10	F	51	SLE	200	24	75	+	

Note: SLE: Systemic Lupus Erythematosus, RA: Rheumatoid Arthritis, CTD: Connective Tissue Diseases, eGFR: estimated Glomerular Filtration Rate, SSZ: Sulfasalazine, MTX: Methotrexate, AZA: Azathioprine

Aim: To reassess and redetermine the overall prevelance of hydroxychloroquine induced retinopathy.

Methods: We retrospectively reviewed the records of 729 patients who were referred to hydroxychloroquine retinopathy screening clinic in the medical eye unit at St Thomas Hospital, London, UK. The following data were collected: age, gender, body weight, indication to use hydroxychloroquine, dosage, duration of treatment, use of steroids or other immunosuppressive therapy, previous kidney disease, estimated glomerular filtration rate (eGFR) and concurrent use of tamoxifen. The analytic statistics was carried out.

Results: A total of 729 patients (88.6% female and 11.4% male) were seen in HCQ retinopathy screening clinic. All patients were on HCQ with mean duration of 7.6 years. The mean age was 48 ±13.9 years (range 13-89). The main indications for HCQ use were systemic lupus erythermatosus (SLE) 50% and rheumatoid arthritis (RA) 17%. Approximately 34% of the patients were on oral corticosteroids and 46% were on conventional and/or biological disease-modifying antirheumatic drugs (DMARDs). Eight patients were on Tamoxifen. The mean HCQ dose was 260 mg (3.9 mg/kg) and the mean eGFR was 83 ml/min. History of renal diseases (lupus nephritis or chronic kidney disease) were reported in 19%, half of them with eGFR less than 60 ml/min. The average daily consumption of HCQ in patients with eGFR less than 30 ml/min was 1.9 mg/kg. Ten patients found to have definitive HCQ retinopathy with overall prevalence 1.4%. The prevalence increased to 2.8% and 5.4% in patients using HCQ for more than 5 years and 20 years or more, respectively. All were female with mean age of 55.8 years (range 35-76). The average daily dosage for patients with retinopathy was 5.17 mg/kg which was higher than patients with normal retinal exam 3.88 mg/kg (P value = 0.1). The mean duration for HCQ use in patients with toxicity was 15.8 years (range 7-32). Renal impairment or tamoxifen use were not observed in our cohort of patients with retinopathy. We found retinopathy is associated with prolonged duration of HCQ use (P< 0.05). The mean duration of HCQ use was 15.2 years in patients with retinopathy compared to 7.5 years for patients with normal retinal exam. In our study, there were no significant correlation between daily HCQ dosage and retinopathy (P=0.903). This might be attributed to the relatively lower daily HCQ dose used in our patient, especially in patients with low eGFR.

Conclusion: In our study, the overall prevalence of HCQ retinopathy was 1.4%, increased to 5.4% in patients using HCQ for 20 years or more. The risk of retinopathy was linked to the prolonged use of HCQ. Lower dosage (2 mg/kg) was found to be safe in patients with low eGFR.

Loss to Follow-up in Registries of Rheumatic Patients Treated with Biologics: A Potentially Valuable Hidden Real-world Data That Is Being Overlooked?

Ana Valido,[1] Joana Silva-Dinis,[2] Rita Cruz-Machado,[3] Maria João Gonçalves,[4] Vasco Romao,[5] Maria João Saavedra,[1] and João Eurico Fonseca[2], [1]Serviço de Reumatologia e Doenças Ósseas Metabólicas, Hospital de Santa Maria, CHLN; Lisboa, Portugal., Lisbon, Portugal, [2]Rheumatology and Bone Diseases Department, Hospital de Santa Maria, Centro Hospitalar Universitário Lisboa Norte; Unidade de Investigação em Reumatologia, Instituto de Medicina Molecular, Faculdade de Medicina, Universidade de Lisboa; Centro Académico de Medicina de Lisboa; Lisbon, Portugal., Lisbon, Portugal, [3]Serviço de Reumatologia e Doenças Ósseas Metabólicas, Hospital de Santa Maria, CHULN; Lisboa, Portugal. SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The information associated with loss to follow-up (LFU) patients may affect real-world data evaluation of the use of biologics that is not being adequately captured in registries.

Methods: We identified all patients (Pts) treated with biologics in our center who had no registered visits for more than 6 months, in the Rheumatic Diseases Portuguese Register, Reuma.pt.,. We retrieved baseline information from Reuma.pt and from the hospital electronic clinical record. We then performed a telephonic interview to characterize the reasons for LFU at our day care unit. For Pts unable to be contacted by telephone a letter of invitation to an appointment at the hospital was sent.

Results: From a total of 794 Pts registered in Reuma.pt at our center with active biologic therapy 227 did not have any information registered in the last 6 months. Of this, 36 Pts were on biologic therapy prescribed by other Departments (gastroenterology and dermatology) and maintained follow-up in these departments. 102 Pts had suspended biologic administration by medical indication and this information was registered in the hospital electronic clinical records but not updated in Reuma.pt. For 89 Pts no information could be retrieved from either the hospital electronic clinical record or Reuma.pt and we classified these Pts as true LFU.

Tabel 1. Demographic characteristics, diagnosis and biologic therapy of true loss to follow up patient.

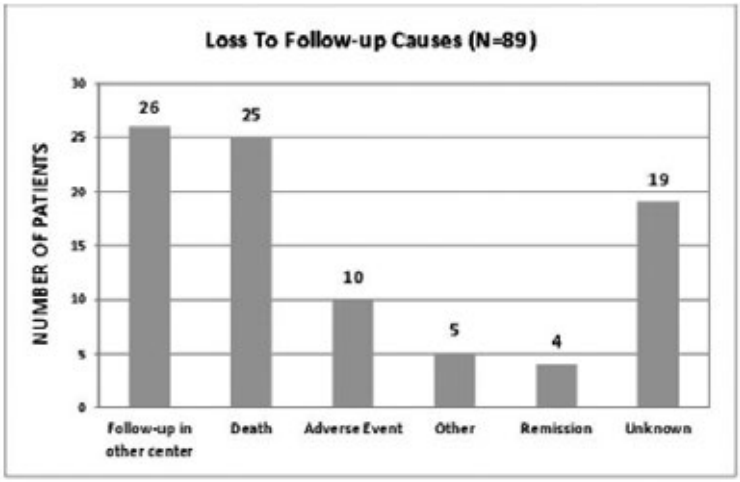

Graphic 1. Identified Causes of loss to follow up.

28 of these LFU Pts were being followed up in another Rheumatology center. The most frequent reasons for this change were: transfer of the follow-up to a newly created and closer Rheumatology Department (15); relocation to another city (6); administrative problems issues related to our Department/Hospital (5) and socio-economic reasons that were interfering with travelling to our department (2).

26 of the LFU Pts died, at a mean age of 66.3 years. The mean disease duration was 14.3 years and 20 Pts had RA. The mean duration of biologics was 5.9 years and 53.8% were under anti-TNF therapy, 16% under Anti-CD20 therapy and 12% under interleukin-6R inhibitors. Cause of death was identified in only 3 Pts: 1 had a myocardial infarction, 2 had complications of surgeries.

11 Pts who were LFU had stopped biologic therapy and abandoned follow-up by their own decision after suffering adverse effects attributed by the Pts to the use of biologics. 6 Pts had infections: cutaneous (n=3) or urinary tract related (n=3; with need for hospital admission in 2 of the cases). The remaining Pts stopped the drug because of cutaneous reactions (n=5).

4 Pts of the LFU were in remission and decided to stop the drug and the medical follow up. All of them believed that the disease was inactive without the need of medical drugs.

We were not able to contact 15 of the LFU pts.

Conclusion: Identifying LFU Pts and clarifying the reason for the loss of data in a register contributes to a better knowledge on strategies to discontinue biologics in stable pts, to a better pharmacovigilance of adverse effects and to more efficiency in data capture by registries. Due to data protection reasons It was impossible to have access to the Pts's death certificates.

Abstract Number: 1132

Facility-Level Variation in Biologic Disease Modifying Agents for Medicare Enrollees with Rheumatoid Arthritis

Deepan Dalal,[1] Tingting Zhang,[2] Hiren Verma,[3] and Theresa Shireman[2], [1]Brown University, Riverside, RI, [2]Brown University, Providence, RI, [3]Brown University School of Public Health, Providence, RI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease modifying agents (DMARDs) are an integral part of rheumatoid arthritis (RA) treatment, but the adoption of infusion-based products has not been reported. We examined Medicare claims to determine the relative market shares for biologic agents in beneficiaries with RA.

Methods: We identified Medicare enrollees with a least one diagnosis code from an inpatient or outpatient claim for RA between 2012-2016. We pulled their Medicare Part B claims (20% Part B sample) for biologic infusions using J-codes. We aggregated procedure claims to the facility level for facilities with at least 50 claims and characterized the distribution of individual biologic agents annually. We report trends in the adoption and reductions in use of agents overall and according to facility size.

Results: There were 27,143 Medicare enrollees with RA: mean age, 68.8 years ± 10.1; white, 86.6%, and black, 7.4%; female, 76.8%. Part B claims for biologics increased 31.3%: Infliximab was most common, though its use dropped from 51.8% to 33.4%; abatacept dropped from 30.6% to 26.0% (Table 1). Tocilizumab, certolizumab and golimumab increased use over time, and rituximab remained consistent (6.8%-7.4%). Biologic use varied significantly by facility size for all agents except infliximab (Table 2). Smaller facilities used more certolizumab (11.2%) and rituximab (11.9%).

Table 1. Annual distribution of claims for Part B biologic agents in Medicare beneficiaries with RA

Biologic agent	2012	2013	2014	2015	2016
Abatacept	30.6%	30.0%	25.5%	25.8%	26.0%
Certolizumab	N/A	N/A	8.7%	11.0%	12.6%
Golimumab	N/A	N/A	3.1%	5.6%	7.3%
Infliximab	51.8%	49.6%	42.2%	37.7%	33.4%
Rituximab	7.3%	7.4%	6.8%	6.8%	6.8%
Tocilizumab	10.2%	13.0%	13.7%	13.2%	14.0%
Number of claims	84,064	87,291	98,047	108,256	110,403

Table 2. Proportion of claims for each biologic by facility claim experience for Medicare beneficiaries with RA (2012-2016)

Biologic claims counts	Small <200	Small-Moderate >= 200 to 500	Moderate >= 500 to 1,000	Large >= 1,000
Abatacept*	24.5% (24.8)	30.6% (20.0)	28.7% (14.6)	26.9% (21.6)
Certolizumab*	11.2% (24.8)	7.3% (13.5)	7.0% (11.1)	5.9% (5.9)
Golimumab*	2.8% (6.7)	3.8% (5.3)	3.6% (4.9)	3.6% (4.3)
Infliximab	40.4% (30.6)	42.1% (21.8)	41.9% (16.4)	43.2% (14.3)
Rituximab*	11.9% (23.5)	4.8% (8.9)	5.3% (6.5)	4.9% (4.6)
Tocilizumab*	9.3% (16.3)	11.4% (13.2)	13.5% (10.9)	15.6% (10.3)
$p < 0.05$ from ANOVA testing means across facility size for each drug				

Conclusion: Office administration of biologic agents for RA has expanded by nearly one-third in 5 years. Infliximab and abatacept lost market share as newer agents were introduced; total share anti-TNF agent remained constant. Further research is needed to determine how facilities select between agents and the impact on patient outcomes.

Abstract Number: 1133

Medicare Spending (2012-2017) on Disease Modifying Agents Commonly Used in Rheumatoid Arthritis

Deepan Dalal,[1] Tingting Zhang,[2] and Theresa Shireman[2], [1]Brown University, Riverside, RI, [2]Brown University, Providence, RI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic disease modifying agents (DMARDs) have become an integral part of rheumatoid arthritis (RA) treatment guidelines, but they are associated with a substantial increase in direct medical care costs. Given Medicare's role in providing health care coverage to older adults, we assessed the impact biologic and conventional DMARDs have had on its drug expenditures.

Methods: We compiled six years (2012-17) of publicly available Medicare spending reports capturing DMARDs expenditures aggregated from Part B (infusions) and Part D (oral) claims. Data included: total expenditures (before rebates), beneficiary counts, and unit drug costs. We distinguished trends at the product level and subclasses, conventional and biologics DMARDs.

Results: Total spending for conventional DMARDs increased from $98 million to $579 million. Expenditures for methotrexate were surpassed by hydroxychloroquine expenditures in 2014-15 (Fig 1). The 6-fold increase in total spending was driven by increase in unit cost of drugs rather than increases in beneficiaries (738,000 to 1.13 million).

Total spending on biologic DMARDs rose from $4.3 billion to $10.0 billion with a more modest increase in the number of beneficiaries (252,225 to 353,960). Adalimumab expenditures rose from $674.8 million (2012) to $2.64 billion (2017): expenditures for etanercept ($1.76 billion) and rituximab ($1.75 billion) were the next highest (Fig 2).

Conclusion: Medicare expenditure for conventional agents increased dramatically but remained a fraction of the total spending (5.7%) on DMARDs when biologic agents were included. Rise in unit drug costs rather than increase in beneficiaries were often responsible for increased total spending. It is important to acknowledge that these products are also used for non-RA indications, and we were unable to account for manufacturers'

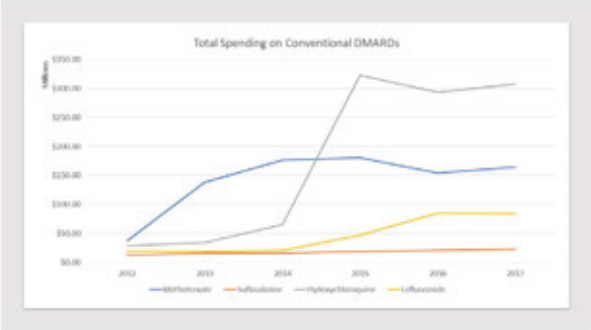

Figure 1. Trends in Medicare spending for conventional DMARDs.

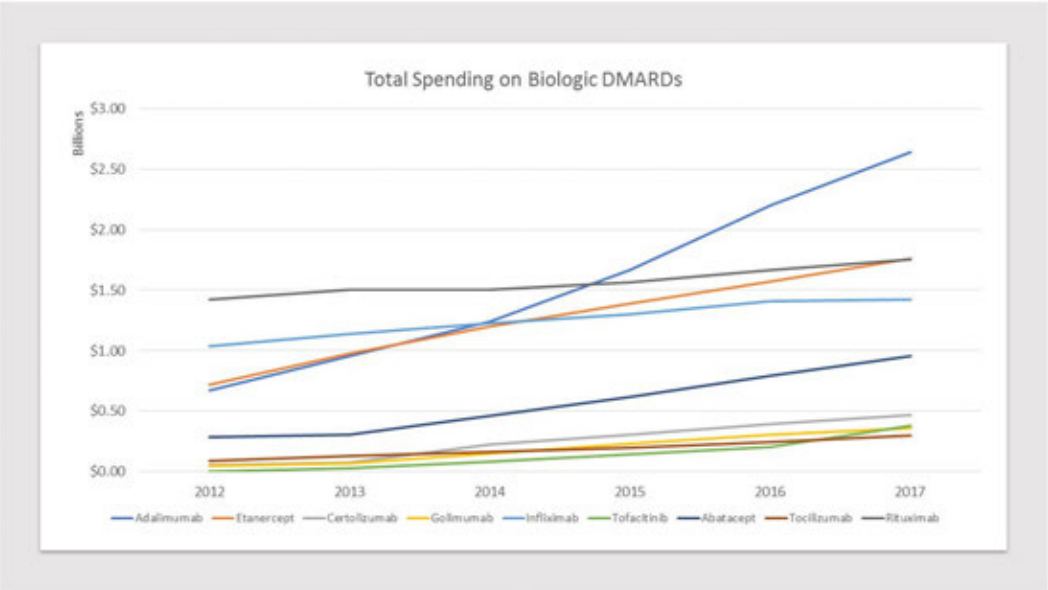

Figure 2. Trends in Medicare spending on biologic DMARDs.

rebates. Further work is needed to determine if increases in DMARD are offset by cost reductions and lead to better patient outcomes.

Abstract Number: 1134

Medicaid Spending (2013-2017) on Disease Modifying Agents Commonly Used in Rheumatoid Arthritis

Deepan Dalal,[1] Tingting Zhang,[2] and Theresa Shireman[2], [1]Brown University, Riverside, RI, [2]Brown University, Providence, RI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The management of rheumatoid arthritis (RA) and other conditions have improved tremendously since the introduction of biologic disease modifying agents (DMARDs). However, these agents command a substantial price, adding more $20,000 to direct medical care costs in people with RA. We examined recent trends in Medicaid (public health insurance for low income US citizens) spending on DMARDs in this era of biologics.

Methods: We compiled data from 5 years (2013-17) of publicly available Medicaid spending reports: total expenditures (before rebates), unit costs, and doses dispensed at the product level. Expenditures were summed and compared between conventional and biologics DMARDs.

Results: Spending on conventional DMARDs increased from $24.2 million to $92.3 million (Fig 1): two-thirds was attributable to hydroxychloroquine which experienced a substantial increase in the price/unit ($0.22 to $1.31). Le-

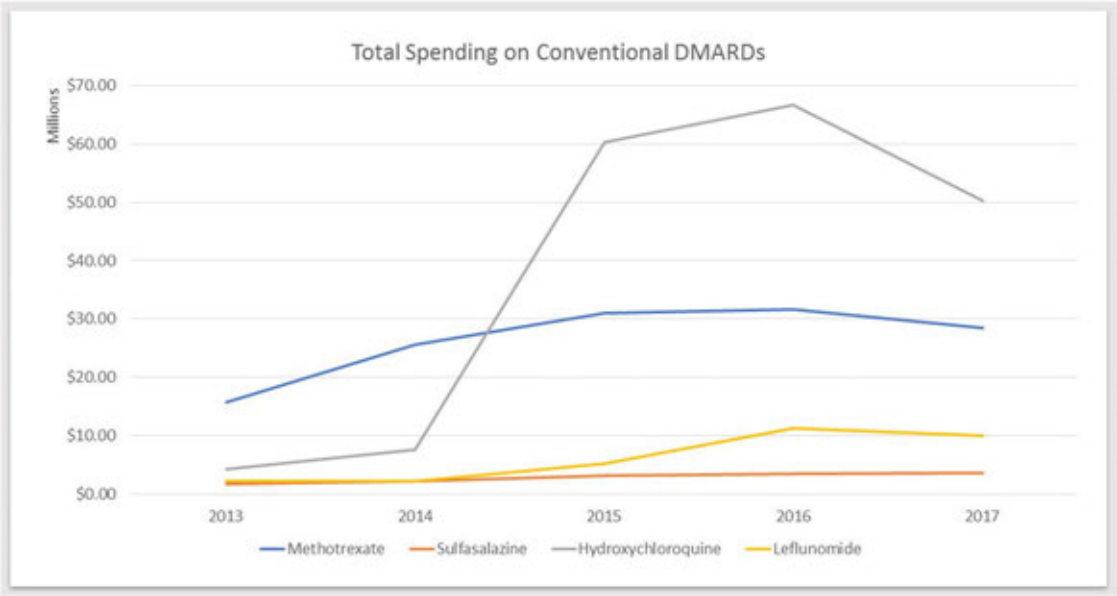

Figure 1. Trends in Medicaid Spending for conventional DMARDs.

flunomide unit costs also more than doubled and spending increased 4.4-fold. Methotrexate and sulfasalazine unit costs were stable.

Spending on biologics increased from $894 million to $3.1 billion: driven by a 5-fold increase in total spending on adalimumab whose cost/unit doubled (Fig 2). Spending on etanercept and infliximab increased more than doubled, unit cost increased by 82% and 45% respectively. Total spending on abatacept increased 5-folds ($19 million to $102 million).

Conclusion: Biologic agents has pushed Medicaid's expenditures for DMARDs from $918.2 million to more than $3 billion in just 5 years. Two conventional DMARDs had substantial unit cost increases, but their expenditure level

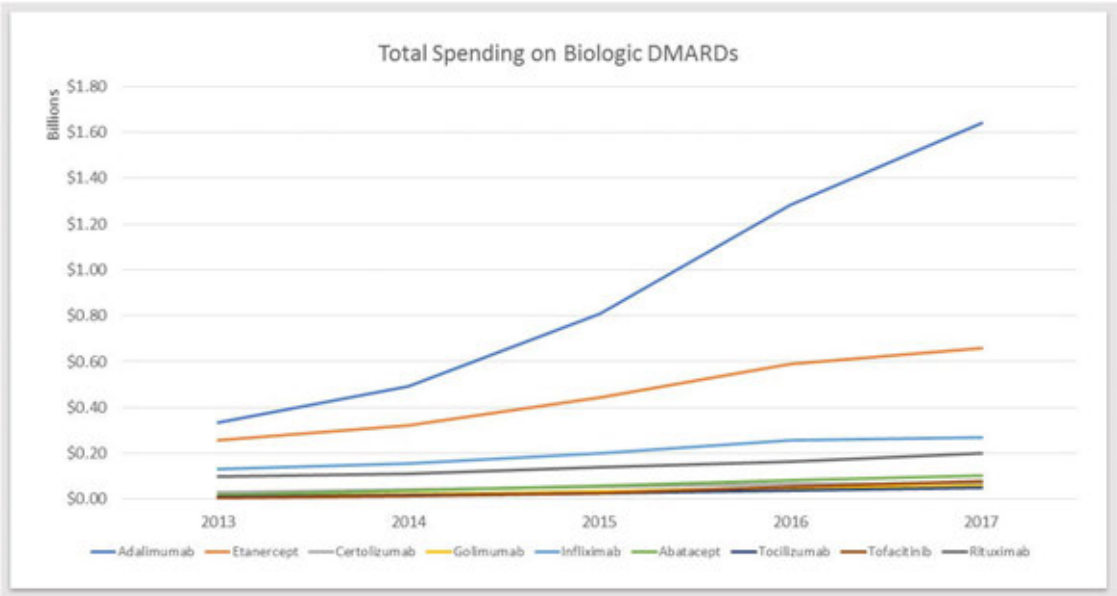

Figure 2. Trends in Medicaid Spending for biologic DMARDs.

remained a fraction (3%) of total DMARD spending. While not all of the biologics were used for RA, these increases should be carefully considered relative to their clinical benefit.

Abstract Number: 1135

Optimizing the Management of Flares in Patients with Rheumatoid Arthritis with the Help of Non-Physician Providers: Results of a Randomized Controlled Trial

Elena Myasoedova,[1] Cynthia Crowson,[2] Rachel Giblon,[1] Kathleen McCarthy-Fruin,[1] Daniel Schaffer,[1] Kerry Wright,[1] Eric Matteson,[3] and John Davis[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, [3]Mayo Clinic College of Medicine and Science, Rochester, Minnesota, USA, Rochester

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Flares in rheumatoid arthritis (RA) are common. The shortage of readily available specialized care may hinder early detection and timely management of RA flares. Engaging non-physician rheumatology providers in care of RA flares may be beneficial. We aimed to evaluate the effect of a flare management intervention guided by non-physician providers versus usual care between rheumatology visits on flare occurrence and RA disease activity.

Methods: Patients with established RA (2010 ACR/EULAR criteria) were randomized to the intervention arm versus usual care. The Flare Assessment in Rheumatoid Arthritis (FLARE-RA) questionnaire was administered monthly during the 24-month follow-up to all patients in the intervention arm to assess flare status [1]. Telephone nurse-led counseling or an expedited visit with a rheumatology provider was offered to patients in the intervention arm who indicated they were in flare. Patients in the usual care arm were followed by their rheumatology providers according to standards of care. OMERACT9 definition of flare was used to compare flare occurrence between the study arms [2]. All patients completed satisfaction surveys at baseline and at the end of the follow-up.

Results: 150 patients with RA were randomized to intervention (n=75) versus usual care (n=75). At baseline, the majority of patients in the intervention arm (51%) and in the usual care arm (60%, p=0.32) expressed interest in expedited appointments with their rheumatology provider if in RA flare. Patients in the intervention arm completed a median of 8.5 (range 1-24) questionnaires. RA flare was reported on 122 (19%) of these questionnaires; average FLARE-RA score: 2.57 on 0 (no flare) to 10 (maximum flare) scale. Patients agreed to have an expedited clinic visit with a rheumatology provider during 39 (32%) of flares. The majority of patients preferred to self-manage their flare (76, 62%) or receive nursing advice on flare management over the phone 7 (6%). There were no differences in DAS28-CRP, CDAI, SDAI, probability of anti-rheumatic treatment change by rheumatology provider, RA flare by OMERACT9 definition, or remission by CDAI between the study arms over 24-months of follow-up. At the end of the study, a higher proportion of patients in the intervention arm (44%) versus the usual care arm (21%, p=0.04) reported positive effect of participation in the study on the management of RA flares.

Conclusion: The flare management intervention guided by non-physician providers did not have any major effect on RA disease activity metrics over the 24-month follow-up. However, patients in the intervention arm reported a

positive effect of the intervention. More studies are needed to further understand patient preferences for optimal RA flare management and to design interventions to meaningfully address these preferences.

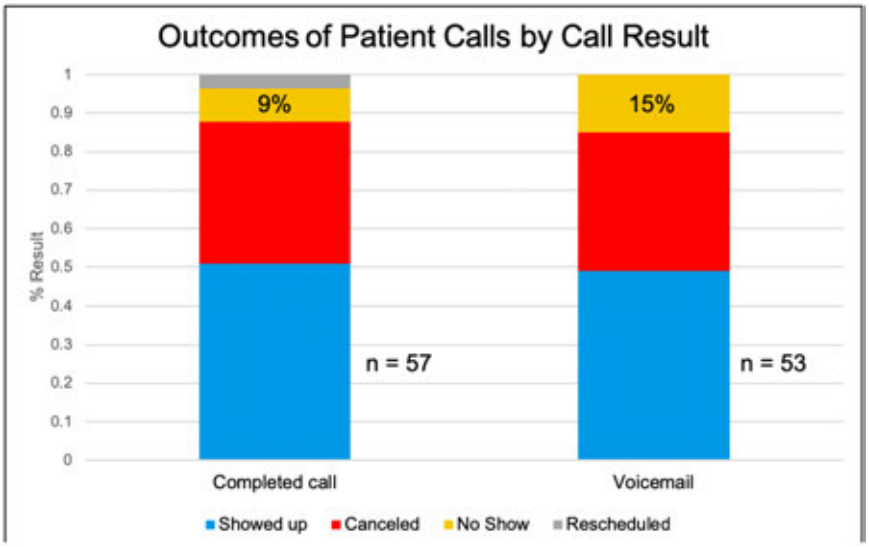
Abstract Number: 1136

Improving Access in an Academic Rheumatology Department by Reducing the No Show Rate

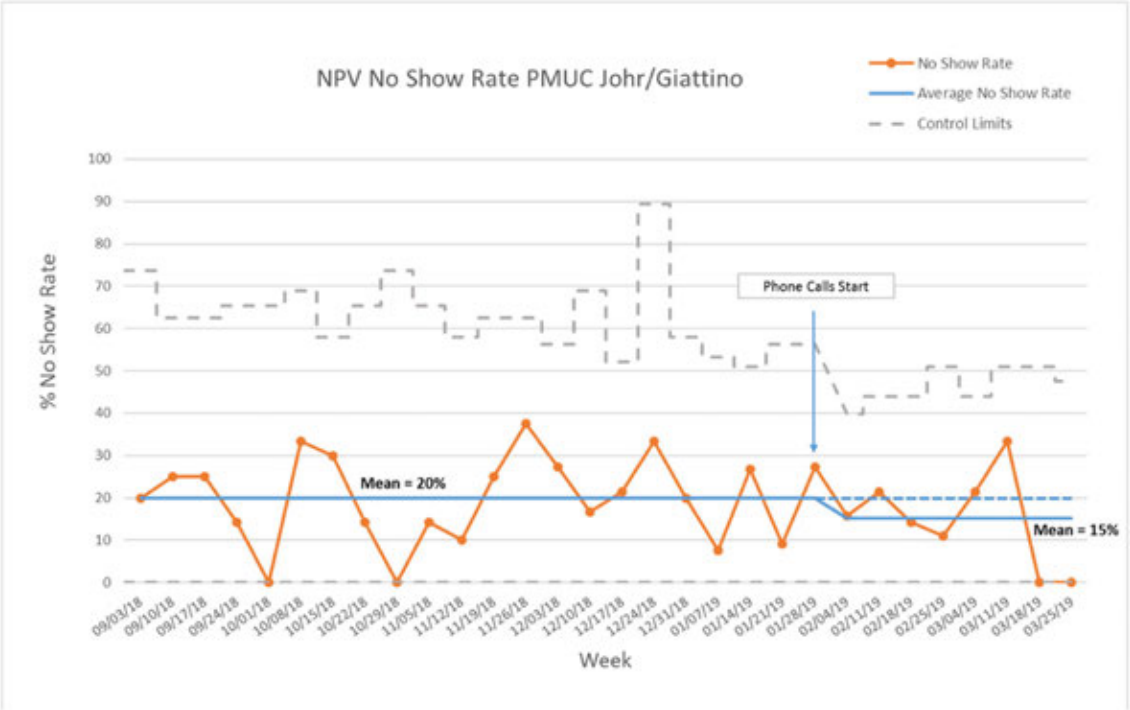
Richard Zamore [1], [1]Hospital of the University of Pennsylvania, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: No shows are a widespread problem across medical practices, and lead to negative consequences for patients and providers (Mendel 2017). The rheumatology division at our institution has an access problem, with wait time up to five months for new patient visits (NPVs). NPV no shows lead to wasted resources that negatively impact patient access. A root cause analysis suggested that the most common reason for patients



Results of phone calls, divided by outcome of call.



Statistical process control chart. No show rate for NPVs by week for providers in pilot from September 2018 through March 2019. Dotted line represents continuation of mean and solid line represents non-statistically significant change in mean after intervention.

no showing for NPVs was because they forgot about the appointment. In addition, most patients (54%) reported not receiving a reminder, despite the fact that our institution sends out automated robocalls 48 hours prior to all appointments.

Methods: We used the A3 model to conduct a quality improvement project to decrease the no show rates for NPVs. Baseline no show rates for our four clinical practice sites were determined, and the site with the highest baseline rate (PMUC) was selected for the intervention. We then conducted a pilot of manual phone call reminders two weeks prior to NPVs for two providers at the PMUC practice site. Data was obtained using EMR reports and analyzed using statistical process control charts.

Results: Over the two month trial period, 110 patients were given manual phone call reminders. 57 patients had completed phone calls and 53 patients were left voicemails [Figure 1]. The no show rate for patients who had completed calls was lower than for those who were left voicemails (9% vs 15%) [Figure 1]. The no show rate for NPVs did not significantly decrease during the intervention period [Figure 2]. However, there was a nonsignificant decrease in the NPV no show rate from 20% to 15%. Secondary metrics to evaluate access were then assessed. The number of short term visits, defined as patients who had appointments made within one week of the visit date (typically patients off the waitlist), more the doubled during the intervention period [Table 1]. The total rate of NPVs seen by the two pilot providers increased by 38% [Table 1]. During the intervention period, an extra 0.57 NPVs were seen per provider per full clinic day, correlating with a revenue generation of about $100 per full provider clinical day.

Conclusion: We conducted a QI project that used manual phone call reminders to reduce the no show rate for NPVs at one of our clinical practice sites. While there was no significant decrease in the no show rate, the mean did decrease by 5% during the intervention period. Notably, there were more short term visits and an increase

Giattino-Johr Combined			
Result	Nov-Jan (before)	Feb-Mar (intervention)	Difference
# short term/clinic day*	0.63	1.32	2.11
# NPVs/clinic day	2.98	4.12	1.38
# RPV&REA/clinic day	15.8	16.56	1.05
# Additional NPVs/clinic day per provider:			0.57

*Short term: Appointments made within one week of appointment date; Giattino-Johr: Providers included in pilot; NPV: New patient visit; RPV: Return patient visit; REA: Reassign visit

in the total NPV rate seen during the intervention period, suggesting improved access. The likely reason for the larger increase in access metrics compared to the no show rate is that the intervention resulted in earlier cancellations leading to an increased opportunity to schedule patients in those open appointment slots. Due to institutional policy, we were not able to adapt automated robocalls, and it is not clear if earlier robocalls would similarly lead to an increase in short term visits and improved access. Our QI project suggests that manually calling patients two weeks prior to their NPV appointments may help decrease the no show rate and likely results in improved access. The revenue generated by the increased productivity suggests this a cost-effective and sustainable change.

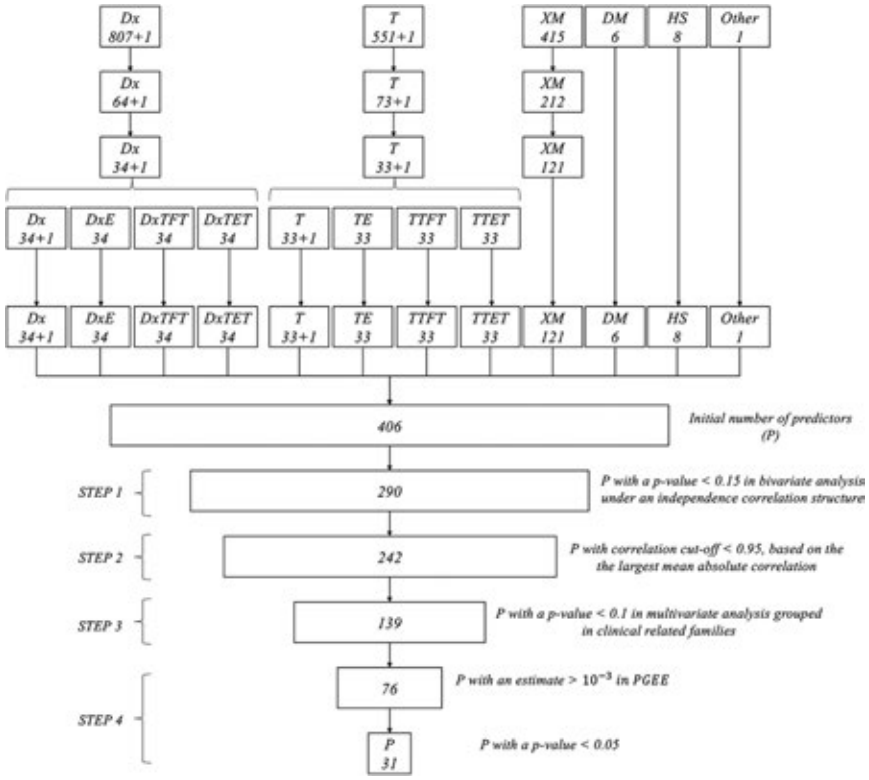
Predictors of Health-Related Quality of Life in Patients with Musculoskeletal Diseases: A Longitudinal Analysis from an Electronic Health Record Database

Luis Rodríguez-Rodríguez,[1] Alfredo Madrid García,[1] Judit Font Urgelles,[2] Leticia León,[3] Dalifer Freites Nuñez,[4] Cristina Lajas,[5] Esperanza Pato Cour,[5] Juan Angel Jover Jover,[5] Benjamín Fernández Gutiérrez,[6] and lydia Abasolo Alcazar[5], [1]Fundación para la Investigación Biomedica, Madrid, Spain, [2]HOSPITAL CLINICO SAN CARLOS, MADRID, Madrid, Spain, [3]Fundación para la Investigación Biomedica, Madrid, Madrid, Spain, [4]Hospital Clínico San Carlos, MADRID, Spain, [5]HOSPITAL CLINICO SAN CARLOS, MADRID, Spain, [6]Hospital Clínico San Carlos, Madrid

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Musculoskeletal diseases (MSKs) are the major cause of disability, affecting the patient's daily activities as well as their Quality of Life (QoL). Our objective is to analyze in a cohort of patients with MSKs the influence of demographic and clinical predictors in repeated measures of Health-Related QoL (HRQoL) obtained from a departamental electronic health record (EHR)

Methods: Patients attending the Hospital Clínico San Carlos rheumatology outpatient clinic (HCSC-MSK cohort) from April 1st, 2007 to November 30th, 2017 who were seen at least twice were included in this study. Our primary outcome was HRQoL collected in each patient's visit using the Rosser Classification Index (it ranges between 0 and



Predictor selection. Dx: Diagnoses. DxE: Diagnoses Episode. DxTFT: Diagnoses Total Follow-up Time. DxTET: Diagnoses Total Episode Follow-up Time T: Treatment. DxE: Treatment Episode. DxTFT: Treatment Total Follow-up Time. DxTET: Treatment Total Episode Follow-up Time. XM: Comorbidities and Concomitant Treatments. DM: Demographics. HS: Health Status.

1, the higher value, the higher HRQoL. It is calculated as the combination of two subscales: disability and distress). Demographic and clinical variables, such as diagnoses, treatments, and comorbidities were included as predictors. Variable selection was carried out in 4 steps. First, we developed a bivariate Generalized Estimating Equations model, selecting those variables with a p-value < 0.15. Second, those with a pair-wise absolute correlation < 0.95 were carried to the next step. Third, multivariate GEE analyses were performed including clinical related variables, and those independently associated with our primary outcome were selected with a p-value < 0.10. Finally, a Penalized GEE was implemented including all selected variables and using an independence correlation structure. Those with an estimate greater than 10^-3 and a p-value lower than 0.05 were considered to be independently associated with the HRQoL.

Results: A total of 19,299 patients with 101,649 outpatient visits were included in this study. From the initial 406 predictors, 290, 242, 139 were selected in the first, second and third steps (Figure 1). After multivariate PGEE analysis, 31 predictors independently associated with HRQoL were identified (Table 1). The predictors with a greater negative impact in HRQoL were the use of 3rd level analgesics and azathioprine, a pressence of kidney failure, fibromyalgia, and ischemic heart disease. Conversely, use of symptomatic slow action drugs for osteoarthritis, statins, lowering uric acid drugs, a diagnoses of mixed connective tissue disease, and better HRQoL in the past six months were independently associated with a positive impact in the HRQoL

Conclusion: We have identified several diagnoses, treatments and comorbidites independently associated with HRQoL in a cohort of patients followed up in a rheumatology outpatient clinic. This represent a first step in the implementation of value-based care for MSK patients, as we can now review the procedures associated with a worse HRQoL in an attempt to improve them.

Outpatient Costs and Evaluation and Management (E&M) Expenditure Trends in Rheumatoid Arthritis (RA) Patients Treated with Biologic Therapies in US Community Practices

Colin Edgerton,[1] Janna Radtchenko,[2] and V. Michael Holers[3], [1]Articularis Healthcare, Charleston, [2]Trio Health, La Jolla, CA, [3]University of Colorado Denver, Division of Rheumatology, Aurora, CO, USA, Denver

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Health Services Research Poster II – ACR/ARP

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: RA is an autoimmune disease affecting over 1.5 million Americans. Biologic disease-modifying antirheumatic drugs (bDMARDs) expanded treatment choices for RA patients (pts) in the last two decades with a significant impact on cost of care. As RA treatment evolves, there is a need for analysis of treatment costs in the modern era, particularly to inform new payment methodologies. As the majority of RA care in the US occurs in the community setting, we evaluated RA-related treatment costs in a community practice cohort.

Methods: Using electronic medical records from 8 large mid-Atlantic rheumatology practices, adult pts with RA diagnosis (International Classification of Diseases 9th revision (ICD- 9) 714, ICD-10 M05, M06) who initiated or switched to a new bDMARD during April 2016-March 2018 were selected. We accounted for cost of care provided by the rheumatology practices including E&M, DMARDs, bDMARDs, steroids, other services including drug administration and labs. Pts were followed for 12 months from initiation of biologic or switch. Annual costs were standardized to 2019 USD using Centers for Medicare & Medicaid Services Average Sales Price, Part D Medication Price, Physician, and Clinical Laboratory Fee Schedules. Comorbidities (comorbids) were assigned based on pt reported medications. Differences between pts with comorbids vs. without were assessed using t-test for continuous variables and chi-square

E&M	575.3 (653.3)	531.2 (559.6)	585.3 (672.5)	0.097	526.5 (558.5)	564.3 (520.5)	0.355

1 Differences for continuous variables were assessed using t-test, differences for categorical variables were assessed using chi-square test. P-value <0.05 was considered significant.
2 PSM=propensity score matched.

test for categorical variables; costs were also assessed using propensity score matching (PSM) and generalized linear models (GLM) with gamma distribution and log link function to account for differences in pt characteristics.

Results: Of 2140 pts, 1744 (82%) had at least 1 comorbid. Compared to pts without comorbids, pts with comorbids were older, more likely to be white, female, and Medicare-insured (Table). Before accounting for differences in demographics, pts with comorbids had significantly higher costs of bDMARDs, labs/other services, and total costs. After accounting for differences in demographics using GLM, pts with comorbids had higher E&M costs ($569 (CI: 524-618) vs. $519 (CI: 471-573), p=0.027) but no difference in costs of bDMARDs, labs, other medications, and total costs. After PSM there were no differences in age, race, insurance, and gender between cohorts and 350 pts per group matched without replacement, representing 20% of pts with comorbids and 88% of pts without comorbids. Among PSM pts, there were no differences in annual costs between cohorts. Prescription of the commercially available biosimilars was found low (1%) during the study period, thus their impact on costs was not evaluated.

Conclusion: Among RA pts treated with bDMARDs in the community from 2016 to 2018, the majority of the pts had comorbids. Pts with comorbids had significant differences in their characteristics compared to those without comorbids and incurred higher RA-related annual costs, however when accounting for differences in pt characteristics, annual costs of RA-related care were not different between the groups. This initial analysis suggests that comorbids may not be driving costs of RA-related care as it has been presumed. Further research is warranted to evaluate the impact of individual comorbids.

Lifetime Direct Medical and Indirect Cost of Knee Osteoarthritis: Impact of Pain and Structural Severity

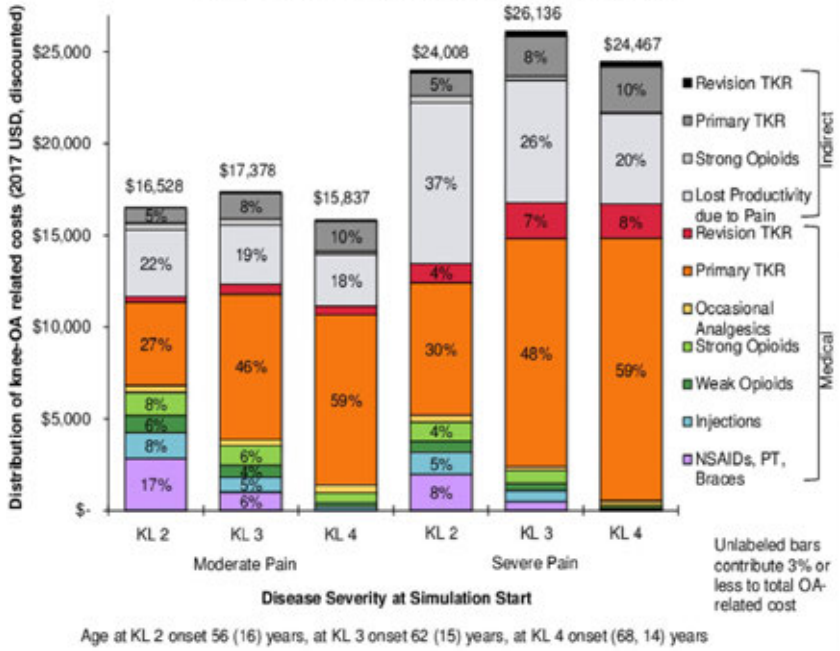
Elizabeth Stanley,[1] James Sullivan,[2] Jamie Huizinga,[1] Jamie Collins,[3] Jeffrey Katz,[4] and Elena Losina[5], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital and Harvard Medical School, Boston, [4]Brigham and Women's Hospital/Harvard Medical School, Boston, [5]Brigham and Women's Hospital and Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Health Services Research Poster II – ACR/ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Symptomatic knee OA is a debilitating condition that affects 14 million adults in the US. We estimated the variability of lifetime OA-related direct and productivity costs as a function of pain and structural severity at presentation to care.

Methods: We used the Osteoarthritis Policy Model, a validated computer microsimulation of knee OA, to evaluate utilization of alternative treatment modalities and lifetime medical and productivity cost for individuals diagnosed with symptomatic and radiographic OA of Kellgren-Lawrence (KL) grade 2, 3, or 4 in moderate (mean 25) or severe (mean 55) pain on the Western Ontario and McMaster Universities Osteoarthritis Index pain scale (0-100, 100 is worst) at the time of presentation for OA care. The combinations of three radiographic grades and two pain categories yielded 6 cohorts. To determine the age of presentation to care for each cohort we used additional model runs, coupled

Figure: Average Lifetime Cost of OA Per-Person



Age at KL 2 onset 56 (16) years, at KL 3 onset 62 (15) years, at KL 4 onset (68, 14) years

with the national data on incidence and structural progression of knee OA. Treatments under consideration included NSAIDs, physical therapy, braces, corticosteroid injections, tramadol, strong opioids (e.g. oxycodone, hydromorphone, hydrocodone, morphine), and total knee replacement. We followed subjects from presentation to OA care until death. Direct medical costs of knee OA treatments were derived from Redbook Online and Medicare reimbursement data. The economic burden of OA was portrayed as the time cost of lost productivity and the societal costs associated with opioid use. Treatment efficacy and opioid-related costs were derived from published literature. Costs were discounted at 3% annually.

Results: Pain severity was the key driver of lifetime time OA-attributable costs, with severe pain adding about $8,000, increasing the discounted direct medical costs by 35% compared to moderate pain across all KL levels considered (Figure). Across all six cohorts, TKR was the largest contributor to the direct medical OA-related cost. The largest contributor to indirect cost was lost work productivity due to OA. The indirect costs comprised between 30%-45% of total (direct plus indirect) OA-attributable costs, ranging from $4,000-$5,000 for those in moderate pain to $8,000-$10,000 among those in severe pain. The percent of patients using strong opioids ranged from 10% (KL 4, severe pain) to 76% (KL 2, severe pain), and the average duration of opioids use ranged from 1.9 (KL 4, severe pain) to 2.7 years (KL 2, moderate pain). The percent of patients receiving TKR ranged from 40% among those followed from diagnosis with KL 2, moderate pain to 82% among those followed from the time they had been diagnosed with KL 4, severe pain. The average age of surgery ranged from 65 to 69 years depending on symptoms and structural severity.

Conclusion: Pain severity at presentation had much greater impact on medical and societal costs than structural severity at presentation. Indirect medical costs comprised between 29% and 44% of total medical OA-attributable costs. These data could be used by policy makers and payers to direct resources toward pain management and optimizing productivity among knee OA patients in the workforce.

The Socioeconomic, Gender, Urban-rural, and Regional Disparities in the Risk of Acute Myocardial Infarction Among RA Patients

Yufei Zheng,[1] Hui Xie,[2] J. Antonio Avina-Zubieta,[3] Kia Yazdani,[4] John Esdaile,[5] and Diane Lacaille[6], [1]Arthritis Research Canada, Richmond, BC, Canada, [2]Arthritis Research Canada and Simon Fraser University, Vancouver, BC, Canada, [3]Arthritis Research Canada and the University of British Columbia, Vancouver, BC, Canada, [4]Arthritis Research Canada and the University of British Columbia, Richmond, [5]Arthritis Research Canada and the University of British Columbia, Richmond, BC, Canada, [6]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To assess socioeconomic (SES), gender, urban-rural, and regional disparities in the risk of acute myocardial infarction (MI) among rheumatoid arthritis patients.

Methods: We conducted a population-based cohort study using administrative health data on all individuals with RA across an entire Canadian province. RA incident cases were defined as first meeting previously published RA criteria between 1997 and 2009, using a 7 year wash-out period. Individuals with prior MI were excluded. The outcome was the first ever ICD code (ICD9 410 or ICD10 I21) for MI recorded in Hospital Discharge Data (in any position) or as the primary cause of death in Vital Statistics Data. Follow-up was from incident RA date to the date of first MI event, death, leaving the province, or March 31, 2015, whichever occurred first. We obtained patients' residency information, such as postal code and health regional authority (HA) from patient registry database, where a zero '0' in the second position of the postal code indicates a rural area. We defined low-income if an individual received a family-income-based MSP premium subsidy.

We compared disparities in incident rates (IR) of MI by SES, gender, rural/urban area and HA. We further estimated their hazard ratios (HR) using Cox proportional hazard model to evaluate the SES, gender, rural residency, and HA disparities in MI, adjusting for potential confounders.

Results: A total of 37,547 incident RA patients were identified, including 12,546 (33.4%) male, 6,527 (17.4%) rural, and 12,838 (34.2%) low income patients. Overall, 2,076 patients developed MI during 378,586 follow-up years with an incident rate of 5.5 per 1,000 person-years (PYs). The MI IRs varied with SES (low vs. med-high: 6.6 vs 4.9 per 1000 PYs), gender (male vs female:.8.1 vs 4.2), rural residency (rural vs urban: 6.4 vs 5.3), and HA (Interior 7.0, Fraser 5.0, Vancouver Coastal 4.7, Vancouver Island 5.1, Northern 6.1).

Adjusting for age, number of GP visits, prior hospital admission, comorbidities and medication use, low socioeconomic status (HR= 1.14, 95%CI=1.04~1.26, p=0.005), and male gender (HR=1.95, 95%CI=1.78~2.14, p< 0.001), rural residency (HR=1.13, 95%CI=1.01~1.27, p=0.038) were associated with an increased risk of MI. Compared with Vancouver Coastal HA, residency in Interior (HR=1.3, 95%CI=1.13~1.49, p< 0.001), and Northern HA (HR=1.62,

Table 3 Gender, SES, Rural-urban, Regional Disparity: Hazard Ratios from Univariate and Multivariable Cox Proportional Model

	Univariate		Multivariable	
	HR (95%CI)	p	HR (95%CI)	p
Low vs Med_high Income	1.36 (1.24 ,1.48)	<.0001	1.14 (1.04 ,1.26)	0.0047
Male vs Female	1.92 (1.77 ,2.1)	0.0003	1.95 (1.78 ,2.14)	<.0001
Rural vs Urban	1.21 (1.09 ,1.35)	<.0001	1.13 (1.01 ,1.27)	0.0381
HA (vs. Vancouver Coastal)				
Interior	1.46 (1.28 ,1.67)	<.0001	1.3 (1.13 ,1.49)	0.0002
Fraser	1.05 (0.92 ,1.19)	0.495	1.05 (0.92 ,1.2)	0.4565
Vancouver Island	1.07 (0.92 ,1.23)	0.3935	0.99 (0.85 ,1.14)	0.8508
Northern	1.27 (1.06 ,1.52)	0.0086	1.62 (1.348 ,1.94)	<.0001

95%CI=1.35~1.94, p< 0.001) was associated with a higher risk of MI, but not Fraser (HR=1.05, 95%CI=0.92 ~1.20, p=0.46) or Vancouver Island HA (HR=0.99, 95%CI=0.85~1.14, p=0.85).

Conclusion: RA patients with a lower SES and male gender, and living in rural areas were more likely to develop a MI. Living in remote communities, such as Interior and Northern HA, were also associated with a higher risk of MI. These findings have important implications for patients, health care providers and health policy makers; and point to the need for further investigations to understand the underlying reasons for the differences identified, so that targeted interventions can be designed to address health inequities.

Racial Disparities in Lupus Medication Adherence

Kai Sun,[1] Amanda Eudy,[1] Jennifer Rogers,[1] Lisa Criscione-Schreiber,[1] Jayanth Doss,[1] Rebecca Sadun,[1] and Megan Clowse[1], [1]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Medication non-adherence is common among SLE patients and is disproportionately more frequent in underrepresented racial minorities. We examined adherence gaps between minority and Caucasian SLE patients and explored factors associated with non-adherence that may present avenues for intervention.

Methods: Cross-sectional data were obtained via survey and chart review from consecutive SLE patients with ≥1 prescribed lupus medication. The Medication Adherence Self-Report Inventory (MASRI) was used to estimate adherence in the preceding month from 0-100%. High Self-reported Adherence was defined as MASRI ≥90%. Pharmacy refill data in the preceding 3 months were obtained by phone calls. High Refills was defined as a medication possession ratio of ≥80% for all prescribed SLE medications. High Composite Adherence was defined as having both High Self-reported Adherence and High Refills. Patient-provider interaction was measured using the Interpersonal Processes of Care survey, which has 7 domains on a 5-point Likert scale. Additional covariates included: self-

Table 1. Comparing those with high vs. low composite adherence.

[ǂ]Part of PROMIS-29, score ranges 0-10

efficacy, patient-reported health status, rheumatic medication regimen complexity, SLEDAI, Systemic Lupus Activity Questionnaire (SLAQ), and SLICC damage scores. Adherence measures were compared by race, and adherence groups were compared.

Results: 125 enrolled (36% Caucasians, 61% African American, 3% other). Median age was 43 (range 22-72), 95% were female, 51% had ≥ college education, and 49% had private insurance. 83 (66%) had High Self-reported Adherence, 59 (47%) had High Refills, and only 48 (38%) had High Composite Adherence. Minorities compared to Caucasians had lower rates of Self-Reported Adherence (58% vs 82%, p=0.005), Refills (40% vs. 60%, p=0.03), and Composite Adherence (30% vs. 61%, p=0.02). Among 75 taking disease modifying agents including MTX, LEF, AZA, and MMF, High Refill rate was 37% vs. 64% (p=0.03) for minorities compared to Caucasians. The racial gap in High Refill rate is largest for those on MMF (39% vs. 88%, p=0.01). Compared to the High Composite Adherence group, those with Low Composite Adherence were younger, more likely to live with parents, rated more Hurried communication with providers, had more anxiety, took a more complex SLE regimen, had higher SLICC Damage score, SLAQ, and more ER visits/hospitalizations. They also had a trend for less compassionate and respectful interaction with providers and lower self-efficacy in managing medications and treatments (table 1).

Conclusion: Significant racial disparities exist in SLE medication adherence, and the gap is most substantial for patients taking MMF, a crucial treatment for moderate to severe SLE. This gap likely contributes to known racial disparities in SLE outcomes. Improving communication, self-efficacy, mental health, and reducing medication burden may be avenues for intervention for a subset of non-adherent patients. Qualitative studies are needed to better understand barriers to adherence and to develop interventions that address this pressing racial disparity.

Abstract Number: 1142

Barriers and Facilitators of Medication Adherence Among Minority SLE Patients: A Qualitative Study

Kai Sun,[1] Carrie Dombeck,[1] Teresa Swezey,[1] Amy Corneli,[1] Amanda Eudy,[1] Rebecca Sadun,[1] Jennifer Rogers,[1] Lisa Criscione-Schreiber,[1] Jayanth Doss,[1] and Megan Clowse[1], [1]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE disproportionately affects underrepresented racial minorities, groups that often have lower rates of medication adherence. This study aimed to explore barriers and facilitators of adherence to SLE medications among minority patients.

Methods: We conducted a qualitative descriptive study using semi-structured interviews. Twelve minority SLE patients who have been prescribed DMARDs and 12 lupus clinic personnel (including 6 doctors, 2 nurse practitioners, 1 pharmacist, and 3 nursing staff) were recruited through purposive sampling. We interviewed 8 patients who had not refilled DMARDs regularly and 4 who did. Interviews were audio-recorded, transcribed, and analyzed using applied thematic analysis. An interdisciplinary stakeholder group consisting of patients, providers, and staff then matched facilitators to barriers to identify potential interventions.

Results: Patient characteristics are summarized in table 1. We identified 4 major themes to barriers of medication adherence. These are:

1. External factors, including medication costs, difficulties with insurance, logistical issues with pharmacy, misinformation, and lapses in communication with providers;
2. Intrinsic factors including forgetfulness in taking medications, denial of having a chronic illness and need to take medications, under-treated depression, concerns about side effects, lack of knowledge of benefits of taking medications and consequences of nonadherence, lack of trust in the provider and health system, low health literacy, and beliefs in religion and alternative medicine;
3. Medication features, including high number of pills, large pill size, and side effects;
4. Physical limitations, including fatigue, mobility issues, and lack of medication taking skills.

The most frequently mentioned barriers were cost, lack of knowledge, and side effects.

We also identified 6 major themes that facilitate adherence. These are:

1. Organizational strategies, including using reminders and pill organizers;
2. Social support, including support from family, friends, and providers/staff at the lupus clinic;
3. Internal motivation, including knowledge of consequences of not taking medications and benefits of taking them, accountability to the provider, and staying healthy to care for others;
4. External factors, including being able to pay for medications, easy access to doctors and/or pharmacist;
5. Medication features, including the small pill size and simplified regimens.
6. Provider communication, including clear, frequent, and motivating communication.

The most frequently mentioned facilitators are using reminders and pill organizers, support from family and friends, and knowledge of consequences.

Table 1. Patient characteristics of interview participants (n=12)

Age, median [IQR]	36 [30-48]
Female	10 (83%)
SLE disease duration, median [IQR]	12 [8-17]
Race	
African American	11 (92%)
Native American	1 (8%)
Insurance status	
Private	6 (50%)
Medicaid	3 (25%)
Medicare	2 (17%)
None	1 (8%)
Marital status	
Single	8 (67%)
Married	3 (25%)
Separated	1 (8%)
Education	
Some high school	1 (8%)
High school degree	4 (33%)
Some college	3 (25%)
College degree	1 (8%)
Graduate degree	3 (25%)
Employment status	
Full time	5 (42%)
Part time	1 (8%)
Home maker	2 (17%)
Retired	1 (8%)
Unable to work	3 (25%)
DMARDs	
Mycophenolate	7 (58%)
Azathioprine	3 (25%)
Methotrexate	2 (17%)

Table 2. Matching facilitators to barriers identified.

Barriers	Matching Facilitators
External factors	• Social worker/pharmacist to help with cost and pharmacy issues • Provider communication
Intrinsic factors	• Organizational strategies such as use of pill boxes, mobile reminder apps • Internal motivation • Provider communication
Medication features	• Simplifying regimen • Remedies for side effects
Physical limitations	• Social support

Table 2 shows matching of facilitators to barriers.

Conclusion: We have identified a number of distinct barriers and facilitators to adherence among minority SLE patients. Although the most frequently cited barriers were cost, knowledge, and side effects, each patient faced a

distinct set of several predominant barriers, and each identified different sets of facilitators. These findings suggest a need for individualized intervention to improve adherence.

*Scores range from 1-5, with lower being better; †Scores range from 1-5, with higher being better

‡A score of 50 represents the US population mean, a difference in 5 is clinically significant. Higher scores are better for self-efficacy and social health, but lower scores are better for fatigue.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Healthcare Disparities In Rheumatology Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Significant racial disparities exist in SLE outcomes. Few studies have examined modifiable factors intrinsic to physician/patient encounters that may contribute to such disparities. We aimed to explore potential areas for intervention to reduce racial disparities with a focus on patient self-efficacy and the quality of patient-provider interactions.

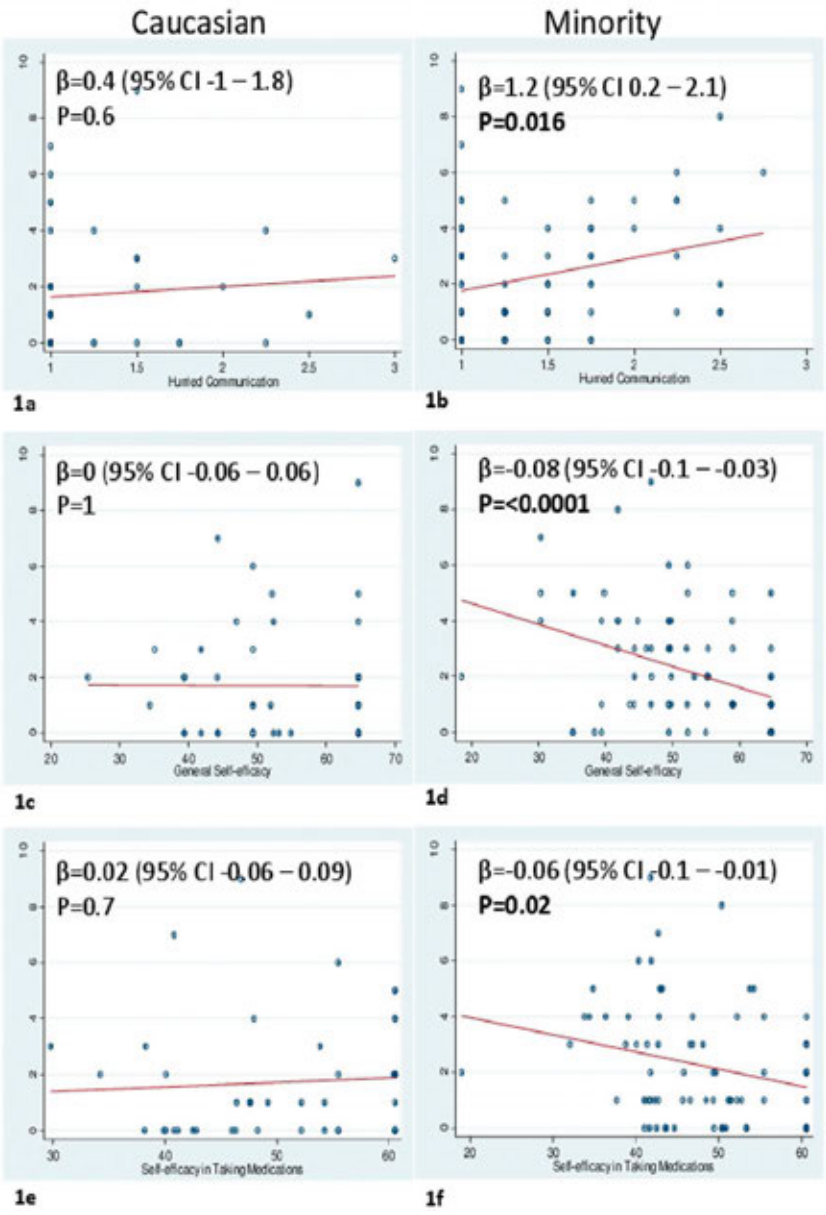

Figure 1 a-f showing correlation between damage scores and hurried communication (a, b), general self-efficacy (c, d), and self-efficacy in taking medications (e, f), stratified by race.

Methods: Cross-sectional data were collected from consecutive patients meeting ACR or SLICC criteria for SLE and actively being treated at a tertiary lupus clinic. Patient-provider interaction was measured using the Interpersonal Processes of Care survey (IPC-29), which has 7 domains on a 5-point Likert scale. General self-efficacy, self-efficacy for managing medications and treatments, and patient-reported health status were measured using Patient-Reported Outcomes Measurement Information System (PROMIS) short forms. Additional demographic and clinical information were gathered by survey and chart review. Bivariate analyses compared characteristics of Caucasian vs. minority patients. Linear regression analysis was performed to assess race-stratified association of SLICC damage scores with age, education, IPC-29 and patient self-efficacy scores.

Results: 125 patients were enrolled (36% Caucasian, 61% African American, 3% other). Minorities compared to Caucasians were younger, less likely to be college educated, married, live with partner or spouse, and more likely to be on Medicaid (table 1). Minorities reported less fatigue and better social health, took more complex rheumatic medication regimens, had higher SLEDAI, lower fibromyalgia symptom severity, and a trend for higher damage scores (table 2). Minorities rated more hurried communication with their providers, and there were no racial differences in self-efficacy scores. Among minorities, more hurried communication, lower general self-efficacy, and lower self-efficacy in managing medications and treatments were each associated with higher SLICC damage scores, but among Caucasians only older age (β=0.09 95% CI 0.06-0.14, $p< 0.001$) and ≤ college education (β= -2.6, 95% CI -3.8- -1.4, $p< 0.001$) were associated with higher damage scores (figure 1).

Conclusion: Minorities were from more disadvantaged sociodemographic backgrounds and had more active SLE. Overall, scores for patient-rated interactions with physicians in this selective sample were very good. However, minorities reported more hurried communication with their providers.

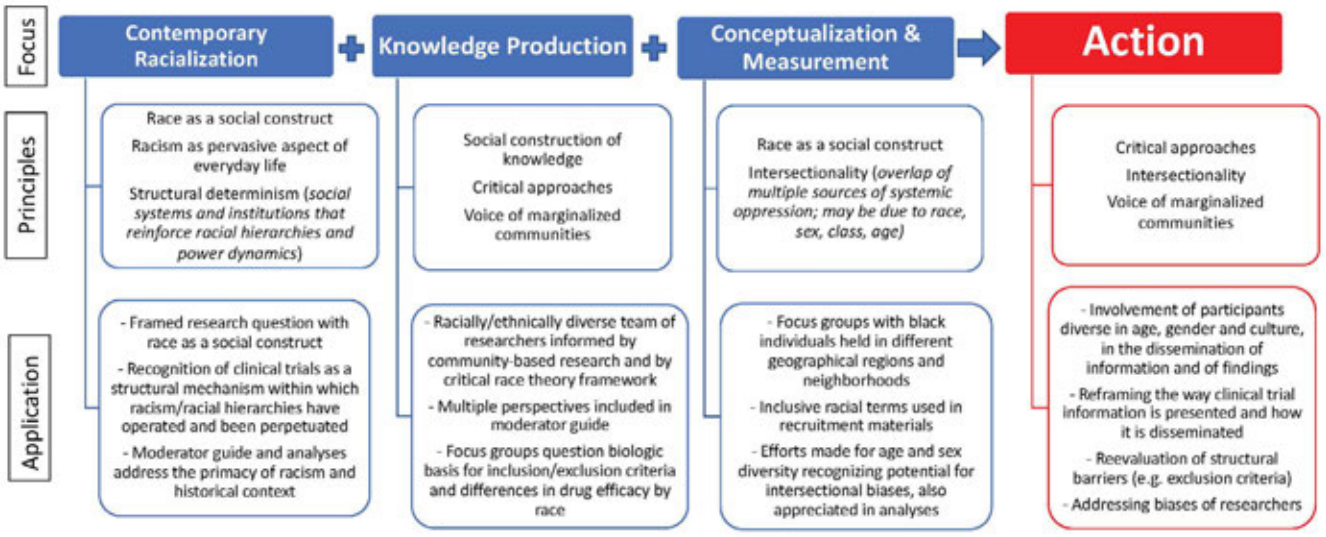
Understanding Clinical Trials Participation Among Individuals of African Descent with Lupus Through the Lens of Critical Race Theory: A Qualitative Analysis

Candace Feldman,[1] Jessica Williams,[1] Courtnie Phillip,[1] Corine Sinnette,[1] Karen Mancera-Cuevas,[2] Patricia Canessa,[3] Gina Curry,[4] Maryann Mason,[2] and Rosalind Ramsey-Goldman[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Northwestern University, Chicago, IL, [3]IPHA, Chicago, IL, [4]University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Despite a disproportionate burden of lupus and poorer outcomes among individuals of African descent (hereafter "black") compared to white individuals, black individuals are underrepresented in lupus clinical trials. We aimed to explore the reasons behind this from the patient perspective using Critical Race

Figure 1. Application of the Public Health Critical Race Praxis (PHCRP) theoretical framework to begin to understand clinical trials participation among individuals of African descent with lupus



Ford CL, Airhihenbuwa CO. *Ethn Dis.* 2018; 28 (Suppl 1): 223-230
Ford CL, Airhihenbuwa CO. *Am J Public Health.* 2010;100 Suppl 1(Suppl 1):S30–S35.

Theory, applied to health equity research with the Public Health Critical Race Praxis (PHCRP). We hypothesized that ongoing racism and historical injustices contribute to the perpetuation of mistrust and to structural barriers within clinical trial design, which result in obstacles and fears that prevent some black individuals from participating in research.

Methods: We recruited black individuals with lupus, age ≥18 years old, and their caretakers (members of their support network who participate in their medical decision-making) to participate in focus groups. Participants were identified through community-based networks and organizations, lupus associations, and academic hospital networks in predominately black Boston and Chicago areas. A racially diverse, multidisciplinary study team developed our moderator guide incorporating PHCRP principles (**Figure 1**), and we used this framework to guide our analyses. Focus groups were transcribed verbatim. Three researchers read the transcripts and coded terms and from this, derived overarching themes, subthemes and proposed actions.

Results: We held 2 focus groups in Chicago (N=16) and two in Boston (N=15). The mean age was 54, 90% were female, and all participants identified as black. Twenty (65%) were diagnosed with SLE and 11 were caretakers. Thematic analysis of transcripts resulted in six key themes: skepticism of clinical trials/research (subthemes of trust, racism and historical context, and placebo arms), the greater good, SLE-specific factors, physician/institutional influences, social support influences, and trial/research-specific factors (subthemes of exclusion criteria, incentives and information presentation/ marketing of studies) (**Table**). Aspects of mistrust stemming from historical context and internalized and structural racism traversed themes. Analyses also revealed recurrent fears (e.g. being a "guinea pig") and structural barriers (e.g. exclusion criteria), as well as mediating factors (e.g. relationships with physicians and social networks), and motivating factors (e.g. contribution to a greater good) (**Figure 2**). Following the PHCRP framework, actions proposed by participants included reframing the way trial information is presented and disseminated, and reevaluation of structural barriers (e.g. exclusion criteria) (**Figure 1**).

Table 1. Selected quotes by focus group participants by theme and subtheme

Themes	Selected Participant Quotes
Skepticism of Clinical Trials/ Research	
*Trust, racism and historical context**	"There is a deep mistrust within the African American community. First thing a lot of us think of is the Tuskegee Experiment…so there's a deep distrust between the medical community and the African American community and that's definitely a barrier, even if you are trusting and see the benefits. It still lingers in your thought process." **(C1)** "A lot of minorities, especially black families, 'cause we don't go to the hospital, we wait until the very last minute, so when we do go to the hospital, we die. Then you'll have people say, "Don't go to the hospital. They kill you..." **(B1)**
Placebo Arms	"If you're in the part of the group that gets the placebo…that borderlines on the ethical part and brings up the ethical questions…" **(C1)** "I would be a little disheartened or disillusioned if I was in this particular thing, this trial, for maybe six months and I was all this time, I was getting the placebo…I might have been in that group that was getting the placebo when they was getting the real deal over here…" **(B1)**
The Greater Good	"…if something's not going to help me immediately, I want to make it better for the future. It may help my daughters, it may help my grandkids. Who knows? Who knows what's in this gene pool?" **(C2)** "It's needed. It's needed. It's needed. Because every time you look around, they're always doing cancer research. Lupus is just as prevalent out there as cancer. It's mainly in our community…the black community." **(B1)**
SLE-specific Factors	"If I'm stable, why would I want to do a trial? Why would I want to rock the boat?" **(C2)** "I'm always afraid to participate because the drug interactions…it may interact negatively with some of the medicines, because I take a lot of medications." **(B1)**
Physician and Institutional Influences	"Another consideration would probably be who is doing this research…Patients may feel more comfortable with a reputable name like that versus some research facility that they haven't heard of, they know nothing about, have no connections." **(C2)**
(continued)	"For me that [the race of the researcher] doesn't matter. I just want to know that the person is truthful…if the person seems truthful and open and whatever, that's fine." **(B2)**
Social Support Influences	"I can't say yes or no [to participation] at this time." It's a topic with my family and myself and quite a few things. I would like to be part of clinical trials but the family is pretty adamant to say no...because they don't trust the process."* **(C1)** "My friends always say "Don't do it. Don't forget your history...It haunts a lot of us…Any person of color."* **(B1)**
Trial/Research-specific Factors	
Exclusion criteria	"A lot of the clinical trials, we would like to do them, but a lot of times, we don't qualify… most of the time, with African American women, we don't qualify for a lot of the studies unless you lie."* **(B1)**
Incentives	"It depends sometimes on the clinical trial, if it pays to participate. If it's a lot going on…I'll be like, are they paying for my parking? Are they compensating me?" **(B1)** "Yeah, I do a lot of research, so money's always good. But if it can help find a cure for certain things...It's for the money too, but it's to help also with research." **(B2)**
Information presentation and "marketing" of studies	"The patients don't feel the personal benefit to them and therefore it's difficult to say, "I'm gonna be part of it." I think part of the reason also is that these things are not well-explained. You see, they don't have people that actually sit down to walk people through what this really is. What are the pros? What are the cons? And how to overcome the things that you've been told to believe."* **(B2)** "To me, the communication on research also would make people at ease too, because the human mind can visualize …or see someone saying, it worked for me. So like a YouTube…if I can look it up and see that this person talked to me visually, saying, yeah, I went through it, this is what happened, and if it's out there you guys can take it." **(C2)**

*The subtheme of trust, racism and historical context was interwoven throughout the discussions and was relevant to multiple themes.

B1=Boston focus group 1, **B2**=Boston focus group 2, **C1**=Chicago focus group 1, **C2**=Chicago focus group 2

Conclusion: Issues of trust, racism and historical context permeated all four focus group discussions regardless of participant age. There were certain mediating factors, notably relationships between patients and their physicians, that increased the likelihood of participation in research. Our efforts to promote more inclusive, representative clinical trials should acknowledge the perpetuation of racism and the intersection of biases that occur with race, age and sex particularly in the context of lupus.

Abstract Number: 1145

The Representation of Skin Tones in Images of Patients with Lupus Erythematosus

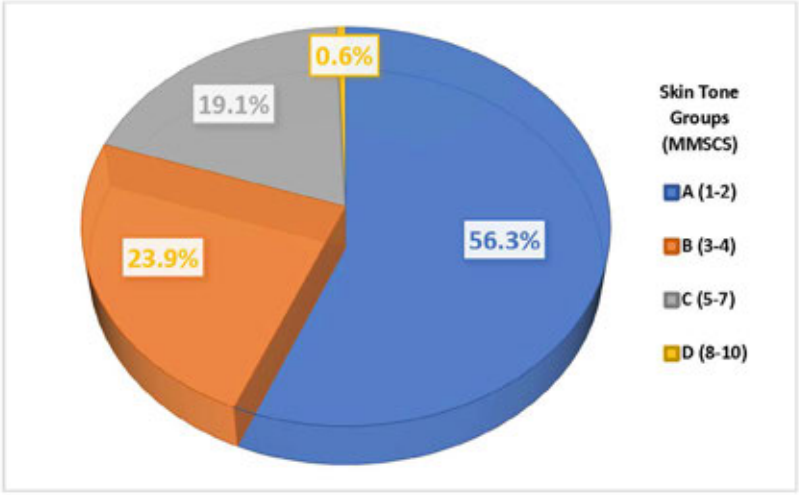
Amaad Rana,[1] Abbey Witt,[1] Heather Jones,[1] Muithi Mwanthi,[1] and Lisa Zickuhr[1], [1]Washington University School of Medicine, Saint Louis

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Racial disparities exist in healthcare. Research shows that the disproportionate representation of race in educational materials contributes to this disparity. Race is a known risk factor for many diseases, including lupus erythematosus (LE), which predilects for women of color. Given the impact of LE in patients of color, healthcare professionals must learn to recognize the systemic and cutaneous manifestations in this population. We explore whether the skin tones in published images represent the populations that LE affects.

Methods: We conducted a descriptive study, reviewing images from internal medicine, dermatology, and rheumatology textbooks, online image libraries, UpToDate and a comprehensive search of Google Images. We selected textbooks published in the last five years that were available through our university's online medical library. We identified images by searching for "lupus" and "lupus rash." We excluded the images if they were in black-and-white, the skin was not clearly visible, or if they were duplicate images. We used the Massey-Martin

Figure 1. Skin Tone Representation in Published Images of Lupus by Groupings of Massey-Martin Skin Color Scale (MMSCS) Scores



Skin Color Scale (MMSCS) to grade skin tones from 1 (very light) to 10 (very dark). We sorted the images into four groups: A (MMSCS 1-2), B (MMSCS 3-4), C (MMSCS 5-7), and D (MMSCS 8-10). Each image was scored twice, once by AR, AW or LZ and once by HJ or MM. In cases of discrepancy, HJ or MM broke the tie. Descriptive statistics were used to analyze the data.

Results: In addition to UpToDate and Google Images, we found 70 dermatology textbooks, 37 rheumatology textbooks, 10 internal medicine textbooks, two minority skin atlases, and two image libraries that met criteria. After exclusions, 1316 images were assessed. The majority (56.3%) of all images represented the skin tones

Table 1. Skin Tone Representation by Resource Type by Groupings of Massey-Martin Skin Color Scale (MMSCS) Scores

Resource Type	A (1-2 MMSCS)	B (3-4 MMSCS)	C (5-7 MMSCS)	D (8-10 MMSCS)	Total
Textbooks	**234 (60.3%)**	**80 (20.6%)**	**73 (18.8%)**	**1 (0.003%)**	**388**
Dermatology	139 (54.7%)	58 (22.8%)	57 (22.4%)	0 (0.0%)	254
Rheumatology	95 (70.9%)	22 (16.4%)	16 (11.9%)	1 (0.01%)	134
Internal Medicine	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0
Minority Atlases	**0 (0.0%)**	**8 (33.3%)**	**15 (62.5%)**	**1 (4.2%)**	**24**
Image Libraries	**331 (49.7%)**	**185 (27.8%)**	**144 (21.6%)**	**6 (0.01%)**	**666**
Visual Dx	300 (49.3%)	172 (28.2%)	131 (21.5%)	6 (0.01%)	609
ACR Image Library	31 (54.4%)	13 (22.8%)	13 (22.8%)	0 (0.0%)	57
Google Images	**158 (75.2%)**	**36 (17.1%)**	**16 (7.6%)**	**0 (0.0%)**	**210**
UpToDate	**18 (64.3%)**	**6 (21.4%)**	**4 (14.3%)**	**0 (0.0%)**	**28**
Total	**741**	**315**	**252**	**8**	**1316**

Table 2. Skin Tone Representation by Specialty Type by Groupings of Massey-Martin Skin Color Scale (MMSCS) Scores

Specialty Type	A (1-2 MMSCS)	B (3-4 MMSCS)	C (5-7 MMSCS)	D (8-10 MMSCS)	Total
Dermatology	438 (49.4%)	238 (26.9%)	203 (22.9%)	7 (0.01%)	886
Internal Medicine	0 (0.0%)	0 (0.0%)	0 (0.0%)	0 (0.0%)	0
Rheumatology	126 (66.0%)	35 (18.3%)	29 (15.1%)	1 (0.01%)	191
Total	**564**	**273**	**232**	**8**	**1077**

of Group A (Figure 1). By resource type, minority atlases were the most inclusive of skin of color with 66.7% of images categorized in Groups C and D (Table 1). Image libraries provided the next best distribution of skin tones, while Google Images heavily published lighter skin tones (75.2%, Group A). By specialty, dermatology included the greatest variety of skin tones, followed by rheumatology (Table 2). No images in internal medicine texts met inclusion criteria.

Conclusion: We show that lighter skin tones are predominantly represented in a sampling of published images of LE. Ironically, this does not match the clinical demographic of LE. The lack of diversity in medical and online resources has been investigated as a potential causative factor in healthcare disparities. Our study adds to the current data highlighting the paucity of darker skin tones in medical resources. Further research is needed to determine if this affects the confidence and ability of healthcare providers to recognize LE in patients of color.

Therapy of Lupus Nephritis with Mycophenolate Mofetil in Routine Clinical Practice: Response Rates and Role of Ethnicity

Prathima Anandi,[1] Alyson Dickson,[2] Vivian Kawai,[2] C. Michael Stein,[2] and **Cecilia Chung** [3], [1]Vanderbilt University Medical Center, Nashville, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Vanderbilt University, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Randomized clinical trials have reported that 56-68% of patients with lupus nephritis treated with mycophenolate mofetil (MMF) respond to therapy, and a randomized clinical trial has suggested that African-American patients respond better to MMF than Caucasians. However, data on rates and the role of ethnicity on MMF response in routine clinical practice are limited. As part of initial efforts to improve prediction models and personalized medicine in patients with systemic lupus erythematosus (SLE), we calculated the response rate and defined the role of ethnicity on response to MMF in patients with lupus nephritis at a tertiary center.

Table 1: Comparison of Clinical Variables by Race

	African-American n=31 (33%)	Other Races n=62 (67%)	p-value
Female sex	31 (100%)	48 (77%)	0.004
Age at start of treatment (Median (IQR))	21 (18 – 37)	29 (19 – 42)	0.21
Serum creatinine at baseline (mg/dl); (Median, IQR)	0.81 (0.70 – 1.60)	0.91 (0.70 – 1.28)	0.63
Urine protein/creatinine ratio or 24hr proteinuria at baseline [g/dl] (Median, IQR)	1.9 (0.59 – 3.42)	1.8 (0.56 – 4.45)	0.99
IV methylprednisolone (concurrent use)	2 (6.5%)	4 (6.5%)	1.00
Hydroxychloroquine (concurrent use)	25 (81%)	51 (82%)	1.00
Prednisone (concurrent use)	31 (100%)	60 (97%)	0.55
Previous cycles of treatment on other immunosuppressants	15 (48%)	34 (55%)	0.66
Year of treatment initiation			0.56
Prior to 2008	9 (29%)	13 (21%)	
2008-2010	7 (23%)	11 (18%)	
2011-2012	7 (23%)	13 (21%)	
2013 to present	8 (26%)	25 (40%)	
MMF drug dosage at 6 months [mg/day] (Median, IQR)	2000 (1000 – 2000)	2000 (1000 – 2000)	0.91

Methods: This is a retrospective study using a de-identified version of patients' electronic health records (EHR) at a University-based Medical Center. We completed EHR review and identified a cohort of patients who met the following inclusion criteria: (1) diagnosed with lupus nephritis; (2) received treatment with MMF for lupus nephritis; (3) were new users of MMF; and (4) had laboratory data available at baseline. All patients had confirmed diagnoses of SLE by clinical record review; they also presented with proteinuria (urine protein-to-creatinine ratio or 24-hour proteinuria >0.5 g/g or g/d, respectively) or a renal biopsy indicating lupus nephritis. Response was defined as: (1) a decrease in urine protein/creatinine ratio (uPCR) to < 3.0 g/g in patients with baseline nephrotic range uPCR (≥3.0 g/g), or by ≥50% in patients with sub-nephrotic baseline uPCR (< 3.0 g/g); and (2) stabilization (±25%) or improvement in serum

Table 2: Multivariate Analysis

	African-American n=31 (33%)	Others n=62 (67%)	p-value
Responders	8	24	0.253
Response rate (%)	25.8	38.7	
Unadjusted odds ratio	0.55 (95% CI, 0.21 – 1.43)		0.220
Adjusted odds ratio – sex and propensity score (PS)*	0.34 (95% CI, 0.11 – 1.00)		0.049

* PS included age at first dose, uPCR at baseline, creatinine at baseline, mycophenolate (MMF) dose at 6 months, previous cycles of treatment with other immunosuppressants, year of treatment initiation, and concurrent use of solumedrol, plaquenil, and/or prednisone.

creatinine at six month. For patients who were lost to follow up prior to six months, we used the last observation carried forward as a method of imputing missing data. Univariate analysis was calculated using Fisher's exact text. To adjust for multiple potential confounders, we used propensity scores including age, baseline creatinine, calendar year, baseline proteinuria, use of hydroxychloroquine, use of methylprednisolone, use of prednisone, and history of prior immunosuppressant use.

Results: 93 patients met inclusion criteria; 31 (33%) were African-American, and 62 (67%) reported a different race or did not report race. Patient characteristics are presented in Table 1. A total of 32 (34.4%) patients were classified as MMF responders and 61(65.6%) as non-responders. Among African-American patients, the response rate was 25.8%; among other patients, it was 38.7% (p=0.25). After adjusting for the propensity score and sex, African-American patients had lower odds of responding to MMF than patients from other races [OR: 0.34, 95% CI (0.11 – 0.99) p=0.049].

Conclusion: A total of 34% patients with lupus nephritis responded to MMF at six months of treatment in routine clinical practice at a tertiary center. Our results suggest that—in contrast to what has been reported in a previous randomized control clinical trial—African-American patients with lupus nephritis had lower odds of responding to MMF than patients who reported other races.

Abstract Number: 1147

Poverty and Systemic Lupus International Collaborating Clinics Damage Index (SDI) Are Significant Risk Factors for Hospitalization in SLE Patients

Allen Anandarajah,[1] Caroline Thirukumaran,[1] Kelly callahan,[1] Jennifer Anolik,[1] and Christopher Ritchlin[2], [1]University of Rochester Medical Center, Rochester, NY, [2]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is associated with a high rate of hospitalizations and is the sixth highest reason for 30-day readmissions among all medical conditions in the USA. In SLE patients, lower socioeconomic status correlates with poorer disease outcomes and a higher mortality rate but whether poverty is a risk factor for hospitalization is not clearly understood.

To identify the impact of poverty as a risk factor for hospitalizations in SLE patients.

Methods: We designed a single center, retrospective study of SLE patients hospitalized to Strong Memorial Hospital in Rochester, New York. Billing data was analyzed to identify all hospitalizations that included an ICD-10 code for SLE as primary or secondary diagnosis for the period between July 1, 2013 and June 30, 2017. A diagnosis of SLE was confirmed by evaluating for the presence of American College Rheumatology Criteria or was assigned by a rheumatologist. The outcomes were high-risk patients (defined as those with 3 or more admissions per year) and we collected data on length of stay (LOS) and cost of admissions. The key independent variable was poverty based on the patient resident zip code. Areas of poverty were as defined by the Finger Lakes Health Systems Agency. Bivariate analysis followed by multivariable regression models that controlled for important patient-level confounders such as age, gender, race/ ethnicity, body mass index, disease activity measures (complements, dsDNA, Systemic Lupus International Collaborating Clinics Damage Index (SDI) and comorbidity index (CMI) were applied to assess the data.

Results: A total of 202 patients with SLE were admitted over the 4 year study period and 68 of these subjects were from zip codes associated with poverty. On bivariate analysis we found that patients living in the poverty associated zip codes were significantly more likely to be categorized as high risk patients (p=0.01) and were of African American origin (p=0.001). We also noted significantly higher median dsDNA levels among subjects from the areas associated with poverty (11.2) compared to patients from other zip codes (4.6) (p=0.01). No significant differences were noted for age, SDI, complement levels, total and average LOS as well as total and average cost of admissions between the two groups. We then created multivariable regression models to assess impact of poverty on the above mentioned outcomes of interest. Patients residing in areas with poverty associated zip codes were significantly more likely to be classified as high risk patients (OR 2.96; CI 1.09, 9.00; p=0.03) with higher SDI scores (OR 1.39; CI 1.07, 1.81; p=0.01). SDI was associated with significant risk for admissions (OR 1.26; P< 0.01), average cost above the median (OR 1.65; p< 0.01) and average LOS above the median (OR 1.37; p=0.01). Analysis focused on the African American population revealed that living in poverty areas remained a significant risk factor for hospitalization (p=0.04).

Conclusion: Socioeconomic factors and damage index are significant risk factors for hospitalizations in SLE patients. Early initiation of therapy, addressing the challenges of poverty and overcoming healthcare disparities are important goals to improve the health of lupus patients.

Abstract Number: 1148

Examining Five Year Lupus Retention in Care in an Academic Cohort

Christie Bartels,[1] and Maria Schletzbaum[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE often causes silent damage, making routine clinic and lab monitoring critical for detecting new manifestations or flares. The 2012 ACR nephritis guidelines recommended lab testing, including complement tests at least every three months, for those with history of nephritis and at least every six months for those without. Using these definitions, we previously characterized lab-defined SLE retention in care as having at least one com-

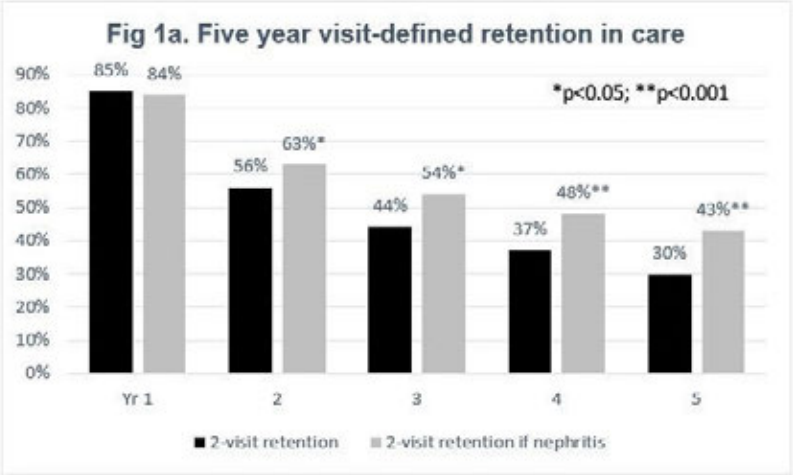
plement lab test every six months and visit-defined retention by at least two annual visits, similar to definitions used by the WHO and CDC in HIV metrics. Previously, we reported 60% visit-based and just 23% lab-based retention at 1 yr. The strongest predictor of retention gaps was living in the most disadvantaged neighborhood quartile, which predicted 59% lower visit retention. In this study, we sought to examine rates and predictors of longitudinal retention in an academic SLE cohort.

Methods: Potential SLE cases were identified using electronic health record searches for adults with at least one SLE code and at least one rheumatology and one primary care visit in 2003-2016. Cases were then manually validated using the 1987 ACR and 2012 SLICC SLE criteria to include definite lupus cases. Baseline sociodemographics, SES, and neighborhood disadvantage were included as potential predictors. For this study, annual rheumatology clinic visits and complement lab tests were counted in each six-month period. Lab-defined retention for patients with nephritis was two labs per six mos, while for patients without current or former nephritis it was one per six mos. Cases were followed up to five years and were censored for death, migration, or loss to follow-up. We used proportions and multivariable logistic regression to report rates and predictors of lab- and visit-defined retention in care using odds ratios and 95% confidence intervals.

Results: Overall, 630 cases met ACR or SLICC criteria for definite SLE and were included in the study, 88% met ACR criteria, and 157 had nephritis history. Overall, 90% were female, 82% white and mean age was 42.4 years old

Table 1. Prevalent lupus cohort description (n=630)

		Overall n (%)
Age at SLE observation		42.35 ± 14.65
Early onset SLE (<18)		31 (4.9%)
Adult onset SLE(18-49)		407 (64.6%)
Late onset SLE(≥50)		192 (30.5%)
Female		571 (90.6%)
Race	White	516 (81.9%)
	Black	77 (12.2%)
	Other	37 (5.9%)
Ethnicity	Hispanic	25 (4.0%)
RUCA	Urban	456 (72.4%)
	Suburban	110 (17.5%)
	Large town	54 (8.6%)
	Small town	10 (1.6%)
Medicaid Ever		140 (22.2%)
Smoking (ever)		252 (40.0%)
Neighborhood Disadvantage (Area Deprivation Index)		
1st (least disadvantage)		146 (23.4%)
2nd		147 (23.6%)
3rd		144 (23.1%)
4th (most disadvantage)		140 (22.4%)
Antiphospholipid Syndrome		83 (13.3%)
ACR Nephritis		157 (24.9%)
ACR Criteria		546 (87.5%)
SLICC Criteria		618 (98.0%)



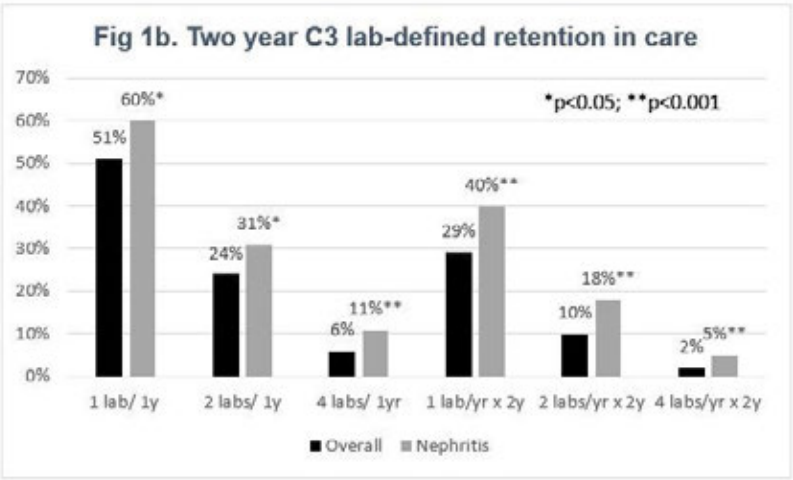


Table 2. Predictors of 2-year SLE retention in care in an academic cohort (n=630)

		Visit-Defined Adjusted OR (95% CI)	Lab-Defined Adjusted OR (95% CI)
Age at observation		1.00 (0.99,1.02)	0.99 (0.98, 1.02)
Female		0.85 (0.46, 1.56)	2.45 (0.71, 8.45)
Race	White	Ref	Ref
	Black	0.74 (0.43, 1.29)	0.54 (0.19, 1.51)
	Other	0.81 (0.39, 1.69)	1.11 (0.39, 3.18)
Ethnicity	Hispanic	0.93 (0.37, 2.36)	0.78 (0.17, 3.69)
RUCA	Urban	Ref	Ref
	Suburban	**1.86 (1.13, 3.07)**	0.52 (0.22, 1.33)
	Large town	1.48 (0.77, 2.85)	0.79 (0.25, 2.44)
	Small town	1.60 (0.37, 6.85)	--
Ever Smoking		0.79 (0.55, 1.15)	0.66 (0.35, 1.24)
Neighborhood Disadvantage by ADI			
1st (least disadvantaged)		Ref	Ref
	2nd Quartile	1.12 (0.69, 1.83)	0.68 (0.31, 1.48)
	3rd Quartile	0.69 (0.41, 1.14)	1.16 (0.55, 2.46)
4th (most disadvantaged)		0.82 (0.49, 1.37)	0.53 (0.22, 1.33)
Medicaid		1.10 (0.70, 1.75)	1.14 (0.54, 2.39)
Lupus Nephritis		**1.73 (1.14, 2.62)**	**2.73 (1.51, 4.91)**

(Table 1). Most patients (72%) were urban, 17.5% suburban, 10% from large or small towns, and 22% ever received Medicare. Two-visit-defined retention in care started at 85% and declined to 30% year five, compared to 84% year one and to 43% year five for patients with nephritis (Fig 1a). Complement defined retention was just 24% by two labs in year one and declined to 10% at year two (Fig 1b). This remained higher in nephritis patients 31% and 18% by two labs, but just 11 and 5% when requiring four labs per guidelines. Multivariable predictors of greater visit-defined retention included suburban residence and nephritis (Table 2).

Conclusion: Retention in lupus care began higher in our academic than our prior urban cohort but declined over time. Nephritis predicted more rheumatology visits, but lab-defined retention still fell far short of ACR guidelines showing opportunities for improvement. Suburban residence, likely representing higher education and resources, predicted better retention, showing the flipside of our prior findings of low retention with disadvantage, supporting a role for neighborhood context as a determinant of lupus care quality.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In psoriatic arthritis (PsA), there is a substantial life impact perceived by patients, although many treatments are now available at least in countries with access to more costly drugs (ref 1,2). Country of patient care, and in particular Gross Domestic Product (GDP) may be linked to PsA outcomes. The lack of large international registries has not up to now allowed any comparison of outcomes according to the country.

Table. Disease activity of PsA patients in different tertiles of country GDP/capita

	Patients in lowest country GDP/capita tertile (N=113)	Patients in middle country GDP/capita tertile (N=179)	Patients in highest country GDP/capita tertile (N=144)	P value between the tertiles
Swollen joint count (0-66), mean (SD)	3.8 (11.1)	1.2 (5.4)	2.3 (3.8)	<0.001
Tender joint count (0-68), mean (SD)	5.6 (10.3)	3.3 (7.9)	5.7 (10.7)	0.003
Tender entheseal points, mean (SD)	0.6 (1.4)	0.5 (1.2)	0.7 (1.6)	0.252
Body surface area of psoriasis ≥5%, n (%)	20 (18.2)	13 (7.7)	7 (5.0)	0.001
Elevated acute phase reactants (CRP >5mg/L), n (%)	62 (54.9)	65 (36.3)	49 (34.0)	0.001
Physician's global assessment of PsA, mean (SD)	4.0 (2.4)	2.6 (2.5)	3.0 (2.4)	<0.001
Patient's global assessment of PsA (0-10), mean (SD)	5.0 (2.5)	3.6 (2.7)	4.2 (2.8)	<0.001
HAQ (0-3), mean (SD)	0.89 (0.72)	0.50 (0.59)	0.70 (0.67)	<0.001
PsAID12, mean (SD)	4.3 (2.4)	2.9 (2.3)	3.3 (2.5)	<0.001
Minimal disease activity state attained, n (%)	21 (18.6)	87 (48.6)	58 (40.3)	<0.001
DAPSA remission or low disease, n (%)	52 (46.0)	114 (63.7)	80 (55.6)	0.012

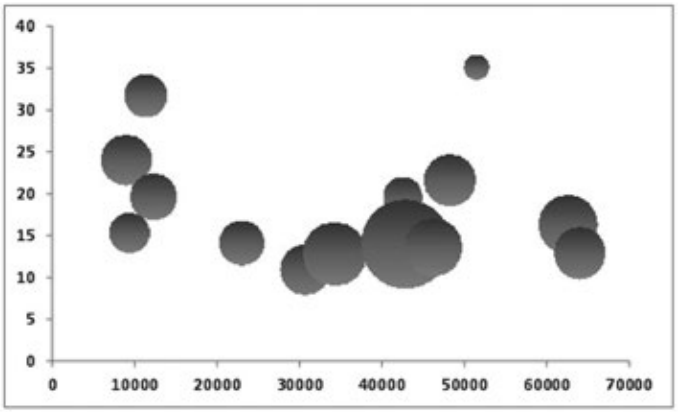
The objective was to explore potential differences in disease activity, disease impact and treatments across countries in PsA.

Methods: This was a cross-sectional analysis of an observational study (ReFlap, NCT03119805, ref3), which included adult patients with PsA with ≥ 2 years disease duration from 14 countries. Countries of inclusion were analysed separately, and classified into tertiles by GDP/capita (lowest tertile, Brazil, Turkey, Russia, Romania, Estonia; middle tertile: Spain, Italy, UK, France; highest tertile, Canada, Germany, Austria, USA and Singapore). Patient demographics, treatments prescribed (conventional synthetic DMARDs, biological DMARDs, glucocorticoids), disease impact (though patient global assessment, PGA, HAQ and the Psoriatic Arthritis Impact of Disease questionnaire, PSAID-12) and PsA disease activity (assessed through swollen and tender joint counts (of 66/68), CRP, entheseal points, psoriasis body surface area and the composite scores DAPSA and MDA) were analysed per coutrny and compared between the 3 tertiles of GDP/capita by non-parametric tests.

Results: Of the 466 patients, 436 had complete data available and were analysed: mean age 52.3 (SD 12.5) years, mean disease duration 10.1 (8.1) years, 218 (50.8%) male.

In countries with a lower GDP/capita, patients were slightly older, with a longer disease duration. There was a similar use of biologics (overall mean 60.5%) and of oral glucocorticoids (18.6%) but use of methotrexate was different (67.0% in the lowest GDP/capita tertile, versus 47.3% in the second and 53.4% in the highest tertile, p=0.007). Disease activity and impact were overall higher in the lowest GDP/capita countries (Table and Figure). The middle and highest GDP/capita tertiles had similar outcomes.

Figure. Mean DAPSA mapped against country GDP/capita for PsA patients from 14 countries



The x-axis represents the GDP/capita in US dollars of each country and the y-axis represents mean DAPSA in patients from each country. The size of the bubble represents the number of patients per country (range, 7 to 89).

Conclusion: In this exploratory comparison of disease patterns and treatments choices in 14 countries, we relied on a relatively small and selected population from tertiary centers which is a limitation. We observed a similar use of biologics but more use of methotrexate in countries with a lower GDP/capita, though glucocorticoid use was similar. Both disease activity and disease impact appeared more important in the lower GDP/capita countries. This raises questions on the link between disease activity, disease impact, treatment choices and other (external) society and culture related elements such as lifestyle/diet or health care systems.

Factors Associated with Participation in Rheumatic Disease-Related Research Among Underrepresented Populations: A Systematic Review

Kaitlin Lima,[1] Courtnie Phillip,[2] Jessica Williams,[2] Jonna Peterson,[1] Candace Feldman,[3] and Rosalind Ramsey-Goldman[4], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Brigham and Women's Hospital, Boston, MA, [3]Brigham and Women's Hospital, Boston, [4]Northwestern University, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Non-white racial/ethnic groups remain underrepresented in rheumatic disease-related research despite being disproportionately affected by these disorders. We aimed to systematically review the literature

Table 1: Summary of study design for studies included for analysis

First Author, Year	Disease of Interest	Number of Participants	Methods/Study Design
Dunbar-Jacob, 2004	RA	N=961	*Prospective cohort study:* Analyzed attrition rates measured at 4 distinct screening points for an RA trial: initial eligibility review, initial contact, adherence screen, and informed consent
Faith, 2018	SLE	N=33	*Prospective intervention study with qualitative analysis*: Patients assigned mentor for weekly meetings over 12 weeks. Post intervention focus groups held to discuss participants' experience in study
Lee, 2005	RA	N=191	*Cross sectional study utilizing clinical surveys:* Identified factors associated with willingness to participate in clinical trials
Lim, 2017	SLE	N=18	*Prospective randomized intervention study with qualitative analysis*: Simulation Phase II and Phase III anifrolumab studies for SLE with post-intervention interviews regarding participants' experience
Uribe, 2005	SLE	N=344	*Prospective Cohort Study:* Identified factors associated with poor compliance with study visits
Vina, 2012	SLE	N=182	*Cross sectional study utilizing telephone surveys:* Assessed predictors of participation in clinical trials
Vina, 2014	SLE	N=343	*Cross sectional study utilizing telephone surveys:* Assessed predictors of participation in clinical trials

Abbreviations: RA= rheumatoid arthritis, SLE = systemic lupus erythematosus

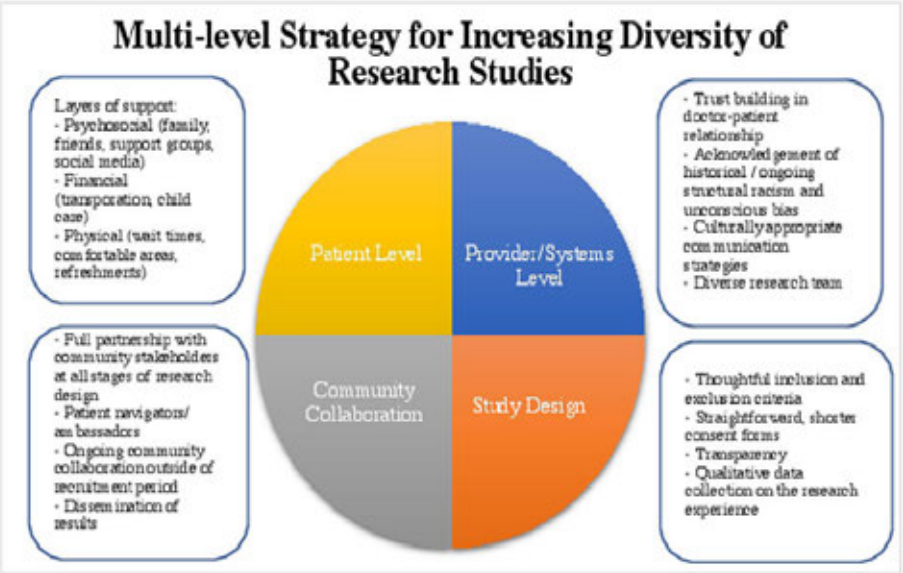

Figure 1. Multi-level Strategy for Increasing Diversity of Clinical Research.

regarding underrepresented patients' perceptions of participation in rheumatic disease research and to develop strategies to improve diversity.

Methods: A systematic search of Embase, Pubmed-MEDLINE, PsycINFO, and Cochrane was performed through November 2018. We identified 642 unique studies; seven met inclusion criteria (peer-reviewed articles, published in English in last 20 years, adult population, focus on underrepresented patients' participation in rheumatic research) by two independent reviewers. Data abstraction was performed and common themes and key differences were determined and adjudicated.

Results: The seven articles included (n=1,892 patients, range n=20 to n=961) evaluated factors associated with research participation of underrepresented populations. Five related to lupus, two to rheumatoid arthritis and five focused on African American patients, one on Hispanic. Five of the studies provided quantitative data through surveys (n=3) and chart review (n=2), while two utilized qualitative analyses. The key themes regarding underrepresented patients' perceptions of participating in research included: 1) importance of trust in the patient-physician relationship, 2) key motivators and barriers affecting willingness to participate, 3) the implications of strict inclusion criteria on study participant diversity and 4) the need for authentic academic-community partnerships with an understanding of heterogeneity within ethnic groups.

Conclusion: Overall, limited evidence exists regarding underrepresented patients' attitudes towards research participation in rheumatology, and further investigation is warranted. The themes identified provide a starting point for future interventions that promote increased diversity in rheumatic disease-related research studies.

Abbreviations: RA= rheumatoid arthritis, SLE = systemic lupus erythematosus

Abstract Number: 1151

The Impact of Gender on Time to Rheumatoid Arthritis Classification

Caitrin Coffey,[1] John Davis,[1] and Cynthia Crowson[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis differs between genders with regard to comorbidities, extra-articular manifestations, core measures of disease activity, and treatment response. Gender has not previously been associated with diagnostic delay in early RA, and the impact of gender on time to meeting ACR/EULAR classification criteria for RA is unknown. This study aimed to compare the time to fulfillment of 1987 and 2010 ACR/EULAR classification criteria between female and male patients with rheumatoid arthritis (RA), and to assess the potential impact of gender on the time to DMARD therapy.

Methods: Time from first provider-documented joint swelling to fulfillment of 1987 and 2010 ACR/EULAR criteria was measured in a population-based cohort of adults with incident RA in 2009-2014, who were stratified by male or female gender. Disease characteristics, time to start of DMARD therapy, and choice of initial DMARD therapy were compared between groups using Chi-square and rank sum tests.

Results: This study included 214 patients with RA (148 females and 66 males). Median times from first joint swelling to fulfillment of 1987 (6.5 vs 2.5 days, p=0.48) and 2010 (1 vs 0 days, p=0.34) classification criteria were not different between female and male patients. There was no difference in time from first joint swelling to first DMARD therapy in female vs male patients (15.5 vs 16 days, p=0.90), and methotrexate was used most frequently as first DMARD in both genders (61% female vs 64% male, p=0.76). Inflammatory markers were more commonly abnormal in male vs female patients at time of meeting 2010 criteria (83% vs 66%, p=0.010).

Table 1. Baseline characteristics of 214 patients at time of meeting 2010 ACR/EULAR classification criteria for RA.

Baseline characteristic	Female, N=148	Male, N=66	p-value
Age, mean (±SD), years	53.6 (±15.2)	59.1 (±12.5)	0.007
RF/ACPA positive	97 (67%)	46 (70%)	0.68
Current smoker	23 (16%)	15 (23%)	0.010
Former smoker	36 (24%)	26 (39%)	
Never smoker	89 (60%)	25 (38%)	
Obese (BMI ≥30kg/m^2)	60 (41%)	25 (38%)	0.71
≥10 joints involved	104 (70%)	46 (70%)	0.95
ESR and/or CRP elevated[1]	98 (66%)	55 (83%)	0.010
Presence of erosions	28 (19%)	19 (29%)	0.11

RF: rheumatoid factor; ACPA: anti-citrullinated peptide antibody; BMI: body mass index; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein.
[1] Elevated ESR and/or CRP were defined as higher than the upper limit of normal as defined by local laboratory standards.

Table 2. Comparison of time in days from first joint swelling to fulfillment of the 1987 or 2010 ACR/EULAR criteria and to first treatments between male and female patients with incident RA between 2009-2014.

Group		Female N=148	Male N=66	p-value
Overall	Median time to 1987 ACR/EULAR criteria, days (IQR)	6.5 (0, 122)	2.5 (0, 57)	0.48
	Median time to 2010 ACR/EULAR criteria, days (IQR)	1 (0, 94)	0 (0, 29)	0.34
	Median time to first DMARD, days (IQR)	15.5 (0, 100)	16 (4, 83)	0.90
	Median time to first glucocorticoid, days (IQR)	5 (0, 97)	9.5 (0, 81)	0.70
RF/ACPA-positive		Female N=99	Male N=46	
	Median time to 1987 ACR/EULAR criteria, days (IQR)	0 (0, 49)	25 (0, 44)	0.59
	Median time to 2010 ACR/EULAR criteria, days (IQR)	0 (0, 23)	0.5 (0, 32)	0.47
	Median time to first DMARD, days (IQR)	11 (0, 73)	16 (4, 83)	0.36
	Median time to first glucocorticoid, days (IQR)	7 (0, 97)	20 (0, 90)	0.32
RF/ACPA-negative		Female N=49	Male N=20	
	Median time to 1987 ACR/EULAR criteria, days (IQR)	65 (0, 398)	11 (0, 153)	0.063
	Median time to 2010 ACR/EULAR criteria, days (IQR)	165 (0, 254)	0 (0, 13)	0.035
	Median time to first DMARD, days (IQR)	60 (5, 210)	15 (1, 155)	0.25
	Median time to first glucocorticoid, days (IQR)	4 (0, 102)	0 (0, 12)	0.035

IQR: inter-quartile range

Among the 49 female and 20 male RF/ACPA-negative patients, females experienced a higher median time from first joint swelling to fulfillment of the 1987 (65 vs 11 days, p=0.063) and 2010 (65 vs 0 days, p=0.035) classification criteria. Similar proportions of females and males had >10 joints involved at the time they met 2010 criteria (82% vs 85%, p=0.74), but the time from first joint swelling to >10 joints involved was significantly longer for females than males (median 65 vs 0, p=0.038). Seronegative females were also more likely to be anti-nuclear antibody (ANA) positive than their male counterparts (30% vs 11%), but this difference did not reach statistical significance (p=0.11).

Conclusion: Overall there was no delay in meeting 1987 and 2010 ACR/EULAR classification criteria between female and male RA patients. However, among seronegative patients, females experienced a significant delay to meeting 2010 criteria from first clinically detected synovitis. This delay may be related to difficulty distinguishing RA from other diseases among seronegative females, or a delay in seeking healthcare among seronegative males.

Abstract Number: 1152

Low Rates of Bone Mineral Density Testing by Rheumatologists in Patients with Systemic Lupus Erythematosus and Glucocorticoid Therapy

JB Boone,[1] S. Bobo Tanner,[1] and April Barnado[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) are at an increased risk of developing osteoporosis and clinical fractures compared to healthy controls. Bone loss in SLE is multifactorial from the negative effects of systemic inflammation and use of glucocorticoids (GCs). The American College of Rheumatology recommends bone mineral density (BMD) testing within 6 months of starting chronic GC therapy for autoimmune conditions, including SLE. Prior studies have not investigated the frequency of BMD testing in the setting of chronic GC therapy and SLE using an electronic health record (EHR) cohort. Using a real-world, EHR cohort, we assessed the frequency of BMD testing in patients with SLE and GC therapy. We evaluated patient and provider factors impacting BMD testing.

Methods: We identified SLE cases from a de-identified EHR with over 2.9 million subjects with decades of follow-up using a previously validated and published algorithm. We chart reviewed to collect demographic, medication, and BMD data. We assessed for ever use of oral or intravenous GCs from inpatient and outpatient electronic prescribing systems, provider notes, and phone messages. Long term GC use was defined as ≥ 90 days of continuous use. Patients prescribed GCs for non-rheumatologic issues were excluded from review. The provider ordering BMD testing was recorded. Lowest T-scores were recorded from the femoral neck and lumbar spine. When multiple BMD tests were performed, the lowest T-score was recorded. Our primary outcome was frequency of BMD testing in SLE patients with long term GC therapy. We also evaluated for differences in SLE cases who had BMD testing vs. not using the Mann-Whitney U test for continuous variables and chi-square or Fisher's exact test for categorical variables.

Results: We conducted chart review on 729 SLE cases. Of these cases, 539 had available medication duration data with 475 (88%) with long term GC use. SLE cases with long term GC use had a current mean age of 54 ± 17 years and were predominantly female (89%) with 72% Caucasian, 22% African American, 4% Hispanic and 2% Asian. The median age at first BMD testing was 51 years. BMD testing was ordered in 40% of cases with long term GC use. Rheumatologists accounted for ordering 75% of the BMD tests. The median time from start of GCs to first BMD testing was 2.5 years. The mean T-score of cases with long term GC use was -1.4 ± 0.9. There were no differences

Table 1. Characteristics of SLE cases with long term glucocorticoid exposure with and without bone mineral density testing performed.

SLE case characteristics with long term GC use (n = 475)	BMD Testing Performed (n = 189)	BMD Testing Not Performed (n = 286)	p value*
Current Age, mean ± SD	60 ± 16	50 ± 16	<0.001
Age at first SLE billing code, mean ± SD	45 ± 15	37 ± 16	<0.001
Sex, n (%)			
Female	173 (41%)	250 (59%)	0.11
Male	15 (29%)	36 (71%)	
Race/Ethnicity, n (%)			
Caucasian	141 (43%)	184 (57%)	0.02
Black	28 (29%)	70 (71%)	
Hispanic	9 (50%)	9 (50%)	
Asian	1 (12%)	7 (88%)	

*Mann-Whitney U test for continuous variables and chi-square or Fisher's exact test for categorical variables.

in sex between cases with or without BMD testing (Table 1). SLE cases with long term GC use and BMD testing were older compared to cases with long term GC use without BMD testing (60 ± 16 v. 50 ± 16, $p < 0.001$). Caucasians and Hispanics were more likely to have BMD testing than African Americans and Asians ($p = 0.02$).

Conclusion: Using a large EHR cohort, only 40% of SLE cases with long term GC use had BMD testing. SLE patients that were younger, African American, or Asian were all less likely to have BMD testing performed. These groups with the lowest rates of BMD testing are the same groups that are at highest risk of requiring a significant amount of GCs during their disease course and developing GC-related bone loss. Screening strategies for BMD testing should be implemented that target these high-risk groups.

Abstract Number: 1153

Double Trouble: Utility of Serial TB Screening in a Rheumatology Clinic Serving a Foreign-Born Population

Alice Fike,[1] Yanira Ruiz-Perdomo,[1] and James Katz[1], [1]NIAMS, BETHESDA, MD

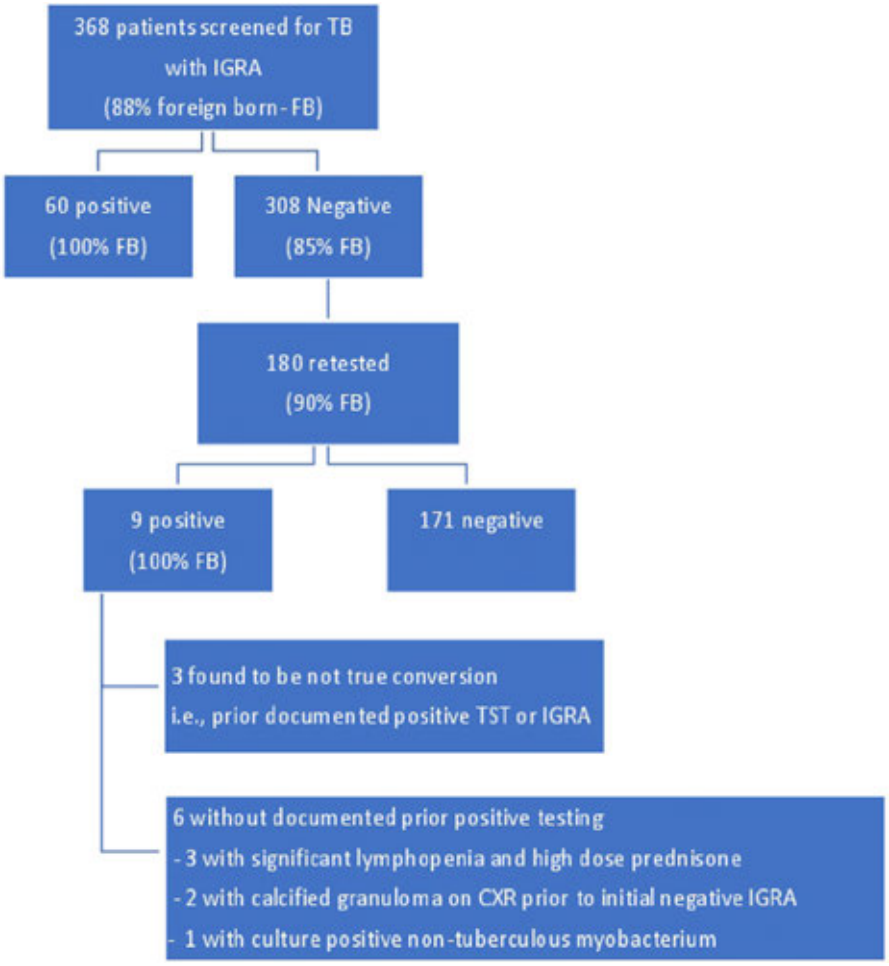
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The potential for reactivation of tuberculosis (TB) in patients treated with anti-TNF or other immunosuppressive agents has been well described. Interferon-gamma release assays (IGRA) have improved latent TB infection (LTBI) detection. Evidence is accumulating that shows a negligible yield for periodic testing in U.S. born rheumatology patients. Does this evidence apply to patients born in TB endemic countries now living in the U.S.? Incident active TB disease in the United States disproportionately affects people born in countries with endemic TB.

Purpose: To determine the yield of serial TB screening using an IGRA (Quantiferon Gold-QFT) in a United States rheumatology clinic with a majority (80%) foreign born population.

Methods: We sought to determine the utility of serial TB screening in this population using retrospective cross- sectional study design. Between January 2013 and December 2018, a total of 368 patients received TB screening using IGRA. Positive results were classified as initial positive or as a conversion if there was evidence of prior negative test. Records showing conversion were reviewed further for evidence of prior positive result outside of our institution and reclassified as not true conversions accordingly.

Results: During the study period, 368 subjects received TB screening using an IGRA. Of those, 60 initially screened positive (16%). The initially positive patients were 100% foreign born and twice as likely than the general clinic population to have been born in a country WHO designated as high burden for TB. 308 patients were initially screened negative. Of those, 180 received serial testing with subsequent testing at least 6 months after the initial test. Nine of those patients later tested positive (5%); all were foreign born. Of these nine, further review revealed three were not true conversions. Of the six who appeared to have a true conversion, three were noted to have had significant lymphopenia (180-660 absolute) and were receiving high doses of prednisone (25-60 mg/day) at the time of their initial negative IGRA. Two other patients were noted to have had calcified granuloma on chest x-ray at the initial negative



Flowsheet of IGRA Screening and Outcomes, 2013-2019

Table 1. Demographics of Screened Patients by IGRA Results.

	ALL	Initial positive IGRA	Initial negative IGRA	Serial IGRA	Subsequent positive IGRA
	N = 368	n = 60	n = 308	n = 180	n = 9
Male	68 (18.5%)	12 (20%)	56 (18.2%)	31 (17.1%)	3 (33.3%)
Hispanic	250 (67.9%)	37 (61.7%)	213 (69.2%)	133 (73.9%)	9 (100%)
Birth Country, High Burden TB	36 (9.8%)	14 (23 .3%)	22 (7.1%)	14 (7.8%)	–
Foreign Born	323 (87.8%)	60 (100%)	263 (85.4%)	163 (90%)	9 (100%)

IGRA. The sixth patient was found to have non-tuberculous mycobacterium and was treated. There were no cases of active TB during the study period. No patients born in the United States tested positive at initial or subsequent testing.

Conclusion: Our study demonstrates utility in serial TB screening with an IGRA in a patient population with birth in TB endemic countries, as well as periodic travel to such regions. In our patient population the yield was greatest in patients from countries with a high burden of TB. History is vital when ordering an IGRA, particularly at the initial testing. Prior positive TB skin test, prior evaluation at the local health department, prior exposure to individuals with TB, or prior TB infection, exposure, and/or treatment should be a regular component of history-taking in clinics responsible for managing immunosuppressive agents. It is important to keep in mind the risk of occult LTBI in patients who are immunosuppressed and born in TB endemic countries despite a negative IGRA result.

Hispanic Patients with Rheumatoid Arthritis Have Greater Discordance Between Patient and Physician Global Estimates Than Other Ethnic Groups, Explained Largely by Fibromyalgia (FM) According to a FM Assessment Screening Tool 3 (FAST3)

Isabel Castrejon,[1] Mariam Riad,[2] Joel A. Block,[1] and Theodore Pincus[2], [1]Rush University Medical Center, Chicago, IL, [2]Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Discordance between patient and physician global estimates has been described in many rheumatic diseases, including rheumatoid arthritis (RA)[1], and has been associated with decreased work productivity[2], greater radiological joint destruction and functional impairment[3], and a lower likelihood to be in remission[4]. The objective of this study was to compare the level of discordance according to self-reported race/ethnicity, and to estimate

Table: Characteristics of patients according to self-reported race/ethnicity and percentage of concordance/discordance in the four groups. **H** denotes the group with highest value.

	Whites N=100 (38%)	Blacks N=64 (25%)	Hispanics N= 60 (23%)	Others N= 36 (14%)	p
Age (yrs), mean (SD)	58.5 (15.2)	61.5 (13.4)	58.2 (15.0)	58.2 (11.7)	0.51

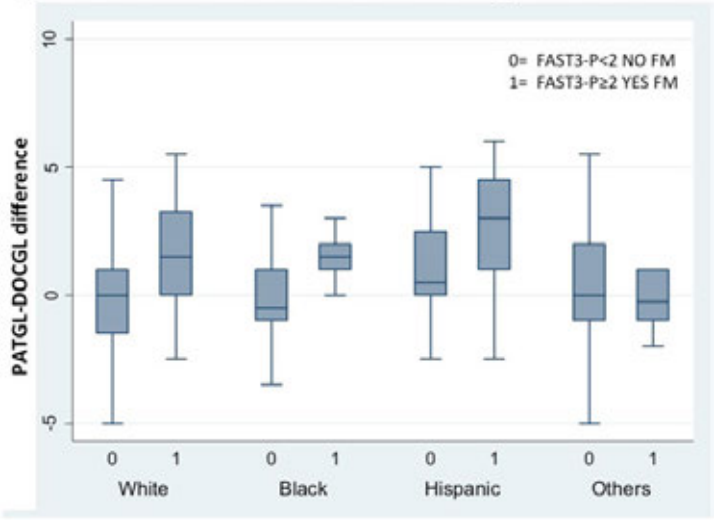
Symptom checklist (0-60)	10.2 (8.5)	14.2 (9.5) **H**	10.5 (7.7)	11.7 (7.8)	0.061
Self-report RADAI (0-48)	10.6 (8.5)	11.3 (9.4)	12.9 (11.1) **H**	8.0 (6.3)	0.002
FAST3-P positive for FM, %	27%	37% **H**	37% **H**	23%	0.29
Global Estimates					
PATGL (0-10)	4.1 (3.0)	4.9 (2.6)	5.5 (2.9) **H**	3.9 (2.5)	0.005
DOCGL (0-10)	3.7 (2.7)	4.4 (2.2) **H**	3.8 (2.1)	3.8 (2.1)	0.10
➢ DOCINF (0-10)	1.7 (1.5)	2.5 (2.1) **H**	1.9 (2.1)	2.5 (2.3) H	0.06
➢ DOCDAM (0-10)	3.2 (2.6)	3.2 (2.2)	4.1 (2.6) **H**	3.4 (2.6)	0.10
➢ DOCSTR (0-10)	1.8 (2.8)	2.0 (2.5) **H**	1.9 (2.6)	1.3 (1.9)	0.68
Concordant/Discordance groups:					
➢ Negative discordance DOCGL-PATGL≥2/10	11 (11%)	8 (12%)	3 (5%)	5 (14%)	
➢ Concordant DOCGL=PATGL	75 (75%) H	44 (69%)	33 (55%)	27 (75%)	0.003
➢ Positive discordance PATGL-DOCGL≥2/10	14 (14%)	12 (19%)	24 (40%) **H**	4 (11%)	

Figure: PATGL-DOCGL difference according to FM status



the level of discordance in patients who met and did not meet criteria for concomitant fibromyalgia (FM) by a FM Assessment Screening Tool (FAST3-P).

Methods: At one site, patients complete a multidimensional health assessment questionnaire/routine assessment of patient index data (MDHAQ/RAPID3) (0-30) as part of routine care, which includes 0-10 scores for physical function, and 0-10 visual analogue scales (VAS) for pain, patient global estimate (PATGL), and fatigue, as well as a 0-60 symptom checklist, and a 0-48 RADAI self-report painful joint count. FAST3-P is a cumulative index based on a 0–3 sum of 1 point each for pain VAS≥6, RADAI self-report joint count≥16, and symptom checklist≥16 (positive screen for FM≥2). The treating rheumatologist completes a RheuMetric checklist including a physician global (DOCGL) and 3 VAS for inflammation (DOCINF), damage (DOCDAM) and distress (DOCSTR). Patients with primary diagnoses of RA (ICD codes) were classified into one of 3 groups based on the difference between DOCGL and PATGL: concordant group (PATGL-DOCGL within ±2/10), negative discordance (DOCGL-PATGL≥2/10), and positive discordance (PATGL-DOCGL≥2/10). Values are reported as medians (standard deviation) and percentages. Comparisons according to self-reported ethnicity groups were performed using ANOVA or Chi^2.

Results: The study included 260 RA patients: 38% Whites, 25% Black, 23% Hispanics, and 14% others. Age and sex were similar in the 4 groups. Education level was highest in “others,” (primarily Asian), followed by White, Black and Hispanic patients. Hispanic patients had poorer scores for pain, physical function, fatigue, and RADAI self-reported compared with other groups ($p< 0.001$) (Table). A higher percentage of Black and Hispanic patients screened positive for FM according to FAST3-P. Higher scores for PATGL with similar scores for DOCGL lead to higher rate of positive PATGL >DOCGL discordance in Hispanic patients versus others. The difference between PATGL-DOCGL was higher in patients with concomitant FM for each group except for “others” (Figure).

