEDAI-2K. Ustekinumab (UST), a monoclonal antibody that targets the shared p40 subunit of the cytokines IL-12 & IL-23, is being investigated in patients with active SLE. We have previously shown in a Phase 2 placebo (PBO)-controlled trial of UST in SLE[1] that not only SLEDAI-2K and the SLE Responder Index 4 (SRI-4), but also S2K RI-50 can discriminate a treatment effect of UST vs PBO at week 24.[2,3] Here, we aimed to ascertain whether a minimal threshold of partial improvement in S2K RI-50 could be used as an early predictor of SRI-4 response.

Methods: This phase 2, PBO-controlled study enrolled adults with seropositive, active disease (SLEDAI score ≥6 with ≥1 BILAG A &/or ≥2 BILAG B scores) despite standard therapy. Patients (n=102) were randomized (3:2) to receive UST IV ~6 mg/kg or PBO at week 0, followed by SC injections of UST 90mg or PBO q8w beginning at week8, both added to standard of care. We calculated S2K RI-50 response through week 24 in all patients, including 60 patients receiving UST and 42 patients receiving PBO, using increasing cut-offs of S2K RI-50 reductions from baseline. To help determining a minimal cut-off that discriminated a treatment effect reflecting partial improvement, nominal p values are reported for this post hoc analysis. Logistic regression models were used to evaluate the relationship between reduction in S2K RI-50 at week 12 or week 16 and SRI-4 response at week 24, followed by correlation of binary response data between the two instruments.

Results: A 2-point reduction from baseline (improvement) in S2K RI-50 appeared to be the lowest threshold of response to demonstrate a treatment difference in the proportion of responders at week 24 with UST (93.5%) vs PBO (79.3%) (Δ14.2%, p=0.03). The relationship between 2-point improvement in S2K RI-50 at week 12 or week 16 and SRI-4 response at week 24 is presented in the total study population and by treatment group (Table). In the total population, 78/102 (76.6%) patients at week 12 and 74/102 (72.5%) patients at week 16 had at least a 2-point im-

Treatment Group	Visit	Correlation	Odds Ratio[a] [95% CI]	Predictive p-value[a]
Total Population	Week 12	0.62	7.6 [2.4-24.3]	0.0007
UST	Week 12	0.49	4.4 [1.1-16.9]	0.0311
PBO	Week 12	NE[b]	NE[b]	NE[b]
Total Population	Week 16	0.76	15.4 [4.2-55.8]	<0.0001
UST	Week 16	0.74	13.5 [2.6-69.8]	0.0020
PBO	Week 16	0.74	15.0 [1.7-130.7]	0.0142

[a] Predictive p-values and odds ratios are based upon logistic regression models. Predictive p-values are nominal and represent measures of the likeliness of association between a 2-point response in S2K RI-50 at week 12/16 and SRI-4 response at week 24 in the model.
[b] Not estimable (NE) due to no values present in one cell in the 2x2 table.
UST = Ustekinumab, PBO = Placebo

provement in S2K RI-50. Of those, 47/78 (60.3%, r=0.62) at week 12 and 48/74 (64.9%, r=0.76) at week 16 achieved an SRI-4 response at week 24. Odds ratios for the association between SRI-4 response at week 24 and 2-point or greater improvement in S2K RI-50 were 7.6 (CI 2.4-24.3, p=0.0007) at week 12 and 15.4 (CI 4.2-55.8, p< 0.0001) at week 16. Similar analyses performed by treatment group demonstrated that these relationships were consistent in the UST and PBO groups (Table).

Conclusion: S2K RI-50 captures partial improvement of ≥50% in SLE disease activity and could be a useful outcome in clinical trials to predict early clinical response. These findings will be confirmed in an ongoing Phase 3 study.

