SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient satisfaction after total hip (THR) and total knee replacement (TKR) is a core outcome selected by the Outcomes Measurement in Rheumatology (OMERACT), yet up to 30% of THR/TKR patients are dissatisfied. Improving patient satisfaction is hindered by the lack of a validated measurement tool that can accurately measure change.

Methods: This was a retrospective analysis using prospectively collected data of 10011 patients undergoing unilateral THR and TKR between 5/ 2007 and 2/2011 in The Hospital for Special Surgery arthroplasty registry. We tested psychometric properties of a proposed satisfaction instrument composed of 4 primary questions rated on a Likert scale, scored 1-100 **(Figure 1)**. Validity was assessed through correlation with similar constructs. We tested reliability with Cronbach's α, and sensitivity to change was assessed through the change corresponding to minimal change or a large change in two global questions, satisfaction with TJR outcome and Quality of Life (QOL).

Results: We included 4,796 TKR and 5215 THR **(Table 1)**; 90% were somewhat/very satisfied with pain relief, and almost 90% of TKR and 95% of THR were somewhat/very satisfied overall. Satisfaction correlated moderately with pain relief (TKR ρ=0.61, THR ρ=0.47) and function (TKR ρ=0.65, THR ρ=0.51) at 2 years; there was no correlation with baseline values. Reliability was demonstrated with overall Cronbach's alpha > 9. HOOS/KOOS improvement of >30 points corresponds to a mean Satisfaction score of 93.25 (11.53) after THR and 90.37 (SD 13.76) after TKR. When HOOS/KOOS pain and function were divided in to quartiles, increasing relief of pain and functional improvement increased the strength of the association of 2 core domains with satisfaction.

Figure 1. Patient questionnaire

1) How satisfied are you with the results of your knee/hip surgery in the following areas? (Please circle one answer for each question).					
	Very Satisfied	**Somewhat Satisfied**	**Neither Satisfied nor Dissatisfied**	**Somewhat Dissatisfied**	**Very Dissatisfied**
a. For relieving pain?	☐	☐	☐	☐	☐
b. For improving your ability to do housework or yard work?	☐	☐	☐	☐	☐
c. For improving your ability to do recreational activities?	☐	☐	☐	☐	☐
d. Overall, how satisfied are you with the results of your knee surgery?	☐	☐	☐	☐	☐

2) How much did your knee/hip surgery improve the quality of your life?					
More improvement than I ever dreamed possible	Great improvement	Moderate improvement	A little improvement	No improvement	The quality of my life is worse
☐	☐	☐	☐	☐	☐

Table 1. Demographic factors by TKR/THR including satisfaction score and quartiles.

	Overall (N=10011)	TKR (N=4796)	THR (N=5215)	p-value
Age	67.0 [59.0, 74.0]	68.0 [61.0, 75.0]	65.0 [58.0, 73.0]	<.0001
Sex				
Female	6397 (59.4%)	3248 (62.5%)	3149 (56.5%)	<.0001
Male	4378 (40.6%)	1952 (37.5%)	2426 (43.5%)	
Race				
Asian	53 (0.5%)	28 (0.5%)	25 (0.5%)	
Black	440 (4.1%)	256 (4.9%)	184 (3.3%)	
Hispanic	224 (2.1%)	134 (2.6%)	90 (1.6%)	<.0001
Native/Pacific Islander	17 (0.7%)	10 (0.2%)	7 (0.1%)	
Other	242 (2.3%)	143 (2.8%)	99 (1.8%)	
White	9788 (90.9%)	4620 (89.0%)	5168 (92.7%)	
SF-12 PCS	33.28 [28.0, 38.8]	33.5 [28.4, 39.0]	33.01 [27.58, 38.6]	0.001
SF-12MCS	53.18 [42.5, 60.7]	53.7 [43.6, 60.9]	52.72 [41.58, 60.43]	<.0001
Charlson Comorbidity Index	0.0 [0.0, 1.0]	0.0 [0.0, 1.0]	0.0 [0.0, 0.0]	<.0001
KOOS Pain Score	47.2 [37.5, 58.3]	47.2 [37.5, 58.3]	----------	---
KOOS Function Score	52.9 [42.7, 66.2]	52.9 [42.7, 66.2]	----------	---
HOOS Pain Score	45.0 [35.0, 57.5]	----------	45.0 [35.0, 57.5]	---
HOOS Function Score	48.5 [37.5, 61.8]	----------	48.5 [38.2, 61.8]	---
ASA Status				

Conclusion: Satisfaction with THR/TKR can be measured with 4 primary item questions. Moderate correlations with pain and function confirm that satisfaction is a separate construct. This satisfaction measure can be included in a TJR core measurement set for TJR trials.

Abstract Number: 0416

Global Management of Patients with Knee Osteoarthritis Begins with Quality of Life Assessment: A Systematic Review

Josep Verges ,[1] Marianna Vitaloni,[1] Rosa Sciortino,[2] Maritza Quintero,[2] Marco Bibas,[1] Jordi Monfort,[3] Francisco de Abajo,[4] Marco Matucci-Cerinic,[5] Patrick du Souich,[6] Ingrid Möller,[7] Guy Eakin,[8] and Angie Botto-van Bemden[8], [1]Osteoarthritis International Foundation, Barcelona, Spain, [2]De los Andes University, Merida, Venezuela, [3]Hospital del Mar, Barcelona, Spain, [4]Universidad de Alcalá, Madrid, Spain, [5]University of Florence, Department of Medicine, Florence, Italy, Florence, Italy, [6]University of Montreal, Montreal, Canada, [7]Poal Institute, Barcelona, Spain, [8]Arthritis Foundation, Atlanta

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Knee OA (KOA) associates with remarkable functional restrictions due to pain that seriously affect social and emotional well-being, reducing the quality of life (QoL). The identification of therapies and factors that influence QoL in KOA patients may mitigate the clinical, economic, and social burden of this disease. Thus, the assessment of QoL in KOA, and individual factors associated has a great interest in research and clinical practice. Still, a general recompilation of these data is missing. Our aim was to recapitulate the existing information on QoL in KOA patients as an international tool to raise awareness on their condition and guide future actions for patient's management.

Methods: We conducted a systematic review examining the breadth of the literature regarding the QoL in patients with KOA (up to 2017). We identify articles in MEDLINE, EMBASE, Cochrane, and PsycINFO using relevant. All articles were reviewed for inclusion by 3 independent reviewers. QoL domains and items relevant to patients with knee OA were extracted. Inclusion criteria were QoL compared to one or more demographic factors (age, gender), lifestyle factor (functional independence), or comorbidity factor diabetes, obesity) or a control group. The quality of included studies was assessed using a quality appraisal tool.

Results: We retrieved 610 articles, 62 fulfilled the inclusion criteria. The instrument used to assess QoL were SF-36 and EQ-5D. The participants' mean in the studies was 561, the majority were female, the mean age was 63 years. KOA patients report a worse QoL compared to a control group, having women a worse QoL than men. Obesity, little or too much physical activity correlate with worse QoL. Higher educational level and mindfulness can improve QoL while poverty, physiological distress, depression and having dysfunctional families can reduce it. The delivery of a knee self-management program by health professionals can improve QoL. Surgical interventions result in good outcomes but the results were influenced by individual factors.

Conclusion: This is the first review pertaining to QoL in KOA patients. KOA has a strong impact on QoL. Individual factors (sex, weight, exercise, mental health, education) can influence QoL. These factors affect treatment outcomes and should be considered for a better patient's management. These data are a valuable tool for health professionals,

to better understand the disease and to implement a more adequate standard of care. This study was coordinated by representatives of patient organizations aiming to shed light on OA patient's condition and the need for a broader evaluation of the individual and human factors affecting their QoL.

Abstract Number: 0417

Contribution of Pain Relief to Function, Fatigue, and Quality of Life When Inflammation Is Controlled in Patients with Rheumatoid Arthritis

Mart A.F.J. van de **Laar** ,[1] Janet Pope,[2] Yvonne Lee,[3] Bruno Fautrel,[4] Kei Ikeda,[5] Amanda Quebe,[6] Xiang Zhang,[6] Carol Gaich,[6] Francesco De Leonardis,[6] Jeffrey Lisse,[6] Jennifer Workman,[6] Roy Fleischmann,[7] Mark Genovese,[8] and Peter Taylor[9], [1]Arthritis Center Twente, Enschede, Netherlands, [2]Western University, London, ON, Canada, [3]Northwestern University Feinberg School of Medicine, Chicago, [4]Pitié-Salpêtrière Hospital, Department of Rheumatology, AP-HP, Sorbonne University, UPMC university, Paris, Ile-de-France, France, [5]Chiba University Hospital, Chiba, Japan, [6]Eli Lilly and Company, Indianapolis, IN, [7]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, [8]Stanford University, Stanford, CA, [9]University of Oxford, Oxford, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib, an oral selective Janus kinase 1 and 2 inhibitor, has shown clinical efficacy and patient-reported pain relief in patients (pts) with RA and an inadequate response to conventional, synthetic DMARDs (RA-BEAM[1]) or biologic DMARDs (RA-BEACON[2]); and in DMARD-naïve pts (RA-BEGIN[3]). The objective of this post-hoc analysis is to quantify the contribution of pain relief to other patient-reported outcomes (PROs) using pooled data from pts who achieved control of inflammation in three phase 3 trials, regardless of treatment.

Methods: Well-controlled inflammation in RA was defined[4] as swollen joint count (SJC) of 28 joints examined ≤1 and CRP ≤1 mg/dL at week 24. Among pts with well-controlled inflammation, PROs were compared between pts who also achieved thresholds of pain relief (defined as ≤20 mm or ≤40mm on a 0-100 mm visual analogue scale) at week 24 versus those who did not. PROs included: HAQ-Disability Index (HAQ-DI) normative value (< 0.5 for RA-BEAM and RA-BEACON, < 0.25 for RA-BEGIN) and minimum clinically important difference (MCID, ≥0.22), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) normative value (≥40.1) and MCID (≥3.56), and the 36-item Short Form Health Survey (SF-36) physical and mental component scores (PCS and MCS) MCID (≥5). Logistic regression models were adjusted for age, gender, body mass index, geographic region, duration of disease, and baseline SJC, CRP, pain, and value of the outcome. Missing data were imputed using modified last observation carried forward.

Results: Of the pts included in these phase 3 trials, 263 pts from RA-BEGIN, 371 pts from RA-BEAM, and 81 pts from RA-BEACON achieved inflammation control at week 24 (Table 1). Among pts who achieved inflammation control in RA-BEGIN and RA-BEAM, those who also achieved pain threshold ≤20 mm were more likely ($p< 0.05$) to report benefit in physical function (HAQ-DI), fatigue (FACIT-F), and general quality of life (SF-36) than pts who did not reach the pain relief threshold (Table 2). Generally, pts in RA-BEACON (inadequate responders to biologic DMARDs) were

* Normative score to facilitate comparison with general population
† For RA-BEGIN, HAQ-DI normative value was <0.25
†† P-value from Chi-square test due to the small sample size
FACIT-F: Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI: Health Assessment Questionnaire-Disability Index; MCID: minimum clinically important difference; MCS: mental component score; PCS: physical component score; SF-36: 36-item Short Form Health Survey.

less likely to achieve all PRO thresholds than pts in other trials. In RA-BEACON, achieving pain ≤20 mm resulted in statistically greater percentages of pts achieving FACIT-F MCID, as well as HAQ-DI and FACIT-F normative values and numerically, but not statistically higher, percentages of pts for HAQ-DI MCID. The statistical insignificance may be due to the small number of RA-BEACON pts included in the analysis. Similar patterns were observed with the pain relief thresholds of ≤40 mm compared to >40 mm.

Conclusion: Despite apparently well-controlled inflammation (SJC ≤1 and CRP ≤1 mg/dL), residual pain may persist. Higher levels of pain >20mm are associated with worse physical function, fatigue, and quality of life. This may have implications for management decisions beyond treating to disease activity targets alone.

Work Productivity Is Associated with Disease Activity and Functional Ability in Chinese Patients with Axial Spondyloarthritis Using a Smart-Phone Management System: A Prospective Cohort Study

Xiaofei Liu,[1] Yanyan Wang,[2] Wenji Chen,[1] Shiyan Mo,[3] Xiaojian Ji,[4] and **Feng Huang** [2], [1]Department of Rheumatology,Hainan Hospital of PLA General Hospital,, sanya, Hainan, China (People's Republic), [2]Department of Rheumatology, Chinese PLA General Hospital, beijing, China (People's Republic), [3]Department of Rheumatology,Hainan Hospital of PLA General Hospital,, sanya, [4]Department of Rheumatology, Chinese PLA GeneralHospital,, Beijing, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) usually affects young people and may lead to work disability(WD). We used the "Smart-phone SpondyloArthritis Management System", an interactive mobile health tool to evaluate clinical characteristics and the status of work ability disorders, to determine the prevalence of axSpA unemployment due to illness and the loss of work efficiency, and to analyze the association between the clinical characteristics and WD in patients with axSpA.

Methods: 1187 patients with axSpA were included. WD was assessed with the Work Productivity and Impairment questionnaire (WPAI) reporting WD as the absenteeism, presenteeism, overall work impairment and activity impairment. Demographic properties, pharmacotherapy, co morbidities, disease activity (BASDAI and ASDAS), functionality (BASFI),spinal mobility (BASMI), C-reactive protein, erythrocyte sedimentation rate (ESR),nocturnal pain, total back pain, patient's global assessment of disease activity and Assessment of Spondyloarthritis International Society health index (ASAS-HI) were investigated and compared in employed and un-employed patients. Logistic regressions were used to investigate the associations between work status and clinical characteristics. The relationships between WPAI scores and disease activity were assessed using Spearman correlation coefficients.

Results: Among them, 60(5.05%) participants were unemployed. 793 patients(66.81%)were employed. Absenteeism, presenteeism, overall work impairment and activity impairment in all employed patients were 7%, 24%, 29%

and 27%, respectively. The predictive factors for not being employed were suffering from inflammatory bowel disease and higher ASAS HI scores (OR value was 0.431, 0.696, respectively). Factors significantly associated with a higher absenteeism, overall work impairment and activity impairment loss were BASDAI,BASFI,ASAS HI,ASDAS, nocturnal pain, total back pain and patient's global assessment of disease activity (r >0.5), while NSAIDs treatment were significantly associated with a lower Absenteeism loss. A decrease in work productivity was related to an increase ASDAS score.

Conclusion: We determined that axSpA had a significant influence on the working conditions and the factors related to the disease had a significant correlation with work productivity using a Smart-Phone Management System.

Real-World Evidence on the Early Effects of Golimumab on Work Productivity and Activity Impairment in Patients with Spondyloarthritis: Interim Results from a Prospective, Observational Study

Panagiotis Athanassiou,[1] Ioannis Kallitsakis,[2] Gkikas Katsifis,[3] Anastasios Kotrotsios,[4] Georgios Vosvotekas,[5] Panagiotis Georgiou,[6] Andreas Bounas,[7] Yiannis Haratsis,[8] Evangelia Petrikkou,[8] and **Dimitrios Vassilopoulos** [9], [1]General Hospital of Thessaloniki "Agios Pavlos", Thessaloniki, Greece, [2]Private Practice, Chania, Greece, [3]Naval Hospital of Athens, Rheumatology Clinic, Athens, Greece, [4]Private Practice, Karditsa, Greece, [5]Euromedica General Clinic of Thessaloniki, Rheumatology Clinic, Thessaloniki, Greece, [6]General Hospital of Patras "Agios Andreas", Patras, Greece, [7]Olympion therapeutirion, Patras, Greece, [8]Merck Sharp & Dohme Pharmaceutical, Industrial and Commercial S.A, Medical Affairs, Athens, Greece, [9]2nd Department of Internal Medicine and Laboratory, National and Kapodistrian University of Athens, School of Medicine, Hippokration General Hospital, Athens, Greece

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There are limited real life data regarding the effect of golimumab on work productivity and activity impairment in rheumatic diseases. The aim of our study was to evaluate these work-related patient reported outcomes (PROs) in spondyloarthritis (SpA) patients treated with golimumab in daily clinical practice.

Methods: This is a 12-month multicenter, non-interventional, prospective study of working adults with active axial SpA (axSpA) or psoriatic arthritis (PsA) treated with golimumab. Prospectively collected data regarding work productivity and activity impairment (using the specific health problem WPAI:SHP instrument) from the first 60 patients who completed the 3-month visit (or were prematurely withdrawn prior to 3 months) are reported here.

Results: Sixty patients, 34 (56.7%) with axSpA and 26 (43.3%) with PsA were enrolled over a 7.7-month recruitment period (from 06-Apr-2017 to 27-Nov-2017) by 10 public/private sector hospitals and 3 private offices in Greece. Fifty-nine patients attended the 3-month visit, while one patient was withdrawn 12.1 weeks after enrollment due to golimumab discontinuation for lack of therapeutic response. The overall SpA population included 47% males with a mean age of 44.8 years at enrollment. Overall, 23% of patients had previously received biologics, while 31.7% were receiving concomitant conventional disease-modifying antirheumatic drugs (csDMARDs) during the study period. At baseline, the mean DAS28-ESR of the overall SpA population was 4±1.2, while the mean BASDAI score among axSpA patients was 5.8±1.8 In the overall SpA population, 72.9% (43/59), 91.4% (53/58), 94.9% (56/59), and 96.7%

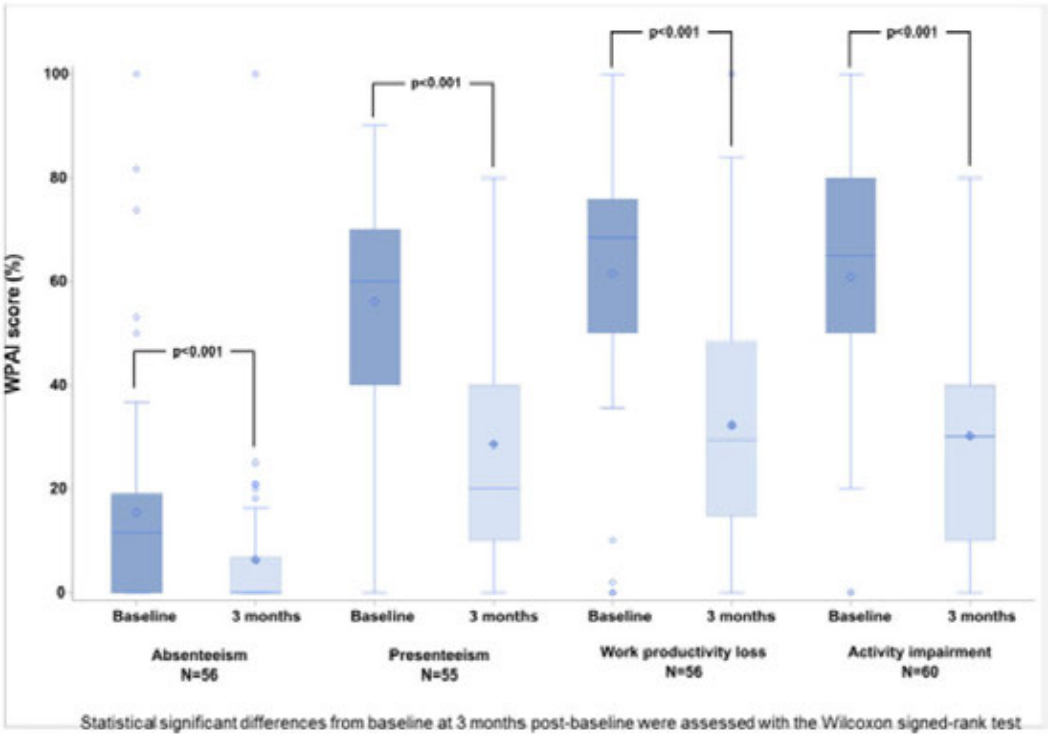

Figure 1. WPAI outcomes at baseline and at 3 months post-baseline in the SpA population

(58/60) of patients, reported absenteeism, presenteeism, work productivity loss, and activity impairment due to SpA, respectively, at baseline. At 3 months the respective rates were 46.4% (26/56), 89.3% (50/56), 91.1% (51/56), and 88.3% (53/60). In the overall SpA population, the median scores for absenteeism, presenteeism, work productivity loss, and activity impairment significantly decreased ($p < 0.001$ for all) by 5.7%, 40.0%, 38.1%, and 40.0%, respectively (Figure 1).

Conclusion: Actively working patients with SpA treated with golimumab in real life settings demonstrated significant improvements in all domains of the work-related PROs as early as 3 months after treatment initiation. These preliminary data, if confirmed at 6 and 12 months, provide valuable work-related information on the effect of a golimumab treatment of SpA patients in real life practice.

Abstract Number: 0420

Assessment of Fatigue in Adults with Moderate to Severe Systemic Lupus Erythematosus (SLE): A Qualitative Study to Explore What Patients Feel Should Be Measured in Clinical Trials

Sally Mannix ,[1] Andrea Beyer,[2] Vibeke Strand,[3] Leslie Hanrahan,[4] Cristina Abel,[5] Bruno Flamion,[2] and Asha Hareendran[6], [1]Evidera, Bethesda, [2]Idorsia Pharmaceuticals, Allschwil, Switzerland, [3]Division of Immunology/Rheumatology, Stanford University, Stanford, CA, [4]Lupus Foundation of America, Washington DC, [5]Evidera, Bethesda, MD, [6]Evidera, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is one of the most common symptoms reported by patients with systemic lupus erythematosus(SLE) and is responsible for considerable loss of time at work and greatly impaired quality of life. There is a lack of patient reported outcome (PRO) instruments developed with input from patients with SLE. To collect evidence of content validity required by regulatory agencies for a PRO tool to support label claims, this qualitative study aimed to understand SLE patients' experience of fatigue and to assess the FACIT-F (Functional Assessment of Chronic Illness Therapy-Fatigue) questionnaire used extensively in health research to evaluate fatigue. Evaluation of the FACIT-F content was informed by a literature review and guided by a project steering committee (PSC; consisting of a patient advocate, a clinical expert, and an outcomes measure expert).

Methods: The study, approved by an institutional review board, involved focus groups (Round 1) and cognitive interviews (Round 2) with adults with moderate to severely active SLE. All participants provided written informed consent. In Round 1, three focus groups were conducted to understand the disease and fatigue-related concepts that were most important to patients; participants also provided high-level feedback on the FACIT-F. Round 2 included 13 one-on-one cognitive interviews to collect more nuanced feedback on the relevance of content, clarity, and comprehensiveness of the FACIT-F. The qualitative interviews were audio-recorded and transcribed; content analysis methods were used to analyze the transcripts to achieve the study objectives. The PSC reviewed the results and contributed to decision making. Specific attention was given to determine the comprehensiveness and participant understanding of the FACIT-F and any gaps in concept coverage to evaluate fatigue in the context of a clinical trial.

Results: A total of 28 adult patients with moderate to severe SLE, mostly female (n=27) with a mean age of 45.5 ± 12.1 years (range: 18–75 years) participated in the study; 23 (82%) had moderate disease activity and five (18%) severe SLE. All participants were receiving treatment to manage their SLE at the time of the study and most (n=23, 82%) reported fatigue among the top three most important SLE-related symptoms. Fatigue was described as profoundly impacting their daily life, including the ability to perform chores, work-related activities, maintain personal hygiene, exercise, and participate in hobbies. Study participants reported that the FACIT-F covered concepts most relevant to their experience of fatigue. Participants were able to understand the instructions, items, and response options of the instrument and felt that the recall period of 7 days was appropriate.

Conclusion: Fatigue was one of the most important symptoms that had a significant impact on adults with moderate to severely active SLE, limiting their ability to perform activities they needed or wanted to do. The FACIT-F was found to be an appropriate measure for the assessment of fatigue in this sample. Evidence of content validity of the FACIT-F in adults with SLE was confirmed for its use to support endpoints in Idorsia's Cenerimod Assessing $S1P_1$ Receptor Modulation in SLE (CARE) clinical trial.

An Examination of Patient-Reported Outcomes Data from a Randomized Trial Examining Etanercept and Methotrexate as Monotherapy or in Combination in Patients with Psoriatic Arthritis

Vibeke Strand ,[1] Philip Mease,[2] Ervant Maksabedian,[3] Bradley Stolshek,[3] Lyrica Liu,[3] David Collier,[3] Gregory Kricorian,[3] and Joseph Merola[4], [1]Division of Immunology/Rheumatology, Stanford University, Stanford, CA, [2]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA, [3]Amgen Inc., Thousand Oaks, CA, [4]Harvard Medical School, Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Health-related quality of life is impacted in patients (pts) with psoriatic arthritis (PsA). Patient-reported outcomes (PROs) are an important means of measuring treatment improvements in PsA pts receiving systemic therapies such as methotrexate (MTX) and tumor necrosis factor inhibitors. PROs reported in the SEAM PsA randomized, controlled trial (RCT)* included SF-36 physical and mental component (PCS, MCS) scores and Health Assessment Questionnaire -Disability Index (HAQ-DI). Results showed significant differences in the SF-36 PCS mean change from baseline (BL) at week 24 in the etanercept (ETN)-containing arms compared to MTX-monotherapy (mono); similar improvements were seen across treatment groups in MCS and HAQ-DI.* Here we report results from analyses of all PROs measured in this RCT.

Methods: Pts with active PsA (N = 851) were randomized to receive 48 weeks of: MTX 20 mg weekly (N = 284), ETN 50 mg weekly (N = 284), or ETN 50 mg plus MTX 20 mg weekly (Combo; N = 283). PROs included: Patient global assessment of disease activity (PtGA); Patient global assessment of joint pain (PtGAJP); HAQ-DI; and SF-36 PCS, MCS, and 8 domains. Analyses included: least squares mean (LSM) changes from BL to week 24 comparing the ETN-containing arms to MTX mono; the proportion of pts reporting improvements ≥ minimal clinically important differences (MCID) at week 24, and the proportion of pts reporting scores ≥ age and gender matched normative values (A/G norms) at 24 weeks in HAQ-DI and SF-36 PCS, MCS, and 8 domains. Tests were not adjusted for multiplicity; P-values are nominal.

Results: PRO BL values were generally balanced across treatment arms. The largest LSM changes from baseline at week 24 were evident in PtGA, PtGAJP, and SF-36 PCS, with significant differences in both ETN-arms compared to MTX mono (Table 1). Compared to MTX mono, significantly larger differences were reported with ETN mono in the SF-36 Bodily Pain (BP) and General Health (GH) domains and with Combo in the SF-36 BP and Vitality (VT) domains (Figure 1).

Compared to MTX mono at week 24, significantly more pts reported improvements ≥ MCID with ETN mono in PtGA and with Combo in PtGAJP (Figure 2A).

Significantly higher proportions of pts in both the ETN mono and Combo arms reported scores ≥ A/G norms at week 24 compared to MTX mono in HAQ-DI; SF-36 PCS; and SF-36 physical function (PF), role physical (RP), BP, and GH domains. In addition to these, significantly higher proportion of patients receiving Combo reported scores ≥ A/G norms in SF-36 VT and mental health (MH) domains compared to MTX mono (Figure 2B). Continued improvements across PROs were reported through week 48.

Table 1. Patient-reported outcomes: least square mean changes from baseline at week 24

Patient Reported Outcome	Methotrexate Monotherapy N = 284	Etanercept Monotherapy N = 284	Methotrexate + Etanercept N = 283
HAQ DI	-0.39	-0.41	-0.44
PtGA	-22.70	-31.64; **P<0.001**[a]	-29.04; **P=0.012**[a]
PtGAJP	-18.95	-24.12; **P=0.032**[a]	-24.90; **P=0.014**[a]

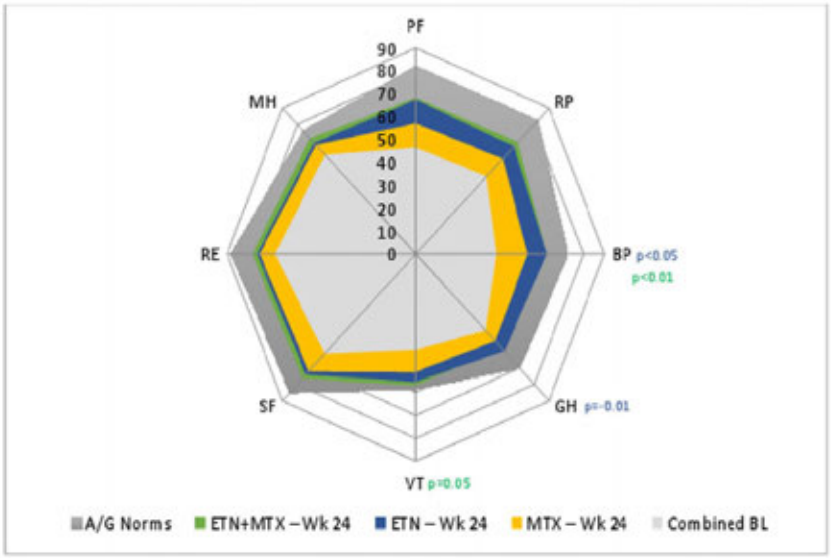
Role Emotional	8.58	9.76	8.08
Mental Health	6.92	7.5	8.91

HAQ-DI, Health Assessment Questionnaire- Disability Index; LSM, least squares mean; MCS, mental component summary; PCS, physical component summary; PtGA, patient global assessment; PtGAJP, patient global assessment of joint pain; SF-36, Short Form (36) health survey version 2.
[a]P-values are for comparison with methotrexate monotherapy. Only P-values ≤ 0.05 are shown.



Missing values were not imputed; spydergrams were generated using domain raw scores (range: 0.100); US age-gender norms were matched to the protocol population. Spydergrams are for illustrative purposes only.
A, age; BL, baseline; BP, bodily pain; ETN, etanercept; G, gender; GH, general health; MH, mental health; MTX, methotrexate; PF, physical functioning; RE, role emotional; RP, role physical; SF, social functioning; VT, vitality; Wk, week.

Figure 1. Spydergram of domain scores from baseline to week 24 versus age- and gender-matched normative scores

Figure 2A. Percentages of patients reporting improvements ≥ MCID at week 24.

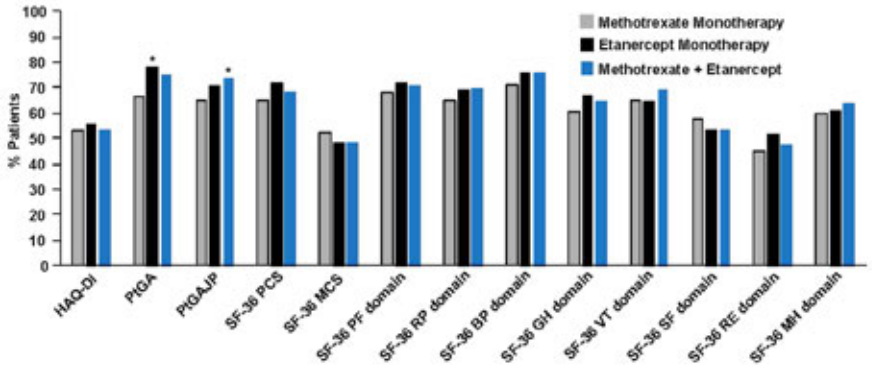


Figure 2B. Percentages of patients reporting HAQ-DI and SF-36 PCS, MCS, and domain scores ≥ A/G normative values at week 24.

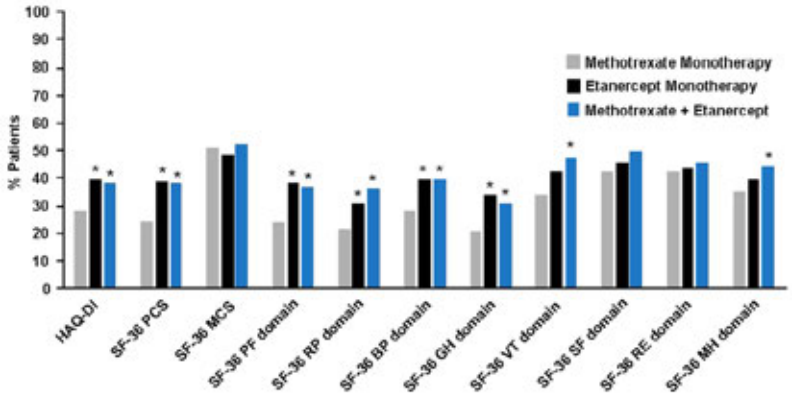

A, age; BP, bodily pain; G, gender, GH, general health; HAQ-DI, Health Assessment Questionnaire- Disability Index; MCID, minimal clinically important difference; MCS, mental component summary; MH, mental health; PCS, physical component summary; PF, physical function; PtGA, patient global assessment; PtGAJP, patient global assessment of joint pain; RE, role emotional; RP, role physical; SF, social function; SF-36, Short Form (36) health survey; VT, vitality.
*P-values compared with methotrexate monotherapy that were ≤ 0.05.
MCID values were change from baseline ≤ -0.35 for HAQ-DI, ≤ -10.0 for PtGA, ≤ -10.0 for PtGAJP, ≥ 2.5 for SF-36 PCS, ≥ 2.5 for SF-36 MCS, and ≥ 5.0 for each SF-36 domain. Normative values were ≤ 0.25 for HAQ-DI; ≥ 50 for SF-36 PCS, and ≥ 50 for SF-36 MCS. Age/gender normalized values for the SF-36 domains were 82.01 for PF, 82.55 for RP, 72.86 for BP, 70.31 for GH, 58.89 for VT, 85.11 for SF, 88.12 for RE, and 75.94 for MH.

Figure 2. Percentage of patients with scores ≥ MCID or ≥ A/G normative values at week 24

Conclusion: In this RCT, significant and clinically meaningful improvements in PROs were reported with ETN mono and Combo compared to MTX mono. In general, pts in ETN-containing arms had greater improvements from BL in several PROs at week 24 compared to MTX mono, with higher percentages reporting improvements ≥ MCID and/or scores ≥ A/G norms.

The Impact of Adalimumab vs Placebo on Patient-Reported Outcomes and Utility Measures Among Patients with Moderately to Severely Active Psoriatic Arthritis

Vibeke Strand ,[1] Pankaj Patel,[2] Naijun Chen,[2] and Elizabeth M Lesser[3], [1]Division of Immunology/Rheumatology, Stanford University, Stanford, CA, [2]AbbVie Inc., North Chicago, IL, [3]AbbVie Inc., North Chicago

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Physical function and health-related quality of life (HRQoL) are negatively impacted in patients (pts) with PsA, and treatment with conventional and biological (b) DMARDs improved patient-reported outcomes (PROs), including HRQoL measures. The objective of this analysis was to assess the impact of adalimumab (ADA) vs placebo (PBO) on PROs following 12-week (wk) treatment in the randomized-controlled ADEPT trial.

Methods: Pts (n=315) with moderately to severely active PsA who were bDMARD naive (50% were receiving MTX) were randomized to ADA 40 mg or PBO every other wk. This analysis assessed PROs at baseline (BL) and wk 12 using the 36-item Short-Form (SF-36) Health Survey physical (PCS) and mental component summary (MCS) scores,

MCIDs: SF-36 PCS=2.5; HAQ-DI= –0.35; PtGA=10; Pt pain=10.
A/G normative values: SF-36 ≥50; HAQ-DI ≤0.25.
Statistical analysis ADA vs PBO: †P<0.05; *P<0.01; **P<0.001

Figure 2. Proportion of Patients Reporting Improvements ≥MCID and (B) Scores ≥Age- And Gender-Matched Normative Values at Week 12

analyzed, based on as observed data. *P* values were assessed by analysis of variance model for continuous variables and Cochran–Mantel–Haenszel test for binary outcomes, adjusting by baseline MTX use and extent of psoriasis; no *P* value adjustments for multiplicity were performed. Numbers needed to treat (NNTs) are reported using proportions of pts reporting improvements ≥MCID in SF-36, PtGA, pain, and HAQ-DI.

Results: In general, BL PRO scores were similar between ADA (n=151) and PBO (n=162; **Table 1**). Improvements from BL at wk 12 with ADA vs PBO were significant in PtGA, pain, HAQ-DI, and SF-36 PCS (change: 9.3 vs 1.4; $P<$ 0.001) but not in SF-36 MCS (1.6 vs 1.2; **Table 1**). Six of 8 SF-36 domains (physical functioning, role physical, bodily pain, general health, social functioning, and vitality) significantly improved from BL to wk 12 with ADA vs PBO (all $P\leq0.05$; **Table 1** and **Figure 1**). SF-6D improvements exceeded MID with ADA (change: 0.071) vs PBO (0.018); the ADA SF-6D score (0.724) also approached the A/G norm of 0.778 at wk 12 (**Table 1**). Proportions of pts reporting improvements ≥MCID at wk 12 were significantly greater with ADA vs PBO in all PROs, except SF-36 role emotional and mental health domains, with corresponding NNTs ≤6.4 (**Figure 2**). Proportions of pts who reported scores ≥A/G norms in HAQ-DI, SF-36 PCS, and 6 of 8 SF-36 domains were significantly greater with ADA vs PBO (**Figure 2)**.

Conclusion: Statistically significant and clinically meaningful improvements and scores ≥A/G norms (higher definition of response) at week 12 were reported with ADA treatment vs PBO in pts with moderately to severely active PsA. These data are consistent with improvements in PROs reported with other bDMARDs in patients with PsA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient Reported Outcomes (PROs) provide important information on assessment of pain, disease activity, fatigue and physical function in patients with psoriatic arthritis (PsA). Knowledge of the evolution in PROs over time in patients, who initiate treatment with their 1st, 2nd or 3rd Tumour Necrosis Factor inhibitor (TNFi) in routine practice is limited. Hence, the aim of this was study was to investigate PROs at 6, 12 and 24 months after TNFi start and the changes from baseline to 6, 12 and 24 months in PsA patients, who initiated their 1st, 2nd or 3rd TNFi in clinical practice.

Methods: Pooled data on PsA patients from 13 European registries participating in the EuroSpA Research Collaboration were analysed (1). Patients were included in the study cohort if they had been followed in the registry from initiation of the 1st TNFi. PROs included Visual Analogue Scale (VAS) scores on a 0-100 mm scale for pain, global disease activity and fatigue, while physical function was captured with Health Assessment Questionnaire (HAQ). The distribution of PROs at 6, 12 and 24 months after TNFi start and the changes from baseline to 6, 12 and 24 months were investigated with descriptive statistics. PRO remission rates were defined as the proportion of patients achieving a state of pain score ≤20 mm, global score 20 mm, fatigue score ≤20 mm and HAQ score ≤0.5. Crude and LUNDEX-adjusted (2) PRO remission rates were assessed for the overall cohort and the individual registries.

Results: Of the 25,988 axSpA patients, who initiated 1st TNFi, 8,294 patients switched to a 2nd TNFi, while 2,842 patients subsequently switched to a 3rd TNFi. Baseline characteristics of the study cohort are shown in Table 1. The 6, 12 and 24 month PRO status and changes in PROs for 1st, 2nd and 3rd TNFi in the pooled cohort are summarized in Table 2. For the 1st, 2nd and 3rd TNFi, median PROs after 6 months ranged from 20mm to 30mm, 27mm to 40mm and 35mm to 50mm, respectively. Similarly, median decreases in PROs from baseline to 6 months ranged from 18 to 30mm, 8 to 18mm and 8 to 18mm for the 1st, 2nd and 3rd TNFi. In the overall cohort 6 month LUNDEX-adjusted PRO

PRO remission rates (%) at 6, 12 and 24 months									
	1st TNFi			2nd TNFi			3rd TNFi		
	Crude* 6/12/24		LUNDEX adjusted**	Crude*		LUNDEX adjusted**	Crude*		LUNDEX adjusted**
Pain ≤ 20	44%/48%/49%		36%/33%/25%	31%/34%/38%		23%/20%/17%	26%/28%/31%		18%/15%/11%
Global ≤20	42%/46%/48%		35%//31%/24%	31%/32%/35%		23%/19%/15%	27%/26%/28%		18%/14%/10%
Fatigue ≤20	36%/39%/40%		29%/27%/20%	28%/27%/29%		20%/16%/12%	21%/24%/28%		15%/13%/10%
HAQ ≤0.5	54%/56%/58%		44%/38%/29%	41%/42%/46%		31%/25%/19%	33%/33%/36%		24%/18%/13%

Data are as observed. Percentage of available data varied from 40-86%. Values are median (Inter Quartile Range (IQR)) unless otherwise stated. PRO: Patient reported outcome; TNFi: Tumour Necrosis Factor inhibitor; HAQ: HIealth Assessment Questionnare.
*Crude value: the fraction of patients in PRO remission of those still on drug with available data at 6, 12 and 24 months.
** LUNDEX-adjusted: Crude value adjusted for drug retention.

remission rates varied from 33% to 41%, 23% to 33% and 17% to 24% for the 1st, 2nd and 3rd TNFi, respectively (Table 2). In the individual registries, LUNDEX-adjusted 6 months PRO remission rates for the 1st TNFi ranged from 32% to 51%, 24% to 50%, 28% to 48%, 32% to 51% and 21% to 47% for pain, global, BASDAI, BASFI and fatigue scores, respectively.

Conclusion: In this large observational study cohort, one-third of patients achieved a state of PRO remission after 6 months of treatment with their first TNFi with significant variation between registries. As expected, improvements in PROs and PRO remission rates were lower in those who had switched to the 2nd or 3rd TNFi, reflecting selection of non-responders and more severe cases (confounding by indication).

A Novel Patient-Reported Outcome Measure in IgG4-Related Disease: The Symptom Severity Index

Tyler Harkness ,[1] Karen Donelan,[1] Xiaoqing Fu,[1] Rachel Wallwork,[1] Cory Perugino,[1] John Stone,[2] and Zachary Wallace[1], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) causes symptoms, the severity of which vary by organ involvement. The Responder Index (RI) captures physicians' judgement of disease activity, but no disease-specific patient-reported outcome measure (PROM) exists. We sought to develop and validate the Symptom Severity Index (SSI), a PROM that measures the frequency of IgG4-RD-specific symptoms and associated distress.

Methods: 40 common IgG4-RD symptoms were identified by three expert clinicians to create a pilot SSI. This was tested in a convenience sample to test usability in a clinic setting and to obtain feedback on the symptom list. Several gaps were identified. Semi-structured qualitative transcribed interviews were then performed with new patients to expand the item set and explore issues that were absent. Newly identified patients described symptoms they attributed to IgG4-RD, associated distress, and other concerns. We reached saturation regarding symptoms and language at 20 patients. The SSI was revised based on these interviews and administered to 5 subjects for feedback on face validity. Minor changes yielded the final SSI which 45 patients completed at routine visits along with SF-36, EQ-5D, and feeling thermometer surveys. For each SSI symptom, a score is calculated by multiplying frequency (range "Never" [0] to "Every Day" [3]) by associated distress (range "None" [0] to "Very Much" [4]). Each symptom score is then summed (e.g., SSI score). We assessed construct validity by measuring known-group and convergent/divergent validity.

Results: The final SSI assesses the frequency and distress of 24 symptoms in 8 categories: General Health, Orbit, Sino-nasal Area, Salivary Glands, Chest, Abdomen, Skin and Extremities, and Genitourinary (Figure). A question on fear of more serious or severe disease was included based on qualitative interview findings. 45 patients completed the SSI 64 times (Table 1). The mean (SD) SSI score was 27.4 (27.1) and the range was 0-138. Fear of more severe disease was reported by 21 (46.7%) patients. The SSI inversely correlated well with the SF-36 (r= - 0.47, p< 0.001) and the feeling thermometer (r= - 0.50, p< 0.001). The symptom frequency score correlated with the RI (r=0.3, P=0.03) but the total SSI score did not (r=0.2, P=0.1). The SSI inversely correlated weakly with the EQ-5D (r= - 0.26, p=0.09). The fear score inversely correlated with the SF-36 item regarding role limitation due to emotional problems (r= - 0.36, p=0.003). Trends suggested that the median (IQR) SSI score was higher in active vs inactive disease (26 [12, 41] vs. 12 [6, 31]) and multi-organ vs one or two-organ disease (25 [12, 33] vs. 13 [6, 33]).

Conclusion: The SSI is an IgG4-RD-specific PROM developed with patient and clinician input to achieve face and content validity. In addition to symptoms and distress related to organ-specific disease, fear of worsening or more serious disease is common. The SSI has good construct validity in comparison with generic quality of life measures.

Example:

	In the past 30 days, how often, if at all, have you experienced this symptom? (Check one)					How much distress does the symptom cause you? (Check one)				
Symptom	**Never**	**A few days a month**	**A few days a week**	**Every Day**		**None**	**A little bit**	**Somewhat**	**Quite a bit**	**Very much**
Orbit (Eye Area)										
Swelling or pressure around the eyes	X					X				
Change in vision	X					X				
Dry or itchy eyes			X				X			

Example of the IgG4-Related Disease Symptom Severity Index

	Overall (N = 43)
Mean (SD) Age (yrs) at SSI Completion	64.8 (11.5)
Male (N, %)	30 (69.8%)
Race	
White	39 (90.7%)
Black	1 (2.3%)
Asian	2 (4.6%)
Other	1 (2.3%)
Organ Involvement	
Single or Two-Organ (N, %)	27 (62.8%)
Multi-Organ (N, %)	16 (37.2%)
Symptom Severity Index (SSI)	
Mean (SD) Score	27.4 (27.1)
Range	0 – 138
Any Fear of Worsening Disease	21 (46.7%)
Mean (SD) Fear Symptom Score*	1.8 (3.0)
Range	0 – 12

*Frequency of fear (Range 0-3) multiplied by distress associated with fear (Range 0-4)

Cohort Characteristics

The symptom frequency score correlated with the RI but the overall SSI score did not, suggesting that the SSI better reflects patient-reported severity. The validity of the SSI should be further investigated in multi-center studies.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

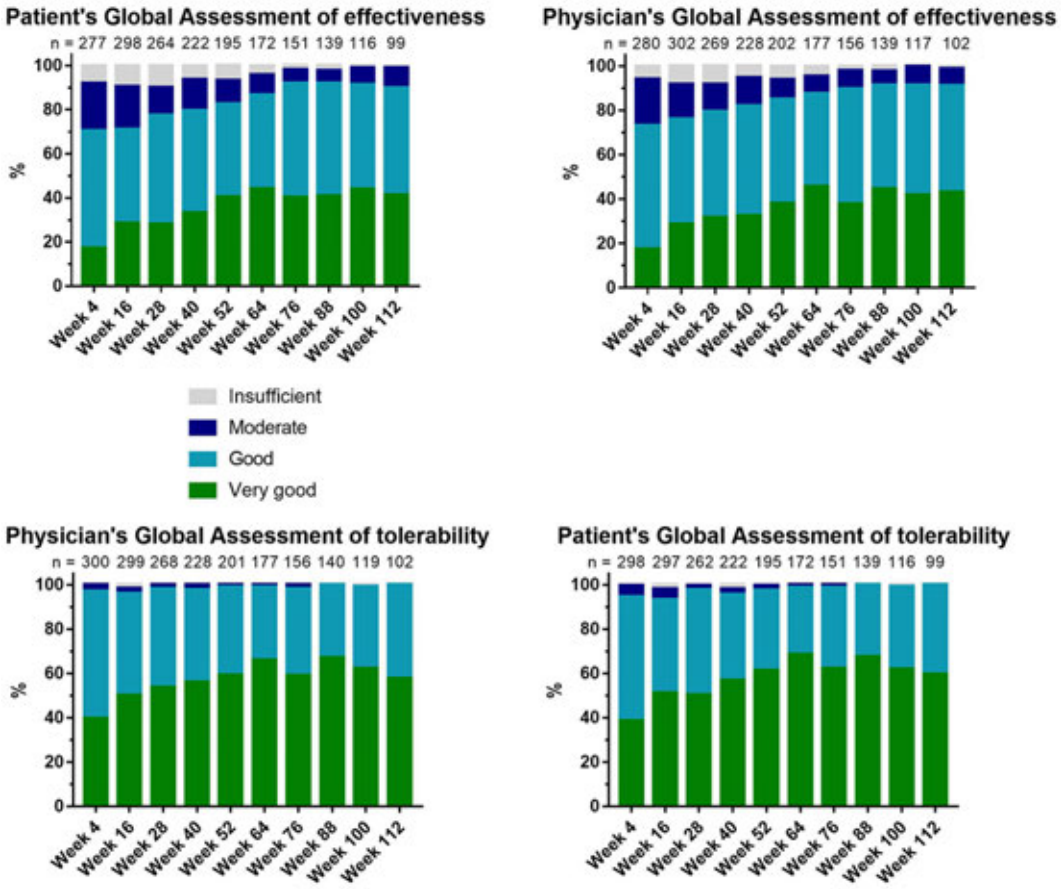
Background/Purpose: The wish of a treating physician is to make sure, that the patient gets an effective and safe therapy and is satisfied with the treatment. The question is how to measure the patient's satisfaction with the therapy.

SUSTAIN is a prospective, multi-center non-interventional study in Germany to observe long term efficacy and safety, quality of life and other patient reported outcomes (PROs) in patients with active psoriatic arthritis (PsA) under treatment with ustekinumab in routine clinical care. In this ongoing study, up to 400 patients were planned to be included at 75 centers for 160 weeks with visit intervals at week 0 and 4 and then every 12 weeks of treatment with ustekinumab according to the label. In this non-interventional study, all patients were diagnosed with psoriatic arthritis according to the CASPAR Criteria.

Here we examine the correlation between treatment satisfaction of the patients with satisfaction of the physicians. Furthermore, we correlate satisfaction with the effectiveness of the therapy for both patients and physicians, regarding the joints and the skin.

Methods: In this interim analysis, results of baseline data of 336 patients and of the documented visits up to week 112 were evaluated. Reported outcomes on satisfaction of patients and physicians with effectiveness and tolerability of therapy were assessed and correlated with disease severity measures such as number of swollen and tender joints and psoriasis affected body surface area (BSA).

The correlation between measured variables was assessed using Spearman's Rank Correlation Coefficient (CC). With a possible range from -1 to +1, a correlation coefficient between -0.3 and 0.3 was defined as no /weak correlation, between -0.3 and -0.7/ 0.3 and 0.7 as moderate correlation, and values below -0.7 or above 0.7 as strong correlation.



Patient's and physician's global assessments of effectiveness and tolerability.

Patient's global assessment of effectiveness	Physician's global assessment of effectiveness N	Physician's global assessment of effectiveness Correlation coefficient	Physician's global assessment of tolerability N	Physician's global assessment of tolerability Correlation coefficient
Week 4	269	0.854	293	0.809
Week 16	294	0.825	292	0.776
Week 28	262	0.802	260	0.722
Week 40	221	0.798	221	0.747
Week 52	194	0.834	194	0.826
Week 64	171	0.822	172	0.830
Week 76	150	0.830	150	0.819
Week 88	138	0.826	139	0.770
Week 100	116	0.846	116	0.802
Week 112	99	0.895	99	0.832
The global assessments range from 1 (=very good) to 4 (=insufficient).				

Correlation Coefficients between patient's and physician's assessments.

Results: The patients' and physicians' global assessments of effectiveness and tolerability were evaluated at every 12 weeks of treatment (Figure 1). The CCs between patient's and physician's assessments over 112 weeks of treat-

ment were in the range of 0.798 and 0.895 for effectiveness and 0.722 and 0.832 for tolerability (Table 1). Therefore, the CCs for global assessments can be classified as strong.

The CCs between physicians' and patients' assessments of effectiveness for tender joint count, based on 78 joints at week 112, were 0.321 (n=96) and 0.247 (n=94) respectively. The CCs between physicians' and patients' assessments of effectiveness for swollen joint count based on 76 joints also at week 112 of treatment, were 0.232 (n=96) and 0.193 (n=94) respectively. The CCs between physicians' and patients' assessments of effectiveness for BSA were 0.227 (n=86) and 0.216 (n=85) respectively. Thus, the correlation between patients' and physicians' satisfaction with the effectiveness of the therapy can mostly be classified as weak.

Conclusion: The results showed strong correlation between patients' and physicians' global assessments of both effectiveness and tolerability with high treatment satisfaction. However, the PROs correlate weakly to moderately with disease measures of tender and swollen joint counts and BSA.

Abstract Number: 0426

Time to Response for Clinical and Patient-Reported Outcomes in Patients with Psoriatic Arthritis Treated with Tofacitinib, Adalimumab, or Placebo

Dafna Gladman ,[1] Laura Coates,[2] Joseph Wu,[3] Lara Fallon,[4] Ming-Ann Hsu,[5] Andrew Bushmakin,[3] Elizabeth Bacci,[6] Joseph Cappelleri,[3] and Philip Helliwell[7], [1]University of Toronto, Toronto, ON, Canada, [2]University of Oxford, Oxford, United Kingdom, [3]Pfizer Inc, Groton, CT, [4]Pfizer Inc, Montreal, QC, Canada, [5]Pfizer Inc, Collegeville, PA, [6]Evidera, Seattle, WA, [7]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: With many disease domains affected in PsA, clinical and patient-reported outcome (PRO) measures are important to assess disease improvement following treatment. Rapid, meaningful improvements in disease activity are a priority for physicians and patients (pts). Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Higher proportions of pts achieved responses in PROs and clinical measures when treated with tofacitinib for 3 months vs placebo (PBO).[1-5] Proportions of responders were also similar between tofacitinib and adalimumab (ADA) after 3, 6, and 12 months.[2,3,5] We aimed to determine the time to initial response using responder definitions for selected PROs and clinical endpoints in pts with active PsA treated with tofacitinib, ADA, or PBO switching to tofacitinib.

Methods: In this post hoc analysis, data were collected from two Phase 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]).[3,4] Pts receiving tofacitinib 5 or 10 mg twice daily (BID), subcutaneous ADA 40 mg once every two weeks (Q2W; OPAL Broaden only), or PBO, switching to tofacitinib 5 or 10

Table 1. Time to initial response

	OPAL Broaden			OPAL Beyond		
	Responders		Median time to initial response	Responders		Median time to initial response
	N at baseline	Number of subjects achieving initial response	Days (95% CI)	N at baseline	Number of subjects achieving initial response	Days (95% CI)
HAQ-DI						
Tofacitinib 5 mg BID	96	84	30.0 (27.0, 57.0)**	115	88	37.0 (29.0, 61.0)
Tofacitinib 10 mg BID	92	71	53.5 (29.0, 90.0)**	123	80	64.0 (57.0, 113.0)
ADA 40 mg SC Q2W	96	73	29.0 (29.0, 57.0)**	---	---	---
PBO → tofacitinib 5 mg BID	48	30	162.0 (85.0, NE)**	57	40	85.0 (57.0, 169.0)
PBO → tofacitinib 10 mg BID	45	36	112.0 (57.0, 169.0)**	59	38	113.0 (84.0, 169.0)
FACIT-F						
Tofacitinib 5 mg BID	107	87	31.0 (29.0, 43.0)	127	95	32.0 (30.0, 85.0)
Tofacitinib 10 mg BID	104	84	85.0 (34.0, 92.0)	132	91	84.0 (32.0, 91.0)
ADA 40 mg SC Q2W	106	83	85.0 (61.0, 92.0)	---	---	---
PBO → tofacitinib 5 mg BID	52	42	86.0 (85.0, 169.0)	65	48	84.0 (35.0, 164.0)
PBO → tofacitinib 10 mg BID	53	41	85.0 (31.0, 170.0)	65	41	92.0 (81.0, 175.0)
MDA						
Tofacitinib 5 mg BID	107	55	337.0 (256.0, NE)	131	46	NE (173.0, NE)
Tofacitinib 10 mg BID	104	54	337.0 (171.0, NE)	132	39	NE (NE, NE)
ADA 40 mg SC Q2W	106	53	339.0 (171.0, NE)	---	---	---
PBO → tofacitinib 5 mg BID	52	21	342.0 (337.0, NE)	66	17	189.0 (NE, NE)
PBO → tofacitinib 10 mg BID	53	25	338.0 (176.0, NE)	65	21	176.0 (174.0, NE)
PASDAS						
Tofacitinib 5 mg BID	107	67	253.0 (174.0, 335.0)	123	49	NE (170.0, NE)
Tofacitinib 10 mg BID	103	67	176.0 (166.0, 258.0)	129	51	182.0 (169.0, NE)
ADA 40 mg SC Q2W	104	59	253.0 (169.0, NE)	---	---	---
PBO → tofacitinib 5 mg BID	52	24	344.0 (251.0, NE)	63	22	189.0 (169.0, 189.0)
PBO → tofacitinib 10 mg BID	52	31	241.0 (170.0, 323.0)	65	28	173.0 (169.0, 190.0)

Response definitions: HAQ-DI ≥0.35-point improvement from baseline, FACIT-F total score ≥4-point improvement from baseline, MDA yes/no composite response (meeting at least five of seven criteria), and PASDAS post-baseline score of ≤3.2 and >1.6-point improvement from baseline
Log rank (Mantel-Haenszel) tests comparing Kaplan-Meier curves across treatments; p-value based on Chi square test with degrees of freedom = number of treatments -1; **p<0.01
PBO → tofacitinib 5 or 10 mg BID groups began treatment with tofacitinib at Month 3.
ADA, adalimumab; BID, twice daily; CI, confidence interval; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; HAQ-DI, Health Assessment Questionnaire-Disability Index; MDA, Minimal Disease Activity; NE, not estimable; PASDAS, Psoriatic Arthritis Disease Activity Score; PBO, placebo; Q2W, once every two weeks; SC, subcutaneous

mg BID at Month (M)3, were included. Responder definitions included: HAQ-DI ≥ 0.35-point improvement from baseline (BL), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) total score ≥ 4-point improvement from BL, Minimal Disease Activity (MDA) yes/no composite response (meeting at least 5/7 criteria), and PsA Disease Activity Score (PASDAS) post-BL score of ≤ 3.2 and > 1.6-point improvement from BL. First post-BL data were collected at Week 2 (eg for HAQ-DI) or M1. Time-to-event analyses were performed using the Kaplan-Meier (KM) method, with pts censored at last observed visit. Log-rank tests compared time to initial response across treatment groups.

Results: KM analyses show days to initial response (Table 1, Figure 1). Time to initial HAQ-DI responses was significantly different between treatment groups in OPAL Broaden ($p < 0.01$): faster in pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, and ADA, vs pts who switched from PBO to tofacitinib at M3. A similar, but not significant (ns) trend was observed for HAQ-DI responses in OPAL Beyond. Generally, initial FACIT-F responses were achieved faster in pts receiving tofacitinib 5 mg BID vs other treatment groups in both studies (ns). Times to initial MDA and PASDAS responses were similar between tofacitinib and ADA treatment groups.

Conclusion: Times to initial response in functional ability and disease activity were similar in pts treated with either tofacitinib or ADA. Time to initial response prior to first post-BL observation (Week 2 or M1) was not estimable in this analysis. These results may help physicians better understand the time frame for a meaningful response in pts receiving tofacitinib.

Correlation Between Patient Reported Outcomes Measurement Information System (PROMIS) and RAPID3 in Rheumatoid Arthritis Patients Starting a New Biologic DMARD

Tyler Williams ,[1] M. Elaine Husni,[2] Yuxuan Jin,[3] Greg Strnad,[1] Sage O'Bryant,[1] and Chad Deal[4], [1]Cleveland Clinic, Cleveland, OH, [2]Department of Rheumatologic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH, [3]Quantitative Health Science, Cleveland Clinic, Cleveland, OH, [4]Cleveland Clinic Foundation, Cleveland, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: RAPID3 is a disease activity measure which relies on patient-reported outcomes (PROs) to assess physical function, pain, and global health but does not require joint count or lab values. Patient Reported Outcomes Measurement Information System (PROMIS) is a validated instrument used to collect PROs across multiple diseases. Compared to RAPID3, PROMIS offers the ability to assess more targeted domains such as fatigue, global mental health, and pain interference. It also allows comparison of patient responses to a normalized US population. The purpose of this study was to assess whether changes in PROMIS domains correlate with changes in RAPID3 in RA patients starting a new biologic DMARD and whether PROMIS could complement a composite measure such as RAPID3 to optimize patient outcomes.

Methods: A retrospective chart review was conducted of RA patients in a tertiary outpatient rheumatology practice starting a new biologic DMARD. Computer Adaptive Testing (CAT) PROMIS domains (global physical health, global mental health, physical function, pain interference, and fatigue) were collected along with RAPID3 at baseline and follow-up visits. CAT uses item response theory and branching logic to quickly assess patient scores. Correlations between PROMIS domains and RAPID3 were calculated using Spearman's correlations.

Results: 126 patients were included in the final analysis. Mean age was 56.2 ± 13.8 years and 75% were female. Disease duration was greater than 2 years in 80% of patients. 81% of patients had been on at least 1 or 2 prior DMARDs. All PROMIS domains, with the exception of global mental health, were significantly associated with changes in RAPID3 ($p \leq 0.05$) and the coefficients suggest moderate correlation ($|r| = 0.48 - 0.60$). Number of days between

Table 1: Demographic characteristics

	Total (N = 126)
Age (mean ± SD)	56.2 ± 13.8
Female (%)	95 (75.4%)
Disease duration	
≤ 2 years	25 (19.8%)
> 2 years	101 (80.2%)
Treatment history	
None	6 (4.8%)
1 or 2 prior DMARDs	102 (81.0%)
3 or more prior DMARDs	18 (14.3%)
Current DMARD	
Yes	108 (85.7%)
No	18 (14.3%)

Table 2: Change in RAPID3 and PROMIS domains from baseline

Measure	Respondents (total = 126)	Median (min, max)	Mean + SD	P-value [a]
RAPID3	126	-0.75 (-7.6, 2.1)	-0.89 ± 1.7	**< 0.001**
PROMIS global physical health	94	2.6 (-7.5, 19.8)	3.3 ± 5.3	**< 0.001**
PROMIS global mental health	93	0.0 (-8.6, 14.5)	0.99 ± 5.1	0.064
PROMIS physical function	125	1.7 (-37.7, 20.3)	2.3 ± 6.5	**< 0.001**
PROMIS pain interference	126	-3.3 (-70.3, 8.9)	-4.2 ± 8.6	**< 0.001**
PROMIS fatigue	125	-1.1 (-39.5, 12.9)	-2.6 ± 7.5	**< 0.001**
Pain intensity (VAS [b])	94	-1.0 (-8.0, 5.0)	-1.3 ± 2.1	**< 0.001**

[a] *Paired T-test*
[b] *VAS = visual analog scale*

initial and follow-up visit was 111.7 ± 48.6. There was no significant difference found between a follow-up period < 90 days compared to a follow-up period > 90 days. At follow up, patients in near remission by RAPID3 (≤ 1.3, n=12) had a PROMIS physical global health median score of 52.5 (min, max = 37.4, 61.9), while patients with high severity RAPID3 (≥ 4.3, n=55) had a PROMIS global health median of 34.9 (min, max = 26.7, 47.79; p< 0.001). A change of > 1.2 for RAPID3 and > 5 for PROMIS domains has been considered the minimal clinically important difference. 52% of patients had a RAPID3 change of >1.2. Of these, 80% had a change of > 5 in PROMIS pain interference, while 76%, 65%, and 59% had changes of > 5 in PROMIS fatigue, physical function, and global physical health respectively.

Table 3: Disease activity by RAPID3 and PROMIS global health percentile at baseline and follow-up

Disease Activity	Baseline n (%)	PROMIS global health median (min,max)	Follow-up n (%)	PROMIS global health median (min,max)	P-value [a]
RAPID3 Near remission [b]	3 (2.4)	54.1 (54.1,54.1)	12 (9.5)	52.5 (37.4,61.9)	**<0.001**
RAPID3 Low severity [c]	8 (6.3)	44.9 (39.8,47.7)	20 (15.9)	47.7 (37.4,57.7)	**<0.001**
RAPID3 Moderate severity [d]	40 (31.7)	42.3 (32.4,54.1)	39 (31.0)	42.3 (32.4,47.7)	**<0.001**
RAPID3 High severity [e]	75 (59.5)	34.9 (19.9,47.7)	55 (43.7)	34.9 (26.7,47.7)	**<0.001**

[a] *p-value by Kruskal-Wallis test refers to comparison of both baseline and follow-up PROMIS global health across RAPID3 groups*
[b] *near remission ≤ 1.3*
[c] *low severity ≤ 2.3*
[d] *moderate severity ≤ 4.2*
[e] *high severity ≥ 4.3*

Conclusion: In RA patients starting a new biologic DMARD, changes in all studied PROMIS domains, with the exception of global mental health, were significantly associated with changes in RAPID3. Compared to RAPID3, use of PROMIS can allow for the assessment of additional domains in a format which is normalized to a broad population. Insight gained from these additional domains can help focus follow-up visits and facilitate joint decision making between patients and providers. A composite index of PROMIS domains predictive of changes in RAPID3 is being developed. Additional studies are needed to validate the use of PROMIS as a tool for disease activity measure in RA patients.

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To date, there are no approved treatments for cutaneous lupus erythematosus (CLE), a disease known to significantly burden a patient's quality of life (QoL). Clinical trials are important for the advancement of new treatments for CLE and outcome measures should reflect clinically meaningful improvement in disease activity and its effect on QoL. Currently, trials use an efficacy measure of ≥50% improvement in disease activity, defined by the Cutaneous Lupus Disease Area and Severity Index score for activity (CLASI-A), in patients with an initial CLASI-A of ≥10. However, the degree of improvement in disease activity needed to predict a meaningful impact on QoL, an important variable in the design and interpretation of future clinical trials, has not been defined.

Methods: This study included 126 patients seen at the Hospital of the University of Pennsylvania who participate in a longitudinal research database. Patients with mild, moderate or severe initial CLASI-A were analyzed separately and using a linear regression model, we calculated the percent change and difference needed in CLASI-A to have an important impact on QoL, defined as a 9.38-point and a 7.37-point improvement in the Emotions and Symptoms subscales of Skindex-29, respectively.

Results: In patients with an initial CLASI-A ≥8, a decrease by 42.1% or 7-points and a decrease by 31.0% or 5-points in disease activity is associated with a meaningful impact in the Emotions and the Symptoms subscales, respectively. For both subscales, patients with increasingly severe initial disease required a smaller percent change in CLASI-A to predict a meaningful change in QoL.

Conclusion: We find that using a CLASI-A ≥8 for trial entry allows for the inclusion of patients with milder disease for whom improvement of CLASI-A by ≥50% results in a meaningful impact on QoL, as determined by the Emotions and Symptoms subscales of Skindex-29. In patients with CLASI-A ≥8, a decrease in activity by seven and five-points is not only a clinically significant improvement but also indicates a meaningful impact on the Emotions and Symptoms subscales, respectively. For trials enrolling a larger proportion of patients with severe disease activity, or CLASI-A ≥20, we recommend stratifying patients by disease severity, as a smaller magnitude of percent change in disease activity predicts meaningful improvement in QoL. Our findings establish appropriate trial endpoints by determining clinically significant change in disease activity associated with meaningful changes in patients' QoL.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Involving patients with rheumatoid arthritis (RA) in the assessment of their disease may increase adherence to treatment, improve disease outcomes and reduce consultation time. Concordance between Disease Activity Score (DAS-28) performed by physicians and patients was substantial in the phase 1 (baseline visit) of this prospective study.

The purpose of the study is to evaluate the persistence of the concordance between physician and patient assessment of disease activity in RA using DAS-28 after 3 months of the baseline visit.

Methods: At baseline visit, patients with RA from 7 Middle Eastern Arab Countries (MEAC) were briefed about DAS-28 by their rheumatologist and were given a smartphone access to a video in easy Arabic language explaining the performance of DAS-28. At visit 2, scheduled 3 months later, patients were asked to self-report DAS-28, blinded to the physician's assessment. Concordance between DAS-28 at each visit was calculated using paired T-Test. Agreement between physician- and patient-DAS categories (remission, low-, moderate- and high disease activity) was calculated at baseline and at 3 months using weighted kappa for category comparison. Predictive factors of positive concordance between physician and patient-DAS were identified using logistic regression.

Table 1. Patients characteristics

Characteristic	
N	229
Age, years, mean (SD)	47.8 (13.4)
Female N (%)	188 (82.1)
Educational level N (%)	
- Illiterate	14 (6%)
- Primary	34 (15%)
- High school	76 (33%)
- University	100 (44%)
Disease duration, years (SD)	11.3 (8.8)
Gap between symptom onset and RA diagnosis, years (SD)	2.8 (8.6)
Positive rheumatoid factor, N (%)	161 (70%)
Positive ACPA, N (%)	138 (60%)
Radiographic erosions, N	84 (37%)
Current treatment, N (%)	
- Corticosteroids	101 (44%)
- cs DMARDs	214 (93%)
- bDMARDs	79 (34.5%)
- tsDMARDs	21 (9%)
Compliance Questionnaire for Rheumatology (CQR) score % (SD)	78.9 (11.8)
Physician DAS-28, mean (SD)	3.76 (1.39)

Results: Two hundred and twenty-nine patients were included in AUTODAS phase II (Characteristics in Table 1). At baseline, mean DAS-28 was 3.76 [SD 1.39] in physicians and 3.94 [SD 1.42] in patients, with a difference delta1 of -0.19 [95% CI -0.26; -0.11] ($p < 0.0001$). At 3 months, mean DAS-28 was 3.57 [SD 1.44] in physicians and 3.75 [SD 1.47] in patients, with a difference delta2 of -0.18 [95% CI -0.25; -0.11] ($p< 0.0001$). The difference between deltas was not statistically significant ($p = 0.81$). Agreement between physician- and patient-DAS categories was 76% at baseline (Weighted Kappa = 0.71), and 73% at 3 months (Weighted Kappa = 0.73). Concordance at 3 months was statistically associated with DAS-patient category ($p = 0.045$) and concordance at baseline ($p = 0.036$) and did not correlate with education, treatment or country.

Conclusion: DAS-28 is numerically slightly overestimated by patients compared to physicians but the concordance between DAS-28 categories was substantial and remained stable at the 3-months follow-up visit.

Self-assessment of disease activity should be decided according to the physician's clinical judgment.

Axial Spondyloarthritis Patients Report Important Impairments in Daily Life and Work Ability – a Web Survey in 472 Patients

Sebastian Ibanez ,[1] Rianne van Bentum,[2] Omar Valenzuela,[3] and Irene van der Horst-Bruinsma[2], [1]Facultad de Medicina Clinica Alemana - UDD, Santiago, Region Metropolitana, Chile, [2]Amsterdam University Medical Center, Amsterdam, Netherlands, [3]Facultad de Medicina Clinica Alemana -UDD, Santiago, Region Metropolitana, Chile

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) can be associated with significant burden and impaired work activity. In Chile, several barriers impede adequate treatment, such as insufficient access to specialists and biologic treatment. Furthermore, there is an important lack of insight into the local situation. This hampers the development of adequate national treatment standards and financial support.

Female versus male patients. a. Correction for age and disease duration. b. Correction for age, disease duration and biological treatment. c. Correction for age, disease duration, biological treatment and NSAIDs. d. Correction for age, disease duration, biological treatment, NSAIDs and opiates. e. Severe daily impairment (ASAS HI sum score ≥12) versus no or moderate impairment (ASAS HI sum score <12). * Additional correction for opiates was not performed because 100% of the patients with opiate treatment reported presenteeism. B, linear regression coefficient; CI, confidence interval; ns, non-significant; OR, odds ratio; p, p-value.

The objectives were to (1) evaluate the disease burden, quality of life, work participation and treatment status in Chilean axSpA patients and (2) to assess the influence of gender.

Methods: A cross sectional online survey among Chilean axSpA patients, recruited via the Chilean SpA Patient Foundation ("Espondilitis Chile") between July and October 2018. The survey requested information on gender, age, disease characteristics (diagnosis, disease duration, treatment), disease burden (BASDAI and BASFI), quality of life (ASAS Health Index) and work participation (WPAI). The association between BASDAI, quality of life or work participation (presenteeism, absenteeism) and subgroups (gender, biologics) was assessed through univariable and multivariable regression analyses, correcting for age, disease duration and concomitant treatment (NSAIDs, opiates).

Results: AxSpA was reported by 472 participants (91% radiographic, 63% women, mean age 42+10 years), and the levels of disease activity (BASDAI ≥4: 83%; ASAS HI ≥moderately impaired: 91%; table 1) and work disability (absenteeism: 41%; presenteeism 82%; table 2) were high. Thirty-four percent used opiates. Biologics use was very low (20%) but significantly associated with lower BASDAI, BASFI, ASAS HI, and risk of absenteeism. Females had significantly higher BASDAI, BASFI and ASAS HI, although were less likely to receive biologics (26% versus 16%, p< 0.01). After correction for treatment, these gender differences were not significant anymore (table 3).

Conclusion: This web survey strongly suggest a high disease burden and work impairment in Chilean axSpA patients. The use of biologics is low, while the use of opiates was alarmingly high. Women used significantly less biologics despite reporting a worse disease state and work disability, which could be due to treatment inequity. This is the first large web survey on axSpA patients in Latin America and the first to describe labor participation and gender differences in disease activity and treatment in Chilean axSpA patients.

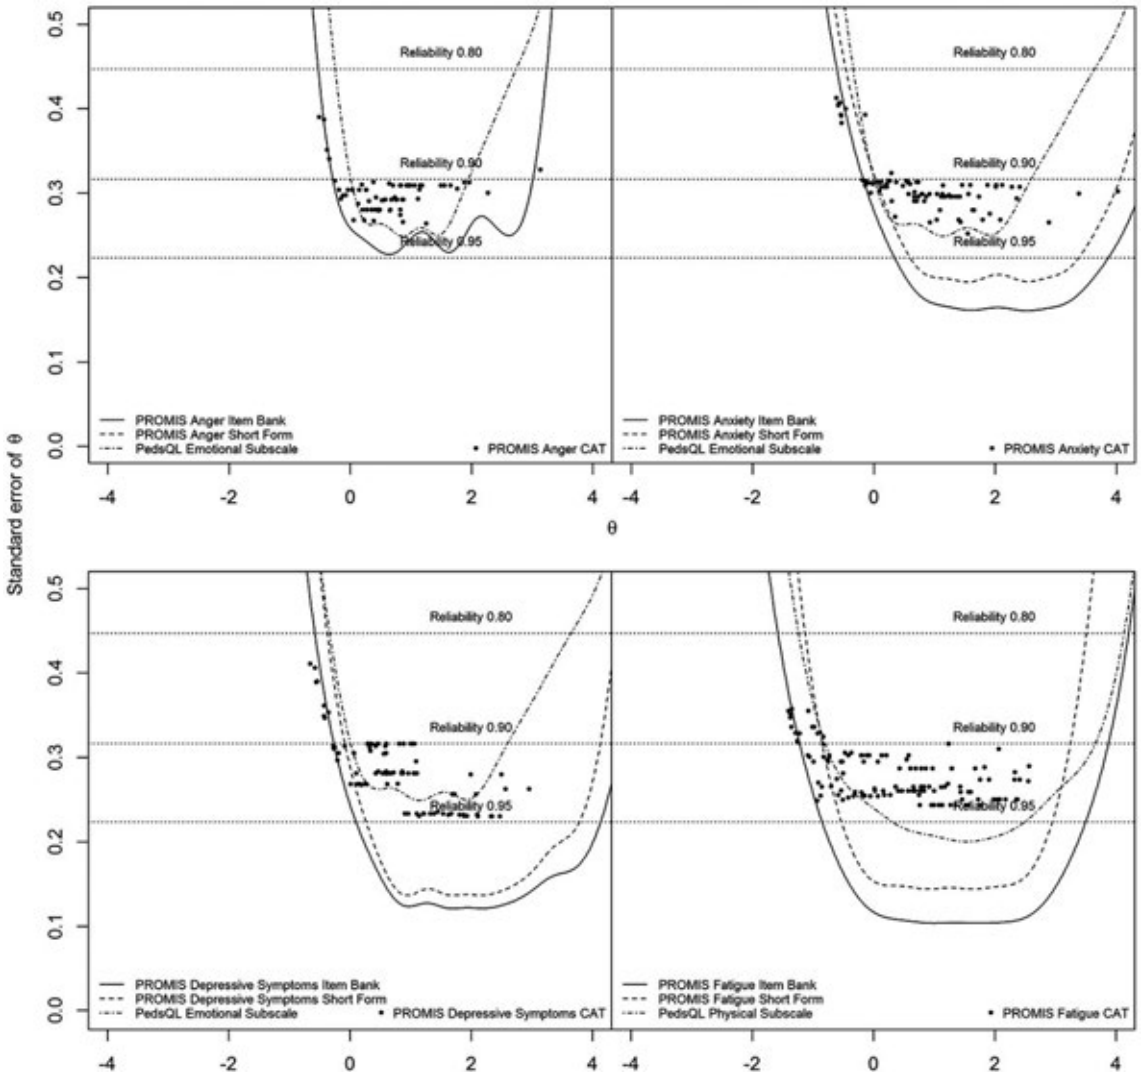
Note: SE(θ), Standard Error of theta; FL, full-length item bank; SF, short-form; CAT, computerized adaptive testing; ICC, intraclass correlation coefficient; CI, confidence interval; SDC, smallest detectable change; * amount of patients with a SE(θ)lower than 0.32. A SE(θ)of 0.32 equals a reliability of 0.90; ** n = 101

Reliability and test-retest reliability of measurements for the full-length (FL) item banks, short-forms (SF) and computerized adaptive test (CAT)s of the pediatric PROMIS item banks in a sample of children with juvenile idiopathic arthritis (n = 155).

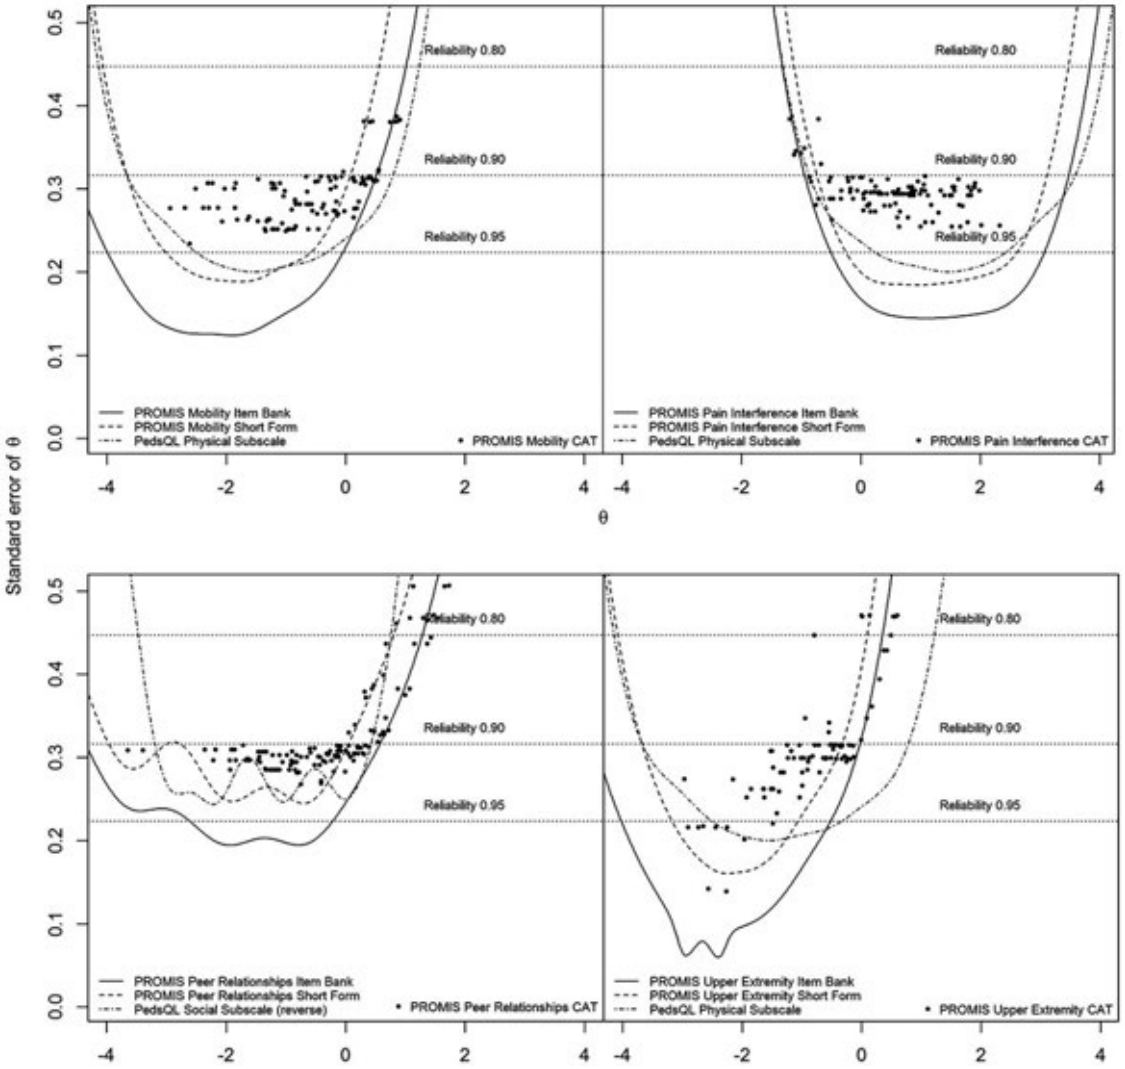


Reliability of measurement (expressed as SE of the theta) plots for the PROMIS item banks: Anger, Anxiety Depressive Symptoms and Fatigue and their associated PedsQL subscale across the range of theta.

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcome measures (PROMs) are often used to include the patients perspective on treatment (outcome). However, the choice of PROMs is difficult, as there are multiple PROMs available to measure a single construct. These PROMs differ in psychometric properties, length and scoring methods and often suffer from ceiling effects. To improve measurements the National Institute of Health (NIH) initiated the development of the Patient Reported Outcomes Measurement Information System (PROMIS®), which contains multiple item banks to assess different construct of Health-Related Quality of Life (HRQoL), symptoms and psychosocial functioning.The purpose of this study was to assess the psychometric properties of eight pediatric PROMIS item banks in a clinical sample of children with Juvenile Idiopathic Arthritis (JIA).

Methods: 154 Dutch children (8-18 years, mean=14.4, SD=3.0) with JIA completed eight pediatric v1.0 PROMIS item banks (Anger, Anxiety, Depressive Symptoms, Fatigue, Pain Interference, Peer Relationships, Physical Function Mobility, Physical Function Upper Extremity) twice and the Pediatric Quality of Life Inventory (PedsQL) and the Childhood Health Assessment Questionnaire (CHAQ) once. Structural validity of the item banks was assessed by fitting a Graded Response Model (GRM) and inspecting GRM fit (CLI, TLI, RMSEA) and item fit (S-X^2). Convergent validity



Reliability of measurement (expressed as SE of the theta) plots for the PROMIS item banks: Mobility Pai Interference, Peer Relationships and Upper Extremity and their associated PedsQL subscale across the range of theta.

(with PedsQL/CHAQ subdomains) and discriminative validity (active/inactive disease) were assessed. Reliability of the item banks, short-forms and CATs was expressed as standard error of theta (SE(θ)). Test-retest reliability was assessed using intraclass correlation coefficients (ICC) and Smallest Detectable Change (SDC).

Results: All item banks had sufficient overall GRM fit (CFI >.95, TLI >.95, RMSEA< .08) and no item misfit (all S-X2 p >.001). High correlations (>.70) were found between most PROMIS T-scores and hypothesized PedsQL/CHAQ (sub) domains. Mobility, Pain Interference and Upper Extremity item banks were able to discriminate between patients with active and inactive disease. Regarding reliability PROMIS item banks outperformed legacy instruments. Post-hoc CAT simulations outperformed short-forms. Test-retest reliability was strong (ICC >.70) for all full-length item banks and short-forms, except for Peer Relationships.

Conclusion: The pediatric PROMIS item banks displayed sufficient psychometric properties in children with JIA. CATs outperformed short-forms in terms of test length and amount of patients reliably estimated. PROMIS item banks are ready for use in clinical research and practice in children with JIA.

Does Improvement in Patient Pain and Fatigue Lag Behind Clinical Remission in Rheumatoid Arthritis Patients? Data from a Rheumatoid Arthritis Registry

Janet Pope ,[1] Emmanouil Rampakakis,[2] Mohammad Movahedi,[3] Angela Cesta,[4] John Sampalis,[2] and Claire Bombardier[4], [1]Western University, London, ON, Canada, [2]JSS Medical Research, Montreal, Canada, [3]Ontario Best Practices Research Initiative, Toronto General Research Institute University Health Network, Toronto, Canada, [4]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) patients are often not in remission due to patient global assessment of disease activity (PtGA) which is included in the formula of all disease activity indices. Given that PtGA may reflect pain or fatigue, the aim of this analysis was to assess the relative timing and perhaps lag of patient-reported outcomes (PRO) after remission is obtained as measured by clinical disease activity index (CDAI) or swollen joint count (SJC28) in a large observational database of RA patients followed in routine clinical care.

Methods: RA patients enrolled in the Ontario Best Practices Research Initiative (OBRI) registry that were not in low disease state at baseline based on the CDAI, SJC28, PtGA, pain and fatigue criteria below, and had at least six months of follow-up, were included in the analysis. Low disease state was defined as CDAI≤10, SJC28≤2, PtGA≤2cm, pain score≤2cm, or fatigue score≤2cm. Remission was defined as CDAI≤2.8, SJC28≤1, PtGA≤1cm, pain score≤1cm, or fatigue score≤1cm. Kaplan-Meier survival analysis was used to assess the time to first low disease state / remission based on each definition.

Results: A total of 986 patients were included with a mean (SD) age and disease duration of 57.4 (12.9) years and 8.3 (9.9) years, respectively, and mostly women (80.0%). Mean (SD) of CDAI, SJC28, PtGA, pain, and fatigue at enrolment was 29.8 (11.7), 8.3 (4.6), 6.4 (1.9), 6.6 (1.9), and 6.7 (2.0), respectively.

Figure 1 shows the time to first low disease state and time to first remission based on different definitions. The median (95%CI) time in months to CDAI≤10 was 12.4 (11.4-13.6), SJC28≤2 was 9 (8.2-10), PtGA≤2cm was 18.9 (16.1-22), pain≤2cm was 24.5 (19.4-30.5), and fatigue≤2cm was 30.4 (24.8-31.7). For remission, the median (95%CI) time to CDAI≤2.8 was 46.5 (42-54.1), SJC28≤1 was 12.5 (11.4-13.4), PtGA≤1cm was 39.6 (34.6-44.8), pain≤1cm was 54.7 (43.6-57.5), and fatigue≤1cm was 42.6 (36.8-48).

Conclusion: Time to achieving low disease state or remission based on PROs is considerably longer compared to swollen joint count which may have significant impact on the time to CDAI low disease activity and remission. Remission and low disease activity composite scores, and PROs lag behind SJCs. Careful interpretation of PROs and composite scores could impact management including prevention of overtreatment and unnecessary switching of DMARDs.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Compared to healthy children, youth with juvenile myositis (JM) often report poorer health-related quality of life (HRQoL). Legacy HRQoL measures may underestimate the impact of JM due to floor/ceiling effects. Patient-Reported Outcomes Measurement Information System® (PROMIS) HRQoL measures have undergone initial validation in pediatric rheumatic diseases, including JM. PROMIS can be administered by using computerized adaptive testing (CAT) item banks or fixed short forms (FSF), but the relative benefits of CAT vs FSF are not known. The purpose of this study was to compare CAT and FSF.

Table 1. Comparison of PROMIS Computerized Adaptive Testing (CAT)-Administered Item Banks and Fixed Short Forms (FSF)

Table 2. Comparison of CAT and FSF by specific T-score ranges

Methods: JM patients (5-17 yo) and their parents were recruited at clinic visits. Demographic and clinical assessments were collected, including: Physician Global Assessment of Disease Activity (PGA); Disease Activity Score (DAS-Muscle/-Skin); muscle enzymes; and Childhood Myositis Assessment Scale (CMAS). Patients (8-17 yo) completed self-report versions and parents (of patients 5-17 yo) completed parent proxy versions of the following PROMIS domains in both CAT and FSF: Fatigue, Pain Interference, Upper Extremity Function, Mobility, Anxiety and Depressive Symptoms. To study the extreme scorers and middle scorers, participants were split into three groups by PROMIS CAT T-scores (< 45, 45-55, >55). Pearson correlations, paired t-tests, and Cohen's d were used to compare PROMIS CAT and FSF for the entire cohort and for each of the three T-score groupings.

Results: Data from 67 patient-parent dyads were analyzed. Most patients were 8-17 yo (n=49; 73%), diagnosed with juvenile dermatomyositis (n=61; 91%), female (n=56; 84%), and white (n=51; 76%). Median [IQR] age of onset was 5.2 [3.9, 7.1] and age at initial study visit was 11.8 [7.4, 15.2]. Median [IQR] clinical data were: PGA 0.5 [0.0, 1.5]; DAS-Muscle 0.0 [0.0, 1.0]; DAS-Skin 1.0 [0.0, 5.0]; and CMAS 52.0 [50.0, 52.0]. Median [IQR] muscle enzyme values were: CPK 92.0 [69.0, 130.0]; AST 28.5 [23.0, 32.8]; ALT 14.0 [11.2, 17.8]; LDH 257.0 [223.0, 307.0]; and Aldolase 5.5 [4.8, 6.0]. PROMIS CAT and FSF were highly correlated (Pearson's correlation coefficients ranging 0.79-0.92) (Table 1). Mean scores between CAT and FSF were not significantly different except in parent proxy anxiety and fatigue, though effect sizes were modest (0.508 and 0.317, respectively). Correlations between CAT and FSF varied based on domains, patient vs parent report, and T-score groupings (Table 2). Review of scatterplots showed floor/ceiling effect at the less symptomatic extreme in all FSF domains (Figure 1).

Conclusion: PROMIS CAT is feasible in clinical settings and is comparable to FSF. Additionally, CAT had less pronounced floor/ceiling effects than FSF, allowing detection of individual differences in low symptom/disability scorers. CAT is recommended for long-term follow-up of JM patients given that deconditioning often persists even in remission. Future studies should focus on multicenter replication of these findings, benefits of CAT vs FSF in patients with more severe symptoms, and clinical interpretability (e.g. minimal important differences, severity strata).

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

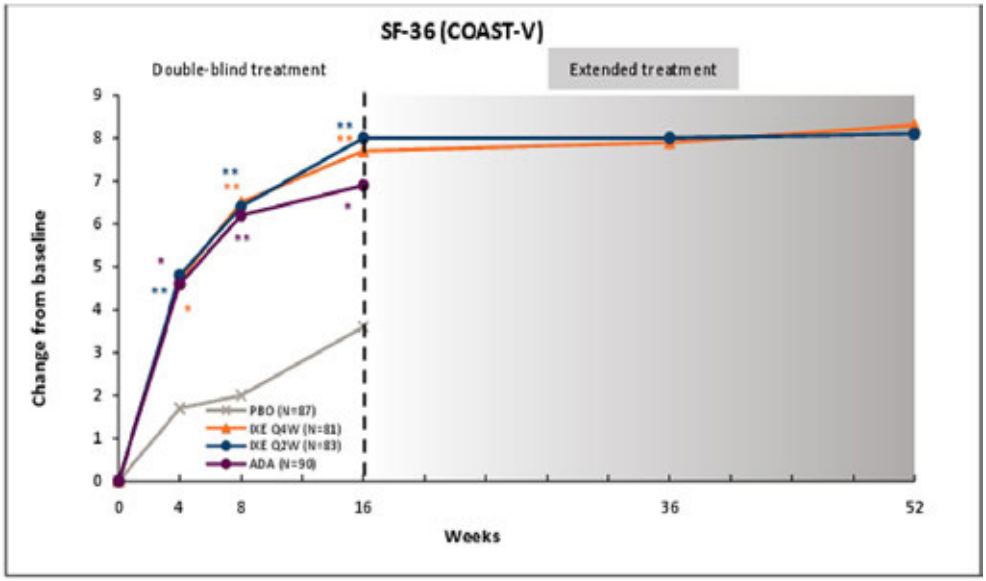
Background/Purpose: Previous trials have used the Short Form (SF)-36 questionnaire to evaluate the impact of ankylosing spondylitis/radiographic axial spondyloarthritis (AS/r-axSpA) on health-related quality of life (HRQoL).[1] Ixekizumab (IXE), is a high-affinity monoclonal antibody that selectively targets interleukin-17A and helps improve HRQoL in patients with AS/r-axSpA.[2] The purpose of this analysis was to evaluate the effect of 52 weeks of treatment with IXE on self-reported HRQoL by SF-36 in patients with active AS/r-axSpA who fulfilled ASAS and modified New York criteria and were naïve to biologic therapy or had failed on/were intolerant to ≥1 but not more than 2, TNF inhibitors (TNF-IRs).

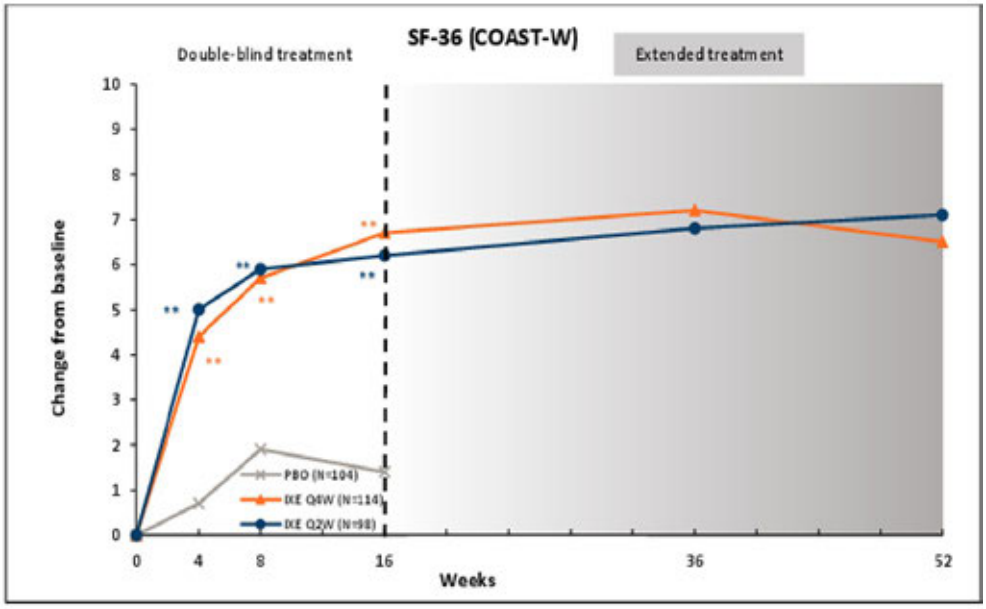
Methods: COAST-V and COAST-W are Phase 3 randomized controlled trials (RCTs) including active and placebo (PBO) comparators in the first 16 weeks in patients with active AS/r-axSpA; BASDAI and back pain scores ≥4; no prior treatment with biologic agents (COAST-V) or TNF-IR (COAST-W). During the double-blind treatment period, patients were randomized 1:1:1:1 to 80 mg IXE every 4 weeks (Q4W) or every 2 weeks (Q2W), active reference arm (adalimumab [ADA] 40mg), or PBO (COAST V) and 1:1:1 to IXE 80 mg Q4W, IXE 80 mg Q2W or PBO (COAST W). At Week 16, patients entered the extended treatment period (Weeks 16-52). Patients initially assigned to PBO/ADA were reassigned to IXEQ4W or IXEQ2W at Week 16. Patients already receiving IXE remained on their assigned treatment regimens through Week 52. Changes from baseline in SF-36 up to Week 16 were analyzed by mixed model for repeated measures. Changes from baseline in SF-36 over Weeks 36-52 were summarized using raw mean with modified baseline observation carried forward (mBOCF) for missing data imputation.

Results: Statistically significant differences in SF-36 Physical Component Summary (PCS) scores were reported in Weeks 4-16 between PBO and IXE Q4W and Q2W groups in COAST-V and COAST-W ($P \leq 0.002$ and $P \leq 0.001$, respectively). Improvements in PCS scores continued at Week 36 and sustained to Week 52 in both COAST RCTs (Figure; Table). Changes in Mental Component Summary scores were modest (Table). Improvements in all domains were reported at 52 weeks with both Q4W and Q2W doses of IXE in both trials (Table).

Conclusion: Improvements in patient-reported HRQoL in A/r-axSpA patients measured with SF-36 were observed at Weeks 4 and 16 and sustained up to 52 weeks of continuous IXE treatment.

Figure 1: SF-36 Physical Component Summary Mean Change from Baseline (COAST-V and COAST-W)





*p≤0.002, **p≤0.001 vs. PBO. Mixed model for repeated measures used to compare least-squares means up to Week 16. No model applied for Weeks 36-52. Missing data imputation was used for Weeks 36-52 only.

Understanding Which Patient-Reported Outcomes Are Important to Rheumatology Patients: Findings from ArthritisPower

W. Benjamin Nowell ,[1] Carol Gaich,[2] Kelly Gavigan,[1] Zhihong Cai,[2] Anabela Cardoso,[2] Theresa Hunter,[3] Julie Birt,[2] Jennifer Workman,[2] and Jeffrey Curtis[4], [1]Global Healthy Living Foundation, Upper Nyack, NY, [2]Eli Lilly and Company, Indianapolis, IN, [3]Eli Lilly and Company, Indianapolis, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcomes (PROs) are important indicators of treatment effectiveness and their role is increasing in comparative effectiveness studies. Little is known about PRO measures patients find most

important for their disease, treatment effectiveness and health outcomes. In this study, we examined PROs voluntarily selected by patients with rheumatologic conditions to further elucidate which disease symptoms they found most important to track within the ArthritisPower registry. These findings will be useful to inform future data collection efforts for trial and clinical study planning. As the study is ongoing, this abstract will discuss initial PRO selections of study participants.

Methods: Adult US patients with self-reported rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), osteoporosis (OP), osteoarthritis (OA), or fibromyalgia syndrome (FMS) in the ArthritisPower registry were invited to participate via an email invitation. Participants were prompted to select up to ten PRO (symptom) measures they felt were important to track for their condition at baseline via the ArthritisPower smartphone and web-based app. Patient-Reported Outcomes Measurement Information System (PROMIS) instruments focusing on symptoms of pain, physical and cognitive function, mental health, fatigue, social function, work impact, sexual function, and sleep were offered. The Outcomes Measures in Rheumatology (OMERACT) RA flare instrument (only for those with RA) and the Lilly-developed morning joint stiffness duration question were also offered. At three subsequent time points (Month [m] 1, m2, m3), participants were given the option to continue tracking their previously selected PRO measures or change to different measures. At m3, participants complete an exit survey to prioritize all measures selected during study participation and to specify other symptoms not available that they would have wanted to track. Descriptive statistics were conducted on baseline data.

Table. **Patient Reported Outcome Measures Selected by Rheumatology Patients**

Domain	N = 251 n (%)
Fatigue	**211 (84.1)**
Mental Health	**206 (82.1)**
Depression	136 (54.2)
Anxiety	108 (43.0)
Applied Cognition Ability	104 (41.4)
Anger	40 (15.9)
Pain (effect on function, behavior)	**205 (81.7)**
Pain Interference	126 (50.2)
Pain Intensity	123 (49.0)
Pain Behavior	107 (42.6)
Physical Function	**181 (72.1)**
Social Function	**167 (66.5)**
Social Isolation	83 (33.1)
Ability to Participate Social	77 (30.7)
Emotional Support	38 (15.1)
Social Satisfaction Discretionary Social Activities	37 (14.7)
Satisfaction Roles Activities	22 (8.8)
Sleep	**162 (64.5)**
Morning Joint Stiffness	**142 (56.6)**
Sexual Function	**27 (10.8)**
Impact on Work	**22 (8.8)**
RA Flare*	**86 (69.9)**

*Measure offered only to participants with RA; N=123

Results: As of May 2019, 292 participants enrolled in this study and 251 completed baseline assessments. Mean age was 55.6 (9.2) years, 89.6% female, 91.2% White, mean disease duration of 12 (10.7) years. These characteristics were similar to the overall ArthritisPower population. The majority (64.1%) self-reported OA, followed by RA (49.0%), FMS (40.6%), PsA (26.3%), OP (20.3%), AS (15.5%) and SLE (5.6%), not mutually exclusive. The top 3 PRO domains that participants chose at baseline, were fatigue, mental health, and pain (Table). The average number of instruments selected for baseline completion was 6.9 (2.4).

Conclusion: Participants prioritized tracking fatigue, aspects of mental health, pain, physical function, social function, sleep, and morning stiffness. These findings provide insights into symptoms rheumatology patients find most important and will be useful to inform the design of future patient-centric clinical trials and real-world evidence generation.

Poor Concordance Between Remission Judged by Physicians and a Patient-Acceptable Symptom State in Psoriatic Arthritis

Rubén Queiro ,[1] Estefania Pardo,[1] Lilyan Charca,[1] Sara Alonso,[1] L. Arboleya,[2] and Mercedes Alperi-López[1], [1]Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Hospital Central Asturias, OViedo

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Both the evaluation of disease activity in psoriatic arthritis (PsA) and the determination of the impact of the disease on patients' lives are subjects of intense research at present. Our objective was to evaluate the concordance between the state of clinical remission and an acceptable symptomatic state for patients.

Methods: Post hoc analysis of a multicentre study that included 223 patients with PsA treated with biologic and non-biologic drugs. Remission was defined according to the evaluating physicians and DAPSA definitions. DAPSA score was calculated by adding the number of tender and swollen joints, VAS pain, patient-reported global assessement (PtGA), and CRP (mg/dl). The cDAPSA was calculated without the contribution of CRP. DAPSA and cDAPSA score ≤ 4 identified clinical remissions.

Table 1. Demographic and clinical characteristics of PsA patients with a PsAID score < 4

	Total N (122)
Male, n (%)	70 (57.4)
Age, mean (SD), yrs.	54.5 (12.7)
BMI, mean (SD) (kg/m²)	27.1 (3.9)
CRP (mg/L), mean (SD)	2.8 (3.3)
Comorbidities, n (%)	
Dyslipidemia	40 (32.8)
HBP	33 (27.0)
Obesity	30 (24.6)
DM	12 (9.8)
PsA clinical patterns, n (%)	
Axial	3 (2.5)
Peripheral	107 (87.7)
Mixed	12 (9.8)
DIP disease	45 (36.9)
Familial history, n (%)	
Psoriasis	60 (49.2)
PsA	11 (9.0)
Ankylosing spondylitis	2 (1.6)
PsA duration, mean (SD), yrs.	9.6 (7.9)
Skin symptoms duration, mean (SD), yrs.	21.6 (14.5)
Articular symptoms duration, mean (SD), yrs.	11.9 (8.7)
Radiologic findings	
Erosions in hands, n (%)	40 (32.8)
Erosions in feet, n (%)	33 (27.0)
PASI, mean (SD)	1.2 (3.8)
HAQ, mean (SD)	0.2 (0.3)
HAQ ≤ 0.5, n (%)	104 (85.2)
MDA, n (%)	76 (62.3)
Kappa [$CI_{95\%}$] HAQ ≤ 0.5 vs. PsAID < 4	0.53 [0.42–0.64]
Kappa [$CI_{95\%}$] MDA vs. PsAID < 4	0.36 [0.24–0.48]

MDA: Minimal disease activity; SD: Standard deviation; BMI: Body mass Index; CRP: C-Reactive Protein; HBP: High blood pressure; DIP: distal interphalangeal joint disease; DM: Diabetes mellitus; PASI: Psoriasis Area and Severity Index; HAQ: Health Assessment Questionnaire; PsAID: Psoriatic Arthritis Impact of Disease; CI : Confidence intervals.

A descriptive statistical analysis of all the variables was performed, including central tendency and dispersion measures for continuous variables, and absolute and relative frequencies for categorical variables. Student's t-test, Mann-Whitney-U test or Kruskall Wallis H test were used to compare quantitative variables and Pearson's chi-square or Fisher's exact tests for qualitative variables. Concordance was assessed using Cohen's κappa (k) and was considered as follows: < 0.20 = poor, 0.21–0.40 = fair, 0.41–0.60 = moderate, 0.61–0.80 = good, and 0.81–1.00

Table 2. Kappa agreement between remission and patient-acceptable symptoms state

			Skin and joint remission*	
			No	Yes
PASS = PsAID <4	No	N	86	15
		%	50,9%	27,8%
	Yes	N	83	39
		%	49,1%	72,2%
Total		N	**169**	**54**
		%	**75,8%**	**24,2%**
Kappa [$CI_{95\%}$]			0,16 [0,05-0,26]	

PASS: Patient-Acceptable Symptoms State. PsAID: Psoriatic Arthritis Impact of Disease.
CI: Confidence Interval. *according to the evaluating rheumatologist.

= very good. Tests were two-tailed with a significance level of 5%. Data were analysed using SPSS V19.0 statistical software.

The PsAID questionnaire reflects the impact of PsA from the patients' perspective. It is comprised of 12 physical and psychological domains. Each domain is rated from 0 to 10 with a different weighting. Total score is divided by 20. The final score has a range from 0 (best status) to 10 (worst status) with a cutoff of 4. A PsAID value below 4 defines a PASS state.

Results: Of the 223 patients analysed, 122 (54.7%) met the PsAID criterion below 4. The characteristics of this sub-population are shown in Table 1. There was fair (k: 0.23) and poor (k: 0.17) agreement between joint and cutaneous remission respectively (according to the evaluating physician) and PASS status. the degree of agreement between a complete clinical remission (both cutaneous and articular according to the evaluating physician) and the PASS status was low (k: 0.16, Table 2). There was a moderate agreement (k: 0.46) between DAPSA remission and PASS, while there was almost a good concordance (k: 0.58) between cDAPSA remission and PASS.

Conclusion: The agreement between the state of remission judged by doctors and PASS is quite low. The degree of agreement between DAPSA remission and PASS is better, but it is still moderate. Both DAPSA and PsAID should be included in the routine clinical assessment of patients with PsA, since both offer a superior overall view to that given by each instrument separately. It is also better to define remission in accordance to a composite index rather than according to physicians´ opinion.

Is There Any Relationship Between Cardiovascular Comorbidity and a Patient-Acceptable Symptom State in Psoriatic Arthritis?

Rubén Queiro ,[1] Estefania Pardo,[1] Lilyan Charca,[1] Sara Alonso,[1] L. Arboleya,[2] and Mercedes Alperi-López[1], [1]Hospital Universitario Central de Asturias, Oviedo, Spain, [2]Hospital Central Asturias, OViedo

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is accompanied by a high prevalence cardiovascular (CV) comorbidity. This comorbidity has been associated with worse therapeutic results as well as worse quality of life. We aimed to evaluate if the presence of this CV comorbidity could be associated with a greater impact of PsA on patients´ lives according to the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire.

Methods: Post hoc analysis of a multicentre cross-sectional study that included 223 patients with PsA according to CASPAR criteria and under systemic treatment. The impact of the disease was assessed by the PsAID questionnaire. The impact of disease was evaluated by the PsAID, a questionnaire recently developed by the EULAR that reflects the impact of PsA from the patient's perspective. It is comprised of 12 physical and psychological domains. Each domain is rated from 0 to 10 with a different weighting. The total score is divided by 20. The final score has a range from 0 (best status) to 10 (worst status) with a cut-off of 4. A PsAID value less than four has been defined as a patient-acceptable symptom state (PASS). A descriptive statistical analysis of all the variables was performed, including central tendency and dispersion measures for continuous variables, as well as absolute and relative frequencies for

HAQ, mean (SD)	0.2 (0.3)
HAQ ≤ 0.5, n (%)	104 (85.2)
MDA, n (%)	76 (62.3)
Kappa [$CI_{95\%}$] HAQ ≤ 0.5 vs. PsAID < 4	0.53 [0.42–0.64]
Kappa [$CI_{95\%}$] MDA vs. PsAID < 4	0.36 [0.24–0.48]

MDA: Minimal disease activity; SD: Standard deviation; BMI: Body mass index; CRP: C-Reactive Protein; HBP: High blood pressure; DIP: distal interphalangeal joint disease; DM: Diabetes mellitus; PASI: Psoriasis Area and Severity Index; HAQ: Health Assessment Questionnaire; PsAID: Psoriatic Arthritis Impact of Disease; CI: Confidence intervals.

categorical variables. Student's t-test, the Mann-Whitney U test, and the Kruskall-Wallis H-test were used to compare quantitative variables, and Pearson's chi-square test or Fisher's exact tests were used for qualitative variables. Concordance between different PsA outcomes was assessed using Cohen's κappa (k) and was considered as follows: < 0.20 = poor, 0.21–0.40 = fair, 0.41–0.60 = moderate, 0.61–0.80 = good, and 0.81–1.00 = very good. The tests were two-tailed with a significance level of 5%. The data was analysed using SPSS V19.0 statistical software.

Results: Out of the 223 patients included in this analysis, 122 (54.7%) were in PASS status. The main characteristics of this subpopulation are shown in Table 1. There were more smokers among patients who did not achieve the PASS (25% vs. 13%, p= 0.08). However, there were more obese among those who did reach a PASS (24.6% vs. 15.8%, p= 0.108). No differences were found in the distribution of other CVRF between patients with and without PASS. Among PASS patients there was a significantly higher frequency of coronary heart disease (6.6%) than in non-PASS patients (1%), p = 0.035. The number of CV risk factors did not differ between the two groups.

Conclusion: In this multicentre study, we found no association between CV risk factors and the achievement of a PASS status in patients with PsA under systemic therapy. All in all, patients with PsA should be encouraged to maintain healthy lifestyle habits.

Table 2. Correlation among HAQDI and MDHAQ and Responsiveness to change

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The multi-dimensional health assessment questionnaire (MDHAQ) is a patient-reported outcome that is commonly used in clinical practice in the US and comprises of 10 items. Although the validated Health Assessment Questionnaire Disability Index (HAQDI) measures similar constructs as the MDHAQ, is less commonly used and has 16 items. Therefore, the objective of this study is to assess if the MDHAQ (divided by 3.33 to transform to the same scale as HAQDI) can substitute for the HAQDI in ACR20 assessment and cohort studies.

Methods: Between 2016-2019, patients with PsA were enrolled in the Psoriatic Arthritis Research Consortium (PARC), a longitudinal observational cohort at four United States institutions: University of Pennsylvania, Cleveland

Clinic, New York University, and University of Utah. Baseline patient characteristics were descriptively reported. A priori we hypothesized that the MDHAQ and HAQDI would have high correlation at baseline (>0.8) and among the change scores (>0.8) and that responsiveness would be similar. Correlations were calculated among the total scores using Spearman's correlation coefficients at baseline and follow-up visit. Change scores (e.g., score at visit 1 minus score at visit 2) and standardized mean responses were calculated. Sensitivity analyses excluding patients with low disease activity were calculated. We additionally examined agreement with the 20% improvement cut-off to determine the potential effect of using MDHAQ in the ACR20 criteria in place of HAQDI.

Results: HAQDI and MDHAQ data were available in 438 visits in which both questionnaires were completed and 161 patients with HAQDI and MDHAQ at two time points. The mean age was 51.5 ± 14.6 years old, 53% were male, and most had low disease activity with mean swollen (66) and tender (68) joint counts 2.3 ± 4.4 and 4.3 ± 6.4, respectively. At baseline, the mean HAQDI was 0.64 ± 0.62 (range 0-3) and the mean MDHAQ was 1.9 ± 1.7 (range 0-10; Table 1). Dividing the MDHAQ by 3.33 to transform it to the same scale as the HAQDI resulted in a transformed MDHAQ mean of 0.56 ± 0.48 with a mean excursion from the HAQDI score of 0.07 ± 0.35 (Figure 1). Among all time points, the Spearman's correlation coefficient between the two instruments was 0.84 and among the first visit only, the coefficient was 0.83. The mean change over two visits in the HAQDI was -0.07 ± 0.4, with a standardized response mean (SRM) of 0.19 and mean change in the MDHAQ was -0.16 ± 1.1 with an SRM of 0.14. The Spearman's correlation coefficient among the two change variables was 0.55 (Table 2). Using the 20% criteria for the ACR20, the agreement among use of HAQ-DI and MDHAQ is 74%. When excluding patients with a clinical Disease Activity index for Psoriatic Arthritis (c-DAPSA) score < 14 (i.e., low disease activity), the correlation coefficients were similar.

Conclusion: Although the HAQDI consists of more questions than the MDHAQ, the total scores correlated well when analyzed cross-sectionally. However, the correlation was moderate between the change over time. Using the 20% improvement cut-off, most were correctly classified with MDHAQ but MDHAQ cannot directly replace HAQDI for the ACR20 criteria.

Improved Patient-Reported Outcomes in Patients with Persistently Active Rheumatoid Arthritis Following Treatment with Repository Corticotropin Injection

Daniel Furst ,[1] George Wan,[2] Jingyu Liu,[3] Julie Zhu,[3] Laura Bartels-Peculis,[3] Mary Panaccio,[3] and Roy Fleischmann[4], [1]University of California, Los Angeles, CA, [2]Mallinckrodt Pharmaceuticals, Bedminster, NJ, [3]Mallinckrodt Pharmaceuticals, ARD, LLC, Bedminster, NJ, [4]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is an autoimmune disorder characterized by progressive inflammation and irreversible joint damage. Treatment of active disease includes disease-modifying anti-rheumatic drugs (DMARDs) and short-term corticosteroid (CS) use. A comprehensive assessment of clinical treatment outcomes should include validated patient-reported outcome (PRO) instruments. Repository corticotropin injection (RCI) is approved by the FDA for short-term adjunctive use in the treatment of RA.[1] A naturally sourced complex mixture of purified adrenocorticotropic hormone ($ACTH_{1-39}$) analogues and other pituitary peptides, RCI stimulates endogenous CS production and is an agonist for all 5 melanocortin receptors (MCRs).[1,2] MCR activation by ACTH has been shown to have direct and indirect anti-inflammatory and immunomodulatory effects.[2] A 2-part, multicenter, placebo-controlled Phase 4 trial explored the effect of RCI treatment on PROs with the greatest impact on quality of life (ie, for pain, fatigue, physical functioning, and ability to work) in patients with persistently active RA. Data presented are from the open-label period (ClinicalTrials.gov ID: NCT02919761).

Methods: Adults with persistently active RA (defined as DAS28-ESR >3.2) despite DMARD and CS use received 80 U of RCI subcutaneously, twice weekly during a 12-week open-label period. PRO measurements included the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) scale, the Work Productivity and Activity Impairment (WPAI) questionnaire, and the Health Assessment Questionnaire – Disability Index (HAQ-DI). Mean changes from baseline were assessed at Weeks 4, 8, and 12. Patients' global assessments of disease activity and pain were also evaluated.

Results: Of the 259 patients in the modified intent-to-treat population, 89.2% were female and 65.6% were Caucasian (mean age, 51 years). During the 12-week open-label treatment period (wherein 62.9% of patients [163/259] achieved low disease activity by Week 12), mean improvements from baseline were clinically and statistically significant at all time points for HAQ-DI and FACIT-F scores. Clinically and statistically significant improvements in 3

PRO Assessment	Baseline, Mean (SD)	Week 4	Week 8	Week 12
		Mean Change From Baseline (SD)		
FACIT-F	22.8 (8.4)	−5.0 (8.2)*	−6.5 (8.4)*	−8.7 (8.4)*
HAQ-DI	1.7 (0.6)	−0.5 (0.5)*	−0.6 (0.6)*	−0.84 (0.6)*
Patient global assessment of disease activity[b]	63.4 (20.0)	−17.8 (23.6)*	−25.7 (25.2)*	−35.0 (27.3)*
WPAI-RA				
Percent work time missed due to RA[c]	24.9 (27.6)	−7.0 (26.6)	−5.2 (28.0)	−10.8 (26.5)**
Percent impairment while working due to RA[c]	50.3 (27.1)	−18.7 (24.4)*	−18.0 (23.9)*	−25.2 (25.3)*
Percent overall work impairment due to RA[c]	58.1 (28.6)	−17.6 (27.0)*	−17.6 (27.5)*	−25.5 (29.2)*
Percent activity impairment due to RA[c]	63.2 (24.2)	−18.1 (24.3)*	−22.5 (25.3)*	−32.8 (27.4)*
Patient global assessment of pain[d]	64.9 (20.4)	−20.8 (23.3)*	−27.6 (25.3)*	−37.4 (27.4)*

of 4 WPAI subscores – percent impairment while working, percent activity impairment, and percent overall work impairment – were observed at all time points; for percent work time missed, significant improvement was achieved by Week 12. Clinically and statistically significant improvements from baseline at Weeks 4, 8, and 12 were found for patient-reported global assessments of disease activity and pain (see **Table** for results).

Conclusion: During the 12-week open-label treatment period, RCI significantly improved patient-reported pain, fatigue, physical functioning, and work-related impairment as early as Week 4. RCI treatment resulted in rapid and clinically meaningful improvements in PROs deemed most relevant to quality of life by patients with persistently active RA.

Disease Activity and Quality of Life in Behçet's Syndrome: The Role of Patient Reported Outcome

Antonio Figliomeni ,[1] Alice Parma,[1] Viola Signorini,[2] Emanuele Calabresi,[1] Rosaria Talarico,[1] and Marta Mosca[3], [1]Università di Pisa, PISA, Italy, [2]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, pisa, Toscana, Italy, [3]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's syndrome (BS) is a systemic vasculitis, characterised by recurrent oro-genital ulcers, ocular inflammation and skin manifestations; articular, vascular, gastro-enteric and neurological involvement may also occur.The complex pattern of BS profile can effect negatively on patients' quality of life. The primary aim of this study was to explore the role of quality of life in BS patients by means of patient reported outcome (PRO); the secondary aim was to study any correlation between disease activity, psychiatric symptoms and quality of life.

Methods: The study enrolled 147 patients (86 M, 61 F), all fulfilling the International Study Group (ISG) criteria for BS. Their mean age was 41 ± 7 years (18-77), while the disease duration was 11 ± 4 years (5-18) and the mean follow-up of 7 ± 3 years. Disease activity was evaluated by means of the Behçet's Disease Current Activity Form (BDCAF), while Short-form-36 (SF-36) was used to evaluate quality of life. Disease activity was compared with the global SF-36 score and with each dimension, that includes physical functioning, physical disability, body pain, general health, vitality, social functioning, emotional disability, mental health according the Diagnostic and Statistical Manual of Mental Disorders fourth edition (DSM-IV). The statistical analysis was performed using Student t-test, Mann-Whitney-U test, ANOVA, and Pearson correlation.

Results: At time of evaluation, according BDCAF, 48 BS patients (33%) had clinically active disease characterized by concomitant types of involvement (40 muco-cutaneous involvement, 18 ocular involvement 8 joint involvement, 5 neurological involvement, 4 gastro-enteric). As expected, the overall SF- 36 scores were significantly lower in patients with clinically active disease. Notably, female BS patients had statistically significant lower scores in all SF-36 domains compared with male patients. When each domain of SF-36 was evaluated, we found that physical disability ($p=0.004$), body pain ($p=0.006$), general health ($p=0.001$), and vitality ($p=0.001$) were significantly lower in patients with disease activity. Notably, vitality ($p=0.001$), physical disability($p=0.004$), social functioning ($p=0.001$), emotional disability ($p=0.003$) and mental health ($p=0.001$) were significantly lower in patients with muco-cutaneous active disease, compared with the other patients with active disease. Moreover, we found a significant correlation between disease activity, high frequency of bipolar disorder and worsening of quality of life.

Conclusion: The combination of PRO measures and disease activity have been demonstrated to add more information compared to the evaluation of disease activity alone. These considerations suggest that the correct assessment of BS needs a multi-dimensional approach, that includes disease activity, disease damage and quality of life.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Associations of depression with clinical status in RA[1] and differences in clinical status in different countries[2] have been reported. We compared MDHAQ (multidimensional health assessment questionnaire) scores for clinical and psychological status, including RAPID3 (routine assessment of patient index data) and psychological index, in patients with rheumatoid arthritis (RA) or spondyloarthropathies (SpA) at one setting in the USA vs another in Spain.

Methods: The MDHAQ is a 2-page self-report questionnaire, which is completed by all RA and SpA patients before seeing the rheumatologist at certain rheumatology settings, including one in the USA and another in Spain. MDHAQ data in the 2 settings were compared in a cross-sectional study of patients with RA or SpA. The MDHAQ includes 0-10 scores for physical function (FN), visual analogue scales (VAS) for pain (PN), and patient global estimate (PATGL), compiled into 0-30 RAPID3, for which minimum clinically important improvement (MCII) is 3.8[3]. The MDHAQ also includes a 0-10 fatigue VAS, 0-48 RADAI self-reported painful joints count, 0-60 symptom checklist, as well as 3 psychological queries in the traditional patient-friendly HAQ format concerning depression, anxiety, and sleep quality

Table. MDHAQ demographic, clinical, and psychological scores of RA and SpA patients at two sites, one in USA and the other in Spain. Data are presented as mean (SD) and %.

	RA patients (n=566)			SpA patients (n=209)		
Site	USA N=464	Spain N=102	p	USA N=141	Spain N=68	p
Demographic data						
Age	55.6 (14.8)	58.8 (12.1)	0.043	46.3 (15.0)	55.6 (12.1)	<0.001
Female	86.2%	82.3%	0.317	36.2%	47.0%	0.132
White	141 (40.9%)	93 (91.2%)	<0.001	80 (57.7%)	66 (97.0%)	<0.001
BMI	29.4 (8.1)	26.1 (4.4)	<0.001	29.8 (7.2)	27.7 (5.0)	0.050
MDHAQ scores						
Physical Function	2.6 (2.0)	2.4 (1.8)	0.214	1.9 (1.7)	3.0 (2.1)	<0.001
Pain	5.7 (2.9)	4.5 (2.8)	0.001	4.3 (3.2)	4.9 (3.0)	0.209
PATGL	5.4 (3.0)	4.6 (2.8)	0.022	4.0 (3.0)	5.3 (2.9)	0.001
RAPID3	13.7 (7.2)	11.6 (6.8)	0.009	9.1 (7.5)	13.3 (7.3)	<0.001
Depression (0-3.3)	0.7 (0.9)	0.8 (1.0)	0.476	0.5 (0.8)	1.1 (1.0)	<0.001
Anxiety (0-3.3)	0.8 (0.9)	0.9 (0.9)	0.907	0.7 (0.9)	1.3 (1.0)	<0.001
Sleep problems (0-3.3)	1.3 (1.0)	1.1(1.0)	0.156	1.0 (0.9)	1.5 (1.0)	<0.001

(scores 0 to 3.3). MDHAQ demographic, clinical, and psychological data were compared by diagnostic groups at the 2 settings using Student t-test and Chi^2 test.

Results: Among 775 patients with RA or SpA, 605 were from USA, 464 with RA and 141 with SpA, and 170 from Spain, 102 with RA and 68 with SpA (Table). Patients in the USA were younger than in Spain. Patients with RA were 82-86% female, while SpA patients were 36–47% female - no significant sex differences by site. Patients in the USA were 41-58% white versus 91-97% in Spain (Table). Mean BMI was higher in the USA in both diagnoses. MDHAQ clinical variables in RA patients were higher in the USA vs Spain, statistically significant for pain and RAPID3, although the RAPID3 difference in RA of 2.2 (13.7 in the USA versus 11.6 in Spain) did not meet MCII of 3.8. No significant differences in self-report psychological scores were seen in RA patients in the 2 settings. By contrast, in SpA patients, MDHAQ clinical and psychological variables were higher in Spain vs USA (Table). The difference in RAPID3 of 4.2 (13.3 in Spain versus 9.1 in the US) was greater than the MCII, indicating statistical and clinical significance. Statistically significantly poorer status for depression, anxiety and poor sleep quality also was seen in SpA patients in Spain versus USA, similar to differences in clinical scores.

Conclusion: In comparisons of a setting in the USA vs one in Spain, somewhat higher scores were seen for RA patients in the USA for clinical measures, which did not meet criteria for MCII, and no differences were seen in psychological status. In patients with SpA, poorer status was seen in Spain vs the USA in both clinical and psychological MDHAQ measures. The findings are consistent with associations between self-report of depression and RAPID3, and component physical function, pain, patient global assessment scores.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) or spondyloarthritis (SpA) are more likely to report depression than the general population, and depression has been associated with poorer outcomes[1,2]. A multidi-

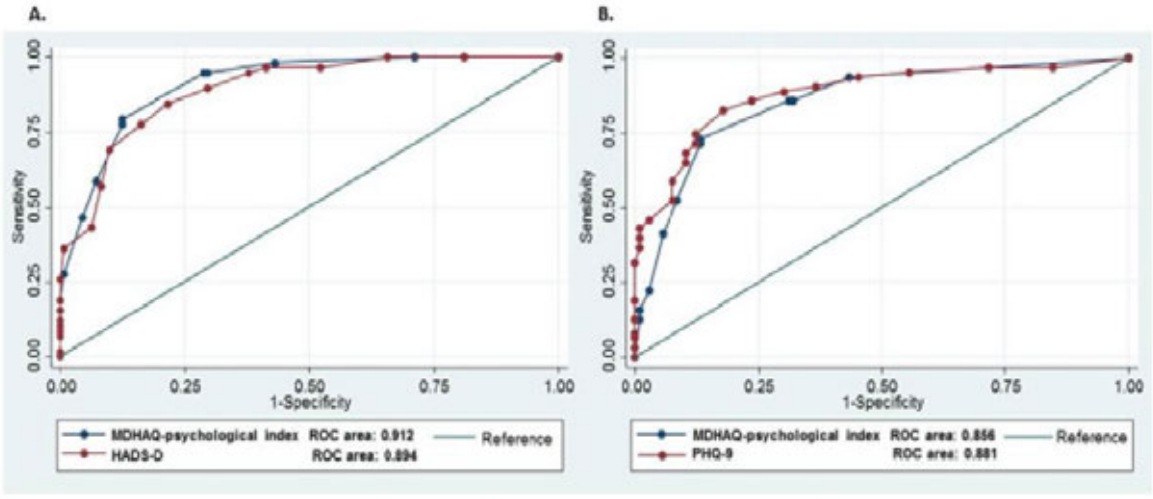
Table: Spearman rank correlations between 3 MDHAQ psychological items and psychological index versus PHQ9 and HADS scores. *p<0.001

MDHAQ/RAPID3: Patient self-report scores	PHQ9	HADS		
		Depression	Anxiety	Total
MDHAQ-psychological items (0-3.3)				
- Sleep problems	0.75*	0.63*	0.62*	0.67*
- Anxiety/being nervous	0.69*	0.64*	0.75*	0.74*
- Depression/feeling blue	0.72*	0.70*	0.70*	0.75*
Total MDHAQ psychological index sleep+ anxiety+ depression (0-9.9)	0.80*	0.73*	0.76*	0.79*
PHQ-9 (0-27)	–	0.78*	0.77*	0.82*

mensional health-assessment questionnaire (MDHAQ) has been found informative in many rheumatic diseases[3], and includes two queries to screen for depression. We compared these 2 MDHAQ depression items to 2 widely-used depression indices: the Patient Health Questionnaire (PHQ-9), and the Hospital Anxiety Depression Scale (HADS).

Methods: Consecutive patients attending two rheumatology clinical settings with a primary diagnosis of either RA or SpA completed a MDHAQ, which includes a 60 Yes/No symptom checklist (one symptom is depression), and a psychological index as the sum of 3 queries in the patient-friendly HAQ format (ranging from "without any difficulty" to "unable to do") concerning dealing with depression, anxiety and sleep quality (each scored 0-3.3 for a total score=0-9.9). Patients also completed the PHQ-9, a depression screening tool (total=0-27, ≥10=depression), and HADS, a 14-item screening tool, 7 for depression (HADS-D) and 7 for anxiety (HADS-A) (total=0-21, ≥8=depression). Spearman correlations between the MDHAQ-psychological index and its 3 individual index items versus PHQ-9 and HADS were computed. Agreement and confidence intervals (CI) between MDHAQ-depression in the symptom checklist versus PHQ-9 ≥10 and HADS-D ≥8 as positive screens for depression was calculated. Receiver-operator characteristic (ROC) curves were analysed for the MDHAQ psychological index, using PHQ-9≥10 or HADS-D≥8 as reference standards.

Figure: ROC curves for MDHAQ psychological index versus 2 external standards: A. PHQ-9≥10 B. HADS-D≥8 (B)



Results: Among 170 patients studied, 102 had RA and 68 had SpA, 82% and 47% females, mean age 58.8 and 55.6 years, respectively. In RA, depression screening was positive in 26% of patients by MDHAQ-depression, 28% by PHQ-9 ≥10, and 33% by HADS-D ≥8, versus 35%, 43%, and 45%, respectively in SpA. Agreement between MDHAQ-depression and PHQ-9≥10 was 83% (kappa= 0.60, 95% CI 0.47, 0.73), and with HADS-D≥8 was 79% (kappa= 0.52, 95% CI 0.39, 0.66). Agreement between PHQ-9≥10 and HADS-D≥8 was 82% (kappa= 0.60 95% CI 0.48, 0.72). Correlations between the MDHAQ psychological index and individual items with PHQ-9 and HADS ranged from 0.62 to 0.82 (p< 0.001) (Table). The area under the ROC curve for the total MDHAQ psychological index was 0.91 (95% CI 0.87, 0.95) with PHQ-9≥10 and 0.86 (95% CI 0.79, 0.91) with HADS-D≥8 (Figure).

Conclusion: The prevalence of positive screening for depression was higher in SpA patients versus RA patients according to each screening tools. MDHAQ self-report of depression showed good agreement with PHQ-9 ≥10 and HADS ≥8 to screen for depression. The three psychological queries on the MDHAQ can be combined into a psychological index to provide a useful clue to screen for depression in busy clinical settings.

Validation of a Risk Perception Questionnaire Developed for Patients with Rheumatoid Arthritis

Irazú Contreras-Yáñez,[1] Pilar Lavielle,[2] Patricia Clark,[3] and **Virginia Pascual-Ramos** [1], [1]Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Distrito Federal, Mexico, [2]Clinical Epidemiology Unit, Hospital de Especialidades, Centro Médico Nacional Siglo XXI, Mexico City, Mexico, [3]Head of the Clinical Epidemiology Unit, Hospital Infantil de México Federico Gómez-Facultad de Medicina UNAM, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment recommendations directed to rheumatoid arthritis patients (RA) may be more easily adopted if they are patient-centered. The adoption of health behaviors is associated with the recognition of risks. Risk perception (RP) is a multidimensional phenomenon that describes the individual's judgment of the likelihood of experiencing something unpleasant (1). Assessing perceived risk helps to explain how RA patients integrate their ideas concerning the disease and its treatments, and how this understanding impacts their self-care management. There is no validated instrument to assess RP in RA patients. The objective of the study was to develop and validate the RP Questionnaire (RPQ) for Spanish speaking patients with RA.

Methods: RPQ development and validation was performed in 3 steps, using convenience samples (**Table 1**). Step-1 included the conceptual model construction (literature review), 20 patient's interviews to identify components from the conceptual model-dimensions and 11 healthcare provider´s consultations who identified RA-related manifestations/complications (network and frequencies analysis). Step-2 consisted of item generation and reduction and ques-

tionnaire feasibility (n=100); for scaling response we selected a direct estimation method of responses, on a visual analogue scale and for item scoring we proposed the method of standard scores to be able to compare our results with those eventually described in other populations. Step-3 consisted of RPQ psychometric validation (n=270), which included content, face, construct (exploratory factor analysis) and criterion validity (logistic regression analysis) and consistency and stability (Cronbach's α and test-retest). The study received IRB approval and patients included signed informed consent form.

Results: Patients included in the 3 samples were representative of typical RA outpatients attending a tertiary care level center (**Table 1**).

Step 1. The initial conceptual model included 7 dimensions, 3 for probability and 1 each, for responsibility, prevention, control and for severity.

Step 2. The final version of the RPQ included 27 items distributed in 5 dimensions (**Table 2**)**,** and was feasible: mean of time required to fill it was of 13 minutes and all patients agreed the time was convenient; 89% of the patients agreed about instructions and item´s semantic clarity and 97% of them agreed about adequacy of the RPQ format. (Mean±SD) RPQ score for the sample was 50±6.69.

Table 1. Description of the sample´s characteristics, and steps of RPQ development and validation.

	N=20 (Step 1) (Conceptual model construction)	N=100 (Step 2) (Item generation and reduction)	N=270 (Step 3) (Psychometric Validation)
Females[1]	19 (95)	95 (95)	262 (97)
Years of age	52 (45-50)	53.5 (42-63)	57 (50-63)
Years of formal education	9 (9-12)	9 (9-11)	7 (7-9)
Patients with medium-low SE level[1]	19 (95)	90 (90)	251 (93)
Years of disease duration	20 (16-24)	13 (7.9-21.5)	12 (7-18)
Patients in remission status[1]	12 (60)	NA	146 (54)

Patients with joint replacement[1]	4 (20)	12 (12)	43 (16)

Data as presented as median (25th-75th interquartile range) unless otherwise indicated. [1]Number (%); SE=socioeconomic; CRP=C reactive protein; ESR=erythrocyte sedimentation rate; RF=rheumatoid factor; ACCP=antibodies to cyclic citrullinated peptides; NA=not available. *Data limited to 230 patients with sample available.

Table 2. Psychometric characteristics of the RPQ by dimension

RPQ Dimension	Cronbach´s α	ICC 95% CI	Mean of inter-item correlations	Floor effect/ceiling effect (%)
Likelihood to develop articular and extra-articular manifestations (9 items)	0.93	0.93 0.91-0.94	0.59	0 / 0.7
Likelihood to develop complications and/or comorbidities and disease severity (7 items)	0.86	0.86 0.81-0.89	0.52	0 / 0.7
Likelihood to develop socioeconomic unfavorable consequences (8 items)	0.89	0.87 0.84-0.90	0.51	0 / 0
Perception of personal responsibility to prevent and develop RA-related complications (2 items)	0.81	0.80 0.74-0.85	0.69	15.9 / 0
Perception of personal control over the disease (1 item)	NA	NA	NA	3.3 / 3.7

NA=not applicable; ICC=intraclass correlation coefficient; CI=confidence interval

Table 3. Logistic regression analysis of RP (presence) based on number of external criteria

	2 vs ≥ 3 external criteria	1 vs ≥ 3 external criteria	None vs ≥ 3 external criteria
OR to RP	2.307	2.934	8.730
95% CI	1.622-3.281	2-4.293	3.715-20.514
R^2	0.296	0.269	0.278
p value	0.000	0.000	0.000

OR= odds ratio; RP=risk perception; CI=confidence interval

Step 3. A five-factor model was most appropriated and resulted in 68.8% of the variance explained; Cronbach's α=0.90, intraclass-correlation-coefficient=0.93 (95% CI=0.90-0.95). Psychometric properties by dimension are summarized in **table 2**. A positive relation between number of external criteria recorded from the charts and RP was found as summarized in **table 3**.

Conclusion: The RPQ was valid and reliable to evaluate RP in RA outpatients; it can be incorporated to routine care and clinical research, and guide interventions to improve patient's health behaviors.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Patient Outcomes, Preferences, & Attitudes Poster I: Patient Reported Outcomes

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Flares are inherent to the rheumatoid arthritis (RA) disease course and associated with poor clinical outcomes including low quality of life, joint damage and disability, suggesting the need for their early detection and timely management. The self-administered Flare Assessment in Rheumatoid Arthritis (FLARE-RA) questionnaire was devised and validated for detection of current and recent flares in RA, taking into account both patient and provider perspectives [1]. The FLARE-RA questionnaire includes arthritis-related subscale and general subscale. The overall score for the questionnaire is defined as the global scale, with scoring from 0 (no flare) to 10 (maximum flare). We aimed to define the cross-cultural criterion validity of the FLARE-RA questionnaire and cut-off(s) for definition and decision in four different countries, using different anchor items in patients with RA.

Methods: This cross-sectional study included adult patients with prevalent RA (per 2010 ACR/EULAR criteria) attending outpatient rheumatology clinics in four countries. Flare occurrence over the past 3 months was assessed using the FLARE-RA questionnaire. The cut-offs for the FLARE-RA score were defined using the following anchor items obtained at the same encounter: 1) Patient report of flare; 2) DAS28-CRP >3.2; 3) Change of anti-rheumatic treatment, based on the area under the receiver operating characteristic curve (AUC) and distance to (0,1).

Results: The study included 571 patients with RA (mean age 56.9 years, 75.3% female). The discrimination for the FLARE-RA was acceptable-to-excellent: AUC for the global FLARE-RA score ranged from 0.71 to 0.92. The summary of optimal cut-offs for the FLARE-RA questionnaire is presented in the Table. The cut-offs for the FLARE-RA score

Table: Summary of FLARE-RA optimal cut-offs by RA disease duration using different anchor selection methods

	Disease duration 2-5 years			Disease duration > 5 years		
	Arthritis subscale	General subscale	Global scale	Arthritis subscale	General subscale	Global scale
Patient report of flare	2.80	1.00	1.82	2.20	1.40	2.18
DAS28 CRP >3.2	4.40	3.67	4.09	1.80	1.67	2.18
Change of anti-rheumatic treatment	4.00	4.50	4.55	4.80	2.33	3.18

were overall lowest using “patient’s report of flare” and highest using “change of anti-rheumatic treatment” as an anchor item: cut-offs for the global score for patients with RA duration 2-5 years: 1.82 and 4.55, respectively; for patients with RA duration >5 years – 2.18 and 3.18, respectively. The cut-offs corresponding to DAS28-CRP >3.2 were lower in patients with RA disease duration >5 years than in those with RA duration 2-5 years.

Conclusion: The FLARE-RA questionnaire has acceptable-to-excellent discriminative capacity across the tested anchor items. Patient report of flare corresponds to a lower FLARE-RA cut-off score than DAS28-CRP and change of anti-rheumatic treatment, suggesting the hierarchy of flare recognition from flare self-perception to its detection by DAS28 to treatment change by the rheumatology provider. More studies are needed to ensure the early recognition of flares and the appropriate alignment between flare and the adjustment of anti-rheumatic and other medications.

Abstract Number: 0445

What Is the Effect of Statins on the Risk of Rheumatoid Arthritis? Results of a Systematic Review and Meta-Analysis

Elena Myasoedova ,[1] Paras Karmacharya,[1] Ali Duarte Garcia,[1] John Davis,[1] M. Hassan Murad,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The anti-inflammatory and immune-modulating effects of statins suggest that these drugs may influence the risk of developing autoimmune diseases, such as rheumatoid arthritis (RA). We aimed to perform a systematic review and meta-analysis of studies assessing the risk of RA in statin-users versus non-users.

Methods: We searched Medline from inception to 01/22/2019 and Embase from 1988 to week 03 2019 for all comparative studies that examined the association between statin use and the risk of RA without restrictions on language. Two reviewers independently selected studies with very good inter-rater agreement (Cohen’s Kappa coefficient 0.90).

Data on study characteristics and adjusted effect estimates were extracted. A random-effects model was used to pool estimates and generate risk ratio (RR) and 95% confidence intervals (CI).

Results: The literature search identified 1,161 references; of which 8 studies (5 cohort and 3 case-control studies) were included in the systematic review. Six studies comparing statin users vs non-users were included in the meta-analysis and showed no significant difference in the risk of developing RA (RR 1.01; 95%CI 0.88-1.15; I^2=65%). Similar results were shown when cohort studies (RR 1.01; 95%CI 0.93-1.10, I^2=17%) or case-control studies (RR 1.01; 95%CI 0.36-2.87, I^2=92%) were analyzed separately. Two studies assessing persistence with or intensity of treatment with statins showed lower risk of RA in persons with higher as opposed to lower treatment persistence or intensity of statin use (pooled RR 0.66; 95%CI 0.5-0.87; I^2=83%).

Conclusion: In this systematic review and meta-analysis, observational evidence suggested that statin users had similar risk of RA as non-users. Considering some imprecision of the effects based on the 95% CIs, potentially with either meaningful benefit or harm of statin exposure on the risk of RA, it appears premature to conclude the lack of effect at this point. The risk of RA may be lower in patients who have higher as opposed to lower treatment persistence or intensity of statin use, suggesting potential heterogeneity of treatment effect. More studies at lower risk of bias are needed to further elucidate the impact of statin use on the risk of RA, considering potential differences by dosage, duration of use, study population and other factors.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Depression in rheumatoid arthritis (RA) patients may be pre-existent, amplified, or may develop after the onset of RA[1]. The Patient Health Questionnaire (PHQ9) is a widely-used tool to screen for depression in primary care[2]. A multidimensional health assessment questionnaire (MDHAQ)[3] includes two screening queries for depression. MDHAQ also includes routine assessment patient index data (RAPID3), an index which is correlated significantly with disease activity score (DAS28) and clinical disease activity index (CDAI), and also is informative in all rheumatic diseases in which it has been studied[4]. We investigated possible associations of PHQ9 scores for depression with MDHAQ demographic, clinical, psychological and laboratory measures.

Table. Demographic and clinical characteristics of rheumatoid arthritis (RA) patients who have or do not have depression according to Patient Health Questionnaire (PHQ9). Data are presented as mean (SD) or %. *p<0.05.

All patients (n=102)	PHQ9	
	Cut-off below 10 N=74 (71.1%)	Cut-off = 10 or above10 N=28 (27.4%)
Demographic variables

% Taking DMARD – Biologic	68%	63%
% Taking DMARD – Non Biologic	31%	33%
% Taking antidepressant	14%	43%*

FINAL TABLE FINAL VERSION

Methods: Consecutive patients with RA, who met EULAR/ACR 2010 criteria, completed both an MDHAQ and a PHQ9 as part of a routine rheumatology visit between November 2018 and February 2019. The 2-page MDHAQ includes 0-10 scores for physical function (FN), and visual analogue scales (VAS) for pain (PN) and patient global estimate (PATGL), compiled into 0-30 RAPID3 (≤3 =remission, 3.1-6=low, 6.1-12=moderate, and >12=high severity), 0-10 fatigue (FT) VAS, 0-48 RADAI self-report painful joint count, and 0-60 symptom checklist, which includes depression. The MDHAQ also includes 3 psychological queries in the patient-friendly HAQ format for depression, anxiety, and poor sleep quality, as well as demographic data. PHQ9 is a 9-item self-report screening tool for depression in primary care (range 0-27); PHQ9 scores ≥ 10 indicate positive screening for depression. MDHAQ demographic, self-report clinical, psychological and laboratory variables were compared according to PHQ9 depression group, ≥10 vs < 10.

Results: 102 RA patients were included in the analysis: 82.3% were females, mean age was 58.8 years and mean formal educational level of 11.7 years. 28 patients (27.4%) had PHQ9 ≥ 10, positive for depression (Table). PHQ9 ≥ 10 patients did not differ significantly from PHQ9 < 10 patients in age and educational level, while 96% of PHQ9 ≥ 10 patients were female (p=0.02). Patients who reported PHQ9 ≥ 10 had significantly higher scores vs those with PHQ9 < 10 for physical function, pain, PATGL, and RAPID3 (Table). High RAPID3 severity (>12) was seen in 82% of PHQ9 ≥ 10 patients versus 34% of PHQ9 < 10 patients. Patients with PHQ9 ≥ 10 also had significantly higher scores on the two MDHAQ depression queries vs those with PHQ9 < 10 (Table). No differences in the two groups were seen in acute

phase reactants ESR and CRP or in treatment with DMARDs. 43% of patients with a PHQ9 ≥ 10 were being treated for depression vs 14% of PHQ9 < 10 patients (Table).

Conclusion: RA patients screening positively for depression according to PHQ9 have high scores for all MDHAQ, including depression scale as well as physical function, pain, RAPID3, fatigue, and others, indicating a high self-report disease burden.

HAQ	0(0-0.25)	0(0-0)	0,05

Background/Purpose: Different dermatological changes and nail abnormalities have been reported in rheumatoid arthritis (RA) patients, some of which are specifically associated with the disease, while others are non-specific. Whether nail changes are associated with disease activity and/or damage has not been properly assessed.

Methods: We performed a cross-sectional study in patients from an early RA cohort, which was initiated in 2004. Up to April 2019, the cohort had 145 patients with active follow-up. All patients were invited to participate and 122 agreed to have a standardized dermatological and nail screening exam. Toenail findings were classified as RA-related findings, RA-unrelated findings and nail-specific diagnoses, using standardized definitions. We described the main findings of the toenail evaluation, as well as their association with different disease parameters.

Results: At study entry, patients had a median age of 45.5 years (IQR 36-58), and most of them were female (91%), with substantial disease duration (median of 9 years [5-13]). The majority of patients (80.3%) had DAS28 remission and 46.7% had erosive disease.

There were 79 patients (64.8%) with nail findings: 62 (78.5%) in toenails, 44 (55.7%) in fingernails and 27 (34.2%) in both (Table 1). Patients with toenail abnormalities (n=60) showed higher disability, as per the HAQ-DI (p=0.019).

Figure 1. 1A and 1B. Nails changes due to trauma showing xantonychia and melanonychia. 1C and 1D

Onychomycosis was found in 11 patients (9%), and the only associated variable was a higher cumulative DAS28 within the previous year: median (IQR) DAS28 of 2.57 (1.97-3.03) vs. 1.89 (1.47-2.48), p=0.047.

We grouped patients with toenail findings which could be attributed to trauma (Table 1); there were 58 patients (47.5%) with one or more lesions and their data were compared to those without these abnormalities (Table 2). Patients from the former group were older (p≤0.001), had a longer disease duration (p=0.034), a higher prevalence erosive disease (p=0.002) and a higher cumulative DAS28 during the first 2 years of follow-up in the cohort (p=0.026). After multivariate analysis, age (Exp β 1.04, 95% CI 1.008-1.073, p=0.014) and erosive disease (Exp β 2.564, 95% CI 1.175-5.598, p=0.018) remained significantly associated with traumatic toenail lesions.

Conclusion: Nail lesions, particularly in toenails, are highly prevalent in RA patients. Although most of them are non-specific, toenail findings suggestive of repetitive trauma may be considered a surrogate marker of disease damage. Routinely performing dermatological exams to RA patients may detect clinically relevant information and foster a multidisciplinary care.

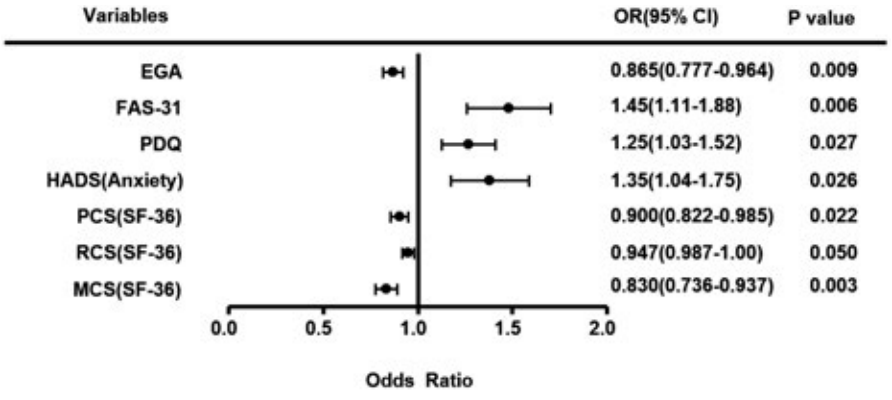
Abstract Number: 0448

Central Sensitization in Patients with Rheumatoid Arthritis Using the Central Sensitization Inventory

Kentaro Noda ,[1] Moe Saitou,[1] Taro Ukichi,[1] Yohsuke Oto,[1] Ken Yoshida,[1] and Daitaro Kurosaka[1], [1]The Jikei University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM



Background/Purpose: Pain of rheumatoid arthritis (RA) is thought to be nociceptive. However, recent studies indicate that RA pain also includes the mechanism of central sensitization (CS). Therefore, we examined the prevalence of CS among RA patients and these patients' clinical characteristics.

Methods: The central sensitization inventory (CSI) was used to evaluate in 240 outpatients (63 Male, 177 Female) with RA from May 2017 to September 2018. The disease activity was evaluated using the disease activity score of 28 joint (DAS28), clinical disease activity index (CDAI), and simplified disease activity index (SDAI). The following parameters were evaluated: swollen joint count on 28 joints (SJC), tender joint count on 28 joints (TJC), patient global assessment (PGA), estimator global assessment (EGA), pain visual analogue scale (PainVAS), serum C-reactive protein (CRP), and ESR. Physical function was evaluated using mHAQ-DI. Health-related quality of life (HRQOL) was evaluated using short-formed 36-Item health survey (SF-36). Fibromyalgia was evaluated using the fibromyalgia activity score 31 (FAS-31). Neuropathic-like pain was evaluated using the painDETECT questionnaire. Depression and anxiety were evaluated using the hospital anxiety and depression scale (HADS). We compared the clinical parameters between the patients with CS (CSI ≧ 40) and without CS (CSI < 39).

Results: Eighteen (7.5 %) of 240 patients had CS according to the CSI. In patients with CS, EGA, PainVAS, mHAQ-DI, FAS-31, HADS scores, physical component summary scores (PCS), and mental component summary scores (MCS) on the SF-36 were significantly higher than in patients without CS. Multivariate analysis of clinical parameters contributing CS showed significant differences in EGA ($p = 0.009$, OR 0.865), PDQ ($p = 0.027$, OR 1.25), FAS-31 ($p = 0.006$, OR 1.45), HADS(Anxiety) ($p = 0.026$, OR 1.35), PCS ($p = 0.022$, OR 0.900) and MCS ($p = 0.003$, OR 0.830) on the SF36.

Conclusion: CS in RA patients was associated with neuropathic-like symptoms, fibromyalgia, anxiety, and decrease of HRQOL. Neuropathic-like symptoms in RA may be helpful to detect CS. Proper treatment of CS in RA patients may improve HRQOL.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have increased disability, in particular due to involvement of the joints of the upper extremities. The Stanford Health Assessment Questionnaire (HAQ) includes questions related to both upper and lower extremity function. The objective of this study was to investigate the course of

Table 1. Change in HAQ-DI UE between every follow-up visit in the early RA cohort

Patients with data at both time points; paired samples t-test

disability related to the upper extremities in early RA, using a subset of the HAQ disability index (HAQ-DI upper extremities; HAQ-DI UE), and to assess associations between HAQ-DI UE and disease parameters, including grip force.

Methods: An inception cohort of patients with early RA (symptom duration ≤12 months), recruited in 1995-2005, was investigated and followed in a structured program (5 examinations over 10 years), including clinical evaluation and grip force measurement. Disability was assessed using the validated Swedish version of the HAQ. In order to more specifically address disability of the upper extremities, we calculated the HAQ-DI UE, based on the 10 questions that cover activities that are mainly dependent on function of the upper extremities. Grip force was measured using the electronic instrument Grippit (AB Detektor, Gothenburg, Sweden). Average grip force values of the dominant hand were evaluated at each visit, and compared to the expected, based on age- and sex-specific reference values from the literature. Grip force was expressed as % of predicted values. Changes in HAQ-DI UE between two consecutive follow-up visits over time, baseline to 10 years follow-up, in the early RA cohort with data on both time points, were estimated using the paired samples t-test. Spearman's test was used to further explore correlations between HAQ-DI UE and grip force, swollen and tender joint counts (SJC and TJC), visual analogue scales for patient global assessment (VAS global) and pain (VAS pain), ESR and CRP at each visit.

Results: A total of 222 patients with early RA (71 % women, mean age 61 years, median symptom duration 7 months) were investigated. At inclusion, the mean DAS28 was 4.6 (SD 1.4), and the median HAQ-DI was 0.75 (IQR 0.38-1.25). Data on both HAQ-DI UE and average grip force of the dominant hand were available for 222 patients at inclusion, 207 patients at 6 month, 209 at 1 year, 200 at 2 years, 167 at 5 years and 110 at 10 years. In the paired analysis of patients with available data at both time points there was a significant decrease in HAQ-DI UE from inclusion to 6 months follow-up (Table 1). HAQ-DI UE levels were stable between 6 month and 2 years, whereas between 2 years and 5 years, there was a significant increase. (Table 1) The mean average grip force of the dominant hand increased from 40 % of expected at inclusion to 66 % of expected at 10 years. There were strong correlations for HAQ-DI UE with grip force, VAS global and VAS pain at all time points, and moderate to weak correlations with SJC, TJC, ESR and CRP (Table 2).

Conclusion: In this study of patients with early RA, disability related to the upper extremities decreased from inclusion to the 6 month follow-up, and increased again after 2 years. HAQ-DI UE scores correlated strongly with grip force and patient reported outcomes, and to a lesser extent with joint counts and laboratory markers of inflammation.

Table 2. Correlations for disease parameters with HAQ-DI UE

ACPA-positive versus ACPA-negative Rheumatoid Arthritis: Two Distinct Erosive Disease Entities on Radiography and Ultrasonography

Julien Grosse ,[1] Edem Allado,[1] Camille Roux,[1] Audrey Pierreisnard,[2] Marion Couderc,[3] Isabelle Clerc-Urmès,[1] Thomas Remen,[1] Eliane Albuisson,[4] Marcelo De Carvalho,[1] Isabelle Chary-Valckenaere,[4] and Damien Loeuille[5], [1]Centre Hospitalier Universitaire de Nancy, Nancy, France, [2]APHP, Paris, France, [3]CHU G.Montpied, Clermont Ferrand, France, [4]Centre Hospitalier Universitaire de Nancy, VANDOEUVRE, France, [5]Rheumatology, Nancy University Hospital and and UMR 7365 CNRS-UL IMoPA, Université de Lorraine, VANDOEUVRE, France

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Several studies have shown that ACPA-positive (ACPA+) patients were more likely to develop erosive disease on radiography (RX) than ACPA-negative (ACPA-) patients, but it has never been demonstrated

on ultrasonography (US). The characteristics of bone erosions on both RX and US according to ACPA status has never been studied before. The objective of this study was to assess the prevalence, localization and severity of bone erosions on RX and US according to ACPA status in patients with rheumatoid arthritis (RA).

Methods: 78 patients with ACPA+ RA and 30 patients with ACPA- RA fulfilling the ACR 1987 and/or ACR/EULAR 2010 criteria were consecutively included. On RX, a modified Sharp erosion score (SHSe) was evaluated by two blinded readers and one adjudicator for discordant cases (number of eroded joints ≤ three). On US, erosions were scored on six bilateral joints (MCP2,3,5; MTP2,3,5) with a four-point scale to calculate the total US score for erosions (USSe).

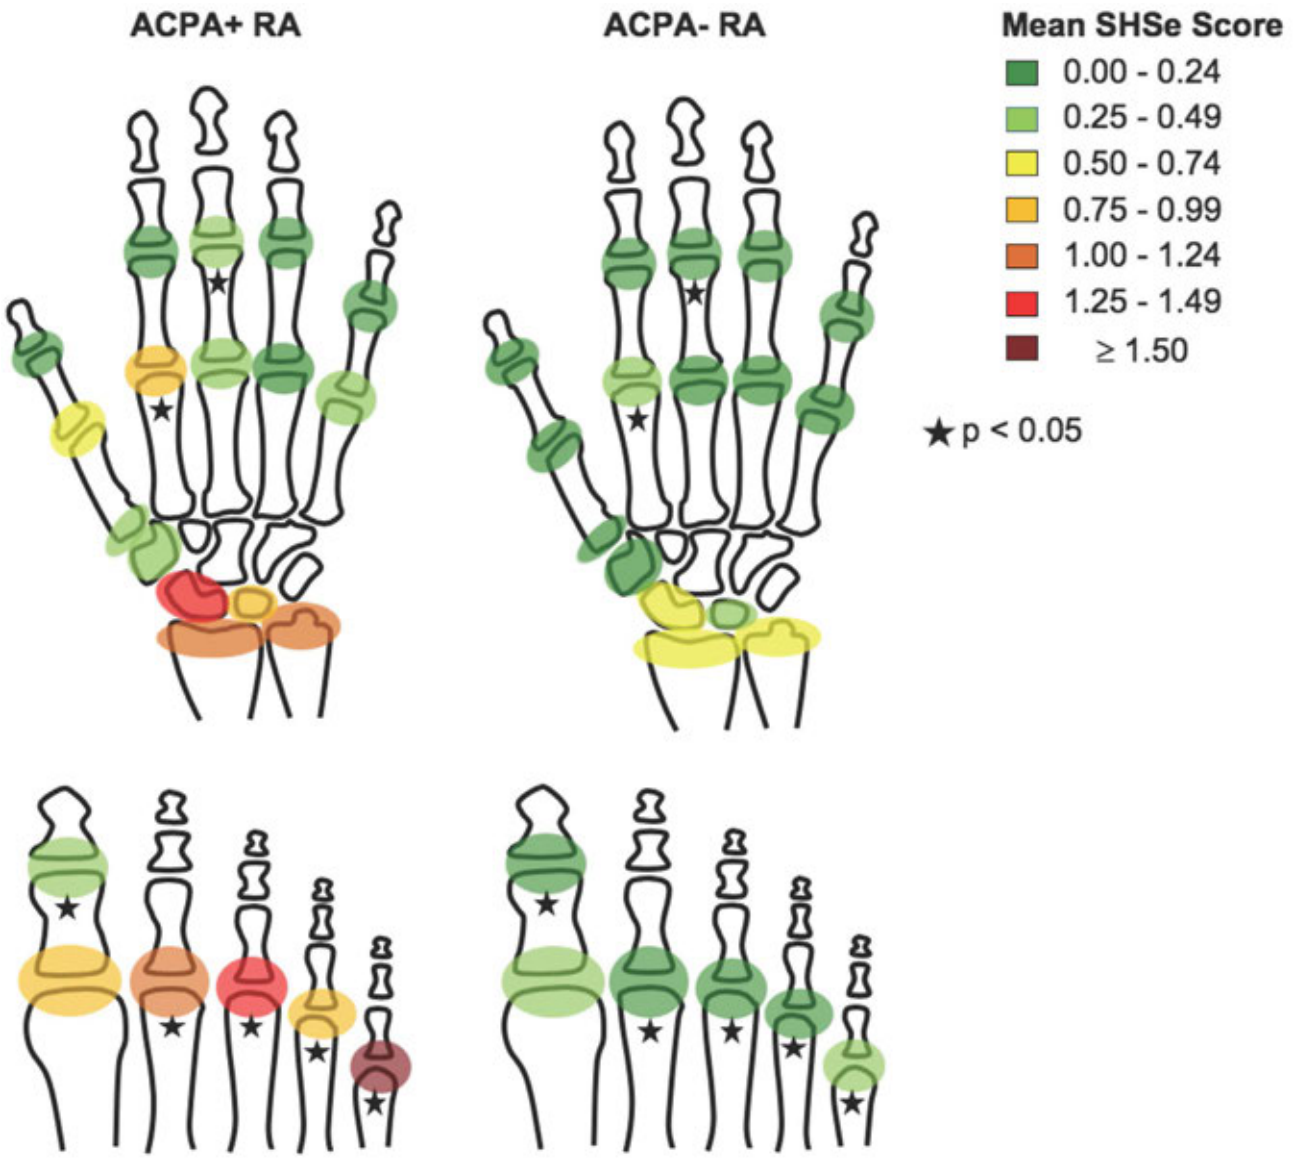

Figure 1. Topography of erosions according to the mean SHSe score for ACPA-positive (ACPA+) and ACPA-negative (ACPA-) Rheumatoid Arthritis

Results: On RX, 33 ACPA+ RA patients (42.3%) and 4 ACPA- RA patients (13.3%) had an erosive disease according to the EULAR 2013 definition criteria. On US, 61 and 63 ACPA+ RA patients (78.2% and 80.8%) versus 14 and 10 ACPA- RA patients (46.7% and 33.3%) had an erosive disease according to the following two definitions: the presence of at least two eroded joint facets (def1) or at least one grade 2 eroded joint facet (def2), respectively.

Erosion patterns were different between ACPA+ RA patients and ACPA- RA patients. On RX, erosions were preferentially observed in MTP joints in the ACPA+ group and in wrists in the ACPA- group (Figure 1). On US, erosions were preferentially found in the lateral facets of MTP5 joints, followed by MCP2 and MCP5 joints in both groups (Figure 2).

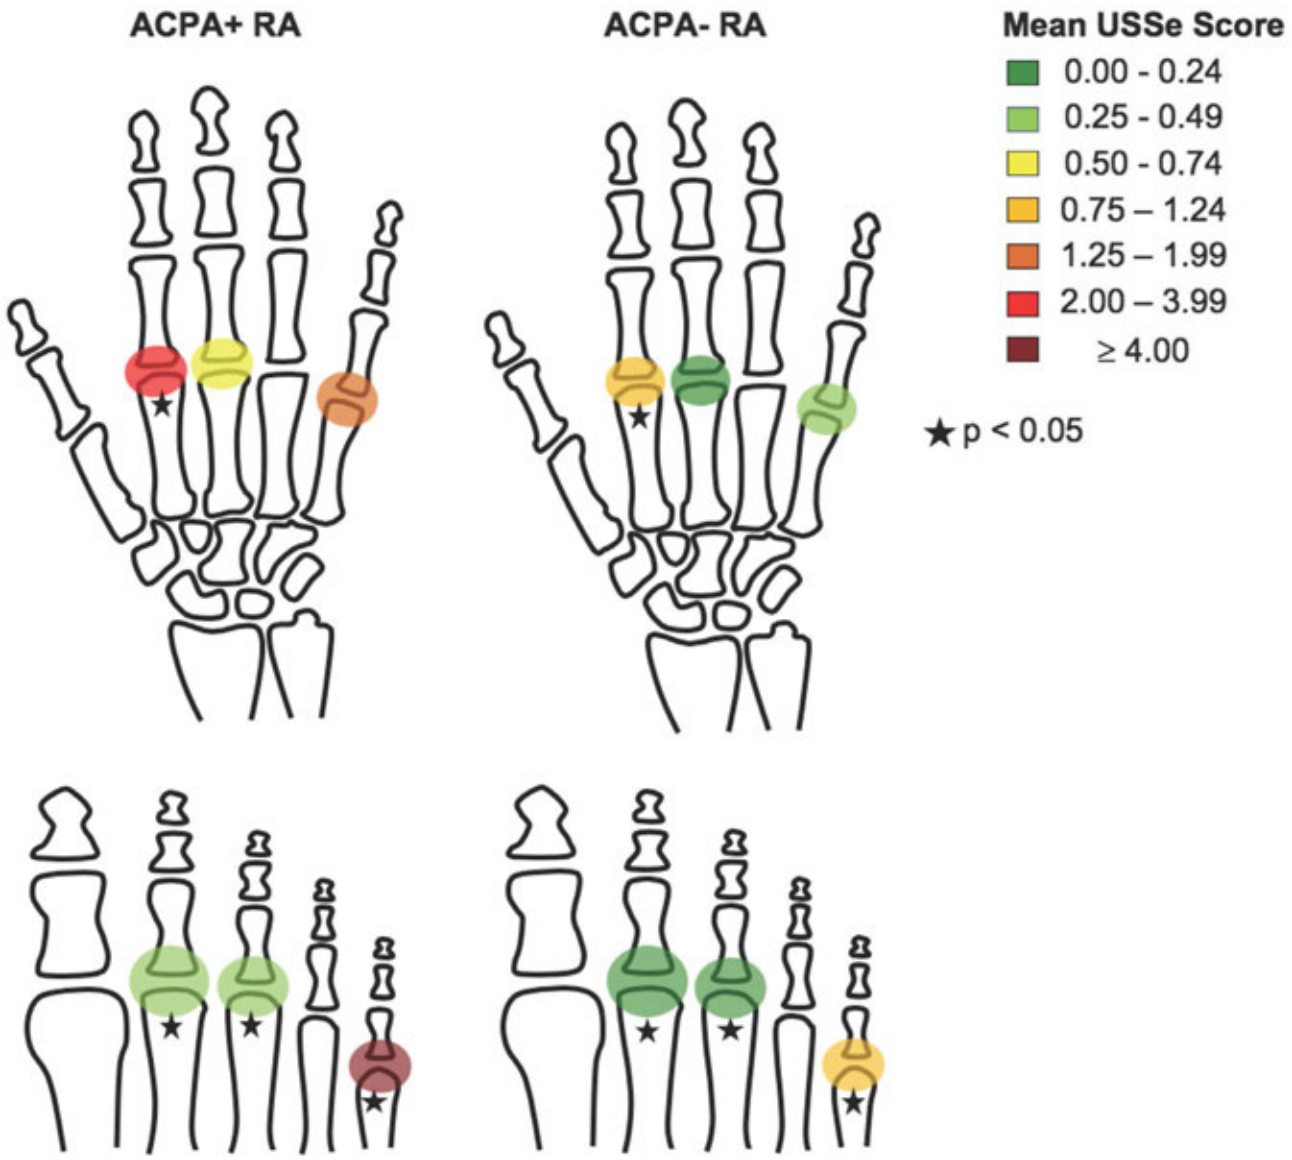

Figure 2. Topography of erosions according to the mean USSe score for ACPA-positive (ACPA+) and ACPA-negative (ACPA-) Rheumatoid Arthritis

On both RX and US, the most discriminating joint between the two groups was MTP5, especially in cases with bilateral erosion (17 ACPA+ RA patients versus 0 ACPA- RA patients on RX, 45 ACPA+ RA patients versus 1 ACPA- RA patient on US; p<0.001). The mean total SHSe were 15.3±22.1 and 4.1±8.3 in the ACPA+ and ACPA- groups, respectively (p< 0.001). The mean total USSe were 12.2±11.7 in the ACPA+ group and 2.8±4.4 in the ACPA- group (p< 0.001).

Based on multivariate analyses, ACPA+ status was associated with erosive RA on RX according to the EULAR 2013 definition criteria (OR 4.4 (95% CI 1.2-16.4)), and on US according to def1 (OR 3.7 (95% CI 1.4-9.9)) and def2 (OR 9.0 (95% CI 2.8-28.4)).

Conclusion: Compared to ACPA- RA, ACPA+ RA is associated independently with more severe erosive disease on RX and US. Both US and RX bilateral erosions in MTP5 joints are highly discriminant for ACPA+ RA patients (97.8% in US, 100% in RX).

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Persisting pain (NRS ≥4,) (PP) and non-articular pain (NAP), reduces quality of life for patients with RA. NAP is often attributed to fibromyalgia (FM), though FM prevalence could be overestimated in patients with unrecognized regional pain (RP) syndromes. Our goal was to understand pain patterns (regional vs. widespread) and its impact on achieving remission in real-world early inflammatory arthritis (EIA) patients.

Methods: Data were from EIA patients (symptoms < 1 year) enrolled in a national prospective cohort study between Mar 2017 – Mar 2019 who completed body pain diagrams (BPD) at baseline (n=317) and repeat assessments every 3-months over 1 year follow up (n=122). Patients were grouped by pattern of NAP reported in left, right, upper, lower and central regions (max 5 regions) as follows: 1. none, 2. regional pain (RP) if 1 or 2 painful regions and 3. widespread pain (WSP) if 3-5 painful regions. We compared sociodemographic, RA clinical and patient reported outcome measures across patient pain groups at baseline as well as associations between pain patterns and achievement of

Pain Measures:	Non-Articular Pain (NAP) identified on Body Pain Diagram (n=317)

Table 1. Baseline Characteristics Across EIA Patients Reporting Absence of Non-Articular Pain, Non-Articular Regional Pain and Widespread Pain

ACR Boolean Remission and DAS Remission, with and without inclusion of patient global assessment at 6 and 12 months. Logistic regression was used to estimate age and sex, and multiple adjusted associations between RP and WSP with remission.

Results: Of 317 eligible patients, the mean (sd) age was 56 (14), baseline DAS28 was 4.9 (1.3); 199 (63%) were female, 225 (71%) met one or both 1987/2010 RA criteria and 287 (91%) were treated with csDMARDS +/- MTX. There were more patients with RP compared to WSP throughout the study period (Figure 1). Patients with no NAP (Gp 1) and RP (Gp 2) had lower scores on the RA-FQ, MDHAQ, and Fatigue. Similarly, patient pain ratings, PtGA, PHQ scores were lower in groups 1 and 2 vs group 3 (Table 1). PtGA was most discordant from MDGA in the WSP group. Depressive Symptoms were lowest in the no pain group as was the mean(sd) DAS28 at baseline (4.8 (1.4)). Patients with RP or no pain smoked less than those with WSP. Age/sex adjusted and fully adjusted logistic regression models predicting associations with remission are shown in table 2. Regional pain was significantly associated with reduced odds of Boolean remission at 6 months, and widespread pain tended to be associated with lower odds of Boolean remission at 6- and 12 months and lower odds of DAS28 remission at 12-months though the sample with widespread pain was small and confidence intervals were inconclusive.

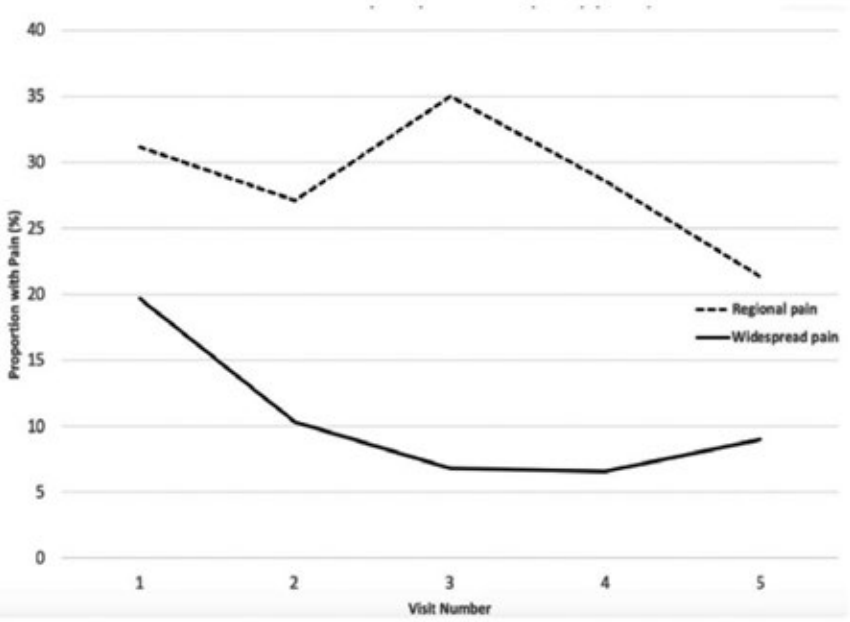

Figure 1. Proportion of EIA patients reporting regional and widespread pain over the first year of follow up

Table 2. Logistic Regression Examining Associations Between Pain Pattern and Remission at 6- and 12-months Follow Up in Patients with EIA

Conclusion: Early RA patients frequently experienced regional and widespread non-articular pain, though regional pain is more common, perhaps reflecting strain injuries following a period of active RA with consequent sarcopenia. Results suggest non-articular pain tended towards fewer patients achieving remission. Clinicians should consider whether their patients have non-articular pain and address these separately to provide more holistic care. Non-articular pain may falsely lower remission status. Awareness of this is needed when implementing targeted care strategies.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoimmunity, characterized by the presence of anti-modified protein antibodies (AMPA), recognizing citrullinated, carbamylated or acetylated proteins, as well as rheumatoid factor (RF) precedes the onset of manifest rheumatoid arthritis (1,2).High resolution peripheral quantitative (HR-pQCT) technique is able to visualize marginal cortical changes in peripheral joints (3).To evaluate presence of deterioration of cortical bone as well as volumetric bone mineral density in finger joints using HR-pQCT technique and correlate these findings to arthritis specific autoimmunity, particularly osteoclast-inducing citrullinated vimentin (cVIM) antibodies and their impact on the later development of RA.

Methods: Patients were part of our individuals at risk cohort Erlangen (ethics approval 333_16B) comprising patients with AMPAs but without clinical manifest arthritis. These patients are regularly followed for arthritis development. Patients receive HR-pQCT scans as part of the protocol analyzing cortical micro-channels (CoMiCs) as well as volumetric cortical and trabecular bone densities of MCP joints as described before (3). Anti-modified protein antibody (AMPA) response was profiled including reactivities against citrullinated proteins (vimentin, enolase, fibrinogen) as well as carbamylated and acetylated vimentin from serum samples at time points

Results: 75 RA at risk patients were included. Patients with high-level (>1000U) cVIM antibodies showed a broader AMPA response. Those patients also displayed more severe deterioration of cortical bone (higher CoMiCs, lower cortical and trabecular bone volume) compared to subjects with low/no cVIM reactivity. High cVIM antibodies and microstructural changes (>15 radial CoMiCs/joint) were associated with the presence of arthralgia. Furthermore, progression to RA was high in subjects with high cVIM (53%) vs. those with low (22%) or no (5%) antibodies and those with microstructural changes (46%) vs. those without such changes (16%).

Conclusion: HR-pQCT technique detects earliest deterioration of cortical bone and volumetric bone mineral density in finger Joints with association to cVIM antibodies. These data support the concept of a non-silent form of autoimmunity regarding bone changes before the onset of RA.

Including Pain, Fatigue and Functionality Regularly in the Assessment of Patients with Early Rheumatoid Arthritis Separately Adds to the Evaluation of Disease Status

Sofia Pazmino ,[1] Anikó Lovik,[2] Annelies Boonen,[3] Diederik De Cock,[1] Veerle Stouten,[1] Johan Joly,[4] Kristien Van der Elst,[5] Delphine Bertrand,[1] Rene Westhovens,[6] and Patrick Verschueren[5], [1]KU Leuven, Leuven, Belgium, [2]Leuven Biostatistics and Statistical Bioinformatics Center, KU Leuven, Leuven, Vlaams-Brabant, Belgium, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]University Hospitals Leuven, Leuven, Vlaams-Brabant, Belgium, [5]University Hospital Leuven, Leuven, Belgium, [6]University Hospitals, Leuven, Belgium

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) level of disease activity, cannot be evaluated by a single clinical or laboratory measurement. Hence, composite indices have been created via factor analysis (FA). FA uncovers the fact that multiple observed variables have similar patterns of responses because they are all associated with a latent, not directly observable, variable. Yet, only one directly patient-reported outcome (PRO), the patient's global (PaGH), has been included in the composite indices. The PaGH answers a very general question of "Considering all the ways your RA has affected you how would you say your health is?", making it easy to apply but hard to interpret. Lately, more specific PROs have been proven to add valuable and unique information on the patient's disease state. We wanted to see if this is the case in early RA.

Methods: In the Care in early rheumatoid arthritis (CareRA) trial, patients with early RA (≤1 year) (n=379) naïve to DMARDs were randomized to one of four remission induction treatment schemes and followed up over 2 years (Verschueren et al, 2015). Key clinical variables such as swollen (SJC) and tender joint count (TJC), patient (PaGH) and physician (PrGH) global health assessment, CRP or ESR; along with pain, fatigue and physical function (Health As-

CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, SJC28: 28 swollen joint count, TJC28: 28 tender joint count, PaGH: patient's global health assessment, PrGH: health provider's global health assessment, Pain and Fatigue: measured on a visual analogue scale 0-100, HAQ: Health Assessment Questionnaire

sessment Questionnaire-HAQ) were recorded at every consultation. Exploratory factor analysis (EFA) was performed for all observations and per time point as well on (1) key set variables only and (2) when also including other PROs. Pearson correlations of all variables were calculated. Firstly, missing data was handled using multiple imputation resulting in 15 complete datasets. Next, clustering was removed by performing multiple outputation 1000 times on the 15 datasets. Each of the 15 000 datasets was analyzed by EFA with oblimin rotation. The analyses were combined after re-ordering the factors by maximizing factor congruence.

Table 3: Factor analysis extracted 3 factors when using all variables			
Variables	Factor 1: Patient's assessment	Factor 2: Clinical assessment	Factor 3: Laboratory
CRP			0.87
ESR			0.78
SJC28		0.92	
TJC28		0.89	
PrGH		0.76	
PaGH	0.87		
Fatigue	0.90		
Pain	0.86		
HAQ	0.57		
Cross-loadings were negligible (<0.3), not presented CRP: C-reactive protein, ESR: erythrocyte sedimentation rate, SJC28: 28 swollen joint count, TJC28: 28 tender joint count, PaGH: patient's global health assessment, PrGH: health provider's global health assessment, Pain and Fatigue: measured on a visual analogue scale 0-100, HAQ: Health Assessment Questionnaire			

Results: The different factor analyses (FAs) based on the classical components of disease activity scores, supported the traditional approach of composite indices extracting 2 factors that are stable over time, meaning no substantial cross-loadings between factors (Table 1). Still, pain (0.83), fatigue (0.65) and HAQ (0.59) were strongly correlated with PaGH in our cohort (Table 2). When rerunning the FA including also these variables, the 2-factor model was no longer stable with variables changing the factors in which they loaded over time. However, when a 3-factor model was extracted, there were large positive loadings on Factor 1 describing the patient's personal assessment, Factor 2 clinical assessment and Factor 3 laboratory (Table 3).

Conclusion: The classical FA with the key variables gives a 2-factor model that bundles everything in one, except for acute phase reactants (CRP and ESR). However, PaGH seems to be associated with pain, fatigue, and functionality. By including these variables, a third factor dedicated to the patient's perceptions is extracted and a very clear factor structure showing three latent factors is present. This could indicate that these patient's assessments should be added to the standard measurements of disease state.

Principal Component Analysis Identifies Unique Sub-Populations in Rheumatoid Arthritis Using a Combination of Serological Biomarkers: A Cross Sectional Study

Jordan Van Dyk ,[1] Bryan Heard,[1] and Cheryl Barnabe[1], [1]University of Calgary, Calgary, AB, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Determining the prognosis of rheumatoid arthritis (RA) could guide more precise treatment selection, optimizing outcomes while minimizing unnecessary therapeutic exposures. It is important that potential biomarkers have widespread availability and provide meaningful input in clinical decision making. While CRP and ESR have been shown to be moderately associated with disease activity and severity, there continues to be uncertainty regarding the utility of these as they may be elevated in other conditions, or be normal even during severe clinical inflammation. While RF and anti-CCP positivity are considered to be associated with more treatment refractory RA, those who are autoantibody negative may experience a negative disease trajectory as well due to lack of recognition of disease and introduced delays in treatment initiation. Our objective was to employ principal component analysis to investigate if biomarkers could determine sub-groups of disease severity.

Figure 1.

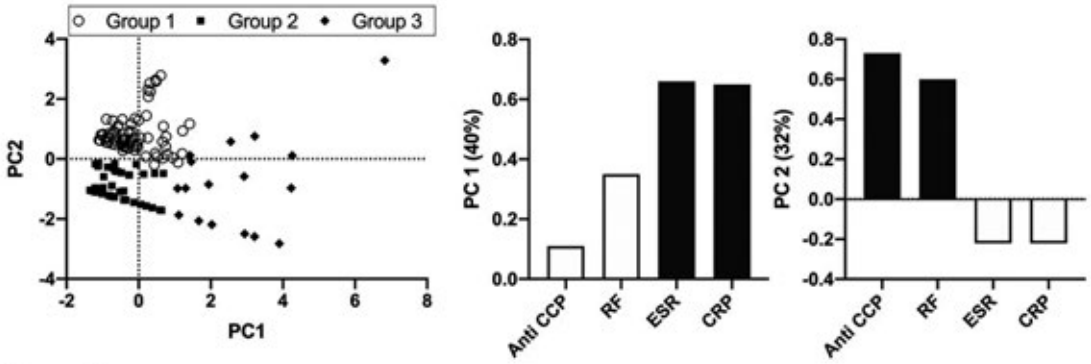

Figure 2.

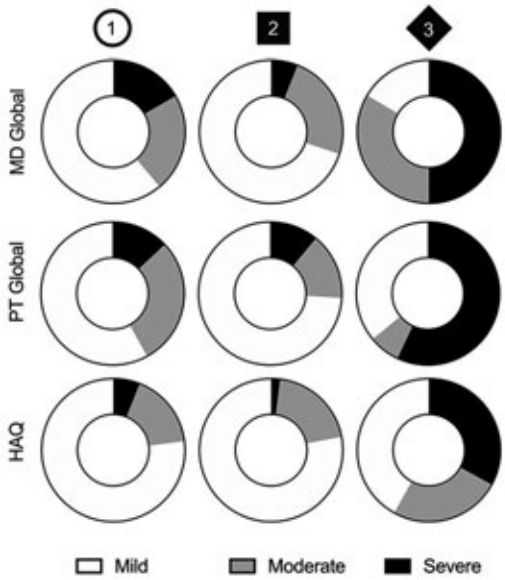

Methods: RA patients were recruited from a single centre to a cross sectional study initiated to investigate influences on disease trajectory (n=145). ESR, CRP, RF, and anti-CCP collected at enrolment to the study were used in the principle component analysis (PCA) to create 2 components, which were subsequently used in k-means clustering (K=3) to demarcate the patient groups. Function (Health Assessment Questionnaire), Physician Global Assessments (MD Global), and Patient Global Assessments (Pt Global) were divided into 3 tertiles of disease activity (mild, moderate, and severe) and used as metrics of disease severity to describe the patient groups identified by PCA and K-means.

Results: Based on correlation analysis, ESR and CRP had a moderate positive relationship with each other (r=0.67), but no correlation with HAQ, Pt Global, or MD Global. Furthermore, there was no relationship between individual serological markers and disease activity as reported by HAQ, Pt Global, or MD Global (r< 0.25 for all). PCA revealed the presence of three visual groupings of data points (PC1, PC2 and PC3), that were then confirmed with K-means clustering (Figure 1). ESR and CRP weighed most heavily in PC1, while PC2 was predominantly influenced by anti-CCP and RF. Disease severity assessments illustrate that PC3 had a higher percentage of severe disease and PC2 showed a higher percentage of mild disease (Figure 2).

Conclusion: Sub-populations with unique serological biomarker combinations that predict disease severity are identifiable. The sub-group that was not influenced as strongly by serology was the group identified to have the largest proportion of patients with mild disease. Furthermore, the group with the highest proportion of patients with severe disease was most heavily influenced by ESR and CRP, and the group with the next highest percentage of severe disease was influenced predominantly by anti-CCP and RF. This suggests 2 unique populations with higher serological values and various weighted combinations of ESR and CRP, or anti-CCP and RF, seem to display RA with a more severe phenotype. Further studies will need to be undertaken to identify factors that make these RA groups unique.

Anti-Protein-Arginine Deiminase (PAD) 4 IgA Are Present in the Sera of Rheumatoid Arthritis Patients and Are Associated with Joint Erosion and Biological Treatment Use

Laura Martinez-Prat ,[1] Victor Manuel Martínez Taboada,[2] Marcos Lopez-Hoyos,[3] and Michael Mahler[4], [1]Inova Diagnostics, Francisco de Vitoria University, San Diego, CA, [2]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [3]Hospital Universitario Marqués de Valdecilla-IDIVAL, Santander, Cantabria, Spain, [4]Inova Diagnostics, San Diego, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Over the past years, novel biomarkers have been described in rheumatoid arthritis (RA) patients, including autoantibodies to the protein-arginine deiminase (PAD) enzymes. Anti-PAD4 IgG are associated with anti-citrullinated protein antibodies (ACPA), worse baseline radiographic joint damage and a better response to treatment escalation. These data suggest that anti-PAD antibodies might play a role in RA pathogenesis. The objective of this study was to evaluate the presence of anti-PAD4 IgG and IgA in the sera of RA patients and to investigate their association with joint erosion and biological treatment use.

Methods: All the samples included in this study were tested for anti-PAD4 IgG and IgA using the novel particle-based multi-analyte technology (PMAT, research use only, research use only). In a first phase, sera from RA patients (n=70) and controls (n=155) were included (Figure 1). Next, anti-PAD4 IgG and IgA were measured in a second cohort of RA patients (n=40) for whom information on erosion status and biological treatment was available. ACPA IgG was also measured in these patients by QUANTA Flash CCP3 (Inova Diagnostics, CA, US).

Results: Anti-PAD4 IgA but not IgG levels were significantly higher in RA patients vs. controls (p=0.0080 and p=0.2740, respectively) (Figure 1). Receiver operating characteristics (ROC) analysis showed significant discrimination in the clinically relevant area (high specificity) for both IgG and IgA (Figure 2). Using the 95th percentile of the controls as cut-offs, anti-PAD4 IgG reported a sensitivity and specificity of 17.1%/94.8% for IgG and 20.0%/94.8% for IgA. Significantly higher levels of anti-PAD4 IgA but not anti-PAD4 IgG or ACPA were found in the RA patients with erosive disease vs. individuals without erosions (p=0.0419, p=0.2126, and p=0.7417, respectively) (Figure 3A), and in patients under biological treatment vs. those that were not on biologics (p=0.0240, p=0.1261, and p=0.8202, respectively) (Figure 3B).