Conclusion: Hispanic patients with RA have poor scores on most MDHAQ self-reported measures compared with non-Hispanic Whites or Black despite similar physician assessments, leading to higher positive discordance rates. Concomitant FM in all RA patients may be an important contributor to discordance between DOCGL and PATGL, recognition of which could help improve the quality of care.

Abstract Number: 1155

The Status of Latin-American Women in Rheumatology

Genessis Maldonado,[1] Maria Intriago,[1] Enrique Soriano,[2] and Carlos Rios[1], [1]Universidad Espiritu Santo, Guayaquil, Ecuador, [2]Rheumatology Section, Internal Medicine Service, Hospital Italiano de Buenos Aires, Argentina., Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Currently, Latin America does not have detailed information of women in rheumatologists based on education, working conditions, productivity, distribution of time between work activities and job satisfaction. The purpose of this survey was to provide more information of the rheumatology women in Latin America.

Methods: A digital survey was created using the Google Forms platform, it was approved and endorsed by the scientific committee of PANLAR and later sent to the different rheumatology associations of the region. The data was analyzed in the statistical program SPSS v.23.

Results: There were 318 women with an average age of 44 ± 10.7 [25-71], mostly mestizo ethnicity 60%, white 38%, indigenous 1%, African American 1% and Asian 1%. 58% are married, 28% are single, 8% are divorced, 5% are in free-union and 2% are widows. The mean number of children was 1.21 ± 1.11 [0-5]. The country with the largest number of rheumatologists was Argentina 32%, Brazil 16% and Mexico 11%. 37% of rheumatologists had at least one comorbidity, 17% thyroid disease, 7% osteoarthritis, 6% hypertension, 4% diabetes, 4% depression, 4% autoimmune diseases, 1% artery disease and 1% gout. 35% work in private hospitals, 27% private practice, 21% in government hospitals, 16% university hospitals and 1% in non-profit organizations. 86% is dedicated to adult rheumatology, 20% internal medicine, 15% pediatric rheumatology and 2% to immunology. The average of weekly work hours was 39.4 ± 18.3 [4-120], male rheumatologist weekly hours mean was 38.3 ± 17.1 [0-120]. 29% have training in musculoskeletal ultrasound, 75% training in densitometry reading and 50% training in musculoskeletal MRI. 72% have access to early arthritis clinic. 39% have an annual income below 19K, 19% between 20-29K, 11% between 30-39K, 14% between 50-99K, 9% between 40-49K and only 8% earn above 100K per year compared to male rheumatologist which 27% have an annual income below 19K, 12% between 20-29K, 12% between 30-39K, 19% between 50-99K, 10% between 40-49K and 20% earn above 100K per year. Regarding the satisfaction of the general practice, the average was 5.2 ± 1.25 [0-7], career options / professional growth 4.16 ± 2.01[0-7], geographic location 4.57 ± 2.11[0-7], income salary 3.2 ± 1.78 [0-7], job security 3.40 ± 1.87[0-7], colleagues and coworkers 4.42 ± 2.07[0-7]. 59% have a malpractice insurance. 88% have medical insurance and 70% retirement plan.

Conclusion: There are more women rheumatologist in the region compare to male rheumatologist. Women rheumatologist feel satisfied with their clinical practice, however, compared to male rheumatologist women have a lower annual income. This is the first study of its kind in Latin America.

Differences in Clinical Outcomes According to the Healthcare Regime in Colombian Patients with Rheumatoid Arthritis

Julian Barahona-Correa,[1] Jorge Florez,[1] Mateo Rodriguez,[2] Karen Ramirez,[3] Paul Mendez-Patarroyo,[1] Paola Coral-Alvarado,[1] and Gerardo Quintana-López[1], [1]Reumavance Group, section of Rheumatology, Fundacion Santa Fe de Bogota University Hospital, Bogota DC, Distrito Capital de Bogota, Colombia, [2]School of Medicine, Universidad de Los Andes, Bogota, Distrito Capital de Bogota, Colombia, [3]School of Medicine, Universidad Nacional de Colombia, Bogota DC, Distrito Capital de Bogota, Colombia

Table 1. Demographic and clinical variables assessed for overall, subsidized, Contributory and Excellence Clinical Care Center healthcare regime in Colombian patients with RA.

Variable	Overall	Subsidized	Contributory	Excellence Clinical Care Center	p-value
n (%)	240(100)	80(33,3)	80(33,3)	80(33,3)	-
Men n (%)	52(21.6)	21(26.2)	12(15)	19(23,7)	-
Mean age (IC 95%)	53.7 (52-56)	50.6 (47-53)	58.6 (56-62)	51.9 (50-54)	0,0008
Early RA n (%)	49 (20.4)	13 (16.2)	17 (21.2)	19 (23.7)	-
Established RA n (%)	191(79.6)	67(83.7)	63(78.7)	61(77)	-
Patients with initial high disease activity n (%)	175(72.9)	48(60)	73(91.2)	55(68.7)	-
Patients with high disease activity at the end of follow-up n (%)	114(47.5)	52(65)	41(51.2)	21(26.2)	-
Mean number of days between scheduled follow-up appointments (CI 95%)	58.2 (55.2-61.2)	48.9 (44.1-53.8)	82.7 (79.6-85.7)	43 (40.5-45.5)	< 0.0001*
Mean number of days between real follow-up appointments (CI 95%)	86 (78.3-93.7)	120.8 (102.3-139.2)	92.9 (85.7-100.2)	44.4 (40.9-47.8)	<0.0005*
Mean percentage of appointments accomplished on time (CI 95%)	50.1 (33.3 - 66.7)	17.08 (0 - 33.3)	62.08 (33.3 – 66.7)	71.25 (66.7 - 100)	<0.0001*
Mean percentage of treatment adherence (CI 95%)	61.9 (66.7-75)	52 (50-67)	57.19 (50-75)	76.7 (66.7-100)	<0.0001*
Mean percentage of time with high disease activity during follow-up (CI 95%)	60.4 (53.7-68.1)	67.26 (53.8-100)	69.1 (60.6-100)	44.9 (28.6-56.8)	<0.0001*

* Statistically significant after applying Bonferroni Test
- High disease activity: patients with moderate (DAS28: 3.2-51) or severe disease activity (DAS28: >5.1) based on DAS28-ESR.
- CI 95%: Confidence interval 95%
- n: number of patients
- %: percentage

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Healthcare Disparities In Rheumatology Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid Arthritis (RA) generates high impact on patients and healthcare systems. Adequate control of disease activity depends to a large extent on the access to a Rheumatologist. The type of healthcare system adopted by the governments constitutes a major determinant for the access of patients to an adequate standard of care. Colombia has a contributory and public-subsidized health insurance system, which ensures a universal coverage of the population; however, differences in care access opportunities persist, especially for appointments with sub-specialties. The aim of this study was to compare the disease outcomes of Colombian patients with RA, based on their type of health regime.

Methods: A retrospective observational study of Colombian patients with RA (Meeting 2010 ACR/EULAR classification criteria), with at least 3 assessments by a rheumatologist, in three outpatient services of different regimes: Contributory (C), Subsidized (S), and an excellence clinical care center (C3). Data collected from clinical records during a follow-up period of 2 years include: age, RA classification, percentage of patients with initial and final high disease activity based on DAS-28 ESR, number of appointments, days between appointments (ordered and real), number of appointments accomplished on time, adherence to treatment, and percentage of time in high disease activity. Mean and 95% confidence intervals were calculated. Statistical differences were calculated using X2 or Kruskal-Wallis test and adjusted for multiple comparisons using the Bonferroni test, with a significance level of p< 0,005. Survival analysis for the achievement of remission/low disease activity during follow-up was developed. Mantel-Cox test was calculated to compare the survival curves for every regime.

Results: A total of 240 patients were included (80 patients per regime). Results are summarized in Table 1. Mean initial age was 53.7 years; 21.6% of patients were men; 79.6% of patients had established RA; 72.9% of patients had initial high disease activity; Mean percentage of time in high disease activity during follow-up was lower in C3 (44.9%), and higher in C (69.1%). At the end of the follow-up, S group had the highest proportion of patients remaining with high disease activity, and C3 the lowest. Survival curve analysis based on Mantel-Cox shows no significant difference between S and C groups (p=0.2903), but were significantly different compared to C3 group (p< 0.0001). Median survival in high disease activity was greater in the S group (293 days), followed by C (254 days), and finally by C3 (64 days).

Conclusion: Patients treated in the clinical care center had better outcomes based on higher adherence and lower disease activity scores, compared to the other regimes, especially those on Subsidized regime. The type of health-

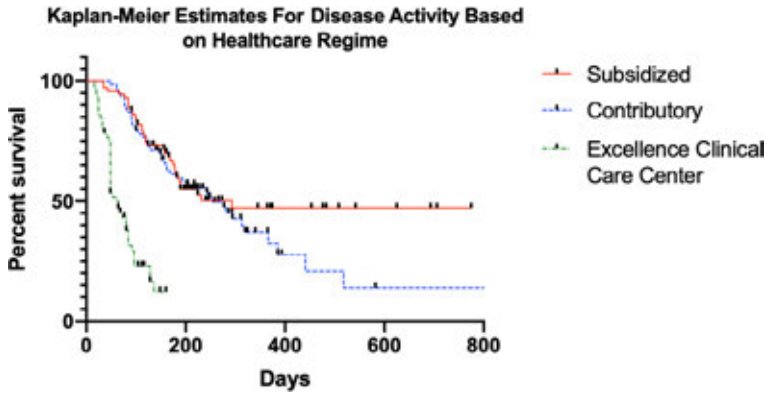

Figure 1. Kaplan-Meier curves for achievement of low disease activity during 2 years of follow-up.

care regime a patient has access to, is a major determinant of the disease outcomes, specially for chronic diseases in which the success of the treatment depends on a strict follow-up by a specialist. This differences in the access and outcomes are reflected in higher expenses for healthcare system, derived from complications and disabilities that patients could suffer, secondary to inadequate control of the disease.

Abstract Number: 1157

#WomeninRheumatology: Is There a Speaker Gender Gap at ACR Meetings?

Kanika Monga,[1] and Jean Liew[2], [1]University of Texas Health Science Center, Houston, TX, [2]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is a gender gap – that is, proportionately more male than female physicians – across most medical specialties in Canada and the U.S. despite the current gender parity in medical school. Limited numbers of role models, sponsors, and mentors may contribute. A lack of women leaders and representation in certain specialties may perpetuate the gap further. A goal of attaining equal (or as close to equal as possible) representation at national conferences is essential.

Recent studies have quantified the gender gap among speakers at academic conferences. The largest study of 181 medical conferences held in North America over one decade found an increase in the proportion of female speakers from 25 to 34% over time, and that the underrepresentation of women was more marked at surgical compared to

Table. Proportion of moderator/speaker slots filled by women, by year.

	2017	2018
overall	42.8%	47.0%
Speakers	41.1%	46.9%
Moderators	46.5%	47.6%
Basic science	39.5%	41.4%
Clinical	43.5%	48.1%
By presentation type		
Pre-meeting	37.1%	43.9%
ACR general	35.2%	42.5%
AHRP general	56.8%	73.7%
Abstract	47.5%	50.1%
Workshop	24.6%	32.8%
Study group	43.3%	56.9%
Meet the Professor	36.3%	32.5%

medical conferences [Ruzycki, et al 2019]. The purpose of our study was to describe the proportion of female representation among speakers and moderators at the ACR meeting over the past two years.

Methods: Using the ACR Session Tracker from 2017 and 2018, we determined the proportions of women for each speaker or moderator slot. Individual speakers could be counted multiple times. We further categorized by basic versus clinical science presentation, and by type of session (pre-meeting, ACR general session, AHRP general session, abstracts, workshop, study group, or Meet the Professor).

Results: Overall, the proportion of combined female speakers and moderators was 42.8% in 2017 and 47.0% in 2018. The representation of female speakers increased from 2017 to 2018 by 4.2%, which in a conference of approximately 1100 presenters (total presenters at the 2018 conference) amounts to 46.2 persons. There were a greater proportion of female speakers in the clinical than in the basic science presentations (average 45.8% versus 40.5%). By session type, the AHRP sessions had the highest proportion of female representation (average 65.3%) while Meet the Professor and workshops had the lowest (34.4% and 28.7%, respectively).

Conclusion: The overall mean proportion of female speakers and moderators at ACR in the past two years was 44.9%. Compared to a prior study, the ACR had female representation slightly above the mean compared to major North American medical conferences held in 2017. This proportion is also comparable to the estimated U.S. adult rheumatology workforce data from 2015. Although the gender gap at recent ACR meetings was narrower as compared to other conferences, we must remain cognizant of its presence and continue to work towards equal representation.

Abstract Number: 1158

Investigating Health Literacy and Numeracy in an Academic Center Lupus Cohort

Mithu Maheswaranathan,[1] Raeann Whitney,[2] Megan Clowse,[2] Amanda Eudy,[2] and Jennifer Rogers[2], [1]Duke University Medical Center, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Up to 50% of American adults have basic or below basic health literacy and numeracy. Low health literacy is associated with increased health care costs and hospitalization rates as well as poor disease knowledge and self-management. Health numeracy is a form of quantitative health literacy with important implications on health. While studies have demonstrated the impact of low health literacy on patient outcomes in many diseases including rheumatoid arthritis, there is no recently published data investigating literacy and numeracy in SLE. The objectives of this study were to (1) assess baseline health literacy and numeracy of our SLE cohort and (2) evaluate clinical associations.

Methods: SLE patients in a university clinic meeting SLICC criteria from March through May 2019 were recruited. Health literacy was assessed using the Basic Health Literacy Screen (BHLS), Rapid Estimate of Adult Literacy in Med-

Table 1: Association Between Numeracy Scores and Patient Characteristics / Clinical Measures

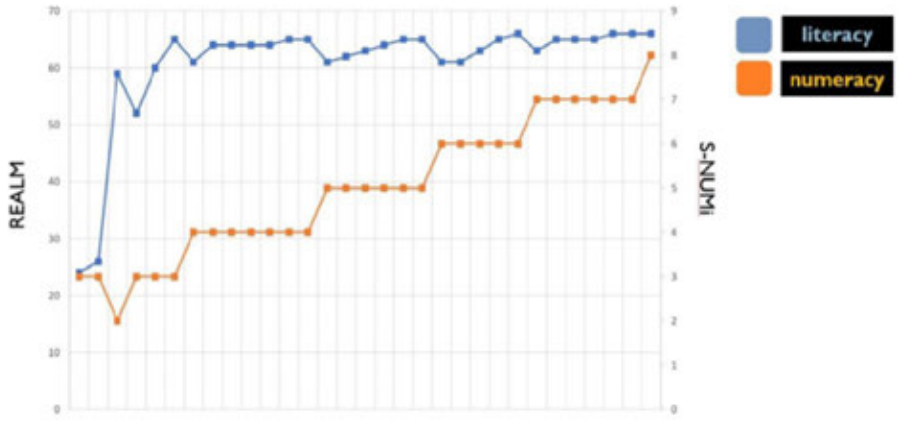
	High Numeracy s-NUMI 7 or 8 (n=8)	Low to Average Numeracy s-NUMI <7 (n=27)	p value
	% of Patients	% of Patients	
Gender			
Men (%)	0%	7%	1.0
Female (%)	100%	93%	
Race			
White (%)	63%	19%	0.03
Non-White (%)	38%	81%	
Age in Years (Range)	42 (34-60)	39 (22-63)	0.4
History of **Lupus Nephritis**	50%	48%	1.0
Cognitive Dysfunction	25%	33%	1.0
Medication Adherence	75% ± 37	82% ± 19	0.6
College Graduate	63%	44%	0.4
Medicaid	12.5%	59%	0.04
Disability	12.5%	41%	0.2
Income <$50,000 annually	38%	78%	0.08
	Score	Score	
Clinical SLEDAI	1.4 ± 2.5	2.4 ± 2.6	0.4
FSS [Fibromyalgia]	8.1±5.6	9.3±7.2	0.7
PHQ9 [Depression]	5.1 ± 4.1	7.0 ± 6.3	0.4

icine (REALM) and the Arthritis-Adapted REALM (A-REALM). Health numeracy was evaluated using the Shortened Subjective Numeracy Scale (SNS-3) and the Numeracy Understanding in Medicine Instrument Shortened Version (S-NUMi). Fisher's exact test was applied to categorical variables using STATA Version 15. The associations between health literacy and numeracy with clinical variables were analyzed using univariate and multivariate models.

Results: The study included 35 patients with SLE with an average age of 39 years, 94% were high school graduates and 49% college graduates, 69% had annual income < $50,000, and 71% were non-white. SLE disease duration averaged 14 years and current average clinical SLEDAI was 2.1. The majority of patients scored in the high school range for literacy (86% with REALM ≥ 61) and self-reported good reading skills (BHLS mean 13.2 [SD 2.5] out of 15). On the other hand, only 23% of patients scored in the high range for numeracy, and patients reported lower subjective math self-evaluation scores (SNS-3 12.5 [SD 4.3] out of 18).

Compared to patients with high numeracy, patients with a s-NUMI score consistent with average or low numeracy were more likely to be black, have significantly lower income or have Medicaid insurance (Table 1). There was not an association between numeracy and prior lupus nephritis, current lupus activity, self-reported medication adherence, or current pain, fatigue or depression; however, the study was under-powered to identify these differences. Interestingly, self-reported cognitive dysfunction was not different between groups.

Figure 1: Distribution of the Objective Literacy (REALM) and Numeracy (S-NUMi) Scores



Conclusion: In our study, the majority of SLE patients scored at the high school range for health literacy (86%) compared to only 23% demonstrating high numeracy scores. Our clinical experience suggests that patient understanding of lupus manifestations and treatment is not reflected in the high literacy scores found in this study. We hypothesize that a patient's ability to read words, as is tested in the REALM and A-REALM, is not sufficient to assess understanding of the complexity of SLE. Further studies are needed to investigate the impact of literacy and numeracy on disease understanding and medication adherence.

Deep Learning Social Media Analysis Demonstrated Gender-Specific Disparity in Side Effects from Rheumatoid Medications

Ahmad P. Tafti,[1] Cynthia Crowson,[2] Kelly O'Neill,[3] Elena Myasoedova,[1] Hongfang Liu,[4] Pamela Sinicrope,[1] and John Davis[1], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester, Rochester, [3]Rheumatoid Patient Foundation, Inc., Winter Springs, FL, [4]Mayo Clinic Rochester, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Healthcare Disparities In Rheumatology Poster
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple studies revealed adverse side effects caused by different rheumatoid arthritis (RA) medications. However, little is known about gender differences in RA treatment and medications. Increasingly patients are sharing and searching for RA information on health-related social media. This study developed deep learning (DL) text analytical tools on top of health-related social media to identify gender-specific disparities in side effects reported by people taking 2 common medications for RA: Methotrexate/Trexall and Leflunomide/Arava.

Methods: Data from three well-known health-related social media, *WebMD* (https://www.webmd.com/drugs), Daily Strength (https://www.dailystrength.org) and and *Drugs.com* (https://www.drugs.com), were extracted from June

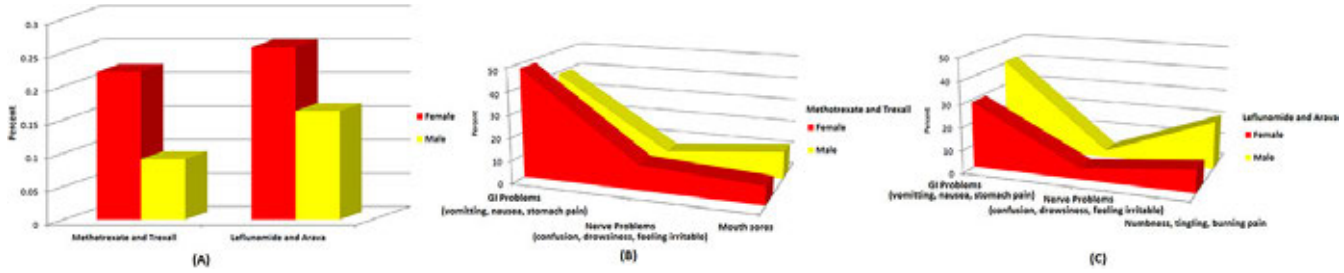

Figure 1. (A) Female and male's percentage who shared side effects experiences associated with Methotrexate (Methotrexate and Trexall) and Leflunomide (Leflunomide and Arava). One can see the number of adverse side effects posts generated by women was greater than those generated by men. Among 1,389 Methotrexate and Trexall associated posts shared by women (including side effects, indication, and/or other topics), over 307 posts were discussing side effects associated with this medication. For Leflunomide and Arava, this was 285 out of 1,105 messages posted by women. For men, it was 102 out of 1,119 posts and 137 out of 841 posts, respectively. (B and C) Gender-specific comparative visualizations across different side effects of Methotrexate-Trexall (B) as well as Leflunomide-Arava (C).

2013 to May 2019, including gender information and the text of posts. Since *Drugs.com* does not provide gender of the users, a top 3 name-to-gender inference service, namely NameAPI (https://www.nameapi.org) has been used to identify gender of the users based on their names. We segmented each post into a set of sentences as the units for DL, which used word2vec feature representation. An ensemble of deep neural networks was developed to identify sentences relating to drug adverse side effects. The training data consisted of a random subset of sentences annotated by three domain experts, where each sentence was classified as either describing a side effect (SE) or no side effect (No-SE). A total of 12,702 sentences (6,453 SE and 6,249 No-SE) were annotated, with high inter-annotator agreement of kappa=0.81. A baseline classifier for comparison was trained using Naïve Bayes with bag-of-word features.

Results: On 4-fold cross-validation, the DL classifier achieved an AUC of 0.897. The accuracy of the ensemble DL classifier outperformed the Naïve Bayes classifier significantly (p=0.04). With the best-tuned configuration, the DL classifier was then applied on 39,191 unseen new sentences for large-scale trend analysis, in which the overall disparity and disparity in five common SEs are shown in Figure 1. To focus on only RA-related sentences, we constrained messages to those that explicitly included at least one of: "RA", "R.A", "R.A.", "bone", and "joint". Figure 1 shows the visualization results.

Conclusion: The study demonstrated feasibility of developing highly accurate DL classifiers for identifying RA medication side effects in social media, providing gender disparity information using this wealth of data. Although social media may reflect biased prevalence of conditions due to subjective user behaviors, we were able to faithfully describe the data. In addition to improving our methods, future work will emphasize verifying/comparing such disparity by applying similar analysis on EHRs along with generic social media (e.g., Twitter, Google+, and reddit). The present work elucidates construction of a holistic patient-centered decision support framework that can be merged with a diverse range of clinical data, such as EHRs and clinical notes to help clinicians and patients assess benefits and risks of RA treatments, conducting the development of personalized medicine within the RA context.

Session Title: Healthcare Disparities In Rheumatology Poster

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Racial/ethnic minorities, women, and the elderly experience a disproportionate burden of disease in Rheumatoid Arthritis (RA), making it particularly important to examine drug therapies in these populations. Clinical evidence demonstrates that treatment responses to new RA biologic drugs differ significantly by race/ethnicity. Despite a national health agenda to improve the representation of diverse populations in clinical trials, there have been few large-scale analyses examining the diversity of clinical trial participants within rheumatology, and none focusing on RA. Our objective was to perform a comprehensive systematic review of RA randomized controlled trials (RCTs) published within the last 10 years in order to characterize the representation of racial/ethnic minorities, women, and the elderly.

Table 1: Characteristics of the 240 Rheumatoid Arthritis randomized controlled trials included in this review.

	Total no. of RCTs (%)	No. of RCTs with ≥1 U.S.-based site (%)
Overall	240 (100.0)	126 (52.5)
Gender inclusion		
Both males and females	231 (96.3)	124 (98.4)
Females only	3 (1.3)	0 (0.0)
Not reported	6 (2.5)	2 (1.6)
Age inclusion		
Trials that had exclusion criteria for any upper age limit	99 (41.3)	38 (30.2)
Exclusion by upper age limit		
Excluded >100 yo or >99 yo	3 (1.3)	3 (2.4)
Excluded >85 yo or >80 yo	21 (8.8)	11 (8.7)
Excluded >75 yo or >74 yo	43 (17.9)	16 (12.7)
Excluded >70 yo or >69 yo	14 (5.8)	4 (3.2)
Excluded >65 yo or >64 yo or >60 yo	18 (17.5)	4 (3.2)
Age reporting		
Trials reporting avg age and SD	193 (80.4)	96 (76.2)
Race/ethnicity reporting		
Race reported AND Hispanic ethnicity not mentioned	86 (35.8)	57 (45.2)
Race reported AND Hispanic reported as separate race	5 (2.1)	5 (4.0)
Race and ethnicity reported	12 (5.0)	11 (8.7)
Ethnicity only reported	27 (11.3)	8 (6.3)
Neither race nor ethnicity reported	110 (45.8)	45 (35.7)

Other	5 (2.1)	1 (0.8)

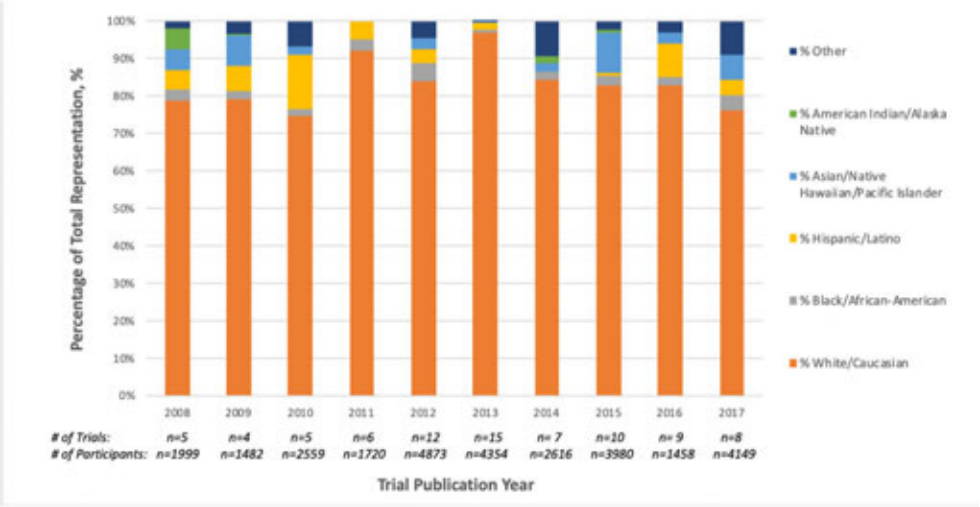

Figure 1: Trends in racial/ethnic representation in Rheumatoid Arthritis randomized controlled trials with at least one U.S.-based site between 2008 and 2017 (N=29,190 participants)

Methods: We identified RA RCTs that were published in PubMed (1/1/2008 to 1/1/2018), searching MEDLINE using "Rheumatoid Arthritis" and "humans" as MeSH terms and "randomized controlled trial" as a publication type. The titles and abstracts for all 1195 identified records were independently screened by two reviewers using a web-based application called Rayyan QCRI (https://rayyan.qcri.org). Full texts of remaining records (n=922) were screened using a process adapted from a previously published systematic review. Logistic regression models were used to assess changes in the proportion of subjects in each racial/ethnic and gender category over time. Chi-squared tests were used to 1) compare the proportion of trial enrollees across racial/ethnic groups to the overall demographics of the U.S. and 2) to compare the proportion of female and male enrollees to the overall age-adjusted gender prevalence of RA.

Results: A total of 240 RA RCTs were included in the review (Table 1). The enrollment of minority racial/ethnic groups in U.S.-based RA RCTs was significantly lower than the representation of these groups in the U.S. census population ($p < 0.001$). While racial and ethnic minorities comprise about 40% of the U.S. population, they only represented 16% of the RCT population for RA. The enrollment of males in RA RCTs with at least one U.S.-based site was significantly lower than the burden of male RA cases nationally (20.4% vs. 28.6%) ($p < 0.001$). There were no significant changes in the representation of racial/ethnic groups or gender over the observed period (p-trend >0.05) (Figure 1). Reporting of an upper age limit as exclusion criterion was observed in 41.3% (n=99) of the RA RCTs (Table 1).

Conclusion: Despite national efforts to increase clinical trial diversity, there was no trend to improved representation of minority racial/ethnic groups in U.S.-based RA RCTs over the period 2008-2017, with significant underrepresentation of these groups throughout. The results also suggest that men are underrepresented in RA RCTs and that the elderly are often excluded from RA RCTs.

Gadolinium-Enhanced Magnetic Resonance Imaging in Shoulders Contributes Accurate Diagnosis and Predicting Recurrence to Patients with Polymyalgia Rheumatica

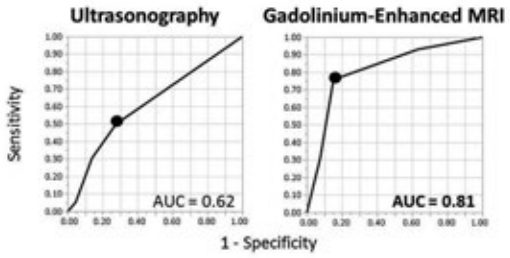
Kazuro Kamada,[1] Hiroyuki Nakamura,[1] Masato Tarumi,[1] Shun Tanimura,[1] and Tetsuya Horita[1], [1]Tomakomai City Hospital, Tomakomai, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polymyalgia rheumatica (PMR) is a glucocorticoid-responsive muscle pain and stiffness, especially in the shoulders and hips. PMR is clinically diagnosed based on the symptoms, although accurate diagnosis is difficult because the symptoms can occur in many other rheumatologic and inflammatory conditions. Recently, it was reported that ultrasonography (US) in shoulders could detect the specific findings to PMR, such as biceps tenosynovitis and subdeltoid bursitis. Magnetic resonance imaging (MRI) also has an advantage of visualizing bone and muscle lesions; however, the application to PMR diagnosis has not been established yet. In this study, we evaluated gadlinium-enhanced MRI findings of the shoulder in patients with PMR. The purpose of this study is to assess whether gadlinium-enhanced MRI could improve diagnostic accuracy and prognosis prediction in patients with PMR.

Methods: This study included the consecutive patients who had bilateral shoulders pain and fulfilled the Bird classification criteria for PMR between June 2012 and June 2018 in Tomakomai City Hospital. Gadlinium-enhanced MRI and US in shoulders were performed in the all patients. We excluded patients declining participation in the study or having contraindications of gadlinium-enhanced MRI. PMR was diagnosed by at least two rheumatologists. MRI and US findings were evaluated by independent radiologists. 20 mg/day of prednisolone was initially administered to patients with PMR, and was tapered after remission. They were followed-up until June 2019 about recurrences.

	PMR (n = 58)	Non-PMR (n = 79)	p value
Ultrasonography in shoulders			
Biceps tenosynovitis, %	43	23	0.02
Subdeltoid bursitis, %	32	12	< 0.01
Glenohumeral synovitis, %	11	11	0.99
Gadolinium-Enhanced Magnetic Resonance Imaging in shoulders			
Enhancement of joint capsule, %	**69**	35	**< 0.01**
Enhancement of rotator cuff tendon, %	**72**	32	**< 0.01**
Enhancement of biceps tendon, %	12	6	0.24
Synovial hypertrophy, %	12	15	0.60
Shoulder joint effusion, %	64	44	0.02
Enhancement of glenohumeral joint, %	5	10	0.29
Focal bone edema in humerus head, %	59	19	**< 0.01**
Diffuse bone edema in humerus head, %	2	9	0.08



Recurrence	No (n = 30)	Yes (n = 24)	p value
Age, years	**76 (71-82)**	72 (66-77)	**0.04**
Sex (female), %	53	75	0.10
ESR, mm/h	87 (80-113)	99 (71-126)	0.68
MMP-3, ng/mL	238 (132-333)	196 (113-403)	0.69
Positive ultrasonography, %	52	52	0.97
Gadolinium-Enhanced Magnetic Resonance Imaging in shoulders			
Enhancement of joint capsule, %	77	67	0.41
Enhancement of rotator cuff tendon, %	**87**	58	**0.02**
Enhancement of biceps tendon, %	10	12	0.77
Synovial hypertrophy, %	3	**21**	**0.04**
Shoulder Joint effusion, %	60	67	0.61
Focal bone edema in humerus head, %	53	63	0.50

Results: 269 patients visited our hospital complaining of bilateral shoulders pain, and 175 of them fulfilled the Bird classification criteria for PMR. 137 patients received gadlinium-enhanced MRI and US examinations, and PMR was diagnosed in 58 patients. Enhancement of joint capsule (Fig. 1A), rotator cuff tendon (B) or biceps tendon (C), synovial hypertrophy (D), shoulder joint effusion (E), enhancement of glenohumeral joint (F) and/or focal (G) or diffuse (H) bone edema in humerus heads were found in the patients. Of these MRI findings, enhancement of joint capsule or

rotator cuff tendon and focal bone edema in humerus heads were significantly frequent in the PMR patients. If the three findings on MRI were used in combination to diagnose PMR, the sensitivity and specificity were 76% and 85%, respectively, higher than 50% and 72% of US findings (Fig. 2). In the follow-up study, PMR recurred in 24 patients (44%). Patients with recurrent PMR had younger ages, less enhancement of rotator cuff tendon and more synovial hypertrophy findings on MRI (Fig. 3).

Conclusion: Gadolinium-enhanced MRI displayed capsulitis, rotator cuff tendonitis and focal osteitis in shoulders, relatively specific to patients with PMR. Besides, rotator cuff tendonitis and synovial hypertrophy on MRI were associated with recurrences of PMR. Our study suggested that gadolinium-enhanced MRI in shoulders could contribute accurate diagnosis and predicting recurrence to patients with PMR.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Composite imaging scores that reflect cartilage damage, bone marrow lesions (BMLs), and effusion-synovitis may enable us to conceptualize knee osteoarthritis (KOA) disease progression as two constructs: 1) disease activity = whole-joint dynamic disease processes that fluctuate over time and relates to knee pain, 2) cumulative damage = joint damage that has accrued over time and relates to radiographic disease severity. We aimed to determine if recently validated composite magnetic resonance (MR) metrics of KOA disease activity and cumulative damage can predict the development of accelerated KOA (AKOA).

Table 1. Baseline Group Characteristics. KOA: knee osteoarthritis; KL: Kellgren-Lawrence; SD: standard deviation; n: sample size.

Variables [(means (SD); except where noted)	AKOA (n=125)	Typical KOA (n=125)	No KOA (n=125)
Females, n(%)	79(63%)	79(63%)	79 (63%)
Age (years)	62.5(8.5)	58.4(8.4)	57.3(8.2)
Body mass index (kg/m²)	29.7(4.6)	28.1(4.4)	26.9(4.4)
Index knee KL Grade=0, n(%)	42(34%)	71(57%)	92 (74%)
WOMAC pain (0-20; score=pain)	2.6(3.3)	1.6(2.1)	1.4(2.0)
Use of Pain Medication, n(%)	72(58%)	61(49%)	47(38%)

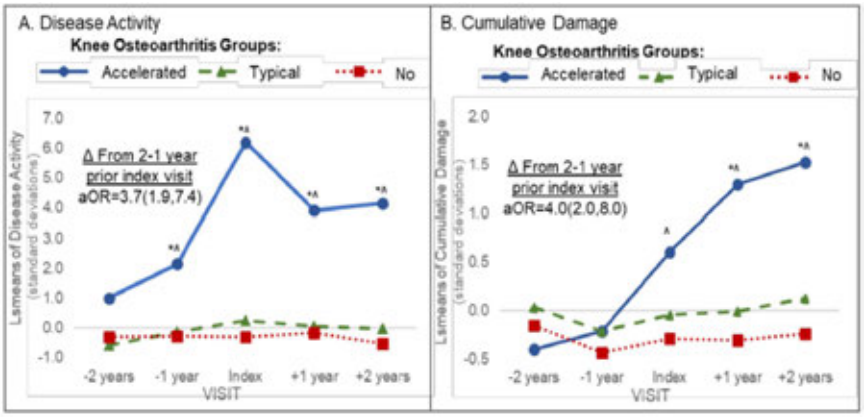

Figure 1. Differences in Disease Activity (Figure 1A) and Cumulative Damage (Figure 1B) in Individuals with Accelerated Compared to Typical and No Knee Osteoarthritis. Greater values for disease activity and cumulative damage are considered disease progression. The standardization of components allows the composite metrics to be interpreted as the amount of standard deviations away from the group overall group mean at the 2 year prior to index visit. LSmeans are statistically different in accelerated compared to typical(*) or no (^) knee osteoarthritis. Generalized linear mixed models were adjusted for sex and factors related to missing magnetic resonance data at the next visit (i.e., age, body mass index, injury, frequent knee pain, days with limited activity in prior month, overall global rating, and WOMAC pain). aOR = adjusted odds ratio (95% confiedence intervals). Logistic regression models were adjusted for sex, race, and baseline age, body mass index, KL grade, WOMAC pain, and use of pain medication.

Methods: We identified adults from the Osteoarthritis Initiative without radiographic KOA (i.e., Kellgren-Lawrence grade [KL] 0/1) at baseline. Three groups were identified based on annual radiographic disease progression over the first 48-months: 1) *AKOA*: progressed to KL 3/4; 2) *typical KOA*: any other increase in KL; 3) *no KOA*: no change in KL. The visit an adult met the AKOA or typical KOA criteria was defined as the index visit. We assessed cartilage damage in four tibiofemoral regions, BML volume in four tibiofemoral regions, and a whole knee effusion-synovitis volume on 3T MR images with semi-automated programs. We used annual images from two years before to two years after the index visit. Each MR metric was normalized to participant size and standardized from the earliest visit. We calculated disease activity as the sum of the standardized score from all four BML regions and effusion-synovitis. We calculated cumulative damage as the sum of the the standardized score from all four cartilage regions. To determine group differences across time in disease activity and cumulative damage, we used generalized linear mixed models with group (3 levels) and time (up to 5 levels) as independent variables. Additionally, change in the composite metrics from two to one year prior to the index visit was converted to a dichotomous variable to compare the worst tertile (greatest progression) to the other two tertiles. To establish the prognostic capability of disease activity and cumulative damage change, we used separate logistic regression models to determine if change in each composite metric prior to disease development was associated with future AKOA status (AKOA vs no AKOA).

Results: Table 1 provides the baseline characteristics for each group. Starting at one year prior to the index visit, the AKOA group had greater disease activity compared to the typical or no KOA groups (Figure 1A). Starting at the index visit, the AKOA group had worse cumulative damage compared to the typical or no KOA groups (Figure 1B). There were no differences at any time for either composite metrics between the typical and no KOA groups (Figure 1A and 1B). However, adults with the greatest increase in disease activity or cumulative damage from two to one year prior to the index visit were 3.7 and 4.0 times more likely to develop AKOA, respectively (Figure 1A and 1B).

Conclusion: Prior to AKOA development, disease activity and cumulative damage change are prognostic of AKOA development and progression.

Erosions Are the Most Often Reported Structural Lesion on MRI of the Sacroiliac Joints in axSpA Patients with IBP

Manouk de Hooge,[1] Ann-Sophie De Craemer,[1] Thomas Renson,[1] Philippe Carron,[1] Liselotte Deroo,[1] Dirk Elewaut,[1] and Filip Van den Bosch[1], [1]Ghent University Hospital, Ghent, Belgium

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: HLA-B27 and sacroiliitis on MRI form the basis of the Assessment of SpondyloArthritis international Society (ASAS) axial spondyloarthritis (axSpA) classification criteria. In addition, while not an entry criterion of the classification criteria, inflammatory back pain (IBP) is fundamental in the axSpA diagnostic process and it is endorsed as referral parameter in primary care. Besides inflammation on MRI, which is the hallmark of axSpA, there is still debate on the value of structural MRI lesions in these patients. The objective of this study was to report on MRI of the sacroiliac joints (MRI-SIJ) findings in newly diagnosed axSpA patients stratified for the presence of IBP and HLA-B27 positivity.

Methods: Newly diagnosed and anti-TNF naive axSpA patients of an ongoing Belgian (Be-Giant) cohort were included in this study. MRI-SIJ assessment was performed independently by 3 calibrated readers according to an adapted method of the Spondyloarthritis Research Consortium of Canada score, evaluating erosions, fatty lesions, sclerosis and ankylosis (T1-weighted and STIR images viewed simultaneously). Also, the ASAS definition of a positive MRI-SIJ was evaluated. MRI sum scores were calculated as 2 out of 3 (median) reader scores.

Results: In 138 axSpA patients MRI-SIJ data was available; 68 (49.3%) patients were male, 104 (75.4%) HLA-B27 positive and 131 (94.9%) patients fulfilled the IBP criteria according to ASAS. In the IBP+ patient groups, a large amount of structural MRI lesions were seen. In these groups, erosions are most frequently reported, with an average extent of 5 erosions. IBP- patients were rarely seen in this cohort and erosions and fatty lesions were the only structural lesions observed in these patients, with a much lower extent compared to the IBP+ patients (see table 1). There were no axSpA patients with negative MRI-SIJ, negative HLA-B27 and without IBP.

Table 1: Structural lesions seen on MRI in axSpA patients stratified for IBP, HLA-B27 and a positive MRI-SIJ.

Structural MRI lesions	IBP+ HLAB27+ MRI-SI+ n=77	IBP+ HLAB27+ MRI-SI- n=22	IBP+ HLAB27- MRI-SI+ n=27	IBP+ HLAB27- MRI-SI- n=5	IBP- HLAB27+ MRI-SI+ n=3	IBP- HLAB27+ MRI-SI- n=2	IBP- HLAB27- MRI-SI+ n=2	IBP- HLAB27 - MRI-SI- n=0
Gender, n(%) male	41 (53.2%)	13 (59.1%)	9 (33.3%)	2 (40.0%)	1 (33.3%)	1 (50.0%)	1 (50.0%)	-
Erosions*	61 (79.2%); 5.3±4.9	8 (36.4%); 4.9±6.6	20 (74.1%); 5.2±4.4	2 (40.0%); 5.0±5.7	1 (33.3%); 1.0±NA	1 (50%); 2.0±NA	1 (50%); 1.0±NA	0
Fatty lesions*	23 (29.9%); 8.6±7.0	5 (22.7%); 12.0±7.7	4 (14.8%); 13.0±5.3	3 (60.0%); 2.3±0.6	1 (50%); 2.0±NA	1 (50%); 2.0±NA	1 (50%); 3.0±NA	0
Sclerosis*	13 (16.9%); 4.4 ±3.1;	0	5 (18.5%); 3.0±1.6	2 (40.0%); 11.5±5.0	0	0	0	0
Ankylosis*	10 (13.0%); 11.2±8.6	2 (9.1%); 32.0±11.3	2 (7.4%); 8.0±5.7	0	0	0	0	0

*numbers reported are: number of patients with 1 or more of the given structural lesion (% from group total); mean±standard deviation of patients with 1 or more of the given structural lesion.

Conclusion: In this cohort of newly diagnosed anti-TNF naïve axSpA patients, structural lesions are frequently and with a high extent seen in IBP+ patients. Only in the IBP+ axSpA patients the previously reported threshold for axSpA patients of ≥3 erosions and ≥3 fatty lesions is maintained, as IBP- axSpA patients have far fewer lesions. IBP seems to be an indicator for the presence of structural MRI-SI lesions in newly diagnosed axSpA patients.

Novel Computer Assisted Methodology for Quantitative Assessment of MRI Treatment Responses to Apremilast in Patients with Psoriatic Arthritis

Paul Bird,[1] Mikael Boesen,[2] Mark Hinton,[3] Eser Sanverdi,[3] Romiesa Hagoug,[3] Chrisotpher Sabin,[3] Priscila Nakasato,[4] Benoit Guerette,[4] and **Olga Kubassova** [5], [1]Optimus Research, Kogarah, New South Wales, Australia, [2]Dept. of Radiology, Copenhagen University Hospital Bispebjerg-Frederiksberg, Copenhagen, Denmark, Copenhagen, Denmark, [3]Image Analysis Ltd, London, United Kingdom, [4]Celgene Corporation, Summit, [5]Image Analysis Group, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Response to treatment in Psoriatic Arthritis (PsA) can be captured using the OMERACT PsA Magnetic Resonance Imaging Score (PsAMRIS). While reliable and valid, PsAMRIS interpretation requires a trained reader to assess inflammatory lesions on a discrete scale ranging from 0 to 3 and gives decrease values of changes which might not capture subtle changes in inflammation in small cohorts. In this study, we propose a novel computer-assisted imaging quantitative methodology to assess early response to treatment on a continuous scale and validate it by comparing its results with PsAMRIS synovitis scores.

Methods: 114 patients were treated with Apremilast 30mg BID, after a 5-day titration period. Patients had MRI scans at baseline, month 3 and 6. Given the need to rapidly assess the impact of new therapies on imaging structures, PsAMRIS responses were compared to those of a new novel computer-assisted quantitative method at 3 months.

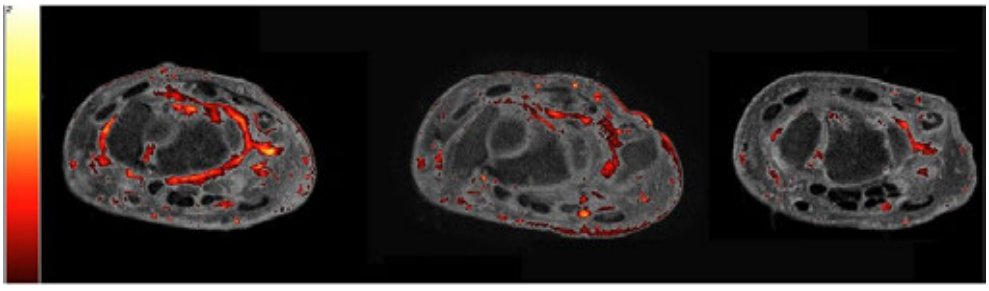

Figure 1. MRI scans and Norml maps superimposed on MRIs for a PsA patient imaged at baseline, Month 3 and 6.

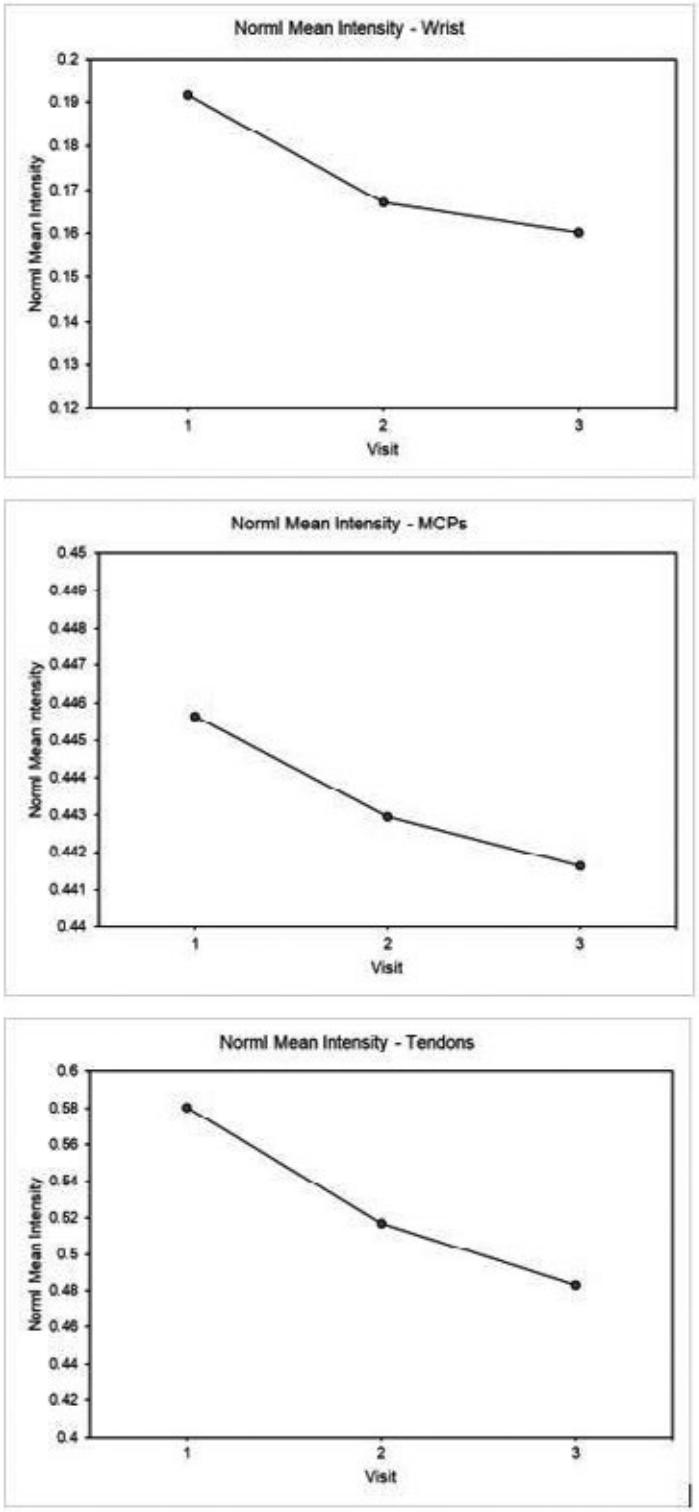

Figure 2. From the top: the mean values of Norml for the wrist, MCP and tendon at baseline, 3 and 6 months, showing reduction in inflammatory activity.

Images at baseline and 3 months were scored for synovitis using the PSAMRIS interpreted by an experienced reader and were read in blinded sequences. Images at baseline, 3 and 6 months were further processed using a novel computer-assisted quantitative method. At a pixel level, each pixel's intensity in the joint was normalized to the in-

tensity of a reference region (muscle). A heat map of normalized intensities was produced, highlighting areas of perfusion higher than that of healthy muscle (NormI), as shown in Figure 1. An experienced reader pre-defined regions of interest (ROIs) around the wrist and the metacarpophalangeal joint (MCP) joints. From these ROIs, the volume of inflammation was calculated in each joint and tendon. This was done by counting pixels that were enhanced above the intensity level of the normal muscle. Each enhanced pixel was given a weight corresponding to the degree of enhancement, allowing to differentiate areas of residual inflammation and high perfusion. This method has been validated, tested and implemented in the CE/FDA510 cleared software package Dynamika (IAG, Image Analysis Group). Patients with non-missing data were included in the final statistical analysis.

Results: IIn all cases a downward trend was observed at 3 months, indicating a reduction in inflammatory activity under treatment with Apremilast. At 3 months the NormI wrist score showed a reduction of 12% compared with the PsAMRIS synovitis score that reduced by 2%. Similar NormI results were observed for the MCPs and tendons (Figure 2). Results suggested continuous improvements over time, with reductions of 16.5% in the wrist, 0.9% in the MCPs and 16.7% in the tendons.

Conclusion: Computer assisted methodology has been developed to assess inflammation in patients with PsA and shown to be more responsive to changes in synovitis than the PsAMRIS at 3 months. Both methods demonstrated reduction of inflammation. This novel method could be used to provide early indications of treatment response. Further validation with larger datasets is planned.

Utility of Coronary Calcium Scoring (CCS) in the Spectrum of Connective Tissue Disorders (CTDs) for the Evaluation of Subclinical Coronary Atherosclerosis – a Systematic Review

Sohail Farshad,[1] Alexandra Halalau,[2] Whitney Townsend,[3] and Elena Schiopu[4], [1]Department of Internal Medicine, Beaumont Health System, Royal Oak, MI, [2]Department of Internal Medicine, Beaumont Health System, Royal Oak, [3]University of Michigan, Ann Arbor, [4]Department of Rheumatology, University of Michigan, Ann Arbor

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent literature shows that connective tissue disorders (CTDs) are positively associated with subclinical atherosclerosis via chronic activation of inflammatory pathways, or direct endothelial injury. Multidetector computed tomography (MDCT) is non-invasive and has emerged as a modality of estimating coronary calcium score (CCS) and prevalence of coronary arterial calcium (CAC) as a potential marker of risk for cardiac events, such as myocardial infarction. The objective of our study is to assess the utility of CCS, based on the current published data in CTDs as it relates to the presence of coronary atherosclerosis in CTDs.

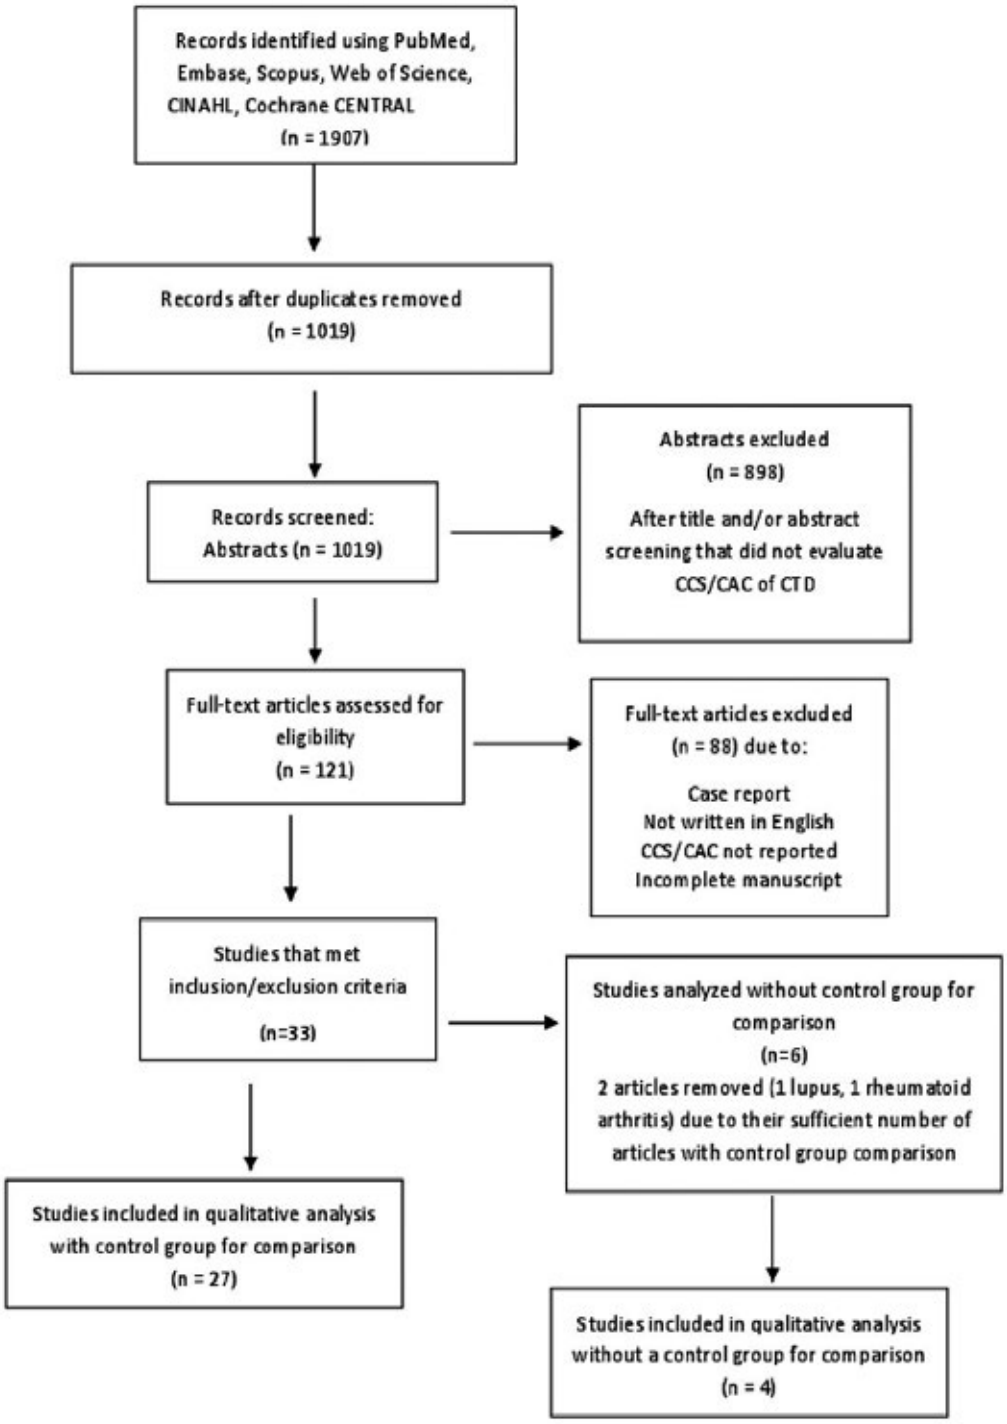

Figure 1. Flow Diagram - Search design

Methods: Following the PRIMSA guidelines, a literature search was done in PubMed, Embase, Scopus, Web of Science Core Collection, CINAHL, and Cochrane Database of Systematic Review. Inclusion criteria consisted of studies that investigated CCS in adults across the spectrum of CTDs, such as: rheumatoid arthritis (RA), seronegative spondyloarthropathies, systemic lupus erythematous (SLE), systemic sclerosis (SSc), idiopathic inflammatory myopathies (IIM) and vasculitides. Studies were excluded if a complete manuscript was not written in English, or if

Author, year	CTD / Sample size	Mean, median, or incidence/prevalence of CAC or CCS results (Agatston units)	Statistical significance

Table 1. Descriptive summary of CCS/CAC of CTDs with control group for comparison. CTD = connective tissue disorder; CAC = coronary arterial calcium; CCS = coronary calcium score; RA = rheumatoid arthritis; SLE = systemic lupus erythematosus; SSc = systemic sclerosis; IIM = idiopathic inflammatory myopathy; NS = not significant; * = sample patients from Multi-Ethnic Study of Atherosclerosis [MESA] Study

it was a single case report. The quality of articles included were assessed using the Newcastle-Ottawa Scale (NOS) assessment scale for cohort studies and the Agency for Healthcare Research and Quality (AHRQ) criteria for cross-sectional studies.

Results: The initial search revealed 1907 citations, but after we eliminated duplicates, studies that did not reference CCS/CAC, and abstracts only, we reviewed 121 full text publications (Figure 1). 31 studies were included in this review (27 with healthy age/gender matched control group and 4 without). The CTDs analyzed in articles with a control group for comparison (Table 1) were: 11 RA, 14 SLE, 4 SSc, 1 IIM, 1 Takayasu arteritis, and 1 psoriasis. 9 out of 11 RA studies, 12 out of 14 SLE studies, and 2 out of 4 SSc studies showed statistically significant increased CCS or CAC prevalence/incidence when compared to control group. The CTDs analyzed without a control group for comparison

Author, year	CTD / Sample Size	Mean, median, or incidence/prevalence of CAC or CCS results (Agatston units)	Statistical significance
Kahn et al. (2012)	Kawasaki – 70 No control group	No coronary dilation (44/70) - none had CAC Transient dilation (12/70) - 1/11 patients had CAC With coronary aneurysm (14/70) – all patients had CAC and the highest CAC burden	NS
Kahn et al. (2017)	Kawasaki – 116 No control group	No coronary dilation (100/160) - 0 CAC Transient/persistent dilation (33/160) – 1 out of 33 patients had CAC Aneurysm (5/33) – all had CAC and the highest CAC burden	NS
Majka et al. (2013)	APS – 2,203* No control group	APS: CAC was prevalent in 9.5% of young adults (age 18-30) with APS antibodies.	NS
Aulie et al. (2014)	JIA – 84 No control group	22 of 84 JIA patients (26%) had a CCS above 0 16 patients had CCS 1-10 6 patients had CCS > 10	NS

Table 2. Descriptive summary of CCS/CAC of CTDs without control group for comparison. CTD = connective tissue disorder; CAC = coronary arterial calcium; CCS = coronary calcium score; APS = antiphospholipid syndrome; JIA = juvenile idiopathic arthritis; NS = not significant; * = sample patients from Coronary Artery Risk Development in Young Adults (CARDIA) study

(Table 2) were: 2 Kawasaki disease, 1 juvenile idiopathic arthritis (JIA), and 1 antiphospholipid syndrome (APS). These studies demonstrated increased CAC burden, however without statistically significant data.

Conclusion: This systematic review demonstrates that some CTDs (RA and SLE) have higher CCS and/or CAC incidence/prevalence compared to normal controls, while the SSc data is still ambiguous. This study also identified that aside from Takayasu arteritis and Kawasaki disease, there is currently no published data in the spectrum of vasculitides, which are associated with high inflammatory burden. Based on the current published data, it is unclear if MDCT-measured CCS is a reliable and generalizable tool to assess subclinical atherosclerosis across the spectrum of CTDs, however we ascertain that it can be useful for cardiovascular risk assessment in patients with SLE and RA.

A New Risk Factor for Predicting the Long-term Outcome of Pulmonary Arterial Hypertension Associated with Connective Tissue Disease: Pulmonary Artery Size Measured by Chest Computed Tomography

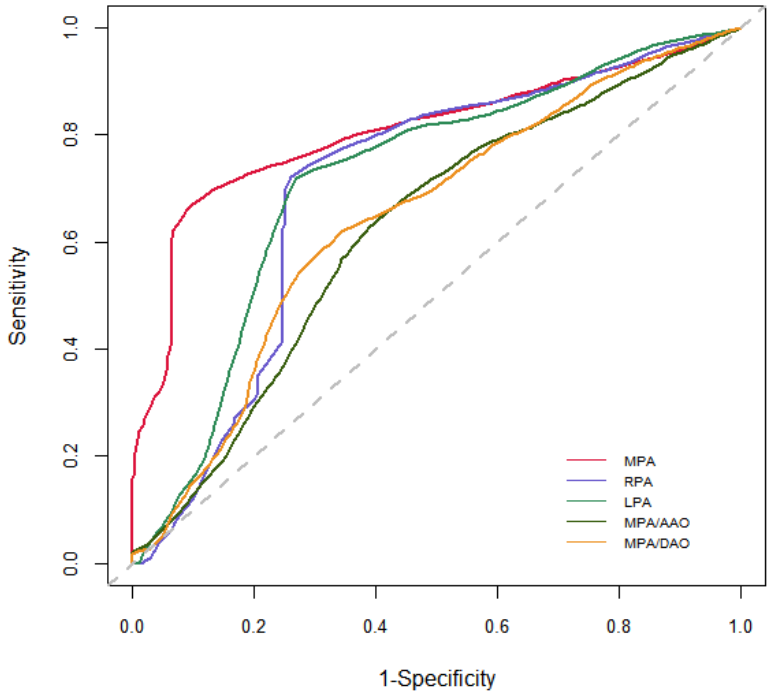
Xiaodi Li,[1] xiaoxuan sun,[1] yinsu zhu,[1] Qiang wang,[1] and miaojia zhang[2], [1]A new risk factor for predicting the long-term outcome of pulmonary arterial hypertension associated with connective tissue disease: pulmonary artery size measured by chest computed tomography, Nanjing, China (People's Republic), [2]c, Nanjing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

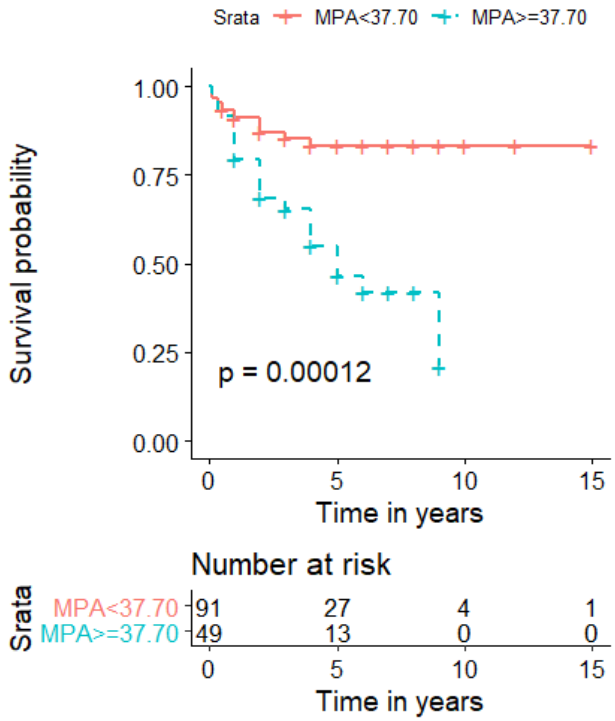
Background/Purpose: Most of the prognostic indicators are derived from right cardiac catheterization or biomarkers in patients with CTD-PAH. It is not clear whether the non-invasive parameters measured by chest CT are related to the clinical outcome of patients with CTD-PAH. Therefore, we want to explore whether the size of pulmonary artery measured on chest CT is related to the long-term prognosis of patients with CTD-PAH in Chinese population.

Methods: We retrospectively investigated 140 CTD-PAH patients diagnosed by echocardiography during Jan 2009 and May 2018 at the first affiliated hospital of Nanjing Medical University. The size of pulmonary trunk and its branches was maesured. by two professional radiologists. The primary endpoint was all-cause death. The ability of chest multi-slice CT parameters to predict all cause mortality was tested by time-dependent receiver operating characteristic (ROC) curve and the corresponding cut-off value were defined by difference maximization method.

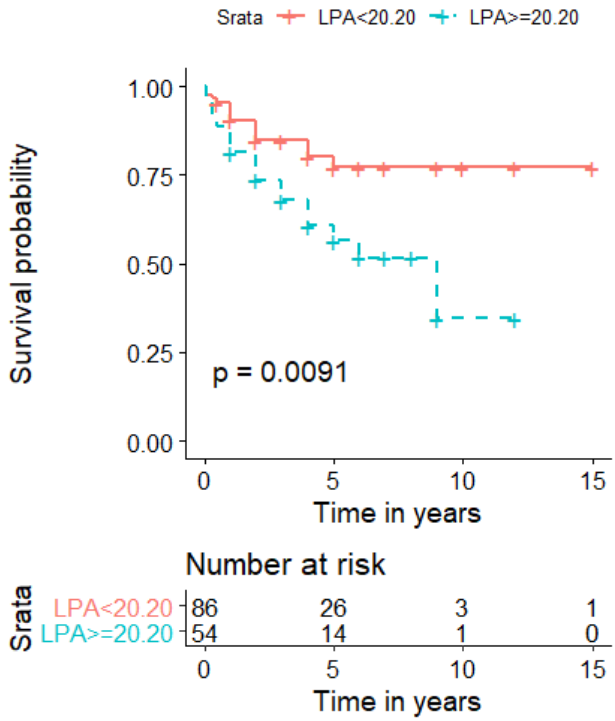
Results: During the observational period of 3.44 ± 0.23 years, 36 patients were died and the longest survival time was 15 years. The time dependent ROC curve suggested that Main pulmonary artery diameter (MPAd), right pulmonary artery diamete (PRAd) and Left pulmonary artery diameter (LPAd) may have the ability to predict mortality in patients with CTD-PAH , the corresponding cut-off values were 37.70 mm for MPAd, 20.46 mm for RPAd and 20.20 mm for LPAd. Patients with MPAd ≥ 37.70 mm (p=0.00012) and LPAd ≥ 20.20 mm (p=0.0091) exhibited poorer long-



Time-dependent ROC curve showing the prognostic value of MSCT parameters



Kaplan-Meier analysis showed significant differences in the prognosis between the patients with MPA diameter <37.70 mm and those with MPA diameter ≥37.70mm



Kaplan-Meier analysis showed significant differences in the prognosis between the patients with LPA diameter <20.20mm and those with LPA diameter ≥ 20.20 mm

term outcome. MPAd ≥ 37.70 mm (HR: 2.74; 95% CI: 1.37-5.48 p=0.004) and WHO functional class III-IV (HR: 3.32; 95% CI: 1.42-7.75 p=0.006) was the independent risk factor of poor outcome for patients with CTD-PAH.

Conclusion: Main pulmonary arterial ≥ 37.70 mm measured by chest multi-slice CT was an independent risk factor of the poor long-term prognosis in Chinese CTD-PAH patients.

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Spine ankylosis is a risk factor of osteoporosis and mortality in ankylosing spondylitis (AS). Recently, thoracic-abdomino-pelvic CT (TAP-CT) has demonstrated its ability to screen bone fragility through the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1). CT-scans is a remarkable imaging technic to assess structural spine ankylosis and vertebral fractures (VF). Our objectives are to assess the association between the SBAC-L1 and spine structural lesions on CT and to determine both VF prevalence and percentage of AS patients under the fracture threshold (SBAC-L1 ≤ 145 HU).

Methods: On 1503 consecutive SpA patients followed from 2009 to 2017 at Nancy University hospital, only patients responding to New York criteria for AS and explored by a TAP-CT scan and X-rays (XR, spine, pelvis) within 2 years were included. Demographic and clinical characteristics were collected. CT spine structural lesions were assessed by two readers on erosions, syndesmophytes and ankylosis for the anterior part and on ankylosis for the posterior part (facet joints) from C7 to S1 vertebrae. mSASSS and anterior, posterior and total (anterior +posterior) ankylosing CT spine scores ranged from 0-72, 0-108, 0-108, and 0-216 respectively. The SBAC-L1 value under ≤ 145 HU defined the fracture threshold.

Results: 67 AS patients were included (median age: 61.2 years, 89% men, 59.7% HLAB27 +, NSAIDs 67.2% and TNF-i 58.2%). All patients presented sacroiliitis on XR and the mean mSASSS was 14.7±17.5. The mean anterior, posterior and total ankylosing CT spine scores were 32.4±39.9, 27±40.9 and 63.7±82, respectively. Ankylosing CT spine scores were highly reproducible (ICC >0.97; Kappa: 0.60-1). No CT structural lesion was observed in 27 patients (45%). Spine Ankylosis was depicted in 38 patients (56.7%). Exclusive anterior or posterior vertebral ankylosis was observed in 8 (11.9%) and 5 (7.4%) patients respectively and both parts in 25 patients (37.3%). The total ankylosing CT spine scores presented good correlations with the mSASSS (r=0.76 (0.60-0.87)). On CT, VFs (n=9) were detected in 5 patients (7.5%). The mean SBAC-L1 was 135.7 HU (±49.2) and 40 patients (59.7%) were under the fracture threshold. For the 5 patients with VFs, 4 patients had a SBAC-L1 ≤ 145UH and 3 of them presented spine ankylosis. We showed an inverse correlation between SBAC-L1 and anterior ankylosing CT spine score (r=-0,40; p≤0,01), with similar level of correlation for the two other scores. AS patients with spine ankylosis (anterior, posterior or both) presented more frequently a SBAC-L1 ≤145UH (p≤0.012).

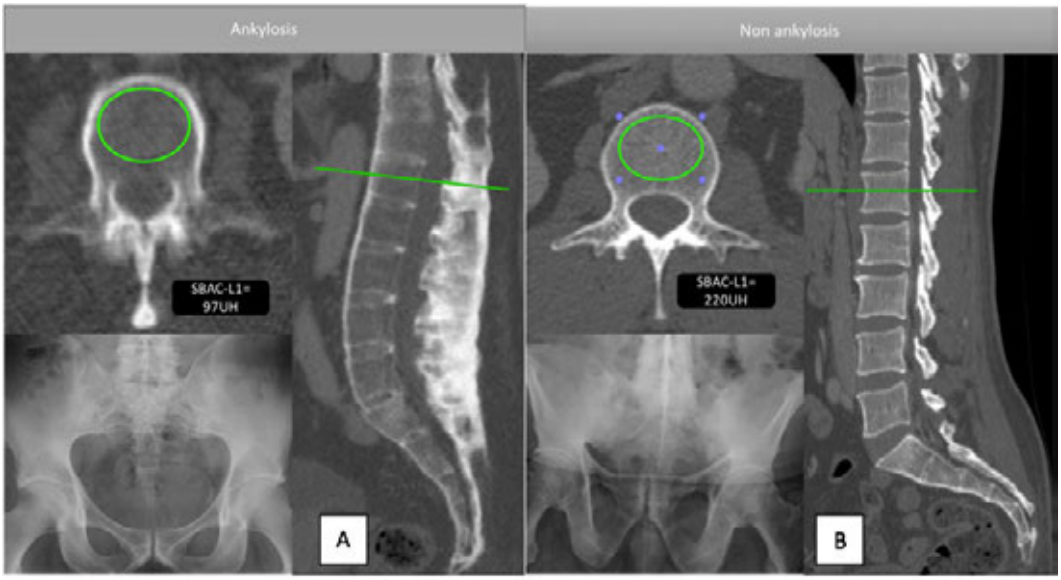

Figure 1: AS patients with sacroiliac joint ankylosis on radiography (A and B). Ankylosed spine in its anterior and posterior parts (A) and normal pattern (B) on sagittal slices. The SABC-L1 was calculated on axial slice of the first lumbar vertebra at 97UH in ankylosed versus 220UH in the non ankylosed spine.

Conclusion: we showed an inverse correlation between SBAC-L1 and total ankylosing CT spine score (r=-0,401; p≤0,01). AS patients with anterior and/or posterior vertebral ankylosis on CT-scans are more frequently under the fracture threshold for the SABC-L1. Four out of five AS patients with VF (prevalence: 7.4%) were under a SABC-L1≤145UH.

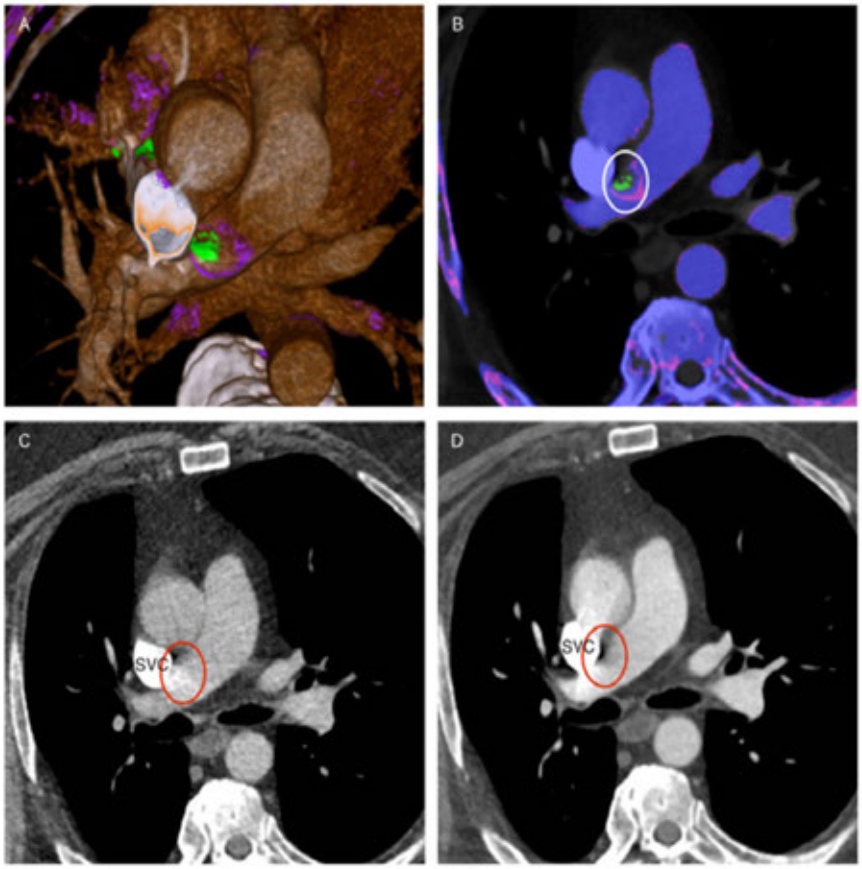
Frequently Encountered Artifacts in Novel Application of Dual-Energy CT to Vascular Imaging: A Pilot Study

Chio Yokose,[1] Sterling Eide,[2] F. Joseph Simeone,[1] Kam Shojania,[3] Savvas Nicolaou,[4] Fabio Becce,[5] and Hyon K. Choi[1], [1]Massachusetts General Hospital, Boston, MA, [2]National University Hospital of Singapore, Singapore, Singapore, [3]Vancouver General Hospital, Vancouver, Canada, [4]Vancouver General Hospital, Vancouver, BC, Canada, [5]Lausanne University Hospital, Lausanne, Switzerland

Image 1: Streak (Beam Hardening) Artifact



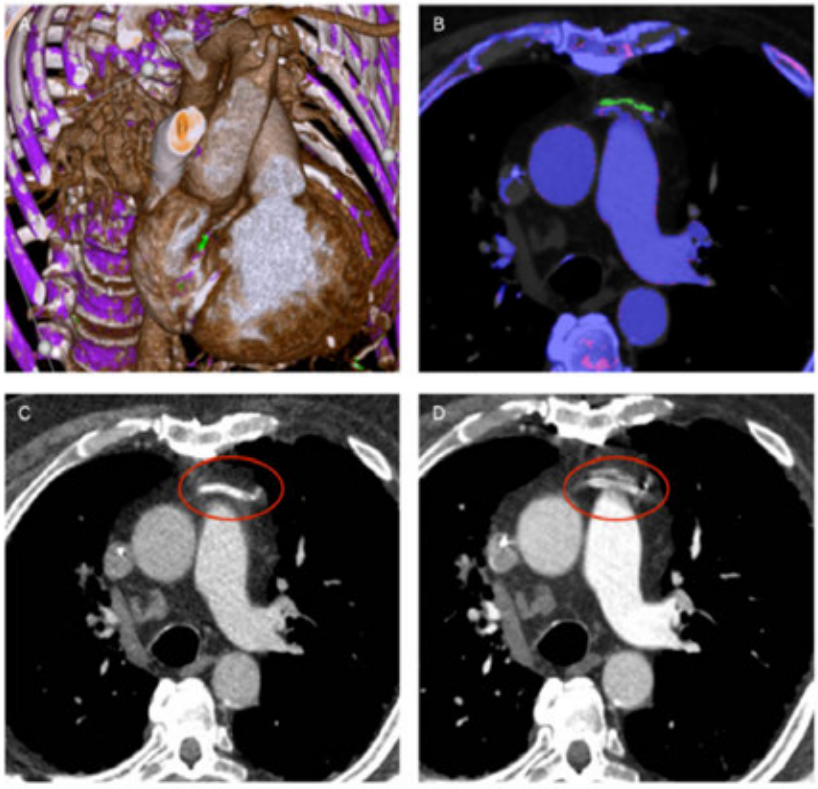
3D [A] and 2D [B] color-coded images that show green material posterolateral to the superior vena cava (SVC) which is filled with dense intravenous contrast. It has the appearance of the green material being in the pulmonary artery. High-energy [C] and low-energy [D] images at the same level which show heterogeneous areas of attenuation (circled in red) posterolateral to the superior vena cava due to beam hardening as the energy beam hits the dense contrast in the SVC.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: One hypothesized link between cardiovascular disease and gout is the direct deposition of monosodium urate (MSU) crystals in atherosclerotic plaque. A 2018 ACR abstract used non-ECG-gated CT scans of the chest and neck in dual-energy mode to evaluate vascular MSU crystal deposition and reported that > 80% of patients with gout had vascular MSU deposition as well as some in healthy control patients, with no significant difference in the volume of MSU crystal deposition among gout and control patients. We reviewed 96 non-ECG gated DECT pulmonary angiograms (similar to the ACR abstract) to identify commonly encountered artifacts which could be misconstrued as true MSU deposition findings.

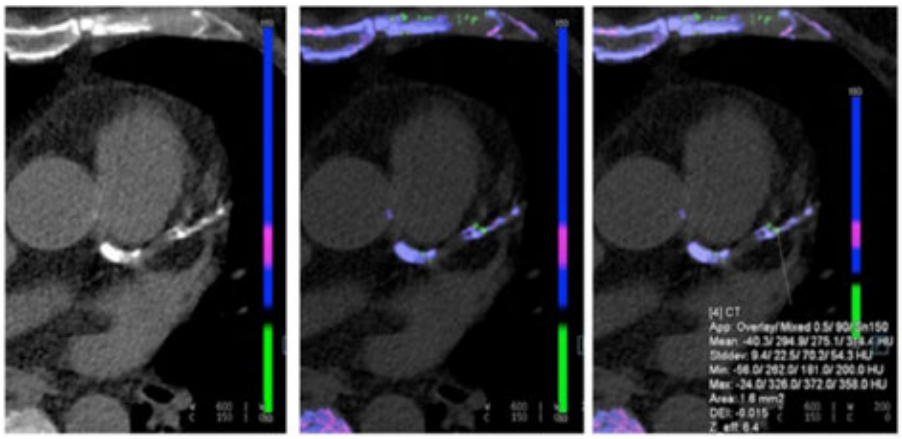
Methods: Consecutive patients with gout (ICD-10 code for gout and serum urate >6 mg/dL) who underwent non-ECG gated DECT pulmonary angiograms between 1/1/15 and 11/29/18 were identified using a clinical data repository. Age- and sex-matched controls were randomly chosen from a list of consecutive patients without gout who underwent the same imaging study. All images were acquired using dual-source, dual-energy CT scanners (Siemens Flash or Force DECT) and loaded into the postprocessing software (Syngo.via, Siemens, Germany) to apply an image-based two material decomposition algorithm to highlight MSU crystals in green. The images were reviewed by two radiologists ex-

Image 2: Misregistration due to Motion



3D [A] and 2D [B] color-coded images that show linear green material corresponding to a CABG vessel. High-energy [C] and low-energy [D] images at the same level. In C, there is one linear white band corresponding to the CABG vessel, while in D, it appears that there are two linear bands. This discrepancy is caused by motion when the low-energy image was acquired.

Image 3:



ECG-gated coronary dual-energy CT scan of a 68-year-old man with gout with subcutaneous tophi reveals evidence of MSU crystal deposition in the coronary artery.

perienced in interpreting DECT for MSU crystals. Presence of any green material in the vasculature was noted with its location for each patient, then further assessed with comparison to the grey-scale source images to determine if it was a true finding or artifact. Artifacts were classified into one of five categories: streak, misregistration due to motion, contrast mixing, foreign body, and noise. Three radiologists also reviewed two cases of ECG-gated coronary DECT scans.

Results: We identified 48 gout patients and 48 age- and sex-matched controls who had undergone 51 non ECG gated PE scans. The patients were mostly men (70.8%) with mean age 67 years. The majority of DECT scans, both of cases and controls, had green material in the vasculature (85% and 84%, respectively). The most common location of green material was in the superior vena cava or right atrium (81% in cases vs. 91% in controls), followed by the aorta (27% vs 47%, respectively) and coronary arteries (40% vs 21%, respectively). However, all green material in the vasculature were ultimately attributed to artifact with the most common types of artifacts being streak (**Image 1**) and misregistration due to motion (**Image 2**). However, images from the two gout patients using ECG-gated DECT scan showed coronary MSU deposits in both the grey-scale source images as well as dual energy impages, not meeting any of artifact criteria (**Image 3**).

Conclusion: Non-ECG gated Vascular DECT images are susceptible to various artifacts. Further investigation of this technology using ECG-gated CTs are warranted.

Influence of Steroid Treatment on ^{18}F-FDG PET/CT Accuracy to Detect Vascular and Musculoeskeletal Involvement in Patients with Polymyalgia Reumatica

Diana Prieto-Pena,[1] Mónica Calderón-Goercke,[2] Isabel Martínez Rodríguez,[3] Ignacio Banzo,[3] Lara Sanchez-Bilbao,[4] Iñigo Gonzalez-Mazon,[1] Belén Atienza-Mateo,[4] Miguel Angel González-Gay,[5] and Ricardo Blanco[4], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [2]Hospital Marqués de Valdecilla, Santander, Cantabria, Spain, [3]Hospital Universitario Marqués de Valdecilla, Santander, Spain, [4]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [5]Universidad de Cantabria and IDIVAL, Hospital Universitario Marqués de Valdecilla, Santander, Spain

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fluorine-18-fluorodeoxyglucose (^{18}F-FDG) PET/CT has been proposed as a promising tool for assessing both musculoskeletal and vascular involvement in patients with polymyalgia rheumatica (PMR). Glucocorticoids (GC) may decrease the intensity of ^{18}F-FDG uptake. Therefore, performance of PET/CT before steroid therapy is recommended. However, in many patients with PMR, large vessel vasculitis (LVV) is precisely suspected because of steroid resistance after a long-term treatment with GC. Our aim was to assess the influence of long-term medium-dose treatment on ^{18}F-FDG vascular and musculoskeletal uptake to discern if ^{18}F FDG PET/CT could be useful to evaluate patients with polymyalgia rheumatica under treatment with GC.

Methods: Single-center study of 75 patients with PMR diagnosis based on 2012 EULAR/ACR criteria. All patients underwent a PET/CT scan due to LVV suspicion based on the presence of atypical symptoms and/or persistent symptoms despite steroid therapy. We considered two groups: a) Steroid-naïve PMR patients. b) Steroid-resistant PMR patients. Both musculoskeletal and vascular ^{18}F-FDG uptake was assessed. The statistical analysis was performed with SPSS. Distributions of categorical variables were compared by Pearson Chi2 or Fisher exact test as appropriate.

Results: We evaluated 75 patients, 27 men and 48 women (mean age ± SD: 68.2 ± 10.7 years). PET/CT was performed in 14 steroid-naïve PMR patients (18.7%) and 61 steroid-resistant PMR patients (81.3%). Patients under steroid treatment had received a median dose of Prednisone of 10.0 [5.0-15.0] mg/day during 9.0 [2.0-22.0] months. Vascular ^{18}F-FDG uptake was more frequently detected in steroid-naïve patients. In regard with musculoskeletal ^{18}F-FDG uptake, no statistically significant differences were seen between both groups (**TABLE**).

Conclusion: Vascular ^{18}F-FDG uptake detection was higher in PMR patients with LVV suspicion who had never received GC. However, PET/CT was also useful to detect vascular involvement in most of the patients under a long-term medium-dose steroid treatment.

TABLE

	PMR patients (N=75)	**Steroid-naive patients (n=14)**	**Steroid-resistant patients (n=61)**	**P#**

Cortical Bone Erosion in the 2nd Metacarpal Bone Head: Association with Its Bone Mineral Density by HR-pQCT in Rheumatoid Arthritis Patients

Camille Figueiredo,[1] Mariana Perez,[1] Ana Cristina de Medeiros Ribeiro,[2] Valeria Caparbo,[1] and Rosa Pereira[3], [1]Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [2]Hospital das Clinicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Sao Paulo, Brazil, [3]Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Periarticular trabecular bone loss and local cortical bone erosions are typical features of bone disease in rheumatoid arthritis (RA)[1] . Little, however, is known about the interactions between periarticular bone

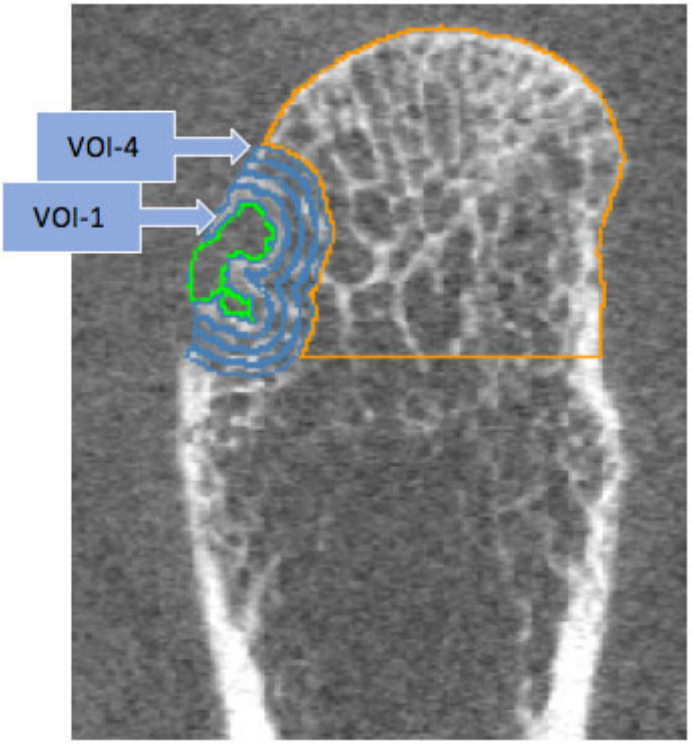

Figure 1. HR-pQCT imaging of 2nd MCP head from a RA patient (coronal plane). Demonstration of bone segmentation by MIAF, showing BMD of MCP head analyzed (orange line), erosion segmentation placed on radial quadrant (green line) and VOIs (1 to 4) (blue lines around erosion).

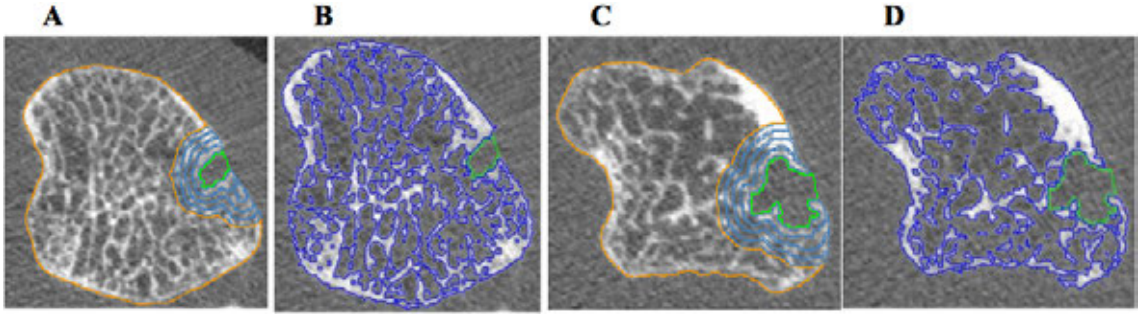

Figure 2. Axial plane of 2nd MCP head using HR-pQCT scan comparing two RA patients with erosion on radial quadrant. First patient: (A) erosion volume=6.75mm3 with 4 VOIs segmentation (blue lines) and (B) BMD segmentation (purple contouring=314.94mg/cm3). Second patient: (C) an important erosion volume= 19.33mm3 with 4 VOIs segmentation (blue lines) and (D) BMD segmentation (purple contouring=284.63mg/cm3).

loss and local bone erosions. The purpose of this study was test whether bone mineral density (BMD) in metacarpophalangeal (MCP) head, radius or tibia are associated with cortical bone erosions in RA patients.

Methods: Forty-seven RA female patients underwent high-resolution quantitative computed tomography (HR-pQCT) of 2 nd MCP joints of the dominant hand, and non-dominant distal radius and tibia in a cross-sectional study. Erosion volumewas assessed by the semi-automated Medical Image Analysis Framework (MIAF) software [2] . Clinical and laboratory variables were assessed, as well as Health Assessment Questionnaire (HAQ) and Hand Grip test. Trabecular bone mineral density (BMD) was measured in 4 particular volumes of interest (VOI-1-4= 1 the nearest to erosion) around the bone erosions (Figure 1). Further, total BMD of metacarpal head was also analyzed. Univariate and multivariate analysis were done to find out a relationship between erosion volume and BMD of metacarpal head, radius and tibia.

Results: The mean age was 40.2±5.9yrs, mean of disease duration 10.9±4.8yrs, median of disease activity score-28 (DAS-28) 2.66(1.97, 3.00), mean of HAQ 0.88±0.70 and mean of hand grip was 18.1±7.1N. Current treatment: glucocorticoids: 61.7%(n=29), conventional DMARDs (Disease Modifying Anti-Rheumatic Drugs): 80.9%(n=38) and biological DMARDs: 48.9%(n=23). There were found 43 erosions (0.9±1.2/patient) and 14 osteophytes (0.3±0.7/patient) in the 2ndMCP head. The joint gap mean was 80.6±34.9mm3, and erosion volume median was 0.26(0, 16.16) mm3. Volume of cortical bone erosions was negatively correlated with BMD in 2ndMCP head (r= -0.53, p< 0.001), VOI-4 (r= -0.48, p=0.017) and joint gap (r= -0.40, p=0.005); and it was positively correlated with number of erosions (r= 0.82, p< 0.001) and number of osteophytes (r= 0.32, p= 0.026). Furthermore, after the sample was categorized by absence or presence of erosion in 2ndMCP head it was found a significant difference between number of osteophyte (0.10±0.41vs.0.50±0.88, p=0.028), BMD of MCP head (321.53±37.12 vs.281.38±67.69mg/cm3, p=0.043) (Figure 2) and joint gap (93.59±36.94 vs.68.20±28.31, p=0.025), respectively. The multiple linear regression showed that BMD of 2ndMCP head was negatively associated with its volume of erosion (B= - 0.813, p=0.003, adjusted R2= 0.32), adjusted by number of erosions, number of osteophytes, joint gap, VOI-4 and volumetric trabecular BMD of radius.

Conclusion: Cortical bone erosions volume were associated with low BMD in the 2 nd MCP head, suggesting that this variable should also be included as an outcome parameter in the follow-up of RA patients.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Subclinical inflammatory lesions detected by MRI are prevalent in hand joints of patients with *cutaneous psoriasis* (1). Yet, it is unknown whether these inflammatory changes persist in patients with *psoriatic arthritis (PsA) in low disease activity/clinical remission*. Minimal disease activity (MDA) is a validated composite index used for clinical evaluation in PsA(2). The purpose of this study is to estimate the prevalence of hand inflammatory changes in PsA patients with MDA versus non-MDA (active disease) using MRI.

Methods: Sixty consecutive prospectively recruited patients with peripheral PsA (CASPAR criteria) underwent clinical evaluation, questionnaires, and MRI of a predominantly involved hand within 72 hours of the clinical examination. MRI scans were scored for synovitis, tenosynovitis, periarticular inflammation, bone edema, bone erosion, and bone proliferation according to the OMERACT PsA MRI scoring system (PsAMRIS) method(3), performed by an expert musculoskeletal radiologist, blinded for clinical data.

Results: Clinical characteristics of the PsA cohort and prevalence of hand MRI lesions are presented in Table 1. The mean total PsAMRIS of the cohort was low (5.5 units [SD 9.1]), with synovitis of MCP joints being the most common finding (n=27 patients, [45%]). PsA duration was moderately correlated with the total PsAMRIS (Spearman's rank correlation rho 0.358, p=0.005).

MDA (n=19) and non-MDA (n=41) groups were comparable in age, BMI, psoriasis/PsA duration, skin disease severity, and treatment modalities. (Table 2) Total PsAMRIS units (mean [SD]) was similar in MDA and non-MDA groups: 6.1 [11.14] vs 6.1 [7.4], respectively (p=0.985). Remarkably, both groups had a similar prevalence of hand synovitis with predominant involvement of MCP joints: MDA vs non-MDA, n=8 [42.1%] vs 19 [46.3%], p=0.978. The prevalence of bone marrow edema, periarticular inflammation, and bone erosions was higher in the non-MDA group but did not reach statistical significance: MDA vs non-MDA, n=3 [15.8%] vs 10 [24.4%], p=0.678; n=1 [5.3%] vs 7 [17.1%], p=0.399; n=2 [10.5%] vs 6 [14.6%], p=0.978, respectively. Flexor tenosynovitis was detected only in the non-MDA group (n=10.0, [24%], p=0.047), whereas bone proliferation was detected only in the MDA group (n=3 [15.8%], p=0.048). Comparison of the prevalence of inflammatory MRI findings by grouping the extent of synovitis, bone marrow edema, and periarticular inflammation by severity did *not* change the results.

Table 1. Clinical characteristics and MRI findings in the PsA cohort (n=60).

Demographic characteristics	
Gender: male/female, n	24/36
Age, mean [SD]	53.3 [12.9]
BMI, mean [SD]	27.7 [4.4]
Disease characteristics	
Psoriasis duration, years, mean [SD]	21.7 [16.5]
Psoriasis severity scores: BSA, mean [SD] PASI, mean [SD]	 1.1 [2.4] 1.5 [3.3]
PsA duration, years, mean [SD]	11 [12.9]
Swollen joint count (SJC66), mean [SD]	1 [1.9]
Tender joint count (TJC68), mean [SD]	9.6 [10.7]
Dactylitis, n, [%]	7 [11.7]
C-reactive protein (CRP; mg/dL), mean [SD]	0.9 [0.9]
Patient pain, VAS, mean [SD]	5.0 [3.2]
Patient global assessment, VAS, mean [SD]	5.2 [3.1]
HAQ, mean [SD]	1.0 [0.8]
Physician global assessment, VAS, mean [SD]	2.4 [2.3]
Psoriatic arthritis disease activity score DAPSA, mean [SD]	22.3 [15.9]
Treatment modalities	
Current sDMARD, n, [%]	31 [51.7%]
Current methotrexate, n, [%]	26 [43.3%]
Current biologic treatment, n, [%] TNF inhibitors, n, [%] IL17 inhibitors, n, [%] IL12/IL23 inhibitor, n, [%]	33 [55.0%] 26 [43.3%] 7 [11.7%] 1 [1.7%]
Hand MRI findings	
PsAMRIS, units, mean [SD]	5.5 [9.1]
Synovitis (MCP, PIP, DIP joints), n, [%]	27 [45.0%]
Flexor tenosynovitis, n, [%]	10 [16.7%]
Periarticular inflammation, n, [%]	8 [13.3%]
Bone marrow edema, n, [%]	13 [21.7%]
Erosions, n, [%]	8 [13.3%]
Bone proliferation, n, [%]	8 [5.0%]

Legend:

BMI – body mass index, BSA – body surface area; PASI - psoriasis area severity index; DAPSA - Disease Activity Index for Psoriatic Arthritis (DAPSA); HAQ, health assessment questionnaire; IL – interleukin; IQR – interquartile range (IQR); MCP – metacarpophalangeal, PIP – proximal interphalangeal, DIP – distal interphalangeal, PsA – psoriatic arthritis; sDMARD – synthetic disease modifying anti-rheumatic drug; TNF – anti-tumor necrosis factor; VAS – visual analogue scale

Conclusion: This preliminary study results corroborate a high proportion of subclinical inflammation detected by MRI in joints of hand in PsA patients in MDA, whereas overall PsAMRIS scores were low in both MDA and non-MDA groups. These results need to be reproduced in a larger cohort.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Many RA patients in clinical remission have evidence of bone marrow edema (BME) on magnetic resonance imaging (MRI), with radiographic bone damage progression appearing in a subset of patients.[1] While MRI provides excellent visualization of subclinical inflammation, bone resolution is relatively poor, limiting the correlation of inflammatory imaging findings to erosive change that may develop. High resolution peripheral quantitative computed tomography (HR-pQCT) provides superior detailed bone resolution, with improved erosion detection and quantification. The purpose of this study was to determine whether subclinical inflammation observed on MRI could be co-localized with erosive change visualized by HR-pQCT, thereby predicting bone damage progression over a 6-month follow-up period for RA participants in clinical remission.

Methods: Nine participants meeting the ACR/EULAR criteria for RA and in clinical remission were recruited to undergo contrast-enhanced MRI and HR-pQCT scans of the hand at two timepoints, six months apart. Disease activity between these timepoints was assessed monthly by questionnaire, examination, and inflammatory biomarkers. A multimodal image registration technique was developed to co-localize imaging findings on HR-pQCT and MRI. Synovitis and BME were assessed semi-quantitatively with MRI using the RAMRIS scoring system.[2] Bone erosion volume quantification was completed using a 3D segmentation technique using MIAF-Finger[3], with joint space width (JSW) assessed using a volumetric approach from HR-pQCT images.[4] Individual changes in HR-pQCT outcomes were compared against the least significant change (LSC) measured from scan-rescan reproducibility.

Results: The mean DAS28 for the 9 participants was 2.16 (SD 0.64) at the initial scan and 1.72 (SD 0.76) at follow-up. All participants had evidence of synovitis on MRI. Eight joints had evidence of BME at baseline. Twelve 2nd and

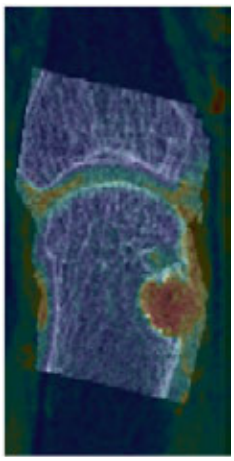

Figure 1. An HR-pQCT image overlaid with a transformed MRI image to localize inflammation (red) with bone damage.

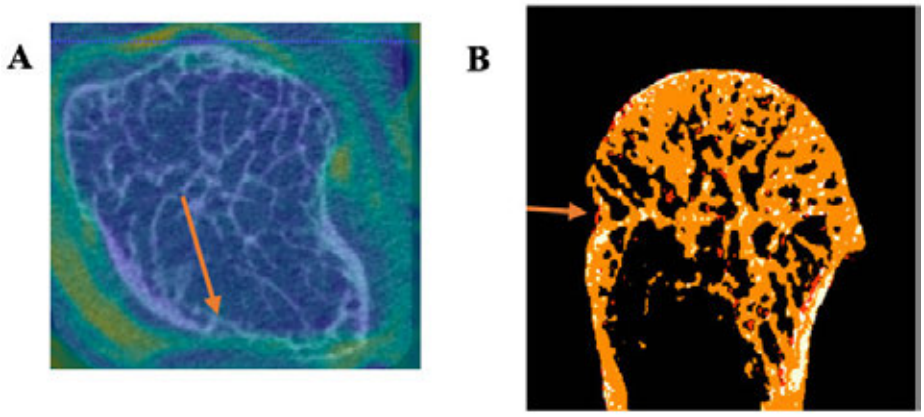

Figure 2. (A) An erosion in HR-pQCT (bone = white) overlaid with MR image indicating no evidence of inflammation at the site of the erosion at baseline. (B) When baseline and follow-up HR-pQCT images are registered and aligned to visualize bone loss and gain, there is evidence of bone formation (red) at the erosion. This erosion showed a decrease in volume over 6 months. Orange indicates stable bone while white indicates resorbed bone.

Table 1. Associations between MRI RAMRIS scores for synovitis and bone marrow edema (BME) at initial scan and 6-month changes in HR-pQCT erosion volume and minimum joint space width (JSW). Decrease, Stable, and Increase characterization determined with respect to the Least Significant Change. (N = 12 joints from 7 participants).

	MRI					
	Initial Synovitis Score			Initial BME Score		
HR-pQCT	0	1	2	0	1	2
Erosion Volume						
Decrease	0	1	0	1	0	0
Stable	0	4	7	7	4	0
Increase	0	0	0	0	0	0
Minimum JSW						
Decrease	0	0	1			
Stable	0	6	5			
Increase	0	0	0			

3rd MCP joints seen on HR-pQCT were co-localized with MRI using image registration (Figure 1). The presence of BME did not predict significant change in erosion volume (Table 1). In contrast, absence of BME and synovitis at the location of the erosion was associated with a decrease in erosion volume in one participant (Figure 2). The JSW outcomes remained stable in all joints, with the exception of one joint that showed a decrease in minimum JSW and another that had a decrease in the maximum JSW.

Conclusion: Even with highly sensitive imaging we did not detect erosive progression over the course of 6 months in patients with subclinical inflammation. However, the absence of localized subclinical inflammation was suggested to predict erosion healing. Findings will be confirmed in a larger cohort. This novel image registration technique for RA was able to co-localize areas of subclinical inflammation on MRI with joint damage on HR-pQCT, which could provide insights on the mechanisms of damage in RA that is not possible with either imaging approach alone.

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Progression of structural joint damage develops in 20-30 % of patients with rheumatoid arthritis (RA) in clinical remission[1]. Known predictors of structural damage progression in both active RA and in remission are magnetic resonance imaging (MRI)-detected synovitis and in particular osteitis/bone marrow edema (BME), but the predictive value of adding MRI tenosynovitis assessment as potential predictor in patients in clinical remission has not been investigated. The purpose was to investigate the predictive value of baseline MRI inflammatory and damage parameters on 2 year MRI and radiographic damage progression in an RA cohort in clinical remission, following MRI and conventional treat-to-target (T2T) strategies.

Methods: Two hundred RA patients in clinical remission, defined as DAS28-CRP< 3.2 and no swollen joints, on conventional DMARDs, were included in the IMAGINE-RA trial[2]. In this study patients were randomized to a conventional DAS28 + MRI-guided T2T strategy targeting absence of BME vs a conventional DAS28 guided T2T strategy. Patients had baseline and 2 years contrast-enhanced MRIs of the dominant wrist and 2nd-5th MCP joints and radiographs

of hands and feet. Two experienced readers evaluated the MRIs and radiographs with known chronology according to the OMERACT RAMRIS scoring system and Sharp/van der Heijde method, respectively. The following potentially predictive baseline variables: MRI BME, synovitis, tenosynovitis, MRI and X-ray erosion and joint space narrowing (JSN) score, CRP, DAS28, smoking status, gender, age and patient group were tested in univariate logistic regression analyses with 2-year progression in MRI combined damage score, Total Sharp Score (TSS), and MRI and X-ray JSN and erosion scores as dependent variables. Variables with p< 0.1, age, gender and patient group were included in multivariable logistic regression analyses with backward selection.

Results: Based on univariate analyses MRI BME, synovitis, tenosynovitis, x-ray erosion and JSN, gender and age were included in subsequent multivariable analyses. Independent MRI predictors of structural progression were BME (MRI progression) and tenosynovitis (MRI and radiographic progression), see table.

Conclusion: This trial is the first to report that MRI tenosynovitis independently predicts both radiographic and MRI damage progression in RA patients in clinical remission. Further studies are needed to confirm MRI-determined tenosynovitis as predictor of progressive joint destruction in RA clinical remission.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sacroiliitis is one of the extraintestinal manifestations associated with inflammatory bowel disease (IBD), and may be underdiagnosed especially in the pediatric age. MR-enterography (Entero-MRI) is currently the imaging gold standard to assess intestinal disease activity and to detect complications in patients with IBD. Only few studies have been conducted on adult patients with IBD in order to define the role of this technique in assessing sacroiliitis, while no data are available on pediatric patients.

To study the prevalence of inflammatory sacroiliitis on MRI performed for intestinal investigation in an IBD pediatric population.

Methods: This is a retrospective study conducted on patients suffering from IBD followed in our gastroenterology department between 2010 and 2018 whose entero-RM (1.5 or 3 Tesla, Philips depending from year of scanning) were blindly and independently scored by two readers experienced in pediatric musculoskeletal imaging. Each sacroiliac joint was divided into 4 quadrants. Signs of sacroiliitis were identified according to the ASAS criteria, with a particular attention to the presence of bone marrow edema (using T2 weighted sequences with fat suppression), diffusion restriction in DWI sequences (Diffusion Weighted Imaging) or DWIBS (Diffusion Weighted Imaging with Background Suppression) and post-contrastographic uptake in dynamic acquisitions. Demographics, IBD characteristics, clinical, radiological, and laboratory data were recorded and a dedicated Excel database was constructed. Results were elaborated using descriptive statistics.

Results: 34 patients (10 F, 24 M, age at scanning range 5-20 yrs, median 15) were included in the study, for a total of 59 entero-MRI evaluated (some patients were subjected to more than one scan). Two out of 34 patients were affected by Ulcerative Colitis, 32 by Crohn disease. Joint examination resulted negative in all patients, and none complained of articular symptoms including back pain.

In 5 IBD patients (4 CD, 1 UC) a monolateral slight degree of sacroiliitis (grade 1) was radiologically identified. They were all males, without clinical-laboratory-radiologic inflammatory signs of intestinal activity, with the exception of a patient who presented signs of intestinal and sacroiliac inflammation at his first entero-MRI, while 18 months later, at his MRI control under pharmacological treatment, signs of sacroiliitis were still present in the absence of intestinal signs of inflammation.

Conclusion: Asymptomatic sacroiliitis was observed in about 15% of our IBD patients. Sacroiliac involvement therefore can be underdiagnosed in these patients. Entero-MRI with specific sequences could be a good tool to detect early signs of sacroiliac inflammation.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis is a hallmark feature of Spondyloarthritis (SpA), and frequently localizes at the Achilles tendon[1]. Enthesitis is predominantly measured with clinical scores like Leeds Enthesitis Index (LEI), however, magnetic resonance imaging (MRI) might represent a more sensitive tool to recognize enthesitis in both, bone and soft tissues[2], providing insight about the potential disconnect between pain at entheseal sites and objective inflammation. ACHILLES is the largest double blind, placebo-controlled, multicenter Phase 3 trial to date, designed to investigate enthesitis by clinical and imaging assessments in patients (pts) with active SpA. Here, we present the MRI parameters of the heel (evaluated by central readers) in pts who were not included in ACHILLES based on a negative MRI evaluation of the (local) investigator.

Methods: Pts (≥18 years) with active SpA (peripheral or axial) had to present in ACHILLES with clinical (LEI) and MRI-positive heel enthesitis (interpreted by either the local radiologist or rheumatologist), defined as enthesitis with/without bursitis and/or bone marrow edema with/without concomitant erosions in the area of the Achilles' tendon insertion and/or the plantar aponeurosis. The present analysis included heel MRI characteristics of pts who failed to meet the MRI study inclusion criteria based on local MRI evaluation. The MRIs of screen-failed pts were evaluated by

Table: MRI Parameters

		MRI positive n/N (%)	Not MRI positive n/N (%)
Enthesitis - Achilles tendon	Yes	6/12 (50.0)	0/34 (0)
	No	6/12 (50.0)	34/34 (100)
Bursitis - Achilles tendon	Yes	6/12 (50.0)	14/34 (41.2)
	No	6/12 (50.0)	20/34 (58.8)
Bone marrow oedema - Achilles tendon	Yes	3/12 (25.0)	0/34 (0)
	No	9/12 (75.0)	34/34 (100)
Enthesitis - Plantar aponeurosis	Yes	5/12 (41.7)	0/ (0)
	No	7/12 (58.3)	34/34 (100)
Bursitis - Plantar aponeurosis	Yes	4/12 (33.3)	2/34 (5.9)
	No	8/12 (66.7)	32/34 (94.1)
Bone marrow oedema - Plantar aponeurosis	Yes	6/12 (50.0)	0/34 (0)
	No	6/12 (50.0)	34/34 (100)
Active inflammation (Global)	Yes	12/12 (100)	17/34 (50.0)
	No	0/12 (0)	17/34 (50.0)
Periarticular inflammation	Present	8/12 (66.7)	6/34 (17.6)
	Absent	4/12 (33.3)	28/34 (82.4)
Quantification of bone oedema (PsAMRIS)	No oedema	6/12 (50.0)	34/34 (0)
	1-33% of bone edematous	6/12 (50.0)	
	1-33% of bone edematous; oedema length ≤ 0.5 cm	5/12 (41.7)	
	1-33% of bone edematous; oedema length > 0.5 cm	1/12 (8.3)	
Quantification of bone erosion (PsAMRIS)	No erosion	10/12 (83.3)	28/34 (82.4)
	1-10% of bone eroded	1/12 (8.3)	4/34 (11.8)
	11-20% of bone eroded	1/12 (8.3)	1/34 (2.9)
	Not applicable	0/12 (0)	1/34 (2.9)
Location of bone erosion	All patients with Location of bone erosion at Achilles tendon area	1/2 (50.0)	1/5 (20.0)
	Achilles tendon area insertion, other	1/2 (50.0)	1/5 (20.0)
	All patients with Location of bone erosion at Plantar aponeurosis area	1/2 (50.0)	2/5 (40.0)
	Plantar aponeurosis area, other	1/2 (50.0)	2/5 (40.0)
	All patients with Location of bone erosion at 'Other'	2/2 (100)	2/5 (40.0)
	Achilles tendon area, other	1/2 (50.0)	
	Plantar aponeurosis area, other	1/2 (50.0)	
	Other		2/5 (40.0)

N, total number of patients in a group
Active Inflammation (Global) is "Yes" in case at least one of the following direct parameters is "yes":
Achilles' enthesitis; Bursitis (Achilles' tendon); Bone oedema (Achilles' tendon insertion); Fascitis plantar aponeurosis; Bursitis (Plantar aponeurosis); Bone oedema (Plantar aponeurosis); Periarticular inflammation (PsAMRIS); Quantification of bone oedema (PsAMRIS)

two independent central readers, blinded to any screen failure reason, in a consensus read fashion. Centralized reading of the heel MRIs was performed according to the Psoriatic arthritis magnetic resonance imaging scoring system (PsAMRIS)[3]. Since PsAMRIS was developed initially for the hands, additional parameters were introduced to allow for more accurate representation of the heel: a) bone oedema (with 1-33% of bone oedematous) were further specified by oedema length ≤/ >0.5 cm and b) bone erosions were further specified by assessing the localization.

Results: Overall, 204 (128 PsA and 76 axSpA) pts were randomized and 94 pts failed screening. Of the 94 screen-failed pts, 46 pts failed due to MRI negative heel enthesitis as assessed by investigators. Upon assessment by central readers, 12/46 (26.1%) were found to be MRI positive and 34/46 (73.9%) MRI negative for heel enthesitis; MRI parameters of both groups are shown in the **Table**. Overall, 8/12 (67%) MRIs evaluated for positive enthesitis presented with periarticular inflammation and 6/12 (50%) with bone oedema. PsAMRIS based quantification of bone oedema revealed 1-33% of bone edematous for 6 cases, with only 1/6 having an oedema length of >0.5 cm. Enthesitis was centrally read in 6/12 (50%) MRIs at the Achilles tendon insertion and in 5/12 (42%) at the Plantar aponeurosis calcaneal insertion.

Conclusion: In central reading, concomitant periarticular inflammation and bone marrow oedema at the tendon insertion were found to be critical for the confirmation of enthesitis on MRI in patients suffering from SpA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with axial spondyloarthritis (axSpA), MRI reliably detects structural lesions in the sacroiliac joints (SIJs). The SPARCC Sacroiliac joint (SIJ) Structural Score (SSS)(1) is a reliable and validated method to assess the individual structural lesions of the SIJs, i.e. fat lesion, erosion, backfill (fat metaplasia in an erosion cavity) and ankylosis. Several MRI studies have indicated that bone destruction, i.e. erosion, is often followed by formation of new bone in the erosion cavity (backfill), ultimately leading to ankylosis(2). The aim was to combine these lesions into a composite score for SIJ structural damage and to test it in a 5-year follow up study with patients with axSpA.

Methods: Thirty-three patients fulfilling ASAS criteria for axSpA were followed for 5 years after initiation of TNF inhibitor in the BIOSPA study(2). T1-weighted (T1w) and STIR MRI sequences of the SIJs acquired at weeks 0 and 46 and

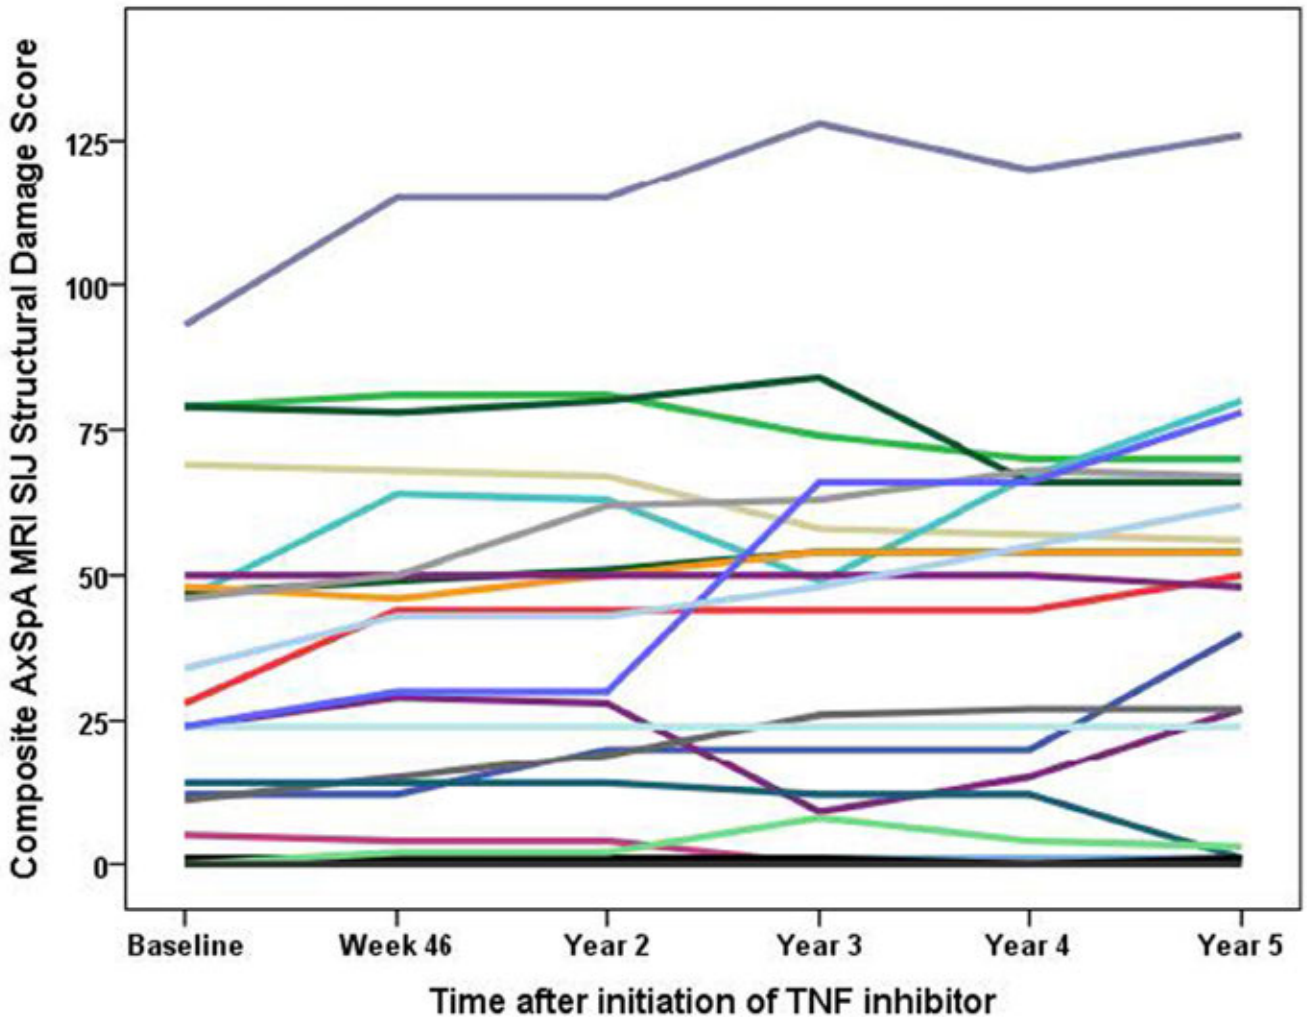
Table 2. Annual change in Composite AxSpA MRI SIJ Structural Damage Score (CSDS) for the sacroiliac joints

	0-46weeks	46weeks-2y	2-3y	3-4y	4-5y
CSDS, adjusted annual change	2.9 (6.3)	0.5 (1.9)	0.6 (8.7)	-0.2 (5.9)	1.8 (7.3)
CSDS<108, adjusted annual change	4.2 (7.3)	0.8 (2.3)	0.9 (10.7)	0.3 (7.1)	2.6 (8.8)
CSDS≥108, adjusted annual change	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)

Data are shown as mean (SD). The progression in CDDS (i.e. annual change) was calculated as the change between MRI scans divided by the exact time interval (yrs) between MRI assessments.

Figure 1



year 2, 3, 4, 5 were evaluated with SPARCC SIJ SSS. In each of 5 slices of each SIJ, erosion is scored 0-1 per joint quadrant (i.e. max score 2 per joint half, 4 per SIJ), backfill scored 0-1 per joint half (i.e. max 2 per SIJ) and ankylosis scored 0-1 per joint half (i.e. max 2 per SIJ). Based on this, a preliminary composite axSpA MRI SIJ Structural Damage Score (CSDS) was calculated: (Erosion score x1) + (backfill score x4) + (ankylosis score x6).

Results: Patients were divided into two groups: patients with almost complete bilateral ankylosis (CSDS≥108, n=10) and patients with no/minimal ankylosis (CSDS< 108, n=23). At baseline patients with CSDS< 108 were younger, had shorter symptom duration, lower BASMI, higher SPARCC Inflammation, lower SSS Fat, Erosion, Backfill and Ankylosis scores, as compared to patients with CSDS≥108. At baseline, CSDS correlated positively with symptom duration, BASMI and SSS Fat and Ankylosis, and negatively with BASDAI and SPARCC inflammation. Change in CSDS over 5 years correlated negatively with change in SPARCC Inflammation and positively with change in SSS Fat and Ankylosis. Change in CSDS over 5 years in patients with no/minimal ankylosis correlated negatively with change in SPARCC Inflammation and positively with change in SSS Fat and Ankylosis. There was no change in the group with almost complete ankylosis at baseline. (Table 1) Table 2 show the annual change CSDS over 5 years. It is noted in Figure 1, that many patients progressed the first 46 weeks, thereafter the progression decreases. However, the mean progression increases in the last year, based on a few patients with markedly increasing scores.

Conclusion: A preliminary Composite Structural Damage Score for MRI assessment of the sacroiliac joints in patients with axial spondyloarthritis, which allows scoring of MRI progression of erosion through backfill to ankylosis, is described for the first time. Progression was most pronounced in the first year after TNF-inhibitor initiation. Further validation is needed. This novel approach may be useful for monitoring structural progression in axSpA patients receiving different therapies.

Near Infrared Indocyanine Green Imaging Reveals Altered Anatomy and Diminished Function in Lymphatic Vessels in the Hands of Rheumatoid Arthritis Patients During Flare

Richard Bell,[1] Homaira Rahimi,[2] Alicia Lieberman,[2] Ronald Wood,[2] Edward Schwarz,[4] and Christopher Ritchlin[4], [1]University of Rochester Medical Center, Rochester, NY, [2]University of Rochester Medical Center, Rochester, [3]University of Rochester, Rochester, NY, [4]Division of Allergy, Immunology and Rheumatology, Center for Musculoskeletal Research, University of Rochester School of Medicine and Dentistry, Rochester, NY, USA, Rochester, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Near infrared (NIR) imaging of indocyanine green (ICG) in rheumatoid arthritis (RA) models identified abnormal lymphatic vessel (LV) function, which can be quantified as ICG clearance from the injection site via longitudinal (days) NIR imaging. As the role of LV function in RA is unknown, we hypothesized that ICG clearance from hand web spaces and efferent LV contraction frequency of RA patients experiencing flare is significantly decreased compared to normal healthy volunteers. We also assessed the characteristics of filled LVs to examine if structural differences are present in RA lymphatics and healthy controls.

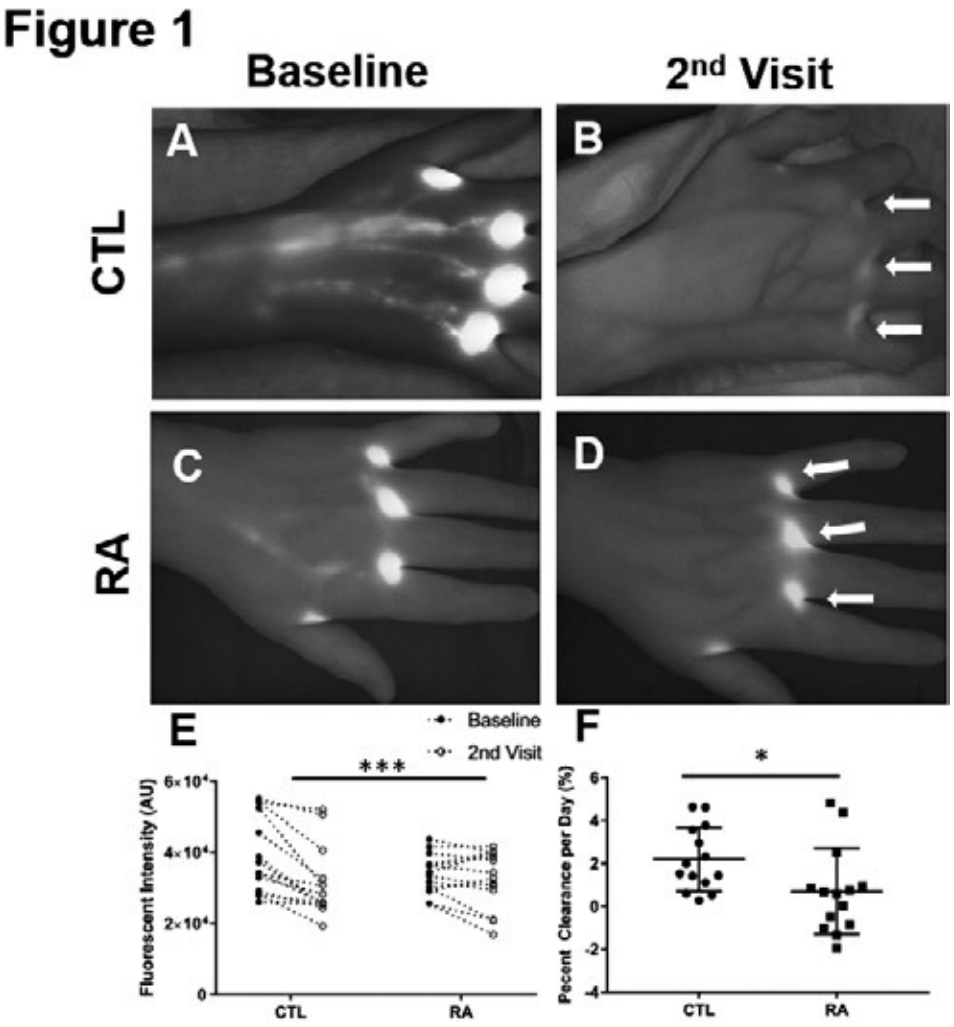

Figure 1. Impaired Lymphatic Clearance of ICG from the Hand in RA Subjects. ICG intensity was measured in left and right hands of 7 healthy control (CTL, n=14) and 5 RA subjects (n=14) after injection at the initial visit (Baseline) and at the second visit 7-15 days later (2nd Visit). Representative NIR images of a control subject at baseline (A) and at the second visit (B) show considerable clearance of the ICG at the injection sites (White Arrows), while in RA subjects (C, D) did not clear the ICG. When this was quantified, RA subjects had significantly less clearance (E, paired t-test,**p<0.001). Due to the variable time period between baseline and subjects second visit, the percent clearance per day is plotted for each interval (F, t-test, *p<0.05).

