cent of participants (9/11) completed the study and found the pillbox acceptable and easy to use. Reasons for not completing the study were forgetting to refill and/or charging the pillbox. The means and standard deviations of a one-way repeated measure ANOVA (conducted for mean electronic measurements of adherence at 3 time points - 1st, 2nd, and 3rd months) are presented in Table 2. There was no significant effect for time, Wilks' Lambda = .52, F (2, 7) = 3.24, p = 0.10, multivariate partial η^2 = .48. Although mean self-reported adherence increased from 70.5% to 80% from baseline to study completion, electronically measured adherence decreased over time (Figure 1).

Conclusion: Measuring adherence to multiple medications is feasible with electronic pillboxes. Results from this study suggest that poor medication adherence will not improve without intervention. Consistent with prior studies, our study indicates that self-report of adherence may overestimate true medication adherence. Despite the small sample size, our study show that electronic pillboxes may be a reliable non-invasive method of measuring adherence to *all* medications taken by patients with cSLE. Establishing a reliable method of measuring adherence to multiple medications is an essential tool for the advancement of adherence research and the ultimate resolution of this significant public health issue.

Abstract Number: 2576

Clinical Evidence Supporting Therapeutic Potential of Activating the Immune Checkpoint Receptor BTLA in SLE

Matthew Linnik,[1] Adam Godzik,[2] Lukasz Jaroszewski,[2] Carl Ware,[2] and Andrew Vendel[1], [1]Lilly Biotechnology Center, San Diego, CA, [2]Sanford Burnham Prebys Medical Research Institute, La Jolla, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors have demonstrated durable benefit in some cancer patients. However, checkpoint inhibitors are also associated with new onset autoimmune adverse events. The link between checkpoints and autoimmune disease suggests that activating immune checkpoint receptors might be useful in treating autoimmune diseases like SLE. As the role of B cells and T cells are implicated in SLE, we became interested in modulating BTLA (B- and T-lymphocyte attenuator) as potential therapeutic target for SLE. The endogenous ligand for BTLA is HVEM (Herpes virus entry mediator), and BTLA attenuates lymphocytes by recruiting phosphatases SHP-1 and SHP-2 to the B cell receptor and T cell receptor signaling complexes, respectively. The current study examined the BTLA/HVEM signaling pathway in two large phase 3 trials in SLE to determine if there was a therapeutic rationale for activating BTLA in SLE.

Methods: Whole blood gene expression data from 1760 SLE patients was obtained from the phase 3 ILLUMINATE-1 and ILLUMINATE-2 studies in patients with SLE and active disease activity defined as SLEDAI-2K $\geq$ 6 (NCT01205438, NCT01196091). Control samples were obtained from healthy donors. Blood was collected in Tempus tubes at baseline, week 16, and week 52. RNA was analyzed using Affymetrix Human Transcriptome Array 2.0.

Results: High levels of BTLA mRNA were observed on B cells, CD4+ T cells, CD8+ T cells and plasmacytoid dendritic cells. HVEM mRNA levels were lower in SLE patients compared to healthy controls, while BTLA levels were similar between SLE and control. Low levels of HVEM mRNA were associated with increased disease activity at baseline, including proportion of patients with SLEDAI ≥ 10, and frequency of patients with anti-dsDNA antibodies, low complement (C3 and C4), and elevated interferon gene signature.

Conclusion: The analysis confirmed that BTLA is present on key immune cells linked to the pathogenesis of SLE. The reduced levels of HVEM in SLE patients compared to control suggests that ligand deficiency in the BTLA system may play a role in SLE. Importantly, low HVEM was associated with increased disease activity across multiple disease characteristics, including measures of high disease activity, serology and gene expression. These data provide clinical rationale for evaluating a BTLA agonist in SLE. A phase 1 trial with a BTLA agonist antibody in healthy volunteers is in progress.

SLE Disease Activity May Be Associated with Choroidal Thickness

Iris Lee,[1] Brigid Marshall,[1] Prabha Ranganathan,[2] Seth Eisen,[3] Rithwick Rajagopal,[1] Alfred Kim,[3] and Tingting Li[1], [1]Washington University in St Louis, St Louis, [2]Washington University in St Louis, St Louis, MO, [3]Washington University School of Medicine, Saint Louis, MO

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is an autoimmune disease with widespread organ involvement. High disease activity has previously been associated with higher risk of organ damage and mortality. However, it is often difficult to resolve which clinical symptoms reflect SLE disease activity, leading to potential over or under treatment. Inflammation of the choroid (the outer vascular layer of the eye) may reflect inflammation of the kidney in lupus, since both have similar vascular designs, contain fenestrated capillaries, are composed of a3-5 type IV collagen, and are organized in lobules. In addition, clinical choroidopathy has been observed in patients with SLE high disease activity, especially renal or CNS involvement. In a recent publication, choroid thickening (CT) was reported in a cohort of SLE patients compared to non-SLE controls, but disease activity was not described. In the present study, we investigated whether CT is associated with extra-renal SLE flare, extra-renal disease activity, or renal disease in complete remission. We hypothesize that CT is associated with SLE disease activity.

Methods: This is a retrospective case-control study of SLE patients meeting either American College of Rheumatology (ACR) or Systemic Lupus International Collaborating Clinics criteria who were followed at Washington University School of Medicine Rheumatology, Nephrology, or Ophthalmology clinics. Data was derived from 21 patients with SLE, 14 of whom had biopsy-proven lupus nephritis (LN). The nephritis of all LN patients was in complete clinical remission as defined by the ACR. Disease activity was assessed using the S2K RI-50 instrument, with scores > 4 defined as active. Major flare was defined by Fortin criteria. CT was measured at three locations through the fovea using optical coherence tomography, a noninvasive imaging modality used by ophthalmologists to follow retinal disease. After exporting images into Adobe Photoshop, CT was measured independently by 2 investigators. Intra-rater and

inter-rater reliabilities were 0.982 and 0.96, respectively. Comparisons were made with Student's t-test for parametric and Mann-Whitney U for nonparametric data.

Results: Compared to control subjects with inactive SLE and no history of LN, the CT of subjects with active SLE was marginally thicker (348 µm [IQR 308-425] vs 264 [IQR 228-343], p = 0.061 at 500 µm nasal to the fovea, n = 4 vs 14 eyes, respectively). However, the CT of subjects who met criteria for extra-renal flare (293±87µm vs 270±74µm, p = 0.286 at 500 µm nasal to the fovea, 310±89µm vs 284±74 µm, p = 0.229 at the fovea, and 301±84µm vs 274±68µm, p = 0.163 at 500 µm temporal to the fovea, n = 21 vs 41 eyes) or inactive LN were not different from controls (272±79 µm vs 268±69 µm, p = 0.862 at 500 µm nasal to the fovea, 281±78 µm vs 288±70 µm at the fovea, and 271±64µm vs 272±72µm at 500 µm temporal to the fovea, n = 23 vs 20 eyes).

Conclusion: CT may be associated with some manifestations of active SLE (S2K RI-50 > 4)**.** CT was not associated with extra-renal flare or LN in remission. Study conclusions are limited by the retrospective observational design and small sample size. The study supports the need for additional research examining CT - SLE disease activity relationships.

Abstract Number: 2578

Effect of Omega-3 Fatty Acids on Systemic Lupus Erythematosus Disease Activity: A Systematic Review and Meta-Analysis

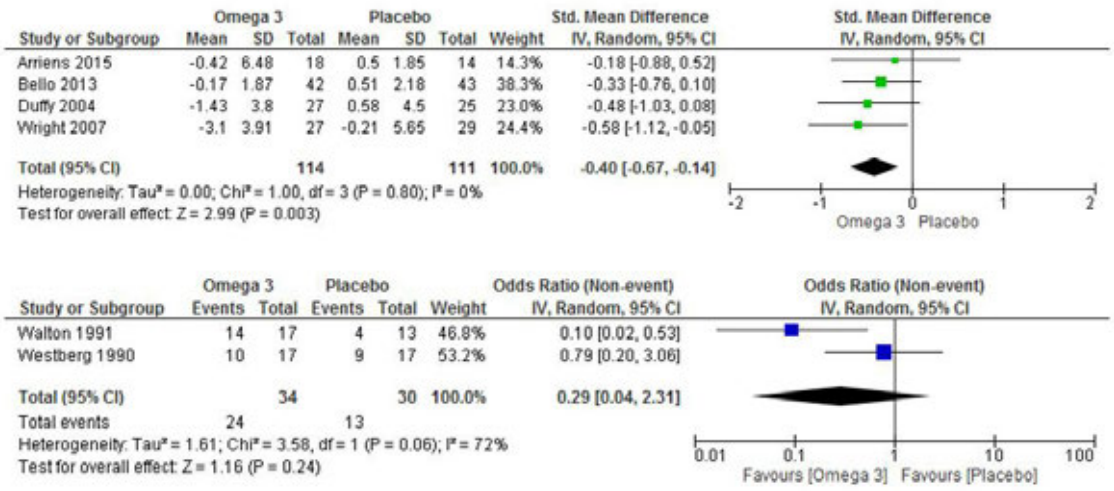
Ali Duarte Garcia,[1] Elena Myasoedova,[1] Paras Karmacharya,[1] Cynthia Crowson,[2] and Kenneth Warrington[3], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, [3]Mayo Clinic Rochester, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)



Forest plot of the effects of Omega 3 fatty acids vs. placebo in trials. Upper panel continuous outcomes. Lower panel dichotomous outcomes.

Session Time: 9:00AM–11:00AM

Background/Purpose: Omega-3 fatty acids may have anti-inflammatory properties. In animal models of systemic lupus erythematosus (SLE) Omega-3 fatty acids decrease autoantibody levels, reduce inflammatory markers and prolong the lifespan of lupus-prone mice. However clinical studies in patients with SLE have been small, with wide confidence intervals and conflicting findings. Thus, we aimed to perform a systematic review and meta-analysis to determine a more accurate and precise estimate effect of omega-3 fatty acids on SLE disease activity in adults.

Methods: Following an *a priori* established protocol, a comprehensive search in any language of several databases designed by two expert librarians was conducted from database's inception to January 11th, 2019. Studies that were randomized controlled trials (RCT) of adults with SLE comparing omega 3 fatty acids supplementation to placebo or standard of care and reported SLE disease activity were included. Abstracts and full text reviews were evaluated independently and in duplicate by two investigators.

To combine outcomes, we standardized the disease activity scales (SLEDAI and SLAM) into standardized mean differences (SMD). Since small sample sizes can lead to biased overestimation of the SMD, we used Hedges' (adjusted) *g* methods. For continuous outcomes we calculated the SMD and 95% confidence interval (95CI), we used the inverse variance approach random-effects model. Dichotomous outcomes were reported as odds ratio (OR) and 95CI. Heterogeneity was calculated with the I^2 statistic. Results were presented in standardized mean response for SLE disease activity and 95CI. To improve clinical interpretability, the pooled data was scaled back to the SLEDAI by multiplying SMD by standard deviation of the studies that utilized SLEDAI.

Results: Six studies were included in the meta-analysis. The studies were published between 1990 and 2015. All the included studies were RCTs. The treatment group sizes ranged from 8-43 patients (median 20). In total 180 patients were in the comparison groups and 183 in the treatment groups. Half of the studies utilized the usual dose 3 grams or less of Omega 3 fatty acids while the rest used up to 20 grams. The trial follow-up time ranged from 22 – 52 weeks. The mean age of the patients was 43.2 years and 80% or more were female.

Four RCTs with 225 participants had continuous outcomes, 2 used SLEDAI and 2 used SLAM to measure SLE disease activity. As shown in the figure, the SMD of the included trials ranged from -0.18 (95CI, -0.88, 0.52) to -0.58 (95CI, -1.12,-0.05). The pooled SMD was -0.4 (95CI, -0.67, -0.14). We transformed the SMD to units of the SLEDAI scale. Compared to placebo, Omega 3 fatty acids reduced disease activity by 1.4 (95CI, -2.9, -1) SLEDAI points. The statistical heterogeneity was low with an I^2 of zero.

Two RCTs with dichotomous variables were included in the analysis. 64 patients were part of these studies. The pooled odds ratio was 0.29 (95CI, 0.04, 2.31). The statistical heterogeneity was high with an I^2 of 72%.

Conclusion: This meta-analysis evaluated the efficacy of Omega-3 fatty acids for the treatment of SLE. Our results suggest that Omega-3 fatty acids are a potential therapy that can be added to the immunosuppressive treatments used for SLE.

Forest plot of the effects of Omega 3 fatty acids vs. placebo in trials. Upper panel continuous outcomes. Lower panel dichotomous outcomes.

Abstract Number: 2579

A Quality Improvement Project in Determining If Cardiac Enzymes Play a Role in Surveillance of Possible Hydroxychloroquine Induced Cardiotoxicity

Eric Liu,[1] and Andras Perl[2], [1]SUNY Upstate University Medical Center, Syracuse, NY, [2]SUNY Upstate Medical University, Syracuse, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is a commonly used medication in our field of work with retinal toxicity being a known possible long-term side effect of the medication. Studies and case reports have described a role of HCQ in cardiotoxicity although, the relation is not completely clear [Drug Saf. 2018 Oct;41(10):919-931]. The gold standard of diagnosis would be an endomyocardial biopsy however, it is impractical to have the biopsy done on anyone suspected of having HCQ induced cardiomyopathy [J Rheumatol. 2019 Apr;46(4):391-396]. Our goal is to evaluate if cardiac injury markers as predictors of HCQ-induced cardiotoxicity.

Methods: This quality improvement project retrospectively analyzed medical record of patients taking HCQ with a diagnosis of an arrhythmia, cardiomyopathy, or heart failure at SUNY Upstate Medical University in Syracuse, New York. Established causes of heart disease, such as hypertension or congenital malformations were excluded. Patients

Table 1. Sensitivity of Two cardiac injury tests in patients taking Hydroxychloroquine before and after a cardiac diagnosis. NT – Not tested

	Start HCQ before a cardiac Dx		Start HCQ after a cardiac Dx	
TEST	Troponin	BNP	Troponin	BNP
Arrhythmia+ Test +	20	26	9	12
Arrhythmia+ Test -	40	25	12	4
Arrhythmia+ NT	49	58	45	50
Sensitivity (%)	33.3	50.1	43	75
p-value		0.06		0.0506
Cardiomyopathy+ Test +	20	21	7	14
Cardiomyopathy+ Test -	19	18	14	4
Cardiomyopathy+ NT	9	9	7	10
Sensitivity (%)	51.2	53.8	33	78
p - value		0.8206		0.0055
Heart Failure+ Test+	58	81	34	42
Heart Failure+ Test-	42	11	23	11
Heart Failure+ NT	73	81	36	40
Sensitivity (%)	58	88	60	79
p-value		<0.0001		0.0263
Total Number of Patients Tested	330	330	187	187

were distinguished as to whether they had the cardiac diagnosis before or after the starting HCQ. Cardiac injury markers, CK, CKMB, troponin, BNP, were evaluated in each subject. Statistical analyses of categorical variables were performed with chi-square test using GraphPad software.

Results: 8220 patients were identified to be on HCQ between 2013 and 2019. 854/8220 (10.4%) had a cardiac diagnosis, such as arrhythmia, cardiomyopathy, or heart failure. 517/854 had a cardiac diagnosis not attributed to a known cause such as hypertension or congenital malformations. Of 517 cases, heart disease was recorded in 187 patients before and 330 patients after initiation of HCQ treatment. Among laboratory tests examined, BNP testing was found to be most sensitive to detect heart disease in both groups. In patients who were diagnosed with heart disease after having started HCQ, BNP was 88% sensitive for detection of heart failure ($p < 0.0001$ over other tests). BNP was also most sensitive to detect cardiomyopathy or heart failure in patients subsequently started on HCQ.

Conclusion: Cardiotoxicity is a newly recognized possible side effect of HCQ therapy. While clinicians are aware of surveillance for possible retinal and guidelines have been established, there are no guidelines for cardiotoxicity monitoring. This study indicates that BNP may be a sensitive test for detecting heart disease in patients taking HCQ either before or after initiation of therapy. These results advocate for including BNP for safety monitoring of patients treated with HCQ.

Pharmacotherapies Targeting Type 2 SLE Symptoms

Raeann Whitney,[1] Amanda Eudy,[1] Megan Clowse,[1] Lisa Criscione-Schreiber,[1] Jayanth Doss,[1] David Pisetsky,[2] Kai Sun,[1] Rebecca Sadun,[1] and Jennifer Rogers[1], [1]Duke University, Durham, [2]Duke University, Durham VAMC, Durham

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We propose categorizing lupus activity to better align with patient experience: Type 1 SLE activity includes classic symptoms such as arthritis and nephritis; Type 2 includes widespread pain, fatigue, depression, sleep disturbance, and perceived cognitive dysfunction. We previously found that only 53% of our patients with active Type 2 SLE received direct treatment for these symptoms, which is currently extrapolated from fibromyalgia treatment. We aimed to evaluate prescription of pharmacotherapies for Type 2 SLE symptoms one year after implementing the Type 1 and 2 categorization system.

Methods: This was a cross-sectional study of SLE patients (SLICC 2012 criteria) in a university lupus clinic from May 2018-March 2019. All patients completed Patient Health Questionnaire-9 (PHQ-9) and 2016 ACR Fibromyalgia criteria questionnaires. Active Type 2 SLE was defined as having a fibromyalgia severity score (FSS) > 10. We defined Type 2 medications as antidepressants (serotonin and norepinephrine reuptake inhibitors (SNRIs), selective serotonin reuptake inhibitors (SSRIs), tricyclic antidepressant **(**TCAs), mirtazapine, bupropion), muscle relaxers (cyclobenzaprine, tizanidine, baclofen, metaxalone), gabapentinoids (gabapentin, pregabalin), topiramate, zolpidem, trazodone, tramadol, anxiolytics, stimulants, and DHEA. Relationships between clinical variables and medications in different groups were analyzed using t-tests and Fisher's exact test.

	n=158

Table 2. Comparing medication use in patients with and without Type 2 SLE activity

Results: Single-visit data from 158 patients were included (Table 1). There was a clear difference in prescribing patterns based on the presence or absence of Type 2 SLE: 70% of patients with active Type 2 SLE took at least one Type 2 medication compared to 40% of those without (Table 2). Medications differentially prescribed to patients with Type 2 activity included SNRIs (prescribed in 31% with Type 2 activity vs 6% without, $p < 0.0001$; primarily duloxetine),

	Active Type 2 SLE		
	No Corticosteroids n=34	Current Corticosteroids n=20	p-value
Fibromyalgia Scores			
Fibromyalgia Severity Score (FSS)	15.5 (4.4)	15.8 (4.8)	0.9
Symptom Severity Score (SSS)	8.1 (2.1)	8.2 (2.0)	0.9
ACR Fibromyalgia Criteria (Moderate or Severe)			
Cognitive dysfunction	15 (47%)	8 (40%)	0.8
Fatigue	29 (91%)	18 (95%)	1.0
Waking unrefreshed	29 (91%)	17 (89%)	1.0
Depression			
Criteria met for depression by PHQ9	5 (19%)	6 (40%)	0.3
PHQ9 Score	9.7 (3.8)	10.1 (4.4)	0.8
Physician assessment of Type 2 severity (0-3)	1.4 (0.8)	1.5 (0.8)	0.7

All outcomes are reported as mean (SD) or n (%)

Table 3 There is no difference in symptom scores among patients with Active Type 2 SLE currently taking and not taking corticosteroids

gabapentinoids (37% vs 13%, p = 0.001; primarily gabapentin), muscle relaxers (20% vs 6%, p = 0.01; primarily cyclobenzaprine), opioids (24% vs 10%, p = 0.02), trazodone (15% vs 4%, p = 0.02), and benzodiazepines (9% vs 1%, p = 0.02). There was no difference in prescriptions for SSRIs, NSAIDs, Vitamins D, or B12. Steroid use was higher in patients with active Type 1 symptoms (51% vs 33%) and average dose was higher (13 mg vs 7 mg). Among patients with active Type 2 SLE, there was no difference in Type 2 symptom severity between those who were taking corticosteroids and those who were not (Table 3).

Conclusion: After instituting formal assessments for Type 2 SLE activity, prescription of medications to address these symptoms has increased from 53% to 70%, aligning treatment patterns with patient symptomatology. Patients with active Type 2 SLE are differentially prescribed SNRIs, gabapentinoids, and muscle relaxers. Corticosteroids are more often prescribed to address active Type 1 rather than Type 2 activity and are not associated with Type 2 symptom severity. Together, these findings highlight the need for longitudinal studies to evaluate therapeutic efficacy of these medications and identify optimal pharmacologic and non-pharmacologic interventions for Type 2 SLE.

Abstract Number: 2581

Clinical Impact of Decreasing Hydroxychloroquine Dose According to the 2016 American Academy of Ophthalmology Guidelines in Patients with Systemic Lupus Erythematosus

Nicolle Medina-Cintrón,[1] Ileana Vázquez-Otero,[1] Mariangelí Arroyo-Ávila,[1] Lorena González-Sepúlveda,[1] and Luis Vilá[1], [1]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is one of the main drugs used for the treatment of systemic lupus erythematosus (SLE). Nonetheless, HCQ-induced retinal toxicity remains a major concern. To reduce the risk of HCQ-induced retinopathy, in 2016 the American Academy of Ophthalmology recommended a maximum daily HCQ dose of ≤5.0 mg/kg real weight. However, it is uncertain if this recommended dose would have an impact on the clinical course and outcome of SLE patients. Thus, we compared outcome measures in a cohort of SLE patients before and after adjusting HCQ dose to ≤5mg/kg/day.

Methods: Sixty Hispanics from Puerto Rico with SLE (per 1997 revised American College of Rheumatology [ACR] criteria) treated with HCQ who were changed to HCQ ≤5.0 mg/kg/day were studied. Visits were ascertained every 6 months for 2 years prior to HCQ dose adjustment (baseline visit) and up to 2 years afterwards. Disease activity (per Systemic Lupus Disease Activity Index [SLEDAI]), SLE exacerbations, emergency room visits, hospitalizations, damage accrual (per Systemic Lupus International Collaborating Clinics/ACR Damage Index [SDI]), prednisone (or equivalent) exposure, prednisone (or equivalent) mean dose, and immunosuppressive drugs exposure were determined before and after HCQ dose change. Statistical analyses were performed using Exact McNemar's test and Wilcoxon signed-rank test, as appropriate.

Results: At baseline visit, the mean age was 44.0 ± 14.9 years. All patients were women. The mean disease duration and HCQ treatment duration were 13.8 ± 9.1 and 12.5 ± 15.1 years, respectively. The mean daily HCQ doses before and after adjustment were 395 ± 28 mg and 256 ± 50 mg, respectively. All patients had at least 1 year of follow-up, 41 (68.3%) had 1.5 years of follow-up, and 39 (65.0%) had 2 years of follow-up after dose adjustment. Before HCQ dose adjustment, patients had more mean hospitalizations (any cause) (0.08 ± 0.20 vs. 0.02 ± 0.07, p=0.031) and mean hospitalizations attributed to SLE (0.04 ± 0.16 vs. 0.00, p=0.045) when compared to visits after HCQ dose reduction. No significant differences (p >0.05) were observed for mean SLEDAI scores (2.2 ± 2.9 vs. 2.1 ± 2.9), lupus exacerbations (0.18 ± 0.25 vs. 0.16 ± 0.25), emergency room visits (any cause) (0.06 ± 0.22 vs. 0.17 ± 0.78), emergency room visits attributed to SLE (0.02 ± 0.78 vs. 0.01 ± 0.06), and mean daily prednisone dose (7.9 ± 17.3 mg vs. 5.2 ± 5.8 mg) before and after HCQ dose adjustment. Likewise, no differences were observed for exposure to corticosteroids, mycophenolate mofetil, azathioprine, cyclophosphamide, tacrolimus, rituximab or methotrexate. Patients did not accrue more damage from baseline visit to last study visit (mean SDI score: 0.9 ± 1.4 vs. 1.0 ± 1.4, p=0.190), and no deaths occurred.

Conclusion: This study suggests that adjustment of daily HCQ dose to ≤5.0 mg/kg real weight does not have a significant impact in the short- and mid-term outcomes of SLE patients. Nevertheless, a larger number of patients and longer follow-up are necessary to reach further conclusions.

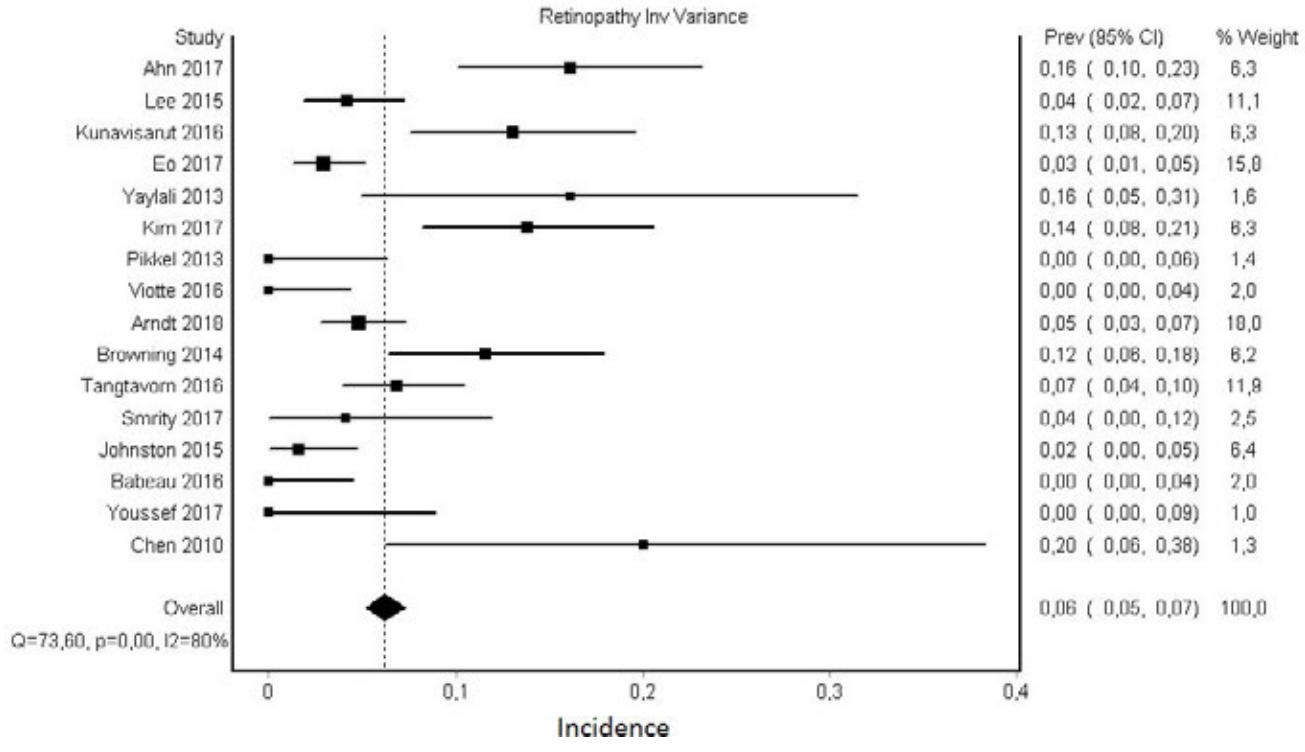
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antimalarials (AM) are frequently used as first-line therapy in mild inflammatory diseases, because of a good benefit/risk ratio. Their most severe side effect is retinopathy, which can potentially lead to blindness, but remains reversible if detected early, provided the treatment is stopped. This complication has been described early [1], but its incidence remains uncertain. A recent update of the American Association of Ophtalmology (AAO) recommendations on screening for chloroquine and hydroxychloroquine retinopathy, suggests to screen patients under AM treatment, with a frequency depending on risk factors, and with the systematic and minimal use of Optical Coherence Tomography (OCT) and Visual Field (VF) test, completed by others tests if required [2]. We aimed at estimating the exact incidence of AM-induced retinopathy, based on available published literature about this issue, with particular reference to detection performed with OCT and VF test.

Methods: A systematic literature search was conducted in Pubmed, Cochrane and Embase databases until April 6th 2018, completed by a manual search in references from the resulting selected articles. We first selected all publications about the incidence of retinopathy linked to AM in patients treated for inflammatory diseases and included them in the systematic literature search. Among them, and in order to minimize heterogeneity of results, we focused on those which had used at least OCT and VF test, as recommended by the AAO, to perform a meta-analysis. Analysis was conducted using MetaXL for Microsoft Excel, applying the Inverse of Variance method.

Results: Among the 3890 articles of potential interest, we selected 91 articles appropriately addressing the topic and included them in the systematic literature search. They were dated between 1964 and 2018, with variable population sizes (10 to 3580 patients). Patients were treated with hydroxychloroquine, chloroquine or both for an inflammatory disease (usually lupus or rheumatoid arthritis). Mean treatment duration ranged from 1 to 14,1 years. Most of them



were retrospectively designed, and diagnostic method were variate. For the aforementioned meta-analysis, we used data from 16 articles published between 2010 and 2018, in which every patient had at least OCT and VF Test. We found a pooled estimate of prevalence of 6.05% (IC 95% [5.18 – 7.31]), with a heterogeneity coefficient of 80 %.

Conclusion: We found a pooled prevalence of approximately 6% of retinopathy linked to AM when OCT and VF test are used. However diagnostic criteria are not consensually well-defined, leading to heterogeneous data.

Abstract Number: 2583

Prevalence and Risk Factors of Herpes Zoster Reactivation in Patients with Biopsy Proven Lupus Nephritis Undergoing Immunosuppressive Therapies

Chi Chiu Mok,[1] Kar Li Chan,[2] Sau Mei Tse,[2] and Ling Yin Ho[2], [1]Department of Medicine, Tuen Mun Hospital, Hong Kong, China (People's Republic), [2]Tuen Mun Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the prevalence of Herpes Zoster (HZ) reactivation in patients with biopsy confirmed lupus nephritis (LN) undergoing immunosuppressive therapies.

Methods: Patients who had biopsy confirmed active LN (2003-2018) were retrospectively reviewed for the occurrence of HZ infection. The following data were collected: age, sex, SLE disease activity scores, maximum daily dose and total duration of high-dose prednisolone and other immunosuppressive drugs in the induction period, maintenance therapies, laboratory parameters at baseline and 6 months post-therapy that included lupus serology, albumin, globulin, IgG/A/M levels, white cell counts, histological classes of LN and renal response. The incidence of HZ reactivation at 2 years of LN treatment and on follow-up was calculated. Risk factors for HZ reactivation were studied by logistic regression.

Results: 251 patients with 311 episodes of active LN were studied (92% women; age 34.2±14.2 years). Histological LN classes were: III/IV±V(69%), I/II/V/VI(31%). Induction regimens were: moderate/high dose prednisolone in combination with cyclophosphamide (17%), azathioprine (11%), mycophenolate mofetil (MMF) (42%), tacrolimus (25%). Renal response at 6m was: complete response (CR) (59%), partial response (PR) (27%) and non-response (NR) (15%).

Within 2 years of therapies, 55(18%) episodes of LN were complicated by HZ infection (incidence: 8.84/100 patient-year). The median time for HZ reactivation since LN therapy was 11 months. 28 patients had HZ infection beyond 2 years (overall prevalence: 3.24/100 patient-years). The distribution of HZ lesions was: head and neck (15%), lower limbs (27%), trunk (55%) and upper limbs (4%). 75% of the episodes were treated by oral acyclovir. Secondary bacterial infection or significant neuralgia occurred in 18% of the episodes. Disseminated disease or mortality was not reported. Patients with HZ reactivation were more likely to have first-time renal disease (76% vs 58%; p=0.02) and a shorter SLE duration at LN (31.4±50 vs 62.7±72 months; p=0.02). A trend of higher SLEDAI, higher anti-dsDNA, lower C3/albumin but more refractory disease was observed in HZ-infected patients. Histological LN classes, neutrophil/lymphocyte counts and immunoglobulin levels at baseline and 6 months post-therapy were not significantly different between HZ-infected and control patients. HZ-infected patients had been treated with a significantly higher dose of prednisolone (0.72±0.40 vs 0.63±0.24 mg/kg/day) at induction. Higher doses of other immunosuppressive drugs had also been used in patients with HZ reactivation but the difference was not statistically significant. Logistic regression revealed first-time LN (OR 2.25[1.08-4.71]; p=0.003), peak MMF dose (OR 1.24[1.10-3.07]; p=0.02) and cumulative CYC dose (OR 1.14[1.01-1.28]; p=0.04) during induction therapy were significantly associated with HZ at 2 years.

Conclusion: HZ reactivation is fairly common in LN patients undergoing immunosuppressive therapies but unpredictable from clinical parameters. Minimization of immunosuppression and HZ vaccination may help reduce the risk of HZ infection.

Management of Cutaneous Manifestations of Lupus Erythematosus: A Systematic Review

Jessica Fairley,[1] Shereen Oon,[2] Amanda Saracino,[3] and Mandana Nikpour[2], [1]Monash University, Melbourne, Australia, [2]St Vincent's Hospital, Melbourne; The University of Melbourne, Melbourne, Australia, [3]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical Poster III: Treatment
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE), occurring with or without systemic lupus erythematosus (SLE), is a group of inflammatory skin diseases that can be very debilitating, causing significant psychological distress, and in some cases scarring. We sought to comprehensively present the evidence for different treatment modalities in patients with cutaneous manifestations of lupus erythematosus (LE).

Methods: Medline, Embase, Scopus and Cochrane CENTRAL were searched electronically from 1990 to March 2019, using keywords related to cutaneous lupus and synonyms and treatment. Articles retrieved were screened for relevance, including reference lists of retrieved reviews. We included clinical trials, observational studies or case series with 5 or more patients focussing on treatment of CLE, with or without SLE.

Results: The search identified 6637 studies, of which 104 were included. Each study commonly included a heterogenous mixture of CLE subtypes, with or without SLE. The 104 included studies investigated 11 different categories of treatment in 6811 patients. Treatments included topical calcineurin inhibitors (CNIs) (13 studies), sun protection (5

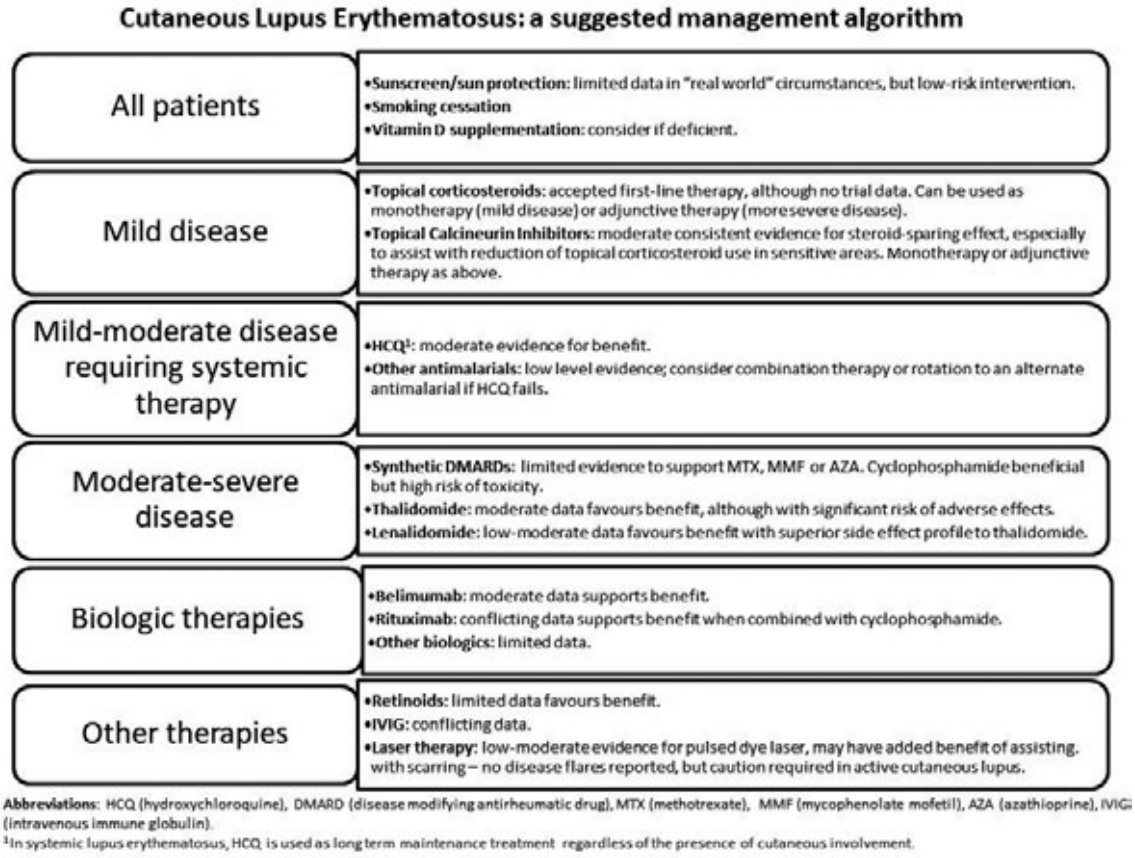

Figure 1. a suggested management algorithm for cutaneous lupus erythematosus

studies), R-salbutamol cream (2 studies), antimalarials (23 studies), synthetic disease modifying anti-rheumatic drugs (DMARDs)(10 studies), retinoids (2 studies), thalidomide/lenalidomide (22 studies), biologic therapies (12 studies), intravenous immune globulin (3 studies), laser (6 studies) and other therapies (6 studies). A suggested management algorithm based on these data, determined by disease severity, is summarised in Figure 1. General measures to be considered include smoking cessation, sun protection measures and optimisation of vitamin D levels. Moderate evidence exists for benefit with topical CNIs, particularly as a steroid sparing agent in areas at high risk of steroid complications (e.g. facial skin). There is moderate evidence for hydroxychloroquine, which is first-line in SLE patients, limited evidence to support other synthetic DMARDs, and moderate evidence supporting thalidomide but with significant risk of toxicity. Of biologic therapies, there are moderate data to support belimumab. Limited evidence exists for other therapies.

Conclusion: Many management options are available for CLE, including topical, systemic and biologic therapies, with a variable balance of efficacy and toxicity. There is a paucity of high-quality clinical trial data. Further trials are required to better understand optimal management of CLE, particularly in specific subgroups.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical Poster III: Treatment

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Premature ovarian failure is a dreaded complication of cyclophosphamide (CYC). It is related to age of initiation of therapy and the cumulative dose. This study was done to evaluate and compare the prevalence of ovarian failure in adult SLE(aSLE) and juvenile SLE(jSLE) post CYC .

Table 1

Hormone (normal range)	Group	Mean level (±SD)	Range	Number of patient's withnormal serum levels (%)
LH (2.4-12.6 mIU/ml)	jSLE (n=14)	3.75 ± 3.86	0.10 – 11.67	8 (57.1%)
	aSLE(n=14)	15.38 ± 26.35	1.38 – 103.00	9 (64.3%)
FSH (3.5-12.5 mIU/ml)	jSLE (n=14)	3.64 ± 1.89	0.75 – 6.85	7 (50%)
	aSLE (n=14)	14.29 ± 37.10	1.41 – 143.00	9 (64.3%)
E2 (12.5 – 166 pg/ml)	jSLE (n=14)	54.08 ± 55.40	5.00 – 179.40	9 (64.3%)
	aSLE (n=14)	117.32 ± 92.18	10.41 – 355.90	10 (71.4%)
AMH (ng/ml)	j SLE (n=14)	2.954 ± 1.57	0.979 – 6.705	14 (100%)
	aSLE (n=14)	2.30 ± 2.91	0.010 – 9.868	13 (92.9%)
Inhibin B	j SLE (n=14)	89.81 ± 122.91	33.33 – 442.03	12 (85.7%)
	aSLE (n=14)	47.47 ± 8.84	35.40 – 66.90	14 (100%)

Ovarian volume	Number	Mean ovarian volume cm^3	Range
jSLE *	11	4.85 ± 3.43	2.09 – 10.99
aSLE**	11	10.10 ± 5.60	2.87 – 18.84
Follicular count	**Number**	**Mean total follicular count**	**Range**
jSLE	7	9.28 ± 4.53	3 – 18
aSLE	8	7.25 ± 3.28	5 – 13

*cSLE ovarian volume was calculated in 11 patients out of 14 patients and three patients had small or streaky ovaries. **aSLE ovarian volume was calculated in 11 patients out of 14 patients and two patients had polycystic ovaries and in one patient ovaries were not visible.

Methods: jSLE and aSLE patients post CYC therapy were enrolled. Their medical records were reviewed and cumulative dose and duration of CYC therapy noted. A detailed menstrual history was sought and serum levels of FSH, LH, E2, AMH, Inhibin and ultrasonography for ovarian volume and follicular count was done between 3-5 days of menstrual cycle.

Results: Twenty eight (14 jSLE, 14 aSLE) patients were included. The mean age was 14.79 ± 4.7 years and 29.07 ± 5.7 years respectively. Mean cumulative dose of CYC was 3996.4 ± 1800 mg in jSLE , and 5235.7 ± 2563.6 mg in aSLE

Among 14 jSLE patients, 12 had not attained menarche when CYC was administered, and all of them subsequently attained menarche (Mean age = 14.78 ± 2.33 years). Two patients in the jSLE group developed menstrual abnormalities: 1 had transient amenorrhea which recovered in 3 monthsof stopping CYC, the other developed persistent oligomenorrhea, although with normal AMH. Among 14 aSLE patients, 11 developed menstrual abnormalities after initiating CYC which recovered to normal in 8 patients. Three patients continued to have oligomenorrhea . Serum levels of FSH, LH, E2, AMH, Inhibin and ultrasound for ovarian volume and follicular count have been summarized in Table 1&2.

Conclusion: There was no delay in attainment of menarche in jSLE patients who received CYC before menarche. None of the patients developed overt ovarian failure in either jSLE or aSL, although persistence of oligomenorrhea was noted in a few patients.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

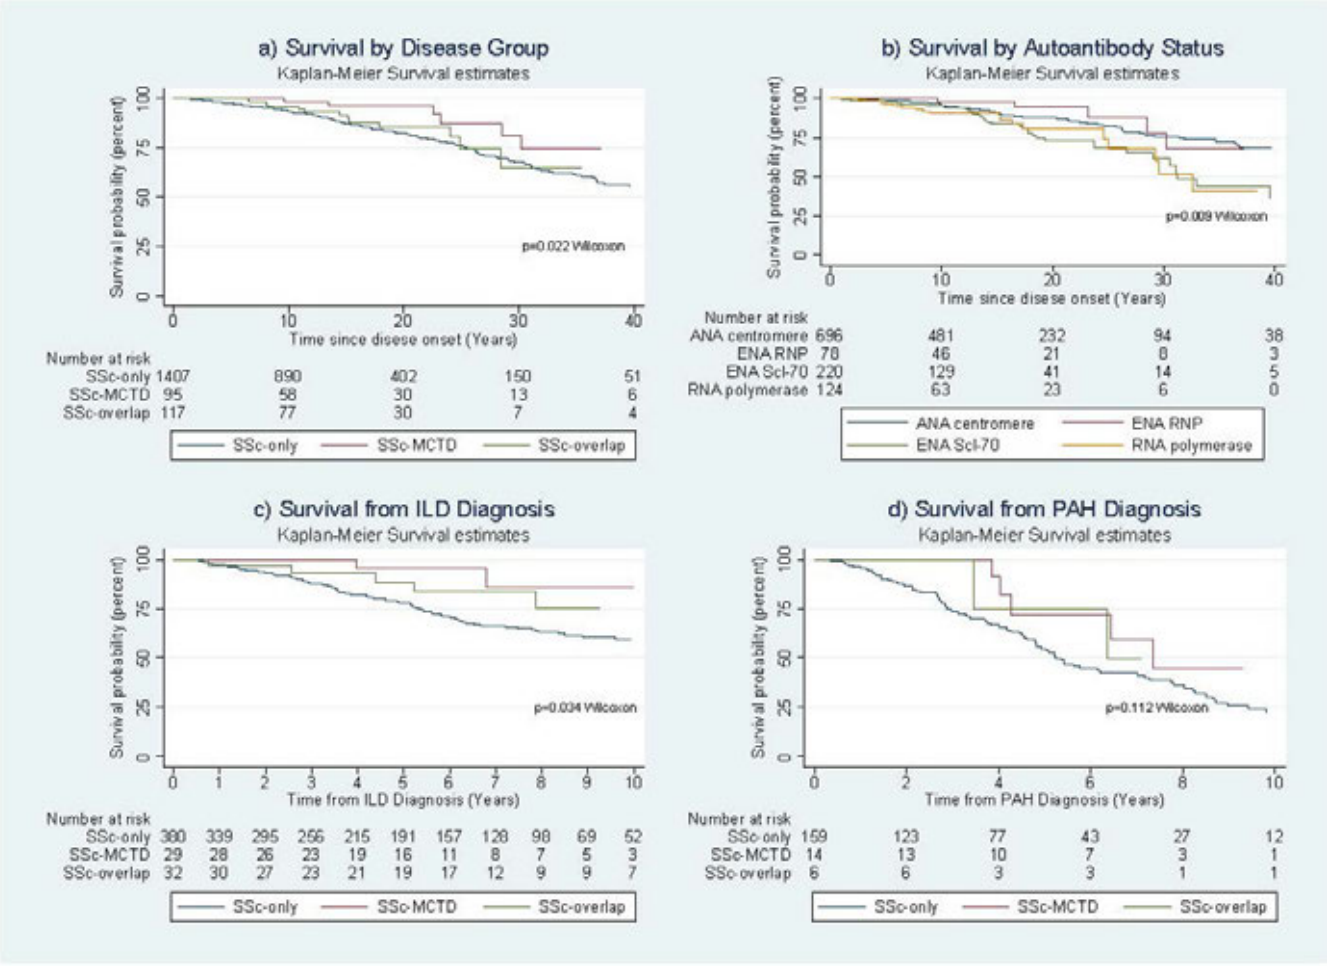

Figure 1. a) Survival by disease group; b) survival by antibody status; c) survival from diagnosis of ILD according to disease group; d) survival from diagnosis of PAH by disease group.

Background/Purpose: Mixed connective tissue disease (MCTD) is defined by presence of anti-RNP antibody together with 3 or more of swollen hands, synovitis, myositis, Raynaud phenomenon or acrosclerosis. Patients who fulfil diagnosis of SSc and have features of other connective tissue diseases are often classified as SSc-overlap. Our study aims to describe the clinical characteristics and outcomes of SSc-MCTD and SSc-overlap.

Methods: We included patients from the Australian Scleroderma Cohort Study (ASCS) who met ACR/EULAR diagnostic criteria for SSc. Three mutually exclusive groups were created: SSc-MCTD, SSc-overlap and SSc-only group (remaining patients). Univariate comparison of clinical features among groups was performed by ANOVA or chi-square. Survival analysis was performed using Kaplan-Meier curves, Wilcoxon test and Cox regression.

Results: Of 1728 patients, 102 (5.9%) had SSc-MCTD and 125 (7.2%) SSc-overlap. Those with MCTD-SSc were more commonly Asian (18.4% vs 9.3% in SSc-overlap and 3.6% in SSc-only, $p< 0.0001$). Those with SSc-MCTD or SSc-overlap were more likely to have limited SSc (81-84% vs. 73.1% for SSc-only). Both SSc-MCTD and SSc-overlap groups were more likely than SSc-only to have numerous positive autoantibodies such as anti-Ro, anti-Jo-1 and anti-Sm. SSc-MCTD and SSc-overlap had similar frequency of interstitial lung disease (ILD), while those with SSc-MCTD had higher frequency of pulmonary arterial hypertension (PAH) (13.7% vs 4.8% in SSc-overlap and 11% in SSc-only, $p=0.0589$). Synovitis and myositis were equally common in SSc-overlap and SSc-MCTD groups. SSc-MCTD or SSc-overlap conferred a higher likelihood of exposure to immunosuppression including prednisolone, synthetic and biologic DMARDs, than SSc-only . Overall survival was better in SSc-MCTD than SSc-overlap or SSc-only (Figure 1 a). However, scleroderma-specific antibodies were also survival prognostic markers, with ANA-centromere or anti-RNP conferring better survival than anti-Scl-70 or anti-RNA polymerase 3 (Figure 1 b). SSc-MCTD and SSc-overlap had lower all-cause mortality following diagnosis of ILD (Figure 1 c) and PAH than patients with SSc-only (Figure 1 d).

Conclusion: This study reveals significant clinical and survival differences between patients with SSc-MCTD, SSc-overlap and SSc-only. Importantly, despite higher frequency of PAH in SSc-MCTD, survival is better in SSc-MCTD and SSc-overlap than in SSc-only patients.

Prognostic Role of Measurement of Renal Resistive Index in Systemic Sclerosis

Shefali sharma,[1] Arghya Chattopadhyay,[2] Siddharth Jain,[2] Varun Dhir,[3] Mahesh Prakash,[3] and Manish Rathi[2], [1]Dr., Chandigarh, Chandigarh, India, [2]Post Graduate Institute of Medical Education and Research, Chandigarh, Chandigarh, India, [3]Post Graduate Institute of Medical Education and Research, Chandigarh, India

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Spectrum of vascular involvement in systemic sclerosis (SSc) is diverse like Raynaud's phenomenon, digital ulcers, pulmonary hypertension and renal disease. Recognition of markers of subclinical disease is an area of active interest in SSc. This study was undertaken to assess the correlation of renal resistive index (RRI) with both renal and systemic vasculopathic manifestations.

Methods: In this single-centre prospective study, RRI was calculated for consecutive SSc patients classified as per the ACR/EULAR 2013 criteria. Elevated RRI (>0.7) was correlated with renal function (eGFR and proteinuria). RRI was compared with other systemic vasculopathic manifestations like digital ulcers, digital infarcts and pulmonary hypertension.

Results: Seventy three patients (mean age= 41.79 ±10.92) were included. Mean RRI in the right and left renal artery was 0.65 ±0.082 and 0.66±0.075 respectively. Sixteen out of 73 patients (21.9%) had increased RRI (>0.7). A negative correlation was noted between elevated RRI and eGFR (r= -0.958 p=0.026). Patients with significant proteinuria was also higher in the group with elevated RRI (r= 1), although not statistically significant (p=0.164). Similarly, digital ulcers and infarcts/pitting were numerically higher in the group with raised RRI, although statistical significance was not reached (p=0.09 and 0.28 respectively). No correlation of RRI with pulmonary arterial hypertension was identified (r=0.009, p=0.948).

Conclusion: Measurement of RRI holds promise as a tool for assessment of subclinical renal vasculopathy and systemic vasculopathy, and needs to be addressed in larger systematically designed studies with longer follow-up.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In systemic sclerosis (SSc) and idiopathic inflammatory myopathies (IIM), auto-antibodies are used in daily practice as potent biomarkers of clinical phenotypes. This study aimed at estimating the prevalence of myositis-specific (MSA) and myositis-associated (MAA) autoantibodies in SSc, and studying their clinical associations.

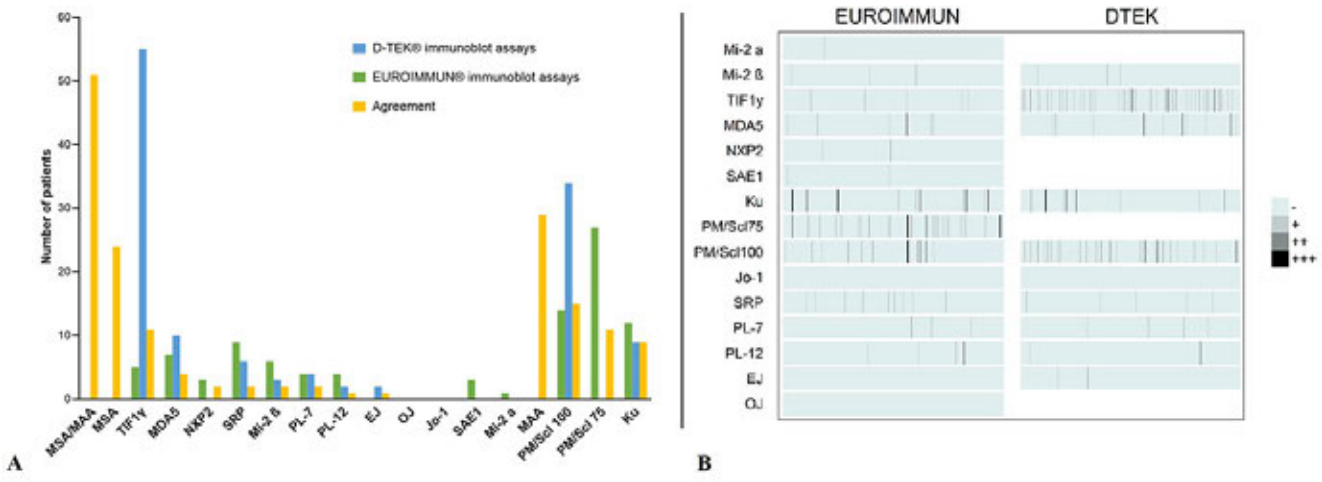

Figure 1. Distribution of patients with positive MSA and MAA in this cross-sectional study of 300 SSc patients. (A) Prevalence of MSA and MAA with EUROLINE, D-TEK immunoblot assays and after agreement. (B) Heatmap of the MSA and MAA immunoblot assay reactivities among patients. EJ: anti-glycyltRNA synthetase; Jo-1: anti-histidyl-tRNA synthetase; Ku: anti-DNA-dependent protein kinase; MAA, myositis associated antibodies; MDA5: anti-melanoma differentiation-associated gene 5; Mi-2: Anti-nuclear helicase/ATPase; MSA, myositis specific antibodies; OJ: anti-isoleucyl-tRNA synthetase; PM/Scl: anti-polymyositis scleroderma antigen; NXP2: anti-nuclear matrix protein 2; PL-7: anti-threonyl-tRNA synthetase; PL-12: anti-alanyl-tRNA synthetase; SRP: anti-signal recognition particle; TIF1γ: anti-transcriptional intermediary factor 1 gamma

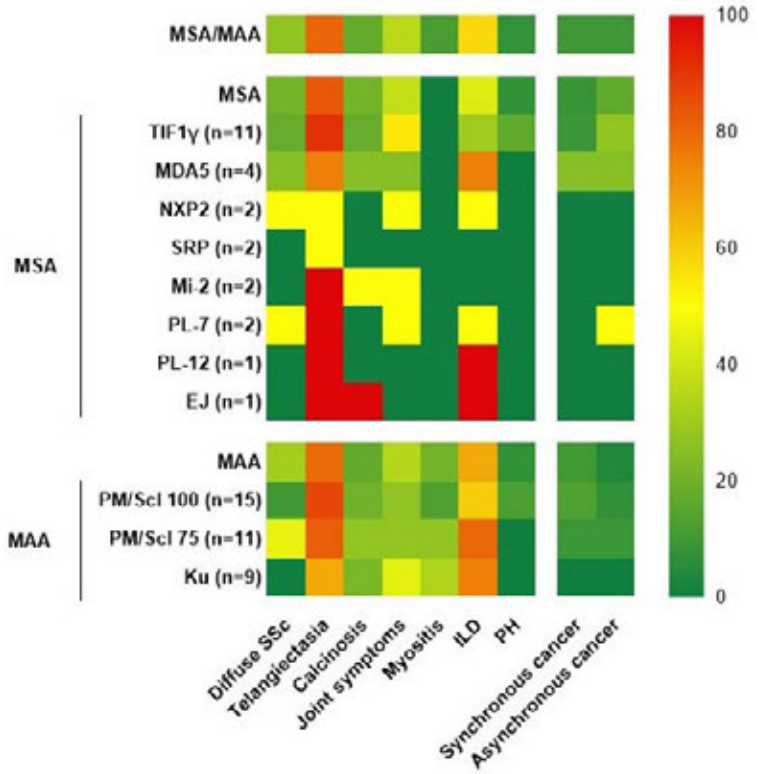

Figure 2. Main characteristics of MSA and MAA positive patients in in this cross-sectional study of 300 SSc patients. EJ: anti-glycyltRNA synthetase; ILD, interstitial lung disease; Jo-1: anti-histidyl-tRNA synthetase; Ku: anti-DNA-dependent protein kinase; MAA, myositis associated antibodies; MDA5: anti-melanoma differentiation-associated gene 5; Mi-2 β: Anti-nuclear helicase/ATPase Béta; MSA, myositis specific antibodies; OJ: anti-isoleucyl-tRNA synthetase; PH, pulmonary hypertension; PM/Scl: anti-polymyositis scleroderma antigen; NXP2: anti-nuclear matrix protein 2; PL-7: anti-threonyl-tRNA synthetase; PL-12: anti-alanyl-tRNA synthetase; SRP: anti-signal recognition particle; TIF1γ: anti-transcriptional intermediary factor 1 gamma.

Methods: We realized a cross-sectional, observational, single-center study. The sera of 300 consecutive patients were tested with myositis antibodies Euroimmun® and D-tek® immunoblot assays to estimate prevalence of MSA and MAA and study their clinical associations.

Results: Prevalence of MSA/MAA, MSA and MAA were 17%, 8.0% and 9.7%, respectively. Anti-PM/Scl 100 were found in 5.0% (95% confidence interval 2.8; 8.1); anti-PM/Scl 75 and anti-TIF1γ in 3.7% (1.8; 6.5); anti-Ku 3.0% (1.4; 5.6); anti-MDA5 in 1.3% (0.4; 3.4); anti-Mi-2β, anti-NXP2, anti-PL7 and anti-SRP in 0.7% (0.08; 2.4); anti-EJ and anti-PL-12 in 0.3% (0.01; 1.8) of patients. No reactivity against SAE1, Jo-1 or OJ was observed (**Figure 1**). Anti-PM/Scl 75 antibodies were associated with interstitial lung disease (80% vs 42%, p = 0.022) and myositis (27% vs 3%, p = 0.005); anti-PM/SCL 100 antibodies were associated with abdominal discomfort (38% vs 8%, p = 0.029); anti-Ku antibodies were associated with myositis (33% vs 3%, p = 0.003). There was a trend towards an association between anti-TIF1γ and cancer (27% vs 8%, p = 0.060) (**Figure 2**).

Conclusion: In this cross-sectional study of 300 SSc patients, the prevalence of MSA/MAA, MSA and MAA were 17%, 8.0% and 9.7%, respectively. MAA positivity was associated with ILD and myositis, but this study did not highlight any clinical associations with MSA positivity.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis usually represents a late manifestation of limited systemic sclerosis (lSSc), inducing chronic calcifications that lead to significant impairment in the quality of life. As an effective treatment for calcinosis in SSc is an unmet need in clinical practice, the identification of risk factors associated with its presence is rather important for the development of therapeutic strategies.

The aim of this study was to compare and analyze clinical aspects and laboratory parameters, including bone metabolism, in female lSSc patients with and without calcinosis, paired by disease duration, age and body mass index (BMI).

Methods: Thirty-six female lSSc patients with calcinosis were compared to 36 female lSSc patients without calcinosis, matched by disease duration, age and BMI. Modified Rodnan skin score (mRSS) was used to determine

the extension of the skin involvement. Organ involvement, autoantibodies, bone mineral density (BMD) by DXA and laboratory parameters were analyzed. The past and current treatment modalities were also questioned. Statistical significance was considered if $p< 0.05$.

Results: Esophageal hypomotility, digital ulcers and interstitial lung disease were the most frequent clinical manifestations of lSSc patients, present in similar frequency in both groups. In univariate analysis, calcinosis was significantly associated with acroosteolysis (69% vs. 22%, $p< 0.001$), higher modified mRSS (4.28±4.66 vs 1.17±2.50, $p< 0.001$), higher 25OH vitamin D (24.46±8.15 vs. 20.80±6.60ng/ml, $p=0.040$) and phosphorus serum levels (3.81±0.41 vs. 3.43±0.45mg/dl; $p< 0.001$). Antinuclear antibodies (ANA) was positive in 89% in both groups. Anticentromere antibody was frequent (44% and 31%), while positive anti-Scl70 was rare in both groups. Regarding treatment, current use of glucocorticoid was lower in patients with calcinosis compared to patients without calcinosis (8% vs. 28%; $p=0.032$). Osteoporosis was more frequent in the group with calcinosis (31% vs.17%), although not statistically significant. Multivariate analysis confirmed and quantified the risk for calcinosis: acroosteolysis (OR=12.04; 95% CI:2.73-53.04; $p=0.001$), mRSS (OR=1.37; 95% CI:1.11-1.69; $p=0.003$), phosphorus serum levels (OR=5.07; 95% CI:1.06-24.23; $p=0.042$), and lower glucocorticoid use (OR=0.07; 95% CI:0.007-0.66; $p=0.021$).

Conclusion: This study showed that lSSc patients with calcinosis present a distinct clinic and biochemical profile, characterized by acroosteolysis, higher mRSS score, higher serum levels of phosphorus and lower glucocorticoid use, when compared to a matched group without calcinosis, paired by disease duration, age, and BMI.

Computer Vision Applied to Dual Energy Computed Tomography Images for Precise Calcinosis Cutis Quantification in Patients with Systemic Sclerosis

Anita Chandrasekaran,[1] Imran Omar,[2] Zhicheng Fu,[3] Shangping Ren,[3] and Monique Hinchcliff[1], [1]Yale University, Section of Rheumatology, Allergy and Immunology, New Haven, CT, [2]Northwestern University Feinberg School of Medicine, Chicago, IL, [3]San Diego State University, Department of Computer Science, San Diego, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis cutis, found in both systemic sclerosis (SSc) and juvenile dermatomyositis patients, can be extensive and debilitating. Potential treatments have been identified, but a standardized and validated method for precise and accurate whole-body calcinosis cutis burden quantification is necessary to allow for valid clinical trials. Dual energy computed tomography (DECT) can differentiate between calcinosis cutis and healthy bone, but a radiologist must manually quantify the irregularly shaped lesions, which is time-consuming and costly. Computer vision, including convolutional neural network (CNN) algorithms, has been increasingly applied to solve problems in clinical medicine with success. The aim of this study is to optimize a CNN algorithm to facilitate quantification of calcinosis cutis disease burden.

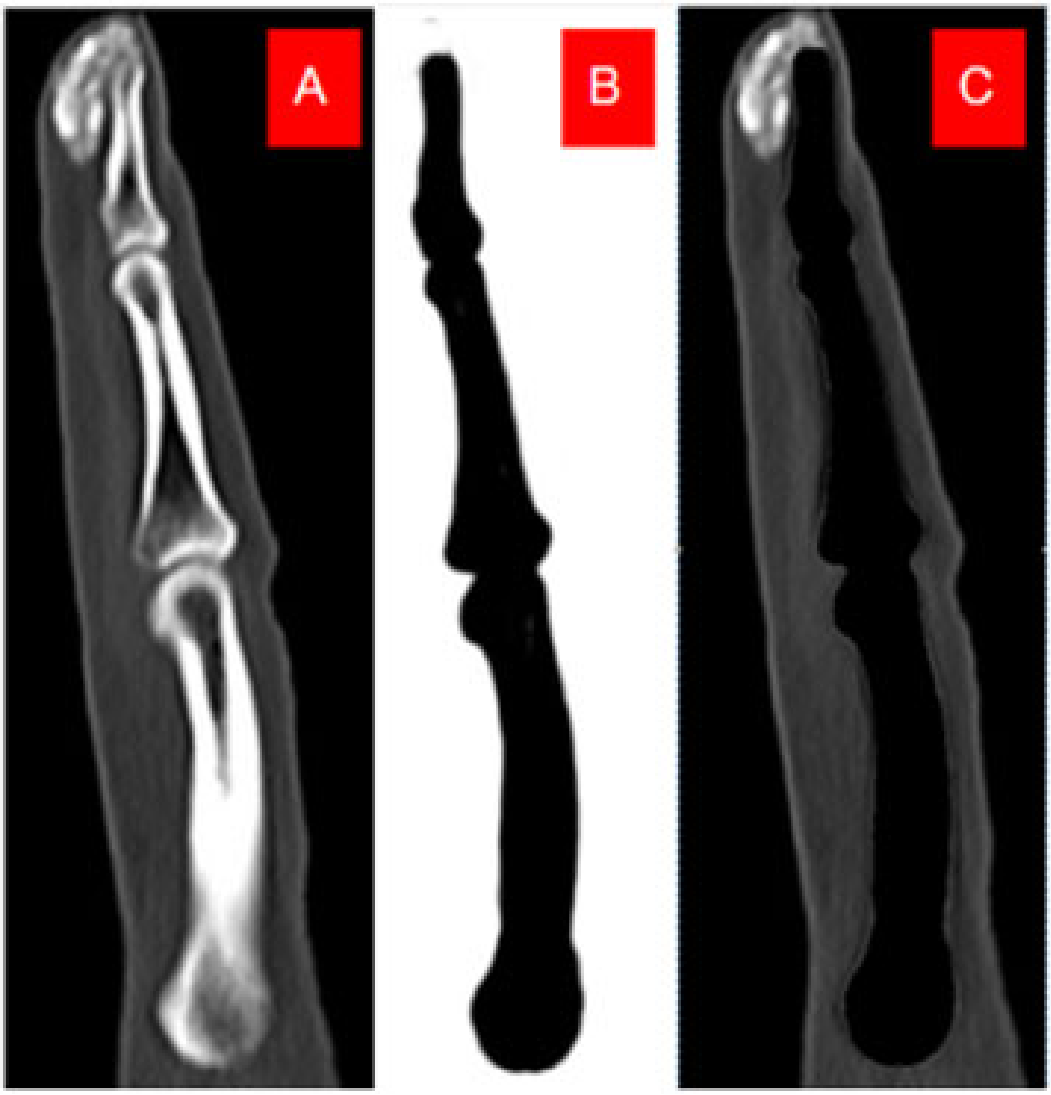

Image 1A. Representative 2D DECT hand image from a patient with SSc Image 1B: Segmented healthy finger bone Image 1C: Highlighted calcinosis cutis lesion, identified by subtracting normal finger bone from the overall image, emphasizing the area of dystrophic calcium

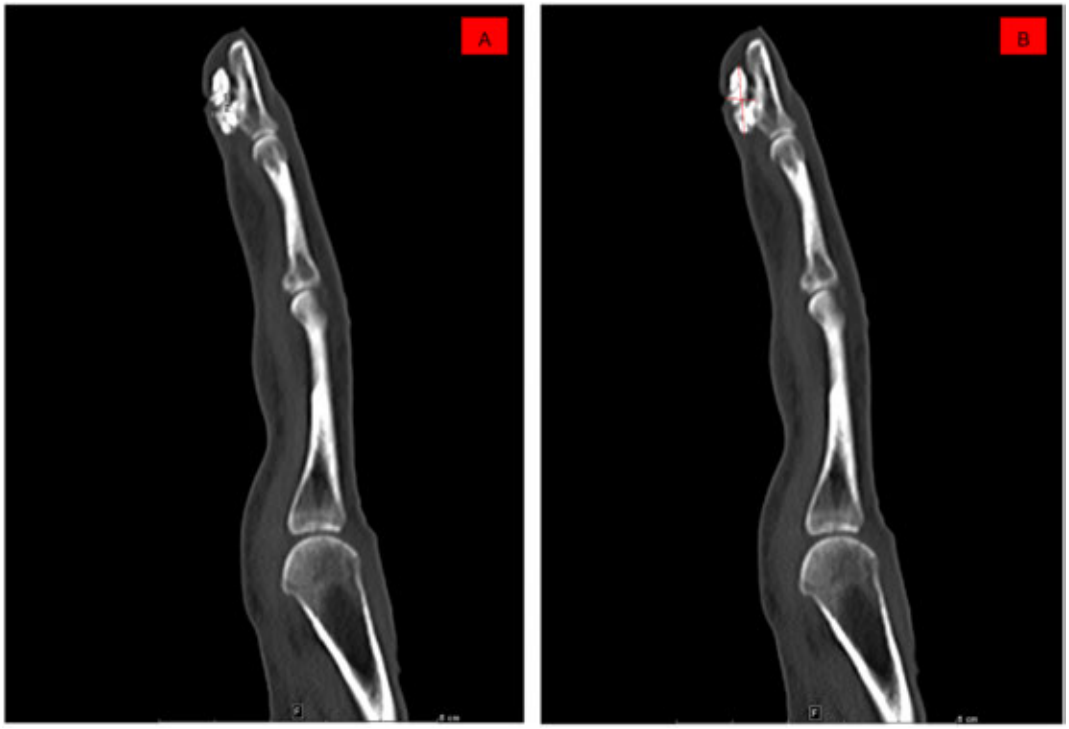
Methods: De-identified 2-dimensional (2-D) DECT images from patients with SSc, with clinically apparent calcinosis cutis, were obtained. An expert musculoskeletal radiologist manually segmented the three forefinger phalanges to serve as the gold standard comparison. Computer scientists then trained and tested the CNN algorithm for finger bone segmentation. After reliable finger bone segmentation was achieved, the area of a calcinosis cutis lesion was measured and compared to measurements performed by a radiologist to test the utility of the CNN approach.

Results: Thirty 2D DECT hand images from patients with SSc were used to identify the most appropriate CNN algorithm for finger bone segmentation (Image 1A, representative image). The U-net CNN algorithm demonstrated superior performance. 500 epochs were necessary to adequately segment healthy finger bones from adjacent dystrophic calcifications (Image 1B). Calcinosis cutis lesions were then identified by subtracting normal finger bones from the image to permit the computer to “see” the dystrophic calcium lesions (Image 1C). When measured by a radiologist, the length x width of the lesion was used to calculate the 2-D area, assuming a relatively smooth lesion contour (Image 2A), whereas the CNN-calculated 2-D area utilized pixel intensities (Image 2B).



A demonstrates a radiologist-measured calcinosis cutis lesion, using the length x width of the lesion and assuming a relatively smooth contour, while B demonstrates the same lesion measured by the CNN algorithm, utilizing pixel intensities.

Conclusion: To our knowledge, the present study is the first to apply computer vision to the challenge of calcinosis cutis quantification. We demonstrate that CNN algorithms applied to DECT hand images of SSc patients can be used to differentiate calcinosis cutis lesions from adjacent healthy bone. When compared to the gold standard of radiologist review, CNN algorithms take into account lesion irregularity, which may allow for more precise measurements.

Hospitalization Among Incident Cases of Systemic Sclerosis: Results from a Population-based Cohort (1980-2016)

Caitrin Coffey,[1] Avneek Singh Sandhu,[2] Cynthia Crowson,[3] Sara Achenbach,[1] Eric Matteson,[4] Thomas Osborn,[5] Kenneth Warrington,[6] and Ashima Makol[5], [1]Mayo Clinic, Rochester, MN, [2]kettering health, dayton, OH, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, [5]Mayo Clinic Minnesota, rochester, MN, [6]Mayo Clinic Rochester, Rochester, MN

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an autoimmune disorder associated with multi-organ dysfunction, requiring long-term and multi-disciplinary care. Few studies have estimated the healthcare resource usage of patients with SSc. The purpose of this study was to compare hospitalization among incident cases of SSc vs age- and sex-matched comparators.

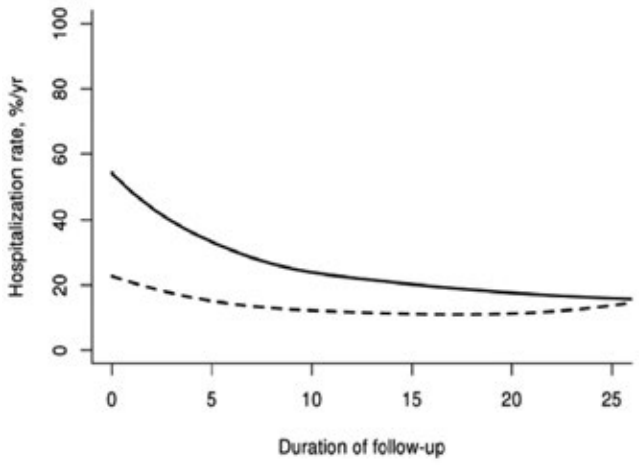
Methods: A retrospective, population-based cohort of physician-diagnosed patients with SSc in a geographically well-defined area from Jan 1, 1980 to Dec 31, 2016 was identified and utilized for this study. A 2:1 cohort of age- and sex-matched non-SSc subjects from the same population was randomly selected for comparison. Patients who died or emigrated from the area prior to 1987 were excluded. Patients were followed until death, migration from the geographic area or Sep 30, 2018. All hospitalizations in the geographic area from Jan 1, 1987 to Sep 30, 2018 were obtained. Primary discharge diagnosis information was available for hospitalizations in 1995 to present. Readmission was defined as occurring within 30 days of a discharge. Rates of hospitalization of cases and comparators were analyzed using person-year methods and rate ratios. Length of stay was analyzed using generalized linear models adjusted for age, sex and calendar year, with random intercepts to account for multiple hospitalizations per patient.

Results: The cohort included 76 incident SSc cases and 155 non-SSc comparators (mean age of 56 ± 16 years at diagnosis/index, both 91% female). Mean length of follow-up was 11.5 (SD 8.5) years for SSc subjects and 13.3 (SD 8.6) years for comparators. Rates of hospitalization among cases and comparators were 31.9 and 17.9 per 100 person-years, respectively (rate ratio [RR]:1.78; 95% confidence interval (CI):1.52-2.08)(Table). By sex, men (RR:4.33;

Table. Hospitalization rates in patients with and without SSc overall and by sex

Group	Cohort	Number of hospitalizations	Person-years of follow-up	Rate per 100py	Rate Ratio (95% CI)
Overall	SSc	278	872.4	31.9	1.78 (1.52, 2.08)
	Non-SSc	369	2062.7	17.9	
Women	SSc	239	813.4	29.4	1.63 (1.38, 1.92)
	Non-SSc	349	1929.9	18.1	
Men	SSc	39	59.1	66.0	4.33 (2.58, 7.60)
	Non-SSc	20	132.8	15.1	

Figure. Age- and sex- adjusted hospitalization rates among SSc patients (solid line) and non-SSc comparators (dashed line) according to disease duration



95%CI:2.58-7.60) and women (RR:1.63; 95%CI:1.38-1.92) with SSc had substantially higher hospitalization rates than comparators.

Hospitalization rates were higher in SSc compared with non-SSc subjects during the first 5 years after SSc diagnosis (RR: 2.16; 95%CI:1.70-2.74). This difference decreased over time and was no longer significant for ≥15 years after SSc incidence/index (Figure). Patients age 65+ were more frequently hospitalized than younger subjects in both SSc and comparator groups, and the difference in hospitalization rates between groups was largest in those age < 50 years (RR: 2.54: 95% CI: 1.73-3.75).

SSc subjects were more frequently hospitalized for infections and diseases involving circulatory, digestive, and respiratory systems than comparators, with ratios ranging from 1.96 to 3.90. Lengths of stay (median (IQR) 4 (2-6) vs 3(2-6); p=0.52) and readmission rates (25% vs 23%; p=0.51) were similar among cases and comparators.

Conclusion: A higher frequency of hospitalization occurred among patients with SSc compared to non-SSc subjects, indicating high inpatient care needs in this population. Hospitalization rates were highest among SSc subjects during the first 5 years of SSc diagnosis. Hospitalization rates approached those of non-SSc comparators over time after diagnosis, possibly due to confounding by age and other comorbidities.

Longitudinal Changes in Health-related Quality of Life in Systemic Sclerosis Treated with Autologous Hematopoietic Stem Cell Transplant Compared to Standard of Care

Nancy Maltez,[1] Mathieu Puyade,[2] Pauline Lansiaux,[3] Mianbo Wang,[4] Murray Baron,[5] Ines Colmegna,[6] Dominique Farge,[7] and Marie Hudson[8], [1]The Ottawa Hospital, Ottawa, [2]CHU de Poitiers Unité d'Hospitalisation d'Aval, Poitiers Cédex, France, [3]Institut de Recherche Saint-Louis, Paris, France, [4]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada, [5]Jewish General Hospital, McGill University, Montreal, Canada, [6]McGill University Health Center, Montreal, QC, Canada, [7]Hôpital Saint-Louis, AP-HP Assistance Publique des Hôpitaux de Paris, Centre de Référence des Maladies Auto-Immunes Systémiques Rares d'Ile-de-France, Filière 'FAI2R', Unité de Médecine Interne: Maladies Auto-immunes et Pathologie Vasculaire (UF 04), Université de Paris, EA 3518, Paris, France; Department of Medicine, McGill University, Montreal, QC, Canada, Paris, France, [8]Jewish General Hospital, Lady Davis Institute for Medical Research, and Department of Medicine, McGill University, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In severe, early progressive systemic sclerosis (SSc), autologous hematopoietic stem cell transplantation (AHSCT) allows significant improvements in overall and event free survival. The objectives of this study were to quantify the magnitude, domains and duration of improvement in HRQoL in SSc subjects treated with AHSCT compared to standard of care in the setting of routine clinical care.

Methods: We compared SSc patients treated with AHSCT to SSc patients who fulfilled ASTIS eligibility criteria for AHSCT but who were treated with standard of care. Outcomes of interest were the Health Assessment Questionnaire

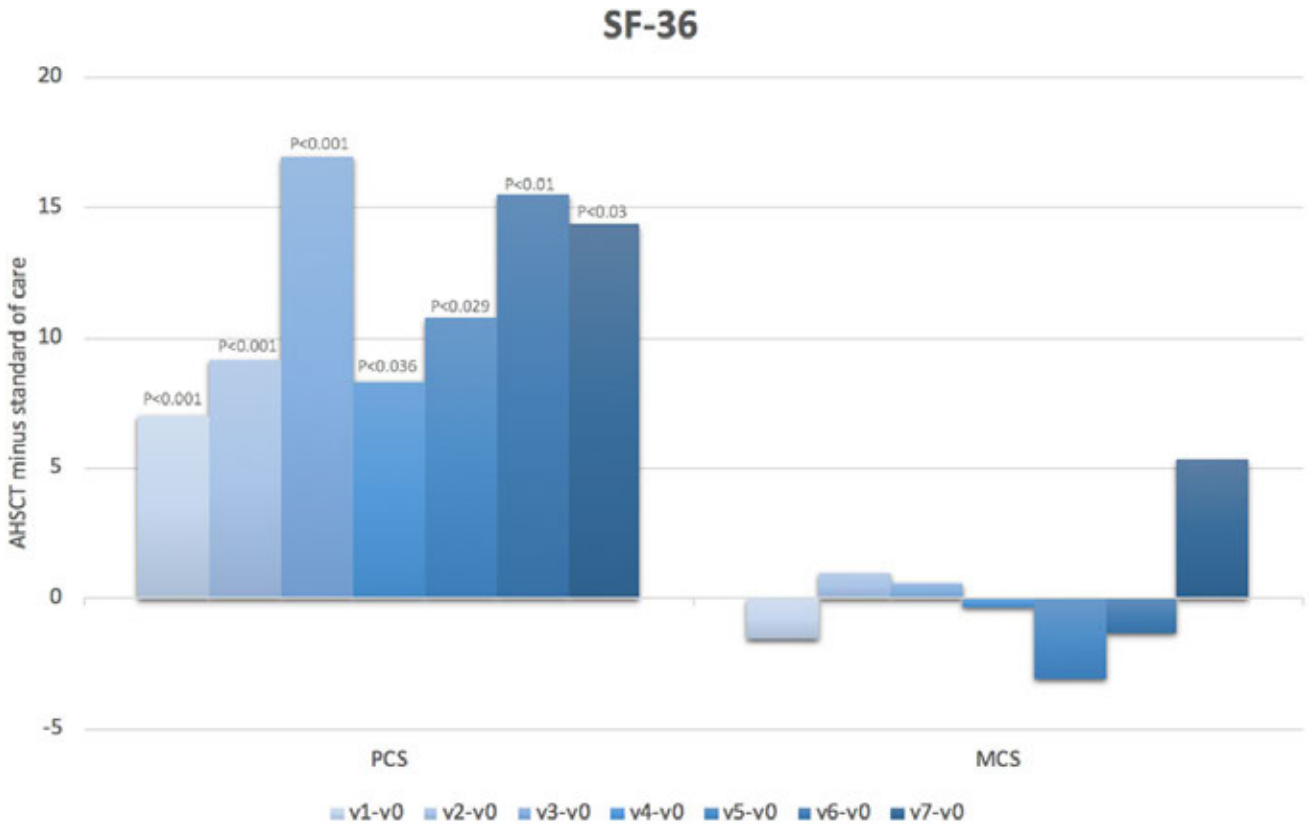

Figure 1. SF-36 Physical and Mental Component Summary Scores. X axis shows differences in scores between follow up study visits and baseline. Y axis shows the differences in scores between subjects treated with AHSCT versus those treated with standard of care.

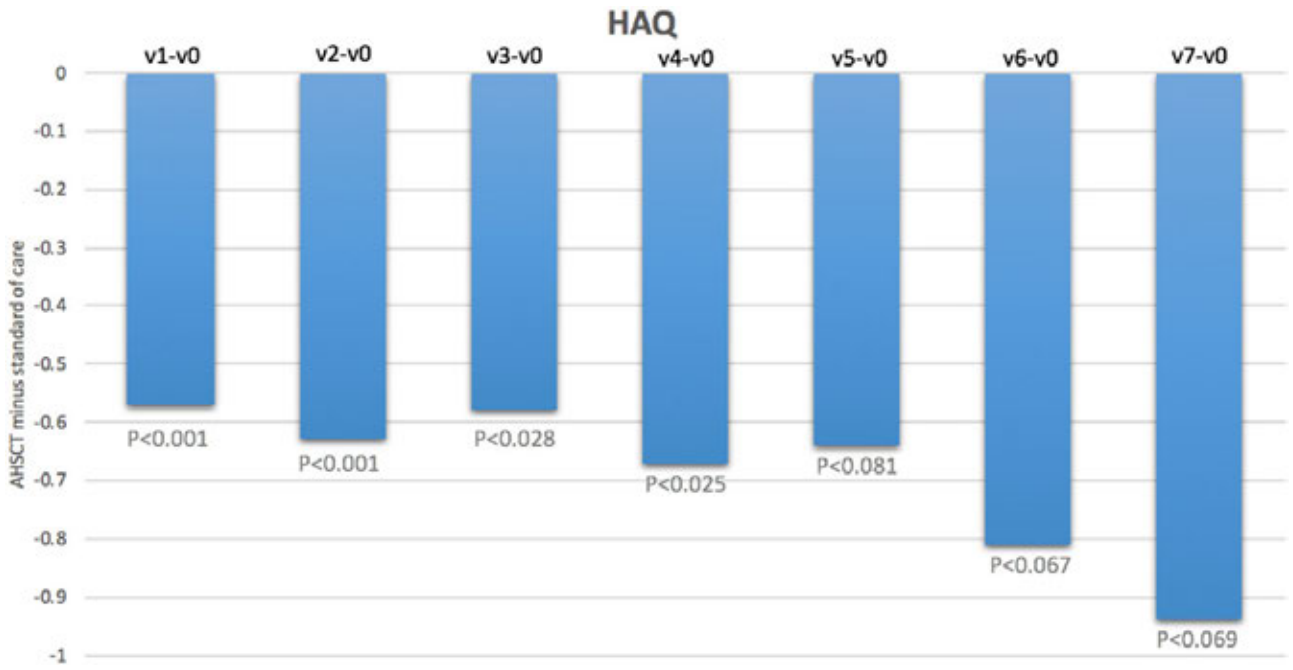

Figure 2. Health Assessment Questionnaire (HAQ) scores. X axis shows differences in scores between follow up study visits and baseline. Y axis shows the differences in scores between subjects treated with AHSCT versus those treated with standard of care.

(HAQ) and its disease-specific visual analogue scales (VAS), and the Short Form Health Survey-36 (SF-36) Physical Component Summary (PCS) and Mental Component Summary (MCS) scores. Differences in HAQ, VAS and SF-36 scores were compared using linear models, adjusting for baseline scores and inverse probability of treatment weights

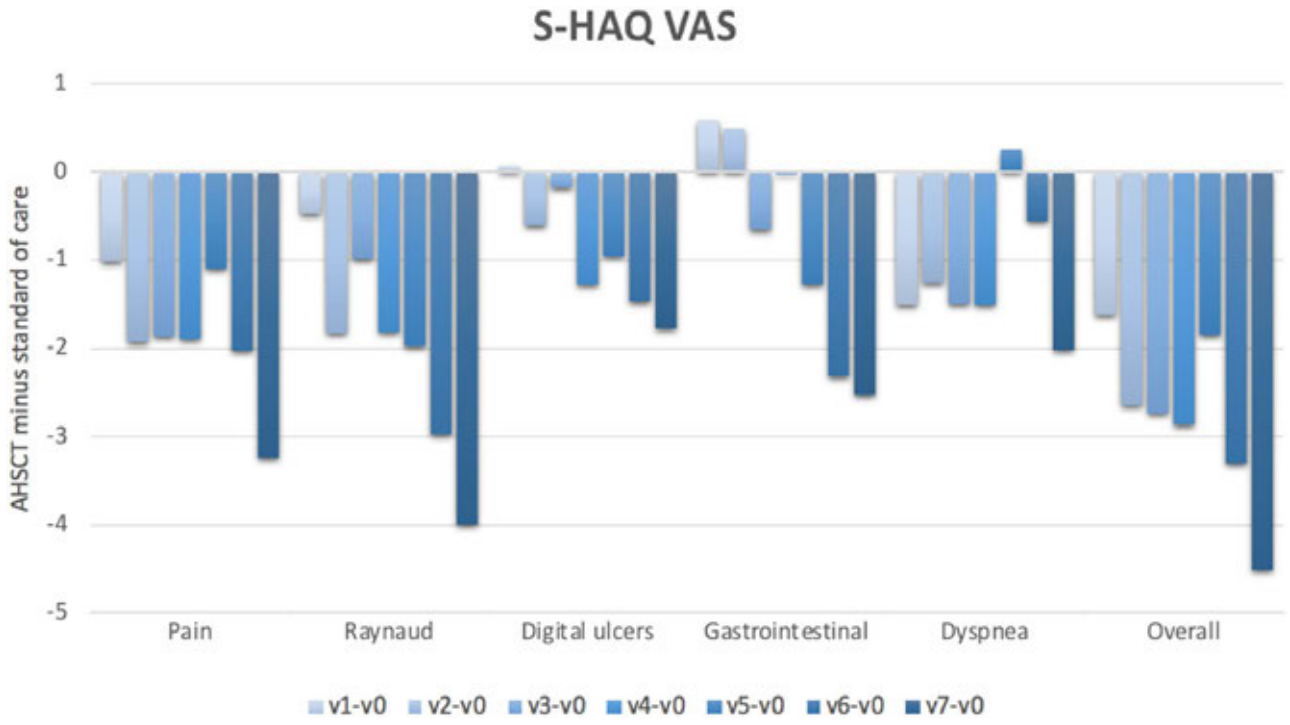

Figure 3. Scleroderma-Health Assessment Questionnaire Visual Analogue Scales (S-HAQ VAS). X axis shows differences in scores between follow up study visits and baseline. Y axis shows the differences in scores between subjects treated with AHSCT versus those treated with standard of care.

(iptw), calculated as 1/propensity score (ps) for the AHSCT subjects and 1/(1-ps) for the standard of care subjects. Propensity scores were estimated using logistic regression including the following covariates: female, age, disease duration, and other variables with a p-value < 0.10 in univariate comparisons. In addition, to account for the potential informative censoring between baseline and follow-up visits, the inverse probability of censoring weights (ipcw) was estimated by logistic regression, using the same covariates as in the propensity score model. The outcome model was a marginal linear model including only AHSCT, weighted by the product of the iptw and ipcw.

Results: We included 41 subjects who underwent AHSCT (66% female, mean age 44.7 years, mean disease duration 2.6 years, mean modified Rodnan skin score (mRss) 25, interstitial lung disease (ILD) present in 93%, FVC %predicted 79% and DLCO %predicted 55%) and 69 subjects treated with standard of care (78% female, mean age 53.9 years, mean disease duration 1.5 years, mean mRss 27, ILD 47%, FVC %predicted 84% and DLCO %predicted 64%). Baseline HAQ scores were 1.4$\pm$0.7 in both groups. Baseline SF-36 PCS and MCS scores were 33.4 and 30.1, and 41.8 and 46.2, respectively, in the AHSCT and standard of care subjects. At baseline, the most severely affected VAS scale was that of general health. On a scale of 0-10, the mean was 4.9 in the AHSCT subjects and 5.1 in the standard of care subjects. In marginal linear weighted models, HAQ, VAS and SF-36 PCS scores were significantly better in subjects treated with AHSCT compared to standard of care, and the differences largely surpassed minimal clinically important differences (Figures 1-3). These differences also increased over time. However, there were no differences in SF-36 MCS scores in subjects treated with AHSCT compared to standard of care.

Conclusion: AHSCT was associated with marked improvement in physical HRQoL compared to standard of care, and the improvement was sustained and increased over time. This adds considerable complementary data to traditional biomedical outcome measures to support the role of AHSCT in severe SSc. Further research will be needed to understand why there is no difference in mental HRQoL after AHSCT compared to standard of care.

Cyclophosphamide for the Treatment of Skin Fibrosis in Systemic Sclerosis: A Systematic Review

Marie Hudson,[1] **Nancy Maltez**,[2] Catherine Ivory,[2] and Melissa Demery-Varin[3], [1]Jewish General Hospital, Lady Davis Institute for Medical Research, and Department of Medicine, McGill University, Montreal, QC, Canada, [2]The Ottawa Hospital, Ottawa, [3]University of Ottawa, Ottawa

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic disease characterized by multi-organ involvement. Excess collagen deposition and fibrosis is thought to result from a complex interplay between vasculopathy and inflammation. Skin fibrosis, and its extent, is a cardinal feature of SSc, and permits its classification in diffuse and limited subsets. Evidence for the pharmacologic management of skin involvement is limited and there is a need for further clinical guidance. Cyclophosphamide is an alkylating agent with potent immunomodulating effects, commonly used in rheumatic diseases. The objective of this systematic review was to assess the efficacy of Cyclophosphamide in the treatment of skin fibrosis in patients with SSc.

Methods: Embase, MEDLINE and Cochrane Central Register of Controlled Trials were searched for all randomized control trials (RCTs), quasi-randomized studies, case-control studies, controlled before-after studies, prospective and retrospective cohort studies, case series and cross-sectional studies on February 7, 2019. Case reports were excluded. The Health Canada registry, clinicaltrials.gov, the ISRCTN registry, and the World Health Organization (WHO) international clinical trials registry were searched for grey literature. Studies pertaining to patients with a diagnosis of SSc were included with no limitation on specific classification criteria. The main intervention of interest was Cyclophosphamide with no limitation of regimens or route of administration. Comparators were other standard disease modifying agents or placebo. The outcome of interest was extent of skin fibrosis defined by the modified Rodnan skin score (mRss). Two review authors completed independent and duplicate abstract and full text screening. Data extraction and quality appraisal were completed independently by two review authors. Meta-analysis was performed for the primary outcome (mRSS) through random-effects models.

Results: Thirty-one studies conducted between 1994 and 2018 were included: 11 RCTs, 13 case series, 4 retrospective cohort studies and 3 prospective cohort studies. The majority of the 11 RCTs showed some concerns in regards to risk of bias. After 12 months of treatment with Cyclophosphamide, mean mRSS decreased 6.30 points (95% CI, 4.95 to 7.64). The effect remained significant when pooling both 6- and 12-month outcomes – mRSS decreased 4.11 points (95% CI, 0.97, 7.25). Heterogeneity of comparators, use of steroids, and outcome endpoints did not allow for subgroup analyses to be completed as planned.

Conclusion: Statistically and clinically significant improvements in mRSS with administration of Cyclophosphamide were demonstrated in patients with SSc. The effect was greater at 12 months of follow-up. The lack of consistent standard of care for the treatment of skin fibrosis in SSc was highlighted by the variability in the type and duration of comparator treatments used in clinical trials. Although the use of Cyclophosphamide for skin fibrosis in SSc is justified by these results, there is a need for more consistent recommendations regarding treatment regimens, and longer clinical follow-up to better understand the role of immunosuppression as a treatment for this disease manifestation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, the hypothesis that autoantibodies to the angiotensin II type 1 (AT1R) and endothelian-1 type A (ETAR) receptors are driving the vascular injury and fibrosis in systemic sclerosis (SSc) has gained support from both clinical and basic science research. Cross sectional studies show levels of AT1R and ETAR are associated with increased risk of pulmonary arterial hypertension (PAH), scleroderma renal crisis (SRC) and digital ulcers (DU). Exposure to immunoglobulins from patients with AT1R and ETAR antibodies directly inhibits angiotensin converting enzyme-2 activity and both antibodies induce fibrotic and vasoconstrictive cellular signaling. We hypothesized that the presence of AT1R and ETAR would be associated with the development of vascular complications in an observational cohort of very early diffuse SSc patients followed from their first SSc Center visit.

Methods: Patients with early stage diffuse cutaneous SSc (< 2 years of disease) who were consented to a prospective, observational cohort study at their first visit between 1/1/2009 and 5/15/2014 were included. Patients were followed for at least 5 years with vascular complications noted at each visit, specifically digital pitting, digital ulceration, digital gangrene, SRCand PAH. SSc-associated antibodies were run by immunoprecipitation and immunodiffusion. ELISA assays of AT1R and ETAR (Cell Trend GmbH) were performed on serum samples obtained at the time of first visit. SAS 9.4 (Cary, NC) was used for statistical analysis.

Results: 56 patients were seen over a period of 5 to 10 years with a median of 7 follow-up visits (IQR 2, 11.5). Baseline characteristics are in Table 1. There was no difference in rates of vascular complications at baseline in those positive for ETAR and AT1R antibodies (Table 1). There was no difference in incidence of vascular complications, although digital gangrene approached statistical significance in ETAR positive patients (Table 2). There was a significantly higher frequency of ETAR antibodies in Scl-70 positive patients which is consistent with prior studies.

Conclusion: To our knowledge, this is the first study to use a inception cohort of early diffuse SSc to evaluate for an association between AT1R and ETAR antibody positivity and incident vascular complications. The lack of association between presence of AT1R or ETAR antibodies and either early or new development of vascular complications in early diffuse SSc does not support the hypothesis that the vascular injury that characterize SSc is due to functional AT1R

or ETAR antibodies nor support utilizing these autoantibodies as prognostic markers for the development vascular complications.

Asymptomatic Scleroderma Antibody Positivity and Progression to Systemic Sclerosis

Derek Jones,[1] Marissa Mangini,[1] Sydney Wearing,[1] and **Victoria Shanmugam** [2], [1]The George Washington University School of Medicine and Health Sciences, Washington, DC, [2]George Washington University, Georgetown, DC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis is an autoimmune disease characterized by inflammation, vasculopathy and fibrosis of the skin, vasculature and internal organs along with disease specific autoantibody formation. Patients are subtyped as limited or diffuse scleroderma based on extent of skin involvement and autoantibody profile. Recent retrospective studies have shown that autoantibodies may precede a clinical diagnosis of scleroderma by several years. However, some individuals with scleroderma specific autoantibodies and no symptoms never progress to a clinical diagnosis of scleroderma. The purpose of this study is to investigate the characteristics of asymptomatic scleroderma antibody positive (ASAP) individuals in a longitudinal biorepository.

Methods: All subjects gave written informed consent for longitudinal collection of their data. Data is collected on demographics, baseline disease phenotype, baseline disease activity scores including modified Rodnan skin score (mRSS), scleroderma health assessment questionnaire disability index (HAQ-DI), gastrointestinal score, physician global assessment and Medsger severity score. Data were analyzed using GraphPad Prism (version 7.0).

Results: At the time of data-lock, there were 90 patients with data available for analysis. At the baseline visit, 41 fulfilled ACR criteria for limited scleroderma, 19 met criteria for diffuse scleroderma, and 30 patients were in the ASAP group. There were no statistically significant differences in age, gender or race in the limited, diffuse of ASAP patients. Patients with limited scleroderma were more commonly centromere antibody positive (p 0.0031). As expected, baseline mRSS was significantly higher in the diffuse scleroderma subset. Over a mean follow up of 1.27 years, patients in the ASAP group demonstrated no significant change in mRSS indicating lack of progression of disease.

Conclusion: The current study investigated a cohort of asymptomatic scleroderma antibody positive individuals enrolled in the STOP scleroderma biorepository who do not exhibit diagnostic criteria for scleroderma at baseline and did not demonstrate progression to clinically diagnosable scleroderma. This cohort of patients with autoantibody positivity but no progression of disease is of interest to investigate molecular biomarkers of non-progression in patients with scleroderma specific antibody positivity.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic sclerosis (SSc) complicates variety of cardiopulmonary diseases which can result in pulmonary hypertension (PH). The types of PH are usually classified by the result of right heart catheterization (RHC) based on values of mean pulmonary arterial pressure (mPAP), pulmonary artery wedge pressure (PAWP), and pulmonary vascular resistance (PVR): Group 1 as mPAP >20mmHg, PAWP ≤15mmHg, and PVR ≥3WU; Group 2 as mPAP >20mmHg, PAWP >15mmHg, and PVR < 3WU. However, by this classification, patients with PH having normal PAWP (≤15mmHg) and normal PVR (< 3 WU) are categorized as neither Group 1 PH nor Group 2 PH and have a possible contribution of left heart disease (LHD). We therefore examined whether LHD is contributing among SSc-PH patients with such RHC results.

Methods: We retrospectively investigated 43 patients with SSc who were diagnosed as PH by RHC from 2006 through 2018 at our University hospital. Nice classification updated in 2018 was used in the diagnosis and classification of PH. To identify lesions responsible for PH, inspections with cardiac echocardiography, cardiac MRI, and myocardial scintigraphy were conducted.

Results: The mean age of the enrolled 43 patients was 66 (11) year-old, 88% of them were female. Twenty-one percent of the patients had diffuse cutaneous SSc. Mean follow-up periods were 56 (33) months. Of the 43, 17 (40%) of the patients had severe interstitial lung disease with % forced vital capacity ≤70% (Group 3). Among the rest of 26 patients, 5 (19%) had PAWP >15mmHg (Group 2). Of the remaining 21 patients, only 10 patients (48%) had PVR ≥3 WU and was classified as Group 1 and another 11 had PAWP ≤15mmHg and PVR < 3WU. Among them, 9 patients (82%) showed less than 7 of diastolic pressure gradient obtained from RHC, indicating the presence of postcapillary PH. Among them, 6 patients (55%) had an elevation of E/e' and/or left atrial volume index (LAVI), suggesting left diastolic dysfunction by cardiac echocardiography. Myocardial damage was detected by cardiac MRI [n = 6 (55%)] or myocardial scintigraphy [n = 6 (55%)]. Based on the results, 5 patients were diagnosed as precapillary PH and another 5 as postcapillary PH in addition to 5 with PAWP >15mmHg [in total, 10 / 43 (23%) with SSc-PH had LHD-associated PH]. The diagnosis was undetermined in one patient who had mixed characteristics of pre- and postcapillary PH. Pulmonary vasodilators were introduced in 5 patients who were clinically diagnosed as precapillary PH while diuretics and/or antihypertensive drugs were introduced in another 4 diagnosed as postcapillary PH. One patient died from PAH during the mean follow-up.

Conclusion: Since significant number of patients may have LHD, particularly diastolic dysfunction-associated PH even among SSc patients with normal PAWP as well as those with PAWP >15mmHg, careful diagnosis and therapeutic intervention with pulmonary vasodilator are required in this patient population. Longitudinal follow up will be needed to study the impact of the LHD on the survival.

[a]Includes patients with sine sclerosis
Abbreviations: ANA=anti-nuclear antibody; GAVE=gastric antral vascular ectasia; PAH=pulmonary arterial hypertension; SRC=scleroderma renal crisis; SSc=systemic sclerosis

Background/Purpose: Degos disease, also known as malignant atrophic papulosis (MAP), is a rare small-vessel vasculopathy that has characteristic cutaneous manifestations consisting of erythematous telangiectatic rims with porcelain-white atrophic centers with variable gastrointestinal vasculopathy that can be fatal (Figure 1). Studies suggest that endothelial dysfunction and immune dysregulation may play a role in subsequent intimal proliferation and occlusive vasculopathy in cutaneous Degos lesions. Lesions that mimic the cutaneous findings in Degos disease have been described in other rheumatic diseases, although their significance is unclear. We sought to evaluate the prevalence and clinical associations of Degos lesions in patients with systemic sclerosis (SSc).

Methods: This was a retrospective cohort study of 504 patients with SSc, who were seen at a tertiary referral center between 1998 and 2018. All patients fulfilled 2013 ACR/EULAR classification criteria for SSc. Demographics, autoantibodies, and cutaneous and internal organ manifestations of patients with and without Degos lesions were compared using chi-squared tests for categorical variables, accounting for missing data. Logistic regression analyses were performed to evaluate whether Degos lesions were predictive of any internal organ complications.

Results: Of 504 SSc patients, 21 (4.2%) had Degos lesions. In 19 (90.5%), Degos lesions were found on the hands, notably the fingers. Two patients had Degos lesions involving the lower extremities. Degos lesions were significantly associated with acro-osteolysis, calcinosis, and digital ischemic loss (Table 1). There was a trend towards statistically significant associations with diffuse SSc subtype and telangiectasias. We further assessed whether Degos lesions were predictive of any internal organ complications. We found a trend, both in univariate and multivariate logistic regression analyses, towards an association with GAVE (Table 2).

Conclusion: Degos lesions are present in 4.2% of our SSc cohort. Degos lesions are associated with other cutaneous manifestations of SSc including acro-osteolysis, calcinosis, and digital ischemia, supporting an underlying ischemic and vasculopathic etiology. Our findings suggest that Degos lesions may be associated with the presence of GAVE.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Aminaphtone treatment improves clinical symptoms of Raynaud's phenomenon (RP) and increases peripheral blood perfusion (BP) in patients with either primary or secondary RP (1-2).The aim of this study was to assess possible interferences of different treatment backgrounds on RP related clinical symptoms as well as on skin BP in patients treated with aminaphtone, during a six-month follow-up.

Methods: Forty-six patients with active RP were enrolled during routine clinical assessment (11 primary RP, mean age 49±19 SD years, mean RP duration 6±3 years; and 35 secondary RP to systemic sclerosis (SSc), mean age 61±17 years, mean RP duration 11±9 years). Aminaphtone was orally administered 75 mg twice daily in addition to current standard treatments, and all patients were on a stable drug regimen since at least two months, which remained unmodified during the follow-up. All patients were taking aspirin. Six groups of treatment backgrounds were identified: 1) hydroxychloroquine (2 patients); 2) methotrexate (3 patients); 3) colchicine (5 patients); 4) cyclosporine A (6 patients); 5) mycophenolate (6 patients); 6) proton-pomp inhibitors (12 patients); 7) no further treatments (12 patients). Raynaud's condition score (RCS) and both frequency and duration of Raynaud's attacks were assessed at the same time. Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA) (3) at the level of fingertip, periungual areas, dorsum and palm of hands, and face at baseline (T0), after one (T1), four (T4), twelve (T12) and twentyfour (T24) weeks of treatment. Statistical analysis was performed by non-parametric tests.

Results: During aminaphtone treatment, a progressive statistically significant increase of blood perfusion, as well as an improvement of RP clinical symptoms (decrease of RCS, frequency and duration of RP attacks/day), were observed in all above reported seven groups of RP patients with different treatments backgrounds from T0 to T12 in all skin areas ($p< 0.01$). There were no statistically significant difference between the seven groups of patients concerning skin BP at different times ($p=0.60$). The results were similar in both primary and secondary (to SSc) RP patients ($p=0.40$). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up.

Conclusion: This study demonstrates that the increase of skin blood perfusion and the improvement of RP clinical symptoms are not influenced by different treatment backgrounds in RP patients treated with aminaphtone.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic autoimmune disease, characterized by microvascular damage and progressive fibrosis. Among clinical complications, abnormal body composition and sarcopenia have been reported in SSc patients (1,2). Nailfold videocapillaroscopy (NVC) is a safe diagnostic tool to assess microvascular progressive damage and may predict severe organ involvement in SSc (3).

The aim of this study was to evaluate body composition in SSc patients and assess possible differences between patients with specific NVC patterns of microangiopathy.

Methods: 42 patients (6 men and 32 women) fulfilling ACR 2013 criteria for SSc underwent NVC (Videocap, DS MediGroup, Milan) to assess their NVC patterns ("Early", "Active" and "Late" pattern) (4) and dual-energy X-ray absorptiometry scan (DXA) (Lunar Prodigy) to evaluate body composition. In particular we analyzed: total mass, total lean mass, total fat mass, bone mineral content (BMC), and bone mineral density (BMD) in seven body areas (head, upper limbs, lower limbs, trunk, spine, ribs, pelvis). Sarcopenia was diagnosed in patients with reduced skeletal

muscle index (RSMI) below 5.45 Kg/m^2 for females and 7.25 Kg/m^2 for males (5). Statistical analysis was performed by non parametric tests.

Results: The mean age of patients was 65±10 years, mean disease duration 18.5 ±7.2 years, mean Rodnan skin score (mRSS) 11.2±9.3, and mean RSMI 6.3±1.1 g/cm^2. All the patients showed a NVC "scleroderma pattern": in particular 15 patients showed the "Late" pattern, 15 patients the "Active" pattern and 8 patients the "Early" NVC pattern. The "Late" NVC pattern group comparing to "Early/Active" group showed significantly lower total mass (57280±8107 *vs* 67025±10456 gr, p=0.01), lean mass (34259±3266 *vs* 40532±7659 gr, p=0.04), RSMI (5.8±0.91 *vs* 6.5±1.0 g/cm^2, p=0.02), BMC (1769±332 *vs* 2075±501 gr, p=0.04), trunk BMD (0.71±0.11 *vs* 0.88±0.13 g/cm^2,p=0.05) and spine BMD (0.90±0.17 *vs* 1.05±0.15 g/cm^2, p=0.008). No statically significant difference between the two group was observed regarding total fat mass, total body BMD and BMD at upper limbs, lower limbs, head, ribs and pelvis. Interestingly, 25% of SSc patients were found affected by sarcopenia, and the most of sarcopenic patients showed the "Late" NVC pattern (65%). Comparing age, disease duration, mRSS between sarcopenic and non sarcopenic patients there was no difference between the groups, but sarcopenic patients presented a statistically significant lower BMI (p=0.02).

Conclusion: This study demonstrates in SSc patients a relationship between a more severe microvascular damage ("Late" SSc pattern) and the body composition, characterized by lower weight, lower total lean mass, lower bone mineral content and sarcopenia, without any significant variation in total fat mass. These clinical conditions seem not to be associated with severity of skin involvement and/or disease duration.

'If You Don't Use It, You Lose It': Rehabilitation of Finger Dexterity and Ability to Perform Activities of Daily Living in Systemic Sclerosis

Elena Eusterwiemann,[1] Marina Anderson,[2] Mark Robinson,[1] and Gabor Barton[1], [1]Liverpool John Moores University, Liverpool, United Kingdom, [2]Aintree University Hospital, Liverpool

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hand involvement due to increased skin thickness and skin collagen content is one of the first manifestations of systemic sclerosis (SSc) leading to a reduced joint mobility, flexion contractures and an reduced ability to perform activities of daily living (ADL) (Young et al., 2016). However, successful execution of ADLs

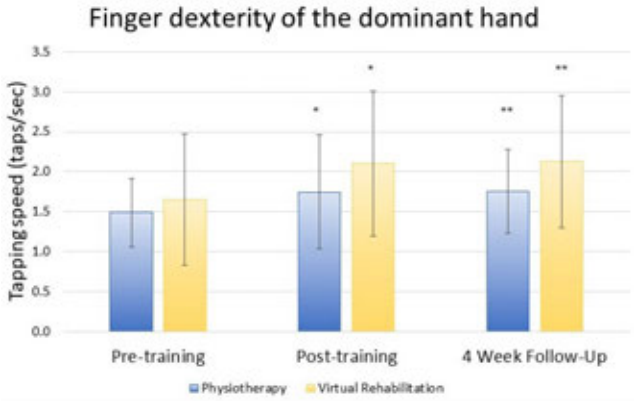

Figure 1. Finger dexterity of Digits 2-4 assessed in a keyboard tapping exercise. Tapping speed over 15 seconds was calculated. *Significant improvement in tapping speed between the pre- and post-training was maintained for 4 weeks after exercise completion (**) significant improvement between pre-training and after 4 weeks wash-out period (4 Week Follow Up).

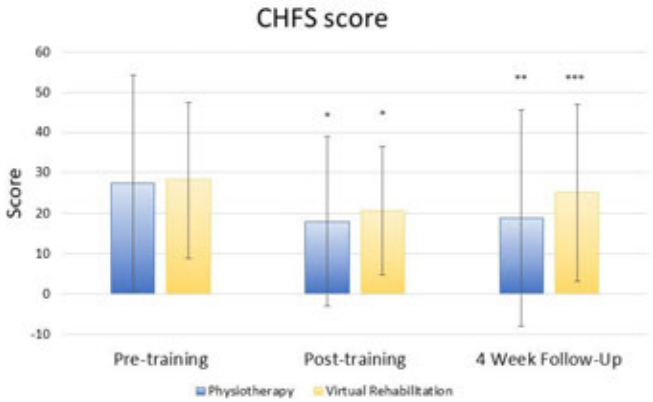

Figure 2. Cochin Hand Function scale (CHFS) score was significantly reduced after exercises (*significant change in CHFS between pre-training and post-training test). In the Physiotherapy group, this was maintained after the four week wash out period (** significant reduced CHFS score between pre-training and 4 Week Follow up). The virtual rehabilitation group showed a loss in hand function after the four week follow up resulting in a non-significant difference between pre-training and 4 week follow up test, but a significant increase between post-training and 4 week follow up (***).

not only relies on hand mobility, but also finger dexterity (Perez-Marmol et al., 2017). The activation of small muscles to synchronise hand and finger movement during ADLs is under neural control and reduced use of muscles leads to inefficient recruitment of motor units, and therefore reduced motor skills. Recommended hand exercises for SSc (Young et al., 2016) train range of motion, but less so dexterity. Virtual rehabilitation programmes have shown beneficial effects on both range and motor control (Levin et al., 2015). The aim of this study was to compare the effect of physiotherapy and virtual rehabilitation on finger dexterity and ability to perform ADLs.

Methods: Twenty SSc patients were recruited from a rheumatology clinic (mean age: 54.8yrs± 23.1yrs; female: n=19, male = 1) and randomly split into two groups (each n= 9, drop out: n =2) performing 90min of hand exercises per week for four weeks. One group followed a novel virtual rehabilitation programme, involving playing a computer game using hand movements. The second group completed a physiotherapy exercise regime. Prior to, immediately after and four weeks after completion of the exercises patients filled in the Cochin Hand Function Scale (CHFS). A finger dexterity test on a customised keyboard was completed using digits 2-4 and the average tapping speed over 15 seconds was calculated. A two-way mixed design ANOVA for the CHFS and finger dexterity test was conducted in SPSS and the change in CHFS and dexterity were correlated using bivariate two-tailed Pearson correlation.

Results: Both interventions showed significant improvements in ability to perform ADLs (Figure 1) ($p = 0.03$) and finger dexterity (Figure 2) ($p = 0.02$) when comparing pre-training and post-training tests. Whilst finger dexterity was maintained over the 4-week wash out period (post-training to 4-Week follow up), the ability to perform ADLs was not sustained in the virtual rehabilitation group ($p = 0.05$). No intervention programme showed a significantly better improvement than the other group on either outcome measure ($p = 0.401$). Change in CHFS and finger dexterity between test sessions was not correlated ($r = -0.09$, $p= 0.72$). This pattern was identical in the non-dominant hand, showing there is no effect of hand dominance.

Conclusion: Exercise improved both functional and neural aspects of hand function. The improvement in finger dexterity suggests that patients not only suffer a structural limitation but also a loss in fine motor skills. Finger dexterity could therefore form an important new outcome measure to assess the key clinical issue of reduced hand function in SSc. Further hand function rehabilitation in SSc should integrate a component to address dexterity in addition to mobility. The loss of neural control over finger motion in SSc should be assessed further assessed in future research.

Trabecular Bone Score and Malnutrition in a Cohort of Systemic Sclerosis Patients

Massimo Patane',[1] Sabrina Paolino,[1] Veronica Tomatis,[2] Andrea Casabella,[3] Carmen Pizzorni,[1] Luca Carmisciano,[4] Alessio Signori,[4] and **Maurizio Cutolo** [5], [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Genoa, Italy, [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy.2Biostatistics Unit, Department of Health Sciences, University of Genoa, Genoa, Italy, genova, Liguria, Italy, [3]1 Research Laboratory and Academic Division of the Clinical Rheumatology Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Genoa, Italy, [4]Biostatistics Unit, Department of Health Sciences, University of Genoa, Genoa, Italy, [5]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genoa, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a connective tissue disease characterized by microvascular damage, immune system activation and progressive fibrosis of the skin and internal organs. Gastrointestinal (GI) involvement induce malnutrition due to gastroesophageal symptoms GI dismotility and malabsorption that are related to fibrosis of bowel wall and bacterial overgrowth[1]. Therefore the disease is associated with secondary osteoporosis with a few studies evaluating the bone microarchitecture.

The aims of the staid is to evaluate a relationship between malnutrition and bone microarchitecture detected by trabecular bone score (TBS) in SSc patients

Methods: 38 patients (6 male and 32 female) fulfilling ACR 2013 criteria for SSc underwent dual-energy X-ray absorptiometry scan (DXA) to detect quantitative lumbar spine bone mineral density and TBS. DXA also assess body composition with a software that provides the physician quantitative parameters, including free fat mass index (FFMI), that identifies the patient with malnutrition (values< 15 kg/m2 in women and 17 kg/m2 in men), according to the

ESPEN criteria. Body mass index was calculated for all SSc patients and every patient completed a diary reporting GI symptoms possibly related to intestinal disbiosis. Fasting blood samples were obtained in order to analyse some biochemical parameters of malnutrition (total proteins, albumin, total cholesterol and blood lymphocyte count)2 Continue variables were summarized as mean and standard deviation or median and inter quartile range, discrete variables were summarized with count and percentage. Correlation was tested with Pearson or Spearman method. T-test was used to compare TBS between dichotomic groups. Uni and multivariate linear regression models were used as well the Multiple R-squared variation was applied.

Results: The mean age of patients was 64.2±11.3 years with mean disease duration 19.2±7.6 years. 36.8% of patients was found malnourished. The univariate analysis showed that only higher age of patients correlated to lower TBS ($p< 0.001$). The R2 of multivariate linear regression showed that about 45% of the TBS variations (TBSv) can be explained by the variation of the following variables (age, disease duration, lymphocyte count). Age explains about 25% of the TBSv. Older patients had lower TBS, with 0.05 points of TBS loss every decade ($p=0.001$). The presence of symptom possibly related to intestinal disbiosis, added to the model, might explains about 12% more of TBSv. Patients with symptom related to bacterial overgrowth had lower TBS respect to patients without (-0.08 $p=0.002$). Disease duration, added to the model, further explains about 4% more of TBSv and suggest a trend between highest disease duration and higher TBS ($p=0.103$). Lymphocyte count added to the model also seems to explain about 4% more of TBSv, in fact lowest number appear to have interference on TBS ($p=0.020$)

Conclusion: This study shows that a more severe microarchitectural bone defect correlates with gastrointestinal involvement in term of symptom related to intestinal disbiosis and with selected blood biochemical markers of malnutrition

Changes in Fecal Microbiota Composition After Fecal Microbiota Transplantation in Systemic Sclerosis

Anna Maria Hoffmann-Vold,[1] Håvard Fretheim,[2] Brian Chung,[3] Henriette Didriksen,[3] Espen Bækkevold,[3] Øyvind Midtvedt,[3] Cathrine Brunborg,[3] Kristian Holm,[3] Anders Tennøe,[3] Torhild Garen,[3] Tore Midtvedt,[4] Marius Trøseid,[3] Johannes Hov,[3] Knut Lundin,[3] and Øyvind Molberg[2], [1]Department of Rheumatology, Oslo University Hospital, Oslo, Norway, Oslo, Norway, [2]University Hospital Oslo, Oslo, Norway, [3]Oslo University Hospital, Oslo, Norway, [4]Karolinska University Hospital, Stockholm, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In the double-blind, placebo-controlled 16-week pilot including 10 systemic sclerosis (SSc) patients with upper and lower gastrointestinal (GI) symptoms we found that fecal microbiota transplantation (FMT) with commercially-available anaerobic cultivated human intestinal microbiota (ACHIM) reduced lower GI symptoms. Here, we aimed to determine relative abundance of gut microbiota at baseline and changes after FMT.

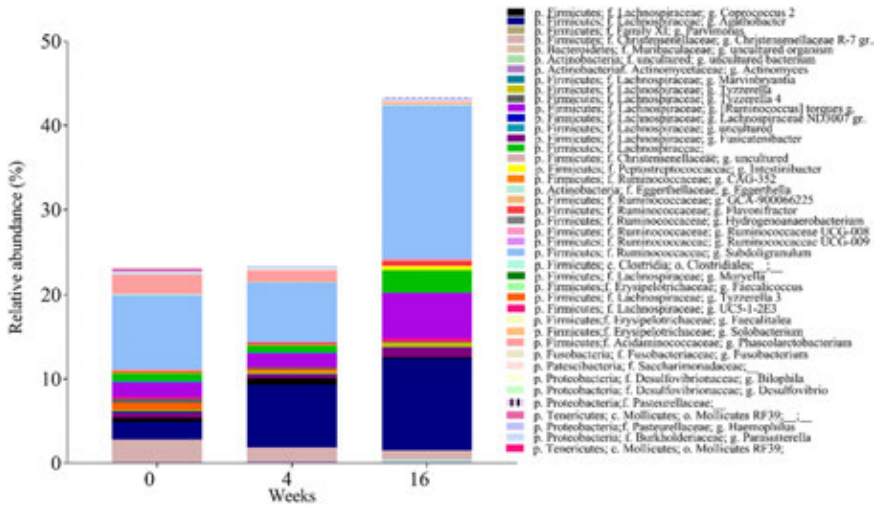

Figure 1. Relative abundance of unsorted (total) bacteria. Only bacteria with change (p<0.1) in relative abundance of unsorted bacteria from week 0-4 or week 0-16 are shown.

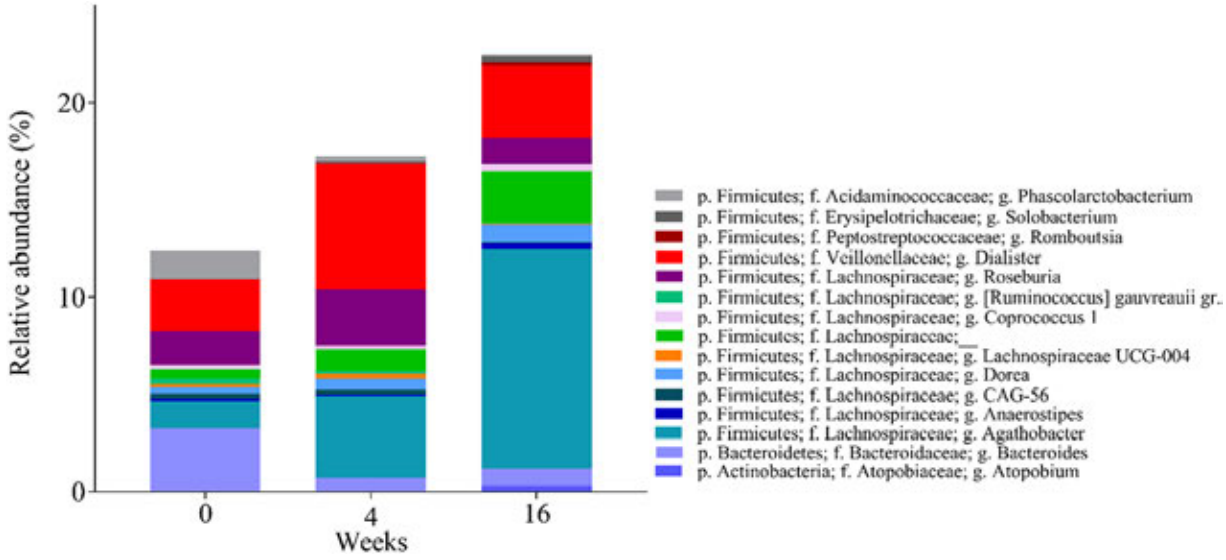

Figure 2A. Relative abundance of IgA coated bacteria. Only bacteria with changes (p<0.1) in relative abundance of IgA coating from week 0-4 or week 0-16 are shown.

Methods: Gastroduodenoscopy transfer of ACHIM or placebo was performed at weeks 0 and 2; fecal material was collected at week 0, 4 and 16. Relative abundance of total, immunoglobulin (Ig) A- and IgM-coated fecal bacteria was measured by 16s rRNA sequencing at week 0, 4 and 16. Relative abundance and taxonomic profiles were computed, alpha diversity and beta diversity were determined. Linear mixed models analysis were used to estimate changes in the microbiota composition and in IgA and IgM coating patterns over the entire follow-up period (i.e. baseline, 4 weeks, and 16 weeks).

Results: At baseline (week 0), there were no significant differences in fecal bacteria composition between the FMT (n=5) and placebo (n=4) groups, as measured by alpha and beta diversity. At week 16, but not at week 4, we identified differences in fecal bacteria composition between the FMT and placebo groups by the beta diversity ($p< 0.02$). The relative abundances of several genera changed at weeks 4 and 16 in the FMT group (Figure 1). The relative abundance of three bacterial families (Ruminococcaceae, Lachnospiraceae and Eggerthellaceae), which are dominant

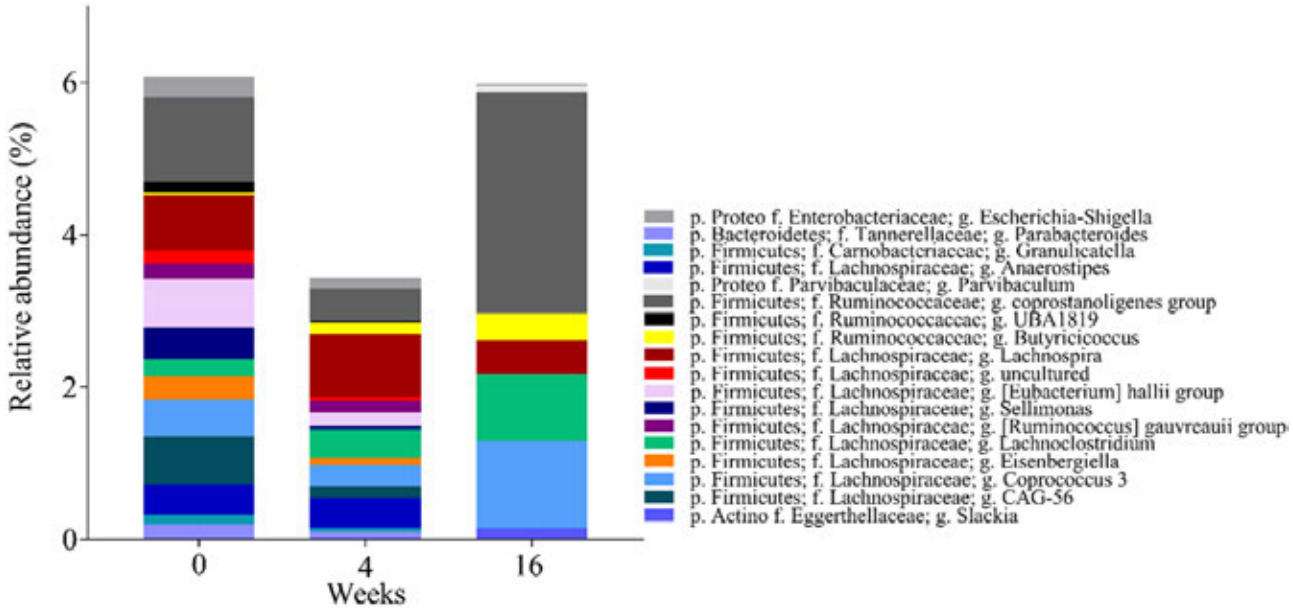

Figure 2B. Relative abundance of IgM coated bacteria. Only bacteria with change ($p<0.1$) in relative abundance of IgM coating from week 0-4 or week 0-16 are shown.

in ACHIM, increased post-intervention, consistent with engraftment after FMT. To assess if FMT triggered adaptive immunity in patients with SSc, we sorted and sequenced IgA and IgM coated bacteria from fecal samples and compared relative coating amongst FMT and placebo. Relative abundance of IgA-coated and IgM-coated bacteria fluctuated more after FMT, than after placebo (Figure 2 A and B). Some of the bacteria that were found to change their IgM coating pattern after FMT, like the genera Parabacteroides, Anaerostipes and Escherichia-Shigella, were present in the in vitro cultured fecal microbiota. Some of the bacteria which have previously been associated with other autoimmune diseases or pro-inflammatory status (Coprococcus, Roseburia, Dialister and Anaerostipes) were altered in their IgA coating patterns after FMT.

Conclusion: These observations support the notion of dynamic and ongoing immune responses to gut bacteria, and indicate that acquisition of a different gut microbiota induce immunological changes, as reflected by alterations in the pattern and/or extent of IgA and IgM coating. As mentioned above ACHIM reduced lower GI symptoms in patients with SSc. A possible link between the present observation and improved intestinal functions with ACHIM will be further studied in an upcoming investigation.

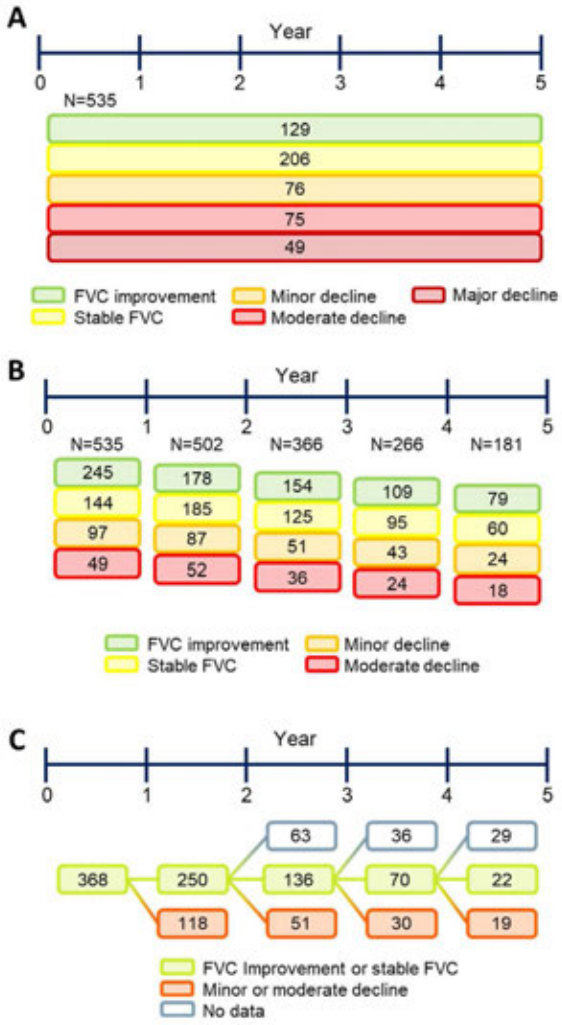
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The course of systemic sclerosis-associated interstitial lung disease (SSc-ILD) is heterogeneous; some patients may experience rapid decline in lung function, while others have relatively stable disease. Large patient registries, such as The European Scleroderma Trials and Research (EUSTAR) database, can assist in mapping the trajectory of SSc-ILD and identifying patients at risk of progression.

Methods: Patients with SSc-ILD by high-resolution computed tomography, according to American College of Rheumatology/European League Against Rheumatism criteria, who were registered in the EUSTAR database with lung function measurements at baseline and after 12±3 months, and known disease duration, were eligible. Patients had to have ≥3 serial annual forced vital capacity (FVC) measurements available. The overall FVC course was assessed using absolute changes in FVC (% predicted) from baseline to last available FVC measurement. Patients were divided into five subgroups: improved FVC (FVC increase of ≥5%); stable FVC (FVC decline or increase of < 5%); minor FVC decline (FVC decline of 5–10%); moderate FVC decline (FVC decline of >10–20%); and major FVC decline (FVC decline of >20%). Absolute FVC changes (% predicted) in individual patients in each 12-month interval during the 5-year follow-up period were then determined and defined as follows: FVC improvement (FVC increase of ≥5%); stable FVC (FVC decline or increase of < 5%); minor decline (FVC decline of 5–10%) and moderate decline (FVC decline of >10%). Candidate predictors of FVC decline were selected based on published reports and expert opinion and tested using linear mixed-effect regression analysis.

Results: Of 826 eligible patients with SSc-ILD, 535 (65%) had ≥3 serial annual FVC measurements available. Overall FVC course among these patients is shown in Figure 1A: over the mean 5-year follow-up period, 335 (63%) patients showed overall improved or stable FVC, while 200 (37%) patients experienced overall mild, moderate or major FVC decline. Among patients whose overall FVC course was improved or stable, 157 (47%) experienced one or more 12-month intervals in which their FVC declined by ≥5% (Table 1). In total during the observation period, 357 patients (67%) experienced one or more 12-month intervals with an FVC decline of ≥5% (Table 1; Figure 1B). 80% of patients who experienced a 12-month interval of FVC decline did not experience further decline in the following 12-month period. Male sex, gastroesophageal reflux disease, skin score, disease duration, age, diffusion capacity of the lungs for carbon monoxide, New York Heart Association class and erythrocyte sedimentation rate were baseline risk factors for FVC decline over a mean of 5 years (Table 2).



FVC, forced vital capacity; SSc-ILD, systemic sclerosis-associated interstitial lung disease

FVC course among patients with SSc-ILD in the EUSTAR database (number of patients per category): A. Overall FVC change during mean 5-year follow-up period; B. FVC changes during 12-month follow-up intervals; C. Subsequent FVC course during 12-month intervals among patients with improved or stable FVC during the first year of follow-up

Overall FVC change from baseline	12-month intervals					
	No FVC decline (n=178)	One with FVC decline (n=220)		Two or more with FVC decline (n=137)		
		Minor decline (n=113)	Moderate decline (n=107)	Only minor declines (n=65)	One moderate and ≥1 minor decline (n=25)	Only moderate declines (n=47)
Improved (n=129)	79 (44)	22 (20)	21 (20)	1 (2)	3 (12)	3 (6)
Stable (n=206)	99 (56)	59 (53)	29 (27)	13 (20)	1 (4)	5 (11)
Minor decline (n=76)		28 (25)	17 (16)	25 (39)	1 (4)	5 (11)
Moderate decline (n=75)		2 (2)	29 (27)	23 (35)	10 (40)	11 (23)
Major decline (n=49)		2 (2)	11 (10)	3 (5)	10 (40)	23 (49)

FVC, forced vital capacity; SSc-ILD, systemic sclerosis-associated interstitial lung disease

Changes in FVC% predicted (n [%]) during 12-month follow-up intervals among patients with SSc-ILD in the EUSTAR database

	Multivariable		
Predictor variable	Coefficient	95% CI	*P* value
Time	0.80	0.22 to 1.39	0.007
Time×mRSS	−0.06	−0.10 to −0.02	0.002
Time×Sex	−1.30	−2.10 to −0.49	0.002
Time×GERD	−0.72	−1.34 to 0.10	0.024
Age	0.47	0.37 to 0.57	<0.001
DL_{CO} (% predicted)	0.45	0.37 to 0.52	<0.001
NYHA class	−4.76	−6.59 to −2.92	<0.001
ESR	−0.09	−0.15 to −0.03	0.005

The model included a random intercept and slope. Time, sex, age, NYHA class, DL_{CO}, CRP, ESR, mRSS, SSc subtype, ATA, ACA and ARA, disease duration, synovitis and muscle weakness were fixed effects. ACA, anticentromere antibody; ARA, anti-RNA polymerase III antibody; ATA, anti-topoisomerase I antibody; CI, confidence interval; CRP, C-reactive protein; DL_{CO}, diffusion capacity of the lungs for carbon monoxide; ESR, erythrocyte sedimentation rate; FVC, forced vital capacity; GERD, gastroesophageal reflux disease; mRSS, modified Rodnan skin score; NYHA, New York Heart Association; SSc, systemic sclerosis; SSc-ILD, systemic sclerosis-associated interstitial lung disease.

Risk factors for FVC% change over the 5-year observation period in multivariable mixed-effect regression analysis in patients with SSc-ILD

Conclusion: These results support close monitoring of patients with SSc-ILD, as most patients experienced at least one 12-month interval with FVC decline during their 5-year follow-up period. Moreover, intervals of FVC decline were seen in some patients who appeared stable overall. Importantly, the risk factors for FVC decline identified herein could help identify patients at risk of disease progression.

Pain Chronification and the Important Role of Non-disease Specific Symptoms in Patients with Systemic Sclerosis

Caroline Evers,[1] Suzana Jordan,[1] Britta Maurer,[1] Rucsandra Dobrota,[1] Petra Hoederath,[2] and **Oliver Distler** [3], [1]Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, Zurich, Switzerland, [2]Centre for Neurosurgery, Hirslanden, St. Gallen, St. Gallen, Switzerland, [3]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is a frequent, yet inadequately explored challenge in patients with systemic sclerosis (SSc). The aim of this study was to conduct an extensive pain assessment, examining pain chronification and its association with disease manifestation.

Methods: Consecutive SSc patients attending their annual assessment in the Department of Rheumatology, Zurich, Switzerland were included into the study. SSc specific features were addressed as defined by European Scleroderma Trial and Research Group (EUSTAR). We conducted a detailed pain analysis including pain intensity, localization, treatment, pain chronification grade according to the Mainz Pain Staging System (MPSS), general well-being using the Marburg questionnaire on habitual health findings (MFHW), as well as symptoms of anxiety and depression using the Hospital Anxiety and Depression Scale (HADS).

Results: One hundred forty seven SSc patients completed a pain questionnaire, 118/147 (80.3%) reported pain and were included for further assessment. The median pain intensity during the last 4 weeks was 4/10 on a numeric rating scale (NRS). The most frequent major pain localizations were hand and lower back. The number of patients with low back pain as main pain was significantly higher in patients with very early SSc than in patients with advanced and established disease stages ($p = 0.01$). Those patients also showed the highest amount of pathological HADS scores for depression as well as for anxiety with 25% each and more pathological scores in the MFHW. Regarding pain chronification, 34.8% of all patients were in stage I according to the Mainz Pain Staging System, 45.2% in stage II and 20.0% in stage III. There was no significant correlation with chronification grade and disease severity, but higher chronification grades were significantly more frequent in patients with low back pain ($p = 0.024$). Advanced chronification was also significantly associated with pathological scores in the HADS ($p < 0.0001$) and was linked with decreased well-being. Therefore, patients with primarily back pain showed more pathological HADS scores than those with primarily hand pain. Patients with higher chronification grades also showed more pain related effects like higher use of analgesics and poorer subjective therapy effects. Furthermore, we found that most patients did not receive adequate pain therapy; only 4.4% of all examined patients reported seeing a pain specialist.

Conclusion: Contrary to our expectations, pain severity and chronification were not associated with more severe disease manifestation in systemic sclerosis. This study showed that low back pain, being associated with advanced

pain chronification and increasing psychological problems, represents an important problem in patients with systemic sclerosis, especially in early stages of the disease. Therefore, our study implies that also non-disease specific symptoms such as low back pain need to be considered in SSc patients and it underlines the importance of preventing pain chronification in order to enhance quality of life for these patients.

Abstract Number: 2605

Men and Black Persons Die at Younger Ages from Systemic Sclerosis: A Nationwide Population-based Study

Ram Raj Singh,[1] Devanshu Singh,[2] and Eric Yen[1], [1]UCLA, Los Angeles, [2]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is more common in women than men, but men tend to have a faster disease progression than women. However, conflicting results with regards to sex differences in SSc mortality have been reported. A few studies found standardized mortality ratios for SSc to be similar between men and women, whereas others found SSc standardized mortality ratios to be higher in men than women. We conducted a population-based study comprising of all recorded SSc deaths across the US to determine: a) the median age at SSc death by sex and race, b) odds ratios for the risk of SSc deaths by sex and race in different age groups, c) trends in the proportions of total SSc deaths by sex and race at different age groups over 5 decades, and d) SSc age-standardized mortality rate (ASMR) and case-fatality rate by sex and race.

Methods: We constructed histograms that depict the absolute number of SSc deaths for each age separately by sex and race. We then assessed the cumulative percent death at each age and determined the median age at death for each demographic group. We then calculated the percent of total SSc deaths by sex/race at different age groups every 10 yrs from 1970. We performed Chi-square test with Yates correction and quantified the odds ratio (OR) with 95% CI. Finally, we calculated ASMRs, and case-fatality rates (i.e., mortality rate in SSc population = SSc mortality rate / SSc prevalence) by sex and race.

Results: SSc was recorded as the cause of death in 5,061 women and 1,222 men in the US during 2011-2015. Deceased SSc persons were 4,426 white and 956 black. The median age at SSc death was 63 yrs in men vs. 68 yrs in

women, and 57 yrs for black persons vs. 70 yrs for white persons during 2011-2015. Higher proportions of men than women (54.5% vs. 40.2%), and of black than white persons (72.5% vs. 34.0%) died of SSc before 65 yrs of age. The risk of SSc death before 65 yrs of age was significantly higher in men than in women (OR 1.8, 95% CI 1.6-2.0, p< 0.0001) and in black than in white persons (OR 5.1, 95% CI 4.4-6.0, p< 0.0001). We then assessed trends in the proportion of SSc deaths by sex and race over 5 decades. The proportions of male and female SSc deaths were similar in all age groups in 1970, but significantly higher proportions of male SSc deaths relative to female SSc deaths were noted in the younger age groups at later timepoints (1990 and later in 45-64 and 2015 in ≤44 age groups). Compared to white persons, black persons had higher percentages of total SSc deaths in younger age groups (≤44 and 45-64) throughout the study period. Black persons also had significantly higher ASMRs than white persons. Women had 3-4-fold higher ASMRs than men, e.g., SSc-ASMR was 4.9 (95% CI 4.6-5.2) in women and 1.4 (95% CI 1.2-1.5) in men in 2015. However, this difference was obviated when mortality rates were corrected tor the differences in SSc prevalence between women and men, e.g., case-fatality rates for SSc were 3.0 in women and 2.1 in men in 2015.

Conclusion: Men and black persons died of SSc at younger ages than did women and white persons, respectively. Understanding the mechanisms of these disparities and identifying potentially modifiable risk factors might inform targeted research and public health programs to promote health equity in all SSc subpopulations.

Evolution of Systemic Sclerosis-Related Interstitial Lung Disease After Autologous Hematopoietic Stem Cell Transplantation

Jacopo Ciaffi,[1] Nina van Leeuwen,[2] Maaike Boonstra,[2] Lucia Kroft,[3] Anne Schouffoer,[3] Maarten Ninaber,[2] Thomas Huizinga,[2] and Jeska de Vries-Bouwstra[2], [1]Leiden University Medical Center, Bologna, Emilia-Romagna, Italy, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Leiden University Medical Centre, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Three trials demonstrated the overall superiority of autologous hematopoietic stem cell transplantation (HSCT) compared to pulsed cyclophosphamide (CYC) in SSc. An improvement in forced vital capacity (FVC) has also been described, but whether this indicates a reduction in extension of ILD has not been extensively evaluated. The main purpose of our study is to evaluate the efficacy of HSCT in inducing reduction of ILD extension assessed through high-resolution computed tomography (HRCT) in SSc patients. The secondary aims are to compare the evolution of fibrosis score after HSCT and after CYC, to evaluate how FVC changes associate with HRCT modifications, and which patients are most likely to show ILD reduction.

Methods: All SSc patients fulfilling the 2013 ACR classification criteria for SSc and treated with either HSCT or pulse CYC between 2004 and 2018 were selected. Patients with evidence of ILD at HRCT and high-quality images before and after treatment (6-18 months) available, were included. Two experienced researchers, blinded for clinical data and treatment, scored HRCTs independently and retrospectively using the “Goh score”. Discrepancies above 10% were discussed to reach consensus. Changes in mean total Goh score, and mean total scores for ground glass and reticular pattern are described. A cut-off of 5% was used to define improvement/progression. PFTs close to the HRCT

FVC, mean (SD), % predicted	79.1 (18)	80.3 (16.5)	ns
FEV1, mean (SD), % predicted	77.9 (16.5)	82.6 (15.7)	ns
DLCO-SB, mean (SD), % predicted	55.4 (19.5)	53.3 (11.6)	ns

*** Of note: at the moment of writing this abstract, the results are preliminary: all HRCTs have been scored by at least 1 reader, and 45% have been scored by 2.**

Legend. HSCT: hematopoietic stem cell transplantation; CYC: cyclophosphamide; SD: standard deviation; dcSSc: diffuse cutaneous systemic sclerosis; ATA: anti-topoisomerase I antibodies; HRCT: high-resolution computed tomography; FVC: forced vital capacity; FEV1: forced expiratory volume in 1 second; DLCO-SB: single-breath diffusing lung capacity for carbon monoxide.

time points were compared to calculate differences between pre- and post-treatment values. Regression analysis was used to study the association of relative changes in FVC and single-breath diffusing lung capacity for carbon monoxide (DLCO-SB), with change in mean total Goh score, and to study which patients are most likely to improve.

Results: Of note: at the moment of writing this abstract, the results are preliminary: all HRCTs have been scored by at least 1 reader, and 45% have been scored by 2. Thus, the reported data consist of the mean score of 2 readers in 45% of patients, and the score of 1 reader in 55%. We included 22 patients treated with HSCT and 31 with monthly CYC (Table 1). In patients treated with HSCT, mean Goh score decreased by 5.1±10.4%, which was mainly determined by a decrease in ground glass score (p= < 0.001 in linear regression). Overall, 7 HSCT patients improved (32%)

Table 2: Comparison between pre- and post-treatment			
	HSCT	**CYC**	**P-value**

*** Of note: at the moment of writing this abstract, the results are preliminary: all HRCTs have been scored by at least 1 reader, and 45% have been scored by 2.**

Legend. HSCT: hematopoietic stem cell transplantation; CYC: cyclophosphamide; SD: standard deviation; HRCT: high-resolution computed tomography; FVC: forced vital capacity; FEV1: forced expiratory volume in 1 second; DLCO-SB: single-breath diffusing lung capacity for carbon monoxide; Improvement: absolute decrease in Goh score >5%; Stability: absolute change in Goh score <5%; Progression: absolute increase in Goh score >5%

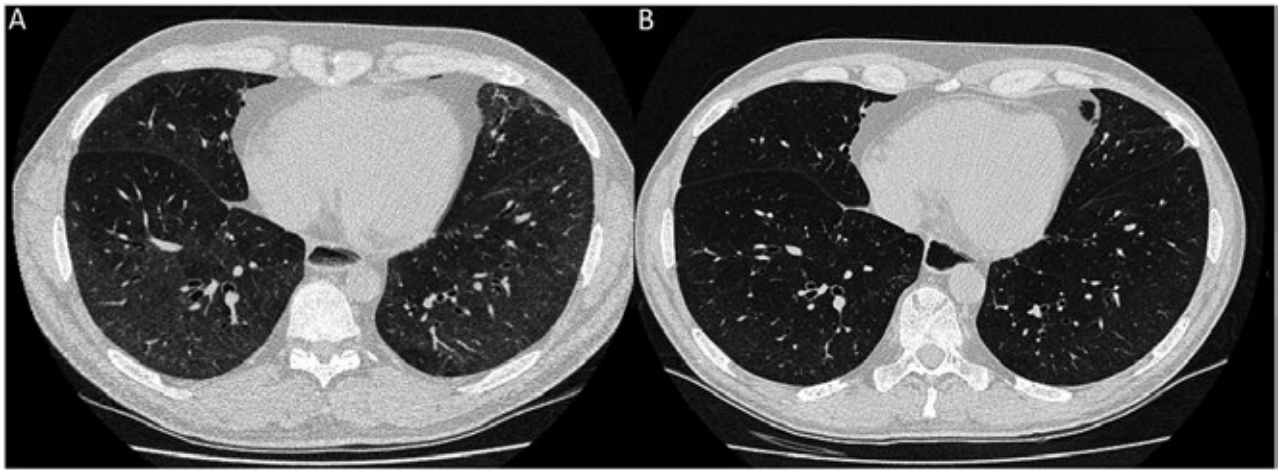

Figure 1. Axial plane HRCT scan above the level of the diaphragm showing marked reduction of ILD extension in a 45-year old man treated with HSCT. Fig. A: 4 months before HSCT; Fig. B: 13 months after HSCT.

(Figure 1), 14 remained stable (64%), and 1 progressed (4%) (Table2). In the CYC group, mean Goh score decreased by 2±9.8%. Six patients improved (19%), 21 remained stable (68%), and 4 progressed (13%) (all p= >0.05) (Table 2). For all patients, changes in FVC (p= < 0.001), and DLCO-SB (p= 0.018) were associated with change in mean total Goh score. In univariate analysis, patients with improvement did not differ with respect to age or disease duration but had higher total Goh score, higher ground glass score, and a trend for lower DLCO-SB at baseline.

Conclusion: HSCT resulted in reduction of ILD in 32% of SSc patients during the first year after treatment, which is mainly explained by a reduction of ground glass opacity. Changes in HRCT findings are significantly associated with changes in PFTs. In this small population, improvement/stable disease was numerically more frequent after HSCT compared to CYC, but no statistically significant difference was found.

Ultrasound Detection of Calcinosis and Correlation with Ulnar Artery Occlusion in Patients with Systemic Sclerosis

Robert Fairchild,[1] Melody Chung,[1] Laurel Sharpless,[1] Shufeng Li,[2] and Lorinda Chung[1], [1]Stanford University, Palo Alto, CA, [2]Division of Immunology and Rheumatology, Department of Medicine, Stanford, Palo Alto, CA

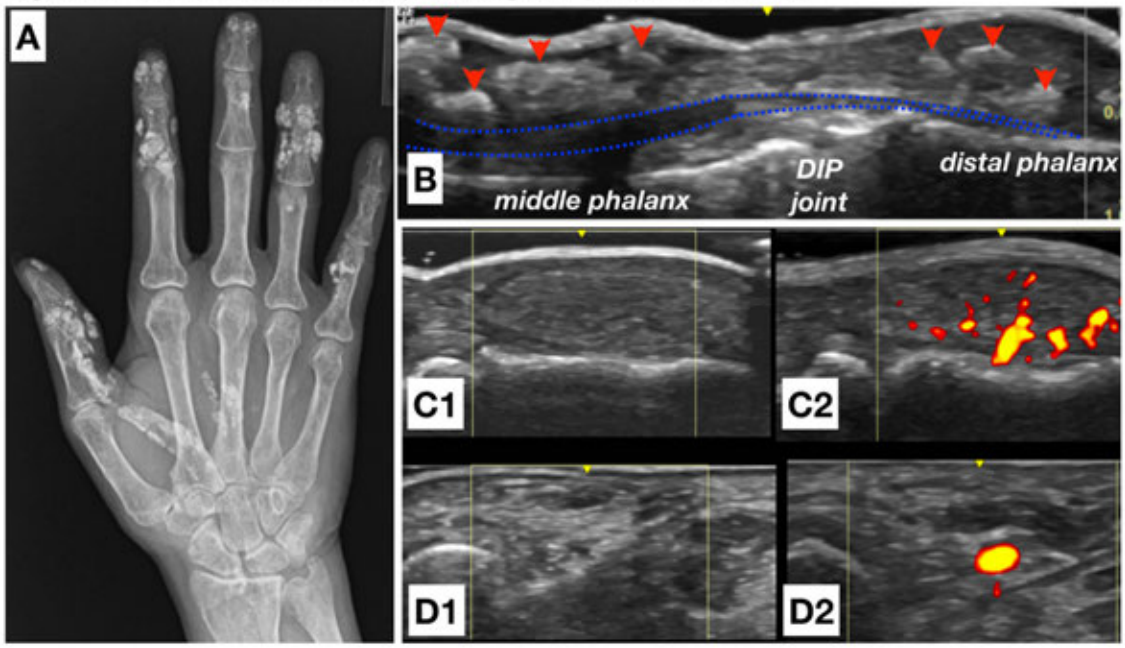
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a progressive fibrotic and vascular disease affecting multiple organs. Calcinosis cutis in SSc is characterized by calcium deposition in the skin and subcutaneous tissues and can lead to significant morbidity. While the pathophysiology of calcinosis in SSc is poorly understood, vascular ischemia is thought to play a role. Ultrasound (US) is well suited to vascular and soft tissue interrogation and may be helpful to detect, monitor, and study calcinosis in SSc. We sought to evaluate the ability of US to detect calcinosis in the hands and wrists of SSc patients versus X-ray identified calcinosis and to evaluate the relationship between ultrasound markers of pathologic perfusion and the presence of calcinosis.

Methods: Patients meeting 2013 ACR/EULAR classification criteria for SSc were prospectively evaluated for calcinosis in the hands and wrists by both X-ray and US. US was performed by submerging the hands and wrists in a water bath for evaluation of all surfaces. The presence or absence of calcinosis was recorded for each of 44 zones (22 left and 22 right) based on our previously published methods, and the sensitivity and specificity for calcinosis detection by US versus X-ray was determined. We also obtained bilateral US vascular measurements of ulnar artery occlusion (UAO) and finger pulp blood flow (FPBF) in the 3rd and 4th digits. For each hand, associations between markers of pathologic blood flow (UAO, FPBF, and a composite severity score of UAO and FPBF) and the presence of calcinosis were assessed using generalized estimating equations.

Results: 43 SSc patients (19 diffuse and 24 limited) were enrolled and 17 (39.5%) were found to have X-ray evidence of calcinosis in at least 1 hand (10 bilateral, 7 unilateral). US identified 13 patients with calcinosis (9 bilateral, 4 unilateral). Of the 748 zones evaluated, X-rays identified 72 zones (9.6%) with calcinosis while US showed 76 (10.2%). The sensitivity and specificity for US detection of calcinosis versus X-ray was 61% and 95% by zone, 78% and 98% by hand, and 76% and 100% by patient, respectively. UAO was seen in 13/43 (30%) and 12/43 (28%) of left and right hands, respectively, and FPBF was absent in 1 or both digits of the left and right hands in 21 (49%) and 19 (44%), respectively. We found a strong association between UAO and X-ray identified calcinosis (OR 8.08, 95% CI 2.45-

Figure 1. Ultrasound and X-ray findings in systemic sclerosis



Systemic sclerosis patients with (A) X-ray findings of calcinosis, (B) ultrasound identified calcinosis [red arrowheads] in the longitudinal palmar aspect of the 2nd finger [blue outline = flexor tendon], (C1-C2) absent and normal FPBF respectively, and (D1-D2) UAO and no UAO, respectively. UAO = ulnar artery occlusion, FPBF = finger pulp blood flow, DIP = distal interphalangeal

Table 1. Sensitivity and specificity of ultrasonography for X-ray identified calcinosis

	Sensitivity	Specificity	TP	FP	TN	FN
By Zone	61%	95%	44	32	644	28
By Hand	78%	98%	21	1	58	6
By Patient	76%	100%	13	0	26	4

TP = true positive, FP = false positive, TN = true negative, FN = false negative

Table 2. US and X-ray features and associations between US markers of pathologic blood flow and calcinosis

	Imaging Features	
	Left Hand n =43	Right Hand n =43
UAO, n (%)	13 (30)	12 (28)
FPBF absent*, n (%)	21 (49)	19 (44)
Calcinosis by US, n (%)	11 (26)	11 (26)
Calcinosis by X-ray, n (%)	15 (35)	12 (28)
	Associations with Calcinosis	
	OR (95% CI)	***p***
UAO	8.08 (2.45, 26.60)	0.001
FPBF	2.66 (0.83, 8.52)	0.10
FPBF + UAO severity score	3.23 (0.96, 10.92)	0.06

US = ultrasound, OR = odds ratio by generalized estimating equations. UAO = ulnar artery occlusion, FPBF = finger pulp blood flow. *FPBF absent if one or both measurements per hand were absent.

26.60, p< 0.001). Both FPBF (OR 2.66, 95% CI 0.83-8.52, p=0.099) and the composite severity score (OR 3.23, 95% CI 0.96-10.92, p=0.059) failed to show a significant association with calcinosis.

Conclusion: In a cohort of SSc patients we developed a new method for ultrasound detection and quantification of calcinosis and found it to be sensitive, and highly specific versus X-ray. We also found a strong relationship between UAO, a marker of decreased peripheral perfusion, and X-ray identified calcinosis. This is the first study to evaluate the performance of ultrasound in the detection of calcinosis and provides further support for an association between vascular disease in SSc and the pathogenesis of calcinosis.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis associated interstitial lung disease (SSc-ILD) is heterogeneous, with varying degrees of severity and risk of disease progression. No consensus-based definitions of disease severity, progression, or risk of progression exist. The purpose of this study was to use expert classification of real-world cases of SSc-ILD to derive definitions of SSc-ILD subsets that can be incorporated into clinical practice and trials.

Methods: All patients included in this study met American College of Rheumatology Criteria for Systemic Sclerosis (N=80).

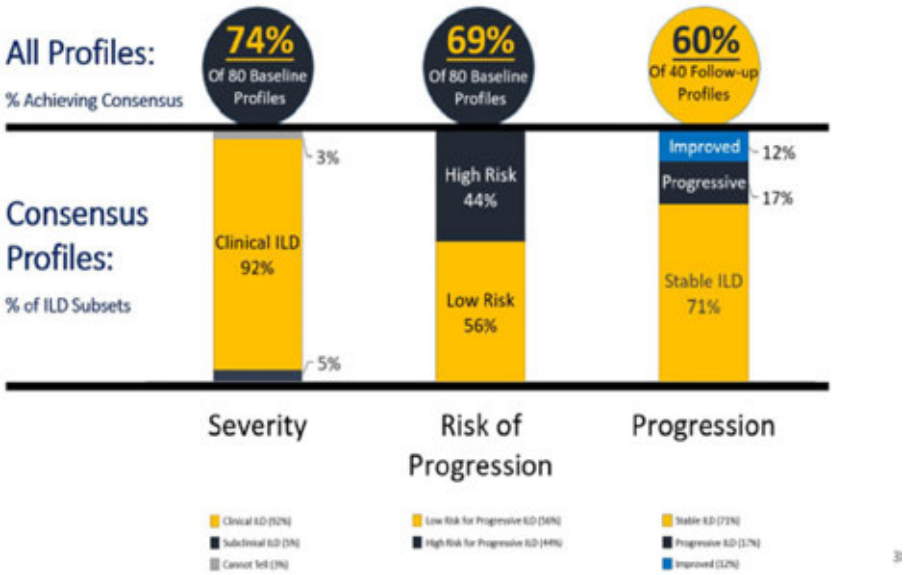

Figure. Percent Profiles Achieving Consensus and Distribution of Consensus Profiles by ILD Subset

	SEVERITY: Clinical vs. Subclinical	RISK OF PROGRESSION: Low vs. High Risk	PROGRESSION: Stable vs. Progression
	Ranking*	Ranking*	Ranking*
Demographics & Disease Features			
Race	10 (least cited)	9 (tied with SGRQ)	--
Duration of SSc	8	1 (most cited)	--
Type of SSc	7	5	--
Antibody Status	9	4	--
Assessments of Disease Severity			
FVC%	1 (most cited)	2	1 (most cited)
DLCO%	4	7	5
Total lung involvement on HRCT	2	3	2
Total lung fibrosis of HRCT	5	6	3
Dyspnea Index	3	8	4
St George Respiratory Questionnaire	6	9 (tied with Race)	6 (least cited)

*Determined by number of times this was chosen as the most influential reason for Experts' choice; ranked from most frequently cited (1) to least frequently cited (10).
– These features were not assessed for Progression.

Table. The Most Influential Factors Used in Classification by Dimension

Patient profiles were developed from participants in the Scleroderma Lung Study-II and ILD patients seen at a Scleroderma Center. Experts in rheumatology, pulmonary medicine, radiology, and members of the OMERACT CTD-ILD Working Group [1] provided key domains to be included in profiles. These included information on demographics, disease features (limited vs. diffuse SSc, ANA status, antibody status), pulmonary function testing, patient-reported assessments, and quantitative analysis of lung involvement on high resolution computerized tomography of the chest (HRCT) for baseline profiles; and for those with follow-up data, how these measures change over time.

Eighty-three ILD experts were surveyed for classification of 80 baseline and 40 follow-up profiles. Baseline profiles were classified based on: 1- Severity (clinical vs. subclinical) and 2- Risk of Progression (low vs. high); follow-up profiles were classified on 3- Progression over time (stable vs. progressive vs. improved). Each profile was rated by a minimum of 4 experts; consensus on a classification was achieved with 75% concordance. For each profile, experts provided input on the top features that helped in making their classification decision.

Results: Fifty percent (N=42) of invited experts, from 10 countries, completed the survey.

Along the dimensions of severity, risk of progression, and progression, a majority of profiles achieved consensus ratings (Figure). Of those profiles achieving consensus, the majority were classified as “clinical ILD”, “low risk”, and “stable”. Table provides a ranking of the most influential features used in classification on these dimensions.

Conclusion: These data represent the first step in creating operational definitions for ILD subsets. This expert-derived classification advances the characterization of a subset of severity (clinical ILD), subsets of risk of progression (low and high risk), and a subset of progression (stable ILD).

Features used to classify profiles on severity and progression overlapped (forced vital capacity, whole lung involvement on HRCT, dyspnea ratings), whereas the risk of progression was influenced by disease duration, type of SSc, and SSc autoantibodies in addition to the measures endorsed for severity and progression.

The next steps are to reach operational definitions for those ILD subsets not yet reaching consensus (subclinical ILD, progressive ILD, improved ILD).

Anti-angiogenic VEGF-A_{165}b Is Associated with Systemic Sclerosis Peripheral Vasculopathy

Victoria Flower,[1] Shaney Barratt,[2] Darren Hart,[3] Amanda Mackenzie,[4] Jacqueline Shipley,[3] Stephen Ward,[4] and John Pauling[1], [1]Department of Rheumatology, Royal National Hospital of Rheumatic Diseases, Royal United Hospitals NHS Foundation Trusts, Bath, England, United Kingdom, [2]North Bristol NHS Trust, Bristol, England, United Kingdom, [3]Department of Clinical Measurement, Royal National Hospital for Rheumatic Diseases, Royal United Hospitals NHS Trust, Bath, England, United Kingdom, [4]Centre for Therapeutic Innovation & Department of Pharmacy and Pharmacology, University of Bath, Bath, England, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

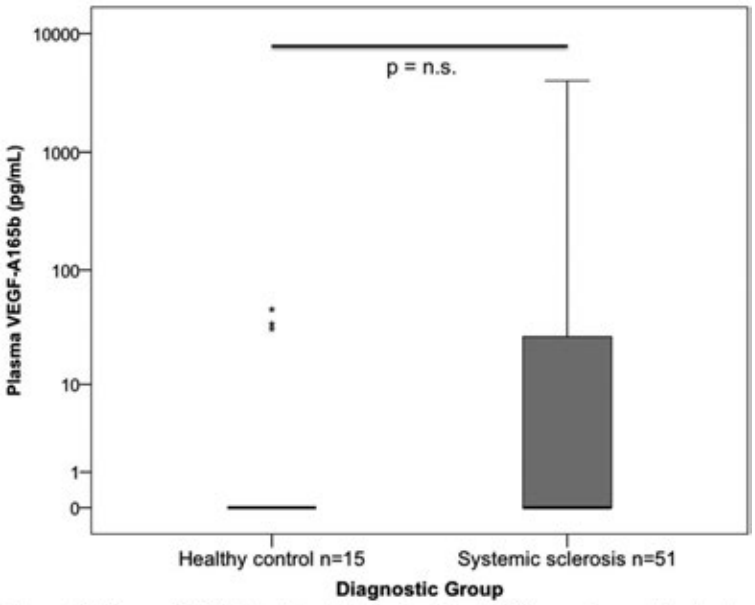

Figure 1. Plasma VEGF-A_{165}b levels. No significant difference in median levels was noted between SSc and controls (Mann-Whitney U) due to high number of undetectable VEGF-A_{165}b in both groups. Plasma VEGF-A_{165}b was detectable in 31% of SSc (max. >4000pg.mL) versus 20% of controls (max. 46pg/mL).

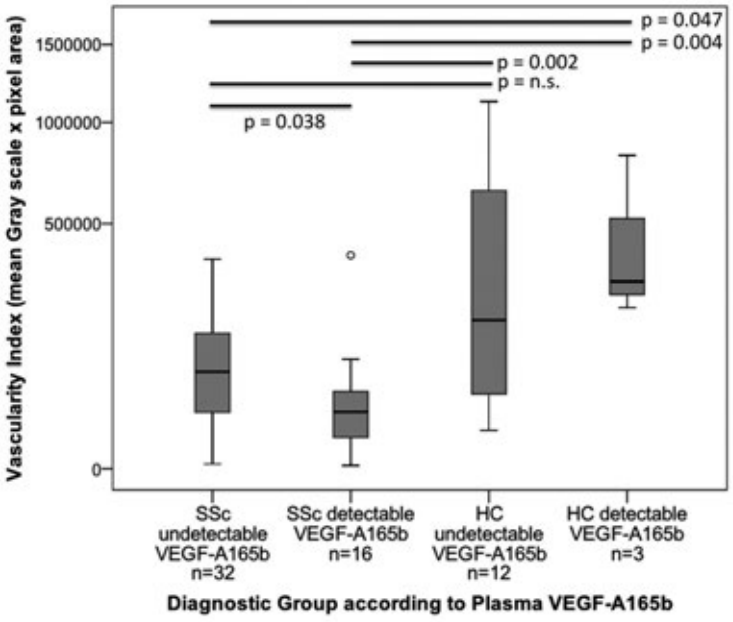

Figure 2. Vascularity Index on HFUS is reduced in SSc. Vascularity index is reduced in SSc compared to controls with a further significant reduction in the presence of detectable VEGF-A_{165}b. Statistical comparisons by Kruskal-Wallis.

Background/Purpose: The anti-angiogenic isoform of Vascular Endothelial Growth Factor-A (VEGF-A_{165}b) has been implicated in Systemic sclerosis (SSc) vasculopathy. High frequency ultrasound (HFUS) is a novel approach to assessing digital perfusion. We report on the relationship between plasma VEGF-A_{165}b and peripheral microvascular perfusion using HFUS in SSc.

Methods: Fifty-one patients fulfilling 2013 ACR/EULAR criteria for SSc and fifteen healthy controls (HC) underwent HFUS Doppler assessment of microvascular flow at the distal middle finger, from which a Vascularity Index was cal-

culated. Plasma VEGF-A_{165}b levels were assessed using ELISA. Ongoing administration of vasodilator and disease modifying therapies were permitted.

Results: Plasma VEGF-A_{165}b was detectable in 16/51 (31%) of SSc with a peak level of >4000pg/mL (Figure 1). In contrast, only 3/15 (20%) healthy controls had plasma VEGF-A_{165}b greater than the lower limit of detection by ELISA, with a maximum plasma level of 46pg/mL. Median levels were not significantly different between groups. When VEGF-A_{165}b was detectable, it was associated with significantly reduced Vascularity Index in SSc (Figure 2). In contrast, HC showed no difference in the Vascularity Index irrespective of VEGF-A_{165}b. Additionally, the Vascularity Index correlated with VEGF-A_{165}b in SSc (Spearman's ρ = -0.289, p=0.039) but not HC. The Vascularity Index was reduced in SSc even in those with undetectable VEGF-A_{165}b compared to HC (both with detectable (p=0.047) and undetectable (non-significant) VEGF-A_{165}b).

Conclusion: Increased levels of VEGF-A_{165}b are associated with reduced digital vascularity in SSc. Low levels of VEGF-A_{165}b are sometimes detected in HC but are not associated with reduced digital perfusion. Peripheral vascular compromise in SSc is evident even in the absence of detectable VEGF-A_{165}b. Further longitudinal studies are needed to investigate the role of VEGF-A_{165}b in determining microvascular flow and the impact of disease duration and intervention on VEGF-A_{165}b and digital perfusion over time.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) and pulmonary arterial hypertension negatively impact on Systemic sclerosis (SSc) prognosis. Chest computed tomography (CT) is the gold standard in assessing ILD and helps in evaluating associated vascular involvement. However, CT scans qualitative analysis is limited by low reproducibility and time constraints. Recently developed quantitative techniques may overcome these limitations. We aimed at

Table 1. Correlation between quantitative parenchymal and vascular data

		TV_cm3	AV_cm3	VV_cm3	TV%	AV%	VV%

evaluating parenchymal and vascular features in SSc-ILD by using quantitative analysis (QA) of CT scans and test correlation with clinical-functional data.

Methods: We analyzed chest CT scans in SSc patients performed with spirometric gating at TLC. A computational platform for texture analysis of ILD patterns (CALIPER), through Imbio LTA Launchpad, quantified the extent of normal pattern (NP%), ground glass opacities (GG%), reticulation (RET%), and honeycombing (HC%) [1]. An automated vessels segmentation was performed using a software program developed by the Ludwig Boltzmann Institute for Lung Vascular Research [2], calculating total, arterial, and venous vascular volumes (TV, AV, VV), and relative volumes (TV%, AV%, VV%). Clinical, lung functional and diffusion data, as well as disability indexes were also collected.

Results: 44 patients/CT scans were eligible (89% female, 42% diffuse, 7% PAH) for both software analysis. CALIPER showed GG% as the most frequent radiological pattern (median 2.7%, 0.2-7.6 IQR), with positive correlation with mRSS (r=0.363, p=0.016) and increasing NYHA class (r=0.306, p=0.037), while negative correlation with FVC (r=-0.371, p=0.009) and TLC (r=-0.356, p=0.024). Similarly, RET% showed positive correlation with mRSS (r=0.491, p=0.001) and negative correlation with desaturation on 6 minutes walking test (r=-0.433, p=0.017). On the vascular analysis, TV% had positive correlation with increasing NYHA class (r=0.319, p=0.048), difficulty increase in walking domains of HAQ-DI (r=0.607, p=0.002) and Dlco/AV (r=0.414, p=0.007), while negative correlation with FVC (r=-0.449, p=0.003) and TLC (r=-0.496, p=0.003), with similar significant correlations replicated for AV%. When testing parenchymal with vascular data (Table 1), higher GG% and RET% correlated with higher vascular relative volumes. In addition, GG% correlated with AV. Conversely, increasing NP% was associated to a decrease in AV and in all vascular relative volumes.

Conclusion: This is the first study that shows a direct link between ILD and increase in lung vascular volume in SSc patients. Different hypothesis could be postulated, such as a reduction in pulmonary volume due to fibrosis, an increase in absolute vascular volumes as a phenomenon of neo-angiogenesis secondary to fibrosis, or a paraphysiological mechanism of redistribution of blood flow in lung areas less involved by ILD. Further studies on lung vessel quantification and distribution are ongoing.

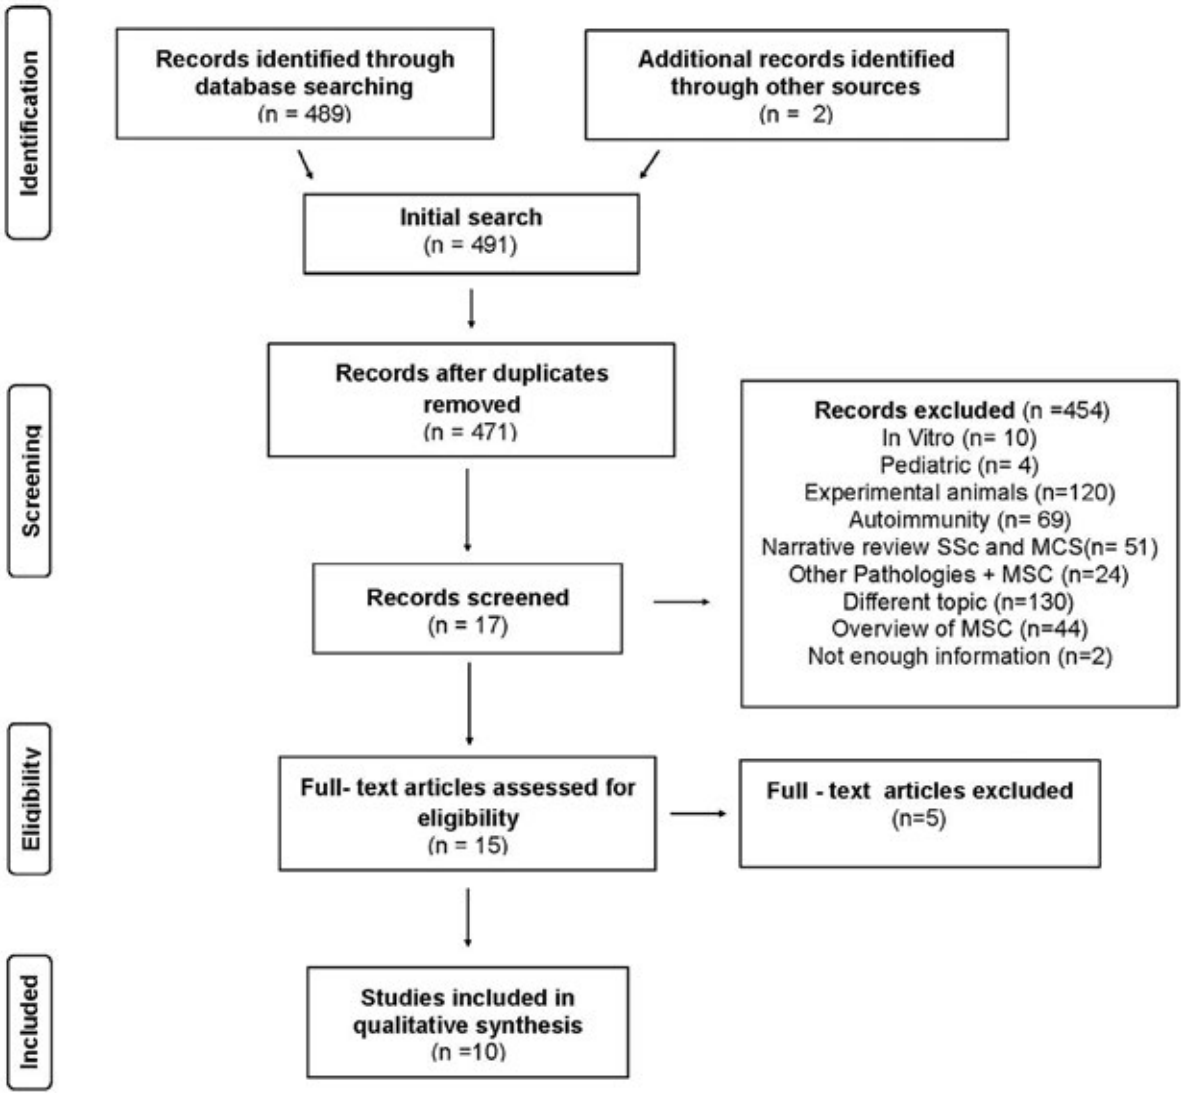

Figure1. PRISMA flowchart

Table 1. Articles included

Reference/ Study design	Population	Intervention	Comparator	Outcome
Serena Guiducci, et al. 2010. / CR	A woman, aged 34 years, with SSc who developed acute gangrene of the upper and lower limbs.	Autologous : bone marrow. 3 IV infusions. First of 0, 9x10^6/ Kg. Second and third of 0,8x10^6/Kg	None	1. **Areas of necrotic skin** were reduced after the first MSC infusion. 2. After the third infusion, angiography showed revascularization of the patient's extremities
Chakr, R. et al. 2013./ **CR**	A 36-year-old. Diffuse SSc (severe scleroderma, Rodnan score 47/51). Skin ulcers and extensive lung fibrosis refractory	Two infusions 2x106/ Kg/infusion. Allogeneic unrelated MSC	None	3 weeks: **death** (shock and respiratory failure)
Kamata, Y. et al 2007. / **CR**	Four SSc patients (49 to 72 yearsold), Longstanding intractable DU and finger necrosis with severe pain	Autologous bone marrow MNCs: 0.5 ml were implanted IM at 20 different sites in palms and/or soles. Peripheral blood MNCs were implanted on the opposite side to compare the difference in effectiveness.	MNCs from bone marrow Vs MNCs from peripheral blood.	1. **Pain:** improved remarkably up to 1 month after implantation of bone marrow or peripheral MNCs to the same extent. 2. **Transcutaneous oxygen pressure and thermogram:** No significant differences were found. 3. **Intra-arterial digital subtraction angiography:** Bone marrow MNCs increased blood flow of the hand Vs peripheral MNCs did not.
Christopeit, M. et al 2008. / **CR**	A 41-year-old female SSc. Painful ulcerations at acral.	MSC from an allogeneic haploidentical-related donor IV of106 MSCs per kg (6 107 MSCs total).	None	Subjective improvement in her condition. (Stiffnes and warming). **Painful ulcerations:** significant decrease in the patient's painful ulcerations (Three months after) **Vascular ultrasound** Marked improvement in the blood circulation of hands and fingers (6 months after) **Rodnan skin score :** reduced from 25 to 11

Table 1. Main characteristics of included studies.

Background/Purpose: Scleroderma (systemic scleroderma or systemic sclerosis, SSc), is a highly heterogeneous autoimmune disease of unknown etiology, with a high rate of therapeutic failure and a progression of the disease. Although recently it has been noted a decrease in mortality It is still high, therefore SSc treatment is considered a therapeutic challenge. The immunomodulatory capacity of the mesenchymal stem cells (MSC), has increased the at-

tention of the scientific community, considering them an alternative therapy that could potentially exceed the efficacy of available therapeutic options; we consider to evaluate through a systematic literature review (SLR), the efficacy, and safety of MSC in patients with SSc.

Methods: A SLR was conducted by two independent researchers (following PRISMA guidelines) in Medline/OVID, Lilacs, Embase and Cochrane/OVID databases (up until February 2019, no language restriction). All clinical study types were considered: Patients over 18 years of age, with SSc who received treatment with MSC (all clinical outcomes). Exclusion criteria: Animal Models, Bone marrow stromal cell transplant, Autologous hematopoietic stem cell transplant, Narrative reviews, Letters to the editor. The specified MeSH terms and keywords were used on the search strategy. Rayyan® Microsoft Excel® and review Manager ® 5.2 software were used for the different steps of the SLR. Data extraction (using a predesigned data extraction form) and quality assessment was also undertaken independently by two reviewers with disagreements resolved by discussion or by a third reviewer. Joanna Briggs Institute quality appraisal checklist was used to appraise the quality of studies. The Oxford Centre classifications for levels of evidence were used.

Results: Once the search was done on electronic bases and the grey literature, it was identified a total of 491 items. Duplicate articles were resolved, obtaining 471. 17 articles were screened by title and abstract, of which 15 articles were chosen and by full text 10 were included (6 case report, 3 Case series, and 1 pilot study). Figure1

The total population corresponds to 62 patients (age range 18 – 75 years old), most of them refractory to conventional treatment. The different interventions and clinical outcomes are shown in Table 1. Overall appraisal through Joana Briggs checkout was inclusion decision. The level of evidence for the majority of studies was 4.

Conclusion: The reported data are too scarce to come to a clear assessment of the benefit/risk on the use of MSC in SSC. Further well-designed, standardized research studies are required assuming the potential challenges of SSc treatment and the great promise of MSC intervention based on its immunomodulatory functions.

Minocycline for Refractory Calcinosis in Systemic Sclerosis: A Single-Centre Observational Cohort Study

Carmen Fonseca,[1] Voon Ong,[2] and Christopher Denton[3], [1]UCL Medical School, Royal Free Campus, London, United Kingdom, [2]UCL Medical School, Royal Free Campus, London, [3]University College London Division of Medicine, Centre for Rheumatology and Connective Tissue Diseases, London, UK, London, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis represents a major challenge for patients with systemic sclerosis (SSc) for which there is no standard therapy. Minocycline has been proposed for treatment of refractory calcinosis in SSc (1,2). We assessed the possible benefit and adverse events (AE) of minocycline in cohort of SSc patients with calcinosis.

Methods: We reviewed patients with SSc, attending a large tertiary referral centre, that were treated with minocycline for severe calcinosis. Data collected included: gender, scleroderma subtype, autoantibodies, dose and regime of administration of the minocycline, response to the treatment, AE, tolerability and proton pump inhibitors (PPI) use, if any, at the time of the treatment with minocycline. Treatment response was recorded either as subjective clinical improvement of the symptoms associated with calcinosis, or lack of response.

Results: We identified 78 SSc patients treated with minocycline and this cohort reflects the spectrum of refractory calcinosis in SSc with typical ANA association (Table 1). Disease duration in the majority of the cases was longer than 10 years. The prescribed oral dose ranged from 50-200 mg daily and was administered in the majority of the cases for 6-12 weeks in repeated courses. Autoantibody status included typical SSc reactivity with 35.8% anti-centromere antibody (ACA), 15.3% Pm-SCL, 14.1% anti-topoisomerase I, 11.5% anti-RNA polymerase antibody (ARA) (Table 1). 34/78 patients (43.6%) reported clinical improvement in calcinosis related symptoms. Response was similar between different autoantibody groups with exception of patients with ARA, in which clinical improvement was reported in 88.9% of the cases ($p< 0.005$). 25.6% reported minor AE: skin pigmentation after 10 years of use (1 case), gastro-intestinal intolerance (3 patients), elevated liver transaminases (1 case), and unspecified poor tolerance (9 patients). AE were more frequent in the group that did not report benefit (2 vs18). No additional serological abnormalities or autoimmune diseases was observed during treatment period. Different types of PPI were prescribed in 65% of the cohort and this was evenly distributed in the 2 outcome groups.

Conclusion: Within the largest reported series of SSc calcinosis treated with minocycline, our results suggest clinical improvement in almost half of the patients treated with acceptable tolerability. We observed that ACA and late-stage ARA positive patients both had troublesome calcinosis but ARA positive were more likely to respond than other sub-groups. This observation suggests that calcinosis pattern may differ amongst autoantibody defined groups, perhaps reflecting distinct pathogenic mechanisms. Overall, minocycline may be helpful in the management of calcinosis in patients with SSc. A future prospective trial, stratified by SSc autoantibodies, is required to confirm these findings.

Table 1: Clinical features of SSc cohort with calcinosis

			Clinical improvement		No response

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Our previous study demonstrated that Hsp90 is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc in a TGF-β dependent manner. We showed that Hsp90 is a new regulator of canonical TGF-β signaling and its inhibition prevents the stimulatory effects of TGF-β on collagen synthesis and dermal fibrosis[1]. The aim of this study was to evaluate plasma Hsp90 of SSc patients and characterize its potential association with skin changes and SSc-related features.

Methods: A total of 92 patients (79 females; mean age 52.7; disease duration 6.0 years; diffuse cutaneous (dc)SSc / limited cutaneous (lc)SSc = 38/54) and 92 age- and sex- matched healthy individuals were included. Plasma Hsp90 levels were measured by ELISA (eBioscience, Vienna, Austria). Data are presented as median.

Results: Plasma Hsp90 levels were increased in SSc patients compared to healthy controls [12.5 (9.6–17.9) vs. 9.8 (7.7–12.4) ng/mL, p=0.0001]. Hsp90 levels in all patients positively correlated with CRP (r=0.271, p=0.015). Furthermore, Hsp90 concentrations were negatively associated with functional parameters of ILD: FVC (r=-0.291, p=0.013), FEV1 (r=-0.248, p=0.036), DLCO (r=-0.290, p=0.012) and SpO_2 (r=-0.317, p=0.038). When adjusted for CRP, these correlations still remained significant in multivariate analysis. Higher Hsp90 concentrations were associated with presence of synovitis [17.6 (15.4 – 24.0) vs. 12.2 (9.3 – 17.3), p=0.039]. In addition, only in patients with dcSSc, Hsp90 levels positively correlated with the mRSS (r=0.437, p=0.006). In a prospective analysis of patients with progressive SSc-ILD treated with 6 (n=21 patients) or 12 (n=14 patients) monthly i.v. pulses of cyclophosphamide (CPA, 10 mg/kg) we did not observe any significant differences between the baseline sample (month 0) and blood drawn after 1,

6 and 12 months. However, baseline Hsp90 was able to predict long-term response after one year of CPA treatment ($DLCO_{m12-m0}$; r=-0.494, p=0.037). Moreover, change in Hsp90 after one month of CPA treatment ($Hsp90_{m1-m0}$) was able to predict the short-term inflammatory response (CRP_{m3-m0}, r=-0.495, p=0.019; ESR_{m3-m0}, r=-0.496, p=0.031). Concentrations of extracellular Hsp90 were not significantly affected by other main clinical parameters of SSc.

Conclusion: We demonstrated higher plasma levels of Hsp90 in SSc patients compared to healthy controls. Concentrations of extracellular Hsp90 increase with higher inflammatory activity, with deteriorated lung functions in ILD and also with the extent and severity of the skin involvement in patients with diffuse cutaneous SSc. These data further highlight the role of Hsp90 as a significant regulator of fibroblast activation and tissue fibrosis in SSc. In addition, Hsp90 could become a predictor of treatment response.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal involvement in systemic sclerosis (SSc) can have a negative impact on body composition, physical activity and nutritional status. The aim was to assess body composition and physical activity of SSc patients and healthy controls (HC) and the association with selected inflammatory cytokines and laboratory markers of nutritional status in SSc.

Methods: 59 patients with SSc (50 females; mean age 52.5; disease duration 6.7 years; lcSSc:34/dcSSc:25) and 59 age-/sex-matched HC (50 females, mean age 52.5) without rheumatic or tumour diseases were included. SSc patients fulfilled ACR/EULAR 2013 criteria. We assessed body composition (densitometry: iDXA Lunar, bioelectric impedance: BIA-2000-M), physical activity (Human Activity Profile, HAP questionnaire), disease activity (ESSG activity index), serum levels of 27 cytokines/chemokines (commercial multiplex ELISA kit, Bio-Rad Laboratories) and serum levels of chosen parameters of nutrition and lipidogram. Data are presented as mean±SD.

Results: Compared to HC, patients with SSc had significantly lower body mass index (BMI), body fat % (BF%) and visceral fat weight (VF), and also significantly decreased lean body mass (LBM), and bone mineral density (BMD). Compared to HC, patients with SSc had increased extracellular mass/body cell mass (ECM/BCM) ratio, reflecting deteriorated nutritional status and worse muscle predispositions for physical activity (Table 1). Increased ECM/BCM in SSc positively correlated with disease activity (ESSG), skin score (mRSS) and inflammation (CRP, ESR), and was associated with worse quality of life (HAQ, SHAQ), fatigue (FSS), and decreased physical activity (HAP). ESSG negatively correlated with BF%. HAP positively correlated with BMD (Table 2). Serum levels of several inflammatory cytokines/chemokines (Table 3) and markers of nutrition and lipid metabolism were associated with alterations of body composition (Table 4 and 5).

Conclusion: Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our SSc patients, which are associated with the disease activity and physical activity, and could reflect their nutritional status, and gastrointestinal and musculoskeletal involvement. Serum levels of certain inflammatory cytokines/chemokines and markers of nutrition and lipid metabolism were associated with alterations of body composition in SSc patients.

Cumulative Incidence, Survival and Predictors of Pulmonary Arterial Hypertension in Disease Subsets of Systemic Sclerosis: PAH Is Not Increased in Limited vs Diffuse Patients by Adjusted Competing Risk Analysis

Tatiana Nevskaya,[1] Yuxuan Jiang,[1] **Mianbo Wang**,[2] and Janet Pope[3], [1]University of Western Ontario, London, ON, Canada, [2]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada, [3]Western University, London, ON, Canada

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a life-threatening complication of systemic sclerosis (SSc), thought to be more commonly found among the limited cutaneous (lcSSc) compared to diffuse (dcSSc) disease subtype. Since lcSSc is associated with better prognosis, it is unclear whether a higher occurrence of PAH in lcSSc is a reflection of survival bias, especially when longer disease duration and older age increase the risk of PAH. We assessed survival and incidence of PAH, after accounting for death as competing event, in a large multi-center cohort of SSc patients, and explored predictors of PAH development and survival.

Methods: The study consisted of 1689 SSc patients from Canadian Scleroderma Research Group registry, followed for up to 14 years. To compare cumulative incidence between disease subsets, a competing risk analysis (Fine-Gray model with death as competing event) unadjusted and adjusted for sex, age and SSc-related autoantibodies was performed (SAS 9.4). Survival was analyzed by Kaplan-Meier with Log-Rank (Mantel Cox) test; Cox proportional hazards analysis with demographic, clinical, and laboratory characteristics as predictor variables was used to develop prediction models for PH (SPSS 25.0).

Results: Out of 1431 patients (43% dcSSc, 57% lcSSc, mean age at SSc diagnosis 48±13, follow up 3.5±2.9 yrs., range 1-14 yrs.) with sufficient data for PAH, 157 patients had PAH either confirmed by RHC or post mortem. Regardless of SSc subtype, patients with PAH had more severe disease (by HAQ-DI and patient's global assessment of health) and higher mortality (74% vs 11%, p< 0.0001), compared to those without PAH (Table 1). The lcSSc patients with PAH were older at SSc diagnosis and had a longer disease duration from Raynaud's phenomenon (RP), compared to lcSSc without PAH. The dcSSc patients with PAH had more severe peripheral vascular (SHAQ RP and finger ulcers) and gastrointestinal (SHAQ intestinal problems) vs dcSSc without PAH. 47% of patients with PAH died: 45 lcSSc and 29 dcSSc. Male gender and anti-Scl70 were associated with earlier development of PAH from both SSc diagnosis (p< 0.0001 and p=0.002, respectively) and first non-RP symptom (p< 0.0001 and p=0.001, respectively).To

Table 1. Characteristics of patients with and without PAH in the entire SSc cohort, as well as separately in dcSSc and lcSSc sub-groups.

		Hazard ratio (95% CIs)	P values
Crude Model	DcSSc vs lcSSc	2.03 (1.13, 3.66)	0.0186
Adjusted model	DcSSc vs lcSSc	1.82 (0.93, 3.57)	0.0818
	Female vs male	0.98 (0.42, 2.32)	0.9660
	Age	1.00 (0.99, 1.02)	0.7041
	Antibodies		
	ACA vs negative	0.95 (0.46, 1.96)	0.8991
	ATA vs negative	1.93 (0.84, 4.42)	0.1198
	Anti-RNAP vs negative	1.24 (0.45, 3.43)	0.6841

Table 2. Sub-distribution Hazard ratio of PAH by Fine-Gray model accounting for death as competing event

avoid left-censoring problem, 113 pts with PAH diagnosed at or before baseline registry visit were excluded from the cumulative incidence and survival analyses. Cumulative incidence of PAH from the onset of first non-RP symptom was higher in dcSSc than in lcSSc after accounting for death as competing event in unadjusted, but not adjusted competing risk analysis (see Table 2 and Figure). Survival (mean±SE) from PAH onset was similar in lcSSc and dcSSc (44±8 mo vs 38±7 mo, p=0.59).

Conclusion: Cumulative incidence of PAH from the onset of first non-Raynaud's phenomenon symptom was not higher in lcSSc, after accounting for death as competing event and adjusting for age, sex and antibody status. Males and a-Scl-70-positive patients developed PAH earlier.

Forced Vital Capacity Trajectories for Systemic Sclerosis-associated Interstitial Lung Disease—Analysis from the University of Michigan Scleroderma Cohort

Mirette Habib,[1] Sara Jaafar,[1] Annie Park,[1] Suiyuan Huang,[1] Wen Ye,[1] Vivek Nagaraja,[1] Eric White,[1] Kevin Flaherty,[2] and Dinesh Khanna[3], [1]University of Michigan, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor, MI, [3]Department of Medicine, University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial Lung Disease (ILD) is the leading cause of morbidity and mortality in systemic sclerosis (SSc) patients. Forced Vital Capacity (FVC, recorded as % predicted) is a valid outcome measure to assess lung function in patients with ILD. Our objective was to determine whether varying trajectories of FVC in patients with SSc-ILD were associated with different phenotypes of disease.

Methods: Patient data was collected from the electronic medical records of SSc patients seen in the senior author's clinic. SSc patients who completed Chest Computed Tomography (CTs), to evaluate presence of ILD, and had at least 3 FVC measurements that were at least 3 months apart were included in the analysis. A latent class growth analysis model, PROC TRAJ, was used to identify heterogeneous groups among SSc-ILD patients according to their FVC trajectories over time.T-test and Chi-square test were used to compare baseline characteristics among the identified subpopulations.

Results: Out of 484 SSc patients in our cohort, 293 had evidence of ILD on a chest CT of which 86% of which were high resolution CTs (HRCTS). Of the 293 patients with ILD,188 also had at least 3 FVC measurements performed at least 3 months apart. The median (IQR) for follow-up was 42 (25) months and estimated change in FVC among all patients was --2.87% in 100 months. We identified 5 subpopulations with distinct trajectories of FVC% in SSc-ILD patients (group mean trajectories as shown in Figure 1). Groups 1-3 had abnormal baseline FVC% (mean < 80%) whereas Groups 4 and 5 had normal mean baseline FVC% (Table 1). The majority of our cohort fell into Group 2 (27%), Group 3 (22%), or Group

Table 1. Baseline Demographics by Trajectory Groups for SSc-ILD

4 (30%). Group 1 had the lowest estimated FVC% at baseline and greatest decline in estimated FVC%, younger age, higher prevalence of males and African-Americans, and had higher deaths compared to the other groups; the median disease duration was similar in the 5 groups (Table 1) at baseline. Significant differences were found in the patterns of ILD on chest CTs, with Usual Interstitial Pneumonitis (UIP) being more prevalent in low FVC Groups (1 and 2).

Conclusion: Our results suggest 5 distinct groups of patients with SSc-ILD with respect to change in FVC over time. Ongoing work will quantify degree of ILD on chest CTs and the impact of immunosuppressive therapy on long term outcomes in this cohort.

Responsiveness to Change of the Modified Rodnan Skin Score in a Phase I/II Double-Blind Randomized Placebo-Controlled Trial

Erica Bush,[1] Vivek Nagaraja,[1] Robert Lafyatis,[2] and **Dinesh Khanna** [3], [1]University of Michigan, Ann Arbor, MI, [2]University of Pittsburgh Department of Medicine, Pittsburgh, [3]Department of Medicine, University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Modified Rodnan skin score (mRSS) is used as primary and secondary outcome measure in different trials of diffuse cutaneous systemic sclerosis (dcSSc) [1]. As part of a Phase I/II trial assessing the safety of tofacitinib 5 mg twice a day versus placebo in dcSSc (clinicaltrials.gov NCT03274076[2]), we assessed the performance of 3 different methods of scoring the modified Rodnan skin score (mRSS)[1].

Methods: A 6-month, double-blind, randomized placebo-controlled trial was conducted in dcSSc with disease duration of ≤ 60 months (defined as first non–Raynaud phenomenon) and mRSS ≥ 10 and ≤ 45 units. Efficacy end point included the change in the mRSS at 6 months. Each anatomical area was scored as Global Average score where the examiner takes average of the area; Maximum score where an examiner scores the area according to the most severe local involvement; and the Representative area where the examiner assigns a score that is most representative of the area. Responsiveness to change was evaluated using the effect size (ES) and standardized response mean (SRM). Both indices are ratios of observed change to a measure of variance (also known as signal to noise). For two indices, the numerator is the mean change from the baseline to Month 6 for mRSS and the denominators are the standard deviation at baseline (ES) and the standard deviation of change (SRM). Cohen's rule-of-thumb for interpreting responsiveness to change was applied to determine the magnitude of change where 0.20-0.49 represents a small change, 0.50-0.79 a medium change, and 0.80 or greater a large change.

Table 1: Responsiveness to change in the mRSS using different scoring methods

mRSS	Baseline Mean (SD)	Change at 24 weeks	Effect Size (Mean Δ/SD at baseline)	SRM (Mean Δ/SD of change)
Global Average Score	23.3 (8.4)	-4.9 (6.7)	-0.58	-0.73
Representative Score	23.5 (8.3)	-5.1 (6.3)	-0.61	-0.81
Maximum Score	27.0 (8.8)	-5.8 (6.9)	-0.66	-0.84

Results: 15 participants were randomized (2:1; 10 to TOFA and 5 to PLA) and formed the mITT group; 10 (100%) and 4 (80%) completed the 6-month treatment period in TOFA and PLA groups, respectively. The mean baseline scores were similar in the Global Average and Representative groups and higher in the Maximum group (Table 1). Using the ES, the magnitude of responsiveness was similar in all 3 groups (Medium change). Using the SRM, the magnitude of change was numerically greater in the Representative and Maximum groups (Large change) vs. Global Average (Medium change).

Conclusion: In a small trial of 15 participants, all 3 methods to score the mRSS yielded similar magnitude of responsiveness to change. The mRSS was conducted by experienced researchers in this trial and these results should be validated in a larger trial with multiple centers.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster III

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-nuclear antibodies (ANA) are present in approximately 90% of sera from systemic sclerosis (SSc) patients and play an important diagnostic and prognostic role in SSc. Besides anti-Scl-70 (topo I), anti-centromere and anti-RNA Polymerase III which are included in the SSc classification criteria, several other antibodies can be found, some of which clearly associate with defined disease phenotypes. Anti-U11/12 Ribonucleoprotein (RNP) antibodies have been reported in a small portion of SSc patients especially with pulmonary fibrosis. RNPC-3, also known as U11/U12 small nuclear ribonucleoprotein, is a 65 KDa protein that has been reported as an autoantibody target and to be associated with a nuclear speckled indirect immunofluorescence (IIF) pattern on HEp-2 cells. Recently we described a novel linear B-Cell epitope that was used for the development of an autoantibody assay to detect a subpopulation of anti-RNPC-3 antibodies. Our aim in this study was to determine the prevalence of anti-RNPC-3 antibodies in a cohort of well characterized SSc patients and to assess clinical associations.

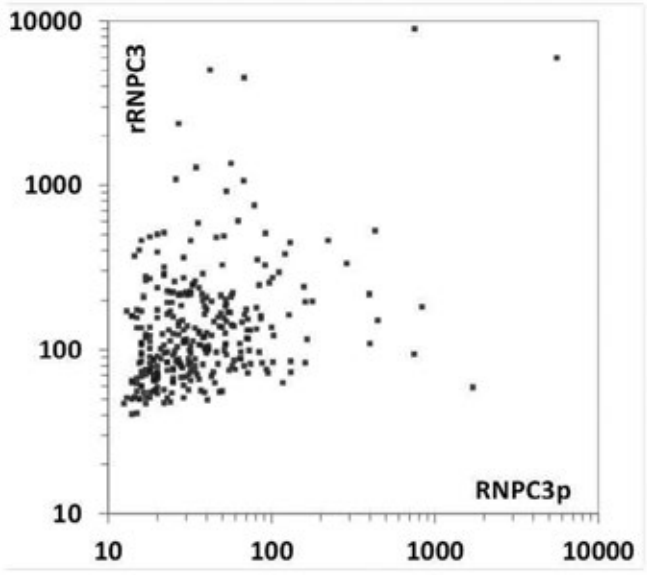

Figure 1
Comparison of rRNPC-3 and RNCP-3p

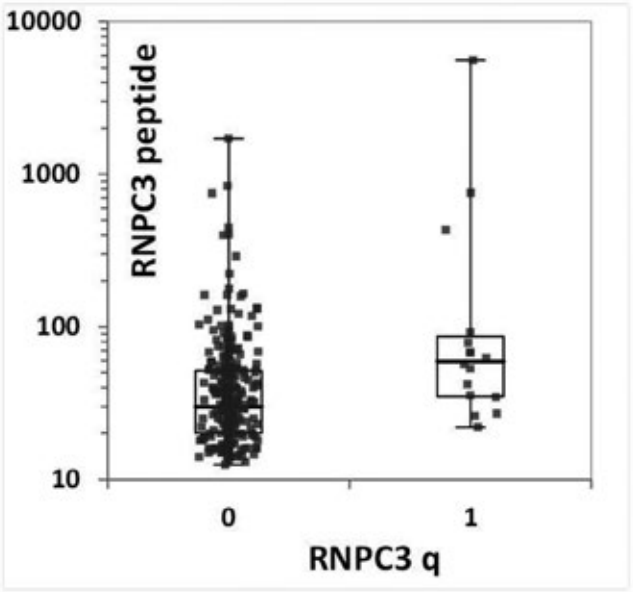

Figure 2
Association of antibodies to recombinant RNPC-3 and the novel linear B-cell epitope.

Total parenteral nutrition at baseline, n (%)	0	1	7 (2.5%)	4	1.000	0	0	7 (2.5%)	5	1.000
Esophageal dilatation at baseline, n (%)	0	0	31 (11.2%)	7	0.382	3 (20.0%)	0	28 (10.1%)	7	0.205
Cancer at all visit, n (%)	0	0	36 (12.7%)	0	0.230	2 (13.3%)	0	34 (12.0%)	0	0.699

Methods: A total of 299 SSc patient samples from a large research cohort enriched for samples with a nuclear speckled IIF pattern were tested using a novel particle-based multi-analyte technology (PMAT) for antibodies to recombinant RNPC-3 (rRNPC-3) and the newly described RNPC-3 derived peptide (RNPC-3p). Immunoadsorption experiments by liquid phase inhibition was carried out to estimate the contribution of antibodies to the novel B-cell epitope compared with the whole anti-RNPC-3 antibody response. Clinical and serological associations were ascertained.

Results: The levels of antibodies to rRNPC-3 and RNPC-3p correlated moderately (See Figure, Spearman=0.32, p=0.0001; chi-squared p=0.0002). As expected, levels of anti-RNPC-3p antibodies were higher in patients positive for the recombinant antigen (p=0.0013). Both rRNPC-3 and RNPC-3p were associated with a speckled pattern. Immunoadsorption showed significant inhibition using the RNPC-3 derived peptide, but not with a control peptide. Prevalence and levels of anti-RNPC-3 antibodies were higher in anti-Scl-70, anti-Cenp, and/or anti-RNA Pol III triple negative patients [10/106 (9.4%) *vs.* 6/193 (3.1%), p=0.03; and median titers 122.0 vs. 107.5, p=0.08]. Patients positive for anti-RNPC-3 antibodies tended to have more interstitial lung disease, especially when considering follow-up. None of the clinical associations reached statistical significance most likely due to limited sample size and prevalence of anti-RNPC-3 antibodies.

Conclusion: Our study confirms the association of anti-RNPC-3 antibodies with the nuclear speckled IIF pattern and their increased prevalence in SSc triple negative patients (anti-Scl-70, anti-centromere, and anti RNA-Pol III antibodies). The previously identified RNPC-3 peptide represents a significant target of anti-RNPC-3 antibodies, but does not capture the entire reactivity indicating the presence of additional epitopes. Further studies are needed to verify the clinical utility of the assays.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: More than 40 studies containing data about adults affected by EGPA treated with Rituximab (RTX) have been published in the last decade. Nevertheless, due to observational design and low methodological quality, its efficacy and safety is still unclear. We conducted a systematic review of the available clinical studies in order to examine the case for undertaking a randomized trial by providing an explicit evaluation of the weaknesses of available research and to provide findings useful to inform the design of a future trial.

Methods: MEDLINE, SCOPUS, Web of Science and Cochrane Central Register were searched up to end of January 2019 without language restriction. Reference lists of pertinent studies were analyzed through manual search to identify additional relevant studies. Missing information or data were required by email to corresponding authors. Articles and conference abstracts including at least one patient affected by EGPA, treated with RTX and assessing

clinical outcomes were included and analyzed by four independent investigators and data extracted in a structured form. Following data were collected: patients' characteristics (age, sex), sample size, diagnostic criteria used, baseline and final (at latest follow-up) vasculitis activity score, disease extension (organ involvement) and refractoriness, Rituximab schedule of administration, co-treatments, median follow-up (months), complete and partial remission rate (according to given definitions) and other secondary outcomes: steroid reduction (PDN≤7.5 mg/die), relapses, serious adverse events, infections, neoplasms and deaths.

Results: A total of 1973 studies were identified, 43 of which met inclusion criteria (see figure 1), accounting for 395 EGPA patients treated with Rituximab. All of the studies were case reports, case series or retrospective cohort studies. Analysis of retrieved data is shown in table 1 and table 2. Overall, 46,1% and 17,2% patients achieved complete and partial remission respectively. A number of counfonding factors affecting the probability to reach remission has been identified and discussed. In particular, the use of standardized criteria for diagnosis and remission definition, the 'ad hoc' outcome selection, and the number of enrolled patients strongly influence the likelihood of response. In particular, case reports tend to overestimate efficacy of the treatment due to publication bias.

Duration of follow-up in month, media (range)	388	38,98 (3-119)

Table 2. Main results from the 43 included studies. BVAS: Birmingham Vasculitis Activity Score; SAEs: Serous Adverse Events

Conclusion: Rituximab might be an effective therapeutic alternative in severe refractory EGPA. However, despite high number (considering the low prevalence of the disease) of RTX treated EGPA patients described in available literature, the high risk of positive effect overestimation which tipically affects case reports and low quality observational studies, as well as flaws in outcome selection, definition and measurement hinder the possibility to achieve reliable conclusions about efficacy and safety of this therapeutic approach. Results from this systematic review could be hopefully used to better design future clinical trials to clarify this relevant topic.

Effects of Tofacitinib Suppressed Pulmonary Vascular Remodeling of Allergic Vasculitis in a Murine Model

Yuka Oikawa,[1] Kohei Yamauchi,[2] and Makoto Maemondo[1], [1]Iwate Medical University School of Medicine, Morioka, Japan, Division of Pulmonary medicine, Allergy and Rheumatology, Department of Internal Medicine, morioka, Japan, [2]Takizawa central Hospital, morioka, Japan

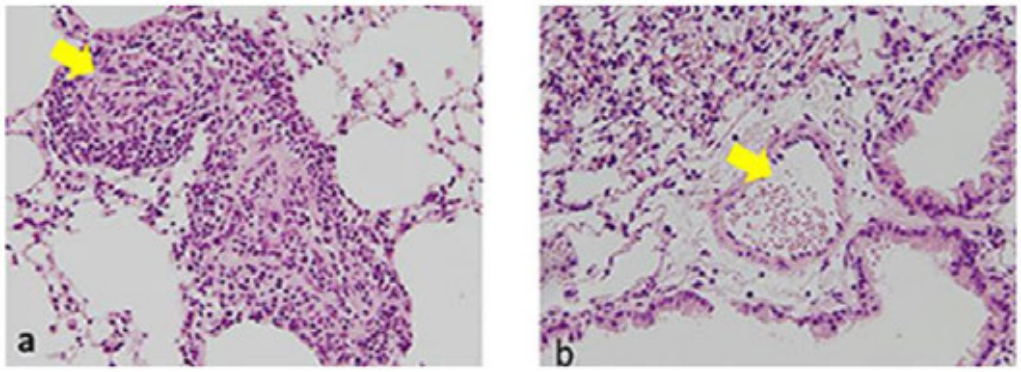
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We reported allergic granulomatous vasculitis with eosinophil infiltration in an asthma model of C57BL/6 sensitized with ovalbumin (OVA). TGF-btea and IL-6 are thought to play an important role in fibroblasts proliferation and is critical to vascular remodeling in vasculitis. Tofacitinib inhibits vascular endothelial cells proliferation and canalization.

To elucidate the role of tofacitinib in vascular remodeling of allergic granulomatous vasculitis, we examined the effects of tofacitinib on the vasculitis of the murine model.

Methods: C57BL/6 mice (6-8 weeks) were sensitized with ovalbumin (OVA) and alum. The positive controls (n=9) were exposed to aerosolized OVA daily for 7 days. The other group of mice (tofacitinib treated mice(n=9)) were administered with tofacitinib (100mg/kg intraperitoneal administration) in parallel with daily exposure to aerosolized OVA for 7 days. On 7th day, bronchoalveolar lavage (BALF) was performed and the lungs were excised for pathological analysis. Cytokines in BALF were measured.

Results: The total cell number and the number of Eosinophils in BALF on the 7th day were decreased significantly in the tofacitinib-treated mice compared with those of the control-positive mice. The blood eosinophil counts in the



a. Positive control: Totally occluded pulmonary artery by intraluminal myofibroblasts in the OVA-sensitized mice with exposure to OVA in 7th day. (HE staining) b. Tofacitinib: Intraluminal myofibroblast accumulation was not observed in the OVA-sensitized mice with exposure to OVA and treated with tofacitinib in 7th day. (HE staining).

positive control increased after OVA inhalation. The blood eosinophil counts in the tofacitinib treated mice were lower on the than those in the positive control.

The concentrations of IL-4, IL-5, IL-6 and TGF-beta in BAL fluids reduced significantly in the tofacitinib treated group. The pathological scores reduced significantly in the tofacitinib treated group compared to the positive control group. Intra luminal infiltration and proliferation of Ki67 positive myofibroblasts, IL-6 positive cell and α-SMA positive cells in pulmonary arteries were reduced dramatically in the tofacitinib treated group compared to the positive control group.

Conclusion: Tofacitinib suppressed pulmonary vascular remodeling in a murine model of allergic vasculitis with eosinophil infiltration. Tofacitinib is a hopeful therapeutic drug for Eosinophilic granulomatosis with polyangiitis.

Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In associated ANCA vasculitis (AAV), rapidly progressive glomerulonephritis (GN) is one of the most serious complications. In 40% of cases they progress to chronic kidney disease (CKD), others to hemodialysis (HD) or death. According to the classification of the European AAV group (EUVAS), the histopathological findings of the biopsy can predict the outcome renal with better results in the focal class, followed by the mixed and sclerotic class. **Our objective is to evaluate the association between outcome renal and histopathological findings of patients with AAV**

Methods: Cohort study, retrospective patients with AAV (ACR 1990 / Chapell Hill 2012) and rapidly progressive GN of three centers of high complexity in the Autonomous City of Buenos Aires between January 2012 - December 2018. Demographic, clinical, analytical variables were recorded and follow-up for one year, at diagnosis. The immunoserology patterns (ANCA and PR3 / MPO), Five Factor Score (FFS), BVASv3 (0-63) and VDI (0-64) per year are evaluated. Renal biopsies (optical microscopy and immunofluorescence) were reviewed. The **glomerular lesions** were classified according to EUVAS and its association with CKD, HD and death was evaluated

Table 1.

Clinical Variable	Basal mean n=33	Year mean n=33
Basal creatinine (Crb)	3 mg / dL (SD +/- 2.8 IC95% 1.8-4.1)	2.18 mg/dL(SD +/- 2.6 IC95% 1.14-3.2)
eGFR	32.5 ml /min/ 1.73m2 (SD +/- 26 IC95% 22-43)	43 ml / min / 1.73m2 (SD +/- 30 IC 95% 31-55)
Proteinuria 24 hs	1,88 g/L(SD +/-1,17 IC95% 1,48-2,28)	

Results: 33 patients were included, 57.6% males. Mean age 51 (SD +/- 16 IC 95% 45-58). GPA 65%, and MPA 33%. ANCAc n: 20, PR3 52%. ANCAp n: 13, MPO 30%. Histopathology: Glomerular lesions: **Focal** 18%, **Crescentic** 27% **Sclerotic** 12% and **Mixed** 43%. **Grade 1**: 24%, **grade 2**: 27% and **grade 3**: 49%. Fibrinoid necrosis in 61%. **Global Interstitial Commitment** (tubilitis, tubular atrophy, fibrosis and inflammatory infiltrate) 97%; **grade 0**: 12%, **grade 1**: 58%, **grade 2**: 30%. **cell infiltrate** in 85% monomorphonuclear 73%, polymorphonuclear 6%. **Vascular damage** (subintimal sclerosis) 79%: **mild** 46%, **moderate** in 36% and **severe** 11%. The patients presented severe clinical compromise with a median BVASv3 15 (RIC 7-48). FFS: I: 24%; II: 42%; III: 18%; IV: 6%. PCR 23 (RIC 1-321) and VDI at year 3 (RIC 2-5), the baseline clinical variables and at one year are summarized in Table 1.

HD requirement at the start of 36%, achieving independence of HD (HDI) per year by 30%, the variables associated with HDI were Crb and eGFR p = 0.014 and p = 0.012 respectively and focal class with p = 0.032. The CKD was 33%, with the mixed class being the most associated p = 0.017. Relapse in 30% associated with the type of glomerular lesion with p = 0.006. Death 4 (activity and infection). The association between tubulointerstitial involvement and CKD and HDI was not significant.

Conclusion: Crb and the glomerular filtration rate were the best predictors of CKD and HDI. The mixed class was associated with CKD. We found an association between the focal class and the HDI. Relapses are associated with the type of glomerular pattern. The percentage of progression to CKD was low and high rate of HDI. There was no association between tubulointerstitial involvement and progression to CKD.

A Single Center Retrospective Analysis of Efficacy and Safety Between Low-Dose versus High-Dose Rituximab as Remission Induction Therapy with ANCA-Associated Vasculitis

Kei Hirose,[1] Manami Hirata,[1] Akiko Ueno,[1] and Masahiro Yamamura[1], [1]Okayama Saiseikai General Hospital, Okayama City, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab therapy for ANCA-associated vasculitis (AAV) patients was covered by insurance from 2013 in Japan. Administration of four once-weekly doses of 375 mg/m2 rituximab (RTX) has been indicated for ANCA-associated vasculitis (AAV) as remission induction therapy. However, randomized controlled trial for Japanese AAV patients have never been conducted, although Japanese AAV patients are characterized by the predominance of elderly patients with microscopic polyangiitis (MPA). To compare the efficacy and safety between low-dose versus high-dose RTX therapy as remission induction therapy in Japanese patients with AAV.

Methods: A single center retrospective analysis of 34 consecutive AAV patients with RTX therapy was performed from 2013 to 2019. 25 patients were treated with low-dose RTX infusions, while 9 patients with high-dose RTX infusions. The primary endpoints were complete remission (CR) rate, defined as Birmingham Vasculitis Activity Score (BVAS)=0 and prednisone < 7.5 mg/day, survival rate and severe adverse effects at 6 months. Fisher's exact test were used for categorical data and Mann-Whitney U test for continuous data to compare background data. Roglank test was used to complete remission rate, compere survival rate and severe adverse effects at 6 months.

Results: The frequency of elder (79 vs 71, P=0.045), female (64% vs 21%, P=0.07) patients were significantly high in low-dose group and the duration of hospitalization (22 days vs 38 days, P=0.339) was shorter in low-dose group, whereas the frequency of smoking (36% vs 89%, P=0.017) was significantly higher in high-dose group and the ANCA titer (93.9 vs 176.0, P=0.081) and PSL dose (30mg/day vs 40mg/day, P=0.062) was higher in high-dose group.

Compared with low-dose group with high-dose group, there was no significant difference with complete remission rate (58% vs 50%, P=0.485), survival rate (87.6% vs 88.9%, P=0.87) and probability of remaining free of severe adverse effects (61.5% vs 88.9%, P=0.176).

	Low dose(n=25)	High dose(n=9)	P=
Age, median	79 (57-85)	71 (64-82)	0.045
Sex, male (%)	9 (36%)	8 (89%)	0.017
Diagnosis, MPA(%)	21 (84%)	8 (89%)	1
BVAS	12 (6-32)	14 (8-35)	0.813
Severity (EUVAS)			
Severe (%)	11 (44%)	4 (44%)	1
Generalized (%)	14 (56%)	5 (56%)	
Smoking history (%)	9 (36%)	8 (89%)	0.017
Duration of hospitalization, days	22 (2-119)	38 (14-91)	0.339

mPSL pulse (%)	15 (60%)	6 (67%)	1
Other ISAs (%)	9 (36%)	5 (56%)	0.435

Backgrounds

	Low dose	High dose	P=
Complete remission rate (%)	58%	50%	0.485
Survival rate (%)	87.6%	88.9%	0.87
Probability of remaining free of severe adverse effects (%)	61.5%	88.9%	0.176

Results

Conclusion: Our retrospective analysis indicated that cumulative CR rates and 6 month-survival rates did not significantly differ between low-dose versus high-dose RTX as remission induction therapy in Japanese AAV patients, mostly elderly MPA female patients, although there was no significant difference in severe adverse effects such as opportunistic infections between them.

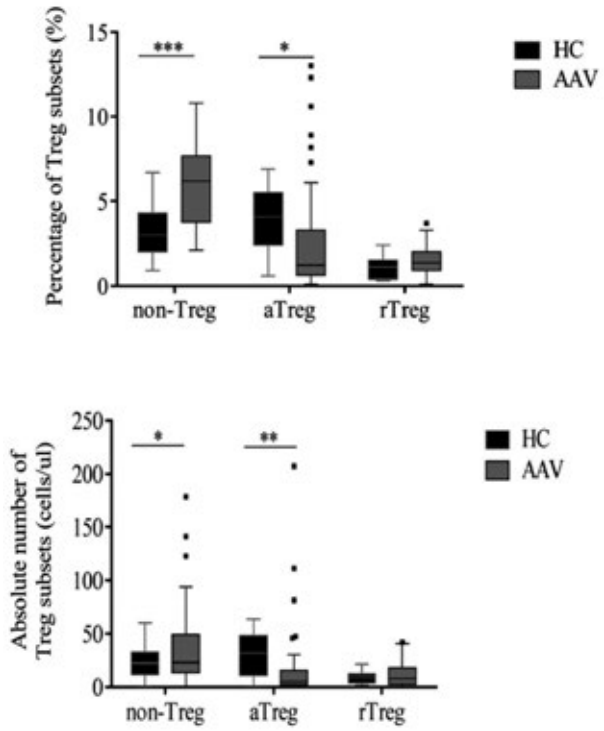
We therefore analyzed the percentages and absolute numbers of CD4+ T cell subsets as well as their diagnostic values in patients with AAV. CD4+ T cell subsets control immune system in check and prevent autoimmunity by keeping a balance among them. However, their levels of blood in ANCA-associated vasculitis (AAV), especially absolute numbers, are still remains unclear. We therefore analyzed the percentages and absolute numbers of CD4+ T cell subsets as well as their diagnostic values in patients with AAV.

Figure 1



Methods: AAV patients (n = 54) and healthy controls (HCs) (n = 19) were enrolled. Of them, 38 patients were renal vasculitis. Proportions and absolute numbers of $CD4^+$T cell subsets were determined by flow cytometry. The diagnostic value for Treg subsets was evaluated by the areas under the receiver operating characteristic curves (AUC). Correlations of clinical indicators with the $CD4^+$ T subsets were systematically analyzed.

Results: Percentages of activated Treg cells (aTreg, p=0.044) in AAV patients were decreased, but those of effector memory T-cell subpopulation (TEM) (p< 0.001) and Treg cells (p=0.001) were increased. Similar results were observed when we compared absolute numbers of the above corresponding cells in AAV patients and HCs, except TEM. Furthermore, the percentage of aTreg (p=0.043) was decreased while that of Th17 cells (p=0.027) was increased in renal vasculitis patients. A significant correlation was observed between the ratio of Th17 to Treg subset and creatinine or BUN in renal vasculitis patient. Interestingly, the AUC of the aTreg improved significantly the diagnostic potential of AAV. In addition, we found that cytokine IL-2 and IL-4 exhibited a downward while IL-6, IL-10, TNF-α, IFN-γ and IL-17A trend upward in AAV patients.

Conclusion: We identified decrease in aTreg cells and increase in $T_{EM,}$ which associated with the ANCA-related immune response. Correcting the above-mentioned T cell abnormality will potentially be powerful therapeutic tools for AAV.

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: MAINRITSAN-trial results[1] demonstrated rituximab superiority (500 mg on days 0 and 14, then at months 6, 12 and 18) to azathioprine to maintain remission of ANCA-associated vasculitides (AAVs). In that trial, at month 28, 5% of rituximab-treated patients had experienced a major relapse but, at month 60 of follow-up, major relapse-free survival was 49.4%.[2]

The MAINRITSAN3 trial (NCT02433522) aimed to evaluate the efficacy of long-term rituximab administration to prevent AAV relapses in patients in remission after a first phase of rituximab-maintenance therapy.

Methods: To be included, patients had to have been enrolled in the MAINRITSAN2 trial[3] (randomized–controlled trial comparing 2 rituximab-infusion strategies for patients with newly diagnosed or relapsing granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) in complete remission after induction therapy: tailored-arm patients received a 500-mg rituximab infusion at randomization, with rituximab reinfusion only when CD19+ B lymphocytes or ANCA had reappeared or ANCA titer rose markedly; controls received a fixed 500-mg rituximab infusion on days 0 and 14 postrandomization, then at months 6, 12 and 18) and be in complete remission at the end of MAINRITSAN2 at month 28. At that time, patients were enrolled in MAINRITSAN3 and re-randomized to receive 4 more rituximab infusions, at inclusion and months 34, 40 and 46, or a placebo. Premedication for all patients comprised acetaminophen (1000 mg), methylprednisolone (100 mg) and dexchlorpheniramine (5 mg).

The primary endpoint was relapse-free survival at 56 months. Relapse was defined as new or reappearing symptom(s) or worsening disease with BVAS >0 and was evaluated by an independent Adjudication Committee.

Results: Between March 2015 and April 2016, 97 patients were enrolled in MAINRITSAN3 in 45 centers in France: 50 to receive rituximab and 47 placebo-group controls. Their mean age was 63.9 years, 35.1% were women, 68 (70.1%) had GPA and 29 (29.9%) had MPA, and 50% were ANCA-positive at enrollment. Comparing rituximab vs placebo groups, respectively: relapse-free survival rates were 96% [95% confidence interval (CI), 90.7–100%] vs 74.3% [62.8–88%], hazard ratio: 7.5 [1.67–33.6%] (p=0.008); major relapse-free survival rates were 100% [100–100%] vs 87.1% [78–97.3%] (p=0.009). Twelve (24%) rituximab recipients vs 14 (29.8%) controls had at least 1 severe adverse event (SAE) (p=0.65). No patient died. Six (12%) rituximab recipients had 9 infectious SAEs (septic shock or urinary, 2 each; Lyme disease, acute cholangitis, neutropenia, bronchitis or pneumonia, 1 each) vs 4 (8.5%) controls with 6 (4 pneumonia, 1 flu or 1 *Pneumocystis jiroveci* infection in a patient receiving methotrexate and glucocorticoids postrelapse after study discontinuation).

Conclusion: Long-term rituximab maintenance achieved significantly lower AAV relapse rates. SAEs were not more frequent in rituximab recipients.

Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to evaluate the predictors of advanced chronic kidney disease (ACKD) in patients with Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis and renal involvement.

Methods: Observational retrospective study. We included all patients with biopsy-proven ANCA glomerulonephritis (GN) diagnosed between 2001 and 2016, with at least one year of follow-up. Data was recorded at diagnosis, end of induction treatment, after one year of treatment, and at the end of follow-up. We analyzed serum creatinine, estimated glomerular filtration rate (eGFR), proteinuria, hematuria, renal histopathology and autoantibodies, as well as received treatments, requirement of dialysis, and renal or extra-renal relapses. Renal biopsies were reviewed and classified in accordance to the 2010 histopathologic classification of ANCA-associated GN. Univariate analysis were performed to identify factors associated with long-term ACKD (eGFR < 30 ml/min, stages 4 or 5 of KDIGO classification). The diagnostic accuracy for ACKD of each predictor variable were compared using areas under the curve (AUC) of ROC (receiver operating characteristic) curves.

Results: Sixty patients with ANCA GN were included: 17 Granulomatosis with polyangiitis (GPA), 14 Microscopic polyangiitis (MPA), 5 Eosinophilic granulomatosis with polyangiitis (EGPA), and 24 Renal-limited vasculitis (RLV). Forty-six patients were women (76.7%), with a mean age of 67.8 years (SD 13.1) at diagnosis. Median follow-up time was 4.2 years (IQR 2.2-6.8). The most frequently found histopathologic class was the focal class (20 patients, 33.3%), followed by mixed (17 patients, 28.3%), crescentic (16 patients, 26.7%), and sclerotic class (7 patients, 11.7%). Regarding treatment, 53 patients (88.3%) received cyclophosphamide, 42 (70%) IV pulse steroid therapy, 11 (18.3%) plasmapheresis and 10 (16.7%) transient dialysis. Seventeen patients (28.8%) needed to be re-biopsied during follow-up, and renal relapse was confirmed on 14 (26.4%) of them. Additionally, 11 patients (19.6%) had an extra-renal relapse. Four patients (6.7%) remained on permanent dialysis. At the end of follow-up, 12 patients (20.7%, 95% CI 11.9-33.4%) had an eGFR < 30 ml/min (Table 1). The univariate analysis showed a statistically significant association of ACKD with the sclerotic class biopsy (OR 7.17, 95% CI 1.34-38.31, p 0.02), and serum creatinine at diagnosis (OR 1.24, 95% CI 1.02-1.52, p 0.03), end of induction (OR 15.4, 95% CI 2.41-98.28, p 0.004), and after

Table 2. Univariate analysis to identify factors associated with long-term ACKD (eGFR <30 ml/min) at the end of follow-up.

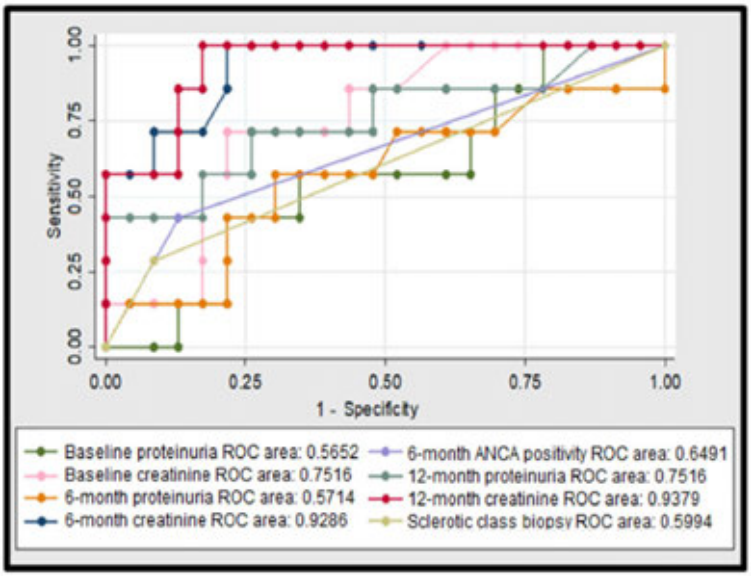

Figure 1. ROC curves to determine ACKD at the end of follow-up.

12 months (OR 19.25, CI 95% 2.75-134.92, p 0.003). We found no significant association of ACKD with proteinuria, hematuria, ANCA positivity at different times nor any other of the analyzed variables (Table 2). The best diagnostic accuracy in ROC curves was shown by serum creatinine at the end of induction (AUC 0.93, 95% CI 0.83-1.00) and at 12 months (AUC 0.94, 95% CI 0.85-1.00) (Figure 1).

Conclusion: In this cohort of patients with ANCA vasculitis and renal involvement, serum creatinine at the end of induction and after 12 months of treatment were the best predictors of ACKD (eGFR < 30ml/min) at the end of follow-up.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating cell-free mitochondrial DNA (mtDNA) is released during non-apoptotic processes such as NETosis. Increased levels of mtDNA are associated with autophagic dysfunction and inflammasome activation. In critically ill patients mtDNA levels correlate with mortality. In Granulomatosis with Polyangiitis (GPA) there is evidence that innate immune system activation is involved in pathogenesis and propagation of disease. The role of autophagic dysfunction and subsequent effects on the inflammasome as it relates to mtDNA has yet to be robustly investigated in GPA. The aim of this study was determine whether increased circulating mtDNA levels correlate with disease activity in GPA.

Methods: Plasma samples and clinical data from the Wegener's Granulomatosis Etanercept Trial were utilized. Cell-free mtDNA levels were measured in banked plasma by applying a SYBR Green-qPCR assay using a PRISM 7300 sequence detection system (Applied Biosciences). All mtDNA level data were log-transformed. Samples were categorized based on disease activity and severity. The primary aim was to determine if mtDNA levels correlated with disease activity as defined by BVAS/WG. Samples were classified as pre-flare, flare, or remission, with flare further subcategorized into severe or non-severe

Results: 100 of the 180 participants in WGET had available plasma at 2 or more visits, and were data from these patients and sample were used for this analysis. No significant differences in patient demographics were observed between those with and without plasma. There was no difference in mtDNA copy number across visit types (pre-flare, flare, and remission). While mtDNA level was not a significant predictor of disease activity in univariate models, there was trend within severe flare: an increase in mtDNA level was indicative of increased odds of severe flare (Odds Ratio = 1.32; (0.78 – 2.22) In paired analysis (n=40), mean mtDNA level was significantly higher during a severe flare

(N=100)	Odds Ratio (95% CI)
Disease activity	
Severe flare	1.320 (0.78 – 2.22)
Non-Severe flare	0.972 (0.61 – 1.56)
Severe persistent	2.78 (0.22 – 35.66)
Non-Severe persistent	0.893 (0.29 – 2.76)
Remission	0.846 (0.56 – 1.28)

Table 1. Univariate logistic models: mtDNA and disease activity

(N=9)	Pre-Severe Flare	Severe Flare	p-value
Mean ± SD	7.23 ± 1.15	7.76 ± 1.32	0.185
Pre indicates 3 months before flare.			
(N=12)	**Pre-Severe Flare**	**Post-Severe Flare**	**p-value**
Mean ± SD	7.25 ± 1.07	7.83 ± 1.00	0.052
Pre/Post indicates 3 months before or after referenced flare.			
(N=40)	**Severe Flare**	**Remission**	**p-value**
Mean ± SD	7.75 ± 1.47	7.36 ± 1.17	0.038

Table 2. Paired t-tests: Log-transformed mtDNA levels across visit type

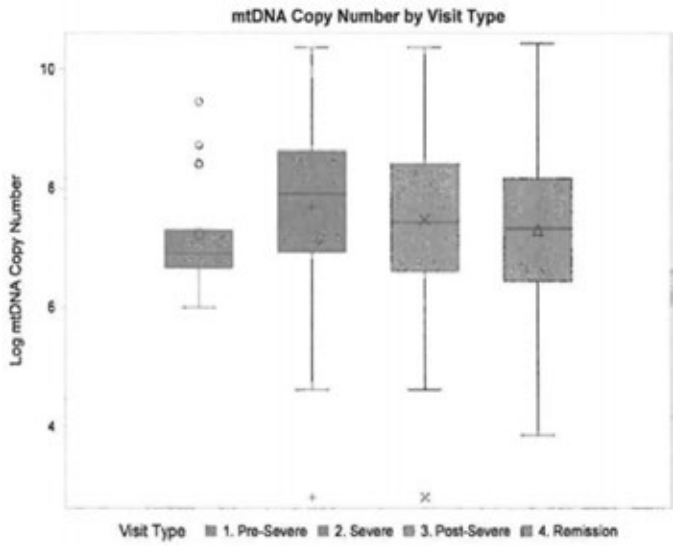

Figure 1. Distribution of mtDNA copy number by visit type

as compared to remission (M=7.75 ± 1.47, M=7.36 ± 1.17, respectively; p=.038). In a subset of the paired analysis (n=13), restricted to pre- and post-severe flare observations, mean mtDNA level was significantly higher 3 months following the flare as compared to pre-flare in relation to an index severe flare (7.83 ± 1.00 vs 7.25 ± 1.07, p=.052). Mean mtDNA between pre-severe flare and severe flare (n=9) was not significantly different (7.23 ± 1.15 vs 7.76 ± 1.32, p=.185).

Conclusion: This exploratory study suggests that mtDNA levels may be elevated in states of high disease activity among patients with GPA. However, firm conclusions are limited by small sample size. These findings suggest a role for deregulated autophagy in GPA. Finally, mtDNA level, a non-invasive and rapidly performed test, may potentially serve as a useful biomarker for disease activity in GPA, although additional examination in a larger cohort of patients is warranted to determine its utility and sensitivity.

Association of Work Productivity Assessed by Absenteeism and Presenteeism with Disease Activity, Damage and Health-related Quality of Life in Patients with ANCA-associated Vasculitis

Shinya Hirahara,[1] Yasuhiro Katsumata,[1] Ken-ei Sada,[2] Hiroko Nagafuchi,[3] Eiichi Tanaka,[1] and Masayoshi Harigai[1], [1]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Kitaku, Okayama, Japan, [3]Division of Rheumatology and Allergology, Department of Internal Medicine, St. Marianna University School of Medicine, Kawasaki City, Kanagawa, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammatory diseases such as antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) substantially affects patients' daily lives, including their ability to work. Although the management of AAV has improved, many patients still have to take sick leave or even stop working because of their diseases (i.e., absenteeism). Even for those remaining in paid work, patients may experience problems due to AAV resulting in productivity loss while at work (i.e., presenteeism). However, little has been reported on absenteeism and presenteeism in patients with AAV. We aimed to investigate the absenteeism and presenteeism in patients with AAV and associated factors.