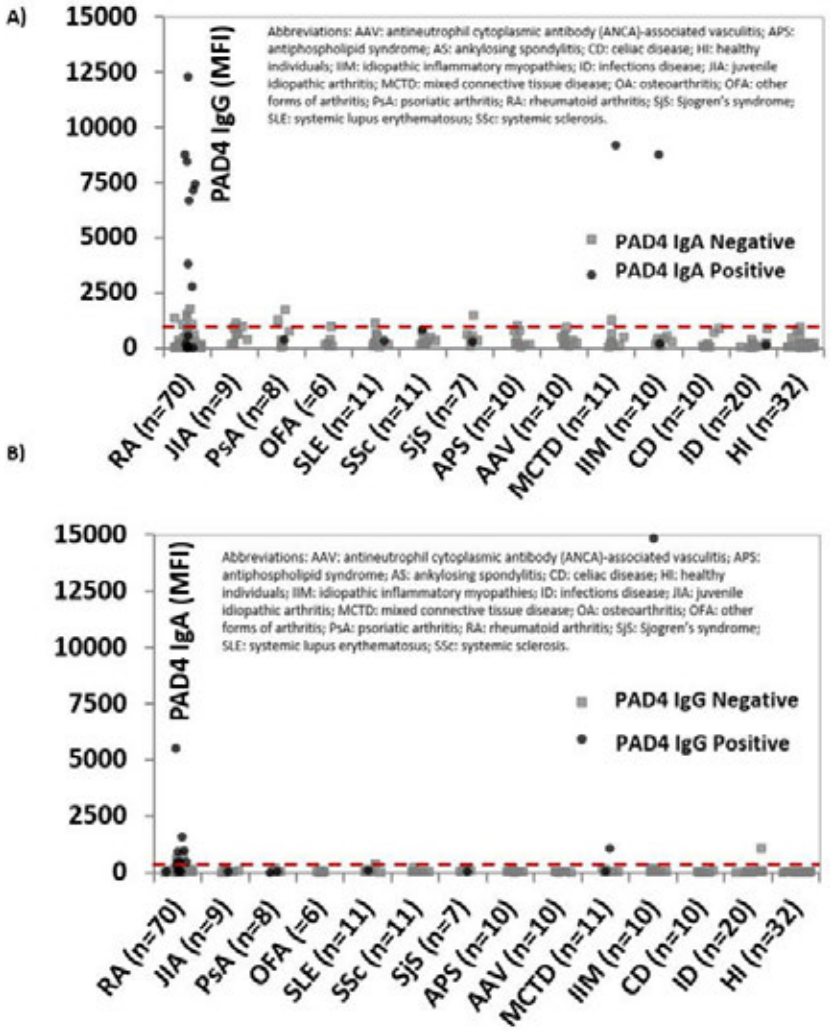

Figure 1. Levels of anti-PAD4 IgG (A) and IgA (B) in the different disease groups. The positivity for the other anti-PAD4 isotype is also represented in each graph. Red dashed lines represent the preliminary cut-offs.

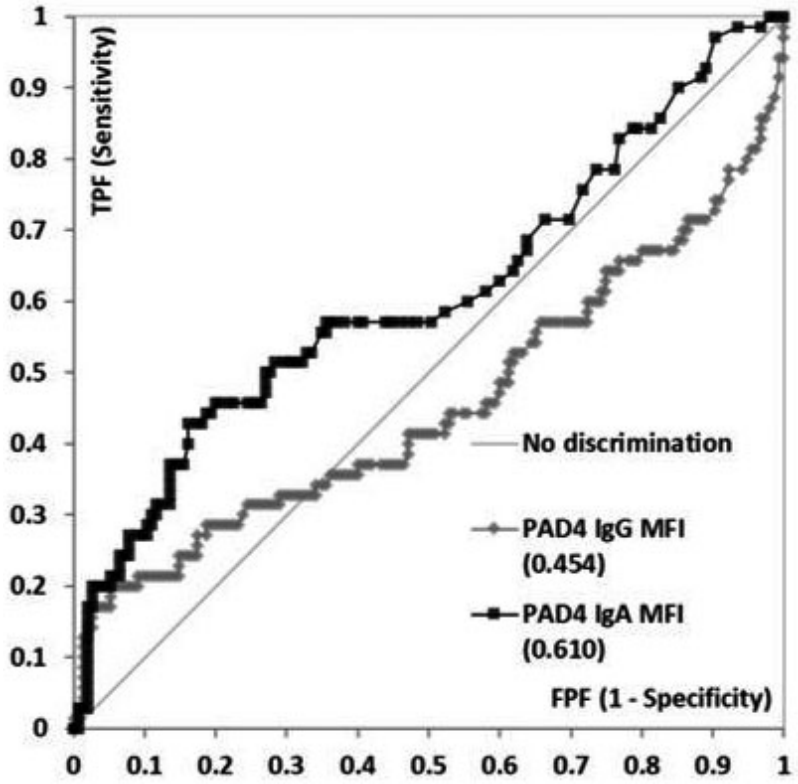

Figure 2. Receiver Operating Curve (ROC) analysis of anti-protein arginine deiminase (PAD) 4 IgG (grey) and IgA (black) for the discrimination of rheumatoid arthritis (RA) versus controls. Area under the curve (AUC) is shown for each isotype.

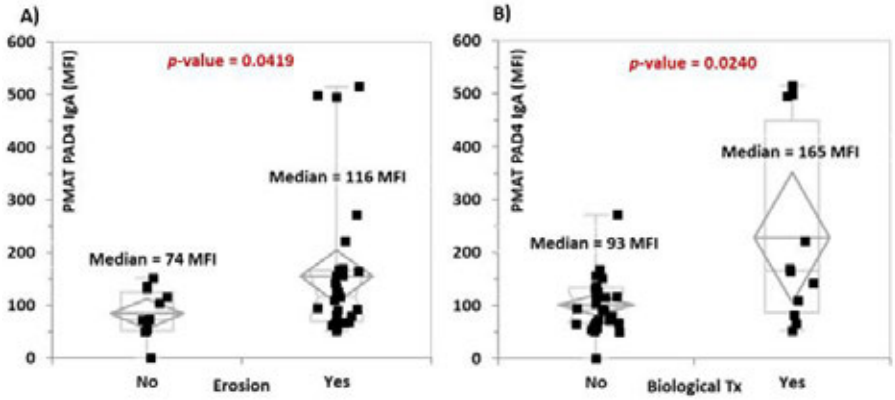

Figure 3. Pairwise comparison (Wilcoxon Mann-Whitney analysis) of anti-protein arginine deiminase (PAD) 4 IgA in RA patients based on erosive status (A) and on the biological treatment use (B). Median of each subgroup and p-values are shown in the figures.

Conclusion: Our study is the first to report anti-PAD4 IgA as a highly specific marker for RA showing strong association with erosive disease as well as biological treatment, suggesting a more severe phenotype. Anti-PAD4 antibodies of the IgA isotype represent a novel biomarker for RA patient stratification and prediction of prognosis.

Vitamin D Is Not Associated with Treatment Responses in Patients with Newly Diagnosed Rheumatoid Arthritis

Juyeon Kang,[1] and **Chan-Bum Choi** [1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vitamin D is known to have immunomodulatory properties and had shown a relationship with susceptibility and disease activity in rheumatoid arthritis (RA). We investigated the relationship between response to treatment and vitamin D levels in patients newly diagnosed with RA.

Methods: This was a retrospective study of 249 patients who were newly diagnosed with RA. They were assessed for 25-hydroxyvitamin D (25OHD) level at diagnosis of RA and after 6 months of treatment. All patients with vitamin D insufficiency (25OHD < 30 ng/ml) received vitamin D supplementation. Correlation between vitamin D levels and disease activity measured by Disease Activity Score 28 calculated with erythrocyte sedimentation rate (DAS28-ESR) at diagnosis and after 6 months were assessed.

Results: The proportion of patient with low, moderate, and high disease activity at diagnosis were 9.2%, 59.4%, and 31.3%, respectively. Mean level of 25OHD was 18.8 ± 11.3 ng/ml. Vitamin D level showed no significant correlation with disease activity at diagnosis with a mean 25OHD value of 17.4 ± 8.6 ng/ml, 19.1 ± 11.3 ng/ml, and 18.8 ± 12.1 ng/ml, respectively. After 6 months of treatment, the proportion of patients in remission, low, moderate, high disease activity were 41.7%, 22.4%, 29.4%, and 6.1%, respectively. Vitamin D significantly increase to mean 25OHD value of 24.7 ± 11.1 ng/ml after 6 months of treatment of RA and vitamin D supplementation in patients with insufficiency. However, it showed no significant correlation with treatment response at 6 months with a mean value of 23.2 ± 11.4 ng/ml, 25.1 ± 10.5 ng/ml, 26.2 ± 10.5 ng/ml, and 26.3 ± 11.9 ng/ml.

Conclusion: Patients showed vitamin D insufficiency at diagnosis of RA, but vitamin D was not correlated with treatment response of RA.

Serum Myostatin in Patients with Rheumatoid Arthritis and Its Correlations with Body Compositions and the Disease Activity

Yoko Wada ,[1] Masanori Sudo,[2] Daisuke Kobayashi,[2] Takeshi Kuroda,[3] and Masaaki Nakano[4], [1]Niigata Rinko Hospital, Niigata, Niigata, Japan, [2]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Niigata, Japan, [3]Health administration office, Niigata University, Niigata, Niigata, Japan, [4]School of Health Sciences, Faculty of Medicine, Niigata University, Niigata, Niigata, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Altered body composition is a common feature of patients with rheumatoid arthritis (RA), up to two-thirds of affected patients showing loss of muscle mass and strength and a concomitant increase in fat mass, so-called “rheumatoid cachexia”. Despite great advances in the treatment of RA, such as biological agents and small-molecule compounds, rheumatoid cachexia persists even after joint inflammation has improved. Myostatin, a member of the transforming growth factor-beta superfamily, is a potent negative regulator of skeletal muscle growth and its inactivation can induce skeletal muscle hypertrophy, whereas its overexpression or systemic administration causes muscle atrophy. As it enhances proteolysis and inhibits protein synthesis in skeletal muscle, it has generated considerable interest as a potential regulator of cachexic status in patients with conditions such as cancers, cardiac failure, and HIV infection. In this study, we investigated the possible role of myostatin in body composition alteration in patients with RA.

Methods: This was a cross-sectional study. Ninety-six RA patients who visited Niigata University Hospital between April and June 2017 were recruited. Body composition in each subject was measured by bioelectrical impedance analysis with a tetrapolar impedance meter (InBody S-10, InBody Japan Inc., Tokyo, Japan). The serum myostatin level was measured by enzyme-linked immunosorbent assay with a commercially available kit (Quantikine ELISA GDF-8/Myostatin Immunoassay, R&D Systems, MN, USA). Patients’ laboratory findings and disease activities were also measured, and the correlations between the titer of serum myostatin and these factors were analyzed by Spearman’s correlation coefficient and stepwise multiple regression. In addition, 70 female patients from the cohort were divided into two groups according to their fat-free mass index (FFMI) (low FFMI group (FFMI< 13.82, n=20) and normal FFMI group (n=50)), and their clinical findings and serum myostatin levels were compared by Mann-Whitney U test. Differences at $p < 0.05$ were considered to be statistically significant.

Results: Spearman’s correlation coefficient analysis showed that the serum myostatin level was positively correlated with skeletal muscle mass index and FFMI, and negatively correlated with percentage body fat (%BF), fat mass index (FMI), the swollen joint count, ESR, and DAS28(4)-ESR. Stepwise multiple regression analysis selected FFMI as a positive independent variable (rho=0.3620, p=0.00019) and DAS28(4)-ESR as a negative independent variable (rho=-0.2298, p=0.0154) against the serum myostatin level, respectively. In these 70 female patients, %BF and FMI/FFMI ratio were significantly higher in the low FFMI group than in the normal FFMI group.

Conclusion: The serum myostatin level was significantly correlated with body composition and disease activity in patients with RA. Patients with a lower level of myostatin showed a tendency to have decreased skeletal muscle and increased body fat, suggesting that serum myostatin could be a possible biomarker of rheumatoid cachexia.

The Influence of Mediterranean Diet in Rheumatoid Arthritis: A Monocenter Cross-sectional Study

Francesca Ingegnoli ,[1] Tommaso Schioppo,[1] Isabella Scotti,[2] Giuseppe Marano,[2] Patrizia Boracchi,[2] Orazio De Lucia,[3] Antonella Murgo,[3] and Roberto Caporali[1], [1]Division of Clinical Rheumatology, ASST Pini-CTO, Università degli Studi di Milano, Department of Clinical Sciences and Community Health, Milan, Italy, Milano, Italy, [2]Università degli Studi di Milano, Milano, Italy, MILANO, Italy, [3]Division of Clinical Rheumatology, ASST Pini-CTO, Milan, Italy, Milano, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mediterranean diet (MD) is considered a well-balanced and potentially anti-inflammatory diet characterized by high consumption of olive oil, unrefined cereals, fresh or dried fruit and vegetables, fish, dairy products, meat and with a moderate amount of red wine. Currently, there is conflicting data for the benefits of MD in rheumatoid arthritis (RA), and not enough evidence to support a role of MD in the prevention and treatment of RA.

The aim of our study was to evaluate the association between MD adherence and disease activity, general health (GH) and comorbidities in patients with RA.

Methods: Consecutive patients with RA (ACR/EULAR Criteria 2010) were enrolled in this cross-sectional study. For each patient, Disease Activity Score on 28 joints (DAS28), Simple Disease Activity Index (SDAI), patient GH and a self-reported questionnaire called MD score were recorded. The association between MD score and the above mentioned variables was assessed through univariate regression models (MD score as response variable and the variables of interest as independent variables). Results from each model were reported in terms of: 1) test of association (Likelihood Ratio test, with a Chi-square distribution); 2) categorical independent variables, estimated differences of mean MD score between groups, with respective 95% CI; 3) numerical independent variables, estimate of correlation coefficient and regression slope coefficient, with respective 95% CI. The analysis was performed using the R software.

Results: 205 RA patients (197 Italian) were enrolled: median age at visit 53 (q1-q3: 44-59) years, age at onset 38 (q1-q3: 28-47), disease duration 12 (q1-q3: 7-19), female 80.49%, rheumatoid factor and/or anti–citrullinated protein antibody positivity 58.54%, radiographic damage 41.79%. Comorbidities were also assessed: gastrointestinal 19% (gastro-esophageal reflux disease; inflammatory bowel disease; gastritis; esophagitis), chronic renal failure 1%, arterial hypertension 21.95%, diabetes mellitus 3.9% and coronary artery disease 1.95%. A significant positive correlation was found between MD score and GH, as shown in the table. This suggests a low/moderate tendency of having better GH with higher MD score. Although not statistically significant, a negative correlation was found with DAS28 and SDAI, suggesting an association between higher MD score with lower disease activity. Among comorbidities, a significant difference of mean MD score values between subjects with and without arterial hypertension was also found (mean difference -2.0 CI: -3.7, -0.2; p=0.029).

Conclusion: In this Italian RA cohort, the adherence to MD was significantly associated with a better GH, but higher MD score was not significantly associated with lower disease activity. Arterial hypertension was the only comorbidity

	Mediterranean diet score		
	Correlation coefficient (r): est (95% C.I.)	Regression coefficient (slope): est (95% C.I.)	LR test: p-value
DAS28	-0,10 (-0.23, 0.04)	-0.45 (-1.05, 0.16)	0.149
SDAI	-0.12 (-0.25, 0.02)	-0,12 (-0.38, 0.15)	0.088
GH	0.19 (0.05, 0.31)	0.05 (0.01, 0.09)	0.007*
Body mass index	-0.05 (-0.18, 0.09)	-0,06 (-0.22, 0.08)	0.483

associated with lower MD score, probably due to the fact that the prevalence of the other comorbidities was low. Our study suggests an overall beneficial effect of MD in RA patients. Further studies are needed to better understand the impact of lifestyle modification (*e.g.* diet) in achieving RA disease control.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Experimental models suggested both erythrocytes and platelets activated immune cells and enhanced inflammation in inflammatory arthritis. Although previous cross-sectional studies showed the form and number of erythrocytes and platelets were associated with disease activity, the cross-sectional design cannot assess the causal relationship between erythrocytes/platelets and disease activity. Other limitations include no adjustment with confounding factors and small sample size. The objective of this multi-center longitudinal large cohort study is, therefore, to identify the effects of erythrocytes and platelets on disease activity in patients with RA.

Methods: Hemoglobin concentrations, mean corpuscular volume (MCV), red blood cell distribution width (RDW), platelet counts, and mean platelet volume (MPV) were measured as exposures. Disease activity was assessed using clinical disease activity index (CDAI) for primary outcome. Considering the estimation of effects of time-varying exposures and clustering effects by individual, linear mixed-effect models were used to examine the association between the indices of erythrocytes and platelets on the previous visit and disease activity on the next visit. The indices of erythrocytes and platelets, and disease activity were used as time-dependent variables while participant identification number and time from baseline were included as random factors. Age, sex, disease duration, RF, ACPA, prednisolone, and DMARDs were included as covariates. Sensitivity analyses were also conducted based on secondary outcomes of DAS28-CRP and simplified disease activity index (SDAI).

Results: A total of 63913 samples (median sampling interval: 66.2 days) from 3973 patients was included. The median age at baseline was 63.0 years with 78.3 % of women and mean disease activity were moderate (CDAI:10.9). Regarding erythrocytes, the next disease activity was significantly higher in patients with lower hemoglobin concentrations (-0.53/mg/dL, $P < 0.001$), MCV (-1.18/fL, $P < 0.001$), and RDW (-0.09/fL, $P < 0.001$) on the previous visit after

adjusting by potential confounding factors. For platelets, higher platelet counts and lower MPV were associated with the next higher disease activity (0.20/μL, $P < 0.001$ and -0.55/fL, $P < 0.001$, respectively). These results were similar using DAS28-CRP and SDAI.

Conclusion: These results suggest the number and form of erythrocytes and platelets capture disease activity that remain unmeasured by established disease activity measures in RA. These may also support erythrocytes and platelets influence immune and inflammatory processes in patients with RA as well as the established opposite causal relationship.

Abstract Number: 0460

Fertility of Women with Rheumatoid Arthritis: Disease Activity Negatively Correlates with Serum AMH Levels

Camille Valdeyron ,[1] Martin SOUBRIER,[2] Bruno Pereira,[1] Arnaud Constantin,[3] Jacques Morel,[4] Philippe Gaudin,[5] Bernard Combe,[6] and Florence Brugnon[1], [1]CHU CLERMONT-FERRAND, Clermont-Ferrand, France, [2]CHU Gabriel Montpied, Clermont Ferrand, Auvergne, France, [3]CHU TOUOUSE, TOULOUSE, France, [4]CHU MONTPELLIER, MONTPELLIER, France, [5]Rheumatology Department, CHU Grenoble Alpes Hôpital Sud and GREPI - Université Grenoble Alpes, EA7408, Grenoble - Echirolles, France, [6]CHU Montpellier, Montpellier University, Montpellier, France

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) display a higher infertility prevalence compared with the general population. Disease-related inflammation and RA treatments are likely to be the main factors explaining the RA patients' infertility. Nevertheless, the tangible link between these different factors and the decline in women's fertility has never been clearly demonstrated. This study sought to examine the impact of RA disease activity and treatments on ovarian reserve measured by serum AMH levels in a large patient cohort over 36 months. Using this analysis, we sought to better define the indications for fertility preservation in RA patients.

Methods: Patient and serum analysis data were derived from the French national prospective cohort ESPOIR (Etude et Suivi des POlyarthrites Indifférenciées Récentes). Enrolled patients (n= 117; 18-37-year-olds) fulfilling ACR/EULAR2010 criteria for RA were not receiving any medication at enrolment time (T0). Patients were examined and serum AMHs level measured at T0, 6(T6), 12(T12), 24(T24), and 36(T36) months post-diagnosis.

Serum AMH measurements were performed using the electrochemiluminescence method (analyser Cobas® e411). The impact of both RA activity (evaluated by DAS28 scores and CRP levels) and treatments (methotrexate and corticosteroids) was evaluated at each study visit.

Results: Overall, 117 women from the ESPOIR cohort, aged 18-37 years, were included. The mean age was 29.2+/-5.3 years, mean body mass index 22.96 (+/-3.57)Kg/m^2, mean DAS 28 4.95 (+/-1.24) (range: 1.57-8.30), thus reflecting moderate RA activity, and mean CRP 22.5+/-34mg/L.

A gradual decrease in patients' serum AMH levels was observed over time, in line with the descending curve described in the literature for healthy women (Kelsey *et al*.,2011). Serum AMH levels of RA patients in comparison with the values considered normal for age did not reveal any significant differences at T6, T12, T24, and T36 ($p > 0.05$). We did not observe any impact of RA treatments on serum AMH levels, irrespective of the medication administered, and even after adjusting for age and DAS 28 score ($p=0.81$). We demonstrated an inverse correlation between serum AMH level variations and inflammation parameters (DAS28: r=-0.27, $p=0.003$; CRP: r=-0.16, $p=0.06$).

Conclusion: This is the first study to determine serum AMH levels of a large cohort of young RA patients over 36 months. A quick disease activity limitation appears required to limit ovarian reserve alterations. Oocytes or ovarian tissues are not likely to be necessary if inflammation is promptly controlled. No impact of RA treatments was observed. More studies are required to further explain the pathophysiological mechanisms underlying these associations.

Maximal Improvement in Fatigue Lags Behind Achievement of Sustained Remission in Early Rheumatoid Arthritis

Melissa Holdren ,[1] Orit Schieir,[2] Susan J. Bartlett,[3] Louis Bessette,[4] Gilles Boire,[5] Glen Hazlewood,[6] Carol Hitchon,[7] Edward Keystone,[8] Diane Tin,[9] Carter Thorne,[10] Vivian Bykerk,[11] Janet Pope,[12] and Canadian Early Arthritis Cohort (CATCH) Investigators[13], [1]The University of Western Ontario, London, ON, Canada, [2]University of Toronto Dalla Lana School of Public Health, Toronto, ON, Canada, [3]McGill University, Montreal, QC, Canada, [4]Laval University, Quebec City, QC, Canada, [5]Sherbrooke University, Sherbrooke, QC, Canada, [6]University of Calgary, Calgary, AB, Canada, [7]University of Manitoba, Winnipeg, Canada, [8]Mount Sinai Hospital and University of Toronto, Toronto, ON, Canada, [9]Southlake Regional Health Centre, Newmarket, Canada, [10]Southlake Regional Health Centre, Newmarket, ON, Canada, [11]Hospital for Special Surgery, New York City, NY, [12]Western University, London, ON, Canada, [13]Canadian Early Arthritis Cohort (CATCH) Study, Toronto, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 80% of rheumatoid arthritis patients report clinically relevant fatigue. Fatigue is a complex multi-factorial process that can result in adverse affects on patients' physical and emotional well-being.

The purpose of this study was to examine the relationship between disease activity and fatigue over time in early rheumatoid arthritis (ERA).

Methods: Data were from patients with ERA (symptoms ≤ 12 months) enrolled in the Canadian Early Arthritis Cohort (CATCH). CATCH participants completed repeat clinical assessments, laboratory investigations and self-reported questionnaires including rating their fatigue over the past week using a 0-10 point numerical rating scale (NRS). Fatigue severity was classified as low (≤2); moderate (>2 but < 5) and high (≥5) based on other published RA studies. T-tests and repeated measures ANOVA were used to compare differences in fatigue in patient who did vs. did not achieve a low disease state using ESR (DAS28 ≤ 3.2) or REM (DAS28 < 2.6) within 3-months of cohort entry. Paired t-tests were used to compare fatigue at different time points in patients achieving remission (DAS < 2.6) at three or more consecutive visits within the first year of follow-up.

Results: Of the 1864 patients included, 1640 (88%) met ACR criteria for RA, 1342 (72%) were women and most had moderate-high baseline disease activity with a mean (SD) DAS28 of 4.9 (1.5). Fatigue was common with 19% reporting moderate and 59% high fatigue at baseline. Patients who reported low fatigue severity by three months continued to have significantly lower fatigue throughout follow-up compared to those with moderate or high fatigue (p< 0.001). Patients who achieved DAS28 REM or LDA within 3-months of cohort entry (N=539) had significantly lower mean fatigue throughout 5 years of follow-up compared to those who did not achieve REM or LDA within 3 months (p< 0.001) (Figure 1). Patients who achieved sustained remission in the first 3-months of cohort entry (N=236) had significantly decreased fatigue at time of first achieving DAS REM and 6 months after initially achieving DAS REM (Figure 2). Patients who first achieved sustained remission after 6-months of cohort entry (N= 141) had significantly decreased fatigue at both 3 and 6-months after cohort entry as well as 6-months after the first time in DAS REM (Figure 3).

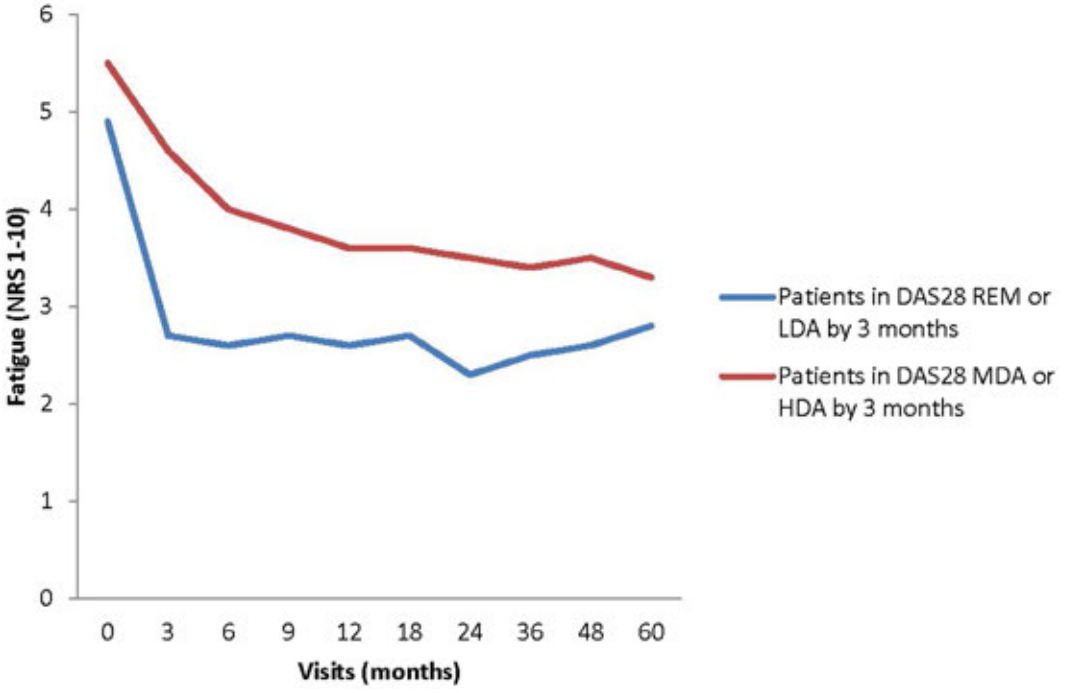

Figure 1. Differences in fatigue scores over time in ERA patients comparing patients in DAS28(ESR) REM or LAD to patients in DAS28(ESR) MDA or HDA at 3 months. DAS28(ESR): disease activity score in 28 joints using Erythrocyte Sedimentation Rate; REM: remission; LDA: low disease activity; MDA: moderate disease activity; HDA: high disease activity.

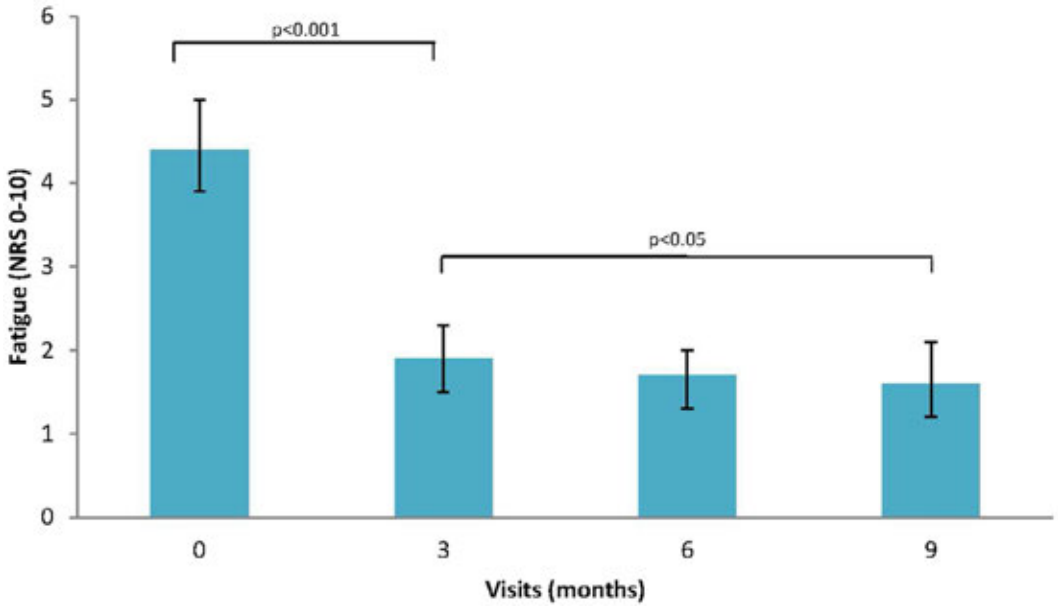

Figure 2. Change in fatigue over time in patients achieving sustained remission (DAS <2.6) from months 3 to 9 (N=236)

Conclusion: Fatigue is common in ERA and is significantly decreased at time of first remission in those with sustained remission within the first year of diagnosis. Maximal improvement in fatigue lags behind with further improvement in fatigue seen 6 months after first remission. Early treatment response within 3-months was associated with short and long-term improvements in fatigue over time. This may have implications for counselling patients.

The Endogenous Plasma Small RNAome of Rheumatoid Arthritis

Michelle Ormseth ,[1] Joseph Solus,[2] Quanhu Sheng,[2] Fei Ye,[2] Haocan Song,[2] Qiong Wu,[2] Yan Guo,[3] Annette Oeser,[2] Ryan Allen,[2] Kasey Vickers,[2] and C. Michael Stein[2], [1]Vanderbilt University Medical Center and Veterans Administration: TN Valley Healthcare System, Nashville, [2]Vanderbilt University Medical Center, Nashville, [3]University of New Mexico, Albuquerque

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Small RNA (sRNA) sequencing has revealed new classes of sRNAs beyond microRNAs. These sRNAs can regulate genes and are also useful biomarkers of disease. The aim of this study was to determine if the endogenous plasma sRNA landscape of patients with RA is altered compared to control subjects and determine their association with disease-related parameters in RA.

Methods: sRNA sequencing was performed on plasma from 165 RA and 90 control subjects who were frequency-matched for age, race and sex. TIGER pipeline was used to quantify endogenous sRNAs including microRNAs and sRNAs derived from small nuclear RNAs (snDRs), small nucleolar RNAs (snoDRs), YRNAs (yDRs), transfer RNAs (tDRs), long non-coding RNAs (lncDRs), miscellaneous sRNAs (miscRNAs), and sRNAs aligning to the human genome but not annotated sRNAs categories (such as sRNAs aligning to messenger RNAs or precursors such as pre-rRNAs). Sequencing reads were normalized to million total reads. The reads in each sRNA category were compared between RA and control subjects and correlated with disease activity measures and general laboratory measures with Spearman correlation. The correlations were presented using heatmap with hierarchical clustering.

Results: The largest proportion of endogenous plasma sRNAs was yDRs, followed by microRNAs. Patients with RA had more microRNAs (1.42-fold, P=0.01), more tDRs (1.14-fold, P=0.04), and fewer yDRs (-1.41-fold, P=0.009) compared to control subjects (Figure 1), but other sRNAs as classes were not significantly different in RA. Disease duration was inversely associated with yDRs (Figure 2). Disease-related parameters such as DAS28 score, swollen

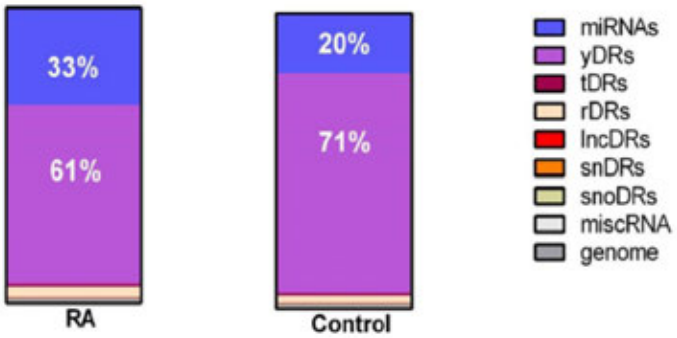

Figure 1. Proportions of endogenous plasma sRNAs in RA and control subjects. Proportions were calculated using the geometric mean of the sRNAs due to skewness.

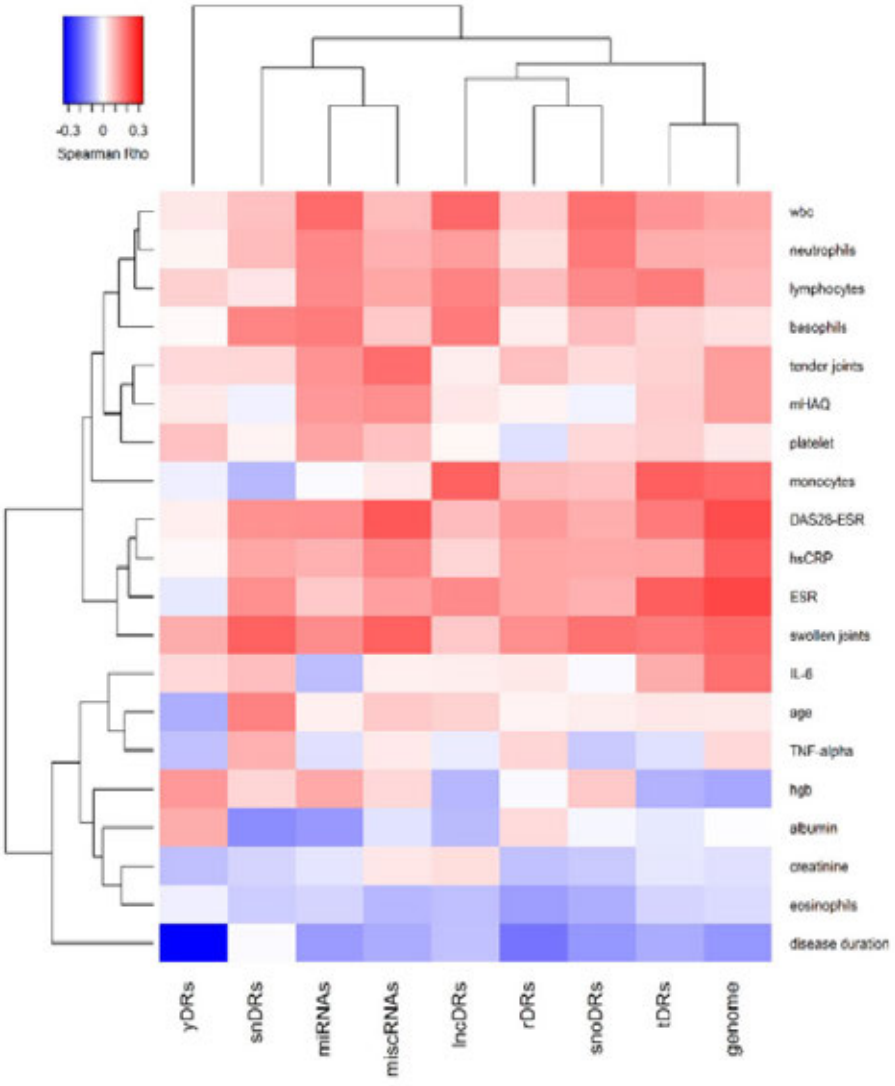

Figure 2. Heatmap with hierarchical clustering demonstrating the relationship between sequencing reads of plasma sRNAs based on category.

joint count, and inflammatory markers were significantly positively associated with genome reads not classified as a sRNA category, tDRs and miscRNAs (Figure 2).

Conclusion: Endogenous plasma sRNAs are altered in patients with RA compared to control subjects. While individual miRNAs have been well studied and many are excellent biomarkers in RA, non-miRNA sRNA and unclassified sRNAs were significantly associated with disease related parameters as classes and may represent novel biomarkers for RA.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The rheumatoid factors (RF) have established roles in rheumatoid arthritis (RA) diagnosis, prediction of disease onset and drug response, and in classifying patients as to prognosis. We assessed the influences of RF presence and titration on real-life management outcomes in a large multicenter RA cohort.

Methods: From August, 2015 to April, 2016, the REAL Study enrolled adult patients diagnosed with RA, according to ARA (1987) or ACR/EULAR (2010) criteria, from eleven Brazilian tertiary healthcare centers. Structured clinical interview and assessment of medical records were performed. DAS28-ESR score, treat to target (T2T) goal attainment (DAS28-ESR < 3.2), disability (HAQ), RF titers, and the presence of erosive disease (EULAR definition) were assessed, as well as several other clinical and demographic variables. A high-titer RF was defined as ≥ 3x the upper limit of normality. Student's t test, Mann-Whitney U, Kruskal-Wallis test, chi-square, and Fisher's exact test were used as appropriate.

Results: 1116 patients were included; 89.4% female and 56.8% white. The mean (SD) age was 57.1 (11.5) years; disease duration: 174.7 (115.1) months; schooling years: 8.3 (4.7). Mean DAS28-ESR was 3.6 (1.5); HAQ score 0.943 (0.769). Only 41.3% of patients were within the T2T goal for DAS28. RF was positive in 78.6% of all patients, and in high titers in 56.1%. Erosive disease was found in 54.9%. The median delay from first symptoms to first DMARD was 12 months (IQR=36). RF titers categories (negative, low and high positive) were comparable as to background characteristics: gender, race, age, disease duration, schooling years, and delay from first symptoms to first DMARD ($p > 0.05$ for all comparisons). The high-titer RF category as compared to the non-high (combined negative or low-titer) RF category showed higher DAS28-ESR scores [3.8(1.5) vs. 3.4(1.5); $p < 0.001$]; higher HAQ scores [0.999(0.796)

vs. 0.870(0.728); p=0.012]; lower attainment of T2T goals [37.2% vs. 46.9%; OR 0.67 (95%CI: 0.51—0.87)]; higher usage of corticosteroids [52.4% vs. 40.2%; OR 1.64 (95%CI: 1.29—2.08)]; higher biological DMARD usage [39.3% vs. 30.9%; OR 1.45 (95%CI: 1.12—1.86)], and higher frequency of extra-articular manifestations [26% vs. 19.6%; OR 1.45 (95%CI: 1.08—1.92)]. Negative and positive low-titer RF categories showed no significant differences between themselves, as to any of the aforementioned outcome variables. Erosive disease was not associated with the RF titer categories (p=0.097).

Conclusion: High-titer RF was associated with worse outcomes in real-life management of RA, with higher disease activity and disability, lower attainment of T2T goals, higher usage of both corticosteroids and biological DMARDs, and higher frequency of extra-articular manifestations. Erosive disease was not associated with RF titer categories in this study, possibly because of the long delay in initiating DMARDs in all RF titer categories, and the overall high frequency of erosions in this population. Negative and low-titer RF categories seemed to perform similarly, regarding clinical outcomes in real-life management of rheumatoid arthritis.

Continuous Decrease in Serum RF Titer During Anti-TNF Therapy Was Associated with Suppression in Progression of RA Joint Damage

Takayoshi Owada ,[1] Kazuhiro Kurasawa,[1] Yuta Takamura,[1] Toshiyuki Miyao,[1] Ayae Tanaka,[1] Ryutaro Yamazaki,[1] Satoko Arai,[1] Reika Maezawa,[1] and Masafumi Arima[1], [1]Dokkyo Medical University, Mibu-machi, Shimotsuga-gun, Tochigi, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A number of studies have investigated the association between serum RF and joint damage in early and established RA patients, and positive and high-titer RF has been a risk or predictive factor of joint damage in RA patients. However, it still remains unclear whether the changes in serum RF titers were correlated with progressions of joint damage in RA. The purpose of this study is to clarify whether continuous decrease in RF titer during anti-TNF therapy was associated with suppression in progression of RA joint damage.

Methods: The subjects were 55 RA patients who filled RA criteria 2010, were treated with adalimumab, certolizumab pegol or golimumab, had serum RF titer ≥45 IU/ml at entry (at starting anti-TNF therapy, month 0), and were followed up until month 12. Their medical records were reviewed retrospectively. Serum RF titers were measured at the entry, month 4 and 12 months after starting TNF inihibitor. More than 10% reduction in RF titer was considered as significant decrease, and continuous decrease in RF titer was defined as significant reductions during both month 0-4 and 4-12. RA disease activity and radiographic progression were assessed by DAS28-CRP and modified total Sharp score (mTSS) at month 0 and 12. In case of withdrawal from anti-TNF therapy during month 4-12 due to some causes, data upon the discontinuation of TNF inhibitor was used as that at month 12 using the last observation carried forward method.

Results: Subjects were 9 male and 46 female, were median age 54.8 years with 3.5 years of disease duration, and were treated with 8 mg/week of median MTX dosage. Median DAS28-CRP and mTSS were 3.23 (interquartile range [IQR] 2.15–4.46) and 6 (IQR 1-20), respectively. After starting TNF inhibitor, the serum RF titer decreased from 104 IU/ml (median) at month 0 to 72 at month 4 ($p< 0.0001$) and 52 at month 12 ($p=0.0122$). Although median DAS28-CRP decreased from 3.23 at month 0 to 1.81 at month 12 ($p< 0.0001$), mTSS increased from 6 (IQR 1-20) to 6 (IQR 2-22) ($p< 0.0001$) and the radiographic progression (yearly change in mTSS >0.5) was found in 43.6%. During anti-TNF therapy, 26 of 55 subjects showed continuous decrease (CD) in serum RF titer, and 29 cases did not (non-CD). Between these groups, there were no differences in baseline characteristics at the entry, and DAS28-CRP at month 0, 4 and 12. The median changes in mTSS during month 0-12 were 0 in CD patients and 1.09 in non-CD, and the yearly radiographic change in mTSS was greater in non-CD group ($p=0.0015$). The radiographic remission (yearly change in mTSS ≤0.5) was found in 71.4% of CD patients and 13.3% of non-CD, and ratio of radiographic remission was higher in CD group ($p=0.0036$). The yearly progression in bone erosion score during month 0-12 was greater in RA patient with non-CD than with CD ($p=0.0037$), but no significant difference between CD and non-CD was observed in the joint space narrowing score. Multiple regression analysis revealed that the continuous RF decrease as well as RA disease activity was significantly correlated with yearly change in bone erosion score during month 0-12.

Conclusion: Continuous decrease in serum RF titer was associated with less progression in mTTS, especially in bone erosion score, of RA patients treated with TNF inhibitors.

Prognostic Factors and Clinical Outcome Modifiers in Patients with Rheumatoid Arthritis: A Review

Leticia Ferri ,[1] Grace Crocket,[2] Xue Han,[1] Boris Breznen,[3] and Mir Sohail Fazeli[3], [1]Bristol-Myers Squibb Company, Princeton, NJ, [2]Bristol-Myers Squibb; Rutgers University, New York City, NY, [3]Doctor Evidence, Santa Monica, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The current goal in treatment of RA is to deliver therapies tailored to individual patients' characteristics. Establishing disease prognosis is a crucial first step in this process. This review maps the current understanding of prognostic factors in the natural history of RA.

Methods: A comprehensive search for the period of Jan. 2000 to Oct. 2018 was conducted using Doctor Evidence LLC's proprietary search platform (DOC Search) containing all relevant databases and RSS feeds. This was supplemented by a search of EULAR and ACR conferences (2017-2019). The search included systematic and narrative reviews, meta-analyses, clinical trials, and observational studies in which prognostic factors in RA were investigated or described.

Results: The results of the search and screening identified 56 publications that were included in the qualitative evidence synthesis (Figure 1).

Qualitative synthesis of the included studies showed that the term “prognostic factor” can be subdivided into 7 broad categories: socio-demographic data, clinical presentation, comorbidities and toxic habits, questionnaire data, biomarkers, genetic markers, and imaging data (Table 1). Once diagnosed, the clinical course of RA is highly variable, which underscores the utility of prognostic factors for predicting the natural history of disease. In clinical settings, the most commonly used factors to strongly predict worsened prognosis are very young age at onset, swollen and tender joint counts at diagnosis, presence of RF, ACPA antibodies, and radiographic erosions. Comorbidities, such as obesity, low bone-mineral density, cardiovascular disease, and extra-articular manifestations, are perceived as moderately associated with prognosis; nevertheless, they are used widely by practicing rheumatologists. Genetic biomarkers and osteitis by magnetic resonance are less accessible for use in daily practice. Prognostic factors that are also outcome modifiers are specific to each therapy . For instance, predictors of remission for treatment with methotrexate include male sex, young age, late-onset RA, low disease activity, RF negative status, and ACPA negative status. For biologics like TNF alpha inhibitors (TNFi), positive treatment response is most strongly correlated with male sex, young age, non-smokers, RF and ACPA negative status, exposure to fewer previous biologic DMARD therapies, low drug immunogenicity, and non-obesity. For patients treated with abatacept, several studies correlate ACPA positive status with greater response when compared with response of patients with the same prognostic factors to TNFi.

CATEGORY	EXAMPLE FACTORS
Socio-demographic data	Gender, Age, Educational level, Family background, Socio-economic status
Clinical Presentation	Swollen joint count, Tender joint count, Morning stiffness, Early onset, RA duration, VAS score
Comorbidities and Toxic Habits	Smoking, Obesity, Diabetes, Depression, Cardiovascular disease
Questionnaire data	Disease activity score, Simplified disease activity index, Clinical disease activity index, Health assessment questionnaire
Biomarkers	Rheumatoid factor, Anti-citrullinated protein antibodies, C-reactive protein, Erythrocyte sedimentation rate, Interleukin-6, Tumor necrosis factor receptor type 1, Calcium binding protein (S100A8/A9), Soluble intercellular adhesion molecule 1, Matrix metalloproteinase 3, C-telopeptide of type II collagen, Tumor necrosis factor α, Fibrinogen, Interleukin 1 α, Anti-perinuclear factor, B lymphocyte chemokine, Myeloid progenitor inhibitory factor 1, Transforming growth factor α, Tumor necrosis factor receptor superfamily member 9, Macrophage colony stimulating factor, Cartilage oligomeric matrix protein, Pyridinoline, Tissue inhibitor of metalloproteinases 1, Deoxypyridinoline glycosylated Pyr, Oncostatin M, Matrix metalloproteinase 10, Matrix metalloproteinase 8, CCL8/monocyte chemotactic protein 2, Chemokine (C-X-C motif) ligand 11, Lymphotactin, Fibroblast growth factor 4, Ciliary neurotrophic factor receptor α, Follistatin, Interleukin 9, Lymphotoxin β receptor, Interleukin 2 (IL-2), Apolipoprotein A-I, Platelet factor 4, CCL8/Myeloid progenitor inhibitory factor 1
Genetic markers	HLA-DR1 and shared epitope, PTPN22, PADI4, CTLA-4
Imaging data	Radiological erosion, MRI and ultrasound signs of inflammation

Table 1. Typology of Prognostic Factors in RA

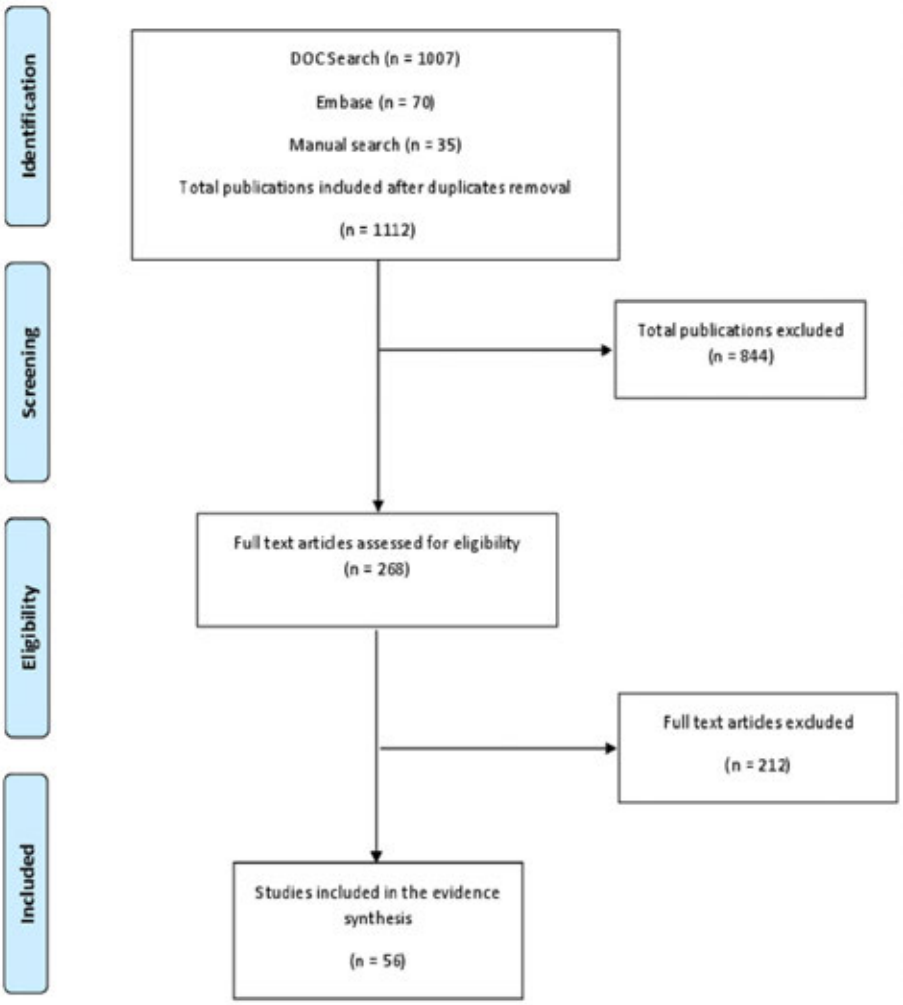

Figure 1. PRISMA Diagram

Conclusion: Although the published literature reports several prognostic factors for RA, only a small subset is routinely assessed in practice and mentioned in clinical guidelines. Interestingly there are already some factors being reported as predictors of response to TNFi and abatacept; specifically the seropositivity (particularly ACPA+) seems to favor abatacept efficacy over TNFi. The barriers to wider and more accurate use of available prognostic factors are both technological, as well as informational, via lack of expert consensus.

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The multi-biomarker disease activity (MBDA) blood test has been shown to be a predictor of risk for radiographic progression in patients with rheumatoid arthritis (RA). Subsequently, the MBDA score was adjusted to account for the effects of age, sex and adiposity and was shown in two cohorts to be better than conventional disease activity measures for predicting risk for radiographic progression [Curtis, J.R., et al. *Rheumatology (Oxford).* 2018. PMID: 30590790]. Here, we combined data from four separate cohorts to validate the adjusted MBDA score as a predictor of radiographic progression. We also evaluated the ability of the adjusted MBDA score, as a continuous variable, to predict risk for radiographic progression.

Methods: Four cohorts with requisite data were identified and combined: the BRASS registry (N=401) and OPERA study (N=154), which have been previously evaluated; and the SWEFOT study (N=235) and Leiden registry (N=163), which are new to these analyses. The associations of radiographic progression (change per year in total Sharp score [ΔTSS]) with the adjusted MBDA score, seropositivity (RF and/or ACPA positive), DAS28-CRP, SDAI, CDAI, CRP, baseline total TSS, age, and sex, were evaluated using linear regression. Logistic regression was used to estimate risk for four levels of radiographic progression (ΔTSS >2, >3, >4 or >5), each as a function of the adjusted MBDA score.

	Pooled Cohort		
Variable	N	Coefficient (95% CI)	p-value
Adjusted MBDA score	953	0.061 (0.044, 0.076)	2.5×10^{-13}
Seropositivity	952	1.47 (0.89, 2.06)	9.9×10^{-7}
log(CRP + 1)	946	0.58 (0.33, 0.83)	4.7×10^{-6}
Baseline TSS	953	0.0074 (0.0028, 0.012)	0.0018
DAS28-CRP	927	0.31 (0.11, 0.50)	0.0024
Male sex	243/953	-0.45 (-1.04, 0.14)	0.14
Age	953	-0.0043 (-0.024, 0.015)	0.66

Table 1. Univariate analyses of risk for radiographic progression (ΔTSS) in four cohorts combined.

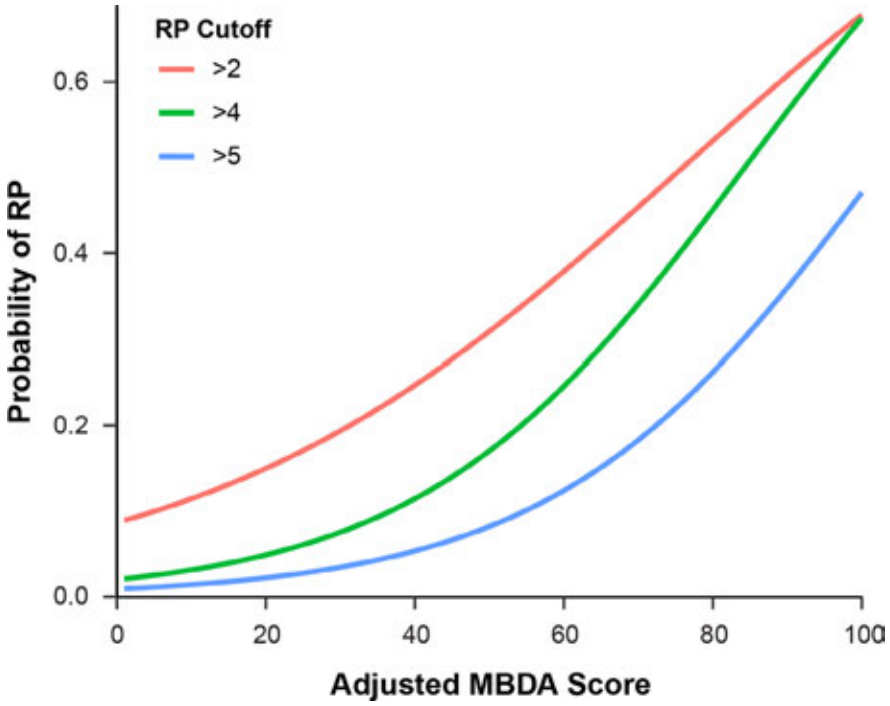

Figure 1. Probability of RP Based on Adjusted MBDA Score.

Results: The four cohorts were similar in age, adjusted MBDA score, and DAS28-CRP, with mean ages ranging from 55.2 to 56.4 years, mean adjusted MBDA scores from 39.9 to 42.5 and mean DAS28-CRP from 3.4 to 5.6. Patients in the OPERA and SWEFOT cohorts had early onset RA (mean durations 87 days and 6.1 months, respectively). Patients in the BRASS and Leiden cohorts tended to have established RA (mean durations 13.8 and 4.6 years, respectively). In a pooled analysis combining all four cohorts (N=953), the adjusted MBDA score was the most statistically significant univariate predicator of radiographic progression ($p=2.5 \times 10^{-13}$) among the tested measures of disease activity, followed by CRP ($p=4.7 \times 10^{-6}$) (Table 1). Curves were generated to display risk for four levels of radiographic progression, relative to the adjusted MBDA score as a continuous variable (Figure 1). The risk for the most severe level of progression that was evaluated, ΔTSS >5, ranged from 1% to 3% in the low (1-30) adjusted MBDA category to 7% to 47% in the high (45-100) adjusted MBDA category (Figure 1).

Conclusion: In a combined analysis of four cohorts of patients with RA, risk of radiographic progression (ΔTSS >5) was nearly absent when the adjusted MBDA score, as a continuous variable, was low, and exceeded 40% for patients with the highest MBDA scores.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Long-chain polyunsaturated fatty acids (PUFAs) of the n3 and n6 families can contribute to modulate inflammatory processes. Dietary intake of n3PUFA is inversely associated with the incidence of RA in different populations. In subject at risk of developing RA, a high erythrocyte content in long-chain n3-PUFA is associated with lower ACPA prevalence and less progression to RA. While long-chain n6PUFA are considered mainly proinflammatory, the erythrocyte content in n6 linoleic acid was inversely associated with the development of RA in a nested-case control study. This study aims to characterize serum profiles of PUFA and to determine their association with baseline variables, with 6-month disease activity and 2-year radiographic progression in a cohort of patients with early RA.

Table 1 Baseline association between PUFA patterns and patient variables

	Pattern 1	Pattern 2	Pattern 3
Active Smoking	p<0.05	ns	p<0.05
BMI	p<0.001	ns	p<0.001
Caucasian ethnicity	p<0.001	ns	ns
Education level	ns	p=0.05	p<0.001*
ACPA positivity	ns	ns	p=0.01
Baseline CRPc	24,2 (+/-34,3) p : ns	17,6 (+/-28,1) p<0.05*	26,5 (+/-49,5) p<0.01
Baseline DAS28 >5.1	p=0.09	p<0.05*	p<0.01

*: inverse association. n.s. : not significant

Methods: Serum PUFAs were quantified by gas chromatography-mass spectrometry in 594 patients with early RA at recruitment in the French ESPOIR cohort. Cluster analysis on 19 serum fatty acids with 14 to 22 carbon atoms allowed to determine 3 patterns of baseline serum PUFA. Pattern 1 included high proportions of n7 and n9 PUFA, pattern 2 was high in n3 long-chain PUFA (EPA et DHA), pattern 3 was rich in n6 long-chain PUFA. Those patterns were not mutually exclusive (i.e. each patient could fit at different level into different profiles). Patients were stratified in tertiles according to how much the fitted into the pattern (tertile 1 meaning lowest and tertile 3 highest fitting into the pattern). The association of PUFA patterns with baseline variables was tested at univariate analysis. The association with 6-month high disease activity (DAS28 >5.1) was tested at multivariate analysis after adjustment on baseline CRP, corticosteroid and/or NSAIDs, socioeconomic status, ACPA, RF, traditional and biologic DMARDs treatment between 0 and 6 months after inclusion. The same model was used to test the association with 2-year radiographic progression.

Results: At baseline, pattern 1 was associated with high BMI, active smoking and with non-Caucasian origin (table 1). Profile 2 was associated with higher socioeconomic status and inversely associated with DAS28 and CRP. Profile 3 was associated with ACPA positivity and higher baseline CRP. At multivariate analysis, fitting into pattern 2 or 3 was associated with lower odds of having active disease after 6 months (OR for tertile 3 vs. tertile 1: 0.49 (95% CI 0.25 to 0.97, p< 0.05) for pattern 2 and 0.51 (0.28 to 0.95) for pattern 3, respectively). None of the patterns associated with 6-month disease activity was associated with 2-year radiographic progression.

Conclusion: In a cohort of early RA patients, we identified a favorable high serum long-chain n3PUFA profile, associated with low baseline inflammation and persistently low disease activity between 0 and 6 months of follow-up in the cohort. This is consistent with a presumed immunomodulatory action of n3PUFA. Despite a clear baseline association with disease severity features, like ACPA positivity and high CRP, a high serum long-chain n6PUFA profile was also associated with 6-month lower disease activity. Despite the longitudinal association with disease activity, none of the baseline PUFA patterns predicted radiographic progression.

Effect of Body Mass Index on the Disease Activity of Patients with Rheumatoid Arthritis in a Gender Specific Manner and Association of Respective Serum C - Reactive Protein Levels with the Body's Inflammatory Status

Shumaila Iqbal ,[1] Linda Burns,[2] Joseph Grisanti,[2] and Cassandra Zhi[3], [1]University at Buffalo, Sisters of Charity Hospital, Buffalo, [2]Buffalo Rheumatology and Medicine, Buffalo, [3]Dexel University College of Medicine, Philadelphia, PA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Current literature evaluating the effect of high Body Mass Index (BMI) on the disease activity of patients with rheumatoid arthritis (RA) is mixed as some studies have shown a positive, linear relationship between BMI and disease activity while others have demonstrated an inverse correlation. Through this study we have expanded upon the relationship between BMI and disease activity in RA. We have further expanded on whether BMI has an effect on the disease activity depending on the gender being studied. Finally, we have studied whether there is a correlation between high BMI values and rising C- reactive protein (CRP) levels.

Methods: This observational study was conducted at the outpatient clinical department of Buffalo Rheumatology and Medicine. The study was ethically approved by Catholic Health Institutional Review Board. The minimum sample size (n=358) was calculated via the World Health Organization sample size calculator. A total number of 451 patients' clinical data was selected on the basis of inclusion/exclusion criteria. The patients were divided into different BMI categories based on the guidelines of National Obesity Education Initiative of the National Heart, Lung, and Blood Institute. The following clinical parameters were studied: BMI, serum CRP level, and severity of disease activity assessed through Routine Assessment of Patient Index Data questionnaire (RAPID3). All data was entered and analyzed through SPSS 16.0.

Results: Our study sample included 98 males and 353 females (22% and 78% respectively). The baseline data of the recruited patients is shown in table 1. Collective data for both the genders showed significantly increased disease activity in RA patients with high BMI values (p=0.04); the highest disease activity was observed in a subgroup of severely obese patients (mean RAPID3 score 13.0 + 7.3 SD) (Figure 1). When the data sets were categorized according to the two genders, it was noted that the aforementioned results remain significant for the females only (p=0.02 for

Table 1. Baseline data for recruited patients. Through independent sample t-test, p values for mean within a group were calculated. Foot notes: BMI= Body Mass Index; RAPID3= Routine Assessment of Patient Index Data; CRP= C Reactive Protein; p value= Pearson's chi-square probability.

Characteristics	Males (n=98) (Mean ± S.D.)	Females (n=353) (Mean ± S.D.)	P values
Age	63.4 ± 13.1	61.3 ± 14.4	0.192
BMI	30.7 ± 7.8	30.9 ± 9.5	0.869
RAPID3 Score	8.3 ± 6.6	10.5 ± 7.3	0.006
CRP	3.2 ± 5.5	4.1 ± 7.5	0.291

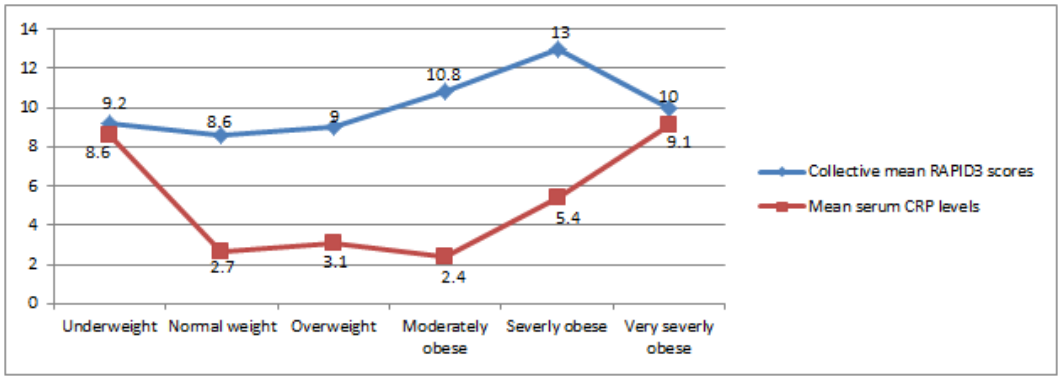

Figure 1. Plots are mean RAPID 3 scores and mean serum CRP levels with BMI categories mentioned on the x-axis. Foot notes: BMI= Body Mass Index; RAPID3= Routine Assessment of Patient Index Data; CRP= C Reactive Protein.

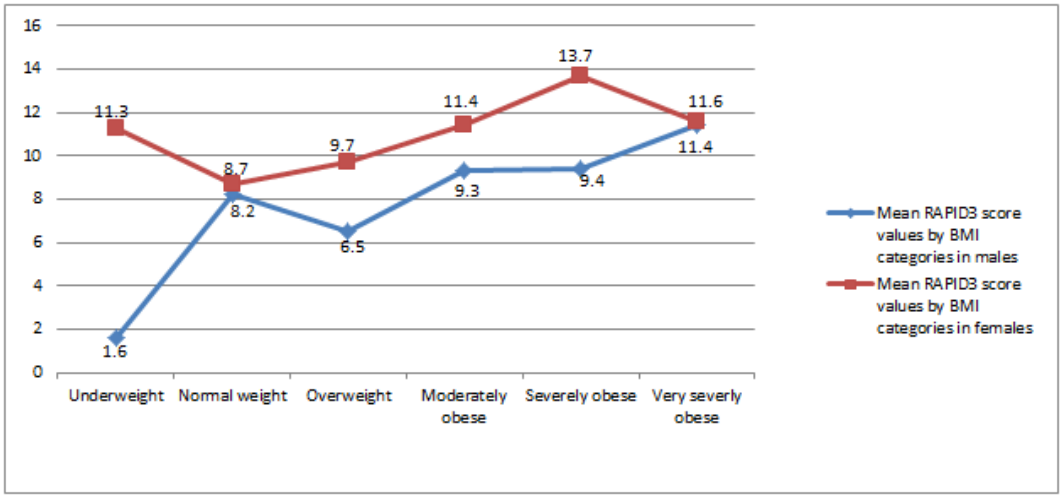

Figure 2. Plots are mean values for RAPID3 scores in individual gender with BMI mentioned on the x-axis. Foot notes: BMI= Body Mass Index; RAPID3= Routine Assessment of Patient Index Data.

females and p=0.57 for males). At all BMI values, mean RAPID3 scoring remained significantly higher for females as opposed to their male counterparts (p=0.006) (Figure 2). Among all three components of the RAPID3 questionnaire, the pain was recorded at the higher side of the scale as stated by the patients. Mean serum CRP levels increased linearly with increasing BMI (p< 0.001); however for the underweight patient population, mean CRP levels were the highest as compared to normal weight, overweight, moderately obese, and severely obese patients (Figure 1)

Conclusion: We conclude that the association between the BMI and the severity of disease remains elusive. High BMI values increases the risk for a pro-inflammatory state of the body due to higher serum CRP levels. Estimating the clinically significant benefit of this theory would require a large scale clinical trial that would highlight the role of losing weight in improving the patients' quality of life, pain control, and mortality.

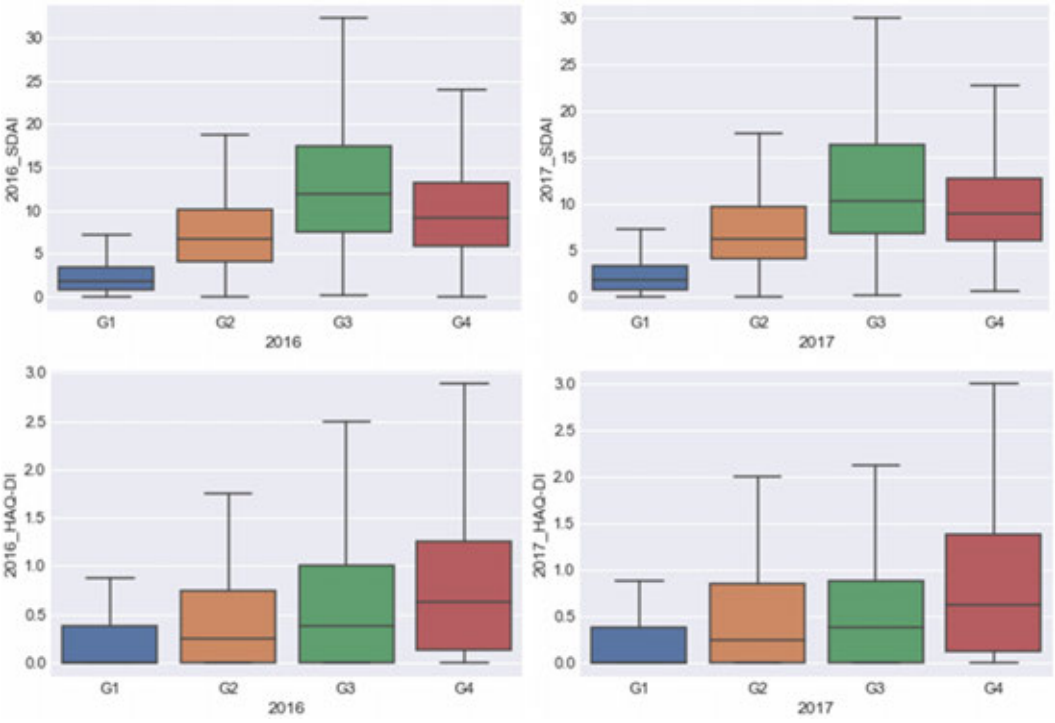
Location and Size of Affected Joints Are Useful to Predict Prognosis of Patients with Rheumatoid Arthritis

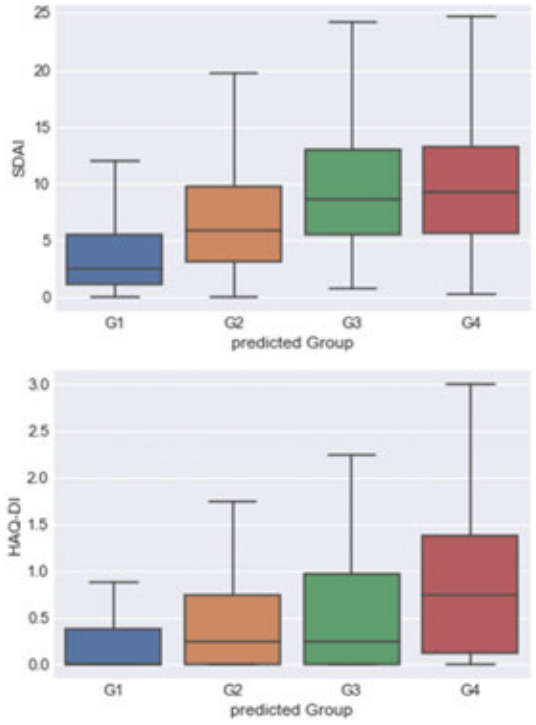
Susumu Nishiyama ,[1] Tetsuji Sawada,[2] and Shigeto Tohma[3], [1]Rheumatic Disease Center, Kurashiki Medical Center, Kurashiki, Japan, [2]Department of Rheumatology, Tokyo Medical University Hospital, Tokyo, Japan, [3]National Hospital Organization Tokyo National Hospital, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To predict prognosis of patients with rheumatoid arthritis (RA) from the location and the size of affected joints.

Methods: Data of 7,776 patients with RA, who were serially registered from 2016 to 2017 without data missing, were extracted from the National Database of Rheumatic Diseases in Japan (NinJa). The joint index (JI) was calculated as the sum of the number of tender and swollen joints divided by the number of evaluable joints in four categories, i.e., upper/large, upper/small, lower/large, and lower/small (Nishiyama S, et al. Proposing a method of regional assessment and a novel outcome measure in rheumatoid arthritis. Rheumatol Int 32:2569-2571. https://doi.org/10.1007/s00296-011-2058-9). Next, the joint index vector V (x, y, z) was calculated as $x = JI_{UL} + JI_{US}$, $y = JI_{LL} + JI_{LS}$, and $z = JI_{UL} + JI_{LL} - JI_{US} - JI_{LS}$, where JI_{UL}, JI_{US}, JI_{LL}, and JI_{LS} indicate the joint indices of the upper/large, upper/small, lower/large, and lower/small joint categories, respectively. Patients were classified into four groups by $|Vxy|$ ($= \sqrt{(x2+y2)}$) and z values (G1: $|Vxy| \leqq 0.1$, G2: $|Vxy| > 0.1$ & $|z| \leqq 0.2$, G3: $|Vxy| > 0.1$ & $z < -0.2$, G4: $|Vxy| > 0.1$ & $z > 0.2$). Transformation matrix was computed using serial registration data of patients with RA who were treated with MTX from the NinJa database





from 2013 to 2014 (Nishiyama S, et al. Joint index vector: a novel assessment measure for stratified medicine in patients with rheumatoid arthritis. Journal of Big Data 2018;5:37. https://doi.org/10.1186/s40537-018-0148-1).

Results: SDAI was the highest in patients of the G3 (small-dominant joint involvement group) and HAQ-DI was the worst in patients of the G4 (large-dominant joint involvement group) independent of registration year (Fig.1). Groups in 2017 were predicted from the vectors estimated using the transformation matrix applied on 4,811 MTX users in 2016, and then 456 patients were classified as the predicted G4. The rest of 4,355 patients had lower SDAI and better HAQ-DI than patients of the predicted G4 (Fig. 2). The concordance rate of the G4 or the others between the predicted group and the real group in 2017 was 82.8%. In 1,001 patients of the G4 in 2016, 452 were predicted to be in the G4 next year, whose SDAI (mean±standard error: 9.90±0.30) and HAQ-DI (0.95±0.04) were significantly higher than those of the rest of 549 patients (7.12±0.22 and 0.67±0.03, respectively).

Conclusion: Classification of RA patients according to the joint index vector which has the affected joints information of the location and the size discriminated patients with a relatively poor prognosis from those with lower SDAI and better HAQ-DI.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: While treat-to-target strategies can dramatically reduce inflammation in RA, persistently high levels of fatigue are present in many patients and represent an important unmet need. Proposed underlying causes include RA disease activity, cognitive/emotional/behavioral factors (CEB), and personal (health) factors. We identified risk factors for persistent high fatigue at 12 months in women and men with ERA receiving guideline-based treatment.

Table 1. Baseline characteristics of participants by sex.

Mean (SD) or N (%)	Women N=714	Men N=288	P value

Methods: Data were from patients enrolled in the Canadian Early Arthritis Cohort (CATCH) between 01-2007 and 03-2017 who met 1987 or 2010 ACR/EULAR RA criteria, had active disease treated with DMARDS, and had complete data on DAS28, BMI, and fatigue severity (0-10) over 12-months. Persistent high fatigue was defined as fatigue ≥ 4

at baseline with < 20% improvement by 12 months. Multivariable logistic regression was used to identify RA disease, CEB, and personal / health factors associated with persistent high fatigue in women and men.

Results: Patients (N=1002) were mostly white (81%), female (71%), with a mean (SD) age of 54 (15), symptom duration of 6 (3) months, and BMI of 28.0 (6.1); 32% were obese (BMI≥30). Women were generally younger, better educated, seropositive, and had greater disability, fatigue, depressive symptoms, and major stress in the year prior to diagnosis (p< .05). 21% of women and 19% of men reported persistent high fatigue throughout the first year (p=.13). Mean fatigue was significantly higher (p< .005) in women at all time points (Figure).

In multivariable regression that included all variables, predictors of persistent high fatigue in women were obesity (OR 1.7; 95% CI 1.1, 2.6), initial steroid use (OR 1.7; 95% CI 1.1, 2.7), seronegativity (OR 0.6; 95% CI 0.4, 1.0) and poor sleep (OR 1.1; 95% CI 1.0, 1.2). In men, obesity was the only significant predictor and was associated with a 2.4 times higher odds (95% CI 1.1, 5.1) of persistent fatigue at 1 yr. Other sociodemographic and RA characteristics, CEB and personal/health factors were not associated with persistent high fatigue in either sex in multivariable models.

Conclusion: Obesity is common in ERA and an important contributor to persistent high fatigue in both women and men. In obese RA patients on guideline-based treatment, lifestyle interventions targeting weight loss may play an important role and strategies to improve mood and manage stress may help reduce persistent high fatigue that does not improve with RA treatment.

Baseline fatigue (0-10)	1.6 (1.2)	7.2 (1.9)	6.6 (1.7)	<0.001	<0.001

and result in poor QoL. Among people with high fatigue at diagnosis, we examined characteristics and identified predictors associated with improved vs. persistent fatigue in the first year of RA.

Methods: Data were from early RA patients (symptoms < 1 year) enrolled in the Canadian Early Arthritis Cohort (CATCH) from 01-2007 to 03-2017. All met ACR1987 or 2010 ACR/EULAR criteria, had active disease, were on DMARDS, and complete fatigue (0-10 NRS) data over ≥ 12 months. Patients were classified at baseline with low (< 4) or high (≥ 4) fatigue; patients who reported high fatigue at baseline were categorized at 12 months as having improved (↓ ≥ 2) or persistently (↓ < 2) high fatigue and multivariable logistic regression was used to identify baseline predictors of improvement.

Results: Participants (N=1002) were mostly white (81%) and female (71%) with a mean (SD) age of 54 (15); 32% were obese. At diagnosis, 70% reported high levels of fatigue; as compared to those with low fatigue, high fatigue patients were significantly (p >.05) more likely to have high disease activity and OA/back pain, be obese, and report greater pain, disability, sleep disturbance, depression, and major stressors in the previous year (Table 1). There was a trend for high fatigue patients to be female and seropositive.

At 12 months, 70% of patients with high fatigue reported significant improvements in fatigue. Patients with improved fatigue were significantly less likely to be obese or have fibromyalgia, and had fewer comorbidities, a shorter symptom duration, and lower initial fatigue (Table 2). In adjusted multivariable models, baseline predictors of improved fatigue at 1 year was BMI < 30 (OR 0.6; 95% CI 0.4, 0.9) after controlling for other Table 1 characteristics.

Conclusion: Debilitating fatigue is common around the time of RA diagnosis and is associated with more active disease, worse pain and disability, and OA/back pain, obesity, depression, poor sleep, and major stressors in the previous year. In patients who presented with high fatigue, 70% improved by the end of the first year. Obesity decreased the odds of improved fatigue at 12 months by 40%. In contrast, other RA presenting characteristics were not associated with improvement. Early MTX use and optimizing weight, sleep, and mood may help address persistent fatigue when RA inflammation is well controlled. These results underscore the potential benefits of multidisciplinary interventions in ERA.

Abstract Number: 0472

Sleep Quality in Women with Rheumatoid Arthritis Is Associated with Disease Activity and Depressive Symptoms

Deborah Da Costa ,[1] Teresa Szlachetka,[2] and Diane Lacaille[3], [1]McGill University, Montreal, QC, Canada, [2]University of British Columbia, Vancouver, BC, Canada, [3]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sleep disturbances, including difficulty initiating sleep, maintaining sleep, and/or early morningawakenings are prevalent in persons with rheumatoid arthritis (RA) and can significantly impact quality of life and worsening of other RA symptoms including fatigue and pain. Despite their high prevalence and negative consequences, sleep disturbances remain poorly understood and inadequately managed in persons with RA. This study aimed to characterize sleep disturbances in RA and identify the role of disease-related, lifestyle behaviors and depressive symptoms in relation to sleep quality in women with RA.

Methods: We conducted a cross-sectional study using 2018 data from an annual survey administered to an RA cohort derived from a population-based cohort from British Columbia. The sample was comprised of 146 women with RA (mean age = 73.7 years ± 10.9). Participants completed self-report questionnaires assessing sociodemographics, anthropometrics, disease activity, functional impairment, leisure time physical activity, alcohol consumption, smoking and depressive symptoms. Sleep quality was measured with the Pittsburgh Sleep Quality Index (PSQI). Descriptive statistics were performed to characterize the sleep parameters. Bivariate associations with the potential determinants of poorer sleep (PSQI global score) were first calculated, followed by multivariate linear regression with variables found to be significantly associated with sleep in the bivariate analyses.

Table 1. Results of bivariate and multivariate regression analyses to identify determinants of poorer sleep quality. * Standardized beta coefficients; Sleep quality assessed with the global PSQI score, with higher scores associated with poorer sleep quality. Abbreviations: RADAI: Rheumatoid Arthritis Disease Activity Index; HAQ: Health Assessment Questionnaire

Variables	Bivariate B* (p-value)	Multivariate B* (p-value)
RADAI	0.51 (<0.001)	0.25 (0.005)
HAQ	0.36 (<0.001)	0.02 (0.228)
> 150 min/wk physical activity	-0.17 (0.035)	-0.08 (0.267)
Alcohol intake		
None	Ref	Ref
Monthly	0.02 (0.813)	0.09 (0.279)
Weekly	-0.02 (0.820)	0.08 (0.282)
Daily	-0.22 (0.027)	-0.05 (0.526)
Depressive symptoms	0.61 (<0.001)	0.46 (<0.001)

Results: The mean global PSQI score was 8.1 (SD=4.1), with 70.5% of the sample classified as poor sleepers (PSQI global score >5). Sleep latency was greater than 30 minutes in 24% of the sample and 35% reported sleep duration < 7 hours. A sleep efficiency of less than 75% was reported by 26% of the sample. Awakening at night three or more times a week was reported by 62.8% of the patients, and this was most commonly attributed in part due to requiring use of the washroom (80.7%) and pain (60.7%). Of the total participants, 44.5% reported using medication to aid sleep in the past month, with 31.5% using sleep medication 3 or more times per week. Significant bivariate relationships with sleep quality are shown in the Table. Age, education, obesity, disease duration, menopausal status, and smoking were not associated with sleep quality. In the multivariate analysis, disease activity and depressive symptoms remained independently associated with poorer sleep quality.

Conclusion: Sleep problems are prevalent among patients with RA. Our findings suggest that in addition to disease activity, depressed mood contributes to poor sleep in RA. Multimodal interventions which include nonpharmacological methods to target sleep require evaluation to optimize the management of sleep disruptions in RA.

RA Presents in Disease Patterns Impacting Treatment Response

Kathryne Marks ,[1] Dana Symons,[2] Cynthia Crowson,[3] Pamela Sinicrope,[4] and Kelly O'Neill[5], [1]Rosalind Franklin University of Medicine and Science, Gurnee, IL, [2]Rheumatoid Patient Foundation, Inc., Rockford, MI, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic, Rochester, MN, [5]Rheumatoid Patient Foundation, Inc., Winter Springs, FL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite significant research on rheumatoid arthritis (RA), disease courses have not been clearly described. Like systemic lupus erythematosus and multiple sclerosis, RA displays a diversity of disease patterns across patients. The purpose of this study was to describe the range of RA disease courses and how they relate to rheumatology treatment including time to diagnosis and degree of improvement with DMARDs.

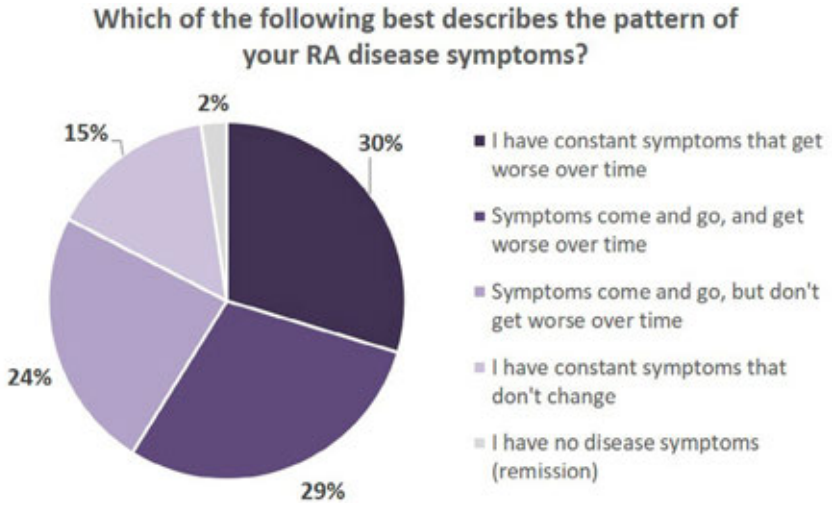

Figure 1. RA disease symptoms can be divided into five categories.

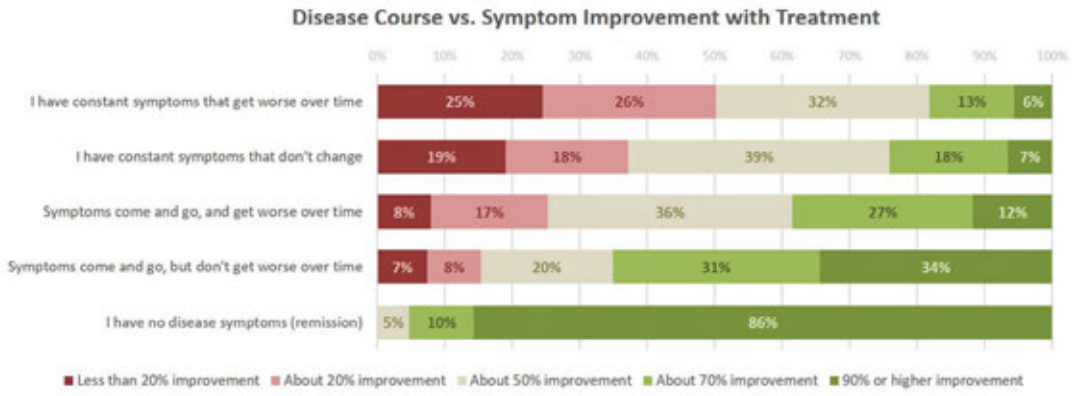

Figure 2. Symptom improvement with DMARDs is associated with particular disease courses.

Which of the following best describes the pattern of your RA disease symptoms?	How long did you experience RA symptoms prior to diagnosis?			
	≤ 1 Year	Between 1-5 Years	5+ Years	Total
I have constant symptoms that get worse over time	24.3%	32.7%	**36.6%**	30%
Symptoms come and go, and get worse over time	27.2%	29.3%	**33.0%**	29%
I have constant symptoms that don't change	14.6%	15.7%	**15.5%**	15%
Symptoms come and go, but don't get worse over time	30.8%	20.3%	**13.9%**	24%
I have no disease symptoms (remission)	3.2%	2.0%	**1.0%**	2%
Grand Total	**100.0%**	**100.0%**	**100.0%**	**100%**

Figure 3. Disease courses are related to length of time between symptom onset and RA diagnosis.

Methods: An anonymous, web-based questionnaire was developed, pilot-tested and presented over 7 days in 2019 on a secure survey system preventing multiple entries. Eligible participants were U.S. residents age ≥18 years with a self-reported diagnosis of RA by a medical professional. Participants recruited by email and social media answered closed and open-ended questions about socio-demographics, their RA disease activity, diagnosis and DMARD history, and improvement from RA treatment. Patients were also asked which of a list of disease patterns best described their RA: "I have constant symptoms that don't change"; "I have constant symptoms that get worse over time"; "I have no disease symptoms"; "Symptoms come and go, and get worse over time"; and "Symptoms come and go, but don't get worse over time". These patterns were categorized in 2 dimensions: (1) constant vs flaring and remitting and (2) progressive vs non-progressive.

Results: 907 people responded (90% women, 10% men), with a mean age of 58 years and 11.1 years since diagnosis (SD 10.1). Patients were asked which of a list of disease patterns best described their RA. The responses as listed above were 15%, 30%, 2%, 29%, and 24%, respectively (Fig 1).

Of respondents who reported a flaring and remitting pattern, 50% reached ≥ 70% improvement from treatment while only 20% of respondents reporting constant disease reached ≥ 70% improvement (Fig 2). Furthermore, 49% of respondents with a non-progressive disease course reached ≥ 70% improvement, while conversely 28% of those with a progressive disease course reached ≥ 70% improvement.

Only 5% of respondents reporting constant progressive symptoms were diagnosed within 3 months of symptom onset. Respondents with this disease pattern were more likely to have had symptoms >10 years before diagnosis compared to other patterns. Those having >10 years between first symptoms and diagnosis were more likely to have progressive disease than non-progressive disease. Thirty-six percent of those who experienced symptoms ≥5 years before diagnosis considered their disease constant and progressive (Table 1). Respondents were 95% more likely to achieve ≥70% improvement if diagnosed within a year of symptom onset versus ≥5 years after symptom onset.

Conclusion: RA patients experience a variety of disease patterns not readily reflected in literature describing RA disease activity. Disease courses may be related to time to diagnosis and treatment and also may impact levels of improvement from RA treatment. While RA is a heterogeneous disease, recognizing patterns of the disease may assist both research and treatment decisions. Further research should explore more thoroughly how RA disease patterns affect rheumatology treatment.

Associations of Plasma Extravesicular (EV) MicroRNA Levels in Seropositive and Seronegative Rheumatoid Arthritis (RA)

Lissette Delgado-Cruzata,[1] Milena Rodriguez Alvarez,[2] **Nickolas Almodovar** ,[3] Toni-Ann Bravo,[3] and Shante Hinson[4], [1]John Jay College of Criminal Justice, City University of New York, New York, [2]SUNY Downstate Medical Center, New York, NY, [3]John Jay College of Criminal Justice, City University of New York, New York, NY, [4]Lincoln Medical & Mental Mental Health Center, New York

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) are biomarkers that allow early diagnosis of RA in seropositive (ACPA+ or RF+) patients. However, some subjects are seronegative (ACPA-/RF-). In addition to a lack of markers to identify ACPA- patients, researchers hypothesize that different serotypes reflect distinct pathogenic and disease entities. RA is mediated by a complex interplay between genetic and environmental factors that mirrors epigenetic deregulation. Recent research has focused on understanding the role of microRNAs (miRNAs), a type of epigenetic modification, in RA. Studies have identified altered expression patterns for miRNAs in synovial fluid and plasma of RA patients, suggesting that changes in miRNA underly the molecular mechanisms of the disease. However, research has not investigated whether miRNA expressions differ by serotype status. In this study, we investigate plasma extravesicular miRNAs associations with serotype and other clinical features of RA. We also attempt to identify whether miRNAs can discriminate seronegative from seropositive RA.

Methods: We recruited 20 patients who satisfied the ACR criteria for RA. The population included 14 seropositive (ACPA+ and/or RF+), and 6 seronegative (ACPA- and RF-) patients. 800 EV miRNAs were extracted from plasma circulating extra-vesicles, and measured using a Nanostring nCounter Human v3 miRNA expression panel. Data was normalized using nSolver software. Statistical analysis was carried out to determine miRNA differences by serotype and to identify miRNA correlations with rheumatoid factor (RF), anti-citrullinated peptide antibodies (ACPA), disease activity index (CDAI), Simple Erosive Narrowing Score (SENS), neuropathic pain (ID pain), Toronto Clinical Neuropathy Score (TCNS), Neuropathy Symptom Score (NSS), and disease duration. Discriminant function analysis was used to investigate whether miRNAs could discriminate between serotypes.

Results: Five miRNAs (*miR-1261, miR-4532, miR-802, miR-595, miR-373-3p*) were differentially expressed between seropositive and seronegative RA ($p \leq 0.05$). *miR-802* and *miR-1261* positively correlated with ACPA levels (Pearson Coeff.ACPA= 0.608, p=0.001) and ID Pain (Pearson Coeff.ID Pain= 0.472, p=0.041), respectively. No other RA clinical

	Seronegative (ACPA-/RF-)	Seropositive (ACPA+ and/or RF+)	p-value

CDAI	19.58 ± 2.73	11.18 ± 2.13	0.06

variables were correlated with miRNA levels. Discriminant function analysis identify *miR-1261* (p=0.004) and ACPA (p=0.002) as the strongest biomarkers differentiating seronegative from seropositive RA.

Conclusion: Our findings suggest that EV miRNAs might underlie serotype pathogenesis in RA. One of these, *miR-595*, has been previously identified as upregulated in RA. We identified four new miRNAs related to RA serotype. Of all these, *miR-1261* was as powerful as ACPA differentiating seronegative from seropositive patients. Interestingly, *miR-1261* did not correlate with ACPA, which suggests independent roles for each biomarker in serotype biology. Further studies are needed to explore the potential of these miRNAs as biomarkers of development and progression of the disease in this population.

Myopenia in Elderly Female Patients with Rheumatoid Arthritis Is Associated with Severe Joint Damage: A Cross-sectional Study

Chu-Tao Chen,[1] Jian-Zi Lin,[1] Jian-Da Ma,[1] Li-Juan Yang,[1] Qian-Hua Li,[1] Le-Feng Chen,[1] Ying-Qian Mo,[1] and **Lie Dai** [1], [1]Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our previous study reported myopenia is associated with joint damage in rheumatoid arthritis (RA). However, little is known about body composition (BC) disorder in elderly patients with RA. Here we aimed to explore the characteristics of BC in elderly RA patients and their clinical significance.

Methods: Consecutive female patients with RA who fulfilled the 1987 revised criteria of ACR or 2010 ACR/EULAR classification criteria for RA were recruited from August 2015 to March 2018. Clinical data including disease activity, function and radiographic assessment were collected. BC was assessed by bioelectric impedance analysis. Overfat was defined by body fat percentage (BF%) as ≥35% in women. Myopenia was defined by appendicular skeletal muscle mass index (ASMI) ≤5.7kg/m^2 in women.

Results: ①There were 425 female RA patients recruited with median age 50 (IQR 40, 58) years, median disease duration 60 (IQR 24, 120) months. There were 65.6% patients with active RA (DAS28-CRP≥2.6), 15.5% patients with functional limitation (HAQ-DI >1) and 56.5% with radiographic joint damage (RJD, mTSS >10). ②There were 23.1% elderly RA patients (age ≥60 years). Compared with young patients (age < 60 years), elderly RA patients had longer disease duration (median 92 months vs. 50 months), higher ESR (43 mm/h vs. 26mm/h), higher rate of functional limitation (24.5% vs. 12.8%) and RJD (67.2% vs. 51.0%), and higher rate of overfat (49.0% vs. 28.7%) and myopenia (54.1% vs. 41.9%, all P< 0.05). ③Compared with RA patients without myopenia, RA patients with myopenia (44.7%) had longer disease duration (median 72 months vs. 48 months), higher DAS28-CRP (median 3.48 vs. 3.02), higher rate of functional limitation (25.8% vs. 7.2%) and RJD (68.4% vs. 46.8%, all P< 0.05). ④There were 44.7% young patients without myopenia, 32.2% young patients with myopenia, 10.6% elderly patients without myopenia, and 12.5% elderly patients with myopenia. Elderly patients with myopenia had the highest rate of RJD (84.9%) in comparison with other three subgroups respectively. They also had higher rate of functional limitation (37.7%) when compared with young patients without myopenia as well as elderly patients without myopenia subgroups respectively (Table 1, all P< 0.0083, Bonferroni correction). ⑤After adjustment for confounding factors including age, smoking habits, disease duration, RF and ACPA status, multivariate logistic regression analysis showed that both young and elderly patients with myopenia had higher probabilities accompanied by functional limitation (young patients with myopenia: OR=3.479, 95%CI: 1.713~7.063; elderly patients with myopenia: OR=5.727, 95%CI: 2.467~13.292) and RJD (young patients with myopenia: OR=1.896, 95%CI: 1.171~3.068; elderly patients with myopenia: OR=4.627, 95%CI: 1.946~10.999) when compared with young patients without myopenia. Moreover, significant additive interaction was observed between the elderly and myopenia in RJD (AP=0.554, 95%CI: 0.125~0.983).

Table 1 Comparisons of disease characteristics among RA patients in age and myopenia subgroups

Characteristics	Young without myopenia (n=190)	Young with myopenia (n=137)	Elderly without myopenia (n=45)	Elderly with myopenia (n=53)	P#

Decreased Muscle Mass, a Novel Predicting Indicator for One-year Radiographic Progression in Rheumatoid Arthritis: A Real-world Cohort Study

Jian-Zi Lin,[1] Jian-Da Ma,[1] Qian-Hua Li,[1] Ying-Qian Mo,[1] Li-Juan Yang,[1] Le-Feng Chen,[1] Chu-Tao Chen,[1] Jun-Wei Wang,[1] Dong-Hui Zheng,[1] and **Lie Dai** [1], [1]Department of Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity paradox based on body mass index (BMI) in rheumatoid arthritis (RA) remain elusive. Our previous cross-sectional study has reported myopenia is associated with joint damage in RA. Here we aimed to explore the association of body composition (BC) with RA clinical outcomes in a real-world cohort.

Methods: Consecutive Chinese patients with RA who fulfilled the 1987 revised criteria of ACR or 2010 ACR/EULAR classification criteria for RA were recruited from August 2015 to January 2018. RA patients were treated according to the T2T strategy and completed at least one-year follow-up. BC was assessed by bioelectric impedance analysis and clinical data were collected at baseline, 3rd, 6th, 9th and 12th months. Myopenia was defined by appendicular skeletal muscle mass index (ASMI) ≤7.0kg/m^2 in men and ≤5.7kg/m^2 in women. One-year radiographic progression was defined as a change of Sharp/van der Heijde modified total sharp score (mTSS) ≥0.5 units.

Results: There were 305 RA patients [median age 49 (IQR 39-58) years old with 84.6% women] completed one year follow-up and 31.8% showed radiographic progression. RA patients with radiographic progression showed worse disease characteristics, lower BMI and lower muscle mass with higher prevalence of myopenia (62.9%-67.0% vs. 30.8%-38.0%) compared with those without radiographic progression during one-year follow-up. After treatment, all muscle indicators increased at almost all visits in all RA patients group especially in those without radiographic progression. Compared with those without baseline myopenia, RA patients with baseline myopenia (45.9%) had worse disease activity indicators at the 12th month, worse functional indicators at each visit, and higher percentage of radiographic progression (43.6% vs.21.8%, all P< 0.05, Figure 1). Multivariate logistic regression analysis showed baseline myopenia was associated with a significantly higher likelihood of radiographic progression (OR=2.139, 95%CI: 1.221-3.747). ROC curve analysis and multivariate logistic regression analysis showed that in patients without baseline myopenia, decreased ASMI from baseline to the 3rd (OR=2.849, 95%CI: 1.156-7.018), 9th (OR=2.837, 95%CI: 1.116-7.209) and 12th (OR=3.791, 95%CI: 1.467-9.794) months revealed significantly higher likelihoods of radiographic progression, with cutoff values of -0.021, -0.156 and -0.083 kg/m2 respectively.

Conclusion: Our data indicated decreased muscle mass, a novel predictive indicator for one-year radiographic progression in RA which imply the importance of dynamic monitoring of BC especially muscle mass during RA treatment.

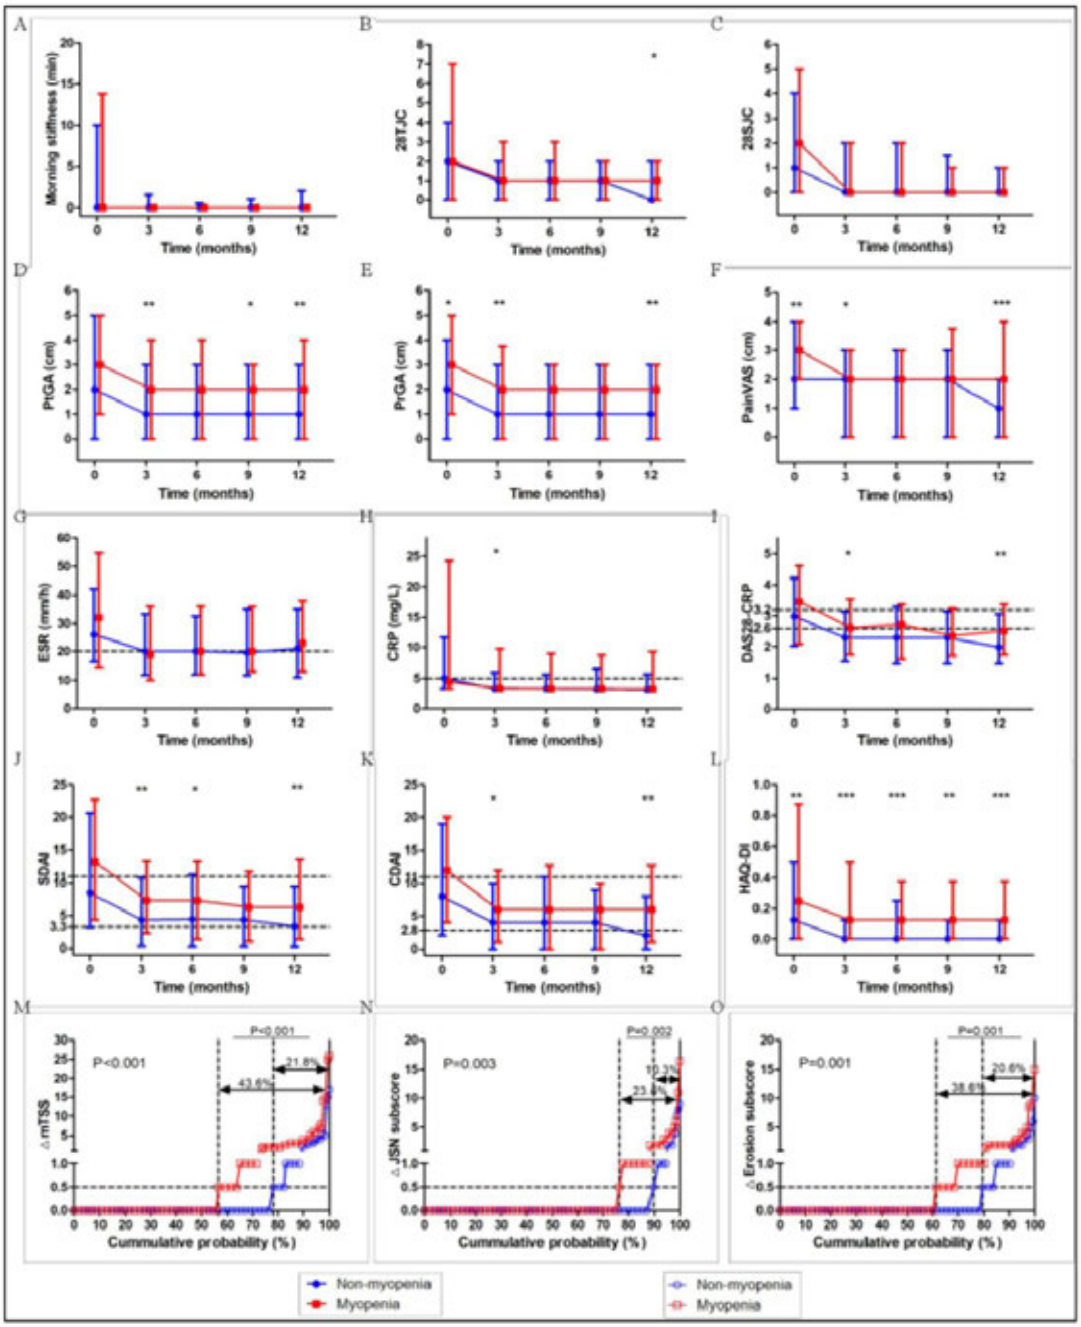

Figure 1 Comparisons of dynamic disease activity indicators (A-K), functional indicator (L) and one-year radiographic change (M-O) between RA patients with and without baseline myopenia.

Myopenia, ASMI≤7.0kg/m^2 in men and ≤5.7kg/m^2 in women; ΔmTSS, a change in mTSS from baseline to the 12th month; ΔJSN subscore, a change in joint space narrowing subscore from baseline to the 12th month; ΔErosion subscore, a change in erosion subscore from baseline to the 12th month.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient Acceptable Symptom State (PASS) represents the maximum level of symptom intensity that a patient considers acceptable. Control of disease activity is associated with the attainment of PASS, but many patients do not reach this status despite being in disease remission. Recognizing the factors associated with PASS status can be helpful in identifying the need for adjunctive treatments besides immunosuppressive therapy, aiming at improving the satisfaction and well-being of patients with rheumatoid arthritis (RA). This study aimed to explore domains of health associated with being in non-PASS in RA patients.

Methods: Data of patients with a diagnosis of RA from 3 databases (NOR-DMARD, RAID study and RAID.Pt) were included. PASS was assessed using the anchored method based on patients' perspective, through the question: "*Think about all the ways your RA has affected you during the last week. If you were to remain for the next few months as you were during the last week, would this be a) Acceptable b) Unacceptable*". Age, gender, disease duration, disease activity based on DAS28-3 variable (joint counts and ESR) and its individual components, the RA Impact of

Table 1: Factor Analysis explaining non-PASS status in RA

	Factor		
	1 "Psychological Impact"	2 "Pain and Function"	3 "Inflammation"
RAID Pain	0.236	0.855	0.172
RAID Function	0.278	0.860	0.139
RAID Fatigue	0.709	0.390	-0.004
RAID Sleep	0.879	0.102	0.052
RAID Emotional well being	0.653	0.549	0.098
RAID Physical well-being	0.719	0.437	0.014
RAID Coping	0.482	0.619	0.060
DAS28-ESR- 3v	0.032	0.174	0.982

Values correspond to rotated loading factors obtained by the Varimax Rotation Method

Disease (RAID) score and its individual components, Patient Global Assessment (PGA) and Physician Global Assessment (PHGA) were collected. Patients who considered themselves in a non-acceptable status and without missing data were selected for statistical analysis. An exploratory factor analysis using the principal components method and Varimax rotation with Kaiser Normalization was performed. A correlation analysis (Pearson's correlation) between the identified factors with PGA and PhGA was performed.

Results: In total, 643 RA patients in non-acceptable status from the three datasets (NOR-DMARD: 388; RAID Study: 179 and RAID.Pt: 76) were included (female: 79.6%, mean age (±SD): 54.0±15.2 years; mean disease duration: 13.4±1.5 years). On average, patients in non-PASS status scored ≥ to 5 in all RAID domains, except Coping (mean:4.79±2.33) and had moderate disease activity (mean DAS28-ESR-3v: 3.77±1.46). Three principal components were identified: "Psychological Impact", "Pain and Function", and "Inflammation" explaining respectively 32.3%, 31.7%, and 12.9% of the total variance (table 1). PGA was moderately correlated with "Psychological Component" (r= 0.43) and with "Pain and Function Component" (r=0.68), but not with the "Inflammation Component". Conversely, PhGA correlated moderately with the "Inflammation component" (r=0.55), but not with the other two factors.

Conclusion: This exploratory analysis suggested that non-PASS status can be due to three main factors: "Psychological impact", "Pain and Function and Inflammation. This suggests the need for a holistic evaluation and consideration of tailored interventions to optimize outcomes, from the patients' perspective.

Dummy variable(male=1, female=0) is used in each models
Coefficients of other independent variables are not shown
Standard Errors are not shown

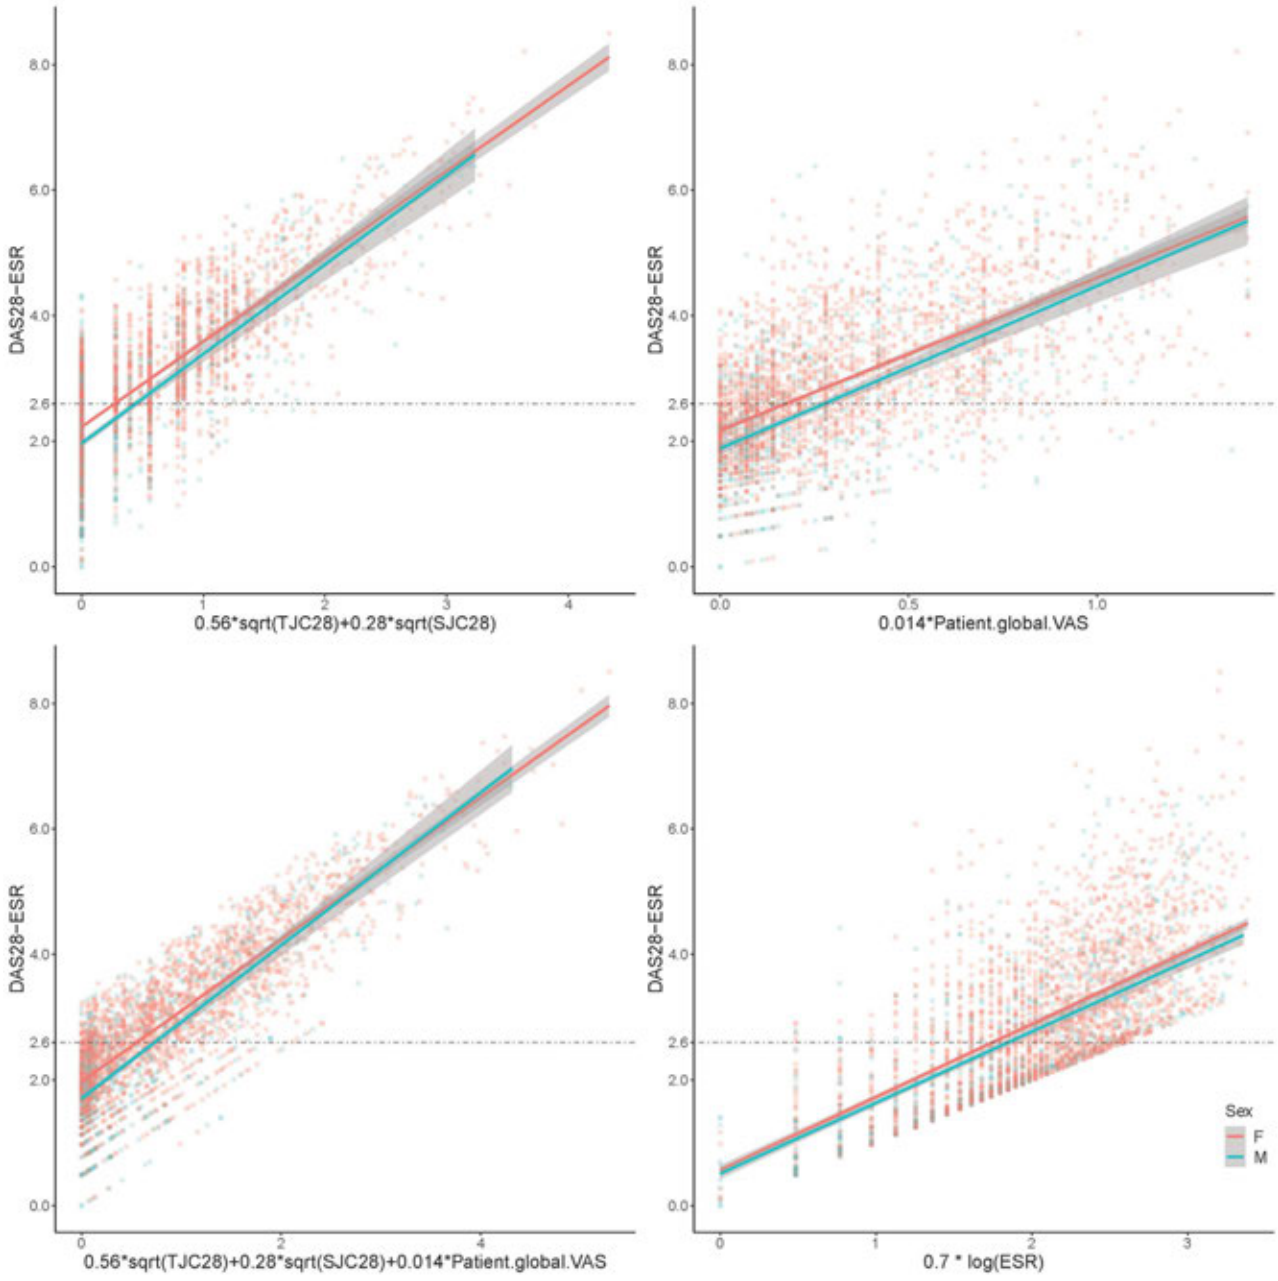

Figure. scatter plots in complete case with regression line(gamma distribution and identity link)

Methods: We analyzed 15056 of patients with rheumatoid arthritis registered in the nationwide observational cohort database(National Database of Rheumatic Diseases in Japan; NinJa) in 2017. We performed regression analysis in each disease activity category (remission, low disease activity, moderate disease activity, high disease activity) for all of DAS28-ESR, DAS28-CRP, SDAI and CDAI using generalized liner model with gamma distribution and identity link: each disease activity indices as a dependent variable and duration of disease, gender, number of artificial joints, BMI, Stage, HAQ-DI, HADS-A and smoking as independent variables. The results of regression analysis are dually confirmed in complete case analysis(listwise deletion) and dataset imputed by chained equation(iteration number:100 × sample size:15056 = 1505600).

Results: In complete case analysis, coefficients of gender in each disease activity category are not significant, except for remission based on DAS28-ESR: -0.21 (Table). In analysis using dataset imputed by chained equation, all coefficients of gender in each disease activity category are significant, except for high disease activity based on SDAI. From the view of clinical knowledge, only the coefficient value of remission based on DAS28-ESR:-0.19 is large enough to affect interpretation of disease activities. To investigate the reason of discrepancy by gender in remission based on DAS28-ESR, we drew scatter plots in complete case with regression line(gamma distribution and identity link):DAS28-ESR as a dependent variable and components of DAS28-ESR as independent variables respectively(Figure). Discrepancy by gender in remission is negligible only in scatter plot of ESR as an independent variable, suggesting gender difference of ESR mainly contribute to the discrepancy. Additionally, we calculated the number of male patients who achieve remission criteria defined as 2.4 for male in DAS28-ESR on the assumption that gender difference is at least -0.2 from the coefficient values. As a result, remission criteria as 2.6 may be overestimated by about 10% in male.

Conclusion: This study indicates we may have to pay attention to gender only when assessing remission based on DAS28-ESR. Considering the current treatment strategy targeting “remission” by composite measures in rheumatoid arthritis, the influence of gender on remission assessed by DAS28-ESR cannot be ignored.

Abstract Number: 0479

Impact of Achieving Early-sustained Remission on Preventing Long-term Functional Loss in Patients with Early Rheumatoid Arthritis

Evelyn Chow ,[1] Isaac T. Cheng,[1] Lai-Shan Tam,[1] and CRYSTAL Study Team Hong Kong[2], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]The Chinese University of Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Preventing functional loss is crucial to early RA (ERA) patients in order to maintain usual activities of daily living. However, whether achieving early and sustained remission could predict long-term functional status remain uncertain. The aim of this study is to ascertain whether early-sustained remission can prevent loss of functional ability in ERA patients.

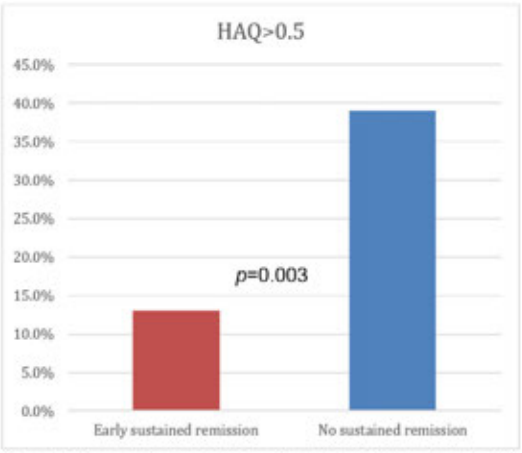

Figure 1. Proportion of patients with substantial functional ability loss at year 4

Methods: ERA patients with symptom onset < 2 years were enrolled into the Clinical Rheumatology Systematic Treat-to-target in Asia Leadership (CRYSTAL) Project. All subjects satisfied the 2010 ACR classification criteria for RA. Clinical assessments were performed for every three months in the first year, then yearly until the sixth year. Disease Activity Score 28 (DAS-28) and Health Assessment Questionnaire Disability Index (HAQ-DI) were recorded each visit. Early-sustained remission is defined as achieving DAS28-CRP < 2.6 consecutively from month 6 to year 4. Substantial functional ability loss is defined as HAQ-DI >0.5 at year 4. Potential independent predictors including baseline characteristics and early-sustained remission at year 4 were determined using multivariate logistic regression analysis.

Results: One-hundred-and-thirteen patients (age: 52.8±12.0 years, female: 90/113 (80%)) who completed year 4 assessment were included. Significant improvement in disease activity is observed (DAS28-CRP: 4.42±1.29 at baseline vs 2.34±0.99 at year 4, p< 0.001). Majority of patients (103/113, 91.2%) were on conventional synthetic DMARDs and 8/113 (7.1%) on biologic DMARDs. 47/113 (42%) patients achieved early-sustained remission, with 5/47 (11%) achieving drug-free remission. Patients with early sustained remission had a milder disease at baseline (Table 1). At year 4, there were less patients with substantial functional loss in the early-sustained remission group (6/46 (13%) vs 25/66 (40%), p=0.003) (Figure 1).

Using multivariate logistic regression, early-sustained remission is a protective factor for substantial functional loss at year 4 (OR: 0.26, 95% CI: 0.09-0.77, *p*=0.015) after adjusting baseline variables. Whereas independent risk factors for functional loss include female gender and HAQ-DI at baseline (Table 2).

Table 1. Baseline characteristics

	In sustained remission = 47	No sustained remission = 66	*p* value
Age	52.83±11.92	55.15±11.04	0.289
Symptom onset, month	9.57±6.75	9.89±6.49	0.800
Gender (Female), n	37 (78.7%)	53 (80.3%)	0.837
VAS[1] Pain Score, 0-100	43.09±26.82	47.8±22.05	0.308
VAS[1] Patient Global, 0-100	48.96±27.67	55.89±22.19	0.143
VAS[1] Physician Global, 0-100	46.51±28.72	58.33±24.31	**0.020**
DAS28-CRP[2]	3.97±1.36	4.74±1.14	**0.001**
HAQ-DI[3], 0-3	0.65±0.67	0.87±0.64	0.080

[1]Visual Analogue Scale, range 0-100; [2]Disease Activity Score-28; [3]Health Assessment Questionnaire Disability Index, range 0-3

Table 2. Multivariate logistic regression

	Odds ratio (OR)	95% C.I.	*p* value
Early sustained remission	0.26	[0.09,0.77]	0.015
Female gender	5.17	[1.01,26.46]	0.049
Baseline HAQ-DI	3.31	[1.58,6.96]	0.002

Conclusion: Long-term functional ability loss can be prevented in ERA patients who achieved early-sustained remission. Baseline HAQ-DI indicates a risk factor for substantial functional loss, therefore early disease control aiming for consistent remission is crucial.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uncontrolled Rheumatoid Arthritis (RA) leads to disability, damage, and poor health-related quality of life (HRQoL). Current treatment recommendations emphasize the importance of achieving remission or Low Disease Activity (LDA) [(1)] to avoid the aforementioned results. In Latin American, RA patients have been shown to achieve low remission but high disability rates. [(2-4)] and the alternative LDA, could be a reasonable treatment goal. Objective: To explore the impact of not achieving remission over time on the HRQoL in RA patients.

Methods: RA patients from a longitudinal established RA cohort (ACR1987/ACR-EULAR2010 criteria) from a single center were studied. This cohort was established to describe the clinical outcomes of RA Peruvian patients; for this analysis, subjects with at least two evaluations (half-yearly) were included. In each visit clinical remission state was defined if they achieved a 3.3 value in the Simple Disease Activity Index (SDAI). Also, non-remission categories were defining in according to SDAI definition (>3.3 to ≤11.0; >11.0 to ≤26 and > 26 to low, moderate and high activity disease, respectively). HRQoL was explored with the Short Form 36 Health Survey Questionnaire (SF-36). A generalized estimating equation model was used to explore each SDAI category as a predictor of the summary measures, mental (MCS), and physical (PCS) of the SF-36 obtained on the subsequent visit. The multivariable models were adjusted for other predictors: gender, age at diagnosis, education, socio-economic level (measured by the Graffar scale), disease

duration, tobacco use, anti-citrullinated protein antibodies level, disability (MDHAQ), use of conventional (c), and biologic (b) DMARDs, use of corticosteroids (current use, past use or non-use) and the baseline score of the corresponding SF-36 summary measure.

Results: Four hundred thirteen patients were included, 375 (90.8%) were women; age at diagnosis was 43.9 (13.5) years, disease duration was 16.7 (11.4) years. At the baseline visit, the SDAI was 25.6 (22.8); only 4.1% patients were in remission; 14.3%, 41.9% and 39.7 were in low, moderate and high disease activity, respectively; MDHAQ was 0.7 (0.5); current corticosteroid use was 31.6%, cDMARD 59.2% and only 7.8% were in bDMARD treatment. The PCS was 40.5(18.4) and the MCS 45.7 (16.6). One thousand and nineteen visits were analyzed in the follow-up (2.71 per patient). In the multivariable analysis, not achieving remission state was associated with a worse HRQoL; these data are depicted in table 1.

Conclusion: Not achieving remission states predicted a worse HRQoL in the follow-up of RA patients, in our *real world* cohort. These results reinforced the importance of remission as a goal of RA management in clinical practice in our region.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: We previously studied evolution of MRI RAMRIS scores in a group of 28 early rheumatoid (RA) patients treated with first-line infliximab (IFX) versus placebo. After 4 months, we observed a significant improvement of the scores in IFX-treated patients, while the changes in placebo-treated individuals were minimal. Here, we used synovial tissue samples obtained at baseline and 4 months after initiation of therapy, in order to study correlations between synovial IL17A and clinical/MRI scores of disease activity.

Methods: Twenty eight patients with treatment naive early ACPA positive RA were enrolled. Disease activity measures (DAS28-CRP) were evaluated at baseline, weeks 2 and 4, and every 4 weeks until week 52. OMERACT RAMRIS scores (and each of their components: erosion, osteitis, synovitis, tenosynovitis), synovial biopsy inflammation and quantitative evaluation of IL17A immunostained sections were evaluated at baseline and month 4.

Results: 28 pts were randomized (mean age: 48 +/- 12 yrs; mean duration of arthritis: 0.34 +/- 0.53 yr; mean CRP level: 1.67 +/- 2.23 mg/dL). A synovial biopsy was performed in 18 patients. A strong correlation was observed between IL17A expression and total RAMRIS score or any of its components (see table and graph). No association of IL17A expression was observed across the different pathotypes (pauci-immune vs myeloid-lymphoid).

Higher synovial IL17A was also associated with a better improvement of the RAMRIS score at month 4 in IFX-treated patients (0.2799 ± 0.2102 vs 0.0216 ± 0.0223, p=0.029).

No correlation was observed between synovial IL17A and disease activity measures.

Conclusion: In this small randomized cohort of ACPA positive early RA patients, we observed a good correlation between IL17A expression in the synovium and MRI RAMRIS score, underlining the potential role of the cytokine in disease severity and progression.

Figure: IL17A expression and baseline total RAMRIS score correlation

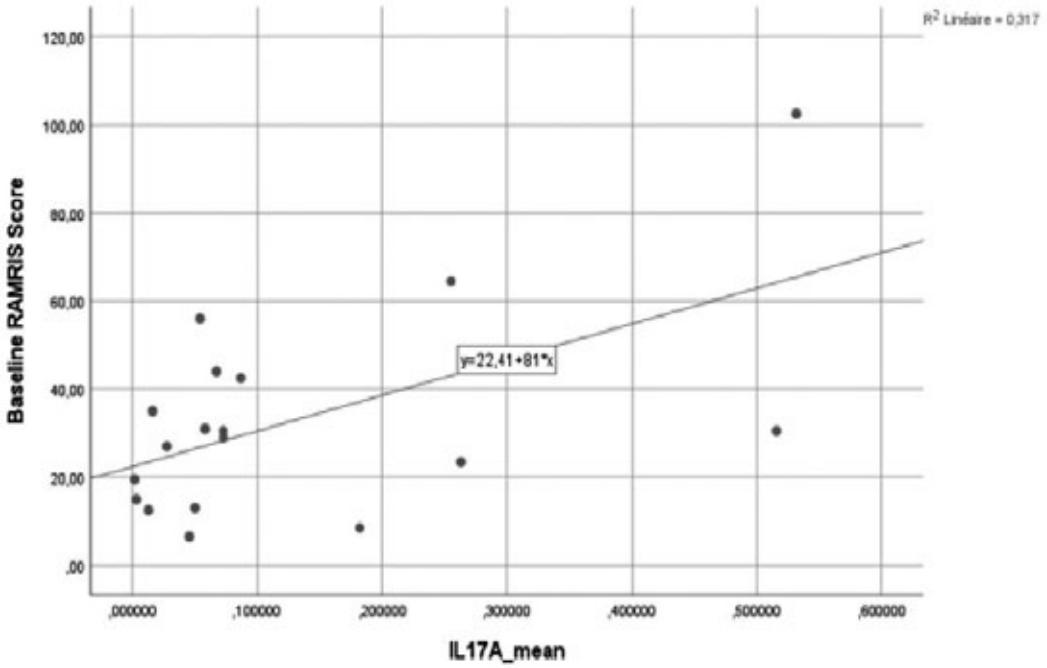

Table: IL17A expression and RAMRIS scores correlations

Correlations Table

		baseline

Antibody Repertoire Sequencing, Antigen Array Analysis, and Cytokine Profiling of Blood from Individuals at High-risk for RA Reveals Candidate Immunoglobulin V Genes, ACPA, and Cytokines That May Promote the Transition to Arthritis

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The "Targeting Immune Responses for Prevention of RA" (TIP-RA) collaboration studies individuals at high risk for developing rheumatoid arthritis (RA) because of serum anti-citrullinated protein antibody (ACPA) positivity in absence of arthritis at baseline, and is focused on defining how they transition from at-risk to classifiable disease. One potential mechanism is through the development, expansion and class-switching of B cells expressing pathogenic ACPA. Previous studies identified blood plasmablasts expressing ACPA in pre-clinical and established RA. Individuals enrolled in the TIP-RA cohort were analyzed by antibody repertoire sequencing, serum ACPA profiling, and serum cytokine analysis to identify features associated with progression to RA.

Methods: Cytokine array and ACPA array profiling were performed on serum samples from CCP- controls (n=156), (n-78), RA converters (n=3), and seropositive early-RA (n = 32). RNA was extracted from PAXgene whole blood tubes from CCP- (n=170), CCP3+ at risk (n=85), RA converters (n=3) and early RA individuals (n=41). Purified RNA was used for paired-end sequencing of immunoglobulin heavy-chain and run on a HiSeq 2500. Bulk IgH data was de-multiplexed with adapter sequences trimmed using MIGEC. Overlapping paired end reads were merged using MiTools. MIXCR was used to align sequencing reads to germline VDJ genes of B cell receptors obtained from IMGT, and subsequently group clones. VDJ gene family usage was analyzed using Alakazam (Immcantation).

Results: ACPA array analysis demonstrated development of ACPA targeting citrullinated fibrinogen and histone 2B as well as native vimentin as associated with transition to clinical arthritis. Cytokine profiling revealed increased levels of multiple pro-inflammatory cytokines and chemokines in the blood. Immunoglobulin heavy chain sequencing identified persistent clones (based on shared V and J gene usage, identical CDR3 lengths, and >60% amino acid homology) that underwent both expansion and class switching to IgA and IgG. Specifically, we identified clones encoding IgH-V3-23/IgHJ4 and IgHV1-2/IgHJ4 that switched and expanded from IgM pre-conversion to IgA and IgG isotypes post-conversion to RA (Figure 1).

Conclusion: Asymptomatic anti-CCP+ individuals that converted to RA exhibited increased levels of blood cytokines and ACPA. These individuals also exhibited expression, expansion and class-switching of B cell clones encoding IgH-V3-23/IgHJ4 and IgHV1-2/IgHJ4, antibody V genes previously identified as being expressed by RA plasmablasts and encoding anti-citrullinated protein antibodies (ACPA). IgH-V3-23/IgHJ4 and IgHV1-2/IgHJ4 may encode ACPA

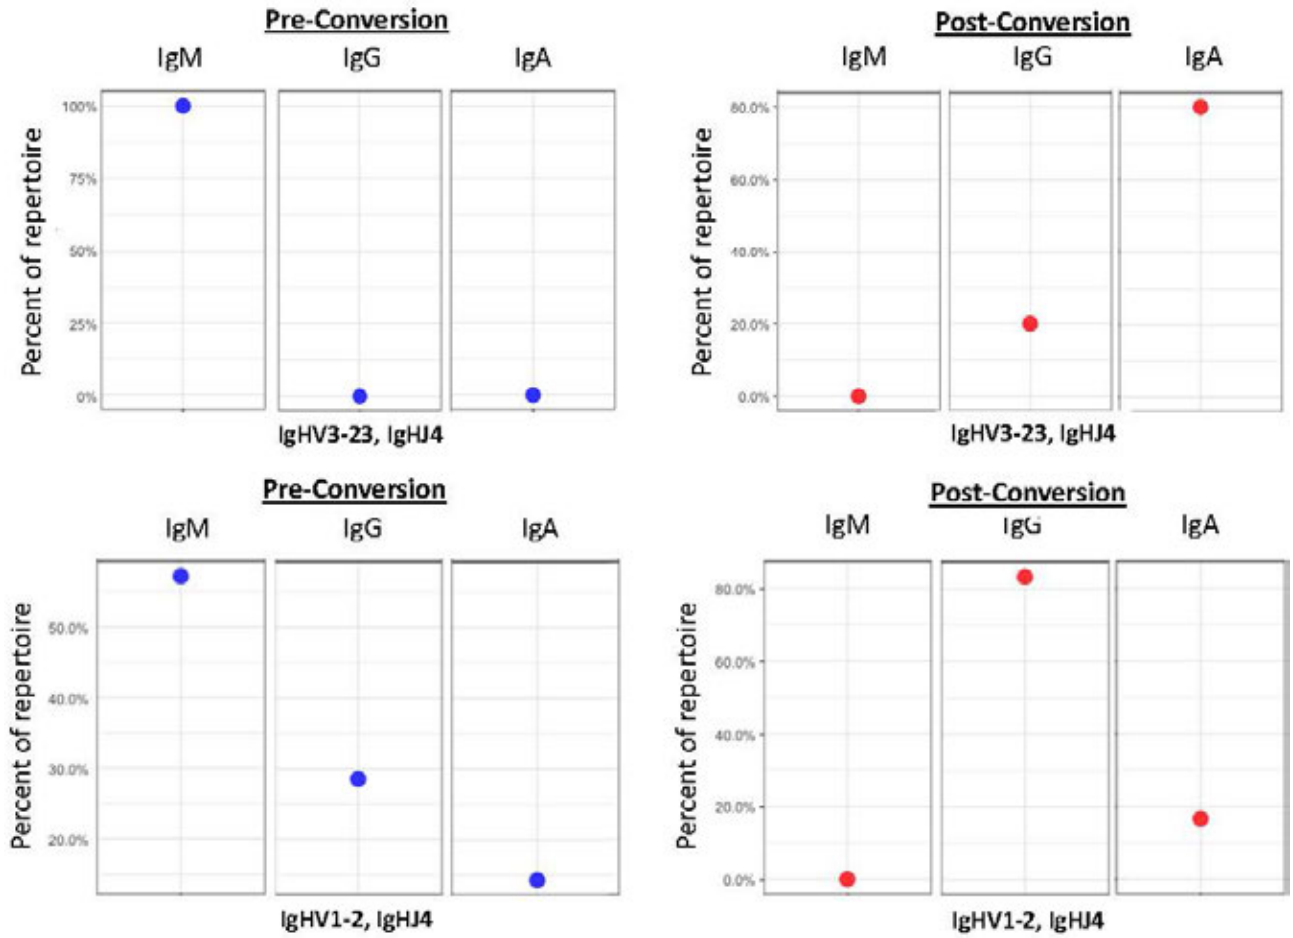

Figure 1. B cell clones encoding IgH-V3-23/IgHJ4 and IgHV1-2/IgHJ4 class switch from IgM pre-conversion to IgA and IgG isotypes post-conversion in TIP-RA converters.

that promote the transition to clinical RA, and further investigation is needed to fully define their citrullinated antigen targets and potential role in promoting the transition to clinical RA.

Can a Single Question on Functional Impairments Facilitate the Diagnosis of Early Inflammatory Arthritis? A Cross-Sectional Derivation and Validation Study in Two Early Arthritis *Recognition* Clinics

Bastiaan van Dijk ,[1] Hanna van Steenbergen,[1] Ellis Niemantsverdriet,[1] and Annette van der Helm-van Mil[2], [1]Leiden University Medical Center, Leiden, Netherlands, [2]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Early treatment initiation in RA is associated with improved outcomes but requires early identification of synovitis. Joint swelling in early inflammatory arthritis (IA) may be subtle, making it difficult to detect at joint palpation, especially for general practitioners (GPs) who have limited experience with this. To promote early recognition of IA, two Early Arthritis *Recognition* Clinics (EA*R*C) were initiated in our country. EA*R*Cs are easy-access outpatient rheumatology clinics, intermediary between primary and secondary care, to which GPs can refer patients if in doubt about the presence of IA (instead of 'watchful waiting'). Although this approach markedly reduced referral delay, it may not be easily implemented in other places. New tools are needed. Since it is unknown if inquiring about functional impairments is helpful in the early detection of IA, we used the unique EA*R*C data of patients with suspected IA to investigate this. Aiming for simple and time-efficient use in daily practice, we evaluated whether a single question on functional impairments could aid the diagnosis of early IA.

Methods: From September 2010 to April 2014, 997 patients with suspected but uncertain IA visited one of the two EA*R*Cs and were included in a derivation cohort. In addition, 557 other patients visiting the same EA*R*C (November 2015-December 2018) and 506 patients visiting another EA*R*C (September 2010-January 2014) served as validation cohorts. IA was assessed by joint examination by rheumatologists, physical functioning with the Health Assessment Questionnaire Disability Index (HAQ-DI). Discriminative abilities of its 20 questions for IA were compared based on the area under the receiver operating characteristics curve (AUC) and test characteristics. Associations between the best discriminating question and IA were assessed with logistic regression. Odds ratios (ORs) were adjusted for age, sex and for six other, previously reported variables predictive of the presence of IA. Overall discriminative ability of multivariable logistic regression models was assessed with the AUC.

Results: IA was diagnosed in 43%, 35% and 53% of patients in the derivation and validation cohorts, respectively. In the derivation cohort, patients with IA had higher mean HAQ-DI-scores (0.84 compared to 0.73, p=0.003). Discriminative characteristics of one question on difficulties with dressing (AUC (95%CI) 0.57 (0.54–0.61); OR 1.83 (1.41-2.38)) paralleled the total HAQ-DI score (AUC 0.55 (0.52–0.59)). In the validation cohorts, ORs were 2.14 (1.48-3.10) and 2.00 (1.39-2.87) in univariable analyses, which remained similar in multivariable analyses. However, the difference in AUC for multivariable models with and without 'difficulties with dressing' was small: 0.73 (0.70–0.77) and 0.72 (0.69–0.76), respectively. Test characteristics are shown in the table.

Conclusion: A yes/no answer on a simple question ("Are you able to dress yourself, including shoelaces and buttons?") was helpful in discriminating patients with and without IA. Findings were validated in independent 1.5-line

	Sens. % (95%CI)	Spec. % (95%CI)	PPV % (95%CI)	NPV % (95%CI)
Derivation cohort n = 997, IA in 43%	60 (55–65)	54 (50–58)	50 (45–54)	65 (60–69)
1st validation cohort n = 557, IA in 35%	67 (60–73)	52 (47-57)	42 (37–48)	74 (70–80)
2nd validation cohort n = 506, IA in 53%	66 (60–72)	51 (44–57)	60 (54–66)	57 (50–64)

Table. Test characteristics of the presence of difficulties with dressing (scores ≥1 on the corresponding HAQ-DI question), with IA at physical examination as outcome.

settings and need to be validated further in primary care. This is a step forward to arrive at practical tools that are helpful for GPs in diagnosing IA.

Effectiveness of Platelet-derived Microparticles for the Diagnosis and Clinical Evaluation of Rheumatoid Arthritis

Hideyuki Horikoshi ,[1] Ko Takamatsu,[1] Rika Suzuki,[1] Yasuyoshi Kusanagi,[1] Fumihiko Kimura,[1] and Kenji Itoh[1], [1]National Defense Medical College Division of Hematology and Rheumatology, Department of Internal Medicine, Tokorozawa, Saitama, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Platelet-derived microparticles (PDMP) are membrane vesicles released from activated platelets and contain various inflammatory or angiogenetic factors; therefore, PDMP may be a new biomarker for the diagnosis of rheumatic disease. Previous studies regarding PDMP levels in rheumatoid arthritis (RA) have compared patients with osteoarthritis or less active RA but not those with undifferentiated arthritis (UA), which requires more differentiation from RA. Moreover, reports on the clinical characteristics of RA patients with high PDMP levels are limited. We conducted the analysis of plasma PDMP levels obtained from 65 patients, including those with RA and UA. Furthermore, we examined the clinical features of RA cases with high PDMP levels.

Methods: In total, plasma PDMP levels in 65 cases (RA, n = 28; polymyalgia rheumatica [PMR], n = 11; UA, n = 6; others, n = 20; and healthy controls, n = 7) were analyzed using PDMP ELISA kit employing anti-GPIX and anti-GPIb monoclonal antibodies (Protein Purify Ltd., Gunma, Japan). In addition, we compared PDMP levels with clinical char-

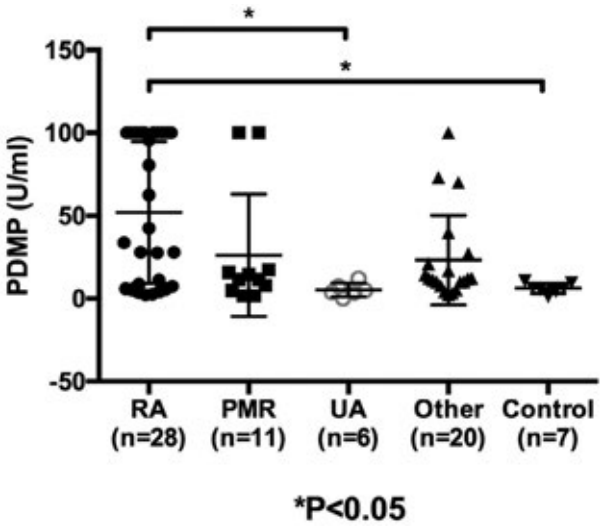

Figure 1. PDMP levels in each disease group. RA, rheumatoid arthritis; PMR, polymyalgia rheumatica; UA, undifferentiated arthritis; Other includes rheumatic diseases, such as systemic lupus erythematosus and dermatomyositis.

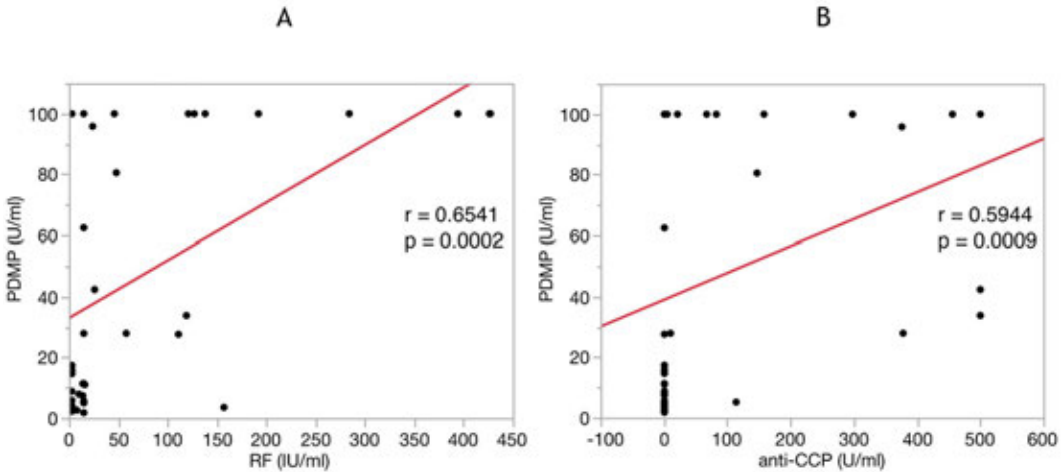

Figure 2. Correlation of PDMP levels with RF (A) and anti-CCP titers (B) PDMP levels positively correlated with RF and anti-CCP. RF, rheumatoid factor; anti-CCP, anticyclic citrullinated peptide antibody.

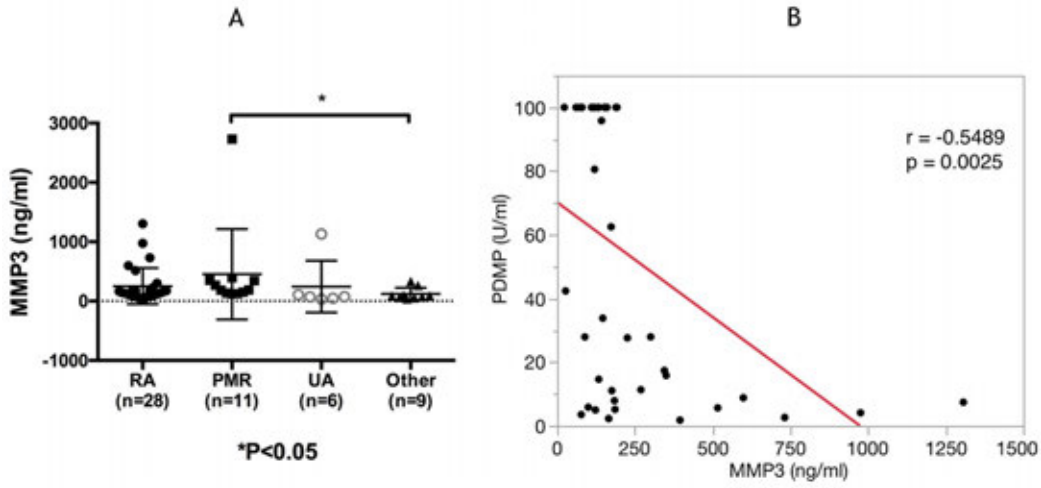

Figure 3. (A) MMP3 level for each disease group. MMP3 level between RA and UA was not significant. (B) PDMP levels negatively correlated with MMP3. RA, rheumatoid arthritis; PMR, polymyalgia rheumatica; UA, undifferentiated arthritis; Other includes rheumatic diseases such as systemic lupus erythematosus and dermatomyositis; MMP3, matrix metalloproteinase-3

acteristics and other biomarkers, including C-reactive protein, erythrocyte sedimentation rate, matrix metalloproteinase-3 (MMP3), rheumatoid factor (RF), and anticyclic citrullinated peptide antibody (anti-CCP).

Results: Mean PDMP levels (± SD) for each disease group and controls were as follows: RA, 51.96 ± 42.87 U/ml; PMR, 26.10 ± 36.92 U/ml; UA, 5.27 ± 4.13 U/ml; others, 23.28 ± 26.93 U/ml; healthy controls, 6.20 ± 3.13 U/ml. Plasma PDMP levels were significantly higher in RA patients than in UA patients and control. Furthermore, in RA patients, PDMP levels positively correlated with RF ($r = 0.6541$; $p = 0.0002$) and anti-CCP ($r = 0.5944$; $p = 0.0009$). Notably, PDMP levels negatively correlated with MMP3 ($r = –0.5489$; $p = 0.0025$); MMP3 levels between RA and UA patients were not significant. In addition, compared with 22 RA patients without interstitial pneumonia, 6 RA patients complicated with interstitial pneumonia showed elevated PDMP levels (85.72 ± 26.60 U/ml vs. 42.76 ± 42.19 U/ml; $p = 0.0281$).

Conclusion: Plasma PDMP levels are useful in the differential diagnosis of RA and UA. Plasma PDMP levels were correlated with RA-associated autoantibody and the complication of interstitial pneumonia, moreover, negatively

correlated with MMP3; therefore, plasma PDMP can be a candidate for an independent biomarker for the diagnosis and clinical evaluation of RA.

Comparison of Clinical Features, Synovial Histology and Immunohistochemistry in Seropositive Arthralgia, Rheumatoid Arthritis, and Osteoarthritis

Candice Low ,[1] Richard Conway,[2] Francis Young,[1] Eamonn Molloy,[3] Anne Barbara Mongey,[3] Gerry Wilson,[3] Ursula Fearon,[4] and Douglas Veale[5], [1]Saint Vincent's University Hospital, Dublin, Ireland, [2]Blackrock Clinic, Dublin, Ireland, [3]St Vincent's University Hospital, Dublin, Ireland, [4]Molecular Rheumatology, Trinity Biomedical Sciences Institute, TCD, Dublin, Ireland, [5]EULAR Centre For Arthritis And Rheumatic Diseases and The Conway Institute, Dublin, Ireland

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Table 1. Characteristics of patients with seropositive arthralgia, RA, and OA

Characteristic	Seropositive Arthralgia	Rheumatoid Arthritis	p value	Osteoarthritis	p value
N	33	14		7	
Age, years, mean (range)	54 (33-81)	55 (36-67)	0.724	62 (49-80)	0.137
Female, n (%)	22 (67)	6 (43)	0.195	6 (86)	0.318
Tender Joint Count	0 (0, 4)	6 (2, 11)	0.008	1 (1, 2)	0.261
Swollen Joint Count	0 (0, 0)	7 (3, 10)	<0.0005	1 (1, 2)	0.169
C Reactive Protein (mg/dL)	3.00 (2.00, 7.00)	14.00 (4.30, 35.00)	0.018	3.00 (1.73, 15.83)	0.805
Erythrocyte Sedimentation Rate (mm/hr)	17 (9, 25)	29 (21, 44)	0.028	15 (5, 18)	0.493
Patient Global Assessment (mm)	50 (28, 70)	52 (70, 90)	0.045	84 (70, 90)	0.013
DAS28-CRP	3.43 (2.38, 4.82)	4.88 (3.45, 5.90)	0.015	3.85 (2.53, 4.58)	0.781
Arthroscopic synovitis (mm)	60 (35, 80)	80 (80, 90)	0.011	80 (30, 80)	0.442
Arthroscopic vascularity (mm)	50 (30, 75)	80 (65, 90)	0.027	50 (30, 60)	0.889

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositive arthralgia is defined as joint pain in patients positive for rheumatoid factor (RF) or anti-citrullinated protein antibodies (ACPA). It is a precursor to rheumatoid arthritis (RA) in some individuals. Clinical and synovial findings in seropositive arthralgia when compared to RA and osteoarthritis (OA) have not been fully

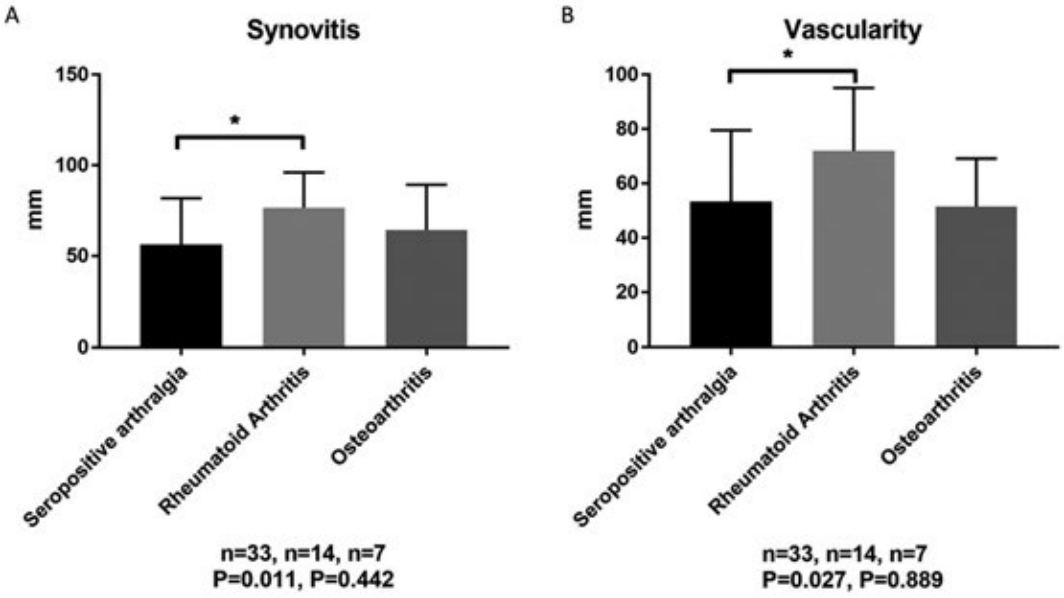

Figure 1. Macroscopic synovitis and vascularity in seropositive arthralgia, RA, and OA.

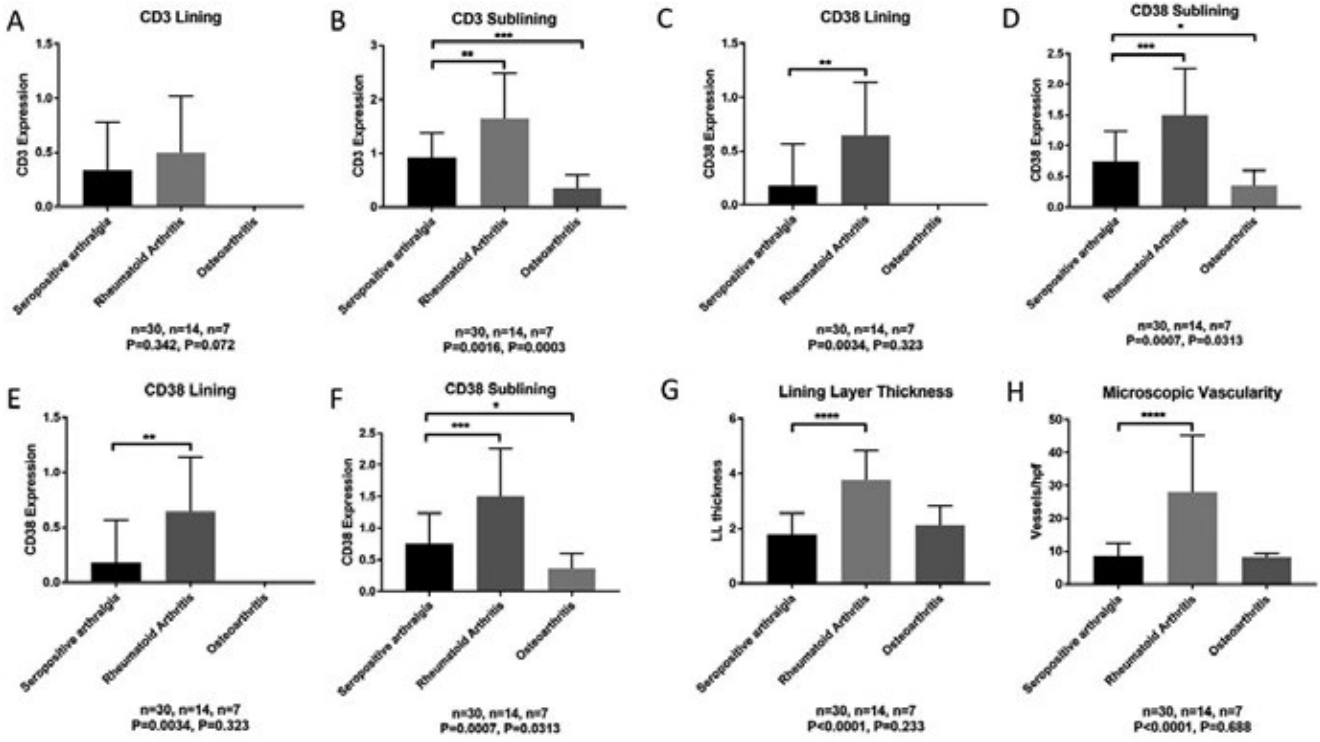

Figure 2. Comparison of synovial biopsy and immunohistochemical findings in seropositive arthralgia, RA, and OA.

defined. Our aim was to compare clinical characteristics, macroscopic arthroscopy findings, and synovial immunohistochemical findings in those with seropositive arthralgia, RA, and OA.

Methods: We performed a prospective study of consecutive patients with seropositive arthralgia. All patients were seropositive for RF and/or ACPA. Demographic and clinical characteristics were collected on all patients. Synovial biopsy was performed by needle arthroscopy in all patients, and macroscopic and histologic features recorded. The degree of synovitis and vascularity were recorded on a 0–100-mm visual analog scale. We compared the findings in this group to 2 other cohorts; patients with established diagnoses of either RA or OA as per ACR classification criteria. Whitney U test was used to compare groups. GraphPad Prism Version 8 and IBM SPSS Statistics Version 24 were used for data analysis.

Results: 54 patients were recruited, 33 with seropositive arthralgia, 14 with RA, and 7 with OA. Compared to seropositive arthralgia, established RA patients had higher tender and swollen joint counts, CRP and ESR, patient global assessment (PGA) of disease activity, and DAS28-CRP, Table 1. In contrast, the only difference between seropositive arthralgia and OA patients was higher PGA in the OA group, Table 1. RA patients had significantly greater macroscopic synovitis and synovial vascularity than seropositive arthralgia patients who were not significantly different to OA patients, Table 1, Figure 1. On synovial biopsy, synovial lining layer thickness and microscopic vascularity were increased in RA compared to seropositive arthralgia; there was no difference between seropositive arthralgia and OA. On immunohistochemical analysis of synovial tissue, CD3 and CD38 but not CD138 expression were higher in RA compared to seropositive arthralgia, Figure 2. CD3 and CD38 but not CD138 expression, were higher in seropositive arthralgia compared to OA, Figure 2.

Conclusion: Baseline clinical characteristics, macroscopic arthroscopic findings, and microscopic histologic findings in seropositive arthralgia are more similar to OA than established RA patients. However, key differences in synovial inflammatory cell populations are identifiable in seropositive arthralgia on immunohistochemical analysis.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Seropositive arthralgia is defined as joint pain in patients positive for rheumatoid factor (RF) or anti-citrullinated protein antibodies (ACPA). In some individuals it is a precursor to rheumatoid arthritis (RA). The factors which determine progression and outcomes in seropositive arthralgia patients remain to be fully defined. Our

Table 1. Baseline characteristics of 37 patients with seropositive arthralgia

Age, years	50 (13)
Sex, female, n (%)	26 (70%)
Tender Joint Count	3 (5)
Swollen Joint Count	0 (0)
Patient Global Assessment (mm)	47 (29)
DAS28-CRP	3.24 (1.31)
Arthroscopic synovitis (mm)	54 (25)
Arthroscopic vascularity (mm)	52 (25)

aim was to evaluate outcomes and prognostic factors, including arthroscopic findings, in a cohort of patients with seropositive arthralgia.

Methods: We performed a prospective study of consecutive patients with seropositive arthralgia. All patients were seropositive for RF and/or ACPA. Demographic and clinical characteristics were collected on all patients. Synovial biopsy was performed by needle arthroscopy in all patients, and macroscopic and histologic features recorded. The degree of synovitis and vascularity were recorded on a 0–100-mm visual analog scale. Diagnosis at last follow-up was recorded in all patients. Mann-Whitney U test was used to compare groups. GraphPad Prism Version 8 and IBM SPSS Statistics Version 24 were used for data analysis.

Results: 37 patients were recruited. Mean (SD) age was 50 (13) years. 26 (70%) were female. 31 (84%) were positive for RF and 32 (86%) for ACPA with 26 (70%) dual positive. Mean (SD) follow-up was 38 (13) months. Baseline characteristics are shown in Table 1. Final diagnosis was RA in 26 (70%), psoriatic arthritis in 2 (5%), connective tissue disease in 1 (3%), calcium pyrophosphate arthritis in 1 (3%), and remained seropositive arthralgia in 7 (19%). Baseline CRP was significantly higher in patients who developed RA than those who remained seropositive arthralgia, median (SD) 3.50 (2.00, 8.25) vs 1.00 (1.00, 2.00) mg/dL (p=0.0096), Figure 1. Baseline macroscopic synovitis and vascularity at arthroscopy were both significantly higher in those who developed RA than in those who remained as seropositive arthralgia, median (IQR) 60 (30, 80) vs 40 (20, 40) mm (p=0.021), and median (IQR) 50 (30, 73) vs 40 (20, 40) mm (p=0.021), Figure 1. Baseline DAS28-CRP, tender joint count, swollen joint count, and patient global assessment were not different between the groups. Baseline synovial cell immunophenotyping did not predict final diagnosis.

Conclusion: Elevated baseline CRP and arthroscopically determined macroscopic synovial inflammation and vascularity predict the development of RA in patients with seropositive arthralgia.

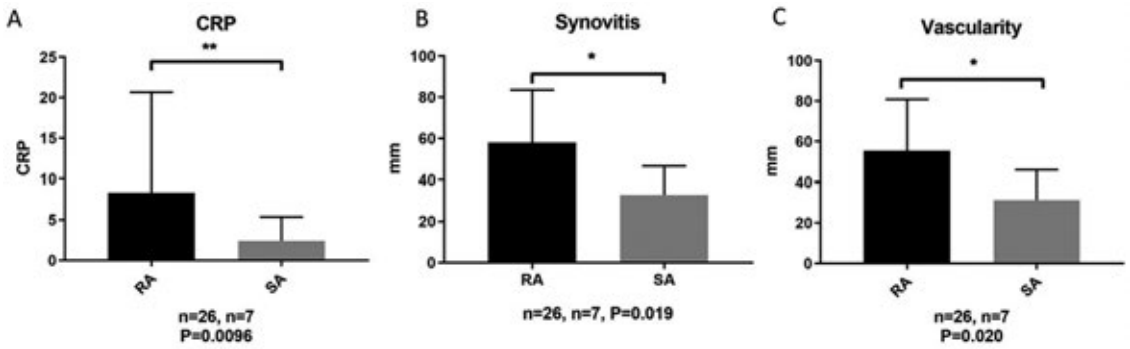

Figure 1. Comparison of CRP, macroscopic synovitis, and synovial vascularity in patients with seropositive arthralgia who did or did not progress to RA (RA: progressed to rheumatoid arthritis; SA: remained seropositive arthralgia)

Third Generation Anti-cyclic Citrullinated Peptide Antibodies Improve Prediction of Clinical Arthritis in Second Generation Anti-cyclic Citrullinated Peptide Positive Subjects at Risk of Rheumatoid Arthritis

Andrea Di Matteo ,[1] Kulveer Mankia,[1] Laurence Duquenne,[2] Leticia Garcia-Montoya,[1] Diane Corscadden,[3] Katie Mbara,[3] Jacqueline Nam,[1] Michael Mahler,[4] and Paul Emery[1], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, England, United Kingdom, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, [4]Inova Diagnostics, San Diego, CA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: ACPA positive individuals with musculoskeletal symptoms are at increased risk of developing RA. In such individuals, ACPA are conventionally identified on the basis of a positive serum IgG anti-CCP2 antibody (Ab) test.

Third-generation anti-CCP (CCP3) tests (Inova Diagnostic) have been recently introduced and their diagnostic value has been evaluated in patients with early and established RA.

The value of anti-CCP3 for predicting progression to RA in at-risk individuals is less understood. Consequently, the main aims of the study were:

- to determine the prevalence of anti-CCP3 Ab in anti-CCP2 positive at-risk individuals and the agreement between the 2 tests;
- to investigate the association between anti-CCP3 Ab and progression to RA;
- to explore the stability of anti-CCP3 Ab status over time.

Methods: Anti-CCP3 Ab were tested on stored serum samples obtained from 337 anti-CCP2 positive (BioRad, USA) at-risk individuals without synovitis from the Leeds CCP study.

Table 1. Agreement between anti-CCP2 and anti-CCP3 tests

	CCP2	
CCP3	***Low +ve***	***High +ve***
-ve	79	59
Low +ve	10	9
High +ve	12	168

Anti-CCP2 and anti-CCP3 tests positivity threshold was >2.99 IU/ml and >20 units, respectively. Anti-CCP2 and anti-CCP3 Ab were considered low titre (LT) or high titre (HT) if < or > than 3 times the positivity threshold, respectively.

Only subjects with at least one follow-up visit were included in the progression analysis (n=308). Sequential samples were tested for CCP3 in 132 individuals.

Results: Anti-CCP3 Ab tended to be either negative (138/337; 40.9%) or HT positive (180/337; 53.4%), with a few subjects showing a LT (19/337; 5.6%). In contrast, for anti-CCP2, more LT were observed (101/337; 30%). The Cohen's k agreement between anti-CCP2 and anti-CPP3 test was 0.22 (0.17-0.26) (p< 0.001) (Table 1). Eighty-three/308 subjects (27%) developed arthritis (median follow up 273 days, min 3 – max 3402), 73 of whom fulfilled 2010 ACR/EULAR classification criteria for RA. The proportions of patients progressing to arthritis (ever) according to anti-CPP2 and anti-CPP3 Ab status are illustrated in Table 2. The rate of progression of LT and HT anti-CCP2, when anti-CCP3 was negative, fell from 6.5% to 2.7%, and from 45.6% to 9.4%, respectively. Progression in anti-CCP2 HT increased

Table 2. Proportions of patients progressing to arthritis (ever) according to CCP2 and CCP3 status

				Progressed (ever) n (%)
CCP2: Low positive	n=92			6 (6.5%)
High positive	n=216			77 (35.6%)
CCP3: Negative	n=126			7 (5.5%)
Low positive	n=16			4 (25%)
High positive	n=166			72 (43.4%)
CCP3: Negative		**CCP2:** Low positive	n=73	2 (2.7%)
		High positive	n=53	5 (9.4%)
Low positive		**CCP2:** Low positive	n=7	1 (14.2%)
		High positive	n=9	3 (33.3%)
High positive		**CCP2:** Low positive	n=12	3 (25%)
		High positive	n=154	69 (44.8%)

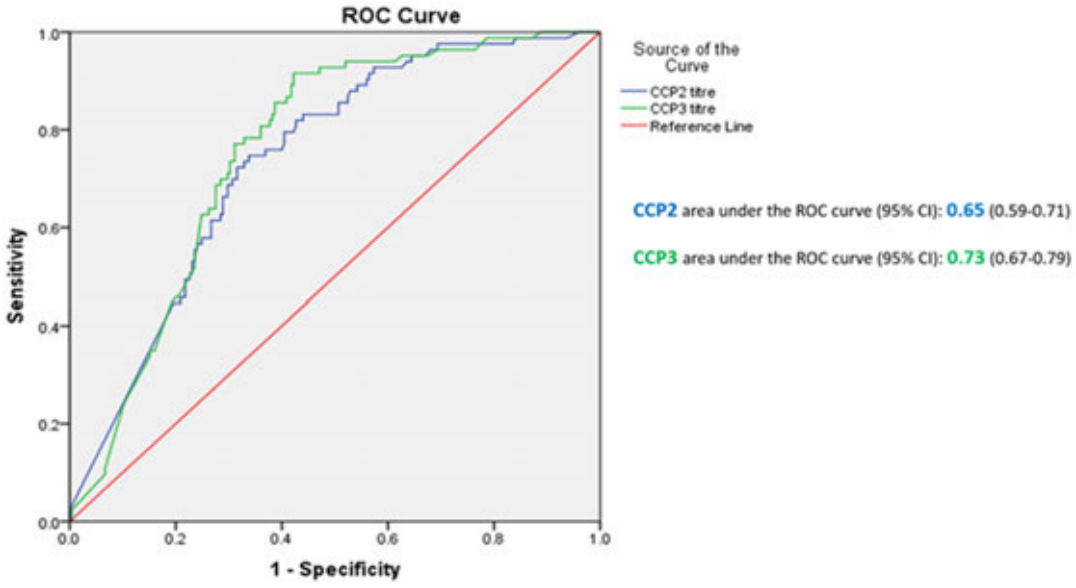

Figure 1. ROC curves for anti-CCP2 and anti-CCP3 tests predicting progression (ever)

from 35.6% to 44.8%, when anti-CCP3 was positive. The hazard ratio for HT anti-CCP2 and HT anti-CPP3 Ab was 4.9 (CI 2.1-11.2) and 6.9 (CI 3.1-15.0) ($p< 0.001$), respectively. The ROC curves for anti-CCP2 and anti-CCP3 tests are shown in Figure 1.

At baseline, 33/132 (25%) individuals who had CCP3 tested at ≥1 timepoint for sequential samples were anti-CCP3 negative and 99/132 (75%) were anti-CCP3 positive (5 LT, 94 HT). The anti-CCP3 Ab titer remained stable in 125/132 (94.7%) individuals, in 559/575 (97.6%) sequential samples (mean follow-up 551 days ±623.53).

Conclusion: The distributions of anti-CCP2 and anti-CCP3 assays differed and their agreement was poor.

Our results suggest a potential value of anti-CCP3 antibodies in improving prediction of clinical arthritis in both LT and HT CCP2 positive at-risk subjects.

Citrullinated Antigens with Multiple Citruline Similar Motif Could Be Used for RA Diagnosis

zhiwei ru,[1] Xuedong Chen,[2] Xiaoyan huang,[1] Jianrong Lou,[1] YongZheng peng,[3] and **Xiang Yang** [1], [1]Leide bioscience Inc, guang zhou, Guangdong, China (People's Republic), [2]Southern Medicine University, guang zhou, Guangdong, China (People's Republic), [3]Southern Medicine University, guang dong, Guangdong, China (People's Republic)

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by chronic joint inflammation that ultimately leads to joint destruction. Diagnosis of RA is important as new therapies can halt the disease progression in its early stages. In the past decade, ACPA measured by antiCCP assay was widely accepted as RA diagnostic biomarker. ACPAs are auto-antibodies produced against proteins of the body modified by citrullination. Although anti-ACPA test specificity reaches around 95%, about 20 to 40 percent of RA patients are ACPA negative.

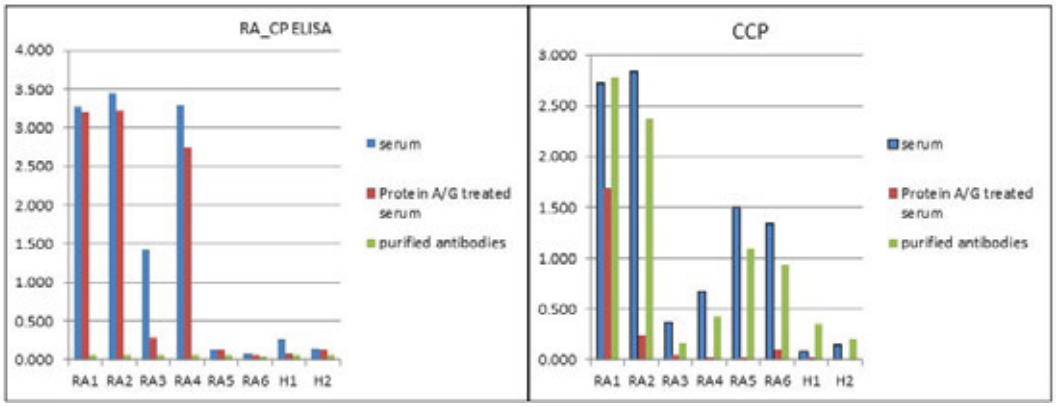
Methods: Peptides with Multiple Citruline Similar Motif (MCSM) were synthesized and used to produce anti-MCSM antibodies. Anti-MCSM antibody recognized MCSM in the citrullinated proteins such as fibrogen, vimentin and enolase which were found in the RA patients. RA_CP ELISA was developed using anti-MCSM antibodies. Clinical samples were collected under the Investigational Review Board approval protocol and RA patients met 2010 ACR classification criteria for RA. Receiver operating characteristic (ROC) curve was used for the analysis of optimal cut-off point for the evaluation of diagnostic capacity. CCP2 assay kits were purchased from European Diagnostic. Protein A/G resin was used to extract IgG/IgM from serum samples.

Fig1 : Total 136 RA patients and 214 health person's samples were used to evaluate RA-CP

RA_CP	Clinical Diagnosis		Total
	Positive (+)	Negative (-)	
Positive (+)	117	8	125
Negative (-)	19	206	225
Total	136	214	350

Positive Coincidence Rate	86.0%
Negative Coincidence Rate	96.3%
Total Coincidence Rate	92.3%

Fig 2: Protein A/G resin separate antibodies from serum of 6 RA patients and two health person's. RA_CP and CCP ELISA were used to test the serum with and without Protein A/G resin treatment. After antibodies removed, RA_CP still can detect target in the serum. RA_CP cannot react with purified Protein A/G fraction. After Protein A/G resin treatment, CCP kit cannot detect target in the serum. But CCP can recognize all purified Protein A/G fractions(antibodies)



Results: Among 25 Anti-ACPA negative RA samples, citrullinated antigens recognized by anti-MSCM antibodies were detected in 11 samples (44%). In the anti-ACPA+ samples, 95.5% samples were RA_CP positive. After antibodies in anti-ACPA+/RA_CP+ samples were depleted by Protein A/G resins, significant RA_CP signals were remained in the serum fraction and no signal was detected in the Protein A/G fraction. However, Anti-CCP signals were greatly reduced in Protein A/G treated serum and its signals were recovered in Protein A/G fraction. A total of 350 clinical samples were further analyzed by anti-ACPA and RA_CP Elisa. The sesentivity for RA_CP is 86.0% which is higher than anti-ACPA assay while maintaining the specificity at 96.3%.

Conclusion: It was well known that up to 40% RA patient samples were ACPA negative and the diagnostic sensitivity in this population needs to be improved to meet patient's clinical management. In this study, anti-MCSM antibodies were developed and detected citrullinated antigens with MCSM in the serum samples. Protein A/G experiments clearly demonstrated that MCSM antigen can be present in the free form or with antigen/antibody immune complex. It was very interesting that MCSM antigens were found in 44% of anti-ACPA- RA samples and over 95% anti-ACPA+

RA samples. Since antigen normally emerges earlier than the antibody, theoretically, RA_CP could be used in early RA diagnosis which needs further study to confirm.

S100A11 (calgizzarin) Is Released During Neutrophil Extracellular Traps (NETs) Formation in Rheumatoid Arthritis (RA)

Adéla Navrátilová ,[1] Jiří Baloun,[2] Hana Hulejová,[2] Karel Pavelka,[3] Jiří Vencovský,[3] Ladislav Senolt,[3] and Lucie Andrés Cerezo[1], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Rheumatology, Prague, Czech Republic, [3]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2, Czech Republic

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: S100A11 protein, a member of S100 family, has been associated with several autoimmune inflammatory conditions such as rheumatoid arthritis (RA). Moreover, its pro-inflammatory effect on mononuclear cells has been reported (1). Although the pathogenesis of autoimmune diseases is not fully understood, the formation of NETs seem to play a certain role. Recent data indicate that some DAMPs including S100A8/A9 are released via NETosis and can further augment inflammatory responses.

Methods: To assess the expression of S100A11 by neutrophils of RA synovial tissue (n=5), immunofluorescence staining of S100A11 and myeloperoxidase (MPO) was performed. The levels of S100A11 and MPO in RA synovial fluid (n=24) and serum (n=36) were measured by ELISAs (RayBiotech and Abcam). For in vitro experiments, NETosis was induced by adding phorbol 12-myristate 13-acetate (PMA) to the neutrophils purified from peripheral blood of RA patients (n=7). Release of NETs was visualised by immunocytochemistry (n=4-7) and the presence of S100A11 in supernatants was analysed by ELISA (RayBiotech). Neutrophils purified from healthy donors were stimulated by S100A11 and the release of cytokines TNFα, IL-6 was measured by ELISA (RayBiotech).

Results: S100A11 was expressed by synovial tissue neutrophils of the RA patients (n=5). The levels of S100A11 in the serum and in the synovial fluid of patients with RA were significantly associated with the levels of neutrophil MPO (r=0.463, p=0.005 and r=0.500, p=0.013). We demonstrated that the neutrophils treated by LPS (n=7) did not up-regulate the secretion of S100A11 compared to unstimulated controls (0.28±0.07 vs. 0.25±0.06; p=ns). However, the release of S100A11 was significantly up-regulated in PMA stimulated neutrophils undergoing NETosis compared to untreated controls (0.30±0.08 vs. 1.14±0.22; p=0.006). Moreover, our results showed that DPI treatment abolished PMA-induced S100A11 secretion. By immunofluorescence staining we demonstrated that the neutrophils activated by PMA release NETs containing S100A11 protein whereas cells stimulated by DPI+PMA were not able to form NETs. In addition, extracellular S100A11 did not modulate the secretion of pro-inflammatory cytokines TNFα and IL-6 by human neutrophils (n=5).

Conclusion: Here we show for the first time that the release of S100A11 by neutrophils could be dependent on NETosis. Moreover, extracellular S100A11 does not further augment the inflammatory response of neutrophils in RA.

Validation of Risk Scores for Predicting Progression in Individuals "At Risk of Rheumatoid Arthritis"

Laurence Duquenne ,[1] Jacqueline Nam,[2] Kulveer Mankia,[2] Andrea Di Matteo,[2] Leticia Garcia-Montoya,[2] and Paul Emery[2], [1]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, England, United Kingdom, [2]Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Risk scores for progression have been described in 2015 in a cohort of 100 anti-cyclic citrullinated peptide (anti-CCP) positive individuals at risk of developing Inflammatory Arthritis (IA) (Rakieh, 2015). The first score, designed for primary care, was based on anti-CCP and rheumatoid factor (RF) titres, small joints tenderness and early morning stiffness (EMS). A second score developed for secondary care added power Doppler presence (PD+) and/or at least one allele positive for the shared epitope (SE+).

The objective is to validate previous data by scoring risk factors in a new cohort of 318 individuals.

Methods: Individuals at risk of developing IA selected by a positive anti-CCP test and a new musculoskeletal symptom have been followed in a single-centre prospective observational cohort since 2008. Previous risks analysis were founded on the data collected among 100 patients, a sequential 318 patients' data are analysed here with the same recruitment and follow-up pathways (Full data were available for 263 patients for secondary care).

Table 1. Patients characteristics

Score	2015	2019	p-value
N	100	318	
Percentage of progression n/N (%)	50/100 (50)	63/318 (19.8)	<0.001
Mean of follow-up before progression to IA (Months (SD))	15.35 (15.27)	13.62 (13.11)	0.511

Table 2.

A. Multivariable Cox regression analysis of time to progression to inflammatory arthritis.

Primary care model	2015 (n=98)			2019 (n=318)		
	HR	p-value	CI	HR	p-value	CI
High anti-CCP or RF titre	4.86	0.031	1.16-20.43	8.73	<0.001	2.73-27.9
EMS≥30min	1.86	0.039	1.03-3.37	2.52	0.004	1.51-4.2
Small Joints Tenderness	1.42	0.252	0.78-2.57	1.62	0.067	0.97-2.73
Secondary care model	**2015 (n=98)**			**2019 (n=263)**		
	HR	p-value	CI	HR	p-value	CI
High anti-CCP or RF titre	3.04	0.147	0.68-13.6	5.55	0.001	1.95-15.78
EMS≥30min	1.56	0.167	0.83-2.92	2.82	0.001	1.53-5.19
Small Joints Tenderness	1.54	0.178	0.82-2.88	2.01	0.033	1.06-3.8
PD signal	1.92	0.033	1.06-3.50	1.74	0.081	0.94-3.23
Shared epitope	1.57	0.272	0.70-3.49	1.12	0.739	0.57-2.20

B. Progression rates

Primary care model score	2015 (n=98) % (n/N)	2019 (n=318) % (n/N)	Risk grade
3	60 (21/35)	29.2 (26/89)	High
4	65 (13/20)	60.0 (27/45)	
Secondary care model score	**2015 (n=98) % (n/N)**	**2019 (n=263) % (n/N)**	**Risk grade**
4	74 (14/19)	39.5(14/43)	High
5	67 (4/6)	77.8 (7/9)	

Participants who had a negative anti-CCP test at first visit control and those followed for less than 6 weeks without progression were excluded.

Results: Participants from both cohorts were similar in terms of age and sex. Although the mean time to progression was comparable, there were significantly more participants with a high titre anti-CCP test in the 2015 cohort (Table 1). Cox multivariable analysis showed similar Hazard Ratios (HR) of progression for the two groups with a better predictive value of the CCP high titre in the 2019 group (Table 2.A). There was consequently a good correlation with progression rates in the highest scores (Table 2.B). The Kaplan-Meier curves in Figure 1 confirms survival rates according to level of risk in 2019. The secondary care score identified 10% more progressors at one year (HR 5.4 for High risk scores, $p< 0.001$).

Conclusion: These data from a new large cohort confirm the validity of previous Leeds Risk Scores for primary and secondary care and the fidelity of the risk factors over time to predict progression.

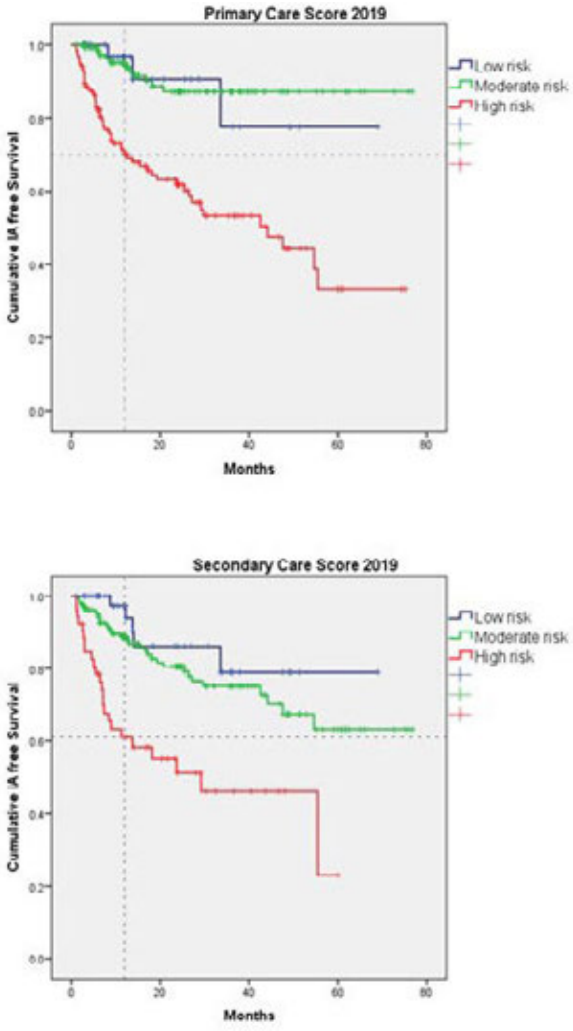

Figure 1. Probability of IA free survival over up to 75 Months of follow-up, according to categories of risk.

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

	CCP3.1	CCP2 IgG	CCP2 IgA
Cut-off (U/ml)	20	10	10
Patients positive (n)	102	96	56
Specificity % (healthy subjects)	95.9	99.0	98.0
Specificity % (disease controls)	90.8	98.9	99.4
Sensitivity %	55.4	52.2	30.4
LR+ (healthy)	13.5	52.0	15.2
LR+ (disease controls)	6.0	47.5	50.7

Table 1. Specificity, sensitivity and positive likelihood ratio (LR+) of CCP2 (IgG, IgA) and CCP3.1 assays

Background/Purpose: Anti-cyclic citrullinated peptide (CCP) antibodies are the most specific markers for rheumatoid arthritis (RA). Different generations of assays (CCP1-CCP3) have been developed which show variability regarding their performance. This may have considerable impact on diagnostic decision making because serological testing is an important diagnostic tool especially in the early stages of disease. Therefore the comparability of different assays is an important issue to address.

Methods: This study aimed to investigate the diagnostic performance of IgG and IgA anti-CCP2 detected by EliA™ (Thermo Fisher Scientific) compared to the combined IgG/IgA Quanta Lite® anti-CCP3.1 assay (Inova Diagnostics) in sera of 184 early RA patients, 98 healthy subjects and 360 disease controls.

Results: Anti-CCP2 IgG and IgA assays were found having very high specificities versus healthy subjects (98.9%; 98%) as well as disease controls (98.8%; 99.4%). Sensitivities were 52.2% for anti-CCP2-IgG and 30.4% for anti-CCP2 IgA, respectively. This resulted in high positive likelihood ratios (LR+) of 47.5 for the IgG and 50.7 for the IgA assay. However, anti-CCP2 IgA antibodies did not show an added diagnostic value since all positive patients were also anti-CCP IgG positive. The anti-CCP3.1 assay was found to be slightly more sensitive than the anti-CCP2 IgG assay with 55.4% of early RA patients being positive. However, specificity was markedly lower and amounted to 95.9% versus healthy subjects and 90.8% versus disease controls which resulted in a relatively low LR+ of only 6.0. The data are summarized in Table 1. When adjusting the cut-off value of the CCP3.1 assay to >98% specificity against disease controls, sensitivity (52.7%) became comparable to the anti-CCP2 assay and LR+ increased to 26.4 which was still somewhat lower than the LR+ of the CCP2 assays.

Conclusion: Thus, when interpreting the results of diagnostic assays the issue of test to test variability must be taken into account as reduced specificity might lead to an increase in false positive diagnosis.

'It Felt Like I Was Walking on Rocks" Patients Share First Symptoms of RA

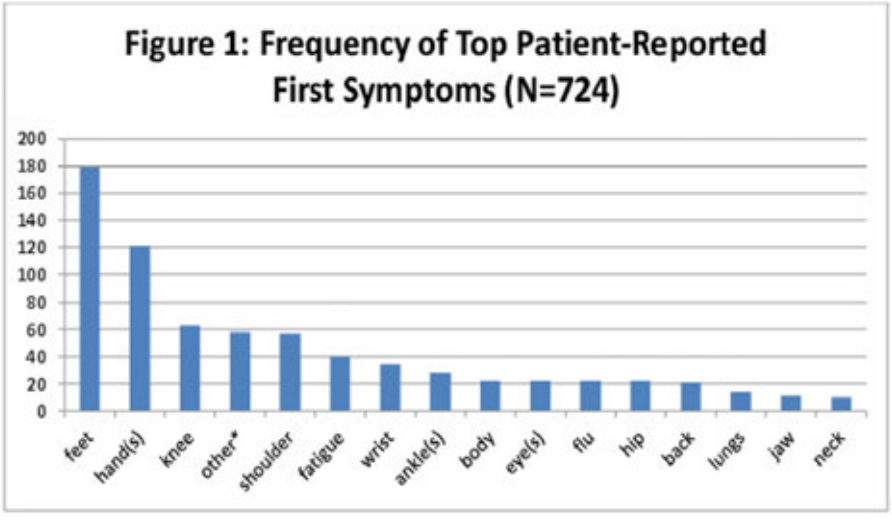
Pamela Sinicrope ,[1] Dana Symons,[2] Ahmad P. Tafti,[1] Christi Patten,[1] Martha Bock,[1] Jon Tilburt,[1] Cynthia Crowson,[1] Elena Myasoedova,[1] John Davis,[1] and Kelly O'Neill[3], [1]Mayo Clinic, Rochester, MN, [2]Rheumatoid Patient Foundation, Inc., Rockford, MI, [3]Rheumatoid Patient Foundation, Inc., Winter Springs, FL

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although early diagnosis and treatment are pivotal for successful outcomes in rheumatoid arthritis (RA), a gap remains in our understanding of its earliest symptoms. Current diagnosis requires physician evaluation for joint involvement, serology, inflammatory markers and symptom duration to allow accumulation of at least 6 points by the 2010 ACR/EULAR criteria. Patients may experience symptoms not accounted for in the criteria, a discrepancy which could impede early identification of RA. Data on patient perceptions of early RA symptoms and first body parts affected could provide important information to help facilitate the earliest recognition of disease and enable earlier treatment. To examine first symptoms, a non-profit organization collaborated with an academic rheumatology center to describe early RA symptoms as reported by patients in their own words.

Methods: From 2009-2017, people with RA who visited an RA-specific blog site or Facebook page were asked to describe their first RA symptom. Responses were extracted and de-identified. Data collected included: date of response, text of response, and source. Responses from moderators and those who said they did not have RA, or who shared unrelated information were not included in the analysis; responses from the same person were combined. Content analysis was performed to identify themes of response and to tabulate: 1) very first symptom reported; 2) number of symptoms reported per respondent (1-4+), 3) data source (RA patient or other), and 4) length or ease of diagnosis experience.

Results: 724 unique responses (99% RA patients self-reporting), 564 (77%) from the blog and 160 (23%) from Facebook were reviewed. People with RA reported 37 different first symptoms, with 83.3% reporting a symptom outside of the hand(s), with feet (24.7%), hands (16.7%), knees (8.7%), fatigue (7.9%) and wrists (4.7%) being most common. When categorizing first reported symptom, we found the top four were: 1) small joints (51.4%), 2) large joints (16.7%), 3) general (e.g. fatigue, pain) (8.7%), and 4) extra articular (e.g. pleurisy, iritis) (7.9%) Overall, we found that among those describing the number and pattern of first symptoms (from 1-4+), the majority reported more than four (50.6%). For example, one respondent wrote: “My eyes were my first symptom, followed by my feet, spine then ankles…my GP [general practitioner] continually said ‘no not RA’, that affects the hands first.” Themes included in responses



*the other category represents a variety of first symptoms reported at a frequency ≤8.

Table 1: Quotes Illustrating Themes Related to Patient-Reported First RA Symptoms

Category	Representative Quote
Traditional Onset	My early symptoms were my feet and hands together. My feet hurt so bad I would dread getting up and having to walk on them while my hands were so stiff and swollen, I could not close my hand to make a fist. Hands. Knuckles and 4 fingers on dominant right hand. Fatigue. Swelling, lack of mobility and function. Fatigue. Yes, I put it twice because I was exhausted. 7 years later still right hand, plus neck, knees, right ankle and general malaise.
Non-Traditional Onset	My first symptoms were iritis (imflammation) in eyes, then ankle problems (torn achilles tendons resulting in surgery on both sides). Not until extreme fatigue hit me last year coupled with finger swelling and pain did I get diagnosed with RA and start on treatment. While my symptoms did eventually spread to all fingers, wrists, elbows, and knees (my latest big battle), it all started with "non typical" RA symptoms that didn't meet the traditional RA patterns. My RA started in my feet 7 years ago. I spent the first 4 thinking I had "hurt" my foot while walking in a Christmas parade. Now, it's in my hands. Even after diagnosis, I still doubted the doctor because I had never heard of anyone getting RA in their feet first. I thought it had to be in your hands or it wasn't RA.
Difficult Diagnosis over long period of time	Left ankle first. Swollen all to heck – looked exactly like I'd sprained my ankle. Except I hadn't. Then left wrist and right knee. Took about a year to settle into a nice, easily diagnosed, bilateral wrists and MCP joints pattern. I wasn't diagnosed until my hands and fingers started acting up. However I can go back 15 years and it was my feet that hurt for years first. My neck and back too. I always blamed it on something else. When I was diagnosed they said I already had holes in my bones in my toes, ankles, fingers and writs.
Straightforward diagnosis over short period of time	All of this summer i had aches and pains in my feet knees back and hips then my elbow and one of my fingers and i was also very tired and would sleep all afternoon at least 2 hours. I went to my dr and he gave me some blood work to do and he sent me to a reumy. I was diagnosed with RA. Mine was very typical. My pinky finger hurt one day. By the end of the week, all my fingers felt tight and strange. Very tight in the morning, and comfortable by 10am. One google search and I knew what it was. My primary care listened to me and confirmed the dx the next month with labs. I was lucky.

were: 1) first symptom(s) and co-morbidities; 2) timing of symptoms to diagnosis/treatment, including pattern of onset and barriers; 3) life events surrounding symptoms (e.g. illness, accident); 4) patient/physician experience, among others.