Methods: The web spaces of both hands of 12 healthy controls (CTL) and 7 subjects with RA flare (ACR 2010 RA criteria) were injected with 0.1ml of 100μM ICG on 2-4 separate occasions, and the hands underwent NIR imaging. To measure clearance of ICG from the web spaces, 7 CTL and 7 RA subjects were reimaged 7-9 or 13-15 days after the first injections, and the remaining NIR fluorescence was measured via region of interest (ROI) analysis (Paired t-test). Controlling for the number of days between subjects, the change in intensity between the initial and second visit was divided by the number of days between visits (t-test). Lymphatic contractions for LVs were determined from graphs of ROI intensity across time to calculate contractions per minute, and assessed via Wilcoxon Rank Test. To assess the branching structure of the vessels, manual segmentation of the lymphatic network and subsequent spatial mapping was performed (t-test). Then two independent graders quantified the total number of bifurcations of the LVs. Median values for each hand across all visits and graders were used to test for differences (Wilcoxon Rank-Sum Test).

Results: Representative NIR images of CTL and RA hands at baseline, and at the second visit, demonstrate the dramatic retention of ICG at the injections sites (White Arrows) in RA subjects (Fig 1 A-D). Statistical analysis revealed a decrease in ICG clearance in the RA subjects vs. CTLs (Fig 1 E, ***p< 0.001). When controlling for days between

Figure 2

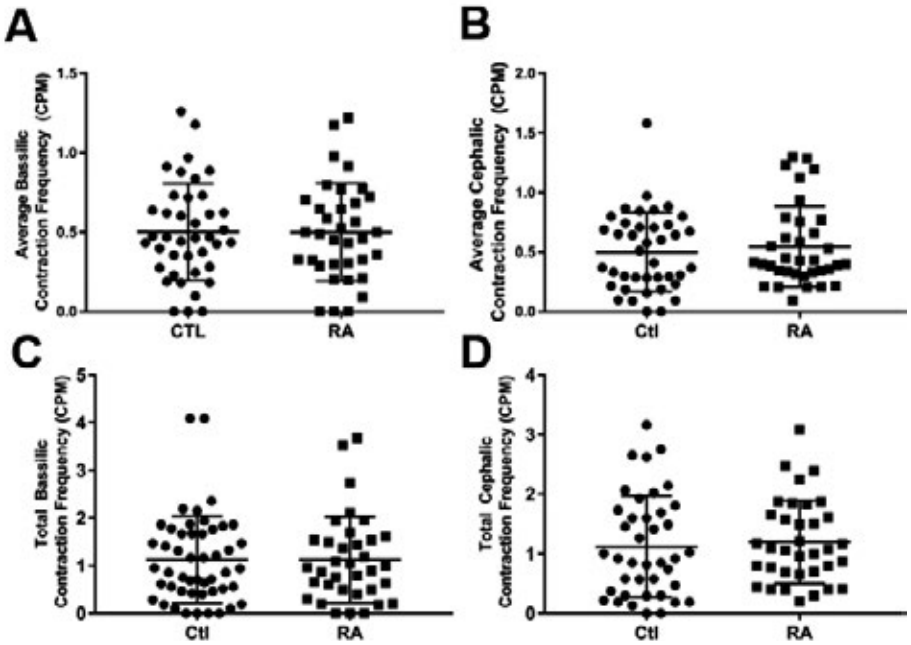

Figure 2. Lymphatic contraction frequency is not different between healthy controls and RA subjects. Lymphatic contraction frequency was calculated via ROI analysis of 10 minutes observing the dorsal aspect of the hand. An ROI was placed over the basilic and cephalic associated vessels at the wrist. These data for each vessel were either averaged or summed to generate average basilic (A) and cephalic (B) contraction frequency; or total basilic (C) and cephalic (D) contraction frequency. There were no statistical difference between the groups for any of these outcomes.

Figure 3

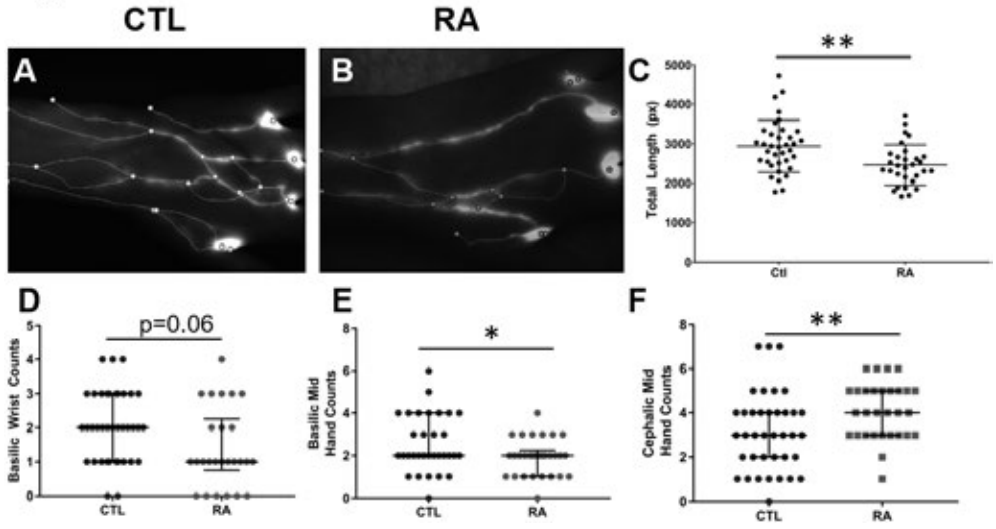

Figure 3. RA subjects have significantly less lymphatic vessels in their hands compared to healthy controls. Videos and still images were used to manually segment the lymphatic vessel network in the dorsal aspects of the hands. Spatial graphs were then generated to map to the lymphatic network. Representative stills of CTL (A) and RA (B) hands with overlaid spatial graphs show significant variation between the two. Accordingly, RA subjects have significantly less total graph length is calculated (C, t-test, M± SD, **p<0.01). To investigate where anatomically these lymphatic network differences, we manually scored how many vessels were present at the wrist, mid hand and near the injection sites. Interestingly, we found significantly fewer vessels on the lateral side of the hand (basilic associated vessels, D and E) while there was an increase in cephalic sided vessels (F, Wilcoxon Sum Rank Test, Median and IQR, *p<0.05, **0.001).

the initial visit and second visit the relationship persisted (Fig 1F, *p< 0.05). Interestingly, no difference in contraction frequency was observed between CTLs and RA subjects (Fig 2A-D). However, there was significantly decreased total length in the spatial structure of the lymphatic network (Fig 3A-C, *p< 0.05). This decreased length was primarily attributed to a lack of basilic associated ICG filled vessels in RA subjects (Fig 3D-F, *p< 0.05).

Conclusion: Imaging outcomes of LV function in mice have demonstrated diminished clearance of lymph from inflamed joints during arthritic progression. Herein, we show a significant reduction in ICG clearance and altered anatomic structure in RA subjects' hands during flare. The accumulation and retention of inflammatory cells and molecules in RA joints as a result of diminished lymphatic clearance may be a critical factor in the initiation and persistence of synovitis. This clinical pilot demonstrates the feasibility of quantifying LV function, and warrants formal investigation in clinical trials.

Abstract Number: 1178

Clinical Utility of DECT in the Diagnosis of Gout at Mayo Clinic in Florida

Emily Gilbert,[1] Hillary Garner,[1] and Andy Abril[1], [1]Mayo Clinic, Jacksonville, FL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is the most common inflammatory arthritis in the United States and worldwide. Precipitation of monosodium urate crystals in joints and soft tissues leads to inflammation and the clinical signs and symptoms of gout. Identification of urate crystals on synovial fluid analysis remains the gold standard for diagnosis. However, arthrocentesis is not always a viable option, particularly if the patient presents without active inflammation or effusion on exam. Dual energy computed tomography (DECT) is another tool for noninvasive diagnosis of gout and

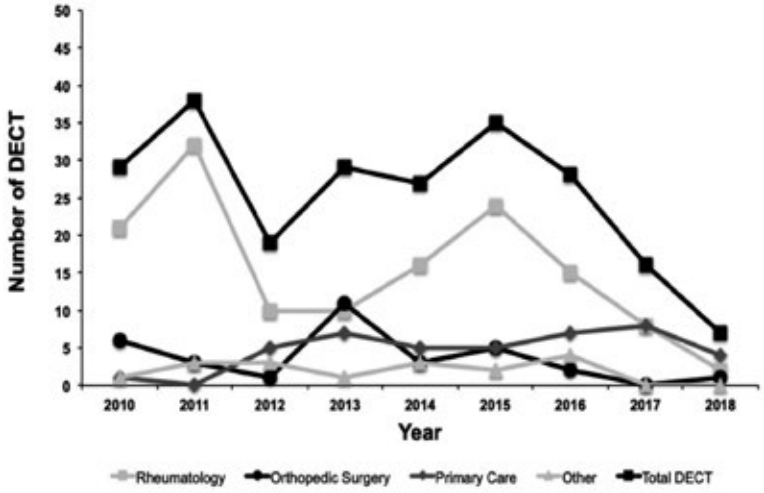

Figure 1. Number of DECT ordered per year by specialty.

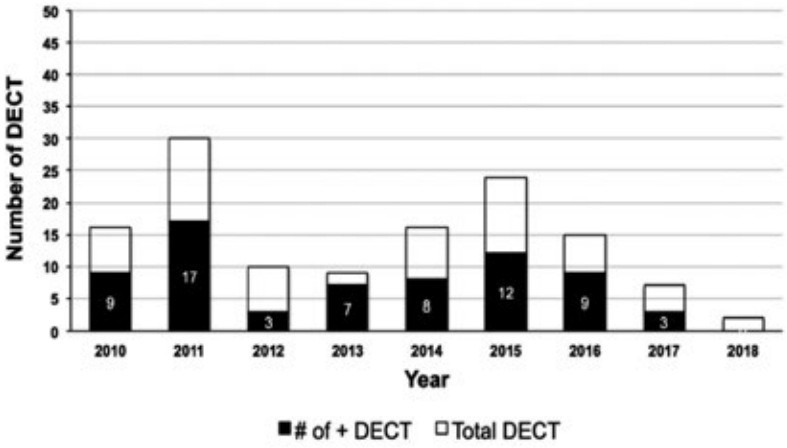

Figure 2. Total number of DECT ordered per year for initial diagnosis of gout by the rheumatology department at Mayo Clinic in Florida. Number of positive of DECT are shown in black. Year 2018 represents January through April.

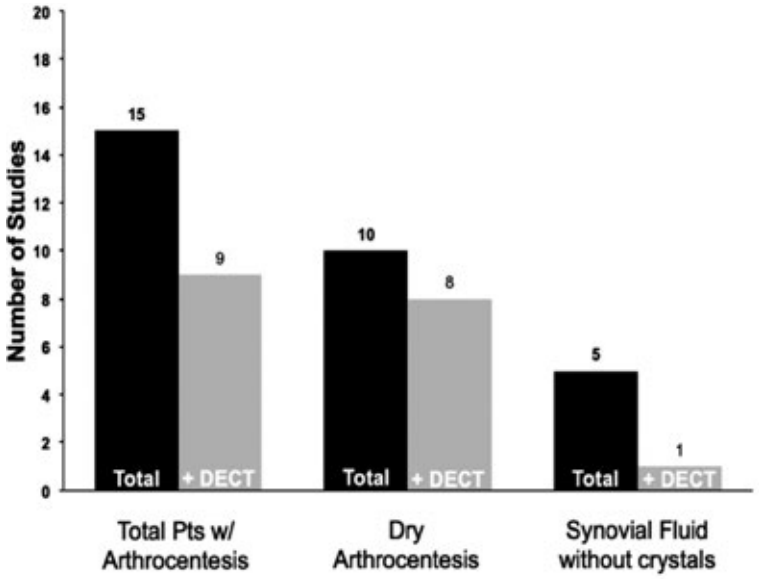

Figure 3. Did DECT aid in gout diagnosis in patients with negative arthrocentesis? 15 total patients underwent arthrocentesis in the rheumatology department. No fluid was obtained on 10 patients. Synovial fluid was examined for 5 patients.

can be utilized in the acute or chronic stages. The 2015 American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR) classification criteria for gout recognize a role for DECT in diagnosis. In our retrospective study, we analyzed how DECT is utilized in a cohort of patients at Mayo Clinic in Jacksonville, Florida. We sought to determine better clinical parameters for ordering DECT in our rheumatology department.

Methods: Our retrospective study was approved by the institutional review board. Informed consent was waived due to the retrospective nature of the study. DECT scans performed from January 2010 to April 2018 were identified using radiology software by a board certified, fellowship trained radiologist with expertise in musculoskeletal imaging. Lower extremity, upper extremity, and spine DECT were included.

Results: 228 DECT were ordered over the observation period. Rheumatology accounted for the highest percentage (60%) of tests ordered, followed by primary care physicians (18%). 211 studies were requested to aid in the initial diagnosis of the patient's concern with 129 ordered by rheumatology. Whereas the number of scans ordered by other departments changed little over the eight year observation period, DECT studies, ordered by rheumatology, decreased from 2015 onward. DECT was positive for urate 53% of the time (68 of 129) when ordered for initial diagnosis by rheumatology. Arthrocentesis was attempted on 15 patients to establish a diagnosis of gout. No synovial fluid was obtained from 10 of 15 patients. 80% of these patients had DECT performed which positively identified urate crystals. The other 5 patients, who underwent arthrocentesis, had synovial fluid examined by microscopy with 4 of 5 identifying no crystals. One patient with negative fluid analysis underwent repeat arthrocentesis showing positively birefringent rhomboid crystals. One patient with no crystals on microscopy had a positive DECT scan. Ultrasound (US) was performed on 6 patients in the clinic by the rheumatologist prior to DECT imaging. Double contour sign was identified on each patient. DECT confirmed the diagnosis of gout in these six patients.

Conclusion: The utilization of DECT in gout diagnosis is likely to continue to increase given that it is noninvasive, an accepted criterion in the ACR/EULAR 2015 guidelines, and more readily available. Our study highlights that DECT can be a useful tool in gout diagnosis when there is diagnostic uncertainty, no active inflammation or effusion on exam, and arthrocentesis cannot be obtained. Though the cohort was small, US can be a viable option as a noninvasive tool in gout diagnosis.

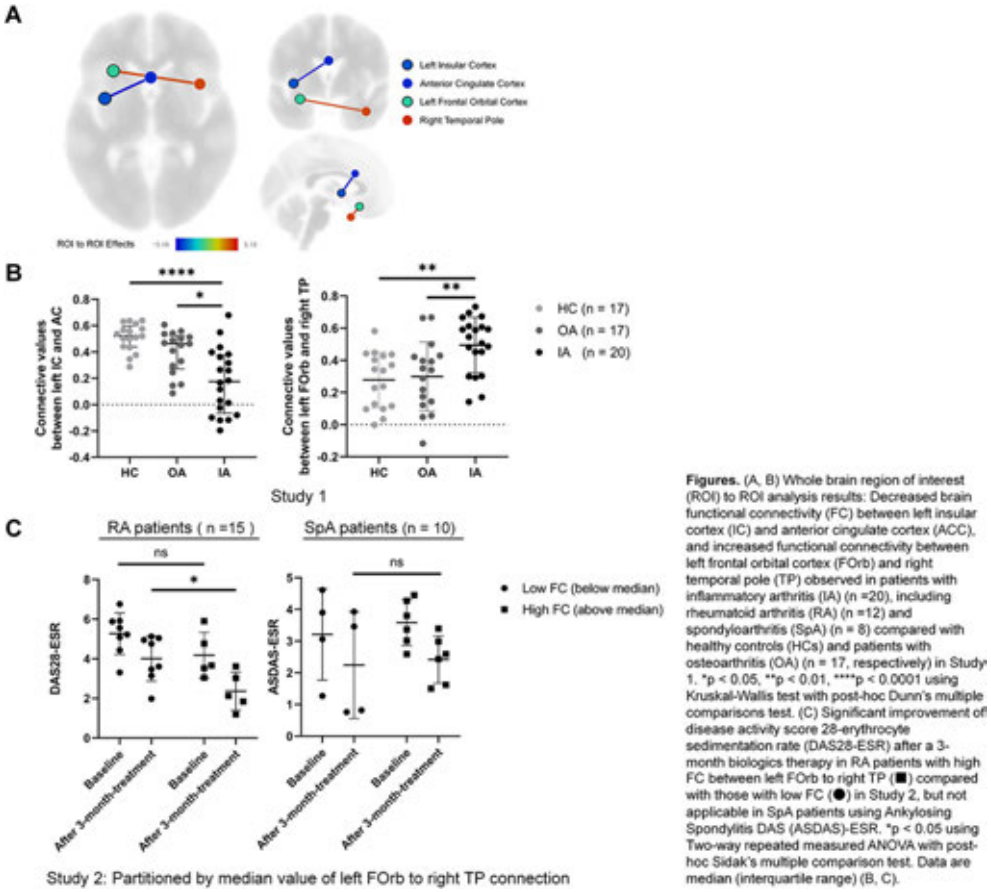
Resting-State Functional Connectivity of Pain Processing Brain Region Associated with Therapeutic Response to Biologics in Rheumatoid Arthritis and Spondyloarthritis

Nobuya Abe,[1] Yuichiro Fujieda,[1] Kuniyuki Asou,[1] Kohei Karino,[2] Michihito Kono,[3] Hisashi Narita,[4] Masaru Kato,[1] Khin Tha,[5] Kenji Oku,[1] Olga Amengual,[1] Shinsuke Yasuda,[1] and Tatsuya Atsumi[6], [1]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [2]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [3]Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Hokkaido, Japan, [4]Department of Psychiatry, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo, Japan, [5]Department of Diagnostic and Interventional Radiology, Hokkaido University Hospital, Sapporo, Japan, [6]Hokkaido University, Sapporo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Discriminating inflammatory pain from non-inflammatory pain is critical to determine therapeutic strategy in inflammatory arthritis (IA) such as rheumatoid arthritis (RA) and spondyloarthritis (SpA). Previous studies showed that resting-state functional MRI (rs-fMRI) could detect abnormal functional connectivity (FC) of brain areas related to chronic pain and could predict disease course as in chronic lumbar pain. However, the difference of FC between inflammatory and non-inflammatory pain is still unknown. This study aimed to clarify the abnormal FC related to inflammatory pain and whether it could predict the response of treatment in IA.



Figures. (A, B) Whole brain region of interest (ROI) to ROI analysis results: Decreased brain functional connectivity (FC) between left insular cortex (IC) and anterior cingulate cortex (ACC), and increased functional connectivity between left frontal orbital cortex (FOrb) and right temporal pole (TP) observed in patients with inflammatory arthritis (IA) (n =20), including rheumatoid arthritis (RA) (n =12) and spondyloarthritis (SpA) (n = 8) compared with healthy controls (HCs) and patients with osteoarthritis (OA) (n = 17, respectively) in Study 1. *p < 0.05, **p < 0.01, ****p < 0.0001 using Kruskal-Wallis test with post-hoc Dunn's multiple comparisons test. (C) Significant improvement of disease activity score 28-erythrocyte sedimentation rate (DAS28-ESR) after a 3-month biologics therapy in RA patients with high FC between left FOrb to right TP (■) compared with those with low FC (●) in Study 2, but not applicable in SpA patients using Ankylosing Spondylitis DAS (ASDAS)-ESR. *p < 0.05 using Two-way repeated measured ANOVA with post-hoc Sidak's multiple comparison test. Data are median (interquartile range) (B, C).

Methods: IA patients requiring biologics (n = 46; RA 28, SpA 18) and healthy controls (HCs, n = 17) underwent rs-fMRI in Hokkaido University Hospital. For controls of non-inflammatory pain, rs-fMRI dataset of patients with osteoarthritis (OA) (n = 17) was obtained from OpenNEURO (https://doi.org/10.18112/openneuro.ds000208.v1.0.0). IA patients were split into two groups (Study 1 or Study 2), depending on whether or not the patients had clinical follow-up data after biologics therapy. In Study 1, to identify the abnormal FC related to inflammatory pain, rs-fMRI-derived FC values to whole brain connectivity were retrospectively analyzed in IA patients (n = 20; RA 12, SpA 8) by comparing with OA patients and HCs (n = 17, respectively). In Study 2, IA patients treated with biologics were prospectively evaluated with disease activity score 28-erythrocyte sedimentation rate (DAS28-ESR) and Ankylosing Spondylitis DAS-ESR (ASDAS-ESR) in RA patients (n = 15) and SpA patients (n = 10), respectively before treatment and after a-3-month therapy. We then analyzed the association between the detected FC and disease activity.

Results: From the whole brain analyses in Study 1, significant connective values between left insula cortex (IC) and anterior cingulate cortex (ACC), and left frontal orbital cortex (FOrb) and right temporal pole (TP) were found in IA patients compared with OA patients and HCs (Figure. 1A, B). In Study 2, the connectivity values of left FOrb and right TP partitioned by median value of IA patients could discriminate significant improvement of DAS28-ESR after treatment in RA patients, although there was no association with the improvement of ASDAS-ESR in SpA patients (Figure. 1C).

Conclusion: RA and SpA patients shared neurobiologic features of the abnormal functional connections between left IC and ACC, and left FOrb and right TP, which are brain regions involving pain processing and decision making. High FC value between left FOrb and right TP would predict the superior therapeutic outcomes regarding disease activity in patients with RA, suggesting that this abnormal FC would be associated with inflammatory pain.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sprifermin is under investigation as a potential disease-modifying osteoarthritis drug (DMOAD). 2-yr results from the FORWARD study showed significant dose-dependent modification of cartilage thickness in the total femorotibial joint (TFTJ), medial and lateral femorotibial joints (MFTC, LFTC), and central medial and lateral TFTJ subregions, by quantitative (q)MRI (Hochberg et al. ACR 2017).

This post hoc analysis aimed to determine whether qMRI findings from FORWARD (manual segmentation) could be reproduced in the same cartilage regions using an independent method (automated segmentation), on the same dataset/time period.

Methods: Pts were randomized 1:1:1:1:1 to: sprifermin 100 µg q6mo; 100 µg q12mo; 30 µg q6mo; 30 µg q12mo; and placebo (n=110/110/111/110/108). Cartilage thickness was assessed at baseline and 6, 12, 18, and 24 months using 1.5- or 3-Tesla MRI images, analysed manually. The same images were analysed by automated cartilage segmentation using active appearance models, a supervised machine learning method, to produce maps of cartilage thickness for weight-bearing femoral and tibial cartilage surfaces, subdivided into anatomical masks. Results were blinded for treatment and timepoint for both methods. No statistical comparisons between methods were conducted.

Endpoints were change from baseline in: 1) cartilage thickness in the TFTJ, MFTC and LFTC, using regions duplicated based on published data; 2) cartilage thickness in the central subregion of the medial and lateral tibia and femur (cMT, cMF, cLT, cLF [conventions used by the automated analysis investigators]). As in previous analyses, treatment effect was assessed by observed changes and adjusted using repeated ANCOVA on change from baseline, including

Table 1. Change in cartilage thickness with sprifermin 100 µg q6mo vs placebo using automated segmentation.

	Mean (SD) change from baseline at Yr 2, mm		
Region	Sprifermin 100 µg q6mo	Placebo	P value
TFTJ	0.05 (0.11)	-0.04 (0.08)	P<0.001
MFTC	0.03 (0.15)	-0.04 (0.14)	P=0.011
LFTC	0.07 (0.12)	-0.04 (0.10)	P<0.001
cMT	0.02 (0.18)	-0.07 (0.17)	P=0.008
cLT	0.09 (0.20)	-0.05 (0.18)	P<0.001
cLF	0.09 (0.11)	0.00 (0.08)	P<0.001
cMF	0.02 (0.17)	-0.04 (0.16)	P=0.061

treatment group, timepoint, and country as fixed factors, baseline value as covariate and treatment by timepoint as interaction.

Results: Based on automated segmentation, statistically significant, dose-dependent structural modification of cartilage thickness was observed over 2 yrs with sprifermin vs placebo for the TFTJ (overall treatment effect and dose response across all doses, both P< 0.001), MFTC (P=0.004 and P=0.044), and LFTC (both P< 0.001). Table 1 shows changes from baseline for sprifermin 100 µg q6mo and placebo. Statistically significant dose-dependent structural modification of cartilage over 2 yrs was observed for sprifermin vs placebo in the cMT (100 µg q6mo), cLT (100 µg q6mo, q12mo) and cLF (100 µg q6mo, q12mo). In the cMF, there was no treatment effect, but there was a linear trend for dose responsiveness. The results showed a consistent pattern to those obtained using manual segmentation.

Conclusion: Cartilage thickness assessed by automated segmentation provided a consistent pattern of structural modification in FORWARD compared with manual segmentation. This is the first time that two independent methods of image analysis have reached the same conclusions in an interventional DMOAD trial. The findings strengthen the conclusions that sprifermin modifies cartilage loss/structural progression in knee OA.

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Aortitis can be idiopathic or associated with other conditions. It is frequently refractory to conventional immunosuppressive therapy. Tocilizumab (TCZ), an anti-IL-6 receptor antibody seems to be effective and safe.

Our aim was to assess the efficacy and safety of TCZ at short and long follow-up in a series of patients with Aortitis.

Methods: Retrospective, multicenter study of 79 patients diagnosed of inflammatory aortitis based on imaging techniques (PET/CT, CT angiography and/or MR angiography).

Results: We study 79 patients (61 w/ 18 m). 59 (74.7%) cases were Aortitis secondary to Giant Cell Arteritis (GCA), while 20 (25.3%) were idiopathic. The mean age was 71±8.5 years vs 64.2±7.1 years, respectively (p=0.001). At time of disease diagnosis more than a half of patients (59.5%) presented as main symptom polymyalgia rheumatica

TABLE

	Idiopathic aortitis (n=20)	Aortitis secondary to GCA (n=59)	p
EFFICACY OF TCZ			
Prolonged remission, n (%)			
Month 6	5 (41.7)	23 (45.1)	0.830
Month 12	5 (45.5)	14 (41.2)	0.803
Month 24	3 (75)	18 (85.7)	0.527
Relapses, n (%)			
Month 1	2 (15.4)	1 (3.3)	0.213
Month 3	2 (16.7)	5 (10.4)	0.546
Month 6	1 (9.1)	8 (16.3)	0.544
Month 12	1 (9.1)	4 (11.8)	1.000
Month 24	0	1 (4.8)	1.000

(PMR). Aortitis was diagnosed with PET/CT (71 patients), angioRMN (12 patients) and angioCT (8 patients). Prior to TCZ treatment, 61 (77.2%) patients had received conventional immunosuppressive drugs, 59 (74.7%) of them received MTX. After 24 months of treatment with TCZ, more than 75% of patients reached a prolonged remission in both groups (p=0.527), with only 4% of relapses after the same follow-up period (p=1.000). 40 (50.6%) patients had a control image technique (PET/CT) throughout follow up. 4 (3 secondary to GCA and 1 idiopathic) patients reached a complete improvement in uptake after one year of treatment.

Conclusion: Our results show that idiopathic aortitis occurs in younger patients compared with aortitis secondary to GCA. TCZ proved to be effective in both pathologies, allowing clinical and analytical improvement, as well as a reduction of corticoid dose, without increasing the risk of relapse. However, the improvement in imaging techniques seems to be slower.

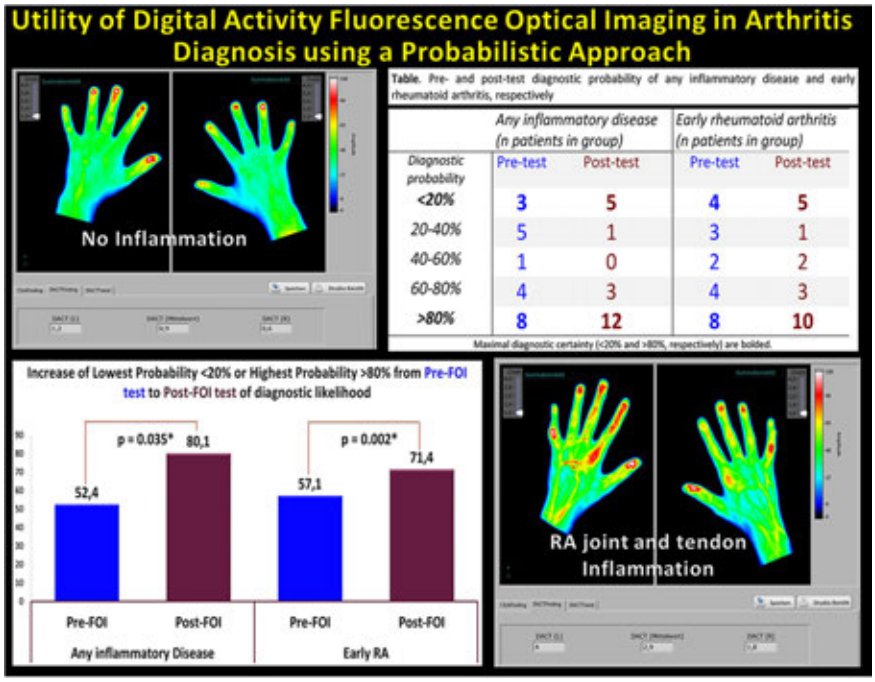
Fluorescence Optical Imaging in the Diagnosis of Individuals Suspected of Arthritis Development – a Probabilistic Approach

Yogan Kisten,[1] Adrian Levitsky,[1] Hamed Rezaei,[1] Aase Hensvold,[2] Per Larsson,[3] Erik Af Klint,[1] Ronald van Vollenhoven,[4] and Anca Catrina[5], [1]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [2]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, [3]Center for Rheumatology, Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [4]Amsterdam Rheumatology and immunology Center, Netherlands., Amsterdam, Netherlands, [5]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Among the arsenal of available techniques for arthritis prediction and diagnosis, fluorescence optical imaging (FOI) has shown to be useful in detecting clinically manifest and silent synovitis of the hands of patients with various rheumatic diseases. Using a probabilistic approach, we now assess the diagnostic utility of FOI in individuals that are at increased risk of inflammatory arthritis (RA in particular).

Methods: Those suspected of inflammatory arthritis were referred to the rheumatology unit and clinic of the Karolinska University Hospital. On acquiring informed consent and medical history, the standard clinical examination coupled with ultrasound findings of the hands and feet were assessed. Laboratory results included ESR, CRP, RF



Fluorescence optical Images of normal and inflamed hand joints together with results of probability changes from minimal to maximal certainty of arthritis diagnosis, before and after FOI examination

and ACPA tests. Using the above information, a diagnostic probability assessment was completed by the responsible rheumatologist, where the probability of a) any inflammatory joint disease and b) Rheumatoid/RA was given on a 5 point scale - ranging from unlikely (0-20%) to very likely (80-100%) probability. Subsequently, an FOI examination was performed. After reviewing the image reports in consensus, post-FOI diagnostic probabilities were again scored using the same scale. If no score change in the probability resulted, then the rheumatologist was asked to mark whether FOI was still helpful in the diagnostic decision making. Proportions of individuals with maximal and minimal diagnostic certainty pre-and post-test were compared using Fisher exact tests, and one-sample binomial tests for assessing the helpfulness of FOI in the absence of pre-and post-test probability score changes.

Results: Of 24 individuals screened, 21 without prior rheumatic diagnosis were included (67% female, 11 RF (+), 10 ACPA (+), with age average and symptom duration (SD) of 56 (±18) years and 14 (±15) months respectively). The final diagnosis were: early RA (n=17), other inflammatory joint disease (n=3), and non-inflammatory joint disease (n=1). Regarding diagnosis of any inflammatory arthritis, where the proportion of patients for whom the diagnostic certainty was maximal - namely, combining < 20% (lowest probability) or >80% (highest probability) of diagnostic likelihood - there was an increase from 52% (n=11/21) maximal certainty before FOI to 80% (n=17/21) maximal certainty after FOI (p=0.035). Regarding early RA, the maximal diagnostic certainty increased from 57% (n=12/21) to 71% (n=15/21) (p=0.002), respectively. The availability of ultrasound findings confirm the FOI effect. Therefore, in the event that the FOI diagnostic certainty scores did not change, pre- vs. post-test (15/21 cases, any inflammatory joint disease; 13/21 cases, early RA), the diagnosing rheumatologist indicated that FOI was still helpful in setting a final diagnosis for most cases (87% (13/15) p=0.007; 85% (11/13). p=0.022, respectively).

Conclusion: Fluorescence optical imaging significantly increased the diagnostic certainty and confidence of rheumatologists in establishing the presence and absence of inflammation in individuals suspected of inflammatory arthritis. The changes from pre-to post-test quantify the diagnostic utility of fluorescence optical imaging in probabilistic terms.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: More than 130 cases of gout of the spine have been reported, with presenting symptoms including acute back pain, neuropathy, and spinal compression; diagnosis is usually based on imaging identification of a mass, followed by tissue confirmation of monosodium urate (MSU) deposition.(Toprover et al. Curr Rheum Rep. 2015.) It is likely that many more cases of gout involve the spine in an asymptomatic manner, or with non-specific back symptoms that are never formally diagnosed.

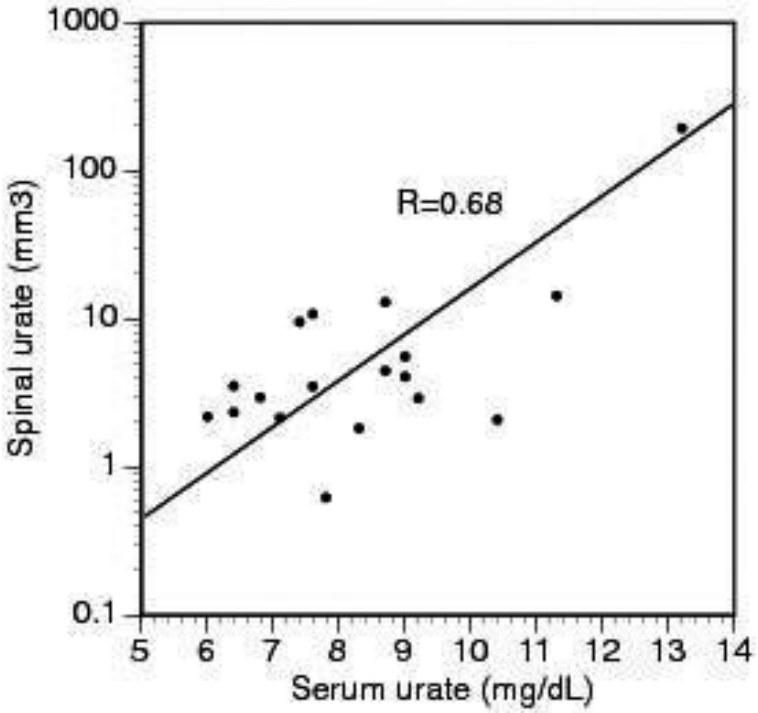

Figure 1. Correlation between serum urate level and spinal urate deposition in subjects with gout

Figure 1. Correlation between serum urate levels and spinal urate deposition in subjects with gout.

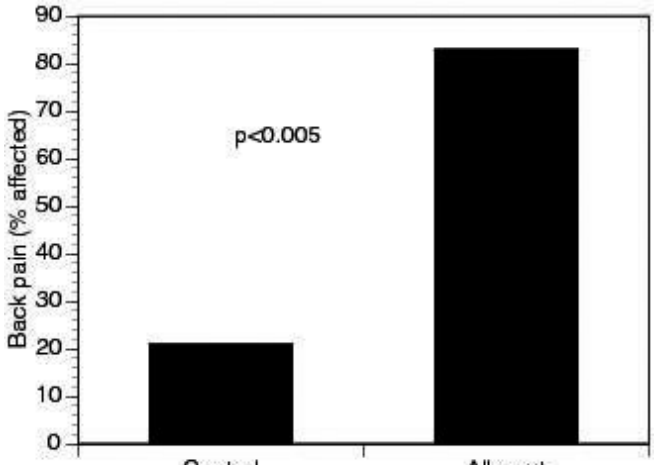

Figure 2. Back pain in controls vs gout subjects.

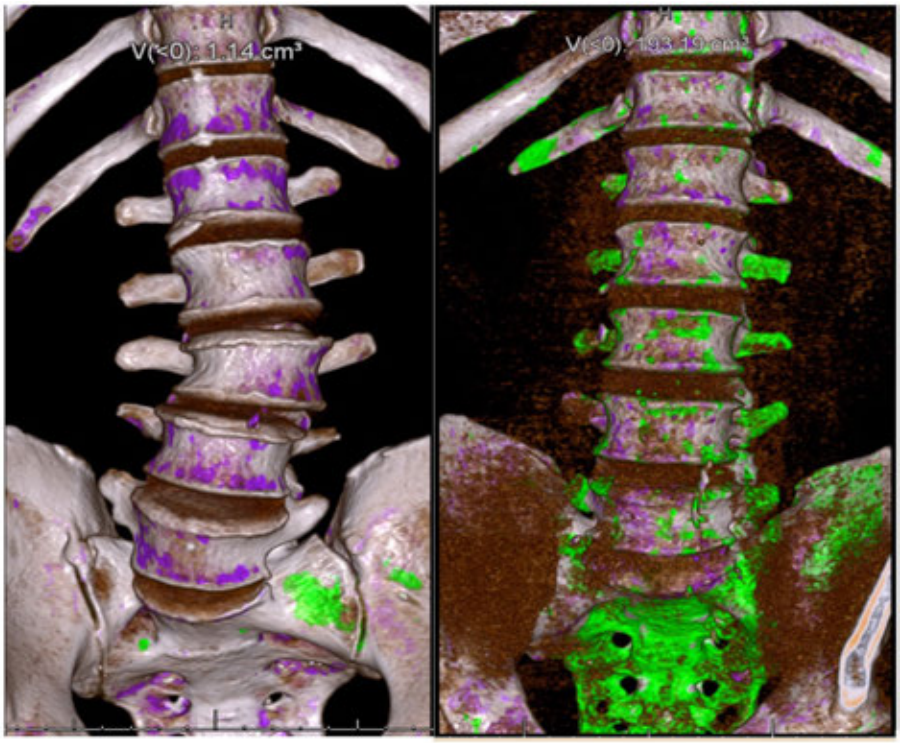

Figure 3. Comparison of DECT scan of control (left) vs gout patient (right)

Methods: Using dual-energy CT (DECT), our study aims to determine the prevalence and extent of urate deposition in the lumbosacral spines of patients with clinical tophaceous gout, vs non-tophaceous gout vs control subjects without gout. We are recruiting 25 controls, 25 non-tophaceous and 25 tophaceous gout patients, 50-80 years old. Exclusion criteria include known pseudogout, RA, spondyloarthropathy or active spinal malignancy. All gout subjects meet current ACR/EULAR classification criteria, and have an entry serum urate (sU) of >6.8 mg/dL, or sU >6.0 mg/dL on ULT for < 6 months. Demographics, gout history, back pain data (including Aberdeen back pain scale), sU, ESR, and CRP are collected. Subjects undergo DECT of the lumbosacral spine to assess for MSU deposition.

Results: To date, 32 subjects have completed the study: 14 controls, 14 non-tophaceous and 4 tophaceous gout subjects. For these preliminary evaluations, all gout subjects (n=18) are pooled together. To date, all recruited subjects are male. All control subjects identify as white; gout subjects identify as white (61.1%), Black (33.3%) or Hispanic (5.5%). Control and gout subjects have similar mean age in years (controls, 61±1.0 vs gout, 63.3±1.5), but differ in serum creatinine (controls, 1.0±0.1 mg/dL vs gout, 1.5±-0.2 mg/dL, p=0.02). Mean sU is higher in the gout group (controls, 5.3±0.2 mg/dL vs gout, 8.4±0.4 mg/dL, p< 0.05). Gout patients have higher CRP (controls, 1.8±0.5 mg/L vs gout, 9.6±3.3 mg/L, p=0.05), ESR (controls, 11.5± 2.6 mm/h, vs gout, 22.3±4.3mm/h, p=0.06), and MSU deposition in the spine (controls, 2.3 ± 0.2 cm3 vs gout, 15.5±10.5 cm3, p=0.28). When a single outlier gout subject with very high sU and extensive spinal MSU was excluded, spinal MSU deposition between controls and gout patients became significant (controls, 2.3±0.8 cm3 vs gout, 5.0±1.0 cm3, p=0.02). Gout patients reported more back pain (controls, 21% vs gout, 83%, p< 0.005) and greater back pain scores (controls, 4.1±1.6, vs. gout, 10.5±3.4, p=0.12). When plotted against sU, spinal MSU volumes were proportional to sU for controls (R=0.32) and more strongly for gout subjects (R=0.68), suggesting the possibility of spinal MSU deposition even in non-gout individuals.

Conclusion: In these preliminary analyses, gout patients had higher inflammatory markers, greater spinal MSU deposition, and increased rates and severity of back pain compared with non-gout controls. In all patients, spinal MSU deposition was proportional to sU. These data suggest that MSU deposition in the spine is common among gout patients, is associated with sU level, and may be associated with low back pain.

Rheumatoid Arthritis Activity Assessment with Cellphone Thermal Camera Imaging Compared to Clinical and Ultrasound Assessments

Caroline Paris,[1] Pierre Lafforgue,[1] Vincent Pradel,[2] Christophe Richez,[3] and **Thao Pham** [1], [1]Aix-Marseille University, CHU Marseille, department of Rheumatology, 13,000 Marseille, France, Marseille, France, [2]APHM -Assistance publique des hôpitaux de Marseille, Marseille, Finland, [3]Pellegrin Hospital, University Hospital of Bordeaux, Bordeaux, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The assessment of active joints is a core component of widely used outcome measures in rheumatoid arthritis (RA). However, variability exists within and across examiners in clinical assessment of active joint counts.

Our objective was to explore the ability of noncontact digital thermographic imaging to assess inflammatory arthritis activity, compared to clinical and ultrasound (US) evaluation.

Methods: Cross-sectional pilot study of 20 RA patients (ACR criteria). Each patient had 3 independent (blinded) assessments of their hand joints activity with: 1) clinical with swollen and tender joints counts (SJC, TJC) and DAS28 score; 2) US with mode B and doppler (DP) according to EULAR/OMERACT" guidleines (MyLab60®, Esaote Biomedica, Genoa, Italy, 4–13 MHz broadband linear array transducer), and 3) thermographic assessment. Thermal images were obtained with an infrared thermal cellphone camera FLIR One® and analyzed either with a software detecting

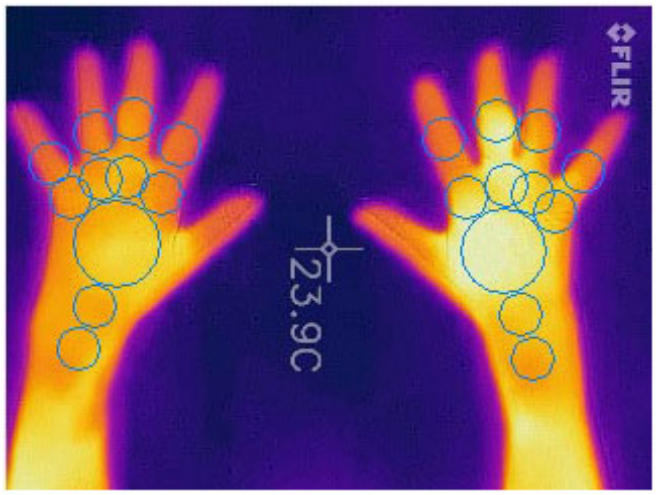

Figure. Automatic detection of 22 ROI (arthritis on the right carp, MCP 3 and IPP 3)

22 predetermined regions of interest (ROI) and either with a simple colour reading (arthritis yes/no) (Figure). For each ROI, we measured the difference between the ROI temperature and the homolateral forearm considered as reference area (ΔT°). Statistical analysis: Description with mean ± standard deviation (SD), and specificity (Sp) and sensitivity (Se) analysis.

Results: The main characteristics of the 20 RA patients were the following (mean±SD): age: 59.5 years, disease duration: 17.5 years, ACPA+: 85%, TJC: 5.1±5.6, SJC : 3.5±3.2, DAS28: 3.8±1,3. The mean ROI temperature of the 351 analyzed joints was 36.3 °C and the forearm temperature was 36.6°C. Clinical vs thermographic assessment: Mean ΔT° of swollen and tender joints was – 0.42 °C ± 0.74 and –0.15°C± 0.88, respectively versus– 0.36 °C ± 0.85 and– 0.46 °C ± 0.62. Mean ΔT° was – 0.08°C ± 0,4 in DAS28 < 2.6 group , – 0.39°C ± 0.91 in DAS 28 ≥ 2.6 - ≤5.1 [TP1] group and – 0.10 ± 0.64 in DAS 28 > 5.1 group. US vs thermographic assessment: The mean ΔT° of the 22 joints with synovitis DP2 and of the 17 joints with DP3 was – 0.48 °C ± 0.99 and – 0.02 °C ± 0.60, respectively. The simple colour reading was able to detect DP2 synovitis with Sp = 0.92 and Se = 0,24 and DP3 synovitis with Sp = 0.94 and Se = 0,19.

Conclusion: Thermographic assessment with a thermal smartphone camera of RA activity is a promising technology, that still needs further refinement before considering its daily use.

Session Date: Monday, November 11, 2019

Session Title: Imaging Of Rheumatic Diseases Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: 95% of the people with SLE experience joint pain, stiffness and swelling at some time during their illness. It is currently difficult to both diagnose and estimate the severity of lupus arthritis.This studyexplores the clinical utility of frequency-domain optical transmission (FDOT) measurements to distinguish affected finger joints from healthy ones.

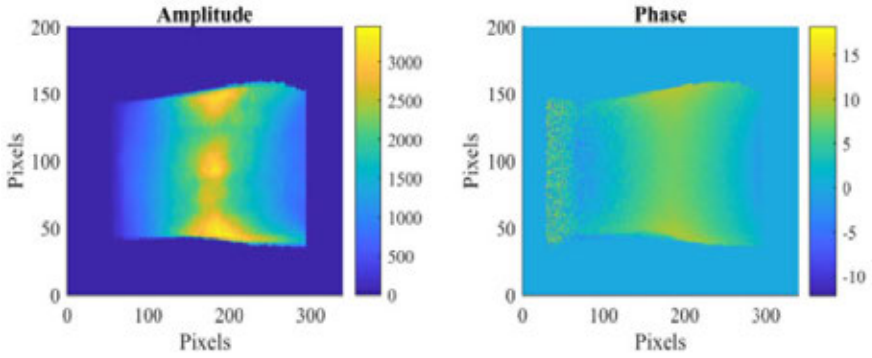

Figure 1. Example of the mean images for amplitude (on the left) and phase (on the right) obtained for the same PIP of a healthy subject.

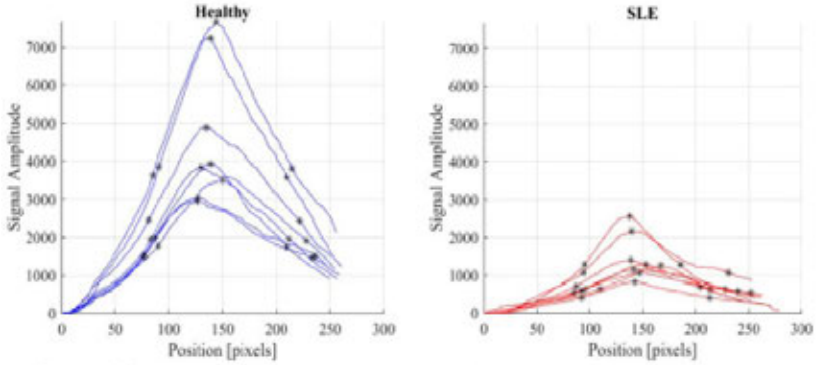

Figure 2. Mean amplitudes of the output signals considering only the finger area in the pictures along the length of the fingers. In blue on the left is a healthy subject, in red on the right a SLE patient. In each graph, there are 8 curves, one for each PIP considered. The black dots mark the peak positions and the positions were the signal is 40% of the peak value.

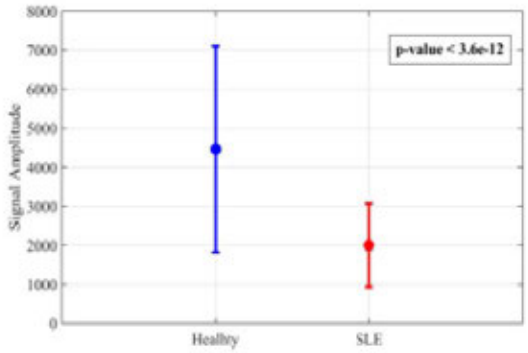

Figure 3. Mean and Standard Deviations of the maximum values of the signal amplitudes estimated in Healthy (blue) and SLE (red) patients. The mean values and standard deviations are respectively 4462 ± 263in Healthy and 2003 ± 1069 in SLE patients.

Methods: The FDOT system is operated at a frequency of 600MHz. The laser diode produces a 1-mm diameter beam at 670nm light with a power of 8mW. Transmitted light intensity is measured using an ICCD camera operated in homodyne mode.

For data acquisition, the laser beam is guided to 11 positions, separated by 2 mm from each other, on the top of the finger, scanning along a sagittal plane in the forward direction with a modulation frequency of 600 MHz. PIP II -V of both hands were scanned. The time required to set-up the system and scan a single finger was about 2 min. 10 patients with SLE with active arthritis were evaluated (9 women, mean age 42 ± 9.1 years). All patients had arthritis by physical exam: swelling, tenderness and pain in each finger joint. 4 healthy controls were also examined (3 women, mean age 28.7 ± 4.4 years). A total of 80 fingers from SLE patients and 32 fingers from healthy volunteers were analyzed.

Results: The raw data obtained consisted in 16 pictures for each of the 11 source positions for a total of 176 images per finger. The data was processed using a fast Fourier transformation, obtaining values for the amplitude, phase and the DC components for all source positions. An example of the 2D distribution of the mean values for amplitude and phase for a healthy PIP subject can be seen in Figure 1. From the 2D images, a linear mean value of the amplitudes and phases along the length of the finger was calculated. An example of the amplitude behaviors from healthy joints and SLE joints are shown in Figure 2.

The maximum values of the signal amplitudes in healthy volunteers is considerably higher (4462 ± 2638) than in SLE patients (2003 ± 1069). An ANOVA analysis (using MATLAB embedded function anova1) shows that these differences are statistically significant between healthy and SLE patients (p value < 3.6e-11), as shown in Figure 3.

From the ROC curve analysis, the best cut-off plane holds a sensitivity of 100% and a specificity of 80% to distinguish between joints of Healthy volunteers and SLE patients, with an area under the curve (AUC) of 0.9.

Conclusion: FDOT can differentiate healthy joints from those of SLE patients. We foundstatistically significant differences between the max signal amplitudes of the two groups. The ROC analysis showed high sensitivity and specificity. Further development of this technology is likely to improve the evaluation of SLE arthritis in clinical trials and practice.

How Accurate Is Physical Joint Inflammation of the MTP-joints and What Can We Learn from Additional MRI on Forefoot Involvement in Early Arthritis?

Yousra Dakkak,[1] Aleid Boer,[1] Debbie Boeters,[1] Annette van der Helm-van Mil,[2] and Monique Reijnierse[1], [1]Leiden University Medical Center, Leiden, Netherlands, [2]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Magnetic resonance imaging (MRI) is more sensitive than physical examination in detecting inflammation. This has predominantly been studied in metacarpophalangeal-(MCP) and wrist-joints. Data on the

concordance and discordance of physical examination (PE) and MRI-detected inflammation of metatarsophalangeal-(MTP)joints is scarce, which is surprising as physical examination of these joints is challenging.We aimed to study the concordance and discordance of arthritis upon PE with MRI-detected inflammation of MTP-joints. Analyses on MCP-joints were included for comparison.

Methods: 1764 MTP(2-5)-joints and 1764 MCP(2-5)-joints of 441 consecutive patients presenting with early inflammatory arthritis (36% RA, 64% other inflammatory arthritides) underwent PE of joint swelling by two independent readers, and 1.5T contrast-enhanced MRI of unilateral MTP- and MCP-joints. MRI-detected synovitis and bone marrow oedema were scored according to the RA MRI score (RAMRIS), and tenosynovitis according to Haavardsholm by two experienced readers. For a joint to be classified as PE+ swelling had to be observed by both assessors. MRI-positivity required the presence of the same MRI-inflammatory feature on joint level that was scored by both readers≥1. MRIs were further studied by two other, independent observers among whom an experienced musculoskeletal radiologist by consensus reading, to investigate the presence of contrast-enhancement of the soft tissues that was not scored according to RAMRIS guidelines. Analyses were done on joint level, joints were grouped as PE+MRI+, PE–MRI–, PE+MRI– and PE–MRI+.

Results: Physical examination of joints and MRI were concordant in 79% of MTP-joints (4% PE+MRI+, 74% PE–MRI–). For the MCP-joints this was 71% (15% and 53% respectively). Next discordance was studied. Subclinical joint inflammation (PE–MRI+) was present in 17% of MTP-joints. This was less frequent than in MCP-joints, where subclinical inflammation was present in 29% joints. Discordance in the opposite direction (PE+MRI–) was present in 5% of all MTP-joints (this was 55% of all PE+ MTPs). PE+MRI- occured less frequent at MCP-joints (3% of all MCPs were PE+MRI, which is 15% of the PE+ MCPs). Subsequently, MRI-detected contrast-enhancement of the soft tissues were studied to see if they could form an explanation for the felt arthritis. Of the PE+MRI- MTP-joints, 43% showed contrast-enhancement of the soft tissues, while in PE-MRI- joints this was 22%. Finally, to better understand this contrast-enhancement, its' frequency was compared between RA and other inflammatory arthritides, And was 53% vs. 22% respectively (OR 4.1, 95% CI 3.3-5.0).

Conclusion: Joint examination and MRI were mostly concordant in MTP- and MCP-joints. In MTP-joints MRI-detected subclinical joint inflammation occured in 14% of joints, which was less frequent than the MCP-joints where this was 27%. Clinical joint swelling without MRI-detected joint inflammation according to RAMRIS occured more in the MTPs and was in part caused by contrast-enhancement of soft tissues; this was more frequent in RA suggesting it to be inflammatory in nature. Further detailed imaging studies are needed to further characterize its' nature

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this longitudinal study is to compare the effect of Adalimumab plus Methotrexate (MTX) versus MTX monotherapy on glycosaminoglycan content (GAG) in cartilage in patients with early rheumatoid arthritis (eRA) who have not received a disease-modifying antirheumatic drug (DMARD) or biological treatment using biochemical gadolinium-enhanced magnetic resonance imaging of cartilage (dGEMRIC).

Methods: Cartilage integrity of finger joints and the wrist of the clinically dominant hand of 14 patients with eRA who met the ACR/EULAR classification criteria were evaluated at baseline prior to any DMARD or biological therapy and 12 and 24 weeks after Adalimumab plus MTX therapy (10 patients, 6 females, mean age 44.9 years, range: 19-65 years) or placebo plus MTX therapy (4 patients, 2 female, mean age 46.7 years, range: 24-64 years). In this prospective double-blind study, patients were randomly assigned to both groups. dGEMRIC of MCP joints of the index and middle as well as OMERACT RAMRI scores, including synovitis, edema, and erosion subscores were registered at all timepoints.

Results: The Adalimumab + MTX therapy group showed a trend to higher dGEMRIC indices of the second and third MCP joints compared to the placebo + MTX therapy group between baseline and 24-week follow-up (ADA+MTX: dGEMRIC mean change 85.8, range -156.2 – 346.5; Placebo+MTX: dGEMRIC mean change -30.75, range -273.0 – 131.0; p = 0.37). Furthermore, there has been an improvement between baseline and 24-week follow-up in RAMRI score for the total RAMRI score (ADA+MTX: mean change -5.6, range -17 – 4; Placebo+MTX: mean change -1.25, range -6 – 6). RAMRI score for synovitis improved for most patients under therapy (ADA+MTX: 70%; Placebo+MTX: 75%). RAMRI score for edema improved for some patients (ADA+MTX: 50%; Placebo+MTX: 25%). RAMRI score for erosion has remained almost unchanged (improvement ADA+MTX: 0%; Placebo+MTX: 25%).

Conclusion: In patients with eRA, Adalimumab therapy showed a trend towards biochemical cartilage improvement after 24 weeks therapy. One possible explanation is a reduction of inflammation at the level of the MCP joint by Adalimumab. These results support the concept of early treatment for RA to stop and even reverse cartilage damage in inflamed joints. Furthermore, dGEMRIC appears to be an important tool for the early detection of molecular cartilage damage in RA.

Novel PET-Coronary Flow Reserve Imaging to Assess for Coronary Microvascular Dysfunction in Systemic Lupus Erythematosus Compared to Subjects with Diabetes Mellitus and Controls

Cameron Speyer,[1] Corine Sinnette,[1] Emma Stevens,[1] Hongshu Guan,[2] Courtney Bibbo,[2] Marcelo Di Carli,[2] Karen Costenbader,[1] and Elena Massarotti[2], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Imaging Of Rheumatic Diseases Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: High risk of premature cardiovascular disease (CVD) among SLE patients is well documented, but the best means to detect the earliest stages of CVD in SLE are not known. Coronary microvascular dysfunction is thought to be one of the earliest detectable abnormalities and can be detected by measuring coronary flow reserve (CFR) with positron emission tomography (PET) scanning. PET-CFR is an emerging prognostic imaging technique used to detect increased CVD risk including death in non-SLE populations, even among those without overt obstructive coronary artery disease. We aimed to measure coronary microvascular function by CFR in active SLE patients and to compare findings to those of patients with diabetes mellitus (DM) and non-SLE, non-DM controls.

Methods: We identified SLE patients with active disease (SLE disease activity index > 6), internal organ involvement and no history of known coronary artery disease, followed at the Brigham and Women's Hospital Lupus Center. Premenopausal women and similar aged female controls without SLE or DM were enrolled as comparisons. Demographic and clinical data were collected. All subjects underwent rest and then stress myocardial perfusion PET scans, from which we measured regional and global left ventricular myocardial blood flow (in mL/min/g of tissue) and calculated the CFR as the ratio of myocardial blood flow during stress to that at rest. We used t-tests and Chi-squared tests to compare subject demographic characteristics, and ANOVA tests to compare mean global myocardial blood flow and CFR values between SLE, DM and control subjects.

Results: We studied 8 SLE, 12 DM and 6 control female subjects, all with normal PET scans indicating no evidence of obstructive CAD. Demographics are shown in Table 1. All SLE subjects were anti-dsDNA positive, 5/8 had lupus nephritis, and their mean SLEDAI score was 10 (SD 4.5) (Table 1). Rest myocardial blood flow was comparable across the three groups. Adenosine-stimulated myocardial blood flow was similar in SLE and pre-menopausal diabetic women (2.64 ± 0.52), but 21% lower in SLE patients than in controls (2.44 ± 0.28 vs. 3.09 ± 0.32 mL/min/g, $p < 0.05$) (Table 2). Although SLE patients were younger than the pre-menopausal DM women, they showed similar reduction in global CFR (Figure 1). Compared to controls, subjects with active SLE had a 22% reduction in global CFR (2.84 ± 0.41 vs 3.63 ± 0.96, $p < 0.05$).

Conclusion: Subjects with active SLE had a significant reduction in coronary microvascular function compared to non-diabetes, non-SLE controls. This reduction was similar to that observed in slightly older premenopausal women

Table 1. Subject Characteristics: SLE, Diabetes Mellitus (DM), and Non-SLE, Non-DM Controls undergoing PET-Coronary Flow Reserve (CFR) Imaging

	SLE n=8	Diabetes Mellitus (DM) n=12	p*	Controls n=6	p**

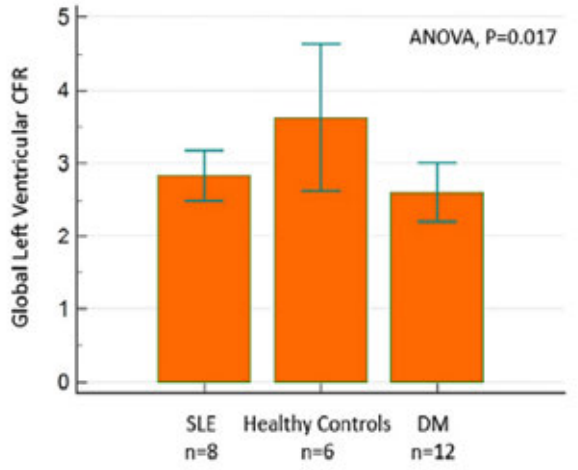
CFR LV, mean (SD)	2.84 (0.41)	2.60 (0.62)	3.63 (0.96)	0.02
* ANOVA test of the differences in the means				

Figure 1. Mean Coronary Flow Reserve (CFR) in SLE compared to subjects with Diabetes mellitus and Non-SLE, Non-DM Controls



with diabetes mellitus. These preliminary findings suggest that coronary microvascular dysfunction, likely driven by inflammation in active SLE, may be an early marker of CVD risk among SLE patients, as it is in DM patients. Although studies are needed, PET-CFR may prove to be a useful tool for stratifying SLE patients in terms of their risks of CVD events and death.

We thank the John J. Holland and Virginia M. Bruen Fund for Systemic Lupus Erythematosus Research for supporting this study.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with pediatric rheumatologic diseases live well into adulthood, necessitating transition from pediatric to adult medical providers. GotTransition.org details 6 core elements clinicians can implement to create effective transition: policy, registry, readiness, planning, transfer and completion.

Methods: The core elements were used to design a transition pathway. A transition policy was created, and a patient registry constructed. Provider-led education on readiness and planning were structured during clinic visits using an electronic medical record-based tool. Patient self-reported transition readiness was assessed with a patient-administered survey, the ADAPT (Adolescent Assessment of Preparation for Transition). All rheumatology providers gave input through monthly transition meetings. Provider participation was encouraged through Maintenance of Certification points.

Results: The transition policy was acknowledged and signed by 33 patients during a pilot release. 481 return patients age 14-19 years were identified by review of clinic schedules and added to the transition registry. ADAPT surveys were completed by 101 patients. Most respondents were 15-18 years of age (79%), female (70%), and Caucasian (77%); 41% were Hispanic. 28% had juvenile arthritis and 18% had lupus. Most patients had private insurance (59%) or Medicaid/Children's Health Insurance Program (36%). Not unexpectedly, ADAPT scores increased with age, and older adolescents (18-19 years) achieved the highest averages: counseling in transition self-management (58/100) and prescription medications (93/100), and in transfer planning (33/100). All patients had scores >50/100 for medications. There was no significant difference in survey results with respect to diagnosis or age at diagnosis. Since the project began, 25 high-risk patients, average age 19.4 years, have transferred into an on-site transition clinic. Transitioned patients attended their first adult appointment an average of 3.2 months from their last pediatric appointment, and only 11% required hospitalization within the first year after transition.

Conclusion: Effective healthcare transitions are critical to the wellbeing of patients with childhood-onset rheumatologic conditions. The creation of a transition pathway in rheumatology clinic has been well received by patients and providers. We have demonstrated good scores for counseling in medications and identified a need to improve self-management and planning counseling. Future directions will include 1) formalizing the final 2 elements of the pathway for all transitioning patients, including standardizing a transition letter to the adult rheumatology provider, and 2) further assessing outcomes. Our ultimate goal is to create a sustainable and successful BRIDGE between pediatric and adult rheumatology care.

A Quality Improvement Project to Increase Documentation Efficiency in an Academic Rheumatology Practice

David Leverenz,[1] Jon Golenbiewski,[1] Brian Andonian,[1] Katherine Kaufman,[1] Philip Chu,[1] Mithunan Maheswaranathan,[1] Andrew Johannemann,[1] Jayanth Doss,[2] and Lisa Criscione-Schreiber[2], [1]Duke University, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: All providers, including rheumatologists, spend approximately half of their day documenting in an electronic health record (EHR). Excessive documentation is a key contributor to burnout, which is associated with reduced quality of care and poor patient satisfaction. We performed a quality improvement project to increase documentation efficiency in an academic rheumatology practice.

Methods: We used Signal, an Epic analytic data tool, to obtain documentation performance metrics. Our primary aim was to reduce average "time in notes per appointment" from over 10 min to 8 min (Epic's nationwide rheumatology average). Secondary measures included average time in the EHR from 7pm-7am and note composition metrics. To assess need and impact, we distributed a pre and post-survey to providers in our practice regarding their documentation practices, satisfaction with documentation time, and engagement with interventions. Using Plan-Do-Study-Act (PDSA) methodology, we conducted these cycles: (1) dictation training, (2) a presentation on recommendations to increase efficiency, and (3) optional individual training sessions with EHR experts. Signal data was recorded weekly except for 7pm-7am time, which was recorded monthly. Data is analyzed using descriptive statistics.

Results: Average "time in notes per appointment" was 11.4 min at baseline, 12 min after PDSA1, 11 min after PDSA2, and 11 min after PDSA3 (Figure 1). Average time in the EHR from 7pm-7am was 33.3 min at baseline vs. 29

Figure 1: Time in Notes per Appointment

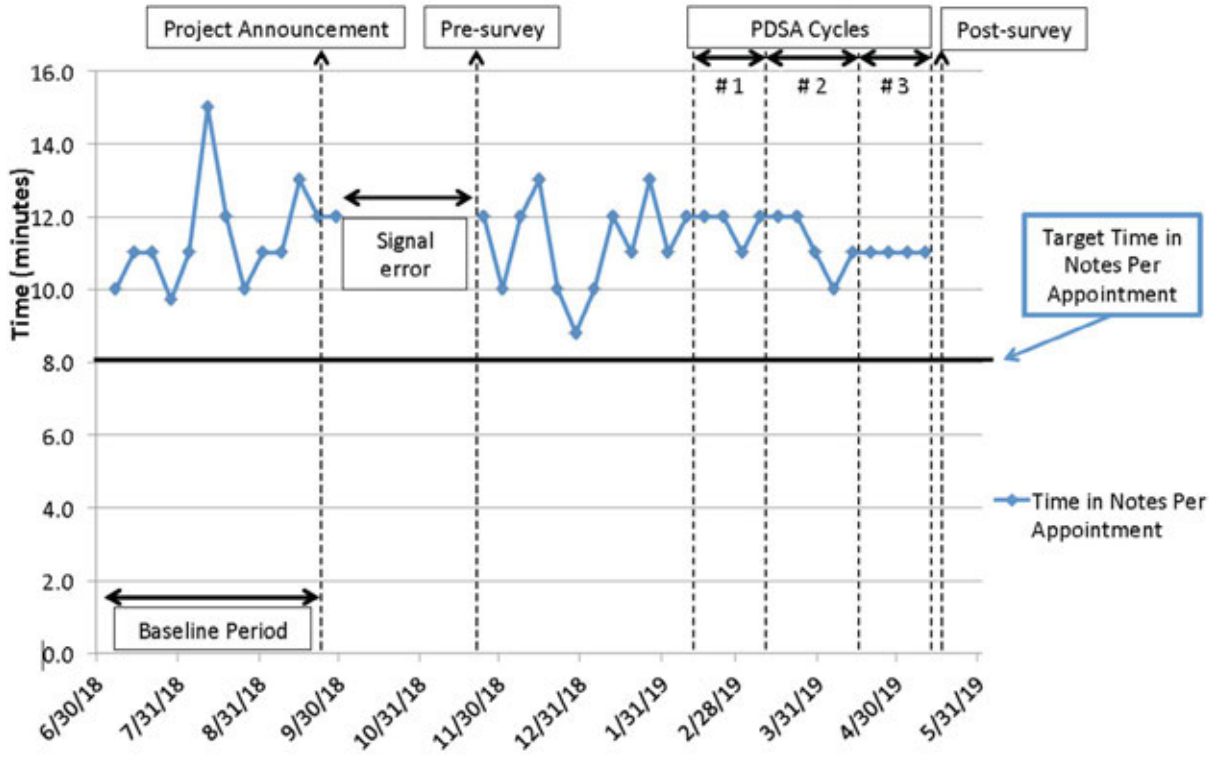

Figure 2: Time in the EHR From 7pm to 7am

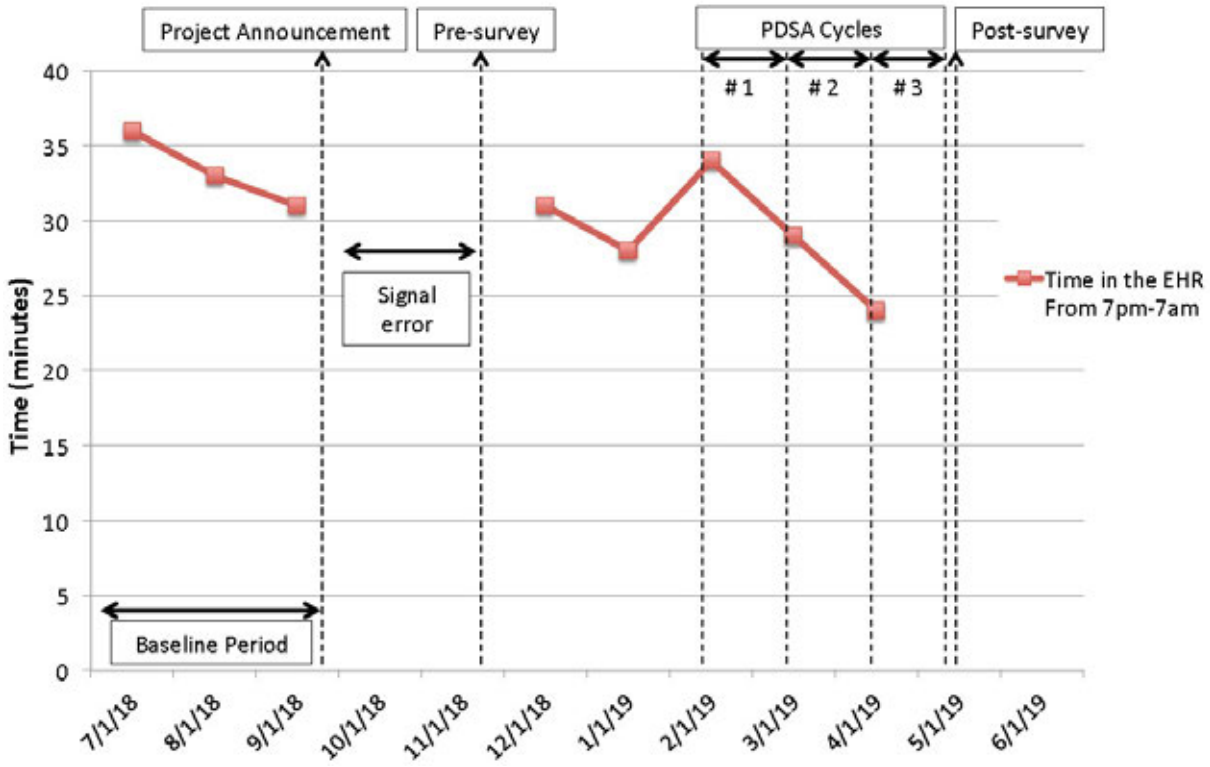

min after PDSA1 and 24 min after PDSA2, data pending from PDSA3 (Figure 2). Average note composition percentages at baseline vs. after PDSA1, 2, and 3 were: manual entry 14.3 vs. 12, 12, and 9.6%; dictation 9.3 vs. 12, 11, and 13%; copy/paste 15.9 vs. 10, 12, and 13%; smart tool 61.3 vs. 66, 66, and 65%. Average documentation length was 6.25K characters at baseline vs. 5.7K, 6.5K and 5.3K (Figure 3). Twenty-five of 27 (93%) providers responded to both the pre and post-surveys. Satisfaction with documentation time on the pre- vs. post-survey was: "completely" or "very dissatisfied" 44% vs. 32%; "dissatisfied" 40% vs. 40%; and "satisfied" 16% vs. 28%. Respondents wrote notes from home "often" or "almost always" in 60% vs. 37.5%. Missing out on activities outside of work in order to finish notes occurred "often" or "almost always" for 24% vs. 12.5%. Regarding engagement with interventions, 32% of post-survey respondents reported newly using dictation software, 36% increased their use of dictation, and 52% modified note templates.

Conclusion: Though we did not meet our aim of reducing average time in notes per appointment, interventions led to providers using more dictation and smart tools with a corresponding reduction in manual data entry. Perhaps most importantly, both Signal and survey data suggested that providers spent less time in the EHR at home after our interventions; the percentage reporting missing out on activities outside work to document dropped by half. Practice-wide focus on improving documentation efficiency led to improved satisfaction with the documentation process and enabled providers to enjoy more activities outside of work. Future measurement targets may include care quality and burnout metrics.

Application of the Systemic Lupus Erythematosus (SLE) Quality Indicators in Patients Attending a Young Adult Transition Program

Aos Aboabat,[1] Earl D. Silverman,[2] and Amanda Steiman[1], [1]University of Toronto, Toronto, ON, Canada, [2]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Translational Medicine, Research Institute, The Hospital for Sick Children, Toronto, Canada

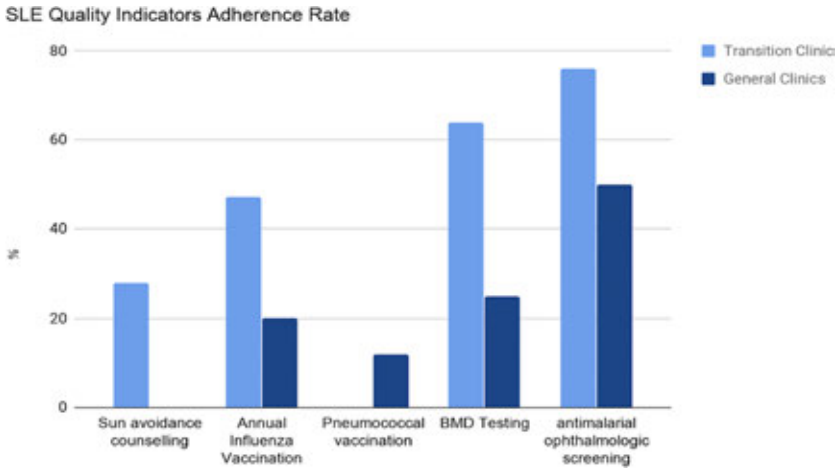
SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures Of Healthcare Quality Poster II: Improving Care

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM



Background/Purpose: Systemic lupus erythematosus is a multisystemic rheumatic disease affecting 1 in 1000 individuals with a 10:1 female predominance. Childhood-onset SLE (CSLE) constitutes approximately 15% of all SLE diagnoses and, when compared to adult-onset disease, CSLE is typically more severe with increased disease and treatment-associated morbidity and mortality. While long term survival of patients with SLE has improved significantly in recent decades morbidity from the disease, itself and its treatment remains an ongoing challenge. Quality indicators (QIs) for SLE have been proposed for adult-onset disease, focused on health maintenance and management of disease- and treatment-related morbidity. These, in turn, may serve as proximate surrogates for longer-term SLE-associated outcomes. The literature reveals that these are performed suboptimally in virtually every clinical setting studied, citing time constraints, forgetfulness, and more pressing issues to address. In efforts to ascertain whether the optimal quality of care is being delivered to these at-risk cSLE patients, and with a view to tailoring Quality Improvement interventions that would be most impactful, we measured the consistency with which five SLE Qis were applied in a young adult transition cohort compared to routine care.

Methods: A comprehensive chart review of all patients attending a young adult SLE transition clinic at a single, tertiary care site was conducted. The three most recent visits were reviewed. Binary data were abstracted from each chart to determine whether there was documentation of sun avoidance counseling, annual influenza vaccine counseling, bone health screening, and anti-malarial-associated ophthalmologic screening, over the visits abstracted. The data were then compared with patients attending the clinics of the two physicians who see the majority of lupus patients at the same institution. Suboptimal adherence was defined as less than 80% in any of the five quality indicators and a difference of < 35% was treated as comparable between the two groups.

Results: A total of 16/57 (28%) patients were counseled regarding sun avoidance. Out of 32 patients on immunosuppressive therapy; 15 (47%) had annual influenza vaccine counseling and none (0/32) received pneumococcal vaccination. Of patients at risk of osteoporosis; 64% underwent BMD testing. Among patients receiving antimalarials; 43/56 (76%) had their eye exam up to date. The comparator group had a comparable rate in sun avoidance counseling (0%), pneumococcal vaccine (12%) and HCQ-associated eye screening (50%) and worse in annual influenza vaccine (20%) and osteoporosis screening (25%).

Conclusion: The Young Adult Transition Program is adhering suboptimally to the five reviewed QIs, as has been demonstrated in studies at other institutions. Efforts to improve uptake of these QIs will be undertaken, with Quality Improvement interventions driven by the results of a root cause analysis for each QI.

Effect of a Clinical Decision Support System on a Quality Indicator of Glucocorticoid-induced Osteoporosis and Trends of Drug Treatment in a Japanese Hospital

Hiroki Ozawa,[1] Sho Fukui,[1] Genki Kidoguchi,[1] Takehiro Nakai,[2] Satoshi Kawaai,[1] Ayako Koido,[1] Yukihiko Ikeda,[1] Masei Suda,[1] Haruyuki Yanaoka,[1] Hisanori Shimizu,[1] Hiromichi Tamaki,[1] Tokutaro Tsuda,[1] Mitsumasa Kishimoto,[3] Kenichi Yamaguchi,[1] and Masato Okada[1], [1]St.Luke International Hospital Immuno-Rheumatology Center, Tokyo, Japan, [2]St.Luke International Hospital Immuno-Rheumatology Center, Tokyo, Tokyo, Japan, [3]Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures Of Healthcare Quality Poster II: Improving Care

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

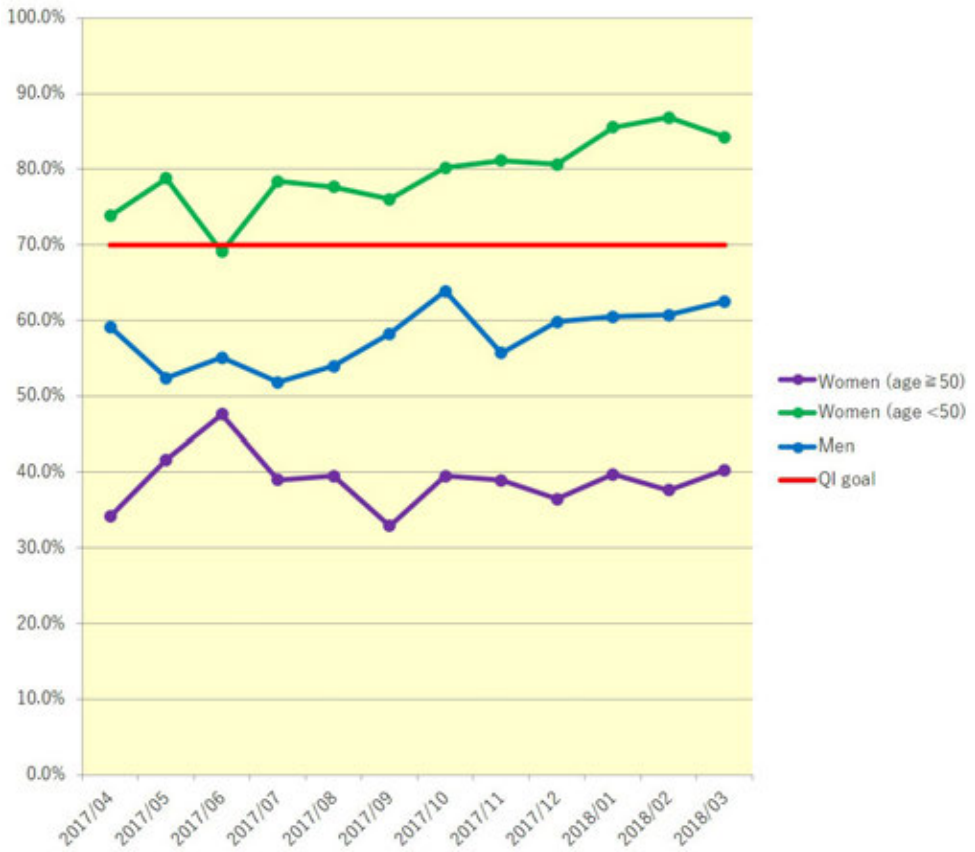

Figure 1. QI trends in each group

Background/Purpose: Glucocorticoid-induced osteoporosis (GIOP) is a common, preventable and treatable complication of glucocorticoid therapy. We defined quality indicator (QI) for GIOP and took a hospital-wide systematic approach with QI monitoring to improve real-world GIOP care. However, there was still room for improvement. Then, we introduced a clinical decision support system (CDSS) in our electronic health record (EHR) to increase the prescription rate of anti-osteoporotic drugs.

Methods: We defined a QI for GIOP care for the prescription rate of anti-osteoporotic drugs according to 2010 American College of Rheumatology GIOP management recommendations, with the target being patients prescribed ≥7.5 mg prednisolone daily or its equivalent for ≥3 months. We monitored the glucocorticoid and anti-osteoporotic medication dose for all patients who visited our hospital, since May 2011. In October 2017, we introduced CDSS to EHR in Immuno-Rheumatology Center (IRC) in our hospital. CDSS were developed as a guide for clinicians to prescribe anti-osteoporotic drugs appropriately. CDSS were designed to appear as a box in a display on the date of target patients' visit, if they have not been prescribed anti-osteoporotic drugs. Clinicians can choose to prescribe the drugs or not. If they didn't prescribe the drugs, they were urged to choose the reasons and such cases were excluded from QI monitoring. We retrospectively analyzed QI trends for 6 months before and after the induction of the CDSS in 2017-2018.

Results: The total number of participants was 3072, 1573 in 6 months before and 1499 after the induction of the CDSS, with pooled QI rates of 57.9% and 61.6%. The number of participants from IRC was 1815(59.0%). Changes in QI improvements between the periods are statistically significant. In subanalysis, the prescription rate for women who were younger than 50 years old and men showed an increasing trend(Fig 1).

Conclusion: CDSS that guide clinicians to prescribe anti-osteoporotic drugs improved QI of GIOP. In addition, changes of rheumatologists' prescription contributed to the improvement of QI in the whole of our hospital.

EMR-integrated Disease Activity Calculators Improve Treatment to Target in Rheumatoid Arthritis

Gabrielle Barbera,[1] Jasleen Kahlon,[2] Manank Patel,[3] Scott Pompa,[4] and Arundathi Jayatilleke[1], [1]Drexel, Philadelphia, PA, [2]Hahnemann, Philadelphia, PA, [3]Rutgers, New Brunswick, NJ, [4]Dartmouth, Lebanon, NH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Undertreatment of RA can lead to cumulative joint damage as well as negatively impact emotional health. Recent evidence favors a treat-to-target strategy to achieve remission or low disease activity (DA) using objective scores such as the clinical disease activity index (CDAI) or the DAS28. We hypothesized that integration of CDAI and DAS28 calculators into electronic medical records (EMR) would improve treatment to target.

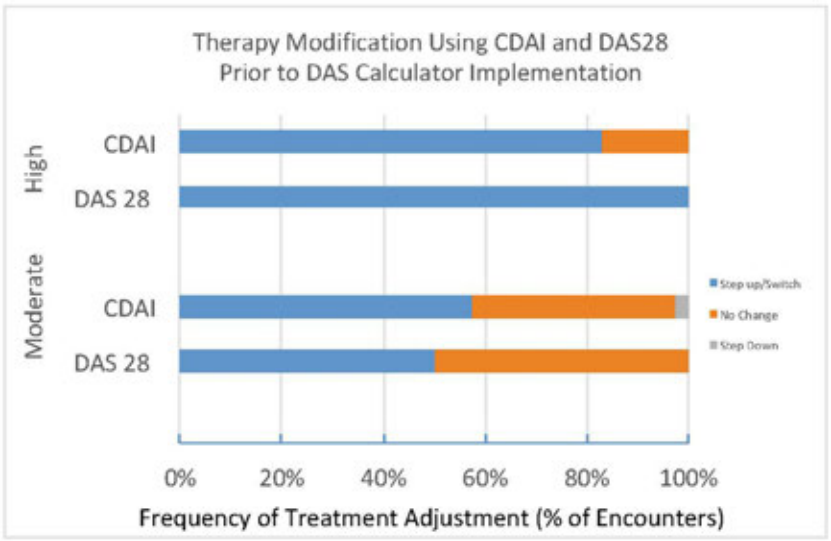

Figure 1. modification of RA treatment to target prior to implementation of EMR DAS calculators.

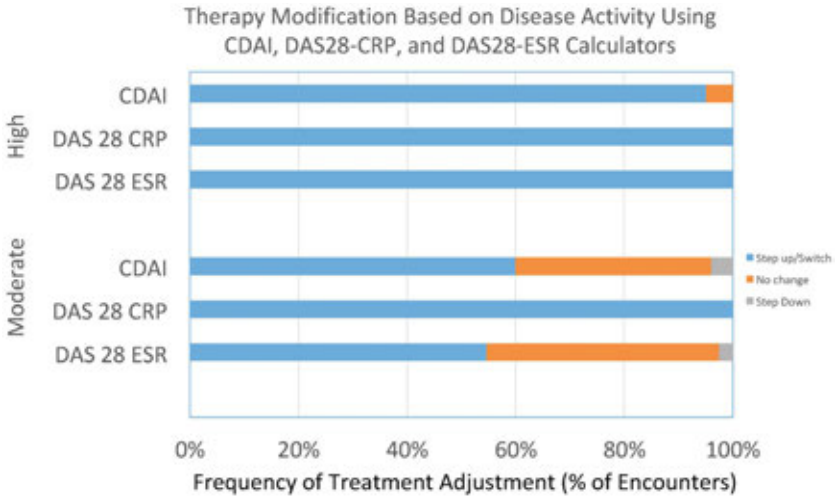

Figure 2. modification of RA treatment to target after implementation of EMR-based CDAI and DAS28 calculators.

Methods: We performed a retrospective chart review of all RA patients in our academic rheumatology clinic who had a documented DA score, comparing treatment practices for 18 months before and after calculator implementation (March 2015). We identified patients using ICD-9 and ICD-10 codes for RA. Before implementation, we used natural language processing to search note text for CDAI, DAS, DAS28, DAS 28, and "disease activity score." After implementation, we searched for results of DAS28-ESR, DAS28-CRP, and CDAI calculators in patient charts. We analyzed charts for a step-up/switch (addition or increase in dose of steroid or addition, dose increase, or change of synthetic or biologic DMARD), no change, or step down in therapy in response to the first moderate or high score for each patient.

Results: Prior to incorporation of DA calculators in the EMR, out of 732 patients, 14% had at least one recorded CDAI and 4% had at least one DAS28, respectively. After implementation, out of 895 patients, 23% , 2.6%, and

17% had at least one recorded CDAI, DAS28-CRP, and DAS28-ESR, respectively. Both before and after calculator implementation, therapy was intensified the majority of the time in patients with moderate (50-60%) or high activity (80-100%) (see figures 1 and 2).

Conclusion: As expected, implementation of EMR-integrated DA calculators greatly improved DA score documentation. However, even after calculator integration in our EMR, scores were recorded < 25% of the time, with CDAI being the most commonly used measure. For patients in whom DA calculators are used, providers in our clinic adjusted therapy in response to DA level about 50-60% of the time after a moderate DAS and about 90% of the time after a high DA score, suggesting that they are following the treat-to-target recommendations. Targeted education to increase provider use of existing DA calculators may thus lead to improved patient outcomes. We plan to systematically examine charts to understand why there was no change or a step down in therapy in patients with moderate or high DA. Future studies include examining the time to initiation of biologic therapy in newly diagnosed RA patients before and after implementation of EMR DA calculators to assess impact on prescribing practices.

Disclosure: G. Barbera, None; **J. Kahlon**, None; **M. Patel**, None; **S. Pompa**, None; **A. Jayatilleke**, None.

Can an MDHAQ (Multidimensional Health Assessment Questionnaire) 60-Symptom Checklist to Monitor Early Medication Outcomes (MDHAQ/MEMO60) Detect Adverse Events of High-Risk Medications?

Sarah Abu Mehsen,[1] Isabel Castrejon,[1] and **Theodore Pincus** [2], [1]Rush University Medical Center, Chicago, IL, [2]Division of Rheumatology, Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adverse events of medications have been reported to account for 5% of hospital admissions in the US, and as many as 10% in the elderly. Strategies for vigilance for adverse events are actively promoted by physicians, pharmacies, pharmacists, and pharmaceutical companies. Some adverse events are relatively obvious, such as a severe rash or severely abnormal laboratory test. However, many adverse events are common symptoms, such as fatigue, headache, anxiety, which might not be recognized as adverse events until present over long periods, particularly in elderly individuals who have one or more chronic conditions. An MDHAQ (multidimensional health assessment questionnaire) has been found to be useful in all rheumatic diseases studied[1]. The MDHAQ includes a 60-symptom checklist that can be used to monitor adverse events. We analyzed a hypothesis that a 60-symptom checklist to monitor early medication outcomes (MDHAQ/MEMO60) could be useful to recognize adverse events in patients who are treated with RA medications.

Methods: At one academic rheumatology site, all patients complete an MDHAQ at all visits prior to seeing the rheumatologist to add to quality of care. The 2-page MDHAQ includes 0-10 scales for physical function + pain + patient global VAS, compiled into a continuous 0-30 RAPID3 (routine assessment of patient index data), to depict

Symptom listed on MDHAQ/MEMO60	RA patients N=711 (100%)	Methotrexate	Leflunomide	HCQ	Etanercept	Infliximab	Adalimumab	Anakinra	Abatacept	Rituximab
Headache	251 (35%)	X		X		X	X	X	X	
Unusual fatigue	237(33%)	X		X		X				X
Anxiety-feeling nervous	179 (25%)			X						
Cough	132 (19%)		X				X		X	
Dizziness	127 (18%)	X		X					X	
Loss of hair	116 (16%)	X	X	X						
Nausea	95 (13 %)	X	X	X		X		X	X	X
Skin rash or hives	92 (13%)	X	X			X	X	X		X
Stomach pain/cramps	92 13%)	X	X	X		X		X	X	
Eye problems	92 (13%)	X		X						
Anorexia/weight loss	90 (13%)	X		X						
Diarrhea	63 (9%)	X	X	X	X			X		
Fever	55 (8%)	X			X	X				
Mouth sores	45 (6%)	X								X

Table. Number and percent of 711 patients with RA who self-reported specific symptoms on the MDHAQ/MEMO checklist at the first visit recorded in the electronic medical record.

clinical status. The MDHAQ also includes a 60-symptom checklist to recognize comorbidities, review of systems, and potential adverse events associated with medications. Completed paper versions of MDHAQ from routine care are scanned into an Epic electronic medical record (EMR) and copied into a data repository for retrospective analyses. A list of common adverse events of many specific DMARDs (disease-modifying antirheumatic drugs) and biological agents used to treat rheumatoid arthritis (RA) was compiled from websites of the FDA, pharmaceutical companies, and Up-to-date.® A retrospective review of scanned MDHAQs at the first visit were included in a database of ICD-code-identified RA patients. This database was analyzed to recognize symptoms self-reported on MDHAQ/MEMO60 which were listed as common adverse events for RA medications , using simple descriptive statistics.

Results: Among 711 RA patients identified at their first visit, 84% were females, mean age was 58.5 (15.2) years, 40% were White, 30% Black, 23% Latino, 7% "other." Among commonly-listed specific adverse events associated with RA medications, more than 30% of 711 patients reported headache and/or unusual fatigue (Table); 20-30% anxiety-feeling nervous; 10-20% cough, dizziness, hair loss, nausea, skin rash or hives, stomach pain or cramps, eye problems, and/or weight loss; and 5-10% diarrhea, fever, and/or mouth sores (Table).

Conclusion: MHDAQ/MEMO60 may prove valuable to detect adverse events of high-risk medications. A program involving completion of a weekly remote electronic MDHAQ at home for 12 weeks after initiation of a new medication may be a cost-effective approach for early recognition of efficacy and detection of adverse events.

Quantitative Physician Global Assessment of Damage And/or Distress, in Addition to Inflammation, at Routine Rheumatology Care: Documenting the Complexity of Rheumatology Patient Encounters as a Rationale for Possible Higher Reimbursement?

Theodore Pincus,[1] Isabel Castrejon,[2] and Joel A. Block[2], [1]Division of Rheumatology, Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Quantitative clinical measures and indices such as DAS28, CDAI, SLEDAI, BASDAI, are designed to assess inflammation, reflecting a goal to prevent long-term damage, and are effective in patients selected for high activity in clinical trials. However, in rheumatology routine care, many patients have clinically important damage of joints and other organs and/or distress, as fibromyalgia, manifested by similar signs and symptoms to those seen in inflammation, i.e., functional disability, pain, fatigue, high patient global assessment and tender joint counts, but damage and distress are not recorded quantitatively. Patients with many non-rheumatic diseases, e.g., diabetes, also may have clinically important damage and/or distress, which is usually ignored unless presenting an acute problem, as signs and symptoms differ from the "gold-standard" biomarker (hemoglobin A1c) that is predominant in clinical decisions[1]. By contrast, rheumatology signs and symptoms of damage and/or distress may be similar to those of inflammation. The expertise of the rheumatologists may be viewed to recognize whether findings are primarily a result of inflammation, damage, and/or distress, and possibly 2 or 3 of these variables. This process involves greater complexity in the examination room than application of a gold-standard biomarker acquired (and reimbursed) elsewhere, and may provide a rationale for higher reimbursement, but is not recorded quantitatively. We examined a hypothesis that many routine care patients have findings of 2 or 3 components of inflammation, damage and/or distress to explain a physician global assessment (DOCGL).

Table. Physician ratings of VAS for inflammation, damage and distress in and % of DOCGL 567 patients and (% of total) seen in routine clinical care

INFLAMMATION %	INF 0-20%	INF 21-40%	INF 41-100%	%INF Total
VAS INF 0-2.0	309 (54%)	35 (6%)	48 (8%)	392 (69%)
VAS INF 2.1-4.0	10 (2%)	28 (5%)	73(13%)	111 (20%)
VAS INF 4.1-10.0	6 (1%)	9 (2%)	49 (9%)	64 (11%)
Total	325 (57%)	72 (13%)	170 (30%)	567
DAMAGE %	DAM 0-20%	DAM 21-40%	DAM 41-100%	% DAM Total
VAS DAM 0-2.0	164 (29%)	24 (4%)	44 (8%)	232 (41%)
VAS DAM 2.1-4.0	20 (4%)	39 (7%)	129 (23%)	188 (33%)
VAS DAM 4.1-10.0	10 (2%)	13 (3%)	124 (22%)	147 (26%)
Total	194 (34%)	76 (13%)	297 (52%)	567
DISTRESS %	STR 0-20%	STR 21-40%	STR 41-100%	% STR Total
VAS STR 0-2.0	126 (22%)	14 (2.4%)	92 (16%)	232 (41%)
VAS STR 2.1-4.0	142 (25%)	10 (2%)	36 (6%)	188 (33%)
VAS STR 4.1-10.0	125 (21%)	9 (1%)	13 (2%)	147 (26%)
Total	393 (69%)	33 (6%)	141 (25%)	567

Methods: Rheumatologists at one academic site complete a RheuMetric checklist which includes a physician global assessment (DOCGL) scores on a 0-10 visual analogue scale (VAS), and 3 additional 0-10 VAS subscales for inflammation (DOCINF), damage (DOCDAM), and distress (DOCSTR), as well as the % of DOCGL attributed to each of the 3 variables (Total=100%) to explain the basis for DOCGL. VAS scores classified as 0-2, 2.1-4, 4.1-10, and % of DOCGL classified as 0-20, 21-40, 41-100% were compared using descriptive statistics and cross-tabulations.

Results: In 567 unselected patients, DOCINF was >4/10 in 11%, vs 26% each for DOCDAM and DOCSTR (Table), indicating that 37% (=100-11-26-26) had at least 2 clinically important (VAS >2) variables, and 9% all 3 (data not shown). The proportion of patients in whom DOCGL was regarded as explained >40% by inflammation was 30%, vs damage in 52% and distress in 25% (Table). Therefore, a single basis for signs and symptoms was most prominent only in a minority of patients.

Conclusion: Quantitative rheumatologist VAS indicate that organ damage and patient distress often are as prominent as inflammation, and patients may have 2 or 3 bases for signs and symptoms. If confirmed at other sites, the results suggest a rationale to record a VAS for inflammation, damage, and distress, to document greater complexity of rheumatology encounters vs those based on a "gold standard" biomarkers, and possible adjustments in reimbursement for quantitative data to document the expertise of rheumatologists.

Patient Preference for an Electronic MDHAQ/RAPID3 (Multidimensional Health Assessment Questionnaire/ Routine Assessment of Patient Index Data), Which Gives Similar Results Compared to a Paper Version

Theodore Pincus,[1] Mariam Riad,[1] Elena Obreja,[2] Candice Lewis,[2] and Isabel Castrejon[2], [1]Division of Rheumatology, Rush University Medical Center, Chicago, IL, [2]Rush University Medical Center, chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A self-report multi-dimensional health assessment questionnaire (MDHAQ) includes RAPID3 (routine assessment of patient index data), which is informative in all rheumatic diseases in which it has been studied. An electronic version of the MDHAQ (eMDHAQ) could offer several advantages, including completion at home rather than in the waiting area, as well as completion from any site between visits to report possible change in status and/or adverse events of a medication. Furthermore, the eMDHAQ includes 3 additional features beyond RAPID3 requiring computer software: a. MDHAQ/FAST3 (fibromyalgia assessment screening tool) - a 0–3 clue to fibromyalgia (FM) with 80% agreement with formal FM criteria; b. MDHAQ/MEMO60 (monitoring early medication outcomes) - using weekly

MDHAQ Variable:	Paper	I-Pad	Diff. (95%CI)	ICC (95%CI)
Physical Function (0-10)	2.0 (1.7)	2.0 (1.7)	0.04 (-0.6, 0.6)	0.96 (0.94, 0.98)
Pain (0-10)	5.3 (3.2)	5.1 (3.1)	0.3 (-0.8, 1.4)	0.87 (0.80, 0.92)
Patient global (0-10)	4.8 (2.8)	4.5 (2.8)	0.3 (-0.7, 1.3)	0.94 (0.90, 0.96)
RAPID3 (0-30)	12.1 (7.1)	11.4 (7.2)	0.7 (-1.7, 3.2)	0.93 (0.88, 0.95)
Symptom checklist (0-60)	9.9 (8.5)	10.8 (9.5)	-0.9 (-4.1, 2.2)	0.75 (0.62, 0.84)
RADAI-48 (0-48)	9.9 (8.9)	11.4 (10.7)	-1.4 (-7.9, 1.9)	0.81 (0.71, 0.88)

Table. Mean (SD) values and ICC for paper MDHAQ versus I-pad e MDHAQ in 65 unselected with various rheumatic diseases patients.

remote electronic monitoring for 12 weeks after a new medication to analyze efficacy and adverse events; c.MDHAQ/LUCID (lifetime updatable clinical informatics database) - to provide medical history information in medical record format for physicians and to allow patients to save and update their medical history at a secure, HIPAA-compliant website for use with any doctor. We compared scores on an eMDHAQ vs paper version of MDHAQ at the same encounter, as well as patient preferences for the electronic vs paper MDHAQ.

Methods: All patients with all diagnoses complete a paper MDHAQ at all visits in the waiting area as part of routine clinical care. The MDHAQ includes 0-10 scores for physical function, pain and patient global visual analog scales (VAS), compiled into 0-30 RAPID3, as well as a 0–48 self-report painful joint count, and 0–60 symptom checklist. For this study, at the conclusion of the visit, the rheumatologist asked a patient if she/he would volunteer to complete an eMDHAQ on an iPad, indicating no problem if a patient declined. Patients who volunteered then completed an iPad eMDHAQ, with identical content to the paper MDHAQ. The patient also completed a 3-query questionnaire of 2 VAS concerning the value of the MDHAQ to the patient or the doctor (0= no value, 10= great value), and a query concerning preference for eMDHAQ vs paper MDHAQ or no preference. Test-retest reliability was examined by intraclass correlation coefficients (ICC).

Results: In 65 study patients, ICCs for physical function, patient global VAS, and RAPID3 were >0.9 indicating excellent reliability between the paper and Ipad eMDHAQ, and for pain, self-report painful joint count, and symptom checklist ≥0.75, indicating good reliability. The mean ratings for the value of MDHAQ were 8.85/10 to the patient and 8.88/10 to the doctor. Among the 65 patients, 43 (66%) preferred the eMDHAQ, 7 (11%) the paper MDHAQ, and 15 (23%) indicated no preference.

Conclusion: An eMDHAQ provides similar results to a paper MDHAQ. Most patients preferred the eMDHAQ to paper, although about 20% of patients likely will require a paper MDHAQ. An eMDHAQ offers remote completion before and/or between visits, and to report problems and/or adverse events, as well as unique electronic features. eMDHAQ is designed to interface with any electronic medical record (EMR), although that requires interaction with the EMR vendor, which may be difficult. The eMDHAQ appears useful independent of the EMR.

Factors Associated with Clinical Disease Activity Index Adoption at an Academic Rheumatology Practice

Tarun Sharma,[1] Kevin Wetherington,[2] Lori Mcaninch,[2] Abdalhamid Al Harash,[1] Nagadarshini Vinod,[2] Sonia Manocha,[3] Adam Dore,[3] Michael Lucke,[3] William Ayoub,[1] and Mary Chester Wasko[4], [1]Allegheny Health Network, Pittsburgh, PA, [2]AHN, Pittsburgh, [3]Allegheny Health Network, pittsburgh, [4]Allegheny Health Network-West Penn Hospital, Pittsburgh, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2015 American College of Rheumatology (ACR) guidelines for the treatment of rheumatoid arthritis (RA) strongly recommend using a treat-to-target (T2T) strategy that has demonstrated improved outcomes compared to a non-targeted approach. The crux of any T2T treatment pathway is accurate and consistent disease activity measurement using an ACR endorsed tool like the clinical disease activity index (CDAI). The aim of our study was to measure trends and predictors of CDAI adoption at our tertiary academic rheumatology practice comprised of community-based and teaching sites.

Methods: Consecutive adult RA patients at our tertiary care rheumatology practice beginning 10/1/18 were prospectively identified using a previously validated codified algorithm. As part of the T2T approach implementation, CDAI questionnaire completion rates by 21 providers were measured longitudinally. The formula utilized for CDAI calculation was 'number of times CDAI score was completed' divided by 'total number of RA outpatient opportunities to complete CDAI'. Performance data was tracked longitudinally over 7 months and shared transparently at monthly intervals as aggregate and individual performance reports with all providers. We also segregated performance data by teaching faculty, trainees, non-physician providers, and disease activity level to help predict performance.

Results: A total of 3838 RA office visits with 21 providers were utilized for calculating aggregate CDAI performance metrics from 10/1/18 through 4/30/19 (Figure 1). Aggregate performance steadily improved from 10% to 26% over the 7 month period. Fellow trainees (NDV, AA) were found to have 90-100% CDAI utilization. Performance was noted to be skewed to a mean of 70% CDAI use by 6 teaching faculty compared to lower or no CDAI use at community-based sites. Sharing performance reports monthly by provider and aggregate via email was correlated with perfor-

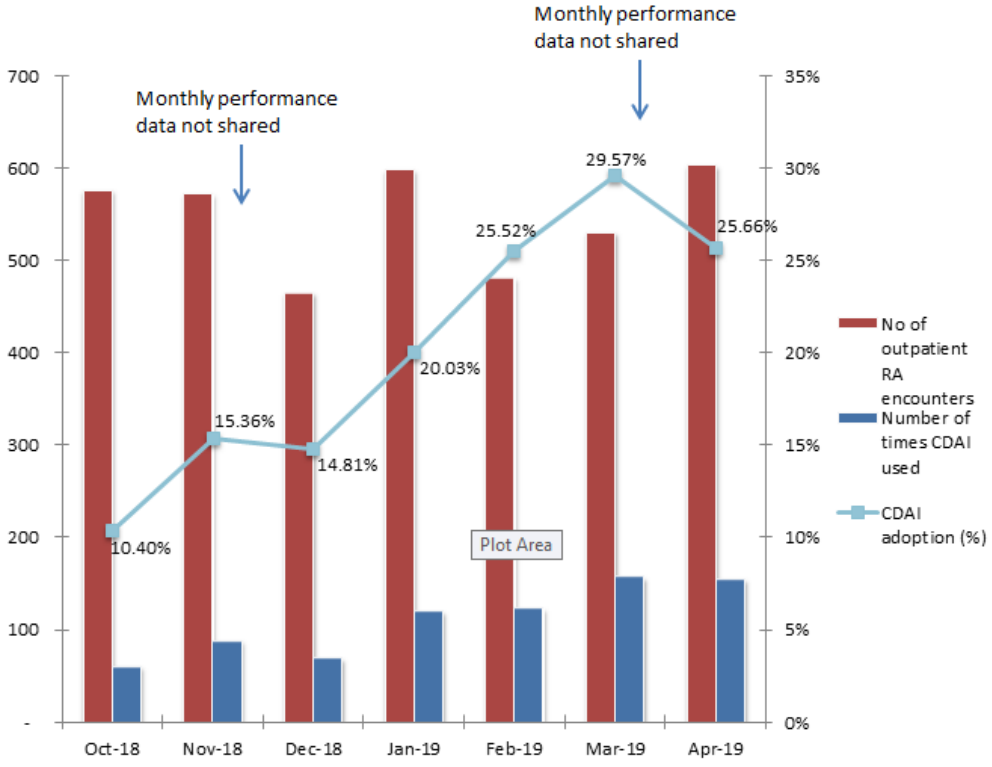

Figure 1. Clinical Disease Activity Index (CDAI) performance trend over 7 months

mance improvement in the month following the report, whereas a decline was noted in months of 12/18 and 4/19 where the previous month's reports were not shared.

Conclusion: Longitudinally tracking performance metrics and sharing data transparently could be vital to implementing a disease activity measurement. Providers at teaching sites and trainees may be early adopters and are more likely to demonstrate steady performance improvement. We believe that this deeper understanding of variation would be helpful in building the foundation of future T2T based treatment pathways.

Practice Based Education Program to Increase Vaccination Rate in Patients on Immunotherapeutic Agents

Andrea Soliman,[1] Soorya Aggarwal,[1] Kyle Kreitman,[1] Kourtney Erickson,[1] Abdul Aleem,[1] and Marie O'Brien[1], [1]Lehigh Valley Health Network, Allentown, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immunosuppressive agents have changed the course of debilitating autoimmune conditions. Despite their advantages, these agents come with risk of vaccine preventable infections.[1]Multiple organizations recommend scheduled influenza and pneumococcal vaccinations in all patients on chronic immunosuppression.[2,3]

Clarity regarding indication and timing of vaccinations has been problematic as new biologic therapies enter clinical practice. A 1996 Medicare survey of 16,000 patients on biologics showed a common reason for low adherence is not knowing the indications or vaccine schedules.[5]While physician specialists often initiate biologic therapy, primary care physicians typically have more access to vaccines. As a result, according to the Center for Disease Control (CDC) in 2014, vaccination adherence remains low amongst high-risk persons aged 19-64 years.[4]

In an outpatient primary care setting, we implemented a protocolized vaccination program for patients on immunosuppressive medications to increase influenza and pneumococcal vaccination adherence by at least 15% for each vaccine.

Methods: A retrospective, chart analysis identified 756 patients on biologic agents in Internal Medicine and Rheumatology practices. From this population, each patient was evaluated for compliance with CDC guidelines for immunocompromised patients for Influenza, Pneumococcal 13-Valent Conjugate and Pneumococcal Polyvalent vaccines. After data was collected, each practice received educational outreach and resources to serve as reminders to improve vaccination adherence. After the completion of the subsequent influenza season, the same patients were reviewed to obtain adherence data after the intervention.

Results: Of the patients studied, a majority of patients 65.2% (n=493) had rheumatoid arthritis, 19.6% had psoriatic arthritis, 7.0% had ankylosing spondylitis, and 8.1% had other conditions. The most common medications used were etanercept (35.5%, n=268) and adalimumab (35.1%, n=265). Prior to the educational program, 62.0% (n=469)

received influenza vaccinations, 34.0% (n=257) received pneumococcal 13-valent conjugate and 51.9% (n=392) received pneumococcal 23 vaccination. After the program, 65.1% (n=487) received influenza, 49.9% received pneumococcal 13-valent conjugate and 59.8% (n=447) received pneumococcal 23 vaccine. Overall, adherence to vaccination schedule increased from 18.9% (n=143) to 29.9% (n=224).

Conclusion: Patients on biologic therapies remain vulnerable to vaccine preventable illnesses such as Pneumococcal Pneumonia and Influenza. Based on our quality improvement initiative, there was an increase in overall vaccination adherence by 11% (n=81) in an at risk patient population. Despite this, inadequate resources and communication issues still remained an obstacle for primary care providers and specialists. In response to feedback from clinicians, a vaccination clinic is being developed in order to improve access to patients requiring vaccinations. Additionally, we have been working to optimize our best practice alert advisory through EMR, to improve communication between providers for our at risk population.

Abstract Number: 1199

Improving Rates of Cervical Cancer Screening and HPV Vaccination in Patients with Lupus

Nancy Desai,[1] Hanni Menn-Josephy,[1] Ramon Bonegio,[1] Christina Lam,[1] Anna Kancharla,[1] and Michael York[1], [1]Boston Medical Center, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with lupus have higher rates of cervical dysplasia and pre-malignant cervical lesions. At our institution, an urban referral center for patients with lupus, rates of HPV vaccination and cervical cancer screening were unknown. The aim of our quality improvement project was to determine the rate of HPV vaccination completion and cervical cancer screening compliance among the lupus patients seen in our institution as well as to implement a process to increase patient education and improve both rates within the outpatient rheumatology, nephrology and dermatology clinics over three months.

Methods: Using administrative records, all patients with a diagnosis of lupus seen in the clinics over a 3-year period were identified, of whom 11.4% were male and 88.6% female. A chart review of 332 patients was performed by a single physician to determine the rate of HPV vaccination completion and the rate of compliance with cervical cancer screening. We implemented a system to flag providers through the electronic health record regarding streamlined access to vaccination and facilitating referral for screening exams. Patients were also provided educational brochures about their increased risk of developing cervical lesions, recommended screening and HPV vaccination guidelines. Three months after implementing these processes, we re-evaluated the rates of HPV vaccination and cervical cancer screening.

Results: Prior to the intervention, 41.6% of lupus patients had received HPV vaccination, which was 24.4% lower than the national average for the general population. Cervical cancer screening was 43.8% pre-intervention, which was 32.2% lower than the national average. After implementing the system to flag providers and increase

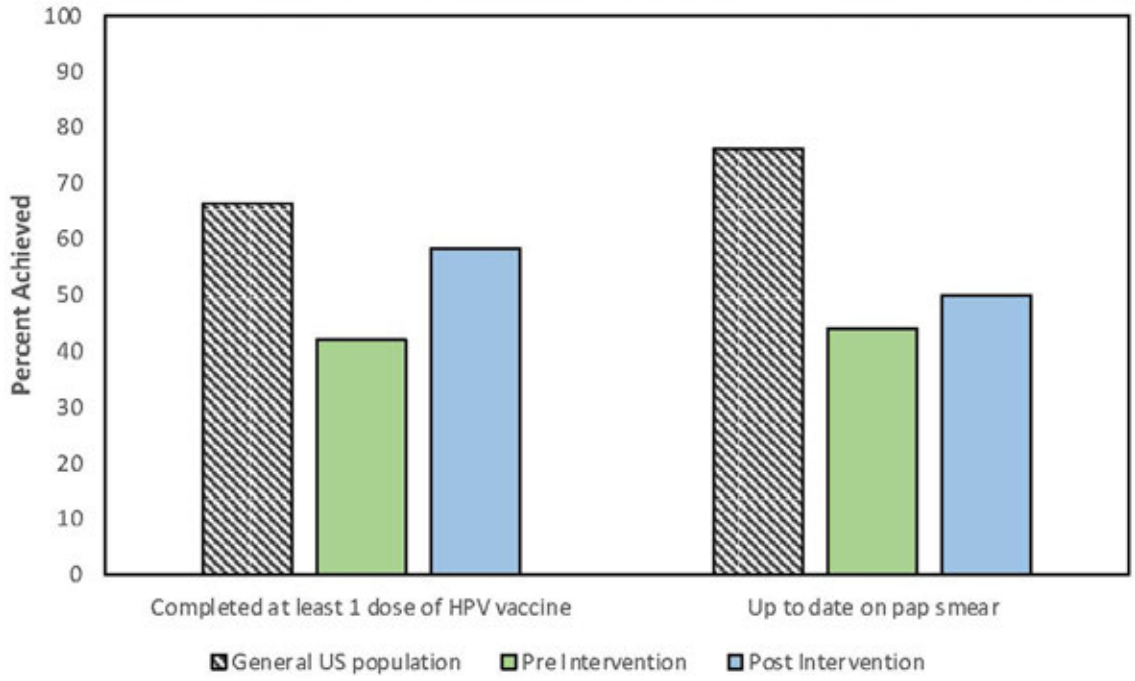

Figure 1. Rates of HPV vaccination and pap smears among lupus patients at our institution and in the general US population.

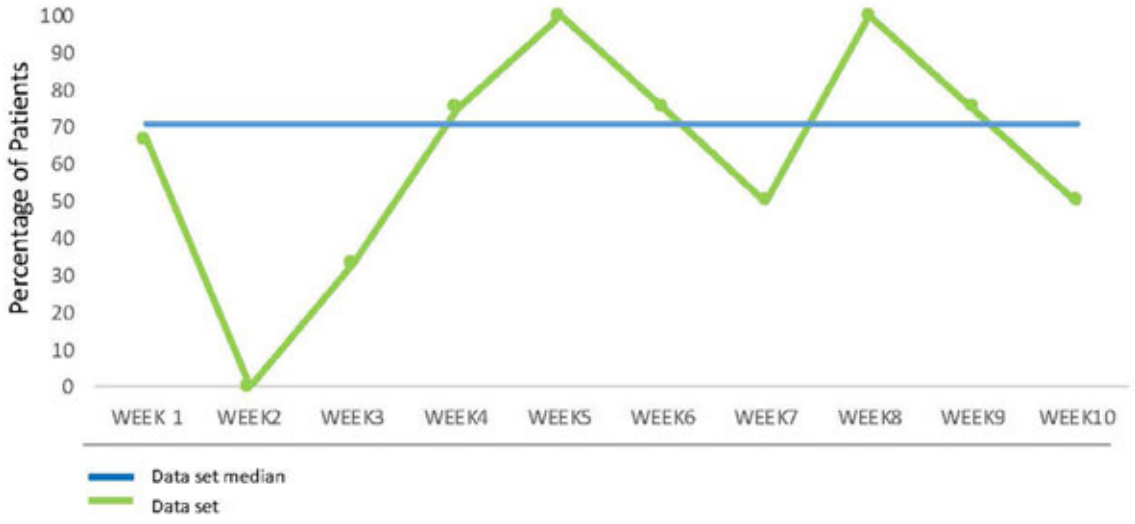

Figure 2. A run chart representing percent of lupus patients seen in outpatient rheumatology, nephrology, and dermatology clinics that were provided educational materials on cervical cancer screening and HPV vaccination.

patient education, we were able to improve these rates. Over three months, 71.8% of all patients seen in the clinics were provided education and 38.5% of eligible patients were appropriately referred to either their PCP or to Gynecology to complete cervical cancer screening. Post-intervention, the HPV vaccination rate increased from 41.6% to 58.3% and cervical cancer screening increased from 43.8% to 50%, both of which remained below the national average.

Conclusion: By raising awareness amongst providers in rheumatology, nephrology and dermatology and by implementing processes to facilitate HPV vaccination and cervical cancer screening, rates for both increased. However, rates are still below the national averages for the general population. Further work is needed to improve rates of cervical cancer screening and HPV vaccination in lupus, given the increased risk of cervical dysplasia.

Abstract Number: 1200

Influenza Vaccination Rates Among Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis on Immunosuppressive Therapy: Findings from a Large Public Hospital

Judith Aniekwena,[1] Titilope Olanipekun,[2] and Valery Effoe[2], [1]Morehouse School of Medicine, Atlanta, GA, [2]Morehouse School of Medicine, Atlanta

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Influenza infection constitutes a significant cause of morbidity and mortality in patients living with Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA). The risk of influenza-related morbidity and mortality is higher in these subsets of patients owing to impaired immune responses and the use of immunosuppressive therapy. Therefore, the Advisory committee on vaccination practices highly recommend yearly influenza vaccination to improve clinical outcomes in these patients. There is limited data on Influenza vaccination rate in patients with SLE and RA on immunosuppressive therapy.

Methods: Data was obtained from the electronic medical record (EMR) system of one of the ambulatory arms of Grady Memorial Hospital. Patients with Systemic Lupus Erythematosus and Rheumatoid Arthritis who visited the clinic during the influenza season from October 1, 2018 to May 31, 2019 were included. Patients were asked to complete a questionnaire on demographics, influenza vaccination status, use of immunosuppressive therapy, method of influenza awareness and smoking status. Data was confirmed with the EMR. MS excel and SAS 9.4 software were used for data management and analysis.

Results: A total of 83 patients were included in the study. 62.6% of the population had Rheumatoid arthritis while 37.4% had SLE. All patients were on immunosuppressive medications which included methotrexate, leflunomide, cyclosporine, mycophenolate mofetil and azathioprine. Based on demographics, 78.3% were female and 21.7% were male. Mean population age was 53.5. Our patient population was predominantly African American (91.6%) and the educational level of majority of the participants was high school (41%). The most common setting for vaccination was during a primary care doctor's visit (66.1%; n=37/56) compared to 32.1% (n=18/56) who received vaccination at their Rheumatology clinic visit. 77% of the total population were non-smokers.

The overall flu vaccination coverage was 67.5% which is higher than the CDC reported 2018-2019 national coverage rate of 46.3% in patients with high risk conditions. 67.3% of the RA population (n=35/52) received the influenza vaccine while 67.7% of the SLE population (n=21/31) received the influenza vaccine. The 2019 flu vaccination coverage amongst SLE patients in this ambulatory arm increased by 37.7% compared to the 2017-2018 coverage rates. For the 32.5% of the total population that declined the flu shot, perceived lack of efficacy of the influenza vaccine was the most cited reason (37%), followed by aversion to all vaccines (25.9%).

Conclusion: Our data demonstrates an overall improvement in coverage rates compared to reports from our local 2017-2018 survey and the recent CDC national coverage rate generally. Given the lower rate of awareness provided by Rheumatologists about the flu shot in comparison to primary providers, we propose more patient education on the part of Rheumatologists on the need for influenza vaccination and on the perceived lack of inefficacy of the influenza vaccine. More studies should evaluate factors that contribute to the relatively high coverage rate seen in RA and SLE patients.

Are We Meeting Benchmarks for Wait Times to Pediatric Rheumatology Care for Juvenile Idiopathic Arthritis (JIA)?

Claire Barber,[1] Natalie Shiff,[2] Cheryl Barnabe,[3] Susanne Benseler,[3] Ricky Chin,[3] Nicole Johnson,[3] Nadia Luca,[3] Paivi Miettunen,[4] Marinka Twilt,[3] Dwaraka Veeramreddy,[3] and Heinrike Schmeling[5], [1]University of Calgary, Calgary, Canada, [2]University of Florida, Gainesville, FL, [3]University of Calgary, Calgary, AB, Canada, [4]Alberta Children's Hospital, Calgary, ON, Canada, [5]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Wait time to pediatric rheumatology care for patients with Juvenile Idiopathic Arthritis (JIA) is a nationally endorsed quality measure in Canada. Target wait times for systemic JIA are 7 days from referral to pediatric rheumatology care, and 4 weeks for other JIA categories. The purpose of this study was to measure this quality indicator and evaluate factors associated with JIA wait times at a single academic pediatric rheumatology center.

Methods: This was a retrospective cohort study of patients with a diagnosis of JIA participating in a pharmacogenetics study who had demographic and disease-related data collected prospectively between 2002-2018. The time between referral date and first pediatric rheumatology visit was extracted from clinic charts and clinical variables from a pharmacogenetics study database. Factors evaluated included JIA category, age, sex, distance from the clinic, baseline number of active joints, pain and C-reactive protein (CRP) at the first clinic visit. Distance from clinic was calculated by geocoding the latitude and longitude of the patient's postal code using the Postal Code Conversion File, with distance calculations made using ArcGIS by calculating the shortest distance to the clinic using roadways. Urban versus rural classification of patient residence was according to Statistics Canada definitions. Descriptive characteristics and wait time measures are reported using medians (interquartile range, IQR) given the non-normal distributions. Non-parametric Kruskal-Wallis rank test was used to examine whether there was any difference in wait times among patients with different categories of JIA. Cox proportional hazard modelling was used to evaluate potential factors associated with wait time.

Results: 164 patients with JIA were eligible for inclusion, of which 116 were female (71%). The median age at diagnosis was 8.0 (IQR 3.5, 12.0) years. The majority of patients had oligoarticular JIA (n=75, 46%) or rheumatoid factor-negative polyarticular JIA (n=48, 29%) and 6 patients had systemic JIA (4%). The majority of patients (n=102, 62%) were from Calgary. The median network distance for patients between their residence and the clinic was 22.8 kilometers (IQR 13.5, 127.8). There was a median of 22 days between referral and pediatric rheumatologist visit (IQR 9, 45), and there was no significant difference between the wait times among JIA categories (p=0.055). Overall, 62% of JIA cases met the established wait time benchmarks. Using Cox-proportional hazard modeling, higher age was associated with longer wait times (HR 0.94, 95% CI 0.89, 0.98, p=0.005).

Conclusion: The median wait time from referral to pediatric rheumatologist visit for patients with JIA in this study met the national benchmark, although some patients experienced long wait times for appointments. Wait times did not significantly differ by JIA category but older patients waited longer. This work highlights the importance of monitoring of wait times as a quality indicator.

Testing Rheumatoid Arthritis Performance Measures to Optimize Treat to Target Strategies

Claire Barber,[1] Dianne Mosher,[2] Glen Hazlewood,[1] Paul MacMullan,[2] Cheryl Barnabe,[2] Victoria Bohm,[2] James Rankin,[2] Joanne Homik,[3] Kelly English,[4] Karen Tsui,[5] Bo Pan,[6] Martina Stevenson,[2] Namneet Sandhu,[2] Andrea Emrick,[2] Liam Martin,[1] Caylib Durand,[2] Michelle Jung,[2] and Diane Lacaille[7], [1]University of Calgary, Calgary, Canada, [2]University of Calgary, Calgary, AB, Canada, [3]University of Alberta, Edmonton, Canada, [4]Arthritis Patient Advocacy Board, Vancouver, BC, Canada, [5]Arthritis Patient Advisory Board, Toronto, ON, Canada, [6]University of Alberta, Edmonton, AB, Canada, [7]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this study was to operationalize and report on 3 Rheumatoid Arthritis (RA) performance measures previously identified in the Patient-Centered Framework for Measuring, Monitoring and Optimizing RA care in Canada: 1) the number of visits where a patient was in moderate or high disease activity where a follow-up visit was booked within ≤ 3 months; 2) the number of visits with moderate or high disease activity where the disease activity was subsequently documented as low or in remission within 6 months; 3) the percentage of patients in remission at any point during the measurement period.

Methods: The performance measures were tested in an RA cohort over the period between 08/2016 to 05/2019 using a web-based tool (Rheum4U). Rheum4U is designed as a pragmatic quality improvement and research tool and collects baseline characteristics, sociodemographic factors, patient reported outcomes, and disease activity using composite scores (DAS28) calculated at the point of care. The study was conducted at 2 outpatient University-affiliated rheumatology clinics staffed by 15 participating rheumatologists and 1 nurse practitioner. Consecutive patients were recruited and consented for inclusion at any point during their disease course and data entered into the Rheum4U platform at each clinical encounter, with the timing of encounters and treatment changes being at the

discretion of the attending rheumatologist and patient. Standard DAS28 cutoffs for disease activity were used in the study.

Results: 500 patients with RA (with n=1627 visits) were included in the analysis, 75% were female with a mean (SD) age of 55 (14) years. The mean length of follow-up was 413 (238) days and the mean number of visits was 4 (2) for patients with > 1 visit. There was a disease activity score (DAS28) calculated at 1202 of the 1627 visits (74%). 503 visits (42% of visits with a DAS28 score) were in patients with moderate or high disease activity with at least 1 follow-up. Amongst all visits (n=503) for patients with a documented moderate or high disease activity score, 147 follow-up visits (30%) occurred within ≤ 3 months and low disease activity or remission was achieved at 100 visits (20%) within ≤ 6 months. The percentage of visits where the patient was documented to be in remission at any point over follow-up was 35% (n=425/1202 with a DAS28 score) and an additional 6% were in low disease activity (n=67).

Conclusion: While just over 40% of patients reached a state of remission or low disease activity over the follow-up period, we have identified critical areas for process and outcome improvements. Specifically, only 30% of visits where a moderate or high disease activity was documented had a follow-up visit within 3 months, and only 20% of follow-up visits documented low disease activity or remission within 6 months. This work highlights the importance of quality measures as a tool to help guide adherence to treat-to-target strategies.