Methods: Patients with AAV were defined and classified according to the European Medicines Agency algorithm. Patients were approached during their outpatient appointments in the three different university hospitals from November 2017 through February 2018. Some of the hospitalized patients were also eligible. Patients were asked to complete the Work Productivity and Activity Impairment–General Health (WPAI-GH) questionnaire, the 5-level EuroQoL 5-Dimensions Questionnaire (EQ-5D-5L), which is the generic measures of health-related quality of life (HRQoL), and other related demographic questionnaires. An EQ-5D-5L health state was converted to a single summary index by applying the formula and ranges from 0 to 1; 0 meaning death and 1 complete health. Physicians, who were blind-

ed to the WPAI-GH and EQ-5D-5L results, completed the the Birmingham Vasculitis Activity Score (BVAS) and the Vasculitis Damage Index (VDI) simultaneously and record other medical information.

Results: A total of 92 patients with AAV (microscopic polyangiitis 42, granulomatosis with polyangiitis 24, eosinophilic granulomatosis with polyangiitis 22, renal limited AAV 3, and unclassified AAV 1) participated. In the study population, the mean age was 65.4, 60 were women, the mean disease duration was 5.5 years, the mean prednisolone dosage was 7.5 mg/day, the mean BVAS was 3.6, and the mean VDI was 1.6. The mean EQ-5D-5L index value was 0.755 and significantly lower than the value of the age- and sex-matched national norms ($p < 0.01$). A total of 25 (27%) patients worked for pay and significantly younger than those who did not work ($p < 0.01$). Of the 25 patients working for pay, 11 reported missing work due to their health problem, accounting for 17% of their working time (absenteeism) on average, and 32% of their work was impaired due to their health problem (presenteeism) on average. WPAI absenteeism was weakly to moderately correlated with the and BVAS and EQ-5D-5L scores ($r = 0.24$ and -0.61, respectively), whereas not with the VDI scores ($r = 0.08$). WPAI presenteeism was weakly to moderately correlated with the BVAS, VDI, and EQ-5D-5L scores ($r = 0.39$, 0.38, and -0.58, respectively). Patients with lower HRQoL status (low/high EQ-5D-5L scores by median) had significantly higher absenteeism (28%/17%, $p = 0.01$), and presenteeism (48%/32%, $p = 0.002$) than those with higher HRQoL status.

Conclusion: Work productivity assessed by absenteeism and presenteeism are associated with disease activity, damage, and HRQoL in patients with AAV.

Mortality Predictors in ANCA-associated Vasculitis: Experience of a Brazilian Monocentric Cohort of a Rheumatology Center

Marilia Dagostin,[1] Sergio Nunes,[2] Samuel Shinjo,[3] and Rosa Pereira[4], [1]University of Sao Paulo, São Paulo, Brazil, [2]Univeristy Of Sao Paulo, São Paulo, [3]Univeristy Of Sao Paulo, São Paulo, Brazil, [4]Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mortality of patients with ANCA-associated vasculitis (AAV) is higher than the general population. There are few papers in the literature regarding the factors associated with this unfavorable outcome, most of them in the eastern population or from nephrology centers. To date, there is no study with this approach in Latin-American patients, a miscegenated population.

Our objective was to identify clinical and laboratory features associated with increased mortality in Latin-American patients with AAV.

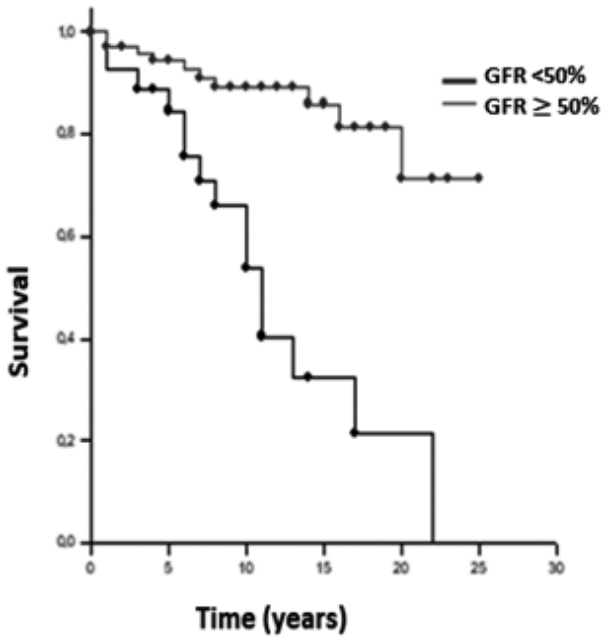

Figure. Survival Analysis of the patients based on their GFR.

Methods: All the patients fulfilling the Chapel Hill Criteria (2012) and ACR criteria (1990) for AAV followed between 2000 and 2018 in our Rheumatology Vasculitis Outpatient Clinics were selected. Data were obtained from an ongoing electronic database protocol that was carried out for all patients at 1- to 6-month intervals. Patients were divided in two groups - dead or alive in 2018. Information about the death was obtained from medical records, family members and death certificates. Variables analyzed were age at the onset of the vasculitis, ANCA frequency, Birmingham Vasculitis Activity Score (BVAS), Vasculitis Damage Index (VDI) and laboratory parameters in the most recent attendance or in the last attendance before death. Comparisons were made by non-paired t-tests or Mann-Whitney tests for continuous variables and Fisher's exact test for categorical variables. Logistic regression was used to analyze association between death (dependent variable) and variables with significance in the univariate analyses. A log-Rank survival analysis was performed. Statistical significance was set at $p < 0.05$.

Results: 128 patients were included; 101 had GPA, 21 had EGPA and 6 had MPA. In 2018, 78 were alive, 25 had died and 25 had lost contact. The main cause of death was infection (64%). The vasculitis was considered a contributing factor in 40% of the deaths. The patients who died were older at diagnosis (40.9 vs. 51.2 years, p=0.007) and had higher activity and damage index (BVAS 3 vs. 8, p =0.001; VDI 3.5 vs. 6.9, p< 0.001). Laboratorial features related with mortality were creatinine (1.24 vs. 3.5 mg/dL, p < 0.001), hemoglobin (13.3 vs. 10.7 g/dL, p< 0.001), ESR (19.7 vs. 38.6 mm/1sthour, p=0.038) and CRP (5.4 vs. 68.9 mg/L, p< 0.001). The dose of prednisone taken in the last attendance was higher in the dead-group (9.8 vs. 18.9 mg/day, p=0.018). No difference was observed regarding the presence of ANCA or the immunosuppressive treatment. Logistic regression showed that VDI (OR 1.35, p=0.03), creatinine (OR 1.31, p=0.01) and CRP (OR 1.04, p=0.04) were independent factors related to mortality. The VDI items statistically different between the groups were: EGFR < 50%, proteinuria >0.5 g/24h, end stage renal disease, chronic breathlessness, significant muscular atrophy/weakness, malignancy, visual impairment and oral ulcers. Survival was importantly decreased among patients with GFR < 50% (p < 0.001) (figure).

Conclusion: This is the first study analyzing outcomes of Latin-Americans patients with AAV. Damage index, renal impairment and high CRP were independent factors associated with mortality. Survival rates were significantly decreased among patients with lower GFR.

Urinary Inflammatory Cell Analysis Reflects the Renal Histopathology in Anti-neutrophil Cytoplasmic Antibody-associated Vasculitis

Yoko Wada,[1] Masanori Sudo,[2] Takeshi Kuroda,[3] Masaaki Nakano,[4] and Ichiei Narita[2], [1]Niigata Rinko Hospital, Niigata, Niigata, Japan, [2]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Niigata, Japan, [3]Health administration office, Niigata University, Niigata, Niigata, Japan, [4]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Niigata, Japan

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The anti-neutrophil cytoplasmic autoantibody (ANCA)- associated vasculitides (AAVs) include microscopic polyangiitis (MPA), granulomatosis with polyangitis (GPA), and eosinophilic granulomatosis with polyangitis (EGPA). These small-vessel vasculitides are characterized by necrotizing inflammation of the vessel wall, particularly affecting small arteries, arterioles, and capillaries in systemic organs, and the kidney is one of the organs most frequently involved. Although kidney biopsy is necessary for deciding the therapeutic protocol, it is invasive and sometimes difficult to perform in patients who are in poor general condition. We have already reported that T cells and macrophages appear in the urine of patients with glomerulonephritis, accompanied by active cellular infiltration such as cellular crescent formation and diffuse interstitial cell infiltration, but not in the urine of patients with glomerulonephritis without the active inflammatory lesions. In this study, we examined the utility of urinary inflammatory cell analysis for assessment of kidney histopathology in AAVs.

Methods: This was a cross-sectional, retrospective chart study. Thirty-six AAV patients who had been referred to Niigata University Hospital between 2002 and 2018, and had undergone percutaneous kidney biopsy and urinary inflammatory cell analysis, participated. Thirty-two patients had MPA, and 4 had GPA. The kidney biopsy findings were classified according to Berden's classification (a method for categorizing glomerular lesions into four classes) and Neumann's classification (a method for evaluating glomerular, tubulo-interstitial, and vascular lesions on the basis of activity indices and chronicity indices). Flow-cytometric analysis of urinary inflammatory cells was performed for each subject. The numbers of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percentage of urinary CD3-positive or CD14-positive cells in the population, respectively. The correlations between the results of the two methods and the numbers of urinary inflammatory cells were examined using Kruskal-Wallis test and Spearmann's rank correlation coefficient. Differences at $p < 0.05$ were considered to be statistically significant.

Results: In Berden's classification, the numbers of urinary inflammatory cells showed a non-significant tendency to be increased in the crescentic category. Meanwhile, in Neumann's classification, activity indices showed significant positive correlations with the numbers of urinary CD3-positive cells ($r = 0.541$, $p = < 0.001$), CD14-positive cells ($r = 0.354$, $p = 0.034$), and total inflammatory cells ($r = 0.449$, $p = 0.006$).

Conclusion: The numbers of urinary inflammatory cells reflect kidney histopathology in terms of active lesions, suggesting the usefulness of urinary inflammatory cell analysis for assessment of kidney biopsy findings in patients with AAVs.

A Dutch Consensus Statement on the Diagnosis and Treatment of ANCA Associated Vasculitis

Ebru Dirikgil,[1] Peter Verhoeven,[2] Sander Tas,[3] Abraham Rutgers,[4] Hein Bernelot Moens,[5] Jacob van Laar,[6] Willem Jan Bos,[7] and Onno Teng[1], [1]LUMC, Leiden, Netherlands, [2]The Dutch Vasculitis Foundation, Silvolde, Netherlands, [3]Amsterdam Rheumatology & immunology Center, Amsterdam UMC/University of Amsterdam, Amsterdam, Netherlands, [4]University Medical Center Groningen, Groningen, Netherlands, [5]Ziekenhuisgroep Twente, Almelo, Netherlands, [6]UMC Utrecht, Department of Rheumatology & Clinical Immunology, Utrecht, The Netherlands, Utrecht, Netherlands, [7]St. Antoniusziekenhuis, Nieuwegein, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Several guidelines have been published on the diagnosis and treatment of anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV). These guidelines provide an evidence-based approach to support clinical-decision making and adequate implementation is needed to improve care. As part of an implementation strategy, national consensus meetings in the Netherlands were initiated in order to establish consensus on broad aspects of the diagnosis and treatment of AAV based upon the recently published guidelines, relevant to daily clinical practice.

Methods: A national, multidisciplinary working group of physicians (nephrologists, rheumatologists, immunologists, pulmonologist, pathologist) with expertise on AAV addressed the broad spectrum of diagnosing, treating and organisation of care for AAV patients. Consensus was established using a Delphi-based method in a national conference in conjunction with a nationally distributed online consensus survey. This survey was distilled from the current published international guidelines. Cut-off for consensus was 70% (dis-)agreement.

Results: Ninety-eight professionals were involved in the Delphi procedure to assess consensus on 52 statements regarding diagnosis, treatment and organisation of care for AAV patients. From 52 statements, consensus was achieved for 39 statements (75%). Consensus was achieved on aspects of AAV disease definition, nomenclature, distinct disease states through follow-up, treatment algorithm and organisation of care for AAV. No consensus was achieved on the necessity of histopathological evidence, regular blood testing for ANCAs and standard BVAS, VDI and PROMs assessment.

Conclusion: This study describes the results of a national consensus statement on diagnosing and treatment of AAV patients as part of an implementation strategy in the Netherlands of (inter-)national guideline-derived recommendations. Future studies should evaluate whether the consensus statement has facilitated local implementation, reduced clinical practice variation and, ultimately, improved care for AAV patients in the Netherlands.

Increased Risk of Acute Coronary Artery Disease and Ischemic Stroke in Patients with Eosinophilic Granulomatosis with Polyangiitis

Morgane Mourguet,[1] Dominique Chauveau,[2] Stan Faguer,[2] JB Ruidavets,[2] Yannick Béjot,[3] Grégoire Prevot,[4] Olivier Lairez,[2] David Ribes,[2] Antoine Huart,[2] Laurent Alric,[2] Leo Astudillo,[1] Laurent Sailler,[1] and **Grégory Pugnet** [5], [1]CHU Purpan, Toulouse, France, [2]CHU Rangueil, Toulouse, France, [3]CHU Dijon, Dijon, France, [4]CHU Larrey, Toulouse, France, [5]CHU de Toulouse, Hôpital Purpan, Service de Médecine Interne, Toulouse, France

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Current treatment approaches have greatly improved the survival of eosinophilic granulomatosis with Polyangiitis (EGPA) patients, however both morbidity andmortality are still significant mainly due to cardiovascular complications.Premature and accelerated atherosclerosis has emerged as an important facet of ANCA associated vasculitis (AAV) cardiovascular risk but, eosinophil infiltration could also be responsible of endomyocardial damage and direct vascular injury in EGPA. Several studies showed a higher frequency of cardiovascular disease in patients with AAV or granulomatosis with polyangiitis but data on cardiovascular disease risk in EGPA patients are scarce. The aim of our study was to assess acute coronary artery disease and ischemic stroke, incidence and predictors, in eosinophilic granulomatosis with Polyangiitis(EGPA).

Methods: We conducted a retrospective cohort study of all EGPA, diagnosed between 1982 and 2018, who met Chapel Hill Consensus Conference classification criteriaafter thorough medical chart review. Major cardiovascular eventwas defined as acute coronary artery disease or ischemic stroke. We calculated the comparative morbidity/mortality figure (CMF)and we used Cox proportional hazards regression models to assess the risk of acute coronary artery disease, ischemic stroke associated with EGPA, after adjusting for covariates.

Results: We identified 67 subjects, only 55 met the inclusion criteria, 29 (55%) were men, with a mean follow-up of 8.1 ±7.7 years since EGPA diagnosis.

Acute coronary artery disease occurred in 9 patients, and ischemic stroke occurred in 2 patients (incidence rates of 21.1 per 1,000 person-years and 4.3 per 1,000 person-years, respectively). Using direct standardization, acute coronary artery diseaseincidence was seven times higher than in the general population (CMF 7.20; 95% CI 6.46 – 14.72) and, ischemic stroke incidence was tree times higher than in the general population (CMF 3.74; 95% CI 3.40 – 13.09). Age over 58 years and purpura were independently associated with coronary artery disease occurrence (adjusted HR 13.3; 95% CI 1.6 – 107.9, and adjusted HR 4.1; 95% CI 1.0 – 16.1, respectively). We did not identify factors significantly associated with ischemicstroke occurrence. In our cohort, none of the classic cardiovascular risk factors were associated with an increased risk of acute coronary artery disease or ischemic strokeoccurrence. Using direct standardization, the age-adjusted overall mortality rate was 8.9 per 1000 person-years and was not different than the general population.

Conclusion: EGPA have a significantly increased risk of acute coronary artery disease and ischemic stroke. Monitoring for these complications and attempts strict management of cardiovascular risk factors are warranted in this population as part of the long-term management of this condition.

Abstract Number: 2632

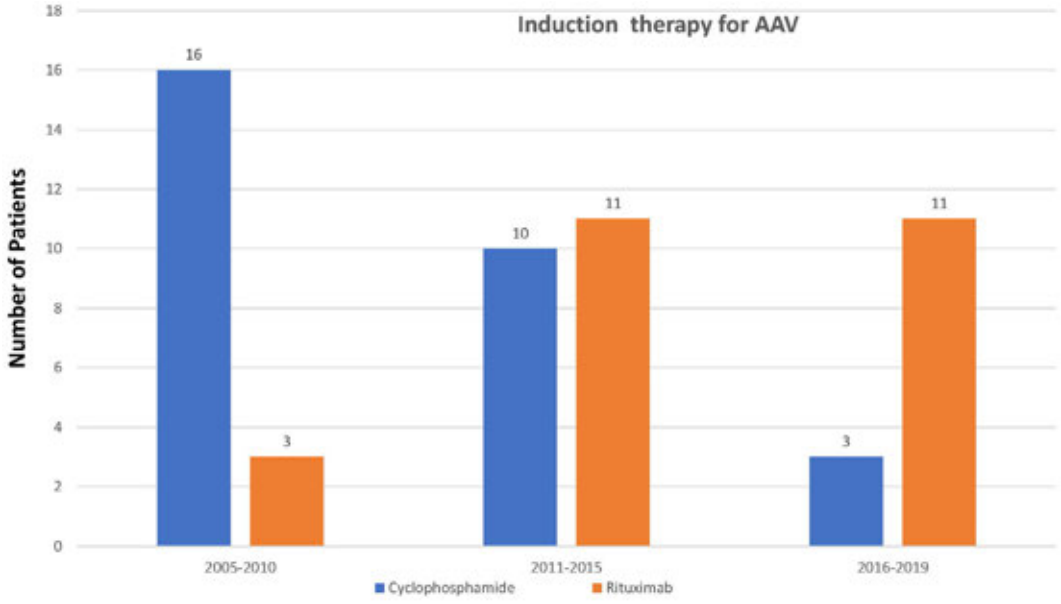
Changing Trends in the Management of ANCA-associated Vasculitis at an Academic Medical Center

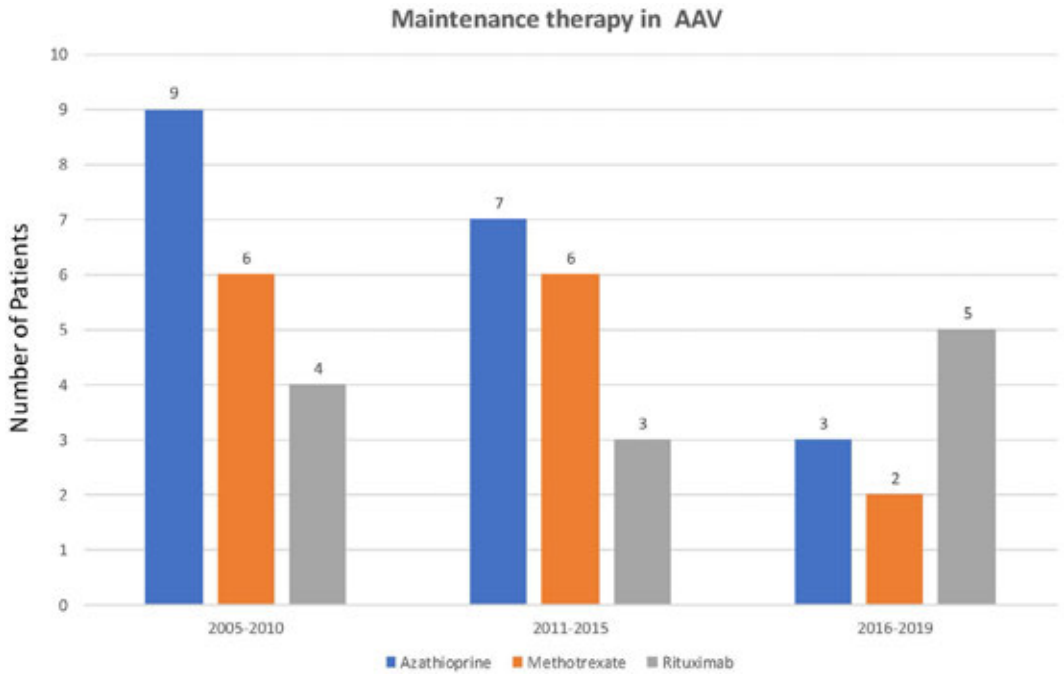
Sana Afroz,[1] and Najia Shakoor[2], [1]RUMC, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For years, cyclophosphamide (CYC) has been the primary treatment for severe anca-associated vasculitides (AAV) and has significantly improved disease related mortality. In addition, maintenance therapy, traditionally with methotrexate (MTX) or azathioprine (AZA), is imperative in preventing relapse. Since the approval of rituximab (RTX) for potential induction and maintenance therapy of AAV, it is unclear how substantially rheumatologists have responded and altered their treatment approach. we evaluated changes in treatment and disease outcomes of AAV at a large medical center.

Methods: IRB approval was obtained for medical record review of patients with diagnoses of AAV at an academic medical center. Consecutive patients seen between 2005 and 2019 were evaluated for diagnosis year, demographics,





disease characteristics, induction and maintenance therapies, and remission and relapse. Patients who had sufficient disease severity to receive either CYC or RTX induction were included. Three time periods were evaluated based on diagnosis year, 2005-2010, 2011-2015, and 2016-2019 and data analyzed using chi-squared for differences in medication use and disease outcomes between time periods and medication regimens.

Results: Fifty-four patients (mean age 58±18 years, 74% female, 28 PR3 positive, 20 MPO positive and 6 both PR3/MPO) who received either RTX or CYC for remission induction were included in the final analysis. The use of RTX for induction increased significantly (p=0.001) during each study time period, from 19%, 53%, and 73%, respectively (Figure 1). However, RTX use for maintenance therapy did increase, but not significantly, from 21% to 50% (p=0.081) (Figure 2). There was no significant difference in the rate of remission following induction therapy during each study time period (63%, 66%, and 75%, respectively, p=0.191). Similarly, the relapse rate was not different during these three time periods (52%, 50%, and 36%, respectively, p=0.167).

At 6 months, 64% (35/54) patients achieved remission at 6 months. There was no significant difference in the achievement of remission between CYC (18/29) and RTX (17/25) (p=0.467). During long term follow-up, 46% (24/54) of patients relapsed. The risk of relapse was significantly lower in the RTX induction group 28% (7/25) compared to CYC group 58%(17/29) (p=0.018). Interestingly, rates of relapse on maintenance therapy were significantly (p=0.042) lower with RTX (36%) and AZA (36%) versus MTX (71%).

Conclusion: Following the approval of RTX for treatment of AAV, its use has significantly increased for induction therapy, however, not for maintenance therapy. This may be due to the lack of clear guidelines and data for optimal maintenance regimens. There were no differences in disease remission at 6 months in CYC vs RTX groups, however, relapses appeared to be fewer in those induced with RTX. Interestingly, the risk of relapse was higher in MTX maintenance group compared to AZA or RTX. These results are promising, suggesting that real world outcomes are mir-

roring what was seen in larger clinical trials. However, it suggests the need for more studies and guidelines regarding optimal management strategies for maintenance therapy in AAV.

Efficacy of Remission Induction Regimens in Elderly Patients with ANCA-Associated Glomerulonephritis

Audrey Hopkins,[1] Stanley Chu,[2] Philip Seo,[3] Eric Gapud,[1] Brendan Antiochos,[1] Shaker Eid,[1] Jason Liebowitz,[1] and Duvuru Geetha[1], [1]Johns Hopkins Bayview Medical Center, Baltimore, [2]Johns Hopkins University, Baltimore, [3]Johns Hopkins Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Induction regimens using either cyclophosphamide (CYC) or rituximab (RTX) have been shown to have similar efficacy and similar rates of adverse events in randomized trials of patients with a mean age of 54 yrs. Little is known about outcomes among older patients with ANCA-associated glomerulonephritis (ANCA GN) receiving such therapies. This study aimed to compare these outcomes in elderly ANCA GN on the basis of induction therapy regimen (CYC vs RTX).

Methods: Patients, ages 60 and above, diagnosed with ANCA GN clinically and histologically from 2004 to 2018 were retrospectively identified. Baseline characteristics and outcomes across several clinical parameters were recorded and compared between groups using t-test, Mann-Whitney-U test and Fisher's exact test for significance as appropriate.

Results: Among a cohort of 64 patients with ANCA GN with a mean (SD) age of 75 ($\pm$7) years at diagnosis, patients treated with CYC (n = 27) compared to those treated with RTX (n = 37) had a higher peak serum creatinine at baseline (4.7 mg/dl vs. 2.5 mg/dl, p = 0.0005), higher hemodialysis dependence pre-renal biopsy (35% versus 2%, p = 0.01), and higher use of plasmapheresis (33% vs. 4%, p = 0.02). The mean GFR at 12 months was higher in rituximab patients (40 vs. 32, p=0.05). There were no statistically significant differences between the two groups in prednisone dose at 6 months (7 mg/day vs. 6 mg/day, p = 0.14) or at 12 months (4 mg/day vs. 3mg/day, p = 0.11), disease remission (100% vs. 97%, p = 1.0), combined outcome of end stage renal disease and/or death at 12 months (7% vs. 3%, p = 0.57), or disease relapse (22% vs. 13%, p = 0.61) (Table 1). Patients treated with CYC had a higher number of patients with bone marrow suppression (30% vs. 5%, p = 0.01) and developed an infection requiring hospitalization at 12 M of follow-up compared to RTX treated group (56% versus 16%, p = 0.001). Additionally, after adjustment for age, GFR and prednisone dose at 6 months, CYC use was associated with higher infection risk [aOR 6.22, 95% CI (1.70-22.80)] (Table 2).

Conclusion: CYC and RTX appear to be effective in remission induction in elderly patients with ANCA GN. Use of CYC was associated with a higher risk of bone marrow suppression and infections requiring hospitalization compared to RTX. More information is needed on the comparative safety of induction therapy strategies in elderly ANCA GN patients.

	Cyclophosphamide treated group (>3,000mg of CYC), *n=27*	Rituximab treated group (RTX and <3,000mg of CYC), *n=37*	p-value
Prednisone dose at 6 months, *mean (SD) (mg)*	7.4 (5.4)	5.8 (5.2)	0.143
Prednisone dose at 12 months, *mean (SD)* (mg)	3.9 (2.5)	3.0 (2.3)	0.113
Remission achieved, *n* (%)	27 (100)	36 (97.3)	1
ESRD or death at 1 year, *n* (%)	2 (7.4)	1 (2.7)	0.568
GFR at 12 months, *mean (SD)*	32 (17)	40 (16)	0.055
Relpase, *n* (%)	6 (22.2)	5 (13.5)	0.609
Infection requiring antibiotic use, *n* (%)	15 (55.6)	6 (16.22)	0.001
Bone marrow suppression, *n* (%)	8 (29.6)	2 (5.41)	0.013

ANCA Response upon Rituximab or Cyclophosphamide in ANCA-associated Vasculitis Patients

Laura van **Dam**,[1] Ebru Dirikgil,[2] Edwin Bredewold,[2] Argho Ray,[2] Ton Rabelink,[2] Cees van Kooten,[2] and Onno Teng[2], [1]LUMC, Leiden, Zuid-Holland, Netherlands, [2]LUMC, Leiden, Netherlands

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have demonstrated that in patients with anti-neutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) with successful remission-induction (RI) after cyclophosphamide (CYC), maintenance treatment with ANCA-guided rituximab (RTX) improved relapse free survival (RFS). However, current recommended RI treatment is RTX, CYC or a combination of both. As yet it is unclear how these different RI therapies affect ANCA levels. Therefore, this study aimed to investigate the potential of RTX, CYC, or RTX+CYC to achieve an ANCA-negative status and its effect on RFS to further improve the insight on ANCA-guided treatment in AAV patients.

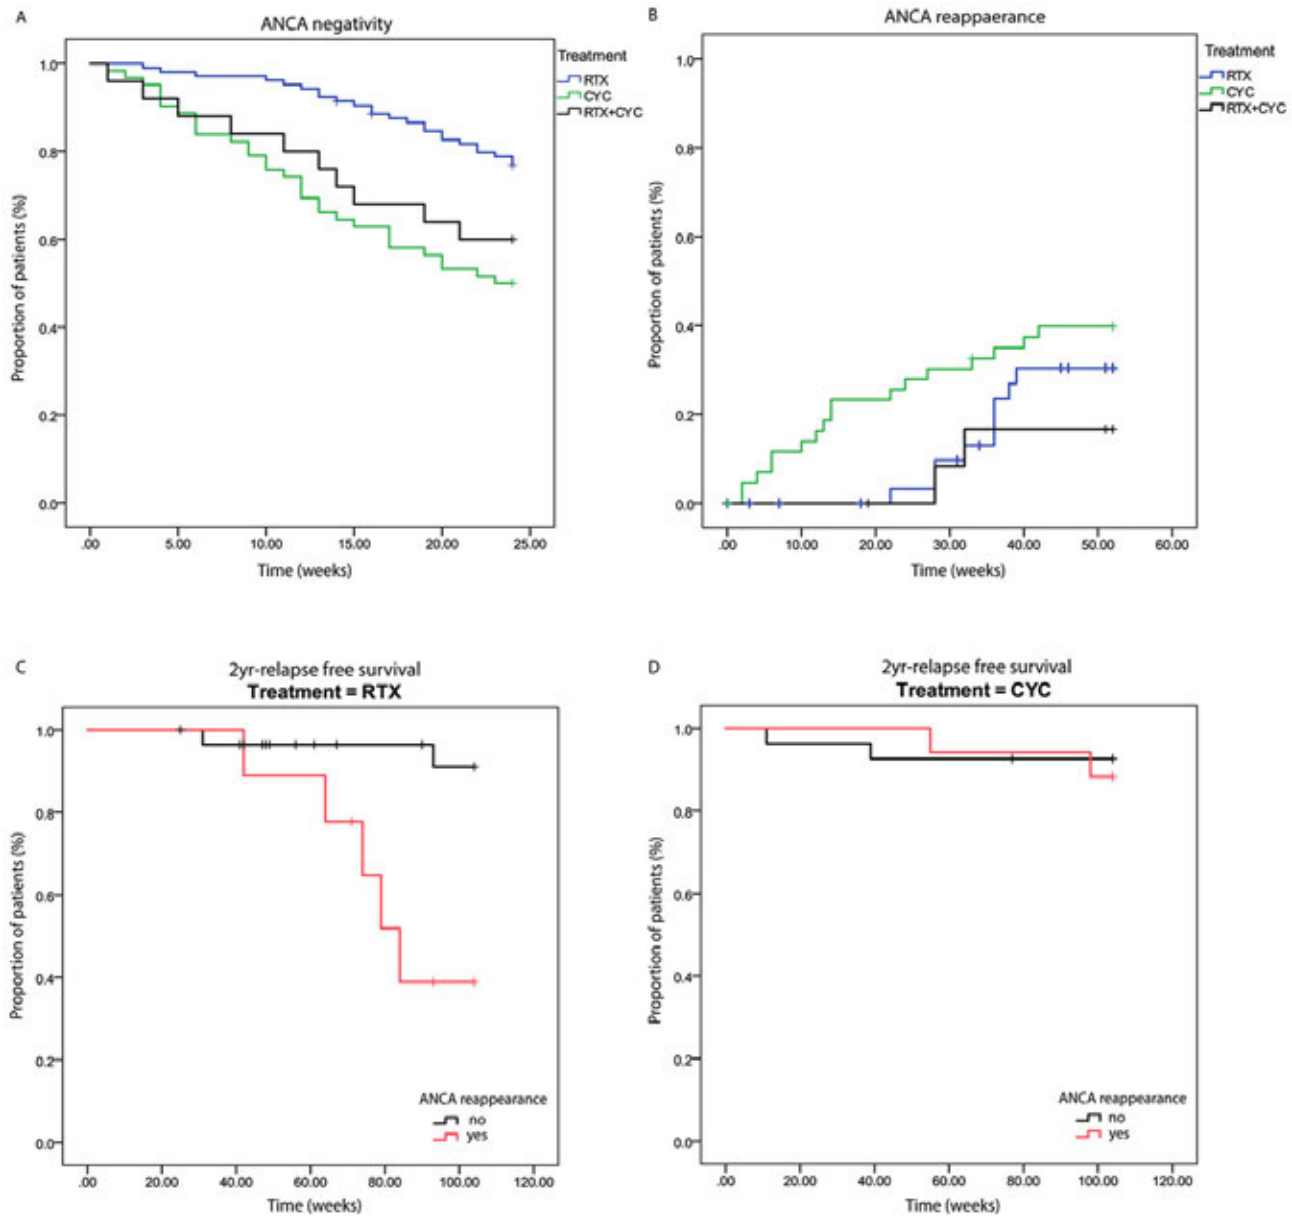

Figure 1. ANCA responses are assessed in ANCA-associated vasculitis patients after different remission-induction regimens. A) The achievement of ANCA negativity within 6 months after remission induction (RI)-therapy with Rituximab (blue line), Cyclophosphamide (green line) or a combination of Rituximab plus Cyclophosphamide (black line). B) ANCA reappearance within one year after achievement of ANCA negativity was investigated for the different RI regimens. C) 2-year major relapse free survival in C) RTX-treated patients and D) CYC-treated patients with (red line) or without ANCA reappearance (black line).

Methods: This retrospective single centre study involved 129 ANCA-positive AAV patients treated with 200 remission-induction regimens, including RTX (n=109), CYC (n=66), or RTX+CYC (n=25) between 1990 – 2018 with a mean follow-up (FU) of 328 weeks. ANCA serum levels and major RFS were assessed.

Results: Within 6 months, 23% of RTX-treated, 50% of CYC-treated and 40% of RTX+CYC-treated AAV patients achieved an ANCA-negative status (p=0.0001) (Figure 1A). Time to ANCA negativity was significantly shorter after CYC+/- RTX (mean±SD: 11±6 weeks) as compared to RTX (16±6 weeks; p=0.02). ANCA reappearance within 1 year after achieving ANCA negativity, occurred in 9 out of 38 (24%) RTX-treated, 17 out of 44 (39%) CYC-treated and 2

out of 14 (14%) RTX+CYC-treated patients (p=0.17), which happened significantly faster in CYC-treated patients at an average of 18 weeks as compared to RTX+/- CYC at an average of 30 weeks (p=0.003) (Figure 1B). Both 1yr and 2yr major RFS was significantly less for RTX-treated (86% and 68%) as compared to CYC-treated (97% and 91%) and RTX+CYC-treated patients (100%, 91%) (p=0.02, p=0.005). Overall, patients that reached an ANCA-negative status had a better 2yr-RFS. ANCA reappearance associated with major relapses in RTX-treated group (56% vs 7%; p=0.002) (Figure 1C) but not in CYC-treated group (12% vs 7%; p=0.68) (Figure 1D).

Conclusion: This study demonstrates that an ANCA-negative status was achieved more frequently and quicker with CYC +/- RTX as compared to RTX and associated with a better 2yr-RFS. ANCA reappearance was associated with relapses in RTX-treated patients but not in CYC-treated patients. Thus, monitoring ANCAs to guide tailored maintenance treatment is most relevant in RTX-treated AAV patients.

Abstract Number: 2635

Accuracy of Self-Reported Diagnosis of Antineutrophil Cytoplasmic Antibody-Associated Vasculitis

Tanaz Kermani,[1] Jason Springer,[2] Antoine Sreih,[3] Dianne Shaw,[4] Kalen Young,[5] Cristina Burroughs,[6] and Peter Merkel[3], [1]University of California Los Angeles, Los Angeles, CA, [2]Kansas University Medical Center, Kansas, MO, [3]University of Pennsylvania, Philadelphia, PA, [4]Vasculitis Foundation, North Carolina, [5]Vasculitis Foundation, Kansas City, MO, [6]University of South Florida, Tampa, FL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine the reliability of self-reported diagnosis of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis: granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), and eosinophilic granulomatosis with polyangiitis (EGPA) from a large, international, internet-based cohort.

Methods: The web-based registry includes data provided by patients (or caregivers) with different forms of primary vasculitis collected through standardized forms including type of vasculitis, disease manifestations, and information regarding how diagnosis was made. This analysis included 150 randomly-selected patients with GPA (out of 484) with complete data and all patients with MPA and EGPA. Primary outcome was percentage of patients who met the 1990 American College of Rheumatology (ACR) classification criteria and/or 2012 Chapel Hill Consensus Conference (CHCC) definitions for vasculitis. ACR criteria for GPA were modified to include ANCA positivity.

Results: The study cohort included 150 patients (70% female) with GPA, 164 patients (81% female) with MPA and 116 patients (66% female) with EGPA.

GPA: Clinical manifestations included sinus/nasal (84%), pulmonary (63%, alveolar hemorrhage in 34%) and renal involvement (57%). ANCA was reported as positive in 123 of 134 patients (92%) who knew their ANCA status. 70% patients reported having at least one biopsy and 61% patients reported diagnosis by a biopsy. Overall, 96% patients

met either the modified ACR criteria or the CHCC definition. 93% patients met both the modified ACR criteria and CHCC definition.

MPA: Clinical manifestations included pulmonary (62%, alveolar hemorrhage in 36%), renal involvement (84%), and neurologic (65%). ANCA was reported as positive in 147 of 153 patients (96%) who knew their ANCA status. Biopsies were performed in 131 patients (80%) with 77% patients reporting diagnosis by biopsy. 95% patients met the CHCC definition.

EGPA: Clinical manifestations included asthma (95%), nasal/sinus (94%), peripheral nerve involvement (88%), non-asthma pulmonary disease (74%). ANCA was reported as positive in 33 of 79 patients (42%) who knew their ANCA status. Peripheral eosinophilia was reported in 108 of 112 patients (96%). 100 patients (86%) met ≥ 4 ACR criteria and 75 (65%) met the CHCC definition. All patients who met CHCC definitions also met ACR criteria.

Conclusion: Patient self-report of a diagnosis of ANCA-associated vasculitis is reliable with 86-96% of patients fulfilling the ACR criteria or CHCC definitions for their disease. Additional confirmation of the findings using medical records is currently underway. These results strongly support the validity of utilizing online, patient-generated data for clinical and epidemiological research in ANCA-associated vasculitis.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The predominance of myeloperoxidase-antineutrophil cytoplasmic antibody (ANCA) and interstitial lung disease (ILD) have beenreported as characteristics of Japanese patients with ANCA-associated vasculitis (AAV) recently. A previous report using cluster analysis showed that the importance of ANCA type and renal involvement in Western countries. Because of the considerable differences in demographic and clinical characteristics, other relevant clusters may be identified in Japanese patients.

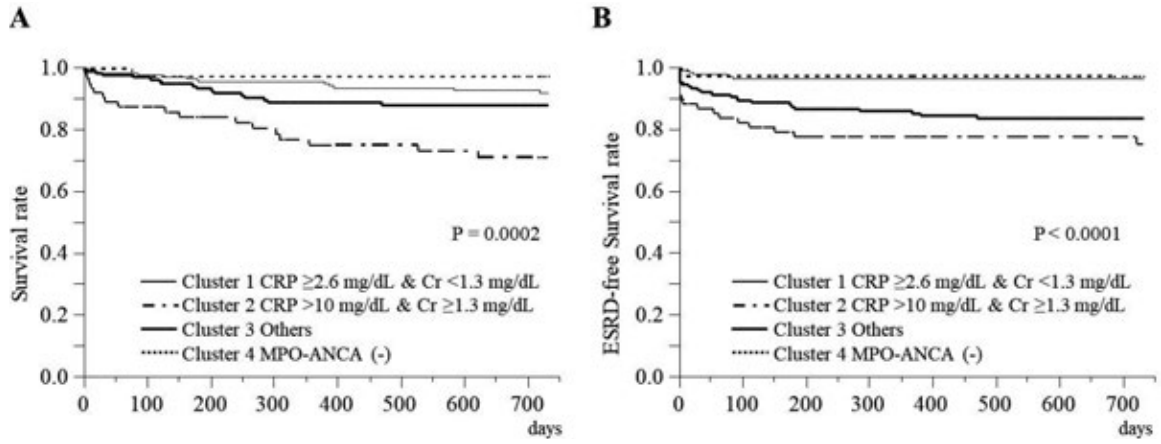

Figure. Overall survival and ESRD-free survival rates according to clusters of Model 2 (A) Overall survival rates and (B) ESRD-free survival rates. Analysis performed using a log-rank test. ESRD, end-stage renal disease; Cr, creatinine; CRP, C-reactive protein; MPO-ANCA, myeloperoxidase-antineutrophil cytoplasmic antibody.

Methods: Using the dataset of two nationwide cohort studies for AAV, we performed multiple correspondence and cluster analysis. Model 1 included ANCA type, items of Birmingham Vasculitis Activity Score (BVAS), and ILD, and Model 2 included serum creatinine and C-reactive protein (CRP) levels additionally. Clustering was performed for finding homogeneous clusters, and clinical characteristics and clinical outcomes were compared among determined clusters. Multivariable regression analysis was conducted to explore factors related to CRP levels among BVAS items and ILD.

Results: After excluding patients with eosinophilic granulomatosis with polyangiitis or missing of proteinase 3 (PR3)-ANCA test, 427 patients were enrolled. Seven and four clusters were determined in Model 1 and Model 2, respectively. In seven clusters of Model 1, ANCA negative (n=8) and PR3-ANCA positive (n=41) group emerged as distinct two clusters. Other myeloperoxidase-ANCA positive five clusters were characterized by ear, nose and throat (n=47), cutaneous (n=36), renal symptoms (n=256), the absence of renal symptoms (n=33), and others (n=6). Four clusters of Model 2 were characterized either by MPO-ANCA negativity (n=42, cluster 4), high CRP (>10mg/dL) and increase of creatinine (creatinine ≥1.3 mg/dL) levels (n=71, cluster 2), increase of CRP (≥2.6 mg/dL) without increase of creatinine (< 1.3 mg/dL) levels (n=157, cluster 1), and others (n=157, cluster 3). Overall survival, renal survival, and relapse rates were significantly different across the four clusters of Model 2 (log-rank test; P=0.0002, P< 0.0001 and P=0.0051, respectively, **Figure**). Multivariable regression analysis revealed that fever (β coefficient [95% confidence interval], 2.1 [1.5–2.6]), myalgia (2.5 [2.0–3.1]), massive hemoptysis/alveolar hemorrhage (1.3 [0.43–2.2]) and mononeuritis multiplex (1.2 [0.47–2.0]) were independently associated with CRP level.

Conclusion: Cluster analysis indicated the association of the distinct clinical and laboratory characteristics with outcomes in Japanese patients with AAV. Prognostic values of improvements in CRP and serum creatinine levels by treatments should be evaluated in future research.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The alternative complement pathway has been implicated in the pathogenesis of ANCA-associated vasculitis (AAV). Change in markers of complement activation within patients have not been reported. This study measured levels of urinary complement fragment Ba (uBa) longitudinally in patients with AAV.

Methods: Urine levels of uBa were measured by ELISA (corrected to urine creatinine) in 3-4 serial samples in 60 patients with AAV: 20 who developed a flare with renal disease (ReF), 20 who developed a non-ReF (NReF), and 20 in long term remission (LTR). Because timing of pre-flare to flare visits differed from patient to patient, these values were averaged for each patient (pre-ReF or pre-NReF), normalized by natural log-transformation, and compared to flare by paired t test. Differences between ReF and NReF levels were assessed by unpaired t test. Differences between pre-ReF, pre-NReF, and average LTR levels were assessed by ANOVA.

Results: The median age of participants was 59 years, 53% were male, 93% were White, and 93% were ANCA positive. There were no differences in uBa levels between pre-ReF, pre-NReF, and LTR (P=0.360) (Figure). Despite overlap,

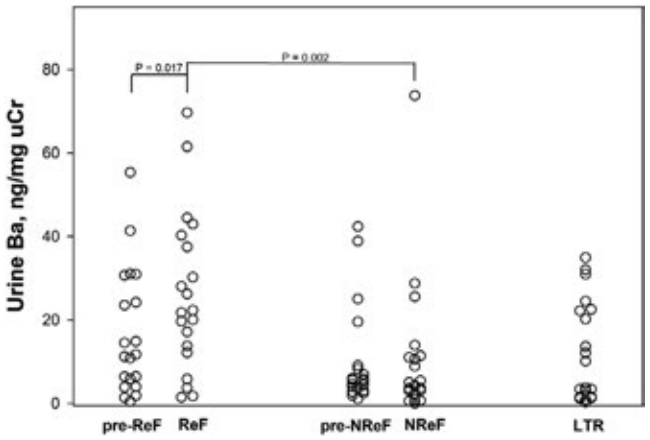

Figure 1. Urine Ba levels in patients with ANCA-Associated vasculitis. Pre-ReF: mean level before renal flare. ReF: level at renal flare. Pre-NReF: mean level before non-renal flare. NReF: level at non-renal flare. LTR: mean level with long-term remission.

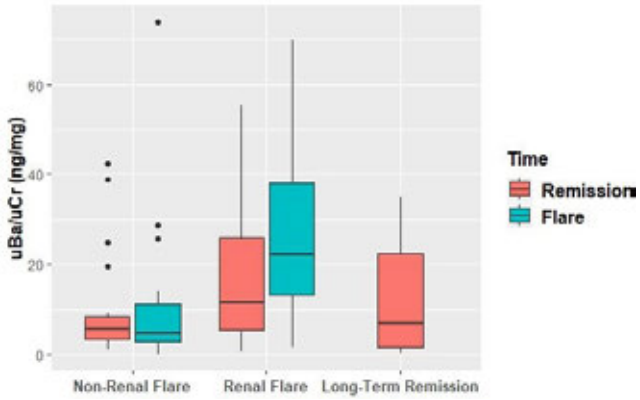

Figure 2. Figure 1: Urine Ba levels in patients with ANCA-Associated vasculitis. Pre-ReF: mean level before renal flare. ReF: level at renal flare. p-value Renal Flare (remission vs. flare 0.017). p-value Flare (Renal flare vs Non-renal flare=0.002)

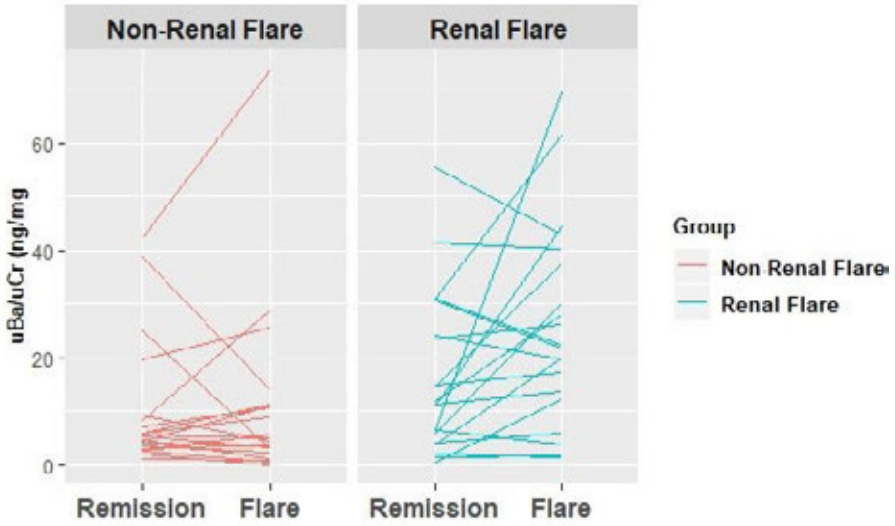

Figure 3: Change in urine Ba levels in individual patients before and at flare.

overall uBa levels were higher in ReF compared to pre-ReF (P=0.017), and to NReF (P = 0.002). Levels of uBa levels did not change from pre-NReF to NReF (P=0.232).

Conclusion: Increased uBa levels suggests that alternative complement pathway activation contributes to the pathogenesis of ReF in AAV. However, many patients experiencing ReF do not show high uBa levels. Thus, uBa may identify a subset of patients with ReF who might benefit from complement-targeted therapies. Other factors defining this subset remain to be determined.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by asthma and other manifestations of vasculitis, some of which can be life-threatening, cause major organ damage, or become chronic. Data on damage in EGPA is limited, mainly due to the rarity of the disease. This study aimed at describing damage in patients with EGPA enrolled in the Vasculitis Clinical Research Consortium(VCRC).

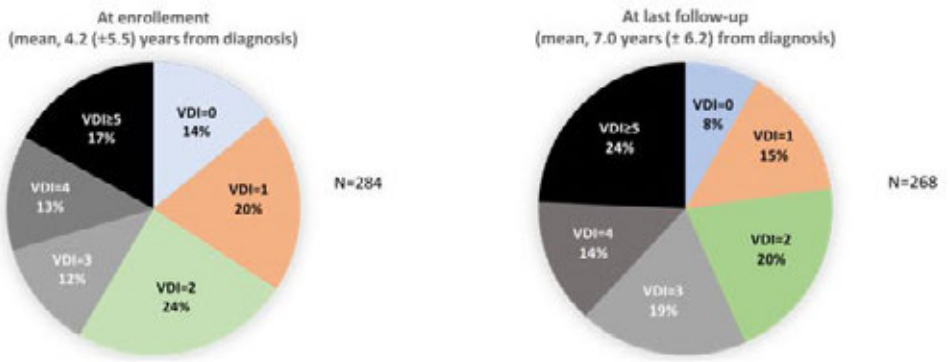

Figure 1. Distribution of vasculitis damage index (VDI) scores for patients with eosinophilic granulomatosis with polyangiitis in the Vasculitis Clinical Research Consortium at enrollment, and last follow-up (for the patients with a follow-up post-diagnosis >1 year).

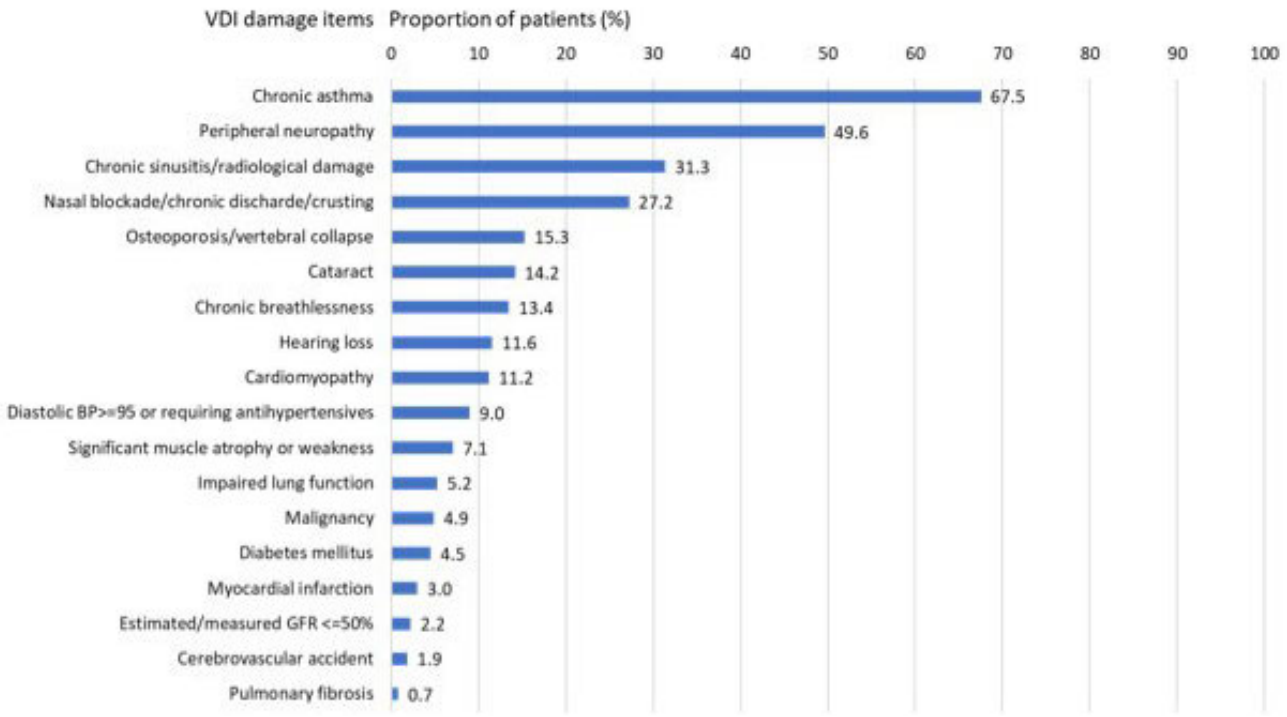

Figure 2. Main items of damage at last follow-up for patients with eosinophilic granulomatosis with polyangiitis in the Vasculitis Clinical Research Consortium. 268 patients with >1 year of follow-up post-diagnosis (mean, 7.0 ± 6.2 years).

Methods: Retrospective analysis of damage in patients with EGPA participating in the VCRC Longitudinal Study (LS) or One-Time DNA (OT) studies from 2003-2019. Patients were ≥18 years of age at enrollment and fulfilled the modified American College of Rheumatology 1990 criteria. Data elements included demographics, ANCA status, use of cyclophosphamide (CYC), cumulative duration of glucocorticoid (GC) use, relapses, all items of the Vascular Damage Index (VDI). VDI is a validated, cumulative damage score, which includes 64 items, grouped by organ or system and each scoring 1 point (range, 0-64; by design, VDI is 0 at diagnosis). VDI scores and items were analyzed at enrollment (for all patients with a diagnosis made >3 months prior to enrollment, and at the farthest visit from diagnosis for patients with a follow-up >1-year post-diagnosis. For the last VDI score, associations of age, sex, CYC use, duration of GC use, and relapses with accrual of damage were explored.

Results: The cohort included 354 patients, of which 336 had a follow-up post-diagnosis >3 months. Mean age at diagnosis for the latter was 50.0 (SD ±14.1) years; 197 (58.6%) were female. Of those tested for ANCA, 132 (42.7%) were positive. A total of 112 (41.9%) LS patients received CYC at some point during their disease; mean duration of GC use was 13.7 (±20.7) months. With a mean follow-up from diagnosis for all 336 patients of 7.2 (±6.1) years, 173 (51.4%) had at least one relapse. VDI at enrollment (for the 284 patients enrolled >3 months' post-diagnosis; mean 4.2 (±5.5) years from diagnosis), and last follow-up visit for patients with >1 year of follow-up post-diagnosis (n=268) were 2.61 (±2.17) and 3.19 (± 2.24), respectively. VDI score distributions and items for the latter are showed in Figures 1 and 2. Univariate analysis of data from the 128 LS patients with a follow-up post-diagnosis >1 year identified male sex, older age, longer duration of GC use, and having relapsed as significantly associated with higher VDI at last visit. Multivariate Poisson regression analysis retained only male sex (mean VDI of 3.80 ±0.31 in male vs. 3.0 ±0.23 in female patients; $P< 0.01$) and longer duration of GC use (increase of the VDI by 0.5% for each additional month of GC use; $P< 0.01$) as being associated with a higher last VDI.

Conclusion: Patients with EGPA accumulate substantial permanent damage from the disease and treatment, even several years after diagnosis. Strategies to attain sustained, long-term limitation of damage should be important as-

pects of the management of patients with EGPA. Identification of more effective and safer treatments for EGPA are needed, especially to limit the use of GC.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – ANCA-Associated Poster I

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Aligning perspectives of patients and physicians in the diagnosis and management of diseases is imperative, particularly in rare, chronic diseases such as vasculitis. We sought to compare patient-reported vs. physician-reported clinical manifestations, treatments, and outcomes in patients with eosinophilic granulomatosis with polyangiitis (EGPA).

Methods: Retrospective, comparative analysis of patients ≥18 years old with EGPA from Canada or the United States, from two separate databases: 1) Vasculitis Patient-Powered Research Network (VPPRN), a self-enrolled, secure patient portal with patient-entered data updated quarterly from 2013-2019, and 2) Vasculitis Clinical Research Consortium (VCRC) Longitudinal (LS) or the One-Time DNA (OT) studies, a combined physician-entered database (2003-2019). A few patients are in both databases, which are not presently linked due to protected health information policies. For validation of the diagnosis, patients in the VPPRN were excluded if they indicated that the diagnosis was not made by doctor and/or if they never used systemic glucocorticoids. Patients in the VCRC fulfilled the modified American College of Rheumatology 1990 criteria. Studied parameters included demographics, clinical manifestations, ANCA status, treatments received since diagnosis, and relapses.

Characteristic	VPPRN n=195	VCRC n=354	P-value
Female, n (%)	135 (69.2)	209 (59.0)	0.02
Age at diagnosis, years ±SD	47.3 ±14.3	50.0 ±14.2	0.04
Positive test for ANCA, n (%)	64/131 (48.8)	123/316 (38.9)	0.07
Manifestations (ever), n (%)			
Asthma	177/184 (96.2)*	329 (92.9)	0.13
Alveolar hemorrhage	24/168 (14.3)	21 (5.9)	<0.01
Lung disease	128/174 (73.6)	295 (83.3)	0.01
Sinus-nasal	165/181 (91.2)	292 (82.5)	0.01
Fever	82/148 (55.4)	62 (17.5)	<0.01
Weight loss	95/171 (55.6)	106 (29.9)	<0.01
Arthralgia	116/173 (67.0)	140 (39.6)	<0.01

Rituximab	47 (24.1)	29 (10.5)†	<0.01

VPPRN: Vasculitis Patient-Powered Research Network.
VCRC: Vasculitis Clinical Research Consortium.
ANCA: antineutrophil cytoplasmic antibody; SD: standard deviation.
* *For the VPPRN patients, denominator is number of patients who responded Yes/No (response of "I don't know" excluded)*
† *Data available only for the 277 patients in the VCRC*

Table 1. Main characteristics of patients with eosinophilic granulomatosis with polyangiitis from the Vasculitis Patient-Powered Research Network and the Vasculitis Clinical Research Consortium

Results: 208 patients self-registered with a diagnosis of EGPA in the VPPRN (195 had a validated diagnosis) and 354 patients were enrolled in the VCRC. 135 (69.2%) of the 195 VPPRN patients were female; 176 (92.1%) were white, 4 (2%) Asian, and 1 (0.5%) Black or African American. Mean age at first disease symptoms and diagnosis were 41.9 (SD ±14.9) years and 47.3 (±14.3) years, respectively. Method of diagnosis reported by patients was based on symptoms (91.3%), laboratory testing (80.5%), biopsy results (50.3%), and imaging (50.3%). At enrollment, 80 (41%) reported that the EGPA was active. **Table 1** shows the main characteristics and outcomes of the VPPRN patients compared to those from the VCRC. Patients in the VPPRN were predominantly female, slightly younger at diagnosis than in the VCRC cohort, and reported more frequent disease manifestations in almost all organ systems, but less lung disease, and similar frequencies of asthma, cardiac and gastrointestinal manifestations. With a mean follow-up of 2.2 (±1.1) years post-enrollment, 63 (32.3%) of the VPPRN patients reported at least 1 relapse post-enrollment, which was comparable to the VCRC patients.

Conclusion: This analysis comparing patient vs. physician data in EGPA showed some differences with patients generally reporting more manifestations of disease. These differences suggest that patient self-reported data can provide additional useful information. How to best combine patient-reported and physician-reported data for research studies in vasculitis warrants additional study.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Renal involvement in ANCA-associated vasculitides (AAVs) is an important factor for morbidity and mortality. Berden's histopathologic classification for ANCA-associated glomerulonephritis has been proven to be helpful for predicting the renal outcome. Recently, the ANCA renal risk score, a new scoring system which needs to be validated, has been proposed to predict end-stage renal disease (ESRD) in AAV patients. In this study, we aimed a) to assess prognostic factors for renal survival in our AAV patients with renal involvement, b) to evaluate the performances of the Berden's histopathological classification and ANCA-renal risk score, for predicting ESRD.

Methods: Patients with AAV who were categorized according to the 2012 Chapel Hill consensus nomenclature were included in this study. Patients with only renal involvement clinically and diagnosed by renal biopsy were classified as renal-limited vasculitis (RLV). Renal biopsies were reviewed according to the Berden's histopathological classification, and the percentages of normal glomeruli, tubular atrophy and interstitial fibrosis were determined in order to calculate ANCA renal risk score. The clinical data and laboratory parameters were collected retrospectively. Renal survival was defined as the time between diagnosis and the development of ESRD. Factors predictive of renal survival were evaluated by Kaplan-Meier method and the Cox proportional hazard model.

*ANCA: Anti-Neutrophil Cytoplasmic Antibody; AAV: ANCA-Associated Vasculitis; GPA: Granulomatosis with PolyAngiitis; MPA: Microscopic PolyAngiitis; EGPA: Eosinophilic Granulomatosis with PolyAngiitis; RLV: Renal Limited Vasculitis; GFR: Glomerular Filtration Rate, HR: Hazard Ratio; CI: Confidence Interval

Table 2. Multivariate analysis models which predict renal survival in ANCA-associated vasculitis

low-risk group, %42 patients in the medium-risk group and %67 patients in the high-risk group (p=0.005). In univariate analysis the age at diagnosis (HR 1.02, 95 % CI 1.00-1.04, p=0.045), AAV subgroups (p=0.01) (Figure), histopathological classification (p=0.009), ANCA renal risk score (p=0.01), maximum creatinine level at diagnosis (HR 1.14, 95 % CI 1.09-1.19, p< 0.001), glomerular filtration rate (GFR) (HR 0.92, 95 % CI 0.89-0.95, p< 0.001), hemodialysis (HR 4.81, 95 % CI 2.53-9.17, p< 0.001) and plasmapheresis at diagnosis (HR 2.36, 95 % CI 1.32-4.22, p=0.004) were the factors associated with renal survival. In multivariate analysis, histopathological classification predicted mortality in model 1, but when GFR at diagnosis is included in the model (model 2), the model lost its significance. However, the ANCA renal risk score was found to be an independent prognostic risk factor for renal survival (model 3, table 2).

Conclusion: According to our results, the ANCA renal risk score may be more advantageous in predicting ESRD development compared to Berden's histopathological classification, and this may be due to the inclusion of glomerular filtration in scoring.

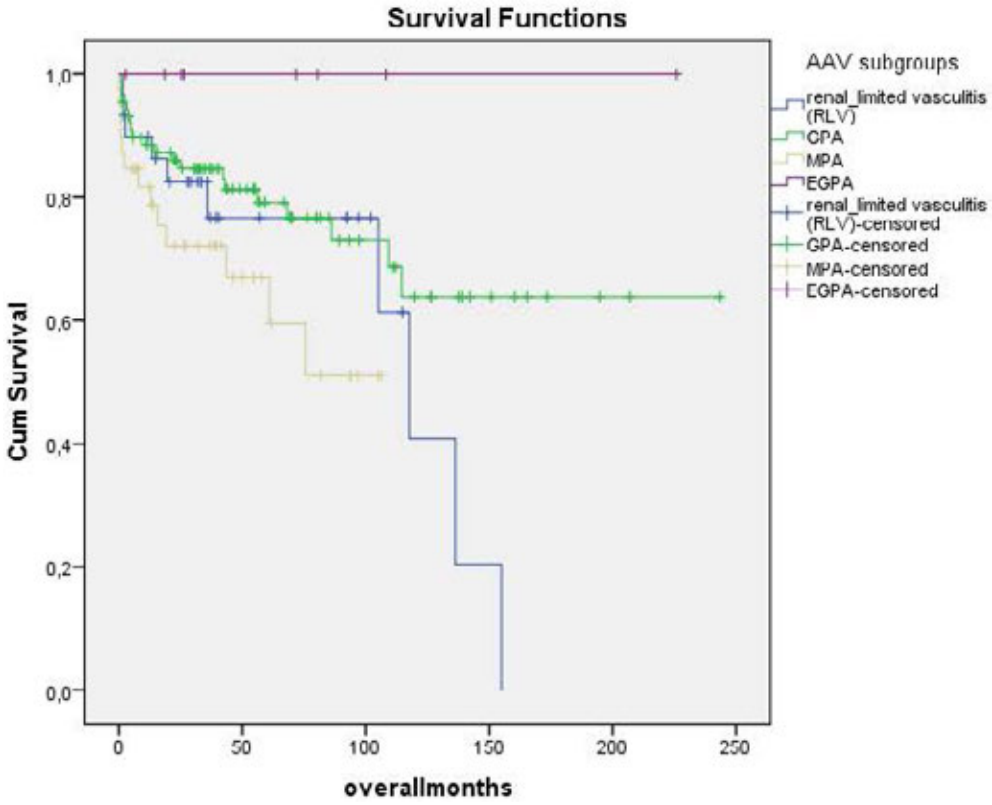

Figure. The results of the Kaplan-Meier analysis. Renal survival was significantly associated with AAV subgroups patients with ANCA-associated vasculitis with renal involvement

* Denominator is number of patients who responded Yes/No (response of "I don't know" excluded)		

Background/Purpose: To provide a feasible and sustainable platform for conducting patient-centered research in vasculitis, a prospective, international, internet-based registry of patients with vasculitis has been established. The aim of this study is to describe the self-reported clinical features of granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) from this registry.

Methods: Patients (or caregivers) with different forms of vasculitis can join the web-based registry. All information is self-reported through standardized forms, including type of vasculitis, symptoms at disease onset and later in the disease course, and information regarding how diagnosis was made. For each manifestation, patients can respond with "Yes", "No", or "I don't know". Only patients with GPA or MPA were included in this analysis. Other analyses demonstrated that in this cohort the accuracy of the self-reported diagnosis of GPA or MPA is > 90%.

Results: The study cohort included 762 patients (68% female) with GPA and 164 patients (81% female) with MPA.

GPA Cohort: 98% of patients reported a physician-confirmed diagnosis. Commonly reported means of diagnosis were combinations of laboratory testing (74%), symptoms (70%), biopsy (62%), and imaging (38%). 562 patients (74%) reported having at least one biopsy, including skin (70 patients), kidney (283 patients), lung (192 patients), nasal/sinus (146 patients), nerve (10 patients), other (36 patients). ANCA was reported in 652/692 (94%) patients who knew their ANCA status. Clinical manifestations at entry into the cohort are summarized in Table 1.

MPA Cohort: 99% of patients reported a physician-confirmed diagnosis. Commonly reported means of diagnosis were combinations of laboratory testing (79%), symptoms (67%), biopsy (77%), and imaging (42%). 131 patients (80%) reported having at least one biopsy, including kidney (103 patients), lung (20 patients), skin (15 patients), nerve (6 patients), and nasal (4 patients). ANCA was reported as positive in 147/153 (96%) patients who knew their ANCA status. Clinical manifestations at entry into the cohort are summarized in Table 1.

Conclusion: In this large cohort patients with a self-reported diagnosis of GPA or MPA, disease manifestations were consistent with each type of ANCA-associated vasculitis. As expected, sinus manifestations were more frequently reported in GPA cohort while renal manifestations were more frequent in the MPA cohort. Given the rarity of these and other vasculitides, conducting some types of research through online registries may provide an efficient alternative to in-person, center-of-excellence clinical trials.

ANCA Testing: Final Diagnoses in Cases with Positive Immunofluorescence and Negative ELISA

Gabriel Breuer,[1] Bashar Fteiha,[1] Alon Benaya,[1] Marwan Abu Sneineh,[1] and Gideon Nesher[1], [1]Shaare Zedek Medical Center, Jerusalem, Yerushalayim, Israel

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: With the widespread availability of anti-neutrophil cytoplasmic antibody (ANCA) testing, interpreting positive results has become increasingly challenging. In addition to ANCA Associated Vasculitis (AAV), the spectrum of diseases associated with ANCAs has broadened to include a wide range of other inflammatory and infectious diseases including Inflammatory bowel disease, systemic lupus erythematosus, rheumatoid arthritis and drug-induced vasculitis, calling into question the diagnostic implications of ANCA positivity in a hospital setting. Immunofluorescence (IF) on ethanol-fixed neutrophils is used to detect ANCA, which can be divided into three patterns; cytoplasmic ANCA (c-ANCA), perinuclear ANCA (p-ANCA) and atypical ANCA (a-ANCA). Enzyme-linked immunosorbent assay (ELISA) is used in diagnostic laboratories to detect ANCA to specific antigens. The most common antigens used in ELISA testing are myeloperoxidase (MPO) and proteinase-3 (PR3).

Discrepancies may exist between IF and ELISA ANCA testing. We studied cases with positive ANCA IF testing but negative ELISA for both MPO and PR3, looking for their final diagnoses.

Methods: ANCA tests performed between 2000-2018 were identified using the medical center laboratory data system. Of those, all cases with negative MPO and PR3 testing were collected. Medical records of those cases were retrieved to look for their clinical features and final diagnoses.

Table 1: Final diagnoses of patients with positive Immunofluorescence Anti-neutrophil cytoplasmic antibodies (ANCA) and negative Enzyme-linked immunosorbent assay (ELISA) tests:

	Diagnosis	Atypical ANCA 62 Cases	P ANCA 22 Cases	C ANCA 9 Cases

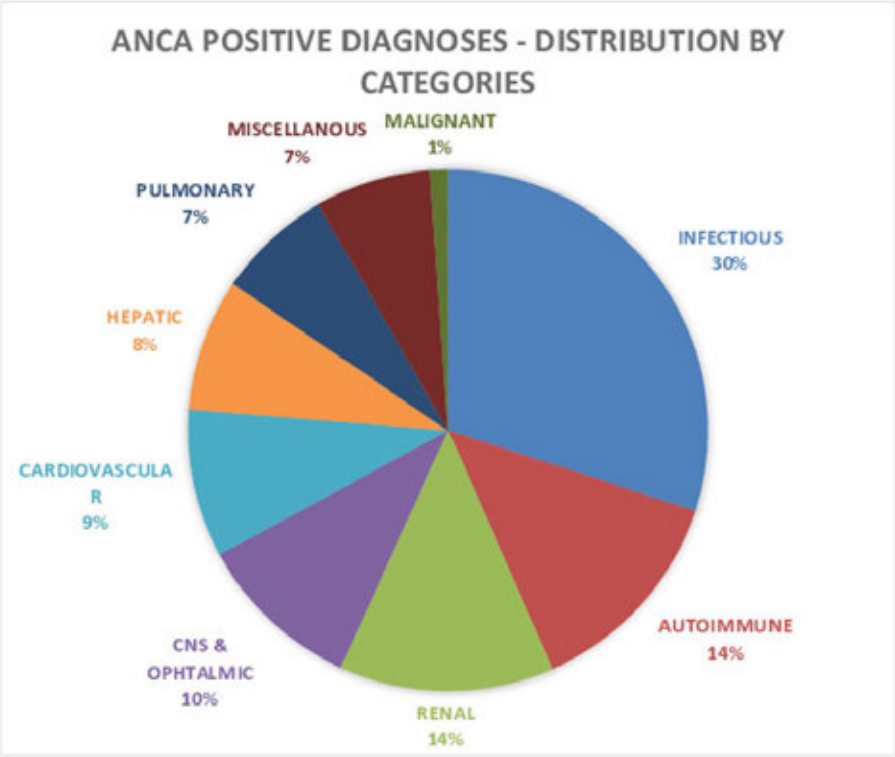
Abbreviations:

ALPS - Autoimmune Lymphoproliferative Syndrome, ANA- Antinuclear antibodies , CDT - Clostridium Difficile Toxin, COP – Cryptogenic Organizing Pneumania, CVA – Cerebrovascular Accident,, FUO – Fever of Unknown origin, GBM – Glomerular Basement Membrane, GPA – Granulomatosis polyangitis, HTN – Hypertension, ITP - Immune throbocytopenia, NPH – Normal Pressure Hydrocephalous, PE- Pulmonary emboli, RPGN - Rapidly progressive Glomerulonephritis, SLE- Systemic lupus Erythematosus, UTI – Urinary tract infection.

Results: 9189 ANCA tests were ordered between the years 2000-2018 of which 549 (5.9% were positive by at least one method. 114 (1.2%) cases showed discrepancy, 93 (0.01%) were ANCA IF-positive ELISA-negative. 62 were a-ANCA positive, 22 were p-ANCA positive and 9 were c-ANCA positive. Only 2 case were diagnosed with AAV, both had p-ANCA. All other patients had a broad spectrum of diagnoses, including autoimmune, infectious, and other conditions involving the renal, hepatic, cardiovascular, and central nervous systems (Table 1, Figure 1).



Conclusion: Diagnosis of AAV is highly unlikely in cases with ANCA IF-positive ELISA-negative.

Comparative Study of Renal Transplantation Due to Rapidly Progressive Glomerulonephritis (RPGN): Study of 42 Patients from a Single Tertiary Centre

Lara Sanchez-Bilbao,[1] Marina De Cos-Gomez,[2] Iñigo Gonzalez-Mazon,[3] Belén Atienza-Mateo,[1] Jose Luis Martín-Varillas,[1] Mónica Calderón-Goercke,[4] Diana Prieto-Pena,[3] Juan Carlos Ruiz-San Millan,[2] Miguel A Gonzalez-Gay,[1] and Ricardo Blanco[1], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [2]Nephrology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [3]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [4]Hospital Marqués de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated Poster I
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rapidly Progressive Glomerulonephritis (RPGN) is characterized clinically by a rapid and severe decline in kidney function. Thus, this entity may lead to an end stage renal disease, with kidney transplantation. RPGN is classificated in three groups: a) Type I or associated to anti-glomerular basement membrane antibodies (RPGN-GBMa), b) Type II or associated to immunocomplexes (RGPN-immunocomplexes), and c) Type III or pauci-immune (RPGN-pauci-immune). Besides, RPGN can be primary, without extra-renal involvement (RPGN-

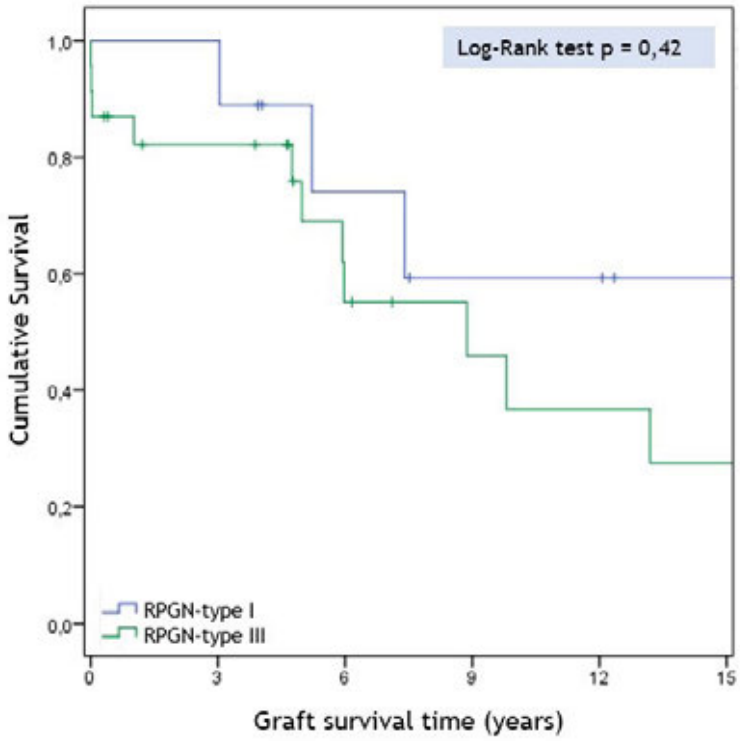
*p<0.05

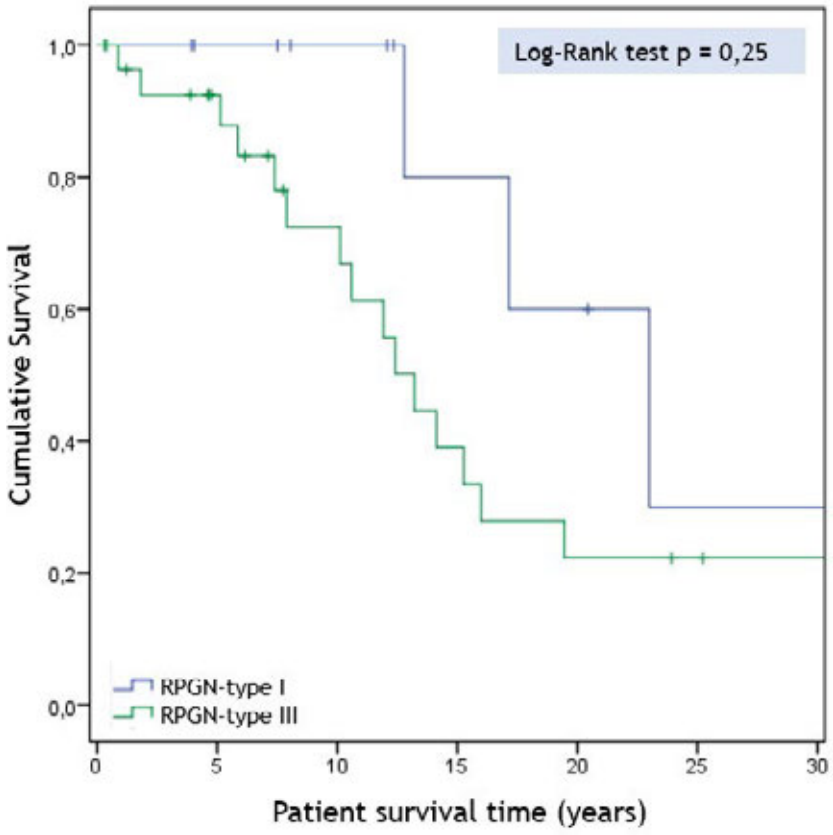
renal-limited), or secondary to systemic autoimmune disorders (RPGN-SAD), infectious diseases or drugs. Kidney transplantation in RPGN-SAD may be associated to a worse outcome.

In a series of 42 patients with first transplantation due to RPGN our aim was to assess **a**) clinical features of the three types of RPGN, **b)** comparison of post-transplant survival and graft survival between these three types.

Methods: We study three groups of patients according to renal biopsy: **a)** RPGN-GBMa (n = 11), **b)** RPGN-immunocomplexes (n = 2) and c) RPGN-pauci-immune (n=29).

All these patients were transplanted in a single reference University Hospital. The main outcome variables were a) graft survival up to 15 years and patient survival up to 30 years and b) evolution of renal function (serum creatinine





and proteinuria) in the first 5 years of follow-up. Cumulative survival rates after transplantation were estimated by the Kaplan-Meier method and compared between groups using the log-rank test. Kruskal-Wallis test was used to compare quantitative variables and chi^2/Fisher's exact test for qualitative variables.

Results: We included a total of 42 patients with renal transplant due to RPGN, with a mean age at diagnosis of 44.87±17.01 years (48.53±17.45 at the time of the transplant). No significant differences at baseline were observed between the three RPGN groups regarding sex, age and cardiovascular risk factors. Renal biopsy had been performed in the 42 patients with RPGN: type I or RPGN-GBMa (n=11, 26.2%), type II or RPGN-immunocomplexes (n=2, 4.8%) and type III or RPGN-pauci-immune (n=29, 69.0%).

It was also reported the presence or absence of systemic autoimmune disorders (31% RPGN-SAD and 69% RPGN-renal-limited). According to the presentation and the clinical characteristics of the patients, another classification has been established: a) type I (18.2% (2) Goodpasture-syndrome), b) type II (100% renal-limited), c) type III (13.8% (4) granulomatosis with polyangiitis and 20.70% (6) microscopic polyangiitis. The evolution of serum creatinine and the proteinuria after the transplant is shown in **TABLE 1**. There were no significant differences between the three groups in the serum creatinine values during at 1st, 6th, 12th, 36th and 60th months post-transplant. Neither differences were found in terms of graft and patient survival between the 3 groups **(Figures 1 and 2).**

Conclusion: Our study shows similar graft and patient survival as well as renal outcome in renal transplant due to the three types of RPGN. Therefore, renal transplantation could be the best option for patients with end stage renal disease due to RPGN regardless of systemic manifestations.

Ultrasound to Monitor Treatment Response in Large Vessel Giant Cell Arteritis

Anne Bull Haaversen,[1] Viktoria Holt,[2] Shagaye Nabizadeh,[2] Annicken Slagsvold,[2] and Andreas P Diamantopoulos[3], [1]Martina Hansens Hospital, Sandvika, Norway, [2]Martina Hansens Hospital, Bærum, Norway, [3]Martina Hansens Hospital, SANDVIKA, Oslo, Norway

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: On ultrasound (US) examinations, large vessel vasculitis (LVV) has been reported to be present in up to 55% of Giant cell arteritis (GCA) patients. No consensus exists on how to evaluate treatment response in LVV. US yields a high sensitivity and specificity on GCA diagnostics . The aim of this study was to examine if the US of the large supraaortic arteries could be used to monitor treatment response in patients with LVV-GCA.

Methods: We included retrospectively patients who were diagnosed with new-onset LVV-GCA (positive US of the supraaortic vessel(s) and typical clinical manifestations) after they had been referred to the Department of Rheumatology, Martina Hansens Hospital in Bærum, Norway between September 2017 and April 2019. The intima-media complex (IMC) thickness of the supraaortic arteries (carotid, subclavian, axillary proximal and distal) was measured at diagnosis (and within 3 days after the initiation of prednisolone) and after one month. C-reactive protein (CRP) and prednisolone dose were also registered. Appropriate statistical tests were applied and p values < 0.05 were considered as significant.

Results: Twenty patients (14 females, 6 males) were included in this study, with a mean age of 67 years. The mean starting dose of prednisolone was 46 mg and one month later, prednisolone dose was reduced by 16 mg (95% CI 9-22, p< 0.005). The mean CRP at disease onset was 80 mg/dl and one month later it was reduced by 77 mg/dl (95%

Artery	Mean difference (onset-1 month later)	95% Confidence Interval	P values
Left axillary proximal	0,16	0,01-0,31	0,03
Left axillary distal	0,45	0,2 -0,69	<0,05
Right axillary proximal	0,22	0,04-0,40	0,02
Right axillary distal	0,41	0,12-0,70	0,01
Right carotid	0,33	-0,04-0,71	0,06
Left carotid	0,36	0,00-0,71	0,05
Right subclavian	0,22	0,08-0,36	<0,05
Left subclavian	0,41	0,11-0,70	0,01

Table 1. Mean differences of the IMC thickness in the supraaortic vessels

CI 40-115, p=0.001). After one month, and except for the right carotid artery, a significant reduction of IMC thickness in all supraaortic vessels was observed (table 1).

Conclusion: The US of the supraaortic arteries may be a useful tool to monitor treatment response in LVV-GCA. Thus, the US of the large vessels has the potential to be used for the assessment of disease activity in LVV-GCA patients. These promising results have to be confirmed in larger cohorts of patients.

Abstract Number: 2645

The Anteromedial Ultrasound Examination of the Large Supraaortic Vessels Identifies Higher Rates of Large Vessel Involvement Than Previous Reported in Patients with Giant Cell Arteritis

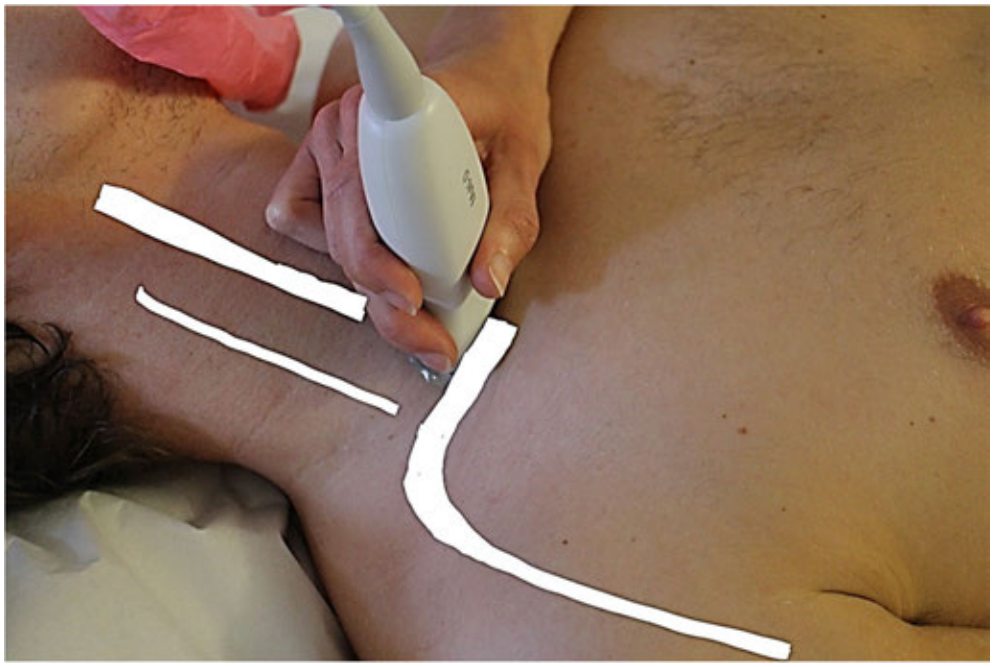
Anne Bull Haaversen,[1] and Andreas P Diamantopoulos[2], [1]Martina Hansens Hospital, Sandvika, Norway, [2]Martina Hansens Hospital, SANDVIKA, Oslo, Norway

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) affects both the cranial and large vessels. Ultrasonographic studies have reported that the incidence of large vessel vasculitis (LVV) in patients with GCA varies from 30% to 55%. The aim of this study was to investigate the rate of LVV in patients with GCA by using the new anteromedial approach to examine the large supraaortic vessels in addition to the cranial arteries.

Methods: Patients with new-onset GCA referred to the Department of Rheumatology, Martina Hansens Hospital in Bærum, Norway between September 2017 and April 2019 were included. The diagnosis was based on typical clinical manifestations and ultrasound findings. All the patients were scanned by ultrasound using the anteromedial approach for the supraaortic vessels (carotid, vertebral, subclavian, axillary proximally and distally), in addition to the examination of the cranial vessels (temporal, facial). The anteromedial approach consists of a continuous ultrasound evaluation of the large supraaortic vessels with the patient in a supine position (figure 1). The examination was performed with a General Electric S8 ultrasound machine with a 9-12 Mhz linear probe for the large vessels and an 18 Mhz hockey stick probe for the cranial arteries. The age, gender, CRP and the distribution of vasculitis in the vessels were recorded. The cut-off for vasculitis of the large vessels was set at 1 mm (homogeneous, hypoechoic or isoechoic thickness of the intima-media complex).

Results: Forty-one patients, 30 (73%) females, and 11 (27%) males were diagnosed with GCA during the recruitment period. The mean age was 71 years (95% CI (67-74)). Mean CRP was 79.6 mg/dl (95% CI (63-96)). Of the 41 GCA patients, 10 patients (24 %) had cranial GCA only, 12 patients (30 %) had LVV only and 19 patients (46 %) had both cranial and LVV GCA. The temporal arteries were the most frequently inflamed in 56 % of the patients, followed by the facial artery(left 29% and right 24%). The large supraaortic vessels mostly inflamed were the right proximal and left distal axillary (41 %), the left proximal axillary (37%) and the subclavian (left 34% and right 32%) (tables 1 and 2).



The anteromedial ultrasound examination of the large supraaortic vessels.

Cranial arteries	% of all GCA patients (number of pts)
Left temporal	56 *(23)*
Right temporal	56 *(23)*
Left facial	30 *(12)*
Right Facial	24 *(10)*

Table 1. Distribution of the inflammation in the cranial arteries

Supraaortic Arteries	% of all GCA patients (number of pts)
Left carotid	27 *(11)*
Right carotid	10 *(4)*
Left vertebral	25 *(10)*
Right vertebral	17 *(7)*
Left subclavian	34 *(14)*
Right subclavian	32 *(13)*
Left axillary proximal	37 *(15)*
Right axillary proximal	41 *(17)*
Left axillary distal	41 *(17)*
Right axillary distal	32 *(13)*

Table 2. Distribution of the inflammation in the supraaortic arteries

Conclusion: The anteromedial ultrasound examination revealed inflammation of the large supraaortic vessels in 76 % of the GCA patients. This indicates that the involvement of supraaortic arteries is more common in GCA than previously reported. Possible explanations may include the visualization of all the supraaortic arteries and both the upper and lower arterial wall when using the anteromedial ultrasound scanning.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the relationship between demographical, clinical, laboratory and imaging data and survival in patients with large vessel giant cell arteritis (LVGCA) in a defined area of Northern Italy.

Methods: All patients with incident LVGCA diagnosed between 1 January 2005 and 31 December 2016 and living in the Reggio Emilia area, were identified by capture and re-capture checking of computerized discharge diagnosis codes (ICD10) and using outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: age at disease onset ≥50 years; evidence of large-vessel vasculitis (LVV) by clinical criteria, angiography, MRA, CTA, PET/CT and/or ultrasonography. Demographic, clinical, laboratory and imaging data collected at first visit and during follow-up (FU) were retrived from patients records. For each case, we identified one control from the same geographic area matched for age and gender. Mortality rates and specific causes of death were reported and compared between cases and controls. Demographical, clinical laboratory and imaging data entered in a Cox proportional regression analysis (CPRA) along with total corticosteroid (CS) cumulative dose, first 6 and 12 months cumulative CS dose, number of flares, and disease remission during the FU period.

Results: There were 93 incident cases of LVGCA (71% women, mean ± SD age at diagnosis 72 ± 9 years, mean duration of FU 65 + 38 months) with complete clinical, laboratory and survival data during the 12-year study period. During the FU period, 16 (17%) patients died (mean survival time from disease onset 16 + 12 months). At univariate analysis (UVA) factors significantly linked to survival ($p< 0.05$) were the presence of hypertrigliceridemia (HTG) and the involvement of brachio-cephalic artery (BCA). All the variables with a value of $p< 0.20$ at UVA (HTG, BCA, hypertension, concomitant PMR, cumulative CS dose at 6 and 12 months and aortic involvement) entered in a CPRA but none of them maintained statistical significance. Survival of LVGCA patients was not different from controls (logrank=0.004, p=0.947). The most frequent causes of death were cardiovascular diseases, cancer, and respiratory diseases. No significant differences in causes of death were observed comparing the patients with control population.

Conclusion: In an incident cohort of LVGCA we have not found any correlation between baseline and follow up clinical, demographical, laboratory and imaging data with survival.

Patients with LVCGA have no difference of survival time and causes of death with the control population.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the frequency, timing, and characteristics of flares and to evaluate the frequency of long-term remission after glucocorticoids (GCs) suspension in an Italian cohort of patients with large-vessel (LV) giant cell arteritis (GCA) and to identify factors that may predict the occurrence of flares and long-term remission.

Methods: We evaluated 75 patients with LV GCA diagnosed and followed up at the Rheumatology Unit of Reggio Emilia Hospital (Italy) for whom information was available from the time of diagnosis until at least 2 years of follow-up. In all patients the diagnosis of LV GCA was confirmed by imaging. Flares were defined as reappearance of signs/symptoms or worsening in vascular imaging requiring treatment adjustment. Long-term remission was defined as complete clinical remission without elevation of inflammatory markers for at least one year after the GC withdrawal.

Results: 34 patients (45.3%) experienced one or more flares. Twenty (38.5%) of the 52 total flares were experienced during the first year after diagnosis. The majority of relapses occurred with doses of prednisone < 10 mg/day (80.7%), while only 3.8% for doses > 25 mg/day. Polymyalgia rheumatica (PMR) (34.6%) and worsening of LV imaging (34.6%) were the most frequently observed flaring manifestations. Cumulative prednisone dose during the first year and total cumulative prednisone dose were significantly higher in flaring patients compared to those without flares ($p = 0.006$ and $p = 0.0001$, respectively). The total duration of prednisone treatment was longer in flaring patients ($p = 0.0001$).

Patients with disease flares had at diagnosis more frequently fever > 38°C ($p = 0.04$) and less frequently jaw claudication ($p = 0.02$) compared to those without flares. In the multivariate model fever > 38 °C (HR 2.94, 95%CI:1.25-6.91, $p = 0.01$), PMR (HR 3.59, 95%CI: 1.61-8.03, $p= 0.002$), visual manifestations (HR 3.24, 95%CI: 1.09-9.67, $p = 0.035$)

were significantly associated with an increased risk of flares, while jaw claudication (HR 0.11, 95%CI: 0.02-0.48, p = 0.004) with a reduced risk.

33 patients (44%) experienced long-term remission. PMR and disease flares were less frequently observed in patients with long-term remission compared to those without (p = 0.002 and p < 0.0001, respectively). The initial prednisone dosage was higher in patients with long-term remission (p = 0.03), while the total cumulative prednisone dose and the duration of prednisone treatment were significantly lower (p = 0.02 and p = 0.003, respectively). In the multivariate model the duration of prednisone treatment was significantly negatively associated with long-term remission (HR 0.97, 95%CI: 0.96-0.98, p < 0.0001).

Conclusion: In our cohort of patients with LV GCA a flaring course and long-term remission were observed in around half of the patients.

Association Between Specimen Length and Number of Sections and Diagnostic Yield of Temporal Artery Biopsy: A Retrospective, Single Center Experience over a 21 Years' Period

Francesco Muratore,[1] Luigi Boiardi,[2] Alberto Cavazza,[3] Giacomo Tiengo,[4] Raffaella Aldigeri,[5] Luca Cimino,[6] and Carlo Salvarani[7], [1]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [2]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]Pathology Unit, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Division of Rheumatology, University of Modena and Reggio Emilia, Modena, Italy, [5]Department of Medicine and Surgery, University of Parma, Parma, Italy, [6]Ophthalmology Unit, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [7]Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the association between specimen length and number of sections and the diagnostic yield of temporal artery biopsy (TAB) for giant cell arteritis (GCA).

Methods: A pathologist with expertise in vasculitis and blinded to clinical data and final diagnosis reviewed all TABs performed for suspected GCA at our hospital between January 1991 and December 2012. The biopsies were routinely fixed in formalin and completely embedded in paraffin. Sections of 4 microns thickness were cut from paraffin blocks and stained with hematoxylin-eosin. TABs were classified into three categories: inadequate, when the biopsy did not sample the muscular artery; negative when the temporal artery was devoid of inflammation and positive when the temporal artery showed inflammation, arbitrarily defined as at least 1 aggregate of at least 15 inflammatory cells. The blocks of all the inadequate and negative biopsies were recut, and at least three further slides at deeper levels were stained with hematoxylin-eosin in order to avoid missing skip inflammatory lesions.

Results: 694 TABs were performed in the study period and were reviewed. 32 (4.6%) were classified as inadequate and were excluded from the analysis. Of the remaining 662 TABs [71% female; mean (SD) age, 73.2 (8.8) years], mean

(SD) post fixation length was 6.63 (4.42) mm, and median number of sections evaluated was 3 (range 1-33). 382 (58%) TABs were classified as negative and 280 (42%) as positive. Compared with negative TAB, patients with positive TAB were older [mean age (SD) 74 (7.5) years vs 72 (9.6), p=0.009] and there was a trend for female predominance (75% vs 68%, p=0.077). Post fixation length of the specimens was significantly lower in negative compared with positive TAB [mean (SD) 6.37 (4.26) mm vs 6.99 (4.61) respectively, p=0.026]. Piecewise logistic regression identified 5 mm as the TAB length change point for diagnostic sensitivity. Compared with TAB length of < 5 mm, age- and sex-adjusted odds ratio for positive TAB in samples ≥5 mm long were 1.536 (95% confidence interval, 1.108 to 2.130).

The median (IQR) number of sections evaluated were 2 (1-3) for positive TAB and 4 (2-5) for negative TAB, p< 0.0001. In 26/280 (9.3%) positive TABs, the first section was negative, and the inflammation was detected only in deeper sections (the positive section was the second in 14 TABs, the third in 9 and the fourth in 3). In all 26 cases, inflammation detected in deeper section was not transmural, but limited to adventitial or periadventitial small vessels.

Conclusion: Our data confirm that a post fixation TAB length of at least 5 mm should be sufficient to make a histological diagnosis of inflamed temporal artery. According to our data, in order to avoid missing skip inflammatory lesions, at least 3 further sections at deeper levels should be cut and evaluated in all negative TABs.

Comparison of Biopsy Proven Giant Cell Arteritis in North America and South Europe: A Population-Based Study

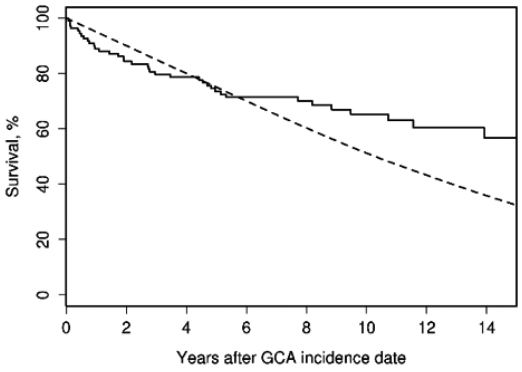
Francesco Muratore,[1] Cynthia Crowson,[2] Luigi Boiardi,[3] Ambra Pinelli,[4] Matthew Koster,[5] Giovanna Restuccia,[1] Tanaz Kermani,[6] Eric Matteson,[7] Carlo Salvarani,[8] and Kenneth Warrington[5], [1]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [2]Mayo Clinic Rochester, Rochester, [3]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Division of Rheumatology, University of Modena and Reggio Emilia, Reggio Emilia, Italy, [5]Mayo Clinic Rochester, Rochester, MN, [6]University of California Los Angeles, Los Angeles, CA, [7]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester, [8]Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To compare clinical characteristics, treatment, long-term follow-up and prognosis of two population-based cohorts of patients with biopsy-proven giant cell arteritis (GCA) from North America (American cohort) and South Europe (European cohort).

Methods: All patients residing in these two geographic regions with a new diagnosis of biopsy-proven GCA in 1986-2007 were retrospectively identified. Patients were followed from GCA diagnosis to death, migration or September 2011. Comparisons were performed using Chi-square and rank sum tests, Kaplan-Meier methods and Cox models. To account for differences in general population survival between the 2 geographic regions, survival in each GCA cohort was compared to expected rates obtained from age-, sex- and calendar year-specific lifetable rates for the general population of its region.

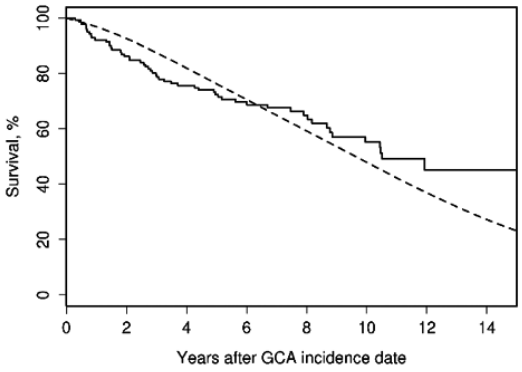
Figure 1A. Survival of North American residents with GCA compared to expected rates from North America lifetables



SMR (95% CI) 0.69 (0.49, 0.95), log-rank p-value = 0.024

(observed: solid line; expected dashed line)

Figure 1B. Survival of South Europe residents with GCA compared to expected rates from South Europe lifetables



SMR (95% CI) 0.66 (0.50, 0.87), log-rank p-value = 0.001

(observed: solid line; expected dashed line)

Results: The study included 110 patients in the American and 144 in the European cohort. Compared with the American cohort, patients from the European cohort were younger (mean±SD age 74.6±7.4 years vs 77.8±7.6, p=0.002), had longer duration of symptoms prior to diagnosis (median [IQR] 1.4 [1.0, 2.7] months vs 0.7 [0.2, 1.3], p< 0.001) and were more likely to have cranial symptoms (93% vs 86%, p=0.048), partial or complete unilateral or bilateral permanent vision loss (21% vs 6%, p=0.001), systemic symptoms (67% vs 46%, p=0.001) and polymyalgia rheumatica at or before GCA diagnosis (47% vs 26%, p< 0.001). ESR and CRP were higher (mean 88±29 mm/h vs 73±77, p< 0.001 and mean 89.0±60.2 mg/L vs 35.2±43.4, p< 0.001 respectively) and hemoglobin lower (mean 11.2±1.4 g/dl vs 11.8±1.4, p=0.004) in European than in the American cohort. Patients from the American cohort received a higher initial prednisone dose (mean 53.6±15.3 mg/day vs 49.5±12.8, p=0.001). There were no differences in relapse rates, cumulative glucocorticoid (GC) dosages at 1, 2 and 5 years, and time to first GC discontinuation.

Overall survival curves showed a better survival of patients with GCA from both study cohorts compared to expected rates obtained from age-, sex- and calendar year-specific lifetable rates for the general population of the respective regions (Figure 1A-B). As shown by survival curves, the mortality of patients with GCA was similar to the general population in the first 6 years from GCA diagnosis (SMR [95% CI] 1.07 [0.72, 1.53], log-rank p-value = 0.71 for the American cohort, and 0.91 [0.65, 1.24], log-rank p-value = 0.55 for the European cohort), but became significantly lower in both study cohorts after 6 years from GCA diagnosis (SMR [95% CI] 0.27 [0.11, 0.57], log-rank p-value < 0.001 for the American cohort, and 0.36 [0.19, 0.61], log-rank p-value < 0.001 for the European cohort). The most common cause of death was heart diseases in both the study cohorts, followed by cancer, pulmonary diseases, infection and stroke.

Conclusion: The clinical features at onset of GCA differ between patients from South Europe and North America. Geographical, genetic and/or environmental factors may contribute to the differences observed in this study. Improvement in survival for the GCA cohorts is a novel finding that will require further validation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Roughly half of giant-cell arteritis (GCA) patients taking only glucocorticoids (GCs) relapse. The relapse rate seems to reflect, in part, the duration of GC intake, more than the initial dose at induction. However, the GCA-relapse rate varied widely in observational studies and randomized–controlled trials. We aimed to identify factors predictive of GCA relapse based on data from patients enrolled in 3 international GCA cohorts.

Methods: This international study included patients ≥50 years old and fulfilling ACR criteria for GCA from three cohorts : Northern Europe (n=351), US (n=285) and Southern Europe (n=142) cohorts. The primary endpoint was the time from diagnosis to first relapse or death. Relapse-free survival was estimated with the Kaplan–Meier product-limit method. Cox proportional hazards models were stratified by cohort. Missing data were handled through multiple imputation by chained equations. Internal validation of the model was carried out using 200 bootstrap resamples, on which the entire model building strategy was repeated. Model performance was evaluated both by the concordance (c) statistic, as a measure of discrimination, and the calibration curve. The final model was presented with hazard ratios (HR) obtained after shrinkage by the calibration slope and their 95% confidence intervals (95% CI).

Results: This study included 778 patients (24% men; median age 71 [IQR 61–78] years). Median follow-up was 51 [IQR 24–102] months. During 36 months of follow-up, 382 patients relapsed; relapse-free survival at 36 months was 45.3% (95% CI 41.6–49.2), with marked differences among the cohorts. French and Reggio Emilia cohorts had better relapse-free survival rates than the Mayo Clinic cohort.

To adjust for optimism induced by the model-selection procedure, regression coefficients where shrunk by multiplying them by the calibration slope, which was 0.714, indicating a reasonable level of overfitting in the original model. The final model (corrected for over-optimism) comprised headaches (HR 1.18, 95% CI 1.00–1.39; P=0.052), limb claudication (HR 1.34, 95% CI 0.95–1.89; P=0.091), aortitis (HR 1.20, 95% CI 0.97–1.48; P=0.096) and CRP levels (after logarithmic transformation) (HR 1.11, 95% CI 1.02–1.22; P=0.014). The model was well calibrated, but with relatively limited discriminative ability. Using the pooled coefficients for each imputed dataset yielded a corrected c-statistic of 0.562 (95% CI 0.525–0.598).

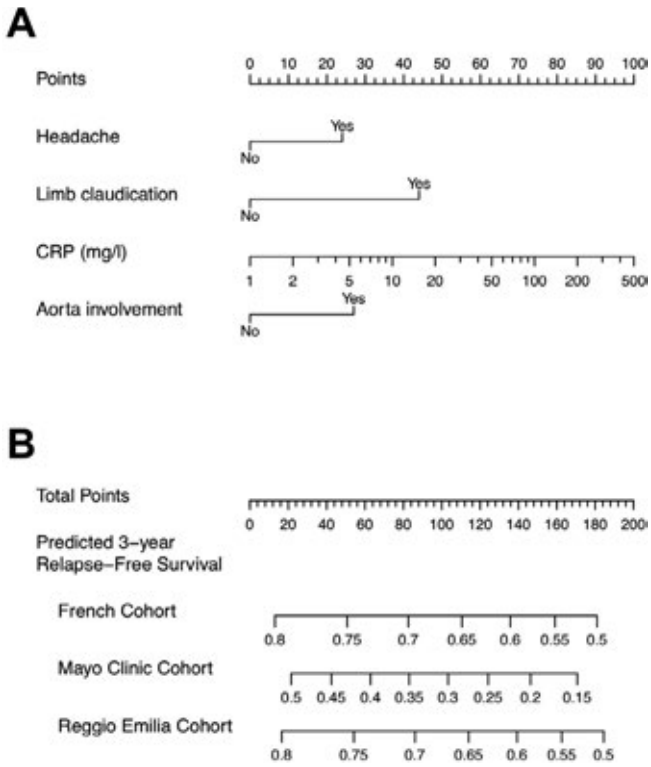

Figure 1. Nomogram allowing the calculation of the predicted 3-year relapse free survival.

We set up a nomogram allowing the calculation of the predicted 3-year relapse free survival. Points (ranging from 0 to a maximum of 100) is attributed for each of the four previous items (Figure A). Total score (ranging from 0 to 200) is used to predict the 3-year relapse free survival in each cohort (Figure B).

Conclusion: The risk of GCA relapse varies among observational cohorts. A model comprising the headaches, limb claudication, aortitis and CRP levels was well calibrated, and could help identify patients at high-risk of relapse. However, this model had relatively limited discriminative ability, possibly due to unmeasured variables that might explain the observed heterogeneity among cohorts.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In parallel to the improvements in imaging, increasing data is accumulated regarding phenotypes of primary vasculitides. Giant cell arteritis (GCA) is a large vessel vasculitis encompassing cranial and extracranial arterial involvements and as well as polymyalgia rheumatica (PMR). Clinical manifestations and treatment responses may be different in the course of GCA. In this survey, we purpose to investigate the phenotypic overlap between the different vascular GCA subtypes and PMR.

Methods: We retrospectively analyzed the 55 GCA patients of the Hacettepe University Vasculitis Center (HUVAC). All clinical, laboratory, imaging and histopathological features were analyzed. The revised 2016 ACR and ACR 1990 GCA classification criteria were applied to patients diagnosed GCA according to the multidisciplinary expert group. Patients were grouped according to cranial, extracranial and PMR symptoms. Cranial GCA group comprised new headache, clinical temporal artery abnormality, visual disturbance, and jaw claudication; extracranial GCA group, limb claudication, bruits and Raynaud's phenomenon; Polymyalgic+GCA group, bilateral shoulder/hip pain, morning stiffness and peripheral arthritis(1). Some patients had characteristics of more than one group, so the key phenotypic features of GCA were evaluated in 87 cases. Two patients were not included in any group because they did not have any symptoms according to this classification. Subgroup comparisons were done in terms of clinical features.

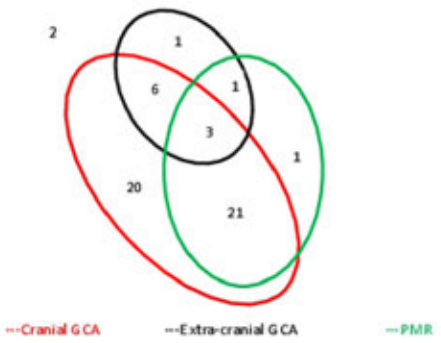
Results: A total of 55 GCA patients (Female/Male: 40/15) with a mean age and mean age of diagnosis patients were 73.0±9.7 and 67.7±9.2 years, respectively. Of the 43 patients (%78) met ACR 1990 classification criteria and 44 patients (%80) the revised 2016 ACR in our cohort. Temporal artery Doppler ultrasonography was applied to 36 patients and 10 (28%) of them were compatible with GCA and temporal artery biopsy was compatible in 26/36 (72%) of the patients. According to this classification 50 patients had cranial, 11 patients extracranial and 26 patients polymyagic symptoms. Of the 21 patients had characteristics features of both cranial and PMR group, 6 patients both cranial and extracranial group, and 3 patients all 3 groups. In comparison with extracranial GCA (9%) and polymyagic+GCA group (3%), cranial GCA group (40%) tends to occur more isolated. The phenotypic overlap between these groups

Table. Clinical symptoms and signs in giant cell arteritis groups

Symptoms and signs	Cranial GCA n=50, (%)	Extracranial GCA n=11, (%)	Polymyagic-GCA n=26, (%)
Headache	43 (86)	7 (64)	20 (77)
Arterial swelling/tenderness	23 (49)	3 (30)	9 (36)
Jaw claudication	23 (46)	6 (55)	13 (50)
Visual symptoms/complications	21 (42)	2 (18)	8 (31)
Fever, weight loss	17 (34)	5 (46)	7 (27)
High ESR and/or CRP	35 (70)	8 (73)	19 (73)
Limb claudication	3 (6)	**4 (36)***	1 (4)
Arterial bruits	2 (4)	**4 (36)****	2 (8)
Raynaud's phenomenon	3 (6)	**3 (27)*****	0
Polymyalgic symptoms	19 (38)	7 (63)	17 (66)
Morning stiffness	11 (22)	3 (27)	10 (39)
Peripheral arthritis	12 (24)	2 (18)	11 (42)

GCA; Giant cell arteritis, PMR; polymyalgia rheumatica, ESR; erythrocyte sedimentation rate, CRP; *C-reactive protein*.
p values; * 0.019, ** 0.018, *** 0.028

Figure. The phenotypic overlap between **Giant cell arteritis subgroups**



was also illustrated in the Figure. The most common clinical signs and symptoms observed in GCA groups were shown in Table. Limb claudication (p=0.019), arterial bruits (p=0.018) and Raynaud's phenomenon (p=0.028) were significantly higher in extracranial GCA group than other 2 groups.

Conclusion: Most of the phenotypic features were similar among GCA groups except for limb claudication, arterial bruits and Raynaud's phenomenon in extracranial GCA group. Although there was a relationship between all groups, the cranial GCA group may exist with less clinical features.

Abstract Number: 2652

Comparison Between Transmural and Isolated Periadventitial And/or Adventitial Inflammation at Temporal Artery Biopsy: A Single Center Cohort of Biopsy-Positive GCA with Long Term Follow-up

Elena Galli,[1] Francesco Muratore,[2] Luigi Boiardi,[3] Alberto Cavazza,[4] Giovanna Restuccia,[2] Luca Cimino,[5] and Carlo Salvarani[6], [1]Division of Rheumatology, University of Modena and Reggio Emilia, Modena, Italy, [2]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [3]Division of Rheumatology, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [4]Pathology Unit, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [5]Ophthalmology Unit, Azienda Unita' Sanitaria Locale IRCCS di Reggio Emilia, Reggio Emilia, Italy, [6]Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Temporal artery biopsy (TAB) showing transmural inflammation is considered the gold standard for the diagnosis of giant cell arteritis (GCA). In some cases, inflammation is confined to the periadventitial small vessels and/or to the adventitia. The aim of the present study was to compare treatment and long-term outcomes of

patients with transmural inflammation with those of patients with periadventitial and/or adventitial inflammation in a single center cohort of patients with biopsy-positive GCA with long term follow-up.

Methods: All TABs performed for suspected GCA between 1986 and 2013 were reviewed by a single pathologist. Based on the localization of the inflammation, inflamed TABs were classified into 2 categories: transmural inflammation (TMI), with external elastic lamina disruption and extension of the inflammation to the media; periadventitial and/or adventitial inflammation (PA/AI), with inflammation limited to small periadventitial vessels devoid of muscular coat and/or to the adventitia without extension to the media. All medical records of these patients were retrospectively reviewed from the date of TAB to 31 December 2018 or death. Only patients with a follow-up duration of at least 18 months after GCA diagnosis were included.

Results: In the study period, 274 TMI and 80 PA/AI were identified. Baseline clinical manifestations and laboratory findings of the two study cohorts have been already reported (1). Large vessel involvement was found in 6/22 (27%) patients with PA/AI and 32/81 (40%) patients with TMI, p=0.292. 118 patients with TMI and 35 with PA/AI had a follow-up duration longer than 18 months and were included for the outcomes analysis. Median (IQR) follow-up duration was 79.5 months (52, 114) for patients with TMI and 67 months (34, 124) for those with PA/AI, p=0.125. Compared to patients with TMI, those with PA/AI received a significant lower initial prednisone dose (mean (SD) 35.8 mg (22.0) vs 46.8 (15.0), p< 0.0001), reached sooner a prednisone dose < 10 mg/day (median 20 weeks vs 26, p=0.004) and < 5 mg/day (median 32 weeks vs 44, p=0.005), had a lower cumulative prednisone dose at 1 year (mean (SD) 5.8 gr (3.8) vs 7.2 (2.3), p=0.005) and at the end of the follow-up period (mean (SD) 10.0 gr (9.0) vs 12.9 (9.6), p=0.015), and showed a trend for an earlier first relapse (median 52 weeks vs 63, p=0.052). There were no differences in the frequencies of relapse (43% of patients with TMI vs 46% of those with PA/AI, p=0.794) and long term remission (53% of patients with TMI vs 49% of those with PA/AI, p=0.616), time to first GC discontinuation (median 72 weeks in patients with TMI vs 62 weeks in those with PA/AI, p=0.080) and treatment duration (median 33.5 months in patients with TMI vs 26 months in those with PA/AI, p=0.159).

Conclusion: Our study demonstrates for the first time that patients with GCA with isolated periadventitial and/or adventitial inflammation and those with the classic transmural pattern have similar frequency of large vessel involvement and similar disease course. These data confirm that TAB showing inflammation confined to the periadventitial small vessels and/or the adventitia could be considered part of the histopathologic spectrum of GCA.

Adventitial Fibroblast, an Important Actor in Giant Cell Arteritis

Simon Parreau,[1] Nicolas Vedrenne,[2] Alexis Régent,[3] Laurence Richard,[4] Philippe Sindou,[2] Luc Mouthon,[3] Anne-Laure Fauchais,[4] Marie-Odile Jauberteau,[2] and Kim Heang Ly[1], [1]Limoges University Hospital, Limoges, France, [2]EA3842-CaPTuR, Limoges, [3]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France, [4]Limoges University Hospital, Limoges

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is a systemic vasculitis affecting large vessels. The diagnosis is based on temporal artery biopsy (TAB) which shows an arterial infiltration accompanied by a destruction of the internal elastic layer of the media and a hyperplasia of the intima by proliferation of myofibroblasts. The origin of these myofibroblasts is controversial. Evidences suggest the activation of adventitial fibroblasts into myofibroblasts and their migration into the intima. The objective of this study was to determine whether adventitial fibroblasts migrate to the intima and thereby contribute to intimal hyperplasia during CGA.

Methods: Immunohistochemistry: Arterial sections from TAB of patients with GCA (n=24) and control subjects (n=24) were analyzed. Immunohistochemical analysis were performed using antibodies directed against fibroblasts (CD90, vimentin), myofibroblasts (alpha smooth muscle actin {ASMA}), vascular smooth muscle cells (desmin {VSMC}), prolyl-4-hydroxylase (collagen secretion activity {P4H}) and myosin (contraction activity). Stainings were quantified using ODPviewer® (Kamax Innovative System). Co-expression of CD90 with different stainings (ASMA, myosin and P4H) was also performed.

Culture cells: TABs were dissected to separate the adventitia from the other two layers (media and intima). Each fragment was seeded separately. Cells were identified by immunocytochemistry. Functional assays were performed using culture cells obtained from GCA patients' TABs (n=8) and controls (n=7): proliferation (bromodeoxyuridine incorporation test), migration (scratch test) and invasion (boyden chamber). Several conditions were used: i) DMEM-Glutamax alone, ii) addition of 10% fetal bovine serum (FBS), iii) addition of platelet-derived growth factor (PDGF) to 40 ng/mL, iv) supernatants of cells.

Results: CD90 and vimentin (fibroblasts) were significantly higher in GCA than controls in adventitia and intima. ASMA (myofibroblasts) was significantly higher in the 3 tunics of patients with GCA. Expression of desmin (VSMC) was only present in the media for both groups. The adventitial and intimal CD90+ cells co-expressed ASMA, P4H and myosin more importantly during GCA.

Cultured cells from adventitia expressed CD90 and did not express desmin. These adventitial cells had an increased in vitro proliferation ability during GCA compared to controls in the presence of FCS, PDGF and fibroblast supernatants of control or GCA patients. Migration and invasion rates of these cells were also significantly increased during GCA in the presence of FCS or PDGF.

Conclusion: Vascular remodeling during GCA would start in the adventitial layer with a key role of fibroblasts. Adventitial fibroblasts could be activated into myofibroblasts and acquire proliferative and migratory abilities. They would participate in the intimal hyperplasia. Finally, the activating signal of adventitial fibroblasts into myofibroblasts is not yet known during GCA and requires further studies.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Aortitis is challenging to diagnose and is often detected on surgical pathology. A subset of these patients could benefit from early medical therapy as a way to prevent progression of disease or improve surgical outcomes. This study compared pathology-diagnosed aortitis to non-inflammatory aortic aneurysms with respect to pre-operative patient characteristics, laboratory, and imaging data.

Methods: This is a single center matched case-control study. Cases had biopsy-proven aortitis following open thoracic aortic aneurysm repair in the University of Pennsylvania Health System between 2007 and 2017, without evidence of infection or prior known diagnosis or symptoms of rheumatologic disease. Approximately five controls were matched to each case by year of surgical repair and lacked significant inflammation on pathology. Preoperative patient data, such as demographics, comorbidities, laboratory testing and vessel imaging were collected. These were compared between the two groups using conditional logistic regression to evaluate associations between exposures and outcomes. Backward stepwise logistical regression was used to determine factors independently associated with aortitis.

Results: The prevalence of newly-diagnosed aortitis was 4% (total 1,373 aortic surgical specimens reviewed). For the analysis, 262 patients were included: 43 patients with aortitis and 219 matched controls. The ascending aorta was the most common site of surgical repair (95% in both groups). Patients with aortitis were more likely than controls to have granulomatous inflammation (35% vs 0%), giant cells (86% vs 0%), and adventitial inflammation (70% vs 0%). Compared to matched controls, patients with aortitis were older at the time of surgery, more likely to be female, and less likely to have a history of coronary artery disease (CAD). Multivariable analysis revealed that aortitis is independently associated with an older age at the time of surgery (OR 1.08 [95% CI 1.03,1.13], p< 0.01), female gender (OR 2.36 [95% CI 1.01,5.51], p=0.04), absence of CAD (OR 6.92 [95% CI 2.14,22.34] p=0.04), larger diameter of aneurysm (OR 1.74 [95% CI 1.02,2.98], p=0.04), and presence of arterial wall thickening on imaging (OR 56.93 [95%CI 4.31,752.33] p< 0.01).

Conclusion: Among patients who underwent open surgical repair of a thoracic aortic aneurysm, elderly females without a prior history of CAD, those with larger aneurysms at the time of surgery or evidence of vessel wall thickening on imaging were more likely to have underlying aortitis. Patients with these risk factors may benefit from further preoperative screening and assistance in peri-operative management by a rheumatologist.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

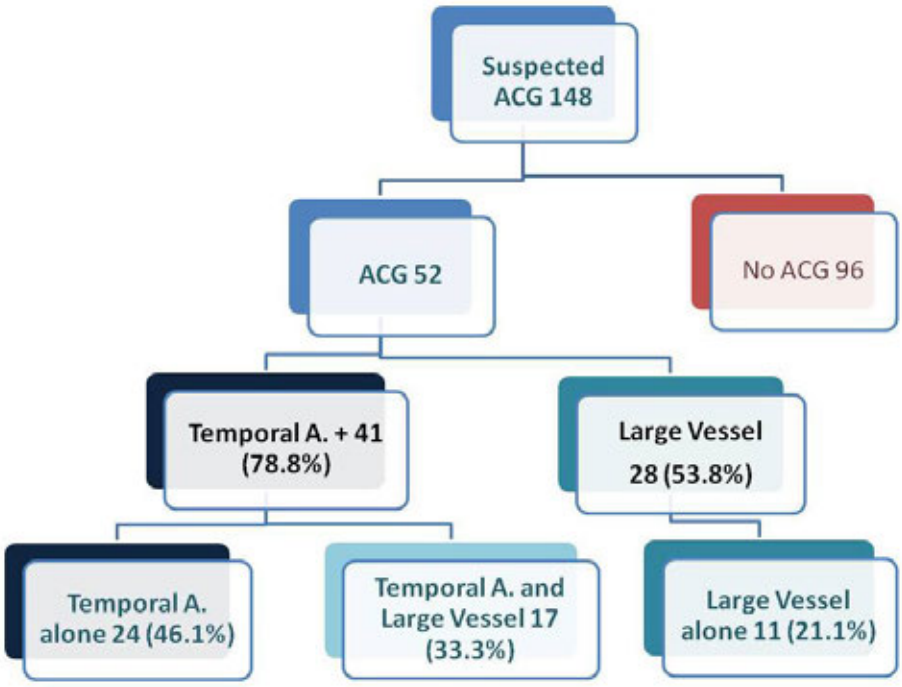

Figure 1: Patterns of GCA

Background/Purpose: Giant cell arteritis (GCA) is the most common systemic vasculitis in the elderly. In the EULAR recommendations of 2018 for the use of imaging in GCA, color Doppler ultrasound (CDUS) is recognized as the first diagnostic tool to be performed in centers with experience and OMERACT 2018 definitions and reliability of elemental ultrasound lesion of GCA have been published. Today the CDUS of TA is well known and used in clinical practice but the involvement of large vessel vasculitis (LVV) remains underdiagnosed by ultrasound and most of the diagnoses are performed by MRI or PET. In other way, TA halo sign responsiveness to the treatment and apparition in relapses is well know, but the information about this finding is sparse and even in the GiACTA study MRI lack of response in many patients was present. The objective of the present study was to know the frequency, pattern and sensitivity to change of CDUS to detect elemental lesions characteristics of cranial and LVV in patients with GCA diagnosis.

Methods: Observational descriptive study of 148 consecutive patients sent to our fast track clinic with suspicion of GCA. Every patient had a clinical history and a CDUS examination of TA and large vessel (LV) including axilary, subclavian, vertebral and carotid arteries. The OMERACT definitions of halo sign with an hypoechoic wall thickness ≥ 0.34 mm for TA pathology was used for GCA ultrasound diagnosis and for axilary, subclavian and carotids arteries and homogeneous hypoechoic thickness ≥ 1mm of the arterial wall were applied, in vertebral arteries we used a clear halo sign. Atherosclerosis lesions were evaluated to detect this disease as a possible false positive halo sign. The medical records of these patients were reviewed and demographic, physical examination, clinical and laboratory data were collected. The clinical diagnosis based on the evolution of the patient over at least one year was established as the definitive diagnosis.

Results: Of the 148 cases explored 52 had GCA, 34 women, mean age 77.2±7,9 years. The patterns of GCA were: 41 (78.8%) had cranial involvement of TA, with 24 patients with only temporal artery pathology in CDUS and 17 with a mixed patter of TA and LVV. In other way, 28 patients had LVV (53.8%) (17 with TA affectation and 11 with isolated LVV). This means that in our cohort we can see three patterns of GCA affectation: 1) a cranial pattern (affectation of TA) in the 46.1% of cases; 2) a mixed pattern of cranial and LVV affected the 33.3% of the patients and 3) an isolated LVV pattern in the 21.1% of the patients. Mean age of patients with LVV was younger that patients with cranial vasculitis 74 vs. 79 years, with a mean age of mixed pattern of 77 years. In the follow-up we can see as 9 patients with LVV

reduce the thickening of the arterial wall below the 1mm cut-off point showing sensitivity to change with the treatment and open the possibility to use ultrasound to measure activity or relapses in GCA LVV.

Conclusion: Ultrasound is an useful tool for the screening GCA including LVV. LVV is very common in our patients (53.8% of GCA cases) and 21.1 % presented only a LVV pattern. LV arteries should be included in the ultrasound examination of GCA suspicions. Ultrasound is sensitive to change in LVV.

The Veterans Health Administration (VHA) National Database Cohort: Incident Ophthalmic Complications in Giant Cell Arteritis (GCA) Patients with a Negative Temporal Artery Biopsy

Sarah Chung,[1] Meredith Morcos,[2] Scott Pollock,[1] and Bernard Ng[3], [1]University of Washington Division of Rheumatology, Seattle, WA, [2]University of Washington Division of Rheumatology, Seattle, [3]University of Washington, Veterans Affairs Puget Sound Health Care System, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: This study aimed to identify the incidence of ophthalmic complication of giant cell arteritis (GCA) among subjects with negative temporal artery biopsy (TAB) and to determine if duration of prednisone exposure prior to GCA diagnosis was associated with the development of ophthalmic complication in TAB-negative subjects.

Methods: The Veterans Health Administration (VHA) national database was queried for subjects between 1999-2017 with 1) ICD-9 or -10 diagnosis code for GCA 2) procedure code for TAB and 3) ICD-9 or -10 diagnosis code for blindness, anterior or posterior ischemic optic neuropathy (AION; PION), or branch or central retinal artery occlusion (BRAO; CRAO) accrued up to 1 year after GCA diagnosis date. TAB result (positive or negative) was reviewed manually and recorded. Prescription data regarding prednisone dosage, dispense date relative to GCA diagnosis and date that TAB was performed were collected. Logistic regression models were run using Stata 11.2.

Results: 11,820 subjects in the database had an ICD-9 or -10 diagnosis code for GCA; incident accrual of an ICD-9 or ICD-10 code for ophthalmic complication within 1 year following GCA diagnosis date was 4.5% (n=528) of the total GCA cohort. 25% (n=2,929) of the total GCA cohort had TAB performed in the VHA system; incident ICD-9 or -10 code for ophthalmic complication was significantly higher in subjects who underwent TAB (6.6%; $p< 0.001$; Table 1) and significantly higher in those with positive TAB (9.7%; $p< 0.05$; Table 1). Age, TAB laterality, and TAB length did not affect the outcome variable of incident ophthalmic complication after GCA diagnosis. Compared to a reference group of prednisone initiation 0-14 days prior to GCA diagnosis, the likelihood of accruing an ICD-9 or -10 code for ophthalmic complication within 1 year after GCA diagnosis was increased with delayed prednisone dispense dates relative to GCA diagnosis and reached statistical significance when prednisone initiation occurred 14-28 days after GCA diagnosis (OR 2.3, CI 1.01-5.34; Table 2).

Table 1. Incident accrual of ICD-9 or -10 diagnosis code of blindness, ischemic optic neuropathy, or retinal artery occlusion within 1 year after GCA diagnosis code. Percentages pertain to corresponding category (TAB performed or not; TAB result positive or negative).		
	Incident ophthalmic complication	
Was TAB performed? Total n=11,820	**No**	**Yes**
No	8,541 (96.3%)	332 (3.7%)
Yes	2,751 (93.4%)	196 (6.6%)
	p<0.001	
Was TAB positive? Total n = 2,929	**No**	**Yes**
No	2,465 (93.8%)	164 (6.2%)
Yes	271 (90.3%)	29 (9.7%)
	p<0.05	

Table 2. Logistic regression of prednisone exposure relative to GCA diagnosis on incident ophthalmic complication within 1 year of GCA diagnosis among subjects with negative TAB. Total subjects with negative TAB n=2,629; total observations 1,734. Prednisone exposure as a categorical variable is producing the reported odds ratio when compared to the reference category (0-14 days before GCA diagnosis).			
Prednisone dispensed relative to GCA diagnosis ICD-9/-10 code date	N (total n=1,734)	**Odds Ratio** (OR)	**p-value** (95% CI)
>42 days after	8 (0.5%)	--	--
28-42 days after	4 (0.2%)	--	--
14-28 days after	51 (2.9%)	2.3	p=0.046 (1.01-5.34)
0-14 days after	468 (26.8%)	1.1	p=0.524 (0.75-1.74)
0-14 days before	1,203 (68.9%)	*Reference*	--

Conclusion: In the Veterans Health Administration national database, incident ophthalmic complication within a year following GCA diagnosis occurred in 6.2% of subjects with negative TAB per pathology report despite prednisone exposure. Among subjects with negative TAB, the odds of developing an ophthalmic complication increased the later prednisone was initiated; this association reached significance in subjects who initiated prednisone 14-28 days after GCA diagnosis.

GCA Prevalence by Age, Gender and Race

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bisphosphonates have been used to treat disorders of bone metabolism for several years. A common adverse reaction associated with their use constitutes a transient acute-phase response mediated by increased pro-inflammatory cytokine release. This can affect up to 40% of patients and is characterized by fever, joint

swelling, and orbit inflammation. GCA is a condition characterized by granulomatous inflammation involving medium-to-large sized arteries. Pro-inflammatory cytokines are known to play a significant role in its pathogenesis. A case report linking the development of GCA with bisphosphonate use was recently published. We sought to describe the prevalence of GCA after bisphosphonate administration to further explore this possible relationship.

Methods: We used the 20% Medicare random sample data (including Part A and Part B) from between 2008 and 2014 to identify elderly patients who received either zoledronate or ibandronate infusions and subsequently developed GCA. We used two ways to identify such patients. In the first method we included patients who had the diagnosis of GCA claimed within 28 days of the infusion and again within 90 days of the initial diagnosis. In the second method we included patients who had a temporal artery biopsy performed within 28 days of the infusion and subsequently had a GCA diagnosis claimed within 90 days of their biopsy being performed. ICD-9-CM diagnosis codes were used to define diagnosis claims and Healthcare Common Procedure Coding System (HCPCS) code was used to identify the biopsy claim.

Results: We identified 677,901 claims for zoledronate and 87,643 for ibandronate out of which 546 and 206 respectively met our criteria for a diagnosis of GCA. Hence, the prevalence of GCA was 0.08% and 0.24% after zoledronate and ibandronate administration respectively. The prevalence of GCA was highest in the 75-85 years old age group with 0.1% for zoledronate and 0.3% acid for ibandronate. We found the prevalence to be higher in females compared to males for zoledronate (0.11% vs 0.03%) as well as for ibandronate (0.24% vs 0.2%). Racially, Hispanics compared to other races had the highest prevalence after zoledronate administration (0.11%), while Caucasians had the highest prevalence for ibandronate (0.25%). Looking at the regional level the highest prevalence was in the northeast for zoledronate (0.1%) and west for ibandronate (0.33%).

Conclusion: Clinicians should be cognizant that there could be an association between bisphosphonate therapy and the subsequent development of autoimmune reactions including GCA. This association may not follow the trend of preference for the Caucasian and Midwest populations as previously described. Further studies are needed to better elucidate this relationship and describe if differences exist in the incidence of GCA after treatment with different bisphosphonate therapies.

Abbreviations: CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; GCA, giant cell arthritis; PMR, polymyalgia rheumatic; TAB, temporary artery biopsy; TA, temporary artery
a Suspected incident GCA defined as GCA claim following at least one year of continuous enrollment with no GCA claims
b Primary Care includes Internal Medicine, Family Medicine, Geriatric Medicine, General Practice, Physician Assistant, Nurse Practitioner, Hospitalist
c Surgeon includes general surgery or vascular surgery
d 536 missing data for healthcare provider specialty
e Only among those beneficiaries who did not have the procedure/test/diagnosis in the prior period (if the procedure/test/diagnosis is on the same date as the first GCA claim, it is considered prior)
f Percent, and Agresti and Coull 95% confidence intervals
g Among beneficiaries with a GCA claim before the TAB; provider specialty categorized from the first GCA claim

Background/Purpose: Giant cell arteritis (GCA) has traditionally been diagnosed by a combination of symptoms, clinical findings, laboratory results, and temporal artery biopsy. More recently, imaging studies have proven to be useful for the diagnosis. The purpose of our study was to describe the diagnostic workup for GCA in clinical practice among Medicare beneficiaries in the United States.

Methods: We conducted a cohort study of Medicare beneficiaries enrolled between 2011 and 2016, using a 5% representative sample. Beneficiaries with incident suspected GCA were identified by requiring at least one year of continuous enrollment in Part A and B prior to the first GCA-related claim, and the specialty of the provider who filed the claim was determined by the referring physician NPI number. We estimated the proportion of beneficiaries with procedures 90 days before or after the initial GCA claim, including temporal artery biopsy (TAB), temporal artery (TA) ultrasound (US), other imaging including MRA, CTA, and PET/CT of different vascular territories, and laboratory tests including CRP and ESR. Diagnosis of polymyalgia rheumatica (PMR) the year before or after the initial GCA claim was also ascertained. Agresti and Coull 95% confidence intervals were calculated for the proportions.

Results: Incident suspected GCA was identified in 9,159 beneficiaries; 71.6% women, 88.1% white, 7.7% African American, with mean age 77.0 (SD: 9.2). Initial GCA-related claims were filed by primary care providers (43.0%), ophthalmologists (20.4%), neurologists (12.6%), surgeons (6.1%), rheumatologists (4.9%), and other types of providers (13.0%); provider specialty from the initial claim was not available for 536 beneficiaries. Among beneficiaries with incident suspected GCA, 19.8% (95%CI: 19.0, 20.6) underwent TAB, 1.2% (95%CI: 1.0, 1.4) had US of the TA, and 10.0% (95%C: 9.4, 10.6) underwent other imaging within 90 days before or after the initial claim. Laboratory tests included CRP (19.4%; 95%CI: 18.6, 20.3) and ESR (27.6%; 95%CI: 26.6, 28.5). PMR was suspected or diagnosed in the year before or after the initial GCA claim for 11.6% (95%CI: 11.0, 12.3), though notably higher for patients seen by rheumatologists (32.8%; 95%CI: 28.5, 37.4). Among beneficiaries who underwent TAB, 46.3% (95CI: 43.6, 49.0) had

a GCA diagnosis claim during the 30 days following the TAB, potentially reflecting the biopsy result; among patients seen by rheumatologists, 57.1% (95%CI: 46.5, 67.2) had a GCA diagnosis claim within 30 days after the TAB. Details by provider specialty are shown in Table 1.

Conclusion: Medicare beneficiaries with suspected GCA did not commonly undergo TAB, imaging studies, and laboratory tests for ESR and CRP between 2012 and 2016, suggesting that clinical criteria were primarily used during diagnostic workup. GCA claims were most often first filed by primary care physicians and uncommonly first filed by rheumatologists. Our results suggest that guidelines for diagnosis of GCA in the United States are warranted. Development of Fast-Track Clinics for GCA to assure rapid access to a multidisciplinary team lead by rheumatologists are also highly recommended.

Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant-cell arteritis (GCA) is a large-vessel vasculitis affecting patients >50 years, whose origin remains widely unelucidated. Recent studies demonstrated that myeloid disease-related somatic mutations were frequent in healthy aged patients, defining the concept of clonal hematopoiesis. Those mutations, especially *JAK2*^{V617F}, which occur even more frequently in patients with atherosclerosis, are suspected of inducing monocyte/macrophage inflammatory responses through IL-1β and IL-6 secretion. Because GCA pathogenesis involves myeloid cells and inflammatory cytokines, and JAK/STAT was shown to be a major inflammatory pathway, we aimed to analyze characteristics of GCA patients with associated myeloproliferative neoplasms (MPNs).

Methods: We conducted a nationwide multicenter retrospective study, including 17 patients with MPN-associated GCA (cases) and 50 GCA patients without MPN (controls), matched for age and sex. All patients satisfied the American College of Rheumatology criteria. Clinical characteristics, laboratory parameters and outcomes were analyzed and compared between groups.

Results: The most frequent MPNs associated with GCA were essential thrombocytosis (n=11), primary myelofibrosis (n=2), polycythemia vera (n=2) and chronic myelomonocytic leukemia (n=1). One case had an isolated *JAK2*^{V617F} mutation without myeloproliferation.*JAK2*^{V617F} mutation was found in 88% of cases with a median [IQR] various allele frequency of 14.5% [4.6–47.2]. Seven cases were diagnosed with MPN before GCA (median 18 [4–44] months), 1 simultaneously, and 9 after (median 12 [5–54] months). MPN–GCA cases, compared to controls, respectively, had less frequent constitutional symptoms (35% vs. 76%; p=0.003), less frequent cephalic symptoms (70% vs. 96%; p=0.003) and scalp hyperesthesia (23% vs. 56%; p=0.003), but more frequent monocular blindness (18% vs. 2%; p=0.04). GPA–MPN case's platelet counts were significantly higher (491 [346–654] vs. 376 [299–475] $\times 10^9$/L; p=0.03); however, their temporal artery biopsy-positivity rates were comparable (p=0.91).

First-line therapy mostly relied on oral prednisone and aspirin for cases and controls, and did not differ between groups. No patient received JAK inhibitors during follow-up. Relapse-free survival was comparable for the 2 groups. Immunosuppressants were used as glucocorticoids-sparing agents for 12% in each group, with methotrexate being the most frequently prescribed. Mortality was higher for GCA–MPN cases (29 vs. 2%; p=0.003) with shorter overall survival (log-rank test, p=0.008), compared to GCA controls.

Conclusion: Essential thrombocytosis is the most frequent MPN associated with GCA. A high platelet count at GCA diagnosis should lead to a search for JAK2*V617F* mutation. Compared to controls, GCA patients with MPN seem to have a poorer prognosis with a low overall survival, probably due to the MPN or associated comorbidities.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been historically difficult to develop effective diagnostic strategies and criteria in giant cell arteritis (GCA). While temporal artery biopsy was previously thought of as a diagnostic standard, there has been increasing recognition of so-called 'biopsy negative' GCA. As such, the disease has become increasingly challenging

Table 2. The multivariable predictive model for the clinical diagnosis of GCA. Receiver-Operator Characteristic = 0.774.

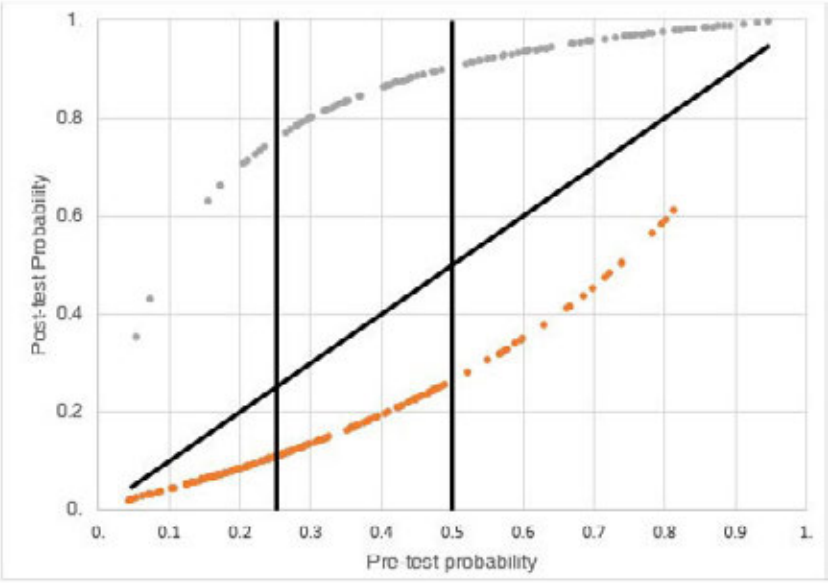

Figure 1. MRISA pre/post-test diagnostic curve. Orange points denote the post-test probability of disease in those who had a negative MRISA using the generated predictive model; grey points for those who had a positive MRISA. The two vertical lines indicate cases that would be included/excluded with calculated probabilities of disease of 0.25 and 0.5 respectively.

to accurately investigate and diagnose. MRI of the scalp arteries (MRISA) has been demonstrated to be more sensitive than temporal artery biopsy, but it's utility in the diagnosis of 'clinical GCA' is thus far unknown.

Methods: This analysis considered a retrospective cohort of 324 patients who had been previously referred to a rheumatologist for evaluation of possible GCA. The clinical information of 171 of these patients was made available from a previous clinical trial; the remaining 153 were consented for participation in a prospective GCA diagnostic database. A clinical diagnosis, regardless of agreement with American College of Rheumatology (ACR) criteria or biopsy, was used as the gold standard. Data concerning clinical features, inflammatory markers, imaging, and biopsy results were extracted for analysis. Best subset forward selection was used to create a multivariable logistic regression model to predict the diagnosis of GCA. Using this model, disease probabilities were calculated and the positive/negative predictive value (PPV/NPV) of MRISA in the diagnosis of clinical GCA was determined.

Results: As seen in table 1, univariate analysis demonstrated that those diagnosed with clinical GCA were older, more likely to have jaw claudication or vision loss, and had higher ESR and/or CRP than those without the diagnosis. An abnormal MRISA was strongly associated with the diagnosis of GCA (OR 19.82, 95% CI 10.5-37.41). Multivariable logistic regression demonstrated that increasing age, the presence of headache, temporal artery tenderness, jaw claudication, vision loss, log(CRP), and the lack of symptoms of PMR were all predictive of the diagnosis of GCA with an area under the receiver-operator curve of 0.774, 95% CI 0.719 - 0.829 (table 2). When a calculated probability of 25% or greater was considered a positive diagnosis, the model was 91.1% sensitive and 46.2% specific for the diagnosis of GCA; at 50% or greater it was 48.2% and 85.4% respectively. This compared to 54.6% and 66.0% using the 1990 ACR criteria. MRISA was found to have 64.7% sensitivity and 91.5% specificity for the clinical diagnosis of GCA. For those determined to be disease negative using the 25% cut-off, a negative MRISA was found to have an 93.5% NPV to rule out GCA; the 50% cut-off was found to have 80.9% NPV (see figure 1).

Conclusion: Multivariable logistic regression was able to fairly model the clinical diagnosis of GCA. MRISA was found to be less sensitive and more specific than previously reported in other studies in the diagnosis of biopsy positive GCA patients; this likely reflects that within this cohort the diagnosis was contaminated by MRISA being used to direct the diagnosis. Regardless, given the high NPV in those of low to medium pre-test probability of GCA, MRISA can assist in ruling out the diagnosis of GCA and avoid temporal artery biopsy.

A Ten-Year Retrospective Review of Temporal Artery Biopsy Lengths in Alberta

Raymond Chu,[1] Caylea Foster,[2] Mohsin Ali,[3] Todd Chaba,[1] Jason Soo,[1] Alison Clifford,[1] Jan Willem Cohen Tervaert,[1] and Elaine Yacyshyn[1], [1]University of Alberta, Edmonton, Canada, [2]University of Calgary, Calgary, Canada, [3]Harvard, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Temporal arteritis or giant cell arteritis (GCA) is a large vessel vasculitis that involves extracranial arteries. The historical gold standard for diagnosis is a temporal artery biopsy (TAB) which has potential for false negativity. Current guidelines recommend biopsy lengths of at least one cm with no suggestion of an upper limit. The purpose of this study is to review all biopsy lengths performed in the province of Alberta, Canada to identify an ideal biopsy length as well as other predictors of a positive diagnosis of GCA.

Methods: A retrospective chart review was performed on patients who had undergone a TAB procedure in 22 sites between January 1st, 2008 to January 1st, 2018.Data extracted included patient's age sex, levels of inflammatory markers (ESR and CRP), side of biopsy, post-fixation length and final pathological diagnoses. Predictors of positive pathology were modelled using logistic regression. Stata 14.1 (StataCorp) was used for data analysis.

Results: A total of 1203 biopsies were identified over the decade. Median age was 73 (quartile range [QR], 64–80) years, with 806 (67%) female patients. A total of 235 (20%) biopsies were diagnosed as GCA, with median biopsy length of 1.3 cm (QR, 0.9–1.8 cm). Biopsy lengths between sites ranged between 0.8 cm (QR, 0.6–1.1 cm) to 2.2 cm (QR, 1.5–3.3 cm). Univariate analysis noted increased age (odds ratio [OR] 1.04 per year, 95% CI, 1.02–1.05; $p < 0.001$), ESR (OR 1.01 per unit, 95% CI, 1.01–1.02; $p < 0.001$), CRP (OR 1.01 per unit, 95% CI, 1.01–1.01; $p < 0.001$) and biopsy lengths (OR 1.25 per cm, 95% CI, 1.06–1.46; $p = 0.007$) were associated with positive GCA diagnosis. In multivariate analysis, only age (OR 1.04 per year, 95% CI, 1.02–1.05; $p < 0.001$) and CRP (OR 1.01 per unit, 95% CI, 1.00-1.01; $p < 0.001$) remained statistically significant predictors of a positive GCA diagnosis. We noted an increasing odds ratio for a positive biopsy with increasing length of biopsy up until 2.00–2.49 cm (OR 2.79 per cm 95% CI, 1.10 – 7.09).

Conclusion: This study indicates the optimal upper end of temporal artery biopsy length is between 2.00-2.49 cm. We note the highest OR of a positive biopsy is associated with biopsies of this length, with longer biopsies not providing additional diagnostic yield to justify risks. Our study also shows that age, ESR, CRP and TAB length were significant independent predictors of pathological diagnosis.

Temporal Artery Biopsy Lengths in Alberta: Which Surgical Subspecialty Achieves Optimal Biopsy Lengths?

Raymond Chu,[1] Caylea Foster,[2] Mohsin Ali,[3] Todd Chaba,[1] Jason Soo,[1] Alison Clifford,[1] Jan Willem Cohen Tervaert,[1] and Elaine Yacyshyn[1], [1]University of Alberta, Edmonton, Canada, [2]University of Calgary, Calgary, Canada, [3]Harvard, Boston, MA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Temporal arteritis or giant cell arteritis (GCA) is a large vessel vasculitis that involves extracranial arteries. Diagnosis requires a combination of clinical manifestations including symptoms of (scalp tenderness, claudication, visual disturbances), in the context of elevated inflammatory markers, in patients > 50 years of age. The gold standard of diagnosis continues to be a temporal artery biopsy. There is varying evidence regarding an ideal

biopsy length, although current guidelines recommend at least 1 cm, with some evidence suggesting longer biopsies being ideal. The purpose of our study is to investigate whether biopsies performed in the province of Alberta, Canada are meeting guideline recommendations and whether different surgical subspecialties affect results of biopsies.

Methods: A retrospective chart review was performed on patients who had undergone a TAB procedure in 22 sites between January 1st, 2008 to January 1st, 2018. Data extracted included location of biopsy, post-fixation length, final pathological diagnoses and surgical subspecialty of individual performing biopsy. Predictors of positive pathology were modelled using logistic regression. Stata 14.1 (StataCorp) was used for data analysis.

Results: A total of 1203 biopsies were identified over the decade. Of these biopsies, we were able to identify the surgical specialist who performed the biopsy of 1003 biopsies. General surgery performed 428 (70 positive [16.36%]) positive biopsies with median length of 1 cm (QR, 0.7 – 1.5), Ophthalmology performed 393 (100 positive [25.45%]) biopsies with median length of 1.6 cm (QR, 1.2 – 2.1), Plastic Surgery performed 162 (28 positive [17.28%]) biopsies with median length of 1.2 cm (QR, 0.8 – 1.7), Otolaryngology performed nine (one positive [11.11%]) biopsies with median length of 1.3 cm (QR, 0.3 – 1.5), Vascular Surgery performed eight (one positive [12.50%]) biopsies with median length of 3 cm (QR, 1.85 – 3.35), Family Medicine surgical assistants performed two (zero positive [0%]) biopsies with median length of 0.825 cm (QR, 0.65 – 1) and Neurosurgery performed one biopsy at 0.8 cm, which was negative for GCA. Univariate analysis noted ophthalmology as the only surgical subspecialty that was associated with positive GCA diagnosis with OR 1.74, 95% CI, 1.24 – 2.46; p = 0.001. We found that of the 22 sites who performed at least 31 biopsies, median lengths ranged between 0.8 cm to 2.2 cm.

Conclusion: This analysis evaluated the various surgical specialties who complete temporal artery biopsies. The surgical specialty with the highest yield of positive temporal artery biopsies was Ophthalmology, who perform the longest biopsies amongst surgical subspecialties and has the highest positive yield for a GCA diagnosis. Our study also indicates there are institutions in the province of Alberta who consistently do not meet the one cm biopsy length recommendations. This baseline data will inform further practice management for optimal biopsy lengths.

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

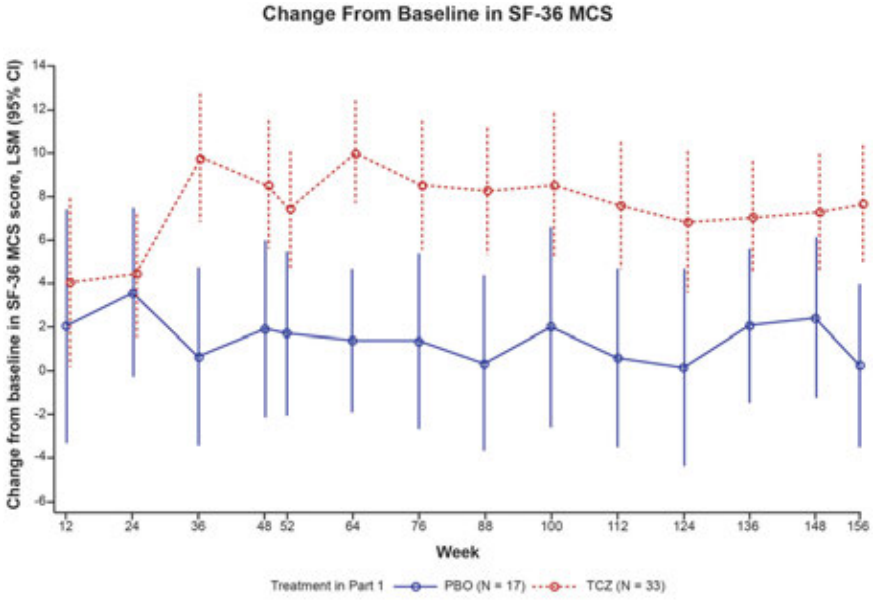
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with giant cell arteritis (GCA) treated with tocilizumab (TCZ) plus prednisone tapering achieved higher rates of sustained glucocorticoid (GC)-free remission and had lower cumulative GC doses than patients treated with prednisone tapering alone in part 1 of the 52-week, double-blind GiACTA trial.[1] During therapy, patients who received weekly TCZ reported improvement in the 36-item Short-Form Health Survey (SF-36) Mental Component Summary (MCS) and Physical Component Summary scores and FACIT-Fatigue scores that were statistically significant and clinically meaningful compared with patients who received prednisone alone.[2] The objective of this analysis was to analyze whether such benefit in SF-36 MCS was maintained in patients originally assigned to receive TCZ in comparison with those originally assigned to receive placebo (PBO) plus a 26- or 52-week prednisone taper (PBO group) among patients who achieved clinical remission at week 52 and maintained treatment-free clinical remission in the 2-year, long-term extension of GiACTA.

Methods: At the end of part 1 of GiACTA, patients entered open-label part 2, in which GCA therapy (including initiation/termination of open-label TCZ and/or GCs) was given at the investigator's discretion according to disease status. The change from baseline in SF-36 MCS score was compared for combined original TCZ (n = 33) and PBO (n = 17) patients who achieved clinical remission at week 52 and maintained treatment-free (no TCZ or GCs) clinical remission in part 2 using a repeated-measures model. The minimal clinically important difference (MCID) for SF-36 MCS is >2.5.[3]

Results: During treatment, SF-36 MCS scores in all 50 patients who maintained treatment-free clinical remission in part 2 had diverged between the TCZ and PBO groups as early as 36 weeks after baseline, with greater improvements evident in the TCZ group (Figure 1). The difference in least squares mean (LSM) change between TCZ and PBO was statistically significant at week 52 (p = 0.016) and maintained at weeks 100 (p = 0.023) and 156 (p = 0.0019). The LSM difference (95% CI) between TCZ and PBO at weeks 52, 100, and 156 was 5.6 (1.1-10.2), 6.5 (0.9-12.1), and 7.4 (2.9-11.9), respectively, exceeding the MCID.



Patients who achieved clinical remission at week 52 and maintained clinical remission while remaining free from GCA treatment (TCZ or GCs) are included. LSM; Least squares mean. MCS, mental component summary; PBO, placebo; SF-36; Short-Form 36. TCZ, tocilizumab.

Conclusion: Among patients who maintained treatment-free clinical remission during part 2 of GiACTA, those originally assigned to receive TCZ plus a prednisone taper during part 1 maintained statistically significant and clinically meaningful improvements in SF-36 MCS up to week 156 compared with those originally assigned to receive PBO plus a prednisone taper in part 1. This was true even though neither of the patient groups received TCZ or GC treatment after they achieved clinical remission at week 52.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) remains challenging to diagnose as false negative temporal artery biopsy (TAB) can occur. Color doppler ultrasonography (CDUS) of the temporal, axillary and carotid arteries is useful when GCA is suspected. A wide range of sensitivities and specificities of CDUS are reported, with better results when performed by a trained sonographer using high resolution equipment. The new GCA probability score (GCAPS) is intended to risk-stratify patients with suspected GCA into those with high probability versus low probability of GCA.

This study aimed to 1) compare CDUS results against TAB with final diagnosis of the specialist as the reference standard; 2) determine how GCAPS performs in relation to the final diagnosis.

Methods: A retrospective chart review was performed for all patients with suspected GCA who had a CDUS from July 2017 to May 2019, at Hopital du Sacre-Coeur de Montreal (University of Montreal). All exams were performed by the same ultrasonographer with the Zonare Z One Ultra Ultrasound System™ using a linear array probe (L14-5Mhz). Data collected included patient characteristics, clinical presentation, physical examination, bloodwork, initial clinical suspicion of GCA (low or moderate/high) and CDUS results of the temporal, carotid and axillary arteries. TAB results and final diagnosis as determined by the treating physician were documented. GCAPS was retrospectively calculated if all the required items were available.

Results: A total of 56 patients had a CDUS examination during the specified time period; amongst them, 31 patients had a TAB. GCA was the final diagnosis in 20 patients, as determined by the treating specialist. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were 95.0%, 100%, 100%, 97.3% for CDUS; and 81.3%, 100%, 100%, 83.3% for TAB, respectively. There were no false positive CDUS in patients without GCA. Only 1 patient with GCA had a negative CDUS while the TAB was positive. A false negative TAB was observed in 3 patients with GCA, all of which had a positive CDUS. In those 3 patients with negative TAB and positive CDUS, one had extra-cranial large-vessel vasculitis on PET/CT, the second had abnormal temporal arteries on physical examination (tenderness and pulselessness) and the third had classic cranial symptoms of GCA with thrombocytosis and elevated inflammatory markers. False negative rate of CDUS was 5% as opposed to 18.7% for TAB.

GCAPS score of < 9.5 points was found in 1 patient with GCA and 21 patients without GCA. At a cut-off value of 9.5 points, Se, Sp, PPV and NPV for the GCAPS were 95.0%, 65.6%, 69.3% and 95.5% respectively. In our cohort, GCA was the final diagnosis for all patients with a GCAPS ≥ 13 points.

Conclusion: CDUS of the temporal, carotid and axillary arteries showed a high Se and Sp and helped to identify TAB negative patients with GCA. We validated that the GCAPS is a useful clinical tool in our patient population; a score < 9.5 points makes the diagnosis of GCA unlikely.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Table 1. Patient Characteristics at GCA Diagnosis and Treatment Received

	With PMR Symptoms (n = 32)	Without PMR Symptoms (n = 28)
Age, mean (SD)	67.0 (9.3)	71.8 (9.1)
Female, n (%)	23 (71.9)	20 (71.4)
White, n (%)	27 (84.4)	26 (92.9)
Clinical manifestations at disease onset, n (%)		
Localized headache	28 (87.5)	19 (67.9)
Scalp tenderness	15 (46.9)	11 (39.3)
Jaw claudication	16 (50.0)	15 (53.6)
Amaurosis fugax	5 (15.6)	6 (21.4)
Blurry vision	9 (28.1)	9 (32.1)
Permanent vision loss	2 (6.3)	6 (21.4)
Diplopia	1 (3.1)	1 (3.6)
Weight loss	6 (18.8)	14 (50.0)
PMR symptom(s) only, n (%)	2 (6.3)	0
ESR (mm/hr), mean (SD)	67.9 (36.5)	78.3 (29.4)
CRP (mg/L), mean (SD)	63.1 (59.7)	92.4 (84.9)
Positive TA biopsy, n (%)*	13/27 (48.1)	13/24 (54.2)
Disease duration before TCZ initiation, median (IQR), years	0.7 (0.2-1.9)	0.6 (0.2-1.4)
Duration of TCZ treatment (years), median (IQR)	0.6 (0.3-1.3)	0.5 (0.2-1.5)

CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; PMR, polymyalgia rheumatica; TA, temporal artery; TCZ, tocilizumab.
* Of patients with TA biopsies performed.

Table 2. Clinical Outcomes Before and After TCZ Initiation

	With PMR at Diagnosis (n = 32)		Without PMR at Diagnosis (n = 28)	
	Before TCZ Initiation	After TCZ Initiation	Before TCZ Initiation	After TCZ Initiation
Patients with ≥ 1 flare, n (%)	24 (75.0)	11 (34.3)	19 (67.9)	7 (25.0)
With PMR symptom(s)*	21 (65.6)	8 (25.0)	4 (14.3)	2 (7.1)
Without PMR symptom(s)*	3 (9.4)	3 (9.4)	15 (53.6)	5 (17.9)
No. of flares	60	23	42	14
With PMR symptom(s), n (%)*	50 (83.3)	18 (78.3)	7 (16.7)	3 (21.4)
Without PMR symptom(s), n (%)*	10 (16.7)	5 (21.7)	35 (83.3)	11 (78.6)
Annual flare rate (95% CI)†	1.34 (0.84 to 2.13)	0.54 (0.28 to 1.05)	1.59 (0.78 to 3.23)	0.71 (0.29 to 1.74)
Time to flare (years), median (IQR)	0.3 (0.2-0.7)	2.1 (0.6-2.6)	0.5 (0.3-0.8)	2.6 (0.9-2.6)

GC, glucocorticoids; GCA, giant cell arteritis; IQR, interquartile range; PMR, polymyalgia rheumatica; TCZ, tocilizumab.
* Symptoms are after GCA diagnosis.
† Rates are estimated from a Poisson regression model with treatment, age, smoking history and new and relapsing GCA as covariates and random patient effect.

Background/Purpose: Approximately 50% of patients with giant cell arteritis (GCA) also have polymyalgia rheumatica (PMR) symptoms.[1] The purpose of this study was to determine whether the presence of PMR symptoms upon GCA diagnosis impacts GCA clinical outcomes and to evaluate the effectiveness of tocilizumab (TCZ) for controlling PMR symptoms in patients with GCA.

Methods: This was a retrospective analysis of patients with GCA treated with TCZ at a single center (2010-2018). Disease flares, defined as re-appearance of clinical manifestations (eg, cranial or PMR signs or symptoms), were assessed among patients with or without PMR at the time of GCA diagnosis. PMR symptoms during disease flares were assessed before and after TCZ initiation.

Results: A total of 60 patients with GCA (71.7% female; mean age, 69.3 years) were followed for a mean (SD) of 2.3 (2.2) years. At diagnosis, 32 had PMR symptoms (2 patients with PMR symptoms only). **Table 1** shows baseline patient characteristics. Among patients with PMR at diagnosis, 75% (n = 24) had a total of 60 flares before TCZ initiation and 34.3% (n = 11) had a total of 23 flares after TCZ initiation (**Table 2**). Among 28 patients without PMR at diagnosis, 67.9% (n = 19) had a total of 42 flares before TCZ initiation and 25% (n = 7) had a total of 14 flares after TCZ initiation (**Table 2**). TCZ was associated with a significant reduction in the annual flare rate both in patients with PMR symptoms ($P = 0.003$) and without PMR symptoms ($P = 0.03$) at diagnosis (**Table 2**). Median time to flare was significantly longer after initiation of TCZ in patients with PMR symptoms (hazard ratio [HR] [95% CI]: 0.18 [0.06 to 0.53]; $P = 0.002$) and without PMR symptoms (HR [95% CI]: 0.21 [0.05 to 0.87]; $P = 0.032$) at diagnosis. Before TCZ initiation, PMR symptoms were observed in 55.9% of flares (57/102) occurring in 43 patients (71.1%). After TCZ initiation, PMR symptoms were observed in 56.8% of flares (21/37) occurring in 18 patients (30%).

Conclusion: TCZ improved clinical outcomes in patients with GCA regardless of the presence or absence of PMR symptoms at diagnosis. These real-world findings suggest that TCZ is also effective in patients with GCA who have symptoms of PMR.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: GCA may affect the aorta and lead to dissections and aortic aneurysms. TCZ treatment may control aortic inflammation as demonstrated by CRP normalization and imaging data. However, limited data is available on the histopathological findings obtained from patients who undergo surgery because of aortic complications during TCZ.

Methods: We performed a retrospective case series of 5 patients with GCA treated with TCZ, who presented in our clinic between 2011 and 2019. Three patients underwent surgery and aortic specimen underwent histopathologic examination

Results: We report on 5 female patients with a mean age of 69 $\pm$ 18 yrs, diagnosed with GCA involving the aorta. 3 patients presented with aneurysms at the time of diagnosis, 1 patient with aortic aneurysm and another patient with dissection developed these complications during TCZ therapy. An enlargement of pre-existing aneurysms was observed in 2 patients after stopping TCZ (after a time interval of 10 weeks and 4 months, respectively). Both patients were not eligible for surgical intervention and died during F/up. 3 patients (2 with aortic aneurysm, 1 with dissection) underwent surgery after having been on TCZ on 7 weeks, 9 months, and 4 years. Imaging before surgery showed remission on MRI and PET-CT, respectively. At the time of surgery, all 3 patients had a normal CRP. Histopathological evaluation of the aortic wall showed persistent lymphoplasmacellular infiltrates (predominantly $CD3^{+}CD4^{+}$ T cells in patient 1) and, in addition, giant cells in pat 2 and 3.

Conclusion: Aortic aneurysms and dissections may occur in patients with aortic involvement during treatment with TCZ, suggesting that regular imaging is necessary in this patient population. Residual inflammation might present an additional risk factor for aortic complications.

tics, reasons for TCZ introduction and discontinuation, concomitant therapies and response to treatment. For each patient we also evaluated potential eligibility for GiACTA trial. For statistical comparisons non-parametric tests were used.

Results: 34 patients (28 women, mean age 71.3±10 years) were included. Table 1 summarizes GCA clinical features, tools for GCA diagnosis (imaging and/or biopsy), and reasons for TCZ introduction. Mean disease duration before TCZ introduction was 23±31.3 months. Only 11 patients met both GiACTA inclusion and exclusion criteria at TCZ introduction. 26 patients were followed up for 3 months, 22 for 6 months and 15 for 12 months. Mean prednisone (PDN) dose at TCZ introduction was 23.23±13.84 mg. Mean PDN dose was 8.41±7.10 mg ($p < 0.001$) at month 3, 4.95±5.63 mg ($p = 0.02$) at month 6, and 2.66±2.7 mg ($p = 0.05$) at month 12. PDN was stopped in 9 patients (2 at

month 3, 5 at month 6, 2 at month 12) due to optimal disease control with TCZ alone. At TCZ introduction 4 patients were already on methotrexate (MTX). MTX was subsequently stopped in 2 patients (1 at month 3, 1 at month 6) due to disease control. TCZ was temporarily held off in 2 patients due to zoster reactivation and in 2 patients due to mild bacterial infections, and definitively stopped after 2 months (when PDN dose was still high) in 2 patients due to severe bacterial infections. No patient experienced severe neutropenia or liver enzymes elevation. In no case TCZ was judged inefficient.

Conclusion: Our data confirm TCZ is highly effective in GCA treatment and has a significant steroid-sparing effect. In our real-life retrospective study TCZ was also shown to be a safe option in patients with relapsing or refractory GCA.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) administered subcutaneously weekly or every 2 weeks with a 26-week prednisone taper (TCZ-QW or TCZ-Q2W) was superior to placebo given with a 26-week or 52-week prednisone taper for the achievement of sustained glucocorticoid (GC)-free remission in patients with giant cell arteritis (GCA) in part 1 of the double-blind phase 3 GiACTA trial.[1] Part 2 was a 2-year, open-label, long-term extension in which TCZ could

Data are presented as mean or mean (SD).

be stopped or started as needed to achieve disease control. In this analysis, the impact of TCZ dosing interruption was assessed on pharmacokinetic (PK) and pharmacodynamic (PD) end points.

Methods: PK was assessed as predose serum TCZ concentrations (C_{trough}), and serum PD biomarkers measured were interleukin-6 (IL-6), soluble IL-6 receptor (sIL-6R), C-reactive protein (CRP), and erythrocyte sedimentation rate (ESR). To assess the impact of TCZ on PK/PD during initial drug exposure and at steady state, data were assessed in patients receiving their first 4 doses in part 2 after a dosing interruption of ≥4 weeks (TCZ-break group) and in patients who had received TCZ QW ≥12 weeks (TCZ-QW group). The 4-week dose interruption was included to allow drug levels to fall to negligible levels in patients treated with TCZ in part 1, thereby allowing data from patients who received placebo or TCZ in part 1 to be pooled for part 2 analyses. The 12-week dosing period in part 2 was based on the time to reach steady state after TCZ-QW dosing as determined in part 1. Data from part 1 were used for comparison. PD parameters from patients who experienced flare in part 2 were also examined to determine the prognostic value of biomarkers, regardless of treatment assignment.

Results: Among 250 patients who received treatment in part 1 (TCZ-QW, n = 100; TCZ-Q2W, n = 49; PBO+26, n = 50; PBO+52, n = 51), 215 entered part 2. Seventy patients had a ≥4-week dosing interruption, received the first 4 consecutive TCZ-QW doses in part 2, and were included in the TCZ-break group. During the first 4 weeks of dosing, TCZ C_{trough} levels were comparable in the TCZ-break group and the part 1 TCZ-QW group (Figure). In part 2, TCZ C_{trough} and PD biomarkers after the first initial 4 doses and at steady state were comparable to the values at the end of part 1 (Table). Patients who experienced flare while on TCZ had low levels of CRP and ESR. Patients who experienced flare while not receiving TCZ had higher levels of CRP and ESR compared to those who experienced flare on TCZ, where flares occurred despite low levels of these inflammatory markers.

Conclusion: Restarting TCZ-QW treatment after dose interruption resulted in exposure and PD biomarker profiles similar to those observed with double-blind TCZ-QW treatment, suggesting there were no negative effects for patients with GCA who stopped and restarted TCZ. Low levels of CRP and ESR confirm that despite adequate control by TCZ, these biomarkers are not the sole indicators of flare in GCA patients receiving TCZ, but, in the absence of TCZ, they could serve as indicators of risk for flare.

Survival Trends in Giant Cell Arteritis: A Population-based Cohort Study

Thomas Garvey,[1] Cynthia Crowson,[1] Matthew Koster,[2] Eric Matteson,[3] and Kenneth Warrington[2], [1]Mayo Clinic Rochester, Rochester, [2]Mayo Clinic Rochester, Rochester, MN, [3]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate survival trends in patients with giant cell arteritis (GCA) diagnosed over a 60-year period.

Methods: We assembled a population-based incidence cohort of patients with GCA diagnosed between 1950 and 2009 based on American College of Rheumatology 1990 GCA classification criteria. Patients aged ≥ 50 years with elevation of erythrocyte sedimentation rate or C-reactive protein and radiographic evidence of large vessel vasculitis attributed to GCA were also included. Patients were followed until death, last contact, or December 31, 2018. Survival trends were analyzed by grouping patients according to year of GCA diagnosis into the following categories: Group A (years of diagnosis (1950-1979), Group B (1980-1989), Group C (1990-1999) and Group D (2000-2009). Mortality rates were estimated using the Kaplan-Meier method and were compared with expected mortality rates for persons of the same age, sex, and calendar year estimated using Minnesota population life tables.

Results: The study population included 245 incident cases of GCA; 194 (79%) women and 51 (21%) men, with mean age (±SD) 76.2 ± 8.3 years and median follow-up 10.6 years. Based on comparison to Minnesota lifetables, there

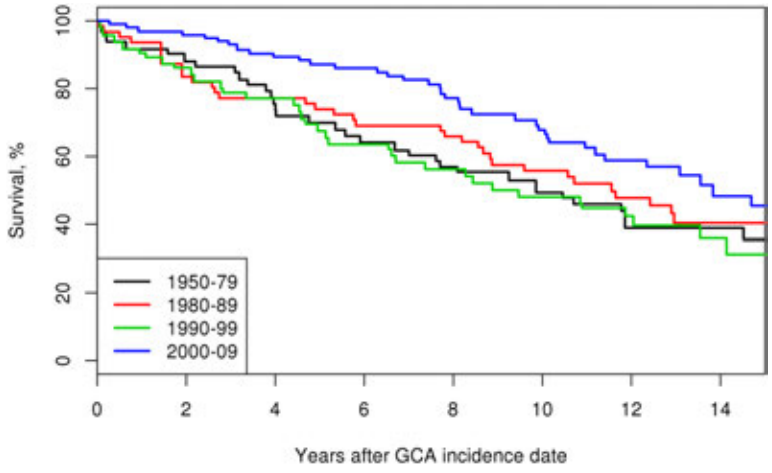

Figure 1. Age and sex adjusted comparison of survival of Olmsted County residents with incident GCA by time period.

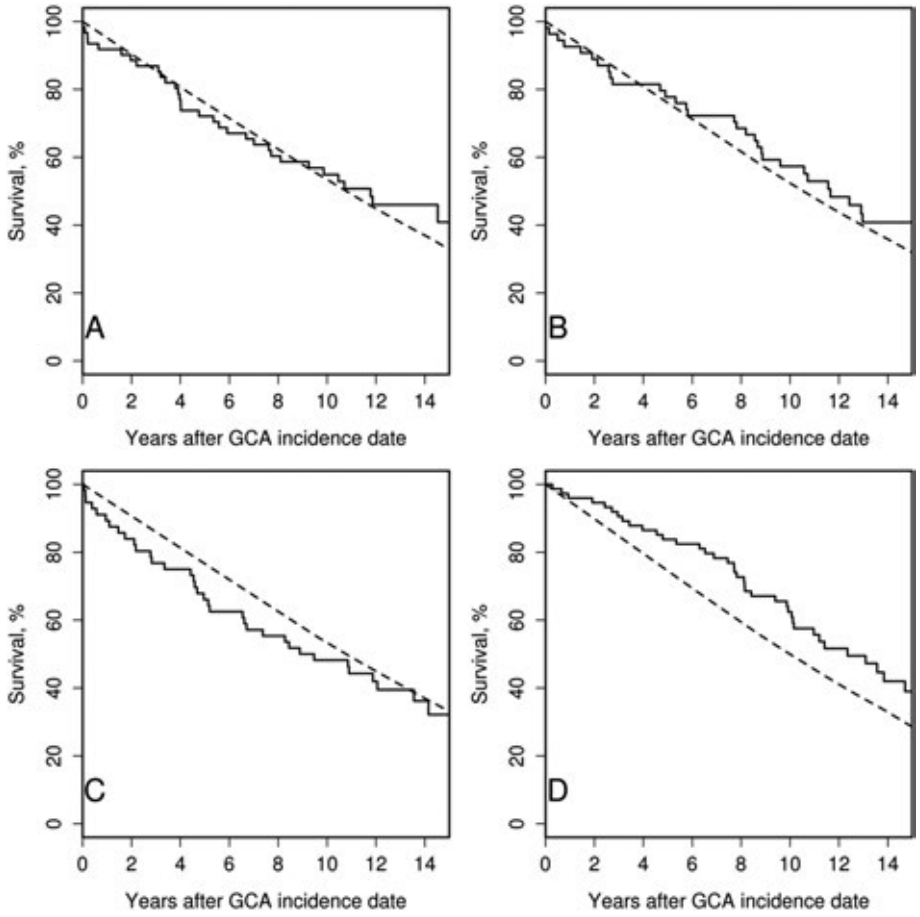

Figure 2. Survival of Olmsted county residents with incident GCA in 1950-2009 compared to expected rates from Minnesota lifetables (observed: solid line; expected dashed line) by time period (A: 1950-79, B: 1980-89, C: 1990-99, D: 2000-09).

was no overall difference in survival when comparing the GCA cohort to the general population. The 2, 5 and 10 year survival rates (95% CI) were 89% (86, 93), 76% (70, 81) and 56% (50, 63) respectively with a standardized mortality ratio of 0.99 (0.86, 1.14). The standardized mortality ratios for Groups A, B, C and D were 0.83 (0.57, 1.17) p=0.30; 0.92 (0.63, 1.3) p=0.63; 1.21 (0.85, 1.69) p=0.25 and 0.70 (0.50, 0.95) p=0.02, respectively.

Conclusion: In this population based-cohort of patients with GCA diagnosed over a 60-year period, the survival of patients diagnosed in recent years was significantly better than that of the general population. The explanation for this novel finding is unclear, but likely to be multifactorial. Improved treatment of co-morbidities, mitigation of glucocorticoid toxicity such as osteoporosis, and improved management of aortic complications may be contributing to improved survival in GCA.

Giant Cell Arteritis with Intracranial Vasculitis: A Case Series

Catalina Sanchez-Alvarez,[1] Alexander Hawkins,[1] Matthew Koster,[2] Vance T. Lehman,[3] Cynthia Crowson,[1] and Kenneth Warrington[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, MN, [3]Mayo Clinic, Rochester

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

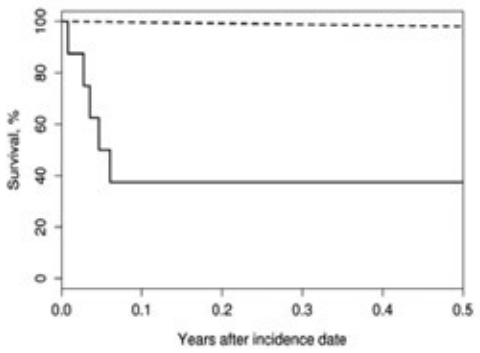
Background/Purpose: Giant cell arteritis (GCA) is a large vessel vasculitis that primarily affects the aorta and its branches. Extracranial branches of the carotid artery are frequently affected; however, intracranial involvement in GCA is rare.

To determine the clinical features and outcome of patients with intracranial giant cell arteritis (IC-GCA).

Methods: A retrospective medical record review was performed to identify all patients with IC-GCA from 1/1996 through 5/2018. Demographic, clinical, laboratory, radiographic, and treatment data at baseline and subsequent follow-up visits were collected. Data was summarized using descriptive statistics

Results: The study cohort included 9 patients with IC-GCA (78% male, mean [±SD] age 72.1 [±7.9] years). 8 of 9 patients had positive temporal artery biopsies. One patient with negative biopsy had evidence of large-vessel GCA on thoracic CT angiography. The mean time from onset of GCA to intracranial involvement was 17 months (±38). All patients had neurologic symptoms, 33% (n:3) had a stroke and 22% (n:2) had a transient ischemic attack. IC-GCA was diagnosed by cranial imaging in 8 patients and by autopsy in one. Cranial imaging modalities used included magnetic resonance angiography (n=8), CT angiography (n=2) and cerebral angiography (n=2). Intracranial vasculitis most commonly affected the internal carotid artery 78% (N=7) followed by the, vertebral artery 56% (n=5), posterior cerebral artery 56% (n=5), middle cerebral artery 44% (n=4), anterior cerebral artery 33% (n=3) and posterior inferior cerebral artery 11% (n=1). Stenosis was present in 89%, occlusion in 33%, dilatation in 11%, and wall thickening in 11%. All patients received glucocorticoids. For treatment of intracranial disease additional agents included: cyclophosphamide (67%), Tocilizumab (22 %). Despite treatment, outcomes for patients with IC-GCA were poor. Five of nine patients died during a mean length of follow-up of 2.4 months. Comparing IC-GCA patient survival to the

Image 1. Survival of 9 patients with intracranial GCA compared to expected rates from US population lifetables (observed: solid line; expected dashed line)



expected rates from the U.S. population (Figure 1), the standardized mortality ratio (95% CI) for IC-GCA was 179.7 (58.3, 419.4); p< 0.001.

Conclusion: Although rare, IC-GCA is associated with significant morbidity and mortality. It occurs predominantly in men, presenting with ischemic cerebrovascular events. Current treatment strategies appear to be of limited efficacy for IC-GCA.

PET/CT Vascular Findings at Baseline and Six Months in Patients with Newly Diagnosed Giant Cell Arteritis

Anthony Sammel,[1] Edward Hsiao,[1] Geoff Schembri,[1] Elizabeth Bailey,[1] Katherine Nguyen,[1] Janice Brewer,[1] Beatrice Janssen,[1] Leslie Schrieber,[1] Peter Youssef,[2] Clare Fraser,[3] and Rodger Laurent[1], [1]Royal North Shore Hospital, Sydney, Australia, [2]Royal Prince Alfred Hospital, Sydney, Australia, [3]Save Sight Institute, Sydney, Australia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: PET/CT is a useful modality to diagnose GCA but there is limited knowledge as to how inflammatory vascular findings evolve on follow-up scans. This cohort study aimed to determine the change and clinical significance in vascular wall tracer (FDG) uptake in GCA patients from diagnosis to six-months.

Methods: This study included a subset of patients from the previously reported Giant Cell Arteritis and PET Scan (GAPS) cohort (Sammel et al. Arthritis Rheumatol. 2019). Patients were newly suspected of having GCA and were prospectively enrolled if they had either 1) mural or periadventitial small vessel inflammation on temporal artery biopsy or 2) unequivocal large vessel vasculitis on baseline CT angiogram. Only patients with a clinical diagnosis of

	Vascular territory	Baseline	6 months	p value
Visual Grade	All vessels	0.81	0.32	<0.01
	Cranial arteries	0.73	0.26	0.01
	Supra-aortic large arteries	1.29	0.41	<0.01
	Thoracic aorta	0.71	0.27	<0.01
SUV_{max}/SUV_{LA}	All vessels	1.26	1.18	0.16
	Vertebral arteries	1.24	1.01	0.03
	Supra-aortic large arteries	1.22	1.14	0.25
	Thoracic aorta	1.38	1.37	0.90

Notes:
P value was calculated using the two-tailed paired samples t-test
SUV was not reported for the temporal, maxillary or occipital arteries to avoid the potential for partial volume errors
Supra-aortic large arteries included subclavian, axillary, carotid and brachiocephalic arteries
Cranial arteries included temporal, maxillary, occipital and vertebral arteries
Visual grade and SUV_{max}/SUV_{LA} definitions are provided in the abstract text

Table 1. Mean visual and standard uptake value (SUV) vascular scores on baseline and six month PET/CT

GCA were included in the final analysis. PET/CT from the vertex to diaphragm was performed at baseline and at six-months. A single PET-experienced physician, blinded to clinical, biopsy and study inclusion details, reported the grade of vascular FDG uptake for 18 artery segments (0 = none, 1 = minimal/equivocal, 2 = moderate, 3 = very marked). The maximum standard uptake value (SUV) for each vessel was compared to the mean SUV in the left atrium to give an SUV_{max}/SUV_{LA} ratio. Patients and clinicians were unaware of the six-month PET vascular findings and were followed for 12-months.

Results: 24/64 GAPS patients met inclusion criteria, of whom 15 consented to six-month PET/CT and had a clinical diagnosis of GCA. From baseline to six-months, the mean vascular uptake grade per patient decreased from 0.81 to 0.32 (Table 1) with significant reductions in all vascular territories ($p < = 0.01$). The average SUV_{max}/SUV_{LA} per patient decreased non-significantly from 1.26 to 1.18 ($p = 0.16$). Over this period the mean CRP fell from 70 to 9 mg/L and ESR fell from 59 to 15 mm/hr. 5/15 (33%) patients had persistent grade 2 (moderate) uptake in at least one artery on the six-month scan. Compared with their counterparts, these 5 patients had a non-significantly higher mean CRP (12 vs 8 mg/L), ESR (16 vs 15 mm/hr) and were taking a lower mean dose of prednisone (8 vs 12 mg). 3 were taking concomitant methotrexate and one an IL-6 inhibitor. None of these 5 patients experienced a clinical flare from 6-12 months but 60% had flares in the preceding six-months.

Conclusion: PET/CT vascular scores decreased in the first six-months following diagnosis of GCA. One-third of patients had significant ongoing vascular uptake at six-months but this did not predict future clinical flare.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Imaging has been recently recognized as a tool equivalent to the temporal artery biopsy in diagnosing giant cell arteritis (GCA). Amongst a variety of imaging modalities, color Doppler Ultrasonography (CDS) is the most convenient. We aimed to evaluate the frequency of cranial- and aortic arch-artery involvement in GCA using CDS.

Methods: We performed CDS examination of cranial and aortic arch arteries in new, clinically diagnosed GCA patients between October 2013 and April 2019, using a Philips IU22 with 5–17.5 MHz linear probe or Philips Epiq 7 with 5–18.5 MHz linear probe. Temporal, facial, occipital, thyroid, carotid, vertebral, subclavian, and axillary arteries were examined bilaterally. A halo with positive compression sign was considered a positive finding. Additionally, the thickness of intima-media complex was measured. .

Results: During the 67-month period 212 newly diagnosed GCA patients (63.2% females, median (IQR) age 75.4 (67.2-80.8) years) underwent vascular CDS evaluation. CDS was performed prior to glucocorticoid initiation in 201 patients (94.8%), and delayed by a median (IQR) of 1 (1-3) days (range 1-6 days) for the rest.

The CDS was positive in 208 (98.1%) patients in at least one of the examined arteries. Temporal arteries, involved in 167 (78.8%) patients, were the most commonly affected vessels. Extracranial large vessel involvement (LVV) was found in 70 (33.0%) patients (30 patients had isolated LVV, and 40 concomitant temporal artery involvement). Among the 142 patients without LVV, 11(5.2% of the studied cohort) had involvement of cranial arteries other than temporal arteries (we found facial, occipital and thyroid artery involvement in 9, 3 and 2 patients, respectively). Table 1 shows the frequency of individual vessel involvement and the intima-media thickness of inflamed and non-inflamed arteries.

Conclusion: CDS of eight preselected cranial and aortic arch arteries provides a high diagnostic yield in GCA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have few real-world data on the natural history and care of patients with giant cell arteritis (GCA). The objective of this observational study (ARTEMIS) was to describe the characteristics and care of patients with GCA in real-life settings in France.

Methods: This cross-sectional, non-interventional, multicentre, single-visit survey was conducted among hospital-based physicians specialized in internal medicine or rheumatology. Investigators enrolled consecutive patients ≥50 years old who consulted for GCA and were under treatment. Information on patient characteristics and diagnostic journey, diagnostic methods and specific GCA treatments were collected on an electronic case report form. Newly-diagnosed GCA was defined as diagnosis-to-visit interval < 6 weeks. Descriptive statistics were used for quantitative and qualitative data.

Results: Over the 3-month inclusion period (August–November 2018), 306 patients were recruited (females: 67%, mean age: 74.0±7.9 years) by 69 investigators (internists: 85%, rheumatologists: 15%) and 53 hospital departments; 13% had newly-diagnosed GCA and overall mean follow-up was 21.0±26.4 months. The original referral of patients to specialized centres was from general practitioners (56%), ophthalmologists (10%), neurologists (7%), emergency physicians (5.6%), internists (4%) and rheumatologists (5%). The most common medical histories were hypertension (46%), psychiatric disorders (10%), dyslipidemia (12%), diabetes (9%) and osteoporosis (6%). Initial GCA presentations included cranial symptoms (89% of patients), constitutional symptoms (74%), polymyalgia rheumatica (48%), and other extra-cranial manifestations (35%). Temporal artery biopsy, high-resolution temporal artery Doppler, 18FDG-PET and aortic angio-CT were performed for 85%, 31%, 26% and 30% of patients, respectively, and contributed to the GCA diagnosis for 67%, 53%, 70% and 37%. All patients received glucocorticoids (GCs) and GC therapy was ongoing for 89%. The mean total cumulative oral GC dose, assessed for 87 patients, was 5179±4987 mg. In all, 87 (28%) patients also received ≥1 adjunctive medication, mainly methotrexate (58 patients [19%]) and/or tocilizumab (47 patients [15%]). Overall, 40% of patients had ≥1 relapse (mean number of relapses: 1.7±1.0) after a mean time to a first relapse of 13.3±12.8 months. Thirty-seven percent had ≥1 comorbidity related to or aggravated by GCs, most frequently diabetes (12%), hypertension (10%), osteopenia/osteoporosis/osteoporotic fractures (7%), insomnia (3%) and infections (3%).

Conclusion: This observational, cross-sectional study of a large number of recently diagnosed patients provides insight into current medical practices for GCA in France. Despite extensive use of large-vessel imaging, the proportion of patients with a diagnosis of non-cranial GCA is low (11%). The substantial proportion of patients with relapsing disease results in high cumulative doses of GCs. Methotrexate and tocilizumab were the most commonly prescribed adjunct medications.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's arteritis (TAK) and giant cell arteritis (GCA) are the two major forms of large vessel vasculitis. The study objectives were to compare clinical symptoms of the head, neck, and upper extremities between TAK and GCA in association with vascular activity on ^{18}F-fluorodeoxyglucose positron emission tomography (FDG-PET) and arterial damage by magnetic resonance angiography (MRA).

Methods: Patients with TAK and GCA were recruited into a prospective observational cohort. Clinical and imaging assessments were performed within a 24-hour period, blinded to each other. Abnormal PET activity was defined as arterial FDG uptake > liver by visual assessment. Vascular damage was defined as stenosis, occlusion, or aneurysm in specific angiographic territories by MRA. Clinical features present on the day of imaging assessment (carotidynia; posterior neck pain; vertigo; lightheadedness, frontotemporal or posterior headache; arm claudication), were compared to corresponding imaging angiographic abnormalities by MRA and PET in TAK and GCA separately. Presence of clinical features at any point during disease, were studied in association with the number of damaged neck arteries (carotid and vertebral arteries). The association between clinical symptoms and imaging features was assessed by generalized mixed model regression, adjusting for repeated study visits. The association between historical symptoms and number of affected neck arteries was assessed by ordinal regression.

Results: 111 participants (TAK=56; GCA=55) contributed data from 270 study visits. Patients with TAK were more likely to report carotidynia than patients with GCA [12 (21%) vs 0 (0%), p< 0.01]. Clinical features and imaging findings are detailed in the Table. Carotidynia was associated with abnormal activity on FDG-PET (Sensitivity 27%, Specificity 96%, p< 0.01) and less strongly associated with damage on MRA (Sensitivity 11%, Specificity 95%, p=0.02) in TAK. Posterior neck pain was more common in patients with GCA than TAK [10 (18%) vs 4 (7%), p=0.09]. Posterior neck pain was associated with vertebral artery PET activity in GCA (p=0.03). Vertigo was associated with vertebral artery damage in TAK (p< 0.01), whereas lightheadedness was associated with carotid artery damage in GCA (p< 0.01). Posterior headache was associated with vertebral PET activity in GCA (p=0.04). Frontotemporal headache was not associated with carotid PET activity or damage in either disease. Arm claudication was associated with subclavian damage in both TAK and GCA (p< 0.01 and p=0.02 respectively). Patients with increased burden of damaged neck arteries were more likely to experience lightheadedness (p=0.03), positional lightheadedness (p< 0.01), posterior neck pain (p=0.02) or a major CNS event (p< 0.01) at some point during the disease.

Table. Association of Clinical features with Imaging Findings In TAK and GCA

Symptom	Arterial Territory	LVV	Image	TN	TP	FN	FP	P value	Sensitivity	Specificity
Carotidynia	Carotid	TAK	PET	166	10	27	7	<0.01	27% (14-44%)	96% (92-98%)
			MRA	90	12	95	5	0.02	11% (6-19%)	95% (88-98%)
		GCA	PET	No patients with GCA had carotidynia						
			MRA							
Posterior Neck pain	Vertebral	TAK	PET	208	0	1	3	1	0% (0-97%)	98% (96-100%)
			MRA	159	0	42	3	1	0% (0-8%)	98% (95-100%)
		GCA	PET	244	3	22	1	0.03	12% (3-31%)	100% (98-100%)
			MRA	229	0	25	4	1	0% (0-14%)	98% (96-100%)
Vertigo	Vertebral	TAK	PET	209	0	1	2	1	0% (0-97%)	99% (97-100%)
			MRA	161	1	41	1	<0.01	2% (0-13%)	99% (97-100%)
		GCA	PET	231	0	25	14	1	0% (0-14%)	94% (91-97%)
			MRA	222	3	21	11	0.7	12% (3-32%)	95% (92-98%)
Lightheadedness	Carotid	TAK	PET	156	4	33	16	0.96	11% (3-25%)	91% (85-95%)
			MRA	92	13	94	3	0.08	12% (7-20%)	97% (91-99%)
		GCA	PET	166	2	99	2	0.95	2% (0-7%)	99% (96-100%)
			MRA	175	1	82	3	<0.01	1% (0-6%)	98% (95-100%)
Posterior Headache	Vertebral	TAK	PET	206	0	1	4	0.98	0% (0-97%)	98% (95-99%)
			MRA	159	1	40	3	0.97	2% (0-13%)	98% (95-100%)
		GCA	PET	238	3	21	4	0.04	12% (3-32%)	98% (96-99%)
			MRA	229	3	22	4	0.11	12% (2-31%)	98% (96-99%)
Frontotemporal Headache	Carotid	TAK	PET	165	4	33	8	0.84	11% (3-25%)	95% (91-98%)
			MRA	92	7	99	3	0.23	7% (3-13%)	97% (91-99%)
		GCA	PET	149	7	63	18	0.92	10% (4-19%)	89% (83-93%)
			MRA	163	11	73	13	0.53	13% (7-22%)	93% (88-96%)
Arm claudication	Subclavian	TAK	PET	142	8	19	42	0.03	29% (14-50%)	77% (70-83%)
			MRA	89	42	60	9	<0.01	41% (31-51%)	91% (83-96%)
		GCA	PET	129	25	81	32	0.57	23% (16-33%)	80% (73-86%)
			MRA	126	49	75	10	0.02	40% (31-49%)	93% (87-96%)

TN = True Negative; TP = True Positive; FN = False Negative; FP = False Positive

Conclusion: The distribution of clinical symptoms and association with vascular imaging abnormalities differs between TAK and GCA. In both diseases, vascular symptoms have low sensitivity and high specificity for imaging abnormalities. These findings may help clinicians predict likely associated PET and MRA findings based on the presence of a specific symptom in patients with TAK and GCA.

Risk of Potential Glucocorticoid-Related Adverse Events in Patients with Giant Cell Arteritis: Results from a US-based Electronic Health Records Database

Jennie Best,[1] Amanda M. Kong,[2] Oth Tran,[2] and Margaret Michalska[1], [1]Genentech, Inc., South San Francisco, CA, [2]IBM Watson Health, Cambridge, MA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Oral glucocorticoids (OGC) have been the mainstay of treatment for giant cell arteritis (GCA). However, OGCs are associated with several adverse events (AEs). The purpose of this study was to estimate the risk of potential OGC-related AEs in patients with GCA.

Methods: This retrospective, observational cohort study utilized the 2008-2017 IBM Explorys Electronic Health Records database which includes laboratory values. Inclusion criteria included age ≥ 50 years with ≥ 2 GCA diagnoses ≥ 7 days apart, 1 OGC prescription within 6 months of the first GCA diagnosis (index date = date of first OGC prescription) followed by a second OGC prescription, no other autoimmune disease requiring high-dose OGCs, no exposure to anti-tumor necrosis factor or anti–interleukin-6 therapies, ≥ 1 C-reactive protein (CRP)/erythrocyte sedimentation

Table 1. Adverse Events During the 12-Month Post-Index Period, Stratified by OGC Daily Dose

	Dose Q1 ≥ 1.00 to ≤ 13.75 mg N = 184	Dose Q2 > 13.75 to ≤ 25.00 mg N = 184	Dose Q3 > 25.00 to ≤ 40.00 mg N = 198	Dose Q4 > 40 mg N = 161
Patients without type 2 diabetes and without HbA1c ≥ 7.5 in the pre-index period, n	120	136	130	110
With type 2 diabetes diagnosis or HbA1c ≥ 7.5 in the post-index period, n (%)	9 (7.5)	16 (11.8)	16 (12.3)	27 (24.5)
Maximum HbA1c value across HbA1c lab results during post-index, mean (SD)	7.75 (2.46)	8.30 (2.86)	8.25 (2.42)	8.61 (3.09)
Patients with diabetes diagnosis in the pre-index period but without HbA1c ≥ 7.5 in the pre-index period, n	31	18	40	15
With worsening diabetes with HbA1c ≥ 7.5 in the post-index period, n (%)	10 (32.3)	6 (33.3)	20 (50.0)	4 (26.7)
Patients without blood glucose level ≥ 200mg/dL in the pre-index period, n	173	169	179	147
With blood glucose level ≥ 200mg/dL in the post-index period, n (%)	13 (7.5)	15 (8.9)	24 (13.4)	22 (15.0)
Adverse events in the post-index period, n (%)				
Serious infection requiring hospitalization for infection and/or IV antibiotics	31 (16.8)	39 (21.2)	44 (22.2)	40 (24.8)
Serious infection requiring IV antibiotics	29 (15.8)	33 (17.9)	42 (21.2)	35 (21.7)
Serious infection requiring hospitalization for infection	6 (3.3)	12 (6.5)	12 (6.1)	8 (5.0)
Cataracts	22 (12.0)	27 (14.7)	34 (17.2)	35 (21.7)
Gastrointestinal bleeding or ulcer	11 (6.0)	11 (6.0)	13 (6.6)	19 (11.8)
Patients with BMI in pre- and post-index, n	171	162	181	141
Increase in BMI by 5, n (%)	7 (4.1)	5 (3.1)	9 (5.0)	9 (6.4)

BMI, body mass index; HbA1c, hemoglobin A1c; IV, intravenous; Q, quartile.

rate (ESR) laboratory test and 12 months of data available pre- and post-index. Potential AEs assessed during the 12 months post-index were descriptively summarized across cohorts of patients based on quartiles (Q) of mean daily dose of OGCs measured over 6 months post-index among this patient sample (Q1: ≥ 1.00 to ≤ 13.75 mg; Q2: > 13.75 to ≤ 25.00 mg; Q3: > 25.00 to ≤ 40.00 mg; Q4: > 40.00 mg). Potential AEs included type 2 diabetes (T2D) diagnosis, hemoglobin A1c (HbA1c), blood glucose level, serious infections, cataracts, gastrointestinal bleeding or ulcer and increases in body mass index (BMI). Actual OGC use by patient could not be confirmed and is a limitation of this study.

Results: Mean age of the 785 eligible patients was 76 years (SD 9); 70% were female. Mean Deyo Charlson Comorbidity Index score at baseline was 1.57 (SD 2.01). The most common baseline comorbid conditions were cerebrovascular disease, diabetes, chronic pulmonary disease, and renal disease. Mean daily OGC dose was 28.9 mg during the first 6 months post-index. Mean (SD) CRP and ESR during the 12-month follow-up was 5.1 (13.6) and 26.5 (20.7), respectively. The proportion of patients with newly diagnosed T2D or with HbA1c ≥ 7.5 during the 12-month follow-up ranged from 7.5% to 24.5% from OGC daily dose Q1 to Q4 cohorts. The proportion of patients with glucose ≥ 200 mg/dL ranged from 7.5% to 15.0% from Q1 to Q4. Serious infections ranged from 16.8% to 24.8% from Q1 to Q4 and cataract ranged from 12.0% to 21.7% from Q1 to Q4. The proportions of patients with gastrointestinal bleed/ulcer ranged from 6.0% in Q1 to 11.8% in Q4. An increase in BMI of 5 ranged from 4.1% to 6.4% from Q1 to Q4.

Conclusion: In patients with GCA, potential OGC-related AEs increased with increased daily OGC dose. This highlights the need for effective therapies for GCA that reduce the exposure and potential risk of OGCs.

Cardiovascular Treatment and the Incidence of Giant Cell Arteritis (GCA) – a Population-Based Case-Control Study

Aladdin Mohammad,[1] Pavlos Stamatis,[1] and Aleksandra Turkiewicz[2], [1]Lund University, Lund, Skane Lan, Sweden, [2]Lund University, Lund, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The aetiology of giant cell arteritis (GCA) is largely unknown. We aimed to evaluate ACE-inhibitors (ACE-i), angiotensin II receptor blockers (ARBs), beta-blocking agents, calcium antagonists, diuretics or other cardiovascular drugs as risk factors for incident GCA.

Methods: We included 574 biopsy-proven GCA cases diagnosed between Jan 1st2006 and Oct 31st2015 in the Skåne region, Sweden and 5740 controls matched on age, sex and residential area. Using the Swedish Prescribed Drug Register containing all prescribed and dispensed drugs, we identified the GCA cases and controls who had at least one dispensation of the following groups of drugs: ACE-i or ARBs (ATC-code C09), beta-blocking agents (C07), calcium antagonists (C08), diuretics (C03), statins (C10AA) or cardiac therapy (C01) between Jul 1st2005 and the index date (i.e. the date of GCA diagnosis for both cases and their matched controls). To study *incident* drug use,

Table 1. Descriptive data.

	Controls, n=5740	GCA, n=574
Age in index year (years), mean (SD)	71 (8)	73 (8)
Sex, male, n (%)	427 (30)	83 (30)
Income, in 100 SEK, mean (SD)	1.78 (2.95)	1.65 (1.4)
Education, up to 9 years, n (%)	477 (35)	100 (36)
Education, 10-12 years, n (%)	527 (38)	117 (42)
Education, 13-14 years, n (%)	146 (11)	22 (8)
Education ,15+ years, n (%)	226 (16)	38 (14)
If married or registered partner, n (%)	1109 (79)	213 (77)
Any diagnosis from group I, n (%)	688 (49)	172 (61)
Myocardial infarction (I25), n (%)	42 (3)	15 (5)
Hypertension (I10), n (%)	303 (22)	89 (32)
Angina pectoris (I20), n (%)	41 (3)	17 (6)
Thrombo-embolic diseases (I80-I82, I74), n (%)	80 (6)	19 (7)
Diabetes mellitus (E10-E14), n (%)	112 (8)	21 (7)

Table 2. Percentage of persons having dispensed the drugs of interest at least once before the index date (the date of GCA diagnosis for cases and the same date for their matched controls).

	Control	GCA
ACE-inhibitors and ARBs	37	34
Beta-blocking	39	36
Calcium antagonists	25	22
Diuretics	41	34

Statins	0.72 [0.60,0.88]	0.64 [0.42,0.98]	0.74 [0.61,0.90]	0.55 [0.28,1.10]	0.79 [0.63,0.97]	0.68 [0.39,1.20]
Cardiac therapy	0.76 [0.60,0.97]	1.02 [0.61,1.71]	0.79 [0.63,1.00]	1.58 [0.72,3.45]	0.80 [0.63,1.02]	1.09 [0.57,2.09]

Table 3. Odds ratios [95% CI] for association between drug exposure and incident GCA. The estimates are from a conditional logistic regression (matching factors: age, sex residential area) adjusted for marital status, education and income.

we performed a second analysis, were all persons that dispensed the any of the drugs listed above at least once between July 1st2005 and Jun 30th2006 were excluded. We used conditional logistic regression adjusted for income, education, and marital status and if being diagnosed with cardiovascular diseases (ICD-10 code from group I). The data on cardiovascular diagnoses were retrieved from Skåne Healthcare Register covering the whole population of the region (including primary care) between the year 1998 and the data of the first dispensation of a cardiovascular drug. A separate regression model was fitted for each drug group of interest. To take into account bias by indication we performed two subgroup analyses, one only among those with a cardiovascular disease, second among those on any cardiovascular drug (ATC code C).

Results: The included persons were on average (SD) 75 (8) years old and 29% were male, 70% were diagnosed with a cardiovascular disease (47% with hypertension, Table 1). Of the GCA cases 71% had at least one dispensation

of any cardiovascular drug before the index date, compared to 74% among controls (Table 2). Among the persons that dispensed at least one drug of interest, 75% had at least one dispensation of a drug from another group (53% among incident users). The odds ratios for the association between drug exposure and GCA were close to 1 for most drugs. The only drug consistently associated with lower odds of GCA were statins with 12% to 40% lower risk of GCA (Table 3).

Conclusion: After taking into account confounding and bias-by-indication, we found that of the evaluated cardiovascular drugs only statins may be associated with lower risk of incident biopsy-proven GCA.

Healthcare Resources Utilization in Giant Cell Arteritis – a Population-Based Study

Aladdin Mohammad,[1] Aleksandra Turkiewicz,[2] Pavlos Stamatis,[1] Carl Turesson,[3] Martin Englund,[2] and Ali Kiadaliri[2], [1]Lund University, Lund, Skane Lan, Sweden, [2]Lund University, Lund, Sweden, [3]Lund University, Malmö, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the healthcare resource utilization (HRU) in patients with giant cell arteritis (GCA) compared with the background population in southern Sweden.

Methods: The study includes patients diagnosed with biopsy-proven GCA between 2001 and 2011 and their randomly selected age-, sex- and residency area matched reference persons (1:10). Data on all healthcare consultations and admissions were extracted from a regional administrative database, the Skåne Healthcare Register, which records data on all healthcare consultations and hospitalizations using the ICD-10 codes. Frequencies of HRU were analysed as numbers and rates of primary healthcare visits, hospital visits and hospitalizations. HRU was assessed from three years prior to index date (i.e. the date of GCA diagnosis for both GCA and their respective matched ref-

Table 1. Incidence rate ratio (95% confidence interval) of different study outcomes (healthcare visits and admission to hospitals) for GCA patients vs. reference subjects.

	Mean no. of visits/hospitalizations during 5-year after index date (95% CI)		Incidence rate ratio (95% CI)
	GCA	References	GCA/References
Any healthcare visit	64.0 (60.6, 67.5)	47.0 (46.1, 47.9)	1.36 (1.29, 1.44)
Primary care physician visit	12.6 (11.9, 13.3)	10.5 (10.3, 10.7)	1.20 (1.13, 1.27)
Primary care non-physician visit	21.0 (18.9, 23.2)	14.9 (14.4, 15.4)	1.41 (1.28, 1.56)
Specialist care physician visit	17.9 (16.9, 18.8)	12.2 (11.8, 12.5)	1.47 (1.39, 1.56)
Specialist care non-physician visit	8.5 (7.5, 9.6)	5.8 (5.5, 6.1)	1.47 (1.29, 1.67)
Hospital admission	2.4 (2.1, 2.6)	1.9 (1.8, 2.0)	1.23 (1.11, 1.36)
Hospital inpatient days	17.1 (15.1, 19.2)	12.2 (11.5, 12.8)	1.40 (1.23, 1.60)

All models were adjusted for sex, age, year of diagnosis, and outcome level over 3-year before index date.

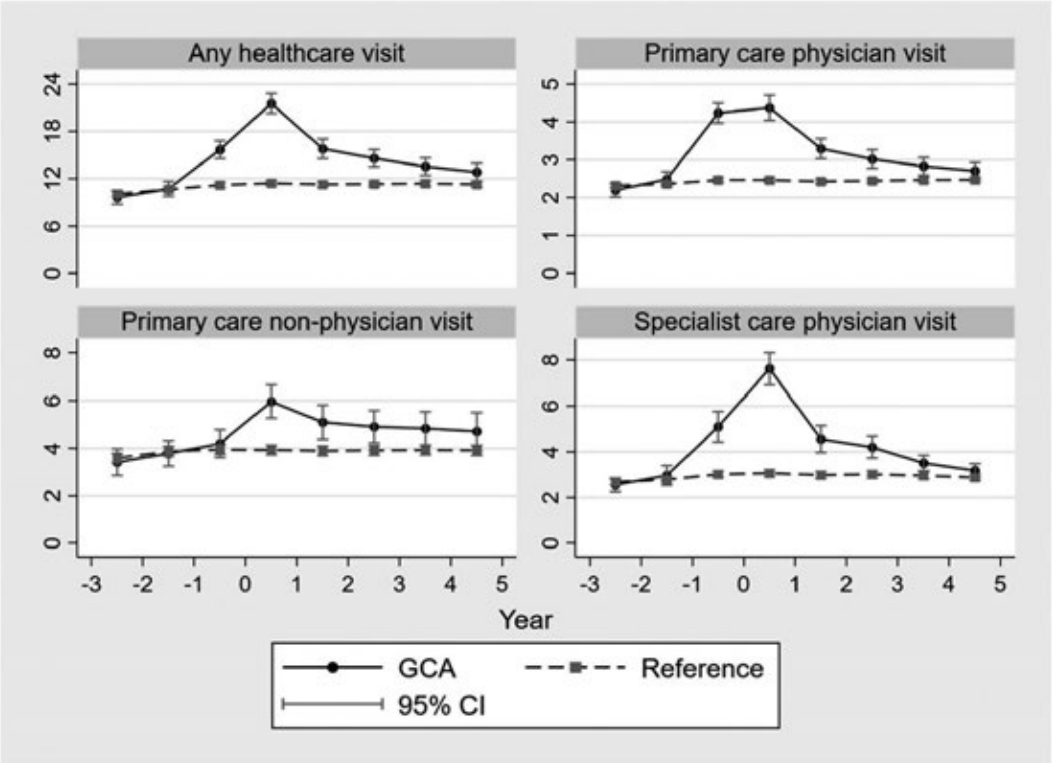

Figure 1. The mean numbers of visits to different level of healthcare providers three years before and five years after date of diagnosis of giant cell arteritis (GCA) or index date for reference subjects.

erence subjects) to five years after. The HRU (i.e. the number of healthcare visits) during 5 years after the index date was analysed using zero-inflated negative binomial regressions assuming the same propensity to use healthcare for both GCA and references and adjusted for sex, age, year of diagnosis, and HRU over 3-year before index date.

Results: The matched cohort included a total of 7,282 subjects (GCA patients, n = 662; references,

n =6,620) with mean (SD) age 75.3 (8.3) years, and 73.4% women. Over 5 years after index date, HRU was higher in patients with GCA compared to reference subjects with incidence rate ratios of 1.36 (95% CI 1.29-1.44) for all visits, 1.21 (1.14-1.28) for primary healthcare physician visits and 1.47 (1.39-1.56) for specialist care physician visits (Table 1). Hospital admissions were more frequent among GCA patients with rate ratios of 1.23 (1.11-1.36) for admissions and 1.41 (1.24-1.60) for inpatient days. Notably, the HRU started to diverge from the year before the index date up to four years after (Figure 1). When stratifying consultations or hospitalization by diagnoses, consultations rates were higher in GCA patients than in reference subjects for the following diagnoses: infections, cardiovascular diseases, respiratory diseases, musculoskeletal, nervous disorders and ear and eye diseases. However, endocrine diagnoses were lower prior to the onset of GCA compared to the period preceding the index date in reference subjects.

Conclusion: In this population-based study, patients with GCA had higher rates of HRU compared to the reference population. The increase in HRU was evident one year before diagnosis and continued over four years after. The systemic inflammatory burden and the adverse effects of treatment may account for the increase in the HRU after GCA diagnosis.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In Giant Cell Arteritis (GCA) two dominant cytokine clusters have been linked to disease activity, IL-6 – IL-17 axis (Th17) and IL-12 – IFN γ axis (Th1). The first one related to systemic symptoms and the second

route responsible for ischemic symptoms. Tocilizumab (TCZ) performs its effect mainly by inhibiting Th17 axis and terminally Th1 route.

Our aim was to evaluate the effect of TCZ on ischemic and systemic symptoms throughout the follow-up.

Methods: Retrospective, multicenter study of 134 patients diagnosed of GCA on treatment with TCZ. We evaluate the efficacy of TCZ by improving ischemic (visual involvement, headache, jaw claudication) and systemic symptoms (fever, constitutional syndrome, polymyalgia rheumatica (PMR)).

Results: We evaluated 134 patients (101 w/33 m) and its main symptoms at TCZ onset, **TABLE**. 73 (54.5%) patients presented PMR followed by headache in 70 (52.2%) cases, constitutional syndrome in 31 (23.1%) and visual involvement in 28 (20.9%) patients. After one month of treatment there was an important clinical improvement, persisting in 13,6% of patients PMR, 10.6% headache and 10.6% visual involvement. Throughout the follow-up, the improvement of ischemic symptoms was slower. At month 12, in 5.6% (4) of patients persisted with visual impairment, and 2.8% (2) patients presented headache and constitutional syndrome. However, the analytical improvement was statistically significant from the first month and sustained during follow-up.

Conclusion: According to the results of our study, we can conclude that in clinical practice, ischemic symptoms take longer to improve than systemic symptoms; being visual affectation the most frequent symptom after 12 months of follow-up.

Background/Purpose: Recently, based on the GiACTA trial results, weekly subcutaneous Tocilizumab (TCZ) has been approved for the treatment of Giant Cell Arteritis (GCA). It has showed to be effective and safety.

Our aim was to compare the efficacy of TCZ according the route of administration.

Methods: Multicenter study of 134 GCA patients in treatment with TCZ. It was performed a comparative study between 2 groups according the route of administration of TCZ, intravenous (IV) or subcutaneous (SC).

Results: We study 134 patients divided in 2 groups: a) IV TCZ, 104 cases and, b) SC TCZ, 30 cases, with a mean age 73.4±8.2 years vs 71.9±10.6 years, respectively (p=0.501). Disease duration, clinical manifestations and acute phase reactants at TCZ onset were similar in both groups with non-statistical difference. 91.7% patients who received SC TCZ achieved prolonged remission after 12 months of treatment (p=0.043). And the glucocorticoid sparing effect of TCZ was greater in the same group, reaching a statistical difference at 3 and 24 months (p=0.017 and p=0.021). Patients under IV TCZ treatment suffered more adverse event during follow up (p=0.043). **TABLE 1** and **2** summarizes the comparative study.

Conclusion: Patients in treatment with SC TCZ, reached prolonged remission after 12 months of treatment and were able to discontinue prednisone dose after 24 months of follow up. The incidence of adverse events was more frequent in the IV TCZ group, without difference in relation to infections.

Our aim was to assess efficacy and safety of TCZ therapy optimization in an unselected wide series of GCA in clinical practice.

Methods: Multicenter study on 134 patients with GCA who received TCZ therapy due to inefficacy or adverse events of previous therapy. Once complete remission was reached and based on a shared decision between the patient and the physician TCZ was optimized in some cases. Complete remission was defined as normalization of clinical an analytical (CRP and ESR) findings. Optimization was done by decreasing the dose and/or prolonging the TCZ dosing interval progressively. We performed a comparison between optimized and non-optimized patients.

Results: We evaluated 134 GCA patients treated with TCZ (101 women/33 men); mean age 73.0±8.8 years. TCZ was administered IV to 106 (79.1%) patients and SC to 28 (20.9%). The initial dose was 8 mg/kg/IV/4 weeks or 162 mg/SC/week, respectively. TCZ was optimized in 42 (31.3%) patients. No demographic, clinical manifestations or laboratory data differences had been found at TCZ onset between both groups **(TABLE1).** After a median [25-75th] follow up of 12 [6-15.5] months, and in a complete remission for 6 [3-12] months; the first TCZ optimization was performed in the optimized group. The median prednisone dose at first TCZ optimization was 2.5 [0-5] mg/day. TCZ IV was optimized from 8 to 4 mg/kg/4 weeks in 11 of 106 (10.4%) and from 162 mg/SC/week to 162 mg/SC/2 weeks in 9 of 28 (32.1%) cases. In **TABLE 2** data of the optimized doses. Five (11.9%) of the 42 optimized cases relapsed. In 4 of these cases, the relapses were treated increasing TCZ up to the pre-optimization dose, and in 1 case the route of administration of TCZ was change (4 mg/kg/4week to 162 mg/SC/week). In 8 of 42 optimized patients (19%), it was possible to withdraw TCZ after complete remission for 30 [16.25-45.75] months. Regarding adverse events, severe infections were less frequent in the optimized group (14.3% vs 11%) with non-statistical significance.

Conclusion: Once remission is reached in GCA patients under TCZ treatment, optimization of TCZ may be performed. Based on our experience it could be performed by reducing the dose with IV TCZ or by prolonging dosing interval with SC TCZ. It seems to be effective and safe.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tocilizumab (TCZ) has been approved for the treatment of Giant Cell Arteritis (GCA). It showed to be effective to induce remission, prevent relapses and decrease the cumulative prednisone dose. However, the glucocorticoids are the mainstay in the acute treatment of GCA.

Our aim was to compare the efficacy and safety of the initial dose of prednisone at the onset of TCZ treatment.

Methods: Retrospective, multicenter study on 134 patients with GCA in treatment with TCZ. We compared two subgroups of patients according to the initial dose of prednisone at TCZ onset. Clinical efficacy, analytical improvement and safety was studied.

Results: We studied 134 patients (101 w/33 m) and made a comparative study between 2 groups: a) TCZ and ≤ 15 mg of prednisone; 68 (50.7%) cases, and b) TCZ and > 15 mg of prednisone, 66 (49,3%) patients. It is summarized

TABLE 1

	PREDNISONE ≤ 15 mg (n=68)	PREDNISONE > 15 mg (n=66)	p

Month 6	2 (3.8)	3 (6.4)	0.664
Month 12	3 (8.1)	6 (18.8)	0.285
Month 24	2 (8.7)	5 (29.4)	0.113
SIDE EFFECTS, n (%)			
Relevant adverse events	8 (11.8)	24 (36.4)	**0.001**
Serious infections	3 (4.4)	13 (19.7)	**0.006**

TABLE 2

	PREDNISONE ≤ 15 mg (n=68)	PREDNISONE > 15 mg (n=66)
SERIOUS INFECTIONS, n (%)		
Cytomegalovirus (bilateral pneumonia)	-	1 (1.5)
Endocarditis	-	1 (1.5)
Facial Herpes Zoster Infection	-	2 (3.0)
Bacterial Infective Bursitis	-	1 (1.5)
Severe Infectious Cellulitis	-	1 (1.5)
Infectious Meningitis	-	1 (1.5)
Infected ulcer	-	1 (1.5)
Infected Necrotizing ulcer	-	1 (1.5)
Pneumonia	2 (2.9)	1 (1.5)
Recurrent urinary infection and sepsis		2 (3.0)
Urinary sepsis	1 (1.5)	1 (1.5)
Anal abscess		1 (1.5)

in TABLE 1. It was no statistical significance according to age, sex and evolution time of disease. In the group receiving > 15 mg of prednisone, the patients presented more visual involvement ($p< 0.001$) at TCZ onset. In terms of prolonged remission and relapses no significant difference was seen between both groups. The risk of presenting adverse effects (11.8% vs 36.4%) and severe infections (4.4% vs 19.7%) was related with the prednisone dose, being more frequent in the group with > 15 mg of prednisone ($p=0.001$ and $p=0.006$, respectively). In TABLE 2 summarizes the infections of our patients.

Conclusion: According with our results, we can conclude that TCZ is equally effective; in terms of prolonged remission and relapses, with doses ≤ 15 mg of prednisone at treatment onset. Being the most important data, the higher risk to develop adverse effects, as well as infections with higher doses of prednisone.

Table 1. Time evolution

Background/Purpose: Tocilizumab (TCZ) has proved to be effective in the management of Giant Cell Arteritis (GCA). Based on results of the GiACTA trial, it has been approved by the FDA and the European Commission for GCA treatment. Nevertheless, almost half of the GiACTA trial patients presented a short time evolution disease.

Our aim was to evaluate the efficacy of TCZ according the time of disease evolution.

Methods: Retrospective, multicenter study of 134 patients with GCA in treatment with TCZ. A comparative study between two groups according to the time from disease diagnosis and TCZ onset was performed.

Results: Our study included 134 GCA patients. TABLE 1 summarizes a comparative study between: a) ≤ 6 months of disease evolution, and b) > 6 months of disease evolution. Non-significant difference in baseline characteristics was found. In terms of visual involvement, we observed more patients affected in the first group (≤ 6 months) (p=0.30). Analyzing clinical improvement non-significant difference was seen during follow-up. At TCZ onset, in the group of ≤ 6 months of evolution, the prednisone dose was higher with a mean dose of 31.3±16.5 mg/d vs 17.7±14.2 mg/d (p< 0.001), however, a similar reduction of corticosteroids was achieved in both groups after 6 months of follow-up. The incidence of adverse events and severe infections was similar in both groups (p=0.132 and p=672 respectively).

Conclusion: In this retrospective analysis, our results support the previously reported efficacy and safety profile of TCZ. We can conclude that TCZ can be used in GCA independently the time of disease evolution.

Visual and Quantitative Assessment of Cranial Arteries on FDG-PET/CT Can Reliably Diagnose Cranial Giant Cell Arteritis

Pieter Nienhuis,[1] Riemer Slart,[2] and Elisabeth Brouwer[3], [1]Dept. of Rheumatology and Clinical Immunology - University Medical Center Groningen, Groningen, Groningen, Netherlands, [2]Dept. of Nuclear Medicine and Molecular Imaging - University Medical Center Groningen, Groningen, Groningen, Netherlands, [3]Department of Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Assessing cranial artery inflammation plays an important role in the diagnosis of cranial giant cell arteritis (GCA). Although an established tool for assessing large vessel vasculitis, fluorine-18-deoxyglucose (FDG) positron emission tomography (PET)/CT imaging is not recommended for detecting cranial artery inflammation. Assessing FDG uptake in the cranial arteries may increase the diagnostic value of FDG-PET/CT for GCA and may provide more detailed information regarding involved arteries and extent of the disease. It may thus provide a viable alternative for Duplex ultrasonography (US) and temporal artery biopsy (TAB) as a first line investigation in GCA.

This study aimed to evaluate the diagnostic accuracy of FDG-PET/CT for the detection of cranial artery inflammation in GCA.

Methods: This retrospective case control study included glucocorticoid-naive TAB positive GCA patients who underwent FDG-PET/CT as part of the diagnostic work-up. Controls were age- and sex-matched melanoma patients in remission with FDG-PET/CT after 6 months follow-up.

To attain high quality PET images on the Siemens Biograph 64 PET/CT, optimal PET image acquisition and reconstruction parameters were determined and applied to all images. Visual assessment by an experienced nuclear medicine physician was based on uptake intensity compared to surrounding tissue on a 0-2 scale (Figure 1). Additionally, FDG uptake in the cranial arteries was quantified by measuring the maximum standardized uptake value (SUVmax) in the target arteries. The temporal arteries (TA), maxillary arteries (MA), vertebral arteries (VA), and occipital arteries (OA) were assessed bilaterally.

Student t and chi-squared tests were used for evaluation of the visual assessment. Receiver operating characteristics (ROC) analysis was performed for evaluation of the quantitative assessment. Cohen's kappa was used to assess agreement of the visual and quantitative assessments.

Results: A total of 24 GCA patients and 24 controls were included. The mean age for both groups was 71 years (SD: 8) and 12/24 were women. Large vessel involvement was seen on PET in 15/24 patients. Duplex US of the temporal artery was performed in 15/24 patients, of which 9 were positive. Median ESR and CRP were 73 ($CI_{95\%}$: 53; 104) mm/h and 73 ($CI_{95\%}$: 37; 110) mg/L, respectively.

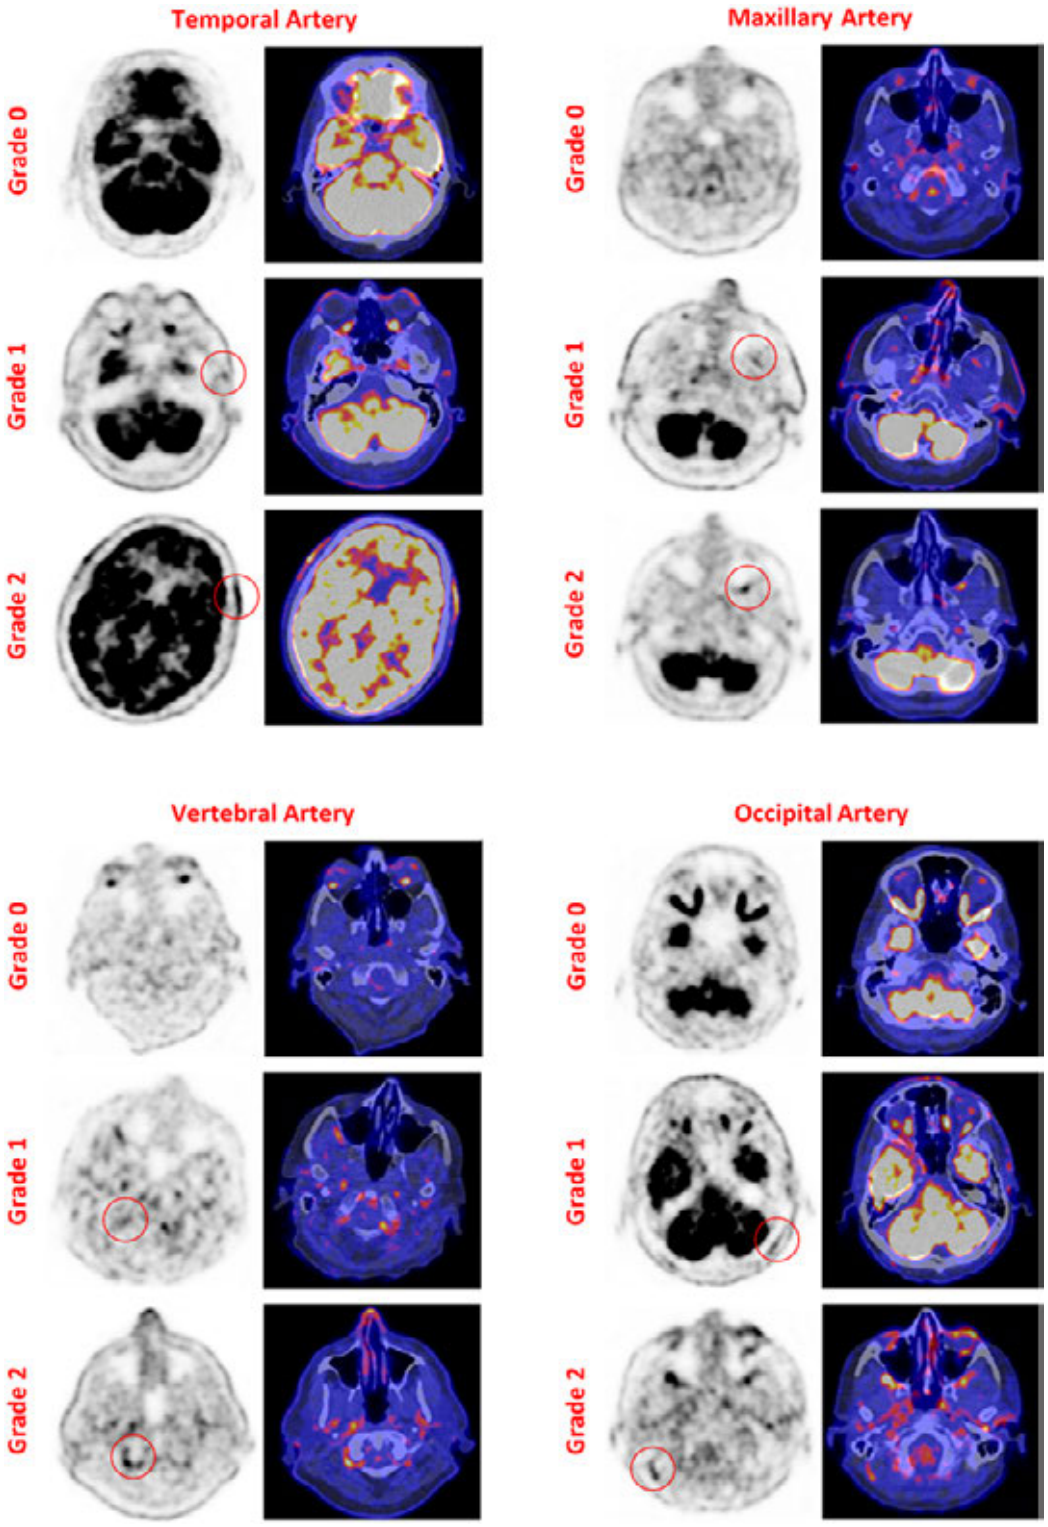

Figure 1. Visual assessment of cranial artery inflammation on FDG-PET/CT. Temporal Artery (TA), Maxillary Artery (MA), Vertebral Artery (VA), and Occipital Artery (OA) were visually scored from 0-2. Scoring definition: 0: no uptake above surrounding tissue; 1: uptake just above surrounding tissue; 2: uptake significantly above surrounding tissue. The red circle denotes the visually determined area of increased uptake.

Visual assessment revealed a sensitivity of 83% ($CI_{95\%}$: 64; 93) and a specificity of 75% ($CI_{95\%}$: 55; 88) for GCA denoted by a score of ≥1 (uptake higher than background). Receiver-operating characteristic (ROC) analysis of the quantitative assessment revealed an AUC of 0.88 ($CI_{95\%}$=0.77-0.99) resulting in a sensitivity of 79% ($CI_{95\%}$: 60; 91) and

Type of Assessment	Cranial Artery	Assessment Conclusion	GCA	Control	Sensitivity ($CI_{95\%}$)	Specificity ($CI_{95\%}$)
Visual Assessment Positive: score=1 Negative: score=0	TA/MA/VA/OA	Positive	20	6	83% (64;93)	75% (55;88)
		Negative	4	18		
	TA	Positive	18	2	75% (55;88)	92% (74;99)
		Negative	6	22		
	MA	Positive	12	1	50% (31;69)	96% (80;100)
		Negative	12	21		
	VA	Positive	10	0	41% (24;61)	100% (86;100)
		Negative	14	24		
	OA	Positive	7	2	29% (15;49)	92% (74;99)
		Negative	17	22		
Quantitative Assessment Positive: SUVmax=5.00 Negative: SUVmax<5.00	TA/MA/VA/OA	Positive	19	2	79% (60;91)	92% (74;99)
		Negative	5	22		
	TA	Positive	19	2	46% (28;65)	100% (86;100)
		Negative	5	22		
	MA	Positive	11	0	29% (15;49)	100% (86;100)
		Negative	13	24		
	VA	Positive	17	1	71% (51;85)	96% (80;100)
		Negative	7	23		
	OA	Positive	3	1	13% (4;31)	96% (80;100)
		Negative	21	23		

Table 1. Cross tabulation of the results of the visual and the quantitative assessments of FDG uptake in the cranial arteries. Visual scoring definition: 0: no uptake above surrounding tissue; 1: uptake just above surrounding tissue; 2: uptake significantly above surrounding tissue. TA, temporal artery; MA, maxillary artery; VA, vertebral artery; OA, occipital artery; SUVmax, maximum standardized uptake value; CI95%, 95% confidence interval.

a specificity of 92% ($CI_{95\%}$: 74; 99) for a SUVmax threshold value of 5.00 (Table 1). The agreement between the two assessment methods was 77% (kappa 0.55).

Conclusion: Using optimal scan data reconstruction, visual and quantitative FDG-PET/CT assessment methods can reliably diagnose GCA based on cranial artery inflammation. Extending the use of FDG-PET/CT to the cranial arteries may improve the diagnostic accuracy for GCA. Moderate agreement between visual and quantitative assessment methods suggests that diagnostic accuracy may be improved when combining both methods.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common large vasculitis in elderly patients. According to previous studies, 50% of patients with GCA in whom PET/CT was performed showed large vessel involvement (LV-GCA). In these patients there is a higher risk of vascular complications. Thus, an early and adequate therapy is needed. Glucorcorticoids (GC) remain to be the cornerstone of GCA. However, relapses are common when the prednisone dose is tapered. Thus, additional therapies are required. In this regard, methotrexate (MTX) is commonly used. However, its efficacy is modest and, in some patients, biological therapy is required. Tocilizumab (TCZ) has demonstrated to be effective.

Our aim was to compare clinical evolution, normalization of acute phase reactants and normalization of vascular ^{18}F-FDG uptake assessed by PET/CT in patients with GCA treated with MTX vs TCZ in clinical practice.

Methods: Comparative multicentric study of 23 patients with GCA treated with MTX compared with 36 patients with refractory GCA to MTX treated with TCZ who had a baseline and follow-up PET/CT scan. We assessed clinical improvement (no improvement/partial/complete), normalization of acute phase reactants (CRP ≤ 0.5mg/dL and/or ESR ≤ 20 mm/1st hour) and reduction of ^{18}F-FDG uptake in PET/CT (no reduction/partial/complete normalization). Images were evaluated qualitatively by experienced nuclear medicine physicians. Prednisone tapering was also assessed.