Conclusion: Results show people with RA report a wide variety of first symptoms that do not always include hands or joints with varying patterns of onset over time. Such findings could provide valuable information to help patients and physicians decrease the time between diagnosis and treatment by considering the possibility of more non-traditional RA presentations.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

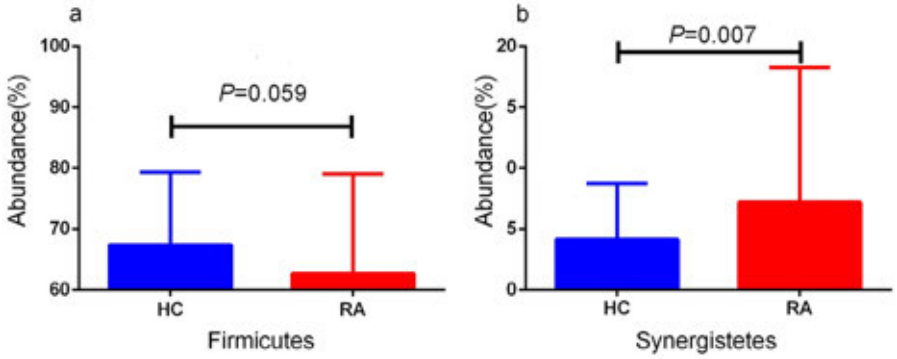

Figure 1. The phylum-level profile for RA patients and healthy control.

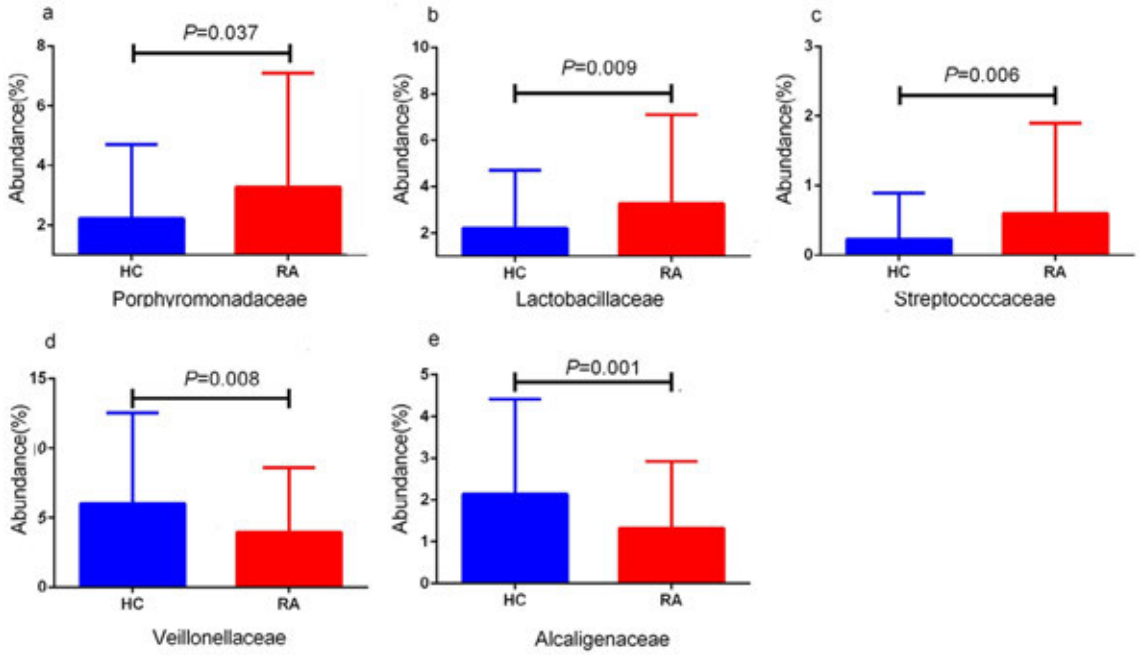

Figure 2. The family-level profile for RA patients and healthy control.

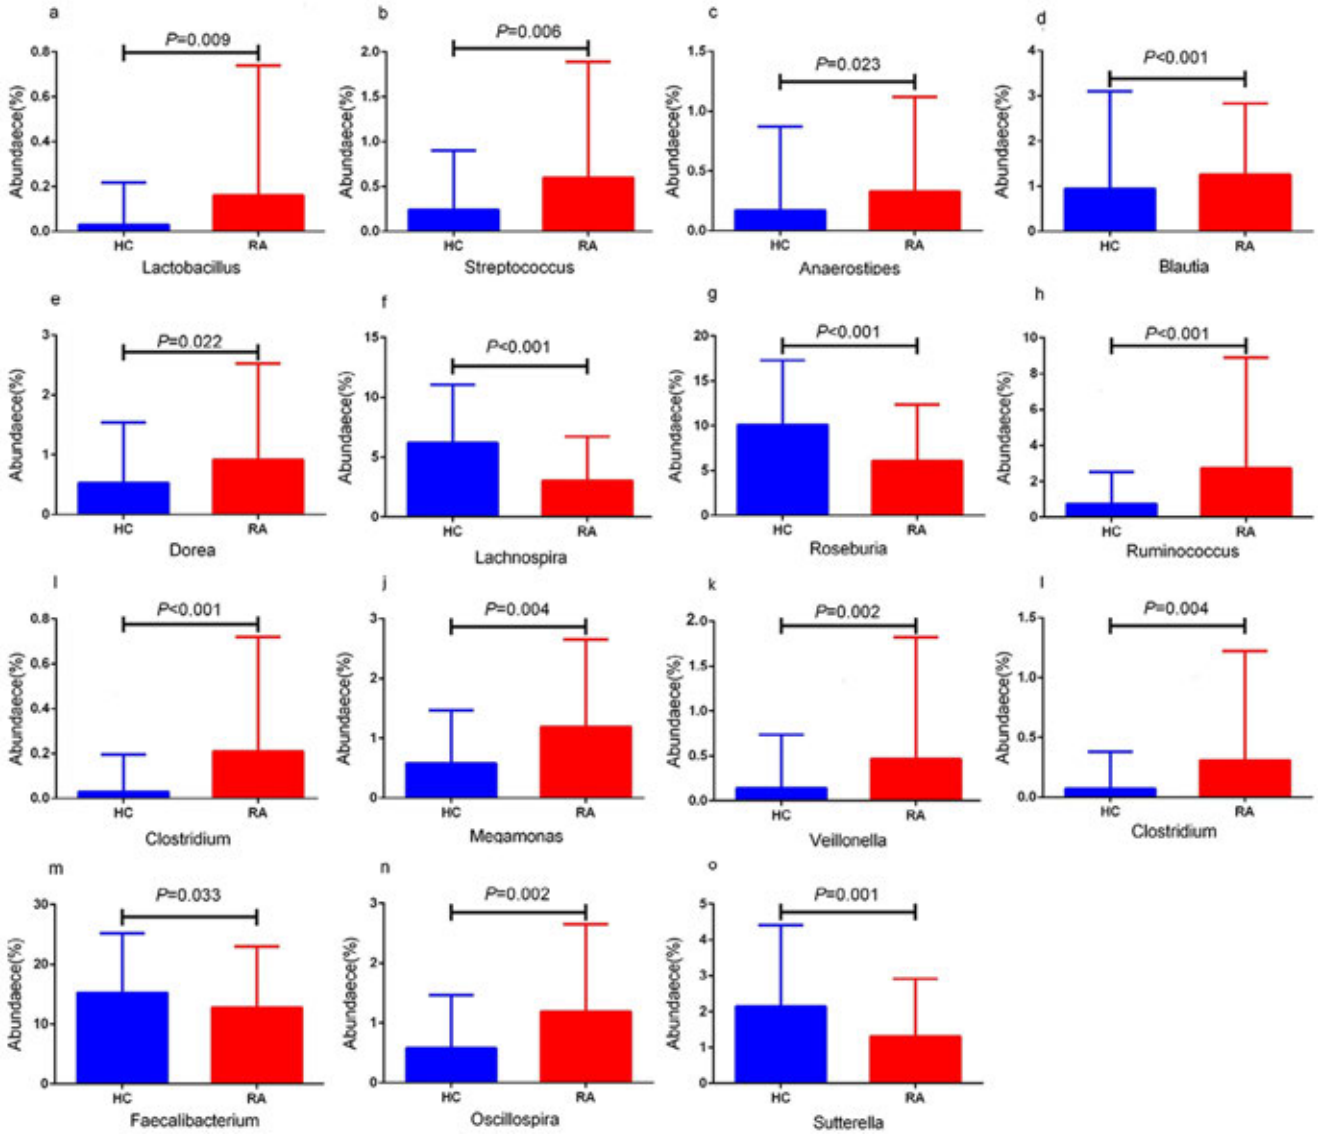

Figure 3. The genus-level profile for RA patients and healthy control.

Background/Purpose: Rheumatoid arthritis (RA) is a systemic autoimmune disease characterized by inflammation of the synovial joints. The gut microbe with RA has been reported recently, though the specific components of the microbiota that affect the host response leading to disease remain unknown. This study aimed to study the diversity and the abundance of intestinal microbes in patients with RA and further provide new strategy and target for the treatment of RA.

Methods: The stool specimens of 100 RA patients were analyzed at the level of the phylum, family and genus, and compared with that of 125 healthy controls(HC).

Results: Compared with controls,the abundance of intestinal microbiota in patients with RA was significantly different (P< 0.05).At the level of Phylum,the abundance of Proteobacteria was significantly increased (P< 0.05),and the abundance of Firmicutes was significantly reduced (P=0.05),the abundance of Actinomycetes and Bacteroidetes increased in RA patients compared with that of HC(P >0.05).Compared with healthy individules,Patients had more abundance of Micrococcaceae, Porphyromonadaceae, Enterococcaceae, Lactobacillus, Streptococcus, Turicibacteraceae, Hyphomicrobiaceae and Enterobacteriaceae(P< 0.05), but less abundance of Veillonellaceae and Alcaligenes was significantly lower (P< 0.05)

at the level of family. At the genus level, in the RA group, the abundance of Rothia, Enterococcus, Lactobacillus, Streptococcus, Turicibacter, Anaerostipes, Blautia, Lauterium, Dorea, Ruminococcus, Clostridium, Veillonella, Oscillospira, Devosia and Halomonas were significantly increased (P< 0.05), but the abundance of Lachnospira, Roseburia, Faecalibacteriu, Megamonas and Sutterella was significantly lower than that of healthy controls. (P< 0.05).

Conclusion: The diversity and balance of bacterial community in intestinal microecological environment of patients with RA are significantly different from the healthy control. Intestinal microbiota disorder may be related to the pathogenesis of RA, which might provide theoretical foundation for the regulation of intestinal flora for disease intervention.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Targeting Immune Responses for Prevention of RA (TIP-RA) Collaborative prospectively studies individuals at high risk for developing RA because of serum ACPA positivity in absence of inflammatory arthritis (IA) at baseline. The objectives of the analyses presented herein are to evaluate ACPA+ ACPA- individuals to identify factors associated with each of these states, and to identify factors associated with incident inflammatory arthritis and classifiable RA.

Methods: 87 ACPA+ subjects were identified who at their baseline study visit did not have historical or examination (66/68 count) evidence of IA, and 160 ACPA- matched controls. ACPA+ was defined as a serum elevation of anti-CCP3 (IgG, Inova) on ≥2 occasions above the manufacturer's suggested cut-off (≥20 units). Subjects were recruited through screening of health-fair particiants, first-degree relatives of patients with RA and individuals referred to rheumatology clinics. Subjects were followed annually or sooner if they had changes in joint symptoms. Clinical and biomarker factors, including RF IgA and M (Inova) and C-reactive protein (CRP), were assessed. Comparisons between ACPA+/- subjects were performed, and factors associated with incident IA/RA within the ACPA+ subjects were evaluated.

Results: The baseline characteristics of ACPA+/- subjects are presented in Table 1. Self-reported fatigue was higher in ACPA+ vs ACPA- subjects. In addition, within ACPA+ subjects, current smoking was associated with increased morning stiffness, and higher CRP was associated with increased fatigue. Within ACPA+ subjects, 15 (17%) developed IA/RA a median of 330 days after baseline. At baseline, higher BMI, greater number of self-reported swollen

joints, the presence of the shared epitope (SE) and positivity for RFIgA and M were each associated with increased risk for developing incident IA/RA (Table 2).

Conclusion: Within this cohort, a greater level of fatigue is associated with ACPA positivity. Furthermore, within ACPA+ subjects, smoking and elevated hsCRP are associated with clinical symptoms of stiffness and fatigue, respectively. These symptoms may be part of a prodrome for future RA, but also may indicate a unique 'autoimmunopathy' that warrants further investigation into pathogenesis and treatment. These findings also suggest a role for smoking and increased joint-related symptoms. The association of high BMI with incident IA/RA has been identified prior (de Hair 2013) and the replication of that herein may identify this as a potentially modifiable risk factor for future RA. Furthermore, the risk of incident IA/RA with a higher number of self-reported swollen joints at baseline suggests that individuals may sense joint abnormalities prior to detection of swelling on physical examination. The risk of incident RA with RFIgA and M positivity also highlights the importance of a combination of ACPA and RF in the pathogenesis of joint disease, and the potential role of the SE in transition from ACPA positivity to arthritis is also intriguing. This study will continue with further evaluation of factors that may be predictive of or causally linked to the future onset of RA.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) related autoantibodies, in particular antibodies to citrullinated proteins (ACPA), predict likelihood of developing future RA. Indeed, clinical trials for RA prevention are underway using ACPA positivity as an inclusion factor. However, there are multiple commercial ACPA assays including several versions of cyclic citrullinated protein (CCP) assays that may differ in diagnostic accuracy for future RA. For this project, we propose to use a novel sample set to evaluate the diagnostic accuracy in preclinical RA of 3 commercial CCP assays that are widely used in the USA.

Methods: Cases who developed classifiable RA (n=196) during military service were identified and up to 3 pre-RA diagnosis and 1 post-RA diagnosis stored serum samples were selected from the Department of Defense Serum Repository along with serum from 208 matched controls. For the analyses herein, the pre-RA diagnosis Case samples were assigned as >3 or < =3 years from diagnosis, with each subject contributing only 1 sample per interval. Case and Control samples were tested using 3 commercially available CCP assays: CCP2 (ELISA IgG, Axis-Shield), CCP3

Table 1. Prevalence of positivity of each CCP assay pre- and post-RA diagnosis and using manufacturer recommended cut-offs for positivity

	Prevalence of positivity >3 years pre-RA diagnosis	Prevalence of positivity <=3 years pre-RA diagnosis	Prevalence of positivity Post-RA diagnosis
N samples/subjects per interval*	196	196	196
Mean (SD) of time of sample from diagnosis within each interval, in years	-12.1 (4.9)	-1.5 (0.6)	+1.2 (0.9)
CCP2	16.3%	64.8%	72.8%
CCP3	20.9%	71.4%	76.5%
CCP3.1	16.8%	67.3%	77.4%
p-value**	0.43	0.36	0.53
Kappa***	0.82-0.87	0.81-0.86	0.85-0.90

*For these analyses, in each interval, only one sample per subject was included. The sample selected was the one closest in time of collection to the middle of the interval.
**p-value comparing positive rates across all 3 CCP assays for each interval
***Kappa values are the range of findings from pairwise comparisons of each CCP assay

Table 2. Likelihood of positivity of each CCP assay at different cut-offs for interval <=3 years prior to RA diagnosis	
	Odds ratio for positivity <=3 years compared to >3 years
Standard cut-off	
CCP2	OR 9.4 (5.8,15.2), p=<0.01
CCP3	OR 9.45 (5.9,15.0), p=<0.01
CCP3.1	OR 10.2 (6.3,16.4), p=<0.01
>=2x standard cut-off	
CCP2	OR 9.1 (5.6,14.8), p=<0.01
CCP3	OR 11.2 (6.9,18.3), p=<0.01
CCP3.1	OR 10.3 (6.3,17.0), p=<0.01
>=3x standard cut-off	
CCP2	OR 8.7 (5.3,14.2), p=<0.01
CCP3	OR 10.6 (6.4,17.3), p=<0.01
CCP3.1	OR 9.7 (5.9,16.0), p=<0.01

(ELISA IgG, Inova) and CCP3.1 (ELISA IgG/A, Inova) with positivity based on the manufacturer recommendations, and specificity determined in a single sample from Controls. The prevalence of CCP positivity in each interval was evaluated using three-way chi-square and kappa analyses. The relationship of positivity for a given test >3 and < =3 years of RA diagnosis was evaluated using a 2x2 table and Mantel-Haenszel odds ratio estimate.

Results: CCP2, CCP3 and CCP3.1 were positive in 72.8 to 77.4% of RA cases post-diagnosis (Table 1). The specificity, using Controls, of CCP2, CCP3 and CCP3.1 was 99.0, 98.6 and 96.6%, respectively; in addition, the specificity for all tests at >=2x the manufacturer recommended cut-off was 99%. In samples >3 years prior to diagnosis, the CCP assays were positive in 16.3 to 20.9% of Cases (Table 1). While CCP3 was positive in this interval in ~5% more subjects than CCP2 and ~4% than CCP3.1, these differences were not statistically significant. In samples < =3 years prior to diagnosis, the CCP assays were positive in 64.8 to 71.4% of Cases. While CCP3 was positive in this interval in ~7% more subjects than CCP2 and ~4% more subjects than CCP3.1, these differences were not statistically significant. For each CCP assay, cases were more likely to be positive < =3 years pre-RA diagnosis compared to >3 years (Table 2).

Conclusion: These results can help inform interpretation of CCP tests in individuals who may be positive in the absence of RA, as well as the choice of assay in clinical trials of RA prevention where the assay or cut-off level (e.g. >=2x) may impact diagnostic accuracy. Furthermore, the finding that positivity for these CCP assays was more likely to occur < =3 years prior to RA diagnosis is useful for informing CCP positive individuals about the potential timeline of development of RA, and in the development of clinical trials where this timeframe can inform trial design. Replication of these findings in additional cohorts is warranted, as well as comparison with additional ACPA assays that are in common use.

Assessment of Anti-Cyclic Citrullinated Protein and Connective Tissue Disease Screening Questionnaire in Healthy Adults from the Oklahoma Immune Cohort

McKayla Muse ,[1] Ly Tran,[1] Carla J. Guthridge,[2] Nancy Redinger,[2] and Judith James[3], [1]Oklahoma Medical Research Foundation, Oklahoma City, [2]Oklahoma Medical Research Foundation, Oklahoma City, OK, [3]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-CCP antibodies are present in the serum of healthy individuals who are at risk of developing RA and serve as an important tool for diagnosing an individual with RA and providing prognostic information. The Connective Tissue Disease Screening Questionnaire (CSQ) is an assessment designed to help identify individuals who may be at risk for CTDs including RA, SLE, and SS. We hypothesize that healthy individuals with elevated levels of anti-CCP antibodies will have higher CSQ scores.

Methods: Demographic information (race, gender, and age) and CSQ scores were obtained from the datasets of 954 individuals who consented to be part of the Oklahoma Immune Cohort (OIC). These individuals were not diagnosed with RA or another autoimmune rheumatic disease. Anti-CCP3 levels were determined by ELISA. Individuals were identified as: < 20 EU/mL = negative, 20-39 EU/mL = weakly positive, 40-59 EU/mL= moderately positive, and ≥60EU/mL as strongly positive for anti-CCP3 antibodies. Associations between CSQ scores and age were determined by Kruskal-Wallis analysis and associations between CSQ scores, race, and gender were determined by Chi-square analysis. Logistical regression was used to determine the relationship between CSQ scores and anti-CCP3 levels while controlling for age, gender, and race.

Results: CSQ scores and anti-CCP3 levels were both found to be significantly different based upon age or race (Table 1). Healthy Native Americans were more likely to have elevated CSQ scores (OR=1.68) than healthy African Americans (OR=0.86) or heathy European Americans. African-American healthy individuals had the lower rate of anti-CCP3 responses. Logistic regression analysis, controlling for race, age and gender, showed that there were no significant associations between CSQ and anti-CCP3 levels (Table 2).

Conclusion: In this cohort of healthy adults, anti-CCP3 levels did not associate with variations in the CSQ score. However, anti-CCP3 levels and CSQ scores both varied with age and race, suggesting that these demographic factors may be relevant when screening for risk of developing rheumatic disease.

Table 1: Demographics and Screening Results, Stratified by CSQ Score and CCP3 Interpretation

Women with Rheumatoid Arthritis Have Higher Lifetime Occupational and Non-occupational Exposure to Silica Dust Compared to French General Population

Johanna Sigaux ,[1] Catherine Cavalin,[2] Odile Macchi,[2] Salima Challal,[3] Mylene Petit,[4] Patrice Decker,[5] Emma André,[4] Paul-André rosental,[2] Marie-Christophe Boissier,[6] and Luca Semerano[7], [1]INSERM UMR 1125, Université Paris 13, Bobigny, France, [2]SILICOSIS project, ERC Advanced Grant, Centre for European Studies, Sciences Po, Paris, France, Paris, France, [3]Assistance Publique-Hôpitaux de Paris, Hôpital Avicenne Service de Rhumatologie, Bobigny, France, [4]INSERM UMR 1125 Sorbonne Paris Cité, Université Paris 13, 93000 Bobigny, France, Paris, France, [5]Inserm UMR 1125, University of Paris 13, Sorbonne Paris Cité, Bobigny, France, [6]Assistance Publique-Hôpitaux de Paris (AP-HP), Rheumatology Department, Avicenne Hospital, Bobigny, France, [7]INSERM UMR 1125 , Université Paris 13, Bobigny, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Occupational exposure to silica dust is a well-known risk factor for ACPA positive rheumatoid arthritis (RA). The role of non-occupational exposure has not been explored so far, as there are no available tools to measure it in clinical practice.

The Dust Exposure Life-Course Questionnaire (DELCQ), developed within a European Research Council Advanced Grant, provides clinical research with a tool derived from social sciences. The DELCQ, longitudinally quantifies both occupational and non-occupational (e.g. body care; hobbies such as DIY, stone cutting etc.) exposure to silica during lifetime.

In the DELCQ, the sources of silica exposure are grounded on an extensive list of products and activities summed up by the International Agency on Research on Cancer (IARC) and on a wide overview of the literature that in medicine, epidemiology and industrial hygiene has been addressing silica exposure and silica-related diseases.

The aim of this study was to use this novel tool to explore occupational and non-occupational silica exposure in a series of consecutive RA patients and to explore the association of quantified silica dust exposure with major disease features (ACPA positivity) or outcomes (erosive disease).

Methods: We administered the DELCQ to 97 consecutive RA patients (77F, 20M, mean age 59.1+/- 13.3 yrs.,75 ACPA positives, 66 with erosive disease) attending the department of rheumatology of the Avicenne teaching Hospital (Bobigny, FRANCE). Patient scores were compared to those of 261 controls, matched for sex, age and smoking status, from a 2739 -subject national cohort (ELIPSSilice), representative of the French general population. Within RA subjects, the association of the scores with ACPA positivity and with erosive disease was assessed after adjustment for tobacco use.

Results: RA patients had higher scores of occupational (10 [0, 17] vs. 0 [0, 4]) silica exposure vs. controls ($p< 0.0001$) (fig 1). In both men and women with RA, occupational exposure was higher compared to sex-matched controls (23.5

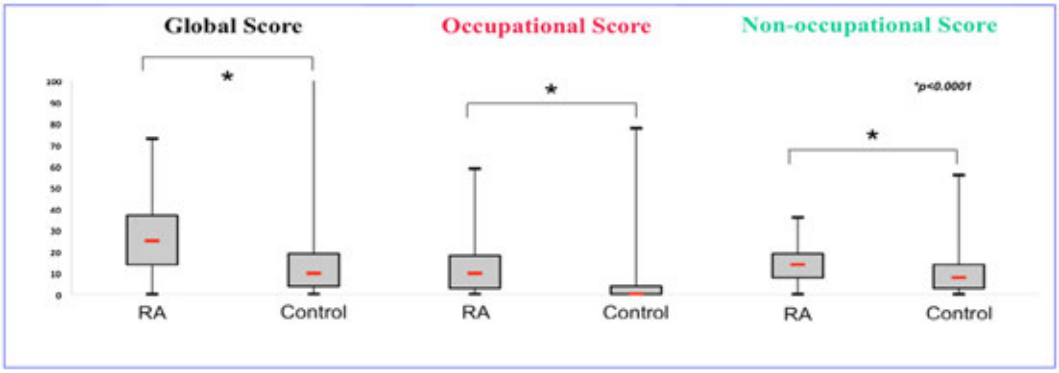

Figure 1. Comparison RA patients vs. Controls of global, occupational and non-occupational silica exposure scores.

[18, 34.5] vs. 2.5 [0, 12] for men and 7 [3, 14] vs. 0 [0, 5] for women p< 0.0001 for both). Non-occupational exposure was higher only in women with RA (15 [9, 21] vs. 12 [5, 21], p< 0.05) (fig 2). Male vs. female RA patients had higher occupational scores of exposure (12 [2, 18] vs. 0 [0, 3] p< 0.005), while non-occupational exposure was not significantly different (fig 3). After adjusting for smoking, neither occupational of non- occupational scores were associated with erosive disease.

Conclusion: RA patients have higher lifetime exposure to silica dust compared to age and sex-matched subjects from the French general population. Women with RA have higher exposure from both occupational and non-occupational sources. In this series, constituted mainly of non-smoking women, exposure to silica may be a relevant environmental factor for the development of RA. In men, only occupational exposure is higher RA patients vs. controls. Neither occupational nor non-occupational exposure was associated with disease severity, likely due to the high prevalence of ACPA positivity and erosive disease in the patient series.

Should There Be Hierarchical Scoring Applied to Serologic Testing in the 2010 ACR/EULAR Classification Criteria?

Barbara Mascialino ,[1] and Teresa Tarrant[2], [1]Thermo Fisher Scientific, Uppsala, Uppsala Lan, Sweden, [2]Duke School of Medicine, Division of Rheumatology and Immunology, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2010 ACR/EULAR classification criteria for Rheumatoid Arthritis (RA) are based on a combination of clinical, laboratory, and imaging investigations. Positive serology contributes to the final score when subjects are either positive to CCP or RFIgM; scoring increases based on the strength of an individual test. No more points are awarded to a patient having one versus two serologies positive.

TABLE 1	Reference	Pooled Sensitivity	Pooled Specificity
ACR Criteria – Full algorithm	Radnar et al., 2014 (Systematic Literature Review and Meta-Analysis)	78%+13%	59%+16%
CCP "and" RF IgM	Sun et al., 2014 (Systematic Literature Review and Meta-Analysis)	57% [55%-59%]	96% [96%-97%]
CCP "or" RF IgM	Sun et al., 2014 (Systematic Literature Review and Meta-Analysis)	78% [76%-80%]	82% [81%-84%]

TABLE 2	True Positives	False Negatives	False Positives	True Positives	Corr Classif	Incorr Classif
ACR Criteria – Full algorithm	139	39	337	485	62%	38%
CCP "and" RF IgM	102	76	33	789	89%	11%
CCP "or" RF IgM	139	39	148	674	81%	19%

The aim of this study was to model the clinical diagnostic outcomes between the ACR/EULAR full algorithm versus serology alone analyzing different combinations of serological positivity (single versus double positive).

Methods: We simulated a cohort of 1000 RA-suspected individuals and calculated the number of correctly/incorrectly classified subjects using the diagnostic accuracies listed in Table 1; results were compared to the ones generated by the full 2010 ACR/EULAR algorithm.

Results: Compared with the 2010 ACR/EULAR diagnostic criteria (Table 2), serology used in isolation in the current ACR/EULAR definition "CCP or RFIgM" reduces False Positives from 337 to 148 respectively, thereby diminishing the misclassification rate by 50%. Combined positivity to both tests ("CCP and RFIgM") decreases False Positives by 90%, but False Negatives increase from 39 to 76 (49% increase); overall, misclassification by this methodology drops to 11% from 38% compared to the full ACR/EULAR criteria.

Conclusion: Results show that serology used in isolation and interpreted as "CCP and RFIgM" can reduce misclassifications and may be useful in adding to the 2010 ACR/EULAR classification criteria. Individuals either positive to one test or seronegative should be re-assessed with the other examinations listed within the criteria to reach a final diagnosis.

Diagnostic accuracies (pooled sensitivities, pooled specificities, and 95% Confidence Intervals) from the two Systematic Literature Review and Meta-Analysis used in input to the simulation model.

By simulating a cohort of 1,000 individuals, all tested with CCP and RF and classified with teh 2010 ACR /EULAR Classification Criteria, this table summarises the number of True Positives, False Negatives, False Positives, True Positives, as well as the total number of correctly / incorrectly classified subjects obtained in each case using the diagnostic accuracies listed in Table 1.

The Generation of Anti-CCP Tests Affects Diagnostic Accuracy in Rheumatoid Arthiritis: A Systematic Literature Review and Meta-Analysis

Barbara Mascialino ,[1] Linda Mathsson-Alm,[1] Maryam Poorafshar,[1] and Teresa Tarrant[2], [1]Thermo Fisher Scientific, Uppsala, Uppsala Lan, Sweden, [2]Duke School of Medicine, Division of Rheumatology and Immunology, Durham, NC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The detection of antibodies to cyclic citrullinated peptides (anti-CCP) may occur long before the onset of rheumatoid arthritis (RA) symptoms.

Several versions of CCP antigen peptide mixtures exist in commercial laboratory testing and are labelled CCP 2, CCP 3.0, CCP 3.1. However, despite the sequential numbering of these antigens, newer generations are not necessarily associated with improved clinical performance [Mathsson-Alm et al., 2018].

The objective of this study was to perform a systematic literature review and meta-analysis aimed at comparing the diagnostic accuracy of the most accurate anti-CCP 2 test as identified in the most recent systematic literature review and meta-analysis published on CCP tests [Mathsson-Alm et al., 2018], with anti-CCP 3.0 and CCP 3.1 tests for the diagnosis of RA, with a focus on early RA.

Methods: Our systematic literature review identified studies from 2004-2018. Estimates for pooled sensitivity, pooled specificity, Area Under the Curve (AUC), Diagnostic Odds Ratios (DOR), positive/negative likelihood ratio (LR+/LR-) were calculated; sub-analyses stratified by study design (single-gated, which are cross-sectional studies, or double-gated studies, which are case-control studies), by test generation, and by early RA (defined as symptoms durarion less than two years).

Results: Out of 5,074 papers, 113 met the inclusion criteria reporting the diagnostic accuracy of anti-CCP tests, and included 84 studies from early RA patients.

The results displayed in the Table show that the CCP 2 test has a stable performance across study designs for un-differentiated RA. As expected, when used in single-gated study designs, the test is characterized by a slightly lower sensitivity (non significant difference). It is worth noting here that single-gated studies are more representative of the scenario in which the tests would be used in practice to diagnose RA. The two CCP 3 tests are characterized by overall good and comparable performance, CCP 3.1 being characterized by a slightly lower sensitivity.

In early RA it was not possible to stratify the analysis by study design due to lack of articles passing the inclusion criteria. Moreover, not enough data was found in the literature for the test CCP 3.1 for this RA sub-type, so the comparison is limited to two tests only. The meta-analysis results show that the CCP 2 test is characterized by significantly higher sensitivity ($p< 0.05$) and by similar specificity compared to the test CCP 3.1.

Conclusion: The meta-analysis highlights that the CCP 2 test considered is in general characterized by higher diagnostic accuracy, demonstrating the greatest combination of sensitivity and specificity for RA, in undifferentiated RA

Test Generation	RA-type	Number of Included studies	Study design	AUC	Pooled Sensitivity (%) [95% CI]	Pooled Specificity (%) [95% CI]	DOR [95% CI]
CCP2	Mixed	10	Double-gated	0.92	73 [64-75]	97 [93-98]	75 [41-135]
CCP3.0	Mixed	11	Double-gated	0.86	76 [72-80]	92 [87-96]	40 [22-73]
CCP3.1	Mixed	6	Double-gated	0.93	70 [54-82]	93 [89-95]	33 [15-72]
CCP2	Mixed	3	Single-gated	0.70	71 [66-76]	96 [91-99]	74 [19-294]
CCP2	Early	3	Double-gated	0.85	78 [69-85]	86 [69-94]	20 [8-50]
CCP 3.0	Early	3	Double-gated	0.64	58 [51-63]	89 [77-96]	15 [3-65]

as well as in early RA. These results suggest that using CCP 3.0 or CCP 3.1 assays may result in the misclassification of some RA patients.

Meta-Analysis results (pooled sensitivity, pooled specificity, Area Under the Curve, Diagnostic Odds Ratio and their 95% Confidence Intervals), stratified by RA type (mixed RA or early RA), and by study design (double-gated, which means case-control, or single-gated, which means cross-sectional).

The Dysregulation of NK Cells and Non-Conventional NK-T and γδ-T Cells in Individuals at Risk of Developing Rheumatoid Arthritis

Klára Prajzlerová ,[1] Olga Kryštůfková,[2] Petra Hánová,[3] Hana Hulejová,[3] Monika Gregová,[1] Nora Petrovská,[1] Herman Mann,[4] Karel Pavelka,[4] Jiří Vencovský,[4] Ladislav Senolt,[4] and Mária Filková[1], [1]Institute of Rheumatology and Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic, [2]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague, Czech Republic, [3]Institute of Rheumatology, Prague, Czech Republic, [4]Institute of Rheumatology, Department of Rheumatology, 1st Faculty of Medicine, Prague, Czech Republic, Prague 2, Czech Republic

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The positivity of antibodies against citrullinated proteins (ACPA) precedes the clinical manifestation and significantly increases the risk of rheumatoid arthritis (RA). EULAR characterised individuals with arthralgia suspicious for progression to RA based on their clinical features (clinically suspect arthralgia, CSA). Natural killer (NK) cells and non-conventional T cells (NK-T and γδ-T cells) are involved in the regulation of immune system and their alteration was previously described in patients with established RA. We aimed to study lymphocyte subpopulations in individuals at risk of developing RA.

Methods: Our study included 71 individuals with arthralgia at risk of developing RA based on ACPA positivity and/or meeting CSA definition and 70 age and gender matched healthy controls (HC). Whole blood samples were analysed by flow cytometry. The % and absolute count of CD3+ T cells and subsequently CD3-CD16/56+ NK cells, CD3+CD16/56+ NK-T cells and CD3bright γδ-T cells were evaluated in CD45+CD14- lymphocyte population. Data were analysed using Mann Whitney test.

Results: Out of 71 individuals with arthralgia (mean age 46.33±12.17 years; 93% females), 46 were ACPA+ and 46 met CSA definition (22 of them were ACPA+). Median symptom duration was 12.5 months [IQR=53], CRP 2.94 mg/L [IQR=3.55 and DAS28-FW score 2.38 [IQR=1.53] that was used as a surrogate parameter of disease activity. As per definition, there was no evidence of clinical arthritis on examination of 66 joints at baseline. Thirteen individuals developed RA within a median of 4 months of follow up.

Analysis of lymphocyte subpopulations showed higher %CD3+ T cells (p=0.004) and lower %NK (p=0.005), %NK-T (p=0.043) as well as absolute count of NK (p≤0.001), NK-T (p=0.012) and γδ-T cells (p=0.027) in all individuals with arthralgia compared to HC. Similarly, higher %CD3+ T cells (p=0.015) and lower %NK (p=0.009), %NK-T (p=0.040) and absolute count of NK (p=0.001), NK-T (p=0.008) and γδ-T cells (p=0.017) were confirmed in a subgroup of ACPA+ individuals (especially those who also met CSA criteria) compared to HC. Also individuals who met CSA criteria irrespective of ACPA status had higher %CD3 T cells (p=0.010) and lower %NK cells (p=0.002) and absolute count of NK (p=0.004), NK-T (p=0.031) and γδ-T cells (p=0.046) compared to HC. Moreover, absolute count of γδ-T cells in individuals with arthralgia negatively correlated with disease activity score DAS28-FW (r=-0.245, p=0.040). There were no differences in lymphocyte subsets in individuals who have developed RA as yet and patients with arthralgia or at the time of RA manifestation.

Conclusion: We show lower numbers of NK cells as well as NK-T and γδ-T cells in individuals at risk of developing of RA irrespective of autoantibody or clinical definition. The decrease of non-conventional T cells was observed despite the increased percentage of the classical T cells. The altered distribution of these lymphocyte subtypes was previously described in established RA. We hypothesize that the dysregulation observed in at-risk individuals may reflect a predisposition leading to further development of RA.

EULAR Definition of "Arthralgia Suspicious for Progression to Rheumatoid Arthritis" in a Cohort of Patients Included in a Program for Rapid Diagnosis: Role of Ultrasound and Antibodies

Jessica Torres Chichande,[1] Santiago Ruta,[2] Einer Sanchez Prado,[3] Alvaro Ruta,[1] Sebastian Magri,[1] Facundo Salvatori,[1] and Rodrigo Garcia Salinas[1], [1]Hospital Italiano de La Plata, La plata, Buenos Aires, Argentina, [2]Rheumatology Department, Hospital San Martín de La Plata and Rheumatology Unit, Hospital Italiano de La Plata, Argentina., La Plata, Argentina, [3]Hospital Italiano de La Plata, La Plata

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the performance of the EULAR definition of arthralgias suspicious for progression to rheumatoid arthritis (RA) in a group of patients admitted to "Reuma-check" ® program with hand arthralgias and to estimate the added value of ultrasound (US) and the determination of antibodies.

Methods: Consecutive patients older than 18 years admitted for predominantly hand arthralgias to "Reuma-check" ® program were included. At baseline, laboratory tests (including ESR, CRP, RF and anti-CCP), US of hands and wrists with power Doppler (PD) technique including 22 joints (bilateral wrist, MCP and PIP) and X-ray of hands and feet were performed. Sociodemographic, clinical and clinimetry data were also collected. EULAR defined characteristics describing arthralgia at risk for RA were recorded: history taking: Joint symptoms of recent onset (duration < 1 year), symptoms located in MCP joints, duration of morning stiffness ≥60 min, most severe symptoms present in the early morning, presence of a first-degree relative with RA; physical examination: difficulty with making a fist, positive squeeze test of MCP joints. Each evaluator (laboratory, images and clinician) was blinded to the data of the other studies. In successive visits, definitive diagnosis of RA according to the ACR/EULAR 2010 criteria was established or not. Only patients with at least 2 visits were included for the final analysis.

Results: A total of 192 patients were included. 74% were women and mean age was 53 years (SD 14.2). Of the 192 patients, 23 (12%, 95% CI: 7-16) were diagnosed with RA at follow-up. Mean of baseline characteristics describing arthralgia at risk for RA was 3.7 (SD 2.2) in patients with final diagnosis of RA vs 2.7 (SD 1.7) in non-RA patients (p= 0.02). The area under the ROC curve for the EULAR defined characteristics describing arthralgia at risk for RA for the final diagnosis of RA was 0.6302, adding US with PD and anti-CCP data, the area under the ROC curve were 0.6845 (p= 0.0009) and 0.6554 (p= 0.02), respectively. Table shows features associated with final diagnosis of RA. In the multivariate regression logistic analysis, the only features associated with a final diagnosis of RA were anti-CCP (OR: 11, CI 95%: 1.6-74.3) and US with PD in at least one joint assessed (OR: 22.1, CI 95%: 3.7-129.5).

Conclusion: The EULAR definition of arthralgia suspicious for progression to rheumatoid arthritis had an acceptable performance to predict the development of RA in patients with arthralgias in our cohort of patients and improves adding information of both US with PD and anti-CCP. 12% of patients (23/192) were diagnosed as RA at follow-up. Anti-CCP and US with PD were the main features associated with final diagnosis of RA.

Disease Activity Measures at Baseline and 3 Months as Predictors of Rapid Radiographic Progression in Methotrexate Naïve Patients with Early Rheumatoid Arthritis

Mohammad Movahedi,[1] Deborah Weber,[1] Pooneh Akhavan,[2] and **Edward Keystone**[3], [1]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada, [2]Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada, [3]Mount Sinai Hospital and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster I: Risk Factors, Predictors, & Prognosis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Progressive rheumatoid arthritis (RA) is responsible for disabilities in this patient population, characterized by radiographic joint damage. Achieving low disease activity (LDA) in RA is associated with reduction in radiographic progression. We aimed to compare different measures of disease activity and patient reported outcomes including disease activity score (DAS), C-reactive protein (CRP), modified (M) DAS28 (CRP), clinical disease

activity index (CDAI), DAS28(CRP) change ≥1.2, and health assessment questionnaire disability index (HAQ-DI) to predict rapid radiographic progression (RPP) in early RA patients.

Methods: Data from the PREMIER study, a 2-year, multicenter, double-blind active comparator–controlled study with methotrexate (MTX) naïve RA patients with active disease of < 3 years, were used. For this analysis, only patients in the MTX arm were analyzed. RRP was defined as change in modified total Sharp (mTSS) > 3.5 at month 12. Logistic regression analysis was used to assess impact of disease activity measures at baseline and 3 months to predict RRP at 12 months. The area under the receiver operating characteristic curve (ROC AUC) was also calculated.

Results: A total of 149 MTX treated patients were included in this analysis with the majority being female (n=113; 75.8%), positive RF (n=127; 85.2%), mean (SD) baseline age 52.9 (13.3) years, disease duration 0.8 (0.9) year, DAS28(CRP) 6.3 (0.9). After adjusting for potential confounders, only M-DAS28(CRP) at baseline ($_{adj}$OR=3.29; 95% CI: 1.70-6.36) and 3 months ($_{adj}$OR=2.56; 95% CI: 1.43-4.56) strongly predicted RRP at 12 months. Analysis of ROC curves also showed that compared with other measures, M-DAS28(CRP) at baseline and 3 months had highest predictive values (AUC: 0.66 and 0.74 respectively). We found the value of MDAS28(CRP) 4.5 and 2.6 at baseline and 3 months, respectively as optimal cut-off points to maximize sensitivity and specificity for prediction of RRP at 12 months.

Conclusion: M-DAS28(CRP) is a stronger predictor at baseline and 3 months for rapid radiographic progression compared with other disease activity measures and patient reported outcomes in early RA patients initiating MTX.

A Pilot Phase 1, Randomized, Double-blind, Two-arm, Parallel Group, Single-dose Study to Evaluate the Safety and Pharmacokinetics of CT-P17 and Humira in Healthy Male Subjects

Edward Keystone,[1] Daniel Furst,[2] Malcolm Boyce,[3] Frans van den Berg,[3] SangJoon Lee,[4] SungHyun Kim,[4] YunJu Bae,[4] GoEun Yang,[4] JuHeon Koo,[4] EunJin Choi,[4] and Jonathan Kay[5], [1]Mount Sinai Hospital, Toronto, Canada, [2]University of California, Los Angeles, CA, [3]Hammersmith Medicines Research, London, United Kingdom, [4]Celltrion Inc., Incheon, Republic of Korea, [5]UMass Memorial Medical Center and University of Massachusetts Medical School, Worcester, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CT-P17 is a recombinant humanized monoclonal antibody that was developed as a biosimilar to the reference product, adalimumab. This was a first in human study of CT-P17 (100 mg/mL) designed to evaluate the safety including immunogenicity and pharmacokinetics (PK) compared to European Union (EU)-reference adalimumab (100 mg/mL) in healthy male subjects

Table 1 Overall Summary of Adverse Events (Safety Population)

Category, n (%) Relationship	CT-P17 (N=15)	EU-reference adalimumab (N=15)	Overall (N=30)
Total number of TEAEs	19	14	33
Total number of SAEs	0	0	0
Number of subjects with at least 1 TEAE	10 (66.7)	8 (53.3)	18 (60.0)
Related Unrelated	5 (33.3) 8 (53.3)	4 (26.7) 5 (33.3)	9 (30.0) 13 (43.3)
Number of subjects with at least 1 SAE	0	0	0
Number of subjects with at least 1 TESAE	0	0	0
Number of subjects with at least 1 TEAE leading to study discontinuation	0	0	0
Number of subjects with at least 1 TEAE leading to death	0	0	0
Number of subjects with at least 1 TEAE due to hypersensitivity/allergic reactions	0	0	0
Number of subjects with at least 1 TEAE due to injection site reactions	0	1 (6.7)	1 (3.3)
Number of subjects with at least 1 TEAE due to infection	5 (33.3)	2 (13.3)	7 (23.3)
Related Unrelated	1 (6.7) 5 (33.3)	1 (6.7) 1 (6.7)	2 (6.7) 6 (20.0)
Number of subjects with at least 1 TEAE due to malignancy	0	0	0

Table 2 Treatment-Emergent Adverse Events (Safety Population)

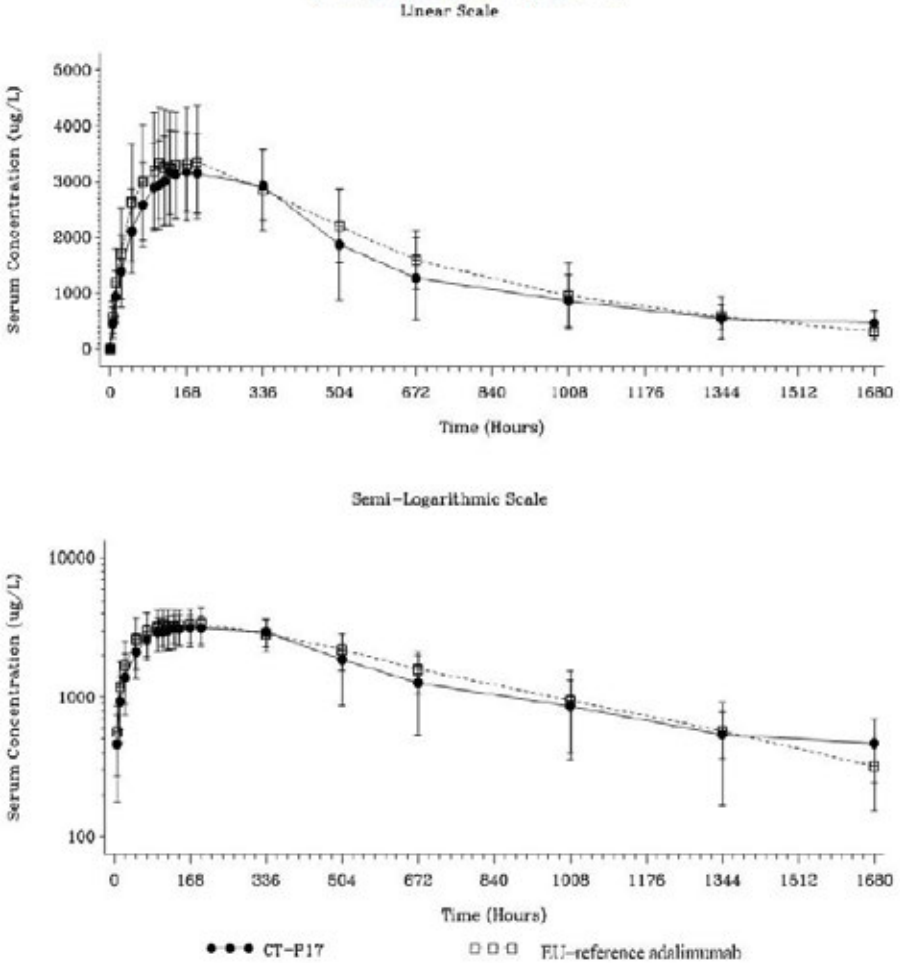
System Organ Class, n (%)	CT-P17 (N=15)	EU-reference adalimumab (N=15)	Overall (N=30)
Ear and labyrinth disorders	1 (6.7)	0	1 (3.3)
Gastrointestinal disorders	3 (20.0)	0	3 (10.0)
General disorders and administration site conditions	1 (6.7)	1 (6.7)	2 (6.7)
Infections and infestations	5 (33.3)	2 (13.3)	7 (23.3)
Musculoskeletal and connective tissue disorders	1 (6.7)	2 (13.3)	3 (10.0)
Nervous system disorders	1 (6.7)	4 (26.7)	5 (16.7)
Respiratory, thoracic and mediastinal disorders	1 (6.7)	2 (13.3)	3 (10.0)
Skin and subcutaneous tissue disorders	1 (6.7)	0	1 (3.3)

Methods: This was a phase 1, randomized, double-blind, two-arm, parallel group, single dose, active comparator study, designed to evaluate the safety and PK of CT-P17 compared to that of EU-reference adalimumab in healthy male subjects. Healthy male subjects aged 18 to 55 years (N=30) were randomized in a 1:1 Ratio to receive 40 mg of either CT-P17 or EU-reference adalimumab by subcutaneous (SC) injection. The primary objective was to evaluate safety in terms of treatment-emergent adverse events (TEAEs). The secondary objective was to evaluate PK parameters and additional safety including immunogenicity.

Results: Demographics and baseline characteristics were similar between the 2 treatment groups. Overall, 33 TEAEs were reported and 10 (66.7%) subjects in the CT-P17 and 8 (53.3%) subjects in the EU-reference adalimumab treatment groups reported at least 1 TEAE (Table 1, 2).

The most commonly reported TEAE was nasopharyngitis (4 [26.7%] in CT-P17 and 1 [6.7%] in EU-reference adalimumab). All TEAEs were grade 1 or grade 2 in intensity. There were no deaths, serious AEs, TEAEs leading to study discontinuation, hypersensitivity/allergic reaction or malignancy case for both treatment groups. One (6.7%) subject in the EU-reference adalimumab treatment group reported grade 1 TEAE of injection site reaction. There were no clinically notable abnormalities reported from other safety assessments, including clinical laboratory testing, vital signs, hypersensitivity/allergic reaction monitoring, ECG, physical examination, chest x-ray and tuberculosis assessment.

Figure 1 **Mean (± SD) Serum Concentrations of Adalimumab by Treatment (Pharmacokinetic Population)**



None of the subjects had a positive anti-drug antibody (ADA) test result at baseline. In the CT-P17 treatment group, 14 (93.3%) and 13 (86.7%) subjects developed at least 1 positive ADA and neutralizing antibodies (NAb) post-dose, respectively. In the EU-reference adalimumab treatment group, 15 (100%) and 14 (93.3%) subjects developed at least 1 positive ADA and NAb post-dose, respectively. Overall, the proportion of subjects with positive ADA and NAb results after study drug administration was similar in the 2 treatment groups.

The mean serum concentrations of adalimumab following a single SC dose of 40 mg of CT-P17 or EU-reference adalimumab were comparable up to Day 71 (Figure 1).

The mean values of $AUC_{0\text{-inf}}$ were 2383.0 h*ug/mL and 2661.1 h*ug/mL and the mean values of C_{max} were 3.415 ug/mL and 3.667 ug/mL for CT-P17 and EU-reference adalimumab, respectively, and were comparable between the 2 treatment groups. All other PK parameters were also comparable between the 2 treatment groups.

Conclusion: Single SC doses of 40 mg of CT-P17 or EU-reference adalimumab were well-tolerated and the safety profile of CT-P17, including immunogenicity, was comparable to that of EU-reference adalimumab in these healthy male subjects.

Pharmacokinetic results were also comparable between the 2 treatment groups.

Abbreviations: AE, adverse event; SAE, serious adverse event; TEAE, treatment-emergent adverse event; TESAE, treatment-emergent serious adverse event. Note: A subject with 2 or more TEAEs within the same system organ class, preferred term, and relationship is counted only once using the most severe intensity.

Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: RA patients who have failed biologic DMARDs represent an unmet medical need. We explored the impact of baseline demographics and clinical characteristics on filgotinib efficacy in patients with active RA who have inadequate response to ≥1 prior bDMARD (bDMARD-IR).

Methods: In the global, phase 3 FINCH-2 study (NCT02873936), 449 patients with moderately-to-severely active RA and inadequate response to ≥1 prior bDMARDs were randomized 1:1:1 to once-daily filgotinib 200 mg, filgotinib 100 mg, or placebo.[1] We evaluated prespecified subgroups including baseline demographic and clinical characteristics such as sex at birth, seropositivity for RF and/or ACPA, disease duration, disease activity, hsCRP levels, concurrent use of corticosteroids, and different classes of DMARDs on filgotinib efficacy as measured by ACR20 and DAS28(CRP) for low disease activity and remission in patients with active RA who were bDMARD-IR.

Table 1. Proportion of Patients Achieving ACR20 Response at Week 24 Unless otherwise noted, data presented as n/N (%) CI, confidence interval; csDMARD, conventional synthetic DMARD; hsCRP, high-sensitivity CRP; QD, once daily.

	Treatment			Δ in Response vs Placebo, 95% CI, p-value

No	8/23 (34.8)	6/26 (23.1)	4/32 (12.5)	22.3 (−4.0, 48.6) 0.095	10.6 (−12.7, 33.9) 0.32

Results: Of the 448 patients randomized and treated at baseline, 80.4% were female with a mean age of 56 years and a mean RA duration of 12.4 years. Clinical efficacy outcomes at week 24 as measured by ACR20, DAS28(CRP) ≤3.2 and DAS28(CRP) < 2.6 by patient demographics and clinical baseline characteristics are described in **Tables 1**, **2**, and **3**, respectively.

Conclusion: Compared with placebo, filgotinib consistently improved clinical outcomes in bDMARD-refractory patients. Benefits were observed for filgotinib across subgroups defined by various demographic and clinical baseline characteristics. There was an absence of impact of disease duration, seropositivity, disease activity and concurrent medication use, notably on the effectiveness of filgotinib.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been recommended that tapering csDMARDs should be considered if a patient is in persistent remission. However, methods for tapering csDMARDs, including MTX, without RA flare have not been established. Previously, we reported that baseline RAMRIS synovitis score predicted half-dose reduction of MTX without disease flare until week 24, in an RA patient who achieved clinical remission. In this study, we extended the study duration to week 52 to determine whether baseline MRI findings can predict successful half-dose reduction of MTX for a full year.

Methods: Outpatients of our hospital's department of rheumatology were included in this study. Inclusion criteria were as follows: diagnosis of RA based on 2010 ACR/EULAR classification criteria; achievement of clinical remission, defined by DAS28-CRP, over 4 weeks; treatment with methotrexate reduced by half according to the patient's wishes; and availability of MRI images of the hand at the time of MTX reduction. Exclusion criteria were as follows: treatment with leflunomide or tacrolimus, tsDMARDs, or bDMARDs; or oral prednisolone > 5 mg/day. In this study, we examined DAS28-CRP until week 52 every 4–8 weeks. Disease flare was defined as DAS28-CRP of ≥ 2.3 at two sequential visits, an increase in dose of MTX, and addition of other DMARDs. MRI of the patient's dominant wrist and second through fifth metacarpophalangeal (MCP) joints was performed using a 1.5 T whole-body MRI unit with contrast enhancement. MR images were assessed for bone erosions, synovitis, and bone marrow edema according to the original OMERACT Rheumatoid Arthritis MRI Scoring System (RAMRIS).

Results: Fifteen patients were enrolled in this study (10 women, 5 men). We evaluated all 15 patients' data until week 52. Mean (±SD) age, disease duration, MTX dose before reduction, and DAS28-CRP at baseline were 66.6 ± 9.8 y, 6.0 ± 3.6 y, 8.8 ± 3.4 mg/w, and 1.32 ± 0.26. Thirteen patients were positive for anti-CCP antibody and RF. Subclinical MRI inflammation was detected in all patients. Median (range) synovitis, bone edema, and bone erosion score were 2 (0–7), 0 (0–4) and 7 (1–22). Two patients experienced disease flare until week 24 and one patients after week 24. Two patients without clinical remission before week 24 had significantly higher RAMRIS synovitis scores (4.5 vs. 1.9, $p < 0.05$). RAMRIS bone erosion score of 3 patients experiencing disease flare until week 52 tended to be higher, and total RAMRIS score (synovitis + bone edema + bone erosion score, but not synovitis score alone) was significantly higher in these patients (18.3 vs. 8.0, $p < 0.05$). Analysis of the ROC curve determined that the most sensitive and specific cut-off value for total RAMRIS score was 11 (AUC = 0.917, 95% CI 0.737–1.000, $p < 0.001$).

Conclusion: MRI evaluation was useful for prediction of successful dose reduction of MTX during clinical remission. In the early phase of reduction, synovitis was an important factor in disease flare, and as reduction became long-term, bone erosion was also important. We conclude that half-dose reduction of MTX in RA patients who achieve clinical remission and have low total RAMRIS scores might be a beneficial option for tapering MTX.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an orally administered, potent and selective inhibitor of Janus kinase 1 (JAK1) that has shown good efficacy and was well tolerated for treatment of rheumatoid arthritis (RA). The objective of this study is to evaluate efficacy and safety of FIL treatment in patients with RA who have had an inadequate response to methotrexate (MTX).

Methods: This phase 3, double-blind, active- and placebo (PBO)-controlled study randomized patients with active RA (3:3:2:3) to FIL 200 mg, FIL 100 mg, active comparator (adalimumab [ADA] 40mg every 2 weeks), or PBO daily for up to 52 weeks; results through week 24 are presented. Patients were also receiving MTX for ≥12 weeks with a stable dose of MTX for ≥4 weeks before initiation of study drug. Primary efficacy endpoint was proportion of patients achieving ACR20 response at week 12; additional clinical assessments were ACR50 and ACR70 responses, DAS28-CRP score ≤3.2 and < 2.6, van der Heijde modified total Sharp score (mTSS), and patient-reported outcomes were HAQ-DI, SF-36 PCS, and FACIT-Fatigue. Safety endpoints included types and rates of adverse events. Logistic regression adjusting for stratification factors with nonresponder imputation was used for superiority test of FIL vs PBO for ACR response and other binary endpoints. Mixed-effect model adjusting for baseline value, stratification factors, treatment, visit, and treatment by visit interaction as fixed effects with observed cases was used for continuous endpoints. Non-inferiority test of FIL to ADA (preserving >50% of ADA response) was performed for DAS28-CRP ≤3.2 and < 2.6.

Results: Of 1,759 patients randomized, 1,755 received study drug and were analyzed, with 475 FIL 200mg; 480 FIL 100mg; 325 ADA; and 475 PBO, of which 89.5%, 90.4%, 88.9%, and 81.3%, respectively, completed week 24 study drug. Most patients (81.8%) were female, mean (standard deviation [SD]) duration of RA was 7.8 (7.6) years, and mean (SD) DAS28-CRP was 5.7 (0.9). At week 12, significantly more patients in the FIL 200mg and 100mg arms

AE, adverse event; MACE, major adverse cardiovascular event

achieved an ACR20 response compared to PBO (Table 1). Similarly, compared to PBO, more patients receiving FIL achieved ACR50 and ACR70 responses, DAS28-CRP scores ≤3.2 and < 2.6, had lower radiographic progression, and reported improvements in HAQ-DI, SF-36 PCS, and FACIT-Fatigue scores (Table 1). Non-inferiority of FIL 200mg to ADA was met based on DAS28-CRP ≤3.2. The FIL safety profile was consistent with prior studies through week 24 (Table 2).

Conclusion: The selective JAK1 inhibitor FIL, at doses of 200mg and 100mg led to significant improvement in signs and symptoms of RA, prevented radiographic progression, and improved physical function compared to PBO, and was well tolerated among patients with RA with prior inadequate response to MTX. Efficacy of FIL 200mg was non-inferior to ADA based on DAS28-CRP ≤3.2.

PEF150	160	1.01 (2.88)	-4.0	0.00	0.00	1.00	15.0	0.002
3. Rank ANCOVA using PPS-mTSS as the analysis set								
PBO	148	3.30 (5.44)	-11.8	0.00	1.08	5.50	31.9	
PEF100	159	1.63 (4.26)	-2.0	0.00	0.00	1.50	30.3	0.002
PEF150	161	1.01 (2.85)	-4.0	0.00	0.00	1.00	15.0	<0.001

Treatment group	N	Mean (SD)	Treatment difference versus PBO[2]		
			LS Mean (SE)	95% CI	P value
4. ANCOVA (FAS)					
PBO	153	3.37 (5.46)			
PEF100	164	1.62 (4.23)	-1.69 (0.48)	(-2.63, -0.75)	<0.001
PEF150	164	1.03 (2.86)	-2.27 (0.48)	(-3.22, -1.33)	<0.001
5. ANCOVA with multiple imputation method (FAS)					
PBO	153	3.37 (5.46)			
PEF100	164	1.62 (4.23)	-1.18 (0.44)	(-2.04, -0.31)	0.008
PEF150	164	1.03 (2.86)	-1.76 (0.44)	(-2.63, -0.90)	<0.001

[1]Based on rank analysis of covariance model: Rank of mTSS Change = Treatment + Baseline Rank of mTSS.
[2]Based on analysis of covariance model: mTSS Change = Treatment + Baseline mTSS. ANCOVA, analysis of covariance; ET, early termination; FAS, full analysis set; PPS, per protocol set; PBO, placebo; PEF100, peficitinib 100 mg/day; PEF150, peficitinib 150 mg/day; SD, standard deviation; SE, standard error; Q1, first quartile; Q3, third quartile.

Background/Purpose: Peficitinib (PEF), a novel oral Janus kinase (JAK) inhibitor, has demonstrated efficacy in Phase 3 studies of patients with RA (NCT02305849).[1] We report the evaluation for suppression of joint destruction of PEF compared with placebo (PBO) in this study.

Methods: This randomized, double-blind, PBO-controlled study was conducted in Japan. Patients with RA (< 10 years' duration) and inadequate response (IR) to MTX were randomly assigned 1:1:1 to receive PEF 100 or 150 mg/day (PEF100 or PEF150) or PBO once daily, plus MTX. Patients receiving PBO were switched to PEF100 or PEF150 at Week (W) 28, or W12 for IR. Hand and foot X-rays were taken at baseline (BL), W12, 28 and 52. Mean change from BL (linear extrapolation) in van der Heijde modified Total Sharp Score (mTSS) at W28 in the full analysis set (FAS) was a primary endpoint, and was analyzed with rank analysis of covariance (rank ANCOVA) with treatment group as factor and BL rank mTSS as covariate in the primary analysis. Sensitivity analyses of the primary efficacy analysis were:

Table 2. Proportions of patients with changes in mTSS of ≤0.5 or >5

	N/n	%	Difference	95% CI	P value[1]
Change in mTSS of ≤0.5: Week 28/ET					
PBO	153/70	45.8			
PEF100	164/110	67.1	21.3	10.0, 32.6	<0.001
PEF150	164/119	72.6	26.8	15.7, 37.9	<0.001
Change in mTSS of ≤0.5: Week 52/ET					
PBO	153/65	42.5			
PEF100	164/105	64.0	21.5	10.2, 32.9	<0.001
PEF150	164/113	68.9	26.4	15.2, 37.6	<0.001
Change in mTSS of >5: Yearly progression					
PBO	153/54	35.3			
PEF100	164/17	10.4	-24.9	-34.5, -15.4	<0.001
PEF150	164/16	9.8	-25.5	-35.0, -16.1	<0.001

[1]Fisher's exact test.
CI, confidence interval; ET, end of treatment; mTSS, modified Total Sharp Score; PBO, placebo; PEF100, peficitinib 100 mg/day; PEF150, peficitinib 150 mg/day

1. rank ANCOVA with LOCF imputation; 2. rank ANCOVA as observed data; 3. rank ANCOVA using the per protocol set-mTSS as the analysis set; 4. ANCOVA; 5. ANCOVA with multiple imputation method. The proportions of patients with no joint damage (mTSS < 0.5) and yearly progression of mTSS >5 were calculated. Subgroup analyses of mTSS for different demographic and BL characteristics were presented, in which interaction term with treatment group was significant at a two-sided significance level of 0.15 by ad hoc analysis.

Results: In total, 518 patients were included in the FAS: PBO n=170; PEF100 n=174; PEF150 n=174. BL demographics were similar between groups. The primary and secondary endpoint results from RAJ4 were met and have been described previously.[1] Sensitivity analyses showed that the change in mTSS at W28 was similar to the primary analysis result, showing the robustness of the primary analysis (**Table 1**). At W28, a significantly greater proportion of patients achieved a change in mTSS of ≤0.5 for both PEF100 and PEF150 compared with PBO (67.1% and 72.6% vs 45.8%, respectively; p< 0.001 for both). This was maintained at W52 (64.0% and 68.9% vs 42.5%, respectively; p< 0.001 for both) (**Table 2**). The proportion of patients showing rapid radiographic progression (yearly progression of mTSS ≥5) was also significantly lower for both PEF100 and PEF150 compared with PBO (10.4% and 9.8% vs 35.3%, respectively; p< 0.001 for both: **Table 2**).

Selected parameters from the subgroup analysis showing significant results for their interaction with treatment group were age group, BL mTSS, BL DAS28-CRP, duration of RA, BL CRP, concomitant steroid at BL, prednisone dose at BL, and body weight at screening at a two-sided significance level of 0.15 by ad hoc analysis (**Table 3**).

Conclusion: Peficitinib 100 mg and 150 mg both demonstrated significant inhibition of joint destruction compared with PBO**.**

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

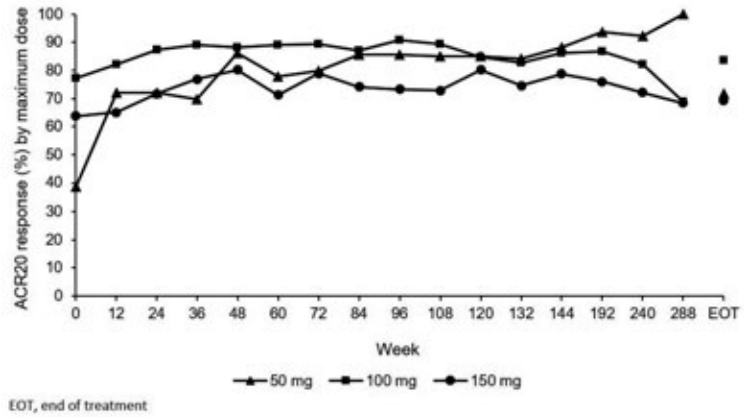
Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Peficitinib, a novel oral Janus kinase (JAK) inhibitor, demonstrated efficacy and an acceptable safety profile in a Phase 2b study (RAJ1 study, NCT01649999) and in Phase 3 studies (RAJ3 study [inadequate

Figure: ACR20 response at each visit by maximum dose level (full analysis set)



EOT, end of treatment

Table: Overview of treatment-emergent adverse events in the overall period (safety analysis set)

	RAJ1 (N=201)	RAJ3 (N=225)	RAJ4 (N=417)	Total (N=843)
All TEAEs, n (%)	193 (96.0)	201 (89.3)	363 (87.1)	757 (89.8)
All SAEs, n (%)	49 (24.4)	40 (17.8)	49 (11.8)	138 (16.4)
Drug-related[1] TEAEs, n (%)	172 (85.6)	148 (65.8)	266 (63.8)	586 (69.5)
Drug-related[1] SAEs, n (%)	19 (9.5)	27 (12.0)	30 (7.2)	76 (9.0)
≥ Grade 3 TEAE[2], n (%)	63 (33.8)	51 (22.7)	70 (16.8)	189 (22.4)
Most common TEAEs occurring in ≥10% of patients in the overall period, n (%)				
Nasopharyngitis	109 (54.2)	79 (35.1)	147 (35.3)	335 (39.7)
Rheumatoid arthritis	47 (23.4)	21 (9.3)	37 (8.9)	105 (12.5)
Herpes zoster	31 (15.4)	25 (11.1)	43 (10.3)	99 (11.7)
TEAEs leading to permanent discontinuation, n (%)				
All	39 (19.4)	19 (8.4)	29 (7.0)	87 (10.3)
Drug-related[1]	22 (10.9)	12 (5.3)	21 (5.0)	55 (6.5)
SAEs	20 (10.0)	12 (5.3)	18 (4.3)	50 (5.9)
Drug-related SAEs	9 (4.5)	8 (3.6)	13 (3.1)	30 (3.6)
Deaths[3]	0	0	1 (0.2)	1 (0.1)
Mean duration of study drug exposure (months)[4]	41.6	17.9	16.2	22.7
Incidence rates (95% confidence interval) of TEAEs of special interest per 100 patient years*				
Serious infections	1.1 (0.6, 2.3)	4.3 (2.6, 7.3)	2.5 (1.5, 4.2)	2.3 (1.6, 3.1)
Herpes zoster-related disease	4.9 (3.4, 6.9)	7.8 (5.3, 11.5)	8.5 (6.4, 11.4)	6.8 (5.6, 8.3)
Malignancy	0.7 (0.3, 1.7)	1.5 (0.6, 3.5)	1.4 (0.7, 2.8)	1.1 (0.7, 1.8)

Treatment-emergent adverse events were defined as any AE that started or worsened in severity after initial dose of study drug in the extension study until the end of the final observation.

*Patient-years definition: PYs = from initial dose date up to first incidence of infections that require intravenous anti-infectious therapy for patients who had at least 1 event. Otherwise, the duration of the patients are summed as from initial dose through follow-up; count = number of patients who had at least 1 infection that require intravenous anti-infectious therapy; incidence rate = calculated as (100 × number of patients who had at least 1 incidence / total patient-year).

[1]Possible or probable, as assessed by the investigator or records where relationship is missing.

[2]National Cancer Institute Common Terminology Criteria for Adverse Events (NCI-CTCAE): grade 3, severe or medically significant; grade 4, life-threatening; grade 5, death related to AE.

AE, adverse event; SAE, serious adverse event; TEAE, treatment-emergent adverse event.

[3]One death during the study due to diffuse large B-cell lymphoma, considered probably related to the study drug, and one death after the end of the study due to uterine sarcoma, considered possibly related to the study drug.

[4]Duration of exposure for overall period (days) was calculated as: date of the last dose of study drug - date of initial dose of study drug + 1

response to DMARDs], NCT02308163, and RAJ4 study [inadequate response to MTX], NCT02305849). In this long-term interim extension study (NCT01638013), we report the safety and efficacy data for peficitinib (mean treatment exposure, 22.7 months) in patients who previously completed these Phase 2b and 3 studies.

Methods: This multicenter, open-label extension study was conducted in Japan, Korea and Taiwan. All patients had RA previously diagnosed according to 1987 ACR criteria or 2010 ACR/EULAR criteria (RAJ1 study followed 1987

ACR criteria exclusively). Patients received oral peficitinib (50 mg, 100 mg or 150 mg) once daily. The starting dose was 100 mg (RAJ3/4) or 50 mg (RAJ1). Doses could be increased to 150 mg/day or reduced (from 100 mg/day or 150 mg/day) to 50 mg/day according to clinical response and safety assessment, as judged by the investigator. Prior and concomitant administration of study-specific non-biological DMARDs was dependent upon the preceding study. For patients in the RAJ1 study and RAJ3 monotherapy study with peficitinib, administration of DMARDs was prohibited from the end of the assessments to the initiation of administration of peficitinib in this extension study. For the RAJ3/RAJ4 peficitinib combination studies, with DMARDs (including MTX) and MTX, respectively, subjects received the concomitant drug concerned from the termination of study to the initiation of administration of peficitinib and throughout the treatment period in this extension study. Discontinuation of the concomitant drug or alteration of the dose was permitted within the range not exceeding or falling below the baseline dose in the previous study. Efficacy outcomes were assessed in the total patient population and grouped according to their preceding study.

Results: In total, 843 patients received peficitinib: RAJ1, n=201; RAJ3, n=225; RAJ4, n=417. During long-term treatment, ACR20 responses were maintained from baseline for patients receiving maximum doses of 100/150 mg/day, and were improved then maintained in patients receiving maximum doses of 50 mg/day **(Figure)**. ACR components and DAS28-CRP also demonstrated continuous improvements from the baselines of preceding studies. Treatment-emergent adverse events (AEs) were reported in 757 (89.8%) patients **(Table)**, primarily grade 1/2 in severity; the most common were nasopharyngitis, RA and herpes zoster. Rates of AEs of special interest (serious infections, herpes zoster-related disease and malignancies) were greater for patients from RAJ3/4 than RAJ1. There was no evidence to support a trend towards increasing incidence rate/100 patient years with treatment duration. One death during and one death after the study were considered probably and possibly related to study drug, respectively **(Table)**.

Conclusion: This interim analysis after 22.7 months mean treatment exposure demonstrated no additional safety concerns were observed with longer term administration of peficitinib in RA patients, and efficacy was maintained for the study duration.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK1-selective inhibitor, was evaluated in a comprehensive clinical program of 5 pivotal Phase 3 randomized-controlled trials (RCTs) across the full spectrum of RA patient (pt) populations[1-5].

Assess the overall safety of UPA as monotherapy (mono) and as combination therapy with background csDMARDs in pts with moderately to severely active RA from the safety database of the Phase 3 clinical program.

Methods: Treatment-emergent adverse events (TEAEs) from 5 pivotal, randomized, double-blind, placebo- or active-controlled Phase 3 trials of UPA 15 mg (included in all 5 trials) or 30 mg QD (included in 4 trials) in RA pts were analyzed and summarized for the integrated placebo (PBO) (3 trials; 12/14 weeks), the integrated methotrexate (MTX) (2 trials; mean exposure: 36 weeks), the originator adalimumab (ADA) (mean exposure: 42 weeks), the UPA 15 mg (mean exposure: 53 weeks) and the UPA 30 mg (mean exposure: 59 weeks) groups as exposure adjusted event rates (EAERs; events/100 patient-years [E/100PY]).

ACR/ARP 2019 *Submission deadline: Tuesday, June 4, 2019, noon Eastern Time*

ISS Overall Safety_Modified Encore

Table. Overall TEAEs and AESIs in patients treated with UPA compared to PBO and active controls

				UPA All Phase 3 Long-term	
	PBO Pooled N=1042, PYS=256.8, E/100 PY (95% CI)	MTX, Pooled[a] N=530, PYS=368.7, E/100PY (95% CI)	ADA 40 mg EOW N=579, PYS=467.8, E/100PY (95% CI)	Any UPA 15 mg QD N=2630, PYS=2655.1 E/100PY (95% CI)	Any UPA 30 mg QD N=1204, PYS=1365.0 E/100PY (95% CI)
Any AE	447.4 (421.9, 474.1)	321.7 (303.6, 340.5)	294.8 (279.4, 310.8)	295.7 (289.2, 302.3)	368.7 (358.6, 379.0)
Any SAE	9.3 (6.0, 13.9)	11.9 (8.7, 16.0)	15.6 (12.2, 19.6)	15.0 (13.6, 16.6)	21.3 (18.9, 23.9)
Any AE leading to discontinuation	10.9 (7.2, 15.8)	9.5 (6.6, 13.2)	11.1 (8.3, 14.6)	8.4 (7.4, 9.6)	13.3 (11.5, 15.4)
Deaths[b]	0.8 (0.1, 2.8)	0.3 (0.0, 1.5)	0.9 (0.2, 2.2)	0.5 (0.3, 0.8)	1.0 (0.5, 1.7)
AESIs					
Serious Infections	3.1 (1.3, 6.1)	2.7 (1.3, 5.0)	4.3 (2.6, 6.6)	3.8 (3.1, 4.7)	6.2 (5.0, 7.7)
Herpes Zoster	1.2 (0.2, 3.4)	1.4 (0.4, 3.2)	1.3 (0.5, 2.8)	3.7 (3.0, 4.5)	7.0 (5.7, 8.6)
MACE (adjudicated)	1.2 (0.2, 3.4)	0.5 (0.1, 2.0)	0.4 (0.1, 1.5)	0.6 (0.4, 1.0)	1.0 (0.5, 1.6)
VTE (adjudicated)	0.4 (0.0, 2.2)	0.5 (0.1, 2.0)	1.1 (0.3, 2.5)	0.6 (0.3, 1.0)	0.3 (0.1, 0.8)
Any non-melanoma skin cancer (NMSC)	0.4 (0.0, 2.2)	0.3 (0.0, 1.5)	0.2 (0.0, 1.2)	0.3 (0.1, 0.6)	1.1 (0.6, 1.8)
Any malignancy other than NMSC	0.4 (0.0, 2.2)	0.8 (0.2, 2.4)	0.6 (0.1, 1.9)	0.9 (0.5, 1.3)	1.4 (0.8, 2.2)

[a]Includes patients on MTX monotherapy censored at time of rescue to combination therapy (either to UPA + MTX or addition of csDMARD); [b]Deaths included non-treatment emergent deaths (3 on UPA 15 mg, 3 on UPA 30 mg and 1 on ADA). MACE was defined as CV death, non-fatal MI, and non-fatal stroke. VTE was defined as deep vein thrombosis and pulmonary embolism.

ADA, adalimumab, AE, adverse events; E, events; EOW, every other week; MACE, major adverse cardiovascular events; MTX, methotrexate; PBO, placebo; PYS, patient years; QD, once-daily; SAE, serious adverse events; TEAEs, treatment-emergent AEs; UPA, upadacitinib; VTE, venous thromboembolic events.

Results: Across the Phase 3 trials, 3834 pts received ≥1 dose of UPA 15 mg (n=2630) or 30 mg QD (n=1204), with no option to switch doses, for a total of 4020.1 PY of UPA exposure. The EAERs of overall SAEs and AEs leading to discontinuation on UPA 15 mg were comparable to ADA; while the rates of both were higher on UPA 30 vs UPA 15 mg and MTX. Across the studies, upper respiratory tract infection, nasopharyngitis and urinary tract infections were the most commonly reported AEs and occurred more frequently in the UPA compared with PBO. Rates of deaths were comparable across the treatment groups. Serious infection (SIEs) rates were comparable between UPA 15 mg and ADA while higher on UPA compared with MTX. Rates of herpes zoster (HZ) were higher in both UPA groups vs MTX and ADA. The rates of SIE and HZ were higher on UPA 30 vs 15 mg. Rates of malignancies (excluding non-melanoma skin cancer [NMSC]) and adjudicated MACE and VTE were comparable across the treatment groups. The rate of NMSC in UPA 15 mg, MTX and ADA groups were similar with higher rates in the UPA 30 mg group, however the rates for both UPA groups were in the range reported for RA patients treated with DMARDs[3]. The age-gender adjusted standardized incidence ratio (SIR, 95% CI) for malignancies other than NMSC (15 mg: 0.98 [0.61, 1.49], 30 mg: 1.49 [0.85, 2.42]) was within the range expected for the general population (SEER 18 Registry 2000-2015).

Conclusion: The rate of SIE on UPA 15 mg was similar to ADA. The rate of HZ was higher on both UPA doses compared to MTX and ADA. The rates of VTE, MACE, and malignancy were comparable with that observed in the MTX and ADA groups while also being consistent with reported rates in the RA population.

Treatment with Upadacitinib Is Associated with Improvements in Reverse Cholesterol Transport in Patients with Rheumatoid Arthritis: Correlation with Changes in Inflammation and HDL Levels

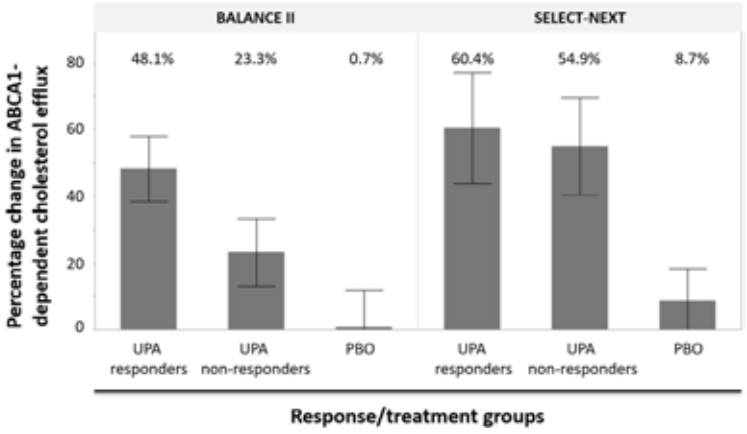
Christina Charles-Schoeman,[1] Thierry Sornasse,[2] and Jeremy Sokolove[2], [1]University of California, Los Angeles, CA, [2]AbbVie Immunology Clinical Development, Redwood City

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a systemic inflammatory condition associated with increased rates of atherosclerotic progression via pathogenic remodeling of high-density lipoprotein (HDL)-associated proteins, resulting in reduction of HDL function.[1] Upadacitinib (UPA), a selective JAK1 inhibitor, has demonstrated efficacy in patients (pts) with moderate-to-severe RA.
We assess UPA treatment on cholesterol efflux capacity (CEC) and evaluate CEC with changes in inflammation and serum lipids.

Methods: A subset of pts from the Phase 2 BALANCE II study[2] and the Phase 3 SELECT-NEXT study[3] were selected from the pool of pts with serum samples available at baseline and Week (Wk) 12. Pts were matched for age and sex, and selected based on level of response to UPA therapy (BALANCE II, UPA 6mg BID: 39 responders [mean change in DAS28-CRP at Wk 12 -3.22] and 30 non-responders [mean change in DAS28-CRP -0.33]; SELECT-NEXT, UPA 15mg

Figure: Changes in ABCA1-dependent cholesterol efflux are significantly elevated in UPA-treated patients at Week 12



QD: 20 responders [mean change in DAS28-CRP -3.78] and 20 non-responders [mean change in DAS28-CRP -0.67]). A demographically similar placebo (PBO) group without selection based on degree of response was also included (20 pts from each study). J774 macrophages labeled with [^{3}H]-cholesterol (treated with cAMP to express ABCA1 or left untreated) were exposed to patient sera. The difference between cholesterol efflux from serum-exposed and unexposed cells provided a measurement of CEC. Results were compared between the responder, non-responder, and PBO groups using Tukey's mean comparison method; correlations were calculated using the Pearson method; all statistical analyses were performed in JMP 13.10 (SAS Institute).

Results: In both studies, changes in global and ABCA1-dependent CEC, and to a lesser extent non-ABCA1-dependent CEC, were significantly higher in the UPA-treated group compared with the PBO group (Figure). In the BALANCE II study, there was a significant increase in CEC among UPA responders relative to PBO and a numerically apparent difference observed between UPA non-responders and PBO. Notably, in the SELECT-NEXT study, a similar and highly significant improvement in CEC was observed for both UPA-treated groups relative to PBO (without a significant difference between the responder and non-responder groups). Despite the lack of a consistent association between change in CEC and change in clinical disease activity, observed increases in CEC correlated significantly with reductions in CRP levels in all groups across all active treatment groups. Additionally, increases in CEC at Wk 12 correlated well with changes in total blood cholesterol and HDL levels, but weakly with changes in blood low-density lipoprotein (LDL) levels.

Conclusion: UPA treatment is associated with significant improvement in CEC. This effect was observed even among those demonstrating minimal clinical response (but not in those treated with PBO). The effect seems to be primarily driven by ABCA1-dependent cholesterol efflux and is strongly correlated with a rise in HDL cholesterol as well as reduction in systemic inflammation as measured by change in CRP.

Wells,[2] Andrea Rubbert-Roth,[3] Manish Jain,[4] Casey Schlacher,[5] Heidi Camp,[5] Yihan Li,[5] Yanna Song,[6] and Peter Nash[7], [1]University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom, [2]Rheumatology and Immunotherapy Center, Franklin, [3]Kantonsspital St. Gallen, St Gallen, Switzerland, [4]Rheumatology, Great Lakes Clinical Trials, Great Lakes, [5]AbbVie Inc., North Chicago, IL, [6]AbbVie Inc., North Chicago, IL, USA, North Chicago, [7]University of Queensland, Brisbane, Queensland, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), a selective JAK1 inhibitor, has demonstrated efficacy and safety in patients with rheumatoid arthritis (RA) as monotherapy and in combination with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) such as methotrexate (MTX).[1,2] However, UPA monotherapy has not been compared directly with UPA combination therapy in the Phase 3 program.
We compare the efficacy of UPA monotherapy and UPA in combination with MTX using data from two Phase 3 trials of RA patients with an inadequate response (IR) to prior MTX therapy.

Methods: In SELECT-MONOTHERAPY, 648 MTX-IR patients were randomized to receive UPA 15 mg or 30 mg monotherapy once daily (QD), or continue with MTX monotherapy (cMTX; given as a blinded study drug), for 14 weeks. In SELECT-NEXT, 661 csDMARD-IR patients were randomized to receive UPA 15 mg or 30 mg QD or placebo (PBO) for 12 weeks on a background of csDMARDs. Only patients receiving concomitant MTX (with or without additional csDMARDs) at baseline in SELECT-NEXT were included in this analysis. The primary endpoints of both studies were the proportion of patients achieving ACR20 and DAS28(CRP) ≤3.2. Additional endpoints included ACR50/70, DAS28(CRP) < 2.6, CDAI remission (≤2.8), CDAI low disease activity (LDA; ≤10), and change from baseline in HAQ-DI. Logistic regression or ordinary least squares analyses were used to compare outcomes with monotherapy versus combination therapy, adjusting for demographics and baseline disease characteristics.

Results: A total of 1114 patients were included in the analysis, of whom 648 received monotherapy in SELECT-MONOTHERAPY and 466 received combination therapy in SELECT-NEXT. Of the patients receiving combination therapy, 338 (72.5%) were receiving MTX background therapy only and 128 (27.5%) were receiving MTX plus other csDMARDs. Baseline characteristics were generally similar between the study cohorts; the majority of patients in both studies were female and of white ethnicity, with a mean age of approximately 55 years and a mean MTX dose of approximately 17 mg/week. Consistent with previously reported results from SELECT-MONOTHERAPY[1] and SELECT-NEXT,[2] both UPA monotherapy and UPA combination therapy led to significant improvements in efficacy outcomes versus cMTX/PBO+MTX (Table). No significant differences were observed between UPA monotherapy and UPA combination therapy across a range of clinical endpoints, including ACR20/50/70 responses and measures of LDA and remission. In addition, improvements in quality of life as measured by HAQ-DI were similar with UPA monotherapy and combination therapy. Efficacy was comparable between the two UPA doses in the combination therapy group, whereas in the monotherapy group numerically higher responses were observed with UPA 30 mg versus UPA 15 mg.

Table. Week 12/14 efficacy outcomes in patients receiving monotherapy and combination therapy.

Endpoint	Monotherapy (Week 14) (SELECT-MONOTHERAPY)			Combination therapy with MTX (Week 12) (SELECT-NEXT)			p-value (mono vs combo)[a]	
	cMTX (n=216)	UPA 15 mg QD (n=217)	UPA 30 mg QD (n=215)	PBO+MTX (n=165)	UPA 15 mg QD+MTX (n=148)	UPA 30 mg QD+MTX (n=153)	UPA 15 mg QD	UPA 30 mg QD
ACR20, %	41.2	67.7	71.2	38.2	66.2	65.4	0.962	0.561
DAS28(CRP) ≤3.2, %	19.4	44.7	53.5	18.2	48.6	49.7	0.564	0.878
ACR50, %	15.3	41.9	52.1	16.4	41.2	43.1	0.578	0.217
ACR70, %	2.8	22.6	33.0	4.8	20.9	26.1	0.172	0.134
DAS28(CRP) <2.6, %	8.3	28.1	40.9	9.7	28.4	30.7	0.594	0.142
CDAI ≤2.8, %	0.9	12.9	19.5	3.0	9.5	13.7	0.063	0.069
CDAI ≤10, %	24.5	34.6	46.5	20.6	41.2	43.8	0.164	0.661
HAQ-DI change from baseline	-0.22	-0.56	-0.63	-0.32	-0.61	-0.60	0.593	0.108

[a]Based on logistic regression (binary outcomes) or ordinary least squares (continuous outcome) analyses for the comparison of monotherapy versus combination therapy, with treatment group as the fixed factor and various demographic (age, sex, race, region, weight, and smoking status) and baseline characteristics (hsCRP, DAS28[CRP], HAQ-DI, RA duration, and RF and anti-CCP positivity) as covariates.

Conclusion: In MTX-IR patients with RA, the efficacy of UPA appears comparable when administered as monotherapy or when given in combination with MTX.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Early treatment of RA within the therapeutic window (0-3 months from symptom onset), has been associated with improved clinical outcomes and physical function. However, ≤42% of RA patients (pts) visit a rheumatologist within 90 days of symptom onset[1,2]. Upadacitinib (UPA), an oral, reversible, potent JAK-1 selective inhibitor[3] demonstrated efficacy in pts with moderate to severely active RA who were MTX-naïve or had an inadequate response to csDMARDs/bDMARDs[4-6].

Methods: In SELECT–EARLY, MTX-naïve pts with active RA and poor prognosis were randomized 1:1:1 to once-daily UPA monotherapy at 15 or 30 mg or weekly MTX (titrated up to 20 mg/week through Week 8). Efficacy (including ACR, DAS28(CRP), CDAI responses and change in mTSS) and safety outcomes from a post-hoc analysis of patients who received treatment within 90 days from diagnosis are reported here. The statistical significance defined as $p< 0.05$ was exploratory in nature.

Results: A total of 270 pts commenced treatment within 90 days from RA diagnosis (median: 44 days [11, 89]). Pts in each arm were mostly female (70%), had moderately to severely active RA with mean DAS28(CRP) =5.9±1.02, had structural joint damage (mean mTSS =7.7±21.5) and were seropositive for both ACPA and RF at baseline (72%)4.

VTE (adjudicated)	0	0	0
	*Deaths: UPA 30, 1 CV death, 1 death due to pneumonia and sepsis ¥Herpes zoster: All events were mild to moderate ϕ Gastrointestinal perforation: UPA 30, 1 pt with large intestinal perforation δ MACE, major adverse cardiovascular events (adjudicated): UPA30, 1 non-fatal MI and 1 CV death (sudden).		

AE, adverse event; NMSC, non-melanoma skin cancer; VTE, venous thromboembolic events; PE, pulmonary embolism. DVT, deep vein thrombosis.

At Week 24, compared to MTX, significantly greater proportions of pts receiving UPA 15 or 30 mg monotherapy achieved efficacy outcomes including ACR20, 50 and 70 responses, DAS28CRP< 2.6, CDAI≤2.8 or Boolean remission. Improvements in physical function (HAQ-DI) and decrease in pain were also significantly greater in pts receiving UPA 15 and 30 mg vs MTX at Week 24. Treatment with UPA was also associated with a greater inhibition of structural joint damage compared with MTX (Table 1). Safety outcomes were consistent with the full study and the integrated

safety analysis (all phase 3 studies of UPA). Compared to MTX, higher frequencies of serious infections and herpes zoster were reported in both UPA groups. There were 2 deaths in total (UPA 30 mg: 1 due to cardiovascular death and 1 due to pneumonia and sepsis) (Table 2).

Conclusion: In RA pts, early initiation of treatment with UPA 15 mg and 30 mg monotherapy within 3 months from diagnosis was associated with clinically meaningful improvements in efficacy, including remission and inhibition of progression of structural joint damage compared to MTX. The safety profile was consistent with the overall study and the integrated phase 3 safety analysis[7]. UPA was more effective than MTX in enabling more patients to reach their treatment targets of remission or low disease activity when treated within 3 months of diagnosis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In the SELECT-MONOTHERAPY trial, upadacitinib (UPA), an oral JAK1-selective inhibitor, showed efficacy when used as monotherapy over 14 weeks (wks) in rheumatoid arthritis (RA) patients (pts) with an inadequate response to methotrexate (MTX).[1]

Safety and efficacy of UPA monotherapy were assessed through 48 wks in an ongoing long-term extension period of SELECT-MONOTHERAPY.

Methods: At baseline (BL), pts on stable MTX were randomized to either continue MTX (cMTX, given as a blinded study drug) or switch to once-daily (QD) UPA at 15 (UPA15) or 30 mg (UPA30) monotherapy for 14 wks. From Wk14, the start of a long-term blinded extension, pts randomized to cMTX were switched to UPA15 or 30mg per pre-specified assignment at BL, pts randomized to UPA15 or 30 continued their initial treatment. No dose adjustments

[§]Serious Infection: Most frequently reported SI were pneumonia, bronchitis, cellulitis, HZ and UTI

[‡]Herpes zoster: mostly 1 or 2 dermatomes,1 opthalmic

[*]Hepatic disorder: mostly transaminase elevations that were mild to moderate in severity.

[Y]Malignancies: 5 breast cancers (UPA15: 3 pts, UPA30: 2 pts), 2 colorectal cancers (UPA15:1 pt, UPA30:1 pt), 1 non-Hodgkin's lymphoma (UPA15), 1 malignant melanoma (UPA30)

[δ]MACE : UPA15: 3 CV deaths; UPA 30: 2 non-fatal MI, 2 non-fatal stroke; 1 CV death

[†]Deaths: UPA15: 1 hemorrhagic stroke (ruptured aneurysm), 1 congestive cardiomyopathy and 1 sudden cardiac death; UPA30: 1 fatal MI.

for UPA were allowed. Starting at Wk26, for pts who did not achieve CDAI ≤10, background csDMARDS could be initiated. Efficacy data up to the Wk48 visit are reported "As Observed". Adverse events (AE) per 100 pt yrs (PYs) are summarized up to May 25 2018.

Results: Of 648 pts randomized at BL, 598 (92%) completed 14 wks and continued on to the extension period. By May 25 2018, 16% discontinued study drug; 5% due to AE, 0.5% due to lack of efficacy, 4% withdrew consent, 1% were lost to follow-up, and 6% discontinued due to other reasons. Cumulative exposures to UPA15 and UPA30 were 336.0 PYs and 337.1 PYs, respectively. Starting from Wk26, background csDMARDs were initiated for approximately18% of pts. Based on As Observed data, for pts on UPA from BL through Wk48 on UPA15 [250/300 (83%)] and UPA30 [251/298 (84%)], clinical and functional outcomes continued to improve, or were maintained (Table 1). For pts continuing UPA15 and 30, DAS28-CRP< 2.6 was 55% and 68%, and CDAI≤2.8 was 28% and 42%, respectively. Pts who were switched from cMTX to UPA15 or 30 at Wk14 had similar responses at Wk 48. The most frequently reported treatment-emergent AEs were urinary tract infection, blood creatine phosphokinase increase, upper respiratory tract infection, nasopharyngitis, worsening of RA, herpes zoster (HZ), alanine aminotransferase increase, and bronchitis. The most frequently reported serious AE was pneumonia (8 events). Events/100PYs were numerically higher in the UPA30 vs UPA15 arm for HZ, and hepatic disorders, and were comparable for serious infections and malignancies excluding non-melanoma skin cancer (Table 2). Adjudicated venous thromboembolic events (VTE) were observed only on UPA15 (2 pts with deep vein thrombosis and 2 pts with pulmonary embolism; all patients had at least one risk factor for VTE).

Conclusion: UPA 15 or 30 monotherapy resulted in similar improvements in signs and symptoms and physical function through 48 wks. The overall benefit-risk profile of both doses of UPA was favorable based on the safety and efficacy data through Wk48 but will be confirmed through an integrated safety analysis across all the phase 3 trials.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: SB4, SB2, and SB5 are biosimilars of etanercept, infliximab, and adalimumab. Phase III randomized, double-blind studies were conducted to compare efficacy and safety between biosimilars and reference products.

The objective of this study is to assess and compare 1-year outcomes among 6-month responders and non-responders.

Methods: Patients who had 6-month data from each phase III study were pooled and categorized, based on their disease status at 6 months (week 24 for etanercept and adalimumab and week 30 for infliximab) and 1 year (week 52 for etanercept and adalimumab and week 54 for infliximab).

Responders included patients who achieved an ACR20 response or low disease activity (including remission) by DAS28, SDAI, or CDAI at 6 months. Those who did not or dropped out were considered non-responders.

Table 1. Proportion of responders at 1 year based on 6-month clinical outcomes

Group	ACR20 responders at 1 year (n,%)		DAS28 (Remission + LDA) at 1 year (n,%)		SDAI (Remission + LDA) at 1 year (n,%)		CDAI (Remission + LDA) at 1 year (n,%)	
	Responder at 6 month	Non-responder at 6 month	Responder at 6 month	Non-responder at 6 month	Responder at 6 month	Non-responder at 6 month	Responder at 6 month	Non-responder at 6 month
All Tx Combined	850 (81.9%)	140 (35.1%)	302 (70.4%)	193 (19.1%)	509 (78.8%)	215 (27.3%)	489 (78.0%)	206 (25.4%)
BS Combined	465 (83.2%)	85 (38.3%)	177 (74.1%)	118 (21.8%)	287 (80.8%)	112 (26.5%)	275 (79.5%)	114 (26.2%)
RP Combined	385 (80.4%)	55 (31.1%)	125 (65.8%)	75 (16.1%)	222 (76.3%)	103 (28.2%)	214 (76.2%)	92 (24.5%)
SB4+ETN	359 (83.9%)	46 (37.7%)	121 (69.9%)	73 (19.4%)	219 (82.0%)	77 (27.2%)	207 (82.1%)	73 (24.5%)
SB2+INF	252 (76.6%)	49 (27.8%)	83 (63.8%)	51 (13.6%)	157 (74.1%)	59 (20.2%)	156 (73.2%)	54 (18.5%)
SB5+ADA	239 (85.1%)	45 (44.6%)	98 (77.8%)	69 (27.0%)	133 (79.6%)	79 (37.1%)	126 (77.8%)	79 (35.9%)
SB4	183 (84.3%)	27 (41.5%)	67 (72.8%)	41 (21.6%)	118 (82.5%)	36 (25.9%)	111 (82.2%)	39 (26.5%)
ETN	176 (83.4%)	19 (33.3%)	54 (66.7%)	32 (17.1%)	101 (81.5%)	41 (28.5%)	96 (82.1%)	34 (22.5%)
SB2	123 (77.4%)	24 (27.6%)	44 (68.8%)	28 (15.4%)	80 (75.5%)	25 (18.0%)	79 (74.5%)	25 (17.9%)
INF	129 (75.9%)	25 (28.1%)	39 (59.1%)	23 (11.9%)	77 (72.6%)	34 (22.2%)	77 (72.0%)	29 (19.1%)
SB5	159 (86.9%)	34 (48.6%)	66 (79.5%)	49 (28.8%)	89 (84.0%)	51 (35.2%)	85 (81.0%)	50 (33.8%)
ADA	80 (81.6%)	11 (35.5%)	32 (74.4%)	20 (23.3%)	44 (72.1%)	28 (41.2%)	41 (71.9%)	29 (40.3%)

ACR, American college of rheumatology; ADA, reference product adalimumab; BS, biosimilars; CDAI, Clinical Disease Activity Index scores; DAS28, disease activity score based on 28-joint count; ETN, reference product etanercept ; INF, reference product infliximab; RP, reference products; SDAI, Simplified Disease Activity Index scores, Tx, treatments

The primary outcome was the proportion of responders who maintained responses from 6 months to 1 year or non-responders at 6 months who achieved responses at 1 year.

Results: Data from 1,437 patients were included in the analysis. For all treatments combined, 81.9% of ACR20 responders, 70.4%, 78.8%, and 78.0% of responders with DAS28, SDAI, and CDAI low disease activity (LDA) at 6 months maintained their responses at 1 year, and 35.1%, 19.1%, 27.3%, and 25.4% of 6-month non-responders achieved responses at 1 year, respectively. The proportions of patients maintaining or achieving an ACR20 response or DAS28, SDAI, and CDAI LDA at 1 year were similar across different treatment groups (Table 1).

Conclusion: A pooled analysis of TNF inhibitor biosimilars and reference products showed that about 20-30% of responders lost their response, while about 20-30% gained it. Thus, the overall stability of disease fluctuation in our 1-year phase III studies is a consequence of a similar success and failure rate. The validity of these data can be seen by the similarities in these outcomes between different types of TNF-inhibitors and similarity between biosimilars and respective reference products.

Clinical Responses in Patients with Inadequate Response to bDMARDs upon Treatment with Upadacitinib

Michael Weinblatt,[1] Glen Thomson,[2] Kun Chen,[3] Sebastian Meerwein,[4] Casey Schlacher,[5] and John Cush[6], [1]Brigham and Women's Hospital, Boston, MA, USA, Boston, MA, [2]CIADS Research, Winnipeg, Canada, [3]AbbVie Inc., North Chicago, [4]AbbVie GmbH Co. KG, Ludwigshafen, Germany, Wiesbaden, Germany, [5]AbbVie Inc., North Chicago, IL, [6]5Baylor University Medical Center, Dallas

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), a JAK1-selective inhibitor, demonstrated efficacy in the SELECT-BEYOND study in patients (pts) with moderate to severe rheumatoid arthritis (RA) on a stable dose of csDMARDs who had inadequate response (IR) or intolerance to bDMARDs,. In this analysis we evaluated clinical responses among pts receiving UPA and placebo (PBO) based on the number and mechanism of action (MOA) of prior bDMARDs.

Methods: 498 pts were randomized to UPA 15mg or UPA 30mg once daily (QD) or PBO for 12 weeks (wks), after which pts on PBO received UPA 15 or 30mg QD from Wk 12 onwards.[1] Pts were subgrouped by the number and/or MOA of bDMARD(s) received prior to enrollment: 1) lack of efficacy (LoE) to ≥1 anti-TNF, 2) LoE to an anti-IL-6, and 3) the number of prior bDMARDs (1 vs 2 vs ≥3). ACR20/50/70 responses, DAS28-CRP low disease activity (LDA, ≤3.2), CDAI LDA (≤10), and CDAI remission (≤2.8) were evaluated at Wk 12. The frequency and percentage of treatment-emergent adverse events (TEAE) in each subgroup was assessed over the first 12 wks. Missing values of the efficacy endpoints were imputed using non-responder imputation (NRI). Nominal *P*-values are reported without multiplicity adjustment.

Table 1

	LoE to Anti-TNF			LoE to Anti-IL-6			Overall

CDAI≤2.8 (REM)	6.0	9.3	18.2	4.3	5.0	5.9	2.5	7.9	8.5	4.7	7.9	11.5*

***, **, * statistically significant at 0.001, 0.01, and 0.05 level comparing either UPA dose vs PBO using Cochran-Mantel-Haenszel test adjusting for stratification factor, respectively.
ACR20/50/70, 20%, 50% or 70% improvement in ACR core criteria; DAS28-CRP, 28-joint disease activity score using C-reactive protein; CDAI, clinical disease activity index; LDA, low disease activity; REM, remission

Results: Overall baseline disease duration was ~13 years. The majority of pts had LoE to ≥1 anti-TNF (449, 90%); 88 (18%) had LoE to an anti-IL-6; 235 (47%), 137(28%), and 125 (25%) had been treated with 1, 2, or ≥3 prior bDMARDs, respectively.[1] At Wk 12, clinical responses were numerically, and often statistically, better for pts receiving either dose of UPA vs PBO, irrespective of their prior bDMARD exposure and the number of prior bDMARDs received. As most pts had LoE to ≥1 anti-TNF, responses in this group were comparable to the overall study population **(Table 1)**. Pts with LoE to an anti-IL-6 receiving UPA 15 or 30 mg QD experienced improvements vs PBO, particularly in achieving LDA and remission, although responses in these pts were generally lower compared to the overall study population. As expected, there was a trend towards lower responses as the number of prior bDMARDs increased **(Table 2).** Responses at Wk 24 were generally consistent with those at Wk 12 (data not shown). TEAEs across the subgroups were consistent with the overall study population (data not shown).

Conclusion: At Wk 12, treatment with UPA at either 15 or 30 mg QD led to significantly better clinical responses vs PBO in this treatment-refractory population, including in pts with LoE to an anti-TNF or an anti-IL-6, and those who had IR/intolerance to 1, 2 or ≥3 prior bDMARDs, with consistent safety profiles as to the overall study population.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral selective JAK1 inhibitor, has demonstrated favorable efficacy and acceptable safety in five Phase 3 global studies in patients with moderately to severely active rheumatoid arthritis (RA).[1–5] This analysis reports the efficacy and safety of UPA in predefined RA patient subgroups based on differences in baseline demographics and disease activity.

Methods: Data were pooled from three pivotal, double-blind, PBO-controlled, multicenter, Phase 3 studies in patients with RA who had an inadequate response (IR) to conventional synthetic DMARDs (csDMARD-IR: SELECT-NEXT [N=661]), MTX (MTX-IR; SELECT-COMPARE [N=1629]), or biologic DMARDs (bDMARD-IR: SELECT-BEYOND

Tertile 3	122/360 (34)	251/346 (73)	37/128 (29)	87/129 (67)	36/360 (10)	146/346 (42)	14/128 (11)	60/129 (47)

[a]UPA 15 mg set: Tertile 1: 0.2 – <6.5 mg/L; tertile 2: 6.5 – <15.6 mg/L; tertile 3: 15.6 – ≤198.0 mg/L
UPA 30 mg set: Tertile 1: 0.2 – <5.7 mg/L; tertile 2: 5.7 – <14.1 mg/L; tertile 3: 14.1 – ≤150.0 mg/L
[b]Patients were required to have CRP >3 mg/L (SELECT-NEXT and SELECT-BEYOND) or >5 mg/L (SELECT-COMPARE)

[N=498]). Two integrated analysis sets were evaluated: one comparing UPA 15 mg QD vs PBO (SELECT-NEXT, SELECT-COMPARE, SELECT-BEYOND) and the other comparing UPA 15 mg QD and UPA 30 mg QD vs PBO (SELECT-NEXT, SELECT-BEYOND). All patients received background treatment with csDMARDs. The proportion of patients achieving ACR20 and DAS28(CRP) ≤3.2 at Week 12 was evaluated by predefined baseline demographics and disease activity measure groups, including age, sex, weight, BMI, race, geographic region, duration of RA, RF, and ACPA status, and level of high sensitivity CRP. Non-responder imputation was used for missing data. Subgroup analyses for safety were performed for age, race, sex, weight, BMI, and Asian region.

Results: Across the three Phase 3 studies, 1036, 384, and 1041 patients received UPA 15 mg QD, UPA 30 mg QD or PBO, respectively. The demographic and baseline disease characteristics in the two integrated analysis sets were balanced across treatment groups. ACR20 and DAS28 ≤3.2 response rates at Week 12 were consistently higher with UPA 15 mg and UPA 30 mg vs PBO across the evaluated demographic and baseline disease characteristics (Table).

The efficacy of UPA 15 mg QD was generally similar to that observed with UPA 30 mg QD. At 12 weeks, the proportion of patients with treatment-emergent AEs, serious AEs, severe AEs, and AEs leading to discontinuation were generally comparable across different age, sex, race, weight, and BMI groups. Compared with the global population, patients receiving UPA in the Asian region had a higher rate of CPK elevations (UPA 30 mg only) and herpes zoster; herpes zoster also has been observed to be higher in the Asian region with other JAK inhibitors.[6,7]

Conclusion: In this analysis of pooled integrated efficacy data in csDMARD-IR or bDMARD-IR patients with RA, UPA 15 mg or 30 mg QD in combination with csDMARDs improved efficacy outcomes at Week 12 when compared with PBO across all predefined subgroups evaluated.

Table 1. Efficacy outcomes ACR20, DAS28(CRP) for low disease activity and remission at week 12 relative to prior bDMARD use Data presented as n (%) unless otherwise specified. bDMARD, biologic DMARD; CI, confidence interval; FIL, filgotinib; MOA, mechanism of action; PBO, placebo; QD, once daily.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is an unmet medical need to treat RA in patients who have failed prior biologic DMARD treatments (biologic DMARD inadequate response; bDMARD-IR), some of which target the IL-6 pathway. Patients who are bDMARD-IR are considered more treatment resistant and have more variable responses to treatment than treatment- or bDMARD-naïve patients. Questions remain as to whether the clinical efficacy of the oral, selective Janus kinase (JAK)-1 inhibitor filgotinib differs among patients with prior exposure to IL-6 inhibitors. We explored the efficacy of filgotinib in bDMARD-IR patients with active RA based on number and mechanism of action (MOA) of prior biologics.

Methods: The global, phase 3 FINCH-2 (NCT02873936) study enrolled 449 bDMARD-IR patients with active RA, who were randomized in a 1:1:1 manner to receive once-daily filgotinib 200 mg, filgotinib 100 mg, or placebo for 24 weeks.[1] This subgroup analysis evaluated filgotinib efficacy respective to the number and MOA of prior bDMARD use. Clinical efficacy was assessed using ACR20, DAS28(CRP) for low disease activity and remission, and patient-reported outcomes at weeks 12 and 24. Quality-of-life outcomes were assessed by change in HAQ disability index (HAQ-DI), change in SF-36-Physical Component score, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) at weeks 12 and 24.

	Δ from baseline			LSM of treatment difference, 95% CI, p-value

Table 2. Quality of life outcomes HAQ-DI, SF-36 physical component, and FACIT-F change from baseline at week 12 with respect to prior bDMARD use Data presented as mean (SD) unless otherwise specified. bDMARD, biologic DMARD; CI, confidence interval; FACIT-F, Functional Assessment of Chronic Illness Therapy-Fatigue; FIL, filgotinib; LSM, least squares mean; MOA, mechanism of action; PBO, placebo; PCS, physical component summary; QD, once daily; SD, standard deviation.

Results: Of the 448 patients randomized and treated at baseline, 80.4% were female with a mean age of 56 years and a mean RA duration of 12.4 years. Prior bDMARD exposure, including the total number and MOA, was well balanced amongst the 3 treatment arms. Clinical efficacy outcomes—as measured by ACR20, DAS28(CRP) ≤3.2, and DAS28(CRP) < 2.6—are provided in **Table 1**. Quality-of-life outcomes—as measured by change in HAQ-DI, change in SF-36-Physical Component score, and FACIT-F at week 12—are provided in **Table 2**.

Conclusion: Compared with placebo, filgotinib demonstrated improved clinical outcomes in bDMARD refractory patients. The efficacy observed with filgotinib was maintained with no significant effects based on the number and MOA of prior bDMARD use, including in patients with prior exposure to IL-6 inhibitors.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients (pts) with active rheumatoid arthritis (RA) and inadequate response or intolerance to bDMARDs, treatment with upadacitinib (UPA), a JAK1-selective inhibitor resulted in significant improvements over 24 weeks (wks).[1]

We assessed UPA safety and efficacy through Wk60 in an ongoing extension of the phase 3 SELECT-BEYOND study.

Methods: SELECT-BEYOND enrolled a population of patients with active RA who had failed at least one prior biologic therapy.[1] Pts received UPA 15mg or 30mg once daily (QD) or placebo (PBO) on top of background csDMARD treatment for 12 wks. From Wk12, pts randomized to UPA at baseline (BL) continued their assigned doses, while pts initially randomized to PBO received UPA 15mg or 30mg QD per pre-specified assignment at BL. Patients who completed Wk 24 entered the blinded long-term extension. Dose adjustments to UPA were not allowed. Adverse events (AE) per 100 pt years (PY) are summarized based on a cut-off date of 16 April 2018. Efficacy data up to the Wk60 visit are reported "As Observed".

Results: 418/498 (84%) pts were randomized, completed 24 wks and entered the extension on study drug. By the safety data cut-off date, 19% pts discontinued study drug: 5% due to AE, 4% due to lack of efficacy, 3% withdrew consent, 2% were lost to follow-up, and 5% discontinued due to other reasons. Cumulative exposures to UPA15 and UPA30 were 301.7 and 290.7 PYs, respectively. Rates (Events/100PYs) of treatment-emergent AEs are reported (Table 1), and were numerically higher in the UPA30 vs UPA15 arm for serious AEs, AEs leading to discontinuation, serious infections, herpes zoster and hepatic disorders. Based on As Observed analysis, for pts completing Wk60 on UPA15 [172/216 (80%)] and UPA30 [168/202 (83%)], clinical and functional outcomes continued to improve compared to Baseline, or were maintained from Wk24 onwards1 in pts initially randomized to UPA15 or 30; Remission by CDAI≤2.8 at Wk60 was achieved by 20% and 32%, respectively, and DAS28-CRP< 2.6 was achieved by 53% and 52%. Pts who were switched to UPA from PBO at Wk12 had comparable efficacy to pts initially randomized to UPA (Table 2).

Table 1. Treatment-Emergent Adverse Events; Event Rate in E/100PYs		
	UPA 15 MG N=236 PYs=301.7 E/100PYs	UPA 30 MG N=240 PYs=290.7 E/100PYs
Any Adverse Event (AE)	353.3	435.8
Serious AE	17.9	29.2
AE Leading To Study Drug D/C	9.6	15.1
Serious Infection[§]	3.0	8.3
Herpes Zoster[ǂ]	4.6	8.9
Hepatic disorder[¥]	4.6	8.3
Any Malignancy (exc NMSC)[γ]	1.7	1.0
MACE (adjudicated)[δ]	1.0	0.3
VTE (adjudicated)[β]	2.3	0.7
Deaths[†]	0.7	1.0

E, events; PYs, patient-years; E/100PYs, events per 100 patient-years; NMSC, non-melanoma skin cancer; MACE, major adverse cardiovascular event (cardiovascular death, non-fatal myocardial infarction (MI), non-fatal stroke); VTE, venous thromboembolism (DVT, deep vein thrombosis; PE, pulmonary embolism).
[§]Most frequently reported serious infections were pneumonia, HZ, influenza, and respiratory tract infections.
[ǂ]HZ: most involved 1 or 2 dermatomes. No meningoencephalopathic/ noncutaneous involvement. Two HZ events were reported as ophthalmic.
[γ]Malignancy (excluding NMSC): UPA15: 1 malignant melanoma in situ, 1 bladder cancer, 1 pancreatic carcinoma Stage IV, 1 colon cancer, 1 non-small cell lung cancer metastatic; UPA30: 2 prostate cancers, 1 rectal cancer metastatic.
[δ]MACE (adjudicated): UPA15: 1 CV death, 1 non-fatal MI, 1 non-fatal stroke; UPA30: 1 pt with 2 concurrent events (non-fatal MI and acute congestive heart failure) adjudicated to non-fatal MI
[β]VTE:UPA15: 3 pts with PE, 1 pt with DVT, 2 pts with PE and DVT, 1 pt with non-assessable thrombotic event; UPA30: 1 pt with PE, 1 pt with PE and DVT; no dose relationship in the rates of VTE or patterns in the time to onset of the events, were observed.
[†]Deaths: UPA15: 1 due to other CV causes, 1 due to cardiac arrest; UPA30: 1 pt with cardiac decompensation, 1 pt with presumed MI, 1 pt with rectal cancer metastasized to liver

Table 2. Efficacy Endpoints at Week 60 (as observed); Responses compared to Baseline, n/N (%)				
	PBO→ UPA 15 MG	PBO→ UPA 30 MG	UPA 15 MG	UPA 30 MG

Conclusion: The benefit:risk of upadacitinib treatment in this refractory population remains favorable. No new safety signals were identified. Some AEs were numerically higher for UPA30 vs 15; however the clinical significance of this, the assessment of rare safety events in this study, and the overall benefit:risk of upadacitinib 15mg and 30mg in the treatment of RA are best evaluated in an integrated analysis across the phase 3 program. UPA15mg and 30mg continued to be effective in treating RA signs and symptoms, and in improving physical function.

Efficacy of Biosimilar Candidate ABP 710 in a Phase 3 Study in Subjects with Moderate to Severe RA: Additional Analysis Focusing on the ACR Individual Components

Mark Genovese,[1] Juan Sanchez-Burson,[2] Éva Balázs,[3] Andrea Everding,[4] MyungShin Oh,[5] Gary Fanjiang,[5] and Stanley Cohen[6], [1]Stanford University, Stanford, CA, [2]Hospital Infanta Luisa, Sevilla, Spain, [3]Dr. Bugyi István Hospital, Szentes, Hungary, [4]HRF Hamburger Rheuma Forschungszentrum, Hamburg, Germany, [5]Amgen, Thousand Oaks, CA, [6]Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ABP 710 is being developed as a biosimilar to infliximab. Both ABP 710 and infliximab reference product (RP) inhibit tumor necrosis factor-alpha. Following demonstration of analytical (structural and functional) similarity and clinical pharmacokinetic equivalence in a phase 1 study, a comparative phase 3 clinical trial in patients with moderate to severe RA was conducted. The objective of this analysis was to show the results of the ACR individual components for ABP 710 in comparison with infliximab RP.

Methods: In this multicenter, randomized, double-blind study, the efficacy and safety of ABP 710 was compared with the RP in subjects with moderate to severe RA. Subjects were maintained on a stable 7.5 to 25 mg/week dose

Table 1. Response (≥ 20% Improvement) Difference at Week 22 in ACR Components

ACR Component	ABP 710 n/N (%)	Infliximab n/N (%)	RD (%) and 90% CI
Swollen joint count	238/260 (91.5)	233/256 (91.0)	0.24 (-3.91, 4.43)
Tender joint count	237/260 (91.2)	225/256 (87.9)	3.23 (-1.27, 7.77)
Subject's global health assessment	183/260 (70.4)	174/256 (68.0)	2.67 (-4.01, 9.33)
Investigator's global health assessment	229/260 (88.1)	223/256 (87.1)	1.32 (-3.48, 6.15)
Subject's assessment of disease-related pain	196/260 (75.4)	169/256 (66.0)	9.71 (3.12, 16.21)
HAQ-DI	172/260 (66.2)	154/255 (60.4)	5.83 (-1.16, 12.75)
C-reactive protein	146/253 (57.7)	148/252 (58.7)	-0.70 (-7.89, 6.51)

Table 2. Change From Baseline in ACR Components at Week 22

ACR Component	ABP 710 Mean (SD)	Infliximab Mean (SD)	Difference Between Means	90% CI for Difference Between means	95% CI for Difference Between Means	MCII
Subject's assessment of disease-related pain	-30.8 (28.75)	-25.1 (29.33)	-3.77	(-7.38, -0.16)	(-8.08, 0.53)	-20
HAQ-DI	-0.53 (0.59)	-0.44 (0.56)	-0.07	(-0.15, 0.01)	(-0.17, 0.02)	-0.375

of methotrexate and received 3 mg/kg infusions of the investigational products at predetermined intervals. The primary endpoint of the study was response difference (RD) of at least 20% improvement compared with baseline in ACR core set of measurements (ACR20) at week 22. Individual components of ACR were summarized descriptively at each visit, which included swollen joint count and tender joint count, Subject's Global Health Assessment, Investigator's Global Health Assessment, Subject's Assessment of Disease-related Pain, Health Assessment Questionnaire - Disability Index (HAQ-DI) total score, and C-reactive protein (CRP).

Results: Of the 558 randomized subjects, 556 were treated (ABP 710 n=278; RP n=278); 484 subjects continued in the study through week 22 to be re-randomized (ABP 710/ABP 710: n=244; infliximab RP/infliximab RP: n=121; infliximab RP/ABP 710: n=119), and 435 subjects completed the study. Results of the ACR components (based on a response of ≥20% improvement) at week 22 are shown in Table 1. ACR components with the largest RD between treatment groups were Subject's Assessment of Disease-related Pain and HAQ-DI; yet the difference in mean change from baseline and associated 90% and 95% confidence intervals (CIs) were well below the thresholds of minimal clinically important improvement and thus, not clinically meaningful (Table 2).

Conclusion: This analysis of ACR individual components further supports the similarity of ABP 710 and infliximab RP.

Abbreviations: CI = confidence interval; HAQ-DI = Health Assessment Questionnaire - Disability Index; RD = response difference. Note: The point estimate of RD was estimated by the Mantel-Haenszel estimate and the 90% CI was estimated using stratified Newcombe confidence limits adjusting for actual stratification factors.

Abbreviations: ANOVA = analysis of variance; CI = confidence interval; HAQ-DI = Health Assessment Questionnaire - Disability Index; MCII = minimal clinically important improvement; RD = response difference. Note: Difference between means, 90% and 95% CIs for difference between means was based on ANOVA model with change from baseline in HAQ-DI or pain as the response and adjusted for baseline HAQ-DI or pain and the actual stratification factors: geographic region and prior biologic use for RA.

Efficacy and Safety Results from a Phase 3 Study of Biosimilar Candidate ABP 710 in Subjects with Moderate to Severe RA

Mark Genovese,[1] Juan Sanchez-Burson,[2] Éva Balázs,[3] Andrea Everding,[4] MyungShin Oh,[5] Gary Fanjiang,[5] and Stanley Cohen[6], [1]Stanford University, Stanford, CA, [2]Hospital Infanta Luisa, Sevilla, Spain, [3]Dr. Bugyi István Hospital, Szentes, Hungary, [4]HRF Hamburger Rheuma Forschungszentrum, Hamburg, Germany, [5]Amgen, Thousand Oaks, CA, [6]Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: ABP 710 is being developed as a biosimilar to infliximab. Both ABP 710 and infliximab reference product (RP) inhibit tumor necrosis factor-alpha and have been shown to be structurally and functionally similar in analytical assessments. In a phase 1 clinical pharmacokinetic (PK) study, both were shown to be bioequivalent for PK parameters. The final step in the demonstration of biosimilarity is a comparative phase 3 clinical trial in a representative indication. The objective of this study was to evaluate the similarity of ABP 710 compared to RP with respect to efficacy across time in patients with active RA.

Methods: In this multicenter, randomized, double-blind, active-controlled, multiple-dose study, the efficacy and safety of ABP 710 was compared with the RP in subjects with moderate to severe RA while being maintained on a stable 7.5 to 25 mg/week dose of methotrexate. Subjects were randomized to receive a 3 mg/kg intravenous infusion of either ABP 710 or RP on day 1 (week 0), at weeks 2 and 6, and every 8 weeks thereafter until week 22. At week 22, subjects initially randomized to RP were re-randomized to either continue RP or transition to receive ABP 710 through week 46. Subjects initially randomized to ABP 710 continued receiving the same treatment through week 46. The primary endpoint of the study was response difference (RD) of ≥20% improvement in ACR (ACR20) at week 22; secondary endpoints included RD of ACR20, ≥50% improvement (ACR50), and ≥70% improvement (ACR70) across time (weeks 2, 6, 14, 30, 34, 38, 36, and 50). Efficacy data were analyzed by initial treatment (ABP 710 or RP) prior to re-randomization and by initial/re-randomized treatment (ABP 710/ABP 710, RP/RP, RP/ABP 710) after re-randomization.

Week 50	-5.25 (-13.24, 3.29)	-1.49 (-11.01, 8.04)	-5.43 (-14.39, 3.71)	2.98 (-7.51, 13.37)	1.95 (-6.81, 10.29)	12.06 (1.74, 22.04)

Results: Of the 558 randomized subjects, 556 were treated (ABP 710 n=278; RP n=278); 484 subjects completed the study through week 22 and were re-randomized (ABP 710/ABP 710 n=244; RP/RP n=121; RP/ABP 710 n=119), with 435 subjects completing the study. Results of the ACR20, ACR50, and ACR70 response rates across time for the initial or initial/re-randomized treatment groups were similar, with overlapping 95% confidence intervals (CIs) of ACR response rates between the treatment groups at all time points and narrow RD at all time points (see Table for RDs with 90% CI). Efficacy was consistently maintained throughout the study, with no impact of the single transition from RP to ABP 710. Through week 22, the percentage of subjects reporting any serious adverse events was 4.1% (ABP 710=3.2%; RP=5.0%) and the binding/neutralizing antibody positive post-baseline in subjects was 58.9%/19.4% (ABP 710=57.1%/18.0%; RP=60.6%/20.8%).

Conclusion: As demonstrated by the narrow RD of ACRs across the entire study, the efficacy of ABP 710 is similar to the RP. Safety was also found to be similar between treatment groups. In addition to previously reported primary efficacy endpoints, these secondary efficacy results support clinical similarity between ABP 710 and infliximab RP with respect to safety and efficacy.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The treatment of Rheumatoid Arthritis (RA) has undergone a big change in the last two decades with the Disease Modifying Drugs (DMARDs). These drugs are widely used in clinical practice, but we have little information about their discontinuation in this conditions especially due to inefficacy. Purpose: to describe the discontinuations of DMARDs due to inefficacy, their causes in patients with incident RA, and to evaluate possible associated factors to inefficacy.

Methods: We conducted an observational longitudinal study. Patients: all recent onset RA diagnosed between January 1st 2007 and December 31st 2015 followed in outpatient clinic at Hospital Clinico San Carlos until January 1st 2017, which used any DMARD (synthetic and biologic) during at least 3 months. Primary outcome: discontinuation of the DMARD due to inefficacy. Covariables: sociodemographic, clinical and treatments. Incidence rates of discontinuation

Table 1	DISCONTINUATIONS

(IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. Factors associated with DMARDs discontinuation due to inefficacy was performed using Cox regression models, and results were expressed in Hazard ratio (HR) and [CI].

	Multivariate		
	Hazard ratio	**CI 95%**	**p**
Age at diagnosis	0.98	0.97-1.00	0.07
Depression	1.68	1.06-2.67	0.025
RF positive	1.32	0.9-1.9	0.1
Other treatment courses vs first one	1.81	1.1-2.38	0.018
Combined therapy vs monotherapy	1.87	1.14-3.05	0.012
Classical DMARDs Anti-TNF Other biologicals	1 3.2 2.8	 1.92-5.3 1.3-6.28	 0.000 0.009
Glucocorticoids (Dose)	1.99	1.6-2.4	0.000
ESR>55	0.7	0.7-2.0	0.1

Results: We included 2388 courses of DMARD treatment in 814 patients (3706.14 patient-years). 77.52% were women with a mean age at diagnosis of 57.53±15.50 years. There were 1094 DMARDs discontinuations of the 2388 courses (45.81%) in 438 patients, of these 149 in 110 patients (13.5%) were due to inefficacy (IR: 4.0[3.4-4.7]). Most patients discontinuing due to inefficacy were women (87.50%) with a mean age at diagnosis of 52.40±13.50 years. 33.5% of the discontinuations due to inefficacy were biological DMARDs. 61.7% were in combined therapy and most of them (77.18%) discontinued during successive courses of therapy. IRs are shown in table 1. The multivariate analysis (table 2) was adjusted by age, gender and disease activity (ESR). Interestingly, younger age and depression also increased the risk of inefficacy. Combined therapy, second courses, dose of glucocorticoids and biologic vs synthetic DMARDs (HR: 3.12 [1.8-5.2]) increased the risk. We repeated the multiple regression model with all the sociodemographic and clinical variables shown in table 2 but changing the reference category of DMARD and found that Certolizumab (HR: 5.0[2.5-9.8]) had the highest risk of discontinuation due to inefficacy compared to the other drugs followed by Abatacept (HR: 4.9[1.9-12.7]), Etanercept (HR: 2.3[1.3-4.2]) and Gold (HR: 1.9 [1.1-3.4]). MTX use (HR: 0.6 [0.42-0.87]) was a protective factor against discontinuation due to inefficacy.

Conclusion: Discontinuations of DMARDs in clinical practice due to inefficacy are frequent (13.5%) with an IR of 4%. We have found differences in discontinuation rates among DMARD with Certolizumab, Abatacept, Etanercept, and Gold being the drugs with the highest risk. MTX is a protective factor for discontinuation due to inefficacy. Caution should be taken in regard to discontinuation due to inefficacy in patients receiving glucocorticoids, biological DMARDs, combined therapy, in subsequent treatment courses, and those with depression.

Abstract Number: 0522

Treatment with Upadacitinib Results in the Normalization of Key Pathobiologic Pathways in Patients with Rheumatoid Arthritis

Thierry Sornasse,[1] Jeremy Sokolove,[1] and Iain McInnes[2], [1]AbbVie Immunology Clinical Development, Redwood City, [2]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) with an inadequate response (IR) to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) or biologic DMARDs (bDMARDs) in the SELECT-NEXT[1] andSELECT-BEYOND[2] trials, respectively. The pivotal immune regulatory pathway targets served by JAK1 in patients have not been comprehensively explored.

We investigate the mode of action (MoA) of UPA in patients with RA via a proteomic approach that evaluates a set of plasma proteins associated with inflammation.

Methods: Patients from the SELECT-NEXT and SELECT-BEYOND (PBO, n=167; UPA 15 mg QD, n=200) studies were randomly selected from the pool of patients with plasma samples available at baseline, Week 2, and Week 12. Samples from 24 age- and sex-matched healthy controls were included. The levels of 92 proteins were analyzed using the Olink® Inflammation Panel. Results from both studies were combined. Data were clustered using the Ward (unsupervised) method; correlations were calculated using the Pearson method; and multiple comparisons were corrected using the Benjamini–Hochberg method; all statistical analyses were performed in JMP 13.10 (SAS Institute). Pathway analysis was performed with Ingenuity® Pathway Analysis (Qiagen Inc.) version 45868156.

Results: At baseline, levels of IL-6, CXCL9, CXCL10, and CCL7 correlated significantly with baseline DAS28-ESR, consistent with effector roles for IL-6 and interferon (IFN) in intercurrent disease activity. Clustering of the differential protein fold change at Weeks 2 and 12 for UPA and PBO groups revealed four clusters enriched for proteins related to: 1) IL-6, IFN, leukocyte trafficking, and macrophage activation (↓↓↓); 2) T helper cell differentiation (↓); 3) T and B cell signaling (↓↓); and 4) hematopoiesis and myeloid cell differentiation (↑). Pathway analysis based on the differential expression of 37 significantly modulated proteins suggests that treatment with UPA results in the normalization of key pathways associated with the pathobiology of RA including: 1) pathways associated with IL-1, IL-6, IL-12, IL-15, IL-18, IFNα, IFNβ, IFNγ, CSF2, and TNF; and 2) pathways associated with behaviors of leukocytes (lymphocytes, myeloid cells, and granulocytes), including leukocyte migration, T cell response, and inflammatory response. In keeping with the latter, the changes in IL-6, CCL23, CCL7, MMP1, and S100A12 levels at Week 12 correlated significantly with the relative change in DAS28-ESR, suggesting a link between UPA MoA and macrophage activation.

Conclusion: In keeping with its selectivity for JAK1, UPA operates via inhibition of multiple JAK1-dependent upstream pathways that result in the normalization of key functional downstream effects associated with the pathobiology of RA, including T cell and myeloid cell-related pathways. Notably, non-JAK signaling pathways also normalize, suggesting functional integration of JAK1 with parallel pathogenic signaling in RA effector cells.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In Phase 3 trials, upadacitinib (UPA), an oral JAK1-selective inhibitor, has been assessed as monotherapy vs MTX (SELECT-EARLY[1]) and in combination with MTX vs adalimumab + MTX (ADA; SELECT-COMPARE[2]) in RA pts who were MTX naïve or with inadequate responses to MTX (MTX-IR), respectively. In this analysis we assessed individual and composite measures of disease activity in SELECT-EARLY and SELECT-COMPARE.

Methods: In SELECT-EARLY, MTX-naïve pts received UPA 15 mg or 30 mg monotherapy once daily (QD), or MTX monotherapy, for 12 wks. In SELECT-COMPARE, MTX-IR pts on stable background MTX received UPA 15 mg QD, PBO, or ADA 40 mg every 2 wks for 12 wks. For this analysis, responses at Wk 12 were defined as ≥50% improvement in the 7 components of the ACR response criteria. Among ACR50 responders, the proportions of pts with ≥50% improvement in all 7 components of the ACR criteria was assessed. The proportion of pts achieving TJC68=0 and SJC66=0 was also determined. All analyses were based on observed data without imputation.

Results: 947 pts were randomized in SELECT-EARLY, and 1629 pts in SELECT-COMPARE. Mean time since RA diagnosis was 2.7 years in SELECT-EARLY (median 6 months) and 8.2 years in SELECT-COMPARE; mean DAS28(CRP) was 5.9 and 5.8, respectively. In SELECT-EARLY, significantly more MTX-naïve pts receiving UPA 15 mg or 30 mg monotherapy achieved ≥50% improvements in all ACR components at Wk 12 compared with MTX (Table). In SELECT-COMPARE, significantly more MTX-IR pts on UPA 15 mg + MTX achieved ≥50% improvement in the ACR components vs PBO (all components) and ADA + MTX (all components except SJC and PhGA). Among pts with ACR50 responses at Wk 12, approximately half of the MTX-naïve pts on UPA 15 mg and 30 mg in SELECT-EARLY had ≥50%

Table. Proportions of pts achieving 50% improvements in core components of the ACR score at Wk 12

[a]All pts were receiving background MTX
[b]Pain, PtGA, PhGA, HAQ-DI, hsCRP (SJC and TJC not included as ACR50 responders must achieve 50% improvement in these parameters)

improvements in all 5 remaining ACR components (pain, PtGA, PhGA, HAQ-DI, hsCRP) compared with 28% with MTX. Corresponding proportions in MTX-IR pts in SELECT-COMPARE were 34% for UPA 15 mg + MTX, 28% for ADA + MTX, and 17% for PBO. UPA treatment also significantly increased the proportions of pts achieving both TJC68=0 and SJC66=0 vs PBO or MTX, and SJC66=0 vs ADA + MTX (Table).

Conclusion: In MTX-naïve and MTX-IR pts, treatment responses at 12 wks occurred in significantly higher proportions of pts receiving UPA monotherapy vs MTX and UPA + MTX vs PBO for all 7 components of the ACR response criteria, and for 5 of 7 ACR components for UPA + MTX vs ADA + MTX. Favorable outcomes with UPA treatment were evident both in composite and individual parameters.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), a selective JAK1 inhibitor, has shown efficacy in patients with rheumatoid arthritis (RA) when combined with methotrexate (MTX) or other conventional synthetic disease-modifying antirheumatic drugs (csDMARDs).[1,2] However, the efficacy of UPA plus MTX has not been directly compared with UPA plus other csDMARDs.

We compare the efficacy of UPA in combination with MTX versus UPA in combination with other csDMARDs in patients with an inadequate response (IR) to csDMARDs (SELECT-NEXT[1]) or biologic DMARDs (bDMARDs; SELECT-BEYOND[2]).

Methods: 661 patients in SELECT-NEXT and 498 patients in SELECT-BEYOND received UPA 15 mg or 30 mg once daily (QD) or placebo (PBO) for 12 weeks; all patients received concomitant csDMARD(s). The primary endpoints

Table. Week 12 efficacy outcomes by concomitant treatment.

[a]Sulfasalazine, leflunomide, hydroxychloroquine, or chloroquine.
[b]Based on logistic regression analyses for the comparison of UPA in combination with MTX versus UPA in combination with non-MTX csDMARDs, with treatment group and background csDMARD type as fixed factors (as well as the interaction between treatment group and background csDMARD type), adjusting for demographic and baseline factors.

References:
1. Burmester GR, et al. Lancet 2018;391:2503–12
2. Genovese MC, et al. Lancet 2018;391:2513–24

for both studies were rates of ACR20 response and DAS28(CRP) ≤3.2. Additional endpoints included DAS28(CRP) < 2.6, CDAI low disease activity (≤10), and CDAI remission (≤2.8). Patients were grouped according to concomitant csDMARD use (MTX vs non-MTX csDMARDs); patients receiving both MTX and a non-MTX csDMARD were included in the MTX group. p-values were calculated based on a logistic regression model with treatment group and type of background csDMARD as fixed factors, adjusting for demographic and baseline factors. p-values from the interaction between treatment group and background csDMARD were also calculated, to assess the consistency of the effects of study treatments for different background csDMARD type. Non-responder imputation was used for missing data.

Results: In SELECT-NEXT and SELECT-BEYOND, 535 and 410 patients, respectively (~80%), were receiving concomitant MTX (mean dose 17 mg/week), and 124 and 82 patients were receiving non-MTX csDMARDs. Demographics and disease characteristics were broadly similar between treatment groups; the majority of patients were female and of white ethnicity, and around half were using oral corticosteroids at baseline. Across all subgroups, the proportion of patients achieving efficacy outcomes was higher with both UPA doses compared with PBO (Table). There were no significant differences between efficacy outcomes with UPA in combination with MTX versus UPA in combination with non-MTX csDMARDs in either patient population. This included ACR20 response as well as low disease activity and remission defined by DAS28(CRP) and CDAI.

Conclusion: In this post hoc analysis, the efficacy of UPA in patients with RA appeared comparable whether administered in combination with MTX or non-MTX csDMARDs.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistent drug-free remission of RA is a condition close to “cure” of the disease. Long-term drug-free remission is considered rare and challenging to reach, little data are available that report how often persistent drug-free remission can be achieved and what kind of clinical characteristics are associated with such state.

Methods: We analyzed the long-term observational follow-up phase of the randomized controlled RETRO study on tapering and stopping of DMARDS in RA patients in stable remission (DAS28-ESR < 2.6) (1,2). We included patients having completed the 1-year randomized controlled phase of RETRO, in which DMARD treatments were either continued, tapered or stopped. In the long-term extension, (i) patients who successfully stopped, continued DMARD stop, (ii) patients who relapsed in any of the 3 groups continued DMARD treatment, (iii) patients in the continuation arm remaining in remission underwent 50% DMARD tapering follwoed by stopping after 6 months if still being in

remission and (iv) patients in the tapering arm remaining in remission underwent DMARD stop. We assessed the percentage of patients in persistent drug-free remission in the overall population and the three randomization groups, the probability of persistent drug-free remission in the intervention groups compared to controls adjusted by baseline aCCP, erosive changes and use of biologic DMARDs in a logistic regression model and the baseline characteristics associated with reaching persistent drug-free remission.

Results: All 141 patients being in the long-term observational follow-up phase of the RETRO study for at least 1 year were analyzed. Among them DMARDs were initially continued (Control, n=38), tapered (Taper, n=50) or stopped (Taper/Stop n=53). 19/141 patients were lost to follow-up and the worst case scenario was assumed that all of them did not reach persistent drug-free remission. Median time after study entry (Q1-Q3) was 69 (37-96) months as by December 2018. Overall number of patients in drug-free remission was 34/141 (24.1%), 10/38 (26%) in the control group, 6/50 (12%) in the taper group and 18/53 (34%) in the taper/stop group. After adjustment for baseline risk factors in the likelihood to reach persistent drug-free remission between the groups (OR:0.76, 95%CI: 0.29-1.99) was highly uncertain. Positive ACPA (OR: 3.38, 1.01 – 11.31) and erosive-state (3.05, 1.32 – 7.06) at baseline were associated with a lower likelihood to reach persistent drug-free remission.

Conclusion: These data show that persistent drug-free remission can be reached in a subset of RA patients following a structured DMARD tapering approach after being in stable long-term DMARD control.

Abstract Number: 0526

Factors Influencing Discontinuation in Long-term RA Treatment

Madison Grinnell,[1] Sofia Pedro,[2] and Kaleb Michaud[3], [1]University of Nebraska College of Medicine, OMAHA, NE, [2]FORWARD, The National Databank for Rheumatic Diseases, Wichita, KS, [3]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While medication persistence can act as a substitute metric for effectiveness, few studies have examined real-world patterns of bDMARD persistence by line of treatment and by patient-reported reasons for discontinuation in patients with RA.

Methods: From 2006 to 2018, participants with RA in FORWARD, The National Databank for Rheumatic Diseases, a US-wide observational longitudinal study, reported medication use and reasons for discontinuation. Discontinuation was defined as stopping the use of biologic medications for RA or adding another DMARD. We determined discontinuation rates of individual bDMARD initiators and grouped by action mechanism, delivery method, previous bDMARD history, concomitant use of csDMARDs such as methotrexate and prednisone and self-reported reasons for discontinuation. The latter were randomly assigned when more than 1 reason was given. Propensity score (PS) analyses were conducted overall and by line of treatment, defined as the conditional probability of being treated with

Table 1. Median Survival (IQR) of discontinuation and annual rate of discontinuation of individual biologics, by mechanism of action, line of treatment, and reasons of discontinuation

NTNF Inefficacy		80	1.00 (1.00 – 2.00)	0.59 (0.47 – 0.73)
NTNF - Cost		12	1.49 (1.00 – 2.00)	0.57 (0.32 – 1.00)
NTNF -Side effects		73	1.00 (0.50 – 2.00)	0.62 (0.50 – 0.79)
NTNF -Other		52	2.00 (1.00 – 3.00)	0.45 (0.34 – 0.59)

*For reason of discontinuation: the definition of discontinuation used was to consider stopping a biologic only (failures =TNF 1229, NTNF =240)

TNF or Non-TNF (NTNF). The goal was to remove the baseline characteristics of patients being assigned to one of the two treatments and reduce the channeling bias. Propensity scores were calculated using a logistic regression with treatment (TNF vs NTNF) as dependent variables and several independent variables used as adjustments in the Cox models to evaluate drug survival.

Table 2 Propensity score adjustment overall and by line of treatment

TNF vs Non-TNF	HR (95% CI) Ending drug or adding other DMARD
Overall	1.09 (0.96 – 1.23), P=0.175
First line	0.85 (0.65 – 1.11), P=0.247
Second line	1.13 (0.86 – 1.48), P=0.387
Third line or more	1.30 (1.07 – 1.57), P=0.008

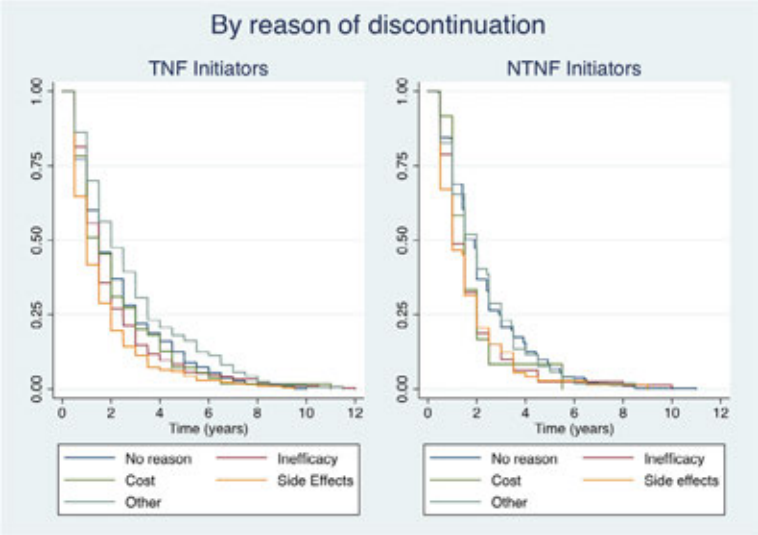

Figure 1 Kaplan Meier curves for reason of discontinuation by TNF and NTNF initiators.

Results: Strict inclusion criteria requiring an observation before and after bDMARD initiation resulted in 4,230 RA patients studied, 3129 initiating a TNF and 1833 initiating NTNF bDMARD or tsDMARD. Mean age of patients was 58 years with a median RA duration of 16 years. TNF had annual discontinuation rates of 0.13 (0.12-0.14) as first line, 0.25 (0.23-0.27) as second line, and 0.42 (0.39-0.46) as third line treatment. NTNF bDMARDs and tsDMARDs showed discontinuation rates of 0.18 (0.14-0.22) per year as first line bDMARD, 0.19 (0.16-0.21) as second line, and 0.21 (0.19-0.23) as third line (see Table 1 for more details). By line of treatment, TNF had lower discontinuation rates used as a 1st line medication compared to NTNF bDMARDs and tsDMARDS, which showed similar persistence regardless of treatment line. However, after adjustment for baseline characteristics through the PS analyses (see Table 2) in the comparison of TNF vs NTNF, only 3rd line treatment showed a difference with TNFs having an 30% increased likelihood of discontinuing compared with NTNF patients. Importantly, long-term persistence was similar for TNF and non-TNF overall. Side effects followed by inefficacy were the most frequent reasons for discontinuation for both action mechanisms (see Figure 1). Cost was also a significant reason among NTNF patients.

Conclusion: While our findings showed relatively low discontinuation rates, the more recently-available non-TNF bDMARDs had similar rates as TNF after propensity score adjustment, which aligns with the latest ACR RA treatment guidelines. With additional follow-up, similar analyses should be done with jakinibs.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In the SELECT-COMPARE study in rheumatoid arthritis (RA) patients (pts) with inadequate response to methotrexate (MTX), upadacitinib (UPA), a JAK1- selective inhibitor, was superior to placebo (PBO) or adalimumab (ADA), for treatment of signs & symptoms and for inhibition of radiographic progression vs PBO up to 26 weeks (wks). All pts were on stable background MTX. [1]

We report safety and efficacy of UPA plus stable background MTX up to 48 wks in this phase 3 study.

Methods: Pts were randomized to once-daily (QD) UPA 15mg, PBO, or ADA 40mg every other wk, with all patients continuing background MTX. The study was double-blind for 48 wks. Between Wks14-26, pts were rescued (from PBO to UPA, UPA to ADA, or ADA to UPA) if there was < 20% improvement in tender/swollen joint count (Wks 14/18/22) or if Clinical Disease Activity Index (CDAI) was >10 (Wk26); all PBO pts who were not rescued were switched to UPA at Wk 26. Efficacy was analyzed by randomized group. Non-responder imputation (NRI) was used

Table 1

Endpoint	Week 12			Week 26			Week 48	
	PBO N=651	UPA N=651	ADA N=327	PBO N=651	UPA N=651	ADA N=327	UPA N=651	ADA N=327

Results are based on following analyses: binary endpoints, NRI, with Wk26 rescue handled by LOCF; mTSS, ANCOVA with linear extrapolation (LE); other continuous endpoints, ANCOVA with rescue handling via LOCF. **, *** p≤ .01 and .001 for UPA vs PBO; #, ##, ### p≤.05, .01 and .001 for UPA vs ADA. For ADA vs PBO, 95%CI are mostly non-overlapping

Table 2. Treatment-emergent adverse event summary; E/100PY in Patients (EAER)		
	Any UPA, N=1417,PY=1243.3	Any ADA, N=579,PY=467.8
Any Adverse Event (AE)	266.4	294.8
Serious AE	12.9	15.6
AE Leading To Discontinuation Of Study Drug	7.4	11.1
Serious Infection	4.1	4.3
Herpes Zoster‡	3.1	1.3
Hepatic disorder¥	17.7	13.9
Any Malignancy (excluding NMSC)ɣ	0.4	0.6
MACE (adjudicated)δ	0.4	0.4
Venous Thromboembolic Events (adjudicated)§	0.3	1.1
Deathsφ	0.4	0.9

†For pts randomized to PBO at BL, ΔmTSS at Wk48 was 1.73; 74% pts had no progression (based on LE). Results are based on 2nd Reading Session.
‡Herpes zoster: majority of cases on UPA were nonserious and involved 1 dermatome
¥Hepatic disorders: majority based on ALT/AST elevations
ɣMalignancies excl.non-melanoma skin cancer: UPA:1 laryngeal cancer, 1 endometrial adenocarcinoma, 1 malignant melanoma, 1 adenocarcinoma gastric; 1adenocarcinoma of colon; ADA: 1 malignant melanoma; 1 colon cancer metastatic), 1 lung neoplasm malignant
δMACE (includes CV death, non-fatal myocardial infarction [MI], non-fatal stroke): UPA : 1 non-fatal stroke; 3 non-fatal MI, 1 CV death; ADA:1 non-fatal stroke, 1 CV death
§VTE: UPA, 1 deep vein thrombosis (DVT), 2 pts with PE, 1 pt with DVT and PE; ADA: 4 pts with PE, 1 pt with DVT.
φDeaths (includes non-treatment emergent deaths): UPA : 2 deaths (undetermined/unknown), 1 cardiac failure, 1 sudden death, 1 arteriosclerosis coronary artery; ADA :1 left ventricular failure, 1 craniocerebral injury, 1 colon cancer, 1 mixed connective tissue disease

for binary endpoints for rescue prior to Wk26. Last observation carried forward (LOCF) was used for continuous endpoints and binary endpoints after Wk26. Treatment-emergent adverse events (AE) per 100 pt yrs (PY) were summarized up to July 6 2018 for pts with any exposure to ADA or UPA.

Results: In SELECT-COMPARE, 1629 pts were randomized at BL. Among 651 pts randomized to UPA, 38.7% were rescued between Wks 14-26; of those who remained on UPA, 86% completed Wk 48, while 5.8% and 0.3% discontinued study drug between BL and Wk 48 due to AE and lack of efficacy (LoE), respectively. Among 327 pts randomized to ADA, 48.6% were rescued between Wks 14-26; of those who remained on ADA, 76% completed Wk48, while 13.1% and 0 discontinued study drug between BL and Wk48 due to AE and LoE, respectively. The cumulative exposures were 1243.3 and 467.8 PYs for UPA and ADA, respectively. At Wk26, and Wk48, significantly more pts in the UPA vs ADA group achieved ACR20/50/70, low disease activity and remission (Table); this was also true for visits between Wks 26 and 48. Similarly, improvements in pain and function were significantly greater in the UPA vs ADA group through Wk48. At Wk26, there was significantly less radiographic progression for UPA vs PBO, which was maintained through Wk48 (based on linear extrapolation).

Adverse events are reported in the table (in events per 100 PY). The rate of AE leading to discontinuation was higher with “any ADA” vs “any UPA”, while the rate of Herpes zoster was higher with “any UPA” exposure.

Conclusion: UPA continued to demonstrate superior clinical and functional responses vs ADA through Wk48. Inhibition of structural joint damage with UPA was also maintained through 48 wks vs PBO. Safety was consistent with observations in the first 26 wks.[1]

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Persistently active rheumatoid arthritis (RA) is an autoimmune disorder characterized by chronic inflammation and bone loss.[1] Although short-term administration of corticosteroids (CSs) is recommended alongside use of disease-modifying anti-rheumatic drugs (DMARDs) for active disease, CS use is often associated with exacerbation of bone loss.[2] Repository corticotropin injection (RCI) is FDA approved for short-term adjunctive use in the treatment of RA. A naturally sourced complex mixture of purified adrenocorticotropic hormone ($ACTH_{1-39}$) analogues and other pituitary peptides, RCI acts as an agonist for all 5 melanocortin receptors (MCRs). RCI activation of MCRs exhibits anti-inflammatory and immunomodulatory effects. *In vivo* data have shown RCI suppression of bone resorption via osteoclast reduction.[3] As an exploratory aim of a broader 2-part, multicenter, placebo-controlled

Marker	Mean (SD)		*P* Value[b]
	Baseline	Week 12

a mITT population, n=153. b From two-sample t test. Bold values are statistically significant. Abbreviations: CRT, creatinine; CTX, C-terminal cross-linking telopeptide; CTX-I, C-terminal cross-linking telopeptide of type I collagen; CTX-II, C-terminal cross-linking telopeptide of type II collagen; mITT, modified intent-to-treat; OPG, osteoprotegrin; PINP, N-terminal propeptide of type I collagen; RCI, repository corticotropin injection; SD, standard deviation; sRANKL, soluble receptor activator of nuclear factor kappa-β ligand.

Phase 4 efficacy and safety study, biomarkers associated with bone loss were assessed to evaluate the impact of RCI treatment on bone turnover in patients with persistently active RA.

Methods: Adults with persistently active RA despite DMARD and CS use were enrolled and remained on their current stable DMARD and CS doses throughout the study. During the initial 12-week open-label (OL) period (Part 1), all patients received 80 U RCI (subcutaneously [SC], 2x/wk). Those who achieved low disease activity (defined as DAS28-ESR < 3.2) at Week 12 were subsequently entered into the double-blind (DB) period (Part 2) and randomized to RCI (80 U) or matching placebo SC 2x/wk for an additional 12 weeks. Mean levels of bone turnover biomarkers (C-terminal cross-linking telopeptide [CTX], C-terminal cross-linking telopeptide of type I collagen [CTX-I], osteoprotegrin [OPG], N-terminal propeptide of type I collagen [PINP], and soluble receptor activator of nuclear factor kappa-β ligand [sRANKL]) and cartilage degradation biomarkers (C-terminal cross-linking telopeptide of type II collagen [CTX-II] and CTX-II creatinine [CRT]) were assessed at baseline (BL) and at Weeks 12 and 24.

Results: Of the 153 patients who entered the DB period (RCI, n=77; placebo, n=76), 127 (83%) completed the study. At completion of the OL period (Week 12), mean levels of bone biomarkers (with the exception of bone formation marker PINP) remained unchanged compared with BL, and significant decreases in mean levels of cartilage degradation markers

CTX-II (P=0.006) and CTX-II CRT (P< 0.001) were observed **(Table 1)**. For those who underwent an additional 12 weeks of RCI treatment during the DB period (n=77), there was a significant increase from BL in mean sRANKL levels at both Week 12 (P=0.036) and Week 24 (P=0.010) compared with placebo, suggesting a potential increase in osteoclast differentiation; however, mean levels of all other bone and cartilage biomarkers remained stable at these time points **(Table 2)**.

Conclusion: Bone and cartilage biomarker levels were mostly stable throughout the study, suggesting a potential bone-sparing effect of RCI.

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Across all phase 3 studies, treatment with upadacitinib (UPA), a JAK1-selective inhibitor, was associated with significantly higher remission (REM) rates, compared to placebo (PBO) or active comparators in RA patients (pts) who were methotrexate (MTX)-naive, had inadequate response to conventional synthetic (csDMARD-IR) or had inadequate response or intolerance to biologic DMARDs (bDMARD-IR).

† For continuous endpoints, results are based on MMRM
For EARLY: *P<.05; **P<.01; ***P<.001 for UPA 15 mg or 30 mg vs MTX.
For COMPARE: *P<.05; **P<.01; ***P<.001 for UPA 15 mg vs PBO. #P<.05; ##P<.01; ###P<.001 for UPA 15 mg vs ADA. Comparison not indicated for ADA vs PBO.
For BEYOND: $^{\delta}$P<.1 *P<.05; **P<.01; ***P<.001 for UPA 15 mg or 30 mg vs PBO
DAS28-CRP, 28-joint disease activity score using C-reactive protein; CDAI, clinical disease activity index; SDAI, simplified disease activity index; SJC28, swollen joint count of 28 joints; TJC28, tender joint count of 28 joints; PtGA, patients' global assessment of disease activity, PhGA, physician's global assessment of disease activity; hsCRP, high-sensitivity C-reactive protein

REM definitions are based on composite scores of various individual assessments of disease activity. To determine the response to UPA on REM and component assessments, we assessed the proportions of pts achieving REM using multiple REM definitions, and the improvement in their respective individual components, compared to PBO or active comparators, in 3 different RA pt populations spanning a range of RA pt populations.

Methods: Three phase 3 studies included pts who were MTX naïve (SELECT EARLY, n=945), MTX-IR (SELECT COMPARE, n=1629) and bDMARD-IR (SELECT BEYOND, n=498). The proportion of pts achieving REM at Week (Wk) 12 by 4 definitions (DAS28-CRP< 2.6; CDAI ≤2.8; SDAI ≤3.3 and Boolean, defined as ≤1 for TJC, SJC, patient's global assessment of disease activity [PtGA], and CRP ≤1 mg/L) were determined. For each definition of REM, the mean change in each of the respective component scores was also assessed. Binary endpoints are based on Non-responder imputation (NRI), and continuous endpoints on mixed-effect model repeat measurement (MMRM). Comparisons were made between UPA-treated groups vs respective control arms (MTX, adalimumab [ADA] or PBO).

Results: Pt demographics and disease characteristics have been previously reported. 1-3 At 12 wks, in EARLY and COMPARE, a significantly greater proportion of pts receiving UPA 15 mg or 30 mg QD achieved REM by all 4 definitions vs MTX, PBO or ADA (Table). In BEYOND, (a refractory population many of whom had inadequate response to multiple bDMARDs), a significantly greater proportion of pts receiving UPA 30mg achieved all REM definitions vs PBO within the first 12 wks, with significantly greater proportions receiving UPA 15mg achieving DAS28-CRP< 2.6 and Boolean REM (Table). Rates of REM in BEYOND further increased through Wk 24 for both dose groups.1 Compared to respective control groups, pts receiving UPA 15 or 30 mg QD had significantly greater improvements in each REM disease component (except for PhGA vs ADA in COMPARE). Significantly more pts

receiving UPA also achieved the required cutoffs on the individual components of Boolean REM compared to respective controls.

Conclusion: Significantly greater proportions of pts receiving UPA 15 or 30mg achieved REM by multiple definitions at 12 wks compared to PBO, MTX or ADA. All disease activity components of each REM definition were significantly improved in pts receiving UPA compared to MTX or PBO, and all Boolean components were significantly improved in pts receiving UPA 15mg compared to ADA.

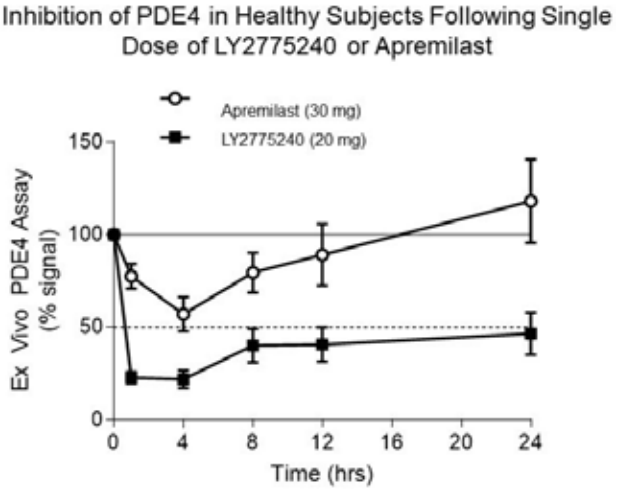
Phase I Evaluation of the PDE4 Inhibitor LY2775240: Head to Head Comparison with Apremilast Using an Ex Vivo Pharmacodynamic Assay

Daniel Dairaghi,[1] Karen Cox,[1] Stephen Ho,[1] Paul Klekotka,[2] Diane Phillips,[1] Jean Lim,[3] Shweta Urva,[1] and Dipak Patel[2], [1]Eli Lilly and Company, Indianapolis, IN, [2]Eli Lilly and Company, San Diego, CA, [3]Eli Lilly and Company, singapore, Singapore

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM



Inhibition of PDE4 using an ex vivo PD assay with LPS as the stimulus. Data for n=11 subjects shown. Mean +/- SEM

Background/Purpose: LY2775240 is a potent and selective phosphodiesterase (PDE4) inhibitor being investigated as a potential treatment for inflammatory disorders, such as psoriasis. PDE4 is expressed primarily in immune cells, and enzymatically degrades cyclic adenosine monophosphate (cAMP). Inhibition of PDE4 leads to increased cytoplasmic cAMP and reduced pro-inflammatory immune responses. Pharmacodynamic (PD) effect measured as inhibition of PDE4 activity can be assessed with an ex vivo whole blood assay where the stimulant is the bacterial endotoxin lipopolysaccharide (LPS) and the readout is secretion of the cytokine TNF alpha.

Methods: In the first part of a Phase 1 (First-in-Human), single-center, randomized, 2-part study evaluating safety, tolerability and pharmacokinetics of LY2775240 in healthy subjects; subjects received LY2775240 or placebo (8:2) in a blinded manner. LY2775240 at 0.1, 0.5, 1.5, 5, 10, 20, 30, or 40 mg was given orally as a single dose. Ex vivo PDE4 inhibition assays were conducted at pre-dose, 4, 12, and 24 hours. The second part was an open-label, 2-period, crossover design in healthy subjects (n=11) that included a single dose of either LY2775240 (20 mg) or apremilast (30 mg) in each period. Ex vivo PDE4 inhibition assays were conducted at pre-dose, 1, 4, 8, 12, and 24 hours. TruCulture (Myriad RBM) assay tubes containing LPS with a 24-hour incubation at 37°C were used for the ex vivo PD assay, with TNF alpha levels measured by MSD assay at Covance (Durham NC).

Results: LY2775240 was safe and well tolerated in this Phase 1 study. The most common AEs were nausea, diarrhea and headache, consistent with those reported with other drugs in the PDE4 inhibitor class. No SAEs were reported. LY2775240 PK was well characterized over the dose range studied, and the half-life supports a once-a-day dosing regimen. In the first part, the ex vivo PD assay showed dose dependent decreases of TNF alpha across the dose range studied. The 20 mg dose of LY2775240 led to near maximal inhibition in this assay and was selected for comparison with the clinical dose (30 mg) of apremilast. LY2775240 maintained >50% inhibition of TNF alpha induction over the 24-hour duration, while apremilast achieved peak inhibition of 50% at 4 hours, while returning to ~10% inhibition within 12 hours post dose.

Conclusion: The 20 mg dose of LY2775240 demonstrated an increased and sustained inhibition of PDE4 activity over 24 hours when compared to the clinical dose of apremilast.

Abstract Number: 0531

Efficacy and Safety of Gonadotropin-Releasing Hormone Antagonism in Severe Biologic Refractory Rheumatoid Arthritis

Anita Kass,[1] Hans Christian Gulseth,[1] and Camilla Zettel[1], [1]Betanien Hospital, Skien, Norway

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The pathogenesis of rheumatoid arthritis (RA) is unclear, and additional therapeutic approaches are needed. The improvement of RA disease activity during pregnancy, and flares during the postpartum has been described. Control of the reproductive axis originates in the hypothalamus with the periodic pulsatile release of gonadotropin-releasing hormone (GnRH). Non-reproductive functions of GnRH include stimulation of immune responses (1), and this hormone has shown proinflammatory effects. A proof-of-concept, double blind, randomized controlled trial of GnRH antagonism in RA showed promising results, including a significant reduction in TNF (2). Here, the efficacy and safety of long-term GnRH antagonism therapy to patients with severe, biologic refractory RA is reported.

Patient 5	6,4	5,9	4,6	3,1
Patient 6	7,2	5,8	4,6	2,4
Patient 7	6,1	6,1	5,5	5,4
Patient 8	6,3	6,0	5,7	4,7
Patient 9	5,5	4,0	2,5	0,7

	CRP Week 0	CRP Week 4	CRP Week 8	CRP Week 12
Patient 1	55	18	20	41
Patient 2	44	25	21	16
Patient 3	33	17	31	19
Patient 4	142	104	89	54
Patient 5	5	7	12	6
Patient 6	5	5	5	5
Patient 7	36	24	23	26
Patient 8	123	136	111	96
Patient 9	5	5	5	5

Methods: Nine patients (8 females and 1 male, mean age 59 years, mean disease duration 22 years, baseline mean DAS28CRP 6.79) with biologic refractory RA, fulfilling the ACR 2010 criteria, received off-label subcutaneous GnRH antagonist treatment in the form of either cetrorelix 0.75mg daily or degarelix 240mg loading dose, tapered down to 80mg approximately every 2 weeks. 12 week efficacy and safety data are reported. All patients were primary non-responders to the last biologic therapy administered. Stable concomitant csDMARDs and oral steroids were allowed. No intra-articular injections were received.

Results: DAS28CRP was significantly reduced ($p < 0.001$, Figure 1) at week 12 compared to baseline. The clinical and laboratory courses during 12 weeks are shown. All outcome measures were reduced, including joint counts, morning stiffness, MHAQ, and VAS patient reported outcomes. GnRH antagonism was well tolerated during this period, although hot flushes and mild to moderate injection site reactions were observed. Patient 3 developed a skin abscess on her foot where she had previously had several infections prior to GnRH antagonist therapy.

Conclusion: This data indicates that long-term GnRH antagonism may be beneficial in therapy-resistant RA patients. A plausible explanation involves the interruption of GnRH signaling on peripheral T cells. Further randomized controlled trials are required to verify these results and further assess safety.CRPcourses

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fractalkine (CX3CL1, designated as FKN hereafter) is the sole member of the CX3C-chemokine which leads to dual actions, chemotaxis and cell adhesion for leukocytes expressing the cognate receptor, CX3CR1, during their migration. We have conducted clinical trials of E6011, a novel humanized anti-FKN monoclonal antibody, for patients with rheumatoid arthritis (RA) in Japan[1]. This is the report of a Phase 2, multicenter, randomized, double-blind, placebo-controlled, parallel-group comparison study of E6011 in RA patients inadequately responding to biologics (NCT02960490).

Methods: During the 24-week double-blind period, patients with moderately to severely active RA of inadequate response to biologics were randomly assigned to E6011 400 mg or placebo groups at a 1:1 ratio. Patients who continued the study beyond Week 12 were further allocated to E6011 200 mg or 400 mg at a 1:1 ratio within the initially assigned group. Patients received either E6011 400 mg or placebo at Weeks 0, 1, 2, and every 2 weeks subsequently until Week 10 and then E6011 200 mg or 400 mg every 2 weeks between Weeks 12 and 22 in a double-blind manner.

Results: A total of 64 subjects (33 in the placebo group and 31 in the E6011 400 mg group) received study drug. Of the 64 subjects, 55 completed and 9 discontinued study treatment prematurely during the 12-week placebo controlled double-blind period. The ACR20 response rate at Week 12 (non-responder imputation), the primary endpoint, was 27.3% (9/33 subjects) in the placebo group and 22.6% (7/31 subjects) in the E6011 group. ACR50 and ACR70 response rate at Week 12 were 3.0%, 0% in the placebo group and 9.7%, 3.2% in the E6011 group, respectively. No statistically significant differences were found in any of the ACR components between the placebo and E6011 groups.

After completion of Week 12, 55 subjects were re-randomized and treated with E6011 200 mg or 400 mg (15 subjects for placebo/200 mg, 14 subjects for placebo/400 mg, 14 subjects for 400/200 mg, 12 subjects for 400/400 mg). Of the 55 subjects, 48 completed the planned treatment regimen and 7 discontinued study treatment prematurely between Week 12 and Week 24. During the Weeks 12-24, no apparent differences were found in any of the efficacy endpoints between the each groups during the Weeks 12–24 (after re-randomization). ACR20 response rate at Week 24 was 46.7% (7/15 subjects) in the placebo/200 mg group, 28.6% (4/14 subjects) in the placebo/400 mg group, 21.4% (3/14 subjects) in the 400/200 mg group and 33.3% (4/12 subjects) in the 400/400 mg group.ACR50 and ACR70 response rate at Week 24 were 20.0%, 0% in the placebo/200 mg group, 0%,

0% in the placebo/400 mg group, 7.1%, 0% in the 400/200 mg group and 16.7%, 0% in the 400/400 mg group respectively.

During the Weeks 0-24, Adverse events that occurred in at least 2 subjects in the 400/200 mg group or 400/400 mg group were injection site erythema and nasopharyngitis.

Conclusion: E6011 was well tolerated with no notable safety concerns, but did not show clear efficacy when administered subcutaneously for up to 24 weeks in RA patients with inadequately responding to biologics. Further investigation to seek an optimal clinical dose and evaluation period of E6011 are warranted.

Abstract Number: 0533

Impact of Formulary Change on TNFi Treatment Patterns and Healthcare Utilization Costs in RA Patients

Jennifer Schenfeld,[1] Scott Stryker,[2] Hafiz Oko-osi,[1] and Bradley Stolshek[2], [1]Amgen, Inc, Thousand Oaks, CA, [2]Amgen Inc., Thousand Oaks, CA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Changes in formulary tiers can potentially have unintended impact on outcomes. Moderate-to-severe rheumatoid arthritis (RA) is often treated with Tumor Necrosis Factor inhibitors (TNFi). A large payer implemented a formulary change on January 1, 2015 that switched the tiering and modified the copayment for two TNFi's: etanercept (ETN) and adalimumab (ADA). The purpose of this study was to assess the effect of formulary changes on treatment patterns and healthcare utilization (HCU) costs among RA patients (pts) on TNFi, specifically ETN compared to other TNFi medications.

Methods: This claims-based, retrospective cohort study utilized Optum Clinformatics Data Mart from UnitedHealth Group. The calendar year 2015 was evaluated. Jan 1, 2015 served as the index-date; the 6 months preceding Jan 1, 2015 served as the pre-index period (baseline); and Jan 1 to Dec 31, 2015 served as the follow-up period. The cohort included pts ages ≥18, with a confirmed RA diagnosis prior to Jan 1, 2015; continuous enrollment from beginning of baseline through end of follow-up; and ≥1 TNFi claim(s) during baseline. The most proximal TNFi to the end of baseline served as the index TNFi. Pts were categorized as ETN or Other TNFi and assessed during follow-up for the first occurrence of a treatment outcome: continuer (no changes or gap ≤59 days); early-gap-restart (EGR) (≥60 but ≤180 day gap then restart index TNFi); early-switch (ES) (prescribed a different TNFi than index ≤180 days); discontinuers (no refills; restart; or switch during entire length of follow-up). HCU and mean costs were measured during follow-up.

Results: In 2015, n=9,058 pts met the inclusion criteria. At baseline, ETN accounted for 44.5% (n = 4,033) of pts, of which, 62.1% continued; 14.2% EGR;10.9% ES; 9.4% discontinued, and 3.4% had a gap-restart or switch occurring ≥ 180 days. Among Other-TNFi pts (55.5%) at baseline, 77.2% continued; 7.8% EGR; 4.4% ES; 8.8% discontinued; and 1.8% had a gap-restart or switch occurring ≥ 180 days (T.1). The total mean HCU costs were lower for ETN continuers compared to Other-TNFi continuers ($36,005, $40,102; p < .0001), and for ETN EGR pts compared to Other-TNFi EGR pts ($29,482, $37,121; p = .0002) (T.2). ES ETN pts were costlier than ETN continuers (T.2). Medical costs (inpatient/outpatient) of continuers and EGR were significantly lower

for ETN compared to similar pts on Other-TNFi. While total mean drug costs based on pharmacy claims for any medication were higher for ETN continuers compared to Other-TNFi continuers, and for ETN ES compared to Other-TNFi ES pts, when evaluating specifically mean costs of TNFi and biologic (pharmacy or physician-administered) they were lower for ETN continuers, EGR, and ES compared to Other-TNFi pts with the same treatment outcomes (T.2).

Conclusion: In this plan, a formulary policy change did not result in healthcare cost savings during the first year of implementation. Continuing and EGR pts using Other-TNFi incurred higher costs than similar ETN pts. Pts switching away from ETN cost more than pts switching away from Other TNFi medications. Overall, ETN patients who experienced a formulary change resulted in higher costs.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: CXCL13 chemokine, by interacting with CXCR5 receptor, attracts B-lymphocytes and CD4+CXCR5+ICOS+ follicular helper T-lymphocytes (THFs) in lymphoid follicles. In rheumatoid arthritis (RA) CXCL13 is expressed by synovial follicular dendritic cells and activated mature antigen-experienced T-helper cells. CXCL13 serum levels are increased in RA and associated with synovial infiltration by lymphoid aggregates, as well as with a preferential response to anti-IL-6R as compared to anti-TNFα monotherapy (1).

Abatacept (ABA), a T-cell co-stimulation blocker, reduces circulating THFs number in RA. This reduction is correlated with CXCL13 serum levels decrease in primary Sjögren's Syndrome, but not much information is available on this issue in RA (2).

The purposes of this study were to analyze the effect of ABA on CXCL13 serum levels in RA and to verify whether they predict the response to the drug.

Methods: 32 RA patients (F/M=25/7; median (25th-75th percentile) age=62 (52-66) years; CRP- DAS28=4.6 (4.0-5.3); ACPA positive: 81%), before and after 6 months of treatment with ABA were evaluated. Serum CXCL13 levels were dosed by commercial ELISA. Circulating TFHs were identifiedby flow-cytometry in 25 subjects. Response to treatment was evaluated with the EULAR criteria.

Results: At baseline, a positive correlation between CXCL13 levels and CRP-DAS28 values was found (r=0.34; p=0.05). After therapy with ABA + methotrexate, a reduction of CXCL13 was observed (158 (109-274) vs 96 (59-154) pg/ml; p< 0.01). It was significant only in responders (n: 22: 158 (104-293) vs 96 (89-182)) pg/ml; p< 0.01; in non-responders (n:10) =164 (95-240) vs 101 (57-142) pg/ml; p=0.06). At baseline, no significant difference was found between the two subgroups (p=0.47) and among patients seropositive for ACPA if compared with the negative ones (ACPA+ vs ACPA-=174 (117-287) vs 96 (73-194) pg/ml; p=0.07). A reduction of THFs was found (0.6 (0-3) vs 0.1 (0-0.7) % of CD4+ T cells; p=0.05), without correlation with the decrease of CXCL13 levels (r=0.20; p=0.33).

Conclusion: Our results confirmed that CXCL13 serum levels are directly correlated with disease activity and demonstrated that ABA therapy induces their reduction, as well as that of circulating THFs. These findings suggest that the co-stimulation blockade at central level and/or in the synovium lead to a reduced generation of THFs and production of CXCL13. We could not demonstrate that CXCL13 levels predict, or are correlated with, clinical response to ABA in this small cohort of patients.

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of pain remains a priority for patients (pts) with RA. Otilimab (GSK3196165) is a human mAb that inhibits GM-CSF, a key driver in a broad range of immune-mediated conditions that is involved in the regulation of musculoskeletal pain. In the Phase 2b dose-ranging BAROQUE study (201755)[1] in pts with moderate to severe RA who failed MTX, otilimab plus MTX provided rapid and substantial improvement from baseline (BL) in pain vs placebo (PBO) as assessed by a 100 mm Visual Analogue Scale (VAS). The objective of this post hoc analysis was to further define the clinical relevance of the effect of otilimab on pain through assessment of responder rates.

Methods: BAROQUE was a Phase 2b multicenter, PBO-controlled study in 222 pts with RA (ACR 2010 criteria). Pts were randomized (1:1:1:1:1:1) to subcutaneous PBO or otilimab (22.5, 45, 90, 135, or 180 mg) plus MTX once weekly for 5 weeks, then every other week until Week 50. Pts without a good/moderate EULAR response at Week 12 or with DAS28(CRP) >3.2 at Week 24 escaped to otilimab 180 mg until study end. Change from BL in pain was assessed using a 100 mm VAS. Percentage of pts with pain improvement ≥minimal clinically important difference (MCID; 10% VAS response) and improvement in pain from BL of ≥30%, ≥50%, and ≥70% were compared by treatment groups at each visit up to Week 12. The analysis was restricted to pts with complete information; missing data or dropouts prior to Week 12 were not imputed.

Results: The BAROQUE study population had high baseline pain VAS (mean 67.0; standard deviation 18.49). Change from BL in pain VAS is shown in **Table 1.** Overall, otilimab dose groups showed a higher proportion of pts with pain improvement ≥MCID vs PBO, with the largest difference vs PBO in the 180 mg dose group at Week 12: 46% (95% CI 22%, 69% [75% vs 29% of pts with MCID]) (**Table 2**). At most timepoints, more pts achieved 30%, 50%, and 70% pain responses in the otilimab groups vs PBO and the difference generally increased with increasing treatment duration (**Table 2**). At Week 12 in the 90–180 mg dose groups, the difference vs PBO in 30% pain response ranged from 25% to 43% (greatest difference with otilimab 180 mg), 50% pain response ranged from 19% to 26% (greatest difference with otilimab 90 mg), and 70% pain response ranged from 5% to 21% (greatest difference with otilimab 90 mg).

Conclusion: Further to the observed clinically relevant change from baseline in VAS pain with otilimab plus MTX in the overall BAROQUE study population, this post hoc analysis shows that a greater number of pts had substantial (≥50%) improvement from BL in pain levels when treated with otilimab plus MTX vs PBO over 12 weeks. Phase 3

studies are ongoing in pts with moderate to severe active RA and will further assess the overall clinical benefit and sustained improvement in pain symptoms with weekly dosing of otilimab plus MTX.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SB2 is approved in the EU as an infliximab (IFX) biosimilar, having demonstrated bioequivalence and similar efficacy, safety and immunogenicity as the reference. There is limited real-world evidence published on persistence or safety of SB2, either in IFX-naiive patients or in those transitioning from originator or another IFX biosimilar. PERFUSE is an ongoing non-interventional study intending to enroll over 1,000 patients receiving SB2 as routine therapy, with the objective of describing clinical characteristics, effectiveness, treatment persistence and safety in patients initiating SB2 in routine clinical practice and followed for 12 months at 6 specialist rheumatology sites across France.

Methods: Eligible adult patients have a diagnosis of Rheumatoid Arthritis (RA), Psoriatic Arthritis (PsA) or Ankylosing Spondylitis (AS) and initiated SB2 in routine clinical practice after September 2017, either as their first IFX or transitioning from treatment with IFX originator or another IFX biosimilar. Data are captured prospectively and/or retrospectively from patient records obtained during routine clinic visits for up to 12 months (M12) following initiation. Outcome measures include persistence on SB2, clinical characteristics at baseline (time of initiation of SB2), disease scores (DAS28, BASDAI and Serious Adverse Events (SAEs).

Results: This interim analysis (IA) includes 177 patients (41 with RA, 23 with PsA and 113 with AS); of these, 24 patients with RA, 8 patients with PsA and 62 patients with AS reached M12 by the data extraction date. Persistence on

Table 1 (to go in Results section)

Table 1: Baseline characteristics, SB2 persistence, and disease scores	RA (N=41)		PsA (N=23)		AS (N=113)	
Age (mean, SD)	42 (12.3)		40.7 (9.9)		34.9 (12.6)

Overall** (n) (%; 95% CI*)	24 (100; 85.8, 100)		8 (100; 63.1, 100)		54 (87; 76, 94.2)	
Disease score	**n**	**mean DAS-28 (95% CI)**	**n**	**mean DAS-28 (95% CI)**	**n**	**mean BASDAI (95% CI)**
Disease score in switched patients						
Baseline	34	2.4 (2.1, 2.8)	13	3.8 (0.7, 6.9)	76	7.6 (4.4, 10.7)
M6	32	2.5 (2.0, 2.9)	8	2.2 (1.4, 2.9)	67	5.2 (2.5, 7.9)
M12	22	2.7 (2.1, 3.2)	6	1.5 (0.9, 2.0)	43	2.6 (2.1, 3.2)
Mean change from baseline in switched patients						
M6	30	0.1 (-0.4, 0.7)	7	-2.3 (-8.8, 4.2)	59	-1.9 (-3.6, -0,1)
M12	21	0.3 (-0.2, 0.8)	5	-0.3 (-1.5, 1.0)	41	-1.6 (-3.8, 0.7)
Data extract: 6 May 2019 * Clopper Pearson 95% Confidence Interval ** Originator + CTP13 (+ Naïve where applicable)						

SB2 at M12 was 100% (95% CI 85.8, 100), 100% (95% CI 63.1, 100) and 87% (95% CI 76, 94.2) in RA, PsA and AS respectively. In the patients with prior IFX, no clinically meaningful difference in disease activity score from baseline to M6 was observed; BASDAI mean individual change was -1.9 (95% CI -3.6, -0.1) in AS (n= 59) and DAS28 mean individual change was 0.1 (95% CI -0.4, 0.7) in RA (n=30). Low sample size precluded effectiveness analysis of IFX-naiive patient data. Four SAEs were reported: One related to SB2 (infected cyst) and three unrelated (two RA disease flares and one overdose of vitamin K antagonists).

Conclusion: This IA indicates that patients with chronic inflammatory rheumatism can be successfully transitioned from originator or biosimilar IFX to SB2, with no loss of disease control and without safety concerns. Over 85% of patients initiated de novo or transitioned from originator or another IFX biosimilar continued SB2 treatment at M12 post-initiation. Subsequent to these preliminary data, the study will provide ongoing, pertinent information about long-term outcomes in these populations, helping to inform evidence-based treatment decisions.

Efficacy and Safety Results from a Randomized Double-Blind Study That Compared the Proposed Biosimilar ABP 798 with Rituximab in Subjects with Moderate to Severe RA

Gerd Burmester,[1] Edit Drescher,[2] Pawel Hrycaj,[3] David Chien,[4] Zhiying Pan,[4] and Stanley Cohen[5], [1]Charité—University Medicine Berlin, Berlin, Germany, [2]2Veszprém Csolnoky Ferenc County Hospital, Veszprém, Hungary, [3]Koscian Municipal Hospital, Koscian, Poland, [4]Amgen, Thousand Oaks, CA, [5]Metroplex Clinical Research Center, Dallas, TX

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ABP 798 is being developed as a biosimilar to rituximab, a CD20-directed cytolytic antibody that is approved in the US and EU for treatment of moderate-to-severe RA (US), severe RA (EU), non-Hodgkin's lymphoma, chronic lymphocytic leukemia, granulomatosis with polyangiitis and microscopic polyangiitis, and moderate-to-severe pemphigus vulgaris (US). A phase 1-phase 3 study was conducted to evaluate the pharmacokinetics (PK), safety and efficacy of ABP 798 in comparison with rituximab reference product (RP) in patients with moderate-to-severe RA. The key efficacy and safety results of this trial comparing ABP 798 with rituximab RP are presented here.

Methods: This was a randomized, double-blind, active-controlled study conducted in adult subjects with moderate-to-severe RA who had an inadequate response or intolerance to other DMARDs. Subjects were randomized (1:1:1) to receive 2 IV infusions of 1000 mg, 2 weeks apart as first dose of either ABP 798, rituximab sourced from the US (rituximab US), or rituximab sourced from the EU (rituximab EU). At Week 24, subjects in ABP 798 and rituximab EU arms received the second dose of the same treatment, while those in the rituximab US arm transitioned to receive ABP 798 for their second dose.

The key efficacy endpoint was defined as the evaluation of change from baseline at Week 24 in DAS28-CRP. Other efficacy endpoints included ACR20, ACR50, and ACR70 at Week 24. Since PK similarity was established between rituximab US and rituximab EU (results presented separately), the 2 rituximab RP arms were pooled for efficacy equivalence assessment.

Results: A total of 311 subjects were randomized (ABP 798, n=104; rituximab EU, n=104; rituximab US, n=103); all subjects were treated with at least one infusion of investigational product. Clinical equivalence between ABP 798 and rituximab RP was established with the 90% confidence interval (CI; -0.225, 0.264) and 95% CI (-0.273, 0.312) for DAS28-CRP change from baseline at Week 24 being within the prespecified equivalence margin of (-0.6, 0.6). The 90% and 95% CIs for the mean differences between ABP 798 and the individual rituximab RP arms were also within the pre-defined margin. Over the first 24 weeks, results from other efficacy endpoints (ACR20, ACR50, ACR70) also supported clinical similarity. Overall safety and immunogenicity profiles of ABP 798 were consistent with that reported for rituximab RP with no unexpected events over this period. Treatment-emergent adverse events (TEAEs) were reported in 50%, 42.3%, and 42.7% of patients that received ABP 798, rituximab EU, and rituximab US, respectively. Infusion reactions including hypersensitivity was the most common event of interest reported. Binding antibodies developed in 13.4%, 10.6%, and 19.6% of patients that received ABP 798, rituximab EU, and rituximab US, respectively; and neutralizing antibodies in 8.2%, 2.1%, and 8.2%, respectively.

Conclusion: Based on the results of this study. clinical equivalence of ABP 798 to rituximab RP was established for efficacy and safety in subjects with moderate-to-severe RA.

Abstract Number: 0538

Long-Term Safety and Efficacy of Upadacitinib in Patients with Rheumatoid Arthritis and an Inadequate Response to CsDMARDs: Results at 60 Weeks

Gerd Burmester,[1] Filip Van den Bosch,[2] Louis Bessette,[3] Alan Kivitz,[4] Yihan Li,[5] Alan Friedman,[6] Aileen Pangan,[6] Heidi Camp,[5] and Joel Kremer[7], [1]Charité—University Medicine Berlin, Berlin, Germany, [2]Ghent University Hospital, Ghent, Belgium, [3]Laval University, Quebec City, QC, Canada, [4]Altoona Center for Clinical Research, Duncansville, PA, [5]AbbVie Inc., North Chicago, IL, [6]AbbVie Inc., North Chicago, [7]Albany Medical College, Albany, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral, JAK1-selective inhibitor showed efficacy over 12 weeks (wks) in patients (pts) with moderately to severely active rheumatoid arthritis (RA) and inadequate response to csDMARDs (SELECT-NEXT).[1]

We assessed safety and efficacy of UPA through Wk60 in an ongoing extension of the phase 3 SELECT-NEXT study.

Methods: Pts received once-daily (QD) UPA at 15 mg (UPA15), 30 mg (UPA30) or placebo (PBO) for 12 wks on stable background csDMARDs. From Wk12, the start of a long-term blinded extension, pts initially randomized to PBO at

BL were switched to UPA15mg or 30mg per pre-specified assignment at BL. Pts randomized to UPA continued their assigned dose. No dose adjustments of UPA were allowed; however, starting at Wk24, adjustments to background RA medications were permitted. Sites/subjects remain blinded to UPA dose throughout the extension period. Efficacy data up to Wk60 are reported "As Observed". Adverse events (AE) per 100 pt yrs (PY) are summarized based on a cut-off date of Mar 22 2018.