Abstract Number: 1203

Psychometric Properities of the Patient Related Outcome Measure FACIT-Fatigue in Rheumatic Arthritis and Psoriatic Arthritis: A Literature Review

M. Elaine Husni,[1] Mark Kosinski,[2] Regina Rendas-Baum,[2] Shelly Kafka,[3] Chenglong Han,[4] Eric K H Chan,[4] Elizabeth Hsia,[5] and Arthur Kavanaugh[6], [1]Department of Rheumatologic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH, [2]Optum, Johnston, RI, [3]Janssen Scientific Affairs, LLC, Horsham, PA, [4]Janssen Research & Development, LLC, Spring House, PA, [5]Janssen Research & Development, LLC/University of Pennsylvania, Spring House/Philadelphia, PA, [6]University of California, San Diego School of Medicine, La Jolla, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is an important patient reported outcome in rheumatoid arthritis (RA) and psoriatic arthritis (PsA) research. FACIT-Fatigue is a 13-item patient reported outcome (PRO) instrument designed to assess fatigue and its impact on daily activities and function over the past seven days. In this study we reviewed published evidence on the psychometric properties of FACIT-Fatigue in patients with rheumatoid arthritis (RA) or psoriatic arthritis (PsA) including content validity, reliability, , and ability to detect change.

Methods: For content validity, a search of PubMed and Ovid databases used the following terms: (“conceptual” OR ”content validity” OR “qualitative” OR “debrief*”) AND (“rheumatoid arthritis”/”psoriatic arthritis” OR “RA”/”PsA”)

Table 1. Content Validity of the Patient Reported Outcome Measure FACIT-Fatigue in Rheumatoid Arthritis and Psoriatic Arthritis

Disease	Results	Reference
RA	Majority of patients (14/17) indicated that FACIT-Fatigue captured their fatigue experience.	Kaiser, 2016, in press
RA	From these 13 studies, 58 patient descriptors were provided. 39 (67%) were mapped to the FACIT-Fatigue items.	Carr, 2003 Connolly, 2015 Feldthusen, 2013 Hewlett, 2005 Kaiser, 2016, in press Mortada, 2015 Nicklin, 2010 Nikolaus, 2010 Repping-Wuts, 2008
PsA		Gossec, 2014 Moverley, 2015 Stamm, 2007 Tillett, 2015

ACR=American College of Rheumatology; CDAI=Clinical Disease Activity Index; CI=confidence interval; DAS-28-CRP=Disease Activity Score 28-C-Reactive Protein ; HAQ-DI=Health Assessment Questionnaire-Disability Index ; Obs=observational study; PASI=Psoriasis Area and Severity Index; PhGA=Physician Global Assessment of Disease Activity; PsA=psoriatic arthritis; PtGA=Patient Global Assessment of Disease Activity; RA=rheumatoid arthritis; RCT=randomized controlled trial; Retro=retrospective study; SDAI=Simplified Disease Activity Index

AND "fatigue". For the psychometric measures, the search used the following terms: ("FACIT-F" OR "FACIT-Fatigue" OR "FACIT Fatigue") AND ("rheumatoid arthritis"/"psoriatic arthritis" OR "RA"/PsA") AND "fatigue." Search filters were used to exclude: 1) articles that are not available in the English language; and 2) articles not published within

the last 15 years (2001 – 2016). Abstracts and full-publications involving observational cohorts and clinical trials were reviewed for reports of FACIT-Fatigue psychometric properties in RA and PsA patient studies.

Results: A total of 81 papers were included in this study. The content of the FACIT-Fatigue items maps well to descriptors used by patients to express their experience of RA-related fatigue, and almost all of the items (except the item "too tired to eat") were found to be acceptable by patients, supporting its content validity. The instrument also possesses good to excellent reliability, including Cronbach's alpha (≥ 0.80), test-retest reliability, and intra-class correlation. Moderate to high correlations were also found between the FACIT-Fatigue and other measures of fatigue, as well as measures of disability and disease activity, such as HAQ-DI, DAS28, Psoriasis Area and Severity Index and, Psoriasis Disability Index. The known-groups validity of the instrument was also demonstrated in studies of RA and PsA patients based on disease status and scores relative to the general population. Studies also showed that changes in FACIT-Fatigue scores were associated with changes in multiple clinical outcome measures, such as ACR improvement criteria, changes in DAS28, and physician global assessment, suggesting the ability of the FACIT-Fatigue to detect changes in RA and PsA disease activity. Table 1 summarizes the content validity evidence and Table 2 provides summaries of the psychometric properties of FACIT-Fatigue.

Conclusion: This review demonstrated evidence of content validity and strong psychometric properties of FACIT-fatigue in patients with RA and PsA, supporting its use in RA and PsA studies.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Measures Of Healthcare Quality Poster II: Improving Care

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In the randomized, phase 3, GO-VIBRANT study, more patients with psoriatic arthritis (PsA) achieved ACR 20/50/70 after 24 weeks IV treatment with the anti-TNFa monoclonal antibody golimumab (GLM-IV) than placebo (PBO) ($p< 0.001$). After cross-over from PBO to GLM-IV at week 24, 52-week achievement of ACR responses was similar between the two treatment groups.[1] Here we examine effects on measures of health-related quality of life (HRQoL) for up to 52 weeks of treatment.

Methods: Adult patients with active PsA who met CASPAR criteria (N=480) were randomized (1:1) to GLM-IV 2 mg/kg at weeks 0, 4, then every 8 weeks or matching PBO through week 20 then cross-over to GLM-IV at weeks 24, 28, then every 8 weeks. Physical function was assessed using the Health Assessment Questionnaire-Disability Index (HAQ-DI). Measures of HRQoL included Short-Form-36 Physical and Mental Component Summaries (SF-36 PCS/MCS), Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue, EuroQol-5D visual analog scale (EQ-VAS), and Dermatology Life Quality Index (DLQI), assessed at weeks 0, 8, 14, 24, 36, and 52.

Results: GLM- IV and PBO groups had comparable HRQoL characteristics at baseline (Table 1). At 24 weeks, changes from baseline were greater for GLM-IV vs PBO, respectively (HAQ-DI, -0.63 vs -0.14; SF-36 PCS, 9.4 vs 2.4; SF-36 MCS, 5.3 vs 0.8; FACIT-Fatigue, 9.2 vs 2.3; EQ-VAS, 20.2 vs 5.5; and DLQI, -8.1 vs -1.9). At week 24 more

†Minimal clinically important differences from baseline are HAQ-DI=0.35[2], SF-36=5[3], FACIT-Fatigue=4[4]. * P vs PBO <0.0001, P values are nominal, not adjusted for multiplicity. FACIT= Functional Assessment of Chronic Illness Therapy; GLM-IV=intravenous golimumab HAQ-DI= Health Assessment Questionnaire-Disability Index; MCID=minimal clinically important difference; PBO=placebo; SF-36 PCS/MCS=Short-Form-36 Physical / Mental Component Summaries				

patients receiving GLM-IV than PBO achieved minimal clinically important improvements from baseline in HAQ (≥0.35 points),[2] SF-36 (≥5points),[3] and FACIT-fatigue (≥4 points).[4] Among patients randomized to GLM-IV, changes in HRQoL measures were maintained from week 24 to week 52. Among patients randomized to PBO, after switching to GLM-IV at week 24, improvements in HRQoL measures from week 36 to week 52 were comparable to those of patients originally randomized to GLM-IV (Tables 1 and 2).

Conclusion: Improvements in HRQoL among patients with PsA after 24 weeks' GLM-IV treatment were greater than PBO and were maintained through week 52 of treatment. Patients switching from PBO to GLM-IV at week 24 experienced improvements in HRQoL by week 36, which were maintained through week 52 and were similar to those achieved by patients originally randomized to GLM-IV.

Session Title: Measures Of Healthcare Quality Poster II: Improving Care

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Early RA diagnosis and initiation of DMARDs following a treat-to -target approach is recommended to optimize remission outcomes. Several RA disease activity indices are commonly used in research and practice. The choice of index however, may impact treatment decisions and quality improvement (QI) program eval-

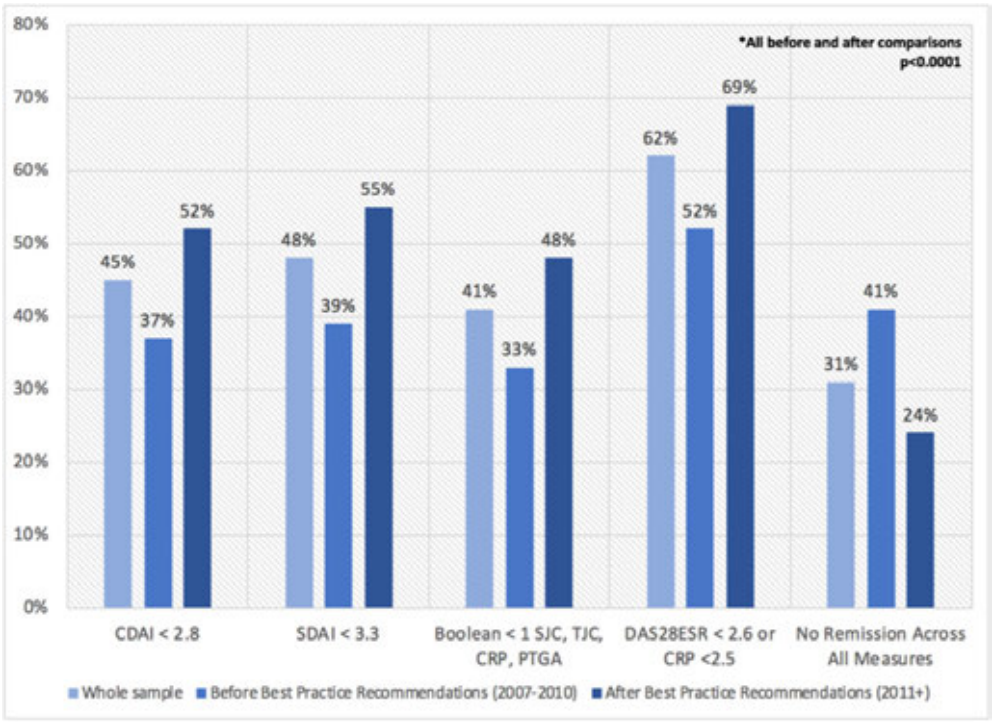

Figure 1 Prevalence and Improvement in Remission Outcomes by 12-Months Across 4 Commonly used Clinical Remission Indices.

Pain	1.13 (1.07, 1.19)	1.12 (1.05, 1.19)	1.15 (1.02, 1.30)

uations. Study objectives were to: 1) compare remission outcomes in the first year across 4 commonly used clinical disease activity indices; 2) estimate changes in remission over time across indices coinciding with release of RA best practice recommendations, and 3) identify predictors of persistent active disease across all measures.

Methods: Data were from patients with early RA (symptoms < 1 year, 100% Met ACR/EULAR RA criteria) enrolled in a prospective national ERA cohort study between Jan- 2007 and Mar-2018. Study participants had active disease at enrollment, were treated with DMARDs, and completed clinical evaluations, laboratory assessments and patient-reported outcomes every 3-months for the first 12-months of follow up. T-tests and chi-squared tests were used to compare patient characteristics, early treatment strategies, and remission outcomes using 4 commonly used clinical indices (DAS28< 2.6 OR DAS28CRP < 2.5, CDAI ≤ 2.8, SDAI≤ 3.3, and ACR/EULAR Boolean remission - SJC28, TJC28, CRP, PGA all ≦ 1). Logistic regression was used to identify predictors of persistent active disease across all measures by 12-months among baseline sociodemographic, RA clinical characteristics and patient-reported outcomes.

Results: Among 1202 adults eligible for this analysis, 877 (73%) were women, mean (sd) age was 55 (14), average disease activity was high across measures (DAS28 5.1 (1.4); CDAI 27 (14); SDAI 29 (15)) and majority (98%) were treated with csDMARDs +/- MTX. Remission by 12-months varied considerably across indices ranging from 33% to 62%, though improvement in remission before and after implementation of best practice recommendations was similar across all indices (~+15%) (Figure 1). 378 (31%) did not achieve remission across all indices. In adjusted logistic regression models, persistent active disease across indices was associated with baseline older age, female sex, longer symptom duration, positive serology, obesity, tender joints and higher pain (Table 1). In stratified analyses by sex, persistent active disease was more strongly associated with obesity and more tender joints in women, and positive serology and smoking in men.

Conclusion: The choice of index had a sizable impact on remission classification with important implications for decision-making surrounding treatment intensification in clinical practice. However all indices showed similar levels of improvement in remission before and after implementation of best practice recommendations suggesting that choice of index may be less important when evaluating QI programs. In the interim, in the absence of a single "best measure" that also takes in to account the patient's perspective, study results looking across measures point to unmet needs for achieving remission in approximately 1 in 3 ERA patients.

Performance of the Patient-Reported Outcomes Measurement Information System 29 (PROMIS-29) Item Profile in a Cohort of Australians with RA, OA and Other Inflammatory Arthritic Conditions

Geraldine Hassett,[1] Dana Gerogevsky,[2] Joseph Descallar,[3] Ray Fang,[4] Frank Huang,[4] and **Kathryn Gibson** [1], [1]Liverpool Hospital, Sydney, New South Wales, Australia, [2]Royal Prince Alfred Hospital, Sydney, Australia, [3]Ingham Research Institute, Sydney, New South Wales, Australia, [4]University of New South Wales, Sydney, New South Wales, Australia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Guarded support for PROMIS-29 assessment in musculoskeletal disease has been reported in RA, OA, FM and SLE patients[1]. The performance of PROMIS-29 compared to legacy measures in Australian patients with RA, OA and other inflammatory arthritic conditions (IA) has not been examined. The aim of this study was to determine similarities and differences to performance of the multidimensional health assessment questionnaire (MDHAQ).

Methods: All consented patients complete a MDHAQ and the static 29 item PROMIS profile (PROMIS-29) questionnaire prior to seeing their rheumatologist. A cross sectional sample of 113 RA, 25 OA and 58 patients with IA (ankylosing spondylitis, psoriatic arthritis and inflammatory arthritis) was analysed. PROMIS-29 assesses 7 domains: physical function, anxiety, depression, fatigue, sleep disturbance, satisfaction with participation in social roles, pain interference and a 0-10 pain intensity scale. Scores are standardised against US normative population data producing T

MDHAQ scores	RA (n=113)	OA (n=25)	IA (n=56)	P value
Physical Function	2.8 (2.2)	3.5 (2.3)	2.6 (2.1)	NS
PTGL	4.6 (3.1)*	6.4 (2.4)*	4.8 (2.7)	*0.02
Fatigue	4.1 (3.3)*	6.1 (2.2)*	4.4 (3.0)	*0.01
Pain	4.8 (3.0)*	6.6 (2.4)*^	4.8 (2.8)^	*0.01 ^0.03
Sleep	1.2 (1.0)	1.5 (1.0)	1.2 (1.1)	NS
Anxiety	0.8 (0.8)	0.8 (0.9)	0.8 (0.9)	NS
Depression	0.8 (0.9)	1.0 (0.9)	0.7 (0.8)	NS
Symptom review	10.7 (9.0)	14.9 (8.5)	10.6 (8.5)	NS
RADAI	15.6 (13.7)	19.8 (12.3)^	12.2 (9.1)^	^0.04
PROMIS-29 T scores				
Physical function	39.9 (8.9)	36.0 (6.8)^	42.5 (9.5)^	^0.007
Satisfaction with social role	46.4 (10.8)*	40.9 (8.9)*^	49.0 (11.2)^	*0.06 ^0.006
Fatigue	52.4 (11.5)	56.3 (10.0)	52.9 (11.7)	NS
Pain interference	59.6 (9.0)*	65.39 (7.1)*^	57.4 (9.8)^	*0.005 ^0.0004
Sleep	54.0 (8.5)	55.6 (9.0)	52.4 (9.9)	NS
Anxiety	52.5 (11.1)	55.2 (11.5)	50.7 (10.3)	NS
Depression	51.7 (10.7)	53.5 (11.5)	49.6 (10.6)	NS
Pain VAS	4.8 (2.8)*	6.7 (2.2) *^	4.5 (2.7)^	*0.006 ^0.003

Values are means and standard deviations
*OA vs RA
^OA vs IA

Table 1 Participating subject MDHAQ and PROMIS-29 characteristics by condition.

scores with a mean of 50 and a standard deviation of 10. The MDHAQ assesses physical function (0-10), sleep disturbance, anxiety and depression (0-3.3), pain (0-10 VAS), patient global assessment (PTGL) (0-10 VAS), self-report joint count (RADAI) (0-48), 60 question symptom review and fatigue (0-10 VAS). Means and standard deviations (SD) of PROMIS T scores and MDHAQ variables and percentage of patients achieving minimum and maximum values for each variable were calculated. ANOVA compared PROMIS-29 T scores and MDHAQ means across disease groups. Floor effect is defined as the 'best' possible score and ceiling as the 'worst' possible score, irrespective of the direction of the scale. A substantial floor or ceiling effect is defined as ≥15% with either score.

Results: Patients were predominantly female with a mean age of 57.4 +/-14.4 years and mean disease duration >14 years. OA and RA patients were significantly older than IA patients ($p< 0.04$). MDHAQ scores for PTGL, fatigue and pain were significantly higher in OA than RA ($p\leq0.04$) (Table 1). Pain and RADAI were also higher in OA than in IA ($p\leq0.04$). The PROMIS-29 mean T scores for physical function, satisfaction with social role, pain interference and mean Pain VAS were significantly worse in the OA patients than the IA patients ($p\leq0.007$). Satisfaction with social role and pain interference were also significantly worse in the OA than the RA group ($p\leq0.06$). No significant differences between RA and IA were seen by any MDHAQ or PROMIS-29 measure. Significant floor effects were found for MDHAQ and PROMIS-29 depression and anxiety in all groups. MDHAQ sleep disturbance, also demonstrated significant floor effects across all groups. A ceiling effect was only seen in OA pain interference.

Conclusion: PROMIS-29 and MDAHQ scores performed similarly across a range of comparable domains but differed for physical function and fatigue assessment. Significant floor effects were found for both instruments. Each provides data for constructs not available in the other, which should be considered when choosing a tool to inform clinical care.

A Quality Improvement Intervention to Reduce 30-Day Hospital Readmission Rates Among Patients with Systemic Lupus Erythematosus

Emily Bowers,[1] Melissa Griffith,[1] Elena Weinstein,[1] Duane Pearson,[1] and Jason Kolfenbach[1], [1]University of Colorado Department of Rheumatology, Denver, CO

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic immune-mediated disease with significant morbidity and mortality that often requires inpatient hospitalization. SLE has one of the highest 30-day hospital readmission rates among chronic diseases in the United States with 30-day readmission rates reported in the literature of 16.5-36%. Prior studies have focused on identifying risk factors associated with readmission. The aim of our study was to reduce 30-day readmission rates among SLE patients at the University of Colorado Hospital by implementing a multidisciplinary post-discharge intervention.

Methods: Using our inpatient consult log, we collected baseline data on the 30-day readmission rate of SLE patients from 7/2016 through 10/2016. We excluded patients who do not get their rheumatology care at our clinic as they would not be impacted by our intervention. We designed a post-discharge intervention that engages the rheumatology fellows, attendings and clinic nurses. We created a message template in the electronic medical record (EMR) that is sent by the rheumatology consult fellow to the clinic nurses when the patient is discharged from the hospital. This includes information about medication changes, future infusions, future labs and follow-up appointments. The nurses contact the patient by telephone within 48 hours of discharge to review the information and answer any questions. We collected post-intervention data from 12/2018 through 2/2019.

Results: Prior to intervention, 87 patient charts were manually reviewed for inclusion and 18 patients met criteria of having SLE and being followed by our clinic. The 30-day readmission rate among these patients was 44%. The patients who were readmitted within 30 days were 100% female, average age 36 years old, 75% non-Caucasian (Hispanic or African American) and 50% had a public payor form of insurance (Medicare or Medicaid). The reasons for readmission were as follows: 37% SLE flare, 37% infection, 25% other medical issue. Following our intervention, the 30-day readmission rate among our patients with SLE was 28%, which is a 16% decrease compared to pre-intervention. Implementation of the intervention was assessed by documentation of the post-discharge message sent by the fellow to the nursing staff in the EMR. This was found in 28% of hospitalized SLE patients. Of those patients who had the message and intervention performed, only 1 was readmitted within 30 days.

Conclusion: A quality improvement intervention involving a post-discharge telephone call decreased the 30-day readmission rate among patients with SLE followed at the University of Colorado rheumatology clinic from 44% to 28%. There was overall low implementation of the intervention by the rheumatology fellows, however, this is likely because the intervention was preferentially performed for only the highest risk patients, which was effective in pre-

venting readmission amongst these patients. In the future, we will be working towards more uniform implementation of our intervention. This is one of the first studies to describe a possible intervention to improve the unacceptably high hospital readmission rates among SLE patients.

Outpatient Readmission in Rheumatology: A Machine Learning Predictive Model of Patient's Return to the Clinic

Luis Rodríguez-Rodríguez,[1] Alfredo Madrid García,[1] Judit Font Urgelles,[2] Mario Vega-Barbas,[3] Leticia León,[4] Dalifer Freites Nuñez,[5] Cristina Lajas,[6] Esperanza Pato Cour,[6] Juan Angel Jover Jover,[6] Benjamín Fernández Gutiérrez,[7] and lydia Abasolo Alcazar[6], [1]Fundación para la Investigación Biomedica, Madrid, Spain, [2]HOSPITAL CLINICO SAN CARLOS, MADRID, Madrid, Spain, [3]Universidad Politécnica de Madrid, Madrid, Madrid, Spain, [4]Fundación para la Investigación Biomedica, Madrid, Madrid, Spain, [5]Hospital Clínico San Carlos, MADRID, Spain, [6]HOSPITAL CLINICO SAN CARLOS, MADRID, Spain, [7]Hospital Clínico San Carlos, Madrid

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Readmissions can be defined as the return of a patient to a healthcare setting after a discharge. Attention has been mainly focused on readmissions following inpatient hospitalizations. In the outpatient setting, readmissions have been far less studied. As the first step in preventing outpatient readmission, the assessment of the individual patient's risk could be useful to help identify those subjects at greatest risk, so, in a further step we could focus the delivery of an intervention in those patients to reduce their risk. Therefore, our objective was to develop and validate a machine learning predictive model based on Random Forest, to estimate the risk of readmission in an outpatient rheumatology clinic after discharge (outpatient readmission).

Methods: Patients stored in a departmental electronic health record from April 1st, 2007 to November 30th, 2016, and followed-up until November 30th, 2017, were included in this study. Only readmissions taking place between 2 and 12 months after discharge were analyzed. Discharge episodes were split into training, validation and test datasets. Clinical and demographic variables, including diagnoses, treatments, quality of life, and comorbidities, were used as predictors. Models were developed using Random Forest in the training dataset, though the combination of several tuning parameters. Models that maximized the area under the receiver operating characteristic curve (ROC-AUC) in the validation set were assessed in the test set. The model with the highest AUC-ROC in the test dataset was considered as the best final model

Results: 17,772 patients (18,648 discharges episodes) were analyzed and 2,513 (13.5%) discharges episodes were classified as outpatient readmissions. 39,120 possible model combinations were finally tested. The best final model showed an AUC-ROC of 0.677 a sensitivity of 0.479 and a specificity of 0.757. The most important variables were related to follow-up duration, number of previous discharges, corticosteroid and Disease-Modifying Antirheumatic Drugs use, polyarthritis diagnoses, and quality of life

Conclusion: We have developed a predictive model for outpatient readmission in a rheumatology setting. Identification of patients with higher risk could optimize the allocation of healthcare resources

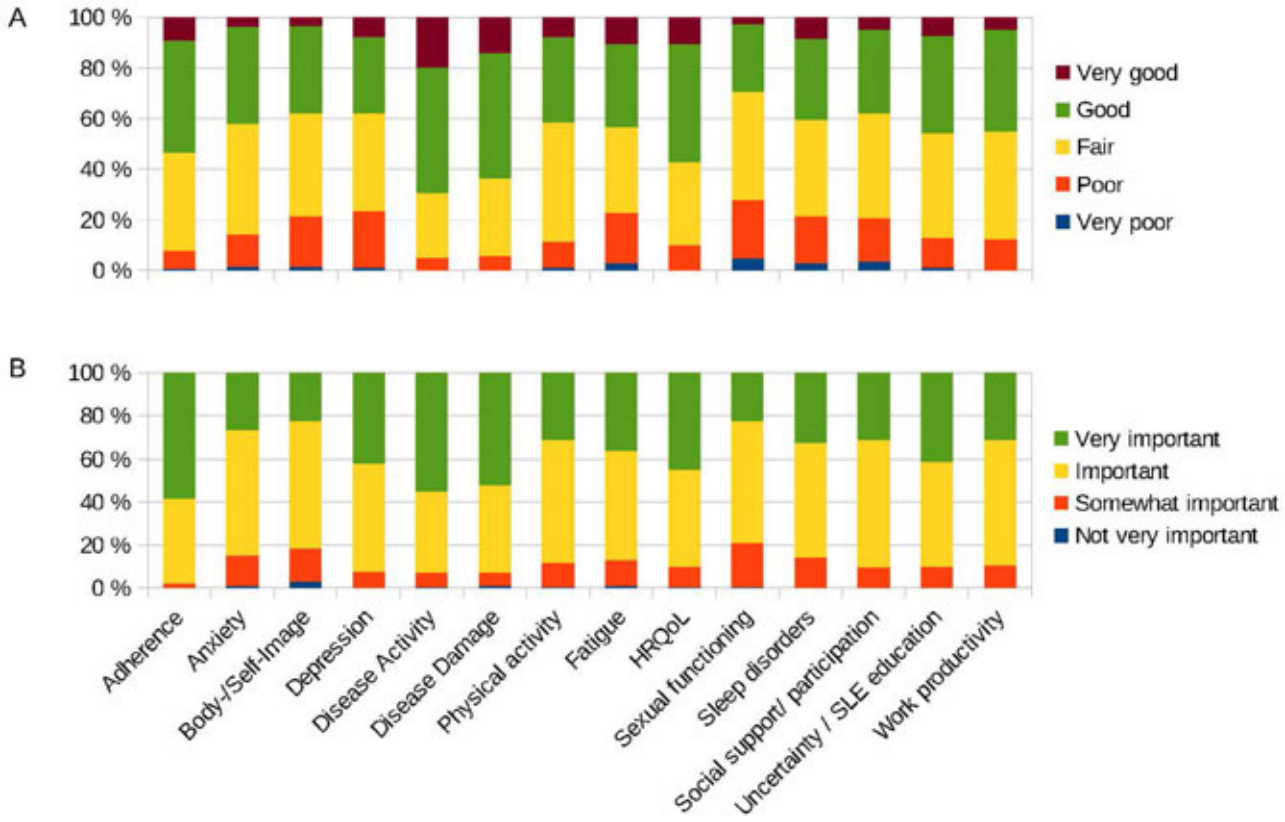
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to improved mortality and morbidity in systemic lupus erythematosus (SLE), non-clinical indicators and outcomes, especially patient-reported ones, have become increasingly important in disease management in the past decades. The objective of our study was to identify dedicated standardized instruments (Patient-reported outcome measures; PROMS) for non-clinical indicators currently in use, and to demonstrate their relevance via their utilization by Lupus experts.

Methods: To identify relevant non-clinical indicators, a systematic literature search was performed using the PubMed database in January 2018. In addition, guidelines, recommendations, consensus reports on the management and monitoring of SLE-patients as well as selected review articles on quality of life, disease burden, and patient-reported outcome were screened. Subsequently, a literature search was conducted for each of the non-clinical indicators to identify all dedicated patient-reported questionnaires in use. A questionnaire for SLE experts was compiled on the basis of the results obtained, covering the utilization of non-clinical indicators, their specific questionnaires and possible obstacles. The questionnaire was distributed to members of the European Lupus Society (SLEuro), as well as other Lupologists.

Figure 1: Self-reported overall experience (A) and the perceived importance (B) of the 14 identified patient-reported outcome domains



Results: A total of 21 non-clinical indicators were identified, 7 of which did not have a standardized questionnaire. For the remaining 14 non-clinical indicators, 50 different questionnaires were found. 167 lupus experts from 43 countries participated in our study, of whom 57% stated to be members of a regional or national reference center for SLE. 73% claimed to treat more than 30 and 37% more than 90 SLE-patients per year (see table 1). Self-reported overall experience and the perceived importance of the 14 identified patient-reported outcome domains by the lupus experts are shown in figure 1. 31% reported to use PROMS to monitor disease outcome in their lupus patients, e.g. for assessing (health-related) quality of life (22.9%) or fatigue (15.7%). The top 5 reasons for not using PROMS were 'Lack of time' 87%, 'Lack of linguistically validated questionnaires' 32%, 'Lack of validated questionnaires' 28%, 'Discordance with my assessment/impression' 15%, and 'Poor credibility of the results' 12%.

Conclusion: Despite the increasing importance of PROMS received for regulatory studies in recent years, their use has not yet become established in routine use among lupus experts. Although numerous PROMS on different endpoints are available, they are relatively rarely used in everyday clinical practice nor for clinical decision-making. Better availability of validated multilingual instruments and better incentives (proven benefit for care, additional remuneration) could contribute to improved utilization.

Abstract Number: 1210

Utilization of a Multispecialty Team for the Diagnosis of Giant Cell Arteritis Reduces Patient Morbidity

Arash Hassantoufighi,[1] **Rachel Lu-Do**,[1] Mamta Sherchan,[1] Christopher Collins,[1] Joshpaul Dhillon,[2] and Florina Constantinescu[1], [1]MedStar Washington Hospital Center, Department of Rheumatology, Washington, DC, [2]MedStar Washington Hospital Center, Department of Internal Medicine, Washington, DC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Giant Cell Arteritis (GCA) is an autoimmune vasculitis, most common in older adults with a peak incidence in the seventh decade. The diagnosis is often considered in any patient over age 50 years with new-onset headache, acute visual disturbances, jaw claudication, or elevated inflammatory markers. Because the manifestations of GCA can vary considerably, accurate diagnosis can be challenging. Even in the setting of a negative temporal artery (TA) biopsy, many patients are treated empirically based on the perceived probability of disease. This approach can lead to significant morbidity from prolonged medication exposure and unnecessary procedures. The aim for this project was to look at the impact of a collaborative effort amongst three specialties, rheumatology, neurology, and ophthalmology, a consultation based "GCA team"; the goal of which was to improve how GCA is diagnosed and subsequently managed.

Methods: We conducted a retrospective study of all patients suspected to have GCA at our institution over the last 2.5 years either been seen by the GCA team or not. The GCA team met either in person or had a conference call to discuss each case to make a joint decision regarding the diagnosis and treatment. Data extracted included patient demographics, symptoms on presentation, labs, biopsy results and accumulative prednisone dose.

Results: A total of 36 patients (23 female, 13 male) were evaluated; 26 were seen by the GCA team and 10 were not. The mean ages of patients between the GCA team and No GCA team were similar [71.2 (SD 11.0) vs 70.4 (SD 13.0)], as well as the mean ESR (52.0 vs 54.4), and presenting clinical symptoms: visual complaints (76.9% vs 80.0%) and headache/ jaw claudication/ TA tenderness (46.2% vs 40.0%).

All patients not seen by the GCA team underwent bilateral TA biopsy; however, none were positive on histology. Regardless, all were continued on high dose prednisone with a 6-month cumulative mean dose of 5,350 mg.

Of the 26 patients seen by the GCA team, 10 were determined to be low probability (LP) for GCA and thus were spared TA biopsy. These patients were recommended a rapid steroid taper and the cumulative mean dose of prednisone was only 491 mg. Over 6 months of follow-up, none of these patients had a subsequent diagnosis of GCA.

Compared to patients deemed high probability (HP) by the GCA team, LP patients were younger in age (71.0 vs 74.0), more often female (80% vs 55%), had lower ESR (44.6 vs 72.8), and presented with more visual complaints (70% vs 54.5%).

In the 13 HP GCA patients, 12 underwent TA biopsy (one refused) with 6 biopsies read as positive for GCA. Over 6 months of follow up, none of these patients had flares after they were started on treatment.

Conclusion: While the accuracy of a GCA diagnosis cannot be determined in our cohort of patients not seen by the GCA team, it is likely that evaluation by a multispecialty team would have found several to be low probability for GCA, especially as none of the patients had a positive TA biopsy. By adopting a collaborative approach to diagnosing GCA, unnecessary biopsies and unnecessary corticosteroid exposure can be avoided. More prospective data are needed to provide an accurate assessment of this team approach for GCA which can serve as a model for other healthcare facilities.

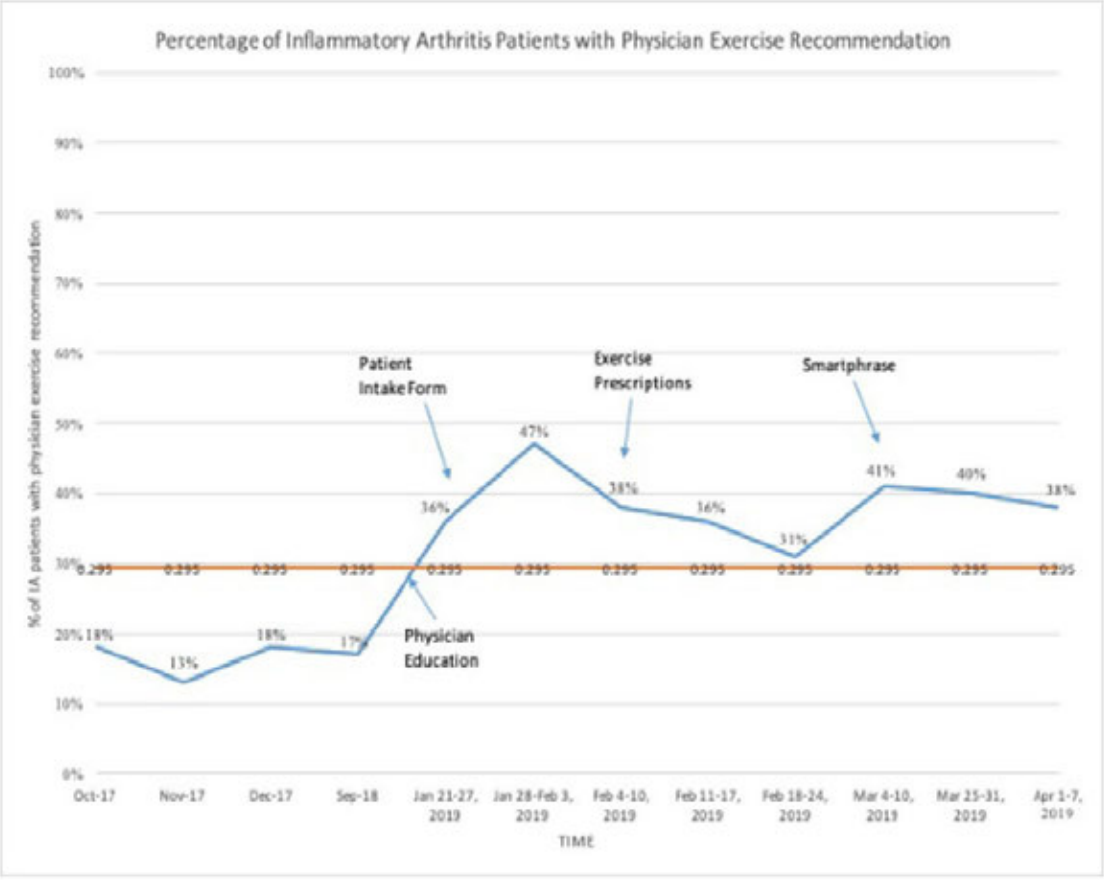
Improving Exercise Counselling of Patients with Inflammatory Arthritis: A Quality Improvement Project

Anwar Albasri,[1] Tariq Al-Araimi,[1] **Stephanie Gottheil**,[1] Lauren King,[1] Sahil Koppikar,[2] Justin Shamis,[1] Shirley Lake,[3] and Gakhal Natasha[1], [1]University of Toronto, Toronto, Canada, [2]University of Toronto, Markham, ON, Canada, [3]Division of Rheumatology, Sunnybrook Hospital, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Regular aerobic exercise has been shown to improve inflammatory arthritis (IA) symptoms and may reduce the risk of cardiovascular events observed in these patients. Practice guidelines recommend regular exercise in the management of patients with IA. Despite this, exercise is infrequently assessed and recommended in routine rheumatology care, and few patients with IA achieve the level of exercise recommended in the Canadian physical activity guidelines. The aim was to increase documentation of physician exercise counselling in patients with IA by 50% by April 30, 2019.

Methods: Baseline data on documented exercise recommendation to patients with IA (defined as a physician diagnosis of rheumatoid arthritis or psoriatic arthritis) were collected at a single academic rheumatology clinic in Toronto, Canada, over four weeks in September 2018. Rheumatologists and patients were interviewed to determine barriers to exercise counselling and uptake. Four Plan-Do-Study-Act (PDSA) cycles were completed between January and April, 2019. Interventions included assessing level of exercise participation on patient intake forms, rheumatologist education, providing a standardized exercise prescription pad in all clinic rooms, creation of a smartphrase to assist electronic record documentation, and poster reminders about exercise counselling in the clinical setting. The primary outcome was the percentage of patients who had documentation of exercise recommendation by their rheumatologist from clinic charts. The weekly percentage of patients with IA, for whom a physician recommendation to exercise was documented, was calculated from a sample (approximately 50%) of weekly follow-up patients.



Run chart demonstrating proportion of patients with inflammatory arthritis who received a physician recommendation to exercise.

Results: Baseline physician exercise recommendation was 15%. Over eight weeks of study, this increased to a mean of 38% (range 31-47%) and showed special cause variation based on eight consecutive points above the mean (Figure). There were no reports of patient adverse events or negative impact on clinical efficiency.

Conclusion: In this quality improvement study, physician education regarding exercise counselling, provision of written exercise prescriptions, education and reminders increased the documentation of physician recommended exercise in patients with IA. Future research is required to determine if increasing exercise counselling translates into increased levels of exercise among IA patients and if this is effective and feasible at other centres.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Measures Of Healthcare Quality Poster II: Improving Care
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The patients with chronic diseases such as rheumatic diseases suffer from physical pain and/or disability. In addition, psychological morbidities have also been found in patients with rheumatic diseases. Hospital Anxiety and Depression Scale (HADS) is commonly applied to assess the mental health of patients with rheumatic diseases.

Smart System of Disease Management (SSDM) is a mobile application which has two application systems for both patients and doctors for rheumatic diseases management. The patient application system provides functions includ-

Table 1. Prevalence of anxiety and depression in patients with rheumatic diseases

Disease	Frequency no. (%)	Female (%)	Age (years)		Anxiety (%)	Depression (%)
			Mean	SD		
RA	12203 (37%)	85%	49.98	17.1	10%	18%
SLE	6327 (19%)	94%	36.03	12.94	12%	21%
SS	2423 (7%)	94%	46.77	14.36	14%	21%
AS	1918 (6%)	42%	32.34	12.11	14%	21%
Gout	1104 (3%)	33%	43.80	15.8	11%	18%
OA	1057 (3%)	80%	49.50	15.8	13%	20%
MCTD	963 (3%)	94%	42.94	14.47	12%	21%
UCTD	935 (3%)	93%	37.59	12.32	13%	19%
PM/DM	863 (3%)	75%	44.86	15.14	10%	17%
APS	442 (1%)	96%	33.36	7.49	9%	14%
Scleroderma	330 (1%)	86%	44.91	13.59	11%	21%
Vasculitis	294 (1%)	68%	47.84	17.74	14%	21%
BD	230 (1%)	72%	39.04	12.73	16%	18%
PsA	263 (1%)	65%	40.65	12.87	10%	15%
Others	3941 (12%)	79%	42.18	15.35	11%	19%
Total	33293 (100%)	81%	41.34	16.55	12%	19%

ing self-assessment, medication management, adverse events management and laboratory records. After input by patients, all the data will be synchronized to the mobile terminal of authorized rheumatologists. Based on these data, rheumatologists can evaluate and follow up with their patients and provide consultation service through SSDM via text or voice message. The rheumatologists can also adjust therapeutic regimens based on patients' profiles.

The purpose of this study is to explore the profile of psychological morbidities in patients with rheumatic diseases.

Methods: The patients were educated and trained to perform HADS assessments using SSDM by the rheumatologists. The HADS self-assessments data could be extracted from the mobile terminal for further analysis. The HADS scale consists of two subscales for anxiety (HADS-A) and depression (HADS-D) which have 7 items, respectively. Both subscales range from 0 to 21, with higher scores indicating greater anxiety and depression. A score between 11 and 21 indicates a probable case of anxiety or depression.

Results: From June 2016 to May 2019, 33,293 adult patients (82% females; 18% males) with a mean age of 41.34 ± 16.55 years from 380 hospitals performed self-evaluation of HADS using SSDM. 34 rheumatic diseases were assessed, including RA (12,203; 37%), SLE (6,327; 19%), SS (2,423, 7%), AS (1,918; 6%), gout (1,104; 3%), OA (1,057; 3%), MCTD (963; 3%), UCTD (935; 3%), PM/DM (864; 3%), etc.

Table 1 presents the number and percentage of patients with rheumatic diseases accompanied by anxiety or depression. The ratio of probable anxiety was 10% in RA, 12% in SLE, 14% in SS, 14% in AS, 11% in Gout, 13% in OA, 12% in MCTD, 13% in UCTD and 10% in PM/DM. The prevalence of probable depression was 18% in RA, 21% in SLE, 21% in SS, 21% in AS, 18% in Gout, 20% in OA, 21% in MCTD, 19% in UCTD and 17% in PM/DM.

Conclusion: SSDM can be used for HADS self-assessments by patients with rheumatic diseases. RA was recorded as the most prevalent condition, followed by SLE. 10% to 21% patients could be classified as probable case of anx-

iety or depression according to HADS scores. The prevalence of anxiety was usually lower than that of depression in patients with rheumatic diseases in this study.

healthcare system due to unnecessary hospital admissions and emergency room visits[2]. Inpatients are often started on high risk medications. Due to lack of F/U in management, they may be at risk of developing adverse events.

Methods: We initiated an IRB-approved retrospective analysis on all hospitalized patients at an urban academic medical center who underwent a rheumatology consultation from 7/17/2017 – 8/31/2017, and whom were expected to follow up in clinic. Tabulated data for each patient included whether the patient followed up within 2 weeks of their expected appointment along with several variables. We subsequently conducted a prospective intervention study for all consulted inpatients during 2/1/2019 – 3/15/2019, which involved: 1) Each patient was explained the importance of F/U (particularly skilled nursing facility (SNF) patients). 2) A business card was provided with appointment date and time. 3) The consult team assured that administrative staff contacted each patient for a convenient appointment if unable to be made during hospitalization before discharge. 4) Disease-specific handouts were given to each patient, particularly gout patients. 5) Financial barriers were addressed by an inpatient social worker, and the option to follow up at satellite campuses was offered. Retrospective analysis was then repeated on data from this intervention group.

Results: The pre-intervention group had an overall low percentage of F/U (33%). Important contributors to low follow up included: patients without an established rheumatologist (18%), patients with no appointment made for F/U (29%), and patients discharged to a SNF (11%).

The post-intervention group (versus the pre-intervention group) had a higher percentage of post-discharge F/U for all patients (58% vs 33%). The post-intervention group F/U rate was also higher for the following: patients without repeat admission (66% vs 40%), scheduling of F/U appointment before discharge (62% vs 25%), patients without established rheumatologist (50% vs 18%), and patients discharged to SNF (66% vs 11%). Interestingly, among specific diseases analyzed (CTD, vasculitis, other), patients admitted for crystal-induced arthritis had the greatest improvement in F/U rate (50% vs 20%). All other categories examined showed improvement in the post-intervention group F/U rate as well.

Conclusion: A systems-based intervention is effective in improving outpatient follow up for hospitalized rheumatology patients. Particular focus should be on patient education, addressing financial and transportation barriers, and arranging follow up before discharge, all in a protocolized manner.

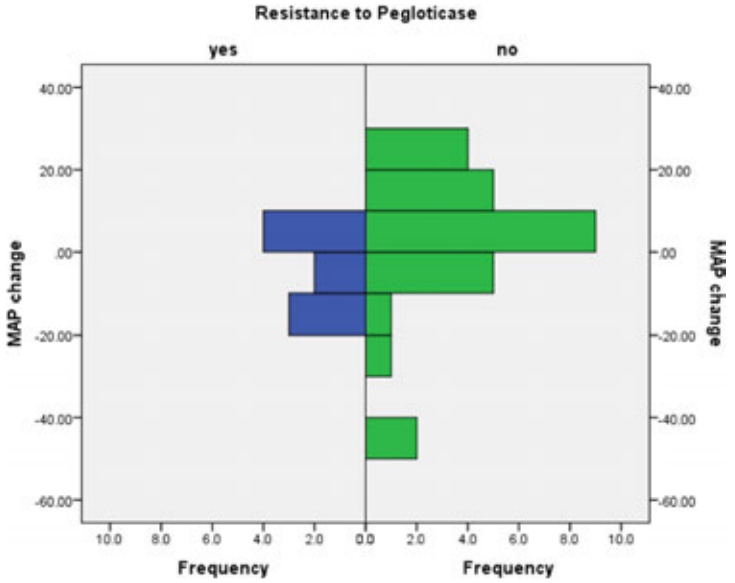
The Effects of Pegloticase on Mean Arterial Blood Pressure: An Age Modulated Relationship?

Saadia Waheed,[1] Hafiz Muhammad Zubair,[2] aamer ubaid,[3] farishta waheed,[3] and Linda Burns[4], [1]Sisters of Charity Hospital, Buffalo, NY, [2]Sisters of Charity Hospital, buffalo, [3]Khyber Teaching Hospital, Peshawar, Pakistan, [4]Buffalo Rheumatology and Medicine, Buffalo

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple studies indicate hyperuricemia as an independent risk factor for hypertension. However, the association is found to be age-dependent and weakens as the patient age. We determined the effect of Pegloticase (a plasma uric acid lowering agent) induced low serum uric acid level on mean arterial blood pressure (MAP). We also studied the following possible confounders to the MAP lowering effects of Pegloticase as mentioned above: Body Mass Index (BMI) estimated Glomerular Filtration Rate (eGFR) and Random Blood Sugar (RBS).

Methods: This retrospective study was conducted at the outpatient clinical department of Buffalo Rheumatology and Medicine. Catholic Health Institutional Review Board ethically approved the study. We recruited 36 patients of age 40 years o above receiving Pegloticase 8mg every two weeks. Patients were divided into two groups: responder and non-responder to Pegloticase, based upon individual serum uric acid levels (< 2mg/dl serum uric acid level was considered to be a response to Pegloticase). The difference in Mean Arterial Pressure (MAP) was noted when treatment was begun until when treatment was completed. A similar trend of difference in following confounders was observed at initiation and completion of therapy: BMI, eGFR and RBS. The data were analysed separately for the Pegloticase resistant and non-resistant group through SPSS 16.0.



Population pyramid showing Mean Arterial Pressure change in the Pegloticase resistant and non-resistant group.

	MAP mmHg	MAP mmHg	Systolic BP mmHg	Systolic BP mmHg	Diastolic BP mmHg	Diastolic BP mmHg
	Pre-Drug	Post-Drug	Pre-Drug	Post-Drug	Pre-Drug	Post-Drug
MEAN	100.26	99.86	141.31	141.64	79.75	78.97
STANDARD DEVIATION	12.008	18.10	17.67	26.43	14	16.65
MINIMUM	77	67.33	107	108	53	42
MAXIMUM	122.67	154.67	179	222	110	136
MEDIAN	101.16	97.83	140	131.5	77.5	77.5

The pre- and post- Pegloticase descriptive statistics for blood pressure

Results: Our study sample included 28 males (77.8 %) and 8 females (22.2 %). The mean age of patients was 67.89 years ± 12.97 SD. Patients' baseline characteristics are summarised in table 1. Each patient received 8 mg of a sustained dose of Pegloticase for a mean of 7.56 months. No statistically significant change in MAP was noted in either responder (t=-1.19, p=0.266) or non-responder group (t=0.534, p=0.598) from the time when therapy was initiated to when therapy was completed. Mean arterial pressure difference remains statistically non- significant and same across different durations of Pegloticase use (p =0.154). Furthermore, no statistically significant change

was noted in following confounders for recruited patients: the eGFR (Z=-1.44, p=0.150), RBS (Z=-0.729, p= 0.46) and BMI (Z=-1.538,p=0.124).

Conclusion: Our study doesn't show any significant change in the mean arterial pressure irrespective of the effect of Pegloticase on serum uric acid levels. This could be because most of our recruited patients were elderly with a mean age of 67.89 years ± 12.97 SD. Thus one can conclude that the relationship of uric acid with hypertension appears to be dampened with age. Although our results could be consistent with a differential role for uric acid in age-related hypertension, other possibilities remain. For example, uric acid may be associated with only certain forms of hypertension (e.g. one accompanying metabolic syndrome) as opposed to the isolated systolic hypertension related to arterial stiffening. More large-scale clinical studies are needed in this regard to dissect the role of uric acid in hypertensive individuals. We also did not find any significant changes in the considered confounding variables from the beginning towards the end of the study, indicating age as a significant determinant for Pegloticase induced lowering of MAP.

A Multicenter, Randomized, Double-blind, Placebo-controlled, Dose-Ranging Study to Evaluate Efficacy and Tolerability of SHR4640 in Patients with Hyperuricemia

Yanwei Lin,[1] Xiaoxiang Chen,[2] Ping Ye,[1] Wenqin Geng,[1] Rui Ning,[3] Yanfei Tai,[3] and Chunde Bao[4], [1]Renji Hospital Affiliated to Shanghai Jiaotong University School of Medicine, Shanghai, China (People's Republic), [2]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of medicine, Shanghai, China (People's Republic), [3]Jiangsu Hengrui Medicine Co., Ltd, Shanghai, China (People's Republic), [4]Department of Rheumatology, Renji Hospital, Shanghai Jiaotong University School of medicine, Shanghai, Shanghai, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia, a common metabolic disorder, predisposes patients to develop gout due to the deposition of insoluble urate in joints. Safety concerns are frequently raised with commonly prescribed uricosurics. The purpose of present trial is to assess the efficacy and safety of SHR4640 - a highly selective URAT1 inhibitor in hyperuricemic subjects in China.

Methods: Subjects with gout and serum uric acid (sUA) ≥480 μmol/L, or subjects without gout but with (sUA ≥480 μmol/L) or without (sUA ≥540 μmol/L) cardiovascular dysfunction were enrolled. All eligible subjects were randomly assigned (1:1:1:1:1) to monotherapy of SHR4640 2.5, 5, 10 mg, benzbromarone 50 mg and placebo, respectively. The primary endpoint was the proportion of subjects achieving sUA target of ≤360 μmol/L after 5-week treatment. This trial was registered with ClinicalTrials.gov, NCT03185793.

Results: A total of 197 subjects received assigned treatments. Subjects were predominantly male (99.5%) and associated with gout (95.9%), with a median age of 41.0 years (range, 18.0 to 69.0). The sUA targets were achieved in 32.5%, 72.5% and 61.5% of subjects receiving SHR4640 5 mg, 10 mg and benzbromarone 50 mg, respectively, which were significantly higher than that of placebo (0%, $P < 0.05$, Figure 1). The sUA was 596.2 ± 87.5 μmol/L at the baseline, and was reduced by 18.0%, 32.2%, 47.0% and 41.4% after 5-week treatment with SHR4640 2.5 mg, 5

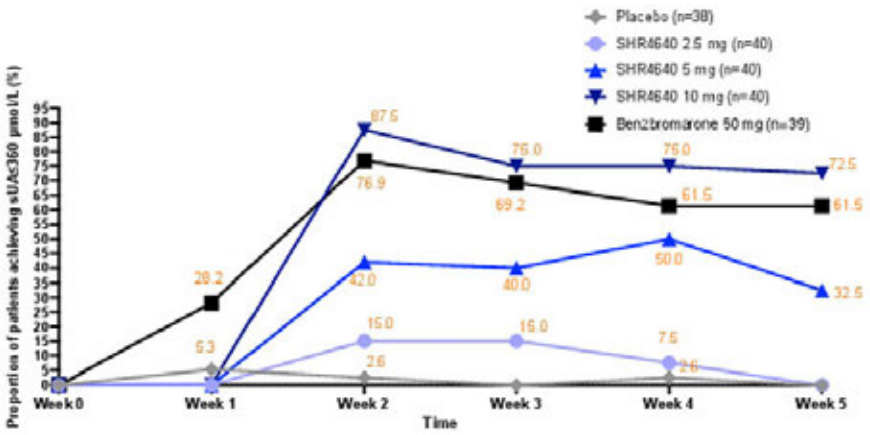

Figure 1. Proportion of patients achieving serum urate (sUA) target levels of ≤360μmol/l by week 1-5. The starting dose of SHR4640 and benzbromarone were 1 and 25 mg once daily at week 1, respectively, and then increased to the fixed dose at weeks 2-5.

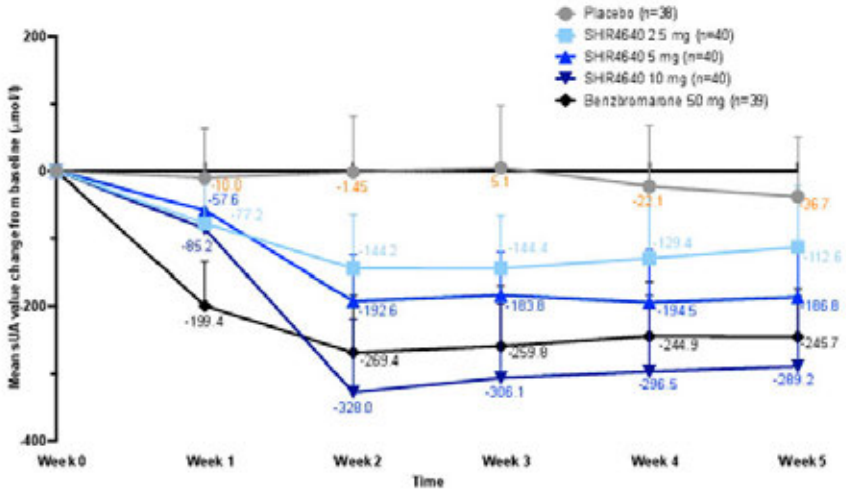

Figure 2. Serum urate (sUA) value change from baseline at each study visit. Values are the mean±SD. The starting dose of SHR4640 and benzbromarone were 1 and 25 mg once daily at week 1, respectively, and then increased to the fixed dose at weeks 2-5.

mg, 10 mg and benzbromarone 50 mg, respectively, which were significantly greater than that of placebo (5.8%, $P < 0.05$, Figure 2). The incidence of gout flare requiring intervention was similar across all groups. SHR4640 was well-tolerated. Occurrences of AEs were comparable across all treatment groups, although the incidence of transient elevated serum creatinine was slightly higher in SHR4640 10 mg as comparing with others (serum creatinine elevations between 1.5-fold and 2-fold over baseline occurred in 5.0% [n=2] of patients on SHR4640 10 mg, 0% in other groups, Table 1). Serious AE including death was not reported.

Table 1. Adverse events.

Adverse event	Placebo (N=38)	SHR4640 2.5 mg (N=40)	SHR4640 5 mg (N=40)	SHR4640 10 mg (N=40)	Benzbromarone 50 mg (N=39)	SHR4640 total (N=120)
Gout flares	14 (36.8)	17 (42.5)	19 (47.5)	17 (42.5)	18 (46.2)	53 (44.2)
Upper respiratory infection	3 (7.9)	8 (20.0)	5 (12.5)	8 (20.0)	10 (25.6)	21 (17.5)
Diarrhea	1 (2.6)	3 (7.5)	5 (12.5)	2 (5.0)	1 (2.6)	10 (8.3)
Hyperlipidemia	2 (5.3)	4 (10.0)	3 (7.5)	2 (5.0)	1 (2.6)	9 (7.5)
Arthralgia	1 (2.6)	1 (2.5)	4 (10.0)	4 (10.0)	2 (5.1)	9 (7.5)
Elevated serum creatinine	3 (7.9)	0	3 (7.5)	5 (12.5)	0	8 (6.7)
Alanine aminotransferase increased	1 (2.6)	2 (5.0)	4 (10.0)	1 (2.5)	2 (5.1)	7 (5.8)
Hypertriglyceridemia	2 (5.3)	0	2 (5.0)	4 (10.0)	3 (7.7)	6 (5.0)
Leukocytosis	1 (2.6)	1 (2.5)	1 (2.5)	2 (5.0)	1 (2.6)	4 (3.3)
Neutrophil count increased	0	1 (2.5)	1 (2.5)	2 (5.0)	0	4 (3.3)
Back pain	2 (5.3)	2 (5.0)	1 (2.5)	1 (2.5)	1 (2.6)	4 (3.3)

Conclusion: The present trial demonstrated greater sUA-lowering effect of SHR4640 5 mg and 10 mg versus placebo, with a generally tolerable safety profile. SHR4640 represents a new treatment option for subjects with hyperuricemia in China.

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is characterized by a build-up of uric acid crystals in and around the joints. Uric acid crystal formation and dissolution is affected by pH. There are reports in the literature of the use of alkalization agents, such as sodium bicarbonate, to treat gout. Theoretically, an alkalinizing agent such as sodium bicarbonate (baking soda) may increase the systemic and/or local pH and may allow pH sensitive uric acid crystals to dissolve

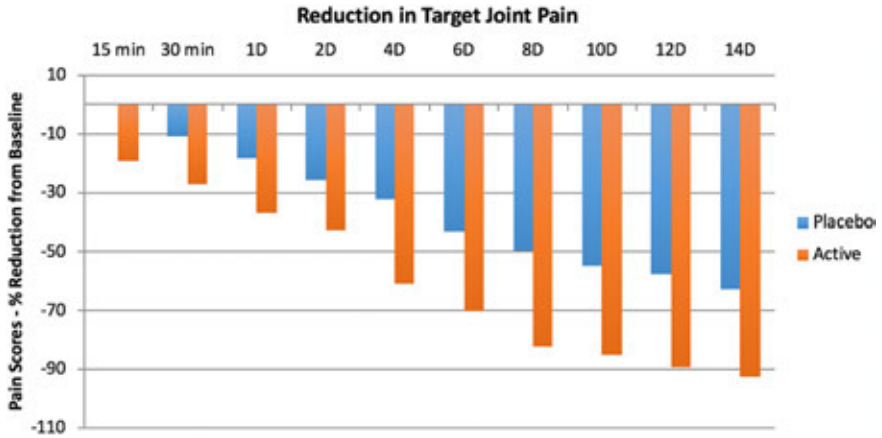

Figure 1. The active treatment subjects (N=12) had pain scores that averaged about 1.3 points lower than the placebo patients (N=12) (p=0.0041). The figure shows the % reduction in pain scores over time in the target joint.

resulting in temporary relief of pain and shortening duration of a gout flare, however oral sodium bicarbonate use causes intolerable gastrointestinal side-effects. Purpose of study was to determine if sodium bicarbonate in a patented transdermal drug delivery system can effectively and safely reduce pain and shorten duration of an acute gout flare. This delivery system has been shown to effectively deliver sodium bicarbonate transdermally in prior animal and human studies.

Methods: This pilot study is prospective, double-blinded, randomized, and placebo-controlled in design. Twenty-four subjects, female and male, aged 18+, with clinical diagnosis of gout, history of uric acid >6.8mg/dl, on stable medication regimen, presenting in clinic within 36 hours of initiation of acute gout attack and prescribed 0.6 mg/ daily colchicine were included. Exclusion criteria included >stage 3 kidney disease, tophaceous gout, and recent/ concurrent initiation of other pain medications (e.g. NSAID, corticosterioids). Subjects were randomized to receive placebo lotion or sodium bicarbonate transdermal lotion (33% sodium bicarbonate and 0.5% menthol) and instructed to apply to the entire limb of up to three affected joints (target joint and up to two other joints). Outcome measures included pain (numeric rating scale, 0-10), time to resolution (50% reduction in pain), range of motion and subject satisfaction. Time-points were baseline,15 & 30 min, and 1,2,4,6,8,10,12, and 14 days. Adverse events were collected. Statistical analysis was repeated measures ANOVA with $p< 0.05$ as significant.

Results: The active treatment subjects (N=12) had pain scores that averaged about 1.3 points lower than the placebo patients (N=12) (p=0.004). The figure shows the % reduction in pain scores over time in the target joint. The secondary joint (N=9 for both groups) also had a significant (p=0.04) reduction in pain with average pain of 1.2 points lower than control. The mean time to resolution for the target joint was 4.1 days in placebo group and 2.2 days in the active group. The mean time to resolution for the secondary joint was 2.8 days in the control group and 1.6 days in the active group. Among those who attained improved ROM, average time was 2.5 days in placebo group and 1.7 days in active group. No treatment related adverse events reported.

Conclusion: Topical transdermal sodium bicarbonate lotion use resulted in a highly significant (p=0.004) reduction in pain, as early as 15 min, and may speed resolution of acute gout attacks and improvement of range of motion.

Phase 2 Dose-ranging Study of SEL-212 in Symptomatic Gout Patients: Selection of Doses for Further Clinical Development

Rehan Azeem,[1] Alan Kivitz,[2] Horacio Plotkin,[1] Lloyd Johnston,[1] Takashi K. Kishimoto,[1] Justin Park,[1] Stephen Smolinski,[1] and Wesley DeHaan[1], [1]Selecta Biosciences, Watertown, MA, [2]Altoona Center for Clinical Research, Duncansville, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is caused by the deposition of monosodium urate (MSU) crystals in joints due to chronic hyperuricemia. Long-term treatment focuses on reducing serum uric acid (sUA) levels, thus allowing MSU crystals to dissolve. Administration of uricase, a non-human enzyme that catalyzes the conversion of uric acid into the water-soluble allantoin, has emerged as a therapy for the treatment of patients with gout that is refractory to conventional treatments. Currently approved uricase products are immunogenic, which results in decreased efficacy as anti-drug antibodies (ADAs) develop as well as increased safety concerns. SEL-212 is a novel combination product consisting of pegadricase co-administered with proprietary ImmTOR tolerogenic nanoparticles. ImmTOR has been designed to mitigate the formation of ADAs to pegadricase by inducing tolerogenic dendritic cells and antigen-specific regulatory T cells. Mitigating the formation of ADAs is vital in maintaining a sustained control of sUA levels in patients. Here we describe the results of a Phase 2 clinical trial (NCT02959918) designed to identify the appropriate doses of the 2 components for further development of SEL-212.

Methods: In this open-label dose-ranging study, patients with symptomatic gout (≥1 tophus, gout flare within previous 6 mo, and/or gouty arthropathy) and hyperuricemia (sUA ≥6 mg/dL) were enrolled and treated with pegadricase at 0.2 or 0.4 mg/kg alone, or combined with 0.05 to 0.15 mg/kg ImmTOR. Treatments were administered intravenously monthly for 3 cycles of SEL-212, followed by 2 additional cycles with pegadricase alone or SEL-212 (see **Table**). Dosing was stopped in patients demonstrating sUA ≥1.0 mg/dL on Day 21 after the previous dose. Safety, tolerability, sUA, ADAs, and clinical outcomes were monitored throughout the study.

Results: A total of 152 patients enrolled in the study. The average age was 54.8 (range 23-75) years, most were male (90.8%), and the mean duration of symptomatic gout was 8.0 years. When administered alone at either dose, pegadricase resulted in a rapid reduction in sUA, which was not sustained due to ADA formation in 5 of 6 patients. The addition of ImmTOR at ≥0.1 mg/kg reduced ADA formation, allowing sustained reduction in sUA, but these responses were attenuated when ImmTOR was removed during cycles 4 and 5. The combination of pegadricase (0.2 mg/kg) and ImmTOR (0.1 or 0.15 mg/kg) was given during all 5 cycles in 3 additional cohorts. In these cohorts, 66% of evaluable patients (21/32) maintained sUA levels below 6 mg/dL at Week 20 after 5 monthly doses of SEL-212, and 100% of patients who had sUA < 6 mg/dL at 12 weeks maintained control through 20 weeks. Sustained reduction of sUA levels correlated with low or no ADAs. The percentage of patients experiencing flares in these 3 cohorts declined from 35% during month 1 to 9%-10% during months 3, 4, and 5.

Conclusion: Based on these results, the combination of pegadricase (0.2 mg/kg) and ImmTOR (0.15 mg/kg) were selected for use in a head-to-head comparison study of SEL-212 to pegloticase, a pegylated uricase currently FDA approved for use in patients with treatment-refractory gout (NCT03905512).

Pegadricase dose mg/kg	ImmTOR dose mg/kg	Evaluable patients, n

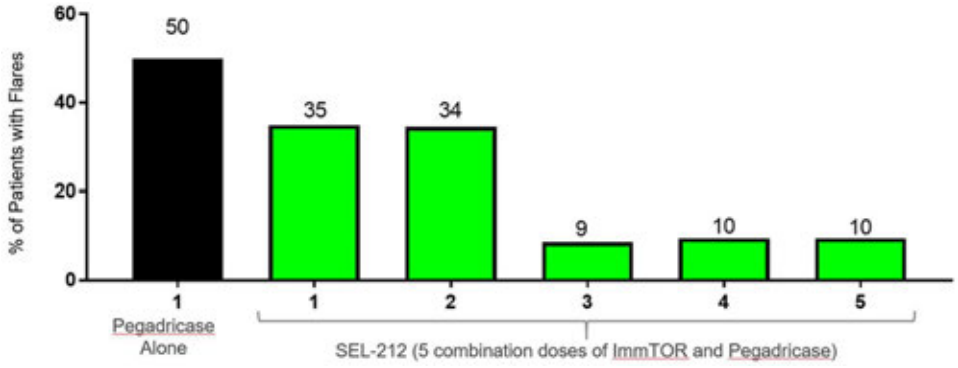
Monthly Dosing of ImmTOR Tolerogenic Nanoparticles Combined with Pegylated Uricase (Pegadricase) Enables Sustained Reduction of Acute Gout Flares in Symptomatic Gout Patients

Rehan Azeem,[1] Justin Park,[1] Horacio Plotkin,[1] Alan Kivitz,[2] Lloyd Johnston,[1] Takashi K. Kishimoto,[1] Stephen Smolinski,[1] and Wesley DeHaan[1], [1]Selecta Biosciences, Watertown, MA, [2]Altoona Center for Clinical Research, Duncansville, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Long term gout treatment focuses on reducing sUA levels, thus allowing MSU crystals to dissolve. Rapid dissolution of MSU crystals during initial phase of urate lowering therapy (ULT) is associated with an increased incidence (75%) and frequency (2.1 flares/patient/month)* of acute gout flares contributing to poor treatment compliance. During ULT initiation, colchicine, NSAIDs or corticosteroids are used for gout flare prophylaxis. Pegylated uricases are therapies for the treatment of chronic gout. However, their efficacy and safety are limited by induction of anti-drug antibodies (ADA). SEL-212 is a novel combination product consisting of pegadricase co-



% of Patients with Flare by Treatment Month

administered with proprietary ImmTOR tolerogenic nanoparticles. We report here data on gout flares from a Phase 2 study in symptomatic gout patients.

Methods: Patients with symptomatic gout (≥1 tophus, gout flare within 6 months or gouty arthropathy) and elevated serum uric acid (sUA) ≥6 mg/dL were randomized to receive doses of pegadricase (0.2 mg/kg or 0.4 mg/kg) alone or in combination with ImmTOR (0.05 to 0.15 mg/kg). Treatments were administered intravenously monthly for 3 cycles of SEL-212, followed by 2 additional cycles with pegadricase alone or SEL-212. Safety, tolerability, sUA, and ADAs were monitored. Here we report on the patients that received 5 combination doses of ImmTOR and pegadricase.

94% (49/52) of all randomized patients received premedication for gout flare prevention as per standard of care in the form of colchicine (1.2 mg as loading dose, 0.6 mg QD for the remainder of their participation), ibuprofen, or equivalent dose of NSAID.

Results: Demographics of 46 patients treated with 28-day cycles x5 combination doses of ImmTOR and pegadricase as compared to 6 patients treated with pegadricase alone were 23-70 years old vs. 41-64 years old (mean 53.6 vs. 51.8 years), male 97.8% vs. 100%, and white 73.9%. vs. 33.3%. The mean BMI at baseline was 34.5 vs. 38.9 kg/m^2. 71.7% vs. 100% of patients were obese with mean duration of established or symptomatic gout was 12.5 vs. 12.8 years. 43 patients were evaluable for gout flare analysis.

In the first month 50% of patients who received pegadricase alone had flares compared to 35% receiving SEL-212. There were no patients with initial flares after second month of treatment.

Data analyzed as combined months in patients receiving SEL-212, showed flare incidence of 37.0% (months 1-3) and 13.6% (months 4-5), flare frequency was 0.83 flares/patient (months 1-3) and 0.27 flares/patient (months 4-5). Mean duration of the gout flares was 6.1 days, with majority of the gout flares (97.7%) being categorized as mild/moderate, with 2.3% (n=1) noted as severe in intensity. Adjustments to gout flare prevention medication were not required for 69.6% of the patients. No gout flares resulted in patient discontinuation or were reported as a study drug related serious adverse event.

Conclusion: Monthly dosing of ImmTOR combined with pegadricase has been well-tolerated and has a lower incidence of flares at the initiation of therapy relative to pegylated uricases alone and the reported ULT flare incidence, and the effect persists over the duration of therapy.

Uric Acid Level as a Predictor of Long Term Mortality in Advanced Age Population

Gabriel Breuer,[1] Marwan Abu Sneineh,[1] and Gideon Nesher[1], [1]Shaare Zedek Medical Center, Jerusalem, Yerushalayim, Israel

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia is associated with the development, progression and outcome of several diseases. The purpose of this study is to evaluate the serum uric acid (UA) levels as predictor of long-term mortality in elderly population aged 60 years and above. In a previous study we showed that short term mortality is inversely related to uric acid levels (Table 1).

Methods: Patients older than 60 years who were hospitalized in the departments of geriatrics and internal medicine in one medical center during a period of 4 months (March-June 2014) were included in this observational study. Data on clinical parameters and UA levels were collected during the first 48 hours of their hospitalization. The short-term mortality of this cohort was reported in a previous study, and we have continued to follow this cohort for 3.5 more years. Mortality data had been collected from databases of the Ministry of Internal Affairs, and the major medical centers in Jerusalem. Excluded were patients for whom mortality data were missing (unknown status or date of mortality). Demographic and clinical data were collected on admission including UA serum levels within 48 hours from admission Effect of UA serum levels and all relevant confounding parameters on all-cause mortality was assessed using regression analyses.

Results: 624 patients were included in our study. Mean age was 77.2 ± 14.6 years. Overall, 381 patients died during the follow up period (61.1%). Mortality rate in the hyperuricemic group (UA > 7 mg/dl) was higher (69.1%) than in normo-uricemic patients (58.4%, p= 0.004). The median survival for hyperuricemic patients was significantly shorter compared to normo-uricemic patients (606 and 1018 days, respectively, (p< .0001). (Figure 1)

Conclusion: Elevated levels of UA in an acute setting is a predictor of both short and long-term mortality.

Table 1 Short term mortality- Published data (Eur J Intern Med. 2017;44:74-76)

Uric Acid Level, mg/dl	Mortality, n (%)
0-3.4	12/119 (10)
3.5-7.5	51/478 (11)
7.6-9.4	29/136 (21)
9.5 and above	34/96(35)

p<0.001 for difference between serum UA above or below 7.5 mg/dl
p =0.008 for difference between serum UA 7.6 -9.4mg/dl and 9.5 and above

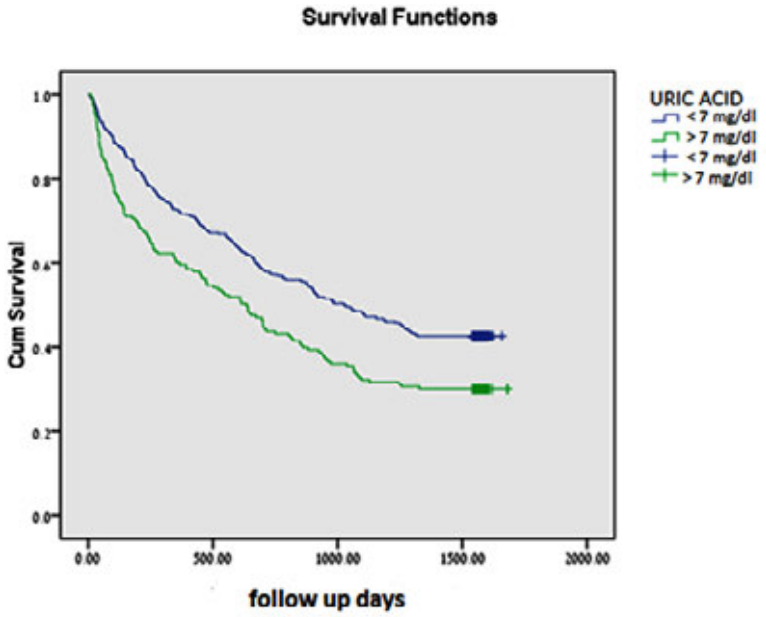

Figure 2: Kaplan-Meier mortality curves during the follow-up period.

How Are Flares Reported in Long-term Gout Clinical Trials? A Content Analysis of Randomized Controlled Trials

Sarah Stewart,[1] Amy Tallon,[2] William Taylor,[3] Angelo Gaffo,[4] and Nicola Dalbeth[2], [1]University of Auckland, Auckland, Auckland, New Zealand, [2]University of Auckland, Auckland, New Zealand, [3]University of Otago, Otago, New Zealand, [4]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Prevention of gout flares is a central concern to patients with gout. There are many potential ways that gout flares could be reported in long-term clinical trials. The aim of this study was to analyse methods used to measure and report gout flare outcomes in long-term randomized controlled trials (RCTs).

Methods: A systematic search of electronic databases, supplemented with hand-searching of relevant references lists, was conducted. Articles were included if they were RCTs or articles reporting on analyses of RCT data (i.e. open label extension studies) and reported the impact of an intervention on the prevention of flares in people with gout. The modified Jadad scale was used to assess quality. Gout flare data relating to protocols, outcomes and reporting methods were extracted and synthesised separately for studies of anti-inflammatory prophylaxis and urate lowering/ other long term therapy.

Results: A total of 38 articles were included, with 10 reporting outcomes for anti-inflammatory prophylaxis and 28 for urate lowering/other long term therapy. The overall quality score of all articles was good. However, there was marked heterogeneity across trials in gout flare-related entry criteria, flare definitions, data capture methods, reporting methods and time periods used to report gout flares. Anti-inflammatory prophylaxis studies used multiple methods to report gout flare outcomes (mean (SD) 4.3 (2.5) methods/article), while the majority of urate lowering/other long term therapy studies used a single method to report gout flare outcomes. The most common reporting method was the proportion of patients with at least one gout flare (n = 29 articles), followed by the mean number of gout flares per patient (n = 18 articles) (**Table**). Only studies of anti-inflammatory prophylaxis therapy reported flare duration or pain (**Table**).

Conclusion: There is wide variation in methods used to measure and report gout flare outcomes in long-term RCTs. Studies of anti-inflammatory prophylaxis interventions generally report a range of flare characteristics, including incidence, number of flares, flare duration, and pain intensity. In contrast, studies of urate lowering/other long term therapy report limited data, mostly the proportion of participants experiencing flare. These findings support the development of standardized methods to measure and report gout flare outcomes that reflect the burden of flares for studies in which gout flare prevention is an outcome of interest.

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Increased serum uric acid (sUA), hyperuricemia, has been reported to be associated with psoriasis (1). Increased cell turnover in psoriatic skin lesions has been proposed as a potential mechanism, but results are conflicting (1). In this study we assessed levels of sUA to degree and severity of skin involvement measured by Psoriasis Area Severity Index (PASI) at baseline and after treatment with the IL-17A inhibitor, secukinumab. The objectives were to adress the following questions: 1) are PASI and sUA levels correlated; and 2) are changes in PASI associated with changes in sUA during treatment of psoriasis.

Methods: Subjects with psoriasis/psoriatic arthritis (N=1042/204 (19.6%)) with concomitant psoriatic arthritis in three RCTs (ERASURE, FIXTURE and SCULPTURE) treated with secukinumab (dose 300 mg, n=628) or placebo (n=414) were pooled and included. At baseline values for sUA and PASI and the following co-variates were assessed; age, sex, BMI, renal function defined as eGFR, medication with diuretics (%), these are all variables known to affect sUA levels. To assess change in PASI (ΔPASI) and sUA (ΔsUA) the differences (week 12 minus baseline) in subjects receiving active drug were used. Multivariable linear regression, adjusting for identified co-variates, was used to assess the association between PASI and sUA at baseline with all subjects pooled and to assess the association between ΔsUA and ΔPASI over 12 weeks intervention in only those treated with secukinumab. All continuous variables

Table 1 Multivariate linear regression at baseline in all subjects (n=1042) with sUA as dependent variable adjusting for all covariates in the table. Increase in continuous variable parameter estimates represent the change in sUA per 1 standard deviation (at baseline) difference in PASI and co-variates.

	Parameter estimate	95% C.L.	p-value	$R^2 = 0.33$
PASI at baseline	11.2 (2.4)	6.5, 15.9	<0.0001	
Age	-20.4 (3.1)	-26.6, -14.3	<0.0001	
Sex (ref: man)	-82.6 (5.2)	-92.9, -72.4	<0.0001	
eGFR	-30.3 (3.1)	-36.5, -24.2	<0.0001	
Diuretic user (ref: no)	33.6 (10.1)	13.7, 53.4	0.001	
BMI	25.5 (2.4)	20.8, 30.3	<0.0001	

Table 2 Multivariate linear regression with ΔsUA (week 12 - baseline) as dependent variable in subjects treated with secukinumab (n=628), adjusting for age, sex, eGFR, Diuretic use and BMI at baseline. Increase in continuous variable parameter estimates represent the change in ΔsUA per 1 standard deviation (at baseline) difference in PASI and co-variates.

	Parameter estimate	95% C.L.	p-value	$R^2 = 0.06$
ΔPASI (SD) (week 12 - baseline)	16.0 (2.9)	10.3, 21.7	<0.0001	

were standardized with the exception of the dependent variable sUA, hence an increase in parameter estimates represent the change in sUA per 1 standard deviation (at baseline) difference in PASI and other continuous co-variates.

Results: Baseline characteristics; 70% were male, 6% were on diuretics and mean (SD) age, BMI and e GFR were 45 (13) yrs, 29.2 (6.8) kg/m2 and 96 (17) mL/min/1.73m2, respectively. From baseline to week 12, in patients treated with secukinumab, mean (SD) PASI decreased from 23.7 (SD: 10) to 2.9 (SD: 5) and sUA from 366 (SD: 96) to 359 (SD: 94) μmol/L. At baseline, covariates explained 33% of the variance in sUA with a significant contribution of PASI. A higher PASI value of 1 SD (10 units) was associated with 11.2 (p >0.0001) μmol/L higher value of sUA in the fully adjusted model. Other co-variates had larger effects (table 1). During 12 week follow-up, co-variates explained little of the variation in ΔsUA (R2=0.06), but there was a significant association with ΔPASI (Table 2) in fully adjusted model.

Conclusion: Both the degree and change in skin involvement in psoriasis were modestly associated with sUA, supporting a potential pathophysiological relationship. Known risk factors for sUA had however a larger impact cross-sectionally. Furthermore, sUA decreased modestly with 12 week treatment with secukinumab.

>60ml/min (n=1091)	0.73 (0.02)	82.9	59.5%	75.7%	60.7%	74.8%

urinol responses, the ability of plasma oxypurinol levels to guide allopurinol dosing would be an advantage. Previous studies examining the relationship between oxypurinol and serum urate have been conflicting, with some showing no relationship and some an inverse relationship. Defining a therapeutic range has been challenging. The aim of this study was to determine the factors that influence the serum urate lowering response to allopurinol dose escalation and the conversion of allopurinol to oxypurinol, and to determine if there is a minimum therapeutic oxypurinol level.

Methods: Data from 129 participants in a 24-month open, randomized, controlled, parallel-group, comparative clinical trial were analysed. Allopurinol dose, serum urate and plasma oxypurinol concentrations were available at multiple time points. A slope for the association between allopurinol dose and serum urate was calculated for each individual as a measure of sensitivity to allopurinol. A slope for the association between allopurinol dose and plasma oxypurinol was calculated for each individual as a measure of allopurinol metabolism. Receiver operator characteristic (ROC) curves were used to identify oxypurinol concentration predictive of achieving serum urate < 6mg/dl.

Results: There were a wide range of serum urate concentrations for each allopurinol dose. Although there was a significant association between sensitivity to allopurinol (change in urate) and allopurinol metabolism (change in oxypurinol) for each 100mg increment in allopurinol dose (r=-0.60; p< 0.001), there was substantial variation between individuals (Figure 1 b and c).Body mass index (p=0.023), CrCL (p=0.037), ABCG2 Q141K (p=0.019), and baseline urate (p=0.004) were all associated with sensitivity to allopurinol, independent of other measured confounding variables. The oxypurinol ROC curve AUC to achieve serum urate < 6mg/dl was 0.65, with similar AUC values across all three CrCL groups (Table). The optimal minimum oxypurinol level for achieving target was strongly associated with CrCL (Table).

Conclusion: Although there is a relationship between change in oxypurinol and change in serum urate concentration, a minimum therapeutic oxypurinol is dependent on CrCL and cannot reliably predict serum urate target. Other variables, including ABCG2 Q141K genotype, impact on sensitivity to allopurinol.

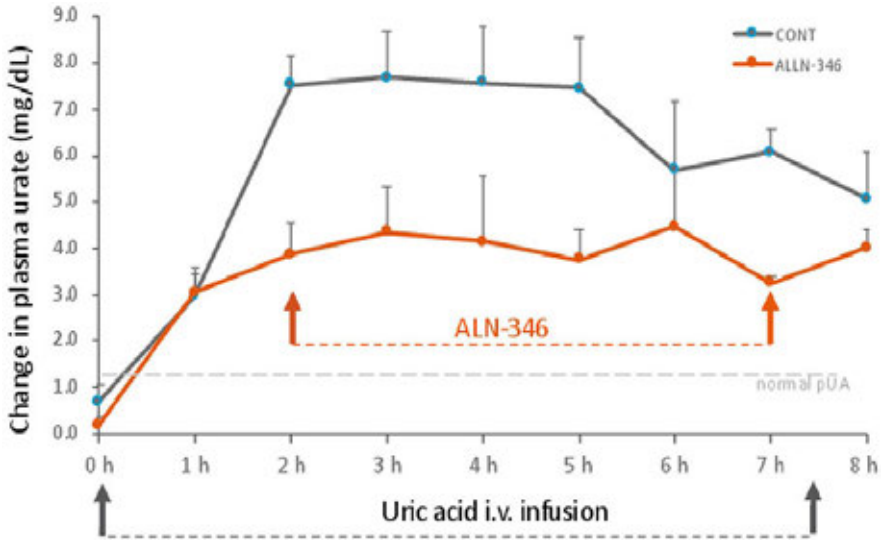
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uric acid homeostasis is determined as a balance between production, intestinal secretion and renal excretion. Around 2/3 of uric acid is excreted by the kidneys, while the remaining 1/3 is excreted by intestine. In people with impaired renal function and hyperuricemia extra-renal elimination ranges between ~50-70% and plays important role in urate homeostasis.[1] Existing urate-lowering therapies including oral xanthine oxidase inhibitors, uricosurics, and intravenous uricase agents have limitations either in efficacy or tolerance which contribute to refractoriness. ALLN-346 is an orally administered, non-absorbed, recombinant urate degrading enzyme designed to degrade urate secreted in the intestinal tract and thereby reduce hyperuricemia. Previously, we demonstrated in a urate oxidase KO mouse that 7d of ALLN-346 oral therapy reduces hyperuricemia to the similar extent as allopurinol.[2] Here, we tested whether enteral administration of ALLN-346 to pigs with acute hyperuricemia[3] could reduce plasma urate (pUA) and urine urate excretion.

Methods: 7 juvenile pigs (mean bw 17.3kg) with normal kidney function, and with jugular vein catheters for uric acid infusion and blood collection, were administered with ALLN-346 via a duodenal port following induction of hyperuricemia with uric acid infusion. Study was done in pigs that were fed 3x/d (1.0% bw/meal) and watered *ad lib.* A control run of hyperuricemia was performed by chronic i.v. infusion of uric acid via jugular catheter (10 mg/kg from 40 mg/mL uric acid in 40% glucose) for 7.5h. After 36h wash out, a treatment with ALLN-346 was performed 2h after



start of uric acid infusion, when hyperuricemia was induced. ALLN-346 was given hourly to duodenum as a bolus suspension in saline (6 x 10,560u). To estimate changes in pUA, blood was collected at baseline and hourly during the 8h experiment, and $AUC_{0\text{-}8h}$ was calculated. Urine was collected for uric acid analysis. Intestinal samples were analyzed for expression of ABCG2 urate transporter, that regulates serum UA, by Western Blot (WB) with pig anti-BCRP/ABCG2 antibody (Abcam).

Results: pUA at baseline was < 1 mg/dL. Uric acid infusion resulted in an immediate increase in pUA, with mean Cmax of 7.7 mg/dL at 3h, and calculated AUC0-8h of 44.3 mg*h/dL. Administration of ALLN-346 attenuated the rise in pUA with Cmax reduced to 4.5 mg/dL and AUC0-8h of 27.5mg*h/dL. The difference between the treatment and control run in pUA was 38% (p=0.0009). The urine uric acid excretion was reduced 16% with ALLN-346 compared to control run. WB confirmed expression of ABCG2 in small intestine, being the highest in the jejunum and ileum.

Conclusion: The results of this pilot experiment in pigs with acute hyperuricemia confirm that intestine plays an active role in urate elimination in conditions of severe hyperuricemia and suggests the potential for ALLN-346 acting in the intestinal tract to reduce pUA levels and overall urate burden in people with hyperuricemia and gout. Further studies are planned to confirm these findings.

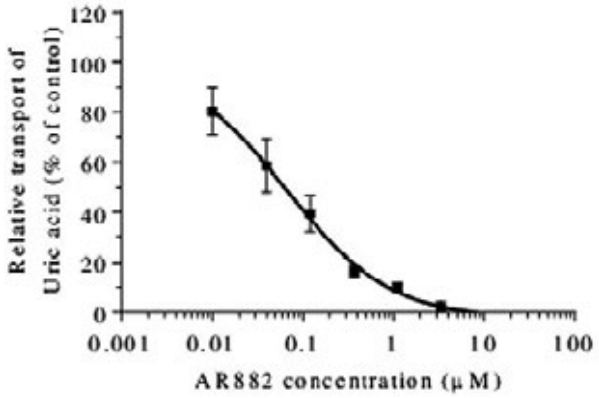
AR882, a Potent and Selective URAT1 Inhibitor with a Favorable Pharmacological, Pharmacokinetic and Toxicity Profile

Rongzi Yan,[1] Nanqun Zhu,[2] zancong shen,[3] Shunqi Yan,[4] and Litain Yeh[1], [1]Arthrosi Therapeutics, Laguna Hills, [2]Consultant, Laguna Hills, CA, [3]Arthrosi Therapeutics, San Diego, CA, [4]Arthrosi Therapeutics. Inc, Laguna Hills, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: AR882 is a potent and selective inhibitor of uric acid transporter 1 (URAT1), which is responsible for a majority of reabsorption of filtered uric acid from the renal tubular lumen. By inhibiting URAT1, AR882 increases uric acid urinary excretion and thereby lowers serum uric acid (sUA). Preclinically, AR882 has demonstrated inhibitory effect on uric acid uptake and good tolerability in pharmacology, pharmacokinetic and toxicology studies.

Methods: The inhibition of AR882 on human URAT1-mediated uptake of [^{14}C]uric acid was studied in Madin-Darby Canine Kidney (MDCKII) cells expressing human URAT1. Inhibitory potential to human organic anion transporter (OAT) 4, a transporter reported involving uric acid uptake, was also tested in human embryonic kidney (HEK) 293



Inhibition of URAT1-mediated Uric Acid Uptake by AR882

cells expressing human OAT4. Absorption, distribution, excretion of AR882 were evaluated following single oral or intravenous administration in multiple species. Metabolic stability of AR882 was evaluated in microsomes and hepatocytes *in vitro* across species including human and *in vivo* in rats, dogs and monkeys. Drug-drug interaction (DDI) evaluations with major renal transporters were conducted in HEK293 cells expressing P-glycoprotein, OAT1, OAT3, OAT4, and organic cation transporter 2 (OCT2) transporters. Toxicity and toxicokinetics of AR882 were assessed following oral repeat-dose administration to Sprague-Dawley rats and cynomolgus monkeys for durations up to 4 weeks.

Results: AR882 exhibited high potency against URAT1 with an IC_{50} of 67 nM, compared to lesinurad (IC_{50} = 7.3 μM, Zurampic® Package Insert) or benzbromarone (IC_{50} = 196 nM). An IC_{50} of 2.89 μM against OAT4 indicated that AR882 is highly selective for URAT1. AR882 was well absorbed in rats, dogs, and monkeys, with a mean T_{max} of 1-2 hours. Bioavailability ranged between 76% and 88% across the tested species. *In vitro* metabolic profiling and *in vivo* clearance suggesting AR882 is extremely stable. In animals, unchanged parent compound was recovered in the urine at concentrations sufficient for complete inhibition of URAT1. Transporter evaluations with major efflux and uptake transporter in kidney revealed no DDI potential and no active-transportation involvement. Using allometric scaling, a low therapeutic dose of AR882 is anticipated in human. Rats and monkeys were selected as the species for toxicology evaluation based on metabolic profiling. In 4-week oral repeat-dose toxicology and toxicokinetic studies, AR882 was well tolerated at doses up to 50 mg/kg/day and 150 mg/kg/day in rats and monkeys, respectively. The exposures achieved in animals were substantially higher than the observed human exposure at the anticipated therapeutic doses of 25 mg – 100 mg in clinical study

Conclusion: AR882, a selective URAT1 inhibitor with superb potency for URAT1-mediated uric acid reabsorption has been discovered and developed for the treatment of gout at a low anticipated daily dose. AR882 exhibited favorable pharmacokinetic and DDI properties, as well as an excellent safety profile in preclinical studies.

Limits of Detection of Monosodium Urate Crystals in Synovial Fluid by Ultrasound

John FitzGerald,[1] Andrea Ramirez Cazares,[2] and Veena Ranganath[2], [1]UCLA, Los Angeles, CA, [2]University of California Los Angeles, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate limits of detection of ultrasound to detect monosodium urate crystals suspended in synovial fluid.

Methods: Serial dilutions were made mixing liquid tophus aspirated from an olecranon bursa with crystal free synovial fluid aspirated from a patient with knee osteoarthritis. For each dilution, beginning with the undiluted liquid tophus aspirate, crystal free synovial fluid was mixed with each subsequent dilution in a 1:1 ratio creating dilutions from 1:1 to 1:1024. At each dilution, the MSU suspensions in eppendorf tubes were scanned with GE Logic linear probe settings ranging from low to high frequency as needed for optimal imaging and penetration. Compensated polarized light microscopy images at 10x and 40x were obtained for each dilution.

Results: Ultrasound evidence of MSU crystals (snowstorm appearance) were still evident in serial dilutions up until 1:128. Corresponding histology imaged by compensated light microscopy revealed that large crystal aggregates were rare but there were still a high number of crystals (~100) per low power field. Further dilutions resulted in ultrasound images that were indistinguishable from crystal free aspirates of synovial fluid despite persistence of lower frequency MSU crystals.

Conclusion: Ultrasound is sensitive for detecting modest frequency of MSU crystals suspended in synovial fluid. Never-the-less, MSU crystals are still present in synovial fluid beyond ultrasound detection.

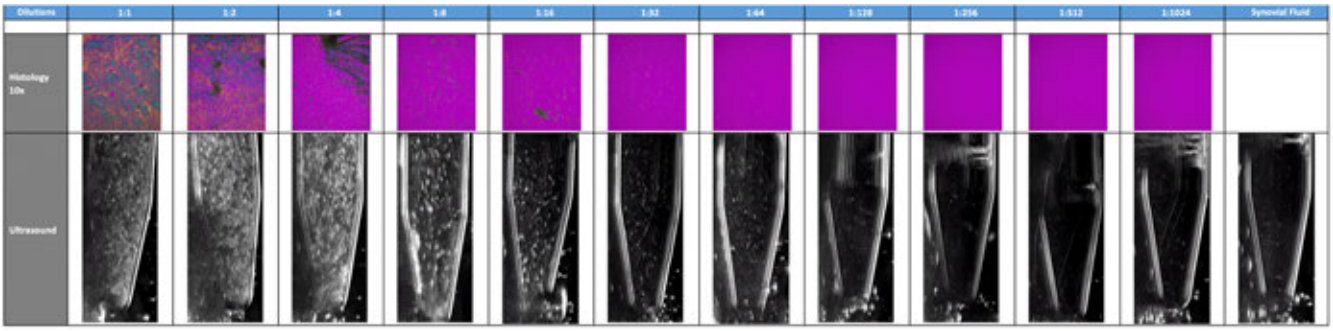

Figure 1: Serial dilutions of liquid tophus.

Neutrophil Activation Identifies Patients with Active Polyarticular Gout – a Role for Neutrophil Biomarkers in Monitoring Gout Disease Activity and Severity

Daisy Vedder,[1] Martijn Gerritsen,[1] Mike Nurmohamed,[2] Ronald van Vollenhoven,[3] and **Christian Lood** [4],
[1]Amsterdam Rheumatology & immunology Center / Reade, Amsterdam, Netherlands, [2]Amsterdam Rheumatology and immunology Center location Reade and Amsterdam UMC location VU medical center, Amsterdam, Netherlands, [3]Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, the Netherlands, Amsterdam, Netherlands, [4]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Neutrophils are key immune cells participating in host defense through several mechanisms, including the formation of neutrophil extracellular traps (NETs). Excessive neutrophil activation has been linked to inflammation and autoimmunity, including gout. In gout models, uric acid crystals induce NETosis. NETs are known to induce inflammation and partake in induction of tissue damage. The role of NETs, however, in human gout has not been extensively investigated.

Our objective is to investigate the clinical utility of neutrophil-derived biomarkers in gout. We hypothesize that uric acid crystals activate neutrophils to form NETs contributing to immune cell activation, with subsequent arthritis and joint damage.

Methods: Plasma samples from 75 gout patients participating in the 'Reade gout cohort Amsterdam' were compared with 30 healthy controls (HC). Levels of NETs, and NET-derived markers (cell-free DNA and peroxidase activity) were analyzed using a MPO-DNA ELISA, as well as fluorimetry. Levels of calprotectin were analyzed by ELISA. Mitochondrial as well as genomic DNA levels were analyzed by qPCR. All markers were compared with HC and related to markers of inflammation and disease activity.

Results: Levels of NETs, as well as other neutrophil biomarkers, were increased in gout patients as compared to HC ($p< 0.01$, Figures 1A-B). No associations were found between markers of cell death (cfDNA and NETs) and disease activity. Genomic DNA, but not mitochondrial DNA, was elevated among gout patients ($p< 0.05$), and related to number of gout attacks ($r=0.44$, $p=0.002$). Peroxidase activity correlated with disease activity (RAPID score: $r=0.43$, $p=0.01$, RAPID function: $r=0.54$, $p=0.001$) and inflammation markers (CRP: $r=0.40$, $p< 0.001$, and ESR: $r=0.43$, $p< 0.001$). Involvement of ankle and wrist resulted in significant higher peroxidase levels compared to mono-articular disease ($p=0.01$, and $p=0.03$, respectively), indicating peroxidase activity being a marker of polyarticular gout (Figure 1C). Calprotectin (S100A8/A9) correlated with the inflammation markers CRP and ESR ($r=0.30$, $p=0.01$, and $r=0.30$, $p=0.001$, respectively) and morning stiffness, especially in patients with chronic polyarticular gout ($r=0.61$, $p=0.001$).

Conclusion: To our knowledge, this is the first report demonstrating presence of NETs in the peripheral blood of gout patients. Although markedly elevated, levels of NETs did not associate with markers of disease activity or inflammation, possibly due to the lack of inflammatory mitochondrial DNA within the NETs. Even so, our data demonstrate an important role of neutrophils in gout pathogenesis, with neutrophil activation markers associating with characteristics of active, and more pronounced polyarticular disease.

A Neutrophil Signature Is Strongly Associated with Cardiovascular Risk in Gout

Daisy Vedder,[1] Martijn Gerritsen,[1] Mike Nurmohamed,[2] Ronald van Vollenhoven,[3] and **Christian Lood** [4],
[1]Amsterdam Rheumatology & immunology Center / Reade, Amsterdam, Netherlands, [2]Amsterdam Rheumatology and immunology Center location Reade and Amsterdam UMC location VU medical center, Amsterdam, Netherlands, [3]Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, the Netherlands, Amsterdam, Netherlands, [4]University of Washington, Seattle, WA

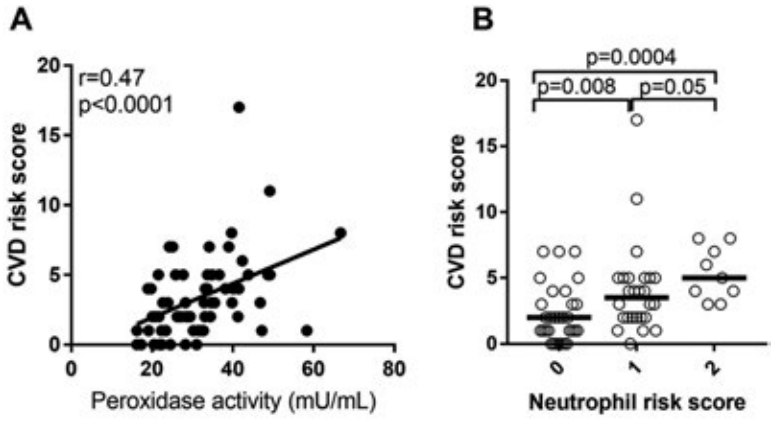
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with gout have an increased cardiovascular morbidity and mortality, not fully explained by traditional cardiovascular risk factors. Xanthine oxidase-induced oxidative stress, increased lipid oxidization and chronic low-grade inflammation have been suggested as important contributors. Neutrophils, through formation of neutrophil extracellular traps (NETs), partake in pro-thrombotic and atherogenic processes contributing to cardiovascular disease. However, the role of NETs in cardiovascular disease in human gout is not known.

Our objective is to investigate the association between neutrophil activation and cardiovascular risk in gout patients. We hypothesize that neutrophil activation mediates inflammation, as well as activation of and damage to endothelial cells, thus partaking in atherosclerosis development.

Methods: Plasma samples from 75 gout patients participating in the 'Reade gout cohort Amsterdam' were analyzed. Patient data was collected on disease activity, demographics, comorbidities, medication and cardiovascular risk assessments. Measurements included anthropometry, vital parameters (RR, HF) and lab variables. Levels of NETs, and NET-derived markers (cell-free DNA and peroxidase activity) were analyzed using an MPO-DNA ELISA, and fluorimetry. Levels of calprotectin were analyzed by ELISA. Markers of NETosis were related to traditional cardiovascular risk factors and 10 year risk of cardiovascular mortality (SCORE EU).

Results: No associations were found between markers of cell death (cfDNA and NETs) and cardiovascular risk. However, markers of neutrophil activation, including peroxidase activity correlated with BMI ($r=0.31$, $p=0.008$), waist-hip ratio ($r=0.52$, $p< 0.001$), cholesterol ratio ($r=0.51$, $p< 0.001$), and triglycerides ($r=0.42$, $p< 0.001$). These associations were even stronger in patients with chronic, polyarticular gout. Peroxidase activity was strongly associated with the 10 year risk of cardiovascular comorbidity ($r=0.47$, $p< 0.001$, Figure 1A). Calprotectin levels were elevated in gout patients with hypertension ($p=0.005$) and diabetes ($p=0.02$), with calprotectin levels associating with diabetes independently of BMI (OR=6.2, $p=0.04$). Finally, we constructed a neutrophil risk score ranging from 0-2 based on positivity for peroxidase and/or calprotectin to identify patients with a 'neutrophil activation signature'. The neutrophil risk score strongly associated with CVD risk (Figure 1B). Patients with neutrophil activation signature (risk score 1-2) had markedly elevated cardiovascular risk score ($p=0.001$), with 67.7% of the patients having high cardiovascular risk, versus 32.3% of the patients without a neutrophil activation signature (OR=2.9, $p=0.03$).



Conclusion: We have demonstrated that neutrophil activation markers are associated with a 10-year risk of cardiovascular comorbidity in gout patients. These results highlight an important, an unappreciated, role of neutrophils in development of fatal comorbidities in gout. Further studies are warranted to determine the prognostic value of a neutrophil activation signature in development of cardiovascular disease.

Abstract Number: 1228

Soluble Triggering Receptor Expressed on Myeloid cells-1 (sTREM-1) Ameliorates Monosodium Urate Crystals (MSUC)-induced Inflammation in a Mouse Air-pouch Model of Gout

Vitaly Kliminski,[1] and **Yair Molad** [2], [1]Laboratory of Inflammation Research, Felsenstein Medical Research Center, Tel Aviv University, Petach Tikva, Israel, [2]Rabin Medical Center, Beilinson Hospital, and Tel Aviv University, Petach Tikva, HaMerkaz, Israel

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Myeloid cells membrane-bound TREM-1 (mTREM-1) amplifies toll like receptor (TLR)-4-mediated myeloid cells activation, accompanied by release of soluble TREM-1 (sTREM-1) that acts as a decoy receptor. Previous studies suggest an upregulation of mTREM-1 in gout. TGFβ was previously shown to play an anti-inflammatory role in the spontaneous resolution of gout attack**.** In this study, we aimed to determine the effect of sTREM-1 in gout.

Methods: We've used a synthetic peptide inhibitor of TREM-1 (LP17) that is a conserved domain (LQVTDSGLYRCVIYHPP) of the extracellular portion of TREM-1 in an air-pouch mouse model of gout to determine the role of sTREM-1 in MSU crystal (MSUC)-induced inflammation.

Results: MSU crystals injected into the air-pouch induced an increase of mTREM-1 surface expression on CD11b-positive leukocytes by magnitude of 1.77 of (assessed by FACS) (p=0.013, n=3), as well as an increase of exudate sTREM-1 level (assessed by ELISA) by 397.4% (2082.02±630.21 vs. 418.6±323.7pg/ml, n=4, p=0.017). The synthetic peptide inhibitor of TREM-1 (LP17) injected into the air-pouch together with MSU crystals attenuated the inflammatory response by significant reduction of leukocyte count (MSUC+LP17: 0.83x106±6.8 vs. MSUC: 1.92x106±15.9, n = 5, p=0.041) , exudate level of TNFα (MSUC+LP17: 14.5±2.1 vs. MSUC: 27.9±3 pg/ml, n=3, p=0.036) and the chemokine CCL3/MIP1α level (MSUC+LP17: 11.8±8.2 vs. MSUC: 23.7±11.8 pg/ml, p=0.049). In contrast, the exudate level of the anti-inflammatory cytokine TGFβ was not affected by LP17 (PBS: 23.4±31.46pg/ml, MSUC: 123.57±51.96pg/ml, p< 0.0001; MSUC+LP17: 156.72±154.75pg/ml, n=10, p=NS).

Conclusion: Soluble TREM-1 (LP17) ameliorates MSU crystal-induced inflammation through several modes of action, as is demonstrated by significant decrease of exudate leukocyte count, as well as TNFα and CCL3 levels. Moreover, LP17 didn't change TGFβ level, suggesting synergistic anti-inflammatory effects of sTREM-1 and TGFβ that leads to the resolution of gout attack.

AR882, a Potent and Selective Uric Acid Lowering Agent Acting Through Inhibition of Uric Acid Reuptake, Shows Excellent Pharmacokinetics and Pharmacodynamics in a Phase 1 Clinical Trial

zancong shen,[1] Elizabeth Polvent,[2] Vijay Hingorani,[3] Shunqi Yan,[4] Rongzi Yan,[4] and **Litain Yeh** [4], [1]Arthrosi Therapeutics, San Diego, CA, [2]Arthrosi Therapeutics, Laguna Hills, CA, [3]Arthrosi Therapeutics, San Diego, [4]Arthrosi Therapeutics, Laguna Hills

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: AR882 is a potent and selective uric acid transporter 1 (URAT1) inhibitor under development for the treatment of hyperuricemia or gout. A Phase 1 single ascending dose clinical study in healthy adult male subjects was conducted to evaluate pharmacokinetics and dose-dependent serum uric acid (sUA) lowering effect.

Methods: Analysis of sUA reduction was conducted in a randomized, double-blind, placebo-controlled single dose study with 31 healthy male volunteers. Eight subjects per group (6 active and 2 placebo) were planned to be dosed AR882 under fasted conditions at 15, 50, or 100 mg with an immediate release formulation, or at 50 mg following a high-fat, high- calorie meal. Correlation of increased uric acid excretion in urine with sUA lowering was assessed to further evaluate the effect of URAT1 inhibition in the tubule. Laboratory safety tests, vital signs, and electrocardiograms were collected throughout the study

Results: Following administration of AR882, exposure of AR882 exhibited dose proportional increase and was significantly lower than the no-observed-adverse-effect level (NOAEL) in rats and monkeys. The rate of absorption was moderate (Tmax 3-5 hours) with a half-life of AR882 of approximately 10-13 hours. When administrated with a high-fat, high-calorie meal, AR882 absorption was slower (Tmax 8 hours), with Cmax lowered by approximately 33% but AUC was similar to that in the fasting conditions. The mean changes in sUA at the 24 hours postdose from baseline

were 2.0% in the pooled placebo group, -5.8%, -42.4% and -58.4% in the 15 mg, 50 mg (P< 0.001 vs placebo) and 100 mg (P< 0.001 vs placebo) fasted groups, respectively. Time to reach highest sUA reduction range between 12 – 36 hr post-dose with median TEmax at 24 hr post-dose. sUA returned to baseline after 4 to 5 days post-dose following 50 mg and 100 mg dosing. Food did not alter sUA lowering effect of AR882. sUA lowering effect was similar among subjects irrespective of differing sUA baseline values which ranged between 3 to 9 mg/dL. Urinary excretion of AR882 and uric acid were evaluated on Day 1 at 6 to 12 hours intervals. Significantly higher amounts of uric acid were eliminated through urine on Day 1 at all collection intervals, indicating sustained inhibition of URAT1 over 24 hours following dosing. AR882 was well tolerated at all doses tested. All adverse events (AEs) were mild in severity and no serious adverse events (SAEs) were reported. There were no clinically significant laboratory or ECG abnormalities noted.

Conclusion: AR882 exhibited outstanding ability to reduce sUA level at ≥ 50 mg (> 40% reduction following a single dose). It is anticipated the sUA lowering will accumulate following multiple doses.

Do Serum Urate-Associated Genetic Variants Influence Gout Risk in People on Diuretics? Analysis of the UK Biobank

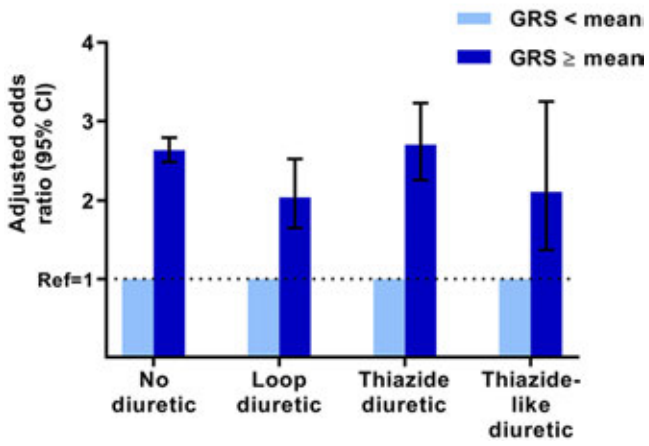
Ravi Narang,[1] Greg Gamble,[1] Amanda Phipps-Green,[2] Ruth Topless,[3] Murray Cadzow,[3] Lisa Stamp,[4] Tony Merriman,[5] and Nicola Dalbeth[1], [1]University of Auckland, Auckland, New Zealand, [2]University of Otago, Otago, Otago, New Zealand, [3]University of Otago, Otago, New Zealand, [4]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand, [5]University of Otago, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Genome-wide association studies have identified single nucleotide polymorphisms (SNPs) associated with serum urate and gout. An association between diuretic use and gout has also been reported by many investigators. The aim of this study was to examine whether serum urate-associated genetic variants differ in their influence on gout risk in people taking a diuretic compared to those not taking a diuretic, and to test for interactions between these genetic variants and diuretic use for gout association.

Methods: This research was conducted using the UK Biobank Resource. Participants of European ethnicity, aged 40-69 years, and with genome-wide genotypes were included. Gout was defined using a validated definition (self-report of gout or urate-lowering therapy use). Medication use (including diuretics) and co-morbidity data were collected via self-report. The 10 serum urate-associated SNPs with the strongest association for gout as reported by Cadzow et al (Arthritis Res Ther 2017) were tested for their association with gout according to diuretic use. Gene-diuretic interactions for gout association were tested using a genetic risk score (GRS) and individual SNPs by logistic regression adjusting for age, sex, body mass index, kidney failure, heart failure and hypertension.

Figure: Association between genetic risk score (GRS) and gout according to diuretic use. Data were adjusted by age, sex, body mass index, hypertension, renal failure and heart failure.



Results: Data were available for 359,876 participants, including 7,342 gout cases (2.0%). Gout was present in 1,197 (4.0%) diuretic users and 6,145 (1.9%) non-diuretic users; OR [95% CI] 2.21 [2.08-2.36] for diuretic users compared to non-diuretic users. After adjustment, use of a loop diuretic was positively associated with prevalent gout (OR 2.34 [2.08-2.63]), but thiazide diuretics were inversely associated with prevalent gout (OR 0.60 [0.55-0.66]). Compared with a lower GRS (below the mean), a higher GRS (mean or higher) was positively associated with gout in those not on diuretics (OR 2.63 [2.49-2.79]), in those on loop diuretics (OR 2.04 [1.65-2.53]), in those on thiazide diuretics (OR 2.70 [2.26-3.23]), and in those on thiazide-like diuretics (OR 2.11 [1.37-3.25]) with similar ORs and overlapping confidence intervals (Figure). The use of a loop diuretic with the presence of a higher GRS exerted the highest ORs for gout association; compared to non-diuretic users with a lower GRS, the OR for gout was 6.04 [5.18-7.04] in loop diuretic users with a higher GRS.

Conclusion: In people on diuretics, serum urate-associated genetic variants contribute strongly to gout risk, with a similar effect to that observed in those not taking a diuretic. These findings suggest that the contribution of genetic variants is not restricted to people with 'primary' gout and genetic variants play an important role in gout susceptibility in the presence of other risk factors.

Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hyperuricemia is associated with non-alcoholic fatty liver disease (NAFLD) (Yang C et al. *PlosOne*2017; 12:e0177249; Jaruvongvanich V et al. *Eur J Gastroenterol Hepatol* 2017; 29:1031), but the relationship to fibrosis remains uncertain (Jaruvongvanich V et al. Eur *J Gastroenterol Hepatol* 2017; 29:694). Moreover, it is not known whether lowering serum urate will affect the course of NAFLD. The availability of data from two randomized trials of pegloticase, a pegylated recombinant mammalian uricase that profoundly decreases serum urate, afforded the opportunity to test the hypothesis that lowering urate might improve NAFLD.

Methods: Databases from patients with chronic refractory gout who participated in two randomized 6-month clinical trials (RCTs) of pegloticase were analyzed (Sundy JS et al. JAMA. 2011; 306 (7):711-20). Sub-sets who had persistent urate lowering to levels < 1 mg/dL in response to biweekly pegloticase (responders, n=36) were compared to those who received placebo (n=43). Since liver biopsy information was not available on these subjects, we relied on the Fibrosis-4 Index (Fib-4), a validated non-invasive estimate of liver fibrosis in a variety of liver diseases (Sterling RK et al. Hepatol 2006; 43:1317; Shah AG et al. Clin Gastroenterol Hepatol 2009;7:1104) calculated from measurements of AST, ALT, platelet count and age (Age x AST/platelets x$\sqrt{}$ALT). A Fib-4 value of 1.3 is an indication that further evaluation of NAFLD is warranted.

Results: At baseline, the mean Fib-4 values were 1.40 ± 0.86 in pegloticase responders and 1.04 ± 0.53 in subjects receiving placebo. Subjects receiving placebo exhibited a change of 0.26 ± 0.41 in the Fib-4 score over the six months of the RCTs compared with 0.13 ± 0.62 in the pegloticase responders (p=0.048; by linear regression). When only the subjects with a Fib-4 value > 1.3 were considered (n=27), a significant difference in the change in the Fib-4 values over the 6 months of the trial between pegloticase responders and those receiving placebo was also observed (-0.15 ± 0.67 vs 0.37 ± 0.42, p=0.04, 2-sample Wilcoxon test). The correlation between serum urate area under the curve (AUC) over the 6 months of the trial and the change in Fib-4 value was r_s=0.33, p=0.0004 (Spearman rank-order correlation coefficient). Finally, multivariate analysis indicated serum urate AUC (as a surrogate measure for group) is the main contributor to the change in Fib-4 values (p=0.018 by linear regression).

Conclusion: The data are consistent with the conclusion that persistent lowering of serum urate had a significant impact on Fib-4 levels, implying a possible effect on the course of NAFLD. These results support consideration of a more complete analysis, involving liver biopsy examinations, of the impact of profound urate-lowering on liver inflammation and fibrosis.

Whole Blood RNA Sequencing Study of Gout Cases and Controls Demonstrates Transcriptomic Differences with Relevance to Inflammatory Cell Activation

Richard Reynolds,[1] Tony Merriman,[2] Alexander Szalai,[3] Nicholas Sumpter,[4] S Louis Bridges,[5] and Jeffrey Edberg[1], [1]University of Alabama at Birmingham, Birmingham, AL, [2]University of Otago, Birmingham, AL, [3]University of Alabama, Birmingham, AL, [4]University of Otago, Birmingham, [5]University of Alabama at Birmingham, Birmingham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The transcriptomic changes accompanying the transition from asymptomatic hyperuricemia to gout are currently unknown but may be important for identifying and understanding important molecular triggers of gout. We tested the hypothesis that gene expression differences would be seen between whole blood from individuals with gout versus normouricemic and hyperuricemic (non-gout) controls.

Methods: Peripheral blood samples were collected (directly into PAXgene RNA tubes) from 13 gout patients, 3 normuricemic and 3 hyperuricemic controls from the gout Rheumatology Database and Repository (RADAR) at the University of Alabama at Birmingham. Whole blood mRNA was isolated using poly A selection and the transcriptome was sequenced. Sequences were quality controlled and then aligned to the genome using the Spliced Transcripts Alignment to a Reference (STAR) software package. We tested for fold change differences in mRNA content between controls and gout cases using the R statistical computing package DESeq2.

Results: RNA sequencing yielded an average of 25 M reads per sample with an average read length of 125 bases. Forty eight gene transcripts were significantly differentially expressed (P value < 0.05), after correction for multiple testing, between gout cases and controls (normouricemic plus hyperuricemic). Of these differentially expressed gene transcripts, six that were overexpressed in gout compared to controls (Transcobalamin 1-*TCN1*, Amine oxidase-*AOC1*, Matrix metallopeptidase 8-*MMP8*, Cysteine rich secretory protein 3-*CRISP3*, Secretory leukocyte peptidase inhibitor-*SLPI* and Olfactomedin 4-*OLFM4*) are known to be involved in neutrophil degranulation. Another notable transcript significantly upregulated in gout cases was the S100 calcium binding protein A8-*S100A8*, which is associated with the production of reactive oxygen species (ROS). Transmembrane protein 176B-*TMEM176B*, was significantly downregulated in gout cases compared to controls.

Conclusion: The upregulation of genes that implicate pathways representing neutrophil biology (degranulation and ROS production) is consistent with the known role of neutrophils in gout pathogenesis. It is possible that this reflects true differences in the neutrophil gene expression program of gout-affected individuals compared to hyperuricemic and/or normouricemic controls. Reduced expression of *TMEM176B* has been shown to associate with activation of the NLRP3 inflammasome. Our whole transcriptomic study in gout patients and controls highlights the central role of inflammatory cell activation in the pathogenesis of gout.

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: *ABCG2* is a high-capacity urate transporter gene. Common dysfunctional variants of *ABCG2* that result in decreased urate excretion in humans are major causes of hyperuricemia and gout – especially in pediatric-onset patients [1]. In the present study, we identified and functionally characterized a novel *ABCG2* variant in a family with early-onset hyperuricemia and gout.

Methods: Fifty-three years old woman was examined for intermittent pain of distal interphalangeal joints and plants of non-inflammatory character. At age of 9, she was found to have hyperuricemia and then she started a strict low-purine diet. Nor medical reports either the levels of uric acid from that period are unfortunately available. At clinical examination, Heberden´s nodes and palpable resistance on plants were observed. In laboratory findings, there was a slightly elevated level of uric acid (371 μmol/L) and low level of vitamin D in her serum. Her son, a 33-year-old man, has the first gout attack at the age of 30 in the first metatarsal joint and since then the gout attack repeats twice a year. In biochemical characterization, hyperuricemia (569 μmol/L of uric acid), hyperglycaemia (5.9 mmol/L of glucose) and low level of vitamin D were found.

To explore the cause of this familial hyperuricemia and gout, we performed a metabolic investigation. The results of purine metabolism suggested that their hyperuricemia were mainly due to a defect in the urate excretion system and did not result from an excess production of urate. Based on two separate measurements of the patients' fractional excretion of urate and urinary urate excretion, their hyperuricaemia could be classified as renal underexcretion type. Since this type of hyperuricemia is reportedly related to ABCG2 dysfunction, we analyzed *ABCG2* coding regions of our patients using their genomic DNA, as described previously [2]. Prediction of the possible impact of allelic variant on protein function was determined using PolyPhen, Provean, Mutation Taster, and SIFT predictive software. Functional validation of an ABCG2 variant we found was performed using ABCG2-expressing plasma membrane vesicles as we report previously [3].

Results: We identified a novel heterozygous variant c.725T >C (p.I242T) in *ABCG2* gene in the proband and her son. In silico predictions of the possible impact of this variant on protein function were consistent as strong deleterious. Cell-based functional assays showed that this novel variant has little effect on the expression and subcellular localization of ABCG2 protein, whereas I242T variant had no urate transport activity.

Conclusion: In conclusion, our findings suggest a causal relationship between the hitherto undescribed variant of *ABCG2* and very early familiar onset of hyperuricemia/gout. Our identification of novel dysfunctional ABCG2 variant confirmed a key role of ABCG2 transporter as a a key genetic determinant in the onset of hyperuricemia/gout.

Abstract Number: 1234

Inconsistency in Uric Acid Reference Ranges Among 20 Top United States Hospitals: What Is "Normal"?

Brittany Frankel,[1] Grant Hughes,[1] and Mark Wener[1], [1]University of Washington, Seattle, WA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Elevated serum uric acid (UA) concentration is associated with the urate crystal deposition disorders gout and nephrolithiasis, as well as hypertension, the metabolic syndrome, chronic kidney disease, and cardiovascular disease. Hyperuricemia is often defined as a serum urate level greater than 6.8 – 7.0 mg/dL, a physicochemical cutoff above which monosodium urate crystals precipitate in body fluids. Here, we determined whether leading United States (U.S.) hospitals used this physicochemical cutoff in their definition of the reference ranges for serum UA, and if the reference ranges were consistent across institutions.

Methods: The top 20 hospitals listed in the U.S. News & World Report Best Hospitals 2018-2019 rankings were queried. Data were obtained in May 2019 using either online publicly available information, or by telephone contact with the laboratory. Information about the type of assay used to measure serum uric acid was obtained. Reference ranges reported by each laboratory for adult males and females were obtained. If a given laboratory reported age-dependent reference ranges for a given sex, the median UA thresholds for that sex were used.

Results: All surveyed laboratories reported utilizing enzymatic (uricase) methods, which were obtained from a variety of instrument manufacturers. The median reported upper limit of the reference range (ULRR) for UA in males was 8.0 mg/dL (range 7.0 – 9.0 mg/dL). The median reported ULRR for females was 6.6 mg/dL (range 5.7 – 8.0 mg/dL). Among the 20 laboratories, 12 different upper limits were used for males, and 11 different upper limits were used for females. For adult males, 15% of hospitals reported an ULRR of 6.8 – 7.0, while 85% used an ULRR greater than 7.0, and 0% used an ULRR less than 6.8. For adult females, 15% of hospitals used an ULRR of 6.8 – 7.0, 30% used an ULRR greater than 7.0, and 55% used an ULRR less than 6.8. Only one laboratory used an age-adjusted reference range.

Conclusion: The upper limits of the reference ranges for serum UA reported by leading U.S. hospitals do not consistently align with the physicochemical definition of hyperuricemia. Additionally, there is considerable variability in the ULRR among surveyed hospitals. This likely reflects use of population-based distributions rather than physicochemical criteria to define hyperuricemia. Most surveyed hospitals used an ULRR for adult females which was lower than 6.8. Most hospitals surveyed used an ULRR for adult males which was higher than 7.0. This practice may result in under-recognition of clinically significant hyperuricemia and under-dosing of uric acid lowering agents in the treatment of gout in male patients.

Monthly Dosing of ImmTOR Tolerogenic Nanoparticles Combined with Pegylated Uricase (Pegadricase) Mitigates Formation of Anti-Drug Antibodies Resulting in Sustained Uricase Activity in Symptomatic Gout Patients

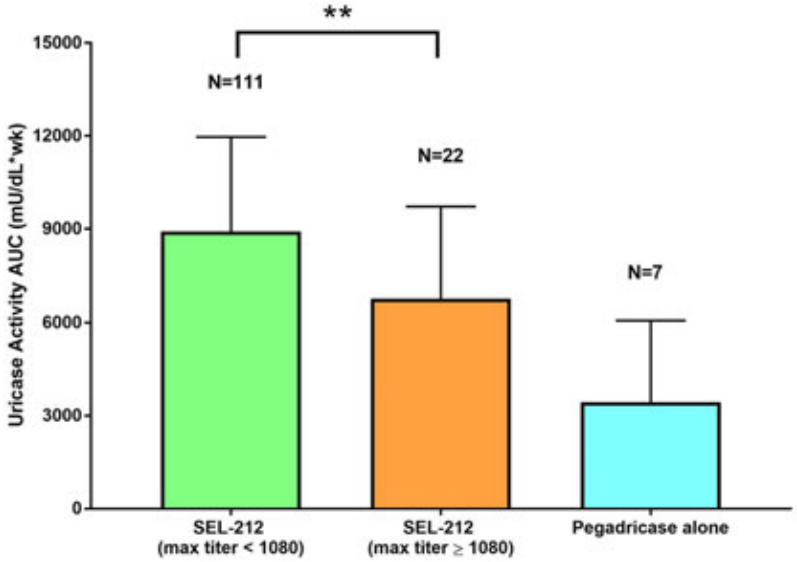
Wesley DeHaan,[1] Alan Kivitz,[2] Rehan Azeem,[1] Horacio Plotkin,[1] Lloyd Johnston,[1] Takashi K. Kishimoto,[1] Justin Park,[1] Stephen Smolinski,[1] and Sheldon Leung[1], [1]Selecta Biosciences, Watertown, MA, [2]Altoona Center for Clinical Research, Duncansville, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gout is caused by the deposition of monosodium urate (MSU) crystals in joints due to chronic hyperuricemia. Long term treatment focuses on reducing sUA levels, thus allowing MSU crystals to dissolve.

Pegylated uricases are therapies for treatment of severe chronic gout. However, uricases are limited by induction of anti-drug antibodies (ADA) that can compromise efficacy and safety. SEL-212 is a novel combination product consisting of pegadricase co-administered with proprietary ImmTOR tolerogenic nanoparticles. ImmTOR has been designed to mitigate the formation of ADAs by inducing tolerogenic dendritic cells and antigen-specific regulatory T cells. Prolonged therapeutic activity of uricase (pegadricase) is vital in maintaining a sustained control of serum uric acid (SUA) levels in patients. We report data on ADA [anti-uricase] and uricase activity from an open label study of monthly SEL-212 treatment in symptomatic gout patients.

Methods: Patients with symptomatic gout (≥1 tophus, gout flare within 6 months or gouty arthropathy) and elevated SUA ≥6 mg/dL were treated with fixed doses of pegadricase (0.2 mg/kg) in combination with ImmTOR (0.1 and 0.15 mg/kg), or pegadricase (0.2 or 0.4 mg/kg) alone as a control. Patients were infused in 28-day cycles up to 5 times. Safety, tolerability, sUA, ADAs, and uricase activity were monitored.



Effect of Treatment and Antibody Titer on Uricase Activity

Results: Demographics of 46 patients treated with 28-day cycles x5 combination doses of ImmTOR and pegadricase as compared to 6 patients treated with pegadricase alone was 23-70 years old vs. 41-64 years old (mean 53.6 vs. 51.8 years), male 97.8% vs. 100%, and white 73.9%. vs. 33.3%. The mean BMI at baseline was 34.5 vs. 38.9 kg/m2. 71.7% vs. 100% of patients were obese with mean duration of established or symptomatic gout as 12.5 vs. 12.8 years. 43 SEL-212 patients were evaluable for this analysis. The majority of treatment periods with SEL-212 had maximum antibody titers < 1080 (83.4%, 111/133) while 14.3% (1/7) treatment periods of pegadricase alone had maximum antibody titers < 1080. AUC of uricase activity was significantly higher in treatment periods where maximum ADA titers were below 1080 (p=0.0029). For all treatment periods for patients receiving SEL-212 in which their maximum anti-uricase titer was < 1080 (n=111), the mean uricase activity AUC was 8924 ± 3044 (mean ± SD) while in treatment periods where the maximum anti-uricase titer was ≥1080 (n=22), the mean uricase activity AUC was 6776 ± 2949. In treatment periods where control cohort patients received pegadricase alone (n=7), uricase activity had a mean AUC of 3437 ± 2635 which was lower than both SEL-212 treated groups. Six of the 7 treatment periods had maximum antibody titers ≥1080. For SEL-212 patients that had titers < 1080, the uricase activity AUCs were sustained over the 5 treatment periods and corresponding serum uric acid levels remained low.