Efficacy Analysis of Patients with Systemic Lupus Erythematosus Treated with Belimumab or Placebo Plus Standard Therapy in Phase 3 Trials by Baseline Levels of BLyS mRNA and Type 1 Interferon Inducible Gene Signature Status

Angela R Jones-Leone,[1] Shaun Flint,[2] Roger Abramino Levy,[3] David Roth,[4] Robert Henderson,[2] Christel Wilkinson,[2] Beulah Ji,[5] and Damon L Bass[3], [1]GlaxoSmithKline, Upper Providence, [2]GlaxoSmithKline, Stevenage, United Kingdom, [3]GlaxoSmithKline, Collegeville, PA, [4]GSK, Collegeville, PA, [5]GSK, Uxbridge, Middlesex, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Belimumab (BEL) is a B-lymphocyte stimulator (BLyS) inhibitor approved as an add-on to standard of care (SoC) for patients with autoantibody-positive SLE with active disease. This meta-analysis was performed to investigate the efficacy of BEL vs placebo (PBO) plus SoC when participants were stratified by whole blood BLyS mRNA levels and by type 1 interferon-inducible gene signature (IFN-1) status at study baseline.

Methods: This study (GSK study 208651) is a *post hoc* analysis of two Phase 3 trials (BLISS-76 [BEL110751] and -52 [BEL110752]) in which patients received intravenous BEL 10 mg/kg plus SoC or PBO plus SoC. The population for the analysis included all randomized patients with an mRNA sample that passed quality control who received at least one dose of BEL or PBO. Co-primary endpoints were SLE Responder Index (SRI)-4 response within each subgroup and the correlation between baseline BLyS mRNA and IFN-1 levels overall. For binary endpoints, a logistic regression model was used to estimate the odds of SRI response for BEL vs PBO within BLyS mRNA subgroups (high/medium/low tertiles according to quantitative PCR mRNA delta cycle threshold), IFN-1 (high/low) subgroups (according to the median mRNA level of IFI27, IFI44, IFI44L, and RSAD2, defined with reference to samples from 25 healthy volunteers and the trough in bimodal distribution) and overall. To assess SRI-4 response, patients were required to have a Safety of Estrogens in Lupus Erythematosus National Assessment-SLE Disease Activity Index score ≥4 at baseline. The

Table 1. SRI-4 response at Week 52 of treatment by BLyS mRNA subgroup

	BLyS mRNA low		BLyS mRNA medium		BLyS mRNA high

p-value†	0.7785		**0.0153**		0.1255	

†Covariates include treatment group, study, baseline SELENA-SLEDAI score (≤9 vs ≥10), baseline proteinuria (<2 g/24 hours vs ≥2 g/24 hour equivalent) and race (African descent or indigenous American descent vs other) BLyS, B-lymphocyte stimulator; BEL, belimumab; CI, confidence interval; PBO, placebo; SELENA-SLEDAI; Safety of Estrogens in Lupus Erythematosus National Assessment - Systemic Lupus Erythematosus Disease Activity Index; SRI-4, Systemic Lupus Erythematosus Responder Index

Table 2. SRI-4 response at Week 52 of treatment by IFN-1 subgroup

	IFN-1 low		IFN-1 high	
	PBO (n=43)	BEL (n=46)	PBO (n=228)	BEL (n=228)
Response, n (%)	18 (41.9)	21 (45.7)	89 (39.0)	117 (51.3)
Odds Ratio (95% CI) BEL vs PBO†	1.36 (0.55, 3.34)		1.58 (1.08, 2.31)	
p-value†	0.5002		**0.0186**	

†Covariates include treatment group, study, baseline SELENA-SLEDAI score (≤9 vs ≥10), baseline proteinuria (<2 g/24 hour vs ≥2 g/24 hour equivalent) and race (African descent or indigenous American descent vs other) BEL, belimumab; CI, confidence interval; IFN-1, type 1 interferon-inducible gene signature; PBO, placebo; SELENA-SLEDAI; Safety of Estrogens in Lupus Erythematosus National Assessment - Systemic Lupus Erythematosus Disease Activity Index; SRI-4, Systemic Lupus Erythematosus Responder Index

correlation between BLyS gene expression and IFN-1 was analyzed by Spearman's rank correlation coefficient and further by Chi Square test to compare subgroups.

Results: This analysis was based on N=281 (BEL) and N=273 (PBO). Baseline demographics were similar across the BLyS and IFN subgroups. There were more SRI-4 responders at Week 52 for BEL vs PBO in all three BLyS mRNA subgroups but the odds ratio (OR) only achieved statistical significance for the BLyS medium subgroup (**Table 1**). Baseline BLyS gene expression and IFN-1 were significantly correlated (Spearman's rank correlation coefficient 0.7799; 95% CI: 0.7451, 0.8106; p< 0.0001). The percentage of responders at Week 52 was greater for BEL vs PBO for both the low and high IFN-1 subgroups and the OR achieved statistical significance in the high IFN subgroup (**Table 2**).