Results: 611/661 (92%) pts completed Wk12 and continued on to the extension. By the safety data cut-off date, 125/611 (20%) had discontinued study drug, 50 (8.2%) due to an AE, and 10 (1.6%) discontinued due to lack of efficacy. Cumulative exposure was 393.3 PYs and 372.4 PYs for UPA15 and UPA30 respectively. Based on As Observed analysis, for pts who continued on UPA15 (262/310 [85%]) and UPA30 (243/301 [81%]), clinical and functional outcomes continued to improve or were maintained through Wk60, with 59% and 56% of pts achieving DAS28-CRP < 2.6 and 35% and 32% achieving CDAI remission (≤2.8) with UPA 15 and 30 mg, respectively (Table 1). Pts who switched from PBO to UPA15 or UPA30 showed comparable efficacy to those initially randomized to UPA. The most frequently reported AEs were nasopharyngitis, urinary tract infection, upper respiratory

Table 1. Efficacy Endpoints at Week 60 (as observed); n/N (%)

†Most frequently reported serious infection were pneumonia, sepsis, staphylococcal wound infection and bronchitis.

‡Herpes zoster: most involved 1 or 2 dermatomes. No meningoencephalopathic/ noncutaneous involvement, except one primary varicella zoster pneumonia (chicken pox). Two HZ events were reported as ophthalmic.

¥Hepatic disorders: Most were asymptomatic lab abnormalities.

δMACE: UPA15: 1 pt with non-fatal MI, 2 pts with non-fatal stroke; UPA30: 1 cardiovascular death, 1 non-fatal MI, 1 non-fatal stroke

§VTE: UPA15: 1 pt with DVT and PE; UPA30:1 pt with DVT

φDeaths: UPA30: 1 CV death in pt prior history of diabetes, hypertension, hyperlipidemia, non-fatal MI with coronary bypasses; 1 due to colon adenocarcinoma; 1 due to lymphangiosis carcinomatosa

References:

Burmester et al. Lancet. 2018 Jun 23;391(10139):2503-2512

tract infection, bronchitis, blood creatine phosphokinase increased, alanine aminotransferase increased, herpes zoster (HZ) and nausea. Most frequent AEs (≥0.8/100PYs) leading to premature study drug discontinuation were pneumonia, transaminase elevations, HZ and pyrexia. Event rates (E/100PYs) were numerically higher in UPA30 vs UPA15 for serious AE, AE leading to discontinuation, serious infections, HZ and malignancies, and were similar in UPA15 and UPA30 for adjudicated major adverse cardiovascular events and venous thromboembolic events (Table 2).

Conclusion: UPA15mg and 30mg on background csDMARD therapy demonstrated consistent efficacy and safety over 60 weeks in RA patients with inadequate response to csDMARDs. Both doses of UPA showed a similar efficacy profile at week 60, with numerically higher rates for certain safety events noted in the UPA30 group. An integrated safety analysis of upadacitinib across the phase 3 program is required to fully characterize the benefit:risk of UPA in RA.

A Randomized Double-Blind Study Comparing Pharmacokinetics (PK) and Pharmacodynamics (PD) of ABP 798 with Rituximab in Subjects with Moderate to Severe RA

Gerd Burmester,[1] Stanley Cohen,[2] David Chien,[3] Vincent Chow,[3] and Zhiying Pan[3], [1]Charité—University Medicine Berlin, Berlin, Germany, [2]Metroplex Clinical Research Center, Dallas, TX, [3]Amgen, Thousand Oaks, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ABP 798 is being developed as a biosimilar to rituximab, a CD20-directed cytolytic antibody that is approved in the US and EU for treatment of moderate-to-severe RA (US), severe RA (EU), non-Hodgkin's lympho-

ma, chronic lymphocytic leukemia, granulomatosis with polyangiitis and microscopic polyangiitis, and moderate-to-severe pemphigus vulgaris (only US). A phase 1-phase 3 study was conducted to evaluate the pharmacokinetics (PK), pharmacodynamics (PD), safety, and efficacy of ABP 798 in comparison with rituximab reference product (RP) in patients with moderate-to-severe RA. Here, we report the results of PK and PD similarity of ABP 798 versus rituximab RP.

Methods: This was a randomized, double-blind, active-controlled study conducted in adult subjects with moderate-to-severe RA who have had an inadequate response or intolerance to other DMARDs. Subjects were randomized (1:1:1) to receive 2 IV infusions of 1000 mg, 2 weeks apart of first dose of either ABP 798, rituximab RP sourced from the US (rituximab US), or rituximab RP sourced from the EU (rituximab EU). After Week 24, subjects continued treatment with ABP 798 or rituximab EU. The primary endpoint was area under the serum concentration-time curve [AUC] from time 0 extrapolated to infinity [AUC_{inf}] and the maximum observed serum concentration [C_{max2}] following the 2nd infusion of 1st dose; secondary PK endpoints were AUC from time 0 on Day 1 prior to the 1st infusion of the 1st dose to 14 days post-dose ($AUC_{0\text{-}14\ day}$), AUC from time 0 to week 12 ($AUC_{0\text{-}12\ wk}$), and C_{max1} following the 1st infusion of the 1st dose. The PD was evaluated based on the percent of subjects with complete depletion in CD19+ cell count from Day 1 to Day 3.

Results: A total of 311 subjects were randomized (ABP 798, n=104; rituximab EU, n=104; rituximab US, n=103); all subjects were treated with at least one infusion of investigational product. For the primary PK endpoints, the study established PK similarity between ABP 798, rituximab (US) and rituximab (EU) based on 90% confidence intervals (CIs) of the adjusted geometric mean ratio (GMR) for AUC_{inf} and C_{max2} following the 2nd infusion of 1st dose being within prespecified equivalence margin of 0.8 and 1.25. PK similarity was also established between rituximab US and rituximab EU for AUC_{inf} and C_{max2} following the 2nd infusion of 1st dose. In addition, 90% CIs for the GMR for the secondary PK parameters ($AUC_{0\text{-}14\ day}$, $AUC_{0\text{-}12\ wk}$, and C_{max1} following the 1st infusion of the 1st dose) were also within the (0.8, 1.25) margin, supporting PK similarity. PD effects of complete CD19+ B-cell depletion were similar between ABP 798 and rituximab RP arms, with 92/97 (94.8%), 93/96 (96.9%), and 90/97 (92.8%) subjects showing complete B-cell depletion in ABP 798, rituximab EU, and rituximab US arms, respectively.

Conclusion: Results of this study demonstrated PK similarity of ABP 798 to rituximab RP in subjects with moderate-to-severe RA. The PD of ABP 798 and rituximab RP were also found to be similar.

Abstract Number: 0540

Comparing Real-world Retention Rates in a Matched Cohort of Rheumatoid Arthritis Patients Who Either Remained on the Etanercept Originator or Switched to a Biosimilar

Lisa Baganz,[1] Anja Strangfeld,[2] Peter Herzer,[3] Andreas Krause,[4] Hans-Peter Tony,[5] and Angela Zink[6], [1]German Rheumatism Research Center, Berlin, Germany, [2]German Rheumatism Research Center (DRFZ), Berlin, Germany, [3]Scientific Advisory Board, München, Germany, [4]Immanuel Krankenhaus, Berlin, Germany, [5]Department of Rheumatology/Clinical Immunology, University Hospital, Wuerzburg, Germany, Würzburg, Germany, [6]German Rheumatism Research Centre and Charité University medicine, Berlin, Germany

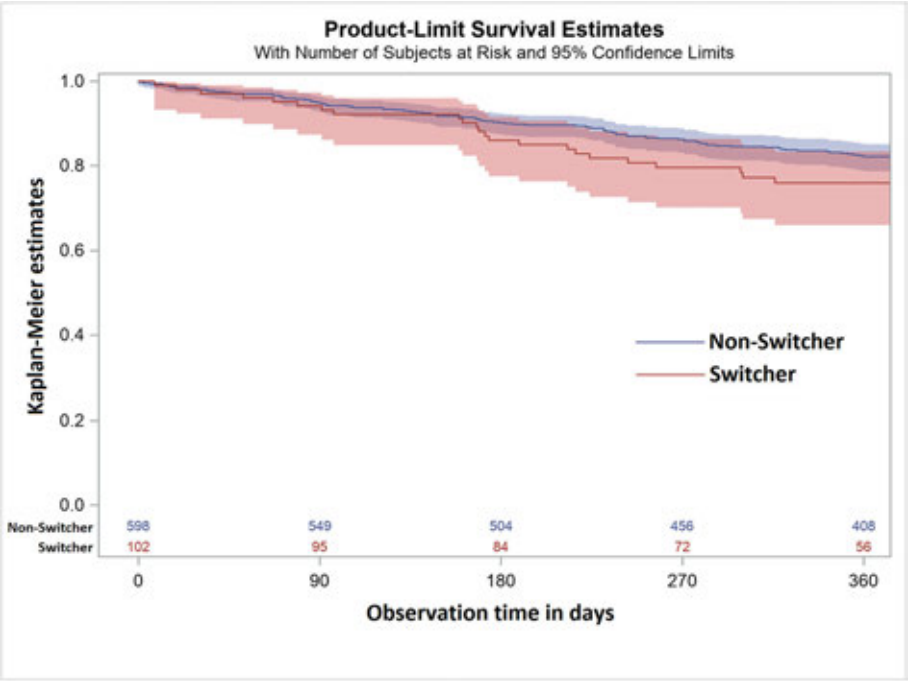
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In Germany, the first etanercept biosimilar was licensed in 2016. In contrast to other European countries there is no uniform recommendation for the prescription of biosimilars. The aim of this study was to compare treatment survival between patients who were switched from the etanercept originator to the etanercept biosimilar SB4 and patients who stayed on the originator treatment.

Methods: We used data of rheumatoid arthritis patients observed in the prospective, longitudinal RABBIT (*R*heumatoid *A*rthritis: *O*bservation of *bi*ologic *t*herapy) cohort until November 2018 who were treated with the etanercept originator (oETA) for at least six months. Patients who thereafter were switched to the biosimilar SB4 (bsETA) were matched (1:n) to patients who stayed on the original treatment using prescription time distribution matching [1] to control for survival bias. Matching criteria were sex, time of switch or corresponding duration of originator treatment in non-switchers and age as well as DAS28 at the time of switching or corresponding time point in non-switchers. The retention rates over one year were analyzed using Kaplan-Meier curves.

[1] Zhou Z et al., Am J Epidemiol. 2005.

Results: Overall, 1,751 patients fulfilled the inclusion criteria of whom 113 were switched to bsETA. Of these, 102 switchers could be matched to 598 patients who remained on oETA. In both groups, 78% of the patients were female, mean age was about 59 years, DAS28 was 3.2 and physical function as well as numbers of prior biologics were similar. Patients who remained on oETA were more often rheumatoid factor positive (71% vs. 63%), had more erosions (56% vs. 47%) and had more frequently three or more comorbidities (34% vs. 28%) than those who were switched to bsETA. The most common reason for switching was costs (79%). After one year, 23% (n=23) of bsETA patients and



Treatment continuation with 95% confidence intervals in etanercept patients who were either switched to the biosimilar SB4 or stayed on the originator.

17% (n=99) oETA patients had stopped the respective treatment. The main reason for discontinuation was “adverse events” in bsETA patients (56%, n=13, thereof 2 serious and 1 planned surgery) and “loss of response” in oETA patients (66%, n=65). Kaplan-Meier curves showed similar retention rates over 12 months for bsETA and oETA (figure). Nine bsETA patients were switched back to oETA.

Conclusion: Retention rates of etanercept treated RA patients who were either switched to the biosimilar SB4 or who stayed on the originator are comparable. Only few patients switched back to the originator.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enerceptan® (EtaBS) has been developed as a proposed biosimilar of etanercept. Phase I study demonstrated pharmacokinetic equivalence with EtaRef.

Methods: A multicenter, non-inferiority, randomized, assessor -blinded, parallel-group, controlled study was conducted in Argentina (NCT03332719). Adults with active moderate or severe RA (2010 ACR/EULAR criteria) with inadequate response to MTX (stable for ≥90 days and throughout the study) were included. Active RA was defined as ≥6 painful joints and ≥8 swollen joints (using 68 and 66-joint assessment respectively) and DAS28 (ESR) ≥ 3.2 and at least one erosion in hands or feet on X-ray at entry. Subjects were randomized in a 2:1 ratio to 32 weeks treatment with EtaBS or EtaREF in a weekly 50 mg dose subcutaneously. Stratification was based on prior use of biological DMARDS and concomitant use of steroids. The primary efficacy endpoint was ACR20 response rate at week 32. Safety, immunogenicity and steady state concentration of both drugs was evaluated. The non-inferiority margin for ACR20 was estimated in 12% with a power of 80%.

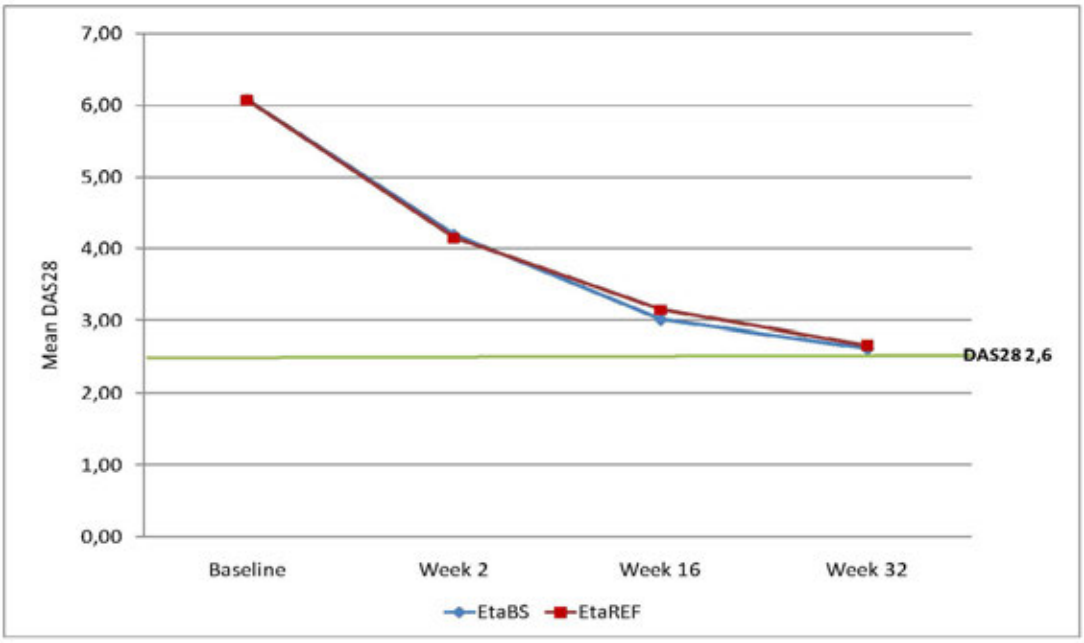

Figure 1. DAS28 average result from baseline to week 32. Per protocol analysis

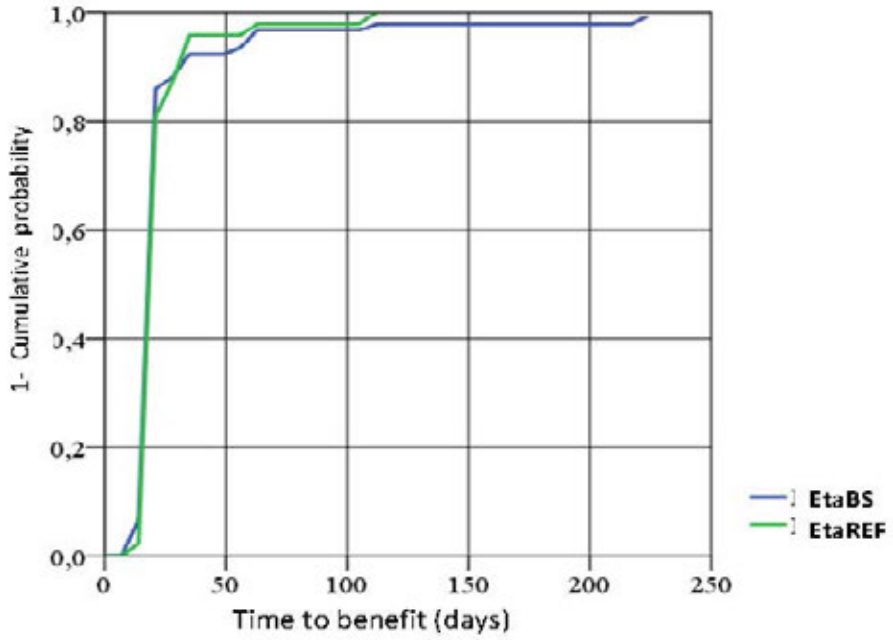

Figure 2. Cumulative probability of benefit. Per protocol analysis

Results: A total of 150 subjects were randomized, 99 were treated with EtaBS and 51 with EtaREF. Five (5) subjects discontinued treatment, 3 subjects treated with EtaBS and 2 treated with EtaREF. *Efficacy:* Per protocol analysis: 85 (92.4%) subjects treated with EtaBS and 44 (93.6%) subjects treated with EtaREF achieved ACR20 (Difference -1.2% CI 95% -10.1; 7.6%). ITT Analysis: 88 (88.9%) subjects treated with EtaBS and 46 (90.2%) treated with EtaREF achieved ACR20 (Difference -1.3%, CI 95% -11.6; 8.9%). ACR50 was achieved by 68.5% and 59.6% subjects and ACR 70 by 48.9% and 42.6%. Sharp/van der Heijde score without radiological progression was maintained by 98.9% and 97.9% respectively. DAS28 results are observed in **Figure 1**. **Figure 2** shows Time to benefit. *Safety*: Frequent

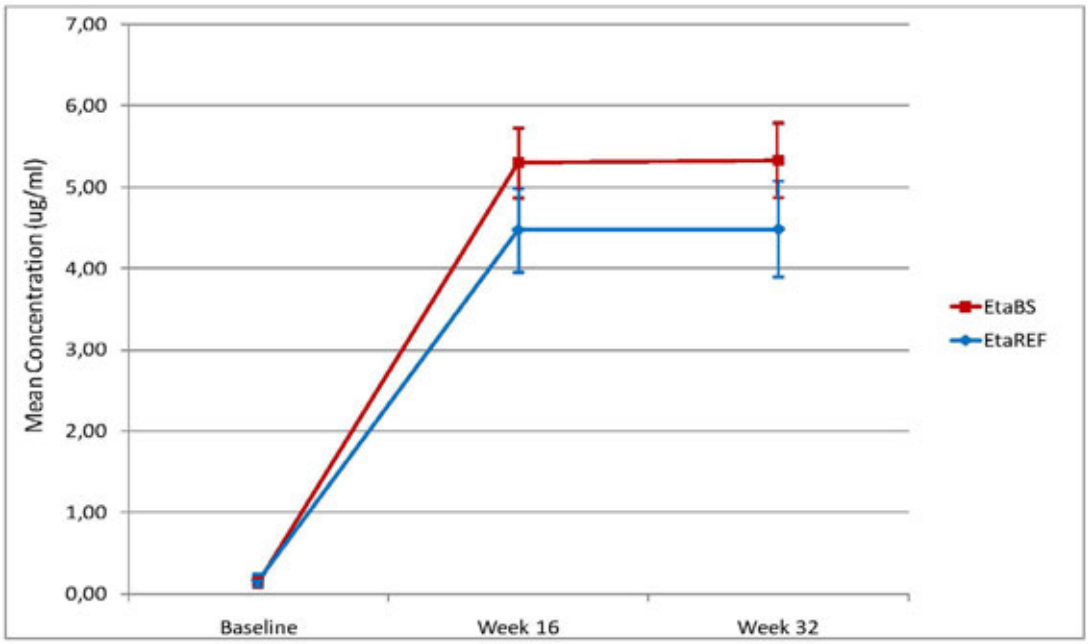

Figure 3. Steady State Concentration

ADRs were developed by 34 subjects (34.3%) treated with EtaBS and by 19 (38.0%) subjects with EtaREF. The most common reaction was upper respiratory tract infection. Six SAEs were developed by 4 subjects treated with EtaBS (lung cancer, epigastralgia, trombophlebitis of left forearm, spondylodiscitis -probably infective- renal colic and colelithiasis). Three subjects treated with EtaREF developed SAEs (unstable angina, acute pelvic inflammatory disease and carpus surgery). No hepatic alterations were developed. Injection site reactions were developed by 67 subjects (67.7%) treated with EtaBS and 33 subjects (66.0%) with EtaREF. Most frequent local reactions were pain and ecchymosis. No subject discontinued due to these reactions. *Immunogenicity*: Three subjects, 2 treated with EtaBS and 1 treated with EtaREF developed antibodies by week 32. All of them had good treatment response. Steady State Concentration results are shown in **Figure 3.**

Conclusion: In this non-inferiority 32 weeks trial, clinical and functional outcomes for EtaBS were not inferior to EtaREF. Both products showed similar safety, immunogenicity and radiographic profiles in patients with moderate to severe active RA on background MTX. EtaBS was granted biosimilarity.

Abstract Number: 0542

'BENEFIT' Pan-European Observational Study to Evaluate the Real-world Effectiveness of SB4 Transition from Originator Etanercept (ETN) in Patients with Rheumatoid Arthritis or Axial Spondyloarthritis: A Switch Success Story

Carlo Selmi,[1] **Klaus Krüger**,[2] Alain Cantagrel,[3] Abad Hernández,[4] Ulrich Freudensprung,[5] Mourad Farouk Rezk,[5] and Janet Addison[6], [1]Humanitas Research Hospital, University of Milan, Milan, Italy, [2]Medical Centre of Rheumatology, Munich, Germany, [3]Center of Rheumatology of CHU, Toulouse, France, [4]FEA Reumatología, Hospital Virgen del Puerto, Cáceres, Spain, [5]Biogen International GmbH, Zug, Switzerland, [6]Biogen UK, Maidenhead, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SB4, a biosimilar to the reference ETN, received EU marketing authorisation in January 2016, based on the totality of evidence from pre-clinical and clinical Phase I and III studies that demonstrated similar efficacy, bioequivalence, and comparable safety and immunogenicity to ETN. The BENEFIT study describes real world evidence on outcomes of transition from originator to biosimilar in both rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA) in 4 EU countries, outside the controlled setting of a randomised clinical trial, with the purpose of providing real world evidence on transition and outcomes of treatment switch in routine clinical practice.

Methods: Eligible patients had RA or axSpA and had initiated SB4 following treatment with a stable dose of originator ETN in a 6-month window. Data were captured from clinic records, retrospectively for 6 months prior and prospectively and/or retrospectively for 6 months after switch. Outcomes include disease score (DAS-28 for RA, BASDAI for axSpA) over time, clinical characteristics and management, and serious adverse events (SAEs).

Results: Of the 557 patients included, 358 had RA and 199 axSpA; data at baseline and after transition are illustrated in Table 1.

One adverse event of pneumonia was reported as Serious (SAE) and related to SB4. Six SAEs unrelated to SB4 were reported: Uveitis, umbilical hernia, relapsing pancreatitis, coronary artery disease, chronic obstructive pulmonary disease and lithium overdose.

Conclusion: These data from clinical practice indicate maintenance of disease status post-switch from ETN to SB4, without the need for dose adjustment, and with high persistence at 6 months after switch, in both RA and axSpA patients**.** No safety concerns were observed. The study data provide pertinent information about 6-month outcomes in these populations, helping to inform evidence-based treatment decisions.

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Different types of cells play pathogenic roles in Rheumatoid Arthritis (RA). The immunogenetics of RA suggests a key role of aberrant pathways of T cell activation in the onset and/or perpetuation of the disease. The differentiation of the naïve CD4 T cell is aimed at differentiating into Th_1, Th_2 and Th_{17}. These molecules probably play a key role in the local generation of specific autoantibodies participating in the autoimmune cascade. Biological treatments for RA interfere different signaling pathways (CD28/CTLA4 system, TNF-α inhibitor, CD20 B cell depleting, IL-6 inhibition, JAKs inhibitors). There are no reports dealing about the impact of serological expression of cytokine profile in RA patients.

Methods: RA patients treated with DMARDs (>3 months) (Methotrexate) and/or biological drugs (Abatecept, Certolizumab pegol, Rituximab, Tocilizumab, Tofacitinib and Baricitinib) attending to two rheumatology outpatient clinics

Table 1. Cytokine profile according to treatment by ANOVA

Variable mean (SD)	Abatacept	Certolizumab	Rituximab	Tocilizumab	Tofacitinib	Baricitinib	Methotrexate	*P* value

were recruited. Blood sample were analyzed by the LEGENDplex Human Inflammation Panel method to perform the profile of cytokines. Disease activity was measured by DAS28-ESR scale, physical functionality with HAQ questionnaire and quality of life of the patient through the EuroQol 5-D questionnaire.

Statistical analysis: Data were presented as numbers, percentage, mean±SD. ANOVA test was performed to compare treatment between groups. P value ≤ 0.05 were considered statistical significant.

Results: Seventy-two RA patients were included, 64 (89%) were female and 19 (26%) smokers. Patients had different comorbidities: 6 (8%) diabetes mellitus, 14 (19%) high blood pressure, 4 (5%) ischemic cardiopathy and 10 (14%) osteoporosis. Ninty-eigth percent were positive for rheumatoid factor and 96% for anti-CCP. Treatment for RA were as follow: Abatacept 11 (15%), Certolizumab nine (13%), Rituximab 11 (15%) Tocilizumab nine (13%), Tofacitinib 10 (14%), Baricitinib 11 (15%), and Methotrexate monotherapy 11 (15%). Cytokine profile according to treatment is presented in Table 1.

Conclusion: Tofacitinib seems to have a better performance inhibiting the cytokine profile in RA patients. More studies and bigger sample are needed to replicate these finding.

Tolerance, Survival, and Adherence to Methotrexate Treatment in Patients with Rheumatoid Arthritis

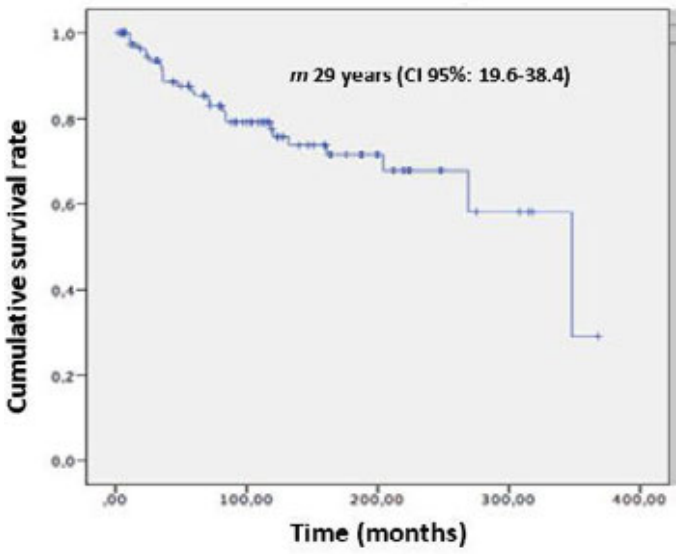
Juan Sevillano,[1] Dafne Capelusnik,[2] Emilce Schneeberger,[3] and Gustavo Citera[4], [1]Instituto de Rehablitacion Psicofisica, Ciudad Autonoma de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [2]Instituto de Rehabilitacion Psicofisica, CABA, Ciudad Autonoma de Buenos Aires, Argentina, [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [4]Instituto de Rehabilitación Psicofísica, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Methotrexate (MTX) is the most frequently used medication in patients with Rheumatoid Arthritis (RA). However, several authors have questioned its success due to the presence of adverse events and the lack of adherence.

Objectives: To determine cumulative survival of MTX, frequency and type of adverse events and causes of discontinuation in patients with RA

Methods: Consecutive patients 18 years and older with a diagnosis of RA (ACR / EULAR 2010 criteria), who had begun treatment with MTX during their disease were included. Sociodemographic, clinical and therapeutic data were collected. Date of initiation and suspension of MTX, route of administration, concomitant treatments, consumption of



m: median; CI: confidence interval

coffee and tobacco, presence of adverse events (AE) were all consigned. Adherence was evaluated using the Compliance Questionnaire Rheumatology questionnaire 5-item summary version (CQR5). Statistical Analysis: Descriptive statistics. Chi² test or Fisher's exact test; Survival of treatment by Kaplan-Meier and log Rank. Multiple logistic regression. A p value < 0.05 was considered significant.

Results: We included 118 patients, 101 were women (85.6%), with a median age (*m*) of 56 years (IQR 49-64) and disease duration *m* 10 years (IQR 6-18). Thirty-five patients (29.7%) were smokers and 56 patients (47.5%) consumed coffee. Eighty-five patients (72%) received MTX orally. 43.2% presented AE associated with MTX, but only 20 patients (16.9%) had to discontinue MTX. Gastrointestinal intolerance was the most frequent AE (27.1%), followed by laboratory test abnormalities (12.7%). 86.6% of the patients presented an adherence ≥80%. The median cumulative survival of MTX treatment was 348 months (95% CI: 235-460.9). In the univariate and multivariate analysis, there was no association of survival of MTX with sociodemographic variables, disease characteristics, concomitant treatment, route of administration, coffee consumption nor level of adherence.

Conclusion: In our cohort, adherence and survival of MTX treatment were good. The cumulative survival was almost 30 years. The presence of AE did not determine the suspension of treatment in most cases.

Molecular Analysis of the Mode of Action of Upadacitinib in Rheumatoid Arthritis Patients: Whole Blood RNA Expression Data from the SELECT-NEXT Study

Samantha Lent,[1] Thierry Sornasse,[2] Robert Georgantas,[1] Jeremy Sokolove,[2] and **Iain McInnes**[3], [1]AbbVie, Inc., North Chicago, IL, [2]AbbVie Immunology Clinical Development, Redwood City, [3]Institute of Infection, Immunity & Inflammation, University of Glasgow, Glasgow, United Kingdom

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients with moderate-to-severe rheumatoid arthritis (RA) with an inadequate response to conventional synthetic disease-modifying anti-rheumatic drugs in the SELECT-NEXT[1] trial. This study provides the translational opportunity to evaluate the pivotal immune regulatory pathway targets affected by UPA in RA patients.

The purpose of the study is to investigate the mode of action (MoA) of UPA in patients with RA by assessing genome-wide RNA expression in whole blood.

Methods: A subset of patients with whole blood samples at baseline, week 2, week 4, and week 12 from the SELECT-NEXT (PBO N = 100; UPA 15 mg QD N = 99) study were analyzed. Gene expression was measured using the Affymetrix Clariom S HT microarray. Out of 800 whole blood samples, 775 passed quality control. Expression intensities were normalized with SCAN,[2] using the BrainArray V23 annotation to map probes to Ensembl gene IDs. For each treatment arm, change in expression from baseline to weeks 2, 4, and 12 was estimated in R using limma,[3] accounting for correlation between samples from the same patient. Association of transcripts with specific immuno-

logical cell type was based on the public domain BLUEPRINT expression database. Pathway analysis was performed with Ingenuity® Pathway Analysis (Qiagen Inc.) version 47547484.

Results: Analysis of the top 100 most affected transcripts by UPA at week 2, week 4, and week 12 identified modest but highly significant modulation of a set of genes known to be differentially expressed in RA peripheral blood. mRNA associated with B and T lymphocytes were increased, while mRNA associated with neutrophils and monocytes were decreased, likely reflecting at least in part changes in leukocyte recirculation. Pathway analysis demonstrated a broad inhibitory effect by UPA on cytokine cytokines associated with the pathobiology of RA (IFNA, IFBNB, IFNG, IL2, IL5, IL6, IL7, IL15, IL21, CSF 2 – 3, OSM, TGFB, TNFA), on intracellular signaling-(STAT, JAK, SYK, PI3K, PRKCA), and on Toll-Like Receptor-pathways (TLR2, TLR3, TLR4, TLR9). Similarly, pathways related to both innate and adaptive immune activation, leukocyte movement, phagocytic cell activity, and leukocyte adhesion were predicted based on mRNA modulation, to be inhibited by UPA. Reciprocally, pathways associated with the numbers of B, T, and hematopoietic cells were predicted to be activated by UPA.

Conclusion: UPA directly inhibits several JAK-dependent pathways, indicative of a key role for JAK1 in multiple pathologic processes. Our data suggest also indirect modulation of a range of JAK-independent pathways. We conclude that UPA normalizes key pathobiological pathways in RA consistent with its clinical effect.

Change in Rheumatoid Arthritis (RA)-Related Autoantibody Profile and Risk of Disease Flare After Withdrawal of Therapy in Patients with Early RA Treated with Abatacept and MTX

René Toes,[1] Thomas Lehman,[2] Joshua Bryson,[3] Amy Min Kim,[2] Sandhya Balachandar,[2] Sumanta Mukherjee,[2] Michael Maldonado,[2] Sean Connolly,[2] and Thomas Huizinga[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Bristol-Myers Squibb, Princeton, NJ, [3]Bristol-Myers Squibb, Princeton

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An emerging concept of "immunologic remission" in RA raises questions about the relevance of the RA autoantibody profile in patients (pts) who are otherwise in clinical remission.[1] The presence of RA autoantibodies indicates adaptive immune activation; several autoantibodies (anti-citrullinated protein antibody [ACPA],

Figure 1. Autoantibody Reactivity Profile and Median Number of Reactivities at Baseline and Month 12 for All Randomized and Treated Patients in the AVERT Trial

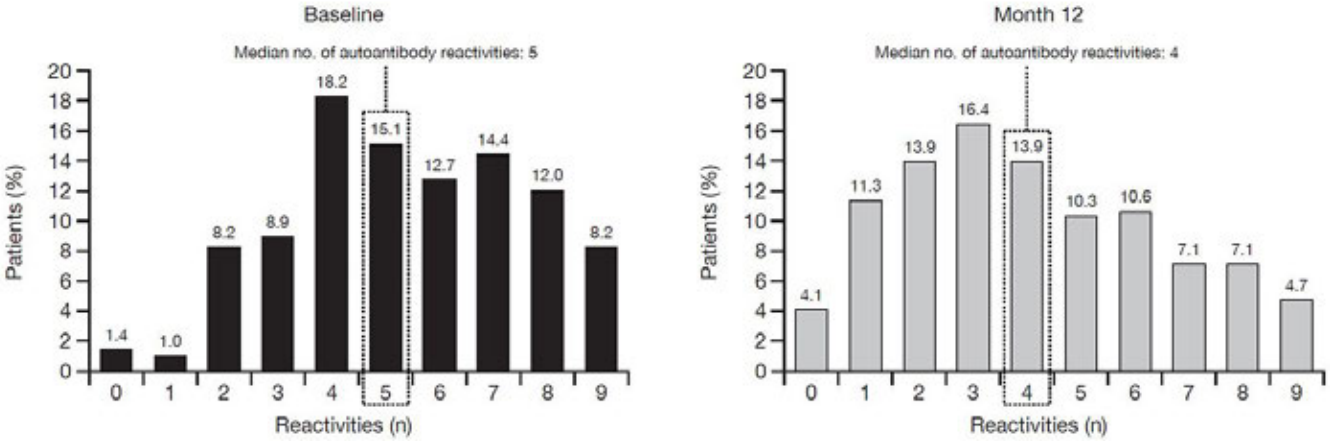

Figure 2. Percentage of Flares by Median Number of Autoantibody Reactivities in Patients Who Entered the Treatment Withdrawal Period of the AVERT Trial With DAS28 (CRP)-Defined Remission (<2.6) at Month 12 of the Treatment Period

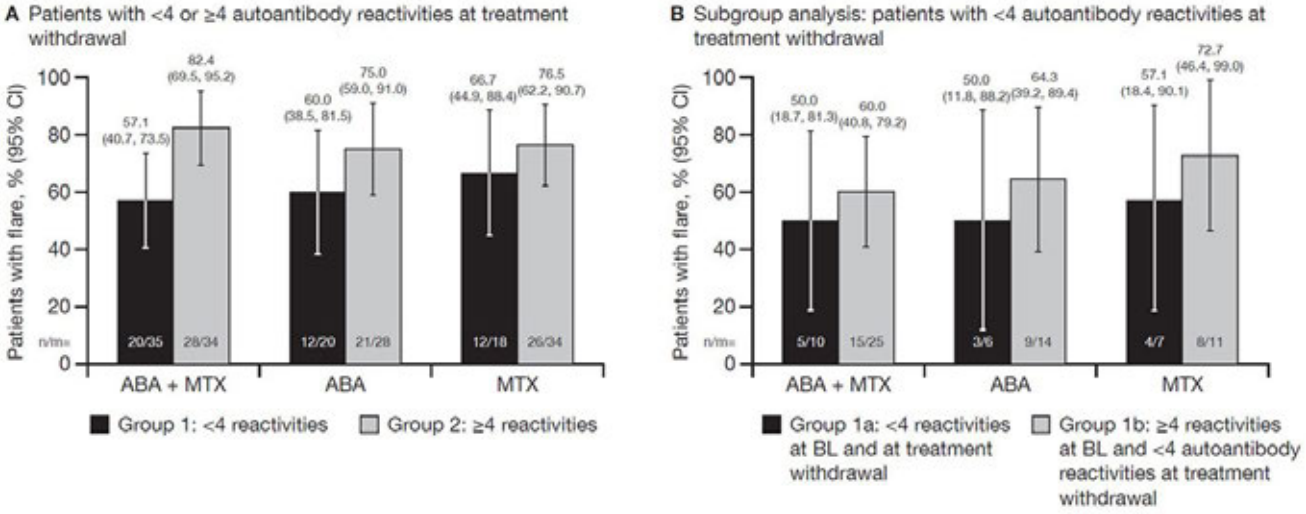
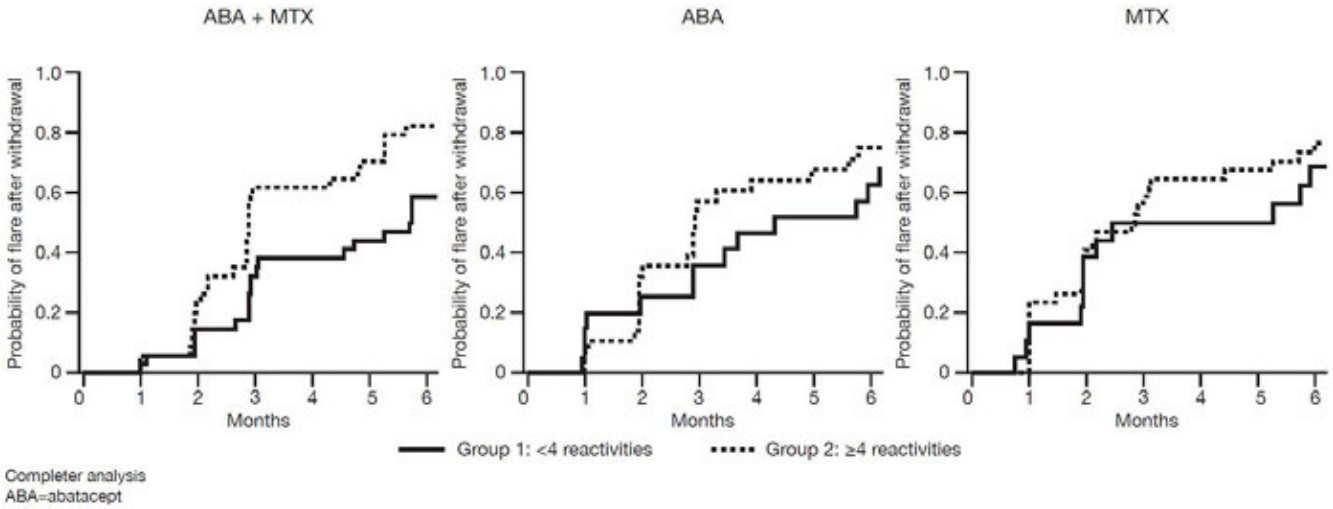


ABA=abatacept; m=number of patients with clinical and autoantibody data available who entered the withdrawal period with DAS28 (CRP) <2.6; n=number of patients with flare after 6 months of treatment withdrawal

anti-carbamylated protein [CarP], RF) and their isotypes (IgG, IgM, IgA) have been identified, but few studies have evaluated the clinical relevance of changes in the complexity of the combined RA autoantibody profile. This *post hoc* analysis of AVERT[2] explored the impact of treatment on the RA autoantibody profile and the relationship between such changes and flare rates following treatment withdrawal for pts in DAS28 (CRP)-defined remission.

Methods: Serostatus of 9 autoantibody reactivities (ACPA, anti-CarP, RF; IgG, IgM, IgA) was assessed by treatment (abatacept [ABA]+MTX, ABA, MTX) at baseline (BL) and Month 12 of the treatment period for pts with clinical and autoantibody data available at both time points. For pts entering the withdrawal period with DAS28 (CRP) < 2.6, the relationship between number of autoantibody reactivities and flare was assessed. Pts were divided into two groups using median number of autoantibody reactivities (4) at treatment withdrawal as a threshold (Group 1: < 4, Group 2: ≥4). Group 1 was further divided: 1a, < 4 reactivities at BL and treatment withdrawal; 1b, ≥4 reactivities at BL and < 4 autoantibody reactivities at treatment withdrawal.

Figure 3. Time to Flare, by Median Number of Autoantibody Reactivities, After 6 Months of Complete Treatment Withdrawal in Patients From the AVERT Trial With DAS28 (CRP)-Defined Remission (<2.6) at Month 12 of the Treatment Period



Completer analysis
ABA=abatacept

Results: In an early RA population (disease duration < 2 years), median number of autoantibody reactivities for 292 pts was 5 at BL and 4 at Month 12 (Fig. 1). Seroconversion rates from + to – for each autoantibody were numerically greater with ABA+MTX than MTX, except for IgA anti-CarP. After 12 months, 169 pts with DAS28 (CRP) < 2.6 with clinical and autoantibody data available entered the withdrawal period. At time of withdrawal, disease characteristics were similar between groups. Following treatment withdrawal, fewer pts in Group 1 vs Group 2 (< 4 vs ≥4 autoantibody reactivities at withdrawal) experienced disease flare (Fig. 2A). In Group 1 subanalysis, fewer pts in 1a vs 1b (< 4 vs ≥4 autoantibody reactivities at BL) experienced disease flare (Fig. 2B). Time to flare was more rapid in patients with ≥4 vs < 4 autoantibody reactivities at withdrawal (Fig. 3).

Conclusion: Differential autoantibody reactivity profile changes were observed following 12 months of abatacept + MTX, abatacept, or MTX. Following complete treatment withdrawal, a less complex autoantibody reactivity profile at both BL and after treatment was associated with a lower rate of disease flare. This suggests that autoantibodies are a modifiable risk factor for disease flare in pts in clinical remission. Additional studies are needed to confirm these findings.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term prevention of structural joint damage is a key treatment goal in the management of RA[1]. Upadacitinib (UPA), a JAK1-selective inhibitor, inhibited the progression of structural joint damage at 6 months as monotherapy in methotrexate (MTX)-naïve RA patients (pts)[2] and in combination with MTX in pts with inadequate response (IR) to MTX[3].

We evaluate the progression of structural joint damage (radiographic) through Week 48 in pts with moderately to severely active RA treated with UPA monotherapy or in combination with MTX.

Methods: Radiographic progression was assessed in 2 phase 3 randomized controlled trials (RCTs), as previously described[2,3]. MTX-naïve pts were randomized to UPA 15 or 30mg QD or MTX monotherapy [SELECT-EARLY, N=945], while MTX-IR pts were randomized to UPA 15mg QD or adalimumab (ADA) 40 mg eow or placebo (PBO), with continuous background MTX [SELECT-COMPARE, N=1629]. Both RCTs specifically enrolled pts at high risk for progression of joint damage (high disease activity including elevated hsCRP, presence of baseline erosions and ACPA and/or RF positivity[2,3]). The mean changes (Δ) from baseline (BL) in modified Total Sharp Score (mTSS), joint space narrowing (JSN), and erosion scores (ES) as well as the proportion of pts with no radiographic progression (ΔmTSS ≤0) at Weeks 24/26 and 48 were determined in both RCTs. Data were analyzed by linear extrapolation (LE) for missing data imputation and treatment switching, and as observed (AO).

Results: BL demographics have been reported previously[2,3]. At Weeks 24/26, UPA as monotherapy and in combination with background MTX significantly inhibited radiographic progression measured by mean ΔmTSS and the proportion of pts with no radiographic progression vs MTX and PBO, respectively (LE and AO, **Table**). The significant inhibition of radiographic progression with UPA was maintained through Week 48 vs MTX (LE and AO) in EARLY and vs PBO (LE) in COMPARE. Following the switch of all PBO pts to UPA in COMPARE by Week 26, no further change in mean mTSS was observed through Week 48 (AO, **Table**). The inhibition of radiographic progression vs comparators was not only observed for the overall mTSS scores but also its components – the JSN and ES in both RCTs (LE and AO).

Conclusion: UPA both as monotherapy, and in combination with background MTX, was effective in inhibiting the progression of structural joint damage through Week 48 in MTX-naïve, and MTX-IR patients, respectively.

Table: Radiographic Progression at Weeks 24/26 and 48 in SELECT-EARLY and SELECT-COMPARE trials.

METHOD of IMPUTATION: Linear Extrapolation

	MTX-naïve (SELECT-EARLY)						MTX-IR (SELECT-COMPARE)					
	Week 24			Week 48			Week 26			Week 48		
	MTX (N=264)	UPA 15 mg QD (N=280)	UPA 30 mg QD (N=273)	MTX (N=268)	UPA 15 mg QD (N=287)	UPA 30 mg QD (N=283)	PBO (N=601)	ADA 40 mg EOW (N=297)	UPA 15 mg QD (N=596)	PBO→UPA 15 mg QD (N=599)	ADA 40 mg EOW (N=298)	UPA 15 mg QD (N=604)
LSM differences in ΔmTSS (within group)	0.66	0.03	0.10	1.00	0.03	0.14	0.94	0.19	0.16	1.73	0.39	0.28
LSM differences in ΔmTSS (UPA or UPA-MTX vs Control)	---	-0.63***	-0.56***	---	-0.97***	-0.87***	---	---	-0.79*** (vs PBO)/ -0.03 (vs ADA)	---	---	-1.44*** (vs PBO)/ -0.11 (vs ADA)

METHOD of IMPUTATION: None (As Observed)

	MTX-naïve (SELECT-EARLY)						MTX-IR (SELECT-COMPARE)					
	Week 24			Week 48			Week 26			Week 48		
	MTX (N=268)	UPA 15 mg QD (N=281)	UPA 30 mg QD (N=275)	MTX (N=247)	UPA 15 mg QD (N=264)	UPA 30 mg QD (N=262)	PBO (N=588)	ADA 40 mg EOW (N=291)	UPA 15 mg QD (N=584)	PBO→UPA 15 mg QD (N=574)	ADA 40 mg EOW (N=276)	UPA 15 mg QD (N=569)
LSM differences in ΔmTSS (within group)	0.65	0.03	0.10	0.85	0.07	0.09	0.67	0.14	0.16	0.51	0.14	0.26
LSM differences in ΔmTSS (UPA or UPA-MTX vs Control)	---	-0.62***	-0.55***	---	-0.78***	-0.76***	---	---	-0.52*** (vs PBO)/ 0.01 (vs ADA)	---	---	-0.26 (vs PBO)/ 0.11 (vs ADA)
Non-progressors, %	78.4	90.4***	90.9***	74.9	89.0***	91.6***	74.1	88.3	86.6***	75.8	85.9	84.7***

Results are summarized by randomized group. In SELECT-EARLY, non-responders (<20% improvement in SJC 66/TJC68 counts) were rescued from MTX monotherapy and UPA monotherapy to UPA+MTX at Week 26. In SELECT-COMPARE, non-responders were rescued from PBO to UPA, UPA to ADA and ADA to UPA at Weeks 14 to 26 (and all remaining non-rescued PBO pts were switched to UPA at Week 26). In AO analysis, observed data at Week 48 are summarized under the randomized group regardless of rescue. In LE analysis, data after rescue are imputed by linear extrapolation. The above mTSS values are from a second reading session of radiographs from Weeks' 24/26 and 48 in both RCTs; previously presented data were from the first reading session and consisted of data for Weeks' 24 and 26 for EARLY and COMPARE RCTs, respectively.

Non-progressors are defined as patients in whom ΔmTSS ≤0. Comparison to control (EARLY: MTX or COMPARE: PBO/ADA) was calculated by ANCOVA; *$p<0.05$, **$p<0.01$, ****$p<0.001$.

ΔmTSS, change from baseline in modified total Sharp score; ADA, adalimumab; EOW, every other week; LSM, least-square means; MTX, methotrexate; PBO, placebo; QD, once-daily.

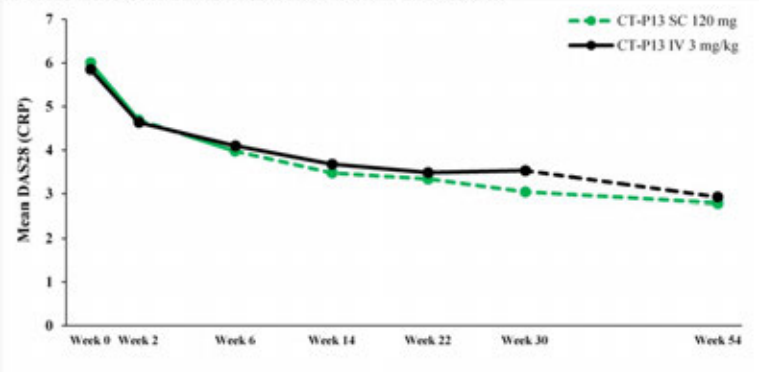
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Efficacy and safety of a new subcutaneous (SC) formulation (CT-P13 SC) were evaluated up to Week 30. The phase I/III randomized controlled trial in patients with active rheumatoid arthritis (RA) study demonstrated non-inferiority of efficacy (mean change [decrease] from baseline in DAS28 [CRP] at Week 22) for CT-P13 SC 120 mg versus CT-P13 IV 3 mg/kg and showed similar safety profile between 2 arms [1]. This is to investigate the efficacy and safety of CT-P13 SC when used over 1-year and after switching from CT-P13 IV in patients with active RA.

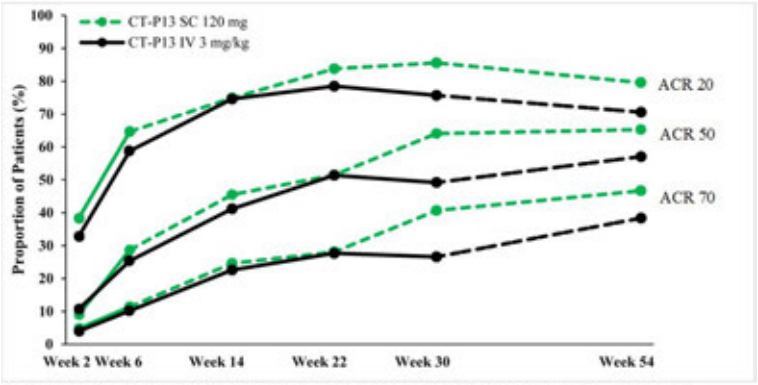
Methods: In this randomized, controlled, double-blinded, phase I/III study, patients who received full doses of CT-P13 IV 3 mg/kg at Weeks 0 and 2 were randomly assigned to receive either CT-P13 SC 120 mg via pre-filled syringe

Figure 1. The Mean Scores of DAS28 (CRP) up to Week 54



Note. All patients in IV 3 mg/kg arm received CT-P13 SC 120 mg from Week 30 to Week 54.
Solid line = IV treatment, Dotted line = SC treatment

Figure 2. The Proportion of Patients Achieving ACR response criteria



Note. All patients in IV 3 mg/kg arm received CT-P13 SC 120 mg from Week 30 to Week 54.
Solid line = IV treatment, Dotted line = SC treatment

Table 1. Summary of Safety Results up to Week 54

Number of patients (%)		Maintenance phase (W6-54)		On or after Week 30 (W30-54)	
		SC 120 mg (N=170)	IV 3 mg/kg (N=178)	SC 120 mg (N=170)	IV 3 mg/kg (N=178)
TEAEs	Total	92 (54.1)	113 (63.5)	72 (42.4)	80 (44.9)
Administration-related Reactions	Total	3 (1.8)	10 (5.6)	2 (1.2)	2 (1.1)
	IRR[1]	0	7 (3.9)	0	0
	SIR[2]	2 (1.2)	3 (1.7)	2 (1.2)	2 (1.1)
	DEL[3]	2 (1.2)	0	1 (0.6)	0
Localized Injection Site Reaction	Total	28 (16.5)	22 (12.4)	22 (12.9)	20 (11.2)
Infection	Total	48 (28.2)	54 (30.3)	31 (18.2)	34 (19.1)

1. Infusion related reaction: occurred between start of administration and 24 hours from the end of IV infusion
2. Systemic injection reaction: occurred between start of administration and 24 hours from the SC injection
3. Delayed hypersensitivity: occurred after 24 hours from the study drug administration

biweekly or CT-P13 IV 3 mg/kg every 8 weeks from Week 6 to Week 28. From Week 30, all patients received CT-P13 SC 120 mg via pre-filled syringe biweekly up to Week 54. Efficacy and safety were evaluated for 54 Weeks.

Results: A total of 362 patients were enrolled, of whom 348 patients were randomly assigned at Week 6 into 2 arms in a 1:1 ratio (169 and 179 patients in SC 120 mg and IV 3 mg/kg arms, respectively). The mean DAS28 (CRP) and ACR response rates were similar between 2 arms up to Week 22 with a slightly greater response in SC 120 mg arm at Week 30. After switching from CT-P13 IV 3 mg/kg to CT-P13 SC 120 mg at Week 30 in IV 3 mg/kg arm, the mean DAS28 (CRP) was similar between 2 arms (Figure 1) whereas ACR response rates were slightly higher in SC 120 mg arm compared to IV 3 mg/kg arm at Week 54 (Figure 2). The safety profiles which occurred on or after Weeks 6 and 30 in SC 120 mg arm were generally comparable to IV 3 mg/kg arm. The majority of the localized injection site reactions were grade 1 or 2 in intensity (Table 1).

Conclusion: The effectiveness and tolerability were confirmed over the 1-year treatment of CT-P13 SC 120 mg. The results after switching from CT-P13 IV 3 mg/kg to CT-P13 SC 120 mg at Week 30 were comparable to that of maintaining CT-P13 SC 120 mg up to Week 54. These results show that the novel SC formulation of CT-P13 via pre-filled syringe could provide a favorable benefit to patients with an alternative convenient way of administration.

Abstract Number: 0549

US Rheumatologists' Beliefs and Knowledge About Biosimilars – an Ongoing Survey

Allan Gibofsky,[1] Dorothy McCabe,[2] and Sam Badawi[2], [1]Weill Cornell Medical College, New York, NY, [2]Boehringer Ingelheim, Ridgefield, CT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A systematic review of survey literature from 2014-2018 found that clinicians in the US and Europe are cautious about biosimilar use (*JMCP;* 2019;25:102). We sought to evaluate current perceptions of biosimilar products among US rheumatologists who prescribe tumor necrosis factor (TNF) α inhibitors now that 8 TNFα inhibitor biosimilars and 1 rituximab biosimilar are FDA approved (thus far, only 1 is marketed in the US).

Methods: A 19-question self-administered online survey was administered by WebMD, LLC from May 7-28, 2019. Rheumatologists (n=9050) who were members of medscape.com and its partner panels were invited to participate via email. The target sample size is 320 board-certified US rheumatologists (self-report); the survey is ongoing and here we present interim results.

Results: Data have been collected from 291 US rheumatologists, 84% are ACR fellows. Nearly all respondents were familiar with the US FDA's definition of a biosimilar product (very/extremely familiar, 82%; moderately familiar, 16%). While 97% of rheumatologists were aware that an infliximab biosimilar was FDA approved, fewer realized that adalimumab, etanercept, and rituximab biosimilars were FDA approved (57%, 62%, and 40%, respectively). When asked to rank what factors are considered when selecting a biosimilar product vs its corresponding reference product (1, most important to 7, least important), responses were varied: 78% selected effectiveness as most important (ranked either 1 or 2), whereas 51% selected physicochemical/functional characteristics as least important (ranked 6 or 7). Most respondents (84%) were aware that an approved biosimilar was not automatically deemed interchangeable by the FDA; 85% felt it important/very important for interchangeable approval to be on the label. Overall, 80% were familiar with the term "totality of evidence." When provided with different patient scenarios, rheumatologists were more likely to initiate biosimilar treatment for a biologic treatment-naïve patient with RA (72%) than they were to switch to

Table. Likelihood of using a biosimilar in different patient scenarios (n=291)

Question	Very Likely/ Likely	Neither Likely or Unlikely	Very Unlikely/ Unlikely
INITIATE treatment with a biosimilar for a biologic treatment-naïve patient who has the **SAME** rheumatologic condition on which the biosimilar approval was based (eg, RA)	72%	18%	10%
INITIATE treatment with a biosimilar for a biologic treatment-naïve patient who has a **DIFFERENT** rheumatologic condition than the one on which the approval was based (eg, extrapolation of RA to psoriatic arthritis)	41%	31%	29%
SWITCH to the biosimilar for a patient **DOING WELL** on the reference product; patient has the **SAME** rheumatologic condition on which the biosimilar approval was based (eg, RA)	33%	22%	45%
SWITCH to the biosimilar for a patient **DOING WELL** on the reference product; patient has a **DIFFERENT** rheumatologic condition than the one on which the approval was based (eg, extrapolation of RA to psoriatic arthritis)	21%	18%	61%
SWITCH to the biosimilar for a patient **NOT DOING WELL** on the reference product; patient has the **SAME** rheumatologic condition on which the biosimilar approval was based (eg, RA)	18%	21%	61%
SWITCH to the biosimilar for a patient **NOT DOING WELL** on the reference product; patient has a **DIFFERENT** rheumatologic condition than the one on which the approval was based (eg, extrapolation of RA to psoriatic arthritis)	16%	19%	65%

Numbers in each row may not total 100% due to rounding.

the biosimilar for a patient with RA doing well on the reference product (33%); see table. About half (54%) of respondents were familiar with the term “non-medical switching” (a misnomer for a biosimilar); among those responding yes, about half (51%; 80/158) had patients for whom this switch had been suggested. The main reasons for non-medical switching included pharmacy benefit insurance/formulary coverage (80%), hospital system formulary (68%) and requirement for a stepped therapy (63%).

Conclusion: This survey suggests that US rheumatologists have an increased understanding and acceptance of biosimilar products, particularly for the initiation of treatment in biologic-naïve individuals. Physicians are hesitant to switch from a reference product to a biosimilar for a patient doing well on the reference product. Additional education on biosimilars is required to help inform treatment decisions by rheumatologists.

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an oral selective Janus kinase (JAK1) inhibitor. In studies to date, FIL has been shown to be effective and safe in patients with RA and other inflammatory diseases (IBD/AS/PsA). DARWIN 3 (NCT02065700) is an ongoing, open-label, long-term extension study of earlier phase 2b studies evaluating the longer-term safety and efficacy of FIL in RA.[1,2]

Methods: All patients who were inadequate responders to MTX completing the 24-week DARWIN 1 (FIL + MTX) and DARWIN 2 (FIL monotherapy) studies were eligible to enter DARWIN 3. All patients in DARWIN 3 received FIL 200 mg/day, with the exception of 15 males, who received FIL 100 mg/day (7 in FIL + MTX, 8 in FIL). Here we present week

Table 1. Event Rates of Adverse Events of Special Interest at Weeks 132 and 156 Interim Analysis a) For week 132, subjects who received MTX for at least 50% of the time while they were receiving FIL in parent study and DARWIN 3, subjects were counted in FIL+ MTX group. b) For week 156, all patients from DARWIN 1 were counted as FIL + MTX and from DARWIN 2 were counted as FIL monotherapy. c) 19 patients in DARWIN 2 started MTX during DARWIN 3 but are categorized as FIL monotherapy. d) Week 132 interim analysis includes adverse events occurring during placebo/screening period, pre-FIL dose. Week 156 interim analysis only includes adverse events that began on or after FIL start date. FIL, filgotinib; NMSC, nonmelanoma skin cancer; PYE, patient-years of exposure.

	Week 132[a]		Week 156[b]	
	FIL + MTX n = 500 (PYE = 1443)	FIL Monotherapy n = 224 (PYE = 599)	FIL + MTX n = 497 (PYE = 1511)	FIL Monotherapy[c] n = 242 (PYE = 692)

156 interim analysis data from the first dose of FIL in the parent studies through 30 May 2018. Patients were analyzed by FIL + MTX (from DARWIN 1) or FIL monotherapy (from DARWIN 2). The event rate was calculated as the total events/total years of exposure of FIL. If the subjects were continuing the study at the time of analysis, the exposure was calculated up to the data cut date.

Results: Of 877 patients completing the parent studies, 739 patients enrolled in DARWIN 3 (497 from DARWIN 1, 242 from DARWIN 2); the majority of patients in DARWIN 1 and 2 were female (81.5%, 81.8%) and white (75.3%, 74.8%) with a mean age of 53 and 52 years, respectively. The mean baseline MTX dose in the FIL + MTX group was 16.8 mg/week. At week 156, 59.9% of patients remained on study treatment. The most common reasons for discontinuation were adverse events (26.5%) and subject request (9.1%). Total exposure to FIL was 2203 patient years; mean ± standard deviation (SD) exposure was 2.86 ± 1.21 years for FIL + MTX and 3.04 ± 1.22 years for FIL monotherapy. Treatment-emergent adverse events (TEAEs) occurred in 419 (84.3%) and 203 (83.9%) patients receiving FIL + MTX and FIL monotherapy; serious TEAEs occurred in 45 (9.1%) and 33 (13.6%), respectively. Event rates of adverse events of special interest remained low at week 156 (**Table 1**). There were 5 deaths (meningococcal meningitis, pneumonia, non-Hodgkin's lymphoma [2], and deep vein thrombosis with pulmonary embolism); none of which occurred after the week 132 analysis (2 in FIL + MTX; 3 in FIL monotherapy). Laboratory values are presented in **Table 2**. Clinical efficacy up to week 156, as measured by ACR20/50/70 responses, and DAS28(CRP) ≤3.2 and DAS28(CRP) < 2.6 using observed cases are shown in **Figure 1**.

Conclusion: FIL was generally well tolerated. No new safety signals emerged. There was no safety difference in patients receiving combination therapy with MTX vs filgotinib monotherapy. Efficacy could be sustained up through week 156 in both the monotherapy and MTX combination groups. Clinical correlations with laboratory value changes are being explored and will be presented at the meeting.

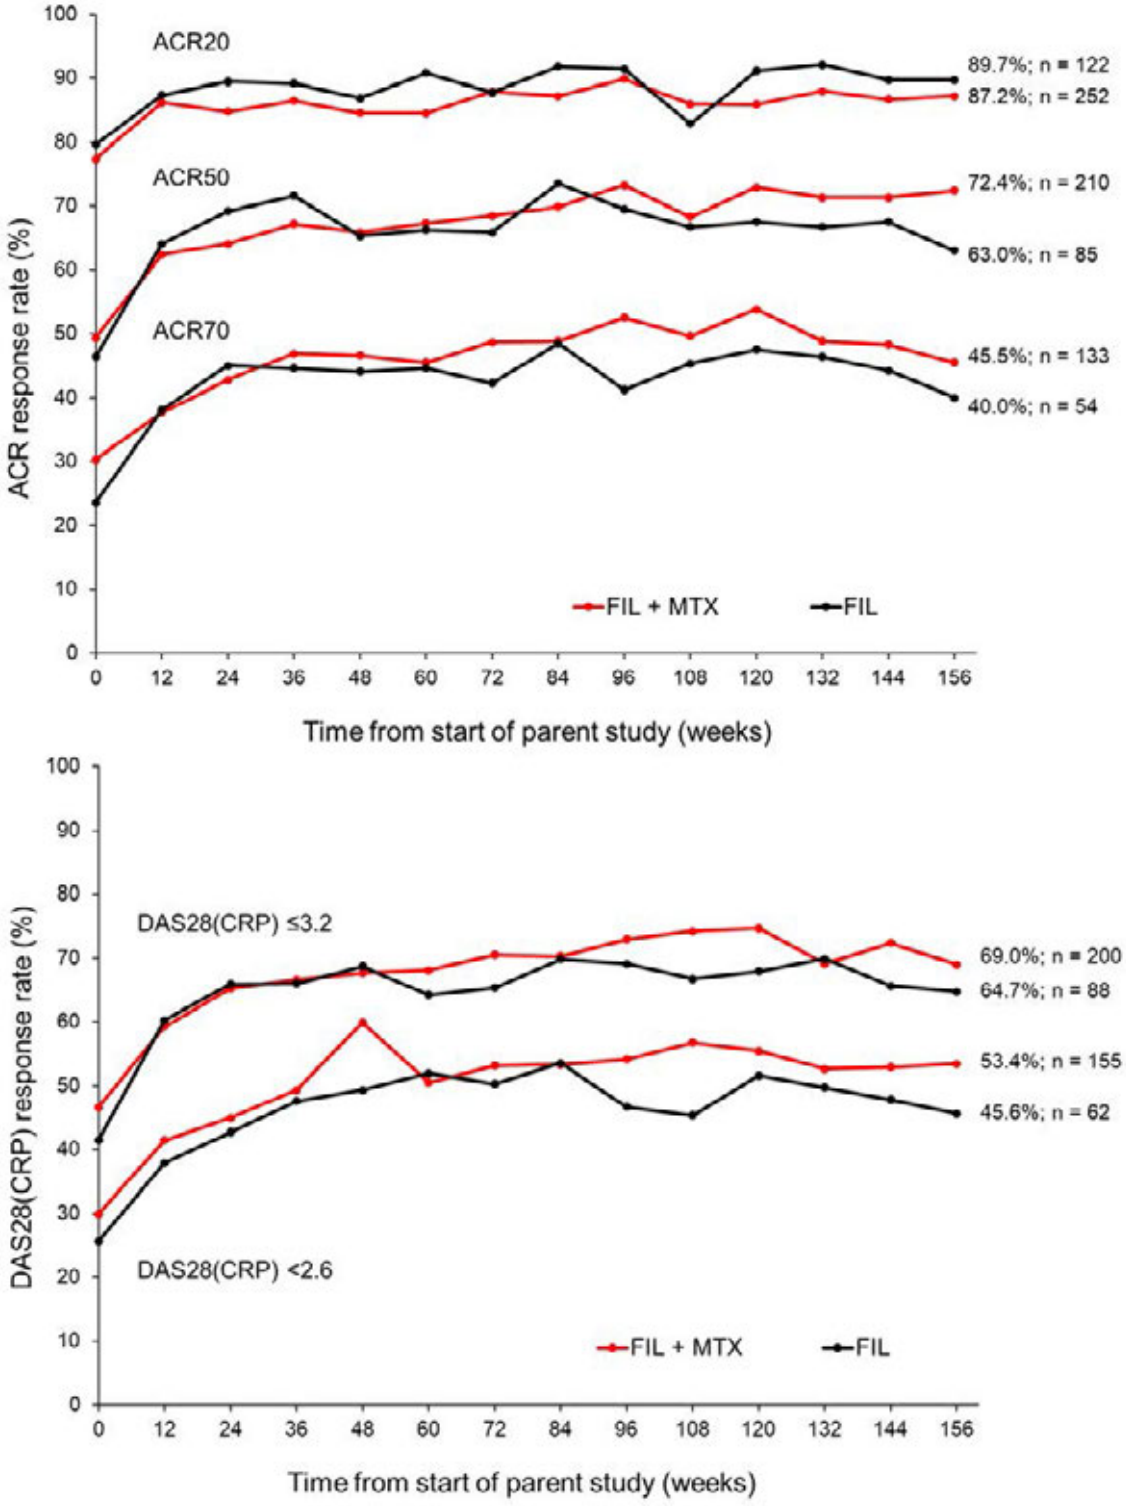

Figure 1. Clinical Efficacy Using Observed Cases by (top) ACR20/50/70 Response by Visit and (bottom) DAS28(CRP) ≤3.2 and DAS28(CRP) <2.6 Response by Visit FIL, filgotinib.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib (UPA) is an oral reversible JAK inhibitor engineered for greater selectivity for JAK1 vs JAK2, JAK3, and TYK2, and is currently being assessed for the treatment of RA. RAPID3 is a pooled index of the three key patient-reported measures: patient global assessment, pain, and physical function. In this analysis we assessed the effect of UPA treatment on RAPID3 in the SELECT-BEYOND, SELECT-COMPARE, and SELECT-MONOTHERAPY trials.

Methods: In SELECT-BEYOND[1], bDMARD-IR pts received UPA 15 mg or 30 mg once daily (QD), or PBO for 12 wks while continuing stable csDMARD therapy. In SELECT-COMPARE[2], MTX-IR pts received UPA 15 mg QD, PBO, or ADA 40 mg every 2 wks for 12 wks while continuing MTX. In SELECT-MONOTHERAPY[3], pts received UPA monotherapy 15 mg or 30 mg QD, or continued MTX monotherapy (cMTX) for 14 wks. We assessed the least squares mean changes from baseline (BL) in RAPID3 and the proportion of pts reporting RAPID3 remission (≤3), low (LDA, >3 to ≤6), moderate (MDA, >6 to ≤12), and high disease activity (HDA, >12). Correlations between RAPID3 remission and remissions defined by CDAI, SDAI, and DAS28(CRP) were also assessed using Pearson correlation coefficients. Non-responder imputation was used for categorical endpoints, and last observation carried forward for continuous endpoints in pts who received rescue therapy in SELECT-COMPARE. Other continuous data are as observed. Data were analyzed descriptively.

Table. Change from baseline in RAPID3 at Wk 12 in SELECT-BEYOND and -COMPARE, and Wk 14 in SELECT-MONOTHERAPY

Phase III study	Group	N	Mean (SD) change from BL
SELECT-BEYOND (bDMARD-IR)	PBO	148	-3.5 (7.1)
	UPA 15 mg QD	159	-6.9 (6.7)
	UPA 30 mg QD	150	-7.4 (6.9)
SELECT-COMPARE (MTX-IR)	PBO	616	-4.2 (6.4)
	UPA 15 mg QD	613	-8.6 (6.6)
	ADA 40 mg EOW	307	-7.0 (6.1)
SELECT-MONOTHERAPY (MTX-IR)	cMTX	203	-3.5 (6.5)
	UPA 15 mg QD	201	-7.2 (7.1)
	UPA 30 mg QD	205	-8.5 (6.3)

ADA, adalimumab; bDMARD, biologic disease-modifying antirheumatic drug; BL, baseline; MTX, methotrexate; IR, inadequate response; PBO, placebo; QD, once daily; SD, standard deviation; UPA, upadacitinib

Results: 498, 648, and 1629 pts were randomized in SELECT-BEYOND, -MONOTHERAPY, and -COMPARE, respectively. Numerically higher improvements from BL in RAPID3 were reported with UPA 15 mg and 30 mg treatment vs PBO in SELECT-BEYOND, and vs cMTX in SELECT-MONOTHERAPY (Table). UPA 15 mg QD was also associated with greater reductions from baseline in RAPID3 vs PBO and ADA in SELECT-COMPARE (Table). Of note, the improvements in RAPID3 with UPA and ADA exceeded the minimal clinically important difference (MCID = 3.8[4]). The proportions of pts achieving RAPID3 remission were numerically higher in the UPA 15 mg and 30 mg groups vs PBO and cMTX in SELECT-BEYOND and SELECT-MONOTHERAPY, respectively (Figure). In addition, the proportions of pts in RAPID3 HDA were lower with UPA vs PBO and cMTX in these trials. In SELECT-COMPARE, higher rates of RAPID3 remission, with fewer pts in HDA, were evident with UPA 15 mg treatment vs PBO and ADA (Figure). Correlations between RAPID3 and other remission endpoints were significant ($p< 0.001$; $r=0.35–0.75$) in all three trials at both baseline and Wk 12/14.

Conclusion: UPA was associated with improvements in RAPID3, both as monotherapy and in combination, in MTX-IR (SELECT-COMPARE and SELECT-MONOTHERAPY) or bDMARD-IR (SELECT-BEYOND) pts. UPA treatment can result in improved patient-reported disease activity, pain, and physical function in RA.

Abstract Number: 0552

In the Real World Clinical Setting Etanercept Biosimilar SB4(BENEPAIL®) Demonstrates Equivalent Safety and Effectiveness in Biological Naïve as Well as with ENBREL® Pretreated RA,SPA, and PSA Patients

Herbert Kellner [1], [1]Praxis Prof. Herbert Kellner, Munich, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: Biosimilar TNFα inhibitors have only become available in the last few years. Etanercept bisosimilar SB-4 Benepali® has been launched in March 2016 in Germany. Although controlles studies have shown equivalent efficacy and safety compared to the originator, so far only limited data about using biosimilar agents in the daily clinical settiing are availalbe.

Purpose: Assessment of safety and effectiveness of etanercept biosimilar (BioETA) SB4 in the daily clinical setting.

Primary study endpoints:

1) To assess the effectiveness of biosimilar SB4 in biologic naive RA, SpA and PsA patients at baseline and 3, 6 and 12 months after SB4 initiation.

2) To assess safety and effectiveness at Baseline and 3, 6 and 12 months post switch to etanercept biosimilar SB4 from etanercept reference product (Enbrel®) in RA, SpA and PsA patients. Mean disease activity will be assessed during the 12 months treatment periods.

Methods: Prospective and retrospective non-interventional study

Number of included patients: n=40 (RA:14, SpA: 8, PsA:4)

Switch patients: n=14 (RA: 8, SpA: 4, PsA: 2)

All patients re3ceived commervially available BioETA SB4 50 mg sc. per weel. Controlled treatment Phase: Data have been collected prior to BioETA therapy and during aq treatment period of 12 months. At Baseline and after 3, 6, and 12 months clinical disease activity scores (DAS28, Haq, BASDAI, BASFI and BASMI, PASI) and lab tests (CRP, ESR) were performed. Also safety data were acquired.

Results: 40 patients (m= 19, f= 21) were included in this IIT. Average diease duration prior to study entry was 5.9 years (RA); 10.1 (AS), 8.1 (PsA) in therapy naive patients and 8.2 years (RA), 15.2 (AS) and 6.1. (PsA) respectively in switchers.

Clinical disease activity indices (DAS28) improved in ETA-naive RA from 5.5 to 3.4, Haq from 1.9 to 1.4 and FFbH from 50 to 90 %. In ETA-naive SpA patients the BASDAI decreased from 5.9 to 3.2, BASMI from 4.8 to 4.2. ETA naive PsA patients showed improvement of skin (PASI 23.1 to 10.1) and musculoskeletal (Haq 2.1 versus 1.2). CRP and ESR rates improved accordingly.

In switched patients, no significant changes in clinical disease activity scorea as well as lab test results were observed.

Regarsding safety aspects, one patient had to stop ETA- Biosimilar therapy due to side effects (developed psoriatic skin lesions).

Conclusion: The result of the observational study confirm the effectiveness and safety of BioETA SB4 (Benepali) in all real-life Setting, which has previously been investigated in controlled studies in ETA naive patients as well as in patients being switched from Enbrel (R) to SB4. These data may support decision making by prescribers as well as on patients' acceptance towards their choice for BioETA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: RA – Treatments Poster I: Novel Treatments

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: GP2015 is an etanercept biosimilar approved for moderate to severely active rheumatoid arthritis (RA), severe active ankylosing spondylitis (AS), and active and progressive psoriatic arthritis (PsA), besides other indications. The COMPACT study is a multicentric, prospective, observational cohort study to evaluate drug persistence, effectiveness, safety and quality of life with GP2015 treatment in patients with rheumatic diseases under

Table 1: Patient enrollment per disease and patient groups*

	Group A n (%)	Group B n (%)	Group C n (%)	Group D n (%)	Total n (%)
Enrolled	162	32	199	37	430
Primary indication RA	96 (59.3)	16 (50.0)	141 (70.9)	3 (8.1)	256 (59.5)
Primary indication AS	39 (24.1)	12 (37.5)	14 (7.0)	28 (75.7)	93 (21.6)
Primary indication PsA	27 (16.7)	4 (12.5)	44 (22.1)	6 (16.2)	81 (18.8)

Group A: switched from reference etanercept (ref ETN; ie., stable, in remission or low disease activity);

Group B: switched from other anti-TNFs (uncontrolled, progressive, high disease activity);

Group C: biologic-naïve (failed treatment with conventional synthetic disease-modifying anti-rheumatic drugs including methotrexate);

Group D: DMARD-naïve (recently diagnosed with severe, active disease).

Table 2: DAS28-ESR scores over 12 Weeks – (RA Patients only)

DAS28-ESR n; Mean (SD)	A (N=96)	B (N=16)	C (N=141)	D (N=3)	Total (N=256)
Baseline	76; 2.1 (0.9)	12; 3.64 (1.2)	119; 3.3 (1.5)	3; 2.2 (1.0)	210; 2.9 (1.4)
Week 12	32; 1.9 (0.8)	3; 3.6 (1.2)	45; 3.0 (1.4)	1; 4.0 (0)	81; 2.6 (1.3)

real world conditions. Here, we report data form an interim analysis in different patient subgroups with first effectiveness data focusing on the largest indication RA as well as safety data for all enrolled patients.

Methods: Patients aged ≥18 years with RA, AS or PsA were initiated treatment with GP2015 prior to enrollment. Patients are categorized based on prior treatment status: (Group A) switched from reference etanercept (ref ETN; ie., stable, in remission or low disease activity); (Group B) switched from other anti-TNFs (previous failure); (Group C) biologic-naïve (failed treatment with conventional synthetic disease-modifying anti-rheumatic drugs including methotrexate (csDMARD–MTX); (Group D) DMARD-naïve (recently diagnosed with severe, active disease). Effectiveness assessments included Disease Activity Score 28-joint count erythrocyte sedimentation rate (DAS28-ESR) until week 12 after enrollment into the study. Functional disability was measured by the Health Assessment Questionnaire Disability Index (HAQ-DI). Incidences of adverse events (AEs), serious AEs (SAE) and adverse drug reactions (ADRs) were reported.

Results: In total, 430 patients were recruited in Germany, UK, Spain, Poland, and Canada until the interim analysis cut-off date in April 2019. Of these, 37.7% of patients were switched from ref ETN, 7.4% were switched from other anti-TNFs, 46.3% were biologic-naïve, and 8.6% were DMARD-naïve. Most patients had RA (59.5%), followed by AS (21.6%) and PsA (18.8%) (Table 1). Comorbidities were more frequent in RA patients (77.7%) than PsA (66.7%) or AS (57%) patients and systemic corticosteroids use was highest in RA patients (47.7%). For RA patients as the largest population, total mean DAS28-ESR scores were 2.9 (1.4) for all 4 groups at baseline, and decreased to 2.6 (1.3) by week 12 (Table 2). HAQ-DI scores in RA patients changed from 0.88 to 0.76 until week 12. Overall, 33% of the patients had at least one AE, while 2.8% of the patients discontinued due to AEs and 8.4% required interruption of the study drug due to AEs (Table 3). No deaths occurred in the study.

Conclusion: COMPACT study is an ongoing observational study of treatment of RA/PsA/AS patients with GP2015 etanercept biosimilar. This interim analysis on real-world treatment with GP2015 showed initial results of effectiveness and safety. Patient distribution in the different patient groups reflect real-life situation. Comorbidities in RA patients were more frequently reported than in AS and PsA. No new safety signals were observed compared to previously published data on etanercept[1-3].

Evidence to Guide Glucocorticoid Tapering Is Lacking in RA

Beth Wallace,[1] David Wallace,[2] Akbar Waljee,[3] and Daniel Clauw[4], [1]Center for Clinical Management Research, VA Ann Arbor Healthcare System; Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [2]Division of General Medicine, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [3]Center for Clinical Management Research, VA Ann Arbor Healthcare System; Division of Gastroenterology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI, [4]Division of Rheumatology, Department of Internal Medicine and Division of Anesthesia, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: RA – Treatments Poster I: Novel Treatments
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Over a third of RA patients are managed with long-term oral glucocorticoids (GC), defined as daily GC use for ≥3 months[1]. Due to dose-dependent toxicity concerns, current ACR guidelines for RA management recommend tapering GC when possible[2]. Despite this, GC tapering is under-studied in RA. This is particularly true among patients with established RA (>2 years' duration) who use long-term GC. These patients often have high cumulative GC exposure levels and GC-associated comorbidities, and are prone to withdrawal symptoms when GC are tapered. Our aim was to review existing clinical trials that evaluate GC tapering in RA.

Figure 2. Search strategy from clinicaltrials.gov (4/18/19)

Table 1 Included studies

Identifier or citation(s)	Acronyms	Subjects	Population	Design	Study groups	Primary Outcome	Initial daily GC dose	GC tapering strategies
Clinicaltrials.gov								
NCT02466581 NCT01491815	NORD-STAR	812	Early RA	Multicenter randomized, open-label, assessor-blinded	MTX + (1a) SSZ + HCQ + IA GC (1b) Oral GC taper (2) Certolizumab (3) Abatacept (4) TCZ	Remission (CDAI), week 24	Prednisone 20mg	Taper over 9 weeks to 5mg/day, stop after 9 months
NCT02930343		150	Early RA	Single-center randomized, open-label	1) MTX + LEF + HCQ + oral GC bridge 2) MTX + SSZ + HCQ + oral GC bridge	EULAR good response, 3 months	Prednisolone 7.5mg	7.5 mg/day for 2 weeks, 5mg/day for 2 weeks, 5mg every other day for 2 weeks
NCT02997605	STAR	122	Long-term oral GC users	Multicenter randomized, double-blinded, placebo-controlled	Pre-enrollment DMARDs + 1) Prednisone taper + hydrocortisone placebo taper 2) hydrocortisone taper + prednisone placebo taper	GC discontinuation, 1 year	Per treating physician	Prednisone: reduce 1mg/mo from pre-enrollment dose until off or 1 year Hydrocortisone: 20 mg/day for 3 months, 10mg/day for 3 months
NCT03649061 Verschuren et al Ann Rheum Dis 2015	CareRA	442	Early RA	Multicenter randomized, double-blinded	MTX + oral GC taper + 1) leflunomide 2) etanercept	Area under DAS-28 curve, 104 weeks	Prednisone 30mg	30-20-12.5-10-7.5mg for 7 days each, 5mg until week 28, 2.5mg for 2 weeks, stop
NCT01219933 Ribbens et al Ann Rheum Dis 2014	ACT-ALONE	68	Current oral GC users	Multicenter open-label, single-arm	Phase 1: tocilizumab + oral GC per treating physician until LDA (DAS-28-CRP) or 6 months Phase 2: Oral GC taper per physician if persistent LDA	Phase 1: Median cumulative GC dose Phase 2: GC discontinuation with continued LDA (DAS-28), 20 weeks	Methylprednisolone 1-20mg	Per treating physician
NCT02644499		186	Early RA	Single-center randomized, open-label	1) MTX + LEF + HCQ + oral GC bridge 2) MTX + oral GC bridge	EULAR good response, 3 months	Prednisolone 15mg	15 mg/day for 2 weeks, 10 mg/day for 2 weeks, 5mg/day for 2 weeks, 2.5mg (duration not given), stop

Methods: We searched clinicaltrials.gov for registered studies of oral GC use in RA patients since 2008 (Fig. 1). In addition, we reviewed studies captured by a previous systematic review of clinical trials of GC tapering in RA, which included years 1972 to 2011 [3].

Results: Results: 2300 entries from clinicaltrials.gov were screened (Fig. 1-2). 179 entries evaluated GC, and 11 evaluated oral GC tapering. Five additional studies were identified from the previous systematic review, for a total of 16 studies. Of the 11 clinicaltrials.gov entries, seven incorporated GC tapers as induction treatment or bridge therapy for early RA patients (Table 1). Two entries did not specify starting GC dose or taper duration. One entry (NCT02573012) compared RA disease activity among patients on tocilizumab randomized to continue vs. stop vs taper off long-term oral GC. The last (NCT02997605) compared efficacy of prednisone vs. hydrocortisone tapers in allowing RA patients to discontinue long-term oral GC. Of the five studies identified from the previous systematic review, three incorporated GC tapers as induction treatment for early RA patients. The remaining two studies compared RA disease activity (Tengstrand et al) or radiographic progression (Pincus et al) among patients randomized to continue vs taper off long-term GC. Of the 16 studies reviewed, only one (NCT02997605) evaluated GC withdrawal symptoms as a secondary outcome. Another (Tengstrand et al) allowed for slower GC taper if "withdrawal symptoms" occurred, but did not specify how these were defined.

Conclusion: There is little published trial data to guide clinicians attempting to taper long-term GC among patients with established RA. We identified only one trial directly comparing two GC tapering regimens, which is currently unpublished. Further work is needed to develop data-driven protocols for GC tapering that account for GC withdrawal symptoms.

Oncostatin M Receptor (OSMR) Underexpression in Patients with Ankylosing Spondylitis

Maria Andreza Correia,[1] **Claudia Marques**,[1] Anderson Almeida,[1] Vitor Silva,[1] Nara Cavalcanti,[1] Moacyr Rego,[1] Angela Duarte,[1] and Maira Pitta[2], [1]Universidade Federal de Pernambuco, Recife, Brazil, [2]Universidade Federal de Pernambuco, Recife, Pernambuco, Brazil

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Oncostatin M receptor (OSMR), that binding to oncostatin M (OSM) cytokine are associated with inflammation and cell's growth and differentiation. OSM uses the OSMR to powerfully induce RANKL production and osteoclast formation and downregulate the expression of Wnt signalling antagonists such as sclerostin in osteocytes, suggesting these cytokines mediate the enhanced bone formation. Our hypothesis is that OSMR are

implicated on physiopathology of syndesmophytes formation in ankylosing spondylitis (AS) patients. The objective of this study was to evaluate the OSMR levels in AS patients compared to health controls and correlate with disease activity and treatment.

Methods: Seventy two adults patients with AS and 32 healthy age and sex-matched healthy controls were enrolled. The disease activity was calculated by both Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and An-

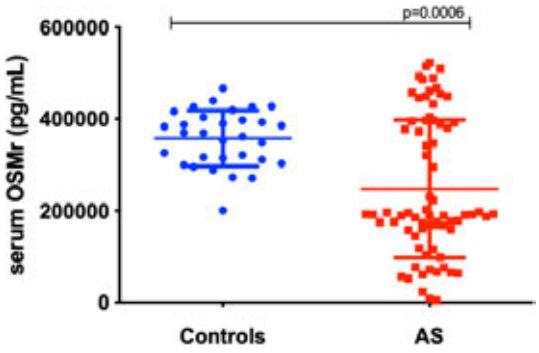

Figure 1. Serum OSMR levels in ankylosing spondylitis patients (AS; n=72) compared with controls (n=31) (CI=95%; Mann Whitney test)

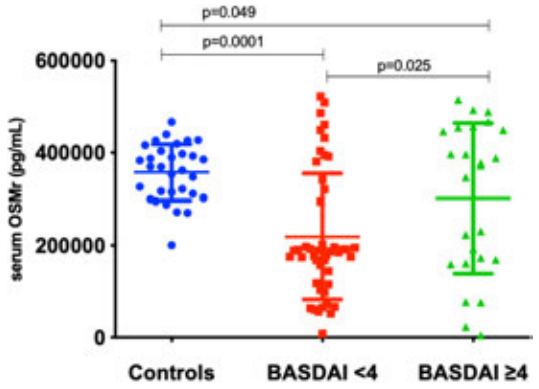

Figure 2. Serum OSMR levels in ankylosing spondylitis patients with low disease activity (BASDAI <4; n=47), high disease activity (BASDAI≥4; n=25) and controls (n=31) (CI=95%; Mann Whitney test)

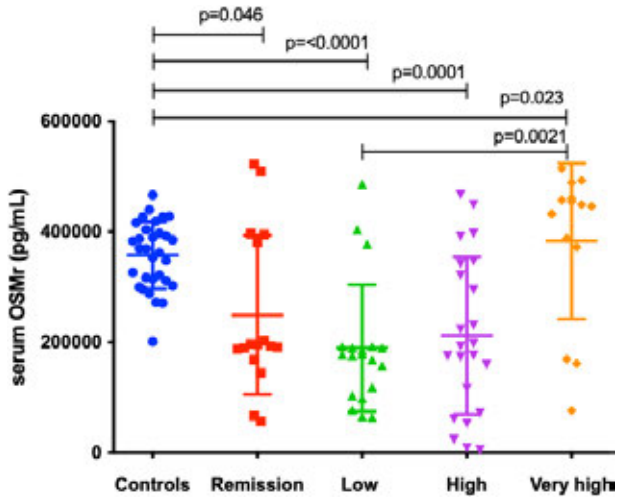

Figure 3. Serum OSMR levels in ankylosing spondylitis patients comparing controls (n=31) and ankylosing spondylitis disease activity using ASDAS cutoff points: remission (2.1 to 3.5; n=23) and very high (>3.5; n=14) (CI=95%; Mann Whitney test).

kylosing Spondylitis Disease Activity Score (ASDAS/CRP). Cytokines in serum samples were quantified by human sandwich ELISA (R&D Systems, Minneapolis, USA and eBioscience, San Diego, CA). The lower limits of detection according to our standard curves were 156.25 – 20000 pg/mL for OSMR.

Results: Among the 72 patients with AS, the majority were male (71.2%; n=52), with a mean age 46.6 (10.5), of the diagnostic time of 8.7 (9.8) years. The mean of BASDAI was 3.18 (2.19) and ASDAS/PCR was 2.32 (1.33). Serum OSMR levels were significantly lower in AS patients than in controls (Figure 1). When the AS group was stratified by disease activity, a statistically significant difference was observed between OSMR levels in patients with low (BASDAI < 4) and high disease activity (BASDAI³ 4) when compared to controls (p=0.001 and 0.049, respectively). Statistical difference was also observed among and patients with low and high disease activity (p=0.025) (Figure 2). These results were similar when we used ASDAS cutoff points to assess disease activity (Figure 3). When patients were stratified by treatment, OSMR levels were similar in those that had not yet been treated and in those using anti-TNF alone (p=0.999). Patients who used only SSZ or NSAID had higher OSMR levels at levels similar to controls.

Conclusion: OMSR expression is reduced in patients with AS compared to healthy controls, and these levels are lower in patients who are either on low disease activity or treated with anti-TNF. These results suggest that despite the control of clinical activity, the OSMR mediates the enhanced bone formation in the form of syndesmophytes in an independent way and may eventually become a potential therapeutic target in ankylosing spondylitis.

The Correlation of Bone Bridge and Low Bone Mineral Density Measured by Quantitative Computed Tomography in Patients with Ankylosing Spondylitis

So-Yun Lee,[1] Sang Wan Chung,[1] Ran Song,[2] Hyung-In Yang,[1] and Sang-Hoon Lee[1], [1]School of Medicine, Kyung Hee University, seoul, Republic of Korea, [2]School of Medicine, Kyung Hee University, seoul

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic inflammation of the spine leads not only to new bone formation in axial joints and vertebral spaces, but also to bone resorption leading to osteoporosis, which is increased in ankylosing spondylitis . We planned this study to know whether the formation of bone bridge correlate with low bone mineral density measured by quantitative computed tomography in patients with ankylosing spondylitis.

Methods: The patient's BMD and medical records were analyzed retroactively through chart review. BMD of the lower thoracic and lumbar spine was assessed using QCT. Vertebrae from T11 to L4 were scanned in the supine position. For the BMD of spinal trabecular bone, thresholds of 120 mg/cm^3 for osteopenia (equivalent to a DXA T-score of –1.0 SD) and 80 mg/cm^3 for osteoporosis (equivalent to a DXA T-score of –2.5 SD) were suggested by the International Society for Clinical Densitometry in 2007 and by the American College of Radiology in 2008. We analyzed the near total or total bone bridge on X-rays at the thoracic and lumbar spine (T11-L5 level). R software packages was used for statistical analysis.

Results: Total 52 AS patients were enrolled : 78% male, mean age 47.3 years, mean disease duration 8.2 years, mean ESR 20.6 mm/h, mean CRP 0.7 mg/dL, all patients fulfil modified New York criteria. The trabecular BMD of the lower thoracic and lumbar spine (T11-L5) ranged from 29.1 to 178.8 mg/cm3 (mean 104.8 ± 34.1 mg/cm3), and lumbar spine (L1-L5) ranged from 22.5 to 177.7 mg/cm3 (mean 102.7 ± 35.5 mg/cm3) as measured by QCT. The lumbar BMD measurements showed that 15 (28.8%) had osteoporosis and 19 (36.5%) had osteopenia. Bone bridge formation showed negative correlation with BMD. Low BMD was significantly correlated with bone bridge of lateral side in vertebral body ($p< 0.05$), but not with bone bridge of anterior side in vertebral body. In particular, the correlation was found to be higher in the lumbar spine than the lower thoracic spine ($p< 0.05$).

Conclusion: The reducing mobility of vertebrae due to bone bridge formation affects low BMD in ankylosing spondylitis patients.

Comparing Symptoms, Treatments Patterns, and Quality of Life of Non-radiographic Axial Spondyloarthritis and Ankylosing Spondylitis Patients: Findings from a US Survey

Theresa Hunter,[1] David Sandoval,[2] Nicola Booth,[3] Elizabeth Holdsworth,[4] and Atul Deodhar[5], [1]Eli Lilly and Company, Indianapolis, [2]Eli Lilly and Company, Indianapolis, IN, [3]Adelphi Real World, Bollington, United Kingdom, [4]Adelphi Real World, Manchester, England, United Kingdom, [5]Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To better understand the symptoms, clinical characteristics, treatment patterns, and quality of life (QoL), of non-radiographic axial spondyloarthritis (nr-axSpA) patients and how they compare to ankylosing spondylitis (AS) patients.

Methods: Data from a cross-sectional survey conducted with rheumatologists and their consulting patients in the United States were analyzed. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Patients who had physician confirmed diagnoses of AS and nr-axSpA were eligible to participate. Demographics, disease status (improving, stable, deteriorating slowly, deteriorating rapidly), symptoms, and medication use were reported by the physician, while work disability and QoL measures were reported by the patient using validated questionnaires. QoL and treatment patterns of nr-axSpA and AS patients were compared using parametric tests and non-parametric tests where appropriate.

Results: Data from 88 rheumatologists, 515 AS patients, and 495 nr-axSpA patients were included in this analysis. A higher proportion of nr-axSpA patients were female (46.7% vs. 28.7%; $p< 0.0001$) and had a younger mean age (44.2 vs. 46.3; $p=0.014$) compared to AS patients. Nr-axSpA patients were less likely to be prescribed biologic therapy (59.6% vs. 73.6%; $p< 0.0001$) than AS patients. On average, AS patients experienced slightly more symptoms at diagnosis (2.31 vs. 2.61; $p=0.023$), however, more nr-axSpA patients were reported to experience enthesitis (24.9% vs. 19.3%; $p=0.048$) and synovitis (20.6% vs. 13.1%; $p=0.003$). Patient reported outcomes such as the Assessment of SpondyloArthritis international Society Health Index (ASAS HI;5.24 vs. 5.74; $p=0.171$), Ankylosing Spondylitis

Quality of Life (ASQoL; 5.81 vs. 6.29; p=0.296), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI; 2.92 vs. 3.19; p=0.124), and Work Productivity and Activity Impairment (WPAI; 27.6 vs. 30.2; p=0.183) were similar between nr-axSpA and AS patients.

Conclusion: Nr-axSpA and AS being part of the same disease spectrum (i.e. axial spondyloarthritis) share the same clinical features. The burden of the disease, as assessed by QoL measurements, is also similar in AS and nr-axSpA patients, but despite these similarities, patients with nr-axSpA are less likely to be treated with a biologic. The treatment approach for nr-axSpA needs to be similar to AS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory bowel disease (IBD) is an extra-articular manifestation that can appear in spondyloarthritis (SpA), as well as uveitis and psoriasis. Its prevalence is 5-10%, although subclinical intestinal inflammation has been found in up to 60%. Biological therapy(BT) can be the treatment for IBD or produce it paradoxically. Fecal calprotectin (FC) is an intestinal inflammation marker, useful for early diagnosis and monitoring disease activity.

Methods: Descriptive and retrospective study (January 2003-January 2019) of patients with SpA that develop IBD in a single center. Epidemiological variables, type of SpA, presence of IBD and its characteristics, levels of FC, presence of BT at IBD onset and treatment received were registered.

TABLE 1. CHARACTERISTICS OF IBD IN SpA SUBTYPES

	AS (n=16, 64%)	PsA (n=6, 24%)	uSpa (n=3, 12%)	TOTAL= 25
MEN/WOMEN	14/2	4/2	2/1	20/5 (80%/20%)
AGE AT IBD DX (average in years)	37.56	45.8	34	39.12

GLM	15	0	0 %
VDZ	2	0	0 %
TOTAL	270	6	2.22%

BT: biological therapy, IBD: inflammatory bowel disease, ETN: etanercept, ADA: adalimumab, IFX: infliximab, SCK: secukinumab, UST: ustekinumab, CZP: certolizumab, GLM: golimumab, VDZ: vedolizumab

For the analysis, frequencies and percentages were used in qualitative variables and mean±standard deviation(SD) in quantitative variables. Statistical analysis was performed with IBM SPSS v.23.

Results: We studied 270 patients with SpA, 70.4% male with a mean age of 39.9±12 years. The subtypes of SpA were: ankylosing spondylitis (AS) (n=133; 49.3%), psoriatic arthritis (PsA) (n=116; 43%), undifferentiated SpA (n=16; 5.9%), SpA non-Rx axial (n=3; 1.1%) and reactive arthritis (n=2; 0.7%).

IBD was observed in 25 patients (9.26%), 80% male. At the time of IBD onset, they had a mean age of 39.12±9.8 years, the mean ESR was 31.15±24mm1ªh, CRP 2.7±2mg/dL and BASDAI 4.6. 16 patients had AS, 6 PsA and 3 undifferentiated SpA. TABLE 1.

Regarding SpA diagnosis, IBD appeared after in 15 patients with an average time of development of 8.39±8 years, before in 7 and was simultaneous in 3. The subtypes of IBD were: Crohn's disease (CD) in 13 patients, ulcerative colitis (UC) in 9 and indeterminate colitis (IC) in 3. The FC was > 200µg/g in 17 patients (68%), normal (< 50µg/g)

in 1 and between 50-200μg/g in 7. The incidence rate adjusted for follow-up of the 25 cases was 7.7 cases/1000 patients-year.

At the time of the IBD onset, 6 patients were with BT: Etanercept (ETN) (n=2), Infliximab (IFX) (n=1), Adalimumab (ADA) (n=1), Secukinumab (SCK) (n=1) and Ustekinumab (UST) (n=1). The BT had been initiated the previous 12 months in 5 of them. The incidence rate adjusted for follow-up of the 6 cases of IBD after BT was 1.83 cases/1000 patient-years. TABLE 2.

The treatment of the 25 patients with IBD was mesalazine (n=15), oral corticoid (n=5), methotrexate (n=7) and BT in all cases. The BT was: ADA (n=11; 44%), IFX (n=6; 24%), UST (n=3; 12%), golimumab (n=3; 12%), SCK (n=1; 4%) and vedolizumab (n=1; 4%). The indication was intestinal in 4 patients, joint in 8 and both in 13.

The clinical and analytical evolution in all patients was satisfactory, with a mean ESR of 11.6±9mm1ªh, CRP 0.6±0.3mg/dL and BASDAI 2 in the last control, after an average time of evolution of 12.5±9 years.

Conclusion: In our series, IBD was observed in 9.26% of patients with SpA of which 64% were AS. The most frequent form was CD and it was diagnosed after SpA in 60% of the cases. 6 patients were with BT at the time of IBD onset. High FC (> 200μg/g) was observed in the majority of patients.

Therefore, we recommend assessing of digestive manifestations presence (abdominal pain, weight loss or diarrhea) in patients with SpA due to their possible association with IBD.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A recent study in German chronic back pain (CBP) patients (pts) with a suspicion of axial spondyloarthritis (axSpA) report on the performance of, among others, the ASAS inflammatory back pain (IBP) criteria and the individual IBP parameters. Pts were diagnosed by a rheumatologist blinded for all clinical features but IBP and by a rheumatologist with all diagnostic tests available as in daily practice (reference standard). Data show high

axSpA, axial spondyloarthritis; IBP, inflammatory back pain; ASAS, Assessment of Spondyloarthritis international Society; CI, confidence interval.
* axSpA diagnosis according to rheumatologist with a level of confidence of ≥7 on a 0–10 scale
^ No axSpA patients according to rheumatologist with a level of confidence of ≥7 on a 0–10 scale
∞ Only patients without axSpA diagnosis according to rheumatologist (level of confidence of <7 on a 0–10 scale) are used as control group to calculate specificity

sensitivity but low specificity of the ASAS IBP criteria and individual IBP parameters(1). Performance of IBP in other countries is less studied. Therefore our objective was to investigate what the diagnostic utility of IBP and the individual IBPpar according to the ASAS IBP criteria is in several rheumatology settings in West- and Northern-Europe?

Methods: Data of the multicentre, observational BelGian inflammatory arthritis and spondylitis (Be-Giant) and international SPondyloArthritis Cause Early (SPACE) cohorts were used. The Be-Giant cohort included ≥18 years old, newly diagnosed axSpA patients who were diagnosed by a team of expert rheumatologists and fulfilled the ASAS axSpA criteria. The SPACE cohort included patients, ≥16 years, with (almost) daily chronic back pain for ≥3 months and ≤2 years, with a symptom onset < 45 years. All patients underwent a diagnostic workup according to a predefined protocol of the corresponding cohort, including data on the individual parameters of the ASAS IBP criteria. AxSpA

patients from the SPACE cohort diagnosed by a rheumatologist with a level of confidence on the diagnosis (LOC) of ≥7 on a 0–10 scale were included as 'axSpA'. All patients in SPACE without axSpA diagnosis (LOC ≥7 for no axSpA) were categorised as 'no axSpA'. For patients with a LOC < 7, diagnosis was considered not sufficiently certain and these patients were excluded from primary analyses. Sensitivity, specificity and positive likelihood ratios (LR+) were calculated using axSpA patients from each cohort separately and no axSpA patients as control group.

Results: Information on IBP parameters was available in 228 patients (Be-Giant) and 559 patients (SPACE) of whom 49.6% and 39.5% were male and mean age was 34.7 (SD9.7) and 30.7 (SD8.0) years, respectively. Few axSpA patients had < 2 IBP parameters (table 1a; Be-Giant 3.9%, SPACE 9.1%). The individual IBP parameters show high sensitivity (>80%) but low specificity (< 36%) with 'pain at night' as exception with slightly better specificity. LR+ of IBP were in both cohorts much lower (table 1b) than the LR+ for IBP of 3.1 previously reported as diagnostic estimate in routine practice.

Conclusion: This study shows that the diagnostic utility of IBP criteria in a rheumatology setting in several European countries is lower than previously assumed with a (very) low specificity and LR+. This suggests that the distinctive impact of IBP is almost fully expressed when physicians refer their patient to the rheumatologist.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Dactylitis is a particular feature shared across the several phenotypical forms of spondyloarthritis (SpA), part of the classification criteria. There are only few data available about incidence of dactylitis in early stage of SpA, and factors associated with dactylitis.

Aim: To study, over 5 years in the DESIR cohort, the prevalence and incidence of dactylitis and to look at the factors associated with presence/incidence of dactylitis.

Methods: DESIR is a prospective observational cohort of patients with recent onset (less than 3 years) inflammatory back pain, beginning before 50 years, suggestive of axial SpA, All available factors in the database (clinical, biological, imaging and medico economic) were compared between patients with and without past or present dactylitis at 5 years (for categorical variables : odds-ratio +/- 95% CI and chi-square/Fisher tests, for continuous variables : unpaired t-tests / Mann-Whitney) , by uni and then multivariate analysis (logistic regression). Baseline factors associated with new cases of dactylitis occurrence were also analyzed. Significance: p less than 0.05.

Results: After 5 years, 138 cases of dactylitis were recorded in 480 patients with complete follow-up : prevalence 28.75 % [CI 95% 24.75-32.75]. At 5 years, dactylitis was significantly associated (multivariate analysis) with : Achilles enthesitis (OR : 3.3), history of psoriasis (OR: 3.9), cumulative number of ASAS criteria (OR: 7.2), modified New York criteria fulfillment (OR: 0.35), DMARD use (OR: 2.7) and elevated CRP (OR:0.9).

Incident new cases were recorded in 41 patients, with an estimated incidence of 1.7/100 patient-years. These incident cases were significantly associated with some baseline factors (multivariate analysis) : female gender (OR: 3.6), psoriasis (OR:3.4), HAQ over median (OR: 5.7), IL-31 levels over median (OR: 1.04), ASQol over median (OR: 0.84), IL-6 over median (0.83).

Conclusion: In the DESIR cohort of patients suspected for early SpA, dactylitis presence or history is recorded in 28.7 % of the cases at 5 years, with an estimated incidence of 1.7/100 p-y over 5 years. It is an early feature associated with peripheral involvement, psoriasis, more frequent use of DMARDs, but with less structural damage. Female gender and psoriasis are associated with incidence of new cases of dactylitis over 5 years in this population.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with axial spondyloarthritis (axSpA) physical functioning is frequently impaired. The current gold standard to assess physical functioning is self-reported questionnaires (i.e. BASFI), which, however, are of subjective nature. Therefore, a performance-based test-battery was designed to measure physical functioning more objectively: the ankylosing spondylitis (AS) performance index (ASPI)) [1]. To imitate activities of daily living (ADL), tasks based on BASFI domains, were designed. Although the ASPI had previously been evaluated, a thorough analysis of the deficits of physical functioning and factors which influence the performance of patients with axSpA has not been performed to date.

Methods: Consecutive patients diagnosed with axSpA fulfilling the ASAS classification criteria underwent standardized assessments concentrating on the following variables: patient and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, ASAS Health Index (ASAS HI), PHQ-9, IPAQ), mSASSSand ASPI (ASPI 1: Bending, 2. Putting on socks, 3. Getting up from the floor) [1]. Performance was measured in seconds as time to complete a task based on published instructions given to the patients. Impairment in physical performance was defined as the inability of patients to perform ≥ 1 ASPI test. Spearman Rho correlation was used to compare self-reported functioning and performed physical functioning. Logistic regression analysis was used to identify factors associated with impaired physical performance.

Results: A total of 200 patients (AS 66%, nr-axSpA 34%) was included: 69% males, 44.3±12.5 years old, mean symptom duration 17.9±12.6 years, BMI 27.2±5.5, mean ASDAS 2.5±1.1, BASFI 4.0±2.7, BASMI 3.5±1.8, ASAS HI 7.0±4.1, PHQ-9 8.8±6.2, and mSASSS(n=157) 10.2±18.8. 133 patients were treated with bDMARDs (66.5%). In total 44 patients (22%) were not able to perform one or more ASPI tests. The mean time for bending was 18.6±9.5 sec (n=179/90%), for putting on socks 12.8±6.4 sec (n=156/78%), and for getting up from floor 6.5±5.0 sec (n=187/94%). A significant correlation was found for all three ASPI-tests with BASFI (0.5-0.7), ASAS HI (0.4-0.6). Self-reported physical activity (IPAQ) correlated weakly with ASPI (all 0.2) and structural damage correlated only with the task putting on socks (r=0.3), whereas the other tests did not correlate. Logistic regression showed an influence of obesity, spinal mobility and global functioning on actual performance but not of disease activity and self-reported physical function (Table 1)

Conclusion: This study confirms a good correlation of the ASPI with standard questionnaires of physical functioning and disease activity. However, the ASPI showed a substantial floor effect, since 22% of patients were unable to perform the tests. This striking finding strongly suggests that more information on the actual performance of patients with axSpA is needed. Our data confirm that self-reported physical activity cannot be used as a substitute for the actual performance of axSpA patients. Moreover, obesity as a potential modifying factor that definitely contributes to limitations in actual performance should also be more carefully addressed in patients with axSpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is wide variation in the management of patients with axial spondyloarthritis (axSpA) worldwide with significant unmet needs such as delayed diagnosis. One way to achieve improvement in quality of care is to define quality standards (QS) in order to identify resources and processes which may need to be optimized. To develop ASAS QS to ultimately improve the quality of care for adults with axSpA.

Methods: The Assessment of SpondyloArthritis international Society (ASAS) QS group developed a step-wise approach starting with (I) open discussions resulting in a proposal for possible key areas for quality improvement. Thereafter, (II) ASAS members and invited patients discussed a provisional list with the possibility to propose additional

Table. ASAS quality standards for patients with axial spondyloarthritis

No	Quality statement
1	People with suspicion of axial SpA are referred to a rheumatologist for diagnostic assessment within 3 working days.
2	People with suspicion of axial SpA are assessed by a rheumatologist within 3 weeks after referral.
3	People with suspected axial SpA have their diagnostic work-up completed within 2 months.
4	Disease activity of people with axial SpA is monitored under the supervision of a rheumatologist with validated composite scores at least twice a year.
5	In people with axial SpA and active disease despite conventional therapy, treatment escalation with biologics is discussed.
6	People with axial SpA are informed about the benefits of regular exercise.
7	People with axial SpA are offered education on the disease including self-management within two months of diagnosis.
8	People with axial SpA and disease flare or possibly drug-related side effects receive advice within 2 working days of contacting the rheumatologist.
9	People with axial SpA have a comprehensive annual review by the rheumatologist.

key areas. (III) The complete list was then evaluated by ASAS members and invited patients. (IV) ASAS QS group prioritized key areas, and (V) phrased QS for the most important key areas. Finally (VI), a draft version was commented on, discussed and finally agreed by ASAS members.

Results: The ASAS QS group, consisting of 20 rheumatologists, 2 physiotherapists and 2 patients, provided 34 potentially key areas for quality improvement which were commented by 140 participants (86 physicians, 42 patients). Within that process 3 new key areas were proposed and all 37 key areas were again evaluated by 120 participants (86 physicians, 29 patients). 5 key areas were identified to be most important to phrase QS: referral, rheumatologic assessment, treatment, education/self-management and comorbidities. Altogether, 9 QS (table) were endorsed by ASAS.

Conclusion: ASAS successfully developed the first QS set for improvement of health care provided for adults with axSpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To explore the impact of sex and disease classification on outcomes in axial spondyloarthritis (axSpA) patients, including both ankylosing spondylitis (AS) and non-radiographic (nr-) axSpA, in males and females respectively.

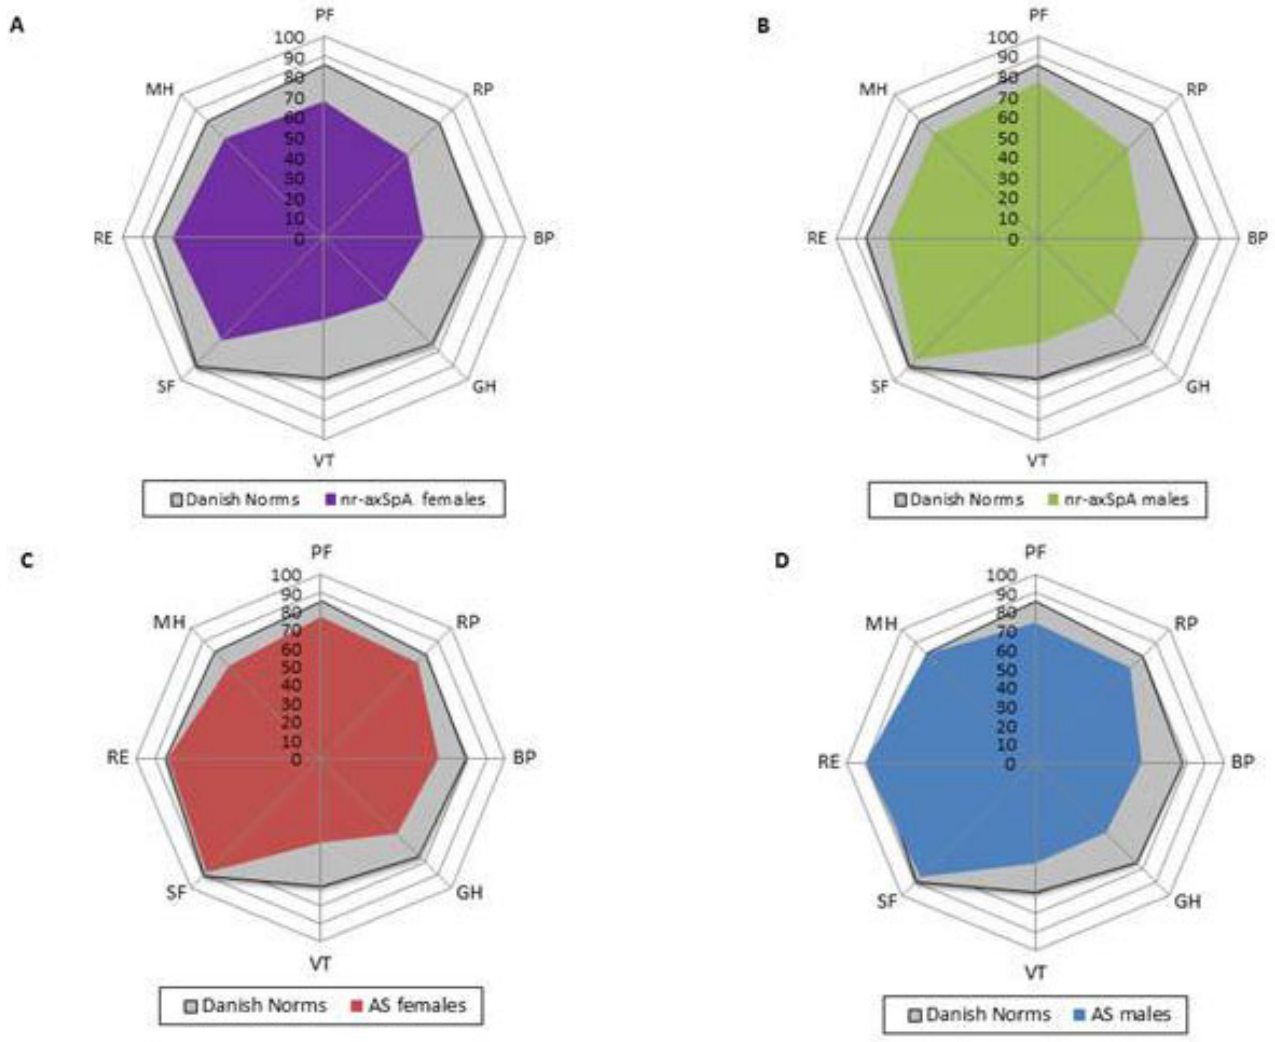

Figure 1. Mean SF-36 scores for Danish axSpA patients stratified on sex and axSpA classification. (A) nr-axSpA females (B) nr-axSpA males (C) AS females (D) AS males. Mean SF-36 scores for Danish norms are also shown. PF, physical function; RP, role physical; BP, bodily pain; GH, general health; VT, vitality; SF, social functioning; RE, role emotional; MH, mental health.

Methods: AxSpA patients were consecutively recruited from 2 rheumatology outpatient university clinics. We explored how sex and axSpA disease classification affected patient-reported outcome measures (PROMs). Statistical tests were applied for group comparisons and interactions. We analyzed the relationship between tender point count (TPC) and the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). The prevalence of extra-articular manifestations (EAMs) and the Charlson comorbidity index (CCI) were determined.

Table 1. Clinical characteristics and patient-reported outcome measures

Comorbidities								
Charlson Comorbidity Index, median [Q_1; Q_3]	1 [0 ; 1]	0 [0 ; 0]	1 [0 ; 1]	1 [0; 1]	0.14[a]	0.03	0.83	0.52
Paraclinic assessment								
HLA-B27 positive, n (%)	27 (90)	9 (90)	15 (60)	19 (54)	0.004[b]	0.66	0.06	0.86

Results: According to the protocol a total of 100 outpatients with axSpA were enrolled (AS males 30; AS females 10; nr-axSpA males 25; nr-axSpA females 35). The BASDAI scores appeared higher among nr-axSpA females (median [Q1; Q3] 47 [21; 60]) compared with the combined median for the three other subgroups 25 [12; 25]. Being classified as nr-axSpA was associated with a lower SF-36 MCS (median SF-36 MCS for the four subgroups: nr-axSpa females: 46.7, nr-axSpA males: 52.3 vs. AS males: 56.9 and AS females: 50.4). Females had a higher tender point count (TPC) compared with females (P< 0.001). TPC and BASDAI were correlated for female nr-axSpA patients (r= 0.44, P=0.008) and male nr-axSpA patients (r= 0.56, P=0.003). EAMs were frequent (up to 50 %) and no difference in the CCI between the subgroups was observed (P=0.14).

Conclusion: This is to our knowledge the first study to evaluate the impact of sex and axSpA classification on PROMs in axSpA patients. AS patients appeared less affected on most PROMs compared with nr-axSpA patients.

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with ankylosing spondylitis, the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) is used to measure disease activity to initiate or maintain TNF inhibitor therapy. However, despite a low disease activity measured by BASDAI, some patients complain of pain or are found in high inflammatory status. In such cases, other disease activity measurement tools such as the Ankylosing Spondylitis Disease Activity Score

Table 1. Difference in disease activity status according to treatment with TNF inhibitors

	Non-TNF inhibitor			TNF inhibitor		
	BASDAI < 4 (N=2,925)	BASDAI ≥ 4 (N=2,184)	p-value	BASDAI < 4 (N=6,569)	BASDAI ≥ 4 (N=1,637)	P-value

*Percentage of available ASDAS in the BASDAI

(ASDAS) may be recommended. The aim of this study was to identify patients with advanced AS who show high disease activity with ASDAS and require active treatment despite low BASDAI.

Methods: In a single center cohort, 1,240 patients with AS were followed up to 18 years. The BASDAI, ASDAS, and modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) were obtained from electronic medical records. The mSASSS was measured almost every 2 years. We used the interpolation method to estimate the mSASSS at the time point when the BASDAI or ASDAS was measured. High disease activity was defined as BASDAI ≥ 4 or ASDAS ≥ 2.1 and low disease activity as BASDAI < 4 or ASDAS < 2.1 at each disease activity measurement. Changes in the distribution of high and low disease activities were investigated by assessing TNF inhibitor use and mSASSS.

Results: A total of 13,315 BASDAI, 4,578 ASDAS-CRP, and 6,066 ASDAS-ESR measurements were obtained from 1,240 patients. The mean duration from diagnosis of AS to the date of measuring the disease activity was 10.2 ± 3.9 years. Of these measurements, 1,435 (44.2%) had ASDAS-CRP ≥ 2.1 and 3,244 measurements had BASDAI < 4. In the TNF inhibitor group, the percentage of measurements with ASDAS-CRP ≥ 2.1 and BASDAI < 4 was similar to that in the non-TNF inhibitor group (492/1,058, 46.5% vs. 943/2,186, 43.1%) (Table 1). The percentage of measurements with ASDAS-CRP ≥ 2.1 and BASDAI < 4 was elevated in patients with mSASSS ≥ 36 compared to that in patients with mSASSS < 36 (323/540, 59.8% vs. 872/2,124, 41.1%) (Table 2).

Conclusion: Despite treatment with TNF inhibitors, some patients remain with high disease activity measurable by tools other than BASDAI. Moreover, the proportion of patients with high disease activity was high in the advanced radiographic progression group. These patients may need active treatment with therapies other than TNF inhibitors.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Management of enteropathic arthritis may be challenging due to differences in treatment response of inflammatory bowel diseases and arthritis to different therapeutic modalities, which may even cause worsening of some manifestations while improving others. Enteropathic arthritis was not addressed in the management recommendations for spondyloarthritis. The aim of this project was to develop a set of evidence based recommendations for the management of patients with enteropathic arthritis

Methods: A task force was formed that included ten rheumatologists and 8 gastroenterologists. Research questions were determined using a Delphi approach. A systematic literature search, data extraction, and statistical analyses were performed according to a pre-specified protocol. Studies that assessed the efficacy of an intervention on inflammatory bowel disease-related outcomes and/or spondyloarthritis related outcomes in patients with enteropathic arthritis were included. Risk ratios were calculated for binary outcomes and mean difference for continuous outcomes, whenever possible. Results of the systematic literature review were presented to the experts and recommendations were formulated after thorough discussions and voting.

Results: A total of 4 overarching principles and 10 recommendations were formulated. The recommendations addressed the use of NSAIDs, corticosteroids, sulfasalazine and 5-ASA derivatives, TNF inhibitors, tofacitinib, secukinumab, ustekinumab, and vedolizumab among patients with active inflammatory bowel disease, active arthritis, active disease regarding both inflammatory bowel disease and arthritis, and among patients in remission. Final voting showed a good agreement among the group on all recommendations.

Conclusion: These recommendations are intended to help rheumatologists, gastroenterologists and other clinicians dealing with enteropathic arthritis and to point out to the shortcomings of the available data on the management of this challenging condition.

IBD: inflammatory bowel disease, *p <0.05

enteropatik artrit süre tablosu-dönüştürüldü

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The correlation between the time frame of the symptoms/diagnosis of spondylitis and the diagnosis of inflammatory bowel disease (IBD) on patients of enteropathic spondylitis (eSpA) is not precisely known. Aim of this study was to determine the timing of symptoms/diagnosis of SpA and the diagnosis of IBD on the patients with eSpA.

Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, single center database of biological treatments since 2005. HUR-BIO SpA registry included 2576 SpA patients, and 90 (3.5%) patients had enteropathic arthritis (EA). Sacroiliitis was defined at 59 (65.5%) patients as modified New York criteria or based on ASAS magnetic resonance imaging. Enteropathic spondylitis defined as inflammatory bowel disease and radiological sacroilitis with inflammatory back pain/spine symptoms. Demographic, clinical, laboratory, therapeutic data and imaging features were collected from this database. Patients with available data about the timing of IBD diagnosis, SpA symptoms and SpA diagnosis were included in the analysis. The temporal relationship between the diagnosis of IBD and the symptom and / or diagnosis of SpA was assessed.

Results: Fifty nine (44.1% female) eSpA patients enrolled in this study. Mean age was 45.0 ± 13.0 years, mean disease duration was 9.9 ± 7.8 years.IBD type was UC in 31 (52.5%) patients, CD in 28 (47.5%) patients. The symptoms of spondylitis were present in 49 (83%) patients before the diagnosis of IBD [CD 96.4% vs UC 71.0%, p=0.009] (Table 1). In 23 patients, SpA diagnosis was made after IBD diagnosis [CD 25% vs UC 51%, p=0.036]. The median time lag between the diagnosis of IBD and SpA was 2 (1-9) years for CD, 7.5 (2-23) years for UC, p=0.027. The mean delay time for the diagnosis of SpA in patients with eSpA was 4 (0-31) years [4 (0-31) years in CD vs 3 (0-22) years UC patients, p:0.57].

Conclusion: In most of eSpA patients, spondylitis symptoms were present before diagnosis of IBD and this finding was more prominent in CD. On the other hand, the diagnosis of spondylitis was made after the diagnosis of IBD in almost 40% of patients. In UC, this condition was more distinct**.**

Worse Outcomes for Female Patients with Axial Spondyloarthropathy

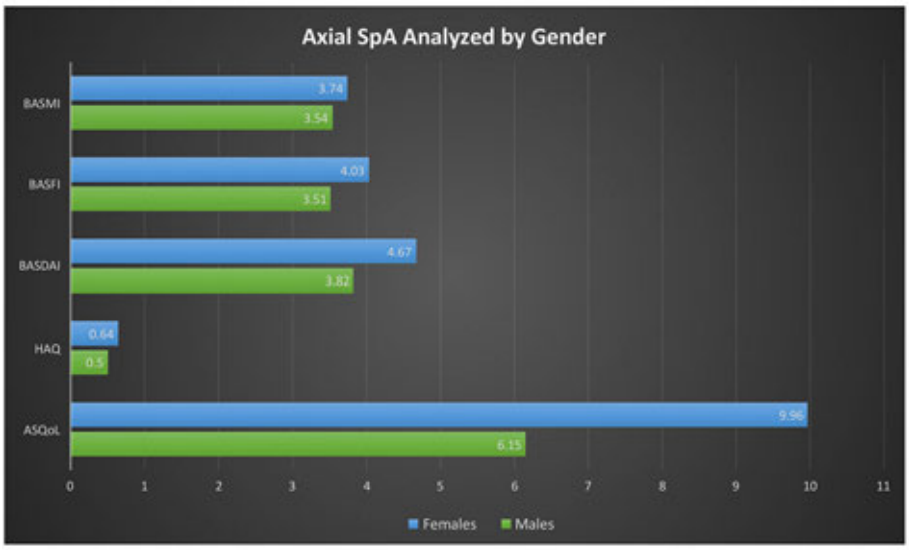
Sinead Maguire,[1] Gillian Fitzgerald,[2] Claire Sheehy,[3] and Finbar O'Shea[2], [1]University Hospital Waterford, Dublin, Ireland, [2]St James' Hospital, Dublin, Ireland, [3]University Hospital Waterford, Waterford, Ireland

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial Spondyloarthritis(axSpA) is known to have a male predominance. There is little available literature examining affected female patients. Previous studies have included small numbers of females, leading to a lack of detailed analysis of variations between genders. The Ankylosing Spondylitis Registry of Ireland (ASRI) is a source of epidemiological data on patients with axSpA in Ireland. The purpose of this study was to determine if there is a significant difference in disease activity and patterns of disease between genders.

Methods: Analysis of the patient population registered in the ASRI using IBM SPSS version 25. Patients were analyzed on the basis of gender. Mean ASQoL, HAQ, BASDAI, BASFI and BASMI scores were compared. Difference between the two groups was tested for statistical analysis using an independent two tailed t test and a Mann Whitney

	Females (n=171)	Males (n=563)	Total (n=734)	p-value
Age	42.73	45.72	45.02	0.01
Disease duration	17.01	19.13	18.64	0.05
Caucasian	22.8% (168)	73.6% (540)	94.5% (708)	0.4
Delay to diagnosis	7.79	8.56	8.39	0.27
HLA B27 +	67% (115)	69% (387)	68% (502)	0.45
Measures of Disease:				
BASDAI	4.66	3.82	4.02	< 0.01
ASQoL	7.96	6.15	6.57	< 0.01
BASFI	4.03	3.51	3.63	0.03
BASMI	3.74	3.54	3.58	0.38
HAQ	0.64	0.5	0.54	< 0.01
Extra-articular Manifestations:				
Uveitis	43.9% (75)	32.1% (181)	34.9% (256)	0.01
Psoriasis	17% (29)	18.1% (102)	17.8% (131)	0.28
IBD	15.8% (27)	7.8% (44)	9.7% (71)	< 0.01
Co-morbidities:				
IHD	4.1% (7)	3% (17)	3.3% (24)	0.47
CVD	0% (0)	2.1% (12)	1.6% (12)	0.08
HTN	18.1% (31)	22% (124)	21.1% (155)	0.29
Hyperlipidaemia	15.2% (26)	16.5% (93)	16.2% (119)	0.72
DM	3.5% (6)	5% (28)	4.6% (34)	0.54
PUD	7% (12)	7.1% (40)	7.1% (52)	0.97
TB	2.9% (5)	3.7% (21)	3.5% (26)	0.62
Osteoporosis	7.6% (13)	4.6% (26)	5.3% (39)	0.13
Depression	13.5% (23)	9.4% (53)	10.4% (76)	0.13
Cancer	4.1% (7)	3% (17)	3.3% (24)	0.49



U test. Further analysis was performed to determine difference in patterns of disease, extra-articular manifestations, medication usage and co-morbidities using a chi-squared test for independence.

Results: Data for 734 patients were reviewed via the registry. The patient population was 14.6% (171) females, 85.4%(563) males, with mean age of 45 years and a mean disease duration of 18 years (means: ASQoL 6.57, HAQ 0.54, BASDAI 4.02, BASFI 3.63, BASMI 3.58). Female patients had higher ASQoL (7.96 vs. 6.15, $p < 0.01$), HAQ (0.64 vs. 0.50, $p < 0.01$), BASDAI (4.66 vs. 3.82, $p < 0.01$), and BASFI scores (4.03 vs. 3.51, $p=0.03$). No significant difference between BASMI was found between genders (3.74 vs. 3.54, $p=0.83$) (Figure 1). No significant difference was found in delay to diagnosis (7.79 years in females vs. 8.56 years in males, $p=0.05$) or HLA B27 positivity (67% vs. 69%, $p=0.45$). Both genders had comparable incidence of arthritis(39.8% vs. 30.4%, $p=0.07$) and enthesitis (18.8% vs. 16.7, $p=0.74$), however females had higher rates of MRI sacroiliitis(48.5% vs. 42.6%, $p=0.02$) and dactylitis(12.3% vs. 5.2%, $p < 0.01$). Analysis of medication usage showed no significant difference in use of sDMARD (18.7% vs 19.7%, $p=0.7$) or biologic exposure (70% vs. 76.8%, $p=0.96$). A higher proportion of females used NSAIDs (58.5% vs. 48.5%, $p=0.02$) while a lower proportion of women are currently on biologic therapy (77.7% vs. 87.2%, $p=0.01$). Regarding extra-articular manifestations, females had higher rates of both inflammatory bowel disease (15.8% vs. 7.8%, $p < 0.01$) and uveitis (43.9% vs. 32.1%, $p=0.01$). A range of co-morbidities were also analyzed, however no statistically significant difference in incidence was found (table 1).

Conclusion: There are significant differences between genders in patients with axSpA. This analysis demonstrates that females tend to have higher disease activity, worse levels of function leading to greater impact on their quality of life. Perhaps as a reflection of this, female patients have higher rates of NSAID usage. Females also have higher rates of extra-articular manifestations including inflammatory bowel disease and uveitis. Dedicated research into female patient with axSpA is needed to appropriately address and treat their disease.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

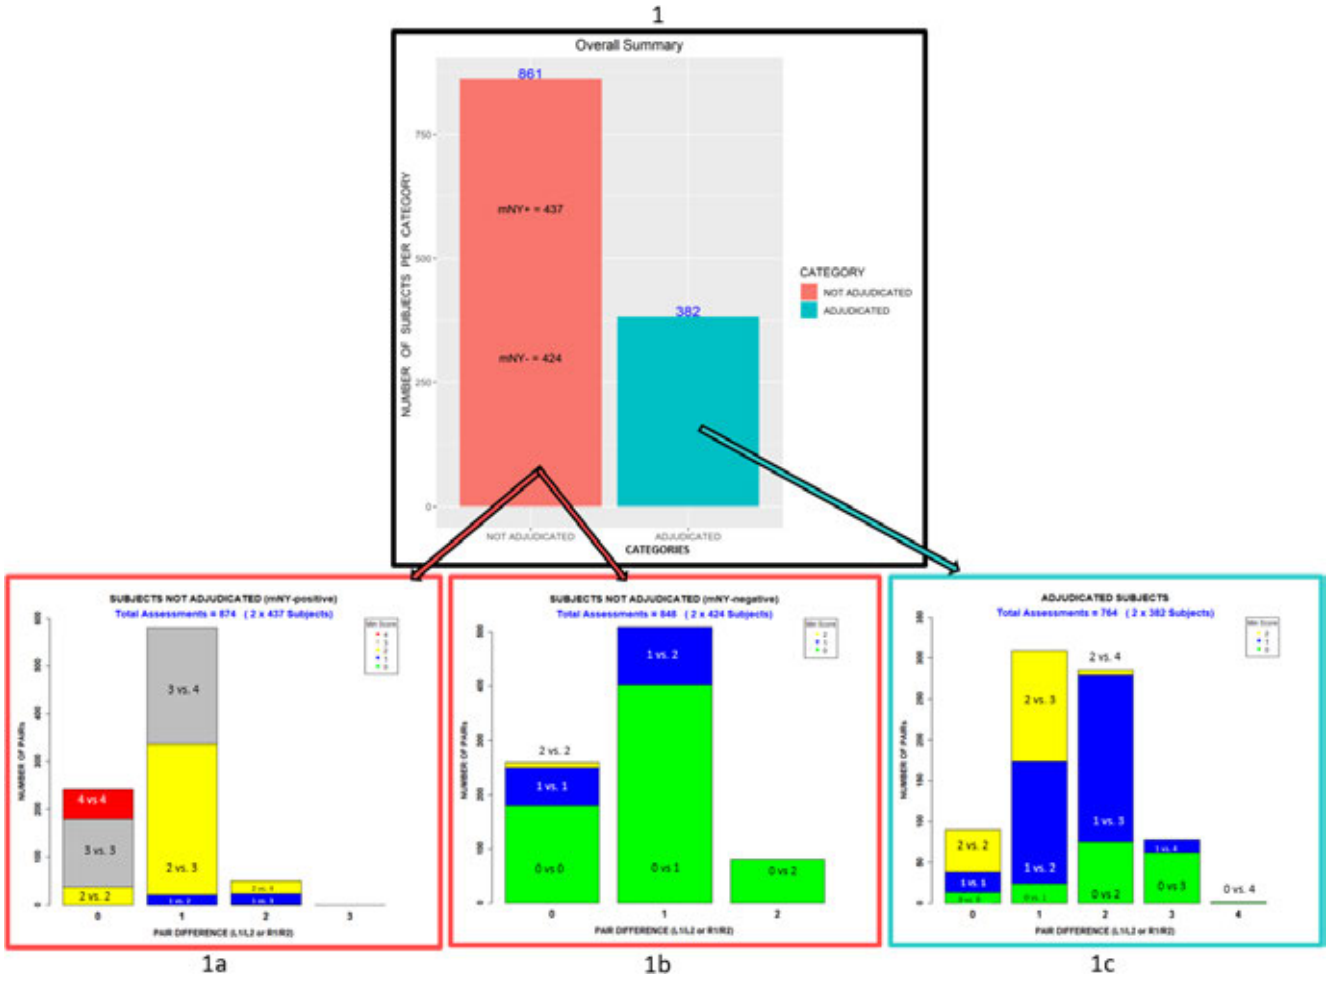
Background/Purpose: Axial spondyloarthritis (axSpA) is typically radiographically confirmed on the sacroiliac joint (SIJ) as assessed by the modified New York (mNY) criteria. In clinical trials, the mNY criteria is used to support determination of subject eligibility for study enrollment. Thus, it is important to analyze the mNY scores most likely to result in disagreement between reviewers and to better understand the impact on enrollment of the target axSpA population.

Methods: Data from central independent review of anterior-posterior (AP) pelvis radiographs in a double read model with adjudication for a total of 1,648 subjects from 3 clinical trials (phases 2 and 3) was analyzed for mNY +/- and individual left (L) and right (R) SIJ score discordance. The mNY scores were categorized per joint (R and L) as follows: 1) independent reviewers agreed on SIJ scores, 2) independent reviewers did not agree on individual joint scores, but mNY +/- was not impacted, and 3) independent reviewers did not agree and mNY +/- was impacted (i.e., adjudication triggered). To identify the score combinations which most often resulted in mNY +/- adjudication discrepancy, the frequency of each combination of scores that led to a discrepancy in categories 2 and 3 was determined.

Results: In 69% of the cases with individual score discrepancies per joint (R or L), the mNY assessment was not impacted; whereas, in 31% of these cases, adjudication was triggered (i.e., the mNY assessment was impacted by the R/L score discrepancy; Fig 1a). The score combinations most often associated with at least one joint for a timepoint where adjudication was triggered were: 1 vs. 2, 2 vs. 3, and 1 vs. 3. The score combination most often discrepant, but did not impact the mNY assessment (i.e., did not trigger adjudication) was 0 vs. 1. Overall, the score of 2 was associated with the most ambiguity.

Conclusion: Discrepancies in SIJ scores per joint (R and L) were not significant in approximately 2 out of 3 (69%) of the cases, considering impact on subject population enrollment. However, in approximately 1 out of 3 (31%) of the cases, the SIJ score discrepancies were associated with a disagreement in subject eligibility for study enrollment resulting in an adjudication.

Based on the data presented (Fig 1), a score of 2 was the most frequently involved score in inter-reader 1-step discordance. This may be related to the definition of a score of 2, which is open to a wider scope of interpretation. These results support the use of a double read and adjudication model for eligibility in clinical trials and potential use



Breakdown of Data from 1,648 subjects (1,243: Evaluable with at least one discrepant joint; 18: Not Evaluable; 8: Incomplete; and 379: no discrepancy)

of other non-radiographic assessments (e.g. MRI) to improve accuracy of classification and appropriate inclusion of subjects into axSpA clinical trials.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sarcopenia is a generalized skeletal muscle disorder characterized by the loss of muscle strength and muscle mass, leading to functional limitation, worse quality of life and increased mortality. Although frequently attributable to ageing, sarcopenia due to inflammatory processes has been recognized. However, data on sarcopenia in axial Spondylarthritis (axSpA) are scarce. Our purpose is to determine the prevalence of sarcopenia in young patients with axSpA; in addition, to assess the muscle strength and body composition of different body segments.

Methods: A cross-sectional study was conducted on 54 participants aged 18 to 50 years, 27 patients with axSpA (according to ASAS classification criteria, with symptoms duration ≤ 10 years), and 27 healthy controls (HC), matched by gender and age (1:1).

Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People 2 (EWGSOP2).

Muscle strength of three different body segments (trunk, upper and lower limbs, on both sides) was measured by resisted hand-held dynamometer performed by a single reader and through five times sit-to-stand test. The criteria for low muscle strength was chair stand test >15 seconds for five rises.

Body composition was measured by octapolar multifrequency bioelectrical impedance analysis (InBody770). Low skeletal muscle mass was defined according to the equipment's inbuilt and personalized reference values.

Physical activity was assessed by the International Physical Activity Questionnaire (IPAQ). Appropriate statistical tests were used to compare differences between groups.

Results: A total of 27 axSpA patients and 27 HC were included. Mean age was 36.5 ± 7.5 years, 67% were males. There was no significant difference between both groups in terms of age, gender, body mass index and physical activity. AxSpA patients had a mean symptoms duration of 6.5 ± 3.2 years, BASDAI 2.7±2.3 and BASFI 0.9±3.1.

Variable	Patients *n*=27	Controls *n*=27	*p*-value
Age*	36.8 ± 7.4	36.3 ± 7.8	0.79
Gender (male), *n* (%)	18 (66.7%)	18 (66.7%)	0.99
Body height (cm)	170.2 (164.1 – 176.9)	173.0 (165.4 – 178.0)	0.52
Body weight (Kg)	73.1 (66.9 – 85.6)	69.7 (64.8 – 79.6)	0.35
BMI (Kg/m^2)	25.0 (22.9 – 29.9)	23.6 (23.1 – 25.8)	0.30
IPAQ (%)			0.80
Low	29.2%	20.8%	
Moderate	37.5%	41.7%	
High	33.3%	37.5%	
BASDAI*	2.7 ± 2.3	-	
BASFI*	0.9 ± 3.1	-	
Disease duration*	6.5 ± 3.2	-	
Sarcopenia, *n* (%) ɵ	0	0	-
Low muscle strength (5-times sit-to-stand >15s), *n* (%)	2 (8.3%)	0	0.15
Low skeletal muscle mass, *n* (%)	2 (8.3%)	1 (4.2%)	0.55
Strength (Nm/s)			
Trunk	56.3 (37.6 – 67.2)	57.3 (51.2 – 63.0)	0.67
Upper Limb	47.6 (40.2 – 73.2)	71.8 (51.9 – 80.5)	**0.02**
Lower Limb	51.0 (38.5 – 57.1)	59.8 (54.6 – 64.5)	**0.001**
Lean Mass (Kg)			
Trunk	24.9 (21.9 – 27.0)	25.3 (20.4 – 27.6)	0.92
Upper Limb	3.1 (2.56 – 3.5)	3.1 (2.3 -3.5)	0.81
Lower Limb	8.0 (7.2 – 9.5)	9.2 (7.5 – 10.0)	0.15
Fat Mass (Kg)			
Trunk	10.3 (6.3 – 15.9)	8.1 (5.1 – 11.1)	**0.045**
Upper Limb	1.3 (0.6 – 2.2)	0.9 (0.5 – 1.5)	**0.050**
Lower Limb	2.9 (1.9 – 4.0)	2.5 (1.6 – 3.4)	0.21
Body water (L)			
Trunk	19.6 (17.1 – 21.3)	18.8 (14.4 – 21.1)	0.84
Upper Limb	2.4 (2.0 – 2.7)	2.3 (1.6 – 2.7)	0.38
Lower Limb	6.5 (5.8 – 7.4)	6.5 (5.1 – 7.5)	0.82

Table 1. Comparison of subjects characteristics between axSpA patients and healthy controls. Values are median (25^{th} - 75^{th} percentiles), except otherwise indicated.
***** Mean ± SD.
ɵ Available for 48 subjects (24 patients and 24 HC).

BMI: Body Mass Index. IPAQ: International Physical Activity Questionnaire. BASDAI: Bath AS Activity Index. BASFI: Bath AS Functional Index.

Comparison of subjects characteristics between axSpA patients and healthy controls.

There were no participants (patients or controls) fulfilling the definition of sarcopenia. Low muscle strength, measured by the chair rise test, was found in 8.3% of patients vs 0% of HC (p=0.15). Skeletal muscle mass was reduced in 8.3% of patients vs 4.2% of HC (p=0.55).

Regarding the different body segments, axSpA patients had median lower muscle strength in the upper limbs (47.60 vs 71.75, p=0.023) and lower limbs (51.0 vs 59.83, p=0.001), compared to HC. Trunk muscle strength did not show any difference between groups (56.3 vs 57.30, p=0.67).

There were no significant differences in lean mass and body water, between both groups, for each segment (upper limbs, lower limbs and trunk). Fat mass was marginally higher in the trunk (10.3 vs 8.1, p=0.045) and upper limbs (1.3 vs 0.89, p=0.05) of axSpA patients, but not in the lower limbs (2.9 vs 2.5, p=0.21) – Table 1.

Conclusion: In our cohort, young patients with axSpA with short disease duration did not show higher prevalence of sarcopenia according to EWGSOP2 definition. However, a reduced appendicular muscle strength was found com-

pared with HC, with no differences in lean mass, suggesting a possible muscle dysfunction. New criteria for sarcopenia in young populations are needed and further studies should be conducted to confirm these findings.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing Spondylitis Disease Activity Score (ASDAS) is adopted to evaluate the degree of disease activity and the inflammatory response in AS patients. ASDAS score ≤ 1.3 represents inactive disease status and achievement of T2T.

The objective of this study is to evaluate the patterns of T2T and related influential factors among AS patients after applying SSDM in the real world.

Table 1 The T2T results at baseline and in final follow up.

Baseline\Last follow-up	Number	%	ASDAS≤1.3	%	ASDAS≥1.3	%
ASDAS≤1.3	227	28.34%	147	64.76%	80	35.24%
ASDAS≥1.3	574	71.66%	178	31.01%	396	68.99%
Total	801	100%	325	40.57%	476	59.42%

Table 2 The patients were stratified according to their frequency of self-assessment: more than 3 times, less than or equal to 3 times self-assessments within 6 months follow-up.

Self-Assessments	Number	Baseline (T2T rate)	Last follow-up (T2T rate)	Improvement
≤3 times	467	26.77%	35.12%	8.35%
> 3 times	334	30.54%	48.20%	17.66%

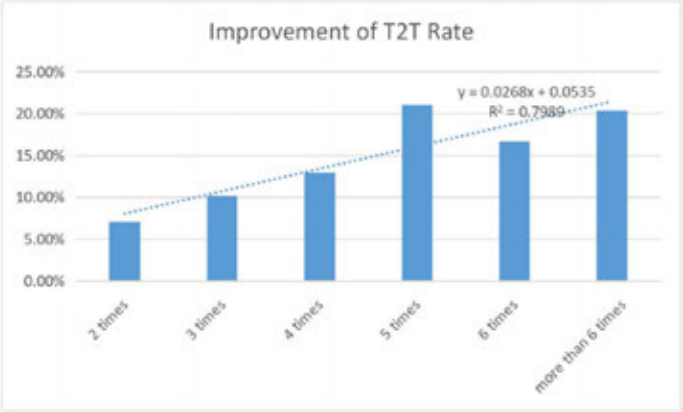

Figure 1. The improvement of T2T rate(y) was positively correlated with times of self-assessment for ASDAS(x) independently. The regression equation as "y = 0.0268x + 0.0535 R2 = 0.7989", p<0.01.

Methods: SSDM is a mobile application for disease management. Patients were trained to master SSDM by healthcare professionals and to conduct ASDAS self-assessments. Patients were also required for repeating self-assessments after leaving the hospital. After entry by patients, data can synchronized to the SSDM terminal of authorized rheumatologists.

Results: From Jan 2015 to May 2019, 13,820 AS patients enrolled in SSDM with the mean age of 33.92±12.61 years old. And median disease duration is 2.91 years. 801 AS patients from 120 hospitals across China were followed up for more than 6 months through SSDM. The results at baseline and in final follow up were summarized in Table 1.

The rate of T2T achievers were 28.34% (227/801) at baseline, and improved significantly to 40.57% (325/801) after 6 months follow up, p< 0.01. Among T2T achievers at baseline, 64.76% (147/227) maintained T2T, 35.24% (80/227) relapsed. Of patients who didn't achieve T2T at baseline, only 31.01% (178/574) of the other AS patients achieved T2T after 6 months follow up. We further analyzed the impact of the times of self-assessment for ASDAS on T2T. The patients were stratified according to their frequency of self-assessment: more than 3 times, less than or equal to 3 times self-assessments within 6 months follow-up. Results show that the more frequent of the self-assessment, the higher improvement of T2T rate (17.66% vs. 8.35%, Table 2). A linear regression analysis of variables in statistics and

parameter estimation was conducted by least square method. The improvement of T2T rate(y) was positively correlated with times of self-assessment for ASDAS(x) independently. The regression equation as "y = 0.0268x + 0.0535 R2 = 0.7989", p< 0.01. (Figure 1)

Conclusion: Significant improvement was observed under applying SSDM through empowering AS patients. After proactive disease management via SSDM for more than 6 months, Patients with ASDAS≤1.3 score at baseline had a significantly higher retention rate of disease activity. The patients who performed more self-assessments through SSDM had lower probability of relapse and higher rate of T2T. SSDM is a valuable tool for long term follow-up through empowering patients.

Effect of Long-term Treatment with TNF-α Inhibitor on Lipid Profile in Spondyloarthritis: Data from Nationwide Korean College of Rheumatology Biologics (KOBIO) Registry

Jina Yeo,[1] Mi Ryoung Seo,[1] Hee Jung Ryu,[1] Hyo-Jin Choi,[1] and Han Joo Baek[1], [1]Division of Rheumatology / Department of Internal Medicine / Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In spondyloarthritis (SpA), the lipid profile changes due to the systemic inflammatory response. Theoretically, the proinflammatory state is associated with a decrease in total cholesterol (TC), high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), triglycerides (TG) than expected, and an increase in these lipid levels after anti-inflammatory therapies, such as tumour necrosis factor alpha (TNF-α) inhibitor. This study aimed to assess the influence of long-term treatment with TNF-α inhibitor on lipid profile and atherogenic index (AI) in patients with SpA.

Methods: Lipid data and AI of SpA patients treated with TNF-α inhibitor were analysed from the Korean College of Rheumatology Biologics (KOBIO) registry between 2012 and 2017. Patients exposed at least for one year to SpA approved dosage regimens of etanercept, infliximab, adalimumab or golimumab as first line treatment were included. The baseline lipid profile and AI were compared with between 0 - 12 months, 12 - 18 months, 18 - 24 months, > 24 months. AI was derived according to the logarithmic (TG/HDL-C).

Results: The records of 361 patients (male 279, female 82) were reviewed. Mean follow-up duration was 2.25 ± 0.03 year (0.24 - 5.66 years) and baseline Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) was 6.0 ± 0.1. Treatment with TNF-α inhibitor was associated with increased levels of TC (173.66 ± 1.82 mg/dL at baseline, 191.93 ± 3.51 mg/dL; p = 0.001 at 0 - 12 months, and 188.88 ± 1.61 mg/dL; p < 0.001 at > 24 months), HDL-C (48.50 ± 0.80 mg/dL at baseline, 55.92 ± 2.83 mg/dL; p = 0.023 at 0 - 12 months, and 53.38 ± 0.88 mg/dL; p= 0.002 at > 24

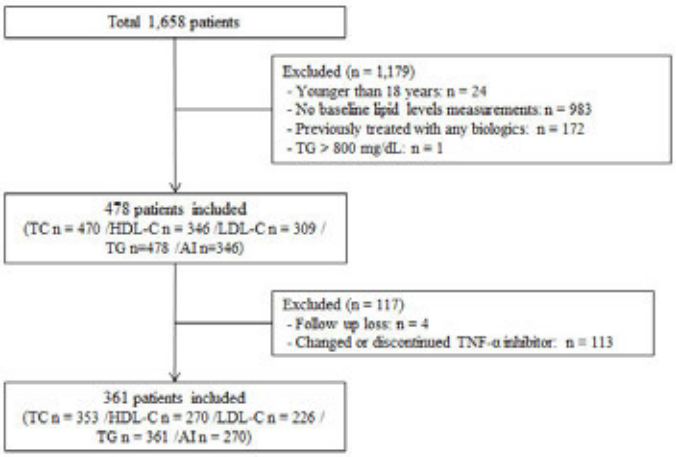

Figure 1. Overview of study design and patient disposition

TC: total cholesterol; HDL-C: high-density lipoprotein cholesterol; LDL-C: low-density lipoprotein cholesterol; TG: triglycerides; AI: atherogenic index

Table 1. Effects of TNF-α inhibitor on lipid profile

		Time				
		baseline value before treatment	0 - 12 months	12 - 18 months	18 - 24 months	> 24 months

[a]Adjusted for age, gender, disease duration, body weight, height, body mass index, systolic blood pressure, diastolic blood pressure, smoking, hypertension, ischemic heart disease, dyslipidemia, congestive heart failure, peripheral artery disease, stroke, diabetes mellitus, and obesity.
TC: total cholesterol; HDL-C: high-density lipoprotein cholesterol; LDL-C: low-density lipoprotein cholesterol; TG: triglycerides; AI: atherogenic index; SE: standard error

months) and TG (118.14 ± 4.04 mg/dL at baseline, 157.05 ± 12.31 mg/dL; p = 0.029 at 18 - 24 months, and 159.90 ± 5.62 mg/dL; p < 0.001 at > 24 months), but no significant change in LDL-C. After treatment, AI increased from 0.77 ± 0.04 at baseline to 1.00 ± 0.04 (p < 0.001) at > 24months.

Conclusion: In patients with SpA, long-term treatment of TNF-α inhibitor was associated with increased TC, HDL-C, and TG levels and AI, whereas it presented no effect on LDL-C levels. Increased HDL-C may have beneficial effects, but evaluation of cardiovascular event rates during long-term treatment is needed to further characterize these findings and their possible clinical implications.

Early Recognition of Patients with Axial Spondyloarthritis by Using a Practical Referral System – Evaluation of the Recently Proposed 2-step Strategy

Xenofon Baraliakos,[1] Styliani Tsiami,[2] doris morzeck,[2] Kirill Fedorov,[2] Uta Kiltz,[2] and Jürgen Braun[3], [1]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [2]Rheumazentrum Ruhrgebiet/Ruhr University Bochum, Herne, Germany, Herne, Germany, [3]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Early recognition of axial spondyloarthritis (axSpA) in primary care (PC) is difficult due to the high prevalence of low back pain resulting in a major delay for a diagnosis of axSpA. Recently we proposed a 2-step referral strategy (1) which concentrates on patients ≤45 years with chronic back pain who are to be referred to a rheumatologist if fulfilling 2 of 3 features: buttock pain, improvement by movement, psoriasis (Step 1), or, in case of ≤1 feature, positive testing for HLA-B27 (Step 2). We prospectively evaluated this 2-step referral strategy in PC.

Methods: Consecutive patients ≤45 years who presented in PC to general practitioners or orthopedic surgeons working in PC with back pain lasting ≥2 months who had not been diagnosed before received questionnaires (Q1) relevant for the referral process. Thereafter, the PC physician asked the same questions in a separate questionnaire (Q2), including the decision on HLA-B27 testing. All patients were then referred to two experienced rheumatologists in a tertiary center who performed a complete workup including clinical, laboratory and imaging with radiographs and magnetic resonance imaging (MRI) examinations before their final diagnosis of axSpA or non-SpA (Q3).

Results: A total of 320 patients (mean age 35.9±10.3 years) was recruited. The proposed referral strategy (prS) was fulfilled by 127 patients in Q1 (39.7%), 160 in Q2 (50%), 102 by both, Q1 and Q2 (31.9%), and 83 with either Q1 or Q2 (25.9%). Overall, 47 patients were diagnosed with axSpA by the rheumatologist at Q3 (14.7%), 66% of which were male, mean age 34.7±10.1 years, 70.2% HLA-B27 positive, mean CRP 0.8±1.4mg/dl, mean ASDAS 3.2±0.8, mean BASDAI 5.1±2.0. Of these, 37 patients had fulfilled the prS in Q1 or Q2 (78.7%), and 31 in both Q1 and Q2 (66%), respectively. In the latter, the HLA-B27 prevalence was significantly higher (27/31, 87.1%) as compared to patients diagnosed with axSpA at Q3 but who did not fulfill the prS in Q1 and Q2 (5/16, 31.3%) ($p< 0.001$). The sensitivity and specificity of the prS was 78.7% and 69.2% in Q1, 78.7% and 62.2% in Q2, and in both, Q1 and Q2, 66% and 74%, respectively. AxSpA patients correctly identified by the prS in Q1 and Q2, were significantly more frequently positive for HLA-B27 and CRP and fulfilled more frequently the ASAS definition of inflammatory back pain in Q3.

Conclusion: A simple two-step referral strategy using a combination of clinical features for identifying axSpA patients in PC without laboratory and imaging examinations was confirmed in a large population from daily practice. This strategy performed well as selection for referral at the patient and PC physician level.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Active (bone marrow edema, BME) and structural (fatty lesions, FL) lesions in the spinal and the sacroiliac joints (SIJ), as assessed by magnetic resonance imaging (MRI), have been described in patients with axSpA but may also occur in healthy individuals (1,2).

We assess factors associated with occurrence of BME and FL in spinal- and SIJ-MRIs in a population-based study.

Methods: Spinal- (sagittal T1/T2-) and SIJ- (semi-coronal STIR sequences) MRIs were evaluated by two trained blinded readers. MRIs were analyzed for BME (SIJ and spine) and FL (spine) 'positive' for axSpA. Degenerative lesions were excluded. BME was quantified using Berlin MRI scores. Clinical information included, sex, smoking (yes/

no), spinal pain (NRS≥4/10 in last 3 months), CRP, HLA-B27 and body mass index (BMI) categories (WHO definition of under- (cat.1), normal (cat.2), overweight (cat.3)). Associations between clinical factors and MRI lesions were analyzed for the presence/absence of lesions using univariate logistic regression and for number and size of lesions using negative binomial count regression.

Results: MRIs of 793 participants (49.4% male, 5.7% CRP-positive, 8.4% HLA-B27+, 62.7% ever smokers) were evaluated. BME lesions were found in 136 SIJ-MRIs (17.2%) and 218 (27.5%) spinal MRIs, and FL in 645 spinal MRIs (81.3%). The median hsCRP was 0.09 [0.05-0.20] mg/dl, 45 (6.4%) had an elevated hsCRP level (cut off < 5 mg/dl); 8.9% were HLA-B27+; 62.7% reported smoking, 45.0% were in the under- or normal weight BMI category. 36.2% in the overweight and 18.8% in the obese BMI category. More and larger SIJ-BME lesions were independently associated with HLA-B27+ (exp(β)=2.8, 1.5-4.9), spinal pain (exp(β)=1.7, 1.2-2.6), and higher BMI (cat. 1 vs 3, exp(β)=1.7, 1.0-3.0). Also, more and larger spinal BME were associated with older age (exp(β)=1.5, 1.2-2.0), while more and larger spinal FL were associated with higher BMI, (cat. 1 to cat. 3 (exp(β)=1.9, 1.5-2.2), older age (exp(β)=1.6, 1.5-1.8) and male sex (exp(β)=1.4, 1.2-1.6). Presence of spinal BME (OR 1.3, 1.0±1.7) and/or spinal FL (OR 1.7, 1.3-2.3) was associated with older age, while alone were associated with a higher BMI (cat. 1 to cat.3, OR 3.3, 1.8-6.1). In total, 22 subjects (16.2%) had large (>33% of surface involvement) and 114 had small (≤33% of surface involvement) SIJ-BME. Large SIJ-BME were found in 4.5% HLA-B27-positive vs. 2.6% HLA-B27-negative subjects (p=0.40). Overall, 35.3% quadrants with SIJ-BME was located in the upper sacral quadrant. Most SIJ lesions (83.4%) were small. For spinal BME, 42% was located in the lower (T7/8-T11/12) thoracic spine. Most spinal lesions (90.9%) were small.

Conclusion: In this large population-based study, higher numbers of large SIJ-BME lesions were significantly associated with HLA-B27, back pain and BMI. Spinal BME and FL were associated with older age, male sex and BMI but not HLA-B27. The association for HLA-B27 was only shown on the quadrant but not on the patient level.

Localization and Morphology of Magnetic Resonance Imaging Features of Pathologic Changes in the Sacroiliac Joints Suggestive of Axial Spondyloarthritis – a Systematic Comparison of Patients and Controls with Chronic Back Pain

Xenofon Baraliakos,[1] jonas tomaschoff,[2] Martin Fruth,[2] and Jürgen Braun[3], [1]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany, [2]Radiology Herne, Herne, Germany, [3]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bone marrow edema (BME), fat metaplasia (FL) and erosions are relevant for magnetic resonance imaging (MRI) changes in the sacroiliac joints (SIJ) in axial spondyloarthritis (axSpA). However, MRI changes have recently also been reported in subjects with no axSpA (1,2). We mapped MRI lesions suspicious of axSpA in patients diagnosed with axSpA and compared them to patients with chronic back pain (cBP, non-SpA).

Methods: Consecutive patients with cBP< 45 years were included with at least one pathologic lesion (any type) in SIJ-MRIs performed during cBP symptoms. AxSpA patients diagnosed by 2 experienced rheumatologists in consensus also had to fulfil ASAS classification criteria. Two experienced readers, blinded for patient´s information) evaluated all MRIs independently. Lesions were only counted positive if readers were in agreement. Both coronal (assessing upper and lower sacral and iliac SIJ) and axial (assessing ventral, middle and retroauricular) MRI orientations were analyzed for localization of BME, FL, sclerosis and erosions. In addition, length and width were digitally measured for BME, FL and sclerosis, and signal intensity was measured in each individual patient (no units). Mann-Whitney-U-test was applied for patients classified as positive by both readers for respective lesions.

Results: 200 consecutive patients (100 axSpA, 100 non-SpA), mean age 36.1±11.3 and 40.3±11.0 years, respectively, were analyzed. BME was found in 85% vs. 80% patients, while 80% vs. 69% had FL, 54% vs. 40% had sclerosis and 64% vs. 12% had erosions, respectively. The largest surface area covered by BME in axSpA vs. non-SpA was found in lower and dorsal SIJ: 60±10.1mm3 in the iliac and 47.3±9.4mm3 in sacral part vs. upper and ventral SIJ: 18.7±3.4mm3 in sacral and 5.2±0.1 mm3 in the iliac part. AxSpA-patients showed larger surface area covered by FL in upper and anterior sacral SIJ (305.5±56.3 mm3), whereas non-SpA-patients showed larger FL areas in lower and posterior sacral SIJ (197.9±1.2 mm3). Upper and anterior iliac part larger sclerosis involvement in both SpA (139.3±11.6 mm3) and non-SpA (81.8±2.8 mm3). Mean signal intensity of all lesions and MRI planes differed between axSpA (102.385) and non-SpA (48.995) patients for BME (p< 0.001) but not for FL. AxSpA patients had significantly more SIJ quadrants with pathologic changes, except for BME and sclerosis in ventral and fat in retroauricular SIJ-part. Erosions in the mid (61 vs. 7) and the ventral (51 vs. 8) part of the SIJ could discriminate best between axSpA and non-SpA (both p< 0.001).

Conclusion: Although all lesion types may be found in both groups, the anatomic pattern of SIJ involvement can still distinguish axSpA from non-SpA. The most frequently involved sites were not necessarily also the best differentiating sites. The localization and morphological appearance of SIJ-MRI features suggestive of axSpA may serve as an additional feature in the definition of a 'positive' MRI both for diagnosis and classification.

Facet Joint Ankylosis on Whole Spine Low-Dose CT in Radiographic Axial Spondyloarthritis

Rosalinde Stal,[1] Floris van Gaalen,[1] Alexandre Sepriano,[1] Jürgen Braun,[2] Monique Reijnierse,[1] Désirée van der Heijde,[1] and Xenofon Baraliakos[3], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet/ Ruhr University, Herne, Germany, [3]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In radiographic axial spondyloarthritis (r-axSpA), whole spine low-dose CT (ldCT) is superior to conventional radiography (CR) in detecting syndesmophytes, mainly due to inclusion of the thoracic spine. Facet joint ankylosis has been studied in r-axSpA in parts of the spine with CR and CT, but not in the whole spine. We aimed to assess readability and interreader reliability of facet joint ankylosis as detected by whole spine ldCT and to describe the prevalence of facet joint ankylosis in each spinal segment in patients with r-axSpA.

Methods: In an observational cohort, r-axSpA patients with syndesmophytes on at least one but no more than 75% of spinal levels of the cervical and lumbar segments on CR and at least one inflammatory lesion on spinal MRI, underwent ldCT (about 4 mSv) of the whole spine. Images were assessed independently by two trained readers and left

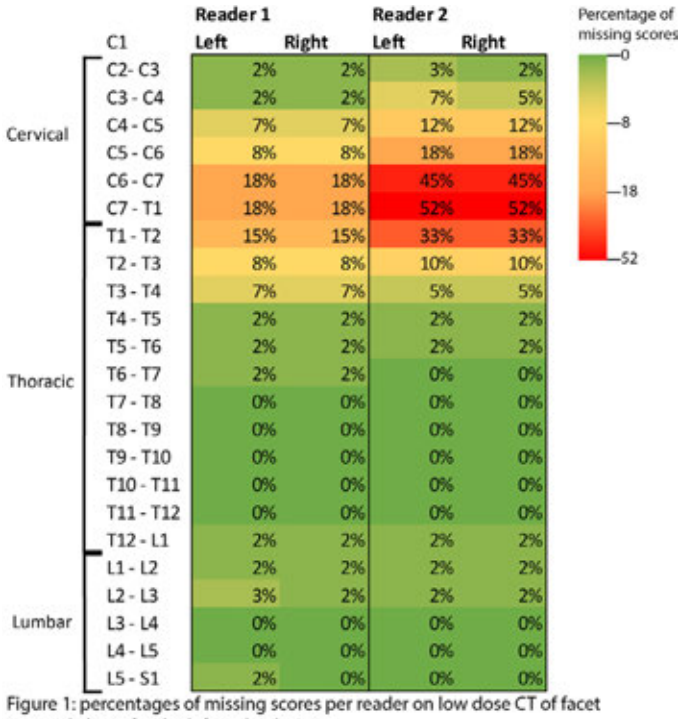

Figure 1: percentages of missing scores per reader on low dose CT of facet joint ankylosis, for the left and right joint.

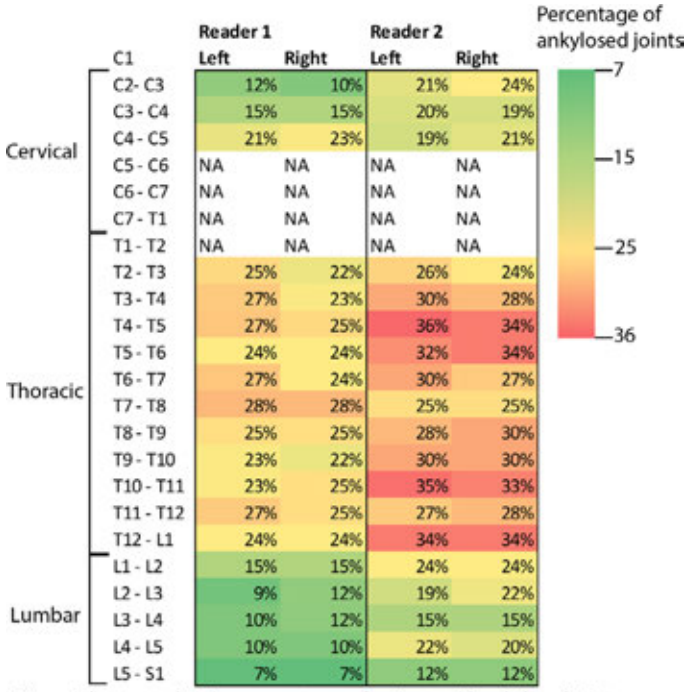

Figure 2: heatmap showing percentages of patients with ankylosed joint per joint level. Levels with >15% missing joint scores for one or both readers are not applicable (NA).

Table: facet joint ankylosis scores per reader and interreader reliability

	Reader 1 mean (SD) *range*	Reader 2 mean (SD) *range*	ICC (95% CI)
Whole spine excluding C5-T2 *max score 38*	7.3 (10) *0 - 34*	9.4 (10.9) *0 - 37*	0.93 (0.87-0.96)
Cervical segment excluding C5-T1 *max score 6*	0.9 (1.8) *0 - 6*	1.1 (2) *0 - 6*	0.84 (0.73-0.90)
Thoracic segment excluding T1-T2 *max score 22*	5.4 (7.4) *0 - 22*	6.5 (7.6) *0 - 22*	0.91 (0.85-0.95)
Lumbar segment *max score 10*	1.0 (2.5) *0 - 10*	1.8 (3.1) *0 - 10*	0.81 (0.67-0.89)

and right C2-C3 to L5-S1 facet joints were scored as ankylosis present (1) or absent (0). The percentage of missing joint scores due to inability to assess, were calculated per reader and joint level. Joint levels with >15% missing joint scores for ≥1 reader were deemed unreliable to score and were excluded from the study. Interreader reliability was assessed by calculating intraclass correlation coefficients (ICCs), two-way average, absolute agreement. Ankylosis scores were summed per patient per segment and for the whole spine and presented as mean scores per reader. The percentage of patients with an ankylosed joint were presented per joint level in a heatmap.

Results: A total of 60 r-axSpA patients were analyzed (mean age 47.7 years, 85% male, 80% HLA-B27+). Reader 1 had between 0% and 18% missing scores per joint, reader 2 had between 0% and 52% missing scores per joint (figure 1). There were >15% missing joint scores for ≥1 reader on levels C5-T2, which were excluded from analyses. Interreader reliability was good to excellent with ICCs ranging from 0.81 to 0.93 (table). Ankylosis occurred at every joint level, but was most prevalent in the thoracic spine (figure 2). Means (SD) of sum-scores for the whole spine and cervical, thoracic and lumbar segments for both readers are presented in the Table.

Conclusion: Facet joints around the cervicothoracic junction were difficult to score in a relatively high percentage of patients and are therefore excluded from scoring. The interreader reliability of the remaining levels was good to excellent. In patients with r-axSpA and at least one syndesmophyte, facet joint ankylosis was detected in all spinal levels, but most ankylosis occurred in the thoracic spine. These results show that ldCT can be used to study facet joint ankylosis in r-axSpA in all spinal segments except the cervicothoracic junction.

Spinal Bone Formation as Assessed by Low-Dose CT Scan in Patients with Radiographic Axial Spondyloarthritis – Comparison of the Progression Observed in Vertebrae and Facet Joints

Rosalinde Stal,[1] Floris van Gaalen,[1] Alexandre Sepriano,[1] Jürgen Braun,[2] Monique Reijnierse,[1] Désirée van der Heijde,[1] and Xenofon Baraliakos[3], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany, [3]Rheumazentrum Ruhrgebiet-Ruhr-University Bochum, Herne, Germany, Herne, Germany

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: By using low dose computed tomography (ldCT) in patients with radiographic axial spondyloarthritis (r-axSpA) we have recently shown that there is substantial progression of new bone formation in the facet joints within two years. We now aimed to assess the added value of scoring progression of whole spine facet joint ankylosis in addition to whole spine syndesmophytes in the quantification of spinal bone formation by ldCT.

Methods: In an observational cohort, patients with r-axSpA (≥1 inflammatory lesion on spinal MRI and 1-18 syndesmophytes in cervical and lumbar spine on conventional radiography) underwent whole spine ldCT (circa 4 mSv) at baseline and after 2 years. Two trained readers independently assessed paired ldCTs, blinded to chronology. Left and

Table: progression of whole spine facet joint ankylosis and syndesmophytes

Progression	FJA	CTSS	FJA and CTSS	FJA not CTSS	CTSS not FJA	Not FJA not CTSS
Change >0.5	21(48%)	39(89%)	17(39%)	4(9%)	22(50%)	1(2%)
Change >SDC	12(27%)	13(29%)	4(9%)	8(18%)	9(20%)	23(52%)

For facet joint ankylosis (FJA), SDC=2; for Computed Tomography Syndesmophyte Score (CTSS), SDC=14.4

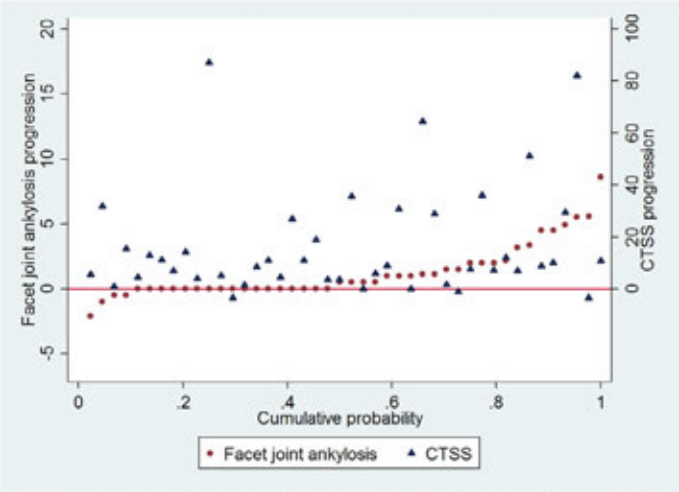

Figure: cumulative probability plot showing 2-year facet joint ankylosis progression and syndesmophyte progression scored with the Computed Tomography Syndesmophyte Score (CTSS). The plot is ordered by the facet joint ankylosis progression scores.

right facet joints from C2-S1, with the exception of C5-T2 due to low visibility, were scored as ankylosis present (1) or absent (0). Syndesmophytes were scored on a scale 0-552 according the Computed Tomography Syndesmophyte Score (CTSS)[1]. Average scores of the readers were used. Patients were included if at baseline they had < 80% ankylosed facet joints and < 80% bridged syndesmophytes on ldCT and had scores from both readers for both time-points. Change scores are calculated as the total change in the whole spine per patient. The proportion of patients with a change score >0.5 and >SDC are presented and in addition net progression, defined as number of patients with change >0.5 minus number of patients with change < -0.5 divided by the total number of patients. Percentage agreement between progression in facet ankylosis and syndesmophyte formation is presented and a cumulative probability plot is shown.

Results: A total of 44 patients was included in the analysis (mean age 49.4, 84% male, 79% HLA-B27+). At the group level, net progression of facet joint ankylosis was 43% (19/44) and net progression of syndesmophytes was 82% (36/44). The proportion of patients with progression is given in the Table. The percentage of patients with progression of facet joint ankylosis >0.5 was 48% and with syndesmophyte progression >0.5 was 89%. Using a more conservative cut-off for progression (>SDC), the percentage of patients with progression of facet joint ankylosis was 27% and syndesmophyte progression was seen in 29%. Bone formation in the facet joints only occurred in 9% and 18% of the patients, and syndesmophytes progression only in 50% and 20% of the patients for the cut-offs of 0.5 and SDC, respectively. The figure shows that there is a tendency that patients with more facet joint ankylosis progression also had more syndesmophyte progression. However, in a number of patients these processes occurred independently.

Conclusion: These data show that scoring facet joint ankylosis in addition to syndesmophyte formation is useful to get full insight in the progression of spinal bone formation in patients with r-axSpA.

Gender Contrasts in Patient Reported Outcomes Don't Alter the Disease Activity Score in Axial Spondyloarthritis Patients

Ann-Sophie De Craemer,[1] Thomas Renson,[1] Liselotte Deroo,[1] Manouk de Hooge,[1] Philippe Carron,[1] Filip Van den Bosch,[1] and Dirk Elewaut[1], [1]Ghent University Hospital, Ghent, Belgium

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease activity in axial spondyloarthritis (axSpA) is often quantified by the Ankylosing Spondylitis Disease Activity Score (ASDAS), a composite index which combines 4 patient reported outcome (PRO) measures and C-reactive protein (CRP) as an acute phase reactant. ASDAS commonly acts as a target in treat-to-target approaches in axSpA patients. This study aims to identify the impact of gender on ASDAS in newly diagnosed axSpA patients and to determine whether possible differences are PRO- or CRP-driven.

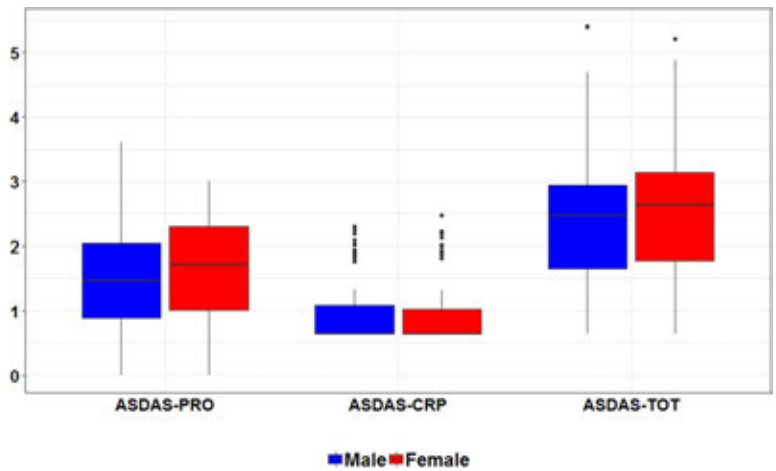

Figure 1. Total ASDAS score (ASDAS-TOT), subdivided in a PRO-component (ASDAS-PRO) and a CRP-component (ASDAS-CRP) in male and female axSpA patients.

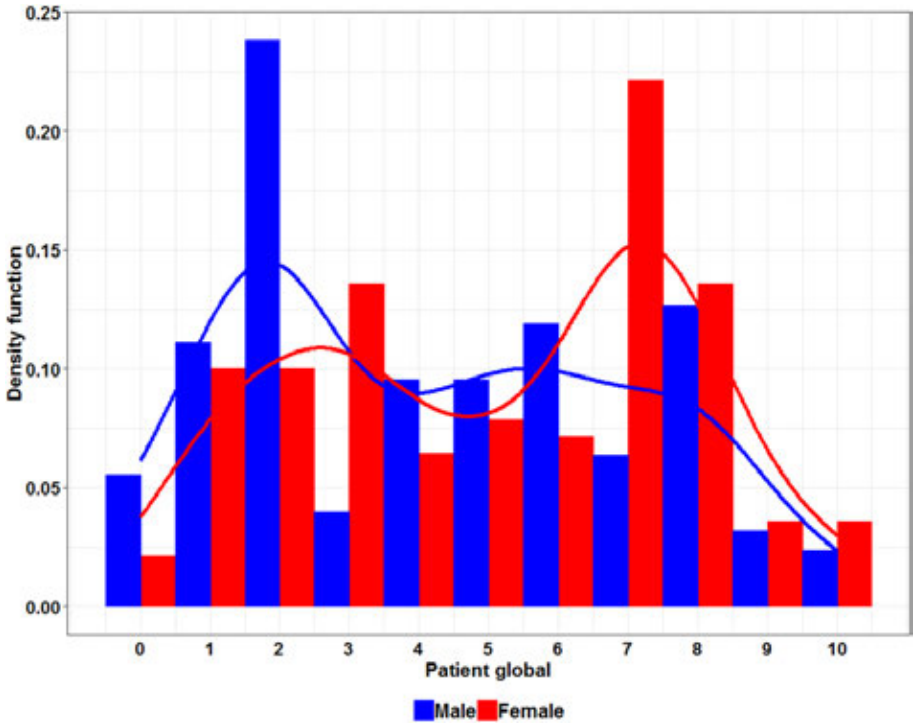

Figure 2. Patient global score in male and female axSpA patients.

Methods: Patients originate from an observational registry of newly diagnosed axSpA patients (expert opinion). Included patients fulfill the Assessment of SpondyloArthritis international Society (ASAS) classification criteria for axSpA and are anti-TNF naïve prior to inclusion. An extensive patient description was performed at baseline, including PRO and laboratory investigations with CRP (mg/L). ASDAS was calculated for each patient and subdivided in a PRO-component (ASDAS-PRO) and a CRP-component (ASDAS-CRP).

Results: By January 2019, 291 axSpA patients were included (138 male, 153 female). At baseline, ASDAS could be calculated in 262 patients. ASDAS-PRO was significantly higher in women compared to men (1,66 vs. 1,48, p = 0,04), while ASDAS-CRP did not differ significantly (0,90 for both genders, p = 0,96). No significant difference was found between the total ASDAS of women and men (2,54 vs. 2,38, p = 0,09) (Figure 1). When categorizing the score into 4 disease activity states, 60,8% (76/125) of men show high or very high disease activity (ASDAS > 2.1) at baseline compared to 67,2% (92/137) of women (p = 0,35).

Concerning the 5 ASDAS components, the discrimination between male and female axSpA patients was most pronounced for *patient global* scores (Figure 2). Men reported a baseline patient global score of 4,3 (95% CI 3,8 – 4,8), compared to a score of 5,1 (95% CI 4,7 – 5,6) in women (p = 0,01).

Conclusion: Female axSpA patients report a significantly higher *patient global* score compared to men. This contributes to a significantly higher ASDAS-PRO in women. However, neither the ASDAS itself nor the ASDAS disease activity categories are significantly affected by gender contrasts in PRO.

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (SpA) generally affects patients at a working age. Despite therapeutic improvements, SpA remains responsible for a significant burden for patients and society in terms of sick leave and work disability. This study aims to assess the determinants of work participation in a Belgian SpA cohort.

Methods: Between May 1st 2018 and April 1st 2019, a cross-sectional survey was conducted amongst patients included in a Belgian SpA cohort ((Be-)Giant), all fulfilling ASAS classification criteria for axial or peripheral SpA. Information on work participation was collected using the Work Productivity and Activity Impairment (WPAI) ques-

Table 1. Demographic and clinical characteristics

	All patients (n = 262)	Axial SpA (n = 192)	Peripheral SpA (n =70)
Male, n (%)	148 (56,4)	107 (55,7)	41 (58,8)
Age, years (mean, SD)	41 (11,0)	40 (11,4)	43 (11,8)
Current smoker, n (%)	40 (15,3)	26 (13,5)	14 (20,0)

Manual labour	**0.2 (0.08 – 0.39)***	**3.1 (1.04 – 9.04)***	**2.3 (1.10 – 4.90)***	**2.4 (1.14 – 4.94)***
ASDAS-CRP	**0.4 (0.29 – 0.62)***	**2.5 (1.44 – 4.53)***	**3.1 (1.89 – 5.22)***	**3.3 (1.99 – 5.48)***
BASFI (/10)	**0.6 (0.52 – 0.72)***	**1.7 (1.35 – 2.24)***	**2.1 (1.60 – 2.79)***	**2.1 (1.61 – 2.79)***
Axial vs. peripheral disease	0.8 (0.37 – 1.63)	3.0 (0.67 – 13.69)	1.6 (0.82 – 2.97)	1.6 (0.83 – 2.94)

tionnaire. Physicians' assessment included standardized clinical and laboratory evaluations. Outcomes of interest were employment status (being employed yes/no), absenteeism (percentage of time absence from the workplace), presenteeism (percentage of productivity loss while at work) and percentage of overall work impairment. Continuous outcomes were categorized because of skewed (zero inflated) distributions. The associations between the four outcomes of interest and patient characteristics were modelled using univariate and multivariate logistic regression. The sample was restricted to SpA patients of working age (≤65 years old).

Results: Data were collected on 262 patients: 214 (81.7%) were employed, 26 (9.9%) work disabled, 8 (3.1%) unemployed, 8 (3.1%) student, 5 (1.9%) early retired and 1 (0.4%) housekeeper. Table 1 summarizes demographic and clinical characteristics. Table 2 shows univariate associations between patient characteristics and the outcomes of interest. Gender, age, symptom duration and SpA subtype are not significantly associated with any of the four outcomes. Higher education increases the odds of being employed and reduces the odds of absenteeism. Manual labour, high ASDAS-CRP and high BASFI show a negative association with employment and significantly increase the odds of absenteeism, presenteeism and overall work impairment. After multivariate adjustment, only ASDAS-CRP and BASFI showed a significant association with employment status (OR 0.39 and 0.69), absenteeism (OR 2.54 and 1.71), presenteeism (OR 2.58 and 1.81) and work impairment (OR 2.67 and 1.82) (all $p < 0,05$).

Conclusion: High disease activity and functional impairment are significantly associated with work participation and overall work impairment in a Belgian SpA cohort. Of interest, neither gender, age, symptom duration, type of work nor SpA subtype significantly affect any of the work-related outcomes. Given the important health economic impact of employment rate in our society, this underscores the need for tight disease control in patients with SpA.

Is There an Impact of Uveitis, Psoriasis and Inflammatory Bowel Disease on Musculoskeletal Disease Activity and Function in Axial Spondyloarthritis?

Imke Redeker,[1] Johanna Callhoff,[2] Falk Hoffmann,[3] Hildrun Haibel,[4] Joachim Sieper,[4] Angela Zink,[5] and Denis Poddubnyy[6], [1]Charité – Universitätsmedizin Berlin and German Rheumatism Research Centre, Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]Carl von Ossietzky University, Oldenburg, Germany, [4]Charité Universitätsmedizin Berlin, Germany, Berlin, Germany, [5]German Rheumatism Research Centre and Charité University medicine, Berlin, Germany, [6]Charité - Universitätsmedizin Berlin and German Rheumatism Research Centre, Berlin, Germany, Berlin, Germany

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis, psoriasis and inflammatory bowel disease (IBD) are common in axial spondyloarthritis (axSpA) but data on their impact on activity of musculoskeletal manifestations and functional status, in general, are

contradictory. The aim of this study was to assess the impact of uveitis, psoriasis, and IBD on disease activity and functional status in a population-based cohort of patients with axSpA.

Methods: A stratified random sample of patients with axSpA (ICD-10 M45) was drawn from health insurance data in Germany. Patients in the sample received a survey on demographic, socioeconomic, and disease-related parameters including history of uveitis, psoriasis, and IBD.

Survey data were linked to health insurance data gathering additional information on recent/current occurrence (within one year) of uveitis, psoriasis, and IBD as well as drug prescriptions and non-pharmacological treatment.

Differences between patients with and without uveitis, psoriasis, and IBD were assessed. Separate multivariable linear regression models were calculated to determine the effect of uveitis, psoriasis, and IBD on disease activity and functional impairment after adjustment for other relevant parameters including treatment.

Results: A total of 1,729 patients with axSpA were included in the analyses. The patients' main characteristics are shown in **Table 1**: The mean age was 55.9 years and 46.1% were female. The prevalence for recent (ever) uveitis, psoriasis, and IBD is illustrated in **Figure**: 9% (27%) of the patients had recently (ever) uveitis, 10% (15%) had recently (ever) psoriasis, and 6% (9%) had recently (ever) IBD. In 1.6% (6.9%) of the patients two of these conditions were recently (ever) present, and in 0% (0.5%) of the patients, all three conditions were recently (ever) present.

Results from the multivariable linear regression analyses are presented in **Table 2** and revealed that history of psoriasis was significantly associated with both higher level of disease activity and higher level of functional impairment. History of IBD was also associated with higher disease activity, whereas recent psoriasis or IBD showed no strong association with disease activity and functional status.

In contrast, history of uveitis showed no strong association with disease activity and functional status while recent uveitis was significantly associated with lower disease activity according to the BASDAI even after adjustment for treatment.

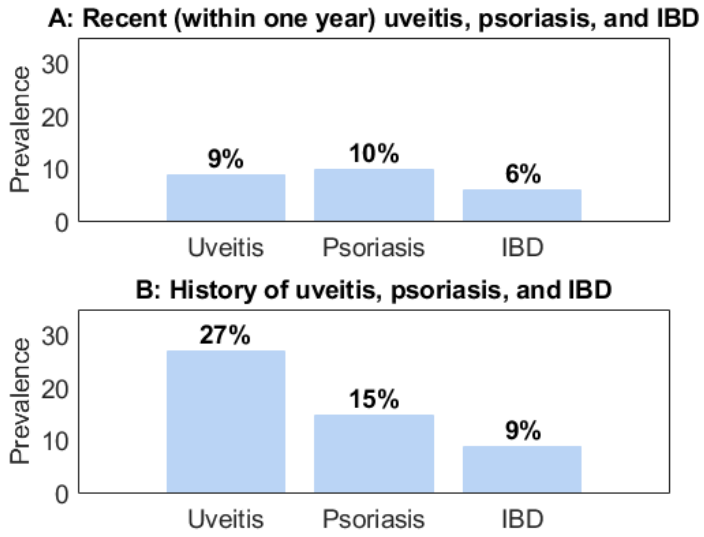
*Model adjusted for age, sex, body mass index, rheumatologic care, smoking, suffering from stress, NSAIDs, bDMARDs, non-opioid analgesics, opioids, systemic steroids, physical therapy; **Model adjusted for age, sex, body mass index, rheumatologic care, lack of exercise, smoking, suffering from stress, non-opioid analgesics, opioids, systemic steroids, physical therapy.
BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; bDMARDs, biological disease-modifying anti-rheumatic drugs; NSAIDs, non-steroidal anti-inflammatory drugs.