- 6 months	0/11 (0.0)	0/8 (0.0)	0.99
- 12 months	0/14 (0.0)	3/13 (23.0)	0.10
- 18 months	0/5 (0.0)	3/11 (27.3)	0.51
- 24 months	1/7 (14.3)	1/4 (25.0)	0.99
Dose of Prednisone (mg/day), *median [IQR]*			
- 6 months	7.5 [5.0-15.0]	5.0 [0.3-5.0]	< 0.01
- 12 months	5.0 [5.0-10.0]	0.0 [0.0-5.0]	< 0.01
- 18 months	5.0 [3.0-6.0]	0.0 [0.0-3.3]	0.03
- 24 months	2.5 [0.0-3.0]	0.0 [0.0-0.0]	0.07

Statistical analysis was performed with SPSS. Student´s t test or Mann-Whitney U test was used to compare continuous variables, and Chi-squared test or Fisher´s exact test for categorical variables as appropriate.

Results: We included 23 patients with GCA treated with MTX (20 women/3 men); mean age 65.6 ± 7.9 years; and 36 patients treated with TCZ (27 women/9 men); mean age 67.5 ± 8.3 years. Baseline characteristics were similar in both groups (**TABLE 1**). All patients with MTX received doses ranging between 20 and 25 mg/week as subcutaneous injections. Most of patients with TCZ received treatment as intravenous infusions (80.6%) and almost half of them (52.7%) received combined therapy with MTX. Clinical, analytical, ^{18}F-FDG vascular uptake evolution and prednisone tapering is shown in the **TABLE 2**. After one year of treatment, the percentage of patients who experienced complete clinical improvement (88.9% vs 44.4%; p=0.003) and normalization of acute phase reactants (92.6% vs 47.6%; p=0.001) was higher in patients who received TCZ. No differences were found between patients who received TCZ monotherapy and those who received combined therapy. In regard with reduction of ^{18}F-FDG vascular uptake, complete normalization was only achieved in 25% of patients who received TCZ and 14.3% of those who received MTX at 24 months. A higher cumulative incidence of infections was found in patients who received TCZ (7.4 vs 4.3 infections/100 patients/year).

Conclusion: Patients with GCA who received TCZ experienced a more rapid and effective clinical and analytical improvement than patients who received MTX. Besides, prednisone tapering was quicker in patients with TCZ. However, complete normalization of vascular ^{18}F-FDG uptake was only observed in around 20% of patients in both groups.

Factors Contributing to Capturing Positive Findings on Temporal Artery Biopsy: An Australian Experience from Two Rheumatology Referral Centers

Victor Yang,[1] Benjamin Sutu,[2] Christopher McMaster,[3] Claire Owen,[1] Alexander Strathmore,[4] Gene-Siew Ngian,[2] Shereen Oon,[4] Jessica Leung,[1] Ian Wicks,[5] Russell Buchanan,[1] and **David Liew** [1], [1]Austin Health, Heidelberg, Victoria, Australia, [2]Melbourne Health, Parkville, Victoria, Australia, [3]Austin Health, Melbourne, Victoria, Australia, [4]Melbourne Health, Melbourne, Victoria, Australia, [5]Melbourne Health, Parkville, Australia

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Temporal artery biopsy (TAB) is widely recognised as the diagnostic gold standard for GCA, despite having a poor sensitivity due to the presence of 'skip' lesions. There is however a lack of consensus guiding TAB practice, particularly in relation to optimal length, need for bilateral specimens and number of segments examined. This study investigated the impact of factors such as total biopsied length, laterality, segment number, and referral center on histopathological outcomes in an Australian setting.

Methods: Reports for all available biopsy specimens labelled "temporal artery" were extracted from the pathology service records of two rheumatology referral centers with adjacent geographic catchments. Each histopathology report was manually reviewed to establish length of biopsied artery, laterality and number of segments, along with

	Negative (n=455)	Positive (n=122)	Overall (n=577)

Unilateral	325 (71 %)	83 (68 %)	408 (71 %)

Table 1. Patient characteristics by biopsy result.

	Overall positive finding	Intimal hyperplasia	Giant cells	Adventitial inflammation
Total Biopsy Length (cm)	1.25 (1.06 – 1.47)	1.18 (0.98 – 1.40)	1.21 (1.00 – 1.46)	1.07 (0.87 – 1.31)
Unilateral (vs bilateral)	1.56 (0.82 – 3.07)	1.12 (0.56 – 2.30)	1.28 (0.61 – 2.77)	0.82 (0.38 – 1.82)
Age (years)	1.02 (1.00 – 1.05)	1.02 (1.00 – 1.04)	1.03 (1.00 – 1.05)	1.00 (0.98 – 1.03)
Male (vs female)	0.83 (0.52 – 1.29)	0.63 (0.37 – 1.05)	0.59 (0.32 – 0.92)	0.75 (0.41 – 1.31)
Center 2 (vs center 1)	0.54 (0.34 – 0.84)	0.41 (0.24 – 0.68)	0.55 (0.32 – 0.92)	0.46 (0.25 – 0.82)

Table 2. Associations with positive TAB on multivariable logistic regression.

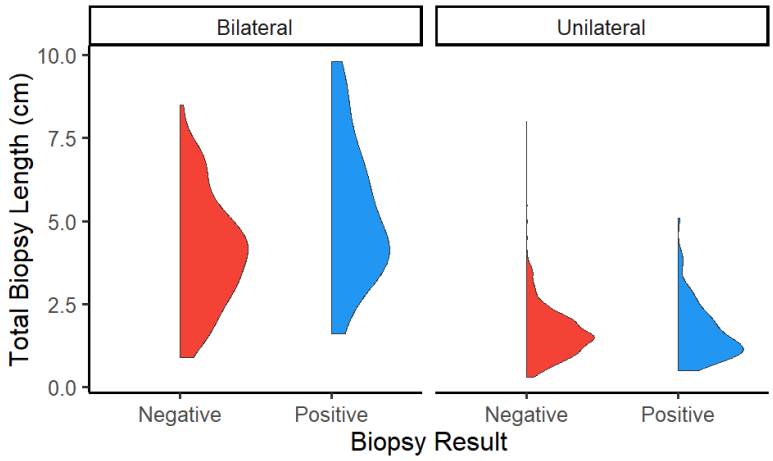

Figure 1. The effect of total biopsy length on result, stratified by laterality.

patient demographics such as age, sex, and referral center. Key histopathological findings including intimal hyperplasia, disruption of the internal elastic lamina, presence of giant cells and adventitial inflammation were recorded. Multivariable logistic regression with site-varying intercept was performed.

Results: TAB reports from a total of 577 patients were captured, with results available from the two centers from 1999-2019 and 2010-2019 respectively. The mean age in this group was 73, and 69% were female (Table 1). A bilateral TAB was performed in 29%, and the mean total biopsy length was 2.5cm. Of these patients, 122 had positive biopsies (21%), with intimal hyperplasia reported in 100 (17%), giant cells in 83 (14%) and adventitial findings in 68 (12%). Positive biopsy weakly correlated with increased total length of biopsy in centimetres (OR 1.25 [1.06-1.47]) (Figure 1) and increased age in years (OR 1.02 [1.00-1.05]) but not laterality or sex (Table 2). There was a substantial difference between the two centers, which was incompletely accounted for once corrected for total biopsy length and calendar year of biopsy, suggesting either unmeasured differences in patient demographics or a difference in clinical practice. This change was preserved across analysis of different histopathological subtypes.

Conclusion: Total biopsy length was weakly associated with a positive TAB result, but differences in results between referral centers independent of biopsy length suggest other selection factors may be important in determining TAB yield. Examination of differences in results between a greater number of referral centers would assist in determining the extent of this variability.

Real Life Data over 4 Years from a Fast Track GCA Pathway in Coventry

Shirish Dubey,[1] Jonathan Pinnell,[2] Carl Tiivas,[1] Kaushik Chaudhuri,[1] and Purnima Mehta[1], [1]University Hospital Coventry and Warwickshire NHS Trust, Coventry, United Kingdom, [2]University Hospital North Staffordshire NHS Trust, Stoke, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: University Hospital Coventry and Warwickshire NHS Trust (UHCW) established its one stop Fast Track Pathway (FTP) for Giant Cell Arteritis (GCA) in 2013. It sought to address previously unmet needs by offering patients a same day clinical review, ultrasound Doppler, diagnosis, and treatment initiation for patients with GCA. It aims to prevent GCA related complications like vision loss by treating affected patients promptly whilst avoiding exposing unaffected patients to corticosteroids. Patients are normally reviewed on the same day and have an USS doppler performed in the vascular lab if indicated and then a decision is made about treatment. This abstract details the results of this pathway for the period of 2014 to 2017.

Methods: The clinical records of all patients with suspected GCA seen on the UHCW GCA Fast Track Pathway between, and including, January 2014 and December 2017 were reviewed. Patients were identified from ultrasonography lists as all patients attending the fast track pathway are required to undergo an ultrasound Doppler of their temporal arteries. A predetermined piloted proforma was used to collect data regarding patient demographics, clinical features, investigation results, steroid use, and final diagnosis. All patients who had been referred with suspected GCA were included and missing data was sought from electronic and paper records.

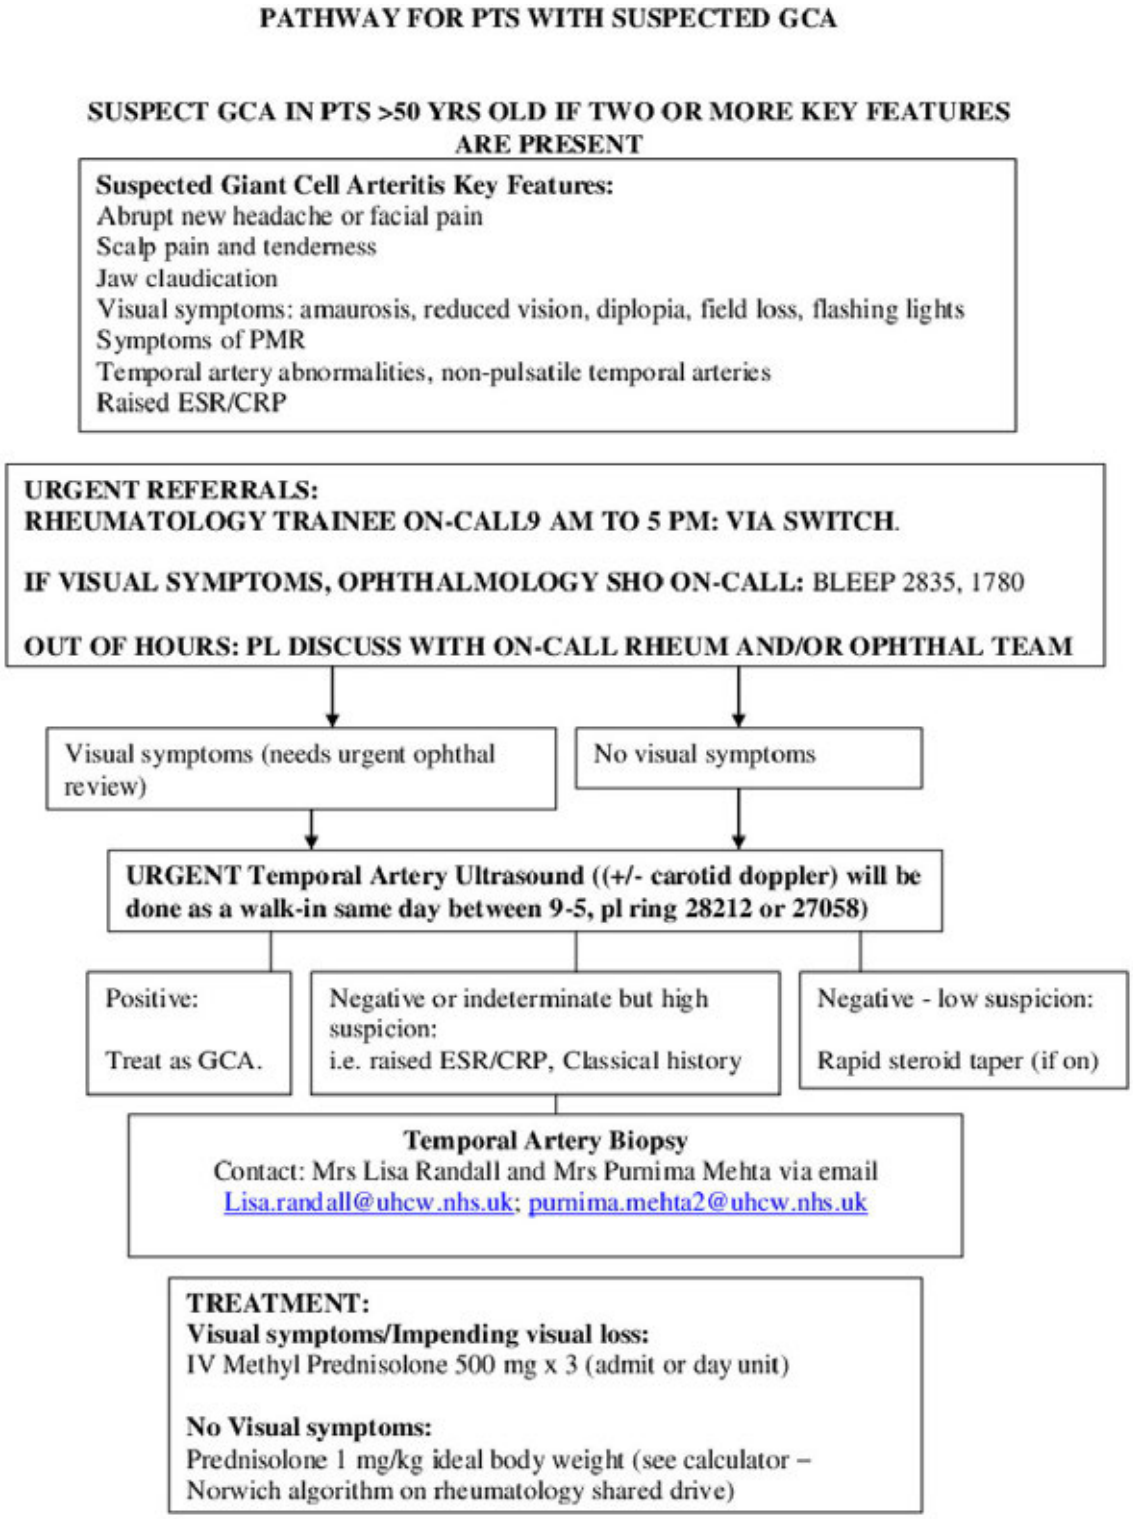
Descriptive analysis was performed on the data using Microsoft Excel. Ethical approval was granted by the UHCW Research and Development Department.

Results: Total of 652 patients were assessed on the GCA pathway between 1st January 2014 and 31st December 2017 (both inclusive). The numbers have progressively increased each year (98/154/123/277). Demographic details revealed that 435 patients were female (~66%). Ages ranged between 52 and 95 years; median age was 70 years. Of these, 143 patients were diagnosed with GCA; 509 patients did not have GCA. Headache was the commonest presenting symptom (~74%), with visual symptoms also being common (~45%).

We evaluated the utilty of our vascular doppler service compared to clinical diagnosis (see table below).

We also evaluated the utility of temporal artery biopsies which are only being performed within our pathway when the diagnosis is uncertain after the initial evaluation. This showed Sensitivity 36.73%; Specificity 100.00%; Positive predictive value 100.00%; Negative predictive value 62.20%.

A very high proportion of patients (~57%) did not need to start steroids at all on the basis of this pathway.



Coventry GCA pathway algorithm

Conclusion:

1. This is the largest series of suspected GCA patients in the world looking at real life performance of vascular doppler and temporal artery biopsy.

2. The UHCW GCA FTP was effective in reducing the proportion of unaffected patients who were exposed to corticosteroids and reduced the duration of exposure for those that did receive them, thereby minimising the risk of harm with unnecessary treatment.

3. Performance of Vascular doppler was at least comparable to previous studies and is an integral part of this pathway allowing clinicians to reassure patients with low clinical probability of GCA and negative USS to be discharged without any steroid exposure.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In addition to aiding in diagnosis, histopathologic findings from temporal artery biopsy (TAB) specimens in giant cell arteritis (GCA) may be valuable for their associations with clinical features of the disease. The study objective was to compare specific histopathologic findings on TAB with biopsy interpretation, demographic, clinical, and imaging features at diagnosis.

Methods: Patients who had a diagnosis of GCA confirmed by expert review were selected from an international, multicenter observational cohort. Associations between demographic, clinical, radiographic, and histopathologic features were identified using bivariate testing and multivariate regression modeling.

Results: Six hundred forty-seven patients with GCA who underwent TAB were included. Pathology interpretations included definite vasculitis (69%), normal temporal artery biopsy (13%), consistent with vasculitis but not definite (9%), or non-diagnostic (8%). For 467 biopsies, specific findings were detailed, including the presence of giant cells (63%), fragmentation of the internal elastic lamina (50%), intimal thickening (39%), predominantly mononuclear leukocytes (39%), vascular thrombosis (6%), granuloma (5%), and perivascular inflammation without vessel wall involvement (1%). In a model that included the common TAB findings (>10% prevalence), a pathology interpretation of definite vasculitis was independently associated with giant cells (OR 123.4, CI 47.1-323.5), predominantly mononuclear leukocytes (OR 11.8, CI 6.0-23.0), and fragmentation of the internal elastic lamina (OR 4.5, CI 2.4-8.3). Out of 207 patients who had a temporal artery ultrasound, 166 patients had a halo sign, which was significantly associated with the presence of giant cells (88% vs. 76% without, p=0.04) and intimal thickening (90% vs. 78% without, p = 0.04). Out of 70 patients who underwent PET scanning, no pathologic findings on TAB were associated with PET abnormalities. Temporal artery abnormalities on exam were associated mononuclear leukocytes (OR 2.01, CI 1.38-2.94). Older age was associated with the presence of giant cells, fragmentation of the internal elastic lamina, and intimal thickening (see Table 1). No pathologic findings were associated with vision loss at presentation.

Conclusion: Pathologic findings of temporal artery biopsies in GCA are associated with diagnostic interpretations but not with clinical manifestations of vasculitis. Associations between pathologic findings and imaging abnormalities should be investigated further.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnostic assessment in giant cell arteritis (GCA) is rapidly changing as large-vessel (LV) involvement becomes increasingly recognized and non-invasive vascular imaging techniques become more available. The purpose of this study was to assess how clinicians around the world use diagnostic assessment strategies to assess arterial involvement in GCA.

Methods: Patients were included from a large, international cohort with standardized data collection from 2011-2017. Study centers were located in Asia, Australia/New Zealand, Europe, and North America. All patients had a confirmed diagnosis of GCA. Diagnostic assessments were performed at the discretion of the submitting physician. LV-imaging included angiography, ultrasonography, or PET imaging of the extra-cranial arteries. Temporal artery assessment included temporal artery biopsy (TAB) or ultrasonography (TA-US). Nominal logistic regression was used to study the associations between the decision to obtain a TAB and demographic data, ischemic cranial symptoms, and large-vessel involvement (aorta and its primary branches).

Results: 941 patients with GCA from 72 centers were included in the analysis, 783 (83%) patients were Europe, 111 (12%) patients from North America, and 47 (5%) patients from other regions. Overall, 704 patients (75%) had a TAB, 446 TABs (66%) were considered diagnostic for GCA. 328 (35%) patients had a TA-US, 258 (79%) patients had a halo sign and most came from European centers (n=321, 98%). 534 patients (57%) had LV-imaging, 40% (n=216) showed LV involvement. 431 patients (45%) had both LV-imaging and temporal artery-assessment. Only 33 patients (4%) did not have any diagnostic testing performed beyond clinical assessment. Male patients were significantly more likely to undergo a TAB than female patients, independent of cranial ischemic symptoms, age at diagnosis, temporal-artery abnormality on physician exam, or presence of LV involvement (Table 1). There was no sex preference in the rate

of TA-US (Male: 37% vs Female: 34%, p=0.38) or LV-imaging (Male: 58% vs Female: 56%, p=0.70). Patients who received a TAB were older (mean age 73 years vs 71 years, p< 0.01) and patients who received LV-imaging were younger (mean age 72 years vs 74 years, p< 0.01). Most patients had multiple forms of diagnostic assessment (Table 2). Regardless of TAB results, approximately 60% of patients had vascular imaging studies performed in addition to biopsy. Vascular imaging was performed in 86% of patients who did not have a TAB and confirmed disease in 70% of these patients. TA-US was rarely used alone as a form of assessment. 69% (n=227) of patients with a TA-US also underwent TAB. Only 1% of patients had TA-US without another form of assessment compared to the 11% and 32% of patients that had only LV-imaging and TAB.

Conclusion: Vascular imaging is increasingly incorporated into the diagnostic assessment of GCA. The majority of patients with GCA underwent multiple forms of diagnostic testing, including TAB and vascular imaging studies. Demographic factors, clinical features, and regional differences in clinical practice influence diagnostic assessment strategies in GCA.

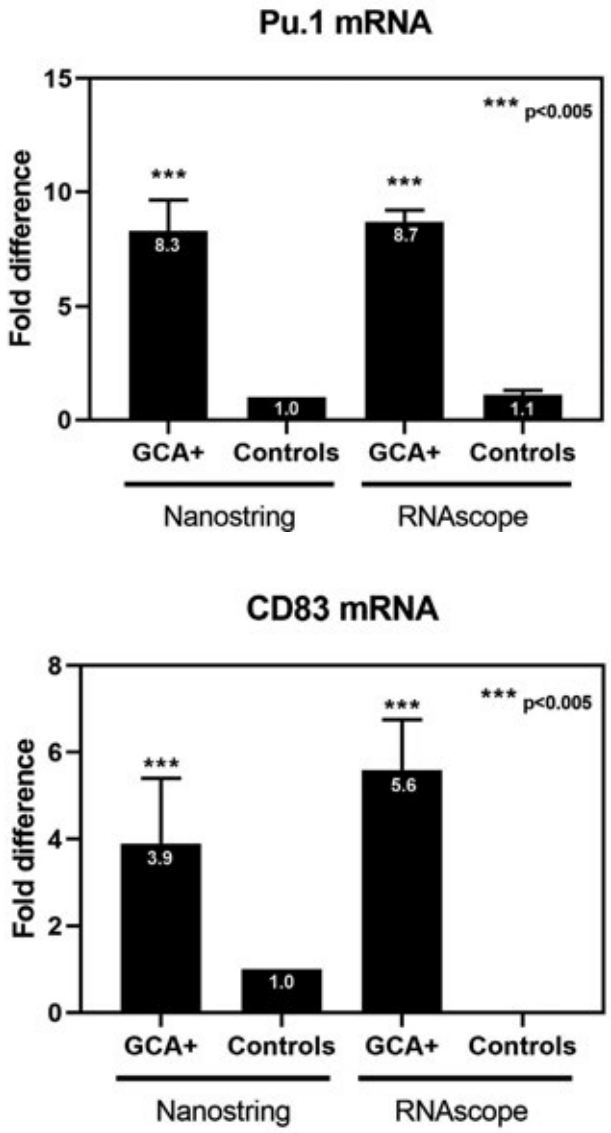
GM-CSF and GM-CSFRalpha Expression in Temporal Artery Biopsies



Background/Purpose: Giant Cell Arteritis (GCA) is a type of large vessel vasculitis that can cause blindness and aortic aneurysms. A significant unmet medical need remains in GCA, as current treatment options are limited and relapse increases corticosteroid (CS) exposure and toxicity.

The primary role of macrophages/dendritic cells (DCs) and T_H1/T_H17 lymphocytes in GCA pathogenesis has been highlighted previously. Granulocyte-macrophage colony stimulating factor (GM-CSF) may contribute to GCA pathogenesis by stimulating giant cell formation. GM-CSF produced by $CD4^+$ T helper T_H1 and T_H17 cells can stimulate conventional DCs and promote differentiation of monocyte-derived DCs. Notably GM-CSF RNA has been reported in GCA lesions and in peripheral blood mononuclear cells of symptomatic patients.

We hypothesized elevation of the GM-CSF pathway signature in GCA vessels versus controls.

Methods: Two independent sources of temporal artery biopsies were utilized. First, GCA (n=17) and control (symptomatic patients suspected for GCA, but with a normal temporary artery biopsy; n=5) biopsies were analyzed for 15 mRNA transcripts representing T_H1, T_H17, and GM-CSF signaling (RNAscope; RS) and for mRNA transcripts

representing the autoimmune panel (Nanostring; NS). Semi-quantitative scoring was performed on RS images and fold-change of representative T_H1, T_H17 and GM-CSF related mRNA transcripts were calculated via NS nCounter analysis. Additional GCA and control biopsies were obtained and analyzed by qPCR for a subset of transcripts (n=10 each) and by confocal microscopy for GM-CSF and GM-CSF-Rα protein (n=2 each). *Ex vivo* cultures of GCA+ arteries were treated with placebo or mavrilimumab for 5 days and assayed for gene expression by qPCR.

Results: Upregulation of the GM-CSF signaling pathway molecular signature was confirmed by 4 independent analyses.

GM-CSF-associated and T_H1-associated genes were upregulated in GCA biopsies versus control (GMCSF: 3-4x RS; GM-CSF-Rα: 6.7x NS, 6x RS; and CD83: 3.9x NS, 6x RS; TNFα: 2x NS, 3x RS; IFNγ: 2x RS; IL-1β: 6x RS). T_H17 associated genes were not elevated, potentially due to concomitant CS treatment.

Upregulation of both GM-CSF (12x) and GM-CSF-Rα (3x) mRNA was confirmed in a separate cohort of biopsies from GCA pts vs. controls by qPCR (Figure). GM-CSF protein was detected in the luminal endothelium, neovessels and inflammatory cells of GCA patients. In normal temporal arteries GM-CSF protein was not detected.

Pu.1, a transcription factor downstream of GM-CSF signaling, was increased 8x in GCA vs. controls (RS, NS) (Figure)

Treatment of ex vivo cultures of GCA arteries with Mavrilimumab (anti-GM-CSF-Rα) reduced expression patterns of known pathogenic cell-types and cytokines (CD3ε, CD83, HLA-DRA Pu.1, and TNFα).

Conclusion: GM-CSF and T_H1 pathway signatures were demonstrated in GCA patient temporal arteries by independent analytical techniques. Active GM-CSF signaling in diseased tissue is evidenced by increased expression of Pu.1 in the vessel wall. Treatment with mavrilimumab reduced inflammatory cell markers and pathogenic cytokines. These data implicate the GM-CSF pathway in GCA pathophysiology and increase confidence in rationale for targeting GM-CSF in GCA.

Fast Track Clinic (FTC) for Giant Cell Arteritis (GCA) – the United States Experience

Ingeborg Sacksen,[1] Elizabeth Jernberg,[1] Scott Pollock,[2] Jean Liew,[3] Sarah Chung,[2] R Eugene Zierler,[3] and **Alison Bays** [2], [1]University of Washington Division of Rheumatology, Seattle, [2]University of Washington Division of Rheumatology, Seattle, WA, [3]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

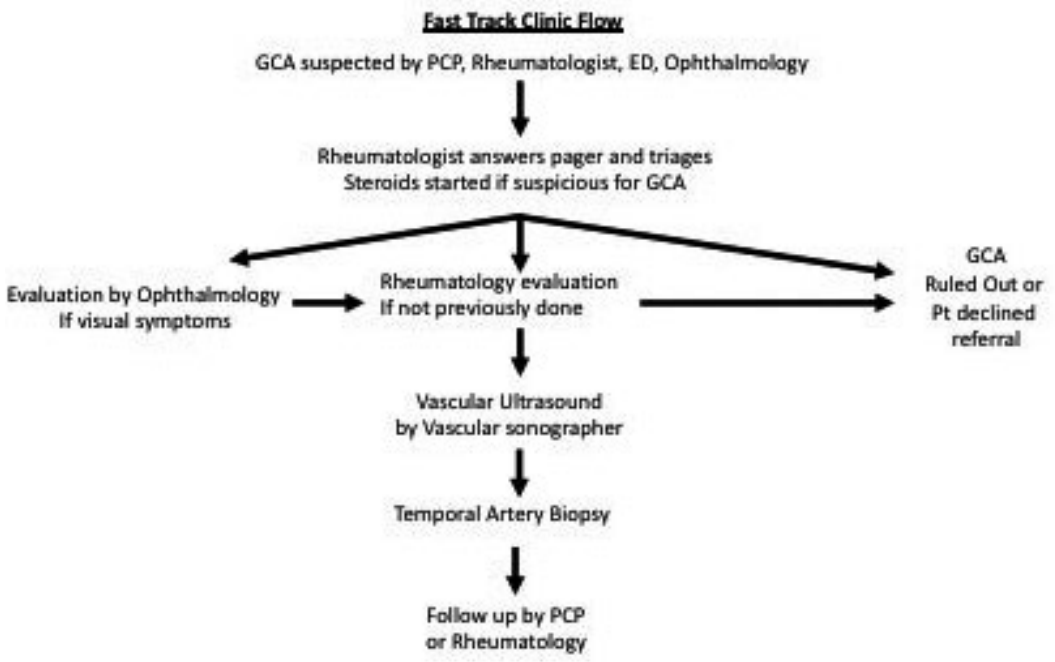

Figure 1. Fast Track Clinic Flow Chart

Background/Purpose: Giant cell arteritis (GCA) is the most common form of vasculitis in adults and if untreated, may result in visual impairment. Although the gold standard for diagnosis is the temporal artery biopsy (TAB), it does not detect extracranial large vessel vasculitis. New guidelines recommend early imaging, including ultrasound. Fast Track clinics (FTC) in Europe have reduced the time to rheumatology evaluation, with ultrasound replacing TAB for diagnosis in selected cases. Four rheumatologists and two vascular sonographers were trained to detect GCA by ultrasound and an FTC was established for early diagnosis and treatment of GCA. This retrospective study reports patients suspected of having GCA who went through the FTC vs those who received standard care (SC).

Methods: We obtained IRB approval and performed a retrospective review of patients seen through the FTC versus SC from November 2017 through May 2019. FTC inclusion criteria were patients over the age of 50 suspected of GCA who had both ultrasound and TAB. SC included patients over 50 years old suspected of GCA who received TAB. A FTC rheumatologist answered calls to a dedicated pager at a major academic center. Steroids were started immediately if diagnosis of GCA was likely; patients were seen by a rheumatologist within 48 hours and at the rheumatology clinic visit, patients were referred to vascular ultrasound and for TAB (Figure 1). Vascular ultrasound was performed by trained sonographers on a Philips Epiq 7 and interpreted by a vascular surgeon (Figure 2).

Results: There were 31 patients who fulfilled FTC criteria (Table 1). There were 7 positive biopsies and 13 positive ultrasounds. In FTC patients, the median time from referral to rheumatology evaluation was 1 day, time to ultrasound was 1 day and time to TAB was 7 days. There were16 patients in the SC group and the median time to rheumatology evaluation was 3.5 days; initial presentation to TAB was 10 days. Ultrasounds were positive in 8 FTC patients who had negative biopsies, including 4 with halo sign of the temporal artery and 4 with extracranial large vessel vasculitis (LVV).

[b]In patients who had not had rheumatology assessment when FTC was activated
Abbreviations: FTC, fast track clinic; GCA, giant cell arteritis; IQR, interquartile range; TAB, temporal artery biopsy

Table 1. Comparison of baseline characteristics and outcomes of FTC and patients receiving standard care (SC) for suspected GCA.

Conclusion: FTCs are new in the United States and may operate differently from European FTCs with some sonographers performing vascular ultrasound rather than rheumatologists. Although FTC and SC groups were not significantly different in time to TAB, vascular ultrasound detected 8 cases of vasculitis in patients with negative TAB. The high rate of positive ultrasounds is likely due to the short turnaround to ultrasound facilitated by FTC as well as detection of extracranial GCA. FTC may improve the rate of GCA and LVV diagnosis and should be considered at major academic centers.

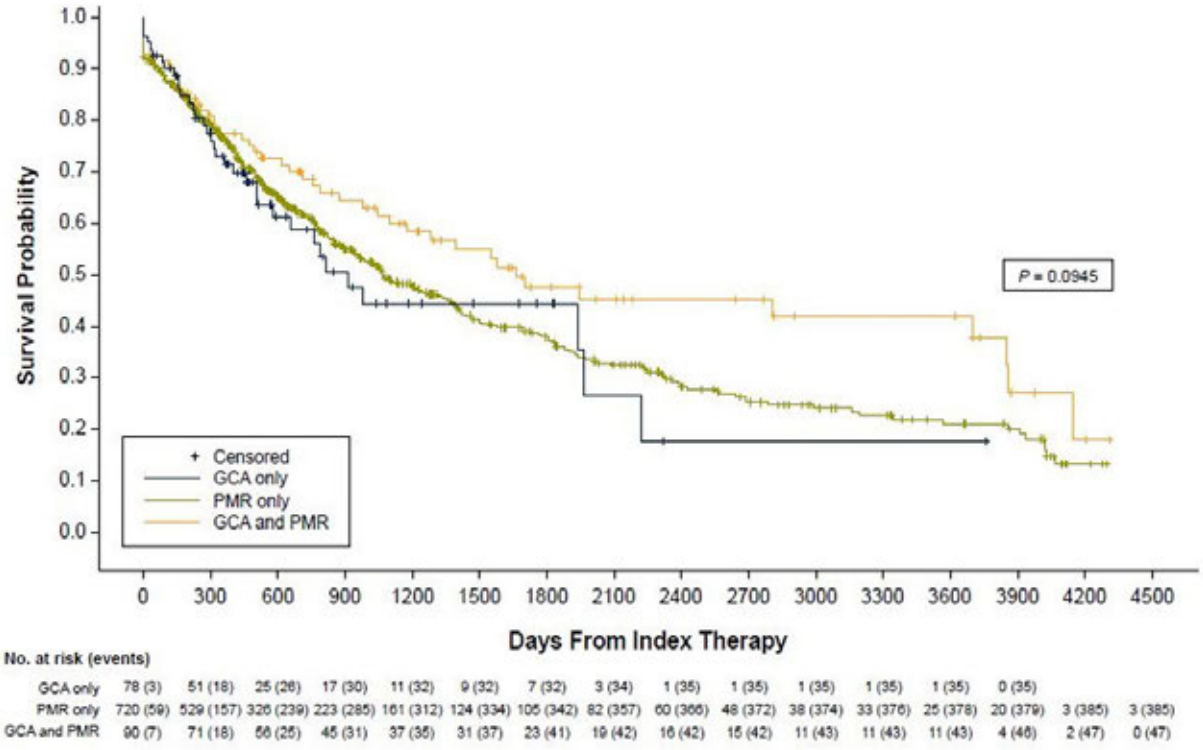
Figure 1. Time to Remission Following Initiation of Glucocorticoids



GCA, giant cell arteritis; PMR, polymyalgia rheumatica.

Background/Purpose: For patients with giant cell arteritis (GCA) and/or polymyalgia rheumatica (PMR), glucocorticoids are the mainstay of treatment. However, due to the chronic nature of these diseases, patients may require continued glucocorticoid treatment to achieve treatment targets or prevent disease relapse, over time resulting in high cumulative doses and associated adverse events. The purpose of this study was to assess patterns of glucocorticoid use and outcomes in patients with GCA, PMR or both.

Methods: This retrospective cohort study used electronic medical records from a single US community-based rheumatology clinic utilizing the JointMan rheumatology software application. Patients age ≥ 50 years with a diagnosis of

either GCA or PMR and ≥ 1 entry for glucocorticoid following the diagnosis were included and followed until lost to follow-up or the end of the study period (30 Nov 2017). The index date was defined as the date of first glucocorticoid prescription received at or after the earliest GCA or PMR diagnosis date. Outcomes at 2 years included the proportion of patients achieving remission (defined as not receiving steroids for ≥ 6 months), time to remission, persistence of remission (defined as not receiving steroids for ≥ 6 months and still not receiving steroids at 2 years) and prednisone dose at follow-up, and were compared between patients with GCA only, PMR only or both GCA and PMR. *P* values are reported using F-test (ANOVA) for continuous variables and Chi-squared test for categorical variables.

Results: We identified 81 patients with GCA only, 779 with PMR only and 97 with GCA and PMR. Mean (SD) age was 70.0 (9.1) years; 64.2% were women. Mean (SD) daily prednisone dose at the index date was 46.7 (30.9) mg for patients with GCA only, 20.1 (14.2) for PMR only and 29.0 (23.4) for patients with both GCA and PMR. Two years after the index date, 32% of patients with GCA only, 32% with PMR only and 27% with GCA and PMR had achieved remission; 17%, 23% and 18% were in persistent remission, respectively (**Table 1**), with no significant differences between groups. Among patients who achieved remission, overall median time to first remission was 202.5 (0-635) days and was shorter for patients with both GCA and PMR (157 [0-619] days) vs GCA (213 [0-577] days) or PMR (203.5 [0-635] days) only. Kaplan-Meier estimates of time to remission for each group are shown (**Figure 1**)**.** Most patients required a daily prednisone dose at 2 years, with similar doses observed between groups (**Table 2**).

Conclusion: Patients with either GCA and/or PMR are exposed to significant doses of prednisone. In this study, fewer than one-third of patients with GCA and/or PMR achieved remission; the majority of patients continued to require prednisone therapy for at least 2 years after its initiation. These data highlight the need for the use of more efficacious and steroid-sparing therapies in patients with GCA and/or PMR.

Coronary Artery Disease in a Population-Based Cohort of Biopsy-Proven Giant Cell Arteritis in Southern Sweden

Pavlos Stamatis,[1] Moman Mohammad,[1] Peter Merkel,[2] Martin Englund,[3] Carl Turesson,[4] David Erlinge,[1] and Aladdin Mohammad[1], [1]Lund University, Lund, Skane Lan, Sweden, [2]University of Pennsylvania, Philadelphia, PA, [3]Lund University, Lund, Sweden, [4]Lund University, Malmö, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Giant Cell Arteritis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to estimate the incidence rate and prevalence of coronary artery diseases (CAD) in patients with temporal artery positive giant cell arteritis (TAB+GCA) from a defined population in southern Sweden, and to describe characteristics of CAD in this sample.

	Patients with GCA without CAD	Patients with GCA with CAD
Number (%)	1076 (89.5)	126 (10.5)
Female sex (%)	795 (73.9)	69 (54.8)
Mean age at diagnosis of GCA; years (SD)	75.2 (7.9)	75.2 (8.4)
Mean age at diagnosis of CAD; years (SD)	N/A	76.8 (9.2)
Percutaneous coronary intervention (%)	N/A	38 (30.2)
Coronary artery bypass grafting (%)	N/A	14 (11.1)
Dead during follow-up (%)	445 (41.3)	54 (42.9)
Mean age at death; years (SD)	85.2 (7.1)	84.6 (7.2)

GCA: giant cell arteritis, CAD: coronary artery disease, SD: standard deviation, N/A: not applicable

Table 1. Characteristics of patients with giant cell arteritis with and without coronary artery disease in a population-based cohort from southern Sweden.

Methods: The study cohort consisted of 1202 patients (71.9% women) diagnosed with TAB+GCA between 1997 and 2016. Patients were identified from the database of the Department of Pathology which covers all the hospitals in the Skåne region of Sweden. The cohort was linked to the registry for acute coronary care (SWEDEHEART) which provides nationwide coverage since 1995. All the GCA patients with symptoms suggesting acute coronary syndrome who had been admitted to a coronary care unit (CCU) were identified. CAD was defined as an admission to a CCU for ST-Elevation Myocardial Infarction (STEMI), Non-ST-Elevation Myocardial Infarction (NSTEMI), stable angina, or unstable angina. For incidence rate analyses, the person-years of follow-up was calculated from GCA diagnosis until first CAD, death or December 31, 2016, whichever came first.

Results: 126 of 1202 GCA patients had suffered at least one acute coronary event (Table 1) yielding the cumulative incidence of 10.5% (95% CI 8.7-12.3). Of the 126 patients with CAD, 44 (34.9%) were diagnosed with CAD before their GCA diagnosis, 11 (8.7%) both before and after their diagnosis, and 71 (56.3%) solely after their GCA diagnosis. The total number of CCU admissions of all the 126 GCA CAD+ patients was 209: 101 admissions (48.3%) for NSTEMI, 55 (26.3%) for stable angina, 29 (13.9%) for STEMI, and 24 (11.5%) for unstable angina. Eighty-two GCA patients (61% women) developed CAD after their diagnosis of GCA. During a total follow-up time of 8047 person-years, the incidence rate of CAD in patients with TAB+GCA was 1.0 per 100 person-years (95% CI 0.8-1.2) for all patients, 0.8 (95% CI 0.6-1.1) for women and 1.6 (95% CI 1.1-2.2) for men, p=0.02. Fifteen GCA patients suffered from a CAD event in 1156 person-years during the first year after the GCA diagnosis, resulting in an incidence rate of 1.3 per 100 person-years (95% CI 0.6-2.0). 703/1202 (58.5%) GCA patients were alive on December 31, 2016, of which 72 patients had at least one previous CAD event yielding a prevalence of CAD in GCA of 10.2%.

Conclusion: The incidence of CAD in GCA is comparable to what has been previously found in the Swedish background population. The incidence rate is higher among men compared to women. Coronary artery disease affects every tenth patient with TAB+GCA in this cohort. Further studies are needed to explore the impact of CAD on clinical outcomes in patients with GCA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

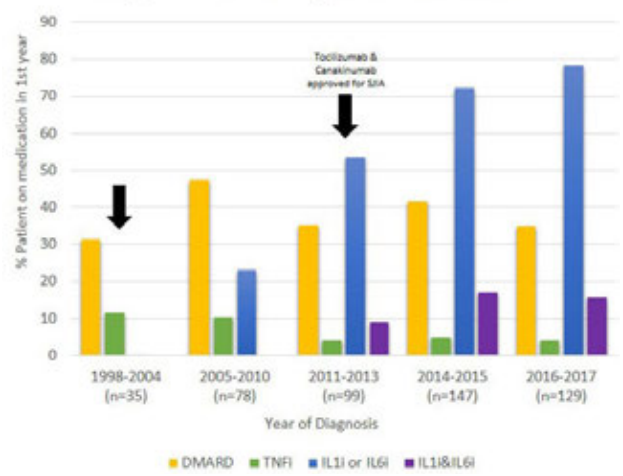
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Prior to the development of anti-cytokine therapies, treatment for systemic juvenile idiopathic arthritis (SJIA) included high dose glucocorticoids and non-biologic disease modifying anti-rheumatic drugs (DMARDs) with suboptimal outcomes. Recent studies of SJIA patients treated with biologics, including IL-1 inhibitors (IL-1i) and IL-6 inhibitors (IL-6i), demonstrated excellent clinical responses, with steroid-sparing benefits and improved short-term outcomes. Our aim was to assess temporal trends in non-biologic DMARD and biologic medication use in the first year after diagnosis of SJIA using data from the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry.

Methods: Medication use during the first year after diagnosis of SJIA was assessed for all patients enrolled in the CARRA Registry through 2017. Medication information is collected retrospectively for all patients at the time of enrollment in the Registry and prospectively after enrollment. Patients with missing diagnosis date or month of medication start date were excluded. Patients were grouped by year of diagnosis based on medication availability at the time and numbers of patients available for assessment: (1)1998-2004: little biologic use; (2) 2005-2010: mostly anakinra use; (3) 2011-2013: post-FDA approval of tocilizumab and canakinumab; (4) 2014-2015; and (5) 2016-2017. Medi-

Figure 1: Trends in Medication Use During 1st Year of Diagnosis Over Time



cations were grouped by mechanism of action, and temporal trends in medication class usage were assessed using frequencies.

Results: A total of 488 patients were included in the analysis: 35 patients in the 1998-2004 cohort, 78 from 2005-2010, 99 from 2011-2013, 147 from 2014-2015, and 129 from 2016-2017 (Figure 1). Non-biologic DMARD use fluctuated between 31% and 47% over the study period. Use of IL-1i or IL-6i consistently increased over time to >75% by 2017. In recent years, approximately 15% of patients received both IL-1i and IL-6i, and TNF inhibitor (TNFi) use decreased to < 5% in the first year.

Conclusion: Our analysis shows a dramatic increase over time in use of IL-1i and IL-6i in the first year of treatment for SJIA patients, with over 75% of patients now receiving these treatments. Use of non-biologic DMARDs was stable over the study period, indicating a change in the standard of care. Use of both IL-1i and IL-6i by a significant minority of patients suggests variability of clinical response in individual patients.

Abstract Number: 2694

Inpatient Treatment Variation in New-Onset Systemic Juvenile Idiopathic Arthritis

Rosemary Peterson,[1] Rui Xiao,[2] Hannah Katcoff,[1] Brian Fisher,[1] and Pamela F. Weiss[1], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The effectiveness of IL-1 and IL-6 inhibitors as first-line therapy in patients with new-onset systemic JIA has led to the concept of a "window of opportunity" in systemic JIA in which early initiation of biologic therapy improves outcomes. Despite this, provider surveys indicate there is significant variation in treatment with biologic therapy at diagnosis. We leveraged encounter data from the Pediatric Health Information System (PHIS) to describe treatment patterns in a large inpatient multi-site cohort of new-onset systemic JIA patients.

Methods: Using the PHIS de-identified data from inpatient encounters across 45 tertiary care children's hospitals across the United States, we identified the index admission for children age ≤ 18 years with a discharge ICD-10 code for systemic JIA (M08.2*) between October 1, 2015 and June 1, 2018. Index admission was defined as the first admission during the inclusion period with the diagnosis code of M08.2* excluding patients with a prior admission with this code or an ICD-9 code for systemic JIA (714.30) in ≥ 1 year prior. Patients were excluded if 1) there was no administration of a conventional or biologic disease-modifying drug, glucocorticoids (GCs), or Nonsteroidal Anti-inflammatory Drugs (NSAIDs), 2) biologic or GC exposure occurred on the day of admission or hospital day 2, or 3) the primary discharge diagnosis was infection. Mixed-effects logistic regression was used to determine patient and hospital level predictors of treatment with admission hospital included as a random effect to account for clustering. Variation in treatment over time was analyzed using an extension of the Wilcoxon rank-sum test for trends.

Admit age, median (IQR)	6.0 (3.0, 12.0)

*Systemic JIA case volume treated as a continuous variable in regression model.

Table 2. Unadjusted and adjusted odds ratios for biologic exposure according to patient and hospital level factors.

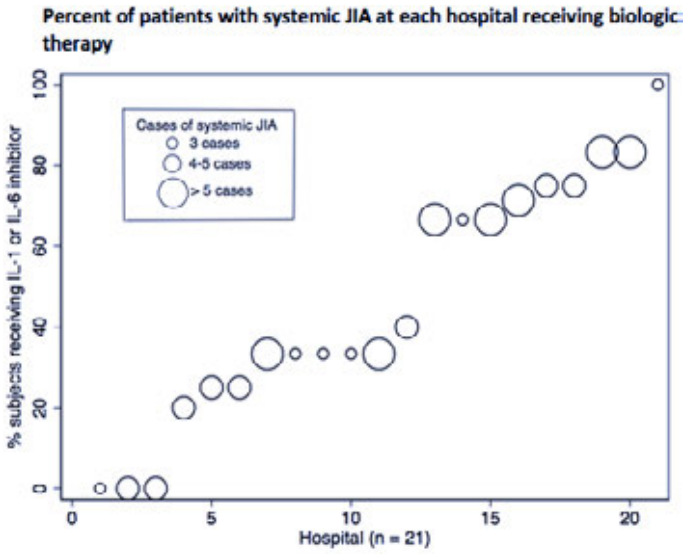

Figure 1. Variation in biologic treatment of children with new-onset systemic JIA across hospitals. Percent of children with systemic JIA at each hospital who received biologic therapy (IL-1 or IL-6 inhibitor). Only hospitals with at least 3 cases of systemic JIA are included.

Results: A total of 138 children with new-onset systemic JIA were admitted across 45 children's hospitals, of which 46% received biologic therapy (89% IL1i, 11% IL6i) and 51% received GCs. Demographics and clinical characteristics are presented in Table 1. The average length of stay was 6 days (IQR 4-9) and all-cause 90-day readmission rate was 9%. After adjustment for patient and hospital level factors, site systemic JIA volume was a positive predictor of biologic exposure (OR 1.28, [1.04-1.58]) (Table 2). Predictors of GC exposure included low hospital volume (OR 30.40, [5.40-171.03]), West region (OR 11.91, [1.89-74.92]), and on-site pediatric rheumatology fellowship (OR 4.45, [1.13-17.55]). Biologic exposure increased over time (p = 0.03), while GC exposure remained unchanged (p = 0.85). The median proportion of patients with GC and biologic exposure within sites was 0.67 (IQR 0.2-1) and 0.33 (IQR 0-0.67), respectively. Variability in the unadjusted use of biologics across hospitals is shown in Figure 1.

Conclusion: Treatment of children with new-onset systemic JIA varies considerably between tertiary care children's hospitals in the United States. Patients admitted to sites with a higher number of systemic JIA cases were more likely to be exposed to biologics, whereas GC exposure was more likely at lower volume hospitals. GC use has remained unchanged over time despite increasing biologic use. Further study is needed to determine the impact of early biologic use on hospital outcomes and contributors to low biologic use and high GC use at certain si tes.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis (sJIA) accounts for 10-20% of all patients with JIA. sJIA should be considered as a polygenic autoinflammatory disease. Interleukin 1 (IL-1) has been shown to be a major mediator of the inflammatory cascade that underlies sJIA. Treatment with anakinra has been reported to be effective in a sizable portion of patients with sJIA.

Objective: To assess clinical response rate and disease course in sJIA patients treated with anakinra. To evaluated whether the response to anakinra was related to baseline variables

Methods: We reviewed 57 (28 F) consecutive patients with sJIA treated with anakinra for at least 6 months in our institution. We analyzed the effect of anakinra on fever, rash, number of active joints, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), white blood cells count, platelets count and ferritin levels. Clinically inactive disease (CID) was defined according to Wallace criteria. Clinical and laboratory data were obtained using a standard data collection form.

Results: The median age at the disease onset was 5.6 (IQR 2.7-10.0) years. The median time from onset to received anakinra was 1.9 (IQR 0.7-9.5) months. At baseline 53/57 (92.9%) of patients had fever and median number of active joints was 2 (IQR 1-4). After 6 months of treatment 40 patients (70.2%) met criteria for inactive disease. Among 57 patients 17 (30.3%) received anakinra in monotherapy and 40 (70.2%) received anakinra with glucocorticoids. There were no statistically significant differences between the two groups for demographic, clinical and laboratory features. 13/17 (76.4%) patients treated with anakinra alone and 27/40 (67.5%) patients treated with anakinra and glucocorticoids met criteria for CID off glucocorticoids at 6 months (p=0.75). Among the 57 patients, 30 (52.6%) received anakinra within 2 months from disease onset. There were no statistically significant differences for demographic, clinical and laboratory features among patients who started anakinra in the first 2 months from disease onset compared to those that started anakinra after 2 months. At 6 months after beginning of anakinra treatment, 28/30 patients (93.3%) who started anakinra within 2 months from disease onset and 12/27 (44.4%) who started anakinra after 2 months from disease onset reached clinical inactive disease off glucocorticoids (p=0.0001). Patients who started anakinra after the first 2 months from disease onset have a significantly higher risk of non-response (OR=8.06, 95% CI: 2.03-32.0).

Conclusion: According with several observations, anakinra is effective in a significant proportion of patients with sJIA. A possible approach to introduce IL-1 inhibitor, with or without concomitant glucocorticoids, early in the disease course taking advantage of a “window of opportunity” has been suggested. Our observation confirms that earlier treatment with anakinra is associated with a better short-term outcome. Moreover, our results show that beginning of treatment after two months of disease is correlated with a high risk of non-response.

Abstract Number: 2696

Long-Term Efficacy and Safety of Canakinumab in Children with Systemic Juvenile Idiopathic Arthritis

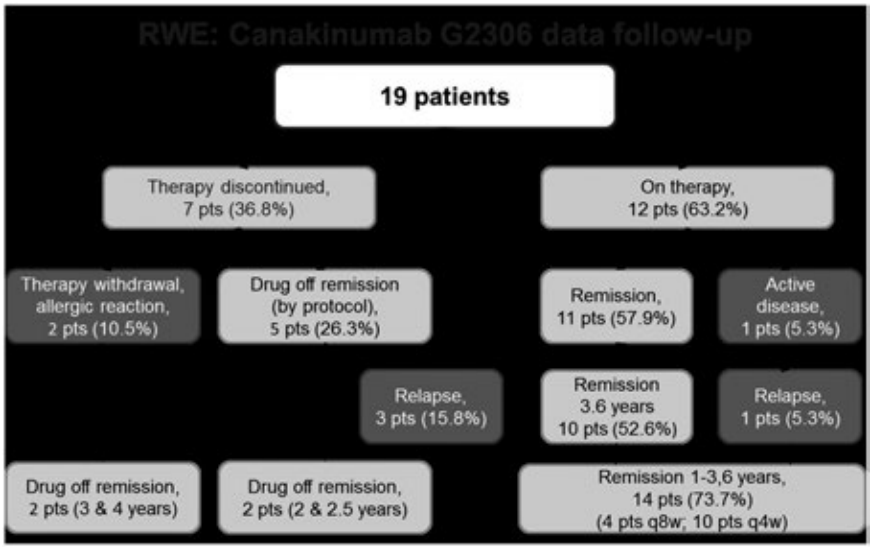
Ekaterina Alexeeva,[1] Rina Denisova,[2] Tatyana Dvoryakovskaya,[2] Ksenia Isaeva,[2] Ivan Kriulin,[2] Alina Alshevskaya,[3] and Andrey Moskalev[3], [1]National Medical Research Center of Children`s Health, Moscow, Russia, [2]NMRCCH, Moscow, Russia, [3]Biostatistics and Clinical Trials Center, Novosibirsk, Russia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Canakinumab (CAN) is an efficacious option for treatment of systemic juvenile idiopathic arthritis (sJIA). However, it is still disputable whether long-term therapy is efficacious and drug-free remission can be achieved. This study aimed to analyze the efficacy and safety of long-term CAN treatment in children.

Methods: Nineteen patients aged 2.3–15.6 years who had started CAN therapy under CACZ885G2306 clinical trial were enrolled in this study. The patients' median age at treatment initiation was 9.6 (IQR 6.4–11.1) years; age at sJIA onset was 3.2 (1.9–5.1) years; and sJIA duration was 4.4 (1.2–7.0) years. Before the initiation of CAN therapy, two (10.5%) patients were biologic-naïve; 12 (63.2%) patients had received one prior biologic agent; and 5 (26.3%) patients had received at least two prior biologic agents. All patients had been earlier treated with NSAIDs; 16 (84.2%) patients had been receiving glucocorticoids; 15 (78.9%), methotrexate; 10 (52.6%), cyclosporine A; and one (5.3%) patient, sulfasalazine. Response to therapy was assessed using the ACRPedi 30/50/70/90 criteria and the C. Wallace criteria for clinical remission. Safety was assessed at each visit

Results: At treatment initiation, disease activity was high in all patients. Depending on the criteria used for evaluation, JIA activity was as follows: 14.7 (12.2–25.3) for JADAS-71; 41 (36.5-69) for physician's global assessment VAS; 54 (45-79.5) for patient's global assessment VAS; and 0.5 (0.1-0.8) for the CHAQ disability index. After 12-month treatment, 14 (73.7%) patients attained inactive disease according to the C. Wallace's criteria. JADAS-71 decreased



Study scheme

by 14.5 (11-25.4) points (p< 0.001 compared to baseline). Fourteen (73.7%) patients achieved an ACR100 response. The median treatment duration was 42.6 (39.5-72.5) months; total treatment duration was 79.2 patient-years. Figure shows the treatment outcomes and the reasons for therapy discontinuation.

One of 11 patients remaining in therapy developed a relapse accompanied by a MAS episode that required elevation of the GC dose. CAN therapy was continued, and the patient achieved remission again. Fourteen (73.7%) of 19 patients receiving CAN therapy achieved remission lasting 1–3.6 years; the interval of CAN administration was increased to 8 weeks in four patients.

Four (21.1%) patients achieved drug-free remission and had no relapses over the follow-up period of 2-4 years.

During the follow-up period, serious adverse events (SAE) were reported in two (6.1%) patients (severe allergic reaction – 1 and enteritis – 1). Five (10.2%) patients had AEs (allergy – 1; hepatotoxicity – 2; exacerbation of herpes infection –1; and neutropenia – 1).

Conclusion: Long-term CAN therapy proved to be efficacious and safe; patients remain in remission after medication discontinuation.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Macrophage Activation Syndrome (MAS) is a severe, life-threatening, complication of rheumatic diseases in childhood, particularly of systemic Juvenile Idiopathic Arthritis (sJIA), occurring in approximately 25% of the patients with sJIA. The mortality rate of MAS is still significantly high. A score that identify sJIA patients who are at high risk to develop MAS would be useful in clinical practice. There are no parameters available to identify from onset sJIA patients with high risk to develop MAS in their disease course.

Table 1. Laboratory parameters and cut-off used to create the MAS risk score in sJIA patients

Laboratory parameters	Cut-off	Rate
Ferritin (ng/ml)	>900	1
AST (UI/L)	>35	1
LDH (UI/l)	>550	1
gammaGT (UI/L)	>30	2
Triglycerides (mg/dl)	>150	2

Table 2. Sensitivity and Specificity of the best Risk core

Sensitivity (Se)	0.950	CI95% 0.842-0.988
Specificity (Sp)	0.848	CI95% 0.718-0.928
Positive predictive value (PPV)	0.792	CI95% 0.654-0.887
Negative predictive value (NPV)	0.966	CI95% 0.864-0.995

Table 3. Sensitivity and Specificity of the MAS risk score in the validation cohort

Sensitivity (Se)	0.833	CI95% 0.691-0.921
Specificity (Sp)	0.724	CI95% 0.572-0.840
Positive predictive value (PPV)	0.652	CI95% 0.499-0.781
Negative predictive value (NPV)	0.875	CI95% 0.739-0.949

Methods: We evaluated whether routine laboratory parameters at disease onset may predict the development of MAS in patients with active sJIA and we defined a risk score of MAS for sJIA patients using these parameters. Laboratory parameters of disease activity and severity (WBC, N, PLT, Hb, ferritin, AST, ALT, gGT, LDH, TGL, fibrinogen, D-dimer and CRP), were retrospectively evaluated in 85 sJIA patients referred to our Division of Rheumatology from 1998 to 2018 with at least one year of follow-up. Laboratory parameters were evaluated during active sJIA, without MAS, at time of hospitalization (T1) and immediately before treatment for sJIA was started (T2). Patients were divided in two groups: group 1 (sJIA patients without history of MAS), group 2 (sJIA patients with at least one MAS episode during disease course). To calculate a MAS risk score, laboratory parameters, collected at T2, with a statistically significant difference between the two groups of patients were selected.

Results: Thirty-two patients, that fulfilled the 2016 classification criteria for MAS [1] at time of sampling, were excluded from the analysis. Therefore, we analysed laboratory parameters of 53 patients with sJIA, 33 of whom without history of MAS (group 1) and 20 who developed at least one episode of MAS during disease course (group 2). Levels of ferritin, AST, LDH, gGT and TGL, collected at T2, were statistically significant higher in patients with a history of MAS compared to those without a history of MAS. For each of these parameters an arbitrary cut-off was defined. In order to define the final score an arbitrary rate was attributed to each parameter (Table1). Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) were calculated to define the best scoring system. The scoring system with the best sensitivity was chosen (Table 2). A MAS risk score >3 identified 19 out of 20 sJIA patients with a history of MAS and 5 out of 33 sJIA patients without history of MAS. In order to validate the MAS risk score on a different population, we applied the score on 47 patients from other Paediatric Rheumatologic centres, 29 without history of MAS and 18 with at least one episode of MAS. Sensitivity and specificity of the score are reported in table 3.

Conclusion: In conclusion we developed a MAS risk score based on routine laboratory parameters, available worldwide, that can help clinicians to identify these patients early in the disease course. The initial validation analysis is promising but we need to validate the score on a larger population.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic juvenile idiopathic arthritis **(**SJIA) is a rare autoinflammatory disease characterized by fever and arthritis, often accompanied by rash. Canakinumab (CAN) was approved in the United States (US) in 2013 for SJIA treatment. However, prescribing patterns among physicians who have initiated CAN in real world settings are not well understood. This study aimed to assess the physician reason(s) for initiating CAN and characterize the clinical and treatment profiles of SJIA patients (pts) in US clinical practice.

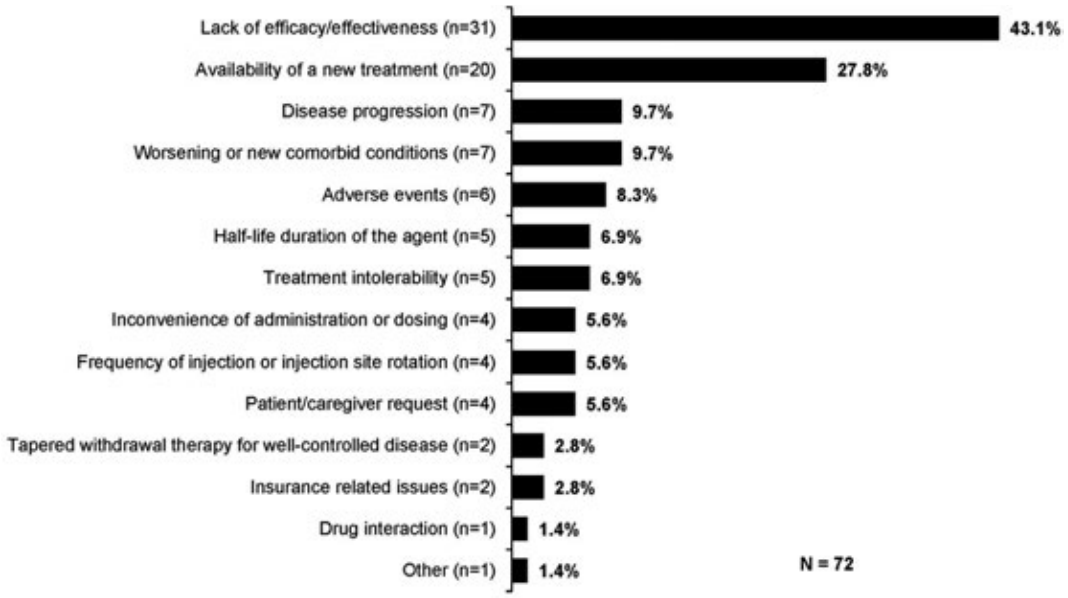

Figure 1. Reasons by SJIA patients for discontinuation of long-term treatments prior to canakinumab initiation

Figure 2. Reasons by SJIA patients for the initiation of canakinumab treatment

Methods: Online medical charts were reviewed retrospectively to collect data from US rheumatologists/ dermatologists/ allergists / immunologists on pts (pediatrics [Ped; < 18 yrs] and adults [Adt; ≥18 yrs]) diagnosed with SJIA who were initiated on CAN therapy by the responding physician between 2016 and 2018. Online case report forms were used to collect information on pt demographics, disease characteristics at CAN initiation, pre-CAN treatment history, and CAN prescribing patterns. Reasons for discontinuation of previous treatment and initiation of CAN were also collected.

Results: Medical charts were reviewed by 43 physicians who had specialty in rheumatology (22; Adt 82%, Ped 18%), dermatology (12; Adt 75%, Ped 25%), immunology (5; Adt 40%, Ped 60%), and allergy (4; Adt 100%). Of the 72 pts, 57% were female and 61% were Ped. The mean age at CAN initiation was 19.4 yrs (Adt, 33.5 yrs; Ped, 10.4 yrs). At CAN initiation, 71% of pts were with and 29% were without active systemic features. Median age at SJIA diagnosis was 11 yrs (IQR: 6.5-16). The key methods of diagnosis were assessment of clinical symptoms and complications (92%), exclusion/rule-out diagnosis (e.g., infection, neoplasms; 75%), and age of onset (67%). The main diagnoses which were ruled out included fever of unknown origin (76%), other JIA subtype (43%), and other PFS (39%). The severity of SJIA was mild (11%), moderate (75%), or severe (14%). The most common symptoms at CAN initiation were fever (72%), fatigue/malaise (58%), skin rashes (47%), and arthritis (46%). A large part of pts at CAN initiation had 1-4 joints with active inflammation (69%) and 1-4 joints with limited range of motion (63%). Nearly all pts (90%) received other long-term treatments in the last line of therapy prior to CAN, including biologics (e.g., 28% etanercept, 19% anakinra, 17% adalimumab, and 11% tocilizumab), methotrexate (9%), and NSAIDs (8%). The main reasons for discontinuation of treatment prior to CAN initiation were lack of efficacy/effectiveness (43%) and availability of a new treatment (28%; Fig. 1). Decision to initiate CAN was decided most often by both physician and pt/caregiver (72%), followed by physician only (26%), and then by the pt/caregiver only (1%). The prime reasons for CAN initiation included efficacy/effectiveness (78%), lack of response to previous treatment (46%) and convenience of administration or dosing (26%; Fig. 2).

Conclusion: Findings from this study provide insight into physicians' characteristics in clinical practice as well as the reasons for CAN initiation in SJIA pts. The efficacy/effectiveness of CAN, lack of response to previous treatment and convenience of CAN administration or dosing were the most common reasons.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis-associated uveitis (JIA-U) is the most common extra-articular manifestation of JIA, leading to ocular complications and blindness when not adequately treated. First line treatment includes topical glucocorticoids followed by methotrexate (MTX). While monoclonal TNF-α inhibitors (TNFi) such as adalimumab (ADA) and infliximab (IFX) are widely accepted as treatment escalation for refractory uveitis or initial therapy in complicated disease, evidence is lacking on the selection of the next optimal agent if MTX and traditional TNFi are ineffective. Our objective is to describe use of immunosuppressive agents for refractory JIA-U immediately following MTX and traditional TNFi treatment failure.

Methods: We retrospectively reviewed medical records for 48 JIA-U children enrolled in a prospective JIA/uveitis study conducted at a tertiary pediatric center since February 2017. All children were treated with systemic immunosuppressive therapy for either 1) uveitis only or 2) uveitis and arthritis. Treatment failure was defined as the escalation of treatment to another biologic indicated for uveitis. Treatment discontinuation was defined as the provider's decision to either 1) permanently discontinue medication or 2) not re-initiate use of medication following patient nonadherence. Traditional TNFi refers to the use of ADA or IFX either concurrently with or following the discontinuation of MTX.

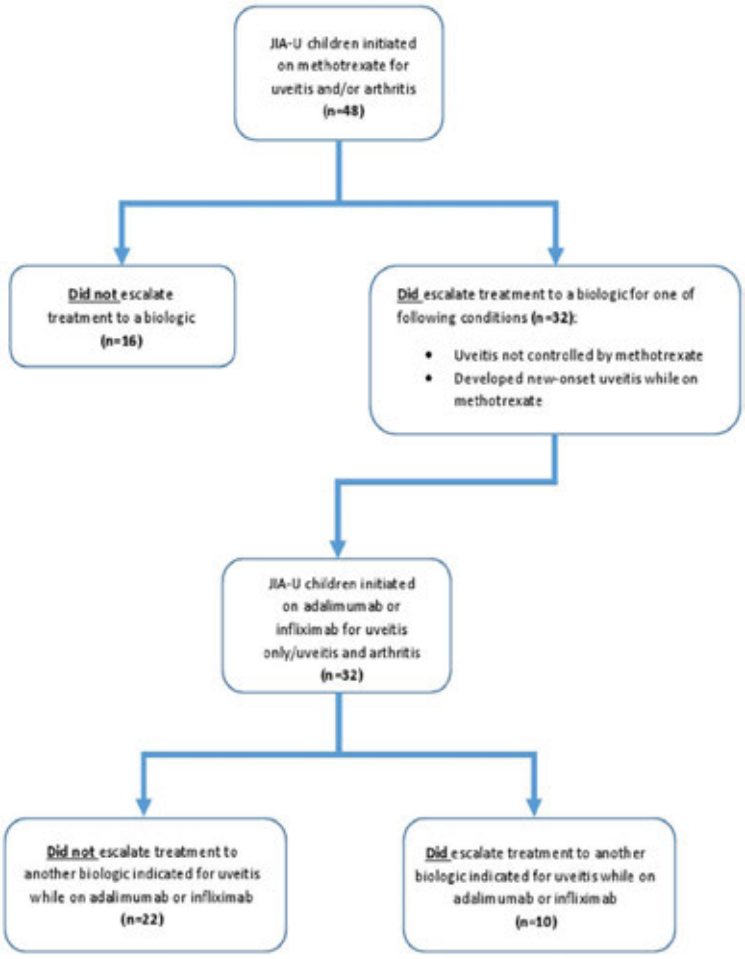

Figure 1: Use of Systemic Immunosuppression in Children with JIA-U

Children were first stratified into 2 groups by treatment response to MTX monotherapy. Those who failed MTX monotherapy and started traditional TNFi were further stratified into 2 groups based on the addition of a third biologic (Figure 1). Additional information (i.e. treatment indication, duration of treatment and reason for discontinuation) were collected for all qualifying systemic medications.

Results: Of the 48 JIA-U children, 16 remained on MTX monotherapy (26%), 22 escalated treatment to traditional TNFi only (46%) and 10 escalated treatment to a third biologic beyond traditional TNFi (21%).

Of the 22 children treated with traditional TNFi only, 18 began on ADA (82%) and 11 began on IFX (50%). Overall, 7 were treated with both ADA and IFX (32%) (Table 1).

Of the 10 children treated with a third biologic beyond traditional TNFi, 5 began on tocilizumab (50%), 3 golimumab (30%) and 2 abatacept (20%). Prior treatment included ADA (60%) or ADA and IFX (40%). Treatment discontinuation occurred only on abatacept (2/2) due to disease activity (Table 2).

Conclusion: 21% of children with JIA-U in our cohort needed treatment beyond MTX and traditional TNFi. Studies report that 50-60% of children with uveitis will fail MTX. Tocilizumab was most commonly used in children requiring treatment beyond traditional TNFi. Both tocilizumab and golimumab were able to control uveitis, suggesting they

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

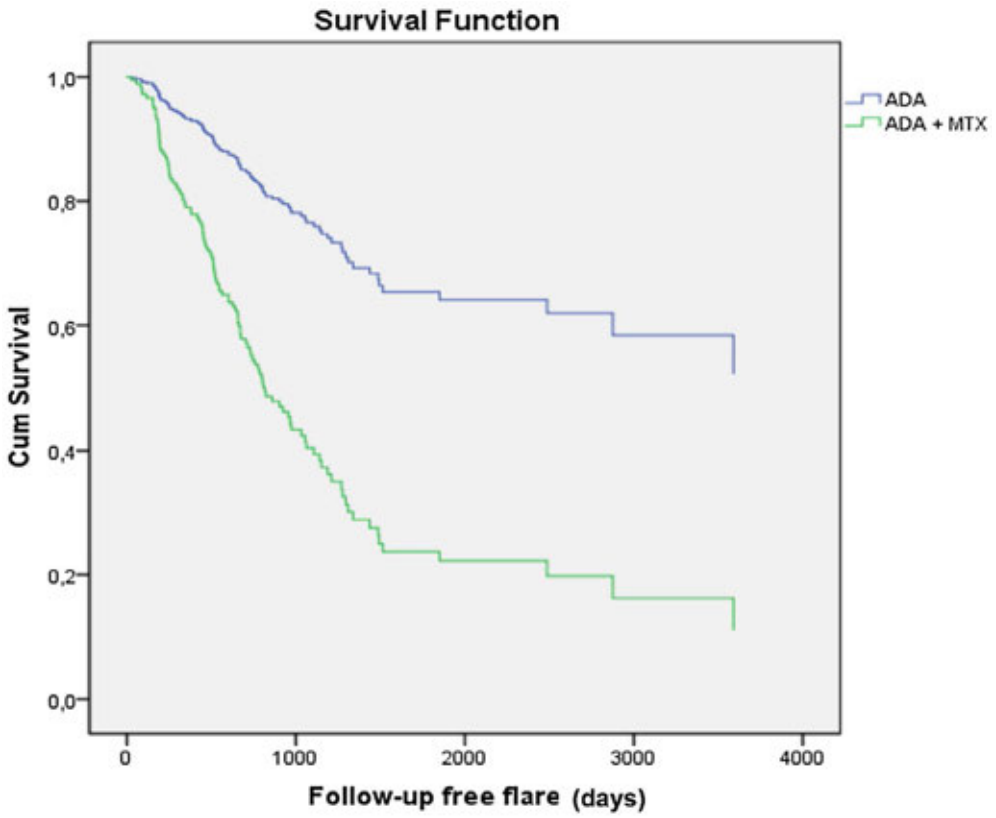
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare the efficacy and safety of Adalimumab alone (ADA) *versus* ADA in combination with Methotrexate (ADA-MTX) in an open-label, retrospective, comparative, multicentre cohort study of Juvenile Idiopathic Arthritis Uveitis (JIA-U).

Methods: Patients with JIA-U treated with ADA were managed by astandardized protocol and data were entered in the ORCHIDEA registry. At baseline, all patients wererefractory to standard immunosuppressive MTX treatment. Data



recordedevery 3 months were uveitis course, number/type of ocular flares and complications, drug-relatedadverse events (AE), and treatment switch or withdrawal. The primary outcome was to assess the time to the first uveitis relapse on ADA treatment, once persistent inactive disease has been achieved. Inactive uveitis was defined as rare or < 1 cell per field at standard slit-lamp examination for at least 3 months. The choice of keeping MTX at 15mg/mq2 with ADA was an opinion-based decision shared between treating ophthalmologist and rheumatologist, at the time of the anti-TNFa start. Data of patients treated for ≥1 year were analyzed.

Results: Up to December 2018, 201 patients (40 Males, median age 4 yrs, range 1-17) with ≥12 months follow-up were enrolled 170 were in the ADA-MTX group, 31 in ADA group. Median age at uveitis onset resulted lower in ADA-MTX group (4 yrs, range 1-17) than ADA (5 yrs, 1-17, Mann-Whitney U test, p< 0.05). No statistical differences between the two groups with regard to age at arthritis onset, number of relapses previous anti TNF treatment, uveitis duration at anti TNF starting and presence of eye complications at base-line have been detected. The overall median time of follow-up without uveitis flares in remission was 24 months (range 1–154). ADA-MTX group showed a shorter relapse-free interval as compared with the ADA group (22 months, range 1-154 vs34 months, range 10-102, Mann-Whitney U test, p= 0.004). Stratifying the two groups by the presence of eye complications at base-line, no significant difference has been noted in 144 JIA-U children without complications. In 57 complicated JIA-U (48 ADA-MTX; 9 ADA), time on remission on treatment resulted shorter in ADA-MTX as compared to ADA (29.2 +24.9 months vs 53.2 +24.5 months, Mann-Whitney U test, p=0.006). Cox regression analysis, at mean of the above-reported covariates, showed a higher probability of maintaining remission on ADA treatment compared to ADA +MTX administration (Mantel-Cox chi-square =19.6, p < 0.001; Figure). The number of pts who experienced drug-related adverse events was not different between the groups: ADA-MTX 44/170 (25.9%) vs ADA 5/31 (16.1%), p: n.s.

Conclusion: JIA-U treating physicians commonly use ADA in combination with MTX. However, according these retrospective data from the ORCHIDEA registry, this approach, even if safe, seems not to provide significant benefits in controlling JIA-U activity over time.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Idiopathic Arthritis (JIA) is a chronic childhood arthritis with onset before age of 16 and has a significant degree of morbidity that negatively affects quality of life. Uveitis, which is defined as the inflammation of the iris, ciliary body and choroid, is the most common cause of morbidity of JIA. This study was planned to collect data from a Turkish cohort to provide the initial national prevalence data of patients with JIA. The objective of this study was to determine the frequency of JIA subtypes in Turkey. We also aimed to assess the frequency and characteristics of eye involvement in JIA.

Methods: This national, non-interventional, multicenter, observational study was conducted in a retrospective manner in four study centers which were main referral pediatric rheumatology clinics across Turkey. Data on patient demography, medical history, JIA disease characteristics, laboratory data, cases of JIA-associated uveitis, JIA treatment history and data on other comorbidities were collected from a cohort of 500 patients.

Results: Oligoarthritis (n=194, 38.8%) was the most common JIA disease characteristic in this study cohort. The frequency of the subgroups was as follows: Enthesitis-Related Arthritis (ERA) in 23.2% (n=116), polyarthritis in 15.6% (n=78), systemic arthritis in 12.2% (n=61), psoriatic arthritis in 5.2% (n=26), idiopathic arthritis in 2.8% (n=14) and

polyarthritis (RF+) in 2.2% (n=11) of patients were identified. The most frequently prescribed treatment for JIA was methotrexate (n=384, 76.8%). A total of 85 comorbidities were reported, and the most frequently reported comorbidity was Familial Mediterranean Fever (FMF) (n=63, 12.6%).

The number of patients with JIA-associated uveitis diagnosis was 34 (6.8%), and the mean duration of uveitis was 3.2 (±2.3) years. The mean duration between the initial JIA diagnosis and diagnosis of uveitis was 1.8 (±1.9) years. Among 34 patients with uveitis, 45 eye involvements were identified; left eye, right eye and both eyes were affected in 5, 8 and 16 patients, respectively. Five patients (14.7%) had uveitis-related complications that required surgical intervention.

Conclusion: The main difference from the European Caucasian population is the lower frequency of oligoarticular JIA and higher frequency of ERA in Turkish JIA patients. Uveitis was also somewhat lower than expected. Geographic and ethnic factors, that may affect these differences, need further investigation.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose:: The OMERACT Juvenile Idiopathic Arthritis Core Set Working Group formed in 2015 as an international initiative to revise the existing Core Set with relevant patient and caregiver input. In efforts to develop an updated, patient-centered Core Outcome, multinational virtual focus groups (VFGs) were conducted to identify main patient-valued themes regarding the impact of Juvenile Idiopathic Arthritis (JIA), with special emphasis on patient and

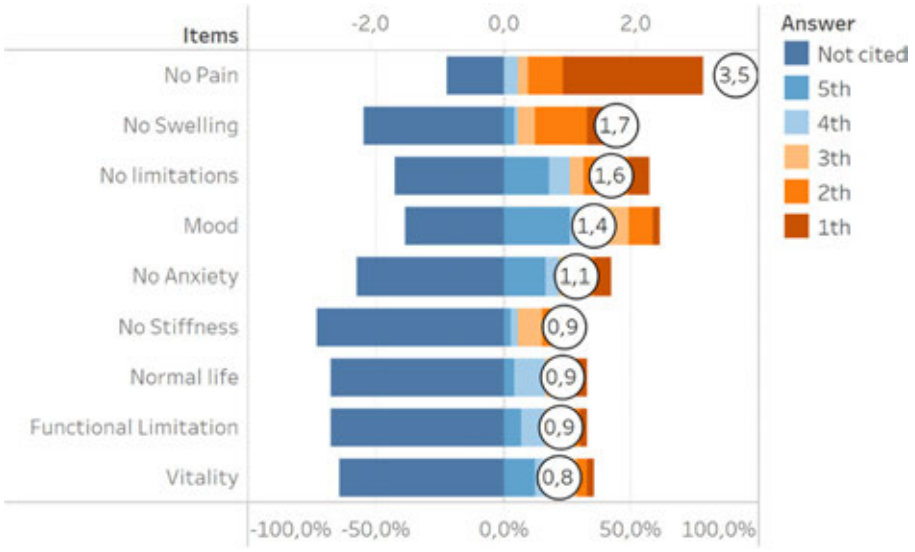
parental perception of disease activity states, and to examine the validity of the identified domains across different populations.

Methods:: Two sets of paired VFGs were conducted with JIA patients (adolescents and young adults) and parents (split by ages of their children) in two clinics, in the US and in Italy respectively. 86 subjects were included. Caregivers were split by ages of their children (under and over 15 years old in the US sample; under and over 10 years old in the Italian sample). Patients were split in adolescents (15-17 years old in the US sample, 15-18 years old in the Italian sample) and young adults (18-24 years old in the US sample, 19-25 years old in the Italian sample). A 3-day facilitated online board was held per group, focusing on the impact of JIA on physical, mental and social health, and the perceived differences between active and inactive JIA. Qualitative analysis of transcripts was first conducted independently in the two centers and compared. Transcripts were further analyzed using text network analysis, that allows studying the interactions between domains and the impact of specific items, as measured by centrality indexes.

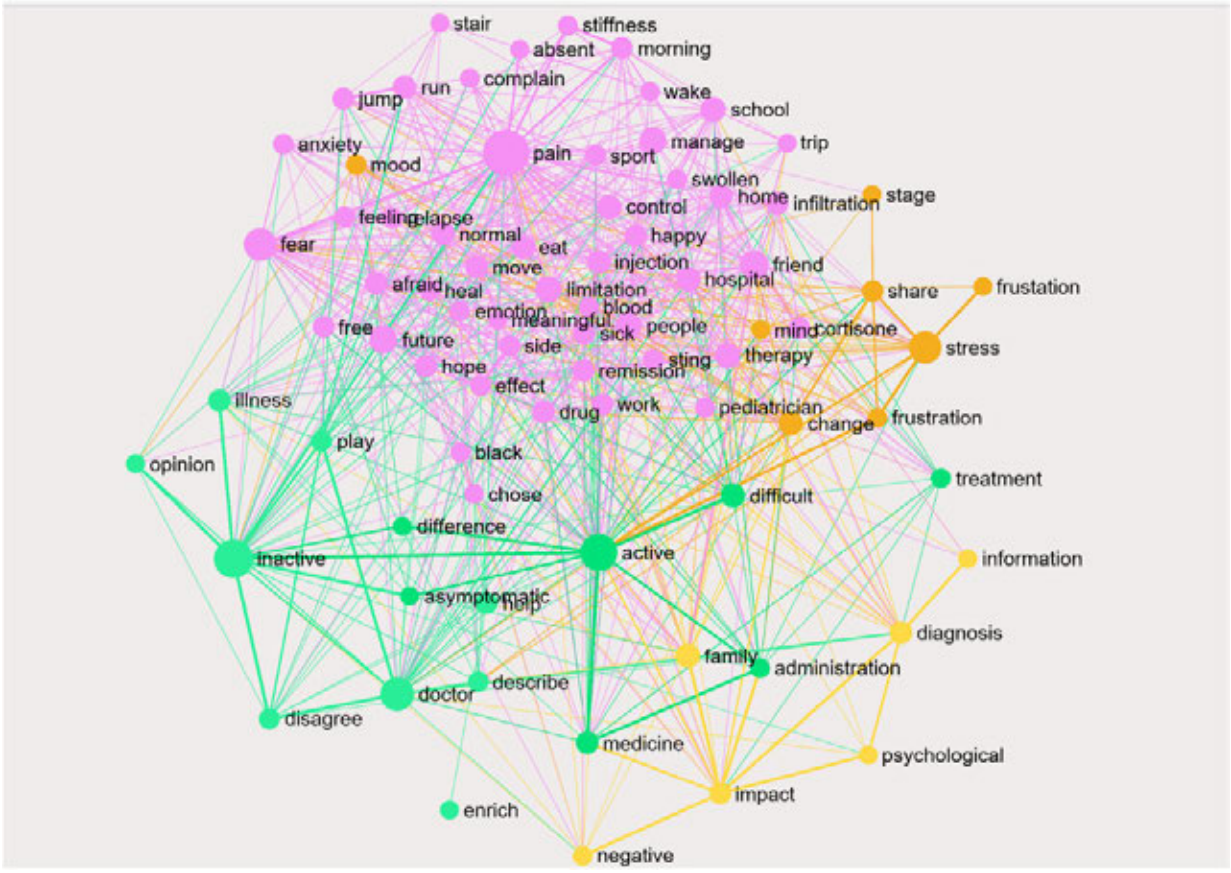
Results: Key domains and group-specific themes were identified, with cross-cultural and age-specific differences between groups, as described in the table. Psychosocial impact and limitations in daily activities emerged as main domains in both samples. Among the main cross-cultural differences, fear of relapses and burden of medications were indicated as concerns by Italian patients and caregivers, while impact on children's activities and family life were more relevant in US groups. Participants were asked to identify and rank their five top priority features defining inactive disease. Absence of pain, swelling and activity restrictions received top-ranking, mood improvement and reduction of disease-related anxiety were ranked as most important, with no significant differences between the two populations (graph 1). Fatigue was cited among relevant themes only by US subjects. Network analysis of transcripts (graph 2) confirmed pain as the single item with the highest degree, closeness and between centrality, indicating high relevance, together with psychosocial distress and activity restriction.

Themes	Italian Groups				US Groups			
	Teens (15-18 y.) N. = 11	Young Adults (19-25 y.) N. = 10	Parents of younger patients (< 10 y.) N. = 10	Parents of older patients (> 10 y.) N. = 10	Teens (15-17 y.) N. = 11	Young Adults (18-24 y.) N. = 13	Parents of younger patients (< 15 y.) N. = 10	Parents of older patients (> 15 y.) N. = 10
Frequent	-Limitations in daily activities -Fear of hospitalization , therapy -Relationship with peers -Fear of Relapses	-Limitations in daily activities -Fear of Relapses -Relationship with peers -Fear of hospitalization , therapy	-Psychosocial impact -Burden of medications -Limitation in daily activities - Fear of Relapses	-Psychosocial impact - Fear of Relapses - Demands on family -Limitations in daily activities -Impact on future abilities	-Relationship with peers -Limitations in daily activities	-Limitations in daily activities -Impact on career trajectory	-Psychosocial impact -Functional limitations, symptoms -Demands on caregivers	-Demands on family -Limitations in daily activities
Less Frequent	Individual costs	-Loss of ability to work -Individual costs		Burden of medications	Loss of ability to work		-Fear of death	Intangible costs
Group-specific		Loss of ability to work	Burden of medications	Side effects (steroids)	Impact on sports	Impact on career goals	-Poor understanding of illness -Guilt about late diagnosis	- Advocacy at school -Concerns about siblings 'well being

Table. Key domains and group-specific themes with cross-cultural and age-specific differences between groups.



Graph 1. «Top Five» remission features, ranked from 1th (most important) to 5th (less important). Percentages of participants assigning each rank are shown for the domains. The average ranking score for each domain is indicated in the circles.



Graph 2. Network graph of trascripts shows the structure of connection between domains, with main macrodomains highlighted in different colors, based on word co-occurrence. The node dimension expresses the between-centrality for each word.

Conclusion: VFGs revealed pain, participation restriction and emotional function as main patient-relevant domains. Differences in the two populations include the role of relapses, treatments and secondary demands in the impact of disease. These results served as inputs for the development of the updated OMERACT JIA Core Domain Set.

Further analysis and cross-cultural validation are planned to inform the development of patient-centered outcomes measures.

High (>8.5)	353 (98)	151 (53.9)	93 (33.0)	51 (22.6)	45 (20.7)

Background/Purpose: There continues to be uncertainty regarding when to start biologic medications for polyarticular juvenile idiopathic arthritis (P-JIA). The Childhood Arthritis and Rheumatology Research Alliance (CARRA) developed consensus treatment plans (CTPs) that reflect the most commonly-used strategies for starting biologic treatment in untreated P-JIA patients. The CARRA STOP-JIA study compares the effectiveness of the CARRA CTPs in achieving clinical inactive disease (CID) at 12 months using a prospective, observational study design. Enrollment was completed in August 2018.

Methods: Untreated P-JIA patients with ≥ 5 active joints were enrolled into the CARRA Registry. One of the CARRA P-JIA CTPs was chosen by the physician and patient/family to follow without randomization or blinding: 1) Step-Up (begin with non-biologic DMARD and add biologic after 3 months if needed); 2) Early Combination (begin both DMARD and biologic at baseline); and 3) Biologic First (biologic monotherapy). Providers prescribed glucocorticoids per their usual practice. Patient Reported Outcomes (PROs) included the CHAQ, Patient/Parent Global Assessment, PROMIS® Pain Interference and Mobility measures.

Results: Four hundred and one patients were enrolled at 44 sites in the US and Canada between 11/2015 and 8/2018. Table 1 shows the baseline data. The most commonly chosen CTPs were Step-Up (n=257; 64%) and Early Combination (n=100; 25%). At baseline, 343 (86%) of patients were started on a non-biologic DMARD (methotrexate). 147 (37%) were started on a biologic DMARD, most commonly etanercept (n=103, 26%) and adalimumab (49, 13%). To date, 320 patients have completed 12-months follow up. 278 patients completed at least one PRO measure at baseline. Table 2 shows mean PROMIS® Pain Interference and Mobiity scores for each treatment group. Table 3 shows the clinical Juvenile Arthritis Disease Activity Scores based on 10 joints (cJADAS-10) and the percentage of participants in each disease activity score category (inactive, low, moderate and high) over time.

Conclusion: STOP-JIA has successfully completed enrollment. Patients enrolled into all CTP choices; however, the Step-Up CTP was most common. There are differences between the treatment groups at baseline, including in

PROMIS® measures, which will require statistical adjustment to reduce bias. Overall, disease activity reduced across all treatment groups over time. Once all patients have completed 12-month follow-up, analyses comparing the effectiveness of the different CTP strategies will be performed.

Abstract Number: 2704

Injection Fear in Juvenile Idiopathic Arthritis Patients Using Injectable Medications

Kathleen Collins,[1] Anava Wren,[2] and Tzielan Lee[2], [1]Stanford University School of Medicine, Palo Alto, CA; [2]Stanford University School of Medicine, Palo Alto

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time:9:00AM–11:00AM

Background/Purpose: Injectable medications are frequently used to treat Juvenile Idiopathic Arthritis (JIA). Fear of pain and needle fear have been identified as barriers to injectable medication adherence. High levels of injection fear have correlated with worse disease outcomes in other chronic diseases such as type 1 diabetes. The purpose of this study was to evaluate the prevalence of injection fear in a population of JIA patients using injectable medicines.

Methods: Inclusion criteria included a diagnosis of Juvenile Idiopathic Arthritis based on ILAR criteria and treatment with an injectable JIA medication. Patients and parents completed questionnaires on injection fear, medication adherence, anxiety, depression, and arthritis disease activity. Data about JIA disease characteristics and details about the patient's injectable medicine were also collected. Injection fear was measured using the injection section of the Diabetes Fear of Injecting and Self-Testing Questionnaire (D-FISQ). Patients age 10-22 completed the self-report D-FISQ, and parents completed the D-FISQ as proxy reporters for patients ages 5-17. The D-FISQ is a 15-item survey about emotions and physical symptoms at time of an injection. Each item has 4 possible answer choices with a corresponding numerical score (almost never 0, sometimes 1, often 2, almost all the time 3). The D-FISQ score is the sum of all items with scores ranging 0 to 45. Previous work has defined a D-FISQ score ≥6 to indicate injection fear with higher scores indicating greater levels of injection fear. The prevalence of injection fear was determined by calculating the number of patients with D-FISQ score ≥6 divided by the total number of patients surveyed. A similar calculation was made for D-FISQ scores obtained by parent report.

Results: Seventy-three JIA patients ages 5-22 and 58 parents from a pediatric rheumatology clinic were enrolled. The patients were 71% female and 63% white. The age range of the enrolled patients was 6-22 with mean age 14.77 (SD 3.98). JIA patient D-FISQ scores ranged from 0 to 41 with median of 11 (IQR 17). Parents proxy report on D-FISQ showed similar scores to patient report with range 0-43 and median 10 (IQR 21.75). The patient report D-FISQ classified 47 patients as having injection fear with a prevalence of injection fear in this cohort as 64.38% by patient

report. Parent proxy D-FISQ identified 37 patients with injection fear with injection fear prevalence of 63.79% by parent report.

Conclusion: This study found that approximately 64% of patients with JIA using injectable medications have injection fear. The prevalence of injection fear in JIA patients as determined by the D-FISQ is higher than previously reported rates of injection fear in pediatric patients with type 1 diabetes (23% in one study, 37% in another). The high rate of injection fear in JIA patients highlights the importance of future research to better understand the association between injection fear and outcome measurements.

Profiling Behavioral and Psychological Symptoms in Children with Spondyloarthritis and Polyarthritis

Anne McHugh,[1] Avis Chan,[2] Carolyn Herrera,[2] Margo Thienemann,[2] and Jennifer Frankovich[2], [1]Stanford University School of Medicine, Palo Alto, CA,[2]Stanford University School of Medicine, Palo Alto

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mental health disorders are thought to be common in patients with rheumatic disease, but studies examining behavioral issues in patients with juvenile idiopathic arthritis (JIA) have shown mixed results. This may be because JIA comprises a heterogeneous group of diseases and few studies examine psychopathology in different subtypes and disease activity states. This study aims to evaluate emotional and behavioral symptoms in children with juvenile spondyloarthritis (SpA) and polyarticular arthritis (PolyA) as compared to a national normative population using the Child Behavior Checklist (CBCL), and the relationship between CBCL scores and disease activity.

Methods: In this cross-sectional study, patients with JIA aged between 6 and 17 years were recruited at follow-up visits from our Pediatric Rheumatology clinic from April 2018 to April 2019. Patients meeting the ILAR criteria of enthesitis-related arthritis, undifferentiated arthritis or psoriatic arthritis and those with IBD-related arthritis or reactive arthritis were classified as SpA, while PolyA included those meeting the ILAR criteria for polyarticular JIA or extended oligoarticular JIA. Patients with active IBD and severe psoriasis (involvement of BSA >10%) were excluded. After enrollment, parents filled out the CBCL for their children while both providers and parents contributed to the Juvenile Arthritis Disease Activity Score (JADAS) using the clinical JADAS10. We abstracted demographic and clinical data from the charts and presented the findings for the two arthritis groups. Primary outcome measures were CBCL total competence, internalizing, externalizing and total problem raw scores. We compared the outcomes from each group to the national CBCL normative data. As exploratory analyses, we also looked at OCD problem scores, self-harm, and individual internalizing and externalizing syndrome scores which were identified apriori. To investigate the relationship between CBCL scores and disease activity, we ran a generalized linear regression model for all arthritis patients with JADAS as the main predictor to control for age, sex and medical co-morbidities.

Results: Our study includes 111 patients (53 with SpA and 58 with PolyA) and 1753 healthy controls. Median age at enrollment is 13-14 years. Most of our patients were on arthritis medications at the time of completing CBCL (table 1).

	Spondyloarthritis (n=53)	Polyarthritis (n=58)
Demographic characteristics		
Age at CBCL (years)	14.0 +/- 3.0	13.0 +/- 6.0

Data are presented as n (%) for categorical variables, and median +/- interquartile range for continuous variables.

[a]Self-reported race and ethnicity

[b]Rheumatologic medication includes NSAID, methotrexate, TNF inhibitor, sulfasalazine, tociliuzimab, abatacept, leflunomide, oral steroids, janus kinase (JAK) inhibitors, and mycophenolate mofetil.

[c]Medical co-morbidites are defined as any current medical diseases through chart reviews and CBCL questionnaires, excluding psychiatric and developmental disorders.

Table 1. Demographic and clinical characteristics of patients with spondyloarthritis or polyarthritis

When compared to healthy controls, patients with SpA or PolyA had worse total competence and internalizing scores (mainly driven by somatic complaints) but better externalizing scores. Self-harm was almost four times more likely in patients with PolyA than healthy controls (table 2). Higher JADAS was associated with worse total competence scores, worse internalizing scores (mainly driven by anxiety/depression) and higher total problem scores (table 3). Most of these differences reached statistical significance ($p< 0.01$).

	Spondyloarthritis (n=53)		Polyarthritis (n=58)	
	Adjusted difference (with reference to healthy controls)[a]	P value	Adjusted difference (with reference to healthy controls)[a]	P value

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time:9:00AM–11:00AM

Background/Purpose: In adults with Rheumatoid Arthritis, obesity has been associated with higher disease activity. However, in Juvenile Idiopathic Arthritis (JIA), the influence of body mass index (BMI) on disease activity is uncertain and a previous study has failed to find any association. We aim to clarify the relationship between BMI and JIA disease activity.

Methods: An international, multicenter, observational analysis was conducted. JIA patients (according to ILAR criteria) aged ≤ 18 years, registered at Rheumatic Diseases Portuguese Register (Reuma.pt) in Portugal and Brazil were included. Anonymized data of the first registered visit was analyzed. Age- and sex-specific BMI percentiles (P) were calculated based on WHO growth standard charts and categorized into underweight (P< 3), normal weight (3≤P≤85), overweight (85< P≤97) and obesity (P >97). Disease activity was assessed by Juvenile Arthritis Disease Activity Score (JADAS-27). Univariate linear regression was used to examine the association of BMI categories with JADAS-27. Two multivariate regression models were performed: a) adjusting for gender, ethnicity, country, disease duration and JIA category (model 1); b) adjusting for those covariates plus use of oral glucocorticoids (GC) and DMARDs (model 2).

Results: 275 patients included, mean age 10.2±4.6 years, mean disease duration 6.1±4.9 years; 62% female. Thirty-two percent were persistent oligoarticular, 8% extended oligoarticular, 26% RF- polyarticular, 7% RF+ polyarticular, 6% systemic, 15% enthesitis-related arthritis, 5% psoriatic arthritis and 1% undifferentiated arthritis. The prevalence

Table 1. Relationship between JADAS-27 (dependent variable) and demographic and clinical characteristics of JIA patients.

*Reference group

Model 1: adjusting for gender, country, ethnicity, disease duration and JIA category.
Model 2: adjusting for those covariates plus use of GC and DMARDs.

of underweight, normal weight, overweight and obesity was 6.9%, 67.3%, 15.3% and 10.5%, respectively. In the univariate linear regression, underweight was significantly associated with higher JADAS-27, compared to normal weight (p< 0.001), overweight (p< 0.001) and obesity (p=0.003). Younger age (p=0.013), shorter disease duration (p=0.001), black race (p=0.026), living in Brazil (p=0.001), RF- polyarthritis (p< 0.001), RF+ polyarthritis (p< 0.001), the absence of DMARD therapy (, p< 0.001) and the use of GC (p=0.017) were also associated with higher JADAS-27 (table 1). In the model 1 of multivariate analysis, the same variables, except the country, remained significantly associated with higher disease activity. When GC and DMARD therapies were added to the model (model 2), the association of normal weight (p< 0.001), overweight (p< 0.001) and obesity (p=0.003) with lower disease activity persisted significant, compared to underweight patients, as well as those under DMARD therapy (p< 0.001). RF- (p=0.006) and RF+ polyarthritis (p=0.024) and the use of oral GC (p=0.002) were associated with higher disease activity.

Conclusion: There seems to be an independent association between underweight and higher disease activity in JIA patients, suggesting that active disease can impair child's weight gain. Longitudinal analysis are needed to confirm these findings and understand the underlying mechanisms of this association.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Efficacy of SC abatacept in patients with polyarticular-course JIA (pJIA) was shown in a 2-year, open-label, Phase III international study (NCT01844518).[1] Pediatric patient-reported outcomes (PROs) were improved with IV and SC abatacept in patients aged 6–17 years.[2,3] Here we report the effect of SC abatacept on PROs (Activity Limitation Questionnaire [ALQ], Childhood HAQ-Disability Index [CHAQ-DI], Pain Assessment and Parent Global Assessment of Overall Patient Well-being [PaGA]) in the 2–5-year-old patients with active pJIA over 2 years.

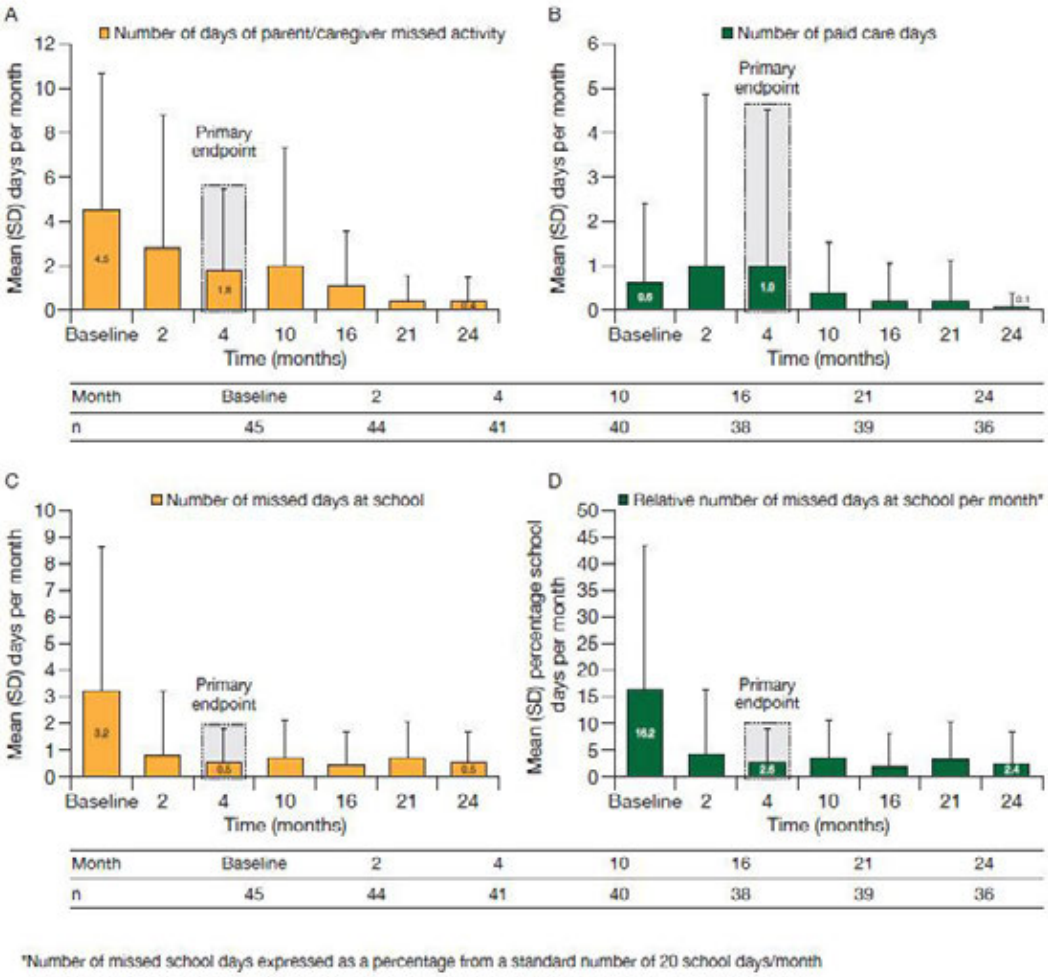
Methods: Patients with pJIA were grouped into two age cohorts (2–5 and 6–17 years) and received weight-tiered SC abatacept (10 to < 25 kg [50 mg], 25 to < 50 kg [87.5 mg], ≥50 kg [125 mg]) weekly for 4 months. JIA-ACR30 criteria

Table. CHAQ-DI, Pain and PaGA Scores Over Time in the 2–5-Year Cohort

	Baseline (n=46)	Month 2 (n=46)	Month 4 (n=42)	Month 16 (n=40)	Month 24 (n=37)
CHAQ-DI	1.1 (0.66)	0.8 (0.69)	0.6 (0.64)	0.5 (0.53)	0.4 (0.49)
Pain (mm VAS)	39.6 (27.02)	22.2 (22.91)	17.8 (22.21)	14.1 (17.62)	7.5 (10.33)
PaGA (mm VAS)	38.6 (23.94)	22.1 (20.48)	15.2 (17.22)	11.8 (15.90)	8.3 (12.72)

Data are mean (SD). For CHAQ-DI (scale 0–3), pain (0–100 mm VAS) and PaGA (0–100 mm VAS), higher scores indicate greater dysfunction and pain, and lower well-being, respectively
CHAQ-DI=Childhood HAQ-Disability Index; PaGa=Parent Global Assessment of Overall Patient Well-being; VAS=visual analog scale

Figure. Change Over Time in Activities of Daily Living Limitation: (A) Days of Parental/Caregiver Missed Activity; (B) Paid Care Days; (C) Missed School Days [Absolute Values]; (D) Missed School/Nursery Days [Relative Values]) in 2–5-Year-Old Patients



*Number of missed school days expressed as a percentage from a standard number of 20 school days/month

responders at Month 4 could receive SC abatacept for another 20 months.[1] For the 2–5-year cohort reported here, ALQ (mean [SD] number of days of parental/caregiver missed activity, paid care and missed school [absolute values per month and percentage of days missed per month relative to an assumed average of 20 school days/month]), CHAQ-DI (0–3 scale across 8 domains of disability component), pain (0–100 mm visual analog scale [VAS]) and PaGA (0–100 mm VAS) were evaluated.

Results: Baseline characteristics of the 46 patients with pJIA from the 2–5-year cohort included median (min, max) age of 4.0 (2.0, 5.0) years and median (interquartile range) number of active joints of 7.0 (6.0, 12.0). At baseline, 80.4% of patients received MTX (median dose: 13.3 mg/m^2/week) and 21.7% of patients had prior biologic failure. CHAQ-DI, pain and PaGA improved from baseline to Month 24 (Table). Most ALQ components improved from baseline to Month 4 (primary endpoint); these improvements were largely maintained over time to Month 24 (Figure). Relative percentage of days missed from school decreased from 16.2% (baseline) to 2.4% (Month 24, Figure D).

Conclusion: In this analysis of patients with pJIA aged 2–5 years, SC abatacept demonstrated a beneficial effect on PROs including improvement in well-being (PaGA) and reductions in disability (CHAQ-DI), pain and activity limitation (ALQ) over 24 months.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients (pts) with polyarticular-course JIA (pJIA) may develop anti-drug antibodies (ADAs) in response to biologics.[1] Presence of ADAs has been associated with treatment (tmt) failure and hypersensitivity in pts with pJIA.[1] Abatacept (ABA), a fully human co-stimulation modulator, consists of the extracellular domain of cytotoxic T lymphocyte–associated antigen-4 (CTLA-4) linked to Fc portion of IgG1. Here we evaluate immunogenicity (IMG) of SC and IV ABA, and effect of IMG on efficacy, pharmacokinetics (PK) and safety in an open-label (OL), Phase III study of SC ABA (NCT01844518) and in a double-blind, Phase III study of IV ABA (NCT00095173).

Methods: Study design and eligibility criteria for both studies were reported previously.2,3 In the SC study, pts with pJIA and prior DMARD failure were stratified by age cohort (2–5 and 6–17 years [yrs]) to receive weight-tiered SC ABA (10 to < 25 kg [50 mg], 25 to < 50 kg [87.5 mg], ≥50 kg [125 mg]) weekly for 4 months. JIA-ACR30 responders at Month 4 could receive SC ABA for another 20 months.2 ADAs were detected by electrochemiluminescence. In the IV study, pts with pJIA and prior DMARD failure received OL IV ABA (10 mg/kg body weight) for 4 months (Period A); JIA-ACR30 criteria responders at Month 4 were randomized 1:1 to receive IV ABA (10 mg/kg) or placebo (PBO) for 6 months or until flare (Period B). Pts could receive OL ABA in a 5-yr follow-up (Period C).3 ADAs were detected by ELISA.

Results: In the SC study, ADA rate was low in both cohorts (Table 1). In the 2–5-yr cohort, of 3 ADA positive (+) CTLA-4-specific pts, 2 had neutralizing antibodies detected (ADA-NAb+); no 6–17-yr-old pts (of 3 ADA+ CTLA-4-specific) were ADA-NAb+ over 24 months. ADA positivity on tmt did not impact JIA-ACR30 response. ABA steady-state serum trough concentration was similar between ADA+ and ADA negative pts (data not shown). Pts treated with ABA+MTX, but not with ABA alone, developed ADAs in the 2–5- (7/36 [19.4%]) and 6–17-yr (8/135 [5.9%]) cohorts.

In the IV study, ADAs were infrequent for pts who remained on ABA versus those on PBO (Table 2). Of 6 ADA+ pts with ADA-NAb assessments, 3 were ADA-NAb+ in Period C. In Period B, of 7 ABA-treated pts with flare and 47 ABA-treated pts without flare, respectively, 0 and 7 (14.9%) were ADA+ CTLA-4-specific; in the PBO arm, 7/26 (26.9%) and 15/28 (53.6%) pts with and without flare, respectively, were ADA+ CTLA-4-specific. In Period A, 2/140 (1.4%) ABA+MTX-treated pts and 2/49 (4.1%) pts treated with ABA alone developed ADAs. Pts treated with ABA+MTX, but not pts treated with ABA alone, developed ADAs during Period B (7/45 [15.6%]).

No new safety signals, including those suggestive of hypersensitivity were reported in ADA+ pts in either study.

Conclusion: IMG of SC and IV abatacept was low and did not have any impact on the efficacy, PK and safety of abatacept. Contrary to previous reports for other biologics,[1] in this study, MTX did not lower the incidence of ADAs when co-dosed with abatacept.

Abstract Number: 2709

Secukinumab Is a Promising Treatment for Patients with Juvenile Enthesitis Related Arthritis Nonresponsive to Anti-TNF Treatment According the Juvenile Spondyloarthritis Disease Activity Index

Ivan Foeldvari,[1] and Jean Baer[1], [1]Hamburg Centre for Pediatric and Adolescence Rheumatology, Hamburg, Germany

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC) is licensed to treat adults with spondyloarthritis and psoriatic arthritis. It is not licensed for juvenile patients yet. As biologic agents up till now only etanercept and adalimumab are licensed for enthJIA. Not all enthJIA patient reaching remission with an anti-TNF therapy. We review our patients, who did not reach remission under anti-TNF and were switched to SEC.

Methods: We conducted a retrospective monocentric chart review of patients with enthJIA, who were ever treated with SEC with enthJIA, at least for 3 months till 15thof March 2019. We used the JADAS10 and the Juvenile Spondyloarthritis Disease Activity Index (jspADA) [1]to evaluate response.

Results: 17 patients with enthJIA were treated till 15thof March 2019. 77 % were female. The mean age of the patients at the start of the treatment was 19.5 years. The mean disease duration was 6.3 years. The patients received in average 1.9 different anti-TNF´s before switching to SEC. The JADAS-10 was 8.3 and the jspADA 2.4 at the time initiation of SEC. SEC was applied according the adult dosing schedule, the mean weight of the patients was 65 kg. The mean dose at week 0 was 185 mg/dose, at 12 months 270 mg/dose (n=15) and at 24 months 280mg/dose (n=9). Mean follow up of the patients under SEC was18months. JADAS 10 dropped from 8.35 at timepoint 0 to 5.8 at 3 months (n=17); 5.1 at 6 months (n=16), 5.5 at 12 months (n=15) and to 6.5 at 24 months (n=9) . jspADA, a more sensitive outcome parameter for enthJIA dropped from 2.41 at timepoint 0 to 1.6 at 3 months (n=17); 1.7 at 6 months (n=16), 1.2 at 12 months (n=15)and to 1.3 at 24 months (n=9) . In two patients SEC after 24 months was switched to tofacitinib, because of nonresponse. There was no SAE observed.

Conclusion: In our anti-TNF nonresponder patients SEC showed quite good effectiveness regarding the improvement in jspADA and less in JADAS 10, which is less specific for enthJIA. The 150 mg dose seems to be not sufficient in anti-TNF nonresponder patients, in most of the patients the dose had to be increased to 300 mg /dose per application.

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarilumab blocks interleukin-6 (IL-6) from binding to membrane and soluble IL-6 receptor-α. Sarilumab is approved for adults with rheumatoid arthritis (RA) and is being investigated in a Phase 2 trial (NCT02776735) in 2–17-year-old patients (pts) with polyarticular-course juvenile idiopathic arthritis (pcJIA), comprising rheumatoid-factor (RF)-positive and RF-negative polyarticular and extended oligoarticular JIA. This study aimed to evaluate pharmacokinetics (PK), pharmacodynamics (PD), safety, and efficacy of 3 subcutaneous (SC) sarilumab doses in pcJIA.

Figure: Mean (CV%) individual sarilumab exposure, following first SC dose, and after repeated SC administration at Weeks 10–12 or Weeks 11–12, in patients with pcJIA

pcJIA treatment		First SC administration			Repeated SC administration (Weeks 10–12 or Weeks 11–12)		
Patient weight group	Sarilumab dose	N	C_{trough} mg/L (CV%)	$AUC_{0-\tau}$ day mg/L (CV%)	N	C_{trough} mg/L (CV%)	$AUC_{0-\tau}$ day mg/L (CV%)
10–<30 kg (Group B)	2.5 mg/kg q2w	6	0.54 (48)	63 (30)	5	1.83 (101)	118 (37)
	4.0 mg/kg q2w	7	3.77 (43)	167 (26)	7	11.90 (41)	310 (26)
	2.5 mg/kg qw	9	5.22 (39)	45 (36)	5	25.10 (29)	203 (25)
30–60 kg (Group A)	2.0 mg/kg q2w	7	0.63 (63)	53 (46)	5	1.99 (86)	114 (18)
	3.0 mg/kg q2w	7	1.84 (69)	123 (24)	6	8.46 (68)	269 (34)
	2.0 mg/kg qw	6	8.07 (32)	61 (22)	6	30.40 (28)	250 (24)

AUC, area under the serum concentration versus time curve, calculated using trapezoidal method during a dose interval; C_{trough}, serum concentration observed before treatment administration during repeated dosing; CV, coefficient of variance; N, number of patients; pcJIA, polyarticular-course juvenile idiopathic arthritis; qw, every week; q2w, every 2 weeks; SC, subcutaneous.

Dose interval ($_\tau$) was 2 weeks for q2w, or 1 week for qw regimen.

Methods: A 12-week dose-finding study was performed to identify an appropriate sarilumab dose for use in the pcJIA population. Pts were divided by body weight into 2 groups: A (30–60 kg) and B (10–< 30 kg), and received sequential ascending doses of sarilumab, Dose 1 (Group A/B): 2.0/2.5 mg/kg q2w; Dose 2 (Group A/B): 3/4 mg/kg q2w; and Dose 3 (Group A/B): 2.0/2.5 mg/kg qw. pcJIA doses were targeted to achieve similar exposure to adult RA doses (150 mg q2w, 200 mg q2w, and 150 mg qw). Primary outcome was PK; secondary outcomes were safety, PD, and efficacy of sarilumab.

Results: 42 pts enrolled (20/22 in Groups A/B); mean age was 13.0/5.2 years. At baseline, mean pcJIA duration, number of active joints, and JADAS27-CRP were 4.6/1.7 years, 17.2/11.0, and 22.2/19.1, in Groups A/B, respectively. As in adult pts, sarilumab exhibited nonlinear PK with target-mediated drug disposition (TMDD). Following repeated SC administrations, exposure increased in a greater than dose-proportional manner and accumulated 1.9–4.5-fold over 12 weeks. Sarilumab exposure was similar in both weight groups for each dose (Figure), and comparable to corresponding adult doses. Treatment-emergent adverse events (AEs) were reported in 36/42 (85.7%) pts (comparable across dose and weight groups); infections (28/42, 66.7%) were the most frequently reported AE. 12 grade 3/4 neutropenias were identified, mostly in Dose 3 (n=6) and in Group B (n=8). None was associated with infection; all resolved in a few days. Overall, 4 pts discontinued due to neutropenia and 1 due to alanine aminotransferase increase. There were no serious AEs, no cases of GI perforation, and no deaths. By Week 12, as observed while on-treatment: all pts attained JIA ACR30; 50%, 62%, and 100% of pts attained JIA ACR70 with Doses 1, 2, and 3, respectively; JADAS27-CRP mean % changes from baseline in Doses 1, 2, and 3 were –74.6%, –73.1%, and –87.9%, respectively.

Conclusion: Sarilumab exhibited nonlinear PK with TMDD. Doses tested in pcJIA yielded similar exposure in both weight groups and were comparable to equivalent doses in adults with RA. All dose regimens proved effective for decreasing disease activity. Safety profile was consistent with class effects; higher incidences of neutropenia were observed with Dose 3, and in pts weighing 10–< 30 kg.

Utilization of Biologic Treatments in Oligoarticular and Polyarticular Juvenile Idiopathic Arthritis

Daniah Basodan,[1] Kathleen M Andersen,[2] Xintong Li,[3] Jeffrey Curtis,[4] and G. Caleb Alexander[5], [1]University of Alberta, Edmonton, AB, Canada, [2]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health,, Baltimore, MD, [3]Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, [4]University of Alabama at Birmingham, Birmingham, AL, [5]Johns Hopkins Bloomberg School of Public Health. Center for Drug Safety and Effectiveness, Baltimore, MD

SESSION INFORMATION

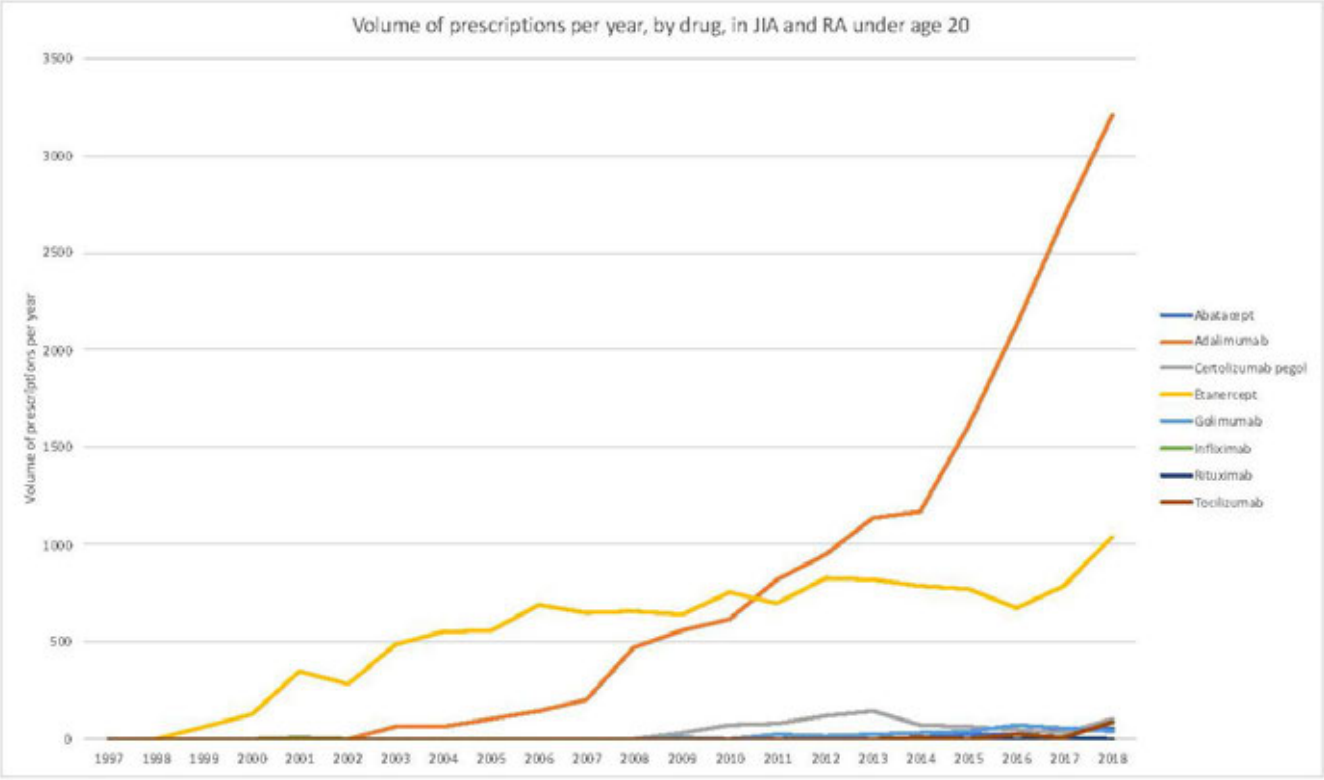
Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In recent years, juvenile idiopathic arthritis (JIA) treatment options have expanded to include biologics such as tumor necrosis factor inhibitors (TNF_i) and non-TNF inhibitors (non-TNF_i). While several studies have characterized utilization of these drugs in adults, few have done so in pediatric and adolescent settings. In this study, we aimed to characterize the trends in biologic utilization among patients with oligoarticular and polyarticular arthritis in the United States.



Volume of prescriptions by year, by drug in JIA and RA under the age of 20

Methods: We performed a retrospective cohort analysis using a large US commercial insurance database to identify patients with a diagnosis of JIA between January 1, 1997 and October 19, 2018. To identify cases of oligoarticular and polyarticular JIA, we included diagnosis codes for JIA (ICD-9 714.3; ICD-10 M08) or rheumatoid arthritis (ICD-9 714.x; ICD-10 M06) under age 20. We identified biologic therapies claims by biologic generic names that included: TNF_i drugs: etanercept, adalimumab, infliximab, golimumab and certolizumab pegol and non-TNF_i drugs: tocilizumab, abatacept and rituximab. Prescription patterns (initiation, switches, and persistence) were described overall, and by drug.

Results: A total of 29,537 unique biologic prescriptions were identified, with prescription volume increasingly steadily over the years examined. Approximately three-fifths (59%) of prescriptions were for females, and the median age of biologic recipients was 16 years (interquartile range 13-18 years). Etanercept accounted for approximately 41% of total prescriptions and increased relatively steadily between 1998 and 2018, whereas adalimumab accounted for more than half (54%) of total prescriptions and increased gradually between 2002 and 2007, moderately between 2007 and 2014 and sharply between 2014 and 2018. Certolizumab pegol, while not approved for use in JIA in the US, comprised approximately 3% of all biologic prescriptions, while other biologics accounted for less than 1% of total volume observed.

Conclusion: To our knowledge, this study is one of the first to examine long-term trends in the biologic treatment of oligoarticular and polyarticular JIA in the US. During the examination period the market was dominated by etanercept and adalimumab with a trend toward a sharp increase of adalimumab use starting in 2014.Further analyses will examine patient-level factors associated with biologic initiation, adherence and persistence in children and adolescents with JIA, as well as the effect that utilization management strategies, clinician and patient preferences may have on the patterns observed.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose:: Etanercept (ETN) is an anti-tumor necrosis factor (anti-TNF) therapy that is FDA approved for the treatment of polyarticular juvenile idiopathic arthritis (JIA). This study describes the use of ETN in JIA patients enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) JIA Registry.

Methods: The CARRA Registry is a convenience cohort of children that includes patients with JIA. Retrospective data is collected at enrolment and prospective observational data is collected twice a year, as well as when a JIA medication is initiated. Data were collected from June 30, 2015 to June 30, 2018 from 60 U.S. and 3 Canadian clinical

Table 1. Characteristics of patients at start of ETN who had a clinical visit within 30 days, by JIA category*

Characteristic	All patients	PersistOligo¶	ExtOligo§	Poly RF+©	Poly RF-β	ERAδ	Psoriaticπ	SJIA⌘	Undiffθ

*in patients with at least 1 study visit ≥6 months after starting ETN

sites were included in this analysis. JIA patients treated with ETN were included if the month and year of initiation were available. Concomitant methotrexate use was described for patients who had >1 follow-up visit ≥ 6 months after beginning treatment with ETN. Descriptive statistics including means, standard deviations, medians, and interquartile ranges for continuous variables, and proportions for categorical variables were calculated as appropriate.

Results: At the time of data extraction, there were 5641 patients with JIA in the registry, and 2032 patients met inclusion criteria (74% female, median age of diagnosis 6.0 years [25th and 75th percentiles 2.0, 11.0]). Reported JIA ILAR categories were: 22.5% oligoarticular, 42.6% polyarticular RF negative (RF- pJIA), 11.9% polyarticular RF positive (RF+ pJIA), 8.1% psoriatic, 10.2% enthesitis related arthritis (ERA), 2.6% systemic, and 2.0% undifferentiated. There were 465 participants with a study visit within 30 days of starting ETN (Table 1). Within this group, ETN was started ≤3 months after diagnosis by 38% and >3 months after diagnosis by 57% (5% missing), while 62% started a non-biologic DMARD prior to ETN, primarily MTX. By ILAR category, RF+pJIA had the highest active joint count and clinical Juvenile Arthritis Disease Activity Score limited to 10 joints (cJADAS10), followed by RF-pJIA (Table 1). Fifty three percent of RF- pJIA, 44% of RF+ pJIA and 58% of ERA with a study visit within 30 days of ETN initiation started ETN >3 months after diagnosis. Table 2 shows the pattern of MTX use in individuals with at least one visit 6 months after starting ETN (n=1681). In all categories of JIA, the most common treatment approach was adding ETN after initiating MTX (step up strategy).

Conclusion: This study describes contemporary patterns of ETN use in the CARRA Registry, a North American convenience cohort that includes a large population of JIA patients. Most JIA patients started ETN >3 months after diagnosi

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time:9:00AM–11:00AM

Background/Purpose:: Herein we describe characteristics of children with juvenile spondyloarthritis (JSpA, i.e. enthesitis-related arthritis [ERA] or juvenile psoriatic arthritis [JPsA]) enrolled in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry, which was established in 2015.

Methods:: All children with physician-diagnosed ERA or JPsA enrolled in the CARRA Registry between June 2015 and June 2018 were identified. Demographics, clinical characteristics, and treatments of children with ERA and JPsA were described and contrasted. Additionally, children with JSpA and sacroiliitis were compared to those without sacroiliitis. Finally, in the group with sacroiliitis, the first visit with clinically active sacroiliitis was compared to the first visit without clinically active sacroiliitis. 'Clinical sacroiliitis' was at the discretion of the treating physician and sacroiliitis by imaging was diagnosed by MRI, X-ray, and/or CT.

Results:: Nine hundred two children with JSpA – 522 (58%) with ERA and 380 (42%) with JPsA - were identified. Children with ERA were older at diagnosis (10.8 versus 8.2 years) and more likely to be male (56% versus 38%). Pol-

Table 1: Characteristics of Children with Enthesitis Related Arthritis (ERA) or Psoriatic Arthritis (PsA) by JIA Category at the Most Recently Occurring Visit

Characteristic	Overall (N = 902)	ERA (N = 522)	PsA (N = 380)
Mean Age at Diagnosis (years)	9.7 (SD 4.2)	10.8 (SD 3.4)	8.2 (SD 4.6)

Enthesitis, Ever	476 (53%)	407 (78%)	69 (18%)
HLA B27 Present**	222 (24%)	197 (38%)	25 (7%)
At least 1 Biologic Taken	622 (69%)	377 (72%)	245 (64%)

*Approximately 8% responded with either 'multiple races', 'other', or 'prefer not to answer'.

**HLA-B27 status unknown in 0% of the ERA patients and in 47% of the PsA patients.

Table 2: Characteristics of Children with Enthesitis Related Arthritis (ERA) or Psoriatic Arthritis (PsA) by Sacroiliitis Category (Ever Reported by Clinical Exam or Imaging)

Characteristic	Sacroiliitis Ever Reported (N = 252; 28%)	Sacroiliitis Never Reported** (N = 619; 69%)
Female, %	137 (54%)	312 (50%)
HLA B27 Present*	86 (34%)	132 (21%)
At least 1 biologic taken	203 (81%)	403 (65%)

*HLA-B27 status unknown in 5% of those with sacroiliitis ever reported and in 25% of those with sacroiliitis never reported.

**Sacroiliitis status was unknown for 31 (3%) of patients

Table 3: Characteristics of Children with Ever Reported Sacroiliitis at First Visit with Clinically Active Sacroiliitis Versus First Visit without Clinically Active Sacroiliitis

Characteristic	1st Visit with Clinically Active Sacroiliitis (N = 163)	1st Visit with No Clinically Active Sacroiliitis (N = 163)	p-value
Mean PGA	2.9 (SD 2.2); N = 154	1.8 (SD 1.9); N = 150	<0.001
Mean Parent/Patient Global	3.5 (SD 2.5); N = 132	2.9 (SD 2.5); N = 122	0.023
Mean Active Joint Count	3.5 (SD 5.1); N = 160	1.5 (SD 2.9); N = 162	<0.001
Mean cJADAS 10	9.3 (SD 6.2); N = 126	5.8 (SD 5.0); N = 115	<0.001
Mean Physical Function Mobility	31.3 (SD 8.0); N = 46	29.8 (SD 4.0); N = 41	0.95
Mean CHAQ	0.5 (SD 0.6); N = 138	0.4 (SD 0.5); N = 116	0.09
Mean Pain Intensity	4.0 (2.5); N = 111	3.6 (SD 2.5); N = 94	0.37
Mean Pain Interference	62.3 (SD 6.2); N = 88	61.5 (SD 6.6); N = 77	0.42

yarticular involvement (ever) was reported in 56% of children with ERA and 71% of those with JPsA. Sacroiliitis (ever, by imaging and/or clinical exam) was reported in 40% of those with ERA versus 12% of those with JPsA. Enthesitis was reported in 78% of children with ERA and 18% of those with JPsA. HLA-B27 was positive in 24% of those with ERA and 7% of those with JPsA (see Table 1 for comment on missing data). At least one biologic was taken by 72% of those with ERA and 64% of those with JPsA (Table 1), mostly TNF inhibitors.

Twenty-eight percent of the children with JSpA had sacroiliitis (by imaging and/or clinical diagnosis). Of the children with JSpA who had sacroiliitis, 54% were female, while 50% of those without sacroiliitis were female. Of those with sacroiliitis, 34% were positive for HLA-B27 versus 21% of the children without sacroiliitis (see Table 2 for comment on missing data). Of those with sacroiliitis, 81% took at least one biologic during follow-up versus 65% of those without sacroiliitis (Table 2).

In those with sacroiliitis, the first visit with active sacroiliitis was compared to the first visit without sacroiliitis. At the active visit, the physician global assessment, parent/patient global, active joint count, and cJADAS 10 were all significantly worse. However, there was no significant difference between visits in the physical function, CHAQ, or pain measures (Table 3).

Conclusion: In the CARRA Registry, there are currently over 900 children with physician-diagnosed JSpA. There are clear phenotypic differences between the children with ERA versus those with PsA. There was high biologic use, especially TNF inhibitors, in this population. It was particularly high in those with sacroiliitis. Further, there was equal sex representation in those with sacroiliitis.

Abstract Number: 2714

Investigation of Inactive Disease Activity States Among JIA Patients in the CARRA Registry

Melissa Mannion,[1] Fenglong Xie,[2] and Timothy Beukelman[3], [1]University of Alabama at Birmingham, Alabama, [2]University of Alabama at Birmingham, Birmingham, [3]University of Alabama Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inactive disease is the stated goal of treatment in juvenile idiopathic arthritis (JIA) and is typically measured by a composite score that combines several different factors including provider and parent or patient assessments. Various definitions of inactive disease may identify different JIA populations because each score utilizes different components. We compared and contrasted the JIA patients who met various definitions for inactive disease.

Methods: We used the Childhood Arthritis & Rheumatology Research Alliance (CARRA) Registry of clinical data from >65 pediatric rheumatology clinics in the United States and Canada. Individuals with JIA with at least 12 months of observable time after enrollment and completion of the 1 year follow up visit were included. Individuals were excluded if they had incomplete inactive disease measures at the 1-year visit. Demographic and disease characteristics were reported at baseline and the 1-year visit to allow for at least 1 year of disease duration. The frequency and proportion of outcomes for all patients at 1-year follow up were reported regardless of disease duration. The Pearson correlation coefficient was calculated between physician global, patient global, active joint count, and pain at 1-year for all patients.

Results: There were 2164 JIA patients enrolled in the CARRA Registry with completion of 1-year follow up visit (Table 1). Of these 2164 individuals, 70% were treated with a conventional disease modifying anti-rheumatic drug (DMARD) between enrollment and 1-year follow up and 66% were treated with a biologic DMARD. Among all 2164 individuals at the 1-year visit, 1453 (67%) had no active joints, 1068 (49%) had a physician global of 0, 1012 (47%) had a patient global of 0, 998 (46%) met the American College of Rheumatology preliminary criteria for clinical inactive disease (ACR CID), and 964 (45%) had a clinical Juvenile Arthritis Disease Activity Score 10 (cJADAS10) < 1 (Figure 1). There was moderate correlation between physician global and active joint count ($R=0.62$, $p< 0.001$), patient global and pain score ($R=0.48$, $p< 0.001$), physician global and patient global ($R=0.45$, $p< 0.001$), patient global and active joint count ($R=0.32$, $p< 0.001$), and a weak correlation between physician global and pain score ($R=0.24$, $p< 0.001$).

Conclusion: In a multicenter cohort of JIA patients in North America, a large proportion of patients had inactive disease by single or composite measures after 1 year of observation in the Registry. There was significant overlap between patients who met ACR CID criteria and cJADAS10 $\leq$ 1 which may indicate acceptable use of either composite measure for disease management in the clinical setting. Additional studies are needed to evaluate the reasons

Incidence of Juvenile Idiopathic Arthritis in the United Kingdom: Estimates from a National Primary Care Dataset

Ruth Costello,[1] Janet McDonagh,[2] Will Dixon,[1] Kimme Hyrich,[2] and Jenny Humphreys[1], [1]Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester, United Kingdom, Manchester, United Kingdom, [2]Versus Arthritis Centre for Epidemiology, Centre for Musculoskeletal Research, Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, Faculty of Biology, Medicine and Health, University of Manchester, Manchester Academic Health Science Centre, Manchester, United Kingdom / NIHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, Manchester Academic Health Science Centre, Manchester, United Kingdom, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile idiopathic arthritis (JIA) is the most common childhood onset inflammatory arthritis. The last estimates of incidence of this disease in the United Kingdom are from nearly 30 years ago, prior to international classification consensus and the emergence of paediatric and adolescent rheumatology as a specialty. The aim of this study was to estimate incidence of JIA from primary care records in the UK since 2000.

Methods: The study used data from the Clinical Practice Research Datalink (CPRD) Gold, a database of UK primary care records considered broadly representative of the UK as a whole in terms of age, gender and ethnicity. A predefined list of JIA Read codes were used to identify incident cases annually from 2000-2018. Incidence rates with 95% confidence intervals (CI) were calculated. The denominator was the population of CPRD < 16 years old on the 31st December each year. Age and gender stratified rates were calculated. Direct standardisation was used to estimate the UK IR using the Office for National Statistics mid-2017 population data (latest available). Incidence rates in 5-year groupings were calculated 2000-2015 to identify any change over time.

Results: There were 1927 incident cases of JIA from 2000-2018, from a total population of 23,328,676 children < 16 years old in CPRD. This gave a total incident rate (IR) (95% confidence interval (CI)) of 8.26 (7.90-8.64) per 100,000 population. There was a slight female preponderance, with IR (95% CI) 9.83 (9.27-10.43) per 100,000 in females, compared to 6.78 (6.33-7.27) per 100,000 in males. Age adjusted direct standardisation to the UK population estimated a total IR of 9.66 per 100,000 person years. Incident rates by age group are shown in table 1. There appeared to be a slightly lower incidence in middle childhood compared to early childhood and adolescents, as well as infancy where lower rates may be due to difficulties in recognising the disease. IRs over time did not appear to change (figure 1).

Conclusion: This is the first study to provide contemporary UK estimates of the incidence of JIA for nearly 30 years. We have shown JIA is more common in girls compared to boys, and is slightly more common in early childhood and

Age *(years)*	Denominator	Cases	IR (95% CI) *Per 100,000*

Long Term Outcomes of Childhood Onset Rheumatoid Arthritis

Rebecca Overbury,[1] Aimee Hersh,[2] CJ Inman,[2] Sara Stern,[2] Karen James,[2] and John Bohnsack[3], [1]Assisstant Professor, University of Utah, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Utah School of Medicine, Salt Lake City, UT

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood onset rheumatoid arthritis (CORA) describes patients with juvenile idiopathic arthritis (JIA) who are rheumatoid factor (RF) or anti-cyclic citrullinated antibody (ACPA) positive. Phenotypically, CORA parallels adult rheumatoid arthritis (RA). Weighted genetic variant testing suggests CORA is more similar to RA than

other JIA subtypes. However, data describing outcomes of this population is limited. Here we describe long-term outcomes of a cohort of CORA patients from our single-center, academic, pediatric rheumatology practice.

Methods: The Intermountain States Database of Childhood Rheumatic Diseases (ISDCRD) is a longitudinal cohort study started at the University of Utah in 1997 which currently includes >700 patients with JIA. Clinical data collected includes date of diagnosis, pre-diagnosis symptom duration, ILAR subtype, and initial clinical presentation (joint count and laboratory studies). CORA subjects were identified in the ISDCRD. A detailed chart review was completed to describe the treatment course and outcomes from diagnosis until current date. Descriptive statistics were used. Study approval was obtained from our Institutional Review Board.

Results: The current cohort includes 51 patients enrolled between 1997 and 2018. Of these, 27 (52.9%) subjects remain in an IRB accessible electronic medical record (EMR). Subject demographic and disease characteristics are summarized in Table 1. 21 subjects were female (77.8%). 25 were White (92.6%). 4 (14.8%) identified as Hispanic. Median number of joints at diagnosis was 13 (range 1 - 44). Median age at diagnosis was 11.8 years (range 2.0-15.9). Median age at time of follow up was 24.6 years (range 10.3 to 35.2). 25 subjects (92.6%) were > 18 years old at the time of most recent follow up. 18 (66.7%) were confirmed polyarticular (≥ 5 active joints) at diagnosis. Of the 4 who were oligoarticular (≤ 4 active joints) at diagnosis, 3 of these extended to polyarticular disease. 15 have known erosive disease (57.7%). 20 (74.1%) were confirmed RF+ (2 positive values ≥ 3 months apart). 7 (25.9%) were confirmed ACPA+ (2 positive values ≥ 3 months apart) . 25 (92.6%) were ever RF+. 22 (81.5%) were ever ACPA+. 1 (3.7%) and 2 (7.4%) were never tested for RF or ACPA respectively. The current treatment of this cohort is described in Figure 1. 21 subjects (77.8%) currently require biologic therapy. 14 (51.9%) failed prior biologic therapies due to intolerance or insufficient response. 2 demonstrated no clinical disease or erosions on last follow up despite minimal treatment (hydroxychloroquine or non-steroidal medication); both were RF+ and ACPA+. Comorbidities included anxiety and depression (n = 4, 14.8%), interstitial lung disease (ILD) (n = 1, 3.7%), and joint surgery (n = 4, 14.8%).

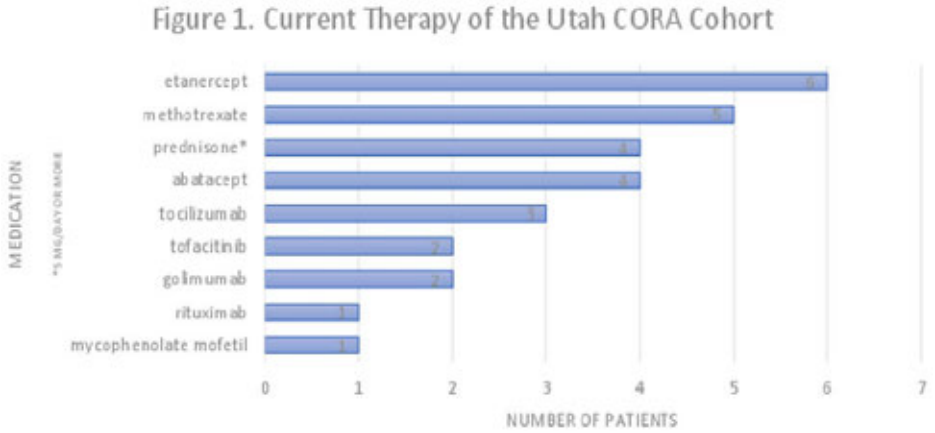
Table 1. Patient characteristics of the Utah CORA cohort

Sex	Race and Ethnicity ±				Age at Onset, median (range)	Current Age, median (range)	Joint Count at Onset, median (range)	Extended Disease	Evidence of Erosion*	Total
	Black	White	Hispanic	South Asian						
Male	0	5	1	0	12.5 (11.8-15.7)	22.6 (19.9-24.6)	10.0 (1-22)	1/1	2	6
Female	0	21	3	1	10.9 (2.0-15.9)	25.6 (10.3-35.2)	15.0 (1-44)	2/3	14	21

± not mutually exclusive
*radiographs, radiograph report, clinic note, problem list

n = 27

Table 1. Incidence rates by age group



Conclusion: This is one of the first studies to describe the long-term outcomes of a cohort of CORA patients. Phenotypically, CORA appears similar to adult RA (e.g. polyarticular presentation, high frequency of erosions, extra-articular disease, need for biologic therapy). In order to better understand the adult-outcomes of CORA we plan to expand this cohort to include data on patients not accessible through EMR review.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is no consensus in the literature with regard to the features and long-term prognosis of psoriatic arthritis (PsA) starting in childhood (jPsA). We aimed to describe the outcome of patients with jPsA in comparison to adult-onset (aPsA).

Methods: A large cohort of PsA patients with known diagnosis date and follow-up were divided into two groups according to the age at PsA diagnosis: jPsA- diagnosis ≤16 years of age and aPsA >16 years of age. The two groups were compared regarding demographics, family history, disease manifestations (number of tender (TJ) and swollen (SJ) joints, enthesitis, dactylitis, the presence of inflammatory back pain, skin involvement (PASI score), comorbidities, functional class (FC), patient and physician assessments of diseases activity at baseline and after 5, 10, 15, 20, and 25 years of follow-up. Patients' contribution to the time interval follow-up groups depended on their follow-up period in the database. Adjusted mean scores were calculated for all disease manifestations during each follow-up period. Chi square test, Student's t-test or Mann-Whitney test were used, as appropriate to compare between the two groups. Comparisons of comorbidities between the two age groups included first time diagnosis during follow up, cumulative morbidity and the influence of disease duration. Generalized estimating equations procedure of repeated measurements were performed to assess the effect of age on study variables. Relative risk ratios and 95% confidence intervals were calculated from the models. The results were considered statistically significant for 2-sided p value< 0.05.

Results: The jPsA group included 78 patients, 41% males, age at diagnosis 11.48±4.97 years, age at baseline 33.53±14.92 years, contributing 612 patient visits. The aPsA group consisted of 2182 patients, 54.2% males (p=0.02),

age at diagnosis 40.29±13.15 years, age at baseline 47.47±13.28 years, contributing 19784 patient visits. Arthritis preceded psoriasis in 21(26.9%) individuals in the jPSA group compare to 123 (5.6%) in the aPsA group (p< 0.0001). After ≥25 years of disease, the following adjusted mean scores were reported in the jPsA group: TJ= 3.86±6.04, SJ= 1.18±3.05, enthesitis 0.21±0.64, dactylitis 0.2±1.22, inflammatory back pain in 20.8%. The majority (62.5%) were in FC I, 32.5% in FC II, and 5% in FC III. No statistically significant differences were noted between jPsA and aPsA groups in TJ, SJ, enthesitis and dactylitis counts, PASI score, inflammatory back pain, or FC nor in the patient and physician assessments of disease activity. There were no statistically significant differences in the prevalence of malignancy, hyperlipidemia, diabetes mellitus and myocardial infarction between the two groups although the jPsA group was much younger. Hypertension was more common in the aPsA (47.2% versus 20.6%, p=0.003) whereas depression was more common in the jPsA group (20.6% versus 8.7%, p=0.03).

Conclusion: The overall prognosis of jPsA ≥25 years following diagnosis is good and resembles that of aPsA group. However, patients with jPsA developed joint symptoms earlier compared to skin disease, and accrue comorbidities at a younger age.

Abstract Number: 2718

A Retrospective Study Comparing Refractoriness to Biologic Disease Modifying Anti-Rheumatic Drugs in Adults with Juvenile Idiopathic Arthritis as Compared to Those with Rheumatoid Arthritis

Kiana Taba,[1] and Elizabeth Ortiz[2], [1]University of Southern California, LAGUNA HILLS, CA, [2]LAC+USC/Keck Medicine of USC, Los Angeles

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose:: The use of biologic DMARDs (bDMARDs) has vastly changed the treatment of autoimmune arthritis, both Rheumatoid Arthritis (RA) and polyarticular and oligoarticular Juvenile Idiopathic Arthritis (JIA). At this time 5 bDMARDs are approved by the FDA for JIA, however, many patients fail these medications, due to adverse effects or inefficacy. Studies looking at retention rate for these medications have found varying reasons for discontinuation of first line treatments between adults and children, however attention has not been paid to those patients who fail multiple rounds of bDMARDs, and have come to be considered refractory. As childhood-onset rheumatic disease is often more severe than adult-onset, we hypothesize that JIA patients will have an increased rate of refractoriness when compared to RA patients. This study aims to characterize and compare refractory patients with JIA and RA.

Methods:: This is a retrospective chart review of adult patients diagnosed with polyarticular or oligoarticular JIA as children and adult-onset RA seen in the Los Angeles County + University Southern California Medical Center (LAC+USC) and Keck University Hospital from January 2010 to December 2017. All JIA patients were diagnosed and treated by pediatric rheumatologists as children and all RA patients were diagnosed based on the 1987 ACR classification criteria. Patients were deemed refractory if they failed ≥ 3 DMARDs, one of which is a bDMARD. Refractory patients were included in the study as cases and controls were selected from non-refractory patients. Descriptive statistics were reported for demographic and clinic data. Logistic regression models were used to evaluate the association between arthritis type (JIA vs. RA) and refractoriness while controlling for disease duration.

Results:: A total of 100 patients were reviewed, 53 adults with polyarticular or oligoarticular JIA and 47 RA patients. Ninety-three percent were women and 76% were Hispanic. The JIA group was younger (mean age 27.7 years, SD of 10.3) than the RA group (mean age 55.9 years, SD of 11.8). However, average disease durations were comparable (mean of 15.5 years in the JIA group, 14.3 in the RA group). There was no difference in number of refractory cases between JIA and RA patients, 50.9% and 53.2%, respectively. Comparison of the refractory cases and their controls, however, showed an increase in disease duration (mean 17.8 years vs. 11.8 years) as well as a higher prevalence of sero-positivity for both RF and anti-CCP status (82.70% and 78.57% as compared with 58.33% and 66.67%) and erosive disease (55.77% as opposed to 20.83%).

Conclusion: This study failed to find an association between adult JIA patients and refractory disease when compared with RA patients. Although JIA patients are equally refractory to DMARDs when adjusted for disease duration, this still presents a formidable problem when it comes to the future of these patients, as they likely have at least double the number of years with disease ahead of them when compared to RA patients. Future studies evaluating the continued bDMARD use in young, refractory patients are necessary to better understand how best to treat these patients.

Predictors of Health Care Transition Practices Among North American Pediatric Rheumatology Providers

Rebecca Sadun,[1] Amanda Eudy,[1] Peter Chiraseveenuprapund,[2] Cuoghi Edens,[3] Aimee Hersh,[4] Kiana Johnson,[5] and Erica Lawson[6], [1]Duke University, Durham, [2]UCSD, San Diego, CA, [3]University of Chicago, Chicago, IN, [4]University of Utah, Salt Lake City, UT, [5]East Tennessee, Johnson City, TN, [6]University of California San Francisco Benioff Children's Hospital, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The transition from pediatric to adult-oriented health care represents a vulnerable period for young adults with chronic rheumatic diseases. In spite of this, a 2010 study of Childhood Arthritis and Rheumatology Research Alliance (CARRA) rheumatologists showed that less than 10% were familiar with existing transition guidelines. Since then, new health care transition guidelines and an ACR transition toolkit have been disseminated. We resurveyed CARRA members to assess the impact of new guidelines and tools on transition practices and explored predictors of transition practices.

Methods: An online survey on health care transition was emailed to CARRA providers in April 2018. Pediatric rheumatology physicians and fellows in the United States (U.S.) or Canada were included in analysis. Univariate comparisons and multivariate linear and logistic regression were performed to identify factors that predict age of transfer and transition practices, including self-assessed performance on Got Transition's Current Assessment of Health Care Transition Activities (CAHCTA), which measures the level of health care transition support provided by a practice, with scores ranging from 6 (basic) to 24 (comprehensive).

Results: The response rate was 212/396 (54%), of which 192 responses were analyzed: 147 pediatric rheumatologists, 8 dual-boarded adult/pediatric rheumatologists, and 37 fellows, inclusive of 180 U.S. and 12 Canadian providers (from 4 academic institutions). Table 1 shows unadjusted, univariate statistics alongside multivariate modeling for transfer age and CAHCTA score. In multivariate analysis, providers who transfer patients prior to age 21 are more likely to practice in Canada (OR=16.6, 95% CI: 3.0-92.4) and to have been in practice for 5-15 years (OR=2.7, 95% CI: 1.3-5.6). Whereas 92% of Canadian providers routinely ask parents leave the room for at least part of the visit before patients reach the age of 18, only 41% of U.S. respondents do so (p=0.001). Similarly, 56% of private practice pediatric rheumatologists use an adult model of care, compared to only 20% in other practice settings (p=0.03). Finally, Canadian pediatric rheumatologists have a significantly higher mean CAHCTA score (15.0 v 10.3; p< 0.0001), whereas providers believing pediatric staff lack skills in transition support have lower scores (8.7 vs 11.0; p=.003).

Table 1. Univariate and Multivariate Modeling of Transition Outcomes

Transfer of Care Before Age 21

Private Practice vs. Other Practice Setting	-2.3 (-4.7, 0.1)	–
Duration in Practice		
5-15 years vs <5 years	1.3 (-0.4, 3.0)	–
>15 years vs <5 years	2.3 (0.5, 4.1)	–
Size of Pediatric Rheumatology Practice		
Solo vs. Large Practice (≥7 providers)	-2.8 (-4.9, -0.7)	-2.1 (-4.0, -0.2)
Small (2-3 provider) vs. Large (≥7 providers)	-1.5 (-3.2, 0.1)	-1.4 (-2.9, 0.1)
Medium (4-6 providers) vs. Large (≥7 providers)	-0.3 (-1.6, 1.1)	-0.4 (-1.7, 0.8)
View "staff lack of transition skills" as Major Barrier	-2.5 (-4.1, -0.9)	-2.0 (-3.4, -0.5)

Conclusion: This survey highlights clinic staff training in transitional care skills as a potential avenue to enhance health care transition support in pediatric rheumatology. In addition, this survey underscores ways in which transition support services are more established in Canada, given stricter mandates to transfer patients at age 18 and the subsequent development of national strategies to support young adults. Canadian CARRA members' experiences with transitional support services will contribute to CARRA's new Transition Learning Collaborative, developed to facilitate dissemination and implementation of transition programs and services in a way that addresses the heterogeneous landscape of health care transition.

Implementation of an Evidence-based Transition Clinic in a Pediatric Rheumatology Academic Institution

Rebecca Overbury,[1] John Bohnsack,[2] CJ Inman,[3] Sara Stern,[3] Karen James,[3] Daniel Clegg,[3] Tracy Frech,[4] and Aimee Hersh[3], [1]Assisstant Professor, University of Utah, Salt Lake City, UT, [2]University of Utah School of Medicine, Salt Lake City, UT, [3]University of Utah, Salt Lake City, UT, [4]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

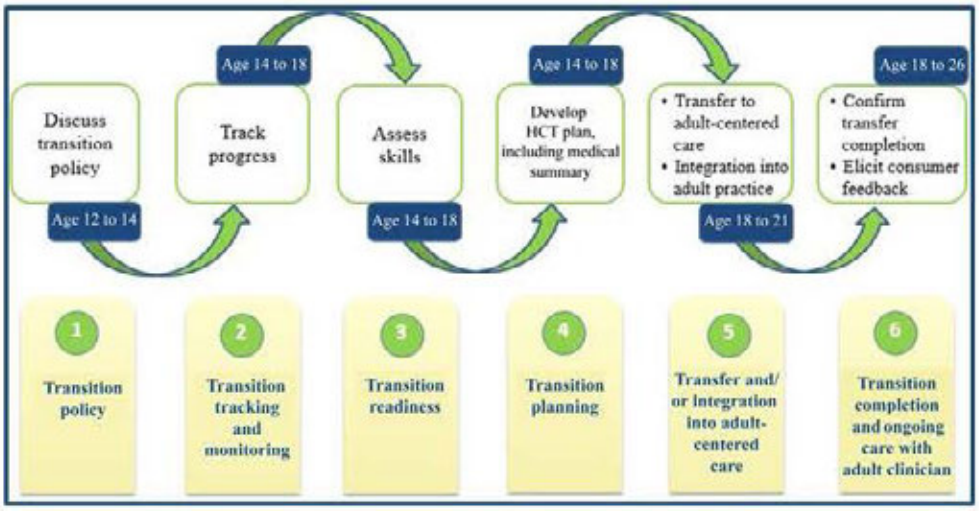
Background/Purpose: Transition from pediatric to adult rheumatology care is more likely to be successful if a transition program is in place. Previously successful interventions to improve transition outcomes have included integrating an adult subspecialist in the pediatric clinic setting. We hypothesize that we will improve transition outcomes by implementing a transition clinic which includes an adult rheumatologist providing care within a pediatric rheumatology clinic.

Methods: We initiated a weekly transition clinic in November 2018 called ACCORD (Adult Center for Childhood Onset Rheumatic Disease). This clinic is staffed by 1 adult rheumatologist (board certified in internal medicine and pediatrics), 1 pediatric nurse, a research coordinator, and a social worker. Patients can be seen if they are ≥ 16 years old with known rheumatic disease or suspicion for rheumatic disease. All patients receive education and monitoring of transition readiness. We provide transition readiness education in 5 discrete modules (Fig 1); education materials

Figure 1. Five modules for transition readiness education

Module 1	*12-14 yo*	Transition Policy	Introductory Information			
Module 2	*14-18 yo*	Transition Readiness Assessment	Medical Plan			
Module 3	*14-18 yo*	Medication List	Medical Summary			
Module 4	*18-21 yo*	"10 Things to Know" about Adult Care				
Module 5	*18-26 yo*	Medical Summary	Medical Plan	Medication List	Transition Readiness	Transfer Letter

Figure 2. "Six Core Elements" (Patience H. White et al. Pediatrics 2018)



are adapted from Got Transition $_{Tm}$ (Fig 2). All patients complete patient reported outcome measures (PRO's). We maximize continuity of care in several ways: our adult rheumatologist meets pediatric patients who anticipate transfer to the transition clinic, she manages all transition clinic visits, and if possible, she migrates care to our institution's associated adult rheumatology clinic. Demographics, PRO's, transition readiness measures, and clinical outcomes are collected in a prospective longitudinal registry. IRB approval was obtained for this study.

Results: In 7 months, 65 patients visited the transition clinic (Table 1). 70.8% were new patients. Of these, we diagnosed 34.8% with a new rheumatic disease (rheumatoid arthritis (RA), mixed connective tissue disease, antiphospholipid syndrome, Raynaud phenomenon, spondyloarthritis (SpA), enteropathic arthritis, gout, Ehlers-Danlos syndrome, and linear morphea). 29.2% were transfers for known rheumatic disease of childhood onset (juvenile idiopathic arthritis (JIA), systemic lupus erythematosus, SpA, and Sjogren's syndrome). Nine (13.8%) have scheduled upcoming visits with the adult rheumatologist in our affiliated adult rheumatology clinic. Four (6.2%) have completed

Table 1. Demographics of transition clinic*

	Sex		Mean Age (years)		Race or Ethnicity					
	Male n (%)	*Female n (%)*	*Male / Female*		*White n (%)*	*Black n (%)*	*Hispanic n (%)*	*Pacific Islander n (%)*	*Native American n (%)*	*Total*

Total	11 (16.9)	54 (83.1)	17.7	17.6	53 (81.5)	3 (4.6)	7 (10.8)	1 (1.5)	1 (1.5)	65

* All percentages are of the entire cohort (n = 65)

durable transfer to our adult rheumatology clinic (defined as one or more scheduled and completed appointments). One (1.5%) patient has successfully transitioned to an outside adult rheumatologist.

Conclusion: We have successfully initiated an evidence-based transition clinic in a pediatric rheumatology academic institution that integrates the care of an adult rheumatologist. The transition clinic has diagnosed 16 new rheumatologic diagnoses in adolescence, eliminating the future need for transition to an adult provider. We have established 19 patients with our adult rheumatologist in the transition clinic, alongside our pediatric rheumatology clinic. We have transferred 9 patients to an adult rheumatology clinic, 8 to our associated adult rheumatology clinic, and 4 have completed a durable transition to date. Future research of this registry will analyze this cohort and the impact of this intervention on clinical outcomes and PRO's.

Subjective and Objective Dyscognition in Adolescents with Juvenile Fibromyalgia Syndrome

Sabrina Gmuca,[1] Maitry Sonagra,[2] Rui Xiao,[2] Elizabeth Mendoza,[2] Kimberly S. Miller,[3] Nina H. Thomas,[1] Pamela F. Weiss,[1] David D. Sherry,[1] and Jeffrey Gerber[2], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, [3]Children's Hospital fo Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dyscognition, including loss of mental clarity and problems with attention and memory, often affects adolescents with juvenile fibromyalgia syndrome (JFMS). Our understanding of this neuropsychological symptom, however, is limited. It is unclear whether adolescents with JFMS experiencing subjective (or self-reported symptoms of) dyscognition have objectively measurable neurocognitive deficits. We aimed to determine 1) the prevalence of subjective and objective dyscognition and 2) the association between subjective and objective dyscognition among adolescents with JFMS.

Methods: We conducted a pilot, prospective cohort study of children ages 12-17 years diagnosed with JFMS according to 2010 ACR criteria for fibromyalgia syndrome seen in a pediatric rheumatology pain clinic from July 2017-February 2019. Exclusion criteria included non-English speaking patients, use of stimulant medication, or a condition precluding completion of assessments. Subjects completed both patient-reported outcomes (PROs) and neurocognitive testing. Subjects with poor effort based on the Memory Validity Profile (MVP) or Medical Symptoms Validity Test (MSVT) were excluded from objective dyscognition analyses. Subjective dyscognition was defined as a Pediatric Quality of Life Inventory (PedsQL) Cognitive Functioning Scale score ≤50 or self-reported Behavior Rating Inventory of Executive Function (BRIEF-2) global executive composite (GEC) score ≥ 70. Objective dyscognition was defined as impairment of more than two standard deviations in any of the domains in the neurocognitive battery. We assessed the association of clinical signs and symptoms with the presence of subjective dyscognition using Fisher-Exact test or Wilcoxon-rank test. The association between subjective and objective dyscognition was analyzed via Fisher-Exact test.

Table.1 Demographics, Clinical Characteristics and Patient-reported Outcome Measures (PROs) among Adolescents with Juvenile Fibromyalgia Syndrome

	All Subjects (n=19)	(+) Subjective Dyscognition (n=12)	(-) Subjective Dyscognition (n=7)	p-value

14-item Resilience Scale (14-98)	72.0 (61.0 – 78.0)	64 (51.5 – 70.5)	79 (75.0 – 86.0)	0.01*
CDI-2 (Depression)	59.0 (52.0 – 70.5)	67 (59.5 – 76.0)	51 (47.0 – 56.0)	<0.01*
MASC-2 (Anxiety)	64.0 (51.5 – 71.5)	70 (64.5 – 83.0)	52 (45.0 – 55.0)	<0.01*
PedsQL Total Multidimensional Fatigue Scale (MFS) (0-100)	39.0 (33.0 – 56.5)	34.5 (30.5 – 38.5)	60 (56.0 – 63.0)	<0.001*
MFS General Fatigue	33.0 (25.0 – 48.0)	27 (21.0 – 37.5)	50 (42.0 – 63.0)	0.01*
MFS Sleep	46.0 (37.5 – 54.0)	42 (27.0 – 50.0)	58 (50.0 – 63.0)	0.01*
MFS Cognitive	42.0 (33.0 – 67.0)	35.5 (25.0 – 42.0)	71 (63.0 – 75.0)	<0.001*
BRIEF-2 Global Executive Composite (GEC) T Score	53.0 (50.5 – 65.0)	62.5 (57.0 – 72.5)	50 (44.0 – 53.0)	<0.01*

*Significant p-values suggesting statistical significance. For subjective dyscognition, 8 subjects were positive on the PedsQL (Pediatric Quality of Life Inventory) Cognitive Functioning Scale only and 4 subjects were positive on the BRIEF-2 (Behavior Rating Inventory of Executive Function-2) Global Executive Composite (GEC) and PedsQL Cognitive Functioning Scale. IQR= interquartile range. PROMIS = Patient Reported Outcome Measurement Information System. CDI-2 = The Children's Depression Inventory, 2nd Edition. MASC-2 = The Multidimensional Anxiety Scale for Children, 2nd Edition. PedsQL MFS = The Pediatric Quality of Life Inventory Multidimensional Fatigue Scale.

Table 2. Objective Dyscognition Based on Subjective Symptoms among Adolescents with Juvenile Fibromyalgia Syndrome

Neurocognitive Battery Test (Objective Measure), n (%)	(+) Subjective Dyscognition (n=11)	(-) Subjective Dyscognition (n=7)	p-value
Any impairment	6 (54.5)	2 (28.6)	0.22
General intellect (WASI-II)	0 (0)	0 (0)	---
Memory (ChAMP, WISC-V, WAIS-IV)	0 (0)	0 (0)	--
Attention (CPT-3)	3 (27.3)	1 (14.3)	0.38
Executive Function (D-KEFS)	3 (27.3)	0 (0)	0.20
Complex Psychomotor Speed (Grooved Pegboard Test)	3 (27.3)	2 (28.6)	0.40

One subject was excluded due to poor effort. WASI-II = The Wechsler Abbreviated Scale of Intelligence). ChAMP = Children and Adolescent Memory Profile. WAIS-IV (Wechsler Adult Intelligence Scale, 4th Edition) and WISC-V (Wechsler Intelligence Scale for Children, 5th Edition) Digit Span subtests test auditory working memory ability. CPT-3 = The Conners Continuous Performance Test, 3rd Edition. D-KEFS = Delis-Kaplan Executive Function System.

Results: Nineteen subjects met criteria and completed the study. Most subjects were female (79%), non-Hispanic (89%) and Caucasian (74%) (Table 1). Median age at enrollment was 15 years (IQR: 12.0-16.0). Sixty-three percent

(n=12) of subjects reported subjective dyscognition and 44% (8/18) had objective dyscognition in ≥ 1 domain. Subjective dyscognition was associated with greater symptoms of anxiety, depression, lower resilience, lower health-related quality of life, greater fatigue, and poorer sleep (all $p < 0.05$; Table 1). The neurocognitive battery domains most commonly impaired included complex psychomotor speed (28%), attention (22%) and executive function (17%) (Table 2). The presence of subjective dyscognition was not significantly associated with objective dyscognition (all $p > 0.05$).

Conclusion: Sixty-three percent and 44% of adolescents with JFMS had subjective or objective dyscognition, respectively. Subjective dyscognition was not associated with objective dyscognition. This discrepancy may be due to the exacerbation of subjective dyscognition by co-morbid depression, anxiety and/or fatigue. As this study is ongoing, we anticipate that analyzation of additional data will help explain this discrepancy and also guide evidence-based recommendations for neuropsychological testing for JFMS.

The down Syndrome Arthropathy Cohort in the New Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry: Clinical Characteristics, Treatment and Outcomes

Jordan Jones,[1] Daniel J. Lovell,[2] Chelsey Smith,[3] and Mara Becker[4], [1]Children's Mercy Kansas City, Kansas City, MO, [2]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, [3]Children's Mercy Kansas City, Kansas, MO, [4]Duke Children's Hospital, Durham, NC

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Down syndrome arthropathy (DA) is under-recognized with a 19-month average delay in diagnosis (1). The majority present with polyarticular, rheumatoid factor (RF) and anti-nuclear antibody (ANA) negative disease. The current therapies for juvenile idiopathic arthritis (JIA) appear to be poorly tolerated, more toxic and less effective in patients with DA (1). The objective of this study was to characterize clinical manifestations and therapeutic preferences in DA, using the new Childhood Arthritis and Rheumatology Research Alliance (CARRA) Registry.

Methods: The new CARRA Registry began prospectively collecting data on children with JIA in the United States and Canada in July 2015. Down syndrome (DS) is documented in the CARRA Registry as a coexisting condition. Within the new CARRA Registry, between the dates of July 2015 and March 2019, patients with JIA and DS were identified and an observational cohort analysis was performed. Collected data included demographics, disease characteristics, laboratory results, and treatment exposure.

Results: Thirty-six patients with DA were identified in the total population of 7337 JIA patients (0.005%) in the Registry with a mean follow-up period of 4.5 years (SD 3.2). The mean age at onset of musculoskeletal symptoms was 7.1 years (SD 3.9) and the mean months to JIA diagnosis was 11.5 months (SD 21.6). At diagnosis, 64% had a polyarticular RF negative presentation, 39% reported morning stiffness with an average of 4 active (SD 7; range 0 - 27) and 4 limited joints (SD 6; range 0-23), and a mean physician global of disease activity of 2.7 (SD 2.6; range 0

Table 1. Therapy throughout course of Down syndrome Arthropathy

Treatment	Patient (n/total)	Response* (n/total)
Oral Steroid	10/36,	1/10
Intra-articular Steroid	15/36	1/15
DMARDs	28/36	
Methotrexate	28/28	5/28
Leflunomide	1/28	0/1
Azathioprine	1/28	0/1
Biologics	27/36	
Etanercept	19/27	7/19
Adalimumab	14/27	8/14
Abatacept	6/27	1/6
Tocilizumab	5/27	2/5
Infliximab	1/27	1/1
Anakinra	1/27	0/1
Canakinumab	1/27	0/1

*Defined as tolerating and not requiring an increase in therapy

Table 2. Outcomes throughout course of Down syndrome Arthropathy

Outcome	At Diagnosis Mean (SD)	At Last Visit Mean (SD)	p - value
Active joints	4.4 (7.0)	2.9 (5.6)	**0.03**
Limited joints	4.3 (6.3)	3.3 (5.5)	0.59
Physician global*	2.7 (2.6)	1.2 (1.4)	**0.01**
Patient global**	4.0 (3.2)	2.3 (2.5)	0.12
CHAQ†	1.2 (0.8)	1.1 (0.7)	0.34

*Physician global assessment of disease activity, 0-10 Likert scale, 0 = inactive disease
**Patient global assessment of disease burden, 0-10 Likert scale, 0 = no disease burden
†Childhood health assessment questionnaire, 0-3, 0 = good physical function

- 9). At diagnosis, 22% had elevated inflammatory markers (CRP, ESR), while 33% and 17% were positive for ANA and HLA-B27, respectively. Over half the patients (64%) were started on a disease modifying antirheumatic drug (DMARD) at diagnosis with 36% simultaneously starting a biologic. Over the course of disease, 78% used a DMARD (100% used methotrexate [MTX] at some point) and 75% used a biologic (mostly etanercept [70%]). Of those exposed to DMARD therapy, fifteen patients (54%) had at least one change of their DMARD (most due to MTX adverse effect [46%]), however, at the last recorded visit, 42% were on methotrexate. Fifteen patients (55%) had at least one change in biologic therapy due to inadequate response to therapy (Table 1). Between the first and last visit significant ($p < 0.05$) improvements were seen for active joint count and physician global of disease activity (Table 2).

Conclusion: In a large multicenter observational registry of JIA patients in North America, patients with Down syndrome arthropathy continue to have an approximate year-long delay in diagnosis from symptom onset. Treatments included corticosteroids (oral and intra-articular), DMARDs and biologic therapies throughout the course of the disease. Although there was a statistically significant improvement in active joint count and physician global assessment, there was no significant difference in limited joints, CHAQ, or patient global assessment with treatment. Optimal therapy remains unclear and current barriers are DMARD intolerance and anti-TNF effectiveness. More research is needed to determine optimal therapeutic approach.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Alagille syndrome is a complex multisystem disease characterized by chronic cholestasis due to a paucity of intrahepatic bile ducts, congenital heart disease and ocular embryotoxon. Skeletal involvement consists mainly of vertebral anomalies and osteoporosis. The association of Alagille syndrome and inflammatory arthritis is exceptional and to date only 4 cases have been described. Our purpose is to collect and describe a cases series of children affected by Alagille syndrome who developed an inflammatory arthritis.

Methods: This was a retrospective analysis of clinical charts from 6 centres in Italy, USA and France, including the Hospital where Dr. Alagille worked and described the syndrome.

Results: We collected 9 cases of Alagille syndrome associated with chronic arthritis, 5 females and 4 males, median age 11 years (range 4-18) at last follow up. All patients had neonatal cholestasis; 9/9 cardiac involvement; 8/9 characteristic facies; 8/9 ocular abnormality; 6/9 kidney disease; 3/9 osteoporosis and 2 butterfly vertebrae. Median age at arthritis onset was 6.2 years (range 2-10); the median number of active joints at onset was 3 (range 1-8). The most common site of arthritis was the knee (8/9) followed by ankle (6/9), elbow (4/9), wrist (3/9), small joints of hands or feet (3/9), cervical spine (2/9), temporomandibular (2/9), shoulder (1/9) and hip (1/9). Two patients also had uveitis, one of which with other signs typical of sarcoidosis. Three patients had skin manifestations. Two patients had ANA positivity (³1:160) and 8/9 high inflammatory markers. Synovial fluid examination, performed in 3 patients, revealed mild to moderate leucocytosis (200-15.000 WBC/mm^3). Five patients received at least one intraarticular injection of corticosteroids, 7/9 received an anti-TNF, 2/9 ustekinumab, and one patient received consecutively methotrexate, anakinra, abatacept and tocilizumab. Two patients underwent liver transplantation with arthritis resolution in one and partial remission in the other one. One patient died before transplantation; 4 patients still had active arthritis despite treatment, 2 had a mild improvement of arthritis with biologic therapies.

Conclusion: In our series the frequency of chronic arthritis among patients affected by Alagille syndrome (9/150 patients followed in the same centers) was 50 times higher than the expected frequency in the general population (1/1000). All patients had arthritis resistant to conventional treatments and only the patient who underwent liver transplantation reached clinical remission. The etiology of chronic arthritis in Alagille syndrome is not known. The two genes associated with Alagille syndrome, JAG1 and NOTCH2, have a role in regulation of angiogenesis and T cells

function, possibly explaining the occurrence of joint inflammation. While the chronic course, the elevated inflammatory markers, the leucocytosis in synovial fluid and the age at onset < 16 years could be suggestive of juvenile idiopathic arthritis, the high incidence among patients with Alagille syndrome, the resistance to common treatments and the resolution with liver transplantation may suggest a role of the underlying disease in the pathogenesis of arthritis.

Farber Disease (Acid Ceramidase Deficiency): The First Natural History Study of This Rare Disease Involving Symptoms Which Can Mimic JIA

Alexander Solyom,[1] Erik Sundberg,[2] John Mitchell,[3] Christina Grant,[4] Carlos Ferreira,[5] Paul Harmatz,[6] Neslihan Mungan,[7] Fatma Bulut,[7] Christina Lampe,[8] Andreas Hahn,[8] Norberto Guelbert,[9] Nur Arslan,[10] Balahan Makay,[10] Ratna Puri,[11] Sunita Bijarnia-Mahay,[11] Laila Selim,[12] Iman Gamal el Din,[12] Seema Kapoor,[13] Maja DiRocco,[14] Seza Ozen,[15] Ezgi Batu,[15] Gulden Gokcay,[16] Marta Torcoletti,[17] Alan Kimura,[18] and Bo Magnusson[2], [1]Enzyvant, Basel, Switzerland, [2]Karolinska University Hospital, Stockholm, Sweden, [3]Montreal Children's Hospital, Montreal, Canada, [4]Children's National Medical Center, Washingotn, DC, [5]Children's National Medical Center, Washington, DC, [6]UCSF Benioff Children's Hospital Oakland, Oakland, CA, [7]Cukurova University Hospital, Adana, Turkey, [8]University Hospital Giessen, Giessen, Germany, [9]Children's Hospital of Cordoba, Cordoba, Argentina, [10]Dokuz Eylul University Hospital, Izmir, Turkey, [11]Sir Ganga Ram Hospital, Delhi, India, [12]Cairo University Children's Hospital, Cairo, Egypt, [13]13Lok Nayak Hospital and Maulana Azad Medical College, Delhi, India, [14]Istituto Giannina Gaslini, Genoa, Italy, [15]Hacettepe University Hospital, Ankara, Turkey, [16]Istanbul University, Istanbul, Turkey, [17]University of Milan, Milan, Italy, [18]Enzyvant, Cambridge, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis
Session Type: Poster Session (Tuesday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The cardinal clinical symptoms of Farber disease (arthritis/contractures, subcutaneous granulomatous nodules, dysphonia) may be misdiagnosed as JIA. Mutations in the *ASAH1* gene and the resulting deficiency of the lysosomal enzyme acid ceramidase leads to accumulation of the pro-inflammatory sphingolipid ceramide, causing a broad spectrum of disease severity and presentation of symptoms, which may delay diagnosis or lead to misdiagnosis. This study represents the first comprehensive, systematic collection of retrospective and prospective clinical data on the natural history of Farber disease.

Methods: The Observational and Cross-Sectional Cohort Study of the Natural History and Phenotypic Spectrum of Farber Disease (NCT03233841) is collecting retrospective and prospective data, including demographics, clinical presentation, phenotype, and diagnostic history, of patients diagnosed with Farber disease who have or have not undergone hematopoietic stem cell transplantation (HSCT). This data, along with specific prospective clinical evaluations in living patients, will be communicated.

Results: Since November 2017, 43 patients (26 living, 17 deceased) have been enrolled in the study. To date, patients have been enrolled at 15 centers in 9 countries. In patients whose data was available for analysis, the average age of the living patients is 9 years (range 1 to 28 years), and the average time from onset of first symptoms to diagnosis is 2 years (range < 1 to 12 years). Of the non-HSCT patients, 32% were treated with a biologic. Childhood Health

Assessment Questionnaire Disability Index Scores (CHAQ DI) ranged from 1.25 to 3 across the non-HSCT population (n=14), including those patients treated with DMARDs and/or biologics.

Conclusion: Among patients representing the broad phenotypic spectrum of Farber disease, from rapidly progressive (severe) to slowly progressive (attenuated), the data confirms that patients can be misdiagnosed as having JIA, and that there is a high disease-related burden as demonstrated by the CHAQ DI scores, which symptomatic treatment with biologics does not resolve. Demographic information and numbers of patients enrolled indicate that Farber disease is likely not as rare as previously thought.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis

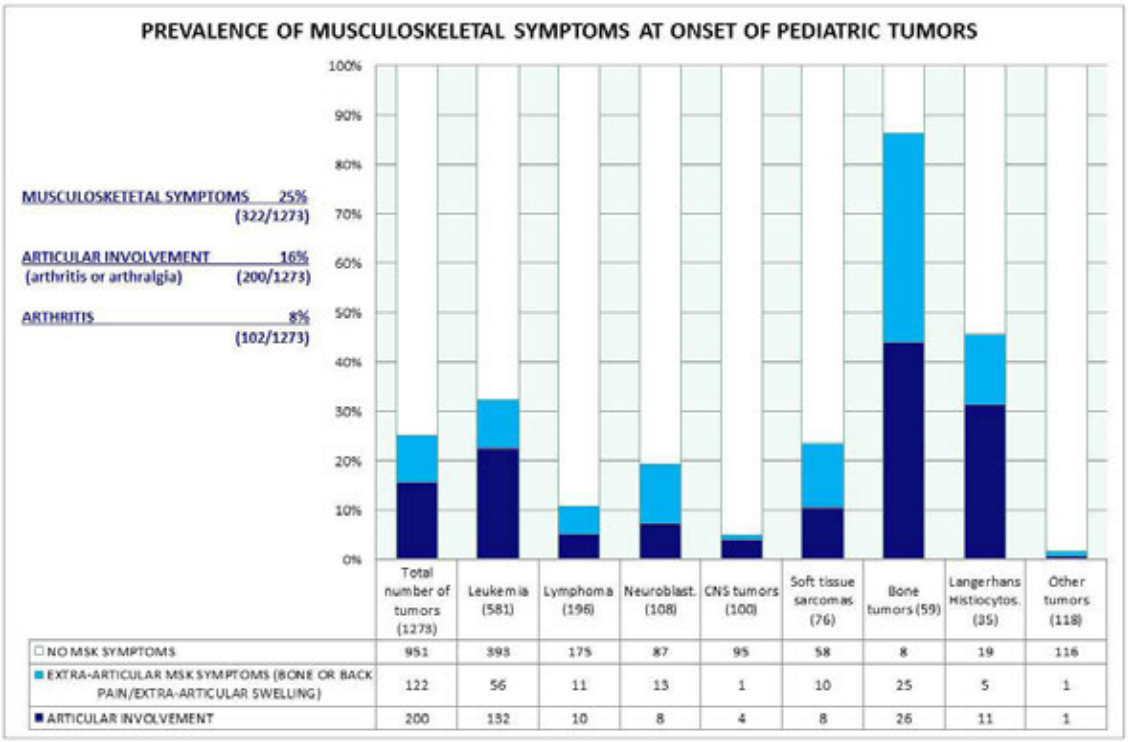
Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

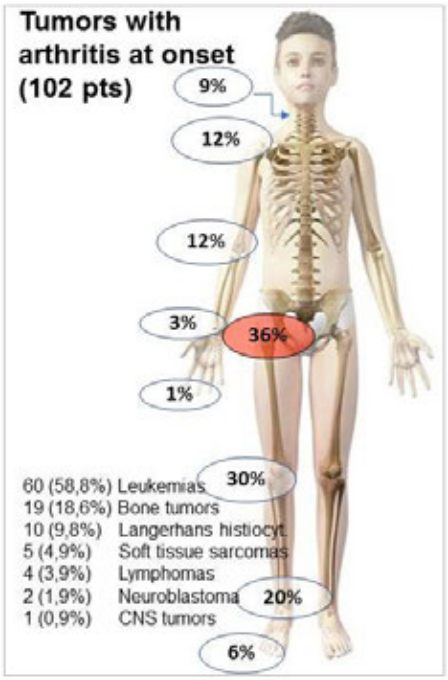
Background/Purpose: Musculoskeletal (MSK) symptoms are a common presenting complaint in pediatric primary care (estimated prevalence 25-50%) and may be the initial manifestation of cancer in rare cases. An articular involvement has been observed in about 20% of onset leukemias, with pictures that can mimic juvenile idiopathic arthritis (JIA) leading to inappropriate steroid or immunosuppressive therapy and diagnostic delay. The primary objective of this study is to assess the prevalence and features of MSK symptoms at the onset of pediatric tumors. The secondary objective is to identify predictors of malignancy comparing tumors with MSK symptoms at onset and new cases of JIA diagnosed in the same period

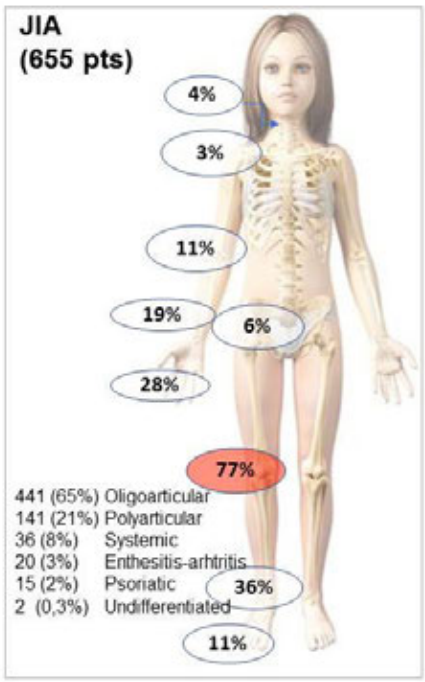
Methods:: The ONCOREUM is a multicenter, observational, cross-sectional study conducted between 2015 and 2018 by 25 Centers of the Italian Association of Pediatric Hematology and Oncology (AIEOP) and 22 Rheumatological Centers of the Italian Society of Pediatrics (SIP). A web based data collection within the AIEOP platform managed by CINECA was performed after local ethics committees approval and written informed consent. We analyzed clinical and laboratory data of patients (pts) < 16 years of age with new diagnosis of tumors or JIA. The data were compare dusing χ^2 for categorical variables and t-test, Welch's test, or Mann-Whitney U test for continuous variables. Statistical analysis was performed by the open source statistical software R.

Results: We considered eligible 1928 pts: 655 of them were affected by JIA and 1273 by tumor. MSK symptoms at onset were found in 25% of cases of tumors, articular involvement (arthritis and/or arthralgia) in 16% and arthritis in 8% (Fig. 1). An initial rheumatological diagnosis was suspected in 9% (29/322) of tumors with MSK symptoms and in 17% (17/102) of tumors with arthritis at onset. The highest frequency of initial rheumatic suspicion was found in neuroblastoma (5/21), Langerhans histiocytosis (3/16) and leukemia (17/188). The most frequent misdiagnosis were hip synovitis, JIA and reactive arthritis. In this preliminary analysis, we compared the clinical features of pts with tumors and arthritis at onset (102) and pts with JIA (655). We found a difference in the frequency of involvement of specific joints: hip and shoulder were significantly associated with tumors; knee, ankle, wrist and small joints of the hands with JIA (Fig 2). We also found that: monoarthritis, arthralgia, bone pain, back pain, disproportionate pain, night pain, refusal to walk, systemic symptoms and male sex were significantly associated with tumors, while poliarthritis (> 4 joints), joint swelling and morning stiffness with JIA (Tab.1)



PATIENTS WITH ARTHRITIS: DISTRIBUTION OF ARTICULAR INVOLVEMENT





Tumors > JIA	
Hip	(p <0,0001)
Shoulder	(p <0,0001)
JIA > Tumors	
Knee	(p <0,0001)
Wrist	(p <0,0001)
Small joints of the hands	(p <0,0001)
Ankle	(p 0,001)

PATIENTS WITH ARTHRITIS: COMPARISON OF CLINICAL FEATURES BETWEEN TUMORS AND JIA

Associated with tumor / Associated with JIA	Tumors (102 pz) (%)	JIA (655 pz) (%)	p
Male sex	54 %	28 %	<0.0001
Age (average)	6 y	6 y	0.629
Duration of symptoms (median)	31,5 d	71 d	<0.0001
Number of joints (average)	1,7 (1-9)	3,3 (1-20)	<0.0001
Monoarthritis	65%	37%	<0.0001
- hip	21%	1%	<0.0001
- knee	16%	29%	0.005
- ankle	8%	4%	0.064
- cervical spine	7%	1%	<0.0001
- elbow	7%	1%	<0.0001
- shoulder	6%	0	<0.0001
- wrist	1%	1%	0.668
2-4 involved joints	29 %	39 %	0.057
> 4 involved joints	6 %	24 %	<0.0001
Swelling	28 %	95 %	<0.0001
Joint pain	98 %	83 %	<0.0001
Limitation of motion	94 %	88 %	0.077
Bone pain	33 %	1 %	<0.0001
Back pain	14 %	7 %	0,011
Disproportionated pain	19 %	1 %	<0.0001
Night pain	9 %	3 %	0.003
Limp	52 %	51 %	0.878
Refusal to walk	31 %	12 %	<0,0001
Morning stiffness	5 %	42 %	<0.0001
Systemic symptoms	65 %	14 %	<0.0001

Conclusion: MSK symptoms at onset of pediatric tumors were observed in 25% of pts, with joint involvement in more than half of cases. Comparing pts with tumors and arthritis with JIA, we found that some clinical feature are useful in differential diagnosis. It is important to carefully evaluate involvement of specific joint at onset (hip and shoulder), monoarticular involvement, specific characteristic of pain, sex and presence of systemic symptoms since these factors have been shown to be significantly associated with oncologic diagnosis.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Pediatric Rheumatology – ePoster III: Systemic JIA, Fever, & Vasculitis – ARP

Session Type: Poster Session (Tuesday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis is a heterogenous group of ocular inflammatory diseases. Underlying disease and treatment can lead to poor quality of life (QOL), depression, and increased health care costs. Our aim is to evaluate overall QOL, vision related QOL, anxiety and depression in a cohort of children with non-infectious uveitis at the Cincinnati Children's Hospital Medical Center.

Methods: Patients and parents completed questionnaires within two weeks of the ophthalmic evaluation which included: Pediatric Quality of Life Inventory (PedsQL) for overall QOL, Effects of Youngsters' Eyesight on Quality of Life (EYE-Q) for uveitis-specific QOL and function, and the Revised Children's Anxiety and Depression Scale (RCADS) for anxiety and depression. PedsQL scores range from 0-100 and EYE-Q ranges 0-2. Higher scores indicate better overall and vision related QOL. RCADS score of >65 indicates clinically meaningful anxiety or depression. We compared children's questionnaire scores using medians and interquartile range by diagnosis, gender, race, use of topical drops, use of systemic medications, presence of ocular complications, and uveitis activity using Wilcoxon rank sum tests (SAS software).

Results: Forty-eight patients were included: 28 JIA-associated uveitis (JIA-U) and 20 non-JIA-U (Other U). Children with JIA-U were primarily female (82% vs. 50%, p = 0.012), white (89% vs 75%, p = 0.012), younger at uveitis diagnosis (6 vs 10 p< 0.001), have a longer mean duration of disease (5.7 vs 2.6 years, p=0.008), and had anterior uveitis (100% vs 70%, p=0.003). (Table 1). The most common ocular complications were ocular hypertension (46%), cataract (35 %), and posterior synechiae (33%) formation. Topical medications were commonly used at last follow up (~60%), with more JIA-U patients requiring systemic immunosuppressive therapy (79% vs 55%, p=0.082). Parent and patients with JIA-U and Other U reported similar median scores on the EYE-Q, PedsQL and RCADS (Table 2). No differences were observed in QOL metrics based on topical or systemic medication use, ocular complications or uveitis activity. Although females had worse RCADS scores for both the parent (female 43.0 vs male 36.7, p< 0.05) and patient (female 33.6 vs male 30.1, p< 0.05) questionnaires, this was not clinically relevant. There was a trend towards worse uveitis related QOL in non-white patients and those with Other-U.

Ocular Complications										
No OC Complications	1.82 (1.78 - 1.96)	1.94 (1.88 - 2)	1.71 (1.5 - 2)	41.44 (37.1 - 49.14)	83.7 (76.09 - 93.48)	1.83 (1.75 - 1.95)	1.88 (1.81 - 1.94)	1.75 (1.57 - 2)	32.5 (29.83 - 35.11)	89.13 (83.7 - 94.02)

Conclusion: We report on the clinical characteristics, QOL and functioning of children with uveitis. Our results suggest there may be differences in QOL and function related to sex, race, and uveitis diagnosis. Larger and more diverse cohorts with varied uveitis, visual impairment and disease activity are needed to better understand the impact of uveitis and treatment on a child and family's QOL and function.

Mitochondrial Contribution to Juvenile Dermatomyositis Pathogenesis

Bhargavi Duvvuri,[1] Lauren Pachman,[2] Richard Moore,[1] Gabrielle Morgan,[2] Marisa Klein-Gitelman,[2] Megan L. Curran,[3] **Stephen Doty**,[4] and Christian Lood[1], [1]University of Washington, Seattle, [2]Northwestern University, Chicago, [3]University of Colorado, Aurora, CO, [4]Hospital for Special Surgery, New York

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Plenary III
Session Type: Plenary Session III
Session Time: 11:00AM–12:30PM

Background/Purpose: Though mainly found intracellularly, we recently observed mitochondrial extrusion upon cell death, contributing to inflammation and organ damage in lupus-prone mice. Of note, mitochondria are immunogenic, promoting development of anti-mitochondrial antibodies (AMAs). Mitochondrial remnants, including DNA, are observed in the circulation of many systemic diseases, including lupus, and thought to partake in the disease pathogenesis. However, the role of mitochondrial extrusion in children with juvenile dermatomyositis (JDM) has not been addressed. The aim of this study was to investigate markers of mitochondrial extrusion, including mtDNA and AMAs, in JDM children to determine their clinical utility.

Methods: AMAs, as well as cell-free mtDNA levels were analyzed in healthy children (HC, n=22), pediatric lupus (n=10), polymyositis (n=7), JDM patients (n=61), and RNP+ myositis (12), by a state-of-the-art flow cytometry technique as well as an in-house qPCR assay. Mitochondrial markers were associated with disease activity score (DAS), calcinosis, as well as autoantibody profiles. Muscle biopsies were analyzed using electron microscopy.

Results: Electron microscopy imaging demonstrated profound mitochondrial abnormalities in JDM muscle, including intramitochondrial calcification associated with degenerate muscle fibers and mitochondrial extrusion. As compared to healthy controls, JDM patients had increased levels of cell-free mtDNA ($p=0.02$) but not genomic DNA ($p=0.09$) in peripheral blood, especially in children with calcinosis ($p=0.002$). As determined by Western blot, JDM patients had autoantibodies reacting towards mitochondrial antigens of 60 kDa, similar to what was seen in jSLE. By flow cytometry, 40% of JDM patients were found to be positive for AMAs ($p< 0.001$). Consistent with the immunogenic nature of mitochondria, AMA levels correlated with presence of antigen, e.g. mtDNA, in peripheral blood ($r=0.28$, $p< 0.05$), as well as with immune complex (IC) levels ($r=0.56$, $p< 0.0001$) and complement C4 consumption ($r=-0.59$, $p=0.01$). Upon activation with mitochondrial ICs, neutrophils induced IL-8 production ($p< 0.01$) as well as underwent formation of neutrophil extracellular traps (NETs, $p< 0.05$), clearly demonstrating the inflammatory potential of mitochondrial ICs. AMA positivity was associated with calcinosis (OR=6.1, $p=0.006$). Of importance, AMA became elevated prior to the clinical diagnosis of calcinosis (OR=11.1, $p< 0.05$), with a sensitivity and specificity of 80% and 73.5%, respectively, to identify calcinosis-prone individuals within the group of children with JDM, suggesting a prognostic potential of AMA in JDM calcinosis development.

Conclusion: JDM patients have obvious mitochondrial abnormalities in tissue and periphery. Our novel findings of mitochondrial antibodies in JDM, preceding clinical diagnosis of calcinosis, support i) mitochondrial extrusion as a potential therapeutic targetable pathway, and ii) the use of AMAs as prognostic markers, allowing for early, preventive treatment, reducing development of disabling calcinosis in those children.

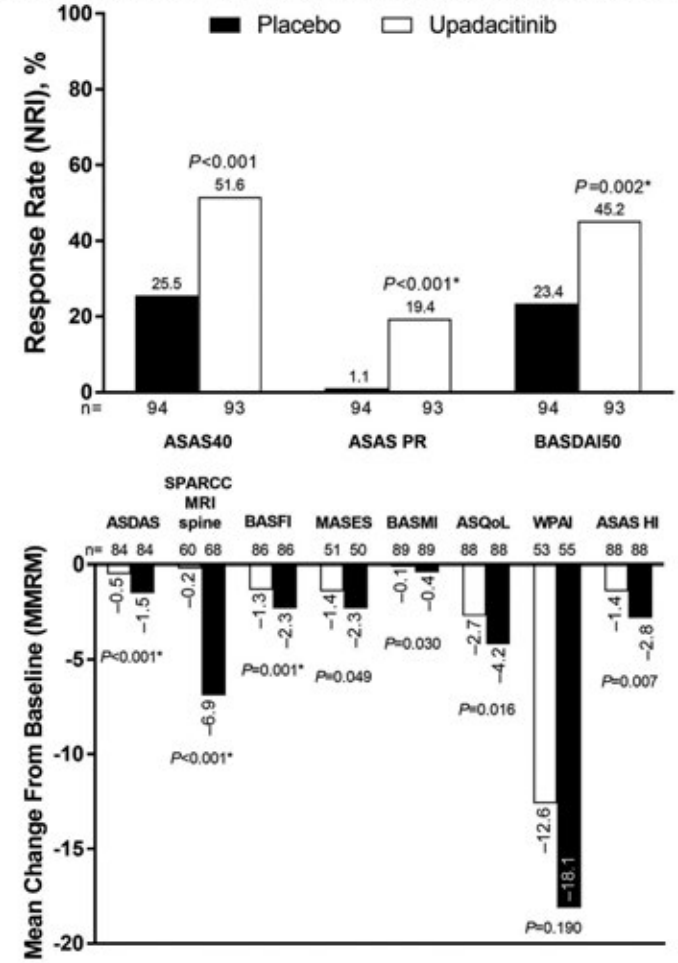
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Plenary III
Session Type: Plenary Session III
Session Time: 11:00AM–12:30PM

Background/Purpose: Patients (pts) with ankylosing spondylitis (AS) who have an inadequate response/contraindication to NSAIDs have limited treatment options other than biologics. The Janus kinase (JAK) pathway is a potential therapeutic target in AS. This study assessed the efficacy and safety of upadacitinib (UPA), a selective JAK1 inhibitor, in pts with active AS.

Methods: In this double-blind, placebo (PBO)-controlled, phase 2/3 study (NCT03178487; SELECT-AXIS 1) pts with AS were randomized 1:1 to UPA 15 mg or matching placebo. Enrolled pts (≥18 y) met modified New York Criteria for AS based on central reading of radiographs, had a BASDAI ≥4 and pt assessment of total back pain ≥4 (numeric rating scale, 0–10) at screening and baseline (BL), were biologic DMARD naive, and had inadequate response to ≥2 NSAIDs or intolerance to/contraindication for NSAIDs. The primary efficacy endpoint was Assessment of SpondyloArthritis international Society (ASAS) 40 response at wk 14. Multiplicity-adjusted key secondary endpoints included change from BL to wk 14 (Δ) in Ankylosing Spondylitis Disease Activity Scores (ASDAS), Δ Spondyloarthritis Research Consortium of Canada (SPARCC) MRI spine, BASDAI50 at wk 14, Δ AS quality of life (QoL), ASAS partial remission (PR) at wk 14, Δ BASFI, Δ BASMI, Δ Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), Δ Work Productivity and Activity Impairment (WPAI), and Δ ASAS health index (HI). Adverse events (AEs) were monitored throughout the study.

Results: All randomized pts (N=187) received assigned treatment (PBO, n=94; UPA, n=93); 95.7% of pts completed the study through wk 14 (PBO, 90/94; UPA, 89/93). Most pts were male (70.6%) and HLA-B27 positive (76.5%). Mean symptom duration was 14.4 y, and mean age was 45.4 y; BL disease characteristics were balanced between arms. Significantly more pts treated with UPA vs PBO achieved the primary endpoint of ASAS 40 response at wk 14 (51.6% vs 25.5%; $P< 0.001$; **Figure**). Accounting for multiplicity-adjustment, the following endpoints were statistically significant for UPA vs PBO at week 14: Δ ASDAS, Δ SPARCC MRI spine, BASDAI50, ASAS PR, and Δ BASFI (**Figure**). Other ranked secondary endpoints, except WPAI, were significant based on nominal P values (**Figure**). The proportions of pts with AEs leading to discontinuation (2.2% vs 3.2%), serious AEs (1.1% vs 1.1%), and infections (20.4% and 27.7%) were similar for UPA and PBO groups, respectively. No serious infections, herpes zoster, malignancy, venous thromboembolic events, or deaths were reported.

Figure. Primary (ASAS 40) and Multiplicity-adjusted Key Secondary Endpoints at Week 14



ASAS40, Assessment of SpondyloArthritis international Society 40% response; ASQoL, Ankylosing Spondylitis Quality of Life score; ASDAS, Ankylosing Spondylitis Disease Activity Score; BASDAI 50, 50% improvement from baseline in BASDAI; HI, Health Index; MASES, Maastricht Ankylosing Spondylitis Enthesitis Score; NRI, non-responder imputation; MMRM, mixed model for repeated measures; PR, partial remission; SPARCC, Spondyloarthritis Research Consortium of Canada; WPAI, Work Productivity and Activity Impairment.
*Significant in multiplicity-adjusted analysis. Nominal P values are shown.
MASES assessment includes patients with baseline enthesitis; WPAI assessment includes patients currently employed; SPARCC MRI assessment population as pre-specified.

Conclusion: UPA 15 mg QD was significantly more efficacious than PBO at wk 14 in pts with active AS for improvement in signs and symptoms, function, and imaging. The proportion of patients with AEs was similar in the UPA and PBO arms, and no new safety findings were observed compared with previous UPA studies in other diseases.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Plenary III
Session Type: Plenary Session III
Session Time: 11:00AM–12:30PM

Background/Purpose: Ixekizumab (IXE), a high affinity IL-17A monoclonal antibody, previously showed efficacy in AS/radiographic-axSpA[1,2]. COAST-X (NCT02757352) is a phase 3 study that assessed efficacy and safety of IXE in patients (pts) with active nr-axSpA and objective signs of inflammation.

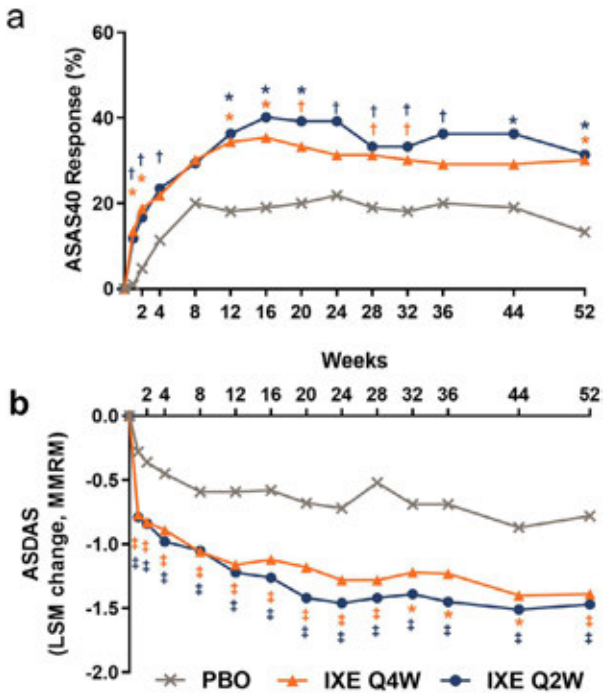

Figure. Key efficacy outcomes over 52 weeks. (a) ASAS40 responses and (b) ASDAS LSM change from baseline over 52 weeks are shown for PBO, IXE Q4W, and IXE Q2W. For ASAS40, a logistic regression model was used for comparisons between placebo and IXE treatment arms; missing data and switch to open-label IXE Q2 were considered as nonresponse. For ASDAS comparisons were made by mixed model of repeated measures (MMRM). ‡p<0.001, *p<0.01; †p<0.05. ASAS, Assessment of SpondyloArthritis international Society; ASDAS, Ankylosing Spondylitis Disease Activity Scores; IXE, ixekizumab; LSM, least squares mean; PBO, placebo; Q2W, every 2 weeks; Q4W, every 4 weeks.

Table 1. Demographics and baseline characteristics

	PBO N=105	IXE Q4W N=96	IXE Q2W N=102
Age (years), mean (SD)	39.9 (12.4)	40.9 (14.5)	40.0 (12.0)
Female, n (%)	61 (58.1)	46 (47.9)	53 (52.0)
Geographic region, n (%)			
North and South America	33 (31.4)	32 (33.3)	37 (36.3)
Asia	15 (14.3)	12 (12.5)	11 (10.8)
Europe	57 (54.3)	52 (54.2)	54 (52.9)
Symptom duration (years), mean (SD)	10.1 (8.3)	11.3 (10.7)	10.6 (10.1)
Years with axSpA diagnosis, mean (SD)	3.1 (4.5)	4.2 (5.5)	3.4 (4.6)
Positive for HLA-B27, n (%)	77 (74.0)	71 (74.7)	73 (72.3)
BASDAI score, mean (SD)	7.2 (1.5)	7.0 (1.5)	7.3 (1.3)
ASDAS score, mean (SD)	3.8 (0.9)	3.8 (0.8)	3.9 (0.8)
BASFI score, mean (SD)	6.7 (2.0)	6.4 (2.1)	6.5 (1.8)
CRP (mg/L), mean (SD)	14.3 (24.4)	12.4 (18.0)	12.1 (17.8)
SI joint SPARCC score, mean (SD)	6.2 (9.1)	5.3 (8.3)	7.5 (10.8)
MRI/hsCRP stratification, n (%)[a,b]			
MRI+/hsCRP+	38 (36.2)	30 (31.3)	39 (38.2)
MRI+/hsCRP-	40 (38.1)	36 (37.5)	34 (33.3)
MRI-/hsCRP+	26 (24.8)	30 (31.3)	28 (27.5)
Concomitant medication, n (%)			
NSAIDs	96 (91.4)	81 (84.4)	95 (93.1)
Methotrexate	17 (16.2)	17 (17.7)	15 (14.7)
Sulfasalazine	21 (20.0)	23 (24.0)	27 (26.5)
Corticosteroid	14 (13.3)	8 (8.3)	20 (19.6)

[a]Randomization stratified by country and screening MRI/hsCRP status (positive MRI and elevated hsCRP, positive MRI and non-elevated hsCRP, negative MRI and elevated hsCRP). [b]Elevated hsCRP defined as >5.00 mg/L. Percentages were calculated based on the number of patients with nonmissing values. axSpA, axial spondyloarthritis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; CRP, C-reactive protein; HLA, human leukocyte antigen; hsCRP, high-sensitivity C-reactive protein; IXE, ixekizumab; MRI, magnetic resonance imaging; NSAIDs, nonsteroidal anti-inflammatory drugs; PBO, placebo; Q2W, every 2 weeks; Q4W, every 4 weeks; SD, standard deviation; SI, sacroiliac; SpA, spondyloarthritis; SPARCC, Spondyloarthritis Research Consortium of Canada.

Table 2: Primary and secondary efficacy outcomes at Week 16 and Week 52 and safety at Week 52

	Week 16			Week 52		
	Placebo N=105	IXE Q4W N=96	IXE Q2W N=102	Placebo N=105	IXE Q4W N=96	IXE Q2W N=102

‡p<0.001, *p<0.01; †p<0.05. [a]Logistic regression analysis with nonresponder imputation for missing data. [b]A primary or major secondary endpoint. Comparisons between each of the ixekizumab treatment arms and placebo for primary and major secondary endpoints were all statistically significant as calculated using a graphical multiplicity testing method. [c]Percentages based on observed cases and initial randomized treatment. [d]Mixed effects model of repeated measures analysis. [e]Analysis of covariance of observed cases. AEs, adverse events; ASAS, Assessment of SpondyloArthritis international Society; CRP, C-reactive protein; HLA, human leukocyte antigen; ITT, intent to treat; IXE, ixekizumab; LDA, low disease activity; LSmean, least squares mean; MRI, magnetic resonance imaging; Q2W, every 2 weeks; Q4W, every 4 weeks; SAEs, serious adverse events; SE, standard error; SF-36 PCS, Medical Outcomes Questionnaire Short Form-36 Principal Component Summary; SI, sacroiliac; SPARCC, Spondyloarthritis Research Consortium of Canada; SpA, spondyloarthritis; TEAEs, treatment-emergent adverse events.

Methods: COAST-X was a 52-wk, randomized, double-blind, PBO-controlled study enrolling adults with an established diagnosis of axSpA who met ASAS classification (but not modified New York) criteria, had BASDAI ≥4, back pain ≥4, inflammation [sacroiliitis on MRI or elevated CRP >5 mg/L], and inadequate response or intolerance to NSAIDs. All images were centrally read. After stratification by country and screening MRI/CRP status, pts were randomized 1:1:1 to 80 mg IXE every 4 wks (Q4W), 80 mg IXE every 2 wks (Q2W), or PBO. Changes to conventional back-

ground medication (NSAIDs, csDMARDs, analgesics, and low dose corticosteroids) as well as escape to open label (OL) IXE Q2W were allowed at investigator discretion after Wk 16. Subsequent escape to OL TNF-inhibitor treatment was permitted after ≥8 wks of OL IXE Q2W. Primary endpoints were ASAS40 at Wks 16 and 52. Patients missing data or switched to OL IXE Q2W were imputed as non-responder. A logistic regression model with nonresponder imputation was used for categorical data. A mixed effects model of repeated measures was used for continuous variables. Analysis of covariance was used for sacroiliac joint (SIJ) MRI SPARCC scores.

Results: Table 1 shows baseline characteristics; 303 subjects were randomized: PBO (N=105), IXE Q4W (N=96), IXE Q2W (N=102). Significantly more pts achieved ASAS40 at Wk 16: IXE Q2W (40%), IXE Q4W (35%) vs PBO (19%, $p< 0.01$) and at Wk 52: IXE Q2W (31%), IXE Q4W (30%) vs PBO (13%, $p< 0.01$) (Fig. & Table 2). Compared to PBO, pts on either IXE regimen had significantly greater changes from baseline at Wk 16 and Wk 52 for disease activity, functional status, and SIJ SPARCC scores (Fig. & Table 2). Statistically significant improvements for both IXE regimens vs PBO were first observed at Wk 1 for ASAS40. A notable proportion of pts who escaped to OL IXE Q2W had ASAS40 response at the time of escape (16.7%, 25%, and 6.5% on IXE Q2W, IXEQ4W, and PBO, respectively), and ASA40 rates increased further on open label IXE Q2 (Table 2). The frequency of serious adverse events and adverse events that led to treatment discontinuation was low and similar across all arms (Table 2). No new safety signal was identified.

Conclusion: The primary endpoint of ASAS40 and all major secondary endpoints for IXE Q4W and Q2W were met at Wk 16 and Wk 52 with no unexpected safety findings. IXE added to conventional background medication was superior to conventional background medication and PBO for improving signs, symptoms, and inflammation on MRI in pts with nr-axSpA.

Abstract Number: 2730

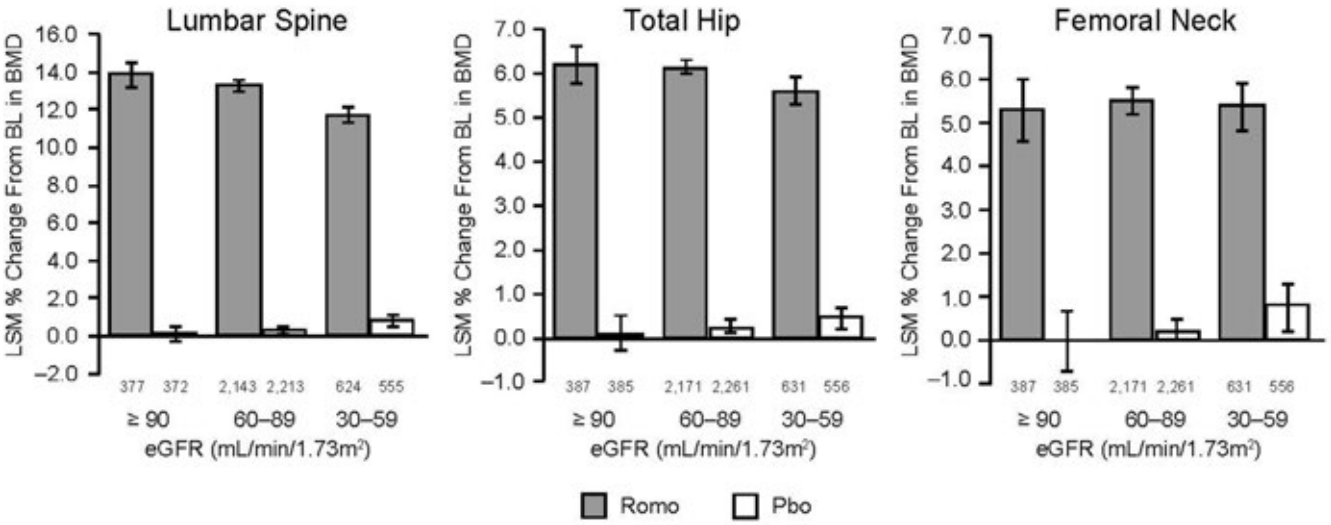
Efficacy and Safety of Romosozumab vs Placebo Among Patients with Mild-to-Moderate Chronic Kidney Disease

Paul Miller,[1] Arkadi Chines,[2] Ben-Hur Albergaria,[3] Evelien Gielen,[4] Bente Langdahl,[5] Akimitsu Miyauchi,[6] Mark Vanderkelen,[7] Cassandra Milmont,[2] Judy Maddox,[2] and Jonathan Adachi[8], [1]Colorado Center for Bone Research at Panorama Orthopedics and Spine Center, Golden, CO, [2]Amgen Inc., Thousand Oaks, CA, [3]Federal University of Espirito Santo, Vitória, Brazil, [4]Gerontology and Geriatrics, Department of Chronic Diseases, Metabolism and Aging, KU Leuven & Center for Metabolic Bone Diseases, UZ Leuven, Leuven, Belgium, [5]Aarhus University Hospital, Aarhus, Denmark, [6]Miyauchi Medical Center, Osaka, Japan, [7]UCB Pharma, Brussels, Belgium, [8]McMaster University and St. Joseph's Healthcare Hamilton, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Plenary III
Session Type: Plenary Session III
Session Time: 11:00AM–12:30PM

Background/Purpose: Osteoporosis and renal insufficiency are coexisting disease states in a substantial proportion of postmenopausal women. Since bisphosphonates are generally contraindicated in patients with estimated GFR (eGFR) < 35 mL/min, it is important to evaluate other osteoporosis treatments in this setting. This post hoc anal-

Figure. LSM (95% CI) % Change in BMD From Baseline to Month 12



Change in BMD from baseline for the eGFR 15–29 mL/min/1.73m^2 subgroup is not reported since there were only 7 pts in the pbo group for each of the measured sites and only 7, 8, and 8 pts in the romo group for LS, TH, and FN, respectively. Number of pts are shown below each bar. Error bars represent 95% CIs.
Abbreviations: BL, baseline; LSM, least squares mean.

ysis of the FRAME study assessed the efficacy and safety of romosozumab (Romo) vs placebo (Pbo) among patients with different levels of renal function.

Methods: FRAME enrolled 7,180 postmenopausal women with T-scores –2.5 to –3.5 at the total hip (TH) or femoral neck (FN). In the Pbo-controlled double-blind treatment phase, patients received Romo 210 mg or Pbo monthly for 12 months. Patients were grouped by baseline eGFR (mL/min/1.73m^2) normalized to body surface area, calculated using the MDRD study equation. Renal function was categorized as normal renal function (eGFR ≥ 90) or mild (eGFR 60–89 [chronic kidney disease (CKD) stage 2]), moderate (eGFR 30–59 [CKD stage 3]), or severe (eGFR 15–29 [CKD stage 4]) renal insufficiency. The least squares mean % change from baseline in bone mineral density (BMD) at the lumbar spine (LS), TH, and FN; incidence of new vertebral fractures and adverse events; and CKD progression were assessed for each eGFR category at month 12.

Results: At baseline, most patients (88%) had mild or moderate renal insufficiency; 0.3% had severe renal insufficiency. In the overall patient population, the least squares mean % change (95% CI) from baseline in BMD (Romo vs Pbo) was 13.1% (12.8–13.3) vs 0.4% (0.2–0.5) for LS, 6.0% (5.9–6.2) vs 0.3% (0.1–0.4) for TH, and 5.5% (5.2–5.7) vs 0.3% (0.1–0.5) for FN. Changes in BMD were similar irrespective of baseline eGFR (Figure). Incidence of new vertebral fractures (Romo/Pbo) in patients with normal renal function, CKD 2, or CKD 3 was 0.5%/3.0%, 0.4%/1.5%, and 0.6%/2.1%, respectively. The overall incidence of adverse events and serious adverse events, and the incidence of positively adjudicated cardiovascular events were similar between treatment groups for all eGFR categories. One patient (CKD 2 at baseline) in the Romo group had grade 2 hypocalcemia. Mild-to-moderate calcium decrease occurred in 4 patients in the Pbo group and 13 patients in the Romo group. Most patients (approximately 80% in each group) had no changes from baseline eGFR category at the end of the 12-month period.

Conclusion: Romo increased BMD across eGFR subgroups vs Pbo, and the reduction in new vertebral fractures was not notably affected by eGFR level. Safety was also generally comparable among eGFR subgroups.

Decomposition Analysis of Spending and Price Trends for Biologic Anti-Rheumatic Drugs in Medicare and Medicaid

Natalie McCormick,[1] Zachary Wallace,[2] Chana Sacks,[3] John Hsu,[4] and Hyon K. Choi[5], [1]Massachusetts General Hospital and Harvard Medical School, Boston, MA, [2]Massachusetts General Hospital, Boston, [3]Department of General Internal Medicine, Massachusetts General Hospital; Department of Medicine, Harvard Medical School, Boston, MA, [4]Mongan Institute, Massachusetts General Hospital; Department of Health Care Policy, Harvard Medical School, Boston, MA, [5]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Plenary III
Session Type: Plenary Session III
Session Time: 11:00AM–12:30PM

Background/Purpose: Billions of public dollars are spent each year on biologic disease-modifying anti-rheumatic drugs (bDMARDs), but the drivers of bDMARD spending and per-patient cost increases are unclear. We characterized changes in total spending and unit-prices for bDMARDs in Medicare and Medicaid and quantified the major sources of spending increases for public programs and beneficiaries.

Methods: Data Source and Measures: We accessed Medicare Parts B & D and Medicaid drug spending data for years 2012-2016. These contained aggregated prescription claims for all beneficiaries enrolled in Medicare Parts B (fee-for-service) or Part D (stand-alone or Medicare Advantage plans) or Medicaid. All bDMARDs with FDA approval for ≥ 1 rheumatic disease through Dec. 2014 were included. For each bDMARD and calendar-year we extracted total annual spending, and number of recipients, claims, and doses dispensed, and calculated drug unit-price (average cost/dose).

Statistical Analysis: We calculated five-year changes in total spending and unit-prices for each bDMARD and in-aggregate, after adjusting for general inflation to 2016 dollars. We then performed standard decomposition analyses to isolate the contributions of four sources of spending growth (drug prices, uptake [number of recipients], treatment intensity [mean # of doses per-claim], and annual # of claims per-recipient) for each bDMARD. We conducted our analysis including statutory Medicaid rebates (as these decrease public spending), and both excluding and including Medicare rebates (as these are paid by manufacturers to Pharmacy Benefit Managers and Part D plans). We used time-varying rebates reported by the Congressional Budget Office.

Table: Spending and Uptake for Biologic DMARDs Covered under Medicare Parts D and B (drugs ranked by 2016 spending)

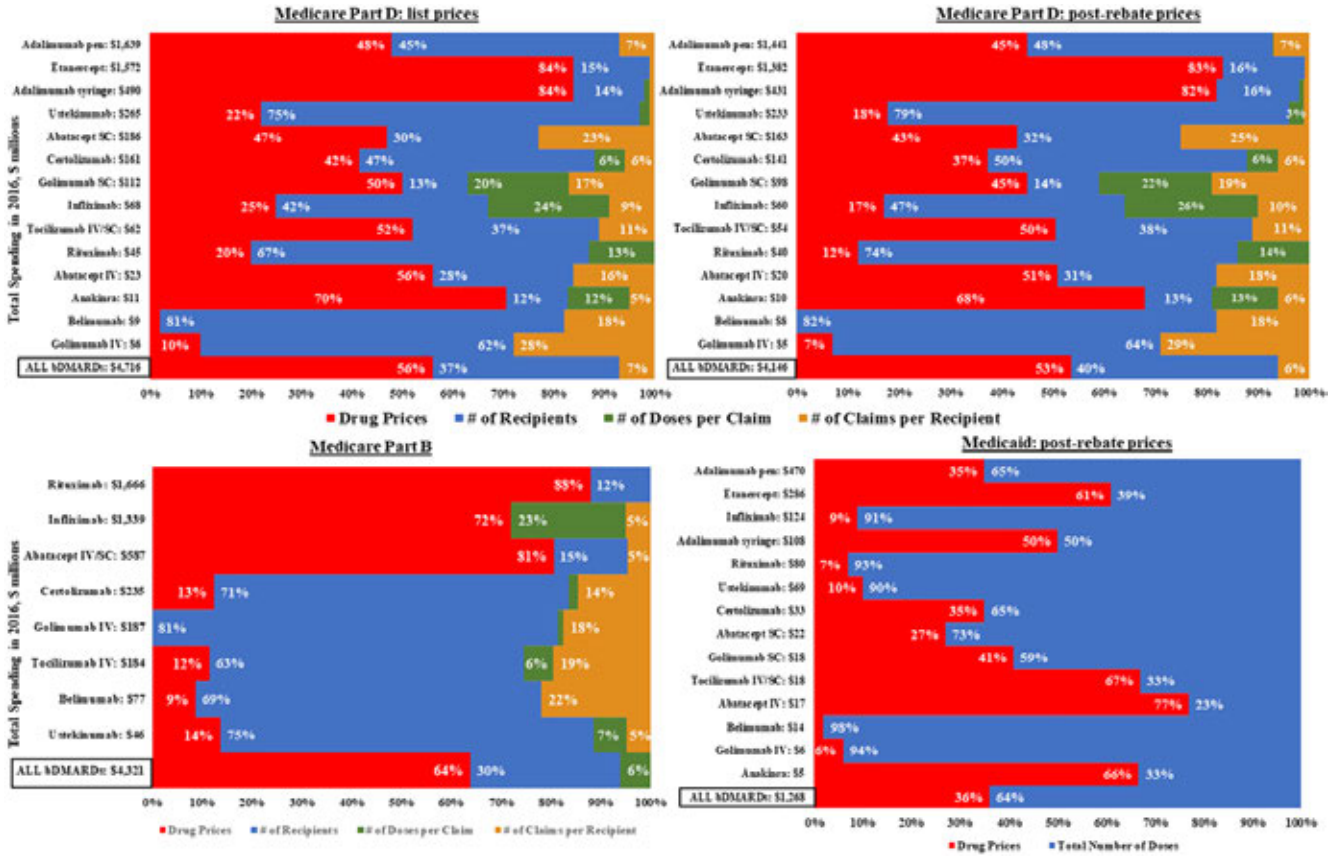
MEDICARE PART D							
Biologic DMARD	Total Spending in 2016[a]	# of Recipients in 2016	Change from 2012				
			Total Spending	Total Spending, Rebate-Adjusted[c]	# of Recipients	Drug Prices	Drug Prices, Rebate-Adjusted[c]
Adalimumab SC (injector pen)	$1,638,715,583	48,164	261%	237%	80%	84%	72%
Etanercept SC	$1,572,038,339	47,795	107%	93%	11%	88%	75%
Adalimumab SC (pre-filled syringe)	$490,135,622	15,477	107%	93%	11%	84%	72%
Ustekinumab SC	$264,877,321	6,616	401%	367%	249%	37%	28%
Abatacept SC[b]	$185,560,929	6,916	72%	66%	19%	31%	26%
Certolizumab SC	$160,787,675	5,903	172%	154%	61%	51%	41%
Golimumab SC	$111,914,458	3,549	124%	109%	11%	49%	39%
Infliximab IV	$68,074,955	2,407	110%	96%	37%	20%	12%
Tocilizumab (IV or SC)[b]	$61,489,157	3,499	142%	134%	60%	100%	93%
Rituximab IV	$45,242,671	1,756	94%	81%	65%	16%	8%
Abatacept IV	$22,475,179	1,162	99%	85%	24%	54%	44%
Anakinra SC	$10,858,651	388	142%	126%	11%	87%	74%
Belimumab IV	$8,612,441	388	385%	352%	304%	3%	-4%
Golimumab IV[b]	$5,836,741	292	149%	141%	70%	17%	13%
ALL	$4,715,757,411	-	176%	158%	-	52%	42%

MEDICARE PART B					
Biologic DMARD	Total Spending in 2016[d]	# of Recipients in 2016	Change from 2012		
			Total Spending	# of Recipients	Drug Prices
Rituximab IV	$1,665,667,928	69,941	11%	2%	18%
Infliximab IV	$1,338,726,191	58,397	27%	-2%	20%
Abatacept (IV or SC)	$586,532,893	22,879	104%	11%	79%
Certolizumab SC[b]	$235,364,173	11,953	93%	60%	8%
Golimumab IV[b]	$186,707,915	10,521	195%	144%	0%
Tocilizumab IV	$184,202,071	11,167	102%	56%	8%
Belimumab IV	$76,797,133	2,922	124%	84%	8%
Ustekinumab SC	$46,408,889	1,752	379%	235%	21%
ALL	$4,320,542,877	-	45%	-	20%

Results: From 2012-2016, annual spending on the 11 included bDMARDs by US public programs and beneficiaries nearly doubled (from $5.3 to $10.3 billion); drug prices increased by a mean of 52% in Part D and just 20% in Part B (**Table**). Controlling for general inflation, unit-price increases alone accounted for 56% ($1.7 billion) of the five-year, $3.0 billion spending increase within Part D (**Figure**); increased uptake accounted for 37% ($1.1 billion). After accounting for time-varying rebates, price hikes were still responsible for 53% ($1.4 billion) of the Part D spending increase. Adalimumab and etanercept, two of the oldest bDMARDs, were prescribed to the largest numbers of Part D beneficiaries and had the biggest unit-price increases: 84% and 88%, respectively. Medicaid spending and price trends were similar to Part D (**Figure**).

Majority of spending growth for the oldest Part B drugs (rituximab, abatacept, and infliximab) was from price increases (72-88%), while for the five newer drugs (golimumab, ustekinumab, tocilizumab, certolizumab, and belimumab), number of recipients was the main driver (63-81% of spending growth).

Conclusion: Post-market drug-price changes alone accounted for the majority of recent bDMARD spending growth, and manufacturers' rebates had little impact on these findings. Beyond rebates, policy interventions that target price increases, particularly under Part D plans, may help mitigate public-payer drug spending and out-of-pocket costs for the elderly and disabled beneficiaries who rely on bDMARDs.



Component proportion of Biologic DMARD spending increases from 2012 to 2016, by public program (drugs ranked by 2016 spending, $ millions)

The Relationship Between Gout and Cardiovascular Disease Outcomes: A Health Data Linkage Study of 1 Million New Zealanders Using Population-level Cardiovascular Risk Prediction Equations

Ken Cai,[1] Billy Wu,[2] Suneela Mehta,[2] Nicola Dalbeth,[2] Rod Jackson,[2] and Poppe Katrina[2], [1]University of Auckland, Auckland, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Plenary III

Session Type: Plenary Session III

Session Time: 11:00AM–12:30PM

Background/Purpose: Some studies have reported that gout is an independent risk factor for cardiovascular events. Furthermore, urate-lowering therapy such as allopurinol may be associated with reduced risk of cardiovascular disease (CVD). Recently, population-level cardiovascular risk prediction equations for health planning have been developed and validated using linked health data in New Zealand (Mehta, Int J Epidemiol. 2018). We examined the association of gout with population-level estimated CVD risk and CVD outcomes using linked national health data.

Methods: National registries of medicines dispensing data, hospitalisation, and death were linked to the Auckland/Northland regional repository of laboratory results from January 1, 2012 to December 31, 2016. There were 65.6% (n=968,986) of the resulting health contact population who had no prior CVD in 2012 and formed the cohort for this study. Sex-specific baseline 5-year CVD risk (of cardiovascular death, non-fatal myocardial infarction, stroke, or other vascular event) was derived using the published population-level CVD risk scores. A validated national health data definition of gout was used to define those with gout: discharge diagnosis of gout (ICD-9 274, ICD-10 M10) from a public hospital admission or having been dispensed gout specific medications (Winnard, Rheumatology 2012). Data were limited to patients aged ≥20 years with a primary residence in the Auckland/Northland region for the last 3 years.

Results: Of the 968 986 people included in the study, 32 805 (3.4%) had gout. The population-level estimated 5-year CVD risk and rates of CVD events (fatal and non-fatal) were higher in both women and men with gout (**Table**). After adjustment for age, gender, ethnicity, deprivation quintile and population-level estimated 5 year CVD risk, gout was independently associated with an increased odds of fatal (adjusted OR 1.37, 95% CI: 1.27-1.48) and non-fatal CVD events (adjusted OR 1.41, 95% CI: 1.35-1.47). Compared with people without gout, there was no statistically significant difference in adjusted odds ratio for those with gout dispensed allopurinol compared with those not dispensed allopurinol (for fatal CVD events, adjusted OR 1.38, 95% CI: 1.27-1.50 vs. 1.33, 95% CI: 1.14-1.55; for non-fatal CVD events, adjusted OR 1.41, 95% CI: 1.34-1.47 vs. 1.42, 95% CI: 1.31-1.54). There was also no statistically significant difference in adjusted odds ratio for those with serum urate above 6mg/dL or below 6mg/dL (for fatal CVD events, adjusted OR 1.38, 95% CI: 1.23-1.54 vs. 1.33, 95% CI: 1.13-1.55; for non-

Outcomes				
CVD deaths	540 (7.7)	1271 (4.9)	10075 (1.9)	8349 (2.1)
Non-fatal CVD events	930 (13.3)	2398 (9.3)	13144 (2.5)	13962 (3.4)

[a] dispensed at least once in the last 5 years, [b] tested at least once in the last 3 years

fatal CVD events, adjusted OR 1.50, 95% CI: 1.42-1.59 vs. 1.35, 95% CI: 1.24-1.47), when compared to people without gout.

Conclusion: Gout is associated with an increased estimated risk of CVD events calculated from population-level cardiovascular risk equations. Even after adjustment for estimated 5 year CVD risk and additional weighting of risk factors within it, gout independently increased the odds for fatal and non-fatal events. This effect was not ameliorated by allopurinol use or serum urate lowering to treatment target.

Inhibition of Neutrophil Elastase Reduces Autoantibody Levels and Renal Inflammation in Murine Lupus

Gautam Sule,[1] Kristen Gilley,[1] Andrew Fernandes,[1] Srilakshmi Yalavarthi,[1] and **Jason Knight**[2], [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Edmond L. Dubois, MD Memorial Lecture: SLE – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Dysregulated neutrophil extracellular trap (**NET**) release has been proposed as a source of autoantigens in lupus. Furthermore, it has recently been shown that the onset of lupus nephritis is predicted by a "neutrophil signature" in lupus blood. Neutrophil elastase (**NE**) is a serine protease uniquely expressed by neutrophils, which is known to activate matrix metalloproteinases, inflammatory cytokines, and degrade extracellular matrix components. NE is also required for many forms of NETosis, and has been reported to circulate at high levels in lupus patients. Inhibition of NE has proven effective in models of cardiopulmonary disease and inflammatory arthritis. Previously, we demonstrated the efficacy of a single NE inhibitor in mitigating organ damage (proteinuria, cardiac fibrosis) in lupus-prone NZW x BXSB F1 mice. However, we have not previously characterized how specific immune-cell populations or autoantibody responses might be modulated by NE inhibition.

Methods: Lupus-prone MRL-*lpr* female mice were treated with two different selective NE inhibitors: GW311616A (**GW**, 2.2 mg/kg by oral gavage three times per week) or Alvelestat (**ALV**, 10 mg/kg by oral gavage three times per week) from 8 to 16 weeks of age. We measured NETosis efficiency and autoantibody levels using standard ELISAs. Spleens, lymph nodes (mandibular, axillary, and inguinal), and kidneys were harvested and immune-cell profiling was performed with flow cytometry.

Results: Both GW- and the ALV-treated mice demonstrated reduced levels of autoantibodies against double-stranded DNA (both groups demonstrating ~50% reduction) and beta-2 glycoprotein I (~30% reduction). Peripheral blood analysis revealed a significant reduction in the number of circulating neutrophils in inhibitor-treated mice (~20% reduction), but no difference in the number of cell-free NETs. Intriguingly, elastase inhibition resulted in a marked re-

duction in CD45+ cells infiltrating kidneys (approximate 3-fold reduction for both inhibitor groups). Regarding specific leukocyte populations, there was a 5-fold or greater reduction in renal-infiltrating CD19+ B cells, CD4+ T cells, and CD8+ T cells. Analysis of lymph nodes demonstrated reduced expansion of activated CD4+ and CD8+ T cells (30% reduction) with NE inhibition, which was accompanied by reduced numbers of CD44+ CD62L+ central-memory T cells. Furthermore, there was a 2-fold reduction in the percentage of germinal-center B cells, and a corresponding increase in immature B cells. Experiments are underway to precisely define kidney histology and immune-complex deposition in NE inhibitor-treated mice as compared with vehicle-treated controls.

Conclusion: Treatment of MRL-*lpr* mice with two distinct orally-bioavailable NE inhibitors (GW311616A or Alvelestat) led to the reduction in autoantibody levels, decreased immune-cell infiltration into kidneys, and altered immune-cell profiles in lymph nodes. These data provide further evidence that NE is a valid therapeutic target in lupus, and perhaps especially as a strategy for preventing lupus nephritis.