Conclusion: This study demonstrated a tendency toward better response to BEL as add-on therapy vs SoC alone in patients who had higher baseline BLyS mRNA and IFN-1. However, this was an exploratory analysis, the sample size was opportunistic, with the consequence that the BLyS and IFN-1 subgroups were not explicitly powered to detect a difference in response rates. More studies are necessary to understand whether these biomarkers should be used as treatment decision tools.

Study funding: GSK. Medical writing support: Jennie McLean, PhD, Fishawack Indicia Ltd, UK (funded by GSK).

Hydroxychloroquine Levels in Patients with Systemic Lupus Erythematosus: Comparison of Whole Blood and Serum Levels

Benoit Blanchet,[1] Jallouli Moez,[2] Marie Allard,[3] Veronique le guern,[4] Jean-Charles Piette,[5] Noémie Jourde-Chiche,[6] and **Nathalie Costedoat-Chalumeau** [7], [1]Cochin, Paris, France, [2]sfax, SFAX, Tunisia, [3]Hôpital Bichat Claude-Bernard, Paris, France, [4]APHP, paris, France, [5]Hôpital Pitié-Salpêtrière, Paris, France, [6]APHM, Marseille, Marseille, France, [7]Cochin University Hospital, Paris, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) levels can be measured in whole blood as well as in serum but both methods have never been compared. Cut offs for non-adherence (200 ng/mL or lower) have been established in whole blood.

The aims of this study were to compare the interest of whole blood versus serum levels for drug monitoring of HCQ, and since it would be very interesting to retrospectively assess severe non-adherence in clinical trials or in large cohort of patients in which only serum samples are usually available, to evaluate if HCQ serum level cut off could be determined to identify non-adherent patients.

Methods: The HCQ and desethylchloroquine (DCQ) levels were measured in serum and whole blood from 573 systemic lupus erythematosus (SLE) patients. The risk factors for active SLE (SLEDAI score >4) were identified using multiple logistic regression. HCQ serum level was also measured in 68 additional non-adherent patients (whole blood HCQ level < 200 ng/mL).

Results: The mean HCQ and DCQ levels were 916 ± 449 and 116 ± 55 ng/mL in whole blood, respectively; and 469 ± 223 and 63 ± 31 ng/mL in serum, respectively. The mean ratio of serum /whole blood level for HCQ was 0.53 ± 0.15.

A strong positive correlation was found between serum and whole blood levels of HCQ (rho=0.837 [CI95% 0.810-0.860], p< 0.0001), and DCQ (rho=0.771 [CI95% 0.736-0.802], p< 0.0001). In the multivariate analysis, only corticosteroids (p=0.044), immunosuppressant (p=0.027), HCQ whole blood level (p=0.023) and hemoglobin (p=0.009) were identified as an independent risk factor of active SLE but serum HCQ level was not.

Given that the mean ratio of serum/whole blood level for HCQ was 0.53, we extrapolated that serum HCQ level cut offs of 106 and 53 ng/mL would correspond to the previously used cut-off of 200 and 100 ng/mL of HCQ in whole blood. The positive and negative predictive values of serum HCQ < 106 ng/ml to detect non-adherence (defined by blood HCQ < 200 ng/ml) were 86.8% and 85.7%, respectively.

All serum HCQ levels of patients exhibiting whole blood HCQ below the detectable levels (< 50 ng/mL) were also below the detectable levels for serum (37.5 ng/mL).

Conclusion: These data suggest that whole blood is better than serum when assessing pharmacokinetic/pharmacodynamic relationship of HCQ. When whole blood is not available, our results support the use of HCQ serum level to assess non-adherence with a cut off of 106 ng/mL corresponding to 200 ng/ml in whole blood.