Figure Prevalence of uveitis, psoriasis, and inflammatory bowel disease in patients with axial spondyloarthritis (N=1,729)



Conclusion: Disease activity and functional impairment are higher in axSpA patients with a history of psoriasis or IBD, whereas history of uveitis does not have a major impact on activity of musculoskeletal manifestations and functional status in axSpA. However, recent uveitis showed a somewhat unexpected association with lower disease activity. The latter might be related to a higher likelihood of being treated with TNF inhibitors in the presence of uveitis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Data on the prevalence of comorbidities and their association with disease activity and functional impairment in axial spondyloarthritis (axSpA) are scarce. The aim of this study was to investigate the prevalence of comorbidities and to analyse their association with disease activity and functional impairment in a large population-based cohort of patients with axSpA.

Methods: A stratified random sample of patients with axSpA (ICD-10 M45) was drawn from health insurance data in Germany. Patients in the sample received a survey on demographic, socioeconomic, and disease-related parameters including disease activity (assessed using BASDAI) and functional impairment (assessed using BASFI).

Survey data were linked to health insurance data gathering additional information on comorbidities and drug prescriptions. Comorbidities were based on Elixhauser coding algorithms (excluding rheumatic diseases and augmented upon osteoporosis).

The prevalence of comorbidities in axSpA patients was compared to a sex- and age-matched control group of patients without axSpA drawn from health insurance data.

* excluding rheumatic diseases and augmented upon osteoporosis. AxSpA, axial spondyloarthritis; CPD, chronic pulmonary disease.

Separate multivariable linear regression models were calculated to determine the association of comorbidities with disease activity and functional impairment.

Results: A total of 1,776 patients with axSpA were included in the analyses. The patients' main characteristics are shown in **Table 1**: The mean age was 56.1 years and 46.4% were female. The most prevalent comorbidities are illustrated in **Figure**: 52% of the patients presented with hypertension, 25% with depression, and 23% with chronic pulmonary disease. The prevalence of the majority of comorbidities was higher in axSpA as compared to controls. Results from the multivariable linear regression models are presented in **Table 2** showing that the number of comorbidities was significantly associated with both disease activity and functional impairment: each comorbidity was associated with BASDAI increase by 0.11 and BASFI increase by 0.10 points independently of other factors including treatment.

Conclusion: Comorbidities are common in axSpA patients and are independently associated with higher disease activity and higher level of functional impairment. Higher disease activity and a higher level of functional disability might be indicators of a severe disease resulting in the development of comorbid conditions.

Allograft Inflammatory factor-1 Drives Th17 Like Pathologic Signature and Predict Poor Response to TNF Inhibitor in Ankylosing Spondylitis

Jeong Seok Lee,[1] Eunyoung Lee,[2] Ji Yong Choi,[3] Yeong-Wook Song,[4] Eui-Cheol Shin,[1] and Eun Young Lee[2], [1]Korea Advanced Institute of Science and Technology, Daejeon, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Seoul, Republic of Korea, [3]Seoul National University College of Medicine, Seoul, Republic of Korea, [4]Seoul National University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory disease that commonly treated with TNF inhibitors for controlling active inflammation. To predict treatment response to TNF inhibitors upon clinical disease activity, differentially expressed genes were screened and AIF-1 was identified and validated in serum protein level in our previous study.

To elucidate the mechanism of how systemically elevated allograft inflammatory factor-1(AIF-1) could affect refractoriness of TNF inhibitors in AS, we focused on the change of $CD4^+$ helper T cells and monocytes induced by AIF-1. The effect of AIF-1 on the response to TNF inhibitors was also investigated.

Methods: Flow cytometry including intracellular staining, ELISA, and whole transcriptome analysis using RNA sequencing were performed in whole PBMCs, $CD4^+$ T cells, and $CD14^+$ monocytes after stimulating by AIF-1 in vitro. Healthy volunteers and AS patients provided peripheral blood. The effect of TNF inhibitors (adalimumab, etanercept) and tofacitinib were also examined in AIF-1 induced inflammatory response.

Results: AIF-1 aggravated inflammatory response via both directly increased TNF secretion from $CD4^+$ T cells and monocytes (TNF dependent) and IL-17 associated pathways (TNF independent). This effect resulted in shifting of $CD4^+$ T cell repertoire toward T helper 17 (Th17) rather than T helper 1 (Th1)(Figure 1). For the monocyte aspect, AIF-1 activated monocytes and increased surface expression of IL-17 receptor. In addition, TNF inhibition lost its positive effect of decreasing Th17 in the AIF-1 high environment. Whole transcriptome analysis showed that increased differentiation of Th17 cells by AIF-1 stimulation was prominent in both isolated $CD4^+$ T cell and monocytes.

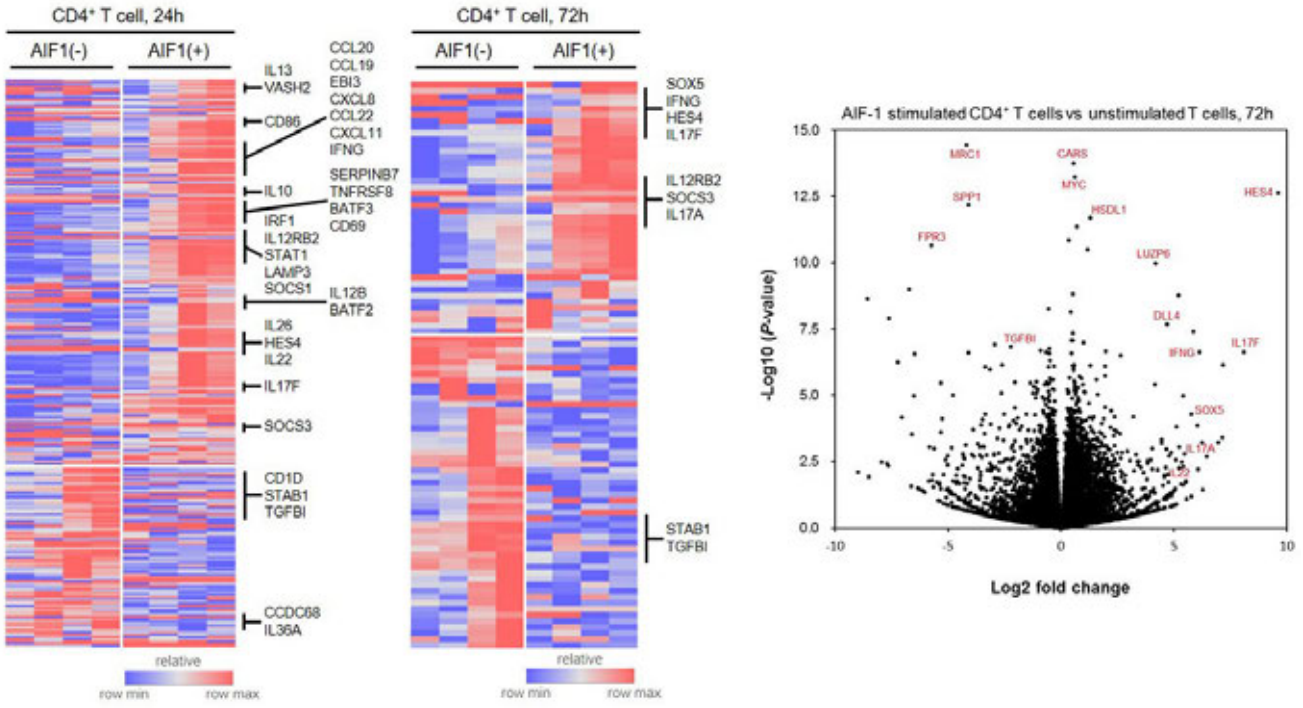

Figure 1. CD4+ T cell transcriptome changed toward Th17 by AIF-1 (n=4)

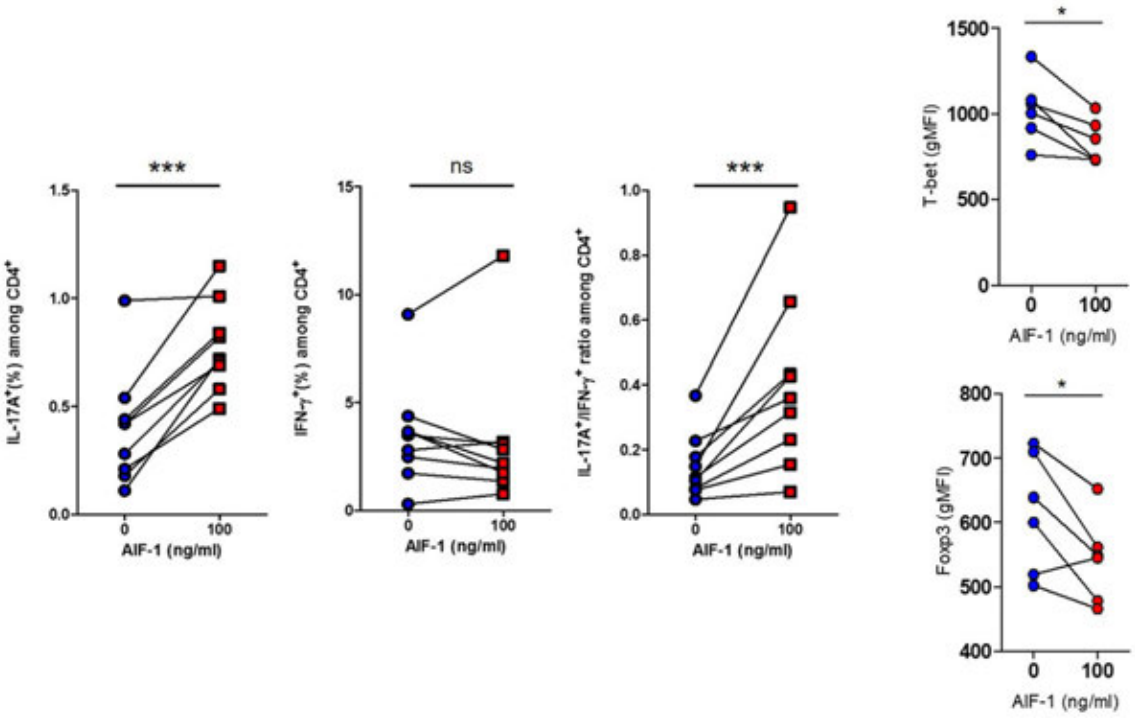

Figure 2. AIF-1 increased Th17/Th1 ratio

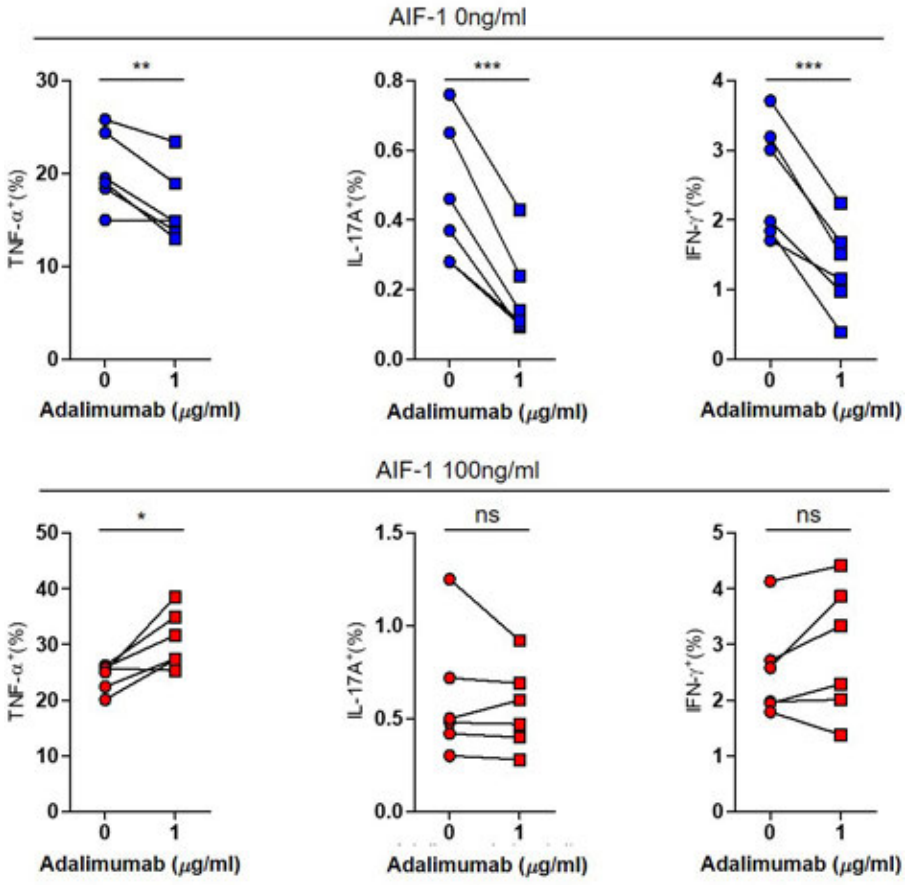

Figure 3. Anti-inflammatory effect or anti-Th17 effect of TNF inhibition may be diminished in the AIF-1 high environment.

Conclusion: AIF-1 aggravated Th17 response of AS and contribute to poor response to TNF inhibitors. Use of IL-17 blockade could be an effective alternative therapy in AS patients who has high AIF-1 level.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In our region, the lack of knowledge, timely referral and access to laboratory tests and images are the main causes in the diagnostic delay of spondyloarthritis (SpA), which is estimated between 6 and 10 years.

	PsA (36)	SpA (47)	chronic back pain (52)	*p*
Male (%)	44,4	51	42	0,38
Age (SD)	48,8 (12,5)	45,8 (11,7)	42,3 (10,3)	0,2
Age at onset symptoms (SD)	45,5 (11,2)	39,6 (11,7)	38,8 (10,1)	0,9
IBP (%)	22	93,6	63,5	**0,003**

Time since the beginning of the symtoms (mth	51 (17-87)	38 (13-121)	24 (12-63)	0,12

Objectives: To evaluate the delay between the onset of symptoms, referral and access to the fast-track diagnosis program. To compare the differential characteristics in patients with axial symptoms**.**

Methods: Patients older than 18 years who entered a Rheumacheck-SpA were included according to the following criteria: peripheral arthritis plus at least one SpA feature (ASAS 2006) or low back pain of 3 months of evolution that began before 45. Patients were perfomored at the same day: blood analysis with acute phase reactants, HLA B27 (low back pain), sacroiliac X-r, sacroiliac MRI, joint and entheses ultrasonography (regardless of symptoms), sociodemographic data , characteristics of the disease (eg: age of onset), clinimetry and treatments. The symptom evaluator was unaware of the results of the complementary studies that were collected by another observer. Previously, a plan of awareness was made to the local community, physicians and health personnel involved (media campaigns, social networks and referral talks). Statistical analysis: descriptive statistics were carried out and, Chi2 and Fisher's exact test (categorical variables) and Student's Test or Mann Whitney (continuous variables) were applied.

Results: 135 patients entered the fast-track diagnosis program for 18 months, 99 with axial symptoms and 36 with peripheral symptoms. 53% female, average age 45.5 yrs (11.3), 74% were employed. SpA feature 40% (77% psoriasis, 10% uveitis, 3% IBD), SpA family history 26% (70% psoriasis, 15% SpA, 10% IBD). Of the patients with peripheral symptoms, 100% met criteria for psoriatic arthritis; and patients with axial symptoms 47.5% (95% CI 33-58) met ASAS criteria for axial SpA. Median delay since symptoms began at diagnosis were 37.7 months (RIC 12-85). Those patients referred by specialists (orthopedics-Dherm) had a delay of 0.75 months (RIC: 0.55-1.3). 25% of patients with a diagnosis were referred after the awareness campaign and 55% attended because saw the social media ads. Table 1 shows the differences between patients.

Conclusion: The delay from the onset of symptoms and access to the program (final diagnosis) was 3 years, and the delay of referral by another specialist was less than one month, 70% attended after the awareness campaign. Patients with axial SpA diagnoses had distinctive clinical, laboratory and imaging characteristics.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (AxSpa) is characterized by inflammation in the sacroiliac joints and spine and associated with extracellular matrix (ECM) remodelling of affected tissues. Type VI collagen (COL6) is an ECM protein located in the interface between the basement membrane and interstitial matrix, where is binds to other ECM proteins and support cell-cell interactions. C6M is a metabolite of COL6 that is released from the inflamed tissue and can be measured in serum as a biomarker of tissue remodelling. The aim of this study was to investigate the association of C6M in patients with AxSpA, and its relationship with treatment of TNF-α inhibitors for 46 weeks in the prospective Biomarkers in Spondyloarthritis (BIOSPA) study.

Methods: C6M was measured in serum from the BIOSPA study (n=55) at baseline, week 2, 22, 46 after treatment with TNF-inhibitors (infliximab, etanercept or adalimumab). Differences between the biomarker levels at the four different timepoints were calculated using repeated measures ANOVA. A t-test was used to calculate the improvement is ASDAS, while Spearman correlations were performed to explore the association of C6M and MRI measures.

Results: Patients included were 82% males, with median age of 40 years (IQR: 32-48), and 84% were human leucocyte antigen-B27 positive. They had a median disease duration of 5.5 years (IQR: 2-10), and a median baseline level of ASDAS 3.9 (IQR: 3.0-4.5). The levels of C6M can be found in Table 1. Levels of C6M were significantly decreased after 2 and 22 weeks of treatment compared to baseline (p=0.0014 and p=0.0015, respectively). C6M was significantly decreased in patients with clinical important improvement after 22 weeks (ASDAS $\geq\Delta$1.1) (p=0.010) and major improvement after 22 and 46 weeks (ASDAS $\geq\Delta$2.0) (p=0.0002 and p=0.018, respectively) as shown in Table 2 and 3. Baseline and week 22 levels of C6M correlated to the total SPARCC Spine and Sacroiliac Joint Inflammation score measured by MRI (Spearmans Rho=0.496, p< 0.001 and Spearmans Rho=0.297, p=0.031 respectively).

Conclusion: The biomarker C6M was associated with changes in ASDAS and MRI measures of inflammation during TNF-inhibitor treatment. This indicates that C6M may be a tissue-based marker of disease activity.

Table 1. Levels of C6M

	Baseline	2 weeks	22 weeks	46 weeks
C6M levels, ng/mL (IQR)	24.9 (14.7-35.0)	15.9 (12.4-21.0)	15.8 (11.4-26.3)	19.5 (15.1-29.9)

Table 2. C6M in relation to changes in ASDAS from baseline to week 22.

Radiographic Association of Hip and SI Joints in Ankylosing Spondylitis Patients

Juyeon Kang,[1] Seoung Wan Nam,[2] Hyo-Kyung Sung,[3] Kyung Bin Joo,[4] Bon San Koo,[5] Seunghun Lee,[4] and Tae-Hwan Kim[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]Wonju Severance Christian Hospital, Yonsei University Wonju College of Medicine, Wonju, Republic of Korea, [3]Hanyang University Hospital for Rheumatic Diseases, Seoul, [4]Dertment of Radiology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [5]Department of Internal Medicine, Inje University Seoul Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) is a representative tool for assessing radiographic progression in spine of ankylosing spondylitis (AS) patients. However, also other joint involvement than spine is common in AS patients. In particular, involvement of hip joints is common in AS patients, but there is not enough assessment of the involvement of the hip joint. The purpose of this study was to investigate the association between radiographic progression of the hip and SI joints and mSASSS in patients with AS.

Table 1. Multivariable linear regression analysis of associated factor of mSASSS

Variables	mSASSS (range 0-72)			
	Univariable analysis		Multivariable analysis	
	B (95% CI)	p-value	B (95% CI)	p-value
Age, years	0.83 (0.59 – 1.06)	<0.001*	0.49 (0.28 – 0.85)	<0.001*
BASDAI (range 0-10)	0.79 (-0.49 – 1.93)	0.242		-[a]
BASFI (range 0-10)	3.02 (1.86 – 4.18)	<0.001*	1.35 (0.37 – 2.33)	0.007*
ESR (mm/hr)	0.02 (-0.10 – 0.14)	0.760		-[a]
CRP (mg/dL)	0.06 (-2.10 – 2.23)	0.953		-[a]
†Use NSAIDs	-6.61 (-20.37 – 7.15)	0.345		-[a]
†Use Sulfasalazine	-6.30 (-10.82 – -1.78)	0.007*		-[a]
†Use Methotrexate	-1.71 (-6.54 – 3.13)	0.487		-[a]
†Use Glucocorticoids	-7.70 (-12.24 – -3.15)	0.001*	-5.63 (-9.09 – -2.16)	0.002*
†Use Biologic DMARDs	4.48 (-0.45 – 9.42)	0.074		-[a]
Hip joint grade	2.61 (1.76 – 3.47)	<0.001*	1.21 (0.46 – 1.96)	<0.001*
SI joint grade	6.84 (5.51 – 8.16)	<0.001*	4.72 (3.38 – 6.04)	<0.001*

B refers to the influence on mSASSS

*Statistically significant variables

[a]These variables were not tested in multivariable regression analysis because the value of the regression coefficient explained by the items already analyzed is the largest

†All drugs were analyzed for the presence or absence of the drug

BASDI, Bath Ankylosing Spondylitis Disease Activity Index; BASFI, Bath Ankylosing Spondylitis Functional Index; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; HLA, Human leukocyte antigen; NSAID, Nonsteroidal anti-inflammatory drug; DMARD, Disease-modifying anti-rheumatic drug

Methods: In a total of 210 patients, simple x-ray images of spine, hip, and sacroiliac (SI) joints were obtained. The changes in SI joints were graded based on New York criteria, and the hip joint changes were assessed as joint space narrowing and osteophyte. The correlation between mSASSS and each joint was analyzed using Spearman's correlation. In addition, the factors were associated with radiographic progression were analyzed using multivariable regression.

Results: The mean age of the patients was 36.02 ± 8.89 years, and males were 91.9%. the grade of joint space narrowing and osteophyte were significantly correlated with mSASSS (r=0.31, r=0.22, r=0.34, p< 0.01), and the grade of SI joint was also significantly correlated with mSASSS (r=0.66, p< 0.01). In the correlation between mSASSS and other variables, Bath Ankylosing Spondylitis Functional Index (BASFI) showed significant correaltion with mSASSS (r=0.39, p< 0.01). In regression analysis, the radiographic progression of hip and SI joints was associated with mSASSS. In addition, age and BASFI were associated with mSASSS (Table 1).

Conclusion: Radiographic change of hip and SI joint was associated with mSASSS. Therefore, when evaluating the radiographic progression of the spine, we should consider hip joint change to evaluate the joint movement in patients with AS.

Effect of Testosterone on Spinal Ankylosis in Ankylosing Spondylitis : *in Vivo* and *in Vitro*

Sungsin Jo,[1] Eun-Ju Lee,[2] Juyeon Kang,[1] Seunghun Lee,[3] Jeehee Youn,[4] Yong-Gil Kim,[5] and Tae-Hwan Kim[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]Ulsan university, seoul, Republic of Korea, [3]Dertment of Radiology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [4]Hanyang University, seoul, Republic of Korea, [5]Division of Rheumatology, Department of Internal Medicine, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a predominantly male disease and spinal ankylosis more severely affect male AS[1] suggesting role of testosterone on spinal ankylosis. In previous studies, dihydrotestosterone (DHT) exhibited promoting osteoblast differentiation in *in vitro* experiment[2]. However, testosterone suppressed IL-17 expression[3] and exogenous IL-17A to primary bone-driven cells from AS promoted osteoblast activity and differentiation[4]. But the effect of testosterone on bony ankylosis in AS is still debated. This study aims to investigate the effect of testosterone on spinal ankylosis and osteoblast differentiation with curdlan-induced SKG mice and human primary osteoprogenitors.

Methods: Eight-week-old male SKG mice were intraperitoneally injected 3mg of curdlan (curdlan group, n=10) or PBS alone as control (n=6) at 0 and 2 weeks. Experimental diet with dutasteride (41.2mg/kg/day), 5α reductase inhibitor that block the conversion of testosterone into DHT, was begun at 9 weeks after the first curdlan injection (dutasteride group, n=10). Clinical scores of peripheral arthritis were monitored weekly, and at 15 weeks after first curdlan injection, whole-body imaging of mice using fluorescent *in vivo* bisphosphonate agent was performed using OsteoSense® 680 EX. At 17 weeks after first curdlan injection, mice were sacrificed and sera and splenocytes were collected. Bone metabolism-related molecules (RANKL, osteoprotegerin, DKK1, and sclerostin) were analyzed using luminex multiplex assay and IL-17A by single molecule arrays. T cell population in the spleen was measured using flow cytometry. Additionally, human bone tissues were obtained at surgery from facet joints of 10 patients with noninflammatory spinal disease from traffic trauma or spinal compression disease. Primary osteoprogenitor cells were cultured to assess osteoblastic activity. the effect of DHT on primary preosteoblasts was assessed by alkaline phosphatase (ALP) activity and staining, alizarin red staining (ARS) for calcium deposit, and qPCR

Results: The accumulation of hydroxyapatite that suggested spinal mineralization and osteoblast activity was increased in dutasteride group compared with curdlan group, and the osteoblast activities were correlated with levels of serum IL-17A. Among bone metabolism-related molecules, level of sclerostin was decreased in dutasteride group compared with curdlan group. Interestingly, increased frequency of Th17 frequency and increased IL-17A secretory Treg population was evident from splenocytes in dutasteride group. In *in vitro* human experiments, continuous exposure of DHT to osteoprogenitors resulted in low calcium deposit with ARS during osteoblasts differentiation, but

not intercellular ALP activity and ALP staining. In terms of gene expressions, DHT treated cells showed decreased *osteocalcin* and increased *DKK1* and *SOST1*.

Conclusion: Conclusively, treatment with dutasteride results in more aggressive mineralization of spine in curdlan-induced SKG mice and DHT treatment attenuates osteoblasts differentiation in *in vitro* model. Therefore, anti-androgen treatment in AS patients may be undertaken with caution when considering the progression of spinal ankylosis.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Almost all protein-based biotherapeutics can induce immunogenicity, which may result in loss of efficacy and/or increased risk of adverse reactions. Despite all the efforts of protein engineering to reduce drug immunogenicity, recent assays still show unexpectedly high immunogenicity rates, even in fully human products. Pre-existing endogenous antibodies (Pre-Abs) (before first biotherapeutic administration) may be a contributing factor to these findings, leading to new challenges in assessing immunogenicity and its clinical relevance. We aim to assess if the levels of anti-drug antibodies (ADA) and drug concentrations influence response to first Tumor Necrosis Factor inhibitor (TNFi), Adalimumab (ADL).

Methods: Patients from the BioEfficacySpa study (Biomarkers identification of anti-TNF alfa agents efficacy in axial spondyloarthritis (axSpA) patients using a transcriptome analysis and mass spectrometry) were included. Data and blood samples (including ADA levels and serum ADL concentrations) were collected at bl (before first ADL infusion) and at w14 post-treatment with ADL. To be considered responders, patients had to achieve both ASAS 20 and AS-DAS clinically important improvement responses. Association between ADA titer/drug concentrations, at both bl and/or w14, and response to TNFi was assessed through logistic regression models, adjusted for relevant confounders.

Results: In total, 30 patients were included (70% males with median age of 43 (IQR: 17.6) years at bl) (Table 1). The majority (n=18; 60%) fulfilled the predefinition of responder at w14. Anti-TNFi antibodies titer at bl was much higher

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The overall mortality rate in ankylosing spondylitis (AS) patients is increased by 60–90% compared with the general population. This higher mortality rate is predominately caused by cardiovascular disease (CVD) comprising both by increased prevalence of cardiac diseases such as valvular heart disease, conduction disturbances and cardiomyopathies as well as atherosclerotic diseases such as myocardial infarctions. However, there is some diversity in the literature and there is a lack of contemporary studies. Therefore, we investigated current prevalences of cardiac disorders in a well characterized cohorts of Dutch patients with AS.

The CARDAS study aims to describe the prevalence of CVD in AS patients in a Dutch cohort.

Methods: We performed a cross-sectional study in consecutive AS patients between 50-75 years. Subjects were recruited from a large rheumatology outpatient clinic (Reade) in Amsterdam, the Netherlands. Patients underwent echocardiography with 2D, spectral and Color Doppler imaging. Diastolic dysfunction was evaluated by an experienced cardiologist based on the AEA/ASE guideline 2009. Furthermore, an ECG, blood sample, surveys and physical examination were performed. Disease activity and function were measured with the BASFI, BASDAI and the ASDAS-CRP.

Table 1. Patient characteristics

	All	50-59 years	60-69 years	70-75 years
N	191			
Men	131 (71%)			
Age (years)	58 (54-65)			
Disease activity				
BASDAI	3.1 (±2,3)			
ASDAS-CRP	2.1 (±1.0)			
BASFI	3.5 (1.6-5.7)			
CVD				
History of CVD*		7.5%	9.4%	19%
Hypertension		45.3%	64.1%	85.7%
Aortic valve regurgitation**		10.4%	12.5%	33.4%
Mitral valve regurgitation**		33%	31.1%	42.9%
Diastolic dysfunction		40.4%	61.9%	89.5%

* Described as angina pectoris, myocardial infarction, stroke and/or peripheral ischemia
** moderate – severe regurgitation.

Results: 191 Consecutive AS patients were included with a median age of 58 years (54-65) of which mostly men (136/191, 71%) (Table 1). The mean disease duration was 34.9 years (± 11.9) The disease activity measures , BASDAI, ASDAS-CRP and BASFI, indicated moderate disease activity and were, respectively 3.1 (±2,3), 2.1 (±1.0) and 3.5 (1.6-5.7). The use of bDMARD's (anti-TNF) was present in 42% of the AS patients. As cardiac manifestations are age related, AS patients were divided in 3 age categories, respectively, 50-59 years, 60-69 years and 70-75 years. Hypertension was diagnosed in respectively 45.3%, 64.1% and 85.7%. History of CVD described as angina pectoris, myocardial infarction, stroke and/or peripheral ischemia were present in respectively 7.5%, 9.4% and 19%. Diastolic dysfunction was present in respectively 40.4%, 61.9% and 89.5% of the AS patients. The diastolic dysfunction present in this population was mainly mild with 60.2% of patients presenting with grade 1 and 39.8% with grade 2 diastolic dysfunction. Moderate to severe aortic regurgitation was present in, respectively 10.4%, 12.5% and 33.4% and moderate to severe mitral valve regurgitation in 33%, 31.3% and 42.9% of the AS patients. These prevalences are substantially increased in comparison to the general Dutch population.

Conclusion: We demonstrated increased prevalences of diastolic dysfunction, aortic valve regurgitation, mitral valve regurgitation and hypertension in Dutch AS patients compared to age matched general population. Although our results suggest mandatory echocardiography screening, this first needs to be established in prospective follow-up studies.

The Gut Enthesis Axis Coming into Focus with the Description of Enriched Entheseal Resident Mucosal Associated Invariant T-cells (MAITs) Capable of IL17A and TNF Production

Richard Cuthbert,[1] Qiao Zhou,[2] Abdulla Watad,[3] Robert Dunsmuir,[4] Peter Loughenbury,[4] Almas Khan,[4] Peter Milner,[4] Charles Bridgewood,[5] and **Dennis McGonagle**[2], [1]University of Leeds, Leeds, [2]University of Leeds, Leeds, United Kingdom, [3]Department of Medicine "B", Zabludowicz Center for Autoimmune Diseases Sheba Medical Center, Ramat-Gan, Israel, [4]Leeds Teaching Hospitals NHS Trust, Leeds, [5]Leeds Institute of Rheumatic and Muscoskeletal Medicine(LIRMM), University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mucosal associated invariant T-cells (MAITs) are innate-like T lymphocytes that express a semi-invariant TCR repertoire that are activated by microbial ligands or cytokines including IL-23 and secrete inflammatory cytokines, including IL-17A. MAIT cells are enriched at mucosal surfaces and have been implicated in the pathogenesis of spondyloarthritis (SpA) and inflammatory bowel disease (IBD). Although the human enthesis is not a mucosal surface it is the primary site of inflammation in SpA which has strong association with IBD. The aim of this study was to investigate if a population of MAITs is present at the normal human enthesis thereby supporting the gut-enthesis axis concept.

Methods: Healthy interspinous ligament and spinous process were harvested from patients undergoing elective surgery for the correction of mechanical spinal defects. Entheseal soft tissue (EST) and peri-entheseal bone (PEB) were separated, and cells were harvested by enzymatic and mechanical digestion respectively. The proportion of cells expressing markers consistent with MAITS (CD45+, CD3+, CD161+, TCRVα7.2+) were measured by flow cytometry in EST, PEB and matched blood. Expression of CD69 and CD45RA were examined for phenotypic analysis and IL-17A and TNF production was measured using intracellular flow following in vitro activation with PMA/ionomycin Transcript analysis for inflammatory, immunomodulatory and genes associated with tissue residency was performed on sorted entheseal MAITs and conventional CD8+ T-cells.

Results: As a proportion of total T-cells, MAITs were of approximately 3 fold and 2.5 fold greater abundance in EST and PEB respectively in comparison to matched peripheral blood (both p=0.034). MAITs in entheseal tissue had an overwhelming resident memory phenotype (CD69+, CD45RA-) median 53.2% (range 42.4 – 78.6%) in EST and 54.9% (45.2 - 82.1%) in PEB compared to those from blood 17.7 (6.8 – 69.4). They readily express IL-17A and TNF protein following PMA stimulation and showed higher basal expression of IL-23R (9-fold), RORC (3-fold), TNF (6-fold) and less TGFb (13-fold) and SOCS2 (5-fold). However, expression of transcripts relevant to tissue localisation was not altered in PEB MAITs compared to those from blood.

Conclusion: Healthy human entheseal tissue contains an enriched population of MAITs at a frequency comparable to that reported in the colon. The majority of these cells express a resident memory phenotype suggesting that they are a distinct population residing in entheseal tissue. These observations are potentially relevant to SpA pathogenesis, the observed link between SpA and IBD and may help to explain entheseal pathology following $\alpha 4\beta 7$ integrin inhibition in patients with IBD since MAITs are known to express this integrin receptor.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In ankylosing spondylitis (AS), smokers have been found to have both higher disease activity and greater syndesmophyte progression, and a higher body mass index (BMI) has been associated with disease activity in cross sectional studies of both late and early disease. In established AS, alcohol consumption (AC) was as-

sociated with lower disease activity. However, little is known about the longitudinal effect on disease activity of such modifiable life-style factors, and very few studies have been performed in early axial spondylarthritis (axSPA). Our aim was therefore to study the relation of baseline smoking, BMI and AC with disease activity over time in early axSPA.

Methods: Data from the SPondyloArthritis Caught Early cohort, which includes patients with chronic back pain for ≥3 months, ≤2 years and onset < 45 years, were used to predict disease activity, measured as ASDAS, during the first year of follow-up. ASDAS was recorded at baseline (inclusion), after 3 and 12 months. Patients included in the analyses had a definite diagnosis of axSPA (physician's level of confidence regarding SpA-diagnosis ≥7 on a 0-10 scale). Exposures measured at baseline were categorized as follows; BMI (normal < 25, overweight 25-29.9, obese > 30 kg/m2), smoking history (never, previous, current) and AC (none, 1-2, 3-5, ≥6 units of alcohol/week). Differences in ASDAS over 1 year by BMI category, smoking status and AC at baseline were estimated using mixed linear regression models, taking into account repeated measures of ASDAS.

Results: Of the 344 included subjects, the mean age at inclusion was 30 years and 49% were men. ASDAS decreased over the year of study with 0.58 in men and 0.46 in women. Obesity was more common in women whereas smoking and increased AC were more frequent in men (Table 1).

In age-adjusted models obesity in women (compared to normal BMI), but not in men, was associated with on average 0.58 (95% CL: 0.26, 0.90) *higher* ASDAS. The highest category of AC (≥6 units/week, compared to no AC) in women was associated with -0.54 (95% CL: -1.04, -0.04) *lower* ASDAS; and current smoking (compared to never smoking) in men with 0.32 (95% CL: 0.01, 0.63) *higher* ASDAS (Table 1).

In multivariate analyses including age, BMI-category, smoking history and AC the point estimates were overall similar, albeit the difference between current smokers and non-smokers in men did not reach statistical significance (Table 1).

Conclusion: Current smoking, AC and BMI, representing modifiable life style factors, were associated with disease activity over time in patients with early axSPA, with modest estimated differences and different patterns in women and men. Further analyses will explore to what extent residual confounding may explain these associations.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Classification criteria for axSpA comprise an imaging and a clinical arm, the former requiring radiographic or MRI evidence of sacroiliitis. Several cohorts have reported the performance of the ASAS classification criteria in settings where clinical, radiographic, and MRI features have been simultaneously incorporated into the diagnostic evaluation in arriving at a gold standard for the testing of the criteria, which introduces circularity. We aimed to test the performance of the criteria in a setting where diagnostic evaluation can be conducted sequentially before and after MRI assessment in unselected patients referred with undiagnosed back pain who have presented with acute anterior uveitis (AAU), psoriasis, or colitis to their respective specialists.

Methods: Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, acute anterior uveitis (AAU), or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis (-10 (definitely not SpA) to +10 (definite SpA)) at 3 sequential stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. We calculated the sensitivity and specificity of the ASAS criteria and the component imaging and clinical arms using the stage 2 (pre-MRI) and 3 (post-MRI) diagnostic assessments by the local rheumatologist as gold standard.

Results: A total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%), after final diagnostic evaluation. Sensitivity/specificity of the ASAS criteria, imaging arm, clinical arm after stage 2 diagnostic evaluation for the entire cohort (prior to assessment of MRI) were 67.4/85.7%, 39.7/95.2%, 48.9/87.6%, respectively (Table). Sensitivity and specificity were higher in patients diagnosed with a high degree of confidence. For the subset of 146 patients who had MRI evaluation, and therefore had diagnostic evaluation at both stage 2 (pre-MRI) and stage 3 (post-MRI evaluation), there was a substantial enhancement in the sensitivity of the imaging arm (from 23.3% pre-MRI to 44.8% post-MRI) without change in specificity (>90%). However, there was a substantial decrease in specificity of the overall ASAS criteria from 83.9% pre-MRI to 74.7% post-MRI. This was primarily due to a substantial decrease in the specificity of the clinical arm from 85.7% pre-MRI to 77.2% post-MRI.

Conclusion: The clinical arm of the ASAS criteria performed less well after MRI assessment was added to the process of evaluation to enhance diagnostic precision. This could reflect rheumatologist diagnostic 'over-call' based on clinical findings in a population presenting with a higher pre-test probability of axSpA.

Table 1.

Patient Category	Stage of diagnostic evaluation	No of Patients	ASAS criteria		Imaging arm		Clinical arm	
			Sen	Spec	Sen	Spec	Sens	Spec
All patients	2	246	67.4	85.7	39.7	95.2	48.9	87.6
Patients diagnosed with high confidence	2	144	86.4	85.9	65.2	96.2	56.1	87.2
Subset of patients with MRI	2	146	58.9	83.9	23.3	94.6	46.7	85.7
Subset of patients with MRI	3	146	67.2	74.7	44.8	92.4	47.8	77.2
Subset of patients with MRI and high diagnostic confidence	2	111	74.1	82.1	44.4	92.3	51.9	84.6
Subset of patients with MRI and high diagnostic confidence	3	111	80.5	78.6	58.5	91.4	53.7	81.4

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Follow up of the ASAS Classification Cohort (CC) indicated a high positive predictive value for the ASAS classification criteria derived from baseline patient and imaging data[1]. Moreover, diagnosis of axSpA was changed by the local rheumatologist in only 11.2% of patients who were available at follow up at 4.4 years. This has raised potential concerns regarding diagnostic ascertainment bias. We aimed to determine the evolution of MRI features of axSpA from baseline to follow up by central reading of scans from this cohort, whether this reflects

Rheumatologist's diagnosis	MRI indicative of axSpA (agreement by ≥ 2 readers)			
	Yes at baseline and yes at follow up (N =48)	Yes at baseline and no at follow up (N = 4)	No at baseline and yes at follow up (N =6)	No at baseline and No at follow up (N = 50)
SpA yes at baseline and follow up (N= 82)	46 (56.1%)	2 (2.4%)	4 (4.9%)	30 (36.6%)
SpA no at baseline and yes at follow up (N =5)	1 (20%)	0 (0%)	1 (20%)	3 (60%)
SpA yes at baseline and no at follow up (N = 4)	1 (25%)	1 (25%)	0 (0%)	2 (50%)
SpA no at baseline and no at follow up (N =17)	0 (0%)	1 (5.9%)	1 (5.9%)	15 (88.2%)

MRI data from at least 2 readers and from the majority (≥5/8) was used to calculate positive and negative predictive values (PPV, NPV)

Table 2

MRI scan at baseline	Rheumatologist Diagnosis of axSpA at follow up n=108			
	Sensitivity	Specificity	PPV(%)	NPV(%)
Active lesions typical of axSpA (any 2 readers)	48.3 (37.4-59.2)	100.0 (83.9-100.0)	100.0	31.8
Active lesions typical of axSpA (majority of readers)	40.2 (29.9-51.3)	100.0 (83.9-100.0)	100.0	28.8
Structural lesions typical of axSpA (any 2 readers)	48.3 (37.4-59.2)	90.48 (69.6-98.9)	95.5	29.7
Structural lesions typical of axSpA (majority of readers)	31.0 (21.5-41.9)	95.2 (76.2-99.9)	96.4	25.0
ASAS positive MRI (any 2 readers)	46.0 (35.2-57.0)	100.0 (83.9-100.0)	100.0	30.9
ASAS positive MRI (majority of readers)	40.23 (29.9-51.3)	100.0 (83.9-100.0)	100.0	28.8
MRI indicative of axSpA (any 2 readers)	56.3 (45.3-66.9)	85.7 (63.7-97.0)	94.2	32.1
MRI indicative of axSpA (majority of readers)	50.6 (39.6-61.5)	100.0 (83.9-100.0)	100.0	32.8

diagnostic assignment by the local rheumatologist, and the predictive utility of baseline MRI considered indicative of axSpA.

Methods: MRI images were available from 108 cases who had MRI performed at baseline and 4.4 years follow up and also had a local rheumatologist diagnosis at both time points. Eight experienced readers from the ASAS MRI group recorded MRI lesions in an eCRF that comprised global assessment (MRI indicative of axSpA: yes or no, active and/or structural lesion typical of axSpA present/absent according to ASAS definitions), whether the features met the criteria for an ASAS positive MRI, and detailed scoring of lesions per SIJ quadrant (SPARCC SIJ quadrantic method). MRI data from at least 2 readers and from the majority (≥5/8) was used to calculate positive and negative predictive values (PPV, NPV).

Results: MRI was considered indicative of axSpA in 52/108 (48.1%) at baseline and in 47/86 (54.7%) diagnosed as axSpA by the rheumatologist. Change in MRI diagnosis was recorded in only 10/108 (9.3%) of cases (4 from yes to no, and 6 from no to yes for axSpA) according to agreement by at least 2 readers (Table 1). Change in MRI diagnosis was recorded in only 3 cases according to a majority of readers. Change in rheumatologist diagnosis was recorded in 9/108 (8.3%), 2 of which had a change in MRI diagnosis. Baseline MRI had very high PPV for follow up diagnosis of axSpA (Table 2).

Conclusion: The lack of change in diagnostic ascertainment of rheumatologists over follow up of the ASAS-CC is supported by the evaluation of MRI scans by central reading. A positive MRI at baseline had very high PPV for a follow up diagnosis of axSpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: xClassification of axial spondyloarthritis is based on the application of either an imaging or clinical arm. Radiographic or MRI evidence of sacroiliitis can be applied for the imaging arm. However, it is well-established that reliability for detection of radiographic sacroiliitis is inadequate, especially in early disease, and radiography is insensitive compared to MRI for detection of either active or structural lesions. Active lesions on MRI (MRI-A) are already included as an alternative to radiographic sacroiliitis in the imaging arm. We aimed to assess the impact of replacing radiographic sacroiliitis with MRI structural lesions (MRI-S) typical of axSpA on the number of patients classified as having axSpA in patients with undiagnosed back pain recruited to the ASAS Classification Cohort (ASAS-CC).

Methods: MRI images (STIR and T1-weighted sequences) of the sacroiliac joint (SIJ) enabling assessment of both active and structural lesions were available from 219 cases in the ASAS-CC, and these also had available clinical, laboratory, and radiographic data. Seven central readers from the ASAS-MRI group recorded MRI lesions in an eCRF that included wording of lesions defining active (MRI-A) and structural (MRI-S) lesions typical of axSpA. MRI-A was deemed to be present according to majority agreement (≥4/7) of central readers. MRI-S was deemed to be present according to the majority (majority reader MRI-S) and also according to any 2 central readers (2-reader MRI-S). We calculated the number of patients that were classified differently after replacement of radiographs by MRI-S for overall fulfillment of the ASAS criteria and for the imaging arm.

Results: In total,124 (56.6%) fulfilled the ASAS axSpA criteria based on local reading of radiographic sacroiliitis and central reading of MRI-A. This changed to 126 (57.5%) and 120 (54.8%) patients after replacement of radiographic sacroiliitis by 2-reader and majority reader MRI-S, respectively (Table). 9 (4.1%) and 4 (1.8%) of patients who were not classified as axSpA were then re-classified as axSpA after substitution with 2-reader and majority reader MRI-S, respectively. Conversely, 7 (3.2%) and 8 (3.7%) were re-classified as not axSpA after substitution by 2-reader and majority reader MRI-S, respectively. When fulfillment of the imaging arm was required (irrespective of the clinical arm), the number of patients reclassified from not axSpA to axSpA was 18 (8.2%) by 2-reader MRI-S and 8 (3.7%) by majority reader MRI-S, while 8 (3.7%) and 11 (5.0%) were reclassified from axSpA to not axSpA, after substitution of radiographic sacroiliitis with 2-reader and majority reader MRI-S, respectively.

Conclusion: The number of patients classified as having axSpA does not change substantially when MRI-S replaces radiographic sacroiliitis. However, it is unclear to what degree MRI structural lesions could have affected the final diagnostic ascertainment, the gold standard for assessment of the performance of the ASAS criteria.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Classification criteria for axial spondyloarthritis (axSpA) that capture the spectrum of disease present challenges due to the frequency of back pain, the relative infrequency of axSpA, and limited physical and laboratory findings in early disease. Several cohorts have reported the performance of the ASAS classification criteria in settings where patients have been selected for certain features such as the presence of inflammatory back pain and/or short symptom duration. We aimed to test the performance of the ASAS classification criteria in unselected patients with undiagnosed back pain who were referred after first presenting with acute anterior uveitis (AAU), psoriasis, or colitis to their respective specialists and whether performance varied according to the presentation of disease.

Methods: The multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA in patients referred after first presenting with these disorders. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis (-10 (definitely not SpA) to +10 (definite SpA)) at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI evaluation. Assessment of imaging was conducted by local and central readers. We calculated the sensitivity and specificity of the ASAS criteria and the component imaging and clinical arms using the stage 3 diagnostic assessment by the local rheumatologist as gold standard but using central reads for imaging.

Results: A total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%), after stage 3 evaluation. Sensitivity/specificity of the ASAS criteria, imaging arm, clinical arm were 65/82.2%, 36.8/97.7%, 50.4/82.2%, respectively (Table). For patients diagnosed with a high degree of confidence sensitivity/specificity was 73.8/84.5%, 47.5/98.2%, 56.3/84.5%, respectively. Performance varied substantially according to presentation of disease characterized by much higher sensitivity but markedly lower specificity, especially for the clinical arm, in patients presenting with AAU. This was noted even in patients diagnosed with high confidence. The imaging arm had high specificity (>90%) in all patient groups and was at least twice as sensitive in males versus females.

Table 1

Patient Category	Number	ASAS criteria		Imaging arm		Clinical arm	
		Sen	Spec	Sen	Spec	Sens	Spec
All SASPIC patients							
All	246	65	82.2	36.8	97.7	50.4	82.2
High confidence in diagnosis	190	73.8	84.5	47.5	98.2	56.3	84.5
Males	129	68.1	84.2	47.2	98.2	48.6	84.2
Females	117	60	80.6	20	97.2	53.3	80.6
IBD patients							
All	127	51	88.2	31.4	98.7	31.4	88.2
High confidence in diagnosis	106	59.5	88.4	43.2	98.6	32.4	88.4
Males	64	55.2	88.6	44.8	100	24.1	88.6
Females	63	45.5	87.8	13.6	97.6	40.9	87.8
AAU patients							
All	73	91.1	60.7	46.7	92.9	82.2	60.7
High confidence in diagnosis	56	94.1	63.6	52.9	95.5	85.3	63.6
Males	41	92.9	61.5	57.1	92.3	85.7	61.5
Females	32	88.2	60	29.4	93.3	76.5	60
Psoriasis patients							
All	46	42.9	88	28.6	100	28.6	88
High confidence in diagnosis	28	55.6	94.7	44.4	100	44.4	94.7
Males	24	46.7	100	33.3	100	26.7	100
Females	22	33.3	81.3	16.7	100	33.3	81.3

Conclusion: The performance of the ASAS criteria in the SASPIC cohort demonstrated lower sensitivity and specificity when compared to published cohorts, even in patients diagnosed with high confidence. This was characterized by much lower specificity for the clinical arm in patients presenting with AAU and raises the potential for 'diagnostic overcall' in the setting of a perceived high pre-test probability of axSpA.

Males	24	46.7	100	33.3	100	26.7	100
Females	22	33.3	81.3	16.7	100	33.3	81.3

Background/Purpose: xThe ASAS classification criteria for axial spondyloarthritis (axSpA) have overall sensitivity/specificity of 82.9%/84.4% but component imaging and clinical arms differ in performance (66.2%/97.3% and 56.6%/83.3%, respectively). We aimed to demonstrate that a data-driven elimination of SpA clinical features that were non-discriminatory in comparisons of patients diagnosed with and without axSpA in a prospective cohort of unselected patients with undiagnosed back pain could enhance the performance of the criteria.

Methods: We used data from the prospective multicenter Screening for Axial Spondyloarthritis in Psoriasis, Iritis, and Colitis (SASPIC) Study, which is aimed at early detection of axial SpA in patients referred by the respective specialist after first presenting with these disorders. Consecutive patients ≤45 years of age with ≥3 months undiagnosed back pain with any one of psoriasis, AAU, or colitis undergo routine clinical evaluation by a rheumatologist for axial SpA and MRI evaluation is ordered per rheumatologist decision. The rheumatologist determines the presence or absence of axial SpA and the degree of confidence in the diagnosis. Imaging was assessed by central readers. Univariable and multivariable logistic regression analysis was performed to determine which clinical SpA features were/were not discriminatory for the final diagnosis of axSpA. We then compared the sensitivity and specificity of the ASAS criteria with and without these features.

Results: xA total of 246 patients were recruited, 47.6% being diagnosed with axSpA (61.5% male, age 33.7 years, symptom duration 7.6 years, B27 positive 52.1%). The following clinical SpA features were non-discriminatory between axSpA/not axSpA: NSAID response, family history of SpA, heel enthesitis, peripheral arthritis, dactylitis. Specificity of the clinical arm and the overall criteria increased from 82.2% to 86.8% without impacting sensitivity. This effect was particularly noteworthy in patients with lower degree of symptomatology (back pain severity < 5/10, specificity increases from 76.7% to 90.7%), short symptom duration (< 5 years, specificity increases from 78% to 84.7%), and in females (specificity increases from 80.6% to 86.1%).

Conclusion: xIn a prospective cohort with a high pre-test probability of axSpA certain clinical SpA features were not helpful in discriminating a diagnosis of SpA from not-SpA. Deletion of these features from the list of SpA features used in the ASAS classification criteria enhanced the performance of the criteria, especially in female patients and those with early disease.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Active MRI lesions typical of axSpA were reported in 61.6% and 2.2% of axSpA and not-axSpA patients, respectively, from the ASAS classification cohort (ASAS-CC)[1]. Discrepancy between local and central reader evaluation of MRI scans regarding could result in differences in numbers of patients fulfilling the imaging arm of the ASAS classification criteria. But final classification may not be impacted if discrepant patients still fulfill the clinical arm. We aimed to assess the impact of reader discrepancy in detection of active MRI lesions on the number of patients classified as having axSpA in patients recruited to the ASAS-CC.

Methods: MRI images of the sacroiliac joints (SIJs) were available from 253 cases in the ASAS-CC, and these also had clinical and radiographic data. Seven central readers from the ASAS-MRI group recorded MRI lesions in an eCRF that included wording of lesions defining active lesions typical of axSpA in the SIJ (MRI-active) that was exactly the same as in the original ASAS-CC eCRF permitting comparisons between central and local site readers. Active lesions were deemed to be present according to majority agreement (≥4/7) of central readers and also any 2 central readers. We calculated the number of patients that were classified differently after central evaluation for overall fulfilment of the ASAS criteria and for the imaging arm.

Results: Discordance between central and local readers for detection of MRI-active was recorded in 70(27.1%) and 47(18.2%) of cases according to 2-reader and majority (≥4/7) central reader data, respectively (kappa (95%CI) of 0.62(0.52-0.71) and 0.58(0.49-0.67)). With central reading as external standard the false-positive rate for MRI-SI was 47.9% and 33.3% ('local overcall') for 2-reader and majority reader data. False-negative rate was 5.4% and 3.1%, respectively. A total of 159(62.8%) patients fulfilled the ASAS axSpA criteria based on local-reading, and 149(58.9%) and 143(56.5%) patients based on 2-reader and majority central-reading, respectively (Table). 25(9.9%) and 20(7.9%) patients who were classified as axSpA after local reading were no longer classified as axSpA after 2-reader and majority reader central evaluation. 7(2.8%) and 4(1.6%) classified as axSpA after central reading were not after local assessment. When fulfillment of the imaging arm was required (irrespective of the clinical arm), 45(17.8%) and 31(12.3%) cases were classified as axSpA after local MRI inflammation reading but not after 2-reader and majority

Table 1

Impact of Central Vs. Local Reader SIJ MRI Inflammation Assessment on SpA Classification in cases with all clinical, radiographic, and central and local MRI inflammation data available (n=253)		
	SpA Classification=Yes after MRI assessment N(%)	SpA Classification=No after MRI assessment N(%)
Local Reader SIJ MRI Inflammation positive	159 (62.8%)	94 (37.2%)
>2 Central Reader SIJ MRI Inflammation Assessment positive	149 (58.9%)	104 (41.1%)
Majority Central Reader SIJ MRI inflammation Assessment positive	143 (56.5%)	110 (43.5%)

central reading evaluation, and 5(1.9%) and 3(1.2%) cases that were not classified as axSpA after local MRI inflammation reading were classified as axSpA after central reading.

Conclusion: Despite substantial overcall for positive MRI SIJ inflammation by local readers when central readers are considered the reference standard, the number of patients classified as having axSpA did not change substantially. However, it is unclear whether reader discrepancy could have affected the final diagnosis, the gold standard for assessment of the performance of the ASAS criteria. Also, the gap of >10 years between local and central reading has to be taken into account.

Abstract Number: 0596

Prostaglandin Receptor EP4 Drives Pathogenic Th17 Cell Development in Ankylosing Spondylitis and Is a New Marker of Disease Activity

Anja Meyer,[1] Charlotte Klasen,[1] Pauline Wittekind,[1] Iris Waqué,[1] Schafiq Nabhani,[1] and David Kofler[1], [1]University of Cologne, Cologne, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Th17 cells are involved in the pathogenesis of ankylosing spondylitis (AS). However, the mechanism underlying enhanced Th17 cell accumulation in AS remains unknown. The prostaglandin E2 receptor EP2/EP4 signaling pathway plays a critical role in the development of autoimmune Th17 cells. Interestingly, recent genome-wide association studies (GWAS) have identified five risk alleles for AS in *PTGER4*, the gene encoding for EP4. The aim of this study was to reveal a possible link between EP4 and disease activity in patients with AS.

Methods: Th17 cells from patients with AS were analyzed for the transcriptional expression of prostaglandin receptor genes by quantitative RT-PCR. Th17 cells from patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) and from healthy individuals served as controls. EP4 receptor expression in Th17 cells was assessed *ex vivo*by flow cytometry and by western blot. Functional analysis using EP4 specific agonists was performed to reveal how EP4 regulates Th17 cells.

Results: EP4 is significantly overexpressed in Th17 cells from patients with AS compared to Th17 cells from healthy individuals or patients with RA or PsA. EP4 upregulation is unique to Th17 cells and is not found in other CD4+ T cell subsets. Interestingly, EP4 expression is not increased in Th17 cells from HLA-B27 negative patients with AS. The highest amount of EP4 expression is found in IL-17+/IFNγ+ double positive CD4+ T cells. This is remarkable, because IL-17+/IFNγ+ Th17 cells have been identified previously as pathogenic autoimmune Th17 cells. Specific activation of EP4 drives Th17 cell development and promotes EP4 expression in a positive feedback loop in AS but not in RA or PsA. Mechanistically, EP4 acts by suppressing the RORγt inhibitor FoxO1 and by enhancing STAT3 phosphorylation. As a consequence, the interleukin-23 receptor (IL-23R) is upregulated on Th17 cells. Importantly, increased EP4 expression levels in Th17 cells from AS patients correlate with high disease activity as defined by a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) score ≥ 4 (r=0.7591,p=0.0016).

Conclusion: EP4 is a potential marker of disease activity in patients with AS. Aberrant EP4 expression might contribute to pathogenic Th17 cell accumulation and represents a new target for the treatment of AS.

High Prevalence of Sacroiliac Bone Marrow Edema on MRI in Post Partum Women: A Temporary Phenomenom

Thomas Renson,[1] Ann-Sophie De Craemer,[1] Liselotte Deroo,[1] Anaïs Depicker,[1] Manouk de Hooge,[1] Nele Herregods,[1] Lennart Jans,[1] Kristien Roelens,[1] Isabelle Dehaene,[1] Philippe Carron,[1] Filip Van den Bosch,[1] and Dirk Elewaut[1], [1]Ghent University Hospital, Ghent, Belgium

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic Resonance Imaging (MRI) is a sensitive method for detection of sacroiliitis. However, recently, concerns have been raised about its specificity. In contrast to radiographic spondyloarthritis (SpA), non-radiographic SpA has a more equal sex distribution. Hence, in young women with back pain a broad differential diagnosis has to be considered. In clinical practice, women occasionally present with inflammatory(-like) low back pain, following pregnancy and childbirth. Up until now, little is known regarding the presence of SpA-like MRI lesions in postpartum women. We hypothesized that physical stress on the pelvis during pregnancy may lead to signs of bone marrow edema on MRI.

The objectives of this study are to explore (A) the association between pregnancy and giving birth on the one hand, and the occurrence of MRI lesions compatible with SpA on the other hand; and (B) if these lesions are transient.

Methods: Twenty-five women underwent an MRI of the sacroiliac joints (SIJ) in the first 10 days after vaginal delivery. The scan was repeated after 6 months. Both time points were scored in pairs by 3 trained readers, blinded for time

Table. Number of MRI-SIJ lesions in 25 postpartum women.

	Baseline			6 months		
Inflammatory lesions	Median	IQR	95% CI	Median	IQR	95% CI
SPARCC (/72)	5	1 – 11	1 – 8	0	0 – 1	0 – 1
Capsulitis (/12)	0	0 – 0	0 – 0	0	0 – 0	0 – 0
Enthesitis (/12)	0	0 – 0	0 – 0	0	0 – 0	0 – 0
High signal intensity (/12)	0	0 – 4	0 – 3	0	0 – 0	0 – 0
Structural lesions	Median	IQR	95% CI	Median	IQR	95% CI
Erosions (/48)	0	0 – 0	0 – 0	0	0 – 0	0 – 0
Fatty lesions (/48)	0	0 – 1	0 – 0	0	0 – 0	0 – 0
Sclerosis (/48)	0	0 – 0	0 – 0	0	0 – 0	0 – 0
Partial ankylosis (/48)	0	0 – 0	0 – 0	0	0 – 0	0 – 0
Ankylosis (/48)	0	0 – 0	0 – 0	0	0 – 0	0 – 0

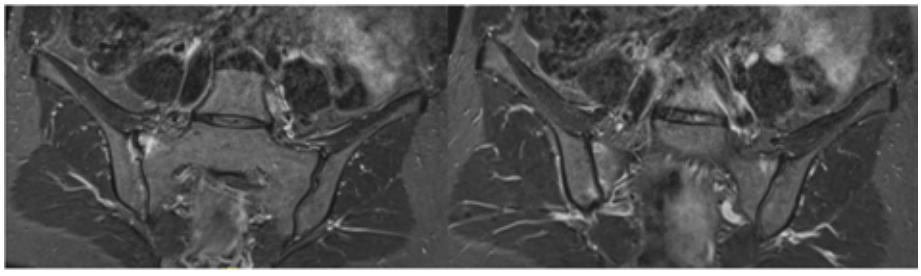

Figure. Baseline MRI T2 short tau inversion recovery (STIR) images of sacroiliac bone marrow edema in a 33-year old postpartum woman.

sequence and subject characteristics. MRI assessment was done on 6 consecutive slices for inflammatory and structural SpA-like lesions; bone marrow edema (BME), capsulitis, enthesitis, high signal intensity in joint space, erosions, fatty lesions, sclerosis and (partial) ankylosis. In addition, the Assessment of SpondyloArthritis international Society (ASAS) definition of a positive MRI-SIJ was applied. MRI reader scores were reported as 2 out of 3 (median) scores.

Results: Twenty out of 25 (80.0%) subjects displayed BME; the median SPARCC score was 5 (IQR 1-11) (see table). One subject was lost to follow-up. After 6 months, 11 out of 24 (45.8%) subjects still showed BME; however, median SPARCC score dropped to 0 (IQR 0-1) ($p = 0.002$). At baseline, 16 out of 25 (64.0%) participants had a positive MRI-SIJ according to the ASAS definition, reducing to 4 out of 24 (16.7%) after 6 months ($p = 0.002$). 75.5% of the baseline lesions were located in the anterior part of the SIJ; 57.3% situated on the iliac side. Structural lesions were rarely detected in this study population (see table).

Conclusion: A very high prevalence of sacroiliac BME on MRI was seen in women immediately postpartum with 64.0% even having a positive MRI for sacroiliitis according to the ASAS definition. A significant decrease in BME was seen over 6 months time, yet a substantial fraction continued to display BME after follow up. History of a recent pregnancy is crucial to take into account when interpreting an MRI-SIJ. In case of a recent pregnancy and clinical suspicion of SpA, it may be wise to postpone MRI-SIJ imaging until at least 6 months after the delivery.

Abstract Number: 0598

Identification of Potential Risk Factors for Spinal Structural Damage in Chinese Patients with Ankylosing Spondylitis

Weiping Kong,[1] Caroline Jefferies,[2] Tom Learch,[2] Feng Zhu,[1] Nan Zhang,[1] Dier Jin,[1] Yingze Zhang,[1] Qingwen Tao,[1] Xiaoping Yan,[1] Michael Weisman,[3] and Mariko Ishimori[2], [1]China-Japan Friendship Hospital, Beijing, China (People's Republic), [2]Cedars-Sinai Medical Center, Los Angeles, CA, [3]David Geffen School of Medicine at UCLA, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Spinal structural damage can lead to physical dysfunction and decline of spinal mobility in patients with ankylosing spondylitis (AS). Although great progress has been made to identify potential risk factors associated with the severity of spinal structural damage, there is no definite consensus on how many factors are actually involved in its development. To yield more information, we conducted a cross-sectional study in 270 Chinese AS patients, aiming to identify potential risk factors responsible for the severity of spinal structural damage, both individually and in combination.

Methods: In total, 270 AS patients fulfilled the modified New York criteria. Computed tomography (CT) scans and lumbar/cervical X-rays were used to separately assess BASRI-SI, BASRI-hips and modified Stoke Ankylosing Spon-

Abbreviations: AS, ankylosing spondylitis; HLA-B27, human leukocyte antigen B27; BMI, body mass index; PGA, patient global assessment; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; ASDAS, ankylosing spondylitis disease activity score; BASDAI, bath ankylosing spondylitis disease activity index; VAS, (10 cm) visual analogue scale; mSASSS, modified stoke ankylosing spondylitis spine score. Data are expressed as either count (per cent) or median (interquartile range). The *p* value was calculated by Chi-squared test or Wilcoxon rank-sum (Mann-Whitney) test, where appropriate.

dylitis Spine Score (mSASSS), which were scored by a trained rheumatologist and a musculoskeletal radiologist where the inter-rater reliability (average *kappa*: 87.3%) was excellent. Spinal structural damage was appraised by mSASSS that was binarized at a cutoff of 10. Hip involvement was defined as BASRI-hips >0. Univariate and multivariate logistic regression analyses were done to identify potential risk factors for the severity of spinal structural damage, and nomogram graph was presented to facilitate clinical assessment. Statistical analyses were completed using the STATA software (v14.1) and R language (v3.5.1).

Results: 183 AS patients had mSASSS < 10 (low mSASSS), and 87 patients had mSASSS ≥10 (high mSASSS) (Table 1). Univariate analysis revealed that AS onset age, body mass index (BMI), duration of smoking, duration

Table 2. Identification of significant risk factors for spinal structural damage

Significant risk factors	Unadjusted model				Adjusted model*			
	OR	95% CI		*p*	OR	95% CI		*p*

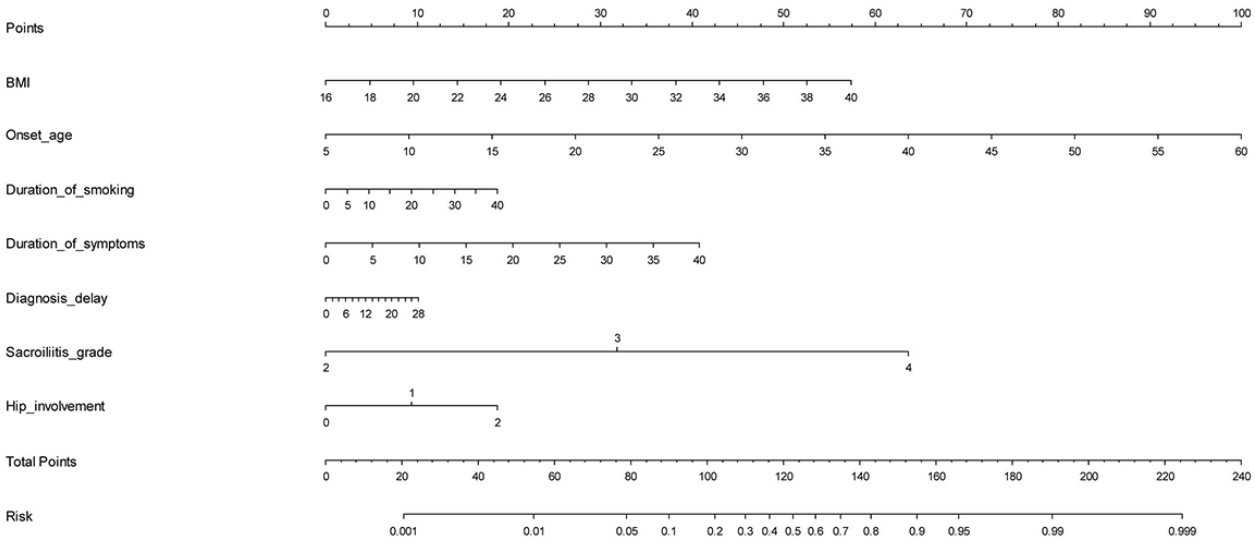
Sacroiliitis grade	5.01	3.27	7.67	<0.001	5.92	3.67	9.55	<0.001

Abbreviations: BMI, body mass index; OR, odds ratio; 95% CI, 95% confidence interval. *The *p* was adjusted for age, gender and human leukocyte antigen B27.

of symptoms, diagnosis delay, hip involvement and sacroiliitis grade were significantly associated with the risk of having high mSASSS, and all remained significant after adjusting for age, gender and HLA-B27 (all p< 0.05) (Table 2). In further analyses, hip involvement was found to be in significant interaction with BMI and duration of smoking in a graded manner. For instance, relative to patients with low BMI and negative hip involvement, those with high BMI and negative hip involvement, low BMI and positive hip involvement, and high BMI and positive hip involvement had a 1.94-, 3.29- and 5.07-fold increased risk of having high mSASSS (95% confidence interval: 0.84-4.47, 1.37-7.89, and 1.97-13.06, p=0.118, 0.008 and 0.001), respectively. To facilitate clinical assessment, a nomogram graph (Figure 1) based on 7 significant risk factors was generated with decent prediction accuracy (C-index: 0.906 and p< 0.001), and importantly besides sacroiliitis grade, onset age and BMI carried a greater weight than other risk factors.

Figure 1. Nomogram graph for the risk prediction of spinal structural damage using significant risk factors. Abbreciations: BMI, body mass index.



Conclusion: We have identified seven potential risk factors responsible for the severity of spinal structural damage in Chinese AS patients. Importantly, positive hip involvement, in combination with high BMI or long duration of smoking, was associated with a remarkably increased risk of having severe structural damage in spine. Hip involvement was prevalent in our cohort and use of CT may have increased identification of hip findings compared to past studies in which X-rays were reviewed.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: An important mechanism regarding axial spondyloarthritis (axSpA) susceptibility and progression is the biomechanical concept, suspected from axial myofascial hypertonicity and stiffness in ankylosing spondylitis (AS). This pathway may promote local tissue microtrauma and contribute to immunological activation and subsequent bony fusion or ankylosis. The MyoSpA study tests the novel hypothesis of increased resting lumbar and appendicular (upper and lower limbs) myofascial tone/stiffness in axSpA patients compared to healthy controls (HC).

Methods: A cross-sectional study was conducted on 54 participants (18-50 years), 27 axSpA (according to ASAS criteria, with less than 10 years since symptoms onset) and 27 HC, matched by gender and age.

Muscle physical properties (stiffness, tone and elasticity) was quantified using the MyotonPro device. This myotonometer is a non-invasive device which applies a slight mechanical impulse to the skin via a probe, which is transmitted to the underlying soft tissue and muscle, and resultant oscillations are electronically recorded. Measurements were performed by a single tester, in three different body locations: lower lumbar (erector spinae myofascia at the L3-4 level), upper limbs (extensor digitorium, 5 cm below the elbow) and lower limbs (gastrocnemius 10 cm below

Table: Median (25th-75th percentile) stiffness (Nm) in combined male and female axSpA and control subjects

Upper Limb			
Average	288.0(266.0–320.0)	293.0(265.0–307.5)	0.598
Dominant	282.0(266.0–334.0)	293.0(254.8–311.8)	0.803
Non-Dominant	283.0(267.0–313.0)	290.0(266.0–313.0)	0.957
Lower Limb			
Average	293.5(277.0–329.5)	289.0(265.0–325.0)	0.749
Dominant	299.0(257.0–349.0)	298.0(271.0–325.0)	0.908
Non-Dominant	295.0(269.0–321.0)	290.0(263.5–314.3)	0.810

knee), on both sides, after 10-minutes prone rest interval. Body composition was measured by octapolar multifrequency bioelectrical impedance analysis (InBody770). Physical activity was assessed by the International Physical Activity Questionnaire (IPAQ). Variables (except age, disease duration, BASDAI, BASFI) are presented as median (inter-quartile range). Non-parametric tests were used to compare groups.

Results: Mean (SD) age of the 27 axSpA patients was 36.8±7.4 years and the 27 HC was 36.3±7.8 (p=0.79), each having 18 males, 9 females. No significant difference occurred between groups in body mass index and physical activity. AxSpA patients had mean (SD) symptoms duration of 6.5±3.2 years, with BASDAI of 2.7±2.3 and BASFI of 0.9±3.1.

AxSpA and HC subjects showed no significant difference in muscle stiffness, tone and elasticity in the lumbar, upper and lower limbs, when the averaged values of combined male and female, right and left measurements were analyzed. AxSpA patients had slightly greater lumbar muscle stiffness [246.5 (230.5–286.5] than HC [232.5 (211.0–293.5], p=0.380. The difference was slightly greater on the dominant side [261.0 (232.0–312.0) vs 241.0 (204.3–303.0), p=0.28]. Gender had no influence on the results.

Conclusion: Young axSpA patients with mainly controlled disease, minor functional repercussion and short disease duration did not show a difference in muscle physical properties compared to HC. Further studies are needed to support the hypothesized biomechanical concept of increased resting lumbar myofascial stiffness in active axSpA patients.

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Disease flares in axial spondyloarthritis (axSpA) might occur even in patients with otherwise stable disease receiving effective anti-inflammatory therapy such as TNF inhibitors. The frequency of disease flares, especially in patients with axSpA receiving long-term stable therapy, and factors associated with flares are not sufficiently investigated. The ASAS group recently developed the first data driven definition of a clinically important worsening (flare) in axSpA based on the ASDAS [1]. Objective of the presented analysis was to assess the frequency of disease flares and to identify factors associated with flares in axSpA patients receiving continuous longterm treatment with a TNF Inhibitor.

Methods: In ESTHER, patients with early axSpA (symptom duration ≤5 years) were treated with ETN (n=40) versus sulfasalazine (n=36) for 48 weeks [2]. After one year all patients were treated continuously with etanercept (n=17 patients temporarily interrupted treatment in the 2nd year to assess time to flare and were then (re-)treated with etanercept, except 4 patients who completed the study in sustained remission) for up to 10 years in total. Only patients who were continuously treated with etanercept for at least 6 months were included in the current analysis. The disease flare was defined as a worsening of the ASDAS by ≥0.9 as compared to the value obtained at the previous visit. Univariate and multivariable cox-regression analyses were performed to analyze the predictors of flares.

Results: Out of 76 patients who entered the study at baseline, 62 patients (n=32 with radiographic (r-) axSpA and n=30 with non-radiographic (nr-) axSpA) fulfilled the criterion of the continuous etanercept treatment. A total of 22 patients (35%) experienced at least one flare over the entire treatment period 10 patients (31.3%) in the r-axSpA and 12 patients (40%) in the nr-axSpA subgroup) - figure. A total of 81 flares occurred (33 and 48 in the r- and nr-axSpA subgroups, respectively) in the 10 years of follow-up. None of the documented disease flares resulted in a direct study withdrawal. The majority of flares occurred within first 4 years of treatment (figure). There were also no statistically significant differences between nr- and r-axSpA in the time until the first flare (p=0.4, Log-rank test). In the multivariable Cox regression analysis, an elevated CRP value (>5mg/l) at baseline, HLA-B27 negativity, a longer symptom duration at study entry, a lower spinal osteitis score and a higher spinal fatty lesion score on MRI at baseline were associated with a higher risk for flares (Table).

Figure. Kaplan-Meier curves indicating time to the first flare and flare free survival propability in patients with early axial spondyloarthritis on stable etanercept treatment

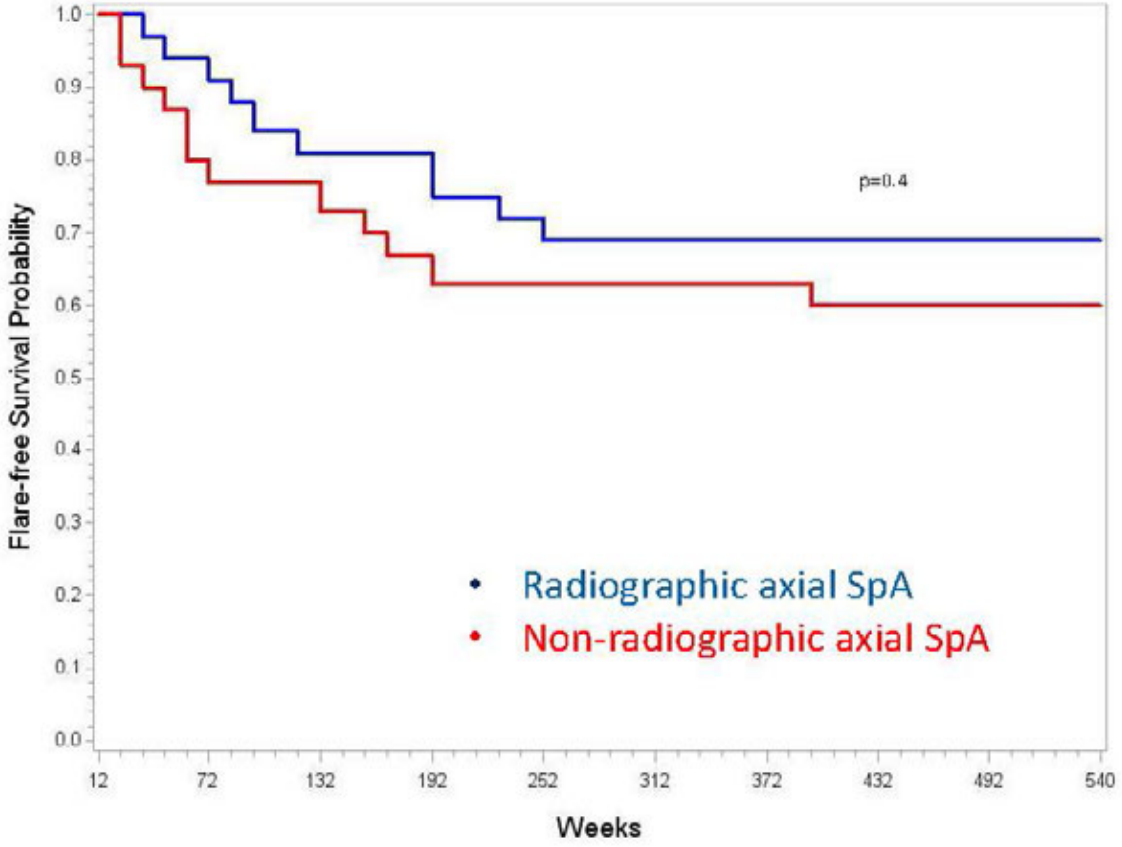

Table: Multivariable Cox-regression analysis of factors associated with flares in early axial spondyloarthritis patients on stable anti-TNF treatment with etanercept.

	Hazard Ratio 95% CI
HLA-B27 negativity	**1.359 (1.08, 1.71)**
CRP positivity (>5mg/l) at baseline	**1.42 (1.01, 2.0)**
Symptom duration at baseline	**1.052 (1.01, 1.1)**
MRI spinal osteitis score at baseline	**0.973 (0.95, 1)**
MRI spinal fatty lesion score at baseline	**1.072 (1.02, 1.12)**

Conclusion: Disease flares according to the ASAS definition of clinically important worsening in axSpA based on ASDAS occurred in approximately one third of patients with early axSpA who received a treatment with the TNF-inhibitor etanercept for up to 10 years without major differences between r- and nr- forms of axSpA. HLA-B27 negativity, elevated CRP at baseline, longer symptom duration with higher fatty lesion and lower osteitis spinal score were associated with a higher risk of flares.

Development of an Optimized Online Self-Referral Tool for Early Recognition of Patients with Axial Spondyloarthritis - Data from the OptiRef Study

Fabian Proft,[1] Laura Spiller,[2] Mikhail Protopopov,[3] Valeria Rios Rodriguez,[2] Burkhard Muche,[2] Judith Rademacher,[2] Susanne Lüders,[2] Anne Katrin Weber,[2] Imke Redeker,[4] and Denis Poddubnyy[5], [1]Charité Universitätsmedizin Berlin, Germany, Berlin, Germany, [2]Charité Universitätsmedizin, Berlin, Germany, [3]Charité Universitätsmedizin Berlin, Germany, Berlin, Berlin, Germany, [4]Charité – Universitätsmedizin Berlin and German Rheumatism Research Centre, Berlin, Germany, [5]Charité - Universitätsmedizin Berlin and German Rheumatism Research Centre, Berlin, Germany, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: One of the major reasons for a long diagnostic delay in axial spondyloarthritis (axSpA) is the late referral of patients by primary care physicians dealing with patients with chronic back pain. We developed and implemented an online self-referral tool (www.bechterew-check.de), which gave access to a rheumatological consultation if patients declared suffering from chronic back pain (≥ 3 months) with a symptom onset ≤ 45 years of age, and at least one feature indicative of SpA. In the prospective "Identification of the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) Study" we could diagnose axSpA in 19% of the self-referred patients. The objective was to optimize the online-self-referral tool for recognition of patients with high suspicion of axSpA in order to increase the specificity by keeping the high level of sensitivity.

Methods: 181 patients who had fulfilled the online self-referral strategy were included and underwent a standardized rheumatology examination. The final diagnosis of axial SpA / no axial SpA by the rheumatologist served as the gold standard. The performance of all possible combinations of the referral parameters (13 parameters in total including 5 features of inflammatory back pain (IBP) and 8 other SpA features) added to both stem parameters (chronic back pain starting at age of ≤45 years) was tested. In addition, the following pre-specified combinations were evaluated: 1) ≥1 IBP parameter AND ≥1 other SpA parameter, 2) ≥1 IBP parameter OR ≥1 other SpA parameter. For all combinations, a sensitivity, a specificity, positive and negative predictive values (PPV and NPV), as well as a positive and negative

Figure 1: The data-driven optimized self-referral strategy.

1	**Does your back pain last 3 months or longer?**	No □ Yes □
2	**Did your back pain start prior to 45 years of age?**	No □ Yes □
3	**What are the characteristics of your back pain?**	
	• The back pain onset was rather slow and was not related to a trauma	No □ Yes □
	• I suffer from stiffness in my back of 30 minutes or longer upon getting up in the morning	No □ Yes □
	• Movement or exercises (but not rest) improve my back pain	No □ Yes □
	• I wake up sometimes in the night (especially 2nd half) because of back pain	No □ Yes □
	• I have or I had alternating (flipping from side to side) pain in my buttocks	No □ Yes □
4	**Other signs and symptoms which might indicate an inflammatory nature of the back pain:**	
	• I took a nonsteroidal anti-inflammatory drug (such as Diclofenac or Ibuprofen) because of back pain, and pain was completely relieved or was much better after the drug intake	No □ Yes □
	• I have / had joint pain with swelling and/or inflammation in the areas of tendons insertion to the bone (e.g., heels).	No □ Yes □
	• The genetic marker HLA-B27 has been tested in my blood already and the result was „positive"	No □ Yes □
	• I have / had elevated markers of inflammation in the blood (C-reactive protein or erythrocyte sedimentation rate), which are unlikely to be explained by other reasons (such as infections)	No □ Yes □
	• I suffer from psoriasis	No □ Yes □
	• I suffer from inflammatory bowel disease (Crohn's disease or ulcerative colitis)	No □ Yes □
	• I suffer / suffered from (iritis)	No □ Yes □
	• One or several of my direct relatives suffer / suffered from ankylosing spondylitis, psoriasis or inflammatory bowel disease (Crohn's disease or ulcerative colitis)	No □ Yes □
	*The strategy is fulfilled if **1** + **2** + ≥ 2 questions in the **3** + ≥ 1 question in the **4** are answered with yes.*	

Table 1: Performance of self-referral strategies based on combinations of SpA parameters in addition to the stem parameters (chronic back pain starting at age of ≤45 years).

10	*7*	*0.43 (3/7)*	*0.82 (128/156)*	*0.10 (3/31)*	*0.97 (128/132)*	*3.19*	*0.93*
11	*1*	*1.00 (1/1)*	*0.81 (132/162)*	*0.03 (1/31)*	*1.00 (132/132)*	*-*	*0.97*
12	*1*	*1.00 (1/1)*	*0.81 (132/162)*	*0.03 (1/31)*	*1.00 (132/132)*	*-*	*0.97*
13	*1*	*1.00 (1/1)*	*0.81 (132/162)*	*0.03 (1/31)*	*1.00 (132/132)*	*-*	*0.97*

**Criteria: insidious onset; improving with exercise, no improvement with rest; waking up in the second half of the night; morning stiffness ≥ 30 minutes; alternating buttock pain; good response to NSAIDs; arthritis/enthesitis ever; HLA-B27 positive; uveitis; psoriasis; inflammatory bowel disease; SpA family history; elevated acute phase reactants.*

***The original strategy, reference for the calculation of the performance of all other strategies*

likelihood ratio (LR+ and LR-) were calculated. We targeted the maximal specificity by acceptable sensitivity (defined as ≥90% of the original strategy).

Results: For 163 of the included patients, full data of the online questionnaire as well as of rheumatology examination including the final diagnosis was available. 31 (19%) of them were diagnosed with axial SpA. Raising the threshold of the number of positive parameters (table 1) resulted in a quick drop of the sensitivity. According to the pre-defined selection criterion, only a strategy with any four positive parameters would be acceptable. An analysis of

combined strategies (IBP parameters and/or other SpA parameters) resulted into identification of a strategy with an improved performance: a combination of ≥2 IBP parameters with ≥1 other SpA parameters (in addition to both stem parameters) showed a sensitivity of 90% (28/31), a specificity of 27% (35/132), a PPV of 22% (28/125), a NPV of 92% (35/38), LR+ of 1.23 and LR- of 0.36. Thus, identifying 28 of 31 patients with axSpA would have been possible after the assessment of 125 patients instead of 163.

Conclusion: The data-driven optimized online self-referral tool (figure 1) requires the following parameters to be positive: chronic back pain (≥3 months) plus back pain onset before 45 years of age plus ≥2 IBP parameters plus ≥1 other SpA feature. The performance of this tool should be confirmed in a prospective study.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is a chronic inflammatory rheumatic disease that primarily affects the axial skeleton and frequently affects the peripheral joints and entheses. AxSpA encompasses ankylosing spondylitis and nonradiographic axSpA. Sex differences have been described for patient reported outcomes (PROs) in SpA; however, more research is needed to better understand the overall clinical burden of axSpA in women, particularly in the United States. We aim to compare the patient demographics, clinical characteristics, treatment profiles, disease activity, quality of life, and work productivity between men and women with axSpA in the US-based Corrona PsA/SpA Registry.

Methods: This study included patients aged ≥ 18 years with axSpA enrolled in the Corrona PsA/SpA Registry between March 2013 and November 2018. Patients who were concurrently diagnosed with PsA were excluded. Patient demographics, clinical characteristics, treatment profiles, disease activity, quality of life, and work productivity were characterized for all patients with axSpA at enrollment and were compared between men and women using *t* tests or Wilcoxon rank-sum tests for continuous variables and χ^2 or Fisher exact tests for categorical variables.

Table 1. Demographic and Clinical Characteristics and Treatment Profiles in Men and Women With AxSpA at Enrollment*

Characteristic	Patients With AxSpA		*P* Value
	Men (N = 307)	Women (N = 191)	
Age, mean (SD), years	47.3 (13.9)	47.7 (13.5)	0.75
Race, n (%)	n = 302	n = 186	0.08
White	276 (91.4)	172 (92.5)

≥ 2	32 (10.4)	24 (12.6)	
Prior csDMARD use, n (%)	41 (13.4)	42 (22.0)	0.01
Prior prednisone use, n (%)	27 (8.8)	30 (15.7)	0.02

AxSpA, axial spondyloarthritis; BMI, body mass index; csDMARD, conventional synthetic disease-modifying antirheumatic drug.
* All values were calculated based on available data, and all variables had < 20% missing data.

Results: Of 498 patients with axSpA who were included in the study, 307 (61.6%) were male and 191 (38.4%) were female. Compared with men, women were less likely to work full time, were more likely to be normal weight/underweight, had a shorter disease duration, and were more likely to have depression, fibromyalgia, and prior csDMARD and prednisone use (**Table 1**; all $P < 0.05$). At enrollment, women with axSpA had a shorter occiput-to-wall distance, but also had worse disease activity compared with men, as reflected by higher BASDAI and BASFI scores, higher enthesitis and tender/swollen joint counts, worse pain and fatigue, worse physical function (HAQ-S) and health state today (EQ VAS), and more severe work and activity impairment (**Table 2**; all $P < 0.05$).

Conclusion: In this US registry of patients with axSpA, women had an increased overall burden of disease compared with men, including higher patient reported symptoms, higher disease activity, and greater work productivity impairment. Women also had lower scores for spinal mobility with increased signs of peripheral arthritis (eg, higher tender/swollen joint and enthesitis counts), suggesting that conventional definitions of axSpA centered around axial symptoms may not be representative of the female population with disease. Improved awareness of sex differences in presentation of axSpA may aid physicians in earlier identification and improved management of the disease.

Table 2. Disease Activity, Quality of Life, and Work Productivity in Men and Women With AxSpA at Enrollment*

Characteristic	Patients With AxSpA		*P* Value
	Men (N = 307)	Women (N = 191)	
ASDAS, mean (SD)	2.6 (1.2)	2.8 (0.9)	0.07
BASDAI (0-10), mean (SD)	4.2 (2.5)	4.9 (2.3)	< 0.01
BASFI (0-10), mean (SD)	3.4 (2.8)	4.1 (2.7)	< 0.01
Lateral lumbar flexion (average of left and right), mean (SD), cm	24.1 (20.1)	23.4 (19.0)	0.76
Occiput to wall, mean (SD), cm	5.8 (7.7)	2.7 (5.0)	< 0.01

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Table 1 Classification of patients with axial spondyloarthritis with radiographic sacroiliitis using the modified New York criteria for the classification of AS, and the ASAS criteria for the classification of radiographic axSpA.

Modified New York criteria for the classification of AS	ASAS criteria for the classification of radiographic axSpA
1. Low back pain and stiffness for at least 3 months, which improves with exercise and is not relieved by rest 2. Limitation of lumbar spine motion in the sagittal and frontal planes 3. Decreased chest expansion, compared to age- and sex-matched controls 4a. Unilateral sacroiliitis grade 3 or 4 4b. Bilateral sacroiliitis grade 2 to 4	1. Back pain ≥3 months 2. Age at onset <45 years 3. Definite radiographic sacroiliitis according to mNY criteria 4. ≥1 SpA feature: – Inflammatory back pain – Arthritis – Enthesitis – Uveitis – Dactylitis – Psoriasis – Crohn's/colitis – Good response to NSAIDs – Family history for SpA – HLA-B27 positive – Elevated CRP (or ESR)
Definite AS if sacroiliitis as described in 4a or 4b and any of the clinical symptoms (1-3)	Definite r-axSpA if fulfilment of 1 and 2, sacroiliitis as described in 3 and at least one of the clinical SpA features as described in 4

Background/Purpose: Patients with axial spondyloarthritis (axSpA) with radiographic sacroiliitis may be classified using the modified New York (mNY) criteria as ankylosing spondylitis and using the more recent ASAS criteria as radiographic axSpA (r-axSpA).

In both the mNY and the ASAS r-axSpA classification sets the radiographic criterion is the same but the additionally required features differ (Table 1). The aim of this study was therefore, to investigate if patients who fulfil the mNY criteria also fulfil the ASAS criteria for r-axSpA and vice-versa.

Methods: Patients diagnosed with axSpA who had back pain > 3 months and definite radiographic sacroiliitis according to the mNY radiographic criterion (#4a or 4b in Table 1), were selected from eight cohorts (ASAS, Esperanza, GESPIC, OASIS, Reuma.pt, SCQM, SPACE, and UCSF axSpA cohort). Subsequently we calculated the percentage of patients who fulfil the ASAS r-axSpA criteria within the group of patients fulfilling the mNY criteria. In six cohorts (all except Esperanza and OASIS) we were also able to calculate the percentage of patients fulfilling the mNY criteria within the group fulfilling the ASAS r-axSpA criteria.

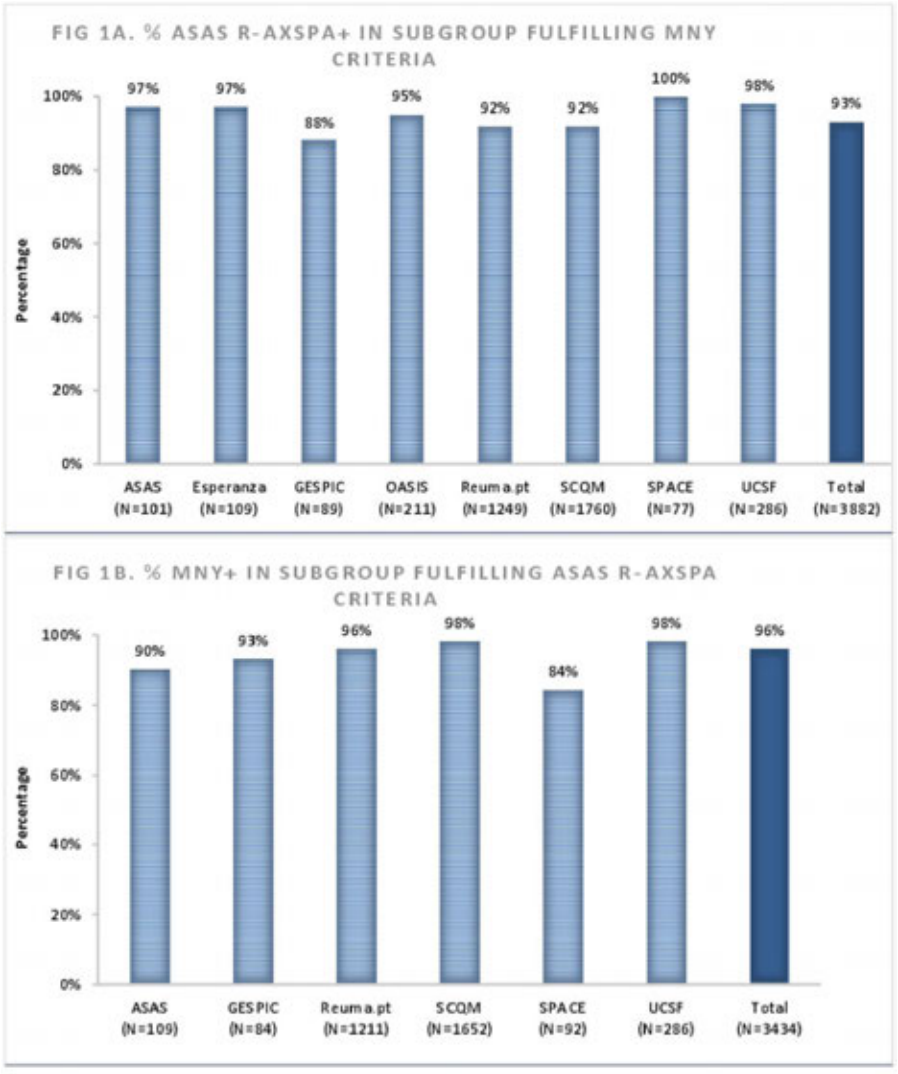

Figure 1: Percentage of patients fulfilling ASAS r-axSpA within subgroup fulfilling mNY criteria (3607/3882 (1a) and percentage of patients fulfilling mNY criteria within subgroup fulfilling ASAS r-axSpA (3300/3434)(1b), per cohort and overall.

Results: Of the 3,882 patients fulfilling the mNY criteria, 93% also fulfilled the ASAS r-axSpA criteria (Figure 1a). Inversely, of the 3,434 patients fulfilling the ASAS r-axSpA criteria, 96% also fulfilled the mNY criteria (Figure 1b). In total, 89% (3607/4041) of patients fulfilled both criteria sets; 7% only the mNY criteria; 3% only the ASAS criteria and 1% neither set.

The main difference between the two criteria sets was caused by reported age at onset of back pain. Out of 275 mNY+ patients not fulfilling the ASAS criteria, 265 (96%) cases were due to the age criterion and 10 (4%) due to the absence of SpA features. The 134 mNY-/ASAS+ patients did not have mobility restriction or IBP but at least one other SpA feature instead.

Conclusion: Agreement between the mNY and ASAS r-axSpA criteria is very high, with mostly the same patients being classified according to both criteria, which supports the interchangeable use of the terms AS and r-axSpA. This has important implications for the axSpA research field, since acknowledging that both criteria sets identify the same patients implies that older literature on AS and newer literature on r-axSpA can be directly compared.

Abstract Number: 0604

Do Illness Perceptions and Coping Change over Time in Patients Recently Diagnosed with Axial Spondyloarthritis? A 2-Year Follow-Up Study in the SPACE Cohort

Miranda van Lunteren,[1] Robert B.M. Landewé,[2] Camilla Fongen,[3] Roberta Ramonda,[4] Désirée van der Heijde,[1] and Floris van Gaalen[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Amsterdam University Medical Center, Amsterdam, Netherlands, [3]Diakonhjemmet Hospital, Oslo, Norway, [4]University of Padova, Padova, Italy

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously shown that in patients with recently diagnosed axial SpA (axSpA), illness perceptions had a negative impact on the relationship between back pain and Health-Related Quality of Life (HRQoL) and work productivity loss (WPL). We investigated if illness perceptions and coping strategies change after axSpA diagnosis.

Methods: Patients recently diagnosed with axSpA and ≥1 follow-up visit (1 year and/or 2 years) in the SPACE-cohort were included in the analysis. Mixed linear models were used to test if illness perceptions (measured by the Revised

Table 1 Overview of illness perceptions and coping strategies measured by the IPQ-R and CORS questionnaires

Label/Dimension	Explanation	Example
Illness perceptions		
Identity	Summed number of experienced symptoms that the patient attributes to his/her illness	Symptoms as *"pain"* or *"fatigue"*
Consequences	Perceived impact of the illness on the patient's life	*"My illness has major consequences on my life"*
Acute/chronic timeline	Perceived likeliness of chronicity of the illness	*"My illness is likely to be permanent/chronic rather than temporary"*
Personal control	Perceived personal control over the illness	*"There is a lot which I can do to control my symptoms"*
Treatment control	Perceived efficacy of treatment	*"My treatment will be effective in curing my illness"*
Illness coherence	Extent to which the patient feels he/she understand the illness	*"My illness is a mystery to me"*
Cyclical timeline	Patient's perceptions of variability of the illness	*"My symptoms come and go in cycles"*
Emotional representation	Experienced negative emotions due to the illness	*"When I think about my illness I get upset/angry/afraid"*
Psychological attributions	Believing that psychological attributions are a possible cause for the illness	*"Stress/worry or my mental attitude e.g. thinking about life negatively "*
Risk factors	Believing that risk factors are a possible cause for the illness	*"Hereditary – it runs in my family"*
Immunity	Believing that immunity is a possible cause for the illness	*"A germ or virus"*
Accident	Believing that accident is a possible cause for the illness	*"Accident or injury"*
Chance	Believing that chance is a possible cause for the illness	*"Chance or bad luck"*
Coping		
Comforting cognitions	Coping with pain by putting pain in perspective	*"I think the pain will decrease in time"*
Decreasing activities	Coping with pain by decreasing activities	*"I stop my activities"*
Diverting attention	Coping with pain by thinking about/focusing on something else	*"I think of pleasant things"*
Optimism	Coping with limitations by being optimistic	*"I try to be optimistic"*
Pacing	Coping with limitations by adapting/lowering the level of activity	*"I take more time for my activities"*
Creative solution seeking	Coping with limitations by searching for creative solutions to cope with limitations in daily life	*"I try to find new ways of getting things done"*
Accepting	Coping with dependence by making efforts to accept the level of dependence	*"I accept my dependence on other people"*
Showing consideration	Coping with dependence by considering other people's feelings	*"I try not to ask too much from any one person"*

CORS, Coping with Rheumatic Stressors; IPQ-R, Revised Illness Perception Questionnaire.

Table 2 Illness perceptions over time in axSpA patients with baseline and/or 1- or 2-years data in the SPACE cohort (n=150)

Dimension	Range	Baseline	Year 1	Year 2	Change per year (B (95%CI))
Identity	0-15				
Age <29 years		4.6 (2.3)	4.6 (2.5)	4.1 (2.0)	-0.3 (-0.5; 0.02)
Age ≥29 years		4.9 (2.6)	5.3 (2.8)	5.1 (2.7)	0.09 (-0.2; 0.4)
Consequences	1-5	2.9 (0.7)	2.8 (0.8)	2.8 (0.9)	-0.09 (-0.2; -0.03)
Timeline (acute/chronic)	1-5				
Age <29 years		3.7 (0.8)	3.7 (0.8)	3.7 (0.8)	0.05 (-0.06; 0.2)
Age ≥29 years		3.6 (0.8)	3.8 (0.8)	4.0 (0.7)	**0.2 (0.08; 0.3)**
Personal control	1-5	3.3 (0.6)	3.3 (0.6)	3.4 (0.6)	0.06 (0.008; 0.1)
Treatment control	1-5	3.5 (0.5)	3.4 (0.6)	3.5 (0.6)	0.01 (-0.04; 0.07)
Illness coherence	1-5	3.3 (0.8)	3.5 (0.8)	3.6 (0.7)	**0.2 (0.1; 0.2)**
Timeline (cyclical)	1-5	3.6 (0.8)	3.6 (0.8)	3.6 (0.8)	-0.04 (-0.1; 0.04)
Emotional representation	1-5	2.7 (0.8)	2.6 (0.8)	2.5 (0.8)	**-0.1 (-0.2; -0.08)**
Possible causes for illness					
Psychological attributions	1-5	2.1 (0.9)	2.1 (0.9)	2.1 (0.9)	-0.005 (-0.06; 0.05)
Risk factors	1-5	2.2 (0.6)	2.2 (0.6)	2.1 (0.6)	-0.01 (-0.06; 0.03)
Immunity	1-5	2.3 (0.8)	2.4 (0.9)	2.3 (0.9)	-0.03 (-0.1; 0.04)
Accident	1-5				
Male		2.3 (1.2)	2.1 (1.1)	2.0 (1.1)	-0.2 (-0.3; -0.04)
Female		1.8 (1.0)	2.1 (1.2)	1.9 (1.1)	0.07 (-0.07; 0.2)
Chance	1-5	3.3 (1.2)	3.2 (1.2)	3.3 (1.2)	-0.02 (-0.1; 0.08)

Results are presented as mean (SD) unless stated otherwise. Changes in illness perceptions were considered to be statistically significant and printed in bold when p<0.002 (p<0.05/21 (illness perceptions and coping strategies combined), correction for multiple testing).

Illness Perception Questionnaire (IPQ-R), **Table 1**) and coping (Coping with Rheumatic Stressors (CORS), **Table 1**) as well as back pain (scale 0-10), HRQoL (physical (PCS) and mental component summary (MCS), scale 0-100, 36-item Short-Form Health Survey (SF-36)), WPL and activity impairment (Work Productivity and Activity Impairment (WPAI, range 0-100%)), changed over time. Results were stratified for gender and age when the interaction term was statistically significant (p< 0.10).

Results: In total, 150 axSpA patients (mean age 30.4 years, 51% female, 65% HLA-B27+) were analysed. At baseline mean back pain (SD) was 4.0 (2.5), PCS was 28.8 (14.0), MCS was 46.6 (13.6), WPL was 34.1% (29.8) and activity

Table 3 Coping strategies over time in axSpA patients with baseline and/or 1- or 2-years data in the SPACE cohort (n=150)

	Range	Baseline	Year 1	Year 2	Change per year (B (95%CI))
Coping with pain					
Comforting cognitions	1-4	2.8 (0.6)	2.9 (0.6)	2.8 (0.6)	0.01 (-0.04; 0.06)
Decreasing activities	1-4	2.1 (0.6)	2.1 (0.6)	2.0 (0.6)	-0.05 (-0.1; -0.008)
Diverting attention	1-4	2.3 (0.6)	2.4 (0.6)	2.4 (0.6)	0.03 (-0.02; 0.07)
Coping with limitations					
Optimism	1-4	2.8 (0.7)	2.9 (0.7)	2.9 (0.7)	0.08 (0.02; 0.1)
Pacing	1-4				
Male		2.1 (0.6)	2.1 (0.6)	2.0 (0.6)	-0.05 (-0.1; 0.006)
Female		2.2 (0.6)	2.3 (0.6)	2.4 (0.6)	0.08 (0.007; 0.2)
Creative solution seeking	1-4				
Male		2.3 (0.6)	2.4 (0.6)	2.3 (0.07)	0.01 (-0.05; 0.07)
Female		2.3 (0.6)	2.4 (0.6)	2.6 (0.06)	**0.1 (0.07; 0.2)**
Coping with dependency					
Accepting	1-4	1.8 (0.6)	1.8 (0.6)	1.7 (0.6)	-0.03 (-0.09; 0.02)
Consideration	1-4	2.7 (0.6)	2.7 (0.6)	2.7 (0.6)	0.004 (-0.05; 0.06)

Results are presented as mean (SD) unless stated otherwise. Changes in coping strategies were considered to be statistically significant and printed in bold when p<0.002 (p<0.05/21 (illness perceptions and coping strategies combined), correction for multiple testing).

impairment was 38.7% (27.9). Over two years, the percentage patients with ASDAS inactive or low disease activity increased from 39% to 68%, back pain (mean change ± SD is -1.5 ± 2.2) and activity impairment (-14.4% ± 27.2) decreased, PCS (11.1 ± 13.3) and WPL (-15.3% ± 28.7) improved statistically significantly (all $p< 0.05$), but MCS did not change (0.7 ± 13.9, $p=0.201$).

Illness perceptions and coping strategies showed little and no clinically meaningful change over time (**Table 2, 3**). Over two years patients remained having negative illness perceptions (which were important in the association between back pain and health outcomes in the previous study). For example, at two years patients strongly believed that their illness had severe consequences ('*consequences*'), they had negative emotions such as feeling upset or having fear towards their illness ('*emotional representation*'), and had strong beliefs in chance or bad luck ('*chance*') being the cause for axSpA.

Patients most often coped with pain by putting pain in perspective ('*comforting cognitions*'), most often coped with limitations by trying to be optimistic ('*optimism*'), and most often coped with dependence of other people by considering feelings of these people ('*consideration*').

Conclusion: Whilst back pain, disease activity, and health outcomes clearly improved over 2 years, illness perceptions about their illness and coping strategies to live with their illness remained remarkably stable in patients recently diagnosed with axSpA.

Macrophage Migration Inhibitory Factor Is a Critical Regulator in a Mouse Model of Spondyloarthritis

Akihiro Nakamura,[1] Fanxing Zeng,[1] Sayaka Nakamura,[1] Richard Bucala,[2] and Nigil Haroon[3], [1]University Health Network, Toronto, Canada, [2]Yale University School of Medicine, New Haven, CT, [3]Toronto Western Hospital, Krembil Research Institute, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (SpA) is a chronic rheumatic disease characterized by severe inflammation in the spine, peripheral joints, intestine, skin and eyes. Although current treatment modalities including tumor-necrosis-factor (TNF) and interleukin (IL)-17 blockers could control inflammation, up to 40% of SpA patients don't adequately response to any medications or lose their efficacies, resulting in severe pain, increased cardiovascular risk and deteriorating mental health. Macrophage migration inhibitory factor (MIF) is a pleiotropic cytokine that exhibits pro-inflammatory effects. MIF has functions in the regulation of immune responses and has been implicated in various inflammatory conditions. We recently discovered that serum levels of MIF were significantly elevated in Ankylosing Spondylitis (AS) patients compared to healthy controls. However, the specific role of MIF in SpA is largely unknown.

Methods: Curdlan (β-glucan) or MIF-plasmid (mini-circle) treated SKG mice (8-10 weeks) were used as SpA mouse models. The expression of MIF in serum or tissues was measured by ELISA, quantitative PCR (qPCR), western blotting, immunohistochemistry (IHC) and/or immunofluorescence (IF). MIF knockout (KO) SKG mice were generated as MIF deficiency mice. MIF inhibitor (MIF098) was used to block the function of MIF in SpA mouse models to assess the therapeutic or prophylactic effects in a curdlan-treated SpA mouse model. Populations of immunological cells were assessed by flow cytometry. Anti-Gr-1 monoclonal antibody (mAb) or isotype control mAb was used to block the function of polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs) or monocytic MDSCs (mMDSCs). Clinical scores, histopathology and microCT imaging were used to assess the severity of inflammation in the various tissues of the mouse models.

Results: The expression of MIF and its receptor CD74 were significantly up-regulated in serum, spleen, ileum, sacroiliac and ankle joints of curdlan-treated SKG mice. MIF-overexpressed SKG mice injected with MIF-plasmid remarkably induced major SpA clinical features including colitis, psoriasis and arthritis in the axial and peripheral joints, while MIFKO SKG mice or blocking the function of MIF with MIF inhibitor (MIF098) dramatically suppressed or attenuated these manifestations, with decreased populations of Th17 and increased regulatory T (Treg) cells. We have also identified the cell populations (PMN-MDSCs and mMDSCs) substantially producing MIF in the disease condition. Interestingly, adopted transfer of these cells into non-disease control mice clearly exhibits SpA phenotype including arthritis, blepharitis and psoriasis. Furthermore, blocking the function of those cells with anti-Gr-1 antibody suppresses the SpA phenotype.

Conclusion: These results indicate that MIF is a crucial regulator of inflammation and may be a promising therapeutic target in SpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Contradictory data has been reported on the effectiveness of a second and third line of TNFi in early axial spondyloarthritis (axSpA). The objective of the study was to evaluate the effectiveness of TNFi after a first switch, in real life conditions, over 5 years of follow-up in this population.

Methods: Observational prospective French cohort (DESIR) with 5 years of follow-up, including 708 TNFi-naïve early axSpA patients. Study visits were scheduled every 6 months in the first two years and then yearly up to 5 years. Treatment (TNFi or other) was at the discretion of the treating rheumatologist's. The characteristics of patients who received a second and a third TNFi were compared to those who never switched. Effectiveness of the first, second and third TNFi was firstly defined by their drug survival, estimated by the Kaplan-Meier method, and compared with the log-rank test. Secondly, we evaluated treatment effect of the second TNFi by the probability to reach an ASAS40 response in both groups (second TNFi vs. responders to the first TNFi), after at least 10months of exposure. To overcome prescriptions bias repeatedly occurring over time, we have applied an iterative method based on inverse propensity score (PS) weighting using a marginal structural model, that allows the integration of the repeated weights derived from the propensity score at each visit (i.e the probability to receive the treatment at each visit). The structural model used for this analysis was a PS-weighted cox regression, to estimate the probability to present an ASAS40 response after at least 10months of treatment.

Results: of the 708 patients included in the analysis, 258 (36.4%) patients initiated a first TNFi during the 5y of follow-up. Of these, 127/258 (49.2%) switched to a second TNFi, and among them, 59/127 (46.5%) switched to a third TNFi. Patients who switched to a second or a third TNFi were more frequently older, predominantly females, HLA-B27 negative, with MRI and radiographic sacroiliitis negative, without history of peripheral arthritis, and with higher BASFI and BASDAI scores at baseline of the DESIR cohort (see table). Estimated median drug survival for the first, second

Baseline characteristics	Patients remaining in their first TNFi	Patients switching to a 2nd TNFi	Patients switching to a 3rd TNFi
	N=88	N=127	N=59
Age (years)	33.6(9.4)	35.3(8.7)	35.4(8.5)
Sex (male)	52(59.1)	40(31.5)	17(28.8)
HLA-B27 positive	57(64.8)	62(48.8)	26(44.1)
MRI sacroiliitis positive	46/85(55.1)	39/125(31.2)	16/57(28.1)
Radiographic sacroiliitis positive	27/85(31.8)	17(13.4)	9(15.3)
History of arthritis	31(35.2)	37/125(29.6)	17/58(29.3)
BASDAI (range 0-10)	4.5(1.8)	5.9(1.5)	6.0(1.4)
BASFI (range 0-10)	3.1(2.1)	4.6(2.1)	4.8(2.1)

and third TNFi was 21.7months [95%CI 17.6-33.6], 18.8months [95%CI 15.1-24.4] and 25.0months [95%CI 11.8-NA] respectively. Drug survival was significantly extended for the first TNFi compared to the second one (p=0.004), but no differences were observed between the 2nd and the 3rd TNFi. Identically, when taking into account the time-varying propension to perform a switch, likelihood of an ASAS40 response was lower for the second TNFi than for the first one (HR=2.4[95%CI 1.9-3.0] vs HR=3.3[95%CI 2.9-3.8] respectively), but remained clinically significant.

Conclusion: Our study suggests a lower but clinically significant TNFi effectiveness after a first switch in real-life conditions in early axial spondyloarthritis.

Expansion of Peripheral Cytotoxic T Cells in Co-morbid Inflammatory Bowel Disease and Spondyloarthritis

Adam Lefferts,[1] Emilie Regner,[2] Andrew Stahly,[3] Rebecca O'Rourke,[1] Kenneth Jones,[2] and Kristine Kuhn[1], [1]University of Colorado, Anschutz Medical Campus, Aurora, CO, [2]University of Colorado, Anschutz Medical Campus, Denver, CO, [3]University of Colorado, Aurora, CO

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The clinical overlap of axial spondyloarthritis (axSpA) and Crohn's disease (CD) has given rise to the hypothesis that these conditions may share pathophysiologic mechanisms. However, the relationship between each of these diseases and the "overlapping" condition of co-morbid CD and axSpA (OVR) remains unknown. Here, we sought to address this question by an initial unbiased immune profiling in the peripheral blood of individuals with axSpA, CD, and OVR relative to healthy controls (HC) using single-cell RNA sequencing followed by validation of potential cellular populations with flow cytometry.

Methods: Peripheral blood was collected from 71 subjects (18 HC, 26 CD, 17 axSpA, and 10 OVR) and peripheral blood mononuclear cells (PBMCs) isolated. Viable CD45+ PBMCs from two representative male patients in each group were isolated by flow sorting and underwent high-depth single-cell RNA sequencing (10X Genomics). Significance with respect to change in transcript abundance was set at $P < 10^{-6}$. Validation of findings was then performed by flow cytometry using PBMCs from the full cohort of 71 subjects. Flow data was analyzed in FloJo and GraphPad Prism, and significance was determined by Mann-Whitney-U test at $P < 0.05$.

Results: Single cell RNA sequencing demonstrated an expansion of CD27+ Granzyme B+ memory (CD45RA-) T cells in our patients with axSpA and OVR. However, in CD, we observed an expansion of a similar memory T cell population expressing the innate-like T cell transcription factor PLZF, which we hypothesized to be gd T cells. B cell and monocyte populations in all disease groups had increased expression of genes within antigen presentation, inflammasome, and apoptotic pathways. Together, our sequencing data suggested upregulated cytolytic activity in

the peripheral blood of individuals with axSpA, CD, and OVR patients. In order to validate these findings in our larger cohort, we utilized flow cytometry to interrogate the cytotoxic T cell population. We observed an increase in gd T cells in CD relative to HCs ($P < 0.005$). In OVR, we saw a significantly decreased naïve T cell compartment ($P< 0.005$) compared to HC, CD, and axSpA, with a corresponding increase in effector memory (CCR7- CD45RA-) T cells ($P < 0.005$). The proportion of CD4 T cells bearing markers of cytotoxicity (Granzyme B+, NKG2a+) was significantly ($P< 0.05$) increased in OVR compared to HC, CD, and axSpA. The overall proportion of cytotoxic CD4s as fraction of total PBMCs in OVR was 1.3%, more than triple that found in the other groups ($P< 0.05$).

Conclusion: Altogether, our data suggest that the immunologic profile of individuals with OVR are distinct from both CD and axSpA. Specifically, we demonstrate an expansion of cytotoxic T cells in OVR relative to HC, CD, and axSpA, and the absence of the gd T cell expansion seen in CD. Given the association between cytotoxic CD4+ T cells and Th1 responses, these data may indicate a shift away from the Th17 dominant disease process found in axSpA. Future directions will validate these findings in an independent cohort of subjects as well as focus on elucidating the functional relevance of cytotoxic CD4 T cells in the pathophysiology of overlapping CD-axSpA.

Abstract Number: 0608

Prevalence of Radiographic Entheseal Lesions at the Hip and Pelvic Region in Patients with Ankylosing Spondylitis versus Controls

Freke Wink,[1] Thomas Diemel,[2] Suzanne Arends,[2] and Anneke Spoorenberg[2], [1]Medical Center Leeuwarden, Leeuwarden, Netherlands, [2]University Medical Center Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is one of the features of ankylosing spondylitis (AS). High prevalence of structural and inflammatory ultrasound lesions of peripheral entheses are found in AS patients. Furthermore, plain radiographs provide good imaging of peripheral enthesopathy at well-defined skeletal sites[1]. There are several entheseal sites at the pelvis and hip region, but little is known about the presence of structural entheseal anomalies at these sites in AS. Our aim was to investigate the prevalence of radiographic entheseal lesions at the hip and pelvic region in patients with AS compared to control subjects.

Methods: The present analysis was performed in 214 patients from the Groningen Leeuwarden Axial SpA (GLAS) cohort study and 100 control subjects. The AS patients were included between November 2004 and December 2010 and had available anteroposterior (AP) pelvis radiographs at baseline. All patients fulfilled the modified New York criteria for AS. AP pelvis radiographs from control subjects matched for age and gender were obtained from the radiology department of the University Medical Center Groningen (UMCG).

Radiographs with blinded sacroiliac joints were randomized and scored by two trained readers. Anomalies with absolute agreement were reported. The entheseal sites scored were: trochanter major, trochanter minor, os ischium, crista iliaca, both left and right side and symphysis pubis. The following 3 anomalies were scored: cortical irregularities/erosions, calcifications and enthesophytes.

Results: Of the 214 AS patients, 148 (69%) were male, mean age was 42.5 ± 11.6 years, 171 (80%) were HLA-B27 positive and median symptom duration was 16 years (IQR 8-24). Patients had active disease with BASDAI 5.6 ± 1.9 and ASDAScrp 3.5 ± 0.9. Reader agreement on the entheseal lesions was overall moderate with Cohen's kappa between 0.42 and 0.78.

Radiographic entheseal lesions at the hip and pelvic region were found in 160 (75%) patients and 58 (58%) controls. In total, 602 lesions were found of which 478 (80%) were present in AS patients. For both groups, the most prevalent lesion was irregularity/erosion (n=333 in 150 (70%) AS patients and n=85 in 50 (50%) controls), followed by enthesophytes (n=129 in 64 (30%) AS patients and n=37 in 21 (21%) controls). In both AS patients and controls, most lesions were found at the os ischii (n=275 in 138 (65%) AS patients and n=97 in 53 (53%) controls).

Conclusion: Radiographic entheseal lesions at the hip and pelvic region are more prevalent in AS patients compared to controls. Irregularities and erosions were most frequently found in both groups, especially at the os ischium. These new findings concerning structural entheseal lesions at the pelvis and hip region contributes to the knowledge of entheseal involvement in AS.

Baseline Characteristics and Natural History of Radiographic versus Non-radiographic Axial Spondyloarthritis: 5 Years Follow-up of the Desir Cohort

Clementina López-Medina,[1] Anna Moltó,[2] Pascal Claudepierre,[3] and Maxime Dougados[4], [1]Cochin Hospital, Rheumatology Department, Paris, France, [2]Paris Descartes University, Cochin Hospital, Rheumatology department, Paris, France, [3]Rheumatology, CHU Henri Mondor Créteil, Paris, France, [4]Cochin Hospital, Paris, France

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is still a debate concerning the concept of non-radiographic (nr-axSpA) axial Spondyloarthritis (e.g. to consider it as a distinct entity from r-axSpA (Ankylosing Spondylitis) or to consider it as the same disease with different phenotypical presentations). This study aims to compare clinical manifestations and burden of disease between r-axSpA and nr-axSpA over 5 years of follow-up in the DESIR cohort.

Methods: Patients from the DESIR cohort with x-ray sacroiliac joints available at baseline and who did not abandon the study because of different diagnosis than axSpA were included. A unilateral rating of "obvious sacroiliitis" according to the local reader (either a radiologist or a rheumatologist) was considered sufficient to be classified as r-axSpA. The incidence of a new episode of peripheral and extra-rheumatological manifestations between r-axSpA vs. nr-axSpA was assessed using incidence/100 person-years, incidence rate ratio and cox regressions adjusted for sex, age and TNF blockers (TNFb) intake. Mean values of c-reactive protein (CRP), patient reported outcomes (PROs) and days of sick leave over 5 years of follow-up were assessed using mixed models with random effects adjusted for sex, age, TNFb intake and baseline values. Disease-modifying drugs (DMARDs) initiation were also evaluated adjusted for CRP mean levels.

Table 1. Prevalence and incidence of peripheral and extra-rheumatological manifestations. *p-value <0.05 between r-axSpA and nr-axSpA

		Prevalence at baseline		Prevalence after 5 years of follow-up		Incidence/100 person-years		
Handling missing data		Without imputation		LOCF and imputed "0" at baseline		LOCF and excluding patients with positive event at baseline		
		Per group	Whole population	Per group	Whole population	Per group	Whole population	Incidence rate ratio (95%CI)
Peripheral arthritis (ever)	r-axSpA	51/185 (27.6%)	183/664 (27.6%)	66/185 (35.7%)	264/669 (39.5%)	2.40	3.70	0.57 (0.33-0.99)*
	nr-axSpA	132/479 (27.6%)		198/484 (40.9%)		4.22		
Peripheral enthesitis (any)	r-axSpA	88/185 (47.6%)*	379/669 (56.7%)	124/185 (67.9%)*	493/669 (73.7%)	9.60	10.54	0.87 (0.58-1.29)

BASFI	24.55 (22.03)	20.74 (20.28)	20.06 (22.50)	**0.002**	**0.004**	0.087	**0.018**	0.236
ASDAS	2.24 (0.94)	2.16 (0.96)	2.27 (0.93)	0.072	**0.003**	0.081	**0.028**	0.351
CRP	5.63 (10.22)	7.69 (13.38)	4.80 (8.49)	**<0.001**	**0.001**	**<0.001**	**<0.001**	**<0.001**
SF-36 MCS	43.30 (11.29)	44.66 (11.20)	42.76 (11.28)	**0.016**	0.148	0.447	0.269	0.662
SF-36 PCS	42.26 (9.42)	44.10 (8.59)	41.53 (9.63)	**<0.001**	**0.003**	0.109	**0.011**	0.214
Days of sick leave	21.74 (61.11)	14.88 (45.46)	24.32 (65.87)	**0.009**	0.082	0.462	0.072	0.424

Results: In total 669 patients were included, of whom 185 (27.7%) and 484 (72.3%) were classified as r-axSpA and nr-axSpA, respectively. At baseline, r-axSpA patients showed significant higher prevalence of males (59.5% vs. 41.7%), smokers (44.0% vs. 34.2%), lower prevalence of peripheral enthesitis (47.6% vs. 60.1%) and lower mean age (31.3±8.9 vs. 34.5±8.4 years) than nr-axSpA. Table 1 shows baseline and 5 years-follow up prevalence, as well as the incidence of new cases of peripheral and extra-rheumatological manifestations. Only peripheral arthritis showed significant lower incidence among r-axSpA patients (2.40 vs. 4.22 new cases/100 person-years, incidence rate ratio 0.57 (95%CI 0.33-0.99)). However, adjusting for age, sex and TFNb intake, cox regressions did not show significant differences in the development of peripheral and extra-rheumatological manifestations between the two groups. Crude mixed models (Table 2) showed significant higher disease activity (BASDAI), poorer quality of life (SF-36 questionnaire) and higher mean days of sick leave over time among nr-axSpA patients. However, these differences disappeared when adjusting for confounders (see Table 2). r-axSpA group showed significant higher incidence of TNFb

initiation (14.77 vs. 9.26 new first prescriptions/100 person-years) than nr-axSpA group, with a HR of 1.56 (95%CI 1.17-2.06) adjusted for sex, age and CRP mean levels.

Conclusion: r-axSpA and nr-axSpA patients showed minor differences at baseline. However, they seem to behave similarly over time, since the incidence of peripheral and extra-rheumatological manifestations as well as the burden of disease development remained similar when adjusted for confounders. Only peripheral arthritis seemed to be more incident among nr-axSpA group, while TNFb was most frequently used by r-axSpA patients.

Ankylosing Spondylitis-associated Killer Immunoglobin-like Receptors Are Strongly Expressed on γδ T Cells

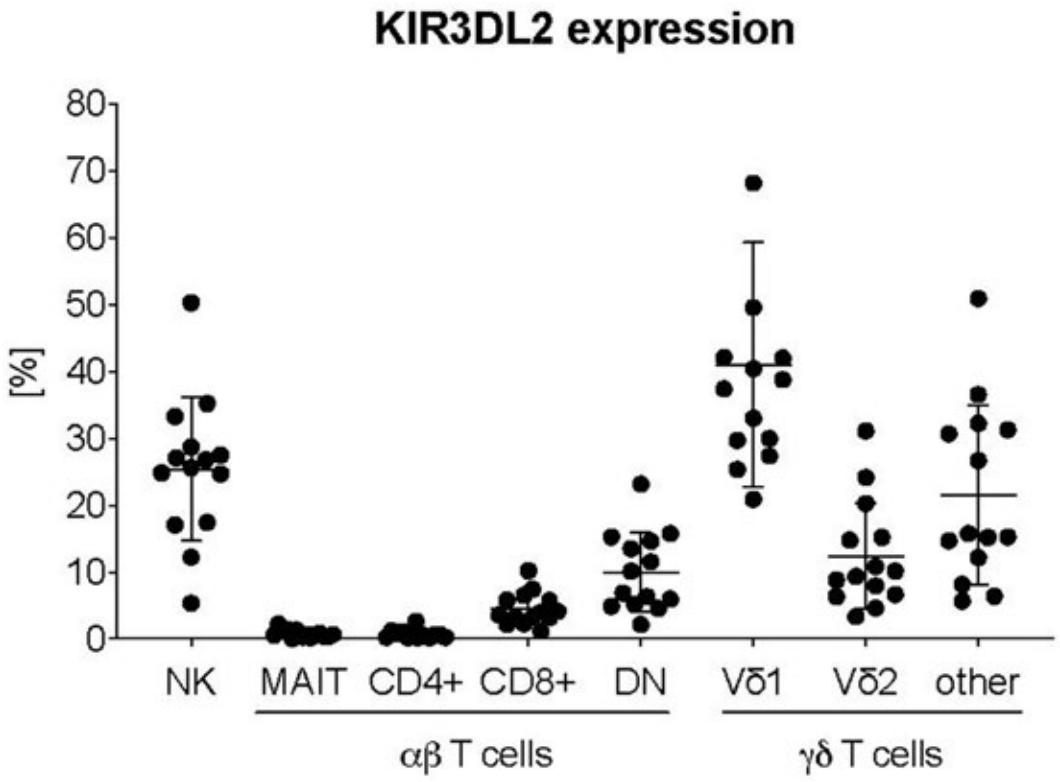
Micah Lefton,[1] Nihaarika Sharma,[1] and Joerg Ermann[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The mechanism underlying the association between ankylosing spondylitis (AS) and HLA-B27 is still unknown. One of the hypotheses involves the interaction of HLA-B27 homodimers with KIR3DL2 receptors on CD4+ T cells. KIR3DL2 is a member of the killer immunoglobin-like receptor (KIR) family of MHC class I ligands that transmit activating or inhibitory signals to KIR expressing lymphocytes. KIR3DL2 binds to HLA-B27 homodimers whereas KIR3DL1 interacts with native HLA-B27 complexes. Previous work has shown an expansion of KIR3DL2 positive IL-17A producing CD4+ T cells in HLA-B27 positive patients with AS. Multiple other IL-17A producing lymphocyte subsets including γδ T cells have been implicated in AS pathogenesis. The purpose of this study was to further characterize the expression of KIR3DL2 and KIR3DL1 on these lymphocyte subsets.

Methods: Human peripheral blood mononuclear cells (PBMC) were prepared by Ficoll density gradient centrifugation from the blood of healthy individuals. To measure cytokine production, PBMC were stimulated with PMA/ionomycin for 4 hours in the presence of brefeldin A/monensin followed by intracellular staining. In other experiments, PBMC were stimulated with phytohemagglutinin (PHA) for up to 3 days in medium supplemented with IL-2 and IL-7. Cells were analyzed using a 19-parameter flow cytometry panel that distinguishes natural killer (NK) cells, mucosal-associated invariant T (MAIT) cells, CD4+ T cells, CD8+ T cells, CD4-CD8- DN αβ T cells and γδ T cells further subdivided into Vδ1+, Vδ2+ and other γδ T cells. MAIT cells were identified using MR1 tetramers. Lineage markers were combined with antibodies specific for relevant KIRs and cytokines. Flow cytometric analysis was performed using a 5-laser BD LSRFortessa cytometer and FlowJo software.

Results: KIR3DL2 and KIR3DL1 were variably expressed by all lymphocyte subsets analyzed. The highest frequencies of KIR expressing cells were observed for NK and γδ T cells, in particular Vδ1 cells. Only a small fraction of CD4+ T cells stained positive for KIR3DL2 in our cohort of healthy individuals. The highest frequency of IL-17A secreting cells was observed amongst MAIT and CD4+ T cells. When stratified based on KIR3DL2 expression, IL-17A expres-



KIR3DL2 Expression on Lymphocyte Subsets in Peripheral Blood of Healthy Individuals

sion was enriched in KIR3DL2+ cells in most subsets, regardless of whether the blood was from HLA-B27+ or HLA-B27- subjects. γδ and other T cells but not NK cells upregulated KIR3DL2 and KIR3DL1 upon stimulation with PHA in vitro.

Conclusion: AS-associated KIRs (KIR3DL2, KIR3DL1) are strongly expressed on γδ T cells in healthy individuals and further upregulated upon stimulation. Our data suggest that studies testing the KIR hypothesis for the HLA-B27 association of AS should consider a wider spectrum of KIR expressing lymphocytes including γδ T cells.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic systemic inflammation in patients with ankylosing spondylitis (AS) contributes to the development of cardiovascular disease (CVD). Early recognition of microvascular changes could improve prevention. The retinal vasculature has been proven to reflect systemic (micro)vascular changes. Narrowing of retinal arterioles, widening of retinal venules and decreased vascular density are associated with coronary artery disease. Furthermore, systemic inflammation was reported to result in wider retinal venules. Remarkably, studies in AS patients are lacking, while the retinal vasculature is easily accessible and could provide an opportunity to recognize preclinical CVD. This study compared the retinal microvasculature of AS patients to healthy controls, and its association with cardiovascular risk.

Methods: Cross-sectional case-control study comparing AS patients with healthy controls from a cohort of the Dutch Twins Register.(1) Inclusion criteria were: age 50-75 years and no history of diabetes mellitus or cerebrovascular disease. AS patients fulfilled the modified New York criteria. Controls with an auto-inflammatory disease were excluded. Consecutive AS patients were recruited from the Rheumatology outpatient clinic of Reade and Amsterdam UMC (VUmc). Controls were selected from the pre-existing EMIF-AD PreClinAD cohort.(1) All subjects underwent Optical Coherence Tomography Angiography (OCTA) and fundus photography, analyzed with Singapore I Vessel Assessment software (Table 1). Data on patient- and disease characteristics, CVD risk factors, medication and lipids were collected. For subjects without a previous CVD, the 10 years cardiovascular comorbidity/mortality risk was calculated (Systematic Coronary Risk Evaluation, SCORE). Data were evaluated with linear regression, correcting for age when comparing patients and controls. The association between the SCORE and ocular parameters was assessed stratified for patients and controls.

Results: In total, 57 AS patients (51% women) and 56 controls (50% women) were included. Both groups differed significantly in mean age (AS: 60±SD6 years; Controls 68±SD4; p< 0.01, Table 2). Fundus photo parameters (Table 1), in particular retinal arteriole and venule diameter, did not differ between patients and controls. However, patients showed significantly lower retinal vessel density (OCTA) compared to controls (age-corrected Beta: -0.53, p=0.046). Only in AS patients, lower retinal vessel density (p=0.02), arteriole fractal dimension; (p=.04) and arteriole diameter (p=.02) were associated with a higher cardiovascular risk (SCORE), but not in controls.

Conclusion: This study did not find differences in arteriolar and venular diameter between AS patients and controls. However, it is the first to report a significantly decreased retinal vessel density in AS patients, which was associated

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In axial spondyloarthritis (axSpA), preservation of physical functioning is an important treatment goal and is usually assessed with the patient-reported BASFI questionnaire. The Ankylosing Spondylitis Physical performance Index (ASPI) test is the first test that assesses physical functioning in axSpA patients with a performance measure (1). However, the ASPI has only been validated in the Netherlands and the interobserver reliability was never evaluated. This study assessed the reliability (interobserver, test-retest) and feasibility of the ASPI test in axSpA patients in Chile.

Methods: The original Dutch ASPI patient instructions were translated into Spanish through a forward-backward procedure by 4 bilingual speakers (2 native Spanish, 2 native Dutch). Radiographic (r-axSpA) and non-radiographic (nr-axSpA) patients, fulfilling the ASAS classification criteria, ≥18 years old, were eligible for study participation. The ASPI consists of 3 tests: 1) 'picking up 6 pencils one by one', 2) 'putting on socks', and 3) 'getting up from the floor'. (1) For each test the performance time was recorded (ASPI; seconds), as well as the patient-reported test-related pain (numeric rating scale, 0-10) and exertion (Borg-scale, 0-10). For test 2 and 3, the mean of three repetitions was calculated. To assess feasibility the total ASPI duration was recorded from the start of instructions until the end of the last test. At baseline, the ASPI was done twice in all patients, by two observers. Test-retest (intra-observer) reliability was done within 1-3 weeks after baseline. In addition, disease characteristics, current treatment, BASDAI, ASDAS, BASFI, CRP, ESR and spinal mobility (BASMI score) were collected. For reliability analyses intra class correlation

Interobserver	61	**0.90**	0.85 – 0.94	**0.84**	0.75 – 0.90	**0.73**	0.64 – 0.82
Test-retest	38	**0.89**	0.75 – 0.94	**0.79**	0.63 – 0.88	**0.61**	0.44 – 0.75
[2] Putting on socks							
Interobserver	60	**0.88**	0.81 – 0.93	**0.91**	0.85 – 0.94	**0.81**	0.75 – 0.87
Test-retest	39	**0.90**	0.68 – 0.96	**0.80**	0.65 – 0.89	**0.63**	0.50 – 0.77
[3] Getting up from the floor							
Interobserver	56	**0.98**	0.96 – 0.99	**0.88**	0.81 – 0.93	**0.75**	0.65 – 0.83
Test-retest	33	**0.96**	0.91 – 0.98	**0.78**	0.61 – 0.89	**0.53**	0.33 – 0.71

Legend: Interobserver- and test-retest agreement of the ASPI performance time and pain and exertion during test performance. ICC, Intra-class Correlation Coefficient; CI, confidence interval. *weighted Kappa

coefficients (ICC absolute agreement) or weighted kappa (for nonparametric variables) were reported with 95% confidence intervals (95%CI).

Results: Sixty-eight patients were included (43% female, aged 44 (SD 12) years, 52% r-axSpA; Table 1). Interobserver and test-retest reliability were tested in respectively 61 and 39 patients. At baseline, the mean ASPI duration was 9 (SD 3) minutes, and 82% was capable of performing all tests (Table 2). The ASPI interobserver and test-retest (intra-rater) reliability were respectively good to excellent (ICC 95%CI: 0.81-0.99; Table 3) and moderate to excellent (ICC 95% CI: 0.68 - 0.98), for all tests. The pain and exertion during the ASPI showed lower reliability (poor to good).

Conclusion: This study is the first to perform the ASPI in non-Dutch- and also nr-axSpA patients. Despite high disease activity and differences in treatment access between patients in Chile, the ASPI was highly feasible. Importantly, the ASPI had high interobserver and test-retest reliability. The test-retest reliability was even somewhat higher than

reported previously. Therefore, the ASPI appears appropriate for objective evaluation of physical functioning in Latin American axSpA patients.

CRP, mg/dL, median (Q1-Q3)	4 (1.14-8)	2.92 (1-4.9)	0.286

Background/Purpose: Inflammatory bowel disease (IBD) is frequently seen in patients with axial spondyloarthritis (axSpA). This study aimed to investigate whether fecal calprotectin levels could predict future development of IBD in axSpA patients.

Methods: This multicenter, prospective observational cohort study used the TReasure database in which web-based registration of rheumatoid arthritis (RA) and SpA patients are being performed in 15 centers across different regions of Turkey. Fecal calprotectin levels were measured in 137 axSpA patients as of September 2018. Fecal calprotectin level ≥200 µg/g was considered significant. All study subjects were evaluated for IBD symptoms (loose defecation, mucous diarrhea, bloody defecation, bloody diarrhea, abdominal pain, obstruction, or pseudo-obstruction). Patients who had previous IBD diagnosis or who used NSAIDs at least 2 weeks before fecal calprotectin measurement were excluded. It was planned to examine patients for IBD by control visits at every 3 months for 1 year. In this paper, preliminary results of the patients were presented.

For axSpA patients, disease activity was evaluated by the ASDAS CRP, BASDAI, *BASFI*, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), visual analog scale (VAS)-pain, VAS-fatigue, and tender and swollen joint count. Moreover, 24 healthy volunteers and 25 RA patients were included as a control group.

Results: This study included 137 axSpA patients (33.6% females) with the median (Q1-Q3) age of 43 years (33-50 years) and median (Q1-Q3) disease duration of 8.9 years (5.0-13.9 years). Among 24 RA patients (79.2% females), the median (Q1-Q3) age was 59 years (48-64 years) and the median (Q1-Q3) disease duration was 10.6 years (8.1-18.6 years). Rheumatoid factor was positive in 79% of the RA patients. The median (Q1-Q3) fecal calprotectin level was 48 µg/g (30-122 µg/g) in axSpA patients. The median fecal calprotectin level was ≥200 µg/g in 23/137 (16.8%) axSpA patients and in 15/24 (62.5%) RA patients. Fecal calprotectin levels were not high in any healthy volunteers. The axSpA patients with calprotectin level of ≥200 µg/g were older [48 years (39-54 years) vs. 41 years (31-49 years); p=0.025] and had higher BMI values [30.3 (26.3-32.7) vs. 26.6 (23.5-29.0); p=0.003]. Disease activity levels of the patients at baseline are given in Table 1; there was no difference regarding fecal calprotectin level. In the axSpA patients, RA patients, and healthy controls, while the rates of abdominal pain were 5.8% (n=8), 16.5% (n=4), and 8% (n=2), respectively and the rates of loose defecation were 5.1% (n=7), 12.5% (n=3), and 4% (n=1), respectively, none of the patients had mucous diarrhea, bloody diarrhea, and obstruction.

Conclusion: In the present study, preliminary results for the fact that whether or not fecal calprotectin levels could predict future development of IBD were presented. Fecal calprotectin levels were higher in 15% of the asymptomatic axSpA patients; the follow-up results of these patients may give information about daily practice.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tapering of tumor necrosis factor (TNF) inhibitors may be considered in patients with ankylosing spondylitis (AS) with low disease activity. However, there is still a lack of evidence that TNF inhibitors can be safely tapered and maintained with low medical costs. The aim of this study was to analyze the pattern of tapering of each TNF inhibitor and to evaluate the reduction of healthcare costs due to tapering of TNF inhibitors in patients with AS using an insurance claims database.

Methods: Data was obtained from an insurance claims database of the Health Insurance Review & Assessment Service in South Korea. Patients with AS who initiated TNF inhibitors such as etanercept, adalimumab, golimumab, and infliximab between July 1, 2013 to June 30, 2016 were enrolled. Among them, patients treated with TNF inhibitors for more than 2 years were included. Tapering of the TNF inhibitor was defined as a reduction of 50% or more of the recommended dose. We compared the rate of tapering and the time to 50% reduction of recommended dose between each TNF inhibitor. In addition, the implication of tapering on healthcare costs related to AS based on whether patients were subjected to a tapering dose was analyzed.

Table 1. Tapering in patients who persist TNF inhibitor

† Adjusted for Age, Sex, CCI; * Using generalized linear models

Results: A total of 1,352 patients were included in the study. Among them, 264 patients were continuously treated with adalimumab, 145 patients with etanercept, 188 patients with golimumab, and 167 patients with infliximab (Table 1). Of these, tapering of TNF inhibitors was more frequently observed in 58 (22.0%) patients on adalimumab and 36 (24.83%) on etanercept compared to 22 (11.7%) on golimumab and 20 (12.0%) on infliximab (p=0.0028). The mean time to 50% reduction was shorter in etanercept (297.4 ± 219.1 days) compared to adalimumab (365.0 ± 192.36 days), golimumab (448.59 ± 157.14 days), and infliximab (380.6 ± 121.78 days) (p=0.0294). The costs of TNF inhibitors was the highest among all AS-related healthcare costs. In addition, tapering significantly reduced AS-related total costs for all TNF inhibitors (Table 2).

Conclusion: TNF inhibitors with short intervals tended to be more frequently tapered in patients with AS. Tapering of TNF inhibitors may also help reduce healthcare costs related to AS.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Most studies show a significantly higher risk of myocardial infarction [MI] (odds ratio [OR] = 1.60) and stroke (OR = 1.50) in ankylosing spondylitis (AS) patients. Whether therapies targeted at controlling inflammation may potentially reduce the risk of cardiovascular events (CVE) in AS, is not well understood. While NSAIDs are known to be associated with an increased risk of CVE in the general population, whether the anti-inflammatory effects of NSAIDs reduce or modify CVE risk in AS is controversial. It is also unclear if CVE risk is reduced by TNF inhibitors (TNFi), which has been shown in rheumatoid arthritis (RA). We aimed to perform a systematic review and meta-analysis to explore the association between NSAIDs, TNFi and CVE in AS.

Methods: We conducted a comprehensive search of several databases from inception to January 16, 2019. We included studies of patients with AS treated with NSAIDs, non-biological DMARDs or biologics, and had a control group. Outcomes of interest were all CVEs, myocardial infarction, stroke, congestive heart failure (CHF), and the composite outcome of major adverse cardiac events (MACE). Reported ORs and hazard ratios reported were converted to risk ratios (RR) using validated statistical formulae. Study specific RR were pooled using random-effects model (DerSimonian and Laird). Between-study heterogeneity was assessed using I^2 statistics.

Results: Nine nonrandomized studies from a total of 1,425 studies screened fulfilled the inclusion criteria (Figure 1). In NSAID users as a whole, no increased risk of CVE was noted; however, the risk of cerebrovascular accident (CVA)

Table 1. Baseline characteristics of the included studies

Author, Year	Study Design	AS definition	Events reported (definition)	Follow-up duration (years)	Treatment				Control

Dubreuil (abstract), 2018	Nested case-control study (OptumLabs Data Warehouse)	Diagnostic code- AS dx after at least 6 months of Claims data prior to AS dx	Incident MI (Diagnostic codes)	23 (1994-2017)	NSAID TNFi	1282 ~89	48.9	59.1 (11.9)	No NSAID No TNFi	21967 23160	48.9	59.1 (11.9)
Lee, 2018	Prospective national cohort study (Australian Rheumatology	ICD-10 codes	All CVE (angina, MI, CABG, PCI, stroke/TIA)	15 (2001-2015)	NSAID TNFi	-	-	-	No NSAIDs No TNFi	-	-	-

was significantly lower (RR: 0.58, 95% CI 0.37 – 0.93, I^2=66%). Cox-2 inhibitor use was associated with reduced risk of all CVE (RR: 0.48, 95%CI 0.33 - 0.70, I^2= 0%) and CVA (RR: 0.58, 95% CI 0.37 - 0.93, I^2= 66%). Non selective NSAIDs did not show a significant association with risk of any CVE. There was only 1 study reporting all CVE with TNFi, which showed a slightly higher risk (RR: 1.60, 95%CI 1.05 - 2.41). Meta-analysis of 3 studies of MI specifically did not show a significant association with TNFi (RR: 0.88, 95%CI 0.57 - 1.35, I^2=76%). Only 1 study each reported risk of CHF and MACE, which were both low in all NSAID groups (Table 1). The certainty in evidence in all estimates was low due to the studies being nonrandomized.

Conclusion: This systematic review suggests that Cox-2 inhibitors in AS patients are associated with a lower risk of the composite CVE outcome and CVA, unlike their use in the general population. Similarly, NSAID users as a whole and users of non-selective NSAIDS did not have higher risk of any CVE. No significant association between TNFi and MI was observed. More studies are needed to study the association between TNFi use and CVE in general to evaluate a possible protective role in AS.

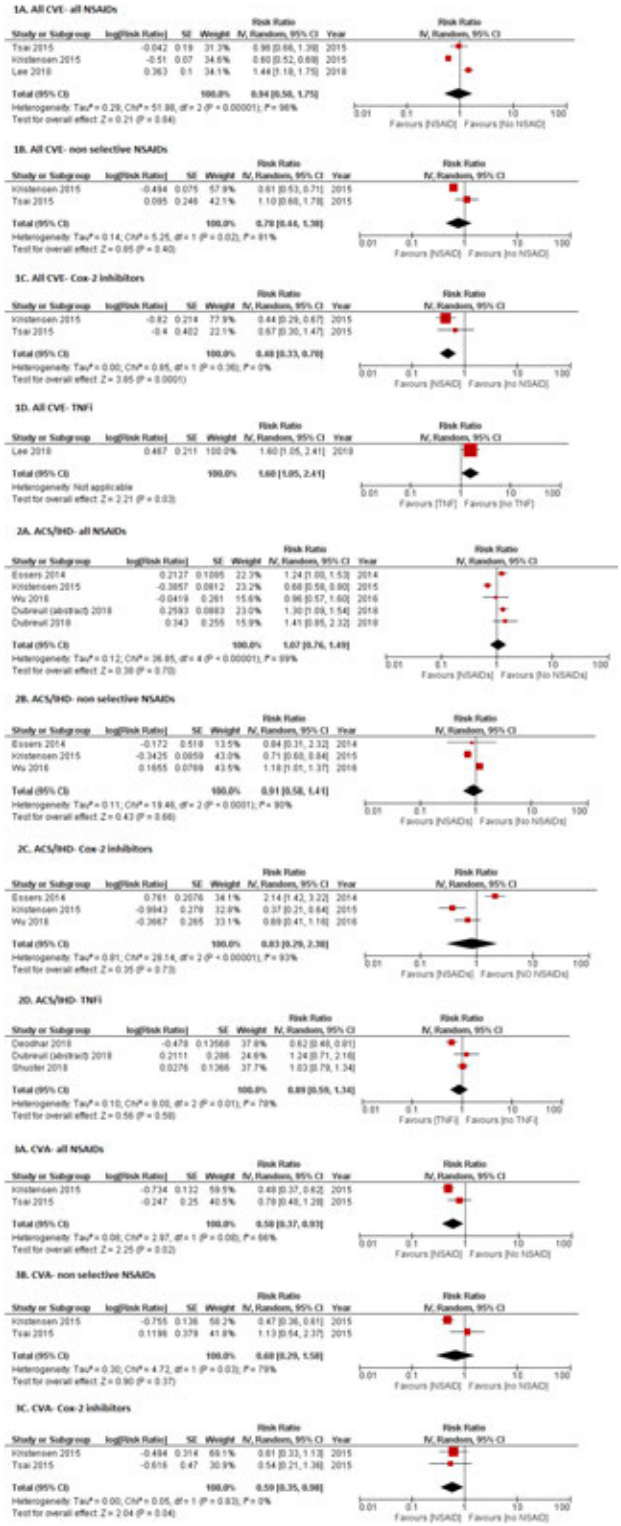

Figure 2. Forest plot of the risk of cardiovascular events with NSAIDs and TNF inhibitors in Ankylosing Spondylitis

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriasis is a common feature of axial spondyloarthritis (axSpA) occuring in approximately 10% of patients with axSpA. It has been presumed that such an association may be associated with a particular phenotype of the disease, which has not been extensively investigated so far. The purpose of the study was to analyze the association between clinical phenotype and radiographic progression and skin psoriasis in patients with axSpA.

Methods: Altogether 210 patients with axSpA (115 with radiographic and 95 with non-radiographic axSpA) were included in the analysis. Radiographs of the spine and sacroiliac joints (SIJ) were scored by two readers in a randomly selected order according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) and the grading system of the modified New York criteria. A sacroiliitis sum score was calculated as a sum of the grades for the left and right SIJ. Mann-Whitney analysis was performed for group comparisons. A multivariable regression analysis was performed to analyze the influence of of the psoriasis on radiographic progression.

Results: Overall, 28 patients (13.3%) with axSpA had skin psoriasis. Patients with psoriasis were less frequently HLA-B27 positive, had higher anamnestic prevalence of peripheral arthritis (16 (57.1%) vs. 58 (31.9%), p=0.01), higher disease activity (Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) 5.0 ± 2.2 and 3.8 ± 2.1, respectively, p=0.01) and worse physical function (Bath Ankylosing Spondylitis Functional Index (BASFI) 3.8 ± 2.3 and 2.8 ± 2.3, respectively, p=0.02) They were also more frequently treated with DMARDs. Baseline radiographic characteristics were comparable between the groups (*Table 1*). Radiographic progression was generally comparable between the groups. (*Table 2*). In a multivariable regression analysis (adjusted for the smoking status, sex, NSAID intake, presence of syndesmophytes at the baseline and time-averaged ASDAS), there was no significant association of psoriasis with radiographic progression in the spine (OR 2.93, 95% CI 0.81 to 10.58) or sacroiliac joints (OR 1.98, 95% CI 0.72 to 5.43).

Conclusion: Presence of skin psoriasis in patients with axSpA was associated with HLA-B27 negativity, peripheral arthritis, higher disease activity and worse functional status and did not impact the radiographic progression in axSpA.

Table 2. Association of skin psoriasis with radiographic progression in axial spondyloarthritis after 2 years of follow-up.

Outcome	Psoriasis (n=28)	No psoriasis (n=185)	p*
Spine			
mSASSS change	1.52 ± 4.02	0.61 ± 1.95	0.55
Progression of mSASSS by ≥2 points	6 (21.4%)	24 (13.2%)	0.25
New syndesmophytes or progression of syndesmophytes	7 (25.0%)	26 (14.3%)	0.16

Peripheral Involvement Is Associated with Less Radiographic Spinal Progression in Patients with Early Axial Spondyloarthritis: Results from the German Spondyloarthritis Inception Cohort

Murat Torgutalp,[1] **Mikhail Protopopov**,[2] Fabian Proft,[3] Joachim Sieper,[3] Hildrun Haibel,[3] Martin Rudwaleit,[4] and Denis Poddubnyy[5], [1]Charité Universitätsmedizin Berlin, Germany and Ankara University Faculty of Medicine, Ankara, Turkey., Berlin, Germany, [2]Charité Universitätsmedizin Berlin, Germany, Berlin, Berlin, Germany, [3]Charité Universitätsmedizin Berlin, Germany, Berlin, Germany, [4]Klinikum Bielefeld, Charité Berlin, Gent University, Bielefeld, Germany, [5]Charité - Universitätsmedizin Berlin and German Rheumatism Research Centre, Berlin, Germany, Berlin, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Peripheral involvement (PI), such as arthritis, enthesitis, and dactylitis, is common in patients with axial spondyloarthritis (axSpA); data showing the influence of PI on radiographic progression of axSpA are controversial. The purpose of this study was to analyze the influence of PI on radiographic structural damage in patients with axSpA.

Methods: A total of 210 patients with axSpA (115 with radiographic and 95 with non-radiographic axSpA) were selected for this analysis. Radiographs of the spine were scored by two trained readers in a randomly selected order according to the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS). Radiographs of the sacroiliac joint (SIJ) were scored according to the grading system of the modified New York criteria; a sacroiliitis sum score was calculated as a sum of the grades for the left and right SIJ. Mann-Whitney analysis was performed for group comparisons. A multivariable regression analysis was performed to analyze the influence of PI on radiographic spinal progression and progression of radiographic sacroiliitis.

Results: Overall, of the 101 (48.1%) patients with PI (documented history or current presence), 78 had peripheral arthritis, 48 had enthesitis, and 12 had dactylitis. 32 patients had more than 1 periferal manifestation. Patients with PI were older were less frequently human leukocyte antigen (HLA)-B27 positive, compared with patients with no PI (73 (73.0%) vs. 93 (85.3%), p=0.028), more frequently had family history for spondyloarthritis as well as psoriasis, had higher disease activity (time-averaged Ankylosing Spondylitis Disease Activity Score (ASDAS) over 2 years 2.6 ± 0.9 vs. 2.3 ± 0.9; p=0.032), worse physical function, higher exposure to disease modifying anti-rheumatic drugs and lower baseline radiographic sacroiliitis sum score. Patients with a documented history or current presence of PI had lower absolute progression in mSASSS after 2 years than those without (0.28 ± 1.39 vs 1.15 ± 2.9, p=0.045); 7.9% of patients with PI had a progression of mSASSS by ≥2 points compared to 20.2% in patients without PI (p=0.011) - **Table 1.**

Progression of sacroiliitis by at least 1 grade in opinion of both readers	11 (10.9)	15 (13.8)	0.528

* Mann-Whitney U-Test for continuous variables, X^2 test for binary variables.

ASDAS – Ankylosing Spondylitis Disease Activity Score; BASDAI – Bath Ankylosing Spondylitis Disease Activity Index; BASFI – Bath Ankylosing Spondylitis Functional Index; BASMI – Bath Ankylosing Spondylitis Metrology Index; BL – baseline; CRP – C-reactive protein; CS – corticosteroids; DMARD – disease-modifying anti-rheumatic drugs; HLA-B27 – human leukocyte antigen B27; mNY Criteria – modified New York Criteria for Ankylosing Spondylitis, 1984; mSASSS – modified Stoke Ankylosing Spondylitis Spine Score; NSAID – non-steroid anti-inflammatory drugs; SpA – spondyloarthritis; TNFi – tumour necrosis factor α inhibitors.

Table 2. Association of peripheral involvement with radiographic progression in axial spondyloarthritis after 2 years of follow-up.

Multivariable linear regression analysis	
Outcome	**β (95 %CI)**
mSASSS change score	**-0.98 (-1.68 to -0.28)***
Change of the sacroiliitis sum score	-0.06 (-0.32 to 0.20)**
Multivariable logistic regression analysis	
Outcome	**Odds ratio (95 %CI)**
Progression of mSASSS by ≥2 points	**0.33 (0.12 to 0.91)***
Progression of sacroiliitis by at least 1 grade in opinion of both readers	0.84 (0.33 to 2.09)**

mSASSS - modified Stoke Ankylosing Spondylitis Spine Score.

*Adjusted for the smoking status, HLA-B27 status, NSAIDs intake, baseline syndesmophytes, and time-averaged ASDAS.

**Adjusted for the smoking status, HLA-B27 status, NSAIDs intake, sacroiliitis sum score at baseline, and time-averaged ASDAS.

In a multivariable regression analysis, presence of PI was associated with a lower mSASSS progression and lower odds for the mSASSS progression by ≥2 points after 2 years: β=-0.98 (95% -1.68 to -0.28) OR=0.33 (95% CI 0.12 to 0.91), respectively - **Table 2**.

Conclusion: Presence of PI is associated with distinct characteristics of SpA including slower radiographic spinal progression which might be explained partly by the numerically lower mSASSS score at baseline.

Factors Associated with Complete Spinal Fusion in Patients with Ankylosing Spondylitis

Yasmin Maldonado,[1] Michael Weisman,[2] Lianne Gensler,[3] Michael Ward,[4] Matthew Brown,[5] MinJae Lee,[6] Mark Hwang,[6] Mariko Ishimori,[7] Amirali Tahanan,[6] Tom Learch,[7] Mohammad Rahbar,[6] and John Reveille[8], [1]The University of Texas-McGovern Medical School, Houston, TX, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, [3]University San Francisco California, San Francisco, CA, [4]NIAMS, Bethesda, MD, [5]Queensland University of Technology, Queensland, Australia, [6]University of Texas-McGovern Medical School, Houston, TX, [7]Cedars-Sinai Medical Center, Los Angeles, CA, [8]University of Texas McGovern Medical School, Houston

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Most patients with ankylosing spondylitis (AS) do not develop complete spinal fusion. The purpose of this study was to compare patients with complete spinal fusion defined here as having a Modified Stoke Ankylosing Spondylitis Scoring System (mSASSS) of score of 72 (indicating complete fusion of the cervical and lumbar spine) versus those with no syndesmophyte formation (mSASSS=0) adjusted for disease duration.

Methods: Patient meeting modified New York Criteria for AS enrolled in a longitudinal study of outcome were included in this study. All films were scored for the modified Stoke Ankylosing Spondylitis Scoring System by the same musculoskeletal radiologist (TJL). Sociodemographic features, medication utilization, comorbidities, disease activity (BASDAI, ASDAS), functional impairment (BASFI), joint counts, metrology and enthesitis assessment was recorded, and HLA-B typing at baseline and C-reactive protein, and ESR obtained at each study visit. Pelvic, lumbar and cervical spine radiographs were obtained at baseline visit as well as every two years thereafter. Univariable logistic regression models were conducted to evaluate the factors that were associated with complete spinal fusion (mSASSS=72) compared with those with no radiographic stigmata of AS in the lumbar and cervical spine (mSASSS=0) after adjusting for study site and disease duration.

Table 1. Factors Associated with Spinal Fusion Based on Logistic Regression Model

variable	No spinal fusion n=308 (83.02%)	Complete spinal fusion n=63 (16.98%)	†adjusted Odds Ratio (95% CI)	p-value
Male, n(%)	60.7	93.7	**18.4 (4.45, 75.7)**	**<.0001**
Age**, mean(SD)	36.48 (11.11)	59.76 (11.16)	**1.12 (1.07, 1.17)**	**<.0001**

HLA-B27 positive, (%)	83.6	84.1	0.52 (0.19, 1.45)	0.2107
Ever smoke at baseline, (%)	34.5	69.8	**2.03 (0.98, 4.22)**	**0.0572**
Current smoke at baseline, (%)	9.56	15.8	2.80 (0.98, 8.00)	0.0544
Race: White, (%)	79.2	76.2	**0.23 (0.09, 0.55)**	**0.0012**
Baseline BASFI, mean(SD)	25.18 (22.64)	58.57 (26.09)	**1.04 (1.03, 1.06)**	**<.0001**
Employed for compensation (%)	43.8	22.2	**0.31 (0.14, 0.71)**	**0.0051**
Family history of AS (%)	20.5	7.27	**0.08 (0.02, 0.35)**	**0.0008**
First available BASDAI, mean(SD)	3.83 (2.46)	4.56 (2.46)	1.08 (0.91, 1.28)	0.3749
First available CRP, mean(SD)	0.73 (1.34)	1.79 (2.58)	**1.45 (1.19, 1.76)**	**0.0002**

†: disease duration was adjusted; * data at the same visit when the last available radiograph data were collected

Results: Of 1253 AS patients meeting modified New York criteria enrolled in a longitudinal study of outcome, 371 had either complete spinal fusion at most recent radiographic assessment(i.e., mSASSS of 72, n=63, of whom only four were women); or no spinal fusion (i.e., mSASSS of 0, n=308). These were included in this statistical analysis. Median Follow-up was 1.92 years (IQR 0,4) (maximum=13 years). Median number of mSASSS sets was 2 (IQR= [1,3]) and mean disease of duration was 17.46 years (SD=12.9). Univariable analysis after adjusting for disease duration (Table 1) showed associations of complete spinal fusion with male gender, nonwhite ethnicity, older age at assessment and at disease onset, a history of smoking, greater functional impairment,not being employed, a negative family history of AS and elevated baseline C-reactive protein.

Conclusion: These data suggest that complete spinal fusion in patients with AS is most highly associated with greater age at disease onset, non-white ethnicity, male gender, as well as with objective (but not subjective) markers of disease activity.

Relation of Therapies for Ankylosing Spondylitis to Risk of Total Hip and Knee Arthroplasty

Rachael Stovall,[1] Christine Peloquin,[2] David Felson,[3] Tuhina Neogi,[2] and Maureen Dubreuil[4], [1]Boston Medical Center, Boston, MA, [2]Boston University School of Medicine, Boston, MA, [3]Boston University School of Medicine, Department of Rheumatology, Boston, [4]Boston University School of Medicine, Boston

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is an inflammatory arthritis that predominantly affects the axial skeleton, but commonly affects peripheral joints as well. Peripheral joint involvement often leads to total hip arthroplasty (THA) or total knee arthroplasty (TKA) in AS. We evaluated the relation of tumor necrosis factor inhibitors (TNFi) and other therapies in AS relative to nonsteroidal anti-inflammatory drugs (NSAIDs) to the risk of THA/TKA.

Methods: We conducted a nested case control study using 1994-2018 data from the OptumLabs® Data Warehouse, which includes medical and pharmacy claims, laboratory results, and enrollment records for commercial and Medicare Advantage enrollees. The database contains longitudinal health information on enrollees and patients, representing a diverse mixture of ages, ethnicities and geographical regions across the United States. Claims were used to identify patients with AS ages 18-89. Subjects were required to have medical and pharmacy coverage at least 6 months prior to AS diagnosis. Incident THA/TKAs were defined by diagnostic codes. THA or TKA cases were matched to four controls by sex, age (+/- 3 years), AS diagnosis year (+/- 1) and insurance type (private or Medicare). We assessed AS treatment in 6-month period prior to THA or TKA, using categories of NSAID (referent), symptom modifying anti-rheumatic drug (SMARD), and TNFi, either alone or in combination with other therapies. We evaluated the relation of each type of treatment to risk of THA or TKA using conditional logistical regression, with adjustment for age and history of chronic kidney disease, diabetes, liver disease, obesity, and peptic ulcer disease at baseline. Sensitivity analyses included 3-month and 14-month exposure assessment periods and models assessing THA and TKA separately.

Results: Among 22,166 adults with AS meeting eligibility criteria, we identified 539 cases of THA or TKA, and 1568 matched controls. Mean age was 58.9 (SD +/- 11.2) years, and 51.5% were female. Relative to NSAID use, the adjusted OR (aOR) within the 6-month exposure assessment period for TNFi only use was 0.45 (95% CI 0.26-0.78) and the aOR for SMARD only use was 0.49 (95% CI 0.32-0.75; see Table). Associations for other combinations of ther-

Table. Odds of NSAID, SMARD, TNFi or combination treatment within 6 months of THA or TKA among adults with AS

	Cases	Controls	Adjusted OR⁺
NSAID only	399	1012	1.0 (referent)
SMARD only	32	178	**0.49 (0.32-0.75)**
TNFi only	20	110	**0.45 (0.26-0.78)**
NSAID + SMARD	44	149	0.81 (0.55-1.21)
NSAID + TNFi	32	72	1.03 (0.64-1.66)
SMARD + TNFi	<20*	20	0.81 (0.31-2.12)
NSAID + SMARD + TNFi	<20*	27	0.43 (0.16-1.15)

OR: odds ratio; NSAID: nonsteroidal anti-inflammatory drug; TNFi: tumor necrosis factor inhibitor; SMARD: symptom modifying anti-rheumatic drug

⁺Adjusted for age, chronic kidney disease, diabetes, liver disease, obesity, and peptic ulcer disease prior to study eligibility.

*Small cells are suppressed to prevent the possibility of patient identification.

apies were not significant. Sensitivity analyses using 3-month and 14-month exposure assessment periods yielded aORs for TNFi only use of 0.39 (95% CI 0.22-0.69) and 0.44 (95% CI 0.23-0.86), respectively, and for SMARD only use aORs of 0.55 (95% CI 0.35-0.84) and 0.56 (95% CI 0.37-0.84). Results were similar for analyses of THA and TKA individually.

Conclusion: In this large sample of US adults with AS, the use of TNFi only and SMARD only were associated with lower odds of THA and TKA relative to NSAID use alone. Combinations of AS therapies were not associated with lower odds of THA and TKA. SMARD or TNFi therapy appear to have beneficial effects beyond the spine in AS on peripheral joints compared with NSAIDs; however, whether this may reflect benefits of those therapies versus detrimental effects of NSAIDs cannot be discerned.

Arterial Elasticity by 2 Dimensional Circumferential Strain and Beta Stiffness Index in Patients with Ankylosing Spondylitis

Helena DElia,[1] Lucy Law,[1] Karin Bengtsson,[2] Mats Geijer,[3] Stefan Soderberg,[4] and Per Lindqvist[5], [1]Department of Public Health and Clinical Medicine, Rheumatology, Umeå, Sweden, [2]Department of Inflammation and Rheumatology Research, Göteborg, Sweden, [3]Department of Radiology, Institute of Clinical Sciences, Göteborg, Sweden, [4]Department of Public Health and Clinical Medicine, Medicine,, Umeå, Sweden, [5]Department of Surgical and Perioperative Sciences, Clinical Physiology, Umeå, Sweden

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is associated with elevated risk of cardiovascular disease (CVD) and increased mortality. Arterial stiffness is associated with atherosclerosis and CV events. Stiffness can be examined by ultrasound providing β stiffness index and by a more recently developed method, 2 dimensional (D) strain by speckle tracking technique, which measures deformation in more dimensions. The aims were to examine bilateral common carotid arterial (CCA) circumferential 2D strain and β stiffness index and in patients with AS and 1) compare the results with age and sex-matched controls and 2) explore relationships between circumferential strain and β stiffness index with disease related and traditional risk factors for CVD in AS patients.

Methods: A cohort of 149 patients with AS from northern Sweden, mean age 55.3±11.2 years, 102(68.5%) men, 146(98%) HLAB27) were examined with radiographs for modified Stoke Ankylosing Spondylitis Spine Score (mSASSS), BASMI, BASFI, ASDAS-CRP, BASDAI and conventional risk factors of CVD. Circumferential 2D strain and β stiffness index were assessed of bilateral CCAs. Forty-six AS patients and 46 age- and sex-matched controls without hypertension, diabetes or history of myocardial infarction or stroke were compared. Univariate and standard multivariable linear regression analyses were used. Variables with a univariate p-value ≤ 0.1 were considered for the multivariable models.

Results: The mean bilateral circumferential 2D strain was lower in AS patients compared with controls, 7.9±2.6% vs 10.3±1.9%, p< 0.001 whereas the mean bilateral β stiffness index was higher, 13.1±1.6 mmHg/mm vs 12.3±1.3

mmHg/mm, p=0.018. Multivariable linear regression analyses with mean circumferential bilateral 2D strain as dependent variable showed inverse significant associations with age, erythrocyte sedimentation rate, history of anterior uveitis and to be on a csDMARD and/or a bDMARD (R2 0.33) while mean β stiffness index as dependent variable showed significant associations with age (R2 0.22).

Conclusion: Both CCAs 2D strain and β stiffness index differed significantly between AS patients and controls indicating worse subclinical arterial status in AS. The circumferential 2D strain was associated with age and AS related variables while the β stiffness index with age indicating that the methods complement each other. Longitudinal studies are required to investigate the clinical importance of these CV surrogate biomarkers in AS.

The Use of Microbial Flow Cytometry to Analyze the Intestinal and Oral Microbiota

Patrick Stauffer,[1] Mark Klick,[1] Tammy Martin,[1] James T. Rosenbaum,[2] and Mark Asquith[1], [1]Oregon Health and Science University, Portland, OR, [2]Devers Eye Institute and Oregon Health & Science University, Portland, OR

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The role of the microbiome in the pathogenesis of autoimmune disorders such as axial spondyloarthritis (SpA) has been well-established through means of describing gross microbial community dysbiosis between healthy controls. However specific mechanisms of how pathogenic bacteria cause disease progression in axial SpA have escaped current research. In this novel project we use flow cytometry to interrogate microbial composition using Quantitative Microbial Profiling (QMP), where we couple flow cytometric microbe counts with 16S rRNA sequencing. We compare QMP to the standard microbial analysis technique, Relative Microbial Profiling (RMP), that does not account for potential inter-sample differences in total microbial load. We also investigate the host-immune response to these microbial communities using the IgA-SEQ technique in which we flow sort and sequence IgA-coated bacteria.

Methods: Fecal samples of healthy controls (n = 23) and axial SpA patients (n = 24) were subjected to QMP through the combination of microbial flow cytometry and 16s rRNA sequencing. Antibiotic use was an exclusion criteria and 12/24 (50%) of the axial SpA patients had exposure to biologics for treatment. Saliva and feces of axial SpA and healthy control patients were subsequently subjected to IgA-SEQ (n = 12-13/group) in which IgA-coated bacteria are sorted and 16s rRNA sequenced to produce an IgA-coating index score for comparison of host immune response. This method identifies targets of the intestinal and oral IgA response in patients with axial SpA. The data was analyzed using the *DADA2* pipeline implemented in R.

Results: For the first time, QMP methods revealed striking quantitative fecal microbial load differences between axial SpA patients and healthy controls, underpinned by a dramatic near log-fold decrease in total microbial concentration as compared to healthy controls ($p < 0.01$). Additionally, IgA-SEQ analysis demonstrated a significantly altered microbiota-specific IgA repertoire between axial SpA patients and healthy controls in both saliva and feces. Of note,

some of the most significantly altered bacterial populations were from the *Lachnospiraceae* family, specifically from the genus *Roseburia*.

Conclusion: Through the use of QMP we identify a number of novel quantitative differences to the composition of the intestinal microbiota in axial SpA patients as compared to healthy controls. We also propose that patients with axial SpA have an altered host immune response to the oral and fecal microbiome that could play a critical role in disease pathogenesis and drive progression. Further research focused on immunogenic microbes, including *L. roseburia* could yield potential treatments to delay or stop disease progression.

Ten-year Atherosclerotic Cardiovascular Disease Risk Scores in Axial Spondyloarthritis versus the General Population: A Cross-sectional Study

Jean Liew,[1] John Reveille,[2] Henna Sawhney,[3] Maria Castillo,[3] Benjamin Naovarat,[4] Susan Heckbert,[1] and Lianne Gensler[5], [1]University of Washington, Seattle, WA, [2]University of Texas McGovern Medical School, Houston, [3]University of California in San Francisco, San Francisco, CA, [4]University of Texas-McGovern Medical School, Houston, TX, [5]University San Francisco California, San Francisco, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular morbidity and mortality are increased in axial spondyloarthritis (axSpA). The 2013 American College of Cardiology/American Heart Association (ACC/AHA) guidelines recommend high intensity statin therapy for primary prevention for 10-year atherosclerotic cardiovascular disease (ASCVD) risk scores ≥ 7.5%. We conducted a cross-sectional study evaluating the ASCVD risk profile of patients with axSpA compared to the general US population.

Methods: We included adults 18 years and older with AS by the modified New York criteria or non-radiographic axSpA by the ASAS criteria, who were followed longitudinally at two sites. After exclusion of ages outside the range of 40-75 years and patients without available cholesterol measures or blood pressures, 208 axSpA patients were included in the analysis. Other variables of interest were singly imputed using the last observation carried forward to the time of the cholesterol measurements. For general population comparators, we used individuals from the 2009-2014 National Health and Examination Survey (NHANES) cycles, who had available data for ASCVD risk score calculation by the Pooled Cohort Equation. Comparators from NHANES were matched 4:1 to subjects with axSpA on age, sex, and race. We performed descriptive statistics and estimated the prevalence ratio for a 10-year ASCVD risk score ≥7.5% comparing AS and matched NHANES comparators using conditional Poisson regression. We performed the same analysis among the subset of patients with AS (n=158).

Results: Overall, subjects had a mean ± SD age of 54.2 ± 11.4years, 68% were male, and 75% were white. The mean 10-year ASCVD risk score was 6.5 ± 6.9% for those with axSpA and 9.5 ± 10.4% for NHANES comparators.

Table 1. Baseline characteristics, comparing axSpA patients with age-, sex-, race-matched NHANES comparators

Variables	Overall n = 1040	axSpA n = 208	NHANES n = 832
Age, years	54.2 ± 11.4	53.9 ± 10.0	54.3 ± 11.7
Male sex	68%	68%	68%
Race/ethnicity			
White	75%	75%	75%
Black	3%	3%	3%
Hispanic	1%	1%	1%
Other	21%	21%	21%
10-year ASCVD risk score, %	8.9 ± 9.9	6.5 ± 6.9	9.5 ± 10.4
SBP, mm Hg	124.7± 15.9	126.7 ± 15.9	124.2 ± 15.8
Taking hypertensive medication	32%	35%	31%
HDL, mg/dl	51.8 ± 16.1	54.9 ± 16.7	51.0 ± 15.8
Total cholesterol, mg/dl	195.0 ± 42.3	189.8 ± 43.8	196.4 ± 41.8
Taking cholesterol medication	25%	21%	26%
ASCVD risk score ≥7.5%	38%	39%	38%
Diabetes	14%	7%	15%
Current smoker	18%	5%	22%

Abbreviations: axSpA: axial spondyloarthritis; NHANES: National Health and Examination Survey; ASCVD: atherosclerotic cardiovascular disease; HDL: high density lipoprotein; SBP: systolic blood pressure

Compared to those with axSpA, the prevalence of current smoking and diabetes was higher among NHANES comparators. The estimated prevalence ratio for a 10-year ASCVD risk score ≥7.5% comparing those with axSpA and their age-, sex-, and race-matched comparators was 0.94 (95% CI, 0.83-1.05). Similar results were seen among the subset of patients with AS.

Conclusion: In our study, the prevalence of a 10-year ASCVD risk score ≥7.5% was not significantly different comparing patients with axSpA and those drawn from the general population, who were similar in terms of age, sex, and race. The increased CV risk associated with axSpA may be underestimated by this risk score calculation. Although axSpA patients may be at lower CV risk overall due to heterogenous disease severity, similar results were seen among an AS subset. In addition, further interpretation of these findings is limited by the small sample size and lack of information on socioeconomic status. Additional investigation of the performance of ASCVD risk scores in patients with axSpA is needed.

Evaluation of the Early Cervical Structural Changes in Patients with Non-Radiographic Axial Spondyloarthropathy

Melike Cengiz,[1] **Şebnem Ataman**,[2] Ayşe Peyman Yalçın,[3] Ismihan Sunar,[3] and Gürkan Yılmaz[3], [1]Ankara Unversity School of Medicine, Physical Medicine and Rehabilitation Department, Ankara, Ankara, Turkey, [2]Ankara University School of Medicine, Physical Medicine and Rehabilitation, Rheumatology Department, Ankara, Ankara, Turkey, [3]Ankara Unversity School of Medicine, Physical Medicine and Rehabilitation, Rheumatology Department, Ankara, Turkey

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this double-blind, controlled, cross-sectional study is to compare the cervical vertebral structural changes of the patients with nr-axSpA, AS and control group using the mSASSS and to determine whether the cervical vertebral involvement is more early and more than the lumbar spine in the early period of the axial SpA.

Methods: A total of 205 people, 71 of whom were diagnosed as AS, 68 of whom were nr-axSpA, and 66 of them were control group were included in the study. Demographic data, CRP values, and HLA-B27 results were recorded. BASDAİ, BASFİ, BASMİ, and MASES values were calculated at the evaluation of the patients. The presence of sacroiliitis on pelvic radiography was evaluated according to the mNY criteria. Radiological evaluation of cervical and lumbar lateral radiographs was performed according to the mSASSS system.

Results: In this study, the duration of symptoms was significantly shorter in the nr-axSpA group than in the AS group (p = 0.010). There was a statistically significant difference at total mSASSS between the AS group and the nr-axSpA group (p= 0,038) but not at cervical and lumbar mSASSS (p=0,449, p=0,460). There was a statistically significant correlation between cervical and lumbar mSASSS scores in the AS group (p: 0.038, CC: 0.248), but not in the nr-axSpA group (p: 0,115, CC: 0,194). In AS and nr-axSpA groups, cervical mSASSS scores were higher than lumbar mSASSS scores in the majority of patients (%82,8 and %89,5). Although in the AS group, the cervical and total mSASSS scores were positively correlated with the duration of symptoms (CC:0,255, CC:0,295), there was no correlation in the nr-axSpA group.

Conclusion: Although the duration of the symptoms was shorter in the nr-axSpA group than in the AS group, there was no statistically significant difference between the cervical mSASSSS scores between the AS and nr-axSpA

Correlation analysis of cervical and lumbar mSASSS values

groups. This situation may indicate that cervical vertebral changes occur in the early period of axial spondyloarthropathy. A similar statistical non-significant result was found between lumbar mSASSS scores of AS and nr-axSpA groups although not at total mSASSS.

However, there was a statistically significant correlation between cervical and lumbar mSASSS scores in the AS group and none in the nr-axSpA group. In AS and nr-axSpA group, cervical mSASSS scores were higher than lumbar mSASSS scores in the majority of patients. In contrast to our traditional knowledge, in patients with axial spondyloarthropathy cervical vertebral involvement was more prominent than lumbar vertebral involvement. This results may support our hypothesis that cervical involvement is early and more severe than the lumbar spine in the early period of the axial SpA.

Raja Rampersaud,[1] Nigil Haroon,[4] and Robert Inman[5], [1]Toronto Western Hospital, Krembil Research Institute, University of Toronto, Toronto, Canada, [2]Toronto Western Hospital, University of Toronto, Toronto, Canada, [3]University Health Network, Toronto, Canada, [4]Toronto Western Hospital, Krembil Research Institute, University of Toronto, Toronto, ON, Canada, [5]University of Toronto, University Health Network, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Early recognition is crucial in improving outcomes in patients with axial spondyloarthritis (axSpA). Despite this, there exists long delay between symptom onset and rheumatology diagnosis, with an average

interval of 8 years. Compounding this issue is uncertainty regarding initial axSpA screening and referral practices amongst primary care providers. The purpose of this study was to examine the knowledge, screening and referral practices for suspected axSpA within primary care.

Methods: Primary care physicians (MDs), physiotherapists (PTs), chiropractors (DCs) and nurse practitioners (NPs), licensed and registered with an Ontario regulatory college or professional association, were sent an electronic questionnaire via their respective professional institutions using Survey Monkey™ from September 2017 to September 2018. The questionnaire was developed based on our results from a qualitative study of primary care axSpA screening and referral practices conducted in 2016 and was piloted by ten primary care practitioners to strengthen face and content validity, clarity, relevance and format. The questionnaire addressed: i) knowledge of clinical and investigative features of axSpA; ii) awareness of axSpA screening tools and iii) referral practices for evaluation of suspected axSpA. Univariate statistics were used to address the above objective. All data analyses were conducted on *SAS version 9.4*.

Results: In total there were 276 respondents: MDs (44.5%), DCs (34%), PTs (19%) and NPs (2.4%). 93.1% worked in urban settings. 61.8% indicated > 10 years of primary care experience. In terms of clinical knowledge, the following were considered "very important" when assessing suspected axSpA: morning stiffness lasting > 30 minutes (81.9%); presence of HLA B27 (66.7%); evaluation of acute phase reactants (46.4%) and radiographs (spine and pelvis) (45.3%). Most respondents "never used" or "were not familiar" with axSpA screening tools (80%). The majority of MDs (90.9%) indicated they would "always" or "often" refer to rheumatology. PTs (90.5%) and DCs (88.0%) would "always" or "often" refer back to the patient's MD to facilitate further investigation and/or referral, as they are not legislated to directly refer to medical specialists in the province of Ontario. Travel (28.8%) and prolonged wait times (53.2%) were identified as referral barriers. DCs and PTs indicated legislative issues pertaining to scope of practice as a barrier to assessing patients with suspected axSpA (82.2%, 50.0%, respectively).

Conclusion: The majority of primary care practitioners demonstrate reasonable knowledge of clinical features for suspected axSpA; however there is little awareness of axSpA screening tools. Although the majority of MDs refer their patients with suspected axSpA for rheumatology consultation, prolonged wait times were identified as a substantial barrier. PTs and DCs, who are also first contact healthcare providers, identified barriers to axSpA screening and referral related legislative scope of practice, that if mitigated, could allow for better early detection of axSpA. The results of this study may inform targeted education of primary care practitioners to improve early recognition of axSpA.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Withdrawal from the workforce is 3.1 times higher in patients with Ankylosing Spondylitis (AS) compared to the general population [Boonen A, et al. 2001]. Functional disability is the most important predictor of total costs in patients with AS [Ward M. 2002]. Age at onset of AS, less formal education, and having physically demanding jobs were significant risk factors for permanent work disability, which had a prevalence of 13% in one AS cohort [Ward M, et al. 2001].

The purpose of our study was to identify factors associated with work disability, including specific work abilities, in patients with AS. We chose to specifically look at trunk strength, and dynamic flexibility because prior research has shown that bending, twisting, and stretching are the occupational activities associated with greater functional limitations and radiographic damage in patients with longstanding AS [Ward M, et al. 2008].

Methods: We included 1115 patients meeting modified New York Criteria from a prospective AS cohort. We used patients' current occupation data reported. Occupations were assigned a code from the Occupational Information Network, the US Department of Labor's job classification database. Each code is associated with a scale ranging from 0-100 that signifies the degree of importance of a particular work ability for that occupation. We used univariable

Table 1: Association of factors with disability based on univariable models (n=1115)

Variable	Not Disabled n=907 (81.35%)	Disabled n=208 (18.65%)	Unadjusted Odds Ratio (95% CI)	p-value
Male sex, n(%)	673 (74.20)	151 (72.60)	0.92 (0.66, 1.29)	0.6347
Age (year), mean(SD)	44.31 (13.97)	48.61 (13.92)	1.02 (1.01, 1.03)	0.0001
Country- Australia, n(%)	70 (7.72)	19 (9.13)	1.20 (0.71, 2.04)	0.4969
White race, n(%)	753 (83.02)	150 (72.12)	0.53 (0.37, 0.75)	0.0003
# years of education, mean(SD)	15.99 (2.95)	14.14 (2.94)	0.81 (0.77, 0.86)	<0.0001
Trunk Strength (1-100), mean(SD)	23.65 (16.39)	30.63 (18.03)	1.02 (1.01, 1.03)	<0.0001
Dynamic Flexibility(1-100), mean(SD)	1.47 (4.74)	2.80 (5.55)	1.04 (1.02, 1.07)	0.0013

Table 2: Association between work-related ability and disability based on a final multivariable logistic regression model

variable	Adjusted Odds Ratio (95% CI)	P-value
Trunk Strength (1-100)	**1.02 (1.004, 1.03)**	**0.0075**
Dynamic Flexibility (1-100)	**0.99 (0.95, 1.02)**	**0.4355**
Age (year)	1.03 (1.02, 1.05)	<.0001
# years of education	0.82 (0.77, 0.87)	<.0001
Country Australia vs. US	0.67 (0.36, 1.23)	0.1909
Sex Male vs. Female	0.83 (0.58, 1.18)	0.2961
Race White vs. other	0.50 (0.34, 0.75)	0.0007

and multivariable logistic regression models to evaluate whether work-related ability that requires trunk strength or dynamic flexibility was associated with self-reported disability.

Results: Our cohort had a mean ± SD age of 45 years, 73.9% were male, 81.0 % were white, and 18.7% reported work disability secondary to AS. In the multivariable model, after controlling for confounders such as demographic characteristics, work activity that required more trunk strength was significantly associated with disability (adjusted OR (aOR) 1.02; 95% CI,1.004-1.03), but no significant association was found between dynamic flexibility and disability (aOR 0.99; 95% CI,0.95-1.02). Older age was also significantly associated with disability (aOR 1.03). Higher education and White race were inversely associated with disability (aOR 0.82 and aOR 0.50, respectively). We did not find any significant effect modification between each variable and trunk strength or dynamic flexibility.

Conclusion: AS patients with occupations requiring higher trunk strength reported significantly higher work disability. Another association included older age. Longer years of education and White race were inversely associated with disability. Disease onset of AS begins when patients are usually in young adulthood; identifying risk factors may identify potential interventions that decrease work disability for AS patients.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Most research studies support the fact that both, radiographic and non-radiographic axial spondyloarthritis (r-axSpA and nr-axSpA), share similar clinical characteristics and equivalent burden of the disease. However, worldwide data about nr-axSpA entity is limited, and specific research on the subject in Spain is almost non-existent. The purpose of the present study is to describe and compare the characteristics and burden of the disease in patients with r-axSpA and nr-axSpA in Spain.

Table 1. Sociodemographic characteristics and PROs of patients with nr-axSpA (N: 35, unless other specified) and with r-axSpA (N: 645, unless other specified)

Methods: The Atlas 2017 is an initiative of the Spanish Coordinator of Patient Associations of Spondylarthritis (CEADE) aiming to better understand the reality of the patients suffering from this disease from an integrated approach. During this project, a cross-sectional on-line survey of unselected patients with self-reported axSpA from all geographical regions in Spain was conducted from May 1st to August 15th 2016 by the University of Seville. Participants were recruited through patient organizations. Patients and disease characteristics and reported outcomes were analysed and compared between patients with r-axSpA and patients with nr-axSpA. These included: sociodemographic characteristics, symptoms duration until diagnosis, patient-reported outcomes on disease activity (BASDAI), mental health (GHQ-12), employment status, treatment and healthcare utilization.