Signaling Lymphocytic Activation Molecule Family (SLAMF) Receptors Deregulation Is Implicated in the Altered Function of NK Cells in Systemic Lupus Erythematosus

Morgane Humbel,[1] Florence Bellanger,[1] Craig Fenwick,[2] Alice Horisberger,[3] Camillo Ribi,[1] and **Denis Comte**[1], [1]Service of Immunology and Allergy, Lausanne University Hospital and University of Lausanne, Epalinges, Vaud, Switzerland, [2]Service of Immunology and Allergy, Lausanne University Hospital and University of Lausanne, Epalinhes, Vaud, Switzerland, [3]Service of Immunology and Allergy, Lausanne University Hospital and University of Lausanne, Lausanne, Vaud, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Edmond L. Dubois, MD Memorial Lecture: SLE – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

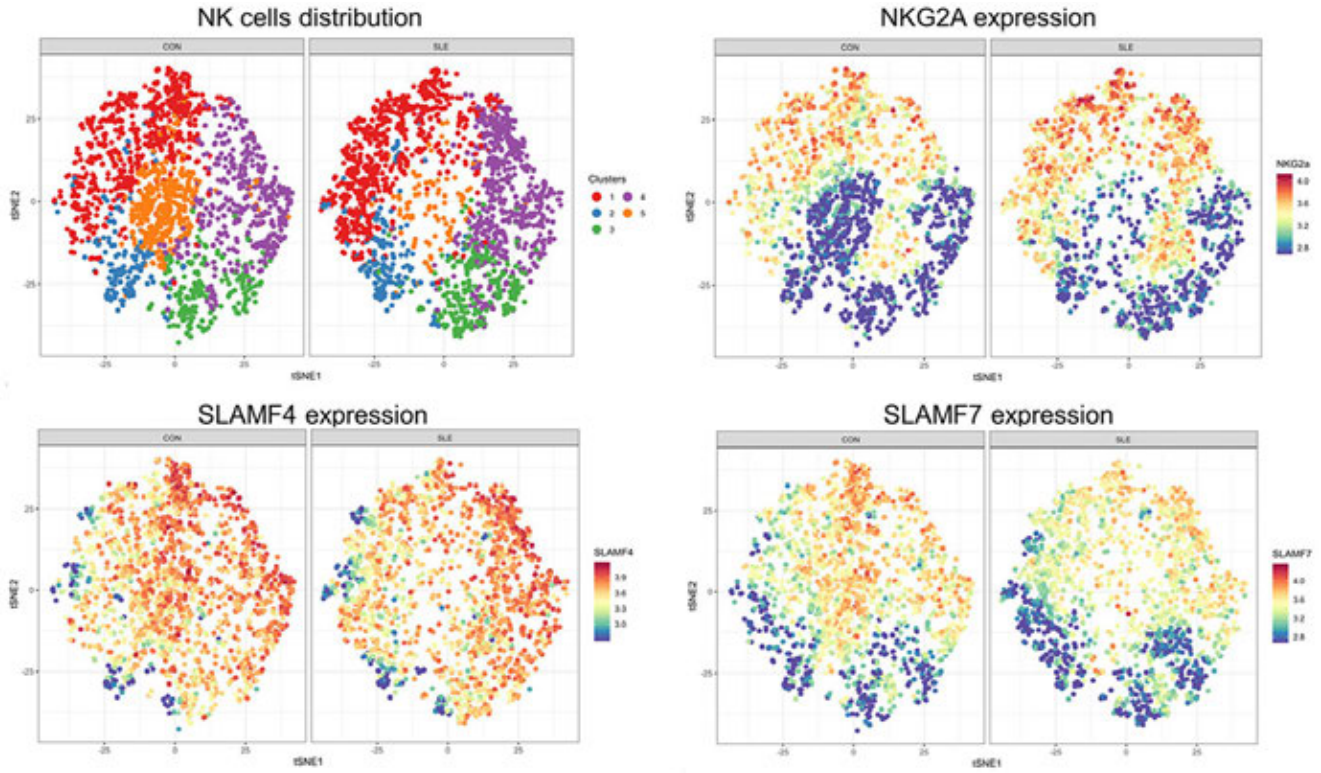
Background/Purpose: Systemic lupus erythematosus (SLE) is a multisystemic autoimmune disease characterized by quantitative and qualitative deficiencies of immune cells. Natural killer (NK) cells are innate lymphoid cells that play an important role in the interaction between innate and adaptive immune systems and contribute to the elimination of infected, damaged and tumor cells. Altered NK function is one of the features that characterizes human SLE and lupus prone mice. Despite recent progress into the understanding of NK cells in SLE, the cellular and molecular mechanisms involved in their dysfunction remain elusive. In this context, we carried out an exhaustive analysis of SLE NK cells.

Methods: Cryopreserved peripheral blood mononuclear cells (PBMC) from 24 SLE patients and gender-, age- and ethnicity matched controls were examined by mass cytometry (CyTOF). A panel of 40 markers comprising the conventional inhibitory and activator molecules was designed to characterize NK cells. Cytolytic enzyme expression, cytokine production and degranulation were examined by flow cytometry. Different type of stimulations were used in the above experiments to activate NK cells: cytokines mix, monoclonal antibodies, phorbol 12-myristate-13-acetate/ionomycin and/or K562 and P815 tumor cells.

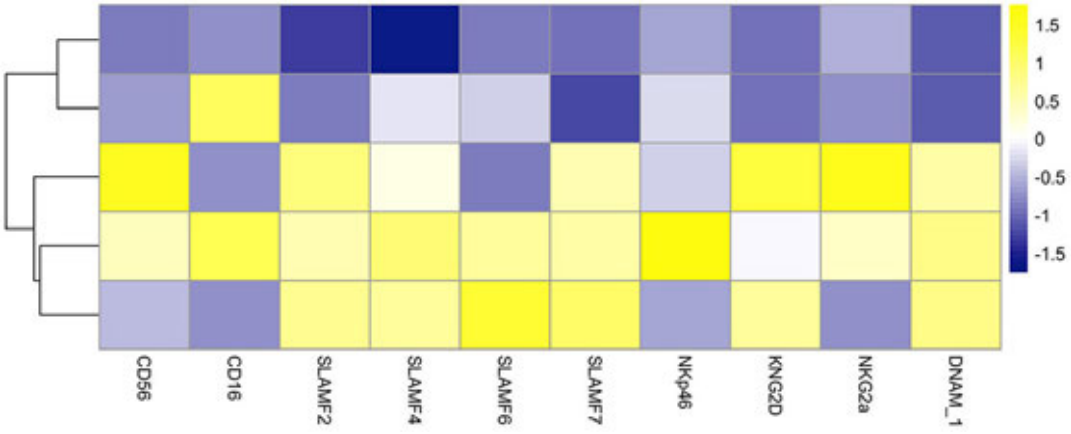
Results: As previously described, our results confirmed a significant decrease in the number and frequency of NK cells in the peripheral blood of SLE patients compared to controls. SLE NK cells exhibited altered functional properties. We observed that cytokine production, cell degranulation and cytotoxic lysis of target tumor cells were reduced. Bioinformatic analysis of mass cytometry data permitted to detect subtle alterations in the expression of phenotypic markers in SLE NK cells discerning them from control NK cells.

This comprehensive analysis emphasized that SLE NK cells display an aberrant expression of receptors belonging to the Signaling Lymphocytic Activation Molecules Family (SLAMF), a group of 8 cell surface receptors, involved in the regulation of immune cells activation. This dysregulation concerns mainly SLAMF1 and SLAMF7, which are respectively positively and negatively regulated on the surface of activated SLE NK cells compared to healthy controls. Further examination of SLAMF1 and SLAMF7 with confocal microscopy show that their distribution is altered on SLE NK cell surface.

Conclusion: Our data confirmed that NK cells isolated from the peripheral blood of SLE patients are dysfunctional, as cytokine production, degranulation and cytotoxic response are compromised. This comprehensive analysis of NK cell surface markers was designed to identify an immune signature characterizing SLE NK cells and permit to demonstrate that SLAMF receptors dysregulation plays a major role in the impairment of SLE NK cells.



t-Distributed Stochastic Neighbor Embedding (t-SNE) plot showing NK cells clustering in controls (CON) and SLE (top left). Examples of colour scale showing the expression of NK surface molecules NKG2A (top right), SLAMF4 (bottom left), SLAMF7 (bottom right).



Heatmap showing NK cells clustering. Surface markers selection is restricted to those that differentiate SLE patients from controls.

Response Gene to Complement -32 Exerts Proinflammatory and Profibrotic Effects in Immune Complex Gediated Glomerulonephritis

Vinh Nguyen,[1] Alexandru Tatomir,[2] Horea Rus,[3] Cinthia Drachenberg,[1] John Papdimitriou,[1] Tudor Badea,[4] Irina Luzina,[5] and **Violeta Rus**[1], [1]Univ of Maryland Sch of Medicine, Baltimore, MD, [2]Univ of Maryland Sch of Medicine, Baltimore, [3]Univ of Maryland Sch of Med and VAMHCS, Baltimore, MD, [4]NIH, NEI, Bethesda, MD, [5]Univ of Maryland Sch of Med AND VAMHCS, Baltimore

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Edmond L. Dubois, MD Memorial Lecture: SLE – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Response Gene to Complement (RGC)-32 is a cell cycle regulator widely expressed in normal tissues, multiple tumors and a variety of cell lines. RGC-32 is induced by TGF-β in fibroblasts, astrocytes and human renal proximal tubular cells and mediates TGF-β dependent profibrotic pathways. In immune cells, RGC-32 is upregulated preferentially in murine and human Th17 cells and promotes their differentiation in vitro and in vivo. Increased expression of IL-17 in kidneys of SLE patients and lupus prone mice is critical for the development of lupus nephritis (LN). We have previously shown that RGC-32 expression is increased in T cells from SLE patients and in tubules and glomerular infiltrating cells in kidney biopsies of patients with LN. To directly assess whether RGC-32 plays a local role in LN downstream of antibody production, we used the nephrotoxic nephritis (NTN) model of immune complex mediated glomerulonephritis to compare parameters of disease severity in RGC-32 deficient and sufficient mice.

Methods: NTN was induced in WT and RGC-32-/- mice by immunization with sheep IgG in Complete Freund's Adjuvant followed by injection of sheep nephrotoxic serum. Proteinuria, blood urea nitrogen and kidney histopathology were determined to assess kidney function and damage. Single cell suspension of kidneys and spleens were analyzed by flow cytometry. Circulating levels and kidney deposition of mouse anti-sheep IgG were quantitated by

ELISA and IF, respectively. Splenic B and T cell responses were characterized by flow cytometry. mRNA expression of IL-17A, CXCL1, CXCL5, collagen I, III, IV and FN was determined by RT-PCR.

Results: RGC-32 mRNA was significantly upregulated in the renal cortex and kidney infiltrating cells of WT mice with NTN compared to controls. RGC-32 KO mice displayed attenuated renal damage as shown by decreased proteinuria and glomerular scores and a trend for decreased blood urea nitrogen. RGC-32 deficiency did not interfere with the induction of NTN as mouse anti-sheep IgG titers, percentage of splenic germinal center B cells, plasma cells, effector $CD4^+$ T cells, Tregs, IL-17A and IFN-g secreting cells did not differ between RGC-32 KO and WT mice. Furthermore, kidney deposition of autologous antibodies and C3 were comparable between the two groups. IL-17 mRNA expression in renal cortex and the proportion of $CD4^+$ $IL17A^+$ cells isolated from kidneys on day 7 after NTN induction were significantly upregulated in WT but not RGC-32 KO mice. RGC-32 KO mice displayed decreased frequency of infiltrating PMN and downregulation of CXCL1 and CXCL5, suggesting a decrease in IL-17 dependent neutrophil recruitement. Collagen I, III , IV and Fibronectin (FN) were significantly lower in RGC-32 KO mice by RT- PCR, while trichrome and FN staining showed decreased interstitial, glomerular and periglomerular fibrosis.

Conclusion: These results suggest that RGC-32 contributes to the pathogenesis of immune complex mediated GN by promoting proinflammatory and profibrotic pathways. These data support further efforts to examine the mechanisms by which RGC-32 modulates these pathways and suggest that RGC-32 is a potential novel therapeutic target in the treatment of LN.

Abstract Number: 2736

Mucosal-associated Invariant T Cells Can Be Therapeutically Targeted in Lupus

Goh Murayama,[1] Asako Chiba,[2] Tomohiro Mizuno,[3] Atsushi Nomura,[2] Taiga Kuga,[4] HIrofumi Amano,[4] Ken Yamaji,[4] Naoto Tamura,[4] and Sachiko Miyake[2], [1]Department of Internal Medicine and Rhumatology, Juntendo University School of Medicine, Tokyo, Japan, [2]Department of Immunology, Juntendo University School of Medicine, Tokyo, Japan, [3]Department of Immunlogy, Juntendo University School of Medicine, Tokyo, Japan, [4]Department of Internal Medicine and Rheumatology, Juntendo University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Edmond L. Dubois, MD Memorial Lecture: SLE – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Mucosal-associated invariant T (MAIT) cells are innate T cells that are restricted by the non-polymorphic MHC-related molecule-1 (MR1) and express a semi-invariant TCRα chain: Vα7.2-Jα33 in humans and Vα19-Jα33 in mice. Previously, we reported that the activated status of MAIT cells correlated with disease activity in patients with systemic lupus erythematosus (SLE), and MAIT cells were accumulated in the kidneys from patients with lupus nephritis. Because MAIT cell deficiency reduced autoantibody production and the disease severity in FcγRIIb$^{-/-}$*Yaa* mice, a spontaneous animal model of lupus, we investigated mechanisms by which MAIT cells enhanced autoimmune response and investigated whether MAIT cells could be therapeutically targeted in lupus.

Methods: FcγRIIb$^{-/-}$*Yaa* mice were crossed to MR1-deficient mice lacking MAIT cells, and the levels of serum anti-dsDNA antibody and urinary albumin were measured. The severity of nephritis was assessed histologically. T and B cell subsets in the spleen and kidneys at 2 months of age were analyzed by using flow cytometry. To evaluate whether inhibition of MAIT cell activation suppress the disease course of lupus, FcγRIIb$^{-/-}$ *Yaa* mice were treated with isobutyryl 6-formyl pterin (i6-FP), a suppressive MR1 ligand, orally three times weekly for 4 weeks starting at 4 weeks of age. B cells from FcγRIIb$^{-/-}$*Yaa* mice were stimulated with lipopolysaccharide in the presence of MAIT cells and autoantibody production was assessed by ELISA.

Results: Activated MAIT cells were infiltrated into the kidneys of FcγRIIb$^{-/-}$*Yaa* mice. Reduced autoantibody production and disease severity by MR1 deficiency was associated with reduced germinal center and T cell responses in FcγRIIb$^{-/-}$*Yaa* mice. The suppression of MAIT cell activation by i6-FP administration decreased serum anti-dsDNA antibody levels and the deposition of IgG and C3 in the glomeruli. i6-FP administration also reduced germinal center responses and activated T cell infiltration into kidneys in FcγRIIb$^{-/-}$*Yaa* mice. MAIT cells directly enhanced autoantibody production by B cells *in vitro*, and this was markedly reduced by blocking CD40L-CD40 or the MR1-TCR pathway.

Conclusion: MAIT cells exacerbated the disease severity of lupus by enhancing autoantibody production and tissue inflammation in FcγRIIb$^{-/-}$ *Yaa* mice. MAIT cells enhanced autoantibody production by B cells dependent on the CD40-CD40L and TCR pathways. Together with our previous findings in patients with SLE, MAIT cells may contribute to lupus pathology and serve as potential novel therapeutic target for autoimmune diseases such as SLE.

HIF-1α and miR-210 Differential and Lineage-specific Expression in Systemic Lupus Erythematosus

Barry Garchow,[1] and Marianthi Kiriakidou[1], [1]Thomas Jefferson University, Philadelphia, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Edmond L. Dubois, MD Memorial Lecture: SLE – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Hypoxia inducible factor 1 is a key transcription factor that regulates the cellular response to oxygen stress. In the adaptive immune system, HIF-1α is mainly expressed by CD4$^+$ T cells in response to TCR ligation and enhanced by exposure to inflammatory cytokines. Transcriptional activation of HIF-responsive genes influence T cell differentiation and function. MicroRNAs are a class of endogenous non-coding RNAs that exert a regulatory influence on almost every aspect of cellular biology. Aberrant expression of many miRNAs have been shown to correlate with poor clinical outcome across a wide spectrum of diseases. MiR-210 is a hypoxia-responsive miRNA transcriptionally regu-

lated by HIF-1α. HIF-1α is also a direct miR-210 target suggesting an important role for miR-210 in regulation of T cell response. Abnormal T cell function is increasingly recognized as a major contributing factor in SLE immunopathology however, the expression and function of HIF-1α and miR-210 in SLE remains largely unexplored.

Methods: Lymphocyte subsets were purified from lupus-prone *Sle123* mice with mild or severe disease and from age-matched WT controls and assayed for miR-210 expression by real-time RT-PCR. Peripheral lymphocytes were purified from human SLE patients and healthy subjects and assayed for HIF-1α, miR-210, RORγt and IL-17 expression by real-time RT-PCR. Mean, error and significance values were determined using an unpaired Student's t test assuming equal variance. *p* values < 0.05 were considered significant. All animal procedures were conducted under an approved IACUC protocol. Human peripheral blood samples were collected with prior written informed consent under an approved IRB protocol.

Results: $CD4^+$, $CD8^+$ and $CD19^+$ lymphocyte subsets were purified from *Sle123* mice with mild or severe disease and assayed for miR-210 expression by real-time PCR. MiR-210 expression was similar across subsets from mice with mild disease compared to age/sex-matched wild-type controls. MiR-210 was 352-fold up-regulated in the $CD4^+$ T cell subset from mice with advanced disease and 2.3-fold and 2.5-fold up-regulated in the $CD8^+$ and $CD19^+$ lineages respectively. $p< 0.001$ ($CD4^+$ and $CD8^+$) and < 0.01 ($CD19^+$), n = 3. We purified peripheral blood mononuclear cells (PBMC) from lupus patients with active disease and quantified HIF-1α and miR-210 expression levels by qRT-PCR. We measured 5.3 HIF-1α and 43.4-fold miR-210 differential-expression in human SLE PBMCs compared to healthy controls ($p < 0.001$ (miR-210) and < 0.05 (HIF-1α), n = 4. RORγt and IL-17 expression associate with HIF-1α and miR-210 activity. We purified peripheral lymphocytes from human lupus patients with active disease and healthy controls and assayed for RORγt and IL-17 expression by qRT-PCR. We measured 4.6-fold RORγ*t* differential-expression and 3.2-fold differential-expression of its transcriptional target IL-17. $p< 0.001$ (RORγt) and < 0.05 (IL-17), n = 4.

Conclusion: Our results suggest that HIF-1α may play an important and previously unrecognized role in the pathobiology of SLE. HIF-1α and HIF-1a regulated pathways may represent a novel and productive direction for future etiological studies in lupus.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

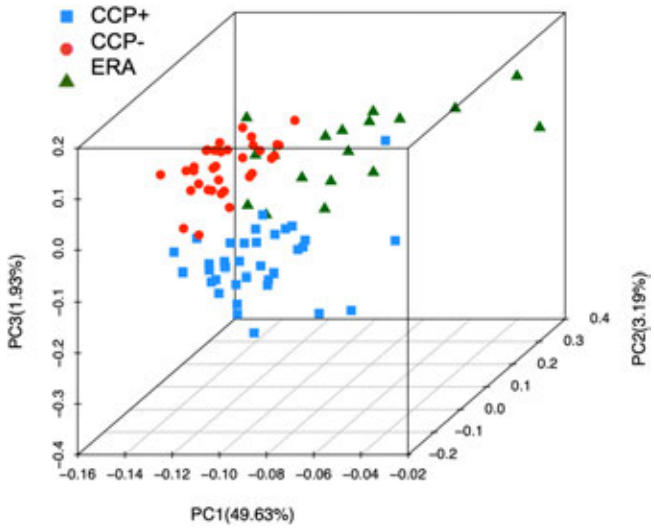

Figure 1. PCA shows the separation of CCP+, CCP- and ERA patients in memory T cells based on DMLs in confirmatory cohort.

Background/Purpose: The "Targeting Immune Responses for Prevention of RA" (TIP-RA) collaboration studies individuals at high risk for developing RA because of serum anti-citrullinated protein antibody positivity in absence of arthritis, and is focused on defining how they transition from at-risk to classifiable disease. One potential mechanism is through alterations in epigenetics patterns in adaptive immune cells. Previous studies showed that DNA methylation patterns of early RA (ERA) synoviocytes differ from long-standing RA, suggesting that abnormal methylation occurs early in synovium and evolves over time. To extend these observations, we performed a cross-sectional analysis in TIP-RA of DNA methylation signatures in peripheral blood cells in ERA, at-risk anti-CCP3+ individuals and demographically matched CCP- controls.

Methods: Genomic DNA was isolated from two independent cohorts of CCP- (cohorts 1 and 2, respectively: B cell: n = 17/34; memory T cell: n = 21/34; and naïve T cell: n = 21/33), CCP3+ (B cell: n = 18/37; memory T cell: n = 20/36; and naïve T cell: n = 20/35), and CCP3+ ERA (B cell: n = 4/18; memory T cell: n = 5/18; and naïve T cell: n = 5/18) after separating PBMCs using antibodies and magnetic beads. Methylation was measured by Illumina Infinium MethylationEPIC chip. Differentially methylated loci (DMLs) were identified using Welch's *t*-test and mapped to gene promoter regions to define DM genes (DMGs). Principal component analysis (PCA) was used to represent relationship among groups. Pathway analysis was applied by Reactome.

Results: For the initial cohort, 1494, 1097 and 1330 DMLs were identified among CCP+, CCP- and ERA in B cells, memory T cells and naïve T cells, respectively. For the confirmatory cohort, 523, 793 and 548 DMLs were found in corresponding cell populations. The DML overlap between the 2 cohorts was highly significant (p= 2.48E-77). The DMLs were combined for both groups and corresponded to 411, 412, and 351 DMGs in B cells, memory T cells and naïve T cells. Of these, we found 246, 198 and 195 DMGs between CCP3+ and ERA in each peripheral blood cell population, respectively. PCA showed separation of CCP+, CCP- and ERA in each of the three blood cell types by DMLs (Fig. 1). DMGs were mapped to biological pathways to identify DM pathways. Although most were not significant, there were several highly significant differences comparing CCP+, ERA and CCP- in memory T cells involving pathways, including "Interferon gamma signaling" (*FDR* 7.48E-14), "PD-1 signaling" (*FDR* 8.71E-10), "Translocation of ZAP-70 to Immunological synapse" (*FDR* 4.75E-10), and "Phosphorylation of CD3 and TCR zeta chains" (*FDR* 8.71E-10).

Conclusion: We identified reproducible methylation signatures of CCP-, CCP+, and ERA in peripheral blood B cells, memory T cells and naïve T cells in initial and confirmatory cohorts. The methylome of ERA also demonstrated a distinctive pattern from CCP+, indicating that progression to RA is accompanied by epigenetic remodeling, especially in

T cell signaling and interferon responses. These signatures identify critical pathways in CCP positivity and classifiable RA and could provide the basis of novel interventions to prevent disease.

Figure 1. PCA shows the separation of CCP+, CCP- and ERA patients in memory T cells based on DMLs in confirmatory cohort.

Skin Disease Activity and Autoantibody Phenotype Are Major Determinants of Blood Interferon Signatures in Dermatomyositis

Mika Tabata,[1] Kavita Sarin,[2] Karen Page,[3] Christine Huard,[3] Shanrong Zhao,[3] Donald Bennett,[3] Jillian Johnson,[3] Kristen Johnson,[3] and David Fiorentino[2], [1]Stanford University School of Medicine, Stanford, CA, [2]Department of Dermatology, Stanford University School of Medicine, Redwood City, CA, [3]Pfizer, Boston

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Genetics, Genomics & Proteomics

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

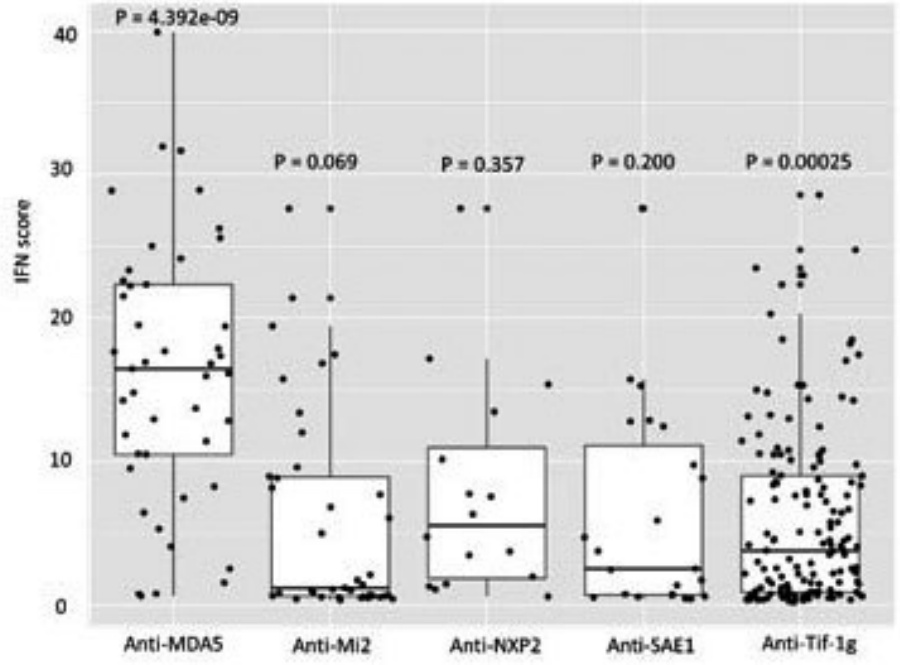

Figure 1. IFN scores by antibody subtype

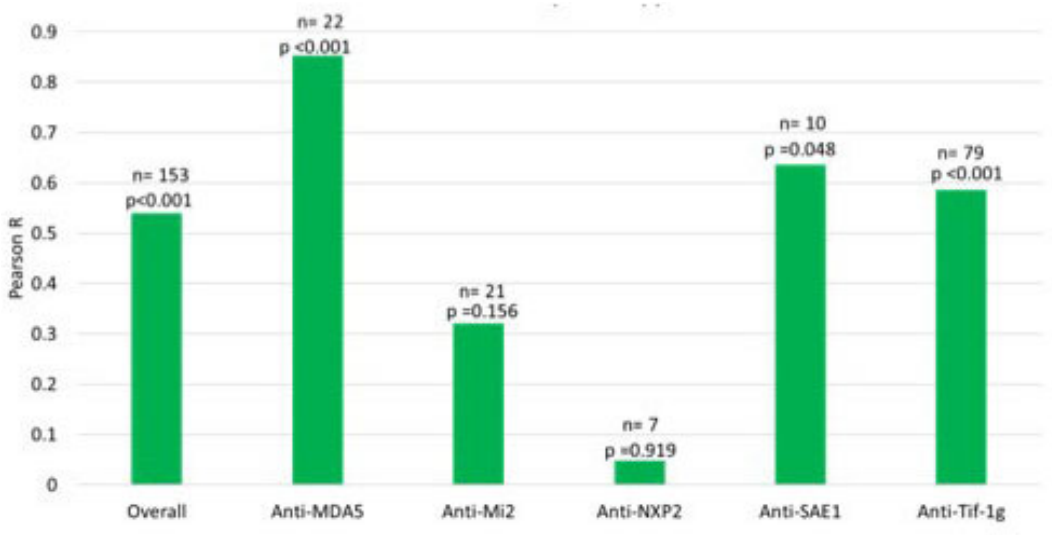

Figure 2. Correlations of longitudinal IFN score with CDASI across antibody subtype

Background/Purpose: Interferon (IFN) signaling is upregulated in dermatomyositis (DM) and thought to play a role in pathogenesis. An IFN gene signature in peripheral blood of DM patients correlates with skin disease and may predict disease activity. However, studies have not analyzed how IFN signaling differs across DM subtypes or how it is influenced by multiple organ system involvement. Autoantibodies in DM distinguish subsets of disease with unique clinical features and outcomes. We hypothesized that strength and clinical utility of the DM blood IFN signature depends on autoantibody subtype and other clinical factors. Utilizing a clinically phenotyped DM cohort, we sought to understand the utility of blood IFN gene signature as markers of skin disease severity across patients differing in autoantibody subtype, muscle disease, interstitial lung disease (ILD), and cancer status.

Methods: Stranded RNA sequencing was performed on 377 whole blood samples derived from 205 DM patients seen at the Stanford Outpatient Clinic. The least absolute shrinkage and selection operator (LASSO) method for linear regression selected optimal gene signatures and errors were calculated in an independent dataset. An IFN score was calculated by averaging the healthy-normalized FPKM values for a selection of genes. Skin disease activity was quantitated using the Cutaneous Dermatomyositis Activity and Severity Index activity score (CDASI-a). Linear regression and Pearson correlation analyzed the association between longitudinal CDASI-a and IFN scores, adjusted and stratified across antibody subtype, ILD, cancer, and muscle disease status.

Results: We found that the blood IFN score is significantly elevated in the anti-MDA5 subtype compared to other subtypes (average 16.12, $p < 0.001$) [Figure 1]. Change in CDASI-a correlates most strongly with change in IFN score in the anti-MDA5 ($R=0.85$, $p< 0.001$) subtype, followed by anti-Tif-1g ($R=0.59$, $p< 0.001$) and anti-SAE1 ($R=0.64$, $p =0.048$) [Figure 2]. Conversely, the correlation is weak in anti-Mi2 and anti-NXP2 subtypes. These patterns persist after adjustment for ILD, muscle disease, cancer, and medications. The correlation is stronger when baseline IFN score is greater than 1.5 ($R =0.59$, $p < 0.001$). The correlation between IFN score and CDASI-a score is weaker in patients with active muscle disease and stronger in patients with active lung disease but is unaffected by cancer status.

Conclusion: Using a large prospective dataset of DM patients, we demonstrate that IFN-driven gene expression as an activity measure in DM is related to specific autoantibody subtypes. This relationship is also impacted by clinical factors such as ILD and muscle disease status. These results suggest that careful attention to antibody status and clinical factors could help inform interpretation of IFN biomarker data in future clinical trials in DM.

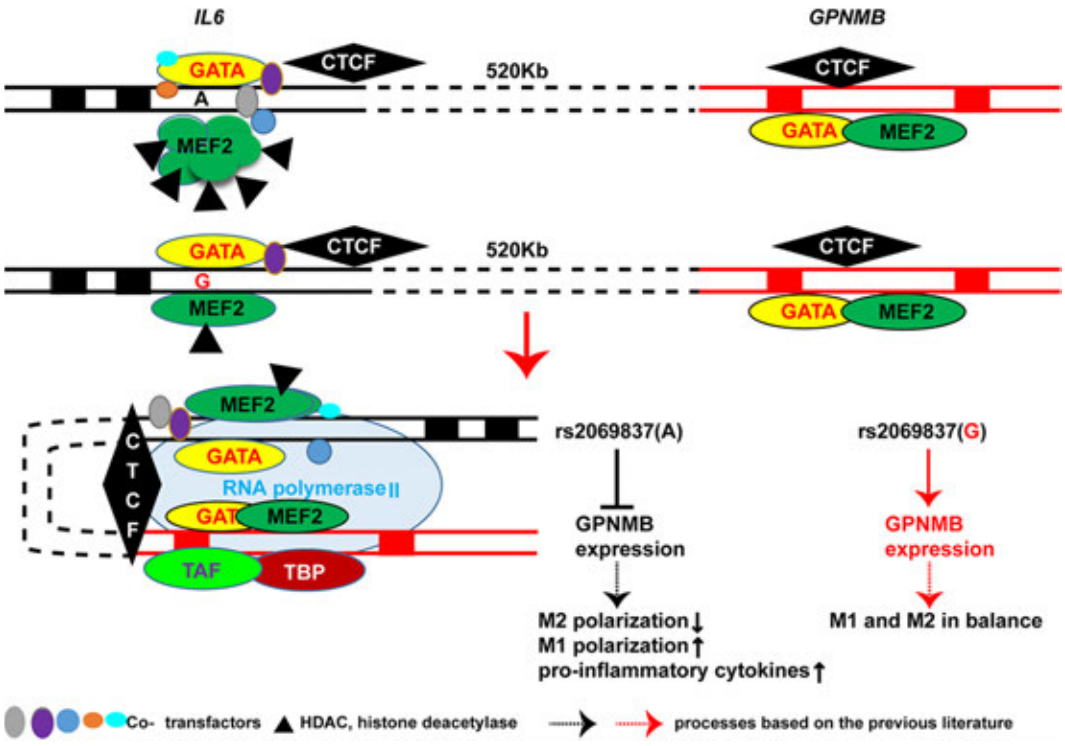
Takayasu Arteritis Associated Risk Locus in IL6 Represses the Anti-inflammatory Gene GPNMB Through Chromatin Looping and Recruiting MEF2-HDAC Complex

Xiufang Kong,[1] and **Amr Sawalha** [2], [1]University of Michigan & Fudan University, Ann Arbor, MI[2]University of Pittsburgh & University of Michigan, Pittsburgh, PA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Previous work has revealed a genetic association between Takayasu arteritis and a non-coding genetic variant in an enhancer region within *IL6* (rs2069837 A/G). The risk allele in this variant (allele A) has a protective effect against chronic viral infection and cancer. The goal of this study was the characterize the functional consequences of this disease-associated risk locus.

Methods: A combination of experimental and bioinformatics tools were used to mechanistically understand the effects of the disease-associated genetic locus in *IL6*. These included electrophoretic mobility shift assay (EMSA), DNA



A proposed model for the regulatory mechanism of rs2069837 on the expression of GPNMB. The Takayasu arteritis risk allele A at this SNP preferentially recruits MEF2 and thereby HDAC proteins compared to the G allele resulting in a repressive effect by weakening the enhancer function of this locus. CTCF binding downstream of this SNP mediates the interaction between this locus to the regulatory locus in GPNMB, where a CTCF binding site also exists. The differential binding of MEF2-HADAC complex between A and G results in differential expression of GPNMB, with inhibited expression in the presence of risk allele A. Inhibiting GPNMB suppresses M2 macrophage polarization and enhances of M1 polarization and overexpression of pro-inflammatory cytokines.

affinity precipitation assays followed by mass spectrometry and western blotting, luciferase reporter assays, and chromosome conformation capture (3C) to identify chromatin looping in the *IL6* locus. Both cell lines and peripheral blood primary monocyte-derived macrophages were used.

Results: We identified the monocyte/macrophage anti-inflammatory gene *GPNMB*, ~520kb from *IL6*, as a target gene regulated by rs2069837. We revealed preferential recruitment of myocyte enhancer factor 2-histone deacetylase (MEF2-HDAC) repressive complex to the Takayasu arteritis risk allele. Further, we demonstrated suppression of GPNMB expression in monocyte-derived macrophages from healthy individuals with the AA compared to AG genotype, which was reversed by histone deacetylase inhibition. Our data show that the risk allele in rs2069837 represses the expression of GPNMB by recruiting MEF2-HDAC complex, enabled through a long-range intra-chromatin looping. Suppression of this anti-inflammatory gene might mediate increased susceptibility in Takayasu arteritis and enhance protective immune responses in chronic infection and cancer.

Conclusion: Takayasu arteritis disease risk locus in *IL6* might increase disease susceptibility by suppression of the anti-inflammatory gene *GPNMB*, which is located about 520kb away, through chromatin looping and recruitment of MEF2-HDAC epigenetic repressive complex. Our data highlight long-range chromatin interactions in functional genomic and epigenomic studies in autoimmunity.

Integration of Single Cells from Inflammatory Disease Tissues Reveals Common and Unique Pathogenic Cell States

Fan Zhang,[1] Joseph Mears,[1] ilya Korsunsky,[1] Kevin Wei,[2] Anna Helena Jonsson,[2] Deepak Rao,[1] Edy Kim,[3] Laura Donlin,[4] Jill Buyon,[5] Michelle Petri,[6] Chaim Putterman,[7] Thomas Tuschl,[8] Nir Hacohen,[9] Betty Diamond,[10] Michael Brenner,[11] and Soumya Raychaudhuri[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [3]Brigham and Women's Hospital, Boton, MA, [4]Hospital For Special Surgery, New York, NY, [5]New York University School of Medicine, New York, NY, [6]Johns Hopkins University School of Medicine, Baltimore, MD, [7]Albert Einstein College of Medicine, New York, NY, [8]Rockefeller Research Laboratories, New York, [9]Broad Institute, Cambridge, [10]Feinstein Institutes for Medical Research, Manhasset, [11]Brigham and Women's Hospital:, Boston

Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Different autoimmune diseases can co-exist in an individual and share similar genetic associations, autoimmune signaling pathways, and clinical manifestations. However, autoimmune diseases present varied cellular heterogeneities and may be distinguished by their primary target organs or tissues. The immune mechanisms that are shared between similar autoimmune diseases remain poorly understood due to limited access to affected human tissues and computational scalability. Recently, high resolution single-cell RNA-seq profiles have provided the opportunity for study of the contribution of diverse cell populations to disease pathogenesis. This advance has enabled unbiased comparison of disease across affected tissues with the goal of understanding autoimmune similarities.

Methods: We have analyzed and integrated ~80,000 cells from 176 donors from publicly available single-cell RNA-seq datasets generated from rheumatoid arthritis (RA) and osteoarthritis (OA) synovium[1], pulmonary fibrosis and healthy lung, systemic lupus erythematosus (SLE) and healthy kidney and skin[2,3], inflammatory bowel disease (IBD)

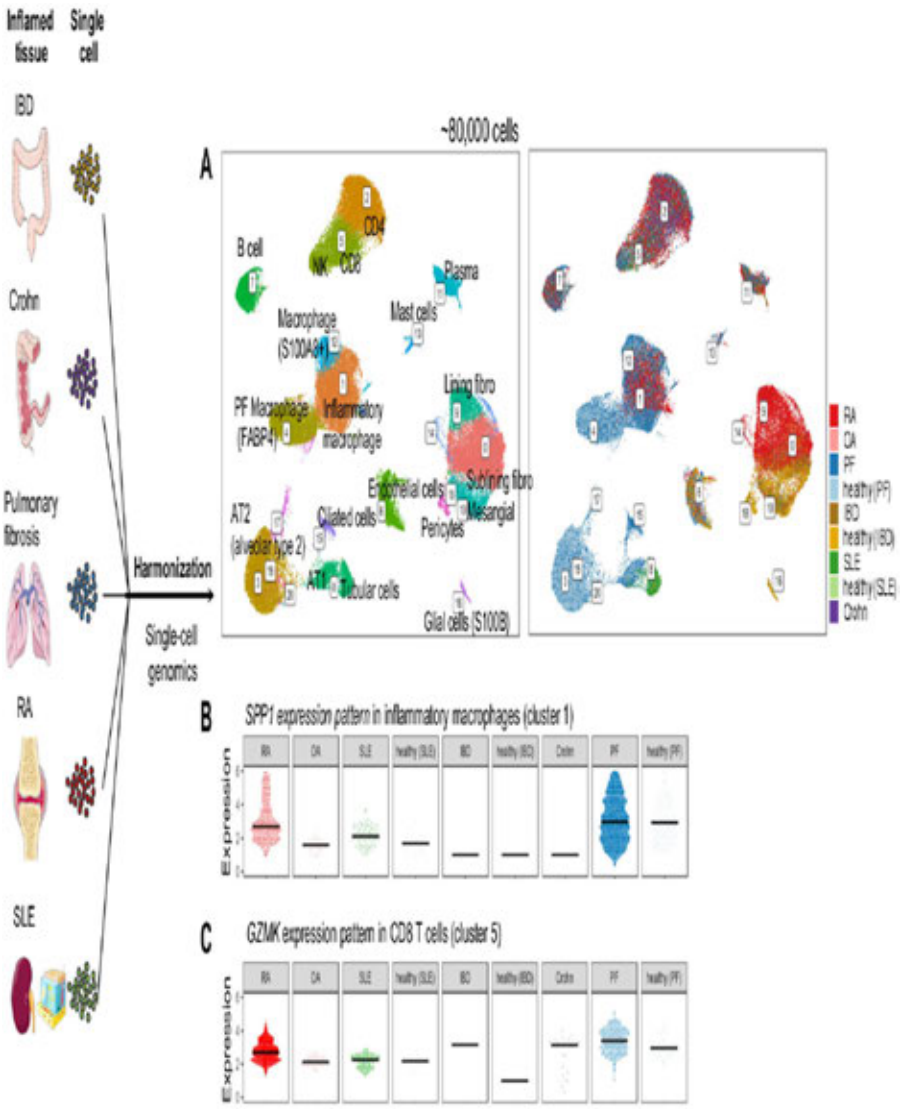

Figure 1. Integration of ~80,000 cells from 176 donors reveal common and unique cell populations from RA and OA synovium, pulmonary fibrosis and healthy lung, SLE and healthy kidney and skin, IBD and healthy colon, and Crohn. **A**. Shared and unique cell states across multiple tissues. **B**. SPP1 expression pattern for each disease and tissue source in inflammatory macrophages. **C**. GZMK expression pattern for each disease and tissue source in CD8 T cells.

and healthy colon, and Crohn intestinal mucosal biopsies. We use a robust integrative strategy[4] to cluster and project all the cells into two dimensional-space by correcting technical batch effect across tissue, donor, and single-cell platform (10X Genomics, Celseq2, Dropseq, Fluidigm, and Smartseq).

Results: We identify 21 diverse cell type populations across multiple tissue sources (Figure 1A). In the myeloid cell population, we observed four distinct subsets including *VSIG4*+ M2-like macrophages, *S100A8*+ macrophages, *SPP1*+ *MMP9*+ inflammatory macrophages, and dendritic cells (DC). The *SPP1*+ *MMP9*+ inflammatory macrophage population with high expression of matrix metalloproteinases genes is co-localized between macrophages in RA synovium, SLE kidney, and alveolar from pulmonary fibrosis lung, and is absent in healthy lung tissue (Figure 1B). For CD8 T cells and nature killer cells, we identified a shared transcriptional gradient of granzyme-expressing cytotoxic effectors between RA synovium, SLE kidney, and fibrotic lung. Interestingly, the *GzmK*+ CD8 T cell population is absent in the healthy lung (Figure 1C). The patterns of cytotoxic effector states may suggest similarities between the

primary sites of inflamed RA and inflamed fibrotic lung, including potential common active pathways. In the stromal cell compartment, we observed distinct populations across different diseases and tissues, including fibroblasts, pericytes, mesangial, and tubular cells.

Conclusion: We demonstrate that integrative analyses between disease tissues by single-cell transcriptomics is capable to discovering shared and unique disease-specific gene expression modules and cell states, and may help predict potential therapeutic targets for inflammatory and fibrotic diseases.

Toward a Liquid Biopsy for Lupus Nephritis: Urine Proteomic Analysis of SLE Identifies Inflammatory and Macrophage Signatures

Andrea Fava,[1] Yuji Zhang,[2] Jill Buyon,[3] H. Michael Belmont,[4] Peter Izmirly,[5] Chandra Mohan,[6] Ting Zhang,[7] The Accelerating Medicines Partnership,[8] and Michelle Petri[9], [1]Johns Hopkins University, Baltimore,[2]University of Maryland, Baltimore,[3]NYU School of Medicine, New York, [4]New York University School of Medicine, Ney York, [5]New York University School of Medicine, New York, [6]University of Houston, Houston, [7]Biomedical Engineering, University of Houston, Houston, TX, [8]Multiple Organizations, USA, [9]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Lupus nephritis (LN) complicates up to 60% of patients with systemic lupus erythematosus (SLE) and carries a high morbidity and mortality. The definitive diagnosis is based on kidney biopsy. This is invasive and not always readily available, thus delaying treatment. Sometimes multiple biopsies are required over the course of the disease. Importantly, while renal pathology is accurate at describing the morphology of renal disease, the underlying biology and molecular pathways are not thoroughly assessed. Urine proteomics is a non-invasive strategy that may provide insights regarding ongoing renal disease.

Methods: One thousand proteins were quantified (RayBiotech Kiloplex assay) on a total of 112 longitudinal urine samples from 32 SLE patients with active LN and 7 healthy controls (HC) enrolled in the Accelerating Medicines Partnership (AMP). All patients underwent treatment as directed by their own physicians. Differentially excreted proteins at baseline (SLE vs HC, proliferative vs membranous LN, responders vs non responders) were identified using a linear

Figure 1. Differentially excreted urine proteins in lupus nephritis.

model with moderated t statistic. Response to treatment was defined based on proteinuria at 1 year as "complete" (< 0.5g/24h) or "partial" (50% reduction but >0.5/24h). In the longitudinal analysis, a mixed model was employed to identify markers associated with proteinuria. Pathway enrichment analysis was performed using the genes coding for the differentially excreted analytes using Ingenuity Pathway Analysis (IPA) and other publicly available pathway libraries.

Results: There were 186 proteins increased in SLE patients (Fig. 1). The most enriched pathway was TNFa ($p < 0.001$). We found 74 differentially excreted proteins comparing proliferative and pure membranous LN. CD4, MCP-1, MIP-1a, RANTES, IL-16, and IL-7, markers involved in CD4 T cell and monocyte biology, were enriched in proliferative disease. A few targets were exclusively identified in either class (i.e. CD4 in proliferative nephritis). We used a longitudinal model to identify specific urine proteins associated with worse proteinuria as a marker of severity. Proteinu-

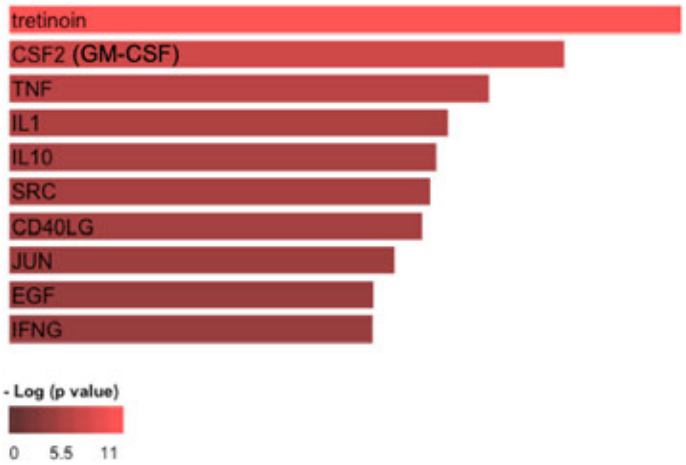

Figure 2. Top canonical pathways associated with proteinuria.

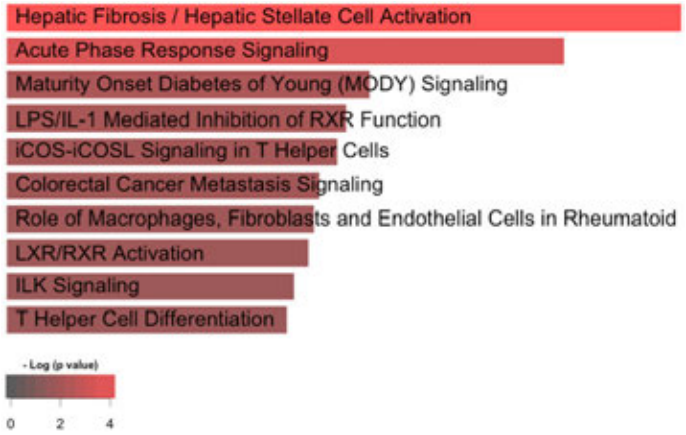

Figure 3. Top upstream regulators: responders vs non-responders.

ria was associated with 105 markers (FDR < 0.05), the strongest association being CD163 (p = 10-9), a phagocyte marker. IPA implicated several pathways involving fibrosis, acute phase response, LPS/IL1, RXR, ICOS signaling and macrophage/fibroblasts (Fig. 2). Next, we identified 27 differentially excreted proteins in non-responders. IPA revealed that tretinoin, GM-CSF, TNF, and IL1 were among the top upstream regulators (Fig. 3).

Conclusion: There is an inflammatory signature in the urine of patients with LN implicating monocyte and TNFa pathways. These signatures are associated with proliferative disease, worse proteinuria, and non-response to treatment. Of note, TNFa is involved in LN and has therapeutic potential. In phase 1 of AMP, monocytes were the main urine cell type identified by singe cell RNA sequencing in patients with LN. These results suggest that urine proteomics might identify and infer active pathological mechanisms in LN, paving the way for a more personalized approach to treatment. Further work in Phase 2 of AMP is being pursued to validate and extend these findings.

Abstract Number: 2743

Characterizing the Epigenomic Landscape of Psoriasis Patients Destined to Develop Psoriatic Arthritis

Remy Pollock,[1] Rohan Machhar,[1] Vinod Chandran,[2] and Dafna Gladman[3], [1]Krembil Research Institute, University Health Network, Toronto, Canada, [2]University Health Network, University of Toronto, Toronto, Canada, [3]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Genetics, Genomics & Proteomics
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Approximately 30% of psoriasis patients develop psoriatic arthritis (PsA), an inflammatory musculoskeletal disease, usually after psoriasis onset. A large proportion of individuals with PsA remain undiagnosed. An understanding of how the epigenome changes during the transition to PsA could yield predictive biomarkers and facilitate PsA diagnosis. We hypothesized that DNA methylation changes occur early in PsA pathogenesis, prior to overt clinical symptoms, and can be used as biomarkers for disease prediction. The specific aim was to characterize the epigenomic landscape of psoriasis patients who later developed PsA (converters) and compare it to psoriasis patients who did not develop PsA (non-converters).

Methods: We performedan epigenome-wide comparison of DNA methylation in baseline whole blood samples from psoriasis converters (n=58) and non-converters (n=59) from a longitudinal cohort. Post-conversion samples taken at the time of PsA diagnosis were available on 23 of the converters. Patients were matched for age, sex, psoriasis duration, and duration of follow-up. No patients were taking biologic agents. DNA was bisulfite converted was analyzed on Human MethylationEPIC BeadChips using the Bioconductor package ChAMP. Cell type heterogeneity was corrected using RefbaseEWAS. Differentially methylated probes (DMPs) and regions (DMRs) were identified using limma and DMRcate. The FEM package was used to infer differentially methylated gene modules (subnetworks) within a protein-protein interaction (PPI) network.

Results: Converter baseline samples were collected a median of 4.2 (interquartile range 1.9-6.3) years prior to the onset of PsA, while non-converters samples were collected a median of 4.3 (1.2-7.3) years prior to the most recent clinic visit. Between converters and non-converters, there were 129 DMPs and 15 DMRs containing at least 4 significant CpGs (FDR< 0.05). DMRs were identified in FBXO27 (fold change [FC]=0.06, FDR=2.2x10-24), a ubiquitin ligase involved in lysosomal degradation, RCAN1 (FC=0.05, FDR=4.2x10-12), a protein involved in bone homeostasis, and PMAIP1 (FC=0.04, FDR=6.0x10-12), which encodes the NOXA protein involved in mediating apoptosis of activated B cells. Differentially methylated promoters mapped to PPI subnetworks involved in canonical toll-like receptor/NFKB signaling (MYD88, TICAM1, TLR6, TOLLIP), alternative NF-KB signaling (MYD88, TICAM1, TNFRSF13C, TNFSF13B), and MAPK signaling (p38, MEF2D, DUSP10, PTPN7, STK39, MKNK2). Between non-converters and post-conversion samples, 25 DMPs and 3 DMRs in genes such as SERPINF1 (FC=-0.04, FDR=1.13x10-18) was found. Significant PPI subnetworks included notch signaling (APH1A, MAML3, NOTCH4, PSEN1) and ephrin signaling (EFNA1, EFNA2, EPHA7, EPHA2).

Conclusion: Changes in individual CpGs, DMRs, and inflammatory pathways were detected in baseline samples of psoriasis converters compared to non-converters and between non-converters and post-conversion samples. These preliminary data support our hypothesis that DNA methylation changes occur early in PsA pathogenesis and can potentially serve as prognostic biomarkers of future onset of arthritis in psoriasis patients.

Altered Expression of CD52 Facilitates Adhesion of Circulating CD14$^+$ Monocytes in Systemic Sclerosis

Michal Rudnik,[1] Mara Stellato,[1] Filip Rolski,[2] Przemyslaw Blyszczuk,[3] Karin Klingel,[4] Joerg Henes,[5] Carol Feghali-Bostwick,[6] Oliver Distler,[7] and Gabriela Kania[3], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [2]Department of Clinical Immunology, Jagiellonian University Medical College, Krakow, Poland, [3]Centre of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [4]Institute for Pathology and Neuropathology, University Hospital Tuebingen, Tuebingen, Germany, [5]University Hospital Tuebingen, Department of Internal Medicine II (Oncology, Haematology, Immunology and Rheumatology), Tuebingen, Germany, [6]Division of Rheumatology & Immunology, Medical University of South Carolina, Charlston, SC, [7]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorder – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Infiltration of inflammatory cells, including monocytes, into the organs is a major process leading to fibrosis, remodelling and organ dysfunction in systemic sclerosis (SSc). Adhesion is a key process for cell infiltration. However, its pathomechanisms in SSc remain elusive.

CD52 protein is highly expressed on CD4$^+$ T-cells and plays an important role in the modulation of T-cell receptor signalling. Nevertheless, the function of this protein on monocytes is not completely understood.

We aimed to investigate the process of monocyte adhesion in SSc with a special focus on the influence of CD52 expression.

Methods: Biopsies from the heart, lungs and skin of SSc patients (n=11, 7, 7, respectively) and healthy controls (HC) (n=10, 7, 9, respectively) were analysed by immunohistochemistry for the presence of CD14$^+$ cells. RNAseq of CD14$^+$ blood monocytes of lcSSc (n=5, age=54.4±6.7), dcSSc patients (n=5, age=51.8±7.2) and age- and sex-matched HC (n=5, age=50.8±9.7) was performed. Differentially expressed genes were computed using DeSEQ2 algorithm. Gene ontology and pathway analysis were performed using Metacore software and ShinyApp. Expression of adhesion molecules was confirmed by flow cytometry (HC n=16, SSc n =76). Adhesion of CD14$^+$ monocytes to ICAM1 and TNFα-stimulated endothelial cells was checked using the 96-well plate adhesion assay (HC n=12, SSc n=40). CD52 regulation in CD14$^+$ monocytes from HC (n=4) was analysed on mRNA level upon stimulation with LPS, IFNγ, IL-4 and IL-13. Adhesion under the physiological shear flow of THP-1 cell lines with overexpression and silencing of CD52 was investigated (n=4).

Results: Immunohistochemistry confirmed higher infiltration of CD14+ cells in the heart ($p< 0.01$), lung ($p< 0.05$) and skin ($p< 0.001$) of SSc patients. 1440 differentially expressed genes were detected between dcSSc vs HC and 225 between lcSSc and HC ($p\leq0.01$; log2 ratio≥0.5). Pathway analysis revealed significant alterations in adhesion and chemotaxis pathways. Flow cytometry confirmed upregulation of adhesion molecules CD11b ($p< 0.01$) and CD18 ($p< 0.05$). In contrast, expression of CD52 was downregulated in SSc patients ($p< 0.05$). SSc CD14$^+$ monocytes exhibited

increased adhesion both to ICAM1-coated plates ($p< 0.01$) and to TNFα-stimulated endothelial cells ($p< 0.05$). CD52 mRNA was increased in a dose-dependent manner after IL-4 and IL-13 stimulation and decreased after LPS and IFNγ stimulation ($p< 0.05$). Overexpression of CD52 in THP-1 monocytes decreased adhesion to TNFα-stimulated endothelial cells ($p< 0.01$) under the shear flow conditions. Accordingly, silencing of CD52 increased adhesion of THP-1 monocytes ($p< 0.01$).

Conclusion: Here we pointed to an increased adhesion of peripheral blood $CD14^+$ monocytes to ICAM1 and endothelial cells in SSc. Our results suggest the primary activation of monocytes in peripheral blood, which may translate into higher organ infiltration in SSc patients. Finally yet importantly, we characterised a novel function of the CD52 molecule on monocytes and its possible contribution during the course of the disease.

Iguratimod Treated Scleroderma with Interrupted Egr1/TGF-β Loop

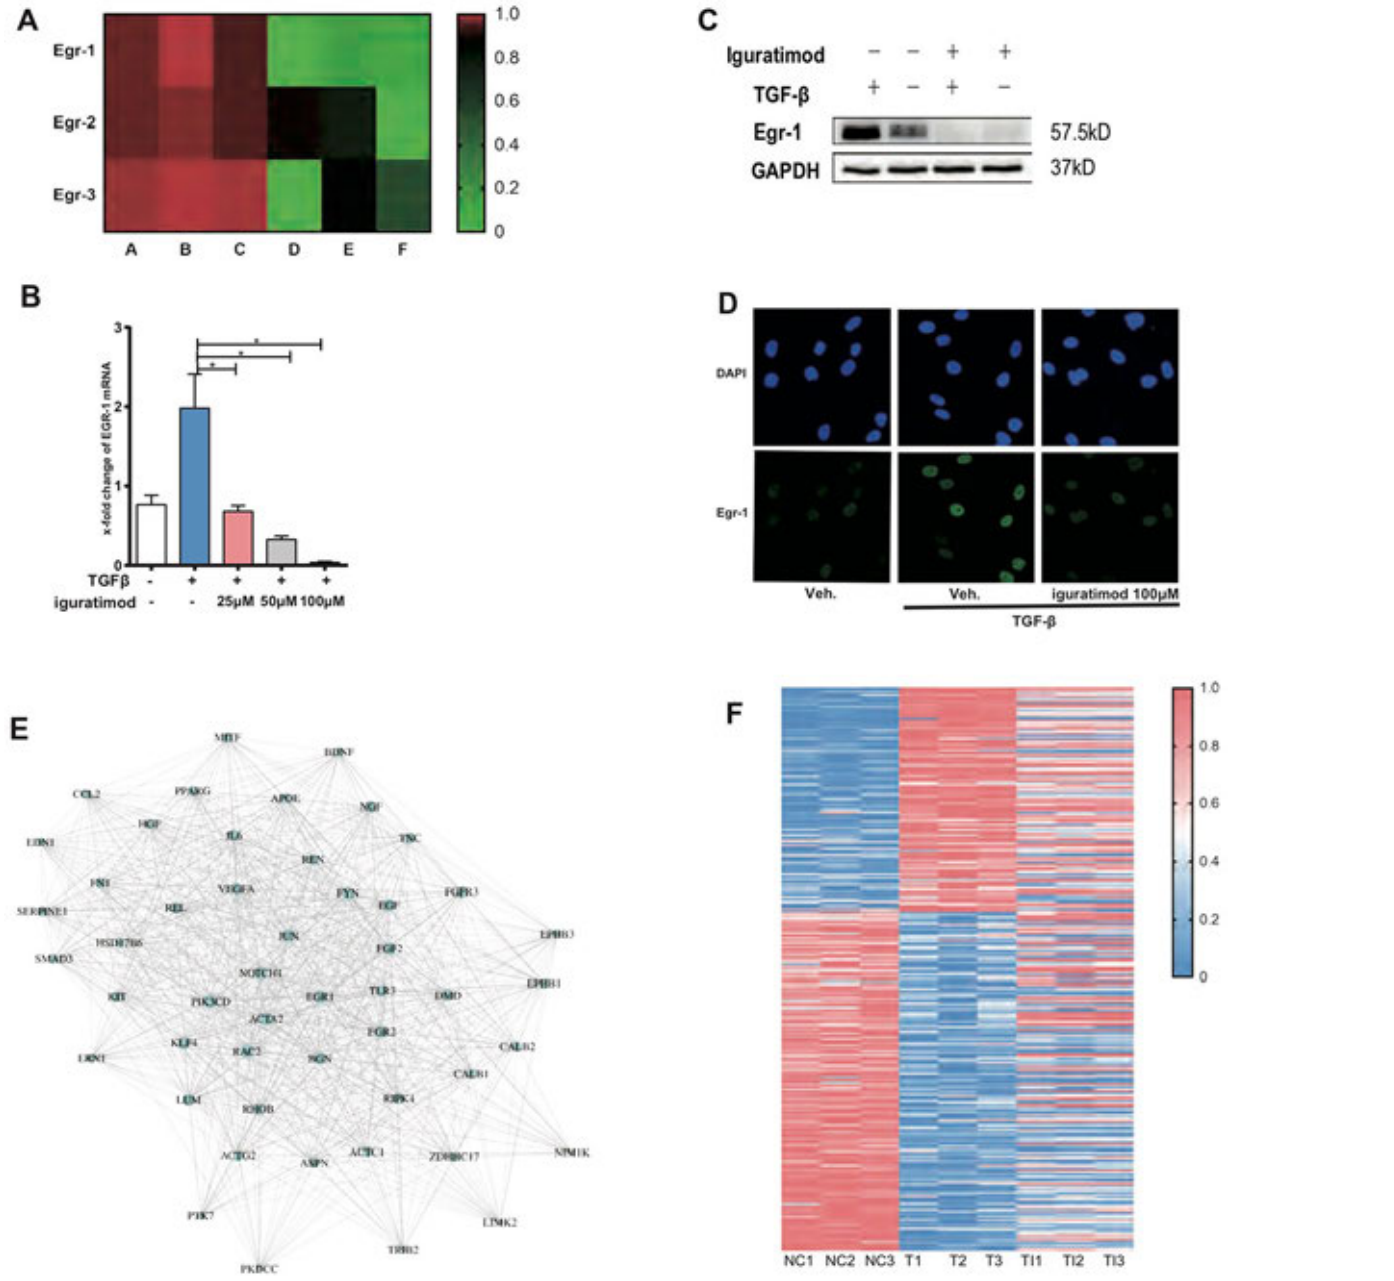
Qingran Yan,[1] Lichong Shen,[1] Xiaoxiang Chen,[1] and Liangjing Lu[1], [1]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of medicine, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorder – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Iguratimod is a novel disease modifying anti-rheumatic drug that has been approved for treating rheumatoid arthritis in East Asia. Transcription factor early growth response 1 (*Egr1*) is one the most down-regulated genes in with iguratimod treatment. Egr1 forms a positive feedback loop with TGFβ and is overexpressed in lesional skin from systemic sclerosis (SSc) patients. This study is aim to investigate the anti-fibrotic effect of iguratimod in scleroderma models and patient skin grafts.

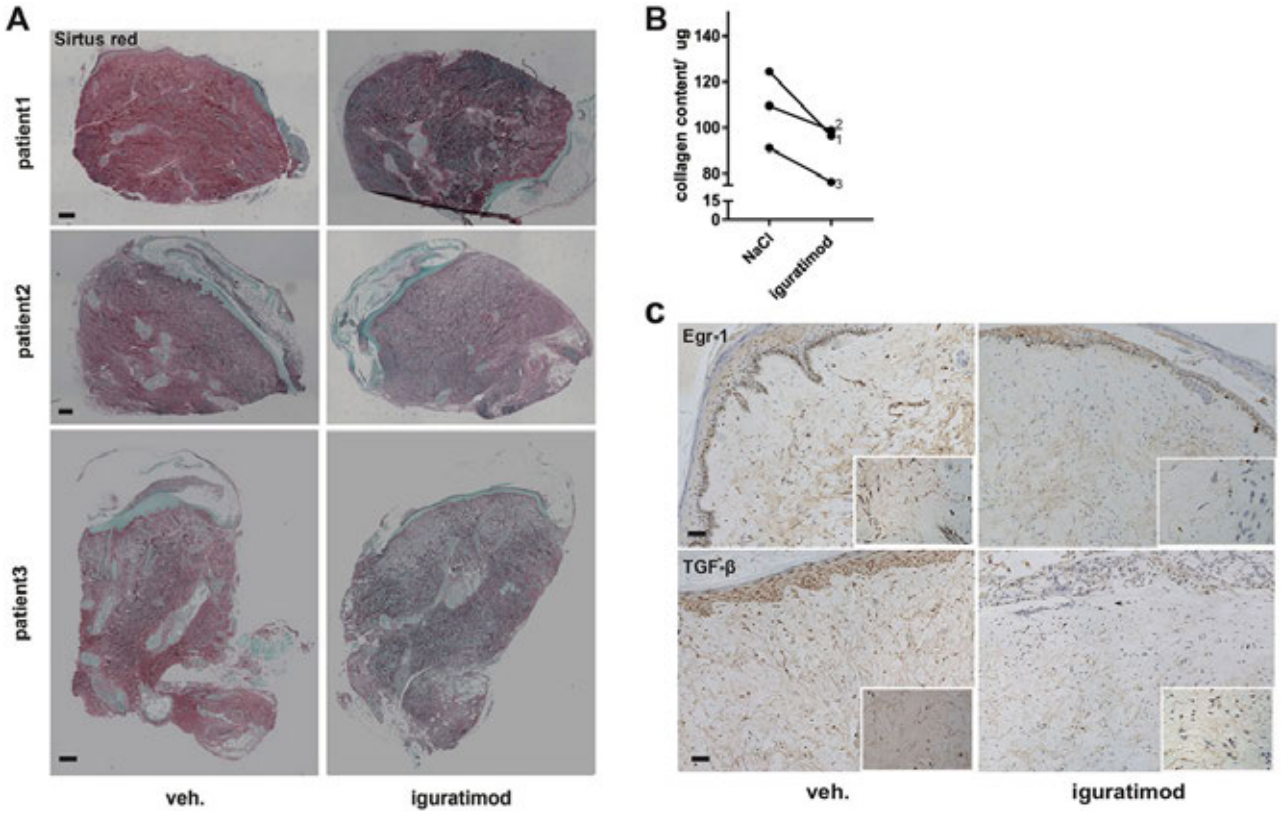
Methods: We used iguratimod to treat TGFβ-stimulated human skin fibroblast, bleomycin induced mice, tight skin 1 (TSK-1) mice and SSc skin grafts. The bleomycin model contained pre-establish fibrosis and late onset treatment. The skin grafts came from three SSc patients and was planted into irradiated nude mice.

Results: Iguratimod strongly inhibited *egr1* expression in human skin fibroblast, with moderate down-regulation of Egr2/3. Iguratimod neutralized effects of TGFβ on 232/327 Egr1 inducible genes according to transcriptome sequencing. Further protein interaction analysis showed that Egr1 was one of the hub genes of iguratimod working network. Collagen production and α-SMA production were decreased by iguratimod. Knocking down Egr1 using siRNA



Iguratimod inhibited Egr1 expression in primary human dermal fibroblast. Human fibroblast were stimulated by TGF-β and treated with 0.1% DMSO (T) or 100μM iguratimod (TI). (A) Iguratimod treatment suppressed multiple egr genes, particularly egr1. RNA was isolated and sequenced to Illumina Hiseq. Each line represents an independent experiment. (B) Iguratimod inhibited egr1 mRNA expression in dose dependent manner. N = 3 per group. *P<0.05, **P<0.01, ANOVA. (C, D) Iguratimod significantly reduced egr-1 protein synthesis at 100μM. (E) Analysis of 327 Egr1 response gene expression (genes with FDR < 0.05; fold change ≥ 1.5 in NC vs T comparison). Iguratimod could largely neutralize the effects of TGF-β on Egr-1 response genes. (F) Gene interaction analysis on the top 50 regulated genes between T and IGT groups using STRINGS data base. Egr1 was in the center of the network.

could mimic these effects. Both oral and topical iguratimod could treat dermal thickening and collagen deposition in bleomycin induced skin fibrosis. α-SMA (+) myofibroblast counts, as well as Egr1 (+) and TGFβ (+) fibroblast counts were significantly reduced by iguratimod. Similarly, topical iguratimod ameliorated dermal fibrosis in TSK-1 mice. Of note, 5-week iguratimod local injection remarkably reduced collagen content in skin grafts from three SSc patients, with simultaneous inhibited Egr1 and TGFβ staining.



Iguratimod treated fibrosis of skin grafts from systemic sclerosis (SSc) patients with interrupted Egr1/TGF-β loop. Lesional skin tissue from each SSc patient were transplanted subcutaneously into two irradiated nude mice. The grafts were injected with 0.1mg/ml iguratimod or vehicle every day for 5 weeks. (A) Sirius red staining for each graft. The red parts represent collagen and green parts represent total protein. (B) The collagen content of each skin tissue was quantified by eluting the dye and colorimetric assay. (C and D) Representative images of Egr1 and TGFβ staining.

Conclusion: We found the potential of iguratimod to treat SSc, which was characterized as the interruption of Egr1/TGFβ loop. Further clinical investigations for its safety and efficacy is warranted.

Dimethyl Fumarate Ameliorates the GATA6 Deficiency-Induced Pulmonary Hypertension by Normalizing Oxidative and ER Stress

Asako Ichihara,[1] Tetsuo Toyama,[2] Tatiana Kudryashova,[3] Yuanjun Shen,[3] Dmitry Goncharov,[3] Elena Goncharova,[3] and Maria Trojanowska[2], [1]Arthritis Center, Boston University School of Medicine, Brookline, MA, [2]Arthritis Center, Boston University School of Medicine, Boston, [3]Pulmonary, Allergy & Critical Care Division, University of Pittsburgh Department of Medicine, Pittsburgh

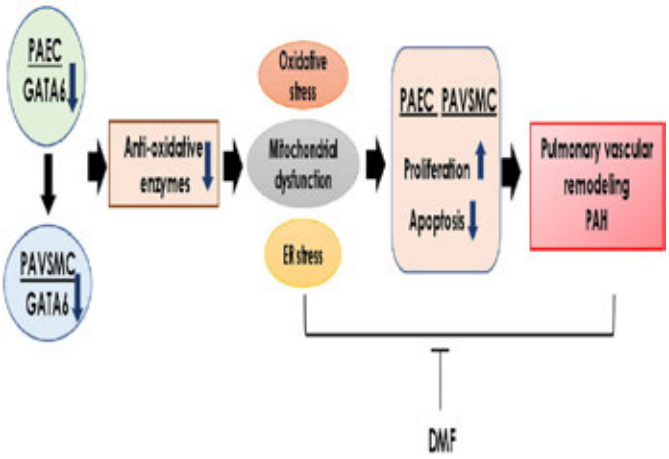
SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorder – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM



Background/Purpose: Pulmonary arterial hypertension (PAH) is a leading cause of death in patients with limited form of systemic sclerosis (SSc). We have previously reported that GATA6 is downregulated in pulmonary vasculature in SSc-PAH and IPAH patients and that endothelial cell deficiency of GATA6 is sufficient to promote PAH development in mice (Ghatnekar et al, 2013). The goal of this study was to gain further insights into the mechanism of deficient GATA6-induced PAH and to evaluate the therapeutic potential of dimethyl fumarate **(**DMF) in preclinical models of PAH.

Methods: In vitro experiments used early-passage distal pulmonary artery endothelial cells (PAEC) and smooth muscle cells (PAVSMC) from PAH and non-diseased lung. GATA6 was depleted in control human PAEC and PAVSMC by transfecting with siRNA GATA6 or restored by transduction with human GATA6 expressing adenovirus. Enzymatic activities of superoxide dismutase 2 (SOD2), glutathione peroxidase 1 (GPX1) and catalase was determined using commercially available kits. Cellular and mitochondrial ROS production was examined using CellROX and MitoSOX probes, respectively. In vivo experiments used mice with endothelial-specific Gata6 deficiency (Gata6 CKO). DMF or vehicle control were administered daily for 3 weeks via i.p. injection.

Results: Transcriptome analysis of human PAEC transfected with GATA6 siRNA revealed downregulation of multiple genes involved in the antioxidant stress response, including SOD2, catalase, and GPX family members. ChIP analysis indicated that GATA6 is a direct transcriptional regulator for SOD2 and GPX1. Human PAEC with siRNA-induced GATA6 depletion showed marked increase in both cellular and mitochondrial ROS production in parallel with the up-regulation of the ER stress genes. Reduced levels of GATA6 were also present in PAEC and PAVSMC obtained from patients with PAH and were associated with increased cell growth. Adenoviral delivery of GATA6 in human PAH PAEC and PAVSMC reduced their growth and induced PAVSMC apoptosis. Importantly, GATA6 and SOD2 were downregulated in control PAVSMC treated with conditioned media obtained from GATA6 siRNA treated PAEC. Increased oxidative and ER stress were also recapitulated in Gata6 CKO mice. Treatment with DMF normalized pulmonary pressure and partially reversed right heart hypertrophy in Gata6 CKO mice. DMF also normalized expression of antioxidant enzymes, including SOD2 and GPX and reversed the oxidative and ER stress in the lungs of Gata6 CKO mice. DMF also restored eNOS expression levels previously shown to be downregulated in these mice.

Conclusion: Deficiency of GATA6 is a shared pathological feature between PAEC and PAVSMC in human SSc-PAH and experimental PAH. GATA6 acts as a direct positive regulator of SOD2 and other antioxidant enzymes, providing protection from oxidative stress and supporting pulmonary vascular homeostasis. GATA6 controls PAEC-PAVSMC communication and endothelial GATA6 deficiency results in GATA6 loss and consequent proliferation of PAVSMC, exacerbating pulmonary vascular remodeling and PAH. Beneficial effects of DMF on the key pathways contributing to PAH, supports its testing in PAH treatment in patients.

Session Title: Systemic Sclerosis & Related Disorder – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

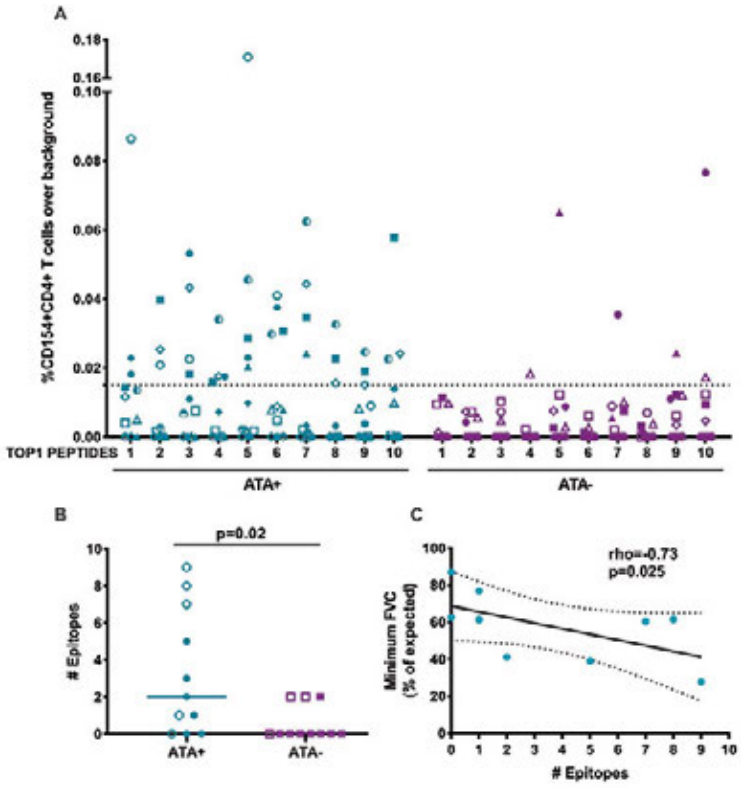

Figure 1. Distribution and clinical significance of CD4+ T cell responses to naturally presented TOP1 epitopes in SSc. (A) %CD154+CD4+ T cell responses over background observed with media alone for 11 ATA-positive and 11 ATA-negative SSc patients for each of the 10 naturally processed TOP1 peptides identified using NAPA are shown. The dotted line represents the cutoff for positivity that was defined as >95th percentile of the T cell responses observed in ATA-negative patients (95th percentile=0.015%). Each colored symbol represents a unique patient. (B) The number of peptides eliciting a response in ATA-positive (n=11) and ATA-negative (n=11) SSc patients is shown (Mann-Whitney, p=0.02). Open symbols represent patients that possess at least one ATA-associated HLA-DRB1 allele. (C) The minimum FVC (% of expected) was plotted against the number of TOP1 epitopes eliciting a T cell response in ATA-positive SSc patients with clinically documented ILD (n=9). The correlation between minimum FVC and the number of stimulatory TOP1 epitopes was analyzed using a Spearman's rho test. A p-value <0.05 was considered significant throughout.

Background/Purpose: Autoimmune responses to DNA topoisomerase-I (TOP1) are found in a subset of patients with scleroderma at high risk for interstitial lung disease (ILD) and mortality. Anti-TOP1 antibodies (ATA) are associated with specific *HLA-DRB1* alleles, and the frequency of HLA-DR-restricted TOP1-specific CD4+ T cells is associated with the presence, severity, and progression of ILD. Although this strongly implicates the presentation of TOP1 peptides by HLA-DR in scleroderma pathogenesis, the processing and presentation of TOP1 has not been studied.

Methods: We developed a novel natural antigen processing assay (NAPA) which relies on the sensitivity and specificity of the cellular MHC class II antigen processing machinery. Monocyte-derived dendritic cells were generated from six SSc patients with anti-Topo-I antibodies (ATA) and pulsed with Topo-I protein. HLA-DR:peptide complexes were isolated by immunoprecipitation and eluted peptides were analyzed by mass spectrometry. We then examined the ability of these naturally presented putative epitopes to induce CD4+ T cell activation, as measured by upregulation of the early activation marker CD154 in PBMCs from ATA-positive (n=11) and ATA-negative (n=11) SSc patients.

Results: Using NAPA, we found that presentation of TOP1 epitopes was restricted to only 10 hot spots within TOP1, across patients with different HLA-DR variants. Further analysis revealed shared peptide-binding motifs within the HLA-DRβ chains of ATA-positive patients and a subset of TOP1 epitopes with distinct sets of anchor residues capable of binding to multiple different HLA-DR variants. The naturally presented TOP1 peptides elicited robust CD4+ T cell responses in ATA-positive patients, and the number of epitopes recognized correlated with the severity of lung fibrosis (Figure 1).

Conclusion: This study suggests a mechanism in which autoimmunity to TOP1 in scleroderma is driven by the presentation of a communal set of TOP1 peptides in patients with diverse *HLA-DRB1* alleles.

Cracking a Novel Profibrotic Molecular Mechanism: lncRNA H19X and DDIT4L Crosstalk

Elena Pachera,[1] Shervin Assass,[2] Gloria Salazar,[3] Mojca Frank-Bertoncelj,[4] Jörg Distler,[5] Gabriela Kania,[6] and Oliver Distler[7], [1]Center of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Zurich, Switzerland, [2]Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, Texas, USA, Houston, TX, [3]University of Texas McGovern Medical School, Houston, [4]University Hospital Zürich, Zürich, Switzerland, [5]Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander-University Erlangen-Nürnberg (FAU) and University Hospital Erlangen, Erlangen, Germany, Erlangen, Germany, [6]Centre of Experimental Rheumatology, Department of Rheumatology, University Hospital Zurich, Zurich, Switzerland, [7]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Systemic Sclerosis & Related Disorder – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Long noncoding RNAs (lncRNAs) are an emerging class of noncoding transcripts involved in the regulation of gene expression in health and disease. LncRNAs function via different mechanisms either acting cis, regulating the expression of nearby genes, or in trans, modulating the expression of distant genes. We have

identified a novel TGFβ regulated lncRNA, H19X, which was strongly and consistently upregulated in a wide variety of fibrotic disorders. Moreover, we were able to demonstrate that H19X is a key driver of myofibroblast formation and extracellular matrix (ECM) overproduction. Here we aimed to define the mode of action of H19X and to assess H19X functions that may drive myofibroblast differentiation and ECM production.

Methods: The function of H19X was investigated in SSc dermal fibroblasts (n=5) by knocking down H19X with locked nucleic acid oligonucleotides (LNA GapmeRs) followed by TGF-β stimulation and microarray analysis with Illumina HT-12 arrays. In situ hybridization for H19X was performed using Stellaris FISH probes. Genomic regions of interaction with H19X were identified by Chromatin Isolation by RNA Purification (ChIRP) using biotinylated probes tiling the transcript, RNA pull-down and sequencing. Chromatin remodeling was investigated by Assay for Transposase-Accessible Chromatin using sequencing (ATAC-seq). DNA damage-inducible transcript 4-like protein (DDIT4L) function was tested using siRNA in parallel to H19X downregualtion.

Results: As analyzed by microarray, none of the 16 genes belonging to the same genomic region (1 Mb) as H19X locus was affected by its downregulation, indicating that in-cis regulation is not a major mechanism of H19X activity. Cellular localization can give a first indication about lncRNA trans function: FISH staining of SSc fibroblasts stimulated with TGF-β revealed tightly localized nuclear foci in TGF-β treated cells. Moreover, increased numbers of positive nuclei were also recorded after TGF-β stimulation. H19X nuclear localization was confirmed by cell fractionation, where H19X expression was peaking in the nucleus of cells after 6h of treatment with TGF-β.

Next, we identified 58 genomic regions that directly interact with H19X using ChIRP. In order to establish the effect of H19X physical presence at these sites, the expression of the genes with the closest transcription start site was analyzed in the microarray data set. Among these genes, DDIT4L displayed the strongest induction following H19X knockdown. Furthermore, we cloud identify chromatin rearrangements caused by H19X knockdown in close proximity with its interaction site with DDIT4L locus using ATAC-seq. Interestingly, DDIT4L expression was consistently repressed by TGFβ stimulation at mRNA and protein level. Additionally, DDIT4L knockdown was able to restore COL1A1 expression that was reduced by H19X downregulation but only in presence of TGFβ. These data indicate that H19X mediates its effects unabeling DDIT4L transcription which, in turn, is a novel repressor of TGFβ pathway activity.

Conclusion: Our data uncover a novel mechanism for the TGFβ regulated profibrotic effects of H19X including direct effects on chromatin organization associated with fibrotic pathways.

Long Non-coding RNA HOTAIR Induces Myofibroblast Activation in Systemic Sclerosis Through EZH2 Dependent De-repression of NOTCH Signalling Pathway Activation

Christopher Wasson,[1] Giuseppina Abignano,[2] Rebecca Ross,[3] Heidi Hermes,[4] Sergio Jimenez,[5] and Francesco Del Galdo[6], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, United Kingdom, [2]3Rheumatology Institute of Lucania (IReL) and University of Leeds, Leeds, United Kingdom, [3]Univesristy of Leeds, Leeds, England, United Kingdom, [4]Jefferson Institute of Molecular Medicine and Scleroderma Center, Thomas Jefferson University, Philadelphia, [5]Jefferson Institute of Molecular Medicine and Division of Connective Tissue Diseases, Thomas Jefferson University, Philadelphia, PA, Philadelphia, PA, [6]University of Leeds and LTHT NIHR Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Systemic Sclerosis & Related Disorder – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Fibroblasts explanted from affected tissues in Systemic Sclerosis (SSc), conserve their pro-fibrotic phenotype characterised by increased secretion of collagens and other extracellular matrix proteins and comprise a large proportion of a-Smooth Muscle Actin (a-SMA) positive myofibroblasts. Long non-coding RNAs (lncRNAs) within the HOX loci have been described as master epigenetic regulators within the connective tissue. Specifically, HOTAIR has been shown to drive the specific phenotype of the hands and feet which are also the first body regions affected by SSc. Here we aimed to unravel the mechanisms responsible for the epigenetically stable activation of SSc fibroblasts

Methods: Full thickness skin biopsies were surgically obtained from the forearms oftwelve adult patients with SSc of recent onset. Fibroblasts were isolated and cultured in monolayers and protein and RNA extracted from the fibroblast cultures. Laser capture was performed to isolate cells expressing or not a-SMA as a marker of myofibroblast differentiation. HOTAIR was expressed in healthy dermal fibroblasts by lentiviral induction employing a vector containing the specific sequence. Gamma secretase inhibitors RO4929097 and DAPT were employed to block Notch signalling in SSc fibroblasts. EZH2 was blocked in SSc fibroblasts with the specific inhibitor GSK126.

Results: HOTAIR expression was increased in SSc patients' skin (100 fold) and in SSc explanted fibroblasts (5 fold). These results were highly significant ($p< 0.001$ for both). Further, laser captured a-SMA expressing myofibroblasts expressed in average 2.5 fold greater HOTAIR RNA levels compared to a -SMA negative cells from the same donors ($P< 0.05$). In vitro, we demonstrated that lentiviral induced stable overexpression of HOTAIR in healthy dermal fibroblasts led to their profibrotic activation, including significantly increased expression of Col1A1 and a-SMA both at mRNA and protein levels (2.8 and 1.8 fold respectively, $p< 0.05$). We further showed that HOTAIR-induced profibrotic activation was due to EZH2 dependent spread of H3k27me3 methylation marker, as demonstrated by complete inhibition by treatment with GSK126. Additionally, we showed that EZH2 led to profibrotic activation by decreasing the expression of miRNA 34a. The reduced miRNA 34a levels in turn led to NOTCH increased expression and signalling pathway activation. Consistent with these findings, treatment of the HOTAIR expressing cells with two different types of gamma secretase inhibitors known to block NOTCH activation, normalised a-SMA expression and suppressed collagen production by 50%. Importantly, treatment with the EZH2 inhibitor GSK126 suppressed collagen production in the HOTAIR expressing cells and SSc fibroblasts by 30% and 50% respectively ($p< 0.05$) and normalised a-SMA levels in both cell lines to control levels ($p< 0.05$).

Conclusion: Here we show that the epigenetically stable activation of SSc dermal fibroblasts is due to HOTAIR led EZH2 dependent de-repression of NOTCH signalling. The results of these studies identify a new venue to modulate fibroblasts biology which could inform clinical research to resolve chronic fibrosis and re-establish tissue homeostasis in SSc.

Development and Preliminary Validation of a Novel Lung Ultrasound Interpretation Criteria for the Detection of Interstitial Lung Disease in Patients with Systemic Sclerosis

Robert Fairchild,[1] Diana Yang,[2] Melody Chung,[1] Laurel Sharpless,[1] Shufeng Li,[3] and Lorinda Chung[1], [1]Stanford University, Palo Alto, CA, [2]Santa Clara Valley Medical Center, Palo Alto, CA, [3]Division of Immunology and Rheumatology, Department of Medicine, Stanford, Palo Alto, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Interstitial lung disease (ILD) is a frequent complication of systemic sclerosis (SSc), and screening, characterization, and monitoring of disease activity are important for therapeutic decision-making and prognostication. High resolution computed tomography (HRCT) is the gold standard for ILD diagnosis. More recently, lung ultrasonography (LUS) has been proposed as a potential alternative imaging modality for ILD detection. In this study, we develop and test a novel LUS interpretation criteria for detecting SSc-ILD.

Methods: Patients with prevalent SSc and prior or planned HRCT within 3 months were prospectively enrolled and assessed by LUS. We included 14 lung positions and used a novel acquisition technique, collecting several seconds of real-time images rather than still images with the probe oriented in a sagittal rather than transverse orientation. This technique affords better visualization and tracking of pleural lesions with respiration. Prior studies identified B-line quantification, pleural irregularity, and pleural thickness as features sensitive for SSc-ILD. Although B-line quantification has been extensively studied, it is a less specific and artifactually based finding and highly dependent on ultrasound technique and machine settings. Given the high resolution of current US machines, granular appearing pleural thickening and pleural irregularity (defects in the pleural surface) were easy to visualize and highly reproducible (Figure 1). Using a combination of these features, we developed LUS interpretation criteria for SSc-ILD detection (Figure 2). These interpretation criteria were used to evaluate LUS examinations of our SSc cohort and were read by

Figure 1. Interstitial lung disease findings on lung ultrasound

Figure 2. Ultrasound interpretation criteria for interstitial lung disease

Lung zones are considered positive if both criteria I and II are met:

I. Lesions must be characterized by *either*:
- A) Discontinuities or cavitations in the linear pleural surface (hypoechoic centers and hyperechoic rims)
- B) A hyperechoic, granular appearance

II. Lesions must demonstrate *all three (3)* of the following conditions:
- A) Be identified as 1 or more distinct lesions > 2 mm in width OR as confluent lesions involving the entire pleural surface
- B) Demonstrate pseudo-thickening: any degree of increased hyperechoic transmission deep to lesions compared to normal pleura
- C) Track with lung movement

1 or more positive lung zones indicates a positive study for interstitial lung disease.

Table 1. Detection of SSc-ILD via LUS versus HRCT using LUS interpretation criteria

	Reader 1 (ultrasonographer)		Reader 2 (non-ultrasonographer)
Patients, n		**20**	
Lung zones examined, n		278	
SSc-ILD per HRCT, n (%)		9 (45)	
LUS – ILD detection per patient			
Read as positive, n (%)	11 (55)		11 (55)
Read as negative, n (%)	9 (45)		9 (45)
Sensitivity vs HRCT	100%		100%
Specificity vs HRCT	84.6%		84.6%
Kappa		1.00	
LUS – ILD detection per lung zones			
Read as positive, n (%)	65 (23)		59 (21)
Read as negative, n (%)	213 (77)		219 (79)
Concordance		93.8%	
Kappa		0.82	

HRCT = high resolution computed tomography, LUS = lung ultrasound, ILD = interstitial lung disease, SSc-ILD = systemic sclerosis associated interstitial lung disease.

two independent readers (1 ultrasonographer and 1 non-ultrasonographer) who were blinded to HRCT results and ILD diagnosis. The sensitivity and specificity for SSc-ILD detection was assessed and agreement was measured with Cohen's Kappa statistic.

Results: We evaluated 20 SSc patients by LUS examination (278 lung zones) and HRCT. HRCT confirmed ILD in 9 patients (45%). LUS was read as positive for SSc-ILD in 11 patients (55%) with a sensitivity of 100% and specificity of 84.6% versus HRCT with perfect agreement between the two readers (κ= 1). Analysis by individual lung zones found excellent agreement between readers with 93.8% concordance and κ = 0.82 (Table 1).

Conclusion: We developed a novel ultrasound technique and interpretation criteria that are highly sensitive and specific for ILD detection in an SSc cohort. Our interpretation criteria are feasible and reliable, affording perfect agreement between ultrasonographer and non-ultrasonographer readers for SSc-ILD detection. Moving forward we hope to validate these criteria in a larger cohort of patients with SSc, dermatomyositis and polymyositis.

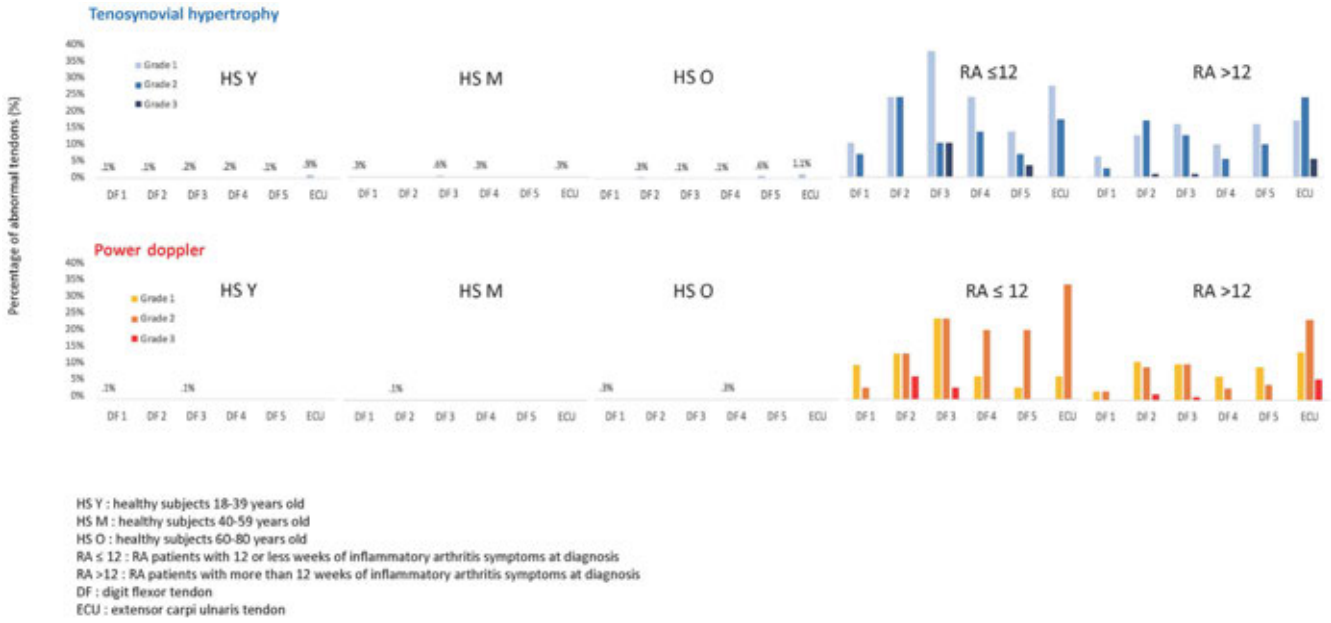
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Tenosynovitis (TS) is a common, often clinically undetectable finding in Rheumatoid Arthritis (RA). Recent data showed TS on ultrasound (US) has a role in predicting outcome in early disease and flare in clinical remission. However data is limited on US measured TS in healthy subjects (HS), none specifically encompassing the older age range when RA commonly presents. This OMERACT study aimed to determine prevalence of US measured tendon abnormalities in HS throughout the age range.

Methods: Adult healthy subjects without: joint pain (VAS < 10/100), hand osteoarthritis (ACR criteria), or inflammatory arthritis were recruited in 23 international centres from Aug 2017-Dec 2018. MCP, PIP and wrist joints were



Percentage of abnormal digit flexor and extensor carpi ulnaris tendons by age group of healthy subjects, and early or late presenters in RA patients

clinically examined. Bilateral digit flexor (DF) 1-5 and extensor carpi ulnaris (ECU) tendons were scanned for tenosynovial hypertrophy (TSH) and power Doppler (PD) signal and graded (OMERACT US scoring system). A comparison cohort of DMARD-naive patients with RA (ACR-EULAR 2010 and/or 1987 criteria) at presentation was taken from the Birmingham Early Arthritis (BEACON) inception cohort, who underwent identical tendon US assessment. They were grouped into ≤12 and > 12 weeks from symptom onset. Abnormal ultrasound findings were dichotomised in to grade 0 (absent) or grade 1-3 (present) for statistical analysis (Fisher's exact test).

Results: Data from 899 HS and 144 RA patients were included. Prevalence of TSH and particularly PD abnormalities in HS was very low in all age groups, and was all grade 1 except in one individual ECU tendon. ECU TSH grade≥1 was more common than DF grade≥1 in the older HS groups, and less common in the 18-39 age group (p=0.011). TSH and PD of grade ≥1 were common in RA patients (p ≤0.001), with DF PD abnormalities more common in early disease (p=0.02).

Conclusion: Very low prevalence of TSH or PD abnormalities in tendons of healthy subjects even in old age suggests ultrasound determined tenosynovitis will be a robust tool in clinical management of RA.

Abstract Number: 2752

Successfull Evaluation of a Predefined Set of Anatomic Sites in the Pelvis of Patients with Polymyalgia Rheumatica Showing Extracapsular Inflammation as Visualized by Contrast Enhanced Magnetic Resonance Imaging

Martin Fruth,[1] Annika Seggewiss,[1] Jessica Kozik,[1] Philipp Martin-Seidel,[1] **Xenofon Baraliakos**,[2] and Jürgen raun[3], [1]Radiology Herne, Herne, Germany, [2]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [3]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The diagnosis of polymyalgia rheumatica (PMR) is based on a thorough clinical evaluation of the patient - including exclusion of other diseases, since there is no decisive diagnostic test. A characteristic pattern of extracapsular inflammation in the pelvis of patients with PMR as assessed by contrast enhanced magnetic reso-

nance imaging (MRI) has been recently described (1). We evaluated the performance of a predefined set of anatomic sites in the pelvis of patients with PMR vs. controls.

Methods: A total of 120 pelvic MRI scans of patients who had presented to our tertiary center with pelvic girdle pain in the last 3 years, including 40 patients with an expert rheumatologist diagnosis of PMR and 80 controls with other reasons of pelvic pain was evaluated by 3 radiologists blinded to clinical diagnosis and patient demographics. The experts scored the presence or absence of contrast enhancement at 19 predefined tendinous and capsular pelvic structures. Different patterns of involvement were compared and statistically evaluated by ROC analysis. Kappa statistics were applied to calculate inter- and intrareader agreement.

Results: Mostly bilateral peritendinitis and capsulitis including uncommon sites such as the proximal origins of the muscles rectus femoris and adductor longus were found almost exclusively and, thus, typically in PMR patients: the difference in the mean number of sites showing contrast enhancement was significantly different with 13.4±2.7 for PMR vs 4.0±2.3 for controls. A cut-off of ≥10 inflamed sites discriminated very well between the groups resulting in a sensitivity and specificity of 95.8% and 97.1%, respectively. Just concentrating on the most frequently involved anatomic sites bilateral inflammation of proximal M. rectus femoris or adductor longus tendons together with at least 3 other bilaterally inflamed sites performed even better with a sensitivity and specificity of 100% and 97.5%, respectively.

Conclusion: This study strongly confirms that the previously described pattern of extracapsular pelvic inflammation as assessed by contrast enhanced MRI is very typical for patients with PMR. In addition, the high sensitivity and specificity of the set of anatomic sites evaluated suggest their definite potential for use as a confirmatory diagnostic test.

Major Salivary Gland Ultrasound: Pilot Study of Findings and Feasibility in Childhood-Onset Systemic Lupus Erythematosus (cSLE)

Joseph McDonald,[1] Patricia Vega-Fernandez,[2] and Tracy Ting[1], [1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Children's Hospital of Atlanta, Atlanta, GA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Ultrasonography is becoming an increasingly useful tool in evaluating patients in pediatric rheumatology. It is predominantly used for musculoskeletal assessments, however, major salivary gland ultrasound (SGUS) is being used in adults for assessment of primary and secondary Sjögren's syndrome. Very few studies have been done examining salivary gland ultrasound in children and they have been confined to primary Sjögren's syndrome. Examining children with rheumatic diseases who may be at risk for Sjögren's syndrome such as childhood onset systemic lupus erythematosus (cSLE) may reveal early changes allowing for targeted intervention. Our primary objective is to determine acceptability and feasibility of SGUS in a pediatric rheumatology clinic. A secondary objective is to evaluate differences in ultrasound findings between cSLE Ro/La+ patients vs. cSLE Ro/La- patients.

Methods: Patients completed questionnaires rating symptoms of dryness, fatigue, pain, and reported any history of difficulty swallowing or episodic cheek swelling. Each patient underwent major SGUS of bilateral parotid glands (in two views) and bilateral submandibular glands (single view). Patients were asked to provide feedback on exam acceptability. Utilizing a previously published scoring system each major salivary gland image was scored by a blinded reviewer using a scale of 0-3 with a score of 0 representing a normal homogenous gland and a score of 3 representing diffuse gland heterogeneity. Scores of 2 or 3 were considered abnormal. The highest score was used as the overall ultrasound score for each patient. We used two sample independent t-tests or Fisher's exact tests to compare disease factors and ultrasound scores between cSLE patients Ro/La+ vs. cSLE patients Ro/La-. A second analysis was

Table 1. Summary of WOMAC OA Pain Score Change from Baseline through Day 94 - mITT Set

performed to compare differences between cSLE patients with abnormal ultrasound score vs. cSLE patients with normal scores.

Results: Twenty cSLE patients were recruited, 90% were female, 50% were Caucasian. The average disease duration among all patients was 5 years. All twenty patients deemed the ultrasound examination acceptable. Average time to complete the ultrasound examination protocol was 4.5 minutes. No negative effects on clinic flow were reported. Age, gender, race, disease duration, SLEDAI, IgG level at diagnosis, dryness, fatigue, pain, and abnormal ultrasound scores did not differ between Anti-Ro/La+ cSLE patients compared to Anti-Ro/La- cSLE patients (Table 1). The data were also analyzed comparing patients with normal vs. abnormal SGUS scores. IgG level at diagnosis and Black race were significantly associated with abnormal SGUS scores (Table 2).

Conclusion: This is one of the first studies to assess major SGUS in a cohort of patients with cSLE. We demonstrate acceptability and feasibility of this ultrasound protocol performed by rheumatologists in a pediatric rheumatology clinic. Although the sample size was small we found SGUS abnormalities in 20% of patients. IgG level at diagnosis and Black race may predict risk for SGUS abnormalities. Larger cohort studies would be helpful to determine risk factors for SGUS abnormalities in children; ultimately leading to earlier diagnosis and treatment interventions.

AxSpA Patients with Symptom Onset < 30 Years Have More Structural Lesions on MRI of the Sacroiliac Joints When Fulfilling the Modified New York Criteria

Manouk de **Hooge**,[1] Ann-Sophie De Craemer,[1] Thomas Renson,[1] Philippe Carron,[1] Liselotte Deroo,[1] Dirk Elewaut,[1] and Filip Van den Bosch[1], [1]Ghent University Hospital, Ghent, Belgium

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The modified New York criteria (mNY) combine clinical symptoms with radiographic sacroiliitis on conventional pelvic radiographs (X-SI) classifying radiographic axial SpA patients (r-axSpA). AxSpA is known to typically start in the third era of life but there is a diagnostic delay of ±7 years. As the mNY criteria classify the most typical and severe expression of axSpA it is suggested that the mNY criteria are less useful in younger patients. Purpose of the study is to explore the diagnostic utility of the mNY criteria in newly diagnosed axSpA patients with a symptom onset < 30 years. In addition, describe the extent of lesions on MRI of the sacroiliac joints (MRI-SI) in mNY positive (mNY+) patients with a symptom onset < 30 years.

Methods: This study involved newly diagnosed axSpA patients, age ≥18 years, from a Belgian (Be-Giant) cohort. Patients underwent diagnostic tests involving clinical examination, lab tests, and imaging assessment containing an X-SI and an MRI-SI. mNY criteria was assessed on X-SI. MRI-SI reads contained the assessment of inflammatory lesions according to the Spondyloarthritis Research Consortium of Canada (SPARCC) scoring method and erosions, fatty lesions (FL), sclerosis, ankylosis using an adapted method of the SPARCC. Also, the ASAS definition of a positive MRI-SI was evaluated. T1-weighted and STIR images were viewed simultaneously. X-SI and MRI-SI were evaluated independently by 3 trained readers who were also blinded for clinical features. Imaging scores (X-SI grading according to the mNY criteria and mNY fulfillment, and MRI-SI lesion scores) were calculated as 2 out of 3 reader scores.

Results: In the 173 patients with available X-SI, the average age at symptom onset was 27.4 years old. In 114/173 (65.9%) patients, the symptom onset was below 30 years. Of those, 11 (9.6%) patients fulfilled the mNY criteria. Seven of the 11 (63.6%) patients that were mNY+ were male, which was slightly lower than in the mNY- patients (n=55; 53.4%). The presence of HLA-B27 was comparable between mNY+ and mNY- patients; 8 (72.7%) patients and 82 (79.6%) patients, respectively. Average X-SI grading in mNY+ patients was 4.7±1.3 (on a scale from 0-8) and in mNY negative (mNY-) patients (n=103) the average X-SI grading was 1.1±1.1.When looking at the MRI-SI assessment, 8/11 mNY+ patients (72.7%) and 60/103 mNY- patients (58.3%) had a positive MRI-SI (ASAS definition). The table shows

Table: Average MRI-SI lesion scores in axSpA patients with a symptom onset of <30 years fulfilling and not fulfilling the modified New York criteria.

MRI lesions	mNY+ (n=11)	mNY- (n=103)	P-value
Inflammatory lesions (SPARCC score)*	8.9 (±6.0)	7.3 (±7.2)	0.341
Erosions*	7.6 (±4.4)	3.5 (±4.2)	0.003
Fatty lesions*	6.6 (±8.3)	1.8 (±4. 6)	0.005
Sclerosis*	1.1 (±2.0)	0.9 (±2.6)	0.237
(Partial) Ankylosis*	7.6 (±11.5)	0.8 (±3.2)	0.030

* mean (±SD)

the mean scores for MRI-SI lesions. In erosions, fatty lesions and ankylosis, either partial or complete ankylosis, there was a statistically significant difference ($p< 0.05$) between mNY+ and mNY- patients.

Conclusion: Patients with newly diagnosed axSpA and a symptom onset before 30 years infrequently fulfill the mNY criteria. A statistically significant difference in the presence of MRI-SI structural lesions was reported between mNY+ and mNY- patients. AxSpA patients with an early symptom onset have more erosions, fatty lesions and ankylosis on MRI when fulfilling the mNY criteria.

Abstract Number: 2755

Assessing the Sensitivity to Change of the OMERACT Ultrasound Structural Gout Lesions During Urate-Lowering Therapy

Sara Nysom Christiansen,[1] Mikkel Østergaard,[2] Ole Slot,[1] George A. W. Bruyn,[3] Helen Keen,[4] Maria-Antonietta D'Agostino,[5] and Lene Terslev[6], [1]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Glostrup, Denmark, [2]Copenhagen Center for Arthritis Research, University of Copenhagen, Copenhagen, Denmark, [3]Department of Rheumatology, MC Groep Hospitals., Lelystad, Netherlands, [4]School of Medicine and Pharmacology Fiona Stanley Hospital Unit, University of Western Australia, Perth, Australia, [5]Department of Rheumatology, Ambroise Pare´ Hospital, and Versailles Saint-Quentin-en-Yvelines University, Boulogne-Billancourt, France, [6]Copenhagen Center for Arthritis Research, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Imaging of Rheumatic Diseases II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: To evaluate the sensitivity to change of ultrasound (US) structural gout lesions, as defined by the OMERACT US group, in gout patients during urate lowering therapy.

Methods: US examination (28 joints, 26 tendons) was performed in patients with microscopically verified gout, who initiated or increased urate lowering therapy. Joints and tendons were evaluated by US for the OMERACT structural gout lesions (double contour sign (DC), tophus, aggregates and erosions), scored binarily (0/1). Synovial changes were graded by grey scale (GS) and color Doppler (CD), both scored semiquantitatively (0-3), where a score ≥ 1 was considered pathological. A sum score was calculated for each lesion for each patient. Numbers of gout attacks within the last 4 and 12 weeks and Patient Reported Outcomes (PROs) regarding pain (visual analogue scale (VAS)) and physical function (HAQ) were obtained, as were CRP, p-urate and clinical joint examination. All examinations were repeated after 3 and 6 months. Changes in patient's sum scores and lesion scores at different locations (joints and tendons) were evaluated using Wilcoxon-Pratt signed-rank test. Furthermore, changes in lesion scores between groups that did/did not achieve the treatment target (p-urate < 0.36 mmol/L) were compared using Mann Whitney U test and Chi square test.

Table 1: Course of ultrasound, biochemical and clinical variables during 6 months follow up.													
		Baseline (n=50)			3 months' follow up (n=46)			6 months' follow up (n=41)			Δ 0-3 months	Δ 3-6 months	Δ 0-6 months

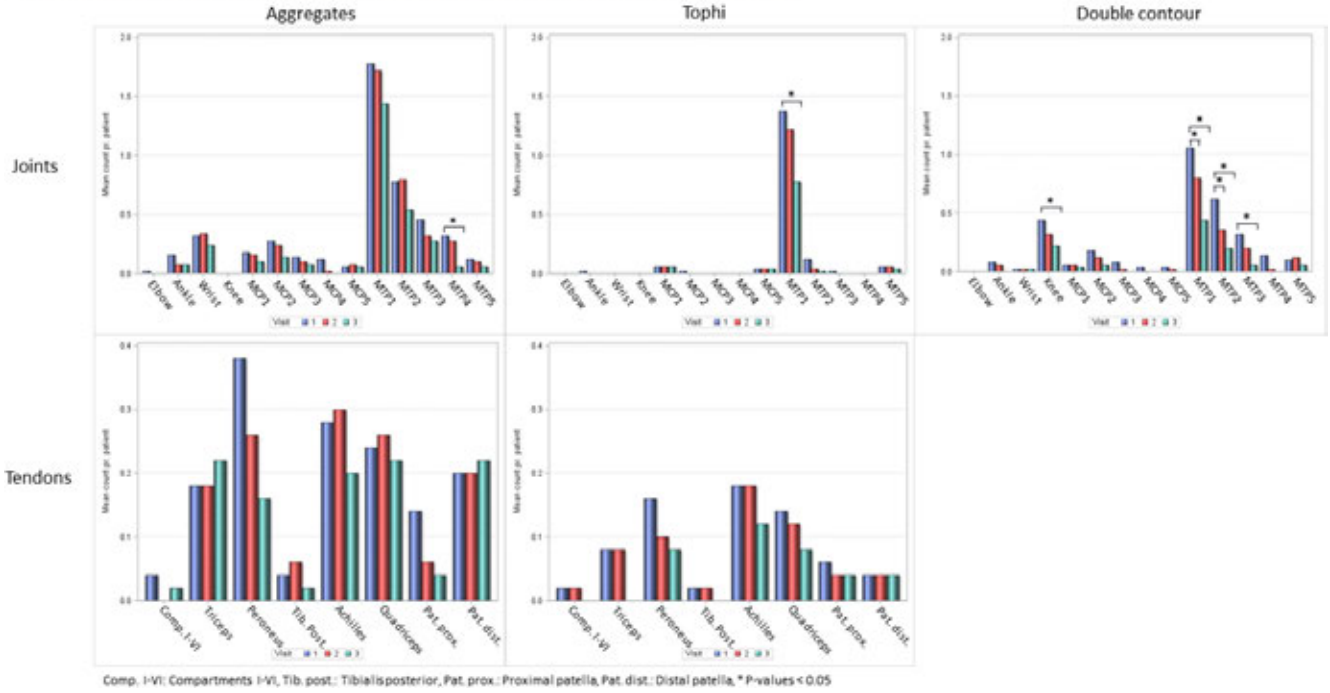
Figure 1: Development in ultrasound structural lesions in joints/tendons during 6 months' follow up



Comp. I-VI: Compartments I-VI, Tib. post.: Tibialis posterior, Pat. prox.: Proximal patella, Pat. dist.: Distal patella, * P-values < 0.05

Results: 50 patients (48 males, 2 females), mean age of 68.9 years (range 30-88) were included. US showed a statistically significant decrease in DC and tophus sum scores from both 0-3 and 3-6 months (table 1). The aggregate sum score only showed a statistically significant decrease from 3-6 months, whereas the erosion sum score was almost unchanged in the follow-up period. GS and CD synovitis sum scores both showed statistically significant decreases at 6 months' follow up, and for CD also from 0-3 months (table 1).

Structural lesions were most commonly found in metatarsophalangeal 1-4 and knee joints, which were also the locations with the most pronounced changes in scores (figure 1).

Tender and swollen joint counts, PROs and number of joint attacks declined statistically significantly from 0-3 months, except for the HAQ, which only declined numerically. P-urate levels decreased statistically significantly from both 0-3 months and 3-6 months (table 1).

No statistically significant differences in US sum score changes during follow up were observed between groups that did/did not obtain the treatment goal.

Conclusion: Of the four US structural gout lesions, DC and tophus showed sensitivity to change after only 3 months of urate lowering therapy, using a binary score, whereas aggregates only showed a change after 6 months follow-up.

This study indicates that US assessment of the OMERACT structural gout lesions, particularly DC and tophus, seems to be a useful tool for monitoring improvement over time. Future studies should investigate whether more sensitive monitoring may be obtained by using a semiquantitative scoring system.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical II: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Tanezumab, a monoclonal antibody inhibiting nerve growth factor (NGF), is under investigation for the treatment of chronic pain conditions. In prior osteoarthritis (OA) studies, intravenous tanezumab was effective and generally well tolerated, and the risk of increased joint damage required further assessment. This study was conducted to evaluate the efficacy and safety of subcutaneous (SC) tanezumab vs NSAID in patients (pts) with OA; findings on the long-term risk of joint safety events are presented here.

Methods: Eligible pts had OA of the hip or knee based on ACR criteria with x-ray confirmation; baseline (BL) WOMAC Pain and Physical Function scores of ≥5 (11-pt numeric rating scale [0-10]); BL Patient's Global Assessment of OA (PGA-OA) of "fair," "poor," or "very poor"; history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance to tramadol or an opioid; or unwillingness to take an opioid. Pts were on a stable dose of oral NSAID before study entry and during screening. Pts were randomized to tanezumab (2.5 mg or 5 mg SC q 8 wk) or NSAID (naproxen 500 mg, celecoxib 100 mg, or diclofenac ER 75 mg orally bid) for 56 wk. Radiographic/magnetic resonance imaging was performed at screening, wk 24 and 56 (treatment period), and wk 80 (safety period). Pts meeting pre-specified criteria for increased severe or persistent joint pain had additional follow-up imaging. All images were evaluated by central reader; joint safety events and total joint replacements (TJR) were adjudicated by blinded committee. Observation time-adjusted rates/1,000 pt-y of adjudicated rapidly progressive OA type 1 or 2 (RPOA1 or 2), primary osteonecrosis, subchondral insufficiency fracture (SIF), and pathologic fracture over 80 wk were analyzed (combined as primary composite joint safety endpoint and individually), as was the TJR rate.

Results: A total of 2,996 pts were randomized, received ≥1 dose of study drug, and were analyzed for joint safety events. During 80 wk of observation, the time-adjusted rate/1,000 pt-y for the primary composite joint safety endpoint was higher with tanezumab 2.5 mg (37.4 [p=0.002]) and tanezumab 5 mg (71.5 [p< 0.001]) than NSAID (14.8) (Table). The majority of joint safety events adjudicated as RPOA were RPOA1 (89 of 107 [83.2%]). Rates of RPOA1 were higher with tanezumab 2.5 mg (28.4 [p=0.005]) and tanezumab 5 mg (49.1 [p< 0.001]) than NSAID (10.9), as were rates of RPOA2 (2.9 [p=0.321] and 13.9 [p=0.001] vs 1.0, respectively). In the tanezumab 2.5 and 5 mg groups, SIF rates were 5.8 (p=0.539) and 6.9 (p=0.364) vs 3.9 in the NSAID group. Primary osteonecrosis occurred in 1 pt in the tanezumab 5-mg group; no pathological fractures were observed. TJR rates were also higher with tanezumab 2.5 mg (51.8 [p=0.003]) and 5 mg (79.7 [p< 0.001]) than NSAID (25.7). Of 159 pts with TJR, 28 (17.6%) had an adjudicated joint safety outcome; in these 28 pts, the event was RPOA1 in 42.9%; RPOA2, 39.3%; primary osteonecrosis, 3.6%; and SIF, 14.3%.

Joint safety outcome	NSAID (n=996)	Tanezumab 2.5 mg (n=1,002)	Tanezumab 5 mg (n=998)
Adjudicated for joint safety*, no. of pts (%)	49 (4.9)	115 (11.5)	171 (17.1)
Adjudicated as normal progression of OA, no. of pts (%)	27 (2.7)	66 (6.6)	79 (7.9)

Rate difference vs NSAID [95% CI]		1.9 [-1.9, 5.8]	12.9 [5.4, 20.4]
p-value		0.321	0.001
TJR, no. of pts (%) [95% CI]	26 (2.6) [1.7, 3.8]	53 (5.3) [4.0, 6.9]	80 (8.0) [6.4, 9.9]
Observation time, pt-y	1,013	1,022	1,004
Observation time-adjusted rate/ 1,000 pt-y [95% CI]	25.7 [17.5, 37.7]	51.8 [39.6, 67.9]	79.7 [64.0, 99.2]
Rate difference vs NSAID [95% CI]		26.2 [9.1, 43.3]	54.0 [33.9, 74.0]
p-value		0.003	<0.001

Statistical method: Poisson model for rate difference.
*Adjudicated joint safety events included possible/probable joint safety events identified by a central reader, TJRs, and investigator-reported adverse events of RPOA, SIF, primary osteonecrosis, or pathological fracture. Dossiers including reports from clinical exams/consultations, available study data and imaging, and narrative of clinical events were provided to a blinded committee for review and adjudication. This adjudication committee of external experts provided the final classification of joint safety events and TJR. †Defined as significant loss of joint space width ≥2 mm (predicated on optimal joint positioning) within approx. 1 year, without gross structural failure. ‡Defined as abnormal bone loss or destruction, including limited or total collapse of ≥1 subchondral surface, that is not normally present in conventional end-stage OA.
CI, confidence interval; NSAID, non-steroidal anti-inflammatory drug; OA, osteoarthritis; pts, patients; pt-y, patient-years; RPOA, rapidly progressive osteoarthritis; SIF, subchondral insufficiency fracture; TJR, total joint replacement

Table. Summary of adjudicated joint safety events and TJR with tanezumab compared with NSAID in pts with OA over 80 wk of observation (56-wk treatment and 24-wk safety period).

Conclusion: In this study, adjudicated joint safety endpoints, particularly RPOA1, and TJR were significantly more common with tanezumab than NSAID. Additional research is ongoing to explore potential reasons for this imbalance and dose-response relationships.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical II: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Evidence of the effectiveness of intra-articular corticosteroid injection for hip osteoarthritis (OA) is limited and conflicting. The HIT trial compared the clinical effectiveness of an ultrasound-guided intra-articular hip injection (USGI) of 40mg triamcinolone acetonide and 4ml 1% lidocaine hydrochloride combined with best current treatment (BCT) with (i) BCT alone (primary objective) and (ii) an USGI of 5ml 1% lidocaine only combined with BCT (EudraCT: 2014–003412-37).

Methods: This was a pragmatic, three-arm, single-blind, randomised controlled trial in adults with painful hip OA recruited from community musculoskeletal services and primary care. Participants were randomised equally to one of three treatment groups: (1) BCT alone, (2) BCT plus USGI of triamcinolone and lidocaine, or (3) BCT plus USGI of lido-

caine only. Outcomes were collected postally at 2 weeks, 2, 4 and 6 months. The primary outcome was self-reported current hip pain intensity (0-10 numeric rating scale (NRS)) over 6 months (repeated measures analysis). Secondary outcomes included pain, stiffness and physical function (Western Ontario and McMaster University Arthritis Index, WOMAC), patient's global impression of change, and pain self-efficacy. 204 participants were required to detect a minimum difference of 1 point in mean pain NRS score between arms (1) and (2) with 80% power (5% two-tailed significance level, 15% loss to follow-up). Analysis was by intention-to-treat.

Results: 199 participants were recruited (43% male, mean age 63 years), 67 to arms (1) and 66 each to arms (2) and (3). Primary outcome completion rates were 95% at 2 weeks, 94% at 2 months, 90% at 4 months, and 89% at 6 months.

Greater mean improvement in hip pain intensity (0-10 NRS) over 6 months was seen with BCT plus USGI of triamcinolone/lidocaine compared with BCT alone: 1: -1.43 (95%CI -0.72, -2.15). Greater mean improvement in pain intensity was seen at 2 weeks (-3.17; -2.28, -4.06) and 2 months (-1.81; -0.92, -2.71), but not at 4 (-0.86; -1.78, 0.05) or 6 months (0.12; -0.80, 1.04). Participants treated with BCT plus USGI of triamcinolone/lidocaine compared with BCT alone had greater mean improvement in function (WOMAC-F -5.47; (-9.41, -1.53)) and pain self-efficacy (5.87; 2.30, 9.45) over 6 months. More participants reported being completely recovered/much better at 2 months with BCT plus USGI triamcinolone/lidocaine than with BCT alone (45.4% v 6.9% RR=6.7; 2.5, 17.9). There was no statistically significant difference over 6 months between BCT plus USGI of triamcinolone/lidocaine compared with BCT plus USGI of lidocaine only for hip pain intensity (-0.52; -1.21, 0.18) or function (-3.60; 7.40, 0.21). There was one treatment-related serious adverse event: a participant with no signs of infection at randomisation died from endocarditis four months after USGI of triamcinolone/lidocaine.

Conclusion: USGI of triamcinolone and lidocaine combined with BCT leads to greater improvements in pain and function over 6 months in adults with hip OA than BCT alone. However, there was no significant difference between the groups receiving USGI of triamcinolone and lidocaine and USGI of lidocaine only raising the possibility of a placebo effect.

Nortriptyline in Knee Arthritis (Nortika): A Randomised Controlled Double Blind Trial of Nortriptyline for Pain in Knee Osteoarthritis

Ben Hudson,[1] Leslie Toop,[2] Jonathan Williman,[1] Gary Hooper,[1] Dee Mangin,[1] John Alchin,[1] Bronwyn Thompson,[1] and **Lisa Stamp** [1], [1]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand, [2]UNiversity of Otago, Chirstchurch, Christchurch, Canterbury, New Zealand

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical II: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Osteoarthritis (OA) is the most common joint disease and is a major cause of pain and disability There is currently no cure for OA and management is focused on relief of pain and maintenance of function

Tricyclic antidepressants (TCAs) have long been used in other chronic pain conditions, but their analgesic effect in OA has not previously been evaluated. To investigate the analgesic effectiveness of nortriptyline in people with OA of the knee.

Methods: We undertook a two-arm parallel-group 1:1 double blind randomised placebo-controlled trial. Participants were recruited from orthopaedic outpatient clinics, primary care, and by public advertising. 205 adults with knee OA as defined by the American College of Rheumatology clinical criteria for the classification of idiopathic OA of the knee, and with pain rated as ≥20 points on the 50 point Western Ontario and McMaster University (WOMAC) pain sub-scale, were randomised to receive either nortriptyline (n=103) or placebo (n=102) in addition to their usual analgesia for 14 weeks. Treatment was divided into a dose-adjustment phase (weeks 0 to 7) and a steady-dose phase (weeks 8 to 14). Participants were instructed to commence taking one capsule (25mg of nortriptyline or placebo) daily for two weeks at which time they were contacted by a research nurse by telephone who advised participants to increase (or decrease) their dose by one capsule per day according to the participant's level of knee pain and adverse effects. Further dose adjustments occurred at four, six and eight weeks, up to a maximum dose of four capsules daily (100 mg nortriptyline daily in the treatment group). Primary outcome was knee pain at 14 weeks measured using the WOMAC pain sub-scale. Secondary outcomes included function, stiffness, non-steroidal anti-inflammatory (NSAID), opioid and/or paracetamol use, participant global assessment, and adverse effects at 14 weeks.

Results: The baseline adjusted mean WOMAC pain subscale score at week 14 was 6.15 points lower (95% CI -0.26 to 12.6, $p = 0.060$) in the nortriptyline vs. the placebo arm. Differences in secondary outcomes generally favoured the nortriptyline arm, but were small and unlikely to be clinically relevant. For example the number needed to treat to achieve one responder was 10 (95% CI = 4.2 to Inf, $p = 0.14$). Dry mouth (87% vs. 51%, $p < 0.001$), constipation (69% vs. 30%, $p < 0.001$), and sweating (31% vs. 21%, $p = 0.033$) were all more commonly reported by participants taking nortriptyline.

Conclusion: This study suggests nortriptyline provides a clinically insignificant reduction in pain in people with knee OA. Adverse effect profile was as expected.

Trial registration: Australian New Zealand Clinical Trials Registry: ACTRN12614000683639.

Abstract Number: 2759

Stopping NSAIDs for Arthritis Pain (SNAP): A Randomized Withdrawal Trial Comparing NSAIDs to Cognitive Behavioral Therapy

Liana Fraenkel,[1] Eugenia Buta,[2] Joseph Goulet,[3] Matthew Brennan,[3] Alicia Heapy,[3] and Lisa Suter[3], [1]Yale School of Medicine and VA Connecticut Healthcare System, New Haven, [2]Yale University/VA CT Healthcare System, New Havne, [3]Yale University/VA CT Healthcare System, New Haven

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical II: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: NSAIDs are associated with uncertain long-term benefits and significant toxicity in patients with knee osteoarthritis (OA). Our objective was to evaluate if discontinuing NSAIDs and engaging in a telephone-based cognitive behavioral therapy (CBT) program is non-inferior to continuing NSAIDs.

Methods: Patients in 4 medical centers, taking NSAIDs for knee OA pain on most days of the week for at least 3 months, were randomized to meloxicam or placebo for 4 weeks (blinded Phase 1). Those on meloxicam continued this medication for 10 weeks while those on placebo participated in a 10-week telephone-based CBT program (unblinded Phase 2). The primary outcome was the WOMAC pain score (LIKERT version) at 4-weeks. The minimum clinically important difference (MCID) is 2.1; the non-inferiority margin was set at 1. Secondary outcomes included time-averaged area under the curve (AUC) pain score at 4-weeks as well as AUC pain, WOMAC pain and disability scores, and global impression of change at end of Phase 2. Data were analyzed using linear regression models adjusted for baseline pain and site. We also estimated the incremental cost effectiveness ratio (ICER) of CBT compared to meloxicam at one year.

Results: 364 participants were randomized: 180 to placebo followed by CBT and 184 to meloxicam. Baseline demographic and clinical characteristics were well-balanced (Table 1). The overall mean pain at baseline was 5.6 (SD= 3.8). At 4 weeks, the raw mean pain score increased to 7.77 (SD= 4.01) in the placebo group and 6.75 (SD= 3.81) in the meloxicam group. After adjusting for baseline pain and site, the mean pain difference between placebo and meloxicam at 4 weeks was 1.35 (95% CI= 0.61 to 2.09, non-inferiority test p-value= 0.82). At week 14, the adjusted mean pain difference between placebo and meloxicam was 1.19 (95% CI= 0.39 to 1.99), non-inferiority p-value= 0.68). Mean pain scores over time (smoothed estimates) are illustrated in the Figure. There was no evidence of a difference in the global impression of change (p= 0.15) or lower extremity disability (p= 0.45) between the two groups at the end of Phase 2. Except for dyspepsia, which was more common in the meloxicam group (7.6% vs 0.6%), there were no significant differences in adverse events across groups. The ICER for CBT compared to continued meloxicam was $22,126.92 per quality-adjusted life year (QALY) gained. One-way sensitivity analyses of all input parameters across their plausible ranges showed that CBT remained cost-effective (ICERs < $100,000/QALY gained) compared to meloxicam.

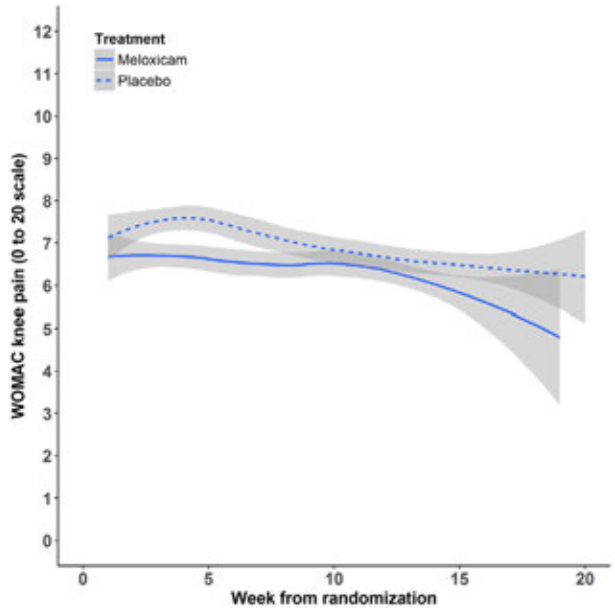
Table 1. Participant Characteristics at Baseline

Characteristic	Placebo (n=180)	Meloxicam (n=184)	Overall (n=364)
Mean age, mean (SD)	58.2 (11.8)	58.5 (10.0)	58.4 (10.9)
Male, n (%)	161 (89.4)	154 (84.2)	315 (86.8)
Non-Hispanic White	120 (66.7)	112 (60.9)	232 (63.7)
4-year college degree or higher, n (%)	65 (36.1)	56 (30.4)	121 (33.2)
Full time employee/student, n (%)	73 (40.6)	73 (39.7)	146 (40.1)
Excellent/very good health status, n (%)	49 (27.2)	62 (33.7)	111 (30.5)
BMI, mean (SD)	33.9 (7.1)	33.4 (7.2)	33.7 (7.2)
Psychiatric comorbidity, n (%)	88 (49.2)	96 (52.2)	184 (50.7)
WOMAC pain (0 to 20), mean (SD)	5.4 (3.8)	5.9 (3.9)	5.6 (3.8)
WOMAC disability (0 to 68), mean (SD)	17.5 (12.1)	17.9 (11.9)	17.7 (12.0)

Table 2. Primary and Secondary Analysis Results

Outcome	Placebo		Meloxicam		Adjusted Difference Placebo vs. Meloxicam	
Primary Analysis	**N**	**LS Mean (SE)**	**N**	**LS Mean (SE)**	**Mean (95% CI)**	**p-value**
WOMAC knee pain at week 4	152	8.08 (0.3)	169	6.73 (0.28)	1.35 (0.61, 2.09)	0.82[1]
Secondary Analyses	**N**	**LS Mean (SE)**	**N**	**LS Mean (SE)**	**Mean (95% CI)**	**p-value**
WOMAC knee pain at week 14 (0 to 20)	140	7.08 (0.32)	146	5.89 (0.32)	1.19 (0.39, 1.99)	0.68[1]
WOMAC knee pain in final week[3] (0 to 20)	176	6.64 (0.27)	179	6.05 (0.27)	0.58 (-0.10, 1.27)	0.12[1]
WOMAC knee pain AUC weeks 1 to 4 (0 to 20)	167	7.73 (0.23)	173	6.65 (0.23)	1.07 (0.49, 1.65)	0.0003[2]
WOMAC knee pain AUC over all weeks (0 to 20)	175	7.48 (0.21)	179	6.43 (0.21)	1.06 (0.53, 1.58)	<0.0001[2]
Global impression of change (1=Much better, 5=Much worse)	160	2.15 (0.08)	176	2.30 (0.08)	-0.15 (-0.36, 0.05)	0.15[2]
WOMAC disability in final week (0 to 68)	160	19.69 (0.93)	176	18.81 (0.88)	0.88 (-1.41, 3.17)	0.45[2]

1. Non-inferiority (1-sided); alpha=.025
2. Difference (2-sided); alpha=.05
3. Last observation carried forward



Conclusion: Among patients with knee OA, we could not conclude that placebo and placebo followed by CBT is non-inferior to meloxicam within a non-inferiority margin of 1. However, the pain score differences between the two groups was small (less than the MCID of 2.1) and there was no difference in participants' global impression of change or function at 14 weeks. Telephone-based CBT is cost effective compared to meloxicam.

Durable Clinical Response up to Day 64	6 (15.0%)	4 (10.0%)	14(34.1%)	0.0365
Durable Clinical Response up to Day 94	5 (12.5%)	4 (10.0%)	12(29.3%)	0.0566
Comparison	**Day**	**Difference in Proportions (%)**	**95% CI[b]**	**p-value**
CGS-200-1 – CGS-200-0	35	7.5	(-15.5, 29.9)	0.5679
	64	-5.0	(-27.6, 18.0)	0.7370
	94	-2.5	(-25.2, 20.4)	1.0000
CGS-200-5 – CGS-200-0	35	21.6	(0.5, 42.4)	0.0415
	64	19.1	(-2.0, 40.1)	0.0703
	94	16.8	(-4.5, 37.8)	0.1004
CGS-200-5 – CGS-200-1	35	14.1	(-7.0, 35.6)	0.2246
	64	24.1	(3.0, 44.7)	0.0148
	94	19.3	(-2.0, 40.1)	0.0488

Notes: Only the assessment from "study knee" was included in the analysis.
Responder represents a reduction of at least 50% in WOMAC OA pain score from baseline. Subjects with missing data were considered a non-responder for that visit.
Percentages are based on the total number of mITT subjects in each treatment group (N).
Durable clinical response analysis is performed based on Section 6.3 in the SAP.

[a] Trend Test p-value was calculated using the Cochran-Armitage trend test.

[b] The 95% Confidence Interval (CI) of the difference in proportions and p-value are calculated using exact method.

Background/Purpose: There is considerable unmet medical need for an osteoarthritic knee pain (OAKP) treatment that does not require regular daily use, does not carry gastrointestinal risk (e.g., NSAIDs), liver risk (e.g., acetaminophen) or addiction risk (e.g., opiates), and can safely provide long-lasting pain relief after a brief course of treatment. The Sponsor has clinically shown that topical OTC-strength 0.25% (w/w) capsaicin is well tolerated and provides OAKP relief. The Sponsor has now produced in the same vehicle (CGS-200) high potency, 5% (w/w) capsaicin (CGS-200-5) and 1% (w/w) capsaicin (CGS-200-1) topical products to evaluate as treatments for the relief of OAKP using the WOMAC subscales for pain, stiffness and function as well as total WOMAC score.

Methods: This was a multi-center, randomized (1:1:1), double-blind, parallel group, vehicle-controlled trial comparing topical CGS-200-1 or CGS-200-5 versus CGS-200-0 in 122 randomized subjects who had OA of at least one knee according to 1986 ACR criteria and a WOMAC pain score of ≥ 250. Subjects continued ongoing non-prohibited analgesic medication(s) (e.g., oral NSAIDs) at study entry with the expectation that the daily dose was to be maintained throughout the study if possible. Treatment was applied for 1 hour to both knees on 4 consecutive days (Study Days 1-4) by the subject under clinic supervision and then washed off. Clinical efficacy and safety assessments were made on Study Days 5, 19, 35 (the primary endpoint was Day 35 change in WOMAC pain score from baseline), 64, and 94. The modified intent to treat (mITT) subset of subjects was used for all efficacy analyses.

Results: CGS-200-5, but not CGS-200-1, met the primary Day 35 OAKP WOMAC pain efficacy endpoint compared to vehicle ($p = 0.020$, mITT population) and post-hoc analysis showed statistical separation from CGS-200-0 (Vehicle) on Days 64 ($p = 0.0001$) and 94 ($p = 0.0111$) **(Table 1)**. Post-hoc analysis showed a statistical difference in WOMAC OA total scores between both treatment groups and Vehicle at Days 35, 64 and 94 **(Table 2)**. The proportion of subjects with a durable clinical response (WOMAC pain reductions ≥ 50% on all study day visits minus one) was higher in the CGS-200-5 group at all visits **(Table 3)**. A slightly larger percentage of CGS-200-5 patients reported ≥ 1 TEAEs (all were mild or moderate in severity) compared to the CGS-200-0 or CGS-200-1 arms, with little difference between groups in the types of TEAEs. Application site pain (mostly mild to moderate) was observed in all treatment groups, with a higher proportion of subjects in the CGS-200-5 group experiencing pain than the CGS-200-5 group. The mean tolerability AUCs in both active treatment groups decreased with each consecutive dosing day.

Conclusion: CGS-200-5 was well-tolerated and efficacious following application to both knees for 60 minutes on 4 consecutive days. Due to the significant efficacy and good safety and tolerability observed in this study, further clinical development of CGS-200-5 is warranted.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Osteoarthritis – Clinical II: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Results from the 5-year Phase II FORWARD study showed significant dose-dependent modification of total femorotibial joint (TFTJ) cartilage thickness change with sprifermin at 2 and 3 years, by quantitative MRI. Total WOMAC scores improved by ~50% in all treatment groups, including placebo (PBO). Selection of a patient (pt) subgroup with higher pain scores and lower joint space width (JSW) at baseline (BL), to identify pts who are at higher risk of further structural and symptomatic progression, may facilitate better WOMAC discrimination.

We undertook a post-hoc analysis to evaluate cartilage thickness changes and symptomatic outcomes in an 'at risk' subgroup (BL medial or lateral minimum [m]JSW 1.5–3.5 mm and BL WOMAC pain score of 40–90 on a scale of 0-100).

Methods: Pts in FORWARD were randomized 1:1:1:1:1 to: sprifermin 100 µg every 6 months (q6mo); 100 µg q12mo; 30 µg q6mo; 30 µg q12mo; and PBO. The treatment period was 2 years, with an extended follow up of 3 years. Post-hoc analysis was conducted in the 'at risk' subgroup.

Changes over time are presented using descriptive statistics and CIs. Treatment benefits were estimated using a repeated measures model, controlling for BL, treatment, time, pooled country and treatment by time interaction. Linear dose-effect trend tests were performed exploratively at each timepoint. Confidence intervals (CIs) for treatment benefit were adjusted for multiplicity of treatments using Dunnett adjustment.

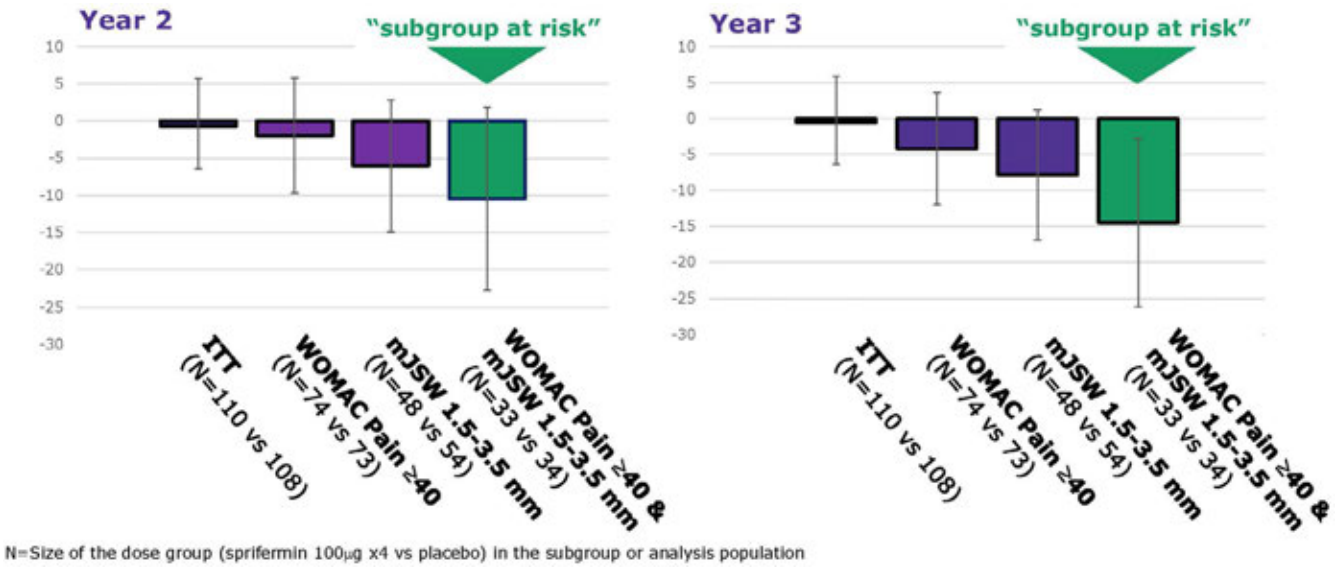

Figure 2. Observed mean differences [95% CI] in WOMAC pain scores for sprifermin 100 µg q6mo vs PBO across different risk subgroups at 2 and 3 years

Results: 161/549 (29%) pts met criteria for the 'at risk' subgroup. In this subgroup, BL characteristics were quite balanced between treatment arms. Pts in the PBO arm had more cartilage loss at 2 and 3 years vs the modified intent-to-treat (mITT) PBO arm (mean change from BL in mm [SD]: Year 2 -0.05 [0.10] vs -0.02 [0.07]; Year 3 -0.07 [0.09] vs -0.05 [0.07]), but TFTJ net cartilage modification with sprifermin 100 µg q6mo vs PBO was similar (adjusted mean difference from PBO [95% CI] in the 'at risk' subgroup vs the mITT group: Year 2 0.06 [0.01, 0.11] vs 0.05 [0.02, 0.08]; Year 3 0.05 [-0.01, 0.12] vs 0.05 [0.02, 0.09]). At Year 3 (18 mos after last injection), the mean difference [95% CI] in WOMAC pain score for sprifermin 100 µg q6mo vs PBO in the 'at risk' subgroup was -8.75 [-22.42, 4.92] vs 0.97 [-6.22, 8.16] for the intent-to-treat (ITT) population (Fig 1). The exploratory dose-effect trend test using the adjusted values had a nominal p-value of < 0.05 (Table 1). Having both medial or lateral mJSW 1.5–3.5 mm AND pain score ≥40 at BL led to greater differentiation in WOMAC pain scores for sprifermin 100 µg q6mo vs PBO than having either BL characteristic alone (Fig 2).

Conclusion: Despite substantial structural and symptomatic progression in the 'at risk' subgroup, structural improvement with sprifermin was maintained, and WOMAC score improvements vs PBO increased over time and were significant at Year 3. This supports further investigation of sprifermin as a potential disease-modifying osteoarthritis drug in a targeted population where structural improvement may translate into symptomatic benefit vs PBO within a reasonable timeframe.

The Preparation and Recovery Experience from Total Knee Replacement of Patients with Osteoarthritis: A Qualitative Study

Iris Navarro-Millan,[1] Sarah Young,[2] Geyanne Lui,[1] Marianna Frey,[3] Janey Peterson,[1] Susan Goodman,[4] Monika Safford,[1] and Lisa Mandl[5], [1]Weill Cornell Medicine, New York, [2]Binghamton University, Binghamton, [3]Hospital for Special Surgery, New York, NY, New York, [4]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY, [5]Hospital for Special Surgery/Weill Cornell Medicine, New York, NY, New York, NY

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes II: Patient Preferences, Beliefs, & Experiences

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Up to 30% of patients may have persistent pain post-total knee arthroplasty (TKA). One possible approach to improve these outcomes is to optimize muscle strength, physical condition, and mental preparation before surgery. Our purpose was to elicit patients' experiences with TKA with the goal of understanding the utility and logistics of implementing a *pre*-habilitation program delivered by peer coaches (i.e. a patient who has already undergone a TKA and has been trained to provide personalized pre-TKA support).

Methods: Qualitative study guided by Social Cognitive Theory (SCT). SCT posits that direct personal agency (*self-efficacy*), proxy agency *(peer or social support); sociocultural factors*, and *outcome expectations* influence *goals* and *outcomes.* Patients were > 65 years old from Hospital for Special Surgery and have had primary TKA with good clinical outcome, defined as a Knee Injury and Osteoarthritis Outcome Score (KOOS) score >65 one year post-operatively. We asked patients about their challenges before and after TKA, potential barriers to accessing a pre-habilitation program and perspectives on what it might be like working with a peer coach to encourage regular exercise prior TKA. We analyzed the data thematically using *a priori* coding that corresponded to SCT constructs.

Results: We conducted four focus groups and two individual interviews (N = 31). Mean age was 75 years (6.85 SD); age range 65-89 years of age. Forty-eight percent had previously had a primary TKA on their contralateral knee. Overall, 61% (N = 19) were women and 90% (N= 28) were white. Table 1 shows the major themes that emerged, grouped by SCT constructs supported patient quotes. Patients with high outcome expectations who were undergoing their contralateral primary TKA learned from their first experience and reported feeling motivated to engage in physical activity before their contralateral TKA (*Theme 1*). Patients expressed that they did not know what type of exercises were good for them once they decided to have a TKA (*Theme 2*). Patients, for whom this was their first TKA, stated that connecting with another patient who already had a TKA was important in their decision making to choose TKA, also in how to prepare for TKA (*Theme 3*). These participants articulated they had gained knowledge from the experience of having a previous primary TKA, and were able to identify factors they felt were important to have a good outcome after TKA (*Theme 4*). They expressed that working with a peer coach would be beneficial for both preparation and recovery from TKA (*Theme 5*).

Conclusion: Preparation and expectations for TKA were influenced by patients' own prior experience with TKA and the experience of other patients who already had TKA. Patients expressed that their own experiences with TKA made them more informed, self-efficacious, and physically active to prepare for their contralateral primary TKA. These data suggest that a formal peer-to-peer intervention that prepares patients for their first TKA by interacting with an experienced post-TKA patient about the mental and physical preparation to undergo TKA was of interest to patients and could help improve TKA outcomes.

Table 1: Themes that Emerged from Focus Groups and Interviews with Patients who had Primary Total Knee Arthroplasty (TKA) with the Corresponding Social Cognitive Theory Construct and Patients' Quotes

Themes	Social Cognitive Theory Construct	Patients' Quotes
1) Expectations from TKA on the basis of previous experience with TKA	Outcome expectation	*Because the second [knee] was much easier than the first, and I think that is because I had gone through it once, and I kind of knew what to expect.* *When I was going to physical therapy after the first surgery, I definitely used to say to the PT, "I want to deal with my other leg too." I wanted to be strong when I have this [going into the surgery for the other knee]. So I learned from surgery one. What I wanted to do for surgery two.* *When I came to the second knee, I knew all about it. I had been doing the exercise before there was pain [in the other knee].*
2) Limited knowledge on how to prepare for TKA	Socio-cultural Factors (Limited resources or knowledge about exercises)	*My surgeon did not say anything about any exercise pre-surgery...* *I was swimming of all things. The thing I wish I would had done before the knee replacement was more strength training. I mean, I was foolish not to do a lot more lower body strength training.* *I think that if I got the doctor's orders to exercise before (TKA), that I would do it.*
3) Advice from other patients about preparation and recovery from TKA.	Peer/Social support Self-efficacy	*I know somebody who had knee surgery, and he told me he had it done and it was pretty good. So I said, "Okay, I'll try it." Just the fact that this person had it done and was okay, that was good enough for me.* *I talked to somebody who had knee surgery and they said, "I made a mistake." he said, "I want to tell you about it so you don't do it. When you were told about the exercises to do in recovery", he said, "follow those absolutely to the letter. If you do, you will be okay. I had to go back in and have my surgery redone."*
4) Advice to other patients about preparation and recovery from TKA.	Self-efficacy Outcome expectation	*Prepare yourself mentally, physically for that event (TKA).* *When I do get a word in edgewise of people who are going to be doing knee replacement surgery, my biggest thing is just do strength exercises. You do not need cardio; you need strength exercises.* *Get yourself; get your legs as strong as you can before you do it (TKA) because it's not going to be fun afterwards.* *As far as afterwards, I think you really have to follow the physical therapy. If you go to physical therapy two, three times a week, you still have to, on your own, on the other days, keep doing the exercises.*
5) Perceptions of working with a peer coach	Peer support	*I would think that a peer coach would have more time to spend (with you) than a doctor.* *I think it's an excellent idea (having a peer coach) because it's one thing if you have a lot of friends and you're sitting across the bridge table, let's say I'm going to have surgery. It's an imposition to ask friends to help you out with this. That I think somebody who has had some kind of training and it's more or less of a professional relationship, I think it's a much better idea.*

What Disease Do You Have? – Assessment and Predictors of Accurate Illness Naming in Rheumatology

Jacob Meindertsma,[1] Kara Harrison,[1] Nicholas Lucchesi,[1] and Adam Carlson[1], [1]University of Virginia, Charlottesville, VA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes II: Patient Preferences, Beliefs, & Experiences
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Shared decision making remains central to the effective treatment of many rheumatologic conditions and is most appropriate when the patient and physician agree on which disease is being treated. Several studies in the oncology literature have shown that patients frequently do not understand their cancer diagnosis, including what stage of cancer or whether their cancer is in remission. Few studies to date have investigated whether patients with rheumatic disease have an accurate understanding of the diagnoses for which they are receiving treatment. In this study, we sought to assess the concordance between physician and patient reported diagnoses and factors associated with this concordance.

Methods: Over a four-week period in 2019, established patients presenting for a follow up visit in the University of Virginia Rheumatology Clinic were asked to complete a brief questionnaire. This questionnaire included self-reported diagnoses, an assessment of current disease activity, and demographic information. Patient reported diagnoses were compared with the diagnoses recorded by their rheumatologist in the electronic medical record. Allowing for misspellings and multiple answers, patients were considered concordant as long as one diagnosis was correctly identified. Eight patient characteristics including demographic and disease-specific variables were then compared between the concordant and discordant groups using chi-squared testing or Fisher's exact test as appropriate.

Results: A total of 170 patients completed the questionnaire. Forty-two of 170 patients wrote responses that did not match their rheumatologist's documented diagnosis (75.3% concordant, 24.7% discordant). Statistically significant predictors of discordance were non-white race ($p = 0.02$), non-English first language ($p = 0.008$), an annual household income below $50,000 ($p = 0.007$), and fewer years of completed education ($p < 0.001$). Predictors that did not associate with concordance were age, sex, disease length, and the type of disease (e.g. connective tissue disease, arthritis, vasculitis, etc.). Binary logistic regression modeling indicated that postgraduate education was the best predictor of concordance with an adjusted odds ratio of 3.4 ($p = 0.002$). Interestingly, patients who incorrectly named their diagnosis had a significantly higher score on a self-reported 100mm visual analog scale of global disease activity with an average of 34mm in the concordant group vs. 56mm in the discordant group ($p < 0.001$).

Conclusion: One quarter of surveyed patients inaccurately named their documented rheumatologic diagnosis. Poor agreement between patient and physician reported diagnoses spanned all types of rheumatic disease and was best predicted by lower levels of education. Poor agreement on diagnoses was also associated with higher patient reported global disease activity. This study reinforces the importance of addressing poor disease understanding in order to improve shared decision making between patients and their rheumatologists.

Medication Necessity and Concerns Beliefs Are Distinct, Interactive Predictors of Treatment Adherence in Rheumatoid Arthritis

George Karpouzas,[1] Elizabeth Hernandez,[2] Lorena Ruiz,[3] Vibeke Strand,[4] and Sarah Ormseth[1], [1]Harbor-UCLA Medical Center and Los Angeles Biomedical Institute, Torrance, CA, [2]Harbor-UCLA and Los Angeles Biomedical Institute, Torrance, CA, [3]Harbor-UCLA andLos Angeles Biomedical Research Institute, Torrance, [4]Division of Immunology/ Rheumatology, Stanford University, Stanford, CA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes II: Patient Preferences, Beliefs, & Experiences

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Medication adherence is instrumental for the successful management of rheumatoid arthritis (RA) to a goal of remission. Awareness of medication necessity and concerns regarding its use influence adherence and respectively foster or undermine the achievement of treatment goals. We here explored the unique and interactive roles of patient beliefs about the necessity of RA medications and concerns about them in predicting adherence to prescribed treatments.

Methods: We evaluated 316 patients with established RA from a single center. Beliefs about the necessity of RA medications and concerns regarding their use were evaluated with the Beliefs about Medicines Questionnaire-Specific (BMQ) Necessity and Concerns scales (range 5-25). Self-reported rheumatoid arthritis treatment adherence was assessed using the Simplified Medication Adherence Questionnaire (SMAQ, range 0-6). Multivariable linear regression evaluated the effects of necessity, concerns and their interactions with adherence. A latent profile analysis (LPA) subsequently classified patients in groups according to patterns of necessity and concerns; adherence scores were then compared across latent groups using analysis of covariance (ANCOVA).

Results: Full adherence (SMAQ score 6/6) was reported by 101 (32%) patients. Necessity and concerns had independent and opposing contributions to adherence (β=0.21 and β=-0.28 respectively, both $p< 0.001$, figure 1a) even after adjustments for age, gender and disease duration. An interaction between necessity and concerns with adherence was also observed (p=0.009); post-hoc simple-slope tests indicated that necessity predicted adherence in the context of

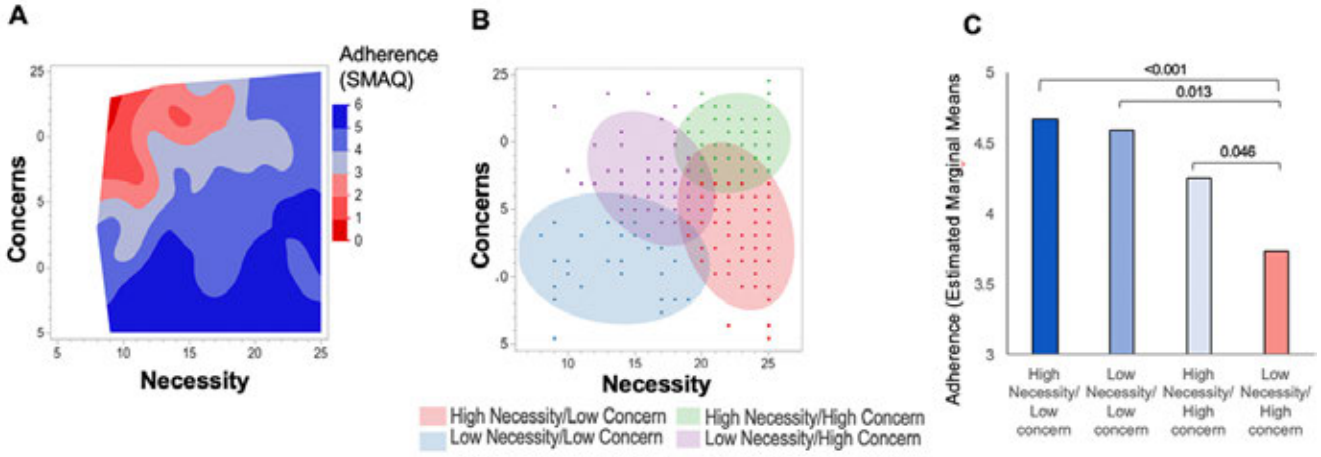

Figure 1: Effect of interaction between Necessity and Concerns on RA medication adherence.

increasing concerns. The Johnson-Neyman technique revealed that while concerns were significantly associated with adherence across the entire range of necessity scores,necessity was significantly related to adherence only at high BMQ Concerns scores (³13).LPA revealed four latent patient groups (figure 1b): Low necessity/ Low concerns (indifferent, n=33), Low necessity/ High concerns (skeptical, n=70), High necessity/ High concerns (ambivalent, n=92) and High necessity/ Low concerns (accepting, n=121). Adherence varied across groups even after adjusting for between-group differences (p=0.002, Figure 1c); adherence was highest in the accepting group and lowest in the skeptical group.

Conclusion: The relationship between necessity and concern beliefs regarding RA medications significantly influences adherence behavior and may further direct physicians to effectively tailor their education efforts in diverse patient groups. A message aimed at reducing concerns might be more effective in the ambivalent group, whereas emphasizing medication necessity may be more fruitful in the skeptical group.

Abstract Number: 2765

Assessing the Impact of Digital Health Coaching on Quality Adjusted Life Years, Symptom Severity and Disease Activity in Patients with Rheumatoid Arthritis

Matt Allsion,[1] Michael McMorris,[2] Dhiren Patel,[2] and B Stephen Burton[3], [1]Pack Health, Birmigham, AL, [2]Pack Health, Birmingham,[3] Pack Health, Birmingham, AL

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes II: Patient Preferences, Beliefs, & Experiences
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Rheumatoid arthritis (RA) is the most common autoimmune inflammatory arthritis in adults. RA has a significant negative impact on the ability to perform daily activities, including work and household tasks as well as health-related quality of life. Improving patients' quality of life by reducing symptoms and reducing functional limitations are some of the goals of RA treatment. This prospective study (n=314) examines the impact of a digital health coaching intervention on an RA population measured by quality-adjusted life years (QALY) as well as symptom severity and disease activity. One QALY equates to one year spent in perfect health and the PROs measure individual aspects of overall RA health.

Methods: RA patients (n=314) were recruited from sources such as the ACR RISE registry, clinical referral, consented, and enrolled in a 12-week digital health coaching behavior modification program with data collection at baseline and upon completion in the program. Information about mental and physical health was collected through Patient-Reported Outcomes Measurement Information System (PROMIS) Global Health-10. Using a formula developed by Revicki et al.1 and patient responses to the PROMIS Global-10 assessment, a calculation on the number of added

QALYs was made for patients receiving the intervention. In addition to PROMIS, the CASE Adherence Index was used to measure medication adherence and patients reported the number of flares they experienced the previous month before and after the intervention.

Results: Results indicate significant improvements in average PROMIS Mental Health score (pre = 42.2 vs post = 48.3, p< 0.001) and PROMIS Physical Health Score (pre = 37.4 vs post = 41.5, p< 0.001) for RA patients with a result of 1.8 QALY. In addition, the average number of flares dropped by 50% (pre = 6.6 vs post = 3.3) and medication adherence improved by 11% (pre = 69% vs post = 80%).

Conclusion: The results of the study indicate that digital health coaching improves healthy behaviors, overall quality of life and decrease RA symptoms. Future studies should examine the impact of coaching in various segments of RA patients such as underserved, those with multiple comorbidities and those newly diagnosed versus patients living with RA for multiple years.

Abstract Number: 2766

Patient Preferences for Attributes of Treatments for Chronic Pain Associated with Osteoarthritis Pain and Chronic Low Back Pain That Differentiate Nerve-Growth Factor Inhibitors, Nonsteroidal Anti-inflammatory Drugs, and Opioids in the United States: A Discrete-Choice Experiment

Dennis Turk,[1] **Marco Boeri**,[2] Lucy Abraham,[3] Brett Hauber,[4] Joanna Atkinson,[3] Andrew Bushmakin,[5] Joseph Cappelleri,[5] Leo Russo,[6] Lars Viktrup,[7] and David Walsh[8], [1]University of Washington, Seattle, [2]RTI Health Solutions, Belfast, Northern Ireland, United Kingdom, [3]Pfizer, LTD, Surrey, England, United Kingdom, [4]RTI Health Solutions, Research Triangle Park, NC, [5]Pfizer Inc, Groton, CT, [6]Pfizer, Inc., Collegeville, PA, [7]Eli Lilly and Company, Indianapolis, IN, [8]Sherwood Forest Hospitals NHS Foundation Trust, Nottingham, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes II: Patient Preferences, Beliefs, & Experiences
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Monoclonal antibodies that inhibit nerve growth factor (NGF-abs) may offer an alternative to current nonsteroidal anti-inflammatory drug (NSAID) and opioid treatments for osteoarthritis (OA) pain and chronic low back pain (CLBP). NGF-abs differ from these treatments in several ways, including mode of administration, duration of effect, efficacy, and safety. NGF-abs also avoid some adverse effects (AEs) associated with opioids and NSAIDs—risk of physical dependence and cardiovascular risks, respectively. However, they may be associated with the risk of rapidly progressive OA (RPOA) and other AEs not seen with opioids or NSAIDs. Our objective was to quantify patients' preferences for attributes of treatments for chronic moderate-to-severe musculoskeletal pain associated with OA and CLBP that both differentiate NGF inhibitors, NSAIDs, and opioids and are relevant to patients.

Methods: We used a discrete-choice experiment (DCE) to elicit preferences for attributes of OA and CLBP pharmaceutical treatments. The survey was completed by 602 United States residents with a self-reported physician diagnosis of hip or knee OA only, CLBP only, or comorbid OA and CLBP (OA/CLBP) diagnosed at least 3 months ago. Respondents had self-assessed moderate-to-severe pain in the hip, knee, and/or lower back, defined as a

rating of 5 or greater on average in the past week on an 11-point numeric rating scale ranging from 0 (no pain) to 10 (worst possible pain). Respondents had to have taken or tried (a) 3 or more classes of pain treatment in the past 2 years, or (b) 2 prior classes of treatment if NSAIDs were contraindicated or if the patient refused to take opioids, or (c) 1 prior class of treatment if both NSAIDs were contraindicated and opioids were refused. In the DCE, respondents chose between two hypothetical treatments in a series of questions. Each hypothetical treatment was defined by six attributes: pain and symptom control, risk of RPOA, risk of heart attack, risk of physical dependence, mode and

Table 1. Attributes and Levels Included in the Discrete-Choice Experiment

Attribute	Attribute Label	Attribute Levels	
Pain and symptom control (patient global assessment)	**Symptom control:** Symptom control while you are taking the medicine	Very good (no symptoms; no limitations on normal activities)	
		Good (mild symptoms; no limitations no normal activities)	
		Fair (moderate symptoms; limitations on some normal activities)	
		Poor (severe symptoms; unable to carry out most normal activities)	
Incremental treatment-related risk of rapidly progressive osteoarthritis (RPOA)	**Additional risk of severe joint problems:** Additional risk each year of having joint problems that are severe enough that you would need a total joint replacement while you are taking the medicine or within 6 months of stopping the medicine	No additional risk (0%)	
		5 people out of 1,000 (0.5%)	
		40 people out of 1,000 (4%)	
Incremental treatment-related risk of heart attack	**Additional risk of heart attack:** Additional risk each year of having a heart attack while you are taking the medicine	No additional risk (0%)	
		2 people out of 1,000 (0.2%)	
		5 people out of 1,000 (0.5%)	
Treatment-related risk of physical dependency	**Risk of physical dependency:** Risk each year of becoming physically dependent on the medicine	No risk (0%)	
		50 people out of 1,000 (5%)	
		250 people out of 1,000 (25%)	
Mode and frequency of administration	**How you take the medicine**	Oral pills 2 or more times a day	
		Oral pills once a day	
		Injection every 4 weeks (about once a month)	
		Injection every 8 weeks (about once every two months)	
Variable created for scope test (not visible to respondents)[a]		Narrow range	Wide range
Personal (out-of-pocket) monthly cost	**Cost:** Personal cost of the medicine to you every month	$0 every month	$30 every month
		$55 every month	$75 every month
		$85 every month	$110 every month

[a] To implement a scope test, respondents were assigned to one of the 2 cost-value ranges in the DCE questions—a narrow or wide range of cost values. This table shows the levels for cost in both the narrow and wide ranges that were include in the DCE questions.

frequency of administration, and cost (Table 1). A random parameters logit model was used to estimate preferences and conditional relative attribute importance.

Results: Patients with OA pain only (n = 201), CLBP only (n = 202), and comorbid OA/CLBP (n = 199) completed the survey. Mean (SD) age was 63.7 (10.8) years. Mean (SD) current pain ratings for OA and CLBP were 6.4 (1.6) and 6.6 (1.4), respectively (Table 2). The relative importance of non-cost treatment attributes (mean [SE]) in descending order, rescaled so that the most important attribute was 10, was: improvement in pain and symptoms (10.00 [1.04]), risk of

T

Table 2. Characteristics of Respondents

Respondent Characteristic		OA Only (n = 201)	CLBP Only (n = 202)	OA/CLBP (n = 199)	Full Sample (N = 602)
Gender	Male	70 (34.8%)	110 (54.5%)	66 (33.2%)	246 (40.9%)
	Female	131 (65.2%)	92 (45.5%)	133 (66.8%)	356 (59.1%)
Age	Mean (SD)	65.7 (8.7)	60.1 (12.8)	65.2 (9.5)	63.7 (10.8)

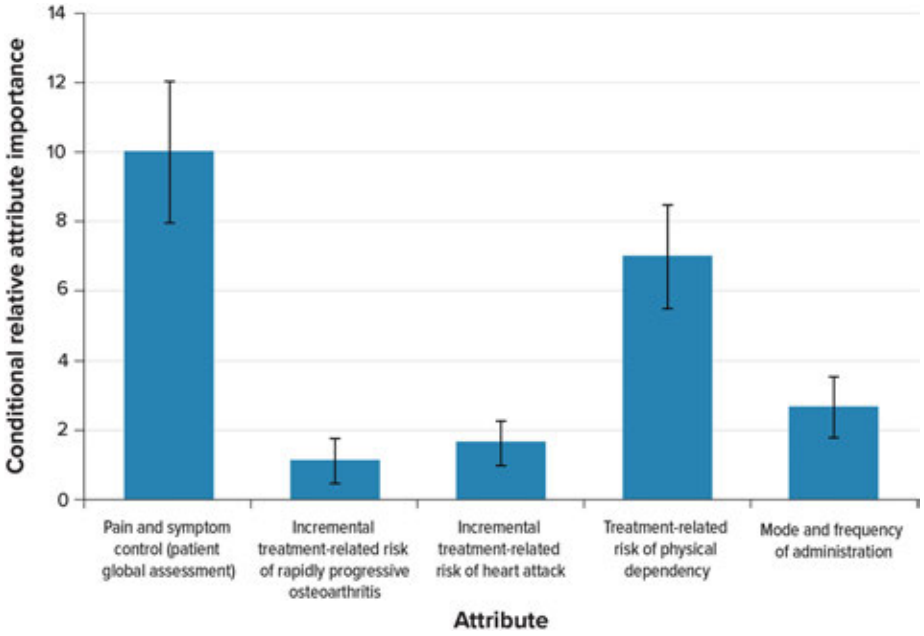
	Mean pain level (SD)	—	6.6 (1.2)	6.6 (1.6)	6.6 (1.4)
	Median pain level	—	6	7	7

CLBP = chronic low back pain; max = maximum; min = minimum; OA = osteoarthritis; SD = standard deviation.
[a] Respondents could provide multiple responses to these questions. Therefore, the totals may exceed the total number of respondents.



physical dependence (6.99 [0.74]), mode and frequency of administration (2.66 [0.43]), treatment-related risk of heart attack (1.64 [0.31]), and treatment-related risk of RPOA (1.10 [0.32]) (Figure 1).

Conclusion: Respondents were willing to accept substantial treatment-related risks to improve pain and symptoms of OA and CLBP and avoid the risk of physical dependence. Having effective alternatives to opioids is important to patients. In patients for whom NSAIDs are contraindicated, providing an effective treatment other than opioids or NSAIDs may be particularly important.

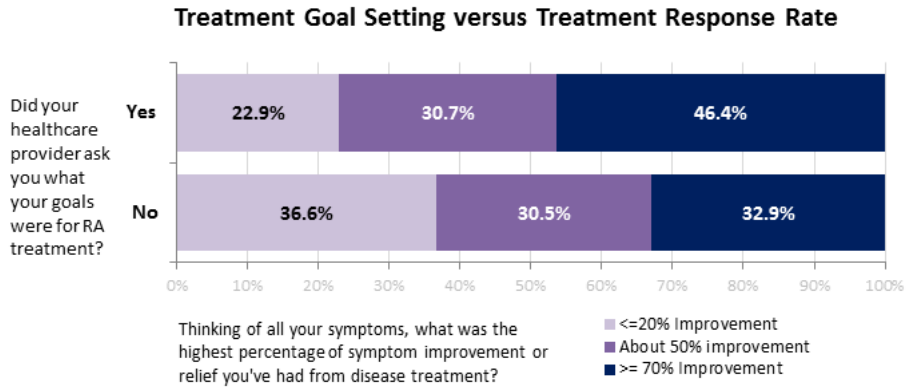
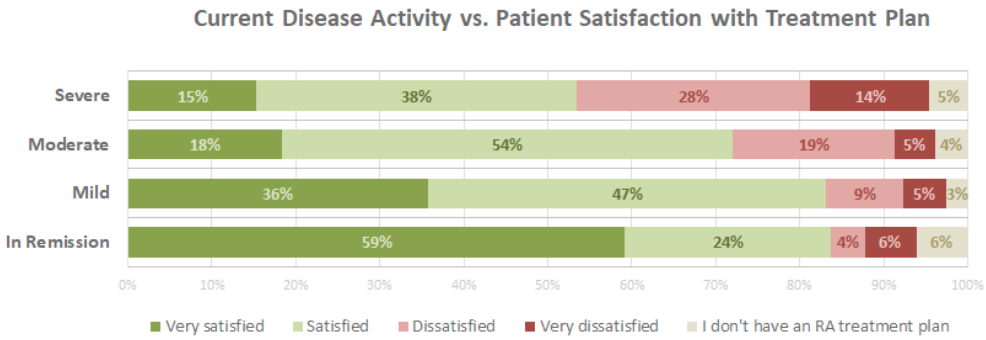
>=90% improvement	75 (13%)	72 (21%)	
How would you describe your state of health?			0.015
Fair	237 (42%)	118 (35%)	
Good	169 (30%)	135 (40%)	
Poor	98 (17%)	44 (13%)	
Very good	31 (5%)	22 (7%)	
Very poor	35 (6%)	17 (5%)	

Background/Purpose: Treat-to-target is a guiding principle in the management of rheumatoid arthritis (RA), and randomized clinical trials demonstrate its value in improving outcomes. However, implementation remains infrequent and standardized methods for establishing individual treatment targets remain problematic and lack input from patients. Building on a collaboration between a non-profit organization and an academic rheumatology center, we





aimed to gain greater understanding of patient treatment goals and preferences and examine how these may relate to treatment satisfaction or success.

Methods: A 28-item anonymous, web-based questionnaire developed and pilot-tested by the study team was presented over 7 days in 2019 on a secure survey system preventing multiple entries. Eligible participants were U.S. residents age ≥18 years with a self-reported diagnosis of RA by a medical professional. Participants were recruited through email, social media, and the web. Participants were asked closed- and open-ended questions about sociodemographics, their RA disease activity (DA), diagnosis and DMARD history, improvement from RA treatment, and the nature of RA treatment goals or plans created with their provider. Analyses included descriptive statistics with chi-square and rank sum tests for comparisons.

Results: The questionnaire was completed by 907 self-reported RA patients (90% women, 10% men), with a mean (SD) age of 58 years and a mean of 11.1 (10.1) years since diagnosis. According to self-reports, 5% were in remission, 22% reported mild DA, 54% moderate DA, and 19% severe DA. The majority (571; 63%) of patients were not asked by a provider about goals for their RA treatment. Of these, 32% were dissatisfied or very dissatisfied with their RA treatment plan, compared with only 13% of those who were asked about treatment goals.

Patients not asked about RA treatment goals had DA improvement levels resembling those of the whole study population. However, those whose providers discussed goals with them were more likely to have more DA improvement. Of those who said they discussed goals, fewer had DA improvement levels of ≤20% (no, 23%; yes, 37%); and more had DA improvement levels ≥90% (no, 13%; yes 21%).

Those who did not discuss treatment goals with their provider were less likely to achieve remission than those who did not (4% and 7% respectively). Those discussing treatment goals were less likely to have severe DA (no, 21%; yes, 18%). When asked whether they were likely to use materials to help set treatment goals with providers, 79% were likely or very likely to use them. Patients with higher levels of DA improvement were as likely to prefer treatment goal setting materials as those with lower levels of improvement.

Conclusion: This web-based survey showed that most RA patients are not asked about their treatment goals by their providers. However, a majority of RA patients favor tools to help patients set treatment goals together with providers. Of those who are not asked to set goals, 75% report having moderate to severe DA. Further research should seek a broader understanding of patient preferences for treatment goals and how they relate to successful management of RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments IV: Novel Therapy & Predicting Response
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: According to the EULAR recommendations, the therapeutic objective in patients with rheumatoid arthritis (RA) should be remission. Biological therapies, as TNF inhibitors (TNFi), have allowed to increase remission rates although these are still limited (20-47%). There is still unknown if peripheral blood mononuclear cells (PBMC) play a role as predictors of response in patients with RA and if they can be modified with treatment. This study aims to analyse the change of peripheral blood mononuclear cells (PBMC) profile after 6 months (m) of treatment with TNFi in order to find baseline cellular markers of response.

Methods: This was a prospective bi-center pilot study including 98 RA patients. PBMC were isolated from patients at baseline and after 6m of treatment with TNFi, and analysed by flow-cytometry. Clinical activity at baseline and after 6m was assessed by DAS28. Clinical remission (DAS28≤2.6) at 6m was considered as optimal response. The association between clinical remission (REM) and the percentage of change (Δ, 6m-0m) within each PBMC subset was analysed through univariable and multivariate logistic regression model. All the analyses were adjusted by sex, ACPA, rheumatoid factor, baseline-CRP and baseline-DAS28.

Characteristics	Total patients (n=98)	DAS28>2.6 (n=60; 61%)	DAS28≤2.6 (n=38; 39%)	p-value
Age (years)	53±13	54±14	52±12	0.5
Female	83 (85)	54 (90)	29 (76)	0.1
Disease duration (years)	8 (4-12)	8 (4-12)	7 (4-11)	0.9
RF positive	76 (78)	42 (71)	34 (89)	<0.05
ACPA positive	82 (84)	46 (78)	36 (95)	<0.05
Smoking habit *(n=82)*				0.2
no	38 (46)	26 (53)	12 (36)	
smoker	44 (54)	23 (47)	21 (63)	
Body mass index (kg/m2)	24.8 (22.9-29.7)	25.4 (23.1-29.6)	24.7 (22.0-30.2)	0.3
DAS28	4.9±1.1	5.3±1.0	4.3±0.9	<0.001
CRP (mg/L)	5.7 (2.1-12.1)	6.4 (2.5-18.3)	3.0 (0.7-9.6)	<0.01
Previous TNFi treatment	12 (12)	7 (12)	5 (13)	1.0
TNFi type				0.1
Monoclonal antibodies	53 (54)	37 (62)	16 (42)	
Etanercept	45 (46)	23 (38)	22 (58)	
TNFi monotherapy	3 (3)	1 (2)	2 (5)	1.0
Concomitant csDMARDs	95 (97)	59 (98)	36 (95)	1.0
MTX [±OD]	74 (76)	48 (79)	26 (68)	1.0
Only OD	21 (21)	11 (19)	10 (27)	0.2
Prednisone	57 (59)	36 (60)	21 (55)	0.8

Table 1. Baseline characteristics of patients included in the study. The table shows mean±SD, median (IQR) or absolute number (percentage) for all patients included (n=98). RF, rheumatoid factor; ACPA, anti-citrullinated protein antibodies; DAS28, Disease Activity Score-28; CRP, C reactive protein; TNFi, Tumour Necrosis Factor inhibitor; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; MTX, methotrexate; OD, other conventional synthetic disease-modifying anti-rheumatic drugs than methotrexate (leflunomide, sulphasalazine, hydroxychloroquine). The differences between DAS28 groups were analysed considering p-value<0.05 as statistically significant result.

Results: Demographic characteristics before starting TNFi therapy are shown in table 1. After 6m of TNFi treatment, 39% patients achieved clinical remission by DAS28. Univariable analyses (odds ratio; 95% CI; p-value) was performed to investigate the association between REM and the baseline variables (table 1). A significant association was found for positivity of rheumatoid factor (OR: 3.44; 95% CI: 1.06-11.19; p: 0.04), presence of ACPA (OR: 5.09; 95% CI: 1.08-24.00; p: 0.04), lower CRP (OR: 0.95; 95% CI: 0.91-0.99; p: 0.03) and lower baseline DAS28 (OR: 0.33; 95% CI: 0.19-0.54; p< 0.0001). In the multivariate analysis, only lower baseline DAS28 (OR: 0.32; 95% CI: 0.18-0.56; p< 0.0001) remained independently associated with REM after 6m of treatment. Decreased percentage of B cells (ΔCD19+) was found after 6m of TNFi treatment in patients in REM, while no-REM patients did not show differences with the baseline (OR: 0.77; 95% CI: 0.61-0.97; p: 0.027). This effect was essentially owing to a reduction of naïve B cells (OR: 0.80; 95% IC: 0.68-0.95; p: 0.009) (figure 1). No significant association was found between the other PBMC subsets (monocytes, NK cells, CD4+ T cells and CD8+ T cells) and REM.

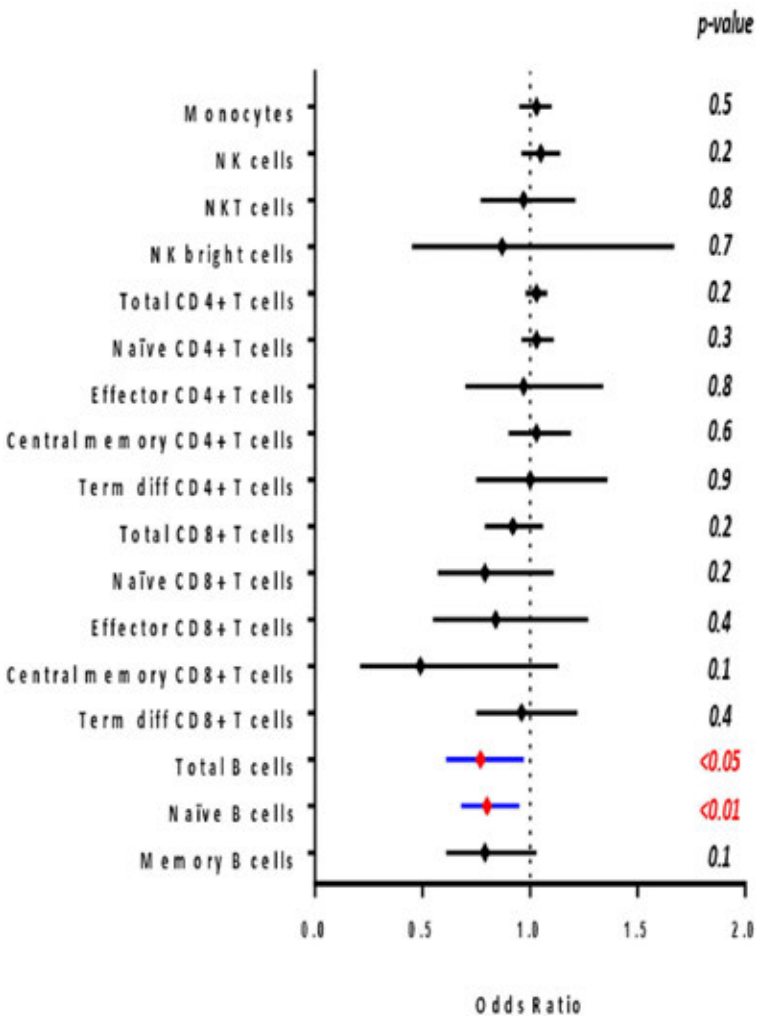

Figure 1. Association between the percentage of change (ΔPBMC, 6m-0m) within each PBMC subset and the clinical remission. Univariate logistic regression analysis was performed for each PBMC subset. The analyses were adjusted by sex, ACPA, rheumatoid factor, baseline-CRP and baseline-DAS28. The percentage of changes (Δ, 6m-0m) in total B cells and in naïve B cells were independently associated with the clinical response. No association was found in other PBMC subsets.

Conclusion: Our results suggest that B cells, specially naïve B cells, are the main PBMC subset involved in patients who respond to TNFi. This cell population was modified by the TNFi therapy only in responder patients. Therefore, we suggest that B cell may be useful as a marker of response to TNFi in RA patients.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments IV: Novel Therapy & Predicting Response

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Early treatment initiation in rheumatoid arthritis (RA) is fundamental to avoid chronic joint destruction and disability. Despite remarkable advances in RA therapeutics, oral methotrexate (MTX) remains the anchor drug and mainstay of treatment worldwide. However, MTX bioavailability has a wide inter-individual variability and >50% of patients with moderate or severe RA show no or suboptimal improvement in their symptoms in response to MTX. The reasons for these disparities in treatment response remain unclear. Prior studies have shown that the biotransformation of MTX is altered in germ-free and microbiome-depleted mice, prompting us to hypothesize that inter-individual differences in the human gut microbiome could impact drug bioavailability and thus clinical efficacy. We sought to determine differences in the microbiome of drug-naïve, new onset RA (NORA) patients that could predict response to MTX therapy.

Methods: We enrolled 27 drug-naïve, NORA patients priori to MTX initiation (test cohort), and classified them as either MTX-responders (MTX-R; 39% of the cohort) or non-responders (MTX-NR; 61%) based on a stringent definition of clinical response (delta improvement of DAS28 >1.8 by month 4). We performed 16S rRNA gene and Shotgun Metagenomic sequencing on the baseline gut microbiomes of these NORA patients and confirmed the results in an independent validation cohort (n=31). NMR and LC-MS were performed in ex vivo incubations to measure the capacity of each NORA microbiome to metabolize MTX.

Results: Our analysis revealed significant associations between the abundance of gut bacterial taxa and future MTX response. Patients that responded to therapy had significantly lower microbial diversity ($p< 0.05$). A significant difference in overall gut microbial community structure was also observed between groups (Bray-Curtis distance; PERMANOVA < 0.05). At the class level, we observed statistically higher abundance of Clostridia and lower abundance of Bacteroidia in MTX-NR ($p< 0.05$; $q< 0.2$). Furthermore, the baseline metagenome separated most MTX-R from MTX-NR (PCoA; PERMANOVA $p< 0.05$). We identified 8 microbial modules and 23 pathways, whose abundance significantly differed between groups ($p< 0.05$, $q< 0.2$), including genes related with purine and MTX metabolism, indicating a major difference in metabolic and biosynthetic potential between the microbiome of MTX-R and MTX-NR patients. Machine learning techniques were applied to this metagenomic data, resulting in a robust model based on bacterial gene abundance that accurately predicted response to MTX in an independent cohort. Finally, MTX available levels remaining after *ex vivo* incubation with distal gut samples from pre-treatment RA patients significantly correlated with the magnitude of future clinical response, suggesting a direct effect of the gut microbiome on MTX bioavailability and response to therapy.

Conclusion: Together, these results provide the first step towards predicting response to oral MTX in NORA patients and support the utility of the gut microbiome as a prognostic tool and perhaps even as a target for manipulation in the treatment of rheumatic and autoimmune disease.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments IV: Novel Therapy & Predicting Response

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

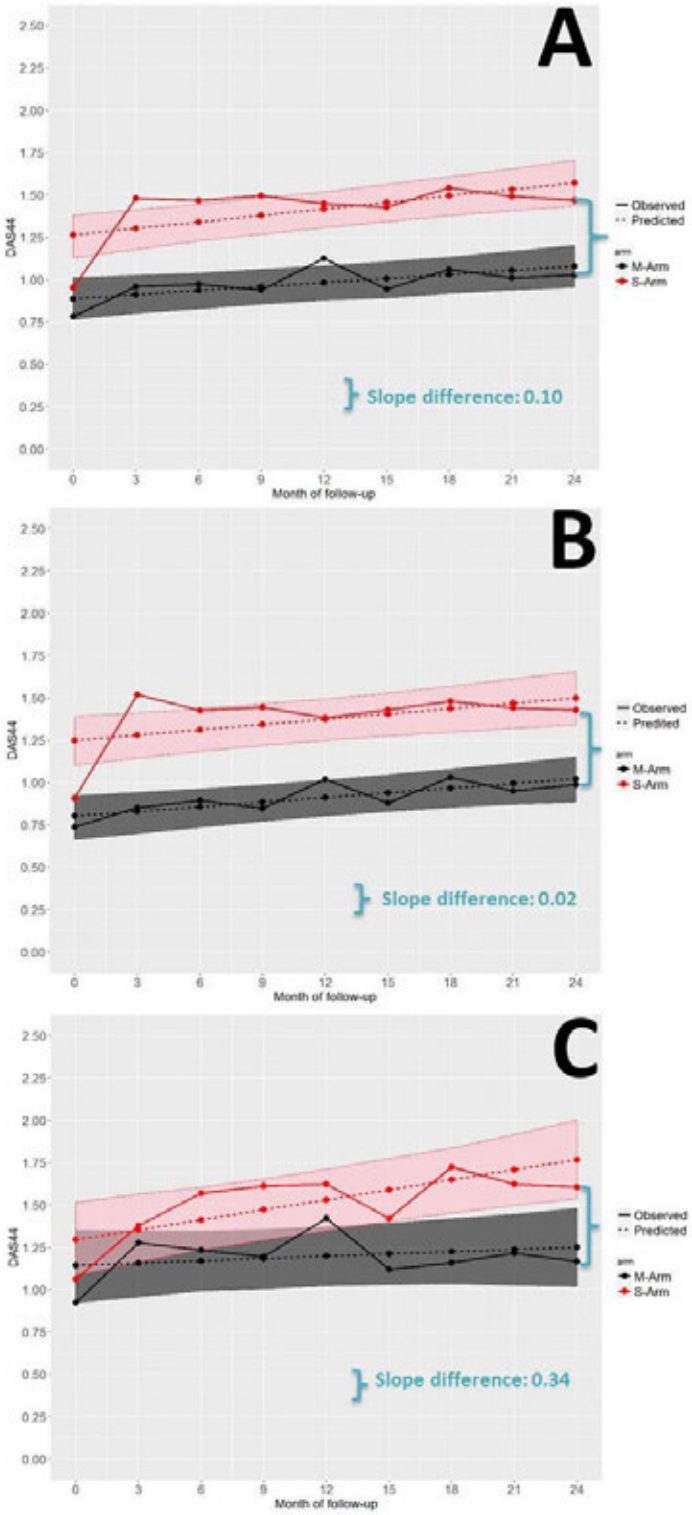

Figure 1. evolution of DAS44 in overall (A), TCZ (B) and ABA populations (C), and between Maintenance arm (black) and Spacing arm (red)

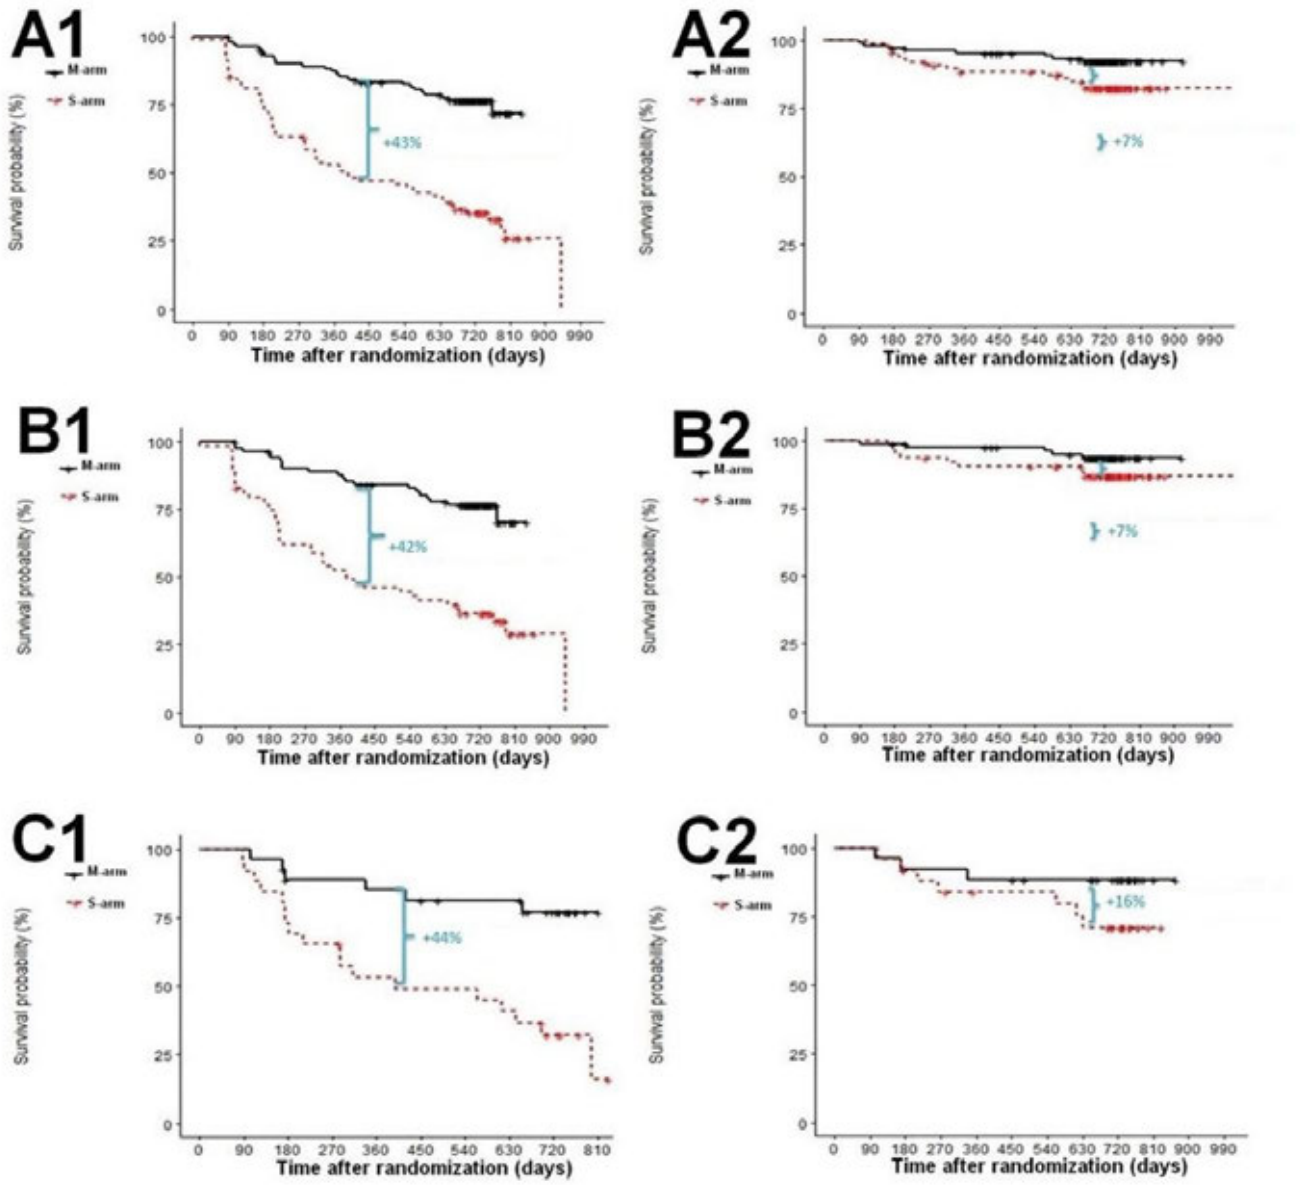

Figure 2. relapse-free (1) and major relapse-free (2) survival in overall (A), TCZ (B) and ABA populations (C), and between Maintenance arm (black) and Spacing arm (red)

Background/Purpose: Biologic Disease Modifying Anti-Rheumatic Drugs (bDMARD) tapering is proposed by clinical practice guidelines in rheumatoid arthritis (RA) patients in sustained remission. However, no randomized control trial (RCT) has been implemented to date to answer the question of tapering tocilizumab (TCZ) or abatacept (ABA).

The ToLEDo (Towards the Lowest Efficacious Dose) trial aimed to assess the impact on disease activity of progressive spacing of TCZ or ABA injections in RA patients in sustained remission compared to their maintenance at full dose.

Methods: ToLEDo is a multicenter open-label non-inferiority (NI) RCT conducted in RA patients fulfilling ACR-EULAR 2010 criteria. Patients had to be 1) treated with ABA or TCZ for ≥ 1 year (monotherapy or in combination with csDMARD, corticosteroid allowed at a dose ≤ 5 mg / day), 2) in DAS28ESR remission (DAS28ESR < 2.6) for ≥ 6 months and 3) with no X-ray damage progression in the year before inclusion. They were randomized into 2 arms: TCZ or ABA maintenance at full dose or DAS28-driven progressive injection spacing arm, in which bDMARD IV or SC injections were progressively spaced out every 3 months according to a predetermined 4-step algorithm up to bDMARD

discontinuation at step 4. Spacing was reversed to the previous step in case of flare. The primary outcome was the evolution of disease activity according to DAS44 during the 2-year follow-up, analyzed in a linear mixed-effect model. Secondary outcomes were flare and major flare rates (respectively defined as DAS28 > 3.2, and DAS28 >3.2 not recovered at the following visit despite bDMARD escalation at previous step) were also compared between the 2 arms. Analyses were done per protocol (PP) according to a NI hypothesis (NI margin at 0.25 for DAS44 and 0.07 for flare rates).

Results: Overall, 233 patients were randomized but 229 were treated and 199 were considered for PP analysis (89 in Spacing arm and 110 in Maintenance arm). 146 (73.4 %) patients were treated with TCZ and 53 (26.6%) with ABA. At the end of the follow-up in the Spacing arm, 18.2% of patients discontinued their bDMARD (step 4), 50.6% had tapered them (step 1 to 3) and 31.2% needed to go back to initial step (step 0) (Table 1). In terms of DAS44, the slope difference was 0.10 [95% CI: -0.10, 0.31] in the whole population, 0.34 [95% CI: -0.07, 0.74] for ABA subgroup and 0.02 [95% CI: -0.22, 0.26] for TCZ subgroup. The upper limit of the 1-sided 95% CI of slope difference exceeded 0.25, failing to demonstrate NI in the whole population and in the ABA subgroup (0.28 and 0.68 respectively), but NI was demonstrated in the TCZ subgroup (0.22, p=0.03) (Figure 1). Flares (Figure 2) were more frequent in the Spacing arm: +0.43 [95% CI: 0.30, 0.55], +0.44 [95% CI: 0.20, 0.68] and +0.42 [95% CI: 0.27, 0.57] in the whole population, ABA and TCZ subgroups respectively. Major flares were more frequent in the Spacing arm: +0.07 [95% CI: -0.01, 0.14], +0.16 [95% CI: -0.05, 0.37] and +0.07 [95%CI: -0.03, 0.16] in the whole population, ABA and TCZ subgroups respectively, compared with Maintenance arm.

Conclusion: The ToLEDo trial failed to demonstrate the NI of the proposed ABA or TCZ tapering strategy in comparison to maintenance at full dose. Thus, it is not in favor of tapering ABA and TCZ according to this scheme.

Session Title: RA – Treatments IV: Novel Therapy & Predicting Response

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Antigen-specific immunological tolerance strategies leverage the natural process of antigen presentation by dendritic cells (DCs) to regulate pathogenic T cells and B cells. We developed a nanoparticulate liposome formulation that encapsulates autoantigenic peptide and NF-kB inhibitor, 1,25 dihydroxycholecalciferol (calcitriol), to target DCs. In mouse models of autoimmune arthritis, multiple doses of liposomes promote disease suppression as well as stable regulation of effector-memory T cells with an increase in the proportion of naive T cells in an antigen-specific manner. We carried out a dose-ranging double-blind placebo-controlled phase I clinical trial of a single dose of liposomes encapsulating 40mg/ml collagen $II_{259-273}$ (CII) peptide + 400ng/ml calcitriol (DEN-181). The primary objective was assessment of safety and tolerability, and the secondary objectives were assessment of peripheral blood (PB) total and CII-specific naïve, effector and regulatory T cells, clinical response, and calcitriol levels after DEN-181 treatment.

Methods: Vehicle or 3 different dose levels of DEN-181 were administered via single s.c. injection to 17 anti-citrullinated peptide antibody (ACPA)+ HLA-DRB1*0401 or *0101+ RA patients on methotrexate. CII-specific and total CD4+ T cells were evaluated 0, 7 and 28 days post-treatment by flow cytometry using haplotype-specific tetramers. Plasma calcitriol was measured using an ultra-sensitive assay, hourly for 4h post-dose.

Results: Seventeen enrolled patients with a mean age of 50 (range 20-64), methotrexate dose 17.1 (5-25) mg/week, disease duration 4.9 (0.5-18) years, and DAS28CRP 2.66 (1.36-4.65) received vehicle or 3 different dose levels of DEN-181 (6x placebo, 4x 0.3ml, 3x 1ml and 4x 3ml). DEN-181 was generally well tolerated. One treated (1ml) and 1 control patient had AST >1.5x normal. Disease flares requiring steroids occurred in 1 control and 1 treated (3 ml) patient Plasma calcitriol levels were greater than placebo in the 3 ml but not in the 1 or 0.3 ml cohort.. Pre-treatment, CII-specific CD45RO+ memory T cells were identified in PB (range 30-66%). Relative to baseline, the % naïve CII-specific T cells increased and DAS28CRP decreased 7 days after a dose of 0.3ml, while the 3ml dose had the opposite effect (p=0.02 naïve, p=0.06 DAS). Changes in CII-specific naïve T cells differed between dose cohorts over time (p=0.04). After 7 days, reduced DAS28CRP of DEN-181-treated patients was associated with decreases in %CII-specific PD1+ T cells, CII-specific TCR expression, and ACPA IgG/IgA titre.

Conclusion: DEN-181 immunotherapy was safe and modulated antigen-specific T cells in RA patients of appropriate HLA type, where the pharmacodynamic effect of the 0.3ml dose suggests a skew toward immunological tolerance.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Treatments IV: Novel Therapy & Predicting Response
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: RA patients often inquire about dietary interventions to improve disease control, as they perceive quick changes in pain and/or swelling after consumption of certain foods. Of particular interest is the influence of diet on modifying circulating pro/anti-inflammatory oxylipins and how this relationship affects pain/inflammation. Here, we determine the effect of a 2-week anti-inflammatory diet on clinical and biological outcomes in RA patients.

Methods: Patients with a diagnosis of RA and at least 3 tender and 3 swollen joints in physical exam and no change on medication in previous 2-3 months, who declined escalation therapy, were offered a 2-week anti-inflammatory diet and recruited in our study. This diet comprises of ingredients that increase omega-3/6 ratio, anti-inflammatory species such as turmeric, anti-oxidants, and prebiotics and probiotics. It also eliminates pro-inflammatory ingredients such as lactose, gluten and red meat. In their first visit (day -14), we established their clinical and biological baseline. In their second visit (at day 0) we collected clinical parameters. Patients were given instruction of how to follow the diet and were asked to follow a daily diet log. In their third visit (at day 14), we evaluated study feasibility outcomes, diet adherence and clinical parameters. We also collected blood in all three visits. Trend in clinical changes were examined between day -14 and 0, and between 0 and 14 in a subgroup of these patients (n=10). Serum oxylipins were determined by mass spectrometry before and after diet. Data processing and statistical analysis were performed in SPSS.

Results: In an ongoing clinical trial, 22 RA patients were recruited from 35 screened patients, and 17 of them (100% seropositive RA women, age average: 55, standard deviation (SD): 5) went through the complete trial. A diet index score (up to 200) showed a good diet adherence (-41.3 (70.9) vs 117.1 (52.1), $p< 0.001$, for before and after diet trial respectively). As shown in table 1, several clinical outcomes including evaluation of the number of tender (TJC) and swollen joints (SJC), Health Assessment Questionnaire (HAQ), and assessments of pain, fatigue, global disease severity by patients and by physicians, and composite measures of peripheral arthritis such as Disease Assessment Score (DAS)28-CRP and Clinical Disease Activity Index (CDAI) were significantly lower after the 2-week

Table 1 **RA clinical outcomes after diet (n=10).**

DAS28 (mean ± SD)	4.42 ± 0.99	4.58 ± 0.97	3.3 ± 1.5	0.006
CDAI (mean ±sd)	22.4 ± 7.7	23.3 ± 8.3	11.6 ± 9.2	0.07
HAQ (mean ± SD)	0.83 ± 0.72	0.8 ± 0.68	0.57 ± 0.63	0.001
VAS Pt global (mean ± SD)	3.9 ± 2.4	3.2 ± 2.25	2.1 ± 2.2	0.003
VAS MD global (mean ±sd)	5 ± 1.33	5.3 ± 1.77	2.3 ± 1.94	<0.001
Number of tender joints MD (mean ± SD)	8.3 ± 3.3	8.6 ± 4	4.4 ± 4	0.017
Number of swollen joints MD (mean ± SD)	5.3 ± 1.6	6.2 ± 1.7	3.1 ± 2.3	0.002
Number of tender joints Pt (mean ± SD)	7.4 ± 4.3	5.8 ± 3.9	3.7 ± 3	0.007
Number of swollen joint Pt (mean ± SD)	5.3 ± 3.7	4.5 ± 3.3	2.3 ± 2.4	0.019
Pain level Pt (mean ± SD)	3.8 ± 1.87	3.7 ± 1.94	2.1 ± 1.8	0.005
Fatigue level Pt (mean ± SD)	4.5 ± 2.9	3.2 ± 2.7	1.7 ± 1.77	0.018
Stiffness (minutes) (mean ± SD)	32.5 ± 32.7	32.8 ± 39.2	23.5 ± 24.9	0.29
Stress level Pt (mean ± SD)	2.1 ± 1.66	1.8 ± 1.47	1.2 ± 1.13	0.011

anti-inflammatory diet (table 1). DAS28-CRP after the 2-weeks of anti-inflammatory diet also correlated with the diet index score at visit 3 (p=0.02). Of interest, several pro and anti-inflammatory linoleic acid-derived oxylipins including 13-HODE, 9,10 diHOME and 9,10 EpOME significantly changed after the diet and correlated with index score at visit 3 (p=0.02).

Conclusion: Modulating diet has the possibility to complement medication and improve quality of life for RA patients. Here we showed that RA patients are motivated and followed the diet with good adherence. Diet index scores after the trial correlated with clinical scores and changes in pro- and anti-inflammatory oxylipins suggesting that these mediators could play a role in the clinical effect of this diet in RA patients.

DAS28: Disease activity score on 28 joints; CDAI: clinical disease activity index; HAQ: health assessment questionnaire; VAS Pt global: patient's visual analogue scale for global disease VAS MD global: MD's visual analogue scale for global disease; Pt: patient. Statistical analysis conducted using Repeated Measures Analysis of Variance.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Treatments IV: Novel Therapy & Predicting Response

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Tapering or stopping conventional and biologic DMARDs in patients with rheumatoid arthritis (RA) in stable remission may be feasible in a subset of patients [1]. However, the prediction of the patients' individual flare risk remains challenging. Hence, reliable models based on machine learning algorithms could be helpful tools for flare prediction [2]. Therefore, the purpose of this study was to investigate the feasibility of building a predictive model for estimating the individual flare probability in RA patients tapering biologic DMARDs using (1) a small cohort of patients, (2) high quality data and (3) a combination of different machine learning models.

Methods: Longitudinal clinical data of RA patients on biologic DMARDs from the phase-3, multicentre, randomised, open, prospective, controlled, parallel-group RETRO study (EudraCT number 2009-015740-42) was used. In order to exploit the flexibility obtained by combining different machine learning models a stacking meta-classifier is used [3]. At first, four models are trained: log. regression, random forest, k-NN and naïve Bayes which output the flare probability at each patient visit. These probabilities are the input features for the stacking logistic regression meta-classifier. The final prediction performance expressed as the AUROC is estimated using the nested cross-validation [4]. The importance of single predictors was estimated using the permutation importance approach [5].

Results: Data of 41 RETRO study patients with 135 follow-ups were used. The measured AUROC of the model was 0.802 (95%CI 0.717 – 0.887, Figure 1). A steadily growing model performance was observed with the increasing size of the available data (Figure 2). Of the ten most important variables for the machine learning model, the dose percentage change of bDMARD, clinical disease activity (DAS28-ESR), disease duration and inflammatory markers such as ESR or CRP reached the highest significance (Figure 3).

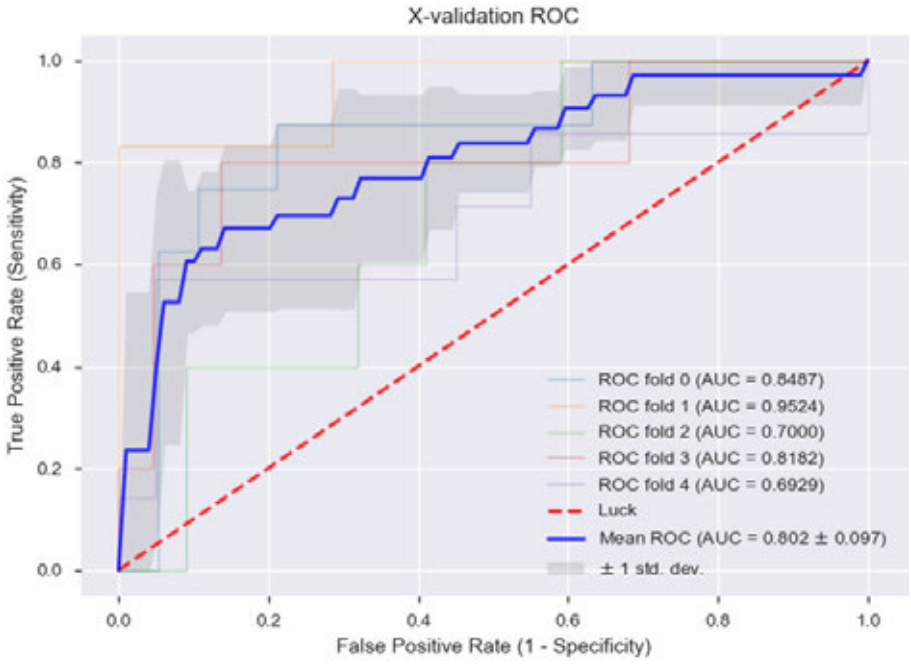

Figure 1. AUROC curve for the predictive machine learning model

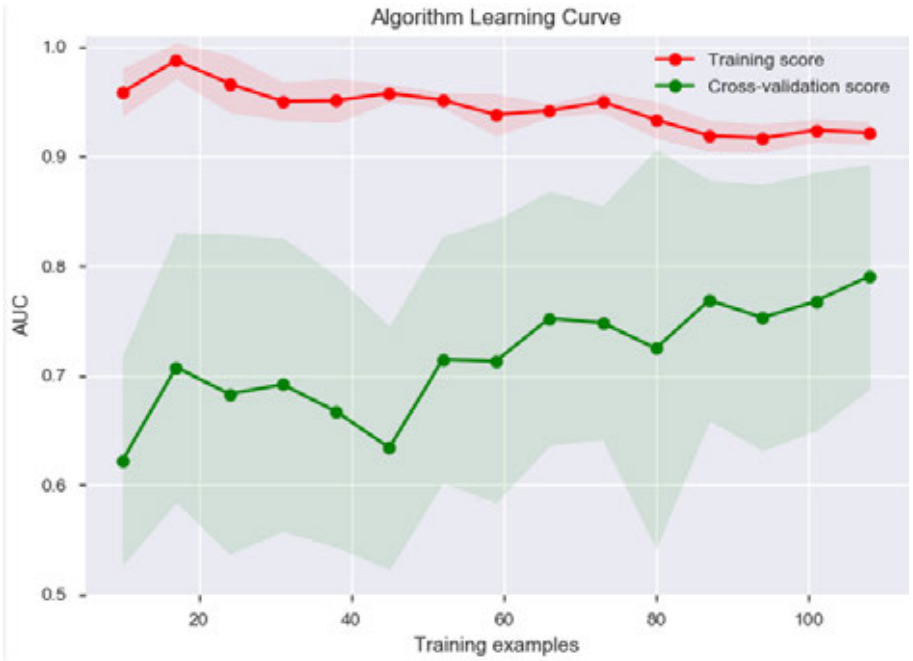

Figure 2. Learning curve of the stacking meta-classifier

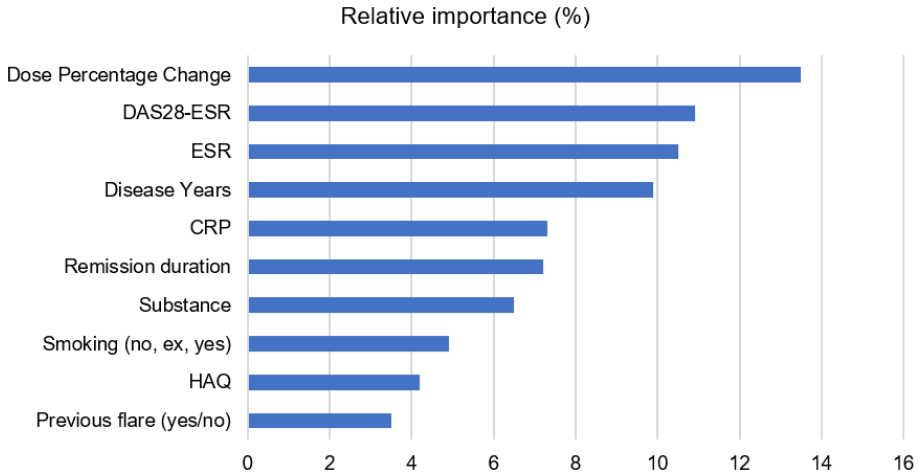

Figure 3. Relative importance of clinical and demographic variables for the machine learning model Dose Percentage Change: change in the percentage of full standard dose from its last value recorded within last 24 weeks; DAS28: Disease Activity Score 28; ESR: Erythrocyte Sedimentation Rate; CRP: C-Reactive Protein; HAQ: Health Assessment Questionnaire

Conclusion: It is possible to train a good predictive model for RA flare probability with small data of high quality using a flexible combination of different classifiers. These results confirm the feasibility of guided tapering based on machine learning models and show that such models could be a reliable flair risk assessment tool for physicians in the future.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: The course of axial spondyloarthritis (SpA) is heterogeneous and remains to be better defined. DESIR is a longitudinal French cohort of early undifferentiated axial SpA, allowing to define different disease courses. We recently performed a cluster analysis, based on baseline characteristics and identified 2 SpA clusters: one, characterized by an isolated axial disorder (A for axial), the other by additional high prevalence of peripheral manifestations (B for both) (Costantino et al. Arthritis Rheumatol, 2016). These two clusters may be linked to different levels of disease severity. The aim of the present study was to assess whether cluster-based SpA phenotypes identified at baseline are stable over time and might predict different severity disease outcomes at follow-up.

Methods: We analysed longitudinal data from the 535 patients fulfilling the ASAS classification criteria (either axial or peripheral criteria) and who completed all follow-up visits until year 5 (months 6, 12, 18, 24, 36, 48 and 60) out of the 679 patients in the DESIR cohort used to define clusters at baseline. We performed a linear mixed-effect analysis for quantitative variables and a generalized linear mixed-effect analysis for qualitative variables with cluster and follow-up visits as fixed effects and subjects as random effect. *P*-values were obtained by likelihood ratio tests of the full model with cluster against the model without cluster as fixed effects. To determine a way to predict a definite cluster in a given patient at baseline, a classification and regression tree (CART) analysis was performed. A 10-fold cross validation was used to estimate misclassification rates.

Results: Over the time, both clusters continued to show significant differences with respect to prevalence of peripheral involvement, higher disease activity, worse patient-reported outcome, higher frequency of conventional DMARDs and TNF inhibitor use in cluster B, and higher prevalence of radiographic and MRI sacroiliitis at 2 and 5 years in cluster A (Table 1). CART analysis (Figure 1) shows that probability to maintain the same cluster over time is very high if a given patient belongs to a definite cluster-phenotype (A or B), with sensitivity of 98%, specificity of 87% and positive likelihood ratio of 7.62 at baseline (Table 2).

Variable (range)	Beta (Cluster B vs A)	95% CI	P-value
Disease activity			
- BASDAI (0-100)	6.89	3.80 – 9.98	1.5×10^{-5}

Cluster B	5	237	242
Predicted total	263	272	535
Accuracy = 93% ; Sensitivity = 98% ; Specificity = 87% ; LR+ 7.62			

Table 2. Performance of the decision tree for cluster determination

Conclusion: Cluster-based SpA phenotypes identify different severity outcomes at 5 years. We develop a decision tree for cluster determination, which shows accurate classification performance. This algorithm is easy to use (only three clinical parameters) and could help to identify patients at risk of poor outcome in early axial SpA.

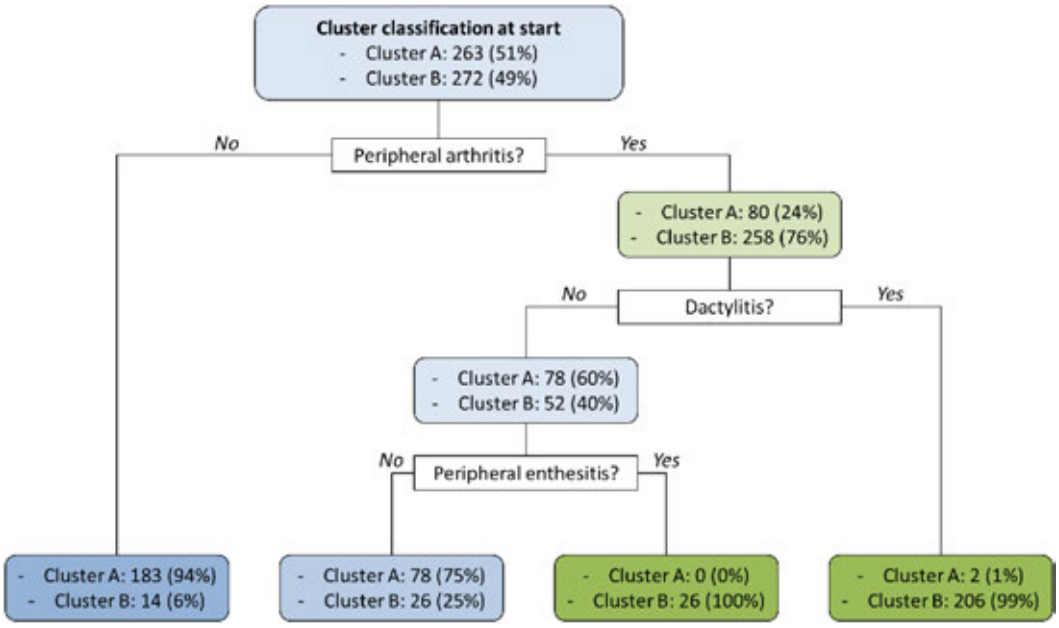

Figure 1. Decision tree for cluster (number of patients in each cluster following by percentages are given in each case

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Only scarce data is available on regarding pregnancy rates and pregnancy outcomes in early axial spondyloarthritis (axSpA). The objectives of this study were to estimate the probability of achieving a clinical pregnancy and presenting an unfavorable pregnancy outcome, and determined their associated factors, in this population.

Methods: Observational prospective French cohort (DESIR) with 6y of follow-up, including 381 of TNF-naïve women with early axSpA. Study visits were scheduled every 6 months in the first two years and then yearly up to 6 years. Data on pregnancy were collected retrospectively (before cohort inclusion) and prospectively (since inclusion) up to

6y of follow-up. Baseline characteristics of nulligravidae and uni/multigravidae patients were compared. The probability of achieving at least one pregnancy over time was estimated (Kaplan Meier). Associated factors were estimated by Frailty Shared Models and mixed models taking into account the correlation between several pregnancies from the same women. The probability to present an unfavorable pregnancy outcome over time (i.e a miscarriage or pre-term delivery or an elective termination of pregnancy) was estimated only during the prospective period (Kaplan Meier). Associated factors to an unfavorable pregnancy outcome were estimated by multivariable Frailty shared Models and mixted models.

Results: Of the 381 women included in the analysis, 289 (75.9%) and 92 (24.1%) women were respectively multigravidae and nulligravidae at the end of the 6y follow-up. Multigravidae women were significantly older (36.7±8.2 vs 27.8 ± 7.2, p< 0.01), less educated (56.9% vs 72.5% university studies, p=0.01), and had higher BASDAI (4.9±1.9 vs 4.4±2.0, p=0.04), and higher BASFI (3.5±2.4 vs 2.8±2.2, p=0.008) scores at baseline. The probability to have at least one pregnancy throughout life was 61.8% [55.1-67.5]. The mean age of the first pregnancy was 27.3 years old. One hundred and twenty-four pregnancies occurred during follow-up. Lack of TNFi use in the 6 months preceding the pregnancy outcome (HR=2.0 [95%CI 1.1-3.3], p=0.01) and a CRP≥ 6mg/L (HR=1.7 [95%CI 1.2-2.5], p=0.01) were found to be associated with pregnancy over follow-up.

Among the 80 pregnancies occurring after inclusion with data available on the outcome, 60 (75%) presented a full-term delivery while 12 (15%) presented an unfavorable pregnancy outcome (6 (7.5%) and 6(7.5%) had a miscarriage or a pre-term delivery, respectively), 2(2.5%) had an elective abortion, and 6(7.5%) were pregnancies still ongoing at the end of follow-up. The probability to present an unfavorable outcome was 16.7% [0.1-0.2]. Only NSAID use (HR=2.5 [95%CI 1.1-5.0], p=0.02) within 6 months of delivery were associated with an unfavorable outcome.

Conclusion: More than 70% patients had at least one pregnancy. A favorable pregnancy outcome (i.e.full-term delivery) was observed in 75% of patients, which is comparable to the general population data. Patients who achieved a pregnancy were more likely to have stopped their TNFi 6 months prior to the pregnancy outcome, and increased their CRP at the previous visit. NSAID use within 6 months of delivery was independently associated with an unfavorable pregnancy outcome.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Only scarce date is available on the long term treatment effect in a real-life setting (i.e. effectiveness) of TNFi in early axial SpA forms and its predisposing associated factors; furthermore, unbiased evaluation of treatment effect in non-randomized clinical trials is challenging, and new methods have been developed to overcome prescription bias.

The objectives of the study were a) to estimate the probability to initiate a TNFi over 5 years of follow-up in real life setting using novel statistical methods to overcome prescription bias; b) to determine the long term effectiveness of first TNFi and its predisposing factors.

Methods: Observational prospective French cohort (DESIR) with 5 years of follow-up, including 708 TNFi-naïve patients with early axial spondyloarthritis. Study visits were scheduled every 6 months in the first two years of follow-up then yearly up to 5 years. Treatment (TNFi or other) was at the discretion of the treating rheumatologist's. The probability to initiate a TNFi was estimated by the Kaplan Meier Method, assuming non informative dropouts. Effectiveness of the first TNFi was defined as the probability to reach an ASAS40 response in both groups (TNFi vs. any other treatment) after at least 10 months of exposure. To evaluate treatment effect and overcome prescription bias repeatedly occurring over time, we have applied an iterative method based on inverse propensity score (PS) weighting using a marginal structural model, that allows the integration of the repeated weights derived from the propensity score at each visit (i.e. the probability to receive the treatment at each visit). The structural model used for this analysis was a PS-weighted cox regression, to estimate the probability to present an ASAS40 response after at least 10 months of treatment. Factors predicting first TNFi effectiveness, were explored by Cox (univariate and then multivariate) regression models.

Results: Of the 708 patients included in the analysis, 258 patients initiated a first TNFi during the first five years of follow-up. The probability to initiate a TNFi treatment was 41.3% [95%CI 37.2-45.1]. Among the 258 patients who received a first TNFi, 163 (63.2%) were exposed for at least 10months. On the original data, ASAS40 response was observed in 50/163 (30.7%) vs.58/450 (12.9%) patients from the TNFi and usual care groups, respectively. The likelihood of an ASAS40 response was greater in the TNFi exposed group (HR= 3.3[95%CI 2.9-3.8], p< 0.001). Male gender (HR=1.5[95%CI 1.1-2.1]), HLAB27+ (HR= 1.4[95%CI 1.1-2.0]) and the presence of at least one objective sign of inflammation (MRI or CRP) or structural damage (radiographic sacroiliitis) (HR = 1.7[95%CI 1.2-2.4]) were jointly predictive of an improved outcome.

Conclusion: Our study, applying novel statistical techniques to overcome prescription bias, confirms the 5-year effectiveness of TNF alpha inhibitors (TNFi) in patients with early axial spondyloarthritis (axSpA), and we confirm that male gender, with HLAB27 positive and the presence of at least one objective sign of inflammation or structural damage are more frequently associated with such effectiveness.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Axial spondyloarthritis (axSpA) is a disease with a rather heterogeneous presentation that may be difficult to diagnose. Classification criteria, such as the ASAS criteria, developed and validated against the gold-standard 'expert diagnosis', exist, but may suffer from circularity because features deemed important by experts may have got a too prominent, and therefore biased, role. If classification criteria are used inappropriately to confirm a diagnosis, overdiagnosis may be an unwarranted consequence. We aimed to gain an unbiased insight into the concept of axSpA, by circumventing expert opinion and investigating its 'latent constructs': We examined the SpA-features' mutual statistical coherence, established the unbiased 'Gestalt' of SpA, and evaluated how the ASAS axSpA criteria capture these 'latent constructs'.

Methods: Two independent cohorts of patients (pts) with early onset chronic back pain (SPACE cohort) and inflammatory back pain (IBP) (DESIR cohort) were included. Latent class analysis (LCA) (different than a cluster analysis) was used to estimate the latent (i.e. unobserved) 'Gestalt' of axSpA by modelling the covariance of the observed SpA features (without 'a priori' assumptions on their 'weights'). The selected best LCA model splits axSpA into a number of (clinically meaningful) classes with best data fit. Each class was labelled by us and named according to most prominent features. The latent axSpA classes were then used as 'gold-standard' against which the ASAS axSpA, pSpA (ignoring IBP) and both (SpA criteria) were tested. Finally, 5-year follow-up data from DESIR were used to perform a latent transition analysis (LTA) in order to examine if patients change classes over 5-year time.

Results: In total, data of 465 (SPACE) and 576 (DESIR) pts were analyzed. SPACE yielded 4 latent classes (Table 1). The 'Axial' class characterized by highest likelihood on abnormal imaging and HLA-B27-positivity; the 'IBP+Peripheral' class had 100% likelihood of IBP in association with peripheral signs. The 'At risk' class is anchored on a positive family history and HLA-B27 positivity in association with IBP; and the 'No SpA' class had very low likelihoods for all SpA-features. The analysis in DESIR (without 'no-SpA' pts) yielded identical latent classes ('Axial':19%; 'IBP+Peripheral':27% and 'At risk':55%) (Table 2). The ASAS axSpA criteria, tested in SPACE ('No SpA' absent in DESIR), captured 67% of patients in the 'Axial' and 'IBP+Peripheral' classes ('latent gold-standard'), but sensitivity was better (87%) if axSpA and pSpA criteria were combined. Of note, the axSpA criteria captured only 4% of the pts from the 'No SpA' class. The LTA suggests that transition between classes over time was unlikely. 'Axial' and 'IBP+Peripheral' patients did not switch and only 11% of 'At risk' pts had switched to 'IBP+Peripheral' after 5 years.

IBD (ever)	0.02 (0.00; 0.10)	0.05 (0.02; 0.11)	0.05 (0.03; 0.08)

* Probability of the latent class. Values are the conditional probability (95% confidence interval) for each SpA feature positivity within each latent class (range: 0-1). Values in **bold** highlight dominant features between latent classes. Values in *italic* highlight dominant features (probability >50%) within each class. BME, bone marrow edema; IBD, Inflammatory bowel disease.

Conclusion: The 'Gestalt' of axial spondyloarthritis comprises three distinguishable clinical entities ('pure axial SpA', 'axial SpA with peripheral signs, and 'axial SpA at risk'). Patients keep their clinical entity over 5 years and transition is very rare. The 'Axial' and 'IBP+Peripheral' entities are best captured by combining the ASAS axSpA and pSpA criteria.

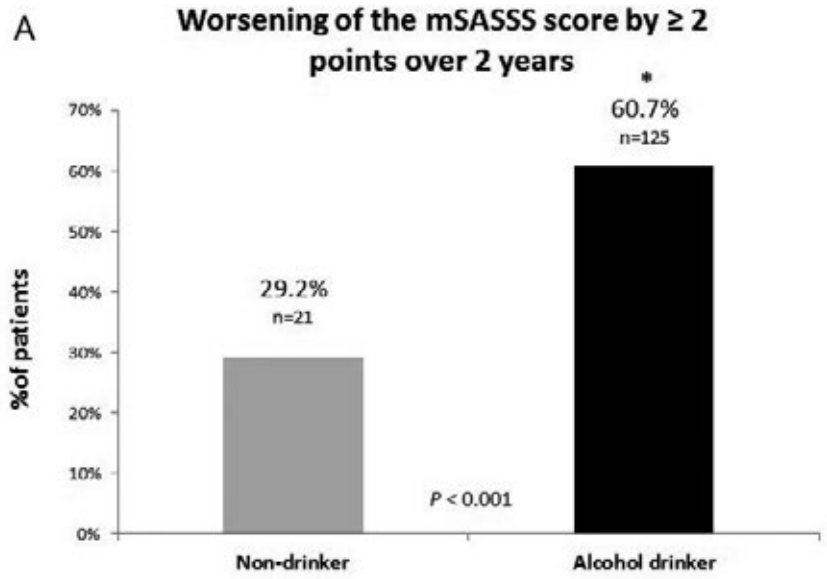
Alcohol Consumption as a Predictor of the Progression of Spinal Structural Damage in Axial Spondyloarthritis: Data from the Catholic Axial Spondyloarthritis COhort (CASCO)

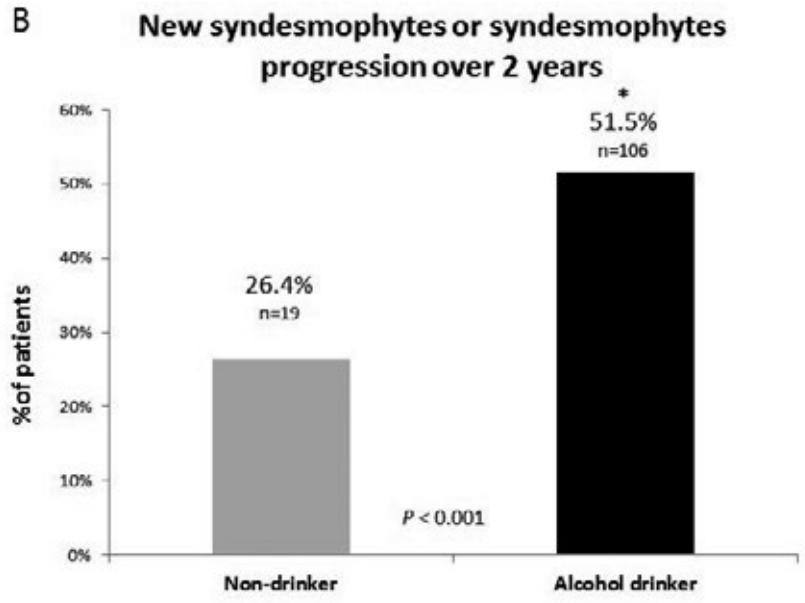
Hong Ki Min,[1] Seung-Ki Kwok,[2] and Sang-Heon Lee[1], [1]Konkuk university medical center, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The purpose of the present study was to demonstrate the predicting factors of spinal structural damage in axial spondyloarthritis (axSpA) in a prospective cohort study.

Methods: AxSpA patients were enrolled from a single tertiary hospital in a prospective cohort. Baseline data were collected, and 2 year follow-up radiographic data were collected. We analyzed the progression of spinal structural damage in 278 axSpA patients and grouped them into alcohol drinkers and non-drinkers. Baseline and follow up characteristics were compared between the two groups. Univariable and multivariable logistic regression analysis were performed to reveal predictors of spinal structural damage.





Results: Change of modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) and syndesmophyte count over the 2 year period were more prominent in the alcohol drinker group than in the non-drinker group (2.7 ± 3.6 vs 1.5 ± 2.8, P=0.007, 0.9 ± 1.3 vs 0.4 ± 1.2, P=0.003). The alcohol drinker group showed more frequent significant mSASSS changes (≥2 units for 2 years follow up) and new syndesmophyte/progression of pre-existing syndesmophyte than the non-drinker group (60.7% vs 29.2%, P< 0.001, 51.5% vs 26.4%, P< 0.001, respectively). On univariable and multivariable regression analysis, drinking alcohol showed a significant relationship with the progression of spinal structural damage for both mSASSS and syndesmophyte progression.

Conclusion: The present study showed that alcohol consumption could predict progression of spinal structural damage in axSpA. This is meaningful because drinking alcohol is a modifiable behavior and education on alcohol consumption could aid in attenuating spinal structural damage in axSpA.

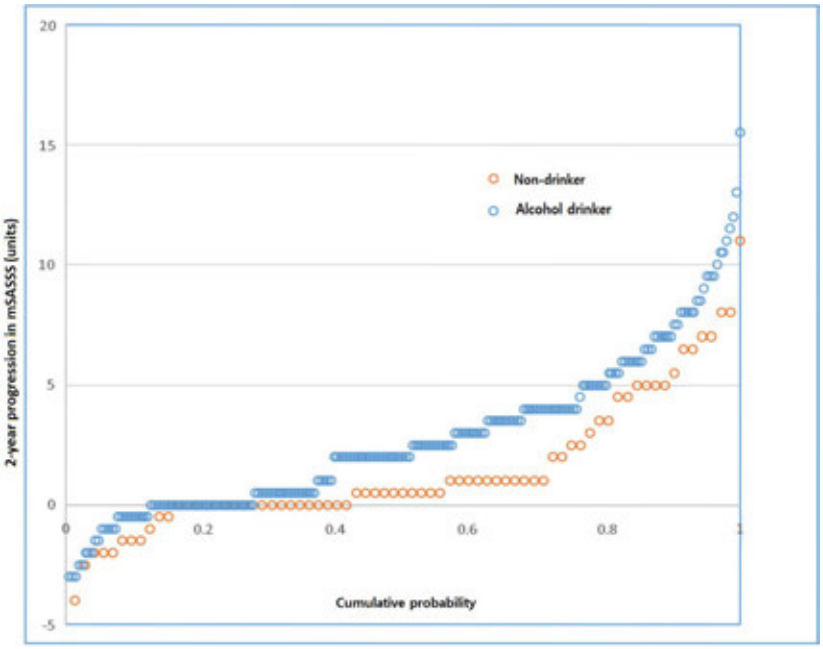


Table 2. Univariable and multivariable regression analysis of predicting worsening 2 unit or more of mSASSS over 2 years

Session Date: Tuesday, November 12, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical V: Axial Spondyloarthritis Clinical Studies

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: The association between disease activity and spinal radiographic progression in radiographic axial spondyloarthritis (r-axSpA) has been previously shown in a cohort of patients (pts) not being treated with TNF inhibitors (TNFi).[1] We aimed to test the possible association between disease activity and spinal radiographic progression in r-axSpA in a real-life cohort, also including patients treated with TNFi.