Safety, Tolerability, Pharmacokinetic and Pharmacodynamic Effect of BIIB059, a Monoclonal Antibody Targeting BDCA2 Following Administration of Subcutaneous Single Doses in Japanese Healthy Volunters

Cristina Musselli,[1] Francois Gaudreault,[1] Naik Himanshu,[1] Hua Carroll,[1] Ankur Sharma,[1] Xiaobi Huang,[1] and Nathalie Franchimont[1], [1]Biogen, Cambridge, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: BDCA2 is a plasmacytoid dendritic cell (pDC)-specific receptor that, when ligated inhibits the production of inflammatory mediators and Type I Interferon (INF), a major player in Systemic and Cutaneous Lupus Erythemtosus's (SLE and CLE) pathogenesis. Targeting BDCA2 with BIIB059, a high affinity humanized IgG1 mAb, represents an attractive therapeutic strategy. BIIB059 was previously tested in a Phase 1 study in non-Japanese healthy volunteers (HV) (NCT02106897)* and is currently in phase 2 development for the treatment of SLE and Cutaneous Lupus Erythematosus (CLE) (NCT02847598) .

Methods: A total of 32 HV from Japanese descend matched for body weight (NCT02106897), were enrolled into 4 cohorts to receive a single subcutaneous (SC) injection of 20-, 50-, 150- or 450 mg of BIIB059 or placebo (6 BIIB059: 2 Placebo). Blood samples were obtained to characterize PK and PD profiles and establish PK-PD relationships for BIIB059. Safety and tolerability data were monitored and reviewed.

Results: BIIB059 was generally well tolerated; no SAEs were observed. Adverse events were reported by 9 (37.5%) and 0 (0.0%) subjects in the BIIB059- and placebo-treated groups, respectively. Overall, 33.3% and 4.2% subjects reported AEs that were mild or moderate in severity, respectively. Three subjects (12.5%) experienced AEs considered related to study drug and mild in severity. All AEs resolved without treatment. There were no clinically significant findings on laboratory measures or in physical examination. Following single SC BIIB059 administration, Cmax and AUC(0-inf) increased with doses. Mean t1/2 ranged from 10 to 27 days. A PK and PD comparison between non-japanese and japanese HV is being conducted and results will be presented here. Eleven subjects (45.8%) treated with BIIB059 tested positive for anti-BIIB059 antibodies at ≥ 1 postdose timepoint (ADA). There was no apparent relationship between incidence of ADA and dose, no apparent effect on drug exposure and no association with clinically relevant observations. Following BIIB059 administration, BDCA2 expression on pDCs sharply decreased with levels returning towards baseline in a dose-dependent manner as serum concentrations of BIIB059 decreased.

Conclusion

- BIIB059 was generally well tolerated.
- BIIB059 exposure increased with dose.
- Preliminary results suggest no apparent PK/PD and safety differences between body weight matched Japanese and Non-Japanese healthy subjects at all doses after single BIIB059 administration.
- BDCA2 expression on pDCs decreased rapidly and sharply and returned to baseline levels in a dose-dependent manner.

Time Point 3 (3rd month)	9	11.78	25.820

Background/Purpose: Young adults with childhood-onset lupus (cSLE) are 20 times more likely to die compared to healthy age- and gender-matched counterparts. Their clinical course is more severe than adult-onset lupus, with a 2-3 times increased mortality rate. Poor adherence (i.e. the extent to which an individual's behavior matches treatment regimens) to therapeutic regimens is a major contributor to negative health outcomes - increased morbidity, mortality, healthcare utilization, and costs. Reliably measuring adherence is critical in targeting this significant problem. However, non-invasive estimates of adherence vary based on measurement method (e.g., self-report, refill data). There is, therefore, a need for objective and reliable methods of measuring adherence to all daily medications. The objective of this study is to examine the feasibility, acceptability, and efficacy of using an electronic pillbox to measure adherence in young adults with cSLE.

Methods: Eleven young adults with cSLE (mean age 20.5±1.6; 36% Caucasian; 55% Black; 1% mixed race) were followed prospectively over 12 weeks. Subjects were recruited during routine pediatric rheumatology clinic visits and met ACR criteria for SLE. All subjects received SimpleMed+ (Viaca, Tel Aviv, Israel) pillboxes that track adherence, for multiple medications and up to four daily doses, using cellular technology. Self-report of adherence using the Medication Adherence Self-Report Inventory (MASRI) was implemented. Additional questionnaires and chart review data were collected. Descriptive analysis and a one-way repeated measures ANOVA were performed.

Results: Demographic and disease characteristics are summarized in Table 1. Forgetting, after taste, current medication side effects, and fertility concerns were top barriers to medication adherence (see Table 1). Eighty-one per-