Conclusion: By mitigating the formation of ADAs, monthly dosing of ImmTOR combined with pegadricase increases uricase activity in symptomatic gout patients relative to pegadricase alone. When anti-uricase titers are < 1080, patients show sustained uricase activity, enabling 28 day treatment intervals.

Abstract Number: 1236

Subcutaneous or Oral Methotrexate Exposure and Response to Pegloticase in Uncontrolled Gout Patients in a Community Rheumatology Practice

John A. Albert,[1] Tony Hosey,[2] and Brian LaMoreaux[2], [1]Rheumatic Disease Center, Milwaukee, IL, [2]Horizon Therapeutics plc, Lake Forest, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pegloticase is an infused biologic for uncontrolled gout patients that is highly effective but can cause anti-drug antibodies that lead to a lack of therapeutic response. Based on data from randomized clinical trials, 42% of uncontrolled gout patients treated with pegloticase remain responders at 6 months of therapy. Low to moderate levels of immunomodulation treatment with medications such as methotrexate have been shown to attenuate the formation of anti-drug antibodies to biologic medicines in patients with rheumatoid arthritis. There are published cases in gout patients suggesting that low to moderate doses of methotrexate or azathioprine attenuate the development of anti-drug antibodies to pegloticase, allowing uncontrolled gout patients in need of pegloticase

therapy to remain on the medicine and achieve a more complete therapeutic outcome. The objective of the present case series was to determine whether exposure to oral or subcutaneous (subQ) methotrexate improved gout patients' response to pegloticase in a single community rheumatology practice.

Methods: A retrospective chart review was conducted in a rheumatology practice where uncontrolled gout patients starting pegloticase therapy are typically co-treated with methotrexate. All patients receiving any form or schedule of methotrexate before or while on pegloticase were included, and data extracted on their response including duration of pegloticase therapy, gout flares, infusion reactions, methotrexate dosing details, and lab values including uric acid levels, liver function tests, renal function, hemoglobin and white blood cell count. Complete blood count (CBC) and comprehensive metabolic panel (CMP) parameters were monitored closely in all patients treated with methotrexate.

Results: Ten uncontrolled gout patients fit the inclusion criteria. Nine patients were male, the average age was 52.3 years, and all had visible tophi. Methotrexate exposure varied, with 1 patient receiving oral and 9 receiving subQ administration; all but 1 patient started on methotrexate prior to pegloticase, and most patients received 25 mg of methotrexate subQ weekly. Of the 10 patients, at the time of data cutoff, 5 were complete responders, having received an average of 16.4 doses or ~32 weeks of therapy. Three were responding and still actively on pegloticase at the time of data extraction, having received 10, 5 and 2 doses respectively. Two patients had ceased therapy, 1 for loss of response and a mild infusion reaction and 1 due to methotrexate injection related issues. One patient had a gout flare requiring prednisone treatment. LFTs and CBC parameters remained stable during therapy with both methotrexate and pegloticase except for 1 patient who had a mild, transient alcohol-related LFT elevation and pancytopenia that improved with transfusion and cessation of methotrexate. This patient remained on pegloticase and continued as a responder.

Conclusion: When used concurrently with pegloticase, methotrexate appears to attenuate the formation of clinically significant anti-drug antibodies allowing uncontrolled gout patients to receive a more complete duration of pegloticase therapy. No new safety concerns were noted during this project.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Gout flares are characteristically mediated by the pro-inflammatory cytokine interleukin (IL)-1β. Uptake of monosodium urate (MSU) crystals by macrophages activates the nucleotide-binding domain and leucine-rich repeat containing family, pyrin domain containing 3 (NLRP3) inflammasome, which converts intracellular

pro-interleukin-1β (pro-IL-1β) to mature bioactive IL-1β by proteolytic cleavage. In the presence of concomitant pro-inflammatory stimuli, i.e., Toll-Like Receptor (TLR) agonists, transcription of IL-1β gene is induced and pro-IL-1β is rapidly converted into its active form. IL-1β binds to its receptor (IL-1R1) and induces a cascade of secondary inflammatory mediators including prostaglandins, cytokines and chemokines, resulting in a fulminant joint inflammation. Recently, OLT1177™, a β-sulfonyl nitrile compound, safe in humans, was shown to inhibit the NLRP3 inflammasome and inhibit joint inflammation in murine models of acute arthritis. This study explores the mechanisms by which oral OLT1177™ inhibits joint inflammation in humans with gout flares.

Methods: 29 patients with a gout flare were treated according to protocol with four different doses of OLT1177™ for 8 days (EudraCT: 2016-000943-14). Blood was drawn at baseline, days 3, 7 and 14 (7 days after finishing treatment). Haematology was evaluated as a marker of systemic inflammation. Plasma was collected for assessment of circulating cytokines. Peripheral blood mononuclear cells (PBMCs) were isolated and cultured under unstimulated or stimulated conditions with a TLR ligand in combination with MSU crystals after which intra- and extracellular cytokine production were assessed.

Results: Treatment of acute gout flares in humans with oral OLT1177™ demonstrates a reduction in white blood cell counts, mainly neutrophils, in all cohorts. In cohorts receiving 2000mg, 1000mg or 300mg, both circulating IL-1β and IL-6 and *ex vivo* IL-1β and IL-6 production by stimulated PBMCs were reduced during treatment with the strongest effect in the cohort with the highest dose OLT1177™. In unstimulated PBMCs on day 3, ratio of intracellular pro-IL-1β and IL-1β revealed inhibition of the NLRP3 inflammasome by oral OLT1177™ treatment. All these markers of inflammation are relevant parameters that correlate with target joint pain.

Conclusion: Oral OLT1177™, safe in humans, is a potential drug for the treatment of gout flares and other NLRP3 mediated diseases.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Monosodium urate (MSU) andmonoclinic calcium pyrophosphate dihydrated(mCPPD)crystals are responsible for relapsing acute arthritis which is driven by interleukin 1β (IL-1β).IL-1βproductionrelies on-

NLRP3 inflammasome activationleading to ASC and caspase-1 recruitment. In tumor cells and in LPS-stimulated macrophages a switch of cell metabolisms toward glycolysis favors IL-1β production.

The aims of this study were to assess 1/ whethercrystal-induced NLRP3 activation and IL-1βproduction involved glucose metabolism and 2/ how MSU and mCPPD crystals induced glucose uptake focusing on the role of glucose transporter Glut1.

Methods: Synthetic and pyrogen-free MSU andmCPPDcrystalswere used to stimulate THP-1 cells and mouse bone marrow-derived macrophages (BMDM). Cells were stimulated in presence or absence of glucose (2g/L) and pyruvate (10mM).Glycolysis was inhibited by 2-deoxy-glucose (2DG) and the role of glucose transporter 1 (Glut1)was assessed by pharmacological inhibitor (STF-31) and siRNA. IL-1β production was quantified by ELISA.Metabolomicanalysis was performed by mass spectrometry.Glucose uptake was determined using ^{18}F-DG (Fluor18 labeled-2DG) and positron emission tomography (PET). Glut1 membrane localization was assessed by flux cytometry and confocal microscopy, ASC speck formation by confocal microscopy. *In vivo*, we used murine air pouch model to assess the effects of 2DG and Glut1 inhibition in crystal-mediated inflammation.Glut1 membrane localization ofcirculating neutrophils was compared to synovial fluid neutrophils harvested during gout flare.

Results: *In vitro*, both MSU and mCPPDcrystal-induced IL-1β secretion and ASC speck formationwere inhibitedwhen cells were cultured in glucose-free medium or in presence of 2DG.Similarly,MSU and mCPPD crystal-induced inflammation was abrogated in mice treated with 2DG.In THP-1 cells stimulated by MSU and mCPPD crystals, metabolomicanalysis displayedalteration of glycolysis pathway and Krebs'cycle and decrease of intracellular ATP production. Interestingly, MSU and mCPPD crystals increased glucoseuptake*in vitro, ex vivo and in vivo*.Crystal-induced glucose uptake was inhibited by STF-31 and decreased in THP-1 cells transfected with Glut1 siRNA.Next, we observed that MSU and mCPPD crystals increased membrane localization of Glut1 in THP-1, BMDM and neutrophils infiltrated in air pouch lavages and membranes. Glut1 membrane localization was positively correlated with IL-1β production. Moreover, during gout flare, the proportion of Glut1 positive neutrophils was higher in synovial fluid neutrophils than in circulating neutrophils. Finally, STF-31 treatment decreased,*in vitro,*glucose uptake and IL-1 β production induced by MSU and mCPPD crystals, and *in vivo*MSU and mCPPD crystal-induced inflammation.

Conclusion: Glucose uptake through Glut1 transporter enhanced IL-1β production induced by MSU and mCPPD-crystals. Studies to decipher how these crystals induced Glut1 membrane localization are ongoing. Similarly, we investigate how glycolysis regulates NLRP3 and ASC activation. Decreasing Glut1 membrane localization might be a potential target to dampen crystal-induced inflammation.

The Association Between Urate and CSF Markers of Alzheimer's Disease in a Population-Based Sample of 70-Year-Olds

Tahzeeb Fatima,[1] Lennart Jacobsson,[2] Lena Johansson,[3] Mats Dehlin,[4] and Ingmar Skoog[3], [1]Department of Rheumatology and Inflammation Research, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden, [2]Dept of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden, [3]Department of Psychiatry and Neurochemistry at Institute of Neuroscience and Physiology, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden, [4]Dept of Rheumatology and Inflammation Research, Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Urate is a powerful antioxidant that accounts for approximately 60% of free-radical scavenging capacity in the human body. The diagnosis of Alzheimer's dementia (AD) is preceded by years of progressive cognitive impairment. Mild cognitive impairment (MCI) or predementia in AD is characterized by a certain pattern of cerebrospinal fluid (CSF) biomarkers beginning with a decrease of amyloid-β_{42} (Aβ) in CSF and followed by its aggregation in brain and hyperphosphorylation of the tau protein. The worldwide prevalence of dementia ranges between 5 to 7% with higher incidence of predementia reported in men before the age of 70-75 years. Urate has been suggested to exert potentially neuroprotective effects and might therefore alter the risk of dementia by virtue of its antioxidant abilities. A long-term follow-up study in Swedish women cohort has recently indicated a protective role of serum urate (SU) in the development of dementia. However, the relationship between urate and predementia remains elusive. The study was aimed to investigate the association between SU and predementia using the baseline data from a general population sample of 70-year-olds in Sweden.

Methods: The baseline sample was derived from the population-based H70 Gothenburg Birth Cohort that includes the data of every 70-year-old in Gothenburg, Sweden, born during 1944 (on prespecified birthdates). Overall, this cohort represents the data for 1,203 individuals (46.5% male) collected between 2014 and 2016. For this

Table 1. Demographic characteristics of the individuals included in the analysis, * Six out of 317 individuals (one male and five females) were missing the information for ApoE allele, ΔValues presented as mean ± standard deviation, β; Beta, ApoE+; Individuals carrying ApoE risk allele, ApoE-; Individuals carrying other/normal allele.

	All	Males	Females
Total number, n (%)*	317	165 (52.05)	152 (47.94)
Serum urate μmol/L)Δ	322.96 ± 76.38	355.84 ± 69.39	286.78 ± 66.94
Amyloid-β (pg/mL)Δ	718.94 ± 224.58	701.81 ± 231.58	737.53 ± 214.85
Total tau (pg/mL)Δ	331.09 ± 134.58	335.41 ± 135.93	326.39 ± 133.39

			Phospho tau			
All	-0.005 (-0.03 ; 0.02)	0.96	-0.025 (-0.06 ; 0.02)	0.19	0.021 (-0.02 ; 0.06)	0.32
ApoE+	-0.004 (-0.057 ; 0.05)	0.86	-0.015 (-0.09 ; 0.06)	0.71	-0.001 (-0.08 ; 0.07)	0.97
ApoE-	-0.0004 (-0.026 ; 0.02)	0.96	-0.021 (-0.05 ; 0.01)	0.23	0.035 (-0.01 ; 0.08)	0.14

study, measurements for SU and three CSF markers, $A\beta_{42}$, total tau and phospho tau, were analyzed from a subset (n=322) of the H70 cohort. The information for the presence of *APOE* risk allele (for single nucleotide polymorphism/ SNPs *rs7412* and *rs42935*) for each individual in this subset was also analyzed. Data for individuals with baseline prevalent dementia (n=5) was excluded from the analysis. Linear regression was performed to assess the association between SU and each CSF marker in overall and gender stratified groups. The groups were further stratified for the presence of *APOE* risk (ApoE+) or otherwise normal (ApoE-) allele. A $p > 0.05$ was designated to indicate a significant association. All analyses were performed using statistical software R (v3.5.2).

Results: Overall, 52% of the participants in the analysis were males. Individuals had a mean SU value of 322.9 (males; 355.8 and females; 286.7). A total of 114 individuals were carrying risk allele for *APOE*, with a higher percentage of males (~60%) being the carriers (Table 1). Regression analysis indicated only a trend of positive association between SU and Aβ in male subset (β = 0.48 pg/mL, $p = 0.06$), which persisted when assessed in ApoE+ group (β = 0.86 pg/mL, $p = 0.08$). The positive estimate was also observed in female subset (β = 0.11 pg/mL, $p = 0.67$), albeit not significant. No association for SU was observed for both total tau (β = -0.004 pg/mL, $p = 0.96$) and phospho tau (β = -0.005 pg/mL, $p = 0.96$) (Table 2).

Conclusion: In seventy-year old males we identify a possible protective effect of urate on predementia, defined as decreased CSF levels of amyloid-β and reflecting amyloid build-up in the brain. This effect seems to be further strengthened in the presence of APOE-ε4.

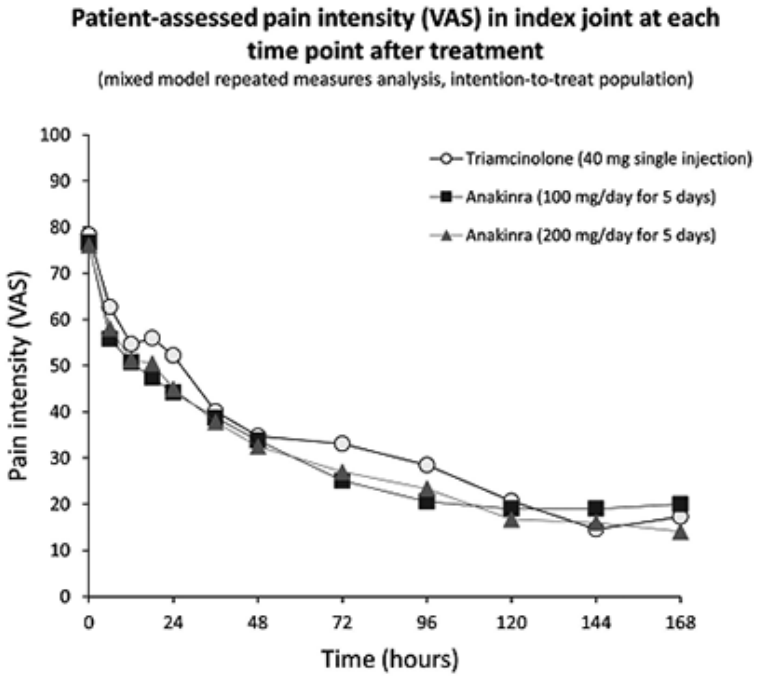
A Randomized, Phase 2 Study Evaluating the Efficacy and Safety of Anakinra in Difficult-To-Treat Acute Gouty Arthritis: The anaGO Study

Kenneth Saag,[1] Alexander So,[2] Puja Khanna,[3] Robert Keenan,[4] Sven Ohlman,[5] Torbjörn Kullenberg,[5] Lisa Osterling Koskinen,[5] Michael Pillinger,[6] and Robert Terkeltaub[7], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Université de Lausanne, Lausanne, Switzerland, [3]University of Michigan Medical School, Ann Arbor, [4]Duke University School of Medicine, Durham, [5]Sobi, Stockholm, Sweden, [6]New York University School of Medicine, New York, [7]San Diego VA/UCSD, San Diego, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Metabolic & Crystal Arthropathies Poster II: Clinical Trials & Basic Science
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In gout, urate crystals deposited in and around joints trigger episodes of acute arthritis, mediated by the proinflammatory cytokine IL-1β. In uncontrolled studies, the IL-1 receptor antagonist anakinra appears effective in reducing pain and signs of acute flares in patients with difficult-to-treat gout. However, confirmatory, adequately-powered, prospective trials are lacking. The 'anaGO-study' (anakinra in gout) was a multi-center, randomized, double-blind, double-dummy, phase 2 study investigating the efficacy and safety of anakinra in acute gout (NCT03002974).

Methods: Patients were recruited who had acute gout based on ACR/EULAR 2015 gout classification criteria, and were unsuitable for anti-inflammatory therapy with NSAIDs and colchicine due to contraindication, intolerance or inefficacy. The primary objective was to evaluate the efficacy of two regimens of anakinra (100 or 200 mg daily s.c.



injections for 5 days) compared to triamcinolone (single i.m. injection 40 mg) with respect to patient-assessed pain intensity. Patients were randomized to each group in a 1:1:1 ratio and stratified by urate-lowering therapy use (yes/no) and BMI (< 30.0 or ≥30.0 kg/m2). The primary endpoint was change in pain intensity from baseline to 24-72 hours (average of 24, 48 and 72 hours) in the most affected joint measured on a visual analogue scale (0-100 VAS). Secondary outcomes included: time to onset of effect, time to response, time to pain resolution, time to rescue medication use, patient's and physician's assessments of global response, clinical signs, inflammatory biomarkers, and safety.

Results: 165 patients were randomized; 110 to anakinra (56 to 100 mg/day, 54 to 200 mg/day) and 55 to triamcinolone; 108 and 53 were included in the primary analysis, respectively. The median (range) age was 55 (25-83) years, 87% were male, mean disease duration was 8.7 years and mean number of self-reported flares during the past year was 4.5. The pain intensity, from baseline to 24-72 hours, decreased in both treatment groups; mean (95% CI) change was -39.4 (-46.8, -32.0) for triamcinolone and -41.2 (-46.3, -36.2) for anakinra. The 100 mg and 200 mg doses of anakinra were comparably effective in decreasing pain (100 mg/day: -41.8 [-48.9, -34.8] and 200 mg/day: -40.7 [-47.9, -33.4]). Mean (95% CI) difference in pain reduction between anakinra and triamcinolone treatment groups was -1.8 (-10.8, 7.1) (p-value = 0.688 for primary endpoint). The majority of secondary efficacy endpoints were numerically in favor of anakinra, and in most instances also statistically significant, in comparison to triamcinolone, e.g. physician's assessment of clinical signs at 72 hours and patient's and physician's assessment of global response at Day 8. No unexpected safety findings were identified in any of the treatment groups.

Conclusion: Anakinra and triamcinolone reduced patient-assessed gout flare pain to similar degrees in patients for whom conventional therapy was ineffective or contraindicated. Both doses of anakinra showed comparable efficacy in pain reduction. The majority of secondary efficacy endpoints favored anakinra. Anakinra was shown to be an additional option for use during acute gout flares.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There have been few large, prospective cohort studies performed on morphea, or localized scleroderma. Most that exist focus exclusively on either pediatric or adult populations, or are retrospective. The objective of this study was to examine two combined prospective databases (Morphea in Adults and Children and National Registry for Childhood-Onset Scleroderma) in order to further characterize these patients and determine subtle features of disease.

Methods: We conducted a cross-sectional analysis using both traditional univariate statistics as well as a multivariate approach – a principal component analysis (PCA). All patients were scored using the Localized Scleroderma Cutaneous Assessment Tool, a validated outcome measure that includes disease activity (modified Localized Scleroderma Skin Severity Index (mLoSSI)) and damage (Localized Scleroderma Skin Damage Index (LoSDI)) components.

* Rotation converged in 10 iterations. Extraction method was a principal components analysis with varimax rotation and Kariser normalization.

Marked numbers indicate factor loadings > |0.5|

Results: Of the 944 participants, 497 (53%) had pediatric onset morphea, and 433 (47%) had adult onset morphea. **[Table 1]** Caucasian (76%), female (78%) and linear morphea (62%) patients compromised the majority of the cohort. Adult onset patients had significantly higher mLoSSI and LoSDI scores than pediatric onset disease ($p < 0.001$ and $p = 0.002$, respectively), but pediatric onset patients had a significantly higher PGA-D score ($p < 0.001$). Adult-onset patients were significantly more likely to have deep (72%, 312/443) and dermal (37%, 160/443) involvement ($p < 0.001$ for both), but children were significantly more likely to have erythema of lesions crossing the joint (24%, 117/497, $p < 0.001$), limited range of motion (LROM) (25%, 123/497, $p = 0.$) and joint deformity (10%, 52/497, $p < 0.001$). Children were also significantly more likely to have functional abnormalities in the trunk (4%, 18/497, $p = 0.022$) and lower extremity (18%, 87/497, $p = 0.003$).

Further analysis of the clinical and patient-reported symptoms by PCA determined 4 relevant latent phenotypes (F1-F3). **[Table 2]** F1 described patients who had LROM in their extremities with high damage scores, while F2 depicted patients with patient reported complaints related to fatigue, pain and depression. F3 described patients with deep dermal and underlying tissue involvement. F4 captures patients with highly active disease.

A PCA of the SKINDEX 30+3 quality of life questionnaire in adults revealed 4 significant factors (F1-F4). **[Table 3]** F1 represented questions regarding social isolation and overall self-consciousness, while F2 represented patients who exhibited pre-occupation with their skin condition and a higher proportion of emotions questions. F3 characterized patients who had functional impairment and F4 patients with mostly skin related symptoms.

Conclusion: In summary, our large, prospective cross-sectional study demonstrated several novel observations in addition to previously reported findings in morphea. These findings change practice by describing new subsets of morphea patients, including a group with characteristics of chronic pain syndrome and various cohorts with psycho-social impact. These results should be further explored to allow providers to provide more targeted management of these cohorts of morphea patients.

Impact of Smoking Status on Remission in Hidradenitis Suppurativa

Amil Agarwal,[1] Marissa Mangini,[1] Derek Jones,[1] Catherine Hood,[1] Richard Amdur,[1] and **Victoria Shanmugam** [2], [1]The George Washington University School of Medicine and Health Sciences, Washington, DC, [2]George Washington University, Georgetown, DC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hidradenitis Suppurativa (HS) is an inflammatory disease of the apocrine sweat glands characterized by recurrent abscessing inflammation. The molecular drivers of HS are poorly understood, but smoking

Table 1. Baseline demographics by smoking status in the current, never and past smoker groups.

	Current smoker (n=28)	Never smoker (n=80)	Past smoker (n=24)	p-value
Age at Baseline, years (Mean ±SD)	44 ± 11	35 ± 13	30 ± 13	0.002
Sex, % female	64%	78%	75%	0.39
Race				
African American	68%	53%	54%	0.77
Caucasian	32%	41%	42%	
Asian	0%	5%	4%	
Other	0%	1%	0%	
Pain score	2.35 ± 3.59	2.15 ± 3.02	4.17 ± 3.50	0.01
Baseline BMI (kg/m^2)	34.12 ± 8.16	32.09 ± 7.19	33.87 ± 7.22	0.36
Baseline HSS	53 ± 52	49 ± 55	49 ± 45	0.62
Hurley Stage	2.0 ± 1.1	1.9 ± 1.1	2.1 ± 0.9	0.76
Active Nodule Count	3.3 ± 2.2	2.9 ± 2.5	3.3 ± 2.0	0.76

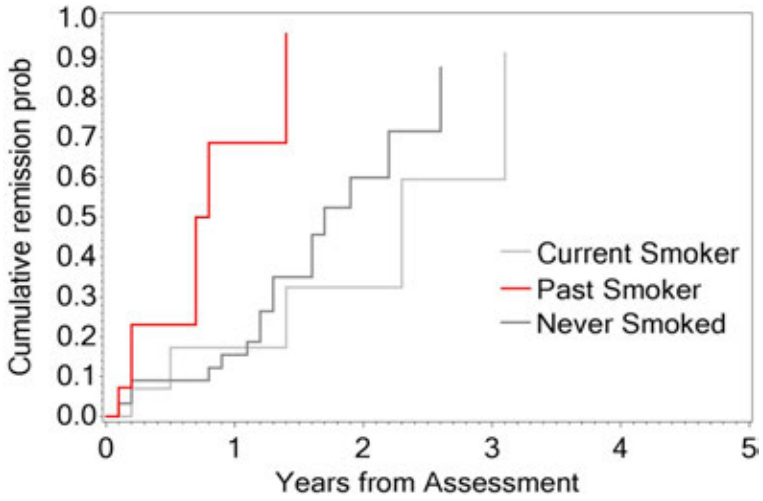

Figure 1. Kaplan Meier analysis of the three cohorts demonstrating cumulative probability of remission based on achieving HiSCR over time (years since enrollment). Patients who continued to smoke had the lowest rates of achieving remission compared to the past and never smokers (p=0.046)

is strongly associated with disease activity. The US Food and Drug Administration (FDA) recently approved tumor necrosis factor-alpha inhibitors (TNF-i) for HS. However, little is known about the relationship between smoking and remission rates in patients receiving TNF-i therapy for HS. The purpose of this study was to investigate the relationship between smoking and HS remission rates in a longitudinal cohort of patients receiving ongoing therapy for HS.

Methods: This study was conducted through the Wound Etiology and Healing Study (WE-HEAL Study), an IRB approved biospecimen and data repository for tracking outcomes in HS. All subjects gave written informed consent for longitudinal collection of their data while they received treatment according to standard of care. Demographic data, baseline medical comorbidities, smoking and disease activity scores were collected. Patients were categorized by smoking status at last follow up (current, never, past). Disease activity was assessed using Hurley Stage, Hidradenitis Sartorius Score (HSS), and Active Nodule (AN) Count. Remission was a binary outcome based on achieving the Hidradenitis Suppurativa Clinical Response (HiSCR). Statistical analysis was conducted using SAS version 9.4. Multivariable Cox proportional hazard model was used for analysis.

Results: At the time of data lock, there were 132 patients in the WE-HEAL HS cohort: current smokers (21%), past smokers (18%), never smokers (61%). There was no statistically significant difference between the groups in regards sex, race or baseline body mass index (BMI). The past smoker group had a higher baseline pain score (p=0.01) and current smokers tended to be slightly older (p=0.002). There was no significant difference between the three groups in baseline disease activity scores (Table 1).

Time to remission did not differ significantly between smoking categories in univarible KM analysis (log-rank p = .18). However, after adjusting for age, ever receiving MTX, TNFi, or opioids, and ever having HS surgery, the HR for current smoker vs past smoker reaching remission is 0.31 (0.10-0.98) (p=.046). This indicates that past smokers reach remission more quickly than current smokers (**Figure 1**). Never-smoked differed from past-smoker only at a trend level of significance (aHR 0.43 [0.18-1.04], p=.06). The only other covariate associated with remission was ever receiving opioids. Those who did receive opioids had reduced likelihood of reaching remission (aHR 0.24 [0.08-0.72], p=.01).

Conclusion: The current analysis shows that patients who continue to smoke demonstrate lower and slower rates of achieving remission than those who stop smoking or never smoked. This data not only supports the strong benefit of smoking cessation in HS management, but also suggests that smoking may impact the immune drivers of HS.

Anakinra Treatment in Recurrent Pericarditis: Single Center Experience

Zeynep Toker Dincer,[1] Osman Corbali,[2] Serdal Ugurlu,[1] and Huri Ozdogan[1], [1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, ISTANBUL, Turkey, [2]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, ISTANBUL

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Recurrent pericarditis (RP), however the etiology is unknown in the majority, may be observed in autoinflammatory diseases such as familial Mediterranean fever (FMF) and tumor necrosis factor receptor-1 associated periodic syndrome (TRAPS). Colchicine has long been used to treat pericarditis related to FMF as well as patients with idiopathic recurrent pericarditis (IRP) (1). Alternative treatments have been reported for cases with colchicine resistant RP.

The aim is to present our data regarding anakinra treatment in recurrent pericarditis either related to FMF or idiopathic, who are resistant to colchicine.

Methods: Patients who had recieved anakinra with a diagnosis of recurrent pericarditis either idiopathic or secondary to FMF followed in our autoinflammatory disease center between 2014-2018 are evaluated retrospectively. From patients' files, demographic and clinical features, response to other treatment approaches such as NSAID, corticosteroid, colchicine, were evaluated. All patients have been genetically screened for monogenic autoinflammatory diseases (MEFV, TRAPS, MVK, NLRP3, NOD2). Patients who had at least 3 attacks were administered anakinra 100 mg/day. Therapeutic efficacy, as well as side effect profile of anakinra is also assessed.

Table 1. Demographic features and treatment response during anakinra therapy

Patient ID #	Age	Sex	Diagnosis	Duration of pericarditis follow-up (mo)	Prior medications	Number of recurrences before anakinra	Anakinra treatment duration (mo)	Time to corticosteroid discontinuation (mo)	Number of recurrences after daily dose of anakinra
1*	23	M	IRP	129	Colchicine, NSAIDs, CS, HCQ	6	52	9	No
2	32	F	IRP	128	Colchicine, NSAIDs	7	4	NA	No
3*	40	F	IRP	21	Colchicine, CS	6	8	1	No
4	20	M	IRP	11	Colchicine, CS	3	8	2	No
5	25	M	FMF	30	Colchicine, CS	5	15	1	No

F: Female, M: Male, CS: Corticosteroid, HCQ: Hydroxychloroquine, NA: Not applicable
*Dose tapering was unsuccessful in these patients

Results: There were 5 patients (3 male and 2 female) with the diagnosis of RP, 1 was related to FMF and 4 were idiopathic. The mean age of the group was 28±8 (range 20-40). All patients diagnosed with IRP were negative for autoinflammatory genetic screening, while a MEFV variant (K695R het.) was detected in the FMF patient. Median duration of follow-up was 30 months (range 11-129). In table 1, demographic and clinical features are given. The median number of recurrence was 6 before anakinra treatment. No episode of pericarditis was observed in any of the patients after the initiation of anakinra. The response to anakinra persisted even after the dose was reduced to 100 mg/alternate day in 3 patients, however in 2, recurrence of pericarditis was observed and anakinra was escalated to initial dose. It was possible to discontinue corticosteroid treatment in all patients. Currently all patients continue anakinra treatment. No side effect including injection site reaction, has been observed by now.

Conclusion: Anakinra seems to be a safe and effective treatment approach for colchicine resistant recurrent pericarditis. However recurrence may occur during dose tapering.

Abstract Number: 1244

Tocilizumab - An Effective Rescue Therapy for Refractory Unclassified Autoinflammatory Diseases in Children

Jasmin B. Kuemmerle-Deschner,[1] Daniel Sturm,[1] and Susanne Benseler[2], [1]University Hospital Tuebingen, Tuebingen, Germany, [2]Alberta Children's Hospital Research Institute, Calgary, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence based treatment options for children and adults with unclassified autoinflammatory diseases (AID) are limited. Frequently, IL-1-inhibition is primarily tried to control the severe autoinflammatory symptoms. Tocilizumab (TMB) is approved for treatment of systemic juvenile idiopathic arthritis[1]. The aim of this study was to evaluate efficacy and safety of Tocilizumab (TMB) in patients with unclassified AID, who did not achieve remission by IL-1-blockade therapy.

Methods: A single-center retrospective cohort study included consecutive children with typical clinical AID features of chronic recurrent fevers and increased inflammatory markers. All children did not meet any of the new classification criteria[2] for either familial Mediterranean fever (FMF); tumor necrosis factor receptor-associated periodic syndrome (TRAPS); mevalonate kinase deficiency (MKD); cryopyrin-associated periodic syndrome (CAPS) or periodic fever, aphthous stomatitis, pharyngitis and adenitis (PFAPA). All patients were non-responders to IL-1-inhibitors (canakinumab or anakinra) and subsequently received TMB (8-12mg/kg i.v. every 2 weeks). Data collection included demographics, clinical phenotype, inflammatory markers, duration and dose of IL-1-inhibition, disease activity (physician and patient global assessment). Outcome: remission was defined as VAS of the physician global assessment ≤ 2 and inflammatory markers in the normal reference range (CRP ≤ 0.5mg/dl and/or SAA ≤ 10mg/l).

Results: Seven patients met the inclusion criteria, five males (71%) and two females (29%); median age at start of TMB therapy was 9 years (range 2-17). First follow-up was after 3 months (range 3-6) and second follow-up was after 12 months (range 10-14) of TMB therapy. At baseline, median disease activity (VAS physician) was 4 (range 2-6) and decreased to 1 (range 0-5) at first follow-up and again 1 (range 0-3) at second follow-up. Median CRP decreased from

1.23 mg/dl at baseline to 0.01 mg/dl at first follow-up. At baseline, median SAA levels were 20 mg/l (range 1-1010) and decreased to 1 mg/l (range 1-1.9) at first follow-up. At first follow-up, 4/7 patients (57%) achieved remission and at second follow-up, 4/5 patients met remission criteria (80%). One patient, who did not achieve remission at first follow-up, fulfilled the remission criteria at second follow-up. Over the entire observation period, a total of 5 patients (71%) achieved remission. Adverse events (neutropenia) were observed in 2 patients (29%).

Conclusion: TMB appears to be an effective treatment option for patients with unclassified AIDs, who do not respond favorably to IL-1-blockade. No unexpected adverse events occured. Clinical features and inflammatory markers rapidly improved; the response was sustained at the 12 months follow-up. Translational studies are urgently required to define the optimal treatment target in unclassified AIDs early on.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adult-onset Still's disease (AOSD) is a rare auto-inflammatory condition characterized by fever, arthritis, skin rash, and multi-organ inflammation. The pathogenesis of AOSD is centrally mediated by the pro-inflammatory cytokine interleukin (IL)-1β; anakinra, a recombinant inhibitor of the IL-1β receptor, has long represented the cornerstone of biologic therapy for AOSD. More recently, a new agent blocking IL-1β has also entered the clinical arena, that is, the monoclonal antibody canakinumab. Here, we describe the use of canakinumab both as first-line and rescue IL-1 blocker in 10 patients with AOSD, and report the highly promising results of this treatment approach.

Methods: Detailed clinical information were retrospectively retrieved for AOSD patients followed up in our Rheumatology Unit and treated with canakinumab. Information pertained to: disease duration; clinical features; AOSD course; previous and concomitant treatment with conventional synthetic DMARD or biologic agents; levels of inflammatory markers (ESR, CRP, and ferritin); dose of corticosteroid therapy before and after canakinumab initiation. Changes in these parameters upon canakinumab treatment were recorded, and statistical significance of differences evaluated with non-parametric tests. A p-value < 0.05 was considered significant.

Sex, Age (years)	Disease duration (months)	Disease manifesations	AOSD course	Therapy before CAN (mg)	bDMARD before CAN	Follow-up (months)	Therapy after CAN (mg)	Response to CAN	Side effects

Table 1. Disease duration refers to the duration of disease before initiation of canakinumab (CAN). Disease manifestations: A, arthritis; F, fever; R, rash; P, pharyngitis; S, serositis; L, lymphadenopathies; HSM, hepatosplenomegaly. Therapy before biologics indicates the treatment regimen that was being administered at the time of biologic initiation; therapy after biologics indicates the maintenance therapy that was being administered together with biologics at the last follow-up visit. PDN, prednisone; MTX, methotrexate,; ANK, anakinra; ETN, etanercept; ADA, adalimumab; TCZ, tocilizumab. SD, systemic disease.

Results: Ten patients with severe AOSD received canakinumab 300 mg 4 weekly following failure of conventional treatment with corticosteroids, DMARDs, or anakinra. Detailed clinical features and responses to therapy are reported in **Table 1.** Median AOSD duration at the time of canakinumab initiation was 36.5 months (range 18-65); median follow-up after canakinumab initiation was 9 months (4-18). Five patients received canakinumab as first-line biologic agent, whereas five patients received it following failure of anakinra. Regardless of previous treatment status, canakinumab treatment led to rapid clinical responses; in 6 out of 10 patient this clinical response was complete. Resolution of fever and skin rash was followed by progressive improvement in arthritis. Inflammatory organ involvement (i.e. pericardial inflammation) also resolved. Efficacy on clinical manifestations was mirrored by significant reductions in serum pro-inflammatory markers CRP, ESR, and ferritin. Sustained efficacy allowed for discontinuation or tapering of corticosteroid or DMARD therapy.

Conclusion: Biologic therapy of AOSD with canakinumab was associated with rapid and marked clinical responses, leading to substantial clinical amelioration in all patients and allowing for robust steroid-sparing effects. Earlier use

was associated with optimal responses, but treatment with canakinumab was also effective in difficult-to-treat patients following failure of IL-1 receptor blockade with anakinra.

Using PROMIS Data to Assess Activity of Inflammatory Eye Disease

Joshua Hedrick,[1] Rula Hajj-ali,[2] Yuxuan Jin,[3] and Sunil Srivastava[1], [1]Cleveland Clinic, Cleveland, OH, [2]Rheumatologic and Immunologic Disease/Cleveland Clinic, Cleveland, OH, [3]Quantitative Health Science, Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Diagnosing and managing patients with inflammatory eye disease (IED) requires close interdisciplinary care with rheumatologists adjusting systemic, potentially toxic, therapies based on exam findings visualized by ophthalmologists. Surveys of patient reported outcomes have been used to influence medical decision making in other chronic medical conditions (including rheumatologic disease), but utility has not been assessed in patients with IED. We evaluated use of PROMIS (Patient-Reported Outcomes Measurement Information System) data in tracking ocular disease activity and response to therapy in these patients.

Methods: We identified patient charts containing an ICD code diagnosis for uveitis or scleritis, who were seen two or more times by specialists in IED through Cleveland Clinic's rheumatology and ophthalmology departments between July 2016 and December 2018. These charts were individually reviewed to ensure there were at least two data points available for study inclusion where PROMIS data was collected within two weeks of a documented ophthalmic exam. Demographics and disease characteristics were noted. PROMIS data and ophthalmic exam findings were documented for each patient's initial and each subsequent encounter meeting inclusion criteria.

Table 1. Repeated measures correlation between eye exam findings and PROMIS measures.

	PROMIS domain	Correlation coefficient	95% CI	p-value*
Conjunctival injection	Physical	-0.064	(-0.19, 0.068)	0.34
	Mental	-0.11	(-0.24, -0.020)	0.094
	Function	0.026	(-0.11, 0.16)	0.70
Anterior chamber inflammation	Physical	-0.21	(-0.34, 0.085)	**0.0012**
	Mental	-0.18	(-0.31, -0.053)	0.0060
	Function	-0.16	(-0.29, -0.034)	0.013
Vitreous inflammation	Physical	-0.004	(-0.14, 0.13)	0.96
	Mental	-0.003	(-0.14, 0.13)	0.97
	Function	0.10	(-0.031, 0.23)	0.13

*p-value less than 0.0025 is considered significant.

Results: 87 patients were included in final analysis (74 uveitis patients and 13 scleritis patients). We found no significant differences in PROMIS or PHQ scores when comparing uveitis to scleritis patients. In regards to correlation of specific exam findings to different PROMIS measures, there was found to be a significant negative correlation ($r = -0.21$, $p = 0.0012$) between extent of anterior chamber inflammation and reported physical health PROMIS scores. Presence of vascular leakage on fluorescein angiography was found to be associated with worse physical health PROMIS scores at 1 year follow-up ($p = 0.007$), though this was not seen at other time points. No association between PROMIS scores and OCT findings was discovered. In comparing groups of patients on different therapies, there were no significant differences found in PROMIS scores reported in patients on biologic vs nonbiologic therapies.

Conclusion: Anterior chamber inflammation correlated with worse reported physical function which is likely a consequence of anterior chamber inflammation more frequently causing symptoms apparent to the patient thereby affecting their perceived health. Presence of vascular leakage on fluoroscein angiography was found to be associated with worse physical health PROMIS scores at 1 year follow-up. Our findings warrant further investigation into how patient reported outcomes can assist in monitoring ocular disease activity outside of an ophthalmology exam room.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Some forms of spondyloarthritis (SpA) such as SAPHO syndrome are classified as autoinflammatory disorders. Association with adult onset Still's disease (AoSD) has never been reported. We reported a case-series of 5 patients who presented features of both diseases.

Methods: Out of our cohort of 57 AoSD patients followed in our reference center, we identified 4 cases combining diagnosis of AOSD, on the basis of Yamaguchi's and/or Fautrel's classification criteria fulfilment, and SpA according to at least one classification criteria fulfilment: ASAS criteria for axial or peripheral spondylarthri-

Table. patients' characteristics. –*The patient presented 2 out of the 3 criteria needed (arthritis + enthesitis). AOSD, Adult-Onset Still's Disease - DIP, distal interphalangeal joint – MRI, magnetic resonance imaging –MTP, metatarsophalangeal joint - PIP, proximal interphalangeal joint - SpA, spondylarthropathy.

	Case 1	Case 2	Case 3	Case 4	Case 5
General Data					
Sex (Female/Male)	M	F	M	F	M
Age (years)	56	45	46	53	17
Age at onset of AOSD symptoms (years)	48	39	28	46	16
Age at onset of SpA symptoms (years)	37	42	40	51	17
Ethnicity	Caucasian	Caucasian	Caucasian	Caucasian	African
AOSD criteria fulfillment					
Yamaguchi's	Yes	Yes	Yes	Yes	Yes
Fautrel's	Yes	Yes	Yes	Yes	Yes
SpA criteria fulfillment					
ASAS criteria – axial Spondyloarthritis	No	No	No	Yes	Yes
ASAS criteria – peripheral Spondyloarthritis	No*	No	No	Yes	No
Amor's criteria for Spondyloarthritis	Yes	No	No	Yes	No
CASPAR for Psoriatic Arthritis	No	Yes	Yes	No	No
Spondyloarthritis data at onset					
Family background with psoriasis	Yes	No	No	No	No
Personal medical history of skin psoriasis	No	Yes	Yes	Yes	No
Swollen joints	Yes	Yes	Yes	Yes	Yes
Enthesitis	Yes	No	Yes	No	Yes
Acne	No	No	No	Yes	No
Skin psoriasis	No	Yes	Yes	No	No
Inflammatory back pain	No	No	No	Yes	Yes
HLA B27 status	Negative	Negative	Negative	Unknown	Negative
Radiological signs (through disease evolution)	Carpal ankylosis, DIP narrowing, bilateral calcaneal enthesophyte	Carpal ankylosis, DIP ankylosis, MTP ankylosis	Bilateral carpal ankylosis; erosion, ankylosis and reconstruction signs	Left sacroiliitis, multifocal osteitis (vertebrae, iliac bone), osteolytic bone	Bilateral sacroiliitis on MRI, bilateral coxitis

tis, Amor's criteria for spondyloarthritis or CASPAR criteria for Psoriatic Arthritis (PsA). A fifth patient, followed in another university center and combining both diseases according to the same criteria, was subsequently included. Medical past history, family background, AOSD and SpA onset and evolution, clinical, biological and radiological features, and treatment response were extracted retrospectively from medical chart through a pre-defined form.

Results: The 5 patients (3M, 2W) displayed the following characteristics **(Table):** mean age 43.4 ± 15.4 years, mean age at AoSD and SpA onset 35.4 ± 13.3 and 37.4 ± 12.5 years respectively, mean follow-up duration 8.0 ± 6.2 years (range 1-18 years). Four patients were Caucasian, one African, with no consanguinity. SpA manifestations occurred after AoSD onset in 4 patients (mean delay 5.2 ± 4.7 years); AoSD was diagnosed 11 years after SpA diagnosis in the 5th patient. At AoSD onset, the 4 cardinal symptoms were present: mean fever 39.2 ± 0.8°C, arthralgia and arthritis and skin rash in all patients, mean white blood count was 16,091 ± 4302/mm3 (89.2% of polymorphonuclears), mean ESR 74 ± 33 mm, mean CRP 156.5 ± 74.5 mg/L, mean ferritin was 658.6 ± 340.9 µg/L.

SpA-related symptoms are indicated in the **Table**. Two patients fulfilled the criteria for axial spondyloarthritis, two for peripheral spondyloarthritis, three for PsA and one for SAPHO syndrome. Three patients had personal and one had familial medical history of skin psoriasis. HLA B27 was negative in 4 patients (status unavailable in one patient). Besides the classical AOSD carpal ankylosis and narrowing of proximal and distal interphalangeal (PIP, PID) joints found in 3 patients, radiological features of SpA were observed: bilateral calcaneal enthesophytes; uni- or bilateral sacroiliitis suggestive of spondyloarthritis **(Figure 1)**; erosion, ankylosis and reconstruction "PsA-like" signs on PIP

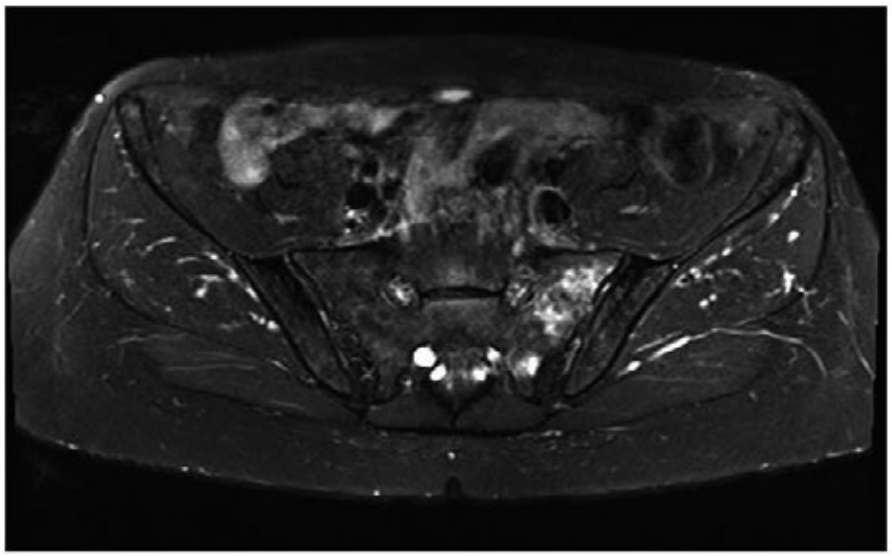

Figure 1. Inflammatory sacroiliitis suggestive of spondylarthritis on MRI.

Figure 2. Besides the classical bilateral carpal ankylosis, please note erosion, ankylosis and reconstruction “Psoriatic Arthritis-like” signs on proximal and distal interphalangeal joints.

and DIP **(Figure 2)**; multifocal osteitis and osteolytic bone lesion suggestive of SAPHO. Articular symptoms responded well to biotherapies prescribed for AOSD (anakinra, tocilizumab or TNF inhibitors) in 4 patients; in the 5th patient, prednisone and methotrexate were sufficient to control symptoms.

Conclusion: The prevalence of SpA in our AOSD cohort was around 7.0%, thus greater than the prevalence of 0.3% in the French general population (Saraux et al. Ann Rheum Dis. 2005 Oct;64(10):1431-5). The association of both diseases suggests a possible pathophysiological link between these 2 entities.

Clinical Manifestations and Management of US Patients with SAPHO (Synovitis, Acne, Pustulosis, Hyperostosis, Osteitis) Syndrome, a Retrospective Study

Delamo Bekele,[1] Paras Karmacharya,[2] Kerry Wright,[2] and Clement Michet[1], [1]Mayo Clinic Rochester, Rochester, MN, [2]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The SAPHO syndrome is a rare inflammatory disorder of bones, joints and skin first coined by Chamot in 1987 characterized by synovitis, acne, pustulosis, hyperostosis and osteitis[1]. No validated diagnostic criteria exist; diagnostic delay is not uncommon and observational data from the Western Hemisphere is sparse

Methods: Adult patients with a diagnosis of SAPHO seen between 2001 and 2018 at a single tertiary referral center were retrospectively identified. Cases were reviewed by a physician abstractor to determine whether they fulfilled either of the following 2 proposed criteria for SAPHO: Benhamou[1,2] or modified Kahn (2003)[3]. Sociodemographics, clinical characteristics, laboratory parameters, radiology, histopathology, management and outcomes were abstracted from direct medical record review. Patients with non-inflammatory bony lesions, infectious osteitis and CRMO were excluded.

Results: Twenty-one patients with complete clinical and treatment data were identified (71% female, 76% Caucasian). The average age at the time of diagnosis was 36.9 ± 13.4 years and the mean time from symptom onset to diagnosis was 3.4 years. 20/21 had cutaneous involvement: 10 with palmoplantar pustulosis or psoriasis vulgaris and 10 with severe acne. Osteoarticular manifestations included anterior chest wall/clavicle 15 (71%), peripheral arthritis 9 (43%), inflammatory back pain 8 (38%) and 2 (10%) with mandibular osteitis. Uveitis and mucositis were uncommon (2 out of 21 cases). 52% had elevated inflammatory markers at diagnosis while HLA-B27 positivity was uncommon (1/11). 13 of 13 radionuclide bone scans performed were positive while 8 of 9 MRI's were diagnostic.

18 patients (86%) were treated with NSAIDs; addition of immunosuppressive therapy with oral DMARDs (n=14, 66%) and TNF inhibitor (n=12, 57%) was quite common. 9 of 12 patients treated with TNFi experienced loss of efficacy requiring an alternate TNF inhibitor or switch to IL 17 or 23 blockade. 6/21 received oral antibiotics (doxycycline or penicillin); 50% of whom responded well. 7/21 proved refractory requiring bisphosphonate therapy; 5/7 responded at time of last follow up. Outcomes were favorable overall with 15 (71%) being in/near remission at the end of the follow up period (mean of 3 years). 2 patients required reconstructive surgery; and they both had active disease at last visit.

Conclusion: This large case series presents a heterogenous group of SAPHO patients with a long period of follow up. A significant delay was noted between symptom onset and diagnosis. Concomitant cutaneous and osteoarticular manifestations were seen in the majority (20) of patients. HLA B27 was frequently negative in our group; advanced imaging with bone scan or MRI helped to confirm the diagnosis. Though NSAID and DMARD use were quite common, biologic and/or bisphosphonate therapy was frequently required. Female predominance and chest wall involvement in this series may explain the lack of response to NSAIDs[4].Further studies are needed to guide diagnostic strategies and management. Greater awareness and multi-disciplinary collaboration are imperative in the provision of care to these patients.

Pelvic Congestion Syndrome, an Uncommon Cause of Osteoarticular Pain

Mireia Castillo-Vilella,[1] Jose Luis Tandaipan,[2] Laura Berbel,[3] Lluís Moga,[3] Georgina Salvador,[3] Silvia Martínez-Pardo,[3] and Nuria Giménez[3], [1]Hospital Universitari Sagrat Cor, Barcelona, Spain, [2]Hospital Universitari Mutua Terrassa, Terrassa, Spain, [3]Hospital Universitari Mútua Terrassa, Terrassa

SESSION INFORMATION

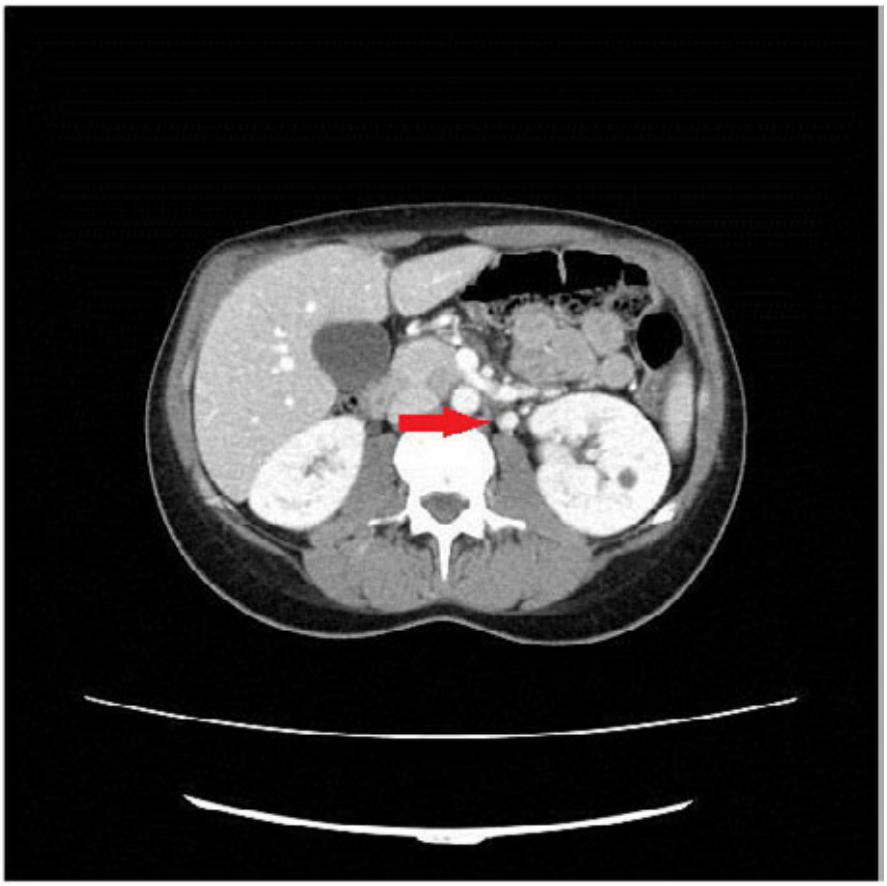
Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Background: The pelvic congestion syndrome (PCS) is an under and often misdiagnosed entity that appears more frequently in premenopausal age and multiparous women. The pathophysiology consists of a sum of phenomena including venous stasis and inversion of the pelvic venous flow that cause varicose veins and congestion. The left ovarian vein is usually the most affected. Typically it presents as a dull, chronic abdominal-pelvic (AP) pain, which worsens with menstruation and prolonged standing, and lasts longer than six months. Pain is associated with dyspareunia and varicosities in lower limbs (LL) and genitals. It is challenging and important to consider



ANGIO CT: left ovarian vein (red arrow) with contrast reflux due to venous insufficiency. It is accompanied by prominence and dilation of the bilateral periuterine venous plexuses with predominance of the left side.

atypical clinical presentations that simulate osteoarticular (OA) pathologies. It is usually diagnosed by Angio-CT, and a safe, definitive and successful treatment is the embolization of the affected vein.

Purpose: to evaluate the characteristics of those patients diagnosed with PCS in our University hospital from January 2014 to May 2018, paying close attention to the atypical forms of presentation that simulate OA pathology.

Methods: We included all patients from our center who were operated by embolization due to a PCS from January 2014 to May 2018. Socio-demographic variables, forms of presentation, pain characteristics, associated symptoms, patient management and outcome data were collected.

Results: Sixty women were included with a mean age of 43 years at diagnosis, 87% (n=52) were multiparous, with a mean of 2 previous pregnancies. In 95% (57) of all cases the duration of symptoms until the diagnosis exceeded 6 months. Patients were classified according to presence and location of pain in 4 groups: 1. Women with AP pain, 23% (14); 2. Women with OA pain 5% (3); 3. Women with mixed AP and OA pain, 59% (35); and 4. Women with other symptoms 13% (8). Regarding patients from groups 2 and 3 (only OA pain or mixed pain) (38), 90% (34) of them presented low back pain, 53% (20) hip pain and 40% (15) sciatic pain. Only 5% (3) of all patients were evaluated by a rheumatologist.

As for the pain characteristics from groups 1, 2 and 3 (52), in 72% (37) of patients it was diurnal, in 48% (25) it worsened with menstruation, in 62% (32) it worsened with prolonged standing and in 35% (18) it worsened at rest. Among

the associated manifestations, stand out the presence of LL varicose veins in 74% (38) of patients, genital varicosities in 58% (30), dyspareunia in 42% (22), dysmenorrhea in 40% (21), hemorrhoids in 37% (19) and dysuria in 18% (9). All patients underwent embolization of the affected vein, with an initial Visual Analogue Scale (VAS) mean of 7.38 over 10, and final VAS mean of 2.63. The mean recovery time was 36 days. The evolution was good or very good in 84% (32) of patients with mixed (AP and OA) pain and in 57% (8) of those who only had AP pain. Less than 2% (1) had a recurrence without the need for reoperation.

Conclusion: PCS is a rare entity, typically associated with long lasting AP pain, but, in more than half the cases, is accompanied with OA symptoms, mainly low back pain. It is important and challenging for the rheumatologist to identify these patients, since treatment is usually safe and effective, and diagnostic delay worsens their quality of life.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Adult-onset Still's disease (AOSD) is a rare, chronic and auto-inflammatory disorder with multisystemic involvement. Patient Acceptable Symptom State (PASS) is the highest level of disease activity that patients feel quite well. Till now, there is no valid information for the possible cut-off values of patient-reported outcomes (PRO) or activity scores for AOSD patients to predict PASS. To determine cut-off values of PROs and activity scores to predict PASS in AOSD patients, we conducted this study.

Methods: We conducted a cross-sectional, multicenter study. All AOSD patients were fulfilled the Yamaguchi criteria. Still activity score (SAS) [1 point for neutrophilia ≥65%, 1 point for ferritin≥350 ng/ml, 2 point for fever and 2 point for arthralgia-additional 1 point if swollen joint number is equal or grater than 2], Pouchet's systemic score (SS) [1

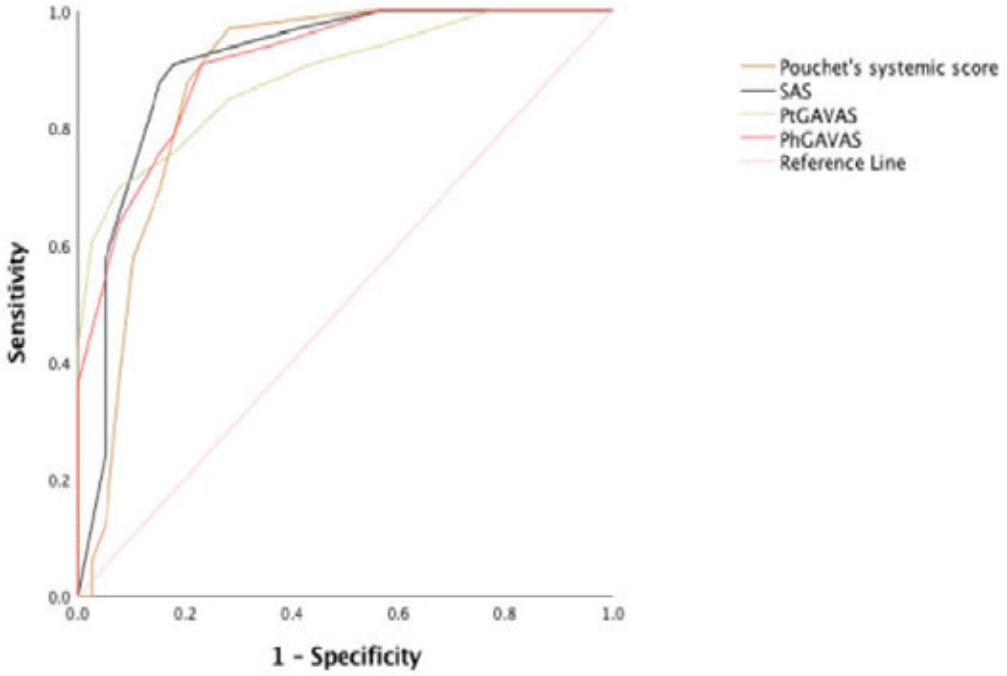

Figure 1. ROC analysis for PROs and disease activity scores.

point for each of the following manifestation: fever, typical rash, pleuritis, pneumonia, pericarditis, hepatomegaly, or abnormal liver function tests, splenomegaly, lymphadenopathy, leukocytosis >15,000/mm2, sore throat, myalgia, and abdominal pain], visual analog scale (VAS) (0–10 cm) for physician's (PhGA) and patient's (PtGA) global assessment

Parameter	Sensitivity (%)	Specificity (%)	Area Under Curve (AUC)	Confidence Interval	P
Pouchet's systemic score (SS)					
-SS ≤ 2	79	87.9			
-SS ≤ 3	82	79	0.87	0.79-0.96	<0.001
-SS ≤4	84	70			
Still Activity Score (SAS)					
-SAS ≤ 3	82.1	91			
-SAS ≤ 4	84.6	87.9	0.91	0.84-0.98	<0.001
-SAS ≤ 5	95	58			
Physician's Global VAS					
- PhVAS≤2	77	91			
- PhVAS≤3	82.1	78.8	0.91	0.84-0,97	<0.001
- PhVAS≤4	84.6	75.8			
Patient's Global VAS					
- PtVAS≤3	72	85			
- PtVAS≤4	82.1	75.7	0.88	0.81-0.96	<0.001
- PtVAS≤5	92.3	69.7			

were used to determination of the disease activity. To assess PASS, we asked patients whether they would be okay or not, if the disease activity will be the same as now during the next month. Receiver operator curve (ROC) analysis was done to find cut-off values.

Results: Total of 72 (71% female) AOSD patients were enrolled. Mean age was 41 (13) years and median disease duration was 2 (0–30) years. Median SS and SAS were 3 (0-10) and 4 (0-7), respectively. Mean PtGA and PhGA were 4.29 (3.15) and 3.54 (3.07), respectively. Cross-sectional frequency of AOSD findings were as follow; fever 34 (47%), rash 27 (37.5%), arthritis 25 (34.7%), arthralgia 52 (72.2%), sore throat 30 (41.7), myalgia 38 (52.8), lymphadenopathy 13 (18.1%), splenomegaly 20 (27.8%), hepatomegaly 16 (22.2%), pleuritic pain 5 (6.9%), pericarditis 4 (5.6%), hemophagocytic syndrome 2 (2.8%). Mean (SD) ESR (mm/h), CRP (mg/dl), ferritin level and leukocyte count were 36.8 (34), 5.4 (7.3), 1758 (4070) and 9960 (4178), respectively. ROC analysis, area under curve, confidence intervals, sensitivity and specificity for different cut-off values were given in **Table 1 and Figure 1**.

Conclusion: In this study, all PROs and activity scores performed well to predict PASS. Still activity score seems to perform better over SS. To the best of our knowledge, this is the best study reporting cut-off values for PROs and activity scores to predict PASS.

The Impact of Aging on Familial Mediterranean Fever Patients

Serdal Ugurlu,[1] Okan Aydin,[2] **Bugra Han Egeli**,[3] Asli Ece Soykut,[2] Deniz Demir,[2] and Huri Ozdogan[2], [1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, istanbul, Turkey, [2]Istanul University-Cerrahpasa, istanbul, Turkey, [3]İstanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is a monogenic autoinflammatory disorder with innate immune activation with an onset before age 20 in approximately 90% of the patients. There is scarce data on the effect of aging on FMF patients over 40 years of age. This study aims to collect data on FMF patients who have survived over 40 years of age. Here we report our preliminary data on disease course and treatment status and comorbidities of our patients with FMF.

Methods: Among the FMF patients who have been followed in our FMF outpatient clinic with a pool of approximately 5000 patients, those who have aged 40 and over are being included to the study. As by today 180 patients are considered for evaluation. The files of patients were reviewed and a standard questionnaire was used to interview the patients. Here we report the results of 100 of these patients (56%) who were contacted for this purpose. These patients were questioned on their demographic characteristics, comorbid conditions, colchicine treatment details, and attack information. In order to see the trend of the change in the parameters assessed, the patients were divided into two groups based on their present age (Group 1: 40-50 years, Group 2: ≥50 years).

Results: A total of 100 (78 F, 22M) patients were evaluated. There were 61(46F, 15M) patients aged between 40-50 years and 39 (32F, 7M) over 50. The demographic characteristics and clinical features of these patients are given in Table 1. Besides 3, all patients were still on colchicine regularly. Ninety-six percent of the patients declared overall benefit from colchicine therapy; however 38% experienced a side effect related to this treatment. Over 88% of the patients reported decrease in severity and frequency of FMF attacks. The mean daily colchicine dose was lower in the age 50 and over group (1.7±0,77 mg versus 1,35 ±0,38 mg). There were no patients with AA amyloidosis in neither age group. The mean duration from the last attack increased from 15.3 ±19.7 months to 35.6± 52 months in the older patients. One or more additional disease was present in 75% of this patient group.

Conclusion: According to our preliminary data the majority of the patients continue to take colchicine after age of 40. However, the frequency of FMF attacks as well as daily colchicine dose decrease as the patients get older. With well-designed trials stopping colchicine treatment may be considered in a subgroup of patients after 50 years of age. Approximately ¾ of the FMF population over 40 years of age has a comorbidity that necessitates additional medications which underlines the need for special attention.

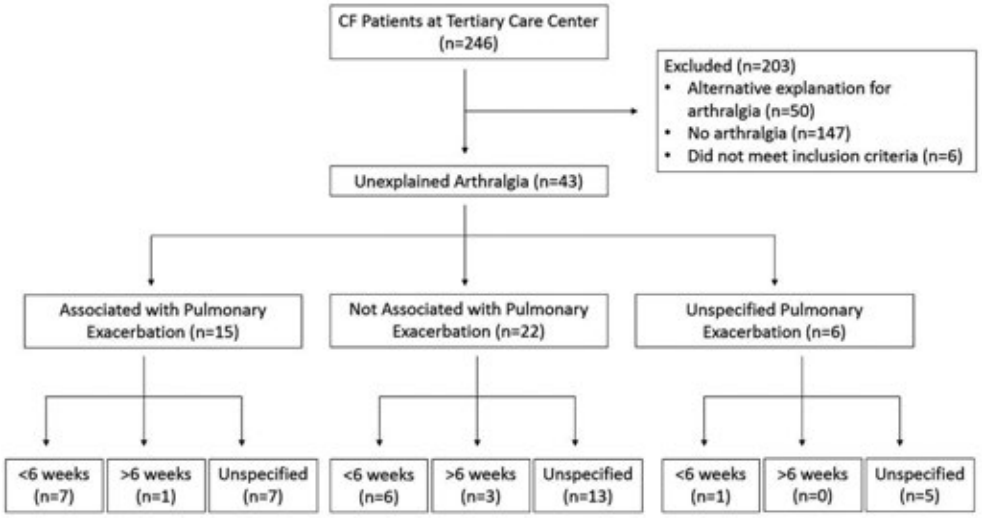
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthropathy is a rare but debilitating manifestation of cystic fibrosis (CF) that has no formal definition. This study attempts to characterize the spectrum of arthropathy in CF patients.

Methods: A retrospective chart review was conducted on 246 adult CF patients within the Pulmonary CF Clinic who were seen at a single tertiary care center between January 1, 2008 and December 31, 2017. Charts were individually reviewed for description of joint symptoms. Patients were excluded if they had an alternative explanation for joint symptoms. Association of joint symptoms with pulmonary exacerbation were abstracted and defined based on clinical diagnosis of the treating physician. Pattern of joint involvement, duration of symptoms (acute as defined by < 6 weeks and chronic >6 weeks), and therapies utilized for joint pain were also abstracted.

Results: In the overall cohort of 246 adult CF patients, 43 (17%) had unexplained joint symptoms; 128 (52%) were female and 42 (97%) self-reported as Caucasian. In those with unexplained arthralgia, 28 of 43 (65%) were female. The joint symptoms were not associated with pulmonary exacerbations in 22 patients (51%). In 15 (35%) patients, there was association between joint symptoms and pulmonary exacerbations while in 6 (14%) it was not specified. In 18 patients, the duration of symptoms was described and 14/18 had symptoms lasting less than 6 weeks. Knee (23), ankles (13), hips (10), and wrists (10) were the most affected joints. However, both small and large joints were affected. Both symmetric and asymmetric presentations were noted. No individuals had findings of sacroiliac joint involvement. No patients had evidence of erosions. The most commonly used medications were NSAIDs. In the overall cohort of CF patients who had unexplained joint symptoms, therapies utilized were NSAIDs (25, 58%), aceta-



Summary of Patient Cohort

minophen (10, 23%), and prednisone (9, 21%). Hydroxychloroquine was the most frequently used DMARD (7, 16%) followed by sulfasalazine (1, 2.3%). No biologics were used in this cohort. There were no individuals with hypertrophic osteoarthopathy in this cohort. There were no reports of fluoroquinolone associated tendinopathy or voriconazole induced periostitis.

Conclusion: This study characterizes the variety of joint symptoms in CF patients and expands on current knowledge. Females were most likely to experience arthralgia and the knee was the most commonly affected joint. Arthralgia was associated with pulmonary exacerbations in only 35% of patients. Understanding the diverse spectrum of arthropathy will result in greater recognition and improvement in quality of life for CF patients.

Novel Nonsense Variant and Entire Deletion of *TNFAIP3* Cause Haploinsufficiency of A20 Clinically Distinct from Behçet's Disease

Naomi Tsuchida,[1] Yohei Kirino,[1] Yutaro Soejima,[1] Hideaki Nakajima,[1] Satoko Miyatake,[2] and Naomichi Matsumoto[2], [1]Department of Stem Cell and Immune Regulation, Yokohama City University Graduate School of Medicine, Yokohama, Japan, [2]Department of Human Genetics, Yokohama City University Graduate School of Medicine, Yokohama, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Haploinsufficiency of A20 (HA20) is caused by loss-of-function *TNFAIP3* variants. Phenotypic and genetic features of HA20 remain uncertain; therefore, clinical distinction between HA20 and Behçet's disease (BD) requires clarification.

Table 1. Clinical features of haploinsufficiency of A20 (HA20) and Behçet's disease (BD)

Characteristics	HA20 (n=54)	(%)	BD (n=520)	(%)	p	Odds ratio	95%CI	
Age at onset (years) (mean ± SD)	6.0 ± 6.5		36.4 ± 12.3		< 0.001			
Childhood onset (< 16 years old)	49 /53	92.5	10 /520	1.9	< 0.001	624.75	188.92	2065.98
Familial	15 /25	60.0	19 /332	5.7	< 0.001	24.71	9.80	62.29
Recurrent fever	37 /51	72.5	39 /364	10.7	< 0.001	22.02	10.99	44.30
Oral ulcer	46 /52	88.5	518 /520	99.6	< 0.001	0.03	0.01	0.15
Genital ulcer	34 /52	65.4	372 /520	71.5	0.35	0.75	0.41	1.37
Eye involvement	5 /52	9.6	330 /520	63.5	< 0.001	0.06	0.02	0.16
Skin involvement	28 /52	53.8	461 /520	88.7	< 0.001	0.15	0.08	0.27
Arthritis	21 /54	38.9	245 /520	47.1	0.25	0.71	0.40	1.27
Gastrointestinal involvement	22 /53	41.5	78 /520	15.0	< 0.001	4.02	2.21	7.31
Vascular involvement	7 /53	13.2	41 /520	7.9	0.18	1.78	0.76	4.19
CNS involvement	5 /53	9.4	57 /520	11.0	0.73	0.85	0.33	2.21
Fulfilling ISG criteria for BD	23 /54	42.6	468 /520	90.0	< 0.001	0.08	0.05	0.15

Methods: We have collected twelve Japanese BD-like families. Probands of these families were analyzed by whole exome sequencing (WES) and subsequent Sanger sequencing or quantitative PCR. Copy number variants (CNVs) were examined using WES data with two algorithms: the eXome-Hidden Markov Model (XHMM) and a program based on the relative depth of coverage ratios developed by Nord et al. To observe mutational effects of the nonsense variant, RT-PCR was performed. Clinical features were compared between 54 HA20 patients (including previously reported and new cases) and BD cohorts (520 Japanese BD patients accumulated at our facility and pediatric BD from the Pediatric Behçet's disease (PEDBD) study by Kone-Paut et al.) Statistical analysis was performed with SPSS version 22 (IBM Japan, Tokyo, Japan). Categorical variables were analyzed using the chi-square test. Continuous variables were examined using Student's t-test. A *p* value less than 0.05 was considered statistically significant.

Results: Among Twenty-five patients from twelve families, two novel *TNFAIP3* pathogenic changes were found in two families (16.7%, 2 of 12): nonsense variant in one family and a 236 kb deletion at 6q23.3 containing *TNFAIP3* in another family. The nonsense variant may be subjected to nonsense-mediated mRNA decay (NMD). Four HA20 patients in the two families presented with childhood-onset recurrent oral and genital ulcers and were initially diagnosed and treated as BD. Consistent with the clinical features of HA20, recurrent, refractory fever attacks (3/4), and digestive ulcers (2/4) were observed. A comparison of clinical features between HA20 patients and cohorts of BD patients revealed that some features are shared between HA20 and BD as previously reported: recurrent oral and genital ulcers, and skin, eye, musculoskeletal and gastrointestinal involvement. While several critical features were more specific to HA20: early-onset, familial occurrence, recurrent fever attacks, gastrointestinal involvement, and infrequent ocular involvement (Table 1).

Conclusion: We identified a novel nonsense variant and deletion of the entire *TNFAIP3* gene in two unrelated Japanese HA20 families. Genetic screening of *TNFAIP3* should be considered for familial BD-like patients with early-onset recurrent fevers.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Periodic fever syndromes (PFS) is a group of rare autoinflammatory diseases that includes cryopyrin-associated periodic syndromes (CAPS), hyperimmunoglobulin D syndrome/mevalonate kinase deficiency (HIDS/MKD), TNF receptor-associated periodic syndrome (TRAPS), and familial Mediterranean fever (FMF). Although canakinumab (CAN) has been approved in the United States (US) for patients (pts) with the aforementioned PFS, there have been limited studies on prescribing patterns among physicians who have initiated CAN in real world

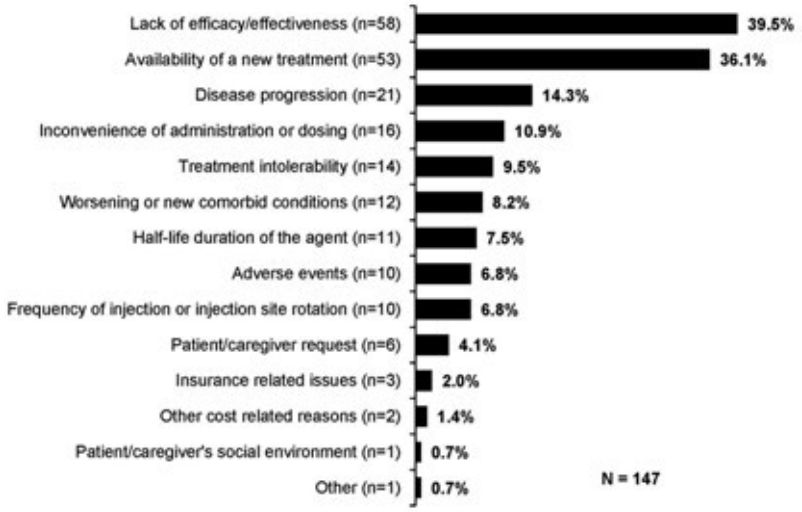

Figure 1. Reasons by PFS patients for discontinuation of treatments prior to canakinumab initiation

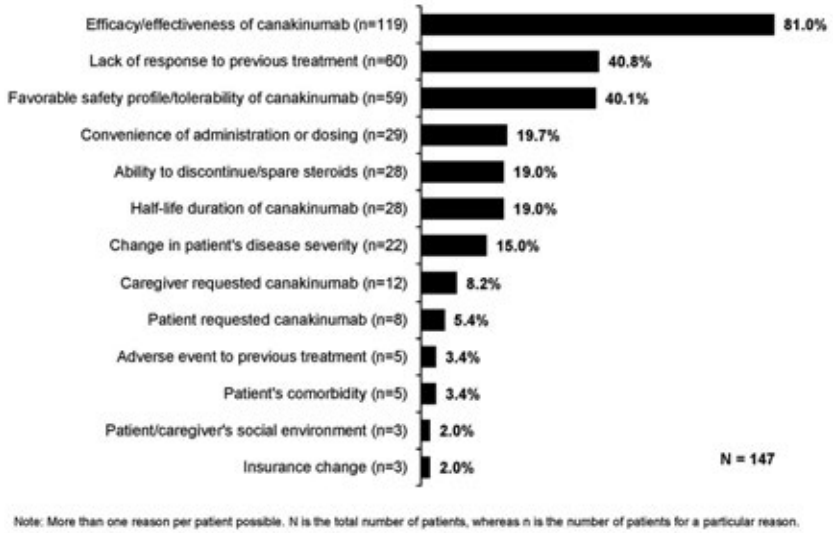

Figure 2. Reasons by PFS patients for the initiation of canakinumab treatment

settings. We assessed the clinical and treatment profiles of PFS pts who were prescribed CAN and the physician reason(s) for initiating CAN in US clinical practice.

Methods: Online medical charts were reviewed retrospectively to collect data from US rheumatologists/ dermatologists/ allergists / immunologists on pts (pediatrics [Ped; < 18 yrs] and adults [Adt; ≥18 yrs]) diagnosed with PFS who were initiated on CAN therapy by the responding physician between 2016 and 2018. Online case report forms were used to collect information on pt demographics, disease characteristics at CAN initiation, pre-CAN treatment history, and CAN prescribing patterns. Reasons for discontinuation of previous treatment and initiation of CAN were also collected.

Results: Medical charts were reviewed by 58 physicians who had specialty in rheumatology (26; Adt 88%, Ped 12%), dermatology (15; Adt 73%, Ped 27%), allergy (9; Adt 44%, Ped 56%), and immunology (8; Adt 38%, Ped 62%). Of the 147 pts, 57% were male and 46% were Ped. The mean age at CAN initiation was 21.7 yrs (Adt, 31.9 yrs; Ped, 9.9 yrs). Among PFS subtypes, 37% pts had CAPS, 27% TRAPS, 27% FMF, 7% HIDS/MKD and 3% mixed PFS subtypes. Median age at PFS diagnosis was 13 yrs (IQR: 6-20 yrs). The key methods of diagnosis were assessment of clinical symptoms and complications (87%), age of onset (63%), and family history/ancestry (57%). The main diagnoses which were ruled out included fever of unknown origin (70%), urticaria or rash/allergy (54%), and recurrent infection (51%). The severity of PFS was mild (22%), moderate (69%), or severe (8%) at CAN initiation. The most common symptoms at CAN initiation were fever (79%), fatigue/malaise (57%), skin rashes (44%), erythema (29%), arthralgia (26%), and myalgia (25%). Most pts (91%) received other long-term treatments in the last line of therapy prior to CAN including NSAIDs (28%), anakinra (24%), and colchicine (22%). The main reasons for discontinuation of treatment prior to CAN were lack of efficacy/effectiveness (40%) and availability of a new treatment (36%; Fig. 1). Decision to start CAN was made by both physician and pt/caregiver (61%), by physician only (35%), and by pt/caregiver only (4%). The prime reasons for CAN initiation included efficacy/effectiveness (81%), lack of response to previous treatment (41%) and favorable safety/tolerability profile (40%; Fig. 2).

Conclusion: Results from this study provide insight into the reasons for CAN initiation in PFS pts, with efficacy/effectiveness, lack of response to previous treatment and favorable safety/tolerability profile being the most common reasons.

Abstract Number: 1255

Is Exon 2 Associated with FMF or a New Disease?

Bilal Kulaksiz,[1] Bugra Han Egeli,[2] Okan Aydin,[3] and **Serdal Ugurlu**[4], [1]Istanbul University- Cerrahpasa, istanbul, Turkey, [2]İstanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey, [3]Istanul University-Cerrahpasa, istanbul, Turkey, [4]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In Familial Mediterranean Fever (FMF), patients having exon 10 mutations, specifically M694V, M680I, and V726A are more common and their disease profiles tend to complicate more. Hence, among the 10 exons of the MEFV gene, the association between FMF and these mutations are well known. Other mutations, especially the ones in exon 2, can be defined as benign polymorphisms due to being rare. The objective of this study was to understand the clinical nature of patients having mutations of E148Q and R202Q in exon 2 as well as how these mutations affect their complaints and treatment response.

Methods: In this study, we reported patients with FMF diagnosis according to Tel Hashomer criteria, who had mutations of E148Q, R202Q or both. These patients were a randomized subset of the ones followed in our outpatient rheumatology clinic. Clinical features of these patients were collected from their files. In terms of symptoms abdominal pain, chest pain, fever, arthritis, arthralgia, myalgia, erysipelas-like rash were noted. In terms of complications, renal FMF-related systemic AA Amyloidosis was noted. Also, we checked the family history of FMF. These patients were compared with the control group of patients having M694V mutation. M694V was selected as the control group because this mutation is well known scientifically and is the most frequent among FMF patients.

Results: The clinical symptoms of the patients are summarized in Table 1. One of the primary outcomes of this study was the treatment response. 98% of the patients were treated with colchicine when they were diagnosed with FMF. Fifty-two patients (91%) responded to colchicine in the control group whereas 33 (78%) responded to colchicine in Exon 2 group. To further digest the exon 2 patients, all of the patients in the R202Q group, 68% of the E148Q group, and 80% of the mixed exon 2 group responded to colchicine. Family history was positive in 9 patients (36%) of E148Q group, in 1 patient (8%) of R202Q group, in 1 patient (20%) in mixed exon 2 group which equals a total of 11 patients (26%). In the control group, 39 patients (68%) had an FMF diagnosis in their family. Amyloidosis was reported in one patient with E148Q mutation, one patient with R202Q mutation, two patients with M694V mutation.

Conclusion: In conclusion, in comparison with M694V patients, patients with exon 2 mutations, tend to have more atypical symptoms of FMF such as chest pain, arthralgia, and myalgia. The presentation of these symptoms is milder than the typical symptoms of FMF. The fact of low colchicine response in exon 2 patients cannot be overlooked as

Table 1. Clinical symptoms of patients with different exon mutations

	E148Q (3H+22h)*(n=25)	R202Q (0H+12h)(n=12)	Mixed E148Q +R202Q (n=5) (0H+5h)	Total of Exon 2 patients (3H+39h) (n=42)	Control M694V (n=57) (20H+37h)
Abdominal Pain	15 (%60)	10 (%83)	3 (%60)	28 (%66)	51 (%89)
Fever	12 (%48)	8 (%66)	3 (%60)	23 (%54)	44 (%77)
Chest Pain	10 (%40)	2 (%16)	2 (%40)	14 (%33)	13 (%22)
Arthritis	8 (%32)	0	1 (%20)	9 (%21)	20 (%35)
Arthralgia	21 (%84)	6 (%50)	4 (%80)	31 (%73)	25 (%43)
Myalgia	10 (%40)	0	0	10 (%23)	3 (%5)
Erysipelas-like rash	3 (%12)	1 (%8)	0	4 (%9)	3 (%5)

*H: homozygous h: heterozygous

well. Therefore, exon 2 mutations can be evaluated as a separate clinical entity; in fact, these cases should also be further searched for a potential autoinflammatory disorder.

Abstract Number: 1256

Comparison of FMF Patients with Age of Onset Before 20 versus 40 Years and Over

Serdal Ugurlu,[1] Okan Aydin,[2] and Huri Ozdogan[2], [1]Istanbul University - Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, istanbul, Turkey, [2]Istanul University-Cerrahpasa, istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Familial Mediterranean fever (FMF) is a disease with an onset before 20 years of age in 90% of the patients. However late onset FMF defined as age of onset over 40 years is being recognized more frequently. To better define patients with FMF who had their first attack before age 40 and compare them with early onset patient group in Turkish population

Methods: The files of 2180 FMF patients followed in a single center between 2008-2017 who have fulfilled Tel-Hashomer criteria, were reviewed regarding the age of onset 40 years and over (index patients, Group 1). For control purposes files before and after the index patients were browsed and first patients with an onset before age 20 years (Group 2) were included. The demographic, clinical and genetic characteristics are compared between these 2 sub-groups.

Results: Patients with an onset after 40 years consisted 2.7% of our FMF population. 50 of the 59 patients with an onset 40 years or over were re-evaluated and compared with early onset group consisting of 100 patients (Table 1). The delay in diagnosis, and disease duration were significantly longer and number of patients with M694V homozy-

Table 1. Demographic, clinical and genetic features of the study groups

	≥40 years n=50	**≤20 years n= 100**	**p**

N of M694Vallelles	**24(48)**	**82 (82)**	**0.014**
No mutation, n (%)	3(6.8)	2(2.2)	NS

gosity and M694V allele frequency were significantly more frequent among group 2. In general, phenotypes of both onset groups were similar, the only significant differences being the frequency of fever and myositis which were less common among group 1. Also, response to colchicine was more pronounced in group 1. One other interesting observation was the low incidence of amyloidosis in a group with such a significant delay in diagnosis and thus treatment.

Conclusion: FMF should be included among the differential diagnosis of patients over 40 years of age with recurrent autoinflammatory manifestations. Less than 3% of FMF patients experience their first attacks after 40 years of age. The frequency of M694V is significantly less in the late onset group, pointing out a milder disease.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Familial Mediterranean Fever (FMF) is the most common monogenic autoinflammatory disease and colchicine is the drug of choice for its treatment. However, about 5-10% of FMF patients do not respond to colchicine, even when they are fully compliant. Anti-interleukin(IL)-1 treatments are used for the patients who are resistant to colchicine. Treatment with IL-1 inhibitors have been shown to be effective in clinical trials and in several case series. The objective of this report is to produce evidence-based recommendations to define "colchicine resistance", as well as compliance and intolerance, to guide rheumatologists and other health professionals in the treatment and follow-up of patients with colchicine-resistant FMF.

Methods: A consensus meeting with 12 experts followed a systemic literature review and Delphi questionnaire. The expert committee consisted of pediatric rheumatologists with expertise in FMF. Parameters for colchicine resistance/intolerance/compliance derived from the literature were evaluated by a pre-meeting online questionnaire. All parameters were discussed with a nominal group technique during the meeting. Recommendations were accepted if more than 80% agreement was reached. If agreement was below 80% a second round of discussion was held.

Results: The systematic literature review yielded 264 articles. Of these, 38 were selected for expert review. After the literature review, Delphi survey, and round table discussion, recommendations that reached consensus levels were:

1. Colchicine is the drug of choice for the treatment of FMF and compliance is a critical issue. For the following statements, it is assumed that the patient is compliant with colchicine.
2. When utilizing colchicine to treat FMF, it is recommended to adjust the dose based on disease activity, with the maximal dose in children depending on age (and weight).
3. The maximum recommended colchicine dose for the treatment of FMF is between 1-3 mg per day, depending on age, limited by signs of toxicity and tolerability.
4. For a patient receiving the maximum tolerated dose of colchicine, resistance to colchicine is defined as ongoing disease activity (as reflected by either recurrent clinical attacks [average one or more attacks per month over a three-month period], or persistently elevated C-reactive protein or serum amyloid A in between attacks [depending on which is available locally)), in the absence of any other plausible explanation.
5. Amyloid A amyloidosis develops as a consequence of persistent inflammation, which may be a manifestation of colchicine resistance.
6. Colchicine intolerance, which generally manifests as gastrointestinal symptoms (such as diarrhea and nausea), is common and can limit the ability to achieve or maintain the effective dose. Dose-limiting toxicity is rare and may include elevated liver function tests, leukopenia, azoospermia etc.
7. Active disease and intolerance to colchicine affect quality of life.
8. Various patient reported outcomes to be used to guide FMF disease management were outlined.

Conclusion: The suggested recommendations are intended to improve patient care in FMF, to make a personalized treatment plan.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with ankylosing spondylitis (AS), IV administration of the anti-TNFa antibody golimumab (GLM-IV) resulted in improvements in composite measures of various aspects of the disease (eg, ASAS percent response, BASDAI, and BASFI) that were greater than placebo (PBO) at week 16 or earlier in the GO-ALIVE

study.[1] The improvements were maintained for up to 1 year of treatment.[2] Here we examine treatment effects on health-related quality of life (HRQoL).

Methods: Adult patients with definite AS (per modified NY criteria), BASDAI ≥4, total back pain VAS ≥4, CRP ≥0.3 mg/dL, and inadequate response to NSAIDs were randomized to GLM-IV 2mg/kg at weeks 0 and 4 then every 8 weeks, or to PBO at weeks 0 and 4 and GLM-IV at weeks 16 and 20, then every 8 weeks. Stable doses of methotrexate (≤ 25 mg/week), sulfasalazine, hydroxychloroquine, NSAIDs, other analgesics, and low dose oral corticosteroids were permitted for patients who were receiving these medications at baseline. Measures of HRQoL included the Ankylosing Spondylitis Quality of Life questionnaire (ASQoL), Short Form-36 physical and mental component summary scores (SF-36 PCS/MCS), Medical Outcomes Study Sleep Scale (MOS-SS), and EuroQoL visual analog scale (EQ VAS), each measured at weeks 16, 28, and 52. P values provided are nominal, not adjusted for multiplicity.

Results: At week 16, patients with AS receiving GLM-IV had greater improvements from baseline in HRQoL than those receiving PBO in each measure, respectively (ASQoL, -5.4 vs -1.8; SF-36 PCS, 8.5 vs 2.9; SF-36 MCS, 6.5 vs 0.78; MOS-SS, 6.6 vs 2.5; and EQ VAS, 20.3 vs 4.8; all p< 0.001), see Table. Changes from baseline were maintained through week 52 in patients randomized to GLM-IV. Patients switched from PBO to GLM IV at week 16 demonstrated improvement from baseline by week 28, which was maintained through week 52 and was similar to that of patients who received GLM IV at baseline (Table).

Table. Changes from Baseline in HR-QoL Measures from Week 16 to Week 52 in the Placebo-Controlled, Randomized, Phase 3 Study GO-ALIVE of Patients with Ankylosing Spondylitis

	GOL 2 mg/kg			PRO → Week 24 crossover to GOL 2 mg/kg		
	n	Baseline Score	Change from Baseline (mean ± SD)	n	Baseline Score	Change from Baseline (mean ± SD)
AS QoL						
Baseline	104	12.8 ± 4.04		102	12.4 ± 4.1	
Week 16	104		-5.4 ± 5.0*	102		-1.8 ± 4.6
Week 28	104		-5.3 ± 5.2	102		-5.3 ± 4.8
Week 52	104		-5.5 ± 5.3	102		-5.4 ± 5.3
SF-36 PCS						
Baseline	104	32.4 ± 5.6		102	32.1 ± 5.9	
Week 16	104		8.5 ± 7.5*	102		2.9 ± 6.2
Week 28			9.1 ± 8.0	102		9.3 ± 7.1

Week 16	104		20.3 ± 24.6*	98		4.8 ± 23.5
Week 28	102		20.5 ± 27.9	97		22.5 ± 23.1
Week 52	101		21.9 ± 26.8	95		24.3 ± 23.7

*P vs placebo<0.001. P values are nominal, not adjusted for multiplicity.
ASQoL and and SF-36 results were calculated using a Mixed-effect Repeated Measures statistical model. MOSS-SS and EQ VAS results were calculated using an Analysis of Covariance model.
ASQoL=Ankylosing Spondylitis Quality of Life EQ VAS= EuroQol-5D questionnaire, visual analog scale; HRQoL=Heath-related Quality of Life; SF-36 PCS/MCS=Short-Form-36 Physical / Mental Component Summaries

Conclusion: Improvements in HRQoL among patients with active AS treated with GLM-IV were greater than PBO at week 16 and were maintained through week 52. Patients switching from PBO to GLM-IV at week 16 experienced improvements in HRQoL by week 28 and maintained the improvement through week 52 at levels similar to those of the patients originally randomized to GLM-IV.

Synovitis, Acne, Pustulosis, Hyperostosis, and Osteitis (SAPHO): A Case Series

Devanshu Verma,[1] Samir Shah,[2] and Arundathi Jayatilleke[3], [1]Drexel University, Philadelphia, [2]Thomas Jefferson University, Philadelphia, [3]Drexel, Philadelphia, PA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: SAPHO is a chronic multisystemic illness with predominantly skin and joint manifestations. Disease presentation is heterogenous; proposed diagnostic criteria include chronic multifocal aseptic osteomyelitis and osteitis of the long bones1,2. Due to SAPHO's rarity, treatment is based on observational studies and case reports. Anti-TNF therapy is increasingly used in refractory SAPHO cases. We present a series of 10 patients diagnosed with SAPHO and their response to various anti-TNF agents.

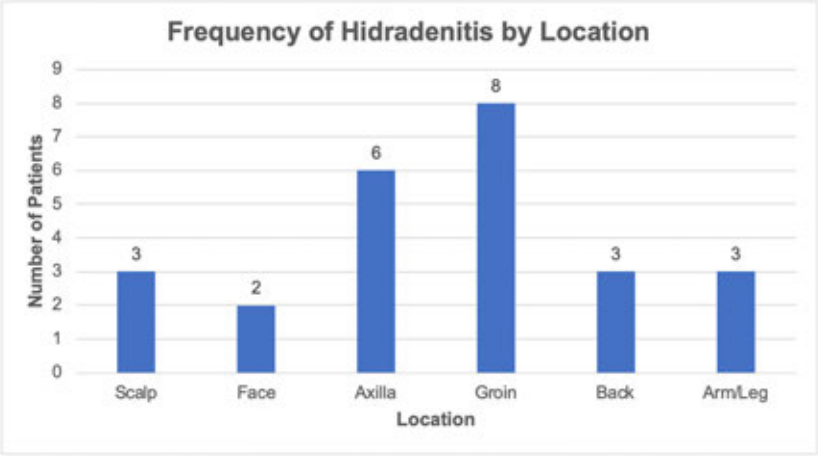
Methods: We performed a retrospective single-center study of SAPHO patients on anti-TNF therapy followed by rheumatology and dermatology from 2014 to 2017. Patients 18 or older were screened for SAPHO using ICD-10 codes for hidradenitis suppurativa, acne vulgaris, pustulosis, palmar pustulosis, palmoplantar pustulosis, AS, inflammatory spondylopathy, seronegative SpA, and inflammatory arthritis in combination. Patients were excluded if an

Patient Age (years), Sex	Treatments Tried					Response		Follow-up Duration (Weeks)
	Methotrexate	Infliximab	Adalimumab	Etanercept	Golimumab	Articular	Dermatologic	
52, Female		Yes					Discontinued due to brittle hair, alopecia	234
	Yes					Persistent synovitis and hand swelling		
32, Male					Yes	Significant improvement in joint pain		9
60, Female				Yes		Joint pain and hidradenitis initially resolved after first dose followed by relapse		395
		Yes				Joint pain resolved	Hidradenitis improved	
24, Male		Yes				Joint pain resolved	Clearing hidradenitis, residual groin drainage; acne resolved. Hidradenitis recurred with treatment lapse	383
			Yes			No joint pain, active hidradenitis or acne. Maintained remission		
40, Female	Yes	Yes					Worsening hidradenitis. New involvement in hands, gluteal folds	160
24, Female		Yes				Second infusion improved joint pain	First infusion improved hidradenitis, facial acne. Occasional flare	14
36, Male *	Yes				Yes	Synovitis and hidradenitis controlled on golimumab		49
61, Female			Yes			Improved hidradenitis and joint pain initially, worsened after four years		532
	Yes	Yes				No acne, hidradenitis or synovitis. Sustained remission.		
46, Male	Yes	Yes					Acne and pustules resolved after infliximab	129
45, Female				Yes		Arthritis improved	No change in acne and hidradenitis	284
	Yes	Yes				Resolution of joint pain with infliximab. Fluctuating joint symptoms closer to infusion due date	Initial clearing of hidradenitis with infliximab	

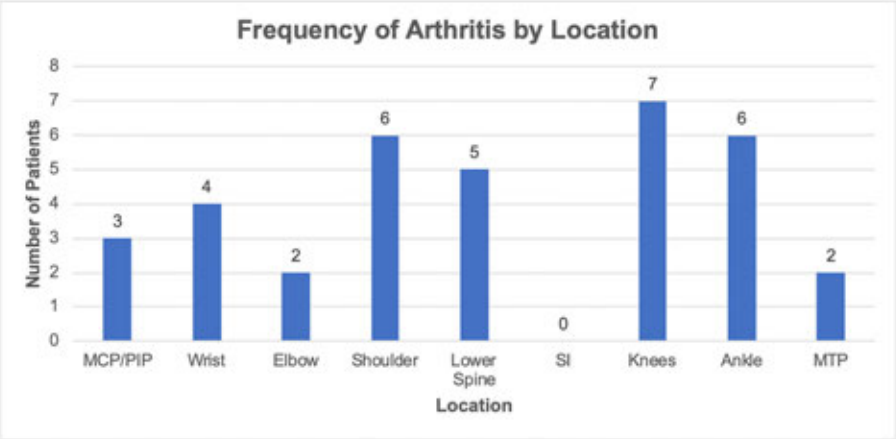
Summary of dermatologic and articular response to various disease modifying treatments.

alternate diagnosis was made, lost to follow-up, or did not start anti-TNF therapy. We identified 10 SAPHO patients treated with TNF inhibitors and characterized their articular and dermatologic responses.

Results: 10 patients (6 female, 4 male) with a mean age of 38 years (range 19-52) were followed for an average period of 50 months (range 2–122). 6 of the 10 patients (60%) had prior MTX or bisphosphonate use. Infliximab was used in 8 patients of whom 6 had significant improvement in pustulosis and joint pain while 2 patients experienced



Hidradenitis predominantly involved the groin and axilla, with less involvement of peripheral limbs, scalp and face.



Location of arthritis varied between axial and peripheral involvement. Predominant joints included shoulders, knees and lower spine.

worsening symptoms. 4 patients (40%) required two or more anti-TNF agents. The average ESR and CRP were 32 mm/hr and 5.8 mg/L at the outset and 26 mm/hr and 2.52 mg/L at the end of therapy, respectively.

Conclusion: Anti-TNF therapy is effective in treating cutaneous and articular manifestations of refractory SAPHO. Infliximab was most widely used in our study and associated with marked improvement in acne, pustulosis and arthritis. Etanercept was less effective in treating skin than articular disease. Golimumab and adalimumab showed similar clinical response. At present, a lack of validated response criteria specific for SAPHO limits objective assessment of therapeutic response. Further research is needed to better gauge response to therapy.

The Study of Peripheral Blood Lymphocyte Subsets and CD4+T Subsets in Recurrent Polychondritis

Fang Yuan Hu,[1] Ning Yan,[1] Jie Liang,[1] Xiao Feng Li,[2] and Cai-hong Wang[3], [1]The second hospital of shanxi medical university, Taiyuan, China (People's Republic), [2]The Second hospital of Shanxi Medical University, Taiyuan, China (People's Republic), [3]The Second Hospital of Shanxi Medical University, Tai Yuan, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is an uncommon systemic connective tissue disorder characterized by recurrent and episodic inflammation of cartilaginous tissues, such as ear, nose, joint, and respiratory tract. Recently, some researches suggest that immune disorders lead to autoimmune diseases. But little research has been done on the status of immune function in RP patients. Therefore, we analyzed the lymphocyte subsets in peripheral blood of RP patients to explore their immune function. Therefore we analyzed absolute counts and percentages of lymphocyte subsets and CD4+T subsets in peripheral blood of RP patients to explore their immune function and laid a foundation for further treatment.

Table I. Absolute counts and percentage of PB lymphocytes in the study participants (n=17).

Variable	RP patients (n=17)	Healthy donors (n=17)	p-value
PB lymphocyte(cells/μl)	median (quartile range)	median (quartile range)	
T	1092.00(900.23-1036.77)	1573.00(1401.71-1825.50)	0.002
B	170.22(118.70-292.74)	246.00(164.50-318.61)	0.213
CD4+T	620.09(502.39-883.28)	913.00(815.84-1073.00)	0.003
CD8+T	391.00(322.72-638.98)	432.11(414.00-718.00)	0.274
NK	203.00(92.45-273.79)	341.00(209.47-429.00)	0.020
CD4+T/CD8+T,ratio	1.46(1.33-1.85)	2.26(1.42-2.48)	0.122
PB lymphocyte %			
T%	72.57(67.77-78.82)	73.00(66.99-75.50)	0.892
B%	12.29(9.01-15.17)	11.00(7.32-14.00)	0.586
CD4+T%	41.20(36.53-46.01)	43.00(39.00-49.00)	0.496
CD8+T%	27.58(22.70-32.00)	21.00(18.91-27.50)	0.079
NK%	12.00(6.00-18.31)	15.21(8.50-17.79)	0.518

Table II. Absolute counts and percentage of cd4+T cells in the study participants (n=17).

Variable	RP patients (n=17)	Healthy donors (n=17)	p-value
CD4+T subsets (cells/μl)	median (quartile range)	median (quartile range)	
Th1	89.43(58.51-175.34)	87.74(68.41-164.13)	0.812
Th2	7.44(4.77-9.53)	10.22(8.00-14.70)	0.031
Th17	6.07(3.53-12.13)	5.59(4.09-9.45)	0.838
Treg	24.28(16.24-34.17)	46.33(42.69-58.04)	P<0.001
Th1/Th2	13.00(7.56-22.19)	10.21(5.45-17.32)	0.245
Th1/Treg	3.33(2.11-6.84)	1.95(1.54-3.65)	0.018
Th2/Treg	0.27(0.21-0.35)	0.21(0.16-0.30)	0.114
Th17/Treg	0.25(0.17-0.37)	0.13(0.08-0.17)	0.001
CD4+T subsets%			
Th1%	13.00(8.40-19.08)	10.76(8.01-20.01)	0.518
Th2%	1.00(0.66-1.67)	1.02(0.90-1.65)	0.586
Th17%	0.88(0.69-1.27)	0.68(0.45-0.92)	0.112
Treg%	3.80(2.37-4.65)	5.21(4.56-5.89)	0.001

Methods: Absolute counts and percentages of peripheral blood lymphocyte subsets and CD4+T subsets, which were from 17 patients (8 women and 9 men) diagnosed as RP and 17 healthy controls, were assessed by flow cytometry and compared. All statistical analyses were performed with SPSS v. 22.0. Continuous variables were reported as median. For all study variables, comparison among controls and RP subjects was based on the non-parametric Wilcoxon Mann-Whitney exact test. For all analyses, we used two-sided tests, with p-values < 0.05 denoting statistical significance.

Results: Our study recruited 17 patients who met the inclusion criteria. The average age of patients was 45.23 year. As shown, when compared with healthy controls, RP patients had lower absolute counts of T cells (1573.00/μl vs. 1092.00/μl, p=0.002), CD4+ T cells (913.00/μl vs. 620.09/μl, p=0.003), and NK cells (341.00/μl vs. 203.00/μl, p=0.02). No difference was reported when comparing the percentage and absolute number of B cell, the percentage of CD8+T cells and the ratio of CD4+/CD8+ T cells between RP patients and healthy group. In CD4+ T cells, the proportion and absolute counts of Treg cells were significantly reduced in RP patients in comparison with controls (proportion,

3.80% vs. 5.21%, p< 0.001; absolute counts, 24.28/μl vs. 46.33/μl,p=0.001). The absolute counts of Th2 cells was reduced in RP patients in comparison with controls (7.44/μl vs. 10.22/μl, p=0.031). But there were no significant difference between the percentage and absolute counts of Th17 or Th1 cells in patients with RP and healthy controls. But RP patients had higher ratio of Th17/Treg (0.25 vs. 0.13, p=0.001), Th1/Treg(3.33 vs. 1.95, p=0.018).

Conclusion: Our data suggested that the immune-inflammation in RP patients may be related to the depletion of NK cells and Treg cells. The relative decrease of Treg cells may lead to the relative increase of helper T cells, which leads to uncontrollable inflammatory response.

The Time Lag – the Race in Diagnosis and Management of Hemophagocytic Lymphohistiocytosis

Sneha Patel,[1] Bibi Ayesha,[2] Anna Broder,[3] Inessa Gendlina,[2] Irina Murakhovskaya,[4] Manish Ramesh,[2] Yevgeniy Balagula,[2] and Anand Kumthekar[2], [1]Montefiore Hospital/Albert Einstein College of Medicine, Bronx, NY, [2]Montefiore Hospital/Albert Einstein College of Medicine, Bronx, [3]Rheumatology, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, NY, [4]Hematologist, Bronx

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Hemophagocytic lymphohistiocytosis (HLH) is an aggressive and life-threatening syndrome of disordered immune activation marked by excessive inflammation. Immunosuppression remains the mainstay of therapy after targeting the underlying trigger. Both the diagnosis and management of HLH remain challenging, as the disease can mimic a wide spectrum of clinical disorders and immunosuppression can become delayed. A multidisciplinary approach is crucial for the early diagnosis and treatment of this disorder to help improve outcomes. The aim of our study is to explore the relation between time to sub-specialty consultation, HLH consideration and immunosuppression initiation with 30-day mortality.

Methods: We performed a retrospective chart review of HLH patients' age >18 years identified in the electronic medical records by ICD 9/10 coding for HLH and confirmed by chart review. Patients were characterized as having definitive HLH (defined as meeting 5/8 parameters according to the 2004 HLH diagnosis criteria) and probable HLH (defined as meeting 4/8 parameters on the HLH criteria or if they had hemophagocytosis on biopsy). Patients with incomplete clinical data and those not meeting criteria for definitive or probable HLH were excluded. Clinical demographics, underlying etiology, HLH parameters, hospital day of HLH as a diagnostic consideration, time to sub-specialty consultation (rheumatology, allergy/immunology, hematology/oncology, infectious disease, and critical care), hospital day of immunosuppression initiation and 30-day mortality were identified. Student's t-test was used for comparison of continuous variables.

Results: During the study period, we identified 90 patients with HLH based on ICD coding. After excluding 64 patients based on insufficient clinical data for diagnosis of HLH, 20 patients were identified as having definitive HLH and 6 patients were identified as having probable HLH (Figure 1). Majority of patients 15/26 (58%) were males with a mean (SD) age of 42 (18). Infection (46%) was the most common secondary cause for HLH with 6/11 (54%) as viral etiolo-

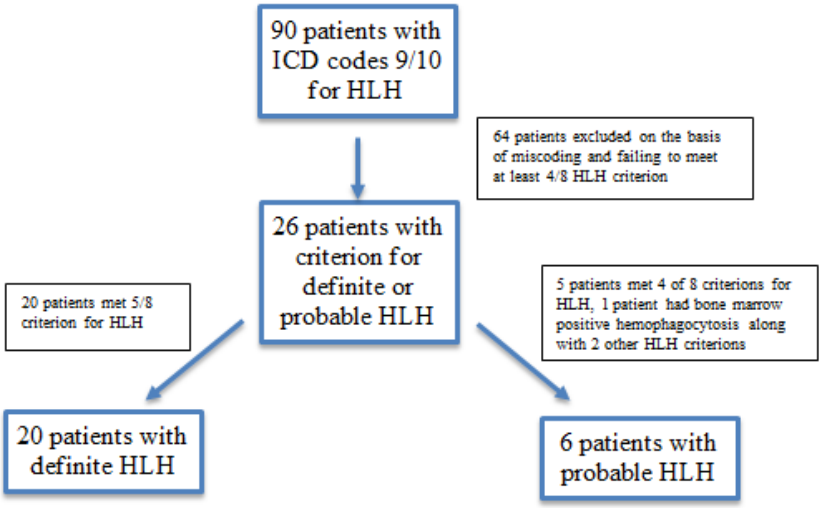

Figure 1. Flowchart of Inclusion/Exclusion Criterion

gies. Corticosteroids were the preferred first line immunosuppressive therapy in all patients. The 30-day mortality in our cohort was 7/26 (27%). The mean (SD) time to any sub-specialty consultation was 1.8 days (1.2) in patients who survived and 3 days (2.3) in patients who died (p=0.23). The mean (SD) time lag from admission to HLH consideration was 6.7 (5.3) vs. 4.6 (3.6) (p=0.26), while the mean (SD) time lag from consideration of HLH to immunosuppression was 2 days (2.7) vs. 8.4 days (8.8) SD (p=0.10) in patients who survived and died respectively.

Conclusion: Among adult patients with definitive or probable HLH seen at a single center, we did not find a statistical significant association between time to sub-speciality consultation, time lag to immunosuppression, and mortality. Our study was not adequately powered to detect small differences and future larger studies are warranted, so appropriate interventions can be developed.

Clinical Features of Elderly-onset Adult Still's Disease

Sayaka Takenaka,[1] Takehisa Ogura,[1] Yuto Takakura,[1] Takaharu Katagiri,[1] Yuki Inoue,[1] Ayako Hirata,[1] and Hideto Kameda[2], [1]Division of Rheumatology, Department of Internal medicine Toho University Ohashi Medical Center, Tokyo, Japan, [2]Toho University, Tokyo, Japan, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The peak age at the onset of adult Still's disease (ASD) has been between 20 and 35 years old. However, the proportion of elderly-onset ASD (EOASD) is increasing in Japan, a country of super-aged society. Therefore, we investigated the clinical features of EOASD in comparison with non-elderly-onset ASD.

Methods: A total of 20 patients with the diagnosis of ASD according to the classification criteria by Yamaguchi et al. between May 2013 and October 2018 in our department were enrolled in this study. Their medical records were intensively reviewed for demographics, clinical manifestations, laboratory data, treatments received and outcome.

Results: Six patients with the age of onset ≥ 65 years (median 71 years old, 5 women) and 14 patients < 65 years (median 38 years old, 12 women). There were no between-group differences in the frequency of fever, sore throat, arthralgia, leukocytosis, liver function abnormality, seronegativity and serum ferritin levels. However, typical rash (50% versus 92%) and lymphadenopathy (50% versus 92%) tended to be less frequently observed in EOASD as compared with non-elderly-onset ASD, and as a result, the number of fulfilled items of Yamaguchi criteria was significantly smaller in EOASD than non-elderly-onset ASD (the median value of 5.5 and 7.5, respectively, p=0.0036). With regard to the treatment, glucocorticoids were administered in 19 patients (initial daily dose of prednisolone 50 mg/day for both groups), and tocilizumab was added in 20% and 35% of EOASD and non-elderly-onset ASD patients respectively. The prognosis was fair except for one patient with non-elderly-onset ASD developing fatal sepsis.

Conclusion: EOASD was not rare (30% of ASD) and showed comparable clinical features and outcomes with non-elderly-onset ASD.

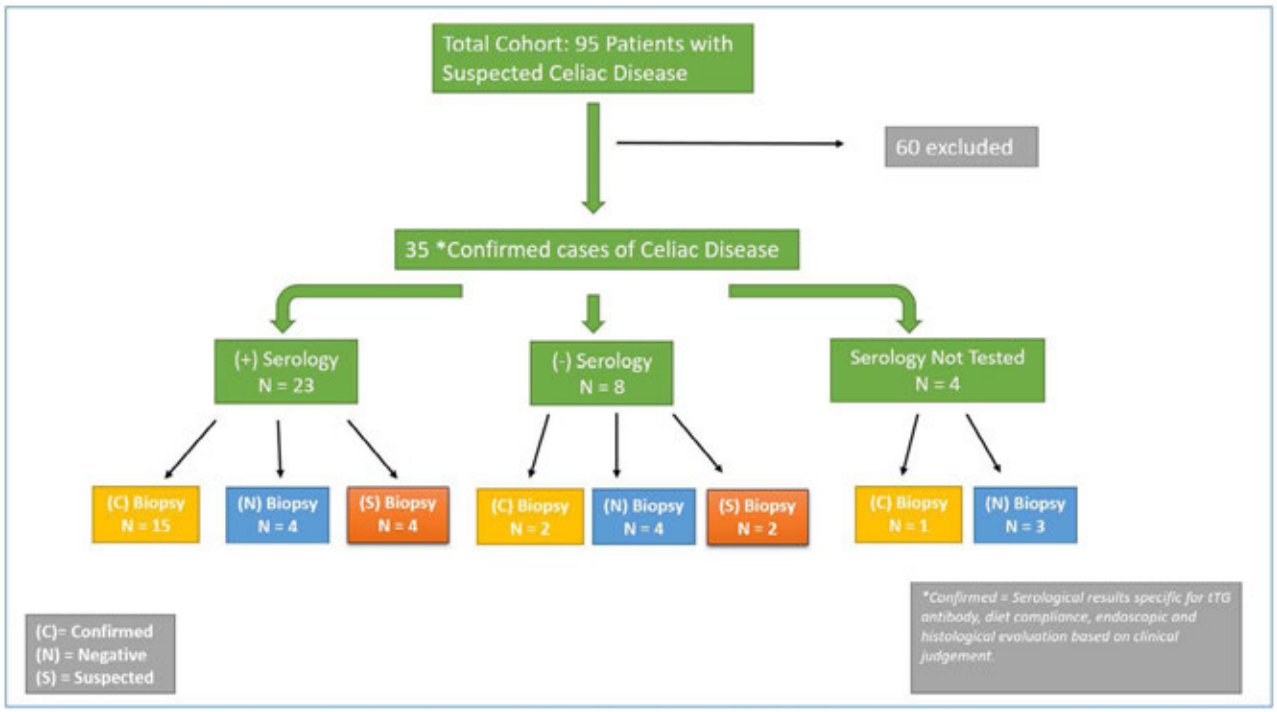
The Prevalence and Patterns of Celiac Disease Associated Arthropathy and Coexistence of Celiac Disease with Rheumatic Disorders in a Single Tertiary Medical Center

Anita Moudgal,[1] Pooja Bhadbhade,[1] Ammar Haikal,[1] and Mehrdad Maz[1], [1]The University of Kansas Medical Center, Kansas City, KS

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Celiac disease (CD) is a gluten-sensitive enteropathy that develops in genetically predisposed individuals. Arthropathy has been reported as an extra-intestinal manifestation of CD. The pathogenesis of arthropathy is unclear; however, the immunologically mediated mucosal injury may lead to absorption of immune complexes or gut-derived antigens which may provoke antibody mediated autoimmune diseases including rheumatic diseases and arthropathy. We report a retrospective chart review of 35 confirmed cases of CD associated arthropathy and coexisting rheumatic or inflammatory disorders.

Methods: Heron database was used to search for patients seen by Gastroenterology and/or Rheumatology between January 2008 to January 2018 with suspected CD based on ICD-9 code for CD. These charts were retrospectively reviewed to determine who had confirmed CD, joint pain and pattern of involvement, dietary compliance, and other inflammatory or rheumatic disorders. The diagnosis of CD was based on serology specific for tissue transglutaminase (tTG) antibody, endoscopic and histological results, compliance with gluten free diet, and clinical judgement.



Celiac Abstract Image 1Total Cohort with Suspected Celiac Disease

Results: A total of 95 patients with suspected CD were identified. 35/95 had confirmed CD. Of the 35 patients, 29 were female and 34 self-identified as Caucasian. The average age of patients was 49 years. Of the 35 patients, 22 patients did not have a co-existing rheumatic or inflammatory disorder. This cohort of 22 patients endorsed symptoms in the following distribution: 82% (18/22) had peripheral only, 0% (0/22) had axial only, and 18% (4/22) had peripheral and axial involvement. Of the 22 patients, 54% (14/22) endorsed arthropathy in small joints, 91% (20/22) in medium joints, and 82% (18/22) in large joints. Improvement in arthralgia after transitioning to a gluten-free diet was reported in 4/22 patients. A total of 13/35 with confirmed CD diagnosis had a rheumatic and/or inflammatory disorder. Rheumatoid Arthritis had the highest prevalence at 11% (4/35) followed by IBD (3), UCTD (2), Sjorgen's Syndrome (1), Scleroderma (1), Symmetric Inflammatory Polyarthritis (1), and Psoriasis (1). Fibromyalgia, a non-inflammatory condition, was reported in 6% (2/35) of patients. 3 patients were not seen by rheumatology.

Conclusion: CD associated arthropathy and coexistence of CD with rheumatic and/or inflammatory disorders are under-recognized. Our data demonstrates that 63% of patients had CD associated arthropathy who appear to be a unique subset separate from those with coexisting CD and rheumatic/inflammatory disorders. Identifying the association and pattern of arthropathy in CD will aid in management of patients who either present to a gastroenterologist with extra-intestinal manifestations or to a rheumatologist with gastrointestinal manifestations. The awareness that CD can coexist in rheumatic diseases will aid rheumatologists in more effective recognition and management of patients with such presentations.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Synovitis, acne, pustulosis, hyperostosis, and osteitis (SAPHO) syndrome is a rare autoimmune disease with heterogeneous presentation and severe disease burden. Factors influencing the quality of life (QoL) in patients with SAPHO syndrome remained under-recognized. We aim to assess the impact of various current symptoms (osteoarticular, dermatological and nail) on QoL in SAPHO patients.

Methods: A cross-sectional survey was conducted based on a previously established single-center dynamic cohort of SAPHO syndrome.[1, 2] Electronic questionnaires were distributed to patients recruited from January 2004 and December 2018 via a patient committee. Patients with active disease were asked to report their current clinical presentation (osteoarticular, dermatological and nail) and fill out the EuroQol five dimensions questionnaire (EQ-5D). Health related quality of life results measured by the EQ-5D were converted to a utility score using the Chinese time trade-off value set.[3] In addition, for those with osteoarticular manifestations, disease activity was measured using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). The Dermatology Quality of Life Index (DLQI) was obtained from the patients with dermatological manifestations.

Results: A total of 588 questionnaires were issued and 521 were retrieved. 60 were in remission at the time of examination. For the EQ-5D dimensions, patients reported the most problems (of any level) with pain or discomfort (52.6% [95% CI 48•0–57.2]) and fewest problems with self-care (10.1% [7.6–13•2]). Patients with current osteoarticular symptoms had a significant lower EQ-5D score than those without, which remained significant after adjustment for covariates (age, gender, smoking, and BMI). Meanwhile, such a relationship was not shown for dermatological and nail manifestations. For patients with skin lesions, DLQI was significantly lower at the presence of osteoarticular symptoms or nail lesions, even after adjusting for covariates.

Table 1 Basic characteristics of patients included in the study

Characteristics	n=521*
Gender, male, n (%)	164 (31.5)
Age, years, mean (SD)	43.3 (12.9)
Current smoker, n (%)	155 (29.6)
BMI (kg/m^2), mean (SD)	23.7 (3.4)
Current osteoarticular symptoms, n (%)	335 (64.3)
Current dermatological manifestations, n (%)	350 (67.2)
Current nail manifestations, n (%)	190 (36.5)
EQ-5D utility index (n=461), median (IQR)	0.847 (0.748-0.939)
EQ-5D mobility, n (%)**	118 (25.9)
EQ-5D self-care, n (%)**	46 (10.1)
EQ-5D usual activities, n (%)**	82 (17.9)
EQ-5D pain or discomfort, n (%)**	240 (52.6)
EQ-5D anxiety or depression, n (%)**	159 (34.9)
BASDAI (n=335), mean (SD)	3.0 (1.8)
DLQI (n=350), median (IQR)	6 (2-10)

*If not indicated otherwise.

**Adjusted percentage reporting any level of problem.

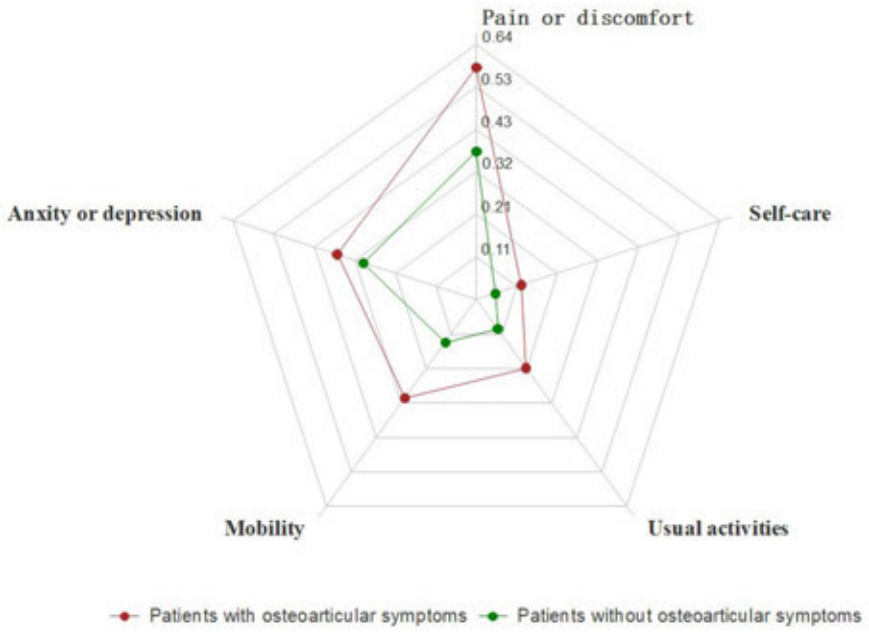

Figure 1. EQ-5D for patients with and without osteoarticular symptoms

Table 2 Correlations between the quality of life and variables

Variables	Outcome	Correlation (95% CI)	P-value
	EQ-5D utility index (n=461)		
Age		**-0.0017 (-0.0028, -0.0006)**	**0.003**
Current osteoarticular manifestations		**-0.065 (-0.096, -0.034)**	**<0.001***
Current dermatological manifestations		**-0.003 (-0.036, 0.030)**	**0.860**
Current nail manifestations		**-0.005 (-0.033, 0.023)**	**0.729**
BMI in Kg/m²		**-0.002 (-0.006, 0.002)**	**0.307**
BASDAI (n=335)		**-0.061 (-0.068, -0.054)**	**<0.001***
	DLQI (n=350)		
Age		**-0.054 (-0.108, 0.001)**	**0.052**
Current osteoarticular manifestations		**2.05 (0.62, 3.47)**	**0.005***
Current nail manifestations		**1.79 (0.45, 3.12)**	**0.009***
BMI in Kg/m²		**0.19 (-0.01, 0.38)**	**0.057**
BASDAI (n=237)		**0.54 (0.34, 0.74)**	**<0.001***

Correlation between different variables was analyzed by univariate regression.

*** Still significant after adjusting for covariates**

Conclusion: Our findings suggested a negative correlation between osteoarticular symptoms and QoL in SAPHO syndrome. Effectively controlling osteoarticular symptoms may be pivotal in improving patient QoL. Nail involvement, which is under-recognized previously, also had a negative influence on QoL in SAPHO patients.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovitis, acne, pustulosis, hyperostosis, and osteitis (SAPHO) syndrome is a heterogeneous chronic inflammatory disease of unknown etiology. Mandibular involvement appeared in approximately 10% of the SAPHO patients,(1) and the treatment for mandible lesions, including surgery and conservative treatment, has not reached consensus. However, these patients were rarely discussed, mainly in case reports. Here we first reported the patients with mandible involvement from the largest cohort of SAPHO syndrome(2) and explored their demographic, clinical, and scintigraphic characteristics and treatment.

Methods: From January 2004 to June 2019, 618 patients were recruited at Peking Union Medical College Hospital (PUMCH) in a previously established single-center dynamic cohort of SAPHO syndrome.(2) The demographic, clinical, scintigraphic, and laboratory data were collected at baseline. The mandibular involvement was confirmed by

Effect of the treatment in PUMCH§	
Improvement in oral symptoms, n(%)	24 (92.3)
Patients with pain now, n(%)	8 (30.8)
VAS now, median (IQR)	1.5 (1, 2.25)
Patients with face swelling now, n(%)	1 (3.8)
Patients with limitation of mouth opening now, n(%)	2 (7.7)
Improvement in other osteoarticular symptoms, n(%)	2 (13.3) †
Improvement in dermatological symptoms, n(%)	4 (26.7) *

† Of the patients with other osteoarticular involvement, 13.3% had an improvement in those osteoarticular symptoms.

* Of the patients with skin lesions, 26.7% had an improvement in dermatological symptoms.

§ SAPHO patients with mandibular involvement only received conservative treatment in PUMCH.

PUMCH: Peking Union Medical College Hospital; IQR: interquartile ranges; NSAIDs: Nonsteroidal Anti-Inflammatory Drugs; DMARDs: disease-modifying antirheumatic drugs; TNF-α inhibitors: Tumor necrosis factor alpha inhibitors; JAK inhibitors: Janus kinase inhibitors; IL-6 inhibitors: Interleukin 6 inhibitors; VAS: Visual Analogue Scale.

X-ray, scintigraphy, or biopsy. In May 2019, the prescription data was collected from the hospital information system, and the electronic questionnaire was distributed to all patients with mandibular involvement to ensure their medical compliance and to obtain their improvement in symptoms.

Results: A total of 26 SAPHO patients with mandibular involvement were identified, and all of them responded (38.5% male, median age 28 years old,and follow-up duration 2.1 years). Their median age at onset of symptoms was 22 years old (IQR 21-40 years old), younger than the median age of oral symptoms (25 years old, IQR 15-28 years old). Seven (26.9%) patients had a positive family history, and ten (38.5%) had received oral invasive operation in one month before the onset. Unilateral mandibular involvement was more common (65.4%). Skin lesions appeared in 15

(57.7%) patients, among which seven (26.9%) were affected by severe acne. The whole body bone scintigraphy revealed more peripheral osteoarticular involvement (46.2%) than anterior chest wall involvement (38.5%) or axial skeleton involvement (14.2%). All of the 14 (53.8%) patients undergoing surgery intervention relapsed, while conservative treatment led to an improvement of oral symptoms in most patients (24, 92.3%). Less improvement was observed in dermatological (13.3%) and other osteoarticular symptoms (26.7%).

Conclusion: Mandibular involvement in SAPHO syndrome is predominant in young-aged women. Familial inheritance factors and oral invasive operation may be possibly correlated with its onset. Conservative treatment instead of surgery might be recommended, although their efficacy on non-oral involvement remains challenging.

Abstract Number: 1266

AGBL3 as a Novel Gene Associated with Hereditary Hypocomplementemic Urticarial Vasculitis and Favorable Response to Rituximab

Ahmet Gul,[1] Nesllihan Abaci,[2] and Sema Sirma-Ekmekci[2], [1]Department of Internal Medicine, Division of Rheumatology, Istanbul University, Istanbul Faculty of Medicine, Istanbul, Turkey, Istanbul, Turkey, [2]Department of Genetics, Istanbul University Institute for Experimental Medical Research, Istanbul, Turkey, Istanbul, Turkey

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Urticarial skin lesions are well-known features of autoinflammatory disorders associated with NLRP3 and NLRP12 variants. However hereditary forms of hypocomplementemic urticarial vasculitis (HUV) with or without lupus features have been associated with DNASE1L3 variants in limited number of Turkish, Arabic and Italian families. We herein aimed to define the clinical phenotype and treatment responses of a patient with HUV due to a homozygous deleterious variant of a novel gene, AGBL3 (ATP/GTP binding protein-like 3).