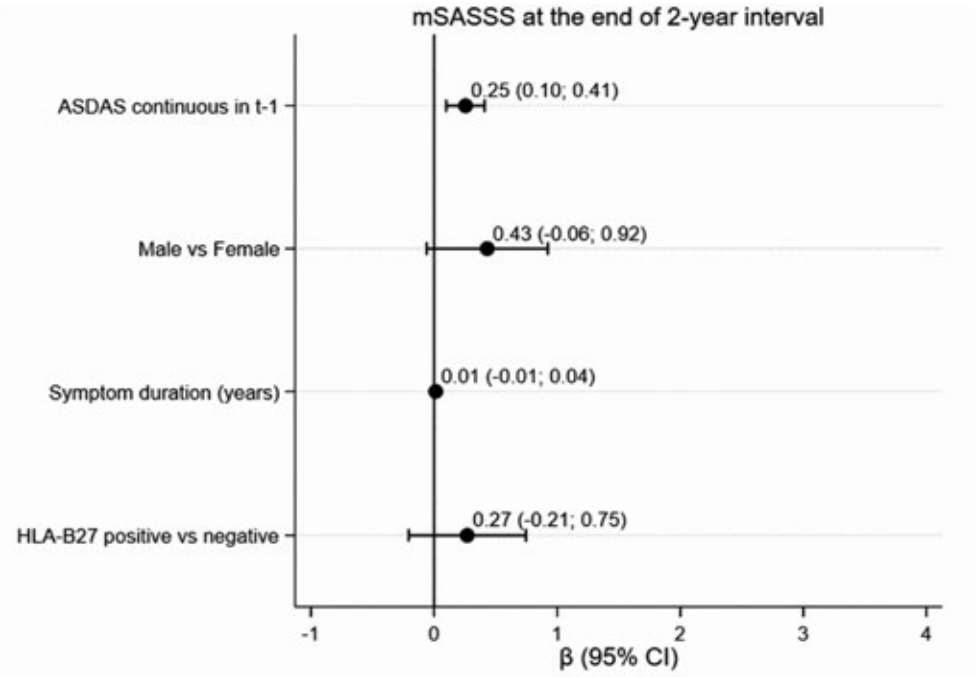

Figure. Longitudinal effect of ASDAS at the start of the interval on mSASSS 2 years later in a multilevel, multivariable linear GEE model with autoregression [N=313; model also adjusted for mSASSS at t-1 ('autoregressor'), Number of TNFi before baseline (continuous) and TNFi at t-1 (yes vs no)].

Methods: Pts with axial spondyloarthritis (axSpA) fulfilling the modified New York criteria (mNY) were included in this prospective, observational cohort (ALBERTA FORCAST). Clinical and imaging data were collected at baseline and every 2 years up to 10 years of follow-up. Radiographs of the spine were independently scored by 2 central readers and one adjudicator (if disagreement), with known chronological order but blinded to clinical data, using the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS). To be included, pts had to have ≥ one 2-year interval with data on mSASSS from ≥1 reader available as well as complete data on ASDAS and TNFi exposure at the start of the interval. The association between ASDAS at the start of the interval (t) and mSASSS 2 years later (t+1) was tested in two types of longitudinal GEE models: i. multilevel (2 readers) model with the individual reader scores as outcome (2-level models); ii. Using as outcome averaged scores between readers (1-level models). Both type of models were adjusted for mSASSS at t (autoregression) and for a set of potential confounders defined a priori on clinical grounds (Figure).

Results: In total, 314 pts (442 intervals) were included [74% males, mean symptom duration 17.8 (SD 11.7) years, 83% HLA-B27 positive and 7% previously treated with ≥1 TNFi]. At baseline the mean ASDAS was 2.7 (1.3) and the mean mSASSS 13.8 (18.9). During follow-up 213 (68%) pts received treatment with TNFi in ≥1 visit. Overall, the average 2-year progression was 1.33 (2.68) mSASSS-units per 2-year interval. In the 2-level multivariable model, 1 ASDAS-unit increase at t was associated with an increase of 0.25 mSASSS-units at t+1 [β (95% CI): 0.25 (95%CI 0.10; 0.41)] (Figure). Results were similar using the averaged mSASSS as the outcome [β (95% CI): 0.25 (0.08; 0.43)].

Conclusion: These data indicate that a higher ASDAS is associated with higher spinal radiographic progression in pts with r-axSpA and this is independent of prior treatment with TNFi.

Identification of SLE Subgroups at Risk for Poor Outcomes After Hydroxychloroquine Taper or Discontinuation

Celline C. Almeida-Brasil,[1] Evelyne Vinet,[2] Christian Pineau,[2] and **Sasha Bernatsky** [1], [1]Research Institute of the McGill University Health Centre, Montreal, QC, Canada, [2]McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical V: Emerging Knowledge of Current Treatments
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The risks and benefits of long-term hydroxychloroquine (HCQ) use in systemic lupus erythematosus (SLE), versus tapering or stopping, remain uncertain. We aimed to identify predictors of a poor outcome once HCQ is tapered or discontinued in SLE.

Methods: We studied a clinical cohort of adult patients meeting ACR classification criteria for SLE. From January 2002 and December 2018, we identified the first visit with HCQ exposure for each patient. We then determined those tapering (sub-cohort 1) or discontinuing (sub-cohort 2) HCQ at a follow-up visit. This follow-up visit represented time zero for the remaining analyses. The primary outcome was time to the first of the following events: a) increase of ≥4 points in the SLE Disease Activity Index (SLEDAI-2K); b) hospitalization for SLE; and/or c) augmented SLE therapy (i.e. an increase in HCQ, or a new start/increase in corticosteroids or immunosuppressants). Cox regression was used to calculate hazard ratios (HRs) and 95% confidence intervals (CIs) to determine if baseline characteristics (age at SLE diagnosis, sex, education and race/ethnicity) were associated with our outcome.

Results: We identified 228 patients tapering HCQ (sub-cohort 1) and 188 stopping HCQ (sub-cohort 2). Most patients were female (90%) and white (70%), and the mean±SD age at SLE diagnosis was 32±13 years. The mean±SD follow-up time from our time zero was 6.7±4.4 years in sub-cohort 1 and 5.6±4.7 in sub-cohort 2. Within the first year of observation, 167 (73%) patients who tapered HCQ and 133 (71%) patients who discontinued HCQ had at least one poor outcome. The most common poor outcome was need for therapy augmentation (70% after tapering and 64% after stopping HCQ), followed by SLEDAI-2K increase ≥4 (37% after tapering and 32% after stopping HCQ) and hospitalization for SLE (7% after tapering and 8% after stopping HCQ). Patients with higher age at SLE diagnosis and those with SLEDAI-2K ≥4 and/or requiring prednisone/mycophenolate at baseline were more likely to experience poor outcomes after HCQ discontinuation (Table 1). Patients with renal damage were more likely to have an increase in disease activity after tapering HCQ (adjusted HR: 2.02; 95%CI: 1.13, 3.62).

Conclusion: Though some SLE patients do well after tapering or discontinuing HQN, others have poor outcomes including SLE-related hospitalization. Our results suggest caution in tapering or discontinuation of HCQ in some groups of SLE patients, such as those with renal damage, unstable disease activity, or requiring prednisone/mycophenolate. The identification of these predictors is an important approach to promote personalized medicine.

Risk of Cardiovascular Disease Associated with the Use of Glucocorticoids in Patients with Incident Systemic Lupus Erytematosus: A Population-based Study

Lingyi Li,[1] Hui Xie,[2] Eric Sayre,[1] and J. Antonio Avina-Zubieta[3], [1]Arthritis Research Canada, Vancouver, BC, Canada, [2]Arthritis Research Canada and Simon Fraser University, Vancouver, BC, Canada, [3]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical V: Emerging Knowledge of Current Treatments
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have an increased risk for cardiovascular disease (CVD). SLE itself predisposes patients to accelerated atherosclerosis. In addition, the risk of CVD may be due to effects of drugs used to treat SLE, particularly glucocorticoid (GC). However, population-based studies assessing the risk of CVD associated with the use of GC with proper adjustment of time-varying confounders that might be also acting as intermediary variables in patients with newly diagnosed SLE are limited. We aim to address this question and the idea that recency of GC use may impact the effect.

Methods: Our data included all outpatient and inpatient visits, demographic data, cancer registry and vital statistics from Jan 1990 to Mar 2015 and all dispensed medication from Sept 1995 to Mar 2015 in the province of British Columbia, Canada. Using a previously validated SLE case definition, we assembled an incident cohort of all SLE patients who received health care between January 01 1997 and March 31 2015 with no exposure to GC before SLE onset. CVD events (myocardial infarction (MI) or stroke) were identified using both hospitalization and vital statistics data. Individuals were followed until they experienced a CVD outcome, died, left BC, or follow-up ended, whichever occurred first. We used the marginal structure Cox model to estimate the impact of the GC initiation on the risk of CVD, adjusting for both baseline and time-dependent covariates (including health resource utilization and relevant medications (listed in table1)) that were updated every three months during follow-up. We defined GC exposure in four more ways: current use (yes/no), current dose (mg/day), cumulative dose (grams), cumulative duration (months). All were used as time-dependent variables. To permit the effect of a GC use in the past 180 days to vary by its recency, we created weighted versions of the cumulative dose and duration (i.e., straight-line, concave, convex, and half-normal weighting function). Cox proportional hazard models were used to estimate the risk of CVD of these GC exposure measures.

Results: We identified 2,653 incident SLE patients with no GC use history at baseline (mean age 47, 86% females). During follow-up, 1,720 (65%) received GC. GC users spend an average 15% of their follow-up time on GC with a median dose of 5 mg/day and a median duration per GC course of 29 days. During follow-up, we identified 108 CVD events (MI 69; stroke 45). Using marginal structure model, the hazard ratio (HR) after GC initiation was 1.82 (95%CI; 1.18-2.81) adjusted for baseline and time-dependent variables. Current GC use and current daily dose were associated with significantly increased risk of CVD (HR; 1.76 (95%CI; 1.06-2.94) and 1.14 (95%CI; 1.03-1.26)) (Table 2). Concave function for both cumulative dose and cumulative duration of use were selected as the best weighting function with the smallest AIC. Both of them were statistically significant (HR: 1.59 (95% CI; 1.23-2.05) and 1.21 (95% CI; 1.04-1.41)).

Characteristics	All SLE patients N=2653	Exposed to GC N=1720	Never exposed to GC N=933

[a]Competing risk models adjusting for the competing risk of death, cumulative corticosteroid dose in the 60 days prior to and including the index date, hypertension, and hyperlipidemia. Corticosteroid dose was categorized as a mean daily dose of 0-5mg, >5-15 mg, and >15 mg. MMF = mycophenolate mofetil; CYC = cyclophosphamide; CVD = cardiovascular disease; 95% CI = 95% confidence interval; HR_{SD} = subdistribution hazard ratio.
[b]CVD events a composite of acute myocardial infarction, cerebrovascular accident, heart failure, percutaneous coronary intervention, or coronary artery bypass graft, determined by primary or secondary hospital discharge diagnosis for CVD event

Background/Purpose: Human studies examining cardiovascular disease (CVD) risk associated with immunosuppressants (IS) have been limited, but mycophenolate mofetil (MMF) was shown to suppress vascular smooth muscle and endothelial cell proliferation in murine models. In a large SLE Medicaid cohort, we compared CVD event risks among those initiating MMF vs. cyclophosphamide (CYC), used interchangeably for lupus nephritis and severe SLE manifestations, and MMF vs. azathioprine (AZA), used interchangeably longer-term for lupus nephritis or moderately active SLE.

Methods: Within the Medicaid Analytic eXtract (2000-2010; 29 most populated US states), we identified adults ages 18–65 years, with ≥2 International Classification of Diseases, Ninth Revision (ICD-9) SLE codes (710.0) ≥30 days apart. Among them, we identified those filling a new prescription for MMF, AZA, or CYC with continuous Medicaid enrollment ≥6 months prior to first prescription (index date). The CVD event outcome included hospitalized acute myocardial infarction, cerebrovascular accident, heart failure, percutaneous coronary intervention, or coronary artery bypass graft by validated administrative algorithms. Based on sociodemographic, comorbidity, and medication use variables during the baseline (pre-index date), we calculated propensity scores for MMF vs. CYC and MMF vs. AZA. After 1:1 propensity score matching, we estimated incidence rates for first CVD events after drug initiation. Fine-Gray regression models estimated subdistribution hazard ratios (HR_{SD}) for incident CVD events and 95% confidence intervals (95% CIs), accounting for the competing risk of death, additionally adjusting for cumulative corticosteroid dose, hypertension, and hyperlipidemia. Intent-to-treat (ITT) analyses followed subjects from index date for 6 or 12 months, censoring at first CVD event, Medicaid disenrollment or 12/31/2010. As-treated analyses additionally censored at > 60 day gaps in index medication.

Results: We studied 674 propensity-score matched pairs of MMF vs. CYC initiators and 1,350 pairs of MMF vs. AZA initiators. Baseline characteristics were balanced in the matched treatment groups (**Table 1**). In those with more severe SLE, the point estimate HR_{SD} for first CVD event for MMF vs. CYC (ref.) was < 1, although not statistically signifi-

Table 3. Intent-to-treat and as-treated analyses for MMF versus AZA for rates and risks of first CVD event[a]

	MMF (n=1,350)				AZA (n=1,350)			
	No. of cases	Total person-years	Incidence rate per 100 person-years (95% CI)	HR_{SD} (95% CI)	No. of cases	Total person-years	Incidence rate per 100 person-years (95% CI)	HR_{SD} (95% CI)
As-treated	29	1,051.3	2.76 (1.92-3.97)	0.76 (0.47, 1.25)	35	875.1	4.00 (2.87, 5.57)	Reference
Intent-to-treat								
6 months	18	634.9	2.84 (1.79-4.50)	0.63 (0.35, 1.14)	29	627.4	4.62 (3.21-6.65)	Reference
12 months	31	1,177.4	2.63 (1.85-3.74)	**0.58 (0.37, 0.91)**	54	1,169.2	4.62 (3.54-6.03)	Reference

[a]Competing risk models adjusting for the competing risk of death, cumulative corticosteroid dose in the 60 days prior to and including the index date, hypertension, and hyperlipidemia. Corticosteroid dose was categorized as a mean daily dose of 0-5mg, >5-15 mg, and >15 mg. MMF = mycophenolate mofetil; AZA = azathioprine; CVD = cardiovascular disease; 95% CI = 95% confidence interval; HR_{SD} = subdistribution hazard ratio.
[b]CVD events a composite of acute myocardial infarction, cerebrovascular accident, heart failure, percutaneous coronary intervention, or coronary artery bypass graft, determined by primary or secondary hospital discharge diagnosis for CVD event

cant: HR_{SD} 0.68 (95% CI 0.37, 1.22) in the as-treated analysis, and HR_{SD} 0.75 (95% CI 0.46, 1.21) in the 12-month ITT analysis (**Table 2**). In those with more moderate SLE, MMF was associated with a reduced risk of CVD vs. AZA (ref). This was non-significant in the as-treated analysis (HR_{SD}: 0.76 [95% CI 0.47, 1.25]), but significant in the 12-month ITT analysis: (**HR_{SD} 0.58 [95% CI 0.37, 0.91]**, **Table 3**).

Conclusion: In a rigorous head-to-head propensity score matched analysis of SLE Medicaid patients in a large longitudinal study, CVD event risks appeared to be reduced among those taking MMF vs. CYC or AZA, although only significantly lower for MMF vs. AZA in the 12 month ITT analysis. These comparisons adjusted for multiple factors, including corticosteroid use and lupus nephritis. We are obtaining longer Medicaid follow-up data to pursue this interesting finding.

Hydroxychloroquine Blood Levels and Risk of Thrombotic Events in Systemic Lupus Erythematous

Maximlian Konig,[1] Jessica Li,[1] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical V: Emerging Knowledge of Current Treatments
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

	Mean HCQ blood level (mean ± SD)		
	With thrombosis	Without thrombosis	p-value
Any thrombosis	679.6 ± 470.7	860.5 ± 573.2	0.0393
Any venous thrombosis			
With superficial	673.4 ± 480.2	873.6 ± 574.6	0.0616
Without superficial	629.4 ± 491.3	872.4 ± 573.8	0.0249
Any arterial thrombosis	761.1 ± 551.8	853.7 ± 578.4	0.3720
Stroke	747.3 ± 599.2	856.3 ± 573.7	0.3457

Table 1. Prospective Analysis of Risk of Thrombosis and Mean Hydroxychloroquine Blood Levels

	Mean HCQ dose in mg/kg (mean ± SD)		
	With thrombosis	Without thrombosis	p-value*
Any thrombosis	4.60 ± 1.45	4.84 ± 1.34	0.0392
Any venous thrombosis			
With superficial	4.49 ± 1.48	4.84 ± 1.34	0.0081
Without superficial	4.45 ± 1.47	4.84 ± 1.35	0.0048
Any arterial thrombosis	4.73 ± 1.39	4.77 ± 1.37	0.7361
Stroke	4.75 ± 1.41	4.78 ± 1.37	0.8660

Table 2. Cross-Sectional Analysis of Risk of Thrombosis and Mean Prescribed Hydroxychloroquine Dose

Background/Purpose: The antimalarial drug hydroxychloroquine (HCQ) has a primary role in the treatment of systemic lupus erythematous (SLE). Beyond its pleiotropic immunomodulatory effects on TLR and type I interferon signaling, HCQ use has been found to be protective for thrombosis in SLE. Optimal dosing of HCQ in SLE is unknown. The longitudinal measurement of HCQ blood levels may provide an opportunity to individualize weight-based dosing strategies and reduce risk of toxicity. We examined the association of HCQ blood levels with thrombotic events in a longitudinal SLE cohort.

Methods: Patients with no HCQ level measured prior to the thrombosis were excluded. 812 SLE patients were included: 93% female, 43% African-American, 46% Caucasian. HCQ blood levels were quantified by liquid chromatography-tandem mass spectrometry. Mean HCQ blood levels (± SD) over all cohort visits prior to occurrence of thrombosis were calculated for each patient. Thromboses were defined as venous (DVT/PE or other venous) or arterial thrombosis (stroke, myocardial infarction, digital gangrene or other arterial).

Results: Thrombosis had occurred during prospective follow up in 44 patients (5.4%), venous in 3.0% and arterial in 2.5%. Lupus anticoagulant was strongly associated with a history of any thrombosis (OR 3.25, P< 0.0001), venous thrombosis (OR 3.53, P< 0.0001), and arterial thrombosis (OR 3.08, P< 0.0001). A prospective analysis (Table 1) shows that for any thrombosis and for venous thrombosis, the HCQ blood level was significantly lower. Higher prescribed doses of HCQ (as opposed to HCQ blood levels) were also associated with decreased odds of any thrombosis and also of venous thrombosis (Table 2) in a separate cross-sectional analysis (OR 0.88, P=0.04 and OR 0.83, P=0.009, respectively for each 1 mg/kg increase in prescribed HCQ).

Conclusion: HCQ blood levels are inversely associated with risk of any thrombosis and of venous thrombosis in patients with SLE in a prospective analysis. Reduction of HCQ dosing, as suggested by the American Academy of Ophthalmologists, could reduce or eliminate the benefit of hydroxychloroquine to prevent thrombosis.

Alterations in Inflammatory, TNF-Superfamily, and IFN-Associated Chemokines Precede Clinical Changes in SLEDAI After Methylprednisolone Treatment of SLE Patients

Melissa E. Munroe,[1] Carla J. Guthridge,[1] Sarah Kleckner,[1] Ly Tran,[2] Joel Guthridge,[3] Debra J. Zack,[4] Judith James,[3] and Joan T. Merrill[5], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, [3]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]Xencor, Inc., San Diego, CA, [5]Okalahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Clinical V: Emerging Knowledge of Current Treatments
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: SLE is typified by a wide spectrum of clinical manifestations and immune dysregulation. Corticosteroids are almost universally effective, but marked by unacceptable side effects. An understanding of steroid efficacy signals may provide clues for safer, more targeted treatments.

Table 1. MP Induced Decrease in Select Immune Mediator Levels

RNP	Significant decrease after MP (23±5 days post-Rx)		

Figure 1. Changes in hSLEDAI, BLyS*, and AutoAbs Post-Flare**

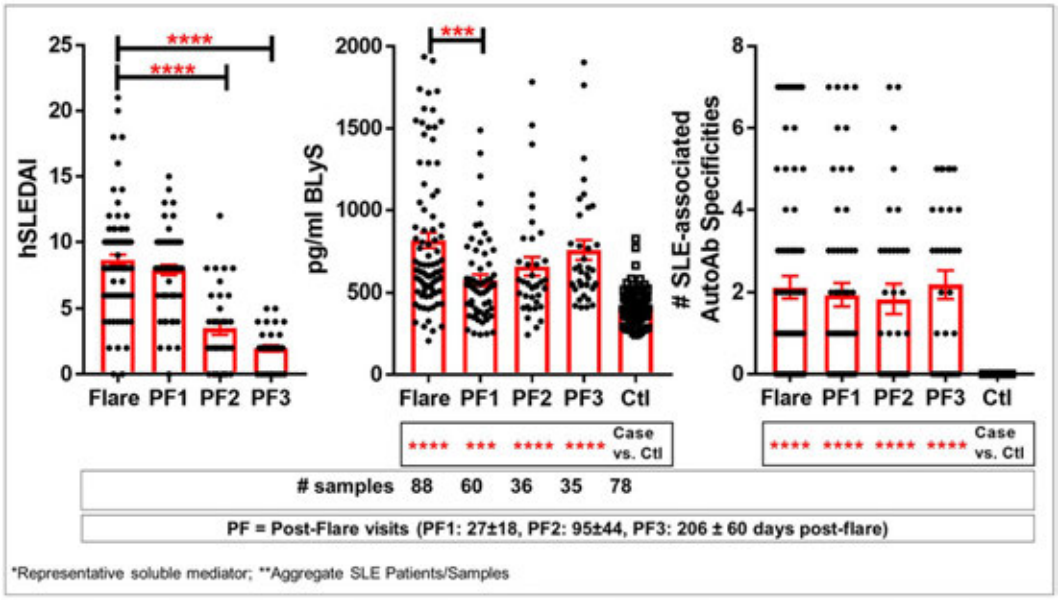

Figure 2. BLyS* Levels Increase Prior to New Flare

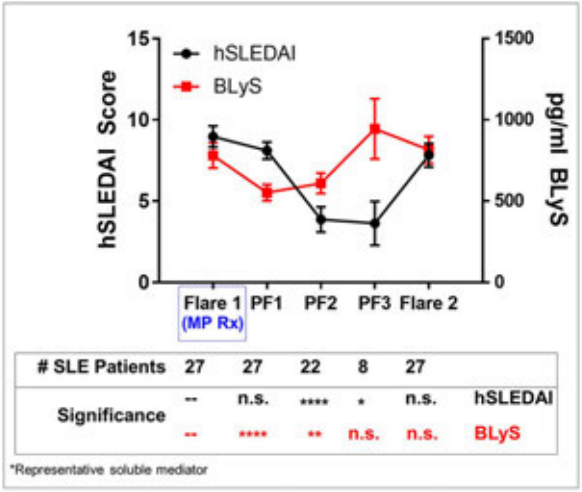

Methods: This study capitalized on entry samples from the Phase 2 **XmAb®5871** study to define which immune effectors are sensitive to methylprednisolone (MP). Plasma immune mediators and serum autoantibodies (AutoAbs) were evaluated by xMAP assay in 103 active SLE pts (≥ 4 ACR criteria) assessed pre- and post-MP Rx vs. race/sex/age-matched controls (n=78). Fifty-two patients were randomized to continue the study on placebo, and were serially followed for 191 ± 75 days for changes in clinical disease activity (by hybrid SLEDAI [hSLEDAI]). Biomarkers (**Table 1**) were measured in an average of 5 serially collected plasma samples (range 3-6, average of 45 days between sample visits). The advantage of this *BOLD* trial design was the control of MP Rx by intramuscular injection and required withdrawal of background immunosuppressants other than HCQ and ≤ 10 mg prednisone/equivalent/day.

Results: MP resulted in decreased levels of a number of immune mediators (all $p \leq 0.02$, **Table 1**) that were readily detected in SLE plasma and higher in cases vs. ctls ($p < 0.0001$); BLyS and Stem Cell Factor (SCF) levels were most affected ($p < 0.0001$). This occurred prior to or in conjunction with decreased hSLEDAI scores ($p = 0.0001$), decreased arthritis ($p = 0.0471$), and decreased serologic ($p = 0.0003$) features (**Figure 1**). Of 52 placebo pts with serial samples, 49 exhibited clinical disease flare at one or more visits, primarily due to increased arthritis and mucocutaneous features. When we evaluated samples at time of clinical disease flare and up to three post-flare samples thereafter in aggregate (**Figure 1**), we noted that specific immune mediators, including TNF-α, TNFRII, SCF, IL-2Rα, MCP-1, IP-10, and BLyS transiently decreased (all $p \leq 0.03$) in the first post-flare sample (PF1).These same mediators then increased again to clinical flare levels in PF2 and PF3 samples, preceding clinical evidence of new disease flares (**Figure 2**). Within the 145 ± 75 days between flares, there was little to no effect on number or type of SLE-associated AutoAbs (**Figure 1**).

Conclusion: Changes in a distinct subset of immune mediators are sensitive to MP Rx and were observed before or with hSLEDAI improvement. Subsequent resurgence of BLyS, TNF-α, TNFRII, SCF, IL-2Rα, MCP-1, and IP-10 preceded new clinical disease flares. This study underscores the probable utility of these markers for early intervention before clinical disease flares.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: SLE – Clinical V: Emerging Knowledge of Current Treatments

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Many studies of cancer risk in SLE are limited by small sample size or use of administrative data, which rely on billing code diagnoses instead of clinical data. No studies to date focused on incident SLE. We studied cancer risk in the largest-ever cohort of clinically confirmed incident SLE patients.

Methods: Patients meeting ACR criteria for new-onset SLE (within 15 months of diagnosis) were enrolled into the SLICC Inception Cohort, across 32 centres. Patients are followed yearly using a standard protocol, with detailed data collection including SLE Disease Activity Index-2000 (SLEDAI-2K) and damage, and drugs in the past year. New cancer diagnoses are recorded by the examining physician at the annual study visit, and confirmed with chart review including pathology reports.

Multivariate proportional hazard regression was performed, using baseline variables for demographics (age at SLE onset, sex, race/ethnicity), and time-dependent variables for drugs (corticosteroids, anti-malarial drugs, immunosup-

Baseline characteristics	No Cancer (N=1608)	Cancer (N=60)
N (%) Female	1435 (89.2)	45 (75.0)

[a] All variables were considered in the model

[b] Adjusted for age at SLE diagnosis, sex, and race/ethnicity.

Table 2. Hazard Ratio for cancer in SLE (univariate, full model and partials models)

Results: Of 1848 new-onset SLE patients enrolled between 1999-2011, 1668 had at least one follow-up; these were the sample for the current analysis. End date was the first of death, last visit, or end of study interval for this analysis (Aug. 2015). Baseline demographics are shown in Table 1.

Over 14,215 years (mean 8.5 years) there were 60 cancers (incidence 4. 2 events per 1,000 patient-years). This included 12 breast cancers, 9 non-melanoma skin, 7 lung, 6 hematological, 5 melanoma, 5 prostate, 3 cervical, 3 renal, 2 gastric, 2 head and neck, 2 thyroid, and one each rectal, sarcoma, thymoma, and uterine. Almost half of the cancer cases (including all of the lung cancers) were associated with baseline smoking, versus only one-third of those patients who did not develop cancer. Univariate analyses of all cancer types suggested a higher risk of cancer among patients of white race/ethnicity and among those with the highest quartile of disease activity at cohort entry.

However, the multivariate proportional hazard regression indicated that among SLE patients, the over-all cancer risk was related primarily to male sex and older age at SLE diagnosis. In those analyses, the effect of race/ethnicity was not clearly evident, and the point estimate for highest quartile of disease activity actually reversed to suggest a non-significant trend towards lower cancer risk.

In the multivariate analyses specifically for breast cancer, age at SLE diagnoses remained a risk factor, and anti-malarials were associated with a decreased risk. This effect of anti-malarials was not clearly seen for any other cancer type. For non-melanoma skin cancer, both age at SLE diagnosis and cyclophosphamide were strongly linked with risk.

Conclusion: This is the first large, multicentre cohort study to clearly show how different cancer types in SLE are associated with specific risk factors. Additional follow-up may allow additional determination of the possible effects of disease activity and drugs on cancer subtypes.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: ANCA-associated vasculitides (AAVs) are the most frequent cause of rapidly progressive glomerulonephritis (RPGN), for which the major prognostic issue is the risk of developing end-stage renal disease (ESRD) or dying. The large, multicenter, prospective PEXIVAS trial, including patients with severe AAVs, i.e. lung hemorrhage and/or renal failure (estimated glomerular filtration rate (eGFR) < 50 ml/min/1.73 m2),showed that plasma exchanges (PLEX) did not lower the ESRD or death risk for AAV patients, but the prognostic impact of renal histology on the renal outcome and response to PLEX was not assessed.We aimed to evaluate whether histopathological findings could predict the renal outcome of PLEX-treated AAV patients.

Methods: This retrospective, multicenter study included patients with microscopic polyangiitis, granulomatosis with polyangiitis or renal-limited vasculitis, fulfilling ACR criteria or Chapel Hill Consensus Conference definitions. All patients had a renal biopsy and were treated with PLEX. Two histopathological classifications were evaluated from renal biopsy reports: Berden's, distinguishing 4 categories (focal, crescentic, mixed and sclerotic), using the percentages of different glomeruli lesions; and Brix's, discerning 3 risk groups (low, medium or high), using the percentages of normal glomeruli, tubular atrophy and interstitial fibrosis, and baseline eGFR. The primary endpoint was dialysis independence and survival at month (M) 12. Secondary endpoints were eGFR >30 ml/min/1.73 m^2at M12, and delta eGFR >15 ml/min/1.73 $m^2$from baseline to M12.

Results: We included 163 patients from 19 centers: 99 (61%) men; 92 (56%) MPO-ANCA+, 65 (40%) PR3-ANCA+; mean±SD baseline serum creatinine 555±274 µmol/L, 62 (38%) with alveolar hemorrhage; 139 (85%) given cyclophosphamide and 30 (18%) received rituximab; 74 (45%) required dialysis at baseline. Mean number of PLEX was 7.0±2.3.

Berden categories were focal (19%), crescentic (39%), mixed (20%) and sclerotic (21%). Brix risk groups were low (11%), medium (48%) and high (41%). Both Berden and Brix histopathological classifications on baseline renal biopsies were associated with the primary endpoint, i.e. dialysis independence and survival at M12 (χ2 24.9; P< 0.0001,

and χ2 11.7; P=0.003, respectively).In contrast, baseline serum creatinine levels did not differ betweenfavorable and poor-prognosis groups (respectively:526±252 µmol/L vs. 597±300 µmol/L; P=0.11). Secondary endpoints were also associated with Berden and Brix classifications, respectively: achievement of eGFR >30 ml/min/1.73 m2at M12 (χ2 14.0; P=0.003, and χ2 17.3; P=0.0002); andimproved renal function with delta eGFR >15 ml/min/1.73 m2from baseline to M12 (χ2 18.1; P=0.0004, and χ2 17.7; P=0.0001).

Conclusion: In a cohort of AAV patients treated with PLEX for RPGN, our findings suggest that renal biopsy classification at diagnosis strongly predicted renal outcome at M12. AAV patients with RPGN should undergo renal biopsy to help physicians identify who among them would benefit the most from PLEX.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Renal involvement in the context of anti-neutrophil cytoplasm antibody (ANCA)-associated vasculitis (AAV) is associated with significant morbidity and higher mortality rates. This study examined predictive factors associated of renal involvement in AAV within a large, international cross-sectional cohort.

Methods: Univariate and multivariate analyses were performed to identify risk factors associated with renal disease, which was defined as i) an increase of serum-creatinine > 30%; ii) a fall in creatinine-clearance < 25%; or iii) haematuria attributable to active vasculitis.

Results: Of the 1230 patients eligible, 723 patients (58.8%) presented with renal involvement. The majority of patients with microscopic polyangiitis (82.2%) and granulomatosis with polyangiitis (58.6%) had renal involvement, while 26.4% with eosinophilic granulomatosis with polyangiitis presented with renalvasculitis. The following clinical factors were more common among patients with renal disease that among patients without renal disease. Older age (57.9 versus 53.9 years, p=0.001), fever (39.8% versus 23.7%, p< 0.001), fatigue (68.0% versus 50.1%, p=0.005), weight loss (43.4% versus 26.2%, p=0.001), polyarthritis (19.4% versus 15.0%, p=0.036), petechiae/purpura (18.0% versus 12.0%, p=0.022), pulmonary haemorrhage (24.8% versus 7.1%, p=0.014), gastrointestinal symptoms (25.9% versus 15.8%, p=0.002), serum albumin below 30 g/L (36.6% versus 11.6%, p< 0.001), higher CRP

Table 1. Disease manifestations and their association with renal involvement in cases with ANCA-associated vasculitis. Multivariate analysis was performed when variables were significantly associated with renal involvement in univariate analysis. Abbreviations used: OR: odds ratio, CI: confidence interval, ENT: ear, nose and throat, PAH: pulmonary alveolar haemorrhage.

Table 2. Laboratory parameters associated with renal involvement. Significant associations in univariate analysis were either confirmed or rejected by multivariate analysis. Abbreviations used: OR: odds ratio, CI: confidence interval, ESR: erythrocyte sedimentation rate, CRP: C-reactive protein, ANCA: anti-neutrophil cytoplasm antibody, c-ANCA: cytoplasmic ANCA, p-ANCA: perinuclear ANCA, PR3: proteinase 3, MPO: myeloperoxidase, ELISA: enzyme-linked immunosorbent assay, GBM: glomerular basement membrane, RF: rheumatoid factor, ACPA: anti-cyclic citrullinated peptide antibody, ANA: anti-nuclear antibody, dsDNA AB: double-stranded DNA antibody.

airway disease (8.2% versus 22.9%, p< 0.001) had a lower likelihood of developing renal involvement. (see Table 1 and Table 2).

Conclusion: In this large international study, we identified clinical factors associated with renal involvement in AAV, including concomitant pulmonary alveolar haemorrhage, low C3, and elevated C-reactive protein. Further large studies arenecessary to confirm our findings.

Longitudinal Changes in the Nasal Microbiome and Disease Activity in Patients with Granulomatosis with Polyangiitis

Rennie Rhee,[1] Antoine Sreih,[2] Jung-Jin Lee,[3] Kyle Bittinger,[3] Lisa Mattei,[3] Ronald Collman,[4] and Peter Merkel[2], [1]University of Pennsylvania, Division of Rheumatology, Philadelphia, PA, [2]University of Pennsylvania, Philadelphia, PA, [3]Children's Hospital of Philadelphia, Philadelphia, [4]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Microbial organisms have been theorized to contribute to disease activity in granulomatosis with polyangiitis (GPA) but little is known about what changes occur in commensal microbes in association with disease relapse. This longitudinal study examined compositional changes in the nasal microbiome and its association with disease activity in patients with GPA. We hypothesized that the overgrowth of pathogenic bacteria in the nasal cavity is associated with local and systemic disease activity (or flare).

Methods: Nasal bacterial composition was examined using 16S rRNA gene sequencing of DNA obtained from nasal swabs of 19 patients with GPA who were followed longitudinally (approximately every 3 months) for a total of 78 visits. Nine patients had at least 1 visit with a flare visit and 10 patients remained in remission during follow-up. Disease activity was determined by BVAS/WG. The main variables of interest were the relative abundance of the 5 most abundant taxa (or bacterial genera) as well as ratios between these taxa (to understand potential interactions between bacteria). As opposed to genus-level comparisons, species-level assignment was predicted based on the 16S gene (R package *Unassigner*) since bacterial interactions and effects can be specific to a particular species. Linear mixed effects models evaluated the association between bacteria and disease activity, accounting for repeated measures within an individual. Models adjusted for use of antibiotic and immunosuppressive medications, and sinus irrigation.

Results: Among the 19 patients enrolled, 10 patients never relapsed while 9 patients had 12 flares during follow-up. Of the 12 flare visits, 8 had clinically-identifiable sinonasal involvement and only 1 flare visit was a patient receiving full-dose trimethoprim-sulfamethoxazole. *Corynebacterium*, *Propionibacterium*, *Staphylococcus*, *Alloiococcus*, and *Streptococcus* were the most abundant bacterial genera in the samples. A higher ratio of the bacterial genera *Staphylococcus* to *Corynebacterium* occurred at the visit prior to flare, even after adjusting for medications and sinus irrigation ($P < 0.01$; **Figure 1**). Higher resolution species-level examination found *Corynebacterium tuberculostearicum* was associated with disease activity while other nasal commensals, such as *Propionibacterium acnes* and *Staphylococcus epidermidis*, decreased during flare ($P = 0.04$; **Figure 2**).

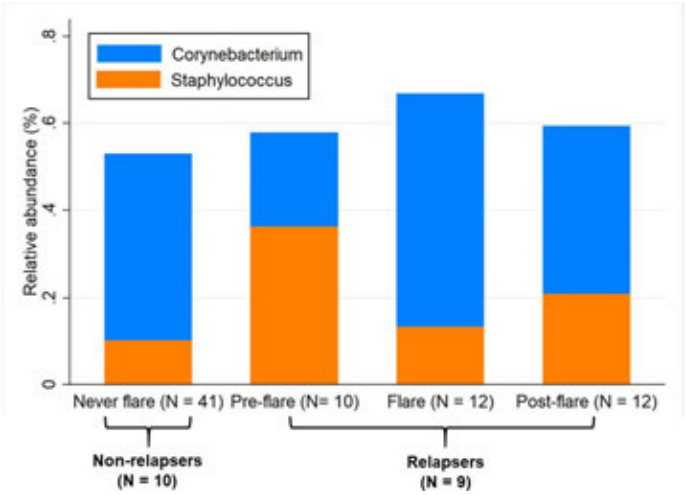

Figure 1. Genus-level analysis demonstrates an increase in Staphylococcus to Corynebacterium ratio that occurs prior to development of flare in granulomatosis with polyangiitis. Stacked bar plots show the median relative abundance of bacterial genera Staphylococcus and Corynebacterium in 2 groups: patients who never flare ("Non-relapsers"; N = 10) and those who develop a flare ("Relapsers"; N = 9). The Relapsers are further separated by visit to show longitudinal changes over time. A significant increase in the Staphylococcus to Corynebacterium ratio occurs prior to the development of a flare (adjusted $P < 0.01$). Patients who do not flare have a consistently lower ratio of Staphylococcus to Corynebacterium.

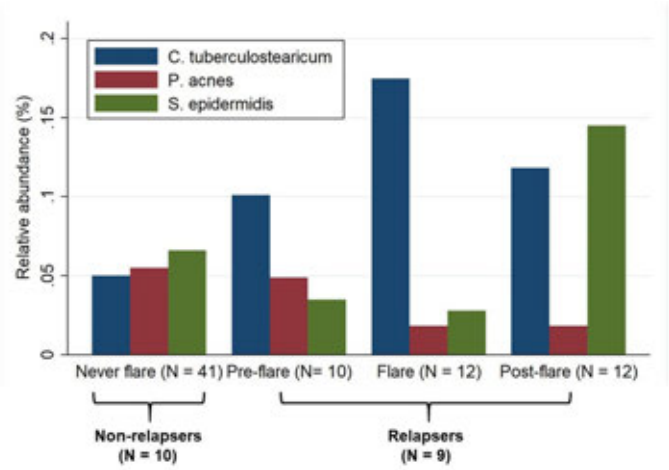

Figure 2. Predicted species-level assignments suggest increase in abundance of species Corynebacterium tuberculostearicum is associated with flare in granulomatosis with polyangiitis. Evaluation of most probable bacterial species (based on 16S gene sequences) identify an increase in the abundance of C. tuberculostearicum during flare while other nasal commensals, such as Propionibacterium acnes and Staphylococcus epidermidis, decrease during flare ($P = 0.04$).

Conclusion: In patients with GPA, significant changes occur in the nasal microbial composition over time in association with vasculitis disease activity. A higher ratio of *Staphylococcus* to *Corynebacterium* prior to development of flare suggests bacterial interactions may be an important risk factor for flare, possibly mediated through the outgrowth of *C. tuberculostearicum*. Notably, prior studies have shown that *C. tuberculostearicum* has pathogenic potential to cause sinusitis in murine models. These findings support the long-standing theory that overgrowth of pathogenic bacteria are potentially implicated in the disease process of GPA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Granulomatosis with polyangiitis (GPA) is a small vessel vasculitis characterized by acute and chronic tissue destruction in the nose, sinuses, lungs and kidneys. In a subset of patients, tissue inflammation predominantly occurs in the ear, nose, throat and eye (ENT-dominated) manifesting with tissue-invasive and space-consuming lesions, such as saddlenose, septal perforation, orbital and ear bony wall destruction, and epiglottitis. ENT-dominated GPA is often chronic-relapsing and associated with autoantibodies against PR-3. A critical element in the pathogenesis of GPA is the production of neutrophil extracellar traps (NETs) from dying neutrophils. Whether NET-related pathology is different in distinct subsets of GPA patients is unknown. We have compared NET-induced inflammatory responses in patients with systemic GPA versus ENT-dominated GPA.

Methods: Patients with renal versus ENT-dominated GPA (rGPA; ENT-GPA) were recruited from a database that prospectively follows vasculitis patients. Patients with disease duration of >5 years and matched for immunosuppressive therapy were enrolled. Neutrophils and monocytes from rGPA, ENT-GPA and age-gender matched healthy donors were isolated from peripheral blood. NETosis was induced in isolated neutrophils and quantified with SYTOX green (ThermoFisher) and analyzed by flow cytometry. Isolated NETS were cocultured with monocyte-derived macrophages and the induction of pro-inflammatory mediators was examined by RT-PCR and flow cytometry. Tissue invasiveness of monocytes/macrophages was measured in a 3D matrix system.

Results: Neutrophils from patients with ENT-GPA had more intense NETosis with higher frequencies of netting neutrophils ($P < 0.01$) and more NETs released ($P < 0.01$). Purified NETs functioned as potent activators of monocytes and macrophages and induced a pro-inflammatory phenotype. Netting neutrophils from ENT-GPA were more efficient in upregulating pro-inflammatory cytokines in monocytes/macrophages ($P < 0.01$) when compared to neutrophils isolated from rGPA or age-matched controls. Measurements of matrix-invasive capacity of monocytes and macrophages exposed to control and patient-derived NETs revealed that ENT-GPA-derived NETs were able to induce monocytes and macrophages that were highly efficient in tissue invasion.

Conclusion: Neutrophils from patients with specified GPA disease patterns differ in NET formation. Highly efficient NETosis is associated with predominance of ENT manifestations. NETs are recognized by monocytes and macrophages and act as pro-inflammatory triggers. NETs derived from ENT-GPA patients are strong inducers of a tissue-destructive and invasive phenotype, reminiscent of the clinical manifestations in ENT-dominated GPA.

Platelet Mediates Neutrophil Extracellular Traps Formation via TLR Signaling in ANCA-associated Vasculitis

Kotaro Matsumoto,[1] Hidekata Yasuoka,[2] Katsuya Suzuki,[1] and Tsutomu Takeuchi[1], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Fujita Health University School of Medicine, Shinjuku-ku, Aichi, Japan

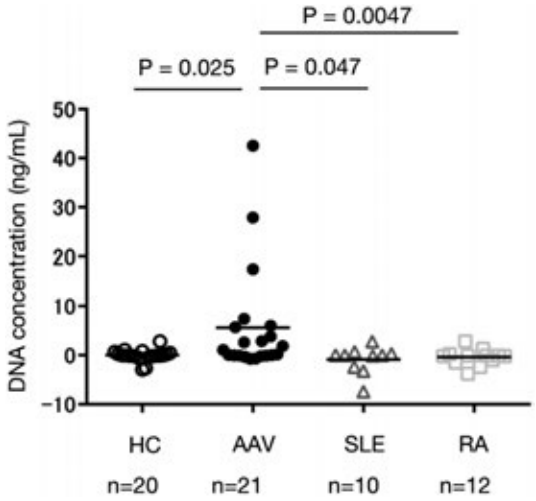
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is an autoimmune disease that affects small- to medium-sized blood vessels and causes vascular inflammation and multiple organ damage. The pathogenesis of AAV is still unclear. However, neutrophil extracellular traps (NETs) is thought to be one of important triggers of vascular endothelial dysfunction in the disease process of AAV, and it is recently reported that platelets stimulated via toll-like receptor (TLR) pathways can induce NETs formation. Thus, platelets may be alternative key players in AAV pathogenesis. In this study, we investigated the role of platelets and involvement of TLR signaling in the process of NETs formation in patients with AAV.

Methods: Twenty-one patients with AAV (granulomatosis with polyangiitis [GPA]: n=12, microscopic polyangiitis [MPA]: n=9) who visited Keio University Hospital between August 2017 and October 2018 were consecutively enrolled. Ten SLE, 12 RA, and 20 healthy controls (HCs) were included as controls. All AAV patients fulfilled the 2012 Revised International Chapel Hill Consensus Conference Nomenclature. Expression of platelet-associated TLRs were examined using flow cytometry. Clinical information was obtained from patients' record and association with expression of TLR was also examined. In order to examine functional involvement of platelets in NETs formation, platelets from AAV patients or HCs were co-cultured with peripheral neutrophils. In some experiments, platelets were stimulated with TLR agonist in advance. NETs formation visualized by Picogreen was detected and quantified using confocal fluorescent microscopy.

Results: As shown in the figure, platelets from AAV patients increased NETs formation compared with those from RA ($p=0.0047$), SLE ($p=0.047$) or HC ($p=0.025$). Flow cytometric analysis revealed that the expression of TLR9 ($p=0.0011$) but not other TLRs, such as TLR2 ($p=0.71$) and TLR4 ($p=0.93$), in platelets was elevated in platelets from AAV patients compared with HCs. In particular, the proportion of $TLR9^{+}$platelets was elevated in patients with pulmonary involvement compared with those without ($p=0.012$), and was correlated with patients' serum Krebs Von Den Lungen-6 level ($r^2=0.31$, $p=0.049$). Interestingly, we found that TLR9 agonist (CpG oligodeoxynucleotides)-stimulated platelets from AAV patients induced NETs formation compared with control oligodeoxynucleotides-stimulated platelets.

Conclusion: These results suggest that platelets play a key role in NETs formation in the pathogenesis of AAV and TLR9 signaling is involved in this process.



Summary of DNA concentration from neutrophils induced by exposure to platelets from HC (n=20) and patients with AAV (n=21), SLE (n=10) and RA (n=12).

Treatment Response Criteria for Anti-neutrophil Cytoplasmic Antibodies (ANCA)-vasculitis: Results of a Scoping Review

Sara Monti,[1] Kaitlin Quinn,[2] Robin Christensen,[3] Alfred Mahr,[4] Christian Pagnoux,[5] Carol Langford,[6] David Jayne,[7] Peter Merkel,[8] and Gunnar Tomasson[9], [1]University of Pavia, Pavia, Italy, [2]Georgetown University Hospital/ National Institutes of Health, Washington, DC, [3]Musculoskeletal Statistics Unit, The Parker Institute, Bispebjerg and Frederiksberg Hospital & Department of Rheumatology, Institute of Clinical Research, University of Southern Denmark, Odense University Hospital, Odense, Denmark, [4]Hospital Saint-Louis, University Paris Diderot, Paris, France, [5]Mount Sinai Hospital and University Health Network, Toronto, ON, Canada, [6]Cleveland Clinic, Cleveland, OH, [7]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, University of Cambridge, UK, Cambridge, United Kingdom, [8]University of Pennsylvania, Philadelphia, PA, [9]Faculty of Medicine, University of Iceland and Landpitali University Hospital, Reykjavik, Iceland

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Vasculitis – ANCA-Associated II
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: A comprehensive assessment of outcome measures to assess response to treatment in ANCA-associated vasculitis (AAV) is necessary to implement.

Methods: We performed a scoping review of available randomized controlled trials (RCTs) to assess the tools previously used as outcome measures in clinical trials of AAV. Medline, Embase, Cochrane Central and ClinicalTrials.gov were searched from inception until November 26, 2018 to identify RCTs enrolling patients with granulomatosis with polyangiitis (GPA) and/or microscopic polyangiitis (MPA). This study is part of an ongoing international project to develop response criteria for AAV.

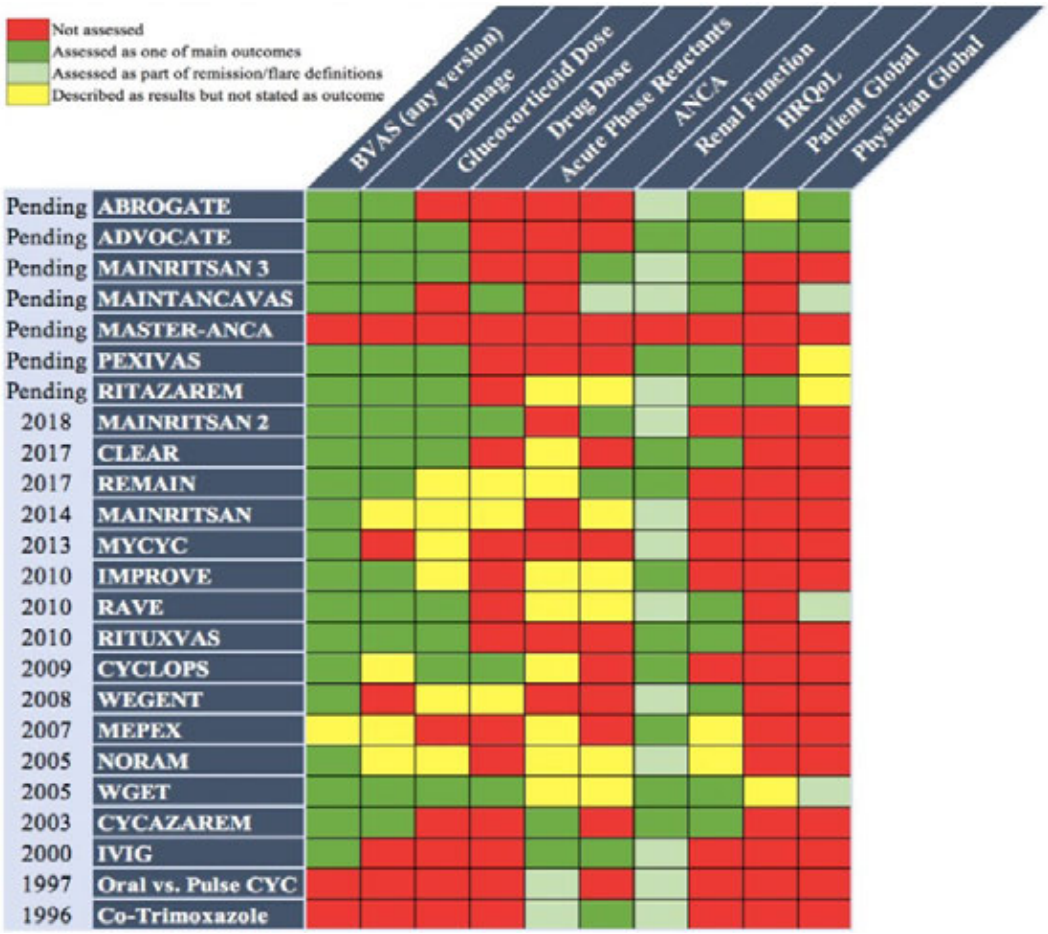

Figure 1. Overview of outcomes assessed in randomized controlled trials of ANCA-associated vasculitis

Results: Various versions of the Birmingham Vasculitis Activity Score (BVAS) were the most widely used instrument for assessing disease activity in AAV. BVAS was almost always used as a dichotomous variable (0 or > 0) providing distinction between remission and active disease. Among 24 eligible RCTs (Figure 1) reduction and/or achievement of BVAS=0 represented a main study outcome (stated as primary or secondary endpoint) in 20/24 (83%) RCTs; 6 of these trials used the BVAS/WG. Damage, mainly assessed by the Vasculitis Damage Index (VDI), was an outcome for 14/24 (58%) RCTs. Physician global assessment and patient-reported outcomes (PROs) were assessed in 7 (29%) and 14 (58%) RCTs, respectively. Assessment of renal function (part of BVAS) was a major outcome or specifically included in definitions of remission/relapse in 23/24 (96%) RCTs. Timing for outcome measure assessment differed significantly among RCTs, with baseline, 6 months (15/20 RCTs), and 12 months (14/20) after enrollment in the study being the most common time points for collecting BVAS and VDI. However, assessment of response occurred as early as 1-4 weeks after enrollment, with 6/24 (25%) RCTs assessing disease activity at 6 weeks and 13/24 (54%) at 3 months.

Conclusion: Review of outcome measures used in RCTs of AAV demonstrates the recurrent use of certain specific tools to assess disease state, although with heterogeneity in the definitions for remission/relapse, and timing of assessment. Intermediate states of disease activity of importance to patients and investigators are currently poorly defined or evaluated. Furthermore, other important outcomes in AAV, including PROs, damage measures, and global assessments are often not included as primary or confirmatory secondary outcomes in RCTs in AAV. Data-driven composite measures integrating a combination of these measures and accounting for different levels of responsiveness to therapy may result in increased power to detect clinically meaningful differences in efficacy of future treatments.

The Need for Personalized, Non-Pharmacological Intervention Programmes in Autoimmune Connective Tissue Disorders: Results of a EULAR-Funded Scoping Review with a Nested, Descriptive Meta-Analysis

Valentin Ritschl,[1] Ricardo Ferreira,[2] Rúben Fernandes,[2] Eduardo Santos,[2] Essi Juutila,[3] Erika Mosor,[1] Kim Fligelstone,[4] Helena Gaspar,[5] Linda Schraven,[6] Judy Ammerlaan,[7] Georg Stummvoll,[8] Maria João Salvador,[2] Janet Poole,[9] Cornelia van den Ende,[10] Carina Boström,[11] and Tanja Stamm[1], [1]Medical University of Vienna, Vienna, Austria, [2]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, [3]Metropolia University of Applied Sciences, Helsinki, Finland, [4]Federation of European Scleroderma Associations, Tournai, Belgium, [5]Portuguese League Against Rheumatic Diseases, Portugal, Portugal, [6]Federation of European Scleroderma Associations, Sweden, Sweden, [7]University Medical Centre, Utrecht, Netherlands, [8]Klinikum Malcherhof Baden, Baden, Austria, [9]University of New Mexico, Albuquerque, NM, [10]Sint Maartenskliniek Nijmegen, Nijmegen, Netherlands, [11]Karolinska Institutet, Stockholm, Sweden

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Clinical Aspects & Outcomes Research

Session Type: ARP Abstract Session

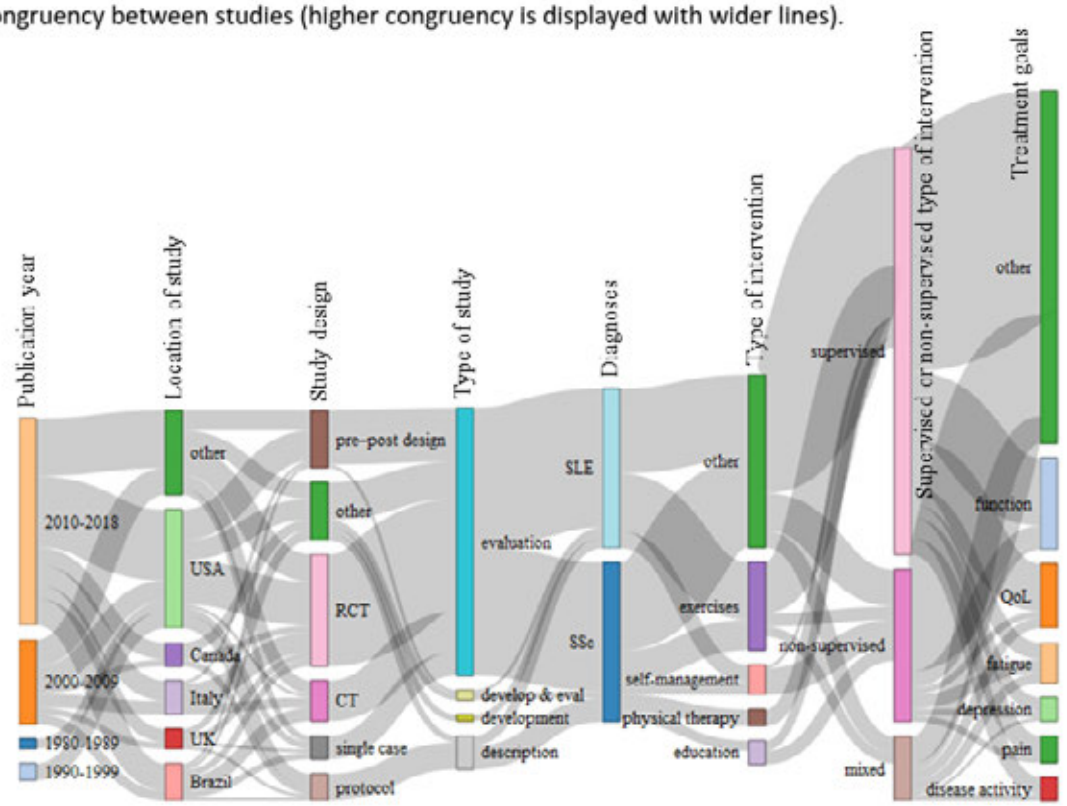
Session Time: 2:30PM–4:00PM

Background/Purpose: Autoimmune Connective Tissue Disorders (CTDs), including Mixed Connective Tissue Disorders (MCTD), systemic sclerosis (SSc) and systemic lupus erythematous (SLE) can lead to Raynaud phenomenon, involvement of internal organs, pain in joints, skin abnormalities and muscle weakness. Consequently, people with CTDs experience limitations in activities of daily life and restrictions in participation. Programmes promoting patient education, self-management, physical activity, and healthy life style, provided by health professionals are therefore essential to these patients. However, there is a substantial gap of knowledge about the content which should be included in non-pharmacological intervention programmes.

The purpose of this study was to identify, map and appraise the content of existent face-to-face, digital and/or distance-learning non-pharmacological intervention programmes for patients with MCTD, SSc and/or SLE to inform a EULAR funded project with the overall aim to develop a new distance learning programme realizable with digital technologies.

Methods: A scoping literature review with a nested descriptive meta-analysis was performed in MEDLINE [Pubmed], EMBASE [OVID], CINAHL [EBSCO], PsycINFO [ProQUEST], the Cochrane Database of Systematic Reviews, OT-

Figure 1. Sankey diagram. This diagram illustrates the relationships between the different study characteristics. The width of the grey connections lines between the bars are reflecting a higher congruency between studies (higher congruency is displayed with wider lines).



Seeker, PEDro, and SciELO in September 2018. Furthermore, an international task-force identified additional grey literature and ongoing research projects. Eligibility checks of the articles based on pre-defined in- and exclusion criteria and data extractions were done independently by two researchers. The interventions contained in these programmes were extracted using the "Better reporting of interventions: template for intervention description and replication (TIDieR) checklist and guide". A Sankey diagram and descriptive statistics were used to illustrate the relationships between the interventions and other characteristics of the studies. The protocol was pre-published on ResearchGate.

Results: Of 6667 identified records, 94 papers were eligible. Sixty-one studies (65%) were conducted between 2000 and 2018, mainly in the USA (35 [37%]), Brazil (11 [12%]) and Italy (10 [11%]). Thirty-three studies (35%) were randomised controlled trials, 17 (18%) were one-group pre-post-test designs and 12 (16%) clinical trials without randomisation (Figure 1). Overall, 4274 patients participated; 2955 had SLE [69%] and 1319 had SSc [31%], thus no studies with MCTD where found. The main content of the intervention programmes included exercises (22 [23%]), self-management (9 [10%]) and education (7 [7%]), with treatment goals focusing mainly on physical function (27 [29%]), quality of life (19 [20%]) and fatigue (12 [16%]). The interventions (67 [72%]) included or were based on an initial face-to-face component.

Conclusion: There was a variety of programmes content and interventions due to different consequences regarding activity limitations and participation restrictions in autoimmune CTDs. This highlights the need for personalized, multicomponent, non-pharmacological interventions.

Abstract Number: 2793

Methotrexate Intolerance: A Qualitative Descriptive Study of the Adult Rheumatoid Arthritis Patients' Perspectives

Elizabeth Salt,[1] Mary Kay Rayens,[2] Leslie Crofford,[3] and Jamie Studts[2], [1]University of Kentucky, Lexington, KY, [2]University of Kentucky, Lexington, [3]Vanderbilt University, Nashville

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Clinical Aspects & Outcomes Research
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: An estimated 11% to 33% of persons taking methotrexate for rheumatoid arthritis (RA) are reported to be at least moderately intolerant to this medication. The published literature has largely measured methotrexate intolerance using a scale composed of four domains: abdominal pain, nausea, vomiting and behavioral symptoms. These symptoms largely ignore the definition of "intolerance" or the "unwillingness or refusal to tolerate or respect opinions or beliefs contrary to one's own". As such, the patients' perspective is not captured. The purpose of this study is to use qualitative methodologies to describe methotrexate intolerance from the adult patient with RA's perspective.

Methods: We conducted semi-structured audio-recorded individual interviews with 14 adult English-speaking patients who have a rheumatology health-care provider confirmed diagnosis of RA, and who had been prescribed, were taking, or had ever taken oral or subcutaneous methotrexate. We identified 489 labels for common words or phrases or codes during line-by-line coding which were categorized using constant comparative analysis and then collapsed into three central themes.

Results: Findings from the conducted interviews suggest that methotrexate intolerance is a construct conceptualized from three themes: *Beliefs about the Risk of Methotrexate, Beliefs about the Benefits of Methotrexate, and Beliefs about the Threat of RA*. The complex beliefs about methotrexate involved both perceived risks and benefits which resulted from knowledge obtained from sources with varying perceived value such as the Internet, others with RA, or their health care provider. The experiences of trusted peers with RA and the relationship with their health care provider were influential in the decision to tolerate methotrexate. The amount of information and timing in which to participants' sought information varied.

Participants also described beliefs about the threat of RA which often resulted from personal experiences with pain and difficulty functioning or observing the experiences of other with RA. Patients often reported the desire to avoid "being crippled" or requiring the use of assistive devices including a wheel chair. The belief in the perceived benefit of methotrexate, which was often improved functioning in activities of daily living, and threat of the RA hindering this functioning often was a stimulus to tolerate perceived risks or to take methotrexate despite known risks (e.g., hair loss and nausea).

Conclusion: Findings from this study suggest that intolerance to methotrexate involves a complex belief system where patients with RA weigh beliefs about risks and benefits of methotrexate alongside beliefs about the threat of RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Clinical Aspects & Outcomes Research
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Our aim was to determine whether demographics, clinical characteristics or appendicular joint osteoarthritis predict the incidence and worsening of lumbar spine disc space narrowing (DSN), facet joint OA (FOA), osteophytes (OST), and spondylolisthesis.

Methods: These analyses used baseline (2006-2010) and follow-up (2013-2015) data from the Johnston County OA Project. Paired (baseline and follow-up) lumbar spine radiographs were graded for OST and DSN (0-3), spondylolisthesis (0-5) and FOA (present or absent). Incidence was defined as the absence of a specific radiographic feature at baseline and the presence of that feature at follow-up. Worsening was defined as ≥ 1-unit increase from baseline to follow-up for a given radiographic feature. Demographic characteristics of age, race (African American vs. white), and sex, clinical characteristics of the history of low back symptoms, comorbidities (diabetes, high blood pressure and ever smoking), and back injury were determined by self-report. Body mass index (BMI) variables of weight and height were measured at the research clinic visit with obesity defined as BMI≥30 kg/m^2. Appendicular OA was defined as a Kellgren-Lawrence grade ≥2 at the knee or hip or a grade ≥2 in a minimum of one distal interphalangeal (IP) joint and 2 other joints (IP or carpometacarpal) at the hand. Weibull models, which account for interval censoring, were used to estimate adjusted (simultaneously for all predictors) hazards ratios (aHR) and 95% confidence intervals (CI) and whether the effects differed in those with and without low back symptoms.

Results: Paired lumbar spine radiograph scores were available for 819 participants. Baseline characteristics were mean age 66.1 (SD 7.5), mean BMI 31.5 (6.1) kg/m^2; 67.9% were women, 31.8% were African American, and 39.6% had radiographic knee OA, 35.5% hip OA, 32.0% hand OA, and 34.8% had low back symptoms. The incidence of OST, FOA, DSN and spondylolisthesis was 59.0%, 11.1%, 38.1% and 9.1%, respectively. Worsening of OST, DSN, and spondylolisthesis occurred in 33.8%, 23.9% and 7.8%, respectively.

AAs were less likely to develop FOA with symptoms and DSN with symptoms. Women were more likely to develop spondylolisthesis. (Table 1a) Obesity was a predictor of incidence for all lumbar spine features. Smokers were less likely to develop DSN and FOA with symptoms. Participants with diabetes were less likely to develop DSN with symptoms and without. (Table 1b) Presence of Knee OA predicted incident: vertebral OST with symptoms, DSN with symptoms, FOA and FOA with symptoms. (Table 1c)

Sx=low back symptoms; OA=osteoarthritis; BMI= body mass index

*Adjusted simultaneously for all predictors in this table and facet joint OA

**Adjusted simultaneously for all predictors in this table and disc space narrowing and OST

Table 2. Predictors of Worsening for Lumbar Spine Degeneration

Conclusion: Obesity consistently predicted incidence and worsening of lumbar spine radiographic features with and without low back symptoms. Notable variation in other predictors for incidence and worsening suggest that the etiological process of degeneration may differ for some radiographic features.

Patterns of Ambulatory Health Care Utilization and Medication Adherence Among Transition-Age Youth with Systemic Lupus Erythematosus

Joyce Chang,[1] Andrea Knight,[2] and Erica Lawson[3], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Toronto, ON, Canada, [3]University of California San Francisco Benioff Children's Hospital, San Francisco, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Clinical Aspects & Outcomes Research
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Youth with child-onset systemic lupus erythematosus (SLE) transitioning from pediatric to adult health care systems may be at higher risk for poor outcomes than children or older adults with SLE. We leveraged US private insurance claims to describe patterns of ambulatory subspecialty care in transition-age youth with SLE, and to compare health care use and medication adherence before and after transfer to adult care. We hypothesized that ambulatory follow-up care and medication adherence decrease during the transfer period with a concurrent increase in acute care use.

Figure 1. Ambulatory rheumatology and nephrology subspecialty care utilization patterns

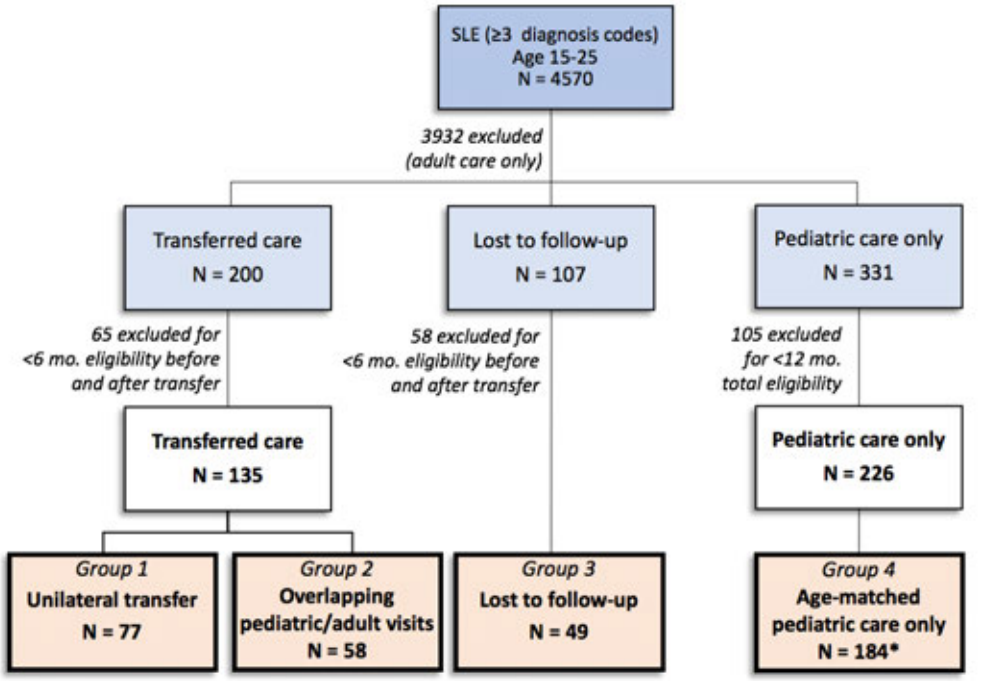

Figure 1. Flowchart demonstrating application of selection criteria and categorization of ambulatory rheumatology/nephrology visits into patterns of pediatric and adult care use. *Represents 107 unique patients sampled with replacement and age-matched to youth in groups 1-3

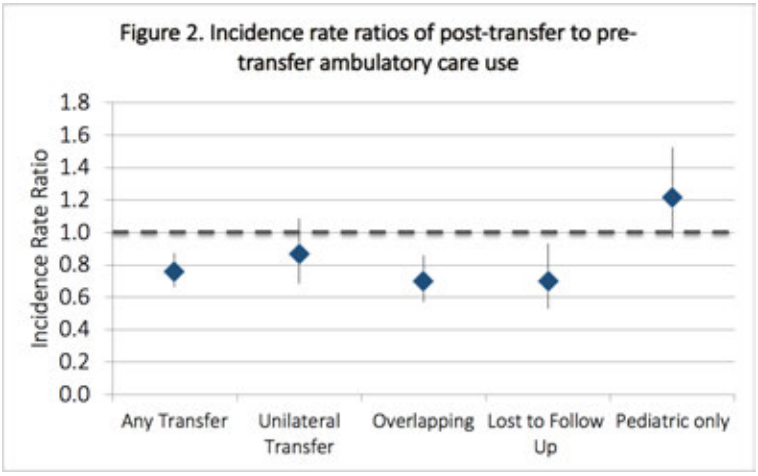

Figure 2. Incidence rate ratios comparing rates of ambulatory care visits before and after the index (transfer) date were estimated using negative binomial regression models for each pattern of subspecialty care, clustered by subject.

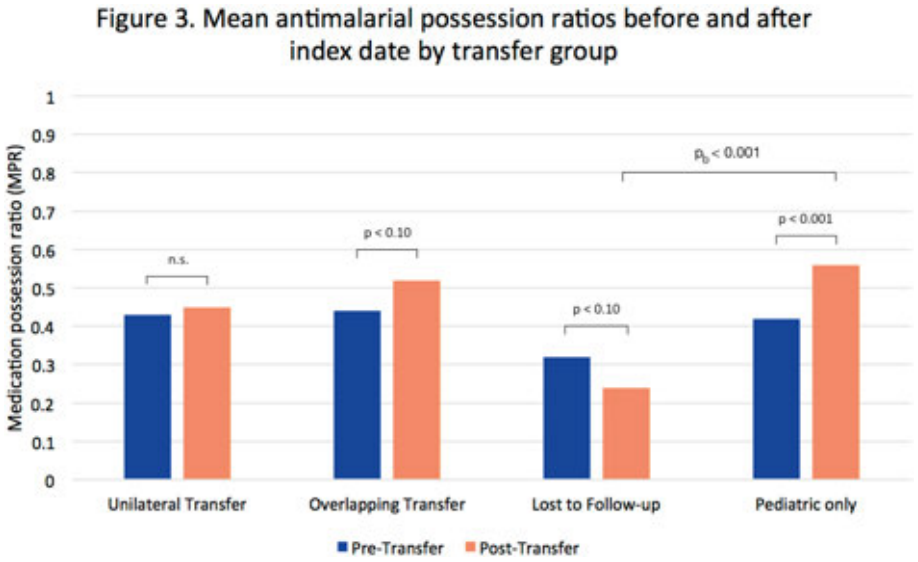

Figure 3. Average medication possession ratios (MPR) one year before and after transfer were compared within groups using paired t-tests. Between-group differences were tested using two-sample t-tests, of which statistically significant differences are also shown (pb).

Methods: Using Clinformatics DataMart® (OptumInsight, Eden Prairie, MN) de-identified US claims data (2000-2016), we categorized youth ages 15-25 yrs with SLE by pattern of rheumatology/nephrology ambulatory care into those that 1) transferred unilaterally to adult care within 1 yr of the last pediatric visit, 2) had overlapping pediatric and adult visits before remaining in adult care 3) were lost to follow-up (> 1 yr between last pediatric and first adult visit or end of enrollment), or 4) remained in pediatric care (Fig 1). The transfer index date was defined as the last pediatric visit for groups 1-3. Pediatric-only youth were age-matched to the other groups. We used negative binomial regression to compare pre- and post-transfer health care utilization rates within groups. We used paired t-tests to compare pre-/post- antimalarial medication possession ratios (MPR) in prevalent users, and compared MPRs between youth in groups 1-3 and their pediatric-only matches.

Results: A total of 184 youth with SLE met inclusion criteria for transfer out of pediatric rheumatology/nephrology care, of which 77 (42%) transferred unilaterally to adult care within a year, 58 (32%) had overlapping pediatric/adult care over a median of 12 months (IQR 4 – 27) before the last pediatric visit, and 49 (27%) were lost to follow-up. Of the 226 youth remaining in pediatric care, 107 were age-matched to each transfer group. Unilateral transfers were older

than the lost to follow-up group (mean age 19.4 vs. 18.5, p 0.02) and more likely to live in the Northeast (p 0.04). Rates of ambulatory visits decreased after transfer among those with overlapping care and loss to follow-up, but remained unchanged among unilateral transfers (Fig 2). Rates of acute care utilization decreased across all groups (IRRs 0.14-0.30, p< 0.01). Average pre-transfer antimalarial MPRs ranged from 0.3-0.5 (Fig 3). Post-transfer MPRs were lower in the lost to follow-up group compared to age-matched peers remaining in pediatric care (mean 0.2 vs. 0.6, p< 0.01).

Conclusion: Among transition-age youth with SLE who have continuous private insurance coverage, acute care utilization does not increase during transfer to adult care. However, a substantial proportion of youth fail to see an adult provider within 12 months of the last pediatric visit. These youth have decreased rates of ambulatory care use and medication adherence compared to the pre-transfer period, and may be at highest risk for inadequate follow-up and poor outcomes. Additional data is needed to determine whether transfer patterns are associated with longitudinal health outcomes.

The Association Between Omega-3 Supplementation and Disease Activity in a Rheumatoid Arthritis (RA) Observational Cohort

Adel Andemeskel,[1] Vivi Feathers,[1] Christine Iannaccone,[1] Jing Cui,[1] and Nancy Shadick[1], [1]Brigham Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Clinical Aspects & Outcomes Research
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Omega-3 supplementation is one of a few complementary and alternative medicine (CAM) therapies that has shown promise in improving RA symptoms through small, randomized control trials. However, there is little research looking at the association of disease activity of RA patients and omega-3 supplementation. This study aims to identify the association between disease activity of RA patients who do and do not take omega-3 in an observational longitudinal cohort.

Methods: Data from a longitudinal RA registry was used for this study. Information concerning use of herbal medications, including omega-3 supplementation, was collected semi-annually. Subjects ever reporting use of fish oil, flaxseed, docosahexanoic acid (DHA), eicosapantaenoic acid (EPA), and alpha linolenic acid (ALA) at least once were identified as an omega-3 user. First, we compared demographic and clinical characteristics between omega-3 users and omega-3 non-users at the date of first supplementation for users and date of cohort enrollment for non-users. Then, a generalized linear mixed model (GLMM) analyzed associations between subjects' omega-3 supplementation and the outcomes, Disease Activity Score (DAS28-CRP3), painful joint count, and swollen joint count one year later. The lagged model (Fig. 1) controlled for repeated measures and adjusted the outcomes for age, gender, education, seropositivity, steroid, NSAID, biologic and methotrexate use.

Results: Overall 1,557 subjects had a mean age of 56 years (± 14), with a median disease duration of 12 (8, 20) years. Subjects were 92% white, 82% female, and 57% had a college degree or higher. Of all participants, 640 indicated

Figure 1: Lagged GLMM Analysis between Omega-3 Supplementation and Disease Outcomes

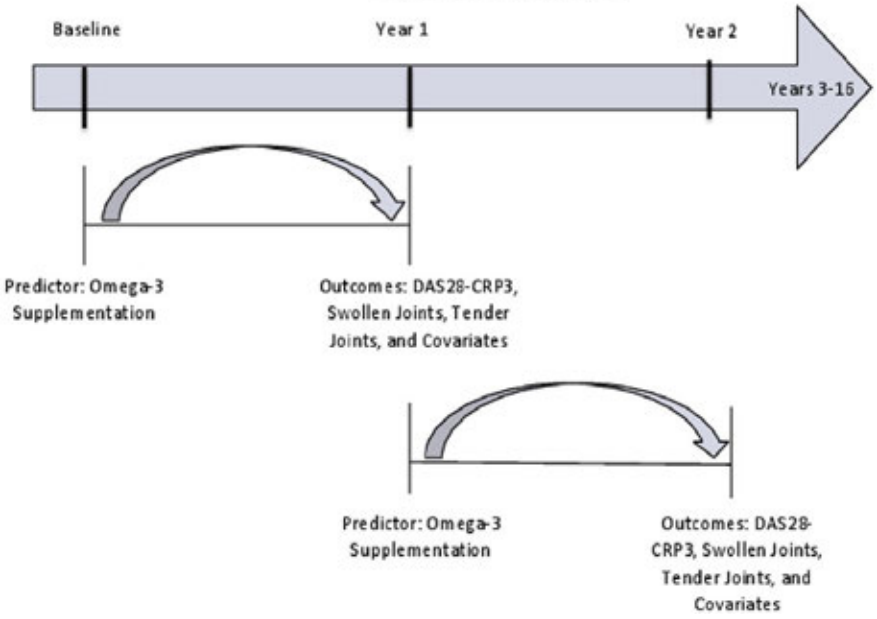

Table 1: Baseline characteristic comparisons between omega-3 users vs non-omega-3 users involving 1,557 RA subjects in an observational cohort

Baseline Characteristics	Omega-3 (n=640)	No Omega-3 (n=917)	p-value
Age (years), mean (SD)	57.1 (13.1)	57.1 (15.0)	0.96
Female, n (%)	541 (85%)	733 (80%)	0.02*
White, n (%)	586 (92%)	839 (92%)	0.84
Education, n (%)			0.001*
High school degree	223 (35%)	386 (42%)	
College degree	214 (34%)	273 (30%)	
Graduate degree	186 (29%)	218 (24%)	
Disease duration (years), median (IQR)	11.4 (8, 18)	12.8 (8, 20)	0.25
DAS28-CRP3, median (IQR)	3.5 (3.4, 4.7)	3.6 (3.4, 4.9)	0.24
Seropositive, n (%)	424 (69%)	576 (68%)	0.65
* indicates significant p-value			

that they had taken an omega-3 supplement at least once. The average duration of omega-3 supplementation was 33 months. Omega-3 users were more likely to be female (p=0.02) with a higher education level (p=0.001) (Table 1). The lagged GLMM showed that omega-3 users were more likely to have a significantly lower DAS28-CRP3 (p< 0.0001), painful joint count (p=0.001), and swollen joint count (p=0.0009) 1 year later after adjustment for seropositivity, demographic and medication variables. (Table 2).

Conclusion: The data suggest that independent of clinical, demographic and medication variables, patients from an observational cohort who take omega-3 supplementation are more likely to have lower DAS28-CRP3 scores, less

Exploring Possible Predictors of Physical Activity in Knee Replacement Patients

Brandy Tanenbaum,[1] **Aileen Davis**,[2] Deborah Kennedy,[3] and Junaid Bhatti[4], [1]Sunnybrook Health Sciences Centre, Toronto, ON, Canada, [2]Krembil Research Institute, University Health Network, Toronto, ON, Canada, [3]Sunnybrook Health Sciences Centre - Holland Bone and Joint Program, Toronto, ON, Canada, [4]Institute of Clinical Evaluative Studies, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Clinical Aspects & Outcomes Research
Session Type: ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Following total knee replacement (TKR), patients do not achieve recommended physical activity for overall health. The implications of physical inactivity on individuals and the healthcare system are substantial and well documented, yet why these patients do not achieve recommended levels are not well understood. The concept of physical literacy - if people have the knowledge, competence and confidence to undertake physical activities effectively to reach optimum levels of performance - has not been explored in an adult population. Given the

grave health implications associated with physical inactivity, this study aimed to examine physical activity levels and potential factors, including physical literacy, that may influence activity levels in this population.

Methods: This study used a prospective observational design and included people having primary TKR for osteoarthritis.The primary outcome was change in physical activity as measured by the Rapid Assessment of Physical Activity survey tool. To examine predictors of physical activity levels, we evaluated the following: age, sex, BMI, comorbidity count, Patient Health Questionnaire Depression Scale, Pain Disability Index, P-4 pain intensity measure, Arthritis Self-Efficacy Scale, and Adult Physical Literacy Assessment.The physical literacy measure evaluates the domains of environment, self-efficacy, and relative rankings of literacies. We hypothesized differences in the amount of physical activity relating positively or negatively to the predictive factors. Standard definitions described categorical variables. Continuous variables were categorized according to the results of Shapiro Wilks and Kolmogrov tests. We compared changes in outcome measure scores using percentage or mean change. The statistical significance of changes was assessed using McNemar's test or a paired *t* test. Lastly, predictors of physical activity at 12 months were assessed using regression models as determined by assessments of normality and verification of assumptions.

Results: The sample included 104 patients; male (31%) and female (72%) with ages ranging from 52-87 years. Physical activity levels were different between T1 and T2 in some participants. There was a significant change in aerobic activities with a small effect size. There was no significant change in strength and flexibility. Age, sex, comorbid illness and depression did not predict aerobic change. However, changes in self-reported measures of physical activity (p=0.02) and depression (p=0.001) were significant from Time 1 to Time 2. Physical literacy scores were not predictive of physical activity scores. However, those who reported lower physical literacy scores also reported lower physical activity scores and those with higher physical literacy reported higher physical activity scores.

Conclusion: As in other studies, individuals who are active prior to surgery resume activity and those who are not active prior to surgery do not increase their activity after surgery. Physical literacy introduces a novel concept that seems to be related to activity level. Future studies should further evaluate this concept as it may be a target for enabling people to be physically active.

Abstract Number: 2798

Trajectories of Opioid Filling Patterns After Total Knee Replacement

Chandrasekar Gopalakrishnan,[1] Jessica Franklin,[2] Yinzhu Jin,[3] Daniel Solomon,[4] Jeffrey Katz,[5] Yvonne Lee,[6] Patricia Franklin,[6] Joyce Lii,[2] Rishi Desai,[7] and **Seoyoung C. Kim** [3], [1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, [4]Brigham and Women´s Hospital, Div. of Rheumatology, Immunology and Allergy, Boston, MA, [5]Brigham and Women's Hospital/Harvard Medical School, Boston, [6]Northwestern University Feinberg School of Medicine, Chicago, [7]Brigham and Women's hospital, Boston

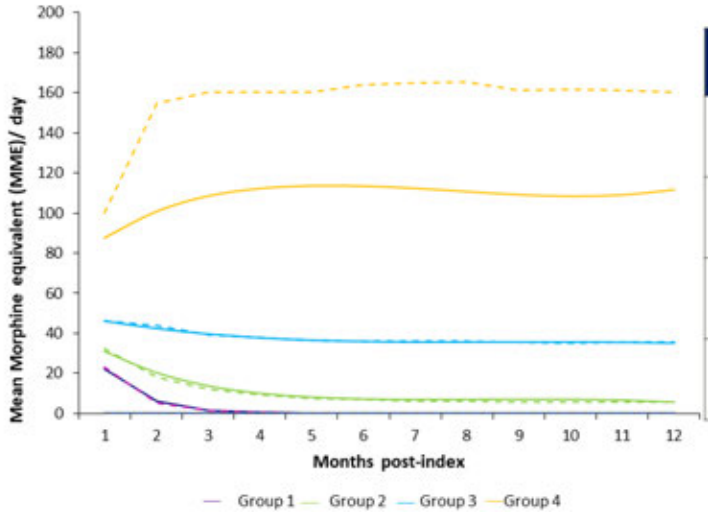
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain & Rehabilitation
Session Type: ACR/ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Patients undergoing total knee replacement (TKR) are at increased risk of persistent opioid use and opioid dependence. Group-based trajectory models can identify clusters of patients with clinically distinct,

dynamic patterns of medication use over time. Evaluating the characteristics of patients prior to TKR within these empirically identified trajectories of prescription opioid use may be useful in identifying high-risk subgroups.

Methods: Using Medicare Parts A, B and D claims (2010-2014), we identified patients aged ≥65 years who underwent a TKR. All patients were required to be continuously enrolled in Medicare for ≥360 days prior to TKR. To determine opioid filling patterns after TKR, patients were followed up to 360 days from the day of TKR. We modeled 12 monthly indicators of filling as both a continuous (Mean morphine equivalents (MME)/day) variable for Model 1 and a binary (Yes/No for any opioid fill) response variable for Model 2 using censored normal and logistic group-based trajectory models, respectively. Model fit was assessed using a combination of the Bayesian Information Criterion (BIC), predicted probability of group membership and number of patients assigned to each trajectory group. Baseline

Figure 1 - Observed and predicted patterns of opioid use (MME/day) in each trajectory group for Model 1



Group	N	Average MME/day, mg Mean (SD)	Total opioid days covered in 360 day follow-up
4	2,175	149.8 (89.8)	220.3 (119.3)
3	8,057	42.4 (16.3)	214.8 (103.8)
2	37,691	18.9 (10.5)	100.4 (69.8)
1	135,450	20.1 (12.1)	18.9 (14.6)

Table 1 – Baseline patient characteristics by trajectory groups from Model 1

Patient Characteristic	Group 1 (Lowest)	Group 2	Group 3	Group 4 (Highest)	Standardized differences (Group 4 vs Group 1)

Drug Abuse (n, %)	84(0.1)	78(0.2)	93(1.2)	48(2.2)	0.20
ER Visit (n, %)	26504(19.6)	10139(26.9)	2836(35.2)	884(40.6)	0.47
Number of Drugs (Mean, SD)	9(5)	12(5.8)	14.5(6.5)	16.4(7.1)	1.21
Number of Office Visits (Mean, SD)	11.3(6.7)	13.3(7.7)	15.5(9)	18.8(10.3)	0.13

patient characteristics (assessed in the 360 days prior to TKR) were then tabulated by trajectory group for the final model.

Results: We identified 183,373 patients who underwent TKR during the study period. We selected the 4-group trajectory model as having the best fit for both continuous and binary indicators of filling. Observed and predicted patterns of opioid use in each of the 4 trajectory groups identified by Model 1 are summarized in **Figure 1.** 78% (n=1,686) of patients assigned to Group 4 (highest opioid use group) from Model 1 were also assigned to Group 4 in Model 2 though the average MME/day in Group 4 was higher (149.8 mg vs. 43.0) in Model 1 compared to Model 2. Hence, Model 1 provided more clinically-meaningful discrimination between patients' opioid use, and we used trajectory membership based on Model 1 to describe baseline patient characteristics **(Table 1)**. Differences were noted in the baseline characteristics of patients assigned to group 4 compared to those assigned to Group 1 (lowest opioid use). Patients in Group 4 were more likely to be younger, female, have opioid use in the year prior to TKR, and had a greater burden of comorbidities (such as depression, anxiety disorders, back pain), more likely to have used tobacco, alcohol and used more healthcare services in general (number of ER visits, physician office visits and medications used). Patients in Group 4 were also more likely to be frail as assessed by the claims-based frailty index.

Conclusion: Group-based trajectory models identified a subgroup of patients with high opioid use and whose baseline characteristics prior to TKR were substantially different than those in other groups. Future work could further determine the predictors of persistently high-dose opioid users after TKR and associated adverse events.

Does Early Anterior Cruciate Ligament Reconstruction Prevent Further Meniscal Damage? Secondary Analysis of a Randomized Controlled Trial

Barbara Snoeker,[1] Frank Roemer,[2] Aleksandra Turkiewicz,[1] Stefan Lohmander,[3] Richard Frobel,[1] and **Martin Englund** [1], [1]Lund University, Lund, Sweden, [2]University of Erlangen-Nuremberg, Erlangen, Germany, [3]Department of Clinical Sciences Lund, Faculty of Medicine, Lund University, Lund, Sweden, Lund, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain & Rehabilitation
Session Type: ACR/ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: It has been suggested that recurrent instability episodes in a non-reconstructed anterior cruciate ligament (ACL) injured knee increase the risk for an incident meniscal tear. However, the evidence comes from observational studies with high risk on selection bias. Our objective was to determine development of meniscal damage over 5 years after ACL injury using data from the only randomized controlled trial in the field, comparing rehabilitation plus early ACL reconstruction ("early ACLR") vs rehabilitation with optional delayed ACL reconstruction ("optional delayed ACLR").

Methods: We used longitudinal knee MRIs including 121 young adults (ISRCTN 84752559; ethics approval LU 535-01). One musculoskeletal radiologist read baseline and 5-year follow-up images using the Anterior Cruciate Ligament Osteoarthritis Score (ACLOAS). We defined development of meniscal damage both dichotomously and as sum score representing severity (based on the sum of reclassified ACLOAS meniscus grades). Using a full analyzis set as randomized, we studied the development of meniscal damage (yes/no) with logistic regression, and severity with zero-inflated Poisson regression. Analyses were performed both on knee and on compartment level, and adjusted for age, sex, and baseline meniscal damage.

Results: In early ACLR, 60 of 62 participants remained (2 missing baseline MRIs). In optional delayed ACLR, 55 of 59 subjects had longitudinal MRIs. After 5 years we found a relative risk for development of meniscal damage on knee level of 1.3 (95% confidence interval [95%CI]=0.9-1.9) in optional delayed ACLR vs early ACLR (Table 1). For medial and lateral meniscal damage, respectively, the relative risks were 2.1 (95%CI=1.1-3.9) and 1.0 (95%CI=0.6-1.5). The mean severity score was 1.5 higher (more severe damage) on knee level in optional delayed ACLR vs early ACLR (95%CI=1.1-1.9) among those with meniscal damage at 5 years. For medial and lateral meniscal damage, respectively, the corresponding scores were 1.7 (95%CI=1.2-2.5) and 1.0 (95%CI=0.8-1.4) (Figure 1).

Conclusion: A strategy of early ACLR may reduce development of medial meniscal damage following ACL injury. For the lateral meniscus, ACLR seems neither to be protective nor to increase the risk of damage.

Table 1 - Results of the logistic regression analysis for development of meniscal damage and the zero inflated Poisson regression analysis for meniscal severity scores at 5 years compared to baseline for the optional delayed ACL reconstruction arm compared to the early ACL reconstruction arm

	Development of meniscal damage		Meniscal damage severity score
	Risk ratio (95%CI)	Risk difference (%) (95%CI)	Ratio of means (95%CI)

Five Year Structural Changes in Patients with Meniscal Tear and Osteoarthritis from an RCT of Arthroscopic Partial Meniscectomy vs. Physical Therapy

Swastina Shrestha,[1] Jeffrey Katz,[2] Elena Losina,[3] and Jamie Collins[4], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital/Harvard Medical School, Boston, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [4]Brigham and Women's Hospital and Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain & Rehabilitation
Session Type: ACR/ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Meniscal tear is an independent risk factor of structural progression in OA; Arthroscopic partial meniscectomy (APM) is also associated with progression, though it is unclear if APM confers additional risk beyond that of the underlying meniscal tear. The goal of this study was to evaluate changes in knee MRI findings over 60 months in patients with meniscal tear and OA treated with either APM (and postop physical therapy (PT)) or with PT alone as a part of a multicenter RCT.

Methods: We used data from an RCT of APM and PT vs. PT alone (denoted in this abstract as APM vs. PT) for patients ≥ 45 years old with knee pain, meniscal tear on MRI, and OA changes on radiograph or MRI. Patients were excluded from this analysis if they were randomized to but did not receive APM, crossed over to APM > 6 months from randomization, or if they had no MRIs. We performed as-treated analysis: subjects who crossed over from PT to APM within 6 months from randomization were analyzed in the APM group.

Baseline (BL), 18-month (18m), and 60-month (60m) MRIs were read using the MRI OA Knee Score (MOAKS), which assesses damage in several joint features including osteophyte, cartilage surface area, and cartilage thickness. Each feature was scored ordinally from 0 - 3, (higher is worse) in each of 14 subregions (SR) for cartilage and 12 for osteophytes. We summed the scores from all SRs within the osteophyte, cartilage surface area and cartilage thickness domains. We used a linear mixed effects model to assess the relationship between the APM and PT groups and the changes in damage scores within each domain for two time intervals: BL-18m and 18m-60m.

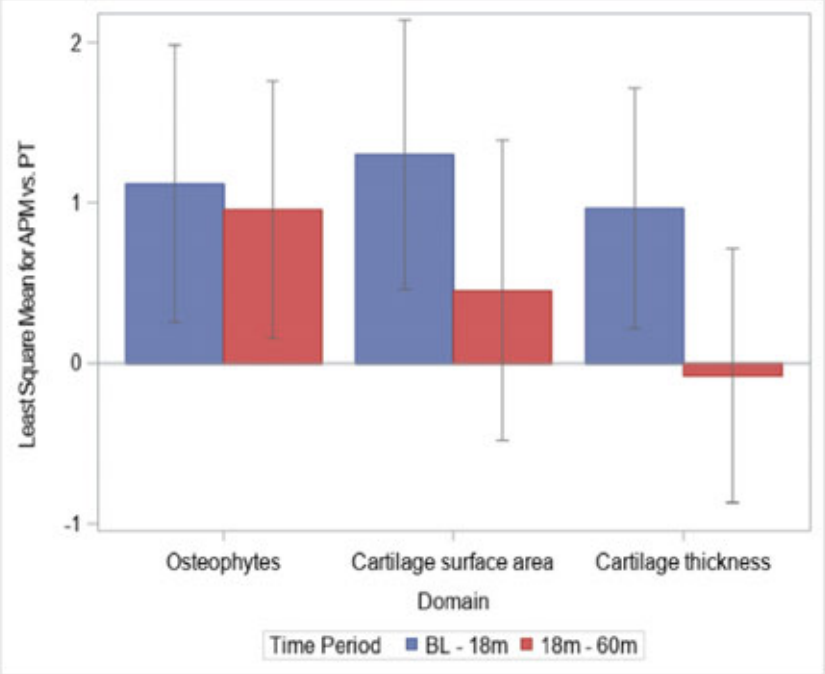
Results: Of 351 randomized subjects, we excluded 10 randomized to but not undergoing APM, 14 randomized to PT who crossed over after 6m and 32 with no MRI. The analytic cohort included 295 subjects with mean age 58 (SD 7) years and mean baseline KOOS pain (0-100, 100 worst) 47 (SD 16). 193 (65%) received APM and 102 (35%) received PT. The groups were balanced on BL demographic and clinical characteristics. 285 (97%) subjects had MRI at BL 221 (75%) at 18m and 165 (56%) at 60m.

Descriptive statistics on change in both time periods are presented in the Table. Both treatment groups worsened in all domains for both time periods, with more worsening over BL – 18m than 18m – 60m. The Figure displays the difference in change in score for each domain for APM vs. PT, from the mixed effects model. Worsening in osteophyte score was significantly greater in the APM group vs. the PT group for both time periods. Change in both cartilage surface area and cartilage thickness scores were significantly different between the groups for the BL – 18m period, but not the 18m – 60m period.

Table 1. Change over Time in Each Domain Score, Overall by Treatment Group

Domain	Overall n Mean (SD)	APM Group n Mean (SD)	PT Group n Mean (SD)
Osteophytes			
BL – 18m	212 3.3 (3.4)	141 3.8 (3.5)	71 2.5 (3.0)
18m – 60m	148 2.2 (2.8)	94 2.6 (3.1)	54 1.5 (2.0)
Cartilage Surface Area			
BL – 18m	210 2.7 (3.1)	139 3.0 (3.2)	71 1.9 (2.9)
18m – 60m	148 1.1 (3.0)	93 1.3 (3.3)	55 0.8 (2.5)
Cartilage Thickness			
BL – 18m	210 1.6 (2.2)	139 1.8 (2.4)	71 1.1 (1.8)
18m – 60m	148 1.4 (2.2)	93 1.4 (1.9)	55 1.5 (2.6)

Figure. Least Square Mean (95% CI) from Mixed Effects Model of Change for APM vs. PT in Score by Domain and Time Period. Positive values indicate that the APM group had more change, and negative values indicate that the PT group had more change. If the 95% confidence interval excludes 0 then the difference is statistically significant.



Conclusion: In subjects with underlying meniscal tear, APM was associated with greater worsening in cartilage surface area, cartilage thickness, and osteophytes over 18m post randomization, and greater worsening in osteophytes, but not in cartilage scores, in the subsequent 42 months. Future work will consider missing not at random imputation for subjects undergoing TKR, examine outcomes from an intention to treat perspective, and determine the magnitude of change in structure that is associated with clinically meaningful changes in symptoms.

Optimal Threshold of Walking Speed Predictive of Mortality Risk over 9 Years in Knee Osteoarthritis: Data from Osteoarthritis Initiative

Hiral Master,[1] Tuhina Neogi,[2] Lavalley Michael,[3] Louise Thoma,[4] Meredith Christiansen,[5] Dana Voinier,[5] Lauren Neely,[5] Jason Jakiela,[5] and Daniel White[1], [1]University of Delaware, Newark, DE, [2]Boston University School of Medicine, Boston, MA, [3]Boston University, Boston, [4]University of North Carolina at Chapel Hill, Newark, [5]University of Delaware, Newark

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain & Rehabilitation
Session Type: ACR/ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Knee osteoarthritis (OA) is associated with mortality, and walking difficulty is known to mediate this relationship. However, little is known about what specific aspects of walking difficulty increase mortality risk. We investigated the relationship of walking speed, as a measure of walking difficulty, to mortality and studied what thresholds that best discriminate risk of mortality in people with knee OA. Since knee OA frequently occurs in mid-life, we additionally investigated if walking speed is a relevant predictor of mortality and studied the thresholds that best discriminate the mortality risk in younger adults (aged < 65 years) with knee OA.

Methods: We used data from the Osteoarthritis Initiative (OAI). Walking speed was measured via the 20-meter (m) walk test. We quantified time to mortality over 9 years, i.e., until the 108-month OAI visit. To examine the association of walking speed with mortality over 9 years, we calculated hazard ratios (HR) and 95% confidence intervals (CI) from the Cox regression model adjusted for potential confounders. To identify an optimal threshold of walking speed predictive of mortality risk, we used the Maximal Likelihood Ratio Chi-square Approach. This approach selects the threshold that is most concordant with mortality risk over the observed follow-up times, a metric similar to maximizing Youden index when using a receiver operating curve method. Specifically, we ran adjusted Cox regression models for different thresholds of the walking speed iteratively. We then identified the optimal threshold from the model that yielded the maximal chi-square value (Table). We repeated these analyses separately for younger adults with knee OA.

Results: Of 4775 participants who completed the 20-m walk at baseline (age [mean (± sd)] 61.1 ± 9.2 years, BMI 28.6 ± 4.8 kg/m^2, 59% female), 6.5% (312/4755) died over 9 years. For younger adults, 3.0% (88/2966) died. Walking 0.1 meters/second (m/s) slower during the 20-m walk was associated with 16% [Adjusted HR 1.16, 95% CI (1.09, 1.23)] and 14% [Adjusted HR 1.14, 95% CI (1.02, 1.28)] higher risk of mortality over 9 years in the overall analytic sample and younger adults, respectively. Walking slower than 1.2 m/s was found to be an optimal threshold to best discriminate those with and without mortality for both the entire cohort, and among younger adults (Table).

Conclusion: Walking speed, an objective measure of walking difficulty is associated with mortality in knee OA. Specifically, walking slower than 1.2 m/s during a 20-m walk test may identify the risk of mortality in people with OA.

Table: Maximal Likelihood Ratio Chi-Square Approach^ to identify the optimal threshold of walking speed that predicted the risk of mortality in A) overall sample and B) younger adults with or at risk of knee OA

Walking speed thresholds	# deaths/total people		*Adjusted HR (95% CI)	**Likelihood Ratio Chi-Square
	Walk < threshold	Walk ≥threshold		
A) Overall sample (N=4775)				
1.4 m/s	246/3089 (8%)	66/1686 (3.9)	1.48 (1.11, 1.99)	278.82
1.3 m/s	200/2185 (9.2%)	112/2590 (4.3%)	1.62 (1.26, 2.09)	285.81
1.2 m/s†	**146/1355 (10.8%)**	**166/3420 (4.9%)**	**1.81 (1.41, 2.31)**	**293.20†**
1.1 m/s	88/686 (12.8%)	224/4089 (5.5%)	1.97 (1.49, 2.60)	292.85
1.0 m/s	48/317 (15.1%)	264/4458 (5.9%)	2.02 (1.44, 2.83)	286.25
0.9 m/s	20/118 (16.9%)	292/4657 (6.3%)	2.43 (1.49, 3.98)	281.57
B) ***Younger adults (N=2966)				
1.4 m/s	63/1734 (3.6%)	25/1232 (2.0%)	1.54 (0.93, 2.54)	36.34
1.3 m/s	48/1171 (4.1%)	40/1795 (2.2%)	1.64 (1.03, 2.61)	37.70
1.2 m/s†	**33/678 (4.9%)**	**55/2288 (2.4%)**	**1.92 (1.19, 3.11)**	**40.06†**
1.1 m/s	19/334 (5.7%)	69/2632 (2.6%)	1.89 (1.06, 3.37)	37.86
1.0 m/s	7/147 (4.8%)	81/2819 (2.9%)	1.13 (0.47, 2.72)	33.42
0.9 m/s	5/61 (8.2%)	83/2905 (2.9%)	2.30 (0.78, 6.74)	35.24

*Adjusted for baseline age, BMI, sex, race, education, comorbidities, the presence of depression (≤ vs. >16), and symptomatic knee OA (yes or no), defined as presence of Kellgren–Lawrence grade ≥ 2 on x-ray in one or both knees, and pain, aching, or stiffness on most days of a month during the previous year

**Likelihood Ratio Chi-Square values are obtained from adjusted Cox regression models

***Younger adults are participants with or at risk of knee OA who are aged less than 65 years old

^Approach states that higher chi-square values represent greater concordance between the threshold and mortality.

† Model that yielded maximum chi-square value

These same thresholds also apply to younger adults with knee OA. Thus, walking speed may be a simple indicator of health in adults with knee OA. Health care professionals may use walking speed to assess expected health and tailor goals of care for knee OA population.

Session Title: Orthopedics, Low Back Pain & Rehabilitation

Session Type: ACR/ARP Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Physical activity reduces pain and increases physical function in people with knee osteoarthritis (OA), but few achieve recommended levels of physical activity because of pain or functional limitations. High-intensity interval training (HIIT) is a time-efficient exercise strategy with minimal joint impact that requires reduced frequency and duration of exercise compared to traditional long duration low-to-moderate intensity exercise. The

purpose of this study was to determine short-term changes in outcomes among patients with symptomatic knee OA participating in a HIIT intervention.

Methods: Twenty-nine participants with symptomatic knee OA enrolled in a single-arm 12-week HIIT intervention. Participants had a mean BMI of 32 kg/m^2 (2/3 were obese) and a mean age of 63 (range 44-75 years); 2/3 were women and 62% were White, 24% were Black, and 7% were Hispanic. All training was performed under one-on-one supervision from trained research personnel, 2 times per week for 12 weeks. Participants chose the mode of exercise (e.g., walking, cycling). Each training session consisted of a 3-5 minute warm-up and 10 repetitions of 1-minute bouts at individualized training intensity (based on the participant's peak oxygen consumption [VO_2peak test]) with 1-minute rest periods. Baseline, 6-week, and 12-week measures included: performance-based physical function (40 meter fast-paced walk test, 30-second chair-stand test, a stair-climb test, Timed Up and Go Test), WOMAC total and subscale scores, balance measures (single leg stance, side-by-side, semi-tandem, tandem), isometric knee extensor and flexor strength, cardiorespiratory fitness (VO_2peak, time to exhaustion, maximum heart rate), and body composition determined from dual energy x-ray absorptiometery (lean body mass, fat mass, visceral fat, leg lean mass, % fat). Separate linear mixed models were fit for each outcome. Fixed effects were time, age, sex, and baseline BMI, and random effects were baseline values (intercepts); correlation among visits was modeled as unstructured. Mean change between baseline, 6-week, and 12-week assessments was estimated for each outcome.

Results: At 6 weeks, statistically significant improvements were noted for all four physical function measures, isometric knee extensor strength, VO_2peak, and time to exhaustion (Table). At 12 weeks, these changes continued to

	Visit effect		
Outcome (each a separate model)	*6 week change from baseline*	*12 week change from baseline*	*6 to 12 week change*
Physical Function			
20 m fast-paced walk test (seconds)	**-0.79 (-1.24, -0.34)**	**-1.13 (-1.61, -0.64)**	-0.33 (-0.81, 0.15)
30 s chair-stand test (no.)	**1.6 (0.9, 2.3)**	**2.6 (1.8, 3.4)**	**1.0 (0.2, 1.8)**
Stair-climb test (seconds)	**-0.98 (-1.65, -0.30)**	**-1.42 (-2.13, -0.71)**	-0.44 (-1.16, 0.27)
Timed Up and Go test (seconds)	**-0.49 (-0.83, -0.15)**	**-0.58 (-0.95, -0.22)**	-0.10 (-0.44, 0.24)
Knee OA Symptomatic Burden			
WOMAC pain subscale (0-20)	-0.6 (-1.7, 0.4)	**-1.7 (-2.8, -0.6)**	-1.1 (-2.2, 0.1)
WOMAC stiffness subscale (0-8)	-0.4 (-0.9, 0.0)	**-1.2 (-1.7, -0.7)**	**-0.8 (-1.3, -0.2)**
WOMAC function subscale (0-68)	-2.9 (-5.9, 0.1)	**-6.3 (-9.6, -3.1)**	**-3.4 (-6.7, -0.2)**
WOMAC total score (0-96)	-4.0 (-8.1, 0.0)	**-9.7 (-13.6, -4.9)**	**-5.7 (-9.6, -0.8)**
Balance			
Single leg stand (seconds) — max=30s	2.78 (-0.17, 5.73)	**3.41 (0.26, 6.56)**	0.63 (-2.55, 3.80)
Muscle Strength: Isometric Strength			
Flexor			
Right knee, maximum (kg)	-1.85 (-5.72, 2.02)	3.34 (-0.74, 7.41)	**5.18 (1.10, 9.27)**
Left knee, maximum (kg)	1.39 (-3.85, 6.64)	-0.84 (-6.36, 4.69)	-2.23 (-7.78, 3.32)
Extensor			
Right knee, maximum (kg)	**9.36 (1.58, 17.14)**	**9.99 (1.80, 18.18)**	0.63 (-7.61, 8.86)
Left knee, maximum (kg)	**9.24 (0.25, 18.23)**	**9.86 (0.40, 19.33)**	0.62 (-8.89, 10.14)
Cardiorespiratory Fitness			
Peak oxygen consumption, VO_2peak (L/min)	**0.18 (0.08, 0.28)**	**0.14 (0.03, 0.24)**	-0.04 (-0.15, 0.07)
Time to exhaustion (minutes)	**0.89 (0.48, 1.29)**	**1.07 (0.63, 1.50)**	0.18 (-0.26, 0.62)
Maximum heart rate (beats/min)	1.5 (-1.3, 4.2)	**4.5 (1.5, 7.5)**	**3.0 (0.1, 6.0)**
Body Composition			
Lean body mass (kg)	0.22 (-0.19, 0.63)	-0.12 (-0.56, 0.31)	-0.35 (-0.78, 0.09)
Fat mass (kg)	-0.46 (-1.23, 0.30)	-0.28 (-1.10, 0.54)	0.19 (-0.63, 1.01)
Visceral fat (kg)	-0.14 (-0.33, 0.05)	-0.19 (-0.40, 0.02)	-0.05 (-0.26, 0.15)
Right leg, lean mass (kg)	0.12 (-0.04, 0.28)	0.11 (-0.06, 0.28)	-0.01 (-0.18, 0.16)
Left leg, lean mass (kg)	0.18 (-0.03, 0.40)	0.23 (-0.00, 0.46)	0.05 (-0.18, 0.28)
% Fat	0.08 (-0.44, 0.60)	0.11 (-0.44, 0.66)	0.03 (-0.53, 0.58)

Significant effects at a 0.05 level shown in bold.
*Linear mixed models adjusted for fixed effects of time, age, sex, and baseline BMI and random intercepts. Where appropriate ($p<0.1$) quadratic effects of age and BMI were included. Models used restricted maximum likelihood method and unstructured covariance matrix for correlations over time and missing data were assumed to be missing at random.

Table. Adjusted* estimates and 95% confidence intervals (95% CI) of change in assessment measure outcome over time using models for each outcome.

increase, and additional statistically significant improvements were observed for the WOMAC, single leg stand, and maximum heart rate (Table). Changes in isometric knee flexor strength and body composition were not statistically significant, although the changes in visceral fat and left leg lean mass at 12 weeks were clinically meaningful.

Conclusion: A 12-week supervised HIIT program improved WOMAC scores, physical function, balance, isometric knee extensor strength, and cardiorespiratory fitness, with most changes occurring as early as 6 weeks.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Orthopedics, Low Back Pain & Rehabilitation
Session Type: ACR/ARP Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Current guidelines emphasize an active lifestyle in the management of knee osteoarthritis (OA), but up to 90% of OA patients are inactive. We previously demonstrated that an 8-week physical therapist (PT)-led counselling intervention, with the use of a consumer-grade wearable device, improved step count and quality of life in people with knee OA, compared to a control [1]. In the current study, we aimed to assess the efficacy of this intervention for improving activity participation and disease status in people with knee OA after the counselling component was withdrawn.

Methods: Eligible participants had a self-reported knee OA diagnosis, or symptoms of knee OA based on a validated questionnaire. After baseline assessment (T0) and randomization, the *Intervention Group (IG)* received standardized education, a Fitbit, access to FitViz (a personalized Fitbit compatible app), and 4 biweekly phone calls by a PT to counsel activity goals over an 8-week period. Participant then continued to use the Fitbit and FitViz app independently up to week 12. The *Control Group (CG)* received a monthly e-newsletter from the research team. Participants were assessed again at the end of 12 weeks (T1). The primary outcome was time in daily moderate/vigorous physical activity at ≥3 METS and in bouts of ≥10 mins (**3+ MVPA**) measured with a SenseWear® monitor. Secondary outcomes were: 1) daily step count, 2) MVPA at ≥4 METS and in bouts of ≥10 mins (4+ MVPA, reflects purposeful activities), 3) time in sedentary activity in bouts of >20 mins, 4) Knee Injury & OA Outcome Score (KOOS); 5) Partners in Health Scale (PIHS; measured self-management capacity). We used Analysis of Covariance (ANCOVA) to assess the effect of the intervention on the outcomes at T1 after adjusting for T0. The robust regression procedure (SAS *proc robustreg*) was used to limit the impact of outliers.

Table 1: Results of outcome measures

	Intervention Group (n = 26)		Control Group (n = 25)	
	T0	T1	T0	T1
Mean 3+ MVPA time [mins]	31.0 (37.3)	37.7 (30.5)	71.3 (99.8)	49.4 (63.6)
Mean daily steps	6294.0 (3418.0)	7133.3 (3603.3)	7030.1 (3921.6)	6232.7 (3086.1)
Mean sedentary time [mins]	567.5 (183.1)	531.4 (173.5)	551.1 (234.9)	558.3 (224.9)
Mean 4+ MVPA time [mins]	11.1 (19.5)	13.3 (20.0)	42.1 (80.2)	23.1 (37.1)
KOOS (0-100; higher = better)				
Symptoms	68.5 (10.7)	69.3 (12.7)	65.7 (12.3)	66.9 (14.9)
Pain	72.6 (13.5)	73.1 (15.3)	65.1 (13.7)	65.9 (15.6)
ADL	75.5 (14.7)	75.0 (13.1)	72.2 (15.8)	70.3 (16.9)
Sports & recreation	47.9 (23.7)	47.1 (22.4)	46.8 (25.4)	52.2 (22.7)
Qol	44.0 (16.0)	48.7 (17.5)	47.5 (16.0)	46.9 (13.6)
Partners in Health Scale	6.4 (0.9)	6.4 (1.0)	6.5 (1.0)	6.8 (0.8)

Results: We enrolled 51 participants (*IG*: n=26, 88.5% women; *CG*: n=25, 76.0% women). Both groups were similar in age [*IG:* 65.0 (8.3) years; *CG*: 64.8 (SD 9.0)] and body mass index [*IG*: 29.8 (SD 9.0); *CG*: 28.9 (SD 6.2)]. **Table 1** summarizes the results. The *CG* accumulated significantly more 3+/4+ MVPA time at baseline. The adjusted mean difference in 3+ MVPA at T1 was 13.1 mins (95% CI: 1.6, 24.5, p=0.03). The secondary physical activity outcomes improved, although not statistically significant - step count: 1,106.5 (95% CI: -19.9, 2,232.9, p=0.05); 4+ MVPA: 1.6 mins (95% CI: -3.0, 6.1, p=0.50); sedentary time: -29.5 mins (95% CI: -75.8, 16.7, p=0.21). We found similar results in the KOOS and PIHS.

Conclusion: Our findings showed that the wearable-enabled intervention improved physical activity in people with knee OA 4 weeks after the counselling component ended. Further research will be required to examine the effectiveness of this intervention for promoting long-term physical activity and improving health outcomes.

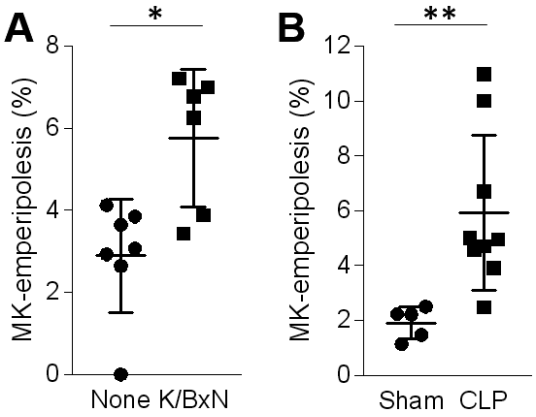
Neutrophil Passage Through the Megakaryocyte Cytoplasm via Emperipolesis Modulates Neutrophil Migration

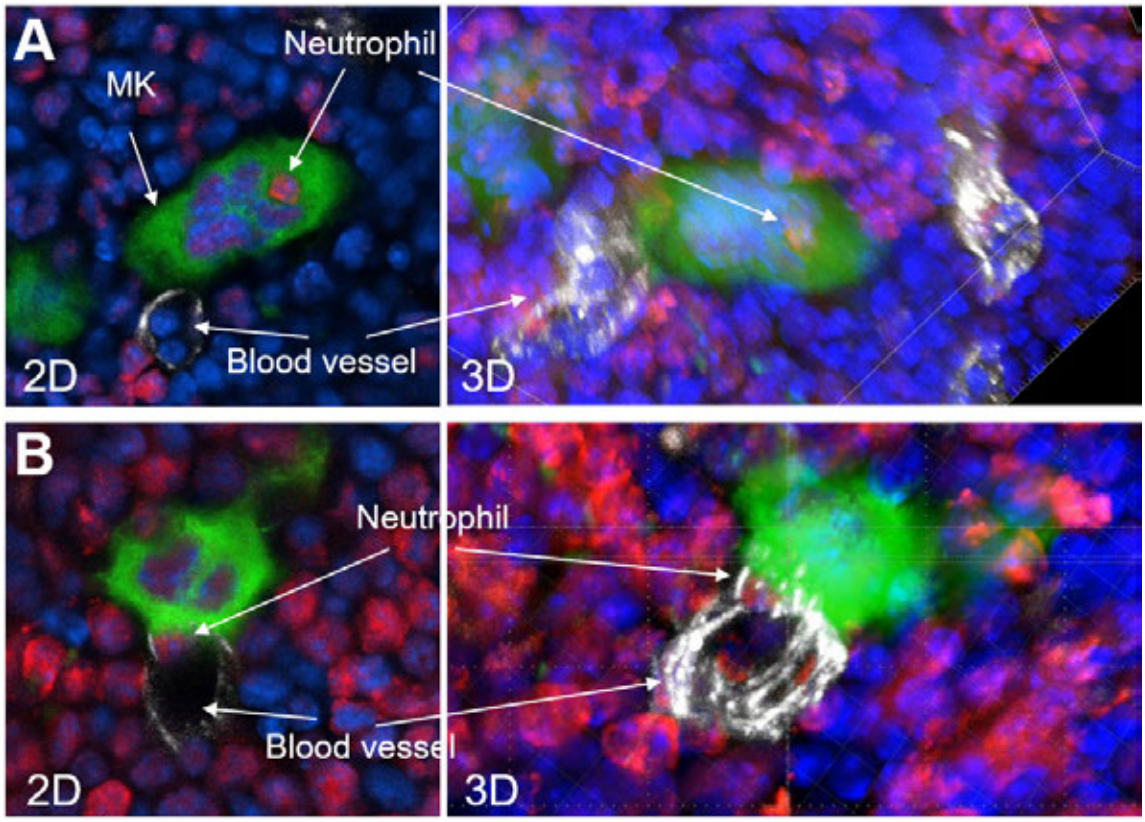
Pierre Cunin,[1] Alexandra Wactor,[2] Li Guo,[3] Andrew Weyrich,[3] Éric Boilard,[4] and Peter Nigrovic[5], [1]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, [3]Program in Molecular Medicine and Department of Internal Medicine, University of Utah, Salt Lake City, [4]Axe maladies infectieuses et inflammatoires, Centre de recherche du CHU de Québec – Université Laval, Québec, Qc, Canada, Québec, QC, Canada, [5]Department of Medicine, Division of Rheumatology, Immunology and Allergy, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA ; Department of Medicine, Division of Immunology, Boston Children's Hospital, Harvard Medical School, Boston, MA, USA., Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

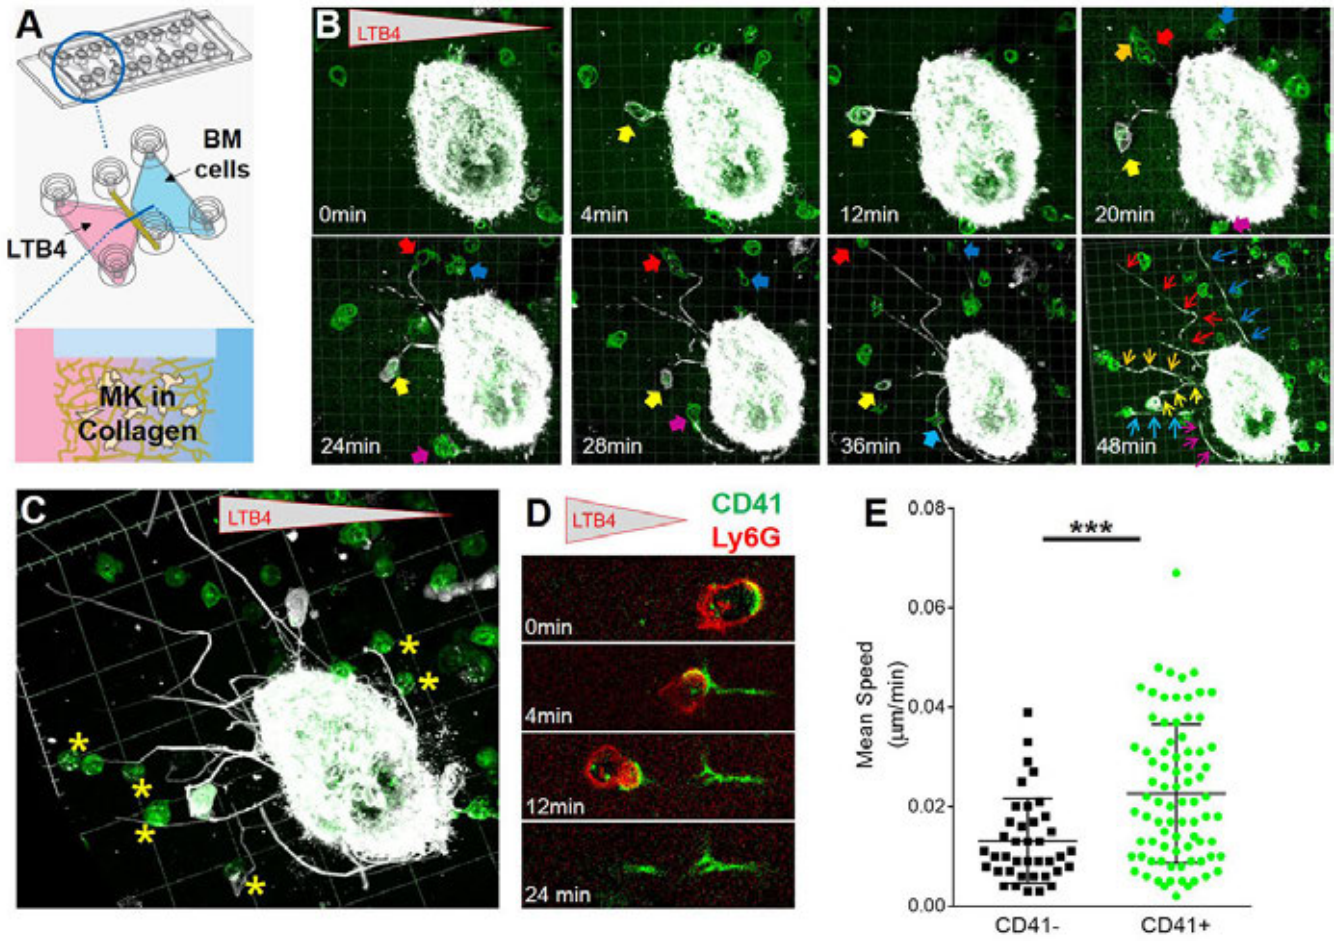
Background/Purpose: Emperipolesis (EP) is a little-understood phenomenon referring to the presence neutrophils within megakaryocytes (MKs). We developed methods to study EP *in vitro* and *in vivo*, finding that EP is a highly regulated cell-in-cell interaction, requires cytoskeleton rearrangement by neutrophils and MKs, and results in the re-



Percent of MK containing neutrophil (A) 8 days after arthritis induction and (B) 4 days after cecal ligation and puncture (CLP) surgery.



Whole bone marrow stained for CD41 (MK, green) Ly6G (neutrophil, red), CD31/CD144 (bone marrow sinusoids, white) and Hoescht (DNA, blue). (A) MK attached on a sinusoid and containing PMN. (B) Neutrophil in a vascular gap, at the interface between circulation and MK in the bone marrow compartment.



(A) µslide chemotaxis chamber (B) Neutrophils (Ly6G, green) migrating through a MK (CD41, white). Each colored arrow follows a neutrophil over time. The passage inside MK is confirmed by analyzing each Z-stacks for each time point (not shown). The image at 48 min shows trails left by neutrophils (colored arrows) (C) 3D reconstitution in high resolution of the MK in (B). Asterisks show neutrophils attached on trails. (D) Trails left by neutrophils are Ly6G negative and CD41 positive, demonstrating a MK origin. (E) Average speed of neutrophils positive for the MK marker CD41 (green circles) or CD41 negative (black squares). Representative of 3 experiments.

ciprocal exchange of cell membrane and proteins between both lineages (Cunin P *et al. eLife 2019;8:e44031*). At the end of EP, neutrophils exit MK cytoplasm alive and intact, but the consequences for neutrophil function are unknown

Methods: We assessed the frequency of EP in healthy mice, in the K/BxN mouse model of inflammatory arthritis and in the cecal ligation and puncture model. A model of EP was developed through incubation of MKs together with neutrophils and characterized using confocal imaging and electron microscopy. The biology of EP was interrogated *in vitro* by time-lapse microscopy on µ-slide chemotaxis chambers, and *in vivo* using whole-mount immunofluorescence of bone marrow. The role of EP on neutrophil migration was investigated *in vitro* using transwell assay and *in vivo* through engraftment of labelled neutrophils co-cultured or not with MKs back into mice subjected to inflammation

Results: Histological sections of bone marrow revealed that EP is increased 2-3 fold in inflammatory arthritis and after cecal ligation and puncture, a model of polymicrobial sepsis (Figure 1). Whole-mount immunostaining in bone marrow showed that EP is restricted to MKs in contact with vascular sinusoids, and neutrophils can be observed in the space between MKs and blood vessels, suggesting egress directly into blood (Figure 2). *In vitro*, we observed that neutrophils enter MKs through a membrane-lined vacuole, termed “emperisome”. We routinely noted the appearance of MK-derived exosomes in the emperisome, and the uptake of MK exosomes by internalized neutrophils. Migration

assay on μ-slide chemotaxis chambers revealed that neutrophils enter and exit MKs following a chemotactic gradient, using a "trans-MK" route (Figure 3A-B). After their passage into MK, neutrophils deposit MK material behind them during their migration, forming a "trail"-like structure made of MK proteins involved in immune cell attachment, and these neutrophils exhibit a clear migratory advantage (Figure 3B-E and not shown). In transwell assay, we observed that neutrophils previously co-cultured with MKs migrate more efficiently toward an LTB_4 gradient. Neutrophil migration is not modulated after culture with MK supernatant or PFA-fixed MKs, excluding an effect from MK-derived microparticles, cytokines, or surface proteins and suggesting a role for EP. *In vivo*, neutrophils previously incubated with MKs migrated more efficiently into the peritoneal cavity during LPS- or IL-1β-induced peritonitis

Conclusion: EP is dramatically increased during inflammation and mediates transfer of membranes and MK-exosome contents to internalized neutrophils. 3-D bone marrow microscopy and migration assays suggest that neutrophils can exit from MKs directly into the circulation, resulting in enhanced migratory capacity. Additional consequences of EP for neutrophil biology remain to be defined

Abstract Number: 2805

Natural Killer Cells Gene Expression Can Differentiate Rheumatoid Arthritis Patients from Healthy Controls

Noha Elemam,[1] Mahmood Hachim,[1] Suad Hannawi,[2] and Azzam Maghazachi[1], [1]Sharjah Institute for Medical Research, College of Medicine, University of Sharjah, Sharjah, Sharjah, United Arab Emirates, [2]Ministry of Health and Prevention-UAE, Department of Rheumatology, Dubai, United Arab Emirates

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Rheumatoid arthritis (RA) is the most prevalent autoimmune diseases (1-3% of the world's population). RA is a prototypic inflammatory disease, being characterized by an altered state of homeostasis, in which immunological stimulation and unwanted inflammation prevail (Pincus, Brooks et al. 1994). The molecular triggers for the development of RA in healthy subjects are still not clearly defined. Identification of RA specific transcriptional signature can shed the light on the molecular pathogenesis of RA. Such signature facilitates the selection of biomarkers that can be used for early detection of RA and prediction of effectiveness of RA treatment. Most of the current transcriptome analyses in RA had focused on whole peripheral blood mononuclear cells (PBMCs). Few studies have indicated that natural killer (NK) cells may play either a pathogenic or a protective role in RA (Shegarfi, Naddafi et al. 2012, Yap, Tee et al. 2018). Hence, in this study we aimed at exploring NK cell markers that could possibly be used to aid in evaluating the differences among healthy controls and RA patients.

Methods: Publicly available transcriptome dataset (GSE93777) of sorted immune cells from RA patients and healthy volunteers were reanalyzed using in house pipeline for normalization and filtration of the raw probes' expression. Gene Set Enrichment analysis was used to identify genes that are differentially expressed (DEG) between different immune cells as compared to NK cells. Next, DEG between NK cells of RA patients and healthy controls were selected. Both lists of identified DEG were validated in peripheral blood collected from healthy controls and RA patients. Whole blood samples were collected from the recruited 11 RA patients (satisfying the 2010 ACR/EULAR classification

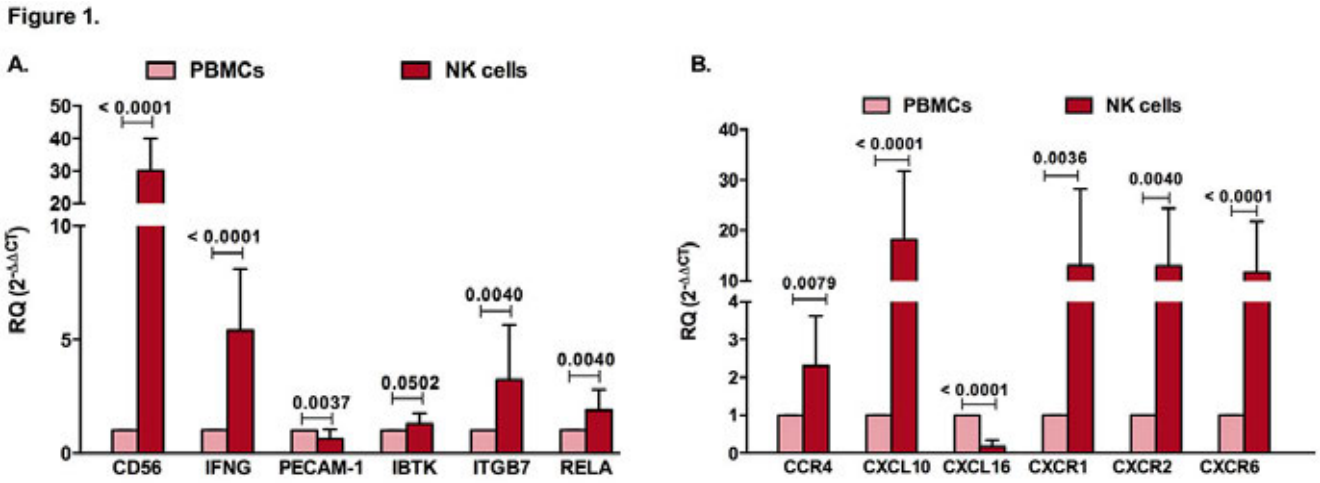

Figure 1. Differentially expressed genes (A) and chemokine ligands/receptors (B) between PBMCs and NK cells.

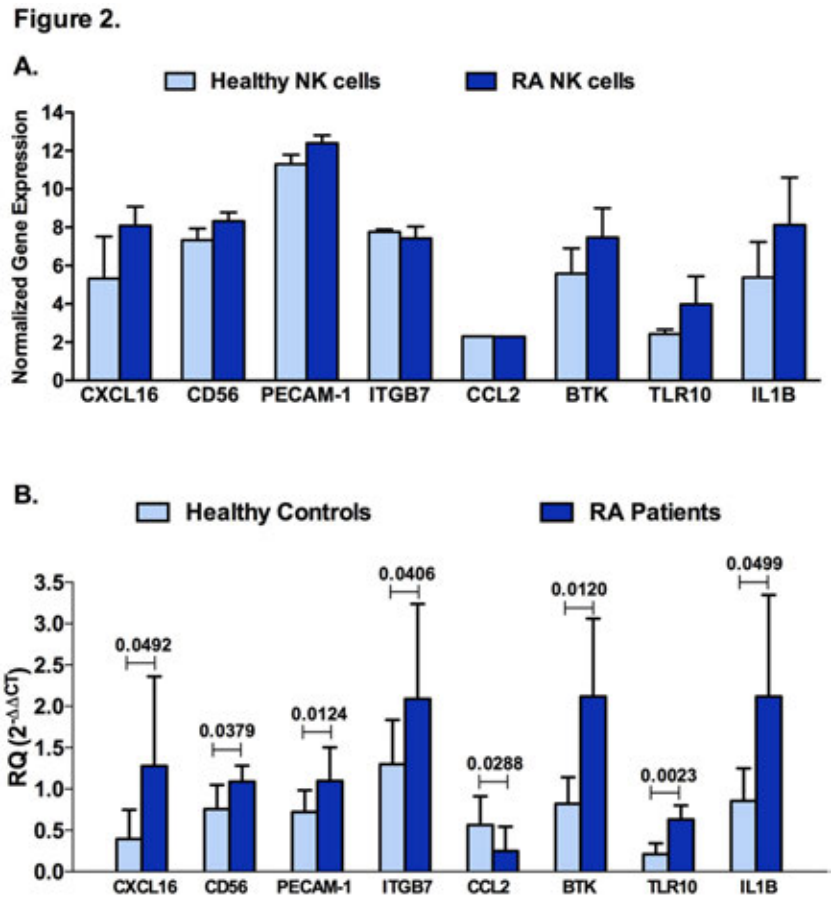

Figure 2. (A) In silico Gene Set Enrichment Analysis identified DEG between NK cells of RA patients and healthy controls. (B) Ex-vivo validation showed that NK cells from recruited RA patients showed differential expression of the predicted genes compared to healthy individuals.

criteria for RA) and 10 healthy controls (with no diagnosis of autoimmune diseases). Then, PBMCs were separated by Ficoll density gradient method, while NK cells were isolated using RosetteSep negative selection method. RNA was extracted and gene expression was assessed using qRT-PCR. Statistical analysis was done using Mann-Whitney test. Binary regression test was used to predict the probabilities of being a case based on the values of the selected genes.

Results: Similar to CD56, a known marker for NK cells, and interferon gamma (IFN-γ), a prototype cytokine secreted by these cells, PECAM-1, IBTK, ITGB7, and RELA were expressed in NK cells (Figure 1A). Furthermore, chemokine ligands and receptors (CCR4, CXCL10, CXCL16, CXCR1, CXCR2, CXCR6) were specifically expressed by NK cells in comparison to PBMCs (Figure 1B). Additionally, as predicted by bioinformatics (Figure 2A), CXCL16, CD56, PECAM-1, ITGB7, BTK, TLR10, and IL-1β were significantly upregulated in NK cells of RA patients when compared to healthy controls, whereas CCL2 was downregulated (Figure 2B). In this study, we applied a logistic regression model using some of the identified NK genes expression (RELA, BTK, IL-1β, CKLF, PECAM-1, TLR10, IL1RN, IFN-γ) where it showed a good prediction power as predictors for RA.

Conclusion: Gene expression of these molecules; namely CXCL16, CD56, PECAM-1, ITGB7, BTK, TLR10 and IL-1β, in NK cells might be used as promising biomarkers for RA disease.

Single Cell RNA-sequencing Reveals Distinct Macrophage Subsets in the Joint with Differing Ontogenies During Steady-state and Arthritis

Anna Montgomery,[1] **Shang-Yang Chen**,[1] Philip Homan,[1] Gaurav Gadhvi,[1] Deborah Winte,[2] and Harris Perlman[2], [1]Northwestern University, Chicago, [2]Northwestern University Feinberg School of Medicine, Division of Rheumatology, Chicago

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Macrophages in the synovial lining of the joint are critical players in the pathogenesis of rheumatoid arthritis (RA). However, their heterogeneity remains poorly characterized.

Methods: Using single cell RNA-sequencing (scRNA-seq), we uncovered 4 distinct subsets of mouse synovial macrophages during steady state distinguishable by expressions of CX3CR1 and MHCII.

Results: MHCII- subsets preferentially expressed markers associated with tissue-residency, including Sepp1 and C1qc, whereas MHCII+ subsets expressed monocyte-associated markers such as Ccr2 and Cd74, Ly6c2, a key maker of classical monocytes, was expressed only in CX3CR1+MHCII+ subset. Fate mapping experiments confirmed the differing ontogenies of synovial macrophage subsets. During inflammatory conditions (serum transfer induced arthritis), we observed the expansion of CX3CR1+MHCII+ subset and increased expression of monocyte-associated genes in all macrophages, which coincides with the recruitment of circulating monocytes. These subsets are recapitulated in scRNA-seq data from synovial biopsies of RA patients.

Conclusion: Our results support a dynamic role for synovial macrophages in inflammation.

Activation of the STING Pathway Is a Shared Feature of Salivary Gland and Lung Inflammation in Sjogren's Syndrome

Joanna Papinska,[1] Grzegorz Gmyrek,[2] **Umesh Deshmukh**,[1] and Harini Bagavant[1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Sjögren's syndrome is a chronic autoimmune disorder characterized by an increased type 1 interferon gene signature. The engagement of stimulator of interferon genes (STING) is a critical pathway involved in the production of type I IFNs. The gain of function mutations in *TMEM173*, encoding STING, results in a severe vasculopathy affecting the skin and lungs. We have previously reported that systemic activation of the STING pathway in mice, using a STING agonist DMXAA, causes an Sjögren's syndrome-like disease characterized by sialoadenitis and salivary gland dysfunction. Considering that lungs are affected in 9-20% of Sjögren's syndrome patients, this study was undertaken to investigate lung involvement in DMXAA treated mice.

Methods: Female C57BL/6 mice (8-10 wks. old) were injected with DMXAA ((20mg/kg body wt) either once (day 0) or twice (days 0 and 21). Serum IFN-α and IFN-β levels were measured by a multiplex bead-based assay. Proinflammatory cytokine gene expression in lungs was analyzed by real-time PCR and by using the Nanostring mouse inflammation panel. The innate lymphoid cell populations and lymphatic endothelial cells in lungs were studied by flow cytometry. H&E stained lung sections were used to evaluate the presence of inflammatory foci in the lungs. The role of STING expression in hematopoietic cells on lung inflammation, was investigated in bone marrow chimeras of WT into STING$^{-/-}$ mice and vice versa.

Results: DMXAA treatment induced a rapid, but transient spike in circulating type I IFN levels, which returned to baseline in 24h. At 4h post-treatment, there was a significant increase in the expression of *IL-6*, *TNF-α*, *IFNβ*, *Mx1,* and *IFNγ*, in the lungs. This was followed by an increase in type 1 innate lymphoid cells on day 8. Histopathologic analysis showed the presence of peri-bronchial inflammatory infiltrates on day 35, which persisted until day 57. The lung inflammation was associated with an increased expression of multiple proinflammatory genes, including *Ccl20*, *Cxcl10*, *Cxcl9*, and *Il17α*. Also, there was an increased frequency of lymphatic endothelial cells, suggestive of lymphangiogenesis. Although STING expression was seen in bronchial epithelium and alveolar cells, bone marrow chimeras between STING$^{-/-}$ and wild type mice suggest that STING expression in bone marrow derived cells was critical for lung inflammation.

Conclusion: Our data suggest that systemic activation of STING is a common pathway involved in the induction of salivary gland and lung inflammation in Sjögren's syndrome. In addition, activation of innate immunity in bone marrow-derived cells is critical for initiating lymphocytic infiltration in organs targeted in Sjögren's syndrome.

Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Since one of the strongest associations with antibodies (abs) to SSA/Ro (Ro60) is the development of congenital heart block (CHB), this model provides an exceptional opportunity to define novel insights that link maternal abs with an inflammatory cellular response which eventuates in fibrotic replacement of the AV node. We recently compiled risk genes based on an agnostic transcriptomic survey of macrophages isolated from hearts of fetuses dying with CHB and healthy aged matched fetuses electively terminated, noting that IFN related genes (IRGs), including IFN induced Protein with Tetratricopeptide Repeats 1(IFIT1) and Sialic Acid Binding Ig Like Lectin 1 (SIGLEC1), are highly upregulated in the CHB hearts. Accordingly, this study addressed the hypothesis that IRGs contribute to CHB pathogenesis.

Methods: hY3 RNA, a noncoding ssRNA and TLR7/8 agonist, was used as a proxy of the Ro60 immune complex. Human derivatives included healthy peripheral blood macrophages and fibroblasts isolated from a healthy human fetal heart. Neutralizing IFNα and IFNβ abs were used to assess the contribution of the respective cytokines to the model. Macrophage readouts included the expression of IFIT1 and SIGLEC1 transcripts (qPCR, units, fold change based on 2-ΔΔCT, relative expression of transcript normalized to GAPDH) and myofibroblast phenotype (EdU imaging and SMAc by IF, respectively).

Results: As expected, exposure of macrophages to IFNα resulted in a significant upregulation of IFIT1 and SIGLEC1 compared to untreated macrophages (70±25 vs 1, and 17±9, vs 1, respectively with both N=3, P< 0.05). Similarly, exposure to IFNβ also resulted in the upregulation of these transcripts (254±237 vs 1, p=0.03, and 21±14 vs 1, respectively with both N=4, p< 0.03). The expression of these transcripts by IFNα- and IFNβ-treated macrophages was completely attenuated by co-treatment using respective Type I IFN-specific neutralizing antibodies. In parallel, transfection of human macrophages with hY3 also resulted in upregulation of IFIT1 (112±30 vs 1, p=0.02, N=3) and SIGLEC (13±7 vs 1, N=3). To confirm TLR7/8 dependency of IRGs, the addition of TLR7/8 antagonist IRS661 to our in vitro model resulted in a significant decrease of IFIT1 expression to 14% (14±10, n=6) and SIGLEC1 to 54% (7±5, n=7, both P=0.03). Co-treatment with neutralizing antibody against IFNα reduced the expression of IFIT1 to 9% (10±9, n=3) and SIGLEC1 to 35% (5±3, n=3). Co-treatment with neutralizing antibody against IFNβ also reduced the expression of IFIT1 to 24% (24±6, n=2) and SIGLEC1 to 59% (3±5, n=3). For a survey of direct effects of type I IFN, IFNα and IFNβ were shown sharing the capacity to stimulate fibroblast proliferation (EdU, % positive) yielding a result of untreated (16%), IFNα (40%), and IFNβ (48%). In addition, exposure of human fibroblasts to IFNα as well as IFNβ induced expression of the myofibroblast marker, SMAc (IF) versus no expression by the untreated fibroblasts.

Conclusion: These results suggest that type I IFN contributes to the inflammatory and profibrosing milieu associated with the development of CHB. Feed forward expression of IFN related genes in response to TLR signaling may provide new targets towards the prevention of disease.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Innate Immunity
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Neutrophils are key first responders of innate immunity, participating in both defense and inflammatory disease. Phenotypic heterogeneity is recognized but the existence of *bone fide* subsets remains unknown. We applied single-cell transcriptomics to define the relationships among individual neutrophils in heathy mice.

Methods: We profiled neutrophils from bone marrow, peripheral blood and spleen from 6-8 week male C57Bl/6 mice. Ly6g+ neutrophils were sorted for single-cell RNA sequencing using the 10X platform. We applied a multinomial model to the raw unique molecular identifier (UMI) counts to assign cells to one of 265 known cell populations and thereby ensure restriction of the analysis to neutrophils. Following exclusion of low-quality cells and transcripts expressed in fewer than 10 cells, 12,011 cells and 2,709 highly-expressed transcripts were retained for downstream analysis. We compared methods for dimensionality reduction, including PCA/tSNE and diffusion maps, to optimally reflect gene expression patterns.

Results: An average of 1,439 UMI and 482 genes were detected per cell. Linear dimensionality reduction could identify clusters of neutrophils, but underlying patterns were in fact best captured through diffusion maps, a nonlinear method. Using diffusion pseudotime analysis, we reconstructed a continuum of neutrophil maturation that defined a sequential gene expression program. The genes anchoring the two poles of this "neutrotime" spectrum were *Ly6g*, *Camp*, *Ltf*, *Lcn2* in less mature cells and *Il1b*, *Ccl6*, *Csf3r* in more differentiated cells. Cells all along the neutrotime continuum were found in all profiled organs, but regional transcriptomic differences were also observed. For example, *Il1b* was highly expressed in blood and spleen but weakly in bone marrow. Conversely, *Ly6g* transcript abundance was highest in bone marrow and to a lesser extent in spleen, but only weakly detectable in blood. Interestingly, we identified a small cluster of cells defined by high expression of interferon response genes including *Ifit1*, *Ifit3*, *Isg15*, *Ifitm3*. This interferon-responding population was present in all profiled organs but less common in bone marrow than in blood and spleen, suggesting a more mature neutrophil population with a function yet to be defined.

Conclusion: Neutrophils have traditionally been characterized by nuclear morphology, cell density, and surface markers. Here we expanded this perspective via unbiased single-cell approach transcriptomics, demonstrating technical feasibility despite low transcript density. We identify a single developmental continuum shared by neutrophils across biological compartments, termed here 'neutrotime', that appears to represent much but potentially not all of their phenotypic heterogeneity. Our data define the baseline gene expression landscape of murine neutrophils and will facilitate further transcriptomic and functional investigations, as well as rational gene perturbations, potentially highlighting opportunities for therapeutic exploitation of the diversity within this important immune population.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis I: Signaling Pathways
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Mendelian inheritances of highly penetrant single gene variants have been reported as monogenic forms of SLE. To explore novel risk variants, we carried out whole-exome sequencing to identify underlying monogenic causes in two multiplex families that each contains unaffected parents and two sons with pediatric-onset SLE, and assessed candidate rare variants for Mendelian inheritance and functional consequences.

Methods: Whole-exome sequencing, variant calling and annotation were conducted using Illumina Hiseq2000, the Genome Analysis Toolkit GATK and ANNOVAR, respectively. Variants in the gene of interest were confirmed by Sanger sequencing. Functions of candidate variants were tested using Minigene assay for differential splicing, and CRISPR/Cas9 mediated knock-in (KI) mice for the frameshift variant.

Results: In each family, we identified a putative loss-of-function variant in the *SAT1* gene that co-segregated with lupus in an X-linked recessive pattern. This variant is extremely rare in the population (absent in > 200,000 individuals), and is not in previously known SLE-associated genes. In one family, a *SAT1* frameshift mutation, which is expected to trigger nonsense-mediated mRNA decay, was transmitted from the mother to the two sons affected with SLE, but not to the unaffected son. Using CRISPR/Cas9, we have 5 founders of frameshift mutation KI mice and are establishing a colony for lupus-like phenotype studies. In the other family, we found a missense variant on exon 2 that was predicted to be deleterious by altering transcript splicing. Using the Minigene assay, we confirmed that the mutant construct

resulted in aberrantly spliced transcripts, including ~30% intron 2 containing, ~20% exon 2 skipping and 50% normal transcripts, in transiently transfected 293T or HeLa cell lines. We further extended Sanger sequencing of *SAT1* in 566 SLE patients enriched in multiplex male lupus and pediatric patients, found 4 common variants and 12 additional rare variants, but none had robust evidence for functions based on HaploReg v4.1 and Regulome database.

Conclusion: We identified two rare *SAT1* loss-of-function variants on the X chromosome that segregate with SLE phenotype in two families that each contained two sons with pediatric-onset SLE. The exon 2 variant disrupted the splice donor site, and the frameshift variant created a premature stop codon. *SAT1* encodes spermidine/spermine-N^1-acetyltransferase, a rate-limiting enzyme that regulates polyamine catabolism. The low or absent function of *SAT1* might perturb polyamine catabolism, predisposing to SLE, especially in boys.

The IRE1α Pathway Mediates Neutrophil Stress and NETosis in Lupus

Gautam Sule,[1] Basel Abuaita,[1] Paul Steffes,[1] Kristen Gilley,[1] Andrew Fernandes,[1] Mary O'Riordan,[1] and Jason Knight[2], [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION

Session Title: SLE – Etiology & Pathogenesis I: Signaling Pathways
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Immune complex (**IC**)-activated neutrophils appear to amplify inflammation in lupus through the release of neutrophil extracellular traps (**NETosis**). There is presently no consensus as to how to most effectively inhibit NETosis in patients. Recent studies have implicated the inositol-requiring enzyme 1 alpha (**IRE1α**) pathway (a mediator of the endoplasmic reticulum stress response) as a perpetuator of inflammation in infections, sepsis, and inflammatory disorders such as rheumatoid arthritis. However, the IRE1α pathway has been little studied in relation to neutrophil function or lupus pathogenesis.

Methods: Total IgG was isolated from lupus patients and bound to ribonucleoprotein to generate lupus ICs, which were used to stimulate neutrophils. IRE1α activity was measured by quantifying splicing of X-box binding protein 1 (**XBP1**) gene transcripts (spliced transcripts encode active XBP1 protein, recognized as a major facilitator of the IRE1α pathway). We tested the impact of specific inhibition of neutrophil IRE1α on reactive oxygen species (**ROS**) production, caspase activation, mitochondrial function, and NETosis. Finally, we assessed the therapeutic efficacy of inhibition of the IRE1α-XBP1 pathway in the toll-like receptor 7 (**TLR7**)-agonist mouse model of lupus.

Results: *In vitro*, control neutrophils stimulated with lupus ICs demonstrated increased IRE1α pathway activity as measured by the ratio of spliced XBP1 transcripts to total XBP1 transcripts. Inhibition of IRE1α's ribonuclease activity with the specific inhibitor 4μ8C alleviated lupus IC-triggered NETosis, as well as "spontaneous" NETosis of patient neutrophils. Treatment of neutrophils with lupus ICs resulted in cytosolic ROS formation (mean 2-fold increase) and caspase 2 activation (mean 6-fold increase), both of which were significantly reversed by 4μ8C. Mitochondrial dysfunction was also appreciated in IC-stimulated neutrophils (mean 8-fold increase in mitochondrial ROS), and could be

neutralized by either traditional ROS scavengers or treatment with 4μ8C. Finally, we induced a lupus-like phenotype in mice by treating BALB/c mice with the TLR7-agonist R848 (topical application, 10 mg/kg three times weekly) over six weeks. R848 treatment resulted in activation of the neutrophil IRE1α-XBP1 pathway (mean 1.5-fold increase in XBP1 splicing). Administration of 4μ8C (10 mg/kg, three times weekly over the duration of R848 treatment) not only reduced IRE1α pathway activation in neutrophils, but also significantly reduced mitochondrial ROS levels. Furthermore, R848 treatment resulted in an elevation of plasma NET remnants (mean 2-fold increase), which returned to baseline levels with 4μ8C treatment.

Conclusion: These data are the first to identify a role for IRE1α-XBP1 in the activated state of lupus neutrophils, with this pathway apparently upstream of mitochondrial dysfunction and ROS generation. Inhibition of IRE1α reduced mitochondrial ROS formation in peripheral blood neutrophils of lupus mice, and normalized plasma NET levels of the same mice. Inhibition of the IRE1α pathway appears to be a potential strategy for neutralizing NETosis in lupus.

Session Title: SLE – Etiology & Pathogenesis I: Signaling Pathways
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In systemic lupus erythematosus (SLE), blood platelets have an activated phenotype, and express high levels of CD40L and P-selectin. Our group demonstrated that SLE patients' platelets increase type I interferon production by plasmacytoid dendritic cells through CD40-CD40L interaction [1]. Recently, we found that T regulatory cells (Tregs) expressed high levels of P-selectin glycoprotein ligand-1 (PSGL-1), suggesting potential Tregs/platelet interactions.

Methods: Flow cytometry was used for analysis of surface and intracellular molecules expressed on blood cells of active (aSLE, SLEDAI ≥ 6, n= 13), inactive (iSLE, SLEDAI < 6, n = 20) SLE patients and healthy donors (HD, n = 17). To assess Tregs immunosuppressive functions, we conducted co-culture experiments of Tregs ($CD25^{high}$ $CD127^{low}$ $CD4^{+}$) and CFSE-labelled T effector (Teff; $CD25^{-}CD127^{high}CD4^{+}$) purified from HD. Cells were cultured at a 1:1 ratio with anti-CD3/CD28 activation +/- platelet or recombinant selectin for 6 days. At the end, Teff proliferation was evaluated using cytometry.

Results: Patients with aSLE had significantly more platelet/Tregs aggregates defined as $CD61^{+}$ Tregs (figure 1a), than patients with iSLE and HD (figure 1b-c). Conversely, levels of platelet/Teff aggregates were similar in the 3 groups suggesting a specific interaction. To understand the impact of platelet/Tregs interaction, we conducted Teff/Treg

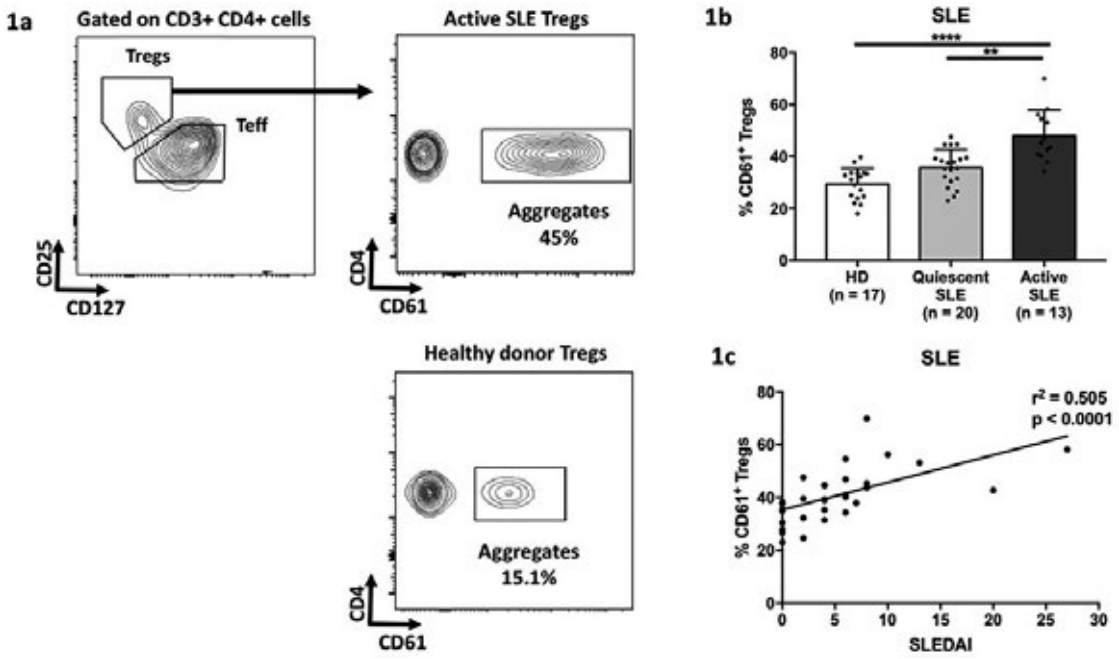

Figure 1. Platelet/Tregs interactions are increased in active SLE. Fresh whole blood samples from healthy donors or patients with SLE were stained for the study of Tregs/platelet interaction. (a) Gating strategy to assess Platelet/Tregs circulating aggregates. (b) Percentage of Platelet/Tregs aggregate in healthy donors or patient with SLE. Quiescent SLE (SLEDAI < 6), Active SLE (SLEDAI ≥ 6).**, $p < 0.01$; ****, $p < 0.0001$. (c) Correlation between the percentage of platelet/Tregs aggregates and SLE disease activity as assessed by the SLEDAI.

co-cultures. Platelets addition to the co-culture inhibited Tregs immunosuppressive functions in a dose-dependent manner. Addition of an anti-PSGL-1 antibody rescued Tregs functions. Lastly, replacing platelets with (P-, E- or L-) selectin could recapitulate these *in vitro* results.

Mechanistically, P-selectin binding on Tregs induced Syk phosphorylation, which induced a strong intracytosolic calcium release. No similar signals were found with P-selectin binding on Teff. In co-culture assays, Syk inhibition rescued immunosuppressive functions from Tregs exposed to P-selectin.

A transcriptomic analysis of P-selectin-exposed Tregs identified a significant downregulation of the TGF-beta axis. We subsequently confirmed *in vitro*, by qPCR and cytometry, that P-selectin induced a downregulation of TGF-beta and its chaperone molecule GARP at the RNA and protein levels.

To assess the relevance of selectins in human SLE, we measured levels of soluble selectins (using ELISA) and selectin+ microparticles (by cytometry). Patients with aSLE had increased level of both soluble and microparticular selectins compared to HD and iSLE ($p < 0.01$ for all comparisons). Microparticular and soluble selectins levels correlated with the SLEDAI ($r^2 = 0.278$, $p < 0.001$ and $r^2 = 0.116$, $p < 0.001$, respectively).

Conclusion: The selectin/PSGL-1 axis represents a new pathway responsible for Tregs dysfunction in SLE through downregulation of the TGF-beta axis. Blocking P-selectin (in development for sickle cell disease [2]) might be an innovative treatment option. To evaluate this strategy, we are currently treating DNASE1L3-KO SLE mouse model with an anti-P selectin monoclonal antibody.

Pentameric, but Not Monomeric C-reactive Protein, Limits the SnRNP-immune Complex Triggered Type I Interferon Response: Implications for Lupus Pathogenesis

Cecilia Svanberg,[1] Helena Enocsson,[1] Klara Martinsson,[1] Lawrence Potempa,[2] Ibraheem Rajab,[2] Jonas Wetterö,[1] Marie Larsson,[1] and **Christopher Sjöwall** [3], [1]Linköping University, Linköping, Sweden, [2]Roosevelt University, Chicago, IL, [3]Department of Clinical and Experimental Medicine, Rheumatology/Division of Neuro and Inflammation Sciences, Linköping University, Linköping, Sweden

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis I: Signaling Pathways
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is an autoimmune systemic disease affecting multiple organs and which is characterized by autoantibodies directed against nuclear constituents. Common autoantibody targets include double-stranded (ds) DNA and small nuclear ribonucleoproteins (snRNPs; *i.e.* U1-snRNP). Uptake of immune complexes (ICs) by plasmacytoid dendritic cells (pDCs) can activate endosomal toll-like receptors (TLRs) such as TLR-7 and TLR-9 if nucleic acids are present in the ICs. Such activation is dependent on IC internalization by Fcγ receptor type IIa (FcγRIIa), and results in production of type I interferons (IFNs), a hallmark of SLE and a target for therapeutic interventions. The acute phase protein C-reactive protein (CRP) binds FcγRs, as well as some nuclear proteins, including snRNPs. Pentameric (native) CRP has previously been suggested to inhibit the production of type I IFNs in peripheral mononuclear cells (PBMCs) in response to ICs formed by autoantibodies against snRNP, an effect which was further investigated herein.

Methods: PBMCs or magnetically (MACS) purified pDCs were retrieved from whole blood of healthy volunteers. Type I IFN gene transcription and production was stimulated by addition of snRNP containing ICs +/- pentameric CRP (pCRP) or monomeric CRP (mCRP) in different sequential order. IC formation was achieved through simultaneous addition of snRNP and bulk IgG, retrieved from an SLE patient with high levels of snRNP autoantibodies, directly to the cells. Type I IFNs and inflammatory cytokines were investigated using quantitative PCR, ELISA and cytometric bead array, and cells responsible for production of the type I IFNs were characterized using flow cytometry. For statistics, a two-tailed t-test was performed.

Results: pCRP had an inhibitory effect on the IFN gene expression in PBMCs after incubation with ICs, p=0.044 for IFNα4 and p=0.047 for IFNβ at the 4h time-point compared to IC only. pCRP also showed a dose-dependent inhibitory effect on the type I IFN production in the cells. The monomeric form of CRP showed modest or no effect on IFN levels; p=0.82 for IFNα4 and p=0.58 for IFNβ at the 4h time-point, compared to IC only. A pre-incubation of the cells with pCRP increased the inhibitory effects compared to simultaneous addition of pCRP and ICs, suggesting that initial binding to the cells is a critical step for inhibition. Flow cytometry suggested that pDCs are the main producer of the type I IFNs. In addition, pCRP seems to have a more general inhibitory effect on type I IFNs, as seen in the reduction of IFN production in response to the TLR-9 ligand CpG.

Conclusion: pCRP has a distinct inhibitory effect on type I IFNs, which is largely not seen for the dissociated form of CRP (mCRP). The more general inhibitory effects shown by pCRP highlights its immune regulatory function in pathologies characterized by high production of type I IFNs. The identity of the initial receptors responsible for pCRP mediated effects, as well as of the involved signaling pathways, will be further investigated.

Session Time: 4:30PM–6:00PM

Background/Purpose: Amino acids play an important role in various metabolic processes. However, the role of amino acid metabolism in the regulation of human B cell function remains elusive. To determine the role of essential amino acids in human B cell differentiation and relevance to the pathogenesis of SLE.

Methods: In the in vitro arm of the study, purified $CD19^+$B cells from healthy donors were cultured withTLR7/9 ligand (LOX or CpG),IFN-α and B cell receptor (BCR) cross-linking, in the presence or absence of amino acids. We determined 1) the types of amino acids that are important for PB differentiation, 2) the amino acid transporters that are important for PB differentiation, 3) the main signaling pathway(s) involved in the presence of amino acids, 4) the transcriptional factors used in the presence of amino acids. In the clinical arm of the study, peripheral blood mononuclear cells (PBMCs) were obtained from 24 patients with RA, 35 patients with SLE, and 21 age-matched healthy controls, and subjected to flow cytometric analysis to determine the expression of amino acids-related markers.

Results: 1) Stimulation with the combination of BCR, IFN-α and TLR7/9 ligand induced PB differentiation accompanied by uptake of amino acids. PB differentiation was abrogated in the absence of essential amino acid methionine, and to a lesser extent leucine, but not in non-essential amino acid cystine. 2) LAT1 and CD98 are known amino acid transporters. The process of plasmablast differentiation encompassed a trade-off balance between upregulation of CD98 and downregulation of LAT1. 3) BCR and mTORC1 signals were susceptible to methionine, while mTORC1 signals were susceptible to leucine. In the presence of methionine, activation of Syk and mTORC1 signals synergistically induced methyltransferase EZH2 expression. EZH2 induced H3K27me3 at BACH2 loci and suppressed BACH2 expression, leading to induction of BLIMP1, XBP1 expression, and plasmablast differentiation. 4)Assessment of the expression of amino acid transporters CD98, LAT1 and EZH2 in B cells in RA and SLE patients showed overexpression of CD98 and EZH2, but not LAT1, in SLE, compared with RA and control. In SLE patients, EZH2 expression

level correlated with that of CD98 in B cells. EZH2 expression also correlated with disease activity scores, such as of SLEDAI and BILAG and anti-dsDNA antibodies in patients with SLE.

Conclusion: The results indicate that methionine activates signaling by controlling immunological metabolism in B cells and plays an important role in differentiation of B cells to plasmablasts through epigenome modification through the induction of EZH2, suggesting that methionine is closely related to the pathogenesis of SLE.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: SLE – Etiology & Pathogenesis I: Signaling Pathways
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Studies to date have primarily focused on stimulators that are overexpressed and activate B cells in SLE subjects. Factors that can maintain B cells in a resting state and may be under-expressed in SLE are largely unknown. We utilized a combined single-cell B cell transcriptome and high dimensional flow cytometry analysis approach for a coordinated understanding of factors that are both over- and under-expressed in B-cell developmental checkpoints in SLE.

Methods: The expression of IL-4R and interferon beta (IFNβ) in subsets of B cells was analyzed using high dimensional flow cytometry analysis (n=47 patients who met the ACR classification criteria for SLE). Total B cells from 3 autoantibody (anti-DNA, anti-Sm, and anti-histone)$^+$ African American (AA) SLE patients, 1 autoAb(–) Europeran American (EA) SLE patient and 1 AA healthy control were purified using the StemCell Human B cell isolation kit. A high-throughput scRNA-seq was carried out using a droplet-based 10x Chromium approach. The effects of IL-4 on

IFNβ-induced IRF7 as well as on IFNɣ + a defined stimulatory media (DSM)(anti-Ig+BAFF+IL-21+TLR7+IL-2)-induced double negative 2 (DN2: $CD21^{-}CD27^{-}IgD^{-}CD11c^{+}T\text{-}bet^{+}$) B cells were analyzed using an *in vitro* culture approach.

Results: At the protein level, within naïve ($IgD^{+}CD27^{-}$) B cells, higher expression of IFNβ and lower expression of IL-4R correlated with the percent of activated naïve $CD21^{lo}IgD^{+}$ and $CD21^{lo}IgD^{-}$ DN B cells. There was higher percent of $IFN\beta^{+}IL\text{-}4R^{lo}$ naïve B cells in AA compared to EA SLE patients. However, in EA, but not AA, patients, higher percent of $IFN\beta^{+}IL\text{-}4R^{lo}$ naïve B cells was found in anti-Sm^{+} and renal disease^{+} patients. scRNA-seq analysis shows that the molecular signature of B cells from autoAb(+) patients is type I IFN stimulated genes (ISGs), including *IRF7*, *ISG15*, *ISG20*, *MX1*, and *STAT1*. The molecular signature of B cells from autoAb(-) patients is *IL4R*, *BACH2*, *S1PR1*, and *FCER2.* The high *ISG* and low *IL4R* was evident during the early transitional stage 1 B cells and persisted in pre-switched *IGHD*+ B cells. Stimulation of B cells with DSM+IFNɣ promoted DN2 development whereas addition of IL-4 inhibited DN2 and preserved B cells at the resting naïve stage ($IgD^{+}CD11c^{-}T\text{-}bet^{-}$). IL-4 also inhibited IFNβ-induced IRF7.

Conclusion: Down-regulation of IL-4R in naïve B cells is a major dysregulation in SLE since it may predispose SLE B cells to both type I IFN and type II IFN stimulation. Further, lower IL-4R together with upregulation of endogenous IFNβ in naïve B cells was an important signature for activated naïve B cells. Such signature was associated with development of DN2 B cells and, in EA patients, development of anti-Sm autoantibody. Modulation of IL-4R signaling may be developed into a novel therapy for SLE.

An Expanded Granzyme K^{+} CD8 T Cell Population Induces Inflammatory Responses in Rheumatoid Arthritis Synovium

Anna Helena Jonsson,[1] Fan Zhang,[2] Gerald Watts,[2] Kevin Wei,[1] Deepak Rao,[2] Soumya Raychaudhuri,[2] and Michael Brenner[3], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital:, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: CD8 T cells represent nearly half of T cells in inflamed synovium from patients with rheumatoid arthritis (RA). Research to date has focused on CD4 T cells, yet we have found that synovial CD8 T cells express IFNgat a higher frequency and TNF at a similar frequency compared to CD4 T cells. Recent single-cell transcriptomic analysis of RA synovial tissue has suggested that CD8 T cells form sub-populations characterized by expression of secreted proteases granzyme K (GzmK) and granzyme B (GzmB).

Methods: We have assembled a single-cell RNA-seq data set of approximately 20,000 CD8 T cells by integrating new and publicly available data from synovial tissue (N=22) and fluid (N=1) from patients with RA and from blood (N=3) from healthy controls. RA patients met the 2010 ACR criteria for RA. Additional data were collected by flow

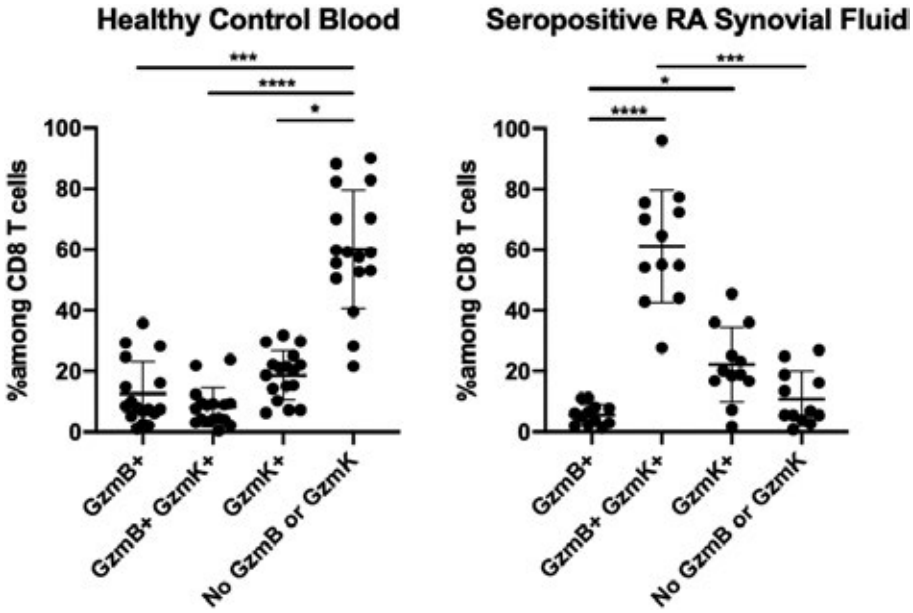

Figure 1. Frequencies of GzmK vs GzmB expression in blood from healthy controls and synovial fluid from patients with seropositive RA. Statistical comparison by Friedman test. * p<0.05 , *** p<0.001, **** p<0.0001.

cytometry or low-input RNA-seq from synovial tissue, synovial fluid, and blood from patients with clinical diagnoses of rheumatoid arthritis or healthy controls. In *in vitro* cultures, human synovial fibroblast cells were treated with recombinant granzyme K. Cytokine production was measured by ELISA, and reactive oxygen species were measured by a H_2DCFDA fluorescence assay.

Results: At both the mRNA and protein levels, the vast majority of CD8 T cells in synovial tissue and fluid from patients with seropositive RA express GzmK, either alone or together with GzmB, a marked enrichment compared to blood (Figure 1). Very few synovial CD8 T cells express GzmB alone, which is the pattern seen in late differentiated cytotoxic T lymphocytes (CTLs). Unlike GzmB, GzmK does not activate apoptotic caspases. Instead, we find that GzmK has pro-inflammatory effects on synovial fibroblasts, inducing them to produce IL-6, CCL2, and reactive oxygen species (ROS), all of which are upregulated in inflamed synovium. GzmK$^+$ CD8 T cells in blood express high frequencies of chemokine receptors CCR2, CCR5, and CXCR3, while CD8 T cells expressing GzmB alone express CX3CR1, suggesting that GzmK$^+$ CD8 T cells and CTLs are recruited to sites of inflammation through different pathways. Interestingly, preliminary analysis of a large,integrated single-cell RNA-seq dataset of CD8 T cells from synovial tissue, synovial fluid, and blood shows selective expression of genes encoding Nur77, Ki67, and activation markers in distinct CD8 subsets, suggesting that some CD8 T cell subsets receive T-cell receptor (TCR)-mediated signals whereas others are activated through TCR-independent mechanisms.

Conclusion: The vast majority of CD8 T cells in RA synovial tissue and fluid express GzmK and express a phenotype and transcriptome distinct from typical GzmB$^+$ CTLs. GzmK$^+$ CD8 T cells appear to traffic to sites of inflammation using different chemokine receptors than CTLs. GzmK induces synovial fibroblasts to produce pro-inflammatory effector molecules including IL-6, CCL2, and ROS. Preliminary analysis of a large single-cell RNA-seq data set suggests differential TCR-mediated and cytokine-mediate activation of CD8 T cell subsets in inflamed joints. Together, these findings form the basis of a new model of CD8 T cell migration and function in RA and potentially other rheumatologic diseases.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: CD4 T cells from patients with rheumatoid arthritis (RA) are metabolically reprogrammed, diverting glucose away from glycolysis towards the production of biosynthetic precursors. Several of the pro-inflammatory effector functions of such CD4 T cells are metabolically controlled; including T cell longevity, differentiation into Th1 and Th17 cells and the formation of tissue-invasive membrane ruffles.

Methods: T cells from seropositive RA patients with active disease and age-matched healthy controls were examined. Intra- and extracellular metabolites were quantified, and energy sensing was assessed by pAMPK and pS6K1 analysis. Lysosomal localization of mTORC1 and AMPK was examined by confocal microscopy and immunoblotting. T cell differentiation into pro-inflammatory effector cells was determined through lineage-determining transcription factors and intracellular cytokines. Tissue inflammation in human synovium was evaluated in NSG chimeric mice engrafted with human synovium and reconstituted with human T cells.

Results: In response to T cell receptor triggering, RA T cells hyperproliferated while intracellular ATP concentrations were significantly lower than in control T cells. Despite a high AMP/ATP ratio, RA T cells failed to activate the energy senor AMPK, but mTORC1 activation was sustained. AMPK activation occurs on the lysosomal surface where the kinase colocalizes with mTORC1 to enable cross-regulation of both energy sensors. Immunoblotting and imaging analysis revealed a lack of lysosomal AMPK in RA T cells, while mTORC1 was maintained on the outer lysosomal membrane. Lysosomal anchoring requires AMPK lipidation through posttranslational myristoylation. RA T cells were deficient in N-myristoyltransferase 1 (NMT1), the enzyme which catalyzes the transfer of myristate from CoA to AMPK. Restoring NMT1 expression rescued the lysosomal recruitment of AMPK, secured the activation of the kinase, inhibited the unopposed activation of mTORC1 and prevented the differentiation of T cells into cytokine producing, pro-inflammatory effector cells in vitro and in vivo. We devised multiple therapeutic interventions to overcome the lack of lysosomal AMPK and tested their tissue-protective effects in the human synovium-NSG chimeras; including forced overexpression of NMT1 in RA T cells; treatment with A769662, an AMPK activator that acts independently of the lysosome, and injection of the mTORC1 inhibitor Rapamycin. All interventions were equally potent in suppressing synovitis.

Conclusion: Pro-inflammatory effector functions of T cells are highly dependent on the subcellular localization and cross-regulation of the energy sensors AMPK and mTORC1. Deficiency of protein myristoylation due to loss-of-function of NMT1 deviates AMPK away from the lysosomal surface, prevents its proper activation and enables unopposed mTORC1 activity. Protein trafficking and subcellular localization of the energy sensors AMPK and mTOC1 may be druggable by novel therapeutic strategies.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The "Targeting Immune Responses for Prevention of RA" (TIP-RA) collaboration studies individuals at high risk for developing rheumatoid arthritis (RA) because of serum anti-citrullinated protein antibody (ACPA) positivity in absence of arthritis at baseline, and is focused on defining how they transition from at-risk to classifiable disease. One potential mechanism is the expansion of antigen specific T cells that recognize self-antigens and acquisition of disease associated T cell phenotypes. ACPA emerge years prior to clinically apparent disease and subsequently increase in their titer and breadth of specificity. However, few studies have characterized T cells during this transition. Therefore, individuals enrolled in the TIP-RA cohort were analyzed by multi-parameter flow cytometry to identify features associated with progression to RA.

Methods: HLA class II tetramer staining and flow cytometry were performed on peripheral blood samples from a baseline visit from CCP3- controls (n=34), CCP3+ at-risk (n=26), CCP3+ positive individuals who transitioned in the near-term to RA (called "RA converters", n=4), and seropositive early-RA (n=21). Our staining panel allowed us to assess the frequencies of T cells specific for citrullinated alpha-enolase, aggrecan, cartilage intermediate layer protein, fibrinogen and vimentin. We then applied both supervised phenotyping and a cluster-based computational approach to compare the phenotypic landscape and specificity of CD4+ T cells in each cohort.

Results: In comparison with controls, we observed higher frequencies of T cells that recognize citrullinated epitopes in CCP3+ at-risk subjects ($p< 0.05$), suggesting that these T cells expand prior to disease onset. Supervised phenotypic analysis revealed an increase in CCR4+ CD4+ T cells in CCP3+ at risk subjects ($p< 0.001$) and a corresponding decrease in CXCR3+ CD4+ T cells that was most pronounced in RA converters and seropositive early-RA ($p< 0.05$). Cluster-based phenotypic analysis revealed a landscape of ten distinct immunophenotypes present within all subjects. Among these, a CCR4 immunotype was progressively enriched in ACPA+ at risk subjects, RA converters, and seropositive early-RA ($p=0.007$). Correspondingly, a CXCR3/CCR4/CCR6 immunotype was progressively depleted in ACPA+ at risk subjects, RA converters, and seropositive early-RA ($p=0.05$). Each of these ten immunotypes was shown to contain tetramer positive T cells that recognize citrullinated epitopes. However, the predominant immunotype varied for different antigens and unique phenotypic patterns were observed for different subject groups.

Conclusion: Our data suggest a progressive change in T cell phenotypes during disease development and subsequent transition to classified RA. Disease associated changes in the antigen specificity and phenotype of CD4+ T cells are present in CCP3+ at-risk subjects before the onset of symptoms and development of classified RA. This

finding suggests that there is a continuum of immunologic changes that drive disease evolution and that exploring emerging antigen specificities and immunophenotypes will aid our understanding of risk and shape approaches for intervention.

Abstract Number: 2819

The Transcription Factor MAF Controls the Ability of T Peripheral Helper (Tph) Cells to Help B Cells

Alexandra Bocharnikov,[1] Vanessa Wacleche,[1] Ye Cao,[1] and Deepak Rao[2], [1]Brigham and Women's Hospital, Boston, [2]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Pathologic T cell-B cell interactions are hallmark features of many autoimmune diseases. PD-1hi CXCR5- T peripheral helper (Tph) cells are B cell-helper T cells that are highly expanded in the joints of seropositive RA patients and in the circulation of SLE patients. Like T follicular helper (Tfh) cells, Tph cells produce IL-21 and stimulate B cell differentiation into plasmablasts *in vitro*. B cell helper-function is often considered dependent on the transcription factor Bcl6, a master regulator of Tfh-cells. However, Tph cells do not express high levels of Bcl6, which suggests that transcription factors other than Bcl6 may control IL-21 production and B cell-helper function in human CD4+ T cells. Here we evaluated the role of the transcription factor MAF in controlling T cell help to B cells.

Methods: MAF expression in human CD4+ T cell subsets was determined by RNA-seq and flow cytometry. To evaluate the role of MAF, we disrupted the gene encoding MAF by nucleofection of a CRISRP/Cas9 ribonucleoprotein (RNP) complex in primary $CD4^+$ T cells and in sorted Tph cells. Expression of IL-21 and other cytokines was determined by RT-PCR and ELISA. B cell-helper function of CRISPR-treated T cells was evaluated by co-culturing sorted T cell subsets from SLE or control donors with memory B cells plus SEB. Plasmablast formation was determined by flow cytometry.

Results: RNA-seq analyses of CD4+ T cell subsets revealed high expression of *MAF*, but not *BCL6*, in both Tph cells and Tfh cells sorted from blood of RA and SLE patients (Fig. 1A). After 2 days of CD3/CD28 stimulation, Tph cells and Tfh cells expressed >2-fold higher levels of MAF protein than did naive or $PD\text{-}1^{neg}$ memory CD4+ T cells. High expression of MAF in both Tph cells and Tfh cells, two subsets that produce IL-21, suggested a possible connection between MAF and IL-21. To test this, we deleted MAF in primary human CD4+ T cells by nucleofection of a MAF-targeting CRISPR/Cas9 RNP. This method abrogated MAF protein expression in >80% of T cells. Compared to a control CRISPR targeting CD8, MAF deletion reduced mRNA expression of *IL21* and *IL10* in 4 independent donors and inhibited secretion of IL-21 protein (Fig. 1B). Using Tph cells sorted from blood of SLE patients, we confirmed that

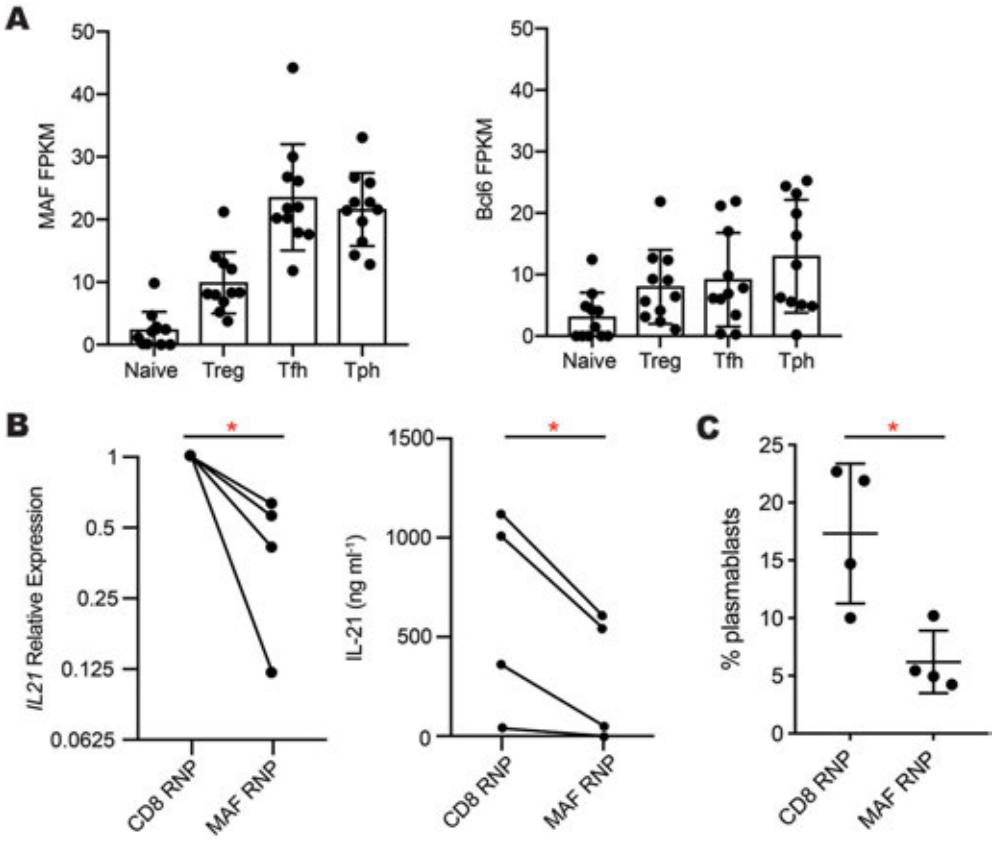

Figure 1. The role of MAF in human Tph cell function. A) MAF and Bcl6 expression in RNA-seq data of T cell subsets sorted from blood of RA (n=5) and SLE (n=6) patients. B) Reduced IL-21 mRNA expression (left) and protein secretion (right) by primary human CD4+ T cells after CRISPR-deletion of MAF (n=4 donors). C) Plasmablast generation in co-cultures of Tph cells treated with MAF- or CD8-targeting complexes co-cultured with allogeneic memory B cells. *p<0.05 by paired t-test.

Tph cells stimulate differentiation of memory B cells into plasmablasts in an IL-21-dependent manner, as neutralization of IL-21, but not IL-10, inhibited plasmablast formation by ~50%. To evaluate the effect of MAF on B cell-helper function, we deleted MAF by CRISPR in sorted human Tph cells from SLE patients or controls and then co-cultured these cells with memory B cells. Deletion of MAF reduced the ability of Tph cells to induce B cell differentiation into plasmablasts by over 50% compared Tph cells treated with a control RNP (Fig. 1C).

Conclusion: High expression of MAF is a common feature of both Tph cells and Tfh cells, two T cell populations that produce high levels of IL-21. Loss of MAF inhibits IL-21 expression in primary human CD4+ T cells and abrogates the ability of Tph cells to help B cells. MAF may regulate key components of T cell help to B cells in autoimmune conditions.

Calcium/ Calmodulin - Dependent Protein Kinase IV Associates with Phosphofructokinase to Promote Glycolysis and Limit IL-2 Production

Milena Vukelic,[1] Nobuya Yoshida,[2] Masataka Umeda,[3] Seo Yeon Orite,[3] Rhea Bhargava,[3] Michihito Kono,[4] Irina Gavanescu-Stockton,[3] Ryo Hisad,[3] and George Tsokos[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, [3]Beth Israel Deaconess Medical Center Harvard Medical School, Boston, MA, [4]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is disease characterized by an imbalance between pro-inflammatory (such as Th1 and Th17) and regulatory cells (Tregs). Th1 and Th17 T cells preferentially rely on glucose as opposed to Treg that utilize fatty acids as an energy source. Treatment of lupus-prone mice with 2DG, a glycolysis inhibitor, reduced disease activity by normalizing T cell metabolism. Our previous work showed that calcium/calmodulin-dependent protein kinase IV (CaMK4) is overexpressed in SLE CD4 T cells reprogramming T cells towards a proinflammatory phenotype. Based on mass spectrometry data, we hypothesized that CaMK4 affects SLE T cell phenotype by regulating the expression of phosphofructokinase (PFKP), a key regulatory enzyme of glycolysis.

Methods: CD4+ cells were isolated from healthy donors (HD), patients with SLE (SLEDAI 0-26) or mice (control, Camk4-/-, MRL-lpr). RNA-sequencing was performed by BGI; CUFFDIFF2 was used for analysis. PFKP was detected by RT-PCR and Western blotting. Glycolysis was measured by ECAR on Seahorse XFp analyzer. Proteins bound to CaMK4 were detected by mass-spectrometry after performing a pull-down assay with Flag-tagged human CaMK4 overexpressed in HEK293T cells.

Results: To address whether CaMK4 is involved in glycolysis we measured ECAR in CD3/CD28-ionomycin stimulated CaMK4-deficient and -sufficient CD4+ cells. Cells lacking CaMK4 had significantly decreased glycolysis ($n=4$; $p< 0.05$) suggesting that CaMK4 promotes glycolysis. To elucidate the mechanistic link between CaMK4 and metabolic reprogramming we performed a pull-down assay followed by mass-spectrometry that identified PFKP as a binding partner. Next, we examined whether the CaMK4-PFKP interaction is important in T cell differentiation. Naïve CD4 cells were cultured under Th1 or Treg-polarizing conditions. We observed 4.8-fold decrease of PFKP mRNA expression in wild type Tregs which was further reduced by 58% in Tregs lacking CaMK4. Moreover, the differentiation potential toward Tregs and IL-2 production was by 18% greater in CD4 T cells lacking CaMK4. This was in contrast to wild type CD4 T cells in which PFKP was overexpressed. We analyzed PFKP expression in CD4 T cells obtained from patients with SLE and found a statistically significant upregulation (vs. HD; $n=14$; $p< 0.01$). PFKP mRNA expression was higher in patients with active disease as measured by SLEDAI ($p=0.003$) even after adjusting for age or sex and degree of immunosuppression ($p=0.01$). PFKP upregulation in T cells obtained from SLE patients, compared to HD, was confirmed at the protein level as well ($p< 0.05$). Similarly, PFKP protein was significantly upregulated in MRL.lpr CD4 T cells compared to cells from control mice ($n=8$; $p< 0.05$).

Conclusion: We have generated evidence that CaMK4 interacts with PFKP to promote glycolysis and limit regulatory potential of Tregs by suppressing their differentiation and IL-2 production. In addition, we found that PFKP is significantly overexpressed in CD4 T cells from patients with SLE and lupus-prone mice. Our data identify PFKP as a novel therapeutic target to restore Treg functional homeostasis.

Clonal Expansion of a Specific Subset of Cytotoxic CD4+T Cells and Tissue Apoptosis in Patients with IgG4-related Disease

Cory Perugino,[1] Naoki Kaneko,[2] Jesper Kers,[3] Takashi Maehara,[2] Hamid Mattoo,[4] Hang Liu,[5] Vinay Mahajan,[5] Musie Ghebremichael,[5] Hugues Allard-Chamard,[5] Yesim Tuncay,[5] Emanuel Della Torre,[6] Zachary Wallace,[1] Lloyd Liang,[1] Sydney Montesi,[7] John Stone,[8] and Shiv Pillai[9], [1]Massachusetts General Hospital, Boston, [2]Kyushu University, Fukuoka, Japan, [3]University of Amsterdam, Amsterdam, Netherlands, [4]Sanofi, Cambridge, [5]Ragon Institute of MGH, MTI and Harvard, Cambridge, [6]Hospital San Raffaele, milan, Italy, [7]Massachusetts General Hospital, Boston, MA, [8]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [9]Ragon Institude of MGH, MIT and Harvard, Charlestown, MA

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: T Cell Biology & Targets in Autoimmune & Inflammatory Disease

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: In IgG4-related disease (IgG4-RD), both activated B cells and CD4+ cytotoxic T lymphocytes (CD4+CTLs) expand clonally, accumulate in tissues, likely recognize distinct epitopes on the same protein antigens, and thus, work together to contribute to fibrosis. We have previously reported that CD4+CTLs synthesize IL-1β and TGF-β in disease tissues, indicating that they are reactivated at lesional sites by antigen presenting cells, possibly activated B cells. However, the effector subset of CD4+CTLs and the mechanism by which they contribute to fibrosis has not yet been determined.

Methods: We used multi-color flow cytometry to identify subsets of CD4+CTLs. CD4+CTL subsets were quantified in the blood of 48 IgG4-RD subjects at the time of active disease and correlated with clinical parameters. Twenty age-matched healthy donors and 19 non-fibrotic sarcoidosis patients were used as controls. We then examined the TCR clonal frequencies and transcriptional profiles comparing CD4+CTL subsets using Next Generation Sequencing. Finally, we used multi-color immunofluorescence to determine tissue infiltration by effector CD4+CTLs and explore the possibility that apoptosis contributes to fibrosis in IgG4-RD.

Results: Compared to other subsets, the $CD28^{Low}CD57^{Hi}$ subset of CD4+CTLs accumulated to the greatest degree in the blood of IgG4-RD patients with the most severe clinical phenotype. The $CD28^{Low}CD57^{Hi}$ subset of CD4+CTLs demonstrated marked clonal-expansion and had a transcriptional profile suggesting that these cells are poised for survival, metabolically active and activated through TCR engagement. In contrast, the $CD28^{Hi}CD57^{Low}$ subset of CD4+CTLs accounted for most CD4+CTLs in the blood of healthy individuals, were reduced in the blood of IgG4-RD patients and enriched for a regulatory transcriptional phenotype with FoxP3 upregulation. These subsets expressed differing chemokine receptors suggesting different tissue honing capacity. In the diseased tissues, CD4+CTLs and B cells make cell-cell contact suggesting that B cells either present antigens to CD4+CTLs or secrete activating cytokines. Additionally, we demonstrated increased activated caspase-3 in disease tissues, particularly, in cells of mesenchymal origin.

Conclusion: The $CD28^{Low}CD57^{Hi}$ subset of CD4+CTLs is clonally-expanded in IgG4-RD and correlates with disease severity. This subset is metabolically active, TCR-activated and infiltrates diseased tissues, suggesting an effector phenotype. The physical contact of B cells and CD4+CTLs in IgG4-RD tissues, along with the observed increase in caspase activation, suggests a possible mechanism of fibrosis in IgG4-RD such that CD4+CTLs, activated by antigen-presenting B cells, may cause apoptotic death of vimentin positive stromal cells. The ensuing cytokine se-

cretion by activated CD4+CTLs and B cells might contribute to an over-exuberant tissue healing process, resulting in fibrosis. (Supported by NIH U19 AI 110495 and UM1 AI144295)

Abstract Number: 2822

Depression and Subsequent Risk for Incident Seronegative Rheumatoid Arthritis Among Women

Jeffrey Sparks,[1] Susan Malspeis,[1] Jill Hahn,[2] Andrea Roberts,[2] Laura Kubzansky,[2] and Karen Costenbader[1], [1]Brigham and Women's Hospital, Boston, MA, [2]Harvard School of Public Health, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health III: RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Depression is associated with elevated systemic inflammation and risk of several chronic diseases including lupus, psoriasis, and inflammatory bowel disease. However, the association between depression and subsequent risk for developing RA is less clear. Therefore, we hypothesized that depression may increase RA risk. Since depression may develop in the period prior to clinical RA diagnosis, we decreased the potential for reverse causation by including a time separation between the assessment of depression and RA risk window.

Methods: We performed a prospective cohort study investigating depression and incident RA. We pooled data from the Nurses' Health Study (NHS, 1992-2014) and NHSII (1993-2015). As in previous studies, depression was defined using a composite definition: report of clinician diagnosis, regular antidepressant use, or Mental Health Inventory-5 score < 60. Women reported RA diagnosis and 2 rheumatologists performed medical record review to confirm diagnosis using objective criteria and identify the date of diagnosis and serologic phenotype (seropositive: RF+ or CCP+). All incident RA cases met 1987 ACR or 2010 ACR/EULAR criteria. Measures of depression and covariates including smoking, body mass index, dietary quality, physical activity, and menopausal factors were obtained using biennial questionnaires. Cox regression estimated HRs and 95%CIs for RA (overall and by serologic phenotype) according to depression status, adjusted for potential confounders. All analyses included a lag that separated depression status and the window for RA risk by at least 4 years to lower the possibility that depressive symptoms preceding RA diagnosis explained the results.

Results: We analyzed n=194,700 women; mean age at baseline of 46.8 (SD 11.5) years and 24% of women had depression. A total of 834 incident RA cases (64% seropositive) occurred during 2,994,244 person-years of follow-up. In the age-adjusted analysis, women with depression had HR for all RA of 1.41 (95%CI 1.22-1.64, **Table**). After adjusting for covariates, the HR for all RA was attenuated, but still showed a modest but significant association (multivariable HR 1.28, 95%CI 1.28, 95%CI 1.10-1.49). After adjustment for covariates, depression was not statistically associated with seropositive RA (multivariable HR 1.10, 95%CI 0.91-1.32). However, depression was strongly associated with risk for incident seronegative RA (multivariable HR 1.70, 95%CI 1.32-2.19), independent of potential confounders including smoking, dietary intake, body mass index, physical activity, and menopause.

	No Depression HR (95%CI)	Depression* HR (95%CI)
Outcome: All RA

Outcome: Seropositive RA		
Case/person-years	355/2,141,798	182/849,534
Age-adjusted	1.00 (Ref)	**1.22 (1.01-1.47)**
Multivariable**	1.00 (Ref)	1.10 (0.91-1.32)
Outcome: Seronegative RA		
Case/person-years	180/2,139,980	117/848,863
Age-adjusted	1.00 (Ref)	**1.86 (1.45-2.37)**
Multivariable**	1.00 (Ref)	**1.70 (1.32-2.19)**

*Depression was defined as a composite of self-reported clinician-diagnosed depression, Mental Health Inventory (MHI)-5 score <60, or regular antidepressant use.
**Adjusted for age, questionnaire cycle, cohort (NHS, NHSII), median household income (quartiles), US region (West, Midwest, Mid-Atlantic, Southeast, New England), smoking pack-years (never, >0 to 10, >10 to 20, >20 pack-years), body mass index (<25.0, 25.0 to <30.0, ≥30.0 kg/m^2), cumulative average sedentary activity (<3, ≥3 MET-hrs/week), cumulative average Alternative Healthy Index score (quartiles), parity/breastfeeding duration (nulliparous, parous/none to <1, parous/1-11, parous/≥12 months), menopausal status/postmenopausal hormone use (premenopausal, postmenopausal/never use, postmenopausal/ever use, perimenopause), physical examination in previous 2 years (yes, no)

Table. Hazard ratios for incident rheumatoid arthritis according to presence or absence of depression* among women in the Nurses' Health Studies (n=194,700), lagged by two questionnaire cycles (at least 4 years between depression and rheumatoid arthritis diagnosis assessments).

Conclusion: In this large prospective study, depression was associated with increased risk for incident RA, using stringent methods for RA case identification. The association of depressive symptoms with seronegative RA was not explained by measured lifestyle factors. We accounted for potential reverse causation of early RA symptoms leading to depression. Future studies are needed to replicate these findings and to elucidate potential mechanisms linking depression and seronegative RA, such as systemic inflammation or aberrant pain sensitivity.

Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health III: RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

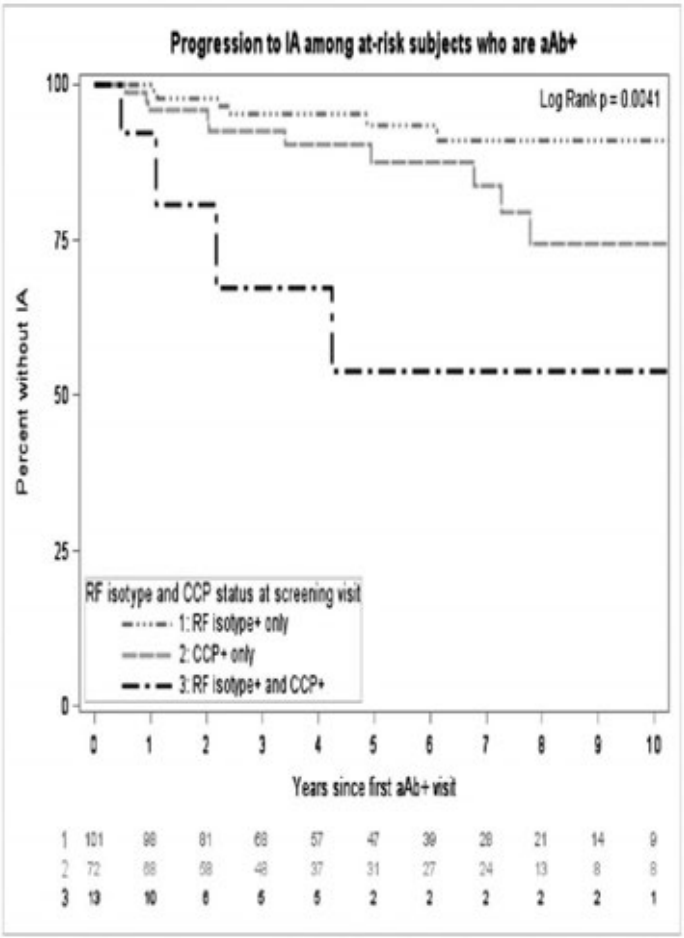

Table. Factors associated with developing IA after screening aAb positive

aAb status at first positive (screening) visit	HR (95% CI)*	p-value	Percentage who develop IA after screening aAb+
Any aAb+ (definition of cohort)	-	-	11.8%
RF+ isotype only	Referent		6.9%
CCP+ only	2.14 (0.82,5.59)	0.12	15.3%
CCP+ and RF+ isotype	5.38 (1.54,18.74)	0.01	30.8%
CCP+ > 2x cutoff versus all others	3.55 (1.49,8.41)	0.004	27.3%
CCP+ > 3x cutoff versus all others	3.04 (1.22,7.57)	0.02	28.6%
RF+ isotype >2x cutoff versus all	1.83 (0.73,4.62)	0.20	14.6%
RF+ isotype >3x cutoff versus all	2.28 (0.80,6.49)	0.12	15.2%

*HR represents the increased hazard of developing IA/RA. Models are adjusted for ever smoker status and education level (which were significant covariates in the models).
CCP+ = positive for either CCP2 or CCP3.1
RF+ isotype = positive for either IgM or IgA

Background/Purpose: Rheumatoid arthritis (RA)-related autoantibodies are typically elevated prior to the onset of seropositive RA. Screening for autoantibody (aAb) positive individuals is a means to assemble a cohort at high risk for future RA for epidemiologic, mechanistic and interventional studies. However, little is known about the stability of RA-related aAbs over time, and the likelihood of developing inflammatory arthritis (IA) in individuals without RA who screen aAb positive in a non-clinical setting.

Methods: The Studies of the Etiologies of RA (SERA) prospectively follows subjects who are RA-free but are at increased risk for future RA because they are a first-degree relative of an RA proband (n=1780), or come from a cohort enriched for HLA-DR4 alleles (n=629). We screened for serum aAbs to CCP (CCP2 and/or CCP3.1), and RF IgA

and IgM isotypes. Positivity was based on cut-offs as defined by manufacturer's recommendations. Overall, 15% (368/2409) tested positive for at least one aAb during screening. To evaluate outcomes of aAb+ subjects identified via screening, the cohort was limited to the 193 subjects that had at least one follow-up visit after their aAb+ visit. Seven subjects that were determined to have IA at screening were removed from the prospective analysis of aAb persistence and progression to IA, for a cohort of 186 aAb+ subjects (mean age: 47.7, SD 15.1). For the IA risk analyses, we explored combinations of aAb and high titer aAb, as defined by 2-times (2x) and 3-times (3x) the cutoff at the screening visit.

Results: Of the 186 screened aAb+ subjects, 61.1% tested aAb+ again on their next visit. During a median follow-up of 4.2 years (IQR: 2.2-7.3), 22/186 subjects (11.8%) developed IA, which was defined as having at least 1 joint with synovitis on exam, and of those subjects 16 were eventually classified as RA by 2010 ACR/EULAR criteria. Risk of developing IA differed significantly by aAb+ status at screening (Figure). Adjusting for ever smoking status and education, subjects that screened positive for both CCP and RF isotypes had over a 5-fold increased risk of developing IA than those positive for RF isotypes alone (Table). Those with CCP+ at >2x the cutoff were at 3.5-fold increased risk of IA compared to those CCP+ using the normal cutoff.

Conclusion: These findings support the utility of screening for RA risk in a non-clinical setting, and provides information regarding the likelihood of both retesting positive and future IA/RA. Specifically, in individuals who screen aAb+, ~60% will re-test positive, and either the presence at screening of both CCP and RF isotypes using the normal cut-offs, or the presence of CCP at > 2x cutoff predicts who will develop IA, while a CCP 3x cutoff does not improve prediction.

Antibiotic Use and the Development of Rheumatoid Arthritis (RA) and Risk of RA Flares: Case-Control and Self-Controlled Case Series Studies in Two National Electronic Patient Databases (SIDIAP and CPRD)

Navraj Nagra,[1] Danielle Robinson,[2] Antonella Delmestri,[1] Stephanie Dakin,[1] Sarah Snelling,[1] Andrew Carr,[1] and Daniel Prieto-Alhambra[1], [1]University of Oxford, Oxford, United Kingdom, [2]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health III: RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The microbiome and specific bacterial triggers have been hypothesised to be involved in the pathogenesis of Rheumatoid Arthritis (RA) and RA flares. Antibiotic usage can mediate changes in the microbiome,

and act as a surrogate for infection with potentially pathogenic bacteria. We aimed to determine the association of antibiotic usage and RA/RA flare diagnosis.

Methods: Analyses were performed using the Catalan SIDIAP, and UK CPRD, national electronic primary care databases. Within SIDIAP, patients with an initial diagnosis of RA and 5 age, gender and practice matched patients were selected. Missing data (present for BMI, smoking and alcohol drinking) was imputed using multiple imputation with chained equations. Within CPRD, RA diagnosed patients with ≥1 RA flare recorded were included.

We performed a case-control study using SIDIAP and a self-controlled case series (SCCS) study using the UK CPRD.

Antibiotics grouped by the WHO ATC classification were the study exposures. Outcomes of interest were initial RA diagnosis in SIDIAP and RA flare in CPRD.

Multivariate conditional logistic regression was performed using SIDIAP data to determine associations with specific antibiotic group use, controlling for age, BMI, gender, smoking status, alcohol consumption socioeconomic status, medical co-morbidities, primary care attendance and other antibiotic group use. Conditional fixed-effects Poisson regression models were used to determine incidence rate ratios of RA flares in relation to antibiotic usage within CPRD.

Results: 13,920 RA patients and 69,535 controls from the SIDIAP database were identified. Use of beta-lactams or quinolones in the 2 years prior to diagnosis were associated with RA (OR 1.23, 1.16-1.29; OR 1.32, 1.26-1.38 respectively; p< 0.0001). Only beta-lactams showed a consistent dose-response gradient (Q1 OR 1.19, 1.10-1.29; Q2 OR 1.22, 1.12-1.34; Q3 OR 1.31, 1.20-1.42; Q4 OR 1.42, 1.31-1.54; p< 0.0001) and association with recency of use (current: OR 1.82, 1.61-2.06; recent: OR 1.54, 1.36-1.74; and previous use: OR 1.20, 1.14-1.26, p< 0.0001). In parallel, 1,192 RA patients were identified from the CPRD (from 31,992 patients), with ≥1 flare/s recorded. Sulphonamide and trimethoprim use was associated with an increased risk of RA flare at 29-90 days (IRR 1.71, CI 1.12–2.59, p=0.012); 91-183 days (IRR 1.57, CI 1.06–2.33, p=0.025); and 184-365 days (IRR 1.44, CI 1.03–2.02, p=0.033) after antibiotic treatment commencement. No other antibiotic groups were associated with RA or RA flare risk.

Conclusion: Usage of broad-spectrum beta-lactam antibiotics was associated with index RA diagnosis in the Catalan population in a dose and time-dependent manner. Usage of sulphonamide and trimethoprim antibiotics appeared associated with a 70% increased risk of RA flare at 1-3 months, which remained significant up to 12 months after treatment. We hypothesise that antibiotic use is a surrogate of a pathogenic bacterial infection in index RA and that the delayed onset of RA flares after specific antibiotics is mediated through the gut or urinary microbiomes. Further epidemiological and mechanistic research is also needed to determine whether acute infections are associated with RA.

Provider Variability in Glucocorticoid Prescribing for Patients with Rheumatoid Arthritis and Impact on Chronic Glucocorticoid Use

Michael George,[1] Joshua Baker,[2] Lang Chen,[3] Qufei Wu,[2] Fenglong Xie,[4] Huifeng Yun,[3] and Jeffrey Curtis[3], [1]University of Pennsylvania, Philadelphia, [2]University of Pennsylvania, Philadelphia, PA, [3]University of Alabama at Birmingham, Birmingham, AL, [4]University of Alabama at Birmingham, Birmingham

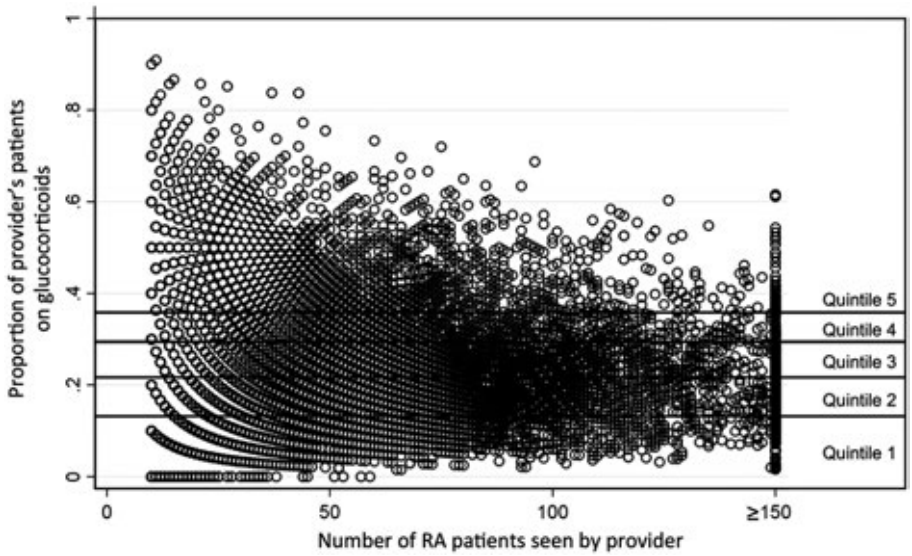

Figure 1. Variability in rheumatologist glucocorticoid prescribing for rheumatoid arthritis. Each circle represents a rheumatologist, with rheumatologists contributing a separate observation for each year they have seen at least 10 RA patients. The proportion of the rheumatologist's patients receiving at least 30 days of oral glucocorticoids within 90 days of the first DMARD prescription of each year is shown.

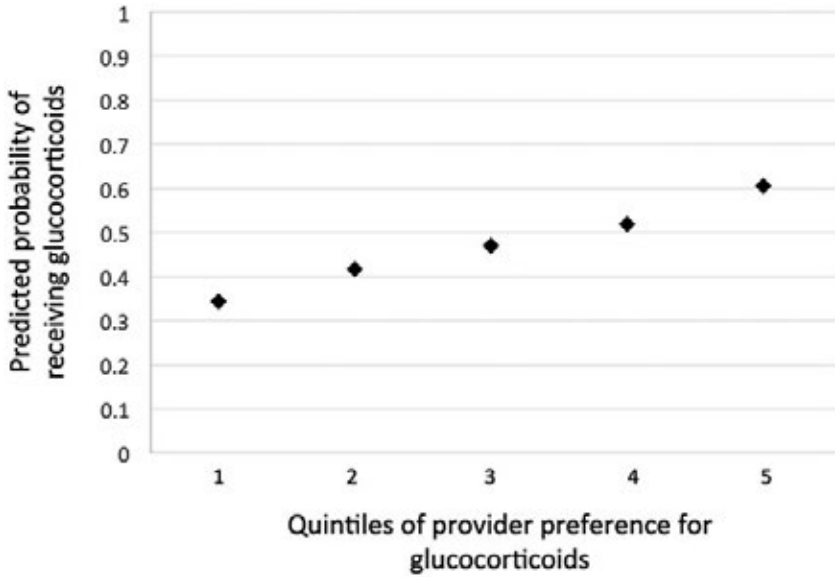

Figure 2. Predicted probability of a patient with RA on stable DMARD treatment receiving oral glucocorticoids 3-6 months after starting their DMARD course, calculated from a logistic regression model including their rheumatologist's preference for glucocorticoids in quintiles (see Figure 1) and covariates including demographics, comorbidities, and healthcare utilization measures (error bars obscured by markers, all $p < 0.001$).

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Epidemiology & Public Health III: RA

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Glucocorticoids are recommended as short-term bridging therapy in patients with rheumatoid arthritis (RA), but as many as 30-40% of patients remain on glucocorticoids chronically. We aimed to measure the variability in the prescribing of glucocorticoids among rheumatologists and determine whether seeing a provider

with a greater preference for glucocorticoids was independently associated with glucocorticoid use among patients on stable DMARD treatment.

Methods: Two cohorts were created using Medicare claims data 2006-2015. First, to measure provider variability, we identified patients with 2 diagnoses of RA within a given year who received methotrexate or a biologic. Patients could contribute to each year in which they fulfilled criteria. Among rheumatologists seeing at least 10 patients with RA in a given year, we defined the "provider preference" for glucocorticoids as the proportion of the provider's patients receiving ≥30 days of oral glucocorticoids within 90 days of the first DMARD treatment of that year. Each year was evaluated separately to allow for changing practices over time. We then identified a separate cohort of patients with 2 diagnoses of RA who initiated methotrexate or a biologic and remained on stable DMARD therapy without biologic additions or changes for ≥6 months. We used logistic regression to determine if provider preference for glucocorticoids (measured in the larger cohort using all other patients seen by the same provider in the same year) was independently associated with a patient receiving glucocorticoids 3-6 months after the start of the DMARD course, adjusting for patient demographics, comorbidities, and healthcare utilization.

Results: We identified 1,272,644 patient-year episodes among 385,597 unique patients. Among providers seeing ≥10 patients in a given year (28,936 provider-year combinations among 6,875 providers), the proportion of a physician's patients receiving ≥30 days of glucocorticoids was highly variable even among providers with a large patient volume (Figure 1) [median 24.3%, IQR 16.7% to 33.3%]. We identified a separate cohort of 192,614 RA patients on stable DMARD treatment for at least 6 months (47% receiving biologics) for whom we could identify the treating rheumatologist and assign a provider preference for glucocorticoids (calculated among all other patients seen by the same rheumatologist that year in the larger cohort). Provider preference for glucocorticoids was highly associated with receiving glucocorticoids 3-6 months after beginning the current DMARD course, with predicted probability ranging from 34.4% (95% CI 33.9-34.8) for patients seen by providers in the lowest quintile to 60.6% (95% CI 60.1-61.1) for those seen by providers in the highest quintile (Figure 2, all $p < 0.001$; first stage regression R^2 0.055, F 1597).

Conclusion: Glucocorticoids prescribing practices for RA vary widely between rheumatologists. **P**rovider preference for the use of glucocorticoids can help predict whether a patient remains on glucocorticoids during treatment. These data support the use of provider preference as an instrumental variable for epidemiologic studies evaluating glucocorticoid risk.

Abstract Number: 2826

Risk of Serious Infections in Tofacitinib versus Other Biologic Drug Initiators in Patients with Rheumatoid Arthritis: A Multi-database Cohort Study

Ajinkya Pawar,[1] Rishi Desai,[1] Nileesa Gautam,[1] and **Seoyoung C. Kim** [2], [1]Brigham and Women's hospital, Boston, [2]Brigham and Women's Hospital and Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health III: RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: It is well-known that biologic or targeted synthetic DMARDs increase the risk of serious infections (SIs), but few studies have directly compared the risk of SI across these DMARDs in a real-world setting. We aimed to compare incidence rate (IR) of serious bacterial, viral or opportunistic infection in rheumatoid arthritis (RA) patients initiating tofacitinib (TOF) (common exposure) versus other biologic DMARDs: abatacept (ABA), adalimumab (ADA), certolizumab (CER), etanercept (ETA), golimumab (GOL), infliximab (INF) or tocilizumab (TCZ).

Methods: We analyzed data from 3 U.S. healthcare claims databases: Medicare (2012-2015), Optum (2012-09/2017) and MarketScan (2012-2017). RA patients aged≥18 years who initiated TOF or other biologic DMARD without any prior use of biologics or JAK inhibitors were identified. We excluded patients with recent infection, malignancy or rituximab use. The primary outcome was a composite endpoint of incident SI that included bacterial, viral or opportunistic infection based on the inpatient principal diagnosis code. Secondary outcomes were specific subtypes of SIs. We adjusted for >70 potential confounders including demographics, prior DMARD and antibiotic use, comorbidities, other medications, and healthcare utilization factors in each database through propensity score (PS)-based

Table 1. Risk of incidence serious infection associated with initiating tofacitinib versus other biologics: a propensity score–based inverse probability treatment weighting (IPTW) as-treated analysis

	Exposure	Reference						
	Tofacitinib (n=5,394)	Abatacept (n= 14,075)	Adalimumab (n= 33,651)	Certolizumab (n= 7,797)	Etanercept (n= 34,394)	Golimumab (n= 6,315)	Infliximab (n= 16,891)	Tocilizumab (n= 4,513)
Outcome	**Hazard Ratio (95%CI)**

Notes: 1. For the primary as-treated analysis, follow-up time started the day after cohort entry and ended on treatment discontinuation (60-day gap and grace period), outcome occurrence, disenrollment, death, or the end of dataset.
2. Hazard ratios for tuberculosis and viral hepatitis (secondary outcomes) are not reported since no events occurred for these endpoints in either tofacitinib or other biologic groups.
3. Hazard ratios (HR) from the 3 PS-weighted cohorts were combined by an inverse variance-weighted, fixed-effects model.

*Required 1 inpatient code at principal diagnosis position with antiviral use within 7 days of the diagnosis claim.
**Required 1inpatient or outpatient at any diagnosis position without requirement of antiviral use.

inverse probability treatment weighting. For the as-treated analysis, follow-up time started the day after cohort entry until the earliest of: treatment discontinuation, switching to any biologic other than index therapy, nursing home admission, death, disenrollment, or the end of study period. For each drug-comparison, weighted Cox proportional hazards models estimated the HRs and 95% CIs. The estimates from 3 databases were combined using an inverse variance-weighted, fixed-effects meta-analysis.

Results: A total of 123,960 biologic initiators were identified across 3 databases, of which 5,531 (4.5%) were TOF initiators. Mean age was 72 years in Medicare, 54 in Optum and 52 in MarketScan. During the 180-day baseline period, 64-71% patients used methotrexate and 68-73% used corticosteroids. After PS-weighting, all covariates were well balanced. The median follow-up time (days) in the as-treated analysis ranged from 164 (Optum) to 182 (MarketScan). A total of 2,958 SI events occurred. In the TOF group, the crude IR for SIs per 100 person-years ranged from 2.80 (MarketScan) to 7.89 (Medicare). Adjusted HRs showed higher risk of composite SIs in TOF compared to ABA (HR 1.20, 95% CI 1.09-1.31), ETA (1.27, 1.14-1.42), GOL (1.35, 1.29-1.40) and TCZ (1.46, 1.31-1.63), but similar risk compared to ADA, CER and INF. Serious bacterial infection risk was higher in TOF than ABA, CER, ETA and GOL. Secondary analyses showed consistent findings (**Table 1**).

Conclusion: This large multi-database cohort study of RA patients found a higher risk for the composite endpoint of SIs requiring hospitalization after initiating TOF versus ABA, ETA, GOL and TCZ as their first biologic or targeted synthetic DMARD therapy. The risk of serious bacterial infection, pneumonia, herpes zoster, and skin and soft tissue infections was also higher in TOF initiators versus several other biologics.

Weight Fluctuation and Risk of Cardiovascular Events in Patients with Rheumatoid Arthritis

Joshua Baker,[1] George Reed,[2] and Joel Kremer[3], [1]University of Pennsylvania, Philadelphia, PA, [2]Corrona Research Foundation, Waltham, MA, [3]Albany Medical College and The Center for Rheumatology; Corrona, LLC, Albany, NY

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Epidemiology & Public Health III: RA
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Fluctuations in weight (weight cycling) occur in rheumatoid arthritis (RA) in association with severe disease features and comorbidity. In the general population, weight fluctuation has been linked to the development of metabolic and cardiovascular disease. Accurate prediction of cardiovascular events is an important challenge in patients with RA. We aimed to determine if fluctuations in weight can help to predict cardiovascular events this population.

Methods: We studied patients with RA from the Corrona registry enrolled from October 2001 to March 2018 with least three recorded visits. The exposure was the time-varying percent change in weight from the prior visit (standardized to a per-year rate of change). Weight change was categorized as loss of ≥10%, loss of 5-10%, stable weight, gain of 5-10%, and gain of ≥10% based on prior definitions of important weight change. We also categorized pa-

Adjusted for age, sex, race, calendar year, disease duration, hx of diabetes, hypertension, hyperlipidemia and CV disease at baseline; and statin use smoking, alcohol, reported exercise, methotrexate use, prednisone use, TNFi use, disease activity, HAQ and work disability as time varying covariates			

Table 2: Sequential Cox proportional hazard models evaluating the risk of weight change from the prior visit adjusting for demographics, CV risk factors, disease characteristics, and disability.

tients by quintile of variability in weight in all prior observation periods as previously described (operationalized as the average absolute difference of weight change over all prior intervals). Incident cardiovascular events were identified and adjudicated in a subset. Sequential Cox proportional hazard models explored independent associations between weight change and variability in weight and the risk of CV events before and after adjusting for baseline characteristics and CV risk factors, RA disease features, and disability as time-varying covariates. We tested for interaction to determine if associations between weight change and CV events were modified by current body mass index (BMI).

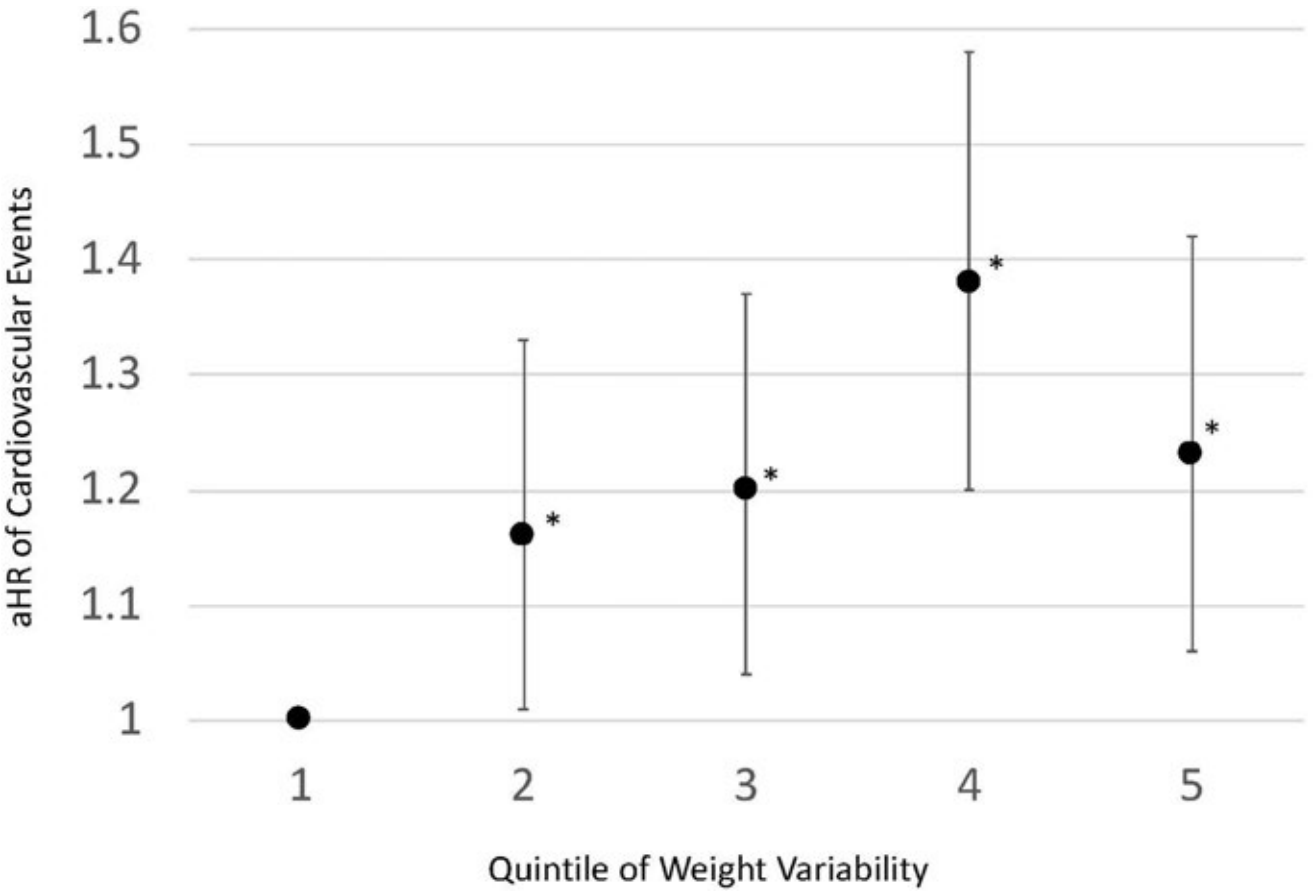

Figure. Hazard Ratio for cardiovascular events for higher variability in BMI over prior observations compared to the lowest variability between observations.

Results: Among 31,381 participants, there were 2,277 events in 135,395 person-years. It was common for participants to lose (10% of observations) or gain (13%) at a rate of 10% per year between observations. Both weight loss and weight gain were associated with greater disease activity, disability, smoking, and use of corticosteroids (Table 1). In models adjusting for demographics, BMI, and calendar year, a greater risk of CV events was observed in those that experienced 10% weight loss [HR: 1.34 (1.17, 1.53) p< 0.001] or 10% weight gain [HR: 1.31 (1.14, 1.51) p< 0.001]. In adjusted models, these associations were slightly attenuated (Table 2). There were significant interactions with current BMI suggesting that the risk of weight loss or gain was greatest in non-overweight participants (BMI < 25 kg/m2). Patients with greater variability in weight over prior observation periods were at higher risk of CV events compared to those with the most stable weight over time, independent of their current BMI (Figure).

Conclusion: Fluctuations in weight (both weight gain and weight loss) predict a greater risk of cardiovascular events in RA over time. The association is observed primarily among non-overweight patients and is independent of traditional risk factors. These findings suggest that weight fluctuation may be a marker of metabolic disturbances that may help in risk prediction in this group. Further study is necessary to determine if fluctuations in weight have direct adverse cardiometabolic consequences by promoting cardiometabolic disease.

Abstract Number: 2828

Implementing the BP Connect Systems-Based Blood Pressure Follow-Up Protocol with Community Rheumatology Clinic Teams

Edmond Ramly,[1] Douglas White,[2] Amanda Perez,[1] and **Christie Bartels** [1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]Gundersen Health System, Onalaska

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Despite recognition that rheumatoid arthritis (RA) accelerates cardiovascular disease (CVD) and hypertension impacts 50% of RA patients, up to 50% lack blood pressure (BP) control, overlooking *the* most modifiable CVD risk factor. Rheumatology clinics record BP routinely but do not routinely manage it. As we previously reported, only 10% of RA clinic notes with high BP included follow-up recommendations. We subsequently reported that our adapted evidence-based BP Connect staff protocol doubled the odds of timely follow-up of high BPs and reduced population level BPs across three academic rheumatology clinics (Bartels et al. *AC&R* 2019). Preparing for wider dissemination, we sought to replicate our findings in a community rheumatology clinic setting.

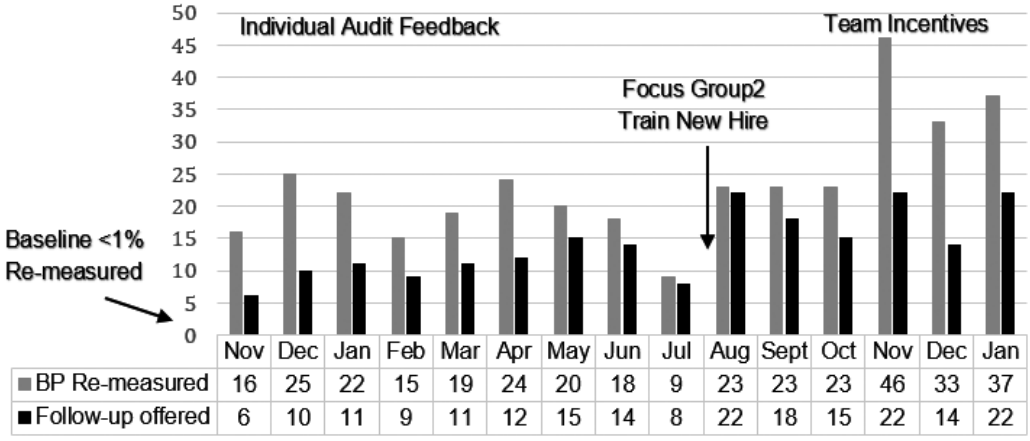
Baseline <1% on BP Re-measured and Follow-up offered.

Figure 1. Monthly Staff Performance of Key Target Behaviors of BP Connect



Methods: We prospectively examined the feasibility and impact of our staff-based BP Connect protocol at a community rheumatology clinic using pre-post design. Pre-and post-protocol rates of primary care BP follow-up referrals were the primary outcome of electronic health record (EHR) data analysis. We first analyzed workflows through a focus group with clinic staff nurses, medical assistants, and schedulers to tailor protocols for the new clinic. Next, a one hour training was provided on rheumatologic CVD risk and BP, BP measurement skills review, protocol talking points, and EHR navigation. Two EHR alerts and monthly staff audit feedback supported implementation. Mid-implementation focus groups and questionnaires evaluated staff feasibility and acceptability.

Results: Overall, compared to < 1% baseline remeasurement of high BPs in the rheumatology clinic, we reached two monthly peaks of 84%, and overall in 353 of 767 (46%) patients, high BP was re-measured post-implementation. Among 263 rheumatology patients with confirmed high BP re-measurement, 209 (79%) were offered follow-up for high BP, and among those, 109 (41%) accepted primary care follow-up (Table 1). After initial gains, a mid-implementation decline corresponded to clinic staff turnover and reduced staff-to-visit ratios. Increases in the last months occurred following focus group problem-solving, new hire training, and the introduction of modest team incentives based on clinic-level goals for staff performance (Fig 1).

Mixed methods findings included staff focus group and questionnaire responses. Rheumatology staff's baseline usual practices followed three steps: (1) identifying high BP, (2) variable follow-up within the clinic, and (3) occasional follow-up across settings (i.e., primary care). Post-implementation, staff were satisfied with protocol support for these steps. Among six pre- and four post-implementation respondents, self-efficacy and confidence in perceived ability to do something to improve BP care increased from 3.8 to 4.5 on a 5-point Likert scale.

Conclusion: Replicating the implementation of the BP Connect systems-based staff protocol in a community rheumatology clinic improved primary care follow-up referrals for high BP. Findings highlight a scalable strategy to improve BP follow-up and rheumatology population health and new findings regarding the potential role of team-based incentives.

Improving SLE Care by Enhancing Medication Adherence Using a Tailored Clinic Intervention: HCQ-Crosswalk

Shivani Garg,[1] Betty Chewning,[2] Karen Hansen,[3] Beth Martin,[2] and Christie Bartels[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI, [2]UW - School of Pharmacy, Madison, Madison, [3]UW Madison, Madison

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Up to 83% of patients with SLE are nonadherent to hydroxychloroquine (HCQ) which results in a 36% higher risk of renal failure, and 8-fold higher risk of premature death. Therefore, clinicians must address HCQ nonadherence. Our recent meta-analysis reported three times higher odds of low HCQ blood levels in SLE patients who self-report HCQ nonadherence. Results suggest that when asked, most patients accurately report HCQ adherence. Despite this, one study reported that patients were *never* asked about medication nonadherence during 200 recorded

Table 1. Crosswalk to Adherence Strategies by Leading Barrier	
Barrier Category	**Crosswalk Strategy Options**
(S) System *Inability to get refills*	Arrange transport services, use auto-refills, involve family members
(M) Motivation *Med side effects*	Conduct motivational interview, strategies to manage adverse effects, alternative anti-malarial options, involve family
(U) Understanding *Outcome concerns*	Use teach back, simple language, visual aids, involve caregivers and family
(M & U) Motivation & Understanding *Other side effects & concerns*	Discuss expected outcomes, use teach back, simple language and treatment recommendations, visual aids, involve family, conduct motivational interview
(R) Recall *Forgetfulness*	Consolidate doses, use pillboxes or phone reminders, involve family members
(F) Financial *Inability to afford HCQ*	Change to low cost alternatives, alt. manufacturers, offer coupons, patient assistance referral

Figure 1. Reported Key Adherence Barriers by Category

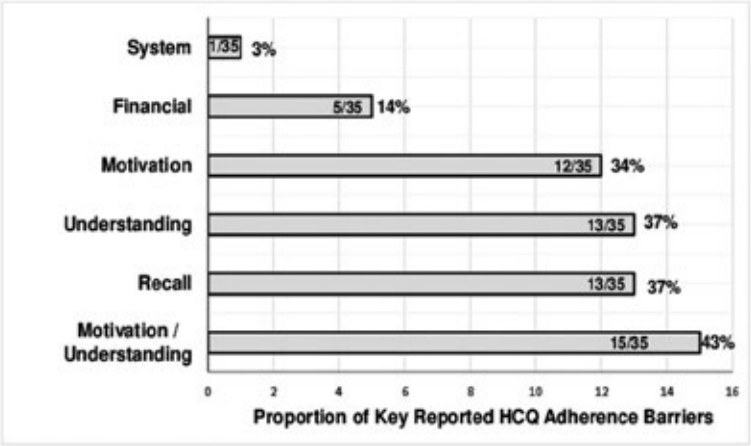

Table 2. Feasibility of Administering HCQ-Crosswalk during SLE visits (n=113 visits)	
Demographics	Mean age 45 (19-78) 92% female; 83% white
Non-adherence (<80%)	33%
Intervention completion	93%
Barriers addressed	86%*
Time to assess & address nonadherence	2.6±1.0 (1-5) mins
Intervention completed by non-MD	40%

**14% had an absolute contraindication to HCQ*

rheumatology visits at 4 centers. Barriers to addressing nonadherence include limited time and expertise in using lengthy gold-standard self-report tools (14+ items). Therefore, we aimed to develop a tool to assess nonadherence, categorize specific adherence barriers, and guide clinicians to prepare an adherence plan with individual SLE patients.