Results: In total, 680 axSpA patients participated in the Atlas survey. Mean age was 45.7±10.8 years, 52.5% were female and 36.9% university-educated. Of those, 35 (5.2%) self-reported a diagnosis of nr-axSpA while the rest (94.8%) reported r-axSpA. Compared to r-axSpA patients, those with nr-axSpA were more frequently women (50.4% vs 91.4%, p< 0.001; respectively), had longer diagnostic delay (10.1±8.9 vs 8.4±7.6 years), similar degree of disease activity (BASDAI: 5.7±2.1 vs 5.7±2.0), higher psychological distress (GHQ: 7.5±4.9 vs 5.7±4.) and approximately the same proportion of unemployment (20.0% vs 21.8%) (table 1). In addition, 20.0% of nr-axSpA received biologics vs 36.7% of r-axSpA p=0.044. The number of visits to the rheumatologist in the past 12 months were similar in both groups (3.8±4.5 vs 3.3±3.9), while the visits to the GP were much higher within the nr-axSpA (8.0±10.7 vs 5.1±13.2 p=0.005).

Conclusion: Patients with nr-axSpA were more frequent women and presented younger age, higher diagnostic delay and lower use of biologic therapy compared to axSpA. However, for the overall sociodemographic characteristics, PROs, employment status and healthcare uses, both groups reported similar trends.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Early intervention in axial spondyloarthritis (axSpA) may prevent pathogenic changes such as bone remodeling and spinal fusion. Unfortunately, early intervention is difficult, as there remains an average 5-10 year gap between onset of symptoms and diagnosis partly due to a lack of diagnostic biomarkers. Currently, diagnosis is based on a combination of clinical features, inflammatory markers, and imaging, as existing biomarkers such as CRP and HLA-B27 are not sensitive/specific enough alone. Ideally, a sensitive and specific biomarker could be used alongside existing tools to lessen the time to diagnosis. We hypothesized that metabolites, which can serve as markers of ongoing cellular functions that are likely altered in axSpA, would reveal a sensitive and specific biomarker that would differentiate axSpA cases from healthy controls.

Methods: Patients were selected from our ongoing mucosal studies cohort in which participants undergo colonic mucosal biopsies alongside blood draw. Healthy controls (n=24) were recruited from the endoscopy schedule while undergoing screening colonoscopies with biopsies and an additional blood draw, while axSpA cases (n=23) were recruited from rheumatology clinics and underwent a flexible sigmoidoscopy with biopsies and blood draw. AxSpA cases met ASAS criteria and had imaging consistent with the diagnosis of axSpA. Blood was drawn at the time of the endoscopy visit, then processed and stored. Collected plasma was analyzed by high-pressure liquid chromatography coupled with mass spectrometry (LC-MS).

Statistical analyses were performed using two-sided t-tests, principle component analysis (PCA), partial least squares discriminant analysis (PLSDA), and Receiver Operating Characteristics (ROC) analysis.

Results: PLSDA analysis showed good separation of groups, chiefly driven by oxalosuccinate and 3-sulfocatechol. Oxalosuccinate and 3-sulfocatechol levels significantly differed between axSpA and healthy controls ($p: < 0.0001$, $p: < 0.0001$). In ROC analysis oxalosuccinate had an area under the curve of 0.962, while 3-sulfocatechol had an AUC of 0.88. Oxalosuccinate alone outperformed any combination of other metabolites in correctly differentiating axSpA cases vs healthy controls, and did not significantly correlate with B27 status, BASDAI, endoscopy type, sex, or medication status.

Conclusion: Significant metabolic differences between axSpA and healthy controls were identified in our study, which may provide insight into the underlying pathophysiology of this disease. Furthermore and most strikingly, oxalosuccinate, a product in the TCA cycle, correctly differentiates axSpA from healthy controls and holds promise as a diagnostic biomarker. More work is needed to validate these results in another cohort and with additional controls as well as investigate the mechanism by which the TCA cycle is impacted in axSpA.

Abstract Number: 0628

Pain Perception and Opiate Use Among Patients with Inflammatory Arthritis

Alexis Ogdie,[1] Sofia Pedro,[2] and Kaleb Michaud[3], [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]Forward, The National Databank for Rheumatic Diseases, Wichita, KS, [3]FORWARD, The National Databank for Rheumatic Diseases and University of Nebraska Medical Center, Wichita, KS

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain is the most common symptom among patients with inflammatory arthritis (IA) and residual pain is common in patients IA despite appropriate treatment. Opiate pain medications have been used in the past to assist in managing patients' pain but have increasingly been recognized as potentially harmful medications. The objectives of this study were to a) examine pain perception among patients with RA, PsA, and AS and b) to examine the prevalence and incidence of opiate pain mediation use between 2001-2018 among patients with IA.

Methods: Using data from Forward/National Data Bank for Rheumatic Diseases between 2001-2018, a cross-sectional study was performed using the most recent visit for patients with AS, PsA, or RA with a rheumatologist confirmed diagnosis. Additionally, a retrospective cohort study was performed in the same cohort to examine time trends in the prevalence and incidence of opiate use. Participants in Forward complete questionnaires every 6 months that include patient reported outcome (PRO) measures such as PROMIS29, a wide spread pain index, and a survey of medications used, including pain medications. Incident opiate use was defined as having no prior report of opiate use in previous questionnaires with at least one completed questionnaire prior to the first report of opiate use. Mean and standard deviations for PRO scores were reported for each group and a Kruskal Wallis test or chi2 test was used to determine whether significant differences existed (for continuous and categorical outcomes respectively).

Results: Among those enrolled in Forward, 13,805, 370, and 126 patients with RA, PsA, and AS respectively met eligibility criteria for this study. Patients with RA generally had more follow up time and were older (mean age 64 vs 58 and 50 respectively) and more likely to be female (80% vs 70% and 66% respectively). In general, pain scores (pain numeric rating scale, PROMIS29 pain score, wide spread pain index, Table 1) were statistically similar across the three diseases but numerically higher in AS. Patients with PsA had higher depression scores while patients with AS had higher fatigue scores. While more patients with RA were using non-opioid pain medications at their most recent

Table 1. Demographics and Patient Reported Outcomes Among Patients with RA, PsA, and AS

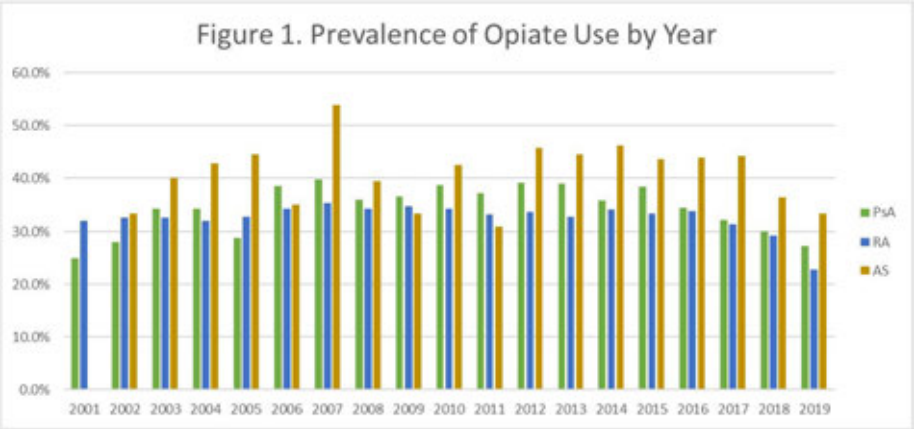
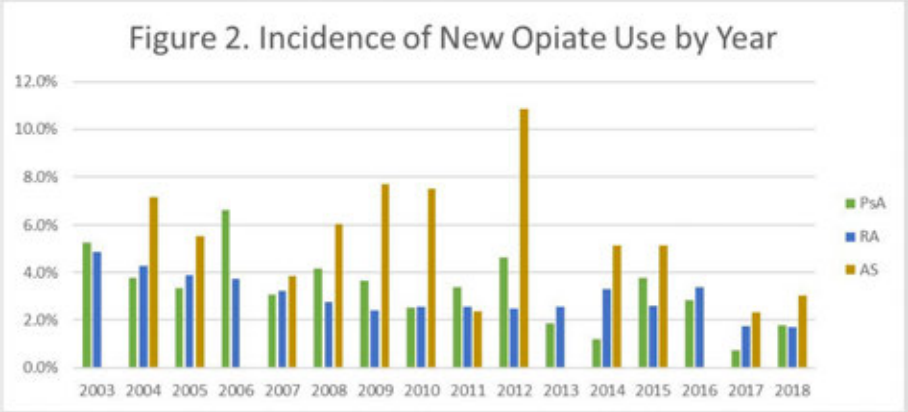
PROMIS 29 Physical T-Score	40.8 (9.4)	42.4 (9.1)	41.3 (8.2)	NS

*PROMIS T-scores increase with more of the concept being measured (i.e., more fatigue results in a higher T-score).





survey time point, more patients with AS reported taking an opioid pain medication. In most years, patients with AS were more likely to be taking opioid pain medications and this was statistically significant overall (p=0.01). AS patients also had a higher incidence of new opioid use. In general, for all three diseases, new opiate use has been declining over the past 3 years.

Conclusion: In this study among patients with IA, statistically similar levels of pain, fatigue, sleep, depression and anxiety were reported though AS patients had numerically higher pain scores. Patients with AS received more opioid medications. However, in general, opioid use has been declining in the last three years.

Abstract Number: 0629

Gender Differences in Comorbidities and Treatment Utilization Among Ankylosing Spondylitis Patients Initiating a Biologic in a Real-World Setting

Anna Sheahan,[1] Maya Balamane,[1] Edward Lee,[2] and Robert Suruki[1], [1]UCB Pharma, Raleigh, NC, [2]UCB Pharma, Smyrna, GA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To identify opportunities to optimize treatment of AS, an understanding of the treatment approaches and patient characteristics is necessary. This study describes comorbidities, comedications, and biologic treatment patterns, including any gender differences, in AS patients initiating biologics in the real-world setting.

Methods: This retrospective observational study analyzed US commercial claims data (IBM® MarketScan®) from 2012–2017. AS patients newly initiating a biologic (1st claim [index date] and no claims for ≥1 year prior), ≥18 years old, with continuous enrollment in the 12-months preceding (baseline) and following (follow-up) the index date were identified. Diagnoses were based on ICD 9/10 codes. Persistence was defined as treatment with the index biologic with gaps of ≤90 days over 12 months. The following treatment outcomes were also assessed: 110% of the label-recommended dose for ≥30 days (above-label dosing), new biologic initiation within 90 days of discontinuing index biologic (switch), and index biologic cessation (>90 days with no treatment [non-switch discontinuation]). Patients were categorized based on the first event experienced.

Results: A total of 1,526 patients met the inclusion criteria. Women (n=668) were more likely than men (n=858) to have ≥1 claim at baseline for anxiety (17% vs 8%), depression (23% vs 10%), fatigue (29% vs 21%) and fibromyalgia (≥2 codes) (16% vs 6%). At baseline, women were more likely to have ≥1 claim for an opioid (59% vs 50%) or an NSAID (72% vs 67%) and to have claims for ≥2 different NSAIDs (33% vs 23%). The same trend was present in follow-up comparing women to men for opioids (69% vs 63%) and NSAIDs (75% vs 66%). The most common index biologics were adalimumab (52%) and etanercept (31%). Persistence of the index biologic at 12 months was 50% and was lower in women (43%) vs men (55%). The most frequent treatment outcome assessed was non-switch discontinuation (35%), followed by switching (16%) and above label dosing (16%). Among those who discontinued without switching, 14% restarted their index biologic within 6 months. Women were more likely to switch than men (20% vs 13%) and were less likely to be receiving a biologic (index or otherwise) at 12 months (71% vs 78%).

Conclusion: Index biologic treatment included primarily adalimumab and etanercept. The comorbidity and treatment exposures depict a more complex profile for women vs men, which may be important to consider when determining the best approach to disease management. Further real-world studies on treatment patterns are needed to understand factors leading to poor persistence and how best to optimize treatment.

Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a major source of pain, functional impairment, and reduced health-related quality of life (HRQoL) in spondyloarthritis (SpA) patients; however, limited information is available in the literature regarding the burden associated with enthesitis in this population. This retrospective cohort study assessed the burden associated with enthesitis among patients with peripheral SpA (known as psoriatic arthritis [PsA]) and axial SpA (axSpA) in the real world.

Methods: Data were taken from the Adelphi Spondyloarthritis Disease Specific Programme, which collected information from rheumatologists/dermatologists and their consulting axSpA and PsA patients across Europe, Asia-Pacific, United States, Latin America, and Middle East between 2015 and 2016. Bivariate descriptive analyses were

P values highlighted in bold indicate statistically significant results; 0.05 is used as the cut-off for significance. n indicates number of patients in the matched population for a given outcome.
Propensity score analyses matched patients on age, sex, current severity, region, advanced therapy status, body mass index, time since diagnosis, the Charlson Comorbidity Index and use of additional pain medication.
EQ-5D-3L: EuroQol five-dimensions three-level; MCS: Mental component score; PCS: Physical component score; PsA: Psoriatic arthritis; SF-36: Short-form-36; WPAI-GH: Work productivity and activity impairment – general health.

conducted to describe differences between patients with and without enthesitis, in terms of demographics, clinical characteristics, and humanistic and economic burden as measured by patient-reported pain, HRQoL (EuroQol five-dimensions three-level [EQ-5D-3L] and short-form [SF]-36), healthcare resource utilization (HCRU), and activity impairment (work productivity and activity impairment - general health [WPAI-GH]). Inclusion in the enthesitis group was based on physician reporting clinical enthesitis as one of the symptoms currently present in the patient. Propensity score matching analyses were conducted to compare differences in outcomes between enthesitis and without enthesitis groups, matching patients by demographic and clinical characteristics.

Results: The analysis included data for 5,660 axSpA (with enthesitis: 506 [9%]; without: 5154 [91%]) and 3,570 PsA (with enthesitis: 260 [7%]; without: 3310 [93%]) patients. Bivariate analysis showed a significantly higher proportion

of axSpA and PsA patients with enthesitis currently had severe disease and were more likely to require additional pain medications compared to those without enthesitis (Table 1). Patients with enthesitis experienced significantly higher levels of pain, worse HRQoL, greater activity impairment, with a higher number of specialist consultations in the last 12 months compared to those without enthesitis, in both axSpA and PsA subgroups (Table 1). After adjusting for confounding factors in propensity score analysis, burden in terms of pain, HRQoL, activity impairment, and HCRU was mostly significantly higher in patients with enthesitis vs those without in axSpA (Table 2). PsA patients with enthesitis experienced higher burden compared to those without enthesitis, although most differences were not statistically significant, in part due to low sample size (Table 3).

Conclusion: Results from this multinational real world analysis demonstrate that axSpA and PsA patients with enthesitis experience more disease burden than patients without enthesitis. Treatment regimens with demonstrated efficacy on enthesitis should be considered to improve patient outcomes.

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

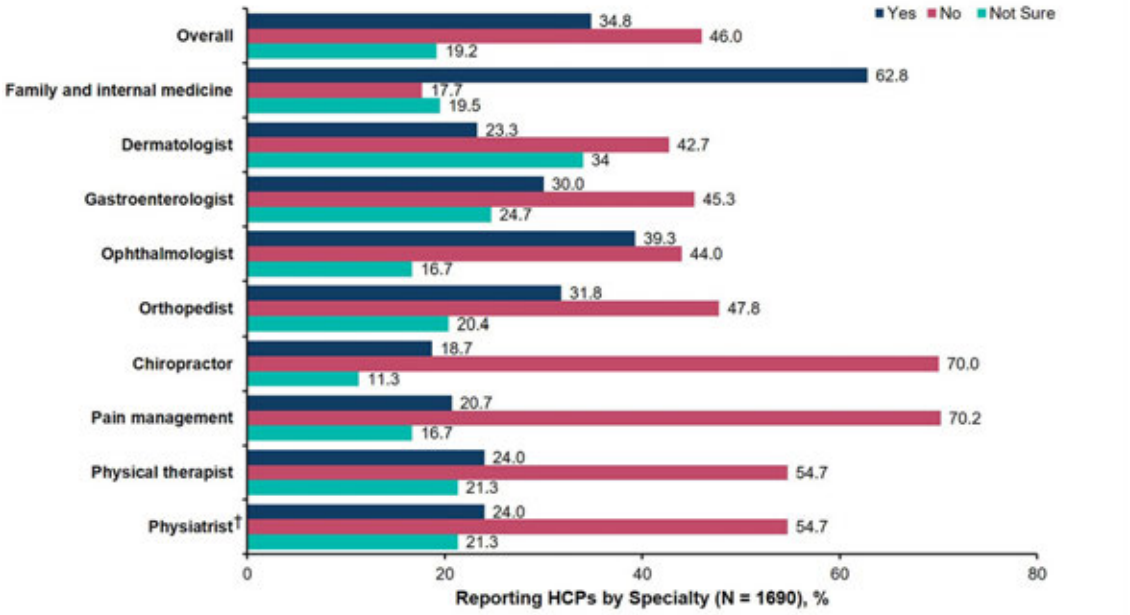
Session Time: 9:00AM–11:00AM

Background/Purpose: Early diagnosis of axial spondyloarthritis (axSpA) in the United States remains challenging due to the high prevalence and nonspecific presentation of chronic back pain treated by non-rheumatology health-care providers (HCPs). We aim to understand the patient referral and follow-up process and barriers to rheumatology referral among patients with putative inflammatory back pain (IBP) suggestive of axSpA.

Methods: Survey content was developed based on concept elicitation interviews with HCPs, and final questionnaires were generated to characterize their patient referral process. The survey was then cognitively tested with HCPs from 10 specialties (family medicine, internal medicine, dermatology, gastroenterology, ophthalmology, orthopedics, chiropractic, pain management, physical therapy, and physiatry), revised, and finalized. HCPs from these 10 specialties were invited to participate in the cross-sectional web-based survey hosted by Survey Sampling International between June 27 and July 20, 2018. HCPs who were currently licensed, actively practicing in the United States, and had referred a patient with suspected IBP (except ophthalmology) or uveitis/iritis (ophthalmology only) within the past 12 months were eligible to participate. Descriptive statistics were used to analyze the data.

Results: Of 2395 HCPs screened, 1690 were eligible and included in our study. Overall, HCPs saw a median of 100 patients with chronic back pain within the past 12 months. HCPs most frequently reported an average time of 3 to 4 months before a patient decided to see them (18.2%), whereas 17.1% reported 1 to 2 years. Overall, almost half of HCPs (46.0%) indicated that their patients had seen other specialists before consulting them; however, 62.8% of primary care HCPs (family and internal medicine) reported that they were the first HCPs seen by their patients (**Figure 1**). Once IBP was suspected, most HCPs (48.5%) would refer the patient after conducting a thorough evaluation, and

Figure 1. Proportion of Treating HCPs Indicating That They Were The First Provider Seen by Patients With Suspected IBP Suggestive of Rheumatic Disease*

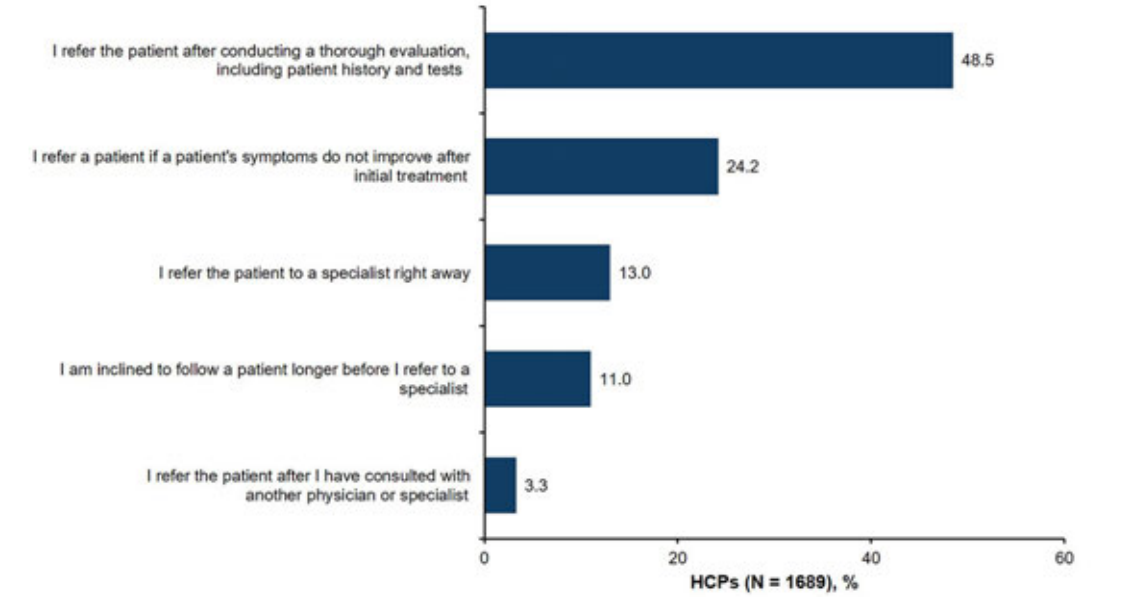


HCP, healthcare provider; IBP, inflammatory back pain.

* The phrase "inflammatory back pain" was used for all specialties except ophthalmology and chiropractic. Ophthalmologists were asked about patients with uveitis who may have "autoimmune rheumatic disease," and chiropractors were asked about patients who may have "inflammatory back pain or back pain due to underlying inflammatory conditions."

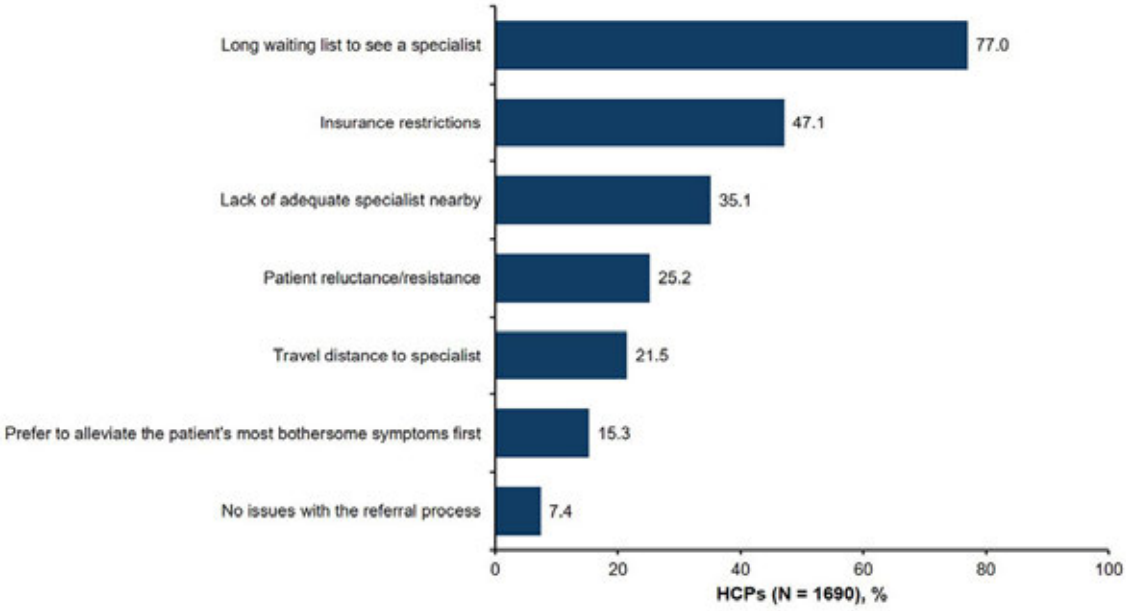
† Specialty category that includes physiatry, rehabilitation, and physical medicine.

Figure 2. Next Course of Action Taken by HCPs After Suspicion of IBP Suggestive of Rheumatic Disease*



HCP, healthcare provider; IBP, inflammatory back pain.
* The phrase "inflammatory back pain" was used for all specialties except ophthalmology and chiropractic. Ophthalmologists were asked about patients with uveitis who may have "autoimmune rheumatic disease," and chiropractors were asked about patients who may have "inflammatory back pain or back pain due to underlying inflammatory conditions."

Figure 3. Barriers Preventing Patients From Promptly Seeing A Specialist



HCP, healthcare provider.

13.0% would refer the patient to a specialist right away (**Figure 2**). Upon referral, 90.2% of HCPs estimated a wait time of up to 2 months for their patient to see a rheumatologist, 9.1% estimated a wait time of 3 to 6 months, and 0.7% estimated a wait time of 7 months to > 1 year; long waiting time (77.0%) and insurance restrictions (47.1%) were the primary reasons that may prevent patients from being able to see a specialist right away (**Figure 3**). Of 1607 HCPs queried, 61.9% ranked the specialist's expertise in treating autoimmune disease as the most important factor influencing their referral.

Conclusion: Nearly two-thirds of primary care HCPs reported that they were the first HCPs consulted by patients with suspected IBP, suggesting that targeted education of primary care HCPs may improve referral rates and yield a timely diagnosis of axSpA. Most HCPs (90.2%) estimated a wait time of up to 2 months for their patient to see a specialist after a referral was made and indicated that the specialist's expertise in autoimmune diseases is the most important factor influencing their referral.

An Observational Analysis of the Co-existence of Brugada Syndrome in Patients with Spondyloarthritis; A Potentially Important Link

Kunal Lall,[1] Robbie Ramsden,[2] Elijah R. Behr,[3] and **Virinderjit Sandhu** [2], [1]St.George's University Medical School, London, United Kingdom, [2]Department of Rheumatology, St.George's Hospital NHS Foundation Trust, London, United Kingdom, [3]Department of Cardiology, St.George's Hospital NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac involvement in Spondyloarthritis (SpA) has been recognised as an important determinant of increased comorbidity and mortality due to atherosclerosis, aortitis, aortic regurgitation and ventricular dysfunction. Cardiac conduction abnormalities are commonly noted and may occur prior to symptom onset.

One potential relationship that warrants further study is with Brugada Syndrome (BrS). This is a rare inherited cardiac disorder characterised by disturbances of the conduction system of the heart. The clinical presentation varies from being asymptomatic to syncope and sudden cardiac death (SCD) due to ventricular arrhythmias. BrS can be associated with mutations in the *SCN5A* gene in a fifth of cases, encoding the cardiac sodium channel alpha subunit leading to cardiac conduction defects.

Methods: A database search of patients diagnosed with BrS at one centre was performed. The diagnosis was made in line with international guidelines (1): the presence of a spontaneous or intravenous Ajmaline (class Ia antiarrhythmic) provoked type 1 or 'coved' electrographic (ECG) pattern with J point and ≥2mm concave ST elevation in at least one ECG lead V1/2 recorded from the 4^{th},3^{rd} and/or 2^{nd} intercostal spaces; J point and 'saddleback' ST elevation with a positive T wave in at least one ECG lead V1/2 recorded from the 4th, 3rd and/or 2nd intercostal spaces (type 2/3: depending on degree of J point and ST elevation) if converted to a type 1 through Ajmaline induction. Documented ventricular fibrillation (VF) or polymorphic ventricular tachycardia (VT), syncope, family history of premature SCD and/or type 1 Brugada pattern was supportive. A validated genetic screen was done. All patients who were also under Rheumatology were identified. An interrogation of their medical records was conducted to extract: demographics, diagnosis of SpA, as defined by the Assessment of SpondyloArthritis International Society (ASAS) criteria, other rheumatology diagnoses, and other co-variates.

Patient	Diagnosis	Disease Duration (years)	HLA-B27 status	EAMs*	Drug Therapy	Resting ECG pattern	Additional criteria
1	Axial SpA, peripheral involvement	8	positive	nil	ETA†	Type1	VF Cardiac arrest
2	Peripheral SpA	9	negative	nil	SSZ	Type 2/3	VF Syncope
3	Axial SpA, predominant peripheral involvement	10	negative	psoriasis	MTX	Type 2/3	Sibling death from SADS‡
4	Peripheral SpA	4	positive	psoriasis	MTX	Type 2	Family history SCD
5	Rheumatoid arthritis	13	Not applicable	nil	MTX SSZ	Type 2	Syncope
6	Supraspinatus tendonitis	1	Not applicable	nil	Nil	Type 1	Offspring confirmed BrS with ICD$, syncope

*Extra-articular manifestations† ETA Etanercept ‡Sudden arrhythmic death syndrome: unexplained SCD $ implantable cardiovertor-defibrillator

Results: Of the 600 patients diagnosed with BrS, n=6, were found to have attended Rheumatology. There were 4 females and 2 males with a mean age= 52.1 years (30-71).
The Table shows the main findings.
All patients demonstrated a Type 1 Brugada pattern during the provocation test or spontaneously. All had structurally normal hearts on echocardiography and cardiac MRI at diagnosis. None of the patients had the *SCN5A* mutation. Patients 1 and 2 had an ICD device fitted as a consequence. All were given preventative lifestyle advice in the form of avoidance of excess alcohol, illicit substances, arrhythmogenic drugs, treating fever promptly with anti-pyretics and keeping hydrated.

Conclusion: There appears to be a preponderance of patients with peripheral SpA who have BrS (0.67%) compared to expected Caucasian and SE Asian population frequencies of 0.05% and 0.2% respectively. Half of the cases were HLA-B27 positive. Aside from psoriasis, there were no other EAMs noted. Whether this reflects inflammatory activity or a genetic link is unclear. This analysis highlights a potential important relationship, which requires further study.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Spondyloarthritis (Spa) is an heterogeneous group of diseases. Diagnostic delay contributes to poor patient outcome. Prompt diagnosis of Spa is the first step towards optimal patient management. The aims of the study were to determinate if there were difference in diagnostic delay of Spa before 2010 vs 2010-2019 and to identify features associated with diagnostic delay more than twelve months.

Methods: Cross-sectional, analytical, multi-center study. Patients older than 18 years, fulfilling ASAS criteria were inclued. Socio-demographic and clinical features, comorbidities and treatments were recorded. Disease activity: patient´s global assessment (GA), physician´s GA; peripheral: joint count (SJC66/TJC68), enthesis evaluation (LEI) and DAS28; axial: BASDAI, ASDAS-ERS, SASDAS-ERS, functional assessment by BASFI. Disability by HAQ; Quality of life by ASQol and global health status by ASAS Health Index. Statistical analysis: descriptive statistics, Mann-Whitney or T-test for continuous variables and Fisher's exact test or Chi^2 for categorical ones, p 0.05 was considered significant. STATA 14.

Results: Two hundred one patients were inclued, 55.7% were males, mean age 48.8 years old (SD 14.3), median evolution time 65 months (IQR 24-132), median BMI 27.3 (IQR 22.7-35.8). More than half had peripheral involvement (53.73%). The 51.74% had enthesitis (*n* 101), 34.33% had dactylitis (*n* 69). Ninety-nine (49.5%) had psoriatic arthritis, 4.98% (*n* 10) inflammatory bowel disease and 13.93% (*n* 28) uveitis. Before 2010: diagnostic delay was longer than after 2010 [median 48 months (IQR 12-84) vs 12 months (IQR 4-24) *p 0.000*]. The greater diagnostic delay was associated to older patients [56 years old (IQR 42-64) vs 47 years old (34-56) *p 0.001*] and more of them loosed their job (*p: 0.001*). Diagnostic delay more than twelve months were associated with more prevalence of hypertension [39.3% vs 18.06% *p: 0.003*], loss of work [43.82 vs 23.61% *p*: 0.006] and use of biologics [58.43% vs 28.89% *p: 0.010*]. We did not find differences in disease activity, disability, quality of life or global health status by ASAS Health Index between both groups.

Conclusion: In recent years we have considerably improved the diagnosis delay of Spa. Even twelve months' delay was associated with loss of work, more comorbidities (hypertension) and greater use of biological treatments. ASAS criteria and the best knowledge of our diseases have contributed to this improvement.

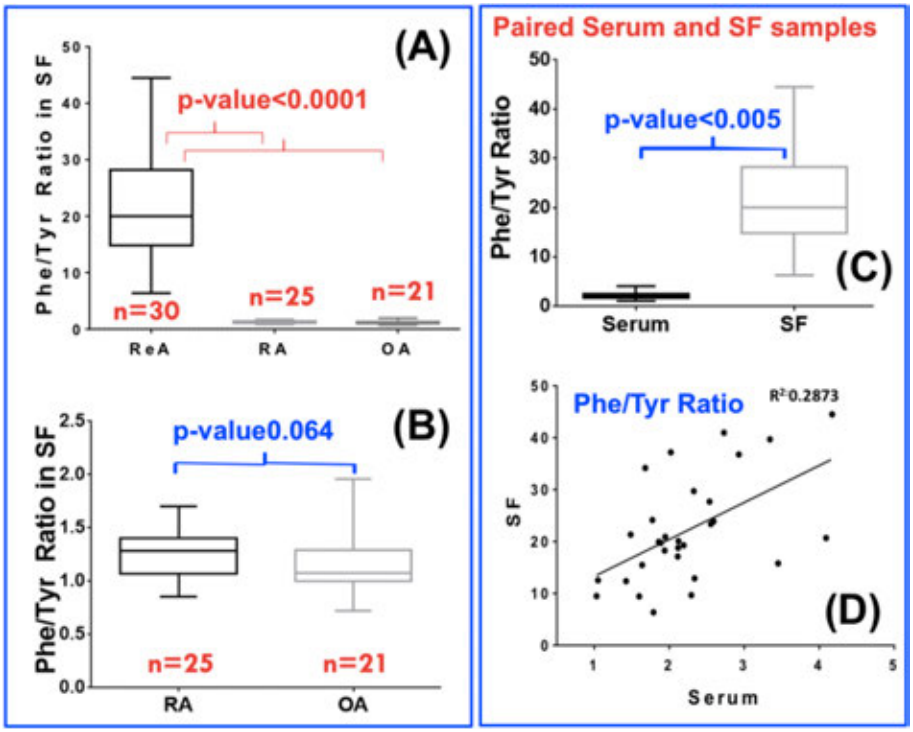
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated phenylalanine-to-tyrosine ratio (Phe/Tyr) is a marker of oxidative stress. We hypothesized that the synovial Phe/Tyr in reactive arthritis is higher than Rheumatoid arthritis(RA) and osteoarthritis(OA). We conducted this study with the objective to compare the synovial Phe/Tyr between ReA/uSpA and RA and OA by NMR spectroscopy

Methods: Paired synovial fluid and serum of 30 patients with ReA/uSpA were collected and analysed using a 1D ^{1}H CPMG NMR spectra recorded on 800 MHz NMR spectrometer equipped with a TCI Cryoprobe (at 300 k). Phenylala-



Synovial Phe/Tyr ratio was significantly higher in ReA/uSpA compared to RA and OA

nine and tyrosine were quantified. Synovial fluid from 25 patients with RA fulfilling ACR classification criteria and 21 patients with OA were taken as inflammatory and non-inflammatory controls.

Results: Synovial Phe/Tyr ratio was significantly higher in ReA/uSpA compared to RA and OA. Synovial Phe/Tyr ratios were comparable in RA and OA patients. Compared to serum, the Phe/Tyr was significantly higher in the SF in ReA/uSpA. The Phe/Tyr was also found to be positively correlated between serum and SF samples with regression coefficient (r^2) of 0.287.

Conclusion: NMR based metabolomics study demonstrates that the synovial Phe/Tyr are specifically elevated in ReA/uSpA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster I: Axial Spondyloarthritis, Clinical Features

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Our objectives are:

1. To analyze the prevalence of comorbidities related to CV risk in a register of patients with spondyloarthritis (CoSpaR).
2. To evaluate if there is an association between structural damage, the presence of atherosclerotic plaques, the endothelial function and the increased CV risk in patients with axSpA.

Methods: Eight-five patients with axSpA from the SpA registry from Cordoba (CoSpaR) were selected for a cross-sectional study. Patients were recruited in a probabilistic and sequential way from a SpA monographic ambulatory, and a complete clinical history, physical examination and a biochemical analysis were performed.

CV risk was evaluated by estimating the SCORE index and assessing the presence of atherosclerotic plaques through carotid ultrasound. The study of endothelial function was performed with laser doppler flowmetry, ana-

Baseline characteristics	Mean (SD) or N(%)
Age (years) (N=85)	44,55±12,22
Sex (males) (N=85)	59 (69,4)
HLA B27 (N=83)	71 (83,5)
axSpA (N=85)	79 (92,9)
Radiographic axSpA (N=77)	63 (74,1)
Psoriasis (N=84)	10 (11,8)
BMI (kg/m^2) (N=80)	26,88± 4,13
Disease duration (years) (N=82)	18,01±13,62
Smokers (N=84)	33 (38,8)
ASDAS-CRP	3,13 ±1,05
ASAS HI (N=82)	4,05 ±3,8
BASDAI (N=84)	3,48 ±2,17
CRP (mg/L) (N=80)	6,64 ±10,86
ESR (mm/h) (N=63)	8,49 ±9,22
Arterial hypertension	16 (18,8)
Diagnosis of hyperlipaemia (N=83)	13 (15,3)

Characteristics related to structural damage and CV risk	Mean (SD) or N(%)
Total mSASSS (N=79)	14,84 ± 18,4
Cervical mSASSS (N=79)	7,27 ± 9,64
Lumbar mSASSS (N=79)	7,72 ± 10,14
Glucose (mg/dL) (N=80)	84,02 ± 14,5
Total Cholesterol (mg/dL) (N=80)	187,84 ± 33,75
HDL-cholesterol (mg/dL) (N=79)	54,92 ± 15,54
LDL-cholesterol (mg/dL) (N=78)	111,96 ± 30,91
Tryglicerides (mg/dL) (N=80)	100,68 ± 65,85
Insuline (N=70)	6,1 ± 4,1
Diabetes Mellitus (N=84)	1 (1,2
Atherosclerotic carotid plaques (N=66)	14 (16,5)
Insuline resistance (N=85)	7 (3,4)
SCORE (N=78) • Low CV risk • Moderate CV risk • High CV risk • Very high CV risk	57 (67,1) 13 (15,3) 4 (4,7) 4 (4,7)

lyzing the response to reactive hyperemia, so as the increase in blood flow occurred after temporary occlusion of blood flow.

Data was collected and analyzed using SPSS v25 program. Independent-samples t test was used to evaluate the association between radiological characteristics and presence of atherosclerotic plaques. The linear lelationship between the variables has been measured by Pearson's linear correlation coefficient. Multiple lineal regression (MLR) was performed to assess the variables potentially associated with increased SCORE. All comparisons were bilateral considering $p \leq 0.05$ as a significant result.

Results: Baseline characteristics are shown in table 1.Characteristics related with radiographic damage and CV risk are shown in table 2. Direct linear relationship was found between the CV risk measured by SCORE index and total, lumbar and cervical mSASSS, and the presence of bone bridges. Analysis of atherosclerotic plaques at the carotid showed that age, disease duration, and variables related to radiographic damage (total mSASSS, cervical spine mSASSS, lumbar spine mSASSS, and bone bridges) were significantly higher in patients with atherosclerotic plaques($p< 0.05$). In addition, mSASSS in cervical spine ($p=0.063$) and age ($p< 0.0001$) were found to be associated with the SCORE index value and were predictors of increased CV risk in MLR analysis. Endothelial function (measured by Laser Doppler measurement of post ischemic reactive hyperemia) correlated inversely ($p< 0,05$) with total and lumbar mSASSS, as shown by the values of hyperemic area after occlusion was released.

Conclusion: The presence of atherosclerotic plaques in patients with axSpA is associated not only with age and disease duration, but also with the degree of radiographic damage present. Age and structural damage predicted the increased risk of CV disease observed in axSpA. Therefore, we have observed that older patients with axSpA and more structural damage, especially in the cervical spine, had a greater risk of CV disease. Endothelial disfunction is also found in patients with axSpA.

Penna", Buenos Aires, Argentina, [3]Hospital General de Agudos José M. Penna, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) develop irreversible organ damage as a consequence of disease activity, chronic inflammation, comorbidities and side effects of medications. Quantifying organ damage is relevant in their assessment. Damage is traditionally evaluated by the Systemic Lupus International Collaborating Clinics Damage Index (SLICC-SDI). Two patient-reported damage questionnaires have been validated: Lupus Damage Index Questionnaire (LDIQ) and Brief Index of Lupus Damage (BILD). BILD was developed from the LDIQ. The original English version has better correlation with SLICC-SDI than LDIQ.

Our aim was to perform validation and transcultural adaptation of the BILD questionnaire to Spanish.

Table 1. Correlation between BILD and SLICC-SDI, LupusQol, SLEDAI, patient and physician global VAS.

Variable	Spearman coefficient	P
SLICC SDI total	0.73	<0.001
SLICC SDI, ocular	0.71	<0.001
SLICC SDI, neurophsychiatric	0.85	<0.001
SLICC SDI, renal	0.72	<0.001
SLICC SDI, pulmonary	0.32	0.003
SLICC SDI, cardiovascular	0.40	0.002
SLICC SDI, peripheral vascular	0.45	<0.001
SLICC SDI, gastrointestinal	-0.02	0.804
SLICC SDI, musculoskeletal	0.58	<0.001
SLICC SDI, skin	0.18	0.094
SLICC SDI, premature gonadal failure	0.79	<0.001
SLICC SDI, diabetes	-	-
SLICC SDI, malignancy	1	<0.001
LupusQol total	-0.11	0.298
SLEDAI	0.12	0.271
Patient global VAS (n=49)	-0.01	0.924
Physician global VAS	0.22	0.036

Table 2. Comparison of demographics and clinical characteristics by BILD score cut-off points

BILD score	≤ 3 (n=70)	>3 (n=15)	p
Female sex, *n (%)*	63 (90)	13 (86.7)	0.70
Age, *years mean (SD)*	40.3 (10.8)	49.9 (14)	**0.004**
Disease duration, *years mean (SD)*	10.7 (7.8)	19.6 (9.6)	**0.001**
SLEDAI, *mean (SD)*	1.43 (2.6)	4 (4.6)	**0.004**
Lupus Qol, *mean (SD)*	87.13 (23.2)	89.8 (18.6)	0.67
Physician global VAS, *median (IQR)*	1.5 (0-3)	3 (1-6)	**0.005**
Patient global VAS, *median (IQR)*	2 (1-3)	3 (1-5)	0.22
Number of immunosupressors, *mean (SD)*	1.9 (1.3)	2.5 (1.7)	0.15
Charlson score, *median (IQR)*	1 (1-2)	3 (1-4)	**0.002**

Methods: The original BILD questionnaire in English was translated to Spanish independently by two bilingual physicians and a first intermediate Spanish version was produced. A back translation was performed and compared with the original BILD to assess conceptual equivalence and detect possible misunderstandings. On the basis of this comparison, a final Spanish version was created.

The BILD questionnaire was administered to 85 consecutive SLE patients from 2 Hospitals (one public and the other private). All patients fulfilled ACR 1997/ ACR-SLICC 2012 SLE criteria. Sociodemographic data, Charlson comorbid-

ity index, SLICC-SDI, SLEDAI score, global physician visual analogue scale (VAS) were obtained from each patient. Patients also completed the LupusQol questionnaire and global patient VAS.

We estimated the stability by a test retest method and a Spearman correlation coefficient. Internal consistency was evaluated with the Cronbach alpha coefficient. To evaluate criterion validity, a Spearman correlation coefficient was calculated for SLICC-SDI and BILD total scores and for item-by-item comparison. To asses construct validity we compared patients characteristics and disease variables in 2 cut off points of the BILD score.

The feasibility was obtained by taking into account the percentage of no answered questions and the time required to answer.

Results: We evaluated 85 patients, 89.4% female, mean age 42 years (SD 11.9) with mean disease duration of 12.3 years (SD 8.8). Eighty percent of patients had more than 12 years of education. Fifty-five patients were white, 20 Amerindian, 9 Mestizo y 1 Asian. The mean SLICC-SDI score was 1.14 (SD 1.44) and the mean BILD score was 1.48 (SD 1.84). The test retest method showed a strong correlation with a Spearman coefficient of 0.91 ($p < 0.001$). The Cronbach alpha coefficient was 0.66. The correlation between total scores of BILD and SLICC-SDI and each of its domains is shown in Table 1. Table 2 shows the construct validity analysis. In the multivariate analysis patients in the upper half of BILD scores were more likely to have longer disease duration and higher Charlson score. No incomplete answers were obtained and the mean time to answer was 4 minutes and 13 seconds (SD 1.92).

Conclusion: We demonstrated that the self-reported BILD questionnaire has a strong correlation with SLICC-SDI. In the item by item analysis we found that only the domains of gastrointestinal system and skin had a weak or none correlation with the corresponding SLICC-SDI items.

Abstract Number: 0637

How Often Should SLE Patients Be Tested for Lupus Anticoagulant?

Laurence Magder,[1] and Michelle Petri[2], [1]University of Maryland School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE patients with persistent lupus anticoagulant (LAC) have been observed to be at significantly higher risk of thrombosis. A common clinical definition of persistent LAC is to have two confirmed tests for LAC separated in time by at least 12 weeks. The likelihood of identifying a patient with LAC based on this definition depends on the frequency with which it is assessed. The purpose of this analysis is to determine the impact of frequent repeated testing of LAC on patient identification and clinical outcomes.

Methods: LAC was measured repeatedly in patients in a large American clinical cohort of prevalent and incident SLE patients. (51% Caucasian-American, 40% African American) . Patients were defined as LAC positive at a clinic visit if they had a dRVVT of 45 or more seconds, a mixing study, and then a positive confirmatory test. For 20% of the

Table 1. Rates of thromboses in months classified by whether the patient was classified as having LAC based on 5 previous measures, or on all previous measures of LAC

Subgroups of Months	Number of thromboses[1] observed	Rate per 1000 person-months (95% CI)	P-value[2]
No prior persistent LAC	140	1.3 (1.1, 1.6)	
Prior persistent LAC based on first 5 tests.	34	2.5 (1.5, 3.5)	0.018
Prior persistent LAC based on all prior LAC assessments but not classified as positive based only on the first 5 tests	14	1.8 (0.5, 3.1)	0.46

[1] Thromboses were clinical diagnoses of stroke, myocardial infarction, other arterial thromboses, deep venous thromboses, or other venous thromboses.
[2] P-value compares rates to those months with No Prior persistent LAC.

patients, the confirmatory test was missing and these values were imputed using multiple imputation based largely on the value of dRVVT. Persistent lupus anticoagulant was defined as having two consecutive visits with confirmed lupus anticoagulant separated by at least 12 weeks. We determined the number of patients who would be identified as having persistent LAC under two scenarios: 1) if only 5 LAC assessments were made, or 2) if multiple repeated assessments were made. In addition, we determined whether those identified with persistent LAC based on multiple repeat assessments but who were not identified based on only 5 assessments were at increased risk of thrombosis. This was based on discrete survival analysis including followup that occurred after at least 5 LAC assessments was included.

Results: The analysis was based on 36,218 clinical tests of LAC from 1457 different patients who had at least 5 LAC tests. The number of tests per patient ranged from 5 to 74 with a mean of 25. Based on only the first 5 tests per patient, the prevalence of persistent LAC was 11.7%. Based on all the LAC tests, the prevalence of persistent LAC was found to be 15.8%. Table 1 shows the rates of thrombosis in months defined by LAC classification based on all prior tests. In those months that were not preceded by persistent LAC the rate of thrombosis was 1.3 per 1000 person-months. In those months that were preceded by a diagnosis of LAC based on the patient's first 5 LAC tests, the rate of thrombosis was 2.5 per 1000 person-months (p=0.018 relative to months without LAC). In those months that were not classified as having prior persistent LAC based on the patient's first 5 LAC tests, but were classified as having persistent LAC based on all prior LAC tests, the rate of thrombosis was 1.8 per 1000 person months (p=0.46 relative to months without LAC).

Conclusion: 26% of those with persistent LAC are missed if LAC assessment is based only on the first 5 LAC tests. However, those classified as having LAC based on their first 5 tests are at highest risk of thrombosis. This information can inform decision-making related to frequency of LAC testing.

Longitudinal Trends for Estimated Glomerular Filtration Rate and Predictors of Change in Patients with Systemic Lupus Erythematosus

Terry Cheuk Fung Yip,[1] Michelle Petri,[2] and **Laurence Magder**[3], [1]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong, Hong Kong, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To characterize the longitudinal trajectory of estimated glomerular filtration rate (eGFR) in patients with systemic lupus erythematosus (SLE) and identify predictors of change in eGFR trajectory.

Methods: All patients with SLE who participated in a large American Lupus Cohort in or after year 2006 were identified. Patients were followed until death, diagnosis of end-stage renal disease or renal failure, or the last follow-up date, whichever came first. The longitudinal eGFR level of patients were modelled by piecewise linear regression. We evaluated the slope of different line segments. The slopes were classified into declining (≤ -4 mL/min/1.73 m^2 per year), stable (-4 to 4 mL/min/1.73 m^2 per year), and increasing (≥4 mL/min/1.73 m^2 per year) states of eGFR. The transition rate between states and the impact of clinical parameters on transition rate were estimated using Proportional Hazards modeling.

Results: We identified 494 SLE patients with 15,329 clinical visits over time. Two hundred and sixty-one (52.8%) patients were between 40 and 59 years old at the first clinical visit (baseline); 183 (37.0%) were younger than 40 years old; 50 (10.1%) were at or above 60 years old at baseline; 455 (92.1%) patients were female; 267 (54.0%) patients were Caucasian; 185 (37.4%) patients were African American. Their mean SLE disease activity index was 2.7 ± 3.4

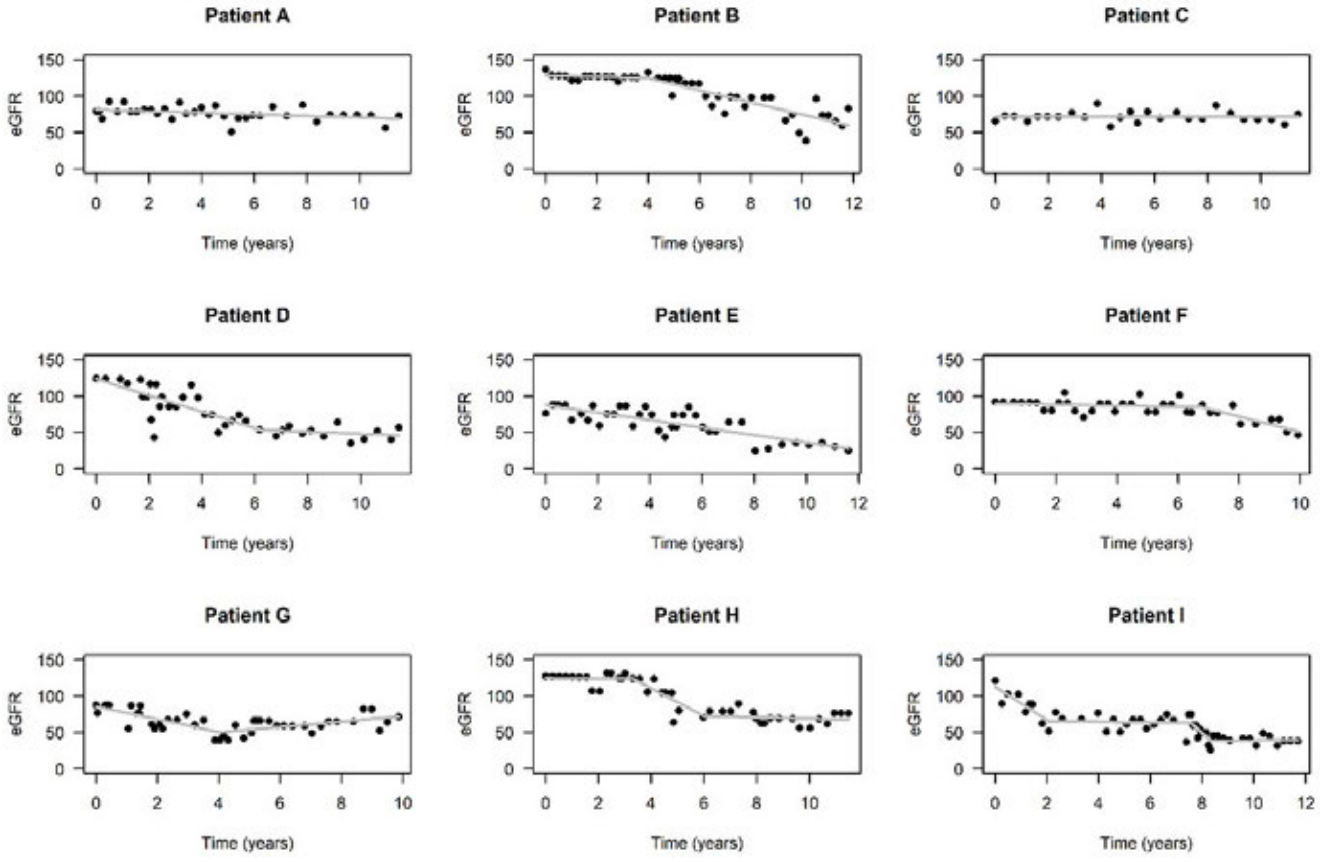

Figure 1. eGFR trajectory of selected patients (Gray line represents the estimated trajectory by piecewise linear regression. Black dot represents the eGFR of the patient in each visit).

Table 1. Univariate and multivariable predictiors of transition from non-declining state to declining state.

Parameters	Univariate analysis		Multivariable analysis	
	Hazard ratio (95% CI)	*P* value	Adjusted hazard ratio (95% CI)	*P* value

High systolic blood pressure [a]	0.72 (0.43 – 1.22)	0.221	0.68 (0.40 – 1.17)	0.167
High urine protein-to-creatinine ratio [b]	0.85 (0.43 – 1.69)	0.647	0.70 (0.33 – 1.52)	0.368
Detectable anti-dsDNA	0.92 (0.57 – 1.47)	0.717	1.21 (0.71 – 2.07)	0.486
SLEDAI without renal variables	0.95 (0.86 – 1.04)	0.246	0.97 (0.86 – 1.10)	0.672
Low complement component 3	0.95 (0.57 – 1.58)	0.836	0.94 (0.51 – 1.75)	0.851
Low complement component 4	0.93 (0.52 – 1.67)	0.810	1.11 (0.55 – 2.23)	0.772
Low hematocrit [c]	1.30 (0.87 – 1.93)	0.206	1.54 (0.98 – 2.41)	0.061
Use of prednisone	1.55 (1.04 – 2.32)	0.032	1.61 (1.04 – 2.49)	0.032
Use of hydroxychloroquine	0.88 (0.51 – 1.50)	0.631	0.85 (0.49 – 1.49)	0.575
Use of antihypertensive drugs	1.82 (1.10 – 3.00)	0.020	1.37 (0.81 – 2.32)	0.234

[a] High systolic blood pressure was defined as systolic blood pressure ≥140 mmHg.
[b] High urine protein-to-creatinine ratio was defined as urine protein-to-creatinine ratio >0.5.
[c] Low hematocrit was defined as <41% for males and <36% for females.
anti-dsDNA = anti-double stranded DNA, CI = confidence interval, eGFR=estimated glomerular filtration rate, SLEDAI=systemic lupus erythematosus disease activity index.

at baseline. Three hundred and eight (62.3%) patients had an eGFR ≥90 mL/min/1.73 m2 at baseline; 152 (30.8%) had an eGFR between 60 and 89 mL/min/1.73 m2 at baseline; 34 (6.9%) had a baseline eGFR < 60 mL/min/1.73 m2. The eGFR trajectory of selected patients is shown in Figure 1. Of all patients, 34.4% experienced a declining state at some point in their follow-up. In patients with one transition, 43 (40.2%) changed from declining to stable state while 29 (27.1%) changed from stable to declining state. High blood pressure, low C4 and low hematocrit were associated with change from non-declining to declining state (Table 1). High urine protein-to-creatinine ratio also tended to be associated with change from non-declining to declining state. African American patients were less likely to move from declining to non-declining state. Use of prednisone was associated with change from declining to non-declining state (Table 2).

Conclusion: A declining eGFR trajectory is common in SLE patients. High blood pressure and urine protein-to-creatinine ratio, and low C4 and hematocrit are risk factors for transition from stable to declining GFR. Use of prednisone may attenuate the declining eGFR. These findings can help clinicians anticipate changes in GFR trajectory.

Table 2. Univariate and multivariable predictiors of transition from declining to non-declining state.

Abstract Number: 0639

African-American Risk of Proteinuria After SLE Diagnosis Increases Throughout Thirty Years of Followup

Michelle Petri,[1] and Jessica Li[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: African-Americans lupus nephritis is more common than in Caucasians, more severe and more likely to lead to end stage renal disease. We asked whether the difference in frequency was just at the time of SLE diagnosis.

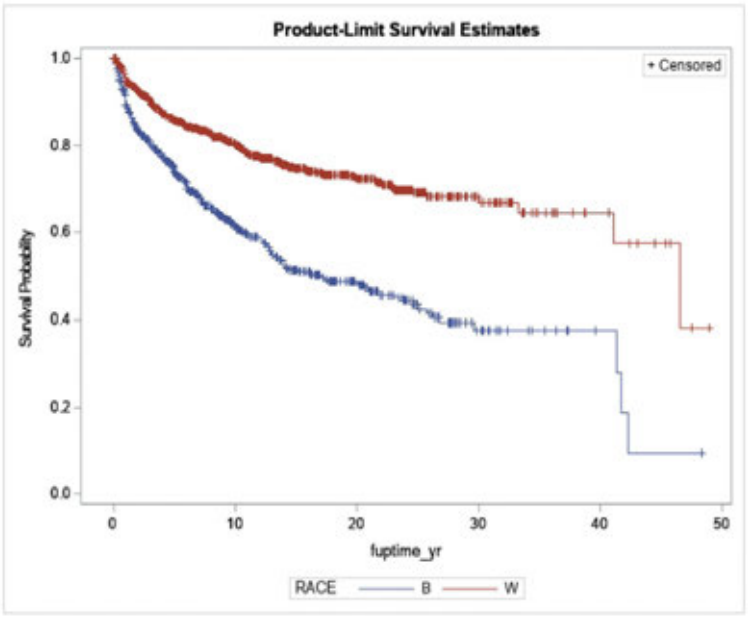

Figure 1 - Time to First Proteinuria for African-Americans (B) and Caucasians (W)

Table 1 - Risk of proteinuria after SLE diagnosis

	Risk of proteinuria after SLE diagnosis (95% CI)[1]		p-value[2]
Risk within:	African American	Caucasian	<0.0001
½ year	4.9% (3.5%, 6.8%)	1.6% (1%, 2.6%)	
1 year	10.5% (8.4%, 13%)	5.4% (4.2%, 6.9%)	
2 years	16.3% (13.8%, 19.3%)	7.6% (6.1%, 9.3%)	
5 years	25.9% (22.7%, 29.4%)	14.3% (12.3%, 16.6%)	
10 years	38.3% (34.5%, 42.4%)	19.6% (17.1%, 22.3%)	
20 years	51.7% (47.2%, 56.4%)	27.4% (24.2%, 30.9%)	
30 years	62.4% (55.7%, 69.2%)	33.1% (28.3%, 38.5%)	
[1] based on Kaplan Meier estimates [2]based on log rank test comparing African American and Caucasian			

Table 2 - Hazard Ratio for Proteinuria After Diagnosis – African-American vs Caucasian

	Unadjusted		Adjusted[1]	
	HR (95% CI)	p-value	HR (95% CI)	p-value
African American	2.19 (1.91, 2.52)	<0.0001	2.14 (1.86, 2.46)	<0.0001
Caucasian	Ref group		Ref group	
[1]adjusted for gender and age at diagnosis				

Methods: 1849 SLE patients were included in this analysis. The patients were 93% female, 39.3% African-American and 60.7% Caucasian. 478 patients (27.2%, 271/997 African-American and 15.6%, 207/1330 Caucasian) who had proteinuria before or at the date of diagnosis (± 1 month) were excluded.

Results: The Kaplan-Meier curve of time to first proteinuria (in those without proteinuria at diagnosis) is shown in Figure 1. The separation between African-Americans and Caucasians starts almost immediately after diagnosis and continues to widen until year 30. Although it appears to level off at year 30, that is likely due to smaller numbers remaining in the cohort. Table 1 shows the estimated risk of proteinuria after diagnosis. The estimated probability of having proteinuria within 5 year is 26% for African-American patients and 14% for Caucasian patients. Risk accumulates even 5 years after diagnosis. Table 2 shows the hazard ratio for proteinuria after diagnosis. The risk of proteinuria is 2.19 times higher among African-American patients compared to Caucasians in the unadjusted model.

After adjustment for age at diagnosis and gender, the risk remains 2.14 higher for African-Americans compared to Caucasians.

Conclusion: The increased risk of lupus nephritis in African-Americans is not limited to diagnosis or even to the first five years after diagnosis. Increased risk is present through 30 years after diagnosis. As these data also show continued risk in Caucasians, monitoring the urine protein/cr at every follow up visit is recommended for all SLE patients.

Elevated Serum Interleukin-23 Level in Patients with Systemic Lupus Erythematosus Is Associated with Disease Activity, Clinical and Immunological Markers

Milena Vukelic,[1] Anita Laloo,[2] and Vasileios Kyttaris[3], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Rheumatology Practice, Fort Lauderdale, FL, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a autoimmune disease characterized by deregulated cytokine production. IL-23 bridges innate and adaptive immunity by inducing the differentiation of T cells into pro-inflammatory Th17. We have previously shown that IL-23 is upregulated in SLE patients and lupus prone mice. Besides inducing the generation of Th1, we found that in lupus, IL-23 promotes the generation of T follicular helper cells (Tfh) and inhibits regulatory T cells, thus increasing production of anti-dsDNA antibodies. Aim of this study was to evaluate IL-23 levels and its association with various clinical and laboratory parameters of SLE.

Methods: Serum IL-23 was measured in 56 SLE patients by ELISA (54 females and 2 males; age:42±12years; racial distribution:43% white, 28% African-American,20% Asian, 8% other). Institutional IRB approved the study. Disease activity was measured by SLEDAI (0-34; mean±sem= 6.71±1.02). 55% of patients were on prednisone at a mean dose of 11.09 mg (1–60). Other medications included hydroxychloroquine (67%), mycophenolate mofetil (34%), azathioprine (10%). Two patients were on IV cyclophosphamide, 3 on belimumab, 1 on tacrolimus, 1 on tocilizumab. STATA was used for statistical analyses: non-paired t-test and Pearson's correlation. Multiple linear regression analysis was used to analyze the effect of SLEDAI and medications on IL-23 expression.

Results: IL-23 levels in the serum of SLE patients were significantly higher in patients with active disease as measured by the SLEDAI (r=0.4363, p=0.0008). Correlation persisted even when we excluded the dsDNA and complement components from the SLEDAI, defined as clinical SLEDAI (r=0.3752, p=0.0044). Serum IL-23 was strongly correlated with skin (r=0.2853; p=0.03), renal (r=0.2928; p=0.0286) domains of SLEDAI and arthritis (p=0.03).There was no correlation with neurological manifestations or presence of serositis. IL-23 levels had significant positive correlation with anti-dsDNA (p=0.005) and negative with complement C3 (p=0.0003). We found no relationship between patients' demographics, prior disease manifestations or other autoantibody profile or cytopenias. Of note, SSA+ patients had a non-statistically significant trend for higher IL-23 levels than SSA- patients (p=0.065). Multivariate regression analysis

was used to account for potential confounding effect of medications on the correlation of SLEDAI and IL-23 levels. We found that IL-23 levels strongly correlate with SLEDAI after controlling for dose and type of medications including prednisone dose ($p< 0.001$).

Conclusion: In this cross-sectional analysis of SLE patients we found that IL-23 levels track disease activity and correlate with renal, skin and musculoskeletal manifestations but not with cytopenias or serositis. This is in line with murine data where blocking IL-23 ameliorated both kidney and skin disease. No immunomodulatory medication seems to be affecting IL-23 levels suggesting that current medications used in SLE are not as effective in shutting down the IL-23/IL-17 axis. Furthermore, our data suggest that IL-23 inhibitors may be helpful not only in non-renal SLE, where they are currently being tested, but also in lupus nephritis.

Abstract Number: 0641

A Novel Method to Analyze Circulating Immune Complexes Predicts Disease Activity and Severity in Systemic Lupus Erythematosus and Rheumatoid Arthritis

Anders Bengtsson,[1] Helena Tyden,[1] Tiffany Pan,[2] J. Lee Nelson,[3] and **Christian Lood** [2,1]Lund University, Lund, Sweden, [2]University of Washington, Seattle, [3]Fred Hutchinson Cancer Research Center, Seattle

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Circulating immune complexes (IC) are detectable in a variety of systemic inflammatory diseases, including rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE), reflecting the autoimmune process, e.g. autoantibodies binding to self-antigens. ICs are main contributors to the disease pathogenesis through engaging FcgR-bearing cells, as well as activating the complement system, mediating inflammation and organ damage, including erosion and nephritis. The main aim of the current study was to explore the clinical utility of analyzing levels of circulating ICs in patients with rheumatic diseases using a novel flow cytometry-based assay developed in our lab.

Methods: Levels of ICs were analyzed by an in-house flow cytometry-based method, analyzing IC binding to FcgRI-IA. Three cross-sectional SLE cohorts (n=92-142), one cross-sectional RA cohort (n=247), and healthy controls (n=100), were analyzed. To determine the capacity of ICs to predict disease flare in SLE, a forth, longitudinal SLE cohort (n=47) was recruited at time-point of low disease activity and followed over three months, with 14 patients remaining in remission, and 33 patients developing worsening of disease. A longitudinal inception RA cohort (n=247), seen for a follow-up a median of 8 years later, was used for predictive analyses. Type I interferon (IFN) activity was analyzed using a cell reporter system (WISH).

Results: Levels of ICs were elevated in SLE as compared to healthy controls ($p< 0.0001$). Whereas only 5% of the healthy controls had elevated levels of ICs, 61% of the SLE patients were positive for ICs, reaching more than 80% in patients with active disease. In contrast, anti-dsDNA antibodies, commonly used to monitor disease activity, were

only detectable in 14% of the patients at time-point of blood draw. Though anti-dsDNA antibodies were associated with active disease (OR=3.5, p< 0.0001), dual positivity for both anti-dsDNA antibodies and ICs further strengthened the association with active disease (OR=5.9., p< 0.0001). Levels of ICs reflected active disease as determined by SLEDAI (r=0.45, p< 0.0001), and were associated with ongoing type I IFN activity (r=0.25, p=0.003), complement activation (r=0.53, p< 0.0001) and active lupus nephritis (p=0.02). Levels of ICs were elevated in patients with a history of nephritis (p=0.002) and anti-dsDNA antibodies (p< 0.0001). In the longitudinal setting, baseline levels of ICs, at time-point of quiescent disease, could predict worsening of disease within three months (OR=4.4, p=0.03). Levels of ICs were elevated also in RA patients (p< 0.0001), though the frequency of patients having circulating ICs was lower as compared to SLE patients (21.7%). Importantly, RA patients with elevated levels of ICs at baseline identified patients developing a severe and erosive disease with joint space narrowing (p< 0.05).

Conclusion: ICs are instrumental in RA and SLE pathogenesis. Analyzing IC levels may facilitate monitoring of disease activity, as well as identify patients at risk of developing flare and/or severe disease, including erosion and nephritis, allowing for early preventive interventions.

Complement Deposition C4d on Platelets Is Associated with Vascular Events in Systemic Lupus Erythematosus

Elisabet Svenungsson,[1] Johanna Gustavsson,[2] Giorgia Grosso,[2] Iva Gunnarsson,[2] Bo Nilsson,[3] Anders Larsson,[3] Anders Bengtsson,[4] and **Christian Lood**[5], [1]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Stockholm, Sweden, [2]Karolinska Institutet, Stockholm, Sweden, [3]Uppsala University, Uppsala, Sweden, [4]Lund University, Lund, Sweden, [5]University of Washington, Seattle

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Complement components, including C4d, can be detected on the surface of activated platelets and they have been associated with vascular disease in systemic lupus erythematosus (SLE). In the current study, we investigate whether platelet C4d (PC4d) adds additional value to traditional and known SLE-associated risk factors when identifying SLE patients with vascular disease.

Methods: We included 308 well-characterized SLE patients and 308 matched population controls in a cross-sectional design. Traditional risk factors including age, gender, smoking, hypertension and lupus associated risk factors aPL and glomerular filtration rate measured by MDRD formula were tabulated. PC4d deposition was analyzed using flow cytometry. Values >95% of controls were considered as PC4d positivity (+). Antiphospholipid antibodies (aPL) were determined by Luminex, and the lupus anticoagulant (LA) test was performed by a Dilute Russel Viper Venom Time method.

Results: SLE patients had increased PC4d deposition as compared to population controls (p< 0.0001). 50.3% of SLE patients were PC4d+. In SLE patients, PC4d+ associated with previous vascular events (AVE), specifically with venous and cerebrovascular, but not with ischemic heart events. PC4d was also associated with all investigated aPL

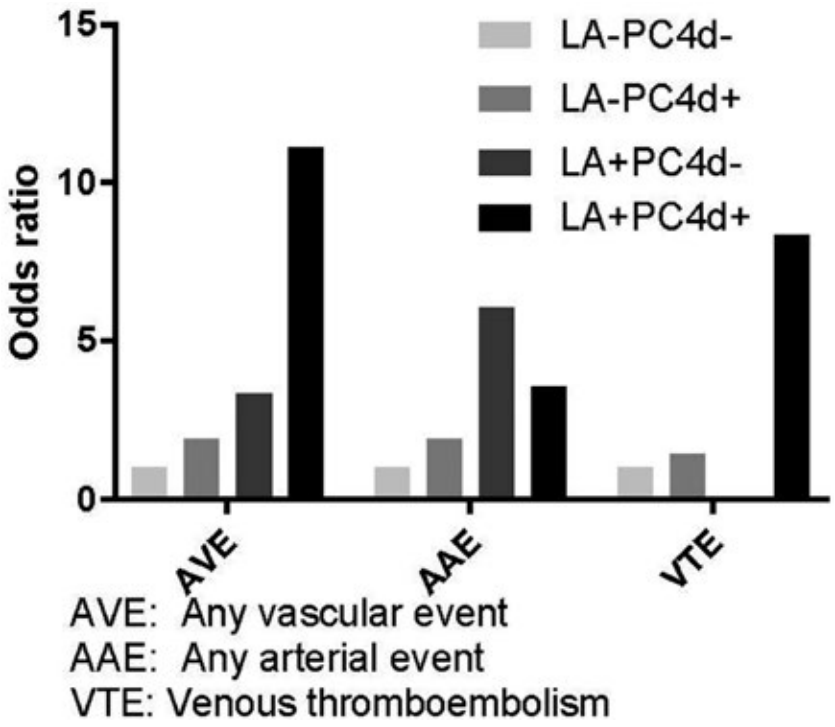

Figure 1. Interaction analysis between lupus anticoagulant and PC4d

Table 1. Multivariable logistic regression model for PC4d and vascular event

Multivariable logistic regression model for Any Vascular Event N=87

	OR	95% CI	P-value
Age/10 years	1.4	1.1-1.8	0.003
Gender female	0.8	0.5-1.4	0.51
Hypertension	1.5	0.8-2.8	0.51
Smoking	1.1	0.5-2.3	0.82
Glomerular filtration rate (MDRD) mL/min	0.9	0.8-1.1	0.24
LA (positive)	4.5	2.1-9.4	<0.0001
PC4d (positivity)	2.4	1.3-4.6	0.006

profiles and the anti-phospholipid syndrome (APS, p< 0.0001). After adjustment for traditional and SLE-associated risk factors that were associated with any vascular event in uni-variable analyses, previous vascular events remained associated with PC4d+ (OR:2.4, 95% CI 1.3-4.5, p=0.006, table). There was furthermore a positive interaction between PC4d+ and LA+ regarding any vascular events (OR:11.1, 95% 5.1-24.3, p< 0.0001, Figure 1) versus patients negative for both PC4d and LA.

Conclusion: PC4d+ is associated with vascular events in SLE, independently of traditional and SLE-associated risk factors. The combination of PC4d+ and LA+ interacted positively and increased the association with vascular events even further. If measurement of both aPL and PC4d can predict vascular events in patients with SLE and/or APS should be evaluated in prospective studies.

Abstract Number: 0643

Association Between Neutrophil to Lymphocyte, Monocyte to Lymphocyte, and Platelet to Lymphocyte Ratios and Lupus Disease Activity and Lupus Nephritis

Philip Carlucci,[1] Elliot Luttrell-Williams,[1] Rohit Bhan,[1] Catherine Trad,[1] Hanane El Bannoudi,[1] Peter Izmirly,[1] H. Michael Belmont,[2] Jill Buyon,[3] and Jeffrey Berger[1], [1]New York University School of Medicine, New York, [2]New York University School of Medicine, Ney York, [3]New York University School of Medicine, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Subjects with Systemic Lupus Erythematosus (SLE) are at elevated risk for end-organ damage. Lupus nephritis continues to be the complication with the highest standardized mortality ratio in SLE, yet clinicians have few tools to identify patients at risk. A complete blood count is a readily available test but little is known about its usefulness in tracking lupus nephritis and activity. In recent years, neutrophil/lymphocyte (NLR), monocyte/lymphocyte (MLR), and platelet/lymphocyte (PLR) ratios have emerged as markers of systemic inflammation. This study sought to evaluate the association between NLR, MLR, and PLR and its individual components and lupus disease activity and lupus nephritis.

Methods: 25 matched healthy controls and 85 patients fulfilling ACR or SLICC criteria for SLE were enrolled in the study and demographics, disease activity, as measured by the Hybrid SLEDAI, medications, and clinical manifestations were recorded. 20 lupus patients included in the study had active lupus nephritis, as defined by proteinuria greater than 500 mg/g creatinine. A complete blood cell count was assessed on all patients and healthy controls. Patients with platelet counts less than 100K or on nonsteroidal anti-inflammatory drugs were excluded from the study.

Results: Overall, SLE patients had a significantly higher PLR (p=0.0001), NLR (p=0.0003), and MLR (p=0.0035) compared to healthy controls. Lymphocyte counts alone negatively associated with SLEDAI (beta=-0.31, p=0.006) but monocyte, neutrophil, or platelet counts did not show a significant association with SLEDAI. All three ratios showed a significant positive association with SLEDAI in linear regression analysis with PLR being a better predictor than lymphocyte counts alone (beta=0.38, p< 0.0001). The associations between PLR or MLR but not NLR and SLEDAI remained significant in a multivariate linear regression model adjusting for age, race, sex, ethnicity, and medications. Specifically, the dose of glucocorticoids did not explain the clinical associations with these cellular ratios. When evaluating active lupus nephritis, PLR (p=0.118) was not significant in a logistic regression and NLR (p=0.007) and MLR (p=0.007) performed equally well. These associations between NLR or MLR and active lupus nephritis persisted in a multivariate logistic regression model adjusting for age, race, sex, ethnicity, and medications. Interestingly, lymphocyte, monocyte, neutrophil, or platelet counts alone did not associate with active lupus nephritis.

Conclusion: These data suggest that by using standard clinical labs to calculate NLR, MLR, and PLR clinicians may be able to better characterize lupus activity and current lupus nephritis.

Decreased HVEM Expression in Lupus Patients and Impact of HVEM Knockout Mouse Model of Lupus Suggest a Role for BTLA Signaling in Disease Pathogenesis

Andrew Vendel,[1] Kimberly Griffiths,[1] Antje Rhode-Kurnow,[2] Eve Merriman,[1] Mark Daniels,[1] William Chang,[1] and Carl Ware[2], [1]Lilly Biotechnology Center, San Diego, CA, [2]Sanford Burnham Prebys Medical Research Institute, La Jolla, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: B and T Lymphocyte Attenuator (BTLA; CD272) is an Ig superfamily member and part of a family of checkpoint receptors that negatively regulate immune cell activation. BTLA is primarily expressed on B cells, T cells, and dendritic cells with highest expression on B and plasmacytoid dendritic cells, followed by CD4+ T cells, then lowest expression on myeloid dendritic cells, gamma-delta (gd) and CD8+ T cells (Murphy & Murphy, 2010). The natural ligand for BTLA is the TNF receptor superfamily member, herpes virus entry mediator (HVEM; TNFRSF14) and binding of HVEM to BTLA leads to attenuation of lymphocyte activation (Gonzalez, 2005). In this study we evaluated the role of BTLA and HVEM expression in the pathogenesis of SLE.

Methods: Healthy volunteer PBMCs were evaluated by mass cytometry (CyToF) to establish baseline expression of BTLA and HVEM on human lymphocytes and compared to SLE patient PBMCs (N=5) acquired by a vendor (SanguineBio) during self-reported flare. The role of BTLA signaling in a mouse model of lupus was examined using the BM12 lupus model where donor cells were transferred into the HVEM knockout or C57BL/6J control recipient mice (N=11 and 9, respectively).

Results: High levels of BTLA protein was observed on B cells, CD4+ T cells, CD8+ T cells and plasmacytoid dendritic cells in healthy control PBMCs. HVEM protein levels were lower in SLE patients compared to RA patients and healthy controls, while BTLA levels were similar between SLE and RA and controls. The BM12 lupus model does not generally present with significant kidney involvement. However, the HVEM recipient mice had increased prevalence of kidney disease (50%), as measured by albumin/creatinine ratio (ACR) greater than 300 mg/mg, compared to C57BL/6J control mice (22%).

Conclusion: These studies confirmed that BTLA protein is present on key immune cells linked to the pathogenesis of SLE. Reduced HVEM protein expression in SLE patients in flare compared to RA and healthy donors indicate that SLE is associated with ligand deficiency in the BTLA system. Furthermore, in a preclinical model of lupus using HVEM knockout mice demonstrate that disrupting this signaling system exacerbates disease pathogenesis. These data provide clinical rationale for evaluating a BTLA agonist in SLE. A phase 1 trial with a BTLA agonist antibody in healthy volunteers is in progress.

Abstract Number: 0645

Association of Co-positivity for Anti-dsDNA, -Nucleosome, and -Histone Antibodies and Disease Activity in Patients with Lupus Nephritis: Results from the KORNET Registry

Seong-Eun Choi,[1] Dong-Jin Park,[1] Ji-Hyoun Kang,[1] Haimuzi Xu,[1] and Shin-Seok Lee[2], [1]Chonnam National University Medical School & Hospital, Gwangju, Republic of Korea, [2]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent studies have shown that the simultaneous positivity of anti-double stranded DNA, -nucleosome, and -histone antibodies (3-pos) is prevalent in lupus nephritis (LN) patients compared to non-renal systemic lupus erythematosus (SLE) patients. The aim of this study was to define the clinical, biologic, histopathologic, and prognostic differences according to the simultaneous reactivity to those antibodies in Korean patients with biopsy-proven LN.

Methods: We studied 102 patients who underwent kidney biopsy prior to the start of induction treatment and who were subsequently treated with immunosuppressives and followed-up for more than 12 months. Sociodemographic, clinical, laboratory, and treatment-related data at the time of kidney biopsy and during follow-up were obtained by a review of patients' charts. Antibodies were detected by immunoblot analysis or ELISA at the time of renal biopsy.

Results: Fifty-eight (35.4%) of the total of 102 LN patients had 3-pos. In comparison with non-3-pos patients, the patients with 3-pos showed a higher SLE Disease Activity Index-2000 score (P=0.002), lower lymphocyte level (p=0.004), higher proportion of proteinuria >3.5 g/24 hr (p=0.005), and higher positivity of urinary sediments (p=0.005) at the time of renal biopsy. In the renal histopathologic findings, the patients with 3-pos had more proliferative LN (p=0.015) and also showed more endocapillary hypercellularity, sub-endothelial hyaline deposits, fibrinoid necrosis/karyorrhexis, and cellular crescents in the disease activity index (p=0.016, p=0.045, p=0.002, and p=0.022, respectively), as well as a higher activity score (p=0.011). After a median follow-up of 83.2 months, rapid glomerular filtration rate decline was frequently observed in patients with 3-pos compared to those without (p=0.012).

Conclusion: Our findings suggest that 3-pos is related to severe LN and, furthermore, that patients with 3-pos show a rapid decline of renal function compared to those without.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-ribosomal P (Rib-P) antibodies have become known as a highly specific biomarker for the diagnosis of SLE and potentially a biomarker for neuropsychiatric SLE (NPSLE). However, despite comparable specificity in comparison to other SLE autoantibodies such as anti-Sm and anti-dsDNA, anti-Rib-P has not been included in classification criteria for SLE. One limitation has been the wide variation of immunoassays and antigenic targets used to detect anti-Rib-P. Furthermore, the definition of NPSLE encompasses a broad spectrum of neuropsychiatric symptoms. To clarify the clinical associations in SLE, we performed a systematic review and meta-analysis to compare the different anti-Ribo-P assay platforms, antigenic targets, and specific clinical features of SLE and NPSLE.

Methods: PubMed, EMBASE, and Web of Science databases were searched. Associations with clinical features of SLE with attention to specific neuropsychiatric symptoms, type of immunoassays and antigenic targets were extracted. Data were pooled using random effects methods. Associations were expressed as pooled odds ratio (OR) and forest plots to visualize the results.

Results: Our preliminary search identified 21 studies (n=3128) that reported a pooled OR of anti-Rib-P positivity in NPSLE of 2.36 (95% confidence interval (CI): 1.74-3.18) (Figure 1). When stratified by different symptoms of NPSLE, depression had the highest pooled OR of 3.77 (95% CI: 1.19-11.93), followed by psychosis (OR 3.33 (95% CI: 1.97-5.62)), and then central nervous system (CNS) involvement (OR 1.65 (95% CI: 1.11-2.45)) (Figure 2). There were 7 studies (n=1060) that reported a pooled OR for lupus nephritis (LN) of 1.61 (95%CI: 0.93-2.77) and 5 small studies (n=504) that reported a pooled OR for lupus hepatitis of 16.07 (95% CI: 4.30-60.08). Seven studies reported that anti-Rib-P was associated with increased disease activity, however, we were not able to pool the results because different disease activity scores were used (SLEDAI, ECLAM, SLEDAI 2K or MEX-SLEDAI) (Figure 3). There was significant heterogeneity between studies that was at least partly explained by heterogeneity in antigenic targets (C22 peptide, ribosomes, P0/P1/P2, tissue extract, and P individual) and assays (double diffusion, enzyme-linked immunosorbent assay, immunoblot, and/or dot blot) used for these studies.

Conclusion: The addition of anti-Rib-P may improve the specificity of SLE classification criteria in patients presenting with NPSLE symptoms. Anti-Rib-P was also found to be an important biomarker for lupus hepatitis and potentially disease activity. Heterogeneity between studies in this meta-analysis is explained by different assays and antigenic targets.

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: We reported that 7.7% (88/1137) of patients in an international inception cohort were ANA-negative at enrolment (*Arthritis Care Res 2018 doi:1002/acr23712*). There are no data on whether long-term outcomes or health care costs differ between ANA-negative versus ANA-positive patients. We compared damage accrual and costs between those who were ANA-negative versus ANA-positive at disease inception.

Methods: Patients fulfilling the revised ACR SLE Criteria from 33 centres in 11 countries were enrolled within 15 months of diagnosis. ANA at enrolment was detected by indirect immunofluorescence in a single laboratory; a positive ANA was defined as a titre ≥ 1/160. Data were collected annually on disease damage (SLICC/ACR Damage Index, SDI) and health care use (i.e., hospitalizations, medications, dialysis, and selected procedures) and supplemented by data on additional resource use and lost work-force/non-work-force productivity in a patient subset. Primary analyses included partial direct cost estimates based on the major health care components for the full sample. Estimates of complete direct and indirect costs were obtained by assuming that the ratios of total direct to partial direct costs and indirect to partial direct costs were the same for the full sample as for the subset. Health care use was costed using 2018 Canadian prices and lost productivity using Statistics Canada age-and-sex specific wages. The average annual rate of damage accrual and average annual costs over follow up were compared between patients who were ANA-negative versus ANA-positive at enrolment using multivariable regressions, adjusting for age and race/ethnicity.

Results: 1052 of the 1137 patients provided cost data and were included; 76/1052 (7.2%) were ANA-negative at enrolment (Table 1). ANA-negative versus ANA-positive patients were older, more likely to be of Caucasian race/ethnicity, and less likely to be on immunosuppressants or have SLE-associated autoantibodies. Mean follow up of the ANA-negative versus ANA-positive was similar (8.6 years (range 0.8 – 17.8) versus 9.6 years (range 0.6 – 18.5).

Table 1. Demographics and clinical characteristics of ANA-negative versus ANA-positive patients at enrolment in an international Inception cohort**

	ANA-negative n=76	ANA-positive n=976	Difference (95% CI) ANA-negative versus ANA-positive

Disease duration, months	4.8	5.7	-0.9 (-1.8, 0.1)
Caucasian, %	81.6	52.2	29.4 (20.2, 38.7) *
Nephritis (based on renal biopsy or ACR Criteria) at enrollment, %	30.9	29.5	1.3 (-10.0, 12.7)
# ACR criteria, mean	4.7	4.8	-0.1 (-0.4, 0.1)
SLEDAI-2K score, mean	4.4	5.4	-1.1 (-2.3, 0.2)
Medications, % ever used			
Glucocorticoids	76.3	80.9	-4.6 (-14.5, 5.2)
Antimalarials	65.8	74.0	-8.2 (-19.2, 2.8)
Immunosuppressants	30.3	44.2*	-13.9 (-24.7, -3.1) *
Autoantibodies, %			
dsDNA***, %	13.2	29.4*	-16.2 (-24.3, -8.1) *
PCNA****	2.6%	7.0%	-4.3 (-10.1, 1.5)
Ribosomal-P	5.3%	16.0%	-10.7 (-16.2, -5.2) *
Ro52/TRIM21	21.1%	36.5%	-15.4 (-25.1, -5.8) *
SSA/Ro60	23.7%	47.4%	-23.8 (-33.8, -13.7) *
SSB/La	6.6%	15.8%	-9.2 (-15.2, -3.2) *
Sm	6.6%	25.2%	-18.6 (-24.8, -12.4) *
U1-RNP	10.5%	33.0%	-22.5 (-30.0, -15.0) *

*Denotes values are significantly different between ANA-negative and ANA-positive patients

** ANA at enrolment was detected by indirect immunofluorescence on HEp-2000 substrate (Immunoconcepts, Sacremento, CA) in a single laboratory; a positive ANA was defined as a titre ≥ 1/160.

***Anti-ds DNA was detected by chemiluminescence immunoassay (QUANTA Flash, Inova, San Diego, CA) in a single laboratory; a positive anti-ds DNA was defined as ≥ 70 IU/ml.

****Antibodies to PCNA, ribosomal-P, recombinant Ro52/TRIM21, native SSA/Ro60, SSB/LA, Sm, and U1-RNP were detected using the extractable nuclear antigen (ENA) FIDIS Connective Profile kit 13 addressable laser bead immunoassay (ALBIA, TheraDiag, Paris) in a single laboratory.

In the ANA-negative versus ANA-positive, the average annual rate of damage accrual was 0.10 versus 0.12 units/year; the difference was not significant in the univariable or multivariable analysis. In the ANA-negative versus ANA-positive, the average annual partial direct, complete direct, and indirect costs were significantly less ($2310 (95% CI 897, 3723), $3902 (95% CI 1516, 6287) and $14,620 (95% CI 5680, 23560) versus $4036 (95% CI 3428, 4645), $6818 (95% CI 5790, 7845) and $25,548 (95% CI 21698, 29398)) (Table 2). However, in multivariable analysis, wide CIs precluded definitive conclusions (β-coefficient for ANA-negativity, -$5684, 95% CI -$24258, $12890).

Conclusion: ANA-negative versus ANA-positive SLE patients at disease inception incurred lower costs in univariable analysis, but with adjustment for age and race/ethnicity, no differences could be detected. More research is required to characterize ANA-status over the disease and determine if costs/outcomes are more associated with persistent ANA-negativity/positivity, rather than ANA-status at disease inception.

Table 2. Average annual partial and complete direct and indirect health care costs (2018 Canadian dollars)

	ANA-negative n=76	ANA-positive n=976	Difference (95% CI) ANA-negative versus ANA-positive
Partial direct costs	2310	4037	-1727 (-3243, -210)*
Hospital visits	437	1416	-979 (-1338, -619)*
Medications	1802	1929	-127 (-1551, 1298)
Dialysis	0	616	-616 (-954, -278)*
Select procedures	70	76	-6 (-45, 34)
Complete direct costs	3902	6818	-2916 (-5478, -354)*
Indirect costs	14620	25548	-10928 (-20527, -1328)*
Total costs	18522	32366	-13844 (-26006, -1682)*

*Denotes values are significantly different between ANA-negative and ANA-positive patients

Merrill,[4] and Judith James[3], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK, [2]Oklahoma Medical Research Foundation, Oklahoma City, [3]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [4]Okalahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus **(**SLE) may have a significant impact on multiple dimensions of quality of life. Patient-reported outcome (PRO) tools may provide valuable insights for clinical trials and treatment decisions in clinical practice. LupusPRO is a disease targeted, patient reported outcome measure designed specifically for patients with SLE. It includes 43 variables of which 30 items are health-related. The SF-36 Health Survey is a widely used, multipurpose, short-form index comprised of 36 items suitable for assessment of all medical conditions. Both instruments are internationally validated and have been correlated to each other in many lupus studies. The aim of this study was to compare SF-36 and LupusPRO scores in a racially and culturally diverse cohort of SLE patients.

Methods: The Cohort for Rheumatic Diseases is a longitudinal real-world study that follows 1,635 patients, including an embedded Lupus Cohort (674 patients who meet ACR classification criteria for SLE). 365 SLE patients completed the LupusPRO questionnaire and SF-36 during the same routine clinical visits between 2011 and 2019. Spearman's rank tests and Kruskal-Wallis methods were used to compare age, race, gender, and year of disease to SF-36 and LupusPRO scores. Linear regression methods were then used to compare LupusPRO and SF-36 scores controlling for these variables.

Table 1: Characteristics of participants (N=367)

Variables	N	(%)
Age, years		
Mean ± SD	45.50	±13.26
Gender		
Female	333	(90.74)
Male	34	(9.26)
Race		
EA	206	(56.13)
AA	83	(22.62)
Others	78	(21.25)
Year of Diseases at Enrollment		
Median(IQR1-IQR3)	14	(6-40)
SF-36		
Median(IQR1-IQR3)	40	(25-60)
Lupus-Pro		
Median(IQR1-IQR3)	70.57	(54.63-84.63)

Table 2: Univariate analyses between SF-36 or Lupus-Pro with other variables

Variables	SF-36		Lupus-Pro	
	Coefficient	p-value	Coefficient	p-value
Age, years	0.01	0.842[a]	-0.00	0.978[a]
Gender	14.42	0.0001[b]	10.91	0.001[b]
Race	36.80	0.0001[b]	65.68	0.0001[b]
Year of Diseases	0.07	0.013[a]	0.03	0.379[a]

[a]From Spearman test results
[b]From Kruskal-Wallis test results

Table 3: Multivariate analyses between SF-36 and Lupus-Pro, controlling for other variables: linear regression

Variables	SF-36	
	Coefficient	p-value
Gender	3.40	0.055
Race		
EA	1	
AA	4.46	0.001
Others	0.92	0.487
Year of Diseases	0.06	0.097
Lupus-Pro	0.62	<0.0001

Results: The patients completed a mean of 3.43 paired results. Subjects were 90% female with a mean age of 45.50 (SD=13.26) years. The population was 56.1% Caucasian, 22.6% African American, and 21.3% Other Race, primarily consisting of American Indian and mixed race. In univariate analysis, results of the PROs were comparable ($p< 0.0001$) (Table 2) and African American patients had higher scores than European Americans ($p=0.001$) (Table 3). The positive correlation between LupusPRO and SF-36 remained in multivariate analysis ($p< 0.0001$) when controlled for race, gender, and year of disease (Table 3).

Conclusion: SF-36 and LupusPRO gave similar results. African American patients have higher scores on both instruments, indicating their report of better functioning and quality of life, despite their known increased disease severity. Both disease-targeted LupusPRO and generic SF-36 tools may be useful for measuring quality of life in SLE studies, but potential cultural and disease impacts on these measures need to be carefully considered.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is the most common symptom in SLE patients with a strong impact on patients' reported quality of life. The cause of fatigue is most likely multifactorial. Previous studies identified possible associations with fatigue with some contradictory results. The aim of this study was to identify additional potentially reversible associations with fatigue to generate a target for future interventions.

Methods: Our study population consisted of 234 consecutively recruited SLE (according to the 1997 ACR criteria) outpatients from our university hospital based lupus reference centre. We analyzed clinical and demographic data from routine visits, laboratory variables, as well as sleeping disorders, disease perception, coping, social activities and health locus of control using validated questionnaires. We captured fatigue using the Fatigue Severity Scale (FSS). A score of ≥ 4 points is considered pathological. To assess depression, we used the German CES-D depression scale (values $\geq 23/60$ points are considered pathological).

Table 1. Potentially reversible associations with fatigue in our cohort of 234 SLE patients, absolute numbers and percentages

Variable	n (%)	FSS ≥ 4 points	FSS < 4 points
Obesity (BMI >30kg/m²)	26/234 (11.1)	15/119 (12.6)	11/115 (9.6)
Signs for depression (ADS-L ≥ 23 points)	59/209 (28.2)	41/110 (37.3)	18/99 (18.2)
Vitamin D deficiency (25-hydroxyvitamin D <30 ng/ml)	73/213 (34.3)	34/107 (31.8)	39/106 (34.0)
Anemia (Hb <11.9 g/dl)	41/234 (17.5)	24/119 (20.2)	17/115 (14.8)
Hypothyroidism (TSH >4,2 µUI/ml)	6/225 (2.6)	4/113 (3.5)	2/112 (1.7)

Results: Our predominantly Caucasian cohort (99.1%) was mostly female (87.6%), with a mean age of 45.3 years (±13.4 [SD]) and a mean disease duration of 16.2 years (±9.5). In our cohort, 50.9% of patients reached a pathological result in the FSS. Depression was significantly associated with fatigue ($p < 0.001$), with 37.5% of patients with fatigue vs. 18.2 % in patients without fatigue showing a clinically relevant CES-D score (mean CES-D score 20.2±9.4 vs. 14.3±8.6). Patients with poor self-assessment of their health condition (including sleeping disorders, pain, disease activity and damage) showed significantly more fatigue ($p < 0.01$). In our gradual regression analysis, reduced social activities exhibited the highest correlation with fatigue (Beta 0.535). Overall, in 71.4 % of our SLE patients, we could identify at least one potentially reversible association for fatigue (shown in table 1).

Conclusion: We observed a high prevalence of depressive disorders in our cohort and a significant correlation of depressive status with fatigue. Therefore, we suggest that psychological wellbeing is assessed in everyday clinical practice and treating physicians should react to patients' needs accordingly. Additionally, obesity, anaemia, hypothyroidism and vitamin D deficiency can easily be assessed. Optimizing these factors represent possible targets in order to improve fatigue in SLE patients.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the performance of the proposed American College of Rheumatology/European League against Rheumatism (ACR/EULAR) classification criteria for systemic lupus erythematosus (SLE) in Korean patients

Methods: We conducted medical chart review study of patients with SLE and defined rheumatic diseases as control group. The clinical diagnosis was used as the gold standard. The classification based on 1997 ACR criteria, 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria and the newly proposed ACR/EULAR criteria were examined with analysis of sensitivity, specificity, accuracy, positive predictive value and negative predicted value.

Results: A total of 335 SLE patients and 337 non-SLE patients were included in the analysis. Non-SLE patients included rheumatoid arthritis (RA) (n=92), anti-phospholipid syndrome (APS) (n=57), mixed connective tissue disease (CTD) (n=52), systemic sclerosis (n=43), primary Sjögren's syndrome (SS) (n=39), undifferentiated CTD (n=28), RA with secondary SS (n=24), dermatomyositis (n=1) and spondyloarthropathy (n=1). The sensitivity of the proposed ACR/EULAR criteria was 97.6% (95% confidence interval (CI), 0.957-0.988) compared with 98.5% (95% CI, 0.967-0.994) for the 2012 SLICC criteria. The specificity for the proposed ACR/EULAR criteria and 2012 SLICC criteria were 91.7% (95% CI, 0.897-0.929) and 92.6% (95% CI, 0.908-0.935), respectively. Eight patients who were classified as SLE with the proposed ACR/EULAR criteria but not with 2012 SLICC criteria, had a tendency of having arthritis domain and highly specific antibody domain which counts for a score of 6. One patient classified as SLE according to the proposed ACR/EULAR criteria had malar rash and arthritis and one patient had serositis, leukopenia and fever (constitutional domain). Three APS patients who were classified as SLE according to the 2012 SLICC criteria did not meet the proposed ACR/EULAR criteria due to the entry criterion of positive anti-nuclear antibody. The ACR/EULAR score $\geq$ 12 rather than a score $\geq$ 10, resulted in higher specificity, positive predictive value, and accuracy and higher sensitivity than 1997 ACR criteria.

Conclusion: The proposed ACR/EULAR criteria for SLE had comparable performance in respect of diagnostic accuracy, sensitivity and specificity in this Korean population of SLE and other rheumatic diseases. However, the proposed criteria could not reach higher specificity than 2012 SLICC criteria.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis and renal damage are serious complications in patients with SLE. Proteinuria < 0.8 g/24 hours at 12 months has proven to be a good predictor of long-term renal outcome. The aim of this study is to identify the predictors of renal damage in Latin American SLE patients.

Methods: Patients with lupus nephritis from a multiethnic, multinational, multicenter cohort were included in this study. Lupus nephritis was defined clinically (proteinuria greater than 0.5 g/day on two or more occasions or the presence of red cell casts) or histologically (renal biopsy compatible with lupus nephritis histopathology class II-V according to the World Health Organization). The following time-dependent variables were considered as possible predictors of renal damage: proteinuria, low complement, anti-dsDNA, red cell casts, creatinine level, hypertension, the renal component of the SLEDAI, prednisone dose, immunosuppressive drugs use, and antimalarial use. The following baseline variables were also included: gender, age at nephritis diagnosis, residence rural or urban, ethnic group and socioeconomic status (SES). Proteinuria was assessed at baseline and after 12 months, to determine if early response (proteinuria < 0.8 g/d within 12 months since the diagnosis of lupus nephritis) is protective of renal damage occurrence in SLE patients; renal damage was defined as an increase of at least one point in the renal domain of the SLICC/ACR damage index. Univariable and multivariable Cox regression models using a backward selection method with alpha-level to stay in the model set at 0.05 were performed.

Table 1. Predictors of renal damage. Univariable and multivariable models.

	Univariable HR (CI95%)	p value	Multivariable HR (CI95%)	p value
Age at nephritis diagnosis	0.99 (0.97-1.01)	0.195		
Gender (male)	1.84 (1.14-2.98)	0.013	1.93 (1.18-3.15)	<0.001

Antimalarial use	0.45 (0.29-0.72)	<0.001	0.48 (0.29-0.76)	0.002

SES: Socioeconomic status. Early treatment response: proteinuria <0.8 g/d within 12 months since the diagnosis of lupus nephritis.

Results: Four hundred and ninety patients were included; 89.4% of them (n = 438) were female, with a median age at SLE diagnosis of 26.4 IQR (19.0-36.0) years and median age at nephritis diagnosis of 27.5 (20.3-37.4) with a median follow-up after nephritis diagnosis of 3.9 (2.0-5.6) years. At baseline, the median creatinine was 0.9 (0.7-1.1) mg/dl. One-hundred and twenty patients (24.5%) accrued renal damage during their follow-up.

Early response to treatment (as defined) (HR 0.604), and antimalarial use (HR 0.477) were protective of the occurrence of renal damage whereas male gender (HR 1.930), low socioeconomic status (HR 3.945), hypertension (HR 1.854) and the renal component of the SLEDAI (HR 1.768) were risk factors for renal damage occurrence. Univariable and multivariable models are depicted in table 1.

Conclusion: Early response and antimalarial use were protective of renal damage occurrence, while male gender, hypertension, low socioeconomic status, higher renal domain of SLEDAI were risk factors for its occurrence in SLE patients. Strict control of modifiable risk factors such as early proteinuria response, antimalarial use and hypertension control, is therefore strongly recommended for patients with lupus nephritis to minimize damage.

Clinical Relevance According to Staining Patterns and Titers of Antinuclear Antibody

Mi Ryoung Seo,[1] Ji Na Yeo,[2] Hee Jung Ryu,[3] Hyo-Jin Choi,[3] and Han Joo Baek[3], [1]Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea, [2]Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea, [3]Division of Rheumatology / Department of Internal Medicine / Gil Medical Center, Gachon University College of Medicine, Incheon, Republic of Korea

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Immunofluorescent antinuclear antibody (ANA) test using HEp-2 cells still plays an important role in the diagnosis of autoimmune diseases. The aim of this study was to investigate the clinical relevance of ANA according to titers and patterns.

Methods: We identified patients who were newly positive in the ANA test between December 2010 to November 2016, and collected data such as, diagnosis, ANA titer and pattern, and specific autoantibody test results.

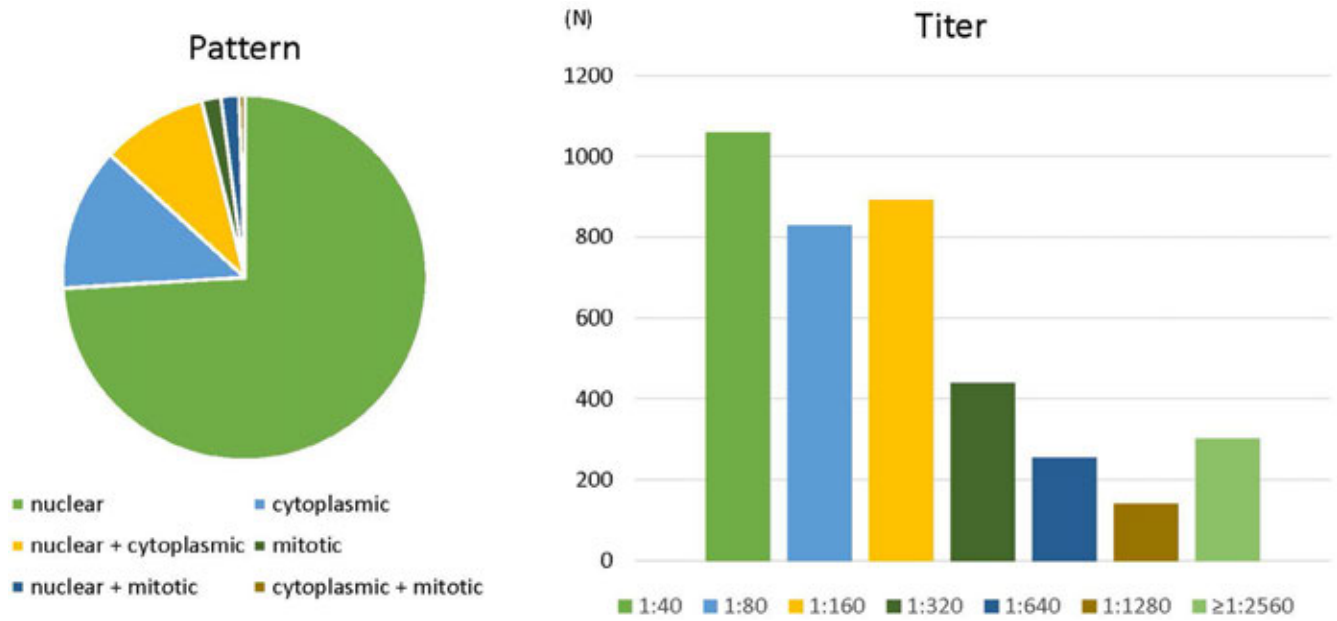

Figure 1. Patient distribution by ANA titer and pattern.

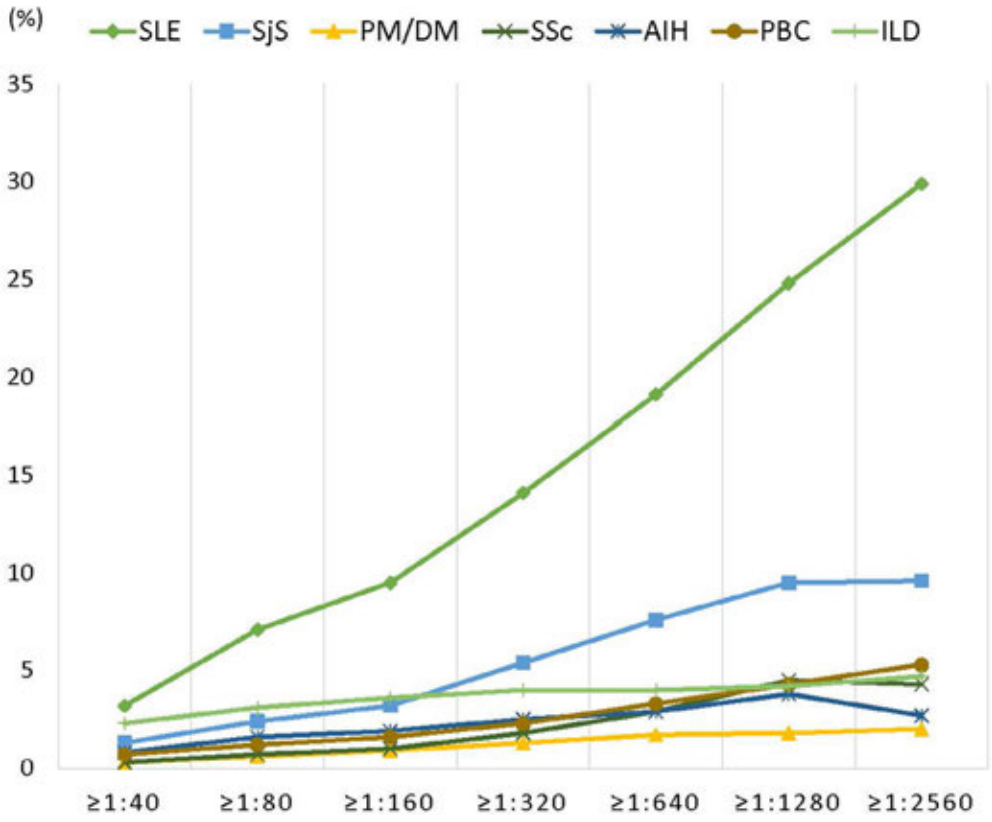

Figure 2. Disease prevalence according to ANA titer

Results: In total, 7591 patients were included in this study. The average age was 51 (interquartile range (IQR): 35-63) years, and 69.4% were women. Figure 1 showed the patient distribution by ANA titer and pattern. The diseases with a difference in prevalence according to ANA titer were systemic lupus erythematosus (SLE), Sjögren syndrome (SjS), polymyositis/dermatomyositis (PM/DM), systemic sclerosis (SSc), autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), liver cirrhosis, hemolytic anemia, immune thrombocytopenic purpura, interstitial lung disease (ILD), chronic obstructive pulmonary disease/bronchiectasis (COPD/BE), cerebrovascular accident, and crystal induced arthropathy (CIA). A multivariable analysis was conducted to determine whether ANA titer was an independent factor. As a result, diseases with increased prevalence with increasing ANA titer were SLE, SjS, PM/DM, SSc, AIH, PBC, and ILD, and the opposite result showed in COPD/BE and CIA (Figure 2).

SLE was the most prevalent in patients with mixed pattern of nuclear and cytoplasmic (6.4% in ≥1:40, 40% in ≥1:2560). SjS and SSc showed the same results (SjS: 1.9% in ≥1:40, 10% in ≥1:2560, SSc: 0.5% in ≥1:40, 6.7% in ≥1:2560). The prevalence of PM/DM, AIH, PBC and ILD was highest in mixed pattern of nuclear and cytoplasmic in all patients, but it was highest in cytoplasmic pattern from 1:160 or more of ANA titer.

Conclusion: SLE, SjS, PM/DM, SSc, AIH, PBC and ILD were the diseases in which ANA titer independently affected disease prevalence. Patients with mixed pattern of nuclear and cytoplasmic had a higher prevalence of SLE, SjS and SSc than purely nuclear pattern. It is necessary to note that the cytoplasmic pattern is accompanied by the nuclear pattern in the ANA test.

Newly Diagnosed Lupus Nephritis in Elderly Predicts Good Renal Outcome: A Distinct Disease Subset from Young-onset Lupus Nephritis

Kazuoto Hiramoto,[1] Hironari Hanaoka,[1] Jun Kikuchi,[1] Shuntaro Saito,[1] Hiroshi Takei,[2] Tatsuhiro Oshige,[1] Noriyasu Seki,[3] Hideto Tsujimoto,[3] Yuko Kaneko,[1] and Tsutomu Takeuchi[1], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, [3]Mitsubishi Tanabe Pharma Corporation Sohyaku. Innovative Research Division, Toda-shi, Saitama, Japan

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Elderly-onset SLE is recognized to be benign disease entity with a favorable nature course. Although late-onset lupus nephritis (LN), long interval between onset of SLE and diagnosis of LN is associated with poor renal outcome, little information has been available in newly diagnosed LN in the elderly. The purpose of this study is to compare renal prognosis and clinical characteristics between elderly-onset and young-onset LN.

Figure 1

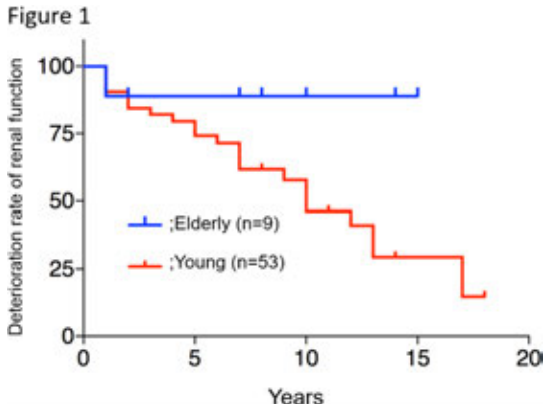

Figure 2

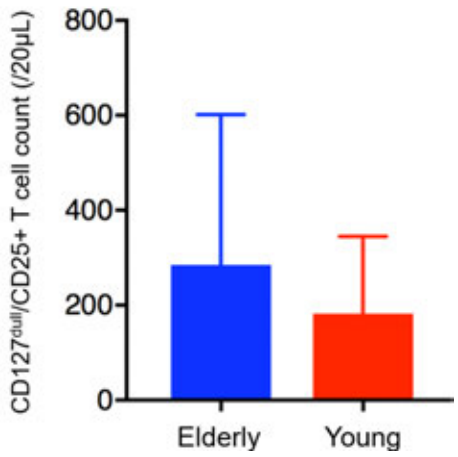

Methods: We reviewed SLE patients with LN from 2000 to 2018 in our hospital. LN was defined as biopsy-proven LN or persistent proteinuria (more than 0.5 g/gCr or ≥3+ for more than 3 months). Patients were classified into two groups based on disease onset: young-onset LN (< 50 years old) and elderly-onset LN (≥50 years old). Deterioration of renal function (more than 30% eGFR decline from baseline) and circulating regulatory T (Treg) cell counts were compared by fluorescence-activated cell sorting (FACS) analysis using anti-CD3, 4, 25, 127 antibodies between them.

Results: Fifty-three patients with young-onset LN and 9 with elderly-onset LN were evaluated. Baseline eGFR was significantly lower in patients with elderly-onset LN than young-onset LN (63.3±19.0 vs 93.4±23.5 ml/min, p< 0.01). There was no significant difference in baseline SLEDAI (16 vs 16, p=0.33), observational periods (8 vs 10, p=0.47), maximum dose of prednisolone (p=0.42), percentage of IVCY use (p=0.15) and MMF use (p=0.46) between the two groups. Cumulative deterioration rate of renal function tended to be lower in the elderly than young-onset LN (p=0.10, Figure 1). A higher tendency of peripheral Treg (CD3+/CD4+/CD25+/CD127dull) counts by FACS analysis was observed in the elderly than young-onset LN (p=0.60, Figure 2).

Conclusion: This study suggests that elderly-onset LN may have better renal prognosis than young-onset LN. Increasing number of peripheral Treg in the elderly-onset LN indicate that alteration of immune system by aging may influence the results. Adequate sample size and a longer period of observation may be required to verify the results.

Applying Systemic Lupus International Collaborating Clinics (SLICC) and Provisional ACR/EULAR Systemic Lupus Erythematosus Classification Criteria in a Cohort of Patients with Undifferentiated Connective Tissue Disease

Kyle Drehmel,[1] Alan Erickson,[1] Bryant England,[2] and Michelene Hearth-Holmes[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]VA Nebraska-Western IA Health Care System & University of Nebraska Medical Center, Omaha

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Undifferentiated Connective Tissue Disease (UCTD) describes the clinical scenario where a patient demonstrates characteristics of a connective tissue disease but does not meet criteria for a defined CTD. The CTD that is most frequently implicated with UCTD is systemic lupus erythematosus (SLE). In recent years, new classification criteria for SLE have been developed. This study investigates the reclassification of UCTD patients using newly proposed SLE criteria.

Methods: Patients were identified within the Rheumatology and Arthritis Investigational Network (RAIN) database at the University of Nebraska Medical Center. Medical records of all patients were reviewed to confirm fulfillment of

Table 1. Disease features at time of diagnosis of UCTD by fulfillment of SLICC SLE criteria.

	All Patients	UCTD	SLE	p-value
Number of Patients (%)	129 (100)	111 (86.0)	18 (14.0)	
Acute Cutaneous Lupus (%)	28 (21.7)	24 (21.6)	4 (22.2)	1.00

Comparison made between group reclassified as SLE and group not reclassified according to ACR/EULAR criteria. Disease features were evaluated according to the definition provided by the ACR/EULAR criteria. *Includes anticardiolipin, lupus anticoagulant, anti-β2-glycoprotein

proposed classification criteria for UCTD: positive ANA, signs and symptoms of a CTD but not fulfilling the criteria for a defined CTD, and a disease duration of at least one year, including early UCTD. Characteristics at the time of diagnosis with UCTD were collected through medical record review and managed using the REDCap electronic data capture tool. The SLICC and ACR/EULAR criteria for SLE were applied at the time of diagnosis with UCTD. We then compared the proportion of patients reclassified as SLE according to these criteria as well as the specific disease features associated with reclassification as SLE.

Results: A total of 129 patients were included in the study. The majority of patients were female and white (90.7%), and the mean (SD) age at UCTD diagnosis was 43.5 (13.9). When applying the SLICC criteria, 18 patients (14.0%) were reclassified as SLE while 26 patients (20.2%) were reclassified using the ACR/EULAR criteria. Disease features which were associated with reclassification for both SLICC (**Table 1**) and ACR/EULAR criteria (**Table 2**) were renal involvement, leukopenia, thrombocytopenia, anti-dsDNA antibody, and hypocomplementemia. Non-scarring alopecia was associated with reclassification as SLE only under the SLICC criteria while the presence of arthritis was associated with reclassification as SLE under the ACR/EULAR criteria.

Conclusion: Both the SLICC and ACR/EULAR criteria exhibit increased sensitivity for SLE classification. The only disease feature associated with reclassification under the ACR/EULAR criteria but not the SLICC criteria was the presence of arthritis. Because arthritis is weighted heavily in this criteria (6 out of 10 points), it will reclassify many patients with this frequent manifestation as SLE.

Assessing Perceptions, Barriers, and Preferences to Exercise in Patients with Systemic Lupus Erythematosus

Gabriel Jeyasingham,[1] Arzoo Alam,[1] Nicholas Steiner,[2] Kimberly Legault,[1] Mark Matsos,[1] and Karen Beattie[1], [1]McMaster University, Hamilton, ON, Canada, [2]Western University, London, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiovascular disease is a significant cause of mortality in patients with SLE. High levels of fatigue are also reported in patients with SLE and negatively impact quality of life. Physical activity is associated with improvements in both cardiovascular disease and fatigue, but trials of exercise interventions involve activities that may not be feasible or sustainable outside the formal setting of a study. Our objective is to understand the perceptions, attitudes, barriers and preferences to exercise in patients with SLE.

Methods: Patients ≥18 years old with SLE seen in the Lupus Clinic at McMaster University Medical Centre were invited to complete a short questionnaire during their routine clinic appointments. This questionnaire, adapted from an exercise questionnaire validated in an osteoporosis population, contained four sections: 1) patient characteristics, 2) perceptions and attitudes towards exercise, 3) perceived barriers to exercise, and 4) preferences to performing exercise.

Results: Respondents included 49 females and 6 males (mean (SD) age 39 (12.9) years), of whom 32 worked full-time, 9 worked part-time and 14 were not employed. Almost half (n=25, 45%) reported caring for children or family

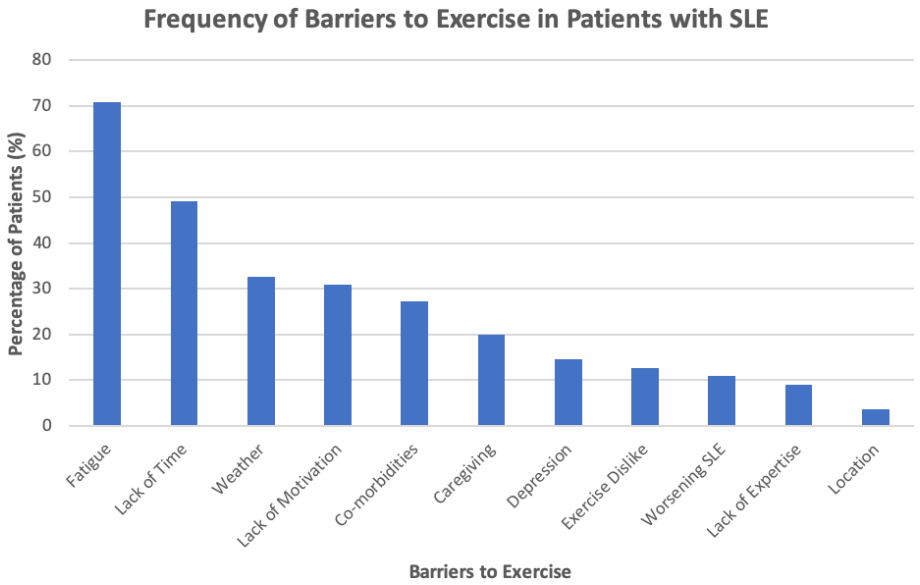

Figure 1. Frequency of barriers to exercise in patients with SLE. The x-axis indicates the barriers to exercise cited by patients. The y-axis depicts the percentage of respondents who cited each barrier. The most frequently cited barriers include fatigue, lack of time, weather, and lack of motivation.

members. Most patients (89%, n=49) reported having barriers to exercise. Those most frequently reported (**Figure 1**) included fatigue (n=39, 71%), lack of time (n=27, 49%), weather conditions (n=18, 33%), and lack of motivation (n=17, 31%). About 87% (n=48) of respondents were willing to change their daily routine to include more exercise. Walking was the most preferred exercise (n=43, 78%), followed by strengthening exercises (n=41, 75%) and flexibility exercises (n=28, 51%). After performing vigorous exercise, 49% (n=27) of patients thought they would feel better compared to when they do not exercise while 18% (n=10) thought they would feel the same and 33% (n=18) thought they would feel worse. After performing moderate exercise, 64% (n=35) of patients reported feeling better, 27% (n=15) reported feeling the same, and 9% (n=5) reported feeling worse.

Conclusion: The majority of our patients were female of child-rearing years. Many were employed full-time and were primary caregivers, which may explain fatigue and time being the most commonly reported barriers to exercise. Walking was overwhelmingly the most preferred type of exercise. Most patients found moderate exercise to be beneficial, while a sizeable minority thought vigorous activity would be detrimental. Most patients expressed willingness to incorporate more physical activity into their daily routine. There is a need for a feasible exercise regimen that considers barriers and personal preferences in patients with SLE.

Serum Albumin as a Long-term Predictor of Renal Evolution in Lupus Nephritis

Vanessa Castro Coello,[1] Alejandro Brigante,[2] Sabrina Porta,[3] Paola Avila,[3] Marina Micelli,[4] Adriana Hamaui,[5] Eduardo Kerzberg,[6] and Diana Dubinsky[5], [1]Sanatorio Güemes, Buenos Aires, Buenos Aires, Argentina, [2]Sanatorio Güemes, Servicio de Medicina Interna – Reumatología, Francisco Acuña de Figueroa 1240, C1180AAD, Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [3]Hospital General de Agudos José María Ramos Mejía, Buenos Aires, Argentina, [4]Hospital General de Agudos Dr. José M. Ramos Mejía, Buenos Aires, Argentina, [5]Sanatorio Güemes, Buenos Aires, Argentina, [6]Hospital Ramos Mejia, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: End-stage renal disease (ESRD) develops in 10-30% of patients with lupus nephritis (LN) despite standard treatment. A biomarker with excellent sensitivity and specificity to predict the evolution of LN would determine the intensity and duration of treatment as a primary end point in clinical trials. It was shown that proteinuria at 12 months has a sensitivity of 71% and specificity of 75% to predict renal outcomes at 7 years. There is evidence that serum albumin could predict renal evolution, the basis of this premise is the clinical observation that, despite proteinuria, preserved serum albumin is associated with sustained renal function. The objective of this study is to evaluate the association between baseline serum albumin and at 12 months with renal evolution at two years.

Methods: Cross-sectional, retrospective study in patients with SLE (SLICC 2012) with LN staged by biopsy, between January/2015 to January/2019. The levels of serum albumin, complement, urinary sediment and proteinuria were evaluated at diagnosis and at 12 months. An adverse renal outcome (ARO) was defined as the doubling of baseline serum creatinine, or creatinine >4 mg/dL if the initial one was >2.5 mg/dL, ESRD requiring hemodialysis (HD) therapy or transplantation. ROC curve analysis was performed for albumin value below 3 g/dL as cut value. Patients had to have at least one additional follow-up visit 24 months after diagnosis.

Results: We included 62 patients, 87% women with a mean age of 32 years (SD +/- 11). FAN positive in all patients. Anti-DNA 63%, Anti-Sm 24%, Anti-Ro 37%. ACL IgM 5%, IgG 6.7%. B2-IgM glycoprotein 5%, IgG 8.3%. LA 10%. Hypocomplementemia 89% (C3 63%, C4 89%). LN: II 16%; III 26%; IV 45%; V 11%; VI 2%. 54% of patients with LN received pulses of steroids. Induction therapy: CFD 61%, RTX 6.5% and MMF 25%. Maintenance therapy: MMF 70%, AZA 20%. They received HCQ 96.7%.

At the diagnosis of LN: proteinuria 4.3 g/day (SD +/- 3), serum albumin 3.4 g/dL (SD +/- 0.9 CI 95% 2.6-4.2); serum albumin at 12 months 4.2 g/dL (SD +/- 0.57 IC 95% 3.7-4.6). Basal hypoalbuminemia association with ARO p = 0.44 (creatinine increase: p = 0.45, ESRD p = 0.43, HD p = 0.93). Hypoalbuminemia at 12 months with ARO p = 0.003 (Creatinine increase p = 0.007, ESRD p = 0.001, HD p = 0.61). A ROC curve is made taking albumin values less than 3 g/dL as a cut-off value AUC = 0.77 p = 0.001; sensitivity 61% and specificity 93%.

Conclusion: We found an association between the level of serum albumin at 12 months and renal evolution at two years, so it should be taken into account as it is a quick, easy and cheap study. Hypoalbuminemia has a moderate sensitivity and good specificity to predict poor renal evolution. The association between serum albumin at diagnosis and renal evolution was not significant. Prospective studies in large cohorts are necessary to validate this association, investigate causality and its usefulness in monitoring and therapeutic decisions.

Abstract Number: 0657

Performance of the "Do You Know What I Mean" Questionnaire in the Assessment of Disease Knowledge in Patients with Systemic Lupus Erythematosus

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: 'Do you know what I mean?' is a self-reported questionnaire developed to assess disease knowledge level in Systemic lupus erythematosus (SLE) patients. It is a 27-item true/false questionnaire based on disease outcomes, complications and treatment. The aim of this study was to validate this questionnaire in a cohort of patients with SLE, to assess the level of knowledge of the disease and its association with disease characteristics.

Methods: Multicenter, observational, cross-sectional, descriptive and analytical study. Consecutive patients ≥ 18 years old with SLE (ACR 97 and SLICC 2012) were included. Sociodemographic variables, disease characteristics and those that could influence the level of knowledge were recorded: level of instruction; age at onset and disease duration; hospitalizations associated with SLE; proximity to SLE (defined as past or current contact with a relative, friend or partner with SLE); and educational exposure (use of internet or social networks, or participation in support groups). The questionnaire was filled out by all the patients. Statistical analysis: Sociodemographic and disease characteristics were described. Cronbach´s alpha and test-retest reliability were determined. For each question, median and interquartile range (IQR) of correct, incorrect and missing answers were recorded. All the comparisons were made with Student's T test, Chi2 and Fisher's exact test or Spearman correlation.

Results: A total of 277 SLE patients from 14 centers were included: 89% women, mean age 38.7 years (SD 13). Mean age at SLE onset was 28.7 years (SD 12.5) and median disease duration was 96 months (IQR 36-168). Sixty

five percent of patients reported hospitalizations due to SLE and 23% proximity to SLE. Forty percent of patients had high school level education. Twenty three percent reported educational exposure to SLE: 71% searched information on social networks, 52% on the internet and only 19% attended informative meetings. Cronbach's alpha was 0.73, no redundant questions were detected and test-retest reliability was 0.78. Median of correct answers was 18 (IQR 15-20) and of incorrect ones 5 (IQR 3-7). An earlier age at disease onset was associated with higher number of correct answers ($p < 0.0001$). In addition, a higher level of education and educational exposure to SLE were associated with higher knowledge level ($p=0.0012$). Individual question analysis showed that 55% to 77% of patients do not consider SLE as a cardiovascular risk factor or as a cause of death; however, 93% recognized that physical activity could improve bone and heart health. Sixteen to 36% of patients gave incorrect answers in questions regarding glucocorticoid-related adverse effects and between 11% and 50% reported that they didn't know the answer.

Conclusion: 'Do you know what I mean?' proved to be a valid and reliable questionnaire in patients with SLE. In addition, this study showed that the areas of highest lack of knowledge were those associated with cardiovascular impact of the disease and glucocorticoid-related adverse effects. We believe that the use of this questionnaire could be useful as a guide of educational strategies in patients with SLE, in order to improve adherence to treatment and prognosis.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Connective tissue diseases (CTDs) are a heterogeneous group of diseases with overlapping clinical features and shared immunopathology. In routine practice, a clinician diagnosis is often made without direct

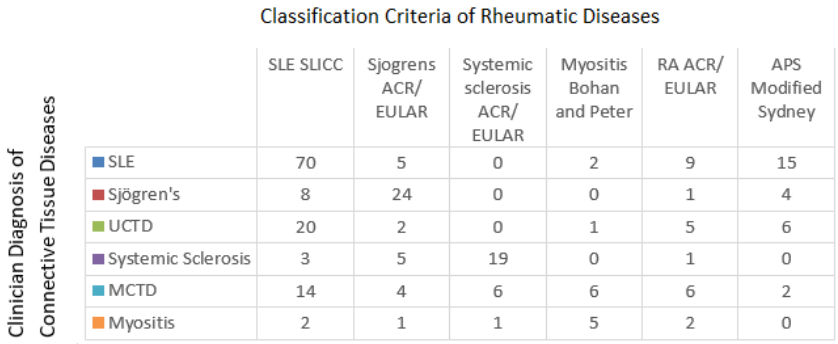

Figure 1. Patients Meeting Classification Criteria for Rheumatic Diseases According to Clinician Diagnosis of CTD

reference to classification criteria however meeting classification criteria is important when recruiting to studies and trials and in accessing medicines. We aimed to assess whether patients clinically diagnosed with a CTD met the relevant classification criteria and describe their clinical manifestations and immunological profile. Secondly, we applied accepted classification criteria to each individual patient.

Methods: Adult patients were recruited with one or more clinical feature suggestive of a CTD and one or more antibody within the antinuclear spectrum. Patients were initially grouped according to clinician diagnosis and we described their clinical features and immunological profile. Patients were then reviewed and classified, where appropriate, using SLICC SLE 2012 criteria, ACR/EULAR 2016 Sjögren's syndrome criteria, ACR/EULAR 2013 Systemic Sclerosis (SSc) criteria, the Bohan and Peter 1975 Myositis criteria, Rheumatoid Arthritis (RA) 2010 ACR/ EULAR criteria and Antiphospholipid syndrome (APS) -Modified Sydney criteria, 2006.

Results: We recruited 249 patients from May 2014-April 2019. Of these, 227 (91.2%) were female with a mean (SD) age of 48.5 (13.0) years. By clinician diagnosis, 86 (34.5%) had SLE, 35 (14.1%) had Sjögren's syndrome, 58 (23.3%) had UCTD, 26 (10.4%) had SSc, 32 (12.9%) had Mixed Connective Tissue Disease (MCTD) and 12 (4.8%) had myositis. Disease duration was shortest in patients with UCTD and myositis (median 3 years), and longest in SLE (median 10 years).

Patients from each clinician diagnosed disease group met SLICC SLE criteria including 20 (34.5%) UCTD and 14 (43.8%) MCTD patients (Fig 1). SLICC/SLE mucocutaneous criteria (including ulcers, alopecia and cutaneous lesions) and arthritis were prevalent across all diseases, affecting 83 (96.5%) SLE patients, 20 (57.1%) of Sjögren's syndrome, 45 (77.6%) UCTD, 12 (46.2%) SSc, 29 (90.6%) MCTD and 6 (50%) myositis patients. In contrast, deep organ involvement (such as renal, neurological and serositis) satisfying SLICC SLE criteria, were mostly observed in SLE patients.

	SLE N (%)	**Sjögren's** N (%)	**UCTD** N (%)	**Systemic Sclerosis** N (%)	**MCTD** N (%)	**Myositis** N (%)

anti-Ro or anti-La	29 (33.7)	26 (74.3)	18 (31)	2 (7.7)	8 (25)	4 (33.3)
anti-Jo	0	1 (2.9)	1 (1.7)	0	0	4 (33.3)
anti-Chromatin	26 (30.2)	3 (8.6)	6 (10.3)	1 (3.9)	15 (46.9)	0
anti-Centromere	0	0	3 (5.2)	14 (53.9)	2 (6.3)	0
anti-Scl70	3 (3.5)	0	1 (1.7)	2 (7.7)	2 (6.3)	0
Rheumatoid factor	12 (14.0)	8 (22.9)	12 (20.7)	5 (19.2)	13 (40.6)	1 (8.3)

Figure 2. Immunology and Auto-Antibody Profiles Across Rheumatic Diseases According to Clinician Diagnosis of CTD

Anti-dsDNA antibodies were found in 22.9% of Sjögren's patients and 19% of UCTD patients (Fig 2). Anti-centromere antibodies had a high specificity for SSc. In contrast, other auto-antibodies were prevalent across a number of CTDs, in particular rheumatoid factor and low complement were observed in all conditions.

Conclusion: Within this CTD cohort, patients met classification criteria for CTDs other than the diagnosis given by the treating clinician and the autoantibody spectrum observed showed significant overlaps across diagnostic and classification subsets. Of note a high proportion of UCTD and MCTD patients fulfil criteria for other CTDs. Our study suggests that CTD patients are likely to have overlapping clinical and immunological phenotypes and they need to be continually reassessed for new or evolving clinical features.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: B-cells play a pivotal role in the initiation and perpetuation of systemic lupus erythematosus (SLE). Recently, it has been demonstrated that in active SLE patients, the peripheral blood is enriched in $CD27^{+}IgD^{-}$ post-switched memory B-cells. The aim of our study was to delineate the B-cell repertoire of SLE patients with low disease activity (SLEDAI – 2K ≤4).

Methods: Peripheral blood samples from 42 patients suffering from SLE (mean±SD; age 42±13 years, 88% females, disease duration 10.9±7 years) and 74 age-matched healthy controls (HC; age 46±17 years, 80% female) were drawn over 2 years. All SLE patients were in remission or with low disease activity (SLEDAI of 2.0±1.7) achieved with different therapies, e.g. rituximab (RTX), cyclophosphamide, hydroxychloroquine or mycophenolate. B-cells were characterized using $CD19^{-}$, $CD20^{-}$, $CD5^{-}$, $CD27^{-}$ antibodies and grouped in naïve ($IgD^{+}27^{-}$), non-switched memory (IgD^{+}, $CD27^{+}$), memory (IgD^{-}, $CD27^{+}$), B1 ($CD5^{+}27^{-}$) and MBL-like ($CD5^{++}$) B-cells. A quantitative flow cytometric bead-based assay (QuantiBRITE PE kit from Becton Dickinson) was used for the estimation of CD19 antibodies bound per cell. All cytometric measurements were performed using a standardized BD LSR Fortessa platform.

Results: SLE patients had significantly higher B1 type B-cells in comparison with HC (median±SE, 16.8±2.1% vs. 9.9±0.7%; p=0.001). In addition, naïve and MBL type B-cells were significantly more frequent (p< 0.005) in patients

with SLE than in HC (77.2±3.6% vs. 61.6±1.4%; 0.3±0.1 vs.0.2±0.1; respectively). In contrast, memory and marginal zone B-cells were significantly reduced (p=0.001) in SLE patients with low disease activity (10.2±1.8% vs.16.6±1.0%; 2.9±0.9% vs. 9.9±0.7%; respectively). Interestingly, also non-switched memory B-cells were significantly lower in SLE patients compared to HC (2.1±0.7% vs. 6.5±0.5%; p< 0.0001). No significant difference was seen for the number of CD19 molecules on the surface of B-cells of SLE patients or HC (7432±449 vs. 7900±225; respectively). In addition, the percentage of CD86+ B-cells capable of activating T-cells were similar between SLE patients and HC (9.3±1.1% vs.8.4 ± 0.4%; p =0.421).

Conclusion: Patients with low SLE activity show an increase of naïve and inactive B-cells. This is true for patients treated successfully with RTX, cyclophosphamide and also for SLE patients treated with mycophenolate and hydroxychloroquine.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) have been associated with organ damage and certain features in SLE patients. Our aim was to investigate the differences between SLE patients according to the presence of aPL and/or clinical antiphospholipid syndrome (APS).

Methods: Patients from the RELESSER-T registry were included. RELESSER-T is a multicenter, hospital-based registry, with retrospective cross-sectional collection of data from a large representative sample of adult non-selected patients with SLE attending Spanish rheumatology services from the public national health system.

Table 1. Main clinical and demographic characteristics of the studied groups.

	SLE, n =2283 (%)	SLE APS, n=552 (%)	SLE aPL, n=816 (%)	*p*
Female sex	2075 (90.9)	486 (88)	737 (90.3%)	0.127
Age, mean±SD (yr)	47.0±15.1	48.6±14.4	45.1±14.2	<0.001
Disease duration, mean±SD (mo)	141.5±100.7	157.5±110.5	135.3±92.7	0.006
Tobacco use: • Current • Former	335 (16.3) 494 (24.1)	97 (18.9) 124 (24.1)	119 (16.4) 184 (25.3)	0.637
High blood pressure	647 (28.6)	224 (40.8)	190 (23.5)	<0.001
Dyslipidemia	664 (30.3)	226 (42.0)	211 (26.8)	<0.001
Diabetes	114 (5.1)	43 (7.9)	22 (2.8)	0.001
Cutaneous manifestations	1700 (74.4)	378 (68.1)	591 (72.3)	0.011
Joint symptoms	1784 (78)	421 (75.9)	626 (76.6)	0.455
Respiratory manifestations	568 (24.8)	185 (33.3)	189 (23.1)	<0.001
Cardiac manifestations	397 (17,4)	147 (26,5)	122 (14,9)	<0.001
Renal manifestations	859 (37.6)	258 (46.5)	287 (35.1)	<0.001
Neuropsychiatric manifestations	348 (15.2)	153 (27.6)	124 (15.2)	<0.001
Ophthalmological manifestations	77 (3.4)	40 (7.2)	39 (4.8)	<0.001
Positive anti DNA antibodies	1599 (71.5)	436 (80.8)	584 (73.9)	<0.001
Hypocomplementemia	1716 (76.7)	441 (82.4)	628 (78)	0.017

Results: We included 3651 SLE patients and 1368 were positive for aPL. Overall 2283 patients were classified as SLE no aPL, 552 as SLE-APS and 816 as SLE-aPL. Demographic data, clinical and laboratory features in the different groups are showed in Table 1. Regarding cardiovascular risk factors, SLE-APS patients had higher rates of hypertension, dyslipidemia and diabetes ($p \leq 0.001$). SLE-APS patients showed higher rates of neuropsychiatric, cardiac, pulmonary, renal and ophthalmological manifestations than the other groups ($p < 0.001$) (Table 1). In accordance with a more severe clinical profile, higher frequency of anti-DNA antibodies were observed in the SLE-APS group comparing with SLE ($p < 0.001$). SLE APS patients presented more damage accrual with higher values in SLICC (1.9±2.2 in SLE APS, 0.9±1.4 in SLE aPL and 1.1±1.6, $p < 0.001$) and Katz indexes (3±1.8 in SLE APS, 2.7±1.7 in SLE aPL and 2.6±1.6 in SLE no aPL, $p < 0.001$). In line with a more severe disease, mortality rate was higher in SLE APS patients ($p < 0.001$).

Conclusion: SLE-APS patients show a more severe clinical profile with higher frequency of major organ involvement and more damage accrual than SLE-aPL and SLE no APL.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: TWEAK, MCP-1 and NGAL, mediators in pathogenesis of systemic lupus erythematosus (SLE), are proinflammatory cytokines/chemokines that are thought as potential biomarkers reflecting disease activity. In this study, we aimed to investigate the association of serum (s) and urine (u) levels of TWEAK, MCP-1 and NGAL with disease activity in both renal and non-renal SLE.

Methods: Thirty active patients with SLE (15 renal and 15 non-renal) were recruited. Disease activity was determined using SLE Disease Activity Index (SELENA-SLEDAI) and British Isles Lupus Assessment Group (BILAG)-2004 index. Thirty-one inactive patients with SLE (16 renal and 15 non-renal), 14 patients with ANCA-associated vasculitis (AAV) all of whom had active renal involvement and 20 healthy volunteers were selected as control groups. In patients with AAV, disease activity was evaluated using Birmingham Vasculitis Activity Score (BVAS) v3. Serum and urine levels of TWEAK, MCP-1 and NGAL were tested using ELISA.

Results: Sixty-one SLE patients, 51 (83.6%) of whom were female, with a median disease duration of 83 (23.5-135) months and a median age of 35 (27-47.5) were included in the study. Serum and urine levels of TWEAK and NGAL were significantly higher in the active SLE group compared with the inactive SLE (n=31) group (sTWEAK: p=0.005; uTWEAK: p=0.026; sNGAL: p< 0.001; uNGAL: p=0.002); whilst no significant differences regarding serum and urine MCP-1 levels were observed (p=0.189 and p=0.106). uTWEAK (p=0.237), sMCP-1 (p=0.141), uMCP-1 (p=0.206), sNGAL (p=0.419) and uNGAL (p=0.443) levels did not differ between patients with active LN and non-renal active SLE; yet levels of sTWEAK were higher in patients with active LN (p=0.006). There were no differences between active LN and renal active AAV. Levels of all biomarkers were correlated with SLEDAI (sTWEAK: p=0.001; uTWEAK: p=0.006; sMCP-1: p=0.049; uMCP-1: p=0.014; sNGAL: p< 0.001; uNGAL: p=0.002).

Conclusion: sTWEAK, uTWEAK, sNGAL and uNGAL are significant biomarkers showing disease activity in SLE. However, our results implicate that these biomarkers may not be specific for SLE, and can be elevated in patients with active renal involvement of AAV. sTWEAK may be of use for discriminating active nephritis from non-renal active disease in SLE. Further studies are awaited to confirm these results (This study was funded by Istanbul University with the project number TTU-2017-24738 and Turkish Society for Rheumatology).

Abstract Number: 0662

Utility of a Mobile Phone Based Application to Collect Patient-Reported Outcome Information from People Living with Systemic Lupus Erythematosus

Brooke Williams,[1] Bridget Muckian,[1] Claire Dykas,[2] Christine Peschken,[3] Richard Furie,[4] Elena Massarotti,[5] Vanja sikirica,[6] Steven Gilbert,[7] Martin Hodge,[7] and Peter Lipsky[8], [1]AMPEL BioSolutions, Charlottesville, VA, [2]AmpelBioSolutions, Charlottesville, VA, [3]University of Manitoba, Winnepeg, Canada, [4]Northwell Health, Great Neck, NY, [5]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, [6]Pfizer, Boston, MA, [7]Pfizer, Boston, [8]AMPEL BioSolutions, LLC, Charlottesville, VA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patient Reported Outcomes (PROs) can provide important data about the impact of a disease on an individual and/or the quality of the response to medication. However, in most circumstances, PRO information is collected only intermittently and usually at the point of care or treatment. The development of mobile technology to collect PRO data electronically (ePRO) provided the opportunity to acquire this information more frequently, in real time, and in the person's normal environment. The objective of the research was to develop a smart phone application (app) and test its utility to collect ePRO information in people with systemic lupus erythematosus (SLE).

Methods: A smart phone app was developed that collects data from a number of PRO instruments, including FACIT-F (fatigue), SF-36 (health-related quality of life) and patient global assessment (PtGA). People living with SLE were involved in the initial development and evaluation of the acceptability of the app. To test to utility of this app, a multicenter clinical study (VALUE, NCT03142711) was carried out in collaboration with people with SLE, in whom ePRO information was collected with the app daily (PtGA) or weekly (FACIT-F and SF-36) in the person's environment and also with the app and a paper form monthly at the clinical site. Demographic information, compliance and intra-class

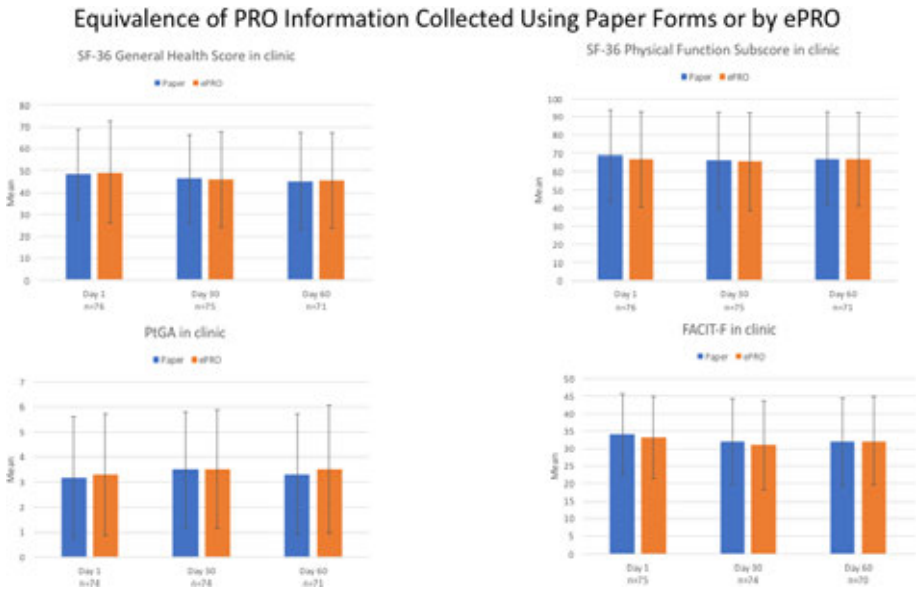

Figure 1

correlation coefficients between information collected with the app and using a paper form at the clinical site were assessed.

Results: Of the 80 people enrolled in this study, 91.3% were women; 57.5%, 16.3% and 17.5% identified themselves as of European, African or Asian ancestry, respectively. The mean age was 42.6 years and the mean duration of education was 15.6 years. Overall compliance with completing the ePRO instruments with the app at the scheduled time was 88%. To determine the consistency of information collected with the app, PRO instruments were completed on three occasions: a) in standard fashion using a paper form and b) using the app, separated by an interruption at the clinical site. The mean (SD) PtGA, FACIT-F and SF-36 Physical Functioning and General Health scores at baseline, month 1 and month 2 using the app and paper forms were similar (Figure 1). The Intraclass Correlation Coefficient (ICC) and 90%CI were 0.97 (0.96-0.98), 0.96 (0.94-0.07) and 0.95(0.93-0.97) at the three time points, respectively for the PtGA; 0.94(0.91-0.96), 0.96(0.95-0.98) and 0.96(0.94-0.97), respectively for the FACIT-F instrument; and , 0.96(0.94-0.97), 0.94(0.91-0.96) and 0.96 (0.94-0.97) for the 3 time points, respectively for the SF-36 Physical Functioning score.

Conclusion: Compliance with completion of ePROs using a mobile app was high and the content collected with the app conformed with that collected using a paper form. Since compliance with the use of a mobile app to collect ePRO information and the consistency of the information obtained compared to that obtained using a paper form were high, the app affords the potential opportunity to acquire frequent and highly reliable information about the impact of disease and response to medication in individuals with SLE.

Abstract Number: 0663

Peripheral Blood Toll Like Receptor 7 Expression and Serum Interferon Lambda 1 Levels in Systemic Lupus Erythematosus and Their Relation to Disease Activity and Lupus Nephritis

Hayam ElAggan,[1] Nahla Farahat,[1] Mohamed Sakr,[1] and Shaymaa Tawfik[1], [1]Faculty of Medicine, University of Alexandria, Alexandria, Egypt, Alexandria, Egypt

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Toll-like receptor 7 (TLR7) can sense single-stranded RNA with subsequent induction of different interferon (IFN) types including IFN lambda (IFNL) and may contribute to the development of autoimmune diseases. The present work was designed to investigate the potential role of TLR7 and IFNL1 in systemic lupus erythematosus (SLE) and their relation to disease activity and development of lupus nephritis (LN).

Methods: Thirty patients with SLE (15 patients without LN and 15 patients with LN) and 15 healthy subjects were enrolled in the study. Disease activity was assessed using the SLE disease activity index (SLEDAI). Antinuclear antibody (ANA) and anti-double stranded DNA antibodies (anti-dsDNA) titer were assayed. TLR7 expression on

peripheral blood CD14+ monocytes was studied by color flow cytometry and the absolute number of CD14+ TLR7+ cells was calculated. Quantification of IFNL1 levels in serum was determined using enzyme-linked immunosorbant assay. Renal function was assessed by estimating serum creatinine, estimated glomerular filtration rate (eGFR) and urinary albumin to creatinine (UAC) ratio. Erythrocyte sedimentation rate (ESR), serum high-sensitivity C-reactive protein (hsCRP) and serum complement 3 and 4 (C3 and C4 respectively) were quantified. Renal biopsy was performed to patients with LN and classified according to the international society of nephrology/renal pathology society.

Results: The number of peripheral blood CD14+ TLR7+ monocytes and serum IFNL1 levels showed significant increases in patients with and without LN compared with healthy controls and in patients with LN compared with those without LN ($P < 0.001$). Changes in TLR7 expression and IFNL1 production in peripheral blood were positively correlated ($P < 0.001$) and both showed positive correlations with SLEDAI score, ANA and anti-dsDNA titers, serum creatinine, UAC ratio, ESR, serum hsCRP levels and renal activity index and inverse correlations with eGFR and serum C3 and C4 levels in SLE patients ($P < 0.05$). By plotting receiver operating characteristics (ROC) curve, the sensitivity and specificity of the number of peripheral blood CD14+ TLR7+ monocytes in discriminating SLE patients with and without LN were higher than those of serum IFNL1 levels (100% and 93.33% respectively, area under the curve (AUC) = 0.996 vs. 86.7% and 40% respectively, AUC = 0.687).

Conclusion: Activation of TLR7/IFNL1 pathway may play an important role in the pathogenesis of SLE in relation to disease activity and development of LN and could be a potential therapeutic target for the treatment of SLE and LN.

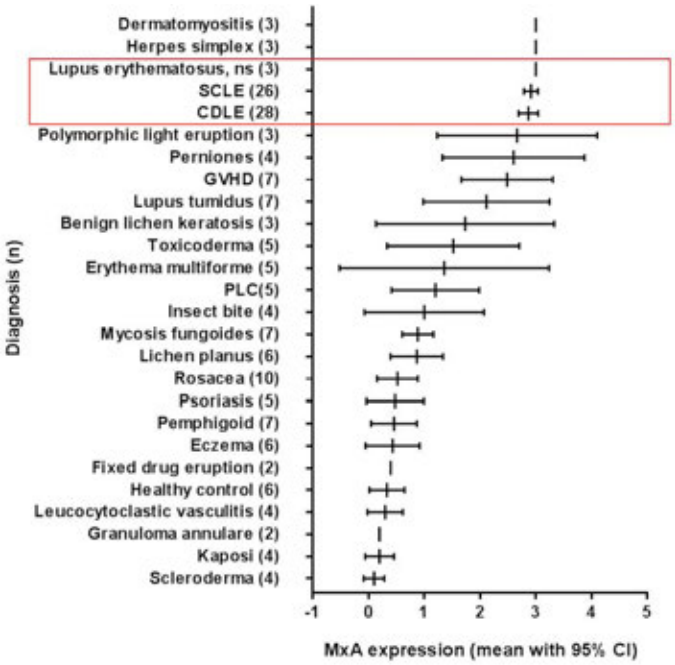
Myxovirus Resistance Protein a Is a Useful Additional Histological Marker for Cutaneous Lupus Erythematosus

Wietske Lambers,[1] Karina de Leeuw,[2] Femke Homan,[1] Berber Doornbos-van der Meer,[1] Hendrika Bootsma,[3] Johanna Westra,[2] and Gilles Diercks[1], [1]UMCG, Groningen, Netherlands, [2]Dept. of Rheumatology and Clinical Immunology - University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands, [3]University of Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cutaneous lupus erythematosus (CLE) is a heterogeneous auto-inflammatory skin disease, that is driven to a great extent by interferon (IFN) type I[1], and is characterized by superficial and deep perivascular and periadnexal infiltration of lymphocytes as well as interface dermatitis. Unfortunately, no specific histological marker for CLE is currently available.

Methods: 163 skin biopsy specimens were collected from the local pathology database. Various conditions (eg. CLE, dermatomyositis, rosacea, psoriasis, graft versus host disease, scleroderma) were selected, provided that clinical diagnosis matched with histological diagnosis. Herpes simplex lesions were used as positive controls. Skin sections were incubated with anti-MxA (R&D systems, AF7946). Consecutively, rabbit anti goat-HRP conjugate (Dako, 0449) was added and sections were stained with diaminobenzidine.



Abbreviations: ns = not specified, SCLE = subacute cutaneous lupus erythematosus, CDLE = chronic discoid lupus erythematosus, GVHD = graft versus host disease, PLC = pityriasis lichenoides chronica.

Figure 1. Myxovirus resistance protein A expression in various skin diseases. Abbreviations: ns = not specified, SCLE = subacute cutaneous lupus erythematosus, CDLE = chronic discoid lupus erythematosus, GVHD = graft versus host disease, PLC = pityriasis lichenoides chronica.

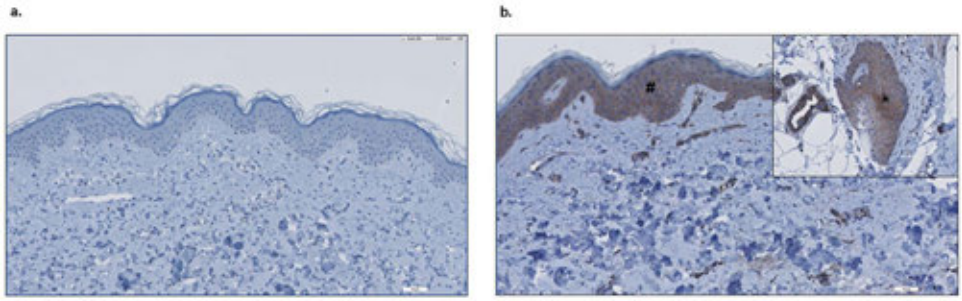


Figure 2. MxA staining in skin biopsies of (a) healthy control and (b) cutaneous lupus erythematosus with MxA expression in epidermis (#), endothelium (->) and adnexa (*)

The expression of MxA was scored semi-quantitatively by 2 researchers in respectively epidermis, dermal structures, fibroblasts, infiltrates, and endothelium (0 for no expression, 1 for moderate expression, 2 for mediate expression, and 3 for strong expression). Mean scores were calculated based on cumulative expression divided by the number of assessable skin parts.

Results: MxA staining was strongly positive in both epidermis, dermal structures, infiltrate, and endothelium in nearly all lesional CLE skin sections (except lupus tumidus), as well as in dermatomyositis (see figure 1), which is also an IFN-driven autoimmune disease. Although most other inflammatory skin diseases did show no or a low expression of MxA. In some conditions, like perniones and graft versus host disease, high expression could be found, but this was less consistent compared to CLE.

Conclusion: MxA is strongly expressed in CLE skin, and therefore is useful as additional diagnostic histological marker, expectedly resulting in restriction of misdiagnosis and treatment delay. The high expression found in skin biopsies from graft versus host disease and perniones, suggests that IFN type I plays a role in the pathogenesis of these conditions.

Abstract Number: 0665

Utility of Repeat Renal Biopsies in Patients with Lupus Nephritis in Western Australia

Warren Raymond,[1] Alexandra Kang,[2] Daniel Wong,[3] Aron Chakera,[4] and Johannes Nossent[1], [1]School of Medicine, The University of Western Australia, Crawley, Western Australia, Australia, [2]PathWest, Nedlands, Western Australia, Australia, [3]PathWest, Perth, Western Australia, Perth, Western Australia, Australia, [4]Renal Medicine, Sir Charles Gairdner Hospital, Perth, Western Australia, Australia

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The role of repeat renal biopsy (RRBx) in lupus nephritis (LN) to guide treatment or predict prognosis is not fully understood. We assessed the association between histopathological changes and clinical outcomes across renal biopsies.

Methods: A retrospective cohort study of 99 patients with biopsy confirmed lupus nephritis (LN), and 39 (39.4%) patients [mean age 29.2 ± 11.0 years; 89.7% female] who had at least one RRBx (median of 2 renal biopsies; interquartile range: 2, 3) for evaluation of persistent/current symptoms. Renal specimens were assessed by ISN classification (Class I and II grouped as mild disease, Class III + IV as proliferative disease, and Class V as membranous proliferative disease), NIH Activity (0-24) and Chronicity (0-12) indices and immunofluorescence findings (0-3) with data on clinical characteristics, serology, medication, disease activity (Systemic Lupus Erythematosus Disease Activity Index - 2K (SLEDAI-2K)), organ damage (SLICC Damage Index (SDI)) at biopsy recorded. Study endpoints included the doubling of serum creatinine, requirement for renal replacement therapy (RRT), and mortality.

Outcomes were assessed comparatively across biopsy events with non-parametric and Chi-square tests; and, logistic regression quantified the odds of study endpoints.

Results: Compared to patients without repeated biopsies; at the initial biopsy, RRBx patients were younger (29 vs 36 years, p=0.026) and, more likely to be lymphopenic (79.5% vs 60.0%, p=0.04) and had “Full house IF findings” (89.5% vs 62.2%, p=0.03). Patients had similar median proteinuria level (300 vs 257, p=0.70) and SLEDAI scores (13 vs 12, p=0.19). RRBx (n=39) occurred 2.95 years (IQR 1.20, 6.10) after the index biopsy; and, clinical characteristics, laboratory levels and SLEDAI scores were similar to the index biopsy data. Class switching occurred in 9 (23%) patients; with Class worsening in 6 and improvement in 3 (p=0.04). NIH Activity Index was not significantly different from the index biopsy; however, Glomerular Sclerosis (0 vs 1), Interstitial Fibrosis (0 vs 1),

and the NIH Chronicity Index (1 vs 2) had worsened at the repeat biopsy, all p< 0.01. Increasing Cellular Crescents increased the odds of RRT [OR 1.7 (95%CI: 1.0, 2.8) p=0.049], and the doubling of serum creatinine at last follow-up [OR 2.0 (95%CI 1.0, 4.00), p=0.05]. Increasing NIH Chronicity Index increased the odds of doubling of creatinine at last follow-up [OR 3.6 (95%CI 1.1, 12.3), p=0.04]. There was no impact of histological findings on repeat biopsy on mortality.

Conclusion: Patients with LN with a RRBx showed low rates of ISN Class switching within 3 years, and NIH Activity Index remained unchanged across biopsies; suggesting that repeat biopsies had little impact on disease management. In contrast, NIH Chronicity Index scores were increased and associated with worse renal outcome.

Abstract Number: 0666

Sensitivity to Change of the Patient Reported Outcomes Measurement Information System (PROMIS) Computerized Adaptive Test (CAT) Measures in a Single Canadian Lupus Cohort

William Fung,[1] Mitra Moazzami,[2] Lisa Engel,[3] Jiandong Su,[4] Dennisse Bonilla,[4] Pooneh Akhavan,[5] Patricia Katz,[6] Dorcas Beaton,[7] and Zahi Touma[8], [1]University of Toronto, Toronto, ON, Canada, [2]George Washington University, Washington, DC, [3]University of Manitoba, Winnipeg, MB, Canada, [4]University Health Network, University of Toronto, Toronto, ON, Canada, [5]University of Toronto, Toronto, Canada, [6]University of California, San Francisco, san francisco, CA, [7]St. Michael's Hospital, Toronto, ON, Canada, [8]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcomes (PROs) measures are a key component of the care of patients with systemic lupus erythematosus (SLE). The Patient Reported Outcomes Measurement Information System (PROMIS) computerized adaptive test (CAT) is a recently developed PRO instrument that has not yet been well studied in SLE. This study seeks to examine the sensitivity to change of PROMIS CAT compared to patient-reported anchors within a cohort of adult SLE patients.

Methods: All consecutive adult (≥18 years old) English-speaking patients with SLE and visiting the Toronto Lupus Clinic between July-September 2018 were approached to participate. Patients completed PROMIS CAT during their clinical visit assessing 14 domains. 89 patients completed PROMIS CAT at baseline and at 3-month follow-up. At 3 months, the generic anchor question "Compared to when you started the study, how have you been during the last 48 hours? (responses: same, worse,)" was asked to identify two subsets of patients, those with improved vs worsened symptoms at 3 months. Similar domain-specific anchor questions were asked at 3 months, with responses graded from -7 (greatest worsening) to +7 (greatest improvement), and 0 representing no change. For domain-specific anchors, patients were deemed to have improved if they graded >1, and worsened if < -1. Responsiveness was evaluated using standardized response means (SRM), with higher SRM values reflecting greater sensitivity to change (0.3-0.5 low, 0.5-0.8 moderate, >0.8 high). SRMs for each domain were determined with respect to the generic as well as domain-specific anchors. We hypothesized that domains demonstrate worsening and improvement in concordance with the anchors.

Table 1. Patient characteristics of entire cohort (n=89)

Characteristic		
Mean age at 3 month visit (years)	48.3 ± 13.6	
Mean SLE duration at 3 month visit (years)	20.2 ± 12.5	
Female	82 (92.1%)	
Ethnicity	Black	11 (12.4%)
	Caucasian	57 (64.0%)
	Chinese	11 (12.4%)
	Others	10 (11.2%)
Education	< Grade 8	1 (1.1%)
	Grade 8	2 (2.3%)
	High school graduate	16 (18.4%)
	College	28 (32.2%)
	University	40 (46.0%)

Table 2. Baseline patient characteristics of groups with improved vs worsened symptoms (based on generic anchor question)

Characteristic	**Improvement of symptoms (n=19)**	**Worsening of symptoms (n=13)**
Mean age at 3-month visit (years)	48.3 ± 15.3	50.2 ± 14.8
Mean SLE duration at 3-month visit (years)	19.5 ± 13.5	22.2 ± 13.9
Female	18 (94.7%)	13 (100%)
Ethnicity		
Black	3 (15.8%)	1 (7.7%)
Caucasian	11 (57.9%)	10 (76.9%)
Chinese	3 (15.8%)	2 (15.4%)
Other	2 (10.5%)	0 (0%)
Education		
< Grade 8	0 (0%)	0 (0%)
Grade 8	1 (5.3%)	0 (0%)
High school graduate	3 (15.8%)	5 (41.7%)
College	6 (31.6%)	5 (41.7%)
University	9 (47.4%)	2 (16.7%)
PROMIS domains	Mean ± SD	Mean ± SD
Physical Function	42.8 ± 7.6	38.2 ± 9.0
Mobility	44.1 ± 10.7	40.2 ± 11.6
Pain Behaviour	54.7 ± 10.2	58.8 ± 8.0
Pain Interference	58.2 ± 9.7	60.0 ± 10.2
Participation in social roles	45.5 ± 8.2	43.6 ± 10.0
Satisfaction in social roles	47.4 ± 12.2	43.9 ± 12.9
Fatigue	59.7 ± 9.3	62.7 ± 12.9
Sleep disturbance	56.7 ± 8.3	60.3 ± 11.2
Sleep related impairment	57.9 ± 9.6	61.8 ± 11.0
Anger	53.0 ± 8.3	53.6 ± 7.3
Anxiety	57.6 ± 9.2	56.5 ± 9.2
Depression	53.0 ± 6.6	56.2 ± 9.1
Cognitive function abilities	44.5 ± 9.5	41.7 ± 6.9
General cognitive function	45.8 ± 9.3	42.3 ± 8.5

PROMIS domains have population mean ± SD = 50 ± 10.

Results: Patient characteristics are in **Table 1**. **Table 2** contains the baseline characteristics of the subsets of patients with improvement and worsening at follow-up.

With respect to the general anchor, of 14 PROMIS domains, 8 demonstrated moderate SRMs: mobility, pain behaviour, pain interference, participation in social roles, fatigue, anxiety, depression, and cognitive function abilities (**Table 3**).

For domain-specific anchors (**Table 3**), only 3 domains (pain behaviour, pain interference, depression) demonstrated moderate SRMs. Only 1 domain (satisfaction in social roles) had a high SRM. SRM were overall larger with the generic anchor compared to domain-specific anchor.

Table 3. Standard response means comparing baseline and 3-month follow-up in patient subsets with improved vs worsened symptoms.

	Generic anchor		Domain-specific anchor	
Domains	**Improvement of symptoms (n=19)**	**Worsening of symptoms (n=13)**	**Improvement of symptoms (n=29)**	**Worsening of symptoms (n=14)**
Physical Function	0.14	0.02	0.27*	-0.18*
Mobility	0.23	-0.52	0.06	-0.37
Pain Behaviour	0.09	0.66	0.06	0.55
Pain Interference	-0.77	0.66	-0.29	0.68
Participation in social roles	0.75	-0.42	0.32	-0.43
Satisfaction in social roles	0.38	-0.33	-0.10	-0.95
Fatigue	-0.64	0.30	-0.28	-0.11
Sleep disturbance	-0.12	-0.03	0.02	0.10
Sleep related impairment	-0.14	-0.03	-0.06	0.03
Anger	-0.45	0.19	-0.12	0.42
Anxiety	-0.51	0.42	-0.25	0.26
Depression	-0.20	0.66	-0.20	0.53
Cognitive function abilities	0.65	-0.49	-0.01	-0.49
General cognitive function	0.33	0.20	-	-

*n=28 for improved; n=13 for worsened for domain-specific physical function
SRM 0.3-0.5 = low, 0.5-0.8 = moderate, >0.8 = high

Notice that for each of 13 Anchor questions, the answers and their corresponding scores are:
0 = "No change"
1 = "Almost the same, hardly any better at all"
2 = "A little better"
3 = "Somewhat better"
4 = "Moderately better"
5 = "A good deal better"
6 = "A great deal better"
7 = "A very great deal better"
-**1** = "Almost the same, hardly any worse at all"
-**2** = "A little worse"
-**3** = "Somewhat worse"
-**4** = "Moderately worse"
-**5** = "A good deal worse"
-**6** = "A great deal worse"
-**7** = "A very great deal worse";

Conclusion: Out of 14 PROMIS domains, 8 were sensitive to change at 3-month follow-up when compared to a generic anchor question. In contrast, for domain-specific anchors, only 4 domains were sensitive to change at 3-month follow-up, of which one had not been sensitive in the generic anchor analysis. This highlights the importance of using appropriate anchor questions when assessing responsiveness. Focusing on patients with more significant reported changes (+/- 4-7 on anchors) may yield larger SRMS. This requires a larger sample size and currently cannot be performed. Further work is needed to evaluate the utility of PROMIS CAT measures in the care of lupus patients as well as to determine minimal clinically important differences.

The PROMIS-29 as a Measure of Type 1 and 2 SLE Activity

Nathaniel Harris,[1] Amanda Eudy,[2] Megan Clowse,[2] Lisa Criscione-Schreiber,[2] Jayanth Doss,[2] Rebecca Sadun,[2] Jennifer Rogers,[2] and Kai Sun[2], [1]Duke University Medical Center, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have developed a new conceptual model that characterizes lupus into subtypes based on physician- and patient-reported measures: **Type 1** is assessed by the rheumatologist and incorporates immunologic activity and organ involvement; **Type 2** is based on patient report of fatigue, myalgia, mood disturbance, and perceived cognitive dysfunction. We have previously defined Type 2 symptoms based on the ACR's Fibromyalgia Severity Score (FSS), and here we seek to assess the impact of Type 1 and 2 SLE activity on the NIH's Patient-Reported Outcomes Measurement Information System (PROMIS) measures.

Methods: Data on physician- and patient-reported measures of disease activity were collected on women with SLE enrolled in a prospective registry at a single academic center from 2018-2019. Patients were classified as having Type

Table 1. Median PROMIS measure T-score by lupus subtype. A score of 50 corresponds to the US population mean, and a score difference of 5 (half standard deviation) is clinically significant.

	LOW TYPE 2 SLE ACTIVITY		HIGH TYPE 2 SLE ACTIVITY		
MEDIAN (IQR)	Minimal SLE Activity	Type 1 SLE Activity	Type 2 SLE Activity	Mixed SLE Activity	p-value
HIGH SCORE IS WORST:					
PAIN INTERFERENCE	52.4 (41.6-55.7)	59.5 (53.0-61.3)	63.1 (61.3-66.7)	64.1 (61.3-69.9)	<0.0001
FATIGUE	51.0 (46.0-58.6)	56.6 (51.0-62.1)	64.8 (62.7-71.5)	69.0 (60.9-75.8)	<0.0001
SLEEP DISTURBANCE	55.7 (53.3-58.7)	56.4 (54.4-58.3)	56.4 (53.9-59.0)	56.0 (54.5-59.0)	0.8
HIGH SCORE IS BEST:					
PHYSICAL FUNCTIONING	45.7 (39.8-57.0)	41.5 (37.2-46.8)	35.0 (32.1-38.8)	36.3 (34.4-38.4)	<0.0001
SOCIAL HEALTH	51.8 (48.0-64.2)	48.8 (44.2-54.5)	40.3 (37.2-44.2)	41.8 (32.0-44.2)	<0.0001

1 SLE activity (SLEDAI ≥6, clinical SLEDAI ≥4, or active nephritis), Type 2 SLE activity (FSS >10), Mixed (both Type 1 and Type 2 SLE activity), or minimal (neither Type 1 or Type 2 SLE activity). We compared the PROMIS composite measures of pain interference, physical functioning, sleep disturbance, fatigue, and ability to participate in social roles and activities between groups using the Wilcoxon rank-sum test. A PROMIS score of 50 is the national average, and a score difference of 5 (half standard deviation) is clinically significant.

Results: Data were collected from 116 women with SLE of whom 63% were African American with an average age 43. Compared to the US general population, patients with either Mixed or Type 2 SLE activity have moderately worse scores (1-2 standard deviation difference), while patients with Type 1 SLE activity alone have only mildly worse scores (< 1 standard deviation difference) in physical functioning, ability to participate in social roles and activities, fatigue, and pain interference. Patients with Minimal SLE activity were the least limited by pain, suffered from less interference with physical and social functioning, and their scores were not clinically significantly different (within a half standard deviation) from the general population. Despite the large differences in fatigue, all SLE groups reported similar degrees of mild sleep disturbance (Table 1).

Conclusion: The presence or absence of Type 2 symptoms was the primary determinant of PROMIS scores in pain, physical functioning, fatigue, and social well-being. This analysis demonstrates that multiple domains of the PROMIS-29 correspond to the Type 1 and 2 SLE model and may be useful in measuring levels of Type 1 and 2 SLE activity. Next steps include identifying and validating the optimal PROMIS domains that can be used to determine current Type 2 SLE activity.

Abstract Number: 0668

Lack of Uptake of Prophylactic Human Papilloma Virus (HPV) Vaccination Among Women with Systemic Lupus Erythematosus (SLE) in the Detroit, MI Area, a High Risk Population

J. Patricia Dhar,[1] Louis Saravolatz,[2] and Susan Szpunar[3], [1]Wayne State University, Bloomfield Hills, MI, [2]Ascension St. John Hospital and Wayne State University, Grosse Pointe Woods, MI, [3]Ascension St. John Hospital Hospital, Grosse Pointe Woods, MI

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with SLE are at increased risk for cervical neoplasia likely because of infection with high risk (HR) HPV and thus should be considered for HPV vaccination. We previously showed quadrivalent human papillomavirus (qHPV) vaccine to be safe and immunogenic in women with SLE. We sought to determine the frequency of HRHPV infection and uptake of HPV vaccination in the female outpatient lupus population. The qHPV vaccine was approved for use in 2006 for women ages 9-26 years.

Methods: We conducted a retrospective chart review of women ages 16-70 years, with an ICD-10 diagnosis of SLE, seen in the Internal Medicine, Family Medicine, OB/Gyn and Rheumatology clinics associated with a large teaching hospital in Detroit, Michigan during the period 10/2015 to 2/2019. After obtaining IRB approval, data were collected

Table 1. Comparison for Women HRHPV+ vs. HRHPV- (N=45 tested)

	HPV + (n=6)	HPV – (n=39)	p-value
Age in years (mean ± s.d.)	40.0 ± 8.3	47.4 ± 10.7	0.11
Race (n, %)			- -
White	1 (7.7%)	12 (92.3%)	
Black	5 (16.7%)	25 (83.3%)	
Other	0 (0%)	2 (100%)	
Smoke Exposure (n, %)			- -
Current	0 (0%)	7 (100%)	
Former	1 (14.3%)	6 (85.7%)	
Never	5 (16.1%)	26 (83.9%)	

on demographic and clinical characteristics. Data were analyzed using Student's t-test, analysis of variance followed by multiple pairwise comparisons using the Bonferroni correction of the p-value.

Results: We collected data on 118 women, mean age 44.5 ± 11.6 years, 40.7% Caucasian (48/119), 50% Black (59/118) and 9.3% other/unknown race (10/118). Current smoking was reported by 17.1% (20/117), with 26.5% being former smokers (31/117) and 56.4% never smokers (66/117). HRHPV testing was performed in 45 (38.1%) of these women; six were positive (13.3%). There were no significant differences in test results by age, race or smoking status (Table 1). Black women (50.8%) were more likely to be tested than Caucasians (27.1%) or other races (18.2%), p=0.02. Only 4.3% of the study group were vaccinated (5/117). Of the 112 women who were eligible to receive an HPV vaccine, 38.4% (43/112) were tested for HRHPV with 5 being positive. Of the 5 that were vaccinated, only one woman had testing for HRHPV and this female was positive for HRHPV.

Conclusion: Despite the fact that HPV related cervical disease and neoplasia are increased in women with SLE, the frequency of testing for HRHPV testing is low (38.4%) and vaccination rate even lower (4.3%) in our region. This highlights the importance of the need for monitoring for HRHPV and including HPV vaccination as part of general health care in this vulnerable population. Promoting awareness of this problem with primary care doctors and the lupus community would improve uptake of prophylactic HPV vaccination and be beneficial to gynecologic health in women with SLE.

Complement Activation in Probable Systemic Lupus Erythematosus (pSLE) May Predict Progression to SLE Defined by Fulfillment of ACR Classification Criteria

Rosalind Ramsey-Goldman,[1] Roberta Alexander,[2] Sonali Narain,[3] Cristina Arriens,[4] Elena Massarotti,[5] Daniel Wallace,[6] Amit Saxena,[7] Christopher Collins,[8] Chaim Putterman,[9] Kenneth Kalunian,[10] Tyler O'Malley,[11] Armida Sace,[2] Rowena LaFon,[2] Jo-Anne Ligayon,[2] Claudia Ibarra,[2] John Conklin,[2] Thierry Dervieux,[2] and Arthur Weinstein[12], [1]Northwestern University, Chicago, IL, [2]Exagen, Vista, CA, [3]Northwell Health, Great Neck, Long Island, NY, [4]Oklahoma Medical Research Foundation, University of Oklahoma Health Sciences Center, Oklahoma City, OK, [5]Brigham and Women's Hospital/Harvard Medical School, Boston, MA, [6]Cedars Sinai Medical Center/UCLA, Los Angeles, CA, [7]New York University School of Medicine, New York, NY, [8]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [9]Albert Einstein College of Medicine, New York, NY, [10]Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, CA, [11]Exagen, Oceanside, CA, [12]Georgetown University & Exagen, Inc, Claremont, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We reported (R*amsey-Goldman et al., Arthritis Rheumatol 2018: 70 [suppl 10])* that cell-bound complement activation products (CB-CAPs) and a multi-analyte assay panel with algorithm (MAP) are positive more frequently than standard immunological markers in patients with probable systemic lupus erythematosus (pSLE) who fulfilled 3 ACR criteria. We followed pSLE prospectively to evaluate whether CB-CAPs and MAP positivity at enrollment predict transition to classifiable SLE by fulfillment of a fourth ACR criterion.

Methods: pSLE were followed prospectively at academic lupus centers and clinical and laboratory data were collected. Biomarkers were measured at every visit. CB-CAPs - C4d bound to erythrocytes (EC4d) and B-cells (BC4d) - were measured by quantitative flow cytometry and expressed as mean fluorescent intensity (MFI). Serum C3 and C4 and autoantibodies were measured by turbidimetry and ELISA, respectively. Anti-dsDNA positivity was confirmed by immunofluorescence (IFA) with *Crithidia Luciliae*. MAP was evaluated as previously described (Dervieux T, et al. *J Immunol Methods* 2017) and consists of an algorithm which utilizes CB-CAPs and autoantibodies. A MAP score >0.1 is considered positive, the higher the number (to 3.5) the greater the likelihood of SLE. For this study, decision analysis with Youden index showed that MAP >0.8 and EC4d >20 MFI reflected the optimal cutoff. Data were analyzed by Fisher's exact test and Kaplan-Meier with log-rank test and Cox proportional hazards model for time to fulfillment of a fourth ACR criterion, expressed as hazard ratios.

Results: Of the 92 pSLE enrolled, 69 had 1 follow up visit 9-18 months after enrollment (average±SD = 12.4±1.7 months; median = 12 months). The time to acquire the 4th ACR criterion was estimated by the investigators at the follow up visit. Twenty pSLE (29%) fulfilled a fourth ACR criterion during this time. SLICC fulfillment at enrollment did not predict fulfillment of ACR criteria (p =0.27). Eight of the 20 (40%) pSLE who transitioned to classifiable SLE by ACR criteria had MAP >0.8 at enrollment while 8/48 (17%) non-transitioned patients had MAP > 0.8 at enrollment (p =0.06). Patients with MAP >0.8 at enrollment fulfilled ACR criteria with a hazard ratio (HR) =3.11 within 18 months (p < 0.01 by log-rank test). HR of MAP was higher than other individual biomarkers, although anti-dsDNA and EC4d >20 MFI were of borderline significance (Table).

Conclusion: Complement activation as detected by MAP >0.8 at enrollment may predict disease evolution of pSLE into classifiable SLE by ACR criteria better than anti-dsDNA and low serum complement.

	HR	95% CI	p value
Low C3 and/or C4	1.93	0.44-8.53	0.375
Anti-dsDNA (IFA)	2.97	0.98-8.99	0.043
Positive CB-CAPs (EC4d and/or BC4d)	1.66	0.67-4.09	0.275
EC4d >20 MFI	2.61	0.99-6.88	0.053
MAP >0.8	3.11	1.26-7.69	0.010

Hazard ratio (HR) of biomarkers in predicting fulfillment of a fourth ACR classification criterion by 18 months in the pSLE population. Data of 69 follow-up visits (n = 68 for MAP) that occurred 9 to 18 months after enrollment were analyzed. CB-CAPs: cell-bound complement activation products; MAP: multianalyte assay panel with algorithm; HR: hazard ratio; CI: confidence intervals.

Association Between Ambient Air Pollutant Exposures and Childhood-Onset Systemic Lupus Erythematosus: A 12-Year Population-Based Cohort Study in Taiwan

Yenju Shih,[1] and Chang-Ching Wei[2], [1]Division of Immunology and Rheumatology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan, Taichung city, Taiwan Republic of China, [2]Division of Allergy, Immunology and Rheumatology, Department of Pediatrics, Children Hospital, China Medical University Hospital, Taichung, Taiwan, Taichung city, Taiwan Republic of China

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Air pollutants exposure has been linked to inducing oxidative stress, pulmonary and systemic inflammation. We hypothesized that long-term exposure to air pollution would be associated with childhood-onset systemic lupus erythematosus (cSLE).

Methods: We collected data from the Taiwan National health insurance research database and linked these data to the Taiwan Air Quality-Monitoring Database. Children < 18 years old, identified from January 1st, 2000, were followed-up until the first diagnosis of cSLE was made or December 31st, 2012. The daily average air pollutant concentrations, including particulate matter (PM2.5) and total hydrocarbons (THC), were categorized into four quartile-

Table 1. Baseline demographics and exposure of air pollutants in Taiwan children, 2000-2012

N=244607		n	%
Gender	Boys	126734	51.8
	Girls	117873	48.2
Age, years	mean, SD	6.09	2.99
Urbanization level	1 (highest)	81894	33.5
	2	77950	31.9
	3	46364	19.0
	4 (lowest)	38399	15.7
Exposure of air pollutants			
$PM_{2.5}$ level (daily average, μ g/m3)	mean, SD	36.8	8.16
THC level (daily average, ppm)	mean, SD	2.42	0.23
Outcome			
Systemic lupus erythematosus	Yes	394	0.16
Follow-up time, years	mean, SD	11.2	2.32

The urbanization level was categorized by the population density of the residential area into 4 levels, with level 1 as the most urbanized and level 4 as the least urbanized.
PM, particulate matter; PM2.5, particles with aerodynamic diameter < 2.5 μm; THC, total hydrocarbons; SD, standard deviation

Table 2. Baseline urbanization level among quartiles of daily average concentration of air pollutants in Taiwan children, 2000-2012

Air pollutant Concentration	Quartile 1 (Q1) (lowest)	Quartile 2 (Q2)	Quartile 3 (Q3)	Quartile 4 (Q4) (highest)	*p-value
N=244607	n (%)	n (%)	n (%)	n (%)	
Particulate matter (PM2.5)					<0.001
Urbanization level					
1 (highest)	19547 (46.2)	24598 (41.7)	21523 (28.7)	16226 (23.8)	
2	7586 (17.9)	16989 (28.8)	27379 (36.5)	25996 (38.1)	
3	6889 (16.3)	9828 (28.8)	11993 (16.0)	17654 (25.9)	
4 (lowest)	8301 (19.6)	7644 (12.9)	14106 (18.8)	8348 (12.2)	
Total hydrocarbons (THC)					<0.001
Urbanization level					
1 (highest)	18880 (28.2)	11292 (22.7)	27324 (34.3)	24398 (50.6)	
2	16322 (24.4)	19580 (39.4)	27636 (34.6)	14412 (29.9)	
3	15493 (23.2)	7905 (15.9)	16466 (20.6)	6500 (13.5)	
4 (lowest)	16155 (24.2)	10971 (22.1)	8351 (10.5)	2922 (6.06)	

*Chi-square test
The urbanization level was categorized by the population density of the residential area into 4 levels, with level 1 as the most urbanized and level 4 as the least urbanized.
The daily average air pollutant concentrations were categorized into 4 groups based on quartiles for each air pollutant.

Table 3. The risk of systemic lupus erythematosus in children exposed to various air pollutants stratified by quartile of daily average concentration in Cox proportional hazard regression

	IR	cHR (95%CI)	aHR† (95%CI)
Particulate matter (PM2.5)			
1st Quartile	4.7	Reference group	Reference group
2nd Quartile	14.1	2.97 (1.88, 4.69)*	2.74 (1.74, 4.33)*
3rd Quartile	13.5	2.86 (1.82, 4.47)*	2.65 (1.69, 4.15)*
4th Quartile	21.9	4.61 (2.98, 7.13)*	4.23 (2.74, 6.55)*
Total hydrocarbons (THC)			
1st Quartile	9.5	Reference group	Reference group
2nd Quartile	8.6	0.91 (0.63, 1.30)	0.93 (0.65, 1.33)
3rd Quartile	16.2	1.75 (1.32, 2.31)*	1.82 (1.36, 2.42)*
4th Quartile	26.1	2.87 (2.16, 3.82)*	3.03 (2.25, 4.09)*

IR, incidence rate (per 100,000 person-years)
cHR, crude hazard ratio; aHR, adjusted hazard ratio; CI, confidence interval
The daily average air pollutant concentrations were categorized into 4 groups based on quartiles for each air pollutant.
†Adjusted HR, adjusted for age, sex, monthly income, and urbanization level
*** p<0.001**

based groups (Q1-Q4). We measured the incidence rate, hazard ratios (HRs) and 95% confidence intervals for cSLE stratified by the quartiles of air pollutant concentration using Cox proportional hazards models, adjusted for age, sex, monthly income, and urbanization.

Results: A total of 394 children (0.16%) were diagnosed with SLE. The incidence rate for SLE increased with $PM_{2.5}$ and THC exposure concentration, from 4.7 (Q1) to 21.9 (Q4) and 9.5 (Q1) to 26.1 (Q4) per 100,000 person-years, respectively. Compared with those exposed to the concentrations in Q1 level, the adjusted HR for SLE increased with the $PM_{2.5}$ and THC exposure concentrations from 2.74 to 4.23 and 0.93 to 3.03, respectively.

Conclusion: The present study provides evidence that long-term ambient air pollutant exposures are risk factors of the development of cSLE.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Although there is a large body of work on central nervous system (CNS) disease in SLE patients, involvement of the peripheral nervous system (PNS) is less well established. The objective of our study was to determine the frequency, clinical characteristics, associations and outcomes in different types of PNS disease in a prospective, multi-ethnic/racial, inception cohort study of SLE patients.

Methods: Patients were evaluated annually for 19 neuropsychiatric (NP) events, including seven types of PNS disease using standardized case definitions. Attribution models were used to determine if the PNS events were due to SLE or other causes. SLE disease activity (SLEDAI-2K), organ damage (SLICC/ACR damage index), autoantibodies, patient (SF-36) and physician (Likert score) assessment of outcomes were measured. Statistical analyses included time to event and linear regressions as appropriate.

Results: Of 1,827 SLE patients enrolled, 88.8% were female and 48.8% Caucasian. The mean ± SD age was 35.1 ± 13.3 years, disease duration at enrollment was 5.6 ± 4.2 months and follow-up was 7.6 ± 4.6 years. There were 161 PNS events in 139/1,827 (7.6%) patients. The predominant events were peripheral neuropathy [66/161 (41.0%)], mononeuropathy [44/161 (27.3%)] and cranial neuropathy [39/161 (24.2%)] and the remaining 4 types of PNS disease accounted for only 12/161 (7.5%) events. The majority of PNS events [118/161 (73.3%)] in 104/139 (74.8%) patients were attributed to SLE. Multivariable Cox regression [HR, (95%CI)] indicated a negative association with Asian race/ethnicity [0.42 (0.19, 0.93)] and a positive association with other concurrent NP events attributed to SLE [2.74 (1.49, 5.03)]. By physician assessment, the majority of neuropathies resolved or improved over time. Multivariable analysis indicated that a longer time to resolution was associated with recurrent PNS events [0.38 (0.16, 0.90)], older age at SLE diagnosis [0.76 (0.60, 0.98)], higher SLEDAI-2K scores excluding NP variables [0.71 (0.51, 0.99)] and peripheral neuropathy [0.45 (0.25, 0.82)]. Patients with neuropathy reported significantly lower SF-36 physical and mental component summary scores compared to patients without NP events. Resolution was associated with improvements in SF-36 physical component summary scores that were both clinically and statistically ($p< 0.01$) significant in patients with peripheral neuropathy (mean change: +8.74) and mononeuropathy (mean change: +9.27).

Conclusion: PNS disease is a manifestation of NPSLE and has a significant negative impact on health related quality of life. The outcome is favourable for most patients, but several factors associated with longer time to resolution were identified.

Mouse SLE Studies Do Not Describe Human SLE

Ecem Sevim,[1] Linjia Jia,[2] David Fernandez,[3] and Michael Lockshin[4], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, NY, [3]Hospital for Special Surgery, Mary Kirkland Center for Lupus Research, New York, NY, [4]Hospital for Special Surgery, Barbara Volcker Center for Women and Rheumatic Diseases, New York, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although mouse models of systemic lupus erythematosus (SLE) are useful proxies for human illness, they are heterogeneous, and publications about mouse SLE may not sufficiently emphasize differences between animals and humans with SLE. We examined recent literature to compare the criteria used to label mice as having SLE to phenotypes of human SLE.