Methods: Last year we described a novel gene variant in a patient with autoinflammatory features and HUV, who was negative for DNASE1L3 variants. Whole exome sequencing of the genomic DNA revealed a deleterious homozygous c.769C >T mutation in AGBL3 gene, which results in early termination of the protein (p.Gln257Ter) and deletion of the functional carboxypeptidase domain. The AGBL3 is suggested to catalyze the deglutamylation of polyglutamate side chains, especially in proteins such as tubulins. This variant was not found before in all reported databases including 1000 Genomes Project data. We herein describe the clinical features and treatment responses of the index case.

Results: The index case was 23-year-old male patient of Assyrian origin, who had consanguineous parents. He was evaluated in our clinic because of recurrent attacks of fever, urticarial rash on the extremities and trunk, conjunctival injections and arthralgia, without a trigger or more frequently following an infection. His 2-3 days lasting attacks started when he was 13 and recurred more frequently at warm conditions or following hot baths. He had highly elevated CRP and ESR during attacks, but his acute phase response did not return to normal values in between the flares. Low C3 and C4 values were also observed during asymptomatic periods. His ANA test became positive during the course of his disease with an increase in titers during the last years. The biopsy of skin lesions revealed findings compatible with urticarial vasculitis. He responded only partially to corticosteroids, but no obvious clinical and laboratory response could be seen with canakinumab and anakinra treatments. Following serologic evolution of the disease, his treatment was switched to rituximab. A favorable response both in clinical and laboratory findings was observed following two cycles of 1g infusions at 2-week intervals. He developed less frequent and milder attacks, which occurred only after infections; and acute phase response was reduced to near normal values in between attacks.

Conclusion: This case reveals AGBL3 metallocarboxypeptidase gene as a novel autoinflammatory gene associated with hypocomplementemic urticarial vasculitis. Potential pathogenic mechanisms and clinical picture are considered to be different from DNASE1L3 variants, which are also associated with monogenic lupus and defects in DNA clearance. Long term follow-up and search for other patients associated with AGBL3 variants among DNASE1L3-variant-negative hypocomplementemic urticarial vasculitis patients are required for better clarification of the AGBL3-associated clinical phenotype.

Epidemology, Clinical Features and Relationship to Biological Therapy of Uveitis in Axial Spondyloarthritis: Single Center University Study

Iñigo Gonzalez-Mazon,[1] Lara Sanchez-Bilbao,[2] Javier Rueda-Gotor,[3] David Martinez-Lopez,[4] Diana Prieto-Pena,[1] Mónica Calderón-Goercke,[5] Jose Luis Martín-Varillas,[2] Belén Atienza-Mateo,[2] Miguel A Gonzalez-Gay,[2] and Ricardo Blanco[2], [1]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Cantabria, Spain, [2]Rheumatology, Hospital Universitario Marques de Valdecilla, Santander, Spain, [3]Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL, Santander, Spain, Santander, Spain, [4]Hospital Universitario Marqués de Valdecilla, Santander, Cantabria, Spain, [5]Hospital Marqués de Valdecilla, Santander, Cantabria, Spain

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis is one of the most frequent extra articular manifestation of spondyloarthritis (SpA). Biological therapy, especially monoclonal TNF inhibitors, are useful to prevent and to treat refractory non-infectious uveitis. However, other biologics had been related to paradoxical uveitis. Our aim was to assess a) the epidemiological and clinical features of uveitis associated to SpA and b) its relationship with biological treatment used in SpA.

Methods: We set up an observational study of patients who developed uveitis form a cohort of 255 consecutive unselected patients with axial SpA (axSpA) classified according to the ASAS criteria. They were divided into: a) ankylosing spondylitis (AS) according to New York modified criteria (n= 193) b) non-radiographic axSpA (nr-axSpA) (n= 62). All these patients were followed in a single reference University Hospital.

Results: We studied 255 patients with axSpA axSpA (151 men / 104 women); mean age 37.8 ± 10.6 years. In 36 (14.2%) patients at least one episode of uveitis was observed after a follow-up 12.4 ± 4.5 years. The underlying ax-SpA diseases were AS (n=31) and nr-axSpA (n= 5). The mean age at onset of uveitis was 45.7±14.2 years. Uveitis was diagnosed in 5 patients before SpA diagnosis. In the remaining patients (n=31) it was detected after a median of 6 [2-15] years of follow-up after SpA diagnosis. Pattern of uveitis was anterior and acute in all cases, and unilateral in 83%. None of them presented intermediate or posterior uveitis. Median of anterior chamber cells was 1 [1-2] cells. Comparison of baseline characteristics and clinical features between patients who developed uveitis and those who did not is shown in **Table 1**. Almost all patients who developed uveitis were HLAB27 positive. In these patients a lower frequency of enthesitis and inflammatory bowel disease was observed.

Table 1.

	Uveitis N= 36	Non uveitis N= 219
Baseline general features		
Age, years (mean±SD)	45.7 ± 14.2	44.7 ± 12.1
Sex, n (m/w) (%)	21/15 (58.3/41.7)	130/89 (59.4/40.6)
HLAB27, positive n (%)	35 (97.2)	130 (59.4)
Disease Characteristics		
Follow-up of AxSpa, year (mean±SD)	13.64 ± 7.6	12.16 ± 9.73
AS, n (%)	31 (86.1)	162 (74.0)
nr-AxSp, n (%)	5 (13.9)	57 (26.0)
Peripheral arthritis, n (%)	9 (25.0)	67 (30.6)
Hip affection, n (%)	3 (8.3)	15 (6.8)
Enthesitis, n (%)	9 (25.0)	81 (37.0)
Dactylitis, n (%)	2 (5.5)	14 (6.4)
Psoriasis, n (%)	4 (11.1)	24 (11.0)
Inflammatory bowel disease, n (%)	1 (2.8)	15 (6.8)
Family history, n (%)	12 (33.3)	58 (26.5)

Table 2.

	Patients (n)	Years after onset of treatment (mean ± SD)	Episodes of uveitis after the onset of treatment (n)
Adalimumab:	3	4.1 ± 3.5	6
Secukinumab:	3	4.2 ± 1.9	1
Certolizumab:	1	3.50 ± 0	0
Golimumab:	1	6.0 ± 0	0
Infliximab:	1	11.8 ± 0	1
Anti TNF	6	5.6 ± 4.0	7
Anti IL-17	3	4.2 ± 1.9	1

Cumulative incidence of uveitis episodes related to each biological agent is shown in **Table 2**. Patients treated with secukinumab developed 2.72 episodes of uveitis/100 patients/year, meanwhile those who received monoclonal anti TNF presented 2.53 episodes/100 patients / year.

Conclusion: The most frequent clinical pattern of uveitis in patients with SpA was acute unilateral anterior uveitis which appeared in most patients after 6 years of follow-up. Almost all of them were HLA B27 positive. No differences were found in cumulative incidence between secukinumab and monoclonal anti-TNF.

Different Colchicine Preparations for Familial Mediterranean Fever: Are They the Same?

Hakan Emmungil,[1] Ufuk İlgen,[1] Sezin Turan,[1] Samet Yaman,[2] and Orhan Küçükşahin[3], [1]Trakya University, Edirne, Turkey, [2]Yıldırım Beyazıt University, Ankara, Turkey, [3]Liv Hospital, Ankara, Turkey

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Colchicine is the mainstay of treatment for prevention of attacks and associated amyloidosis in Familial Mediterranean Fever (FMF). Two approved colchicine preparations are currently available in Turkish market. In case of resistance or adverse effects, it is a common practice for Turkish rheumatologists to change the colchicine preparation with an imported one. The aim of this study was to assess the benefit of the imported colchicine in Turkish adult patients with FMF resistant or intolerant to domestic colchicine preparations.

Methods: Adult patients followed up with a clinical diagnosis of FMF, meeting Tel Hashomer criteria, resistant or intolerant to domestic colchicine preparations, and under treatment with a particular brand of imported colchicine were identified retrospectively and included in the study. Patients using anti-interleukin-1 or other biological agents were excluded. Disease characterisitcs, *ME*diterranean *FeV*er gene (*MEFV*) mutations, attack frequencies before and after the imported colchicine were specified for each patient from their medical records. Resistance to colchicine was defined as suggested by the EULAR. Frequency of attacks and colchicine doses before and after the imported colchicine were compared. Mann-Whitney U or Kruskal-Wallis tests were used for comparison of distributions of unrelated samples and Wilcoxon signed rank test for repeated measurements. $p< 0.05$ was considered statistically significant.

Results: A total of 59 patients were included in the study. Thirty-six (61%) patients were female and median age was 29 (interquartile range: 22-38) years. Median duration of disease was 6 (interquartile range: 2-14) years. There were 46 (78%) patients carrying exon 10 mutations in homozygous or compound heterozygous forms. Eight (14%) patients had isolated exon 10 mutations in heterozygous form and three (5.1%) had an exon 10 and the E148Q mutations together. No patient had isolated E148Q mutation in homo- or heterozygous forms. Mutant allele frequencies and characteristics of the attacks were given in Figure 1.

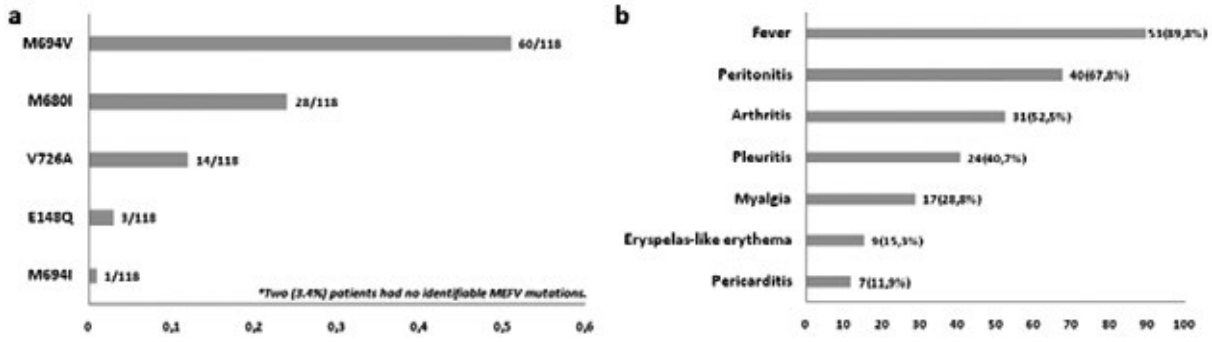

Figure 1. a. Allelic frequencies of the MEFV gene mutations. b. Characteristics of the attacks.

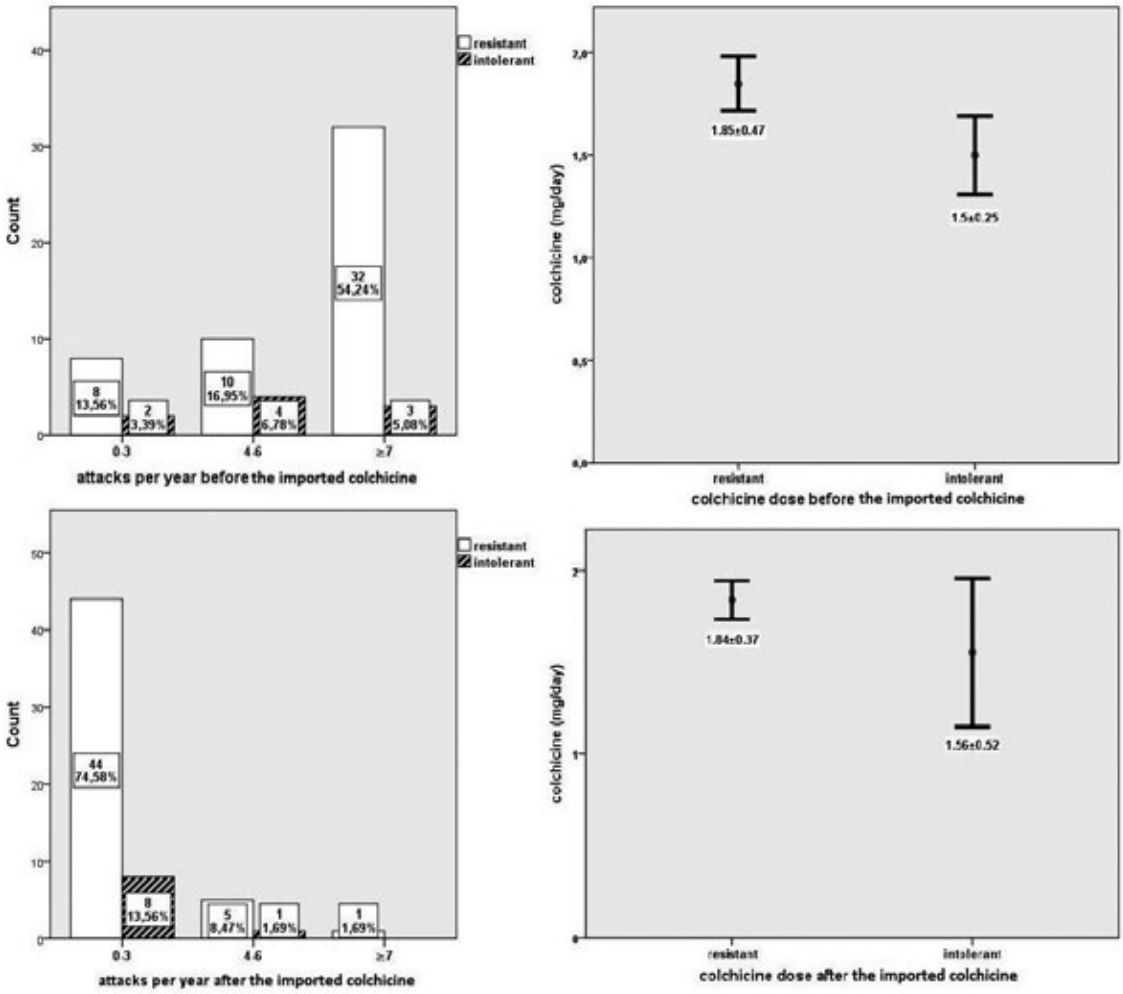

p<10⁻⁶ for difference of distributions of attacks in resistant cases; p=0.014 for difference of distributions of attacks in intolerant cases; p=0.9 for difference of daily colchicine doses in resistant cases; p=0.71 for difference of daily colchicine doses in intolerant cases before and after the imported colchicine.

Figure 2. Distributions of attacks and daily colchicine doses before and after the imported colchicine.

Fifty (84.8%) and 9 (15.2%) patients had resistance and intolerance to domestic colchicine preparations, respectively. Median number of attacks in the last three months before the imported colchicine was three (range 0-6). Although daily colchicine doses did not differ before and after the imported colchicine, number of attacks per year significantly

Study	Method	Dose	Form	C_{max} (ng/mL)	T_{max} (h)	$AUC_{0\text{-}last}$ (ng·h/mL)	Last Measurement (h)	Brand (Country)
Achtert G, 1989	RIA	0.76 mg	coated tablet	4.15 ± 2.35	1.15 ± 0.38	23.95 ± 12.1	72	Brand A (Germany)
		1 mg	oral solution	4.88 ± 3.9	1.13 ± 0.42	28.01 ± 14.74		
Girre C, 1989	RIA	1 mg	tablet	3.9*	1*	26.3 ± 3.52	48	Brand B (France)
Rochdi M, 1994	RIA	1 mg	tablet	5.5 ± 1.4	1.03 ± 0.5	N/P	48	Brand B (France)
Ferron GM, 1996	RIA	1 mg	tablet	5.64 ± 1.37	1.01 ± 0.56	47.9 ± 12.2	48	Brand B (France)
		1 mg	oral solution	6.5 ± 1.03	1.07 ± 0.55	62.3 ± 15.5		
Amanova A, 2014	HPLC	1 mg	coated tablet	0.13 ± 0.02	3.3 ± 1	2.12 ± 0.64	24	Brand C (Turkey)

*RIA = Radioimmunoassay; HPLC = High Performance Liquid Chromatography; C_{max} = peak plasma concentration; T_{max} = time to reach C_{max}; $AUC_{0\text{-}last}$ = area under plasma colchicine concentration - time curve from time zero to the last colchicine measurement; N/P = not provided. *Standard deviations were not reported.*

Table 1. Pharmacokinetic properties of different colchicine preparations after single oral doses in subjects with normal renal and hepatic functions.

reduced both in resistant and intolerant cases (Figure 2) after a median follow up of 19 (range 8-60) months under the imported colchicine. The decrease in number of attacks were more prominent in resistant cases (Figure 2).

Pharmacokinetic studies performed with different brands of colchicine after single oral doses in healthy subjects or FMF patients with normal renal and hepatic functions were summarized in Table 1.

Conclusion: Turkish FMF patients with ongoing attacks under domestic colchicine preparations may benefit from imported colchicine. This seems to be explainable by difference in pharmacokinetic properties of different colchicine preparations.

Effective Treatment of TNFα Inhibitors in Chinese Patients with Blau Syndrome

Jing Chen,[1] Yi Luo,[1] Mengzhu Zhao,[1] Di Wu,[1] Yunjiao Yang,[2] Wen Zhang,[3] and **Min Shen**[1], [1]Peking Union Medical College Hospital, Beijing, Beijing, China (People's Republic), [2]Peking Union Medical College Hospital, Beijing, China (People's Republic), [3]Department of Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, Peking Union Medical College and Chinese Academy of Medical Sciences, Beijing, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Blau syndrome (BS) is a rare dominantly inherited autoinflammatory disorder associated with mutations in the *NOD2* gene. BS is mainly seen in Caucasian patients. Biologic therapy of BS yielded diversity results. We aimed to evaluate clinical features and outcomes of Chinese patients with BS who were treated with TNFα inhibitors.

Methods: A total of four patients with BS were diagnosed and treated with infliximab (IFX) at Peking Union Medical College Hospital during 2015 to 2018, and were followed up for 18 months. All patients were systematically studied for treatment outcomes including the clinical manifestations and inflammatory markers. We also conducted a comprehensive literature review about TNFα inhibitors therapy in BS.

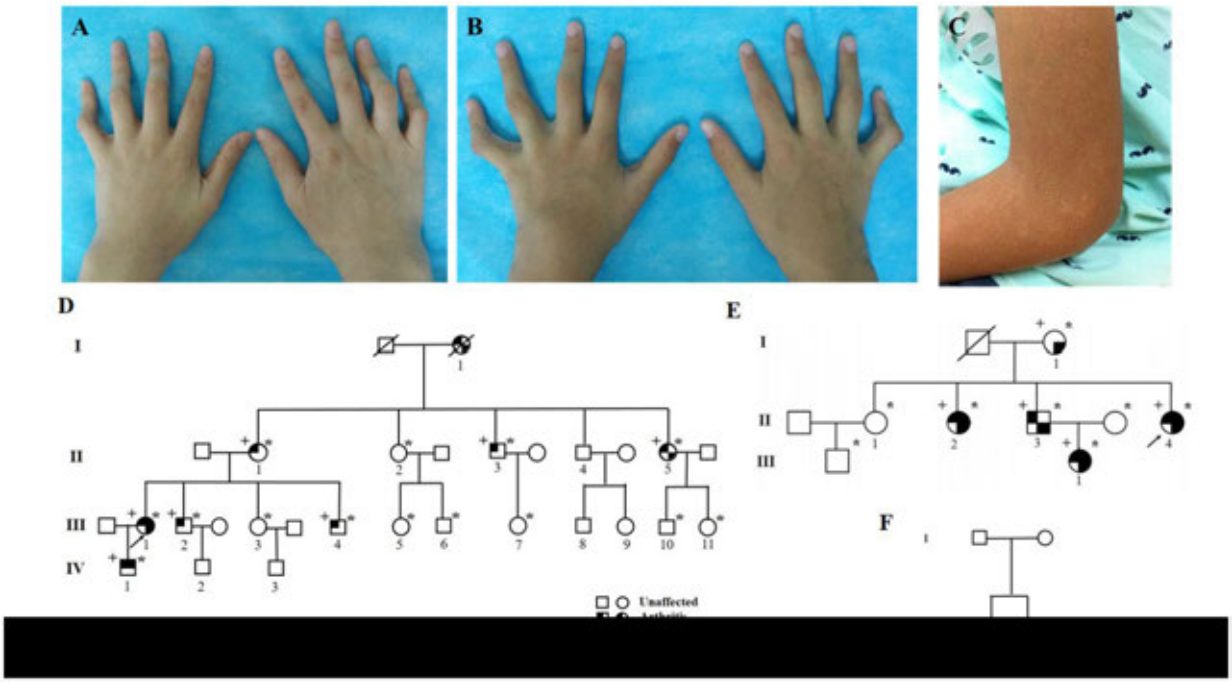

Figure 1. Pedigrees and phenotypes of Chinese patients with BS. Camptodactyly of patients 1 (A) and 2 (B); Papules on the upper limbs of patient 2 (C); Pedigrees of patients 1 and 2 (D), 3 (E) and 4 (F).

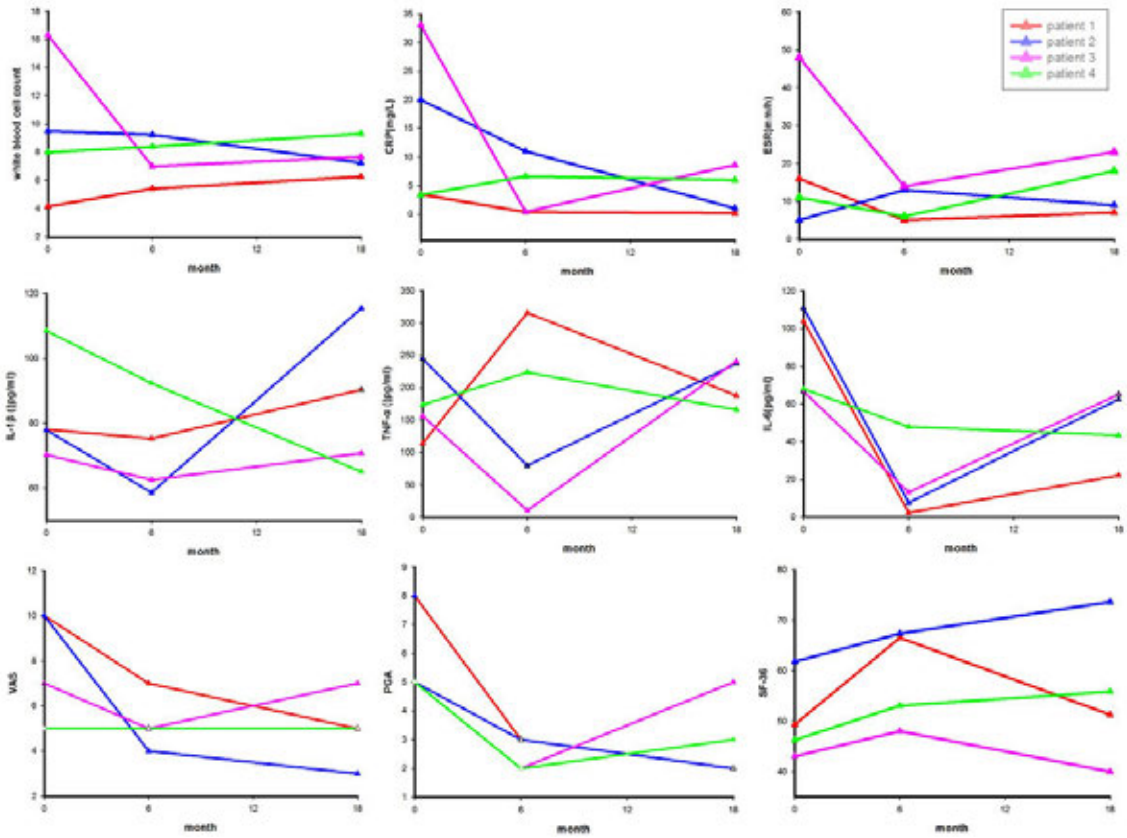

Figure 2. Changes in disease activity and inflammatory markers of patients. Overall, WBC, CRP, ESR, IL-1β, IL-6, VAS and PGA decreased, and SF-36 increased at the first follow-up of 6-month. TNFα decreased at the first follow-up for patients 2 and 3, but increased for patients 1 and 4. At the last visit of 18-month, WBC, ESR and CRP remained normal in all except patient 3, whose ESR and CRP increased to above normal range. Among all the patients, serum levels of IL-1β, TNFα and IL-6 were higher than those at the first follow-up, except patient 4. For patients 1 and 2, VAS and PGA reduced further at the last follow-up, while for patients 3 and 4, they slightly increased. CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; VAS: visual analogue scale; PGA: physician global assessment; SF-36: Short Form-36.

Table 1 Demographic and clinical features of four Chinese patients with BS

Patients	1	2	3	4
Gender	female	male	female	female
Age at diagnosis (years)	32	8	36	25
Age at onset (years)	6	0.5	7	6
Ethnicity	Han	Han	Han	Han
Family history	+	+	+	-
Clinical features				
Joint	+	+	+	+
Skin	+	+	+	-
Eye	+	-	+	+
Fever	+	-	-	-
NOD2 variants	R334W	R334W	R334W	R334Q
Laboratory findings				
WBC ($\times 10^9$/L)	4.15	9.5	16.3	7.99
CRP (mg/L)	3.48	20.0	33.01	3.4
ESR (mm/h)	16	5	48	11
IL-1β (pg/ml)	78.0	77.8	70.2	108.5
TNFα (pg/ml)	114.0	245.0	156.2	174.0
IL-6 (pg/ml)	104.0	111.0	66.7	68.0
VAS	10	10	7	5
PGA	8	5	5	5
SF-36	49.31	61.81	43	46.25
Treatments				
IFX	5 mg/kg every 6-8 weeks for 6months/5 mg/kg every 12 weeks	5 mg/kg every 8 weeks	5 mg/kg every 6-8 weeks for 6months/5 mg/kg every 12 weeks	3 mg/kg every 8 weeks for 6 months/3 mg/kg every 12-16 weeks
MTX	15 mg weekly for 6 months/12.5 mg weekly	10 mg weekly	15 mg weekly for 6 months/Discontinuation due to side effects	10 mg weekly for 6 months/Discontinuation due to side effects
Prednisone	Not used	Not used	Not used	15mg/day tapered to 5mg/day

WBC: white blood cells; CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; VAS: visual analogue scale; PGA: physician global assessment; SF-36: Short Form-36; IFX: infliximab; MTX: methotrexate

Results: These four BS patients were all Chinese Han, and three of them were women. The mean age of disease onset was 4±3.5 years, and the mean time of diagnosis delay was 19±11 years. All of the 4 patients received IFX plus methotrexate, and had achieved clinical remission of skin lesions and polyarthritis rapidly, and normalization of ESR and CRP, improvements in inflammatory cytokines, patient visual analogue scale, physician global assessment and SF-36 as well, at the first follow-up of 6 months. The disease relapsed in two patients after they lengthened the interval of IFX due to the financial limitation and discontinued methotrexate because of the side effects. According to the 38 English-language publications, 62 patients with BS were presented who underwent TNFα inhibitors therapy, including IFX used in 31, adalimumab in 24 and etanercept in 7. IFX was well tolerated in 27 patients, while 2 still had uveitis, and the other 2 experienced an adverse drug reaction to IFX infusion. Adalimumab was useful in 21 BS

patients, although the other 3 didn't get well controlled. Five BS patients who were given etanercept yielded good responses, but 2 discontinued because of etanercept-induced myelopathy or an exacerbation of arthritis.

Conclusion: Early recognition and effective treatment of BS is very important to avoid the irreversible organ damage such as loss of vision, joint deformities. TNFα inhibitors including IFX may be a promising approach for BS patients who have unsatisfactory response to corticosteroids and traditional DMARDs. Due to the sample limitation of our study, more clinical trials are required.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There is increasing evidence of Tocilizumab (TCZ) efficacy in refractory auto-immune diseases. The present study aimed at evaluating the real-world experience of using TCZ in patients with refractory autoimmune diseases.

Methods: This is a retrospective, descriptive and multicenter study from 9 departments of Internal Medicine. Demographic, clinical and therapeutic data were collected. Glucocorticoid sparing effect was evaluated with Fisher's exact test, with statistical significance set at 0.05.

Results: Fifty five patients were included (20 men, 35 women). Mean age was 56 ± 16.7 years (range 23 - 80).

TCZ was used in:

- 15 connective tissue diseases (27%): relapsing polychondritis (n=6), systemic sclerosis (n=5), anti-synthetase syndrome (n=1), and unclassified connective tissue disease (n=3).
- 10 vasculitis (18%): Takayasu arteritis (n=7), Cogan disease (n=1), panarteritis nodosa (n=1), unclassified vasculitis (n=1).
- 12 ophthalmologic conditions (21.8%): non infectious posterior uveitis (n=10), sympathetic ophtalmia (n=1), Basedow orbitopathy (n=1).
- 8 adult-onset Still's diseases (AOSD) (14.5%).
- 7 cases of polymyalgia rheumatica (12.7%)
- 3 miscellaneous diseases (5.5%): idiopathic AA amyloidosis, multicentric non HHV8 Castelmann disease, Erdheim

Chester disease (1 case each).

Mean disease duration of the disease at TCZ initiation was 7 ± 6.3 years. In 48 cases (87%) TCZ was administered for refractory diseases to corticosteroids and/or immunosuppressive drugs. Previous therapies included corticosteroids (83%), methotrexate (66%), TNF inhibitor drug (44%), azathioprine (20.8%), mycophenolate (12%), cyclophosphamide (8%), rituximab (10%), hydroxychloroquine (6%), anakinra in 2 patients and interferon, dapsone, etoposide, leflunomide, abatacept, salazopyrin or intra-venous immunoglobulin in 1 patient each.

TCZ was associated with methotrexate in 3 cases (5.4%) and route of TCZ administration was mainly intravenous (96%).

At the end of the follow up, 43 patients (78%) were still using TCZ, with a mean follow up period of 21.7 ± 22.6 months (range 1-90). Daily corticosteroid use significantly decrease from 15.3 ± 15.5 mg to 4.47 ± 4.9 mg ($p< 0.005$).

A complete response was observed in 5 patients (71%) with polymyalgia rheumatica, in 6 patients (75%) with AOSD, in 4 patients (66%) with relapsing polychondritis, in 7 patients (70%) with uveitis, in six patients (85%) with Takayasu arteritis, in 3 patients (75%) with unclassified connective tissue disease and in 3 patients (60%) with systemic sclerosis.

TCZ was withdrawn in 12 patients (2%), because of treatment failure in 3 patients, loss of efficacy in 2 patients or side effect in 7 patients. Side effects occured in 15 patients. They were infection (2 pneumonias, zona, sinus infection), pruritus (n=2), urticaria (n=1), dyslipidemia (n=1), high blood pressure (n=2), infusion-related reaction (n=1), bullous dermatitis (n=1), acute renal failure (n=1), angioedema (n=1), mouth ulcers (n=1).

Conclusion: In conclusion, TCZ is used off-label in daily practice to treat various refractory autoimmune diseases with a good short-term efficacy and tolerance.

No	40 (62,5)	36	4		

Background/Purpose: Adult-onset Still's disease (AOSD) is a low prevalent disease with an unpredictable clinical course and variable prognosis. Sometimes, it requires biologic treatment in early phases of the pathology. A prognosis score has been described, which has never been applied in a Spanish case series.

Methods: Retrospective analysis realized in two University Hospitals. Clinical, laboratory, AOSD-related complications data, administered biologic treatments and number of deaths (AOSD related or not) were recorded. SS

was applied at the onset of the disease development, assigning a point to each of the following 12 variables: fever, exanthema, pleuritis, pneumonitis, pericarditis, alteration of liver tests or hepatomegaly, splenomegaly, lymphadenopathy, odynophagia, leukocytosis > 15,000/mm^3, myalgia and abdominal pain. A ≥ 7 score has been validated on other populations as the one which identifies the patients with high risk of complication. The relationship between prognosis score value and the next parameters was determined: clinical course, complications, biologic treatments administered and AOSD-related mortality. Sensitivity and Specificity of the SS value as a predictor of biologic treatment necessity was determined.

Results: Data from 64 patients was analyzed. Each patient was characterized for the presence of AOSD-related complications such as macrophage activation syndrome (MAS), myocarditis, renal involvement (tubulointerstitial nephritis, acute renal failure), secondary amyloidosis and AOSD-related death and all-causes death. After applying the SS, values of < 7 were obtained in 50 patients (78,13%) and of ≥7 in 14 patients (21,87%). MAS and renal involvement were significantly related with a score of ≥7 (Table 1). Myocarditis and secondary amyloidosis were not significantly associated with a high SS value. Even so, analyzing each case individually, it was found that they presented a score of ≥7, except for lung involvement. Biologic treatment requirement along the disease course was related to a score of ≥7 (OR: 6.4, IC95% [1.8%-26.7%]). Instead, it was not related to the different clinical patterns or the all-cause deaths. Related to sensitivity and specificity of the SS as a predictor of biologic treatment requirement, we observed that a value of ≥7 was the one which the highest area under the curve in the ROC curve (AUC = 0,629) in our population, with a sensitivity of 41,7% and specificity of 90%.

Conclusion: The prognosis score described by *Pouchot et al* could be useful to identify those patients with high risk of developing clinical complications and those who will need biologic treatment along the course of their disease. If a patient has a >7 score, the development of a macrophage activation syndrome or renal complications may be considered. Furthermore, the necessity of biologic treatment should be considered (Sensitivity: 41,7%, Specificity: 90%). It is necessary a higher number of patients to determine if the score could be useful to estimate the death risk related to AOSD complications.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Non ischaemic optic neuritis (NION) is a severe inflammation of the optic nerve that may lead to blindness. It can be primary or associated to immune mediated inflammatory diseases (IMIDs). The treatment of the NION is based on systemic corticosteroids and conventional immunosuppressive drugs. Our aim was to assess the efficacy of the biological treatment in refractory NION to conventional treatment.

Methods: Multicenter study of 12 patients diagnosed with NION refractory to systemic corticosteroids and at least one conventional immunosuppressive drug. The main outcomes were visual acuity (VA) and optical coherence tomography (OCT) of the optic nerve and the ganglionar cells. Comparisons were made between baseline and the 1st week, 1st and 6th month and 1st year. (STATISTICA, StatSoft Inc. Tulsa, Oklahoma, USA).

Results: We studied 12 patients (19 affected eyes) (5 men/ 7 women); mean age of 29.8 ±12.9 years. The underlying diseases were systemic lupus erythematosus (n=1), neuromyelitis optica (n=1), neuroretinitis (n=1), relapsing polychondritis (n=1), pars planitis (n=1), Behçet´s disease (n=2) and idiopathic (n=5). Before biological treatment and besides oral corticosteroids, patients had received intravenous (IV) methylprednisolone boluses (n=9), cyclosporine A (n=1), cyclophosphamide (n=2), mycophenolate (n=2), hydroxychloroquine (n=1), methotrexate (n=8) and azathioprine (n=5). Biological treatment was bases on rituximab (n=2) (2 IV, doses of 1 g/every 2 weeks and every 6 moths), adalimumab (n=5) (40 mg/1-2 week), tocilizumab (n=4) (8 mg/kg/2-4 weeks) and infliximab (n=3) (5 mg /kg at 0, 2 and 6 week and then every 8 weeks). The characteristics of the 12 patients are shown in the TABLE.

After biological treatment we observed an improvement in the ocular parameters: VA [0.66±0.32 to 0.84±0.29; p= 0.03], OCT of the optic nerve [123.20±58.28 to 190.54±175.38; p= 0.11], and OCT of the ganglionar cells [369.55±137.37 to 270.67±23.21; p= 0.03] at one year. After a mean follow-up of 29.09 ±19.23 months, there were no severe adverse effects.

Conclusion: Biologic therapy in NION idiopathic or associated to IMIDs, refractory to conventional treatment, seems to be effective.

Session Title: Miscellaneous Rheumatic & Inflammatory Disease Poster II: Autoinflammation Related Diseases & Therapies

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Uveitis often occur in women who are in their reproductive years. The management of uveitis during pregnancy is a challenge, making the physician to re-evaluate the patient's current therapy and offer alternative options with the lowest risk to the patient and fetus. Certolizumab pegol (CZP) is a PEGylated Fc-free anti-TNF therapy that differs from others anti-TNF because it does no bind the neonatal Fc receptor (FcRn). Thus,

TABLE 1

Case	Age (years)	Underlying disease	Uveitis pattern	Laterality	Immunosuppressive drugs before CZP	Combined treatment during pregnancy
1	34	SpA	Anterior	Unilateral	MTX, AZA, ADA	Yes (AZA)
2	37	SpA	Anterior	Bilateral	MTX, AZA, IFX, ADA, GOLI	No
3	40	SpA	Anterior	Bilateral	AZA, ADA	Yes (AZA)
4	38	SpA	Anterior	Unilateral	CyA, ETN, ADA, IFX, GOLI	No
5	23	Vogt-Koyanagi-Harada	Panuveitis	Bilateral	AZA	Yes (AZA)
6	33	Idiopathic	Anterior	Unilateral	MTX, AZA, ADA, ETN	No
7	35	Rheumatoid Arthritis	Anterior	Unilateral	MTX	Yes (AZA)
8	35	SpA	Anterior	Unilateral	SSZ, ADA	Yes (SSZ)

ADA: adalimumab, AZA: azathioprine, CyA: cyclosporine A, ETN: etanercept, GOLI: golimumab, IFX: infliximab, MTX: methotrexate, SpA: spondyloarthritis, SSZ: sulfasalazine.

TABLE 2

1	Full term	no	yes	1,2,3	no	No	No	no	no
2	Full term	no	no	2,3	no	No	No	no	no
3	Full term	yes (dichorionic)	no	2,3	no	No	No	no	no
4	Full term	yes (dichorionic)	no	2,3	no	No	No	no	no
5	Full term	no	yes	1,2,3	no	No	No	no	no
6	Full term	no	no	2,3	no	No	No	no	yes
7	Full term	no	no	2,3	no	yes (urinary tract)	No	no	yes
8	Full term	no	yes	1,2,3	no	No	No	no	yes
9	Full term	no	yes	1,2,3	no	No	No	no	no

CZP does not undergo across the placenta conferring a more secure profile. However, clinical data about the use of CZP in patients with uveitis during pregnancy are absence. Our aims were: a) to assess the evolution of uveitis in pregnant patients under treatment with CZP and b) to provide information on the pregnancy outcomes of women and neonates exposed to CZP.

Methods: National Multicenter study of 8 women with uveitis who received CZP during pregnancy and their 9 neonates who were exposed to CZP. The main visual outcomes were visual acuity (VA) and anterior chamber (AC) cells. We also assessed the presence of complications during pregnancy and labor, maternal and neonatal infections and malformations. Comparisons were made between baseline and the 1st week, 1st and 6th month and 1st year. (STATISTICA, StatSoft Inc. Tulsa, Oklahoma, USA).

Results: We studied 8 women (11 affected eyes); mean age of 34.3 ± 5.1 years. The underlying diseases were spondyloarthritis (n=5), Vogt-Koyanagi-Harada (n=1), rheumatoid arthritis (n=1) and idiopathic (n=1). Before CZP treatment and besides oral corticosteroids, patients had received methotrexate (n=4), azathioprine (n=5), adalimumab (n=5), infliximab (n=2), golimumab (n=2), etanercept (n=2), sulfasalazine (n=1) and cyclosporine A (n=1). The characteristics of the 8 patients are shown in **TABLE 1**. Seven out of 8 patients had anterior uveitis while the remaining patient had panuveitis diagnosis. During CZP treatment we observed an improvement in the mean of VA [0.6±0.27 to 0.72±0.29; p= 0.14] and the mean of AC cells [2.25±1.28 to 0.33±0.08; p= 0.03] after 6 months of treatment. Pregnancy and neonatal outcomes are shown in **TABLE 2**. In half of the patients CZP was initiated before pregnancy. In the remaining patients CZP was initiated during the first trimester. No pregnancy nor labor complications were reported (preeclampsia, premature rupture of membranes, miscarriages or pre-term births). There was one case of multiple gestation (dichorionic). Cesarean delivery was reported in two patients. All neonates were healthy newborns with a mean birth weight of 3080±560 grams and a mean birth length of 50.9±2.8 cm. Fetal pH and APGAR score was normal in all of them. Three neonates received maternal lactation. In regard with infections, only one woman presented a mild urinary tract infection during pregnancy. No infections nor malformations were found in neonates after a follow-up of 6 months.

Conclusion: CZP seems to be effective and safe in patients with uveitis during pregnancy.

Abstract Number: 1274

New Aspects of Clinical and Immunological Characteristics in Patients with Anti-KS Antibody

Sho Sasaki,[1] Akira Ishii,[2] Mai Sugiyama,[2] Yuto Izumi,[2] Yoko Nakagome,[2] Kazuki Hirano,[3] Takayoshi Kurabayashi,[1] Shinichi Nogi,[4] Noriko Sasaki,[2] Chiho Yamada,[2] and Shinji Sato[5], [1]Tokai Universitiy School of Medicine, Isehara, Japan, [2]Tokai University School of Medicine, Isehara, Japan, [3]Tokai University School of Medicine, Isehara, [4]National Hospital Organization Sagamihara Hospital, Sagamihara, Japan, [5]Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Yokohama, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-KS antibody, an anti-aminoacyl tRNA synthetase (ARS) antibody, is found mainly in patients with interstitial lung disease (ILD) accompanied by polymyositis/dermatomyositis (PM/DM). Although anti-KS antibody has a stronger association with ILD compared with PM/DM, the clinical characteristics of anti-KS antibody have not been examined in detail. The aim of this study was to clarify the clinical and immunological features of patients with anti-KS antibody.

Methods: PM/DM or ILD patients who visited Tokai University Hospital between 2010 and 2018 were screened. Autoantibodies were identified by immunoprecipitation assays and all clinical and immunological data were collected retrospectively. ILD was diagnosed based on the findings of computed tomography. The clinical and immunological features of anti-KS positive patients were assessed. Comparisons between anti-KS positive patients and other anti-ARS positive patients were examined. Statistical analyses were performed using the Fisher's exact test.

Results: Fifteen anti-KS positive patients were identified. Ten were female and 5 were male, with an average age of 62.5 years (range, 40-80 years). Final diagnoses were 6 patients with ILD alone, 4 with clinically amyopathic DM (CADM) and ILD, 3 with Sjögren's Syndrome (SjS) and ILD, one each with rheumatoid arthritis (RA) and ILD, or CADM/SjS overlap and ILD. Although various diagnoses were determined for these patients, all patients had ILD with chronic onset and a chronic clinical course. Five patients (33%) presented with dyspnea as an initial symptom. On high-resolution computed tomography analysis, 10 (67%) of 15 patients revealed radiographic features of non-specific interstitial pneumonia (NSIP) and 4 (27%) had a usual interstitial pneumonia (UIP) pattern and one (7%) had an organizing pneumonia (OP) pattern. As for skin manifestations, 9 (60%) had mechanic's hands, 4 (27%) had Gottron's sign and one (7%) each had the heliotrope rash or palmar papules. Interestingly, all anti-KS positive showed no clinical muscle weakness or serum creatine kinase elevation. Moreover, seven of 15 patients (47%) had sicca syndrome and were positive for anti-SSA and/or anti-SSB antibodies. There was a significantly high frequency of sicca syndrome in anti-KS positive patients compared with anti-Jo-1 positive patients (47% vs. 12%, P=0.02).

Conclusion: These results suggest that anti-KS antibody positive patients might form a distinguishable subset that is closely associated with sicca syndrome and CADM as well as chronic type ILD.

Abstract Number: 1275

Spectrum of Organ Involvement in Idiopathic Inflammatory Myopathies, Frequency of Comorbidities, and Relationship to Anti-SSA/SSB Positivity

Ana Valle,[1] Galina Marder,[1] Maria-Louise Barilla-Labarca,[1] and Sonali Narain[2], [1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY, [2]Northwell Health, Great Neck, Long Island, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic inflammatory myopathies (IIM) are chronic autoimmune diseases with systemic features and multiple comorbidities. Of the myositis associated antibodies seen in this population, anti-SSA/SSB are most frequently reported. However, limited literature has been published on their utility in clinical risk assessment.

Aim: To describe the spectrum of organ involvement and frequency of comorbidities in IIM patients and relation to anti-SSA/SSB positivity.

Table 1: Comparison of demographics in anti-SSA/SSB positive and negative groups

	SSA/SSB positive (n=34)	SSA/SSB negative (n=65)
Age (yrs)	55	53.5
Sex	79% female 21% male	75% female 25% male
Race	32% Caucasian 32% African-American 18% Asian or Pacific Islander 3% American Indian or Alaskan Native 15% Unknown	48% Caucasian 32% African-American 6% Asian or Pacific Islander 0% American Indian or Alaskan Native 14% Unknown
Myositis subset	69% DM 20% PM 3% DM and IMNM 8% PM and IMNM	53% DM 35% PM 3% DM and IMNM 6% PM and IMNM 3% PM and UCTD
Antibody Subtypes	26% Anti-Jo-1 Ab 0% Anti-PL-7 Ab 3% Anti-PL-12 Ab 0% Anti-EJ Ab 0% Anti-OJ Ab 9% Anti-MDA5 Ab 3% Anti-PM/Scl-100 Ab 15% Anti-RNP Ab	8% Anti-Jo-1 Ab 2% Anti-PL-7 Ab 0% Anti-PL-12 Ab 3% Anti-EJ Ab 0% Anti-OJ Ab 3% Anti-MDA5 Ab 2% Anti-PM/Scl-100 Ab 9% Anti-RNP Ab

DM = dermatomyositis, PM = polymyositis IMNM= immune-mediated necrotizing myopathy , UCTD= undifferentiated connective tissue disease

Methods: We queried the Northwell Myositis Center database for patients with IIM between 1/1/2007 to 4/6/2018. Patients were selected if they met 2017 European League Against Rheumatism (EULAR)/American College of Rheumatology (ACR) classification criteria for IIM and had anti-SSA/SSB data available. Anti-SSA/SSB was measured using a commercially available fluorescent bead-based immunoassay. Anti-SSA and SSB were combined and analyzed as a single group because anti-SSB was only found in association with anti-SSA in this cohort. The frequency of myositis specific antibodies, organ involvement and comorbidities was collected. Statistical analyses included Chi-square, Fisher's Exact test, and Wilcoxon Rank Sum test to determine statistical differences in group distributions and McNemar's test was performed to compare groups.

Results: Ninety-nine (99) patients were included in this analysis. The SSA/SSB positive (n=34) and negative (n=65) groups had similar distributions for age, gender, and race (Table 1). Despite the presence of muscle weakness during their clinical course, the majority (82/99) did not show evidence of muscle atrophy on magnetic resonance imaging (MRI). There was no difference in the prevalence of calcinosis, cardiac, or gastrointestinal involvement between groups. As anticipated, the frequency of ILD was significantly higher in the anti-SSA/SSB positive cohort (56% of SSA/SSB positive in comparison to 25% of SSA/SSB negative, p-value= 0.0084). The overall frequency of diabetes in our cohort was 42%, four times higher than reported for general population. The frequency of hypertension in our cohort was also as high (40%). There was no significant difference in the rate of diabetes, hypertension, or cardiovascular events between SSA/SSB positive and negative groups. There was 4% (4/99) myocardial infarctions and no cerebrovascular accidents. Venous thromboembolic events (VTE) were observed in 10% of patients with the majority (83%) occurring within three years of diagnosis. Presence of anti-SSA/SSB did not confer additional risk for VTE. Finally, SSA/SSB positivity was not associated with malignancies in our cohort. Neoplasms occurred in 14 anti-SSA/SSB negative patients (compared with 2 anti-SSA/SSB positive), though more than 18 years prior IIM diagnosis and not likely associated with the autoimmune disease.

Conclusion: Patients with IIM had high frequencies of diabetes, hypertension and VTE which was independent of anti-SSA/SSB status. We observed a statistically significant increase in prevalence of ILD in the anti-SSA/SSB positive IIM cohort patients suggesting that the presence anti-SSA/SSB antibodies is a harbinger of pulmonary manifestations in IIM.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To know the frequency of myositis specific antibodies (MSAs) and myositis associated antibodies(MAAs) and their relation with clinical features in patients with idiopathic inflammatory myopathy(IIM) from a Registry of Argentina.

Methods: Adults with IIM were enrolled in a retrospective way.Demographics,clinical and laboratory features were registered.Diagnosis of interstitial lung disease (ILD) was based on physician review of chest-x-ray, CT and/or pulmonary function tests.ANA were done in 291 patients, anti-Ro in 283, anti-Pm-Scl in 205,anti-Jo-1 in 263. MSAs against PL-12, PL-7, SRP and Mi-2 were done in 190 and anti: EJ, OJ, TIF1ϒ, MDA5, SAE, NXP2,Ku and Ro 52 were studied in 83 patients. These antibodies were detected by Immunoblot and ANA by IFI. Statistics: descriptive and Chi-squared.Stata v.11

Results: Were included 304 patients, 217(71%) women, mean age at diagnosis 46±15 years. Caucasian 42%, mestizos 37% and amerindios 8%. DM was described in 43%, PM 31,5%,IBM 1,6%, antisynthetase syndrome(ASS) in 18%, CADM 3,6%,IMNM 1,6% and overlap myositis in 21,7%. Arthritis was present in 32%, RP 34% and ILD in 26,6%.

MAAs(±): ANA 62,5%, Ro 19% and Pm-Scl: 4,8%.

MSAs (±): Jo-1 16%, Mi-2 11%, SRP and Pl-7 2,6% each and Pl-12:1,5%. Other MSAs were studied in 83 patients: anti-MDA5 13,2%, TIF1ϒ 8,4%, NXP2 3,6%,anti-SAE1,2%.Two patients had OJ and EJ.

Anti-Jo-1(+) was found in 37/41(90%) PM patients (p< 0,000), arthritis in 56% vs 31% in Jo-1(-) (p=0,005), ILD in 73% vs 15% Jo-1(-) (p< 0,000).

Anti-Mi-2 was found in 20/21 DM patients, 12 caucasians and 6 mestizos, none had ILD or anti Ro+ when were compared con Mi-2(-) 0% vs 27,3%(p=0,002) and 0% vs 26% (p=0,008),respectively, all Mi-2+ had increase CK value (100%) vs 78% Mi-2(-) p < 0,000.

The presence of MDA5 was associated with arthritis 72% vs 29%(p=0,01), ILD 63,6% vs 19,4% (p=0,005) and normal CK values 91% vs 16,6%(p< 0,000) when it was compared with patients without the antiboby. Anti Tif1 was present in 7/83 patients (8.4%),5 had DM and 2 had CADM, 1 patient had cancer.

Conclusion: Anti-Jo-1,anti-MDA5 and anti- Mi-2 were the most frequent MSAs found in our population, followed by anti- TIF1γ.

Anti-Mi-2 was present in DM while anti-Jo-1 was frequent in antisynthetasa syndrome with ILD and mainly in PM patients.

Anti-MDA5 was seen in DM with normal CK and also related to ILD and arthritis.

All patients anti-Tif1γ positive had DM and only one had cancer.

There are differences in the frequency of MSAs probably related with ethnic background or geography but the clinical phenotypes remains similar.

Abstract Number: 1277

Damage and Comorbidities in a Cohort of Patients with Idiopathic Inflammatory Myopathy

Ana Campar,[1] and Carlos Vasconcelos[2], [1]Centro Hospitalar do Porto, Porto, Portugal, [2]University of Porto, UMIB Abel Salazar Biomedical Sciences Institute, Porto, Portugal

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Idiopathic Inflammatory Myopathies (IIM) remain a major clinical challenge worldwide. The precise aetiopathogenesis of this chronic and disabling disorder remains elusive which precludes the development of novel and effective therapeutic strategies. The most visible consequence of this lack of effective therapies is the damage caused to these patients with the consequent decrease in quality of life, high morbidity and mortality. The complexity of managing these diseases is even higher because of the vast comorbidities affecting these patients.

Methods: Retrospective review of the cohort of patients followed in a dedicated unit of a tertiary hospital, with special incidence in damage and comorbidities, between January 2008 and December 2018. Damage was assessed by Myositis Damage Index (MDI) score. Comorbidities were scored according to Charlson Comorbidity Index in the last year of the study (2018).

Results: Ninety four patients were included, 79 women and 15 men, with a medium age at diagnosis of 46 years-old and a medium follow-up of 12 years. Paraneoplastic myopathies accounted for 20.2% of the cases and overlap myopathies were present in 19.1%. A definitive diagnosis was obtained in 37.2% of patients, according to Bohan and Peter criteria and 42.6% according to ACR/EULAR classification criteria. Only 8.5% of patients were documented in sustained remission without drugs. Damage scores were calculated as a whole and individually for the 11 dimensions of MDI score. Only 13.8% of the patients presented with MDI score of zero, meaning that more than 86% presented with some kind of damage. The majority of this was cardiovascular damage, along with its end-organ consequenc-

es, and psichiatric. Mortality occurred in 17% of patients with a medium age of 65 years-old and the most common cause was malignancy. Average MDI extent was 5.56 (range: 0-38) but average MDI severity was 87.6 (range: 0-110). Comorbidities were present in 90.5% of patients and essentially overlap with damage as they are mainly its consequence and so the most common are also cardiovascular risk and secondary organic diseases. Average Charlson Comorbidity Index was 4.6 predicting an average survival at 10 years of 52%. Of note, almost 10% of patients present with immunodeficiency unrelated to immunosuppressive therapy, mainly humoral.

Conclusion: Damage is high in IIM patients and is mainly cardiovascular, as opposed to muscle/ cutaneous damage. This appears essentially the result of the therapy used to control the disease, particularly prolonged systemic steroids, and persistent inflammation in refractory patients. A better knowledge of the disease physiopathology is essential for an improvement of its therapeutic strategies, particularly aiming steroid-free regimens.

Inpatient Epidemiology of Dermatomyositis and Polymyositis in the United States

Patompong Ungprasert,[1] Wisit Cheungpasitporn,[2] Charat Thongprayoon,[3] Karn Wijarnpreecha,[4] and Paul Kroner[5], [1]Cleveland Clinic, Cleveland, OH, Bangkok, Thailand, [2]University of Mississippi Medical Center, Jackson, MS, [3]Mayo Clinic Rochester, Rochester, MN, [4]Mayo Clinic Florida, Jacksonville, FL, [5]Mayo Clinic Florida, Jacksonville

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM), collectively known as idiopathic inflammatory myositis (IIM), are autoimmune disorders characterized by inflammation of skeletal muscle, especially in the proximal group. Data on inpatient epidemiology, resource utilization, and healthcare expenditures of IIM are not well described. The aim of this study was to explore those characteristics using a large national inpatient database.

Methods: This retrospective cohort study used the data from the National Inpatient Sample (NIS), the largest public inpatient database in the US, in the year 2005-2014. Data for more than seven million individual hospitalization across all-payers from over 4,000 non-federal acute care hospitals across 40 states are recorded annually in the NIS database. All patients with ICD9-CM diagnostic codes for DM or PM were included. Patients with inclusion body myositis were excluded. The primary outcome was determining the inpatient prevalence of IIM. Secondary outcomes included determining inpatient mortality, morbidity, most common discharge diagnoses, resource utilization, hospital length of stay (LOS), and inflation-adjusted total hospital costs and charges. Multivariate regression analyses were used to adjust for age, gender, Charlson Comorbidity Index, income in patient zip code, hospital region, location, size, and teaching status.

Results: A total of 160,528 admissions of patients with a diagnosis of DM/PM occurred in the study period. The mean age was 58.0 years and 68.7% were female. For the primary outcome, the inpatient prevalence of DM/PM was 41.9 cases per 100,000 discharges. The most common reasons for hospitalization were DM/PM itself, pneumonia, sepsis, AKI, and urinary tract infection. Patients with DM/PM displayed significantly increased odds of inpatient all-cause mortality compared to patients admitted for all other causes. Patients with DM/PM displayed significantly high-

Table 1 – Adjusted odds ratios, means and additional adjusted means in patients with IIM compared to patients admitted with other medical conditions

Variable	Odds Ratio	95% Confidence Interval	p-value
Mortality	2.22	2.10-2.35	<0.01
Shock	2.33	2.18-2.50	<0.01
ICU	1.94	1.84-2.05	<0.01

Costs ($USD)	$16,817		
Charges ($USD)	$55,774		
Length of Stay (days)	7.0		
Variable			
Additional Adjusted Costs	$4,217	3869-4563	<0.01
Additional Adjusted Charges	$13,531	12184-14879	<0.01
Additional Adjusted LOS (days)	1.7	1.6-1.8	<0.01

er morbidity odds of shock, ICU stay, AKI, and multiorgan failure when compared to patients admitted for all other reasons. Patients with DM/PM were also found to have increased odds of utilizing special investigations, including CT, MRI, and arteriography. Patients with associated diagnosis of DM/PM displayed higher hospital costs, charges and LOS compared to patients with no DM/PM (Table 1).

Conclusion: The inpatient prevalence of DM/PM was higher than what would be expected from the overall incidence. Hospitalizations of these patients were associated with a significantly higher morbidity and mortality. The mean total hospital costs, charges, and LOS for patients admitted with DM/PM were higher than patients without DM/PM.

Response Rate and Sustained Remission in Idiopathic Inflammatory Myopathies Receiving Conventional Immunosuppressive Stepwise Management

Alain Sánchez-Rodríguez,[1] Citlallyc Josefina Gómez-Ruiz,[2] Abril Montes-Yanes,[2] and Gabriel Medrano-Ramírez[2], [1]Hospital General de Mexico, Mexico City, Distrito Federal, Mexico, [2]Hospital General de Mexico, Rheumatology Department, Ciudad de Mexico, Distrito Federal, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Information regarding response rate and sustained remission in patients with idiopathic inflammatory myopathies (IIM), polymyositis (PM), dermatomyositis (DM), in Hispanics with non-biological treatment is scarce. We performed a study to estimate the response rates and sustained remission during the disease course of patients with IIM treated with conventional immunosuppressive agents.

Methods: A retrospective longitudinal study from medical records of patients with MII at a single rheumatology reference center in Mexico was performed. Medical records were reviewed to determine clinical presentation, serum creatine kinase (CK) levels, initial treatment and outcome measures such as the muscle strength assessed by the manual muscle testing of 8 muscle groups (MMT8), Health Assessment Questionnaire Disability index (HAQ-Di) during follow-up. The primary outcome was time to achieve sustained remission, defined as no evidence of active myositis for ≥ 6 months while not receiving glucocorticoids and the presence of all of the following: 1) improvement of muscle strength; 2) normal muscle enzyme levels; 3) tapering immunosuppressive agents or withdrawal. Interval between first remission and first relapse was recorded. Additionally, status of remission was reported at the end of follow up for each patient.

Results: Data from 76 patients, which 81.4% had DM and 14.6% had PM; female 8.26%, mean age of 39 (SD ± 12.6) years; Interval between symptom onset and first assessment showed a median of 185 (RIQ 64 - 518) days; All patients received a standardized stepwise treatment with glucocorticoids and either a single or combined therapy with methotrexate (MTX) or azathioprine (AZA) until remission was achieved; Remission was observed in 68.42%, with a median time required for achieving remission of 22.2 (RIQ 11 - 46) months. From the sub group of patients achieving remission 78.85% had sustained remission and 41.18% showed relapses with a median of relapse-free survival time of 15.16 (RIQ 6 - 32) months during follow up. The median follow-up period for the entire cohort was 38 (RIQ 21 - 108) months; During final visit, the proportion of subjects in remission were 55.3%, normal muscle strength 58.9%, chronic

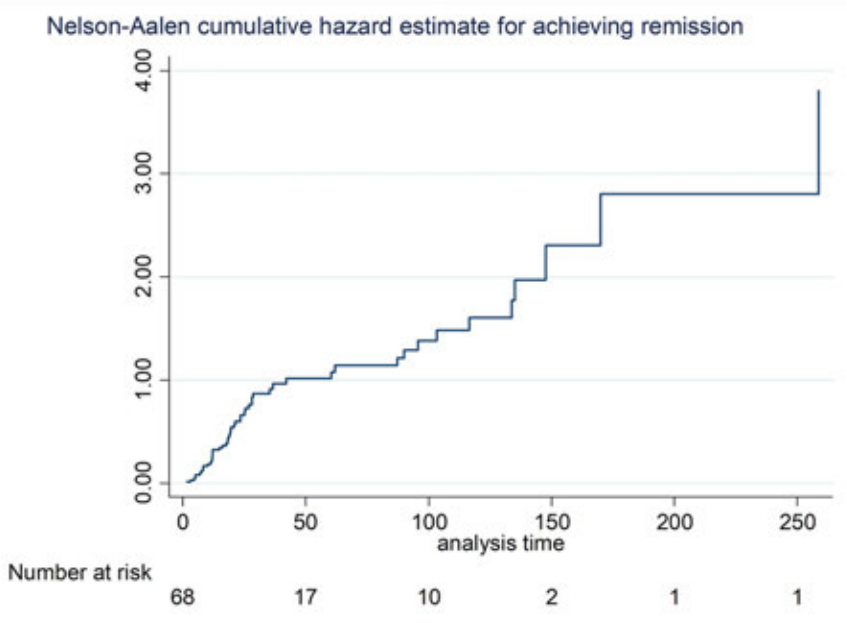

Figure 1. Cumulative hazard estimate for achieving remission.

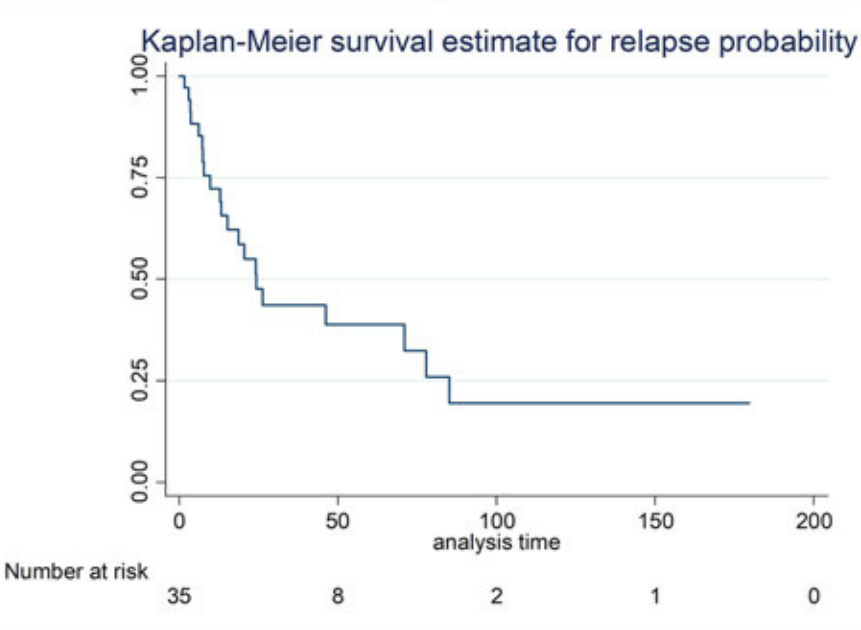

Figure 2. Kaplan Meier estimate for relapse-free survival.

muscular damage in 16.1%, normal CPK and muscle enzymes in 75%; Treatment with glucocorticoids in 46.4% and any immunosuppressive agent in 82.1% With median of HAQ-Di score of 0 (RIQ 0 - 0.35).

Conclusion: Treatment of IIM with conventional immunosuppressive agents results in a high rate of subjects achieving remission, however, most subjects required prolonged time with continued immunosuppressive therapy and relapses are frequent, which may account in significative muscle damage burden during follow up.

JAK Inhibitors: A Promising Molecular-targeted Therapy in Dermatomyositis

Océane Landon-Cardinal,[1] Perrine Guillaume-Jugnot,[2] Lois Bolko,[2] Ségolène Toquet,[2] Aude Rigolet,[2] Baptiste Hervier,[3] Nicolas Champtiaux,[2] Mathieu Vautier,[4] Olivier Benveniste,[5] and Yves Allenbach[5], [1]Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [2]Pitié-Salpêtrière University Hospital, Paris, France, [3]Hopital Pitie-Salpetriere, Paris, France, [4]Paris - Pitié salpétrière, Paris, France, [5]Sorbonne Université, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously observed *in vitro* that IFN-I reproduces dermatomyositis (DM) pathological findings, that pathogenic effects may be prevented *in vitro* by JAK inhibitor (JAKinh) therapy and an improvement was observed clinically using JAKinh in four refractory DM patients. Our objective was to expand this observation clinically and to describe the evolution of refractory DM patients treated with JAKinh.

Methods: DM patients were considered refractory if the disease remained active after at least two different lines of immunosuppressive therapy combined with corticosteroids (CS) +/- intravenous immunoglobulins (IVIg). Disease activity was assessed using the Medical Research Council scale (MRC-5) and the Cutaneous DM Disease Area and Severity Index (CDASI) every 3 months. Health Assessment Questionnaire (HAQ) and modified Rankin Scale (mRS) were performed to assess patients reported quality-of-life and disability, respectively. Tolerability and adverse events were also monitored.

Results: Twelve refractory DM patients treated with JAKinh were identified. All patients were females, mean age at diagnosis was 49.4±23.2 years and most patients (n=9/12) presented a myositis-specific autoantibody (TIF1gamma n=6; SAE n=2; MDA5 n=1). One patient presented an ovarian cancer at initial diagnosis, 7 years prior to JAKinh therapy. On average, these patients previously received 3±2 lines of immunosuppressive therapy and all of them IVIg. At JAKinh initiation (ruxolitinib n=6; baricitinib n=6), mean disease duration was 8.3±10.4 years, CS dose was 7±7 mg/day, all other immunosuppressive agents were discontinued and 3 patients were treated with IVIg concomitantly. At baseline, mean CDASI-activity score was 31±13, deltoid MRC-5 was 4.3±0.7, psoas MRC-5 was 4.2±0.8, CK level was 333±783, HAQ was 1.5±0.8 and mRS was 1.4±1.0. At 3-months follow-up, a significant improvement of CDASI-activity score (>5 points) was observed in all patients, except one, and mean CDASI-activity score was 16±10 (p=0.0036). At last-follow up, mean treatment duration with JAKinh was 11.6±6.8 months and all patients were still receiving JAKinh therapy. Mean CDASI-activity score was 8±1 (absolute delta % change -74%, p< 0.0001), deltoid MRC-5 was 4.4±0.9 (-2%, NS), psoas MRC-5 was 4.4±0.8 (+5%, NS), CK level was 127±79 (-62%, NS), HAQ was 0.8±0.6 (-46%, NS) and mRSwas 1.3±0.9 (-13%, NS). Mean CS dose was 4±4 mg/day (-42%, NS) and no patients had IVIg. Over this period, 1 patient presented a herpes zoster infection and another a bronchitis. One patient was briefly hospitalized for a non-severe pneumonia and a superficial thrombophlebitis, and presented one year later a deep vein thrombosis and pulmonary embolism requiring hospitalization.

Conclusion: Altogether this case series support the use of JAKinh in the management of refractory cutaneous DM patients demonstrating a sustained remission at one year.

Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) accompanied by anti-melanoma differentiation associated gene 5 (MDA5)-positive dermatomyositis (DM) is often rapidly progressive and associated with poor life prognosis in Japanese patients. Recently, combined immunosuppressive therapy such as high-dose glucocorticoid (GC), cal-

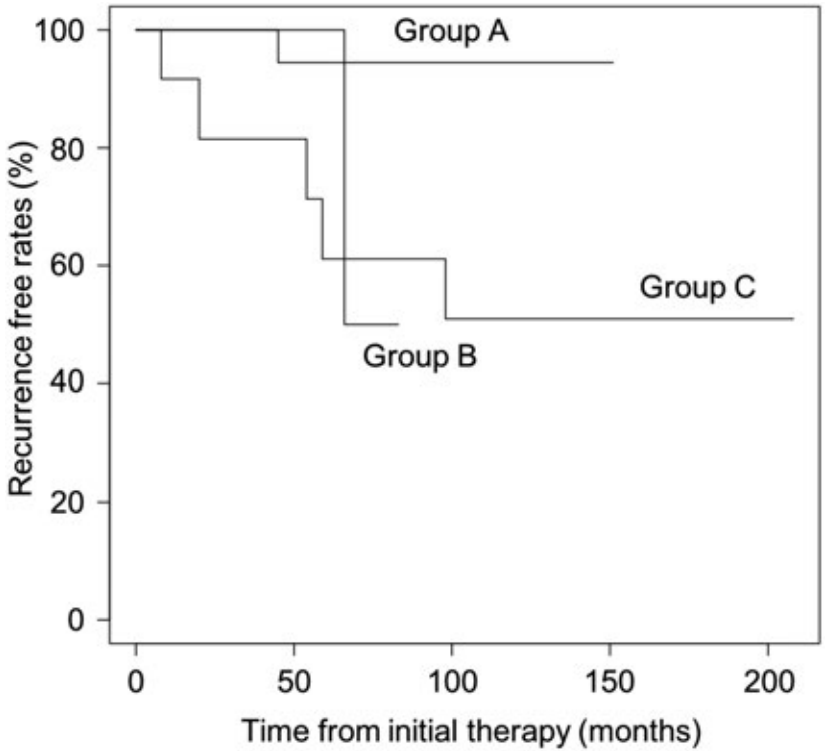

Figure 1. Relapse-free survival rates (Kaplan-Meier)

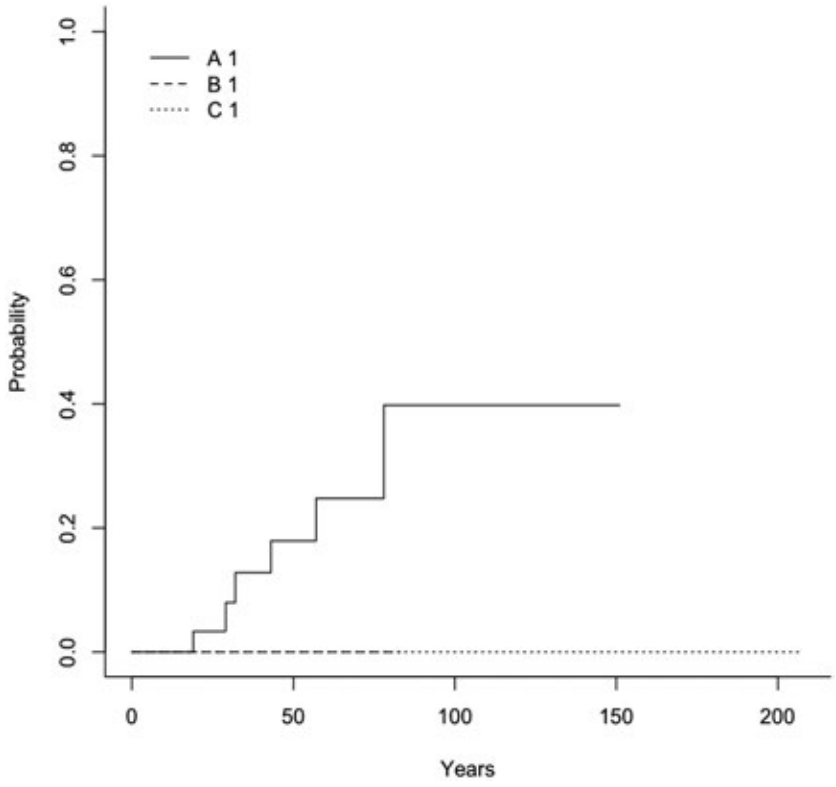

Figure 2. Drug free rates from Glucocorticoid

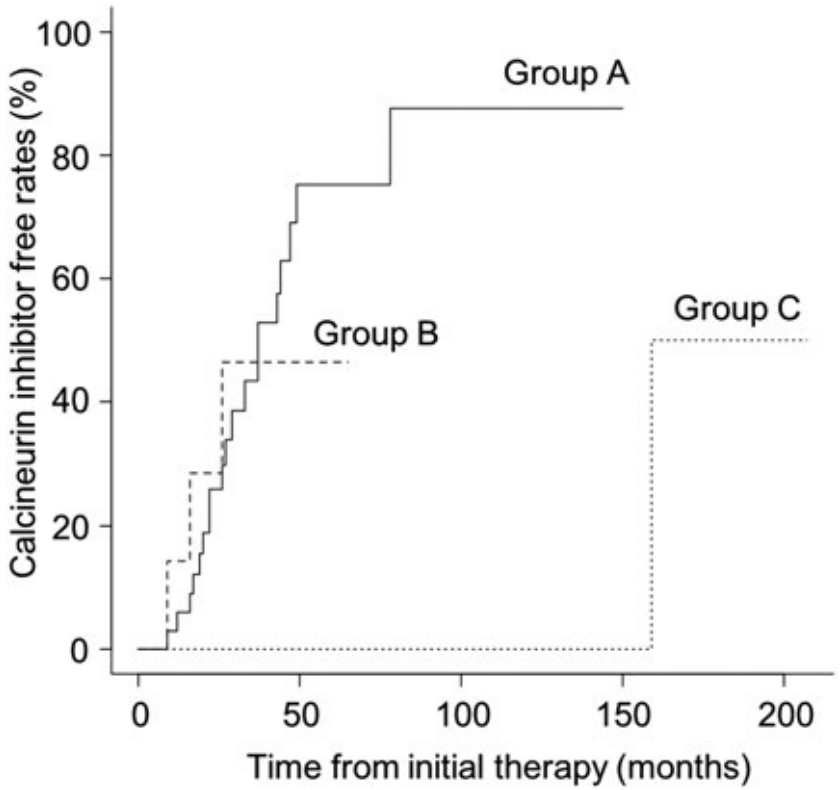

Figure 3. Drug free rates from Calcineurin inhibitor

cineurin inhibitor (CNI), and intravenous cyclophosphamide (IVCY) has been suggested to be so effective that the prognosis has been improved. However, after achieving remission, appropriate maintenance therapy is still unclear. In this study, we evaluated the effect of induction therapy on maintenance therapy and looked into the possibility of drug-free remission.

Methods: We retrospectively examined the medical records of 86 anti-MDA5-positive adult DM-ILD patients in Kyoto university hospital. There were 57 patients who had achieved remission and survived more than 6 months. According to the induction treatment, we classified into 3 groups, Group A (n=37); simultaneous triple combination therapy (GC, CNI and IVCY with all drugs started within a week), Group B (n=8); step-up triple combination therapy (initiation of IVCY delayed up to 3 month)) and Group C (n=12); mono/dual-therapy (GC with or without CNI). We compared the recurrence rates by using log-rank test. We also compared the maintenance dose of GC at 36 months since initial treatment and the rates of drug free patients.

Results: The recurrence rates of Group A, B and C were not significantly different (p=0.07, log-rank test). The recurrence rates at 36 months since initial treatment were 0%, 0%, 19%, respectively (Figure 1). The dose of GC in Group A, B and C were 3.4±2.2 vs 4.0±1.2 vs 6.3±2.2 mg/day, respectively (p< 0.05, Kruskal-Wallis test). Although the drug free rates from GC were not significantly different (13% vs 0% vs 0%, p=0.07, Figure 2), the CNI free rates of Group A were significantly higher than that of Group C (43% vs 0%, p< 0.01 with Bonferroni correction, Figure 3).

Conclusion: Triple combined immunosuppressants for induction therapy could reduce the maintenance dose of immunosuppressants and the risk of recurrence in anti-MDA5-positive DM-ILD. Moreover, initial combination therapy might lead some patients to achieve drug-free remission.

Female Sex Is a Risk Factor for Failure to Achieve Remission in Polymyositis

Prasanth Lingamaneni,[1] Carrie Richardson,[2] Soumyasri Kambhatla,[3] and Augustine Manadan[2], [1]John H. Stroger Hospital of Cook County, Chicago, IL, [2]Rush University Medical Center, Chicago, IL, [3]John H. Stroger Hospital of Cook County, Chicago

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adults with polymyositis demonstrate wide variability in responses to treatment, and the risk factors for failure to achieve remission in polymyositis are largely unknown. The aim of our study was to identify risk factors for failure to achieve remission in adult polymyositis.

Methods: In this retrospective chart review, we collected data on patients with a diagnosis of polymyositis who were seen in the rheumatology clinic at John H. Stroger Hospital of Cook County (Illinois, USA) between 2006 and 2011. Patients were included if they had “definite” or “probable” polymyositis based on the 1975 Bohan and Peter criteria. Remission was defined as normal muscle strength and creatinine kinase (CK) level < 200 mg/dL. Baseline characteristics were compared between those who achieved remission at any point during follow-up and those who did not. Chi square tests or Fisher’s exact test were used to compare categorical variables and two-tailed Student’s t-tests were used to compare continuous variables. Univariate logistic regression analysis was used to calculate unadjusted odds ratios (ORs) for the outcome of failure to achieve remission. A multivariable logistic regression was conducted using age, female sex, race, follow-up time, and clinical variables with a univariate screen p-value < 0.2 as predictors. A p-value of 0.05 was set at the threshold for statistical significance.

Results: 40 patients, 95% of whom had biopsy-proven polymyositis, were included in this study. The mean age of the study population was 43.7 years, and 65% of the patients were women. African Americans and Hispanics constituted 80% and 18% of our study population, respectively. Mean duration of follow-up (in months) was 71.6 and 81.8 in those who failed to achieve remission and those who achieved remission respectively. 78.3% of those who failed to achieve remission were women, versus 47.1% of those who achieved remission (p=0.041). Women were less likely to achieve remission compared to men (OR 5.39 [95% CI 1.18-24.57]; p=0.019), even after adjusting for age, race and months of follow-up. Treatments were similar between those who achieved remission and those who did not.

Conclusion: In this small retrospective cohort of African American and Hispanic patients with polymyositis, female sex was a risk factor for failure to achieve remission. Because treatments were similar between groups, we hypothesize that less aggressive treatment of polymyositis disease activity in women may be the cause of this sex disparity.

Table 1. Characteristics of patients with polymyositis who failed to achieve remission versus those who achieved remission

Values listed as mean (95% CI) or % (N/Total)	No remission (N=23)	Remission (N=17)	P-value

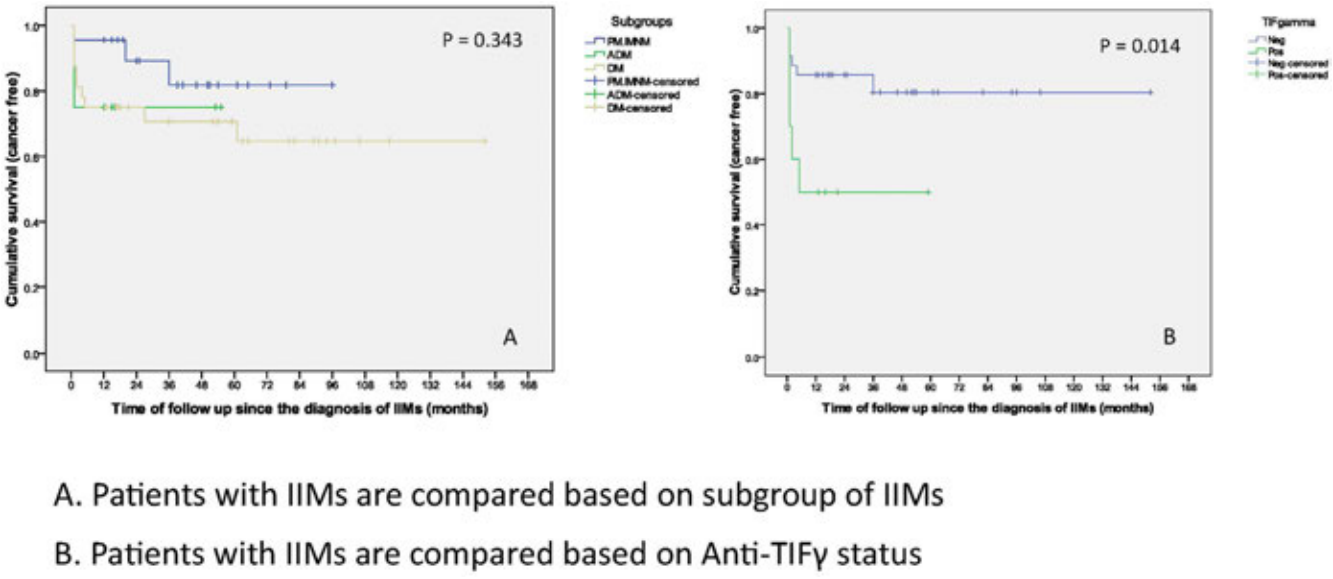
Risk Factors of Cancer-Associated Inflammatory Myopathies: A Multicenter Study

Nantakarn Pongtarakulpanit,[1] Khemmapop Yongchairat,[2] Wanruchada Kachamart,[2] Charungthai Dejthevaporn,[1] Natta Rajatanavin,[1] and Parawee Chevaisrakul[1], [1]Ramathibodi hospital, Mahidol University, Bangkok, Thailand, [2]Siriraj Hospital, Mahidol university, Bangkok, Thailand

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The association between idiopathic inflammatory myopathies (IIMs) and malignancies in Thai population has been rarely reported. The objective of our study was to determine the risk factors of cancer in IIMs patients and to describe cancer screening methods, natural history and response to treatment in Thailand.

Methods: We retrospectively studied 74 IIMs patients according to 2017 EULAR/ACR classification criteria from 2 tertiary hospitals (Ramathibodi Hospital and Siriraj Hospital, Bangkok, Thailand). Clinical, and laboratory data, cancer screening methods, natural history, and treatment outcome were recorded. After enrollment and informed consent, blood collection for myositis-specific autoantibodies (MSAs) was done in some feasible patients to complete the laboratory data. We performed a univariate analysis using logistic regression analysis to identify clinical and laboratory predictors for cancer.



A. Patients with IIMs are compared based on subgroup of IIMs

B. Patients with IIMs are compared based on Anti-TIFγ status

Figure 1. Kaplan-Meier method with log-rank test for comparison of survival curves of cancer free status

Results: Form 74 IIMs patients, we classified 25 patients in polymyositis/immune-mediated necrotizing myopathy (PM/IMNM) subgroup, 40 patients in dermatomyositis (DM) subgroup, and 9 patients in amyopathic dermatomyositis (ADM) subgroup. The mean age at diagnosis IIMs was 54.7 ± 14.7 years. Fourteen patients (18.9%) were male. Cancer was identified in 26 out of 74 IIMs patients (35.1%). Blood collection for myositis profile after enrollment was done in 17 patients. Factors that were associated with an increased risk of malignancy included DM subgroup (OR 3.27, 95%CI 1.02-10.45, P=0.045) and positive anti-TIFγ (OR 8.80, 95%CI 2.37-32.64, P=0.001). Malignancy risk also increased in IIMs patients with a positive antinuclear antibody (ANA), at titer ≥ 1:80 (OR 4.24, 95%CI 1.71-10.49, P=0.002). However, the difference was not statistically significant with the higher titer (≥1:320) of ANA (OR 1.88, 95%CI 0.63-5.59, P=0.258). While interstitial lung disease (ILD) was associated with below-than-average risk of malignancy (OR 0.11, 95%CI 0.01-0.88, P=0.040). Eighteen cases of cancer (69.2%) were diagnosed within one year before or after the diagnosis of IIMs. Median cancer diagnosis time was 1.0 month, range -57 to 61 months after IIMs diagnosis. Breast cancer was the most common cancer (31%), followed by ovarian cancer (15%). In 5 patients, cancer was detected by more extensive screening beyond age-appropriate cancer screening. IIMs patients with cancer tended to use less immunosuppressive agents compared with IIMs without cancer. However, they had a worse prognosis, with more proportion of expired patients compared to IIMs patients without cancer (OR 30.5, 95% CI = 3.45-270.83, P= 0.002). The causes of death in IIMs were cancer in 6 patients and infection in 3 patients.

Conclusion: DM subgroup and the presence of anti-TIFγ significantly increased the risk for malignancy, while ILD decreased the risk. Most cancer cases were diagnosed within one year before or after the diagnosis of IIMs, and some of them were detected by more extensive cancer screening. IIMs patients with cancer used less immunosuppressive agents, but they had a worse prognosis.

Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory myopathies (IM) are a heterogeneous group of diseases characterized by muscle inflammation. In Argentina, there are few pathologists specialized in muscle biopsies and for this reason, there are limitations to perform good quality biopsies.

The objectives of this study are to estimate the frequency of muscle biopsy in patients with IM belonging to Argentinean Society of Rheumatology database, identify the variables associated with its performance and to apply the new EULAR-ACR criteria to the subgroup of patients with biopsy.

Methods: 179 patients with IM were included. Demographic, clinical, laboratory, images and treatment characteristics were collected from medical records.

The muscle biopsy information was obtained from the pathology report of each participating hospital. Therefore, there was no standardization in the report.

To analyze differences between the groups, Chi square was performed for categorical variables and T test or Mann Whitney for continuous variables according to their distribution. Logistic regression analysis was performed for the analysis of variables associated with performing a muscle biopsy.

Results: Table 1 describes clinical characteristics of the cohort. The frequency of muscle biopsies in the cohort was 58 (32%). Table 2 shows variables associated to not having muscle biopsy performed.

In the logistic regression analysis, the presence of positive antibodies OR 0.21 (CI 95% 0.05- 0.99) and heliotrope rash 0.11 (CI 95% 0.02 to 0.75) were independently associated with NOT performing biopsy.

The complete biopsy report was available in 37 of 52 patients who undergone biopsy. In those patients we applied the EULAR-ACR criteria for inflammatory myopathies with and without biopsy(1).

Conclusion: Muscle biopsy was performed in only one third of patients with IM from our cohort. Patients with myositis-specific antibodies and heliotrope rash were biopsied less frequently. If criteria without biopsy are applied to

Changes in Nail-fold Capillary Abnormalities, and Serum FGF and VEGF Levels in Dermatomyositis Patients with anti-MDA5 Antibody During the Clinical Course

Yasuhito Hamaguchi,[1] Takashi Matsushita,[1] Naoki Mugii,[2] and Kazuhiko Takehara[1], [1]Department of Dermatology, Kanazawa University, Kanazawa, Japan, [2]Kanazawa University Hospital, Kanazawa, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Capillary abnormalities in the nail-fold are a characteristic finding of microangiopathy in autoimmune connective tissue diseases, including dermatomyositis and systemic sclerosis. A previous study reported an association between nail-fold capillary findings and disease activity in patients with dermatomyositis. To examine the changes in nail-fold capillary abnormalities, and serum fibroblast growth factor (FGF) and vascular endothelial growth factor (VEGF) levels in dermatomyositis patients with anti-melanoma differentiation-associated gene 5 (MDA5) antibody (Ab) during the clinical course.

Methods: Capillary abnormalities were evaluated by capillaroscopy in 11 patients with anti-MDA5 Ab at baseline and after treatment. Capillary abnormalities included

irregularly enlarged capillaries, reduced capillaries, hemorrhage, capillary ramifications, disorganization of the vascular array, loss of capillaries, and giant capillaries. Serum levels of FGF and VEGF were measured by ELISA.

Results: At baseline, i rregularly enlarged capillaries were observed in 10 of 11 cases, but after treatment, they were significantly reduced in only 3 cases (91% vs 27%, $p < 0.001$). Hemorrhage was observed in all cases at baseline, but disappeared in all cases after treatment (100% vs 0%, $p < 0.001$). Although the difference was not significant, reduced capillaries slightly improved (58% vs 33%, $p = 0.219$). Serum FGF levels significantly increased between baseline and after treatment (0.5 ± 0.8 pmol/L vs 1.0 ± 0.6 pmol/L, $p < 0.005$), but serum VEGF levels were comparable between baseline and after treatment (382 ± 330 pg/ml vs 302 ± 200 pg/ml, $p = 0.11$).

Conclusion: These data suggest that capillary abnormalities are reversible and improved by treatment. In addition, F

GF may function in the pathophysiology of microvascular abnormalities in dermatomyositis patients with anti-MDA5 Ab.

Table 1. Nail-fold capillary findings between baseline and after treatment

	At baseline (n = 11)	After treatment (n = 11)	P
Irregularly enlarged capillaries	10 (91%)	3 (27%)	<0.001
Reduced capillaries	7 (64%)	4 (36%)	0.219
Hemorrhage	11 (100%)	0 (0%)	<0.0001
Capillary ramifications	0 (0%)	1 (9%)	0.307
Disorganization of the vascular array	0 (0%)	1 (9%)	0.307
Loss of capillaries	0 (0%)	0 (0%)	-
Giant capillaries	0 (0%)	0 (0%)	-

Patients with Anti-tRNA Synthetase Syndrome Are More Likely to Present to Pulmonary Clinic and Have a Higher Prevalence and Severity of Lung Disease Than Patients with Other Types of Myositis or Systemic Sclerosis

Bret Sohn,[1] Erin Wilfong,[1] and Leslie Crofford[1], [1]Vanderbilt University, Nashville

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a significant cause of morbidity and mortality in idiopathic inflammatory myopathies (IIM) as well as systemic sclerosis (SSc). The purpose of this study is to compare the prevalence, physiology, and radiographic findings in IIM as well as to analyze the utilization of screening/monitoring plans in different clinical and antibody defined patient subsets.

Methods: Patients diagnosed with polymyositis (PM), dermatomyositis (DM), anti-aminoacyl tRNA synthetase syndrome (ARS), limited cutaneous systemic sclerosis (lcSS), or diffuse cutaneous systemic sclerosis (dcSS) were identified from the MYSTIC cohort (VUMC IRB 141415) and using subject locator (VUMC IRB 180672). The presence of ILD was identified from chart abstraction. Radiographic patterns of ILD were ascertained from the initial CT scan. American Thoracic Society (ATS) criteria were used to grade severity of lung disease by forced vital capacity (FVC) and diffusion lung capacity for carbon monoxide (DLCO) percentages. If multiple pulmonary function tests (PFTs) were available, the most severe value was used. Symptom onset was defined as the start of any clinical manifestation of IIM or SSc.

Results: Patient characteristics are shown in Table 1. Sixty-nine of 131 patients had ILD with the highest prevalence in ARS (81.5%) and dcSS (71.4%). Overall, most patients had CT morphology other than usual interstitial pneumonia (UIP) (Table 2). Non-Jo1 (45.5%) ARS were most frequently classified as UIP. Severe restriction was present in 36.4%

of Jo-1+ and 63.6% of non-Jo-1 ARS patients, compared with 33.3% of dcSS patients. Similarly, 72.7% of ARS patients (54.5% Jo-1+ and 90.9% non-Jo-1) and 55.6% of dcSS had severe gas exchange deficits. Supplemental oxygen use was 25.9% in ARS and 14.3% in dcSS. Despite the prevalence of ILD at 45% and 43.9% in lcSS and DM, respectively, physiologic severity was less than for ARS or dcSS. FVC was severely restricted in only 12.5% of lcSS cases and 5.6% of DM cases. Over 62% of lcSS patients had severe reduction in DLCO, but this is likely due to concomitant pulmonary hypertension. The time from symptom onset to first PFT or HRCT was the shortest with

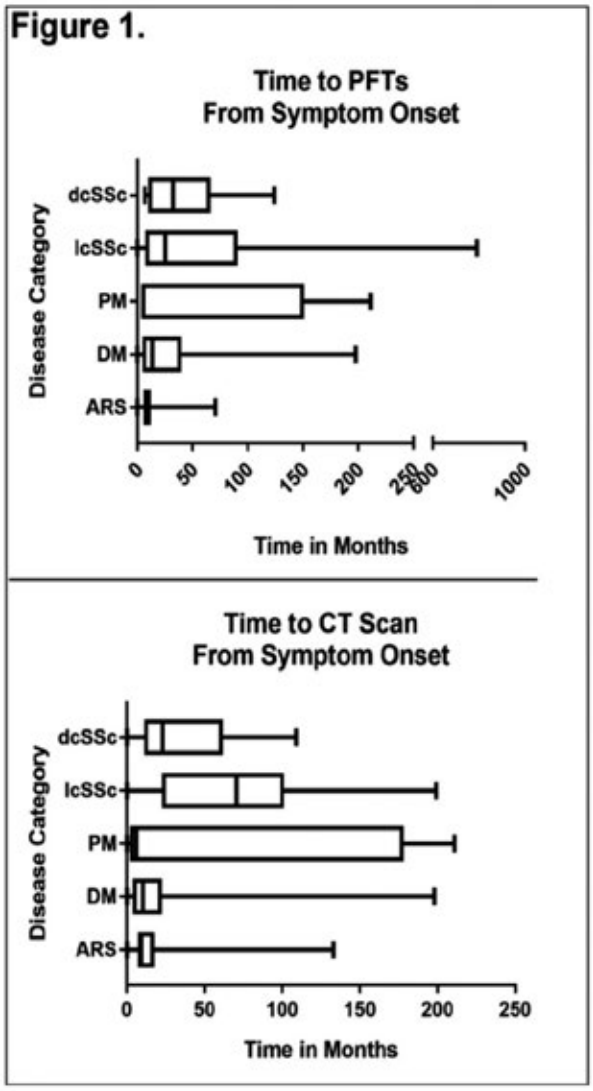
	DLCO - <50%	10 (55.6%)	0	6 (54.5%)	10 (90.9%)	10 (62.5%)	5 (55.6%)



the ARS group (Figure 1). ARS patients (72.7%), particularly the non-Jo-1 ARS (100%), were more likely than other groups (34%) to be seen first in pulmonary clinic.

Conclusion: In our cohort, ARS had the highest prevalence and severity of ILD. ARS patients, especially non-Jo-1 ARS patients, were more likely to be seen initially in pulmonary clinic and receive earlier screening for ILD. However, these patients may also have delayed diagnosis due to lack of extra-pulmonary symptoms thus presenting with more severe disease. Implementing routine screening for ARS in pulmonary clinics may identify patients earlier and change management.

Anti-mitochondrial Autoantibodies in Idiopathic Inflammatory Myopathies

Sara Sabbagh,[1] Iago Pinal-Fernandez,[2] Maria Casal-Dominguez,[3] Frederick W. Miller,[4] Andrew L Mammen,[3] and Lisa G. Rider[5], [1]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, MD, [2]National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health (NIH), Bethesda, [3]National Institutes of Health, Bethesda, [4]NIEHS, NIH, Bethesda, MD, [5]Environmental Autoimmunity Group, Clinical Research Branch, NIEHS, NIH, Bethesda, MD

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibodies found in adult and juvenile myositis patients are often associated with specific clinical features. Prior reports have suggested that the myositis-associated autoantibody, anti-mitochondrial autoantibodies (AMA), may be associated with cardiac involvement in adults with myositis. No studies have examined the prevalence or significance of AMA in children with myositis. The purpose of this study was to define the prevalence of AMA in juvenile myositis and to investigate phenotypic differences between myositis patients with and without AMA.

Methods: We screened sera from 302 patients with juvenile dermatomyositis, 25 patients with juvenile polymyositis, and 44 patients with juvenile connective tissue disease-myositis overlap from a national myositis registry study and 92 juvenile healthy controls for AMA by ELISA, [M2 EP (MIT3) ELISA, Quanta Lite, INOVA Diagnostics, San Diego, CA]. Clinical characteristics were compared between myositis patients with and without AMA.

Results: AMA were found in 4/371 (1%) of juvenile myositis patients and 1/92 (1%) of juvenile healthy controls. Of the juvenile myositis patients, 3/4 had dermatomyositis and 1/3 had polymyositis. Onset of myositis was between 3.6 and 12.4 years of age. Two patients were positive for anti-p155/140 autoantibodies, one was positive for anti-MJ autoantibodies and one was myositis-specific autoantibody negative. All patients had muscle weakness and 3/4 patients had either Gottron's papules or heliotrope rash. Three patients had dysphagia, 2/4 patients had calcinosis, and 2/4 patients had atypical cutaneous findings including orbital swelling and panniculitis. Overall, no distinguishing clinical features were present in the AMA positive children, and none of the AMA positive children had cardiac involvement.

Conclusion: AMA are rare in juvenile myositis and the prevalence of AMA is equivalent to that observed in healthy controls. AMA are not associated with a specific clinical phenotype in juvenile myositis.

Line Blot Immunoassay in Inflammatory Myopathies: Diagnostic Accuracy and Factors Predicting Positive Results in Routine Clinical Practice

Fergus To,[1] Clara Ventín Rodríguez,[2] Shuayb Elkhalifa,[3] James Lilleker,[4] and Hector Chinoy[4], [1]University of British Columbia, Vancouver, Canada, [2]Complejo Hospitalario Universitario de A Coruña, A Coruña, Spain, [3]Department of Immunology, Salford Royal NHS Foundation, Salford, United Kingdom, [4]University of Manchester, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the real-world accuracy of a line blot immunoassay (LIA) for myositis-specific (MSA) and myositis-associated (MSA) autoantibody testing in patients at a tertiary rheumatology and neurology centre.

Methods: Adults tested with the EUROLINE Inflammatory Myopathies 16 Ag LIA at Salford Royal NHS Foundation Trust between January 1, 2016-July 30, 2018 were identified. Cases were reviewed to determine if LIA results were true or false positives. Accuracy was calculated for the autoantibodies (Abs), stratified into strong and weak positivity. Factors associated with true positive results were evaluated.

Results: In total, 342 patients were analysed. 67/342 (19.6%) had a final diagnosis of IIM, 120/342 (35.1%) with connective tissue disease (CTD) without IIM, and 121/342 (35.4%) without IIM or CTD. In IIM patients, 50/71 (70.4%) Abs detected were strongly positive and 48/50 (96.0%; 19 MSAs, 29 MAAs) of these were true positives. 21/71 (29.6%; 7 MSAs, 14 MAAs) were weakly positive. Only 15/21 (71.4%; 3 MSAs, 12 MAAs) of these were true positives. In CTD without IIM patients, 31/61 (51.0%; 5 MSAs, 26 MAAs) Abs detected were strong positives. Only 24/31 (77.4%; 0 MSAs, 24 MAAs) were true positives. 30/61 (49.2%; 13 MSAs, 17 MAAs) were weakly positive and 16/30 (53.3%; 0 MSAs, 16 MAAs) of these were true positives. In patients without CTD or IIM, 46 Abs (24 MSAs, 22 MAAs) were detected. All were false positives, 17/46 (37.0%; 7 MSAs 10 MAAs) of which were strong positives. Individual Abs specificities were 98.2-100% for weakly positive Abs and 97.5-100% for strongly positive Abs. The odds ratio (OR) of a true positive result was significantly associated with a pre-test working diagnosis of IIM (OR 50.8, 95%CI 13.66-189.22, $p< 0.001$) and strongly positive antibody results (OR 4.38, 95%CI 2.32-8.26, $p< 0.001$).

Conclusion: We demonstrated a high diagnostic specificity for IIM in a real-world setting using a commercially available LIA. However, a significant burden of false positive results was evident in those with low pre-test likelihood of IIM and for weak positive Ab results.

Antigen Bead Array versus ELISA to Detect anti-cN1A Antibodies in Patients with Sporadic Inclusion Body Myositis and Correlation with Clinical, Serological and Histological Features

Antonella Notarnicola,[1] Francesco Bonomi,[2] Cecilia Hellstrom,[3] Elisa Pin,[3] Helena Idborg,[1] Peter Nilsson,[4] and Ingrid E Lundberg[1], [1]Division of Rheumatology, Department of Medicine Solna, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden, [2]Vita-Salute San Raffaele University, Milano, Italy, [3]Affinity Proteomics, SciLifeLab, Department of Protein Science, KTH - Royal Institute of Technology, Stockholm, Sweden, [4]Science for Life Laboratory, Affinity Proteomics; KTH − Royal Institute of Technology, School of Biotechnology;Stockholm (Sweden), Stockholm, Sweden

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Antibodies to cytosolic 5'-Nucleotidase 1A (anti-cN1A or NT5C1A) are considered the only currently known serum biomarker for sporadic Inclusion Body Myositis (sIBM). They are reported in 33-76% of sIBM patients but little is known on their possible correlation with clinical, serological and histological features. Few studies have shown that anti-cN1A positive patients with sIBM present with a more severe phenotype and increased mortality risk.

Aims: To analyze the prevalence of anti-cN1A autoantibodies in a Swedish cohort of patients with sIBM by applying suspension antigen bead array and a commercially available ELISA assay. To explore whether the anti-cN1A autoantibodies could identify a distinct subgroup of sIBM with specific clinical or laboratory characteristics.

Methods: Reactivity to one N-terminal and one C-terminal protein fragment of the NT5C1A antigen was investigated by using a suspension bead array platform in serum samples from 46 patients with sIBM, 30 with Polymyositis (PM) and 30 with Dermatomyositis (DM), HLA matched. The ELISA kit was then used for 31/46 sIBM samples as well as in 33 DM and 43 PM samples. Plasma samples from 17 patients with Systemic Lupus Erythematosus (SLE) and 9 SLE-controls were also screened by ELISA. Clinical, serological and histological data of the sIBM cohort were collected at time of diagnosis and accumulated data during the disease course. The 46 sIBM patients were defined as having anti-cN1A antibodies if they tested positive by at least one of the two assays.

Results: The antigen bead array showed a sensitivity of 34.8% of identifying sIBM and a specificity of 83.3% when performed with the N-terminal fragment. The sensitivity decreased to 6,5% and the specificity increased to 93,5% when the test was run with the C-terminal fragment. The sensitivity and specificity for the ELISA assay were 41,9% and 74,5%, respectively. A statistically significant correlation was found between the ELISA and the antigen bead array results (N-terminal fragment) (Spearman's rho 0.74, p value < 0.001). In the sIBM cohort, 19 seropositive and 27 seronegative to anti-cN1A antibodies were identified. No statistically significant differences in any of the analyzed variables were found between the 2 groups, but some interesting trends were observed. At time of diagnosis, seropositive patients had more frequently finger flexor weakness and reported higher score on patient visual analogue scale (VAS) for disease activity than the seronegative group. At first biopsy, increased amount of connective and/or fat tissue was found more commonly in anti-cN1A positive patients. More anti-cN1A positive than negative patients had positive history of falls and did not reach stabilization nor remission after the first year from diagnosis, independently of the use of immunosuppressive treatment.

Conclusion: Positivity to anti-cN1A antibodies is highly specific for sIBM diagnosis, as previously reported. The results from the antigen bead array suggest that the main epitope may be localized at the N-terminal region of the NT5C1A protein. In our cohort, anti-cN1A antibodies were not associated to any specific features but the seropositive group seemed to present with a more aggressive disease course.

Identification of Distinctive Interferon Gene Signatures in Different Types of Inflammatory Myopathy

Iago Pinal-Fernandez,[1] Maria Casal-Dominguez,[1] Assia Derfoul,[1] Katherine Pak,[1] Paul Plotz,[1] Frederick W. Miller,[2] Jose C Milisenda,[3] Josep M Grau-Junyent,[3] Albert Selva-O'Callaghan,[4] Julie Paik,[5] Jemima Albayda,[6] Lisa Christopher-Stine,[7] Thomas E Lloyd,[5] Andrea M Corse,[5] and Andrew L Mammen[1], [1]National Institutes of Health, Bethesda, [2]NIEHS, NIH, Bethesda, MD, [3]Clinic Hospital, Barcelona, [4]Department of Systemic Autoimmune Diseases, Hospital Universitario Valle de Hebron, Barcelona, Spain, Barcelona, [5]Johns Hopkins, Baltimore, [6]Johns Hopkins University, Baltimore, MD, [7]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Activation of the type 1 interferon (IFN1) pathway is a prominent feature of dermatomyositis (DM) muscle and may play a role in the pathogenesis of this disease. However, the relevance of the IFN1 pathway in patients with other types of myositis, such as the antisynthetase syndrome (AS), immune-mediated necrotizing myopathy (IMNM), and inclusion body myositis (IBM), is largely unknown. Moreover, the activation of the type 2 interferon (IFN2) pathway has not been comprehensively explored in myositis. In this cross-sectional study, our objective was to analyze both IFN1 and IFN2 pathway activation in myositis by performing RNAseq on muscle biopsy samples from 119 patients with DM, IMNM, AS, or IBM as well as on 20 normal muscle biopsies.

Methods: The expression of IFN1- and IFN2-inducible genes was compared between the different groups.

Results: The expression of IFN1-inducible genes was high in DM, moderate in AS, and low in IMNM and IBM. In contrast, the expression of IFN2-inducible genes was high in DM, IBM, and AS but low in IMNM. The expression of IFN-inducible genes correlated with the expression of genes associated with inflammation and muscle regeneration. Of note, ISG15 expression levels alone performed as well as composite scores relying on multiple genes to monitor activation of the IFN1 pathway in myositis muscle biopsies.

Conclusion: IFN1 and IFN2 pathways are differentially activated in different forms of myositis. This observation may have therapeutic implications since immunosuppressive medications may preferentially target each of these pathways.

Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prometheus study was a prospective, randomized, assessor-blind multicenter trial, comparing the efficacy and safety of the glucocorticoid (GC) monotherapy versus combination therapy with methotrexate (MTX) and GC in patients with polymyositis (PM) and dermatomyositis (DM). Muscle MRI has been used to assess disease activity and response to treatment. To assess MRI findings two different methods were used: semi-quantitative scoring system and quantitative assessment using manual measuring tool and picture analysis provided by TomoCon® Workstation.

Methods: For semi-quantitative assessment of edema, we used scoring 0, 1, 2, and 3 according to intensity of signal in each of the 16 thigh muscles. Muscle damage was evaluated in three basic thigh muscle compartments and pelvic muscles using Goutallier grading (0 – 5) based on extent of fatty replacement. Both sides were assessed by two evaluators, an average was made for each muscle, and values were summed up in the total score (MRI Semi-Quantitative total edema score = MRI S-Q TES). TomoCon® software provides pixel analysis in manually selected regions of interest. Manual muscle test (MMT8) and CK were measured and patient's global assessment (PGA), physician's GA (PhGA) and muscle disease activity (MDA) were recorded on visual analogue scales.

Results: Seventeen patients had MR images taken before the baseline visit, 8 had also the second MRI after 3 months of therapy. There was a significant reduction of MRI S-Q TES after 3 months in patients with PM and DM (from the mean 17.4 points, SD 13.7 to 8.0 points, SD 12.3; p=0.025). No significant progression of fatty atrophy was observed (from 16.0 points, SD 8.8, to 19.4, SD 4.6; p=0.3). At baseline, a significant correlation between MRI S-Q TES and PGA was noted (p=0.027). There was also a borderline negative association of MRI S-Q TES with muscle strength evaluated by MMT 8 (p=0.053). We noted a significant association between MRI S-Q TES and MRI Quantitative total edema score (MRI Q TES) (p=0.04) as well as between semi-quantitative and quantitative edema scores comparing individual muscles (p=0.0004). There was also a borderline association of MRI S-Q TES with MRI atrophy score (p=0.061). In a subset of 8 patients with longitudinally performed two MRI evaluations we found a good correlation between initial MRI S-Q TES and the level of serum CK (p=0.028). However, no correlation was seen between the level of improvement in MRI S-Q TES and drop in CK or with any other clinical parameters after 3 months of treatment.

Conclusion: Compared to the results of established semi-quantitative scoring method we demonstrated a good reliability of newly proposed quantitative evaluation system of muscle edema. This system was applied to record degree of muscle edema in a subpopulation of patients with PM and DM, treated in the clinical study. A significant association between MRI S-Q TES and MRI Q TES was found. Correlations of MRI scores with clinical and laboratory parameters were demonstrated.

Abnormal High Density Lipoprotein Particle Size and Number in Idiopathic Inflammatory Myopathies

Sangmee Bae,[1] Ilana Golub,[2] Ani Shahbazian,[3] Jennifer Wang,[3] and Christina Charles-Schoeman[4], [1]UCLA, Los Angeles, CA, [2]UCLA, Los Angeles, [3]UCLA Medical Center, Los Angeles, [4]University of California, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Vascular inflammation and damage are implicated in the pathogenesis of idiopathic inflammatory myopathies (IIM), particularly dermatomyositis (DM). High and low density lipoprotein (HDL, LDL) particles strongly influence the vascular endothelium, but little data has characterized these particles in IIM patients. The current work evaluates standard cholesterol levels as well as the particle number and size of HDL, LDL and very low density lipoproteins (VLDL) in IIM patients compared to healthy controls.

Methods: In a cross sectional analysis of 87 patients with IIM and 47 healthy controls (HC), we measured the quantitative lipoprotein profile by nuclear magnetic resonance spectroscopy (NMR). Cardiovascular risk factors and medications were obtained by questionnaire/chart review, and inflammatory markers and autoantibodies (ab) were measured by standard methods. Myositis disease activity was assessed using physician global 100 mm visual analogue scales (VAS) and CPK levels.

Results: The majority of patients in the IIM group had DM with a mean disease duration of 5 years and moderate disease activity (Table 1). Traditional fasting cholesterol levels were generally similar between patients with IIM and HC with mildly elevated triglycerides in the IIM group. Multiple differences in particular size and number including higher LDL particle number (LDL-P), larger HDL and VLDL size, and lower HDL particle number (HDL-P) were noted between IIM patients and HC. Multivariate (MV) models adjusted for demographics, factors known to affect lipid particle size/number (hypertension, diabetes, body mass index, statin use) and variables different in univariate comparison (ESR), were constructed for each significant lipid variable in table 1. Larger HDL size was strongly associated with IIM diagnosis, and smaller HDL-P was associated with disease activity in MV models. Triglycerides, LDL-P number and VLDL size were no longer associated with IIM diagnosis or disease activity in MV analysis. Patients with p155/140 ab had significantly larger HDL size, and patients with MDA5 ab had significantly lower HDL-P compared to patients without ab.

Mean(SD) unless specified, T test or Wilcoxon rank sum test for continuous variables, chi-square test or Fisher's exact test for categorical variables, *ab data available in 61 IIM patients

N=78 IIM patients with physician global disease activity VAS availableFigure 2_revised

Table 3. Multiple Linear Regression Models for Lipid Outcomes

Variables	HDL-P model				HDL size model			
	Total group (N=134)		IIM group (N=87)		Total group (N=134)		IIM group (N=87)	
	β	p	β	p	β	p	β	p
IIM vs controls	-1.4	0.40	-		0.4	**0.001**	-	
Physician global disease activity VAS (0-10cm)	-		-1.3	**0.01**	-		0.003	0.94
Age, every 10yrs	0.6	0.19	0.5	0.41	0.01	0.81	-0.001	0.98
Gender, Female (vs Male)	0.5	0.76	2.0	0.31	0.4	**0.001**	0.4	**0.01**
Race, White (vs non-white)	2.6	0.07	3.6	**0.04**	-0.1	0.45	-0.2	0.24
Hypertension, yes	-0.9	0.69	-0.2	0.94	0.3	0.07	-0.4	0.05
Diabetes, yes	4.1	0.20	8.7	**0.03**	0.3	0.21	0.3	0.29
Body mass index, kg/m^2	0.004	0.96	-0.2	0.17	-0.01	0.38	-0.01	**0.60**
Statin use, yes	0.2	0.94	-6.2	0.11	-0.13	0.49	-0.1	0.79
ESR every 10mm/hr	-1.0	**0.003**	-0.9	**0.01**	-0.01	0.66	-0.02	0.35
Prednisone, mg/day	-		0.03	0.41	-		0.004	0.30

Conclusion: In a cross sectional analysis of IIM patients and healthy controls, larger HDL size was strongly associated with IIM diagnosis, and lower HDL-P was associated with higher physician global disease activity by VAS. Altered HDL size and particle number have previously been associated with vascular risk, and further work is needed to evaluate their role in vascular damage in patients with IIM.

Multiple Subpopulations of Lymphocytes Were Absolutely Decreased in Dermatomyositis/polymyositis Patients and Restored by Low-dose IL-2

Jia Wang,[1] He-hua Sun,[1] **Sheng-xiao Zhang**,[2] Jia-qian Zhang,[1] Jiang Bai,[3] Jing Luo,[3] Cai-hong Wang,[4] Chong Gao,[5] and Xiao-feng Li[1], [1]The Second Hospital of Shanxi Medical University, Taiyuan, China (People's Republic), [2]The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China (People's Republic), [3]Shanxi Medical University, Taiyuan, China (People's Republic), [4]The Second Hospital of Shanxi Medical University, Tai Yuan, China (People's Republic), [5]Brigham and Women's Hospital, Harvard Medical School, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) and polymyositis (PM) are rare chronicinflammatory disorders with significant associated morbidityand mortality despite treatment, characterized by subacute onset of proximal muscle weakness, elevated muscle enzymes, and inflammatory infiltrates on muscle biopsy. Although several hypotheses

have been proposed for triggers of inflammation in the diseases, growing evidences have focused on the immune disorders. However, the quantitative changes of lymphocyte subsets in DM/PM are unclear and whether low-dose IL-2 could rebalance the lymphocyte subsets and further benefit to remission disease activity of DM/PM patients is unknown. This study aimed to investigate the quantitative status of peripheral blood lymphocyte subsets in the patients for the exploration of pathogenesis and evaluate the safety and efficacy of low-dose IL-2 therapy in patients with DM/PM.

Methods: From February 2016 to October 2018, total 147 patients with PM/DM and 128 gender and age matched healthy individuals were enrolled in this study. The absolute numbers of T, B, NK, CD4+T, CD8+T, Th1, Th2, Th17 and Treg cells in peripheral blood of these individuals were detected by flow cytometry combined with standard absolute counting beads. Patients in IL-2 group (n=31) were not only given traditional treatments, but injected subcutaneously human IL-2 (aldesleukin) at 50 WIU per day for a 5-day course. The demographic features, clinical manifestations and laboratory indicators were compared before and after the treatment.

Results: Patients with PM/DM had lower levels of Treg cells as well as T, CD4+T, CD8+T, Th1, Th2, and Th17 compared with those of the healthy controls ($P < 0.05$), which was correlated with disease activity($P < 0.05$).

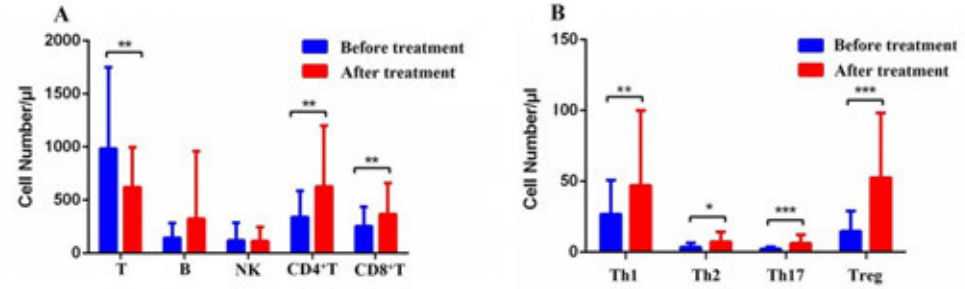

Figure 2: Changes of peripheral lymphocyte subsets after different treatments (n=31). Absolute numbers of T, CD4+T, CD8+T, Th1, Th2, Th17 and Treg cells in patients were significantly increased after treatment. *P<0.05, **P <0.01, ***P <0.001.

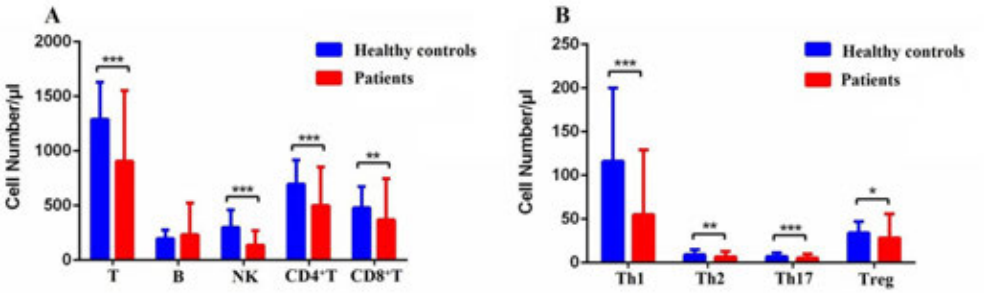

Figure 1: Comparison of absolute numbers of peripheral lymphocyte subsets between patients with PM/DM (n=147) and health controls (n=128). All the lymphocytes subpopulations were analyzed by detected by flow cytometry combined with standard absolute counting beads. Data were presented as mean±SD and statistical analysis was determined by two-tailed unpaired *t*-test. Patients had lower levels of T, NK,CD4+T, CD8+T, Th1, Th2, Th17 and Treg cells in PB compared with those of healthy controls. *P < 0.05, **P <0.01, ***P <0.001.

After IL-2 administration, the absolute numbers of peripheral lymphocyte subsets in patients were significantly increased ($P < 0.05$), leading to a better remission compared with the patients received conventional therapy ($P < 0.05$).

Conclusion: The difference status of peripheral lymphocyte subsets, especially Tregs, between PM/DM patients and healthy individuals suggests that lymphocyte subsets may be involved in and play an important role in the pathogenesis of patients. Low-dose IL-2 can effectively increase the level of Treg cells as well as other lymphocytes to some degree and maintain the immunologic balance, which may help for PM/DM patients' symptoms remission without over-treatment and evaluated side effect. But long-term benefits of IL-2 therapy are required to further study.

Alterations in Activin A-Myostatin-Follistatin System Associate with Disease Activity in Inflammatory Myopathies

Session Date: Monday, November 11, 2019

Session Title: Muscle Biology, Myositis & Myopathies Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The aim of this study was to investigate myokines involved in muscle atrophy such as myostatin, follistatin and activin A, in idiopathic inflammatory myopathies (IIM). Recent findings show that rather than myostatin alone, the activin A-myostatin-follistatin system is believed to play an important role in musculoskeletal growth, development and aging. The myostatin biology known by now encourages considering its blocking therapy in IIM as the muscle weakness and atrophy persist in patients even after the suppression of inflammation.

Methods: A total of 94 patients with IIM and 155 healthy controls (HC) were enrolled in the study. Apart from serum samples taken during regular patients' visits, 20 IIM patients and 21 HC underwent a muscle biopsy. Circulating concentrations of myostatin, follistatin, activin A and TGF-β1 were assessed by ELISA. The expression of myokines and associated genes involved in myostatin signalling pathway in muscle tissue was determined by real-time PCR using TaqMan® Gene Expression Assays.

Results: We report decreased levels of circulating myostatin (2024±1111 vs. 2647±792 pg/ml; p=0.0003) and increased follistatin (1542±564 vs. 1332±670 pg/ml; p=0.008) in IIMs compared to HC. Activin A levels were higher in IIM (394±142 vs. 334±132 pg/ml; p=0.013) compared to controls while no significant difference was observed for serum TGF-β1. Myostatin was significantly correlated to disease activity measures such as muscle disease activity (muscle DA) (r=-0.289, p=0.015) and manual muscle testing of 8 muscles (MMT8) (r=0.366, p=0.002). On the other hand, follistatin correlated positively with muscle DA (r=0.235, p=0.047). Gene expression analysis showed higher follistatin (p=0.040) and myostatin inhibitor FSTL3 (p=0.008) levels and lower expression of activin receptor type 1B (ALK4) (p=0.034), signal transducer SMAD3 (p=0.023) and atrophy-related E3 ligase atrogin-1 (p=0.0009) in IIM muscle tissue compared to controls.

Conclusion: The findings of this study contradict the expected pattern of activin A-myostatin-follistatin system in muscle wasting diseases by showing lower myostatin and higher follistatin in circulation and attenuated expression of ALK4, SMAD3 and atrogin-1 in skeletal muscle of patients with inflammatory myopathies, suggesting the existence of an internal mechanism aimed at reducing further loss of muscle proteins during myositis. Furthermore, we show that the activin A-myostatin-follistatin system disturbance is more profound in patients with more active disease.

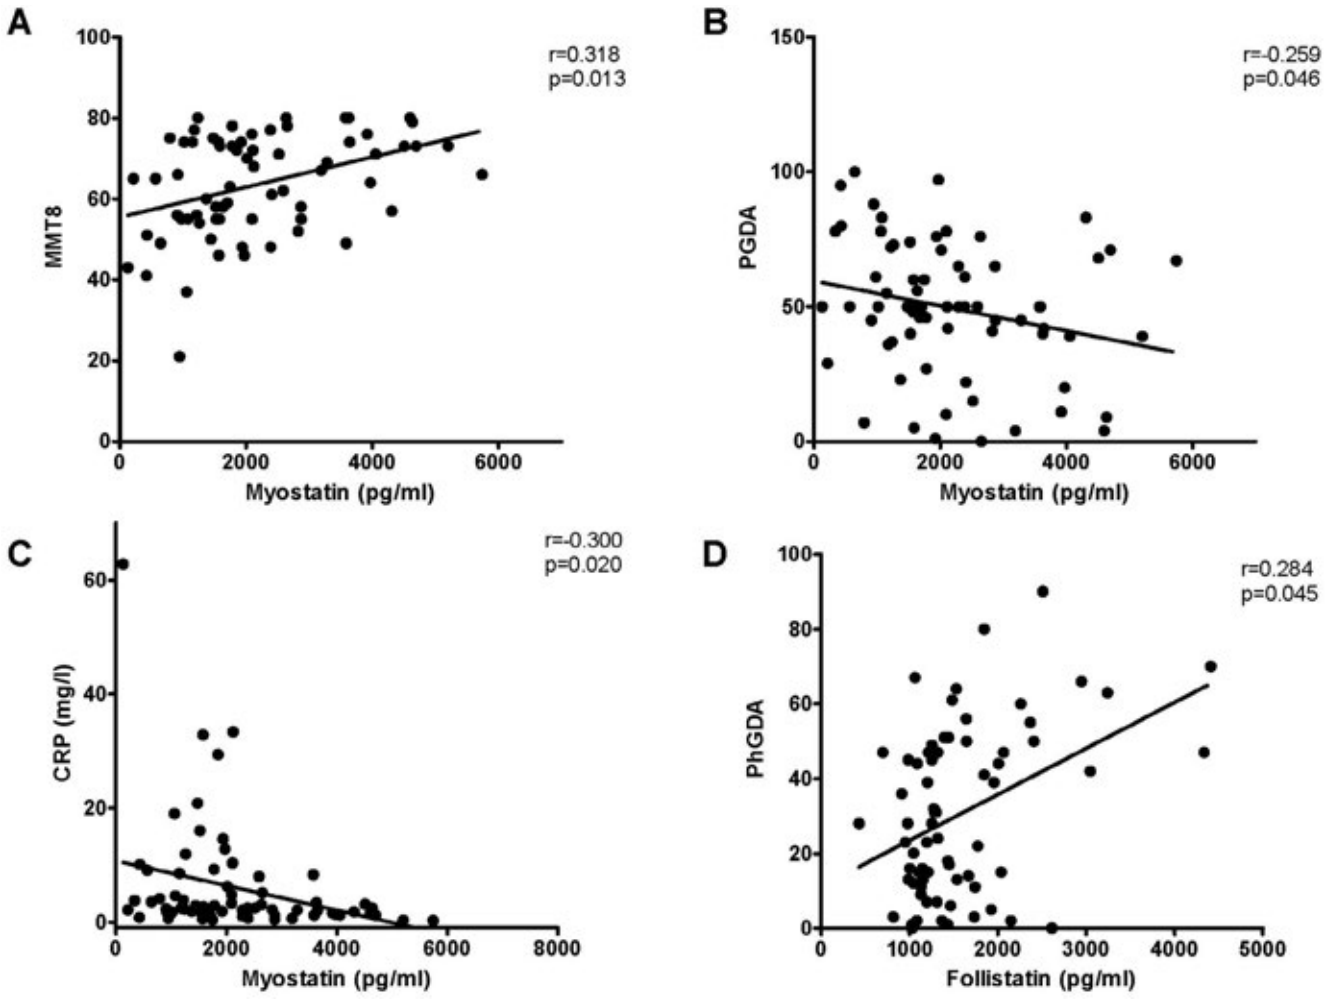

Figure 2_revised

The associations of serum myostatin (A, B, C) and follistatin (D) levels with clinical parameters in IIM patients. Correlation coefficients and significance levels displayed in scatterplots were calculated by partial correlation analysis with correction for age, BMI and glucocorticoid dose. MMT8 - Manual muscle testing of 8 muscles; PGDA - Patient's global assessment of disease activity; CRP - C-reakctive protein; PhGDA - Physician's global assessment of disease activity.

Lurie Children's Hospital of Chicago, Chicago, IL, [5]University of Milwaukee, Milwaukee, WI, [6]Washington University at St.Louis, St.Louis, MO

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile Dermatomyositis (JDM) is a rare inflammatory myopathy in which the immunoregulatory control is not well understood. Collaboration with A.R. French, MD/PhD, documented the hypophosphorylation of phophplipaseCγ2 in Natural Killer (NK-CD3-CD16/56+) cells from untreated JDM (JCI Insight 123236, 2018). This investigation evaluates JDM skin, muscle and blood for the presence of Otoferlin. Otoferlin is a member of the dysferlin family, and has strong Ca^{+2} binding ability in its C2 domain. Among other potential targets, NK cells utilize calcium flux to discharge their granules which create pores and inflict cellular damage. The goal of this study was to validate the increased Otoferlin levels in JDM tissues and determine the possible association between levels of Otoferlin and NK cells in blood drawn from untreated JDM.

Methods: After obtaining age-appropriate informed consent (IRB# 2008-13457), the JDM child's clinical variables, including age, gender, duration of untreated disease (DUD) and Disease Activity Scores (DAS skin, muscle total), were entered into REDCap. The study had 2 phases: 1) *discovery* by RNASeq of increased tissue based Otoferlin in untreated JDM skin, muscle and blood compared to healthy controls. The RNASeq study also compared healthy children's peripheral blood mononuclear cells (PBMCs) with those from active, untreated JDM (n=11) and 7 samples when the same child was clinically quiescent. Otoferlin levels were determined at both time points by qRT-PCR; 2) *validation,* by qRT-PCR of the increased Otoferlin in a larger cohort of 23 untreated JDM PBMCs (2 had no NK values); definite/probable JDM, mean age7.33 (±4.16), 90.5% female, 90.5% white compared with sera from 15 age-gender -matched healthy controls. The data were analyzed by Pearson correlation and student's T test.