Methods: We implemented a 26-week single center study to test the feasibility of administering our adapted seven-item HCQ Adherence Tailoring Crosswalk (HCQ-Crosswalk) intervention in all consecutive SLE visits (n =113). The intervention was based on key domains of two gold-standard adherence tools (MASRI & BMQ). The first item, a visual-analogue adherence scale, was completed by SLE patients. Those who reported nonadherence (adherence < 80%) on the first item were prompted to complete the next six questions to identify their key adherence barrier(s). Upon identifying 1-2 key adherence barrier categories, clinicians were directed to the crosswalk to adherence strategies (Table 1) which were discussed with patients to tailor an individual adherence plan. To assess the tool's feasibility, we calculated the percentage of visits completing the intervention, the mean time spent, the percentage of barriers addressed, and proportion completed by a non-MD (e.g. pharmacy student).

Results: Nonadherence was identified at 33% of 113 consecutive visits among 65 SLE patients. Nonadherence rates were comparable to published rates using a gold-standard tool (33% vs 51%, *p 0.08*). The HCQ-Crosswalk intervention was completed in 93% of visits. Patients reported Motivation & Understanding as the key barrier (43%), which included the fear of side effects and lack of knowledge on long-term benefits of HCQ (Figure 1). Other commonly reported barriers included forgetfulness (Recall) and inability to afford medications (Financial). Using this intervention, we addressed 86% of barriers within 2.6±1 mins and 40% of the discussions were completed by a non-MD (Table 2).

Conclusion: The HCQ-Crosswalk is a feasible intervention to assess and address nonadherence in under 3 minutes. Future work will aim to validate HCQ-Crosswalk intervention versus gold-standard tools and to examine its role in improving HCQ adherence in SLE.

Treatment Delays Associated with Prior Authorization for Infusible Medications: A Cohort Study

Zachary Wallace,[1] Tyler Harkness,[1] Xiaoqing Fu,[1] John Stone,[2] Hyon K. Choi,[3] and Rochelle Walensky[1], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [3]Massachusetts General Hospital, Boston, MA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Prior authorizations (PA) are commonly required by health payers as cost-containment strategies for expensive medications, including infused biologics. In rheumatology, these medications are frequently prescribed to treat rare conditions that can be organ- or life-threatening and for which few or no medications have regulatory approval because of their relative scarcity. Infused medications often have neither generic substitutes nor oral or subcutaneous formulations and inevitably require advanced planning to administer. There are scarce data about the effect of PA requirements for infused medications on patient-oriented outcomes.

	Overall N (%)	No PA Required N (%)	PA Required N (%)

Baseline Cohort Demographics

Methods: We included subjects for whom an infusible medication was prescribed in our academic rheumatology practice for a rheumatologic condition. The exposures of interest were a PA requirement and the PA outcome (approved vs. denied). The primary outcome was the difference in days from medication request to infusion. Secondary outcomes included time to PA approval, the proportion of denied PAs, and glucocorticoid exposure among those approved and denied following PA request.

Results: Of the 225 subjects (Table 1), 160 (71%) required a PA. Of the PA-requiring cases, the conditions most often being treated were inflammatory arthritis (44, 28%) and vasculitis (37, 23%). In 67 (42%) cases requiring a PA, the condition had no FDA-approved medication. The PA request was initially denied in 33 (21%) subjects, 21 (64%) of whom had conditions with no FDA-approved medications (Table 2); twenty-seven (82%) of these denials were eventually approved. Thus, 96% of all PAs were ultimately approved. PAs were associated with a greater median number of days to infusion compared to cases in which no authorization was required (31 days [15, 60] vs 27 days [13, 41], p=0.045; Table 3). Compared to those in whom no PA was required, subjects in whom a PA request was initially denied had substantially longer time to approval (22 days [15, 41] vs 0 days [0, 0]), P< 0.001) and infusion (50 days [31, 76] vs 27 days [13, 41], P< 0.001). PA denials were associated with a 3.8-fold greater median prednisone-equivalent

Characteristics of Denied Prior Authorizations

glucocorticoid exposure in the 3 months following the request than when a PA was not required (605mg [0, 1575] vs 160mg [0, 675], P=0.01).

Conclusion: PA requirements for infusible medications are associated with delays in treatment. There is a striking three-week delay to approval and one-month delay to treatment among those whose PAs are initially denied. PA denials are further associated with excess glucocorticoid exposure. Thus, PAs constitute a barrier to the introduction of effective treatment in an expeditious manner. Because the great majority of PA requests are ultimately approved, the value of PA requirements and their impact on patient safety should be re-evaluated.

	Overall	No PA Required	PA Required		
			All	Approved	Denied

Cracks in Your Referral Process? Find Your Sustainable Solution Here

Sheetal Vora,[1] Amanda Moyer,[2] Lynn Kalhagen,[2] Anna Sherrod,[2] Thomas Griffin,[2] Kristen Corcoran,[2] Sarah Mabus,[2] and Talia Buitrago[2], [1]Atrium Health, Charolotte, [2]Atrium Health, Charlotte

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Early diagnosis for rheumatic conditions is crucial for children to achieve the best functional outcomes. Access to care is difficult due to the volume of referrals and paucity of pediatric rheumatologists. This compelling need to expediently triage dire and complex rheumatology referrals has been painfully demonstrated in our clinic. When this project was initiated there was a 3-month backlog to see a new referral. During this time, several patients were assigned delayed appointment dates due to our lack of a triage process. Improving the referral process so the appropriate patient is seen quickly is important for early diagnosis and earlier treatment, which improves quality of care for children with chronic debilitating rheumatic conditions. We intended to increase from 35% to 85% our rate of appointments scheduled within 30 business days for referred pediatric patients who require ongoing rheumatologic care by December 30, 2018. Our process measures were 0 to 90% increase in use of referral tool by primary care providers and 0 to 90% increase in appropriate use of triage tool by our clinic staff. Our balancing measures were no show rates and patient volume.

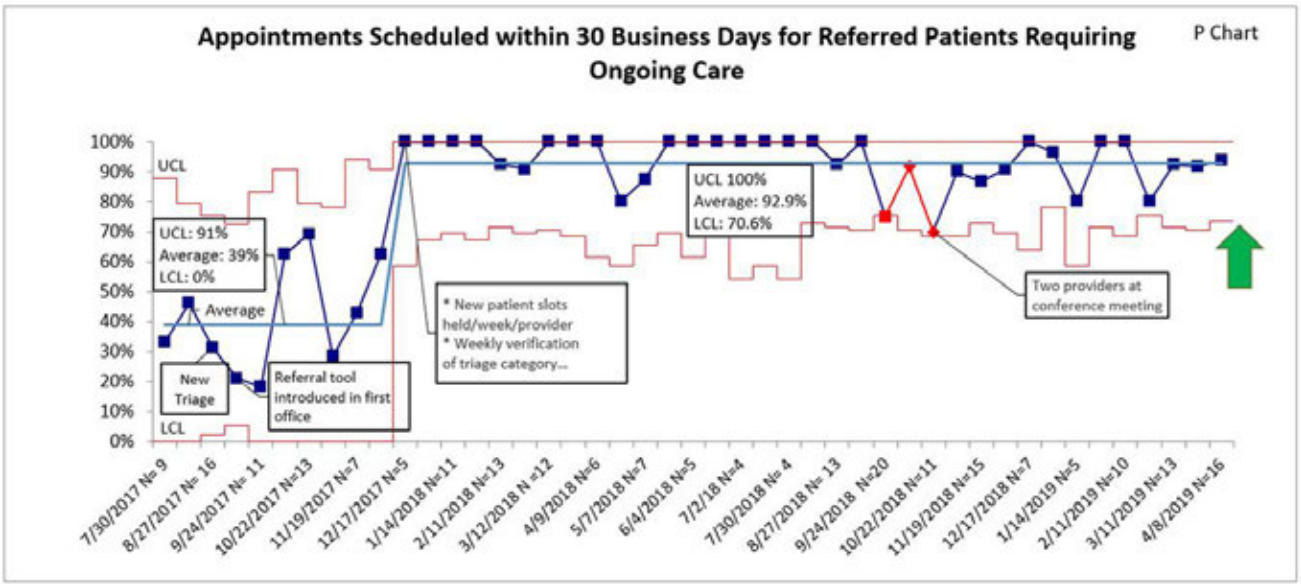

Figure 1. Appointments Scheduled within 30 Business Days for Referred Patients Requiring Ongoing Care Figure 2. Business Days Between Referral Date and Consult Figure 3.

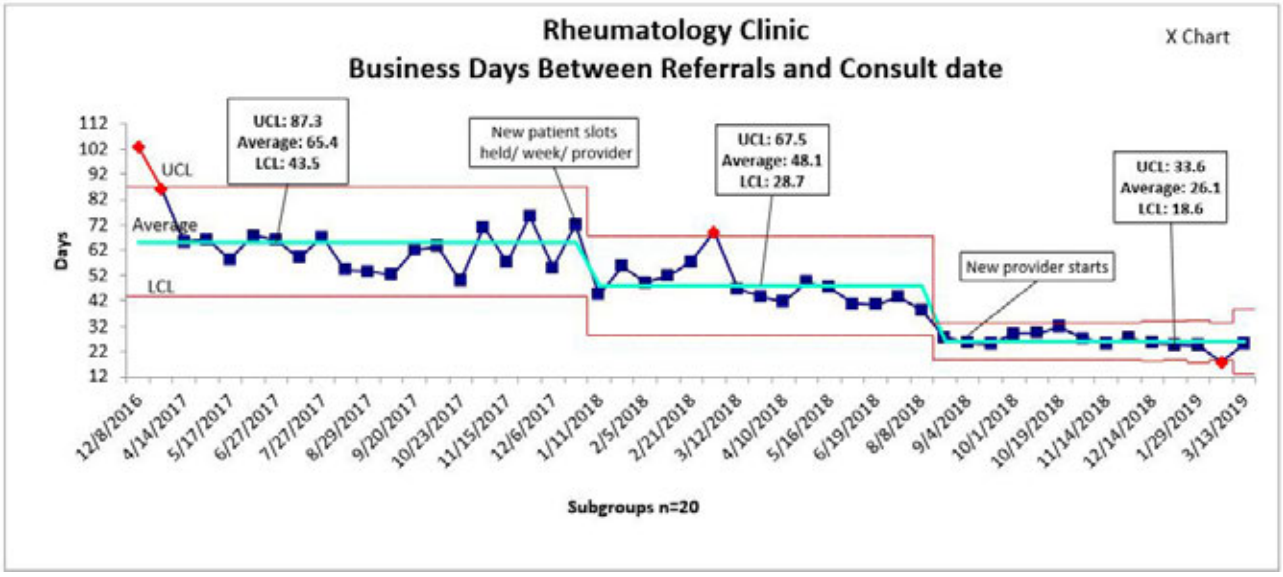

Figure 2. Business Days Between Referral Date and Consult

Methods: The improvement methodology used for this project was the Model for Improvement with rapid Plan, Do, Study, Act cycles. We defined current state by collecting baseline data, completing a root cause analysis, and surveying staff and patients to identify the most common and impactful barriers of lack of a standardized referral and triage process, lack of available appointments for higher acuity patients, and limitations in staff and families' ability to make contact.

We used a Key Driver Diagram to define leading factors and guide change ideas, and an aim statement and data management plan to guide the work and data collection. Our measures were evaluated using run charts and later moved into a Statistical Process Control Chart.

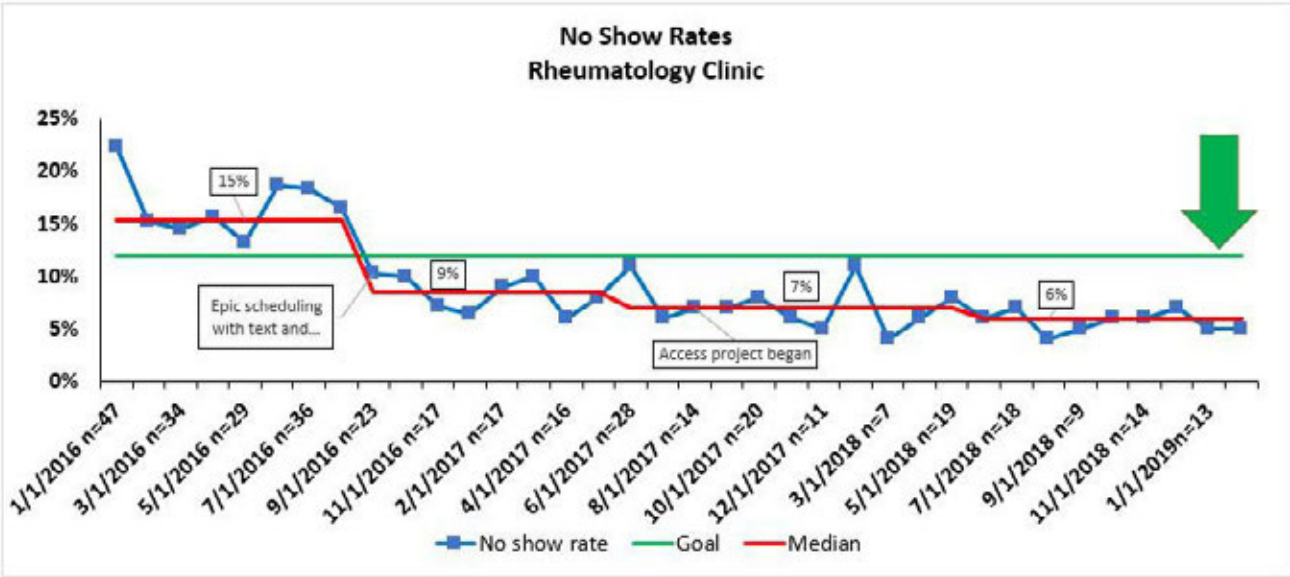

Figure 3. No Show Rates

Results: We have sustained our average performance for our target population at 92% since December 2017 (Figure 1). This represents an 8% improvement over our initial goal of 85% and a 135% improvement over baseline.

Additionally, we reduced time from referral received to the patient being seen by a provider for the overall clinic population from an average of 65.4 business days to 26.1 (Figure 2). Our no-show rate was reduced from 15% to 6% (Figure 3) and our total volume of patients increased by an average of 30 per month. This ultimately yielded a return on investment of greater than $300k in sixteen months.

Conclusion: Improvement science offers a methodology to strategically address inefficiencies and communication barriers, ensuring improved quality and safety, and better patient experience. By investing time in creative problem-solving, streamlining, and clear communication, and by facilitating staff empowerment and ownership, this project achieved remarkable gains in patient access and care delivery. Most importantly, we ensured longevity for this crucial improvement, thus promising significant long-term benefits. This result is a process that can be transferred to other settings, and holds great value given the universal challenges of supply/demand.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: A treat to target (T2T) approach in managing RA can improve patient outcomes. A key component to T2T is establishing personalized treatment targets through shared decision-making (SDM) with patients, which can be difficult to implement in practice. We established a learning collaborative to develop a patient communication tool to help promote SDM and T2T in RA.

Methods: The RISE Learning Collaborative (RISE-LC) was established in March 2019 to share and coordinate quality improvement (QI) efforts in adult rheumatology practices across multiple centers. The structure of the RISE-LC is based on the Institute for Healthcare Improvement's Breakthrough Series[1], where Collaborative faculty and participants work together to improve performance on agreed upon quality measures. Participants completed a survey ranking quality measures of interest, then attended in an in-person meeting with Collaborative faculty to develop goals for RISE-LC, including 1) improving physician-patient communication about disease activity (DA) and patient-reported outcomes (PRO) and 2) formally soliciting patient goals and incorporating them into a personalized treatment target through SDM. We used a human-centered design process to develop components of a DA communication tool, based on a series of patient and physician focus groups. The RISE-LC participants implemented the tool through Plan-Do-Study-Act (PDSA) cycles, and iterative changes were made based on participants' input.

Results: We recruited a total of 9 sites from 8 states, mostly representing academic centers (7/9). At baseline, all sites had a workflow in place for measuring RA DA, although performance was variable (range 30% to 90%). Participants agreed on a group QI project to solicit patient goals and improve SDM to support T2T. The first iteration of tool development was based on findings from patient focus groups that revealed that patients prefer a graphic display for DA[2]. Participants performed initial PDSA cycles to pilot use of the tool in their practices. Subsequent iterations of the tool incorporated the open-ended question "What's on your mind today?" (used in one faculty's [PB's] health system) and RA-specific questions based on an Arthritis Conversation Tool developed by one faculty expert (JLB) (Fig 1). A second PDSA cycle of the revised tool demonstrated feasibility and patient acceptance (3/9 sites).

Conclusion: The RISE-LC is a continuous, systematic model for sharing in QI efforts across rheumatology clinics. Through broad participant input, human-centered design, and iterative tests of change, an innovative patient communication tool was developed. Future work will examine the impact of the tool on improving documentation of DA, treatment goals, and patient satisfaction and engagement.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Measures of Healthcare Quality II: Quality Improvement in Rheumatology – Still Getting Better

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: International guidelines for rheumatoid arthritis (RA) treatment emphasize that all treatment decisions should be made through a shared decision making (SDM) process between clinicians and patients (1,2). Observations of routine clinical practice are needed to obtain insight into the actual implementation of SDM. The aim of this study was to assess the level of SDM in RA treatment from an observer perspective and the association with characteristics of the clinician, patient, and consultation.

Methods: Audio-recordings of 168 unique consultations with RA patients were available. The level of SDM was assessed by scoring the audio-recorded consultations with the 5-item observation-based OPTION scale (3). The OPTION scores ranged from 0 to 100 with higher scores indicating higher levels of SDM. Descriptive statistics were computed. First, associations with characteristics of the clinician (age, sex), patient (age, sex, educational level, disease duration, comorbidities, medication beliefs, health status), and consultation (length, type of treatment decision) were assessed using univariate regression analyses. Thereafter, variables with a p-value < 0.2 were included in a multilevel model with random intercepts. Statistical significance was set at $P < 0.05$.

Results: Characteristics of the clinician, patient, and consultation are shown in table 1. The mean OPTION score was 28.3 ± 15.1. The multilevel model included 4 variables, namely the clinician's age, patient's age, consultation length, and type of treatment decision. The level of SDM was significantly associated with the consultation length (B=0.63, P=0.01), decision for stopping and/or starting medication (B=14.3, P=0.00), decision for adjusting doses (B=8.38, P=0.00), and decision for administering single dose glucocorticoids (B=15.03, P=0.00). No other significant associations were found.

Conclusion: A higher level of SDM is associated with a longer consultation length and the type of treatment decision. Overall, the level of SDM in RA treatment leaves room for improvement. However, an observer's assessment of the efforts of clinicians to involve patients in decision making may not be congruent with clinicians' and patients' perspectives of SDM.

Assessing the Risk of Gout with Sodium Glucose Co-Transporter-2 Inhibitors: A Population-Based Cohort Study

Michael Fralick,[1] Sarah Chen,[2] Elisabetta Patorno,[3] and Seoyoung C. Kim[4], [1]Mount Sinai Hospital, University of Toronto, Toronto, [2]Brigham and Women's Hospital and Harvard Medical School, Boston, [3]Harvard University, Boston, [4]Brigham and Women's Hospital and Harvard Medical School, Boston

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Hyperuricemia is common in patients with type 2 diabetes mellitus and is associated with an increased risk of gout. Sodium-glucose cotransporter 2 (SGLT2) inhibitors, the newest class of medications for adults with diabetes mellitus, promote glycosuria and also lower serum uric acid levels through urinary excretion. The objective of our study was to assess the risk of gout among adults prescribed an SGLT2 inhibitor versus a glucagon-like peptide-1 receptor (GLP1) agonist.

Methods: We conducted a population-based new-user cohort study from March 2013 to December 2017 using claims data from a US nationwide commercial insurance database (IBM MarketScan). Patients with type 2 diabetes mellitus newly prescribed an SGLT2 inhibitor were 1:1 propensity score-matched to patients newly prescribed a GLP1 agonist. Patients were excluded if they had a history of gout or had received gout-specific treatment previously. The primary outcome was new diagnosis of gout based on an inpatient diagnosis of gout or the combination of an outpatient diagnosis and use of a gout-related medication within 14 days thereafter. The rate of heart failure hospitalization (positive control based on the known effect of SGLT2 inhibitor on reducing heart failure) and cellulitis (negative control) were also assessed. Cox proportional hazards regression was used to estimate hazard ratios (HR) of the primary outcome and 95% confidence intervals (CI).

Results: We identified 295,907 adults with type 2 diabetes mellitus who were newly prescribed an SGLT2 inhibitor or a GLP1 agonist. After 1:1 propensity score matching, we identified 111,419 pairs of patients prescribed an SGLT2 inhibitor or GLP1 agonist. The mean age was 54 years, 52% were female, and 26% were prescribed insulin at base-

Table 1. Baseline characteristics before and after matching

	After matching		
	SGLT2i	GLP1	SD

Insulin	28,638 (25.7%)	28,774 (25.8%)	0.003
Diuretic	19,320 (17.3%)	19,448 (17.5%)	0.003
Oral steroids	11,324 (10.2%)	11,310 (10.2%)	0
Anti-inflammatory drugs	21,487 (19.3%)	21,544 (19.3%)	0.001

Legend: GLP1 - glucagon like peptide-1 analogue, SGLT2i - sodium glucose co-transporter 2 inhibitor, sdev = standard deviation, SD = standardized difference, values below 0.1 indicate adequate balance. Anti-inflammatory drugs include NSAIDS and COXIBs.

Table 2. Rate of gout after use of SGLT2 inhibitor versus GLP1

	SGLT2i	GLP1
	N = 111,419	N = 111,419
Number of person-years	91,231	79,200
Number of events	448	640
Rate per 1,000 person-years	4.91	8.08
Hazard ratio (95% CI)	0.61 (0.54, 0.69)	Ref.
Legend: GLP1 - glucagon like peptide-1 analogue, SGLT2i - sodium glucose co-transporter 2 inhibitor.		

line (Table 1). The incidence rate of gout was lower for patients prescribed an SGLT2 inhibitor (4.9 events per 1,000 person-years) compared to those prescribed a GLP1-agonist (8.1 events per 1,000 person-years), with a HR of 0.61 (95%CI 0.54-0.69) over a median follow-up of 177 days. As anticipated, SGLT2 inhibitor initiators had a lower rate of heart failure (HR 0.63, 95%CI 0.51-0.78) and a similar rate of cellulitis (HR 1.05, 95%CI 1.00-1.11) compared to patients prescribed a GLP1 agonist.

Conclusion: Adults with type 2 diabetes prescribed an SGLT2 inhibitor had a lower rate of gout compared to those prescribed a GLP1 agonist. SGLT2 inhibitors may reduce the risk of developing gout among adults with type 2 diabetes mellitus, though future studies are necessary to confirm this observation.

A Burden of Missense Genetic Variants in Urate Secretory Genes Is Associated with Inadequate Response to Allopurinol in People with Gout

Niamh Fanning,[1] Ruth Topless,[2] Christopher Frampton,[1] Murray Cadzow,[2] Mary Wallace,[3] Nicola Dalbeth,[4] Tony Merriman,[5] and Lisa Stamp[6], [1]University of Otago, Christchurch, Christchurch, New Zealand, [2]University of Otago, Otago, New Zealand, [3]University of Otago, Dunedin, New Zealand, [4]University of Auckland, Auckland, New Zealand, [5]University of Otago, Birmingham, AL, [6]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Current understanding of why the urate lowering effect of allopurinol varies among individuals with gout is limited. The rs2231142 (Q141K) variant of *ABCG2* is associated with inadequate response to allopurinol. The goal of this research was to identify variations in genes grouped by function and how they affect allopurinol response.

Methods: The exomes of 77 people with gout recruited in New Zealand were sequenced. Gout was defined by American Rheumatism Association classification criteria. Thirty-six participants had a good response to allopurinol, defined as serum urate < 360μmol/L (6mg/dL) with allopurinol dose ≤300mg/day. Forty-one participants had an inadequate

Table 1.- Total counts of variants (1 or 2 copies of a variant in an individual was given a score of 1) clustered by function, in good and inadequate responders to allopurinol

Functional cluster	Good responders n (rate)	Inadequate responders n (rate)	Ratio inadequate/good responder	p value
Number of participants	36	41		
Secretory transporter (including Q141K)	**48 (1.33)**	**105 (2.56)**	**1.92**	**1.37×10^{-4}**
Secretory transporter (excluding Q141K)	**38 (0.78)**	**71 (1.73)**	**1.64**	**1.28×10^{-2}**
Reuptake transporter	**32 (0.89)**	**41 (1.00)**	**1.13**	**0.62**
Allopurinol to oxypurinol metabolism	**56 (1.56)**	**53 (1.29)**	**0.83**	**0.33**

Secretory transporter genes: *ABCC4, ABCC5, ABCG2, SLC17A1, SLC17A3, SLC22A6, SLC22A8*

response, defined as serum urate ≥360μmol/L with allopurinol dose >300mg/day. Participants with a plasma oxypurinol level < 20μmol/l were excluded due to potential non-adherence to allopurinol treatment. Variants (missense and nonsense) were grouped by the function of candidate causal genes– secretory urate transporters (*ABCC4, ABCC5, ABCG2, SLC17A1, SLC17A3, SLC22A6, SLC22A8*), reuptake urate transporters (*SLC22A12, SLC2A9, SLC22A11*) and genes involved in conversion of allopurinol to oxypurinol (*AOX1, MOCOS, XDH*). The rate of variants within a functional group was compared between good and inadequate responder subsets by Poisson approximation.

Results: A higher rate of variants in secretory urate transporter genes was observed in inadequate responders (105 variants in 41 participants) compared with good responders (48 variants in 36 participants, $p=1.37 \times 10^{-4}$, Table 1). This difference remained significant when the *ABCG2* Q141K variant was excluded from analysis (71 variants in 41 inadequate responders versus 38 variants in 36 good responders, p=0.013). No difference was observed in the rate of variants in urate reuptake transporter genes (41 variants in 41 inadequate responders versus 32 variants in 36 good responders, p=0.62) or allopurinol to oxypurinol metabolism (53 variants in 41 inadequate responders versus 56 variants in 36 good responders, p=0.33).

Conclusion: A burden of variants in secretory transporters of urate is associated with inadequate response to allopurinol. There was no evidence that genetic variants relating to reuptake-transport and allopurinol to oxypurinol conversion were associated with inadequate response.

Do Serum Urate-associated Genetic Variants Differentially Contribute to Gout Risk According to Body Mass Index? Analysis of the UK Biobank

Vicky Tai,[1] Ravi Narang,[1] Greg Gamble,[1] Lisa Stamp,[2] Tony Merriman,[3] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand, [3]University of Otago, Birmingham, AL

SESSION INFORMATION

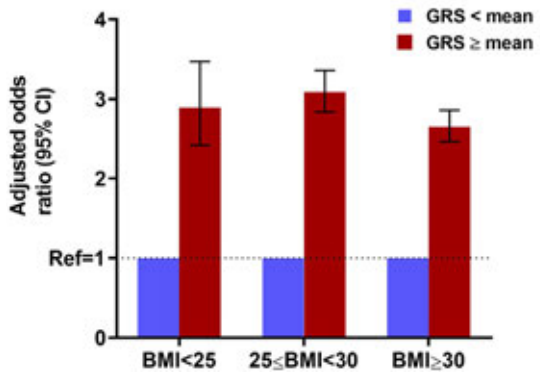
Session Date: Tuesday, November 12, 2019

Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Figure: Association between genetic risk score (GRS) and gout for each body mass index (BMI) category. Data were adjusted by age, sex, diuretic use, renal failure, diabetes mellitus, hypertension, hypercholesterolemia, alcohol intake and smoking. Adjusted odds ratio (95% CI) are shown.



Background/Purpose: Both serum urate-associated genetic variants and body mass index (BMI) are associated with gout risk. The aim of this study was to systematically examine whether serum urate-associated genetic variants differ in their influence on gout risk according to BMI, and to test for interactions between these genetic variants and BMI.

Methods: This research was conducted using the UK Biobank Resource. Participants of European ethnicity, aged 40-69 years, and with genome-wide genotypes were included. Gout was defined using a validated definition (self-report of gout or urate-lowering therapy use). Medication use and co-morbidity data were collected via self-report. Participants were divided into three BMI groups (BMI < 25 kg/m^2 [low/normal], 25 kg/m^2 ≤ BMI < 30 kg/m^2 [overweight], and BMI ≥ 30 kg/m^2 [obese]). The 30 serum urate-associated SNPs reported by Kottgen et al. (Nature Genetics 2013) in the large (>140,000 European participants) Global Urate Genetics Consortium GWAS were tested for their association with gout according to BMI group. A weighted genetic risk score (GRS) for gout risk was calculated to model the cumulative effects for the 30 variants. Gene-BMI interactions for gout association were tested using a genetic risk score (GRS) and individual SNPs by logistic regression, adjusting for age, sex, diuretic use, renal failure, diabetes mellitus, hypertension, hypercholesterolemia, alcohol intake and smoking.

Results: Data were available for 358,728 individuals, including 7,311 gout cases (2.0%). Gout was present in 634 (0.5%) individuals in the low/normal BMI group, 3100 (2.0%) in the overweight BMI group, and 3577 (4.3%) in the obese BMI group. Mean GRS was higher in those with gout compared to those without gout in the low/normal BMI group (mean [SD] 1.82 [0.29] vs 1.65 [0.27], P = 2.45×10^{-60}), overweight BMI group (mean [SD] 1.83 [0.27] vs 1.65 [0.27], P < 1×10^{-300}), and obese BMI group (mean [SD] 1.80 [0.27] vs 1.64 [0.27], P = 6.43×10^{-261}). Compared with a lower GRS (< mean), a higher GRS (≥ mean) was positively associated with gout in all BMI groups (Figure). A GRS-BMI interaction was observed, due to a mildly attenuated effect of a higher GRS on gout risk in the obese BMI group compared to the overweight BMI group (interaction P = 0.046). There was no GRS-BMI interaction for comparisons between the low/normal and overweight BMI groups, nor between the low/normal and obese BMI groups. No individual SNP-BMI interactions for gout were observed.

Conclusion: In individuals of European ancestry, the association of genetic factors is mildly attenuated in individuals with obesity compared to overweight. However, even for those with obesity, genetic variants have a strong effect on gout risk.

Asymptomatic Monosodium Urate Crystal Deposition Associates with Increased Expression of Pro-Inflammatory Genes

Gabriela Sandoval-Plata,[1] Kevin Morgan,[2] Tamar Guetta-Baranes,[2] Ana Valdes,[3] Michael Doherty,[4] and Abhishek Abhishek[5], [1]Human Genomics and Molecular Genetics, School of Life Sciences, University of Nottingham / Academic Rheumatolog, School of Medicine, University of Nottingham, Nottingham, England, United Kingdom, [2]Human Genomics and Molecular Genetics, School of Life Sciences, University of Nottingham, Nottingham, England, United Kingdom, [3]Academic Rheumatology, School of Medicine, University of Nottingham / Nottingham NIHR BRC, Nottingham UK, Nottingham, England, United Kingdom, [4]Academic Rheumatology, Division of Rheumatology,School of Medicine, University of Nottingham, Nottingham, UK\Arthritis Research UK Pain Centre, Nottingham, UK\National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham, UK, Nottingham, England, United Kingdom, [5]Academic Rheumatology, School of Medicine, University of Nottingham,Nottingham,UK \National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham,UK, Nottingham, England, United Kingdom

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Persistent hyperuricaemia is a prerequisite for gout. However, only 10% of people with hyperuricaemia develop symptomatic gout, whereas 25-35% have asymptomatic monosodium urate (MSU) crystal deposits. Whether these asymptomatic deposits are truly inert, or exert a sub-clinical pro-inflammatory effect is unknown. Since the immune response in gout is mediated primarily by the NLRP3 inflammasome, we hypothesized that the presence of MSU crystals in people with hyperuricaemia but no previous gout flares will initiate changes in the expression of inflammasome-associated genes.

Methods: Individuals recruited into the study were screened for serum urate (SU) levels and presence of MSU crystals within joints by ultrasonography. They were divided into 3 groups: (a) normal SU (< 360μmol/L) without MSU deposits; (b) high SU (>360μmol/L) without MSU deposits; and (c) high SU with MSU deposits. Peripheral blood was collected in PAXgene blood RNA tubes and total RNA was extracted according to the manufacturer's protocol. Quan-

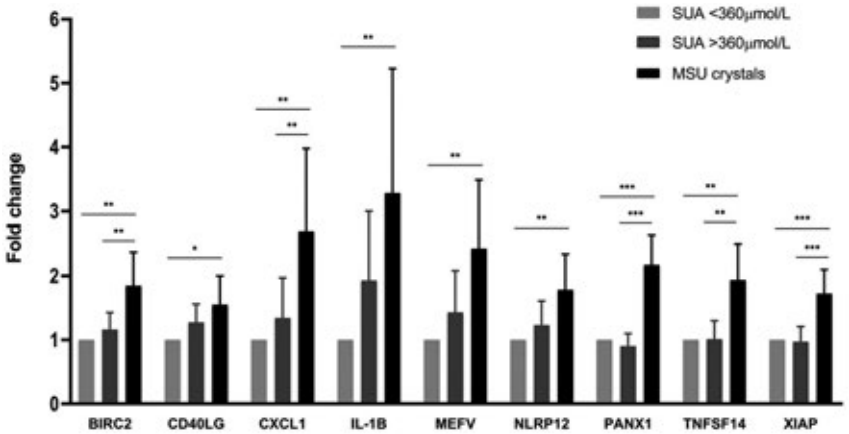

Figure 1. Significant fold changes relative to the normouricaemic group. Relative mRNA levels were evaluated by quantitative RT-PCR. The expression was normalised to RPLP0 gene and compared among groups using the Kruskal-Wallis H test. FDR 5% was used to correct for multiple testing. Note there was not a significant difference between normal SU and high SU without crystal deposits in all genes. *p=0.01, **p=0.001, ***p<0.0001.

titative RT-PCR was used to analyse the expression of 86 inflammasome and toll-like receptors (TLRs)-associated genes using a customised QIAGEN RT^2 Profiler Array. Data were normalised to RPLP0, and the $2^{-\Delta\Delta CT}$ method was used to calculate fold changes. Differences in relative expression among groups were evaluated using the Kruskal-Wallis H test. P values were corrected for multiple testing using a false discovery rate of 5%. Genes were clustered into four groups, specifically NLRP3 inflammasome-assembly mechanisms, TLRs, NLRP3 inflammasome-effector mechanisms, and inflammasome down-regulators, to evaluate their variation across normouricaemia, hyperuricaemia, and hyperuricaemia with MSU crystal deposits. The models were evaluated using linear regression.

Results: After RNA extraction and cDNA synthesis, 92 samples passed the quality control parameters and underwent the expression profiling. There were 31 participants in the normouricaemic group, 44 in the hyperuricaemia only group, and 17 in the hyperuricaemia with MSU crystal deposit group. Out of 86 genes, 13 showed a significant difference among groups (adjusted p value < 0.05). However, only BIRC2, CD40LG, CXCL1, IL-1β, MEFV, NLRP12, PANX1, TNFSF14 and XIAP had a large upregulation (fold change >1.5) in at least one of the high SU groups, compared to the normal SU group (Figure 1). IL-1β had the largest fold changes in both high SU without MSU crystals and high SU with MSU crystals (1.9 and 3.3 respectively). Moreover, from the four gene-groups, the TLRs gene cluster showed the highest R^2 (0.458), followed by the NLRP3 inflammasome-effector mechanism (R^2=0.371), the R^2 for inflammasome-assembly mechanisms and inflammasome negative regulators were 0.244 and 0.233 respectively.

Conclusion: The differences in the expression of immune-associated genes observed in this study suggest that initial MSU crystal deposition within joints, although asymptomatic, initiates the activation of pro-inflammatory mechanisms. These results only reflect systemic responses on gene-expression, and cytokine assay is underway. Further studies are needed to validate these results in synovial fluid samples.

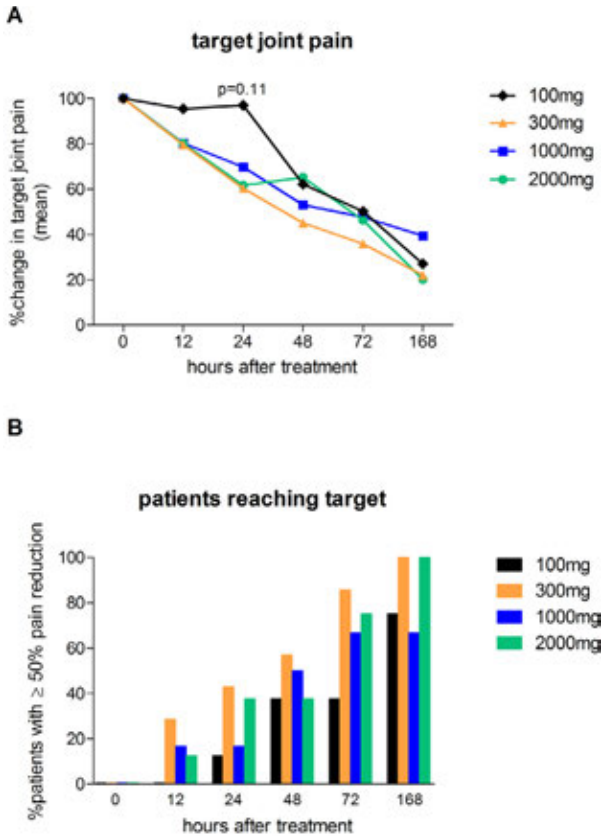
Session Date: Tuesday, November 12, 2019

Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Acute gout is a severe debilitating type of arthritis that is treated in the acute phase with potent anti-inflammatory drugs. To date, prednisolone, colchicine and/or non-steroidal anti-inflammatory drugs are the standard of care despite serious side effects of chronic use, especially in the elderly population. In addition, interleukin (IL)-1 biologics (e.g., canakinumab/rilonacept/anakinra) have proven efficacy in RCTs, however, these biologics have not been broadly adopted due to barriers such as the requirement of parenteral administration, cost and risk of



A: Percent change in pain scores up to 1 week of Dapansutrile treatment; Patients scored target joint pain scored on a 0-100mm VAS scale. Data presented as mean of the percent change in target joint pain (baseline was set at 100%). p=0.11 for Mann-Whitney test between cohorts of 100mg and 2000mg at t=24h. B: % patients who reached the primary outcome target of ≥50% pain reduction during the first week of Dapansutrile treatment.

infection. Therefore, there is an unmet need for a safe, oral, cost effective IL-1 inhibitor targeting the NLRP3 inflammasome pathway.

Dapansutrile™ (OLT1177™) was shown to inhibit the NLRP3 inflammasome and inhibit joint inflammation in murine models of acute arthritis. Dapansutrile's™ Phase 1 dose escalation clinical trial demonstrated safety at doses up to 1000 mg/day for 8 days.

Methods: A Phase 2a, dose ranging, proof-of-concept trial was conducted to demonstrate safety/tolerability, pharmacokinetics (PK), pharmacodynamics (PD) and the clinical effectiveness of Dapansutrile™ in treating the clinical signs and symptoms of acute gout over an 8-day treatment period. Four cohorts of 8 patients per cohort were included at doses of 100mg, 300mg, 1000mg or 2000mg daily (of which 29 were analyzed per protocol). Clinical effect was targeted to be greater than 50% pain reduction from baseline at approximately 72 hours after the first dose. VAS pain, general disability and walking disability scores were measured by daily diary and blood sampling was conducted on study days 0 (baseline), 3, 7 and 14 to assess PK and PD (including hsCRP, SAA and plasma cytokine levels). Safety was measured over the duration of the study with clinic visits on study days 0 (baseline), 3, 7, 14 and a follow-up telephonic visit on day 35.

Results: The ≥50% target joint pain reduction on a 0-100mm VAS scale at day 3 was met in the 300, 1000 and 2000mg Dapansutrile™ cohorts; contrary the 100mg dose appeared inadequate. Investigator-assessed joint tenderness and swelling at day 3 showed a dose-dependent response. Treatment responses at day 7 were similar for all cohorts. As markers for systemic inflammation, hsCRP and SAA demonstrated a dose-dependent reduction in

cohorts taking 2000mg, 1000mg and 300mg daily, but demonstrate no reduction in the cohort taking 100mg daily. Oral intake of Dapansutrile™ resulted in adequate plasma concentrations for NLRP3 inflammasome inhibition, there were no metabolic, physiological or haematological changes and all doses were well tolerated.

Conclusion: Dapansutrile™ was shown to have a significant positive clinical anti-inflammatory effect and clean safety profile in the treatment of monoarticular gout attacks. The oral NLRP3 inhibitor showed a broad therapeutic range dosed at a daily 300-1000-2000mg and holds promise for further clinical development in acute gout.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Metabolic & Crystal Arthropathies II: Genetics & Physiology
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: This study aimed to determine whether a polygenic risk score (PRS) based on gout-associated genetic variants is associated with gout disease severity phenotypes such as age at onset, presence of tophi and flare frequency.

Methods: A genome wide association study (GWAS) for gout was performed on all genotyped SNPs (single nucleotide polymorphisms) in approximately 500,000 individuals from the UK Biobank cohort. All genome-wide significant SNPs ($P < 5 \times 10^{-8}$; total 129) were extracted and manually grouped into loci if they were within 500 kb of eachother.

This resulted in a total of 12 loci, from which the most significant SNP of each locus was selected for analysis. Three cohorts of gout patients were involved in this analysis: the New Zealand Gout Study Caucasian cohort (NZ Gout; 782 males, 164 females), the Ardea cohort (1121 males, 57 females) and the EuroGout cohort (1114 males, 143 females). A PRS was calculated for each individual based on their genotypes at the 12 SNPs of interest and weighted by the effect size (odds ratio) of each SNP as determined by GWAS. The PRS was modelled against each of the three phenotypes of interest using linear and logistic models, adjusted by age at collection, sex and BMI (for all three cohorts) and the top 10 principle components (for the NZ Gout cohort). The adjusted models were meta-analysed.

Results: The PRS was distributed similarly for all three cohorts and ranged from 4.73 to 28.49. It showed a highly significant positive association with gout status in the NZ Gout study cohort (OR = 1.21 (95%-CI: 1.16 to 1.26), P = < 2E-16; performed using matched non-gout controls from the NZ population). Meta-analysis of the three cohorts identified a statistically significant negative association between the PRS and the age at onset phenotype with each PRS unit increase associated with a 0.43 year decrease in age at onset (95%-CI: -0.61 to -0.25, P < 0.0001). Presence of tophi was also found to be statistically significantly associated with increasing PRS in the three cohorts (OR = 1.059 (95%-CI: 1.03 to 1.09), P < 0.0001). However, when adjusting for disease duration, the strength of the association was reduced (OR = 1.031 (95%CI: 1.00 to 1.062), P = 0.046). The flare frequency phenotype did not show significant association with the PRS in any cohort, or under meta-analysis (Beta = 0.022 (95%-CI: -0.063 to 0.107), P = 0.61).

Conclusion: A polygenic risk score may be useful for predicting the severity of gout for severity phenotypes that are non-confounded, such as age at onset. Earlier age at onset results in a longer disease duration, which in turn may be causally associated with increased risk of tophi, and those with tophi may experience significantly more gout flares per year. As the PRS can aid in prediction of age of onset, it may be possible to effectively predict and manage those that are more likely to experience severe gout. As GWAS become larger, more gout associated loci will likely be identified, thus enabling improvement of the current PRS and likely improving prediction for severe gout phenotypes.

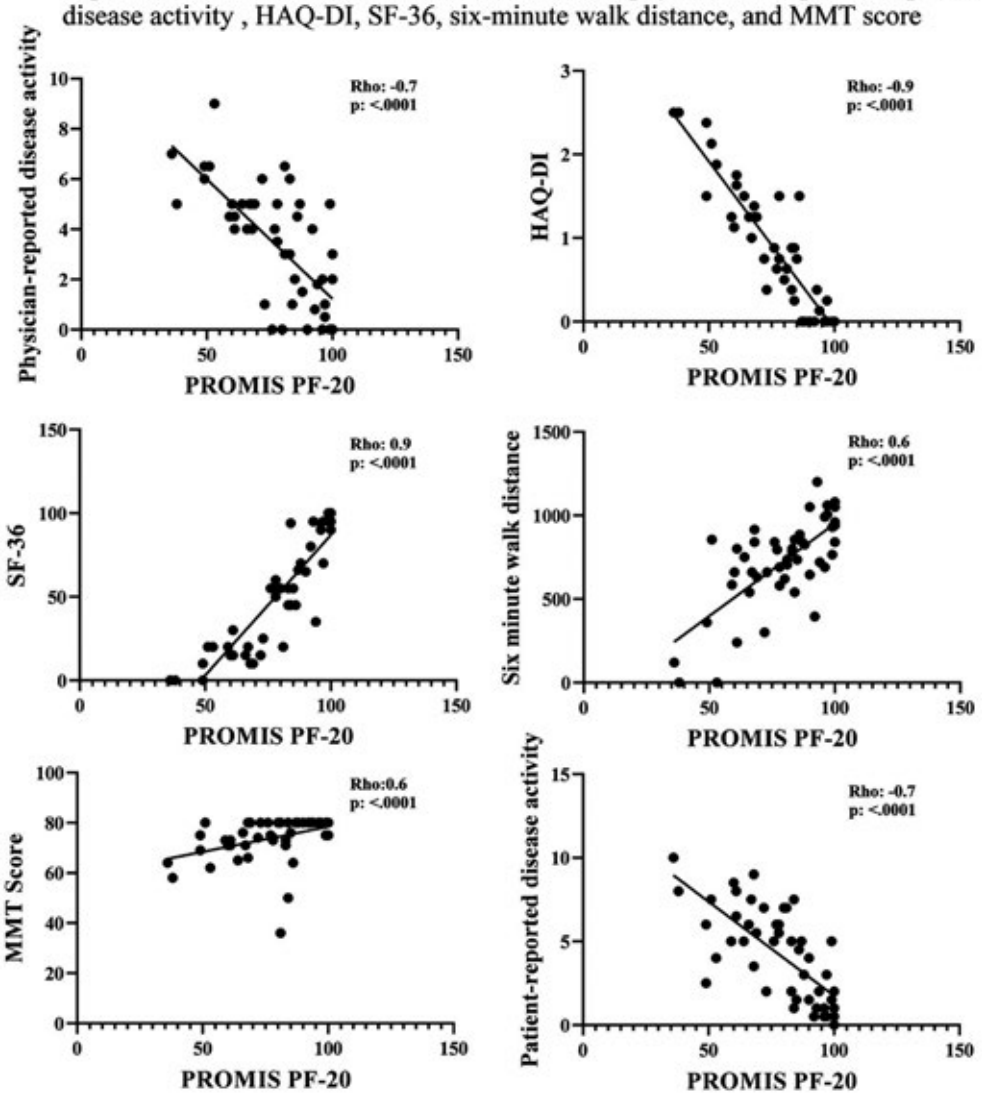
Figure. Correlations between PROMIS PF-20 and physician- and patient-reported disease activity , HAQ-DI, SF-36, six-minute walk distance, and MMT score



Background/Purpose: Idiopathic inflammatory myopathies (IIM) are a group of rare, debilitating systemic diseases characterized by proximal muscle weakness, which limit activities of daily living and lower health-related quality of life. Patient's assessment of physical functional status is a core outcome measure in IIM contributing to treatment decisions and the FDA has strongly endorsed development and validation of patient-reported outcomes as critical measures in rheumatic diseases. Patient Reported Outcomes Measurement Information System (PROMIS) is a validated, patient-reported outcome measure developed by the NIH, but it has not been studied in adult IIM. Currently, the most commonly used PRO in IIM is Health Assessment Questionnaire (HAQ-DI), which has several limitations. PROMIS-physical function-20 (PF-20) offers several superior features over HAQ related to clarity of questions, improved items, computer adaptive options and allowing comparison across different disease states. In this study, we investigated reliability, validity and responsiveness of PROMIS PF-20 in patients with IIM compared to HAQ-DI by employing a longitudinal prospective study design.

Methods: Patients with IIM [dermatomyositis (DM), polymyositis (PM), necrotizing myopathy (NM) or anti-synthetase syndrome] completed PROMIS PF-20 as well as 6 myositis core set measures [manual muscle testing (MMT), physician global disease activity (MD-GDA), patient global disease activity (PT-GDA), extra-muscular global disease activity (EM-GDA), HAQ-DI and creatine kinase (CK)], SF-36 and 3 functional measures [six-minute walk (6MWD), timed

HAQ-DI: Health assessment questionnaire-disability index, MMT: Manual muscle testing, SF-36: Short-form 36

Table 2. n = number, GI = gastrointestinal, FMS = fibromyalgia syndrome, CK = creatine kinase, AST = aspartate aminotransferase, MMT8 = manual muscle testing 8, HAQ = health assessment questionnaire, VAS= visual analogue scale, PGA = patient global activity scale, MDGA = physician global activity, IGA = investigators global assessment of skin involvement, SSI = symptom severity index, WPI = widespread pain index.

up-and-go (TUG) and sit-to-stand tests (STS)] at baseline, 3 and 6 months. PROMIS PF-20 consists of 20 items. Each item is scored on a 5-point rating scale, with higher scores indicating better functioning (0-100). HAQ-DI consists of 20 items. Each item is scored on a 4-point scale with higher scores indicating worse functioning (0-3). Physician-reported change and total improvement score (TIS) using 2016 ACR/EULAR myositis response criteria were obtained at each visit as measures of change.

Results: Fifty patients [mean age, 53.6 (±14.6); 60% females] were studied; 11 PM, 28 DM, 7 NM and 4 with anti-synthetase syndrome. PROMIS PF-20 showed strong test-retest reliability when repeated in 1 month in stable patients (Rho:0.9, p< .0001). PROMIS PF-20 at baseline correlated strongly with MD-GDA, PT-GDA, MMT, HAQ-DI, SF-36, and 6MWD and moderately with STS and weakly with EM-GDA (Figure). There was no correlation with cutaneous and pulmonary disease activity, TUG, and CK levels. Longitudinal change in PROMIS PF-20 strongly correlated with TIS (Rho:-0.8, p< .0001) at 6 months and showed significant differences between physician-reported change demonstrating excellent responsiveness (p< .0001). HAQ and PROMIS-20 showed similar correlations with other outcome measures, however changes in PROMIS-20 over 6 months had stronger correlations with TIS which may indicate better responsiveness (Table).

Conclusion: PROMIS PF-20 demonstrates good test-retest reliability, construct validity and responsiveness in a large cohort of patients with IIM and could replace the HAQ-DI as a core-set measure in myositis.

A Double-Blind, Placebo-Controlled, Phase 2 Trial of a Novel Toll-Like Receptor 7/8/9 Antagonist (IMO-8400) in Dermatomyositis

Yoo Jung Kim,[1] Elena Schiopu,[2] Katalin Dankó,[3] Tahseen Mozaffar,[4] Srinivas Chunduru,[5] Kirstin Lees,[6] Namita Goyal,[4] David Fiorentino,[7] and Kavita Sarin[7], [1]Stanford University School of Medicine, Redwood City, CA, [2]Department of Rheumatology, University of Michigan, Ann Arbor, [3]Department of Clinical Immunology, Medical Faculty, University of Debrecen, Debrecen, Hungary, [4]Department of Neurology, University of California Irvine, Irvine, CA, [5]Idera Pharmaceuticals, Inc., Cambridge, MA, [6]Idera Pharmaceuticals, Inc., Cambridge, [7]Department of Dermatology, Stanford University School of Medicine, Redwood City, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Muscle Biology, Myositis & Myopathies II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Dermatomyositis (DM) is a rare inflammatory disease of skin and muscle associated with characteristic skin findings, muscle weakness, interstitial lung disease, pruritus, and malignancies. Increased interferon (IFN) signaling is a prominent feature of DM, but the mechanisms leading to IFN production in DM are not understood. As toll-like receptor (TLR) 7/8/9 activation can lead to type I IFN production, TLR7/8/9 antagonism may provide therapeutic benefit in DM.

Methods: A double-blind, randomized, placebo-controlled, 24-week trial of IMO-8400 (a novel investigational oligonucleotide TLR7/8/9 antagonist [Idera Pharmaceuticals, Inc.]) was conducted with 30 eligible participants with definite or probable DM based on the criteria of Bohan and Peter. Participants were randomized to treatment with IMO-8400 0.6 mg/kg, IMO-8400 1.8 mg/kg, or placebo. The primary endpoint was the change in the Cutaneous Dermatomyositis Disease Area and Severity Index (CDASI) activity score after 24 weeks of treatment. Exploratory analysis included type I IFN signaling as measured by a 10-gene expression score and patient-reported 5-D Itch Scale, a validated inventory for pruritus. Blood and skin samples were obtained at baseline and end of treatment to measure changes in type I IFN signaling.

Results: CDASI activity scores decreased in all trial arms by the end-of-trial visit, per repeated measures mixed model analysis: -9.3 in 0.6 mg/kg, -8.8 in 1.8 mg/kg, and -7.3 in placebo. We observed no change in skin and blood type I IFN signature scores or CDASI activity scores across treatment arms. We found an association between CDASI and skin IFN signature scores ($\beta = 12.9$, $P = 0.0002$), a moderate association between 5-D Itch Scale and skin IFN signature scores ($Rho = 0.65$, $P < 0.0001$), a lack of association between 5-D Itch Scale and blood IFN signature scores ($Rho = 0.22$, $P = 0.24$), and a positive correlated trend that did not reach significance between CDASI and 5-D Itch Scale scores. 5 patients experienced treatment-emergent adverse effects prompting discontinuation: 3 in low-dose (abdominal discomfort/flu, anxiety, urticaria), 1 in high-dose (thrombocytopenia), and 1 in placebo (muscle weakness).

Conclusion: IMO-8400 did not reach clinical efficacy in reducing cutaneous DM disease activity nor in decreasing the type I IFN signature in skin or blood, suggesting that TLR7/8/9 signaling may not play a causal role in IFN dysregulation in DM. Furthermore, our exploratory findings suggest that skin type I IFN signature scores provide a stronger indication of DM skin disease activity than blood type I IFN signature scores and that skin type I IFN signaling may be a pathway to target in improving pruritus symptoms in DM patients.

Background/Purpose: Inflammation and damage to the vascular endothelium are implicated in the pathogenesis of idiopathic inflammatory myopathies (IIM), particularly dermatomyositis. Paraoxonase 1 (PON1) is a high density lipoprotein (HDL)- associated enzyme, which normally protects the vascular endothelium from damage due to oxidized phospholipids, which accumulate under conditions of oxidative stress. The current work evaluates PON1 activity in IIM patients compared to healthy controls.

Table 3. Multivariate model for PON1 activity

Model 1 including IIM and HC (N=281), Model 2 including IIM only (N=169) with disease activity measured as VAS, Model 3 including IIM only with disease activity measured as CPK.
For Model 2, although Total cholesterol and HDL were both significant in univariate analysis, only HDL was included in the model as the two lipid variables were significantly correlated.

Methods: In a cross sectional analysis of 169 patients with IIM and 112 healthy controls we measured plasma PON1 activity using the arylesterase assay (Clin Chim Acta. 402(1-2):67-74, 2009). Lipoprotein cholesterol levels, inflammatory markers, and myositis autoantibodies(ab) were assessed by standard assays, and myositis disease activity was assessed using physician global 100 mm visual analogue scales (VAS) and CPK levels.

Results: Patients with IIM had significantly lower PON1 activity compared to healthy controls (Table 1). Univariate analysis of PON1 activity in IIM patients showed associations of lower PON1 activity with higher disease activity measured by VAS and CPK, as well as with the presence of antisynthetase antibodies (Table 2). PON1 activity remained strongly associated with IIM diagnosis and myositis disease activity measures after multivariate adjustment for demographic factors (age, gender, race) and factors that were significantly different in univariate analysis (Table 3).

Conclusion: In a large cross sectional cohort of IIM patients, plasma PON1 activity was significantly lower than healthy controls of similar demographics, and was associated with myositis disease activity. Low PON1 activity has been previously associated with increased vascular risk and may warrant further investigation for its role in perpetuation of vascular damage in IIM patients.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Muscle Biology, Myositis & Myopathies II

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Lenabasum is a rationally-designed preferential cannabinoid receptor type 2 agonist that activates resolution of innate immune responses to reduce tissue inflammation and fibrotic processes. Lenabasum had acceptable safety and tolerability and improved efficacy outcomes in the initial 16-week double-blinded, randomized, placebo-controlled Part A of Phase 2 trial JBT101-DM-001 (NCT02466243) in classic or amyopathic dermatomyositis (DM) subjects with refractory skin disease and minimal or no active muscle involvement at the time of enrollment.

Methods: To provide long-term safety and efficacy data in DM subjects in study JBT101-DM-001, subjects who completed Part A were eligible to receive oral lenabasum 20 mg BID in an open-label extension (OLE) of that study that assessed safety and efficacy at 4 weeks, then every 8 weeks.

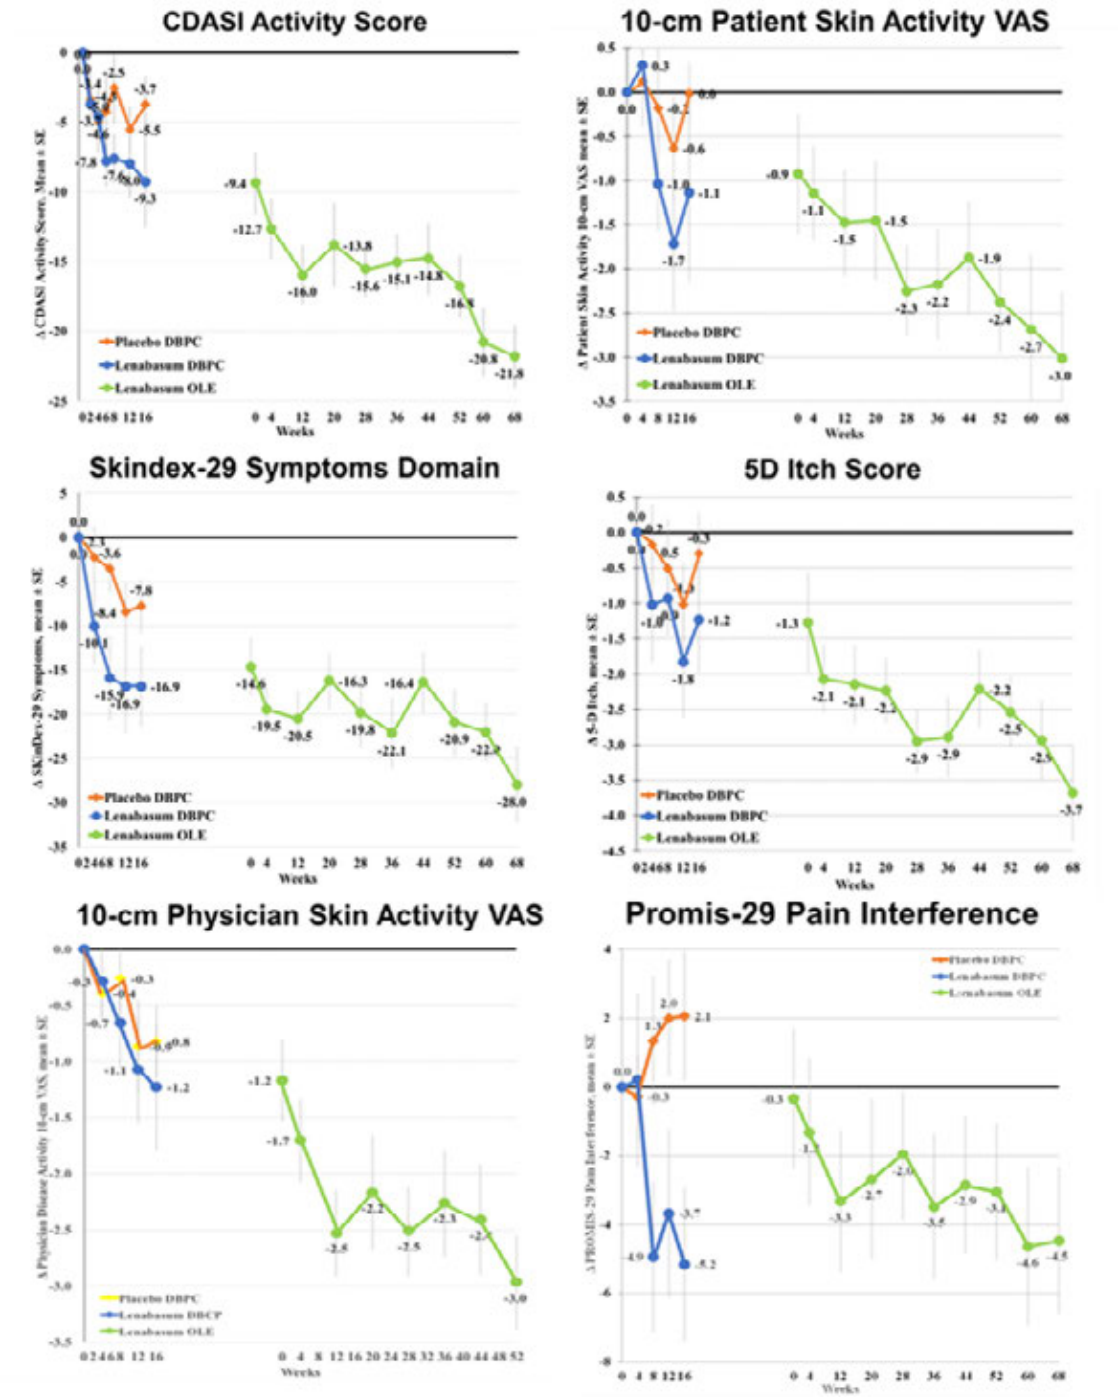
Results: 20/22 (91%) eligible subjects received lenabasum in the OLE. Seventeen (85%) subjects were on stable baseline immunosuppressive drugs. At the time of data cut-off, 18 (90%) subjects who enrolled in the OLE had entered the second year of the OLE, and all 18 had completed Week 68.

Twenty/20 (100%) of subjects experienced at least 1 AE, with 65 total AEs occurring among the subjects during the OLE to date. The majority of AEs were mild (n = 16, 80%), and only 1 subject had an AE probably or definitely-related to lenabasum (mild fatigue). Only 1 subject had a severe AE (fatigue) and that AE was considered unrelated to lenabasum. AEs occurring in 3 (15%) subjects were dermatomyositis worsening (2 mild, 1 moderate), dizziness (all mild), fatigue (2 mild, 1 severe), nasopharyngitis (all mild). AEs occurring in 2 (10%) subjects were headache, herpes zoster, nausea, sinusitis, upper respiratory tract infection, and urinary tract infection – all were mild except 1 AE of sinusitis was moderate. No serious AEs have been reported in this study to date.

Improvement was seen in multiple physician- and patient-reported efficacy outcomes; selected outcomes are presented in Figure 1. Mean (SE) changes from study start at Week 68 in the OLE were: CDASI activity score = -21.8 (2.26), Patient Skin Activity VAS = -3.0 (0.75); Skindex-29 Symptoms Domain = -28.0 (SD); 5D Itch Score = -3.7 (SD); Physician Overall Disease VAS = -3.0 (SD); and Promis-29 Pain Interference = -4.5 (SD). Improvements were seen in other patient- and physician-reported efficacy outcomes. During the OLE, 2 subjects reduced mycophenolate, 2 were switched from methotrexate to mycophenolate, 1 started methotrexate, and 1 had a burst and taper of steroids.

Conclusion: To date, lenabasum treatment has been safe and well tolerated in the Phase 2 study JBT101-DM-001, with no serious AEs or study discontinuations related to lenabasum. The CDASI activity score and multiple other physician and patient-reported outcomes improved, although limitations of attributing efficacy to lenabasum in the

Figure 1. Change from Baseline in Selected Efficacy Outcomes in OLE of Phase 2 Trial JBT101-DM-001



setting of open-label dosing is acknowledged. These data support further testing of lenabasum for the treatment of DM, and a Phase 3 study of lenabasum in DM has started.

Predictive Factors for Mortality in Anti-melanoma-associated Gene 5 Antibody-associated Interstitial Lung Disease

Takahisa Gono,[1] Kenichi Masui,[2] Naoshi Nishina,[3] Shinji Sato,[4] and Masataka Kuwana[5], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Tokyo, Japan, [2]Department of Anaesthesiology, Show University School of Medicine, Saitama, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan, [4]Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Yokohama, Japan, [5]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Muscle Biology, Myositis & Myopathies II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Anti-melanoma differentiation-associated gene 5 (MDA5) antibody is useful to predict mortality in patients with myositis–associated interstitial lung disease (ILD) because of high prevalence of rapidly progressive ILD, which is often refractory to conventional immunosuppressive treatment. In Japan, an intensive combination therapy consisting of corticosteroids (CS), calcineurin inhibitor, and intravenous cyclophosphamide, named the triple combo therapy, is widely used in patients with anti-MDA5-associated ILD anecdotally without evidence. A number of reports have shown that a group of anti-MDA5-associated ILD patients poorly respond to triple combo therapy. The aim of this study is to identify baseline characteristics that predict a poor response to triple combo therapy in patients with anti-MDA5-associated ILD, using a multicenter retrospective/prospective cohort JAMI, involving 497 incident cases of adult myositis-ILD.

Methods: We selected 212 patients with anti-MDA5 from the JAMI database. First, baseline characteristics and treatment regimens were compared between survivors and non-survivors to identify factors associated with mortality using univariate analysis. We then conducted a multivariate logistic regression analysis to identify independent risk factors for mortality with stepwise selection method, in which explanatory variables were selected using backward deletion ($P \geq 0.15$) and forward inclusion ($P < 0.1$). A stratification tree model was constructed based on the combination of risk factors. Finally, we compared survival rates between patients treated with initial triple combo therapy and those without, by selecting patients randomly using JMP®13 software (SAS Institute Inc., Cary, NC, USA) by matching the baseline risk stratification and additional treatment regimen such as CS pulse therapy. Cumulative survival rates were compared using log-rank test.

Results: Mean age at disease onset was 55, 136 (64%) were female, and median disease duration at entry was 2 months. 73 patients died due to respiratory insufficiency at median of one month after treatment introduction. In-

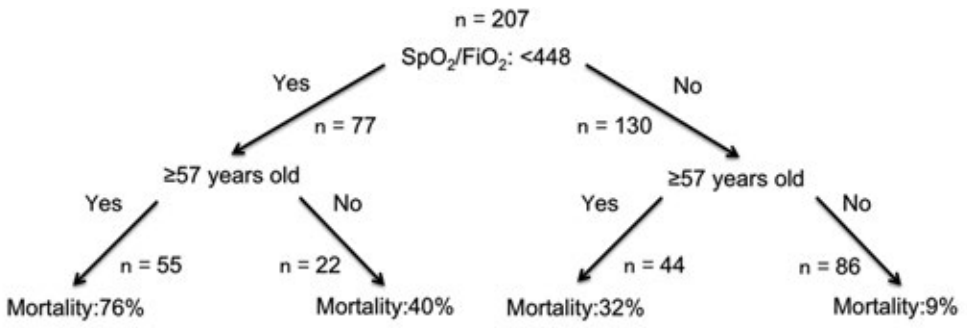

Figure 1. Stratification tree model for mortality in patients with anti-MDA5 antibody-associated ILD

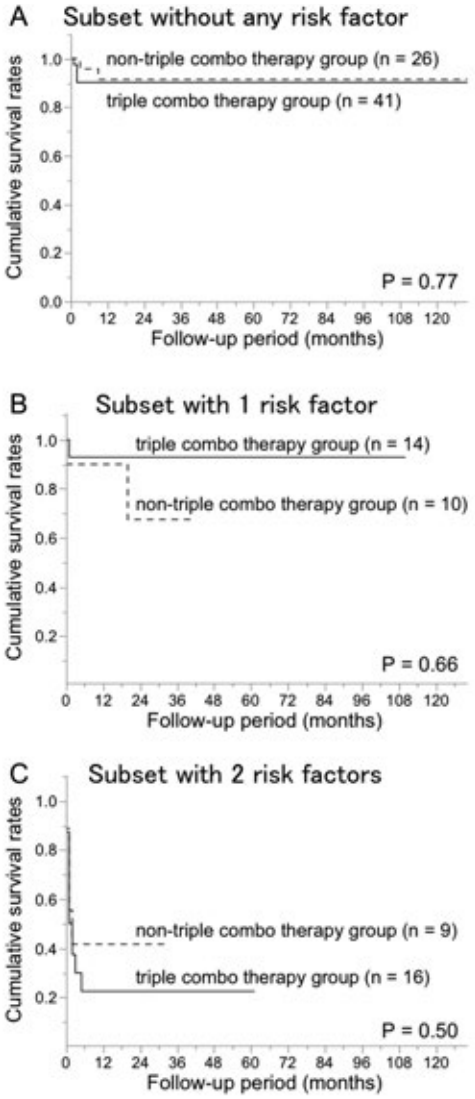

Figure 2. Comparison of overall survival rates between triple combo therapy group and non-triple combo therapy group in each subset stratified by risk factors

dependent risk factors for mortality were older age (odds ratio [OR] 1.07, 95% confidence interval [CI] 1.04-1.12, P < 0.0001), and lower SpO_2/FiO_2 ratio (OR 0.98, 95%CI 0.96-0.99, P < 0.0001). Cut-off values that best discriminate survivors and non-survivors identified using ROC curve analysis included age of 57 years and SpO_2/FiO_2 ratio of 450. We successfully generated a stratification tree model for mortality (Figure 1). Patients older than 57 years with SpO_2/FiO_2 ratio < 450 at diagnosis had the worst outcome with mortality rate of 76%. Cumulative survival rates were comparable between patients treated with initial triple combo therapy and those without even after matching the baseline risk stratification and additional treatment regimen (Figure 2).

Conclusion: Age and SpO_2/FiO_2 ratio at diagnosis are independent predictors for mortality in patients with anti-MDA5-associated ILD. We failed to demonstrate superiority of triple combo therapy over conventional therapy even adjusting baseline risk factors, suggesting urgent need of other therapeutic regimen for this devastating condition.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Muscle Biology, Myositis & Myopathies II
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: IIMs associate with significant lifelong disability due to progressive loss of muscle function and lack of curative interventions; little is known about the relative contribution of different pain patterns in IIMs. Although not commonly associated with inflammatory myositis, myalgia is a sine qua non component of central pain states and is frequently perceived by patients as a sign of “inflammation”. Our objective is to evaluate the prevalence of central pain in different types of IIM (dermatomyositis (DM), polymyositis (PM), immune-mediated necrotizing myositis (IMNM), overlap myositis (OM), anti-synthetase syndrome (ASS) and inclusion body myositis (IBM)) and how it relates to objective disease activity measures and patient-reported quality of life measures.

Methods: In a single Myositis Center we collected demographic and clinical information in a cross-sectional manner in 51 consecutive IIM patients (2018-present): age, gender, race, type of IIM, disease duration (from diagnosis to clinic visit), anti-nuclear antibody pattern and titer, myositis specific antibodies, presence/absence of gastrointestinal (GI) and pulmonary (interstitial lung disease, ILD) comorbidities, serum muscle enzymes (creatine kinase (CK), aldolase and aspartate aminotransferase (AST)) and manual muscle testing 8 (MMT8). In addition, each patient completed the Health Assessment Questionnaire-Disability Index (HAQ-DI), which includes the pain visual analogue scale (pain VAS), the patient global activity scale (PGA) and the 2010 American College of Rheumatology self-reported Fibromyalgia (FMS) diagnostic criteria, including the symptom severity index (SSI) and widespread pain index (WPI) (Fig. 1). A single assessor (ES) performed the physician global activity (MDGA) and the investigators global assessment of skin involvement (IGA: 0=no involvement, 1= minimal-, 2= mild-, 3= moderate- and 4= severe skin erythema). Descriptive statistics and comparisons on demographic and disease variables between those with or without fibromyalgia using non-parametric statistics (Wilcoxon Mann-Whitney) are presented.

UMHS: Department of Rheumatology: Patient Questionnaire

1. For each symptom listed below, use the following scale to indicate the severity of the symptom **during the past 7 days.**

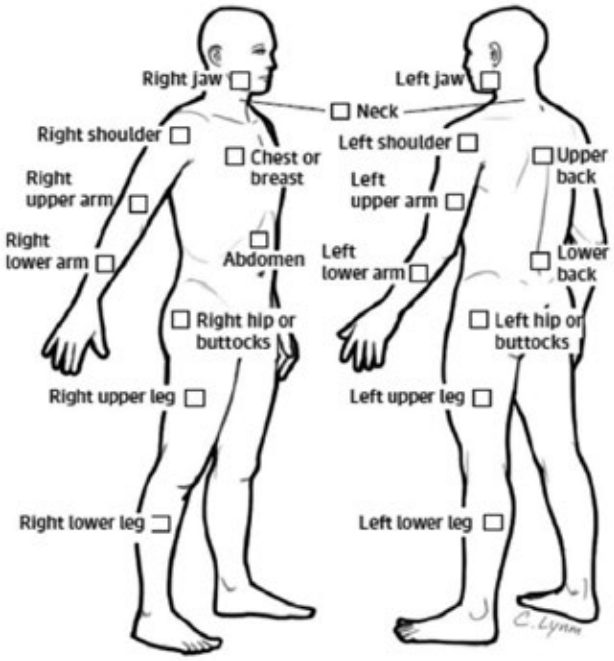
	No Problem	Mild (Mild/Intermittent)	Moderate (Considerable /often present)	Severe (Continuous/life disturbing)
Fatigue	☐	☐	☐	☐
Trouble thinking or remembering	☐	☐	☐	☐
Waking up tired (unrefreshed)	☐	☐	☐	☐

2. Indicate which of the following symptoms you have had over the past **7 days** by (circling) the symptom:

Bladder spasms	Easy bruising	Insomnia	Numbness/tingling
Blurred vision	Fatigue	Irritable bowel syndrome	Oral ulcers
Chest pain	Fever	Itching	Pain in upper abdomen
Constipation	Frequent urination	Loss of appetite	Pain/cramps in abdomen
Depression	Hair loss	Loss/Change in taste	Painful urination
Diarrhea	Headache	Muscle pain	Rash
Dizziness	Hearing problem	Muscle weakness	Raynaud phenomenon
Dry eyes	Heart burn	Nausea	Hives
Dry mouth	Seizure	Shortness of breath	Sun sensitivity
Vomiting	Wheezing	Ringing in ears	Thinking/memory problem
Nervousness			

3. Have the symptoms in 1-2 been present at a similar level for at least **3 months**? **Yes** ☐ **No** ☐

4. On the image below, **CHECK ALL** areas of your body where you have had pain or tenderness which has **persisted or recurred** for **the last 3 months or longer**.



5. If you have had **NO PAIN** please check this box: ☐

6. If you marked pain, do you have a disorder that would otherwise explain the pain? If so what disorder?

Yes ☐ ---------- (list the disorder)

No ☐

Adapted from Clauw DJ. Fibromyalgia: A Clinical Review. JAMA. 2014;311(15):1547-1555. doi:10.1001/jama.2014.3266

Results: Mean age/SD at the time of analysis was 54/13.3yrs, and the mean/SD disease duration from diagnosis was 113/84 months; most of our cohort had DM (54.9%) and AAS (17.6%), were female (72.5%), white (84.3%), 30 (58/8%) had GI involvement and 17 (33.3%) had ILD. Differences among different IIMs are presented in Table 1. Twelve (23.5%) of the 51 IIM patients met the classification criteria for central pain syndrome (FMS-ness) and the parallels between the groups with and without FMS are presented in Table 2.

Conclusion: A large proportion of patients with IIM met classification criteria for FMS, and when compared to patients without FMS, they were almost a decade younger, weaker, had significantly higher AST (but not aldolase or CK), were more likely to have PM or INMN, and had significantly lower levels of function (ΔHAQ almost 1.0). Myalgia is not specific or included in the IIM diagnostic criteria, but it could interfere with rehabilitative exercise. Careful phenotyping of pain patterns in IIMs could help functionality by customizing treatment approaches.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: To analyze the evolution over 20 years of disease activity, treatments and radiographic progression over the first 5 years of follow up of patients with incident RA.

Methods: Since July 1998, the Early Undifferentiated PolyArthritis (EUPA) cohort recruited consecutive adults with recent-onset immune-mediated synovitis affecting at least 3 joints. From the start, patients were treated aiming at 0 swollen joint. Outcomes over 5 years were compared in patients fulfilling RA criteria according to date of inclusion (Period 1: 1998-2004; Period 2: 2005-2010; Period 3: 2011-2018). Disease activity was measured according to DAS28-CRP and SDAI; remission was also studied according to ACR/EULAR criteria. Use of conventional DMARD treatments was defined as none, simple, double and triple; mean MTX dose and biologic DMARD use were also compared across periods. Erosive damage was scored according to Sharp/van der Heijde; erosive status was defined as ≥5 Erosion units. False discovery rate correction was used to adjust p-values for multiple comparisons.

Results: 753 patients were included: 247, 263 and 243 in Periods 1, 2 and 3, respectively. Over the 5 years of follow up, DAS-28 scores significantly decreased and the number of patients reaching DAS-28 remission increased between Periods 1 and 2 (RR(95%CI)= 1.14 (1.03-1.26), p=0.04) and Periods 1 and 3 (RR=1.13 (1.01-1.27), p=0.055), but not between Periods 2 and 3. SDAI remission was not significantly different between Periods; however, SDAI remission was reached earlier during Period 3. Nonetheless, ACR/EULAR remission was reached earlier and was significantly more frequent in Period 3 than in Periods 1 and 2 (RR=1.43 (1.14-1.79), p=0.005; RR=1.36 (1.10-1.68), p=0.006 respectively), but not between Periods 2 and 1. There were no significant differences in mean HAQ scores nor Patient Evaluation of disease activity between Periods. The use of combination DMARDs increased between Periods at each follow up visit, reaching a peak of 25.7% receiving triple therapy at 18 months during Period 3 (versus 5.6% and 12.4% during Periods 1 and 2). Mean MTX dosage increased significantly from Period 1 to Period 2

Table
Outcome comparisons during 5 years of follow up in 753 RA patients recruited over 3 successive Periods: 1998-2004; 2005-2010; 2011-2018

to Period 3. The use of biologic DMARDs markedly increased between Periods 1 and 2 (RR=3.27 (1.92-5.57), p< 0.001), but significantly decreased from Period 2 to 3 (RR=0.62 (0.41-0.93), p=0.02). The use of corticosteroids did not differ significantly between Periods. Erosive damage decreased significantly over each Period (Periods 2 versus

1: RR= 0.65 (0.53-0.81), p=0.002; Periods 3 versus 1: RR=0.42 (0.31-0.56), p=0.002; Periods 3 versus 2: RR=0.64 (0.46-0.88), p=0.007).

Conclusion: In this cohort of recent onset (mean 3.8 months) RA recruited over 20 years, we observed during the 2005-2011 Period, relative to 1998-2004, a marked improvement in control of disease activity and in erosive damage concomitant with use of higher doses of MTX, more combination DMARDs and more biologic DMARDs. The major changes observed after the 2011 launch of Treat-to-Target initiative, were faster control of disease activity and faster attainment of deep levels of remission, resulting in improved radiographic outcomes despite less frequent use of biologic DMARDs.

Testing Different Thresholds for Patient Global Assessment in Defining ACR-EULAR Boolean Remission Criteria for RA

Paul Studenic,[1] David Felson,[2] Maarten de Wit,[3] Farideh Alasti,[4] Tanja Stamm,[1] Josef Smolen,[1] and Daniel Aletaha[1], [1]Medical University of Vienna, Vienna, Austria, [2]Boston University School of Medicine, Department of Rheumatology, Boston, [3]Department of Medical Humanities, Amsterdam Public Health (APH), Amsterdam University Medical Centre, Amsterdam, Netherlands, [4]Medical University of Vienna, Department of Medicine III, Division of Rheumatology, Vienna, Austria

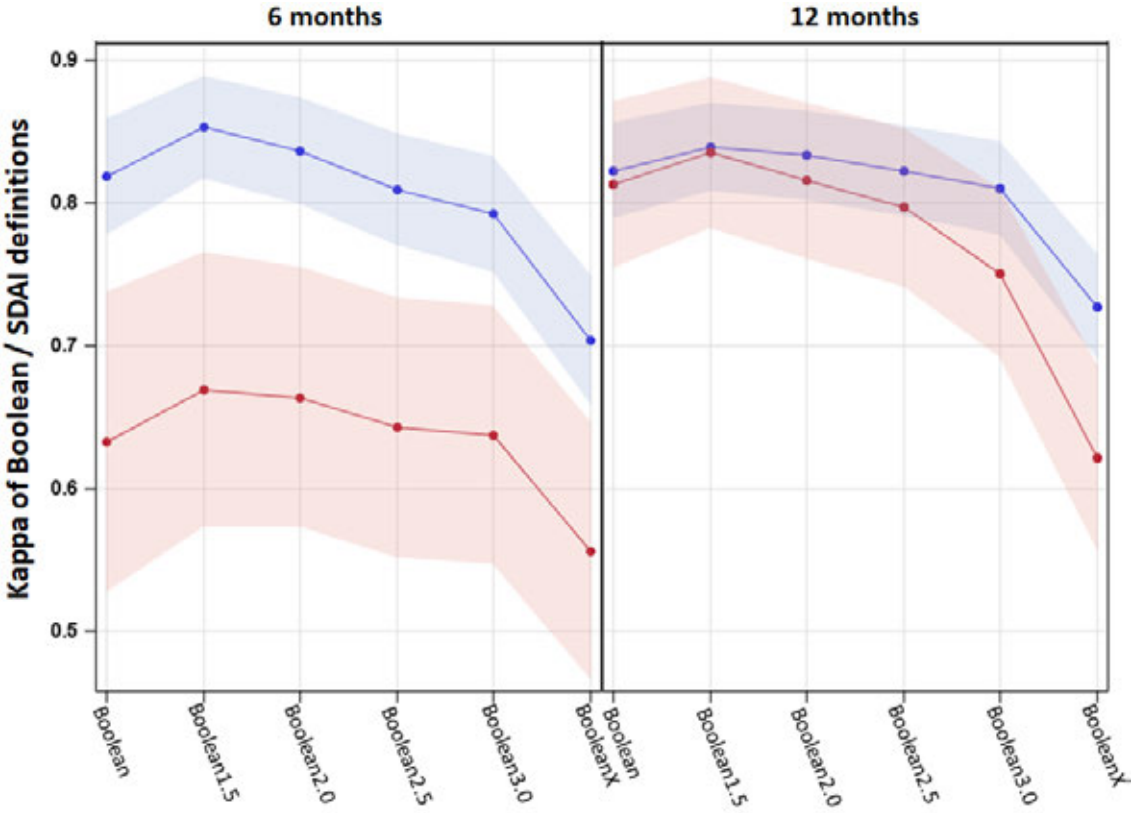

Figure: Kappa with confidence intervals between Boolean remission categories and SDAI remission, separately for early RA (blue line) and established RA (red line) at 6 month and 1 year.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The patient global assessment (PGA) is a core set variable to assess RA disease activity. It is strongly linked to patient-reported pain and is a limiting factor for reaching when the ACR/EULAR Boolean remission definition is used, where PGA may not be greater than 1 on a 0-10 scale. Here we assessed different PGA criteria.

Methods: We used data from six RCTs testing the efficacy of TNF inhibitors vs MTX. Included were 3 trials of early RA: ASPIRE (infliximab), Go Before (golimumab), PREMIER (adalimumab); and 3 of established RA: ATTRACT (infliximab), DE019 (adalimumab) and Go Forward (golimumab). We increased the threshold for the 0-10 score for PGA gradually by 0.5 (Boolean1.5) up to 3 (Boolean3.0), and also omitted the criterion completely (BooleanX, i.e. requiring only CRP, SJC, TJC≤1). We assessed frequencies of remission by these definitions at 6 and 12 months and evaluated agreement with the Index based (SDAI) definition of remission (which does not include an inherent cut-off for PGA). Further the impact on functional and radiographic outcomes after 1 year were explored based on achievement of each of these remission definitions at 6 months. Using recursive partitioning (CART) we attempted to determine a PGA cut-off that optimized agreement with SDAI remission.

Results: Data from 2600 trial patients, 1680 with early RA (mean disease duration: 1.5±2.96years) and 920 with established RA (mean disease duration: 9.7±8.44 years) were included. The proportion of patients achieving Boolean remission increased with higher thresholds for PGA from 12.4% to 19.7% in early RA and 5.9% to 12.3% in established RA at 6 month and 19.9% to 30.1% and 11.4% to 22.5% respectively at 1 year. Best agreement with SDAI remission occurred at a PGA cut-off of 1.5 and 2.0, while agreement decreased with PGA thresholds of ≥ 2.5 (**Figure**). Compared with Boolean (using 1.0), at Boolean2.0 the number of persons who were in remission per SDAI criteria increased from 74% to 85% of all SDAI remitters at 6 months. In early RA patients evaluating data at 6 months CART analyses showed that optimal agreement with SDAI remission occurred at a PGA threshold between 1.4 and 1.7cm.

Changing PGA thresholds at 6 months did not affect radiographic outcome with scores similar across different thresholds (mean ΔsmTSS for Boolean, 1.5, 2.0, 2.5, 3.0 and BooleanX were: 0.35±5.4, 0.38±5.14, 0.41±5.1, 0.37±4.9, 0.34±4.9 and 0.27±4.7). However, for both early and late RA, the lower the PGA threshold, the lower the HAQ score. The proportion attaining HAQ≤0.5 was 90.2%, 87.9%, 85.2%, 81.1%, 80.7% and 73.1% for Boolean, 1.5, 2.0, 2.5, 3.0 and BooleanX respectively. Omitting PGA was associated with much worse functional outcomes.

Conclusion: Increasing the PGA cut-off to 1.5cm would provide highest consistency between Boolean with the Index based remission; the integer cut-off of 2.0cm performed similarly and would also allow the use of numerical rating scales. This new cut-off discounts the excessive stringency of the current PGA cut-off in the remission context, while maintaining similar functional and radiographic long-term outcomes.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Ultrasound (US)-guided minimally-invasive Synovial Tissue (ST) biopsy is a well tolerated procedure for basic and translational studies on chronic inflammatory joint diseases as Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) and Spondyloarthritis (SpA). The aim of the study was to evaluate the utility of histopathologic criteria to differentiate US-guided ST biopsies in daily clinical care in relation to diagnosis, disease characteristics, US parameters and treatment response in a large single center ST biopsy Unit.

Methods: 1064 patients [545 RA, 167 PsA, 75 SpA, 199 Undifferentiated Peripheral Inflammatory Arthritis (UPIA), 18 crystal arthritis, 26 connective tissue diseases and 34 osteoarthritis (OA) respectively] who underwent US-guided ST biopsy were enrolled. US parameters (Synovial Hyperthrophy and Power Doppler signal respectively) were recorded for each biopsied joint. RA, PsA and SpA patients were stratified based on disease activity phase (naive to DMARDs, DMARDs resistant and in sustained remission, respectively). Clinical, demographic and immunological characteristics were recorded for each patient. All ST FFPE specimens were routinely processed and stained with H&E and classified by a pathologist, blinded to clinical characteristics, using the Krenn score to assess the degree of ST inflammation[1]. Moreover, the presence/absence of lymphocytes, plasmacells, granulocytes and oedema was assessed for each ST. All naive to treatment RA were treated according to the T2T scheme and followed for at least 12 months and DAS remission rate was recorded.

Results: In the cohort, the distribution of synovitis score was significantly different among patients with inflammatory chronic diseases (RA, PsA, SpA and UPIA respectively) compared to OA (ANOVA Test $p< 0.001$). Moreover, Krenn score directly correlated with synovial hyperthrophy ($R=0.36;p< 0.001$) and Power Doppler signal ($R=0.40;p< 0.001$) of the biopsied joint. Considering the RA cohort, naive RA showed a higher Krenn score compared to resistant RA ($p< 0.001$) and RA in sustained clinical and US remission ($p< 0.001$), directly correlating with DAS28 ($R=0.51;p< 0.001$). Moreover, ACPA and RF positivity was related to the Krenn score and to ST plasmacells presence at RA onset ($p< 0.05$ and $p< 0.001$, respectively) but not at the time of DMARDs-failure or sustained remission achievement ($p >0.05$ for both). Stratifying naive RA based on disease duration at ST biopsy, naive RA with symptoms duration >1 year, showed higher Krenn score compared to those with symptoms duration < 3 months ($p< 0.001$). Finally, logistic

regression analysis revealed that, in naive RA, Krenn score ≥4.5 at baseline is an independent factor of no DAS remission achievement within 12 months [OR(95%CI):0.37(0.20-0.67)p< 0.001].

Conclusion: Krenn score is a reliable tool for the semi-quantitative assessment of ST inflammation on US-guided ST biopsies being differentially distributed among various chronic inflammatory joint diseases and contingent to disease phase, autoimmune profile and therapeutic response in RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: In early arthritis, identification of patients at risk of developing joint damage is an important issue. In rheumatoid arthritis (RA), the rate of progression is highest during the first 2 years and most of the damage occurs within the first 5 years.

The aim of this study was to describe the patterns of radiographic progression during a 10-year follow-up in the French cohort ESPOIR.

Methods: In this national multicenter cohort, 813 adult patients with suspected or confirmed early RA were included between December 2002 and March 2005, and followed up during 10 years. Radiographs were obtained and modified Sharp scores (vSHS) were determined by a blinded reader. The primary outcome was radiographic progression (RP) at 10 years, defined as a significant increase of vSHS (smallest detectable difference ⩾11). Secondary outcomes were rapid radiographic progression (RRP), defined as >5-point annual increase in vSHS, and non-progression (NP), defined as < 1-point increase in vSHS at the end of the follow-up. Quantitative variables were described by mean ± SD and qualitative variables by number and percentage. The patient groups were compared using Fisher exact test for qualitative variables and Mann-Whitney test for quantitative variables. P values ≤ 0.05 were considered statistically significant.

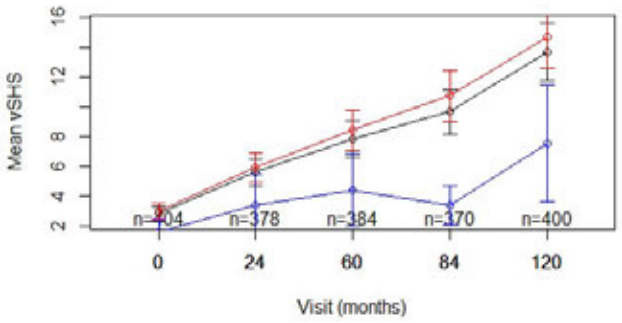

Figure 1. mean radiographic progression during the 10-year follow-up (black: overall population; red: patients fulfilling ACR-EULAR 2010 criteria at baseline; blue: patients not fulfilling ACR-EULAR 2010 criteria at baseline)

Results: Overall, 400 patients (49.2%) had complete data at the end of the follow-up; among them, 343 patients fulfilled ACR-EULAR 2010 criteria at baseline. Radiographs scoring was available for M0, M24, M60, M84 and M120.

The mean progression was of 10.9 (SD=17.9) during the 10-year follow-up, and was significantly higher in patients fulfilling ACR-EULAR 2010 criteria compared with those who weren't (11.9 (SD=18.5) and 5.9 (SD=12.4) respectively, p=0.002). Progression was more important during the 5 first years (Figure 1). The mean progression on erosion score was of 4.0 (SD=8.4) and the mean progression on joint space narrowing score was of 6.9 (SD=10.7).

At the end of the follow-up, 93 patients (23.3%) experienced RP, 16 of whom (4.0%) experienced RRP, 227 patients (56.7%) progressed below the smallest detectable change, and 80 patients (20.0%) did not progress, 8 of whom (2.0%) had an improvement in their vSHS. There was a significant difference in terms of RP between patients fulfilling or not ACR-EULAR 2010 criteria (N=86 (21.6%) and N=7 (10.8%) respectively, p=0.03), but there was no difference for RRP (N=15 (3.8%) and N=1 (1.5%) respectively, p=0.49) and NP (N=63 (15.8%) and N=13 (20%) respectively, p=0.10).

Conclusion: Overall, about 20% of the patients experienced RP at the end of the 10-year follow-up, with significantly more progressors among patients fulfilling ACR-EULAR 2010 criteria. Predictors of RP are currently investigated.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) may share characteristics that relate to their future outcomes. We investigated clinical outcomes over a 4-year follow-up period in objectively identified RA patient clusters derived empirically via a data-driven approach using the BRASS registry.

Methods: Patient clusters were identified by principal components (PC) and cluster analysis of demographic, socio-economic, health and disease characteristics using patient data collected at entry (baseline) into the BRASS registry. Patients in BRASS are followed in the clinic at least annually and are sent questionnaires at 6-month intervals. Mean score of clinical measures were observed at 12- and 24-months of follow-up including Clinical Disease Activity Index (CDAI), Disease Activity Score 28-joint count C-reactive protein (DAS28-CRP), BRASS self-administered Rheumatoid Arthritis Disease Activity Index (RADAI), swollen and tender joint count (SJC and TJC), Multidimensional Health Assessment Questionnaire (MDHAQ), and Functional Status Mental Health Index (FSMHI). Time to first infection and to first RA medication change over 4 years were analysed via Kaplan-Meier curves.

Results: PC analysis of variables among 1443 patients recorded at entry into BRASS identified 41 PCs that capture the fundamental characteristics involved in RA. These PCs informed the identification of 5 novel patient clusters. Cluster 1 patients ("health low, RA uncontrolled, shorter RA duration") exhibited the greatest reduction in TJC. Cluster 2 patients ("health high, RA controlled, shorter RA duration") remained free of infection longer than other clusters. Cluster 3 patients ("health high, RA controlled, longer RA duration") sustained the lowest mean SJC throughout follow-up. Cluster 4 patients ("health low–moderate, moderate RA, moderate RA duration") exhibited the greatest improvement in mental health (FSMHI; Figure). Cluster 5 patients ("health low, RA uncontrolled, longer RA duration") exhibited the highest CDAI scores (Figure) and the highest persistence of therapies at baseline without change.

Conclusion: Five patient clusters identified by data-driven PC analysis of the BRASS registry exhibited distinct patterns of clinical outcomes and management over 4 years. The clinical outcomes data suggest the clusters represent clinically meaningful profiles of RA and illustrate the potential of data-driven patient profiling as a tool to support personalized medicine in RA. Validation in an independent dataset is ongoing.

Session Title: RA – Diagnosis, Manifestations, & Outcomes IV: Outcomes
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: Abrogation of inflammation is important to prevent irreversible joint damage and maximize health-related quality of life in early RA patients. The ACR/EULAR Boolean remission criteria have the most stringent remission definition.(1) It has been reported that patient global assessment (PGA) is the variable most commonly scored above the cut-off in patients who almost fulfill the ACR/EULAR Boolean remission criteria.(2) Our objective was to assess which components of the ACR/EULAR Boolean criteria that most often limit attainment of remission in modernly treated early RA, and quantify the extent of subclinical inflammation in these patients.

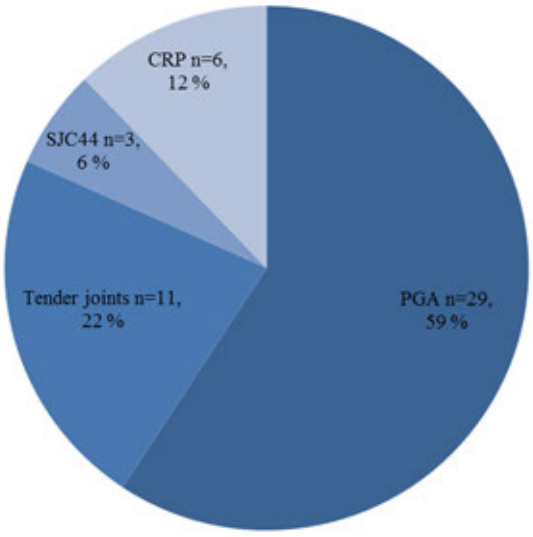
Methods: DMARD-naïve early RA patients included in the treat-to-target ARCTIC trial were followed by a strict tight control regime aiming for DAS remission and no swollen joints, with an additional target of ultrasound remission in half of the patients.(3) Examination of all patients included 44SJC, Ritchie articular index (RAI), laboratory tests, patient reported outcomes included physical function (PROMIS), ultrasound (US) of 32 joints and magnetic resonance imaging (MRI) of the dominant hand and wrist (scored according to RAMRIS). Patients with complete clinical data at the 2-year follow-up visit were included in the current analyses. We assessed the proportion of patients fulfilling ACR/EULAR Boolean remission (based on 44 joints) and the proportion of patients fulfilling three out of four remission criteria, and in such cases, which were the limiting factors. We compared physical function and imaging inflammation (assessed by US power Doppler score, US grey scale score, MRI synovitis and bone marrow edema) in patients reaching complete ACR/EULAR Boolean remission to patients not reaching ACR/EULAR Boolean remission due to the most often limiting factors. Chi2 test and Wilcoxon rank sum test were used for the comparisons.

Results: Of the 203 patients included, 62% were females, mean (SD) age was 52 (13) years, and 81% were ACPA positive. ACR/EULAR Boolean remission was achieved by 112 of 203 patients after 24 months (55%), while 49 (24%) fulfilled three of the four remission criteria. Among these 49 patients, the major limiting factor for not reaching remission was PGA (n=29, 59%), with tender joints as the second most common limiting factor (n=11, 22%) (Figure). In patients not achieving remission due to PGA, the median [IQR] PGA value was 3.1 [2, 4.4]. Subclinical inflammation measured by ultrasound and MRI was not significantly different for patients in ACR/EULAR Boolean remission

Table: Characteristic of patients in ACR/EULAR Boolean remission (N=112) and patients with SJC44≤1 & CRP≤1 (N=61) after two years of treat-to-target. Variables are median [IQR] unless otherwise stated. P-values <0.05 in bold.

	ACR/EULAR Boolean remission	SJC44≤1 + CRP≤1 + PGA >1 and/or tender joints >1	P-value for difference
Age	53.6 [41.1, 63.4]	53.3 [43, 61.2]	0.77
Female, n (%)	65 (58.0)	44 (72.1)	0.07
ACPA, n (%)	88 (78.6)	53 (86.9)	0.18
RF, n (%)	74 (66.1)	43 (70.5)	0.55
PROMIS physical function t-score	62.5 [50.0, 62.5]	45.3 [40.2, 50.0]	**<0.001**
Fatigue VAS (0-100)	3.5 [1.0, 12.0]	34.0 [17.0, 50.0]	**<0.001**
Physician's global (0-10)	0.2 [0.1, 0.8]	0.8 [0.4, 1.2]	**<0.001**
Ultrasound power Doppler score (0-96)	0.0 [0.0, 0.0]	0.0 [0.0, 0.0]	0.75
Ultrasound Grey Scale score (0-96)	3.0 [1.0, 5.5]	3.0 [0.0, 6.0]	0.69
MRI RAMRIS synovitis (0-39)	5.4 [3.7, 7.1]	5.0 [3.8, 6.2]	0.68
MRI RAMRIS bone marrow edema (0-105)	1.0 [0.0, 3.2]	1.8 [0.0, 3.2]	0.21

Figure: The proportion of patients with failure to fulfill the ACR/EULAR Boolean remission criteria due to one of the four components; tender joint count >1 or SJC44 >1 or CRP>1 mg/dl or PGA>1. N=49.



compared to patients not fulfilling these criteria due to PGA and /or tender joints (Table), but the latter reported more subjective symptoms such as fatigue and impaired physical function.

Conclusion: PGA and tender joints are the variables most often limiting patients from achieving ACR/EULAR Boolean remission, also in a treat-to-target setting with high remission rates. The level of subclinical inflammation is not elevated in these patients compared to patients in ACR/EULAR Boolean remission. Further research is still needed to assess which clinical remission criterion is best suited to guide treatment.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Psoriatic Arthritis Clinical Studies
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: While a handful of clinical risk factors for the development of inflammatory diseases have been identified, to date, no studies have compared risk factors across multiple inflammatory diseases. The objective of this study was to compare the strength of association of selected potential risk factors for the development of psoriasis, PsA, RA, and AS.

Methods: We performed a series of case-control studies in The Health Improvement Network, a general practitioner database in the United Kingdom. Data between 1994-2015 were included. We identified patients with at least one code for PsA, RA, AS, or psoriasis using validated code lists and matched them to up to ten controls from the general population without these diseases based on age (within 2.5 years), sex, practice and year of diagnosis (controls were required to be in the practice on the diagnosis date and were assigned the same 'diagnosis date'). We began with an extensive code list of over 100 potential risk factors including common comorbidities, infections, trauma, and a limited number of medications (e.g., statins). Potential risk factors were assessed from the time of enrollment into a THIN practice until the end of the observation period, end of enrollment, or death. Hypothesized risk factors with a

Depression	1.29 (1.21, 1.37)**	1.11 (1.00, 1.23)	1.05 (1.03, 1.07)**	1.14 (1.10, 1.17)**
Back Pain	1.17 (1.11, 1.24)**	606.83 (386.41, 952)**	0.90 (0.88, 0.91)**	1.01 (0.98, 1.04)
In this analysis, we only included risk factors with a prevalence of 1% in the control population. Highlighted in yellow are those with an effect size >1.15 or <0.75 and significant association with p value<0.01. P values <0.001 have two asterisks and <0.02 have one asterisk.				

prevalence of ≥1% were included in the final models and tables. Univariable logistic regression was used to screen risk factors for association with the disease of interest. Multiple testing was accounted for by setting a p-value of 0.02 as the level of statistical significance. Finally, a multivariable logistic regression model was constructed for each disease using the significant risk factors, stratified by sex.

Results: Demographics of the patient population are shown in Table 1. 7,594 incident PsA cases, 3, 253 incident AS cases, 111,375 incident psoriasis cases, and 28,341 incident RA cases were identified and matched to 75,930, 32,530, 1,113,345, and 282,226 controls respectively. Median age at diagnosis was 48.3 (IQR 38-59), 40.7 (31-54), 43.1 (31-54), and 59.9 (48-71) respectively. Sex was balanced in psoriasis and PsA but more female in RA (68%) and more male in AS (70%). Mean follow up time ranged from 6.4-7.2 years and was slightly longer among controls. In univariable analyses (Table 2), previously identified risk factors in PsA were replicated including obesity, uveitis, and trauma. Smoking was identified as a risk factor in RA as previously described. There were some similar risk factors

across all 4 diseases including a positive association between pharyngitis, IBD and uveitis (strongest for AS and PsA) and a similarly strong protective effect of statins. Skin infections were associated with PsA and psoriasis, skin trauma with psoriasis and joint trauma with PsA. Diarrheal infections were associated with PsA and AS. Most risk factors maintained statistical significance in the multivariable models though final models differed slightly by sex.

Conclusion: This set of parallel case-control studies identifies differences between PsA, psoriasis, AS and RA that supports the previous theories of pathophysiologic triggers related to these diseases but also demonstrates some commonalities between diseases.

Patient	Ultrasound	0.08 (0.04, 0.12)	0.21	0.81	0.39

PABAK - Prevalence Adjusted and Bias Adjusted Kappa

Background/Purpose: There is limited information about the constellation of musculoskeletal symptoms experienced by patients with early psoriatic arthritis (PsA). This study aims to describe the pattern of musculoskeletal symptoms and their correlation with clinical and sonographic findings among psoriasis patients with suspected PsA.

Methods: The study evaluated patients with psoriasis and musculoskeletal complaints who did not have a prior diagnosis of PsA. These patients were evaluated in a rapid access clinic that included a central triage system using the following modalities: 1) screening questionnaires that included homunculus where patients marked the location of the affected joints, 2) assessment by an advanced practice physiotherapist, 3) musculoskeletal ultrasound (MSK-US) of joints and entheses. In addition, patients completed questionnaires about the nature and duration of their musculoskeletal symptoms, physical function and quality of life. All patients were then assessed by a rheumatologist who classified each patient to: “PsA”, “Not PsA”, or “Possibly PsA”. Agreement between modalities was assessed using Kappa statistics.

Results: 203 patients with psoriasis and musculoskeletal symptoms were enrolled in the study. 18 (8.8%) and 48 (23.6%) were classified as “PsA and “possible PsA”, respectively. There was no difference between the two groups in the presence, distribution and duration of musculoskeletal pain (Table 1). Patients with PsA had higher intensity of musculoskeletal and skin-related symptoms (DLQI) and worse scores in domains such as physical function (HAQ), quality of life (PSAID) and fatigue (FACIT). Patients who were classified as “PsA” were more likely to use systemic medications for psoriasis (< 0.05), have severe psoriasis (p=0.02) and nail lesions (p=0.02) and have synovitis/enthesitis by MSK-US (p=0.01). Patients with positive MSK-US inflammation were older (p< 0.001), reported more joint stiffness (p=0.02) and physical dysfunction (by HAQ, p=0.02, Table 2), irrespective of the clinical diagnosis. Analysis of agreement between modalities revealed the strongest agreement between the rheumatologist and physiotherapist (k=0.28, Table 3). The lowest levels of agreement were found between ultrasound and patient (k=0.08) and physiotherapist and ultrasound (k=0.08).

Conclusion: The intensity, rather than the type, duration or distribution of musculoskeletal symptoms, is associated with psoriatic arthritis among patients with psoriasis. The correlation between musculoskeletal symptoms, patient reported outcomes and sonographic findings is poor in patients with suspected PsA. MSK-US provides additional information to the clinical assessment and aid in diagnosing PsA patients at earlier stages.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Psoriatic Arthritis Clinical Studies

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Psoriatic arthritis is a heterogenous disorder not only with respect to patterns and components of musculoskeletal involvement but also with respect to types of skin involvement and the timing of joint and skin disease. The interrelationships between characteristics of skin psoriasis, arthritis and the timing of arthritis are not well studied; we therefore sought to explore these in a large international cohort.

Methods: PsART-international is a web-based registry of PsA patients under routine care in Turkey, Italy and Canada including detailed disease history about type and onset of skin and joint disease. We extracted data on demographic characteristics, family history of psoriatic disease (regardless of skin or arthritis) , types of skin psoriasis, site of skin psoriasis onset, and components of psoriatic arthritis ever observed. For descriptive purposes we tabulated patient characteristics in three groups; arthritis-first, psoriasis-first and synchronous, the latter indicating the onset of skin and joint disease within 12 months. The primary analysis outcome was the absolute time elapsed in months after skin disease to arthritis (negative values indicating arthritis onset before psoriasis). We constructed a linear regression model for this primary outcome using demographic, skin disease and arthritis characteristics to explore the associations.

Table-1 Patient characteristics

		Arthrtitis first	Psoriasis first	Synchronous	Overall
N		71	1251	309	1631
Education years, mean (SD)		9.8 (4.8)	9.4 (4.8)	10 (4.7)	9.5 (4.8)
Age at PsA, mean(SD)		40.8 (13)	42.2 (13.5)	40.2 (13.7)	41.8 (13.5)
Age at Pso, mean(SD)		46.3 (12.3)	29.4 (14.8)	40.1 (13.7)	32.2 (15.4)
Delay, mean(SD)		-67.4 (60.9)	155.6 (125.8)	1.8 (3.9)	116.7 (132)
PsA duration, mean(SD		11.4 (8.7)	4.6 (6.4)	6.5 (7.9)	5.3 (7)
BMI		29.3 (5.1)	28.1 (5.2)	28.6 (5.5)	28.2 (5.2)
Male gender		30 (42.3)	473 (37.8)	103 (33.3)	606 (37.2)
Smoking status	Current	15 (21.1)	256 (20.5)	60 (19.4)	331 (20.3)

	Nail involvement,N(%)	34 (47.9)	616 (49.2)	124 (40.1)	774 (47.5)
Initial lesion,N(%)	Scalp	25 (35.2)	604 (48.3)	123 (39.8)	752 (46.1)
	Torso	9 (12.7)	235 (18.8)	48 (15.5)	292 (17.9)
	Extremity	46 (64.8)	736 (58.8)	178 (57.6)	960 (58.9)
	Genital	9 (12.7)	77 (6.2)	15 (4.9)	101 (6.2)

Table-2 Regression analysis for the delay between onset of psoriasis and arthritis.

Term	Estimate	P	Conf. limits	
			5%	95%
(Intercept)	65.3	<0.001	40.7	89.9
Female	8.8	0.229	-5.6	23.3
Nail involvement	27.3	<0.001	13.2	41.4
Skin psoriasis type				
Erythrodermic	15.5	0.313	-14.6	45.5
Flexural	-11.3	0.682	-65.3	42.8
Inverse	-18.9	0.542	-79.8	41.9
Plaque	20.0	0.012	4.3	35.7
Pustular	-28.7	0.009	-50.4	-7.1
Initial skin involvement				
Scalp	12.4	0.122	-3.3	28.1
Torso	5.4	0.550	-12.4	23.2
Extremity	11.9	0.168	-5.0	28.7
Genital	-6.3	0.678	-36.3	23.6
Family history	24.7	0.001	9.9	39.4
DIP involvement	-4.3	0.671	-24.0	15.5
Dactylitis	11.2	0.180	-5.2	27.6

Results: We included 1631 patients; 71 had arthritis first, 309 had synchronous onset and 1251 had psoriasis first. Data shows that the age of psoriasis onset and not that of arthritis determined whether arthritis or psoriasis would be the first to appear (Table-1). Results of the regression analysis shows that the model intercept, delay of arthritis after psoriasis when other independent variables are set to their baseline values, is 65 months, pustular psoriasis is associated with onset of arthritis circa 2 years earlier than the intercept interval whereas nail involvement, plaque psoriasis or family history of psoriasis are associated with an increased delay from psoriasis to arthritis, by approximately 2 years-each (Table-2). Adding all types of articular involvement into the model did not cause a material change in the point estimates however reduced the precision of terms for skin psoriasis type (data not shown).

Conclusion: The age of psoriasis determines whether arthritis or psoriasis starts first in PsA patients. Pustular psoriasis is associated with a shorter time interval after psoriasis to arthritis while nail involvement, plaque psoriasis and psoriatic family history are associated with a longer interval.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

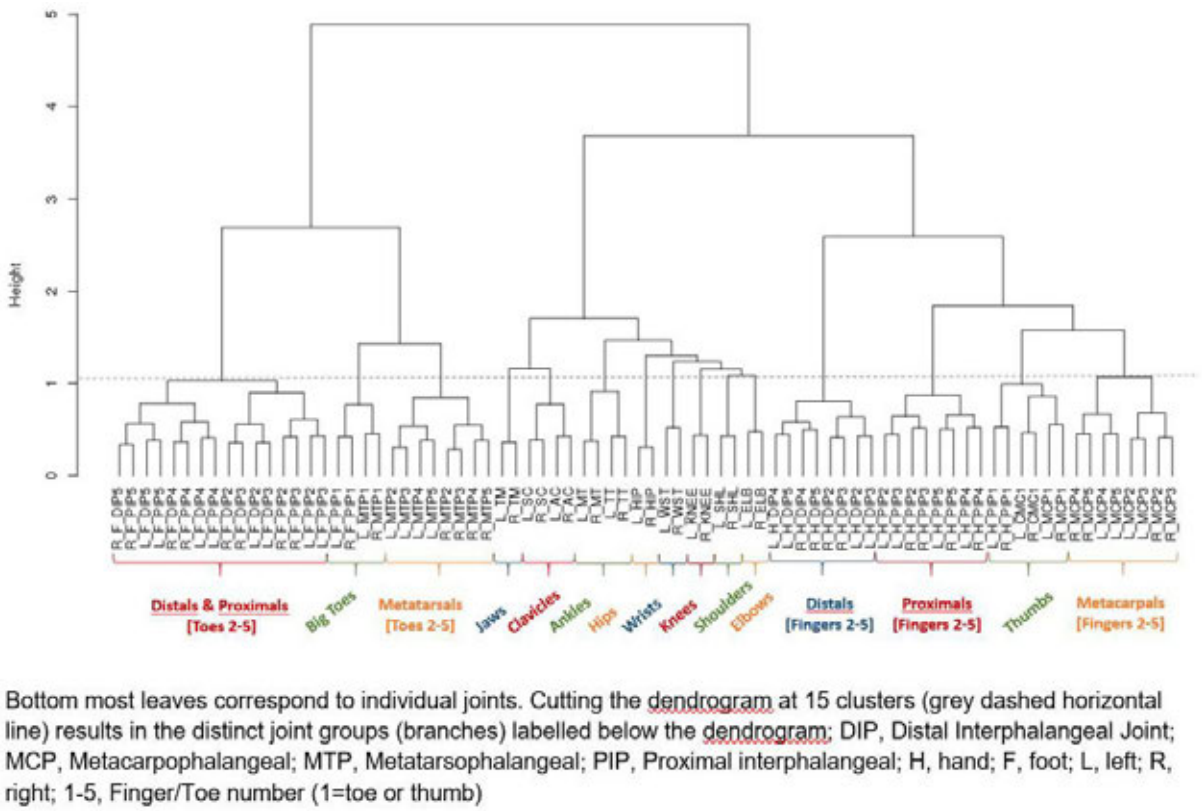
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Psoriatic Arthritis Clinical Studies

Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

Background/Purpose: Identifying clinically relevant patient phenotypes amidst the variability and heterogeneity of the clinical manifestations of psoriatic arthritis (PsA) is currently challenging. Using machine-learning (ML) techniques could be the first critical step towards better understanding of disease pathotypes, and support progression towards precision medicine.[1] Clusters of PsA patients based on presence/absence of disease domains were identified using ML from the secukinumab FUTURE trials program.

Methods: Hierarchical clustering was performed on the composite using "1-correlation" as the dissimilarity metric and Ward's agglomeration method for pairwise grouping; a dendrogram was used to visualize and assess the resulting groupings. Pairwise correlations were explored in various clinical domains of PsA including dactylitis, NAPSI,



Bottom most leaves correspond to individual joints. Cutting the dendrogram at 15 clusters (grey dashed horizontal line) results in the distinct joint groups (branches) labelled below the dendrogram; DIP, Distal Interphalangeal Joint; MCP, Metacarpophalangeal; MTP, Metatarsophalangeal; PIP, Proximal interphalangeal; H, hand; F, foot; L, left; R, right; 1-5, Finger/Toe number (1=toe or thumb)

Figure 1. Dendrogram of Hierarchical Clustering of 78 Joints

PASI, enthesitis, swollen or tender joints, spondylitis, and CRP measurements from >2,700 patients across five phase 3 studies with ≈425,000 data entries at baseline and were visualized using heatmaps. Mixture (of Bernoullis) Model was applied to obtain the clusters across all domains. The model assumes that two patients share a cluster only if they have similar probability of presence of symptom across all clinical domains.

Results: The hierarchical clustering algorithm grouped the 78 individual joints into distinct and natural clusters. At higher level of the dendrogram, the algorithm grouped separately all foot, larger (jaws, clavicles, ankles, hips, wrists, knees, shoulders, elbows), and hand joints. An example for hierarchical clustering of 78 joints is shown in **Figure 1.** Cutting the dendrogram at 15 clusters separated all the joints into distinct groups; hand joints (distal and proximal phalanges, metacarpals and thumbs), and foot joints (distal and proximal phalanges, metatarsals and big toes). Associations of the joint clusters with other disease manifestations such as skin and nail involvement revealed distinct patient clusters, enabling to investigate differences in disease pathogenesis and treatment outcomes. For example, in one of the clusters with patients having high polyarticular burden (high number of affected joints), there was a high probability of nail involvement and psoriasis. These clusters were further refined when response to treatment over time was added in the model.

Conclusion: Machine learning methodology confirmed a natural grouping of joints in patients with psoriatic arthritis based on baseline swelling and tenderness and revealed complex correlation patterns. Additional cluster analyses including psoriatic arthritis disease manifestations and response to treatment revealed distinct patient clusters with potential clinical implications.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Psoriatic Arthritis Clinical Studies

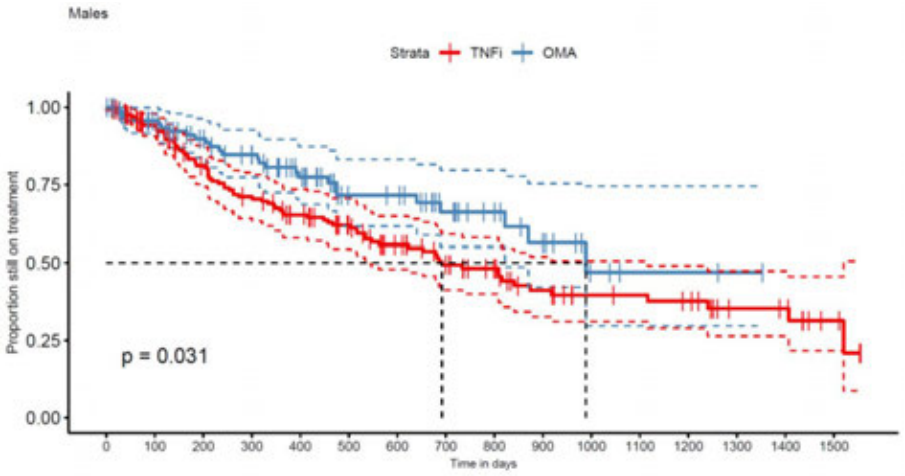
Session Type: ACR Abstract Session

Session Time: 4:30PM–6:00PM

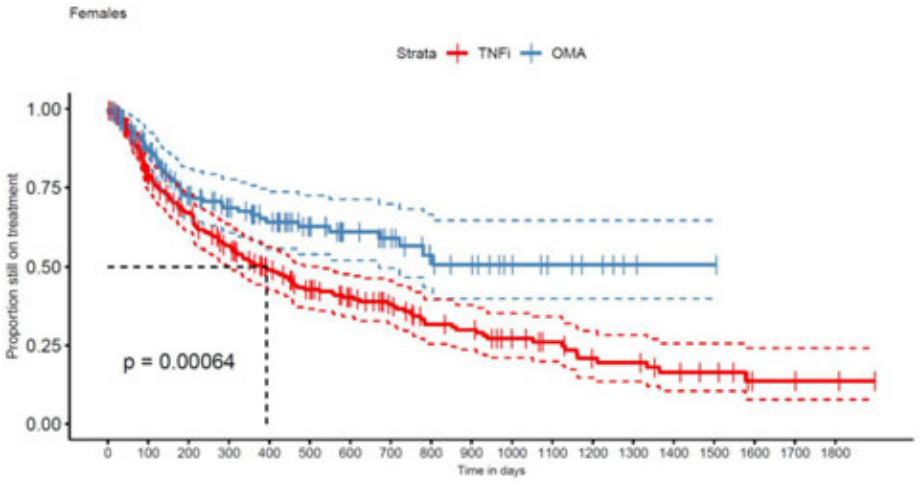
Background/Purpose: Tumor necrosis factor inhibitors (TNFi) were the first approved biological disease modifying antirheumatic drugs (bDMARDs) for psoriatic arthritis (PsA). IL-12/23 and IL-17-specific antibodies provide another mode of action (OMA) than TNFi and were more recently approved for PsA. In 2018, ACR recommended TNFi as a first-line treatment option for PsA. Here, we aimed to compare these two bDMARD classes for PsA in a real world setting.

We hypothesized that response to a bDMARD rather depends on the disease-related activation of a target than the pharmacological profile of different inhibitors for the same target. Consequently, we postulated better drug persistence of OMA bDMARDs than another TNFi bDMARD after having stopped a TNFi either for lack of efficacy or tolerability reasons.

Methods: We analyzed all available bDMARD treatment courses (TC) of PsA patients in the Swiss register for Clinical Quality Management in Rheumatology (SCQM), after date of launch of the first OMA bDMARD in 2014 and after use of a first TNFi. We estimated drug retention by using Kaplan-Meier plots and equality of survival using Log-Rank tests. After multiple imputation of missing covariates, we included line of bDMARD treatment with two levels, 2nd



Kaplan-Meyer plot for drug retention in male



Kaplan-Meyer plot for drug retention in female

versus 3rd or later line of therapy, smoking, age, BMI and disease activity score (DAS28-CRP) baseline covariates together with the bDMARD treatment category into adjusted models

Results: A total of 663 TC from 449 patients met our inclusion criteria, with 422 TNFi TCs and 241 OMA bDMARD TCs. An IL-12/IL-23 inhibitor was used in 97 and an IL-17i specific compound in 144 OMA bDMARD TCs. At baseline, median DAS28-CRP was 2.7 [1.9; 3.9] in the TNFi group and 3.2 (2.5; 4.0) in the OMA bDMARD group (p=0.02). Furthermore, TNFi were more frequently used as a second line treatment (n=191, 45%) than OMA bDMARDs (n=53, 22%). TNFi TCs (n=397, 94%) were more frequently observed in OMA bDMARD naïve patients, but OMA bDMARD TCs were more frequent after another previous OMA bDMARD TC (n= 198, 82%, p< 0.0001). Other covariates such as sex (399 women and 264 men, p = 0.87), smoking status (n=90, p=0.30), median age (51 [42; 59] years, p = 0.25) and BMI at baseline (28 [24; 31.5] kg/m2, p = 0.57), were similarly distributed between the two treatment groups. In the crude analyses, the estimate of median drug retention time was 516 days for TNFi as compared to 989 days for the OMA bDMARD group (p < 0.0001). OMA bDMARDs had a longer drug retention both in men (p=0.031, Fig 1) and women (p< 0.001, Fig 2). In multivariable-adjusted analyses in 208 TNFi and 111 OMA bDMARD TCs, OMA bDMARDs were on average late discontinued than TNFi (HR=0.49 [0.33, 0.72], p< 0.001), but second line indication (HR=1.44 [1.02, 2.03]) and male sex (HR= 1.52 [1.07, 2.15] were associated with better drug retention rates.

Conclusion: After use of a first TNFi, OMA bDMARDs displayed better drug retention in PsA than another TNFi. As OMA bDMARD were more often used in less favorable later line indication, they appear according to this analysis as the preferential choice among the alternative bDMARD treatment options in TNFi experienced patients.

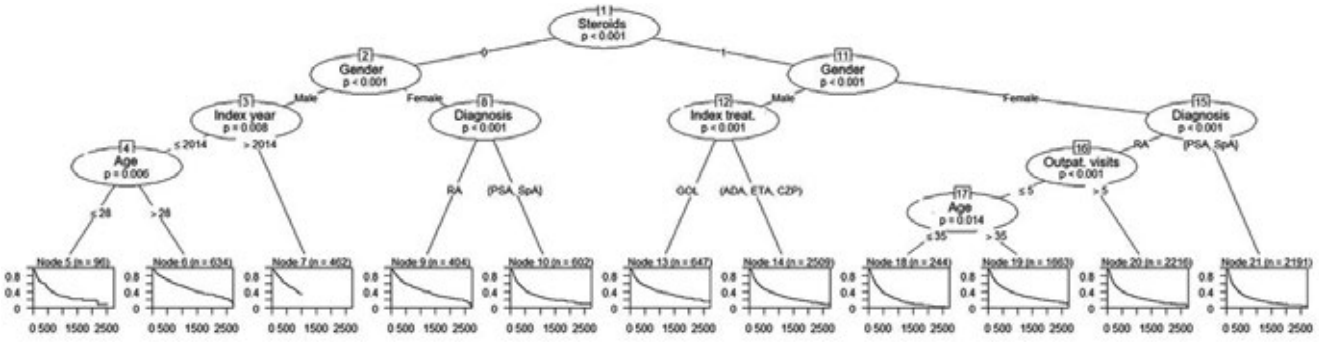
Decision Tree Analysis to Identify Inflammatory Arthritis Patient Subgroups with Different Levels of Treatment Persistence with First-Line Subcutaneous TNF-alpha Inhibitors

Emma Hernlund,[1] Johan Klint,[1] Axel Svedbom,[1] Johan Dalén,[1] Christopher Black,[2] and **Amy Puenpatom** [2], [1]ICON plc, Stockholm, Sweden, Stockholm, Sweden, [2]Merck & Co., Inc., Kenilworth, NJ, United States, Kenilworth, NJ

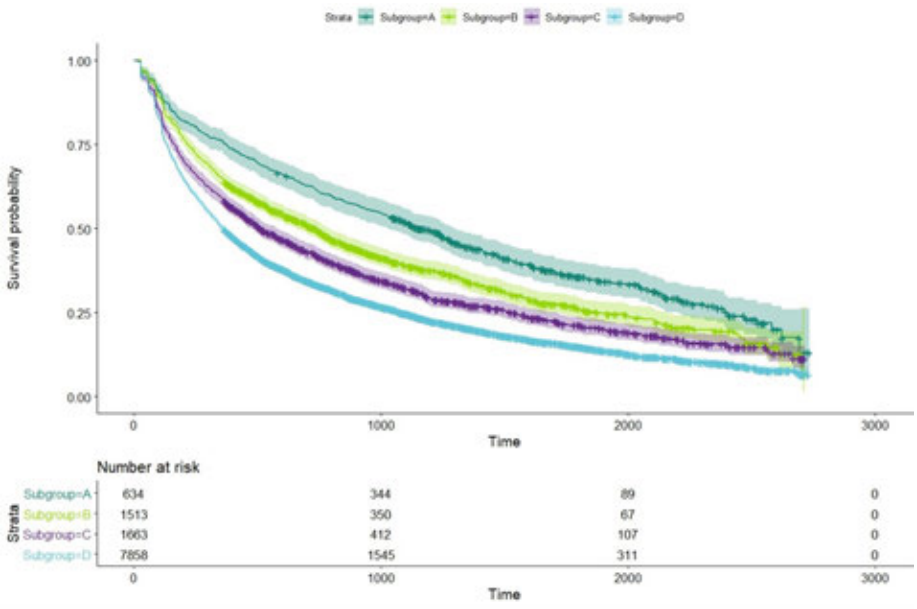
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VI: Psoriatic Arthritis Clinical Studies
Session Type: ACR Abstract Session
Session Time: 4:30PM–6:00PM

Background/Purpose: The advent of biologic medications, such as subcutaneous TNF-alpha inhibitors (SC-TNFi), has transformed the management of inflammatory arthritis (IA) during the last decades. However, a significant proportion of patients with IA fail to respond, lose response, or experience adverse events while being treated with a biologic, and may therefore be required to discontinue or switch treatment. The aim of this study was to identify IA patient subgroups with different levels of treatment persistence through decision tree analysis using recursive partitioning methods.

Methods: Using data from Swedish Health Data Registers, adult, biologic treatment-naïve patients initiating treatment for IA with any available SC-TNFi (adalimumab, etanercept, certolizumab, and golimumab) between May 1, 2010 and October 31, 2016 were included. Treatment persistence was derived based on information from filled prescriptions (e.g. dispensing date, pack information, and defined daily dose) and a grace period of 60 days. A number of covariates were derived from data collected in the year prior to treatment initiation, including Charlson Comorbidity Index and its components, number of visits and inpatient stays in specialized care, and treatment initiation year, and



Decision tree for drug persistence in IA patients. GOL=golimumab, ADA=adalimumab, ETA=etanercept, CZP=certolizumab pegol, RA=rheumatoid arthritis, PsA=psoriatic arthritis, SpA=spondyloarthritis



Drug persistence for combination of terminal nodes into groups. Group A=node 6, group B=nodes 7, 13 and 9, group C=node 19, group D=nodes 14, 5, 10, 20, 18 and 21. Patient characteristics by node are presented in Figure 1.

filled prescriptions for systemic corticosteroids, DMARDs and/or NSAIDs. In addition, age at treatment initiation, sex, IA diagnosis [spondyloarthritis (SpA) / psoriatic arthritis (PsA) / rheumatoid arthritis (RA)], index biologic treatment were included as covariates in the analysis. The decision tree was created through recursive partitioning, and the analysis was performed with the cTree method (in R statistical software), which uses a conditional inference framework. Differences between terminal nodes were examined using log-rank tests.

Results: A total of 11,668 patients were included in the study. The decision tree analysis resulted in 11 terminal nodes (Figure 1). The highest persistence was found in male patients, aged over 28 years who did not use systemic corticosteroids in the year prior to SC-TNFi initiation, and who initiated treatment prior to 2015. The lowest persistence was found in females with a diagnosis of SpA or PsA using systemic corticosteroids in the year prior to treatment initiation. Four groups of patients were found to have significant differences in drug persistence when the terminal node subgroups were compared. Median survival by group ranged between 1 year and 3.2 years (Figure 2). Golimumab was the only therapy that has a positive predictive effect on persistence.

Conclusion: This study uses a conditional inference method for decision tree analysis to identify patient subgroups with different levels of treatment persistence. The results may serve as a basis for further research needed to understand the reasons for treatment discontinuation in subgroups with low drug persistence. In addition, the results from this analysis may aid physicians in anticipating treatment persistence and monitor certain subgroups of patients more closely who are more likely to discontinue treatment.

The Role of Bradykinin Receptor B1 and Its New Ligand Soluble CD13 in Rheumatoid Arthritis and Inflammatory Arthritis Mouse Model

Chenyang Lu,[1] Phillip Campbell,[1] Jonatan Hervoso,[2] Stephanie Rasmussen,[2] Wenyi Fu,[2] Jeffrey Ruth,[2] David Fox,[3] and **M Amin** [4], [1]the University of Michigan, Ann Arbor, MI, [2]the University of Michigan, Ann Arbor, [3]University of Michigan, Ann Arbor, [4]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is an inflammatory disorder characterized by synovial hyperplasia, inflammatory cell infiltration and pannus formation. We have shown that soluble CD13 (sCD13) induces angiogenesis, monocyte and lymphocyte chemotaxis and arthritis through G protein-coupled receptors (GPCRs). However, the receptor for sCD13 is not yet defined.

Methods: A GPCR screening assay for potential receptors for sCD13 identified bradykinin receptor B1 (B1R). Binding of sCD13 and B1R was studied by immunoprecipitation and immunoblotting of lysates of FLS that had been treated with a chemical cross-linker, BS3. Immunofluorescence was performed to verify the physical binding of sCD13 to B1R on cell membranes. The expression of B1R on RA synovium and fibroblast-like synoviocytes (FLS) was tested using immunofluorescence and flow cytometry, respectively. We also tested the inducibility of B1R on RA FLS by quantitative PCR and Western blotting. Western blotting was performed to test the role of B1R in sCD13 induced phosphorylation of signaling molecules in RA FLS, including use of the B1R antagonist, R715. Monocyte (MN) chemotaxis assays using a modified Boyden chamber were done to examine the effect of B1R antagonism on sCD13 induced MN migration. We also performed RA synovial tissue organ culture with a B1R antagonist, SSR240612 (SSR), and cytokines in the culture media were measured by ELISA. In vivo, B1R antagonists including R715 and SSR, or vehicle were injected intraperitoneally in C57Bl/6 mice daily for 9 days during induction of K/BxN serum-transfer arthritis, and ankle circumference was measured every day.

Results: B1R was found to be a potential receptor for sCD13 by GPCR screening. Following cross-linking of sCD13 to FLS, biochemical analysis showed a band that was identified by both anti-B1R and anti-CD13 at an apparent molecular mass consistent with the sum of the masses of sCD13 and B1R. Blockage of RA FLS with recombinant human CD13 decreased the binding of anti-B1R antibody to B1R on the FLS surface, confirming the binding of sCD13 to the same receptor. B1R was present in RA synovium and was highly expressed by RA FLS. Both TNF-α and IL-1β upregulated the expression of B1R in RA FLS, indicating B1R is inducible in inflammation. Blocking B1R with R715 reduced sCD13 induced phosphorylation of signaling molecules such as Erk1/2, and Akt in RA FLS. We also found that R715 inhibited sCD13 induced MN migration ($p< 0.01$). Synovial tissue organ culture showed that blocking B1R with SSR reduced the secretion of Monocyte Chemoattractant Protein-1 by RA synovium compared to non-treated ($p< 0.05$). In vivo, R715 or SSR suppressed the development of K/BxN serum-transfer arthritis as shown by significantly reduced ankle swelling compared to vehicle, starting from the 6th day ($p< 0.05$).

Conclusion: B1R is highly expressed in RA synovium and RA FLS and is inducible in inflammation. B1R is a receptor for sCD13 and mediates CD13 induced chemotaxis and signal transduction. The potent arthritogenic properties of sCD13 indicate that B1R could be an important pro-inflammatory receptor in both RA and an inflammatory arthritis mouse model, and also a compelling novel therapeutic target.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: RA – Etiology & Pathogenesis II

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Structural changes, increased tissue citrullination, signs of local inflammation and anti-citrullinated protein autoantibodies (ACPA) are present in the pulmonary compartment of early untreated seropositive rheumatoid arthritis (RA). These findings provide evidence of a potential role for the lungs in generation and initiation of RA-associated autoimmunity. Here we aimed to investigate the presence of citrulline-reactive B cells in the lung compartment of early untreated RA patients by single-cell cloning of monoclonal antibodies (mAbs) from lung-derived B cells.

Methods: Bronchoalveolar lavage (BAL) fluid cells were obtained from ACPA positive individuals with arthralgia (n=2) and early untreated ACPA positive RA patients (n=5) at the time of diagnosis.The demographics of the individuals included in the study are shown in Table 1.CD19+ B cells were single cell sorted by flow cytometry. Immunoglobulin heavy and light chain variable regions were PCR amplified, sequenced, and analyzed by V-Quest and IgBLAST towards the IMGT database to annotate variable gene usage. Sequences having high somatic hypermutations (SHM) and Fab N-glycosylation sites were selected to be cloned and expressed as humanIgG1 recombinant mAbs. Citrulline reactivity was determined by CCP2 assay and in-house ELISA against citrullinated and native peptides from vimentin, a-enolase, fibrinogen and filaggrin. Polyreactivity was determined by reactivity against double stranded DNA, bacterial lipopolysaccharides (LPS) and insulin.

Results: Significant numbers of B cells could be retrieved from the BAL. CD19+ B cells [n=6144, median(range): 960 (288-1248)] were single sorted from 5 early RA as well as 2 risk-individuals. PCR amplification and subsequent BCR sequencing from 2 of the early RA patients (n=1536 CD19+ B cells) yielded 192 and 213 paired heavy and light chain sequences. 44 monoclonal antibodies (22 from each patient) were selected for expression based on high number of SHM and predicted Fab N-linked glycosylation. Notably, four of the mAbs (9%; 2 antibodies from each patient) were determined to be ACPAs by CCP2 ELISA. The 4 ACPAs had varying ACPA fine-specificity against citrullinated a-enolase, filaggrin, vimentin and fibrinogen peptides (figure 1) without any native peptide binding (figure 1). All the 4 monoclonal ACPAs were negative in polyreactivity test. Sequence analysis of the heavy chain variable region revealed unique V gene usage of the ACPAs arising from different patients, V4-39 or V3-49.

	Early RA	Risk RA
No. of Subjects	5	2
Age	43 (28-77)	67 (65-67)
Male : Female	1:4	2:0
Non : Ex : Current Smoker	4:1:0	0:0:2
Cells obtained ($X 10^6$)	14.8 (13.0-22.5)	70.2 (66.6-73.8)

Table 1: Demographics of the individuals

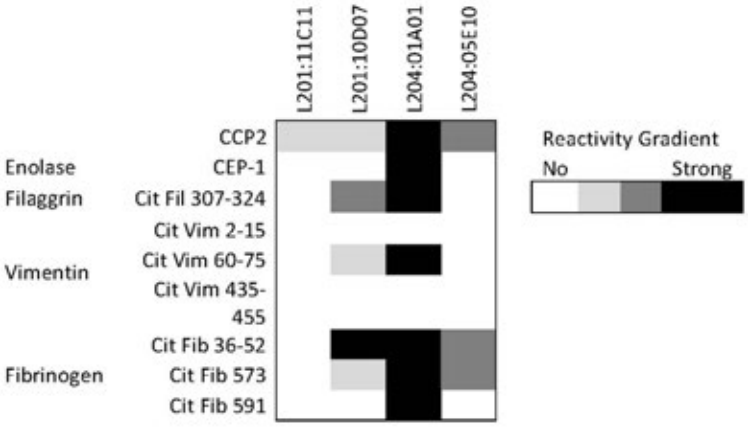

Figure 1. Heatmap showing reactivity of the 4 ACPA against various citrullinated antigens.

Conclusion: We demonstrate for the first time that citrulline-reactive B cells are present in the lung compartment of early untreated RA. This provides a strong link between the lung and the adaptive autoreactive response in RA, and support the hypothesis of the lung as one of the key sites of initiation and propagation of disease in RA.

Perturbation of the Human Gut Microbiome by Methotrexate Contributes to the Resolution of Inflammation and Autoimmune Disease

Renuka Nayak,[1] Margaret Alexander,[1] Kye Stapleton-Grey,[2] Carles Ubeda,[3] Jose Scher,[4] and Peter Turnbaugh[1], [1]UCSF, San Francisco, [2]Carnegie Mellon, Pittsburg, [3]Centro Superior de Investigación en Salud Pública - FISABIO, Valencia, Spain, [4]Division of Rheumatology, New York University School of Medicine and NYU Langone Orthopedic Hospital, New York, NY

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The trillions of microorganisms (microbiota) found within the human gut play a critical role in shaping the immune system, yet these complex microbial communities are also highly sensitive to numerous environmental factors. While much of the focus to date has been on dietary intake, emerging data has begun to suggest that the use of pharmaceutical drugs, even those that are not considered to be antibiotics, can alter the human gut microbiota with unknown consequences for treatment outcomes. Here, we examine the effect of methotrexate (MTX), which is first-line therapy for rheumatoid arthritis (RA), on microbiota composition and physiology as well as downstream consequences on the host's immune system.

Methods: To examine the effect of MTX on human gut microbiota composition *in vivo*, gnotobiotic mice were colonized with microbiota from either healthy or RA patient donors and treated with oral MTX at varying doses. We performed high-throughput sequencing of the 16S rRNA gene to examine changes in taxonomic composition. We looked at the effects of varying the route of administration or co-administration with folic acid. To determine the direct effects of MTX on bacterial growth, we treated monocultures of 42 different human gut isolates with MTX and monitored growth using optical density. To identify MTX-induced transcriptional changes, we performed RNA-Seq on 4 isolates treated with MTX. To determine the effects of MTX on bacterial taxonomy *in vivo*, fecal samples from RA patients (100% fulfilling ACR criteria) starting MTX were profiled longitudinally using 16S sequencing. To determine if MTX-induced shifts reduce the inflammatory potential of the RA microbiome, microbiota from RA patient donors either before or after MTX initiation were transplanted into germ-free mice. These mice were challenged with an inflammatory trigger with dextran-sodium sulfate (DSS), and immune profiling was done to assess inflammation.

Results: MTX altered community composition *in vivo* in humanized mice, leading to reduced Bacteroidetes and increased Firmicutes. Varying the route of drug administration or co-administration with folic acid produced similar, reproducible shifts. MTX directly altered growth of many human gut isolates. At the phylum level, Bacteroidetes tended to be more sensitive than Firmicutes, recapitulating the trends observed in gnotobiotic mice *in vivo*. RNA-Seq revealed that MTX alters transcriptional pathways involved in purine and pyrimidine metabolism. Furthermore, longitudinal analyses of the *in vivo* gut microbiotas of RA patients showed that MTX-induced shifts in bacterial relative abundance are associated with improved drug response. Transplant experiments revealed that mice harboring MTX-altered microbiota exhibited a reduced Th17 and Th1 response to DSS compared to mice harboring pre-treatment microbiota, suggesting that MTX alters the inflammatory potential of the RA patient microbiome.

Conclusion: Together, these results suggest that the mechanism-of-action of non-antibiotic drugs may be due in part to off-target effects on the gut microbiota, while providing a critical first step towards explaining long-standing differences in drug response between patients.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Systemic autoimmunity associated with RA precedes the onset of inflammatory arthritis (IA) by several years. In particular, the presence of systemic anti-cyclic citrullinated peptide (CCP) antibody is a strong predictor of developing classified RA in the future. However, the mechanisms involved in the transition from systemic anti-CCP to IA classifiable as RA are unknown. Our group has previously identified the local generation of anti-CCP and rheumatoid factor (RF) antibodies in the sputum of subjects at-risk for RA, including those with serum anti-CCP positivity. It has also been demonstrated that a portion of serum anti-CCP+ individuals have chronic lung disease preceding joint disease in RA. Herein, we aimed to determine the relationship between lung-related factors and the transition from systemic autoimmunity to classified RA.

Methods: In 49 subjects who were serum anti-CCP-IgG+ without IA, we collected baseline induced sputum using hypertonic saline. Baseline serum and sputum supernatant were tested by ELISA for CCP-IgG (CCP3, Inova), RF-IgM (Inova) and RF-IgA (Inova). Sputum antibody positivity was defined as a level above the 95th percentile in values determined from a separate cohort of 80 serum anti-CCP negative controls without IA. All subjects were followed longitudinally up to 3 years. Incident RA was determined by 2010 ACR/EULAR classification criteria. Chi-square and Wilcoxon rank-sum testing was used to compare factors associated with incident RA.

Results: Eight (16%) of 49 subjects developed classified RA during follow-up (median time to RA 14 months). Factors associated with developing RA are listed in the Table. Similar to previous data, we found that higher serum anti-CCP-IgG level (p=0.05) and serum RF positivity (p< 0.01) were associated with developing RA. In addition, we also found multiple lung-related factors associated with developing classified RA, including a self-reported history of any chronic lung disease (OR=7.6, 95% CI 1.2-48.4), sputum positivity for anti-CCP-IgG or 2 RF isotypes (RF-IgA and RF-IgM) (OR=12.0, 95% CI 2.2-66.3) and a trend toward an association with current smoking (OR=13.3, 95% CI 1.0-170.6). Of note, both current smokers who developed classified RA had sputum autoantibody positivity. When considering these lung factors in aggregate, incident RA was 15 times more likely in subjects with sputum RA-related antibodies or chronic lung disease (OR=14.6, 95% CI 14.4-87.7).

Table. Baseline clinical features, serologic biomarkers and sputum biomarkers associated with developing classified RA in serum anti-CCP-IgG positive individuals			
	Developed RA (N=8)	Did not develop RA (N=41)	p-value
Clinical Features			
Age, in years	57 (47-65)	60 (45-68)	0.72
Women	7 (88)	26 (63)	0.25
Ever smoker	4 (50)	13 (32)	0.42
Current smoker	2 (25)*	1 (2)*	0.07
Smoking pack-years	1 (0-5)	0 (0-1)	0.33
Chronic lung disease**	3 (38)	3 (7)	**0.05**
Study follow-up, in months	14 (10-17)	22 (12-35)	0.10
Serologic Biomarkers			
≥ 1 shared epitope allele	5 (63)	20 (49)	0.70
Serum anti-CCP-IgG level, in ELISA units***	150 (34-239)	40 (27-72)	**0.05**
Serum RF-IgA+ and RF-IgM+	4 (50)	1 (2)	**<0.01**
Sputum Biomarkers			
Sputum anti-CCP-IgG+	3 (38)	5 (12)	0.11
Sputum RF-IgM+	3 (38)	2 (5)	**0.03**
Sputum RF-IgA+	4 (50)	9 (22)	0.18
Sputum RF-IgM and RF-IgA+	3 (38)	0 (0)	**<0.01**
Sputum anti-CCP-IgG+ or Sputum RF-IgM and RF-IgA+	5 (63)	5 (12)	**<0.01**
Chronic lung disease or Sputum anti-CCP-IgG+ or Sputum RF-IgM and RF-IgA+	6 (75)	7 (17)	**<0.01**

All values are median (IQR) or N (%)

* The 2 current smokers who developed RA were sputum anti-CCP+ or RF-IgM+ and RF-IgA+. The 1 current smoker that did not develop RA was sputum anti-CCP and RF negative.

**The presence of chronic lung disease was based on questionnaire and self-report. In the group that developed RA, 2 reported asthma and 1 reported interstitial lung disease. In the group that did not develop RA, 2 reported asthma and 1 reported bronchiectasis.

*** Anti-CCP-IgG was measured using CCP3 (IgG, Inova) ELISA which has a positive cut-off level set by the manufacturer at ≥20 units.

Conclusion: In a cohort of serum anti-CCP+ subjects, we found that lung-related factors at baseline, including sputum anti-CCP, sputum RF isotypes and a history of chronic lung disease, were associated with developing classified RA within a short duration of follow-up (< 3 years). These data support that biological pathways in the lung may be important in transitions from systemic autoimmunity to arthritis in RA. Based on our findings, it will be particularly important to understand whether the generation of anti-CCP and RF in the lung is a mediating factor that links smoking and RA. In addition, 2 of 8 subjects who developed RA did not have sputum autoantibodies or chronic lung disease, which could suggest other mucosal site involvement in their transitions to RA.

Hypoxia Resistant Pathogenic B Cells Accumulate in the RA Synovial Tissue in a CXCR3 Dependent Manner

Achilleas Floudas,[1] Candice Low,[2] Monika Biniecka,[3] Kieran Murray,[2] Ronan Mullan,[4] Douglas Veale,[5] and Ursula Fearon[6], [1]Trinity Biomedical Sciences Institu, DUBLIN, Ireland, [2]Saint Vincent's University Hospital, Dublin, Ireland, [3]Molecular Rheumatology, Trinity Biomedical Sciences Institute, DUBLIN, Ireland, [4]Dept of Rheumatology, Tallaght University Hospital, TCD, Dublin, Ireland, [5]EULAR Centre For Arthritis And Rheumatic Diseases and The Conway Institute, Dublin, Ireland, [6]Molecular Rheumatology, Trinity Biomedical Sciences Institute, TCD, Dublin, Ireland

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of unknown and complex aetiology with severe detrimental effects for the patient's quality of life. While autoantibodies have been used extensively for the diagnosis of RA, no clear mechanism of action towards disease pathogenesis and progression has been identified. Importantly, both seropositive and seronegative RA patients experience significant improvement in disease severity following B cell depletion. Therefore, we hypothesized that B cells have a central, autoantibody independent, role in RA.

Methods: Synovial tissue biopsies from RA patients with paired blood/synovial fluid, were obtained through key-hole arthroscopy followed flow cytometric analysis of B cell subpopulations and chemokine receptor expression in the periphery and synovial tissue. Multiparametric SPICE analysis for the chemokine receptor expression (CXCR5, CXCR3, CCR7, CCR6. CCR4) of synovial tissue invading B cells was performed followed by B cell invasion assays. Functional characterization of RA sorted B cells, cultured *in vitro* in a hypoxia chamber simulating the unique environment of the inflamed joint. Characterization of B cell Glut1 expression and pSTAT3 was achieved by flow cytometric analysis and Western blot analysis. Glucose uptake inhibition by 2DG.

Results: There is a significant accumulation of $CD27^+$ and double negative ($CD27^-IgD^-$) memory B cells in the synovial tissue and synovial fluid of RA patients irrespective of ACPA status. SPICE analysis of peripheral blood B cells for a panel of chemokine receptors revealed a definitive bias towards a specific disease dependent chemokine receptor expression pattern, present from arthralgia-early in disease subjects. Tissue invading B cells showed a clear preference for the expression of CXCR3. Blockade of CXCR3 in invasion assays performed *in vitro* resulted in reduced B cell invasion in response to RA patient synovial tissue conditioned media. Importantly returning RA patient B cells following rituximab mediated B cell depletion express high levels of CXCR3. By simulating the unique hypoxic conditions of the inflamed joint, we observed significant alteration in B cell activation with RA B cells showing increased pro-inflammatory cytokine production and Glut1 expression. B cell Glut1 expression correlates with pSTAT3, while blockade of glucose uptake by 2DG abolishes RA B cell pro-inflammatory cytokine production under normoxic or hypoxic conditions.

Conclusion: The accumulation of pro-inflammatory B cell subpopulations in the synovium of RA patients, is CXCR3 mediated and offers an opportunity for early therapeutic intervention. Once in the hypoxic environment of the inflamed RA joint, B cells show altered activation, pro-inflammatory cytokine production and metabolism that could prove important for understanding the role of B cells in disease pathogenesis of RA.

Session Title: RA – Etiology & Pathogenesis II

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

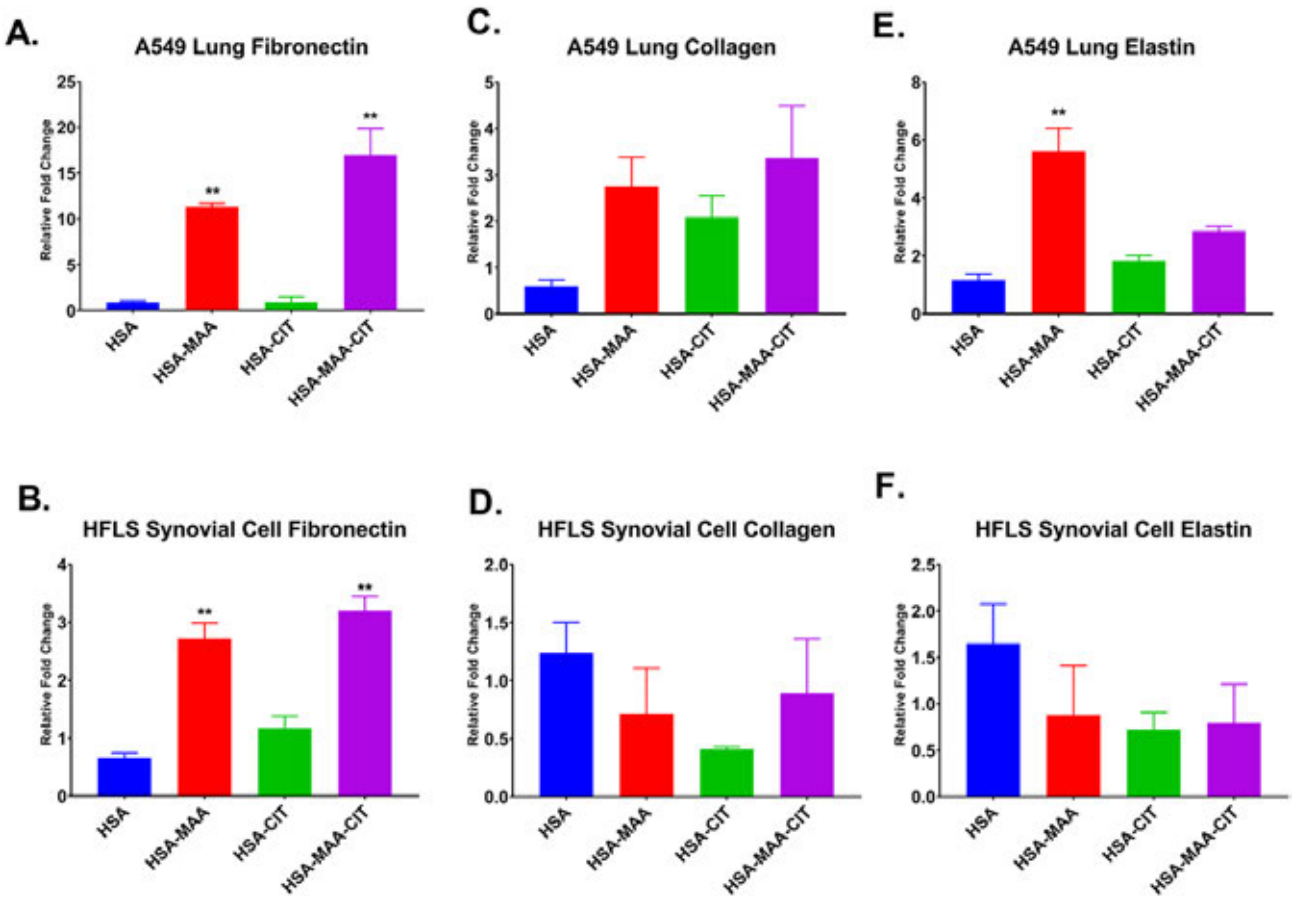

Figure 1. Increase in Extracellular Matrix Proteins in Lung and Synovial Cells. (A). Increased expression of fibronectin message in A549 cells. Significantly increased in HSA-MAA ($p<0.001$) and HSA-MAA-CIT ($p<0.001$) compared to HSA or HSA-CIT antigen stimulation. (B) Increased expression of fibronectin message in HFLS-RA cells. Significantly increased in HSA-MAA ($p<0.001$) and HSA-MAA-CIT ($p<0.001$) compared to HSA or HSA-CIT antigen stimulation. (C) No significant differences seen for Collagen expression in either A549 cells or (D) HFLS-RA cells. (E) Elastin expression was significantly increased ($p<0.001$) in only HSA-MAA stimulated A549 cells compared to all other treatments. (F) No significant increase in elastin was observed in the HFLS-RA cells. (N=6)

Background/Purpose: Recently we have shown that both malondialdehyde-acetaldehyde adducts (MAA) and citrullinated proteins (CIT) are co-localized in joint and lung tissues of patients with rheumatoid arthritis (RA). Therefore, to investigate the possibility that these post-translational modifications pose a synergistic pathogenic role in RA, human synovial fibroblasts and lung epithelial cells were exposed to MAA, CIT or the combination of MAA-CIT and the expression of extracellular matrix proteins (ECMP) were determined.

Methods: Human fibroblast-like synovial cells (HFLS) and lung epithelial cells (A549) were grown to confluency in 24-well plates. Following serum starvation, the cells were incubated with 25 μg/ml of human serum albumin (HSA), HSA-MAA, HSA-CIT, or HSA-MAA-CIT for 4 hours (n=5 each group). RNA was extracted from the cells and subjected to RT-PCR for expression of select ECMPs including fibronectin, collagen, and elastin.

Results: Stimulation with either HSA-MAA or HSA-MAA-CIT significantly increased fibronectin expression (mRNA) compared to stimulation with HSA or HSA-CIT in both the HFLS (Panel A) and A549 (Panel B) cell lines (Figure 1). Stimulation with HSA-MAA, HSA-CIT, and HSA-MAA-CIT did not significantly alter collagen expression in either cell line ($p > 0.05$; Panels C and D), although collagen expression was quantitatively increased with HSA-MAA, HSA-CIT, and HSA-MAA-CIT stimulation (vs. HSA alone) in the A549 lung cell line (Panel D). HSA-MAA stimulation significantly ($p < 0.001$) increased elastin expression in the A549 lung cell line as compared to all other groups (Panel E). Stimulation with HSA-MAA, HSA-CIT, and HSA-MAA-CIT (vs. HSA) did not significantly alter elastin expression in the HFLS cell line (Panel F).

Conclusion: Proteins that are MAA modified or MAA modified and citrullinated induce fibronectin expression in both lung epithelial cells as well as synovial fibroblasts. This effect appears to be particularly striking in lung epithelial cells where dually modified protein induced a ~15-fold increase in fibronectin exposure. While the impact of these protein modifications on collagen and elastin expression were more variable, these data suggests MAA and/or CIT modifications may expert relevant pathogenic (pro-fibrotic effects) in RA that could be both protein and site-dependent.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Belimumab (BEL) is the first treatment approved for children with systemic lupus erythematosus (SLE) from 5 years of age and older.[1] This approval was based on the PLUTO trial (NCT01649765), which was designed to assess the safety and efficacy of BEL in children with SLE.[2] Additional evidence to support the consistency of effect of BEL in children included an across-trial comparison of efficacy and safety in adult SLE with

	PLUTO (Pediatric)		BLISS-52 (Adult)		BLISS-76 (Adult)	
	PBO N=40	BEL 10 mg/kg IV N=53	PBO N=287	BEL 10 mg/kg IV N=290	PBO N=275	BEL 10 mg/kg IV N=273
SRI4 Wk 52 Response, n (%)	17 (43.6)	28 (52.8)	125 (43.6)	167 (57.6)	93 (33.8)	118 (43.2)
Difference BEL vs PBO (%) OR (95% CI)	9.24 1.49 (0.64, 3.46)		14.03 1.83 (1.30, 2.59)		9.41 1.52 (1.07, 2.15)	
SRI6 Wk 52 Response, n (%)	13 (34.2)	21 (41.2)	81 (28.2)	127 (43.8)	52 (18.9)	84 (30.8)
Difference BEL vs PBO (%) OR (95% CI)	6.97 1.35 (0.56, 3.22)		15.6 2.20 (1.51, 3.20)		11.9 2.00 (1.33, 3.01)	
Time to first severe flare over 52 wks HR (95% CI)	0.38 (0.18, 0.82)		0.57 (0.39, 0.85)		0.72 (0.50, 1.05)	

AIA, African or indigenous American descent; HR, hazard ratio; SELENA-SLEDAI, Safety of Estrogens in Lupus Erythematosus National Assessment-Systemic Lupus Erythematosus Disease Activity Index.
Note: Results of the BEL 1-mg/kg arms are not included from the adult studies as this is not a commercially approved dose. For BLISS-52 and BLISS-76, OR (95% CI) was calculated using a logistic regression for the comparison between BEL and PBO with covariates (baseline SELENA-SLEDAI score (≤9 vs ≥10), baseline proteinuria level (<2 g/24 hour vs ≥2 g/24 hour equivalent) and race (AIA vs Other). A Cox proportional hazards model was used for the comparison between BEL and PBO adjusting for baseline stratification factors. For PLUTO, OR (95% CI) was calculated using a logistic regression model for the comparison between BEL and PBO with covariates (treatment group, baseline age (5–11 vs 12–17), and baseline SELENA-SLEDAI score (≤12 vs ≥13). A Cox proportional hazards model was used for the comparison between BEL and PBO adjusting for baseline age (5–11 vs 12–17) and baseline SELENA-SLEDAI score (≤12 vs ≥13).

Table 1. Efficacy endpoints: PLUTO, BLISS-52, BLISS-76 (ITT population)

	Number (%) patients				
	PLUTO (Pediatric)		BLISS-52/BLISS-76/LBSL02 (Pooled adult)		
Patients with ≥1:	PBO N=40	BEL 10 mg/kg IV N=53	PBO N=675	BEL 10 mg/kg IV N=674	BEL (All doses) N=1458
AE	33 (82.5)	42 (79.2)	623 (92.3)	625 (92.7)	1354 (92.9)
Treatment-related AE	15 (37.5)	19 (35.8)	282 (41.8)	268 (39.8)	586 (40.2)
Serious AE	14 (35.0)	9 (17.0)	103 (15.3)	113 (16.8)	248 (17.0)
Death	1 (2.5)	0	3 (0.4)	6 (0.9)	11 (0.8)

Note: The category "All doses" includes the 1-mg/kg, 4-mg/kg, and the 10-mg/kg dose of belimumab.

Table 2. Adverse event summary: PLUTO, pooled adult trials (BLISS-52, BLISS-76, LBSL02)

the BLISS-52 (NCT00424476), BLISS-76 (NCT00410384), and LBS02 (safety only; NCT00071487) trials. Results are presented below.

Methods: The trials enrolled patients aged 5–17 years (PLUTO) and ≥18 years (BLISS-52 and BLISS-76) with a diagnosis of SLE, and active disease and seropositivity at screening. Patients were randomized to BEL 10 mg/kg given intravenously (IV) or placebo (PBO), plus standard of care (SoC) in PLUTO; and BEL 1 mg/kg or 10 mg/kg IV or PBO, plus SoC, in the BLISS trials. The primary endpoint across these trials was the SLE Responder Index 4 (SRI4) at Week (Wk) 52. Additional endpoints included SRI6 at Wk 52 (*post hoc* endpoint in the BLISS trials) and time to first severe

flare over 52 wks. An across-trial comparison (intent-to-treat [ITT]) of PLUTO, BLISS-52, and BLISS-76 summarizes the treatment effect of BEL IV plus SoC versus PBO plus SoC on SRI4 and SRI6 at Wk 52, reported as odds ratio (OR; 95% confidence interval [CI]), and time to first severe flare, reported as a reverse hazard ratio (95% CI). Safety analyses included adverse events (AEs), serious AEs (SAEs), and AEs of special interest (AESI) for PLUTO and pooled data from BLISS-52, BLISS-76 and LBSL02. The results of both the efficacy and safety across-trial comparisons are descriptive only.

Results: SRI4 and SRI6 responses at Wk 52 consistently favored BEL IV plus SoC. Reduction in the risk of severe flare was seen with BEL IV plus SoC versus PBO plus SoC in the PLUTO, BLISS-52, and BLISS-76 trials (**Table 1**). The incidences of patients experiencing ≥1 AE and ≥1 SAE in the PLUTO trial and the pooled safety data from the adult studies were similar (**Table 2**). With respect to AESI, there was no difference between treatment groups across the pediatric and adult studies in malignant neoplasms and post-infusion systemic reactions. The rate of all infection AESI was higher in PLUTO (PBO 7.5% and BEL 13.2%) compared with the adult studies (PBO 5.5%, BEL 10 mg/kg 4.7%), with an observed increase in herpes zoster events but no clinically meaningful differences in serious infections in PLUTO compared with the adult studies. There was no imbalance between treatment groups in depression/suicide/self-injury AESI in PLUTO, and the incidence was lower in the BEL group in PLUTO (1.9%) compared with that in the adult studies (BEL 10 mg/kg 8.8%).

Conclusion: The efficacy and safety of BEL IV plus SoC in children with SLE are consistent with those in the adult BEL study populations and support a favorable benefit/risk profile in ages 5 and older.

Study funded/conducted by GSK.

Application of Bayesian Statistics to Support Approval of Intravenous Belimumab in Children with Systemic Lupus Erythematosus in the United States

Ginto Pottackal,[1] James Travis,[1] Rosemarie Neuner,[1] Rebecca Rothwell,[1] Gregory Levin,[1] Lei Nie,[1] Jing Niu,[1] Anshu Marathe,[1] and Nikolay Nikolov[1], [1]FDA, Silver Spring, MD

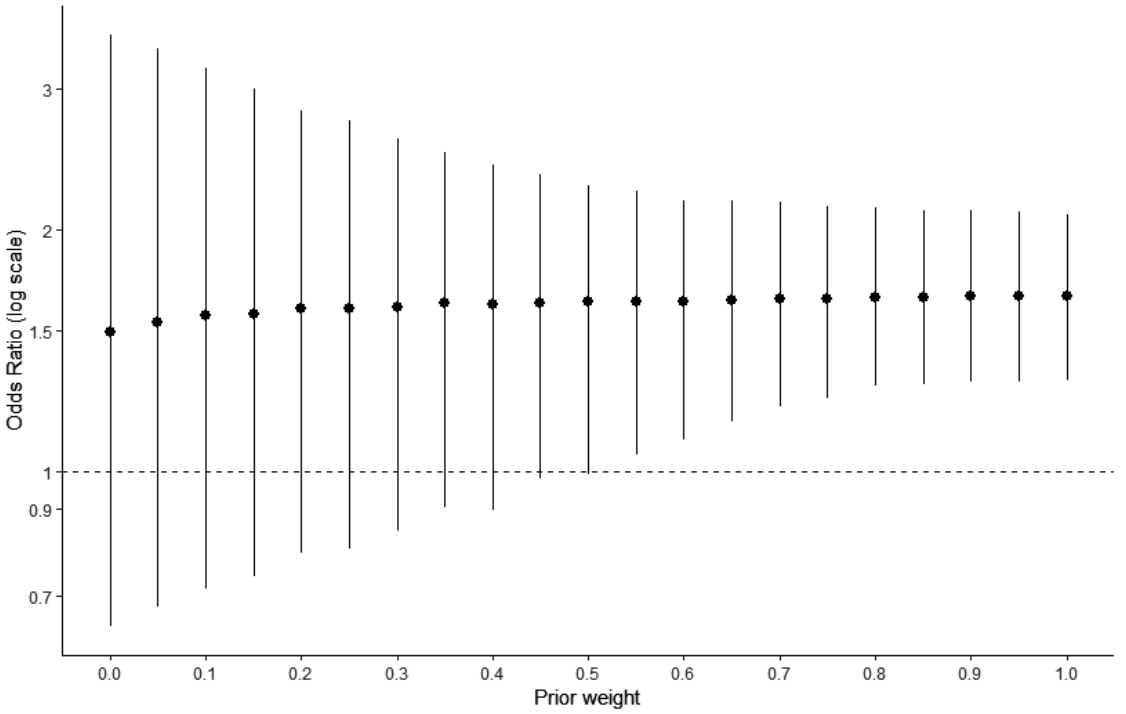
Session Date: Wednesday, November 13, 2019
Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Figure 1. Posterior Distribution of the Odds Ratio of SRI Response across Different Weight Value



Background/Purpose: In April 2019, FDA approved the first treatment, intravenous (IV) belimumab (BEL), specifically for children 5 to 17 years of age with active, seropositive SLE receiving standard care (SOC). The approval was supported by a single post-marketing required randomized, controlled trial (NCT01649765) that evaluated the efficacy, safety and pharmacokinetics (PK) of 10 mg/kg IV BEL vs placebo in 93 pediatric patients. Due to the rarity of childhood onset SLE limiting enrollment, by design, the study was not adequately powered to make formal statistical inferences on its own. Determination of efficacy was therefore based on PK and efficacy results from the study, as well as extrapolation of the established efficacy of IV BEL from the two phase 3 adult studies. To provide more reliable efficacy estimates in this context, FDA also employed a novel post-hoc Bayesian analysis which borrowed information from the phase 3 adult IV studies, under a reasonable assumption about the similarity between the adults and pediatric subjects.

Methods: A Bayesian logistic regression model was used to analyze the treatment effect in SLE Responder Index (SRI) response in pediatric patients, which adjusted covariates for treatment group, baseline SELENA SLEDAI score (< 13 vs. ≥ 13), and age group (5-11 vs. 12-17 years of age). A prior for the treatment effect in the pediatric population was constructed using a weighted combination of a skeptical prior and the treatment effect estimate distribution in adults, where the weight represented the degree of belief in the similarity of the pediatric and treatment effects estimated using two phase 3 adult studies.

Results: The key baseline disease characteristics and PK were similar between the pediatric and adult IV study populations. A plot of the point estimates and 95% credible intervals for varying weights is shown in Figure 1. A prior weight of 55% or larger provided 95% credible intervals that excluded an odds ratio of one, corresponding to a 97.5% posterior probability of efficacy (positive estimate of treatment effect) which is analogous to a rejection of the null hypothesis with a one-sided type I error of 0.025. These results were further supported by the secondary efficacy endpoints and safety, described in the FDA-approved belimumab labeling.

Conclusion: We applied a Bayesian approach to support approval of IV BEL, the first treatment for children with SLE in the United States. Given the similarity between the adult and pediatric populations and studies, a weight of at least 55% weight on the relevance of the adult information to the pediatric population is reasonable, ensuring that there is at least 97.5% posterior probability that belimumab 10 mg/kg has a positive treatment effect in pediatric subjects. The results of this unique analysis supported a conclusion that the treatment effect of IV BEL in the pediatric population favored BEL 10 mg/kg as compared to placebo under reasonable assumption. This innovative approach, especially if pre-specified, may help expedite clinical development in pediatric rheumatic diseases, and address some of the challenges with conducting trials in the setting of these rare conditions.

Factors Associated with Cardiac Dysfunction in a Longitudinal Follow-Up of Neonatal Lupus

Amit Saxena,[1] Peter Izmirly,[2] Rebecca Bomar,[3] Shireen Golpanian,[4] Deborah Friedman,[5] Ruth Eisenberg,[6] Mimi Kim,[7] and Jill Buyon[2], [1]New York University School of Medicine, New York, NY, [2]NYU School of Medicine, New York, [3]New York University School of Medicine, New York, NY, New York, [4]Miami Miller School of Medicine, Miami, [5]New York Medical College, Valhalla, [6]Albert Einstein College of Medicine, New York, [7]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Cardiac manifestations of neonatal lupus (NL) have been associated with significant morbidity and mortality, however there has been minimal information on long-term outcomes of affected individuals. This study was initiated to evaluate the presence of and risk factors associated with cardiac dysfunction in NL after birth in multiple age groups to improve counseling, further understand pathogenesis and provide potential preventative strategies.

Methods: Echocardiogram reports throughout life were evaluated in 239 individuals with cardiac-NL: 143 from ages 0-1 years, 176 from >1-17 years, and 64 >17 years. Cardiac dysfunction was defined as one or more of the following 1) qualitatively decreased left ventricular function on echocardiogram, 2) concurrent use of cardiac medications 3) heart transplant. Aortic dilation was defined as root or ascending aorta z-score >2.0. Multivariable logistic regression analyses were performed to evaluate associations of cardiac dysfunction at each age group with demographic, fetal and postnatal factors.

Results: Cardiac dysfunction was identified in 22.4% of children at ages 0-1, 14.8% ages >1-17 and 28.1% ages >17. In multivariable analysis of the age 0-1 group, female sex (OR 0.41, p=0.046), older age at the time of echo (OR 0.14, p=0.067) and higher in utero nadir ventricular heart rate (OR 0.95, p=0.077) were protective, while greater length of time paced (OR 10.82, p=0.035) was associated with increased odds of cardiac dysfunction. In the age >1-17 group, black race (OR 10.28, p=0.021), length of time paced (OR 1.31, p=0.039), in utero extranodal disease (OR 3.11, p=0.061) and a severity score representing overall fetal disease weighted by mortality risk factors (OR 1.17, p=0.048) associated with cardiac dysfunction. In those >17, a greater length of time paced (OR 1.29, p=0.018) and

the severity score (OR 1.42, p=0.037) were associated with dysfunction. In 106 children with echos at ages 0-1 and >1-17, 43.8% (95% CI: 19.8, 70.1%) of those with dysfunction at 0-1 were also affected at >1-17, while all others reverted to normal. Of those without dysfunction at ages 0-1, 8.9% (CI: 3.3, 16.8%) developed new dysfunction at >1-17 years. Among the 34 with echos at ages >1-17 and >17, 6.5% (CI: 0.8, 21.4%) with normal function at >1-17 developed dysfunction in adulthood. Aortic dilation was present in 13.5% at ages 0-1, 15.0% at >1-17, and 9.4% at >17. Of the 15 (14.3%; CI: 8.2, 22.5%) of 105 children with dilation at age 0-1, 9 (60.0%; CI: 32.2, 83.7%) still had dilation at >1-17, while the other 6 reverted to normal. Among the 90 cases without dilation at age 0-1, 8 (8.9%; CI: 3.9, 16.8%) developed dilation at >1-17 years. For the 34 children with echos at both >1-17 and >17, none had aortic dilation at age 1-17, with one (2.9%; CI: 0.1, 15.3%) developing dilation after 17.

Conclusion: Risk factors in early fetal life can influence cardiac morbidity into the adult years. Cardiac dysfunction in the first year normalizes by later childhood in the majority of cases, possibly due to the short-term effects of cardiac pacing or resolution of inflammation with the clearance of maternal autoantibodies. New onset dysfunction and aortic dilation, albeit rare, can occur de novo after the first year of life.

Nocturnal Blood Pressure Dipping as a Marker of Endothelial and Cardiac Function in Pediatric-onset Systemic Lupus Erythematosus

Joyce Chang,[1] Taylor Goldberg,[1] Sarah McGuire,[1] Lindsay Waqar,[1] Kevin Meyers,[1] Laura Mercer-Rosa,[1] Pamela F. Weiss,[1] and Andrea Knight[2], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: There is a need for clinically useful measures of cardiovascular (CV) risk in pediatric-onset SLE (pSLE). Nocturnal blood pressure (BP) non-dipping (loss of the physiologic nocturnal decline in BP) is a reversible

Table 1. Blood Pressure Categories by ABPM

	All (N = 18)	Nocturnal HTN	<10% Nocturnal Dip
	n (%)	n	n
Normal	10 (55%)	1	5
White coat hypertension	6 (33%)	0	3
Masked hypertension	1 (6%)	1	0
Unclassified*	1 (6%)	0	1
Totals		2 (11%)	9 (50%)

Blood pressure categories based on updated definitions from the 2017 AAP guidelines:
Nocturnal Hypertension: SBP/DBP load ≥ 50% by ABPM
White coat hypertension: Clinic BP ≥ 95th%ile but mean S24-hr BP/DBP < 95th%ile and SBP/DBP load < 25% by ABPM
Masked hypertension: normal clinic BP but mean 24-hr SBP/DBP > 95th%ile and SBP/DBP load ≥ 25% by ABPM
*Unclassified: elevated clinic BP (> 90th but < 95th%ile) with normal ABPM

Table 2. Factors Associated with Attenuated Nocturnal Blood Pressure Dipping

	Total (N = 18)*	Normal Dipping (N = 9)	Non-Dipping (N = 9)
Demographic Characteristics

*Pearson's correlation coefficients (*r*) estimating the relationship between percent nocturnal BP dipping and measures of arterial stiffness and cardiac function, at a significance level alpha of 0.10.
† Spearman rank correlations (*ρ*) were used to assess associations with BP load (% of total BP readings >95th%ile).
SBP = systolic blood pressure; DBP = diastolic blood pressure; PWV = pulse wave velocity (m/s); Aix = augmentation index (%); Aix@HR75 = augmentation index normalized to heart rate of 75 bpm; IVRTc = isovolumetric relaxation time (seconds) corrected for age
§ Left ventricular global peak circumferential strain; more negative strain values represent greater circumferential wall shortening during contraction.
† Digital reactive hyperemia index measured by EndoPAT; higher values correspond to better vasodilatory function of the endothelium

Methods: Twenty subjects 9-21 years of age with prevalent pSLE underwent comprehensive vascular testing, including 24-hour ABPM, peripheral endothelial function (EndoPAT), pulse wave velocity (PWV) for arterial stiffness, pulse wave analysis (PWA) for central BP, carotid ultrasound for intima-media thickness (cIMT), echocardiography for left ventricular (LV) strain and diastolic function, and fasting lipids. Additional clinical data was abstracted from charts, including longitudinal disease activity (SLEDAI-2K) scores. The primary outcome was prevalence of non-dipping (< 10% nocturnal decline in mean SBP or DBP). Secondary outcomes included prevalence of nocturnal and masked hypertension, defined by BP load (% of readings >95th%ile). We used descriptive statistics to assess patient characteristics in dippers and non-dippers. We used Pearson or Spearman rank correlation tests to evaluate relationships between SBP/DBP dipping, BP load and vascular measures.

Results: The majority of subjects had inactive disease at the time of assessment (median SLEDAI 2 [interquartile range 0-2]), with a mean disease duration of 2.9 years (±2.1). 18/20 ABPM studies were evaluable. Agreement between hypertension category by manual office BP and 24-hour ambulatory mean SBP/DBP was poor (kappa 0.08). The prevalence of non-dipping and nocturnal hypertension was 50% and 11%, respectively, which occurred even in the absence of white coat or masked hypertension (Table 1). Compared to subjects with normal dipping, non-dippers were more often from low-income households and still using glucocorticoids. They also tended to have higher body mass index and time-averaged cumulative disease activity (Table 2). Reduced SBP/DBP dipping correlated with poorer endothelial function, decreased myocardial shortening (less negative strain) and increased LV stiffness (prolonged isovolumetric relaxation) (Table 3). In contrast, higher BP load was strongly correlated with increased arterial stiffness and central BP, but not with endothelial or cardiac function.

Conclusion: In a racially diverse group of children and adolescents with pSLE with low disease activity, there is a high prevalence of nocturnal BP non-dipping even in the absence of systemic hypertension. BP load relates to arterial stiffness, whereas nocturnal BP dipping relates to subclinical LV strain and endothelial function, and therefore ABPM abnormalities may represent two distinct mechanisms of early CV disease in pSLE. There is a potential role for routine ABPM in cardiovascular risk stratification of youth with pSLE.

Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: DLE is a rare, disfiguring disorder in children. Small retrospective studies suggest 20-25% of patients progress to SLE. Progression risk factors are poorly understood, but DLE has been associated with delay in SLE diagnosis and reduced access to care. This multicenter retrospective cohort study aimed to describe baseline characteristics and clinical phenotypes of pediatric DLE patients at diagnosis.

Methods: Medical records at eighteen sites were reviewed for pediatric dermatology and rheumatology patients with DLE. For inclusion, patients required clinical and/or histopathologic findings consistent with DLE. Baseline data were collected at the first documented visit including sociodemographic data, ACR/SLICC SLE criteria (i.e. DLE+SLE), date of DLE onset/diagnosis, DLE distribution, family history, comorbidities, and treatment. Outcome variables included

Table 1. Baseline data for patients with DLE at diagnosis

	DLE n, (%)	DLE + SLE n, (%)	Total n, (%)	p-value
Female sex	185 (67)	133 (81)	318 (72)	**0.003**
Race/Ethnicity				
Asian	17 (16)	23 (14)	40 (9)	**0.006**
Black	88 (32)	65 (39)	153 (35)	0.1
Hispanic	69 (25)	27 (16)	96 (22)	**0.03**
White	67 (20)	20 (12)	87 (20)	**0.002**
Not Reported	38 (14)	29 (18)	67 (15)	
DLE distribution				
Localized	222 (81)	97 (59)	319 (73)	**<0.001**
Generalized	47 (17)	63 (38)	110 (25)	
Any family history of SLE	39 (14)	37 (22)	76 (17)	**0.03**

Bolded values represent statistically significant differences between patients with DLE vs DLE + SLE diagnosed at the baseline visit.

Table 2. Baseline clinical and laboratory characteristics based on ACR classification criteria for patients with DLE at diagnosis

ACR classification criteria	DLE n, (%)	DLE + SLE n, (%)	Total	p-value
Malar rash	12 (4)	75 (46)	87 (20)	**<0.001**
Photosensitivity	31 (11)	63 (38)	94 (21)	**<0.001**
Oral/nasal ulceration	10 (4)	63 (38)	73 (17)	**<0.001**
Non-erosive arthritis	7 (3)	77 (47)	84 (19)	**<0.001**
Pleuritis	0 (0)	9 (6)	9 (2)	**<0.001**
Pericarditis	0 (0)	10 (6)	10 (6)	**<0.001**
Seizures	0 (0)	7 (4)	7 (4)	**<0.001**
Psychosis	0 (0)	8 (5)	8 (2)	**<0.001**
Persistent proteinuria	7 (5)	48 (34)	55 (20)	**<0.001**
Cellular casts	2 (1)	28 (17)	30 (7)	**<0.001**
Hemolytic anemia	1 (0.4)	13 (8)	14 (3)	**<0.001**
Leukopenia	17 (8)	77 (49)	94 (26)	**<0.001**

Anti-La/SSB	13 (7)	41 (27)	54 (16)	**<0.001**
Anti-Ro/SSA	43 (23)	72 (47)	115 (34)	**<0.001**
Anti-Smith	10 (7)	100 (67)	110 (38)	**<0.001**
Anti-U1RNP	15 (12)	94 (65)	109 (40)	**<0.001**
Lupus Anticoagulant	4 (6)	31 (28)	35 (20)	**<0.001**

Bolded values represent statistically significant differences between patients with DLE vs DLE + SLE diagnosed at the baseline visit.

ACR (primary outcome) /SLICC SLE criteria. Rates of progression from skin-limited DLE (DLE) to SLE (DLE+SLE) were evaluated. Analysis included descriptive statistics, chi-square and Wilcoxon tests.

Results: Out of >1,000 patients reviewed, 441 met inclusion criteria. The cohort was predominantly female (72%) and racially/ethnically diverse (Table 1). A minority presented at baseline with SLE based on ACR and SLICC criteria, respectively (n=165, 37%; n=183, 42%). DLE+SLE patients were older (median 13.7y vs 10.2y) with shorter time from DLE onset to diagnosis (median 2 mo vs 7 mo), compared to DLE patients ($p< 0.001$). DLE patients presented with low incidence of renal involvement, serositis, seizures or psychosis ($p< 0.001$, Table 2). DLE+SLE patients had more positive serologies and higher-titer ANAs ($p< 0.001$, Table 3), although 5% were ANA negative. Among 231 DLE patients with³1 follow up visit, median follow-up was 2.7 y (range 0-13.9y) with 747 total subject-years. Progression to SLE occurred in 20% and 25% of patients based on ACR and SLICC criteria, respectively.

Conclusion: To date, this is the largest investigation of pediatric DLE. Patients with DLE + SLE were most likely to present in adolescence with abnormal serologies and end-organ disease. Progression of DLE to SLE occurred at rates consistent with previous literature. All patients with DLE require SLE surveillance at diagnosis and regular follow-up, particularly during adolescence. Limitations include the retrospective study design with potential for misclassification, and analysis restricted to the baseline visit. Further analysis of follow up visits will evaluate for baseline risk factors and biomarkers of evolving SLE, as well as timing of progression, identifying DLE patients at highest risk for systemic disease.

Access to Care and Diagnostic Delays in Juvenile Dermatomyositis

Jessica Neely,[1] Susan Kim,[1] Hugh Sturrock,[2] and **Julia Shalen** [2], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF, San Francisco

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Pediatric Rheumatology – Clinical III: Juvenile SLE & Dermatomyositis
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Factors associated with diagnostic delay in Juvenile Dermatomyositis (JDM) are not known. We hypothesized that limited access to pediatric rheumatologists can lead to delay in the diagnosis of JDM and worse outcomes. We investigated demographic factors, including access to care, associated with diagnostic delays and clinical outcomes of subjects with JDM in the Childhood Arthritis and Rheumatology Research Alliance (CARRA) Legacy Registry.

Methods: This was a cross-sectional study of JDM subjects enrolled in the CARRA Legacy Registry from 2010-2015. We used two measures of access to care: distance to care, calculated as miles by driving from subject zip code to treating rheumatology center using the R package "gmapsdistance", and state density of pediatric rheumatologists calculated as child population divided by number of pediatric rheumatologists. An ordered generalized additive model (GAM) was used to determine the association these two predictors, included as smoothed terms, and diagnostic delay adjusting for age, sex, income, and race. Delay was categorized as early (< 30 days), typical (1-3 mos), moderate (3-12 mos) and severe (>12 mos). The association between access to care and patient outcomes, including physician and parent global scores, childhood HAQ, and ACR functional class, was also assessed.

Results: A total of 464 JDM subjects were included in the analysis. The median time to diagnosis was 3.1 months (IQR 1.4-7.0). Moderate to severe diagnostic delay was found in nearly 52% of subjects. The median distance to care was 37.5 miles (IQR 17.0-90.3). The median density of children per pediatric rheumatologist was approximately 250,000 (IQR 147,000-399,000). In an ordered GAM, there was a modest association between greater delay in states with more children per pediatric rheumatologist (AIC decrease of 1.4, p = 0.060, Fig 1), a trend that was observed up to 500,000 children per rheumatologist, after which the confidence intervals widened due to few observations in very underserved states. Younger age at JDM onset was associated with diagnostic delay (OR 0.94 per year increase, p = 0.01), while having a household income >$150,000 compared to < $25,000 was protective (OR 0.47, p = 0.04). Non-black minority race compared to white race was also protective against delay (OR 0.43, p = 0.01). There was a modest trend toward having more functional limitation as measured by current ACR class of 2 or greater with increasing distance to care (AIC decrease of 0.9, p = 0.08, Fig 2).

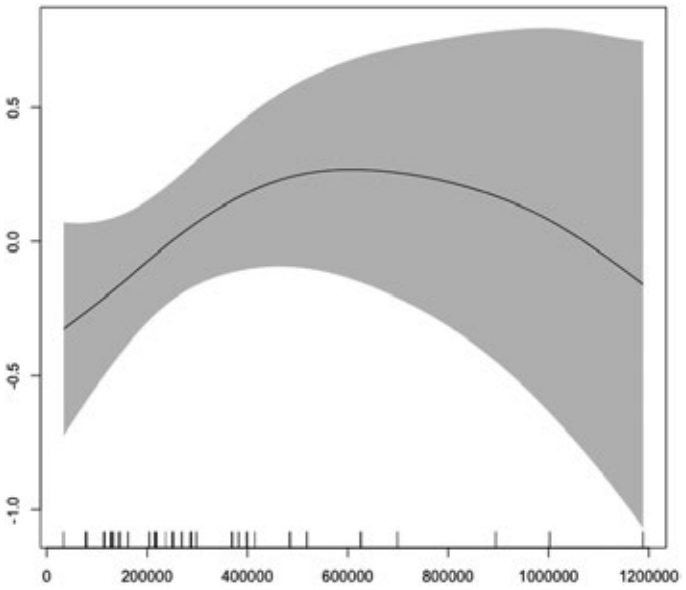

Figure 1. Log odds of increasing by one or more delay categories as number of children per rheumatologist increases. There are very few states with fewer pediatric rheumatologists than 1 per 500,000 children.

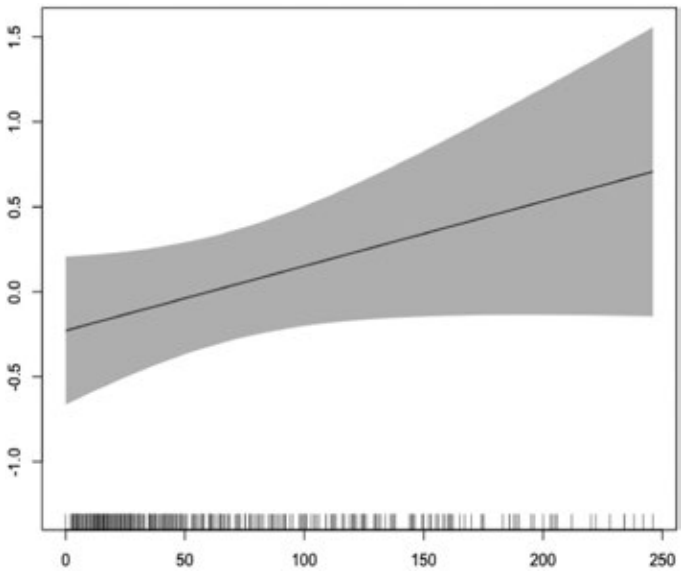

Figure 2. Log odds of increasing by one or more delay categories as distance from treating rheumatology center increases.

Conclusion: In the CARRA Legacy Registry, we found moderate to severe diagnostic delays in the majority of subjects with JDM. Our data suggests that access to care, measured as density of rheumatologist by state, is an important factor associated with delay in care but also highlights other contributing demographic factors, including younger age at disease onset and poverty. We also found a trend towards more functional limitation in patients with increasing distance to care. In addition to increasing the pediatric rheumatology workforce, efforts to increase awareness of rare conditions like JDM among general practitioners and subspecialists may help shorten referral time to pediatric rheumatologists and improve outcome in patients with JDM.

Persistence of B Cell-rich Synovitis Following Conventional Synthetic Disease Modifying Anti-Rheumatic Drug Treatment in Early Rheumatoid Arthritis Is Associated with Radiographic Progression Independently of Clinical Response

Felice Rivellese,[1] Gloria Lliso-Ribera,[2] Alessandra Nerviani,[1] Frances humby,[3] and Costantino Pitzalis[1], [1]Centre for Experimental Medicine & Rheumatology, Queen Mary University of London, London, United Kingdom, [2]Centre for Experimental Medicine & Rheumatology, Queen Mary University of London, London, [3]Queen Mary University of London, London, United Kingdom

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes V: Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Synovial B cell aggregates in patients with early Rheumatoid Arthritis (RA) have been associated with disease severity and radiographic progression. Here, we analysed the presence of B cells and their association with clinical outcomes in matched synovial biopsies pre- and post- treatment with conventional synthetic Disease Modifying anti-Rheumatic Drug (scDMARDs).

Methods: DMARD-naïve patients with early (< 12 months) RA (n=164) fulfilling the 2010 ACR/EULAR criteria were recruited as part of the Pathobiology of Early Arthritis Cohort at Barts Health NHS Trust. Patients underwent ultrasound-guided synovial biopsy at baseline (n=164) and 6 months after standard treatment with synthetic DMARDs (n=104). Sequentially-cut sections were stained by HE for semi-quantitative (SQ) assessment of synovitis and by IHC for SQ

Table 1

		Baseline biopsy n=143#			6 months biopsy n=104#

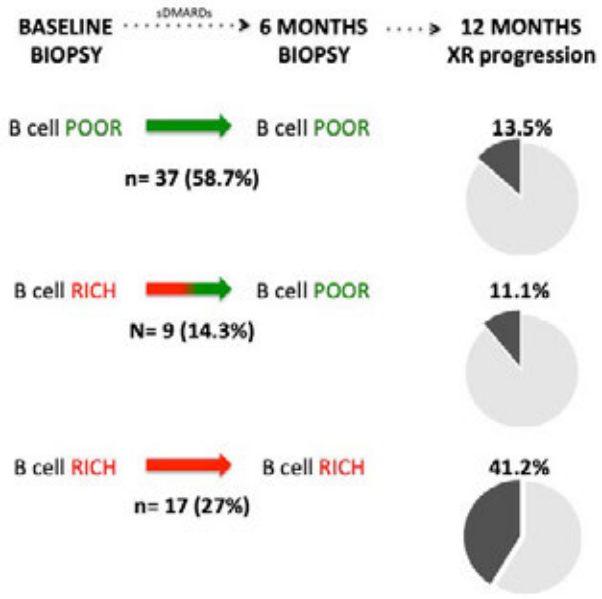
excluding patients with ungraded synovial biopsy samples;



assessment of CD20+ B cells (0-4) and classification into B cell-rich (≥2) or poor (< 2). X rays at baseline and 12 months underwent scoring for erosions and joint space narrowing, with radiographic progression defined as an increase in total score ≥ 1.

Results: At baseline, patients classified as B cell-rich (35%) had significantly higher disease activity, inflammatory markers, autoantibody positivity and synovitis score when compared to B cell-poor (Table 1). There were no differences between B cell-rich and poor patients in terms of drug exposure and EULAR clinical response at 12 months. However, patients with B cell-rich synovitis had a significantly higher rate of radiographic progression at 12 months. At the 6 months repeated synovial biopsy, 21.2% of the patients had B cell-rich synovitis, which still associated with ACPA positivity and higher synovitis score but not with other clinical features, including the use of csDMARDs and clinical response at 12 months. However, patients with a B cell-rich synovitis at 6 months showed significantly higher rates of radiographic progression at 12 months. Upon assessing the change of B cell infiltrates between 0 and 6 months, patients with a reduction in synovial B cell score (from B cell rich to poor) had a lower rate of radiographic progression compared to patients with persistent B cell-rich infiltrate (Figure 1).

Conclusion: We here confirm that B cell-rich synovitis in early RA patients is associated with disease severity and radiographic progression, particularly when the B cell-rich synovial infiltrate persist after 6 months treatment with csDMARDs, independently of the clinical response. This suggests that the presence of B cell-rich synovitis represents an important prognostic factor in RA.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes V: Treatment
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The last 25 years, treatment of rheumatoid arthritis (RA) has changed considerably. Although clinically relevant joint damage has become infrequent, it is less established to what extent other long-term outcomes have improved. Moreover, anti-citrullinated anti-bodies (ACPA)-positive and ACPA-negative disease subsets were discovered and it is unknown they have benefited equally from these improvements. Therefore our aim was to investigate the influence of improved treatment strategies on disease activity (DAS), sustained drug-free remission (SDFR) and functional disability, and if this differed for ACPA-positive and ACPA-negative RA-patients.

Methods: In the Leiden early arthritis cohort, consecutive patients with RA (1987 criteria) were included between 1993-2016. Patients were treated in routine care; initial and subsequent treatment changed over time; divided in 5 inclusion periods: 1993-1996 delayed mild disease modifying anti-rheumatic drug (DMARD) initiation; 1997-2000 early

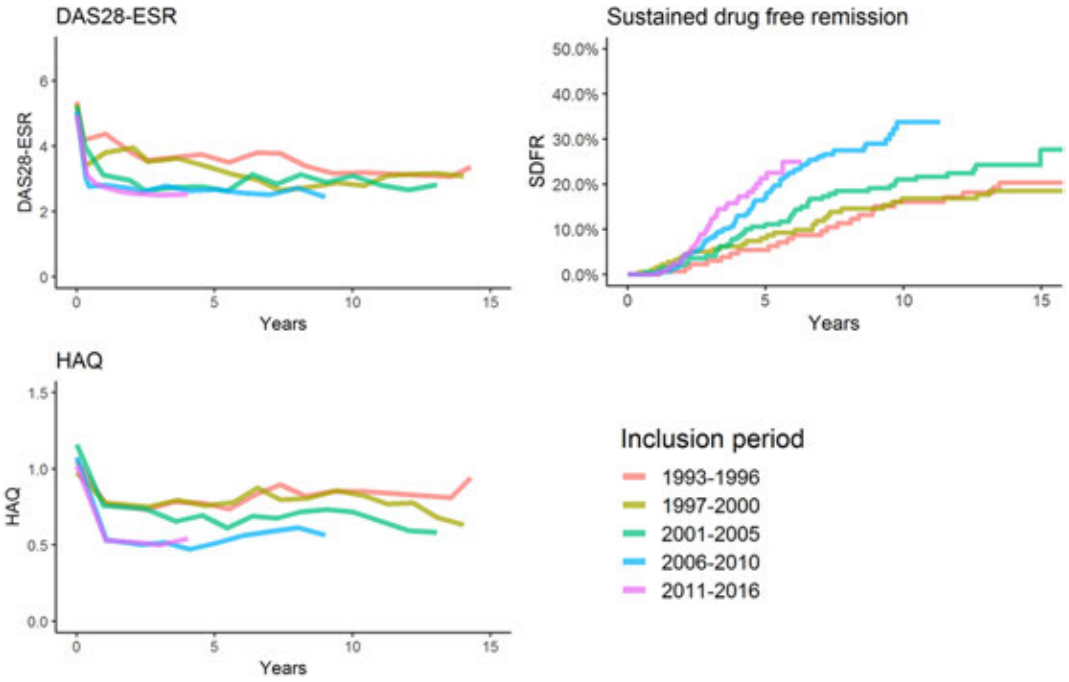

Figure 1. Outcomes over time stratified per inclusion period Legend: For DAS28-ESR and HAQ mean values of imputed data from visits that were attended are shown; When <15% of patients attended the visit, lines were truncated.

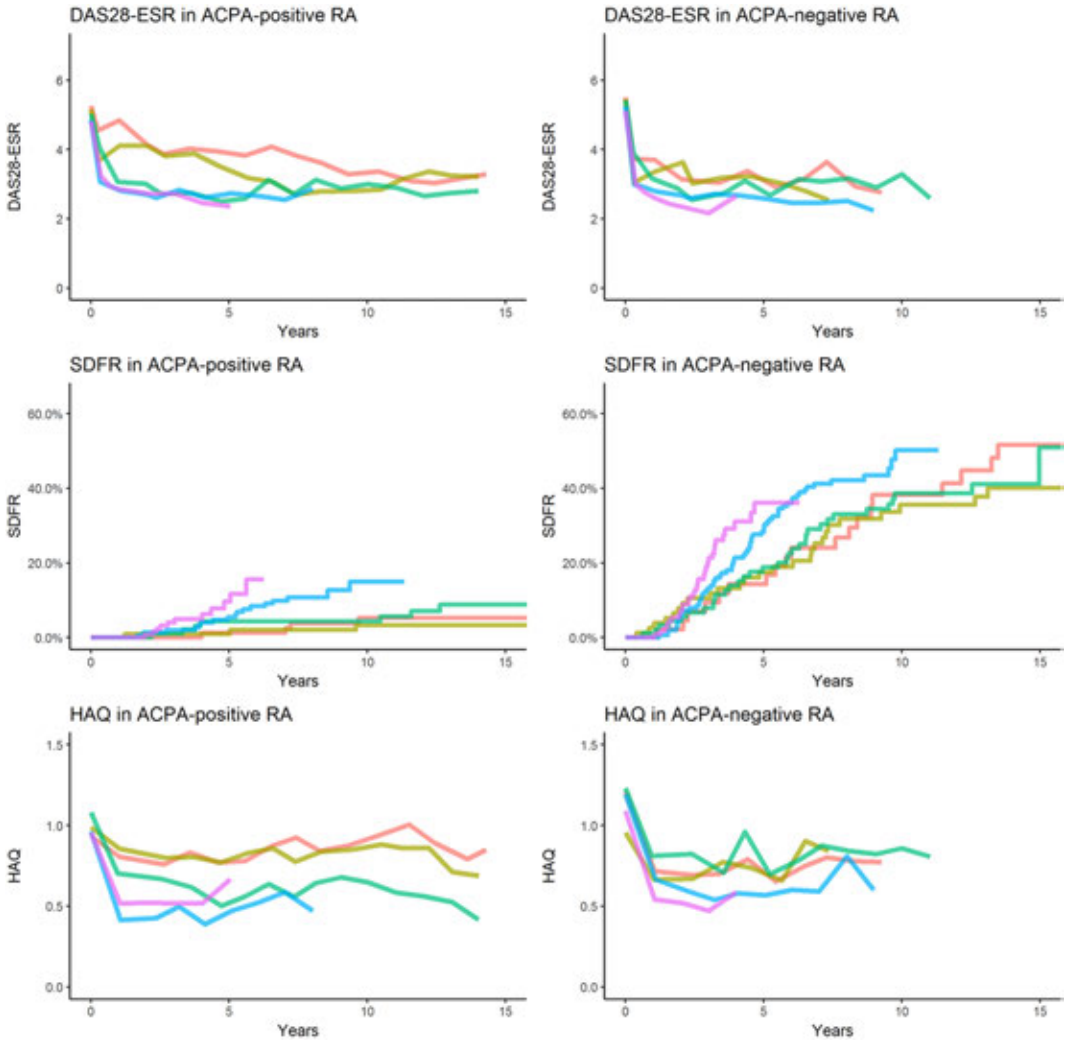

Figure 2. Outcomes over time stratified per inclusion period and ACPA-status Legend: Inclusion periods: Red: 1993-1996; Yellow: 1997-2000, Green 2001-2005, Blue 2006-2010, Purple 2011-2016. RA: Rheumatoid Arthritis; SDFR: Sustained drug-free remission. For DAS28-ESR and HAQ mean values of imputed data from visits that were attended are shown; When <15% of patients attended the visit, lines were truncated.

mild DMARDs; 2001-2005 early methotrexate; 2006-2010 early methotrexate followed by treat-to-target treatment adjustments; 2011-2016 idem plus additional efforts for very early referral.

SDFR was defined as persistent absence of synovitis after DMARD-cessation and was determined during all follow-up. Disease activity was measured yearly by the DAS28-ESR and functional disability by health assessment questionnaires (HAQ) and analysed with linear mixed models; time to SDFR with Cox regression. Analyses were stratified for ACPA (IgG anti-CCP2).

Results: In total 1291 RA-patients were included (168, 185, 210, 338 and 390 in the respective inclusion periods); baseline age, gender and ACPA-status were similar. All outcomes improved significantly over time (Figure 1) and this differed between ACPA-positive and ACPA-negative patients (Figure 2). In the reference period (1993-1996), ACPA-positive RA had worse outcomes than ACPA-negative RA in DAS (Difference of 0.81 points (0.48;1.13)), SDFR (HR 0.07 (0.02;0.21)) and HAQ over time (Difference of 0.15 points (-0.02;0.32)). Compared to the reference period, DAS improved gradually and significantly in ACPA-positive RA whereas the improvement was significantly less in ACPA-negative RA. SDFR-rates increased significantly in ACPA-positive RA, whereas there was no significant improvement in ACPA-negative RA. Functional disability over time improved more in ACPA-positive RA (improvement of -0.18

points in 2001-2005, -0.35 in 2006-2010 and -0.29 in 2011-2016) than in ACPA-negative RA (improvement of -0.19 in 2011-2016). In the most recent inclusion cohort (2011-2016), HAQ was similar in ACPA-positive and ACPA-negative RA. SDFR rates had become more similar although they remained higher in ACPA-negative RA.

Conclusion: ACPA-positive RA, traditionally the most severe RA-subset, benefited most from the improvements in treatment strategies, whereas ACPA-negative RA benefited little; This further demonstrates that these are indeed separate disease subsets that deserve equal attention.

Risk of 30-day Readmission and Adverse Events After Primary Hip or Knee Arthroplasty: A Comparison of Patients with Rheumatoid Arthritis versus Osteoarthritis Using the Nationwide Readmission Database

Ali Yazdanyar,[1] Anthony Donato,[2] Kathleen McElwee,[3] Mary Chester Wasko,[4] and Michael Ward[5], [1]Lehigh Valley Hospital- Cedar Crest, Allentown, PA, [2]Reading Hospital, PA, Reading, [3]Reading Hospital, Reading, PA, [4]Allegheny Health Network-West Penn Hospital, Pittsburgh, PA, [5]NIAMS, Bethesda, MD

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes V: Treatment
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: To assess the risk of 30-day readmission, mortality, and adverse events among adults with Rheumatoid Arthritis as compared to Osteoarthritis after primary hip or knee arthroplasty.

Methods: We identified index hospitalizations with a principal procedure of primary HA or KA using a nationally representative U.S. sample, the Nationwide Readmission Database (2010-2013). Excluded were persons aged < 18 years or who did not survive the index hospitalization. The principal procedure and diagnoses were identified using

Table of Abbreviations	
RA	Rheumaoid Arthritis
OA	Osteoarthritis
HA	Total or Partial Hip Arthroplasty
KA	Total Knee Arthroplasty
CAD	Coronary Artery Disease
VHD	Valvular Heart Disease
CHF	Congestive Heart Failure
CKD	Chronic Kidney Disease
PVD	Peripheral Vascular Disease
AKI	Acute Kidney Injury
COPD	Chronic Obstructive Pulmonary Disease
OR	Odds Ratio
CI	Confidence Interval

ICD-9 codes. Using survey logistic regression, we calculated the unadjusted and adjusted risk of 30-day readmission, all-cause mortality, and composite adverse events which included infections, cardiovascular events, venous thromboembolic events, mechanical complications, and AKI, after adjusting for age, sex, and major comorbidities.

Results: There were 1,977,214 index hospitalizations of which 10,802 were in persons with RA and 1,966,413 in persons with OA. Persons with RA were older (66.9 vs. 65.6; P< 0.01), more likely to be women (80.7% vs. 59.5%; P< 0.01), and to have existing comorbid conditions of CAD (10.0% vs. 8.0%;P< 0.01), chronic CHF (2.4% vs. 0.6%;P< 0.01), CKD (6.6% vs. 3.8%; P< 0.01), cancer (1.6% vs. 0.9%; P< 0.01), PVD (3.1% vs. 1.4%; P< 0.01), and COPD (20.8% vs. 14.0%; P< 0.01). There were 68,897 (3.5%) 30-day readmissions. The readmission rate was higher among persons with RA compared to OA (7.1% vs. 3.5%; P< 0.001). Stratified readmission rates for RA versus OA were (9.3% vs. 3.4%; P< 0.001) and (4.2% vs. 3.5%; P=0.18) in HA and KA, respectively. The adjusted OR for readmission was 2.06 [95% CI: 1.75,2.42], all-cause mortality 9.87 [95% CI:5.02,19.41], and composite event 2.29 [95% CI:1.81,2.89]. In analyses stratified by procedure type, the adjusted OR post-HA for readmission was 2.35 [95% CI: 1.94,2.83], all-cause mortality 6.16 [95% CI:2.96,12.82], and composite event 2.32 [95% CI:1.79,2.99] while post-KA the risk of readmission was 1.36 [95% CI: 1.02,1.80], all-cause mortality 13.81 [95% CI:3.35,56.90], and 1.78 for composite event [95% CI:1.14,2.78]. The overall adjusted risk for mechanical complications [OR:4.38; 95% CI:2.56,7.47], all-type infections [OR:2.23; 95% CI:1.71,2.92], and AKI [OR:3.78; 95% CI:1.41,10.13] was higher in RA while the risk for CVD [OR:1.73; 95% CI:0.77,3.87], DVT/PE [OR:0.95; 95% CI:0.45,2.02], or surgical site infections [OR:1.51; 95% CI:0.98,2.31] did not differ relative to OA. In stratified analyses, the risk for AKI and all-type infections was higher among persons RA in both procedure types while the risk for mechanical complications was only significant in HA [OR:1.99; 95% CI:1.14,3.47].

Conclusion: After primary joint arthroplasty, the 30-day rehospitalization, all-cause mortality, and composite events were more likely among persons with RA relative to OA, even after accounting for demographics and major comorbidities. All-type infections and acute kidney injury were more likely among person with RA after both hip and knee arthroplasty, while mechanical complication was significantly higher in persons with RA as compared to OA only after hip arthroplasty.

Session Time: 9:00AM–10:30AM

Table 1

Antibiotic use as mean number of prescriptions (NP) and defined daily dose (DDD), per individual, two years before and after TNFi therapy.

	NP		DDD	
	RA *n = 366*	**Control** *n = 1830*	**RA** *n = 366*	**Control** *n = 1830*
Antibacterial *before TNFi*	2.6 ± 3.3	1.5 ± 2.4	33.4 ± 70.9	17.3 ± 34.9
after TNFi	3.2 ± 3.6**	1.5 ± 2.4	34.7 ± 58.7	17.4 ± 39.2
Antifungal *before TNFi*	0.16 ± 0.7	0.06 ± 0.5	0.43 ± 2.9	0.13 ± 1.2
after TNFi	0.25 ± 1 *	0.08 ± 0.4	0.78 ± 4.6*	0.23 ± 1.9
Antivirals *before TNFi*	0.05 ± 0.47	0.06 ± 0.45	0.36 ± 3.4	0.3 ± 3.3
after TNFi	0.15 ± 0.73**	0.06 ± 0.64	0.77 ± 4*	0.33 ± 3.6

*p<0.05; **p<0.001 by Wilcoxon-squared test

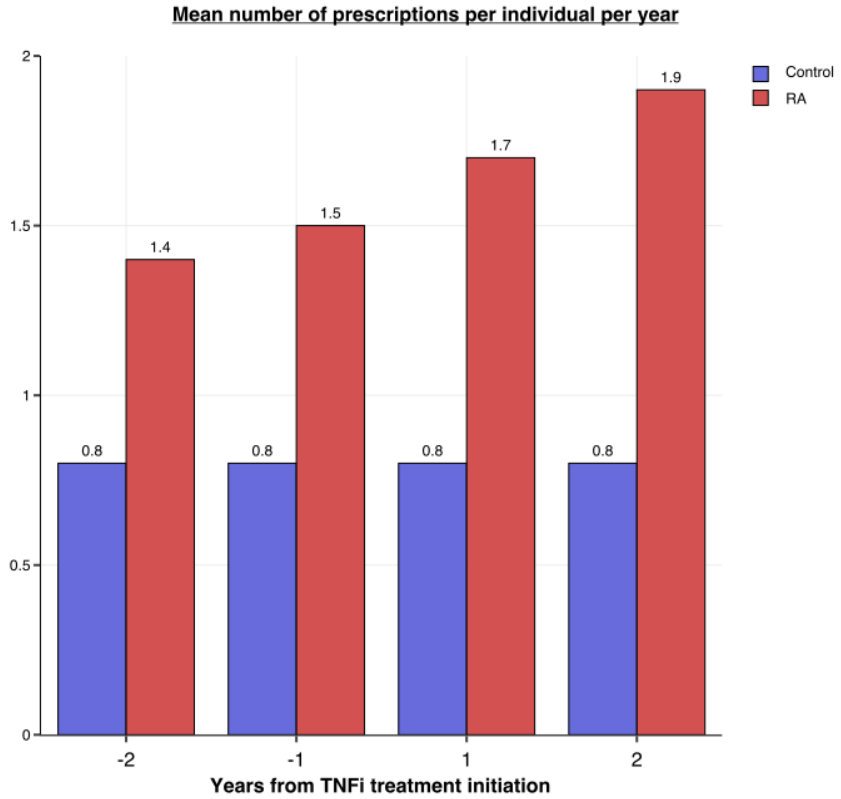

Figure 1. Antimicrobial use as mean yearly number of prescription per individual in relation to initiation of TNFi therapy (baseline). Patients with RA (red) received significantly higher number of prescriptions compared to controls (blue). Antimicrobial usage in patient with RA increased through the two-year period following TNFi therapy.

Background/Purpose: Severe infections, frequently resulting in hospitalization, are a well-known adverse effects of tumor necrosis factor inhibitors (TNFi). However, studies regarding outpatient treated infections are needed.

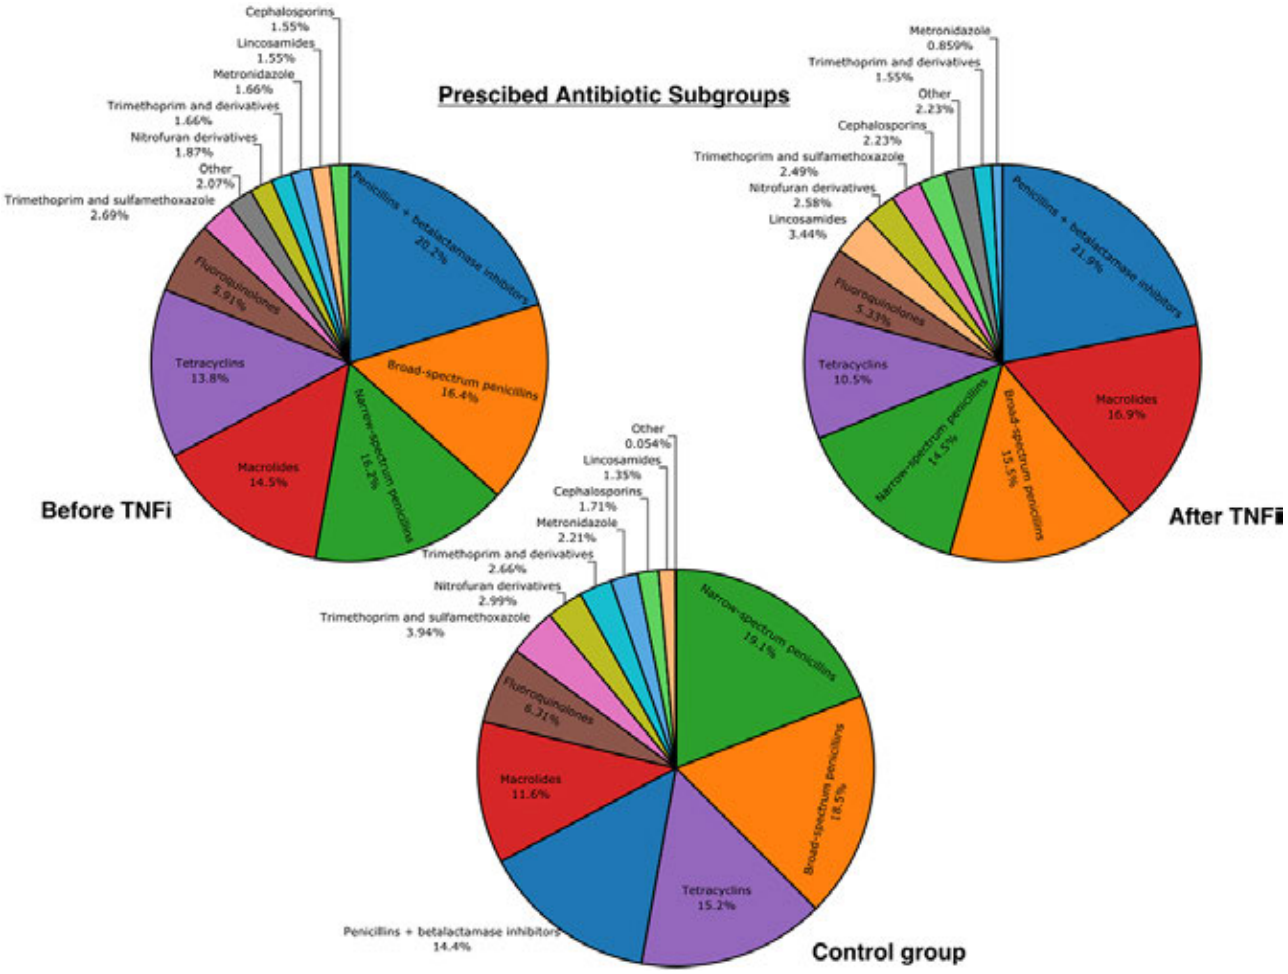

Figure 2. Pie chart of prescribed antibiotic subgroups as defined by the Anatomical Therapeutic Chemical (ATC) classification system. Prescription patterns are similar before (upper left) and after (upper right) initiation of TNFi therapy. Below is the pie chart for the control group.

Our objective was to investigate the use of antimicrobials (antibiotics, antifungals and antivirals; excluding antimycobacterials) in patients with rheumatoid arthritis (RA) and the effect of initiation of TNFi in biologic-naïve patients.

Methods: Over 98% of patients with inflammatory arthritides who are treated with biologic DMARDs in Iceland are registered in ICEBIO, a nationwide registry. On February 1st 2016, ICEBIO contained information on 1058 individuals. Information about all biologic-naïve patients with RA was extracted and each patient matched on age, sex and calendar time to five randomly selected individuals. All filled antimicrobial prescriptions in the two years before and after initiation of first TNFi were extracted from the Icelandic Medicine Database (IMD), a registry that includes over 95% of all filled prescriptions in Iceland. Antimicrobial use was quantified using the number of filled prescriptions (NP) and defined daily dose (DDD). NP and DDD are shown as individual means per two years before and after TNFi therapy.

Results: We extracted information on 366 patients with RA and 1833 controls. Patients with RA received nearly twice the number of antimicrobial prescriptions compared to controls before TNFi therapy (2.9 vs 1.6 NP; $p< 0.001$, figure 1). After initiation of TNFi the mean NP for RA patients increased (2.9 to 3.6; $p< 0.001$) and further increased over a two-year period (figure 1); antibiotics 2.6 to 3.2 ($p< 0.001$), antivirals 0.06 to 0.15 ($p< 0.001$) and antifungals 0.16 to 0.25 ($p< 0.05$) (table 1). Conversely, DDD of antibiotics was stable (33.4 to 34.7; $p >0.1$). However, DDD for both antivirals and antifungals increased ($p< 0.05$). After TNFi initiation, antifungal usage increased predominantly in women (0.4 to 0.84 DDD; $p< 0.05$) and antivirals in men (0.00 to 0.82 DDD; $p< 0.05$). No correlation was found between NP

and age, BMI or baseline DAS28-CRP. However, a minor positive correlation (r 0.2) was between NP and HAQ score at beginning of TNFi therapy. Patients with HAQ score higher than 2.0 received significantly higher NP after TNFi therapy (3.1 vs 5.7 NP; p< 0.001). No difference was found between smokers and non-smokers (3.1 vs 3.8; p=0.38). Interestingly, mean DDD per prescription decreased after initiation of TNFi (14.5 to 10.2 DDD, p< 0.001). Physicians selection of antibiotics did not appear to change after TNFi treatment (figure 2).

Conclusion: Patients with RA use significantly more antimicrobials two years antedating TNFi treatment compared to controls. TNFi treatment further increases antimicrobial use in patients with RA and usage increased throughout the two-year period. This contrasts the literature regarding hospital admissions due to infections, where admissions frequency peaks the first year after TNFi treatment, but then decreases with TNFi treatment duration[1]. High HAQ score at the start of TNFi treatment was related to increased antimicrobial usage following TNFi therapy.

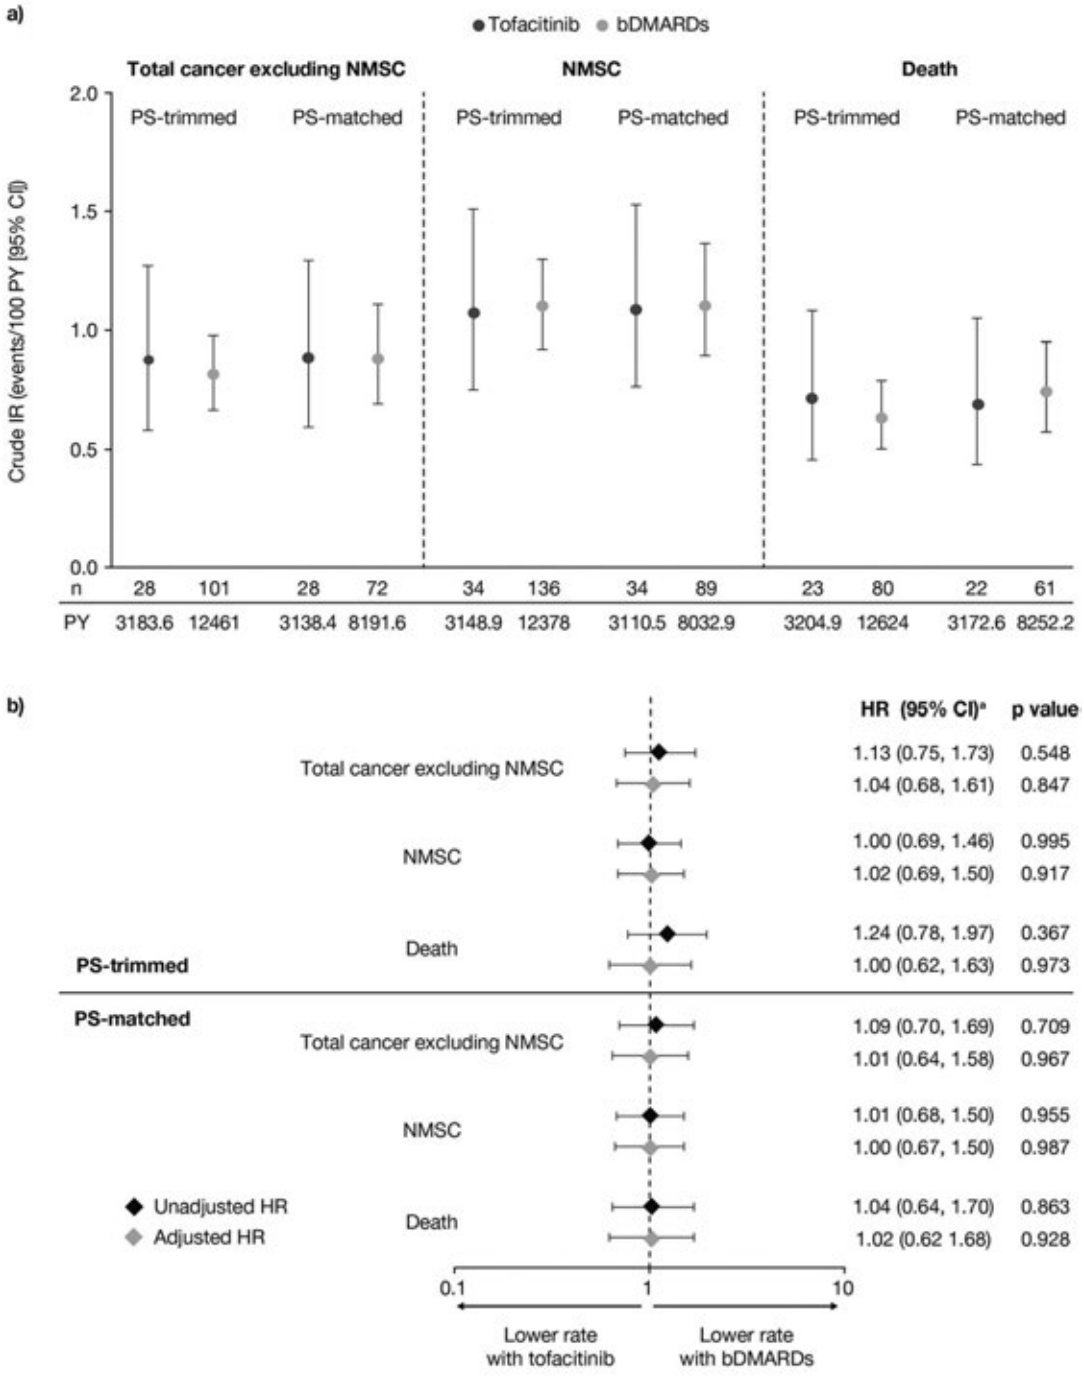
SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes V: Treatment
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Real-world evidence (RWE) is key to understanding post-approval long-term safety of medications. Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. A prospective observational 5-year study, embedded within the US Corrona RA registry, was initiated to evaluate the safety of tofacitinib after US Food and Drug Administration approval on Nov 6, 2012. The objective of this analysis was to compare 5-year incidence rates (IRs) of malignancy and mortality in patients (pts) initiating tofacitinib vs biologic (b)DMARDs using US Corrona RA registry cohorts.

Methods: This prospective, observational 5-year study derived from the ongoing US Corrona RA registry routinely collects structured safety data on serious adverse events (AEs) and AEs of interest from investigators. IRs (no. of events/100 pt-years [PY]) of total cancer (excluding non-melanoma skin cancer [NMSC]), NMSC, and death were compared using propensity score (PS) methods to adjust for non-random treatment assignment among RA pts who newly initiated tofacitinib (US approved dose 5 mg twice daily) or a bDMARD regardless of dose/schedule between Nov 6, 2012 and July 31, 2018 (follow-up through Jan 31, 2019). Sufficient malignancy and mortality events occurred

Figure 1. a) Crude IRs (events/100 patient-years) for total cancer excluding NMSC, NMSC, and death, and b) HRs for total cancer excluding NMSC, NMSC, and death



[a]bDMARD initiators were the reference population for calculation of HR
bDMARD; biologic disease-modifying antirheumatic drug; CI, confidence interval; HR, hazard ratio; IR, incidence rate; NMSC, non-melanoma skin cancer; PS, propensity score; PY, patient-years

to provide 80% power to detect a hazard ratio (HR) of 2.0. Baseline variables with standardized difference > | 0.10 | between cohorts and *a priori* selected covariates (gender, age, line of therapy, history of AE of interest) were used to derive PS-trimmed (primary analysis) and PS-matched populations (ratio: max. 4 bDMARD:1 tofacitinib; caliper=0.05). Analyses used a 'once exposed, always exposed' approach following patients from therapy initiation until an AE of interest, loss to follow-up, or end of data collection period, whichever came first; follow-up continued if a patient discontinued or switched therapy. Multivariable-adjusted Cox regression was used to estimate HRs of first events between cohorts.

Results: In total, 1999 tofacitinib (4505.62 PY) and 6354 bDMARD (16670.84 PY) initiators were included. Following PS trimming, analyses for total cancer excluding NMSC, NMSC, and death, respectively, included 1420/1419/1419 tofacitinib initiators, and 4820/4820/4821 bDMARD initiators. Of tofacitinib and bDMARD initiators, respectively, 88% and 59% had prior bDMARD use. IRs of all three outcomes were similar in both cohorts; the adjusted HR (95% confidence interval [CI]) was 1.04 (0.68, 1.61) for total cancer excluding NMSC, 1.02 (0.69, 1.50) for NMSC, and 1.0 (0.62, 1.63) for death (Figure 1). Similar results were observed in PS-matched populations.

Conclusion: To our knowledge, this is the first comparative RWE for tofacitinib and bDMARDs to use PS-trimmed/matched analyses to adjust for channeling/prescribing patterns. RA pts initiating tofacitinib or bDMARDs had similar rates of total cancer excluding NMSC, NMSC, and death.

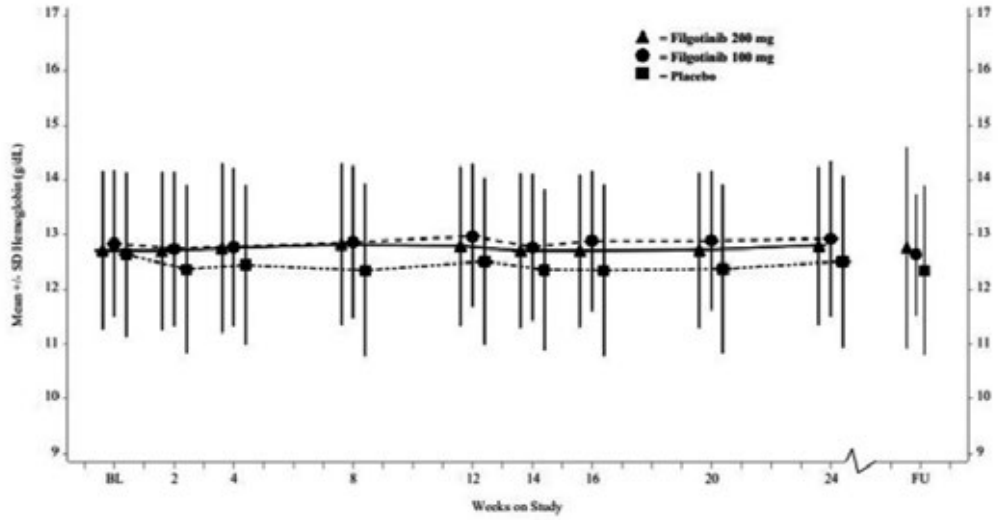
Session Type: ACR Abstract Session

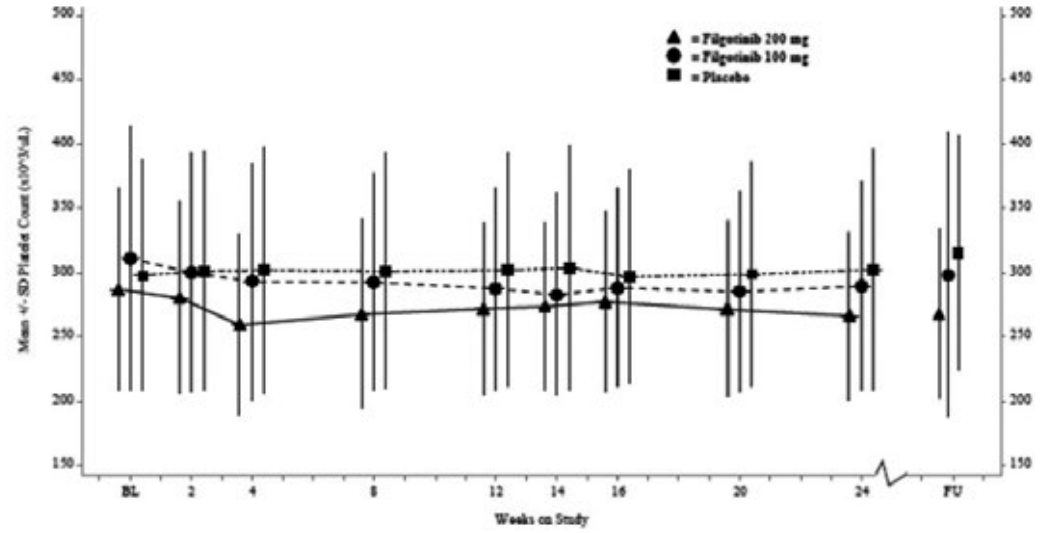
Session Time: 9:00AM–10:30AM

Figure. Mean (±SD) hemoglobin, platelet, lymphocyte and neutrophil count by study visit

A.



B.



Background/Purpose: Anemia, thrombocytopenia and leukopenia in RA patients treated with non-Janus Kinase 1 (JAK1) selective inhibitors may be due to inhibition of hematopoietic growth factors signaling through JAK2. Therefore, we investigated the extent of anemia, thrombocytopenia and leukopenia in patients with active RA with a prior inadequate response/intolerance to biological DMARD (bDMARD) treated with filgotinib (FIL), a novel and selective JAK1 inhibitor, during a Phase 3, 24-week trial (FINCH-2; NCT02873936).

Methods: In the randomized, double-blind, placebo-controlled Phase 3 FINCH-2 trial, patients were randomized 1:1:1 to receive oral FIL 200 mg, 100 mg, or placebo (PBO) once daily for 24 weeks in addition to conventional synthetic DMARDs. We assessed shifts from baseline at 12 and 24 weeks in hemoglobin, platelets, neutrophils and lymphocytes in FINCH-2 patients, assessed by baseline values as normal, mild-moderate and severe for these variables.