Methods: Using "lupus AND animal NOT (review OR systematic review OR meta-analysis)" as the search terms, and filtering for full-text availability and English, we systematically reviewed studies published between July 3, 2013

Table 1: Mouse Models Used in 693 Animal Systemic Lupus Erythematosus Studies, Between July 3, 2013 - July 3, 2018

Mouse Models	N (%)
Spontaneous Models	440 (63)
- MRL/*lpr*	231 (33)
- NZB/WF1	134 (19)
- B6.*Sle123*	22 (3)
- NZM (2328/2410)	9 (1)
- MRL/*lpr* + NZB/W F1	8 (1)
- MRL/*lpr* + B6.Sle	4 (1)
- Others	32 (5)
Transgenic / Knockout	137 (20)
Induced Models	69 (10)
- Pristane	35* (5)

and July 3, 2018, excluding review articles, papers from journals with impact factor (IF) < 2, and non-mouse animal studies. We recorded main mouse model groups (spontaneous, induced, transgenic/knockout, or combinations), sub-groups (MRL/lpr, NZB/W F1, pristane), and gender for each study; how lupus was defined in the model (clinical manifestations, immunohistochemistry, and serology); and how and when authors defined clinical and serological disease onset (< 8 weeks, 8-16weeks, >16weeks). Additionally, asked whether the title of the article easily informed the reader whether the study was of animals or humans.

Results: Of 1572 articles identified, 693 were suitable for analysis. Table 1 presents mouse models used in 693 animal SLE studies. Four hundred forty (63%) used models of spontaneous heritable SLE (243 [35%] MRL/lpr and 147 [21%] NZB/W F1); 69 (10%) used induced models, of which 35 (5%) were pristane-induced; 138 (20%) used transgenic/knockout models; and 44 (6%) used combinations of models. Determinants of diagnosis, as shown in Table 2, were anti-DNA antibody and/or ANA autoantibody in 58% of studies, proteinuria in 41%, both serology and proteinuria in 32%, and immunohistochemistry in 72%. Of the latter, 500 (63%) included renal pathology. Other criteria included behavioral tests in 2%, skin manifestations in 2%, and arthritis in 1%. Only 64% of papers defined time of clinical and/or biological onset of illness (< 8 weeks, 4%; 8-16 weeks, 28%; >16 weeks 32%; not indicated, 36%), and only 30% defined time of serological onset (< 8 weeks, 3%; 8-16 weeks, 14%; >16 weeks, 14%; not indicated,

**: spontaneous vs transgenic/knockout p: 0.000; induced vs transgenic/knockout p: 0.009
δ: spontaneous vs transgenic/knockout p: 0.006; induced vs transgenic/knockout p: 0.02
ϕ: spontaneous vs transgenic/knockout p: 0.001; induced vs transgenic/knockout p: 0.003

70%). Table 3 compares disease onset, clinical, biological, and serological definitions of the mouse model groups, excluding studies that used combinations of these models. Seventy-one percent of papers' titles mentioned SLE; but in only 38% of those, and 44% of all papers, did the titles indicate that the study concerned animal rather than human SLE.

Conclusion: Publications about mouse SLE use the term SLE in ways that do not easily translate to human SLE. SLE is defined by histopathology in most mouse studies and by autoantibodies in slightly more than half. Many studies do not define sex, age of onset, or disease activity of diagnosed animals. While mouse models play an important role in understanding human lupus, the different criteria used to define mouse and human lupus may mislead readers seeking information about SLE who are unfamiliar with details of mouse models.

Abstract Number: 0673

Clinical Characteristics of Lymphadenopathy in Systemic Lupus Erythematous: A Case Control Study from a Tertiary Care Center

Elizabeth Graef,[1] Daniel Magliulo,[1] Norris Hollie,[1] Chelsea Marcus,[2] and Vasileios Kyttaris[3], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Boston, [3]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While lymphadenopathy and/or lymphadenitis (LAD) is considered a relatively common clinical finding in SLE patients, its clinical significance is poorly understood. Previous studies described the prevalence of lymphadenopathy, but not the prognostic significance and/or characteristic serologic associations. We report the prevalence, type of LAD, and the phenotypical profile of SLE patients who develop this manifestation over the course of their disease.

Methods: We conducted a retrospective case series analysis on 220 SLE patients enrolled at Beth Israel Deaconess Medical Center Lupus Cohort in 2008-2019 comparing patients with and without LAD. Patients were recruited from the Rheumatology clinic and eligible to participate if they met 1994 ACR SLE criteria and provided informed consent. Data on LAD was obtained from physical exam documentation and/or imaging reports. When available, pathology samples were reviewed from tissue obtained during routine clinical care. The study was IRB approved. Statistical analysis: Chi-square Test and Fisher's exact test were used for categorical variables using VassarStats.

Results: In our cohort, 13% (28/220) of patients developed LAD, a significantly lower proportion than previously reported (Dubois et al, JAMA 1964). LAD typically was a presenting and/or early manifestation occurring within the 12 months of diagnosis for most patients (82%) and typically predicted more active clinical course. The mean duration of time since SLE diagnosis for all patients was 15.2 years. Within the LAD group, 19 patients underwent lymph node biopsy as part of their workup. The predominant pathology patterns were necrotizing (26%), reactive (47%), and proliferative (16%) lymphadenitis. Of note, one biopsy revealed Non-Hodgkin lymphoma, one patient had sequential biopsies with initial reactive hyperplasia followed by diffuse large B cell lymphoma on a deeper pelvic node, and one biopsy was non diagnostic. We then asked whether the disease phenotype was different between the LAD group and the non-LAD group. Patients with LAD were more likely than non-LAD patients to have fever (OR 5.4, p=< 0.0001) nephritis (OR 1.7, p=0.1897), splenomegaly (OR 22.9, p=0.0076), and leukopenia (OR 2.0, p=0.0969). LAD patients also had more serologically active disease than non-LAD patients; specifically LAD patients were more likely to have positive Smith (OR 4.18, p=0.005), RNP (OR 4.05, p=0.0087), and SSB (OR 2.41, p=0.0424) as well as hypocomplementemia (C3 OR 4.80, p=0.0051; C4 OR 4.03, p=0.0039).

Conclusion: In our cohort, lymphadenopathy was an uncommon SLE manifestation. Interestingly, necrotizing LAD, which is often associated with infection, was relatively prevalent in our cohort. Our data suggest that patients with lymphadenopathy are more likely to have constitutional symptoms, cytopenias, and splenomegaly as well as increased auto-antibodies and hypocomplementemia. These symptoms can be seen with lymphomas and two patients were ultimately found to have lymphoma (DLBCL and NHL). These patients developed LAD either within 12 months or after more than 10 years of SLE diagnosis. This suggests that biopsy is warranted in SLE patients with LAD at any point in their disease course.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Among rheumatologic conditions, SLE is associated with very high healthcare and out of pocket costs. Little is known about patients' concerns regarding costs of care. We analyzed patterns of patient perceptions of affordability of care and medication costs and explored associations with disease measures in SLE.

Methods: Data derive from the California Lupus Epidemiology Study (CLUES), a diverse population-based cohort of individuals with SLE. As part of an extensive interview, 259 participants answered 2 questions about affordability of care (at diagnosis [recalled] and at present) and 6 questions about medication costs (Is paying for your lupus medicines financially difficult?; Have you ever: taken less medicine; delayed filling a prescription; asked about lower cost medicine; bought medicine out of the country; applied for patient assistance program?). These 8 items were combined to describe "affordability concerns." We compared prevalence of affordability concerns by race/ethnicity and socioeconomic status and examined associations with patient reported measures in linear regression models [with and without adjustment for age, gender, age of diagnosis, race/ethnicity, income below poverty, education (no bachelor's degree vs bachelor's), insurance (private vs public) and employment].

Results: Concern about affordability of care at diagnosis (56%) and at present (53%) were greater than concerns about medication costs (25%). Most patients with SLE (77% of 259 respondents) reported at least one affordability concern. There were no differences in affordability concerns by race/ethnicity, either at diagnosis or at present. Affordability concerns were most prevalent among those with public insurance (83% vs 70%, p< 0.01), an education

below a college degree (88% vs 66%, p< 0.01) and income below the poverty level (98% vs 70%, p< 0.01). Individuals with affordability concerns had worse patient-reported scores of disease activity, damage, depression and physical function than non-concerned peers, even controlling for sociodemographic factors (Table).

Conclusion: Most people with SLE are concerned about cost of treatment among individuals with SLE both at diagnosis and over time. Concern about affordability is associated with poorer patient-reported outcomes. Our findings support strategies to proactively assess affordability concerns and develop resources that focus on mitigating cost of care for this population.

Clinical and Serological Lupus Activity Before and After Developing End Stage Renal Disease

Maria Salgado Guerrero,[1] Alejandra Londono Jimenez,[2] Chrisanna Dobrowolsky,[2] Shudan Wang,[2] Wenzhu B. Mowrey,[3] and Anna Broder[2], [1]Internal Medicine, Jacobi Medical Center/Albert Einstein College of Medicine, Bronx, NY, [2]Rheumatology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [3]Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE disease activity tends to diminish after the development of end stage renal disease (ESRD)[1, 2]. Nonetheless, some patients continue to show signs of active disease and experience flares after ESRD[3]. To date, little is known about the evolution of SLE-related symptoms pre and post ESRD. Whether specific symptoms abate after ESRD or a shift towards different manifestations occurs deserves further study. Prompt identification of subtler SLE manifestations is further complicated by a trend towards poor rheumatology follow once ESRD develops. SLE manifestations post-ESRD may be underdiagnosed and undertreated contributing to increased morbidity and mortality. Therefore, the objective of this study was to analyzed the different clinical manifestations and serological markers of SLE disease activity before and after ESRD development.

Methods: We performed a retrospective chart review of SLE patients with ESRD at a tertiary care center between the years of 2010 and 2017. SLE was defined by ACR and/or SLICC criteria. SLE ESRD patients were included if they had at least one visit with rheumatology, nephrology, or primary care pre- and post-ESRD. SLE-related symptoms and serologic markers of disease activity were identified from chart review before and after ESRD onset.

Results: Fifty-eight patients were included. Twenty-five patients had a least one clinical non-renal criteria documented pre-ESRD. Of them, 14 achieved complete clinical remission post-ESRD. Post-ESRD, cytopenias persisted in 49 of the 55 patients who were cytopenic pre-ESRD. Arthritis persisted in 3 of the 13 patients who had arthritis pre-ESRD. Of the 37 patients with hypocomplementemia pre-ESRD, 29 remained hypocomplementemic post-ESRD. Twenty-nine had elevated dsDNA pre-ESRD, of them, dsDNA remained elevated in 16 patients post-ESRD. Six

patients developed at least one new clinical criteria post-ESRD. Three patients developed low complement and 5 developed elevated dsDNA post-ESRD.

Conclusion: Lupus activity may diminish after ESRD onset. However, many patients experience persistent disease activity. New arthritis, low complements and elevated dsDNA may develop after ESRD. Limited evaluation and documentation of disease activity by non-rheumatology providers may have resulted in under-reporting of SLE signs and symptoms on this study. SLE ESRD patients should be carefully evaluated for subtle signs of active SLE.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous systemic lupus erythematosus (SLE) studies have identified potential clusters of SLE clinical manifestations.

To describe the presentation of SLE across different cohorts of patients and describe standard of care within clusters.

Methods: Cross-sectional study of 263 rheumatologists in the US and EU5. Data were collected from the Adelphi Real World 2015 Lupus Disease Specific Programme. Physicians completed patient record forms (PRFs) for the next 5 patients consulting with SLE; these patients completed patient self-completion (PSC) forms describing how SLE affected them. PRFs data include patient's characteristics and management history. PSCs focused on similar data collection, including patient reported outcome measures on the humanistic burden. Principal-component factor analysis reduced 39 unique SLE symptoms to 8 factors. These factors were used as covariates in latent class cluster analysis to provide discrete cohorts of patients. Chi-squared and Kruskal-Wallis tests compared patient outcomes across clusters.

Table 1 Cluster analysis

		Clusters				
Factors, n (%)	Overall (n=1376)	1 (n=325)	2 (n=743)	3 (n=143)	4 (n=165)	p-value
Joint	956 (69.5)	0	729 (98.1)	62 (43.4)	165 (100.0)	<0.0001
Haematological	289 (21.0)	17 (5.2)	112 (15.1)	48 (33.6)	112 (67.9)	<0.0001
Constitutional/Mental	413 (30.0)	11 (3.4)	251 (33.8)	14 (9.8)	137 (83.0)	<0.0001
Skin	688 (50.0)	69 (21.2)	389 (52.4)	81 (56.6)	149 (90.3)	<0.0001
Circulatory	71 (5.2)	0	0	39 (27.3)	32 (19.4)	<0.0001
Cardiovascular	130 (9.4)	0	0	68 (47.6)	62 (37.6)	<0.0001
Renal	297 (21.6)	18 (5.5)	146 (19.7)	48 (33.6)	85 (51.5)	<0.0001
Muscular	268 (19.5)	6 (1.8)	109 (14.7)	38 (26.6)	115 (69.7)	<0.0001

Results: Data were extracted from 1376 PRFs. Factor analysis resulted in 8 clusters of concurrent symptoms; joint, haematological, constitutional/mental health, skin, circulatory, cardiovascular, renal, and muscular symptoms respectively. The four-cluster solution was selected. Cluster 1 displayed the lowest symptom burden, characterised by low skin involvement. Cluster 2 is characterised by joint and skin involvement. Cluster 3 & 4 had a high frequency of all factors, with cardiovascular involvement high in cluster 3 and renal/constitutional involvement high in cluster 4 (table 1). Significant between-cluster differences were observed when comparing clinical and humanistic outcomes; physician/patient satisfaction were greatest in cluster 1 (physician satisfied 94.2% vs. 2: 90.8%, 3: 85.2%, 4: 74.4%, $p< 0.0001$; patient 94.7% vs. 2: 93.9%, 3: 91.5%, 4: 79.2%, $p< 0.0001$), whilst disease progression (deteriorating slowly 2.5% vs. 2: 12.9%, 3: 9.8%, 4: 25.5%, $p< 0.0001$) and flaring in the last 12 months (flared 30.0% vs. 2: 54.8%, 3: 62.2%, 4: 70.8%, $p< 0.0001$) differed significantly with worst outcomes seen in cluster 4. Significant differences were also observed between clusters in relation to treatment proportions; anti-malarials (highest cluster 1: 70.5%), biologic DMARD (highest cluster 3: 17.5%), glucocorticoid and immunosuppressants (highest cluster 4: 85.5%, 74.5%).

Conclusion: This study adds to the evidence demonstrating the heterogenous nature of SLE experienced within distinct patient clusters. Significant proportions of SLE patients experience high symptom burden and low levels of satisfaction. Additional analysis to understand limited biologic use in more severe patients is needed.

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive impairment (CI) is a common neuropsychological manifestation of Systemic Lupus Erythematosus (SLE) with a prevalence of 38% [95% confidence interval: 33,43%]. Previous studies, have reported promising results on the utility of the Montreal Cognitive Assessment (MoCA) as a screening tool for CI in SLE compared to a comprehensive neuropsychological battery (CNB). The aim of this study was to assess the utility of

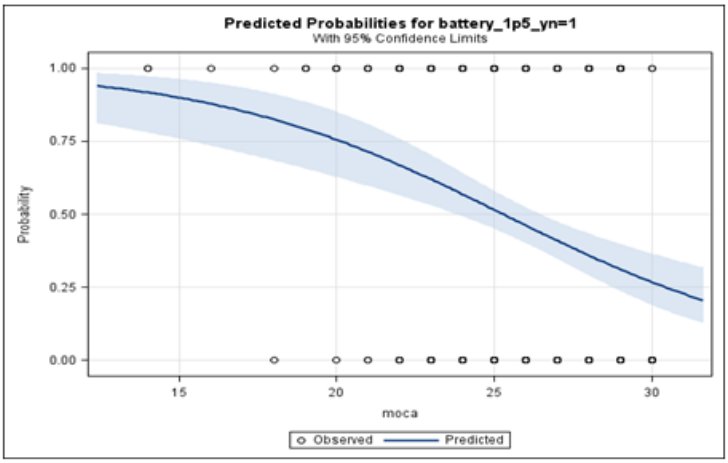
the MoCA as a screening test for the detection of CI using a comprehensive NB as the gold standard for classification of cases.

Methods: From 2016 to 2019, 276 consecutive consenting adult SLE patients (excluding those with learning disabilities, and less than semi-fluent English language skills were administered the MoCA followed by a CNB. The MoCA, ranging from 0-30, was designed to screen for Mild Cognitive Impairment (MCI) in dementia a score of ≥26 considered above the threshold for MCI. In this study, patients were classified as having CI if they had a z-score of ≤-1.5 in ≥2 domains of the 6 domains of CNB, and otherwise non-CI. Descriptive statistics and two-by-two contingency tables with a MoCA cut-off score of 26 were applied to determine its sensitivity (Se) and specificity (Sp) to CI. The Se, Sp, positive predictive value (PPV) and negative predictive value (NPV) were evaluated. Additionally, a **discriminant function analysis** was applied to assess the ability of the MoCA to differentiate between CI, undetermined CI (one domain with a z-score of ≤-1.5) and non-CI patients.

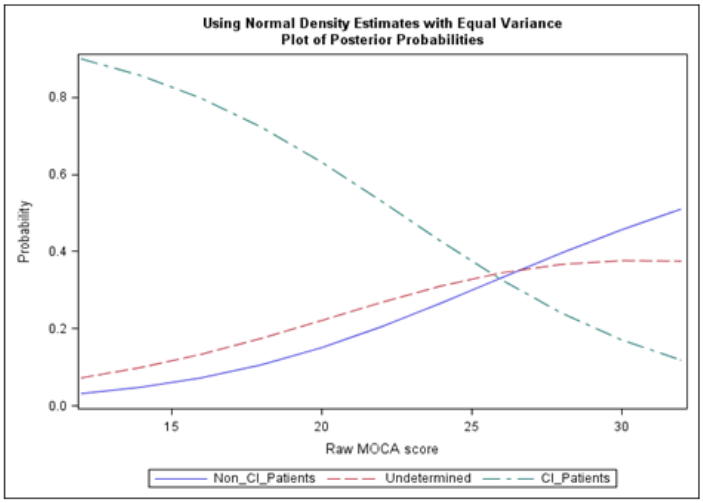
Results: 276 SLE patients were enrolled; 89.5% were females and the mean age was 41.2 ± 12.2 years at enrolment, and mean SLE duration of 14.1 ± 10.1 years (demographics in **Table 1**). Based on the CNB, 129 patients (47%) had CI, 85 (31%) had undetermined CI, and 62 (22%) were non-CI patients.

Figure 1. The Predicted probability of having CI by MoCA scores (n=276)



Even with the highest MoCA score, 30, there was 25% predicted probability of being CI.

Figure 2. The probability of belonging to three CI groups at each MoCA scores (n=276)



The three groups (CI, undetermined-CI and non-CI) overlap around the MoCA scores 25 to 27, indicating poor discriminative ability of MoCA.

CI was not accurately predicted by MoCA with an area under curve (AUC) of 65% [95% Confidence interval: 0.59, 0.72]. The *cut-off* **of 26** yielded Se, Sp, PPV and NPV of 50%, 70%, 59% and 61%, respectively.

There was a 25% predicted probability of CI with the highest score (30) on the MoCA **(Figure 1).** Although the MoCA cut-off score of 27 reached a sensitivity of 80%, the specificity was very low at 45%.

Based on the discriminant function analysis, the misclassification rates in the 3 categories (CI, undetermined-CI and non-CI) were 50%, 83%, and 44%, respectively. All three categories overlapped between the scores 25 to 27 (**Figure 2**). Thus, the MoCA had low ability to accurately identify CI status.

Conclusion: This analysis does not provide sufficient evidence to recommend MoCA as a screen for CI in SLE compared to a CNB. There was a low predicted probability of having CI with a low MoCA score and a relatively high predicted probability of having CI with a high MoCA score.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The EULAR/ACR 2019 Classification Criteria for SLE have been validated in an international cohort of 696 SLE patients and 574 non-SLE patients with a sensitivity of 96.1% and a specificity of 93.4%. We comparatively evaluated the performance characteristics of the SLE classification systems in subsets of the validation cohort with regard to gender, race/ethnicity, and disease duration.

Methods: 21 SLE expert centers from 16 countries submitted up to 100 SLE cases and 100 SLE mimicking controls each, using a standardized form without knowledge of the new criteria system to form the validation cohort. Cases and control diagnosis (SLE or not SLE) were independently verified by 3 SLE experts. The EULAR/ACR 2019 classification criteria validation cohort consisted of female (n=1,098) and male (n=172) patients; Asian (n=118), Black (n=68), Hispanic (n=124) and White (n=941) patients; and patients with an SLE duration of less than 1 year (n=34), 1-3 years (n=196), 3-5 years (n=157), and 5 or more years (n=879). Sensitivity and specificity with 95% confidence intervals (CI) were estimated for the EULAR-ACR 2019 criteria, the SLICC 2012 criteria and the ACR 1997 criteria.

	n	EULAR/ACR 2019 Criteria		ACR 1997 Criteria		SLICC 2012 Criteria	
		Sensitivity	Specificity	Sensitivity	Specificity	Sensitivity	Specificity
Full cohort	**1,270**	**0.96**	**0.93**	**0.83**	**0.93**	**0.97**	**0.84**
95% CI		0.95-0.98	0.91-0.95	0.80-0.85	0.91-0.95	0.95-0.98	0.80-0.87
Gender							
Women	1,098	0.97	0.94	0.83	0.93	0.97	0.82
Men	172	0.93	0.96	0.78	0.94	0.94	0.90
Race/ Ethnicity							
Asian	118	0.97	0.91	0.77	0.93	0.99	0.91
Black	68	0.98	1.00	0.82	1.00	0.98	0.92
Hispanic	124	1.00	0.96	0.86	0.96	1.00	0.78
White	941	0.95	0.94	0.83	0.93	0.96	0.83
Disease duration							
< 1 year	34	0.89	0.92	0.56	0.92	0.89	0.92
1 to <3 yrs	196	0.97	0.96	0.81	0.95	0.98	0.88
3 to <5 yrs	157	0.96	0.99	0.81	0.94	0.91	0.89
≥5 years	879	0.96	0.93	0.84	0.93	0.97	0.81

Table 1

Results: As shown in Table 1, most of the point estimates for sensitivity and specificity in subsets lay within the 95% confidence intervals of the sensitivity and specificity of the EULAR/ACR 2019 criteria validation. In particular, sensitivity and specificity for all race/ethnicity groups were within the confidence intervals or even higher. Formally, the sensitivity was slightly lower for male patients, corresponding to a higher specificity, but the male 95% confidence intervals (0.86-0.98 for sensitivity, 0.90-0.99 for specificity) overlapped with those of the full cohort. Sensitivity appeared independent of disease duration at least from year 1 on, with all 95% confidence intervals overlapping (for the first year after diagnosis 0.52-1.00 for sensitivity, 0.69-0.97 for specificity).

Conclusion: The point estimates of sensitivity and specificity suggest that the EULAR/ACR 2019 SLE classification criteria perform well in diverse race/ethnicity groups, in men and in early disease. These results now need to be independently validated in larger groups of African American/Black, Asian, and Hispanic patients, male patients and in early disease.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Our group has developed a conceptual model to categorize SLE manifestations into two dimensions termed Type 1 and Type 2. Type 1 SLE consists of active inflammatory manifestations like arthritis, nephritis, and rashes, and Type 2 SLE includes symptoms of fatigue, myalgia, mood disturbance, and cognitive dysfunction. SLE is characterized by waxing and waning of Type 1 inflammatory features considered to be disease activity. To advance lupus symptom characterization, we assessed whether Type 2 symptoms fluctuate over time.

Methods: SLE patients meeting SLICC criteria with ≥2 visits at a university rheumatology clinic between January 2018 and May 2019 were included. At each visit, SLEDAI was measured and patients completed the ACR FM Diagnostic Criteria. The FM severity score (FSS) is the sum of the widespread pain (0-19) and symptom severity scores (0-12). Patients were classified as having Type 1 SLE manifestations (SLEDAI ≥6, clinical SLEDAI ≥4, or active nephritis), Type 2 SLE symptoms (FSS >10), Mixed (both Type 1 and Type 2), or Minimal (neither Type 1 or Type 2). A clinically significant change in SLEDAI and FSS was defined as a +/- 2-point change between two visits for either of these measures. Changes in Type 1 and Type 2 severity between the two visits were estimated using simple statistics.

Results: 84 patients were included in the analysis (mean age 42 years, mean duration of SLE 14 years, 95% female, 65% African American, 56% with history of lupus nephritis). The average time between visits was 19 weeks (range: 4-34). At the first visit, 17% of patients were classified as Type 1, 12% as Type 2, 25% as Mixed, and 46% as Minimal.

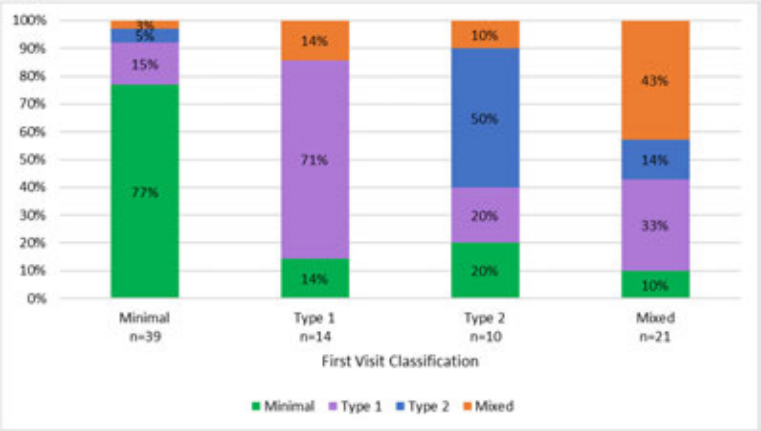

Figure 1. Change in Type 1 and Type 2 SLE Classification Between Visits. The bars represent the distribution of patient symptoms at Visit 2 for each Visit 1 classification group.

Figure 2. Change in Fibromyalgia Severity Score and SLEDAI between visits.

In patients with Minimal or Type 1 SLE at Visit 1, 8-14% experienced active Type 2 symptoms at Visit 2 (Figure 1). In comparison, for patients with Type 2 or Mixed SLE at Visit 1, approximately 40% were no longer classified as having active Type 2 symptoms at Visit 2.

Overall, 44% of patients had an improved FSS at Visit 2 and 30% had improvement in SLEDAI (Figure 2). Type 2 symptoms fluctuated in all patient groups between visits. Type 2 SLE symptoms worsened in 21% of Minimal and 36% of Type 1 SLE patients. Interestingly, patients with Mixed activity appeared to have a greater improvement in FSS (81%) compared to patients with only Type 2 SLE activity (50%). When specific Type 2 symptoms were explored, 78% of patients who reported moderate or severe fatigue at Visit 1 continued to have moderate or severe fatigue at Visit 2, whereas only 16% of patients without fatigue at Visit 1 experienced fatigue at Visit 2. Fatigue was more prevalent and persistent in patients classified as Type 2 and Mixed at Visit 1. Improvements were seen in cognitive dysfunction, muscle weakness, and muscle pain, with approximately 40% of patients reporting improvement in symptoms at Visit 2.

Conclusion: Our findings suggest that, similar to Type 1 features, Type 2 symptoms vary over time, with almost half of the patients in the analysis having an improvement in FSS between visits. Future studies are needed to determine Type 2 fluctuations over a longer follow-up period, as well as to identify treatment approaches to improve Type 2 symptoms.

Patients Who Do Not Fulfill the 2018 EULAR/ACR Criteria for Systemic Lupus Erythematosus Accrue Less Damage: Data from a Multicenter, Multiethnic US Cohort

Manuel Ugarte-Gil,[1] Guillermo Pons-Estel,[2] Luis Vilá,[3] Russell Griffin,[4] and Graciela Alarcón[5], [1]Universidad Científica del Sur, Lima, Peru, [2]Centro Regional de Enfermedades Autoinmunes y Reumáticas (GO-CREAR), Rosario, Argentina, [3]University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico, [4]University of Alabama at Birmingham, Birmingham, AL, [5]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2018 EULAR/ACR Criteria for the classification of patients with systemic lupus erythematosus (SLE) were proposed in order to improve the sensitivity and specificity of the previously published SLE criteria. In addition to its sensitivity and specificity, it is important to know if those patients who would not be classified as having SLE according to these criteria have a different prognosis than those who continue to be classified as SLE. The aim of this study was to determine the difference in damage accrual in patients who achieved or not these new criteria.

Methods: Patients from a well-defined multicenter, multiethnic US lupus cohort were included. For this cohort, SLE was defined using the 1982/1997 ACR criteria. For these analyses, we compared those patients who achieved the 2018 EULAR/ACR criteria any time during the follow-up to those who did not. The predefined outcome was the last SLICC/ACR damage index (SDI). Possible confounders included were age, gender, race/ethnicity, poverty, disease duration at baseline, baseline SLAM, baseline SDI, antimalarial, glucocorticoids and immunosuppressive drugs use

Table 1 Impact of achieving or not the 2018 EULAR/ACR criteria on the damage accrual

Parameter	Estimate	Standard Error	p value
Intercept	-1.6924	0.2224	<0.0001
Not achieving the 2018 EULAR/ACR criteria	-0.3773	0.1416	0.0077
Age at baseline	0.0174	0.0037	<0.0001
Ethnicity			
Hispanic (Texas)	0.9339	0.1740	<0.0001
African-American	0.9513	0.1592	<0.0001
Caucasian	0.5969	0.1661	0.0003
Puerto Rican	Referent		
SLAM at baseline	0.0562	0.0084	<0.0001
Poverty	0.1785	0.0946	0.0593
Disease duration at baseline	0.1439	0.0327	<.0001
Immunosuppressive drugs at baseline	0.3626	0.1125	0.0013

at baseline. Univariable and multivariable negative binomial regression models were performed; adjustment model was based on a forward selection process. An alternative analyses was performed in order to evaluated the impact of being classified earlier, at the same time or later with the 2018 EULAR/ACR criteria.

Results: Ninety-eight out of 640 patients never achieved the 2018 EULAR/ACR criteria. The 98 patients were older and less likely to be Hispanic or African American than those who did achieve the criteria. There was no difference in mean baseline SDI among the patients who did not achieve the criteria (0.6±1.2) compared to those who achieved the criteria (0.8 ± 1.2, p=0.3580). Conversely, the mean SDI at last visit was lower for those who never achieved the criteria (1.2±1.7 vs. 2.0±2.3, p=0.0004). In the final adjusted model (Table 1), the SDI score at last visit was 31% lower for those not achieving the criteria (p=0.0077). There were not differences on damage accrual if the patients were classified earlier, at the same time or later with the 2018 EULAR/ACR criteria (data not shown).

Conclusion: In our cohort, those who did not achieve the 2018 EULAR/ACR criteria accrued less damage, suggesting that these criteria could allow us to identify a subset of patients with more severe disease than previous criteria.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There are several instruments to measure disease activity in patients with systemic lupus erythematosus (SLE); however, none of them are able to capture all possible clinical events/manifestations. The LFA-REAL ClinRO has been proposed in order to address this problem as it allows the clinician to evaluate every possible manifestation of SLE. Additionally, the LFA-REAL PRO includes a comprehensive patient-reported disease activity measure. The aim of this study was to determine the correlation between both, the LFA-REAL ClinRO and the LFA-REAL PRO, with other disease activity measures.

Methods: A cross-sectional analyses of patients from a single-center cohort was performed. Disease activity measures included were LFA-REAL ClinRO (0-1400), LFA-REAL PRO (0-1200), SLEDAI-2K, clinical SLEDAI-2K and Physician Global Assessment (PGA, 0-100). The correlation between these indices were evaluated with the Pearson correlation. As an alternative analysis, the correlation between the corresponding domains of LFA-REAL PRO and LFA-REAL ClinRO were examined.

Results: One-hundred and sixty-nine patients with SLE, with a mean age of 45.8 (SD: 14.2), 156 (92.3%) were female. The mean (SD) LFA-REAL ClinRO was 23.8 (34.3), the LFA-REAL PRO was 239.6 (187.7), the PGA was 10.0 (14.2), the SLEDAI-2K was 2.4 (3.4) and the clinical SLEDAI-2K was 1.7 (3.0), the SDI was 1.7 (1.5). LFA-REAL ClinRO correlated with LFA-REAL PRO (R=0.192; p=0.012), PGA (R=0.693, p< 0.001), SLEDAI-2K (R=0.688, p< 0.001) and clinical SLEDAI-2K (R=0.705, p< 0.001); the LFA-REAL PRO correlated with PGA (R=0.301, p< 0.001), SLEDAI-2K (R=0.161, p=0.037) and clinical SLEDAI-2K (R=0.167, p=0.030). The correlations between these disease activity measures are depicted in table 1. Additionally, the LFA-REAL PRO rash correlated with the LFA-REAL ClinRO global mucocutaneous involvement (R=0.154, p=0.046) and with the LFA-REAL ClinRO rash (R=0.245, p=0.001); the LFA-REAL PRO global articular correlated with the LFA-REAL ClinRO global musculoskeletal involvement (R=0.346, p< 0.001).

Conclusion: The LFA-REAL ClinRO and the LFA-REAL PRO had a good correlation with other physician-based disease activity measures. These measures need to be evaluated in other cohorts in order to determine their real value for the monitoring of SLE patients.

Work productivity impairment	30.8 (28.1)	0.545	<0.001
Activity impairment	36.1 (29.9)	0.626	<0.001

*Range for all scales is 0-100 except for the FACIT which is 0-52.

Background/Purpose: Disease activity in systemic lupus erythematosus (SLE) is understood differently by patients and physicians; furthermore, there are no reliable measures for patients to assess their levels of disease activity. The LFA-REAL PRO has been proposed for addressing this void, and it is expected to correlate with HRQoL and with other PROs. The aim of this study was to determine the correlations between LFA-REAL PRO and HRQoL, fatigue and work disability.

Methods: A cross-sectional analyses of patients from a single-center cohort was performed. The disease activity measure included was the LFA-REAL PRO (0-1200); PROs included were LupusQoL (with its eight domains), SF-36 (with its eight domains and two main subcomponents), FACIT (as a measure of fatigue) and WPAI (as a measure of work productivity impairment). For the LFA-REAL PRO and WPAI, the higher the scores, the worse the disease activity and the more impaired the patient is; for the SF-36, LupusQoL and FACIT is the opposite. The correlation between these indices was evaluated with Pearson correlations.

Results: One-hundred and sixty-nine patients with SLE, with a mean age of 45.8 (SD: 14.2), 156 (92.3%) were female. The mean (SD) the LFA-REAL PRO was 239.6 (187.7), the Physical Component Summary SF-36 was 53.7 (22.1) and the Mental Component Summary SF-36 was 54.6 (21.0). The mean value of the components of the LupusQoL ranged between 41.0 and 69.4. The FACIT was 33.2 (10.5), the percentage of overall work productivity impairment was 30.8 (28.1) and of activity impairment was 36.1 (29.9). LFA-REAL PRO correlated with all domains of LupusQoL, SF-36, FACIT and WPAI, with the exception of absenteeism.

Conclusion: The LFA-REAL PRO correlates with several measures of HRQoL and other outcomes relevant to lupus patients like fatigue and work disability, suggesting that this index could be useful in monitoring them.

Prednisone	7 Dose Range: 5-40mg	2 Dose Range: 5-7.5mg	0.04
Immunosuppression	8 [1]	4 [3]	0.09
Medications for Type 2 symptoms	4 [2]	10 [4]	0.005

Medications in patients with Type 1 lupus activity:

[1] Immunosuppression: mycophenolate (6), cyclophosphamide (1), azathioprine (1), belimumab (1)

[2] Type 2 medications: amitriptyline (3), gabapentin (1), pregabalin (1), venlafaxine (1), mirtazapine (1)

Medications in patients with Type 2 lupus activity:

[3] Immunosuppression: Leflunomide (2), methotrexate (1), adalimumab (1)

[4] Type 2 medications: duloxetine (5), gabapentin (4), trazodone(3), cyclobenzaprine (2), zolpidem (2), pregabalin (1), amitriptyline (1), venlafaxine (1), milnacipran (1), buproprion (1), tramadol (1), baclofen (1), melatonin (1), tizanidine (1).

suppression. Distinguishing between Type 1 and 2 SLE can be challenging, especially for the non-rheumatologist. We sought to determine whether transcriptomic differences distinguish between these categories of lupus.

Methods: Using a book-ended approach to avoid clinical overlap in the populations, we identified two cohorts of women with lupus. The first consisted of 10 women with Type 1 disease, defined by a SLEDAI ≥6 and a fibromyalgia severity score (FSS) < 9. A second cohort of 10 women had Type 2 lupus with a SLEDAI of 0 and an FSS > 9. Whole blood was collected in PAXgene Blood RNA tubes and whole transcriptome RNA sequencing was performed. Hierarchical clustering and limma differential expression (DE) analysis were used to compare women of African heritage in the Type 1 and Type 2 cohorts to limit heterogeneity by race. Gene set variation analysis (GSVA) was carried out on all Type 1 and Type 2 lupus patients using modules of co-expressed genes obtained from DE analysis. Clinical characteristics were compared by Fisher's Exact test.

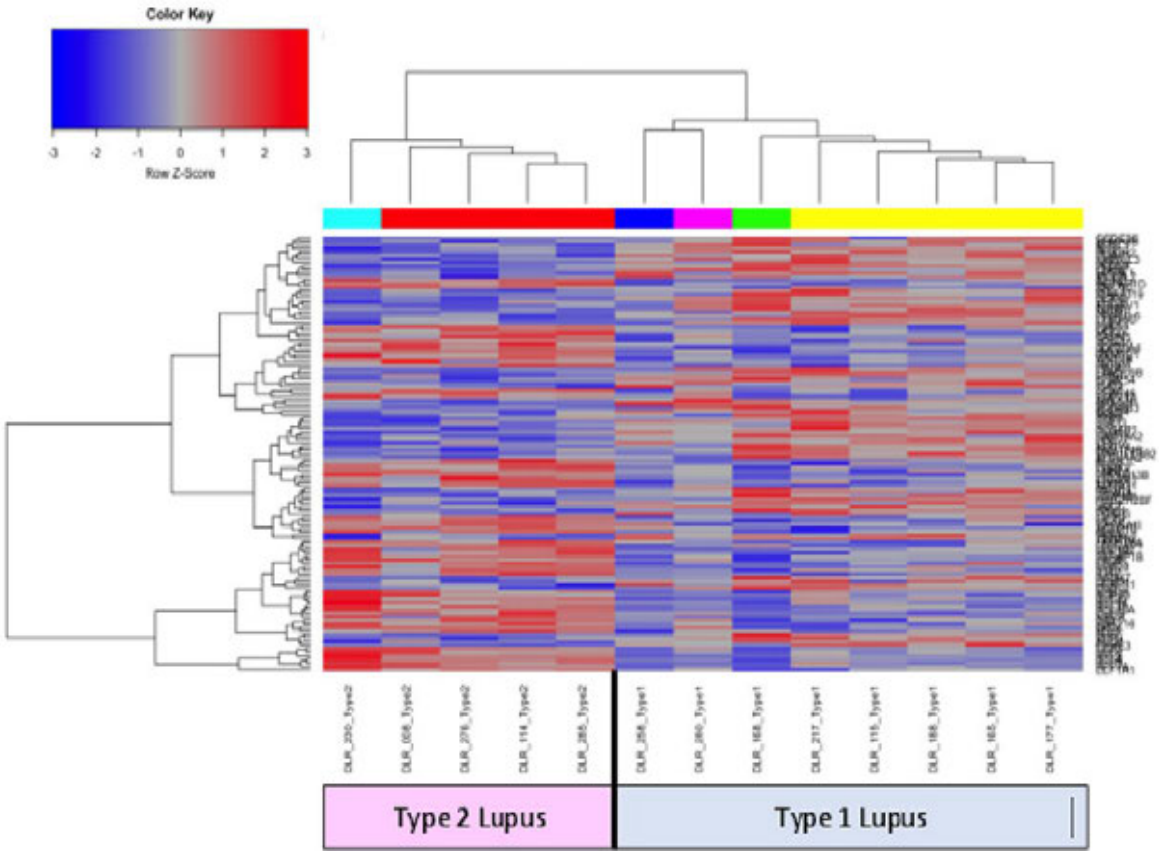

Figure 1. Heat map of differential expressed gene between Type 1 and Type 2 African American women with lupus.

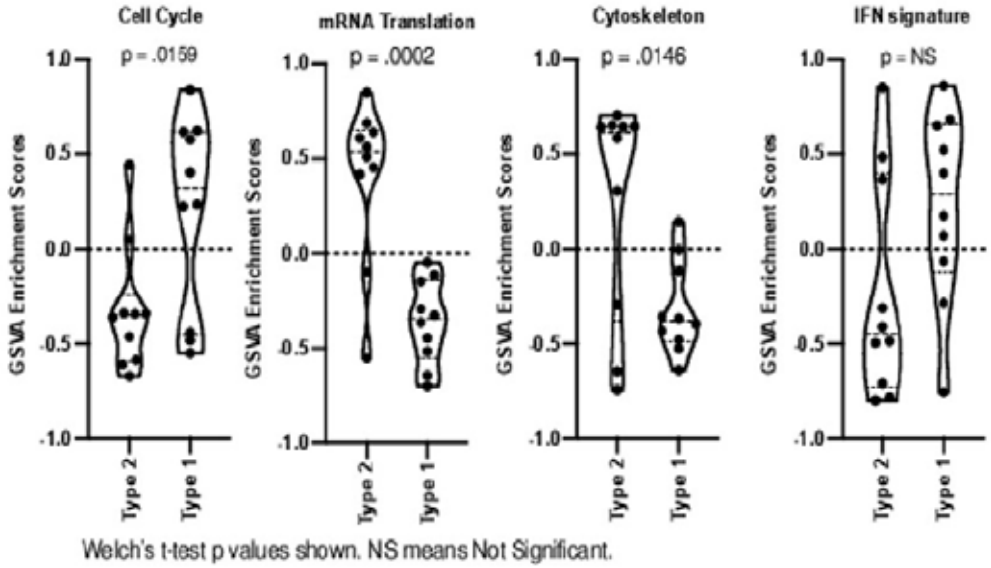

Figure 2. Enrichment of gene modules by GSVA in women with Type 1 and Type 2 lupus.

Results: Women with symptomatic Type 1 lupus were younger and had a shorter disease duration; most had prior and current nephritis; 5 had elevated dsDNA antibodies, and 7 had low complement (Table 1). The average SLEDAI was 9.8 (range 6-18). Of women with Type 2 lupus, 20% had a history of lupus nephritis and none had current proteinuria. Women with Type 2 lupus had more areas of pain, symptoms of fatigue, brain fog, and non-restorative sleep.

Interestingly, the patient assessment of lupus activity did not differ between the groups. The large majority of women in both groups were taking hydroxychloroquine. More women with Type 1 lupus took immunosuppressants and corticosteroids whereas more women with Type 2 lupus took medications for pain and depression.

DE analysis determined distinct hierarchical clustering between Type 1 and Type 2 lupus (Figure 1). Biologically-informed gene clustering identified transcripts for interferon signature genes, low density granulocytes, cell cycle genes, and *SDC1*, a marker of plasma cells, as increased in Type I lupus; transcripts associated with mRNA translation and the cytoskeleton were increased in Type 2 lupus. GSVA using these signatures demonstrated that the cell cycle signature was significantly ($p < .05$) enriched in Type 1 lupus and mRNA translation and the cytoskeleton were significantly ($p < .05$) enriched in Type 2 lupus (Figure 2).

Conclusion: Our new conceptual model characterizes lupus in terms of two categories: Type 1, with immunologic activity and organ involvement, and Type 2, with minimal immunologic activity but debilitating chronic symptoms. Transcriptomic analysis provides evidence that these categories are biologically distinct and can be distinguished by uniquely aberrant molecular pathways.

Abstract Number: 0684

Clinical Biomarkers at Renal Flare Are Associated with Histologic Changes in Repeat Renal Biopsy in Patients with Biopsy-proven Lupus Nephritis

Min Jung Kim,[1] Hajeong Lee,[1] Yeong-Wook Song,[1] and Eun Bong Lee[2], [1]Seoul National University Hospital, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, seoul

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Renal flares are common during treatment of biopsy-proven lupus nephritis (LN). However, it is unknown whether biopsy should be repeated in the event of renal flare. This study aimed to reveal the clinical biomarkers which predict the histologic changes in the repeat renal biopsy during renal flare.

Methods: We evaluated all patients with biopsy-proven LN who underwent repeat renal biopsies at the time of renal flare in Seoul National University Hospital between 2004 and 2018. Renal flare is indicated by an increase in proteinuria, serum creatinine or abnormal urinary sediments. Clinical lupus biomarkers included serum C3/C4, anti-dsDNA antibody level at the time of repeat biopsy. Histologic changes were defined as 1) histologic switch to other ISN/RPS class or alternative pathology, 2) active inflammation (activity index ≥ 7, presence of cellular crescents, interstitial inflammation) and 3) chronic damage (chronicity index ≥ 5, tubular atrophy or interstitial fibrosis). Associations between clinical biomarkers and histologic changes were examined using univariate and multivariate logistic regression analysis adjusting for potential confounding factors.

Table 1. Histologic switch in repeat renal biopsy

	Repeat biopsy			
	Proliferative*	Pure non-proliferative†	Class VI	Alternative pathology‡
Reference biopsy				
Proliferative	42	0	4	2
Pure non-proliferative	1	1	0	0

*Proliferative class included ISN/RPS class III, IV, III+V or IV+V.
†Pure non-proliferative class included ISN/RPS class II or V.
‡Alternative pathology: diabetes nephropathy (n=1), minimal change disease (n=1).

Results: We analyzed 50 pairs of repeat renal biopsy from 46 LN patients with two or more biopsies. The median age was 26 [IQR 18-32] years at reference biopsy and 32 [27-40.7] years at repeat biopsy. 84% was female and the median duration between biopsies was 5.9 years. Of the 50 cases of repeat biopsies, ISN/RPS class switch or alternative pathology was observed in 22 (44%) cases. 6 (12.5%) cases showed histologic switch from proliferative to class VI or alternative pathology, but no pure non-proliferative class. Pure non-proliferative class in the reference biopsy was rare (4%). Low C3 (adjusted odds ratio, 0.04; 95% CI, 0.002 to 0.41; *P*=0.02) or increased anti-dsDNA antibody (adjusted odds ratio, 0.10; 95% CI, 0.009 to 0.96; *P*=0.05) was associated with lower conversion rates of proliferative to class VI or alternative pathology at renal flare. In addition, low C3 was associated with higher activity index (adjusted odds ratio, 19.83; 95% CI, 2.05 to 191.57; *P*=0.01) and presence of cellular crescent (adjusted odds ratio, 10.73; 95% CI, 1.11 to 104.04; *P*=0.04), while serum creatinine was associated with advanced tubulointerstitial damage at renal flare (adjusted odds ratio, 2.62; 95% CI, 1.25 to 5.46; *P*=0.04).

Conclusion: Low C3 at renal flare is associated with the retention of proliferative class and active glomerular inflammation at renal flare in patients with originally proliferative LN. These results support C3 as a surrogate marker to distinguish active LN from change to class VI or alternative pathology at renal flare. Hence, it will be helpful for making decisions about repeat renal biopsy or immunosuppressive therapy.

Neutrophil Lymphocyte Ratio as a Marker for Immune Complex-Driven Inflammation in Patients with Systemic Lupus Erythematosus

Bobby Kwanghoon Han,[1] Katherine Wysham,[2] Anders Bengtsson,[3] Muhsen Al-Ani,[1] Grant Hughes,[1] Jenna Thomason,[1] Bernard Ng,[4] Mark Wener,[5] and Christian Lood[1], [1]University of Washington, seattle, [2]Veterans Health Administration Puget Sound, Seattle WA, Seattle, [3]Lund University, Lund, Sweden, [4]University of Washington, Veterans Affairs Puget Sound Health Care System, Seattle, WA, [5]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils play a crucial role in pathogenesis of systemic lupus erythematosus (SLE). Recently, neutrophil to lymphocyte ratio (NLR) has been studied as a biomarker for various rheumatic diseases including

in SLE. The aim of the current study was to evaluate if NLR reflects underlying pathogenetic mechanisms including reactions driven by immune complex (IC) in SLE.

Methods: Clinical information including peripheral blood cell counts, SLE disease activity index (SLEDAI), autoantibody (autoAb) profiles, complement levels, and treatment were collected for 104 SLE patients through the University of Washington (UW) Lupus Repository. Univariate and multivariate linear regression analyses were performed to determine associations between NLR and these variables, including clinical SLEDAI (calculated by subtracting any score for anti-dsDNA and complement from total SLEDAI). A second SLE cohort (n=143), recruited from Lund University (LU), Sweden, was included to investigate associations between NLR and immunological and inflammatory markers, serum type I interferon (IFN) activity as measured by a reporter cell system, and neutrophil subpopulations. For theses analyses, high NLR was defined as above 90th percentile of healthy individuals, and Mann-Whitney U test and logistic regression analyses were performed.

Results: In the first cohort from UW, log-transformed NLR levels were significantly associated with clinical SLEDAI, anti-dsDNA, number of autoAbs, C3, C4, and prednisone dose in univariate analyses. In multivariate analyses, anti-dsDNA remained significantly associated with NLR (β= 0.3, p = 0.003) after controlling for age, gender, clinical SLEDAI, and prednisone dose. Among anti-DNA positive patients, NLR was independently associated with low C3 (β= 0.3, p = 0.02). In the second cohort from LU, high NLR correlated with increased circulating immune complexes (p=0.02) and downstream type I IFN activity (OR=2.3, p=0.04). Lastly, we observed a strong association between high NLR and elevated levels of the serum neutrophil activation marker, S100A8/A9 (p=0.001), and enrichment for low-density granulocytes (LDGs, p=0.001), a neutrophil subset known to be pathogenic in SLE patients.

Conclusion: Our findings support an association in SLE patients between NLR and markers of IC-driven inflammation, including anti-dsDNA, low C3, and type I IFN activity. Additionally, high NLR may reflect abnormal production of immature LDGs, known to promote inflammation and organ damage. Further studies are needed to determine the significance and underlying mechanisms of elevated NLR in SLE.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a lack of reliable biomarkers for disease activity in SLE. While C3a, an anaphylatoxin generated during of complement activation, could be predictive for disease flares, a possible role of the soluble terminal complement complex, sC5b-9, in active SLE has yet to be elucidated. It's proinflammatory effects on a number of cells types, e.g. glomerular mesangial cells and synovial fibroblasts, have been described.

Objectives: To study whether the sC5b-9 is associated with clinical disease activity in SLE and to compare it with C3 and C4, well characterized in active disease, and the split product C3a, in addition to laboratory parameters of standard of care.

Methods: *Study population and design*

Patients included into the Swiss SLE Cohort Study (SSCS, from St. Gallen centre fulfilling the ACR criteria at inclusion), were entered consecutively into a prospective observational study (Oct. 2015 - Dec. 2017). The following were determined at two clinical visits, at least 6 months apart, and compared with 18 healthy controls:

- clinical disease activity by clinical examination, SELENA-SLEDAI, and by SLICC-Damage, SF-36, PGA, and FACIT
- C3a and sC5b-9 by ELISA,
- a spectrum of routine laboratory of standard routine care

Table 1. Patient characteristics at inclusion in 127 patients with systemic lupus erythematosus

	All
No. (%)†	254 (100)
Female sex, no. (%)	208 (82)
Age, mean ± SD, years	51 ± 17
Disease duration, median [IQR], years	5.8 [3.5-9.1]
Overlap-syndromes, no. (%)‡	24 (9)
Disease activity	
LLDAS, no. (%)	222 (87)
SLEDAI >0, no. (%)	124 (49)
SLEDAI >0, mean ± SD	4.2 ± 3.1
ACR criteria at baseline,	
Arthritis, no. (%)	152 (60)
Haematological disorder, no. (%)	144 (57)
Photosensitivity rash, no. (%)	120 (47)
Oral ulcers, no. (%)	86 (34)
Malar rash, no. (%)	72 (28)
Discoid rash, no. (%)	48 (19)
Pleuritis, no. (%)	44 (17)
Renal disorder, no. (%)	40 (16)
Pericarditis, no. (%)	28 (11)
Psychosis, no. (%)	8 (3)
Seizures, no. (%)	4 (2)
ANA positive, no. (%)	254 (100)
anti-APL positive, no. (%)	126 (50)
anti-dsDNA positive, no. (%)	102 (40)
anti-Sm positive, no. (%)	16 (6)

† two samples (one per time point) per patient; ‡Overlap-syndromes: dermatomyositis (N=1), polymyositis (N=1), rheumatoid arthritis (N=1), systemic sclerosis (N=9). Standard deviation (SD); interquartile range [IQR]. LLDAS = Lupus Low Disease Activity State; anti-APL, anti-phospholipid antibodies

Statistics

Correlation analyses were performed calculating nonparametric Spearman rank correlation coefficients. Independent associations of continuous and categorical variables were studied by analysis of covariance (ANCOVA) models, using the general linear model approach.

Results: The disposition at inclusion of our 127 patients is shown in table 1, with 87% of patients in Lupus Low Disease Activity State and 49% with a SELENA-SLEDAI > 0.

There were significant association/correlations (univariate analyses) between:

- sC5b-9 and haematuria ($p < 0.001$)
- sC5b-9 and glomerular dysmorphic erythrocytes ($r=0.139$, $p=0.020$)
- dsDNA ab and sC5b-9 ($r=0.221$, $p < 0.001$) with IgG ($r=0.421$, $p \leq 0.001$)

There were further correlations between:

- C3a with sC5b-9 ($r=0.299$, $p \leq 0.001$), C3a with C3 ($r=0.318$, $p=0.01$), and C3a with C4 ($r=0.137$, $p=0.02$)

Sensitivities/specificities (with regard to haematuria or increased glomerular erythrocytes) were 75/63% or 64/62% for sC5b-9, 8/68%, or 27/69% for C3, and 8/84% or 18/84% for C4, respectively.

Of note, Immunoglobulin G (IgG) levels were associated with SELENA-SLEDAI ($F=4.94$, $p=0.027$) in a multivariate model after adaptation for age, gender, CRP, ESR, ANA titre, dsDNA antibody value, complement factor C3 and C4.

A significant association of C3a with routine laboratory parameters of standard of care, and of sC5b-9 with overall disease activity or other components of the SLEDAI, could not be detected.

Conclusion: Soluble C5b-9, elevated in our cohort concomitant to urinary signs of renal manifestation, may contribute to the pathogenesis in SLE and be a useful marker of active renal disease.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-cyclic citrullinated peptide (anti-CCP) antibodies are a hallmark of RA but are widely distributed in other autoimmune diseases. Although SLE is well characterized as a complex autoimmune disease eliciting a broad spectrum of autoantibodies, the significance of CCP antibodies in SLE patients (pts) remains poorly understood. This study evaluated the prevalence of anti-CCP antibodies in pts with SLE and their associations with demographic characteristics, clinical history, and other autoantibodies.

Methods: SLE patients pts (n=499) consented for research in the Oklahoma Cohort for Rheumatic Diseases were tested for anti-CCP by ELISA. Demographic information, clinical characteristics, and autoantibody profiles were extracted from medical records. Clinical features of pts who had ever tested positive for anti-CCP antibodies were compared to those who consistently tested negative for anti-CCP antibodies. Variables were analyzed using Fisher's exact test.

Results: In 499 pts meeting ACR classification criteria for SLE 12% (61) were anti-CCP positive. Malar rash was the only classification criterion significantly less frequent in the CCP+ SLE group (CCP+: 44% vs CCP-: 58%, $p < 0.05$). Anti-nuclear antibody positivity did not vary between these groups. Anti-CCP antibodies were not more common in any racial subgroup including African American (AA), Native American (NA), and European American (EA) pts. Subsetting by race into AA, EA, and NA subgroups revealed significant enrichment of serositis criteria in the AA CCP+ subgroup compared to the CCP+ EA and CCP+ NA subgroups. In the CCP- subgroups, EA subjects were enriched for malar rash compared to the CCP- AA subgroup and enriched for photosensitivity compared to the CCP- AA and CCP- NA subgroups. The CCP- AA subgroup was significantly enriched for renal criteria compared to the CCP- EA subgroup and enriched for immunologic criteria compared to the CCP- EA and CCP- NA subgroups. In both the CCP+ and CCP- AA subgroups, discoid rash was enriched compared to the EA and NA subgroups and anti-Sm positivity was enriched compared to the EA subgroups. Among the CCP- subgroups, SS-B (La) was enriched in the NA subgroup compared to the AA subgroup and Cent B was enriched in the NA subgroup compared to the AA and EA subgroups. All RNP autoantibodies were enriched in the CCP- AA subgroup, but not the CCP+ AA subgroup.

Conclusion: Race contributes to variations in the frequency of ACR criteria and antinuclear autoantibodies which were observed between the CCP+ and CCP- SLE patients.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosis and classification of patients as having systemic lupus erythematosus (SLE) is critical in daily clinical practice as well as for clinical trials and observational studies. The objective of this study was to identify whether patients would be classified earlier using the 2018 EULAR/ACR criteria than the physicians' diagnosis and what items may help for the earlier diagnosis in a multiethnic lupus cohort.

Methods: Patients from a Latin American, multiethnic, multicenter cohort were included. For these analyses, the 2018 EULAR/ACR items were evaluated to determine which clinical manifestations and/or laboratory parameters could be of help to attain an earlier classification of patients. Categorical variables were compared using Chi-square. A p-value of 0.05 was set as the level of statistical significance. The statistical analyses were performed using SAS software version 9.4.

Table 1. Characteristics at the time of EULAR/ACR -based classification in GLADEL cohort patients classified at the same time, earlier, or later than based on the physicians' diagnosis.

EULAR/ACR criteria, Items	EULAR/ACR classification earlier, %	EULAR/ACR classification at the same time, %	EULAR/ACR classification later, %	p-value*
	n=177 (18.1%)	n=483 (49.3%)	n=319 (32.6%)	
CLINICAL				
Fever	67.2	62.3	65.2	0.452

Oral Ulcers	41.8	44.9	44.8	0.756
Nonscarring alopecia	63.8	66.3	60.5	0.252
Synovitis	85.9	82.0	83.7	0.479
Seizures	10.7	10.1	9.4	0.886
Psychosis	6.8	6.6	9.4	0.315
Delirium	NA	NA	NA	NA
Acute pericarditis	17.0	17.4	14.7	0.598
Serositis	32.2	32.3	27.9	0.381
Thrombocytopenia	26.6	24.6	23.2	0.704
Autoimmune hemolysis	11.9	16.2	10.7	0.065
Leucopenia	57.1	53.4	60.2	0.163
Proteinuria	47.5	46.0	50.5	0.456
Renal Biopsy II or V	6.2	6.8	10,0	0.177
Renal Biopsy III or IV	17.0	18.8	20.4	0.643
IMMUNOLOGIC				
aCL>40 or LAC (+)	37.9	34.8	43.6	0.043
Low C3 or C4	51.4	61.9	58.6	0.052
Low C3 and C4	36.2	47.6	42.6	0.027
Anti-Smith	22.6	29.4	23.5	0.085
Anti-dsDNA	65.5	69.2	64.6	0.363
* Estimated from a Chi-square test				

Results: One thousand forty-seven patients out of 1480 were analyzed. Of them, 979 patients fulfilled the 2018 EULAR/ACR criteria and 68 patients did not. Of those who fulfilled the 2018 EULAR/ACR criteria, the mean (±SD) age at diagnosis was 28.0 (12.5) years; 10.6% were African-Latin Americans, 38.5% Mestizos, 48.9% Caucasians, and 2.0% others. A total of 177 (18.1%) patients achieved the 2018 EULAR/ACR criteria earlier, 483 (49.3%) at the same time and 319 (32.6%) did it later. So considering patients diagnosed later (n=319) and those that could not be included (n=68), the 2018 EULAR/ACR criteria recognized as lupus at the same time or earlier, only about two-thirds [660/1047 (63%)] of the patients diagnosed by expert physicians. Patients who accrued the 2018 EULAR/ACR later were more likely to have positive anticardiolipin antibodies and/or the lupus anticoagulant; low complement levels were not uniformly distributed among the three groups but a clear pattern did not emerge. No differences were found in the clinical items of the criteria.

Conclusion: When the 2018 EULAR/ACR set of criteria were compared to the judgment of expert physicians no clinical or laboratory variable was found to allow earlier classification of lupus except for the presence of aPL antibodies which were more frequent among those diagnosed later. As compared with the physician's clinical diagnosis, the new criteria do not seem to have a good performance for the early classification of lupus patients in this real-life scenario in a multiethnic cohort. To our knowledge this is the first independent comparison of the new proposed criteria for SLE and the gold standard diagnostic method, that is the physician's diagnosis.

Patterns of High Disease Activity Status and Outcomes in Systemic Lupus Erythematosus

Alberta Hoi,[1] Hieu Nim,[2] Rachel Koelmeyer,[2] Ying Sun,[3] Amy Kao,[4] Oliver Guenther,[3] and **Eric Morand**[2], [1]School of Clinical Sciences, Monash University, Meloburne, Victoria, Australia, [2]Monash University, Melbourne, Victoria, Australia, [3]Merck Healthcare KGaA, Darmstadt, Germany, [4]EMD Serono Research & Development Institute, Inc., Billerica, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: High Disease Activity Status (HDAS), defined as ever attainment of SLEDAI-2k of 10 or greater, may be a useful indicator of overall disease severity in systemic lupus erythematosus. The natural history and disease course following episodes of HDAS has not been previously described.

Methods: Using prospectively collected data from the Australian Lupus Registry and Biobank, we examined the patterns and consequences of HDAS. A HDAS episode (until resolution) was defined as the interval from first visit with a

Table 1. Odds ratio of damage accrual is dependent of the number of HDAS episodes.

Number of HDAS episodes	OR	95% CI	p-value
0	1	-	-
1	1.51	0.81-2.84	0.24
2	4.12	2.06-8.23	<0.001
3	6.24	2.15-18.13	<0.001
4	14.98	1.63-137.48	0.01
5 or more	18.72	2.13-164.49	0.003

recorded SLEDAI -2K≥10, to the time when patient achieved Low Lupus Disease Activity State (LLDAS)[1]. Recurrent HDAS was defined as patients who had at least 2 visits with SLEDAI-2k≥10 that were at least 2 months apart. Persistent HDAS was defined as a subset of recurrent HDAS patients in whom SLEDAI-2k was ≥10 at consecutive visits. The associations of these time course patterns with clinical outcomes were analysed.

Results: Data on 286 patients followed for 4.5 +/- 3.3 years were studied. A total of 128 patients had at least one visit that met the criteria for HDAS, accounting for 254 HDAS episodes. The duration of HDAS episodes was variable (median 133 days, IQR 70-245 days), and were significantly longer in patients entering an HDAS episode with SLEDAI-2K > 10 compared to those entering the HDAS episode with SLEDAI-2K = 10 (p=0.003, unpaired heteroscedactic t-test). Accordingly, the likelihood of an HDAS episode lasting > 12 months was 1.89 (95% CI 1.03-3.46, p=0.04) if starting SLEDAI was >10 compared to =10. The number of HDAS episodes increased the odds of damage accrual, with an odds ratio for increased SLICC damage of 4.12 (p< 0.001) if the patient experienced 2 episodes during the observed period (Table 1).

Most HDAS patients had recurrent HDAS (95/128, 74%). Forty-four patients fulfilled the definition of persistent HDAS. Compared to patients who never experienced HDAS, the risk of damage accrual was markedly increased in recurrent HDAS patients, with an OR 3.1 (95% CI 1.82-5.32, p< 0.001). Persistent HDAS patients have the highest risk of damage accrual with an OR 7.13 (95% CI 3.45-15.62, p< 0.001).

Conclusion: HDAS is a clinically relevant SLE disease severity measure, but its disease course can be highly variable. The risk of damage accrual increased progressively according to exposure to HDAS. Patients with persistent HDAS are at the highest risk of damage accrual.

Background/Purpose: Monocytes/macrophages are the most abundant cells infiltrating the glomeruli and in the active urinary sediment of patients with Lupus Nephritis (LN).[1] These cells also have relative abundance of Toll Like Receptor 4 (TLR4) as compared to other white blood cells.[2] Therefore MRP8/14 (Calprotectin), an endogenous

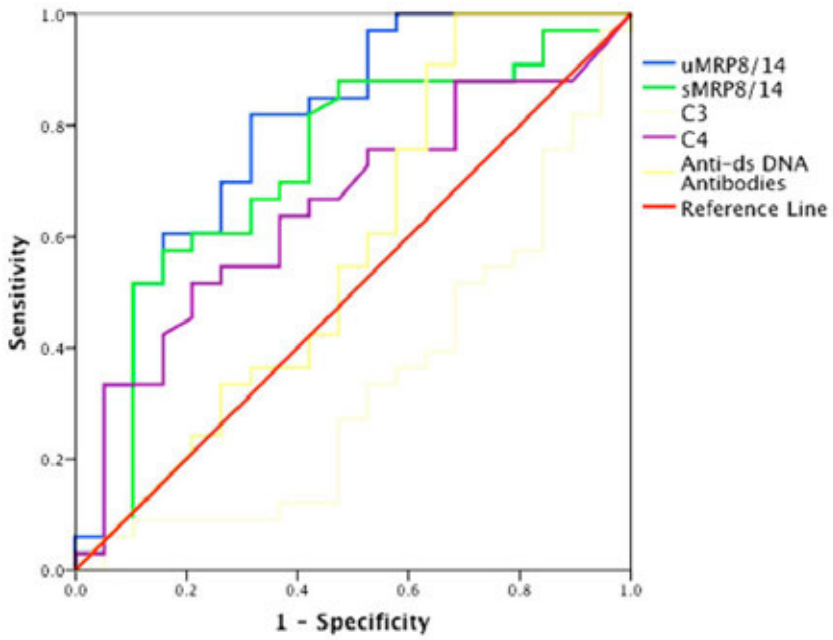

Figure 1. ROC analysis at baseline for conventional disease activity parameters and serum and urinary MRP8/14 levels

TLR4 ligand, could be responsible for their activation in LN and may serve as a biomarker of renal disease activity in urine.

Methods: SLE patients with active nephritis (AN), active disease without nephritis (active non-renal; ANR) and inactive disease (ID) were enrolled. Disease activity was assessed using SLEDAI and renal SLEDAI (rSLEDAI). Patients in AN group were treated according to the ACR 2012 guidelines and followed up every 3 months for 1 year. AN disease was defined as SLEDAI ≥5 with rSLEDAI ≥4, ANR was defined as SLEDAI ≥5 with rSLEDAI =0 and ID was defined as SLEDAI ≤4 with rSLEDAI =0. Urine and serum samples were collected at baseline for all patients and at every 3 months for 1 year in AN group. Urine samples from 10 healthy subjects (HC) and 10 patients of rheumatoid arthritis (RA) served as controls. Serum MRP8/14 (sMRP8/14) and urinary MRP8/14 (uMRP8/14) were measured using commercially available ELISA kits (BioLegend, San Diego, CA, USA) and urinary values were normalized for creatinine excretion. Variables are expressed as median (range) and non-parametric tests were used for analysis. A p-value < 0.05 was considered significant.

Results: A total of 52 SLE patients (F:M = 49:3) were enrolled. Among these, 32 were in AN category whereas 10 patients each were enrolled in ANR and ID categories. Complete response rates at 3, 6, 9 and 12 months were 24%, 42%, 50% and 50% respectively and 3 patients expired at 3 months because of high disease activity. At baseline, normalized uMRP8/14 (ng/mg of creatinine) was significantly higher in AN group [4464 (569-128894)] as compared to ANR [1167 (4-18357)], ID [438 (147-4320)], HC [1348 (3-2726)] and RA [339 (6-11519)] (p-value < 0.05) groups. At baseline, uMRP8/14 showed good correlation with urinary protein:creatinine ratio (r=0.55; p-value< 0.001), rSLEDAI (r=0.5, p-value < 0.001) and SLEDAI (r=0.3, p-value < 0.001) but not with sMRP8/14 (r=0.25). Baseline uMRP8/14 but not sMRP8/14 could differentiate between AN and ANR groups (Table 1) and on ROC analysis, uMRP8/14 (AUC=0.8) performed better than sMRP8/14 (AUC=0.72), C3 (AUC=0.67), C4 (AUC=0.35) and anti-ds DNA antibodies (AUC=0.58) (Figure 1). On follow-up of AN patients, with a reduction in disease activity, uMRP8/14 also decreased significantly at 6,9 and 12 months visits as compared to baseline (p-value < 0.05) (Table 2). sMRP8/14 also decreased significantly at 6 and 9 months but had an erratic and irregular trend. uMRP8/14 also showed a rise before conventional markers in 6 patients who relapsed within 1 year of follow-up requiring change of therapy.

Conclusion: uMRP8/14 is a potential biomarker of LN disease activity. In patients with active SLE, it helps differentiate between patients with and without renal involvement. It correlates with renal disease activity and has a potential to predict relapse of LN.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Assessment of risk both for pregnancy morbidity and thrombosis in the presence of antiphospholipid antibodies (aPL) is still a challenge. The Global Antiphospholipid Syndrome Score (GAPSS) takes into account the aPL profile (criteria and non-criteria), the conventional cardiovascular risk factors and the autoinmune antibody profile. An adjusted model of the score (aGAPSS) suggests that the score is able to stratify patients for their rate of events making it widely applicable in daily clinical practice. The aim was to evaluate the aGAPSS in an external multicentric cohort of Systemic Lupus Erythematous (SLE) patients in Argentina.

Methods: SLE patients from seven Rheumatologist centers were included. Traditional cardiovascular risk factors as Arterial Hypertension (AH), diabetes, smoking, obesity and hyperlipidemia were collected, as well as immobilization, surgery, pregnancy and contraceptive pills/ Hormonal Replacement Therapy (HRT). Immunological tests: antinuclear antibodies (ANA), anti-DNA, anti-Ro, anti-La, anti-RNP, anti-Sm and anti-phospholipid antibodies (Lupus Anticoagulant (LA), anti-cardiolipin (aCL) and β 2 Glycoprotein I (β2GPI) were evaluated. Received treatment: hydroxychloroquine, low doses of aspirin and oral anticoagulants. The score aGAPSS was calculated in each patient by adding together the points corresponding to the risk factors: 1 for AH, 3 for dyslipidemia, 4 for LA and B2GPI and 5 for aCL Score ranges from 0 to 17. Quantitative data were presented as a mean (SD) and were compared by using the t-test, analysis of variance (ANOVA) or the non-parametric Mann- Whitney test. A 95% confidence interval (CI) was selected and a p value< 0.05 was considered significant. The discriminative ability of the aGAPSS was calculated by

Table 1. Associated factors with thrombotic events.

Table 1. Associated factors with thrombotic events.

Variables	Event n (%)	No Event n (%)	p-value
Female Sex	108 (93.1)	150 (88.2)	0.17
Diabetes	6 (5.2)	5 (2.9)	0.33
Obesity	20 (17.2)	24 (14.1)	0.47
Smoking	18 (15.5)	19 (11.2)	0.28
Immobilization	7 (6)	2 (1.2)	0.021
Surgery	15 (12.9)	9 (5.3)	0.022
Contraceptive pills/ HRT	5 (4.3)	7 (4.1)	0.93
Cancer History	3 (2.6)	4 (2.4)	0.90
Pregnancy	5 (4.3)	1 (0.6)	0.031
LAC+	42 (36.2)	37 (21.8)	0.007
Anti- Cardiolipin +	47 (40.5)	37 (21.8)	0.001
Anti- Beta2 GPI +	22 (19)	24 (14.1)	0.27
Arterial Hypertension	36 (31)	35 (20.6)	0.04
Dyslipemia	15 (12.9)	24 (14.1)	0.77
Triple + antibodies	12 (10.3)	15 (8.8)	0.66
ANA +	107 (92.2)	160 (94.1)	0.53
Anti-DNA +	49 (42.2)	91 (53.5)	0.06
Anti- Sm +	29 (25)	66 (38.8)	0.015
Anti-RNP +	30 (25.9)	52 (30.6)	0.38
Anti- Ro +	43 (37.1)	75 (44.1)	0.23
Anti- La +	16 (13.8)	22 (12.9)	0.83
Low dose Aspirin	39 (33.6)	45 (26.5)	0.19
Hydroxychloroquine	108 (93.1)	160 (94.1)	0.72

measuring the area under the receiver operating characteristic curve (AUC). Multivariate logistic regression analysis was accomplished to examine the impact of multiple cardiovascular risk factors and laboratory parameters on the occurrence of thrombosis.

Results: Two-hundred eighty-six SLE patients were included (90.2% women, mean age at SLE diagnosis of 31.8 years (SD±12.3). One-hundred and sixteen patients (40.6%) presented thrombotic/ pregnancy complications. Fifty-four patients (18.9%) presented at least one thrombotic episode (64 events; 34 arterial and 30 venous thrombosis). Table 1 shows associated factors with thrombotic/ obstetrical events. Multivariate logistic regression analysis showed that aCL [OR 2.1 (CI 95% 1.15-3.9); p 0.016] and anti-Sm [OR 0.45 (CI95% 0.25-0.8); p 0.006] antibodies were independent risk factors for thrombotic events. Mean aGAPSS was significantly higher in patients who experienced a thrombotic event compared with those without [4.9 (SD±4.4) versus 3.1 (SD± 4.3); p 0.009]. The AUC showed that aGAPSS ≥4 presented the best diagnostic accuracy (0.63 p 0.03 IC95% 0.57- 0.70) with 61.2% sensibility and 62.9% specificity. The aGAPSS ≥4 was independently associated with thrombotic events OR 1.89 (CI 95% 1.89-3.85); p 0.013.

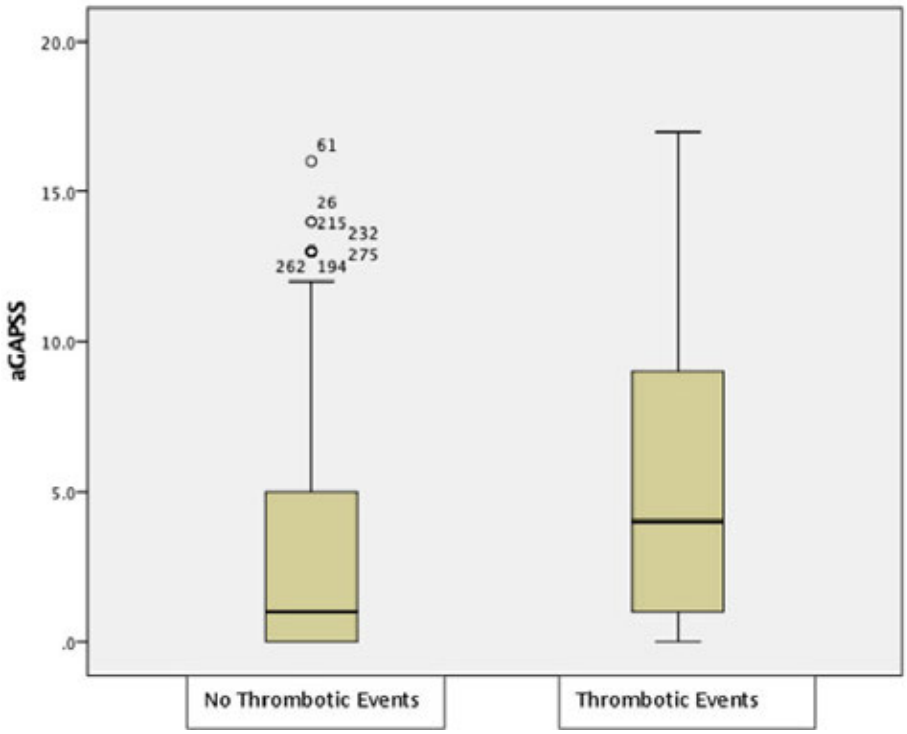

Figure Distribution of aGAPSS in SLE patients.

Conclusion: aGAPSS was significantly higher in patients who experienced a thrombotic event compared with those without. This score is a simple tool to use in SLE patients in daily practice.

Correlation of Urinary Soluble CD163 Levels with Clinicopathological Features in Lupus Nephritis: Its Role as a Potential Biomarker

Shilpa Venkataraman,[1] Ankita Singh,[2] Manjula Murari,[3] Vinita Agrawal,[2] Amita Aggarwal,[3] and Rakesh Pandey[4], [1]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Post Graduate institute of medical science, Lucknow, India, Lucknow, Uttar Pradesh, India, [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India, [4]Sanjay Gandhi Postgraduate Institute for Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis (LN), is seen in 30-50% patients with SLE and 5-10% patients progress to end-stage renal disease. The clinical disease activity indices do not reliably predict the renal histological activity. Hence, biopsy is still the gold standard to help in treatment decisions and prognosis assessment.

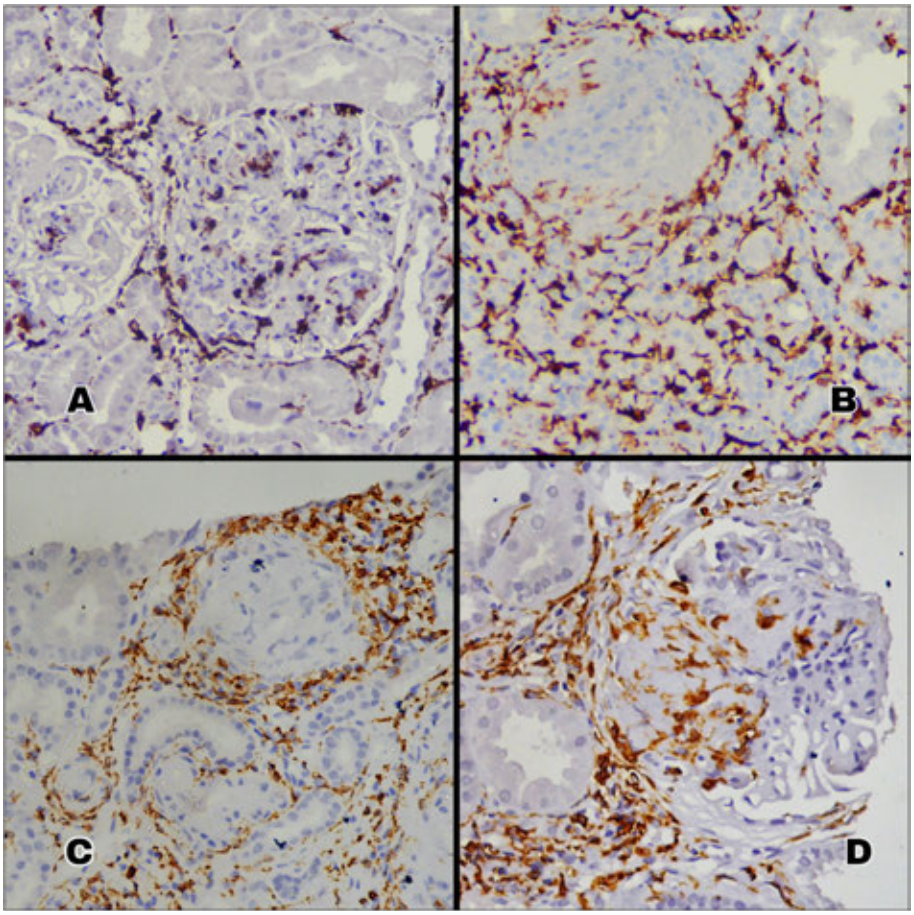

Figure 1. CD163 positive cells in renal biopsies at different sites

Soluble CD163 (sCD163), receptor shed from the alternatively activated macrophage (M2) has been recently found to be a potential urinary biomarker of active LN. To explore further, we studied the urinary sCD163 levels and CD163 positive cells in renal biopsies and studied their correlation with histological features.

Methods: SLE patients undergoing renal biopsy for LN were enrolled. The clinical data regarding disease activity and other parameters was collected. Pre-biopsy urine sample was collected and cell free supernatant was stored at -80C till analysis. Urinary sCD163 (uCD163) was measured by ELISA and the values were normalized to urinary creatinine excretion. 10 healthy control (HC) urine samples were also tested for comparison. The renal biopsies were classified according to the ISN-RPS classification. Activity index (AI) and chronicity index (CI) were calculated using modified NIH scoring system. Immunohistochemistry (IHC) for CD163 positive macrophages was done. Statistical analysis was done using SPSSv20.0

Results: Forty SLE patients with active LN were enrolled [37 females, median age 27 years (12-56)]. All patients had active disease [median SLEDAI 16 (6-43), renal SLEDAI 8 (4-16)]. Among 40 patients, 1 had class II LN, 11 had class III, 26 had class IV and 2 had class V nephritis. The median AI was 8 (1-15) and CI was 2 (0-8).

Urinary sCD163 levels were higher in proliferative LN as compared to healthy controls.[49.6 ug/mg of creatinine (3.6-451) versus 4.2 ug/mg of creatinine (0.7-12) in HC; $p< 0.001$] and showed significant correlation with biopsy activity index ($r=0.50$; p-value < 0.001), presence and frequency of subendothelial hyaline deposits ($r=0.39$; p-value < 0.05) and karyorrhexis ($r=0.42$; p-value < 0.01). They also correlated with the percentage of glomeruli with endocapillary hypercellularity ($r=0.39$; p-value < 0.01). The average number of CD163 positive cells/glomerulus was 7.8 (0-18). The

positive association of uCD163 with activity Index was supported by the localization of CD163+ macrophages in the areas of interstitial inflammation, tubulointerstitial damage and glomeruli with proliferative lesions (Figure 1).

Renal SLEDAI (r=0.46, p-value < 0.01), serum creatinine (r=0.531; p-value < 0.001) and serum total protein (r=-0.34; p-value< 0.05) significantly correlated with chronicity index. The CD163 positive cells were seen along periglomerular fibrosis and around sclerosed glomeruli, though uCD163 levels did not correlate with chronicity index.

Conclusion: Urinary CD163 is a good marker of active LN and correlates with histological activity. CD163+ macrophages are localized to areas of activity as well as chronicity and may contribute to pathogenesis of LN.

Hair Chemicals and Systemic Lupus Erythematosus: A Case-Control Study

Jessica English,[1] Trevor Faith,[2] Dulaney Wilson,[1] and Diane Kamen[3], [1]Medical University of South Carolina, Charleston, SC, [2]Medical University of South Carolina, Charleston, [3]Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, South Carolina, USA., Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a complex chronic autoimmune disease of unknown etiology. Previous studies of beauty products as potential triggers of SLE development have shown conflicting results. Our study evaluates the use of hair chemicals in patients with SLE and controls and the relationship of use with disease severity among patients.

Methods: Data was obtained from an ongoing longitudinal registry of patients with SLE and non-SLE population-matched controls at a single center. Participants seen over a 12 year period. Information on demographics, medical history, social history, types of hair chemicals used, and SLE characteristics (if applicable) was gathered from in-person interviews. Chart review and telephone follow-up was done for missing values. Disease damage was determined by SLICC/ACR Damage Index ("damage present" if score ≥1). Males and children were excluded from the study population. "Cutaneous lupus" includes SLE patients with documented malar rash, discoid rash, photo-

Table 1. Group Characteristics

Characteristics	SLE n = 359	Controls n = 175	p-value
Current age (mean years ± sd)	48.5±15.6	51.5±16.9	<0.01
African American (%)	70.2	70.3	0.98 (NS)
Insured, any (%)	95.0	93.7	0.56 (NS)
High school graduate (%) (adults)	90.3	88.8	0.61 (NS)
Any hair chemical usage (%)	65.5	49.7	<0.01

Table 2. Disease Characteristics

Disease Characteristics	Hair Chemical Users with SLE n = 235	Non-Users with SLE n = 124	p-value
African American (%)	79.8	55.7	<0.01
Age of SLE diagnosis (years +/- sd)	31.0 ± 13.5	30.8 ± 13.9	0.84 (NS)
History of cutaneous manifesations (%)	85.0	76.7	0.10 (NS)
History of lupus nephritis (%)	45.6	43.3	0.71 (NS)
History of hematologic manifestations (%)	60.2	54.9	0.40 (NS)
Any damage by SLICC-DI (%)	57.9	58.1	0.97 (NS)

sensitivity, and/or alopecia. Pearson's chi-squared testing was performed for categorical measures and two-sample t-tests were performed for continuous measures. Significance was set at alpha = 0.05.

Results: A total of 359 female SLE patients and 175 female controls were included, Table 1. Hair chemical use was more frequent in self-identified black patients (p< 0.01). Patients with SLE were significantly more likely to use hair chemicals compared to controls (65.5% vs. 49.7%, p< 0.01), specifically with higher proportions of patients using hair relaxers/straighteners (p=0.91), hair dyes (p=0.07), and permanent wave products (p=0.23). SLE damage did not differ among patients who use hair chemicals compared to non-users (p=0.97), Table 2. A higher percentage of hair chemical users had cutaneous manifestations, but was not statistically significant (p=0.10)

Conclusion: In conclusion, we found that hair chemical use among females was significantly higher in patients with SLE compared to controls, especially hair dyes. These results provide a basis to look further in to hair chemical use and its relation to autoimmunity. Ongoing analyses are examining the timing and duration of hair chemical use and the development of autoimmunity.

Body Mass Index at Time of Diagnosis Is Predictive of Future Disease Activity in SLE

George Stojan,[1] Jessica Li,[2] and Michelle Petri[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity is more common in patients with SLE compared to the general population. The prevalence of obesity among SLE patients is between 28 and 50 percent. We previously demonstrated an inverse correlation between body mass index and disease activity in systemic lupus, even after adjusting for prednisone dose. The question of whether these findings were epiphenomena related to disease activity itself remained unanswered. We thus hypothesized that the BMI at cohort entry was predictive of future disease activity.

Methods: 2406 patients in a prospective SLE cohort had their weight assessed at each visit. Patients were categorized into five predetermined groups based on weight: low (BMI< 20 kg/m2), normal weight (reference, BMI 20-24.9 kg/m2), overweight (25-29.9 kg/m2), obese (BMI 30-34.9 kg/m2), and severely obese (BMI >35 kg/m2). Disease activity was characterized on the basis of SLE Disease Activity Index (SLEDAI) scores; for each BMI category we created an Adjusted Mean SLEDAI score. This involved calculating the area under the curve of SLEDAI scores over time. The area under the curve between each two visits was the average of the SLEDAI values at those two visits multiplied by the length of time between the two visits. All the calculated areas were then summed and divided by the total length of the time period. The adjusted mean SLEDAI had the same units as SLEDAI. The adjusted mean SLEDAI has been shown to be a valid measure of SLE activity. To calculate adjusted mean of SLEDAI over time, we only included patients attending the clinic at 3 month intervals for a minimum of 3 visits. 1896 patients were included in the analysis. 1763 (93.0%) were females. Majority (53.0%) were Caucasians, 39.0% African American. To determine whether BMI at cohort entry was predictive of future disease activity, we compared the categorized BMI at cohort entry with the adjusted mean SLEDAI by pairwise t test and ANOVA test. Data were adjusted for prednisone use at cohort entry.

Results: SLEDAI (adjusted mean) by Body Mass Index at baseline visit

BMI	N (%)	SLEDAI Mean (SD)	P value*
Low (Reference)	183 (9.7)	2.9 (2.2)	REF
Normal	655 (34.5)	2.7 (2.4)	0.1912
Overweight	531 (28)	2.5 (2.1)	0.0328
Obese	290 (15.3)	2.6 (2.1)	0.0464
Severely Obese	237 (12.5)	2.5 (2.1)	0.0755

* p-values adjusted for prednisone dose (as a continuous variable) at cohort entry

Conclusion: Body weight at cohort entry was predictive of future disease activity. Overweight and obese patients had a significantly lower adjusted mean SLEDAI over time (P< 0.05). This analysis adds further support to the existence of an obesity paradox in SLE.

Environmental and Atmospheric Factors in Systemic Lupus Erythematosus: A Regression Analysis

George Stojan,[1] Frank Curriero,[2] Anton Kvit,[2] and Michelle Petri[3], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, [3]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding the role of environmental exposures in the development of SLE and their association with SLE activity may help identify modifiable risk factors and potential etiological mechanisms. We hypothesized that changes in fine particulate matter (PM2.5) concentration, ozone concentration, temperature, resultant wind, relative humidity, and barometric pressure are predictive of organ specific flares in lupus.

Methods: 1628 patients who fulfill 4 of the 11 ACR or SLICC classification criteria for SLE were included in the analysis. The data ranged from 1999 to 2017. Maximum distance between visits was 110 days with 1 month time aggregation units. Disease activity was expressed as Physician Global Estimate (PGA), taken at every patient visit. A flare was defined as a PGA score increase of 1 point or more compared to the previous visit. Environmental and atmospheric data was obtained from the EPA, including PM2.5 and ozone concentration, temperature, residual wind, relative humidity, and barometric pressure. The average values of each factor 10 days prior to patient visit was calculated. Univariate and multivariate models were built in order to study the association of these variables with lupus disease activity. The models were adjusted for age, sex, income, racial distribution, and rural vs. urban patient residence. Multivariate logistic regression was used to identify significant determinants associated with lupus flares. Regression was performed for each organ flare outcome. Regression inference was based on generalized estimating equations (GEE) to account for the time repeated outcomes.

Results: Rash, serositis, hematologic, and joint flares were statistically significantly associated ($p< 0.0.5$) with an increase in temperature in univariate and multivariate analysis. Renal flares were negatively associated with increases in temperature ($p< 0.05$) in both univariate and multivariate analysis. Renal flares were negatively associated with increases in ozone concentration ($p< 0.05$) in univariate and multivariate analysis. Joint ($p< 0.001$), neurologic ($p< 0.001$), renal ($p< 0.01$), hematologic ($p< 0.05$), and pulmonary ($p< 0.001$) flares were directly associated with residual wind in univariate and multivariate analysis. Humidity was significantly associated with joint ($p< 0.001$), and serositis ($p< 0.05$) flares in univariate and multivariate analysis. Barometric pressure had no significant associations. PM2.5 concentration was significantly associated with rash ($p< 0.001$), joints ($p< 0.001$), serositis ($p< 0.001$), and hematologic flares ($p< 0.001$) in univariate and multivariate analysis.

Conclusion: There is a strong association between changes in atmospheric and environmental variables 10 days prior to patient visit and organ specific lupus activity at the visit. No environmental or atmospheric factor had a general association with all organ specific lupus flares. These data could add an important aspect to lupus trials, the outcomes of which may be affected by so far unrecognized environmental factors, and ultimately it could allow predictive modelling of lupus flares which would revolutionize the approach to treatment.

The Performance of a Renal Activity Index in Lupus Nephritis in Induction Therapy

Najla Aljaberi,[1] Qing Ma,[2] Theresa Hennard,[3] Arjun Mathur,[4] and Hermine Brunner[5], [1]Divison of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Division of Nephrology and Hypertension, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Division of Rheumatology, Cincinnati Children's Hospital and Medical Center, Cincinnati, OH, [4]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

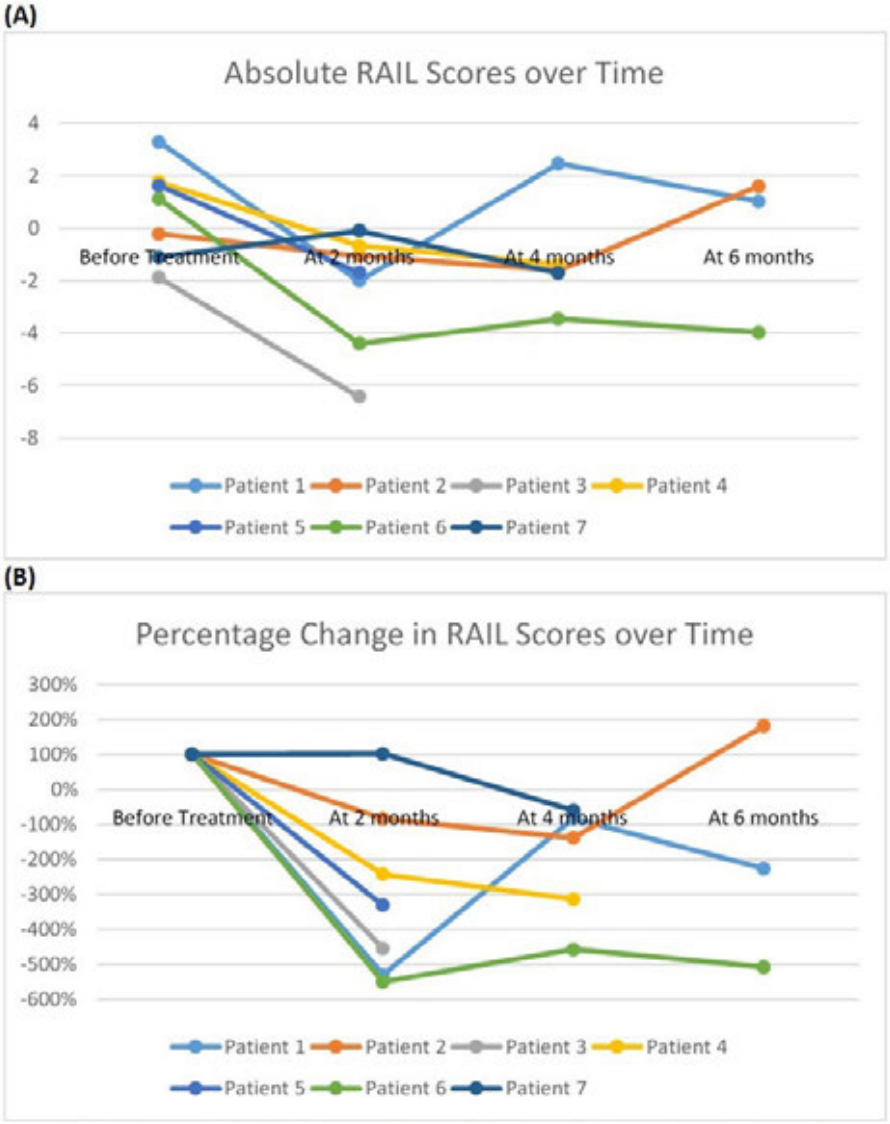

Figure 1. Changes in the RAIL score from baseline, at 2 months, at 4 months and at 6 months in 7 patients with LN: (A) Absolute RAIL scores over 6 months, (B) Percentage change of RAIL scores over 6 months.

Background/Purpose: Lupus nephritis (LN) is associated with high morbidity and mortality. Current standard tools to monitor LN are suboptimal compared to the invasive renal biopsy. The *Renal Activity Index In Lupus* (RAIL) considers the urine concentrations of 6 biomarkers (neutrophil gelatinase-associated lipocalin, ceruloplasmin, monocyte chemoattractant protein-1, adiponectin, hemopexin, kidney injury molecule-1) and has been shown to reflect histologic activity with 92% accuracy. Biomarkers part of his score have also demonstrated changes that predicted response to LN therapy at least 3 months earlier. We aimed to study the changes in the RAIL score in relation to induction treatment in LN.

Methods: Urine samples were collected from active LN patients prior to induction treatment for LN and serially afterwards, coinciding with clinical visits. Luminex Bead Multiplex Assay was used for the analyses of urine biomarkers included in the RAIL. RAIL scores were calculated per the defined algorithm for each urine sample[1]. Serial data collected between 0 and 6 months post LN diagnosis included LN histologic class as per

the International Society of Nephrology (ISN)/Renal Pathology Society (RPS), renal SLE disease activity index (rSLEDAI) score, and type of therapy.

Results: At the time of the analysis, data from 6 active LN patients were collected longitudinally. Patients were all females and all had class IV LN per the ISN/RPS. All patients were started on intravenous (IV) methylprednisolone and cyclophosphamide (CYC) therapy. All but one patient completed 6 doses of monthly CYC before switching to oral mycophenolate mofetil therapy. The RAIL scores for the 6 patients ranged between -1.8 and 3.3. All patients had reductions in their RAIL score at 4 months period (mean absolute decline of 4.3 points; Figure 1A, mean % decline of 211%; Figure 1B). Among 3 with longer follow-up information, all but 2 patients maintained a decline of RAIL scores below the baseline. Patient 1 is known to have medication non-adherence. At 4 months Patient 1 had a prominent rise in RAIL score after which repeat renal biopsy showed persistently high activity of LN leading to commencement of Rituximab therapy. Patient 2 had only 3 monthly doses of CYC. All rSLEDAI scores decreased between baseline and the 6 months interval, except for Patient 2.

Conclusion: RAIL scores show overall improvement from baseline with LN induction therapy. Lack of improvement was associated with flare of disease. Additional data points and a larger study sample are required to study the ability of the RAIL score to reflect clinical improvement of LN. As with other biomarkers, biologic variability creates a variable distribution across patients, therefore it is important to analyze the relative change in the score over time.

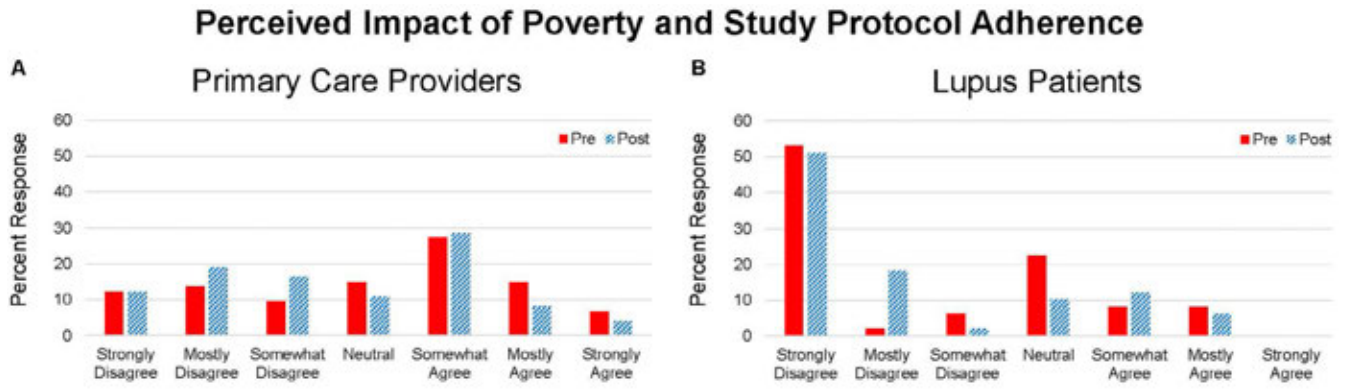

Figure 1. A & B. Mixed responses were obtained from primary care providers (A) when asked whether they believe poverty might reduce protocol adherence in clinical trials. Patients (B) were less likely to agree that poverty reduced protocol adherence both before the program ($p<0.0001$) and after the program ($p<0.0001$) when compared to providers. Providers shifted towards disagreement after completing the educational program ($p=0.02$).

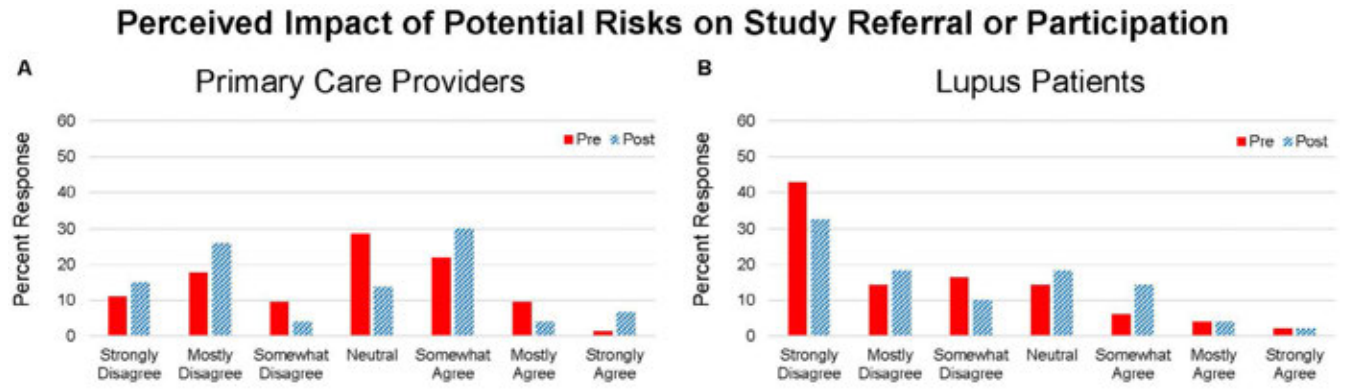

Figure 2 A & B. Significant differences in responses between providers and patients were noted before the program ($p<0.0001$) and after the program ($p=0.02$) with providers more concerned than patients about potential risks in clinical trials. Following the program patients shifted slightly towards more concern about risks and providers slightly less, neither of these changes were significant

Background/Purpose: Although SLE disproportionately affects minority racial groups, this population is significantly under-represented in clinical trials, increasing risk for underpowered, incorrect conclusions in race-based subgroup analyses. The decision to participate in clinical research is complex. Primary care providers (PCPs) have the ability to inform their patients about research and refer to specialists who participate in clinical trials. We evaluated knowledge of SLE and thoughts about clinical research participation with both PCPs and lupus patients.

Methods: Lupus patients and PCPs completed a pre-test consisting of knowledge and belief questions prior to engaging in an educational program about lupus, clinical research, and human subjects' protections. As part of the post-test, the same set of questions were repeated. Knowledge questions were analyzed by Fisher's exact test or McNemar's test for between group and within group comparisons. Belief questions (Likert scale ratings) were analyzed by Mann-Whitney or Wilcoxon matched pairs for between group and within group comparisons.

Results: 73 providers and 49 lupus patients completed the questionnaires and program. Knowledge topics included 1) triggers of SLE, 2) racial differences in lupus, and 3) elements of informed consent. On the pre-test there were differences between groups in scoring of the informed consent question (PCP 82% correct and patient 49%, $p=0.0001$). On the post-test the patients' scores improved (PCP 92% and patient 73%, $p=0.0098$). The education program resulted in improvement in all knowledge scores for PCPs and patients (Table 1). Points of view about clinical trials

included questions about the impact of differing racial background between provider and patient, education level of study participants, risks of trial participation, and effect of poverty on protocol compliance – the latter two resulted in the greatest incongruence (Figure 1 and 2).

Conclusion: Concepts about race, education, and poverty may impact interactions between clinicians and patients that could inhibit referral to clinical trial centers and clinical trial participation. We found that some providers may hold a belief that indigent patients are poor candidates for clinical trials. Despite a shift away from this opinion following an educational program, providers remained much more likely to retain this point of view compared to lupus patients. Further effort to optimize conditions for clinical trial access to all patients is needed. This work may benefit from better understanding of the barriers that have led to underrepresentation of minority patients.

Measurement of Type I IFNα Production at the mRNA Level and Its Potential Use as a Biomarker in Systemic Lupus Erythematosus

Ilana Abeles,[1] and Vasileios Kyttaris[2], [1]Beth Israel Deaconess Medical Center, Boston, MA, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gene expression studies have previously demonstrated increased Type I interferon α (IFN) inducible genes in peripheral blood mononuclear cells of systemic lupus erythematosus (SLE) patients as compared to controls. Prior studies also showed increased IFNα gene expression is associated with markers of disease activity, both by disease activity scores and serological markers (Kennedy et al, 2015 and Kirou et al 2005). Despite the success of large phase II trials of anti-IFN therapies in patients with SLE, phase III trials were reportedly negative. Identifying the optimal biomarker in order to target the appropriate population of SLE patients to receive anti-IFN therapy remains elusive and a critical goal. Rather than using IFNα inducible genes as biomarkers, we investigated IFNα subtype expression in SLE patients versus healthy controls. We also evaluated associations of IFNα subtype expression in SLE patients with disease-related characteristics and clinical phenotype.

Methods: Patients were recruited from Beth Israel Deaconess Medical Center and the protocol was approved by our institution's IRB. We obtained serum samples from 26 patients and 4 controls. Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) of interferon α subtypes (1, 2, 4, 5, 6, 7, 8, 10, 14, 16, 17, 21) and β-actin mRNA were done using the Inexsia/Amplikine platform (PBL InterferonSource, Piscataway, NJ). For each mRNA/cDNA in the sample, the fluorescence threshold cycle (Ct) during the amplification reaction was identified. The Dct was then calculated for each interferon α subtype mRNA by subtracting its Ct from the β-actin Ct ($Dct_{\text{interferon α subtype}} = Ct_{\text{actin}} - Ct_{\text{interferon α subtype}}$). Statistical analyses were done using SPSS. Between group differences were analyzed with independent samples t-test. Multiple linear regression analyses were conducted to evaluate for independent associations between

IFNα expression, SLEDAI, autoantibodies, markers of disease activity and clinical phenotypes. Follow up correlational analyses were done using Pearson's correlation.

Results: Analyses revealed that Type I IFN α2 mRNA expression in patients' peripheral blood mononuclear cells was elevated as compared to controls (p = 0.02, t= -2.65). No other subtypes demonstrated between group differences. Type I IFN α2 mRNA expression in patients trended towards correlating with disease activity as measured by SLEDAI scores (p =0.07, F= 4.2). There was also a trend found for a correlation between IFN α2 expression and lupus nephritis (R=.48, p=.067). No serological markers of disease activity or autoantibodies were significantly associated with IFN α2 expression.

Conclusion: Prior studies and clinical trials investigating IFNα in SLE used surrogate markers to deduce IFNα production. We propose that direct measurement of IFNα production at the mRNA level is feasible and can potentially be used as a biomarker for guiding anti-IFNα therapy in patients with SLE.

Revising the SLEDAI-2K to Include Additional Constitutional Symptoms to More Accurately Assess Lupus Disease Activity

Bhakti Shah,[1] Erik Anderson,[2] Meggan Mackay,[3] Cynthia Aranow,[4] Marissa Sansone,[5] and Joseph Hong[6], [1]Northwell Health, Highland, NY, [2]Northwell Health System, Feinstein Institute for Medical Research, New York, [3]Feinstein Institute for Medical Research, New York, [4]Feinstein Institute for Medical Research, Manhasset, NY, [5]Jersey City Medical Center, Jersey City, [6]Northwell Health System, Feinstein Institute for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The SLEDAI-2K, a widely-used measure for disease activity, does not incorporate symptoms such as weight loss, lymphadenopathy (LAD) or fatigue which may limit accurate assessment of disease activity. Another instrument, the Physician Global Assessment (PGA), derives from physician perception of overall disease activity. Our primary objective was to determine whether the addition of weight loss, LAD, and fatigue to the SLEDAI-2K improves the accuracy of disease activity assessment as measured by the PGA.

Methods: A revised SLEDAI (SLED-R) was created that substituted the "Fever" descriptor with a new "Constitutional" descriptor that included the original fever > 38 °C plus weight loss of more than 5%, lymphadenopathy ≥ 0.5 cm (categorized 0.5cm-1cm or ≥1cm), and/or fatigue (defined as fatigue limiting activities of daily living ≥ 50% of the time) in the preceding 28 days (excluding Fibromyalgia or other known causes). In order to preserve integrity of the original SLEDAI (SLED-O) scoring, total points for the new descriptor remained 1. A total of 414 SLED-O and SLED-R scores were prospectively collected from 163 SLE subjects in the Rheumatology clinics at Northwell Health. Concomitant PGA and Patient Global Assessment (PtGA) scores were also collected (Table 2). The primary analysis was a Steiger's test to compare correlation coefficients obtained using a Spearman's Rank correlations test between SLED-O vs. PGA and SLED-R vs. PGA. Similar analyses were performed comparing SLED-O and SLED-R to the PtGA.

Results: Demographic data is presented descriptively (Table 1); PGA, SLED-O and SLED-R were collected on all subjects, PtGA were collected on 390. The new Constitutional descriptor was scored in 45 of the 414 SLEDAIs collected; among these, fatigue scored in 20, LAD scored in 23 (> 1 cm in 9, 0.5 -1 cm in 14), weight loss in 1 and fever in 5. The original descriptor, Fever alone, was scored in 3 in contrast to an additional 42 that scored with the new Constitutional descriptor. The correlation between PGA and SLED-R (R 0.790, p< 0.00) is significantly greater than the correlation between SLED-O and PGA (R 0.784, p< 0.00), (p=0.048, Steiger's test). Significance was lost if either fatigue or LAD was removed from the new descriptor (Table 3). The correlation between PtGA and SLED-R (R 0.436, p< 0.00) is significantly greater than the correlation between SLED-O and PtGA (R 0.417, p< 0.00), (p< 0.00, Steiger's test).

Conclusion: Expansion of the Fever descriptor to include other constitutional symptoms, both subjective (fatigue) and objective (LAD, fever, weight loss), resulted in higher SLEDAI scores in 10.86% of this cohort. This was driven by both fatigue and LAD and removal of either negated the significance, suggesting that both measures contribute. Importantly, the addition of more constitutional signs/symptoms improved the SLEDAI correlations with PGA, suggesting increased accuracy of the revised SLEDAI. Further clinical studies would be needed to assess the applicability of the SLED-R as a tool in guiding therapeutic changes and long-term outcomes in SLE patients.

Abstract Number: 0700

Sleep Quality Among Patients with Systemic Lupus Erythematosus

Alexandra Schwab,[1] and Diane Kamen[2], [1]Medical University of South Carolina, Charleston, SC, [2]Division of Rheumatology and Immunology, Department of Medicine, Medical University of South Carolina, Charleston, South Carolina, USA., Charleston, SC

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Poor sleep quality is a frequent concern among patients with systemic lupus erythematosus (SLE) and contributes to fatigue and other comorbidities. This study investigates the prevalence of poor sleep quality among patients with SLE and the relationship between sleep quality and SLE-related medication use.

Methods: Patients with SLE participating in a longitudinal observational study at a single academic center were invited by email to complete a web-based sleep questionnaire and medication inventory. The Pittsburg Sleep Quality Index (PSQI), a self-reported validated questionnaire ascertaining sleep habits over the past month, was the metric chosen for measuring sleep quality and was scored using the PSQI scoring algorithm. Demographics, medical history including classification criteria for SLE and SLE disease damage scores were obtained from the existing research registry for each participant. Pearson's chi-squared testing was performed for categorical measures and two-sample t-tests were performed for continuous measures. Significance was set at alpha = 0.05.

Results: Of the 142 patients that completed the Pittsburg Sleep Quality Index (PSQI), 99% were female and 86% were African American. The mean PSQI score was 11.98 +/- sd 3.63 with a minimum score of 4 and maximum of 20 out of a possible 21. Higher PSQI scores (corresponding to worse sleep quality) were significantly associated with getting less than 7 hours of sleep ($p< 0.01$), taking sleep medications at least weekly ($p< 0.01$), and having a diagnosis of obstructive sleep apnea ($p< 0.01$), but there was no significant difference found between patients based on age, race, history of lupus nephritis or accumulated disease damage by SLICC-DI. Having a poor PSQI score was not associated with prednisone dose ($p= 0.09$), however taking greater than 7mg of prednisone daily was inversely correlated to the number of hours patients slept per night ($p< 0.01$). Mean number of hours per sleep per night was 5.7 +/- sd 1.5, despite a mean of 8.0 +/- sd 2.0 hours spent in bed. 42.3% of patients reported taking medications for sleep at least once a week.

Conclusion: In this study of patients with SLE, we found a high prevalence of poor quality sleep and a mean of less than 6 hours of sleep/24 hours despite an average of 2 additional hours spent in bed. Although we did not find SLE-specific predictors of poor sleep quality, the overall sleep habits of the patients reflect a critical need to address sleep with patients and work toward interventions for improvement of sleep quality.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Podocytes, glomerular visceral epithelial cells, function as molecular sieve not to filter high molecular weight proteins such as albumin and globulins. Various immunological insults damage podocyte to cause detachment from capillary wall in lupus nephritis, leading to reduced podocyte number per glomeruli, glomerulosclerosis, and end stage kidney disease, because podocytes are unable to proliferate and regenerate itself. Therefore, we hypothesized that more podocyte loss or more podocyte damage in a certain period relates to poor renal outcome. It was recently reported that urinary podocyte number (U-Pod) and urinary podocalyxin (U-PCX) were related to podocyte injury in lupus nephritis. We conducted the longitudinal study to clarify the association of accumulated U-Pod and U-PCX with long-term renal prognosis.

Methods: U-Pod were determined by counting PCX-positive cells in sediments from urine samples. U-PCX were measured by sandwich ELISA, normalized to urine creatinine levels. All patients were diagnosed as lupus nephritis with fulfilment of 1997 ACR classification of systemic lupus erythematosus and renal biopsy, and recruited between January 2011 and February 2015 (ISN/RPS Classification III: 2 patients, III+V: 3 patients, IV: 12 patients, IV+V: 7 patients, V: 1 patients). U-Pod, U-PCX, and eGFR were obtained around the treatment start, and at 1, 3, 6 and 12 months (mo) after treatment. eGFR was additionally obtained 5 years after treatment. Cumulative U-Pod (c-U-Pod) and (c-U-PCX) were generated by the summations of values measured at all 5 time points as above. U-Pod and U-PCX were compared between eGFR decliner and non-decliner (eGFR after 5 years – eGFR after 6 months). Correlation of c-U-Pod and c-U-PCX with the change of eGFR was analyzed. Statistical analysis was done with Mann-Whitney U test and Spearman correlation. $p < 0.05$ was defined as statistical significance. Each value was described as median and interquartile range.

Results: In this study, 10 eGFR decliner and 15 eGFR non-decliner were obtained. Both of c-U-Pod and c-U-PCX were not significantly different between eGFR decliner and eGFR non-decliner (c-U-Pod cells/mgCr, decliner: 3.18, 0.69-7.43, non-decliner: 5.93, 1.73-13.78, p=0.40, c-U-PCX mg/gCr, decliner: 911.1, 561.2-1401.0, non-decliner: 985.6, 396.6-1785.0, p=0.76). There was no significant correlation of c-U-Pod and c-U-PCX with long-term (4 years and 6 months) eGFR change (c-U-Pod: r 0.32, p=0.14, c-U-PCX: r 0.18, p=0.39).

Conclusion: c-U-Pod and c-U-PCX were not significantly associated with long-term eGFR change. Podocyte loss could not solely explain long-term renal prognosis.

Abstract Number: 0702

Seasonality of Cutaneous and Systemic Flares in Adults and Children in the Einstein Lupus Cohort

Tamara Tanner,[1] Dawn Wahezi,[2] Ilir Agalliu,[3] Chaim Putterman,[4] Anna Broder,[5] Nicole Jordan,[4] Dalynah Maldonado Andujar,[4] and Tamar Rubinstein[6], [1]Children's Hospital at Montefiore, Bronx, NY, [2]Children's Hospital at Montefiore, New York, [3]Albert Einstein College of medicine, Bronx, [4]Montefiore Medical Center, Bronx, [5]Rheumatology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [6]Children's Hospital at Montefiore/Albert Einstein College of Medicine, Bronx, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ultra violet light (UV) exposure has been implicated as a major contributor to pathogenesis and flares in lupus. While some studies have looked at the association between seasons (as proxy for sun exposure) and cutaneous or systemic flares in lupus patients, results are mixed and few include racially diverse cohorts. Our objectives were to study whether a seasonal relationship exists with cutaneous and systemic lupus flares in a racially and ethnically diverse cohort of pediatric and adult lupus patients.

Methods: We retrospectively analyzed consecutive study visits from 2002-2019 of adult and pediatric lupus patients enrolled in the Einstein Lupus Cohort at Montefiore Medical Center in Bronx, NY. We defined cutaneous flare by SELENA SLEDAI inflammatory rash, and systemic flare as SLEDAI ≥ 4. Mixed-effects regression models were used to determine whether cutaneous or systemic flares were associated with season adjusting for race/ethnicity and sex as potential confounders and accounting for repeated measures for each patient. We examined the relationship in a second model including average UV index (UVI) in New York City for the month preceding study visits, to account for the expected lag between UV exposure and onset of symptoms.

Results: We examined 2,351 patient visits for 704 individual patients. Our patients were 87% female; 36% were Black non-Hispanic, 47% were Hispanic and 3% were white non-Hispanic. Among all visits, 9% were associated with new inflammatory rash. Looking at cutaneous disease in a mixed effects model, to account for repeated measures from the same patient, we found that summer (July-Sept) was significantly associated with cutaneous flare compared to winter (Jan-Mar); results remained significant when we adjusted for race/ethnicity and sex (OR 1.8, [95% CI 1.0-3.1], p=0.04). Once adjusting for the previous month's UVI there was no longer an association between summer and cutaneous flare. There was no association between season and systemic flare (OR 1.0 [95% CI 0.7-1.4], p=0.9). However, a bi-modal distribution of systemic flare rates was observed (1st peak in Mar/April, 2nd peak in July-Oct). In an adjusted mixed-effect model with sex, race/ethnicity and previous month's UVI included, Mar/April and Jul-Oct were both still significantly associated with systemic flare compared to other months: Mar/April (OR 2.0 [95% CI 1.4-2.9], p< 0.001), Jul-Oct (OR 2.9 [95% CI 1.7-4.7], p< 0.001).

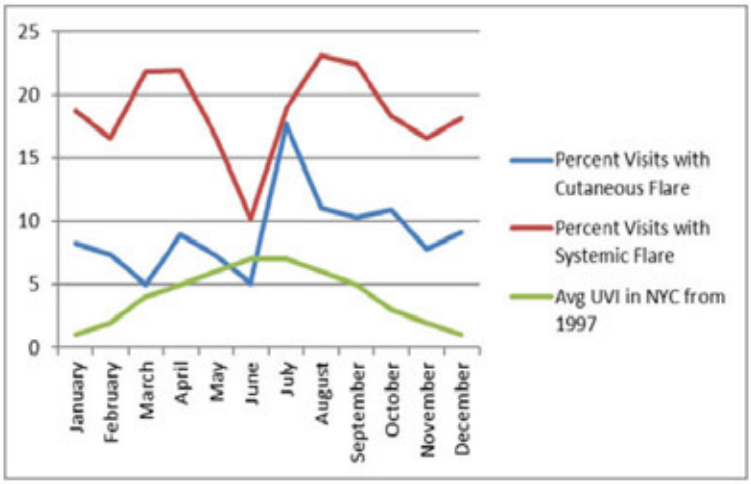

Figure 1. Percent visits with cutaneous or systemic flares across calendar months

Conclusion: We found as association between cutaneous flare and summer in a racially and ethnically diverse cohort of patients with SLE, a relationship that appears to be mostly explained by the previous month's UVI. Though we found no association between systemic flare and season, a bimodal relationship was observed in systemic flares with peak rates in early spring and again in summer through early fall. These two peak periods were associated with systemic activity even while accounting for previous month's UVI. Further epidemiologic studies examining other potential exposures that vary with season may help elucidate triggers that help explain this relationship.

Prior Knowledge Feature Reduction Improves Performance in a Machine Learning Model of Systemic Lupus Erythematosus Flare Status Using Serum Proteomics

Nimisha Schneider,[1] and Andrew Thompson[1], [1]PatientsLikeMe, Cambridge

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic auto-immune condition characterized by systemic inflammation that can exacerbate (flare) unpredictably, causing widespread organ damage. Identification of SLE flares, particularly at an early stage, remains a challenge for rheumatologists because many flare symptoms mimic those of other conditions but is critical in order to resolve systemic inflammation and spare patients unnecessary treatment if their symptoms are not SLE-related.

Methods: We use a machine-learning approach to classify patient-reported flare status from proteomic measurements in serum from a cohort of 144 individuals with SLE. Proteomic measurements collected from serum samples were inputed to a logistic regression model. The cohort was split 70-30% into training and test sets; 5 fold cross validation was performed within the training set to select hyperparameters. Performance in the test set is reported as area under the receiver operating characterisic curve as an average from 100 test-training split iterations.

Results: We find improvement in the performance of a logistic regression model of patient-reported flare status when the substrate feature pool is reduced from the full proteomic panel of 900 proteins to a 6-protein panel of cytokines selected through curation of peer-reviewed biomedical literature. Use of this prior knowledge protein panel as input to the learning algorithm boosts performance from AUC=0.66 using the full panel to AUC=0.83 using the 6-feature selected panel.

Conclusion: Our results point to a critical role for prior experimental knowledge of molecular disease drivers in creating accurate mathematical, molecular models with diagnostic potential.

Abstract Number: 0704

Improving Patient-Centered Care by Utilizing Lupus Wellness Program

Jacinta Renaldi,[1] Fotios Koumpouras,[1] Lenore Buckley,[1] and Mei Xue Dong[1], [1]Yale University, New Haven

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although the mortality rate of lupus has decreased with improvement of treatment options, it remains high compared to non-SLE mortality. The factors that contribute to this increased mortality are heterogonous including both disease and patient related factors. Several studies have shown the discordance between physician and patient agendas regarding SLE care. Physicians have a greater focus on screening for and treating SLE-related organ involvement, whereas patients are often more concerned with symptoms of burden which often leads to frustration on both sides. This disparity in priorities, along with diminishing time availability of the physician for patient counseling and overall poor health literacy of patients have significantly affected treatment efficacy and adherence. The Lupus Wellness Program aims to serve as an intervention to bridge the care gap.

Methods: SLE patients participated in a Lupus Wellness Program in which they met with a rheumatology nurse practitioner in a one-to-one session every 2 to 12 weeks (depending on preference and availability of the patient) for a total of about 4 sessions. The program followed a curriculum with written information and materials given to the participants at each visit. Forty-seven patients with lupus completed the program. All patients were given a pre-program and post-program knowledge assessment. We measured cardiovascular risk factors (blood pressure, inflammatory markers such as ESR and CRP, prednisone dosage and bodyweight) of the patient 1 year

before starting the program and 1 year after the completion of the program. We also compared health practices over the last 5 years of the participants of the program (intervention group) to a control group of lupus patients who had not participated in the lupus program. Our outcome measurements were 1)rate of flu vaccination, 2) rate of pneumonia vaccinations, 3) cholesterol screening and 4) access to MyChart (patient portal to electronic medical record).

Results: Our study indicates that lupus patients who completed the Lupus Wellness Program had about 80% improvement in knowledge assessment between their pre and post program assessments. Patients who participated in the program within the first 3 years after their diagnosis of lupus tended to have greater improvements in their knowledge assessment compared to those who started the program 4 or more years after diagnosis. Participants had better control in blood pressure and inflammation markers and used less amount of prednisone, but less changes on body weight, as compared to before the intervention. Compared to non-participants, participants of the program received more PNA and Flu vaccinations, and signed up to use MyChart more often.

Conclusion: Our study indicates that usage of an individualized educational program for lupus patients may serve as valuable tool to help to improve long term health outcomes in this population, especially when implemented early on in the disease course. With the increasing demand and decreasing time availability of rheumatology physicians, an advanced practice provider may serve as valuable asset to bridge the gap in patient care.

Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE diagnostic criteria are important for reliable epidemiologic data. The prevalence of SLE in West Africa is falsely low due to barriers including limited access to both resource and labor-intensive diagnostic testing. Recently, the ACR and EULAR have proposed a weighted classification tool which is thought to improve diagnostic sensitivity and specificity compared to the established ACR and SLICC criteria. Here we aim to investigate the performance of each classification criteria in two West African cohorts--Korle bu Teaching Hospital, Accra Ghana (GH); and Lagos University Teaching Hospital, Lagos, Nigeria (N)--compared to an NYU Langone-African American (AA) cohort.

Methods: We collected data on a total of 355 SLE patients: AA: n=151, GH: n=110, and N: n=94, diagnosed by expert clinicians. Clinical information including demographics, SLE criteria, SLEDAI scores, SLICC damage indexes,

vital signs, and laboratory values as available was obtained at the initial patient encounter. Longitudinal data was collected over the course of at least 1 year at 6 month intervals during routine clinical visits. Where necessary, clinical charts were retrospectively reviewed, and the proportion of patients in each cohort meeting ACR, SLICC and the ACR/EULAR classification criteria was calculated.

Results: The demographics per cohort were as follows: Age (in yrs): AA=43.1, GH=32.4yrs, N=35.5; percent female: AA=90, GH=100, N=97; Mean SLE disease duration (yrs): AA=14.3, GH=2.2, N=4.4. In each cohort, the percentage of patients meeting ACR, SLICC, and ACR/EULAR criteria were AA=96%, 96%, and 95%; GH=85%, 84%, 62%; N=90%, 87%, 61%. This discrepancy was largely due to missing laboratory data particularly with regard to immunologic and hematologic studies. ANA was missing in 0% of the AA cohort, 26% of the GH cohort, and 33% of the N cohort respectively. Compared to the GH and N cohorts, the reference AA cohort was more likely to meet ACR, SLICC, and ACR/EULAR criteria with likelihood ratios (LR) of GH=10.2 $p< 0.001$ and N=3.0 p=0.08; GH=11.5, $p< 0.001$ and N=6.3, p=0.01; and GH=46.1 $P< 0.001$ and N=44.9, $p< 0.001$ respectively. On average, the mean number of ACR/EULAR points by cohort was AA: 26.1±11.8, GH: 21.3±8.1, and N: 19.0±6.2. While the ANA entry criteria greatly diminished the new ACR/EULAR diagnostic utility in the GH and N cohorts, the weighted point system performed better than either of the ACR or SLICC criteria with 96% of the AA cohort, 92%of the GH, and 95% of the N cohort meeting criteria (LR: AA vs GH=1.9, p=0.2; AA vs N=0.23, p=0.6).

Conclusion: Due to a relative lack of resources, supportive laboratory assays including an ANA may be more difficult to attain in developing nations. SLE is a clinical syndrome that may be efficiently diagnosed using the new weighted ACR/EULAR criteria. The entry criteria of ANA 1:80 greatly diminished the diagnostic utility of this classification system in the Ghanaian and Nigerian cohorts compared to the African American cohort. Clinical trials should consider offering wide ANA testing to cohorts in the developing world.

Neuronal BC RNAs: Systemic Lupus Erythematosus Autoantibodies Cause Dendritic Transport Impairments

Ilham Muslimov,[1] Anna Iacoangeli,[2] Taesun Eom,[3] Anne Ruiz,[3] Madisen Lee,[3] Stacy Stephenson,[3] and Ellen M Ginzler[4], [1]Suny Downstate Medical Center Center, Brooklyn, NY, [2]Tisch MS Research Center of New York, New York, NY, [3]Suny Downstate Medical Center, Brooklyn, NY, [4]State University of New York Downstate Medical Center, Brooklyn, NY

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: SLE – Clinical Poster I: Epidemiology & Pathogenesis – ARP
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In systemic lupus erythematosus (SLE), autoantibodies are often directed against nucleic acids or their binding proteins. Regulatory Brain-specific Cytoplasmic (BC) RNAs operate as translational regulators at neuronal synapses. BC RNAs are transported to synapto-dendritic sites of function by heterogeneous nuclear ribonucleoprotein A2 (hnRNP A2). Dysregulation of BC RNA control has been associated with cognitive impairment and epilepsy. Here we hypothesize that transport-specifying structural motifs in BC RNAs can become targets of autoimmune reactivity in neuropsychiatric SLE.

Methods: We collected sera from 69 patients diagnosed with SLE. Sera from non-SLE human (n = 38) subjects were collected as follows: healthy subjects (HS), patients with rheumatoid arthritis (RA), and patients with multiple sclerosis (MS). IgG was purified from sera using Protein A/G and Protein G spin columns (Nab Spin Kit, Thermo Fisher Scientific). BC RNA transcripts were generated by in vitro transcription (Promega). RNA-protein interactions were analyzed by electrophoretic mobility shift assays (EMSAs). Microinjection transport analysis was performed with sympathetic neurons in primary**.** BALB/c mice were used for in situ hybridization. Quantitative and statistical analysis was performed with Prism (Graphpad) and SPSS Statistics.

Results: Autoantibodies against BC RNAs (anti-BC abs) were detected in a subset of lupus patient sera. Strength of SLE anti-BC autoimmune reactivity and occurrence of neuropsychiatric manifestations correlated strongly (Spearman's $r_s = 0.89$, $P < 0.0001$, $n = 69$). Anti-BC abs were not detected in sera from RA or MS patients or in sera from HS. RNA transport experiments were performed as follows. Following preincubation with IgGs, radiolabeled BC RNAs were injected into sympathetic neurons in primary culture. Preincubation with SLE IgG SLE, but not with non-SLE IgG, significantly reduced dendritic delivery of BC RNAs (one-way ANOVA, $P < 0.0001$). In a second set of experiments, we bath-applied IgGs to sympathetic neurons in culture prior to microinjection of BC RNAs. Bath application of SLE IgG, but not of non-SLE IgG, resulted in significantly reduced dendritic targeting of BC RNAs ($P < 0.0001$). In vivo experiments showed that SLE IgG, but not non-SLE IgG, prevented endogenous BC1 RNA from localizing to pyramidal cell dendrites in hippocampal CA1 (Dunnett's test stratum pyramidale vs. strata oriens and radiatum: $P < 0.0001$). SLE anti-BC abs were specifically directed at BC RNA structural motifs that serve as dendritic targeting elements (DTEs). Interaction of SLE anti-BC abs with such motifs caused displacement of RNA transport factor hnRNP A2 from BC RNAs. As a result, SLE anti-BC abs significantly reduced BC RNA dendritic targeting.

Conclusion: Our findings demonstrate that lupus anti-BC abs effectively compete with hnRNP A2 for DTE access and significantly diminish BC RNA delivery to synapto-dendritic destination sites. Lack of BC RNA causes phenotypic abnormalities including cognitive impairment and epileptogenic responses. The combined data indicate a role of anti-BC RNA autoimmunity in SLE and its neuropsychiatric manifestations.

gressive GIT involvement could help tailor disease management and allow earlier access to appropriate treatments for patients at risk; as well as facilitate inclusion of patients in clinical trials. The aim of this study was to evaluate the severity and evolution over time of GIT involvement in SSc patients measured by the UCLA GIT 2.0 questionnaire (UCLA GIT score) and assess predictive factors for progression of GIT involvement in two large and independent SSc cohorts.

Methods: All SSc patients fulfilling the American College of Rheumatology (ACR 2013) criteria followed at the Leiden University Medical Centre (LUMC) or Oslo University Hospital (OUH) between 2013-2018 were included. Clinical and demographic features were collected and GIT involvement assessed by the UCLA GIT score at baseline and annually up to 5 years. Progression of GIT involvement was determined for total GIT and each subdomain using the minimal clinical important difference (MCID, Khanna et al. 2011). Univariable and multivariable logistic regression were used to identify baseline variables associated with baseline GIT involvement. Linear mixed-effect regression analysis models

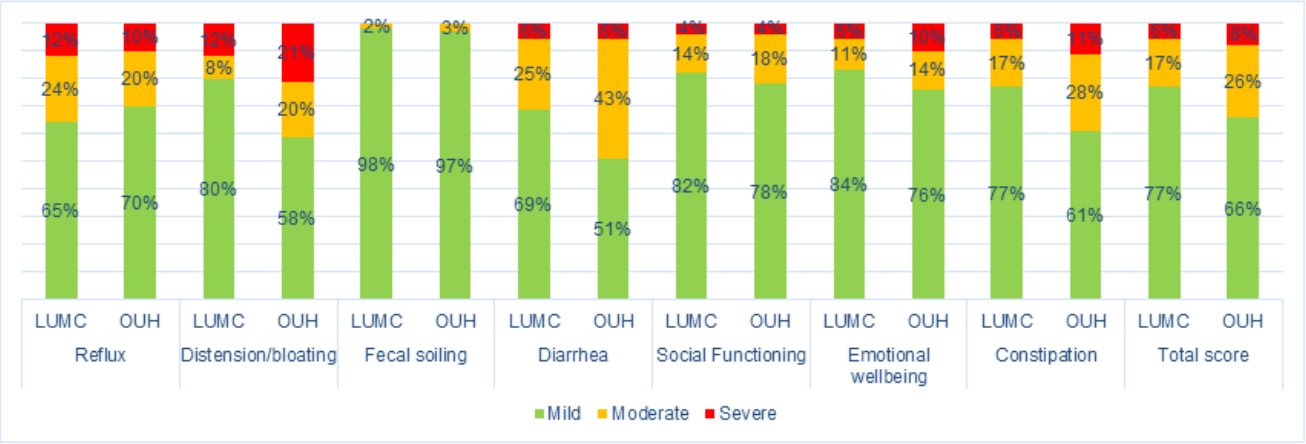

Figure 1. Gastro-intestinal involvement severity per subdomain at baseline in both cohorts.

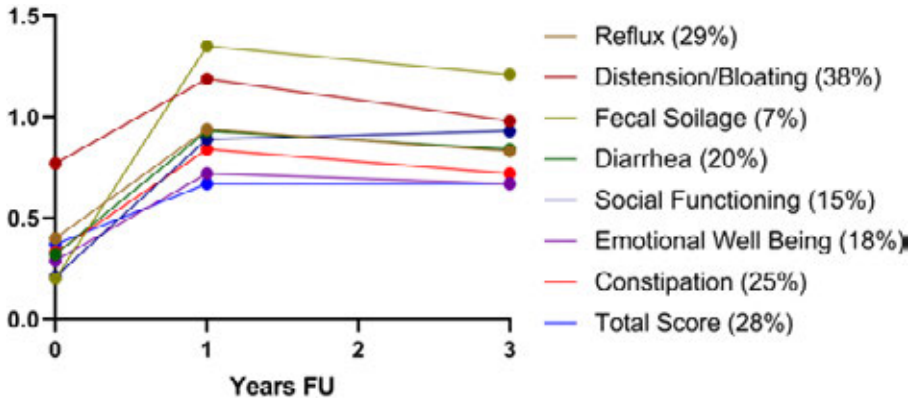

Figure 2. Mean score of the GIT subdomains at baseline, after 1 year and after 3 years of follow-up measured in patients who met the MCID per subdomain. Percentage indicates amount of patients meeting the MCID after 1 year on each subdomain.

were used to assess changes in UCLA GIT scores over time, to control for repeated measurements and to identify predictive factors associated with any change in UCLA GIT score during the observation period.

Results: In total 834 SSc patients were included (LUMC n=456, OUH n=380), of these 536 (64%) had at least one year, and 270 (32%) had at least three year of follow-up. The majority was female (81%) and median disease duration since non-Raynaud was 4.1 years (Table 1). The severity of GIT involvement was similar in both cohorts with 6% (LUMC) and 8% (OUH) patients with severe GIT involvement (Figure 1). Disease duration since onset non-Raynaud (OR 1.03 CI 1.01-1.06), smoking (OR 2.30 CI 1.1-5.0) and anti-centromere antibody (ACA; OR 1.84 CI 0.9-3.9)) were significantly associated with severity of GIT involvement at baseline. Evaluation of GIT progression during the first year showed progression for total GIT score in 28%, with clear variation between the subdomains (Figure 2). In the mixed-effect models, predictive factors for progression of GIT involvement over the observation period were time from onset non-Raynaud, female gender and ACA. Treatment with calcium channel blockers (CCB) was protective for severe GI involvement and for progression

Conclusion: These data from two large and independent SSc cohorts provide novel and important insights regarding the frequency, severity and course of GIT involvement in patients with SSc. We show that assessing GIT involvement using the UCLA GIT subdomains identifies more patients with relevant GIT progression than using the total score. ACA and female gender were identified as the strongest predictors for progression and interestingly CCB treatment was protective.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mean change in forced vital capacity percent predicted (FVC %pred) is a common endpoint in the assessment of treatment-related outcomes in patients with interstitial lung disease (ILD), including those with systemic sclerosis-associated ILD (SSc-ILD). However, it is important to determine the extent to which changes in FVC %pred for individual patients are clinically meaningful. In a previous analysis of two large randomized trials of cyclophosphamide versus placebo (Scleroderma Lung Study [SLS]-I) or versus mycophenolate mofetil (SLS-II) in patients with SSc-ILD, improvement in FVC %pred of ≥3% or deterioration of –3.3% were estimated to be the minimal clinically important differences (MCIDs) associated with statistically significant improvements or worsening in patient-reported outcomes, computer-assisted extent of fibrosis and total ILD (Kafaja et al. Am J Resp Crit Care Med 2018; 197:646–52). A Phase III randomized trial (SENSCIS®, NCT02597933) compared nintedanib 150 mg twice daily with placebo in patients with SSc-ILD, with the primary endpoint the annual rate of decline of FVC. In this analysis, we have assessed the proportions of patients with improvement, and stabilization or deterioration of disease after 1 year of treatment, according to the MCIDs established by Kafaja et al.

Methods: The SENSCIS® trial was a randomized, double-blind, placebo-controlled, parallel group trial conducted in 32 countries. Patients with SSc-ILD, defined as ≥10% lung fibrosis with a baseline FVC ≥40% predicted and DL_{co} of 30–89% predicted, were randomized 1:1 to receive oral nintedanib 150 mg twice daily or placebo. Background stable mycophenolate or methotrexate therapy was permitted. Spirometry (read and analyzed centrally) was conducted over 52 weeks. In this responder analysis, individual changes in FVC %pred from baseline at Week 52 were defined according to MCIDs defined for SLS-I and SLS-II as improvement (≥3% increase), stabilization (change between 3% and –3.3%) or deterioration (at least –3.3%).

Results: A total of 575 patients were included in the analysis, and baseline characteristics were comparable between treatment groups. An improvement in FVC %pred of ≥3% was observed after 52 weeks in 66/287 (23%) patients treated with nintedanib, and 43/288 (15%) who received placebo (OR 1.69; 95% CI 1.11–2.59; P=0.014) (Table). Significantly more patients in the nintedanib arm also experienced either an improvement or stabilization (66% vs 56%;

Minimal clinically importance difference in FVC %pred, n (%)	Nintedanib 150 mg twice daily n=287	Placebo n=288	OR (95% CI)	P-value (exploratory)
Improvement (increase ≥3%)	66 (23)	43 (15)	1.69 (1.11–2.59)	0.014
Improvement (≥3%) or stabilization (change between 3% and –3.3%)	190 (66)	162 (56)	1.52 (1.08–2.13)	0.015
Deterioration (decline ≥–3.3%)	97 (34)	126 (44)	0.66 (0.47–0.92)	0.015

OR 1.52; 95% CI 1.08–2.13; P=0.015) and significantly fewer patients in the nintedanib arm experienced deterioration (34% vs 44%; OR 0.66; 95% CI 0.47–0.92; P=0.015).

Conclusion: In patients with SSc-ILD, more patients treated with nintedanib than placebo experienced improvement in FVC %pred, and more experienced stabilization or improvement in FVC %pred, while fewer experienced deterioration, applying thresholds of clinical meaningfulness established in SLS-I and II, which included a similar patient population.

Minimal clinically importance difference in FVC Table

Number of patients who met or exceeded the MCID (from SLS I and II) for improvement, stabilization or deterioration in lung function over 52 weeks in patients with SSc-ILD participating in the SENSCIS® trial.

Structural Abnormalities of the Optic Nerve Head and Retinal Nerve Fiber Layer Using Optical Coherence Tomography in Patients with Systemic Sclerosis

Cecilia Agapito Tito,[1] Izabela Almeida,[2] Elise Taniguchi,[2] Juliana Silvatti,[2] Tiago Prata,[2] Augusto Paranhos,[2] and CRISTIANE KAYSER[1], [1]Universidade Federal de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [2]Universidade Federal de Sao Paulo, sao paulo, Brazil

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vascular dysfunction, characterized by vasospasm and endothelial activation, represents a central and early event in systemic sclerosis (SSc). Ocular vasospasm may induce optic nerve head (ONH) damage and have been involved in the pathogenesis of glaucoma, especially normal-tension glaucoma (NTG). Swept-source optical coherence tomography (OCT) is a high-resolution noninvasive imaging method for the quantitative assessment of the ONH and retinal nerve fiber layer (RNFL) structure changes, which are affected in glaucoma. The present study aimed to investigate the presence of structural abnormalities associated with NTG in SSc patients using OCT. In addition, we evaluated the correlations between OCT parameters and nailfold capillaroscopy and measures of digital blood flow using laser Doppler imaging in SSc patients.

Methods: In this cross-sectional study, patients with SSc (2013 ACR/EULAR classification criteria) and age- and sex-matched controls were included. All participants underwent complete ophthalmological examination, including visual acuity, intraocular pressure, slit-lamp biomicroscopy, gonioscopy and visual field examination. The following parameters were measured using high-speed swept-source OCT (SS-OCT, DRI OCT, Topcon, Tokyo, Japan); mean and sectoral RNFL thickness, sectoral and global macular RNFL thickness, macular ganglion cell layer (GCL), GCL + inner plexiform layer (IPL), RNFL+GCL+IPL thickness and ONH morphology. Furthermore, nailfold capillaroscopy (NFC) and the measurement of the digital blood flow of the second to fifth fingers of the non-dominant hand using Laser Doppler imaging before and after cold stimulus were performed in all patients.

Results: A total of 23 eyes of 23 controls (mean age 55.0 ± 9.2 years), and 40 eyes of 40 SSc patients (mean age 51.9 ± 11.2 years) were evaluated. The mean RNFL was of 104.28 ±11.99 µm in SSc patients and of 108.70 ± 12.14 µm in controls (p=0.19). SSc patients showed a thinner temporal RNFL compared with the controls (63.23 ± 11.74 µm versus 83.35 ± 20.19 µm, respectively; p=0.001). The other parameters were similar between the two groups. In SSc patients, the disease duration showed an inverse correlation with the superior RNFL thickness (p=0.01), and the macular RNFL thickness in the outer nasal (p = 0.04), inner inferior (p=0.04) and inner nasal (p=0.04) areas. There was also a significant inverse correlation between the disease duration and the total and superior GCL+IPL thickness (p=0.04, p=0.04, respectively). Laser Doppler imaging measurements did not show significant correlation with OCT parameters. There was an inverse correlation between the avascular score in NFC and the vertical cup/disco ratio (p=0.012) and a positive correlation with the central macular and the fovea thickness segments (p=0.037, p=0.006, respectively).

Conclusion: The significantly thinner temporal RNFL, but not ONH abnormalities observed in patients with SSc, suggest the presence of early structural damage that may result in ganglion cell damage. Further prospective studies with higher number of patients are necessary to better understand the impact of structural RNFL damage in SSc.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is one of the leading causes of mortality in scleroderma-spectrum disorders (SSc). FVC% has been used to differentiate Group 1 (PAH) vs. Group 3 (PH due to chronic lung diseases) in different trials and cohorts. The objective of the current analysis was to assess the relationship between the degree of lung disease on high-resolution computed tomography (HRCT, gold standard) vs. FVC% in identifying those with PH due to Group 1 vs. Group 3 PH.

Methods: In this single center retrospective analysis, 268 patients with SSc who had right heart catheterizations (RHCs) at a tertiary center in US were included. HRCTs were reviewed by 2 thoracic radiologists who assessed the degree of total lung involvement in increments of 10% to up to 30% or > 30% lung involvement, and if there was concomitant emphysema. If emphysema was present, it was classified as mild, moderate, or severe. Chronic lung disease was defined as HRCT showing > 20% total lung involvement due to ILD; or if the total lung involvement due to ILD was 10-20% but the patient had concomitant moderate-to-severe emphysema. Each HRCT was categorized based on FVC% performed closest to the RHC into < 70% or ≥ 70%. Sensitivities and specificities were calculated .

Results: Of 268 RHCs, 57 had Group 1 and 36 had Group 3 PH based on the updated hemodynamic definition of pulmonary hypertension[1], as proposed by the 6th World Symposium on Pulmonary Hypertension[2]. In 75 of 93 patients with Group 1 or 3 PH, we had available HRCT data and 54 were reviewed by thoracic radiologists. Of 75 HRCTs, 34 (45%) patients had moderate-to-severe lung disease (based on the definition above), 20 had mild disease, and 21 did not have any ILD and/or significant emphysema. When we included all HRCTs, FVC% had a sensitivity

Table 1. Relationship between HRCTs and FVC% in the Whole Cohort

(N = 75)

FVC %, N(%)	HRCT consistent with moderate to severe chronic lung disease (N = 34)	HRCT- normal or mild chronic lung disease (N = 41)
FVC < 70%, 51 (68%)	25 (74%)	26 (63%)
FVC ≥ 70 %, 24 (32%)	9 (26%)	15 (37%)
	Sensitivity 74% 95% CI (59%, 88%)	Specificity 37% 95% CI (22%, 51%)

Table 2. Relationship between HRCTs and FVC% in those with ILD Involvement on HRCT (N = 54)

FVC %, N(%)	HRCT consistent with moderate to severe chronic lung disease (N = 34)	HRCT- mild chronic lung disease (N = 20)
FVC < 70%, 35 (65%)	25 (74%)	10 (50%)
FVC ≥ 70 %, 19 (35%)	9 (26%)	10 (50%)
	Sensitivity 74% 95% CI (59%, 88%)	Specificity 50% 95% CI (28%, 72%)

of 74% (95% CI (59%, 88%)) and specificity of 37% ((95% CI (22%, 51%)) Table 1). When we excluded those with normal HRCTs, FVC% had a sensitivity of 74% (95% CI (59%, 88%)) and specificity of 50% (95% CI (28%, 72%)) when compared to FVC% (Table 2).

Conclusion: FVC% misclassifies a large number of patients into Group 1 vs. Group 3 PH as it may be influenced by other SSc-related disease processes. Future studies should incorporate the degree of HRCT involvement to differentiate between the 2 groups.

Ultrasound Evaluation of the Hands in Patients with Systemic Sclerosis: Osteophytosis Is a Major Contributor to Tender Joints

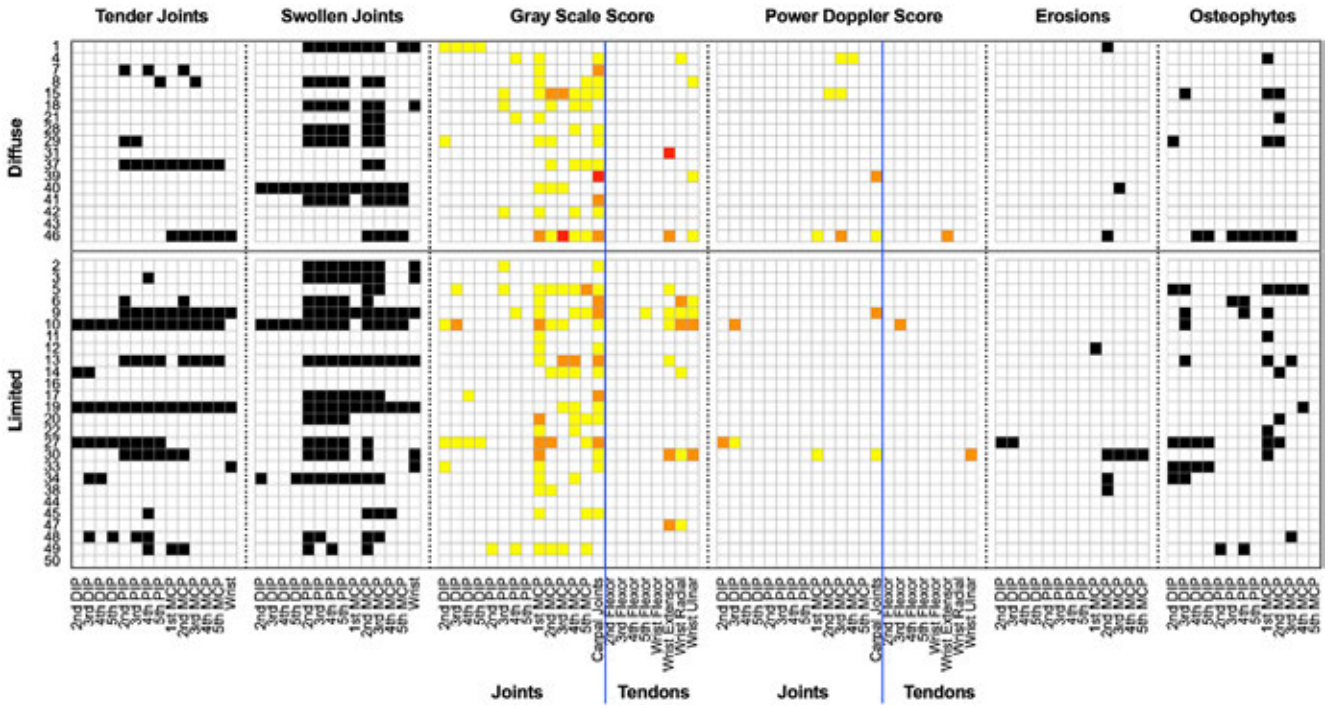
Robert Fairchild,[1] Melody Chung,[1] Laurel Sharpless,[1] Shufeng Li,[2] Jison Hong,[1] Khushboo Sheth,[1] and Lorinda Chung[1], [1]Stanford University, Palo Alto, CA, [2]Division of Immunology and Rheumatology, Department of Medicine, Stanford, Palo Alto, CA

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) is a progressive fibrotic and vascular disease with peripheral manifestations including arthritis, tendinopathy, sclerodactyly, contractures, calcinosis, acroosteolysis, and vascular disease which can lead to significant pain, deformity, and functional impairment. Tender joints (TJs) and swollen joints

Figure 1. Heat map of ultrasound and clinical examination findings



Rows corresponds to an individual patients. Black = present, white = absent or 0, yellow = 1, orange = 2, red = 3.

(SJs) are frequently encountered in SSc, but identifying their exact cause remains challenging. Prior studies have suggested inflammatory arthritis is present in anywhere from 25% to 49% of SSc patients. We sought to use ultrasound (US) to evaluate the prevalence of inflammatory arthritis and other joint and soft tissue pathology and to assess for associations with presence of TJs and SJs.

Methods: Patients meeting ACR/EULAR classification criteria for SSc were prospectively evaluated by US of the hands and wrists. Bilateral B-mode and power doppler exams of the joints and tendons were rated on a semiquantitative scoring system (0-3) for both gray scale (GS, a marker of synovial hypertrophy) and power doppler (PD, a mark-

Table 1. Ultrasound, clinical, and X-ray features.

Ultrasound Features	**n = 43**
Highest GS score, n (%)	
GS 0	6(14)
GS 1	21 (49)
GS 2-3	16 (37)
Highest PD score, n (%)	
PD 0	35 (81)
PD 1-3	8 (19)
ER (1 or more, excludes wrist), n (%)	8 (19)
OS (1 or more, excludes wrist), n (%)	21 (49)
Median nerve area, mean (±SD) mm^2	12.1 (3.7)
UAO, n patients (%)	16 (37)
Clinical and X-ray Features	
Contractures, n patients (%)	22 (51)
Ulcers, n patients (%)	7 (16)
MRSS, total, mean (± SD)	10.2 (8.2)
MRSS, fingers, hands, arms, mean (± SD)	2.2 (1.7)
Calcinosis, n patients (%)	15 (35)

GS = gray scale, PD = power doppler, ER = erosions, OS = osteophytes, UAO = ulnar artery occlusion, MRSS = modified Rodnan skin score.

Table 2. Concordance and correlations of severity between gray scale and clinical and ultrasound findings.		
	Gray Scale (GS)	
	κ*	ρ† (p)
Tender Joints (TJs)	0.72 (0.69, 0.76)	0.47 (0.001)
Swollen Joints (SJs)	0.52 (0.47, 0.57)	0.32 (0.04)
Osteophytes (OS)	0.88 (0.86, 0.90)	0.59 (<0.001)
Power Doppler (PD)	0.85 (0.83, 0.88)	0.55 (0.001)
Erosions (ER)	0.87 (0.85, 0.89)	0.17 (0.26)

GS = gray scale, TJs = tender joints, SJs = swollen joints, OS = osteophytes, PD = power doppler, ER = erosions. Since multiple GS, PD, ER, and OS measurements were recorded per joint region, single scores corresponding to the highest values observed in the region were recorded. *κ value = chance-corrected Cohen's Kappa statistic (GS and PD scores were transformed into binary variables 0 versus 1-3). †ρ = Spearman correlation coefficient using severity scores (severity scores calculated by summing individual joint region scores).

er of hyperemia and active inflammation). Studies were scored blindly by 3 experienced sonographers using OMERACT consensus guidelines. US also evaluated for erosions (ER), osteophytes (OS), ulnar artery occlusion (UAO), and median nerve cross sectional area. TJs, SJs, modified Rodnan skin score (MRSS), contractures, and ulcerations were assessed clinically. Concordance between US features and TJs and SJs was assessed using chance-corrected Cohen's Kappa statistic. Severity scores for GS, PD, OS, ER, TJs and SJs for each patient were obtained by summation. Correlations between the severity of TJs and SJs and US features were assessed by Spearman's rank correlation.

Results: 43 SSc patients (17 diffuse, mean age 58 ± 13.5) were evaluated by US. GS = 2-3 in at least one joint or tendon was seen in 16 (37%) of patients and PD > 0 in at least one joint or tendon was observed in 8 (19%) of patients (Table 1). TJs and SJs did not correlate with median nerve cross sectional area, UAO, calcinosis, digital ulcers, MRSS, or contractures. GS had higher concordance with and severity correlated more strongly with TJs than SJs. Both OS and PD severity strongly correlated with GS severity (Table 2). Of the 37 SSc patients with positive GS findings, PD and OS were seen in 22% and 54% of patients, respectively. Of the 19 patients with TJs, PD and OS were seen in 26% and 74% of patients, respectively.

Conclusion: US revealed a relatively low prevalence of active inflammatory arthritis of 19% as noted by infrequent PD findings. A majority of patients with GS and TJs were found to have OS while PD was less frequent, suggesting US findings of synovial hypertrophy and clinical TJs may be better explained by osteophytosis rather than active inflammatory arthritis.

Serious adverse events	45 (22.4)	43 (23.1)	16 (25.8)	12 (14.8)	8 (40.0)	7 (43.8)	29 (24.2)	26 (22.2)	40 (23.8)	36 (21.1)

Data shown are n (%) of patients with ≥1 such event. Adverse events are listed by preferred term in the Medical Dictionary for Regulatory Activities (MedDRA) except for liver test abnormalities, which were based on the standardized MedDRA query "liver related investigations, signs and symptoms" (broad definition). The adverse events shown are those reported in >15% of patients and >5 patients in any of the subgroups shown. Serious adverse events were defined as events that resulted in death, were life-threatening, resulted in hospitalization or prolongation of hospitalization, resulted in persistent or clinically significant disability or incapacity, were a congenital anomaly or birth defect, or were deemed to be serious for any other reason.

Background/Purpose: In the SENSCIS trial in patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD), the adverse events associated with nintedanib were manageable for most patients and characterized mainly by gastrointestinal events. We assessed the safety and tolerability of nintedanib in subgroups defined based on demographic characteristics at baseline.

Methods: Adverse events that occurred over 52 weeks of treatment, irrespective of causality, were assessed in subgroups of patients by age (< 65, ≥65 years), gender, race (White, Asian, Black/African-American) and weight (≤65, >65 kg) at baseline. Descriptive analyses, based on comparing the proportions of patients who had adverse events across subgroups, were performed in subjects who received ≥1 dose of trial drug.

Results: A total of 576 patients received trial drug (288 nintedanib; 288 placebo). At baseline, mean (SD) age was 54.0 (12.2) years and weight was 69.7 (15.9) kg. The majority of patients were female (75.2%) and white (67.2%). The adverse event profile of nintedanib, and the proportions of patients with adverse events leading to treatment discontinuation, were generally similar across subgroups defined by age, gender, race, and weight (Tables 1 and 2). Diarrhea was the most frequently reported adverse event with nintedanib in all the subgroups. Decreased appetite and decreased weight were reported more frequently in nintedanib-treated patients aged ≥65 years than < 65 years. Nausea and vomiting were reported more frequently in female than male patients treated with nintedanib. Liver test abnormalities were reported more frequently in nintedanib-treated patients who were female, aged ≥65 years, or Asian. Premature treatment discontinuations were more common in patients who were female, aged ≥65 years, or had a weight < 65kg.The number of Black/African-American patients was too small to allow conclusions to be drawn about adverse events in this subgroup.

Conclusion: The safety and tolerability profile of nintedanib in patients with SSc-ILD was generally consistent across subgroups of patients defined by age, gender, race and weight. A management plan based on the recommendations given in clinical trials may help patients to manage the most common adverse events associated with nintedanib therapy.

NEMO Score in Nailfold Videocapillaroscopy Is a Good Tool to Assess Both Steady State Levels and Overtime Changes of Disease Activity in Patients with Systemic Sclerosis: A Comparison with Both the Composite EScSG and EUSTAR Indices for This Disease Status Entity

Francesca Pignataro,[1] Antonina Minniti,[1] Wanda Maglione,[1] Francesco Campanaro,[1] Domenico Sambataro,[2] Gianluca Sambataro,[2] Claudio Vitali,[3] and **Nicoletta Del Papa**[1], [1]UOC Day Hospital Reumatologia, ASST Gaetano Pini, Milan, Italy, [2]Istituto ArtroReuma, Catania, Italy, [3]Sezione di Reumatologia, Istituto San Giuseppe, Como, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously demonstrated that NEMO score, i.e., the cumulative number of microhaemorrhages (MHEs) and microthrombosis (MTs) observed in nailfold videocapillaroscopy (NVC), was a good indicator of the steady state level of disease activity (DA) in patients with SSc when the European Scleroderma Study Group (EScSG) index was taken as gold standard. *Aim of the study*. To verify whether the NEMO score could be *(i)* a valid tool to assess DA, even when the modified European Scleroderma Trials and Research (EUSTAR) index was considered as comparator; *(ii)* a sensitive method to capture the overtime changes of DA.

Methods: NEMO score, EScSG and EUSTAR indices were assessed at baseline (T0) and after a follow up of 6-12 months (T1) in a cohort of 98 patients affected by SSc according to ACR/EULAR 2013 criteria (48 with limited and 50 with diffuse SSc). It was preliminarily established that at least 50% of SSc patients should be active at enrolment time (score ≥3, according to the EScSG DA index). The area under the curve (AUC) of the receiver operating characteristic (ROC) curve was calculated to measure the sensitivity and specificity of NEMO score in classifying patients with predefined level of DA (≥ 3.0 and ≥ 2.5 scores for EScSG and EUSTAR indices, respectively). To assess overtime changes of DA, the differences (Δ) between T0 and T1 values of NEMO score, EScSG and EUSTAR indices were calculated and compared to each other.

Results: NEMO score values were very closely correlated with the corresponding values of both EScSG and EUSTAR indices at T0 and T1 observations [$p < 0.0001$ in all cases with the exception of the correlation with EScSG values at T1 ($p < 0.03$)]. Values of the two composite DA indices were also strictly related to each other either at T0 or T1 observations ($p < 0.0001$). NEMO score showed a very good performance in classifying patients with predefined level of DA. AUCs of ROC curve analysis were 0.91 and 0.88 considering the respective predefined levels of EScSG and EUSTAR indices as standard measures of significant levels of DA ($p < 0.0001$ in both cases). Δ values of NEMO score were significantly correlated with the corresponding values of both EScSG and EUSTAR indices. Weighted Cohen's k level of agreement between Δ values of NEMO score and those of EScSG and EUSTAR indices was moderate (0.55 and 0.60, respectively), but close to the level of good agreement (>0.60).

Conclusion: NEMO score confirms to be a feasible, non-invasive and valid tool to assess steady state levels and overtime changes of DA in patients with SSc. Thus, this NVC evaluation can represent an alternative or complementary method to measure this disease status entity in this disorder.

Characteristics of Patients with Systemic Sclerosis in the Rheumatology Informatics System for Effectiveness (RISE) Registry

Ankoor Shah,[1] Jeffrey Curtis,[2] Yvonne Lee,[3] Fenglong Xie,[4] Lang Chen,[2] and Huifeng Yun[2], [1]Duke University, Durham, NC, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Northwestern University Feinberg School of Medicine, Chicago, [4]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SS), is characterized by fibrosis of the skin and internal organs and vasculopathy with relatively high morbidity and mortality. Given the rarity of the disease, studying epidemiology, treatment and natural history is challenging without large patient cohorts. We conducted a cross-sectional study to understand the prevalence, disease characteristics, demographics, and treatment patterns ofSS patients using the Rheumatology Informatics System for Effectiveness (RISE) EHR-based registry.

Methods: Between 2015 and 2017, we identified patients who had at least one physician diagnosis code of SS (M34.x or M34.xx) and aged 18 years or older at the first encounter. The demographics included age, gender, race, region, and body mass index (BMI). We identified relevant comorbidities that associated with scleroderma including other autoimmune diseases, interstitial lung disease (ILD) and pulmonary arterial hypertension (PAH). In addition we evaluated relevant medications including prednisone, immunomodulation, calcium channel blockers (CCB), phosphodiesterase type 5 (PDE 5) inhibitors, endothelin receptor antagonists (ERA), proton pump inhibitors (PPIs), H2 blockers, angiotension-converting enzyme inhibitors (ACEIs), angiotensin II receptor antagonist (ARBs) and opioids. We identified comorbidities associated with scleroderma using ICD 9/10 diagnosis codes, and identified medications using prescriptions or associated procedures. We also evaluated the patients' characteristics across different practice sites.

Results: We identified 12,057 scleroderma patients who had >=1 physician diagnosis in RISE 2015-2017, representing 210 separate sites. After limiting to patients who were 18 year or older, 10,286 patients were eligible for the analysis. The majority of SS patients were female (88.5%) and white (56.8), with average age of 59.6 (SD: 13.8) years. 11% and 12% of patients had a diagnosis codes for ILD and PAH, respectively. Among all eligible patients, 24.5% ever had prednisone, 42% had immunomodulation, 33% had CCB, 9.1% had PDE5, 3.2% have ERAs, 42.7% had PPIs, 10.7% had ACEI, 8.2% had ARBs, and 16.1% had opioids. Only 25 sites reported orders for pulmonary function testing (PFTs) with the proportion of patients undergoing these ranging between 4 and 90% per site.

Conclusion: The RISE registry serves as one of the largest patient cohorts for systemic sclerosis. It is comprised largely of patients from community practices, identified by rheumatologists. The demographics and identified treat-

ments may differ from other academic cohorts but potentially better represents management of patients seen in a general practice. PFT use varies significantly amongst practices, however this finding may be more a reflection of how the registry captures this data and where these tests are performed which is a limitation of this cohort. Disclaimer: This data was supported by the ACR's RISE Registry. However, the views expressed represent those of the authors, not necessarily those of the ACR.

Imaging Technique (R)evolution to Measure the Digital Microcirculatory Flow in Systemic Sclerosis: A Systematic Review

Karin Melsens,[1] Amber Vanhaecke,[1] Wies Van Eenoo,[2] Maurizio Cutolo,[3] and Vanessa Smith[4], [1]Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium; Dept. of Internal Medicine, Ghent University, Ghent, Belgium, Ghent, Belgium, [2]Faculty of Medicine, Ghent University, Ghent, Belgium, Ghent, Belgium, [3]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genoa, Italy, [4]Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium; Dept. of Internal Medicine, Ghent University, Ghent, Belgium; Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium, Gent, Belgium

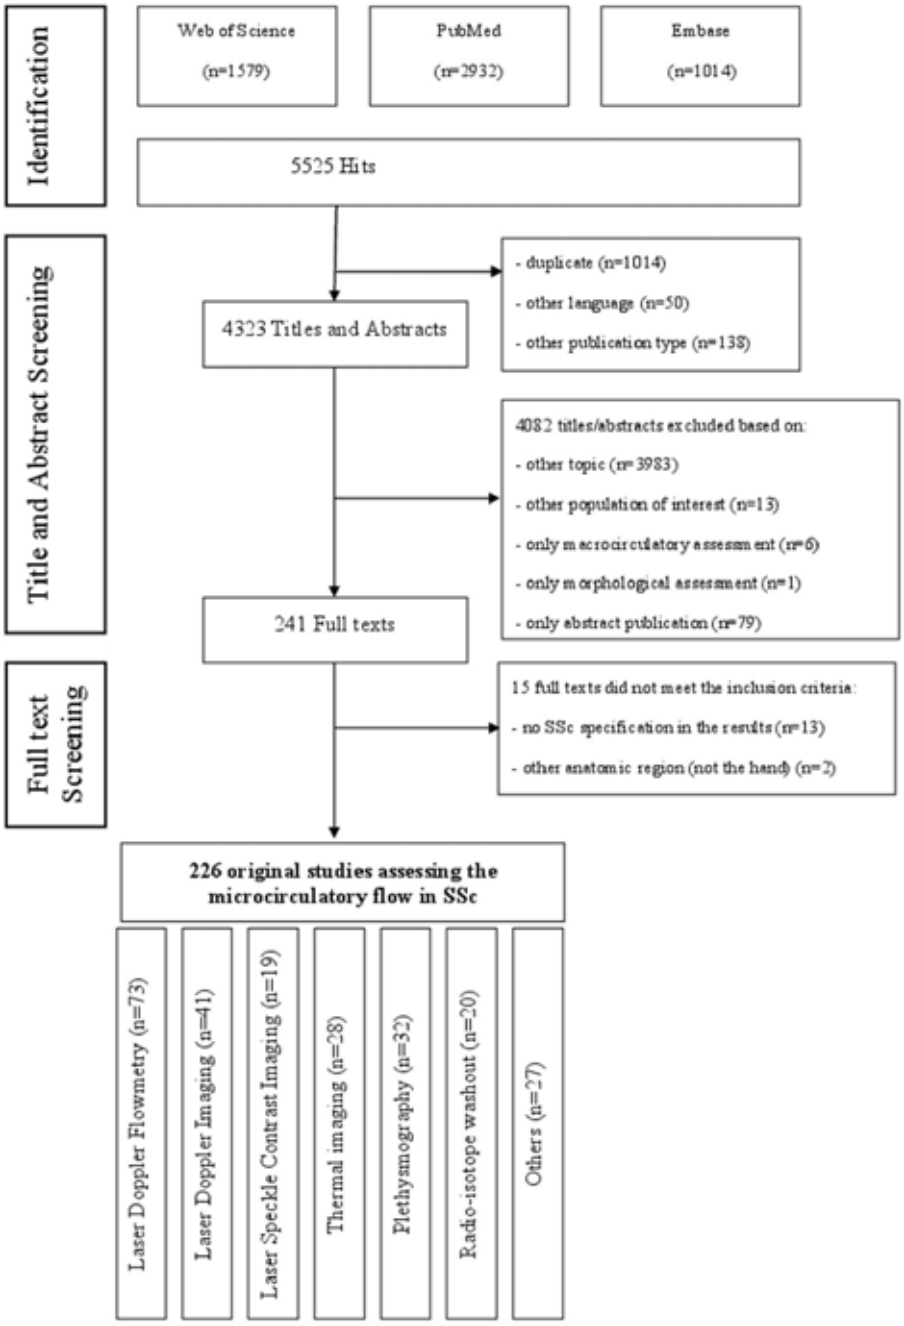
SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a chronic, auto-immune disease characterised by a widespread vasculopathy. There is a high need to obtain validated outcome measures for use in clinical and research setting. The last decades numerous techniques have been developed to quantify the microcirculatory flow in the hands of patients with SSc-related digital vasculopathy. The aim of this study is to give a time related overview of the different techniques used to assess the microcirculatory flow in SSc.

Methods: A systematic search was done on the 21st of January 2019 by two reviewers in PubMed, Embase and Web of Science to detect all original studies assessing the microcirculatory flow in SSc patients. Studies including only the morphological aspects of the microcirculation were excluded. The resulting publications were sorted in the following groups: radio-isotope techniques, plethysmography, infrared thermal imaging, laser doppler flowmetry (LDF), laser doppler imaging (LDI) and laser speckle contrast imaging (LSCI). A time dependent evolution in publication rate per technique was evaluated.

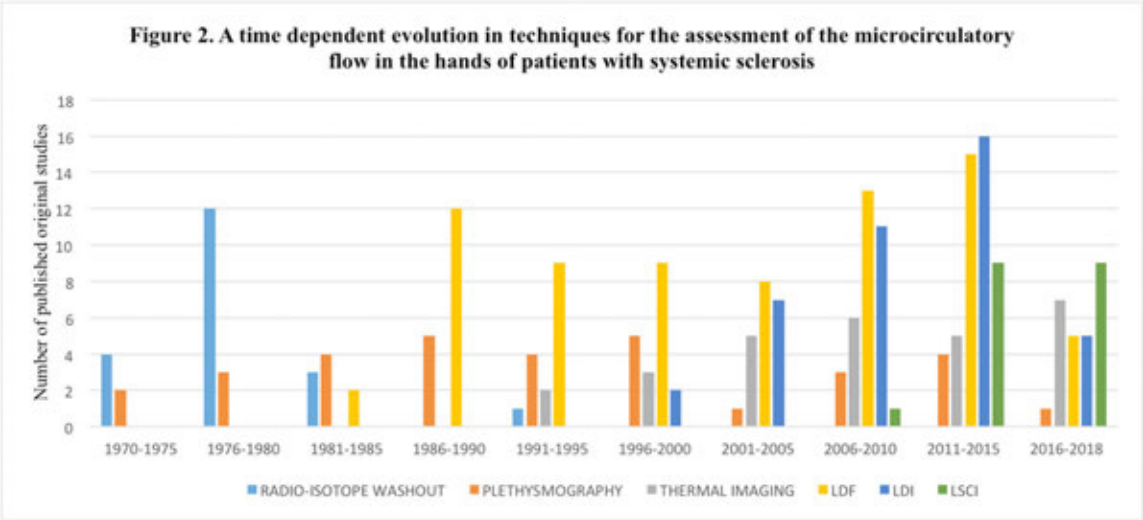
Results: The systematic literature search resulted in 4323 hits. After title and abstract screening 241 original studies were retained. Finally, 15 more full texts were excluded because there were no details of their results on SSc or the region of interest was different (fig 1). The majority of the publications reported on LDF (n=73), though in the last decade emerging techniques are LDI (n=41) and LSCI (n=19). There is a peak in publication rates between 2011 and 2015,

Figure 1. Flowchart of search strategy and results from 1970-2019



especially concerning the laser doppler based techniques. Infrared thermal imaging was steadily investigated in the past 20 years. LSCI is the last upcoming technique with publication rates that are growing in comparison to other techniques (fig 2). Photoacoustic imaging and optical microangiography are two related novel techniques, which are in the pipeline to assess the microcirculatory flow in SSc patients.

Conclusion: This systematic review reveals in a visual way the change in publication rates per technique, and indirectly the change in ongoing investigations concerning the objective quantification of the microcirculatory flow in SSc. The results are in favor of the LSCI technique, which is increasingly being used compared to other techniques.



Acknowledgment: This literature study was performed on behalf of the EULAR studygroup on microcirculation in rheumatic diseases.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this pilot study is to identify, in a cohort of Systemic Sclerosis (SSc) patients, a "very early" nailfold videocapillaroscopy (NVC) pattern able to predict the evolution to the already defined NVC scleroderma-patterns (early (E), active (A), late (L), scleroderma-like (SL)).

Methods: We selected NVC images from 273 patients affected by SSc (according to 2013 ACR criteria) presenting one of the validated NVC scleroderma-patterns [1]: 81 had an "E" pattern, 84 an "A" pattern, 92 a "L" pattern, 16 a "SL" pattern. Among the 273 SSc patients, 54 had a NVC analysis performed before the development of the "E" scleroderma-pattern; thus, we enrolled them for an accurate study of time of evolution and capillaroscopic characteristics. A detailed pilot study of NVC features was initially random performed on 10 of the 54 patients selected. Since we have previously demonstrated that capillary diameter over 30 μm is an independent predictor for development of SSc associated secondary Raynaud's phenomenon (SRP) [2], the analysis included the number and the limbs diameters (arterial, venous, and apical) of capillaries with a diameter over 30 μm, together with the total number of capillaries and microhemorrhages, in 16 images per subject.

Results: The average time of evolution in a scleroderma-pattern was 4 years: 31 (57%) patients developed an "E" scleroderma-pattern in the following 3 years; over longer time, 6 (11%) patients evolved in "A" pattern in 4 years and 3 (6%) patients in "L" NVC pattern in 5 years; 14 (26%) patients developed a "Scleroderma-like" pattern in 4 years. All the 54 SSc patients (100%) showed enlarged capillaries with an average diameter over 30 μm in their previous NVC. The detailed pilot morphological study conducted on 10 patients at last non-specific NVC analysis revealed an average total number of capillaries of 8.6/mm. Capillaries with a diameter over 30 μm were 2.66 (31%); among these, the mean value diameter of the most dilated capillary was 35.74 μm (arterial 33.34 μm, apical 43.94 μm, venous 30 μm). The mean value for microhemorrhages was 0.6/mm. The mean number of capillaries reduced from 8.6±0.8 to 6.9±2.2/mm (p=0.01) during follow-up (4 years).

Conclusion: Present pilot study demonstrates for the first time that, before developing a validated NVC scleroderma-pattern, all SSc patients enrolled present a significant increase of nailfold capillary diameter over 30 μm at NVC. Together with the total number of dilated capillaries, the subsequent reduction in total number of capillaries (as shown at follow up) and the presence of microhemorrhages, it lets to identify a "Very Early" scleroderma pattern, able to intercept patients with SRP at higher risk of evolution in a validated SSc NVC pattern. A larger sample of patients is under investigations.

Dental Health in Systemic Sclerosis Patients Risk Factors and Comorbidities

Sabrina Paolino,[1] Francesco Cattelan,[2] Schenone Carlotta,[3] Alberto Sulli,[4] Andrea Casabella,[5] Carmen Pizzorni,[1] and **Maurizio Cutolo**[6], [1]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Genoa, Italy, [2]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy, [3]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, genova, Liguria, Italy, [4]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genoa, Italy, [5]1 Research Laboratory and Academic Division of the Clinical Rheumatology Department of Internal Medicine, University of Genova, IRCCS San Martino Polyclinic Hospital, Genoa, Italy, Genoa, Italy, [6]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genoa, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a rare multisystemic autoimmune disease characterized by microvascular damage and progressive fibrosis of skin and internal organs. Global oral health in SSc may depend by skin fibrosis of oral facial region or masticatory apparatus and quality of bone that is sustaining dentition (1). Trabecular Bone Score (TBS) analysis provides an indirect measurement of microarchitecture and get information about bone quality in several rheumatic diseases such as SSc (2).

Objectives: The aim of the study was to evaluate the most frequent dental/oral alterations in a cohort of SSc patients and the relationship between dental loose and quality of bone evaluated by TBS.

Methods: 32 patients, fulfilling the ACR/EULAR 2013 criteria for SSc underwent a dual-energy X-ray absorptiometry scan (DXA) to evaluate bone mineral density and TBS. All patient performed a standard questionnaire regarding dental health

Results: Patients were 5 men (16%), 27 women (84%), mean age 60.3+8.7 years, disease duration from the first Raynaud symptoms was 13.2+4.5 years. All patients came from urban environment: 65.6% affected by limited SSc (lSSc) and 34.4% by diffuse SSc (dSSc). Most of patients were taking immunosoppressive drugs (MTX 15%, MMF 32%, previous cyclophosfamide treatment 25%, cyclosporine 13%, RTX 6%) and 28 % were treated with only symptomatic drugs (i.e. vasodilators). Nobody was treated with bone antiresorptive drugs (bisphosphonates). Smokers were 19%.

The most frequent oral/dental alterations observed were: oral ulcers 31.3%; painful gums 46.8%; bleeding gums 37.5%; loos teeth 56.3%; dentures 66%; halitosis 46,8%; xerostomia 53.1 (sicca syndrome); swollen gums 25%; receding gums 59%; dental caries 65.6%; cewing issues 28.1%; microstomia 46.9%. The clinical evaluation looking at risk factors found: gastrointestinal involvement with dysmotility and disfagia (31%) and “claw hand” with difficult handgrip and related limited teeth brushing (19%). Most of patients (67%) presented low bone mass and osteopenia, only one case was diagnosed as true osteoporosis. Of note, no statistically differences in TBS were reported between patients with or without dental loose (1.276±0.08 vs 1.19±0.08 P=0.70).

Conclusion: SSc is associated with poor dental health with high prevalence of dental loose. Bone quality assessed by TBS do not seems to influence the unstable dentition and teeth loose; most probably the mechanism is related to ischemic bone area induced by microangiopathy as recently reported in literature (3).

Abstract Number: 0718

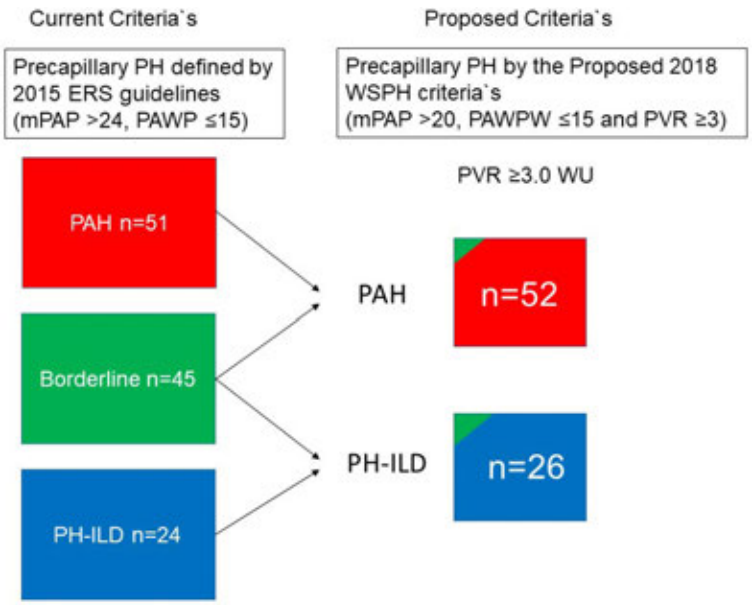
Diagnosing Pulmonary Hypertension Using the Proposed 6th World Symposium on Pulmonary Hypertensions New Definitions

Håvard Fretheim,[1] Øyvind Midtvedt,[2] Torhild Garen,[2] Arne Kristian Andreassen,[2] Einar Gude,[2] Øyvind Molberg,[3] and Anna Maria Hoffmann-Vold[4], [1]Oslo University Hospital, Oslo, [2]Oslo University Hospital, Oslo, Norway, [3]University Hospital Oslo, Oslo, Norway, [4]Department of Rheumatology, Oslo University Hospital, Oslo, Norway, Oslo, Norway

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pre-capillary pulmonary hypertension (PH) is a feared complication in patients with systemic sclerosis (SSc) and is associated with high mortality despite new treatment options. Pre-capillary PH is diagnosed by right heart catheterization (RHC) with mean pulmonary artery pressure (mPAP) ≥25 mmHg and a pulmonary artery wedge pressure (PAWP) of ≤15 mmHg. The 6th World Symposium on Pulmonary Hypertension proposed new definitions for pre-capillary PH, lowering the mPAP value to ≥ 21 mmHg and including pulmonary vascular resistance (PVR) ≥3.0 Wood Units (WU). The aim of this study was to explore the impact on prevalence of PH in an SSc cohort by applying the new definitions.

Methods: All SSc patients from the Oslo University Hospital SSc cohort who had performed at least one RHC (n=191) were included. We used data from the first RHC with mPAP ≥ 21 mmHg when available. Using the current pre-capillary PH definitions, PH was defined as mPAP ≥25 mmHg and PAWP ≤ 15 mmHg. Borderline PH was defined as mPAP 21-24mmHg. Pulmonary arterial hypertension (PAH) and PH due to interstitial lung disease (ILD) were defined as pre-capillary PH in absence or presence of ILD on high resolution CT scan with < / >10 % pulmonary fibrosis, respectively. Secondly, the newly proposed haemodynamic definitions for pre-capillary PH including mPAP ≥ 21 mmHg, PAWP ≤15 mmHg and PVR ≥3 WU were applied.



Results: Of the 191 SSc patients, 150/191 (79%) were female, 143/191 (75%) had limited cutaneous SSc and 85/191 (45%) were anti-centromere antibody positive. Mean age of the patients was 57 years and mean time from SSc diagnosis to PH diagnosis was 6 years. Using the current PH criteria 51/191 (27%) SSc patients were diagnosed with PAH, 36/191(19%) patients with PH-ILD and 45 (24%) patients with borderline PH. Using the newly proposed definitions the frequency of PAH and PH-ILD changed as shown in Figure 1. 24 patients had an mPAP ≥ 21 mmHg and a PVR value 2.0-2.9 WU. The mean mPAP in these 24 patients was 23.8 mmHg, the mean PAWP 10.1 mmHg, 20/26 (77%) were female and 16/26 (62%) were anti-centromere antibody positive.

Conclusion: Lowering the mPAP to ≥ 21 mmHg and including PVR ≥ 3.0 WU did not substantially change the PH prevalence in our cohort due to the PVR cut-off value. We still need more knowledge about the long-term outcome of SSc patients with pre-capillary PH when changing definitions for pre-capillary PH. Also, it will be important to decide how and when to treat these patients.

Distinct Characteristics of the Gut Microbiome of Patients with Systemic Sclerosis and Small Intestinal Bacterial Overgrowth

Hanyan Zou,[1] Giada De Palma,[2] Premysl Bercik,[2] Elena Verdu,[2] Karen Beattie,[2] and Maggie Larche[2], [1]McMaster University, Mississauga, ON, Canada, [2]McMaster University, Hamilton, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The gastrointestinal tract (GIT) is commonly involved in SSc with up to 98% of patients reporting GIT manifestations. Small intestinal bacterial overgrowth (SIBO) is more prevalent in patients with SSc than the general population, but little is known about the relationship between SIBO and SSc. To better understand the gut microbiota of patients with SSc, we compared fecal bacterial compositions of SSc patients to a healthy cohort. We additionally examined differences in the gut microbiota of SSc patients with or without SIBO and inflammatory seromarkers.

Methods: Adults with SSc (ACR/EULAR criteria) were assessed as having SIBO (SIBO+) or no SIBO (SIBO-) using an H_2/CH_4 breath test. GIT symptoms were assessed using the UCLA SCTC GIT 2.0 questionnaire. To analyze microbiome composition, DNA was isolated from fecal samples of individual patients, and 16S rRNA gene was amplified and sequenced with Illumina technique. The gut microbiota of patients with SSc was compared to controls with no history of autoimmune disease and GIT symptoms. Additional analyses were conducted according to the presence/absence of anti-centromere antibody (ACA) and antibodies against topoisomerase I (Scl-70) in patients with SSc. Microbiome B-diversity of SIBO+ and SIBO- patients was compared using Bray Curtis dissimilarity matrix.

Results: Of 25 SSc patients (mean (SD) age = 56.4 (11.2) years, 96% female), 13 (52%) tested SIBO+, 19 (76%) ACA+, 4 (16%) anti-Scl70+ and 2 (8%) were seronegative. The healthy cohort consisted of 20 participants (mean (SD) age = 33.1 (13.5) years, 70% female). After correcting for multiple comparisons and the effect of age differences, the composition of microbiota in SSc patients was significantly different from healthy controls; notably, patients with SSc

	Bacteria|Firmicutes|Clostridia|Clostridiales|Lachnospiraceae|Pseudobutyrivibrio	1.60 (2.74)	3.69 (9.42)	0.011

Q-value represents p-value corrected for multiple comparisons.

had increased abundance of Odoribacter, Bilophila and Lachnospira species ($p < 0.05$) and decreased abundance of Erysipelotrichaceae, Adlercreutzia, Lactococcus, and Pseudobutyrivibrio species ($p < 0.05$) (Table 1). Compared to SIBO- patients, SIBO+ patients had significantly higher bacterial richness (Chao1 and observed species) and diversity (Shannon diversity index) (Figure 1). Although SIBO+ and SIBO- patients did not have significantly different microbiome compositions, SIBO+ ACA+ SSc patients had significantly higher abundance of Rikenellaceae species in comparison to SIBO- ACA+ SSc patients. SIBO- patients reported significantly more reflux [SIBO+ mean SD 0.59 (0.56), SIBO- 1.31 (0.59), $p < 0.01$], while SIBO+ patients experienced more (but $p > 0.05$) soilage [SIBO+ 0.62 (0.87), SIBO- 0.18 (0.40)] and diarrhea [SIBO+ 0.62 (0.46), SIBO- 0.36 (0.45)].

Conclusion: The current study is the first to examine the relationship between SIBO and SSc on a bacterial level and found notable differences between the microbiota composition of SIBO+ and SIBO- SSc patients. These differences

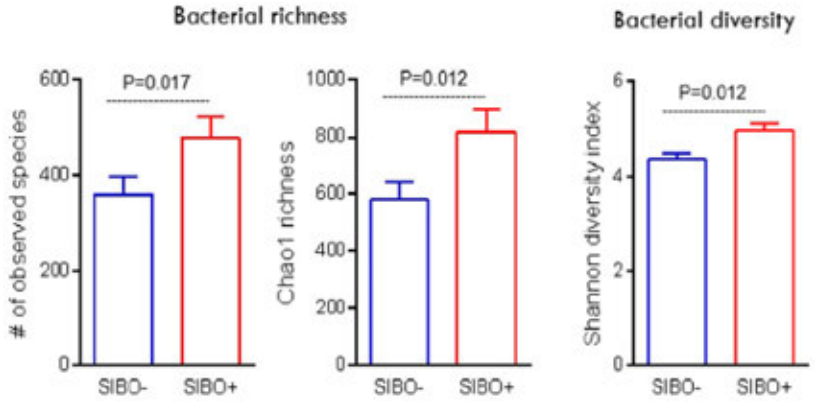

Figure 1. SIBO+ SSc patients had significantly greater bacterial richness and diversity than SIBO- patients.

in gut microbiota appeared to affect the presentation of GIT symptoms. The increased microbiota richness and diversity of SIBO+ patients may exacerbate inflammatory disease activity, and the effects of SIBO on SSc progression and response to treatment warrant further exploration.