Results: These studies confirmed that the 21 untreated active JDM had decreased circulating NKs in 71.4%. NK cell # was inversely associated with increased serum concentrations of Otoferin, p=0.008; Pearson's correlation coefficient=-0.556. The serum levels of Otoferlin were not associated with the age, gender or DUD of the children with JDM, but were highly associated with the DAS-muscle, p=0.0036, but not skin (p=0.94); or total (p=0.10). Otoferlin was increased in PBMCs from untreated active, but not treated inactive JDM, p=0.00056.

Conclusion: Conclusion: We have documented a new component in the pathophysiology of untreated JDM—Otoferlin–which is increased in JDM muscle > PBMCs > controls, and appears to be associated with decreased NKs. Speculation: Otoferlin, perhaps by virtue of its Ca+2 binding capacity and interaction with lipid membranes, may contribute to both NK dysfunction and distribution in untreated children with active JDM.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Dermatomyositis (DM) is conventionally characterized by interface dermatitis (ID) on skin histopathology. A subset of patients with clinically diagnosed DM have skin biopsies showing spongiotic dermatitis (SD), a histopathology more commonly seen in eczema. Diagnosis of DM is challenging, with significant delays following initial presentation. Our goals were as follows: 1) to identify the percentage of clinically diagnosed DM patients with skin biopsies showing SD, 2) to identify cytokine and cell markers that can determine if a skin biopsy showing SD is consistent with DM in a patient with clinical DM.

Methods: Biopsies from 10 DM patients with SD histopathology (DM-SD) were compared to biopsies from 10 healthy controls, 10 patients with eczema, and 12 DM patients with ID histopathology (DM-ID). Skin biopsies were stained by H&E and by immunohistochemistry for MxA, IFN-β, CD11c (mDC), and BDCA2 (pDC). Mucin expression was assessed using Hale's iron colloidal stain. Cytokines and mucin were quantified as area percent and mean intensity. Cells were quantified as mean number of cells per high power field. Fisher's exact test was used to compare baseline patient characteristics. One-way ANOVA with Bonferroni's multiple comparison test was used to compare protein expression between groups.

Results: 11 of 164 (6.7%) patients with a clinical diagnosis of DM at our tertiary care center were identified as having SD. MxA, IFN-β, CD11c (mDC), and BDCA2 (pDC) protein expression was significantly higher in DM-SD compared to eczema ($p < 0.01$) and healthy controls ($p < 0.0001$) (Fig. 1, 2). Expression of MxA, IFN-β, and BDCA2 were not significantly different between DM-SD and DM-ID (Fig. 1, 2). Eosinophils identified on H&E were not significantly dif-

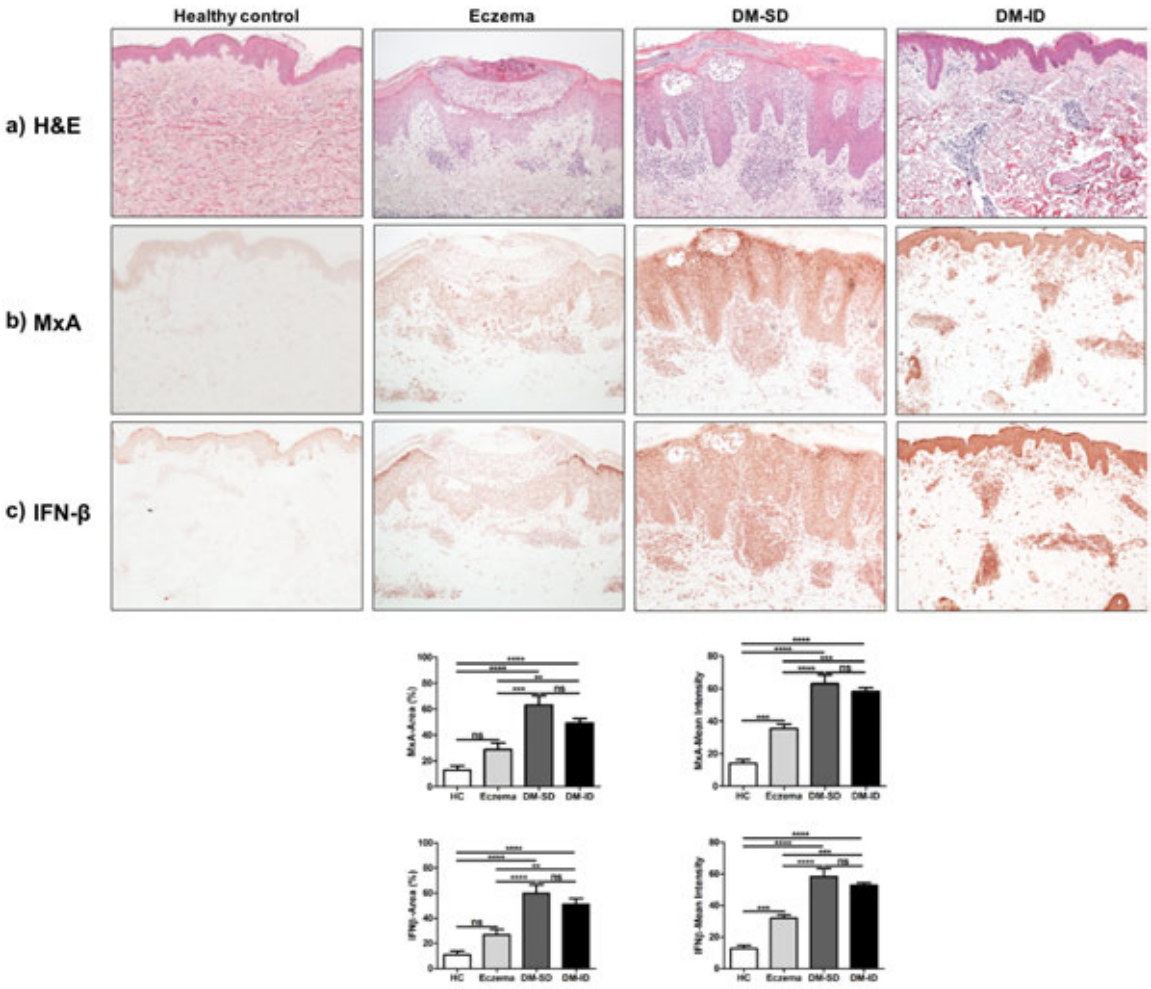

Figure 1. Comparison of skin biopsies from healthy controls, and patients with eczema, DM-SD, and DM-ID. a) H&E stain; b) MxA immunohistochemical protein expression; and c) IFN-b–β immunohistochemical protein expression. Note: All images at 10x objective magnification. Area and intensity values represent both epidermis and dermis. Data are displayed as group mean ± SEM.

ferent between DM-SD and eczema patients, although both were significantly higher compared to healthy controls and DM-ID ($p < 0.01$) (Fig. 2). Mucin was not significantly different between eczema, DM-SD, and DM-ID, although all were significantly elevated compared to healthy controls ($p < 0.0001$).

Conclusion: MxA, IFN-β, CD11c (mDC), and BDCA2 (pDC) protein expression were significantly higher in DM-SD compared to eczema skin lesions. These markers can therefore be helpful to distinguish between DM-SD versus eczema.

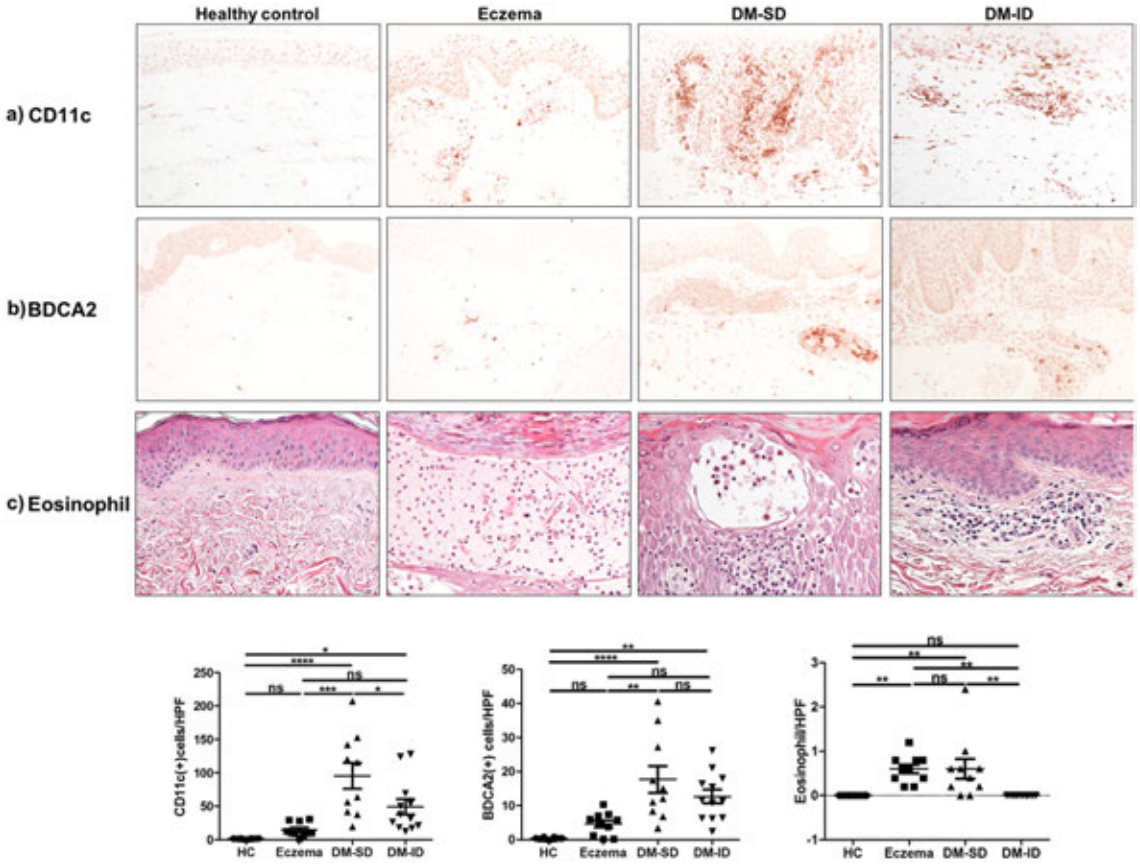

Figure 2. Comparison of cell types in skin biopsies from healthy controls, and patients with eczema, DM-SD, and DM-ID. a) CD11c immunohistochemical protein expression; b) BDCA2 immunohistochemical protein expression; c) Eosinophils on H&E 40x stain. Note: All other images at 10x objective magnification. CD11c is a marker for myeloid dendritic cells and BDCA2 is a marker for plasmacytoid dendritic cells. Data are displayed as group mean ± SEM.

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Muscle Biology, Myositis & Myopathies Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Heat shock proteins (Hsps) are chaperones playing important roles in skeletal muscle physiology, adaptation to exercise or stress, and activation of inflammatory cells.

The aim of our study was to assess Hsp90 expression in muscle biopsies and plasma of patients with idiopathic inflammatory myopathies (IIM) and to characterize its association with IIM-related features.

Methods: Total of 277 patients with IIM (198 females; mean age 54.8; disease duration 4.1 years; dermatomyositis (DM, 104)/polymyositis (PM, 108)/cancer associated myositis (CAM, 31)/ necrotizing myopathy (IMNM, 25) and 157 healthy individuals (92 females; mean age 47.0) were included in plasma analysis. Muscle biopsy samples (PM, DM, IMNM, myodystrophy, myasthenia gravis) were stained for Hsp90α (Thermo Fisher Scientific, USA) and Hsp90β (Abcam, UK). Plasma Hsp90 was measured by ELISA kit (eBioscience, Vienna, Austria). The cytokines were performed using Bio-Plex Pro™ human Cytokine 27-plex Assay (BIO-RAD, California, USA .Data are presented as median.

Results: In muscle biopsies, Hsp90 expression of both subunits was higher in IIM than in controls. Increased Hsp90 was detected in perifascicular degenerating and regenerating fibers, inflammatory cells (DM, PM), and necrotic and regenerating fibers (IMNM). Plasma Hsp90 levels were increased in IIM patients compared to healthy controls ($p< 0.0001$), and in individual subgroups of IIM vs. healthy controls ($p< 0.0001$ for all) (Tab1). When adjusted for age and sex, these differences remained still significant ($p< 0.0001$). Hsp90 was higher in males compared to females ($p=0.040$) and in patients with ILD ($p=0.003$), with cardiac involvement ($p=0.004$), with dysphagia ($p=0.018$) and with presence of anti-Ro52 autoantibodies ($p=0.036$) (Tab2). Hsp90 levels in all patients positively correlated with muscle enzymes (Tab.3). Increased Hsp90 was associated with disease activity and skeletal muscle involvement (Tab.3). Interestingly, out of all clinical parameters listed in above-mentioned univariate analysis, in multiple regression analysis Hsp90 levels in IIM patients were significantly affected by muscle enzymes only ($p< 0.0001$, $\beta=0.345$). Furthermore, Hsp90 positively correlated with some crucial cytokines involved in pathogenesis of myositis (Tab.3).

Conclusion: We demonstrate increased Hsp90 expression in IIM muscle biopsy samples, specifically in inflammatory cells, degenerating, regenerating and/or necrotic fibers. Increased Hsp90 plasma levels in IIM patients are associated with disease activity and damage, and with the involvement of proximal skeletal muscles, heart and lungs.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

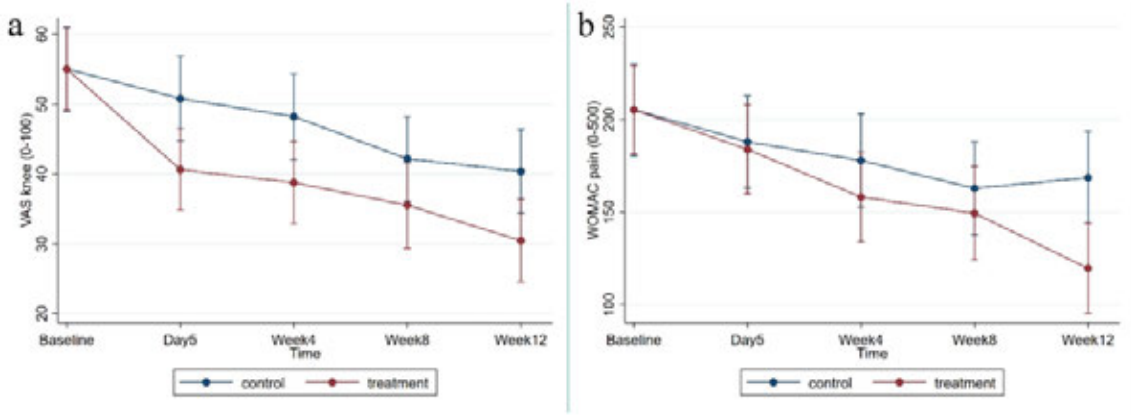

Figure 1. Change in knee pain over 12 weeks in the treatment and placebo groups a) VAS Pain; b) WOMAC pain

Background/Purpose: Pharmacological therapies are limited, associated with off-target effects, are frequently contraindicated, and only modestly effective for pain in osteoarthritis (OA). Effusion and synovitis are common in OA and are associated with symptomatic and structural progression of OA. *Curcuma longa* (Turmeric) extract has anti-inflammatory effects and is gaining popularity in the treatment of OA despite the lack of high-quality evidence. The CurKOA trial aimed to compare the efficacy of *Curcuma longa* extract versus identical placebo for treating knee pain and effusion-synovitis in an inflammatory phenotype of OA identified using ultrasound scan.

Methods: In this double-blind trial, we randomised 70 participants with significant knee pain (≥40 mm knee pain on visual analogue score [VAS] scale), knee OA (ACR clinical criteria) and presence of a moderate amount of ultrasound-defined effusion/synovitis (≥4 mm thickness in the suprapatellar region) to receive *Curcuma longa* extract (80% Turmerosaccharides and 20% Curcumin extract, 2x500 mg capsules/day) (n=36) or identical placebo (n=34) for 12 weeks. The primary outcome measures were change in knee pain (assessed by VAS) and MRI-defined effusion-synovitis volume over 12 weeks. Secondary outcomes included changes in knee pain and function (WOMAC), OARSI-OMERACT treatment responders and change in T2 relaxation time (milliseconds, ms) of the cartilage. Linear mixed-effects models were used, with adjustment for baseline values of the outcome measure.

Results: Of the 112 participants screened, a total of 70 participants (age 61.8±8.6 years, 56% female) were randomised, and 68 (97%) completed the 12 week assessments.

Primary outcomes: There was a reduction in VAS knee pain in the treatment (-23.75 [-29.78 to -17.73]) and placebo (-14.64 [-20.80 to -8.47]) group, with a significant between-group difference of -9.11mm [-17.79 to -0.44] (Figure 1a) equivalent to a standard effect size of 0.49. There was a reduction in the MRI assessed effusion-synovitis volume in the treatment (-2.38 mL [-4.09 to -0.68]) and placebo (-3.63 mL [-5.39 to -1.88]) group, with no significant between-group difference (1.25 mL [-1.21 to 3.72]).

Secondary outcomes: Significant changes favouring the treatment group were seen in WOMAC knee pain (between-group difference: -47.22 [-81.22 to -13.22]) (Figure 1b), WOMAC function (between-group difference: -112.26 [-222.79 to -1.74]) and OARSI-OMERACT treatment responders (63% in the treatment group and 38% in the placebo group [Risk Ratio, RR=1.64 (1.00 to 2.70)]. No significant change in T2 relaxation time of the femoral cartilage (average values of T2 relaxation time between group difference -0.38 ms [-1.10 to 0.34]) was seen. The number of adverse

events was similar in the treatment (n=18) and placebo (n=29) groups, and there were no adverse events related to the treatment.

Conclusion: *Curcuma longa* extract significantly improved knee pain in an inflammatory phenotype of knee OA patients over 12 weeks. There was a moderate standard effect size of the treatment which appears greater than other conventional pharmacological therapies. In this short term study, *Curcuma longa* extract had no effect on knee structural measures assessed using MRI.

Clinical Significance of Magnetic Resonance Imaging Derived Femur Bone Shape in Young Adults

Minh-Tu Vo,[1] Michael Bowes,[2] Alison Venn,[3] Flavia Cicuttini,[4] Lyn March,[5] Terence Dwyer,[6] Tao Meng,[3] Marita Cross,[5] Graeme Jones,[7] Saliu Balogun,[1] Changhai Ding,[7] and **Benny Antony**[7], [1]University of Tasmania, Hobart, Tasmania, Australia, [2]Imorphics, Manchester, England, United Kingdom, [3]University of Tasmania, Hobart, Australia, [4]Monash University, Melbourne, Australia, [5]University of Sydney, Sydney, Australia, [6]University of Oxford, Oxford, United Kingdom, [7]Menzies Institute for Medical Research, University of Tasmania, Hobart, Australia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The femur bone shape derived from magnetic resonance imaging (MRI) of the knee is associated with the incidence and progression of knee osteoarthritis (OA), and predicts total knee replacement in older adults. However, the clinical significance of the femur bone shape has not been studied in a population-based young adult sample. This study aims to describe whether three-dimensional (3D) femur bone shape derived from knee MRI is associated with knee symptoms in young adults.

Methods: Participants (n = 180, age 31 to 41 years) were selected from the Childhood Determinants of Adult Health (CDAH) Knee Cartilage Study, which was a follow-up of the CDAH study. Participants' knee symptoms were assessed using the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) questionnaires, and participants underwent a 1.5T MRI scan of their knee. T1-weighted, fat suppressed, 3D SPGR MRI sequences were segmented with an active appearance model (AAM) previously constructed and validated in an Osteoarthritis Initiative study. The femur bone shape found by AAM is projected orthogonally onto a femur shape vector to obtain a vector score. The femur shape vector defined 0 as the average healthy femur shape and higher values in the positive direction portray more likeness to OA with each unit representing one standard deviation. Logistic regressions were used to describe the associations between the highest quartile of femur shape vectors (OA-like shape) with demographic factors and WOMAC knee symptoms.

Results: Participants had a mean age of 35.5±2.8 years, mean BMI of 25.1±4.1 kg/m^2, were 51% male and largely asymptomatic (34% with any knee pain). The highest quartile of femur vector scores–the group considered to have

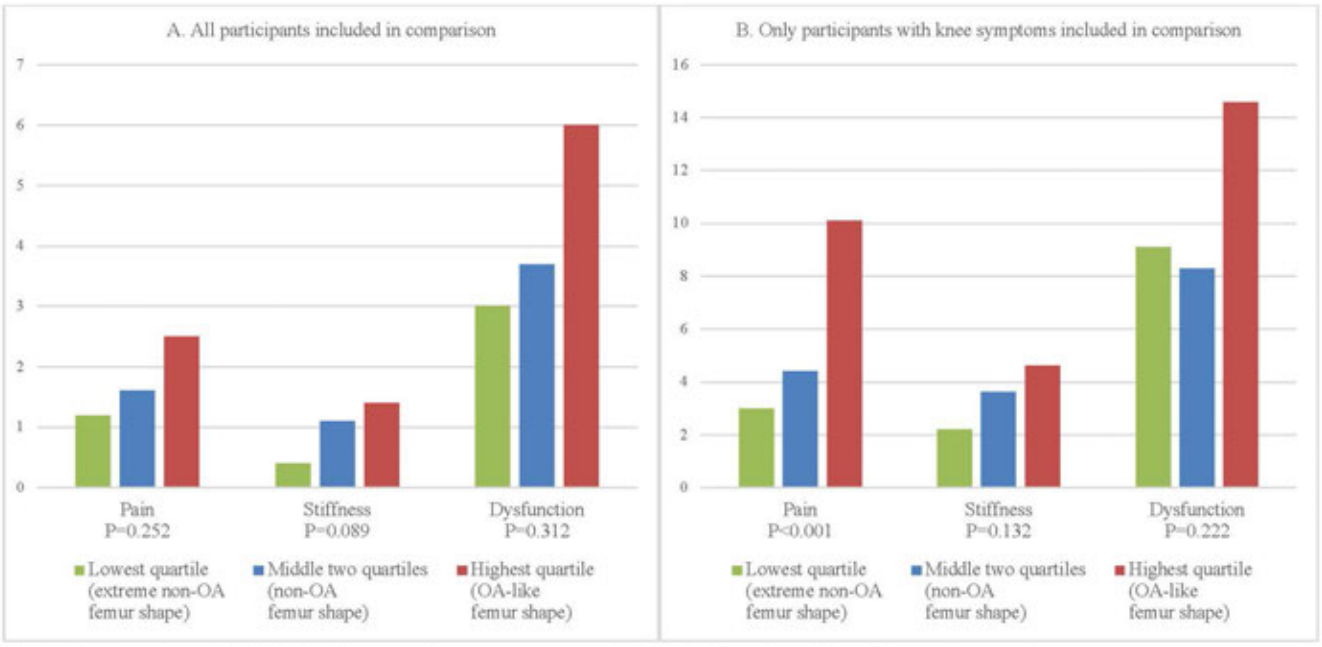

Figure 1. Comparisons of WOMAC knee symptoms among young adults in different quartiles of femur shape vector scores

*** bar graphs show the average total WOMAC pain, stiffness and dysfunction scores for each group**

an OA-like femur shape–had vector scores higher than +0.40. OA-like femur shape was not associated with age (OR 0.96, 95% CI 0.85 to 1.09), gender (OR 1.93, 95% CI 0.95 to 3.93), or body-mass index (OR 1.05, 95% CI 0.97 to 1.14). There was no association between OA-like femur shape and total WOMAC pain (OR 1.06, 95% CI 0.97 to 1.15), total WOMAC stiffness (OR 1.08, 95% CI 0.93 to 1.25) and total WOMAC dysfunction (OR 1.02, 95% CI 0.98 to 1.06) (Figure 1A). However, in symptomatic young adults, OA-like femur shape was associated with higher knee pain scores (OR 1.33, 95% CI 1.07 to 1.66) (Figure 1B).

Conclusion: OA-like femur bone shape is not associated with knee symptoms in population-based young adults. However, OA-like femur bone shape is associated with higher pain scores in young adults experiencing any knee pain.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) in hands is common in middle-aged and elderly population. The mainstay treatment of hand OA is to control the symptoms with a combination of non-pharmacological and pharmacological interventions. Prior randomized clinical placebo-controlled trials (RCT) involving patients with hand OA showed that placebo itself significantly improved pain in those patients. The objective of this post hoc analysis was to identify the factors associated with good placebo response in patients with hand OA.

Methods: This post hoc analysis of two double-blind, placebo-controlled, randomized trials investigating efficacy of GCSB-5 or diacerein in hand OA analyzed the efficacy of the placebo in patients with hand OA. The efficacy endpoints included the changes at baseline and 4 weeks for the following variables: AUSCAN (Australian/Canadian

Osteoarthritis Hand Index) pain score (0–100), AUSCAN stiffness score (0–100), AUSCAN function score (0–100), patient global assessment (0–100), physician global assessment (0–100). A clinically meaningful improvement in pain was defined as an improvement in AUCAN pain of 10 (0-100) or more.

Results: In RCT 1, the mean improvement in AUSCAN pain was -6.0 ± 19.7. However, the placebo-response varied markedly between the OA patients (range -76.4 to 33.2) from baseline. Clinically meaningful improvement in pain was observed in 37 (36.3%) patients. Patients with worse AUSCAN pain (44.9 ± 19.8 vs. 53.1 ± 19.0, p=0.044) and physician global assessment (38.9 ± 11.4 vs. 44.6 ± 14.8, p=0.031) at baseline was associated with clinical meaningful improvement. Structural joint changes such as tender, swollen, enlarged or deformed joint counts did not differ between placebo responders and non-responders. Pain improvement correlated with the respective pain level at baseline (r=0.155, p< 0.001). In a validation study with RCT 2, patients showed a similar placebo response. Improvement in pain, stiffness and function correlated with their respective baseline value in RCT 2 as well.

Conclusion: This post hoc analysis of two prospective, double-blind, randomized, placebo-controlled studies showed that clinically meaningful response to placebo was observed in up to one third of patients with hand OA. This positive placebo response was associated with high pain level at baseline. Further researches are needed to optimize and utilize the benefit of placebo response in OA.

Figure 1

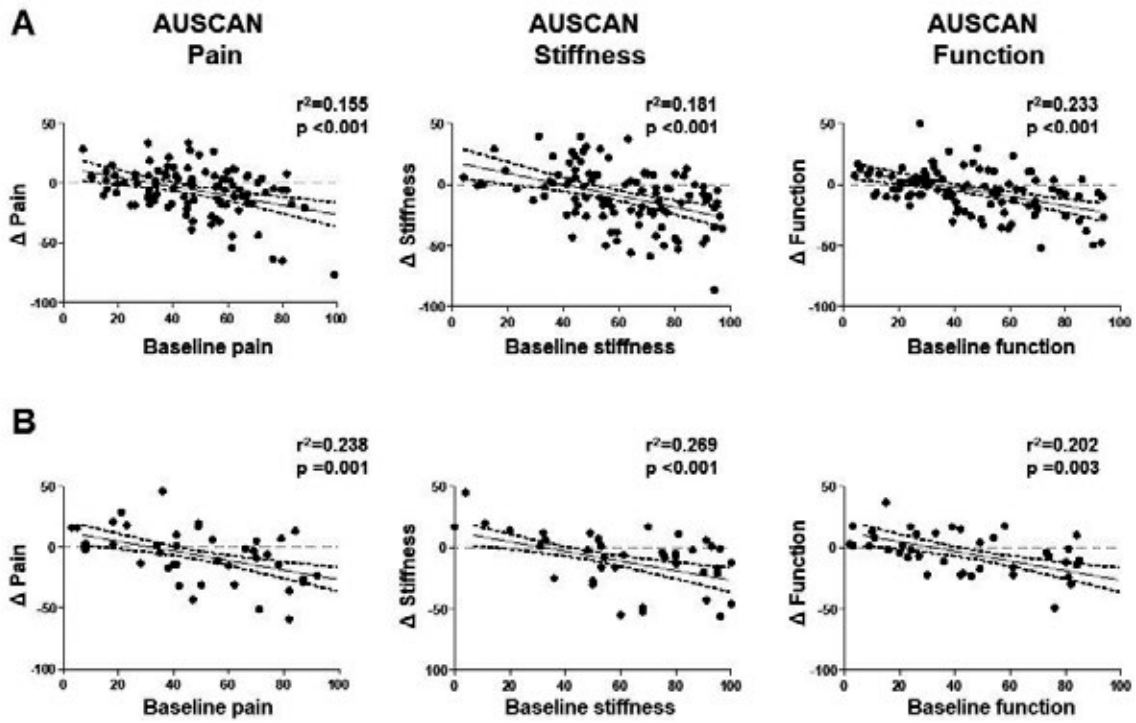

Figure 1. Correlation between pain, stiffness and function at baseline and placebo response in patients with hand osteoarthritis in RTC 1 (A) and RTC 2 (B). Correlation was examined using Pearson correlation.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have suggested differences in the development of incident radiographic knee osteoarthritis (RKOA) and the receipt of knee replacement (KR) by sex and race. We now have the opportunity to compare outcomes from three of the largest and most diverse osteoarthritis cohorts, that is, the Osteoarthritis Initiative (OAI), the Multicenter Osteoarthritis Study (MOST) and the Johnston County Osteoarthritis Project (JoCo OA). Our objective was to describe sex- and race-specific rates of incident RKOA and KR in OAI, MOST and JoCo OA.

Methods: Participants from OAI, MOST and JoCo OA with knees at risk of developing incident ROA (i.e., Kellgren-Lawrence Grade [KLG] 0 or 1 at baseline) or knees at risk for KR (KL 0 to 4 at baseline) were eligible for inclusion. Participants in all three cohorts underwent bilateral posteroanterior fixed-flexion weight-bearing knee radiographs with similar acquisition protocols. RKOA was defined as KLG ≥ 2. KR (i.e., total or partial) was verified by operative

Table 1. Baseline Characteristics, Rates of Incident RKOA and KR

	OAI (n=4796)	MOST (n=3026)	JoCo OA (n=3288)
Mean age (SD, range), years	61.2 (9.2) 45-79	62.5 (8.11) 50–79	62.1(9.0) 45-89

Crude Rate of KR per 1000 knee-years (95% CI)			
White women	12 (10 - 13)	16 (14 – 18)	5 (3 – 7)
AA women	8 (5 - 11)	9 (6 – 14)	7 (5 – 11)
White men	10 (9 - 12)	11 (9 – 13)	3 (1 – 5)
AA men	6 (4 - 11)	2 (0.8 – 4.9)	1 (0 – 5)

reports or on a subsequent knee x-ray. We used Poisson regression with ln(time) offset and robust standard errors to estimate rates of incident RKOA and rates of KR, adjusted for age and BMI.

Results: Baseline characteristics and results are summarized in Table 1. The baseline characteristics were similar between OAI (n=4796) and MOST (n=3026). JoCo OA (n=3288) had a larger proportion of women, African Americans (AA), and milder disease (i.e., proportionately more KLG 1 at baseline) due to its population-based nature. The sex- and race-specific rates of incident RKOA were comparable in JoCo OA, whereas rates of incident RKOA were notably higher among women, and particularly AA women, compared to men in OAI and MOST. KR rates were higher for white men and women in OAI and MOST; overall rates of KR were lower in JoCo OA, but AA women had the highest rates in that cohort.

Conclusion: These preliminary results represent the first step in harmonizing data across three large, diverse, longitudinal OA cohort studies and will allow direct comparison across these cohorts in the future. These data point to potential regional differences in incident RKOA and KR by sex and race, or to potential differences in enrollment criteria across the three cohorts. Future work will include pooling data from these cohorts, taking advantage of the substantial number of AAs, to allow for direct comparisons and the investigation of underlying risk factors that may explain differences in the rates of incident RKOA and KR, as well as other outcomes.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tanezumab is a monoclonal antibody that inhibits nerve growth factor and is under investigation for chronic pain treatment. Tanezumab administered intravenously was effective and generally well tolerated in prior osteoarthritis (OA) studies. In patients (pts) with OA and moderate-severe pain taking oral nonsteroidal anti-inflammatory drugs (NSAID), we assessed the efficacy and general safety/tolerability of switching to subcutaneous (SC) tanezumab vs further treatment with oral NSAID. (Adjudicated joint safety events are reported in a separate abstract.)

Methods: Eligible pts had hip or knee OA based on ACR criteria with x-ray confirmation; baseline (BL) WOMAC Pain and Physical Function subscale scores of ≥5 (11-pt numerical rating scale); BL Patient's Global Assessment of OA

(PGA-OA) of "fair," "poor," or "very poor"; history of inadequate pain relief with acetaminophen; inadequate pain relief with/intolerance to tramadol or an opioid; or unwillingness to take an opioid. Pts were on a stable dose of oral NSAID before study entry and during the 1-mo screening period. Pts were randomized to receive tanezumab (2.5 mg or 5 mg SC every 8 wk) or NSAID (naproxen 500 mg, celecoxib 100 mg, or diclofenac ER 75 mg orally bid) over the 56-wk treatment period. Co-primary efficacy endpoints were change from BL to wk 16 in WOMAC Pain, WOMAC Physical Function, and PGA-OA scores. The key secondary efficacy endpoint was the proportion of pts with ≥50% reduction in WOMAC Pain score at wk 16. Efficacy endpoints were also assessed at wk 56. Safety monitoring included treatment-emergent adverse events (TEAEs) during the 56-wk treatment period and 24-wk safety period.

Results: Of 3,021 randomized pts, 2,996 were included in both the efficacy and safety analyses. A total of 1,312 completed the treatment period (NSAID, n=446 [45%]; tanezumab 2.5 mg, n=447 [45%]; and tanezumab 5 mg, n=419 [42%]) and 2,227 completed the safety period (n=757 [76%]; n=741 [74%]; and n=729 [73%], respectively). At BL, mean age was 60.3-61.2 y; OA duration, 8.5-9.1 y; 64-66% were female; and for 85-86%, the knee was the OA index joint. At wk 16, pts receiving tanezumab 5 mg had statistically significant improvement in WOMAC Pain and WOMAC Physical Function compared with pts receiving NSAID, but not in PGA-OA (Table 1). Improvement in co-primary endpoints with tanezumab 2.5 mg was not significantly different than that with NSAID at wk 16. At wk 56, neither tanezumab dose was significantly different than NSAID. The incidence of TEAEs overall and serious TEAEs was greatest with tanezumab 5 mg and similar between tanezumab 2.5 mg and NSAID (Table 2). Eight deaths occurred in tanezumab-treated pts and none in NSAID-treated pts; the investigators did not consider any deaths to be treatment-related.

Conclusion: In pts with hip or knee OA and moderate-severe pain despite NSAID therapy, pts who switched from NSAID to tanezumab 5 mg SC had greater improvement in OA pain and physical function, but not PGA-OA, at wk 16 than pts who continued NSAID therapy. Differences in efficacy endpoints between tanezumab 2.5 mg SC and NSAID

Co-primary Efficacy Endpoint*	NSAID (n=996)	Tanezumab 2.5 mg (n=1,002)	Tanezumab 5 mg (n=998)

Intra-Articular TPX-100 Significantly Delays Pathological Bone Shape Change at 6 and 12 Months in Moderate to Severe Tibiofemoral OA

Dawn McGuire,[1] Michael Bowes,[2] Alan Brett,[2] Neil Segal,[3] Meghan Miller,[4] David Rosen,[4] and Yoshinari Kumagai[4], [1]OrthoTrophix, Orinda, CA, [2]Imorphics, Manchester, England, United Kingdom, [3]University of Kansas Medical Center, Kansas City, KS, [4]OrthoTrophix, Oakland, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pathological bone shape changes in the femur precede cartilage changes in knee OA and predict disease onset and progression to joint failure (Neogi 2013; Barr 2016). As reported previously, TPX-100-1, a randomized, double-blind, placebo-controlled, 12-month trial of IA TPX-100 in subjects with bilateral, mild-moderate (ICRS grades 2-3) patellofemoral OA, demonstrated statistically significant and clinically meaningful improvements in knee physical function (KOOS/WOMAC scales) in TPX-100-treated knees compared to placebo-exposed knees at 6 and 12 months (McGuire 2017). On quantitative MRI, only 14% of knees had measurable patella cartilage thickness changes, with no treatment differences demonstrated in this primary structural outcome measure. Post-hoc analyses

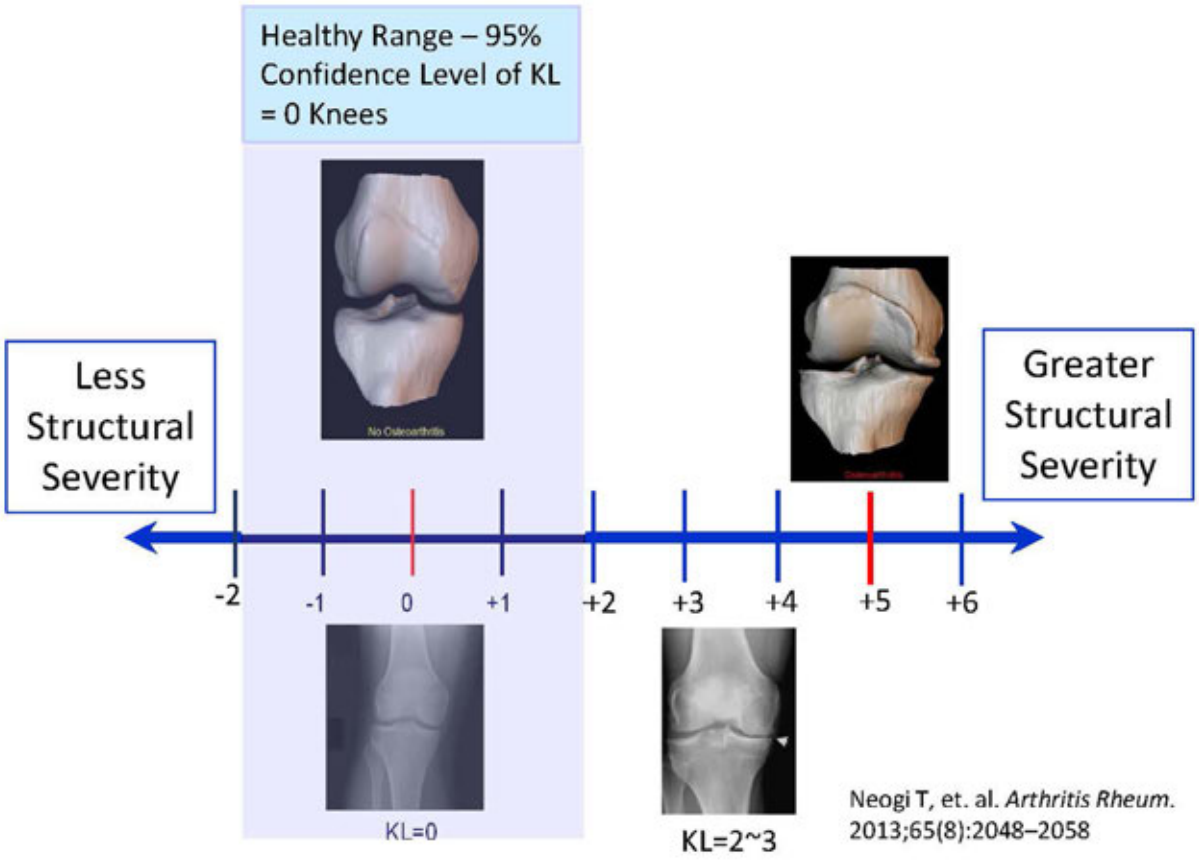

Figure 1. Three Dimensional Bone Shape: B Score

McGuire_Femur Bone Shape_ Figure 1

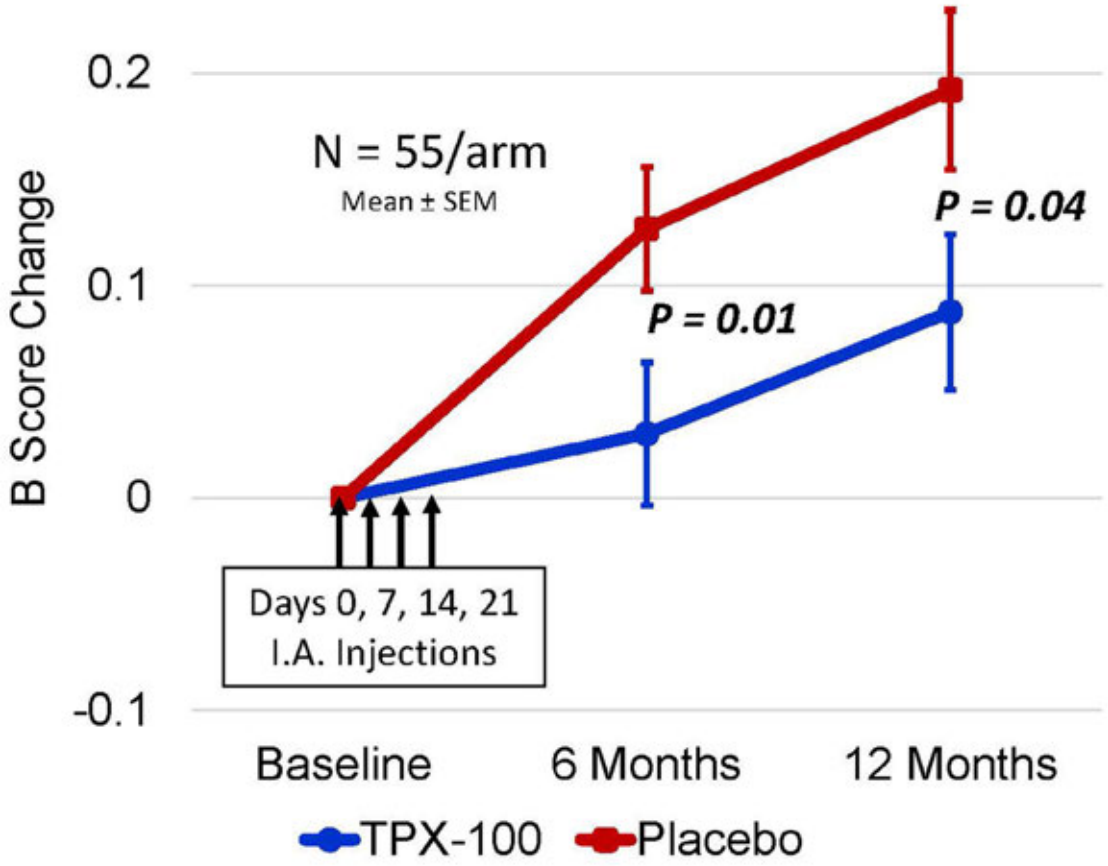

Figure 2. TPX-100 Significantly Delayed Pathological Bone Shape Change in Femur

McGuire_Femur Bone Shape_ Figure 2

revealed that 68 (73%) of these subjects also had moderate to severe (ICRS 2-4) bilateral tibiofemoral OA (TFOA), in whom similar significant clinical benefits in favor of TPX-100 were demonstrated (McGuire 2018). Study TPX-100-5 was designed to investigate MRI-based femoral bone shape changes in TPX-100-treated knees compared with placebo knees in subjects with bilateral moderate-severe TFOA at baseline.

Methods: Bone shape changes from baseline to 6 and 12 months were analyzed by an automated method (Imorphics, Inc.) blind to treatment assignment, clinical and cartilage imaging results. Sufficient MRI image quality allowed analysis of bone shape changes in 55 of 68 subjects (81%) using active appearance model (AAM), a form of statistical shape analysis that can be used to discriminate OA versus non-OA shapes. Computed “B-Scores” range from -2 (‘non-OA’) to +6 (‘severe OA’) (Fig 1).

Results: MRIs of 110 knees from 55 subjects were analyzed. Of these, ≥91% had moderately-severe or severe (ICRS Grade 3 or 4) TFOA at baseline, equally distributed between TPX-100-treated and placebo-exposed knees. TPX-100-treated knees had significantly less bone shape change at 6 and 12 months (p=0.01 and P=0.04, respectively; Fig 2). Compared with historical controls from the OAI, the trajectory of bone-shape change in TPX-100-treated knees was

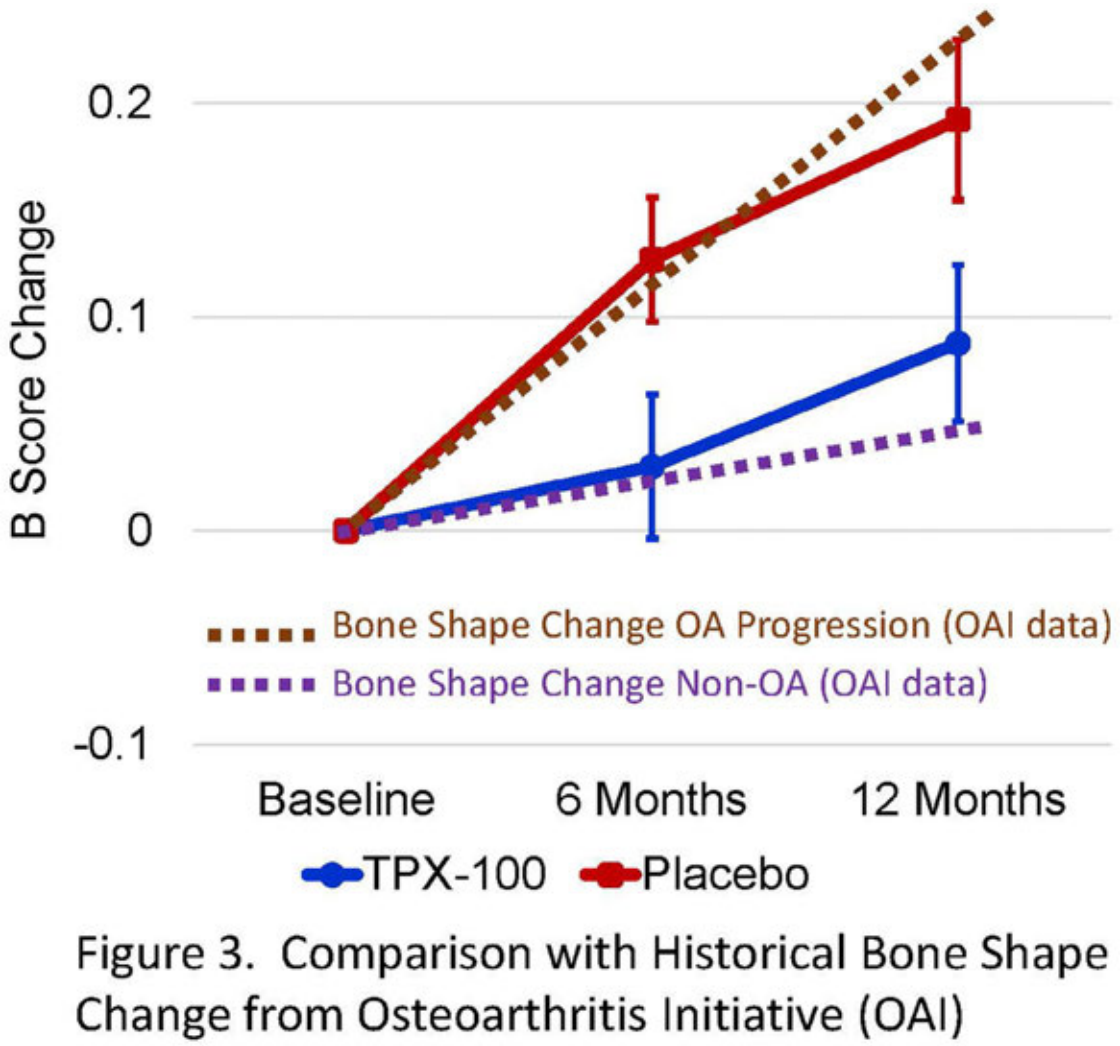

Figure 3. Comparison with Historical Bone Shape Change from Osteoarthritis Initiative (OAI)

McGuire_Femur Bone Shape_Figure 3

similar to that observed in “non-OA” knees at 6 months, while that of placebo-exposed knees was similar to that of OA progressors (Fig 3).

Conclusion: Femoral bone shape change is progressive in normal aging and is accelerated in knee OA. Increasing change predicts worsening of symptomatic and radiographic knee OA and joint failure. After a single, 4-injection series (200 mg/injection), TPX-100 treatment in subjects with moderate to severe TFOA was associated with significantly slowed pathological femoral bone-shape change at 6 and 12 months compared with placebo. Delay or stabilization of structural pathology combined with robust and sustained improvement in physical knee function strongly supports further development of IA TPX-100 as a candidate DMOAD.

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

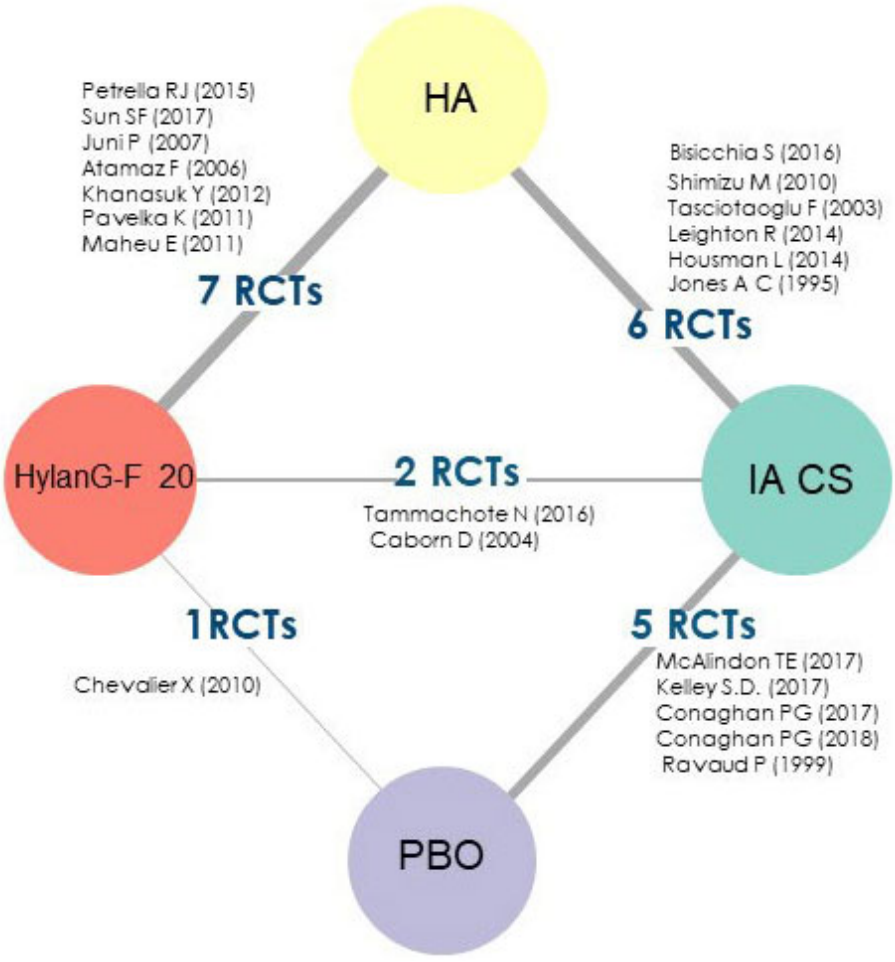

Figure 1. Network diagram for analysis of WOMAC/VAS pain at 6 months

Background/Purpose: Knee OA is a progressive joint disease which affects more than 250 million people worldwide. Meta-analysis (MA) has demonstrated that IA CS were more effective for pain relief than IA HA in the short term (up to 6 weeks) for knee OA. Hylan G-F 20 (Synvisc/Synvisc-One) is a high molecular weight HA indicated for the treatment of knee OA. However, the relative efficacy and safety of Hylan G-F 20 versus IA CS is not well understood due to the lack of head-to-head randomized controlled trials (RCTs). The objective of this research was to better evaluate the clinical efficacy and safety of Hylan G-F 20 versus IA CS in knee OA using both direct (pairwise) MA and network meta-analysis (NMA).

Methods: We systematically searched MEDLINE, Embase, and CENTRAL to identify RCTs on Hylan G-F 20 and IA CS compared to any treatment of knee OA. Two independent reviewers performed the literature review. Relevant study and patient characteristics (including whether ACR criteria were used for the diagnosis of knee OA) and outcome data were extracted. In a direct meta-analysis, we compared Hylan G-F 20 and IA CS using a random-effects model to estimate the pooled standardized mean difference (SMD) or mean difference (MD). In a Bayesian NMA framework, we used a random-effects or fixed-effect model based on the best fit. Efficacy was evaluated at 1, 3, and 6 (+/- 0.5) months (mo); and at the final follow-up for safety outcomes. A pain hierarchy was used to select one outcome from each study: (1) WOMAC pain (2) VAS pain (3) WOMAC, Walking Pain (4) VAS, Pain on Nominated Activity (5) VAS, Walking Pain (6) VAS, Weight-bearing Pain.

Results: Forty-five RCTs (8,047 patients) met the inclusion criteria. Of these, 26 (5,858 patients) used ACR diagnostic criteria, and 2 directly compared Hylan G-F 20 with IA CS. The NMA network consisted of 4 nodes (Hylan G-F 20, other IA HA, IA CS, and IA placebo) (see Figure 1 for an example of the network). In the direct meta-analysis, Hylan G-F 20 was superior to IA CS by 6 months based on the WOMAC index (overall score), SMD (95% Confidence Interval [CrI]): -6.08 (-10.00, -2.17). In the NMA, the analysis of change in WOMAC/VAS pain showed that Hylan G-F 20 may be equivalent to IACS in the short-term, but superior by 6 months, SMD (95% Credible Interval [CrI]): -0.13 (-0.25, -0.01) (See Table 1). In terms of the WOMAC overall score, WOMAC physical function and Lequesne Index, the results were not statistically significant at any timepoint. With regard to safety relative to IA CS, patients treated with Hylan G-F 20 had a estimated higher odds of treatment-related adverse events (AEs) (OR 2.72 [95% CrI]: 0.83, 9.75), but a lower odds of serious AEs (OR 0.53 [95% CrI]: 0.05, 2.53) and injection-site reactions (OR 0.71 [95% CrI]: 0.12, 4.45), even though the differences between the two groups were not statistical significant.

Effect Estimate	WOMAC Overall, 1 mo	WOMAC Overall, 3 mo	WOMAC Overall, 6 mo	WOMAC/VAS Pain, 1 mo	WOMAC/VAS Pain, 3 mo	WOMAC/VAS Pain, 6 mo
SMD (95% CrI)	-0.12 (-0.57, 0.38)	-0.32 (-0.68, 0.043)	-0.48 (-1.07, 0.16)	0.183 (-0.08, 0.43)	-0.126 (-0.41, 0.16)	-0.13 (-0.26, -0.01)*
Comparison	WOMAC Physical Function, 1 mo	WOMAC Physical Function, 3 mo	WOMAC Physical Function, 6 mo	Lequesne Index, 1 mo	Lequesne Index, 3 mo	Lequesne Index, 6 mo
SMD (95% CrI)	-0.45 (-1.3, 0.19)	-0.38 (-0.95, 0.091)	-0.28 (-1, 0.46)	-0.7 (-2.3, 1.0)	-0.15 (-0.2, 0.96)	-0.39 (-1.8, 1.0)
Comparison	Adverse Events	Serious Adverse Events	Treatment-Related Adverse Events	Injection Site Reaction	Study Withdrawal Due to Adverse Events	Study Withdrawal Due to Lack of Efficacy
OR (95% CrI)	1.32 (0.94, 1.93)	0.53 (0.05, 2.53)	2.72 (0.83, 9.75)	0.71 (0.12, 4.45)	0.96 (0.32, 2.82)	0.96 (0.41, 2.12)

Table 1. Summary of the network meta-analysis results (Hylan G-F 20 versus IA CS). Note. Negative SMD values indicate an effect favoring Hylan G-F 20. An OR above 1 favors IA CS. *Statistically significant ($p < 0.05$).

Conclusion: Overall, the results of this analysis suggest that in patients with knee OA, Hylan G-F 20 may be similar to IA CS in improving symptoms in the short term, but superior to IA CS by 6 mo. Both agents were relatively well tolerated, with no clear differences in safety while SAE seem to be more frequent with CS injections.

Quality Improvement in Diagnostic and Therapeutic Arthrocentesis in the Flexed Knee Using Pneumatic Compression of the Suprapatellar Bursa

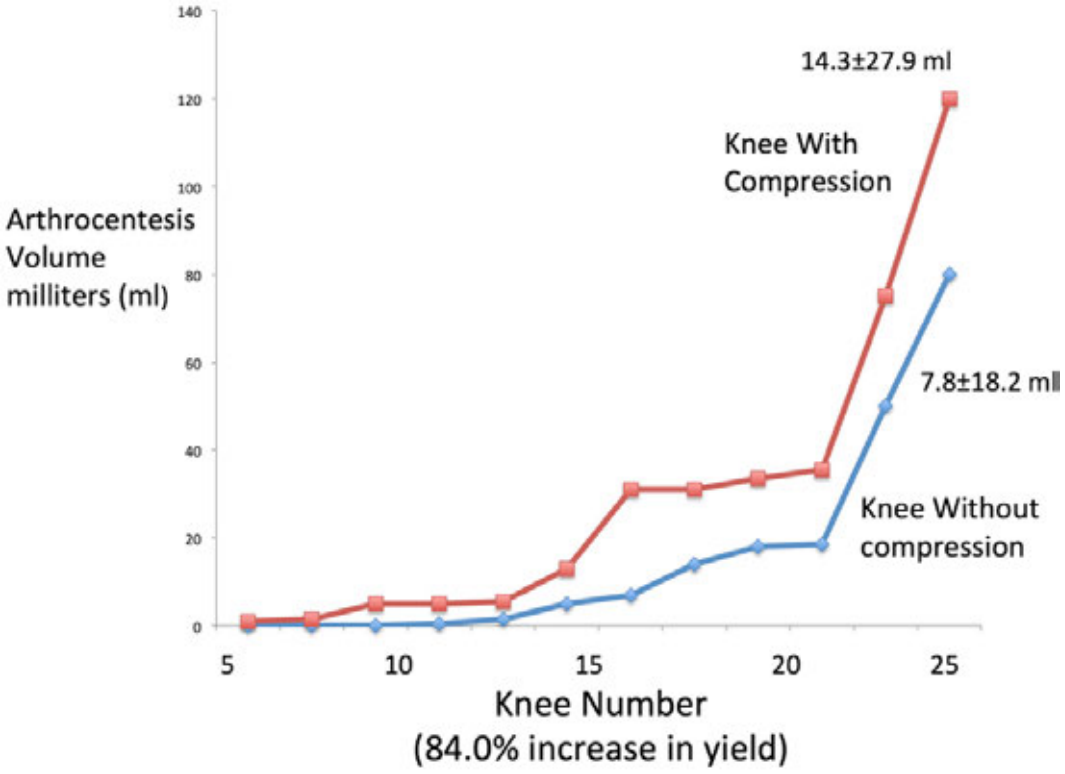
Fatemeh Jafari Farshami,[1] Jaren Trost,[2] Wilmer Sibbitt,[2] Maheswari Muruganandam,[2] Philip Band,[3] Monthida Fangtham,[1] Nicole Emil,[1] William Hayward,[4] Luke Haseler,[5] and Arthur Bankhurst[1], [1]Department of Internal Medicine, Division of Rheumatology and School of Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, [2]Department of Internal Medicine, Division of Rheumatology and School of Medicine, University of New Mexico Health Sciences Center, Albuquerque, [3]Department of Orthopaedic Surgery, Biochemistry & Molecular Pharmacology NYU School of Medicine, New York City, New York City, NY, [4]The Department of Exercise and Sport Sciences, New Mexico Highlands University, Las Vegas, NM, [5]Faculty of Health Sciences, School of Physiotherapy and Exercise Science, Curtin University, Perth, Australia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Arthrocentesis is an essential procedure in diagnosing inflammatory and septic arthritis and is a basic procedure for intra-articular therapy, including therapeutic arthrocentesis and intra-articular injection. Complete arthrocentesis before injection of corticosteroid or hyaluronan confirms the diagnosis, reduces the possibility of superimposed infection, reduces patient pain, and improves response to the injected drug. Meehan et al and others have demonstrated that constant external compression of the knee improves arthrocentesis yield and outcomes. As a quality improvement process, we used a pneumatic compression cuff to apply constant compression to the flexed knee to remove the operator`s hands from potential needlestick, mobilize synovial fluid, and permit more complete arthrocentesis.

Methods: 25 consecutive painful knees (11 OA, 9 OA/RA, 4 RA, 1 RA/septic joint) underwent arthrocentesis performed conventionally and with pneumatic compression. The mean age of the population was 61.3±14.3 years with male:female of 1: 2.1. Pre-procedural pain according to the 10 cm Visual Analogue Pain Scale (VAS) was 8.0±1.2 cm.The quality intervention was designed as a paired study in the same knee: that is, first conventional arthrocentesis in the flexed knee position using the inferolateral approach was performed and quality and outcome measures were obtained. After fluid return ceased, a pneumatic leg cuff, which was placed over the suprapatellar bursa prior to starting the procedure, was inflated to 60 millimeters Hg. Arthrocentesis was then re-attempted, and quality measures were obtained once again.

Arthrocentesis in flexed knee position, using a pneumatic leg cuff



Arthrocentesis yield from the knee with and without pneumatic compression

Results: Procedural pain according to the 10 cm VAS was 3.9±2.8cm and post-procedural pain was 1.0±1.3 cm. In 25 painful knees, conventional arthrocentesis yield was 7.8±18.2 ml and using pneumatic compression was 14.3±27.9 ml, an 84.1% increase (Figure 2). When the 13 effusive knees were analyzed separately, conventional arthrocentesis yield was 18.2±22.7 ml and using pneumatic compression was 27.9±28.6 ml, a 53.3% increase. The mean enhanced arthrocentesis yield reported here with the pneumatic compression in the flexed knee is similar to improved fluid yield that we have reported previously of 16.7±11.3 ml with elastomeric compression of the flexed knee ($p = 0.69$) and both are similar to the 16.9±15.7 ml arthrocentesis yield that was reported in conventional extended knee arthrocentesis ($p = 0.69$) (Yaqub et al 2018).

Conclusion: The technique of constant compression using a pneumatic cuff mobilizes residual synovial fluid and improves arthrocentesis success. The use of a pneumatic leg cuff in the flexed knee is a low-cost quality improvement technique that can readily be incorporated into clinical musculoskeletal practice and is particularly useful for performing arthrocentesis in patients in the sitting position, confined to wheelchairs, or with flexion contractures of the knee. Further, since the pneumatic cuff is spatially superior to the inferolateral portal at the puncture site, errant synovial fluid flows down the leg away from the cuff and does not contaminate the device unlike compression devices used in the extended knee positioning.

Abstract Number: 1306

Risk Factors for Pain After Total Joint Replacement in Osteoarthritis: Different Pain Measures, Distinct Predictors?

Joana Barroso,[1] Kenta Wakaizumi,[2] Thomas Schnitzer,[1] Vasco Galhardo,[3] and Apkar Apkarian[1], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Chicago, IL, [3]Porto University, Porto, Portugal

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Prognostic factors for pain persistence after total joint replacement (TJR) in osteoarthritis (OA) have been repeatedly proposed. These factors are commonly considered to act independently, unrelated to each other, even with regard to the various pain intensity measures used. Here, we purpose that pain outcomes post-TJR relate to different aspects of the pain experience and explore how predictive modeling may lead to different results regarding pain persistence risk factors.

Methods: We conducted a prospective longitudinal study of knee and hip OA patients, assessing multiple measures by questionnaires of quality, mood, affect, health and quality of life, together with radiographic evaluation and performance-based tasks before and 6 months after TJR. These factors were firstly used in a principal component analysis (PCA), thus applying a data reduction technique, and then used to build multivariate regression models (stepwise hierarchical regression: α-to-enter 0.05 and α-to-remove 0.10) for four distinct pain intensity outcomes (NRS, BPI Pain, KOOS pain and SF-36 pain). All pain outcomes were modeled at baseline and post-surgery, both as absolute value and also as score change (% residual pain) for the latest.

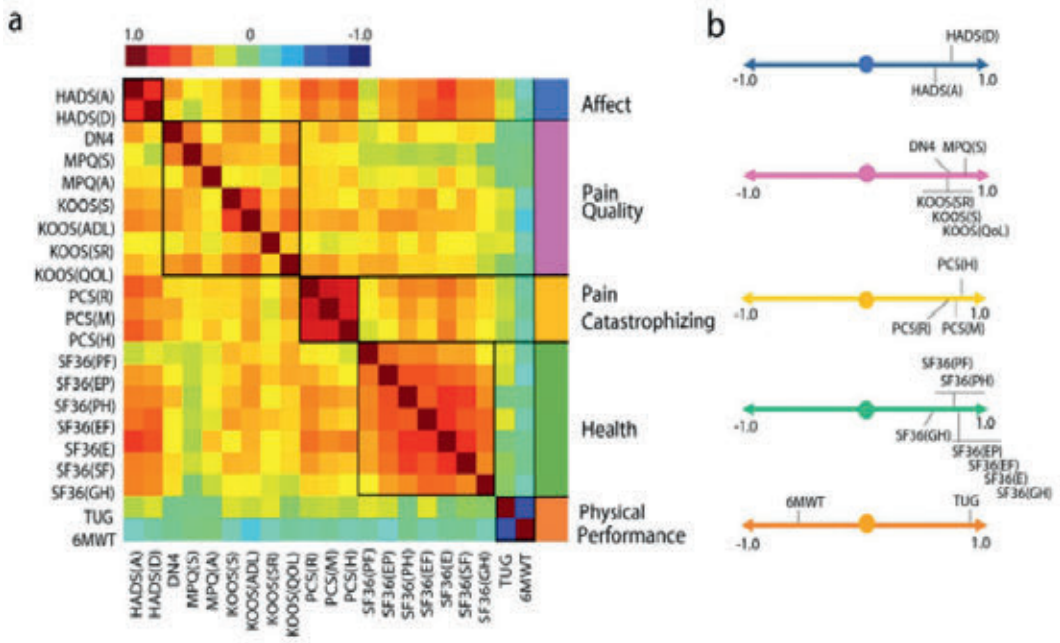

Figure 1. Principal component analysis identified five factors characterizing baseline KOA. a. Correlation matrix ordered based on principal component analysis results (Pearson's r represented by color bar). The five identified components were labeled according to membership properties. b. Factor loadings are shown for the five components. 6MWT, six minute walking test; DN4, The Neuropathic Pain 4 questions; HADS(A), The Hospital Anxiety and Depression Scale, Anxiety; HADS(D), The Hospital Anxiety and Depression Scale, Depression; KOOS, Knee Injury and Osteoarthritis Outcome Score, (ADL – Function in daily living), (S -Knee Symptoms), (SR – Function in sport and recreation), (QOL – knee related quality of life); MPQ, McGill Pain Questionnaire, (A – Affective score) (S – Sensory score); PCS, Pain Catastrophizing Scale, (R – Rumination subscale), (M – Magnification subscale), (H – Helplessness subscale); SF36, Short-form (36) Health Survey, (PF – Physical Functioning), (PH – physical role functioning), (EP – emotional role functioning), (EF – energy/fatigue), (E – emotional well-being), (SF – social functioning), (GH – general health); TUG, Timed -up and go test.

						F(2,92)=50.504

Results: A total of 84 knee OA and 24 hip OA patients completed the study. For the four pain scales, pair-wise comparisons revealed that pain intensity estimates were significantly lower only for BPI pain severity at baseline (mean differences [SD]: NRS: -1.72 [-2.44, -0.99], KOOS/HOOS: -1.436 [-2.158, -0.71], SF36: -2.06 [-2.78, -1.4], p< 0.001) and higher 6 months post-surgery with SF-36 pain (NRS: 1.038 [0.23,1,81], BPI: 1.354 [0.57,2.14], p< 0.003). The PCA for questionnaire variables identified 5 distinct components, accounting for 70% of the variability of the data. These were labeled accordingly to its factor loadings as pain quality, affect, catastrophizing, health and physical performance (Figure 1). Hierarchical models showed pain quality as the common dominant factor accounting for higher pain intensity throughout all scales pre-surgery, with additional

influences for each outcome (Table 1). Different models were elicited for absolute versus relative pain intensity (change in pain vs pre-TJR) after surgery, with the variance explained by each model being overall lower for change in pain. Again, explanatory variables were also distinct considering the four different pain outcome measures (Table 2).

Conclusion: These results demonstrate that different pain scales relate to distinct facts of the pain experience, resulting in defining distinct prognostic factors for persistence of pain post-TJR. These models allow for distinction between post-TJR absolute pain levels vs degree of improvement from the pre-op state. Structured and comprehensive methodological approaches regarding pain metrics are necessary in order to better understand and derive clinical prognostic factors in post-TJR pain.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: This prospective, randomized, multi-center study was conducted to compare pain relief, functional improvement, and the safety of cooled radiofrequency ablation (CRFA) to hyaluronic acid (HA) to treat OA knee pain.

Methods: 177 patients underwent diagnostic block injections and those who had a minimum of 50% pain relief were randomized to receive either CRFA on 4 genicular nerves or a single intraarticular HA injection. 175 patients were treated (n=88 CRFA and 89 HA) and subsequently evaluated for pain (numerical rating system=NRS), function (WOMAC), Global Perceived Effect (GPE), and safety at 1, 3, and 6 months.

Results: The two treatment groups had statistically similar demographics and pain at baseline. One hundred and fifty-eight patients completed 6-months post treatment (n=76 CRFA and 82 HA). In the CRFA group, 71.1%

of patients (95%CI 60.9-81.2) had ≥50% reduction in NRS pain score compared to 37.8% (95%CI 27.3-48.3) in the HA group (p< 0.0001, primary endpoint) (Table 1). The mean NRS was 2.7 ± 2.3 for the CRFA group and 4.5 ± 2.7 for the HA group (p< 0.0001). The mean WOMAC score improvement from baseline was 48.2% in the CRFA group and 22.6% in the HA group (p< 0.0001) (Table 2). At 6 months, 72.4% (55/76) of subjects in the CRFA group reported improvement in Global Perceived Effect compared to 40.2% (33/82) in the HA group (p< 0.0001) (Table 3). No serious adverse events related to either procedure were noted, and overall adverse event profiles were similar.

Conclusion: In this study, CRFA treated patients demonstrated a significant improvement in pain relief and overall function compared to patients treated with HA. Further follow-up from this study will evaluate the long-term durability of cooled RFA in this patient population.

Subject Enrichment Criteria for Phase 3 Studies of Lorecivivint (SM04690), a Potential Disease-Modifying Knee Osteoarthritis Drug: A Post Hoc Study on the Effects of Baseline Comorbid Pain and Joint Space Width on Patient-Reported Outcomes

Sarah Kennedy,[1] Chris Swearingen,[1] **Jeyanesh Tambiah**,[1] Daniel Clauw,[2] and Philip G Conaghan[3], [1]Samumed, LLC, San Diego, [2]Division of Rheumatology, Department of Internal Medicine and Division of Anesthesia, Michigan Medicine, Ann Arbor, MI, [3]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patient-reported outcomes (PROs) in knee osteoarthritis (OA) trials have been difficult to accurately measure due to heterogenous sources of pain (e.g., from comorbid conditions or joint structure damage) which confound subjects' symptom discrimination. To improve the measurement accuracy of changes in PROs due to knee OA treatments, trial inclusion criteria must be optimized. Lorecivivint (LOR) is a CLK/DYRK1A inhibitor that modulates the Wnt pathway and is a potential disease-modifying knee OA drug. A post hoc analysis from a 24-week Phase 2b trial assessed the effects of LOR on PROs in subjects without comorbid pain and with baseline medial joint space width (mJSW) 2-4 mm, limiting JSW heterogeneity. Results from the selected Phase 3 dose of 0.07 mg LOR are reported here.

Methods: Knee OA subjects with KL grades 2-3 and Pain Numeric Rating Scale (NRS, [0-10]) ≥4 and ≤8 in the target knee and < 4 in the contralateral knee received a single, 2mL, IA injection of 0.03 mg, 0.07 mg, 0.15 mg, or 0.23 mg LOR or vehicle placebo (PBO) in the target knee at baseline. Positioned, fixed-flexion radiographs were captured at

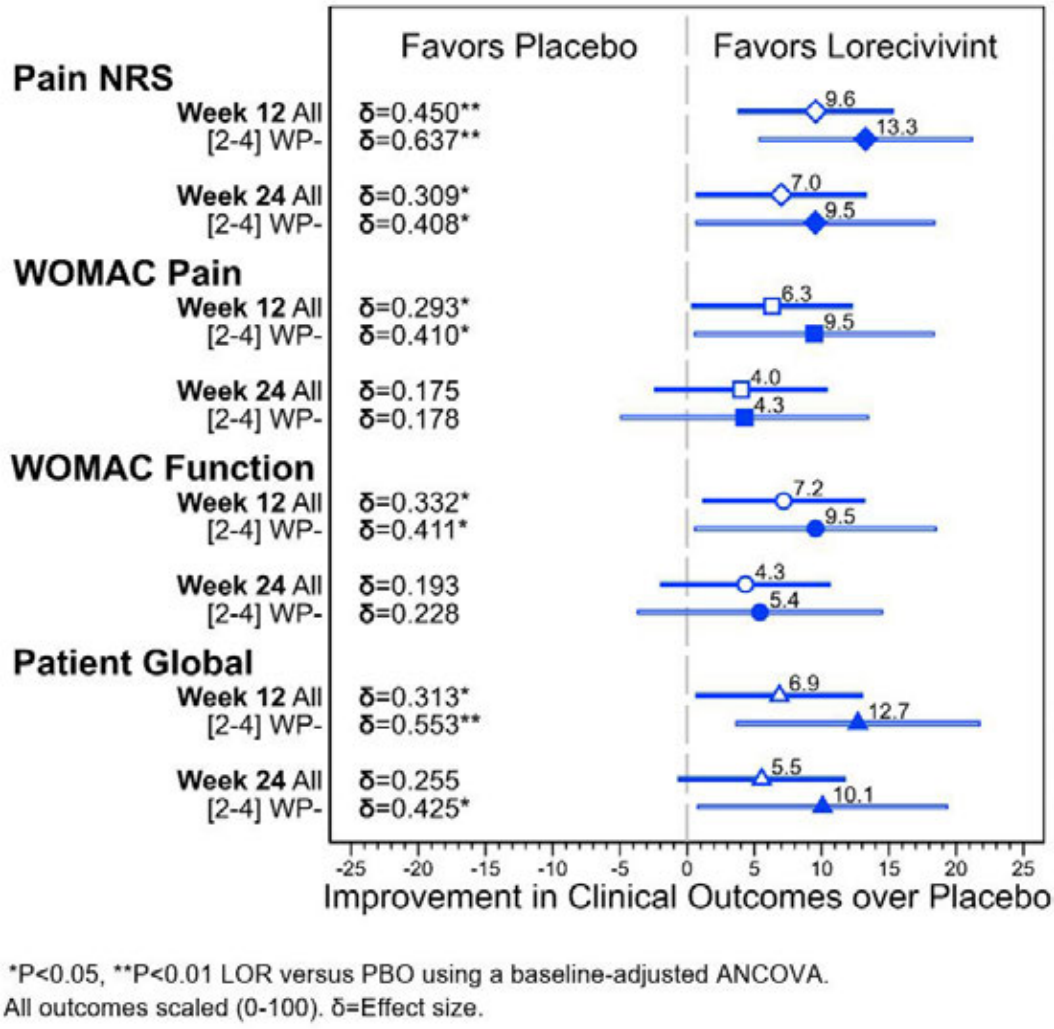

Figure 1. Treatment estimates (95% CI) and effect sizes of clinical outcomes of lorecivivint 0.07 mg compared to placebo using All Subjects and subjects with baseline mJSW [2-4mm] without widespread pain (WP-).

baseline with fixed-location mJSW measured by a central, treatment-blind reader. WPI was collected at screening with pre-specified enrollment of 80% of (WP-, Widespread Pain Index [WPI] ≤ 4, and Symptom Severity Score Question 2 ≤ 2) subjects. PRO endpoints included change from baseline in weekly average of daily OA target knee pain by NRS, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain [0-100], WOMAC Physical Function [0-100], and Patient Global Assessment (PtGA) (VAS [0-100]). Point estimates and effect sizes of the Full Analysis Set (FAS, all dosed subjects) compared to a post hoc completer analysis of subjects with baseline mJSW 2-4 mm who were WP- are reported.

Results: 635 subjects (91.4%) completed the study (mean age 59.0 [±8.5] years, BMI 29.0 [±4.0] kg/m2, female 58.4%, KL3 57.3%). In both FAS and mJSW 2-4 mm who were WP- subjects, significant improvements compared to PBO (P< 0.05) were seen in Pain NRS, WOMAC Pain, WOMAC Function, and PtGA for the 0.07 mg LOR dose group at Week 12 (Figure 1).The effect sizes were improved in the mJSW 2-4 mm who were WP- group in comparison to the FAS for the 0.07 mg LOR dose at Weeks 12 and 24.

Conclusion: In this post hoc analysis of LOR-treated knee OA subjects, those with baseline mJSW 2-4 mm without widespread pain showed improved PRO effect sizes compared to those in the Full Analysis Set beyond the initial significant improvements seen in the Full Analysis Set. These increased point estimates and confidence intervals may help to improve power calculations and create more homogenous populations to test new therapies.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In a Phase 3 randomized controlled study, differing efficacy results were observed when triamcinolone acetonide extended-release (TA-ER) was compared to conventional TA crystalline suspension (TAcs) with two different pain measures, average daily pain (ADP) using a 0-10 numeric rating scale (NRS) and Western Ontario

and McMaster Universities Osteoarthritis Index (WOMAC-A subscale). Trial enrollment criteria may have contributed to this discrepancy, as a moderate-to-severe ADP score of ≥5 to ≤9 was required at baseline whereas no limitations were placed on baseline WOMAC-A score (0-4 Likert). This allowed for randomization of patients who reported their knee pain as mild via WOMAC-A criteria. This post hoc analysis assessed treatment effects in those patients who reported moderate-to-severe OA pain prior to treatment on both ADP and WOMAC-A scales.

Methods: This post hoc analysis included adults (≥40 years) with knee OA (Kellgren-Lawrence Grade 2-3) who reported moderate-to-severe knee OA pain at baseline using both instruments (ADP ≥5 to ≤9 and WOMAC-A ≥2) from a Phase 3 randomized controlled study (concordant pain reporters; n=292). Patients received a single intra-articular injection of TA-ER 32 mg (n=95), TAcs 40 mg (n=100), or Saline-placebo (n=97). Patient-reported ADP-intensity (including area under the effect [AUE] curves), WOMAC-A (pain), WOMAC-B (stiffness), WOMAC-C (function), Knee In-

ADP-intensity scores rated on a 0–10 NRS, with 0 indicating "no pain" and 10 indicating "pain as bad as you can imagine."
ADP, average daily pain; NRS, numeric rating scale; TAcs, triamcinolone acetonide crystalline suspension; TA-ER, triamcinolone acetonide extended-release.

Figure 2. Frequency Distribution of ADP Scores at Baseline, Week 1, and Week 12

jury and Osteoarthritis Outcome Score Quality of Life (KOOS-QoL), rescue medication use, Patient Global Impression of Change (PGIC), and adverse events (AEs) were assessed throughout the study.

Results: Baseline characteristics (**Table 1**) and AE profiles were consistent with the full analysis population. TA-ER significantly ($P < 0.05$) improved ADP scores compared with TAcs (Weeks 5-19) and Saline-placebo (Weeks 1-20) (**Figure 1**). $AUE_{Weeks1–12}$ and $AUE_{Weeks1–24}$ were statistically significantly greater for TA-ER compared with TAcs (-47.7 [-94.4, -1.0] and -98.4 [-194.5, -2.3], respectively; $P < 0.05$ for both) and Saline-placebo (-136.1 [-184.2, -88.0] and -212.1 [-311.1, -113.1], respectively; $P < 0.0001$ for both). At Week 12, the proportion of patients who reported they had no knee pain (ADP score=0) was greater with TA-ER (~28%) compared with TAcs (~8%) (**Figure 2**); ~20% of patients who received TA-ER still reported no knee pain at Week 16. TA-ER significantly ($P < 0.05$) improved WOMAC-A, -B, -C, KOOS-QoL, rescue medication use, and PGIC compared with TAcs and Saline-placebo through at least Weeks 4-12.

Conclusion: In patients with knee OA who reported concordant moderate-to-severe pain at baseline across two different reporting instruments, TA-ER provided statistically significant and clinically meaningful pain relief for ≥16 weeks compared with conventional TAcs and Saline-placebo, and also improved stiffness, function, and QoL. Concordant pain reporters were better able to discern treatment effect; results of this post hoc analysis have implications for study design and patient recruitment of future trials evaluating efficacy of analgesics.

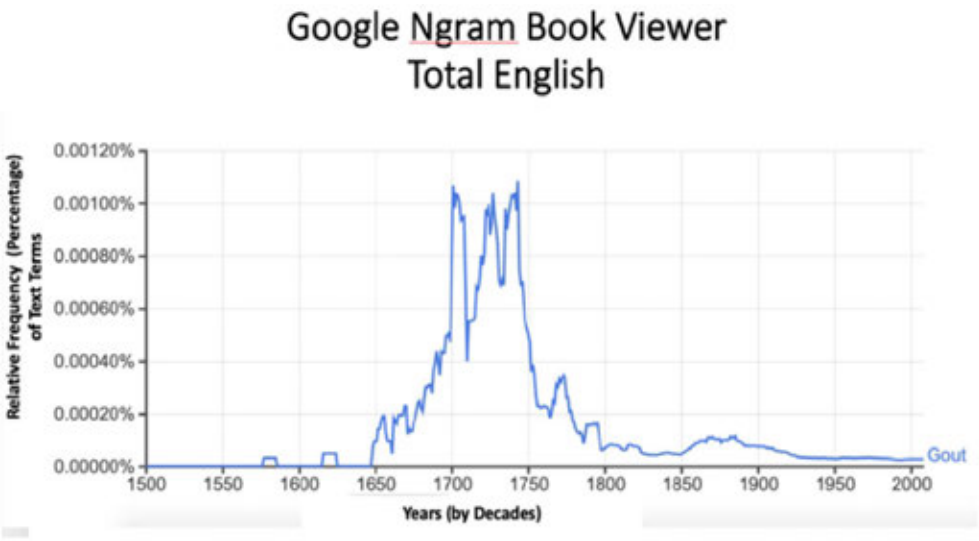
Osteoarthritis: What's in a Name?

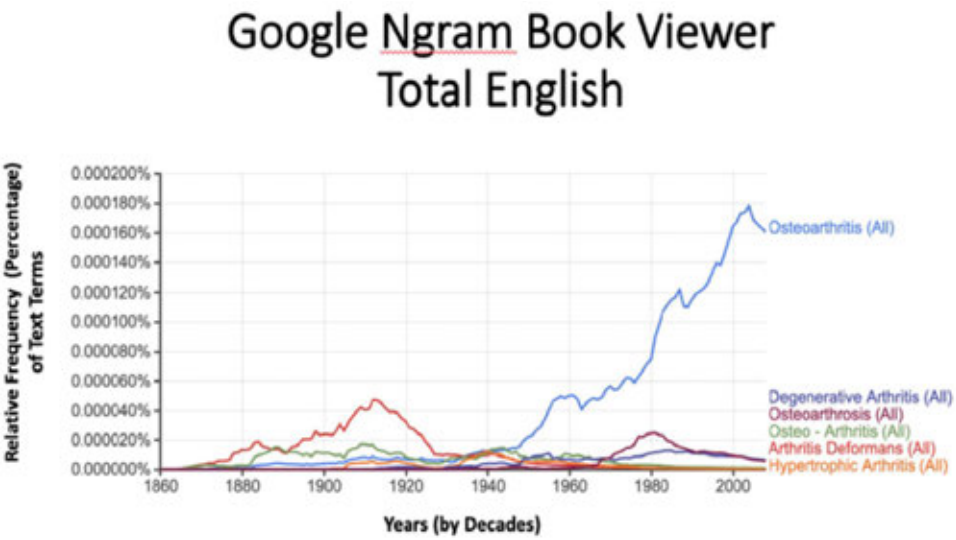
Warren A Katz[1], [1]Penn Medicine; University of Pennsylvania School of Medicine, Upper Gwynedd, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The nomenclature of "osteoarthritis" (OA) has been a source of confusion and likely misdiagnosis for centuries. Prior to 1759, most patients with joint diseases were labeled as having gout. It was then that the physician-anatomist, John Hunter, first documented the gross pathology of cartilage deterioration that would eventually be called OA. Other pundits variously referred to it by many different names. The goal of this research was to analyze the chronology and rationale for naming the conventional predecessors of OA.



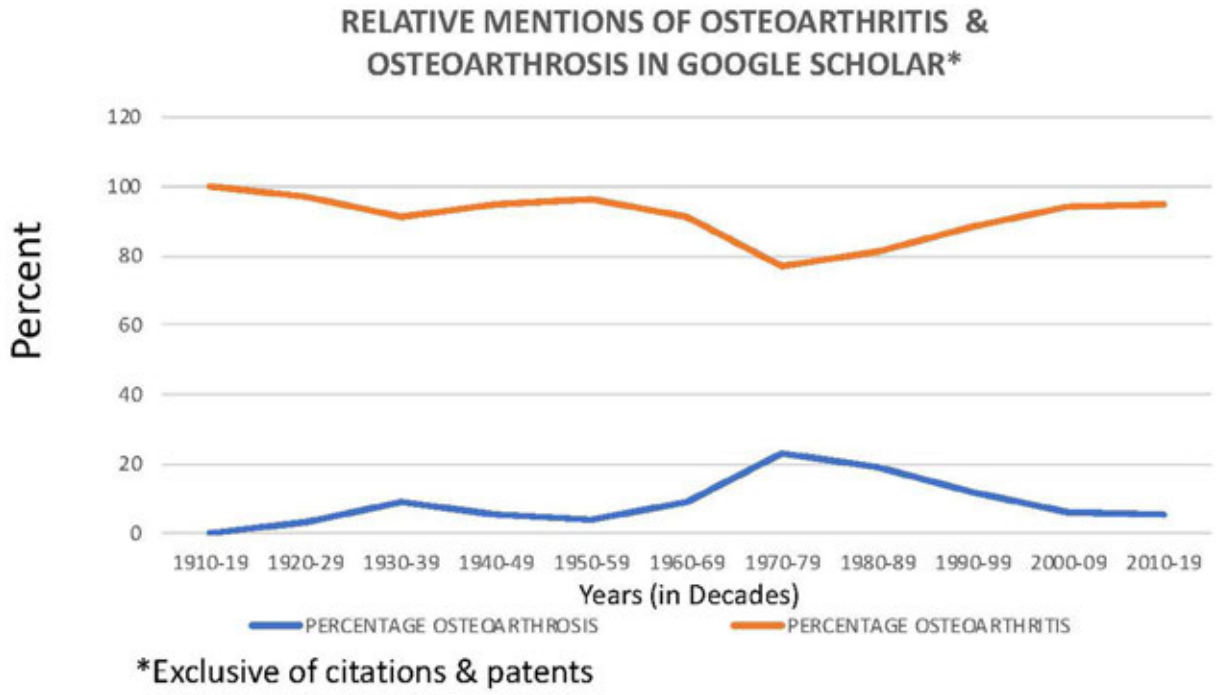
Google Ngram Viewer Gout 5-31-19 Google Ngram Viewer - Gout



Abstract Google N-Gram.docx. 5-31-19 Google Ngram Viewer - OA, O-A, Arthritis Deformans, DJD, Hypertrophic Arthritis

Methods: Google Scholar (GS), a search engine that indexes the text of academic literature, measured the usage of the terms: OA, osteo-arthritis (O-A), arthritis deformans (AD), hypertrophic arthritis (HA), degenerative joint disease (DJD) and osteoarthrosis. The terminology prevalence was plotted on a graph for each decade after 1800 to create a timeline. The Google Ngram Viewer (GNV), an online search engine that charts printed word citations, enabled a comparative graphic display between the years 1500 and 2008. A comprehensive literature search of significant discoveries and insights during this period was performed to determine if there was associated joint inflammation.

Results: The peak use of “gout” between ~1760 and 1840 may have reflected an age of scientific enlightenment rather than true prevalence. A century after Hunter’s discovery, Rudolf Virchow’s introduction of AD in 1863 applied to a mix of now-recognized OA and RA. This confounding designation persisted in the literature, eventually being adopted by his student, Sir William Osler, in 1892 and Ralph Pemberton as late as 1929. Richard von Volkmann is often credited for first using hyphenated O-A for the degenerative process, but a computerized search of his 1865 writings failed to reveal any mention of the term. In 1869, O-A originally appeared in The Nomenclature of Diseases published



OA vs Osteoarthrosis Mentions 5-31-19
Google Scholar Percentage of Literature Mentions for Osteoarthrosis & Osteoarthritis

by the Royal College of Physicians of London. The report, though it conflated O-A with RA, gained some traction with increased usage of O-A by the mid-1860s. In 1890, the influential physician Archibald Garrod still listed both O-A and AD as clinical varieties of RA. In 1910, he completely reversed his position by announcing: "I am convinced that the malady called 'osteo-arthritis'… is wholly distinct from those already referred to…," thus using O-A as a recognizable separate entity for the first time in the medical literature. In that same year, Joel Goldthwait and his group introduced with regularity the unhyphenated form of OA. Despite these clarifications, AD, DJD and HA continued to prevail. "Osteoarthrosis" was prevalent, mainly in the British literature, from ~1960 to 2000 because of the inference that OA was noninflammatory. By 1950, the term OA gained rising popularity and now reflects an inherent scientifically proven inflammatory component.

Conclusion: In the history of humanity, OA has been appropriately titled for only ~100 years. Reviewers of pre-20th century literature cannot be confident that O-A, as described then, was the actual disease known today. Optimistically, the validity of "itis" as a suffix in OA indicating inflammation will translate to improved management.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteoarthritis (OA) is a heterogeneous group of diseases with common clinical and radiographic manifestations involving the peripheral and axial skeletal. OA is the most prevalent rheumatic disease. There are very few publications focused in axial OA. In 2016, the Spanish Society of Rheumatology (SER) started a population descriptive study (EPISER 2016) to analyze the prevalence of 13 rheumatic diseases in Spain, including peripheral (hip, knee and hand) and axial (cervical and lumbar spine) OA.

Objectives: To estimate in adult population the prevalence in Spain of symptomatic OA of hand, knee, hip, cervical and lumbar spine and associated factors.

Methods: EPISER 2016 study is a cross-sectional, population-based descriptive study. To estimate the symptomatic OA prevalence, adult population aged 40 or older was selected. The initial recruitment was made through by a call center. In a second phase rheumatologists confirmed the diagnosis. Diagnostic criteria to confirm new diagnosis of peripheral OA were ACR criteria of hand, knee and hip. The axial OA diagnostic criteria to confirm new diagnosis were both clinical and radiographic. Clinical criteria: mechanical pain longer than 3 months of evolution and stiffness of less than 30 minutes or absence of it; and radiographic criteria: vertebral osteophytes or reduction of intervertebral space with sclerosis of vertebral plate and sclerosis in interapofisary joints. To confirm the diagnosis, it was necessary that both clinical criteria and at least one radiographic criterion were met.

Results: The sample of the EPISER study was 3,336 subjects ≥ 40, of whom 978 had peripheral or axial OA. The mean age was 64.72 years, 730 were women, 62.6% had basic education, 64,8% were overweight or obese and 83,9% were ex-smokers or non-smokers . The prevalence of global OA (peripherical+axial) was 29.35%. Prevalence of peripheral and axial OA was 19,62% and 19,17% respectively. According the prevalence of polyarticular phenotypes, the phenotype combining axial and peripheral OA was 9,66% and the phenotype combining OA in 2 or more peripherical joints (hand, knee o hip) was 5,64%.

The characteristics of patients with peripheral and axial OA follow similar patterns (Table 1).

Table 1: Sample of OA patients of the EPISER study

	GLOBAL	PERIPHERAL	AXIAL

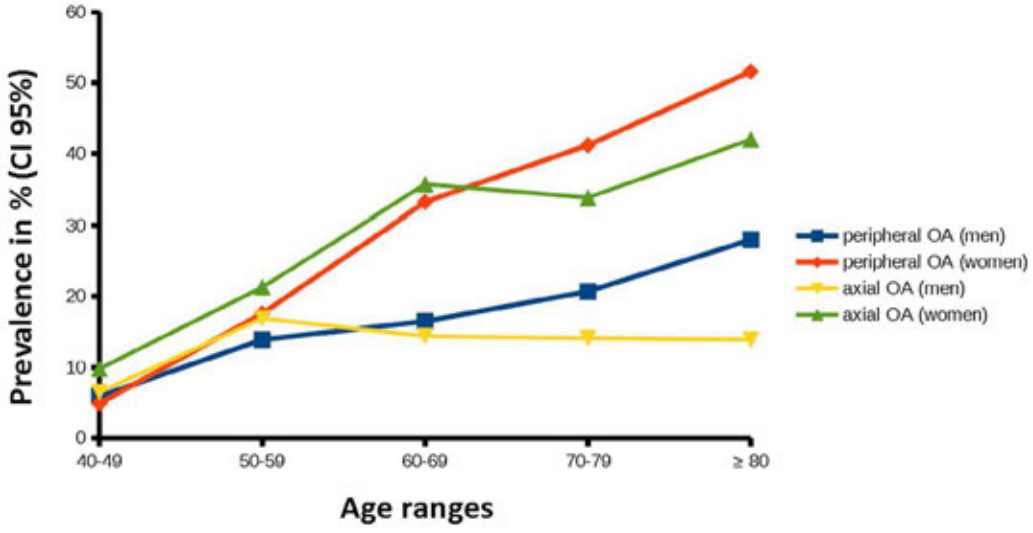
Basic studies				
Medium	0,009	0,659 (0,481-0,902)	0,071	0,788 (0,609-1,020)
Higher	<0,001	0,431 (0,304-0,613)	<0,001	0,433 (0,322-0,583)
Normal weight				
Under weight	0,840	0,857 (0,192-3,821)	0,998	<0,001
Overweight	0,208	1,197 (0,905-1,584)	0,001	1,528 (1,201-1,945)
Obesity	0,002	1,679 (1,209-2,332)	<0,001	2,490 (1,881-3,295)

Prevalence of cervical OA was 10.10%. In the multivariate analysis, it was observed that cervical OA is more frequent in women and older subjects, with the prevalence peak between 60-69 years. It is also more frequent in subjects with obesity and in subjects with a basic education level (Table 2 and Figure 1).

Prevalence of lumbar OA was 15.52%. Multivariate analysis also showed that lumbar OA is more frequent in women and it increases with age (prevalence peak in ≥80 years). Greater association was observed with obesity or overweight and with basic study levels. Lumbar OA prevalence was higher in population from centre of Spain compared with other areas.

Conclusion: EPISER2016 study shows similar prevalence of peripheral and axial OA. Lumbar OA is more prevalent than cervical OA. Axial OA in Spain is more frequent in women, increases with age with a peak between 60-69 years

Figure 1: Prevalence of peripheral and axial OA by gender



for cervical OA and ≥ 80 years for lumbar OA. Both cervical and lumbar OA are more frequent in patients with obesity or overweight and with basic studies.

Knee Morphology Associates with Tibio-Femoral and Patello-Femoral Osteoarthritis: A Case-Control Study

Anand Ramachandran Nair,[1] Weiya Zhang,[2] Michael Doherty,[3] and Abhishek Abhishek[3], [1]Academic Rheumatology, School of Medicine, University of Nottingham, Nottingham, UK, Nottingham, England, United Kingdom, [2]Academic Rheumatology, Division of Rheumatology,School of Medicine, University of Nottingham, Nottingham, UK\Arthritis Research UK Pain Centre, Nottingham, UK\National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham, UK, Nottingham, England, United Kingdom, [3]Academic Rheumatology, School of Medicine, University of Nottingham,Nottingham,UK \National Institute for Health Research, Nottingham Biomedical Research Centre, Nottingham,UK, Nottingham, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although several morphological features of the hip joint predispose to hip osteoarthritis (OA), only a few are known to associate with knee OA. The aim of this study was to identify novel morphological features associated with knee OA in addition to those already known.

Table 1 Association of morphological features and Knee OA, PFJOA and TFJOA

Morphological features	Knee OA aOR (95%CI)	PFJOA aOR (95%CI)	TFJOA aOR (95%CI)
PFJ			
Sulcus angle*	0.83(0.80,0.87)*	0.85(0.80,0 .90)*	0.88(0.84,0.92)*
Condylar angle*	0.52(0.48,57)*	0.48(0.41,0.56)*	0.60(0.55,0.66)*
Patellar angle	0.99(0.96,1.02)	0.96(0.91,1.01)	0.98(0.95,1.02)
Patellar thickness*	0.93(0.86,1.01)	0.74(0.61,0.89)*	0.96(0.87,1.05)
Patellar width	0.97(0.94,1.04)	0.96(0.91,1.00)	0.98(0.95,1.02)
Condylar width	1.02(0.99,1.05)	1.00(0.93,1.08)	0.99(0.96,1.01)
Intercondylar width*	0.92(0.88,0.96)*	0.91(0.83,1.02)	0.97(0.93,1.01)
Medial condylar height	0.95 (0.81,1.1)	0.93(0.80,1.10)	0.86(0.75,1.98)
Lateral condylar height	0.79(0.71,1.8)	1.18(0.02,1.36)	1.23(0.01,1.35)
TFJ			
Condylar plateau angle	0.96(0.80,1.2)	1.07(0.70,1.62)	1.02(0.83,1.25)
Distal femoral tilt*	1.13(1.01,1.07)*	1.25(0.99,1.58)	1.37(1.20,1.57)*
Proximal tibial tilt*	1.19(1.00,1.43)*	1.15(0.87,1.50)	1.38(1.15,1.64)*

**-Significant association at p<0.004(Bonferroni corrected); aOR- odd ratio adjusted for age, gender, height and weight; PFJ- Patello -femoral joint; TFJ- Tibio-femoral joint.*

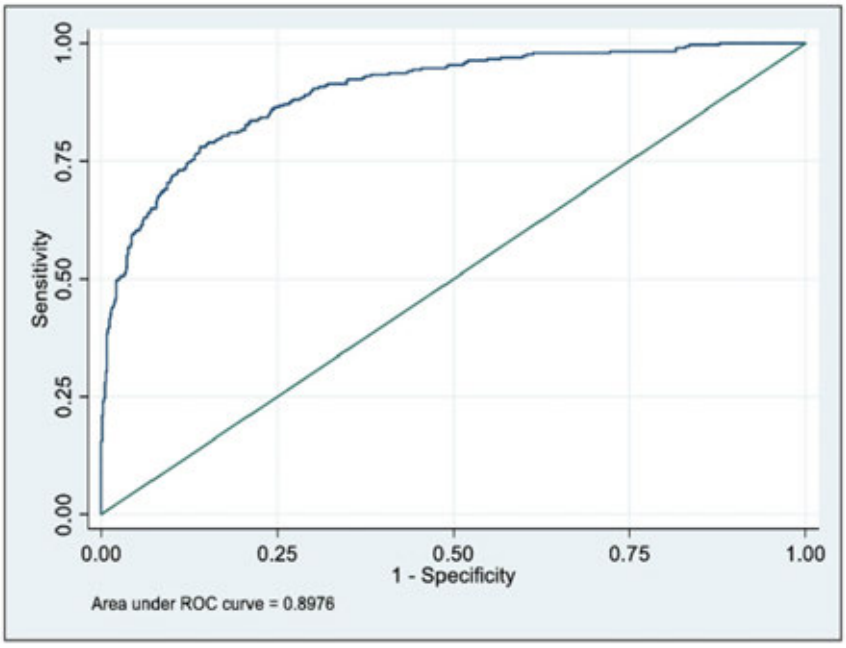

Figure 1 ROC curve for PFJOA (with sulcus angle, condylar angle, patellar thickness and distal femoral tilt, age, gender, height, weight)

Methods: This was a case control study using data from the Genetics of Osteoarthritis and Lifestyle (GOAL) study. It included: (1) 315 unilateral knee OA cases, defined as no knee pain and no radiographic OA (defined as osteophyte score ≤1 and joint space narrowing score 0 according to Nottingham line drawing atlas) in one knee but pain and

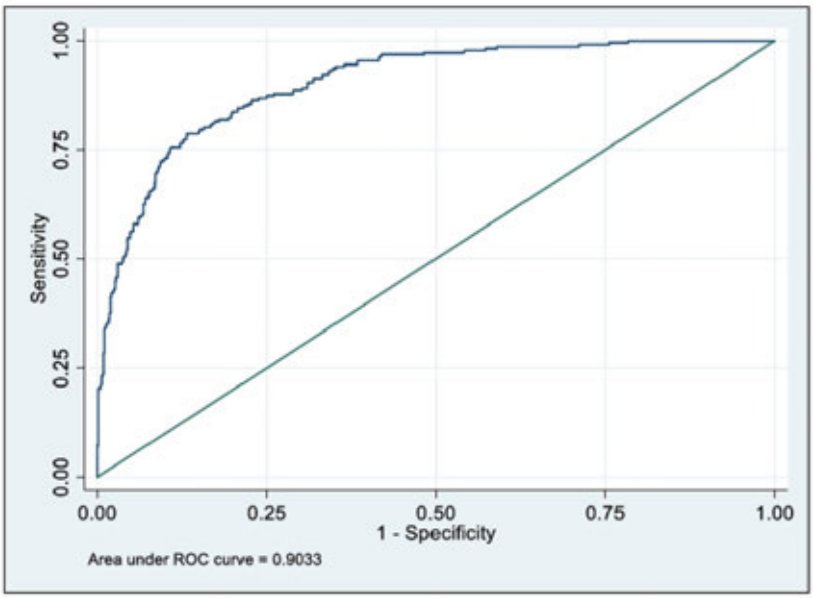

Figure 2 ROC curve for TFJOA (with sulcus angle, condylar angle, distal femoral tilt, age, gender, weight, height)

radiographic OA in the contralateral knee which also fulfilled ACR criteria for knee OA; (2) 816 controls, defined as participants without knee pain and radiographic OA in both knees.

The morphology of unaffected knees of people with unilateral knee OA were compared to the morphological features of the same side of normal controls under the assumption that the unaffected knees in cases would have the same morphologic feature as the affected knee before it developed OA.

Patello-femoral joint (PFJ) and tibio–femoral joint (TFJ) radiographic measurements were undertaken by a single observer (Table 1). Symmetry of measurements between right and left knees were examined in controls using minimal detectable change (MDC). Association of individual morphological measure and unilateral knee OA (defined as OA in PFJ or TFJ), PFJ OA or TFJ OA was determined using logistic regression adjusted for age, gender, height and weight. Diagnostic ability of the significant morphological features, together with age, gender, height and weight for each OA outcome was determined using receiver operating characteristic (ROC) curves.

Results: The mean (SD) for age, height and weight of cases and controls were 64(8.6) and 62(8.5) years, 166.7(14.2) and 167.5(11.1) cm, and 78.3(14.4) and 77.1(15.7) kg respectively. Mean difference between left and right sides in controls was less than the MDC for all measurements suggesting right-left symmetry. Narrow sulcus and condylar angles, increasing patellar thickness and intercondylar width associated with knee OA (Table 1). Increasing distal femoral and proximal tibial tilt associated with knee OA. ROC curves including all significant morphological features and age, gender, height and weight predicted knee, PFJ, and TFJ OA with area under the curve (AUC) of 0.91, 0.89, and 0.90 respectively (Fig.1, 2). As distal femoral and proximal tibial tilt were correlated (r=0.54), only distal femoral tilt was included in the model. Sensitivity analysis replacing distal femoral tilt with proximal tibial tilt did not change the results

Conclusion: We have identified six morphological features associated with knee OA. These features together with age, gender, height and weight predicted OA status accurately. There were some variations between morphological features associated with TFJ OA, and PFJ OA. However, sulcus angle and condylar angle associated with both PFJ and TFJ OA suggesting potential shared mechanisms for these variants in predisposing to both PFJ and TFJ OA.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The safety of bilateral total knee replacements (BTKR) under the same anesthesia as compared to staging within 12 months is debated. The advantage is one anesthesia, one postoperative rehabilitation and a shorter recuperation., but may . incur greater risk of complications and readmissions, Our aim is to compare the rate of readmissions for patients undergoing 1) simultaneous BTKR 2) unilateral TKR, 3) staged BTKR >12 months or 4) staged B TKRs < 12 months.

Methods: All New York State (NYS) residents enrolled in the Hospital for Special Surgery Knee Replacement Registry >18 years old with a first primary TKR between 1/1/2008 and 12/31/2010 were eligible. We excluded prior revision TKR, inflammatory arthritis, 2 non-TKA surgical procedures. Demographics and PROs(HOOS/KOOS and SF12) were collected at the time of surgery. We used the NY Statewide Planning and Research Cooperative System (SPARCS) to identify readmissions via links to claims from all non-federal NYS hospitals. The cohorts were 1) simultaneous BTKR 2) unilateral TKR, 3) staged BTKR >12 months or 4) staged B TKRs < 12 months. Included readmission diagnoses were the Center for Medicare and Medicaid (CMS) Complications (TKR specific) and cerebral vascular accident ,acute renal failure, GI bleed, and mortality within 90 days. The distribution of continuous variables was assessed using the Shapiro-Wilk test. Non-normally distributed variables are summarized as median [IQR] and compared using the Kruskal-Wallis test. Categorical variables are summarized as frequency (percent) and compared using the Chi-Squared test.

Results: We included 4,640 patients linked to SPARCs with 95 unplanned readmissions (Table 1). Simultaneous BTKR patients were younger, more often male, had fewer co-morbidities, and had higher rates of American Society of Anesthesiology Score of 2. Health related QOL at baseline was better for simultaneous BTKR than staged < 1 year on the SF-12 PCS and SF-12 MCS . More staged < 1 year were readmitted, however there was no significant difference in readmission across the four cohorts compared (p=.961). At >90 days, there was a trend towards significance in readmissions for transfusions (p=.090) across the four cohorts. Readmissions for sepsis differed across the four cohorts (p=.019), with higher rates in the simultaneous BTKR group. No differences in VTE or MI were observed. Readmission for mechanical complications at >90 days differed across the cohorts (p=.0006) with a slightly increased rate of readmission in those staged < 1 year.

Conclusion: Further study is required to address whether simultaneous BTKR increases risk for readmission, compared to BTKR staged < 1 year. BTKR patients in our institution were younger and had less comorbidities,, which may reflect careful screening for simultaneous BTKR candidates, and the comparatively lower rates of early readmission for simultaneous BTKR patients (with the exception of readmission for sepsis). While we observed potentially meaningful differences in rates of readmission for transfusions, sepsis, and mechanical complications, across four cohorts of TKR replacement patients, these unadjusted comparisons require additional research.

Session Date: Monday, November 11, 2019

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite an inter-play between objective physical function measures and various patient characteristics, no large-scale investigations in knee osteoarthritis (KOA) have explored complex interactions or established patient-specific reference values for these tests across sex, age, radiographic severity, and body mass index (BMI). The purpose of this study was to: 1) determine the extent to which interactions among patient characteristics were associated with objective physical function, and 2) use a large community-based cohort of adults with or at risk for KOA to establish patient-specific reference values of objective physical function tests.

Methods: We included participants from the Osteoarthritis Initiative (OAI) with data on objective physical function tests and patient characteristics (i.e., age, BMI, and radiographic KOA severity: Kellgren-Lawrence Grade [KL]) at the baseline visit. We included three objective physical function tests: 20-meter walk test (20m), chair stand test (CS), and 400-meter test (400m). For the 20m, participants completed two trials at their habitual walking speed. For the CS, participants completed two trials in which they completed sit-to-stands as quickly as possible. For the 400m, participants completed one trial of walking ten 40-meter laps at their habitual walking speed. To determine how each

Degree of Interaction	Variables Included in Model	Objective Physical Function Test		
		20-meter walk Interaction p-value	Chair stand test Interaction p-value	400-meter walk Interaction p-value
2-way	sex*age	0.09	0.23	**<0.01***
	sex*KL	**<0.01***	**0.01***	**0.02***
	sex*BMI	**0.03***	0.64	**<.0001**
	age*KL	0.33	0.34	0.93
	age*BMI	0.79	0.10	0.14
	KL*BMI	0.44	0.88	0.29
3-way	sex*age*KL	0.17	0.15	0.39
	sex*age*BMI	0.16	0.06	0.93
	sex*KL*BMI	0.13	0.31	**0.05***
	age*KL*BMI	0.64	0.57	0.54
4-way	sex*age*KL *BMI	0.48	0.51	0.32

Table 1. Regression Analysis Results Highlighting the Interaction Between Patient Characteristics that Relate with Objective Physical Function Tests. BMI = body mass index, KL = Kellgren-Lawrence Grade, p = regression analysis interaction p-value, *: p<0.05

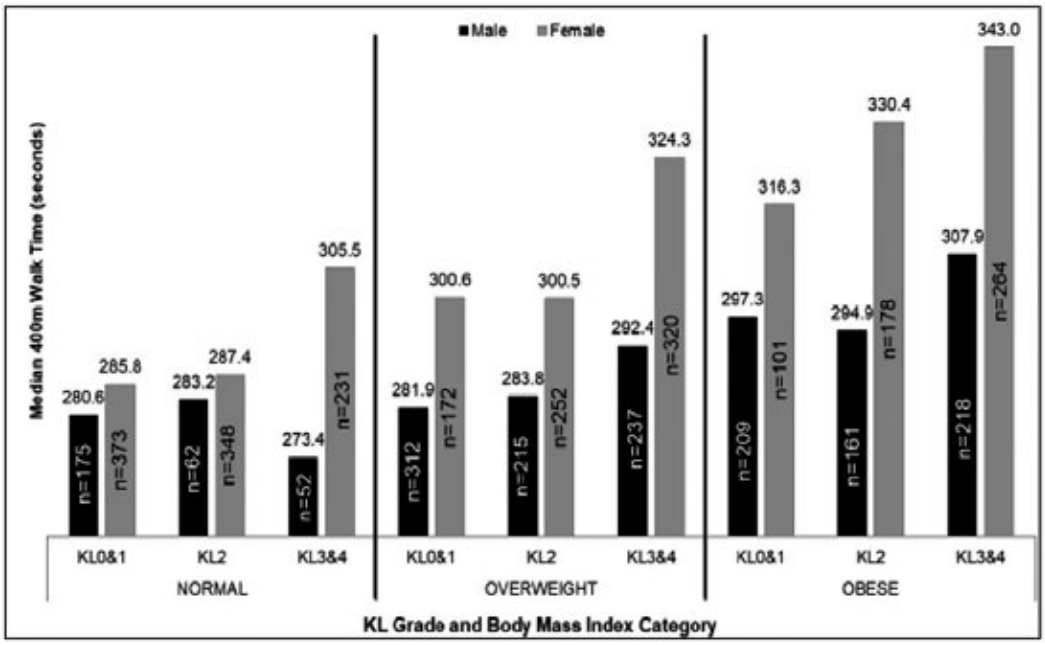

Figure 1. 400-Meter Walk Performance by Sex, KL Grade, and BMI Category. Greater median 400-meter walk time indicates worse objective physical function; KL = Kellgren-Lawrence Grade

objective physical function is influenced by any combination of these patient characteristics, we used a single linear regression model to evaluate all two-, three-, and four-way interactions. To establish patient-specific reference values for each objective physical function test, we created percentile scores from minimum to maximum in 10% increments for all combinations of the patient characteristics for each test. Subsets for two-way reference values were separated by: sex (male, female); age (five-year increments from 45-80 years); KL (KL0 - KL4); and BMI (18.5-25 kg/m^2, 25-30 kg/m^2, 30-35 kg/m^2, >35 kg/m^2). Due to smaller subset sample sizes, three- and four-way references were separated by: age (45-60, 60-70, and 70-80 years); KL (KL0/1, KL2, KL3/4); and BMI (18.5-25 kg/m^2, 25-30 kg/m^2, >30 kg/m^2).

Results: We included 3,880 individuals who were on average 61$\pm$9 years old with a BMI of 29$\pm$5 kg/m^2. For all physical function tests, there was no statistically significant four-way interaction between sex, age, KL, and BMI (Table 1). However, all physical function tests had at least one significant three-way or two-way interaction. Figure 1 highlights the interaction between sex, KL, and BMI for the 400m. We created reference value tables for each physical function test across all combinations of patient characteristics for two-, three-, and four-way interactions. Table 2 provides an example of two- and three-way interaction tables for the 400m.

Conclusion: Rather than rely on a single cut-off for all adults with or at risk for KOA, our analysis highlights the need for reference values within clinically relevant subsets that indicate a patient's relative level of physical function. Further work is needed convert these extensive reference value tables to a format that can be easily translated into clinical practice.

Background/Purpose: Osteoarthritis (OA) of the knee is one of the most common causes of disability in the U.S. Often overlooked, OA specific to the patellofemoral joint of the knee (PFJ OA) is highly prevalent, and often occurs

in isolation from tibiofemoral (TFJ) OA. While MRI-detected structural damage in the PFJ are related to the development of TFJ lesions, little is known about the clinical significance of these lesions, or the impact of cumulative tissue damage across the four subregions of the PFJ (medial/lateral patella and trochlea). The purpose of this study is to determine the cross-sectional relationship of the number of PFJ subregions with structural MRI-defined tissue damage with knee pain, performance-based function, and physical activity in people with or at high risk of knee OA.

Methods: We performed a cross-sectional analysis using 60-month data from the NIH-funded Multicenter Osteoarthritis Study. OA features in the four PFJ subregions were scored semi-quantitatively using the WORMS method by two musculoskeletal radiologists. We created a 3 level exposure variable for the number of PFJ subregions with structural damage: (0, 1 or 2, 3 or 4). Three different MRI features were assessed separately: full-thickness cartilage damage (WORMS 2.5, 5-6), bone marrow lesions (BMLs) (≥1), and definite osteophytes (≥2) in the PFJ. Relation of number of PFJ subregions to knee pain severity (VAS pain) and repeated chair stand time was assessed using ANCOVA. Relation of the odds of at least mild pain with stairs (WOMAC pain scale) and walking < 6,000 steps/day (a level of physical activity associated with risk of incident functional limitation) was assessed using logistic regression. Separate models were created for each PFJ MRI feature. Each analysis was adjusted for age, sex, BMI, previous knee injury/surgery, and coincident TFJ MRI feature.

Results: 1099 knees had complete MRI WORMS readings and performance based function assessed at the 60-month visit. The mean (SD), age and BMI of this sample was 66.8 (7.5) and 29.6 (4.8), respectively; 65% were female. In general, a higher number of PFJ subregions with any MRI-defined structural damage were associated with higher pain levels and longer time to complete 5 chair stands than those with fewer subregions affected (Table 1). Participants with full-thickness cartilage damage or BMLs in 3 or 4 compartments had three times the odds of pain on climbing stairs (Table 2). Participants with full-thickness cartilage damage in at least three compartments or osteophytes in at least one compartment have 2.3 and 2.1 times the odds of walking < 6,000 steps/day (Table 2).

Conclusion: Having damage in multiple subregions of the PFJ is associated with increased pain, decreased function, and greater odds of walking < 6,000 steps/day. The specific outcomes affected depended on the type of tissue damage, with full-thickness cartilage damage appearing to have the most impact across all outcomes. In addition to cartilage damage, osteophytes are associated with walking less steps/day, and BMLs with pain on stair climbing.

PROMIS fatigue	48.6 [43.2, 55]	55.2 [53.1, 62.7]	**<0.001**
PROMIS sleep disturbance	51.1 [44.2, 55.1]	53.1 [49.2, 60.9]	**0.04**
PROMIS ability to participate	46.9 [42.4, 53.6]	43.3 [39, 48]	**0.007**
PROMIS pain interference	61 [55.7, 65.5]	64.2 [59.9, 66.7]	**0.006**
PROMIS pain intensity score	6 [4, 7]	7 [6, 8]	**0.003**
HOOS symptoms	50 [35, 60]	36.3 [22.5, 60]	**0.035**
HOOS pain	47.5 [37.5, 57.5]	40 [26.3, 47.4]	**0.003**
HOOS daily living	48.5 [39.7, 61.8]	41.2 [25.7, 54.4]	**0.026**
HOOS sport and rec	25 [12.5, 43.8]	9.4 [0, 28.1]	**0.003**
HOOS quality of life	25 [12.5, 37.5]	18.8 [6.3, 31.3]	**0.025**

BOLD=p-value < 0.05
HOOS Scores represent patient-reported outcome measures scored along a normal distribution with a mean of 50. A score of 100 indicate no problems and 0 indicates extreme problems.

PROMIS T-scores are reported as standardized T-scores, with 50 representing the population mean. A T-Score of 5 is considered a clinically meaningful difference.

AAOS.2020.Hips.Frailty.Table

Background/Purpose: To determine whether frailty is associated with patient outcomes 1 year after total hip replacement (THR).

Methods: Patients ≥65yo scheduled for elective primary THR for osteoarthritis were recruited from a musculoskeletal specialty hospital. All were approved for surgery by an internist. Frailty was defined using composite criteria designed for surgical candidates, evaluated at point of care. Hip Injury and Osteoarthritis Outcome Score (HOOS) and PROMIS29 were administered pre-operatively and at 1-year. Depression was measured using the Center for

Epidemiologic Studies Depression Scale (CES-D 10). A subset of patients had frailty assessed by their surgeon pre-operatively using the brief, self-report Clinical Frailty Scale for Physicians. Wilcoxon rank-sum and Fisher's exact tests were used to compare continuous variables and categorical variables, respectively, across frailty status. Multivariable linear and logistic regressions were modeled for each patient-related outcome, adjusting for confounders identified *a priori* using a directed acyclic graph approach. Spearman correlation coefficients were calculated to evaluate the correlation between frail scales.

Results: 332 hip replacement subjects enrolled, 9% of whom were frail. Frail THR subjects were older, more likely to be depressed, have concurrent back pain, and were also more likely to have had a previous hip or knee replacement. 91.4% provided 1-year follow-up. In a multivariable linear regression controlling for age, gender, race, back pain, education, Charlson comorbidity index, and PROMIS29 anxiety and depression, frailty predicted a clinically meaningful improvement in HOOS pain (β=10.4), which was statistically significant (p=0.01). Frailty also predicted a significant decrease in PROMIS pain interference T-score at 1-year, (β=3.9; p-value 0.023), controlling for the same potential confounders. Frailty did not predict other HOOS subscales or PROMIS29 domains at 1-year. Frailty did not predict cumulative severe adverse events through 1 year or OMERACT-OARSI responder status at 1-year. There was a strong correlation between our frailty definition and the Fried frailty phenotype, (r=0.79; p< 0.001), but a poor correlation with the orthopedic surgeon's frailty assessment (r=0.16; p=0.78).

Conclusion: Frailty was a strong predictor of less hip-related pain and less overall pain interference 1 year after THR in older adults undergoing elective primary THR. Frailty was not associated with odds of adverse events or OMERACT-OARSI responder status. Surgeon assessment of frailty is not an accurate proxy for the frailty phenotype. Appropriately screened frail patients should not be discouraged from having THR for pain relief, particularly given the known risks of long term NSAIDS and narcotics. These data can aid in surgical decision making for frail patients contemplating THR.

BOLD=p-value < 0.05
KOOS Scores represent patient-reported outcome measures scored along a normal distribution with a mean of 50. A score of 100 indicate no problems and 0 indicates extreme problems.

PROMIS T-scores are reported as standardized T-scores, with 50 representing the population mean. A T-Score of 5 is considered a clinically meaningful difference.

Pre-Op Table (TKR)

Background/Purpose: To determine whether frailty is associated with patient outcomes 1 year after total knee replacement (TKR).

Methods: Patients ≥65yo scheduled for elective primary TKR for osteoarthritis were recruited from a musculoskeletal specialty hospital. All were approved for surgery by an internist. Frailty was defined using composite criteria designed for surgical candidates, evaluated at point of care. Knee Injury and Osteoarthritis Outcome Score (KOOS) and PROMIS29 were administered pre-operatively and at 1-year. Depression was measured using the Center for Epidemiologic Studies Depression Scale (CES-D 10). A subset of patients had frailty assessed by their surgeon pre-

operatively using the brief, self-report Clinical Frailty Scale for Physicians. Wilcoxon rank-sum and Fisher's exact tests were used to compare continuous variables and categorical variables, respectively, across frailty status. Multivariable linear and logistic regressions were modeled for each patient-related outcome, adjusting for confounders identified *a priori* using a directed acyclic graph approach. Spearman correlation coefficients were calculated to evaluate the correlation between frail scales.

Results: 487 knee replacement subjects enrolled, 6% of whom were frail. Frail TKR subjects were more likely to be depressed and have concurrent back pain. 89.9% provided 1-year follow-up. In a multivariable linear regression controlling for age, gender, race, back pain, education, Charlson comorbidity index, and PROMIS29 anxiety and depression, frailty predicted a statistically significant decrease in KOOS Function in Daily Living score at 1-year (β=7.0; p=0.04). Frailty also predicted a significant decrease in PROMIS29 physical function, (β=4.7; p-value 0.002), and a small increase in PROMIS29 Pain Intensity, (β=0.69; p-value 0.047), at 1-year. Frailty did not predict other KOOS subscales or PROMIS29 domains at 1-year. Frailty did not predict cumulative severe adverse events through 1-year or OMERACT-OARSI responder status at 1-year. There was a strong correlation between our frailty definition and the Fried frailty phenotype, (r=0.79; p< 0.001), but a poor correlation with the orthopedic surgeon's frailty assessment (r=0.18; p=0.6).

Conclusion: Frailty was a strong independent predictor of worse KOOS knee-specific function and PROMIS29 global physical function 1 year after TKR in older adults undergoing elective primary TKR. Frailty was not associated with odds of adverse events or OMERACT-OARSI responder status. Surgeon assessment of frailty is not an accurate proxy for the frailty phenotype. These data can help manage expectations of frail patients contemplating TKR. Future studies should assess if targeted interventions to improve frailty can lead to better post-operative function.

Abstract Number: 1318

In an International, Multicentre, Double-blind, Randomised Study in Knee Osteoarthritis Patients, Diacerein Was Found as Effective as Celecoxib in Reducing Pain and Disease Symptoms

Jean-Pierre Pelletier,[1] Jean-Pierre Raynauld,[2] Patrice Paiement,[3] Marc Dorais,[4] and Johanne Martel-Pelletier[5], [1]University of Montreal Hospital Research Centre (CRCHUM), Montreal, QC, Canada, [2]Institut de Rhumatologie de Montréal, Montreal, QC, Canada, [3]ArthroLab Inc., Montreal, QC, Canada, [4]StatSciences Inc., Notre-Dame-de-l'Île-Perrot, QC, Canada, [5]University of Montreal Hospital Research Centre (CRCHUM), Montreal, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There was a need to ascertain in a clinical trial the comparative efficacy of diacerein, an IL-1 inhibitor, vis-à-vis celecoxib, a COX-2 inhibitor, in relieving knee osteoarthritis (OA) symptoms. The primary outcome of this study was to show that diacerein is non-inferior to celecoxib in terms of pain reduction (WOMAC A pain subscale) after 6 months of treatment in moderate-to-severe symptomatic knee OA patients.

Methods: A randomised double-blind multicentre trial was conducted in four European countries (Spain, Belgium, Austria, Czech Republic) and in Canada evaluating treatment with diacerein versus celecoxib in patients with OA diagnosed according to ACR criteria, with KL grade 2-3 knee OA and moderate-to-severe pain (VAS pain score [0-100 mm] while walking on a flat surface ≥ 40 mm). Eligible patients were randomised to treatment for 6 months with either diacerein 50 mg once daily for the first month and twice daily thereafter, or celecoxib 200 mg once daily. The primary outcome was the change from baseline in WOMAC pain subscale (0-50 scale) after 6 months of treatment. Secondary outcomes included WOMAC function and stiffness, VAS pain, presence of joint swelling/effusion, rescue medication consumption, percentage of OMERACT-OARSI responders, and SF-36. A total of 380 patients were randomised in the study. The primary outcome assessment on the per protocol set (PPS) (n=288) was followed by sensitivity analysis on the ITT population (n=370). Exploratory statistical analysis on other efficacy criteria and safety were performed.

Results: The analysis of the PPS population showed that the adjusted mean change in WOMAC pain was -11.14 (SEM, 0.91) with diacerein (n=140) and -11.82 (0.89) with celecoxib (n=148). Diacerein met the non-inferiority criterion, as the upper bound of the 95% CI is inferior to the pre-specified non-inferiority margin of 5 (inter-group difference 0.67; 95% CI -1.83 to 3.18; p=0.597). The sensitivity analysis using the ITT population was supportive of those results. All other exploratory outcomes demonstrated no difference between the two treatment groups. The OMERACT-OARSI responder rate (PPS) at 6 months was similar in the diacerein (62.1%) and celecoxib (60.1%) groups. The incidence of adverse events related to drug treatment was in general low and balanced between groups. The only exception was a greater incidence of gastrointestinal side effects (diarrhoea) in the diacerein vs. the celecoxib group (10.2% vs. 3.7%, respectively), but accounted for 4.8% of permanent discontinuation in the diacerein group compared to 1.6% in the celecoxib group. In all but one patient, this diarrhoea was considered to be of a mild-to-moderate grade with complete resolution in all cases.