Table: Shift from baseline in hemoglobin, platelet, neutrophil and lymphocyte category at Weeks 12 and 24

Neutrophil							
Baseline level	**Normal***			**Mild-Moderate†**			**Severe**

Results: A total of 448 patients were enrolled and treated, FIL 200 mg, n = 147; FIL 100 mg, n = 153; PBO, n = 148. Overall, hemoglobin levels, platelet, lymphocyte and neutrophil counts remained consistent throughout the study (Figure). At baseline, 129 (28.8%), 4 (0.9%), 10 (2.2%) and 26 (5.8%) patients had mild-moderate low levels of hemoglobin, platelet, neutrophil and lymphocyte, respectively, and 5 (1.1%) had severely low levels of lymphocytes. Of the patients with mild-moderate hemoglobin levels at baseline, 13.1% with FIL 200 mg, 9.5% with FIL 100 mg, and

7.6% with PBO achieved normal hemoglobin at Week 24, respectively (Table). Of those with normal baseline hemoglobin levels, only 6.0–9.8% had mild low levels at Week 24. All patients with baseline mild-moderate low platelets and neutrophils had normal levels at Week 24, except for one patient with mild neutropenia receiving FIL 100 mg. Of the patients with normal platelet and neutrophil levels at baseline, >94% maintained these at Week 24 in all treatment groups. By Week 24, 3.2%, -5.2% and 2.2% of patients treated with FIL 200 mg, FIL 100 mg and PBO, respectively in the mild-moderate subgroup and 1.7% in the severe subgroup treated with FIL 100 mg had normal lymphocyte counts.

Conclusion: In this FINCH-2 subgroup analysis, most patients with normal hemoglobin, platelet, lymphocyte and neutrophil levels at baseline maintained them over 24 weeks of FIL treatment. Of the patients with mild-moderately low hemoglobin at baseline, >9% shifted towards hemoglobin normalization. Similar patterns of improvement from baseline were observed for platelet, lymphocyte and neutrophil counts. These results suggest that FIL does not increase the incidence of anemia, thrombocytopenia or leukopenia in patients who entered the study with active RA despite prior biologic therapies.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) dactylitis is associated with an increased risk of erosions and higher disease activity. Dactylitis treatment strategies are however controversial due to the absence of evidence from randomized controlled trials studying dactylitis as a primary outcome. The objective of this trial was to assess the efficacy of golimumab in combination with methotrexate (MTX) versus MTX monotherapy in active PsA dactylitis.

Methods: GO-DACT was a proof-of-concept multicentric, investigator-initiated randomized, double-blind, placebo-controlled, parallel-design, phase 3b trial. PsA patients, fulfilling the ClASsification for Psoriatic ARthritis criteria, naïve to MTX and biologic disease modifying anti-rheumatic drugs (bDMARDs), with active dactylitis, were randomly allocated to receive subcutaneous injections of golimumab 50mg or placebo, administrated every four weeks for 24 weeks, both in combination with MTX. The primary endpoint was the change from baseline in the Dactylitis Severity Score (DSS) assessed at week 24. Key dactylitis secondary endpoints included DSS20, 50 and 70 response rates, changes and response rates in the Leeds Dactylitis Index (LDI20, 50 and 70) and changes in the magnetic resonance imaging (MRI) dactylitis score. Analysis was by intention to treat for the primary endpoint.

Results: 44 patients were centrally randomized, 21 to golimumab plus MTX and 23 to placebo plus MTX, for 24 weeks, and 1 patient from each arm dropped out. The median baseline DSS was 6 in each arm. The mean MTX dose reached in the golimumab plus MTX group was 16.3mg/week and in the MTX monotherapy group was 19.2mg/week. Patients treated with golimumab plus MTX experienced significantly greater improvements in the DSS at week 24

(median change of 5) as compared to the MTX group (median change of 2) (p=0.026). At week 24, significantly higher proportions of patients treated with golimumab plus MTX achieved DSS50/70 responses, as well as LDI20/50/70 responses (p< 0.05). At week 24, significantly lower median dactylitis MRI scores were observed in patients treated with golimumab plus MTX in comparison with those treated with MTX monotherapy (p=0.017). The median changes from baseline in the Disease Activity Score 28 (DAS28), the Disease Activity Index for PsA (DAPSA), the PsA Disease Activity Score (PASDAS) and the target Nail Psoriasis Severity Index (tNAPSI) at week 24, were significantly higher for those treated with golimumab plus MTX. Patient' inclusion was halted at 50% of recruitment due to a favorable interim analysis. There were no new safety issues for golimumab during this trial.

Conclusion: GO-DACT shows additional benefits from the combination of golimumab and MTX as first-line bDMARD therapy versus MTX monotherapy, in the treatment algorithm of active PsA dactylitis.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Psoriatic arthritis (PsA) is characterized by peripheral synovitis, enthesitis, dactylitis and spondylitis, and IL-23 is involved in the pathogenesis of these conditions either directly or indirectly. Risankizumab (RZB), a potent humanized IgG1 monoclonal antibody and selective IL23p19 inhibitor, exhibited superior efficacy vs placebo via ACR responses and PASI scores in patients (pts) with active PsA over 24 weeks (wks). Here, the objective is to report the safety and efficacy of RZB in pts who continued into the open-label extension (OLE, NCT02986373) after completing a 24-Wk Phase 2 study.

Methods: Pts who completed the 24-Wk double-blind Phase 2 study and met the inclusion criteria were eligible to enroll in this 52-Wk, single-arm, OLE and received 150 mg RZB every 12 wks for 36 wks. Safety and efficacy assessments (ACR and PASI responses, DAS28[CRP], Leeds Indices [dactylitis and enthesitis], and SF-36) were recorded at each visit (wks 0, 4, 12, 24, 36, 48, 52).

Results: Of 173 pts who completed the 24-Wk study, 145 (83.8%) enrolled in the OLE. The median age was 51 years and 61 (42.1%) pts were female. At baseline (BL, Week 0 of the 24-Wk study), 63 (44.4%) pts had psoriasis (PsO) ≥3% BSA, 40 (27.8%) / 73 (53.5%) showed presence of dactylitis/enthesitis, 35 (24.1%) had prior TNFi exposure and 83 (57.2%) were receiving concomitant MTX. Compared with response rates for pooled RZB data from the 24-Wk study, the ACR and PASI (in pts with PsO ≥3% BSA) response rates were higher/similar at Wk 52 (n/N: ACR20: 68/135 to 76/101; ACR50: 31/135 to 44/101; ACR70: 18/136 to 25/101; PASI90: 33/57 to 30/41; PASI100: 23/57 to 25/41; observed data). Mean change from BL (ΔBL) in DAS28[CRP] increased from -1.4 to -1.9 (Wk 52 mean: 2.7) and ΔBL in Leeds indices for dactylitis and enthesitis were -74.5 and -1.8, respectively. Pts also reported increase in ΔBL in physical and mental component summaries of SF-36 at Wk 52. There were no deaths, malignancies or cases of active tuberculosis in the study. A total of 60% pts had treatment-emergent adverse event (TEAEs), with viral upper respiratory tract infection being the most common (11.0%). Serious TEAEs and TEAEs leading to RZB discontinuation were low (3.4%).

Conclusion: Pts with active PsA treated with RZB maintained improvement in joint and skin symptoms throughout the OLE with no new or unexpected safety findings. These results were substantiated by enhanced patient quality-of-life.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Tildrakizumab (TIL), a high-affinity anti–interleukin-23p19 monoclonal antibody, is approved for moderate-to-severe plaque psoriasis treatment and is under investigation for PsA. This study evaluated the 24-week efficacy and safety results from a randomized, double-blind, placebo-controlled, multiple-dose, phase 2b TIL study in patients with active PsA (NCT02980692).

	TIL 200 mg Q4W (N = 78)	TIL 200 mg Q12W (N = 79)	TIL 100 mg Q12W (N = 77)	TIL 20 mg Q12W (N = 78)	PBO (N = 79)
Patient demographics					
Age, years, median	50.0	49.0	50.0	47.5	47.0
Female, n (%)	46 (59.0)	37 (46.8)	47 (61.0)	41 (52.6)	44 (55.7)
White, n (%)	76 (97.4)	78 (98.7)	75 (97.4)	75 (96.2)	74 (93.7)
BMI, kg/m^2, median	30.0	29.3	27.8	28.9	27.8
Baseline disease characteristics					
Swollen joint count, median (range)	8.0 (3.0–35)	7.0 (3.0–45)	8.0 (0–38)	8.0 (3.0–38)	8.0 (3.0–42)
Tender joint count, median (range)	13.5 (3.0–64)	15.0 (4.0–63)	19.0 (3.0–59)	14.0 (4.0–54)	15.0 (3.0–64)
BSA ≥3%, n (%)	53 (67.9)	44 (55.7)	54 (70.1)	41 (52.6)	42 (53.2)
Physician GADA, mean ± SD	54.0 ± 16.1	55.4 ± 16.2	57.3 ± 17.3	59.4 ± 14.4	59.5 ± 15.6
Patient GADA, mean ± SD	57.8 ± 18.3	61.1 ± 20.7	60.3 ± 20.2	61.9 ± 17.4	65.2 ± 18.1
Patient's pain assessment, mean ± SD	55.4 ± 19.1	59.6 ± 23.5	59.2 ± 22.1	60.9 ± 19.7	64.2 ± 20.4

Table 1. Demographics and Baseline disease characteristics. BMI, body mass index; BSA, body surface area; GADA, global assessment of disease activity; Q4W, every 4 weeks; Q12W, every 12 weeks; PBO, placebo; SD, standard deviation; TIL, tildrakizumab.

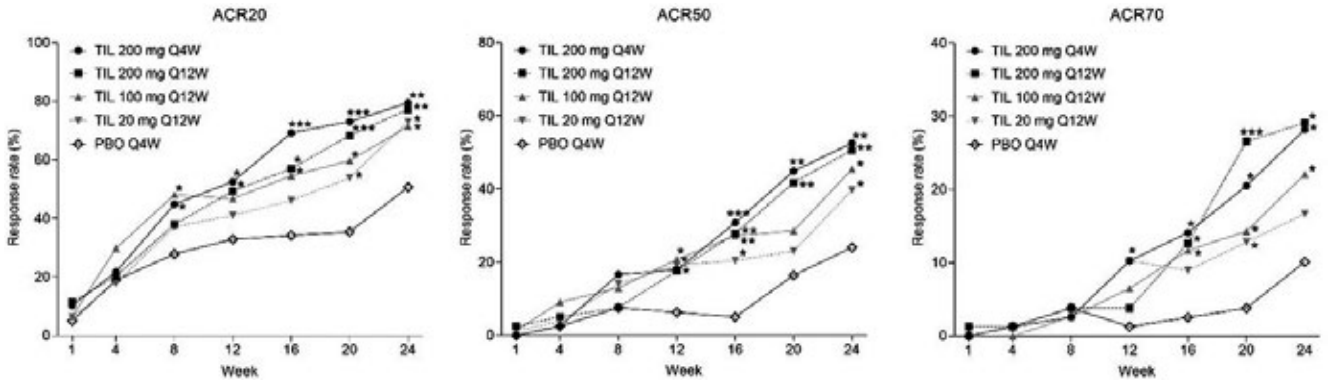

Figure 1. ACR 20/50/70 response rates. *P <0.05; **P <0.001; ***P <0.0001 vs PBO. PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; TIL, tildrakizumab.

	TIL 200 mg Q4W (N = 78)	TIL 200 mg Q12W (N = 79)	TIL 100 mg Q12W (N = 77)	TIL 20 mg Q12W (N = 78)	PBO (N = 79)
PASI 75 [a], %	64.2***	79.6***	55.6***	46.3*	16.7
PASI 90 [a], %	47.2***	50.0***	38.9**	36.6*	7.1
Swollen joint count, median change from BL	−6.0*	−6.0	−6.0*	−6.0	−5.0
Tender joint count, median change from BL	−9.0	−10.0*	−11.0*	−10.0	−8.5

Table 2. Efficacy endpoints at week 24. aResponse rates only calculated in patients with BSA ≥3% at baseline, missing responses were imputed as nonresponses. *P <0.05; **P <0.001; ***P <0.0001 vs PBO. BL, baseline; BSA, Body Surface Area; PASI, Psoriasis Area and Severity Index; PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; TIL, tildrakizumab.

Methods: Patients with active PsA were randomized 1:1:1:1:1 to receive TIL (200 mg once every 4 weeks [Q4W] [n = 78], 200 mg every 12 weeks [Q12W] [n = 79], 100 mg Q12W [n = 77], 20 mg Q12W [n = 78] to week 24), or placebo (PBO) Q4W to week 24 (n = 79). Stable concomitant methotrexate or leflunomide use was permitted but not mandated. The primary efficacy endpoint was the proportion of patients who achieved a 20% reduction from baseline in ACR response criteria (ACR20) at week 24. Other outcome measurements included proportion of patients achieving ACR50/70 response and Psoriasis Area and Severity Index (PASI) 75, PASI 90, and changes in swollen and tender joint count at week 24. Safety assessments included monitoring of treatment-emergent adverse events (TEAEs).

Results: Of 500 patients screened, 391 patients met the inclusion criteria (including ≥18 years old, PsA diagnosis with symptoms for 6 months, and ≥3 tender and ≥3 swollen joints). Demographics and baseline disease characteristics are shown in Table 1. There were significantly greater proportions of ACR20/50/70 and PASI 75/90 responders with TIL vs PBO at week 24, and in some cases differences in parameters were noted as early as week 8 (Figure 1 and Table 2).

The most frequent TEAEs through week 24 included nasopharyngitis (pooled TIL arms: 5.4% [17/312]; PBO: 6.3% [5/79]); and diarrhoea (TIL: 1.3% [4/312]; PBO: 0). There were no reports of candidiasis, inflammatory bowel disease, major adverse cardiac events, or malignancy. No patients discontinued treatment due to TEAEs and no deaths were reported. Serious TEAEs occurred in 2.2% (7/312) of TIL-treated patients vs 2.5% (2/79) in PBO-treated patients.

Conclusion: By week 24, TIL was significantly more efficacious than PBO in the treatment of joint and skin manifestations of PsA. Furthermore, there was a clear separation between TIL and PBO as early as 8 weeks for ACR20 (TIL 200 mg Q4W and 100 mg Q12W) and 12 weeks for both ACR20 (TIL 200 mg doses) and ACR50 (all TIL groups).

Shortening the dosing interval from Q12W to Q4W for the 200-mg dose did not result in a measurable increase in skin or joint response scores. There was a low rate of TEAEs in the TIL-treated group.

Editorial support was provided by Claire Daniele, PhD, CMPP; and Marie-Louise Ricketts, PhD, of AlphaBioCom, LLC, and funded by Sun Pharmaceutical Industries, Inc.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

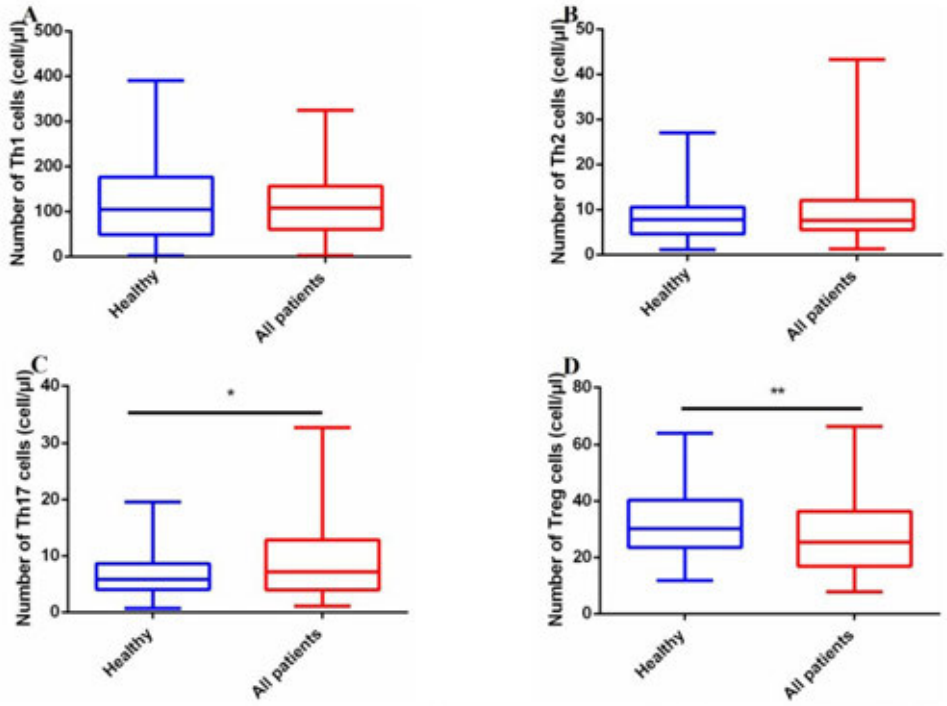

Figure 1: Comparison of absolute numbers of peripheral CD4⁺T cell subsets between PsA patients (n=95) and health controls (n=106). The level of Th17 was significantly increased while that of Tregs reduced in patients with PsA. Data were calculated and compared with Mann-Whitney *U* test. **P* < 0.05, ***P* <0.01, ****P* <0.001.

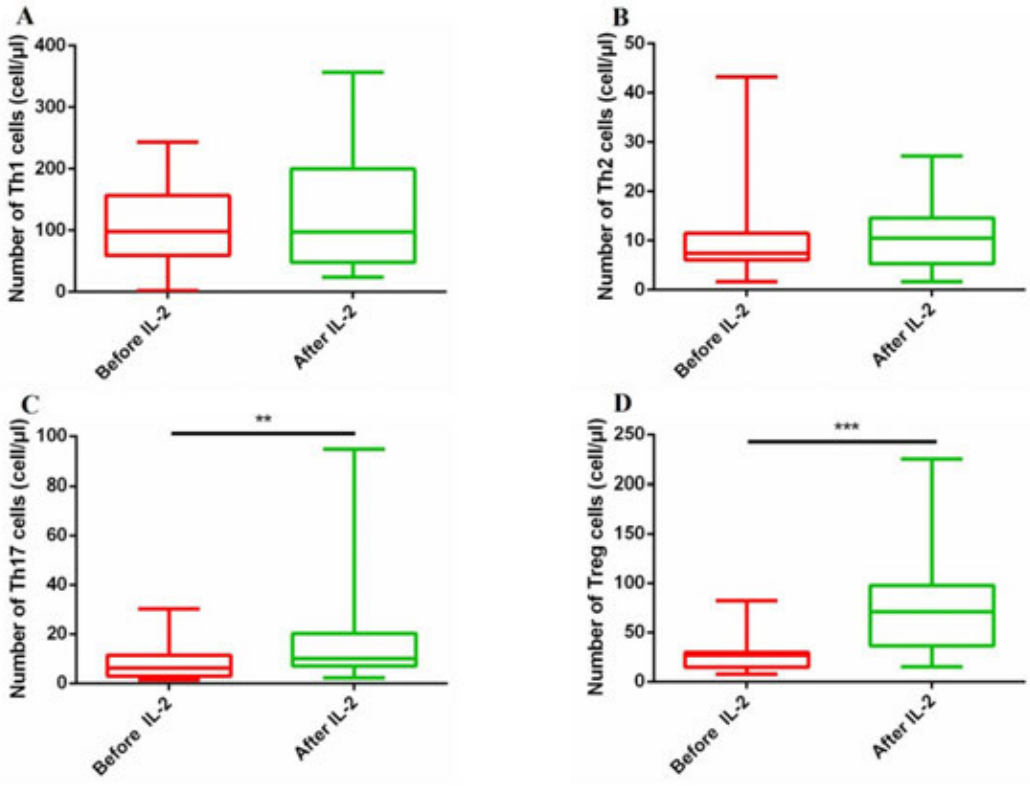

Figure 2: Comparative analysis the changes of CD4⁺T cell subsets in patients with PsA between pre- and post-treatment (n=22). Low-dose IL-2 markedly raised the absolute numbers of Treg and moderately increased the level of Th17 cells in PsA patients. **P* < 0.05, ***P* <0.01, ****P* <0.001.

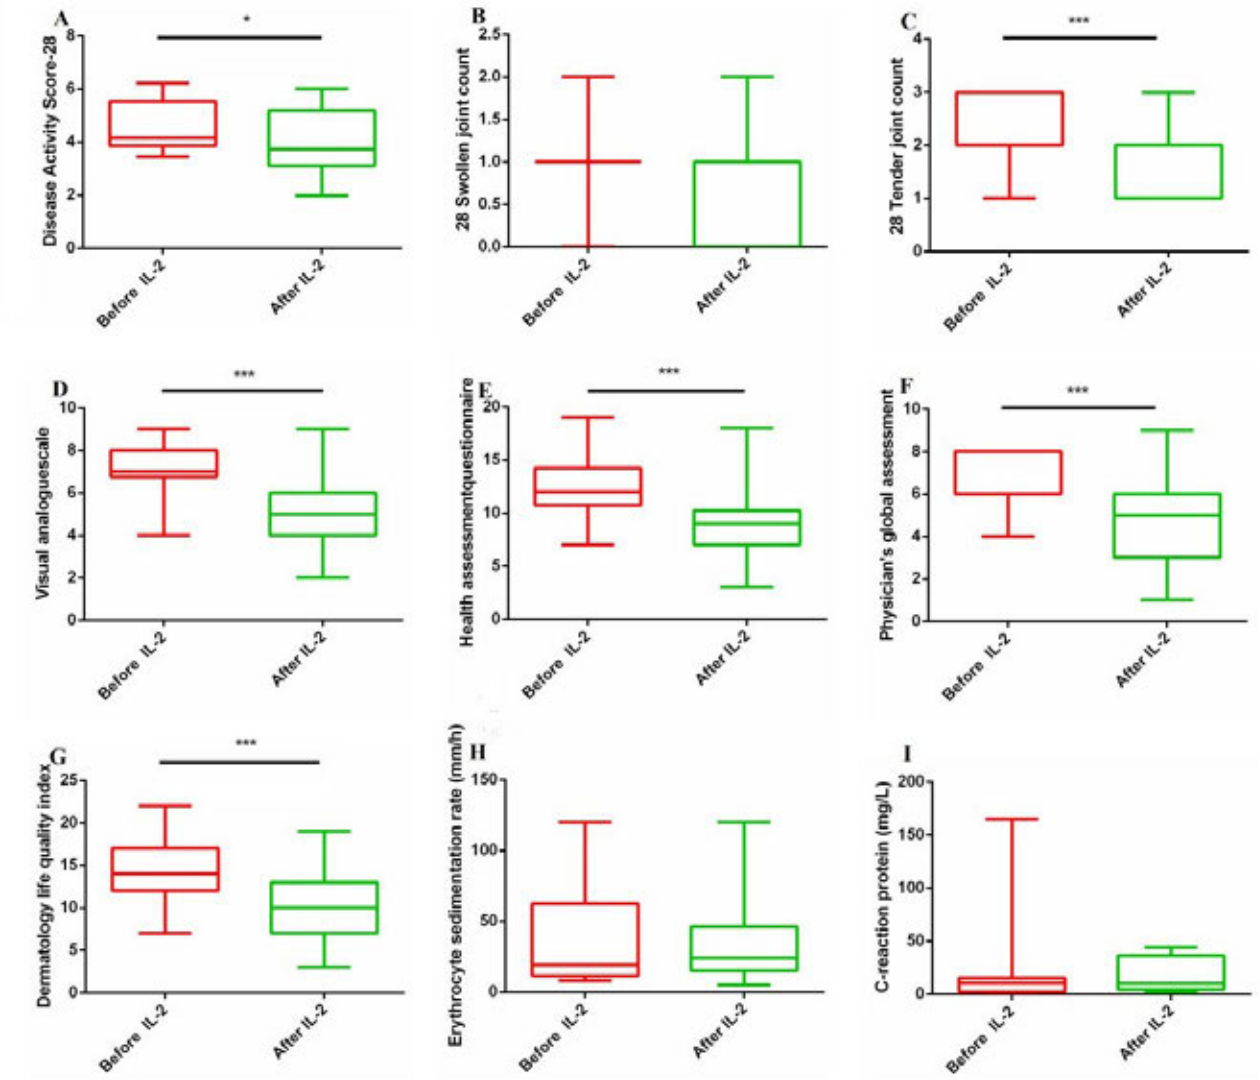

Figure 3: Comparative analysis the changes of PsA signs and symptoms between pre- and post-treatment (n=22). Data were presented as median(range) and calculated and compared with Mann-Whitney *U* test.(A-I) show that low-dose IL-2 treatment provided a significant decrease in 28 tender joint count, DAS28-ESR index, VAS index, PHGA index, DLQI index and HAQ index. $*P < 0.05$, $***P < 0.001$.

Background/Purpose: Psoriatic arthritis (PsA) is a T lymphocytes-mediated inflammatory condition. Although regulatory T cells (Tregs) isolated from blood and psoriatic skin have been showed a functional deficiency in suppressing effector T-cells in PsA, absolute quantitative status of peripheral Treg or Th17 cells is still unclear. On the other hand, recent studies have revealed that low-dose IL-2 alleviate**s** some of autoimmune disease activity by upregulating Treg cells, which is expected to control the development of PsA.This study aimed to assess the absolute numbers of peripheral lymphocyte subpopulations and the efficacy and safety of low-dose IL-2 therapy in PsA patients.

Methods: Total 95 PsA patients and 106 age-and sex-matched healthy controls were recruited. Of them, 22 cases received the treatment of low-dose IL-2 at 0.5 million IU per day for 5 days subcutaneously. The absolute numbers of lymphocyte subgroups and $CD4^+$T subsets in peripheral blood were measured by flow cytometry. The clinical mani-

festations and laboratory indicators as well as the levels of peripheral lymphocyte and $CD4^+$T subsets were compared before and after the treatment.

Results: Notably, the absolute numbers of lymphocyte subpopulations in peripheral blood such as NK, CD4+T, Th17 and Tregs in PsA patients were lower than those of healthy controls ($P< 0.05$). The absolute number of Treg was significantly and negatively correlated with the levels of disease indicators, including DAS28, the number of tender joints, visual analogue scale, physician's global assessment, dermatology life quality index, and health assessment questionnaire($P< 0.05$). After low-dose IL-2 treatment, compared with the baselines, there was a significant increase in the absolute numbers of NK ($P< 0.05$), CD4+T ($P< 0.01$), Th17 ($P< 0.01$) and Treg cells ($P< 0.001$). Interestingly, IL-2 markedly raised the level of Tregs in PsA patients even higher than that of healthy donors ($P< 0.001$), leading to re-balance of Th17 and Tregs. Further, low-dose IL-2 treatment rapid reduced the disease activity such as DAS28, the number of tender joints, visual analogue scale, physician's global assessment, dermatology life quality index, and health assessment questionnaire ($P< 0.05$).

Conclusion: Patients with PsA had an imbalance between pro- and anti-inflammatory cells, particularly the reduction of the absolute number of Tregs. Low-dose IL-2 combination treatments restored the decreased number of Treg cells and lowered disease activity indicators of these patients without over-treatment and evaluable side effect. Further studies are needed to evaluate the long-term immunoregulatory ability of IL-2 treatment.

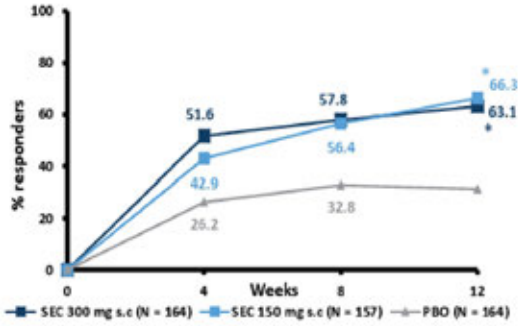
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Secukinumab (SEC) has provided significant and sustained improvement in the signs and symptoms of active psoriatic arthritis (PsA) and ankylosing spondylitis[1]. Evidence is limited on the efficacy of biologics in the treatment of patients (pts) with PsA having axial manifestations that affect between 30–70% of pts[2], particularly as validated classification criteria for this subtype of PsA are not yet available; an effort to develop criteria is being undertaken by ASAS/GRAPPA. MAXIMISE is an ongoing study evaluating the efficacy and safety of secukinumab 300 mg or 150 mg in managing axial manifestations in pts with PsA. Here, we report the primary analysis results at Week (Wk) 12 from the MAXIMISE trial (NCT02721966).

Figure: ASAS20 Response rate through Week 12 (Full Analysis Set)



*P<0.001 vs placebo; ASAS, Assessment of Spondyloarthritis International Society; N, number of patients randomized

Table: Demographic/ BL Disease Characteristics

Mean (SD) unless specified	SEC 300 mg SC (N = 167)	SEC 150 mg SC (N = 165)	PBO (N = 166)
Age (years)	46.2 (12.3)	46.9 (11.5)	46.6 (11.5)
Male, n (%)	77 (46.1)	81 (49.1)	88 (53.0)
Evidence of current psoriasis, n (%)	152 (91.0)	147 (89.1)	153 (92.2)
Time since first axial symptoms (years)	6.8 (7.7)	7.4 (7.6)	7.7 (9.5)
Total back pain score, VAS	72.5 (13.8)	73.6 (15.3)	74.0 (13.7)
Inflammatory back pain parameters, n (%)			
Onset of back pain is insidious	150 (89.8)	147 (89.1)	152 (91.6)
Back pain improving with exercise	148 (88.6)	139 (84.2)	146 (88.0)
Back pain worsening with rest	152 (91.0)	151 (91.5)	157 (94.6)
Night pain with improvement upon getting up	147 (88.0)	147 (89.1)	143 (86.1)
Awakening due to back pain in 2nd half of night	143 (85.6)	145 (87.9)	137 (82.5)
Alternating buttock pain	102 (61.1)	98 (59.4)	101 (60.8)
Back pain improved after NSAID intake in past	136 (81.4)	134 (81.2)	138 (83.1)
BASDAI	7.3 (1.2)	7.2 (1.4)	7.3 (1.2)
HLA-B27 positive, n/M (%)	31/85 (36.5)	24/82 (29.3)	26/74 (35.1)

M, number of pts with available HLA-B27 status; N, number of randomised patients; SEC, secukinumab; BL, baseline; PBO, placebo; SC, subcutaneous; SD, standard deviation; VAS, visual analog scale; NSAID, nonsteroidal anti-inflammatory drug; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; HLA, human leukocyte.

Methods: This phase 3b, double blind, placebo (PBO)-controlled, multicenter 52-wk trial included 498 pts (aged ≥18 years) with PsA (CASPAR criteria), clinician-diagnosed axial involvements, spinal pain VAS > 40/100 and BASDAI > 4 despite trial of at least two NSAIDs. Pts were randomized to subcutaneous (SC) SEC (300/150 mg) or PBO weekly for 4 wks and every 4 wks thereafter. At Wk 12, PBO pts were re-randomized to SC SEC 300/150 mg. The primary endpoint was ASAS20 response with SEC 300 mg at Wk 12. The key secondary endpoint was ASAS20 response with SEC 150 mg at Wk 12 after superiority of 300 mg was established. Analyses used multiple imputation.

Results: Demographic and baseline (BL) disease characteristics were comparable across groups (Table). Primary and key secondary endpoints were met; ASAS20 response rates at Wk 12 were 63.1% (SEC 300 mg; P< 0.0001) and 66.3% (150 mg; P< 0.0001) versus 31.3% (PBO; Figure). ASAS20 responses in pts using concomitant methotrexate (MTX) were 65.1% [300 mg], 67.3% [150 mg] versus 33.9% [PBO]; corresponding values in pts without concomitant MTX use were 60.5%, 64.4% versus 27.1%. The safety profile was similar across groups through Wk 12.

Conclusion: MAXIMISE is the first randomized controlled trial evaluating the efficacy of a biologic in the management of the axial manifestations of psoriatic arthritis. Secukinumab 300 mg and 150 mg provided rapid and significant improvement in ASAS20 responses through Week 12 in patients with psoriatic arthritis with axial manifestations and inadequate responses to NSAIDs.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical VII: Psoriatic Arthritis Treatment
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The ultimate goal of therapy in patients with psoriatic arthritis (PsA) is clinical remission, defined as 'the absence of clinical and laboratory evidence of significant inflammatory disease activity'.[1,2] Since many patients with PsA may not achieve clinical remission, treatment recommendations recognise minimal or low disease activity as an important alternative treatment target.[1,2] Bimekizumab is in development for the treatment of psoriasis, PsA, and axial spondyloarthritis; it potently and selectively neutralizes both IL-17A and IL-17F.[3] The efficacy and

*Last observation carried forward (LOCF) analysis
DAPSA, disease activity index for psoriatic arthritis; MDA, minimal disease activity; VLDA, very low disease activity

safety of bimekizumab in patients with active PsA was assessed in a Phase 2b study over 48 weeks (NCT02969525);[4] disease activity outcomes are reported here.

Methods: Patients with active PsA, ≥3/76 swollen joint count and ≥3/78 tender joint count and fulfilling the Classification Criteria for PsA (CASPAR, score ≥3), were randomized (1:1:1:1:1) to receive subcutaneous bimekizumab 16 mg, 160 mg, 160 mg with 320 mg loading dose (160 mg [LD]), 320 mg, or placebo every 4 weeks (Q4W) for 12 weeks (double-blind period). After Week 12, patients receiving placebo or bimekizumab 16 mg were re-randomized (1:1) to receive bimekizumab 160 mg or 320 mg; all other patients continued on their previous dose (dose-blind period). The primary endpoint was a ≥50% improvement in American College of Rheumatology response criteria (ACR50) at Week 12; key results up to Week 48 have been reported previously.[4] Other and post-hoc efficacy variables included: minimal disease activity (MDA), very low disease activity (VLDA), disease activity index for psoriatic arthritis (DAPSA) remission, and DAPSA low disease activity (LDA).

Results: Of 206 patients randomized, 203 and 190 completed the double- and dose-blind periods, respectively. In patients receiving bimekizumab 160 mg, 160 mg (LD) or 320 mg throughout the study, 46.3–58.5% achieved MDA, 22.0–36.6% achieved VLDA, 34.1–43.9% achieved DAPSA remission and 22.0–43.9% achieved DAPSA LDA at Week 48 (Table 1). In general, disease activity improved across these measures from Week 12 to Week 24, with improvements typically maintained or further increased to Week 48.

Serious adverse events were reported by 9/204 (4.4%) patients up to Week 48 (8/204 [3.9%] receiving bimekizumab). The most common treatment-emergent adverse event up to Week 48 was nasopharyngitis (25/204 [12.1%]). Up to Week 48, oral candidiasis occurred in 10/204 (4.9%) patients (all on bimekizumab treatment). No deaths, cases of inflammatory bowel disease, uveitis, or major cardiovascular adverse events were reported.

Conclusion: Treatment with bimekizumab 160 mg, 160 mg (LD) or 320 mg throughout the study was associated with achievement of low and/or minimal disease activity. Disease activity measures generally improved to Week 24 and were maintained to Week 48. These data provide further support that neutralizing both IL-17F and IL-17A with bimekizumab is a promising therapeutic approach in patients with active PsA.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: The Lupus Low Disease Activity State (LLDAS) is a treatment endpoint for SLE that has been shown in prospective validation studies to be associated with protection against disease flares and damage accrual. In addition to improved physician-measured outcomes, attainment of treatment endpoints should also result in improvement in patient-reported outcomes such as health related quality of life (HR-QoL). The objective of this study was to assess the effect of attainment of LLDAS on HR-QoL.

Methods: 1,735 SLE patients in 11 centres were prospectively recruited, and followed for (mean ± SD) 2.2 ± 0.9 years, totalling 12,717 visits. HR-QoL was captured using SF-36 at baseline and annually until completion of the study. At each visit LLDAS status was ascertained. Generalized estimating equations models were used to assess the association of LLDAS status with low SF-36 scores (threshold for low SF-36 based on the median across all visits). Time dependent Cox proportional hazard models were used to assess increasing proportion of cumulative time in LLDAS and protective association against low SF-36 scores.

Table 1: Association of cumulative time in LLDAS with PCS and MCS scores

% Cumulative time in LLDAS	N % patients	Low PCS* HR (p value)	Low MCS* HR (p value)
LLDAS 0 (no visit in LLDAS)	455 (26.2%)	0.97 (0.874)	1.07 (0.660)
LLDAS 25	1133(65.3%)	0.71 (0.013)	0.76 (0.037)
LLDAS 50	813 (46.9%)	0.65 (0.001)	0.78 (0.050)
LLDAS 75	544 (31.4%)	0.61 (0.002)	0.70 (0.011)
LLDAS 100 (all visits in LLDAS)	325 (18.7%)	0.44 (<0.001)	0.59 (0.003)

Results: LLDAS attainment was observed in 6091 (47.9%) visits. LLDAS status was associated with a significant protective effect against low physical component summary scores (PCS, RR 0.88, 95% CI 0.84-0.94, p< 0.001) and low mental component summary scores (MCS, RR 0.90, 95% CI 0.86-0.95, p< 0.001). Increasing proportions of cumulative time in LLDAS were associated with graded protective effect against low PCS and MCS scores (table 1).

Conclusion: In this large prospective cohort study, LLDAS was significantly associated with protection from low HR-QoL, as measured by SF-36. Importantly, increasing cumulative time in LLDAS was associated with a dose dependent protective effect against low SF-36 scores, providing further validation for the use of LLDAS as a treatment endpoint in SLE.

Systemic Lupus Erythematous Risk Alleles Drive Autoimmune Features in a Population Without Diagnosed Autoimmune Diseases

April Barnado,[1] Lee Wheless,[1] Leslie Crofford,[2] and Joshua Denny[1], [1]Vanderbilt University Medical Center, Nashville, TN, [2]Vanderbilt University, Nashville

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogeneous disease with > 100 known risk alleles. Some of these risk alleles associate with ACR SLE criteria such as renal disease. We examined if nine of these SLE risk alleles would identify autoimmune features in a population without diagnosed autoimmune diseases.

Methods: We investigated subjects from BioVU, a databank that links DNA extracted from routine, clinical blood samples to a de-identified electronic health record (EHR) with several decades of clinical data. BioVU contains 250,000 subjects, over 80,000 of which have been genotyped on Illumina MEGA chip. We selected individuals who had available data for 9 SLE risk single nucleotide polymorphisms (SNPs) (ITGAM rs1143683 and 1143679, STAT4 rs7574865, IRF5 rs10488631, IRF7 rs4963128, TFAF3IP2 rs13190932, PTPN2 rs2542151, UBE2L3 rs5754217, ICAM1-ICAM4-ICAM5 rs3093030), which have been associated with ACR SLE criteria. Subjects did not have ICD9 or ICD10 billing codes for autoimmune diseases including SLE, rheumatoid arthritis, Sjogren's syndrome, systemic sclerosis, or myositis. We compared subjects with or without these nine SLE risk SNPs using phenome-wide association studies

Table 1. SLE related PheWAS codes associated with SLE risk alleles in a population without diagnosed autoimmune diseases.

Gene SNP	SLE related PheWAS codes	Odds Ratio 95% Confidence Intervals	p value
ITGAM	Pleurisy, pleural effusion	1.09 (1.02 – 1.16)	0.01
rs1143683	Urinary complications	1.82 (1.10 – 2.99)	0.02
	Nephritis	1.50 (1.05 – 2.14)	0.03
	Symptoms and disorders of the joint	1.08 (1.01 – 1.17)	0.04
	Diseases of white blood cells	1.09 (1.01 – 1.19)	0.04
	Anemia of chronic disease	1.11(1.01 – 1.22)	0.05
STAT4	Joint effusions	1.28 (1.10 – 1.49)	0.002
rs7574865			
IRF7	Urinary complications	1.41 (1.02 – 1.96)	0.04
rs4963128	Dermatitis due to solar radiation	1.13 (1.01 – 1.29)	0.05
PTPN2	Other derangement of joint	1.25 (1.03 – 1.51)	0.03
rs2542151	Synovitis and tenosynovitis	1.14 (1.01 – 1.29)	0.03
UBE2L3	Alopecia	1.26 (1.02 – 1.55)	0.03
rs5754217			
ICAM1- ICAM4- ICAM5	Other arthropathies	1.10 (1.01 – 1.19)	0.02
	Proliferative glomerulonephritis	1.55 (1.07 – 2.25)	0.02
rs3093030	Raynaud's syndrome	1.36 (1.02 – 1.82)	0.04

(PheWAS). PheWAS is a technique that scans across EHR billing codes. Subjects with a SLE risk SNP and multiple codes corresponding to SLE ACR criteria were chart reviewed to determine if they had an undiagnosed autoimmune disease and assessed for other comorbidities.

Results: We identified 56,496 Caucasian subjects without billing codes for autoimmune diseases that had available genetic data for the 9 SLE risk SNPs. Of these subjects, 56% were female with a mean age of 53 years. Compared to subjects without the SNPs, subjects with the risk SNPs were more likely to have codes related to ACR SLE criteria including nephritis, arthritis, serositis, and hematologic disorders (Table 1, Figure 1). Subjects with the ITGAM

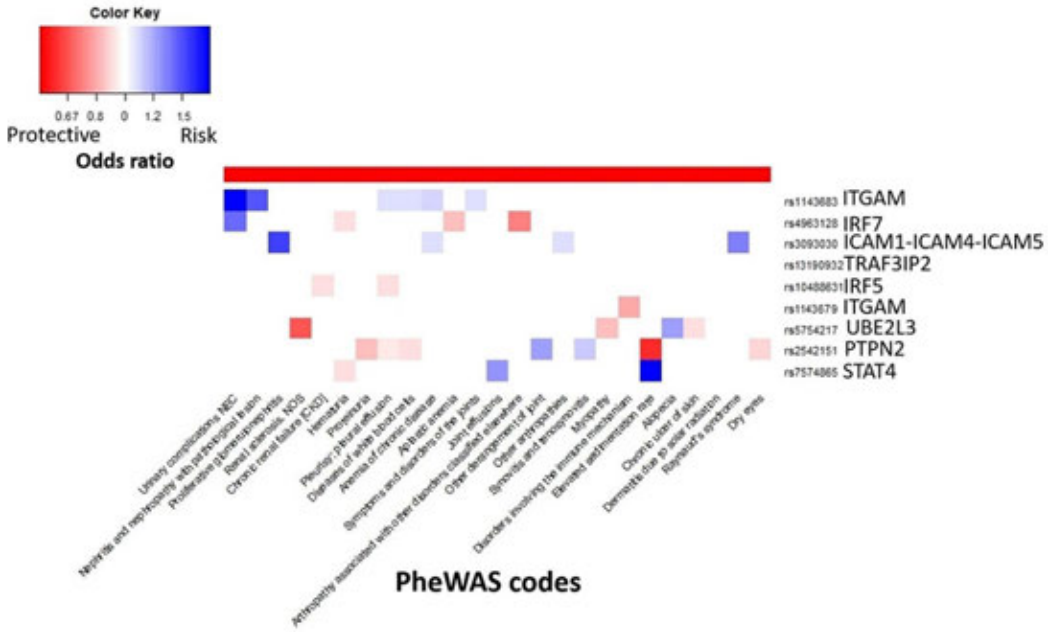

Figure 1. Heat map of SLE risk alleles and SLE related PheWAS codes in a population without diagnosed autoimmune diseases. Across the horizontal axis are PheWAS codes that represent SLE disease criteria and features organized by organ system (i.e. renal codes, codes related to hematologic diagnoses, codes related to arthritis). The nine SLE risk alleles with SNP number and gene name are labeled on the vertical axis. Odds ratio for each of the SLE risk alleles and PheWAS codes are shown per the above color key with non-significant associations in white on the heat map.

Table. Abnormal CB-CAPs compared to low C3/C4 in distinguishing SLE from other autoimmune rheumatic diseases

rs1143683 SNP were more likely to have codes related to nephritis (p = 0.03), arthritis (p = 0.04), and diseases of white blood cells (p = 0.04). Renal codes were also associated with IRF7 rs4963128 (p = 0.04) and ICAM1-ICAM4-ICAM5 rs3093030 (p = 0.02). On chart review of the 50 subjects with the greatest number of codes related to ACR SLE criteria, 2 subjects fit SLICC SLE criteria but were not formally diagnosed with SLE. Both of these subjects had renal biopsies suggestive of SLE nephritis. An additional two subjects had incomplete SLE and 1 subject ANCA-associated vasculitis, 1 amyloidosis, and 2 Henoch-Schonlein purpura. Notably, 45 (90%) of the subjects had renal disease with 19 requiring dialysis or a renal transplant.

Conclusion: Carriage of SLE risk alleles confers risk of SLE features in undiagnosed subjects. Some of these subjects may be pre-SLE or undiagnosed SLE cases or other autoimmune disease cases. The combination of SLE risk alleles plus early features of the disease may identify a population who are at high risk for developing clinical SLE who would be candidates for early treatment. Subjects with SLE risk alleles had a significant burden of renal disease. SLE risk alleles may share common pathways for renal disease and act as accelerants for organ damage.

Combined Trajectories of Fatigue and Disease Activity in an Inception Cohort of Lupus Patients over 10 Years

Mitra Moazzami,[1] Vibeke Strand,[2] Jiandong Su,[3] and Zahi Touma[4], [1]George Washington University, Washington, DC, [2]Division of Immunology/Rheumatology, Stanford University School of Medicine, Palo Alto, CA, USA, Palo Alto, CA, [3]University Health Network, University of Toronto, Toronto, ON, Canada, [4]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Fatigue is very common in SLE patients. We aim to: **1)** determine if different trajectories of fatigue associate with specific latent classes of disease activity and **2)** define the patient characteristics and associated factors in different latent classes.

Methods: This is a retrospective analysis on a prospectively collected dataset from an inception cohort and followed from 1997 to 2018. Fatigue levels was measured using Fatigue Severity Scale (FSS- scores range from 1-7, higher scores reflect more fatigue) and disease activity using the adjusted mean SLEDAI-2K (AMS). Ten-year cumulative SLE organ involvement were ascertained by SLEDAI-2K organ system. Joint latent class trajectory analysis for fatigue and AMS was performed using a group-based trajectory model in SAS PROC TRAJ. Each trajectory was fitted for the FSS and AMS. Models with the lowest Bayesian Information Criterion and groups containing > 9% of the total sample size were selected as the final models. Univariate and multivariate ordinal logistic regression analyses, using baseline variables, were performed to determine the predictors of both worse fatigue and AMS scores. This was performed on members with both latent class posterior probability ≥ 0.80.

Results: Among 280 inception patients with mean age of 35.8± 13.3 years, 4 latent classes (C) were created (figure 1): C1- very low disease activity and low fatigue (18.2%); C2 second lowest disease activity and highest fatigue trajectory (34.6%); C3 median disease activity and the lowest fatigue trajectory (35.0%); and C4 high disease activity

Figure 1. Trajectories of both fatigue (FSS) and disease activity (AMS) scores in an inception cohort of 280 patients over 10 years

	Descriptive Statistics	Univariate Regression		Multivariable regression	
Covariates at baseline visit	**Overall proportions n (%) or mean ± SD**	**Odds Ratio Estimate (95% CI)**	**p value**	**Odds Ratio Estimate (95% CI)**	**p value**
Mean age at SLE diagnosis	35.8 ± 13.3 years	0.98 (0.96,0.99)	0.01	0.98 (0.99,0.99)	0.01
Sex (Female)	252 (90.0%)	0.86 (0.39,1.91)	0.71		
Ethnicity (Caucasian vs. others)	163 (58.2%)	0.48 (0.29,0.79)	0.00	0.57 (0.34,0.94)	0.03
Education level (>high school or lower)	257 (91.8%)	1.75 (0.58,5.32)	0.32		
Marital status (married or common law vs. others)	127 (45.4%)	0.55 (0.34,0.91)	0.02		
Fibromyalgia	19 (6.8%)	0.39 (0.15,1.02)	0.06	0.41 (0.15,1.07)	0.07
Baseline SLEDAI	9.2 ± 7.5	1.05 (1.01,1.09)	0.00	1.04 (1.001,1.07)	0.04
SLICC score one year after diagnosis	0.3 ± 0.7	0.94 (0.64,1.38)	0.75		
Glucocorticoid use	238 (85.0%)	4.18 (1.98,8.84)	0.00	3.17 (1.45,6.92)	0.003
Antimalarial use	263 (93.9%)	1.39 (0.46,4.20)	0.56		
Immunosuppressive use	70 (25.0%)	1.36 (0.78,2.38)	0.28		

Table 1. Univariate and multivariate ordinal logistic regression analyses

and high fatigue trajectory (12.2%). C2 and C3 had similar AMS scores over time but different fatigue trajectories. C2 (highest fatigue) and C4 (high fatigue) had the highest proportion of individuals living with fibromyalgia (34.1% vs. 14.0% respectively) and cumulative glucocorticoid use at 10 years (37.2 ±15.7 grams vs. 44.4 ± 19.7 grams). SDI was highest in C4 (second lowest disease activity, highest fatigue score) with 67% of individuals having SDI >0. SDI was lowest in C3 (median disease activity, low fatigue score) with 53.2% of individuals having SDI >0. Cumulative organ involvement over 10 years showed that C4 included the most amount of individuals with central nervous system (43.8%), vasculitis (43.8%), renal (68.8), skin (100%), serosal (18.8%), immunologic (100%), and hematological (50%) manifestations; C2 had the most musculoskeletal findings (72.9%). Regression analyses showed that age at SLE diagnosis (OR: 0.98, 95% CI: 0.96; 0.99), Caucasian (OR 0.57, 95% CI: 0.34; 0.94), SLEDAI-2K scores (1.04, 95% CI: 1.00; 1.07) and glucocorticoid use (OR 3.2, 95% CI: 1.4; 6.9) were significantly associated with fatigue trajectories (Table 1).

Conclusion: There are **4 distinct joint classes of fatigue and disease activity trajectories**. Disease activity alone cannot fully explain fatigue trajectories over time. Trajectories with higher FSS and AMS scores, classes C2 and C4, are associated with more **fibromyalgia and cumulative glucocorticoid use**. Baseline SLEDAI-2K scores were more likely associated with worse trajectories of fatigue, being a Caucasian and older age at SLE diagnosis were associated with better fatigue trajectories.

Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Gut microbiota may be relevant in the regulation of immune processes and in the development of systemic autoimmune diseases (SADs). A reduction of microbiota diversity and a selective decrease of commensal pro-regolatory bacteria have been observed in systemic lupus erythematosus (SLE), Sjogren syndrome (SJS) and primary anti-phosholipid syndrome (PAPS). None studies have been performed on undifferentiated connective tissue disease (UCTD) and into an enlarged panel of SADs at the very same time, integrating microbiome data with the plasma metobolomic profile.

Objectives: to perform an integrated investigation of microbiomic and metabolomic profile in patients with SADs and healthy controls (HC) within the PRECISESADs study.

Table. Clinical and demographic characteristics

Methods: a total of 125 subjects (29 SLE, 22 SJS, 12 PAPS, 26 UCTD, 36 HC) were enrolled (**Table 1**). Gut microbiome analysis through 16s-RNA sequencing on stool samples and metabolomic analysis on plasma samples with high-performance liquid chromatography coupled to electrospray ionization and quadrupole time-of-flight mass spectrometry (HPLC-MS-ESI-QTOF) were performed. Data mining algorithms were used to assess a single subset of microbiomic and metabolomic variables capable of to jointly distinguishing the groups of subjects. Microbial and metabolic signals were correlated adjusting for potential confounders (age, therapy) and corrected with stepwise procedure, minP. A Kruskall-Wallis (KW) test with a post hoc Dunn test were used for statistical analysis of microbial genera relative abundance and for metabolic peaks within groups.

Results: From 130 gut bacterial genera, a subset of 29 was able to jointly distinguish the study groups (AUROC=0.730±0.025). Similarly, of 254 metabolic peaks, 41 were able to discriminate study groups (AUROC=0.748±0.021). In both models, HC were well separated from SADs, while UCTD largely overlapped with other disease groups (Figure 1). The relative abundance of pro-tolerogenic bacterial strains such as Lachnospiraceae was

reduced in SADs (p=1.77E-06) while an increase of pro-inflammatory genera (Collinsella, Streptococcus, Clostridiales with p< 0.001) was observed. Metabolic alterations included mostly members of the carnitine family and phospholipids. Microbiomic genera significantly correlated with metabolic peaks as shown in Figure 2 and Acylcarnitines were directly correlated with a Prevotella-enriched cluster and inversely correlated with a butyrate-producing bacteria-enriched cluster. The latter was also inversely correlated with a phospholipid-enriched cluster.

Conclusion: A common microbiomic and metabolomic profile jointly distinguish SLE, PAPS, SJS, UCTD and HC. SADs are characterized by a reduction of pro-tolerogenic bacterial genera and the presence of correlations between microbial genera and metabolites support the hypothesis of an interaction between intestinal microbiota and metabolic functions.

Prevalence of Systemic Lupus Erythematosus in the United States: Preliminary Estimates from a Meta-Analysis of the Centers for Disease Control and Prevention Lupus Registries

Emily Somers,[1] Lu Wang,[2] W Joseph McCune,[3] S Sam Lim,[4] Cristina Drenkard,[4] Elizabeth Ferucci,[5] Maria Dall'Era,[6] Caroline Gordon,[7] Charles Helmick,[8] Hilary Parton,[9] and Peter Izmirly[10], [1]University of Michigan Schools of Medicine & Public Health, Ann Arbor, MI, [2]University of Michigan, Ann Arbor, [3]University of Michigan, Ann Arbor, MI, [4]Emory University, Atlanta, GA, [5]Alaska Native Tribal Health Consortium, Anchorage, AK, [6]University of California, San Francisco, San Francisco, CA, [7]University of Birmingham, Birmingham, United Kingdom, [8]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, GA, [9]New York City Department of Health & Mental Hygiene, Long Island City, NY, [10]NYU School of Medicine, New York

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes
Session Type: ACR Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The heterogeneity of the clinical manifestations of systemic lupus erythematosus (SLE) and lack of a diagnostic test make SLE difficult for epidemiologists to study. The Centers for Disease Control and Prevention (CDC) supported five population-based SLE surveillance registries, using harmonized methodology, to better estimate incidence and prevalence of SLE in diverse areas in the United States (US). Leveraging these data, we performed a meta-analysis to estimate the general prevalence of SLE in the US.

Methods: The CDC registries were established in Michigan, Georgia, California, New York and the through the Indian Health Service (IHS). All registries used the 1997 revised ACR classification criteria for SLE as their primary case definition, and the surveillance time periods ranged from 2003 to 2009. Age-standardized prevalence was stratified by sex and race/ethnicity from the state-based registries; the American Indian/Alaska Native (AI/AN) estimate was based on the IHS registry that covered multiple states. For pooling data across the four sites with data on different racial/ethnic groups, we used Cochran's Q and I^2 statistic to test for heterogeneity across sites. Due to significant heterogeneity, we used a random effects model to calculate pooled prevalence, which allows for more variation across

Table 1. Sex, race and ethnicity-specific estimates for systemic lupus erythematosus prevalence in the United States (2003-2009), and estimated number of persons in the US living with SLE according to the ACR classification criteria (2017)

	FEMALE		MALE	
	Prevalence [a] per 100,000 (95% CI)	Estimated # in United States	Prevalence [a] per 100,000 (95% CI)	Estimated # in United States
Race				
Black	230.9 (178.2, 299.2)	55,089	26.7 (19.6, 36.4)	5,881
White	84.7 (68.4, 104.84)	108,472	8.9 (8.0, 10.1)	11,202
Asian/PI	84.4 (48.3, 147.4)	9,293	11.2 (5.7, 21.9)	1,138
AI/AN	271 (238, 307)	6,333	54 (36, 77)	1,270
Total [b]	***128.7 (113.3, 146.2)***	***179,186***	***14.6 (12.2, 17.5)***	***19,491***
Ethnicity				
Hispanic [c]	120.7 (84.0, 173.4)	35,205	18.0 (15.6, 20.8)	5,360

[a] Estimates for blacks and whites are based on pooled estimates from the four state-based registries; Asian/Pacific Islanders (Asian/PI) and Hispanics are based on pooled estimates from Michigan, California and New York; American Indian/Alaska Native (AI/AN) estimates are based on the IHS Registry.

[b] The pooled 'total' estimate includes black, white and Asian/Pacific Islanders (Asian/PI). Since the American Indian/Alaska Native (AI/AN) prevalence was based on one registry and was significantly higher, it was not included in the pooled prevalence.

[c] Hispanic ethnicity is not mutually exclusive from the race categories, i.e., all Hispanic persons are included in one of the race categories. Thus, the pooled estimates do not incorporate the Hispanic rates since that would lead to duplicate counting.

sites. We then extrapolated to the 2017 Census population data according to sex and race-stratified groups, including data from the IHS registry, and summed the stratum-specific estimates to provide a total population estimate of SLE cases in the US.

Results: The registries contributed 5,417 classified cases of SLE from a mix of urban and rural areas. From the meta-analysis of the four state-based registries, the overall prevalence was 72.8 (95%CI 65.3, 81.0) per 100,000 population. The prevalence among females was about 9 times higher than males (128.7 vs 14.6). In the meta-analysis, prevalence was highest among black females (230.9, 95%CI 178.2, 299.2), followed by Hispanic females (120.7, 95%CI 84.0, 173.4), white females (84.7, 95%CI 68.4, 104.8) and Asian/Pacific Islander females (84.4, 95%CI 48.3, 147.4). Among males, prevalence followed a similar pattern with the highest rates among black males (26.7, 95%CI 19.6, 36.4) followed by Hispanic males (18.0, 95%CI 15.6, 20.8), Asian/Pacific Islander males (11.2, 95%CI 5.7, 21.9), and white males (8.9, 95%CI 8.0, 10.1). The AI/AN prevalence estimates, which were not included in the meta-analysis, had the highest rates of SLE for both females (271, 95%CI 238, 307) and males (54, 95%CI 36, 77). Applying our sex- and race-specific prevalence estimates to the corresponding population denominators from 2017 Census data, we estimated that 198,677 persons (179,186 females and 19,491 males) in the US fulfill ACR SLE classification criteria, Table 1.

Conclusion: Using estimates from a coordinated network of population-based SLE registries, a more accurate prevalence estimate for the US was obtained. Our methods did not capture undiagnosed, "incomplete", or other forms of lupus such as cutaneous lupus. Other case definitions may yield different results.

Session Title: SLE – Clinical VI: Epidemiology, Diagnosis, & Outcomes

Session Type: ACR Abstract Session

Session Time: 9:00AM–10:30AM

Background/Purpose: Cell-bound complement activation products (CB-CAPs) are stable forms of classical complement activation ex-vivo, with high sensitivity and specificity for systemic lupus erythematosus (SLE). We sought to compare the performance of CB-CAPs to the gold standard low complement C3 or C4 in distinguishing SLE from other rheumatic diseases and healthy individuals.

Methods: Multiple academic centers in the United States contributed to the adult (>= 18 years) cross sectional cohort (n=1200) consisting of SLE (n=450), healthy individuals (n=252), and other rheumatic diseases (n=450; 189 RA, 88 Sjögren's, 90 fibromyalgia, and 83 other connective tissue diseases). Abnormal CB-CAPs status (erythro-

	Sensitivity	Specificity	AUC 95% CI	OR 95% CI	AIC
Low C3 (<81 mg/dl)	27%	97%	0.620 (0.599, 0.641)	10.9 (6.28,18.91)	1200
Low C4 (<12.9 mg/dl)	27%	97%	0.618 (0.596, 0.639)	9.57 (5.67,16.15)	1206
Low C3 or low C4	38%	93%	0.656 (0.632, 0.681)	8.34 (5.55,12.53)	1174
Abnormal EC4d (>14 net MFI)	43%	92%	0.675 (0.650, 0.700)	8.67 (5.9,12.72)	1153
Abnormal BC4d (>60 net MFI)	50%	94%	0.718 (0.693, 0.743)	14.95 (9.81,22.77)	1082
Abnormal EC4d or BC4d	62%	88%	0.746 (0.719, 0.772)	11.05 (7.95,15.37)	1067
Complement Score (>1)	45%	98%	0.812 (0.788, 0.836)	36.0 (18.76,68.98)	1037

Table. Abnormal CB-CAPs compared to low C3/C4 in distinguishing SLE from other autoimmune rheumatic diseases

cyte bound C4d [EC4d] and/or B-Lymphocyte bound C4d [BC4d] >99th percentile of normal healthy group) was determined using flow cytometry. Serum low C3 (< 81 mg/dl) and low C4 (< 12.9 mg/dl) levels was determined using immunoturbidimetry. Performance of the markers, either alone or in combination, to distinguish SLE from other rheumatic diseases and healthy controls were established using sensitivity, specificity, odds ratio (OR) and area under the curve (AUC) of the receiver operating characteristic curve (ROC). Youden Index (Sensitivity + Specificity – 100) and Akaike information criteria (AIC) were also calculated. The combination of 4 complement marker abnormalities was also evaluated using logistic regression and composite score cumulating the presence of these abnormalities was calculated.

Results: Abnormal CB-CAPs status yielded 62% sensitivity with 88% specificity in distinguishing SLE from the group with other diseases (Table). Youden index was 0.492±0.027. Low C3/C4 status yielded 38% sensitivity and 93% specificity in distinguishing SLE from the group with other diseases. Youden index for low C3/C4 (0.313±0.025) was significantly lower than the index associated with abnormal CB-CAPs status ($p< 0.01$). Specificity of low C3/C4 and abnormal CB-CAPs in distinguishing SLE from healthy individuals was 93% and 99%, respectively. AUC was significantly higher with BC4d (0.718) than with EC4d (0.675; $p< 0.01$), low C3 (0.620; $p< 0.01$), low C4 (0.618; $p< 0.01$) and low C3 and/or C4 status (0.656; $p< 0.01$). Average (SEM) composite score cumulating all 4 abnormalities (range 0-4) was higher in SLE (1.47±0.06) than disease control group (0.21±0.02) ($p< 0.01$) and healthy individuals (0.01±0.02) ($p< 0.01$). The cumulative complement scoring system yielded higher AUC (0.812), higher OR (36.0 CI95%: 18.8-69.0), lower AIC (1037) than low C3/C4 or abnormal CB- CAPS; score greater than 1 abnormality yielded 45% sensitivity and 98% specificity.

Conclusion: Our data suggest that the combination of CB-CAPs with low complement have superior diagnostic performance in SLE than either abnormality alone.

Abstract Number: 2888

Deriving Accurate Prednisone Dosing from Electronic Health Records: Analysis of a Natural Language Processing Tool for Complex Prescription Instructions

Francine Castillo,[1] Adrienne Strait,[2] Michael Evans,[3] Julia Kay,[4] Milena Gianfrancesco,[5] Zara Izadi,[6] Laura Trupin,[1] Mylien Hoang,[7] James Shalaby,[8] Gabriela Schmajuk,[9] and Jinoos Yazdany[4], [1]University of California, San Francisco, San Francisco, CA, [2]UCSF School of Medicine, San Francisco, CA, [3]University of California San Francisco, San Francisco, [4]UCSF Division of Rheumatology, San Francisco, CA, [5]University of California, San Francisco, San Francisco, [6]UCSF Division of Rheumatology, San Francisco, [7]Touro University, San Francisco, [8]Elimu Informatics, San Francisco, [9]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Health Services Research II: Health Economics

Session Type: ACR/ARP Abstract Session

Session Time: 9:00AM–10:30AM

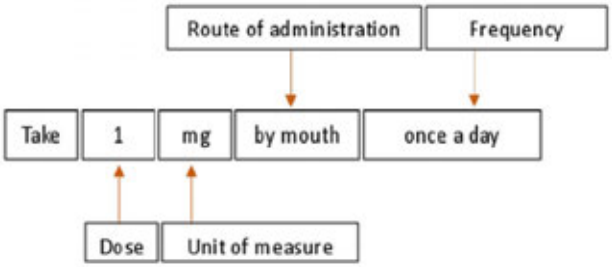

Figure 1. Sample sig from an electronic prescription. Electronic prescriptions are a potential data source for tracking prednisone use. The sig is the free-text portion of electronic prescriptions that conveys medication instructions for the patient, containing a maximum of 140 characters.

Background/Purpose: Prednisone is commonly used to treat rheumatic diseases, yet few comparative effectiveness studies on different dosing regimens are available. Electronic health records (EHR) and prescriptions are potential data sources for such research. However, a barrier to this work is organizing non-standardized prednisone "sigs", or free-text instructions within a prescription, into a standardized and analyzable format. Natural language processing (NLP) tools can potentially be used to extract accurate doses from complex sigs across large prescription data sets. In this study, we compared the daily prednisone dose derived from application of a commercially available NLP tool to manual review of prednisone sigs. Additionally, to understand if sigs accurately captured physicians' recommendations, we compared the prednisone dose derived from analysis of the sig alone to a review of the clinical notes.

Methods: Data for this study were derived from the EHR of an academic health center. 284 prescriptions from 113 randomly selected patients receiving prednisone in clinical encounters between January 1, 2018 and June 22, 2018 were analyzed. Two reviewers independently codified each prescription's sig into discrete structured data, which were used as the benchmark for comparison. An NLP tool, Sigmaster, was then used to automate this data extraction. Sigmaster uses a database of common sigs to map clinical text and translates this information into discrete data, such as dose, frequency, duration, and units. Its performance in determining patients' prednisone doses was assessed by applying it to the sig data and evaluating its output to our manual review-adjudicated benchmark. The validity of sigs as a data source was also evaluated by comparing daily doses of prednisone derived from our manual review of sigs with physician-recommended prednisone doses as recorded in clinical notes. Doses were considered concordant if they were an exact match.

Results: The NLP tool achieved 88.6% concordance with the manual review-derived sig interpretations. The most common reasons for discordance were ambiguous sigs ("Take 1 tab daily, or as directed") and sigs containing multiple phrases ("Take 1 tablet (5 mg total) by mouth daily. Take with one mg tablets to achieve prednisone taper"). However, only 50% of sigs were concordant with physician recommendations derived from clinical notes. The most common reasons for this latter discordance included failure to record tapers in sigs, inaccurate doses in sigs, and sigs with ranges larger than the dose recorded in the note. Given the discordance between manually reviewed sigs and clinical notes, application of the NLP tool to the sig alone would have captured the physician's recommendation in the note only 44% of the time.

Concordance of Dose Data Codified by the NLP tool vs. Manual Sig Review		Concordance of Dose Data Extracted from Clinical Notes vs. Prescription Sigs	
Classification	Unique Sigs (n=123)	Classification	Prescriptions (n=284)
NLP tool and manual sig review concordant	109 (88.6%)	Clinical note and sig concordant	142 (50%)
NLP tool and manual sig review discordant	14 (11.4%)	Clinical note and sig discordant	121 (42.6%)
		Unable to determine concordance	21 (7.4%)

Table. Concordance between NLP tool and manual review of sigs and concordance between manually reviewed sigs and clinical notes.

Conclusion: Although application of an NLP system to extract prednisone doses from complex prescription sigs had relatively high accuracy, significant discordance between sigs and physician notes suggests that sigs alone may be inadequate for research studies. Our study suggests that future NLP systems may need to create a hierarchy to capture physician-intent in glucocorticoid prescribing from EHRs, prioritizing data from clinical notes over prescription sigs alone.

TOTAL: Medicare and Medicaid[d]	$871,850,059	-	99%	100%	-		

Data pertains to Medicare Part D, unless otherwise indicated

[a]Amounts paid by Medicare, beneficiaries (as deductible, coinsurance, or copayment), and third-parties

[b]Applying time-varying manufacturers' rebates on brand-name drugs, ranging from 20% (year 2012) to 30% (year 2017); rebates not applied to generics nor drugs dispensed under Part B

[c]Amounts paid by Medicare, beneficiaries (as deductible, coinsurance, or copayment), and third-parties (e.g., supplemental Part B insurance plans)

[d]Excluding rasburicase. Pegloticase and rasburicase are both recombinant forms of urate oxidase, but only pegloticase is formally indicated for gout.

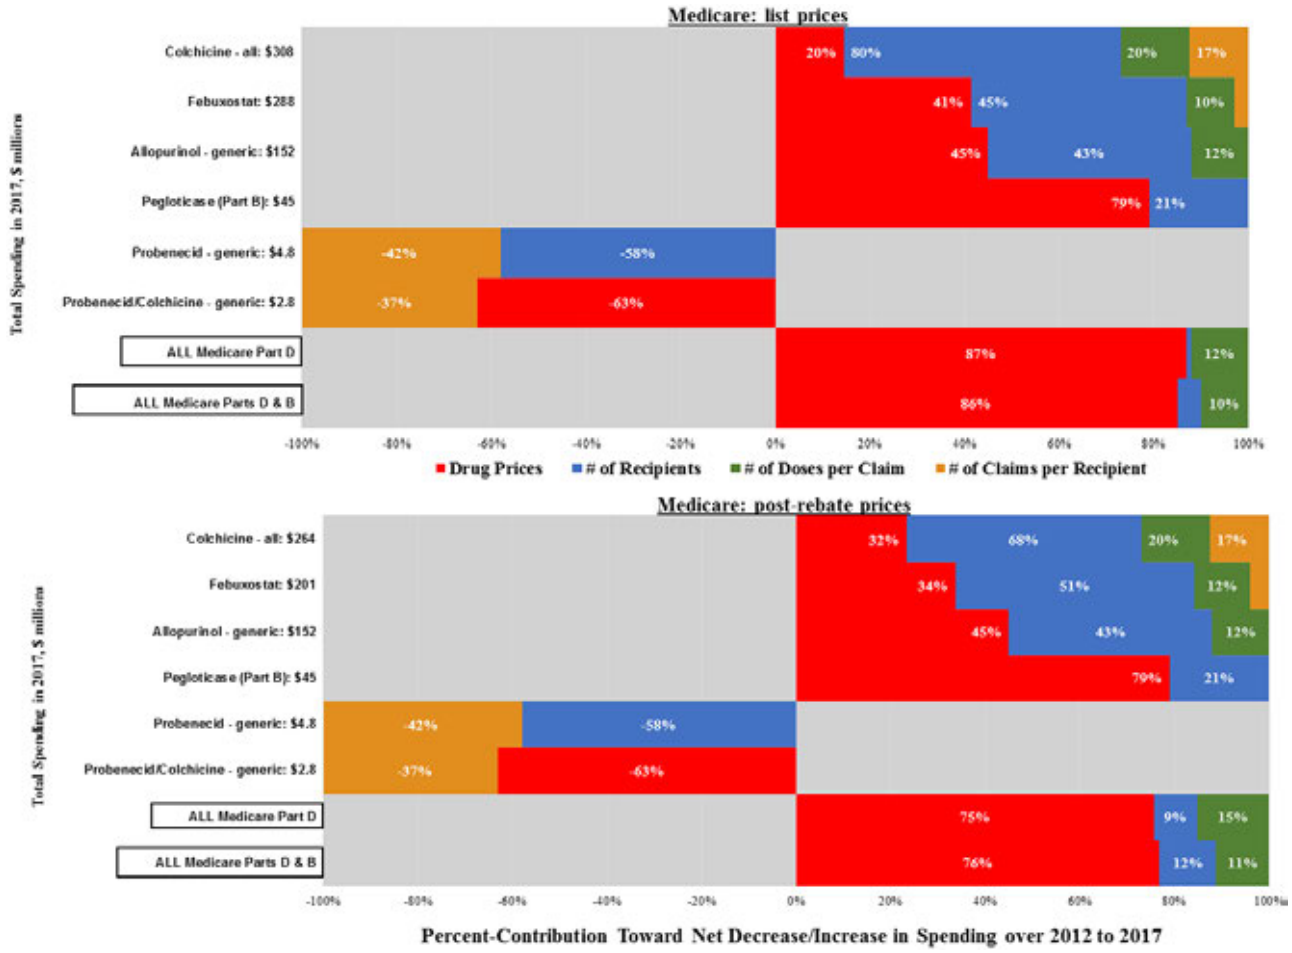
Spending and Utilization for Gout Drugs Covered Under Medicare Parts D and B

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Health Services Research II: Health Economics
Session Type: ACR/ARP Abstract Session
Session Time: 9:00AM–10:30AM

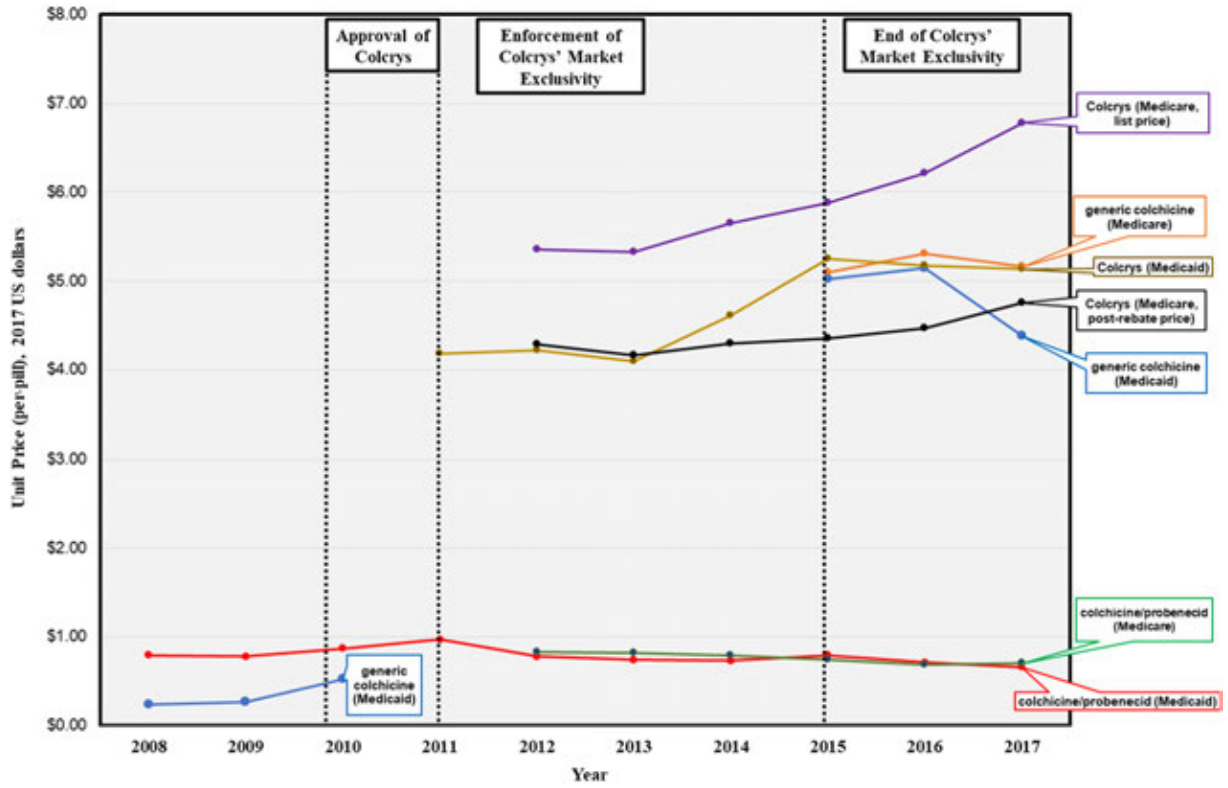
Background/Purpose: Gout affects >4 million US adults aged ≥ 65 years, but little is known about the scale and drivers of public spending on gout medications, including colchicine. Used for decades, its price rose drastically after one brand-name form (Colcrys) was granted market exclusivity from 2011-2014, as part of the FDA Unapproved Drugs Initiative.

We quantified changes in total spending and unit prices for gout drugs in Medicare and Medicaid, and key drivers. We also assessed colchicine prices and spending before, during, and after Colcrys' market exclusivity.

Methods: We used Medicare Parts B & D and Medicaid drug spending data for years 2012-2017, and Medicaid Drug Utilization Data for 2008-2017. These contain aggregated prescription claims for the > 42 million beneficiaries enrolled in Medicare Part B (fee-for-service) or Part D (stand-alone or Medicare Advantage plans) or Medicaid. We included 5 drugs in our main analysis (colchicine, probenecid, allopurinol, febuxostat and pegloticase) along with rasburicase (a urate kinase, like pegloticase, but not indicated for gout).



Component proportion of gout medication spending changes from 2012 to 2017, before and after adjustment for time-varying Medicare Part D rebates



Mean annual drug unit-prices (cost per-pill) for colchicine before, during, and after brand-name Colcrys' period of market exclusivity

Analysis: We calculated six-year changes in total spending and unit prices (mean cost/dose) for each drug and in aggregate, standardised to 2017 dollars, and assessed colchicine over 2012-2014 (Colcrys-only) and 2015-2017. We performed standard decomposition analyses to isolate four sources of spending growth: drug prices, uptake [# recipients], treatment intensity [mean # doses/claim], and annual # of claims/recipient.

We conducted our analysis including statutory Medicaid rebates (as these decrease public spending) and excluding and including estimated time-varying Medicare rebates for brand-name drugs (which are paid to Pharmacy Benefit Managers and Part D plans).

Results: From 2012-2017, public-payer and beneficiary spending on the five main gout drugs nearly doubled, from $439 to $872 million (**Table**). Colchicine accounted for 39% of 2017 spending, followed by febuxostat (35%), allopurinol (19%), pegloticase (6%) and probenecid (1%).

Spending on allopurinol and febuxostat increased ~200% over six years, driven nearly equally by growth in recipient numbers and unit prices (**Figure 1**). Pegloticase spending rose by 600%, mainly due to a > 5-fold unit-price hike (from $327 to $1,828 per-mg), while price hikes drove just 25% of spending growth for rasburicase.

Medicare spending on colchicine rose by 19% over the six years, from $258 to $308 million. Annual spending rose by 25% from 2012-2014 (Colcrys only) but changed little from 2015-2017 (Colcrys + generics) (**Table**).

Still, unit prices for the generics ($5.13/pill in 2017) were only marginally lower than Colcrys' ($6.78/pill), and considerably higher than colchicine before Colcrys' approval (~$0.50/pill) and the probenecid-colchicine combination pill in any year (~$0.70/pill) (**Figure 2**).

Trends were similar with and without Medicare price rebates (**Table, Figures**).

Conclusion: Main drivers of increased public spending were the substantial, > 5-fold price hikes for colchicine and pegloticase, and greater uptake of urate-lowering drugs (which may be positive). The re-entry of generic forms did little to mitigate the large financial burden colchicine now imposes on taxpayers and patients.

The Effect of Rheumatoid Arthritis and Biologics on the Acquisition of Subsequent Diseases and Adverse Events: A Matched Longitudinal Population Study

Mark Tatangelo,[1] George Tomlinson,[2] Edward Keystone,[3] Michael Paterson,[4] Nick Bansback,[5] and Claire Bombardier[6], [1]University of Toronto, Toronto, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Mount Sinai Hospital and University of Toronto, Toronto, ON, Canada, [4]Institute for Clinical Evaluative Sciences, Toronto, Canada, [5]University of British Columbia, Vancouver, Canada, [6]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Health Services Research II: Health Economics
Session Type: ACR/ARP Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The direct and indirect effects of rheumatoid arthritis (RA) are difficult to measure in observational studies because:

(1) The inflammatory effects of RA are difficult to separate from underlying age-sex related risk of comorbid conditions

(2) Long-term large sample follow-up of patients is expensive, arduous, and difficult to standardize

(3) Limited methods for selecting appropriate non-diseased controls for matching with RA patients in case-control attribution studies

Our purpose was to utilize an administrative database over a long-term time horizon among a population of patients with identical insurance coverage with RA to separate the underlying age-sex related risk of acquisition of subsequent comorbid conditions, from conditions arising from RA related inflammation.

As a secondary exposure, we tested the plausibility of the introduction of biologics as an avoidance mechanism for subsequent comorbid conditions.

Methods: The study was a matched case-control cohort of adult RA patients from Ontario Canada, identified by validated algorithm. RA patients (cases) were matched 1-1 with age and sex matched controls, and re-matched 1-1 with a separate control group on age, sex, and available disease history using distance matrices.

The index date (exposure) of the match was the year of RA diagnosis for cases from 1995-2015 (Figure 1. Study Diagram).

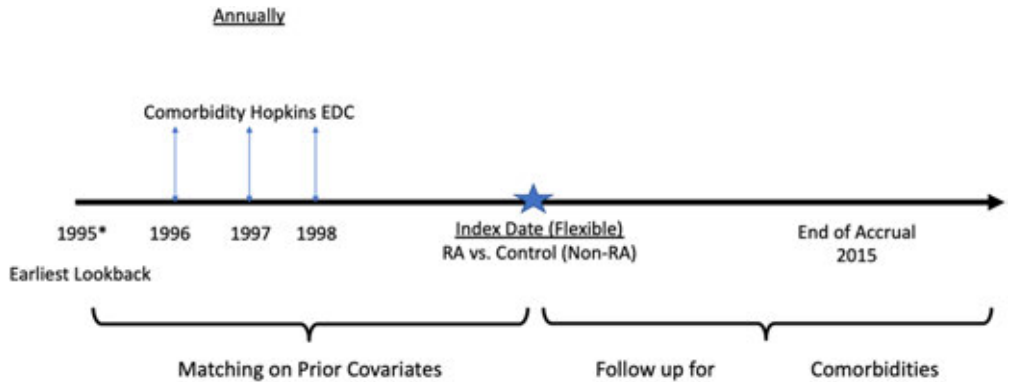

Figure 1. Study Diagram

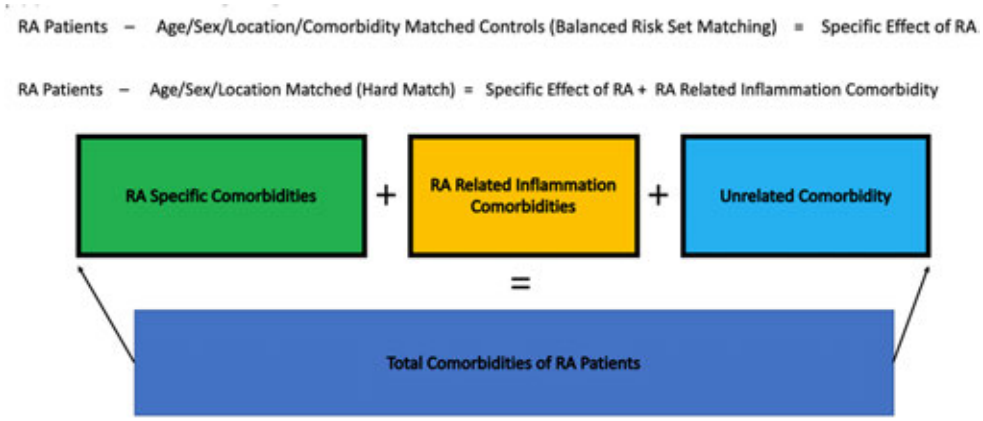

Figure 2. Matching Diagram

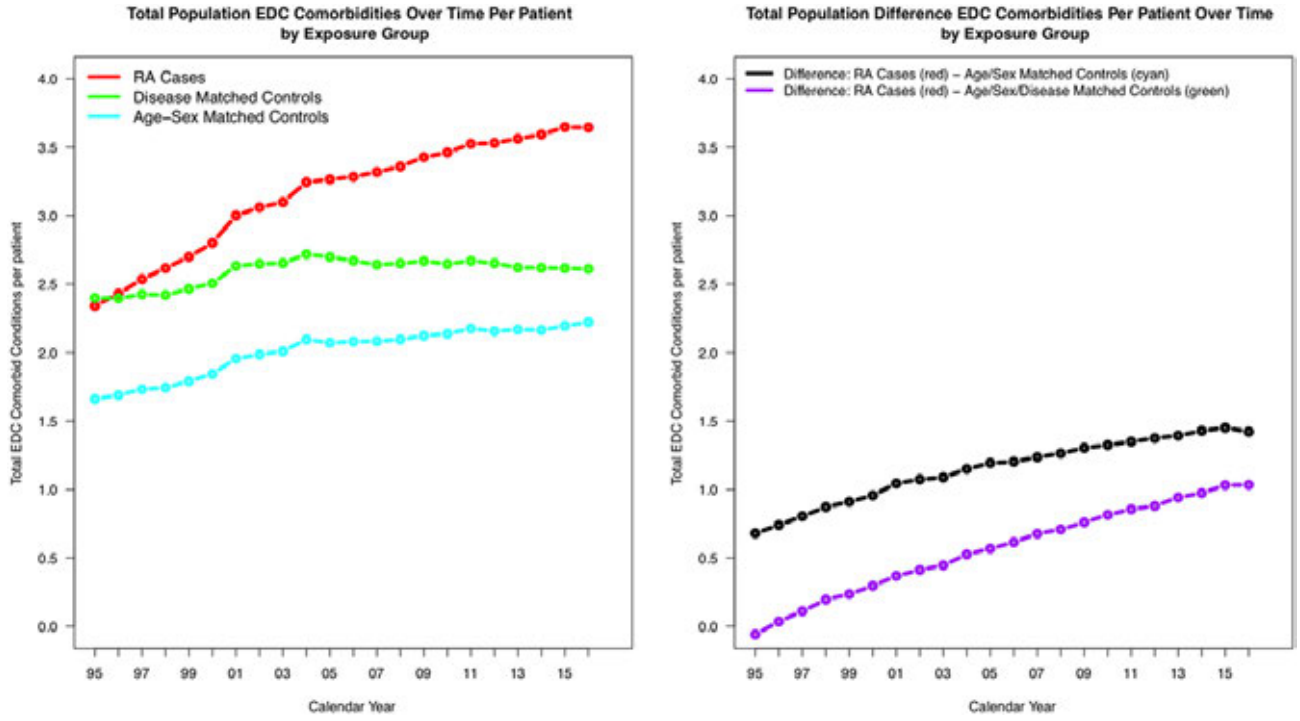

Figure 3. Per Capita Comorbid Conditions Over Time

The outcome variables were comorbidities accrued per patient in each year after diagnosis measured by Hopkins Expanded Diagnostic Clusters (EDC), a summary measure of administrative billing codes mapped on to clinical diagnosis of comorbidities.

The difference between the accrued comorbid conditions between each RAcase and age-sex hard matched control in each year yields the comorbidities assoiciated with RA patients (Figure 2. Matching Diagram) :

RA case - age/sex matched control = age-sex specific underlying risk of comorbid conditions.

The difference between each case and age-sex-disease history matched control yields the direct conferred risk by having RA.

The secondary outcome of modification of downstream disease acquisition was tested by using calendar year as an instrumental variable. From 1995-2001 no biologics were available with greater usage in each subsequent year. Biologics could plausible offset future comorbid conditions if the relative number of comorbid conditions of RA cases compared to similarly matched controls decreased over time.

Results: Of the 136,000 RA patients in Ontario, a random sample of 71,002 RA cases were matched with 71,002 Age/Sex and 71,002 Age/Sex/Medical History Matched Controls. Patients were 75% female, mean age=72, mean year of incidence 2005.

Figure 3. panel shows the per patient comorbidities in each year for all exposure years grouped together by match group. The right panel of Figure 3. shows the difference between RA cases and each matched control group.

Conclusion: This study separates the comorbidities of RA patients relative to age-sex, and age-sex-medical history matched controls. Although this study was a random sample of the population, the plausibility of biologics as a comorbidity avoidance mechanism at the population level may be detectable in administrative data with sufficient analytic tools.

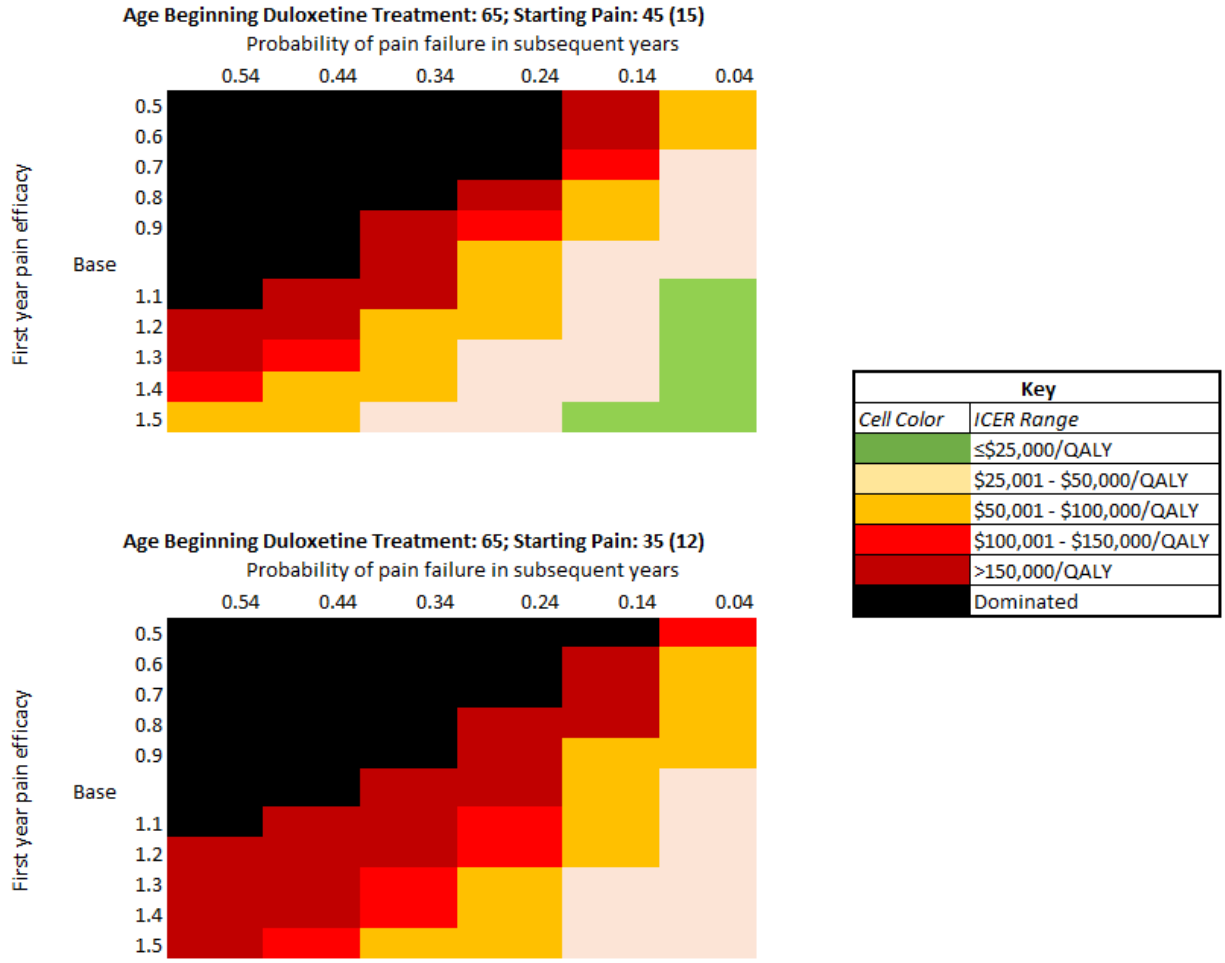
Abstract Number: 2891

Cost-effectiveness of Duloxetine for Knee OA Patients Whose Pain Can't Be Controlled by NSAIDs

James Sullivan,[1] Jeffrey Katz,[2] and Elena Losina[3], [1]Brigham and Women's Hospital, Boston, [2]Brigham and Women's Hospital/Harvard Medical School, Boston, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Health Services Research II: Health Economics
Session Type: ACR/ARP Abstract Session
Session Time: 9:00AM–10:30AM



Two-way sensitivity analysis of probability of pain failure in subsequent years and pain efficacy of duloxetine for subjects beginning duloxetine treatment at age 65 with WOMAC pain 45 (top) and 35 (bottom).

Background/Purpose: Knee OA is a disabling condition affecting over 14 million adults in the US. NSAIDs provide only short-term pain relief, creating the need for additional pain management. Growing evidence indicates that chronic knee OA pain is associated with centralized pain pathways. Based on these considerations, ACR and OARSI recommend or conditionally recommend the use of duloxetine. The cost-effectiveness of generic duloxetine in the US has not been assessed in knee OA.

Methods: We used the Osteoarthritis Policy Model, a validated widely published microsimulation of knee OA, to evaluate the cost-effectiveness of adding duloxetine to usual care (UC) after NSAIDs fail to maintain pain relief for knee OA patients. The UC included intra-articular injections, tramadol, oxycodone, and total knee replacement (TKR). We generated the cohort with the demographic and clinical characteristics (age, BMI, and radiographic severity measured as Kellgren-Lawrence (KL) grade) of knee OA patients who failed NSAID treatment. We then conducted the evaluation of four different cohorts stratified by pain severity (starting WOMAC Pain (0-100, 100 is worst) scores of 25, 35, 45, and 55) and continued treatment with regimens that either did or did not contain duloxetine. We followed subjects until death, recording quality-adjusted life years (QALYs) accrued, total lifetime medical costs, likelihood of using opioids and/or TKR. We used national databases and previously published data to estimate the probability of KL progression, quality of life utilities (stratified by pain, number of comorbidities, age, and BMI), treatment efficacy, direct medical costs of knee OA treatments ($800 for NSAIDs and tramadol, $1,100 for oxycodone, and $1,200 for duloxetine), cost and risk of complications. We discounted costs and QALYs at 3%/year and used a healthcare perspective. We assessed cost-effectiveness by evaluating incremental cost-effectiveness ratios (ICERs) calculated as

the ratio of change in costs to change in QALYs for two competing strategies at a Willingness-to-Pay (WTP) threshold of $100,000/QALY.

Results: Adding duloxetine in addition to UC treatments in OA patients with high pain (45 (15) WOMAC points) resulted in adding 2 QALYS per 100 persons taking duloxetine and increased direct lifetime medical costs by $1,500 per person with resulting ICER of $81,000/QALY. Knee OA patients spent on average 2.25 years on duloxetine. Based on the age of starting duloxetine (56 vs. 75 years), duloxetine reduced the risk of opioid use by 7.2%-15.6% and reduced the use of TKR by 6.8% -12.5%. Duloxetine was not cost-effective (at $100,000 WTP) in those with lower pain (25 or 35 WOMAC points) with resulting ICERs of $580,000 and $148,000/QALY respectively. 2-way sensitivity analyses of pain efficacy and failure found the cost-effectiveness of duloxetine sensitive to both regardless of starting pain (Figure 1).

Conclusion: The addition of duloxetine to the UC for knee OA after failure of NSAIDs is cost-effective for those with high pain and may lead to appreciable reduction in risk of opioid use and utilization of TKR. Use of duloxetine in OA patients with mild pain is not justified based on cost-effectiveness.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Health Services Research II: Health Economics
Session Type: ACR/ARP Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: To assess the cost-effectiveness of various combinations of urate lowering therapy (ULT) and anti-inflammatory treatment in the management of newly diagnosed gout patients, from the Dutch societal perspective.

Methods: The Anakinra versus Treatment as usual in the Treatment of ACute Gout (ATTACG) study was the primary data source for this study. Since only patients with crystal proven gout were included in that study, all patient satisfy the ACR/EULAR gout classification criteria.

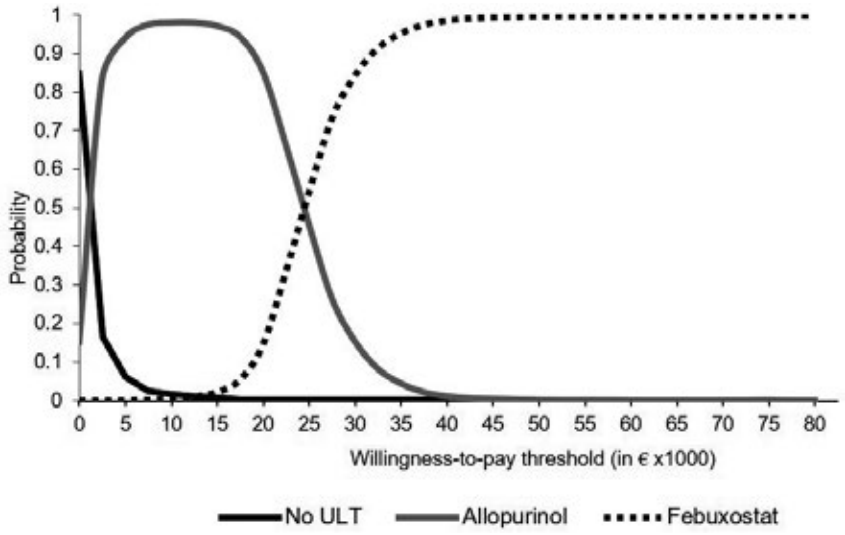
A probabilistic patient-level simulation estimating costs and quality-adjusted life years (QALYs) was performed to compare gout and hyperuricemia treatment strategies. Pain was the main determinant of both QALYs and costs,

	Costs (€)	Effects (QALY)	Δ Cost (€)	Δ Effect (QALY)	ICER (Δ€/Δ QALY)
Allopurinol					
Naproxen	4051.37	0.812493	-	-	-
Colchicine	4066.48	0.812356	15.11	-0.00014	Dominated
Prednisone	4074.27	0.812356	22.9	-0.00014	Dominated
Anakinra	4299.31	0.81274	247.94	0.00025	1,003,805.67

QALY = Quality adjusted life years; ICER = incremental cost-effectiveness ratio; ULT = urate lowering therapy;

	Costs (€)	Effects (QALY)	ΔC (€)	ΔE (QALY)	ICER (Δ€/Δ QALY)
Naproxen					
No ULT	4,031.19	0.78877	-	-	-
Allopurinol	4,063.94	0.81248	32.75	0.02371	1,381.27*
Febuxostat	4,385.40	0.82525	321.46	0.01277	25,173.06**

QALY = Quality adjusted life years; ICER = incremental cost-effectiveness ratio; ULT = urate lowering therapy;



ULT = urate lowering therapy; WTP = willingness-to-pay. Figure displays the CEAC for different ULT combined with naproxen as the anti-inflammatory agent.

with disutility assigned to patients who failed to reach the serum urate (SUA) target (< 0.36 mmol/L). Patients faced a daily risk of a gout flare, with a higher risk for patients who failed to achieve the SUA target level. Health states were no flare, severe pain, mild pain, moderate pain, or no pain in the presence of a flare. Model input was derived from patient level clinical trial data (i.e. SF-6D utility, indirect costs in €'s and pain transition probabilities), meta-analyses or from previously published health-economic evaluations. The results of probabilistic sensitivity analyses were presented using incremental cost-effectiveness ratios (ICERs), and summarized using cost-effectiveness acceptability curves (CEAC). Scenario analyses were performed for gout patients not necessarily experiencing a gout flare at model entry, and for patients with a higher daily flare probability.

Results: In the base case, the ICER for allopurinol versus no ULT was €1,381, when combined with naproxen. Febuxostat yielded the highest utility but also the highest costs (€4,385 vs. €4,063 for allopurinol), resulting in an ICER of €25,173 when compared to allopurinol, all combined with naproxen. No ULT with naproxen was not cost-effective, yielding the lowest utility. For the gout flare medications, comparable effects on utility were achieved. Combined with allopurinol, naproxen was the cheapest option (€4,051), and anakinra the most expensive (€4,299). The ICER of anakinra compared to naproxen, when combined with allopurinol was €1,003,805.67 . Colchicine and prednisone were dominated by naproxen when combined with any of the ULT options. Results of the scenario analyses did not

change the conclusions drawn from comparison of ULT and anti-inflammatory treatment. Results remained robust in scenario analyses.

Conclusion: Allopurinol and febuxostat were both cost-effective compared to No ULT. Febuxostat was cost-effective when compared to allopurinol in case of higher willingness-to-pay thresholds. Anakinra was not cost-effective at any regularly acceptable willingness-to-pay threshold. For treating acute gout flares, colchicine, naproxen and prednisone offered comparable health economic implications. However, naproxen was the favoured and dominant option.

Abstract Number: 2893

Long-term Clinical and Economic Benefits of a Short-term Physical Activity Intervention Among Inactive Knee Osteoarthritis Patients in US: A Model-based Evaluation

Genevieve Silva,[1] James Sullivan,[2] Jeffrey Katz,[3] Stephen Messier,[4] and Elena Losina[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital/Harvard Medical School, Boston, [4]Wake Forest University, Winston Salem, [5]Brigham and Women's Hospital/Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Health Services Research II: Health Economics
Session Type: ACR/ARP Abstract Session
Session Time: 9:00AM–10:30AM

Background/Purpose: The United States (US) knee osteoarthritis (OA) population has low levels of physical activity (PA), despite its well-defined health benefits. Interventions to promote PA are often stymied by concerns of lack of sustainability of intervention efficacy. We sought to evaluate lifetime benefits and cost-effectiveness of a short term (3-year) PA intervention in this population.

Methods: Using the validated computer microsimulation Osteoarthritis Policy Model, we examined the long-term clinical and economic impacts of a 3-year PA intervention for inactive adults, aged 55(5) (mean(SD)), with knee OA. The PA program was concurrent with standard of care (SOC), which included non-pharmacologic, pharmacologic, and surgical guideline-based regimens. The PA intervention, based on the SPARKS (Studying Physical Activity Rewards after Knee Surgery) trial, cost $287/person-year and incorporated wearable activity monitors, health coaching, and financial incentives for reaching predetermined PA goals. We considered 3 PA levels: inactive (< 30 minutes of moderate-to-vigorous PA/week), insufficiently active (30-149 min/week), and active (150+ min/week). Intervention efficacy was derived from the SPARKS data as the probability of increasing PA by at least one level, estimated as 0.38. We used accelerometry data from the Osteoarthritis Initiative to derive the impact of PA level on quality of life (QoL). Annual background medical cost savings for active ($714) and insufficiently active ($313) persons and reduction in incidence of cardiovascular disease (CVD) and type 2 diabetes mellitus (DM) compared to inactive persons were derived from the published literature. In sensitivity analyses we varied PA program cost, impact of PA on QoL, and PA-related background medical costs. All cost and QoL results were discounted by 3% annually. Cost-effectiveness of the PA program was defined using incremental cost-effectiveness ratios (ICERs), calculated as the difference in

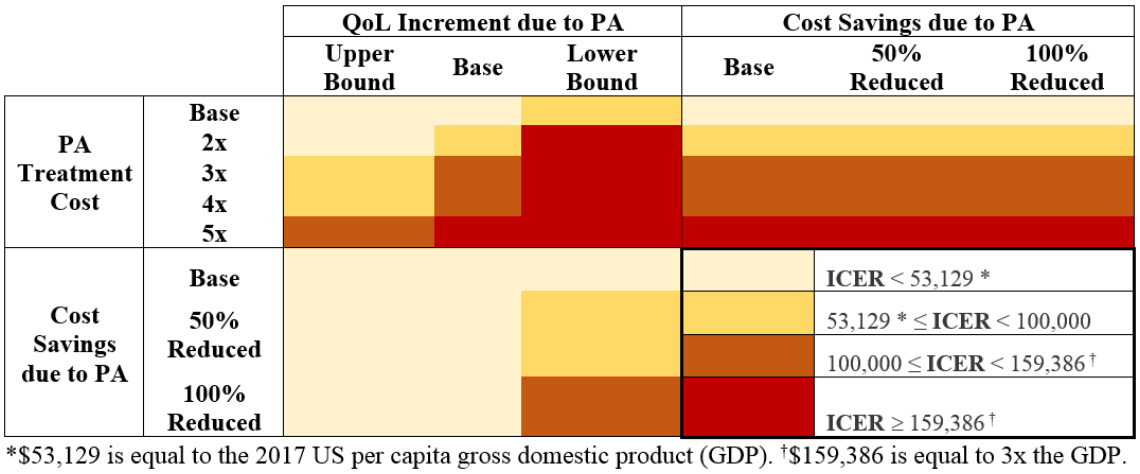

Figure. ICERs (USD/QALY) varying PA treatment cost and impact of PA on annual QoL and background medical costs

cost over the difference in accrued quality-adjusted life-years (QALYs) due to the PA program. This analysis was conducted from a healthcare systems perspective.

Results: The addition of a 3-year PA intervention to SOC for inactive adults with knee OA had an ICER of $16,000/QALY. Participation of 10% of the estimated 4 million inactive US adults with knee OA in such a program could prevent 212 cases of CVD and 319 cases of DM and save 7,476 quality-adjusted life years. Increasing cost of the PA program by 4x raised the ICER to $152,000/QALY (< 3x the US gross domestic product); varying QoL increment due to PA yielded ICERs from $10,000-58,000/QALY; varying background cost due to PA did not qualitatively affect ICERs. Results of two-way sensitivity analyses are presented in the Figure. Offering this program to all US adults with knee OA, regardless of baseline PA, yielded an ICER of $42,000/QALY.

Conclusion: A short-term PA intervention with no sustainability of efficacy beyond a 3-year time horizon in the knee OA population is cost-effective. Given its cost-effectiveness and clinical benefits, providers and payers may consider incorporating a PA intervention into usual care of knee OA patients.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: SLE – Etiology & Pathogenesis II

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

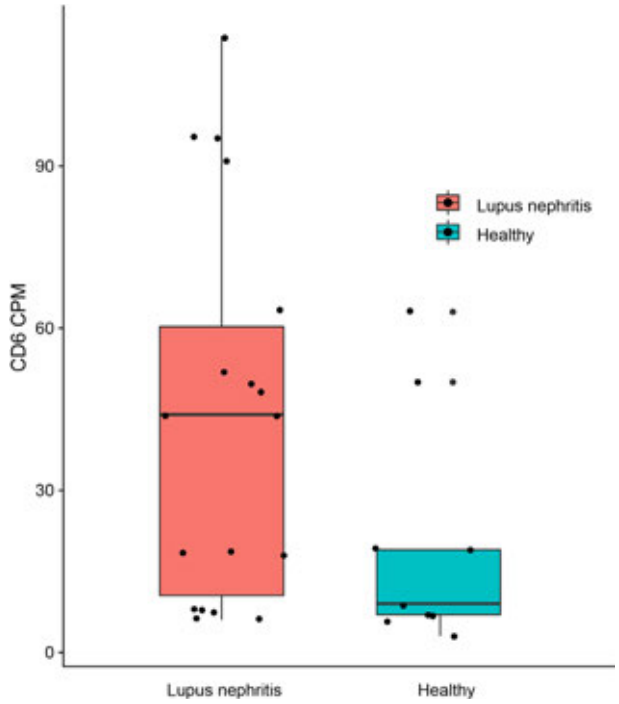

Figure 1. Numbers of CD6 expressing cells in LN (n = 19, red) and healthy control (n = 11, blue) biopsies by single-cell RNA-seq.

Background/Purpose: Lupus nephritis (LN) is a leading cause of morbidity and mortality in Systemic lupus erythematosus (SLE) patients. However, the pathogenesis of renal disease in lupus patients is not yet fully understood. CD6 is a co-stimulatory receptor, predominantly expressed on T cells, that binds to activated leukocyte cell adhesion molecule (ALCAM), a ligand expressed on antigen presenting cells (APCs) and various epithelial and endothelial tissues. The CD6/ALCAM pathway plays an integral role in modulating T cell activation, proliferation, differentiation and trafficking, and is central to immune mediated inflammation. The objectives of this research were to study the expression of CD6/ALCAM in kidneys of LN patients, and evaluate the potential of urine ALCAM as a disease biomarker in LN.

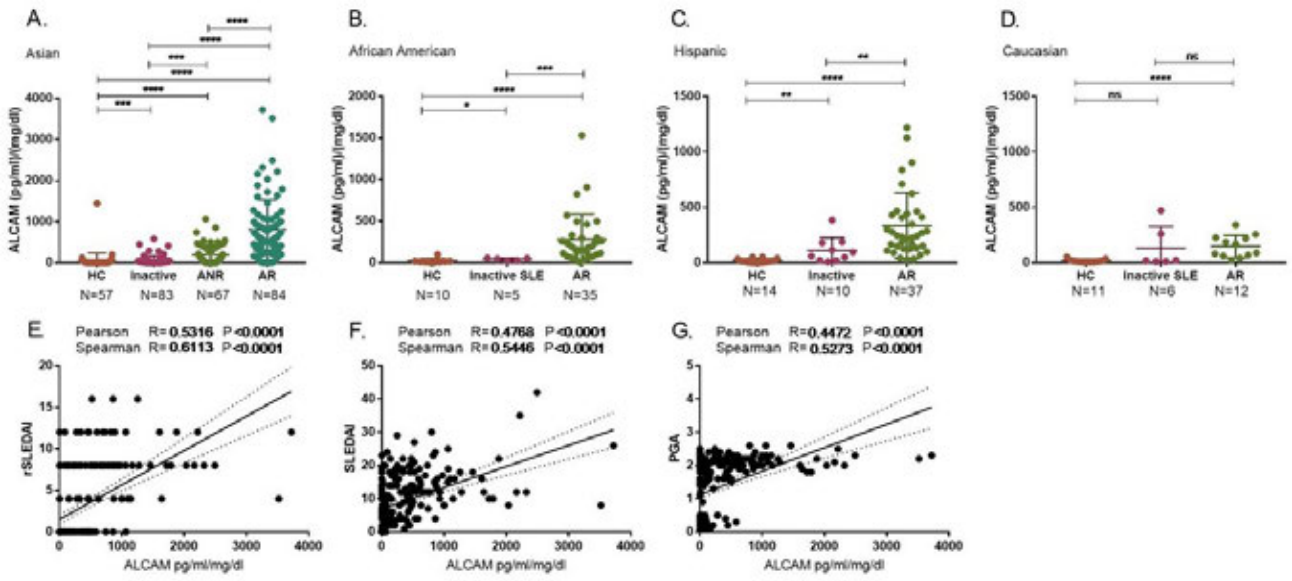

Figure 2. A-D: Cr-normalized urine ALCAM was significantly elevated in active LN patients of multiple ethnicities and discriminated patients with diverse disease activities. E-G: Urinary ALCAM correlated well with several clinical parameters including SLEDAI, renal domains of SLEDAI and PGA. HC, healthy controls, ANR, active non-renal lupus; AR, active renal lupus. *, p<0.05; **, p<0.01; ***; p<0.001; ****, p<0.0001.

Methods: Publicly available single-cell RNA sequencing (scRNA-seq) profiles of clinically indicated renal biopsies obtained from patients with active LN were acquired. scRNA-seq analysis was performed on these datasets using the Seurat package for R. Urine samples were collected from SLE patients of multiple ethnicities and diverse disease activities. ALCAM concentrations were assayed by ELISA then normalized to urine creatinine.

Results: Analysis of biopsies from 19 patients with LN and 11 healthy controls was performed. This analysis confirmed the expression of CD6 exclusively in T cells. ALCAM was expressed in both professional APCs such as macrophages, dendritic cells, and tubular cells. The number of CD6 expressing T cells was elevated in patients with LN compared to healthy controls ($p = 0.08$) (Figure 1). Patients with class III or IV LN trended towards having more CD6 expressing cells than controls. Furthermore, the number of ALCAM expressing tubular cells and macrophages were elevated in LN compared to healthy controls as well. Urine ALCAM was significantly elevated in patients with active LN when compared with controls across multiple ethnicities. In African American, Hispanic, and Asian patients, urine ALCAM further discriminated active LN from inactive SLE or active SLE patients without LN. Urine ALCAM correlated significantly with SLEDAI, rSLEDAI and PGA in Asian SLE patients (all $p< 0.0001$) (Figure 2).

Conclusion: Here, we demonstrate increased activity of the CD6/ALCAM pathway within the renal tissues of LN patients. More specifically, infiltrating T cells do indeed express *CD6* and the number of *CD6* expressing T cells are greater in renal biopsies from patients with LN vs. healthy controls, and in patients with proliferative vs. membranous LN. *ALCAM* expressing macrophages were also numerically elevated in patients with LN, suggesting increased activation of the CD6/ALCAM signaling pathway in LN. Patients with LN also had elevated levels of *ALCAM* expressing tubular cells, indicating these resident kidney cells may contribute to signaling and migration of T cells in the context of LN. Finally, urine ALCAM was significantly elevated in active LN patients in multiple ethnicities, and correlated well with clinical disease status, thus representing a promising biomarker for disease evaluation in LN. These data suggest that a targeted CD6-ALCAM therapy, such as itolizumab, may be a promising for the treatment of LN.

Complement Protein CL-K1 at High Concentrations Protects Against the Development of Lupus Nephritis

Anne Troldborg,[1] Anne Voss,[2] Søren Werner Karlsjov Hansen,[3] Jens Christian Jensenius,[4] Kristian Stengaard-Pedersen,[5] and Steffen Thiel[6], [1]Department of Rheumatology, Aarhus University Hospital, Aarhus, Denmark, Aarhus, Denmark, [2]Odense University Hospital, Department of Rheumatology, Odense, Denmark, [3]University of Southern Denmark, Odense, Denmark, [4]Aarhus University, department of biomedicine, Aarhus, Denmark, [5]Department of Rheumatology, Department of Clinical Medicine, Aarhus University Hospital, Aarhus University, Aarhus, Denmark, Aarhus, Denmark, [6]Department of Biomedicine, Aarhus University, Aarhus, Denmark, Aarhus, Denmark

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Nephritis is a severe manifestation of systemic lupus erythematosus (SLE) that develops in 30 to 50 percent of the patients. At the time of diagnosis, it is not possible to predict which patients will develop nephritis.

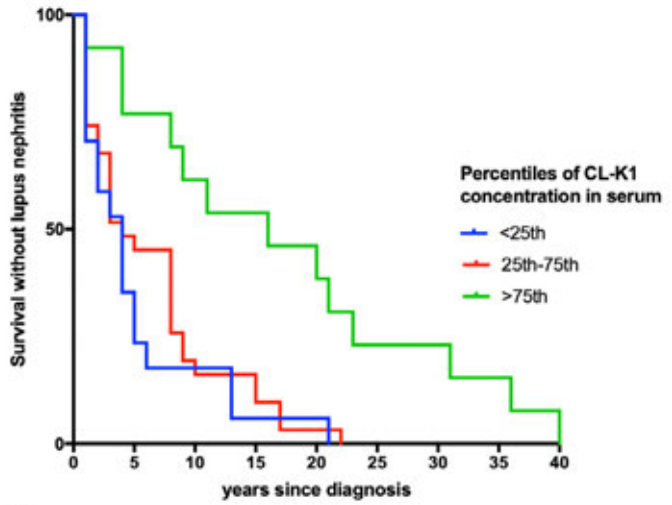

Fig.1

Time to development of lupus nephritis based on low, medium or high serum concentration of CL-K1.

CL-K1 (collectin kidney-1, collectin-11) is a soluble C-type lectin, with collagenous stalks like C1q, that through recognition of suitably spaced patterns of mannose glycans or negatively charged molecules can activate the complement system. It is found in low concentrations in the circulation in heteromeric complexes with collectin-10 (CL-L1). CL-K1 plays a role in the clearance of apoptotic cells through engagement of DNA displayed on the cell surface. Whereas other complement activating lectins, i.e., MBL, is produced only be hepatocytes, CL-K1 is widely distributed in several tissues in the bodyand it seems to distinguish itself by its capacity for production locally in different tissues.

We hypothesized that complement proteins like CL-K1, could play a role in modifying the local response to deposited DNA containing immunocomplexes, that cause inflammation and tissue damage in SLE, and hence play a protective role in the disease.

Methods: Patients included in the study fulfilled the 1997 ACR revised criteria for the classification of SLE. The cohort was included at two Danish university hospitals and has previously been described (1). A total of 372 SLE patients were included out of which 121 had biopsy verified nephritis. Disease onset was defined as the date of fulfillment of the 1997 ACR revised criteria for the classification of SLE. Lupus nephritis was defined by biopsy verified glomerulonephritis classified after the WHO classification system. Serum concentrations of complement proteins were measured in samples available from all included patients using in-house-developed time resolved immune fluorometric assays (TRIFMA).

Results: SLE patients with nephritis were clinically different from patients without this manifestation. They were on average younger at diagnosis (median: 27 vs 35, $p< 0.05$), a larger percentage was positive for anti-double-stranded-DNA (93 vs 85 %, $p >0.05$), and all patients with nephritis were positive for ANA (anti-nuclear antibody). Patients with nephritis had a lower concentration in serum of CL-K1 compared with patients without nephritis ($p< 0.05$). No difference was found for CL-L1. Amongst the SLE patients with nephritis, the patients with high concentrations in serum of CL-K1 had a significantly longer time from diagnosis to the onset of lupus nephritis (fig.1).

Conclusion: High serum concentrations of the complement protein CL-K1 were associated with delayed onset of lupus nephritis in a Danish cohort of 372 SLE patients. CL-K1 could play a protective role against the kidney inflammation and damage seen in lupus nephritis.

The Role of Alterations in the Splicing Machinery in the Pathogenesis of Lupus: Does It Impact Lupus Nephritis?

Chary Lopez-Pedrera,[1] Alejandro Ibañez-Costa,[1] Mª Ángeles Aguirre-Zamorano,[2] Laura Pérez-Sanchez,[3] Alejandra Patiño-Trives,[1] Maria Luque-Tevar,[1] Maria del Carmen Abalos-Aguilera,[1] Ivan Arias de la Rosa,[4] Nuria Barbarroja,[5] Mario Espinosa,[6] Eduardo Collantes-Estevez,[4] Justo Castaño,[7] Raúl Luque,[7] and Carlos Perez-Sanchez[8], [1]IMIBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain, [2]IMIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain, [3]MIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain, [4]University of Cordoba/IMIBIC/Reina Sofia Hospital, Cordoba, Spain, [5]University of Cordoba/IMIBIC/Reina Sofia Hospital and CIBER Fisiopatología de la Obesidad y Nutrición (CIBEROBN), Instituto de Salud Carlos III, Cordoba, Spain, [6]UGC de Nefrología. SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: SLE – Etiology & Pathogenesis II

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: The aim of this study was to evaluate whether alterations in the splicing machinery of immune cells could influence the development and activity of the disease and the kidney involvement in systemic lupus erythematosus (SLE) patients.

Methods: Monocytes, lymphocytes and neutrophils from 43 SLE patients and 34 healthy donors (HD) were purified by immunomagnetic selection. Then, 45 selected elements of the splicing machinery and a set of 48 genes related to inflammation, renal and cardiovascular disease (including interleukins, adipocytokines, chemokines, and oxidative stress markers, among others) were evaluated using a microfluidic qPCR array (Fluidigm). In parallel, an extensive clinical/serological evaluation was performed, comprising renal and CV involvement along with autoantibodies, and inflammatory molecules. Correlation and association studies and logistic models among those clinical and analytical parameters were developed. Separately, mechanistic *in vitro* studies were carried out by incubation of HD-leukocytes with purified anti-dsDNA-IgG from SLE patients.

Results: Altered expression of spliceosome components was demonstrated in the 3 leukocyte subsets: 29, 13 and 22 components were differentially expressed in monocytes, lymphocytes and neutrophils, respectively, vs HD. Intriguingly, any spliceosome component was commonly deregulated among the three leucocyte subsets except for PRPB8, a key component of the spliceosome, that acts as a scaffold protein essential for spliceosome assembly.

Correlation studies demonstrated multiple links among altered spliceosome components and the score of disease activity along with a number of inflammatory and oxidative stress mediators. Remarkably, the levels of those altered components were associated to the presence of lupus nephritis in the three leukocyte subsets. Moreover, we could build different logistic models to precisely identify patients with renal involvement, which integrated the concomitant alteration of: RNU12, RNU4ATAC and RNU6ATAC, in monocytes; RNU4, SRRM1 and U2AF2 in lymphocytes; and PRPF8, SF3B1 and KHDRBS1 in neutrophils.

On the other hand, a logistic model combining RNU6, CELF1 and RAVER1 could classify anti-dsDNA positivity in lymphocytes, thus suggesting the involvement of these autoantibodies in the splicing process. Finally, in vitro treatment of HD lymphocytes with anti-dsDNA promoted the decrease of several spliceosome components found altered in vivo in SLE lymphocytes, such as KHDRBS1, SRSF5 and TRA2B.

Conclusion: 1) The splicing machinery is profoundly altered in leukocytes from SLE patients and closely related to the development and activity of the disease. 2) Evaluation of specific components of the spliceosome in leukocytes subsets might be used to clinically typify kidney involvement. Ongoing studies would clarify the physiological implications of these findings, which may provide novel diagnostic-biomarkers and therapeutic-tools to treat SLE.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is an autoimmune disease with various subsets and clinical manifestations. T lymphocytes are the predominant cell type found in lesional skin, but plasmacytoid dendritic cells (pDCs) and myeloid dendritic cells (mDCs) also play an important role in the pathogenesis. Oral antimalarials, including hydroxychloroquine (HCQ) and quinacrine (QC) are first-line systemic therapy for all CLE sub-types. Although HCQ is effective in approximately 50% of patients, some patients still do not respond to antimalarials. Some of these patients benefit from additional QC, but there is a subset of patients who remain refractory to both antimalarials. Refractoriness poses a huge challenge as patients continue to have active disease despite antimalarial therapy. To better understand reasons for refractoriness in CLE, we investigated the immunologic characteristics of patients who responded to antimalarials versus those who did not.

Methods: One hundred fifteen patients with a diagnosis of CLE were recruited from the Autoimmune Skin Disease Center at the Hospital of the University of Pennsylvania. Sixty-five were well-characterized in terms of response to treatment as (i) HCQ-responders (n=22), (ii) HCQ+QC-responders (n=24), or (iii) HCQ+QC-nonresponders (n=19).

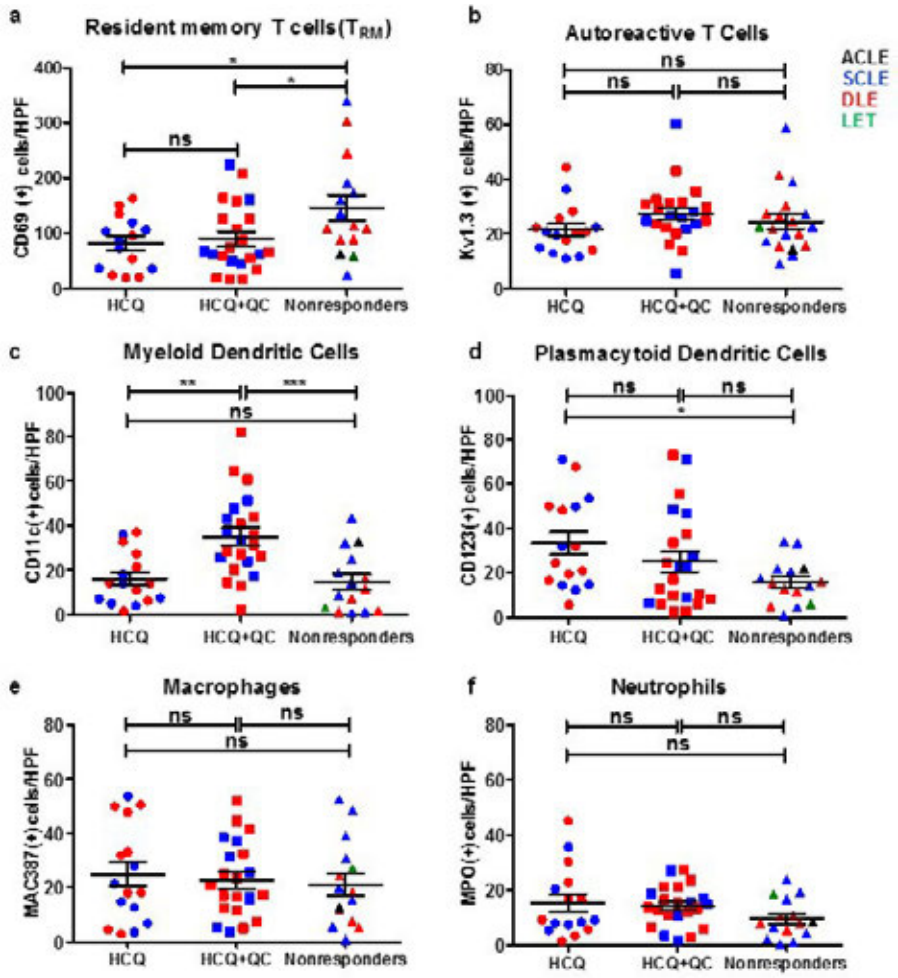

Figure 1. Immune Cell Quantification in HCQ-responders, HCQ+QC-responders, and Nonresponders. There was a significantly higher number of tissue-resident memory T (TRM) cells in nonresponders compared to HCQ-responders and HCQ+QC-responders ($p<0.05$, Figure 1a). There was a significantly higher number of mDCs in HCQ+QC-responders compared to the nonresponders ($p<0.001$, Figure 1c) and HCQ-responders ($p<0.01$, Figure 1c). There was a significantly higher number of pDCs in the HCQ-responders compared to the nonresponders ($p<0.05$, Figure 1d). There was no significant difference in the number of auto reactive T cells (Figure 1b) macrophages (Figure 1e) and number of neutrophils (Figure 1f) among the three groups.

Lesional skin was biopsied before starting treatment with antimalarials. We defined treatment failure to HCQ as continued skin activity requiring a second intervention after at least 2 months of HCQ therapy. Immunohistochemistry was used to characterize the inflammatory cells and cytokine expression in lesional skin biopsies from patients. Total RNA was extracted from these biopsies to analyze specific gene signatures. The patient's CLASI score – a measure of disease activity – at the time of the biopsy was also determined.

Results: Immunohistochemistry showed that CD69+ tissue-resident memory T (T_{RM}) cells were significantly higher in HCQ+QC-nonresponders compared to HCQ- and HCQ+QC-responders. mDCs were significantly higher in HCQ+QC-responders compared to HCQ- and HCQ+QC-nonresponders. There were significantly higher pDCs in the HCQ-responders compared to the nonresponders. There was no significant difference in the number of autoreactive T cells, macrophages, and neutrophils among the three groups (Figure 1). The HCQ+QC-nonresponder group was distinct from the other groups in that their CLASI scores correlated positively with the number of T_{RM} cells ($r=0.6254$, $p=0.017$) and macrophages ($r=0.5726$, $p=0.041$) (Figure 2). mRNA expression demonstrated high STAT3 expression in HCQ+QC-nonresponders (Figure 3). There was a significantly higher percentage of area stained for IL-17 in the HCQ+QC-responders compared to HCQ-responders and HCQ+QC-nonresponders while IL-22 expression was not significantly different between groups.

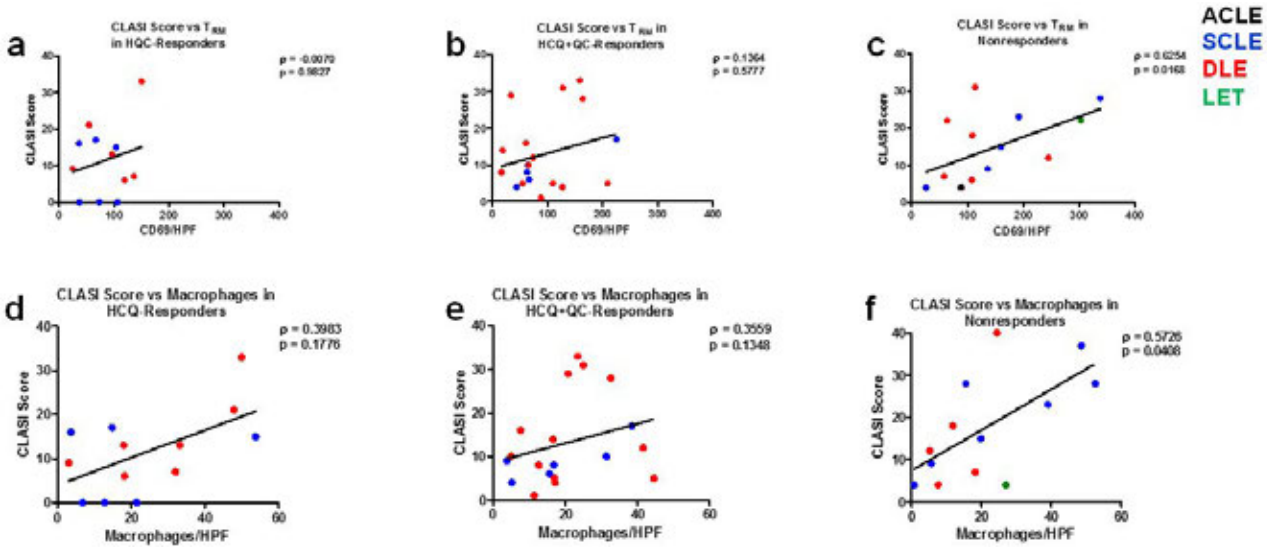

Figure 2. CLASI Score versus tissue-resident memory T (TRM) cells and Macrophages in HCQ-responders, HCQ+QC-responders, and Nonresponders. For the nonresponders, there was a significant positive correlation between the CLASI score with the number of tissue-resident memory T (TRM) cells and macrophages ($p<0.05$, Figures 3c&3f). There was no significant correlation between the CLASI score with the number of tissue-resident memory T (TRM) cells and macrophages counts in the HCQ-responders and HCQ+QC-responders.

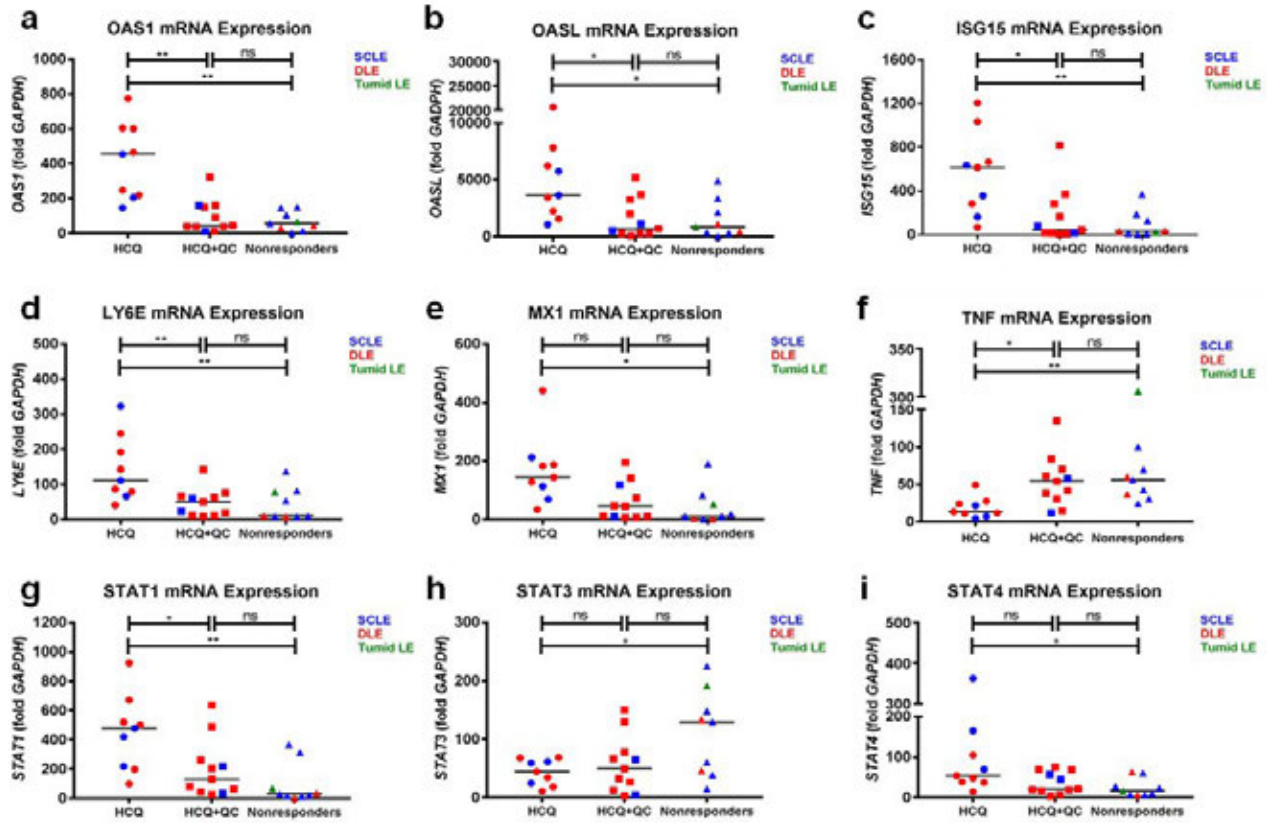

Figure 3. Type 1 Interferon, TNF, and STAT Gene Expression in HCQ-responders, HCQ+QC-responders, and Nonresponders. The nonresponders were found to have a significantly decreased type 1 IFN signature and elevated TNF-α expression compared to the HCQ-responders (OAS1 $p<0.01$; OASL $p<0.05$; ISG15 $p<0.01$; LY6E $p<0.01$; MX1 $p<0.05$; TNF $p<0.01$, Figures 4a-f). In terms of the STAT genes, the nonresponders had increased expression of STAT3 ($p<0.05$, Figure 4h) and decreased expression of STAT1 ($p<0.01$, Figure 4g) and STAT4 ($p<0.05$, Figure 4i) compared to the HCQ-responders. The nonresponders and HCQ+QC-responders had a similar expression profile for all analyzed genes.

Conclusion: An increased number of CD69+ T_{RM} cells and correlation between CD69+T_{RM} cells and macrophages with CLASI scores in the HCQ+QC-nonresponders, a finding not seen in either HCQ or HCQ+QC-responders, may indicate that CD69+ T_{RM} cells and macrophages are involved in antimalarial-refractory skin disease.

Evaluation of the Transcriptome of Non-Lesional, Non-Sun Exposed Skin in Patients with Lupus Nephritis

Hemant Suryawanshi,[1] Robert Clancy,[2] Evan Der,[3] Peter Izmirly,[2] H Michael Belmont,[4] Chaim Putterman,[5] Jill Buyon,[2] and Thomas Tuschl[1], [1]Rockefeller Research Laboratories, New York, [2]NYU School of Medicine, New York, [3]Albert Einstein College of Medicine, New York, [4]NYU Langone Health, New York, NY, [5]Albert Einstein College of Medicine, New York, NY

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: The impact of renal injury in lupus nephritis (LN) is widespread with consequences to resident cells in other tissue beds, even non-lesional, non-sun exposed skin. Faithful reflection of a relevant renal tissue pathway in a more readily accessible compartment would allow for less invasive diagnostic alternatives. While ongoing studies are exploiting single cell RNA sequencing to link phenotype to "biotype" and identify cell specific pathways in the kidney, this study was initiated to address the hypothesis that these pathways may be reflected in uninvolved skin which is more likely to be serially biopsied.

Methods: Single cell RNAseq was performed on cell suspensions prepared from ~2 mm punch biopsies of non-lesional, non-sun-exposed skin from the buttocks of 5 healthy controls, 4 SLE patients without LN and 18 SLE patients with proteinuria (with skin biopsies obtained within 24 hrs of the kidney biopsy). Histology revealed Class III (*n=6*), Class III/V or IV/V mixed (*n=11*), Class V (*n=1*), and nephrosclerosis (*n=1*). Dissociation of cryostored skin biopsies with collagenase and trypsin enzymes was followed by scRNA-seq using the 10x Genomics platform using V2 and V3 reagents.

Results: We obtained 8,019 and 17,655 high-quality scRNA-seq profiles from single cell suspensions of control and SLE non-lesional, non-sun-exposed skin, respectively. A graph-based clustering method was applied and identified major clusters of cells as visualized by t-distributed stochastic neighbor embedding (tSNE). Differential gene expression analysis guided by established markers revealed these cell clusters as keratinocyte (KC), one smooth muscle cell cluster (SMC), fibroblast (FB), melanocyte (MEL), vascular endothelial cells (VEC), lymphatic endothelial cells (LEC), macrophages-dendritic cells (MAC-DC), T cells (TC) and sweat gland cells (SGC) (Figure 1A). Ranking cells by abundance, the result of the SLE skin cells was KC >FB >VEC >LEC, SMC, MAC-DC, TC, MEL and SGC. Overall, samples processed using the recent V3 single cell reagent kit showed higher genes and transcript captures compared to V2. However, these samples also captured more mitochondrial transcripts (Figure 1B). An analysis of gene expression changes in KC, SMC, and VSC from the LN patients versus controls demonstrated overexpression of interferon stimulated genes. However, the degree of interferon response varied in these cell types with KCs (basal KC, p=0.00312 and hair follicle KC, p=0.000012) showing the highest response followed by VECs (p=0.0043) and SMCs

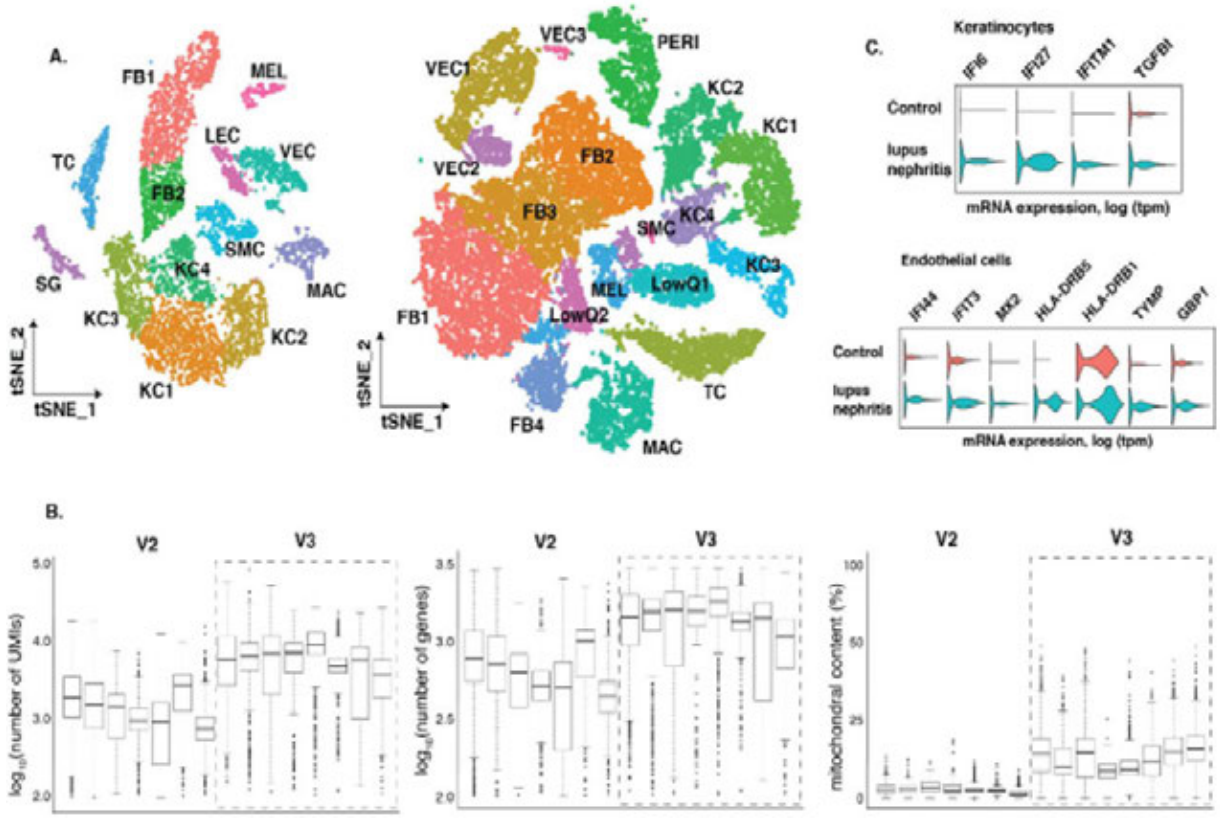

Figure 1. Single cell analysis of skin samples from SLE and healthy controls. A. tSNE plot showing 8019 (left) and 17,655 (right) cells processed using V2 and V3 reagents of 10x Genomics, respectively. B. Comparison of number of genes, transcripts (UMIs) and mitochondrial content in keratinocytes from samples processed on V2 and V3. C. Violin plots showing interferon induced and other differentially expressed genes in LN.

(p=0.0068). In addition to the interferon response signature, VECs from the LN patients also showed upregulation of MHC-II genes such as HLA-DRB5 and HLA-DRB1, suggesting increased antigen presentation capacity (Figure 1C).

Conclusion: scRNA-seq identifies major skin cell types and further clustering identifies rarer cell populations. KCs, SMCs, and VECs from the skin of LN patients reveal diverse IFN response states and additionally VECs also show higher antigen presentation potential. The V3 upgrade of 10x Genomics single cell reagents capture more genes and UMIs per cell, but also higher mitochondrial content compared to the V2 version.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: SLE – Etiology & Pathogenesis II
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Systemic lupus erythematosus (SLE) affects various organs and tissues, but whether pathologic processes in each organ are distinct or whether dysregulated molecular functions are found in common in all tissues is not known. We, therefore, conducted a meta-analysis of gene expression profiles in four affected SLE tissues to identify commonly dysregulated pathways.

Methods: Gene expression datasets for discoid lupus erythematosus (DLE), lupus arthritis (LA), lupus nephritis (LN) glomerulus (Glom), and LN tubulointerstitium (TI) were obtained from GEO. Differentially expressed genes (DEGs) were identified by LIMMA analysis for each dataset. DEGs from each tissue were analyzed with a multi-pronged bioinformatics approach to elucidate common immune cell infiltrates and common functional categories. These findings were then utilized to form modules of co-expressed genes to determine their enrichment using Gene Set Variation Analysis (GSVA).

Results: All tissues demonstrated the presence of immune cells with the fewest immune cell transcripts in LN TI. Analysis of bulk gene expression revealed enrichment of antigen presenting cells (APCs), monocytes, and myeloid cells in all four tissues. Notably, enrichment of B cells, plasma cells, germinal center (GC) B cells, and CD8 T cells was only detected in DLE and LA. All four tissues demonstrated upregulated immune activity, including interferon-stimulated genes, pattern recognition receptors (PRRs), and antigen presentation (MHC Class II). Pro-apoptosis genes were also found enriched in DLE, LN Glom, and LN TI. A generalized decrease in biochemical processes was found in all four tissues and a specific decrease in both fatty acid biosynthesis and the tricarboxylic acid cycle was found in DLE and LN. Ingenuity Pathway Analysis (IPA®) further confirmed the activation of Dendritic Cell Maturation, Interferon, NFAT Regulation of Immune Response, PRRs, and TH1 signaling pathways in all four tissues. Additionally, IPA demonstrated cholesterol biosynthesis was decreased in all tissues except LA.

To confirm the aforementioned cellular infiltrates and aberrant pathways, as well as additional pathways, were operative in individual SLE tissues, GSVA was used to analyze enrichment of gene modules in patient samples. As shown in **Table 1**, **Figure 1**, and **Figure 2**, specific abnormalities were found in the majority of tissues, including enrichment of myeloid cells/monocytes, APCs, and GC B cells, whereas others were observed in some but not all tissues.

Conclusion: Common cellular infiltrates and molecular pathways were found in all affected tissues, suggesting commonalities in lupus organ pathogenesis. However, certain cell types and signaling were predominant in some tissues over others and GSVA illustrated heterogeneity between patients. Together this analysis informs a tissue-specific model of lupus immunopathogenesis and metabolic dysfunction with common and unique features and highlights the importance of patient specific identification of dysfunctional pathways in lupus organ pathogenesis.

Interferon Signature Predicts Response to Tofacitinib in Haploinsufficiency of A20

Sarah Blackstone,[1] Daniella Schwartz,[1] Natalia Sampaio Moura,[1] Deborah Stone,[1] Meryl Waldman,[1] Patrycja Hoffmann,[1] Anne Jones,[1] Tina Romeo,[1] Karyl Barron,[1] Joshua Milner,[1] Daniel Kastner,[1] and Amanda Ombrello[1], [1]National Institutes of Health, Bethesda, MD

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease III: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: The protein A20, encoded by *TNFAIP3*, represses signaling upstream of the inflammatory transcription factor nuclear factor (NF)-kB by regulating ubiquitination. Heterozygous loss-of-function mutations in *TNFAIP3* cause the systemic autoinflammatory disease Haploinsufficiency of A20 (HA20) [1]. Because no FDA-approved medications directly target NF-kB signaling, current HA20 therapies target NF-kB activating cytokines, with biological agents chosen based on clinical experience rather than mechanistic data [2].

Methods: HA20 patients were selected from NHGRI protocol 94-HG-0105 “Genetics and Pathophysiology of Autoinflammatory Disorders”. All patients had mutations in *TNFAIP3* diagnosed by targeted sequencing. Functional activity was confirmed using a reporter assay. Whole blood was extracted into PAXgene tubes, RNA was extracted,

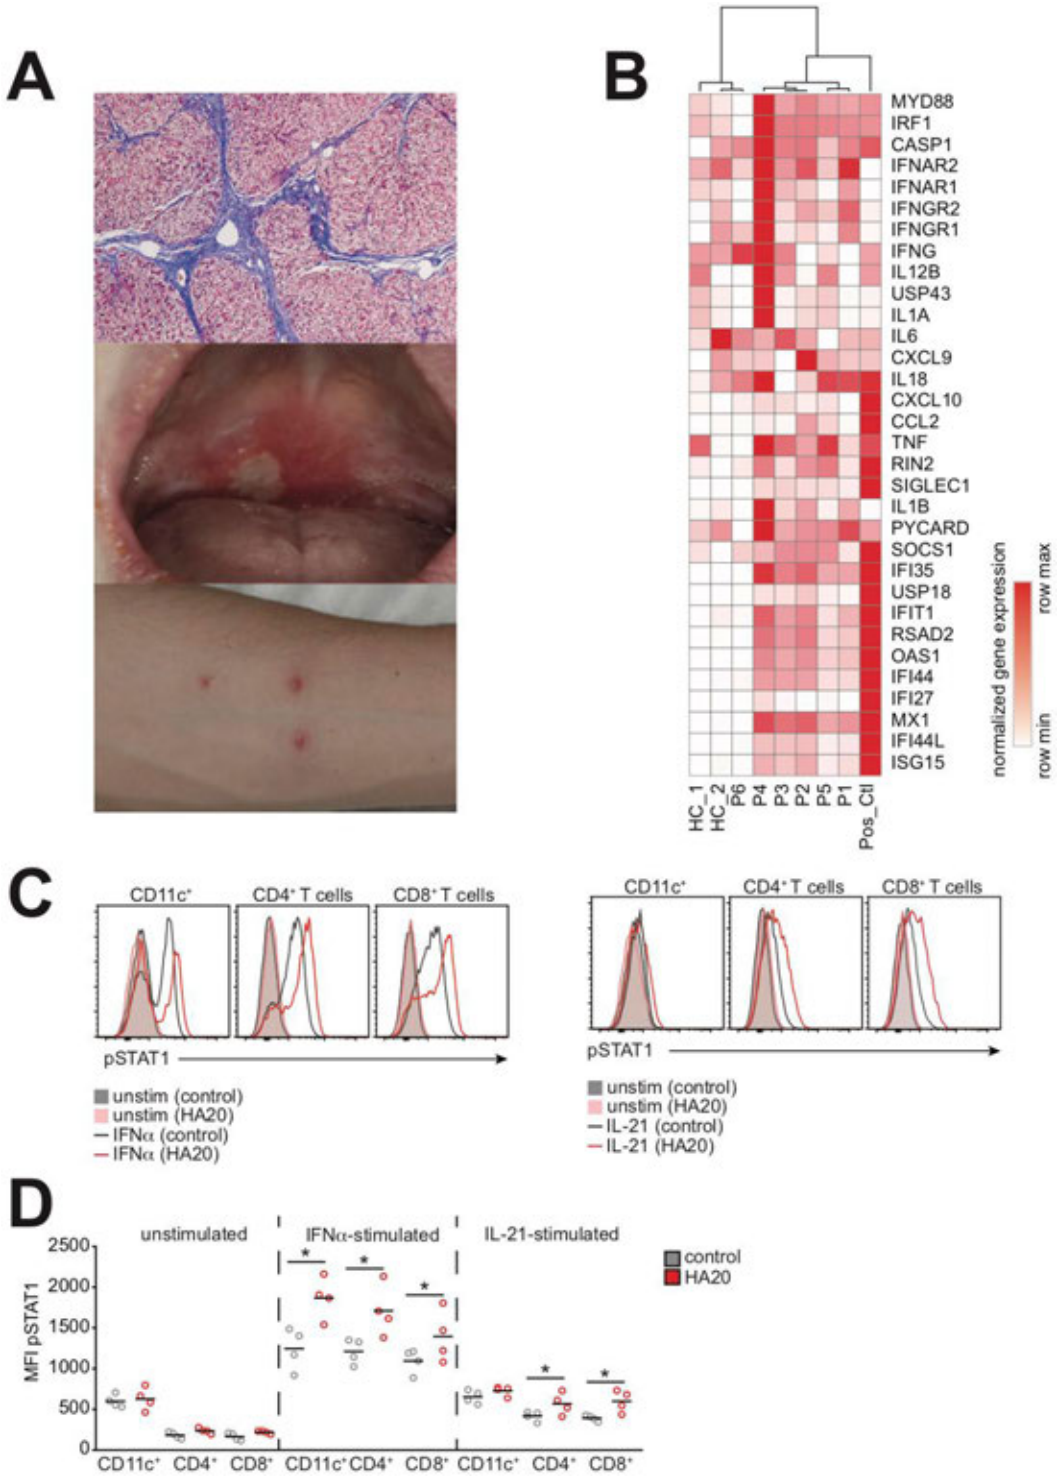

Figure 1. A. Clinical manifestations of HA20: hepatic fibrosis, nephritis, and orogenital ulcerations. B. Expression of interferon-stimulated genes. C-D. STAT1 phosphorylation in response to interferon (IFN)-α and Interleukin (IL)-21.

and Nanostring was used to assess expression of interferon-stimulated genes (ISGs). Peripheral blood mononuclear cells (PBMCs) were isolated and stored in liquid nitrogen. After thawing, cells were rested in R10 media for 2 hours, then in R0 media for 30 minutes before measuring STAT phosphorylation by flow cytometry. Patients were followed every 3-6 months during tofacitinib treatment. Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) were obtained by CLIA-certified clinical laboratories.

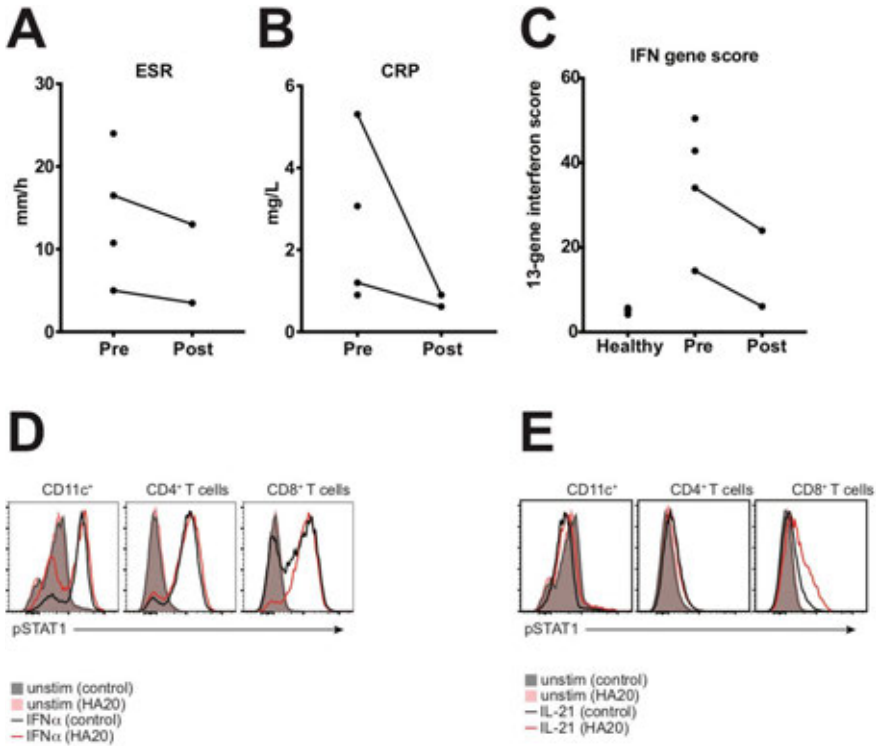

Figure 2. A-C. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), and IFN gene score. D-E. Post tofacitinib treatment STAT1 phosphorylation in response to interferon (IFN)-α and Interleukin (IL)-21.

Results: ISG expression was measured on 5 patients with treatment-refractory active disease and 1 patient with inactive disease. Clinical manifestations were heterogeneous and included hepatic fibrosis, nephritis, and orogenital ulcerations (Fig 1A). All patients with active disease had increased expression of ISGs (Fig 1B). STAT1 phosphorylation was enhanced in response to both interferon (IFN)-α and Interleukin (IL)-21 (Fig 1C-D). STAT3 phosphorylation was not affected by HA20.

To date, 4 patients have undergone treatment with the JAK inhibitor tofacitinib, with treatment planned for the 5th patient. Treatment duration was 3-18 months at the time of analysis. All 4 patients reported improvements in clinical disease activity, and post-treatment data were available for 2 patients. Reduction in ESR, CRP, IFN gene score, and STAT1 phosphorylation were seen after treatment with tofacitinib (Fig 2). Tofacitinib was well-tolerated with no major adverse effects.

Conclusion: A group of treatment-refractory HA20 patients had increased expression of ISGs and enhanced STAT1 phosphorylation. Treatment with tofacitinib led to a clinical and immunological response. These results indicate that STAT1 signaling contributes to HA20 pathology, and that IFN signature predicts response to tofacitinib.

Anakinra Treatment in Patients with Familial Mediterranean Fever: A Single-center Experience

Serdal Ugurlu,[1] **Bugra Han Egeli**,[2] Bilgesu Ergezen,[3] Oguzhan Selvi,[3] and Huri Ozdogan[3], [1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, istanbul, Turkey, [2]İstanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [3]Istanul University-Cerrahpasa, istanbul, Turkey

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease III: Novel Therapies

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: The main goal of Familial Mediterranean Fever (FMF) treatment is to prevent attacks and subclinical inflammation. Mainstay of treatment is colchicine; however, 5-10% of patients are unresponsive to colchicine even in maximum tolerated dosage. Anakinra has been proven to be effective in controlled trials in terms of attack frequency and subclinical inflammation in colchicine resistant patients. The objective of this study is to review the patients followed in our single center with FMF who received Anakinra because of insufficient colchicine response.

Methods: The study is conducted in a tertiary rheumatology center experienced in autoinflammatory diseases. The patients are treated with at least one month of Anakinra in order to be included in the cohort. Patients with amyloidosis and pregnancy are not included. Genetic mutation of all patients was checked and recorded. Attack frequency, patient global assessment scales of disease severity (10-cm Visual Analogue Scale [VAS]), and acute phase reactants were recorded before and throughout Anakinra treatment. Treatment termination was also noted. Criteria of treatment termination were side effects, disease remission, inadequate response, pregnancy plan, and noncompliance.

Table 1: Demographic characteristics of the patients

Gender	69F, 37M
Mean age (years)	34.43±9.68
Mean time since the beginning of FMF symptoms (years)	21.68±10.7
Mean time since the initial FMF diagnosis (years)	12.47±7.49
Mean Colchicine dose before Anakinra*	2.34±1.02
Mean follow-up on Anakinra (months)	16.01±17.21
Comorbidities	24
Spondyloarthropathies	8
Inflammatory Bowel Disease	1
Rheumatoid Arthritis	1
Hypertension	6
Polyarteritis Nodosa	1
Psoriasis	1
Pericarditis	3
Asthma	2
Diabetes Mellitus	1

*97 patients were on colchicine.

Table 2. Reasons for Treatment Discontinuation

Causes of Treatment Discontinuation	n: 34
Insufficient Response	12
Remission	8
Noncompliance	3
Pregnancy plan	1
Side effect	10
Injection site reaction	2
Skin reaction	5
Increased liver enzymes	3
Leukopenia	4

Results: 106 patients diagnosed with FMF were treated with Anakinra. Table 1 represents the demographic characteristics and FMF-related clinical features of the patients. 45.92% of our patients had a homozygous M694V mutation. 83 of the 98 patients tested for MEFV carried at least one copy of M694V. Attack frequency decreased while on Anakinra treatment. Seventy five patients reported no attacks after anakinra treatment whereas 16 patients reported at least 50% decrease in the attack frequency. VAS score decreased from 7.49±2.03 to 3.08±2.82 ($p< 0.0001$). Currently, 70 patients are still on Anakinra treatment. Treatment of 34 patients was discontinued (32% of all patients). The reasons of Anakinra treatment discontinuation are shown in table 2. Insufficient response and side effects are the most common reasons for treatment discontinuation. All of the side effects observed were reversible and the patients alleviated after treatment cessation. In 4 patients, leukopenia was observed and was managed with dose reduction to alternating treatment. Treatment of 8 patients was successful enough that it was terminated due to remission.

Conclusion: In conclusion, in patients with colchicine treatment failure, anti-IL-1 agent Anakinra is shown to be effective and safe. The effectiveness of Anakinra stems from preventing attacks, and increasing the quality of life.

matology. CTD-ILD has different histological patterns, the most common being non-specific interstitial pneumonia (NSIP), usual interstitial pneumonia (UIP), and organizing pneumonia (OP). Literature has showed that Rituximab (RTX), a B lymphocyte depleting monoclonal antibody, can be useful in CTD-ILD. For that reason, we decided to evaluate the use and safety of RTX in patients who failed conventional immunosuppressant therapy.

Methods: In a retrospective chart review, we identified all patients with CTD-ILD expanding from 2015 to 2018, seen in the Rheumatology Clinic of University Medical Center New Orleans, Louisiana (UMCNO). This was done by performing a review of our clinical database by cross referencing International Classification of Diseases (ICD) 10 code J84.9 & 84.10, with M35.9, M05.10, M34.81, D89.89, M32.1, G72.4, M35.02, M35.0. Eighty charts were retrospec-

tively reviewed. Total of 24 patients were given RTX in addition to other immunosuppressive therapy. Data extracted from the chart included patient age, sex, race, tobacco history, CTD history, ILD histological pattern based on High Resolution Computer Tomography (HRCT) of the chest, pre and post pulmonary function test (PFT), other therapy used, and side effects after RTX.

Results: The patients average age was 48 years old. The study had a female to male ratio of 5:1, with 17 of 24 being of African descent. Of the 24, six had prior tobacco use. The most common CTD in our cohort was SSc with 6 of 24, then SLE, IM, RA and MCTD. There was one case of Sarcoid and another of an overlap of RA/IM. Average disease onset at time of RTX infusion was 7 years. The average PFT post RTX therapy was 10 months. NSIP was the most common ILD pattern seen in 12 of 24, then mixed pattern 6 of 24, UIP 5 of 24, and one OP. RTX was most commonly combined with Mycophenolate, 17 of 24 patients were receiving both therapies. Low dose prednisone (< 7.5mg/daily) was concurrently being given in 10 of 24 patients. Only 3 adverse events were encountered during chart review post RTX infusion: Tooth Abscess, Urticarial Rash, and Hemolysis. Pre and Post RTX PFTs are in the table below showing in average stability of the values.

Conclusion: As our data shows RTX is not only safe in CTD-ILD but also proves that it provides stability in lung function on repeat PFT at 10 months average. Our cohort was unique in that the majority were African Americans, and that it included a wide array of ILD patterns and CTD. We also demonstrated that it can be combined with other immunosuppressants and the side effect profile is not much different than using it by itself. As well as no clear trend towards improvement with any combination of immunosuppressants.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease III: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Targeting the interleukin(IL)-1 pathway with anti-IL-1 drugs is a treatment option in patients with autoinflammatory diseases like monogenic periodic fever syndromes. The study aims to gain further insights into long-term effectiveness and safety of canakinumab (CAN), an anti-IL1 inhibitor, under routine clinical practice conditions in pediatric and adult patients with CAPS (cryopyrin-associated periodic syndrome, including Muckle-Wells syndrome [MWS], familial cold autoinflammatory syndrome [FCAS], neonatal onset multisystem inflammatory disease [NOMID]/chronic infantile neurological cutaneous and articular syndrome [CINCA]), FMF (familial Mediterranean

fever), TRAPS (tumor necrosis factor receptor-associated periodic syndrome) and HIDS/MKD (hyperimmunoglobulinemia D syndrome/mevalonate kinase deficiency).

Methods: RELIANCE is a prospective, non-interventional, multi-center, observational study based in Germany with a 3-year follow-up enrolling pediatric (age ≥2 years) and adult patients with clinically confirmed diagnoses of CAPS,

FMF, TRAPS and HIDS/MKD who routinely received CAN. 6-monthly clinical assessment and evaluation of patient-reported outcomes is aligned with routine clinic visits. Endpoints were effectiveness and safety of CAN under standard clinical practice conditions.

Results: The interim analysis includes 58 CAPS patients (45.6% females; 41.4% participated in the β-Confident study) with prior long-term CAN treatment enrolled by September 2018. The mean age was 21.7 years (4.0–79.0 years) at baseline and the mean duration of prior CAN treatment was 5.2 years (0.0–11.0 years). 48 patients (82.7%) were diagnosed with MWS, the other patients had FCAS (N=1), NOMID/CINCA (N=6) or atypical CAPS (N=1) (subtype diagnosis of 2 patients not available). The following parameters were determined at baseline, month 6 and month 12: (1) disease activity by patients' assessment (table 1), (2) days absent in school/from work due to study indication (table 2), (3) hearing ability (table 3). The results demonstrate a sustained remission and control of disease in patients with long-term CAN treatment. Serious adverse events were reported for 4 patients including pyrexia (N=1), tonsillitis (N=2) and a delivery at week 31 (N=1).

Conclusion: An interim analysis of the RELIANCE study, the longest running real-life CAN registry, shows that long-term CAN treatment is safe and effective in CAPS patients.

Abstract Number: 2904

Rituximab as Rescue Therapy in Treatment-Refractory CTD-ILD

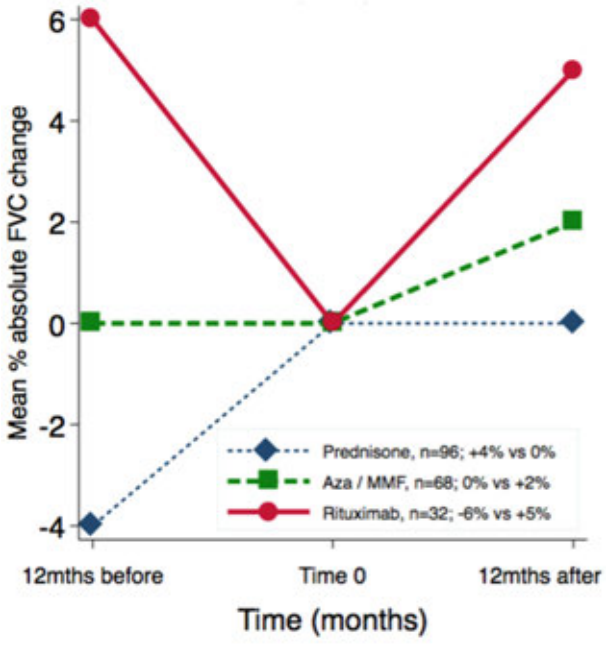
Julia Sun,[1] Charles Oshinsky,[2] Nicole Garcia,[3] Iazsmin Ventura,[3] Renea Jablonski,[4] Rekha Vij,[4] James Curran,[5] Mary Strek,[4] and Ayodeji Adegunsoye[4], [1]University of Chicago Department of Internal Medicine, Chicago, [2]University of Chicago, Department of Internal Medicine, Chicago, [3]University of Chicago, Chicago, [4]University of Chicago, Department of Pulmonary and Critical Care, Chicago, [5]University of Chicago, Department of Rheumatology, Chicago

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease III: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of mortality and carries significant morbidity in connective tissue disease (CTD). Corticosteroids are often used as first line therapy, yet the use of additional immunosuppressive (IS) agents remains largely empiric. In this study we evaluated the effect of Rituximab (RTX) as rescue therapy on lung function in a cohort of patients with severe, progressive CTD-ILD.

Methods: We identified patients with CTD-ILD in the University of Chicago ILD registry who received conventional IS therapy with or without RTX from 2008 to 2018. Results of forced vital capacity (FVC) stratified by IS therapy pre- and post-RTX were compared.

Results: A total of 196 patients (65% female) with a mean age of 57.5 years were included. Rheumatoid arthritis (24.5%), mixed CTD (17.9%), and scleroderma (16.3%) were the most common CTD diagnosis. Of these, 96 received prednisone alone, 68 received azathioprine or mycophenolate without or without prednisone, and 32 received RTX in addition to these IS agents. In the RTX cohort, annualized FVC decline over 12 months pre-RTX was -6%, resulting



Time 0 = initiation of therapy in Rituximab cohort

in a mean FVC of 56% (95% CI=49%-62%) at the time of first RTX administration. One year post-RTX, there was a mean absolute increase of +5%, resulting in a post-RTX FVC of 61% (95% CI=49%-73%). In comparison, FVC remained stable to slightly improved in patients who did not receive RTX (0% in prednisone group; +2% in azathioprine/mycophenolate group) over this 12-month time period (Figure 1).

Conclusion: RTX may be an effective rescue therapy in patients with severe, progressive CTD-ILD refractory to conventional IS therapy.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease III: Novel Therapies
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Recurrent pericarditis (RP) is characterized by the recurrence of pericarditis signs and symptoms after a symptom-free period of ≥4 to 6 weeks and affects 20-30 % of acute pericarditis patients. IL-1α/β, mediators of the inflammatory process, predominate in recurrent pericarditis (RP).

Fever	0/7	0/2	0/2	0/0	0/0
Pericardial effusion on ECHO	0/7	0/1	0/2	0/0	0/0

ECHO, echocardiography; TP, treatment period.

Methods: Participants with symptomatic or corticosteroid (CS)-dependent idiopathic or post-pericardiotomy RP receive subcutaneous rilonacept: 320 mg load, 160 mg weekly plus NSAIDs, colchicine and/or CS for the 6-week treatment period (TP). During optional 18-week treatment extension (EP), weekly rilonacept treatment continued while background therapy may be weaned. Primary endpoints are change in patient-reported pericardial pain (NRS, 11-point scale) and CRP in Parts 1, 2, 4 (symptomatic) and disease activity after CS taper in Parts 3, 5 (CS-dependent).

Results: As of Jan 23, 2019: 25 idiopathic RP patients enrolled (mean 3 episodes). Part 1: mean pericardial pain (NRS score) decreased from 4.6 (baseline) to 0.8 and CRP decreased from 4.9 mg/dL (baseline) to 0.30 mg/dL at 6 weeks (Figure 1); median 9 days to CRP normalization and objective pericarditis features (pericardial effusion, ECG changes, pericardial rub) resolved (Table 1). Parts 2, 4: reductions in NRS (Pain) and CRP were observed during the TP. Parts 3 and 5: pain and CRP remained low on rilonacept therapy during the TP and the effects of rilonacept on

NRS and CRP were maintained during CS-taper/discontinuation in EP among those that completed 24 weeks of therapy. Among the 11/25 who completed the EP; 4/4 on baseline CS successfully tapered off CS; 3/3 discontinued NSAIDs and 2/8 discontinued colchicine. AEs occurred in 23 participants (92%; 12/23 drug-related), most commonly mild transient injection site reactions (no discontinuations).

Conclusion: Data from this ongoing Phase 2 study suggest weekly rilonacept administration results in improvement in patient-reported pericardial pain and objective measures in patients with idiopathic RP. Improvements were durable, supporting CS tapering. AEs were consistent with the known safety profile of rilonacept. These data supported the design of a Phase 3, placebo-controlled, global RHAPSODY trial (NCT03737110).

*p<0.01.
ACPA: anti-citrullinated protein antibody; csDMARD: conventional synthetic disease modifying anti-rheumatic drug; DAS: disease activity score measured in 44 joints; EQ5D: European Quality of Life – 5 Dimensions; HAQ-DI: Health Assessment Questionnaire Disability Index; RF: rheumatoid factor.

Table 1. Baseline characteristics and results after 24 months.

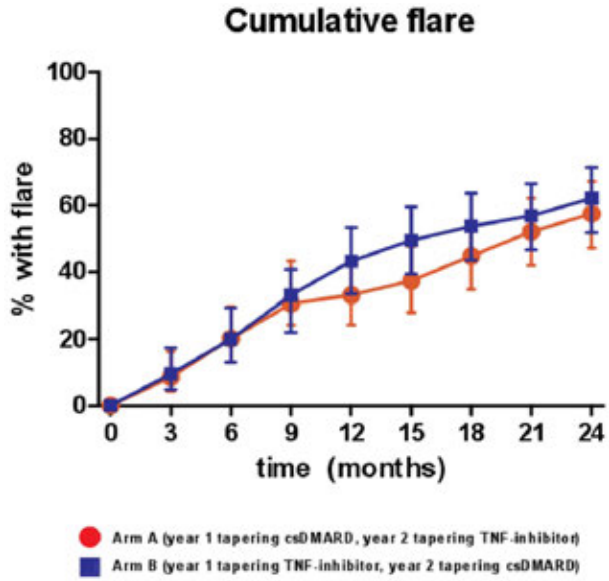

Figure 1. Cumulative flare rate over time. csDMARDs; conventional synthetic disease modifying antirheumatic drug.

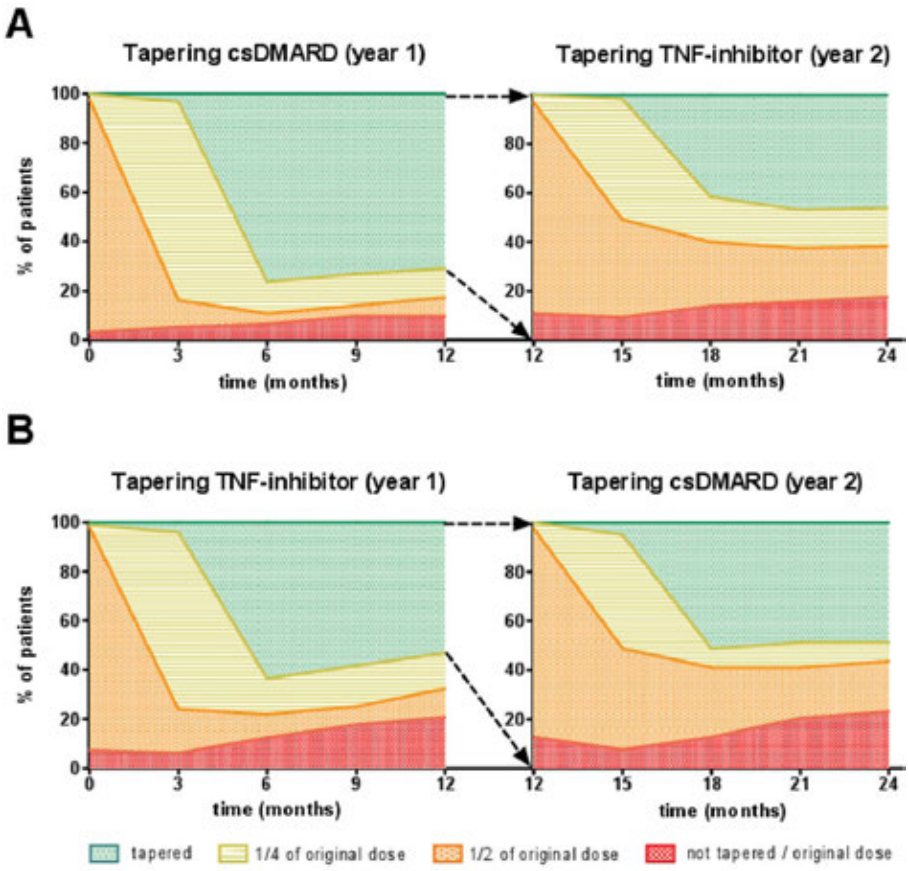

Figure 2. Overview of gradual tapering per time point indicated for tapering arm A and tapering arm B. Numbers indicate percentages of patients. Every 3 months the TNF-inhibitor or csDMARD was tapered until after 6 months the drug could be stopped. In case of a flare, defined as DAS>2.4 and/or SJC>1, patients were set back at their previous effective dose. No further tapering was allowed after having a flare. For the second year (T12 – T24), only tapering status was shown for patients who – according to protocol – should have tapered their medication in the second year. csDMARD; conventional synthetic disease modifying antirheumatic drug.

tirheumatic drugs (DMARDs) and biologicals, RA patients are in sustained remission more often. This raises the subsequent questions whether treatment should be continued, tapered or stopped. Although DMARD free remission (DFR) is nowadays achievable for increasing numbers of RA patients, the optimal tapering approach still needs to be defined. In this study, we want to evaluate the 2-year clinical effectiveness of two gradual tapering strategies, namely tapering DMARDs first followed by the TNF-inhibitor, or vice versa.

Methods: In this multicenter single-blinded randomised controlled trial RA patients with controlled disease for at least 3 consecutive months, defined as a DAS≤2.4 and a swollen joint count (SJC) ≤1, which was achieved with csDMARDs and a TNF-inhibitor were included. Eligible patients were randomised into gradual tapering csDMARDs followed by the TNF blocker or vice versa. Medication was tapered in three steps over the course of 6 months. After 12 months, the other DMARD was tapered. Gradual tapering was done by cutting the dosage into half, a quarter and thereafter it was stopped. The primary outcome for the clinical effectiveness was the number of patients with a disease flare, defined as DAS44 >2.4 and/or SJC >1. Secondary outcomes were DFR, disease activity, quality of life and functional ability. Outcomes were calculated in an intention-to-treat analysis, using all available data.

Results: A total of 189 patients were randomly assigned to tapering csDMARDs first (arm A) or tapering TNF-inhibitor first (arm B). The cumulative flare rate after 24 months in A was 61% (95% CI, 50% - 69%) and in B 62% (95% CI, 50%-70%) (p=0.35)(figure 1). In the second year the cumulative flare rate differs the most between the two groups between T12 and T18 (figure 1). Figure 2 shows an overview of how gradual tapering took place in the TARA study, and how many patients were at a certain point of tapering at the separate time-points (figure 2). This was indicated for both tapering arms (A and B), and for the first and second year (figure 2). In arm A there were significantly more patients able to taper their medication (n=30), and more patients reached DFR (n=15) (table 1). However, mean DAS, mean HAQ, and mean EQ5D over time, and after 2 years, did not differ between both tapering arms (table 1).

Conclusion: The order in which tapering and stopping medication was performed was not superior to each other based on flare rates, DAS and HAQ. However, patients that first tapered csDMARD reached DFR more often and more patients were able to taper their medication.

Lymphopenia	1 (0.4)	1 (0.6)	2 (0.8)	1 (0.6)
Creatinine phosphokinase elevation (CPK)	2 (0.8)	0	3 (1.2)	1 (0.6)

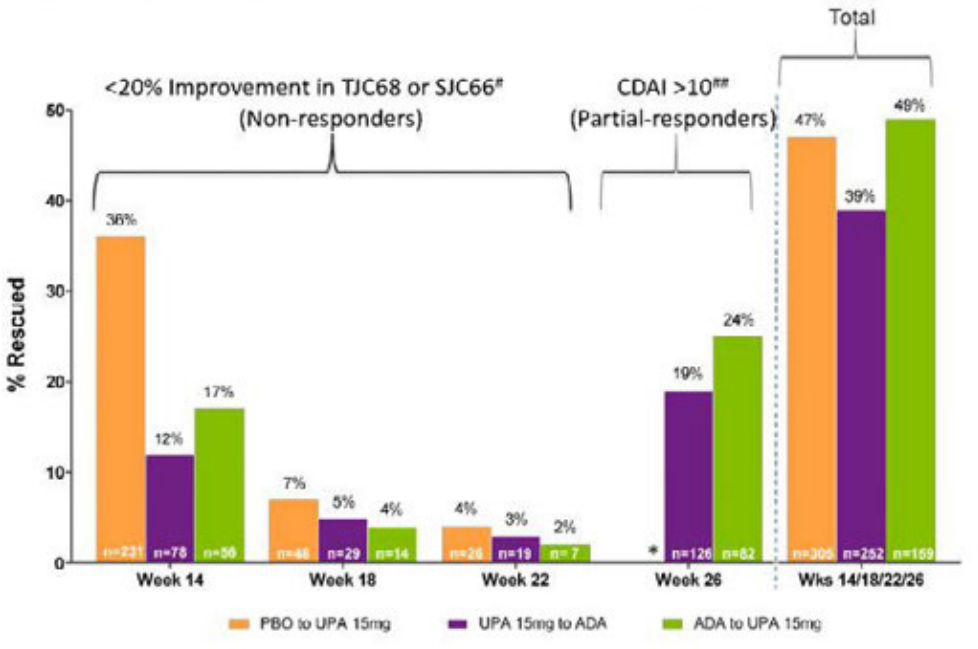
*Adverse events reported for all patients who switched treatments.
UPA: upadacitinib; ADA: adalimumab.
** for any of 3 months post switch adverse events, 95% confidence intervals were overlapping between the 2 switch groups.
*** for any of 6 months post switch adverse events, 95% confidence intervals were overlapping between the 2 switch groups. 6-months post-switch adverse event data include events from 3-months post-switch as well.

sis factor inhibitor (TNFi), or Janus Kinase inhibitor (JAKi) may be needed following an inadequate response (IR).[1] Switches in mechanism of action have been advocated in TNF- and JAK-IR patients (pts); however, controlled data describing switches between JAKi and TNFi are lacking.

Methods: In a phase 3, double-blind study of the JAK1-selective inhibitor upadacitinib (UPA) 15 mg once daily vs PBO or adalimumab (ADA) 40 mg every other week in MTX-IR pts (all on background MTX), pts without ≥20% improvements from baseline (BL) in tender or swollen joint counts by wks 14, 18, or 22 [non-responders (NR)] were switched from UPA to ADA and vice versa in a blinded fashion and without washout. Pts who did not achieve LDA according to CDAI (CDAI ≤10) at wk 26 [partial-responders (PR)] were switched to the alternate treatment as above. Post-hoc analyses assessed clinical outcomes (**Table 1**) at 3m(onth) and 6m (±2 wks) post-switch. Adverse events (AEs) were summarized as n% through 3m and 6m post-switch. Data were as observed.

Results: In total, 651 and 327 pts were randomized to receive UPA and ADA. 252 pts were switched from UPA to ADA (39%, NR:126; PR:126), and 159 were switched from ADA to UPA (49%, NR:77; PR:82) (Figure). At 6m post-switch, DAS28(CRP) < 2.6/CDAI ≤2.8 were achieved by 21%/5% of UPA to ADA pts, and 40%/41% achieved

Figure 1: Proportion of patients rescued at each treatment-switch timepoint



Treatment Switch:
Non-response at Weeks 14, 18, or 22 defined as not achieving ≥ 20% improvement in TJC (tender joint counts) or SJC (swollen joint counts) compared to baseline.
Partial-response at W26 defined as not achieving LDA (Low Disease Activity) according to CDAI (LDA defined as CDAI [Clinical Disease Activity Score]≤ 10).
* At Week 26, all placebo subjects who were not rescued prior to Week 26 were switched to UPA 15mg QD regardless of the response.

UPA dose: 15 mg QD; ADA dose: 40 mg every other week (eow)

DAS28(CRP) ≤3.2/CDAI ≤10. In pts who switched from ADA to UPA, 35%/15% achieved DAS28(CRP) < 2.6/CDAI ≤2.8 and 56%/53% achieved DAS28(CRP) ≤3.2/CDAI ≤10 at 6m post-switch. ACR20/50/70 (based on original BL) after switch are shown in Table 1. Mean change from the original BL in HAQ-DI were -0.58 and -0.73 for pts switching from UPA to ADA and ADA to UPA, respectively. The safety profiles of all pts who switched treatments appeared consistent with those observed for ADA and UPA during comparable periods. During 3m post-switch, the proportions (n%) of pts with serious AEs were 2.4% and 3.8% in the UPA-ADA and ADA-UPA groups, respectively; while serious infections were reported in 0.8% in the UPA-ADA group and in 2.5% in the ADA-UPA group. Safety at 6m overall was comparable to 3m post-switch (Table 2).

Conclusion: Data from this blinded, controlled study indicate that pts with initial insufficient response, either non-response or partial response, to either UPA or ADA may benefit from switching to the other therapy. No additional safety concerns were observed. These data suggest that a patient failing either UPA or ADA may respond to the alternate therapy.

Abstract Number: 2908

Remission in Patients with Rheumatoid Arthritis Receiving Triple Therapy Compared to Biological Therapy - A Swedish Nationwide Register Study

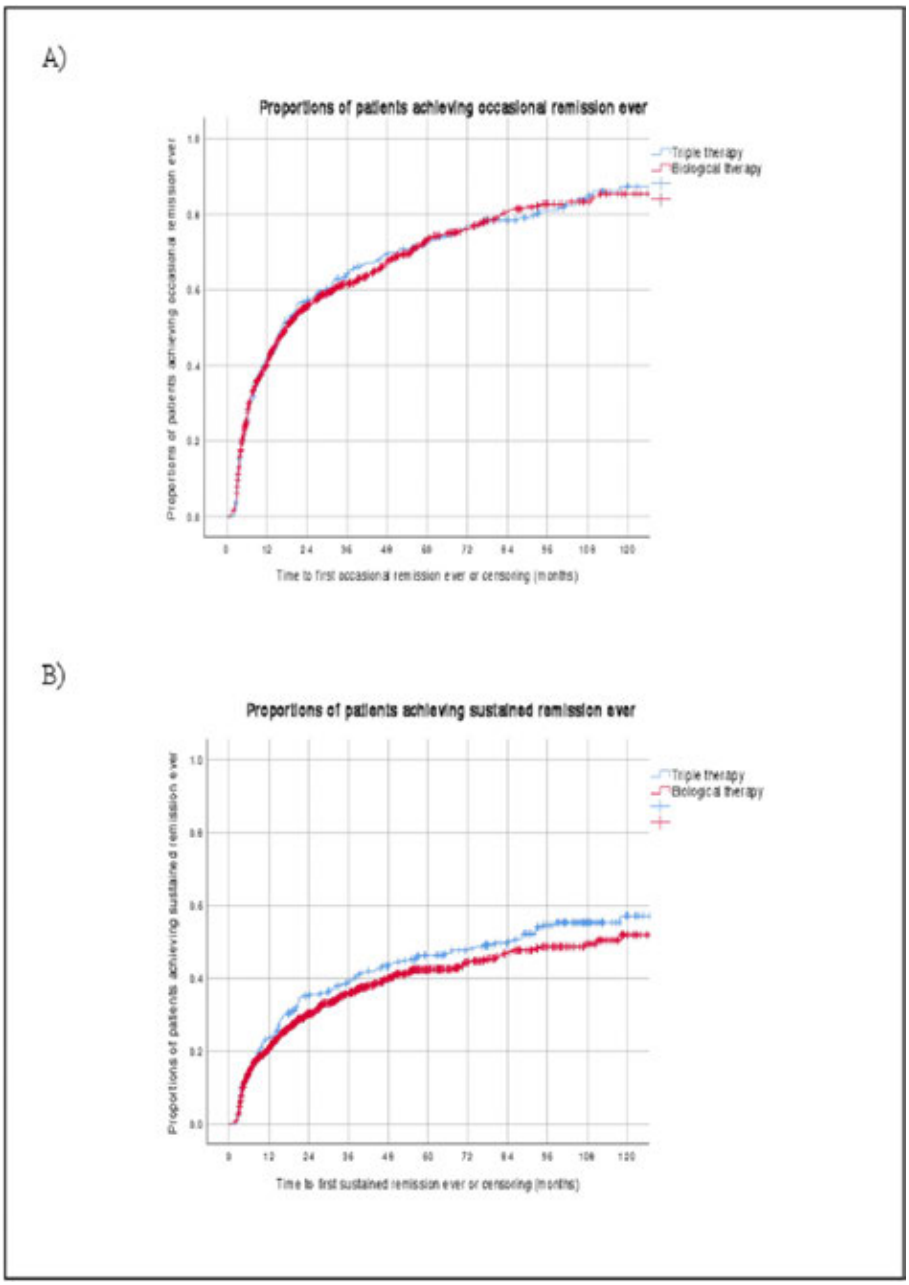
Hanna Källmark,[1] Jon Einarsson,[2] Jan-Åke Nilsson,[3] and Meliha Kapetanovic[2], [1]Lund University, Lund, Sweden, [2]Lund University, Skane University Hospital, Department of Clinical Sciences Lund, Section of Rheumatology, Lund and Malmö, Sweden, Lund, Sweden, [3]Skane University Hospital, Lund and Malmö, Sweden, Lund, Sweden

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Treatments V: Switching & Tapering RA Medications
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Current treatment guidelines for rheumatoid arthritis (RA) recommend a treat-to-target approach with early treatment initiation of disease-modifying antirheumatic drugs (DMARDs), most commonly methotrexate (MTX), and treatment escalation in case of insufficient response. In this scenario, similar efficacy of biological DMARDs (bDMARDs) + MTX compared to conventional triple therapy (MTX + sulfasalazine + hydroxychloroquine) has been shown in randomized control trials. We aimed to compare occurrences of occasional and sustained remission in patients receiving triple therapy versus bDMARDs + MTX as first treatment strategy after MTX monotherapy, using real-life data from the Swedish national Rheumatology Quality Register (SRQ).

Methods: Adult patients with a clinical diagnosis of RA registered in the SRQ between 2000/01/01 and 2012/12/31 receiving triple therapy or any bDMARD + MTX as first treatment strategy after MTX monotherapy were included. ACR 1987 criteria were satisfied by 96.8% of patients. Occasional remission was defined as a disease activity score with 28 joint counts with erythrocyte sedimentation rate (DAS28) < 2.6 at one occasion and sustained remission as remission for ≥6 months. Per protocol analyses were used for occasional and sustained remission achieved during treatment at 12 and 24 months (*during*), and intention to treat analyses were used for occasional and sustained remission achieved at any time in the follow-up (*ever*). Propensity score adjusted regression analyses were performed.

Results: In total, 347 patients receiving triple therapy and 1156 patients receiving a bDMARD + MTX were included. Crude Kaplan Meier analyses of proportions of patients achieving occasional and sustained remission *ever* showed no statistically significant differences between triple therapy and bDMARDs + MTX (Figure). Propensity score adjusted odds ratios (ORs) (biological/triple therapy) with 95% confidence intervals (CIs) for occasional remission during treatment at 12 and 24 months



A) Occasional remission ever, Mantel-Cox p-value = 0.763. B) Sustained remission ever, Mantel-Cox p- value = 0.145. MTX = methotrexate; triple therapy = MTX + sulfasalazine + hydroxychloroquine/chloroquine; biological therapy = biological disease-modifying antirheumatic drug + MTX; censoring = last registered visit; DAS28 = disease activity score with 28 joint counts with erythrocyte sedimentation rate; remission = DAS28<2.6; sustained remission = remission for ≥6 months.

were 1.38 (95% CI 0.90-2.11) and 1.51 (95% CI 0.87-2.60) respectively. For sustained remission during treatment at 12 and 24 months, ORs were 1.34 (95% CI 0.86-2.10) and 1.22 (95% CI 0.70-2.14) respectively. For occasional and sustained remission *ever*, hazard ratios were 1.13 (95% CI 0.96-1.33) and 1.12 (95% CI 0.91-1.38) respectively.

Conclusion: In this nationwide Swedish register study, we found no statistically significant differences between triple therapy and bDMARDs + MTX as first treatment strategy after MTX monotherapy in odds of achieving occasional and sustained remission *during* treatment at 12 and 24 months, or *ever* in the follow-up. This suggests that in RA, conventional triple therapy is a good alternative to bDMARDs + MTX.

Efficacy and Safety of the Selective Interleukin-1 Receptor Associated Kinase 4 Inhibitor, PF-06650833, in Patients with Active Rheumatoid Arthritis and Inadequate Response to Methotrexate

Spencer I Danto,[1] Negin Shojaee,[1] Ravi Shankar P Singh,[1] Zorayr Manukyan,[2] Jessica Mancuso,[1] Elena Peeva,[1] Michael Vincent,[1] and Jean Beebe[1], [1]Pfizer Worldwide Research & Development, Immunology, and Inflammation Research Unit, Cambridge, MA, [2]Pfizer Worldwide Research & Development, Immunology, and Inflammation Research Unit,

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Treatments V: Switching & Tapering RA Medications
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Adaptive and innate immune pathways are involved in inflammation and pathogenesis of rheumatoid arthritis (RA). Toll-like receptor (TLR) stimulation activates the innate immune system, and may be involved in the pro-inflammatory response to ACPA protein complexes found in severe RA.[1] Interleukin (IL) receptor-associated kinase 4 (IRAK4) is a key signal transducer downstream of the myddosome-associated TLRs and IL-1 receptors. IRAK4 inhibition blocks inflammatory cytokine production, so is a potential therapeutic target for RA.[2] This study evaluated the efficacy and safety of PF-06650833, a highly selective, small molecule, reversible IRAK4 inhibitor in development for RA treatment.

Methods: In this Phase 2b, multicenter, randomized, double-blind, double-dummy, placebo and active-controlled parallel-group study, patients (pts) with moderately to severely active $ACPA^+$ RA and an inadequate response to methotrexate were randomized (6:6:6:5:5:5) to 12 weeks' dosing with PF-06650833 20 mg, 60 mg, 200 mg, 400 mg modified-release tablets once daily (QD), tofacitinib 5 mg twice daily, or placebo. The primary endpoint was change from baseline (CFB) at Week 12 in simplified disease activity index (SDAI). Secondary endpoints included ACR20, 50, and 70 responder rates and CFB in disease activity score 28 with 4 components-C-reactive protein (DAS28-4[CRP]) at Week 12. Adverse events (AEs) were also monitored.

Results: Overall, 269 pts from 19 countries were randomized and treated (PF-06650833 = 187; tofacitinib = 43; placebo = 39). Mean CFB in Week 12 SDAI was significantly higher in the PF-06650833 arms vs placebo ($p \leq 0.005$) using the primary Bayesian analysis with an informative placebo prior distribution and in the 200 mg and 400 mg groups with non-informative placebo prior distribution (sensitivity analysis; $p < 0.05$), suggesting improved response. Statistically significantly greater ACR50 response rate vs placebo was observed at Week 12 in 20/50 (40.0%) and 21/48 (43.8%) pts in the PF-06650833 200 mg and 400 mg group ($p=0.040$, $p=0.016$), respectively. Statistically significant CFB in DAS28-4(CRP) vs placebo was observed in PF-06650833 60 mg, 200 mg, and 400 mg QD groups at Week 12 ($p < 0.05$). Of 222 all-causality treatment-emergent AEs (TEAEs) reported across treatment groups, 8 were serious AEs (SAEs); 64 were treatment-related (reported in 48 pts; one was an SAE due to elevated liver transaminases, resolved) and were not dose-dependent. TEAEs of the system organ class (SOC) infections and infestations were most commonly reported (55/269 [20.4%] pts). Herpes zoster occurred in 3 pts (1 treatment-related). Twelve pts permanently discontinued due to TEAEs and no deaths occurred.

Conclusion: All PF-06650833 doses displayed improvement in clinical disease scores vs placebo at Week 12 in pts with moderate to severe RA. Infections and infestations were the most common TEAE SOC, and no deaths occurred.

Improving the Efficiency of Clinical Trial Recruitment Using Electronic Health Record Data, Natural Language Processing, and Machine Learning

Tianrun Cai,[1] Fiona Cai,[2] Kumar Dahal,[3] Chuan Hong,[4] and Katherine Liao[1], [1]Brigham and Women's Hospital, Boston, [2]Stuyvesant High School, New York, [3]Brigham and Women's Hospital, Boston, MA, [4]Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: RA – Treatments V: Switching & Tapering RA Medications
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Efficiently identifying eligible patients is an important component of a successful clinical trial. Billing codes from electronic health record (EHR) data are commonly used to first screen for potential patients, followed by labor-intensive chart review to identify the eligible patients by trial criteria. The objective of this study was to test whether a machine learning screening algorithm (ML-screen) incorporating ICD codes and data extracted from notes using natural language processing (NLP), could improve the efficiency for identifying eligible patients for an ongoing clinical trial.

Methods: We studied EHR data used for a clinical recruitment study of rheumatoid arthritis (RA) and cardiovascular disease recruiting from a tertiary care center (TCC) and a community hospital (CH). The target population were RA patients, age >35, about to initiate a tumor necrosis factor inhibitor, and not on a statin. Prior to this study all patients with ≥1 RA ICD codes (RA_{ICD}) and age >35 years were selected for chart review. The CH and TCC data sets were both manually reviewed as gold standard labels including 642 and 2387 patients, respectively. All notes were processed with NLP to obtain the number of mentions for the concept of RA and inflammatory arthritis. Three groups of features were considered for the ML-screen (**Table 1**): (1) inclusion criteria features, e.g. RA_{ICD}; (2) exclusion criteria features, e.g. # of electronic prescriptions for a statin; (3) the total # ICD codes as a proxy for healthcare utilization. For the ML-screen we considered features within a 2-year timeframe prior to the chart review as well as all years prior. The ML-screen combined two ML methods, random forest (RF) and penalized logistic regression. The goal for the ML-screen was to reduce the number of patients requiring chart review without excluding potentially eligible patients. The ML-screen was compared to alternative approaches using RA_{ICD} ≥1, RA_{ICD} ≥2, and RA_{ICD} ≥1+exclusion criteria features. To test whether the ML-screen can be successfully ported to other institutions, we trained at TCC and applied at CH, and vice versa.

Results: The current method reviewing all charts with RA_{ICD}≥1 yielded 346 (14.5%) eligible patients out of 2387 at TCC, and 74 (16.0%) out of 642 at CH. Applying the ML-screen would result in reviewing 33% less patients in TCC

Table 1.

Category	Feature	Description
Inclusionary features	RA_{ICD}	# RA ICD codes
	RA_{NLP}	# mentions for the concept of RA in the narrative notes
	IA_{NLP}	# of mentions for the concept of inflammatory arthritis in the narrative notes
	$RA_{ICD+NLP}$	the sum of RA_{ICD} and RA_{NLP}
Exclusionary features	JRA_{ICD}	ICD codes for juvenile rheumatoid arthritis
	SLE_{ICD}	ICD codes for systematic lupus erythematosus
	PsA_{ICD}	ICD codes for psoriatic arthritis
	$Melanoma_{ICD}$	ICD codes for melanoma
	$bDMARD_{COD}$	electronic prescriptions for biologic disease modifying anti-rheumatic drugs
	$Statin_{COD}$	electronic prescriptions for statin
Other	HU	Health care utilization, total # of ICD codes

and 44% less in CH, compared to $RA_{ICD} \geq 1$, without screening out potentially eligible patients (**Table 2**). In contrast, $RA_{ICD} \geq 2$ high sensitivity 0.93-0.98, but did not reduce as many patients for chart review, 2.7-11.3%. The $RA_{ICD} \geq 1$+exclusion yielded a larger reduction of patients for review, 63-65%, however excluded approximately 22-27% of eligible patients. The ML-screen had similar performance when trained on one institution and tested on the other (**Table 3**).

Conclusion: The ML-screen incorporating EHR and NLP data can increase the efficiency of clinical trial recruitment by reducing the number of patients requiring chart review; importantly, this approach did not screen out eligible patients. Moreover, the ML-screen can be trained at one institution and applied at another for multi-center clinical trials.

Session Title: RA – Treatments V: Switching & Tapering RA Medications

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Although biologic therapies have transformed the outlook for rheumatoid arthritis (RA), the lack of a major treatment response in over 50% of patients, the potential side effects and the high cost of these drugs have highlighted the need to define predictive markers of response and to stratify patients according to therapeutic outcome. B-cells are pivotal to RA pathogenesis, validated by the efficacy demonstrated by the B cell depleting agent rituximab (RTX). RTX is licensed for use following failure of conventional synthetic (cs)-DMARDs and TNF inhibitor (TNFi) therapy. However, in this increasing therapeutically resistant cohort only 30% of patients achieve an ACR50 response at 6 months. We have recently demonstrated in an early RA cohort[1]synovial heterogeneity with over 50% of patients showing low/absence of synovial B-cell infiltration. This prompted us to test the hypothesis that in these patients an alternative biologic agent targeting alternative pathways maybe more effective. We report results from the first pathobiology-driven randomised controlled trial (RCT) in RA (R4RA) evaluating whether patient stratification according to the synovial B-cell rich/poor status enriches for response/non response to RTX.

	Overall	Rituximab	Tocilizumab

DAS28 (CRP)	5.3 (1.2)	5.3 (1.2)	5.3 (1.3)

*There were no significant differences among treatment groups at baseline.
Continuous variables are here reported as either mean(SD) or median[IQR], depending on normality
CDAI=Clinical disease activity index. DAS28 =28 joint count disease activity score. CRP=C-reactive protein. ESR=erythrocyte sedimentation rate.

Table 1. Patient demographics

Methods: R4RA is a 48 week phase IV open-label RCT conducted in 19 European centres that recruited patients failing or intolerant to csDMARD therapy and at least one TNFi. Synovial tissue was obtained at trial entry and classified histologically as B-cell rich (BCR) or B-cell poor (BCP). Patients were randomised to receive standard therapy with RTX or tocilizumab (TCZ) stratified according to histological classification. The study was powered to test in the BCP population superiority of TCZ over RTX at 16 weeks. The primary and co-primary end-points were defined respectively as Clinical Disease Activity Index (CDAI) ≥50% improvement from baselineand Major Treatment response (MTR)= CDAI improvement ≥ 50% and CDAI ≤10.1. Secondary outcomes included assessment of CDAI response in the BCR cohort where non-inferiority of RTX compared to TOCI was evaluated. Safety data up to week 48 is reported.

Results: The trial recruited to target with a power of 89.5%. 164 patients were randomised, 83 received RTX and 81 TCZ. 81/83 RTX and 73/81 TCZ patients completed treatment to week 16 (primary endpoint). Baseline characteristics were comparable among treatment groups (Tab 1). In the BCP population a numerically higher number of patients achieved the primary outcome and a statistically significantly higher number of patients achieved co-primary endpoint (MTR) as well as in a number of additional secondary endpoints in the TCZ group (Tab 2). In the BCR population there was no significant difference in the majority of endpoints (Tab 2). A higher number of adverse and serious adverse events such as infections in patients treated with TCZ compared to RTX were recorded (Tab 3).

	16 weeks

FACIT Fatigue Score	-1.57	-5.55*	-8.48	-7.75

Post primary endpoint only includes patients that stayed on the randomized medication. For secondary end points, no adjustments were made for multiple comparisons. A P value of 0.05 or less was considered to indicate statistical significance. CDAI: Clinical Disease Activity Index; DAS: Disease Activity Score; EULAR: European League against Rheumatism. LSM: Least-Squares Mean. MTR: Major treatment response (defined as CDAI ≥50% improvement and CDAI<10.1) Missing data were imputed with the use of Multiple Imputation of Chained Equation (MICE) ‡P≤0.05 for the comparison with Rituximab

Table 2. Primary and co-primary and Secondary Efficacy End Points after 16 weeks

	Rituximab (n=82)	Tocilizumab (n=79)	Total [1] (n=161)
Adverse Events - n (%)	284(46.5)	327(53.5)	659
Patients with adverse events - n (%)	62(47.7)	68(52.3)	135
Serious Adverse Events - n (%)	8(30.8)	18(69.2)	26
Patients with serious adverse events - n (%)	8(40)	12(60)	20
Infections - n (%)	3(50)	3(50)	6
Patients with serious infections - n (%)	3(50)	3(50)	6
Discontinuation of study drug because of serious adverse event - n (%)	2(50)	2(50)	4
Confirmed cancer - n (%) [2]	0(0)	0(0)	0
Deaths - n (%)	1(100)	0(0)	1

The total number of events/patients with events up to week 48 is reported. This includes some adverse events occurring before the first prescription of IMP
No cancer was observed during the treatment period. However, there was one kidney carcinoma after week 48

Table 3. Safety data from Weeks 0 to 48 (+30 days)

Conclusion: In a RA BCP population failing csDMARDs and TNFi therapy,TCZ is more effective than RTX in achieving both low levels and significant falls in disease activity. In a BCR RA population RTX is non inferior to TCZ for the majority of outcome measures evaluated.

LVEF < 50%	**5.4 (1.2 to 23.6)**	**13.1 (2.0 to 89.0)**
DLCO % pred < 40%, n= 83	1.5 (0.5 to 4.1)	
Increase mRSS > 5 pre HSCT (n= 64)	**0.1 (0.0 – 0.7)**	0.3 (0.1 to 0.5)

Abbreviations: SSc: systemic sclerosis; HCT-CI: hematopoietic cell transplant comorbidity index; ESR: erythrocyte sedimentation rate; FVC % pred: forced vital capacity % predicted; LVEF: left ventricular ejection fraction; DLCO % pred: diffusion capacity % predicted; prog. mRSS: progression in skin involvement prior to stemceltransplantation;

Background/Purpose: Autologous hematopoietic stemcell transplantation (HSCT) has shown to improve survival of SSc patients with poor prognosis, but is hampered by treatment related mortality (TRM). Better selection of eligible patients could improve outcomes.

Objectives: 1. To evaluate event-free survival, TRM and response after HSCT in SSc and 2. To explore patient characteristics that associate with events.

Methods: Data on event-free survival of all patients treated with HSCT for SSc in the Netherlands between 1998 and 2017, performed as previously described (1) and with ≥ 1 year of follow-up were collected. Baseline characteristics including hematopoietic cell transplant comorbidity index (HCT-CI) (2) and left ventricular ejection fraction (LVEF) and data for skin involvement (modified Rodnan skin score (mRSS)), pulmonary function (forced vital capacity % predicted (FVC% pred), diffusion capacity % predicted (DLCO% pred)) and staging for interstitial lung disease on high resolution CT scan (HRCT) assessed according Goh (3) were collected at baseline and at 1,2, 5 years ; data for events and death were collected until end of study. All deaths were discussed in a consensus meeting (SB, MB, JV, MV) and classified as TRM, SSc progression or other. Event-free survival was defined as described before (4). Relapse was defined as an increase in mRSS of > 25% and > 5 points compared to the lowest value since HSCT, or either a ≥10% decline in FVC% pred, or ≥5 – < 10% decline in FVC% pred and ≥15% decline in DLCO% pred or initiation of immunosuppression (4). The association between event-free survival and baseline characteristics was examined by univariate Cox regression analysis. Factors with a significant association were entered in a multivariate analysis on imputed missing data.

Results: In total 92 patients were included (Table 1). Event-free survival estimates at 5, 10 and 15 years were 0.79, 0.79 and 0.68 respectively. Twenty deaths occurred, which were classified as TRM (n=10, 11%), SSc progression

(n=4, 4%) and other (n=6 7%). Relapse occurred in 22 patients in the first 5 years: skin relapse in 5, lung relapse in 11 and initiation of immunosuppression in 12 (in 7 patients without skin or lung relapse). FVC, DLCO, mRSS and Goh scores improved significantly over time in patients surviving the first 5 years (n=75) (Figure 1). Events were independently associated with male sex, LVEF < 50% and older age (table 2).

Conclusion: Event-free survival at 10 years after HSCT for SSc was 79%; male sex, lower LVEF and older age were identified as independent risk factors for events. Our data confirms efficacy of HSCT in improving survival and skin and lung involvement.

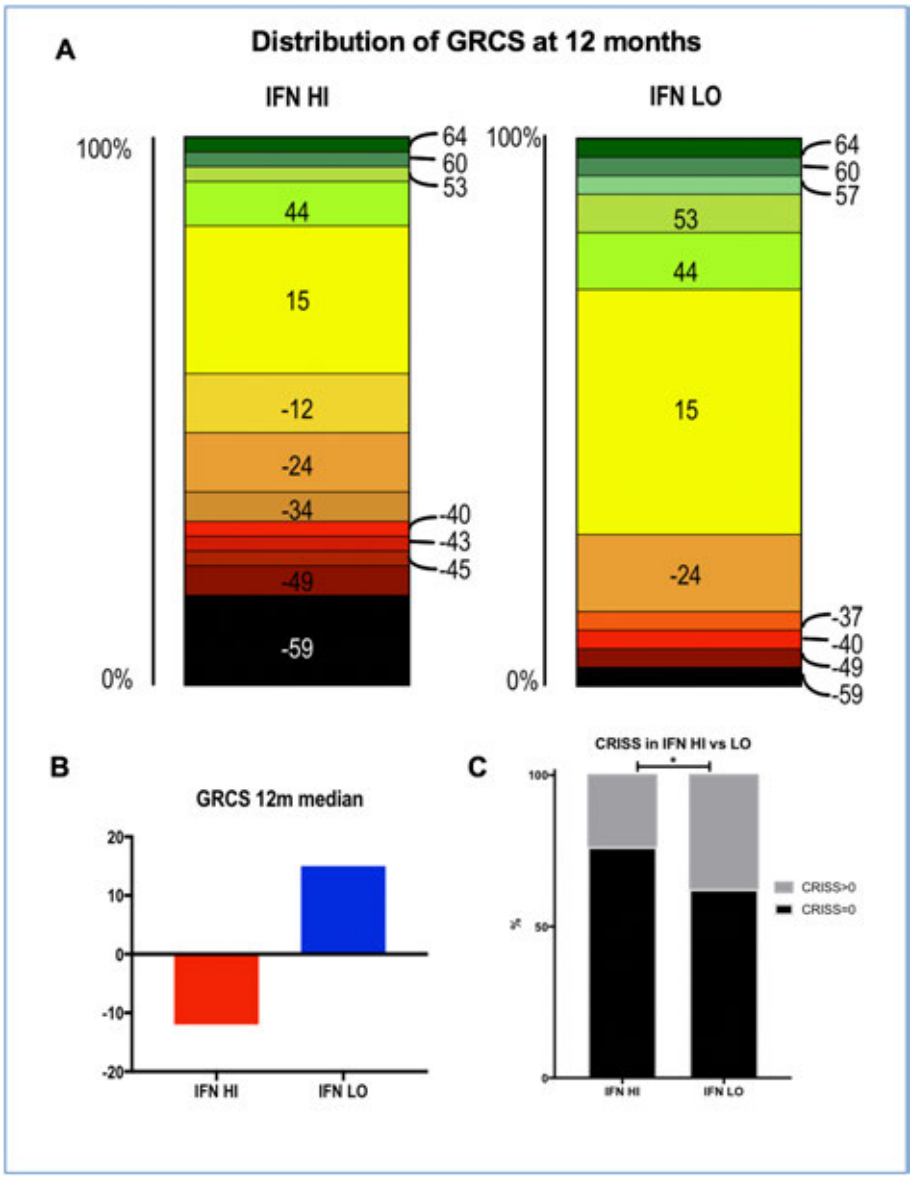
Abstract Number: 2913

Serum Interferon Score Predicts Clinical Outcome at 12 Months in Diffuse Cutaneous Systemic Sclerosis as Measured by Global Ranked Composite Score (GRCS) and Composite Response Index in SSc (CRISS)

Antonio Carriero,[1] Giuseppina Abignano,[2] MIchelle Hutchinson,[3] Karri Ballard,[4] and Francesco Del Galdo[5], [1]University of Leeds, Leeds, England, United Kingdom, [2]3Rheumatology Institute of Lucania (IReL) and University of Leeds, Leeds, United Kingdom, [3]University of Leeds and LTHT NIHR Biomedical Research Centre, Leeds, England, United Kingdom, [4]Myriad RBM, austin, TX, [5]University of Leeds and LTHT NIHR Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Systemic Sclerosis & Related Disorder – Clinical III: Predictors of Outcome
Session Type: ACR Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Systemic sclerosis (SSc) is a highly heterogeneous disease orphan of effective disease modifying agents. The diffuse cutaneous clinical subset (dcSSc) is currently targeted in most clinical trials. Nevertheless, there is still high variability in clinical outcome within dcSSc, which is limiting effective clinical trial design and interpretation. Global Ranked Composite Score (GRCS) and Composite Response Index in SSc (CRISS) are two of the most recent attempts to capture overall response to treatment in dcSSc. Activation of interferon type 1 (IFN) pathway is associated with severe clinical manifestations in SSc. Microarray and proteomic studies have



Distribution of GRCS and CRISS in dcSSc patients stratified for serum Interferon Score. A: Distribution of GRCS in dcSSC patients with less than 6 years disease duration. HIght of color coded boxes reflects the proportion of patients with the GRCS score descibed in or on the side of the box. B: Median GRCS score in IFN HI (RED) or LO (Blue) dcSSc patients. C. Bar chart representing the proportion of patients with CRISS = 0 or higher than 0 in dcSSc patients stratified for their seum IFN score. * = P<0.05 according to Mann-Whytney test.

indicated that the serum concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11 are the most relevant serum measures of IFN induced activation of PBMCs. Here we aimed to determine whether their serum concentration of the above chemokines combined in a IFN score could be used to stratify patients with dcSSc for severe clinical outcome at 12 months as measured by GRCS and CRISS.

Methods: Serum concentration of CCL2, CCL8, CCL19, CXCL9, CXCL10, and CXCL11 was measured by Luminex xMAP technology (Myriad RBM) in 143 SSc patients and 35 healthy controls (HC). IFN score was calculated as the average of the natural logarithm of the above chemokines. GRCS were compared by Mann Whitney test and the effect size for the Mann Whitney test by Wilcoxon Paired ranked test, as described. Fisher exact test was used to analyse the proportion of patients with CRISS of 0% or >0%.

Results: All chemokines had a higher serum concentration in SSc vs HC ($p < 0.0001$ for all). Median IFN score was higher in SSc than HC (5.26 vs 4.70, $p < 0.0001$), but within SSc group, there was no difference associated with disease subset or duration. As with the dichotomization for IFN activity already described for RNA IFN Score, we defined IFN LO or HI patients as a score within or above mean + 2STDV of IFN Score of HCs. Sixty six 12-month outcome data of dcSSc patients were available for analysis. 37 were IFN HI and 29 IFN LO. GRCS ranged from -59 to 64. IFN HI patients had a worse outcome at 12 months with GRCS median score of -12 vs 15 in IFN LO ($p=0.0271$). Accordingly, GRCS favored IFN LO in 68.4% of 1073 (37*29) pairwise comparisons versus 31.6% of IFN HI ($p=0.0001$). 12 month CRISS was >0 in 24% of IFN HI vs 38% of IFN LO ($P=0.0464$).

Conclusion: Serum IFN Score predicts worse clinical outcome at 12 months in dcSSc. Stratification for IFN score could aid both in clinical trial design and clinical management. Moreover, here we show that GRCS and CRISS may be sufficiently sensitive to measure difference in composite outcome at 12 months in dcSSc in an observational setting.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical III: Predictors of Outcome

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: The very early diagnosis of SSc is a challenge today. The aim of the VEDOSS project was to study in an at-risk population, the clinical signs that could predict the progression toward a definite SSc.

Indipendent predictors for progression into definite SSc	PPV	NPV
Disease specific abs ACA Scl70	70,2% 71% 60,7%	60,5% 52,3% 41,8%
NVC abnormalities	75%	50,4%
Puffy fingers (PF) PF + NVC abnormalities	**78,9%** 77,8%	**45,1%** 42%
PF + disease specific abs	**94,1%**	**43,9%**
Disease specifc abs + NVC abormalities	**82,2%**	**50,4%**

Methods: Patients with Raynaud phenomenon (RP), with or without anti-nuclear antibodies (abs) (ANA) were recruited for this longitudinal, observational study. Fulfilling the 2013 classification criteria at baseline was an exclusion criterion. Patients with ANA negative RP were recruited as controls. Patients had an annual assessment according to EUSTAR standards to determine organ involvement and severity. The endpoint was defined as fulfilment of the 2013 SSc classification criteria. The time to fulfilling 2013 classification criteria was evaluated with Kaplan-Meier analysis, and predictors of evolution were determined by univariate and multivariate Cox regression. The study was conducted in accordance with principals of Declaration of Helsinki.

Results: Out of 1,150 recruited patients, 35 were excluded due to non-RP at inclusion and 1.115 patients were analysed. After separating patients with missing ANA status (1), or already fulfilling ACR/EULAR 2013 (240) or ARA 1980 criteria at inclusion (110), the sample was distributed as followed: i) 237 patients (143 with follow up) RP/ANA negative (ANA^-/pRP), ii) 498 patients (401 with follow up) RP/ANA positive (ANA^+/pRP)): 87 had puffy fingers (PF), 199 had anti-centromere abs (ACA) positive, 45 had anti-topoisomerase-I abs (topo-I) positive and 182 had nailfold videocapillaroscopy (NVC) abnormalities at baseline. Out of 401 ANA^+/pRP patients, 7.4% within 1 year, 29.3% within 3 and 44.1% within 5 years satisfied the 2013 classification criteria. Out of the 143 ANA^-/pRP patients, none (0%) within 1 year, 4.6% within 3 years, and 4,6% within 5 years satisfied SSc criteria. After adjustment for age, the following baseline parameters were identified as independent predictors for progression into definite SSc by multivariate analysis: PF (OR=3.4 [2.0;5.6]), ACA (OR=2.6 [1.6;4.1]) and Topo-I (OR=3.1 [1.6;5.8]), and NVC abnormalities (OR=1.9 [1.3;2.9]) The presence of PF had a positive predictive value (PPV) of 79% . Combination of PF + specific

abs showed 94% PPV and disease specifc abs + NVC abormalities a 82,2% PPV to satisfy ACR/EULAR 2013 criteria within 5 years (Table 1).

Conclusion: The data show that 44% of VEDOSS patients develop, within 5 years of follow up, definite SSc according to classification criteria. At first visit, PF and SSc specific abs were identified as independent parameters predicting the development of definite SSc. These data may allow the risk stratification of patients with very early SSc in clinical practice and clinical studies.

Session Title: Systemic Sclerosis & Related Disorder – Clinical III: Predictors of Outcome

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: We analyzed a phase 2 study designed to assess the efficacy of abatacept in patients with diffuse Systemic Sclerosis (SSc). In this work, we analyze data from ASSET and seek to confirm the hypothesis that patients in the inflammatory subset on abatacept show a significant decline in modified Rodnan Skin Score (mRSS), which is correlated to modulation of pathways related to the mechanism of action of abatacept.

Methods: SSc patients, who met 2013 ACR/EULAR criteria, were randomized to receive abatacept or placebo for 12 months. RNA sequencing was performed on 84 SSc patients at baseline, 3-month, and 6-month timepoints. Samples were assigned to an intrinsic gene expression subset (inflammatory, fibroproliferative, limited, or normal-like) using a Support Vector Machine (SVM) classifier. Treatment differences in longitudinal outcomes were assessed using linear

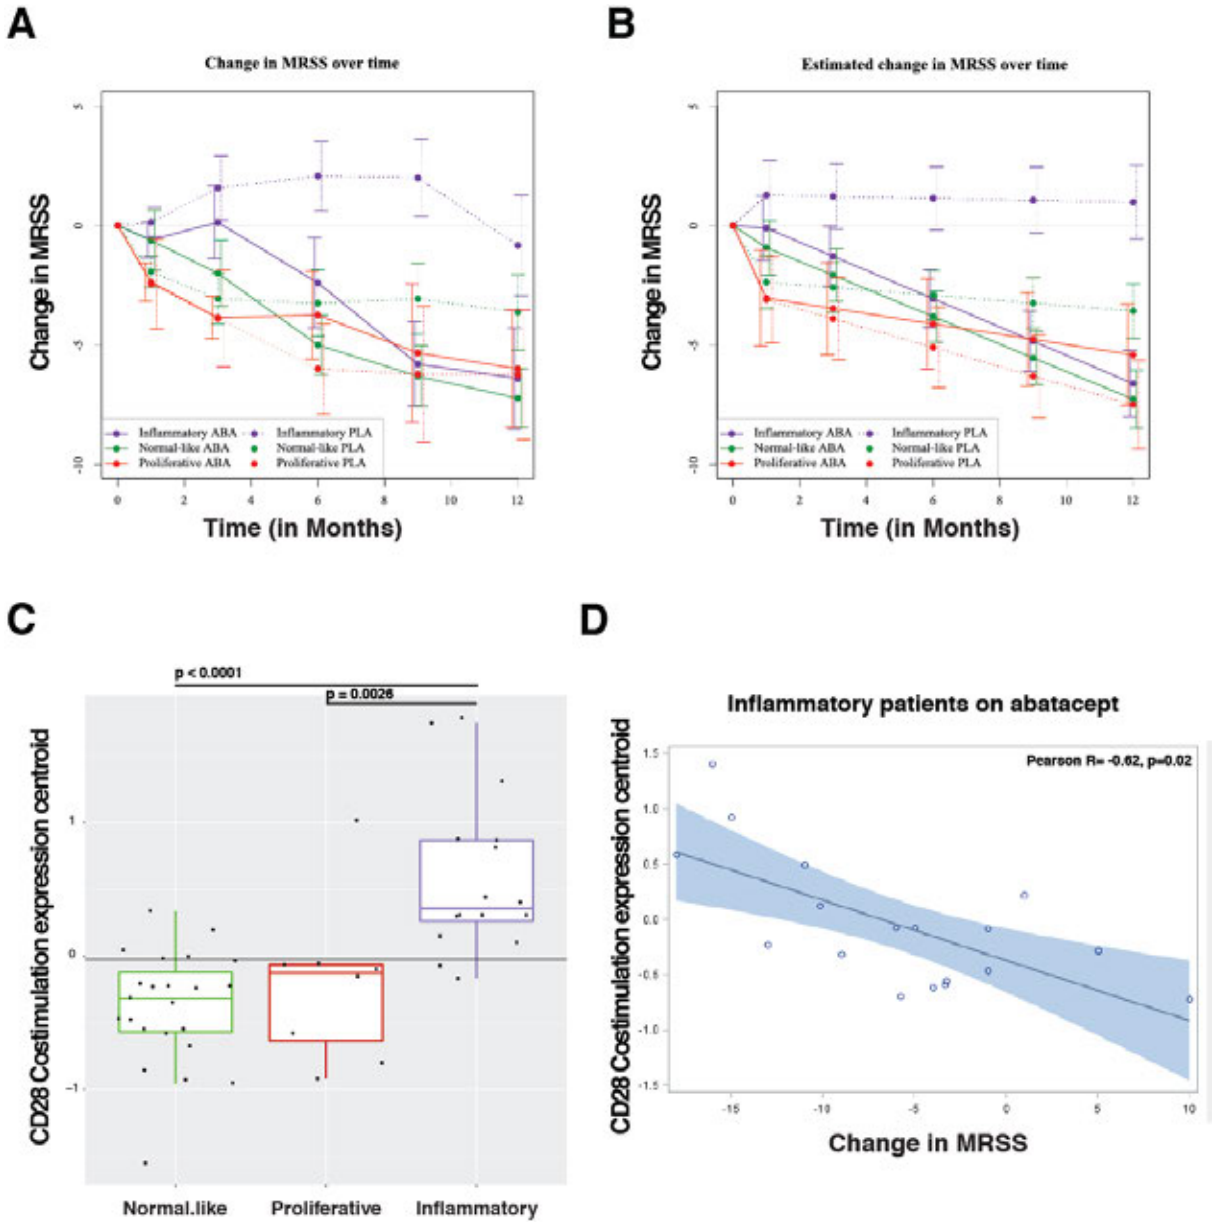

Figure 1. A) Observed average and B) estimated average change from baseline in MRSS in the placebo and abatacept group across intrinsic gene expression subsets. Estimates are obtained from a linear mixed model. C) Core expression genes from Costimulation of the CD28 family were log2 and median centered across the intrinsic subsets. An ANOVA found the means to be significantly different ($p<0.001$). P-values shown are using Tukey's test for multiple comparisons. D) Core gene expression from the Costimulation of the CD28 family were log2 and median centered for patients of the inflammatory subset on abatacept.

mixed effect models. Improvement was defined as a 5 point or >20% change in mRSS between baseline and 12 months. A machine-learning approach, trained on gene-gene relationships in the skin, was used to identify features beyond those simply differentially expressed. Gene Set Enrichment Analysis (GSEA) was used to identify pathways enriched in comparison groups.

Results: Patients were assigned to intrinsic subset at baseline (33 inflammatory, 18 fibroproliferative, and 33 normal-like). Differences in trajectory for intrinsic subsets are evident (Figures 1a, 1b). In the abatacept arm, change in mRSS was most pronounced for the inflammatory ($p< 0.001$) and normal-like ($p=0.03$) subsets when compared to placebo. The gene-gene network from skin, returned CD86 as being highly related to genes that decrease in abatacept improvers. For gene expression analyses, the dataset was parsed for quality and patients that completed the

trial, the remaining (n=140) biospecimens were analyzed. The pathway Costimulation by the CD28family decreases (FDR=5.88x10 -4) in patients that improve on abatacept; this decrease is specific to the inflammatory subset (FDR=0%) of patients. At baseline, patients in the inflammatory subset have an elevation in the Costimulation by the CD28 family pathway relative to proliferative (p = 0.0026) or normal-like (p=0.0001) patients (Figure 1c). In inflammatory patients, we see a correlation (R=-0.62, p=0.02) between DmRSS and baseline expression ofthe Costimulation by the CD28 family pathway (Figure 1d).

Conclusion: Abatacept shows the most benefit for inflammatory patients. CD28-related pathways are elevated in inflammatory patients relative to fibroproliferative or normal-like patients. Importantly, we find that the extent of improvement in inflammatory patients is directly correlated to their baseline expression of the *Costimulation by the CD28 family*pathway. We show that baseline gene expression can predict differential response to biological intervention by directly modulating pathways pertinent to a drug's mechanism of action. This data suggests that stratifying patients by baseline signatures may clarify the effects observed and act as a step towards precision medicine for future clinical practice.

ns = not significant at a threshold of P = 5 x 10^{-5}; independent associations by conditional regression analysis shown in bold.

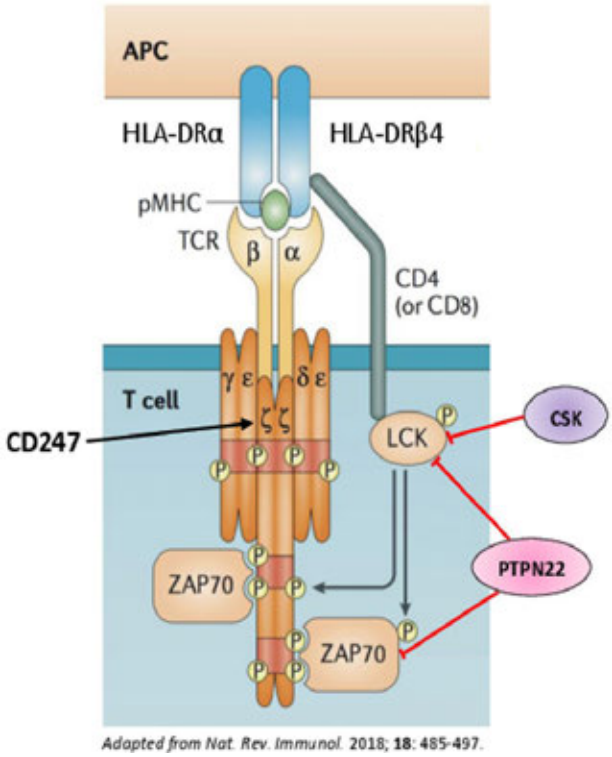

Figure 1. Scleroderma risk factors and the T cell receptor (TCR) signaling pathway. Three genes (CD247, CSK, and PTPN22) that have been previously implicated in scleroderma susceptibility are all involved in the initiation of the TCR signaling pathway. HLA-DRB4, which was identified in this study, is also involved in this pathway, suggesting an important role of TCR signaling in scleroderma pathogenesis.

Background/Purpose: Systemic sclerosis (SSc), or scleroderma, is a heterogeneous disease that is divided into limited cutaneous (lcSSc) and diffuse cutaneous (dcSSc) forms based on the extent of skin involvement, and internal organ involvement also adds to phenotypic variability. The three main internal organ complications are interstitial lung disease (ILD), pulmonary arterial hypertension (PAH) and scleroderma renal crisis (SRC).

Methods: We investigated classical *HLA* alleles and polymorphic amino acids for association with clinical subsets of SSc. A conditional association analysis with a Bonferroni-corrected significance threshold of P-value (P) < 0.00005 identified multiple subset-specific SSc risk factors in an African American cohort of 934 SSc patients and 946 unaffected controls.

Results: *HLA-DRB1*08:04*, an African-ancestry predominant allele, was the strongest risk factor with odds ratios (ORs) ranging from 2.7 to 3.3-fold in the lcSSc, dcSSc, ILD+ and PAH+ subsets of SSc. The allele *HLA-DPB1*13:01* also independently increased risk in the dcSSc and ILD+ subsets, with ORs of 2.0 (95% CI 1.4-2.8) and 2.5 (95% CI 1.8-3.6), respectively. There were no significant associations in the SRC+ subset at the chosen P threshold, but the strongest association was with *HLA-DQB1*03:19* (P = 0.0002), which is in linkage disequilibrium with *HLA-DRB1*08:04*. For the first time, a protective effect of *HLA-DRB4*01:01* was identified in SSc, with a stronger effect in the lcSSc subset (OR = 0.4, 95% CI 0.4-0.7) than in the dcSSc subset (OR = 0.5, 95% CI 0.4-0.7). The presence of this allele is also linked to *HLA-DRB1*07:01*, which has been reported as protective for SSc in European ancestry cohorts. Further stratification of clinical subsets by autoantibody status revealed more striking effects of certain alleles, despite the reduced sample size. On comparing the dcSSc with the lcSSc none of the alleles met the statistical significance threshold due to reduction in sample size. Interestingly, the top two associations were both class I *HLA* alleles, *HLA-A*74:01* (OR = 0.5, 95% CI 0.3-0.8) and *HLA-C*17:01* (OR = 1.7, 95% CI 1.1-2.6), and these associations

became even stronger upon comparing patients with dcSSc to those with CREST syndrome (OR = 0.4 and 2.0 and P = 0.0008 and 0.003, respectively).

Conclusion: This is the largest genetic study of African American SSc patients identifying classical *HLA* alleles increasing risk in clinical subsets of SSc. Class II *HLA* alleles are responsible for increasing risk for scleroderma in general and the class I *HLA* alleles play a more prominent role in defining the extent of skin involvement. Increased risk from the *HLA* genes along with previously implicated genes in SSc susceptibility (*CD247*, *CSK, PTPN22*) together with the newly identified role of *HLA-DRB4* point towards the important role of CD4 T cells and the relevance of T cell receptor (TCR) signaling in SSc pathogenesis.

Geographic Disparities in Systemic Sclerosis Mortality in the United States: 1999 to 2017

Alicia Rodriguez-Pla,[1] and Robert W Simms[2], [1]University of Arizona/Banner Health Medical Center, Tucson, AZ, [2]Boston University, Boston, MA

SESSION INFORMATION

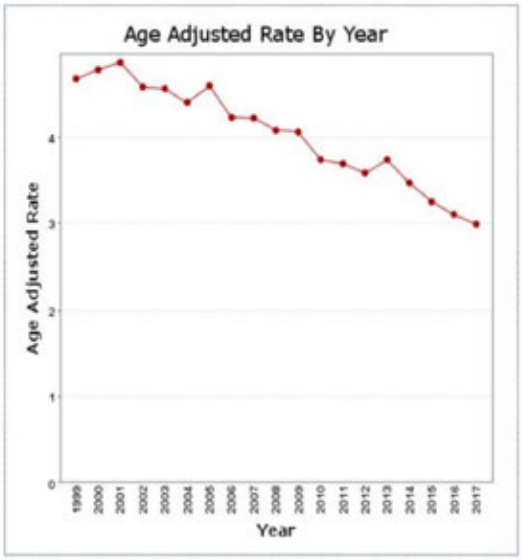
Session Date: Wednesday, November 13, 2019

Session Title: Systemic Sclerosis & Related Disorder – Clinical III: Predictors of Outcome

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Figure 1. Age-adjusted mortality rate for scleroderma as underlying cause of death by year.



Background/Purpose: Population mortality studies in the United States have previously reported a progressive increase in the scleroderma (SSc) mortality rates from 1959 to 2002. Identification of areas with clusters of higher mortality rates is important to implement targeted interventions and may provide clues about possible etiology factors, especially environmental. In this study, we aimed to estimate the mortality rates of patients with SSc and to determine whether there is a geographic variability in scleroderma mortality rates at the state level in the United States using publicly available data from 1999 to 2017.

Methods: To obtain mortality rates of scleroderma as the underlying cause of death, we used the CDC Wonder Underlying Cause of Death database and its query system, which contains data from 1999 to 2017. We used the corresponding ICD-10 codes for SSc for the queries. Age-adjusted rates were calculated by state and demographics, including, gender, race, and Hispanic ethnicity. Mortality rates were given as number of deaths per million. A linear regression model was applied to evaluate trends over time.