Background/Purpose: We report the baseline characteristics of a large cohort of diffuse cutaneous systemic sclerosis (dcSSc) patients enrolled in a Phase 3 trial of lenabasum, a preferential cannabinoid receptor type 2 agonist. Treatment with lenabasum, a cannabinoid receptor type 2 agonist, was safe and well-tolerated in a prior Phase 2 study in dcSSc patients and associated with improvements in ACR Combined Response Index in diffuse cutaneous Systemic Sclerosis (CRISS) score and multiple secondary efficacy outcomes.

Methods: The RESOLVE-1 Phase 3 study was designed with input from Principal Investigators, other study investigators, and regulatory authorities in the US, EU, and Japan. An important intent of the design was to have eligibility criteria that allow testing of efficacy and safety of lenabasum in an inclusive group of dcSSc subjects to maximize relevance to patients in current practice. The study is ongoing and remains blinded.

Results: Primary efficacy outcome is the ACR CRISS score at 12 months, comparing lenabasum 20 mg BID to placebo. Key inclusion criteria are males and females ≥ 18 years of age with dcSSc and disease duration ≤ 6 years who are on stable standard of care medicines, with immunosuppressive mediations allowed. Exceptions are concomitant treatment with > 10 mg per day prednisone or equivalent is disallowed and mRSS needs to be ≥ 15 if disease duration is > 3 to ≤ 6 years. The study enrolled 364 subjects over 15 months who received ≥ 1 dose of study drug at 77 sites in 13 countries in North America (n = 139), Europe (n = 109), and Israel (n = 37), and Asia-Pacific (n = 79), with last subject first visit on May 1, 2019. Baseline characteristics as shown in Table 1. The majority were middle-aged, female, and white, and 77% were on immunosuppressive drugs. Mycophenolate/mycophenolic acid used in 48% of subjects, and 35% of subjects took ≥ 2 concurrent immunosuppressive drugs (max = 4 concurrent). Subjects with disease duration ≤ 3 years and > 3 to ≤ 6 years had similar demographics and disease characteristics, except a lower proportion of the subjects with longer disease duration were on methotrexate (p = 0.041, Chi-square), low dose corticosteroids (p = 0.006, Chi-square), or multiple immunosuppressive medications (p = 0.055, Chi-square). Subjects with longer disease duration also had slightly lower FVC % predicted (p = 0.018, t-test).

Conclusion: This is the first Phase 3 study to use ACR CRISS as the primary efficacy outcome, a composite outcome of multiple clinically relevant measures of SSc, and the largest interventional study to date in diffuse cutaneous SSc. Benefits of having inclusive eligibility criteria are that they facilitated timely full enrollment and will make the study population representative of real-world practice, if trial is positive. This study provides a template for Phase 3 dcSSc trials and will give valuable information on outcome with routine care as well as test efficacy of lenabasum.

Ultrasound Measurement of the Nail Bed Matrix Thickness as a Useful Marker for Scleroderma-Related Interstitial Lung Disease

Marian Sidor,[1] Roman Zuckerman,[1] Naomi Schlesinger,[2] Ross Sussman,[3] Huma Jaleel Sabahath,[4] and Vivien Hsu[5], [1]Rutgers-RWJ Medical School, New Brunswick, NJ, [2]Rutgers Health- RWJ Medical School, New Brunswick, NJ, [3]Rutgers-RWJ Medical School, East Brunswick, NJ 08816, NJ, [4]AtlantiCare Regional Medical Center, Atlantic City, NJ, [5]Rutgers- RWJ Medical School, SOUTH PLAINFIELD, NJ

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lung involvement is the leading cause of death in systemic sclerosis (SSc) (1). Pulmonary function tests (PFTs) and chest high-resolution CT scan (HRCT) are used to confirm this common complication.

We performed high resolution musculoskeletal (MSK) ultrasound of the nailbed to assess digital clubbing and attempted to correlate with the presence of scleroderma-related interstitial lung disease (SSc-ILD).

Figure 1. Ultrasound 2D Mode (long axis view) of the third finger's distal phalanx in two SSc subjects with normal (top) and abnormal (bottom) nail bed matrix thickness (NBMT). Red line represents the NBMT, measured distance between volar plate of the nail and dorsal surface of the distal phalanx bone.

Table 1: Clinical characteristics and NBMT measurements in control population and SSc patients with and without ILD

*TLC - total lung capacity, FVC - forced vital capacity, DLCO - diffusing capacity for carbon monoxide; SD-standard deviation p-value <0.05 was statistically significant (by ANOVA)

Since Hippocratic times, digital clubbing has been described in patients with hypertrophic osteoarthropathy (2), associated with many chronic illnesses such as cardiovascular and pulmonary diseases (3). Digital clubbing is associated with abnormal proliferation of skin and periosteal tissues of the fingertips characterized by periostosis of

tubular bones, uniform swelling of soft tissues of the terminal phalanx and increased nail-to-nail bed angle (4). The increased nail bed matrix thickening (NBMT) is associated with digital clubbing, normal reported 1.7+/-0.18mm (5). Our hypothesis is that measurement of the NBMT by MSK Ultrasound can be an effective marker for clinically significant SSc-ILD.

Methods: In this IRB-approved study, we evaluated the dominant hand of 47 subjects by MSK ultrasound. Twenty-nine patients met the 2013 ACT criteria for SSc (6) and were divided into 2 subgroups (Group 2A with ILD and Group 2B without ILD). Eighteen subjects served as the age-matched control group (group 1, no SSc). Using the Phillips Epiq 5, all subjects underwent MSK ultrasound of the dominant hand utilizing linear high frequency probe with 2-22 MHz frequency. The NBMT of all 5 fingers were examined and 235 nail beds were recorded. SSc-ILD was confirmed by HRCT associated with restrictive pattern on PFTs. We used ANOVA testing to calculate differences between groups and a p-value < 0.05 was statistically significant.

Results: Table 1 shows a significantly higher NBMT for the 2nd, 3rd and 4th fingers in the SSc lung cohort, and interdigital analysis determined that the 3rd finger NBMT had the highest NBMT between the fingers. The mean cutoff value for normal NBMT in the 3rd finger was less than 2.27mm. The PFT parameters of SSc cohort (Table 2) showed a trend towards increased NBMT in those with SSc-ILD, although only %DLCo was significant in our small cohort.

Conclusion: Our study suggests common mechanisms that may be responsible for digital clubbing in SSc resulting from chronic local tissue hypoxia due to chronic lung disease (7). This is readily visible by MSK ultrasound, often before it is evident on physical exam and may be a predictor of more clinically significant pulmonary disease. We found that a NBMT greater than 2.27mm in the 3rd finger was associated with presence of SSc-ILD. Larger studies are needed to verify our findings.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a major complication in systemic sclerosis (SSc) and is characterized by abnormalities in vascular pathways. In murine models of PAH increased lymphangiogensis has been shown in lung tissue by elevated vascular endothelial growth factor receptor 3 (VEGFR-3) expression, which is a known lymphatic marker. The ligand acting through VEGFR-3 is vascular endothelial growth factor C (VEGF-C), a major growth factor in the lymphatic vessels under physiological conditions. We have shown that VEGF-C is down-regulated in SSc patients and aim to assess the characteristics of VEGF-C and its receptor VEGFR-3 in SSc patients, and investigate the VEGF-C/VEGFR-3 axis in SSc-PAH.

Table 1. Longitudinal clinical and demographic data.

	OUH Identification cohort			USZ Validation cohort		Healthy controls
	Total (n=457)	PAH (n=47)	No PH (n=57)	Total (n=95)	PAH (n=21)	HC (n=68)

Anti-Centromere Ab, no (%)	249 (54.4)	28 (70.0)	43 (56.8)	34 (39.5)	12 (57.1)	n.a.
Mean VEGF-C level, ng/ml (SE)	2.10 (0.04)	1.80 (0.12)	2.12 (0.10)	1.33 (0.09)	1.05 (0.13)	2.89 (0.12)
Mean VEGFR-3 level, ng/ml (SE)	1.57 (0.18)	2.29 (0.79)	1.67 (0.56)	0.81 (0.19)	0.66 (0.23)	0.50 (0.06)

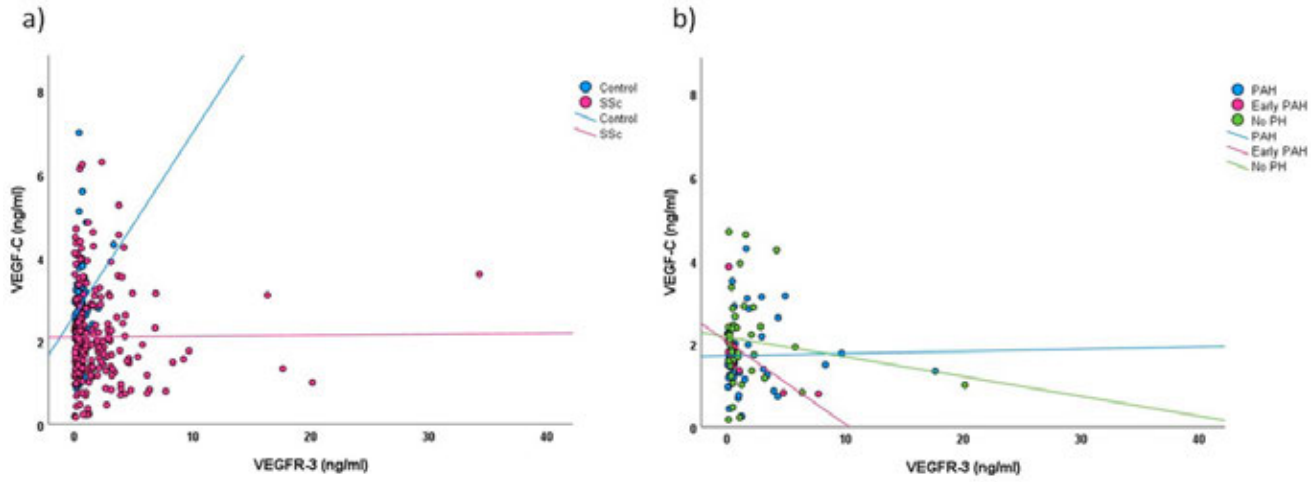

Figure 1. Correlation between VEGF-C and VEGFR-3 levels in a) Systemic sclerosis patients and healthy controls, and b) PH-patients in OUS and USZ cohorts combined.

Methods: Sera samples from the SSc cohorts at Oslo University Hospital (n=457, identification cohort) and Zurich University Hospital (n=95, validation cohort), as well as age and gender matched healthy controls (n=68) were included in the study, and analyzed for soluble VEGF-C and VEGFR-3 levels by Luminex kits from Millipore. SSc patients with clinically suspect PH were referred to right heart catheterization (RHC). Mean pulmonary arterial pressure (mPAP) ≥21 mmHg in the absence of significant interstitial lung disease and a PVR ≥ 3 Wood Units (WU) was defined as PAH, whereas PVR < 3 WU was defined as early PAH. Descriptive statistics were performed and correlations were calculated by non-parametric Spearman's rho analysis.

Results: The demographics and clinical data of SSc patients were similar in the Oslo identification and Zurich validation cohorts (Table 1), and were assembled for further analysis. Serum levels of VEGF-C were significantly lower in SSc patients than in healthy controls (2.1±0.04 ng/ml vs. 2.9±0.12 ng/ml, p< 0.001), while serum levels of VEGFR-3 were significantly higher in SSc compared to healthy controls (1.8±0.20 ng/ml vs. 0.5±0.06 ng/ml, p=0.001) in both cohorts. A total of 238 (43.1%) patients were assessed by RHC. Patients with post-capillary (n=51), PH-ILD (n=32) and early PH-ILD (n=6) were excluded, while the remaining 149 RHC verified patients were included in the investigation of VEGF-C and VEGFR-3 serum levels; including 68 patients with PAH, 22 with early PAH and 59 with no PH. Correlation of VEGF-C and VEGFR-3 were weak in SSc patients and healthy controls (r=0.1, p=0.150 vs. r=0.3*, p=0.020), and the difference between the correlation coefficients were not significant (p=0.083). The correlation between VEGF-C and VEGFR-3 in SSc cases having RHC findings of PAH and no PH were also weak (r=0.3*, p=0.034 vs. r=-0.1, p=0.337) with no significant difference between the correlation coefficients (p=0.057). Notably, the correlation in early PAH subjects were strong (-0.8*, p=0.001), and there was a significant difference between the correlation coefficients of early PAH and PAH (p=0.001) and early PAH and no PH groups (p=0.003) (Figure 1).

Conclusion: VEGF-C and its receptor VEGFR-3 is associated with SSc, and the observed skewing of VEGF-C/VEGFR-3 ratios in early and established PAH indicates dysregulation of the VEGF-C/VEGFR-3 axis during development of PAH.

Diagnosis of Systemic Sclerosis: How and When

Cristina Sobrino,[1] and Carlos De la Puente[2], [1]Rheumatology Department, Ramón y Cajal University Hospital & IRYCIS, Madrid, Spain, [2]Hospital Universitario Ramon y Cajal, Madrid, Spain

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is a heterogeneous disease regarding its clinical expression, evolution and forms of presentation. In spite of the lack of a disease modifying therapy, there are effective treatment options to control complications such as pulmonary arterial hypertension (PAH), interstitial lung disease (ILD) or digital ulcers (DU). Early diagnosis is crucial and allows the physician to start these treatments as soon as possible. Our objetive is to study the main clinical manifestations that lead to diagnosis of SSc, the delay of the diagnosis after the beginning of the first symptom, and to analyze the role of the different clinical features in the diagnosis.

Methods: A retrospective and descriptive study was conducted, which included patients with SSc from our Rheumatology Department. Clinical data and specific autoantibodies profile (ACA, Scl-70, RNP) were recorded, paying special attention to the clinical manifestations that led to diagnosis. We classified them in eight categories: secondary Raynaud's phenomenon (SRP), digital ischemia or DU, musculoskeletal symptoms, skin induration, ILD, PAH, specific autoantibodies detection, and others. The date of starting of Raynaud's phenomenon (RP), of the first non-Raynaud symptom and the date when the diagnosis was established were registered. Analysis were conducted using STATA.

Results: The sample included 149 patients with SSc, meeting the 2013 ACR/EULAR criteria. RP appeared several years prior to the diagnosis (median of 3 years, IQR 0-8), and typically before the first non-Raynaud symptom. 141 out of 149 patients (94,6%) presented RP prior to the diagnosis. However, SRP was the manifestation that led to diagnosis in only 42/149 patients (41,6%), followed by skin induration (18,1%) and DU (12,7%). Surprisingly, 30/149 patients (20,1%) were diagnosed after the appearance of severe complications such as DU, ILD or PAH. Most patients started symptoms related to SSc several years before diagnosis (details in Table 1). 40/48 patients (83%) that were diagnosed due to SRP, presented abnormalities in nailfold capillaroscopy as well as specific autoantibodies (Table 2). Presenting telangiectasia, calcinosis, ILD or PAH was not associated with an early diagnosis, nor was ACA, Scl-70 or RNP positivity.

Table 1. Signs and symptoms that led to the diagnosis of SSc. n (%) are shown.

Clinical manifestation that leads to diagnosis	Patients	Years from first symptom to diagnosis	Years from Raynaud's phenomenon to diagnosis
	n (%)	median (IQR)	median (IQR)
Raynaud's Phenomenon	62 (41,6)	3 (1-10)	3 (1-9)
Skin induration	27 (18,1)	1 (0-4)	1 (0-4)
Digital Ischemia/UD	19 (12,7)	2 (0-12)	2 (0-12)
Musculoskeletal symptoms	18 (12,1)	3 (0-6)	3,5 (0-6)
ILD	8 (5,3)	2,5 (1-4)	3 (0-4)
Specific autoantibodies	6 (4)	5,5 (4-9)	3 (0-9)
Others	6 (4)	5,5 (0-10)	5,5, (0-10)
PAH	3 (2)	35 (20-35)	35 (20-35)

Table 2. Frequency of positive antibodies (%) in patients with RP and abnormal capillaroscopy.

Patients with Raynaud's Phenomenon	n (%)
With abnormal capillaroscopy	48/59 (81)
...and only ACA+	36 (75)
...and only anti Scl-70+	3 (6,2)
...and only anti-RNP+	2 (4,1)
... and ACA+ and/or Scl70+ and/or anti-RNP+	40 (83,3)
... without autoantibodies	8 (16,6)

Conclusion: One out of five patients with SSc was diagnosed after the onset of complications. The study of RP by capillaroscopy and specific antibodies allows to reach the diagnosis of early SSc in up to 83% of patients. Early referral of patients with RP to the Rheumatologist and a multidisciplinary management of complications would improve the diagnosis of this potentially serious disease.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Skin involvement is one of the early features of scleroderma and an important predictor of internal organ involvement and mortality. Skin fibrosis alters the normal dermal architecture and compromises biomechanical skin properties. Therefore, biomechanical parameters can not only provide quantitative assessment of the disease severity, but also help physicians monitor disease progression. However, no systemic review has summarized recent findings about the role of biomechanics in the assessment of scleroderma. This systemic review evaluates the effectiveness of biomechanical tools in diagnosing and tracking skin diseases for patients with scleroderma.

Methods: A comprehensive search of PubMed/Medline and Cochrane databases was performed until May, 2019. In addition, a manual search was conducted in which reference lists of selected articles were screened to include relevant ones. Several related synonyms were used, including biomechanics, scleroderma and assessment. Selection criteria included studies that were comprised of participants with either limited cutaneous (lcSSc) or diffuse cutaneous systemic sclerosis (dcSSc), with a sample size greater than 20, and investigated at least one biomechanical property of the skin.

Results: 46 relevant studies were identified and 12 articles were eligible to be included in this review, with a total of 212 participants. The techniques developed for quantitative measurements of skin properties included durometer (2 articles), indentation (2 articles), suction method (3 articles), surface wave technique (2 articles), ultrasound (1 article), atomic force microscopy (1 article) and photoacoustic elastic tomography (1 article). All studies reported at least one skin biomechanical property that was significantly different in patients with scleroderma compared to normal controls. The skin of patients with scleroderma was found to have decreased extensibility ($p< 0.05$), increased stiffness ($p< 0.03$), and decreased skin viscoelasticity ($p < 0.03$ in patients with dcSSc). Besides, skin sclerosis was associated with smaller difference in viscoelasticity among different anatomic sites ($p < 0.05$). One study reported that some anatomic sites of patients already showed significantly different biomechanical properties ($p < 0.05$), even with a modified Rodnan score of 0, suggesting that biomechanical measurements could be helpful for diagnosis at early stages and might provide more sensitive assessment of disease progression.

Conclusion: Current evidence suggests that biomechanical properties of the skin can be used as a marker for diagnosis and monitoring of disease progression in scleroderma. Compared to the modified Rodnan skin score, they may

provide a more objective, reliable and sensitive way to evaluate skin disease. Rigorous and large-scale randomized control trials are warranted to further assess the clinical value of tracking skin biomechanical properties in patients with scleroderma.

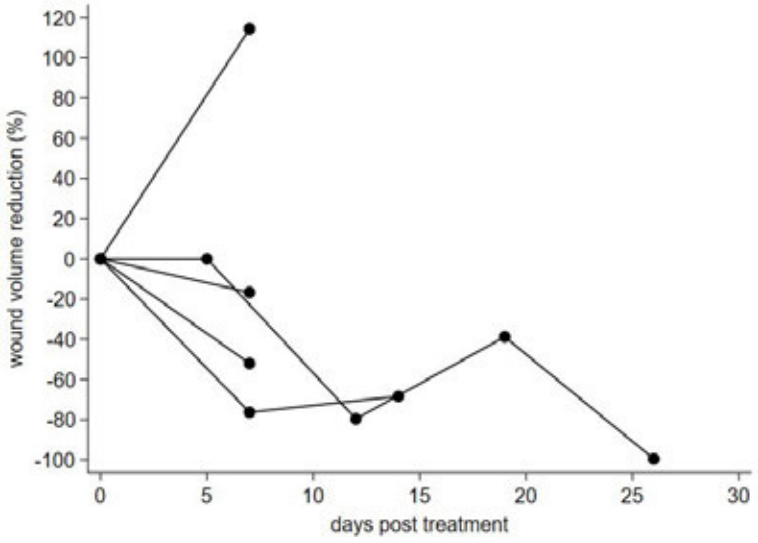
Amniotic Membrane Dressings Provide an Effective Treatment for Systemic Sclerosis Digital Ulcers

Tracy Frech,[1] Jan Pierce,[2] Greg Stoddard,[3] Constance McNeill,[4] Mislav Radic,[5] and Jo-Anna Reems[6], [1]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT, [2]University of Utah Regenerative Medicine, Salt Lake City, United Kingdom, [3]University of Utah Study Design and Biostatics Core, Salt Lake City, UT, [4]University of Utah Hospitals and Clinics, Salt Lake City, UT, [5]University Hospital Split, Split, Croatia, [6]University of Utah Regenerative Medicine, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc)-related digital ulcers are a major burden for patients. The purpose of this study was to assess the effectiveness of amnion membrane treatments on healing rate as determined by manual and ultrasound weekly measurements.

Methods: SSc patients that met 2013 ACR/EULAR classification criteria and presented to clinic with a digital ulcer between 02/2019-05/2019 were consented to participate. Consented participants were asked to complete a Raynaud's Condition Score (RCS), Hand Mobility in Scleroderma (HAMIS), Scleroderma Health Assessment Disability Questionnaire (HAQ-DI), and return every 5-7 days for a wound nurse's visit until complete healing. All patients received education on wound care management including assessment, cleaning, and dressing. The volume of the wound was calculated and change in volume was tracked over time at the time of wound care.



Wound volume change with amniotic membrane dressing

Results: During the two-month study period, 15 SSc patients with a DU were approached for consent at the time of their routine SSc care visit. Two patients refused consent due to perceived burden of participation. Of the 13 consented patients, nine patients subsequently withdrew due to burden of participation; length questionnaires and driving to wound care were the most common reported reasons. Five patients had at least two formal measurements of their DU during wound care. Three patients did not return to wound care after the first follow-up visit due to complete healing reported. The demographics of the 5 SSc patients that returned for care included three female; four white patients; three limited cutaneous SSc, with a mean age of 62 (SD 11). The duration from first non-RP symptom of SSc was 5.8 years (SD 4). Wound volume (length x width x depth) ranged from 3 to 182 mm^3. Two wounds (3 mm^3 and 9 mm^3) healed completely after one application and these patients did not return to wound care. One wound (39.2 mm^3) was over a joint contracture and traumatic in origin increased in volume at follow-up measurement. The change in wound volume of these 5 wounds over time after amnion dressing was applied is shown in **Figure 1**. None of these SSc wound patients completed all questionnaires.

Conclusion: Assessments of SSc-related DU healing must minimize patient burden; the appropriate number of questionnaires used for assessment must be carefully assessed in the study design of this outcome, and remote wound monitoring should be considered. DU healing can be measured effectively by weekly ultrasound that estimates wound volume. Amnion membrane dressings are effective for wound healing in this patient population, especially for wounds that are vascular in origin.

Digital Blood Perfusion Differences Between Black Africans and Caucasians with Systemic Sclerosis

Claudia Ickinger,[1] Valerie Lambrecht,[2] Eustasius Musenge,[3] Mohammed Tikly,[1] Maurizio Cutolo,[4] and Vanessa Smith[5], [1]Division of Rheumatology, Chris Hani Baragwanath Academic Hospital, Faculty of Health Sciences, University of the Witwatersrand, Joahnnesburg, South Africa, [2]Department of Rheumatology, Ghent University Hospital, Ghent, Belgium, [3]School of Public Health, University of the Witwatersrand, Johannesburg, South Africa, [4]Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, IRCCS Ospedale Policlinico San Martino, Genoa, Italy, Genoa, Italy, [5]Dept. of Rheumatology, Ghent University Hospital, Ghent, Belgium; Dept. of Internal Medicine, Ghent University, Ghent, Belgium; Unit for Molecular Immunology and Inflammation, VIB Inflammation Research Center (IRC), Ghent, Belgium, Gent, Belgium

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Microvascular dysfunction is a prominent feature in SSc. Laser speckle contrast analysis (LASCA) has been shown to be a reliable tool to quantify skin blood perfusion (BP) in SSc (1,2). Patients of African descent have a more severe disease burden than their European counterparts (3). Data are lacking on race/ethnic related differences in peripheral BP measured by LASCA in SSc. The objective of this study was to assess and compare BP at the level of fingertips between black Africans and Caucasians.

Methods: Forty black Africans and 29 Caucasian consenting patients fulfilling 2013 ACR/EULAR classification criteria for SSc were enrolled at 2 different geographic sites. Cutaneous BP in the hands was assessed by LASCA, calculating flows in regions of interest created at the 2-5 volar and dorsal fingertips (4). Standardized protocols for instrumental, environmental and patient conditions were applied at both study sites (1). Median BP was reported as perfusion units (PU).

Table 1. Digital blood perfusion between black Africans and Caucasians with systemic sclerosis

	Median volar fingertip blood perfusion (PU)		
Variable	Black Africans (n=40)	Caucasians (n=29)	p-value
Females	58.73 (n=35)	131.89 (n=23)	0.001
Males	59.40 (n=5)	133.28 (n=6)	0.018
Disease duration > 5 years	55.48 (n=23)	138.82 (n=10)	0.003
LcSSc	65.64 (n=13)	135.13 (n=24)	0.026
DcSSc	55.48 (n=23)	98.18 (n=5)	0.031
Skin score fingers none/mild	53.86 (n=22)	76.62 (n=12)	0.061
Skin score fingers moderate/severe	62.52 (n=18)	138.37 (n=12)	0.000
Anti-centromere+	139.03 (n=2)	124.85 (n=5)	1.000
Anti-topoisomerase 1+	57.44 (n=6)	130.04 (n=14)	0.008
Calcinosis	52.51 (n=6)	93.78 (n=1)	0.617
Current DU and/or Pits	54.17 (n=24)	201.74 (n=6)	0.001
Pits	54.17 (n=24)	199.86 (n=5)	0.002
Vasodilator CCB	58.73 (n=39)	199.86 (n=11)	0.001

PU: perfusion units; DU: digital ulcers; CCB: calcium channel blocker

Digital blood perfusion between black Africans and Caucasians with systemic sclerosis>

Results: With respect to demographic and clinical characteristics, the significant differences between the 2 cohorts were that blacks were younger (mean age 48.5±9.9 vs 55.5±12.3 years, p=0.01), had a longer disease duration (mean 9.2±7.1 vs 5.8±6 years, p=0.04), a greater proportion of the diffuse cutaneous disease (67.5% vs 17.2%, p< 0.001), and were more likely to be on vasodilator calcium channel blocker therapy (97.5% vs 37.9%, p< 0.0001), compared to Caucasians. In both groups the median BP values were significantly higher for the volar fingertips compared to dorsal fingertips (Blacks: 59.07 vs. 37.39 PU, p=0.0002; Caucasians: 131.89 vs. 96.64 PU, p=0.03). Table 1 shows the univariate analysis comparing the groups with respect to demographics, disease subsets, autoantibodies and selected clinical features in relation to volar fingertip BP measured by LASCA. Overall, the average BP was significantly lower in blacks compared to Caucasians (59.07 vs. 131.89, p=0.0001). Multivariable analysis showed that when using Caucasian females as the referent group, black females and males has significantly lower digital BP (t= -3.86, p< 0.0001; t= -2.93, p=0.005, respectively), with black females showing the lowest BP.

Conclusion: This study shows better BP at the volar fingertips compared to the dorsal fingertips in both groups. We found several differences in digital BP between blacks and Caucasians with SSc. Caucasian females had the best BP and black females had the most impaired digital BP. These racial differences in peripheral BP warrant further investigation of possible ethnic differences in endothelial function.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

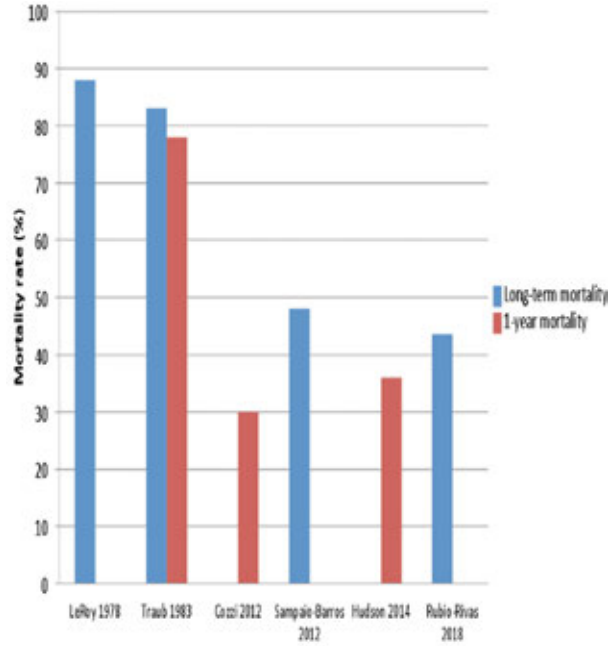

Figure 2. Mortality in scleroderma renal crisis and trends over time

Figure 2. Mortality in scleroderma renal crisis and trends over time.

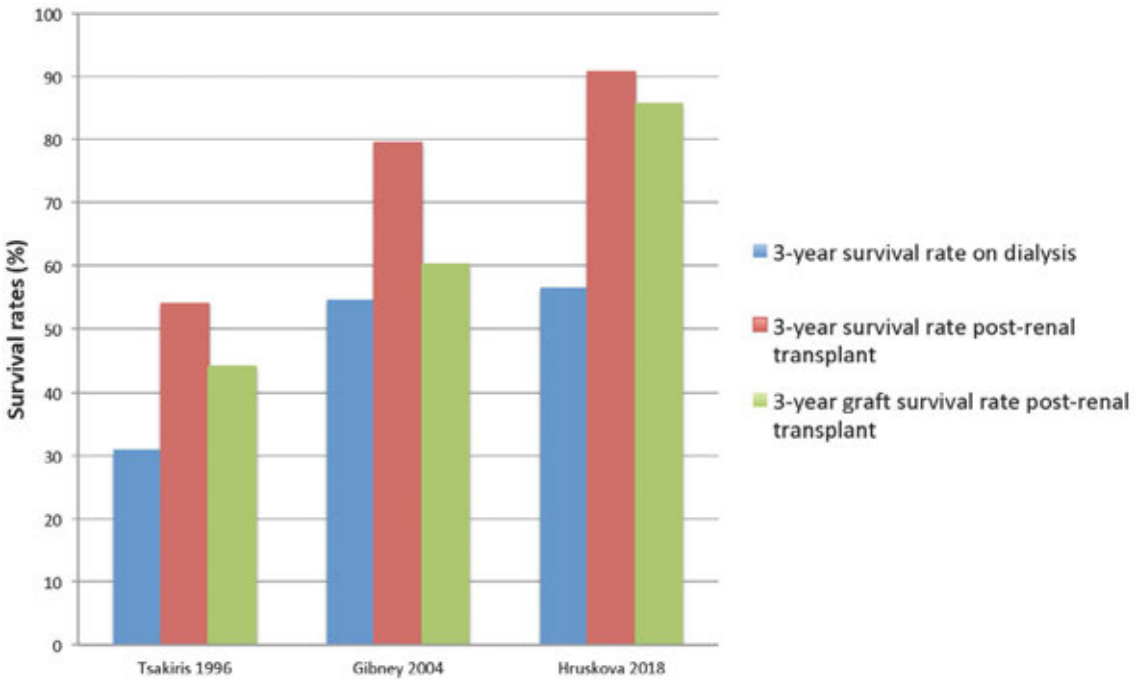

Figure 3. 3-year outcomes in SSc-end stage renal disease

Figure 3. 3-year outcomes in scleroderma end stage renal disease.

Background/Purpose: The introduction of angiotensin converting enzyme (ACE) inhibitors in the early 1970s resulted in marked improvement in clinical outcomes of scleroderma renal crisis (SRC).Despite the undisputed improvement in outcomes of SRC since the availability of ACE inhibitors, estimates of mortality and morbidity vary considerably. The objective of this study was to systematically review the mortality and morbidity associated with SRC and to determine temporal trends.

Methods: We searched Medline, EMBASE and the Cochrane Database of Systematic Reviews from database inception to January 15, 2019. Bibliographies of selected articles were hand-searched for additional references. Data were extracted using a standardized extraction form. Study quality was assessed using the Newcastle-Ottawa scale. Results were analyzed qualitatively.

Results: Twenty studies with 14,059 SSc subjects, of which 854 had SRC and 4095 had SSc-associated end stage renal disease (SSc-ESRD), met inclusion criteria. Study quality was generally moderate. Cumulative mortality in the post-angiotensin converting enzyme (ACE) inhibitor era was approximately 20% at 6 months, 30-36% at 1 year, 19%-40% at 3 years and almost 50% at 10 years from SRC onset. Although the introduction of ACE inhibitors in the early 1970s resulted in a 50% improvement in SRC mortality, there was no further improvement thereafter. SRC mortality rates were proportionally higher than mortality rates associated with other SSc organ involvement. The rate of permanent dialysis after SRC in the post-ACE inhibitor era ranged from 19-40%. Three to 17% of SSc patients underwent renal transplant. Survival was better in patients post-renal transplant (54-91%) compared to those on dialysis (31-56%). Graft survival improved over time and appeared similar to that of patients with other types of ESRD.

Conclusion: SRC mortality and morbidity remain high. Novel treatments are required to improve outcomes of SRC.

Nailfold Videocapillaroscopy Patterns and Digital Occlusive Arterial Disease on Laser Doppler Flowmetry Strongly Predicts the Diagnosis of Systemic Sclerosis and Other Connective Tissue Diseases

Yasser Radwan,[1] Tina Gunderson,[2] Cynthia Crowson,[3] David Liedl,[4] Alicia Hinze,[1] Kenneth Warrington,[4] Paul Wennberg,[4] and Ashima Makol[1], [1]Mayo Clinic Minnesota, rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic Rochester, rochester, MN

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vasculopathy is a key feature of systemic sclerosis (SSc), a chronic autoimmune disease associated with widespread fibrosis and internal organ dysfunction. While structural abnormalities of the microcirculation are best seen on nailfold videocapillaroscopy (NVC), laser doppler flowmetry (LDF) with a thermal challenge is a highly accurate, safe, and noninvasive means to detect digital occlusive arterial disease (DOAD) with a sensitivity

Table. Sensitivity, specificity, positive and negative predictive values of nailfold videocapillaroscopy (NVC) alone and in association with digital occlusive arterial disease (DOAD) on laser doppler flowmetry (LDF) in predicting systemic sclerosis (SSc) and connective tissue disaeses (CTDs)

Outcome	Predictor	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)

CI=Confidence Interval

and specificity of >90% (1).We reviewed NVC patterns and DOAD on LDF in a cohort of patients referred to our NVC clinic for evaluation of Raynaud's or suspected connective tissue disease (CTD), their correlation, and their predictive value in diagnosing SSc or any CTD.

Methods: Medical records of patients that underwent NVC and LDF at our institution between 1/1/2017 and 3/31/2019 were retrospectively reviewed. NVC results were classified as normal or abnormal (non-specific or SSc specific pattern- early, active or late). Presence or absence of DOAD on LDF was abstracted. Clinical diagnosis of CTDs and fulfilment of ACR/EULAR 2013 SSc classification criteria and Very early diagnosis of Systemic sclerosis (VEDOSS) criteria was ascertained.

Results: 190 patients (mean age 46 ± 15 yrs, 81% females, 93% white) underwent NVC and LDF during the study period. NVC was normal in 102 (54%) patients and abnormal in 88 (Non-specific 31[35%], SSc pattern 57[65%]).

On LDF with thermal challenge, 78% of patients had vasospasm and DOAD was noted in 30 (16%) patients. Among 30 patients with DOAD, a CTD was diagnosed in 24 (80%), of which 17 (57%) met SSc criteria.

Among the 30 patients with DOAD, 24 (80%) had abnormal NVC patterns with SSc NVC pattern in 18 (60%) (3 early, 8 active and 7 late). Among the 160 patients without DOAD, 93 (58%) did not have any CTD and NVC was normal in 96 (60%) of the patients.

SSc NVC pattern was strongly predictive of meeting VEDOSS (positive predictive value (PPV):84%) and diagnosis of CTDs (PPV: 77%). Addition of DOAD to SSc NVC pattern increased the likelihood of meeting SSc criteria (PPV increased from 46% to 83%), diagnosis of CTDs (PPV increased from 77% to 100%) and slightly improved fulfillment of VEDOSS.

Having normal NVC was associated with very low likelihood of SSc diagnosis (negative predictive value (NPV): 98%) and VEDOSS (NPV: 91%), but did not help significantly in exclusion of other CTDs (NPV: 66%). Using a composite predictor of abnormal NVC or DOAD did not significantly change the NPV for excluding SSc or CTDs, compared to NVC alone (Table).

Conclusion: Our study suggests that the presence of DOAD on LDF in patients with RP and/or suspected CTD is strongly associated with presence of an underlying CTD, particularly SSc. Patients with DOAD and SSc, are more likely to have an 'active or late' SSc pattern on NVC rather than 'early'. A SSc pattern NVC in combination with DOAD is very strongly predictive of an underlying CTD, with SSc in >80% cases. A normal NVC virtually excludes the presence of SSc, but not other CTDs. Adding LDF to NVC, can further increase the predictive value of NVC alone for CTD diagnosis.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: For most patients with diffuse cutaneous systemic sclerosis (dcSSc), skin thickness improves over time, especially with background immunosuppressive treatment. This has reduced confidence in group level skin score (mRss) change as a meaningful endpoint in clinical trials that may not convincingly demonstrate greater improvement in active treatment arms compared to control. Nevertheless, skin thickening contributes significantly to dcSSc morbidity. We explore the association between skin change over time and outcomes in a cohort of early dcSSc patients.

Methods: DcSSc subjects with at least one mRss assessment within the first 5 years from onset were included. Observed change in mRss between first assessment and 12(±2) months follow-up was calculated and categorised as improvement, if there was a decline by ≥ 5 units or 25%; worsening, if we observed increase by ≥ 5 units or

Slope	0.751	0.599	0.942	0.013
Slope^2	0.300	0.101	0.885	0.029

25% and stable, if change was within 5 units and 25%. Random effect models were fitted to evaluate continuous changes in mRss over time. Model-predicted individual patient intercept and slope were used to assess association between absolute mRss at baseline (12 months from onset), mRss change and time to death or development of organ disease.

Results: Of the 467 patients, 106 (22.7%) were male and mean age of disease onset was 45.5 (SD 13.2) years. Most frequent autoantibodies were anti-topoisomerase I antibody (ATA) in 141 (30.2%) and anti-RNA polymerase antibodies (ARA) in 140 (30.0%) of the subjects. Other antibodies included anti-U3RNP in 32 (6.9%), anti-PmScl in 21 (4.5%) and 73 (15.6%) of the subjects were ANA positive, but ENA negative (ANA+ENA-). In 94 patients (20.1%) mRss was assessed once, while 278 (59.5%) had three or more mRss assessments.

Average mRss at 12 months from onset was estimated to be 25 and there was consistent decline over subsequent years, which slowed down with longer disease duration (3.4, 2.7, 1.9 and 1.2 units at years 2, 3, 4 and 5). As previously shown, there was a weak negative correlation between mRss at 12 months and subsequent change (correlation coefficient -0.3), suggesting higher initial mRss associates with greater subsequent decline (Table 1).

Of the 147 patients who had two mRss assessments within 12(±2) months, only 12.9% had worsening mRss, 34.7% had improvement and the majority (52.4%) experienced very little change. Both higher intercept and higher slope predicted increased risk of death with 8% increase in hazard for every unit higher baseline mRss

and 4% increase for every unit higher change per year (Table 2). Pulmonary fibrosis and pulmonary hypertension development associated with higher change in mRss, but not with baseline absolute mRss values (3.5% and 7% increase in the hazard respectively for one unit higher mRss change over 12 months). It appeared that higher slope associated with lower hazard of scleroderma renal crisis, while we found no associations between skin and cardiac SSc.

Conclusion: Skin changes over the initial 5 years of disease vary between patients. At a group level there is an improvement, however, for individual patients slower improvement or deterioration in skin predicts increased risk of pulmonary complications and higher mortality rates.

Energy Levels: An Overlooked Element in Patient Assessment in Scleroderma

Yossra Suliman,[1] Suzanne Kafaja,[2] Mohamed Alemam,[3] and Daniel Furst[4], [1]Rheumatology and Rehabilitation Department. Faculty of Medicine. Assiut University, Assiut, Egypt, [2]Department of Medicine. Rheumatology Division. UCLA, Los Angeles, CA, [3]Clinical Pathology and Chemistry Department. Qena Faculty of Medicine. South Valley University, Assiut, Egypt, [4]University of California, Los Angeles, CA

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Scleroderma (SSc) is a debilitating multi-system chronic disease which directly affects patient related Quality of Life. We wanted to identify how the patient interprets their inability to work and get their perspective on energy levels during daily activities. We hypothesized that there are abnormal constitutional symptoms in SSc patients (i.e. energy levels, sleep quality and time to feeling fatigued) which may directly affect patient productivity.

Objective:

- To assess the proportion of SSc patients with abnormal energy levels, sleep and with early fatigue.
- To evaluate the relation between energy levels and sleep quality, time to fatigue, pain visual analogue scale (VAS), Pt global VAS, MD global VAS.

Methods: Eighty -five SSc patients meeting the ACR/EULAR 2013 SSc criteria were recruited from Pacific Arthritis Scleroderma Clinic. Laboratory and clinical data were obtained from charts for statistical correlations. Data were cross-sectional and were from the first clinical record available, usually the first clinical visit.

Table 1: demographics and pt characteristics of Scleroderma patients

variable	Mean(SD), number (%)
Age	55.7(13.2)
Sex, females	76 (89 %)
mRSS	7 (7.5)
ILD	37 (43%)
PAH	14(16 %)
HgB	12.2 (1.2)
Pt Global VAS	4 (2.4)
MD global	4(1.6)
Pain VAS	3(2.8)

Table 2: Number (%) of patient in each category of Energy level, sleep and time to fatigue

	Good	Ok	Fair	poor
Energy	31 (36%)	6 (7%)	24(28%)	24(28 %)
Sleep	31(36%)	15 (17%)	11(12%)	26 (31%)
Time to fatigue	(9.5-≥12hrs) 25(29%)	6.5-9hrs 18 (21%)	3.5-6hrs 12(14%)	(0-3hrs) 29 (34%)

Energy levels were assessed by the question “how is your energy?” and Sleep was ascertained as: ” How well do you sleep?” or “How is your sleep?” For these questions, answers were categorical: “Good” (0), “OK” (1), “Fair”(2) or” Low”(3).

Fatigue was ascertained as “How long after you get up ,do you start to get tired or fatigued?”. Answers were in hours, including 0 for fatigued immediately upon awakening to 12+(maximum); responses were in 0.5-hour increments. Regression modelling used energy levels as the dependent variable and time to fatigue , sleep quality, pain VAS, pt global, MD global as independent variables.

Results: The 85 SSc patients’ characteristics were as follows: mean age 55 (13%), female 76 ILD (37), mean MRSS 7 (±7.5) Table 1. Energy levels were fair-poor in more than 50%, while significantly shortened time to fatigue (< =3 hrs) occurred in 29(34%)) . Sleep quality was only fair-poor in 37/85(43%) Table 2. Regression model identified fatigue, sleep , pain VAS, patient global and MD as strong predictors of Energy levels in SSc pts (p =0.0001, 0.0001, 0.009,0.0001 and 0.0001 respectively).

Conclusion: Energy levels among other constitutional symptoms (ie, sleep and fatigue) are significantly altered in SSc patients, more care is to be given to address possible causes , assessment tools and to improve management plans.

Abstract Number: 0731

A Systemic Review of Factors Associated with Systemic Sclerosis-associated Pulmonary Arterial Hypertension (SSc-PAH)

Yuxuan Jiang,[1] Matthew Turk,[1] and **Janet Pope** [2], [1]University of Western Ontario, London, ON, Canada, [2]Western University, London, ON, Canada

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) in systemic sclerosis (SSc) is a lethal complication affecting approximately 8-15% of patients. Screening methods including echocardiography and pulmonary function tests exist to triage patients for definitive diagnosis by right heart catheterization. Improving our understanding of SSc-PAH associated risk factors could help stratify high-risk patients for regular screening.

Methods: A systematic review was performed in SCOPUS, Medline, EMBASE, Web of Science, and the Cochrane Library from their inception to February 22, 2019. Terms included phrases related to pulmonary arterial hypertension, systemic sclerosis, and prevalence. Studies were included if they reported on the frequency of a risk/association factor related to SSc-PAH. Studies were included if they determined PAH with right heart catheterization, compared SSc patients with and without PAH, and had sample size larger than 20.

Results: The search found 2654 articles of which, 984 were duplicates and 1578 were excluded due to irrelevant title. After the remaining 92 were screened, 37 articles met eligibility criteria. Forty-three risk/association factors for SSc-PAH were identified and placed into seven categories. The most frequently mentioned categories included: patient characteristics, pulmonary physiology, antibody profiles, and genetics/epigenetics factors. In contrast, biomarkers and other labs featured the fewest distinct risk factors. Specific risk factors found for patients were lowered

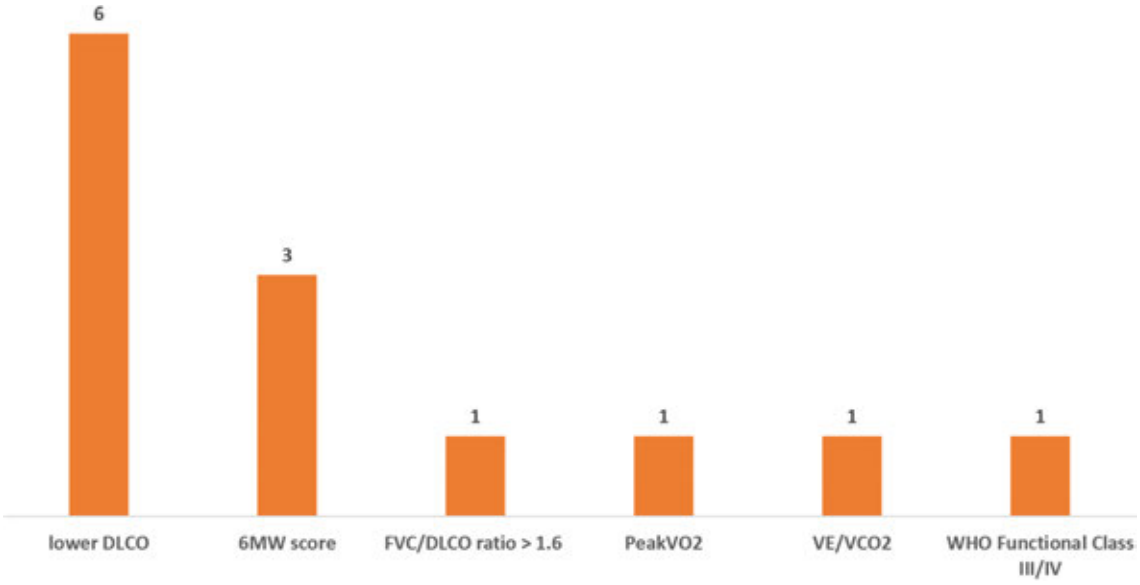

Figure 1. Pulmonary physiology measurements related to literature reported SSc-PAH

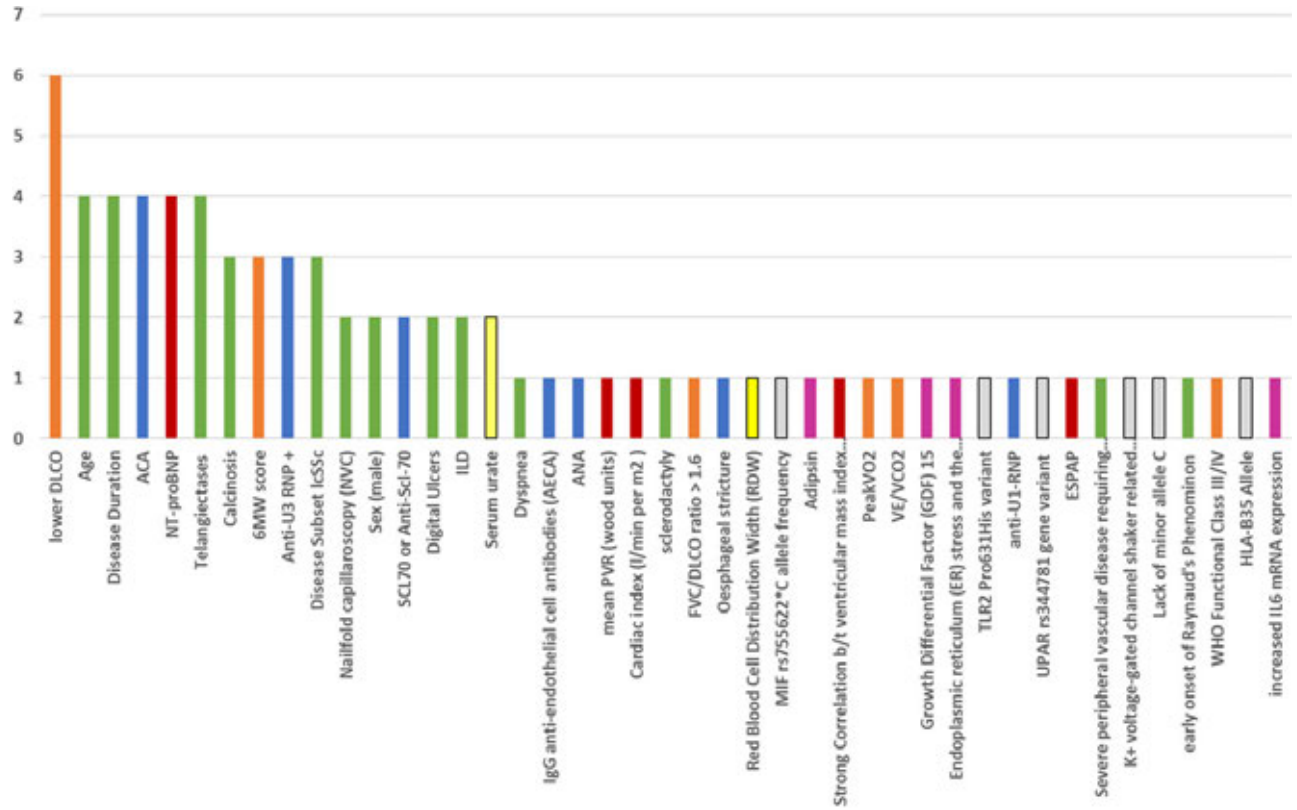

Fig. 2 All clinical parameters associated with SSc_PAH as reported in the literature

diffusing capacity of the lungs for carbon monoxide, older age, and longer disease duration among others. Interstitial lung disease and anti-centromere antibody (ACA) were also frequently associated (Figure 1 and 2).

Conclusion: Presence of ILD, ACA, older age, and disease duration are consistently identified risk factors in PAH-SSc. Risk factors for SSc-PAH such as limited-SSc, ACA, older age, longer disease duration and presence of ILD may enrich screening programs. Patterns in genotypes and antibody profiles are inconsistent and requires further validation. Understanding these risk factors may give insight into which patients will need further screening but some risks are associated with Class I PAH (ex. ACA) and others with Class III (ILD, hypoxia) which may be why risk factors are inconsistent in the literature.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Cardiac valve involvement in patients with Systemic Sclerosis (SSc) is uncommon, except for tricuspid regurgitation associated with pulmonary hypertension, and data regarding its frequency is inconsistent. Our objective was to estimate incidence rate of moderate to severe valvular disease in patients with SSc compared with controls.

Methods: We included patients with SSc diagnosis (ACR 2013 criteria) belonging to our health management organization (HMO) and followed by our unit from january 1st 2000 to december 31th 2017. Each patient with SSc was

	Patients with Systemic Sclerosis (n=127)	Controls (n= 497)	p
Female, n (%)	122 (96.1)	477 (95.9)	0.96
Follow-up time, in years, median (IQR)	10.7 (6.4-14.7)	11.3 (6.6-14.6)	0.81
Age at the las cardiac ultrasound, years (SD)	68.6 (14.7)	68.2 (16.6)	0.81
N° of cardiac ultrasound performed, median (IQR)	2 (1-3)	4 (2-8)	< 0.001
Arterial hypertension, n (%, 95% CI)	69 (54.3, 45.6-62.8)	343 (69.0, 64.8-72.9)	0.002
Diabetes, n (%, 95% CI)	2 (1.6, 0.4-6.1)	44 (8.9, 6.7-11.7)	0.005
Dyslipidemia, n (%, 95% IC)	46 (36.2, 28.3-44.9)	255 (51.3, 46.9-55.7)	0.002
Ever smoke , n (%, 95% CI)	32 (25.2, 18.4-33.5)	113 (22.8, 19.3-26.7)	0.06
Coronary disease, n (%, 95% CI)	7 (5.5, 2.6-11.1)	35 (7.0, 5.1-9.7)	0.54
Chronic renal failure, n (%, 95% CI)	14 (11.0, 6.6-17.8)	45 (9.1, 6.8-11.9)	0.51
Stroke, n (%, 95% CI)	6 (4.7, 2.1-10.2)	24 (4.8, 3.3-7.1)	0.96
Past rheumatic fever, n (%, 95% CI)	1 (0.8, 0.1-5.4)	2 (0.4, 0.1-1.6)	0.58
BMI, median (IQR)	24 (21.0-26.2)	27.2 (24.0-30.9)	< 0.001
Moderate-severe aortic regurgitation, Incidence rate, 100 patients-year (95% CI)	1.4 (0.1-2.1)	1.1 (0.8-1.4)	0.16
Moderate-severe aortic stenosis, Incidence rate, 100 patients-year (95% CI)	1.1 (0.7-1.8)	0.3 (0.2-0.5)	**< 0.001**
Moderate-severe mitral regurgitation, Incidence rate, 100 patients-year (95% CI)	1.9 (1.3-2.7)	0.9 (0.7-1.2)	**0.001**
Moderate-severe mitral stenosis Incidence rate, 100 patients-year (95% CI)	0.2 (0.08-0.7)	0.06 (0.02-0.17)	0.06
Moderate-severe pulmonary regurgitation, Incidence rate, 100 patients-year (95% CI)	0	0.02 (0.003-0.13)	0.40
Moderate-severe tricuspid regurgitation, Incidence rate, 100 patients-year (95% CI)	1.9 (1.3-2.7)	0.4 (0.3-0.6)	**< 0.001**
Aortic sclerosis, Incidence rate, 100 patients-year (95% CI)	6.7 (5.9-7.5)	5.1 (4.7-5.5)	**0.02**
Mitral sclerosis, Incidence rate, 100 patients-year (95% CI)	2.3 (1.7-3.1)	0.9 (0.7-1.2)	**< 0.001**
Aortic calcification, Incidence rate, 100 patients-year (95% CI)	2.1 (1.5-2.9)	0.9 (0.7-1.2)	**< 0.001**
Mitral calcification, Incidence rate, 100 patients-year (95% CI)	2.9 (2.2-3.8)	1.6 (1.3-1.9)	**0.001**
Pulmonary hypertension, by cardiac ultrasound (PSP* > 40 mmHg), n (%, 95% CI)	29 (22.8, 16.3-30.9)	22 (4.4, 2.9-6.6)	**< 0.001**
Valvular surgery, Incidence rate, 100 patients-year (95% CI)	0.4 (0.2-0.9)	0,1 (0.05-0.3)	**0.03**

*PSP: pulmonary artery systolic pressure

Risk of Heart Valve Disease in Systemic Sclerosis.

matched by age and sex with 3 to 4 controls of our HMO with at least 1 cardiac ultrasound performed during the study period. Subjects were followed until: a) their death, b) the end of the study, c) they voluntarily left the HMO. Electronic medical records were reviewed, demographic and disease characteristics were collected and incidence rates of valve involvement were calculated for each valve (moderate/severe valvular disease, valve calcification and valve sclerosis) and compared between SSc and controls.

Results: 127 patients with SSc (108 with limited and 18 with diffuse SSc; 96.1% females; 18.4% Scl-70 positive and 67.2% anti centromere positive) and 497 controls were included. Patients with SSC had significantly more incidence of aortic stenosis (1.1 vs 0.3 per 100 patients-year, $p < 0.001$), mitral regurgitation (1.9 vs 0.9 per 100 patients-year, $p = 0.001$) and tricuspid regurgitation (1.9 vs 0.4 per 100 patients-year, $p < 0.001$) than controls. Valvular surgery was significantly more frequent in SSc than controls (0.4 vs 0.1 per 100 patients-year, $p = 0.03$). Aortic sclerosis (6.7 per 100 patients-year), aortic calcification (2.1 per 100 patients-year), mitral sclerosis (2.3 per 100 patients-year) and mitral calcification (2.9 per 100 patients-year) were also more frequent in SSc patients than controls ($p < 0.05$ for all comparisons).

Conclusion: We found significant higher incidence rates of aortic stenosis, mitral regurgitation and tricuspid regurgitation in SSc patients compared to their matched controls. Patients with SSc also required more valvular surgery. Moreover, aortic and mitral valves sclerosis and calcification were found more often in SSc patient's echocardiographies than in controls.

Abstract Number: 0733

Vonoprazan, a Novel Potassium-competitive Acid Blocker, for Treatment of Proton Pump Inhibitor-resistant Reflux Esophagitis in Patients with Systemic Sclerosis

Yuichiro Shirai,[1] Noriyuki Kawami,[2] Katsuhiko Iwakiri,[2] and Masataka Kuwana[1], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan, [2]Department of Gastroenterology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Esophageal involvement is one of the most frequent organ manifestations in patients with systemic sclerosis (SSc). Gastroesophageal reflux disease (GERD) is associated with reflux esophagitis, resulting in

impaired quality of life and increased risk for esophageal stricture and cancer. Continuous use of proton pump inhibitors (PPIs) is recommended as the primary treatment for SSc-associated GERD and leads relief of the symptoms. However, some patients experience reflux esophagitis refractory to the maximum dose of conventional PPIs. Vonoprazan is a novel potassium-competitive acid blocker, and is shown to have several advantages over conventional PPIs, including long duration of acid suppression. Several clinical trials have consistently demonstrated superiority of vonoprazan over conventional PPIs in terms of achieving healing of mucosal breaks and maintaining the healing. The present study investigated the efficacy of vonoprazan for treating PPI-resistant reflux esophagitis in SSc patients.

Methods: This study enrolled SSc patients with PPI-resistant reflux esophagitis, who were selected from SSc database of Nippon Medical School Hospital, composing of 228 patients who visited our clinic after August of 2014. Patients eligible for this study included i) fulfillment of 2013 ACR/EURAR classification criteria for SSc; ii) reflux esophagitis proved by endoscopy on treatment of PPIs; iii) medication switch from PPIs to vonoprazan; and iv) endoscopic and patient-reported outcome evaluations available before and after switch to vonoprazan. Vonoprazan was started orally at a dosage of 20mg or 10mg daily, and the dosage was adjusted if necessary. Reflux esophagitis was graded using Los Angeles (LA) classification, and patient-reported outcomes were assessed using a frequency scale for the symptoms of GERD (FSSG) questionnaire. Safety was also evaluated by retrospective chart review.

Results: Of 13 patients with endoscopy-confirmed reflux esophagitis resistant to PPI treatment, PPIs were switched to vonoprazan in 12 patients. Complete before-and-after data were available in 7 patients, and follow-up evaluations were conducted after an interval of 3.4 ± 2.7 months. All the patients were female, mean age at study entry was 62 ± 13 years, mean disease duration from non-Raynaud's symptom was 13 ± 8 years. Baseline LA classification was A in one, B in 3, C in 2, and D in one, but follow-up endoscopic evaluation revealed that reflux esophagitis was completely healed in 6 of 7 (86%) patients after switching to vonoprazan. Total FSSG score significantly improved from 18.4 ± 9.9 to 11.3 ± 14.2 ($P = 0.04$). The acid reflux component of the FSSG score improved significantly (12.0 ± 6.2 to 7.0 ± 7.9; $P = 0.03$), whereas the dysmotility component did not change (6.4 ± 4.7 to 4.3 ± 6.6). Vonoprazan has been continuously used for 18.7 ± 9.4 months without any adverse events. One patient had vonoprazan-resistant reflux esophagitis based on lack of improvement of the endoscopic findings, but symptomatic improvement was somewhat observed by the FSSG score.

Conclusion: This pilot study suggests that vonoprazan is beneficial for PPI-resistant reflux esophagitis in patients with SSc. A randomized clinical trial is warranted.

Risk Assessment in Connective Tissue Disease Associated Pulmonary Arterial Hypertension

Yuichiro Shirai,[1] Hidekata Yasuoka,[2] Yuichi Tamura,[3] and Masataka Kuwana[1], [1]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Fujita Health University School of Medicine, Aichi, Japan, Toyoake, Aichi, Japan, [3]Pulmonary Hypertension Center, International University of Health and Welfare Mita Hospital, Tokyo, Japan, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) still holds a poor prognosis in patients with connective tissue diseases (CTD), especially those with systemic sclerosis (SSc). A variety of pulmonary vasodilators are currently available, but treatment regimen should be optimized based on risk for poor outcomes in individual patients. The 2015 ESC/ERS guidelines recommended the use of risk assessment based on variables to predict prognosis. The simplified version of the risk assessment using 6 variables that stratify the patients into low, intermediate, and high risk groups has been validated in large cohorts of PAH patients. However, utility of this risk stratification strategy in patients with CTD-PAH has not been established. The present study evaluated risk stratification approaches in patients with CTD-PAH using our database.

Methods: This study enrolled 61 consecutive patients who were diagnosed as having CTD-PAH at Keio University Hospital between 2000 and 2014 and Nippon Medical School Hospital between 2014 and 2019. All clinical information had been prospectively recorded on the database. Six variables, including WHO functional class (WHO-FC), 6 minutes walking distance, BNP/NT-proBNP, right atrial pressure, cardiac index (CI), and mixed venous oxygen saturation at PAH diagnosis were used to categorize the patients into 3 risk groups. The cut-off values and the risk grading were determined according to the 2015 ESC/ERS guidelines. Survival curves were obtained using Kaplan-Meier method and cumulative survival rates were compared by log-rank test.

Results: Baseline characteristics of the enrolled patients included 98% female, age at PAH diagnosis of 51 ± 18, 64% WHO-FC III/IV, and mean pulmonary arterial pressure of 45 ± 10 mmHg. Underlying CTDs were SSc in 33%, systemic lupus erythematosus in 30%, mixed connective tissue disease in 13%, and primary Sjogren's syndrome in 15%. Risk stratification using the standard approach failed to stratify cumulative survival rates in 3 risk groups (Figure 1). When individual variables were used to stratify patients into 3 risk groups, survival rates were significantly different between patients with low risk and intermediate or high risk judged based on WHO-FC (P = 0.016 and 0.011), and between patients with low or intermediate risk and high risk judged based on CI (P = 0.009 and 0.018). Therefore, we modified the original stratification approach by weighting WHO-FC and CI for dividing the patients into the risk groups. Specifically, risk was judged to be low if WHO-FC was I or II, and high if CI was < 2.0 L/min/m2, regardless of

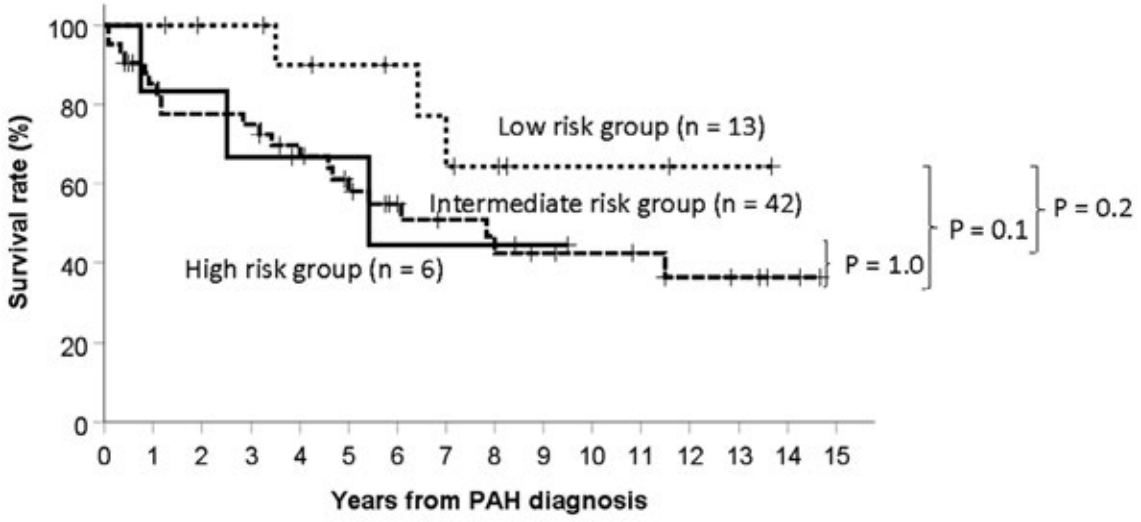

Figure 1 The standard approach

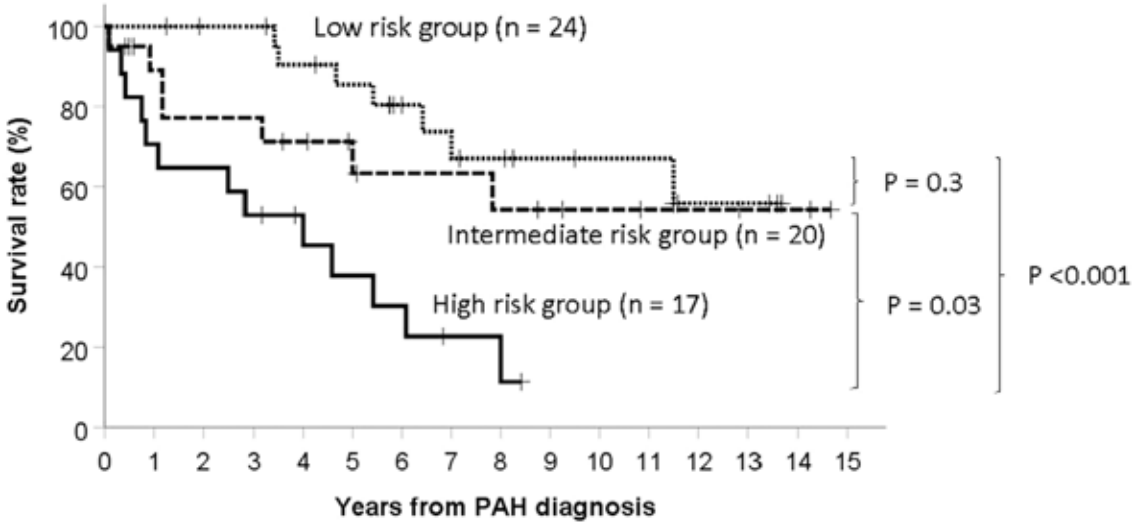

Figure 2. The modified approach by weighting WHO functional class and cardiac index

the risk of other variables. The modified version successfully separated survival curves of 3 risk groups, and survival rates were significantly different between high risk group and low or intermediate risk group ($P < 0.001$ and 0.025) (Figure 2). Principally concordant results were observed in SSc-PAH sub-population.

Conclusion: The simplified 2015 ESC/ERS PAH risk stratification using 6 variables at baseline failed to predict prognosis of patients with CTD-PAH accurately. The modified approach weighting WHO-FC and CI might be useful to discriminate survival rates among risk groups, but it should be verified using independent patient cohorts.

Normal ranges: Esophageal transit time (ETT) = >15 seconds; Escophageal emptying at 10 sec= = 83%; liquid emptying = at 1 hour <39%, or at 2 hours <78%; Delayed liquid T1/2 >74 min solid emptying 2 hrs = 40%; solid emptying 4 hrs = 90%; small bowel transit time at 6 hrs <50%; colonic transit time at 72 hrs <67%

Background/Purpose: The gastrointestinal (GI) tract is the most commonly affected internal organ system in systemic sclerosis (SSc), resulting in significant morbidity and mortality. Several studies that objectively evaluated GI tract dysfunction and abnormal transit in SSc have shown that such abnormalities associate inconsistently with clinical symptoms and severity, resulting in challenges related to diagnosis, risk stratification, and therapeutic inter-

Table 2. Pearson Correlation Table between Whole Gut Transit Study and GI Symptoms (UCLA GIT 2.0)

ventions. We sought to determine whether clinical symptoms associate with objective evidence of GI dysmotility in SSc, and to determine how patterns of abnormal transit fit with existing GI symptom and severity scales in the field of scleroderma.

Methods: Patients with SSc and GI symptoms were recruited from clinic in the Johns Hopkins Scleroderma Center. Patients completed the UCLA GIT 2.0 survey, were assessed by the Medsger GI severity score, and underwent a nuclear medicine-based whole gut transit (WGT) study. The association between patient GI symptoms, GI severity, and characteristics of abnormal transit in each region of the GI tract were compared, and the association between areas of abnormal transit and GI severity was also examined.

Results: WGT scintigraphy was performed on 63 SSc patients with active GI symptoms and 18 healthy controls. In the cohort, the average age was 58.4 years, with 84.1% being female and 80.6% being Caucasian. Median disease duration was 10 years, and 27.1% had diffuse cutaneous disease. Approximately 60% of SSc patients had more than one abnormal region on WGT studies. SSc patients were more likely to have delayed esophageal transit time [28% vs. 10%; p=0.004], delayed esophageal percentage emptying at 10 seconds [80% vs 92%; p=< 0.001], delayed gastric emptying at both 2 hours [61% vs. 84%; p=0.003] and 4 hours [95% vs. 98%; p< 0.001], and delayed colonic emptying at 72 hours [44% vs. 84%; p=0.008] compared to healthy controls (Table 1). Evaluating the association between Medsger GI severity scores (MGISS) and WGT results, patients with MGISS of 2 had slower esophageal transit and more gastroparesis compared to other Medsger groups. Patients with pseudo-obstruction and/or malabsorption (MGISS=3) were significantly more likely to have severe colonic delay (p< 0.05). Patients requiring total parenteral nutrition (MGISS=4) were significantly more likely to have small bowel dysmotility (p< 0.05). When comparing symptoms assessed by the UCLA GIT 2.0 with WGT measurements, symptoms of distention and bloating were inversely associated with percent gastric emptying at 2 hours (r=-0.34; p=0.011), and symptoms of diarrhea were positively associated with higher colonic transit times (r=0.031; p=0.026) (Table 2).

Conclusion: WGT provides a non-invasive assessment of bowel dysfunction and defines specific anatomical areas that associate with clinical symptoms and GI severity. This has implications not only in enhancing our understanding of symptom etiology, but also to guide therapy. These results are exciting in the face of known challenges in capturing objective pathology in SSc GI disease, and determining the association with active GI symptoms and outcome measures.

SSc (calcinosis)	2.05	1.38 – 2.73	1.84	1.19 – 2.49

* p-for group difference= 0.0137
** p-for group difference= 0.0734

Background/Purpose: Calcinosis cutis due to ectopic mineralization is a common and disabling complication of systemic sclerosis (SSc) that has poorly understood pathogenesis and no effective treatment. Inorganic pyrophosphate (PPi) is a key regulator of ectopic mineralization acting by inhibiting hydroxyapatite crystal growth (1,2). Ectopic mineralization has been attributed to low PPi levels in several genetic disorders such as pseudoxanthoma elasticum, generalized arterial calcification of infancy, and arterial calcification due to CD73 deficiency (3). Herein, we sought to test the hypothesis that reduced plasma PPi levels may be associated with SSc and play a pathogenic role in calcinosis.

Methods: Subjects meeting the 2013 ACR criteria for SSc (4) and age-matched controls without SSc were recruited from Rheumatology outpatient clinics for this IRB-approved study. Calcinosis was confirmed either by clinical criteria or by imaging. Levels of PPi in platelet-free plasma were measured by enzymatic reaction using ^{14}C-labeled uridine-diphosphoglucose as substrate (5). Student T-test was used to compare mean PPi levels between control and SSc groups and linear regression to compare means between the 3 groups (control, SS-calcinosis and SSc-no calcinosis) with adjustment of potential confounders.

Results: We studied 33 subjects (19 control and 14 SSc, 5 of whom had SSc-calcinosis). In the SSc cohort, 60% had limited cutaneous SSc, as did 4 of 5 subjects with SSc-calcinosis. The mean disease duration (from non-Raynaud symptoms) was 18.7 (SD 8.7) years in SSc-calcinosis and 10.3 (SD 7.4) years in SSc-no calcinosis groups.

Figure 1 shows that the SSc cohort had significantly lower plasma levels of PPi (mean=2.25 uM vs 3.04uM, p=0.0083) compared to the control group (see Table 1, p for group difference= 0.0137). After adjusting for sex, the highest mean PPi levels were seen in the control group and the lowest in the SSc-calcinosis group.

Conclusion: Our findings indicate PPi levels are significantly reduced in SSc patients with calcinosis. The results suggest that PPi deficiency may be due to genetic or environmental influences that may be important in the pathophysiology of calcinosis, and could serve as a biomarker of the ectopic mineralization process. Larger clinical studies to confirm our findings are warranted.

The MUC5B Promoter Variant Does Not Predict Outcomes in Systemic Sclerosis-related Interstitial Lung Disease

Elizabeth Volkmann,[1] Donald Tashkin,[2] Michael Roth,[3] Ning Li,[2] Grace Kim,[2] Jonathan Goldin,[2] Maureen Mayes,[4] Julio Charles,[5] Philip Clements,[2] Daniel Furst,[6] Dinesh Khanna,[7] Robert Elashoff,[2] and Shervin Assassi[4], [1]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, [2]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, [3]University of California, Los Angeles, David Geffen School of Medicine, Los Angeles, CA, [4]Division of Rheumatology and Clinical Immunogenetics, University of Texas McGovern Medical School, Houston, Texas, USA, Houston, TX, [5]University of Texas, Houston, Houston, [6]University of California, Los Angeles, CA, [7]Department of Medicine, University of Michigan, Ann Arbor, Michigan, USA, Ann Arbor

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) affects the majority of patients with systemic sclerosis (SSc). The disease course of ILD varies among SSc patients and no reliable clinical or biological parameters consistently predict outcomes. We investigated whether the presence of a gain-of-function MUC5B promoter polymorphism, previously shown to be strongly associated with idiopathic pulmonary fibrosis and rheumatoid arthritis-related ILD predicted response to immunosuppression with cyclophosphamide (CYC) and mycophenolate (MMF) in SSc-ILD.

Methods: 142 patients in Scleroderma Lung Study (SLS) II (Tashkin et al. Lancet Resp Med 2016) were randomized to receive either MMF for 2 years or oral CYC for 1 year followed by 1 year of placebo. Presence of ground glass opacity was a requirement for enrollment. Genotyping of the MUC5B rs35705950 single nucleotide polymorphism was performed using TaqMan Genotyping Assaysin all patients with an available DNA sample. The forced vital capacity (FVC) and the diffusing capacity for carbon monoxide (DLCO) were measured every 3 months. Quantitaive Lung fibrosis (QLF) and Quantitative

ILD (QILD) scores for whole lung (WL) and zone of maximum involvement (ZM) were measured at baseline and 24 months. Linear regression models with the outcomes of change in radiographic fibrosis and ILD scores at 24 months were created to investigate the relationship between the presence of the MUC5B variant and SSc-ILD progression.

Results: Among 128 SLS II participants, 23 (18%) possessed at least one copy of the MUC5B rs35705950 minor allele. There were no significant differences in the baseline characteristics between SSc-ILD patients with and without this variant with respect to age, sex, %diffuse disease, disease duration, FVC, DLCO, radiographic extent of fibrosis, nor the presence of honeycombing on high resolution computed tomography. Similar to available data from the general population, this variant was rare among African Americans (4%) in our cohort. The presence of this MUC5B variant was not significantly associated with the change of QLF-ZM, QLF-WL, QILD-ZM, QILD-WL scores at 24 months, even after adjusting for baseline extent of fibrosis, treatment arm, and race (Table 1). In addition, using a joint model analysis with the covariates of FVC, treatment arm, race and a time trend, the presence of the MUC5B variant did not predict the course of the FVC%-predicted.

Conclusion: Among SSc-ILD patients with ground glass opacity on imaging who received treatment with CYC or MMF in a rigorously-conducted clinical trial, the presence of MUC5B rs35705950 minor allele did not predict ILD disease progression. Future studies are needed to further investigate how the presence of this variant affects outcomes in other SSc populations.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Myocarditis is a life-threatening inflammatory disease increasingly reported in Systemic Sclerosis(SSc); the histological, clinical and prognostic features of SSc-myocardits have not been elucidated yet. We aimed to evaluate clinical, histological and prognostic features of SSc-myocarditis compared to patients with endomyocardial biopsy(EBM)-proven virus-negative myocarditis(VNM).

Table 1. Demographic and clinical characteristics of our cohort.

SSc patients (12)	
Females, n (%)	11 (91.7)
Age (years), mean ± SD	49.3 ± 14.2
Disease duration (months), mean ± SD	47.6 ± 18.3
Diffuse cutaneous disease, n (%)	7 (58.3)
Anti-Scl70, n (%)	8 (66.7)
Anti-centromere, n (%)	4 (33.)
Clinical onset	
Subclinical onset, n (%)	6 (50.0)
Heart failure, n (%)	3 (25)
Ventricular arrhythmias, n (%)	2 (16.7)
Chest pain, n (%)	1 (8.3)
Cardiac deaths, n (%)	6 (50)*
Patients with i-VNLM (12)	
Age (years), mean ± SD	47.7 ± 10.8
Clinical onset	
Subclinical onset, n (%)	2 (16.7)
Heart failure, n (%)	0 (0)
Ventricular arrhythmias, n (%)	7 (58.3)
Chest pain, n (%)	3 (25)
Cardiac deaths, n (%)	0 (0)
Patients with a-VNLM (8)	
Age (years), mean ± SD	48.4 ± 16.3
Systemic Lupus Erythematosus, n (%)	3 (37.5)
Anti-synthetase syndrome, n (%)	2 (25.0)
Anti-phospholipid syndrome, n (%)	1 (12.5)
Undifferentiated connective tissue disease, n (%)	1 (12.5)

Clinical onset	
Subclinical onset, n (%)	6 (75)
Heart failure, n (%)	0 (0)
Ventricular arrhythmias, n (%)	2 (25.0)
Chest pain, n (%)	0 (0)
Cardiac deaths, n (%)	0 (0)

*SSc= systemic sclerosis, classified according to ACR/EULAR 2013 classification criteria; VNLM=virus negative lymphocytic myocarditis; i-VNLM= isolated VNLM; a-VNLM= VNLM in the course of systemic immune-mediated diseases other than SSc; SD= standard deviation; n= number; *3 patients died suddenly do to fatal arrhythmias, 3 patients died for congestive heart failure.*

Methods: we enrolled 12 SSc patients with EBM-proven myocarditis(SSc-VNM), 12 patients with isolated VNLM(i-VNM) and 8 patients with VNLM in the context of other systemic autoimmune diseases(a-VNM), matched by age, gender and cardiovascular risk profile. On EMB, VNM was classified as acute, chronic and subacute, and the degree of fibrosis was scored as 0=absent,1=mild;2=moderate;3=severe. Clinical data, cardiac enzymes, echocardiogram, 24h-ECG-Holter and cardiac magnetic resonance(CMR), were obtained at baseline and at 3, 6 and 12 months, then during follow-up as clinically needed. Myocarditis-related complications(cardiac death, end-stage heart failure[HF], malignant arrhythmias or need for ICD-implantation) were recorded during a 1-year follow-up. Non parametric tests were used.

Results: clinical and demographic characteristics of our cohorts are represented in Table1. Clinical presentation did not statically differ between the 3 groups(p=ns), although dyspnoea class was significantly higher at presentation in SSc-VNLM patients compared to i-VNLM and a-VNLM (median 2 vs 0,p=0.047) and we found HF only in SSc-VNLM(25%). At CMR, myocardial oedema was more frequent in i-VNLM and a-VNLM, compared to SSc-VNLM(75% and 75% vs 8.3%,p=0.002), whereas late gadolinium enhancement(LGE) was present in all SSc-VNLM patients and in the majority of i-VNLM(87.5%) and a-VNLM(83.3%) patients(p=0.457). Levels of troponin T and NT-proBNP, left ventricular ejection fraction and number of ventricular ectopic beats on 24h-Holter did not differ between groups(p=ns). On EBM, acute myocarditis was diagnosed in 50% of both i-VNLM and SSc-VNLM patients, compared to 12.5% of a-VNLM patients(p=0.178); chronic myocarditis was diagnosed in 25% of both i-VNLM and SSc-VNLM patients, compared to 12.5% in a-VNLM patients(p=0.758), while subacute myocarditis was almost statically significantly more frequent in i-VNLM(75%), as compared to a-VNLM and SSc-VNLM patients(25% for both,p=0.063). The mean fibrosis score was significantly higher in SSc-VNLM patients(1.5±1.08) compared to a-VNLM(0.87±0.35) and

i-VNLM(0.58±0.52)(p=0.046). As about the clinical outcome, the number of patients who died during follow-up due to cardiac complications (sudden cardiac death and HF) was significantly higher in SSc-VNLM patients(6 patients,50%), as compared to a-VNLM(0%) and i-VNLM(1 patient,8.3%)(p=0.006). Arrhythmic complications and need for ICD implantation were comparable between groups(25% and 8.3% in SSc-VNLM, 25% and 12.5% in a-VNLM, and 33.3% and 33.3% in i-VNLM,p=ns).

Conclusion: SSc-related myocarditis tends to present more frequently with HF and a higher dyspnoea class and to show higher degrees of fibrosis on EBM. These peculiar features are paralleled by a worst cardiac prognosis.

Does Digital Thermal Monitoring Correlate to Specific Nailfold Videocapillaroscopy Abnormalities?

Mislav Radic,[1] Rebecca Overbury,[2] and Tracy Frech[3], [1]University Hospital Split, Split, Croatia, [2]University of Utah, Departments of Pediatrics and Internal Medicine, Division of Rheumatology, Salt Lake City, UT, [3]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The fingers have specialized structural and functional features for thermoregulation, and are the most common areas of Raynaud's phenomenon (RP) in systemic sclerosis (SSc). Nailfold videocapillaroscopy (NVC) is the gold standard for quantification of vascular abnormalities in SSc-RP. Digital thermal monitoring (DTM) of vascular reactivity assesses Doppler ultrasound hyperemic, low frequency, blood velocity of radial artery and fingertip vascular function. In this study, we investigated the correlation of NVC patterns and DTM variables in SSc patients.

Methods: Patients enrolled in a single center SSc (2013 ACR/EULAR Classification Criteria) registry who had NVC and DTM performed at a time standard care visit were included in this analysis. The SSc clinical features were recorded. DTM of both hands was obtained during 5 min stabilization, 5 min cuff inflation to 50 mm Hg greater than systolic blood pressure, and 5 min deflation using an automated, operator-independent protocol (VENDYS, Endothelix Inc., Houston, TX). Thermal changes during a 5 min arm-cuff induced reactive hyperemia test were monitored continuously in the fingertip of both the occluded and non-occluded arms using VENDYS software. Dual channel temperature data were simultaneously recorded at a 1 Hz sampling rate. Temperature rebound is defined as temperature prior to cuff inflation subtracted from temperature maximum after cuff relief. Temperature rebound area under the curve is provided as a single value of DTM. Vascular reactivity index (VRI) was calculated on adjusted temperature rebound. NVC was performed to classify the patients into one of the three main patterns of SSc microangiopathy ("early", "active", "late"). The following parameters were analyzed in eight fingers of the hands (excluding thumbs): number of

capillaries/mm, number of enlarged and giant capillaries, microhemorrhages, and avascular score. Statistical evaluation was performed by non-parametric tests to assess the correlation of NVC and DTM variables.

Results: Thirty-one SSc subjects with interpretable NVC and DTM performed on the same day were included in the study. Thirty subjects were female (91%) and mean age ± SD was 58 ± 12 yrs. Mean duration from first non-RP symptom of SSc was 10.8 ± 8 yrs. VRI was progressively higher in SSc patients with the 'early', 'active' and 'late' NVC patterns of microangiopathy ($p< 0.0001$, Kruskal-Wallis test). There was a significant negative correlation between VRI and microhemorrhages score ($r=-0.363$, $p=0.044$, Spearman's rank correlation). There was no correlation between VRI and other NVC parameters (data not show).

Conclusion: Correlation of NVC patterns and microhemorrhages parameter with VRI seen in this non-invasive study warrants further research. The lack of complete correlation between functional and morphological microvascular abnormalities, measured by DTM and NVC, suggests each of these tools has a place in the evaluation of microangiopathy aspects in SSc patients and complement each other.

Rituximab Rescue Therapy in Patients with Systemic Sclerosis or Other Connective Tissue Diseases and Refractory Interstitial Lung Disease

Magdalena Benad,[1] Dirk Koschel,[1] Kristine Herrmann,[1] Kristin Wiefel,[1] Alexander Kleymann,[1] and **Martin Aringer**[2], [1]University Medical Center and Faculty of Medicine TU Dresden, Dresden, Germany, [2]Division of Rheumatology, Department of Medicine III, University Medical Center & Faculty of Medicine Carl Gustav Carus, TU Dresden, Dresden, Germany, Dresden, Germany

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster I
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common and life-threatening organ manifestation of patients with various connective tissue diseases (CTDs), and with systemic sclerosis and anti-synthetase syndromes, in particular. B cell depletion with rituximab (RTX) is used as an off-label rescue therapy in patients with CTD-ILD progressing despite conventional immunosuppression. The purpose of this study was to systematically evaluate the outcome of such RTX rescue therapy in our center.

Methods: For the years 2009 through 2018, a monocentric historical prospective chart review was performed on all patients with RTX treatment for interstitial lung disease and a connective tissue disease. Patients were identified by systematically screening documentation of all CTD patients treated for ILD on the Rheumatology ward and of all patients with systemic sclerosis (SSc), poly- or dermatomyositis, mixed connective tissue disease (MCTD) and Sjögren's syndrome for patients with ILD and treated with rituximab. All patients were followed until the end of 2018, death, or loss of follow-up (n=1). ILD was confirmed by both high resolution CT imaging and pulmonary function tests (PFT) with forced vital capacity (FVC) and/or total lung capacity (TLC) and/or corrected diffusion capacity for carbon monoxide (DLCOc) < 80% of predicted value. Mean changes in %FVC (n=18), %TLC (n=20) and %DLCOc (n=17) to baseline were compared between 2-12 months before (pre-RTX) and 2-12 months after (post-RTX) the initial RTX administration. Paired t-test and Wilcoxon matched pairs signed rank test were used as appropriate.

Results: A total 21 patients were identified, of whom 15 and 2 patients met the ACR/EULAR criteria for SSc and primary Sjögren's syndrome (SjS), respectively, and 4 patients the EULAR/ACR criteria for polymyositis (PM). Patients received RTX at a median of 13 [IQR 5-49] months after the ILD diagnosis. The median follow-up after initial RTX treatment was 2.1 (0.1-9.8) years. The baseline median FVC was 63.2% [IQR 52.9-78.2%], mean±SD TLC 72.1±17.3% and mean±SD DLCOc 38.4±18.3%. Before RTX administration, patients had received a median of 2 (1-4) other immunosuppressive therapies, including cyclophosphamide in n=14 patients. In contrast to a mean decline of -6.4±11.8% in FVC and -3.2±8.5% in TLC in the pre-RTX interval, paired analysis of PFT data showed a mean improvement of +5.2±9% in FVC ($p< 0.01$) and of +2.6±8.1% in TLC ($p=0.04$) post-RTX. No significant improvement in DLCOc was seen (pre-RTX -2.8% [IQR -12.2-0.8%], post-RTX -1.8% [IQR -3.3-11.1%]). A total of five of the 21 RTX-treated patients died. One SSc patient died of non-small-cell-lung cancer with brain metastases, diagnosed 1.5 years after last RTX treatment. One patient with SSc developed pneumonia after the first RTX administration and died in septic shock. Two other SSc patients (one with sigmoid cancer) died of right heart failure due to pulmonary embolism 1 and 7 months after last RTX administration. The death of one patient with PM was reported due to an unspecified malignancy.

Conclusion: Our monocentric experience is in line with stabilization of lung function in CTD patients undergoing RTX rescue therapy for severe, refractory ILD, and in SSc, in particular.

Vascular Damage Is Less Present in an Early Inception Cohort in Takayasu's Arteritis

Fatma Alibaz-Oner [1], [1]Marmara University Faculty of Medicine,Department of Rheumatology,Istanbul,Turkey, Istanbul, Turkey

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is only retrospective and very limited data for the long term prognosis of Takayasu's Arteritis (TAK), a rare large-vessel vasculitis. In this study, we aimed to present the preliminary results of a Takayasu Inception Cohort settled for long term, prospective follow-up of only newly-diagnosed patients with TAK.

Methods: Patients fullfilling the American College of Rheumatology 1990 criteria for TAK and diagnosed in the last 12 months were included to the study. Patients' data were recorded in an electronic database of an international "Takayasu's Arteritis Registry" requiring baseline and at least annual visits. Data is compared with an historical Turkish cohort previously published (*Bıçakçıgil, et al, 2009).*

Results: The study included 170 patients (age: 38.5±13.1 years, F/M: 143/27) with TAK from 15 tertiary Rheumatology centers in Turkey. The mean symptom duration of patients was 5.2 years at diagnosis. According to the angiographic classification, 68.2% of the study group had type I and only 18.3% had type V disease. When we

Table 1: Clinical characteristics of Inception and Retrospective Cohorts from Turkey

	Inception Cohort (n=170)	Retrospective Cohort (*Bicakcigil, et al*) (n=248)
Constitutional symptoms	115/165(69.6%)	163/248/ (66%)
Limb claudication	87/131(66.4%)	119/248 (48%)
Carotidynia	31/130 (18.2%)	-
Pulseless	45/130(34.6 %)	218/248 (88%)
Musculoskeletal manifestations	90/163 (52.9%)	104/248 (42%)
Mucocutaneous manifestations	30/162 (17.6%)	22/248 (8.8%)
Respiratory manifestations	47/163 (28.8%)	22/184 (12%)
Neurologic manifestations	69/163 (40.6%)	156/248 (63%)
Cardiac involvement	64/146 (43.8 %)	141/248 (57%)
Ophthalmologic involvement	27/166 (16.2%)	57/248 (36%)

compared our results to our retrospective cohort (previously published by Turkish Takayasu Arteritis Study Group), constitutional symptoms (115/165= 69.6% vs 66%) and limb claudication (87/131= 66.4% vs 48%) were observed to be more frequent, whereas pulselessness (45/130=34.6 %vs 88%) was less in the inception cohort.(Table 1) Carotidynia was present only in the inception cohort. Similarly, mucocutaneous symptoms also seem to be a feature of newly-diagnosed disease (30/162=18.5% vs 8.8%). Regarding comorbidities at diagnosis, the rate of dyslipidemia was 17.6 (30/165)%, diabetes mellitus 15.1(25/165)%, smoking 20 (34/164)% and obesity (BMI >30) 14 (22/157)% among TAK patients. All patients were given oral corticosteroid (CS) therapy (0.5-1 mg/kg) at diagnosis, 17 patients (17/170=10%) also having CS pulses. In addition to CSs, 86 patients (50.6 %) were given methotrexate, 31patients (18.2%) azathioprine, 6 (3.5%) cyclophosphomide, 12 patients (7.1%)leflunamide, 2(1.2%) patients mycophenolate mofetil and 5(2.9%) patients biologics at disease-onset(2 tocilizumab, 2 infliximab, 1 adalimumab). Biologic agents were chosen for 7 patients (7/32) at last vizit(1 adalimumab, 4 tosiluzumab, 2 infliximab). Seventy-three patients (42.9%) had follow-up > 3 months. Remission was observed 78% of patients. At least one relaps was observed 40% of these patients. Mortality rate was 4.1% (3/73 patients) during a mean 25.7 months follow-up.

Conclusion: Our results suggest that, in an inception cohort, signs and symptoms of 'systemic inflammation' is more prominent in newly-diagnosed TAK patients, whereas vascular extent and damage accumulates during the disease course. The long term follow-up of our inception cohort shows that 40% of patients relapse within 2 years after diagnosis in spite of IS treatments.

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatic (PMR) is a common rheumatic inflammatory disease in the elderly. Glucocorticoids (GC) are the therapeutic mainstay in PMR but induce significant toxicity in this population. Methotrexate (MTX) has demonstrated efficacy as a steroid sparing agent in two randomized clinical trials but has not been studied as first line therapy. Our objetive is to evaluate the efficacy and safety of first-line MTX plus initial and on demand local GC infiltrations without oral GC.

Methods: In a single-center prospective observational study, 26 patients with newly diagnosed PMR (EULAR/ACR criteria) who had not received oral GC, were treated with MTX plus initial and on demand shoulder infiltrations with 40 mg triamcinolone acetonide for 24 months. At each visit (at one month and on a quarterly basis) patient 100 mm VAS pain for shoulders and hips, morning stiffness duration and HAQ were recorded. Remission was defined as absence of reported pain and morning stiffness and normalization of acute phase reactants (APR). After two years of treatment, MTX was withdrawn and patients were followed-up for additional 14±4 months. The primary end point was the rate of PMR remission at 6 months. Secondary outcomes were toxicity, remission at 24 months and relapses after MTX withdrawal.

Results: 26 patients were included. Three patients did not complete the study due to prostate cancer, an asthmatic episode requiring high dose GC, or MTX intolerance. These 23 patients (57% female) had a mean age of 74±8 years and a mean disease duration of 110±55 days. Initial weekly MTX dose was 5 mg in 14 patients and 7,5 mg in 9, and further increased according to efficacy/toxicity. Only 5 patients required more than 10 mg and the mean dose was 9±3 mg. Mean time until remission was 2.7±1.9 months. Other measures of efficacy are shown in Table 1. The mean number of GC infiltrations along the 24 months was 1.4±0.7 per shoulder. During the first 24 months, 5 patients had relapses that resolved with MTX dose increase and/or GC shoulder infiltration. MTX was well tolerated in all but one patient initially excluded due to digestive intolerance. Side effects included one alopecia, one mild thrombopenia, one diabetes onset, and one respiratory infection, but none required MTX suspension. None suffered osteoporotic fractures. In 20 of the 23 patients, MTX was stopped after 24 months, and after 14±4 months of follow-up no relapses were observed.

	Baseline	Month 6	*p value*	Month 24	*p value*
mVAS shoulders	7,87 (0-6)	0,57 (0-6)	*p=0,000**	0,74 (0-4)	*p=0,000**
mVAS hips	6,39 (3-9)	0,61 (0-5)	*p=0,000**	0 (0-0)	*p=0,000**
Morning stiffness (min)	90 (60-120)	0 (0-90)	*p=0,000**	0 (0-0)	*p=0,000**
mHAQ	2.2 (1-3)	0.3 (0-2.1)	*p=0,000**	0 (0-0.4)	*p=0,000**
Abnormal CPR	22 (97)	3 (13)	*p=0,000***	0 (0)	*p=0,000***
Abnormal VSG	21 (91)	2 (9)	*p=0,000***	0 (0)	*p=0,000***

*Wilcoxon rank test, **McNemar test.

Conclusion: Low dose methotrexate is effective as initial therapy for PMR in combination with a very limited exposure to local GC infiltrations. Randomized controlled trials are warranted to confirm this observation that may significantly reduce GC side effects in this population

Association Between Acute-phase Reactants, interleukin-6(IL6), Tumor Necrosis Factor-a(TNFa) and Disease Activity in Takayasu's Arteritis During Follow-up with Repeated Evaluation of Vascular Imaging Manifestations

JIng LI,[1] Yunjiao Yang,[1] Yanhong WANG,[2] Jiuliang Zhao,[1] Mengtao Li,[3] Xinping Tian,[1] and Xiaofeng Zeng[1], [1]Peking Union Medical College Hospital, Beijing, China (People's Republic), [2]Institute of Basic Medical Sciences, Chinese Academy of Medical Sciences, School of Basic Medicine, Beijing, China (People's Republic), [3]Dept. of Rheumatology, Peking Union Medical College Hospital (West Campus), Beijing, China, Beijing, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the laboratory indicators of disease activity during follow-up of Takayasu's arteritis(TAK).

Methods: Electronic data of 588 patients with TAK enrolled in the Chinese Registry for Systemic Vasculitis (CRSV) from 2013 to April 30 of 2019 were exported for analysis. Disease activity was judged with clinical manifestations, BVAS and VDI scoring, laboratory results and vascular imaging including Doppler and/or CTA by a senior rheumatologist in each visit. Records of visit with repeated vascular imaging examinations were collected,and erythrocyte sedimentation rate(ESR), the serum levels of high sensitive C-reactive protein(hsCRP), interleukin-6(IL6), and tumor necrosis factor-a(TNFa) of these patients in each visit were analyzed for the association with disease activity by logistic regression.

Table 1 Univariate and multivariate logistic regression analysis of ESR, hsCRP, IL6 and TNFα with TAK disease activity

Variations in equation	Total		After correction of age		After correction of gender		After correction of disease duration		Exclude patients with medication of TNFα or IL-6 inhibitor and/or pregnancy	
	P-value	Expectancy(95%CI)	*P*-value	Expectancy(95%CI)	*P*-value	Expectancy(95%CI)	*P*-value	Expectancy(95%CI)	*P*-value	Expectancy(95%CI)
Log_{10}ESR	<0.001	7.69 (5.55, 10.65)	<0.001	7.70 (5.56, 10.66)	<0.001	7.69 (5.55, 10.65)	<0.001	7.69 (5.55, 10.65)	<0.001	7.88 (5.48, 11.32)
Log_{10}hsCRP	<0.001	4.65 (3.81, 5.66)	<0.001	4.67 (3.83, 5.70)	<0.001	4.65 (3.81, 5.67)	<0.001	4.65 (3.81, 5.67)	<0.001	4.94 (3.96, 6.16)
Log_{10}IL6	<0.001	8.78 (6.00, 12.84)	<0.001	8.83 (6.03, 12.92)	<0.001	8.71 (5.95, 12.75)	<0.001	8.80 (6.02, 12.87)	<0.001	12.68 (8.09, 19.87)
TNFα(2)	0.001	1.50 (1.17, 1.93)	0.001	1.51 (1.17, 1.93)	0.001	1.50 (1.17, 1.93)	0.001	1.50 (1.17, 1.93)	0.006	1.46 (1.11, 1.90)
Log_{10}ESR	0.02	1.69 (1.07, 2.68)	0.03	1.68 (1.06, 2.65)	0.02	1.70 (1.07, 2.69)	0.03	1.68 (1.07, 2.66)	0.05	1.64 (0.99, 2.69)
Log_{10}hsCRP	<0.001	2.53 (1.92, 3.34)	<0.001	2.56 (1.94, 3.39)	<0.001	2.55 (1.93, 3.37)	<0.001	2.54 (1.92, 3.35)	<0.001	2.49 (1.82, 3.41)
Log_{10}IL6	<0.001	3.72 (2.42, 5.72)	<0.001	3.72 (2.42, 5.71)	<0.001	3.67 (2.39, 5.64)	<0.001	3.74 (2.43, 5.74)	<0.001	4.05 (2.37, 6.91)
TNFα(2)	0.19	1.22 (0.91, 1.65)	0.17	1.23 (0.91, 1.66)	0.18	1.23 (0.91, 1.66)	0.19	1.22 (0.91, 1.65)	0.24	1.21 (0.88, 1.66)

Results: 1483 records of visit were collected. After transformation, log_{10}ESR, log_{10}hsCRP and log_{10}IL6 were found to be distributed normally. Due to the non-normal distribution pattern, TNFa was stratified into 2 groups by the upper normal range in healthy people(< 8.1pg/ml).In univariate logistic regression analysis, log_{10}ESR, log_{10}hsCRP, log_{10}IL6 and TNFa were strongly associated with the disease activity respectively. But in multivariate logistic regression analysis, the association between TNFa and disease activity disappeared. After correction of age, gender or disease duration, the result of logistic regression analysis were similar.After exclusion of records from the patients with medication of TNFa and/or IL6 inhibitors, and the patients with pregnancy during follow-up, the results of univariate logistic regression analysis were similar, but in multivariate analysis association between log_{10}ESR and disease activity disappeared.(Table 1)

Conclusion: Repeated vascular imaging examination in each follow-up visit combined with other clinical evaluation methods had proved the reliability for using ESR, hsCRP, IL6 and TNFa as indicator in evaluation of disease activity in patients with TAK. The effect of hsCRP and IL6 may be stronger than ESR and TNFa.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recently, the use of hematologic indexes as markers of systemic inflammation has been reported in oncological, cardiovascular and rheumatic diseases. Only 2 studies evaluated their role in polymyalgia rheumatica (PMR).

Our objective was to primarily compare the levels of neutrophil- (NLR), monocyte- (MLR), eosinophil- (ELR), basophil- (BLR) and platelet to lymphocyte ratio (PLR) in PMR and control patients without inflammatory conditions and, secondarily, to evaluate their use as prognostic markers in PMR.

Table 1. Age, gender and laboratory date of both populations

	PMR (n=63)	Controls (n=101)
Age, *years mean (SD)*	76.7 (7.6)	73.2 (6.9)
Gender, *M/F*	21/42	17/84
WBC, *10^9/L mean (SD)*	8.48 (2.37)	6.51 (1.57)
Neutrophil count, *10^9/L mean (SD)*	5.35 (1.86)	3.73 (1.21)
Lymphocyte count, *10^9/L mean (SD)*	2.11 (0.81)	2 (0.55)
Monocyte count, *10^9/L mean (SD)*	0.72 (0.25)	0.53 (0.18)
Eosinophil count, *10^9/L mean (SD)*	0.23 (0.24)	0.21 (0.16)
Basophil count, *10^9/L mean (SD)*	0.03 (0.02)	0.03 (0.02)
Platelets count, *10^9/L mean (SD)*	284.02 (82.41)	249.09 (55.22)

Table 3. Comparison of NLR in PMR patients based on relapses, recurrences and use of methotrexate

		NLR	p
Relapses	yes	2.33 (0.77)	0.07
	no	3 (1.59)	
Recurrences	yes	2.55 (1.02)	0.57
	no	2.81 (1.46)	
Use of MTX	yes	2.54 (0.92)	0.3
	no	2.91 (1.60)	

Methods: This retrospective case control study included 63 patients with PMR and 101 patients without inflammatory conditions who attended our Hospital. Clinical data and blood cell counts at diagnosis (prior to start treatment) were obtained from medical records and laboratory reports.

We compared the indexes of both groups at diagnosis by a Student's t test and sequentially performed a subgroup analysis in PMR patients in order to determinate the utility of the indexes to evaluate prognosis, relapses and recurrences. We also analyzed the use of methotrexate as a marker of more severe disease. A correlation with inflammatory markers using Student's t test and Pearson correlation coefficient was performed

Results: Age, gender and laboratory data of PMR and control patients are shown in Table 1. The control group included patients with osteoarthritis (78,2%), fibromyalgia (9.9%) and others soft tissue non inflammatory conditions (11.9%). NLR and MLR levels were significantly higher in PMR patients than controls (NLR 2.77 vs 1.99, $p < 0.001$ and MLR 0.37 vs 0.27, $p < 0.001$). All the other indexes did not differ between populations. Clinical characteristics of PMR patients are shown in Table 2. The median time of follow up of PMR patients was 24.1 months (IQR 10.5-35.3). When evaluating this subgroup of patients, neither NLR nor MLR were associated with relapses, recurrences or need of methotrexate during follow up. Results shown in table 3. No correlation was found between both indexes and the duration of symptoms before diagnosis and duration of glucocorticoid treatment. The median erythrocyte sedimentation rate (ESR) was 41.5 mm/hr (19 – 62) and C reactive protein (CRP) level was 2.48 mg/L (0.54 – 3.38) at diagnosis. We found a poor correlation between NLR and MLR and ESR and CRP levels. Fourteen PMR patients (22.2%) had normal values of ESR and CRP. However, the treating physician considered the diagnosis on a clinical basis and started treatment accordingly. When comparing NLR and MLR levels, there were no differences between this group and control patients; on the other hand, a significant difference was found with PMR patients who presented with high levels of acute phase reactants.

Conclusion: NLR and MLR levels were significantly higher in PMR patients than controls. Baseline indexes did not correlate adequately with acute phase reactants and they were not able to predict a poor outcome in PMR.

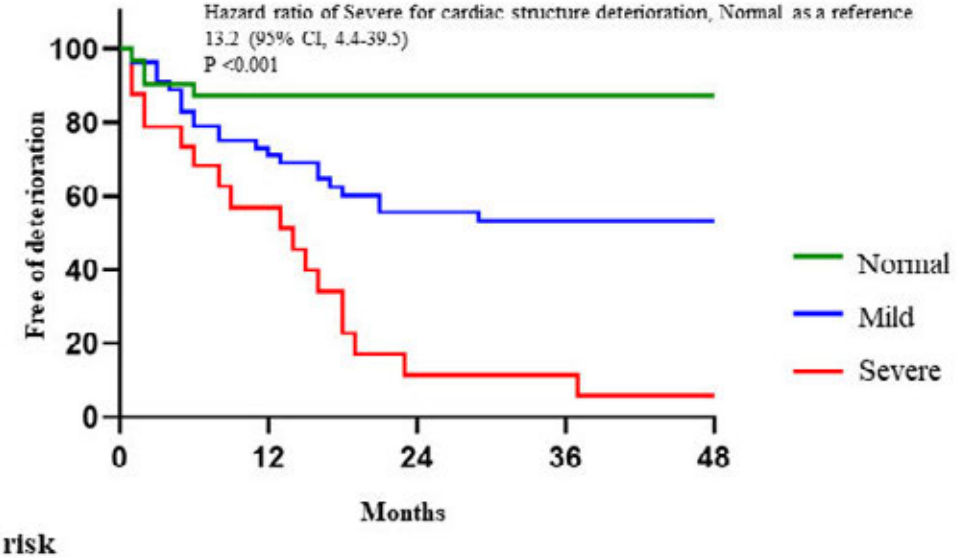
Background/Purpose: Heart involvements are closely associated with prognosis in patients with Takayasu's arteritis (TA). This study was aimed to assess the long-term adverse outcomes of cardiac structure and function and their underlying risk factors in TA.

Methods: One hundred and ninety-eight patients, diagnosed as TA, at the Department of Rheumatology, Zhongshan Hospital from January 2012 to December 2017 were recruited in the present study. Patients were divided into normal, mild and severe groups based on the severity of cardiac structure and function impairment. Data, including demographics, clinical characteristics, treatment at baseline, and cardiac outcomes during long-term follow-up were collected.

Results: 60.1% (119/198) patients exhibited heart involvement on echocardiography. 70.6% (84/119) and 79.8% (95/119) cases showed pathological valvular and atrioventricular abnormalities, respectively. The median follow-up duration of patients with heart involvement was 14.25 (8.47-24.92) months, and more than two echocardiography were performed. 3 cases of death were noted. That onset age (p=0.005) and baseline interleukin-6 level (p= 0.031)

Survival curve indicating the deterioration rate of cardiac structure in three groups.

	No. of events / No. of patients	1-year rate of deterioration (95% CI) %	2-year rate of deterioration (95% CI) %
Normal	4/31	2.1 (1.1-3.2)	2.1 (1.1-3.2)
Mild	23/57	11.3 (9.9-12.7)	28.3 (26.2-30.5)
Severe	19/30	20.0 (16.5-23.5)	69.2 (65.0-73.4)



No. at risk

Normal	31	27	27	27	27
Mild	57	42	35	34	34
Severe	30	20	12	12	11

were risk factors for the deterioration of cardiac structure. Using normal group as a reference, the risk of worsening cardiac structure (p< 0.001) and function (p< 0.001) was greatest in the severe group, with hazard ratios (HRs) of 13.2 (95% CI, 4.4–39.5) and 52.6 (95% CI, 6.8–403.9)respectively, which mostly occurred within 2 years after onset.

Conclusion: The prognosis of TA patients with severe cardiac structure and function impairment is relatively poor, particularly during the first 2 years after onset.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset Takayasu's Arteritis (TAK) may differ in presentation, clinical manifestations and treatment, as previously shown[1]. We aimed to compare the clinical manifestations, vascular involvement patterns, activity, damage and treatments used in childhood- and adult-onset TAK patients.

Methods: Patients from two cohorts of TAK from two tertiary-care centers in Turkey were retrospectively studied. Patients of the adult clinic were also classified as childhood-onset if they were diagnosed before the age of 18. Clinical presentation, angiographic data and treatment regimens were reviewed from clinical charts. The activity was determined by Indian Takayasu Clinical Activity Score (ITAS) on the first visit. Takayasu Arteritis Damage Score (TADS) and Vasculitis Damage Index (VDI) were employed to document the damage.

Results: Twenty four childhood-onset and 121 adult-onset TAK patients were included in the analysis (**Table 1**). In the basal visits, claudication of the arms [74 (62.2%) vs. 5 (20.8%), p< 0.001], carotidynia [19 (16%) vs. 0, p= 0.043], subclavian bruit [63 (58%) vs. 8 (35%), p= 0.044] and the loss of radial pulse [63 (57.8%) vs. 8 (34.8%), p= 0.044] were more common in adult-onset patients. In contrast, ischemic abdominal pain [5 (21%) vs. 8 (7%), p= 0.07], renal [9 (39%) vs. 15 (14%), p= 0.014] and abdominal bruits [11 (48%) vs. 9 (8%), p< 0.001] were more common in childhood-onset patients. Angiographic distribution of the involved vessels is shown in **Table 2**. Median ITAS score on the first visit was 15 (IQR: 10) for pediatric-onset and 13 (IQR: 6) for adult-onset cases (p=0.57). Medical treatment and surgical/interventional modalities are shown in **Table 3**. Median TADS score was 8 (IQR: 8) and 8 (IQR: 4) for pediatric and adult cases, respectively (p=0.91). Median VDI of the pediatric cases were slightly lower [4 (IQR:3) vs. 5 (IQR:3), p: 0.037]. Four of the adult patients and none of the pediatric patients died during follow-up. At least one episode of remission was achieved in 12 (50%) of pediatric cases and 91 (75%)

of adults (p=0.013). Among patients who had information regarding activity status, 12 (50%) of pediatric cases, and 88 (82%) of the adults were in remission at the last visit.

Conclusion: In childhood-onset TAK, the involvement of the aorta was more common, whereas the upper extremity was relatively spared as evidenced by symptoms and imaging. Remission was harder to achieve in pediatric cases,

Table 1. Demographics, clinical characteristics and angiographic classification of childhood-onset and adult-onset TAK patients

	Pediatric (n = 24)	Adult (n = 121)
Female	21 (87.5)	108 (89.3)

Detrimental Factors Affecting the First-year Clinical Response in Korean Patients with Polymyalgia Rheumatica

Yoon-Jeong Oh,[1] Seung Min Jung,[2] Byoong Yong Choi,[3] and **Kichul Shin** [4], [1]Kanwon National University Hospital, Chuncheon, Republic of Korea, [2]Yonsei university college of medicine, severance hospital, Seodaemun-gu, Republic of Korea, [3]Seoul Medical Center, Seoul, Republic of Korea, [4]Department of Internal Medicine, Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Seoul, Korea., seoul, Republic of Korea

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a chronic inflammatory disease in which patients respond well to glucocorticoids (GCs). However, a number of patients experience a flare in the course of tapering GCs. We aimed to elucidate the negative factors that hinder the early clinical response in PMR patients.

Methods: Electronic medical records of 85 PMR patients between Jan 2011 and Dec 2017 were reviewed in second and tertiary centers. We analyzed the clinical and laboratory data at diagnosis (baseline), then at follow-up visits of these subjects. The tapering schedule of GC was determined by the attending rheumatologist. Patients were classified into subjects with a good versus poor clinical response mainly based on the daily GC (prednisolone or its equivalent) dose at the end of the year. Logistic regression analysis was performed to assess the factors related to an unfavorable response in our subjects.

Results: The mean age of PMR patients was 70.7 years with mean disease duration of 38.9 months, and 60% patients (51/85) were females. The mean dose of daily GC at the end of the year was 5.7 mg; 61.2% of patients tapered GC to less than 5 mg/day. The patients with hip pain or restricted range of hip motion at diagnosis showed a good clinical response (p = 0.002). In contrast, the presence of peripheral arthritis at diagnosis was associated with a poor clinical response to GCs (p = 0.002). A multivariable logistic regression analysis revealed that absence of hip involvement [hazard ratio (HR); 0.179, 95% confidence interval (CI); 0.053-0.600, p = 0.005], presence of peripheral arthritis [HR; 4.099 (1.412-11.900), p = 0.009] and concurrent diabetes mellitus (HR; 3.524, 95% CI; 1.064-11.672, p = 0.039) at diagnosis were independently associated with a poor clinical response during the first year of treatment.

Conclusion: Our study demonstrates that PMR patients with peripheral arthritis or diabetes mellitus, and those without hip involvement are prone to a poor first-year clinical response to treatment.

Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A lot of clinical case descriptions about spondyloarthropathy in TAK patients were reported. Recently, a paper about an increased incidence of spondyloarthropathy in TAK patients (Guzel Esen S., Joint Bone Spine 2019 in press) was published. The diagnosis of sacroiliitis may be performed by X-ray, CT or MRI. CT findings of sacroiliitis are: contour irregularities, joint space alterations, joint erosion, subcondral bone changes (osteoporosis or sclerosis), enthesitis, ankylosis. Patients with Takayasu Arteritis (TAK) performe routinely FDG-CT-PET for monitoring disease activity. The aim of this study is to understand if there are an increased association of sacroiliitis in TAK patients in our monocentric cohort.

Methods: We collected retrospectively imaging data (CT) from 28 patients affected by TAK and 28 controls undergoing FDG-PET-CT scan in our center. Controls were selected among patients who performed FDG-PET-CT in our Nuclear Medicine Unit, excluding patients with bone tumors, tumors with bone metastasis and thyroid cancers. The majority of controls were affected by lymphoma in a complete remission. Controls and patients were matched for sex and age. An expert rheumatologist read the CT scans of sacroiliac joints.

Results: No patients and no controls demonstrated FDG-uptake in sacroiliac joints.

In the control group, we detected sacroiliac sclerosis in two cases: one due to a degenerative changes and another to a sacroiliitis (1/28, 4%).

In the TAK group four patients presented CT alterations suggestive for sacroiliitis: bilateral erosions in one case, a bilateral sclerosis in one case, a mono lateral sclerosis in two cases (4/28,14%). One of these patients complained an inflammatory back pain.

Conclusion: In our cohort of TAK patients we demonstrated an increased prevalence of sacroiliitis, diagnosed by CT scan. Only one patient of TAK group reported an inflammatory back pain, while three patients had only radiological signs of previous sacroiliitis. This reinforce the need to look for spondyloarthropathy in TAK patients even if asymptomatic.

Childhood Takayasu Arteritis: Characteristics and Outcomes of a Mexican Cohort

Grissell Alejandra Valero-Gaona,[1] Enrique Faugier-Fuentes,[2] and Angélica Vargas Guerrero[3], [1]Departamento de Reumatología, Instituto Nacional de Cardiología "Ignacio Chávez", Ecatepec, Distrito Federal, Mexico, [2]Department of Rheumatology, Hospital Infantil de México Federico Gómez, Mexico City, Mexico, [3]Departamento de Reumatología del Instituto Nacional de Cardiología Ignacio Chávez, Mexico City, Mexico

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TA) is a large vessel vasculitis that affects aorta and its main branches. Despite being the third most common vasculitis in childhood, it still rare and data are scarce in the literature. Diagnosis may be delayed due to its non-specific manifestations. Early diagnosis and treatment are essential due to its high morbidity and mortality in these patients.

Methods: A descriptive single-center study of pediatric patients that met the EULAR/PRINTO/PReS criteria for childhood TA (cTA) between January 2000 and April 2019. Demographic data, time to diagnosis, clinical features, laboratory markers, imaging features, extension according to the Numano classification and treatment were documented. Disease activity was retrospectively assessed at the time of diagnosis by Paediatric Vasculitis Activity Score (PVAS). Damage was assessed by Paediatric Vasculitis Damage Index (PVDI) at last follow-up.

Results: Ten patients were included. Demographic data and main features are shown in table 1. Non-specific symptoms were the predominant ones at presentation (90%) followed by more specific manifestations in most cases. In our population, there is a tendency to present extensive vascular disease (Numano V in 50%). Most frequently involved vessels are shown in table 2. All patients were active at the time of their recruitment in our institution (documented by clinical and laboratory findings or by positron emission tomography). Nevertheless, only 40% of them had acute phase reactants elevation (ESR 30% and CRP 30%), which suggests that these analytes do not always correlate with cTA activity. Medical treatment included: glucocorticoids (100%), methotrexate (80%), azathioprine (20%), biological therapy (20%) and others (mycophenolic acid and cyclophosphamide). Six patients (60%) required interventional treatment, five of them (50%) endovascular intervention with stenting. Arteries that required interventional treatment (Stenting) are shown in table 3. Thoracic and abdominal aorta were the more frequently arteries that required surgical replacement with stenting. Two patients required intra-stent balloon angioplasty; one of them required this procedure 3 times. In the first time with placement of a non-medicated stent in one renal artery and twice more placement of medicated stents in both renal arteries because stent restenosis (intra-stent stenting in one side). One patient was treated with balloon angioplasty in both renal arteries and abdominal aorta without stenting. Only three patients (30%) required a surgical procedure. Mortality was 10%, after non-coronary Valsalva sinus plasty with supra-coronary replacement of ascending aorta).

Table 1. Demographic data and main features	
Characteristic	**Patients (n=10)**
Median age at diagnosis	10.4 years (1 a 16)
Female gender	9 (90%)

Table 2. Arterial Vessel involvement (CT/MR)		
Artery	**At diagnosis**	**Last follow-up**
Supra-aortic vessels	5 (50%)	5 (50%)
Carotid	3 (30%)	3 (30%)
Vertebral	4 (40%)	5 (50%)
Subclavian	3 (30%)	4 (40%)
Ascending aorta	2 (20%)	2 (20%)
Aortic arch	0	1 (10%)
Thoracic aorta	3 (30%)	3 (30%)
Abdominal aorta	5 (50%)	7 (70%)
Renal	6 (60%)	6 (60%)
Iliac	2 (20%)	3 (30%)
Superior mesenteric	3 (30%)	3 (30%)
Celiac trunk	1 (10%)	2 (20%)
Pulmonary	1 (10%)	2 (20%)

Conclusion: In our cohort, cTA tends to present with extensive vascular disease, associated in most of the cases with nonspecific symptoms. The percentage of acute phase reactants elevation was less than 50% despite having detected cTA activity in 100% of patients at diagnosis, so thorough exploration is essential. Mortality was related to a surgical complication (part of the treatment) and not to the activity of vasculitis.

Table 3. Arteries that required interventional treatment (Stenting)

Artery	Patients (N=6)

Extravascular Inflammatory Manifestations of Takayasu Arteritis in a Monocentric Cohort

Elena Baldissera,[1] Alessandro Tomelleri,[1] Silvia Sartorelli,[2] Corrado Campochiaro,[3] and Lorenzo Dagna[1], [1]Unit of Immunology, Rheumatology, Allergy and Rare Diseases. IRCCS San Raffaele Hospital. Vita-Salute San Raffaele University., Milan, Italy, [2]Vita-Salute San Raffaele University, IRCCS San Raffaele Hospital, Milan, Italy, [3]Unit of Immunology, Rheumatology, Allergy and Rare Diseases (UnIRAR), IRCCS San Raffaele Hospital, Vita-Salute San Raffaele University, Milan, Italy

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TAK) is an inflammatory disease which primarily affects large vessels. However, as a systemic disease, the spectrum of its manifestations is not limited to the arterial wall.

Methods: Data records of TAK patients diagnosed according to the 1990 ACR criteria and followed-up at our Large Vessel Vasculitis Clinic were reviewed. Any significant inflammatory/autoimmune comorbidity and family history for inflammatory/autoimmune disease were considered. For each comorbidity, temporal correlation with TAK diagnosis was assessed. Need for biological therapy for TAK control, as an indirect measure of TAK aggressiveness, was evaluated. Non-parametric statistic tests were used.

Results: In our cohort of 128 TAK patients, 46 patients (35.9%) were identified as having an inflammatory/autoimmune comorbidity, for a total of 64 comorbidities (14 patients experienced >1 comorbidity). Comorbidities were classified into 6 categories: systemic inflammatory diseases (11 patients, 14.3%); gastro-intestinal (6 patients, 7.8%), articular (7 patients, 9.1%), ocular (13 patients, 16.9%) and muco-cutaneous (25 patients, 32.5%) involvement; miscellaneous (autoimmune hepatitis, retroperitoneal fibrosis). In 33 cases (51.6%) the comorbidity onset preceded, in 25 (39%) followed and in 6 (9.4%) was synchronous with TAK diagnosis (Table 1). In 25 patients (54.3%) use of a biological therapy to control TAK activity was needed (versus 35.4% in TAK patients without comorbidities, p = 0.042). Having a comorbidity increased the risk for the introduction of a biologic therapy, odds ratio=2.176 (1.042-4.541). Of

Prevalence and characteristics of inflammatory/autoimmune extravascular comorbidities in a cohort of 128 patients with Takayasu arteritis (TAK), temporal correlation with TAK diagnosis, and need for biological therapy.

the 128 TAK patients, 17 (13.3%) had a positive family history for inflammatory or autoimmune diseases (8 psoriasis, 5 rheumatoid arthritis, 3 inflammatory bowel disease, 1 sarcoidosis).

Conclusion: In TAK patients, extravascular involvement is a common finding and usually precedes the vascular involvement (the only significant exception is represented by inflammatory arthritis). Inflammatory and autoimmune extravascular comorbidities seem to be associated with a significant higher burden of vascular inflammation, as inferred by the higher rate of biological therapies use in these TAK patients.

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's arteritis (TAK) is a large vessel vasculitis of the young women in their reproductive age. According to our previous report from single center TAK pregnancies may have a favorable outcome. On the other hand, pregnancy outcomes were worse in the French TAK cohort. Herein, we reported fetal and maternal complications of pregnancy in a larger group of Turkish TAK patients.

Methods: A total of 68 TAK patients, followed by Turkish Takayasu Study Group in 7 tertiary centers and diagnosed according to the 1990 ACR criteria were consecutively assessed for pregnancy and newborn outcome. Pregnancies were divided into 2 groups as pre-diagnosis (pre-d) and post-diagnosis (post-d) pregnancies and compared to feto-maternal complications (FMC) such as hypertension (HT), preeclampsia-eclampsia, abortion, prematurity, low birth weight. Post-d pregnancies were also divided into 2 groups according to FMC development status and baseline demographic data and TAK clinical characteristics were compared between groups.

Results: The mean age of the patients who received 167 pregnancy data retrospectively was 43±12.1 years. 42 (25.1%) of these pregnancies developed after the onset of the disease. FMC rate was higher in the post-d pregnancies than in the pre-d pregnancies [15 (35.7%), 20 (15.7%); p = 0.006]. FMC are shown in Table 1. Maternal heart failure, cardiovascular event or death was not observed in any pregnancy. Disease characteristics of patients with post-d pregnancies according to FMC development are seen in Table 2. None of the patients was smoker and had cardiovascular events.

Conclusion: The most common maternal complications of TAK patients are associated with HT. It was observed that TAK negatively affected the fetal outcomes of pregnancies however the majority of the pregnancies were found as successful in our cohort.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

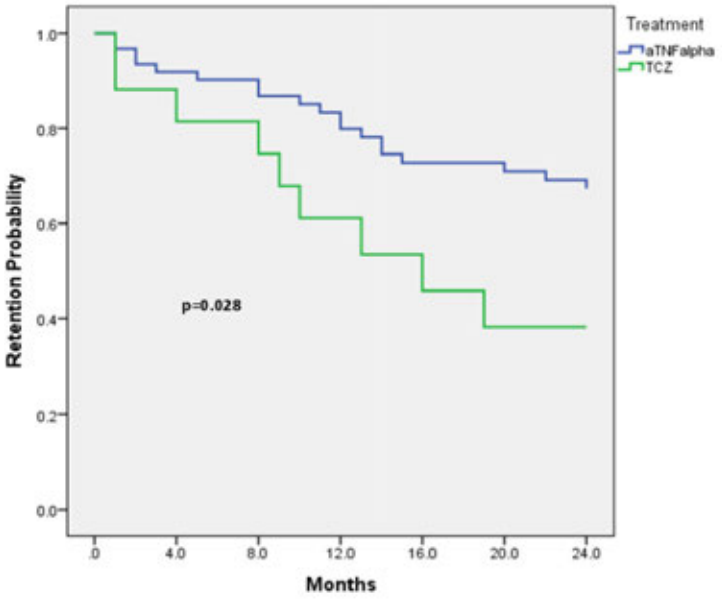
Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu's arteritis (TA) is a large vessel vasculitis affecting mainly young women. Biologic agents are currently use to treat refractory TA patients but no data are available on drug retention rate (DRR) of biologic disease-modifying anti-rheumatic drugs (bDMARDs) TA patients. We retrospectively investigated DRR and reasons for discontinuation of seven bDMARDs in TA patients in a real-world setting.

Methods: TA patients followed-up in our Centre fulfilling the 1990 ACR criteria and treated with ≥1 bDMARD were selected. Data about disease duration, number of bDMARDs, reasons for bDMARDs discontinuation, concomitant conventional synthetic (cs)DMARDs were collected. Survival curves were examined by the Kaplan-Meier method

Figure 1. Kaplan-Meier curves comparing Takayasu patients treated with anti-TNFalpha (infliximab, adalimumab, golimumab) and with tocilizumab at 24 months.



Number of subjects at risk (%)

aTNF	61 (100%)	56 (92%)	53 (87%)	47 (77%)	43 (70%)	42 (69%)	41 (67%)
TCZ	17 (100%)	14 (82%)	13 (76%)	10 (59%)	8 (47%)	7 (41%)	7 (41%)

and compared using a stratified log-rank test. 24-month DRR was calculated. Hazard ratio (HR) for concomitant csDMARDs and for previous bDMARDs was evaluated. A comparative sub-analysis between anti-TNFα drugs and tocilizumab was performed.

Results: We identified 50 patients and 86 bDMARD-courses. Patients characteristics are summerized in Table 1. No significant differences were observed in age and disease duration between the seven groups (data not shown). Infliximab was the most frequent first-line bDMARD (78.6%). At bDMARDs initiation, all patients were on prednisone (mean dose, 13.5±10.3 mg/day) and 85.2% on concomitant csDMARD therapy. 43% of treatment courses were stopped by 24 months. Golimumab had the highest DRR (71.4%), followed by infliximab (69%), adalimumab (56.3%), abatacept (50%), tocilizumab (41.1%), anakinra (0%) and rituximab (0%), p=0.016. Concomitant csDMARDs therapy showed positive effects on DRR (HR=2.87, 95% CI=1.19-6.92, p=0.019). Anti-TNFα drugs had significantly higher DRR compared to tocilizumab (67.2% vs 41.1%, p=0.028), see Figure 1. Even in these subgroups, csDMARDs showed positive effects on DRR (HR=3.79, 95% CI=1.49-9.6, p=0.005).

Conclusion: Anti-TNFα agents had the highest DRR overall and a higher DRR in a head-to-head comparison with tocilizumab. Concomitant csDMARDs had a significant positive effect on bDMARDs DRR.

Initial Clinical Presentation Is Associated with Outcome in Takayasu's Arteritis

Kaitlin Quinn,[1] K Bates Gribbons,[2] Elaine Novakovich,[3] and Peter C. Grayson[4], [1]Georgetown University Hospital/ National Institutes of Health, Washington, DC, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, [3]National Institutes of Health, Bethesda, MD, [4]National Institute of Arthritis and Musculoskeletal and Skin Diseases (NIAMS) of the National Institutes of Health, Bethesda, MD, Bethesda, MD

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The natural history of Takayasu's arteritis (TAK) remains poorly characterized. A "triphasic" pattern of disease has been proposed where constitutional symptoms precede vascular inflammation and subsequent vascular damage. However, this pattern is often not seen, and there is wide variability in the initial features of disease, including asymptomatic patients diagnosed based on incidental findings on vascular examination or imaging. This study aimed to characterize patients with Takayasu's arteritis based on the presenting features of disease in association with clinical outcomes.

Methods: An observational cohort of patients with TAK was prospectively recruited. All patients fulfilled the 1990 ACR Classification Criteria for TAK. Patients were divided into four categories based on initial presentation as follows: 1) asymptomatic, 2) nonspecific constitutional symptoms alone, 3) vascular inflammation (defined as carotidynia), and 4) vascular ischemia [defined as a symptom secondary to arterial damage (i.e limb claudication, stroke, etc.)]. Group status was studied in association with demographics, diagnostic delay, acute phase reactant levels, relapse

Table. Clinical Characteristics of Patients with Takayasu's Arteritis Grouped by Initial Clinical Presentation

Co-existing chronic disease**	5 (56)	0 (0)	1 (13)	8 (24)	0.03

ACP: acute phase reactants

*6 patients diagnosed after discovery of an abnormal physical examination finding and 3 patients diagnosed from an incidental imaging finding

** Inflammatory bowel disease (n=3), Ankylosing spondylitis (n=2), Juvenile Idiopathic Arthritis (n=2), Sarcoidosis (n=2), Tuberculosis (n=4), HIV (n=1)

rate, treatment received, a history of antecedent pharyngitis, and presence of chronic inflammatory co-morbidities. Differences among groups were assessed by chi square test and Kruskal-Wallis test as appropriate.

Results: 61 patients with TAK were studied, with a median disease duration of 6 years (Table). Most patients reported vascular symptoms as the first feature of disease. Eight patients (13%) presented with carotidynia, and 34 patients (56%) presented with an ischemic vascular event. Ten patients (16%) presented with nonspecific constitutional symptoms alone, and nine patients (15%) were asymptomatic at presentation. Initial presentation was not associated with gender, race, ethnicity, or age. Elevated acute phase reactants were most frequent in the group presenting with constitutional symptoms (100%) and carotidynia (88%) ($p< 0.01$). The group presenting with carotidynia had the most frequent relapses, with 100% of patients relapsing at some point in their disease course ($p=0.03$). This group was the most frequently refractory to treatment with corticosteroids and DMARDS; biologic therapy was required in 88% patients ($p=0.04$) and >1 biologic was required in 63% patients ($p=0.02$). Many patients in the group with nonspecific constitutional symptoms also had refractory disease with 70% patients requiring biologic therapy and 30% requiring >1 biologic. Antecedent pharyngitis was seen in five of the eight patients (63%) presenting with carotidynia ($p< 0.01$). Co-existing chronic inflammatory disease was most frequently seen in the patients who were asymptomatic at disease diagnosis ($p=0.03$).

Conclusion: There is heterogeneity in clinical presentation at time of diagnosis in TAK, and patients do not necessarily progress sequentially through multiple phases of the disease. Initial clinical presentation may dictate future disease trajectory and inform treatment response, risk for relapse, and potential causal factors.

Dynamic Distribution and Phenotype Shift from M1 to M2 of Macrophages in Vascular Lesions of Naïve and Treated Patients with Takayasu Arteritis

Xiufang Kong,[1] Ming Xu,[2] Xiaomeng Cui,[2] Lingying Ma,[2] Huiyong Chen,[3] Lili Ma,[2] and Lindi Jiang[2], [1]University of Michigan & Fudan University, Ann Arbor, MI, [2]Zhongshan Hospital, Fudan University, Shanghai, China (People's Republic), [3]Department of Rheumatology, Zhongshan Hospital, Fudan University, Shanghai, P. R. China, Shanghai

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TA) is a chronic inflammatory disease characterized by arterial vascular fibrosis. Type I (M1) and type II (M2) macrophages play very important roles in the development of TA, and monocyte chemotactic protein-1 (MCP-1) has also been implicated in TA. However, the roles and interactions of these three factors with each other and with the current therapeutic agents for TA are unclear. Therefore, in the current study, we investigated the M1 and M2 profile in the vascular tissue of TA patients and detected the concentration of monocyte chemotactic protein-1 (MCP-1) in vascular tissue and peripheral blood before and after treatment.

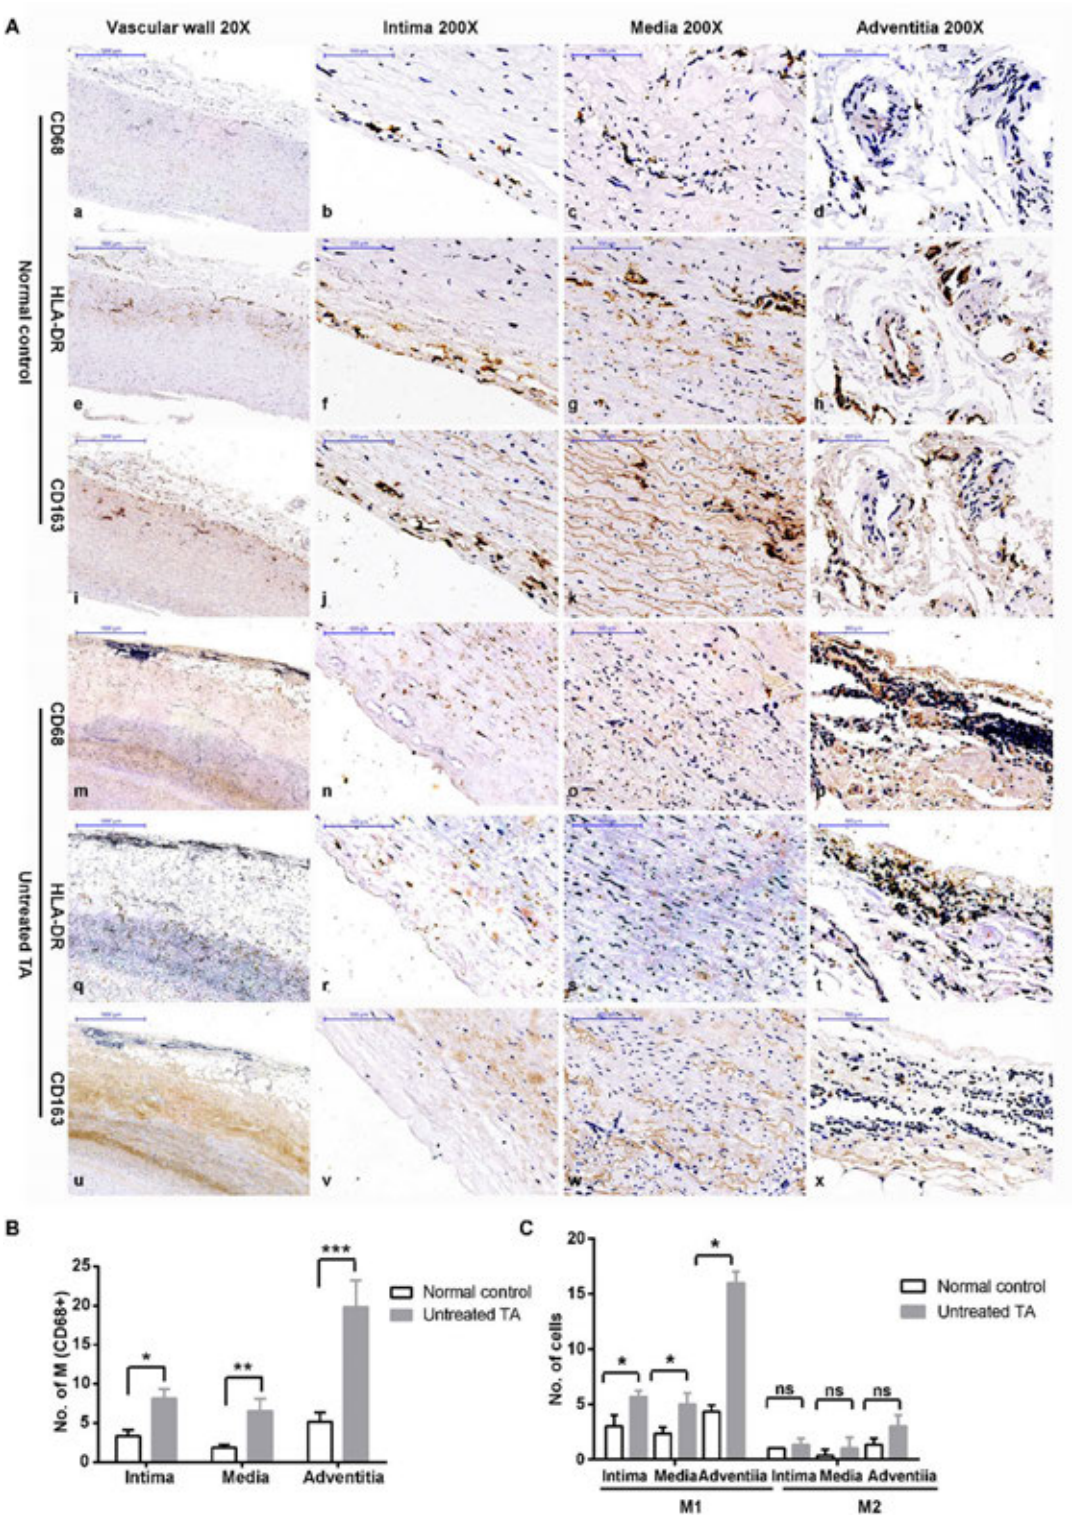

Figure 1. Distribution and phenotype of macrophages in untreated vascular tissue (inflammatory stage)

Methods: This study included 8 untreated TA patients, 7 treated patients and 4 controls who provided vascular tissue specimens, as well as 38 treatment-naïve patients and 28 healthy controls who provided their serum samples before and after treatment (only 19 TA samples were obtained after treatment). The treatment strategy was prednisone combined with immunosuppressants. Immunohistochemical staining for M1 and M2 markers and MCP-1

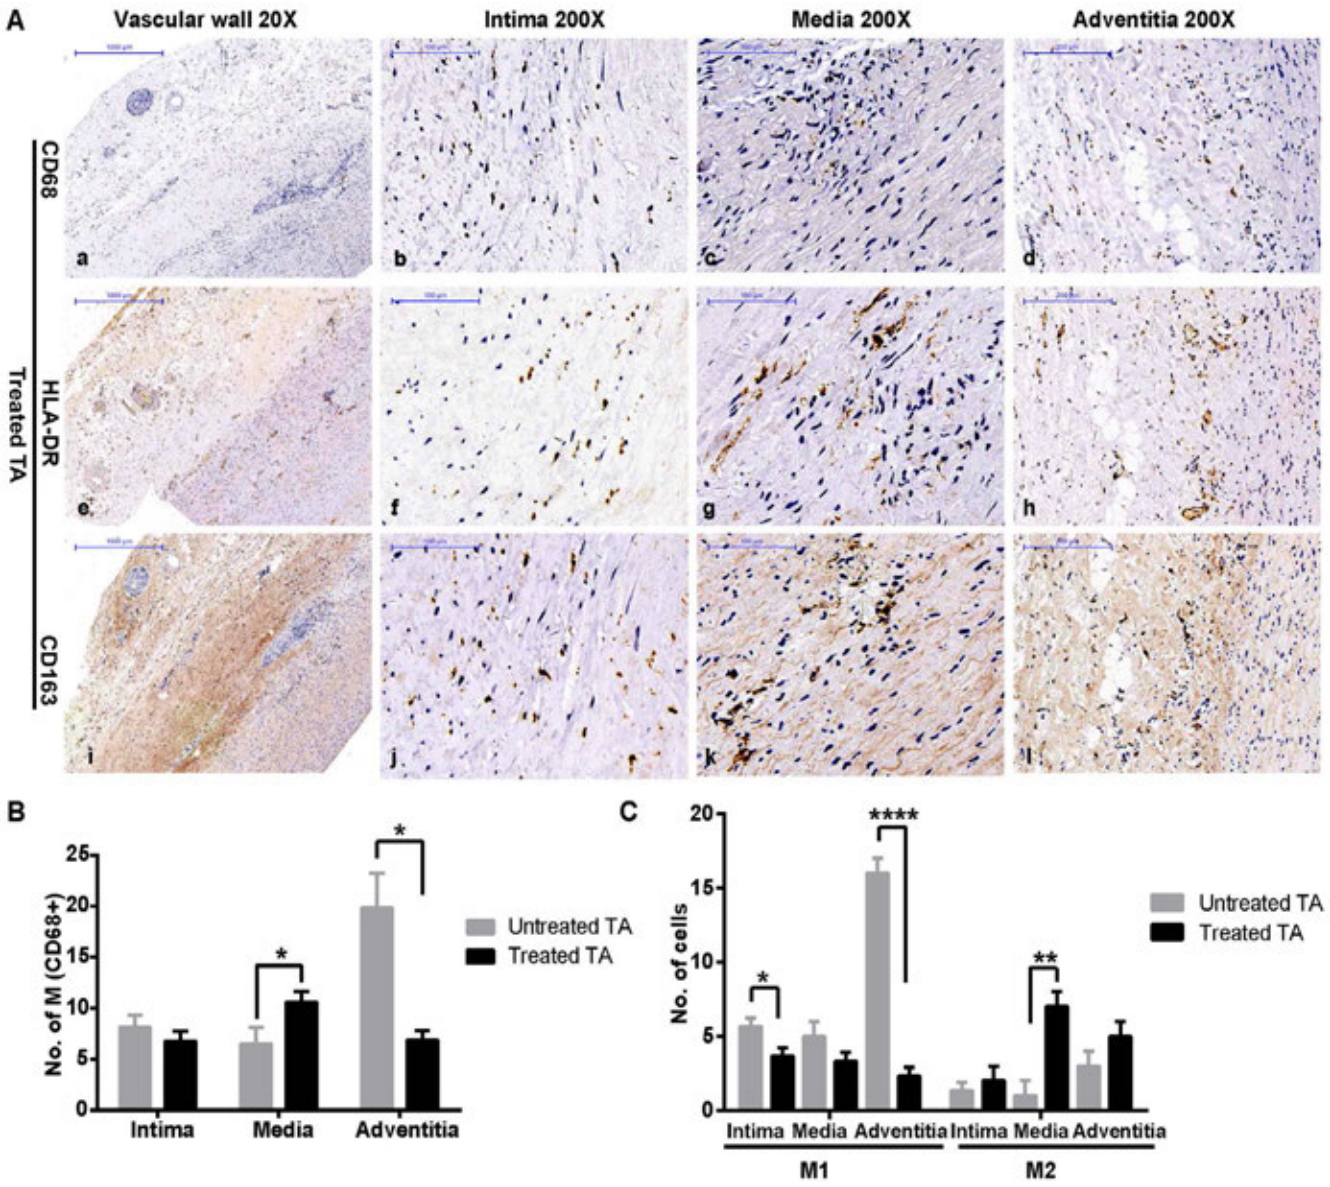

Figure 2. Distribution and phenotype of macrophages in treated vascular tissue (fibrotic stage)

was performed in the vascular tissue samples. The serum level of MCP-1 was detected by ELISA. Disease activity was evaluated by the Kerr activity score.

Results: M1 macrophages were more prominent in the acute (pro-inflammatory) stage of TA and in naïve patients, while M2 macrophages were more prominent in the chronic (pro-fibrotic) stage and in treated patients. This pattern was also observed in MCP-1 expression. Macrophages and MCP-1 showed increased levels in vascular tissue (mainly in the adventitia), along with an increase in peripheral MCP-1, in the treatment-naïve patients. In contrast, in the patients who had received 6 months of treatment, both the macrophage and MCP-1 (vascular adventitia and peripheral) levels were decreased. In the vascular media from treated patients, an increase in MCP-1 levels and M2 infiltration was observed. Furthermore, peripheral MCP-1 was correlated Kerr activity score (Rho = 0.50, P = 0.002) and peripheral IL-6 levels (Ro = 0.55, P < 0.001).

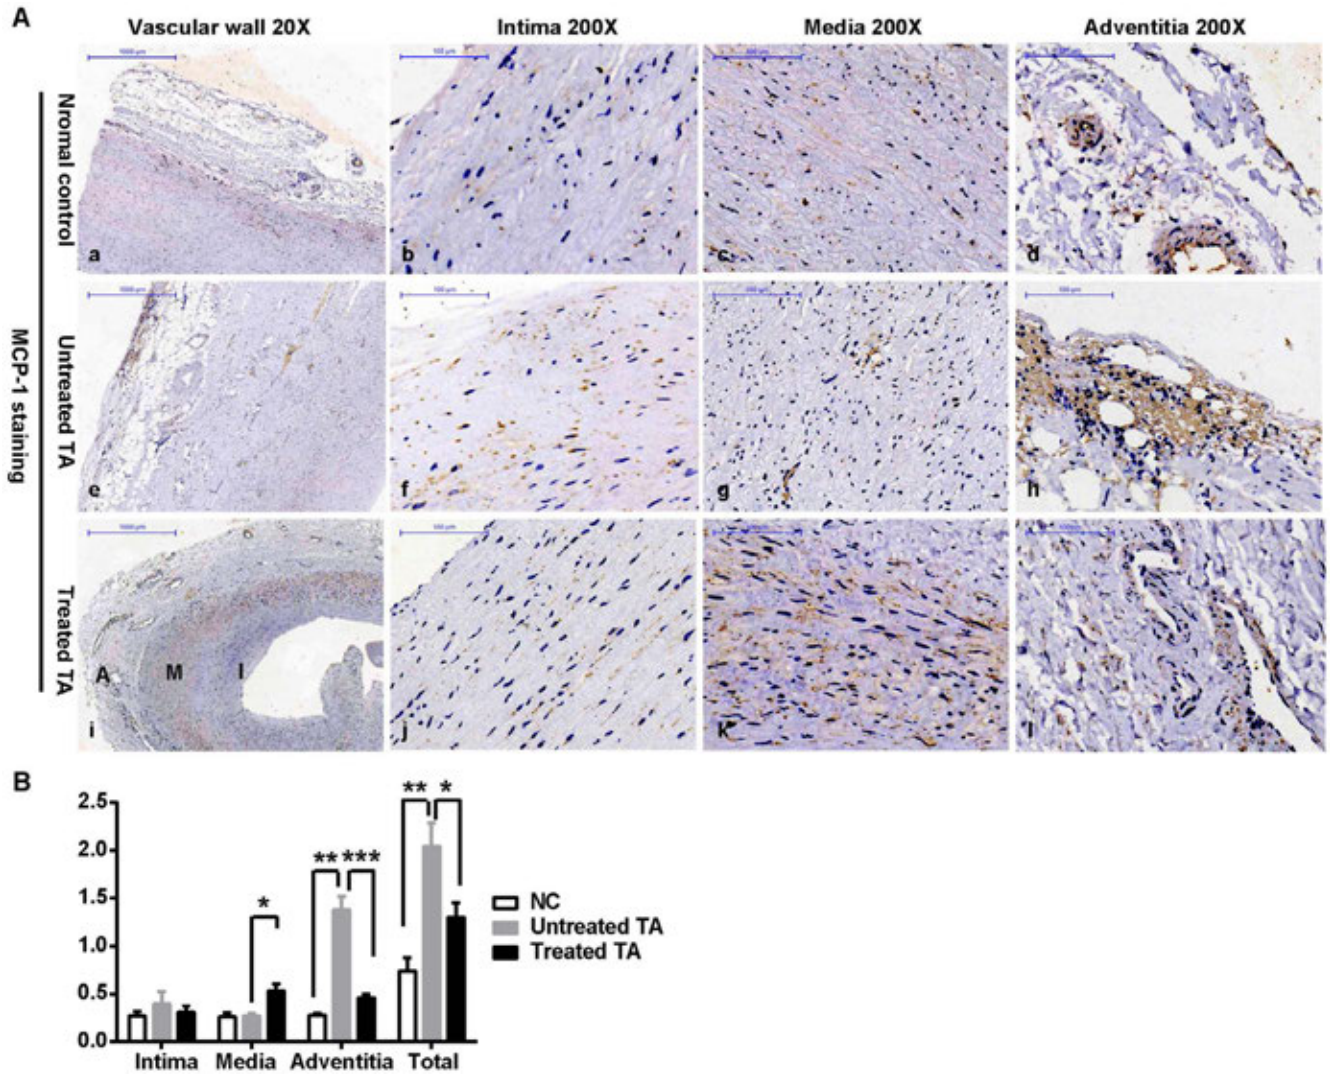

Figure 3. MCP-1 expression in normal aorta, untreated TA aorta and treated TA artery

Conclusion: In the vascular wall, M1 and M2 distribution is dynamic and is closely associated with MCP-1 expression, which is increased in the serum and vascular tissue of TA patients. The current treatment strategies do not target M2 infiltration, as a result of which fibrosis is aggravated. Thus, more efficacious treatment strategies that target both M1 and M2 should be used. Further, the serum level of MCP-1 may prove to be a useful indicator of disease stage and treatment efficacy in the future.

A Novel Diagnostic Algorithm for Polymyalgia Rheumatica Using Three Musculoskeletal Sites on Whole Body PET/CT

Claire Owen,[1] Aurora Poon,[1] Victor Yang,[1] Chris McMaster,[1] Sze Ting Lee,[1] David Liew,[1] Jessica Leung,[1] Andrew Scott,[1] and Russell Buchanan[1], [1]Austin Health, Heidelberg, Victoria, Australia

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: PMR is associated with a pattern of abnormal ^{18}F-Fluorodeoxyglucose (^{18}F-FDG) uptake on whole body PET/CT that is increasingly recognised to correlate anatomically with inflammation of extracapsular structures.(1) The aim of this study was to evaluate the sensitivity and specificity of PET/CT findings in PMR including novel involvement at the posteromedial knee and develop a representative diagnostic scoring algorithm utilising results from a minimum number of musculoskeletal sites.

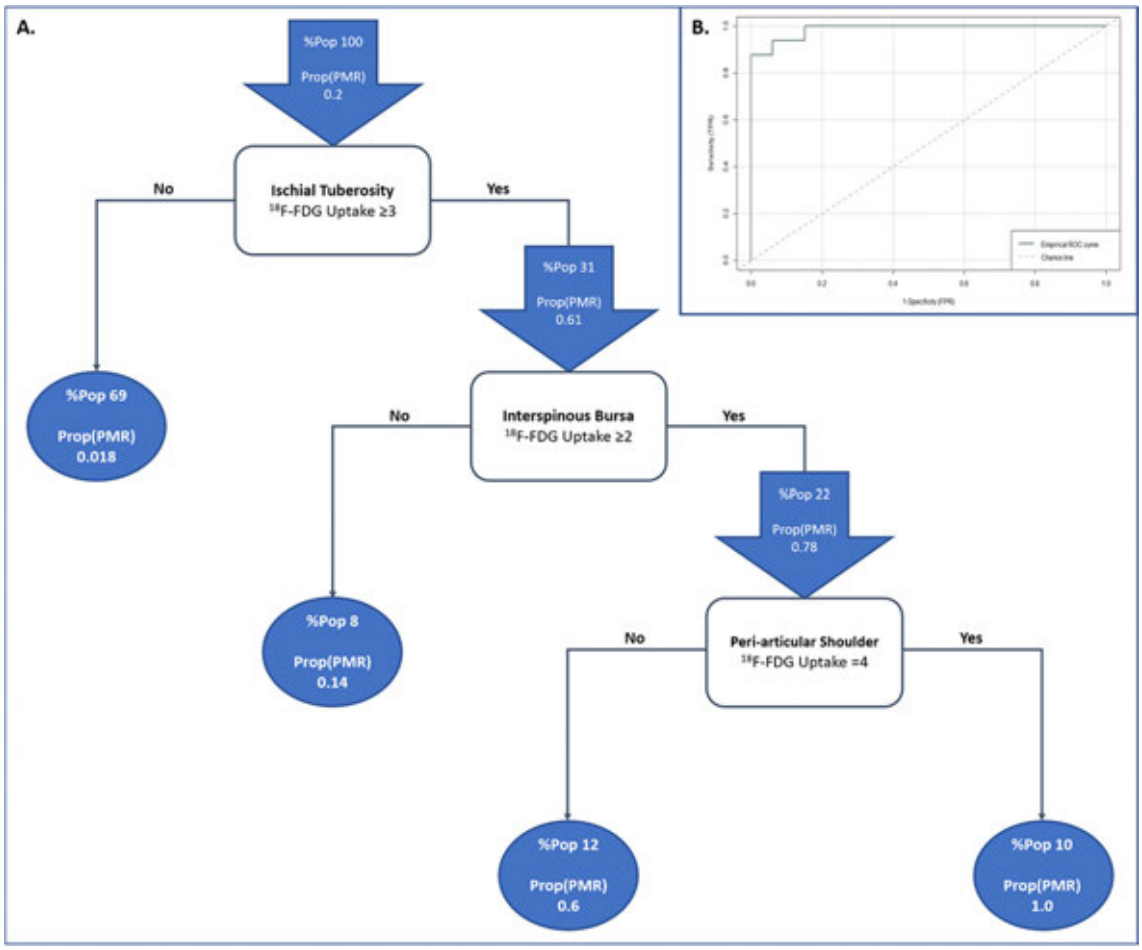

Figure 1. A – A diagnostic algorithm for PMR utilising Meller scores at three musculoskeletal sites. %Pop represents the percentage of the total study population with this abnormal finding. Prop(PMR) represents the proportion of PMR cases in that subset; B – ROC curve for the diagnostic algorithm (AUC 0.987; sensitivity 93.9%, specificity 93.9%).

Table 1. Incidence, mean Meller score and mean SUVmax for cases compared with controls. Results for continuous variables are reported as mean ± standard deviation.

Musculoskeletal Site	^{18}F-FDG Uptake ≥1 Cases (n=33)	^{18}F-FDG Uptake ≥1 Controls (n=132)	Mean Meller Score Cases	Mean Meller Score Controls	p-value	Mean SUV_{max} Cases	Mean SUV_{max} Controls	p-value
Peri-articular Shoulder	32 (97.0%)	103 (78.0%)	3.5±0.8	2.1±0.9	0.0001	3.4±1.3	2.2±0.9	0.0001
Interspinous Bursa	30 (90.9%)	23 (17.4%)	3.1±1.0	1.3±0.6	0.0001	2.9±1.5	1.7±1.1	0.0001
Peri-articular Hip	32 (97.0%)	81 (61.4%)	3.3±0.9	1.9±0.8	0.0001	3.4±1.8	2.0±0.7	0.0001

Adjacent to Ischial Tuberosities	33 (100%)	77 (58.3%)	3.7±0.5	1.8±0.8	0.0001	3.6±1.4	2.0±0.7	0.0001
Posteromedial Knee	24 (72.7%) (n=32)	25 (19.8%) (n=126)	2.7±1.1	1.3±0.6	0.0001	2.7±1.0	1.4±0.7	0.0001

Table 2. AUC, sensitivity and specificity for PMR diagnosis of abnormal findings at different musculoskeletal sites and their combinations.

Musculoskeletal Site	AUC	Sensitivity	Specificity
Peri-articular Shoulder	0.898	81.8%	90.9%
Interspinous Bursa (Int Bursa)	0.959	100.0%	82.6%
Peri-articular Hip	0.888	75.8%	95.4%
Trochanteric Bursa	0.901	97.0%	79.5%
Adjacent to Ischial Tuberosities (Ischial Tub)	0.980	93.9%	96.2%
Posteromedial Knee (Post Knee)	0.940	100.0%	80.3%
Peri-articular Shoulder + Int Bursa	0.941	84.8%	96.2%
Peri-articular Shoulder + Ischial Tub	0.962	93.9%	91.7%
Peri-articular Shoulder + Post Knee	0.930	93.9%	83.3%
Int Bursa + Ischial Tub	0.971	93.9%	93.9%
Int Bursa + Post Knee	0.959	93.9%	85.6%
Ischial Tub + Post Knee	0.976	93.9%	92.4%
Peri-articular Shoulder + Int Bursa + Ischial Tub	0.964	93.9%	97.0%
Peri-articular Shoulder + Ischial Tub + Post Knee	0.965	93.9%	91.7%
Int Bursa + Ischial Tub + Post Knee	0.971	93.9%	92.4%

Methods: Steroid-naïve patients with newly diagnosed PMR (2012 EULAR/ACR classification criteria) were prospectively recruited. Participants with giant cell arteritis were excluded. A whole body ^{18}F-FDG PET/CT scan from skull vertex to toes was performed at baseline. Each PMR case was age- and sex-matched to four consecutive historic PET/CT controls, with relevant data pertaining to scan indication, underlying diagnosis and medical history extracted from the clinical record. Qualitative (Meller score) and semi-quantitative scoring (standardised uptake value maximum [SUVmax]) of abnormal ^{18}F-FDG uptake at 21 musculoskeletal sites was undertaken for cases and controls. Results were compared using the Mann-Whitney U test, a p-value < 0.05 being considered statistically significant. Receiver operating characteristics (ROC) curves were generated for abnormal findings at each musculoskeletal site, along with calculation of the area under the curve (AUC), sensitivity and specificity.

Results: 33 cases met the inclusion criteria and were matched to 132 controls. Mean age was 68.6±7.4 years for cases cf. 68.2±7.3 for controls, and 54.5% of patients were male. Mean EULAR/ACR score was 5.2±0.6 for the PMR group, with median CRP 49 (32 – 65) and ESR 41.5 (24.6 – 64.4). The predominant indication for whole body PET/CT in the controls was malignancy (47.0%). 43/132 controls (32.6%) had a history of a rheumatic condition including 9 (6.8%) with an inflammatory arthritis. Table 1 summarizes the incidence of abnormal findings on whole body PET/CT in cases compared with controls. Individual musculoskeletal sites proved insufficient for diagnostic purposes, however ^{18}F-FDG uptake at the peri-articular shoulder in combination with interspinous bursa and adjacent to the ischial tuberosities achieved a sensitivity of 93.9% and specificity of 97% (Table 2). A diagnostic algorithm utilising scores at

each of these 3 musculoskeletal sites is depicted in Figure 1 (AUC 0.987; sensitivity 93.9%, specificity 93.9%). When tested on the study population, none of the controls were misdiagnosed with PMR.

Conclusion: The combination of abnormal ^{18}F-FDG uptake at the peri-articular shoulder, interspinous bursa and adjacent to the ischial tuberosities on whole body PET/CT is highly sensitive and specific for a diagnosis of PMR.

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

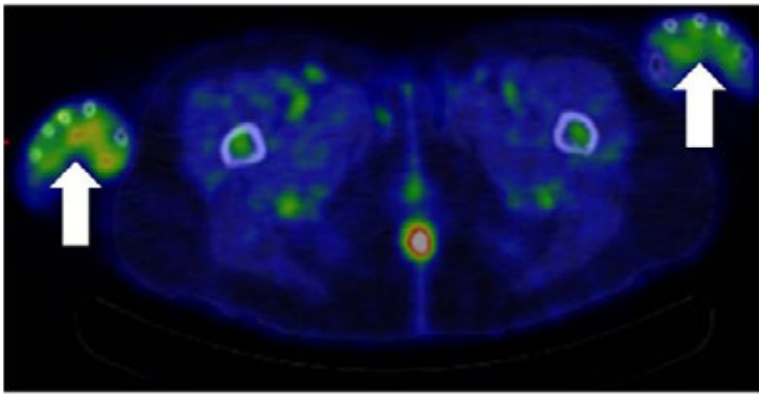
Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Almost half of all patients diagnosed with PMR require a protracted duration of glucocorticoid therapy due to relapsing disease.(1) On whole body PET/CT, PMR possesses a distinctive pattern of abnormal ^{18}F-fluorodeoxyglucose (^{18}F-FDG) uptake, however the prognostic potential of this test is unknown. The aim of this study was to characterise ^{18}F-FDG uptake on whole body PET/CT and investigate its ability to predict relapsing PMR.

Methods: Steroid-naïve patients with newly diagnosed PMR (2012 EULAR/ACR Classification Criteria) were prospectively recruited. Participants with GCA were excluded. Disease activity (PMR-Activity Score [PMR-AS]) was assessed and whole body PET/CT including dedicated hand views undertaken prior to the commencement of a standardised weaning course of prednisolone (BSR Guideline). PMR-AS was recalculated at weeks 4, 8, 16, 24, 32 and 46. Relapse was defined by a PMR-AS score of ≥9.35 in a patient who had achieved clinical remission (PMR-AS < 9.35) or an increase in PMR-AS by ≥6.6 if the participant had been previously responding to treatment (PMR-AS ≥9.35 but falling between successive visits). Qualitative (Meller score) and semi-quantitative (standardised uptake value maximum [SUVmax]) scoring of 21

Figure 1. A novel pattern of volar 18F-FDG uptake at the hand on whole body PET/CT.



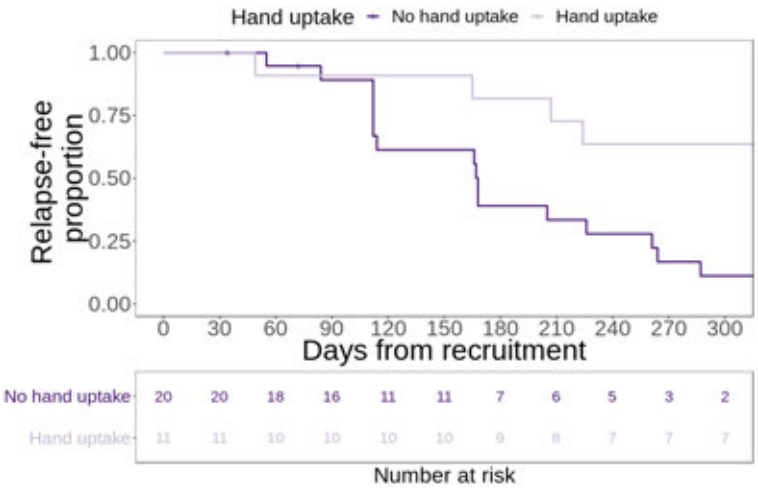


Figure 2. Kaplan-Meier plot demonstrating the relationship between the presence or absence of volar hand 18F-FDG uptake and time to first relapse.

musculoskeletal sites on whole body PET/CT was performed by two experienced nuclear medicine physicians, with any difference in opinion resolved by consensus. The Cox proportional-hazards model investigated the relationship between relapse and 18F-FDG uptake, with a p-value < 0.05 representing statistical significance.

Results: 35 patients met the inclusion criteria. Mean age was 69.5±7.15 years and 19/35 (54.3%) were male. Findings on whole body PET/CT are presented in Table 1, with a peri-articular pattern of abnormal ^{18}F-FDG uptake predominating at the shoulder and hip. A high frequency of knee (79.4%) as well as wrist and/or hand involvement (68.6%) was appreciated, including a novel pattern of volar ^{18}F-FDG uptake (Figure 1). Longitudinal PMR-AS data was available for 32 participants, 25 (78%) of whom relapsed during follow-up. Figure 2 depicts the statistically significant relationship identified between the presence of volar hand ^{18}F-FDG uptake and later time to first relapse/no relapse (HR 0.25 [0.09 – 0.71], p=0.004).

Conclusion: A novel pattern of volar ^{18}F-FDG uptake at the hand was associated with glucocorticoid-responsive disease in a prospective cohort of newly diagnosed PMR patients.

Long-term Clinical Course and Outcomes of 2013 Patients with Takayasu Arteritis

Hajime Yoshifuji,[1] Haruhito Uchida,[2] Yoshikazu Nakaoka,[3] Takahiko Sugihara,[4] Mitsuaki Isobe,[5] and Masayoshi Harigai[6], [1]Kyoto University, Kyoto, Japan, [2]Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan, [3]National Cerebral and Cardiovascular Center Research Institute, Osaka, Japan, [4]Tokyo Medical and Dental University, Tokyo, Japan, [5]Sakakibara Heart Institute, Tokyo, Japan, [6]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Takayasu arteritis (TAK) occurs at a young age and has a long-term clinical course. Progression of arterial stenosis or dilatation leads to organ dysfunction. To provide information for improvement of the treatment strategies, we surveyed the treatments, complications, damages, and activities of daily living in the long-term clinical course of TAK, using the data of 2013 patients from the national registry of Japan.

Methods: Data of 211 newly registered and 2584 continuously registered patients were obtained from the case report forms for TAK in the year 2013 from the national registry. We excluded cases with inconsistent data and age of onset >60 years, leaving 76 newly registered and 1937 continuously registered patients. The patients were analyzed by stratification into four groups: 1) new and 2) disease duration < 5 years, 3) 5–20 years, and 4) >20

Table 1. Long-term clinical course of 2013 patients with Takayasu arteritis

Disease duration	New	<5 years	5-20 years	>20 years
Glucocorticoid	65 / 73 (89.0%)	244 / 267 (91.4%)	574 / 743 (77.3%)	434 / 855 (50.8%)
Mean PSL dose (mg)	34.4 (n = 63)	13.6 (n = 240)	7.8 (n = 553)	5.7 (n = 420)
Immunosuppressant	11 / 70 (15.7%)	114 / 260 (43.8%)	201 / 713 (28.2%)	58 / 801 (7.2%)
Mean ESR (mmHg)	73.3 (n = 63)	18.6 (n = 188)	18.5 (n = 466)	21.1 (n = 506)
Mean CRP (mg/dL)	6.7 (n = 76)	0.8 (n = 261)	0.5 (n = 717)	0.6 (n = 817)
Fever	51 / 76 (67.1%)	82 / 273 (30.0%)	83 / 766 (10.8%)	37 / 898 (4.1%)
Brain ischemia	8 / 75 (10.7%)	17 / 271 (6.3%)	52 / 758 (6.9%)	142 / 882 (16.1%)
Blindness	0 / 76 (0.0%)	0 / 273 (0.0%)	3 / 766 (0.4%)	16 / 898 (1.8%)
Aortic regurgitation	17 / 72 (23.6%)	59 / 264 (22.3%)	226 / 716 (31.6%)	392 / 843 (46.5%)
Aortic aneurysm	9 / 76 (11.8%)	24 / 271 (8.9%)	91 / 758 (12.0%)	132 / 877 (15.1%)
Ischemic heart disease	2 / 75 (2.7%)	12 / 271 (4.4%)	46 / 762 (6.0%)	168 / 886 (19.0%)

n=76, 273, 766, and 898 (New, <5 years, 5-20 years, 20 years<). Items with missing data have smaller numbers. PSL, prednisolone.

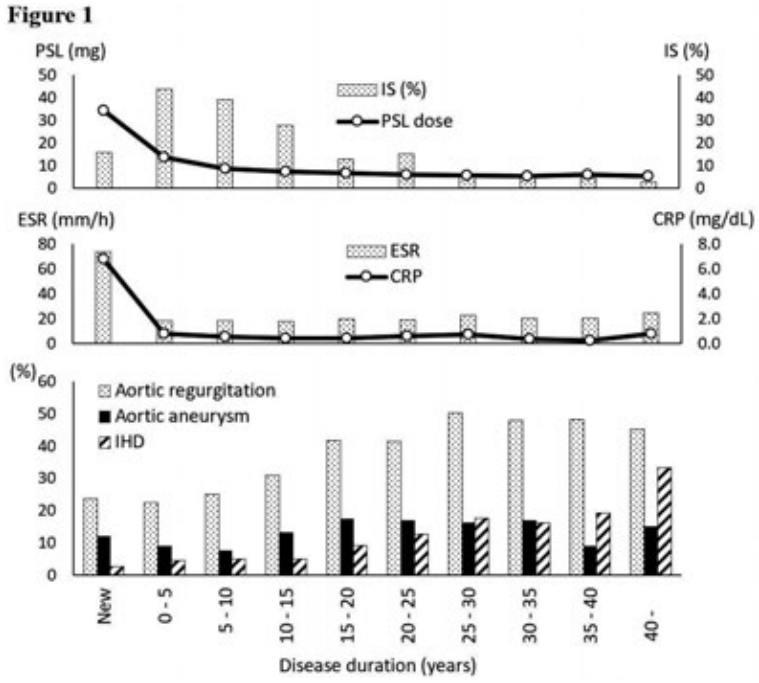

Figure 1. Long-term clinical trends of Takayasu arteritis. We stratified 2013 patients by disease duration divided into 5-year intervals and plotted the mean values or percentages of clinical items. IHD, ischemic heart disease; IS, immunosuppressant; PSL, prednisolone.

years (n=76, 273, 766, and 898; mean current age=34, 35, 46, and 62 years; female ratio=84%, 85%, 86%, and 95%, respectively).

Results: The mean prednisolone dose was lower in patients with longer disease duration: (new, < 5 years, 5-20 years, >20 years = 34, 14, 8, and 6 mg/day, respectively) (**Table 1**). Immunosuppressants (IS) were used in 44% of patients after initiation of glucocorticoid (GC). The frequencies of fever (67%, 30%, 11%, and 4%, respectively) and CRP levels (6.7, 0.8, 0.5, and 0.6 mg/dL, respectively) were also lower in patients with longer disease duration. Conversely, the frequencies of aortic regurgitation (24%, 22%, 32%, and 47%, respectively), aortic aneurysm (12%, 9%, 12%, and 15%, respectively), ischemic heart disease (3%, 4%, 6%, and 19%, respectively), and blindness (0%, 0%, 0.4%, and 1.8%, respectively) tended to be higher in patients with longer disease duration (**Fig. 1**). The percentage of patients with severe disease (Class IV + V) (20%, 10%, 13%, and 22%, respectively) was high at onset, decreased

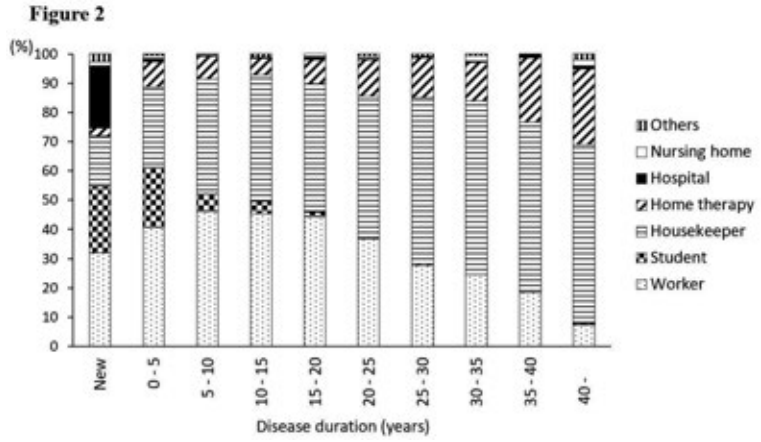

Figure 2. Social situation of 1963 patients with Takayasu arteritis. We stratified 1963 patients with available data by disease duration divided into 5-year intervals and calculated the percentage of each item.

after initiation of therapy, and showed an increasing tendency depending on disease duration. The percentage of workers was < 50% irrespective of disease duration (**Fig. 2**).

Conclusion: In this cohort, treatments with GC (initially medium dose) and IS (approximately 40%) were suggested to improve the disease activity of TAK. However, the frequency of complications and damages showed an increasing tendency depending on disease duration, leading to a limited social role.

Interleukin-6 May Predict Disease Relapse During Long-term Follow-up in Takayasu's Arteritis in a Han Chinese Population

Ying Sun,[1] Kong Xiufang,[2] and Lindi Jiang[3], [1]Department of Rheumatology, Zhongshan Hospital, Fudan University, Shanghai, P. R. China, Shanghai, [2]Zhongshan Hospital Fudan University, ShangHai, China (People's Republic), [3]Zhongshan hospital, Fudan University, Shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the role of interleukin-6 (IL-6) in predictinglong-term disease prognosis for Takayasu's arteritis (TA).

Methods: Thirty-one patients diagnosed with TA between January 2012 and December 2013 were enrolled. The baseline IL-6 levels were detected in all, and a 5-year follow-up was suggested. Data including clinical presentations, laboratory indices, treatments, and radiological images during the 5-year follow-up were recorded. The value of IL-6 in predicting disease relapse and imaging progression was analyzed.

Results: Patients were divided into three groups according to baseline serum IL-6 levels: low group (≤8.8 pg/mL, n=13); medium group (8.9–18.9 pg/mL, n=9); and high group (≥19.0 ng/mL, n=9). Patients in the high and medium group had higher disease activity than those in the low group ($p< 0.01$). Baseline IL-6 levels were correlated with luminal stenosis ($p< 0.05$), although no significant correlations with long-term imaging progression were observed. Patients with more than 2 episodes of disease relapses were more commonly seen in the medium and high groups ($p=0.03$). Multivariate Cox proportional hazard regression analysis indicated that medium and high IL-6 levels were both positive predictors for disease relapse (medium group: HR 8.26, 95%CI 0.67–53.44, $p=0.072$; high group: HR 14.77, 95%CI 1.09–92.31, $p=0.041$) in TA. Goodness-of-fit test further confirmed the value of high levels of IL-6 in predicting disease relapse ($R=0.71$, $R2=0.57$, $p=0.06$).

Conclusion: IL-6 is a valuable predictor of TA disease relapse during long-term follow-up. Thus, treatments targeted at IL-6 pathways may reduce disease relapse and have better long-term prognostic effects for TA patients.

Polymyalgia Rheumatica Patients with and Without Elevated Baseline Acute Phase Reactants: Distinct Subgroups of Polymyalgia Rheumatica?

Diane Marsman,[1] Aatke van der Maas,[1] Alfons den Broeder,[1] Nathan den Broeder,[1] Nadine Boers,[2] and Frank van den Hoogen[1], [1]Sint Maartenskliniek, Nijmegen, Netherlands, [2]Sint Maartenskliniek, Nijmegen

SESSION INFORMATION

Session Date: Sunday, November 10, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica
Session Type: Poster Session (Sunday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic signs of inflammation such as raised CRP or ESR are a classical feature of PMR, but some patients present with normal acute phase reactants (APR).[1,2] It is not known whether these patients represent milder forms of PMR, whether their disease is not yet fully expressed, or whether they represent another disease entirely. We will explore baseline differences in demographics and clinical characteristics in PMR patients with and without elevated APR to evaluate whether they are distinct subgroups of PMR.

Methods: We conducted a retrospective cohort study of newly diagnosed PMR patients (clinical diagnosis) who visited our outpatient clinic between April 2012 and September 2017. Patient with concomitant inflammatory rheumatic disease were excluded. Data on patient-, disease,- and treatment characteristics were extracted from the electronic health record. Descriptive statistics were used [mean (SD), median (p25-p75) or n (%) as appropriate], and differences between patients with normal versus high APR(CRP >10 mg/L and/or ESR >30mm/hour) were tested using Fischer's exact test for categorical data, t-test for normally and Wilcoxon test for non-normally distributed data.

Table 1. Baseline characteristics of patients with normal versus elevated APR

Characteristic	Normal APR (N= 62; 14%)	Elevated APR (N= 392; 86%)
Female (%)	32 (52)	218 (56)
Age in years at diagnosis (SD)	66.0 (7.5)	66.6 (8.9)
History of previous PMR (%)	10 (16)	32 (8)

‡Fever, night sweats, weight loss, anorexia

**N=46 in normal APR group; N= 358 in elevated APR group

***Rheumatoid factor: N= 36 versus N= 257; anti-CCP: N= 33 versus N= 242

**** Angina pectoris, myocardial infarction

***** Cardiovascular disease: cerebrovascular event, peripheral arterial disease, heart failure, thrombosis

¤ N=42 in normal APR group; N= 339 in elevated APR group

Results: 454 patients were included (table 1). Sixty-two patients had normal, and 392 had elevated APR. Fewer patients with normal APR had peripheral arthritis (2 versus 9 %; p=0.044) and anemia at diagnosis (17 versus 43%; p=0.001). Furthermore, patients had a longer median duration of symptoms before diagnosis (13 versus 10 weeks; p=0.02) and were more likely to have a history of PMR (16 versus 8 %;p=0.057). Patients with normal APR had a shorter median time to referral general practitioner due to GC-free remission (552 versus 693 days; n= 36 versus 160; p=0.023). In both groups flares occurred more often between 12-24 versus < 12 months compared to the first 12 months (35 versus 13%; p=0.001 and 30 versus 20%; p=0.010 in normal and elevated APR group respectively). Fewer patients with normal APR were prescribed methotrexate; 3 versus 12%; p=0.046).

Conclusion: The results of this cohort suggest that patients with normal APR are a somewhat milder subset of PMR patients and have a better prognosis. However, flare risk does not differ from APR positive patients.

Session Date: Sunday, November 10, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster I: Takayasu's Arteritis & Polymyalgia Rheumatica

Session Type: Poster Session (Sunday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with polymyalgia rheumatica (PMR) and giant cell arthritis (GCA) constitute approximately 20% of diseases chronically treated with glucocorticoids (GC) with a daily dose of 7.5 mg or more,[1] and GC-related adverse events (AE) are reported in up to 65% of PMR patients.[2] Additionally, 50% of secondary care patients are not able to discontinue their GC treatment, emphasizing the need for GC-sparing agents.[3] The recent guidelines on management of PMR recommend early introduction of methotrexate (MTX), especially in patients at risk for worse prognosis such as female gender, high erythrocyte sedimentation rate (ESR) and peripheral arthritis at

*SD= Standard deviation

**IQR = Interquartile range

***Fever, night sweats, weight loss, anorexia

****Rheumatoid factor: N= 293; anti-CCP: N= 275

‡Reason for prescribing in PMR: azathioprine (AZA) : all due to ineffectiveness GC. Leflunomide: all due to ineffectiveness GC in PMR and failure on MTX. Tocilizumab (TCZ) 1; adverse events GC

‡‡ GC-related adverse events described: Cushingoid face, hair loss, hot flashes, brittle skin, stomach ache, dizziness, weight gain, cataract, osteoporosis

diagnosis.[4] However, evidence regarding MTX use in daily clinical practice is limited.[4] Therefore our aim is to assess MTX treatment in GC dependent PMR patients in a large Dutch rheumatology clinic.

Methods: This is a retrospective cohort study of newly diagnosed PMR patients (clinical diagnosis) who visited our rheumatology clinic between April 2012 and September 2017. Patients with concomitant active inflammatory rheumatic disease were excluded. Data on patient, disease and treatment characteristics were extracted from the electronic health records. Descriptive statistics were used as appropriate.

Results: Baseline, follow-up and treatment characteristics of the 454 included patients are described in table 1. MTX was prescribed in 52/454 (11%) PMR patients while 33% of patients had two or more flares during follow-up. Other disease modifying anti-rheumatic drugs (DMARDs) were prescribed in 2% of patients. Reasons for prescribing MTX were GC ineffectiveness in 46%, GC adverse events in 8%, both GC ineffectiveness and adverse events in 21% and unknown in 25% of patients. Mean time to MTX introduction was 535 days (SD 353) and the starting MTX dose was 10mg in 10%, 15 mg in 46%, 20mg in 15% and 25mg in 29% of PMR patients respectively. Of the PMR patients treated with MTX, 83% was on oral GC (mean dose was 8.9mg, SD 5.5mg) and 8% on intramuscular GC (mean dose 95mg per approximately one month, SD38mg). At the start of MTX treatment, 38% of patients had experienced three or more flares, 27% two flares and 35% one flare.

Conclusion: Early introduction of concomitant MTX early in GC dependent PMR is limited in our rheumatology clinic. Several interventions can be conceived to enhance follow-up to (inter)national guidelines on management of PMR.

Background/Purpose: The cause for polymyalgia rheumatic (PMR) is currently unknown. Disease onset may be triggered by a combination of genetic predisposition and environmental factors such as infection.[1] In different regions of Denmark a simultaneous peak incidence of giant cell arthritis and PMR occurred together with epidemics of Myco-

plasma pneumoniae, Chlamydophila pneumoniae and Parvovirus B19.[1] A seasonal epidemics pattern for PMR would be supporting evidence for an infectious cause.[1] However, the current evidence of seasonal effect on the occurrence and disease severity of PMR is limited and show conflicting results.[2,3] We therefore aim to evaluate whether there is a seasonal effect on the risk of developing PMR in the Netherlands.

Methods: We retrospectively collected data on patient-, disease,- and treatment characteristics from newly diagnosed PMR patients (clinical diagnosis) who visited our outpatient clinic during April 2012 and September 2017. Exclusion criteria was other concomitant inflammatory rheumatic disease. Based on the onset of PMR (start symptoms, not time of diagnosis) patients were grouped per month. Descriptive statistics were used [mean (SD), median (p25-p75) or n (%) as appropriate]. The Chi square goodness of fit test was used to determine whether the incidence of onset of symptoms was different between months of the year.

Results: In total 448 patients were included and 55 % were female and mean age was 66 years. Other baseline characteristics are described in table 1. The chi-square goodness of fit test to determine whether there was a peak incidence in months was p=0.06. As shown in figure 1 the incidence of onset PMR symptoms is higher in December-January, April through June with a peak in August. The April-June peaks coincides with incidence peaks of Mycoplasma pneumoniae infections and possibly Parvovirus B19 in spring and summer, The December-January peak coincides with Parvovirus B19 infections.[4,5]

Conclusion: No definitive seasonal effect was found on risk of developing PMR, although a bimodal seasonal pattern compatible with the proposed respiratory infections is suggested.

Obesity, n (%, 95% CI)	19 (11.2, 7.3-16.9)	20 (11.8, 7.7-16.7)	0.86
Statin initiation, n (%, 95% CI)	17 (10.1, 6.3-15.6)	9 (5.3, 2.8- 9.9)	0.10
Any vaccine received and recorded, n (%, 95% CI)	31 (18.3, 13.2-24.9)	24 (14.2, 9.7-20.4)	0.30
Infections requiring antibiotics or ambulatory consultation, n (%, 95% CI)	25 (18.3, 13.2-24.9)	18 (10.6, 6.8-16.3)	0.25
Infections requiring hospitalization, n (%, 95% CI)	4 (2.4, 0.9-6.2)	2 (1.2, 0.3-4.6)	0.41
Surgery, n (%, 95% CI)	7 (4.1, 1.9-8.5)	6 (3.6, 1.6-7.7)	0.78
Cardiovascular event, n (%, 95% CI)	2 (1.2, 0.3-4.6)	1 (0.6, 0.1-4.1)	0.56

Background/Purpose: As many other rheumatologic diseases, pathogenesis of Polymyalgia Rheumatica (PMR) is not well understood. Genetic factors seem to play a role. Some studies have suggested a seasonal variation, indicating a possible infectious trigger; others have shown and association with statins initiation. Our objective was to compare PMR patients with matched controls in order to identify possible triggers in the year previous to PMR development.

Methods: PMR patients (fulfilling ACR 2012 criteria) belonging to a Health Management Organization (HMO) of a tertiary university hospital were matched 1:1 by gender and date of birth with controls belonging to the same HMO. Date of PMR diagnosis was considered as the index date for patients and their correspondent control. Electronic medical records were manually reviewed and data on infections, hospitalizations, surgeries, vaccines and starting of statins in the year previous to the index date were recorded for both PMR patients and controls and compared between them. For PMR patients, season where disease symptoms started was also analyzed.

Table 2. PMR patients' characteristics

	PMR patients (n=169)
Females, n (%)	135 (79.9)
Age at diagnosis, years, mean (SD)	79.5 (6.1)
Erythrosedimentation rate at diagnosis, mm/h, mean (SD)	54.0 (24.1)
Shoulder girdle pain, n (%, 95% CI)	91.1 (85.7-94.6)
Pelvic girdle pain, n (%, 95% CI)	84.0 (77.6-88.8)
Arthritis, n (%, 95% CI)	60 (35.5, 28.6-43.0)
Initial dose of meprednisone, mean (SD)	9.3 (5.4)
Duration of corticosteroid treatment, median (IQR)	21 (13-33)
PMR symptoms starting in summer, n (%, 95% CI)	50 (29.6, 23.1-36.9)
PMR symptoms starting in autumn, n (%, 95% CI)	50 (29.6, 23.1-36.9)
PMR symptoms starting in winter, n (%, 95% CI)	42 (24.8, 18.9-31.9)
PMR symptoms starting in spring, n (%, 95% CI)	27 (15.9, 11.1-22.4)

Results: 169 PMR patients and 169 controls were included. 79.9 % were females. Age at PMR diagnosis was 79.5 years (SD 6.1). No differences were found between PMR patients and controls regarding infections, hospitalizations, vaccines, surgeries or statin initiation in the year previous to PMR diagnosis (table 1). PMR symptoms started in summer in 50 patients (29.6%, 95% CI: 23.1-36.9), in autumn in 50 (29.6%, 95% CI: 23.1-36.9), winter in 42 (24.8%, 95% CI: 18.9-31.9) and spring in 27 (15.9%, 95% CI: 11.1- 22.4) (Table 2).

Conclusion: We didn't find an identifiable trigger for the development of PMR when analyzing the year previous to diagnosis comparing to matched controls. No seasonal pattern was clearly seen.