Results: During the 19-year period of our study, a total of 24,525 deaths had SSc as the underlying cause of death of an underlying population of 5,761,465,567. The age-adjusted mortality rate was 3.962 per million (95% CI: 3.912-4.012). The SSc-related mortality rates have progressively decreased from a rate of 4.679 (95%CI: 4.423 - 4.934) in 1999 to 2.993 (95% CI: 2.817 - 3.170) per million in 2017. Linear regression found a significant negative slope, indicating a trend to the decrease of age-adjusted mortality rates over time (Age-adjusted rate = - 0.1015*year + 207.8; $p < 0.0001$) (Figure 1).

There were more deaths in females than in males with a ratio: 4.1 to 1. The age-adjusted mortality rate was 5.885 (95% CI: 5.802 - 5.967) per million in females and 1.651 (95% CI: 1.604 - 1.698) per million in males. The highest age-adjusted mortality rate was in Blacks or African-Americans, at 5.703 per million (95% CI: 5.521 - 5.885), followed by American Indians or Alaska Native at 5.047 per million (95% CI: 4.428 - 5.667) (Table 1). Clusters of contiguous states with higher and lower mortality rates were identified. South Dakota was the state with the highest whereas Hawaii was the one with the lowest mortality rate. In Table 2, we list the states with the highest mortality rates.

Table 1. Age-adjusted mortality rate per million for scleroderma as underlying cause of death, by race and gender.

Race	Gender	Deaths	Population	Age-Adjusted Rate (95% CI)	% of Total Deaths
Black or African American	Female	2,981	406,808,112	7.867 (7.582 - 8.152)	12.155%
	Male	940	372,183,341	2.981 (2.784 - 3.179)	3.833%
	Total	**3,921**	**778,991,453**	**5.703 (5.521 – 5.885)**	**15.988%**
American Indian or Alaska Native	Female	224	36,894,044	7.660 (6.622 - 8.697)	0.913%
	Male	57	37,044,572	2.142 (1.585 - 2.832)	0.232%
	Total	**281**	**73,938,616**	**5.047 (4.428 – 5.667)**	**1.146%**
White	Female	16,118	2,326,457,753	5.620 (5.533 – 5.708)	65.721%
	Male	3,704	2,275,993,219	1.516 (1.466 - 1.565)	15.103%
	Total	**19,822**	**4,602,450,972**	**3.766 (3.713 – 3.819)**	**80.824%**
Asian or Pacific Islander	Female	413	158,995,020	2.887 (2.603 - 3.171)	1.684%
	Male	88	147,089,506	0.773 (0.615 - 0.960)	0.359%
	Total	**501**	**306,084,526**	**1.952 (1.777 – 2.128)**	**2.043%**
Total		**24,525**	**5,761,465,567**	**3.962 (3.912 – 4.012)**	**100%**

CI: Confidence interval.

Conclusion: Our study found a trend towards a decrease of mortality rate in SSc compared to previous studies, and a trend to a progressive decrease in mortality rates during the years of our study. In addition, we found relevant state-by-state variation in mortality with several geographical clusters with higher mortality rates. Further analyses of those geographical clusters are warranted in order to better understand the factors associated to the observed geographic disparities and to implement targeted interventions to decrease disparities.

Table 2. The 12 States with the highest mortality due to scleroderma as underlying cause of death with age-adjusted rates and 95% confidence interval.

	Deaths	Population	Age-Adjusted Rate per 1,000,000 (95% CI)
South Dakota	106	15,276,970	6.285 (5.076 – 7.495)
New Mexico	237	37,679,448	5.862 (5.108 – 6.616)
Montana	121	18,443,327	5.567 (4.563 - 6.571)
Colorado	457	93,127,301	5.152 (4.672 - 5.631)
Wyoming	54	10,296,319	4.818 (3.598 - 6.318)
New Jersey	837	165,736,728	4.582 (4.270 - 4.894)
District of Columbia	52	11,515,629	4.578 (3.409 - 6.019)
North Carolina	857	174,209,369	4.574 (4.265 - 4.882)
Louisiana	402	86,182,287	4.535 (4.087 - 4.982)
Iowa	302	57,386,432	4.523 (4.009 - 5.038)
Alaska	51	13,100,743	4.518 (3.283 - 6.066)
Minnesota	472	99,446,183	4.511 (4.101 - 4.921)

CI: Confidence Interval.

Metabolic Signatures of Pathogenic T Cells in Medium and Large Vessel Vasculitis

Mitsuhiro Akiyama,[1] Hui Zhang,[1] Ryu Watanabe,[1] Toshihisa Maeda,[2] Gerald Berry,[1] Jorg Goronzy,[1] and **Cornelia Weyand** [1], [1]Stanford University, Stanford, CA, [2]Matsubara Mayflower Hospital, Kobe, Japan

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is an autoimmune vasculitis that causes aortic arch syndrome, blindnesss, and stroke. Embedded in granulomatous infiltrates, CD4 T cells persist over long periods in the inflamed vessel wall where they drive wall remodeling, intramural neoangiogenesis, intimal hyperplasia and luminal occulsion. To survive and function in a nonlymphoid tissue environment, T cells need access to nutrient supply and communicate with their surroundings through metabolic signals. Signaling pathways regulating the metabolic profile of tissue-residing T cells are currently unknown.

Methods: Metabolic gene expression was assessed in tissue biopsies from patients with temporal arteritis and in circulating CD4 T cells from patients with active GCA. Antibody blocking studies were performed in human artery-SCID chimeric mice. Effector cell differentiation was analyzed by detecting intracellular cytokines by flow cytometry. Intramural microvesssels and intimal thickness were quantified by immunohistochemistry.

Results: When compared to age-matched controls, CD4 T cells from GCA patients were characterized by high expression of the glucose transporter GLUT1 and induction of the glycolytic machinery ($P < 0.001$). Transcription factors relevant for glucose utilization, such as c-myc and HIF-1a, were strongly upregulated ($P < 0.001$). Tissue-residency of CD4 T cells was linked to $GLUT1^{hi}$ expression ($P < 0.001$). Upregulation of the metabolic machinery was dependent on CD28 signalinng via activation of the AKT signaling pathway. Costimulation through CD28 induced GLUT1 expression ($P < 0.01$), glycolytic enzymes ($P < 0.05$) and mitochondrial oxygen consumption ($P < 0.05$). Multiple disease-relevant processes required engagement of CD28 and enhanced glycolytic flux, including effector T cells differentiation into IFN-gamma producing Th1 cells and IL-21-producing Tfh cells, intramural neoangiogenesis and hyperplasia of the intimal layer. Notably, CD28 costimulation was needed to sustain $CD4^{+}CD103^{+}$ tissue-resident memory T cells that secure long-term persistence of vasculitic infiltrates.

Conclusion: CD4 T cells in GCA patients are metabolically reprogrammed, relying on massive upregulation of glucose uptake and breakdown. In the tissue microenvironment, unopposed CD28 costimulation enables optimal utilization of glucose. Pathogenic remodeling of the vessel wall is metabolically controlled, identifying new therapeutic opportunities through metabolic interference.

Endothelial Protein C Receptor and Scavenger Receptor Class B Type 1 Negatively Regulate Vascular Inflammation and Are Major Autoantigens in Takayasu Arteritis

Tomoyuki Mutoh,[1] Tsuyoshi Shirai,[1] Tomonori Ishii,[2] Yuko Shirota,[3] Hideo Harigae,[1] and Hiroshi Fujii[1], [1]Department of Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan, [2]Tohoku University Hospital, Sendai, Japan, [3]Department of Hematology and Rheumatology, Tohoku Medical and Pharmaceutical University, Sendai, Japan

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Takayasu arteritis (TAK) is a chronic vasculitis which predominantly affects large vessels. Although anti-endothelial cell antibodies (AECA) had been reported to be involved in vascular inflammation in TAK,

their target antigens remained unclear. We had constructed an expression cloning system for specific identification of cell-surface antigens, which we named SARF. The aim of this study was to identify autoantigens expressed on the cell surface and to clarify their pathogenic relevance in TAK.

Methods: AECA activity against human umbilical vein endothelial cells (HUVEC) was measured and prototype AECA for SARF was determined. HUVEC cDNA library was inserted into rat myeloma cells by using retroviral vector, and cells expressing proteins derived from cDNA library of HUVEC were incubated with prototype AECA-IgG. Cells bound to AECA-IgG were sorted by flow cytometry, and inserted cDNA in sorted cells was analyzed to identify autoantigens. The prevalence of autoantibodies identified was measured among collagen diseases, and the clinical characteristics of patients with TAK were evaluated according to the presence of autoantibodies. To examine the pathogenic roles of identified autoantibodies, the activation of HUVEC and differentiation of Th17 cells were evaluated.

Results: We performed SARF by using nine TAK sera, and successfully completed in three patients. Four clones bound to the prototype AECA were established, and endothelial protein C receptor (EPCR) and scavenger receptor class B type 1 (SR-BI) were identified as novel autoantigens in TAK. Among 52 TAK patients, anti-EPCR or anti-SR-BI activity was observed in 18 (34.6%) or 19 (36.5%) patients, respectively, with minimal overlap. Their presence was mostly specific for TAK in collagen diseases. TAK was classified into 3 subtypes based on the activity of autoantibodies. Anti-EPCR positive group showed high prevalence of stroke, ulcerative colitis, and type II lesion. Anti-SR-BI positive group presented higher levels of inflammatory markers, type V lesion, and older age at onset. Aortic regurgitation (AR) was rare in anti-SR-BI group. Double-negative group presented higher rates of surgery for AR. In mechanistic studies, EPCR and SR-BI negatively regulated the upregulation of adhesion molecules on HUVEC upon stimulation. The expression of EPCR was induced upon Th17 differentiation, and its agonist suppressed Th17 differentiation. These functions of autoantigens were inhibited by autoantibodies, which resulted in the activation of endothelial cells and the promotion of Th17 differentiation.

Conclusion: EPCR and SR-BI were identified as novel autoantigens in TAK, and these autoantibodies were observed in 67.3% of TAK patients. These autoantibodies blocked the negative regulatory effects of their targets, and thus would contribute to the chronicity of vascular inflammation in TAK.

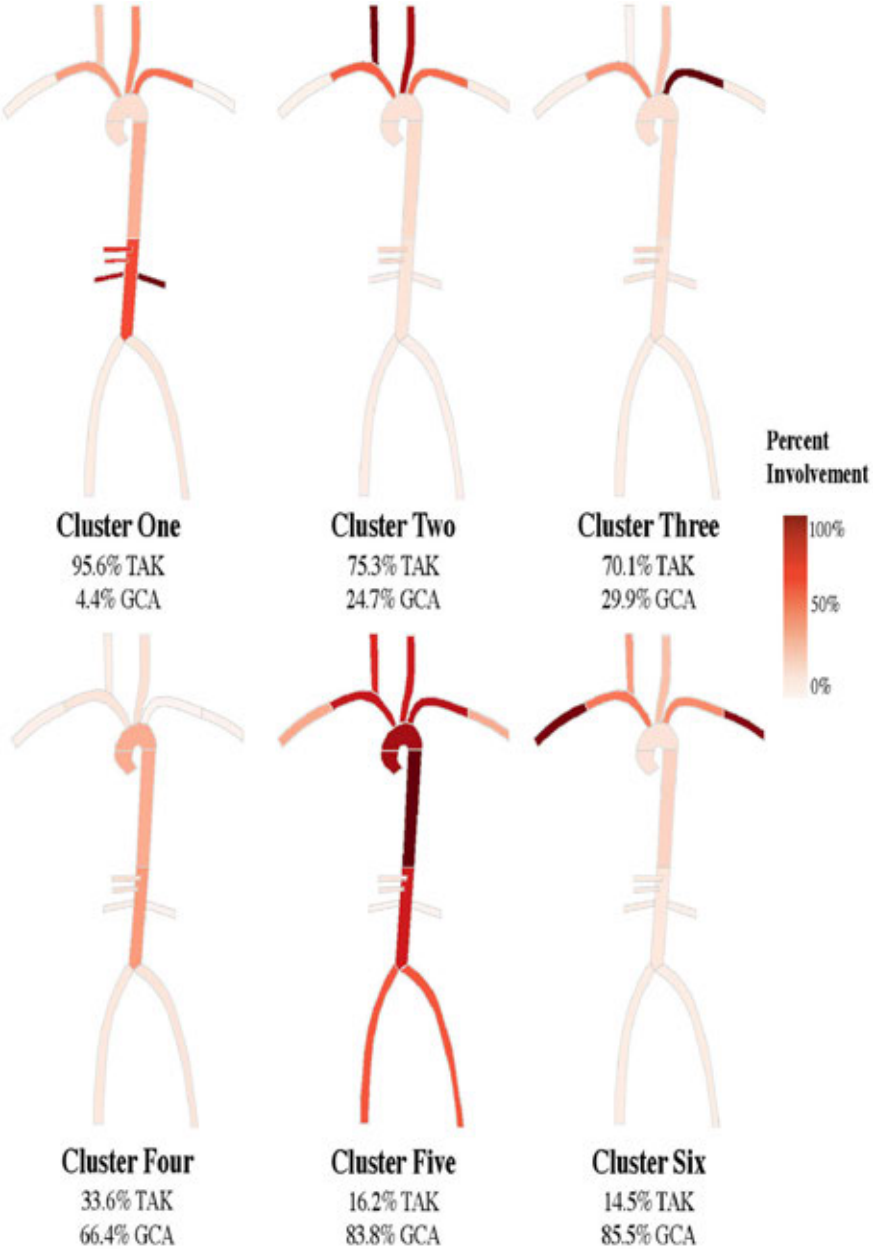
SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM



Heatmaps of the large arteries indicating the percent of patients in each cluster from the international cohort with involvement of the 11 arterial territories of interest (right and left carotid, subclavian, axillary, and renal arteries, mesenteric arteries, and descending and abdominal aorta). Increasingly darker red indicates an increasing percentage of patients in the cluster have involvement of the artery. The weighted proportion of patients with Takayasu's arteritis (TAK) and patients with giant cell arteritis (GCA) in each cluster are listed. Clusters One, Two, and Three were specific for TAK in the International (development) and North American (validation) cohorts. Clusters Four, Five, and Six were specific for GCA in the International cohort but only Clusters Four and Six was specific for GCA in the North American cohort.

Background/Purpose: Current classification criteria differentiate between Takayasu's arteritis (TAK) and giant cell arteritis (GCA), the two most common forms of large-vessel vasculitis, based primarily on clinical assessment, yet patients with TAK and GCA may differ in patterns of arterial disease. This study aimed to use computer-based algorithms to determine if patterns of arterial disease are useful to differentiate TAK from GCA with large-vessel involvement (LV-GCA).

Methods: Patients with TAK or LV-GCA were studied from four independent cohorts: a large, international cohort and three separate cohorts combined into one North America cohort. Case inclusion required evidence of large-vessel involvement, defined as stenosis, occlusion, or aneurysm by imaging or catheter-based angiography or ultrasound, or increased FDG uptake by positron-emission tomography (PET) in at least one of 11 specified arterial territories. K-means cluster analysis was performed to identify clusters of patients based on pattern of arterial involvement. Cluster groups were identified in the international cohort and independently validated in the combined North American cohort.

Results: A total of 1,068 patients were included (International: TAK=461, GCA=217; NA: TAK=225, GCA=165). Patients with TAK underwent angiography (95%), ultrasonography (28%), and/or PET imaging (14%). Patients with LV-GCA underwent angiography (50%), ultrasonography (52%), and/or PET imaging (58%). Six distinct clusters of patients were identified in the international cohort and validated in the North American cohort (Figure). Patients in Clusters One, Two, and Three were significantly more likely to have TAK, and patients in Clusters Four, Five, and Six were significantly more likely to have LV-GCA. Out of all study patients, involvement of the abdominal aorta and renal/mesenteric arteries was the most specific pattern for TAK (TAK: 134 (92%) vs GCA: 11 (8%), $p< 0.01$), while bilateral subclavian/axillary disease was the most specific pattern for GCA (GCA: 92 (80%) vs TAK: 23 (20%), $p< 0.01$). Among patients who underwent both angiography and PET, patients with TAK were more likely than patients with GCA to have damage by angiography without associated inflammation by PET (TAK: 52% vs GCA: 7%, $p< 0.001$), and patients with GCA were more likely than patients with TAK to have arterial FDG-uptake by PET without associated vascular damage (GCA: 80% vs TAK: 23%, $p< 0.001$).

Conclusion: These findings support the incorporation of arterial patterns of disease into classification criteria for large-vessel vasculitis and highlight shared and divergent vascular phenotypes between TAK and GCA.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is the most common form of vasculitis of large arteries affecting people older than 50 years. Temporal artery biopsy (TAB) is still considered as the gold standard for GCA diagnosis but it is invasive and its sensitivity ranges from 39 to 86%.Color Doppler Ultrasonography and PET-scanner have been proposed as alternative methods for GCA diagnosis but are not widespread in routine clinical practice. Recent recommendations suggest the use of MRI as an alternative method for GCA diagnosis. To our knowledge, there is no evaluation of 3D sequences in the diagnosis of GCA

Methods: We decided to evaluate the diagnostic performance of pre and post-contrast fat-suppressed 3D-Fast Spin echo T1-weighted black-blood magnetic resonance imaging (CUBE-T1), of the external carotid in the diagnosis process of GCA.

Results: Thirty-two patients (7 men, 25 women, mean±SD age 70.2±12.1 years) were included. The final diagnosis, blinded to CUBE T1 results, was GCA for 10 of them. 3D CUBE T1 displayed the arteries wall clearly, allowing an easy identification of parietal enhancement and the 3D TOF coregistration was helpful in image analysis. Intra- and inter-observer agreement for mural enhancement on CUBE T1 was 1 and 0.84, respectively.

Height of the 10 patients with GCA had a strong mural enhancement in CUBE-T1 (Figure 1), while none of the 22 patients without GCA had mural enhancement in MR images. Therefore, sensitivity was 80% and specificity was 100 %. The positive predictive value of post-contrast CUBE T1 was 100% and the negative predictive value was 92%. In our cohort, only 6 of the 10 GCA patients had a positive TAB. Therefore sensitivity of TAB was 60%. If TAB was used as the reference standard, MRI yielded a sensitivity of 100%. Two patients with a final diagnosis of GCA despite normal TAB had an arteritis on MRI and vessel enhancement was observed in occipital artery only for one patient.

Conclusion: We here demonstrate the feasibility and accuracy of a 3D post-contrast CUBE-T1 in the diagnosis of GCA. Indeed, we observed a sensitivity of 80%, which is higher than the 64.1% that was observed by Rhéaume et al. with 2D sequences on his series of 172 patients. We hypothesize that 3D MRI acquisition allowing multiplanar reconstructions together with the 3D TOF coregistration might explain the higher sensitivity and the excellent reproducibility. The reproducibility and short scan duration is a clear advantage of CUBE-T1 sequences with sub-millimetric voxels acquisition. Additional studies are required to confirm our preliminary results.

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: ^{18}F-flurodeoxyglucose (FDG) positron emission tomography (PET) is one of several imaging modalities used in the assessment of patients with large-vessel vasculitis (LVV). Conventionally PET images are obtained 1 hour after radiotracer injection; however, delayed imaging may be more sensitive to detect vascular inflammation.

The objectives of this study were to: 1) determine the impact of imaging acquisition time on interpretation of disease activity on FDG-PET in LVV and 2) assess the relationship between clinical features and image acquisition time.

Methods: An observational cohort of patients with giant cell arteritis (GCA) or Takayasu's arteritis (TAK) was prospectively recruited. Patients fulfilled the 1990 ACR Classification Criteria for TAK or modified 1990 ACR Criteria for GCA. Following injection, whole-body FDG-PET magnetic resonance imaging (MRI) was performed at one-hour uptake time followed by FDG-PET computed tomography (CT) at two-hours uptake time. A single reader with vascular imaging expertise interpreted the PET studies for evidence of active vasculitis. Patients were categorized as 1) both time points active (dual active), 2) both time points inactive (dual inactive), 3) only the one-hour time point active (early time point active), and 4) only the two-hour time point active (delayed active). Imaging and clinical assessments were performed blinded to each other within a 24-hour period.

Agreement was assessed by percent agreement, Cohen's kappa, and McNemar's test. Nominal logistic regression was used to study factors associated with the PET categories, including age, BMI, gender, LVV type, clinical status (active/remission), ESR, CRP, and treatment status (yes/no). Significant variables in the univariable model were included in multivariable regression.

Results: 79 patients (GCA=44, TAK=35) contributed 168 paired one and two-hour PET studies. A total of 94 out of 168 scans (56%) were interpreted as active at the one-hour time point, and 129 scans (77%) were interpreted as active at the two-hour time point ($p< 0.01$). Scans were interpreted as both active in 90 cases and both inactive in 35 cases (percent overall agreement=74%, cohen's kappa=0.45(fair agreement)). In discordant cases, delayed active only was observed in 39 cases versus early active only in 4 cases (McNemar's $p< 0.01$).

Associations between clinical variables and PET activity categories were also evaluated. Using multivariable nominal regression, clinically active disease was significantly more common in patients in the delayed active group (Odds

Clinical Features Associated with PET Activity Categories

Predictor Variable	Odds ratio	95% Confidence Interval	P-value
Dual active			
Clinically active disease	1.71	1.06—2.93	0.04
CRP (per 1mg/L)	1.05	1.00—1.14	0.12
Female gender	1.13	0.68—1.85	0.62
LVV type (GCA)	1.33	0.86—2.04	0.19
Delayed active only			
Clinically active disease	1.94	1.13—3.53	0.02
CRP (per 1mg/L)	1.01	0.92—1.08	0.88
Male gender	1.67	1.00—2.86	0.05
LVV type (TAK)	1.31	0.81—2.14	0.28

Ratio 1.94, 95%CI 1.13 – 3.53; p=0.02) and the dual active group (Odds Ratio 1.71, 95%CI 1.06 – 2.93; p=0.04) compared to the dual inactive group as shown in *Table 1*.

Conclusion: Imaging protocol significantly influences interpretation of PET activity in LVV. A substantial proportion of patients with LVV had PET activity only detected by delayed imaging. These patients were significantly more likely to have concomitant clinically-determined active disease. Imaging acquisition protocols should be standardized in LVV and encourage delayed imaging.

SESSION INFORMATION

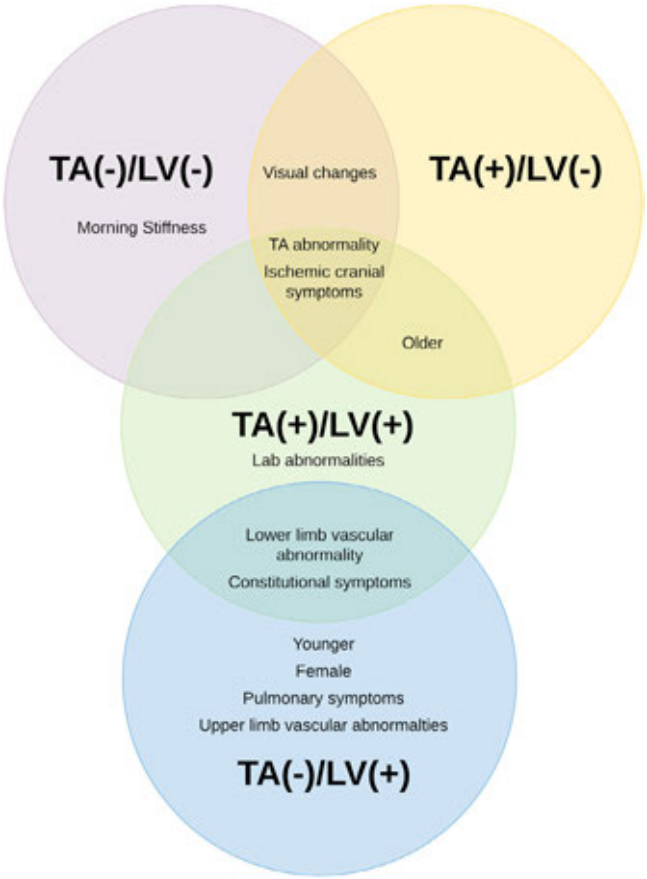
Session Date: Wednesday, November 13, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders III: Large Vessel Vasculitis Pathogenesis & Imaging

Session Type: ACR Abstract Session

Session Time: 11:00AM–12:30PM

Background/Purpose: Giant cell arteritis (GCA) is a clinically heterogeneous disease. Disease subsets based upon cranial versus extracranial artery involvement have been proposed. The study objective was to determine if GCA subsets are associated with distinct clinical profiles or merely reflective of differential diagnostic assessment.



Clinical and demographic associations of patients with giant cell arteritis (GCA). Patients with TA(-)/LV(-) have a clinical diagnosis of GCA without evidence of temporal artery (TA) or large vessel (LV) involvement. Patients with TA(+)/LV(-) have evidence of TA involvement without evidence of LV involvement on imaging. Patients with TA(+)/LV(+) have evidence of both TA involvement and LV involvement on imaging. Patients with TA(-)/LV(+) have evidence of LV involvement on imaging without evidence of TA involvement.

Methods: Patients were included from a large international cohort with standardized data collection. Patients with a confirmed diagnosis of GCA were divided into four subsets based on a temporal artery (TA) abnormality [definite vasculitis by biopsy (TAB) or halo-sign positive ultrasound (TA-US)] and/or imaging evidence of large-vessel (LV, aorta and/or its primary branches) involvement on imaging: 1) patients with evidence of *both* LV involvement and TA abnormality (**TA(+)/LV(+) GCA**); 2) patients with TA abnormality without LV involvement (**TA(+)/LV(-) GCA**); 3) patients with LV involvement without TA abnormality (**TA(-)/LV(+) GCA**); and 4) patients with a clinical diagnosis of GCA without LV involvement or TA abnormality (**TA(-)/LV(-) GCA**).

Results: Out of 941 patients, 329 (35%) had TA-US, 705 (75%) had TAB, 536 (57%) had LV imaging, and 431 (46%) had both LV imaging and TA-US/TAB. GCA subsets had distinct clinical profiles (Figure). TA(+)/LV(-) GCA (n=480) had the highest burden of visual changes (e.g. amaurosis fugax, sudden ongoing visual loss; $p< 0.01$), other cranial ischemic symptoms (e.g. jaw claudication, scalp tenderness; $p< 0.01$), and TA abnormalities on physical examination ($p< 0.01$), with little evidence of other vascular exam abnormalities. Patients with TA(-)/LV(-) GCA (n= 245) were nearly indistinguishable from TA(+)/LV(-) GCA with a high prevalence of visual changes and other cranial ischemic symptoms ($p< 0.01$) but also had a high burden of musculoskeletal symptoms ($p=0.02$). Patients with TA(-)/LV(+) GCA (n=116) were younger ($p< 0.01$) and more frequently female ($p< 0.01$), with a lower burden of visual changes ($p< 0.01$) and cranial ischemic symptoms ($p< 0.01$), and a higher burden of vascular abnormalities (e.g. upper/lower limb claudication/pulse abnormality, arterial bruit, blood pressure differences; $p< 0.01$), constitutional (e.g. weight loss, night sweats; $p< 0.01$), and pulmonary symptoms (e.g. non-productive cough, dyspnea; $p< 0.01$). Patients with TA(+)/LV(+) GCA (n=100) were older and more likely to be male with a high prevalence of cranial ischemic symptoms like TA(+)/

LV(-) GCA and a high prevalence of lower-limb vascular abnormalities and constitutional symptoms like TA(-)/LV(+) GCA. Patients with TA(+)/LV(+) GCA also had the highest prevalence of lab abnormalities ($p< 0.01$). When analyses were restricted to 431 patients who had both TA assessment (TAB or TA-US) and LV assessment by imaging, the four subsets had similar patterns of clinical associations.

Conclusion: Patients with GCA can be divided into subsets based on temporal and extracranial artery involvement. Each subset has a unique clinical profile that is not explained by differences in diagnostic assessment. Longitudinal studies comparing immunologic differences and clinical outcomes across these subsets are warranted.

^ This study's index date is the 12-month follow-up OAI visit
*Adjusted for baseline age, BMI, sex, race, education, comorbidities, the presence of depression (≤ vs. >16), and symptomatic knee OA (yes or no), defined as presence of Kellgren–Lawrence grade ≥ 2 on x-ray in one or both knees, and pain, aching, or stiffness on most days of a month during the previous year.

Background/Purpose: Slow walking speed (WS) is a risk factor for mortality in well-functioning older adults and speeds slower than (<) 1.22 meters per second (m/s) are a risk factor for poor health outcomes in knee osteoarthritis (OA). WS is known to decline with age, with some declining faster than other, though it is unclear if the rate of decline in WS is additionally relevant for mortality risk in knee OA. If so, considering the degree of decline over a prior year in addition to the present level of WS may be important. Therefore, the purpose of this study was to investigate whether WS at one time-point, degree of decline in WS over past one year, or both predict mortality risk over 9 years in knee OA.

Methods: We used data from the Osteoarthritis Initiative. WS was measured from a 20-m walk test at baseline and the 12-month visit. The index date for this analysis is the 12-month visit. Walking < 1.22 m/s represents the inability to cross a street with a timed crosswalk, and change >0.08 m/s is considered to be a clinically meaningful decline. We classified people into one of four groups depending on the WS at one time-point (the 12-month visit) and degree of decline over the previous year (from baseline to 12-month visit): [1] < 1.22 m/s and >0.08 m/s decline, [2] at least (>) 1.22 m/s and >0.08 m/s decline, [3] < 1.22 m/s and < 0.08 m/s decline or [4] >1.22 m/s and >0.08 m/s decline. Mortality was assessed up to 9 years of follow-up. We used Kaplan-Meier curves to determine the survival probability for the four groups. We examined the association of the 4 groups with mortality using Cox proportional hazards regression, adjusting for potential confounders.

Results: Of 4229 participants in the analytic sample (58% female, age 62.3±9.2 years, BMI 28.5±4.8 kg/m2), 6% (n=270) died over 9 years. Groups with WS < 1.22 m/s at one time-point were at higher risk of mortality irrespective of history of decline in WS (Figure). Those walking < 1.22 m/s with and without decline had 108% and 96% greater risk of mortality compared with those walking >1.22 m/s without meaningful decline over previous year (Table). Those walking ≥1.22 m/s with decline had a lower risk of mortality than the group walking ≥1.22m/s without meaningful decline in WS, likely related to the latter having started with a higher WS at baseline.

Conclusion: Walking slower than 1.22 m/s was associated with increased mortality risk, irrespective of degree of decline in WS in adults with knee OA. Those walking at least 1.22 m/s who had a meaningful decline in WS over the prior year, did not have increased risk of mortality, and in fact had nonsignificant lower risk, suggesting a potential threshold effect such that WS assessed at one time-point may be sufficient to gauge mortality risk.

The Effects of Leisure Time Sitting and Sitting at Work on Worsening Radiographic Knee Osteoarthritis over Two Years: Data from the Osteoarthritis Initiative

Dana Voinier,[1] Tuhina Neogi,[2] Hiral Master,[3] Louise Thoma,[4] Meredith Christiansen,[1] Jason Jakiela,[1] Lauren Neely,[1] and Daniel White[3], [1]University of Delaware, Newark, [2]Boston University School of Medicine, Boston, MA, [3]University of Delaware, Newark, DE, [4]University of North Carolina at Chapel Hill, Newark

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Epidemiology & Public Health
Session Type: ACR/ARP Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Sitting is associated with many poor health outcomes, which may include knee osteoarthritis (OA). When the knee is subject to minimal load, knee cartilage becomes thinner and may be more susceptible to damage. Thus, people who spend more time in **sitting**, whether during leisure time or during work, may be at greater risk for worsening structural damage in the knee. We examined the relation of time sitting to worsening radiographic OA over 2 years in a cohort of adults with or at risk for knee OA, assessing time spent sitting during leisure time and at work separately. We hypothesized that people with more leisure-time sitting **and** more sitting at work are at greater risk for worsening radiographic OA.

Methods: We used data from the Osteoarthritis Initiative (OAI). At study baseline, participants reported their leisure time sitting (hours/day) via the Physical Activity Scale for the Elderly (PASE). We dichotomized **leisure time sitting** as < 4 hours/day vs ≥4 hours/day, as this was the approximate mean for the sample. Participants also reported their **work activities** via the PASE as: sitting, sitting/standing/walking, walking/handling < 50 lbs, or walking/handling >50 lbs. We dichotomized work activities as "sitting only" vs "sitting and other activities". All OAI participants had bilateral knee radiographs obtained and scored for Kellgren and Lawrence (KL) grade at baseline, 1-year, and 2-year follow-up visits. We defined our outcome, **worsening radiographic OA over 2 years**, as an increase in KL grade from baseline to end of follow-up, including within-grade changes. We examined the relation of leisure time sitting with worsening radiographic OA using binomial regression with GEE, adjusting for potential confounders (age, sex, race, body mass index [BMI], and self-reported leisure time walking [hours/day]). We then repeated analyses of the effect of leisure time sitting on worsening ROA among those whose work involves "sitting only" and separately among those whose work involves "sitting and other activities".

Table: Siting and risk of worsening radiographic OA over 2 years.

	All OAI Participants n=5632 knees		Work: Primarily "Sitting" n=1641 knees		Work: "Sitting and Other Activities" n=3991 knees	
	% *(n/N)*	RR* *[95%CI]*	% *(n/N)*	RR* *[95%CI]*	% *(n/N)*	RR* *[95%CI]*
Leisure Time Sitting: <4 hours/day	9.2% (349/3804)	1.0 [REF]	7.0% (67/954)	1.0 [REF]	9.9% (282/2850)	1.0 [REF]
Leisure Time Sitting: ≥4 hours/day	11.3% (206/1828)	1.17 [0.98-1.39]	10.6% (73/687)	1.44 [1.01-2.06]	11.6% (133/1141)	1.12 [0.91-1.38]

*Adjusted for age, sex, race, BMI, and self-reported leisure time walking.

Results: We included 5632 knees in our analysis (2826 participants, BMI: 28.4 ± 4.8 kg/m2, age: 59.4 ± 8.6 years, 57% women, 83% white). People who spent ≥ 4 hours/day in leisure time sitting had greater risk (1.17[0.98-1.39]) of worsening radiographic OA over 2 years, compared with those who spent < 4 hours/day in leisure time sitting. Among participants who reported "sitting only" at work, those who spent ≥4 hours/day in leisure time sitting had greater risk (1.44[1.01-2.06] of worsening radiographic OA compared with those who spent < 4 hours/day in leisure time sitting. Conversely, among participants who reported "sitting and other activities" at work, there was no relationship between leisure time sitting and worsening radiographic OA (see Table).

Conclusion: People who spend at least 4 hours/day of leisure time sitting, and also primarily sit at work, may be at increased risk for worsening radiographic OA. Reducing leisure time sitting, and potentially reducing sitting at work, may be targets for intervention in people with or at risk for knee OA.

Session Title: Epidemiology & Public Health
Session Type: ACR/ARP Abstract Session
Session Time: 11:00AM–12:30PM

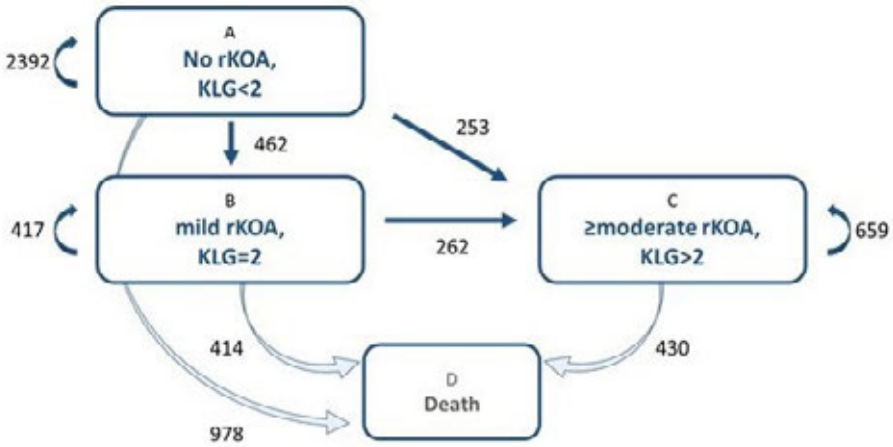

Figure 1. Four-state progressive model for knee OA status. The number of times each pair of transition states was observed at successive follow-up times is indicated next to its respective transition arrow. A curved arrow beside a state (A, B, or C) indicates no transition.

State transition	Normal	Overweight	Obese Class I	Obese Class II or III
A No rKOA → **B** mild rKOA	1.14 (0.60, 2.18)	1.29 (0.87, 1.90)	1.03 (0.65, 1.64)	*1.73 (0.96, 3.15)*
B mild rKOA → **C** ≥moderate rKOA	1.13 (0.43, 3.01)	1.45 (0.86, 2.44)	0.69 (0.41, 1.16)	0.91 (0.56, 1.47)
A No rKOA → **C** ≥moderate rKOA	1.05 (0.13, 8.81)	*3.38 (0.99, 11.5)*	*2.36 (0.99, 5.65)*	0.74 (0.14, 3.97)

*Adjusted for age, sex, race, self-reported diabetes, and self-reported cardiovascular disease.

Table 1. Adjusted* hazard ratios and 95% confidence intervals of the association of knee injury and radiographic knee osteoarthritis (rKOA) transitions for body mass index categories on modeled transition states, over the full follow-up period of 18 years.

Background/Purpose: Musculoskeletal injury is a known risk factor for osteoarthritis (OA). Cumulative effects of comorbid conditions on the association of injury and OA have not been previously examined. The purpose of this study was to clarify associations between knee injury and radiographic knee osteoarthritis (rKOA) and determine whether associations vary by sex, race, body mass index (BMI), diabetes mellitus (DM), and cardiovascular disease (CVD).

Methods: Data were from 4093 participants of the Johnston County Osteoarthritis Project who were enrolled during 1991-1997 (Original Cohort) and 2003-2004 (Enrichment Cohort). Data were from baseline and up to three follow-up study visits (over ~18 years). All knee radiographs were read for Kellgren-Lawrence grade (KLG) of 0-4. Using Markov multi-state models in a time-to-event approach, a progressive model included states of: (A) no rKOA (KLG< 2), (B) mild rKOA (KLG=2), and (C) ≥moderate rKOA (KLG >2 or total knee replacement; Figure 1). Hazard ratios and 95% confidence intervals (HR [95% CI]) were estimated to determine associations between knee injury and rKOA transitions, examining six variables as potential effect modifiers or covariates: age, sex, race (White, African-American), BMI (normal [< 25 kg/m2], overweight [25-< 30 kg/m2], obese class I [30-< 35 kg/m2], and obese class II [35+ kg/m2]), self-reported DM, and self-reported CVD.

Results: At baseline, participants had a mean age of 61 years (SD±10), were 63% women, and were 34% African American; 19% reported a prior knee injury, 40% were obese,13% reported DM, and 22% reported CVD. During the study period, 2738 participants had no transitions. In adjusted models, the hazards of incident mild and ≥moderate rKOA were higher among those with baseline knee injury (1.25 [0.99, 1.59] and 1.71 [0.99, 2.96], respectively). Knee injury was associated with incident mild rKOA among Whites (1.38 [1.04, 1.81]) but not among African Americans (0.93 [0.57, 1.51]). Associations did not differ between any transition states in interactions with sex or DM. Knee injury was not associated with incident rKOA transitions among individuals with normal BMI, but positive associations were observed in some higher BMI categories (Table 1). Among those without CVD, knee injury was associated with rKOA (1.48 [1.13, 1.93]). Among those with CVD, knee injury was not associated with rKOA but was associated with ≥moderate rKOA (4.15 [1.12, 15.4]).

Conclusion: The relationship of knee injury and rKOA transitions differs by race, CVD, and BMI. Maintaining a normal BMI in the setting of knee injury may mitigate the impact of a joint injury upon development of knee OA.

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Epidemiology & Public Health
Session Type: ACR/ARP Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Osteoarthritis (OA) is a major source of disability worldwide yet dietary exposures that might be associated with its progression have not received significant research attention. We aimed to examine the prospective association of major dietary patterns derived by principal component analysis (PCA) with symptomatic progression of knee OA.

Methods: From the Osteoarthritis Initiative (OAI), 2,757 individuals with mild to moderate knee OA in at least one knee (defined as Kellgren-Lawrence (KL) grade of 1, 2, or 3) at baseline were followed annually up to 72 months. Dietary intake was assessed with a Block Brief Food Frequency Questionnaire completed at baseline. Two dietary patterns were identified by PCA: the prudent pattern characterized by high intakes of fruit/vegetables, legumes, whole grains, fish, etc.; the Western pattern characterized by high intakes of red / processed meats, refined grains, French fries, etc. (Table 1). A combined score was calculated as the difference between the Western and prudent pattern scores to evaluate the overall dietary quality since the two patterns are uncorrelated. We categorized the Western Ontario & McMaster Universities Arthritis Index (WOMAC) pain, disability and total scores at each time point into 5 grades: (zero and quartile thresholds based on baseline non-zero scores). Symptomatic progression, defined as either an increase in WOMAC grade or remaining in one of the two highest WOMAC grades, was evaluated at each follow-up time point. Generalized linear mixed models for repeated binary responses were developed to evaluate the associations after adjusting for age, sex, race, baseline K-L grades, injury/surgery, depression, pain medications and total energy intake. BMI and weight changes from baseline were additionally adjusted in separate models to assess the potential mediation effect.

Results: The progression increased significantly with higher Western pattern quartiles in a dose-response fashion (p trend < 0.01) (Table 2). In contrast, symptomatic knee OA progression generally decreased with a higher score of prudent dietary pattern. Consistent with a Western pattern, we observed a strong dose-response relationship between the combined score, which indicated not only high consumption of a Western diet but also low consumption of a prudent diet, and symptomatic knee OA progression (p trend < 0.01). The observed associations generally remained after additionally adjusting for BMI and weight change from baseline.

Conclusion: Adherence to a Western dietary pattern was associated with increased symptomatic knee OA progression, while following a prudent dietary pattern was associated with reduced knee OA progression. For participants already diagnosed with knee OA, eating a healthy diet rich in fruits, vegetables, fish, whole grains and legumes, lower in red/processed meats, refined grains and French fries, may slow symptomatic disease progression.

Block Group Poverty ≥20%, N (%)	92 (47.4%)

SESSION INFORMATION

Session Date: Wednesday, November 13, 2019
Session Title: Epidemiology & Public Health
Session Type: ACR/ARP Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: In prior cross-sectional analyses of African Americans (AA) with RA, we observed that low education, income and home ownership were associated with clinical damage and patient reported outcomes (PROs) among those with mean disease duration of 7.8 years. However, when restricted to those with disease duration of < 2 years, associations with PROs remained, but were no longer observed with damage, most likely due to the low damage scores in individuals with early disease. Therefore, we hypothesize that socioeconomic status (SES) measures may be related to clinical progression and PRO worsening in AA with early RA.

Methods: We conducted analyses using data from 194 individuals with RA who completed a follow-up at 5 years of disease duration. Patients who had been diagnosed in the previous 2 years were enrolled from 5 medical centers in the southeastern US. SES measures were educational attainment (< high school diploma [< HS EDUC], or ≥HS); occupation (professional or not [Non-Pro OCC]); home ownership (yes or non-HOME); annual household income (≤$30,000 [≤$30K INC] or >$30K); and percent block group poverty (BGP ≥20% or < 20%). Outcomes were based on radiographs (erosion and JSN score) and PROs (Health Assessment Questionnaire [HAQ], self-rated pain and fatigue from visual analog scales [VAS] and the Rheumatology Attitudes Index [RAI]). Progression was defined as those who

Table 2. Outcome measures over time in the Consortium for the Longitudinal Evaluation of African Americans with Early Rheumatoid Arthritis Registry (CLEAR) (n=194)

	Baseline	60 Months
Patient Reported Outcomes		
HAQ Score, Mean (Std Dev)	1.39 (0.8)	1.25 (0.8)
Pain VAS, Mean (Std Dev)	6.10 (3.0)	5.82 (3.1)
Fatigue VAS, Mean (Std Dev)	5.89 (3.1)	5.61 (3.4)
RAI Score, Mean (Std Dev)	2.89 (1.1)	2.60 (1.0)
Radiographic Disease Scores		
Erosion Score, Mean (Std Dev)	1.27 (3.8)	2.12 (7.6)
JSN Score, Mean (Std Dev)	1.79 (5.0)	5.29 (12.6)

were in the highest quintile of disease progression (top 20% of increases in severity of outcome scores): erosions ≥1, JSN ≥7, HAQ ≥0.37, Pain and Fatigue VAS ≥3, RAI ≥0.4. We multiply imputed missing values of covariates. Multi-level logistic regression models with study site considered as a random effect were used to estimate odds ratios (OR) and 95% confidence intervals (CI) for the association between SES measures at baseline and progression. All models were adjusted for age, sex, BMI, number of comorbidities, smoking, disease duration at study entry, methotrexate/leflunomide use, and were simultaneously adjusted for other SES measures.

Results: Baseline demographics are shown in Table 1. At 5 years disease duration, mean outcome scores tended to increase for both erosion scores and JSN scores, but decreased for PROs (Table 2). We did not observe any association between SES measures and either erosion or JSN score progression (Table 3). However, < HS EDUC and Non-Pro OCC were both associated with worsening pain VAS, while non-HOME was inversely associated with worsening pain VAS, and non-Pro OCC was inversely associated with worsening RAI.

Conclusion: As with the previous cross-sectional analyses examining associations between SES measures and outcomes in AAs with < 2 years of disease who are being treated with RA therapies, we did not observe associations between SES and radiographic progression in adjusted analyses. However, some SES measures were associated with increased Pain VAS, after simultaneously adjusting for all SES measures and covariates. These results are possibly due to the relatively short disease duration (5 years) and length of follow-up (4 years) of the population and warrants further research with longer periods of follow-up.

Abstract Number: 2929

Cannabis Use Among Patients in a Large US Rheumatic Disease Registry

Kristin Wipfler,[1] **Teresa Simon**,[2] Patricia Katz,[3] Frederick Wolfe,[4] and Kaleb Michaud[5], [1]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [2]Bristol-Myers Squibb*, Princeton, NJ, [3]University of California, San Francisco, san francisco, CA, [4]FORWARD, The National Databank for Rheumatic Diseases & University of Nebraska Medical Center, Wichita, KS, [5]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION
Session Date: Wednesday, November 13, 2019
Session Title: Epidemiology & Public Health
Session Type: ACR/ARP Abstract Session
Session Time: 11:00AM–12:30PM

Background/Purpose: Legalization of cannabis use is rapidly increasing worldwide, raising the need to evaluate trends and medical implications. A systematic literature review showed inconsistent results on tolerability and safety of cannabis-based medicines for any chronic pain [1]. Additionally, little is known about the use and effectiveness of cannabis in rheumatic diseases [2]. We sought to evaluate the trends of cannabis use and associations with rheumatic disease characteristics in a US-wide registry.

Methods: Study patients were participants in FORWARD, The National Databank for Rheumatic Diseases, a longitudinal study of rheumatic disease outcomes, who indicated in a 2014 and/or 2019 questionnaire whether they had ever used marijuana, cannabis, or cannabidiol (hereafter cannabis) for symptom relief, and if so, whether they found it helpful. Demographics, disease activity/status assessments (PRO), medications, comorbidities, and diagnosis were compared between cannabis users and nonusers in 2014 and 2019. Significance was assessed using t-tests and Chi-square tests as appropriate. Choropleth maps were generated based on prevalence of cannabis use in each US state. Logistic regression models were generated to determine the probability of cannabis or opioid use by polysymptomatic distress (the score used to determine whether fibromyalgia criteria are met).

Results: Among the 11,006 unique respondents, the prevalence of past or current cannabis use has increased from 6.3% in 2014 to 17.6% in 2019. At both time points, patients reporting use were younger, had worse measures on all PROs, and were more likely to have a history of smoking cigarettes, have fibromyalgia, report a history of depression, and report opioid use (Table 1). In 2014, users were also less likely to be Caucasian, married, and have health insurance. In 2019 there were fewer demographic differences. Most patients reported that cannabis was helpful in relieving symptoms (74% in 2014 and 62% in 2019). Since 2014, prevalence of use increased in 49 of 50 US states, with the highest prevalence in and near states where cannabis use is legal (Figure 1). Logistic regression models indicate that the probability of cannabis use increases with increasing polysymptomatic distress, and the same is true for opioid use (Figure 2).

Conclusion: Reported cannabis use among patients with rheumatic diseases has increased significantly, and most patients stated it was helpful for symptom relief. Patients who tried cannabis tended to have worse pain, disease activity, and symptoms and were taking more analgesics. While interpretation of cannabis effectiveness is beyond our study's scope, the association with prior opioid use and polysymptomatic distress highlights areas for future work.

Comparative Risk of Hospitalized Serious Infection in Patients with Psoriasis and Psoriatic Arthritis: A Population-Based Multi-Database Study

Yinzhu Jin,[1] Hemin Lee,[1] Moa Lee,[2] Joan Landon,[3] Joseph Merola,[4] Rishi Desai,[5] and **Seoyoung C. Kim**[1], [1]Brigham and Women's Hospital and Harvard Medical School, Boston, [2]University of North Carolina Chapel Hill, Chapel Hill, North Carolina, [3]Brigham and Women's Hospital, Boston, Massachusetts, [4]Harvard Medical School, Brigham and Women's Hospital, Boston, [5]Brigham and Women's hospital, Boston

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Late-Breaking Abstracts ePoster

Session Type: Late-Breaking Abstract Poster Session

Session Time: 9:00AM–11:00AM

Background/Purpose: The risk of serious infection when using disease-modifying antirheumatic drugs (DMARDs), including biologic drugs is one of the major concerns for psoriasis/psoriatic arthritis (PsO/PsA) patients. Limited evidence exists on the comparative risk of infection among newer medications including ustekinumab (anti-IL-12/23), secukinumab and ixekizumab (anti IL-17), and a phosphodiesterase-4 inhibitor apremilast compared with TNF inhibitors (TNFi) in patients with PsO or PsA.

Methods: We conducted a cohort study using two large US claims databases, MarketScan (9/25/2009–12/31/2017) and Optum (9/25/2009–12/31/2018). We identified the initiators of one of the following biologic DMARDS: ustekinumab, secukinumab, ixekizumab, or TNFi, (i.e., adalimumab, etanercept, infliximab, certolizumab, golimumab). Apremilast, albeit not a biologic DMARDs (bDMARDs), was also included since it is a relatively new medication used to treat PsO and PsA. The index date was the date of the 1st dispensing for a given drug. We required a 6-month washout period to define new users of each study drug. Patients were required to have at least two PsO or two PsA diagnosis

Figure 1. Selected baseline characteristics before PS fine stratification weighting

during the 6-month baseline period. We excluded patients with a recent serious infection, rheumatoid arthritis, inflammatory bowel disease, malignancy, HIV, or organ transplant at baseline. Our primary outcome was a composite endpoint of hospitalized serious infection including bacterial, viral, or opportunistic infection. Follow-up time started from the day after the index date to the earliest date of the outcome, disenrollment, death, end of database, discontinuation, or switching to other study drugs. Propensity score (PS) was estimated as the predicted probability of receiving ustekinumab versus each of the aforementioned study drugs conditioning on >50 baseline characteristics. Cox proportional hazards regression estimated hazard ratios (HR) for serious infection associated with each study drug versus ustekinumab after controlling for confounding using PS-based fine stratification weights. Database-specific HRs were combined using a random-effects meta-analysis.

Results: We identified 123,383 PsO/PsA patients who initiated one of the study drugs. Among these, 61% had PsO, 22% had PsA, and 17% had both PsO and PsA. The mean (SD) age of the total cohort was 48.2 (12.8) years, and 50.6% were female (see **Figure 1)**. The crude incidence rate per 100 person-years was highest in Infliximab (2.47 in MarketScan and 3.17 in Optum) and the lowest ixekizumab (0.69 in MarketScan) and ustekinumab (1.03 in Optum). After the PS stratification, ustekinumab had lower risk of hospitalized serious infection compared to other bDMARDs or apremilast (**Figure 2**). However, our estimates comparing certolizumab and golimumab versus ustekinumab were imprecise due to a limited sample size even after combining results from the two databases.

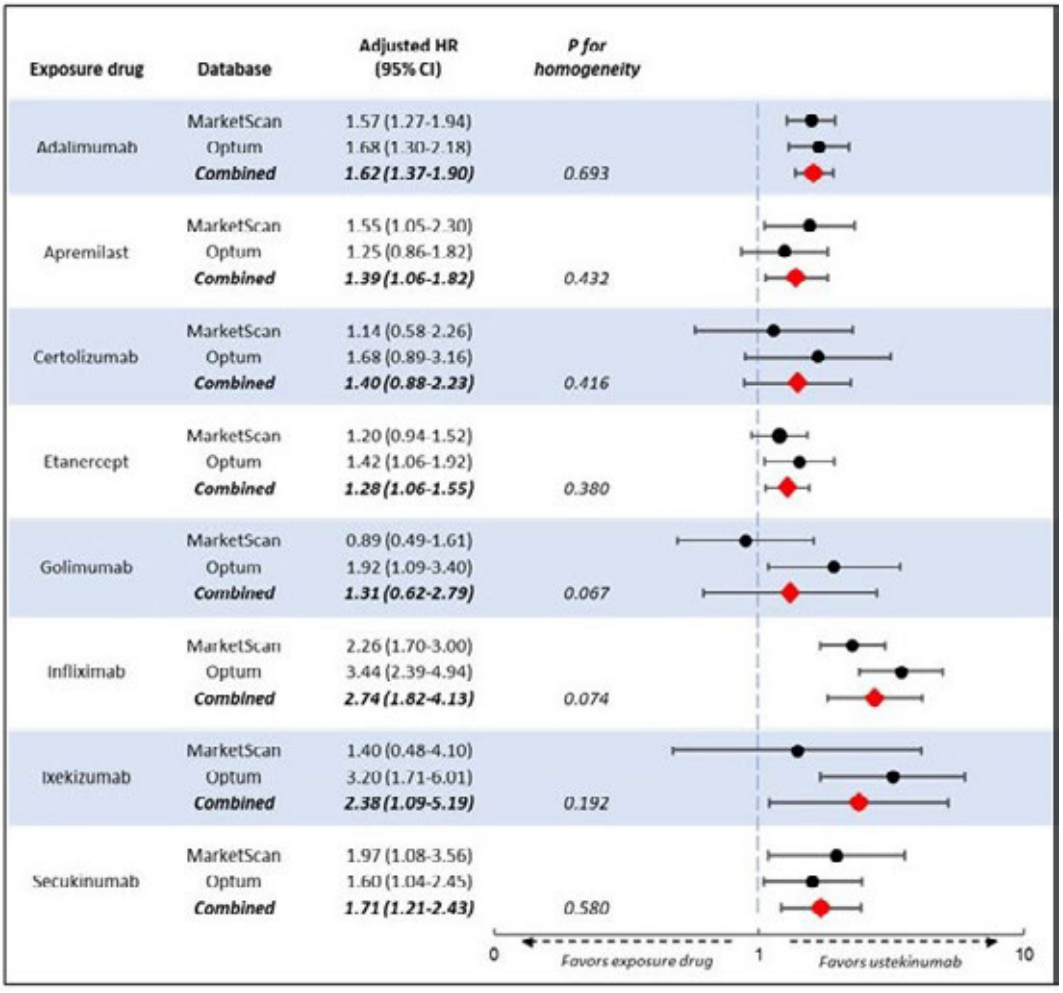

Figure 2. Forest plots for hazard ratios of serious infection of DMARDs comparing to ustekinumab

Conclusion: In this multi-database cohort of 123,383 PsO or PsA patients, ustekinumab initiators had a generally lower risk of hospitalized serious infection compared to TNFi, IL-17 therapy, and apremilast initiators.

Multiple Industrial Air Pollutants and Anti-Citrullinated Protein Antibody Positivity

Naizhuo Zhao,[1] Audrey Smargiassi,[2] Marianne Hatzopoulou,[3] Ines Colmegna,[4] Marie Hudson,[5] Marvin Fritzler,[6] Philip Awadalla,[7] and **Sasha Bernatsky**[8], [1]Research Institute of the McGill University Health Centre, Montreal, Canada, [2]University of Montreal, Montreal, Canada, [3]University of Toronto, Toronto, Canada, [4]McGill University Health Center, Montreal, QC, Canada, [5]Jewish General Hospital, Lady Davis Institute for Medical Research, and Department of Medicine, McGill University, Montreal, Canada, [6]Cumming School of Medicine, University of Calgary, Calgary, Canada, [7]Ontario Institute for Cancer Research, Toronto, Canada, [8]Research Institute of the McGill University Health Centre, Montreal, QC, Canada

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Studies of associations between industrial air emissions and rheumatic disease, or diseases-related serological biomarkers, are few. Moreover, previous evaluations typically studied individual (not mixed) emissions. We investigated associations between individual and combined exposures to industrial sulfur dioxide (SO_2), nitrogen dioxide (NO_2), and fine particles matter ($PM_{2.5}$) on anti-citrullinated protein antibodies (ACPA), a characteristic biomarker for rheumatoid arthritis (RA).

Methods: Serum ACPA was determined for 7600 randomly selected CARTaGENE general population subjects in Quebec, Canada. Industrial SO_2, NO_2, and $PM_{2.5}$ concentrations, estimated by the California Puff (CALPUFF) atmospheric dispersion model, were assigned based on residential postal codes at the time of sera collection. Single-exposure logistic regressions were performed for ACPA positivity defined by 20 U/ml, 40 U/ml, and 60U/ml thresholds, adjusting for age, sex, French Canadian origin, smoking, and family income. Associations between regional overall $PM_{2.5}$ exposure and ACPA positivity were also investigated. The associations between the combined three industrial exposures and the ACPA positivity were assessed by weighted quantile sum (WQS) regressions.

Results: Significant associations between individual and combined industrial exposures and ACPA positivity (defined by the 20 U/ml and 40 U/ml thresholds) were seen with both single-exposure logistic and multi-exposure WQS regression models, for industrial emissions of $PM_{2.5}$ and SO_2, without clear associations for NO_2. The WQS model suggested that industrial $PM_{2.5}$ may have a stronger effect than the other exposures.

Model	Exposure variable	ACPA positivity defined by 20 units/ml (N positive =786)	ACPA positivity defined by 40 units/ml (N positive =292)	ACPA positivity defined by 60 units/ml (N positive =134)
Logistic	Industrial SO_2	1.03 (1.00 – 1.06)	1.03 (1.00 – 1.07)	1.03 (0.98 – 1.08)
	Industrial NO_2	1.01 (0.86 – 1.17)	1.14 (0.91 – 1.41)	0.90 (0.63 – 1.28)
	Industrial $PM_{2.5}$	1.19 (1.04 – 1.36)	1.21 (1.02 – 1.42)	1.17 (0.92 – 1.48)
	Regional overall $PM_{2.5}$	0.98 (0.95 – 1.01)	0.95 (0.91– 1.01)	0.94 (0.89– 1.01)
WQS	three industrial pollutants	1.36 (1.10 – 1.69)	1.43 (1.05 – 1.96)	1.33 (0.85– 2.10)

Conclusion: We noted positive associations between ACPA and industrial emissions of $PM_{2.5}$ and SO_2. Industrial $PM_{2.5}$ exposure may play a particularly important role in this regard.

Odds ratios - ORs (95% confidence intervals – CIs) from the single-pollutant logistic and the weighted quantile sum (WQS) regression models, adjusting by age, sex, ancestry, smoking, and family income.

NYX-2925 Impacts Functional and Chemical Neuroimaging Biomarkers and Patient-reported Outcomes of Pain in Patients with Fibromyalgia

Steven Harte,[1] Leslie Arnold,[2] Eric Ichesco,[1] Christopher Crumb,[1] Mary Suh,[3] Laurel Sindelar,[3] Chelsea Kaplan,[1] Tony Larkin,[1] Andrew Schrepf,[1] Daniel Clauw,[4] Stephen Sainati,[3] and **Richard Harris**[1], [1]University of Michigan, Ann Arbor, [2]University of Cincinnati College of Medicine, Cincinnati, [3]Aptinyx Inc, Evanston, [4]Division of Rheumatology, Department of Internal Medicine and Division of Anesthesia, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Fibromyalgia (FM) is a chronic, debilitating disease typified by widespread musculoskeletal pain and accompanied by fatigue, sleep disturbance, memory issues, and mood disorders. FM has been described as the prototypical centralized chronic pain syndrome. NYX-2925 is a novel, non-opioid small-molecule modulator of the N-methyl-D-aspartate receptor (NMDAR) that is in Phase 2 development for fibromyalgia and painful diabetic peripheral neuropathy.

Methods: An exploratory Phase 2, placebo-controlled neuroimaging clinical trial was conducted in 22 right-handed female subjects with FM according to ACR 2010 criteria. Following a screening period, subjects received two weeks of placebo once-daily, followed by two weeks of 20 mg NYX-2925 once-daily, followed by two weeks of 200 mg NYX-2925 once-daily. Subjects underwent resting state functional connectivity magnetic resonance imaging (rs-fcMRI) and proton magnetic resonance spectroscopy (^{1}H-MRS) during screening and during the second week of each of the three dosing periods. Subjects and neuroimaging analysts were blinded to study drug and dose sequence.

Table 1: Patient reported measures of pain and fibromyalgia symptoms in Study NYX-2925-2002

	Placebo (Week 2)	20 mg NYX-2925 (Week 4)	200 mg NYX-2925 (Week 6)	Follow-up (Week 7)

p-value	NA	0.6829	0.0072	0.1358
Worst Daily Pain	N=19	N=20	N=19	N=15
Change from baseline	-0.34	-0.41	-0.98	-0.76
p-value	0.1477	0.1652	0.0169	0.0695
Change from placebo	NA	-0.13	-0.61	-0.39
p-value	NA	0.5547	0.0360	0.1197
Total FIQR Score	N=22	N=21	N=21	N=20
Change from baseline	-2.9	-3.8	-9.6	-0.4
p-value	0.2380	0.1389	0.0085	0.8712
Change from placebo	NA	-0.5	-6.3	2.4
p-value	NA	0.8746	0.0135	0.4339
Total $PROMIS_{FM}$ Fatigue Profile Score	N=22	N=21	N=21	N=20
Change from baseline	0.2	-3.2	-5.4	0.4
p-value	0.8702	0.1500	0.0081	0.7980
Change from placebo	NA	-3.4	-5.6	0.0
p-value	NA	0.2000	0.0049	>.9999

Testing for differences between treatment periods was performed using 2 sided paired t tests, comparing pre- and post-values based on analysis visits. The p-values were not corrected for multiple comparisons in this exploratory neuroimaging study.

Results: Neuroimaging showed that compared to placebo, administration of NYX-2925 resulted in statistically significant reductions of Glx/tCr (glutamate and glutamine ratio to total creatine) levels in key pain-regulating brain regions, including the dorsal anterior cingulate cortex (dACC) at rest (Placebo: 2.167+/-0.178; 20mg NYX-2925: 2.055+/-0.197; p=0.032) and the posterior insular cortex following an evoked pain stimulus (Placebo: 1.993+/-0.140; 200mg NYX-2925: 1.903+/-0.162; p=0.039). Greater concentrations of pain-evoked Glx pre-treatment in the posterior insular cortex were associated with greater reductions in patient reported sensitivity to evoked pain (increased pressure pain threshold) following 20mg NYX-2925 (r=0.58; p=0.009). In addition, 20mg NYX-2925 administration resulted in reduced connectivity between brain regions that are known to be associated with the processing of centralized chronic pain, including dACC to primary somatosensory cortex connectivity (p=0.030 Family Wise Error [FWE]).

Clinically meaningful and statistically significant clinical improvements were observed following treatment with 200mg NYX-2925 compared to baseline (Week 0) and placebo (Week 2) on the average daily pain score, worst daily pain score, total Revised Fibromyalgia Impact Questionnaire (FIQR) score, and $PROMIS_{FM}$ fatigue profile total score (Table 1). Clinical data further demonstrate that NYX-2925 is safe and well tolerated with no discontinuations due to treatment-emergent adverse events.

Conclusion: In this exploratory study, NYX-2925 demonstrated antinociceptive activity in neuroimaging evaluations. Clinically meaningful and statistically significant improvements were also observed in pain, fatigue, the overall intensity of fibromyalgia symptoms, and their impact on function. These data provide support for further evaluation of NYX-2925 for treating the hallmark symptoms of fibromyalgia.

Cardiovascular Disease Risk in Calcium Pyrophosphate Deposition Disease

Maaman Bashir,[1] Katherine Sherman,[2] Sara K. Tedeschi,[3] and Ann Rosenthal[1], [1]Medical College of Wisconsin, Milwaukee, [2]Milwaukee VAMC, Milwaukee, [3]Brigham and Women's Hospital, Div. of Rheumatology, Immunology and Allergy, Boston

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcium pyrophosphate deposition (CPPD) disease results from precipitation of calcium pyrophosphate (CPP) crystals in joints. Prior studies demonstrated that vascular calcification is more common in patients with CPPD compared to those without CPPD. Vascular calcification is implicated in the development of cardiovascular disease, yet studies of cardiovascular risks in CPPD are lacking. We aimed to assess the risk of cardiovascular events and all-cause mortality in patients with CPPD vs. those without CPPD.

Methods: Using a retrospective cohort study design within the national Veterans Affairs (VA) database (2010-2014), we compared the risk of major adverse cardiovascular events (MACE) in US veterans with CPPD vs. veterans without CPPD. CPPD was defined by ≥1 ICD-9 code for chondrocalcinosis or calcium metabolism disorder (712.1-712.39 or 275.49; positive predictive value 91%).[1] CPPD patients were age and sex-matched 1:4 to patients without those ICD-9 codes (controls). Only males were included in the analysis, as MACE was extremely uncommon in females. All subjects had at least 1 healthcare encounter in the 365 days before index date, defined as the first ICD-9 code for CPPD or a matched date for controls, to allow for covariate assessment. Covariates were included if present during the study period prior to MACE.

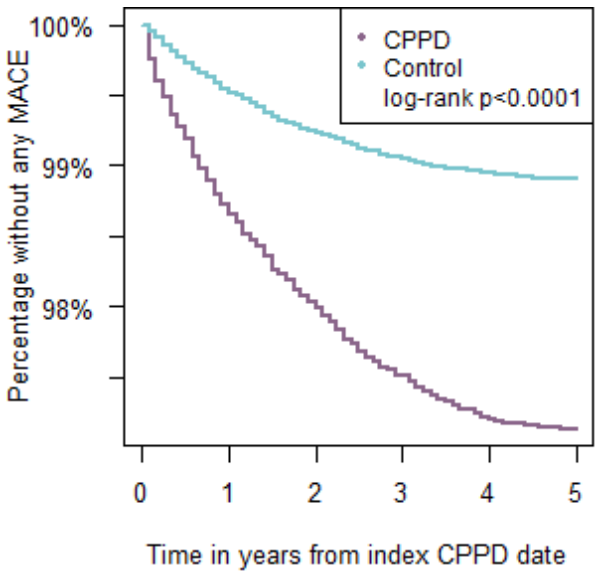

Figure 1. Percentage of patients without any MACE over time in CPPD and control groups

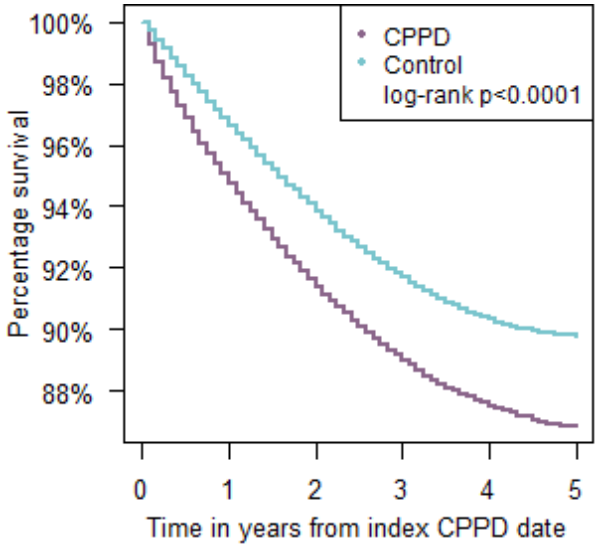

Figure 2. Percentage of patient survival over time in CPPD and control groups

The primary outcome was any MACE, defined by ICD-9 and/or procedure codes for myocardial infarction (MI), acute coronary syndrome (ACS), re-vascularization, or ischemic stroke. Secondary outcomes included individual types of MACE and all-cause mortality. We estimated incidence rates (IR) per 1,000 person-years and incidence rate ratios (IRR) for MACE and all-cause mortality. Stepwise Cox proportional hazards regression models were adjusted for traditional cardiovascular (CV) risk factors (hypertension, hyperlipidemia, diabetes, chronic kidney disease, peripheral vascular disease, smoking, obesity, gout, osteoarthritis, rheumatoid arthritis and prior history of MACE). Kaplan Meier curves and log-rank tests estimated the difference in MACE and mortality rates between groups.

Results: We identified 24,413 CPPD patients matched to 97,591 controls. MACE occurred in 702 (2.88%) patients with CPPD and 1069 (1.10%) controls (Figure 1). The IR of any MACE was nearly three times higher in patients with CPPD (IR 11.5 [95% CI 10.7-12.4]) compared to controls (4.3 [4.1-4.6]), with IRR 2.66 (2.42-2.93). The IRR for each individual type of MACE was also higher in CPPD vs. controls (Table 1). Findings were similar in adjusted Cox models.

The all-cause mortality rate was higher in patients with CPPD (IR 57.7 [55.7-59.7]) than controls (42.9 [42.0-43.7]) with IRR 1.35 (1.29-1.40). Cox analysis could not be performed because CPPD violated the proportional hazards assumption for mortality. In unadjusted survival analysis, time to death was shorter among CPPD patients than controls (log rank p< 0.0001) (Figure 2).

Conclusion: CPPD was associated with an increased risk of MACE after adjusting for known cardiovascular disease risk factors. Patients with CPPD also had a higher mortality rate compared to patients without CPPD.

Variable		CPPD		Controls		IRR (95% CI)
		n= 24,413 (%)	IR per 1000 PYs (95% CI)	n=97,591 (%)	IR per 1000 PYs (95% CI)	
Cardiovascular Event	MI	291 (1.19%)	4.7 (4.2-5.3)	400 (0.41%)	1.6 (1.5-1.8)	2.93 (2.52-3.40)
	ACS	486 (1.99%)	7.9 (7.2-8.6)	713 (0.73%)	2.9 (2.7-3.1)	2.75 (2.45-3.08)
	Re-vascularization	204 (0.84%)	3.3 (2.5-3.8)	337 (0.35%)	1.4 (1.2-1.5)	2.43 (2.04-2.89)

Safety, Tolerability, Pharmacokinetics, and Clinical Outcomes Following Single-Dose IA Administration of UBX0101, a Senolytic MDM2/p53 Interaction Inhibitor, in Patients with Knee OA

Benjamin Hsu,[1] Jennifer Visich,[2] Mark Genovese,[3] Kimberly Walter,[2] Mahru An,[4] Remi-Martin Laberge,[4] and Jamie Dananberg[4], [1]Unity Biotechnology, Brisbane, [2]Unity Biotechnology, Brisbane, California, [3]Stanford University, Stanford, CA, [4]Unity Biotechnology, Brisbane, CA

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: A non-drug biomarker study showed senescent cell (SnC) burden in OA synovial tissue to correlate with disease severity, inflammation, and knee pain (C. Yohn, Poster, this meeting). UBX0101 is a MDM2/p53 interaction inhibitor that can induce apoptosis of SnCs. Clearance of SnCs from joints by UBX0101 may create a pro-regenerative environment and lead to pain reduction. We assessed in a Phase 1 study the safety, pharmacokinetics (PK), and clinical outcomes of intra-articular (IA) UBX0101 treatment in patients (pts) with painful knee OA.

Methods: This was a Phase 1, double-blind, randomized, placebo-controlled, single, ascending dose (SAD) study in 48 pts randomized 3:1 to UBX0101 (dose range of 0.1 to 4.0 mg) or placebo IA. Key eligibility criteria included knee OA by ACR criteria, Kellgren-Lawrence grade (KLG) 1-4, and mean daily pain 4-9 on a Numeric Rating Scale (NRS, 0-10). Clinical outcomes through 12 weeks included WOMAC sub-scores for pain, function, and stiffness derived from the Knee Injury and Osteoarthritis Outcome Score (KOOS) Survey and NRS. PK modeling was used to pre-define low (0.1 to 0.4 mg) and high (1.0 to 4.0 mg) dose groups, predicted to achieve knee concentrations below and above pharmacological EC50 thresholds, respectively. Thirty additional subjects were randomized 2:1 to UBX0101 4.0 mg or placebo IA to assess the impact of UBX0101 on synovial fluid (SF) and plasma senescence-associated secretory phenotype (SASP) and OA disease biomarkers (BMKs). In this BMK sub-study, SF collected by arthrocentesis or lavage at Weeks 0 and 4 along with plasma were assayed using a custom multiplex panel. The SAD study design and sample size were chosen for evaluation of safety, while the BMK sub-study was sized to detect a meaningful change from baseline for BMKs.

Results: The SAD study population was balanced regarding demographic and baseline OA characteristics; mean age was 62 years, 67% were female, 89.6% white. Single IA doses of UBX0101 up to 4 mg were well-tolerated. Most adverse events (AEs) were mild. No serious AEs occurred and no AEs led to discontinuation. The plasma PK of UBX0101 following single IA injection demonstrated minor interpatient variability at all dose groups and systemic concentrations were low and further minimized by a ~4 hour half-life. Improvements in pain and function were dose-dependent, clinically meaningful, and durable through 12 weeks for the three highest UBX0101 doses of 1.0, 2.0, and 4.0 mg (table). A greater proportion (50%) of pts in the high dose group achieved a 50% decrease in WOMAC pain sub-score at Week 12 compared to the placebo and low dose groups (36% and 25%, respectively). SF/lavage fluid analyses in the BMK sub-study revealed modulation of multiple SASP/OA markers such as tissue remodeling and inflammatory factors, after one dose of UBX0101 IA compared to placebo.

Table: Clinical Outcomes at Week 12			
		UBX0101	
Endpoint	**Placebo (n=14)**	**Low doses, 0.1-0.4 mg (n=16)**	**High doses, 1.0-4.0 mg (n=18)**

Baseline, mean	6.47	6.29	6.31
LSM CFBL Week 12 (95% CI)	-1.96 (-3.14, -0.77)	-2.66 (-3.78, -1.55)	-3.95 (-4.74, -3.16)
p-value		0.42	**<0.01**
WOMAC-C Function			
Baseline, mean	1.93	2.05	1.94
LSM CFBL Week 12 (95% CI)	-0.72 (-1.12, -0.31)	-0.49 (-0.88, -0.10)	-1.05 (-1.36, -0.74)
p-value		0.43	0.13

WOMAC= Western Ontario and McMasters Universities Osteoarthritis Index (Likert) 0-4, LSM= Least-squares mean, CFBL=Change from baseline, CI=Confidence Interval, NRS=Numeric rating scale 0-10.

Conclusion: Single IA doses of UBX0101 up to 4.0 mg were well-tolerated by knee OA patients, and its PK was well-characterized. The activity of UBX0101 is supported by its effects on multiple BMKs, as well as the clinically meaningful and durable improvements in pain and function. UBX0101 as a senolytic agent may be an important future therapeutic option for pts with knee OA.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: MAS is a severe complication of rheumatic diseases, most frequently sJIA and adult-onset Still's disease. It is characterized by fever, hepatosplenomegaly, liver dysfunction, cytopenias, coagulation abnormalities and hyperferritinemia, potentially progressing to multiple organ failure and death. MAS is classified among the secondary forms of HLH. Overproduction of IFNγ is a major driver of hyperinflammation/hypercytokinemia in several MAS and HLH murine models. We assessed efficacy, safety and timing of response of clinical and laboratory parameters of the neutralizing IFNg monoclonal antibody emapalumab in patients with MAS.

Methods: In a pilot open-label single-arm international study (NCT03311854), patients with MAS (defined according to the 2016 criteria), on a background of sJIA and inadequate response to high-dose glucocorticoids, received emapalumab (first dose: 6 mg/kg; subsequent doses: 3 mg/kg twice weekly) for a total of 4 weeks or less upon achievement of complete response (CR). Serum concentrations of the IFNg-induced chemokine CXCL9 and of sIL2R were measured. Safety assessments included adverse events and laboratory abnormalities. CR (week 8) was defined as absence of MAS clinical signs AND white blood cell and platelet counts above lower limit of normal, LDH, AST/ALT< 1.5 x upper limit of normal, fibrinogen >100 mg/dL, and ferritin decreased by >80% or to < 2000 ng/mL, whichever was lower. Twin protocols (minimum 5 patients each) are in place in Europe and North America. We report on the first 6 patients recruited in Europe; subsequently 2 additional patients recruited in the US and 1 in Europe.

MAS features, median (range)	SCREENING	BASELINE
Physician VAS (1to10) of MAS activity	9.5 (7-10)	9.5 (8-10)
Ferritin (mg/L)	26 768 (1 071-192 584)	21 689 (716-192 584)
Platelets (x10^9/L)	173 (82-229)	133 (70-229)
WBC (x10^9/L)	5.78 (0.31-25.73)	7.83 (0.85-25.73)
ALT (IU/L)	166 (139-575)	156 (70-852)
LDH (IU/L)	2 553 (859-12 734)	2 063 (588-12 734)
Fibrinogen (mg/dL)	217 (137-341)	204 (110-465)
D-Dimers (mg/L)	10 940 (790-57 421)	10 615 (550-89 552)

Table 1. Baseline and screening disease parameters

	Baseline	Day 1	Day 2	Day3	Day 5	Day 7
Pt 1	3 413.7	2 909.2	1 302.3	997.5	538.4	407.8
Pt 2	13 259.4	16 298.7	21 962.0	20 266.3	1 656.1	461.8
Pt 3	1 518.2	2 672.3	774.0	405.1	228.0	192.2
Pt 4	98 120.5	43 211.9	11 132.4	NA	1 681.6	767.8
Pt 5	18 011.4	4 204.0	1 910.2	920.7	513.7	468.6
Pt 6	3 752.9	2 024.1	1 124.1	1 307.5	854.0	624.0
Median (Range)	8 506.1 (1 518.2-98 120.5)	3557.11 (2 024.1-43 211)	1 606.3 (774.0-21 962.0)	997.5 (405.1-20 266.3)	696.2 (228.0-1 681.6)	465.2 (192.2-767.8)

Table 2. Serum CXCL9 levels at baseline and during the first 7 days of treatments with emapalumab

Parameters	Days of treatment, median (range)
D-dimers to < 1000 mg/L	6.8 (1-49)
sIL-2R to < 2000 UI/ml	17.7 (6-37)
Ferritin < 500 mg/L	28.7 (9-35)
Physician VAS of MAS activity ≤ 1	37.0 (12-56)
All MAS laboratory parameters within range of complete response	23.8 (18-55)
Glucocorticoid tapering at < 1 mg/Kg PDN equivalent	49.0 (18-53)

Table 3. Time (days of treatment) of D-dimers to < 1000, sIL-2 receptor (sIL-2R) to < 2000 UI/ml, ferritin < 500 mg/L, physician VAS < 1, all MAS laboratory parameters within range of complete response and glucocorticoid tapering at < 1 mg/Kg PDN equivalent

Results: Six patients (4 females, median age 11 years, range: 2-25 years), who had failed methylprednisolone (in 2 patients plus cyclosporine A (CsA) and in 2 patients plus CsA and anakinra) received emapalumab (Table 1). CXCL9 showed initial substantial decrease between day 2 and 5, showing rapid IFNg neutralization (Table 2). In all patients but one (who presented a single measurement of 37.6 at SD 21) fever resolved (< 37.5) within 3 days. These effects were followed by progressive improvement in all MAS clinical and laboratory parameters (Table 3). CR was achieved in all patients after a median of 23.8 (18-55) days. Glucocorticoids were tapered in all patients (median % tapering -92%, range -45-98% at week 8). Emapalumab was well tolerated; no patient discontinued emapalumab. A CMV reactivation, reported as a serious event possibly related to emapalumab, resolved with treatment.

Conclusion: All 6 patients receiving emapalumab achieved CR. Progressive improvement and subsequent normalization of all clinical and laboratory parameters occurred following rapid and sustained CXCL9 decrease.

A Serum Proteomic Signature Defines Transition from the Preclinical State to Rheumatoid Arthritis

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-citrullinated protein antibodies (ACPA) are currently the primary biomarker for identifying individuals at increased risk for future RA development. However, we have recently shown in a prospective study that most unaffected ACPA+ individuals do not develop RA. We hypothesized that abnormalities in the serum

proteome may serve as additional biomarkers in the prediction risk for future disease onset. The aim of our study was to mine the serum proteome of individuals who ultimately developed RA to detect biomarkers that predict disease onset.

Methods: Using the SOMAscan (slow off-rate modified aptamer) array, SomaLogic, Boulder Co, we generated quantitative levels of 1307 proteins in serum samples from seventeen first-degree relatives (FDR) of Indigenous North American (INA) RA patients who developed inflammatory arthritis (IA) synovitis after having been followed prospectively for a mean of 3.2 years. All were ACPA+ at time of IA diagnosis. Each individual had two preclinical samples, one at the time of IA onset, and one at an earlier time point. We also analyzed samples from ACPA+ FDR (n = 63) and ACPA- FDR (n = 47) who did not develop inflammatory arthritis. Differentially expressed proteins were identified using ANOVA corrected for multiple comparisons. We applied a machine learning lasso regression model to identify a minimum set of proteins that classified patients who transition into clinical arthritis.

Results: Differential expression of 669 proteins (260 upregulated, 409 downregulated) were identified between pre-Transition samples (TR-pre) and ACPA negative FDR. ITGA2B and HIST1H3A were the highest upregulated proteins in TR-pre samples, while protease inhibitors SERPINA5 and ITIH4 were highly downregulated in the TR-pre samples. Compared with ACPA- FDR, overlap between TR-pre baseline and non-baseline samples of highly upregulated (log2 difference > 0.5) proteins was 60%, suggesting alterations in the serum proteome occur years before the development of RA. A lasso regression model identified a 23-marker panel that classified TR-pre samples from the larger pool of ACPA+ and ACPA- FDR serum samples. In a validation cohort (n = 34), the model correctly classified 31/34 samples (91.2% accuracy) with a sensitivity of 95.6% and specificity of 85.7%. Area under the curve (AUC) was 0.931 for the model. Transition scores were extracted from the model, which were higher in ACPA+ FDR compared to ACPA- FDR ($p < 0.001$). There were no differences in Transition score comparing TR-pre samples that were remote or close to the time of IA onset.

Conclusion: Compared to at-risk individuals who did not develop IA, clear and reproducible differences in the serum proteome are demonstrable in the serum samples of individuals who ultimately developed IA, even several years before the onset of clinically evident disease. Our findings suggest that a small serum biomarker panel can serve to accurately classify at-risk individuals who have a high likelihood of progressing to develop IA.

Transition scores generated from lasso model for FDR, binned by ACPA positivity (**** $p < 0.001$) and Transitioner samples binned by Remote and Imminent ($p = 0.897$) relative to the development of inflammatory arthritis (IA).

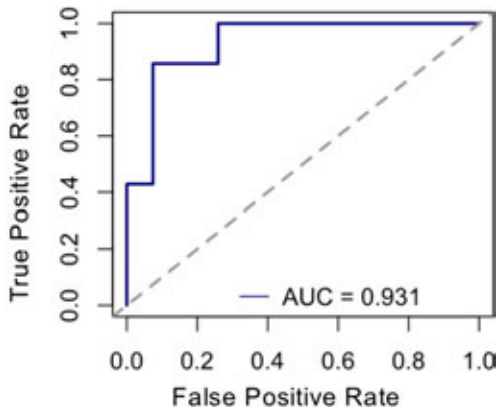

Figure 1. Area under the curve (AUC = 0.931) from a lasso model to identify pre-RA (pre-Transition) samples from FDR with and without ACPA positivity in a validation cohort (n = 34)

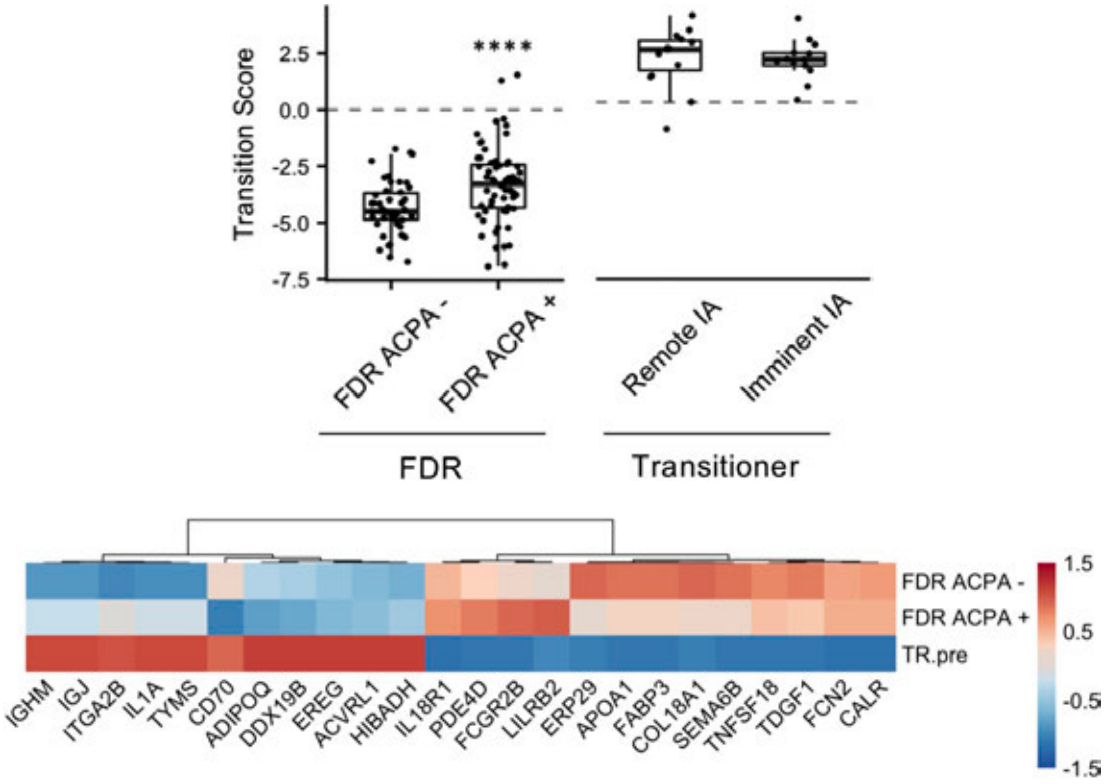

Representative heatmap of the average expression data by group, normalized for each protein included in the Transition Score. TR.pre: pre-RA samples, FDR ACPA - : First degree relatives without ACPA, FDR ACPA + : First degree relatives with elevated ACPA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Sustained remission is the goal of rheumatoid arthritis (RA) care, and more patients reach and maintain this state on conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) after the implementation of treat-to-target strategies. The knowledge about whether csDMARDs can be tapered in RA remission is limited. The primary objective of the study was to assess the effect of tapering of csDMARDs on the risk of flares in RA patients in sustained clinical remission.

Methods: In the non-inferiority ARCTIC REWIND trial, RA patients in clinical remission for at least 12 months on stable csDMARD therapy were randomly assigned to continued stable csDMARD or half dose csDMARD, with visits

Table 1. Characteristics of patients at baseline.*

* Full Analysis Set. Plus – minus values are means ± SD. Median values are given with interquartile range (IQR). † The Disease Activity Score for 44-joint counts (DAS) ranges from 0 to 10. The Simplified Disease Activity Index (SDAI) ranges from 0 to 86. ACR/EULAR remission is defined as tender joint count ≤1, swollen-joint count ≤1, CRP ≤1mg/dL and patient's global assessment ≤10. ‡ 44 swollen joint count ∫ Ritchie Articular Index ¶ The patient's and investigator's global assessments 0 to 100 mm. ** Patient-reported Outcomes Measurement Information Score (PROMIS) †† Fatigue and pain is self-reported on a visual analogue scale, 0 to 100 mm. ‡‡ Total van der Heijde modified Sharp based on radiographs of hands and feet, range from 0 to 448. ∬. Ultrasound examination was performed using 0-3 semi quantitative scoring systems for both grey-scale and power Doppler in 32 joints; ranges from 0 to 192 for total ultrasound score, and from 0 to 96 for grey-scale and power Doppler ultrasound score.

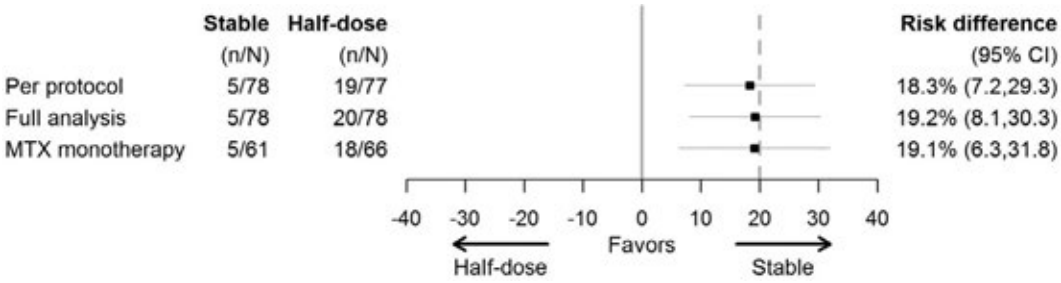

Figure 1. Non-inferiority plot of stable vs half-dose csDMARD treatment in per protocol set, full analysis set and in patients treated by methotrexate monotherapy, with the proportion of patients with a disease flare during the 12-month study period as outcome

every four months. Patients had to be in DAS remission at inclusion with no swollen joints (of 44 assessed). The primary endpoint was the proportion of patients with a disease flare during the 12-month study period (a combination of DAS > 1.6, a change in DAS > 0.6 and at least 2 swollen joints, or both the physician and patient agreed that a clinically significant flare had occurred). The non-inferiority margin was 20%, with a predefined superiority test if non-inferiority was not shown. The inferiority null-hypothesis was tested in the per-protocol population using mixed effect logistic regression. Radiographic joint damage at 0 and 12 months was scored by van der Heijde modified Sharp score (progression: ≥1 unit change/year). Clinicaltrials.gov number NCT01881308.

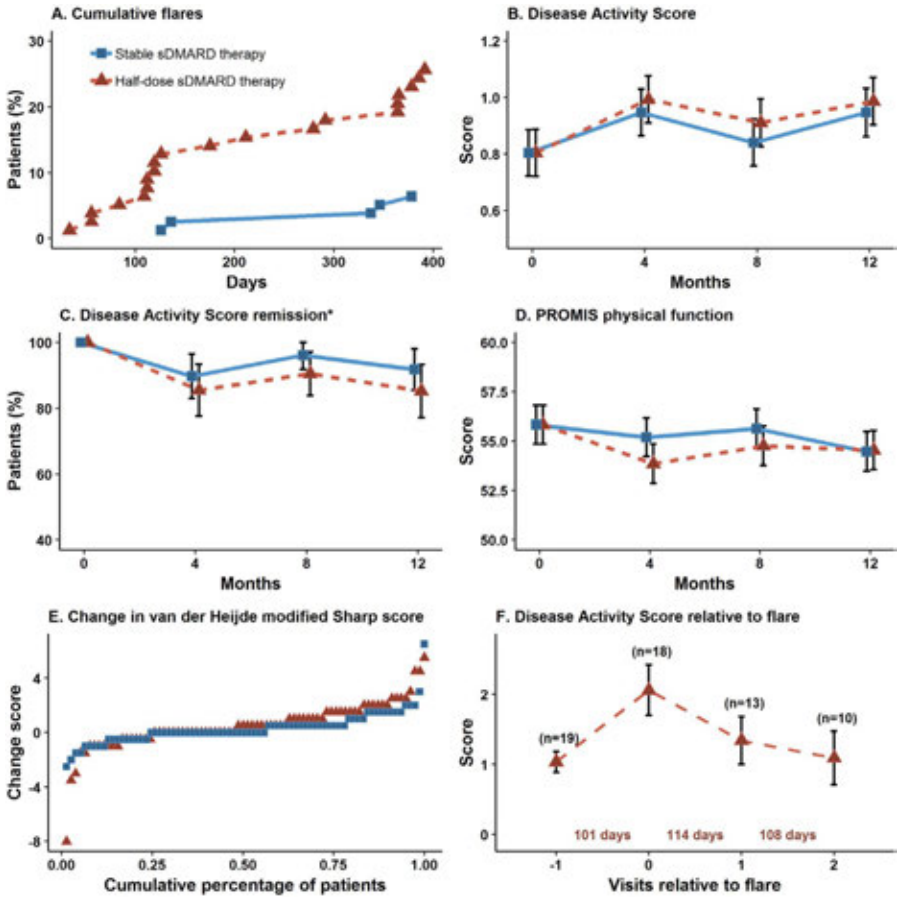

Figure 2 Secondary endpoints. Panel A shows the cumulative percentage of patients who have experienced flares. Panel B shows the Disease Activity Score. Panel C shows the percentage of patients in Disease Activity Score remission. Panel D shows the PROMIS physical function score. Panel E Panel F shows the cumulative probability plot for radiographic joint damage, scored by van der Heijde Sharp score. Panel F shows the Disease Activity Score at the visit before a flare occurred, at the flare visit and at visits after flare in the half-dose arm.

Results: We enrolled 160 patients, 155 received the allocated treatment strategy. Baseline characteristics were overall well balanced in the two arms (Table 1). 61/78 (78.2%) patients in the stable csDMARD arm and 65/78 (84.4%) in the half-dose csDMARD arm were methotrexate monotherapy users. In the primary analysis, 5/78 (6.4%) of patients in the stable csDMARD arm experienced a flare during the 12 months, compared to 19/77 (24.7%) in the half-dose csDMARD arm, giving a risk difference (95% confidence interval [CI]) of 18.3% (7.2% to 29.3%, Figure 1). Non-inferiority could not be claimed as the confidence interval crossed the non-inferiority margin. However, the confidence interval did not include the null, showing superiority of the stable arm over the half-dose arm, with similar results in methotrexate monotherapy users. In the stable arm, 2/5 (40.0%) adjusted DMARD medication following the flares, compared to 18/19 (94.7%) in the half-dose arm. No progression of radiographic joint damage was observed in 79.5% of patients on stable DMARDs and 62.7% in the half-dose arm, difference (95% CI) -17.7% (-33.0%, -2.3%, Figure 2E). At 12 months, 67 (91.8%) patients in the stable arm and 63 (85.1%) patients in the half-dose arm were in DAS remission (Figure 2), with similar results for other remission definitions. We observed 75 adverse events in the stable arm and 53 in the tapered arm, with serious adverse events in 2 (2.6%) of patients in the stable arm and in 4 (5.1%, including two serious infections) of patients in the tapered arm.

Conclusion: In RA patients in sustained remission on csDMARDs, continued csDMARD therapy with stable doses led to significantly fewer disease activity flares and less frequent radiographic joint damage progression than tapered csDMARD treatment.

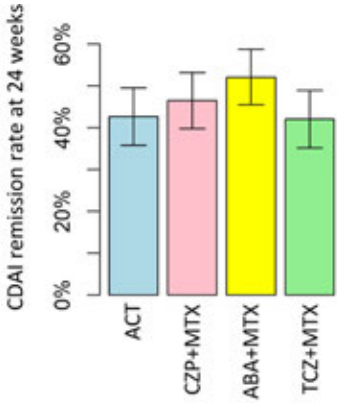
Session Title: Late-Breaking Abstracts ePoster

Session Type: Late-Breaking Abstract Poster Session

Session Time: 9:00AM–11:00AM

Background/Purpose: The optimal first-line treatment of patients (pts) with early rheumatoid arthritis (RA) is yet to be established. The primary aim was to assess and compare the proportion of pts who achieved remission with active conventional therapy (ACT) and with three different biologic therapies after 24 wks. Secondary aims were to assess and compare other efficacy measures and safety.

Methods: The investigator-initiated NORD-STAR trial (NCT01491815) was conducted in Sweden, Denmark, Norway, Finland, The Netherlands and Iceland. In this multicenter, randomized, open-label, blinded-assessor, phase 4 study pts with early RA (ACR/EULAR 2010 criteria, 18+ years old, < 24 months' symptom duration, disease activity score



Estimated CDAI remission rates at 24 weeks, intention-to-treat population, adjusted for gender, ACPA status, country, age, body-mass index and baseline DAS28-CRP, with 95% confidence intervals. ABA, abatacept; ACT, active conventional therapy; CZP, certolizumab-pegol; MTX, methotrexate; TCZ, tocilizumab.

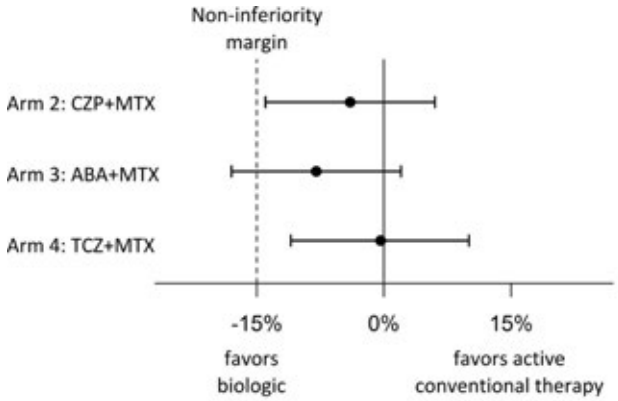
Figure 1.

(C-reactive protein, CRP (DAS28)) >3.2, ≥2 (of 66) swollen and ≥2 (68) tender joints, rheumatoid factor (RF) or anti-citrullinated protein antibody (ACPA) positive or CRP >10mg/L)) were recruited and randomized 1:1:1:1 (stratified by country, gender and ACPA). All received methotrexate (25 mg/week after one month). To this was added: Arm 1 (ACT): either oral prednisolone (tapered from 20 mg/d to 5 mg/d in 9 wks); or: sulphasalazine (2 g/day), hydroxychloroquine (35mg/kg/wk) and mandatory intra-articular (IA) triamcinolone hexacetonide (TCH) in ≤4 swollen joints (≤80

Table 1. Primary and key secondary outcomes at 24 weeks for the intention-to-treat (ITT) population.

	Arm 1: Active conventional therapy (ACT)	Arm 2: CZP+MTX	Arm 3: ABA+MTX	Arm 4: TCZ+MTX
No of patients in ITT population	200	203	204	188[§]
Table 1a	Remission and response rates			
CDAI remission	**42.0%**	**47.8%**	**52.5%**	**41.0%**
ACR/EULAR Boolean remission	34.0%	38.4%	37.3%	31.4%
DAS28 remission	63.5%	68.5%	69.6%	63.3%
SDAI remission	41.5%	49.8%	51.5%	42.6%
EULAR good response	71.5%	76.9%	79.9%	71.3%
Table 1b	Difference (95% CI) in rates with Arm 1 as the reference			
CDAI remission*	**Ref**	**4% (-5 to 13%)**	**9% (0.1 to 19%)**	**-1% (-10 to 9%)**
ACR/EULAR Boolean remission	Ref	4% (-6 to 13%)	5% (-5 to 14%)	-4% (-13 to 6%)
DAS28 remission	Ref	3% (-6 to 11%)	5% (-4 to 13%)	-1% (-10 to 8%)
SDAI remission	Ref	6% (-3 to 18%)	9% (-0.3 to 18%)	1% (-8 to 11%)
EULAR good response	Ref	4% (-4 to 14%)	8% (-2 to 18%)	0.4% (-10 to 11%)

*Primary outcome is **shown in bold.** Values in table 1a are unadjusted with NRI imputation. Values in table 1b are adjusted (for details see text) with NRI imputation; ABA: abatacept; ACR: American College of Rheumatology; ACT: active conventional therapy; CDAI: clinical disease activity index; CZP: certolizumab-pegol; DAS28: disease activity score (ESR); EULAR: European League Against Rheumatism; MTX: methotrexate; NRI: Non responder imputation; SDAI: simplified disease activity score; TCZ: tocilizumab. [§]17 Finnish patients allocated to Arm 4 did not receive Tocilizumab due to unavailability of the drug, and were excluded from the ITT population.



Non-inferiority analysis, per protocol population. Estimated differences in CDAI remission rates between Arm 1 (active conventional therapy) and Arms 2, 3 and 4 (biologic arms) as reference with 95% confidence intervals, adjusted for gender, ACPA status, country, age, body-mass index and baseline DAS28-CRP. ABA, abatacept; CZP, certolizumab-pegol, MTX, methotrexate; TCZ, tocilizumab.

Figure 2.

mg/visit up to wk 20); Arm 2 (CZP): certolizumab (CZP) 200 mg EOW SC (400 mg at 0, 2 and 4 wks); Arm 3 (ABA): abatacept 125 mg/wk SC; Arm 4 (TCZ): tocilizumab 8 mg/kg/4wks IV or 162 mg/wk SC. IA TCH was allowed in all arms up to wk 20. Primary outcome was clinical disease activity index remission (CDAI≤2.8) at wk 24 (ITT analysis). Dichotomous outcomes were analyzed by adjusted (stratification variables, age, body mass index (BMI) and baseline DAS28) logistic regression with non-responder imputation (NRI). Non-inferiority analyses (per protocol population) had a pre-specified margin of 15%.

Results: In total, 812 pts were randomized. At baseline age was 54.3±14.7 yrs (mean±SD), 31.2% were male, DAS28 5.0±1.1, 74.9% were RF positive and 81.9% ACPA positive, BMI 26.2±5.1 kg/m2, time since diagnosis 7 (1-18) days (median, IQR). Crude CDAI remission rates (ITT) were: ACT: 42.0%, CZP: 47.8%, ABA: 52.5%, TCZ: 41.0%. Figure 1 shows the estimated remission rates with 95% CI. Table 1 shows the primary and key secondary outcomes (ITT population). With ACT as the reference, the absolute difference in adjusted remission rate (delta) was 9% (95%CI: 0.1 to 19%) for ABA, 4% (-5 to 13%) for CZP and -1% (-10 to 9%) for TCZ. Differences in remission rates with CZP and TCZ, but not with ABA, remained within the pre-defined non-inferiority margin versus ACT (per-protocol population), Figure 2. Total numbers of (serious) adverse events (SAEs/total AEs) across ACT, CZP, ABA, TCZ were 13/552, 20/530, 10/527, 10/653, respectively.

Conclusion: High remission rates were found across all four treatment arms at 24 wks. Higher CDAI remission rate was observed for ABA versus ACT (delta 9%) and for CZP (4%), but not for TCZ (-1%). With the predefined 15% margin, ACT was non-inferior to CZP and TCZ, but not to ABA. These results underscore the efficacy and safety of active conventional therapy based on MTX combined with glucocorticoids and may guide future treatment strategies for early RA.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic systemic autoimmune disease associated with a prothrombotic state. Tocilizumab, an interleukin-6 receptor inhibitor, is highly effective in controlling disease activity and thrombotic risk. Factor XIII (FXIII), involved in thrombotic complications, has been reported to be reduced in RA patients during maintenance treatment with tocilizumab, but no data are available before and after the drug administration. Thus, we investigated the effects of tocilizumab on FXIII, thrombin generation and inflammation in patients with RA naïve for the drug.

Methods: We studied fifteen consecutive adult patients with RA at baseline and four weeks after the onset of parenteral administration of tocilizumab, measuring disease activity and plasma levels of C-reactive protein (CRP), FXIII, and prothrombin fragments F1+2 by immunoenzymatic methods. Fifteen healthy subjects, sex-and age-matched with patients served as normal controls for laboratory measurements.

Results: At baseline, patients with established RA had a median DAS28 of 4.8 (3.2- 8.3) and, compared to healthy controls, had higher plasma levels of CRP ($p < 0.0001$), FXIII ($p = 0.017$) and F1+2 ($p < 0.0001$). Four weeks after starting treatment with tocilizumab, based on the EULAR response criteria, eight patients were classifiable as responders and seven as non-responders. In responders, we observed a statistically significant reduction not only of the values of DAS28 and CRP ($p = 0.012$ for both), but also of plasma levels of FXIII ($p = 0.05$) and F1+2 ($p = 0.025$). In nonresponders, all the studied parameters were unchanged. At baseline, patients with established RA had a median DAS28 of 4.8 (3.2- 8.3) and, compared to healthy controls, had higher plasma levels of CRP ($p < 0.0001$), FXIII ($p =$

0.017) and F1+2 ($p < 0.0001$). Four weeks after starting treatment with tocilizumab, based on the EULAR response criteria, eight patients were classifiable as responders and seven as non-responders. In responders, we observed a statistically significant reduction not only of the values of DAS28 and CRP ($p = 0.012$ for both), but also of plasma levels of FXIII ($p = 0.05$) and F1+2 ($p = 0.025$). In nonresponders, all the studied parameters were unchanged.

Conclusion: The decrease of FXIII and F1+2 levels after tocilizumab treatment observed only in those patients who responded to the drug indicates that the effect of tocilizumab on the prothrombotic state is linked to the control of inflammation and disease activity and not to a direct effect of the drug, thus contributing to the reduction of the cardiovascular risk.

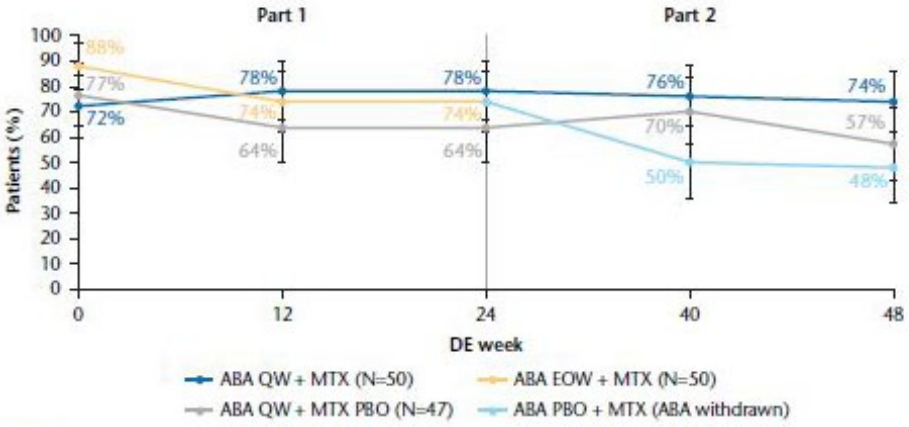
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Although EULAR/ACR guidelines suggest tapering biologics following sustained remission in patients (pts) with RA, specific de-escalation (DE) regimens are not fully defined. The Phase IIIb Assessing Very Early Rheumatoid arthritis Treatment (AVERT)-2 trial (NCT02504268) is evaluating SC abatacept (ABA) + MTX versus ABA placebo (PBO) + MTX in ACPA-positive pts with early (ACR/EULAR 2010 criteria; disease duration ≤6 mths), active RA (SDAI >11). AVERT-2 was designed to investigate achievement of SDAI remission and a clinically meaningful dose DE strategy among pts in sustained remission who completed induction with ABA + MTX. We report results on the maintenance of remission during the DE period of AVERT-2.

Methods: Pts were randomized 3:2 to blinded SC ABA (125 mg once wkly [QW]) + MTX or ABA PBO + MTX induction treatment for 56 wks. Pts who completed induction with ABA + MTX and had sustained SDAI remission (≤3.3 at Wks 40 and 52) were re-randomized 1:1:1 to ABA QW + MTX for 48 wks, ABA every other wk (EOW) + MTX for 24 wks followed by ABA PBO + MTX for 24 wks, or ABA QW + MTX PBO for 48 wks in the DE period. MTX and oral corticosteroid doses in DE were stable. Pts with sustained SDAI remission who received ABA PBO + MTX during induction were not re-randomized and continued this treatment in the DE period in a blinded fashion; no comparisons between this arm and ABA arms were made. Endpoints: proportion of pts in SDAI remission, adjusted mean change from DE Day (D) 1 in SDAI score and safety to DE Wk 48; radiographic progression at DE Wk 48.

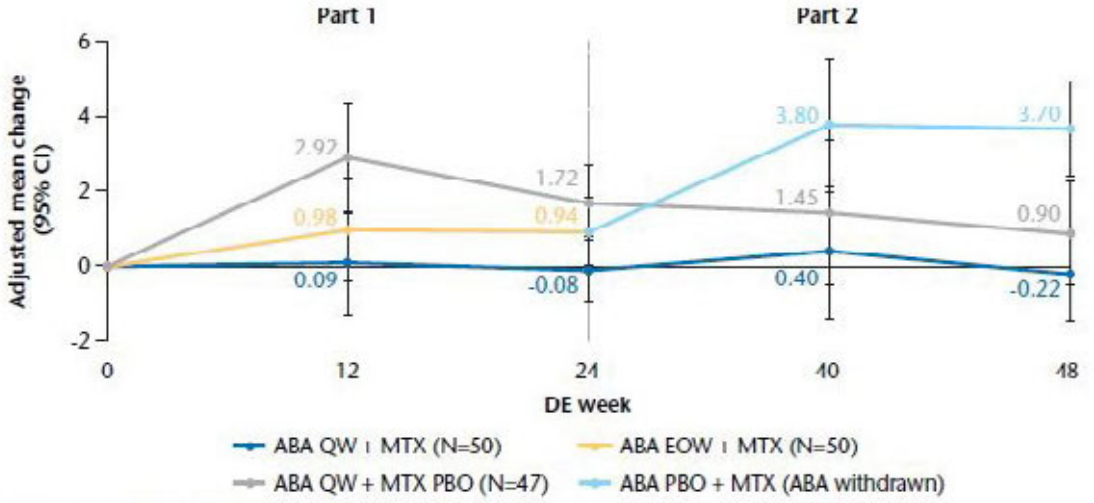
Figure 1. Proportion of re-randomized patients in SDAI remission (≤3.3) in the de-escalation period



Estimate of difference vs ABA QW + MTX (97.5% CI)					
ABA EOW + MTX (part 1)/ABA PBO + MTX (part 2)	16.0 (–1.6, 33.6)	–4.0 (–23.1, 15.1)	–4.0 (–23.1, 15.1)	–26.0 (–46.8, –5.2)	–26.0 (–47.1, –4.9)
ABA QW + MTX PBO	4.6 (–15.3, 24.4)	–14.2 (–34.6, 6.3)	–14.2 (–34.6, 6.3)	–5.8 (–26.0, 14.4)	–16.6 (–37.9, 4.8)

Missing values are imputed as not achieving remission. Patients receiving ABA EOW + MTX were switched to ABA PBO + MTX at DE Week 24, in a blinded manner.
ABA=abatacept; DE=de-escalation; EOW=every other week; MTX=methotrexate; QW=weekly; SDAI=simplified disease activity index.

Figure 2. Adjusted mean change in SDAI score in the de-escalation period among re-randomized patients



Adjusted mean difference from ABA QW + MTX (97.5% CI)				
ABA EOW + MTX (part 1)/ABA PBO + MTX (part 2)	0.89 (–1.38, 3.16)	1.01 (–0.47, 2.49)	3.40 (0.50, 6.30)	3.92 (1.84, 6.01)
ABA QW + MTX PBO	2.83 (0.47, 5.18)	1.79 (0.23, 3.36)	1.05 (–2.01, 4.12)	1.12 (–1.08, 3.32)

Estimates of adjusted mean changes are from a repeated measures mixed model which includes treatment group, time, time-by-treatment interaction, baseline value, and time-by-baseline value interaction. Patients receiving ABA EOW + MTX were switched to ABA PBO + MTX at DE Week 24, in a blinded manner. Number of patients with measurement at DE Weeks 0, 12, 24, 40 and 48, respectively: ABA QW + MTX: 50, 45, 42, 41, 42; ABA EOW + MTX/ABA PBO + MTX: 50, 45, 43, 41, 37; ABA + MTX PBO: 47, 39, 34, 33, 31.
ABA=abatacept; CI=confidence interval; DE=de-escalation; EOW=every other week; MTX=methotrexate; PBO=placebo; QW=weekly; SDAI=simplified disease activity index.

Results: 147 ABA + MTX–treated pts were re-randomized in the DE period (ABA QW + MTX, n=50; ABA EOW + MTX, n=50; ABA QW + MTX PBO, n=47); 37 pts with sustained remission who received ABA PBO + MTX during induction continued in DE period. Across the re-randomized arms, mean DAS28 (CRP), SDAI and HAQ-DI scores ranged from 1.63–1.79, 1.87–2.52 and 0.18–0.30, respectively, at DE D1. 74% of pts receiving ABA QW + MTX maintained remission at DE Wk 48 (Fig 1). Withdrawal of MTX (ABA QW + MTX PBO) led to an initial drop in remission rates to

Table 1. Radiographic progression* from DE Week −4 to DE Week 48 among re-randomized patients

	ABA QW + MTX (n=50)	ABA EOW + MTX/ ABA PBO + MTX (n=50)	ABA QW + MTX PBO (n=47)
Mean (SD) score at DE Day 1	4.11 (5.65)	8.67 (19.83)	4.96 (8.26)
Mean (SD) change from DE Day 1 at Week 104	0.21 (0.60)	0.28 (0.84)	−0.03 (0.73)
p value†	N/A	0.9736	0.0812
Patients without radiographic progression,‡ % (95% CI)	87.0 (77.2, 96.7)	84.1 (73.3, 94.9)	87.2 (76.7, 97.7)
Estimate of difference versus ABA QW + MTX (97.5% CI)	N/A	−2.9 (−19.5, 13.8)	0.2 (−16.1, 16.6)

Number of patients with assessments available at DE Week −4 and DE Week 48: ABA QW + MTX n=46, ABA EOW + MTX/ABA PBO + MTX n=44, ABA QW + MTX PBO n=39

*Measured using the modified total Sharp/van der Heijde total score

†p value is based on a rank-based non-parametric analysis of covariance model with treatment group and DE Week −4 rank score as covariates. For patients missing a DE Week 48 assessment, if DE Week −4 data and data collected during the DE period were available, imputation at DE Week 48 was done by linear extrapolation using the available assessments at DE Week −4 and time of discontinuation in DE

‡Change from DE Week −4 to DE Week 48 ≤0.5

ABA=abatacept; DE=de-escalation; EOW=every other week; N/A=not available; PBO=placebo; QW=once weekly

64%, with stabilization from DE Wk 12. After halving ABA dose to ABA EOW + MTX upon entry to the DE period, remission decreased from 88% at DE Wk 0 to 74% at DE Wk 24, and then further decreased to 48% at DE Wk 48 after ABA was fully withdrawn at DE Wk 24. At DE Wk 48, 59% of pts who received ABA PBO + MTX during induction maintained remission with this treatment. Adjusted mean change in SDAI score in the ABA arms in the DE period was numerically low, but varied between arms and increased following ABA withdrawal from the ABA EOW + MTX arm at DE Wk 24 (Fig 2). Sustained inhibition of structural damage was seen in all ABA arms (Table 1). Safety was similar across treatments with no new signals.

Conclusion: In the DE period of AVERT-2, combination therapy (abatacept + MTX) resulted in the best maintenance of remission and inhibition of structural damage progression in early seropositive pts with RA and sustained SDAI remission following abatacept + MTX treatment. Tapering of abatacept EOW + MTX to MTX only was associated with the greatest loss of remission. Abatacept-containing DE regimens should be investigated further as a viable option in clinical practice.

1 - 100% patients were on MTX; 2 - Upper Limit in Original Unit 6 mg/L			

Background/Purpose: Olokizumab (OKZ) is a new humanized monoclonal antibody targeting IL-6 [1, 2]. Here we present the results of the first phase III study of OKZ in patients with Rheumatoid Arthritis (RA).

Methods: This randomized, double-blind, placebo-controlled, multicenter study in patients with moderately to severely active RA despite methotrexate (MTX) (ClinicalTrials.gov Identifier NCT02760368, CREDO1) was carried out in Russia, Belarus and Bulgaria. Patients were randomized 1:1:1 to receive SC injections of OKZ 64 mg every 2 weeks (q2w), OKZ 64 mg once every 4 weeks (q4w), or placebo (PBO) for 24 weeks with continuation of their background MTX. Starting at Week (Wk) 14, non-responders were prescribed rescue medication (sulfasalazine and/or hydroxychloroquine) in addition to study treatment. After Wk 24, subjects either rolled over into an ongoing open-label study or entered the Safety Follow-Up Period. The primary endpoint was American College of Rheumatology 20% (ACR20) response at Wk 12. Secondary endpoints included: percentage of subjects with low disease activity, defined as Disease Activity Score 28-joint count - C-reactive protein (DAS28-CRP) < 3.2 at Wk 12, improvement of physical ability from baseline to Wk 12 measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI), ACR50 response at Wk 24, and percentage of subjects with Clinical Disease Activity Index (CDAI) ≤2.8 (remission) at Wk 24. Safety outcomes, including adverse events (AEs), serious adverse events (SAEs) and laboratory abnormalities (via central lab) were assessed.

Results: A total of 428 patients were randomized to OKZ 64mg q2w (n = 143), OKZ 64mg q4w (n = 142), or PBO (n = 143). Baseline characteristics were comparable across treatment arms (Table 1).

The vast majority of patients completed 24 weeks of the study: 130 (90.9%) in q2w, 134 (94.4%) in q4w and 132 (92.3%) in PBO arms and enrolled to open label extension study CREDO4: 122 (85.3%), 127 (89.4%) and 126 (88.1%) patients, respectively.

Both regimens of OKZ were significantly better than placebo in all primary and secondary endpoints (Table 2).

Table 2. Key efficacy results (intent-to-treat population) NRI [1]			
	OKZ q2w	**OKZ q4w**	**PBO**
Number of Subjects	**143**	**142**	**143**

ACR50 Response, n (%) Wk 24	61(42.7)***	69(48.6)***	11(7.7)
CDAI ≤2.8 Response, n (%) Wk 24	12(8.4)**	11(7.7)**	0
1 - NRI= Non-Responder Imputation; 2 - LSM=Least Squares Mean; **p-value difference from PBO <0.001; ***p-value difference from PBO <0.0001; SE=Standard Error			

Table 3. Number and percentage of key TESAE (Safety Population)			
	OKZ q2w	**OKZ q4w**	**PBO**
Number of Subjects	**143**	**142**	**142**
Subjects with at Least One TESAE	8(5.6%)	8(5.6%)	4(2.8%)
Serious Infections	4(2.8%)	0	2(1.4%)
Subcutaneous abscess	2(1.4%)	0	0
Gastroenteritis	0	0	1(0.7%)
Pneumonia	0	0	1(0.7%)
Pulmonary tuberculosis	1(0.7%)	0	0
Staphylococcal sepsis	1(0.7%)	0	0
Toxic shock syndrome	1(0.7%)	0	0
Herpes zoster	0	0	0
Neoplasms benign, malignant and unspecified (incl. cysts and polyps)	0	1(0.7%)	0
Cervix carcinoma stage II	0	1(0.7%)	0
Gastrointestinal disorders	0	1(0.7%)	0
Obstructive pancreatitis	0	1(0.7%)	0
Gastrointestinal perforation	0	0	0
Vascular disorders	0	1(0.7%)	0
Diabetic vascular disorder	0	1(0.7%)	0
Venous thromboembolism	0	0	0
Death	1(0.7%)	0	0

The key efficacy outcomes were maintained throughout the 24-week period of the study.

Overall incidence of treatment-emergent adverse events (TEAEs) was 58.0% in OKZ q2w arm; 57.0% in OKZ q4w arm and 43.7% in PBO, TEAEs leading to study treatment discontinuation were reported in 4.9%, 3.5% and 0.7% patients, respectively. There was one death due to septic shock in the OKZ q2w arm.

Incidence of treatment-emergent serious adverse events (TESAEs) were numerically higher in the OKZ groups, compared to placebo with no unexpected safety signals (Table 3).

Conclusion: In this Phase III trial, treatment with OKZ over a 24-week period was associated with significant improvements in the signs, symptoms and physical function of RA, with a safety profile consistent with Phase II data for OKZ and with the data for the agents with similar mechanism of action.

There were no discernible differences between the two regimens of OKZ in efficacy or safety outcomes.

Data were analyzed in randomized pts who received at least 1 dose of study drug according to the treatment assigned and based on composite estimand, where pts meeting treatment-failure criteria were considered nonresponders for binary endpoints and as having no improvement from baseline for continuous endpoints. Missing data were imputed as nonresponders for binary endpoints; multiple imputation was used to impute missing data for continuous endpoints. Treatment difference for binary endpoints was assessed via Cochran-Mantel-Haenszel test stratified by baseline use of non-biologic DMARDs (yes/no) and CRP prior to randomization (<2.0 vs ≥2.0 mg/dL). Treatment difference for continuous endpoints was assessed via an analysis of covariance model.

[1] Randomization was stratified by Week 0 DMARD use [Y/N] and CRP [<2.0 vs ≥2.0 mg/dL].

[2] Two multiplicity-controlled procedures were prespecified to satisfy different regulatory requirements. The adjusted p-values presented herein derive from the testing procedure in which: 1) the primary endpoint was first tested in sequence by dose at the ≤0.05 significance level, 2) the major secondary endpoints shown above were subsequentially tested for both GUS doses using a graphic procedure that specified testing sequences and alpha allocations, and 3) the overall type I error was controlled at p≤0.05 for the specified endpoints for both GUS doses.

[3] Assessed in 184, 176, and 183 pts with ≥3% BSA PsO and IGA score ≥2 at W0 in the guselkumab q4w, guselkumab q8w, and placebo groups, respectively .

[4] Unadjusted (nominal) p values are not controlled for multiplicity and are descriptive/supportive only; no statistical significance should be implied.

[5] Assessed in 228, 228, and 236 patients with HAQ-DI ≥0.35 at W0 in the guselkumab q4w, guselkumab q8w, and placebo groups, respectively.

Methods: In DISCOVER-2, adults with active PsA (≥5 swollen+≥5 tender joints; CRP ≥0.6mg/dL) despite non-biologic DMARDs and/or NSAIDs (biologic-naïve) were randomized (1:1:1) to GUS 100mg every 4 wks (Q4W); GUS 100mg at W0, W4, Q8W (Q8W); or placebo (PBO). Concomitant stable select non-biologic DMARDs, oral corticosteroids, and NSAIDs were allowed. At W16, patients (pts) with < 5% improvement in tender+swollen joints could initiate/increase the dose of permitted medications. The primary endpoint was W24 ACR20 response. Major secondary endpoints (MSEs) at W24 were Investigator's Global Assessment (IGA) PsO response (IGA=0/1 and ≥2-grade reduction) in pts with ≥3% BSA PsO&IGA ≥2 at W0; changes in HAQ-DI, PsA-modified van der Heijde-Sharp (vdH-S), and SF-36 PCS/MCS scores; resolution of enthesitis/dactylitis (using pooled DISCOVER-1&2 data); change in DAS28-CRP; and ACR50/70 responses. MSEs at W16 were ACR20/50 responses. Multiplicity-adjusted p-values for controlled endpoints, and nominal (unadjusted) p-values for uncontrolled endpoints, are presented. Adverse events (AEs) through W24 are reported.

Results: 739 treated pts in DISCOVER-2 with moderate-to-severe disease (mean swollen/tender joints: 12/21, median CRP: 1.2 mg/dL, mean BSA with PsO: 17.4%, IGA=3 or 4: 46.1% of pts) were analyzed. Significantly more GUS Q4W (63.7%) and Q8W (64.1%) vs PBO (32.9%) pts achieved ACR20 response at W24 (both adjusted p< 0.001). Both GUS doses separated from PBO by W4 (Figure). Among pts with ≥3% BSA PsO&IGA ≥2 at W0, significantly more GUS Q4W and Q8W vs PBO pts achieved IGA response at W24 (both adjusted p< 0.001). Significantly greater improvements from baseline in HAQ-DI (adjusted p< 0.001) and SF-36 PCS (adjusted p≤0.011) were seen with GUS Q4W and Q8W vs PBO at W24. Mean changes in total modified vdH-S scores at W24 were significantly lower for GUS Q4W (0.29) and numerically lower for GUS Q8W (0.52) vs. PBO (0.95; adjusted p=0.011 and p=0.072, respectively). Numerically larger mean improvements in SF-36 MCS scores were seen with GUS Q4W (4.22) and Q8W (4.17) than PBO (2.14; both adjusted p=0.072; Table 1). Among pooled DISCOVER-1&2 pts with the condition at baseline, significantly higher proportions of GUS Q4W and Q8W vs PBO pts had resolved enthesitis or dactylitis at W24 (all

Unadjusted p value[3]	*0.017*	*<0.001*	

See Table 1 for details of statistical testing.

[1] 381 treated pts with active PsA (≥3 swollen+≥3 tender joints, CRP ≥0.3mg/dL), including 118 pts who previously received 1-2 tumor necrosis factor inhibitors, were analyzed in DISCOVER-1, which was similar to DISCOVER-2 in trial design with the exception of no radiographic evaluations. Subsets of the DISCOVER-1 patients presenting with dactylitis (N=142) and enthesitis (N=222) at baseline are included in these pooled analyses.

[2] p-values derive from multiplicity-controlled procedure (see Table 1).

[3] Unadjusted (nominal) p values are not controlled for multiplicity and are descriptive/supportive only; no statistical significance should be implied.

adjusted p< 0.05; Table 2). Numerically higher proportions of GUS Q4W and Q8W than PBO pts with PASI75/90/100 (among pts with ≥3% BSA PsO&IGA ≥2 at W0) and MDA responses at W24 (Table 1) were observed. Serious AEs and serious infections occurred in 18/739 (2.4%) and 5/739 (0.7%) pts, respectively, and no pt died through W24.

Conclusion: In pts with active PsA, GUS Q4W and Q8W significantly improved joint and skin symptoms, physical function, and quality of life, and resolved enthesitis/dactylitis. GUS Q4W significantly reduced radiographic damage progression vs. PBO. GUS was well tolerated, and observed AEs were consistent with GUS safety in PsO pts.

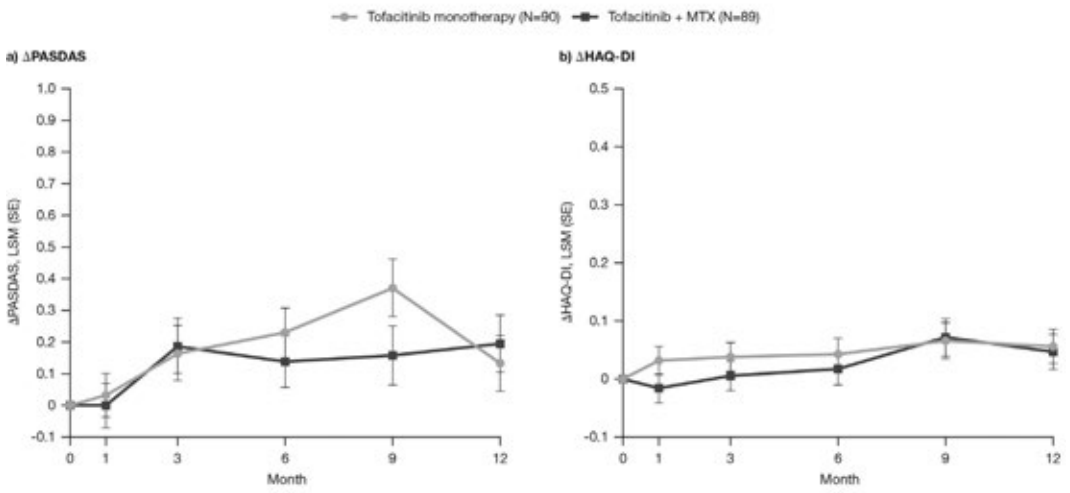
Session Date: Tuesday, November 12, 2019

Session Title: Late-Breaking Abstracts ePoster

Session Type: Late-Breaking Abstract Poster Session

Session Time: 9:00AM–11:00AM

Figure 1. LSM (SE) a) ΔPASDAS[a] and b) ΔHAQ-DI[a] up to Month 12 of the MTX withdrawal sub-study



[a]Primary endpoints at Month 6
Results were based on a repeated measures model with the fixed effects of treatment, visit, treatment by visit interaction, and baseline value, without imputation for missing values; a common unstructured covariance matrix was used. The numbers of patients included in the repeated measures model from tofacitinib monotherapy and tofacitinib + MTX arms were 90 and 89, respectively, for both PASDAS and HAQ-DI. For each endpoint at each time point, the 95% CI of the LSM difference between the tofacitinib monotherapy and tofacitinib + MTX arms included 0
Δ, change from sub-study baseline; CI, confidence interval; HAQ-DI, Health Assessment Questionnaire-Disability Index; LSM, least squares mean; MTX, methotrexate; PASDAS, Psoriatic Arthritis Disease Activity Score, SE, standard error

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Tofacitinib monotherapy has not been previously studied in PsA. This sub-study of OPAL Balance assessed tofacitinib 5 mg twice daily (BID) as monotherapy after MTX withdrawal vs with continued background MTX in patients (pts) with PsA.

Methods: OPAL Balance (NCT01976364) was an open-label (OL), long-term extension (LTE) study of tofacitinib in pts with PsA who had participated in Phase 3 studies (OPAL Broaden [NCT01877668]; OPAL Beyond [NCT01882439]). The MTX withdrawal sub-study was a multicenter, 12-month, randomized, double-blind, placebo (PBO)-controlled, parallel group, estimation study of pts who had completed ≥24 months' tofacitinib treatment in the LTE (5 mg BID; stable for ≥3 months) and were receiving oral MTX (7.5–20 mg/week; stable for ≥4 weeks) before sub-study entry. Pts remained on OL tofacitinib 5 mg BID and were randomized 1:1 to receive PBO (tofacitinib monotherapy; ie, underwent blinded MTX withdrawal) or MTX (tofacitinib + MTX; same stable doses) for 12 months. Primary endpoints were changes from sub-study baseline (BL; Δ) in Psoriatic Arthritis Disease Activity Score (PASDAS) and HAQ-Disability Index (HAQ-DI) at Month (M)6. Secondary efficacy endpoints (Table 1) were assessed at all time points. Safety (Table 2) was assessed throughout the sub-study. No specific statistical hypothesis was tested.

Results: Of 180 pts randomized, 179 were treated in the sub-study (tofacitinib monotherapy, n=90; tofacitinib + MTX, n=89). Demographics and BL characteristics were similar between tofacitinib monotherapy/tofacitinib + MTX (mean age, 53.1/51.8 yrs; female, 52.2%/55.1%; mean disease duration, 11.3/11.2 yrs; low disease activity [PASDAS ≤3.2], 70.0%/62.9%). At M6, least squares mean (LSM) (SE) ΔPASDAS was 0.229 (0.079) for tofacitinib monotherapy and 0.138 (0.081) for tofacitinib + MTX, and LSM ΔHAQ-DI were 0.043 (0.027) and 0.017 (0.028), respectively (primary endpoints; Figure 1; Table 1); no clinically meaningful differences were observed. In general, efficacy and patient-reported outcomes were similar between treatment arms at M6 and M12 (Table 1); rates of minimal disease activity were maintained regardless of MTX withdrawal. Rates of adverse events (AEs), serious AEs, discontinuations due to AEs, and AEs of special interest were comparable between treatment arms; laboratory changes were also similar, except that elevations in liver function enzymes were more common with tofacitinib + MTX (Table 2). One (1.1%) and two (2.2%) pts receiving tofacitinib + MTX met monitoring criteria for absolute neutrophil (< 1.2 x 10^3/

[a]Tofacitinib monotherapy – tofacitinib + MTX. Reported as LSM difference (95% CI) for continuous endpoints and proportion difference (95% CI) for binary endpoints. For continuous endpoints, results were based on a repeated measures model with the fixed effects of treatment, visit, treatment by visit interaction, and baseline value, without imputation for missing values; a common unstructured covariance matrix was used

For binary endpoints, results were based on normal approximation to the difference in binomial proportions

[b]Primary endpoint at Month 6

[c]Missing response = non-response

[d]In patients whose BSA, LEI, or PGA-PsO was >0 at baseline for %ΔBSA, ΔLEI, and ΔPGA-PsO, respectively

[e]In patients whose LEI or DSS was 0 at baseline for mean LEI and DSS, respectively. Only sample means based on patients evaluable at each visit were reported

[f]LSM ΔDSS was not calculated due to the low number of patients with DSS >0 at baseline

95% CI for all treatment comparisons between tofacitinib monotherapy and tofacitinib + MTX included 0 unless noted otherwise

N is the number of patients randomized and treated; N1 is the number of patients evaluable at each visit if differing from the overall N

Δ, change from sub-study baseline; BSA, body surface area; CI, confidence interval; DSS, Dactylitis Severity Score; EQ, EuroQoL; FACIT-F, Functional Assessment of Chronic Illness Therapy – Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; LSM, least squares mean; MCS, Mental Component Summary; MDA, minimal disease activity; MTX, methotrexate; PASDAS, Psoriatic Arthritis Disease Activity Score; PCS, Physical Component Summary; PF, physical functioning; PGA-PsO, Physician's Global Assessment-Psoriasis; PGJS, Patient's Global Joint and Skin Assessment; SE, standard error; SF-36v2, Short Form-36 Health Survey (Version 2, Acute); SJC, swollen joint count; TJC, tender joint count; VAS, visual analog scale

mm^3) and lymphocyte (< 0.5 x 10^3/mm^3) counts, respectively; no pts met discontinuation criteria (ie, values were not confirmed).

Conclusion: In general, no clinically meaningful differences in efficacy and safety were observed in pts with PsA who received OL tofacitinib 5 mg BID as monotherapy after MTX withdrawal vs with continued MTX. No new safety risks were identified. Limitations include that the sub-study was designed as an estimation study and not powered for hypothesis testing, and only pts on long-term treatment who had responded well to, and tolerated, tofacitinib and MTX were included.

Early Study Discontinuations, *n* (%)	22 (26)	21 (24)	22 (25)
Received Escape Therapy[c]**, *n* (%)**	8 (10)	7 (8.2)	10 (12)
Safety, *n* (%)			
Total number of patients with at least one			
AE	64 (76)	77 (89)	68 (77)
Serious AE	8 (10)	4 (5)	12 (14)
AE leading to death[d]	2 (2)	1 (1)	0

a- Note: SLEDAI, BILAG, and PGA are presented with the last observation carried forward. Study discontinuations are accounted for in the SRI-4 Response but not in the SRI-4 Components.
b- Based on the BICLA-Evaluable Population.
c- Escape therapy defined as receipt of SLE medications exceeding limits in protocol.
d- Deaths due to salivary gland tumor (150 mg QD); respiratory failure (PBO); infected skin ulcer (PBO).

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts ePoster
Session Type: Late-Breaking Abstract Poster Session
Session Time: 9:00AM–11:00AM

Background/Purpose: Fenebrutinib (GDC-0853, FEN) is an oral, non-covalent, and highly selective inhibitor of Bruton's tyrosine kinase (BTK) in clinical development for autoimmune diseases. The efficacy, safety, and pharmacodynamic effects of fenebrutinib in patients with moderate-to-severe systemic lupus erythematosus (SLE) activity were assessed in this Phase 2, randomized, placebo-controlled, multi-center study.

Methods: Patients who met SLICC or revised ACR SLE criteria, had ≥1 serologic marker of SLE (ANA, anti-dsDNA, or anti-Smith), SLEDAI ≥6 (later amended to ≥8) at screening, and were on ≥1 standard of care (SOC) therapy (corticosteroid, antimalarial, and/or immunosuppressive) were included; patients with renal or CNS involvement, recent exposure to B cell depleting therapy, or who were receiving a calcineurin inhibitor were excluded. Enrolled patients were randomized to placebo, FEN 150 mg QD, or FEN 200 mg BID, for 48 weeks of therapy. Corticosteroid taper was recommended, with burst and taper permitted from week 0 to week 12 (W0 to W12) and W24 to W36. SRI-4 at W48 was the primary endpoint, comparing the FEN arms with placebo using a sample size of 240 patients targeted for 88% power. BICLA response at W48 was a secondary endpoint.

Table 2: Key Biomarker Results

	PBO	FEN 150 mg QD	FEN 200 mg BID
Median Biomarker Levels at Baseline			
Plasmabast signature (-ΔCt)	**1.29** (*n*=85)	**1.22** (*n*=87)	**1.34** (*n*=88)
CD19⁺ B cells (cells/µl)	**136** (*n*=63)	**140** (*n*=71)	**126** (*n*=70)
Anti-dsDNA# (IU/ml)	**154** (*n*=41)	**124** (*n*=47)	**180** (*n*=48)
Total IgG (g/L)	**14.1** (*n*=85)	**14.3** (*n*=86)	**15.0** (*n*=87)
C3 (g/L)	**1.03** (*n*=85)	**1.03** (*n*=87)	**1.03** (*n*=88)
C4 (g/L)	**0.18** (*n*=85)	**0.17** (*n*=87)	**0.16** (*n*=88)
Median (IQR) Change from Baseline at Week 48			
Plasmablast signature	**-19.7%** (-42.6 to 15.8) *n*=52	**-54.3%*** (-74.7 to -20.6) *n*=53	**-51.7%*** (-77.8 to -15.3) *n*=57
CD19⁺ B cells (cells/µl)	**-0.50** (-38.3 to 28.8) *n*=38	**-57.0*** (-128.0 to -6.0) *n*=49	**-57.5*** (-121.0 to -24.8) *n*=48
Anti-dsDNA# (IU/ml)	**+6.9** (-27.3 to 78.2) *n*=31	**-38.3*** (-91.7 to -3.9) *n*=36	**-75.7*** (-263.7 to -18.4) *n*=33
Total IgG (g/L)	**-0.20** (-1.30 to 1.55) *n*=65	**-1.25*** (-2.63 to 0.05) *n*=64	**-1.56*** (-3.73 to -0.68) *n*=64
C3 (g/L)	**-0.02** (-0.12 to 0.08) *n*=65	**+0.01** (-0.12 to 0.12) *n*=67	**-0.01** (-0.12 to 0.13) *n*=66
C4 (g/L)		**0.00** (-0.03 to 0.02) *n*=65	**+0.02*** (-0.01 to 0.05) *n*=67

Reference ranges: CD19+ B cells (80-616 cells/µl), Anti-dsDNA (<30 IU/ml), IgG (5.65-17.65 g/L), C3 (0.9-1.8 g/L), C4 (0.1-0.4 g/L)
#Patients who were positive at baseline (>30 IU/mL)
*Denotes significant versus PBO; Kruskal-Wallis false-discovery rate controlled two sided (*p*-value ≤0.05).

Results: This study enrolled 260 patients from 44 sites in 12 countries, with the majority of patients recruited in Latin America, USA, and Western Europe. At week 48, the SRI-4 response rates for FEN 150 mg QD and FEN 200 mg BID were 51% (95% CI: -8.5, 21.2) and 52% (95% CI: -7.3, 22.4), respectively, compared to 44% for the placebo arm (**Table 1**). The week 48 BICLA response rates for FEN 150 mg QD and FEN 200 mg BID were 53% (95% CI: -3.4, 26.8) and 42% (95% CI: -14.2, 16.1), respectively, compared to 41% for the placebo arm (**Table 1**). Safety results were similar between FEN and placebo, although more serious adverse events were observed in the FEN 200 mg BID arm (**Table 1**). Treatment with both doses of FEN significantly reduced levels of CD19+ B cells, anti-dsDNA autoantibodies, IgG, and a BTK-dependent RNA signature highly expressed in plasmablasts by week 48 compared to placebo; C4 levels modestly improved with FEN versus placebo (**Table 2**).

Conclusion: The primary endpoint of SRI-4 for FEN was not met despite evidence of strong BTK target and pathway inhibition. FEN had an acceptable safety profile.

SESSION INFORMATION

Session Date: Tuesday, November 12, 2019

Session Title: Late-Breaking Abstracts ePoster

Session Type: Late-Breaking Abstract Poster Session

Session Time: 9:00AM–11:00AM

Background/Purpose: Giant cell arteritis (GCA) is the most common cause of primary vasculitis in adults. Corticosteroids are the cornerstone of the treatment. However, approximately 50% of patients will relapse, and up to 86% will experience steroid-induced adverse events. The objective was to study the risk factors for relapse, including prednisolone clearance and glucocorticoid-induced transcript 1 (*GLCCI1*) promoter polymorphism (rs37972), which acts on steroid-induced apoptosis.

Methods: This multicenter prospective study included steroid-naive patients with a diagnosis of GCA, defined by ≥3/5 American College of Rheumatology (ACR) criteria (trial registration: NCT01400464). Patients received steroids, with a 10 to 16 months predefined taper schedule, with a planned follow-up of 18 months after inclusion. Genotyping of GLCCI1 (rs37972) and prednisolone clearance were performed between 14 and 28 days of treatment. Variables with p< 0.20 on univariate analysis were considered for multivariate analysis. Relapse was defined as the combination of inflammatory syndrome (C-reactive protein >15 mg/L or sedimentation rate >40 mm/h), GCA symptoms and resolution with increasing the dose of prednisone. The primary objective was the link between the prednisolone clearance and the risk of relapse.

Results: A total of 139 patients were included, but 20 were excluded from analysis (missing prednisolone clearance, n=18; cortico-resistant, n=2). Among the 119 patients (70 women), the mean age was 72.2 +/- 7.6 years with a median follow-up duration of 74 [32-82] months. Thirty-seven (31%) had polymyalgia rheumatica, the median C-reactive protein level and sedimentation rate were 78 [13-102] mg/L and 70 [35-94] mm/h, respectively, and 59 (49.6%) patients had at least one relapse. The mean prednisolone clearance was 7.2 +/- 6.7 L/h. For each increase of 1 unit of clearance, the relapse risk increased, although not significantly, by 2.6% (hazard-ratio, HR=1.026, IC95% 0.99-1.06) in univariate analysis. On multivariate analysis, only platelets were associated with a decreased risk of relapse (HR=0.98, IC95% 0.96-0.9997, for each increase of 10,000 platelets/mm^3, Tables 1 and 2).

Additionally, based on an ancillary study among 121 patients who had a determination of *GLCCI1* rs37972 polymorphism, patients with a CC genotype experienced fewer relapses than patients with at least one T allele (Figure 1) in multivariate analysis adjusted for polymyalgia rheumatica (HR=0.498, IC95% 0.26-0.97, p=0.04).

Table 1: Univariate analysis of predictors of relapse in patients with giant cell arteritis

Other factors		*n*	HR	IC 95%	p
Sex	Male	49	1		
	Female	70	1.05	(0.60-1.83)	0.87

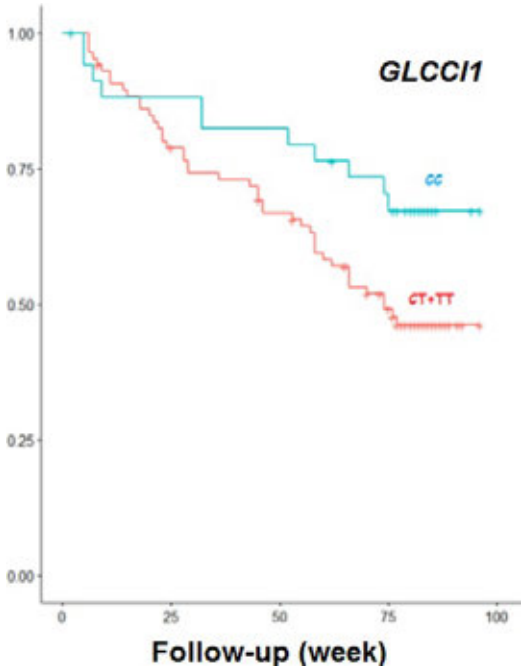
Polymyalgia rheumatica	No	82	1		
	Yes	37	1.46	(0.83-2.58)	**0.19**
Hemoglobin level (per increase of 1 g/dL)		118	1.12	(0.91-1.38)	0.30
Sedimentation rate (per increase of 10 mm/h)		102	0.90	(0.83-0.98)	**0.020**
C-reactive protein (per increase of 50 mg/L)		117	1.07	(0.90-1.27)	0.44
Fibrinogen (per increase of 1 g/L)		98	0.85	(0.72-1.00)	**0.052**
Neutrophil (per increase of 1,000 cells/mm^3)		116	1.03	(0.96-1.11)	0.43
White blood cells (per increase of 1,000 cells/mm^3)		118	1.03	(0.96-1.10)	0.43
Platelets (per increase of 10,000 cells/mm^3)		118	0.98	(0.96-1.00)	**0.075**

Table 2: Multivariate analysis of predictors of relapse in patients with giant cell arteritis

Factors		Adjusted HR	IC 95%	p
By adjusting on all variables with a p-value <0.2 on univariate analysis (n=83)				
Clearance (per increase of 1 unit)		0.978	(0.91 - 1.06)	0.58
Polymyalgia rheumatica	No	1		
	Yes	1.46	(0.75 - 2.85)	0.27
Platelets (per increase of 10,000 cells/mm³)		0.98	(0.96 - 1.01)	0.17
Fibrinogen (per increase of 1 g/L)		0.87	(0.69 - 1.11)	0.27
Sedimentation rate (per increase of 10 mm/h)		0.97	(0.84 - 1.12)	0.68
By adjusting only on prednisolone clearance, polymyalgia rheumatica and platelets (n=118)				
Clearance (per increase of 1 unit)		1.016	(0.97 - 1.07)	0.51
Polymyalgia rheumatica	No	1		
	Yes	1.62	(0.92 - 2.89)	0.098
Platelets (per increase of 10,000 cells/mm³)		0.98	(0.96 – 0.9997)	**0.047**



Conclusion: To our knowledge, this study is the largest prospective study including steroid-naive GCA patients treated with uniform predefined taper schedule, and the first one assessing prednisolone clearance as a risk factor for relapse.

On multivariate analysis, a higher platelet count and a CC rs37972 polymorphism were associated with a decreased risk of relapse.

Further studies are needed to determine the effect of a steroid-sparing treatment as a first-line treatment in association with steroids in patients with the CT or TT rs37972 polymorphism.

Relapse-free survival in giant cell arteritis patients according to GLCCI1 rs37972 polymorphism

Session Title: Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 4:00PM–6:00PM

Background/Purpose: Anifrolumab, a human monoclonal antibody to the type I IFN receptor subunit 1, had robust efficacy in a phase 2 study in patients with active SLE. The first phase 3 trial, TULIP-1, did not meet its primary endpoint, SLE responder index (SRI[4]), but multiple other endpoints, including BILAG–based Composite Lupus Assessment (BICLA), suggested clinical benefit. We report results of the second phase 3 trial of anifrolumab.

Patient Characteristic	Placebo (n=182)	Anifrolumab 300 mg (n=180)
Age, years, mean (SD)	41.1 (11.47)	43.1 (11.95)
Female, n (%)	170 (93.4)	168 (93.3)
Time from initial SLE diagnosis to randomization (months), median (min, max)	78.0 (6, 494)	94.5 (6, 555)
SLEDAI-2K global score, mean (SD)	11.5 (3.88)	11.4 (3.64)
BILAG-2004 ≥1 A, n (%)	95 (52.2)	81 (45.0)
BILAG-2004 no A and ≥2 B, n (%)	78 (42.9)	91 (50.6)
PGA (0–3), mean (SD)	1.76 (0.397)	1.68 (0.411)
CLASI activity, mean (SD)	7.6 (7.75)	8.3 (7.94)
SDI, mean (SD)	0.5 (0.79)	0.5 (0.91)
Swollen joint count, mean (SD)	7.4 (6.55)	6.2 (5.65)
Tender joint count, mean (SD)	11.0 (7.89)	9.0 (7.07)
High type I IFNGS, n (%)	151 (83.0)	150 (83.3)
Elevated anti-dsDNA antibodies, n (%)	73 (40.1)	86 (47.8)

Other secondary endpoint:					
SRI(4) at wk 52‡‡	68/182 (37.3)	100/180 (55.5)	18.2 (8.1, 28.3)	NA/ <0.001	NA

*Percentage response, the difference in response estimates, and the associated 95% CIs are weighted and are calculated using a stratified Cochran–Mantel–Haenszel approach with pre-specified stratification factors (SLEDAI-2K score at screening [<10 points vs ≥10 points], week 0 OCS dose [prednisone <10 mg/d vs ≥10 mg/d or equivalent] and type I IFN gene signature test result at screening [high vs low]).

†BICLA response is defined as reduction of all baseline BILAG-2004 A to B/C/D, baseline BILAG-2004 B to C/D, and no BILAG-2004 worsening in other organ systems (≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B items); no worsening (increase >0 points) from baseline SLEDAI-2K; <0.3-point increase in PGA from baseline, no use of restricted medications beyond protocol-allowed thresholds, and no discontinuation of investigational product.

‡Treatment comparison using a stratified Cochran–Mantel–Haenszel approach. *P*-values adjusted per weighted Holm procedure.

§In patients with baseline OCS prednisone ≥10 mg/d or equivalent.

¶In patients with CLASI activity score ≥10 at baseline.

**In patients with ≥6 swollen and ≥6 tender joints at baseline.

††Values are annualized flare rates rather than responder percentages. A flare is defined as either ≥1 new BILAG-2004 A or ≥2 new BILAG-2004 B items compared with the previous visit (ie, a worsening from an E, D, or C score to a B score in at least 2 organ systems or a worsening from an E, D, C, or B score to an A score in any 1 organ system compared with the previous visit).

‡‡SRI(4) response was defined as a ≥4-point reduction in SLEDAI-2K score, <1 new BILAG-2004 A or <2 new BILAG-2004 B organ domain scores, <0.3-point (10%) increase in PGA score from baseline, and no discontinuation of investigational product and no use of restricted medications beyond the protocol-allowed threshold.

‖Calculated as a rate ratio (anifrolumab/placebo).

BICLA = BILAG-based Composite Lupus Assessment; BILAG = British Isles Lupus Assessment Group; BL = baseline; CI = confidence interval; CLASI = Cutaneous Lupus Erythematosus Disease Area and Severity Index; IFNGS = interferon gene signature; NA = not applicable; OCS = oral corticosteroids; SRI = Systemic Lupus Erythematosus Responder Index.

Table 2. Primary and Secondary Efficacy Outcomes

Methods: TULIP-2 (NCT02446899) is a randomized, double-blind, placebo-controlled trial that evaluated efficacy and safety of IV anifrolumab 300 mg vs placebo every 4 weeks for 48 weeks in patients with moderate to severe SLE despite standard-of-care (SOC) treatment. Patients met ACR SLE criteria and had SLEDAI-2K ≥6 and BILAG ≥1 A or ≥2 B. The primary endpoint was BICLA response at week 52. SOC was stable except for mandatory attempts at oral corticosteroid (OCS) tapering to prednisone equivalent ≤7.5 mg/d for patients receiving ≥10 mg/d at baseline. Safety was also assessed.

Results: Of 365 randomized patients, 362 received ≥1 dose of study drug and were included in the analyses (anifrolumab, n=180; placebo, n=182). Baseline demographic and disease characteristics were similar between treatment groups (**Table 1**). Treatment completion was 85.0% for anifrolumab and 71.4% for placebo.

Anifrolumab was superior to placebo for BICLA response (47.8% vs 31.5%, respectively, *P*=0.001) and key secondary endpoints: OCS reduction (51.5% vs 30.2%; *P*=0.014) and Cutaneous Lupus Erythematosus Disease Area and Severity Index response (49.0% vs 25.0%; P=0.039); annualized flare rate was numerically lower in anifrolumab-treated patients (0.43 vs 0.64; rate ratio 0.67 [95% CI: 0.48, 0.94]; *P*=0.081; **Table 2**).

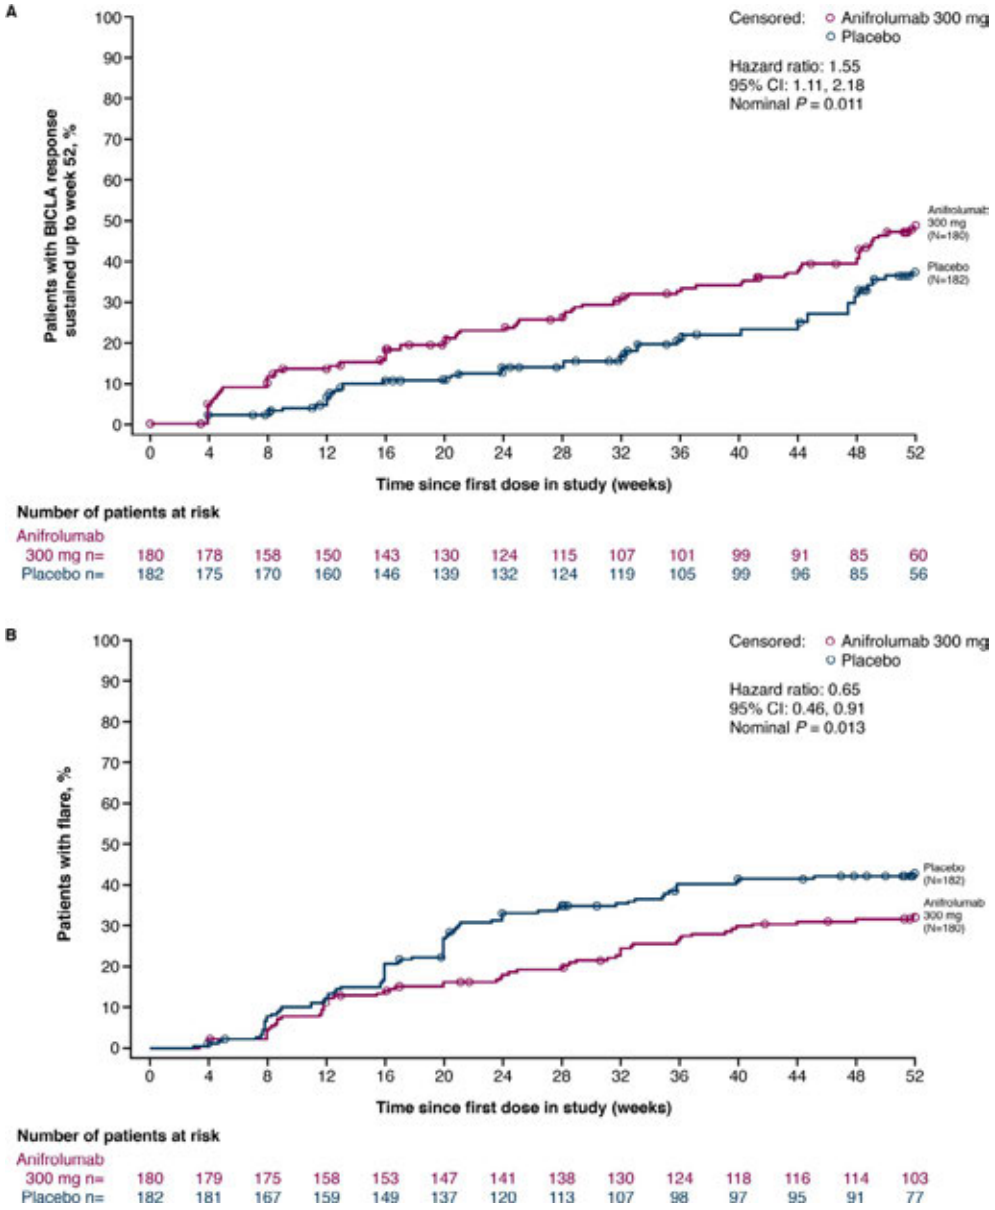

Figure. Time Course of Onset of BICLA Response Sustained Through Week 52* (A) and Time to First Flare,* Defined as Either ≥1 New BILAG A or ≥2 new BILAG B Items Compared With the Previous Visit (B)

Efficacy was further supported by numeric differences favoring anifrolumab in multiple secondary endpoints (unadjusted), including SRI(4) response (55.5% vs 37.3%; nominal *P*< 0.001) and higher thresholds of SRI(5–8), time to onset of BICLA response sustained to week 52 (hazard ratio [HR], 1.55; 95% CI: 1.11, 2.18; nominal *P*=0.011; **Figure 1A**), and time to first flare (HR, 0.65; 95% CI: 0.46, 0.91; nominal P=0.013; **Figure 1B**). In patients with high baseline IFN gene signature (IFNGS), anifrolumab induced neutralization of IFNGS by week 12 (median suppression 88.0%) that was maintained through week 52. Serum anti-dsDNA trended toward normalization with anifrolumab.

The safety profile of anifrolumab was similar to that of previous trials. Herpes zoster was more common in those receiving anifrolumab (7.2%) than placebo (1.1%). In contrast, serious adverse events were less frequent among anifrolumab- than placebo-treated patients (8.3% and 17.0%, respectively), as were adverse events leading to treatment discontinuation (2.8% and 7.1%). One death occurred in the anifrolumab group (pneumonia). Few patients (0.6%) developed antidrug antibodies.

Conclusion: Anifrolumab was superior to placebo for multiple efficacy endpoints, including overall disease activity, skin disease, and OCS tapering. No new safety signals were identified. TULIP-2 demonstrates efficacy of anifrolumab in moderate to severe SLE.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 4:00PM–6:00PM

Background/Purpose: Telitacicept, also named RC18, is a novel recombinant fusion protein constructed with the extracellular domain of the human transmembrane activator and calcium modulator and cyclophylin ligand interactor (TACI) receptor and the Fc domain of human immunoglobulin (Ig) G1 targeting and neutralizing B lymphocyte stimulator (BLyS) and a proliferating-inducing ligand (APRIL). This phase 2b study evaluated the efficacy and safety of Telitacicept versus placebo in combination with standard therapy in SLE patients.

Methods: SLE patients aged 18 to 65 years with positive ANA and/or anti-dsDNA and with a SELENA-SLEDAI score ≥8 were randomized 1:1:1:1 to receive subcutaneous Telitacicept at 80 mg, 160 mg, 240 mg or placebo once a week in combination with standard therapy for 48 weeks. The primary endpoint was response rate of SLE Responder Index 4 (SRI4) at Week 48. The SRI4 response was defined as: ≥4 points reduction from baseline in SELENA-SLEDAI score, and no new BILAG A organ domain score or 1 new BILAG B organ domain score compared with baseline, and no worsening (increase of < 0.30 points from baseline) in Physician's Global Assessment (PGA). This trial is registered with ClinicalTrials.gov, number NCT02885610.

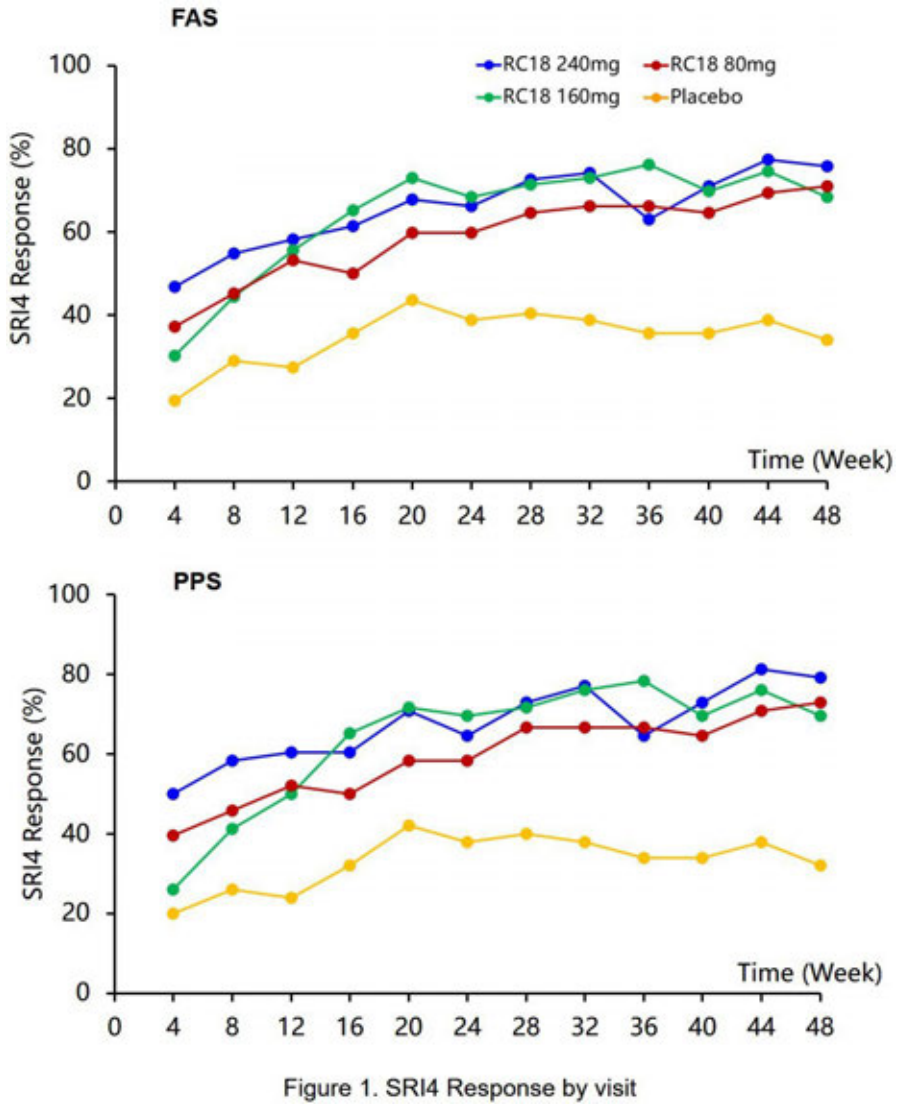

Figure 1. SRI4 Response by Visit

Results: 249 patients were randomized to receiving Telitacicept 80 mg (n=62), 160 mg (n=63), 240 mg (n=62) or placebo (n=62). Results from full analysis set (FAS) showed significantly higher response rates of SRI4 with Telitacicept 80mg (71.0%, p< 0.0001), 160 mg (68.3%, p=0.0001) and 240 mg (75.8%, p< 0.0001) than with placebo (33.9%) at Week 48; more patients had a reduction of ≥ 4 points in SELENA-SLEDAI score at Week 48 with Telitacicept 80mg (75.8%, p=0.003), 160 mg (77.8%, p=0.001) and 240 mg (79.0%, p< 0.001) than with placebo (50.0%); no worsening in PGA score was noted in more patients with Telitacicept 80mg (96.8%, p< 0.001), 160 mg (92.1%, p=0.013) and 240 mg (96.8%, p< 0.001) than with placebo (75.8%) at Week 48. Results from Per protocol set (PPS) were consistent with that from FAS. The incidences of AEs was 93.5%, 92.1%, 90.3%, 82.3% in the Telitacicept 240mg, 160mg, 80mg and placebo group. There were 13 SAEs in 8 subjects treated with 240mg Telitacicept, 16 SAEs in 10 subjects treated with 160mg Telitacicept, 12 SAEs in 8 subjects treated with 80mg Telitacicept, 12 SAEs in 10 subjects treated with placebo, the incidences of SAEs were 12.9%, 15.9%,12.9%, 16.1% in the Telitacicept 240mg, 160mg, 80mg and placebo groups, respectively. The incidence of AEs and SAEs was similar across groups (p >0.05). There was 1 death in Telitacicept 240mg group which was considered not related to the study drug. The most common AEs were upper respiratory tract infection and injection site reactions. 11 pregnancies occurred during the study in subjects received Telitacicept (4 on 240mg, 3 on 160 mg and 4 on 80 mg) while no pregnancy occurred in the placebo group. 1 pregnancy resulted in live birth and 10 in elective termination.

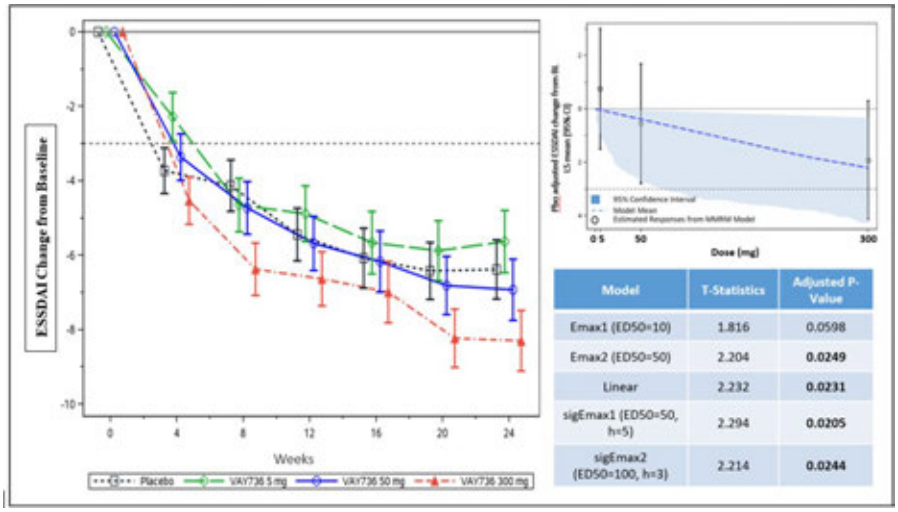
Session Date: Tuesday, November 12, 2019

Session Title: Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 4:00PM–6:00PM

Background/Purpose: Primary Sjogren's syndrome (pSS) is a multi-organ autoimmune disease primarily affecting excretory glands and characterized by B-cell hyperactivity. No approved systemic treatments are available. Ianalumab (VAY736) is an anti-B-cell activating factor (BAFF) receptor fully human IgG1 monoclonal antibody, engineered for direct ADCC-mediated B-cell depletion, thus providing a dual mode of action and targeted approach to treat pSS. The current phase 2b study aimed at establishing a dose-response relationship over a wide range of VAY736 doses, using change from baseline (BL) in the EULAR Sjogren's Syndrome Disease Activity index (ESSDAI) over 24 Weeks (Wks) as the primary endpoint. Here we report Wk24 efficacy and safety. The study is ongoing with a second blinded treatment period up to Wk52.



Model	T-Statistics	Adjusted P-Value
Emax1 (ED50=10)	1.816	0.0598
Emax2 (ED50=50)	2.204	**0.0249**
Linear	2.232	**0.0231**
sigEmax1 (ED50=50, h=5)	2.294	**0.0205**
sigEmax2 (ED50=100, h=3)	2.214	**0.0244**

Methods: 190 patients with pSS were randomized 1:1:1:1 to monthly s.c. administrations of placebo (PBO) or one of three VAY736 doses; 5mg, 50mg and 300mg. First-dose premedication was 250mg IV methylprednisolone. To be eligible, patients had to fulfill the American European Consensus Group (AECG) criteria for pSS, be anti-Ro/SSA positive, have an ESSDAI ≥6 (on 7/12 domains: glandular, articular, lymphadenopathy, constitutional, cutaneous, hematologic, biologic), and EULAR Sjogren's Syndrome Patient Reported Index (ESSPRI) ≥5. Statistical methods included MCP-Mod to assess the dose-response on change of ESSDAI (12 domains) from BL and responder analysis to calculate the proportion of patients with ≥3 points improvement on ESSDAI as secondary analysis. Secondary endpoints included ESSPRI, Functional Assessment of Chronic Illness Therapy Fatigue (FACIT-F), Physician's (PhGA) and Patient's Global Assessments (PGA), SF-36, stimulated salivary flow (sSF) and Schirmer's test.

Results: The primary endpoint of the study was met with a statistically significant dose-response for ESSDAI (**Figure 1**). The largest reduction in ESSDAI was 1.92 points over PBO for VAY736 300mg at Wk24. Secondary analysis on ESSDAI revealed for 300mg vs PBO responder rates of 42/47 (89.4%) vs 30/49 (61.2%), a difference of 28.1% (p=0.0019), while no differences were seen for 5mg and 50mg vs PBO. Consistent with this result, PhGA change from BL was significantly different between VAY736 300mg and PBO (p=0.022). A numerical trend for improvement of sSF for VAY736 300mg compared to PBO was notable at Wk24 (p=0.092). However, the secondary efficacy endpoints ESSPRI and FACIT-F showed no benefits over PBO for improvements in the burden of illness. PBO responses were generally high. Incidence of treatment emergent adverse events were comparable across PBO and active groups, whereby local injection reactions were most frequent, mostly mild and showed a dose-response.

Conclusion: The defined primary endpoint assessing ESSDAI was met, showing statistically significant dose-response for ianalumab with clinically important improvement over placebo at the highest tested dose. The preliminary safety profile was good. Future analysis will focus on PK and immunogenicity, salivary and tear flow parameters and the exploration of ESSDAI domains, and the ongoing-blinded treatment period up to Week 52.

ESSDAI Change from Baseline over Time up to Week 24 Reveals a Statistically Significant Dose Response Relationship

Session Title: Late-Breaking Abstracts

Session Type: Late-Breaking Abstract Session

Session Time: 4:00PM–6:00PM

Background/Purpose: Multiple biologic DMARDs (bDMARDs) are available for treatment of PsA, but there are few direct comparisons of their efficacy and safety. Furthermore, efficacy of bDMARDs with or without concomitant MTX is one of the most clinically relevant questions for clinicians. Ixekizumab (IXE) was superior to adalimumab (ADA) at Week (Wk) 24 for simultaneous achievement of ACR50 and 100% improvement from baseline in the Psoriasis Area

	Week 24			Week 52

Values are presented as n/N (%)
After the initial database lock and analysis run, nine patients who met baseline criteria for active psoriasis had baseline PASI=0 and BSA≥3% (a medical inconsistency). This inconsistency was not anticipated in the protocol or statistical analysis plan and was resolved using medical judgement. The primary analysis was re-run with these patients considered PASI100 responders if PASI=0 and BSA=0 at Week 24.
[a]Assessed for patients with NAPSI >0 at baseline.
[b]Assessed for patients with LEI score >0 at baseline.
[c]Assessed for patients with SPARCC Enthesitis Index score >0 at baseline
[d]Assessed for patients with LDI-B score >0 at baseline.
[e]Assessed for patients with HAQ DI score ≥0.35 at baseline. A response of ≥0.35 CFB is the minimal clinically important difference in HAQ-DI.
Abbreviations: ACR, American College of Rheumatology; ADA, adalimumab; CFB, change from baseline; DAPSA, Disease Activity in Psoriatic Arthritis; HAQ-DI, Health Assessment Questionnaire-Disability Index; IXE, ixekizumab; LDA, Low Disease Activity; LDI-B, Leeds Dactylitis Index-Basic; LEI, Leeds Enthesitis Index; MDA, Minimal Disease Activity; PASI, Psoriasis Area and Severity Index; SPARCC, Spondyloarthritis Research Consortium of Canada; VLDA, Very Low Disease Activity

and Severity Index (PASI100) (primary endpoint) in patients (pts) with active PsA (SPIRIT-H2H) (Mease et al, Ann Rheum Dis 2019). We report final 52-wk efficacy and safety, and efficacy in subgroups defined by concomitant MTX use in SPIRIT-H2H.

Methods: Pts with active PsA fulfilling Classification for Psoriatic Arthritis (CASPAR) criteria, ≥3/66 tender and ≥3/68 swollen joints, ≥3% psoriasis body surface area (BSA) involvement, no prior treatment with bDMARDs, and prior inadequate response to ≥1 conventional synthetic DMARD (csDMARD), were randomized 1:1 to open-label IXE or ADA (label dosing according to presence/absence of moderate-to-severe psoriasis [baseline BSA≥10%, PASI≥12, and static Physician's Global Assessment≥3]) through 52 wks. Outcomes included the percentage of pts achieving both ACR50 + PASI100 simultaneously, ACR20/50/70, PASI75/90/100, Nail Psoriasis Severity Index (NAPSI)=0, Minimal Disease Activity (MDA), Very Low Disease Activity (VLDA, defined as MDA 7/7), Disease Activity in Psoriatic Arthritis Low Disease Activity (DAPSA LDA), DAPSA remission, Leeds Enthesitis Index (LEI)=0, Spondyloarthritis Research Consortium of Canada (SPARCC) Enthesitis Index=0, Leeds Dactylitis Index-Basic (LDI-B)=0, and HAQ-Disability Index (HAQ-DI) ≥0.35 change from baseline. Efficacy was also analyzed in subgroups based on concomitant MTX. Efficacy outcomes were analyzed using logistic regression with nonresponder imputation for missing data. There were no adjustments for multiple comparisons. Safety outcomes are summarized for pts who received ≥1 dose of study treatment.

	IXE N=283	ADA N=283
Treatment-emergent adverse events	209 (73.9)	194 (68.6)
Mild	95 (33.6)	85 (30.0)
Moderate	105 (37.1)	89 (31.4)
Severe	9 (3.2)	20 (7.1)
Serious adverse events	12 (4.2)	35 (12.4)
Discontinuations due to adverse events	12 (4.2)	21 (7.4)
Deaths	0	0
Adverse events of special interest		
Infections	119 (42.0)	111 (39.2)
Serious infections	5 (1.8)	8 (2.8)
Injection-site reactions	30 (10.6)	10 (3.5)
Allergic/hypersensitivity reactions	11 (3.9)	13 (4.6)
Potential anaphylaxis	1 (0.4)[a]	0
Cytopenias	9 (3.2)	12 (4.2)
Cerebrocardiovascular events	5 (1.8)	7 (2.5)
Malignancies	0	4 (1.4)
Depression	5 (1.8)	9 (3.2)
Inflammatory bowel disease	2 (0.7)[b]	0
Ulcerative Colitis	1 (0.4)[b,c]	0
Crohn's Disease	1 (0.4)[b,d]	0

[a]Patient experienced mild injection site pain, cough, and dizziness at the baseline visit, which was resolved on the same day.
[b]EPIdemiologique des Maladies de l'Appareil Digestif (EPIMAD) criteria for adjudication of suspected inflammatory bowel disease define "probable" and "definite" classifications as confirmed cases. Only 1 case met the EPIMAD criteria of confirmed inflammatory bowel disease.
[c]Event was reported as colitis ulcerative and was adjudicated as possible ulcerative colitis and did not meet the EPIMAD criteria of confirmed inflammatory bowel disease.
[d]Event was reported as colitis and was adjudicated as probable Crohn's disease.
Abbreviations: ADA, adalimumab; IXE, ixekizumab

Table 2. Safety outcomes at Week 52

Results: Overall, 87% (246/283) and 84% (237/283) of pts randomized to IXE and ADA, respectively, completed Wk 52. IXE provided significantly greater response than ADA for simultaneous ACR50 + PASI100 through Wk 52 (Figure 1A). IXE performed at least as well as ADA at Wk 52 for all other outcomes (Figure 1B, 1C, Table 1). Simultaneous ACR50 + PASI100 response was numerically greater with IXE than ADA, regardless of concomitant MTX use (Figure 1D). MTX use by treatment interaction was significant for ACR20/50/70 at Wk 52 (Figure 1E-F). Treatment-emergent adverse events (AEs) occurred in 73.9% (IXE) and 68.6% (ADA) of pts. Serious AEs occurred in 4.2% (IXE) and 12.4% (ADA) of pts, and discontinuations due to AEs occurred in 4.2% (IXE) and 7.4% (ADA) of patients; no deaths occurred. (Table 2).

Conclusion: IXE provided significantly greater simultaneous joint and skin improvement versus ADA as early as Wk 8 and through Wk 52. IXE performed at least as well as ADA across multiple PsA domains including musculoskeletal and skin domains through Wk 52. Safety outcomes for IXE and ADA were consistent with their previously established safety profiles.

SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 4:00PM–6:00PM

Background/Purpose: Non-radiographic axial spondyloarthritis (nr-axSpA) and ankylosing spondylitis (AS) are considered part of the spectrum of axSpA. Patients (pts) are classified as nr-axSpA due to absence of definitive radiographic sacroiliitis but suffer from similar disease burden as pts with AS. NSAIDs are first-line therapy, and one anti-TNF therapy is approved for nr-axSpA pts with objective signs of inflammation in the US[1]. Secukinumab (SEC) provides significant and sustained improvement in signs and symptoms of pts with AS[2].

Methods: PREVENT (NCT02696031) is the first phase 3 study evaluating the efficacy and safety of SEC 150 mg with (LD) or without loading (NL) in pts with nr-axSpA. The study had 2 independent analysis plans as per EU (Week [Wk] 16) and US (Wk 52) regulatory requirements. Here, the Wk 16 efficacy results and safety to Wk 20 from the EU analysis plan are reported. This phase 3, double blind, placebo (PBO)-controlled, multicenter trial included 555 pts (aged ≥18 years) fulfilling the ASAS classification criteria for axSpA plus abnormal CRP and/or MRI, with no radiographic changes in the sacroiliac joints meeting modified New York Criteria. All images were assessed by central reading. Pts were randomized (1:1:1) to subcutaneous SEC 150 mg LD, 150 mg NL, or PBO. The LD group received SEC 150 mg at baseline (BL), Wks 1, 2, 3, and 4 , and then every 4 wks (q4wk) through Wk 52. NL group received SEC 150 mg at BL and PBO at Wks 1, 2, and 3, and then SEC 150 mg q4wk starting at Wk 4. PBO group received PBO at BL, Wks 1, 2, 3 and 4 and then q4wk. The primary endpoint was ASAS40 response with SEC 150 mg LD in anti-TNF-naïve pts at Wk 16. Secondary

Table 2: Secondary Efficacy Results# at Week 16			
Variables	**Secukinumab 150 mg with loading (N = 185)**	**Secukinumab 150 mg without loading (N = 184)**	**Placebo (N = 186)**
ASAS40, % responders	40.0‡	40.8‡	28.0
Total BASDAI, LS mean change from baseline (SE)	-2.4‡ (0.2)	-2.4‡ (0.2)	-1.5 (0.2)
BASDAI50, % responders	37.3‡	37.5‡	21.0
BASFI, LS mean change from baseline (SE)	-1.8‡ (0.2)	-1.6‡ (0.2)	-1.0 (0.2)
SF-36 PCS, LS mean change from baseline (SE)	5.7‡ (0.7))	5.6‡ (0.7)	2.9 (0.7)
ASQoL, LS mean change from baseline (SE)	-3.5‡ (0.4)	-3.6‡ (0.4)	-1.8 (0.4)
ASAS partial remission, % responders	21.6‡	21.2‡	7.0
‡P<0.05 vs. placebo (p values are adjusted for multiplicity of testing). Data presented as non-responder imputation (binary variables) and MMRM (continuous variables). #Pre-specified primary and secondary endpoints were analyzed according to a statistical hierarchy. Endpoints are shown in the order of testing. N, total number of randomized patients ASAS, Assessment of Spondyloarthritis International Society; ASQoL, Ankylosing Spondylitis Quality of Life; LS, least square; MMRM, mixed-model repeated measures; SE, standard error; SF-36 PCS, Short Form-36 physical component score			

Table 2. Secondary Efficacy Results# at Week 16

endpoints included ASAS40 response rates, total BASDAI, BASDAI50, BASFI, SF-36 PCS, ASQoL, and ASAS partial remission in the overall population. Analysis used NRI for binary and MMRM for continuous variables. Endpoints were analyzed according to a statistical hierarchy. Safety analyses included all pts who received ≥1 dose of study treatment.

Results: 94.6% (175/185; 150 mg LD), 96.2% (177/184; 150 mg NL) and 94.1% (175/186; PBO) pts completed 24 wks of treatment. Demographic and baseline disease characteristics were comparable across groups (**Table 1**). The primary and all secondary endpoints were met. At Wk 16, ASAS40 in anti-TNF-naïve pts was significantly higher in the SEC 150 mg LD group than PBO (**Figure**). SEC 150 mg LD and NL also showed significant improvement vs PBO in all secondary endpoints (**Table 2**). Three cases of serious infections/infestations (0.8%), and 1 case of Crohn's disease (0.3%) were reported with SEC. No cases of oesophageal candidiasis, major adverse cardiovascular events, malignancy or death were reported on any SEC dose up to Wk 20.

Conclusion: PREVENT is the first randomized controlled trial evaluating the efficacy and safety of SEC in pts with nr-axSpA. SEC 150 mg LD and NL provided significant improvement in signs and symptoms of nr-axSpA through Wk 16. The safety profile of SEC was consistent with the established safety profile across indications[3].

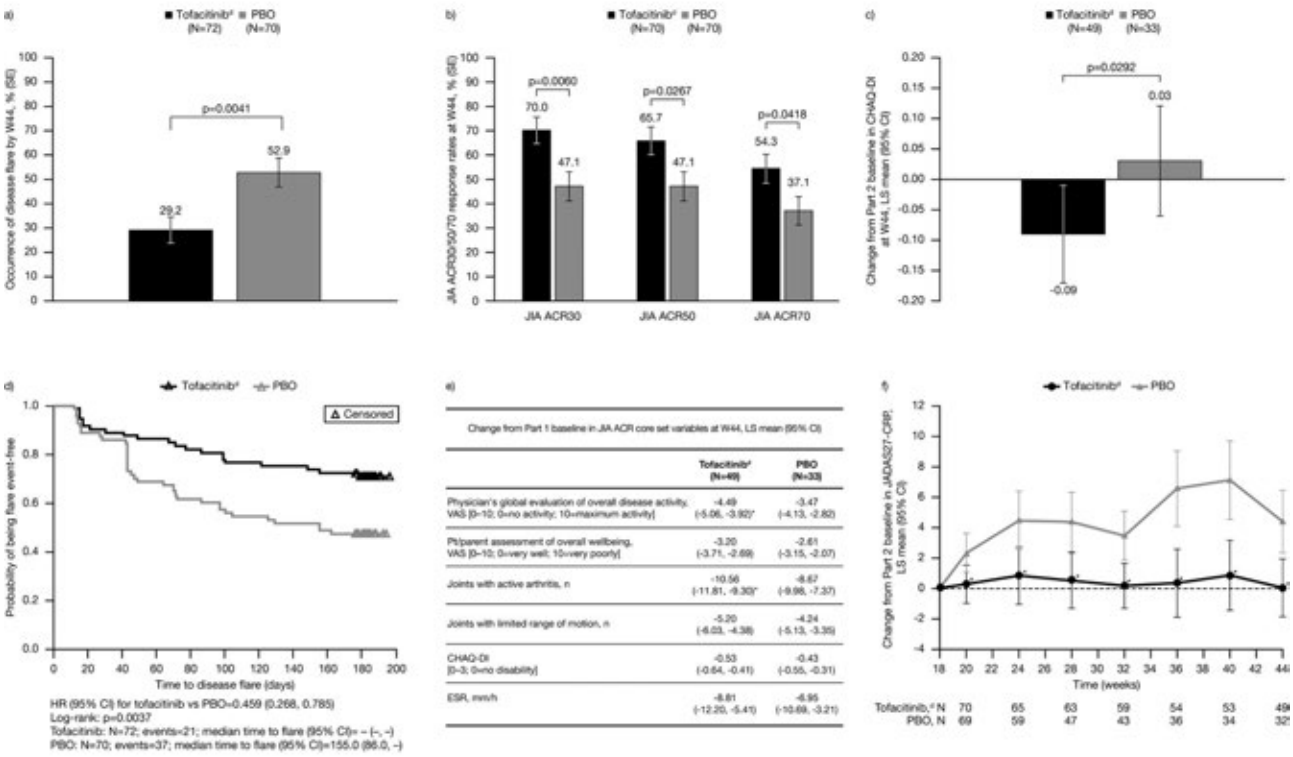
SESSION INFORMATION
Session Date: Tuesday, November 12, 2019
Session Title: Late-Breaking Abstracts
Session Type: Late-Breaking Abstract Session
Session Time: 4:00PM–6:00PM

Background/Purpose: Tofacitinib is an oral JAK inhibitor that is being investigated for JIA. Here we assess the efficacy and safety of tofacitinib in patients (pts) with JIA.

Methods: This was a Phase 3, randomized, double-blind (DB), placebo (PBO)-controlled withdrawal study in pts aged 2 to < 18 years with polyarticular course JIA (pcJIA), PsA or enthesitis-related arthritis (ERA) (NCT02592434). In the 18-week, open-label (OL), run-in phase (Part 1), pts received tofacitinib. Pts achieving ≥ JIA ACR30 response[1] at Week (W)18 were randomized 1:1 in the DB phase (W18–44; Part 2) to continue receiving tofacitinib or withdraw tofacitinib and newly receive PBO. Tofacitinib was administered according to body weight: 2–4 mg BID oral solution in pts < 40 kg; 5 mg BID tablet or oral solution in pts ≥ 40 kg. The primary endpoint was occurrence of disease flare[2] by W44 (W26 of Part 2). Key secondary endpoints were JIA ACR50/30/70 response[1] rates and change (Δ) from Part 2 baseline (BL) in Childhood Health Assessment Questionnaire Disability Index (CHAQ-DI) at W44. The primary and key secondary endpoints were type 1 error-controlled with statistical significance declared at $p < 0.05$. Other efficacy endpoints included time to disease flare in Part 2, Δ from Part 1 BL in JIA ACR core set variables[1] at W44, and Δ from Part 2 BL in Juvenile Arthritis Disease Activity Score (JADAS27-CRP) during Part 2. Pts with PsA or ERA were exclud-

Figure 1. Efficacy of tofacitinib vs PBO in 142 pts with pcJIA in Part 2: a) occurrence of disease flare[a] by W44[b]; b) JIA ACR30/50/70 response[c] rates at W44[b]; c) mean change from Part 2 baseline in CHAQ-DI at W44[b]; d) Kaplan-Meier plot of time to flare in Part 2; e) mean change from Part 1 baseline in JIA ACR core set variables at W44; f) mean change from Part 2 baseline in JADAS27-CRP over time



*p < 0.05 tofacitinib vs PBO; nominal p values, not type 1 error-controlled
[a]Flare is defined as a worsening of ≥ 30% in ≥ 3 of the 6 variables of the JIA core set, with ≤ 1 variable improving by ≥ 30%[1]
[b]Type 1 error-controlled endpoints were tested sequentially as follows: occurrence of disease flare by W44 (primary endpoint); JIA ACR50/30/70 response rates at W44; change from Part 2 baseline in CHAQ-DI at W44. Using this gatekeeping approach, statistical significance could be claimed for the next endpoint only if the prior endpoint in the sequence met the requirements for significance
[c]The JIA ACR30/50/70 response criteria are: 3 out of 6 JIA core set variables improved ≥ 30%, 50%, and 70%, respectively, with ≤ 1 variable worsening by ≥ 30%. In pts with systemic JIA, the absence of spiking fever related to systemic JIA is also required[1]
[d]5 mg BID or equivalent weight-based lower dose in pts < 40 kg
[e]These data are for pts with pcJIA in Part 2 (26-week DB phase); pts with PsA or ERA are not included and were analyzed separately
BID, twice daily; CHAQ-DI, Childhood Health Assessment Questionnaire Disability Index; CI, confidence interval; DB, double-blind; JADAS, Juvenile Arthritis Disease Activity Score; LS mean, least squares mean; pcJIA, polyarticular course juvenile idiopathic arthritis; PBO, placebo; pts, patients; SE, standard error; W, Week

[a]5 mg BID or equivalent weight-based lower dose in pts < 40 kg

[b]Adjudicated events

[c]One SAE of pilonidal cyst repair was coded to surgical procedures instead of infections and was inadvertently not identified as a serious infection. Following adjudication, it was determined that the SAE did not meet opportunistic infection criteria; it is also included in the table as a serious infection

The OLFAS included pts enrolled who received ≥ 1 dose of study medication in Part 1 (18-week OL run-in phase); the DBSAS included pts who received ≥ 1 dose of study medication in Part 2 (26-week DB phase) reported under received treatment; these analysis sets include pts with pcJIA, PsA, or ERA

AE, adverse event; ATE, arterial thromboembolism; BID, twice daily; DB, double-blind; DBSAS, double-blind safety analysis set; DVT, deep vein thrombosis; ERA, enthesitis-related arthritis; ILD, interstitial lung disease; LLN, lower limit of normal; MACE, major adverse cardiovascular event; MAS, macrophage activation syndrome; OL, open-label; OLFAS, open-label full analysis set; PBO, placebo; pcJIA, polyarticular course juvenile idiopathic arthritis; PE, pulmonary embolism; pts, patients; SAE, serious adverse event; ULN, upper limit of normal; URTI, upper respiratory tract infection

ed from these efficacy analyses and analyzed separately. Time to flare was analyzed by the Kaplan-Meier method. Safety was evaluated throughout the study.

Results: 225 pts with pcJIA (n=184), PsA (n=20) or ERA (n=21) were enrolled and received OL tofacitinib in Part 1 (Table 1). At W18, 173/225 (76.9%) pts entered Part 2 (pcJIA [n=142], PsA [n=15], ERA [n=16]). In pts with pcJIA, occurrence of disease flare in Part 2 was significantly lower with tofacitinib (29.2%) vs PBO (52.9%) by W44 (p=0.0041; primary endpoint; Figure 1a). JIA ACR50/30/70 response rates (Figure 1b) and improvement from Part 2 BL in CHAQ-DI (Figure 1c) at W44 were greater with tofacitinib vs PBO. Time to disease flare was greater with tofacitinib vs PBO in Part 2 (Figure 1d). Tofacitinib had a greater effect vs PBO in reducing signs and symptoms of pcJIA, in terms of Δ from Part 1 BL in JIA ACR core set variables at W44 (Figure 1e). From early time points in Part 2, disease activity (assessed by JADAS27-CRP) worsened with PBO but remained stable with tofacitinib (Figure 1f). Safety was generally similar in pts receiving tofacitinib or PBO (Table 2): 77.3% and 74.1% had adverse events (AEs); 1.1% and 2.4% had serious AEs. There were no cases of death, opportunistic infection or tuberculosis.

Conclusion: In pts with pcJIA, treatment with tofacitinib vs PBO resulted in significantly fewer disease flares, improved time to flare, improvements in disease signs and symptoms and physical functioning, and a sustained clinically meaningful improvement in disease activity. The safety profile of tofacitinib was consistent with that in adults with RA.

From Diagnosis to the Establishment of the Labalaba Foundation: My Journey from Surviving to Thriving

Chisa Nosamiefan ,[1] Courtnie Phillip,[2] and Candace Feldman[2], [1]The Labalaba Foundation, [2]Brigham and Women's Hospital, Massachusetts

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: After having my youngest son in 1994, I developed discomfort in my fingers which I ignored. In 1997, I had pericarditis, and two years later, pleurisy. I was diagnosed with lupus at the Cleveland Hospital in Florida about 20 years ago, 4-5 years after my initial symptoms. My initial treatment was inconsistent, because I lived 4 hours away from the healthcare facility, and I did not have adequate health insurance. At this time, my symptoms were frequent fevers, weight loss, abdominal pain, and generalized myalgias. I took acetaminophen or naproxen and medicines like Zantac for the abdominal pain.

Treatment: I moved to Boston in 2008 and I started a consistent treatment regimen: prednisone, hydroxychloroquine, omeprazole, azathioprine, lisinopril, nifedipine. My disease also progressed. I experienced increased myalgias and developed blood clots and pulmonary hypertension. I continued to experience pericarditis and pleurisy. I was switched from azathioprine to mycophenolate mofetil, and warfarin and gabapentin were added. Abatacept was tried for my joints but I developed a rash. I was switched to belimumab.. Finding the right cocktail of drugs required the masterful skill of my healthcare team to move me from barely surviving with lupus, and now, well on the way to thriving despite lupus.

Maintenance: After setbacks to my health between 2008-2015 (falls, increased pain, hospitalizations, difficulty coping, and having to stop work) I began to improve. I earned my master's degree and started a consulting practice. I became active again with my Christian ministry and my stress level lessened, which seemed to be tied to reduced lupus activity. As a woman of Nigerian descent, it occurred to me that I had never met another Nigerian living with lupus. If lupus is prevalent in people of African descent in the US then it must be present in Africa and in Nigeria, the most populous African nation. I embarked on a fact finding trip and then started The Labalaba Foundation for Lupus Awareness and Advocacy in Nigeria. I also began to participate in Boston-based research studies and became a member of the Patient Advisory Board of the largest lupus center in New England.

Figure 1. Timeline of my journey with lupus, from my initial symptoms until the present time

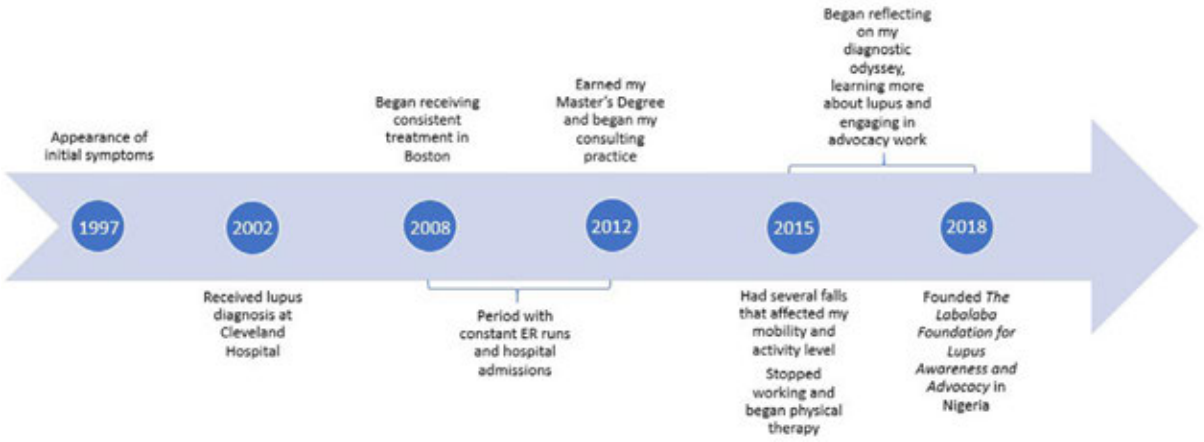

Figure 2. *The Labalaba Foundation for Lupus Awareness and Advocacy* programs and initiatives

Think Lupus Campaign	• Offers training to primary healthcare professionals - doctors, nurses, social workers and clinics to sensitize them to SLE symptoms and encourage the testing and consideration of a lupus diagnosis sooner
Erase Lupus Awareness Program	• Lupus educational workshops and seminars to raise awareness and foster early detection of lupus • Targets schools, community organizations, religious houses of worship, general public
The Pill Box Program	• A prescription assistance program that aims to to keep lupus patients, who are unable to afford their medications, on their medication and stable • It costs about 18,000 Naira ($50) per month for maintenance and 80,0000 Naira ($220) per month for a critical lupus patient.
"The Frank Talk"	• Caregivers roundtable meetings for support and discussions about the unique challenges that spouses, parents and others who care for lupus patients face on a daily basis
Free Individual and Family Counseling	• Relate Africa has a team of highly qualified professionals and has partnered with The Labalaba Foundation (TLF) to provide free counseling for lupus patients and their families
The Odelia Academic Scholarship for Pediatric SLE	• TLF annually awards an academic scholarship to a child living with lupus in honor of Odelia, an amazing girl who fought a hard fight with lupus

Chisa Nosamiefan, patient and founder of The Labalaba Foundation, pictured with Labalaba Champions in Nigeria

Quality of Life: My quality of life has drastically improved over the past three years. I am more active at home, I have socially re-engaged, I go shopping, and I travel. For many years I was unable to do this. Most amazing is that I am now a lupus advocate, educator and champion. Since I began helping lupus patients I have not been hospitalized. Lupus is a complex disease and the complexity goes beyond the clinical symptomatic manifestations. Each lupus manifestation is influenced by a patient's social circumstances and access to good medical care. The health and wellbeing of lupus patients may improve when definite steps are taken to address stress factors and other lifestyle triggers. Through my own journey and the creation of The Labalaba Foundation, I have taken charge of my health and hope to help others do the same.

Living and Adjusting to a Diagnosis of Rheumatoid Arthritis (RA) with an Interdisciplinary Team

Marie-Claude Beaulieu ,[1] Julie Robindaine,[2] Hélène Tremblay,[2] Stéphanie Demers Dubuc,[2] Patrick Liang,[3] and France Gervais[2], [1,2]Quebec, Canada, [3]Universite de Sherbrooke, Quebec, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: RA affects all age groups and all occupational settings. I was diagnosed at age 58, while I was still very active at work, at sports and as a grandmother. I had to adapt to this new reality in several ways. Initially, the presentation was atypical (polymyalgia-like), and the disease was difficult to control with steroids. During steroid tapering, severe limitations in my hands, wrists, shoulders, ankles and feet associated with subtle hand synovitis (ultra sound exam negative once) made my rheumatologist suspect RA despite normal biomarkers. I started treatment with a combination of hydroxychloroquine and methotrexate injection, failed an anti-TNF and finally got sustained improvement with the addition of tofacitinib.

Treatment: I can attest how much an interdisciplinary team helps: rheumatologist, nurse, occupational therapist (OT) and physical therapist (PT) working with each other. Their support was especially important at the beginning of my disease, with the possibility to phone and ask questions to the specialized nurse to reduce my stress and improve my adherence to treatment. To overcome physical limitations, an OT provided orthotics for my hands, and several useful tips for energy conservation and activities of daily living. A PT gave me valuable tips and exercises to do at home. It would be particularly helpful if all patients should have access to these services early in their disease, although a supporting team may be important over all the disease stages, and particularly during flares or loss of efficacy of drugs. Our Faculty of Medicine in Sherbrooke developed a special teaching clinic “CURE” (OT and PT services) to give low-cost access to these services for patients without insurance. When receiving a diagnosis of arthritis, a grieving process ensues, a reorganization of daily activities is required and a lot of resilience to accept these changes is needed! I had to stop working temporarily and then returned to work progressively with adaptations and changes. The support of my rheumatologist was most important in this process.

Maintenance: My rheumatologist offered several effective treatments to slow down the progression of the disease, and we found together the winning combination (with trial and error). The availability and support from the interdisciplinary team, family and co-workers is very important, as there are good and bad periods. I need to keep hope, continue to be active, allow for rest periods, eat healthy and take the medication despite sometimes annoying side effects. Daily mindfulness meditation (offered to interested patients in our clinic) helps me a lot.

Quality of Life: It is very encouraging to regain control of one’s life through better control of the disease and to feel better and lead an almost normal life. However, I have to remain vigilant and be careful of infections since my immune system is weaker with the medication. The initial frequent consultations, regular check-ups, discouragement periods over my limitations and the frequent medication adjustments made me realize the importance of working as a team where the patient is a partner in care. Information about the disease and its treatments is important for the patient and health professionals as well.

Bridging the Gap: Leveraging Social Media to Improve Patient Support; Build a Path to Collaborative Medicine

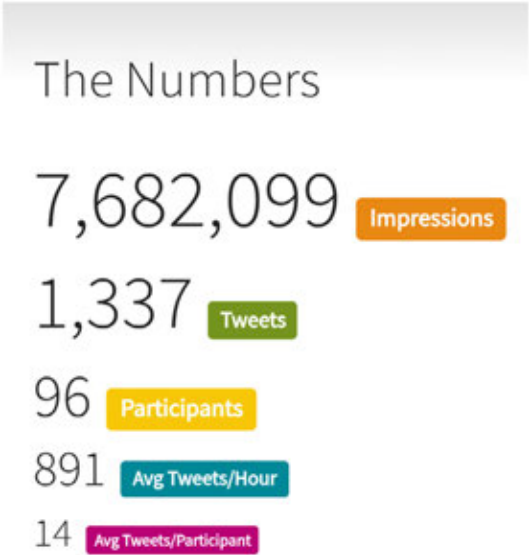
Carlene Harrison ,[1] and Tiffany Peterson[1], [1]Lupus and Allied Diseases Association, Inc.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: Due to the heterogeneous nature of disease presentation, when diagnosed with Systemic Lupus Erythematosus (SLE) patients often experience overwhelming feelings of isolation. This comes as a result of not knowing there are others, that may be experiencing the same types of symptoms. These sentiments proved true for two patients living six hours apart who would come to meet years later through their individual quests to attain more knowledge about SLE and find support from others facing the same challenges they met daily. Both Carly and Tiffany, patients diagnosed with SLE and secondary illnesses including Raynaud's Phenomenon, Fibromyalgia, and Nephritis within a year of each other, would come to connect years later through an online patient led community.

After spending years in search of resources for patients, Tiffany founded the online community #LupusChat to offer educational information about SLE to patients and provide a safe space for patients to feel supported. Through the years the community grew to include patients, advocates, physicians, scientists, industry leaders, and other partners in healthcare.

Treatment: SLE patients are treated with traditional interventions including immunosuppressants, corticosteroids, and antimalarials. Considerations are oftentimes only made in terms of treating the physical symptoms of the disease. This approach doesn't typically account for mental or emotional complications associated with SLE. This leads to a disconnect between patients and healthcare professionals, where patients feel physicians aren't empathetic to their needs outside of lab results and physicians complain of low treatment adherence and lack of interest in the patient's own medical care. Through online discussions with topics ranging from interpreting lab test results and connecting with doctors to becoming advocates, #LupusChat works to connect all healthcare stakeholders.



Maintenance: Both Tiffany and Carly found solace through the connections made from this online community. Starting out as solely a member of the community, Carly now joins Tiffany and two other Patient Advocates in curating discussions and sharing health literacy tools with the chronic illness community. They also work with groups like the patient founded national non-profit organization, Lupus and Allied Diseases Association, Inc. (LADA) on advocacy initiatives. This includes working with legislators at the state and federal level, attending and speaking at conferences, and educating patients on the importance of clinical trial participation.

Quality of Life: These patients have not only become advocates themselves, but have helped others to become empowered. Their roles in the Lupus community have also led them to become more adherent to their own treatment plans. They receive testimonials from other patients about the impact the community has had on their lives and how things like daily community medication reminders have impacted their health. Healthcare professionals have also become more involved in patient outreach and often seek their assistance in learning to use social media as a tool to educate patients. Through social media engagement, they amplify the Patient voice and help foster healthcare partnerships.

Reclaiming Medical Autonomy Through Healthcare Advocacy

Christele Felix[1], [1]LADA, Rosedale, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: When I received my diagnosis in 2007, I had never heard the word Lupus before and had no idea what it meant. I don't remember having any reaction to the news, because I did not know to be alarmed by the gravity of the situation. Newly diagnosed patients often cannot imagine the extent to which this health issue will take over their lives. I was diagnosed at 18 years old, while trying to juggle with young adulthood and an ambitious college career. I would soon discover that there was a lot to learn in managing a complex and long term condition like Lupus. In doing so I'd learn to raise my voice and help others raise theirs.

Treatment: Evolving as a chronic patient takes a lot of reevaluation on patients' part of what their priorities are. It takes some time, and is an ongoing experience, to learn how to appropriately manage stress and energy levels, in addition of staying on top of a complex treatment regiment and coordinating with a health team of multiple specialists. Very often, patients also learn a lot about patients' rights issues. I got involved in a support group as a quiet participant, observing and learning until I found my own voice. Pretty soon, and bolstered by the positive doctor-patient interactions with my rheumatologist and gastroenterologist, I became very vocal about patient-centered care and patient-centered research. My goals as I navigated this new life with chronic illness were to improve quality of life and make a better future for myself and for people living with similar conditions.

Maintenance: My background in research and education made it easier to piece together the medical jargon related to Lupus in medicine and research, and I have enjoyed educating myself so that I can educate others as well. As a result of this, I took a more active role in my care; my health and my quality of life have improved dramatically. My new-found drive to advocate on behalf of myself and others has influenced my personal health in a great way. Patients' motivation can falter in the face of such a long term condition, and it often takes years to figure out the right approach that works for each person. As patients find their voices and stand up for their rights and the rights of patients like them, they may discover that their personal health also improves for the better.

Quality of Life: My advocacy sustains me, both as an individual and as a patient. I believe that it is very important to let patients know that they have a voice that they can use if they so wish. Patient education starts with the patient itself, then gradually evolves to benefit others. As part of a community of patients and patient advocates, we give each other support and encouragement, as well as medicine reminders and helpful tips for people living with Lupus. Additionally, I constantly seek to have conversations with doctors and health professionals on ways to engage patients and improve their quality of life.

Disclosure: C. Felix, Aurinia Pharmaceuticals Inc, 5.

Race for Relapsing Polychondritis Drives Awareness, Accelerates Research, and Improves the Quality of My Life: How Motorsports Help Me Overcome the Hopelessness of an Incurable, Rare Disease

Nancy Linn[1], [1]RPASF Inc.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: Like many other patients with a rare disease, I felt relieved when I finally received a diagnosis: relapsing polychondritis or "RP". However, once I started researching the disease, the scant information available wasn't encouraging. Most sources described RP as fatal – a shock to read at 54 years of age. Through a Facebook group for RP patients, I was introduced to physicians, specialists, and researchers, all of whom became essential for our future collaborations benefiting RP patients. However, I soon realized that my communications with doctors and other patients all revolved around RP, and I wanted a forum where we could engage outside the hopelessness of an incurable illness.

Treatment: In 2016, I founded Race for RP, an organization that partners with motorsports drivers and teams to support research, awareness, and quality care for RP patients. Since then, we've seen our logo zip across the finish line first, but the real victories have been solidifying the ties between care providers. For example, at one race, we invited the leader of an autoimmunity institute to have the organization's logo on a professional sports car. He accepted, and that car won the race, garnering international publicity and paving the way for future partnerships. At the same time, engaging with my community outside of hospitals and the Facebook group provides support centered on positive actions, like riding my bike for our cycling fundraisers.

Maintenance: In between getting news of more cartilage damaged, Race for RP gives me purpose and hope. Over Memorial Day Weekend, I was on my way to a friend's wedding instead of watching one of our professional drivers compete in a world-renowned automobile race – with our logo on the car! As I traveled to the wedding, I watched footage of the race on my phone. After losing cell service, I listened on satellite radio. Thankfully, the last lap was finished before the wedding reception, or I may have had to sneak into the bathroom to hear who won. The awareness generated by Race for RP's drivers and teams has been wonderfully distracting from the symptoms of the disease and sparked many positive, fun conversations with other autoimmune disease patients and motorsports enthusiasts. Race for RP has also improved my physical health through its collaboration with other organizations, which has provided me (and other patients) with access to specialists I never could've found on my own.

Quality of Life: Race for RP has greatly improved my quality of life, and one of my proudest moments was after last year's ACR/ARP Annual Meeting. There, Race for RP provided funding for 2 Exhibitor booths and hosted 2 affiliated educational events with highly regarded rheumatologists and epidemiologists. These awareness-generating events helped make RP the most searched disease (on a top search engine) in the host state. I feel this same pride when

Art for Arthritis: A New Approach

Jennifer Walker[1], [1]Global Healthy Living Foundation, San Antonio, Texas

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: Chronic 24/7 pain, fatigue, and swelling are all part of my journey with rheumatoid arthritis (RA) and Axial Spondyloarthritis (AxSpa). My RA is moderate to severe, and my AxSpa has taken 7 years to be properly diagnosed resulting in a loss of 3 inches in height, stenosis, osteophytes and a broken piece of disc floating near my spine. My experience is unique with only 1% of the population experiencing RA and 2% experiencing AxSpa. The coexistence of these diseases in one patient is exceptionally rare.

‘Spots’ - digital art

‘Rocks in a paper boat’ - digital art

Treatment: I am an expressive person finding myself discussing my diseases a lot due to the need for accommodation or pain levels. Constant exhaustion, lack of sleep, high pain levels, RA flares, bouts of back pain and episodes that leave me without the capacity to function is often too much for words. I found an amazing outlet in art to not only

'Unraveling' - digital art

express my journey but to reach out to others. It gives me the ability to look back on a piece of artwork and remember the pain and my resilience and power in the face of intense circumstances. I'm able to process my grief over lost abilities, deteriorating health, and describe my journey through art in a more universal way than just words. It fulfills my need to be creative but also my need to take control of my life and body in a way that makes sense, allowing me to accept where I am and heal. Art reminds me how powerful my mind and heart are, so I can pick myself up one more day and living for good instead of being lost in the pain. It helps me to listen to my body, enabling a more flexible reaction to pain episodes or flares. It gives me the chance to process what is happening so I don't fight the disease process; facing my body and my life with courage.

Maintenance: Creating art that expresses my pain and health struggles helps me trust my body. I began to publish these pieces on social media and the response has been overwhelming. Reminding me that I'm not alone on this journey and my body is telling the truth. Listening to my body in the first place got me diagnosed, getting me the medical help that I need. After being diagnosed with RA and fibromyalgia 9 years ago, I was angry and frustrated ending up in the hospital from a panic attack. The last 4 months have been an intense struggle and expressing that through art has helped me to admit how bad my body and my pain levels have been when I wanted to run away from the downswing

in my health. As a patient with multiple chronic illnesses I go through a cycle of acceptance and grief. My health and body took an upturn when I learned to not fight the cycles of flares, pain and disease.

Quality of Life: Listening to my body for cues allowed me to function more because I rested or pushed when needed. I learned my patterns and strengths, allowing accomplishing more when I do have energy without overdoing it. These diseases won't go away and I no longer fight that, increasing my quality of life. Because I have accepted my body I can also create art in a very vulnerable and open way that reaches out to others. My art allows me to show my life and struggles in a way that makes the abled folks stop and take notice. Visual representation helps other patients point to a piece that validates their pain and creates better connections with their loved ones. Patients need to know that what we experience is normal - my art helps me to see that so I can cope better daily.

This piece represents the places on my body that are always in pain. This pain causes constant fatigue and the need to adapt. I created this piece right before I was diagnosed with AxSpa. I had a lot of frustration because my lower back pain was not really acknowledged or treated. After diagnosis this reminded me to always trust my body's signals about something being wrong. This is piece #1 in my fatigue series. This piece received 490 likes and 409 shares on the CreakyJoints Facebook page.

This piece helped me express frustration from intense pain, a rough day at work, and some intense gastro issues that have been amping up lately. It got over 575 views on my Facebook page.

This is #10 in my fatigue series. This series takes input from other people with autoimmune diseases and illustrates what fatigue feels like for them so they can use these images to speak with loved ones and/or HCPs. I love this piece.

Coming to Terms with Lupus: How Learning to Listen to My Body and Letting it Tell Me What to Do Improved My Quality of Life

Debbie Schwartz,[1] and Diane Gross[2], [1]Georgia, [2]Lupus Research Alliance, New York, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: A diagnosis in my teens of epilepsy resulted in shifting my dreams of being a teacher, but after successful brain surgery I began living what was a normal life. But medical issues continued to come and go. I went to the hospital several times and no one could figure out what was wrong. In fact, some did more harm than good. A cardiac catherization led to emergency surgery. Then my husband and I decided to find an answer, no matter what. After visiting many specialists, we found a rheumatologist who listened. I was tested for leukemia, MS, and others, but not lupus. Meanwhile, I was swollen and sore all the time with severe fatigue and weakness throughout my body. Finally, I asked the rheumatologist to test for lupus. He still didn't think it was lupus, but after more tests I was diagnosed. Listening to my body and my own instincts led to a diagnosis!

Treatment: After being diagnosed with SLE and other autoimmune diseases my rheumatologist started me on several medications and a couple worked. I began swimming and playing volleyball to keep moving. Then I moved

and the first doctor I met pushed chemo, even though I was in remission. That was the last day I saw this doctor. I contacted a patient advocacy group that pointed me to a new rheumatologist who listened to me and suggested keeping the status quo. After a year, she started to wean me off some of the medications. I learned you can find the right doctor by searching and speaking up.

Maintenance: As my rheumatologist decreased some medications, my neurologist increased some vitamins and minerals. Their working together and sharing information is key to my mental and physical health. I have learned to deal with three main issues:

- Sensitivity to sunlight
- Burning of my face
- Body aches

These all got more severe since my lupus diagnosis and I took on a new perspective of life through this challenge.

Quality of Life: I have learned that in order to succeed through my day, I must listen closely to my body. For instance, despite loving the sun, I now avoid it as much as possible. I have learned to always wear a hat, sunglasses and use a lot of sunblock with high UV protection. Often, I just stay inside. When I feel my face burning, I don't go out. A cool, wet washcloth on my cheeks and eyes helps the symptoms subside. The key is to feel it coming on. If I catch it early, I can usually continue my day without much impact. If I'm out, I find a cool, dark place to minimize the flare. Part of my daily life is dealing with different aches - fingers swelling, joints aching, body fatigue. Every day is different, and when I push myself, I pay for it the next day. I now know that when my body tells me to slow down, I must listen. I don't like to stop, or even slow down, but I know that in order to live with lupus I have no choice. Swimming is one way I have adapted to this new normal. The water helps support my body and relaxes the pain. Walking our dogs is another way to exercise but not put too much stress on my body. Every day I listen carefully to what my body is telling me. What can I do today, what should I do differently? Think back to yesterday…what did I do, and how is it affecting me today? Understanding my body has been one of the most beneficial things in my fight with lupus.

Framework for Enhancing Patient-Physician Communication in the Context of Rare Disease

Ida Hakkarinen,[1] and Kaitlin Quinn[2], [1]Vasculitis Patient-Powered Research Network (VPPRN) / Member, Vasculitis Foundation, Greenbelt, Maryland, [2]Division of Rheumatology / Department of Medicine / Georgetown University Medical Center, Washington, District of Columbia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: For over two years, I experienced a variety of symptoms including: joint aches, sinus congestion, shortness of breath and chronic cough. An episode of hemoptysis led to laryngoscopy and a diagnosis of subglottic stenosis. Test results showed a high ANCA titer. Referral to a rheumatologist resulted in a diagnosis in 2012

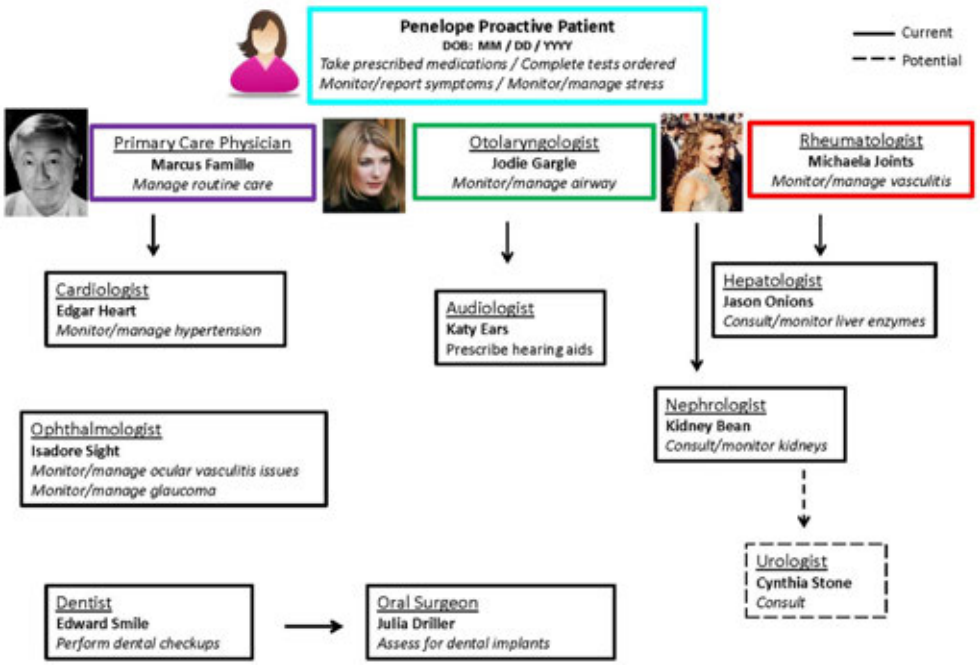

Figure 1. org chart

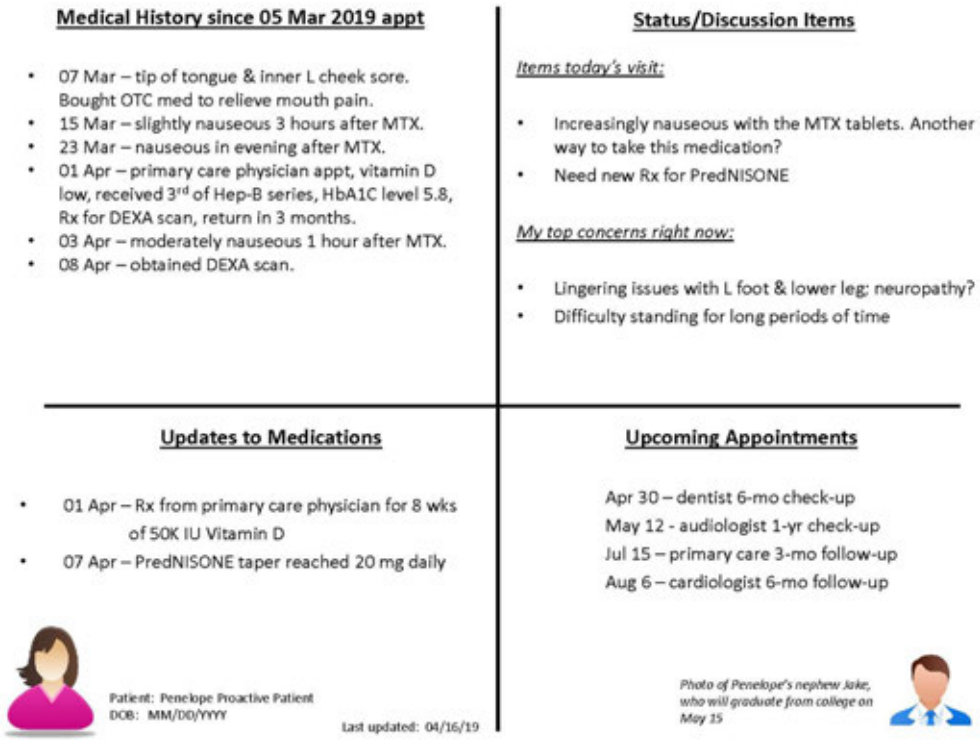

Figure 2. quad chart

of Granulomatosis with Polyangiitis (GPA), a rare disease with estimated incidence of 10-12 per million in the U.S. (Banerjee and Grayson, 2017). I've been hospitalized twice with relapses and received serial rituximab.

Treatment: To provide a framework for enhancing patient-physician communication, I applied work tools I use regularly: 1) an org chart, 2) a quad chart, and 3) a risk chart. I made my org chart about 6 months after diagnosis, updating

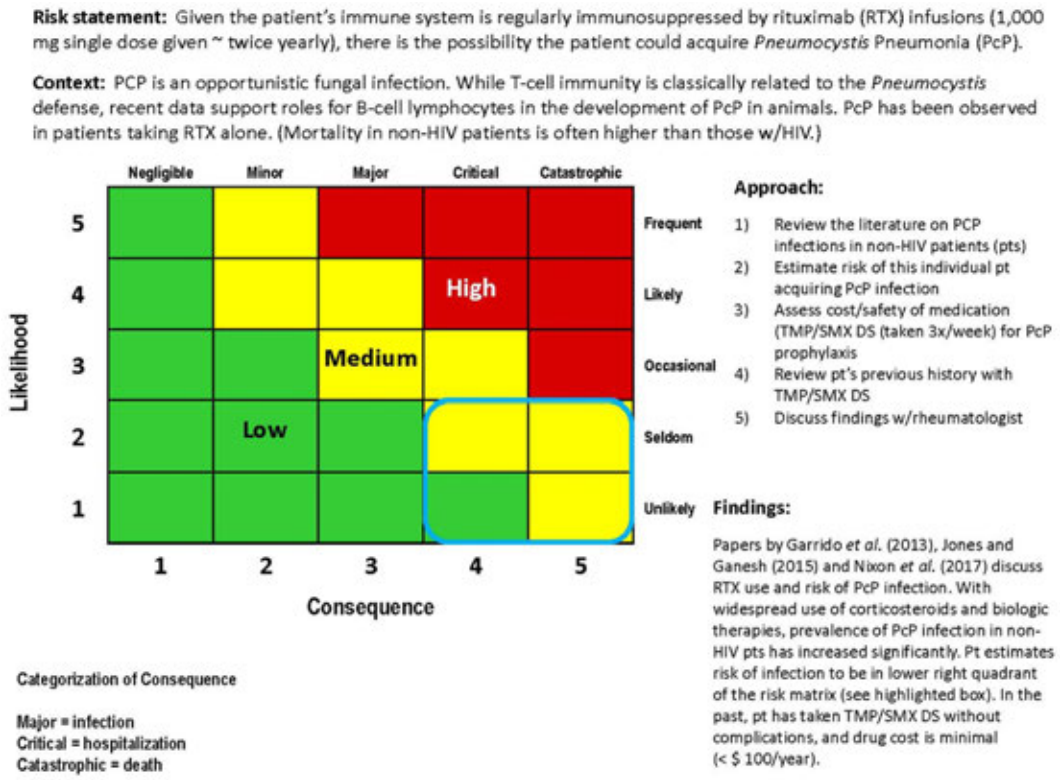

Figure 3. risk chart

it in 2018 to add photos. The chart lists my physicians, their specialties, and their roles in managing my health. I use a quad chart as a briefing tool for clinic visits to list medical history, updates to medications, topics I want to cover, and upcoming appointments. I made a risk chart to assess the likelihood of acquiring *Pneumocystis* pneumonia given I was having rituximab infusions. I used the chart with my rheumatologist in the shared decision-making process regarding trimethoprim/sulfamethoxazole for prophylaxis.

Maintenance: KQ: I first met this patient in 2015 during my rheumatology fellowship and became her clinical rheumatologist in 2017. The charts she provides help to inform and enhance our communications and coordination. The org chart provides an overview of other specialists involved in care and the quad chart highlights her main concerns to be discussed at the clinic visit. Additionally, her quad chart always includes a picture of a family member so that we discuss other important events going on in her life. These charts are an easy way to make sure we are addressing the patient's health needs in an organized and efficient manner.

IH: Use of these tools has positively impacted communication with my physicians. With my org chart, a new doctor may see at a glance my medical team, as well as their faces. The quad chart provides a systematic way to organize my thoughts prior to a clinic appointment. The risk chart provides an assessment of benefits and risks for a given course of action as an aid to discussion with my physician.

I have a rare disease that all physicians learned about in medical school but most never experience in clinical practice. Consistent briefing tools for my clinic visits enhance the efficiency and effectiveness of the patient-physician interaction.

Quality of Life: I'm grateful my GPA remains quiescent. I appreciate my team of medical professionals who work in partnership with me to monitor and treat this rare, chronic, and potentially life-threatening disease. Shortly after diag-

nosis, I became a member of the Vasculitis Foundation, a patient advocacy group. In 2014, I joined a natural history study in the Vasculitis Translational Research Program at the National Institutes of Health. My six-word memoir is: “Thanks to research, living with vasculitis.”

Journeying Towards Hope: Making a Difference in The Lives of Lupus Patients in Mauritius

Dalilah Kalla[1], [1]Lupus Alert, Rose Hill, Plaines Wilhems, Mauritius

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: Growing up in the small island of Mauritius, I received the unexpected diagnosis of lupus at the young age of 13. The journey that followed was an arduous one filled with perseverance and survival. During these past 22 years, I have been overwhelmed with feelings of hopelessness. The hardest aspect of having lupus as a teen is the inevitable sense of isolation from the normal world. Living with lupus is challenging and disturbing from the moment of diagnosis. There were times when my condition did not allow me to attend school or pain and other physical restrictions prevented me from participating in school activities. I felt frightened, angry and depressed but with the support of my mother, I soon realised that living a life paralysed with fear was not living at all. Gradually, I had to accommodate my life to this dreadful disease, to adjust to the impact of strong daily medications and to resolve stress, pain, depression and fatigue.

Treatment: It took me two to three years to get to grips with lupus, but my grasp was strengthened by contact with other people who have the disease. Life with lupus is a Journey. Throughout the years, I found out that sharing my story with others helped in ending the isolation and depression created by the disease. I, therefore, made it a priority to

Educating others and raising awareness of lupus will save lives. The Quality of Life Programme

The Quality of Life Programme has been established to assist those patients who have needs not covered by community resources of assistance. We consider requests for help with home health care, child care, certain medications, transportation, personal care items or other products and services which will help alleviate some of the trauma of living with Lupus.

Spread Awareness

Raising public awareness of lupus to increase understanding and support for those affected by this autoimmune disease.

educate others and raise consciousness about lupus and other autoimmune diseases. Passionate about this awareness, my goal has been to ensure that all the work achieved ultimately benefited every individual affected by Lupus.

Maintenance: In 2000, my mother, Babs and I founded Lupus Alert, a non-profit organization in Mauritius providing moral, emotional and financial support to people living with lupus as well as spreading awareness of the disease to the public. Our goal is to provide lupus education to others including teachers, friends, family members and even health and government professionals who are not aware of its symptoms and complications. Lupus Alert also provides patient services and community awareness promotion to advance research initiatives.

Quality of Life: Lupus awareness in Mauritius has become a passion for me and all the work achieved has ultimately benefitted every individual who is touched by this disease. As a patient, I encourage other patients to accept and talk

openly about their illness. By providing a network of support for patients throughout the island I have been able to reach out to patients and their families teaching them how to manage and cope with lupus and provide the best opportunity for improving quality of life for patients and for controlling morbidity and mortality. In Mauritius, it has been particularly difficult to make the Health Authority recognise lupus as a significant public health issue. Through a wide awareness campaign, we have been able to create a synergy which today responds to the needs of those affected by this destructive illness. The mutual confidence between physicians and patients has improved and proved to be a large element in the effectiveness and the economy of healthcare. The next step now is to continue enhancing the progress made in creating local awareness about the disease and strengthening the position of Lupus Alert as a beacon of hope and support for the entire community of lupus patients in Mauritius and beyond.

The Practice of Reiki and Meditation in Maintaining Medical Compliance and Decreased Anxiety in an Adult with Juvenile Rheumatoid Arthritis

Shannan O'Hara-Levi [1], [1]Staten Island, New York

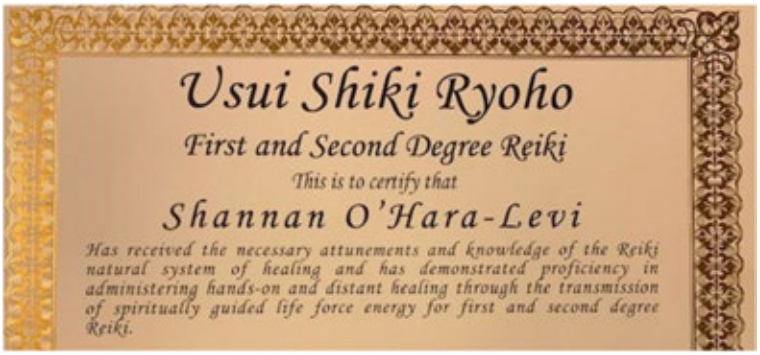
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Perspectives Poster Session
Session Type: Poster Session (Sunday)
Session Time: 11:30AM–1:30PM

Background/Purpose: Up until a few years ago, my 30+ year journey with Polyarticular Juvenile Rheumatoid was treated mostly with medication management alone. I was diagnosed at age 3 with Polyarticular Juvenile Rheumatoid Arthritis. At time of diagnosis I was expected to be in a wheelchair by age 6. With the help of NSAIDs, prednisone and Gold Injections, this was not the case. Eventually, I began trials of various drug cocktails that included those previously listed with the addition of DMARDs and a rotation of various supplements including shark cartilage and vitamins. The ever changing trials of these cocktails continued until my mid-teenage years when biologic medication came to market. After being unsuccessful long term on any one medication, disease progression continued and I underwent bilateral shoulder replacement surgery in 2018. The integration of additional treatment options such as diet, exercise and mindfulness was the logical next step in my treatment journey.

Treatment: Through desperation in search of a better quality of life due to the progression of my illness, I was introduced to Reiki and meditation. I have added meditation and Reiki into my care plan in addition to current medication treatments and surgical interventions. Meditation and Reiki have enabled me to become more empowered and less fearful of the future of illness. I have studied and become certified as a Reiki Practitioner as well as regularly meditate through various Apps, walking mediation and mindfulness practice.

Maintenance: In order to fully feel the benefits of mediation and Reiki, I practice regularly as well as attend classes, certifications and educate myself about furthering my practice in this approach. By ensuring that mediation and Reiki are a regular part of my current lifestyle, I am able to be more present in the care of my illness and work better with my medical team. This also helps me stay more compliant with medications and medical appointments as my anxiety has decreased regarding these major parts of my life.

Shannan with JRA



Reiki Certification

Meditation Tools

Quality of Life: Although physical disease progression continues, I have had a better sense of control of fear and anxiety related to my illness. By practicing Reiki, I feel empowered and more peaceful. Regular meditation has allowed me to reflect on my disease and anxiety related to it. Without incorporating these practices into my treatment plan, I believe that my illness complications may have worsened. These practices have allowed me peace and acceptance with what is and the ability to play a strong, more active role in my disease management on a daily basis.