Conclusion: This clinical trial showed that in patients with moderate-to-severe knee OA pain, diacerein has comparable efficacy to celecoxib with respect to reducing pain and stiffness and improving function after 6 months in a clinically relevant manner. The drug also demonstrated a good safety profile with positive benefit to risk ratio.

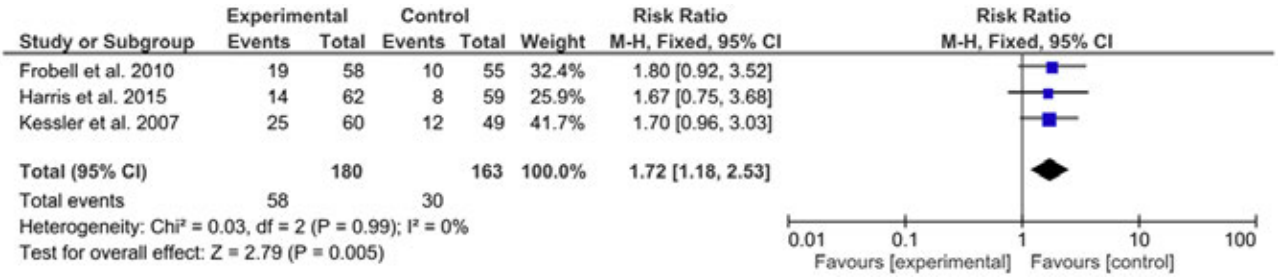
Impact of ACL Injury Management on the Development of Knee Osteoarthritis: A Meta-analysis

Stéphanie Ferrero,[1] Marion Louvois,[1] Thomas Barnetche,[2] Thao Pham,[3] Véronique Breuil,[1] and Christian Roux[4], [1]University of Nice, nice, France, [2]FHU ACRONIM, Department of Rheumatology, Centre Hospitalier Universitaire, Bordeaux, France, Bordeaux, France, [3]Aix-Marseille University, CHU Marseille, department of Rheumatology, 13,000 Marseille, France, Marseille, France, [4]CHU Pasteur Nice, Nice, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Osteoarthritis – Clinical Poster I



Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background: The development of knee's osteoarthritis after anterior cruciate ligament ACL injury is now widely recognized. The impact of surgical or rehabilitative management on the development of post-traumatic osteoarthritis is still debated.

We present here a meta-analysis about the evolution and progression of knee's osteoarthritis after ACL surgery or conservative management

Methods: A systematic litterature's review was conducted using PubMed, EMBASE, Medline, and Cochrane library data. Only RCTs with a conservative group and a surgical group after anterior cruciate ligament (ACL) injury were included, and if they reported radiographic results of injured knees using the Kellgren and Laurence (KL) classification score. Heterogeneity was evaluated by Cochrane's Q and *I2* statistics.

Results: Six studies were included after litterature's review (February 8, 2019 at May 15, 2019). Three studies met the inclusion criteria and were retained for the meta-analysis. Of the 343 injured knees, 180 underwent ACL reconstruction and 163 received conservative treatment. The relative risk of knee's osteoarthritis was higher after surgery than after conservative treatment (RR 1.72[1.18-2.53], I^2=0%.

Conclusion: The results of this meta analyse show that ACL reconstruction surgery predisposes to knee's osteoarthritis compared to conservative management. This suggests that a review of practices could be considered by promoting non-surgical management in the young subject.

Individual Socio-economic Status and Symptomatic Hip and Knee Osteoarthritis: A Longitudinal Study, Results from the KHOALA Cohort

Pauline Baudart,[1] Anne-Christine Rat,[2] Christian Marcelli,[1] and Joséphine Bryère[3], [1]CHU Caen, rheumatology department, Caen Normandie University, Caen, France, [2]CHU Caen, rheumatology department, Caen Normandie University, Université de Lorraine, EA 4360 APEMAC, Caen, France, [3]Inserm, university of Caen research U1086 Anticipe, Caen, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We analyzed the association between individual socio-economic status (SES) variables and clinical symptoms (function, pain and quality of life) in patients with symptomatic knee and/or hip osteoarthritis.

Methods: The prospective study used data from baseline to the 7-year follow-up visit of the Knee and Hip OsteoArthritis Long-term assessment (KHOALA) cohort. Function and pain were measured by Western Ontario and McMaster Universities Index of Osteoarthritis (WOMAC), and the quality of life by Medical Outcomes Study Short Form 36 (SF-36). Individual SES variables included educational level (5 categories), occupational status (7 categories), the monthly income per household (5 categories) and precarious status (EPICES score ≥30.17). We used a mixed model for repeated measures to analyze our outcomes measured annually at baseline to year 7 of follow-up.

Results: Eight hundred and seventy-eight patients were included. In univariate analyses, SES characteristics were significantly associated with WOMAC function, pain scores and SF-36 score ($p< 0.0001$ for educational level, occupational status, monthly income and precarious status), with a gradient against the less educated, the least qualified professional categories, the lowest monthly income and against precarious patients. In multivariate analyses adjusted on confounding factors (body mass index (BMI), axe, sex, year, education, occupational status, monthly income, precarious status, Kellgren-Lawrence score, groll score, metabolic equivalent of task (MET), evolutive time….), the WOMAC function score was associated with occupational status ($p=0.0393$) and precarious status (ß=1.81, 95% CI=0.72 to 2.90, $p=0.00011$). The WOMAC pain score was associated with occupational status ($p=0.0128$) and with educational level ($p=0.0232$). We didn't observe a significant interaction between the time and the SES variables. Mental SF-36 score was associated with monthly income per household ($p< 0.0001$) and the precarious status (ß=-2.41, 95% CI=-3.83 to -0.99, $p=0.0016$). The physical SF-36 score was associated with educational level ($p=0.0059$) and precarious status (ß=-1.52, 95% CI=-2.15 to -0.88, $p< 0.0001$).

Conclusion: Our results suggest that individual SES characteristics have a significant impact on function and pain in hip and knee OA even taking into account various risk factors.

What Is the Relationship Between the 3 Knee Bones in Osteoarthritis? Baseline and Longitudinal Associations Using a Latent Growth Modelling Approach on 37,583 MR Images from the Osteoarthritis Initiative

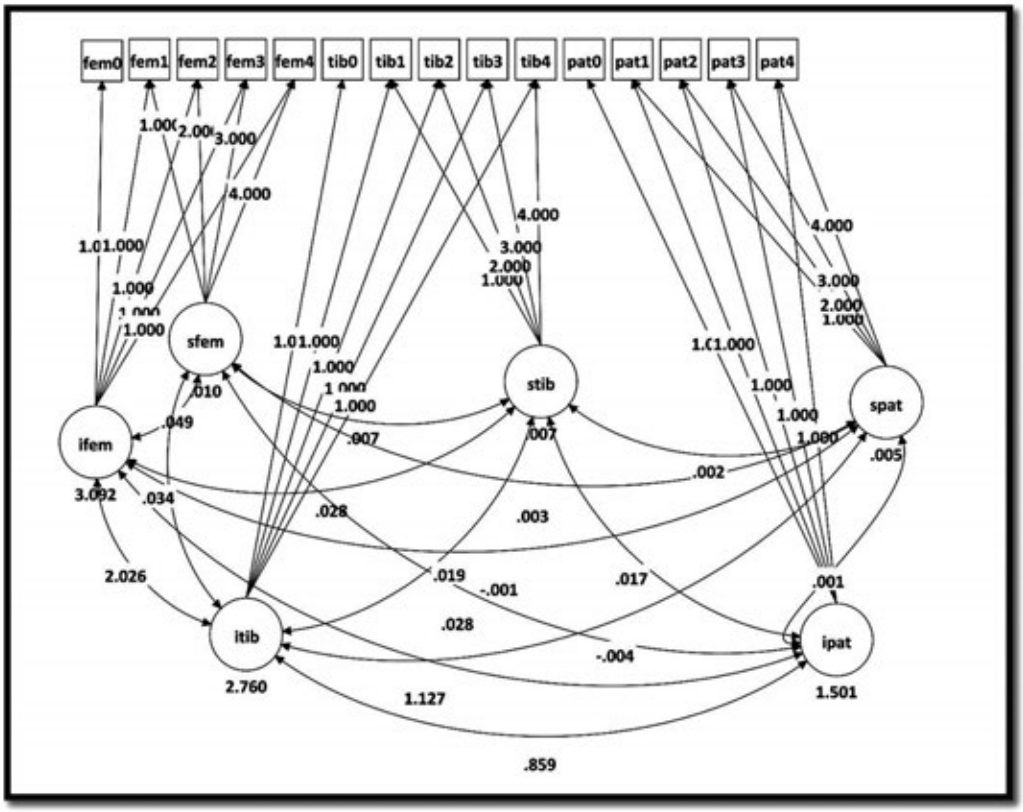
Bright Dube,[1] Michael Bowes,[2] Elizabeth Hensor,[1] Sarah Kingsbury,[3] and Philip G Conaghan[4], [1]University of Leeds, LEEDS, England, United Kingdom, [2]Imorphics, Manchester, England, United Kingdom, [3]University of Leeds, Leeds, United Kingdom, [4]Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds & NIHR Leeds Biomedical Research Centre, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 3D femur bone shape measured by statistical shape modelling (SSM) provides a responsive biomarker of knee OA. However it is unclear how the 3 knee bones (femur, tibia and patella) relate to each other and whether responsiveness is only femur-specific. We assessed baseline and longitudinal relationships between the 3 knee bones and examined factors influencing these.

Methods: We included 4796 Osteoarthritis Initiative participants with 4 year follow up (37,583 MRIs, 5031 knees without OA at baseline). 3D bone data was computed by Imorphics (Manchester, UK) from MRIs using SSMs. Briefly, an OA vector is constructed for each bone, defined as a line passing through mean shapes of bone with

Fig. 1 Parallel process growth curve model of change in all 3 bones



* fem0-fem4 = femur baseline to year 4; tib0-tib4 = tibia baseline to year 4 & pat0-pat4 = patella baseline to year 4
*ifem= femur intercept, sfem= femur slope
*itib= tibia intercept, stib=tibia slope
*ipat=patella intercept, spat=patella slope
* Values at the bottom of each growth factor ("6 o`clock posit ion") represent variances of that growth factor

and without OA, parameterised as shape components. Individual bone shapes are projected orthogonally onto this vector. Zero is defined as the mean position along the vector in those with a KL score of 0 for 4 consecutive years (Non-OA group); +1 unit is 1SD of the Non-OA group. Analyses were stratified by gender, independently for each bone. Correlation analysis was performed between bones. Next, bones classed as “OA” (bones falling above the 95th percentile of the Non-OA group) were described for all possible combinations using proportions. Latent Growth Curve Modelling (Mplus) identified growth patterns for each bone. After establishing the best-fitting models we tested the effect of covariates (age, weight, ethnicity, pain and history of knee surgery) on intercept and slope. Lastly parallel process growth models were fitted by modelling growth in all bones using one model, allowing each bone to co-vary.

Results: Positive correlation was seen between bones (femur vs tibia, *r*=0.68; femur vs patella, r=0.55& tibia vs patella, *r* =0.45). In the 3775 OA knees, 25% had all 3 bones classed as OA, 19% exclusively femur, 15% tibia, 11% patella and 20% had femur+tibia. Linear growth models showed excellent fit to the data (Table 1).Greatest rate of change, representing worsening was seen in femur (slope ~ 0.10). Increase in femur was 0.06 units/unit of baseline femur (Table 1). Rate of change in females was twice that of males. Age had no effect, but ethnicity particularly in females influenced all bones (lower intercepts in Caucasians). Ethnicity was also associated with slopes in both femur and tibia in females (Table 2). Only weight in females was associated with patella slope. Knee pain and body weight explained most intercept and slope variance (Table 2), prior knee surgery influenced baseline scores but explained

* As covariates were added to the unconditional model, the significance of the variance accounted for by the covariates was tested by fitting a reduced model in which the covariates' effect on the growth parameters were constrained to be zero and conducting the appropriate chi square test between the 2 models.
Ethnicity reference = non-white group, Pain = WOMAC Knee pain, Surgery = history of knee surgery (includes meniscectomy, arthroscopy and ligament repair)

little variance. Interrelationships between all 3 bones in their disease starting points and rates of change were statistically significant (Table 1, Figure 1).

Conclusion: There was positive correlation between the 3 bones, stronger between femur and tibia. All bones changed linearly; rate of change of femur twice that of tibia and patella and the rate in females twice that of males. Level of baseline disease, body weight and pain were important determinants of change, with similar effects on femur and tibia. Effects on patella were small, possibly due to difficulty in measuring this small bone. It therefore seems likely that the femur, tibia and patella bones are part of a single disease process, with the femur providing the greatest change.

Evaluation of Intra-articular CNTX-4975 in Subjects with Painful Bilateral Knee Osteoarthritis: Effects on Pain with Walking and Patient Impression of Change in Pain

Randall Stevens,[1] Kimberly Guedes,[1] Nilam Mistry,[1] Paul Tiseo,[2] Duncan Lascelles,[3] **Mario Mendoza**,[1] and David Ball[4], [1]Centrexion Therapeutics Corp, Boston, MA, [2]Centrexion Therapeutics Corp, Boston, [3]Translational Research in Pain, North Carolina State University, Raleigh, NC, [4]MAC Clinical Research, Manchester, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A double-blind, randomized, placebo-controlled trial (TRIUMPH; NCT02558439) with a single 1 mg intra-articular (IA) injection of CNTX-4975 (highly purified *trans*-capsaicin) into one knee for management of moderate to severe pain associated with knee osteoarthritis (OA) revealed a statistically significant and clinically meaningful decrease in pain with walking vs placebo through 24 weeks post-dose. The present open-label study (NCT03472677) evaluated the efficacy and safety of a prefilled syringe with an aqueous formulation of CNTX-4975. Presented here are the 6-week outcomes after bilateral CNTX-4975 injections.

Methods: Subjects (aged 45-75 y) with bilateral moderate to severe painful knee OA (numeric pain rating scale [NPRS, 0–10]) score of 4–9 inclusive required for enrollment) for ≥3 months before study entry received a single IA injection of CNTX-4975 1 mg into each knee, with 7 days (±2 days) between injections. ACR criteria were met by 67% of subjects for knee OA as assessed by knee pain, radiographic findings, and age >50 y; the other 33% had pain and radiographic findings, but were aged 47–49 y. IA lidocaine 2% (without epinephrine, 15 mL) was given 3–30 minutes before injection of CNTX-4975. Skin around the knee was cooled before lidocaine injection and throughout the procedure using different methods, and temperature changes in the knee joint were documented with an IA temperature probe. Pain with walking over the previous 24 hours was rated by the NPRS at baseline and at 6 weeks (trial end). Subjects also rated the change in pain in each knee using the Patient Global Impression of Change (PGIC) scale (7-point categorical scale from very much worse to very much improved). Knees were examined to determine the presence of injection site reactions, and adverse events were recorded.

Results: Fifteen subjects (30 knees) with bilateral knee OA (12 male, 3 female; mean age, 57 y) were enrolled and completed the study. Baseline and day 42 NPRS scores were averaged across both knees. At 6 weeks, pain rating by NPRS was reported as 0 in 13 of 30 assessments (15 subjects, both knees), and pain score was reported as ≤3 of 10 for 26 of 30 knees. A similar pattern of improvement was evident with the PGIC (**Table**): in 26 of 30 recordings, subjects described pain at trial end as much or very much improved. No subject reported pain as being unchanged or worse in either knee. Treatment-emergent adverse events (TEAEs) reported on the day of injection were nausea (n=3), headache (n=2), vasovagal attack, dizziness, elevated blood pressure, and tachycardia (n=1 each); all were reported as mild with 2 (vasovagal attack and 1 report of nausea) deemed possibly related to treatment. TEAEs reported after the day of injection were insect bite (n=2) and hay fever, vasovagal attack, back pain, acid reflux (esophageal), allergic conjunctivitis, and bruise (n=1 each); all were mild and deemed unlikely or not related to study treatment.

Table: PGIC* in Subjects With Bilateral Painful Knee Osteoarthritis		
	Day 42	
Subject	Left	Right
1006	1	1
1007	1	1
1008	1	1
1009	2	3
1010	2	2
1011	2	2
1012	2	3
1013	1	1
1014	1	1
1015	1	1
1016	1	1
1017	1	1
1018	2	1
1019	1	1
1020	3	3

PGIC, Patient Global Impression of Change.
*7-point categorical scale; 1=very much improved, 2=much improved, 3=minimally improved, 4=no change, 5=minimally worse, 6=much worse, 7=very much worse.

Conclusion: Pain in bilateral osteoarthritic knees was rated much or very much improved in 87% of assessments, and >40% of knees were reported pain free at 5–6 weeks post CNTX-4975 injection.

Autologous Conditioned Serum and Plasma Rich in Growth Factors Show Stronger Evidence of Efficacy Than Other Kinds of Platelet-Rich Plasma

Lilian SOLE,[1] Arthur Beck,[1] Thomas Barnetche,[2] and Pascale Vergne-Salle[3], [1]CHU de Limoges, LIMOGES, France, [2]CHU, Toulouse, France, [3]CHU limoges, Limoges, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Osteoarthritis – Clinical Poster I

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: While there is growing evidences for the efficacy of platelet-rich plasma (PRP), there is still no standardized composition. There are 3 major types of PRP: Leukocytes Rich (LR), Leukocytes Poor (LP), and Autologous Conditioned Serum (ACS) or Plasma Rich in Growth Factor (PRGF) which are without any cells. Since 2014 no meta-analysis tried to compare separately the different type of PRP. The purpose of this meta-analysis was to compare separately each kind of PRP versus hyaluronic acid (HA) for osteoarthritis (OA) to find if one of them stands out.

Methods: Randomized Controlled Trials (RCTs) at least single blinded, comparing the use of PRP an HA for OA were retrieved from PubMed, Cochrane, Embase until May 2019 and from abstracts of EULAR and ACR congrersses for the last 3 years. We chose the most used follow-up time, which was 6 months. Two readers extracted the Western Ontario and McMaster University Arthritis Index (WOMAC) and any other pain scale, and adverse events. The pooled data where analyzed with Review Manager 5.3.5.

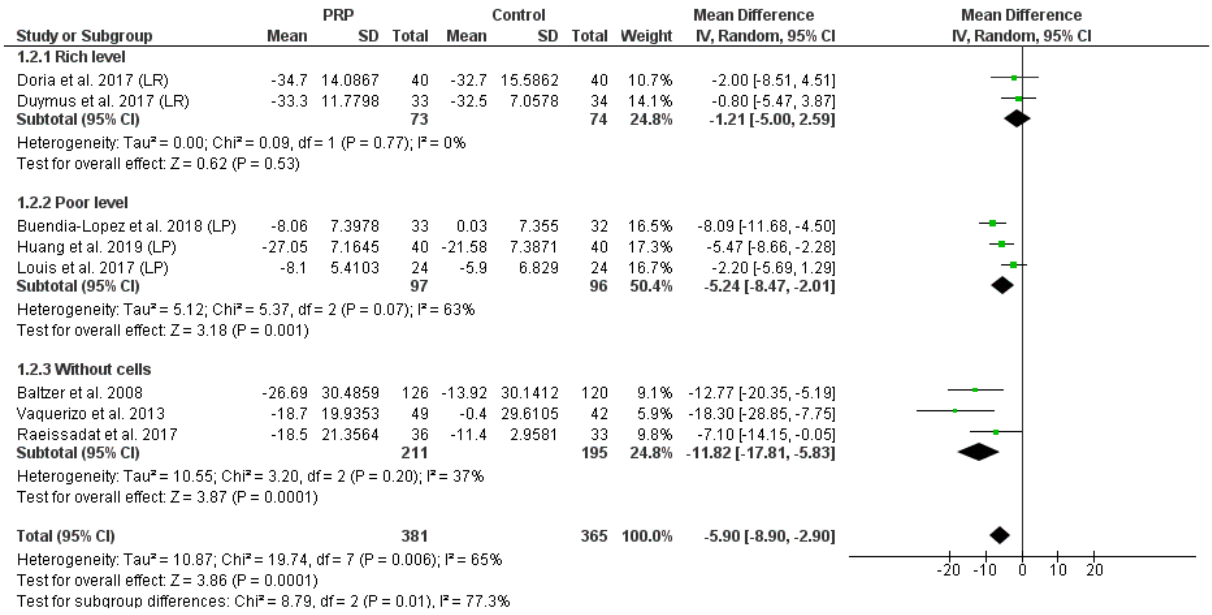

Figure 1. WOMAC changes at 6 months in different subgroups of PRP versus HA

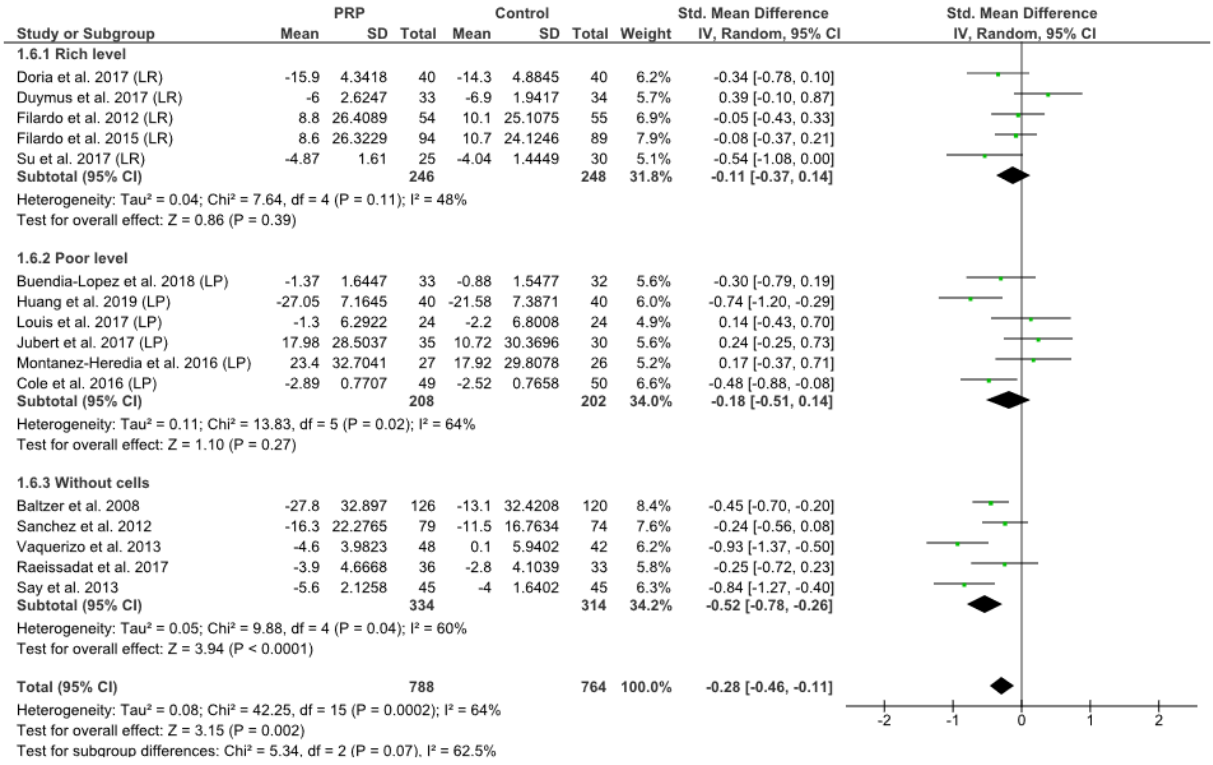

Figure 2. Standardize mean difference of pain scales at 6 months in different subgroups of PRP versus HA

Results: 1139 results were screened, 24 RCTs met the inclusion criteria, and only 16 where enough detailed to be meta-analyzed. The present meta-analysis indicated that only PRGF/ACS and LP PRP reduced significantly the WOMAC score compared with HA. The WOMAC was reduced by 5.24 points with LP-PRP and 11.82 points with ACS/PRGF (Fig.1). Concerning the pain scales only the ACS/PRGF group shown a significant difference versus HA (Fig.2). We found no link between injected platelet quantity and WOMAC index.

Conclusion: ACS/PRGF have stronger evidence of efficacy than LP or LR PRP. These results are consistent with the theorical models explaining the ways of action of PRP. Numbers of authors theorizes that anti-inflammatory cytokines contained in the platelets (like IL-1ra, TGF-β, IL-10) are responsible for the effect of PRP, while leukocyte (containing pro-inflammatory cytokines and metalloproteases) are harmful for the cartilage. The principal limit of this meta-analysis is the heterogenicity of the studies probably due to the absence of standardization of PRP, indeed inside this 3 subgroups, the preparations can still differs by the platelet concentration, the activation of platelet -chemical, physical or unactivated- or the injection scheme . No conclusion can be drawn about the superiority of one kind of PRP since we lack face to face studies.

Visceral Fat Deposition Associated with Pain in Osteoarthritis

Shanshan Li,[1] **Nancy Desai**,[2] Tuhina Neogi,[3] Ann Schwartz,[4] Lavalley Michael,[1] Na Wang,[3] Xianbang Sun,[1] Michael Nevitt,[5] Beth Lewis,[6] Ali Guermazi,[2] Frank Roemer,[7] Neil Segal,[8] and David Felson[9], [1]Boston University, Boston, [2]Boston Medical Center, Boston, [3]Boston University School of Medicine, Boston, MA, [4]University of California San Francisco, San Francisco, [5]University of California at San Francisco, San Francisco, CA, [6]University of Alabama at Birmingham, Birmingham, AL, [7]University of Erlangen-Nuremberg, Erlangen, Germany, [8]University of Kansas Medical Center, Kansas City, KS, [9]Boston University School of Medicine, Department of Rheumatology, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Animal model studies have demonstrated the significant role of inflammation in the pathogenesis of osteoarthritis (OA) and of pain. Visceral fat, rather than subcutaneous fat, is a major source of proinflammatory cytokines and adipokines. In this study, we examined whether amount of visceral fat was associated with the risk of knee OA or musculoskeletal pain.

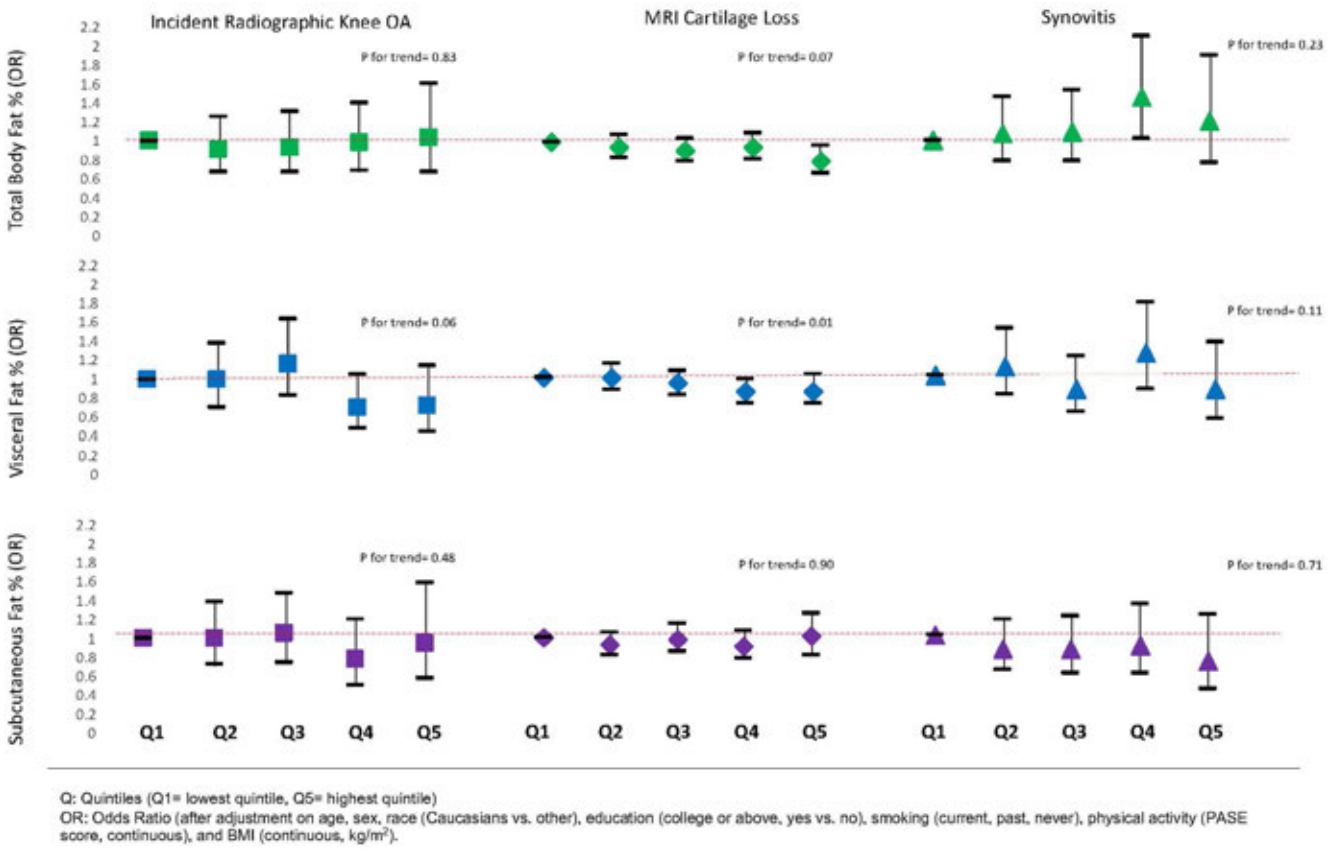

Figure 1. Association Between Fat Depots and Structural Outcomes

Methods: Participants in the Multicenter Osteoarthritis Study (MOST), a NIH funded longitudinal cohort study of persons at risk of or with knee OA underwent whole body dual energy x-ray absorptiometry (DEXA) scans at baseline that were assessed for total body fat as well as visceral fat and subcutaneous fat in the torso. In addition, participants had knee x-rays, rated severity of their knee pain and identified sites of joint pain on a body homunculus at the baseline, 30 month, and 60 month study visits. The association between the size of the fat depots with structural outcomes from baseline through 60 months (incident x-ray OA, MRI cartilage loss and worsening synovitis scores) and with pain outcomes over the same period (worsening pain; widespread pain and the number of painful joint sites) was assessed. We tested the association of sex specific quintiles of fat depot size with OA and pain outcomes performing regression analysis adjusted for age, sex, race, education, smoking, physical activity and BMI. For pain outcomes, we also adjusted for depressive symptoms and for all outcomes, adjusted for baseline status of the outcome (e.g. for WOMAC pain change, we adjusted for WOMAC pain at baseline).

Results: We studied 2,961 participants, of whom, 60.7% were women, mean age was 62.5 years and BMI 30.5 kg/m^2. After adjustment for covariates including BMI, we found no association of any fat depot size with incident

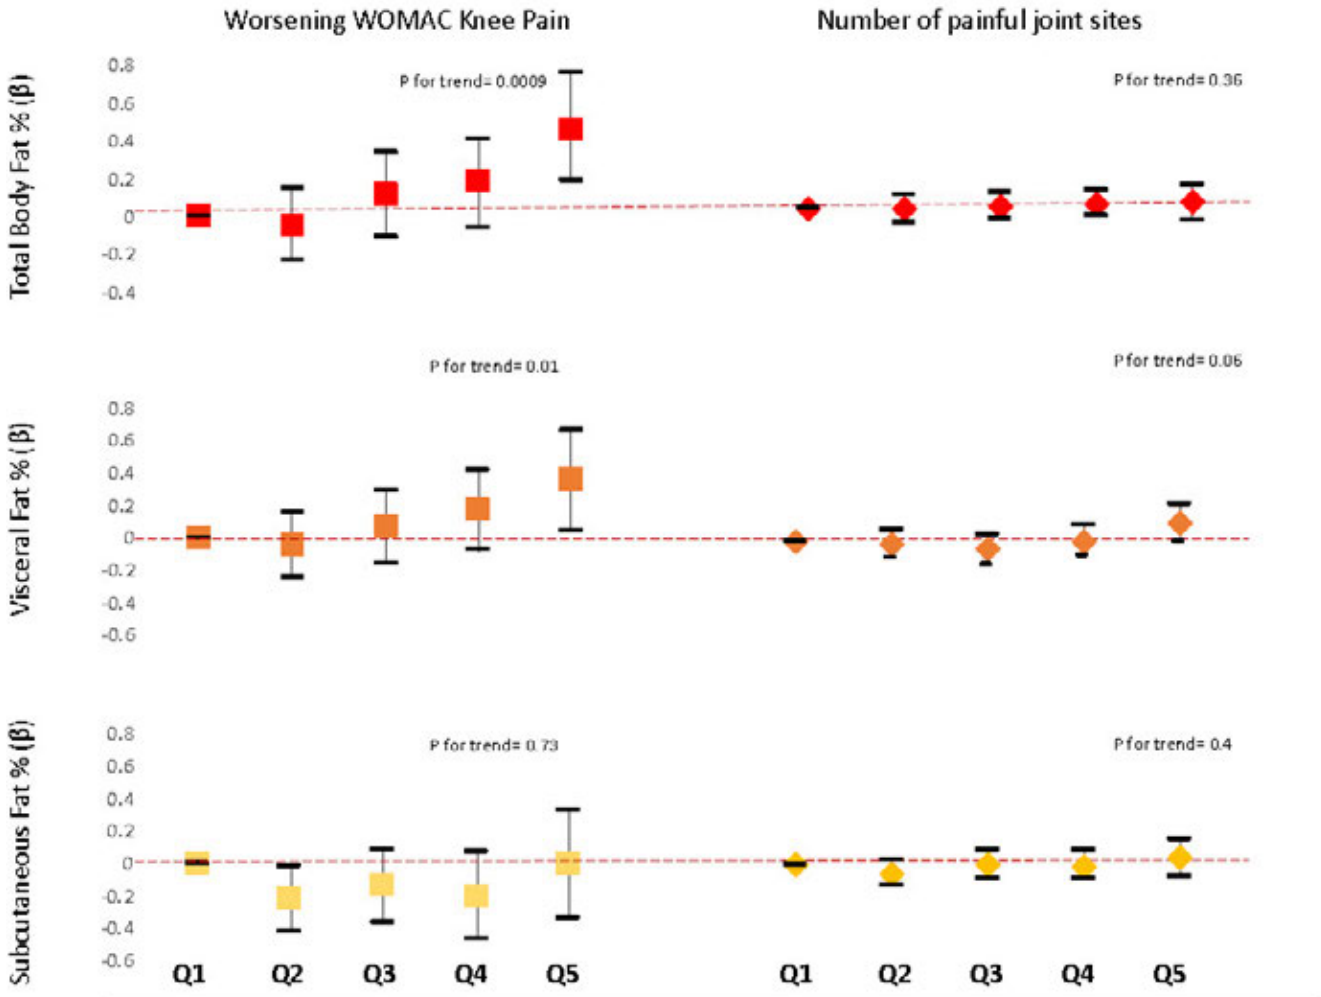

Figure 2. Association Between Fat Depots and Pain Outcomes

x-ray OA, cartilage loss or worsening synovitis on MRI (see figures below). On the other hand, total body fat and visceral fat deposit size were associated with worsening knee pain. Visceral fat in addition was associated with the number of painful joints and similar results were seen in the analyses of incident widespread pain. Subcutaneous fat was not associated with any of these pain measures. In these analyses, fat depots were associated with OA outcomes before analytic adjustment for BMI but positive results for only pain outcomes persisted after BMI adjustment.

Conclusion: Visceral fat and total body fat are associated with increased musculoskeletal pain. We found no relationship between body fat and structural changes in OA. Further investigation into identification of specific inflammatory markers produced by body visceral fat may provide further insight into these findings.

Safety, Tolerability, Pharmacokinetics and Pharmacodynamics in Healthy Male Japanese Subjects of the ADAMTS-5 Inhibitor S201086/ GLPG1972, a Potential New Treatment in OA

Agnès Lalande,[1] Nadya Kuzniatsova-Mouchette,[2] Florian Chassereau,[1] Julia Geronimi,[1] Staffan Larsson,[3] Andre Struglics,[3] Stefan Lohmander,[3] and **Maria Pueyo**[1], [1]Institut de Recherches Internationales Servier, Suresnes, France, Suresnes, France, [2]Institut de Recherches Internationales Servier, Suresnes, France, Suresnes, [3]Department of Clinical Sciences Lund, Faculty of Medicine, Lund University, Lund, Sweden, Lund, Sweden

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The disintegrin and metalloproteinase with thrombospondin motifs-5 (ADAMTS-5) is a key enzyme in OA (Verma P, *et al.* J Cell Biochem 2011;112:3507-14). In preclinical models of OA, S201086, a potent and selective inhibitor of ADAMTS-5, protects from cartilage degradation (Clement-Lacroix, *et al.* Osteoarthritis Cartilage 2017;25:S58). Therefore, S201086 is co-developed by Servier and Galapagos (GLPG1972) as a potential new treatment in OA.

The objective of this phase I study was to assess and compare the safety, tolerability, pharmacokinetics and pharmacodynamics of S201086 in healthy male Japanese and Caucasian subjects.

Methods: Six ascending single doses of S201086 (50 mg to 1500 mg) were administered orally as tablets in fasting conditions in 6 groups of 8 Japanese subjects (aged 20-45 years) and 3 ascending multiple doses (300, 600 or 1050 mg/day for 14 days) were administered orally as tablets in fed conditions in 3 groups of 8 Japanese subjects. Additionally, 2 cohorts of 8 Caucasian subjects received either a single oral dose of 300 mg or repeated oral dose of

Analysis of variance model on factor dose
(1) Estimate (Standard Error) of the difference between dose means: Placebo minus 300 mg Japanese, 600 mg or 1050 mg
(2) Two-sided 95% Confidence Interval of the estimate
(3) Two-sided p-value of the dose effect

300 mg once daily for 14 days. In each group, 6 subjects received S201086 and 2 placebo. Plasma was collected at several time points for the quantification of S201086 by LC-MS/MS. Plasma pharmacokinetic parameters were calculated via non-compartmental analysis using Phoenix® WinNonlin® software. Pharmacodynamics was assessed by measurement of the aggrecan ARGS neoepitope levels in serum by ELISA.

Results: No serious adverse drug reactions were observed after administration of single and multiple ascending doses of S201086 in either Japanese or Caucasian subjects. Most adverse events were of mild to moderate intensity and were resolved by the end of the study. Following single administration to Japanese subjects, C_{max} and AUC increased proportionally with doses from 50 to 600 mg and slightly less than dose-proportionally from 600 to 1500 mg, consistent with what was previously observed in the first in-human study in healthy Caucasian subjects (van der Aar E, *et al.* Osteoarthritis Cartilage 2018;26:S310). In Japanese subjects, after 14-days administration, a limited 1.2- to 1.4-fold accumulation was observed on both C_{max} and AUC at Day 14 as compared to Day 1, and the steady-state exposure increased dose-proportionally within the 300-1050 mg dose range. Taking the inter-subject variability into account, no difference was observed in C_{max} and AUC between Caucasian and Japanese subjects after single administrations of 300 mg and repeated administrations of 300 mg once daily for 14 days. The serum ARGS neoepitope levels decreased between baseline and last day of treatment for S201086-treated subjects but not for subjects receiving placebo. This decrease was similar for the 3 tested doses in Japanese subjects and was significant as compared to the placebo-treated subjects (see Table).

Conclusion: S201086 was shown to be safe and well-tolerated in Japanese and Caucasian healthy male subjects with a suitable PK profile and a significant decrease of the ARGS neoepitope, indicating target engagement. A global Phase 2 study to evaluate the efficacy of S201086 in patients with knee OA is ongoing (NCT03595618).

Safety Profile to Date of the Novel, Intra-articular Agent Lorecivivint (LOR; SM04690), a CLK/DYRK1A Inhibitor That Modulates the Wnt Pathway, in Subjects with Knee Osteoarthritis

Ismail Simsek,[1] Chris Swearingen,[1] Sarah Kennedy,[1] Jeyanesh Tambiah,[1] **Yusuf Yazici**,[2] Nancy Lane,[3] and Marc C. Hochberg[4], [1]Samumed, LLC, San Diego, [2]Samumed, LLC, San Diego, CA, [3]University of California at Davis Medical Center, Sacramento, CA, [4]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Recent concerns over osteoarthritis (OA) pharmacotherapy safety have led to revision of treatment guidelines and highlight the need for therapies with good safety profiles. Lorecivivint (LOR; SM04690) is a small-molecule, intra-articular (IA) CLK/DYRK1A inhibitor which modulates the Wnt pathway and is in development as a potential disease-modifying treatment for knee OA. A pooled analysis of safety data from three completed placebo-controlled studies of this new agent is reported here.

Methods: Safety data were pooled from three randomized controlled trials evaluating four concentrations (0.03 mg, 0.07 mg, 0.15 mg, and 0.23 mg) of a single IA LOR injection in subjects with moderate-to-severe symptomatic knee OA. Two trials (NCT02095548; NCT03122860) evaluated subjects for 24 weeks and one trial (NCT02536833) for 52 weeks. Two subject groups were compared: a LOR-exposed group (subjects who received any dose of LOR) and a control group (non-LOR treated subjects). Adverse events (AEs) and serious AEs (SAEs) were collected and categorized using the Medical Dictionary for Regulatory Activities (MeDRA) classification. Bone health AEs were also categorized upon medical review. Proportions of subjects with treatment-emergent AEs and SAEs were calculated for control and LOR-exposed groups. Incidence rates of bone health AEs were estimated per 100 person-years [PY] exposure for LOR and control groups.

Results: The overall incidence of AEs and SAEs were infrequent in both treated (total 350/848 [41.3%], SAE 20/848 [2.4%], 559 PY exposure) and control subjects (total 138/360 [38.3%], SAE 4/360 [1.1%], 219 PY exposure). The most common AE reported in the treated subjects was arthralgia (treated 7.6%, control 7.2%) and it was the only AE reported at >5% in either subject group (Fig. 1). Of joint-specific AEs categorized by the affected joint (Fig. 2), target-knee arthralgia was most common (treated 6.5%, control 5.3%). No AEs in other joints exceeded an incidence of 2% in either group. In all categories, individual AEs were reported at comparable rates between groups and no SAEs were deemed related to LOR by investigators.

There were 16 bone-health-related AEs in 12/1208 (1.0%) subjects; the rate of bone health AEs per 100 PY exposure was 1.61 for LOR and 1.37 for control. Of the bone health AEs, 2 were osteopenia/osteoporosis in 2 LOR-treated postmenopausal women and 14 were fractures in 10 subjects (7 LOR 1.25/100 PY, 3 control 1.37/100 PY). All frac-

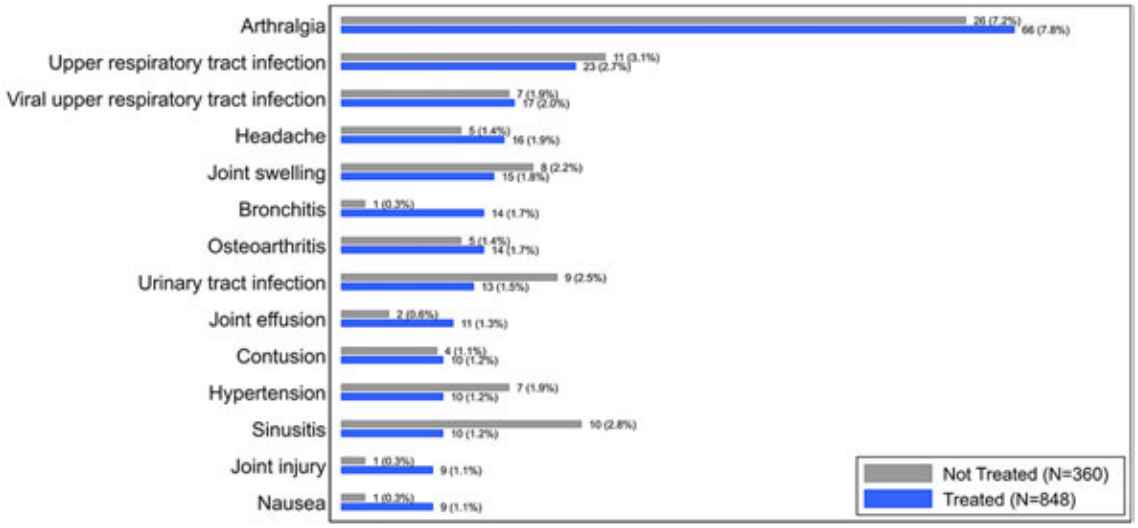

Figure 1. Adverse event summary of the total clinical trial population (N=1208) for events occurring in at least 1% of the treated population.

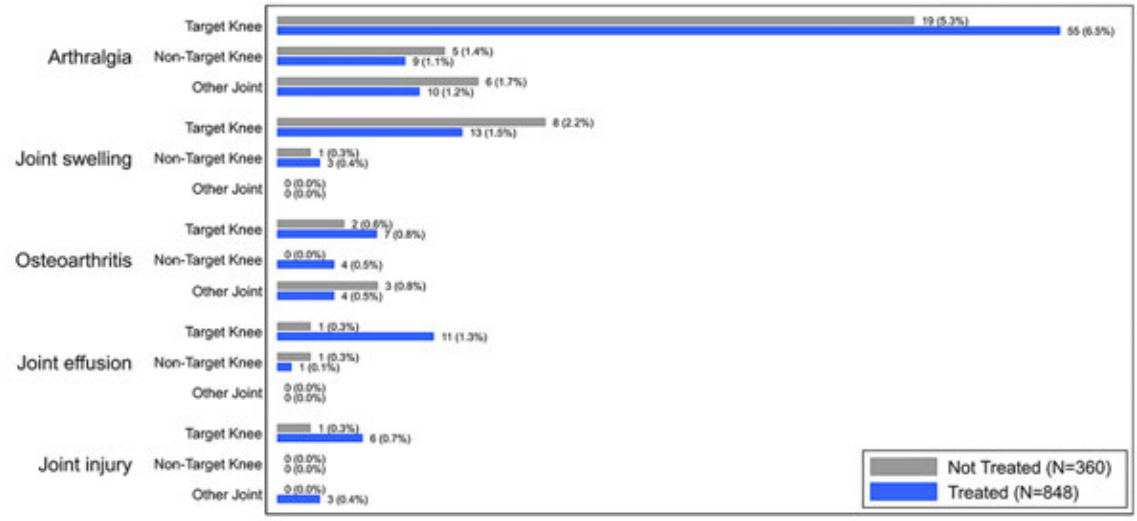

Figure 2. Joint-specific adverse event summary of the total clinical population (N=1208) for events occurring in at least 1% of the treated population and subcategorized by affected joint.

tures were adjudicated and determined to be caused by trauma and all healed uneventfully within the expected timeframe. Bone health AE incidence rates between LOR and control were similar.

Conclusion: In total exposure to date (559 PY), IA LOR for the treatment of knee OA appeared to be safe and well tolerated. These data support the continued evaluation of LOR as a treatment for OA.

The Novel, Intra-articular CLK/DYRK1A Inhibitor Lorecivivint (LOR; SM04690), Which Modulates the Wnt Pathway, Improved Responder Outcomes in Subjects with Knee Osteoarthritis: A Post Hoc Analysis from a Phase 2b Trial

Yusuf Yazici,[1] Sarah Kennedy,[2] Chris Swearingen,[2] and Jeyanesh Tambiah[2], [1]Samumed, LLC, San Diego, CA, [2]Samumed, LLC, San Diego

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Osteoarthritis – Clinical Poster I
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lorecivivint (LOR, SM04690) is a small-molecule, intra-articular (IA) CLK/DYRK1A inhibitor which modulates the Wnt pathway and has demonstrated beneficial effects on patient-reported outcomes (PROs) in two Phase 2 trials in subjects with knee OA relative to placebo (PBO). Representing PROs as discrete threshold responses instead of as changes in mean point estimates may better evaluate clinically meaningful benefits experienced by trial subjects. This post hoc analysis was conducted to measure the proportion of subjects treated with LOR in a 24-week Phase 2b study who achieved 30%, 50%, or 70% improvement over baseline by Pain Numeric Rating Scale (NRS), Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) Pain, WOMAC Function, and Patient Global Assessment (PtGA). Results from the Phase 3 selected dose of 0.07 mg LOR are presented here.

Methods: Subjects had ACR-defined knee OA, Kellgren-Lawrence (KL) grades 2-3, and Pain NRS scores ≥4 and ≤8 in the target knee and < 4 in the contralateral knee. A single, 2mL, IA injection of 0.03 mg, 0.07 mg, 0.15 mg, or 0.23 mg LOR or vehicle PBO was given in the target knee at baseline. The proportion of subjects meeting thresholds of 30%, 50%, and 70% improvements over baseline in the PROs of weekly average of daily Pain NRS [0-10], WOMAC Pain [0-100], WOMAC Function [0-100], and PtGA [0-100] at Week 12 was determined. The odds ratios (OR) of achieving each threshold improvement level were calculated.

Results: 635 subjects (91.4%) completed the study (mean age 59.0±8.5 years, BMI 29.0±4.0 kg/m2, female 58.4%, KL3 57.3%). Treatment with 0.07 mg LOR versus PBO at Week 12 led to 1) significantly ($P< 0.05$) increased odds of having a 30% response in Pain NRS (OR 2.47 [1.45, 4.19]) and WOMAC Function (OR 1.86 [1.10, 3.12]), 2) significantly increased odds of achieving a 50% response for WOMAC Pain (OR 1.79 [1.06, 3.03]) and PtGA (OR 2.28 [1.25, 4.16]), and 3) numerically, but not significantly, more subjects achieved a 70% response in all PROs. Improvements were maintained through Week 24.

Conclusion: LOR, in development as a potential disease-modifying knee OA drug, demonstrated significantly higher odds ratios of achieving and maintaining clinically relevant improvements in PROs compared to placebo from Week 12 through Week 24. Phase 3 studies are ongoing.

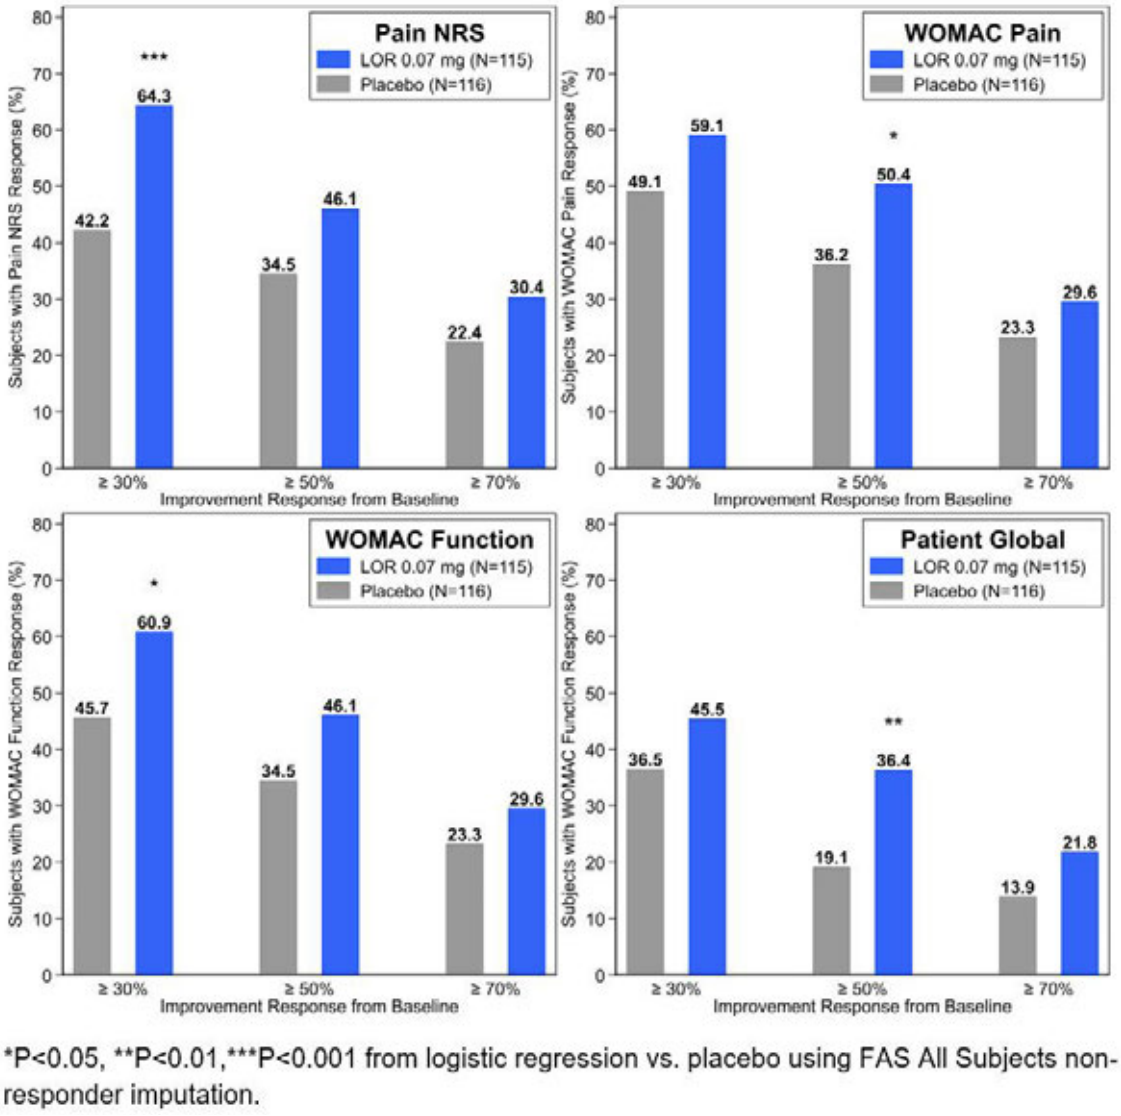

Figure Responder outcomes at Week 12 from a Phase 2b LOR trial for Pain NRS, WOMAC Pain, WOMAC Function, and Patient Global Assessment

The Patient's Perspective on a Disease Flare During Tapering of DMARDs in Rheumatoid Arthritis

Elise van Mulligen,[1] Angelique Weel,[2] Martijn Kuijper,[2] Mieke Hazes*,[3] Annette van der Helm-van Mil,[4] and Pascal de Jong[1], [1]Erasmus MC, Rotterdam, Netherlands, [2]Maasstad Hospital, Rotterdam, Netherlands, [3]Erasmus MC, University Medical Center Rotterdam, Department of Rheumatology, Rotterdam, The Netherlands, Rotterdam, Netherlands, [4]LUMC, Leiden, Zuid-Holland, Netherlands

SESSION INFORMATION

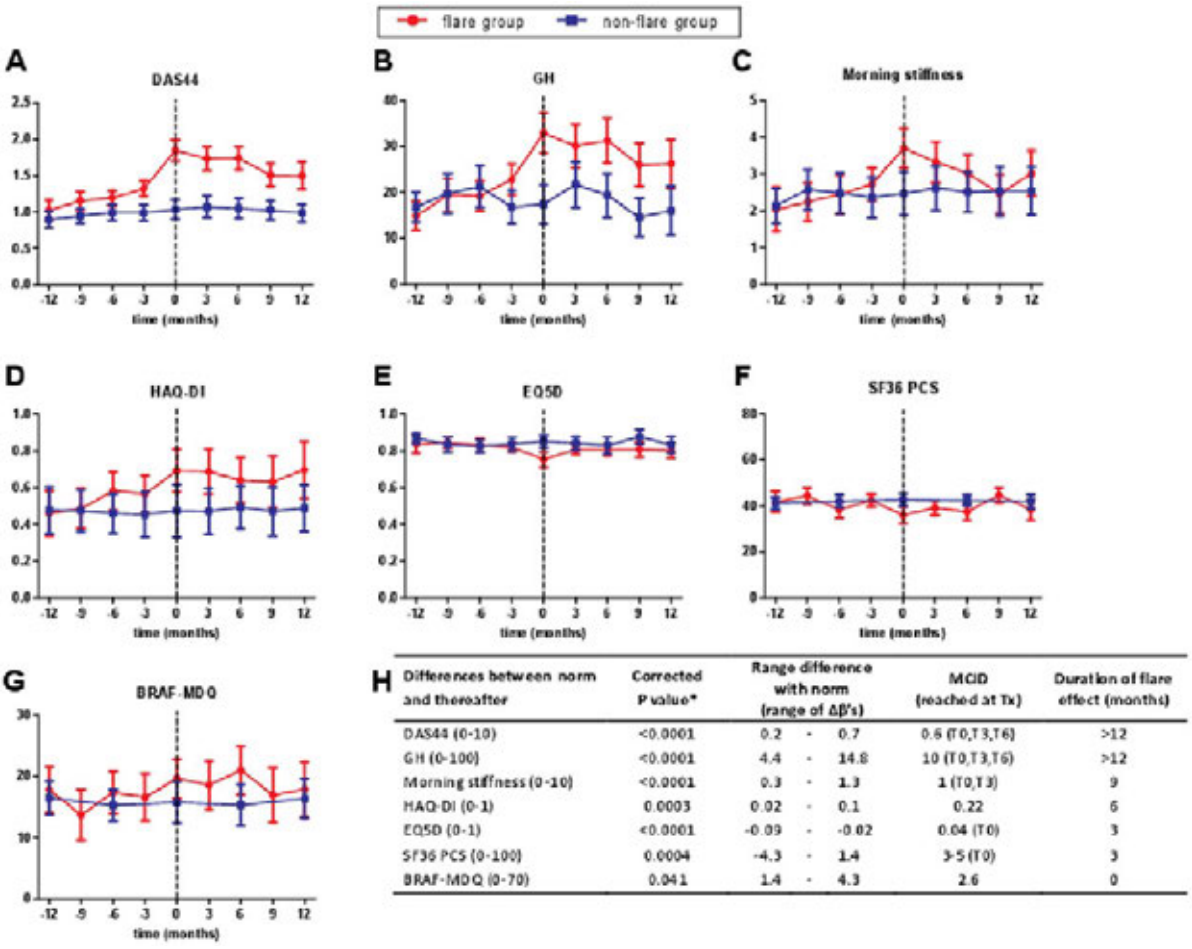
Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have shown that it is possible to taper DMARDs in RA patients with an inactive disease, but this is accompanied with a higher chance of disease flares. Current recommendations advise to taper DMARDs from a clinical viewpoint. However, data on the feasibility of tapering DMARDs from a patient's perspective are sparse. Therefore, the objective of this study is to determine the impact and length of a disease flare, on patient reported outcome (PROs) in rheumatoid arthritis (RA) patients, who are tapering treatment.

Methods: Data were used from the TARA trial; A multicenter, randomised controlled trial with well-controlled RA patients, DAS≤2.4 & SJC≤1, gradually tapering treatment. PROs of patients with a flare, DAS >2.4 or SJC >1, were compared at the moment of flare, 3 months prior to flare and every 3 months thereafter with their own norm. The norm was set at the average of DAS and PROs 12, 9 and 6 months prior to flare, which in our opinion was the best reference for well-controlled disease (figure 1A-G). Linear Mixed Models were used to determine within flaring patients if a flare altered DAS, VAS general health (GH), morning stiffness, functional ability (HAQ-DI), fatigue (BRAF-MDQ), quality of life (EQ-5D, SF36), anxiety and depression (HADS), and worker productivity over time, and if so, the duration was determined. For sick leave and unemployment we used descriptive statistics.



H

Differences between norm and thereafter	Corrected P value*	Range difference with norm (range of Δβ's)	MCID (reached at Tx)	Duration of flare effect (months)
DAS44 (0-10)	<0.0001	0.2 - 0.7	0.6 (T0,T3,T6)	>12
GH (0-100)	<0.0001	4.4 - 14.8	10 (T0,T3,T6)	>12
Morning stiffness (0-10)	<0.0001	0.3 - 1.3	1 (T0,T3)	9
HAQ-DI (0-1)	0.0003	0.02 - 0.1	0.22	6
EQ5D (0-1)	<0.0001	-0.09 - -0.02	0.04 (T0)	3
SF36 PCS (0-100)	0.0004	-4.3 - 1.4	3-5 (T0)	3
BRAF-MDQ (0-70)	0.041	1.4 - 4.3	2.6	0

Figure 1 (A-G) Patient reported outcomes that show an effect of flare. For all outcomes the mean is shown, error bars indicate 95% confidence intervals. T0 indicates the moment of flare for the flare group, for the non-flare group this is the original T12. (H) Summary of the comparison of the overal differences with the norm, which is the mean of -T12, -T9, and -T6. *Bonferoni corrected, n=11. Abbreviations: BRAF-MDQ; Bristol Rheumatoid Arthritis Fatigue - Multidimensional Questionnaire, DAS; disease activity score, EQ5D; European Quality of Life questionnaire with 5 dimensions, GH; visual analogue scale (VAS) for General Health, HAQ-DI; health assessment questionnaire, MCID; minimal clinically important difference, SF36 PCS; Short form 36 physical component score.

Results: In total, 113 patients experienced a flare. Patients who had a flare had a less stable course of the outcomes over time, compared with patients without a flare (Figure 1A-G). When comparing all time points to the norm, statistical significant differences were found for DAS ($p< 0.0001$), GH ($p< 0.0001$), morning stiffness ($p< 0.0001$), HAQ-DI ($p=0.0003$), EQ-5D ($p< 0.0001$), SF36 physical component scale (SF36-PCS) ($p=0.0004$), and the BRAF-MDQ ($p=0.04$) (Figure 1A-H). The DAS and GH significantly worsened at the moment of flare and this effect lasted >12 months. Morning stiffness and HAQ-DI worsened at the moment of flare and these PROs returned to their norm values 6 months thereafter (Figure 1H). The EQ5D and the SF36-PCS only worsened at the moment of flare. The BRAF-MDQ was not significantly different from the norm when comparing separate time points. For DAS, GH, morning stiffness, EQ-5D, SF36-PCS, and BRAF-MDQ the effect sizes were above the minimal clinically important difference (MCID) for >3 months (figure1H). Although the amount of sick leave increased from 1 to 1.3 days per month in the 6 months after flare and the worker productivity declined with 10% in the 3 months after a flare, these differences were not significant.

Conclusion: A disease flare influenced patients' lives, which was mainly physical, and lasted at least 6 months. Although on a group level the effect size for each PRO is not always greater than the specific MCID, a disease flare can still be of great importance for the individual patient**.**

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an orally administered, selective inhibitor of Janus Kinase 1 (JAK1) that is under development for the treatment of RA and other inflammatory diseases. The safety and efficacy of FIL has been investigated in the FINCH clinical program that includes three Phase 3, randomized, multicenter studies in patients (pts) with moderate to severely active RA, who had an inadequate response to MTX (FINCH 1; NCT02889796); who were receiving conventional DMARDs and had an inadequate response to biological therapies (FINCH 2; NCT02873936); or who were MTX naïve and initiating MTX alone or in conjunction with FIL or receiving FIL monotherapy (FINCH 3; NCT02886728). Here we present pooled safety data from the double-blind, active and placebo controlled periods of FINCH 1–3 up to 24 weeks.

Table 1. Frequency of treatment-emergent AEs and all deaths across FINCH 1–3 Phase 3 studies (weeks 0–24)

n (%)	Placebo + MTX/csDMARD N = 1,039	ADA 40mg + MTX N = 325	FIL 100 mg + MTX/csDMARD N = 840	FIL 200 mg + MTX/csDMARD N = 1,038	FIL 200 mg N = 210	FIL Total N = 2,088
Treatment-emergent AE	614 (59.1)	185 (56.9)	527 (62.7)	663 (63.9)	113 (53.8)	1303 (62.4)
Treatment-emergent serious AE	37 (3.6)	14 (4.3)	37 (4.4)	44 (4.2)	10 (4.8)	91 (4.4)
Treatment-emergent AE of Interest	253 (24.4)	91 (28.0)	232 (27.6)	289 (27.8)	54 (25.7)	575 (27.5)
Infectious AE	244 (23.5)	88 (27.1)	229 (27.3)	283 (27.3)	53 (25.2)	565 (27.1)
Serious Infectious AE	10 (1.0)	8 (2.5)	13 (1.5)	13 (1.3)	3 (1.4)	29 (1.4)
Herpes Zoster	4 (0.4)	2 (0.6)	5 (0.6)	6 (0.6)	1 (0.5)	12 (0.6)
Hepatitis B or C	1 (0.1)	1 (0.3)	0 (0)	2 (0.2)	0 (0)	2 (0.1)
Opportunistic Infections	0 (0)	1 (0.3)	0 (0)	1 (0.1)	0 (0)	1 (0)
Active TB	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
MACE	5 (0.5)	1 (0.3)	2 (0.2)	2 (0.2)	1 (0.5)	5 (0.2)
DVT/PE	3 (0.3)	0 (0)	0 (0)	1 (0.1)#	0 (0)	1 (<0.1)#
Malignancy Excluding NMSC	4 (0.4)	1 (0.3)	1 (0.1)	0 (0)	0 (0)	1 (<0.1)
NMSC	0 (0)	0 (0)	0 (0)	1 (0.1)	0 (0)	1 (<0.1)
Gastrointestinal Perforations	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)	0 (0)
Death	2 (0.2)	0 (0)	1 (0.1)	3 (0.3)	0 (0)	4 (0.2)

ADA, adalimumab; csDMARD, conventional synthetic DMARD; DVT, deep vein thrombosis; FIL, filgotinib; MACE, major adverse cardiac event; NMSC, Nonmelanoma Skin Cancer; PBO, placebo; PE, pulmonary embolism; TB, tuberculosis. # excludes one event of retinal vein occlusion.

Methods: The FINCH studies enrolled pts who had a diagnosis of RA (2010 ACR/EULAR criteria) and had ≥ 6 swollen joints and ≥ 6 tender joints at both screening and Day 1. Safety analyses included pts who had received at least one dose of study drug. Pts in FINCH 1 and 2 who did not experience at least a 20% improvement in both swollen joint count and tender joint count by Week 14 discontinued study drug and switched to standard of care. Week 24 safety data from the FINCH 1, 2, and 3 were aggregated and summarized by the number and percentage of pts with events or abnormalities for categorical values. The key safety endpoints reported are treatment-emergent adverse events (AE), treatment-emergent serious AEs, treatment-emergent AEs of interest, all death and treatment-emergent laboratory abnormalities.

Results: This pooled safety analyses assessed 3,452 pts across FINCH 1–3, including 2,088 pts who received FIL. At Week 24, the frequency of treatment-emergent AEs were similar between pts who received FIL and those in the control arms of the FINCH studies (Table 1). Furthermore, the proportions of pts with treatment-emergent AEs of interest were also similar across groups. The most common treatment-emergent AEs were infections, notably upper respiratory tract and nasopharyngitis. Laboratory abnormalities occurred at similar rates with FIL and placebo or active control and were mostly mild to moderate (Grade 1 & 2). Overall, the frequency of major adverse cardiac events (MACE), herpes zoster virus, deep vein thrombosis (DVT) and pulmonary embolism (PE) was low, and similar across groups. The incidences of MACE were 0.2% for FIL, 0.3% for adalimumab (ADA), and 0.5% for placebo/csDMARD. Additionally, the incidences of DVT/PE were < 0.1% for FIL, 0% for ADA, and 0.3% for placebo/csDMARD.

Conclusion: Although gathered over a short duration (24 weeks), pooled data from this large safety database describing a broad population of pts with RA highlights the favorable safety and tolerability profile of FIL in pts with RA both as a monotherapy and in conjunction with MTX/csDMARD.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Due to demographic changes an increasing number of persons reach an age above 70 years. Therefore, the adequate therapy of elderly patients with rheumatoid arthritis (RA) is an increasingly important topic. The aim of this study was to compare treatment continuation of several biologic (b)DMARDs in patients ≤ 65

with elderly patients > 70 years, stratified by onset of disease (young onset (< 65 years) and late onset (≥ 65 years)) and by seropositivity.

Methods: The German register RABBIT is a prospective longitudinally followed cohort of RA patients enrolled with a new start of a DMARD after at least one conventional synthetic (cs)DMARD failure. For the current analysis patients who were enrolled with a bDMARD between 01/2007 and 04/2018 were included. Kaplan Meier methods were applied to analyse treatment continuation.

Results: Among the 9,819 RA patients included in the analysis, 7,972 were ≤ 65 years old and 1,847 were older than 70 years (among them 180 patients above 80 years). Among the patients ≤ 65 years, 28% received a csDMARDs and 72% a bDMARD, while among the patients above 70 years, 35% received a csDMARDs and 65% a biological. Elderly patients with a young disease onset (YORA) were more frequently women and more frequently seropositive, on average had a higher number of prior csDMARD treatment failures, a worse physical function and were more likely to have joint erosions than elderly patients with late disease onset (LORA) (Table 1). On all bDMARD treatments investigated, elderly RA patients showed the same treatment continuation as seen in younger patients. While neither the age of the patients nor the age at disease onset changed the continuation of biologicals, patients being seronegative had a significantly lower continuation with rituximab and abatacept treatment, irrespective of age (Figure 1).

Conclusion: These results suggest that bDMARD treatment may be used for elderly patients with the same effectiveness as in younger patients.

Table 1. Baseline characteristics of patients, stratified by age and disease onset. Where not otherwise indicated numbers are mean (SD)

Parameter	*≤ 65 years*	*> 70 years, LORA*	*> 70 years, YORA*
N	7,972	1,009	838
Age in years	51.6 (9.5)	76.4 (3.9)	74.3 (2.9)
Female patients	74.7%	72.7%	79.4%
Disease duration in years	8.6 (7.8)	4.4 (3.4)	20.4 (10.4)
Number of prior csDMARDs	2.1 (1.1)	1.7 (0.9)	2.5 (1.2)
ESR	27.2 (21.3)	34.6 (24.5)	33.9 (23.6)
CRP	13.4 (20)	15.3 (20.5)	16.4 (23.4)
DAS28	4.8 (1.3)	5.0 (1.3)	5.2 (1.3)
Number of comorbidities	1.8 (1.9)	3.4 (2.6)	3.7 (2.5)
Patients with >3 comorbidities	26.9%	55.5%	62.4%
Patients with no comorbidities	28.1%	4.6%	4.2%
Seropositive patients (RF/ACPA)	72.4%	69.1%	81.3%
% of full physical function	67.5 (22.4)	60.3 (24.4)	55.4 (23.4)
Glucocorticoid dose in mg/d	6.0 (6.2)	6.1 (4.5)	5.6 (4.4)
Patients with joint erosions	47.9%	46.2%	76.0%

No Confirmation of Increased Risk of Idiopathic Facial Nerve Palsy Under Tocilizumab

Anja Strangfeld,[1] Yvette Meissner,[2] Martin Schaefer,[3] Lisa Baganz,[2] Matthias Schneider,[4] Elke Wilden,[5] Silke Zinke,[7] and Angela Zink[7], [1]German Rheumatism Research Center (DRFZ), Berlin, Germany, [2]German Rheumatism Research Centre, Berlin, Germany, [3]German Rheumatism Research Center, Berlin, Germany, [4]Policlinic for Rheumatology & Hiller Research Centre for Rheumatology, Heinrich-Heine-University Duesseldorf, Düsseldorf, Germany, [5]Rheumatologist, Cologne, Germany, [6]Rheumatologist, Berlin, Germany, [7]German Rheumatism Research Centre and Charité University medicine, Berlin, Germany

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Spontaneous reports of nine facial paralyses and five facial pareses made by healthcare professionals from Europe have recently prompted EMA's Pharmacovigilance Risk Assessment Committee (PRAC) to consider a potentially increased risk of idiopathic facial nerve palsy for patients receiving tocilizumab. The objective was to assess whether this signal can be confirmed with data of a large data set with known denominators for various treatments, comparing the risk in patients with rheumatoid arthritis (RA) receiving tocilizumab with the risk in patients receiving other DMARDs.

Methods: The German register RABBIT is a prospective longitudinally followed cohort of RA patients with a new start of a DMARD after at least one conventional synthetic (cs)DMARD failure. For this analysis, patients were included who were enrolled with a biologic (b)DMARD start between 01/2007 and 04/2018. DMARD specific, unadjusted incidence ratios were calculated.

Results: Between 2007 and 2018, a total of 20 facial nerve palsies were observed in 11,963 RABBIT patients, of those, three were excluded due to obvious reasons (e.g. stroke) leaving 17 idiopathic facial nerve palsies. Three of them were observed in tocilizumab patients, leading to an incidence rate of 0.47 per 1,000 PY (95% CI: 0.10, 1.14), which is higher than the incidence rate observed in patients receiving conventional synthetic (cs)DMARDs (0.21, 95% CI: 0.04; 0.51) but does not stand out among the incidence rates observed for other biologicals (see figure). The overall incidence of an idiopathic facial nerve palsy among patients receiving (synthetic or biological) DMARDs was 0.37 (95% CI: 0.22, 0.57) which is higher than the incidence of idiopathic facial nerve palsies in the general population (with 20-25 cases per 100,000 [1]). Age and gender were roughly equally distributed among patients with and without idiopathic facial nerve palsies. Patients with idiopathic facial nerve palsies had longer disease duration, more frequently presented with joint erosions and with prior treatment with biologics (see table). They also had more comorbidities. In one patient with idiopathic facial nerve palsy receiving treatment with rituximab (original biologic) a Sjoegrens' syndrome was reported as comorbidity, which is associated with an increased risk of neuropathies.

Conclusion: The overall incidence of idiopathic facial nerve palsies among RA patients receiving DMARDs was higher than the incidence in the general population. However, an increased risk for patients receiving tocilizumab compared to patients treated with other biologicals cannot be confirmed. The incidence of idiopathic facial nerve palsies is higher for patients receiving biologicals compared to patients receiving csDMARDs. This might be due to the higher disease activity. However, the small number of cases with an idiopathic facial nerve palsy is a limiting factor in analysing and interpreting these results.

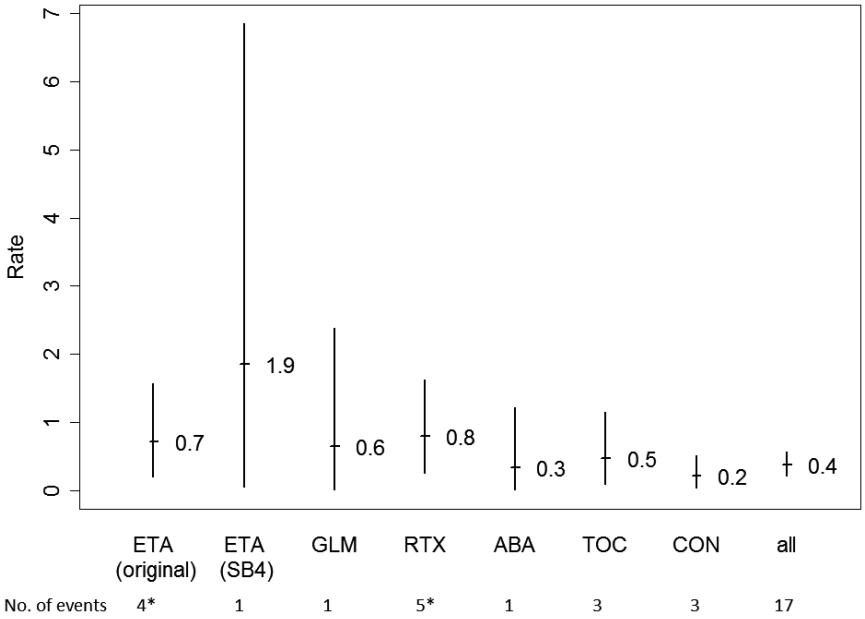

Figure. Unadjusted incidence rates for idiopathic facial nerve palsies per 1,000 patient years under treatment and 95% confidence interval. *One patient was exposed to both Etanercept (original) and Rituximab at the time of event.

Parameter	FNP	No FNP
N	17	11,946
Age	60.6 (12.6)	57.5 (12.7)

United States Rheumatology Practice-Based Real-World Evidence of Infusion Reactions in Rheumatoid Arthritis Patients Treated with Intravenous Golimumab or Infliximab: Impact of Prior Biologic Exposure and Methotrexate Utilization

Sergio Schwartzman,[1] Aaron Broadwell,[2] Alan Kivitz,[3] Shawn Black,[4] Stephen Xu,[5] and Shelly Kafka[6], [1]The Hospital for Special Surgery, Weill Medical College of Cornell University, New York Presbyterian Hospital, New York, NY, [2]Rheumatology and Osteoporosis Specialists, Shreveport, LA, USA, Shreveport, LA, [3]Altoona Center for Clinical Research, Duncansville, PA, [4]Janssen Scientific Affairs, LLC, Horsham, RI, [5]Janssen Research & Development, LLC, Spring House, PA, [6]Janssen Scientific Affairs, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis) is an ongoing Phase 4 comparator study designed to provide a real-world assessment of intravenous golimumab (GLM) and intravenous infliximab (IFX) in patients with rheumatoid arthritis (RA). The study recently reached its Primary Endpoint (comparison of the overall incidence of infusion reactions in GLM- vs IFX-treated patients after 52 weeks) with the last patient reaching 52 weeks of treatment or discontinuation from the study. AWARE also records prior use of biologic medications and concomitant use of methotrexate (MTX). Here we report the incidence of infusion reactions among GLM and IFX patients, examining the influence of prior biologic exposure or concurrent use of MTX, reported at baseline.

Methods: AWARE is a prospective, noninterventional, observational, multicenter, 3-year study conducted in the US. RA patients (1,270 adults) were enrolled at the time of initiating treatment with GLM or IFX. All treatment decisions were made at the discretion of the treating rheumatologist. An infusion reaction was any adverse event that occurred during an infusion or within 1 hour after the infusion of either GLM or IFX. Imputations were not performed on these AWARE data. Data shown are mean ± standard deviation.

Results: Demographics are shown in Table 1 and the incidence of infusion reactions in the different AWARE cohorts is shown in Table 2. Demographically, GLM and IFX patients were, sex and utilization of MTX at baseline. Both age and disease duration of GLM patients was greater than IFX patients by approximately 2 years. There was a higher proportion of bionaïve patients in the IFX-treated group compared with the GLM-treated group. Overall, infusion reactions occurred more frequently among IFX-treated patients compared with GLM-treated patients. The difference in infusion reaction rates between the IFX- and GLM-treated patients was also evident among subgroups of both

Table 1. Baseline Characteristics in the AWARE Study		
	GLM (n=685)	IFX (n=585)
Age (years)	60.9 ± 13.43	58.0 ± 12.85
Sex (% female)	85.0 %	79.5 %
Disease Duration (years)	9.16 ± 9.975	7.20 ± 9.716
Bionaïve (%)	33.0%	48.6%
MTX plus (%)	75.4%	75.1%
MTX=methotrexate		

Table. Baseline characteristics of patients with idiopathic facial nerve palsy (FNP) compared to all patients without the event. For continuous variables, mean and standard deviation are reported, while for categorical variables absolute numbers and percentages are reported.

Table 2. Infusion Reactions in AWARE in Subsets of Patients ± Prior Biologic Use or ± Concurrent MTX								
	GLM (n=685)		IFX (n=585)		GLM (n=685)		IFX (n=585)	
	Bionaïve	Non-Bionaïve	Bionaïve	Non-Bionaïve	No MTX Use	MTX Use	No MTX Use	MTX Use
Infusion Reactions	6/242 (2.5%)	21/443 (4.7%)	36/251 (14.3%)	47/334 (14.1%)	15/265 (5.7%)	12/420 (2.9%)	44/229 (19.2%)	39/356 (11.0%)
Medication for Infusion Reactions	33.3%	59.1%	78.9%	73.6%	50.%	58.3%	73.6%	77.6%
MTX=methotrexate								

bionaïve vs non-bionaïve patients, and among both MTX non-users vs MTX users (characteristics reported at baseline). GLM patients did not report any serious or severe infusion reactions. These were reported rarely (3 of 585 pts) in IFX-treated patients. Among GLM and IFX pts with an infusion reaction, 55.6% of GLM and 77.1% of IFX pts had at least one medication for infusion reaction. Infusion reactions accounted for 9.7% and 35.1% of discontinuations due to adverse events in GLM and IFX pts, respectively.

Conclusion: Whether bionaïve, non-bionaïve, MTX non-user or MTX user at baseline, the incidence of infusion reactions was notably lower among GLM- vs IFX-treated pts. Serious and/or severe infusion reactions did not occur among GLM patients and were rare among IFX patients. IFX patients were more commonly administered mediation for an infusion reaction compared to GLM patients. Infusion reactions accounted for almost four times the number of discontinuations related to adverse events in IFX patients compared to GLM patients.

Abstract Number: 1333

The Comparative Risk of Osteoporotic Fractures Among Patients with Rheumatoid Arthritis Receiving TNF Inhibitors versus Other Biologics: A Nation-wide Cohort Study in Korea

Eun Hye Park,[1] Anna Shin,[2] Yaa-Hui Dong,[3] You-Jung Ha,[1] Yun Jong Lee,[4] Eun Bong Lee,[5] Yeong-Wook Song,[6] and Eun Ha Kang[1], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea, [2]Seoul National University Bundang Hospital, Seongnam, Republic of Korea, [3]Graduate Institute of Epidemiology and Preventive Medicine, National Taiwan University, Taipei, Taiwan (Republic of China), [4]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea, [5]Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, seoul, [6]Seoul National University Hospital, Seoul, Republic of Korea

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is associated with an increased risk of osteoporosis and osteoporotic fracture, but little is known about comparative risk of osteoporotic fractures between different biologic agents. We therefore aimed to investigate the comparative risk of osteoporotic fractures among RA patients who initiated TNF inhibitors (TNFi), abatacept, and tocilizumab.

Table 1. Risk of osteoporotic fractures in TNF inhibitor initiators vs. abatacept initiators and tocilizumab initiators

	TNF inhibitor (n=2,307)			Abatacept (n=588)			HR (95% CI)
	Events	PYs	IR per 100 PY	Events	PYs	IR per 100 PY	
Primary outcome							
Osteoporotic fracture	47	2,898	1.62	12	715	1.68	0.98 (0.48-2.03)
Secondary outcomes							
Vertebral fracture	25	2,916	0.86	8	719	1.11	0.87 (0.36-2.09)
Non-vertebral fracture	22	2,925	0.75	4	725	0.55	1.23 (0.33-4.61)
	TNF inhibitor (n=2,462)			Tocilizumab (n=640)			HR (95% CI)
	Events	PYs	IR per 100 PY	Events	PYs	IR per 100 PY	
Primary outcome							
Osteoporotic fracture	54	3,153	1.71	16	771	2.08	0.90 (0.48-1.70)
Secondary outcomes							
Vertebral fracture	30	3,175	0.95	10	778	1.29	0.90 (0.41-1.99)
Non-vertebral fracture	24	3,185	0.75	6	782	0.77	0.91 (0.32-2.58)

IR is per 100 person-years. IR=incidence rate, HR=hazard ratio, CI=confidence interval, PY=person-years

Methods: We identified patients aged ≥ 40 years with at least two ICD-10 diagnosis codes for RA who initiated TNFi, abatacept, or tocilizumab from the 2002-2015 Korean National Health Insurance Service datasets. The primary outcome was a composite osteoporotic fracture endpoint of spine, hip, forearm or humerus requiring hospitalization. Secondary outcomes were vertebral and non-vertebral fractures. Follow-up period started from the day after the first dispensing date of the study drug to the earliest date among the following events: discontinuation of the study drugs, outcome occurrence, disenrollment, end of study dataset, or death. Propensity score (PS) matching with a variable ratio up to 10:1 was conducted for TNFi versus abatacept initiators and for TNFi versus tocilizumab initiators to adjust for baseline confounding. We estimated hazard ratios (HRs) and 95% confidence interval (CI) of osteoporotic fracture risks comparing TNFi to abatacept or tocilizumab by Cox proportional hazard models stratified by a matching ratio.

Results: We included 2,307 TNFi initiators and 588 abatacept initiators, and 2,462 TNFi initiators and 640 tocilizumab initiators in each PS-matched cohort. The incidence of the primary outcome per 100 person-years was 1.62 and 1.68 for initiators of TNFi and abatacept, and 1.71 and 2.08 for initiators of TNFi and tocilizumab, respectively. The HRs for the primary outcome were 0.98 (95% CI 0.48-2.03) comparing TNFi versus abatacept initiators and 0.90 (95% CI 0.48-1.70) comparing TNFi versus tocilizumab initiators. The adjusted risks of secondary outcomes were also comparable between RA patients initiating TNFi versus abatacept, or versus tocilizumab (Table 1).

Conclusion: We did not find a significant difference in the risk of osteoporotic fractures between TNFi and abatacept initiators, or between TNF inhibitor and tocilizumab initiators in this Korean population-based cohort study.

Abstract Number: 1334

Patterns of Fatigue in Rheumatoid Arthritis Patients Who Received Biological and Targeted Synthetic Disease-Modifying Antirheumatic Drugs

Dalifer Freites Nuñez,[1] Leticia León,[2] Marta Redondo,[3] Cristina Vadillo Font,[4] Pia Lois,[5] Arkaitz Mucientes Ruiz,[4] Luis Rodríguez-Rodríguez,[6] Benjamín Fernández Gutiérrez,[7] Juan Angel Jover Jover,[4] and lydia Abasolo Alcazar[4], [1]Hospital Clínico San Carlos, MADRID, Spain, [2]Fundación para la Investigación Biomedica, Madrid, Madrid, Spain, [3]Universidad Camilo José Ceja, Madrid, Madrid, Spain, [4]HOSPITAL CLINICO SAN CARLOS, MADRID, Spain, [5]Hospital Clínico San Carlos, Madrid, Madrid, Spain, [6]Fundación para la Investigación Biomedica, Madrid, Spain, [7]Hospital Clínico San Carlos, Madrid

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is one of the most frequent symptoms in patients with rheumatoid arthritis (RA), affecting more than 80% of them. The experience of fatigue is multidimensional. **Purpose:** to identify the factors associated with fatigue on its different subscales (Physical, Living, Cognitive and Emotional).

Methods: Cross-sectional study. 79 patients were included, patients were being followed up in the rheumatology outpatient clinic of Hospital Clínico San Carlos, Madrid, Spain. Data were collected between July 2018 and May

2019. All patients met the ACR/EULAR 2010 criteria and they were in treatment with Biological agent (anti-TNF and Non anti-TNF) or Targeted Synthetic DMARD (jakinibs). Main variable: Fatigue was assessed by the multidimensional fatigue scales, the Bristol Rheumatoid Arthritis Fatigue Multidimensional Questionnaire (BRAF-MDQ). Covariables: Sociodemographic, Disease-related variables, clinical and treatment. Statistical analysis. A descriptive analysis was carried out for the different variables. To identify factors independently associated to BRAF-MDQ and its subscales, multivariable linear regression was applied. Results were expressed as coef with their corresponding 95% CI. A value of $p < 0.05$ was accepted as statistically significant.

Results: A total of 79 patients were evaluated, 66 were females (83%), the mean age (SD) was 56.64(11.63) years old and mean disease duration (SD) was 14.81 (7.60) years. RF was positive in 54% of patients. 67% of the patients were in active on work status and 22% were retired. Regarding comorbidities, 42% had dyslipidemia, 43% hypertension, 14% hypothyroidism and 15% depression. DAS28-ESR and SDAI mean scores of the patients were 2.63 (0.94), 8.54 (6.30) respectively. HAQ mean (SD) was 0.88 (0.64) and the rest of the clinical, treatment characteristics, and the scores of the fatigue instruments are shown in *Table 1*. The factors affecting the BRAF-MDQ and its different subscales was evaluated in multivariate analyze *Table 2*. Our results shows a correlation between disability and the different dimensions of the BRAF-MDQ ($p < 0.001$). Patients who reported good sleep quality had less physical and living fatigue. Age and male sex was negatively associated with physical fatigue, besides a positive RF was associated with less physical and living fatigue. In addition, an association between depression and cognitive fatigue was observed. Different disease activity index and treatments did not result statistical significance in the final multivariate model.

Conclusion: It is important to evaluate fatigue in a multidimensional perspective, each of the different subscales could be modulated by different factors. The results of our study indicated that disability predicts in all subscales of fatigue, however, other factors can configure different patterns of fatigue in RA patients, and identify them is key to the approach of this complex symptom.

Tumor Necrosis Factor Alpha Inhibitor (TNF-α Inhibitor) Exposure and Risk of Hip Fracture in Veterans with Rheumatoid Arthritis: A Nested Case Control Study

Sarah Homann,[1] Carlos Grijalva,[1] S. Bobo Tanner,[1] and James Morrow[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have a much greater risk of sustaining a hip fracture than those without RA. Hip fractures cause significant morbidity and mortality. Some studies have reported beneficial effects of tumor necrosis alpha-inhibitors (TNFα-I) on markers of bone health. However, whether use of TNFα-I decreases the risk of hip fractures in patients with RA remains unclear.

Methods: Using national VA data from 2000-2011, a retrospective cohort of adult veterans with RA was identified using an algorithm that combined coded diagnoses with use of specific antirheumatic medications. This algorithm had a positive predictive value of 81% for identification of patients with RA compared with manual chart review. Two years of continuous baseline enrollment was required prior to cohort entry. Veterans with prior hip fracture, cancer, and serious renal, liver, or lung disease identified during the baseline period were excluded. From this RA cohort, cases of incident hip fracture that required hospitalization were identified using a validated algorithm. Incidence density sampling was used to select up to 20 at-risk controls per case. Controls were matched to cases on age, VA integrated service network and time since cohort entry. Pharmacy data were used to assess disease modifying anti-rheumatic drug (DMARD) exposure in the 12 months preceding the index date of hip fracture. To be considered a user of a given medication, a minimum of 180 days of use was required. Cases and controls were classified into one of four mutually exclusive exposure categories: non-biologic DMARD users (reference), TNFα-I biologic DMARD users, non-TNFα-I biologic DMARD users, and other users. Multivariable conditional logistic regression was used to assess the association between medication exposure and the risk of hip fracture by computing odds ratios adjusted for demographics, glucocorticoid use, BMI and other risk factors for hip fractures.

Results: During follow-up, 462 hip fracture cases and 8226 matched controls were identified from the underlying cohort of veterans with RA. The mean age of cases and controls was 75 years. In multivariable analyses that accounted for relevant covariates, hip fracture cases had similar odds of exposure to TNFα-I compared with controls (adjusted odds ratio [aOR]: 0.97 [95% confidence interval, 0.60 – 1.60]).

Conclusion: In this preliminary assessment, use of TNFα-I was not associated with a decreased risk of hip fractures compared with use of non-biologic DMARDs among veterans with RA. The cohort is currently being updated to include data through 2017.

Systematic Literature Review and Meta-Analysis of DAS28 Clinical Response Rates Among Advanced Therapies in Biologic-Naïve Patients with Rheumatoid Arthritis

Daniel Aletaha,[1] Ruta Sawant,[2] Patrick Zueger,[3] Erin Cook,[4] Fan Mu,[4] Vishvas Garg,[2] and Keith A. Betts[4], [1]Medical University of Vienna, Vienna, Austria, [2]AbbVie Inc., North Chicago, IL, [3]AbbVie Inc., North Chicago, [4]Analysis Group, Inc., Boston, MA

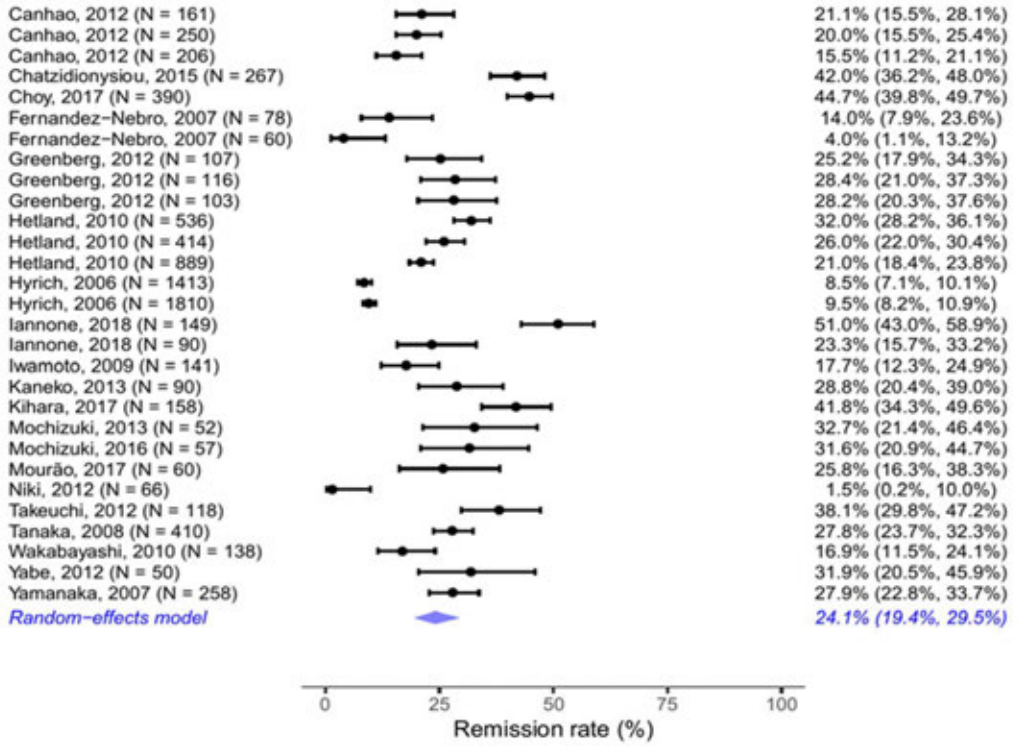
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic (b) and targeted synthetic (ts) DMARDs have demonstrated efficacy for the treatment of rheumatoid arthritis (RA) in clinical trials; however, real-world evidence on the effectiveness of bDMARDs/tsDMARDs has demonstrated a high unmet need reaching remission or LDA, even for the non-stringent DAS28 definitions. This systematic literature review (SLR) and meta-analysis was conducted to quantify real-world DAS28 clinical response rates, due to its high frequency of DAS28 reporting in the past literature, among patients with moderate to severe RA after 6 months of their first bDMARD/tsDMARD treatment.

Methods: An SLR was conducted using the MEDLINE and EMBASE databases and ACR (2015–2017) and EULAR (2015–2018) congress databases. The SLR included single- and multi-arm real-world observational studies that reported DAS28 remission outcomes (DAS28 < 2.6) at 6 months after bDMARD/tsDMARD treatment initiation in biologic-naïve adults with RA (N ≥50 per treatment arm). A traditional random-effects meta-analysis was conducted to estimate the DAS28 remission rates overall. Heterogeneity of studies for each treatment was assessed using the Cochran's Q statistic and I^2 statistic. In addition to DAS28 remission, DAS28 LDA rates, SDAI and CDAI remission rates were summarized descriptively.

Results: A total of 20 studies reported 6-month DAS28 remission data and were included in the analysis; only studies using bDMARDs met the inclusion criteria. Based on the meta-analysis (8,637 patients from studies conducted in 11 countries), the overall DAS28 remission rate was 24.1% (95% credible interval [CrI]: 19.4%, 29.5%; Figure). Remission rates by DAS28 measurement type were similar: DAS28–CRP, 24.5% [CrI 20.2%, 29.4%]; DAS28–ESR, 29.8% [CrI 24.8%, 35.4%]. Among the 20 included studies, a total of 9 reported the percentage of patients with LDA

Figure. Remission Rates Among All Studies



Heterogeneity	
	DAS28
I^2	95.7%
Q	652.0
Q p-value	<0.001

Note:
Multiple rows per study are shown when the study included multiple treatments

at 6 months, with some studies defining LDA as DAS28 ≥2.6 to < 3.2 while others as DAS28 ≥2.3 to < 2.7. The LDA rates ranged between 15% and 60% for DAS28 ≥2.6 to < 3.2 and between 11% and 56% for DAS28 ≥2.3 to < 2.7.

Conclusion: Despite treatment with bDMARDs, a large proportion of patients with RA do not achieve remission, even by the least stringent definition of remission, as by the DAS28 criteria (the rates of which are often higher than ACR70 response rates). Results from stringent remission criteria, e.g. the ACR/EULAR remission, have been reported too infrequently, but would show even much lower numbers indicative of a high unmet need in the RA treatment landscape and call for better treatment strategies.

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a sensation of weakness and lack of energy which is common in patients with rheumatoid arthritis (RA), contributing to reduced quality of life. Fatigue may be associated with inflammatory activity as well as with bio-psycho-social factors. However, these associations may be changed during effective treatment. The present study explores this issue by assessing the cross-sectional and longitudinal associations between fatigue and inflammatory markers (ultrasound, clinical and C-reactive protein (CRP) assessments) as well as bio-psycho-social factors.

Methods: A total of 208 patients with established RA (mean (SD) age 53 (13) years, disease duration 10 (9) years, 81% women, 79% anti-CCP positive) were examined when initiating biologic DMARDs at baseline as well as after 1, 2, 3, 6 and 12 months, including fatigue (0-10, as part of the RAID score), patient-reported outcome measures

(PROMs) (joint pain VAS, patient's global disease activity VAS (PGA), MHAQ, pain catastrophizing , SF-36 Mental Health scale score), clinical examinations (performed by a study nurse including examiner's global disease activity VAS (EGA), 28 tender and swollen joint counts (28TJC, 28SJC)) and CRP. Ultrasound examinations (semi-quantitative scoring (0-3)) of grey scale (GS) and power Doppler (PD)) were performed of 36 joints and 4 tendons by one rheumatologist (HBH; Siemens Acuson Antares, excellence version, 5-13 MHz probe). Correlations were assessed by Spearman's rho. The predictive value of baseline fatigue on ultrasound, clinical and laboratory assessments as well as PROMs were explored for all follow-up visits by use of multiple linear regression analysis with adjustment for demographic values (age, sex and disease duration).

Results: Fatigue levels diminished during follow-up (baseline median (IQR) 5 (3-7), 12 months 2 (1-5)). Table 1 shows the strong cross-sectional correlations between fatigue and scores of PROMs, low correlations with EGA/SJC/CRP and lack of correlations with ultrasound scores. Baseline fatigue levels predicted scores of PROMs at all examinations (table 2). No/low associations were found between baseline fatigue and 28SJC/EGA/sum score GS and PD at follow-up.

Conclusion: Fatigue was strongly correlated with all PROMs but had low/no associations with objective measures of inflammation. Baseline fatigue predicted all the subjective outcomes at follow-up, but not CRP, SJC or ultrasound. Thus, fatigue was presently not associated with inflammatory activity, but with subjective outcomes.

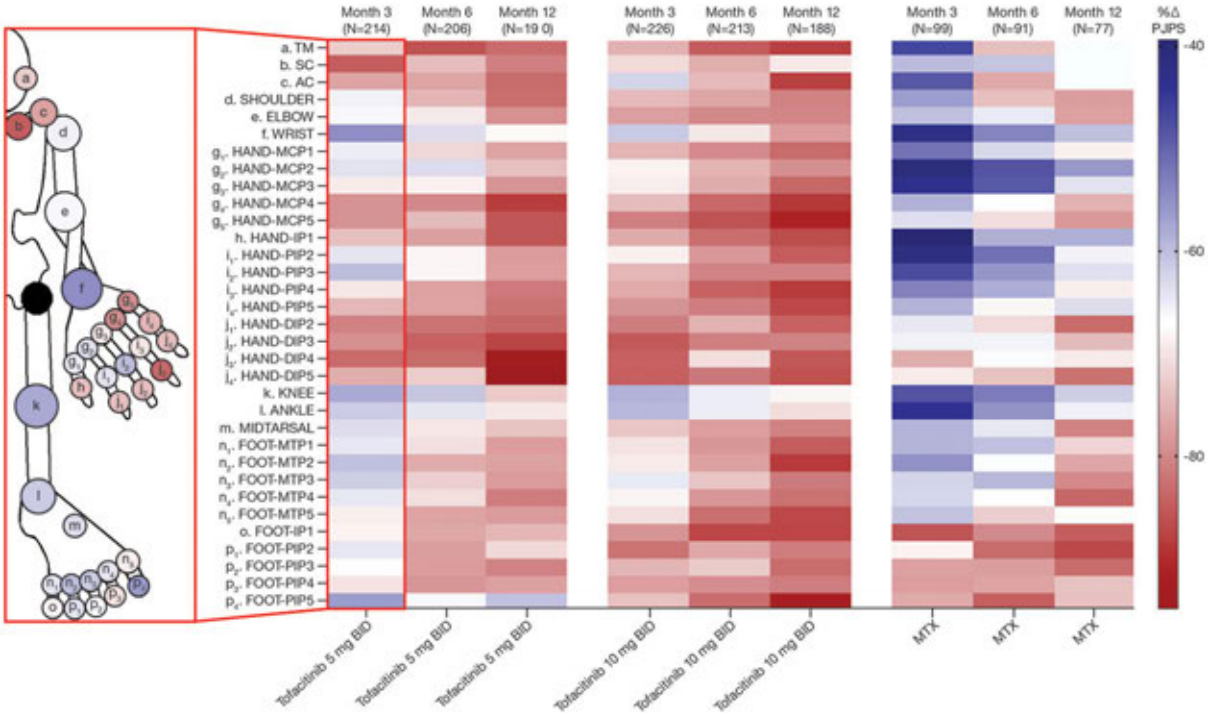
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

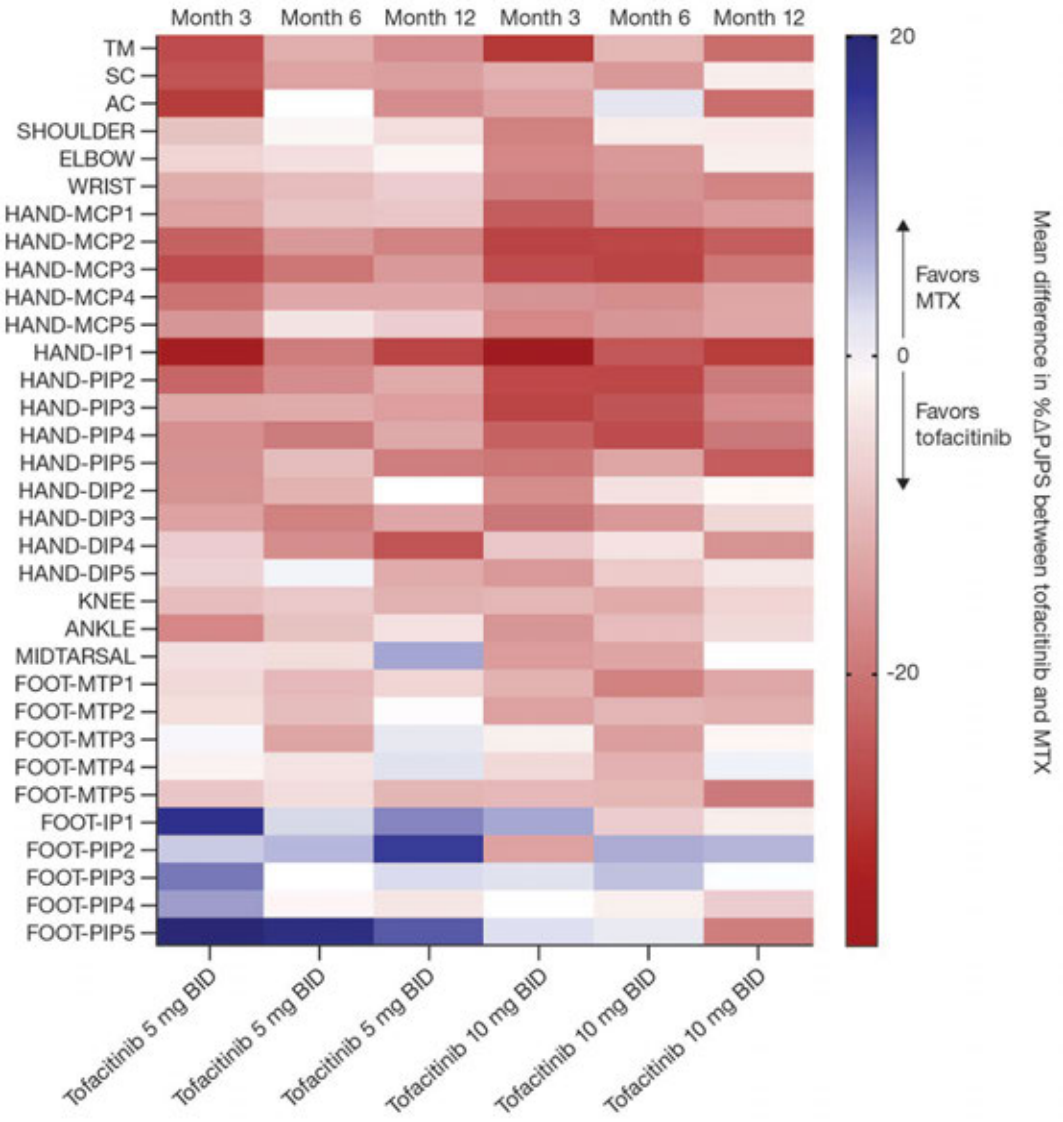
Background/Purpose: Despite systemic inflammatory cues, RA affects synovial joints variably. Tofacitinib is an oral JAK inhibitor for the treatment of RA. Previous post hoc analyses of data from ORAL Standard and ORAL Strategy showed differences in the degree/rate at which joints respond to tofacitinib ± MTX and adalimumab + MTX.[1] However, clear patterns relating to specific agents were generally not seen, possibly as most patients (pts) received combination therapy with MTX. Here, we further characterize joint-specific responses to tofacitinib monotherapy and MTX using data from the Phase 3 study ORAL Start (NCT01039688).

Figure 1. Heat map of %ΔPJPS for each joint across treatment groups at Months 3, 6, and 12, and homunculus illustrating the joint-specific %ΔPJPS for tofacitinib 5 mg BID at Month 3



Pts were enrolled from ORAL Start (NCT01039688). This analysis was based on pts who had baseline PJPS >0
N for each joint may vary; the maximum value of N is listed for each time point
Lower %ΔPJPS represents better efficacy
%Δ, percentage change from baseline; AC, acromioclavicular; BID, twice daily; DIP, distal interphalangeal; IP, interphalangeal; MCP, metacarpophalangeal; MTP, metatarsophalangeal; MTX, methotrexate; PIP, proximal interphalangeal; PJPS, paired joint pathology score; SC, sternoclavicular; TM, temporomandibular

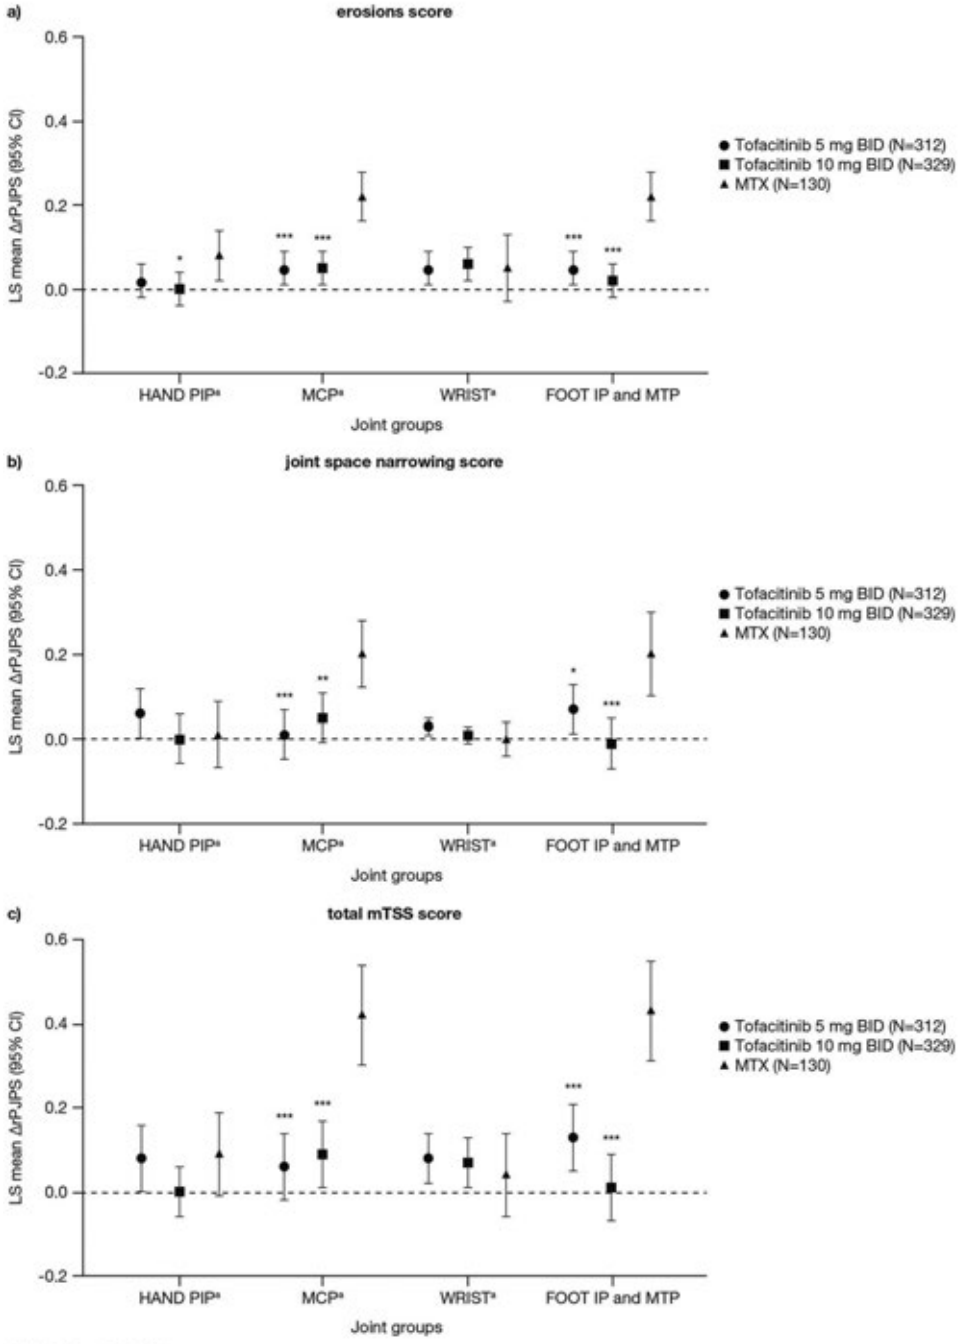
Figure 2. Heat map of the mean difference in %ΔPJPS between tofacitinib doses and MTX



Refer to Figure 1 for N numbers
%Δ, percentage change from baseline; AC, acromioclavicular; BID, twice daily; DIP, distal interphalangeal; IP, interphalangeal; MCP, metacarpophalangeal; MTP, metatarsophalangeal; MTX, methotrexate; PIP, proximal interphalangeal; PJPS, paired joint pathology score; SC, sternoclavicular; TM, temporomandibular

Methods: This was a post hoc analysis of Month (M)3, 6, and 12 data from ORAL Start in which pts with newly diagnosed, active RA received tofacitinib 5 or 10 mg twice daily (BID), or MTX (starting dose 10 mg/week and titrated up to 20 mg/week). A paired joint pathology score (PJPS), a combination of bilateral tender/swollen joint counts ranging from 0 (neither) to 4 (both sides tender/swollen), was calculated. Percentage changes from baseline in PJPS (%ΔPJPS) for each joint were presented in a heat map. To show treatment-specific effects at each joint, differences in %ΔPJPS for each tofacitinib dose, minus the MTX group, were calculated and presented in a further heat map. Joint damage in the hand PIP joints, MCP joints, wrist, and foot IP and MTP joints was assessed using the modified Total Sharp Score (mTSS). For each component of the mTSS composite score (erosion, joint space narrowing) and total score, a radiographic PJPS (rPJPS; combination of bilateral mTSS subscores in each joint group) was calculated

Figure 3. LS mean change from baseline (95% CI) in radiographic PJPS for a) erosions score, b) joint space narrowing score, and c) total mTSS score in 4 joint groups at Month 12



[a]Tofacitinib 5 mg BID, N=311
Data are based on a mixed model for repeated measures adjusted for age, geographic region, RA disease duration, disease activity (measured by DAS28-4[ESR]), and baseline value of the endpoint
Tofacitinib 5 or 10 mg BID vs MTX: *p<0.05; **p<0.01; ***p<0.001; No multiplicity adjustments were made for statistical comparisons as they were for exploratory use only
Δ, change from baseline; BID, twice daily; CI, confidence interval; IP, interphalangeal; LS, least squares; MCP, metacarpophalangeal; MTP, metatarsophalangeal; mTSS, modified Total Sharp Score; MTX, methotrexate; PIP, proximal interphalangeal; rPJPS, radiographic paired joint pathology score

and mean ΔrPJPS at M12 for each joint group presented. Statistical comparisons between tofacitinib vs MTX were performed using a repeated measures mixed model.

Results: Across treatment arms, all joints showed a treatment response (%ΔPJPS ranged from -95% to -39%), with responses generally improving over time (Figure 1). As previously reported,[1] irrespective of treatment, the wrist,

knee, and ankle responded less well than other joints. Differences in %ΔPJPS showed better responses for tofacitinib vs MTX in most joint locations, excepting some foot joints (Figure 2). Radiographic progression was minimal in all 4 joint groups (hand PIP joints, MCP joints, wrist, and foot IP and MTP joints) with both tofacitinib doses (Figure 3). The greater %ΔPJPS seen in the foot for MTX vs tofacitinib did not translate into improved radiographic outcomes at M12: ΔrPJPS in the foot were significantly worse for MTX vs tofacitinib across each endpoint (Figure 3), as were ΔrPJPS in the MCP joints.

Conclusion: Wide variation in RA joint-specific responses to tofacitinib 5 and 10 mg BID, and MTX, was seen in this post hoc analysis. Tofacitinib was generally more effective than MTX in all joints, except some foot joints. Enhanced efficacy in the distal lower limb has not been described with MTX before. Radiographic progression was minimal in the tofacitinib arms, while in the MTX arm, significantly more radiographic progression was observed in the MCP joints and foot.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Immune checkpoint inhibitors (ICIs) have changed the therapeutic landscape in oncology leading to cures in some cancer types. However, patients with pre-existing autoimmune diseases (AIDs) were largely excluded from ICI trials due to concern for increased toxicity. In clinical practice some patients with rheumatoid arthritis (RA) have been treated with ICIs, but the risks of toxicity and/or disease flare have not been clearly outlined. Here we present data on the safety and efficacy of ICI therapy in patients with RA.

Methods: We conducted a single institution retrospective analysis to evaluate the safety and efficacy of ICI therapy (anti-CTLA-4 and anti-PD-1) among patients with pre-existing AIDs treated from 2011 to 2018. Primary endpoints were incidence of immune-related adverse events (irAEs) and AID flares. The secondary endpoint was overall survival (OS). Subgroup analysis for patients with RA was performed with percentages and medians reported.

Results: Of 84 patients with pre-existing autoimmunity who developed malignancy and were treated with ICIs, we identified 22 patients with RA. Sixteen (73%) were female and 6 (27%) male (median age 67). Most patients had no evidence of active disease 20 (91%) as indicated by their treating physician. Sixteen (73%) patients were receiving RA immunomodulatory therapy at start of ICI, with 8 (36%) patients receiving systemic corticosteroids and 7 (32%) patients on methotrexate.

Malignant conditions included 7 (32%) with melanoma, 7 (32%) with non-small cell lung cancer (NSCLC) as well as others. Thirteen patients (59%) were treated with pembrolizumab, 9 (41%) with nivolumab and 4 (18%) received ipilimumab.

IrAEs occurred in 7 (32%) patients with only 2 (9%) developing severe, grade 3 irAEs, a total of 41% developing toxicity of any grade. The most common toxicities were dermatitis 4 (18%) and colitis 3 (14%). ICI was temporarily discontinued due to irAEs in 5 (23%) patients. Only 1 patient required permanent ICI discontinuation. RA flares occurred in 12 (55%) patients. Most patients 9 (75%) received treatment with oral corticosteroids for RA flare. ICI was permanently discontinued due to flare in only one patient. Overall either flare, irAE or both occurred in 16 (73%) patients. Median OS for patients with RA after start of ICI was 10.5 months.

Conclusion: In our cohort, approximately half of the RA patients experienced flare and fewer had an irAE after initiation of ICI compared to a rate of 5-60% for any grade irAEs and 7-30% in severe irAEs in patients without autoimmune diseases depending on agent used. Most symptoms were manageable and a minority of patients required discontinuation of cancer-directed therapy. While this is a small cohort, the results of this analysis suggest that patients with RA experience severe irAEs at a rate similar to the population without autoimmune diseases. Further study is warranted to determine if ICIs may be offered to patients with RA as first line agents when used for an FDA approved indication. The choice of ICI and its effect on OS in this population also requires further prospective investigation.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) treatment emphasizes aggressive titration of disease-modifying antirheumatic drugs (DMARDs) with the goal of achieving disease remission. This often includes the use of multiple DMARDs in combination, which can have a significant impact on patients' lives and add costs to the healthcare system. The primary objective of our study was to describe the patterns of sustained remission and subsequent treatment reduction in the usual clinical practice for patients with early RA. Furthermore, we wished to assess for an effect of tapering medications on the risk of disease flare.

Methods: Patients (age >18) enrolled in the Canadian early ArThritis CoHort (CATCH) between January 2007 to March 2017 were analyzed. CATCH is a prospective, observational study of patients with early inflammatory arthritis (symptoms < 1 year) treated in rheumatology clinics across Canada. The analysis cohort included patients with a diagnosis of RA according to the 1987 or 2010 ACR/EULAR classification criteria, active disease at enrolment (DAS28 >2.6) and those treated with at least one DMARD or biologic agent within the first three months of study enrolment. We defined sustained remission as achieving a DAS28 < 2.6 at two consecutive follow-up visits at least six months apart. Reduction of therapy was defined as a minimum of a 25% dose reduction of conventional synthetic, targeted, or biologic DMARDs. Descriptive statistics were used to summarize the time to remission and reductions in DMARD therapy. Logistic regression analysis was used to assess predictors of sustained remission.

Results: Eight hundred and thirty-seven (40%) of the 2,097 eligible patients achieved sustained remission during the study period. Of these, 60% did so within the first 18 months and 92% within the first four years (Figure 1). The mean (SD) baseline DAS28 was 5.1 (1.3), and HAQ-DI was 1.0 (0.7). At the time of remission, 80% were prescribed methotrexate (55% subcutaneously), 71% were prescribed combination therapy with other conventional synthetic DMARDs, and 13% were prescribed a biologic agent. In the year after attaining sustained remission, 327 (39%) patients reduced treatment in the following pattern (patients may have had more than one change): 250 patients reduced or stopped methotrexate, 196 patients reduced or stopped non-methotrexate DMARDs, and 34 patients reduced or stopped biologic agents. For those that reduced or stopped a biologic, only one patient did so due to side effects. Of the 250 patients who reduced or stopped methotrexate, 25 were for a side effect. Of the 636 patients with outcome data available, 54% remained in sustained remission 12-18 months after first achieving it. This was not associated with tapering DMARDs [odds ratio (95% confidence interval) tapering versus not tapering: 0.96 (0.66 – 1.41)].

Conclusion: Achieving sustained remission occurred in 40% of early RA patients in usual clinical practice. Treatment reductions following sustained remission occurred in over a third of patients over the next 12 months and consisted mainly of adjustment in non-biologic DMARDs. Further study is required to determine whether or not medications can be tapered safely without disease flare.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mood disorders, such as anxiety and depression are extremely prevalent amongst patients with rheumatoid arthritis (RA). In this study we sought to assess the impact of treatment with tocilizumab (TCZ), an IL-6 antagonist, upon anxiety and depressive symptoms in a cohort of RA patients.

Methods: This study was part of a larger, multi-center study performed at 13 medical centers in Israel between January 2014 and July 2015. Study participants were adults diagnosed with RA who received a weekly subcutaneous injection of tocilizumab for 24 weeks. We used the Hamilton Depression (HDRS) and Anxiety (HAMA) scores in order to assess the severity of depression and anxiety respectively. RA disease activity indices and depression and anxiety levels were assessed at baseline, 4 weeks and study completion. Patients whose anxiety and/or depression levels decreased significantly, e.g., a decrease ≥ 25% in anxiety and/or depression levels between baseline and study end, were compared with patients for whom they did not. Logistic regression identified factors associated with significant decrease, in addition we assessed correlations between levels of depression and anxiety with scores reflecting the disease activity of the rheumatoid disease.

Results: Ultimately, 91 patients were included in the study. The mean age was 54 years and the majority were female (79%). The mean score in all disease activity indices as well as depression and anxiety levels decreased dramatically from baseline to study completion. Sixty patients (66%) demonstrated a significant decrease in anxiety and/or depression levels. When logistic regression was performed, an HDRS score indicative of depression at study baseline demonstrated an independent association with a significant psychiatric response whilst older age and increased weight were negatively associated. Older age and increased weight were negatively associated with a significant decrease. The following correlations were observed with the HAMA and HDRA scores respectively; HAQ-DI ($r=0.4$, 0.42), DAS28 ($r=0.29$, 0.32) and CDAI (0.28 and 0.33), all of them were statistically significant ($p< 0.01$).

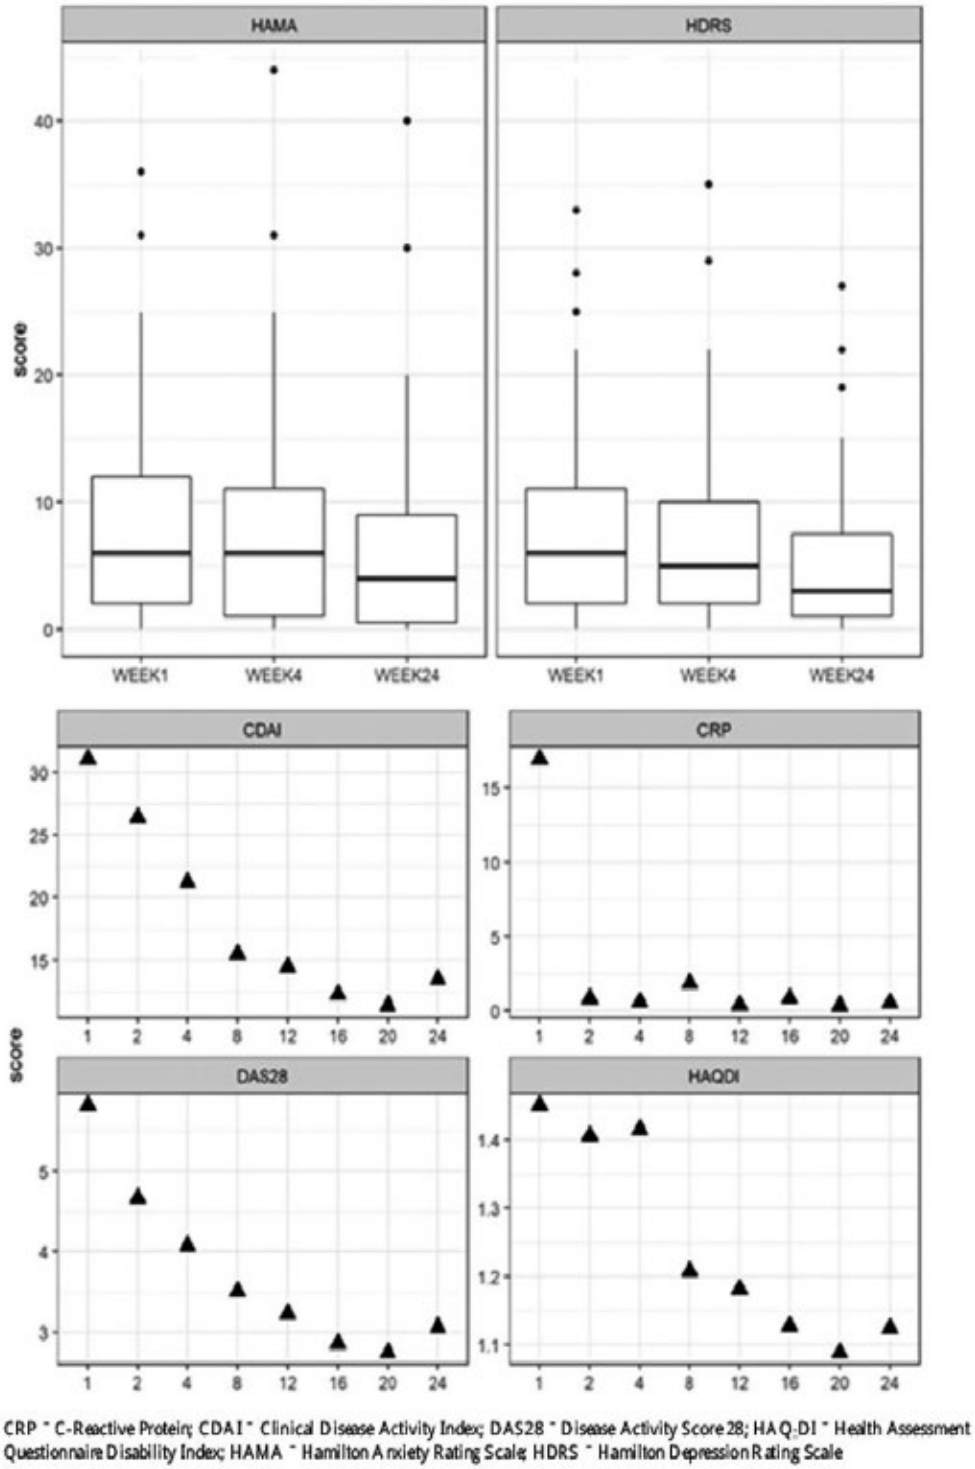

Fig.1
Comparison of variation in disease activity indices throughout the study

Conclusion: This study has demonstrated a favorable impact of TCZ therapy on parameters reflecting depression and anxiety severity in patients with RA.

	Odds Ratio	CI 95%	P-value
Pre-anxiety**	0.28	0.07 ¯ 1.01	0.058
Pre-depression***	9.70	1.93 ¯ 65.38	0.010

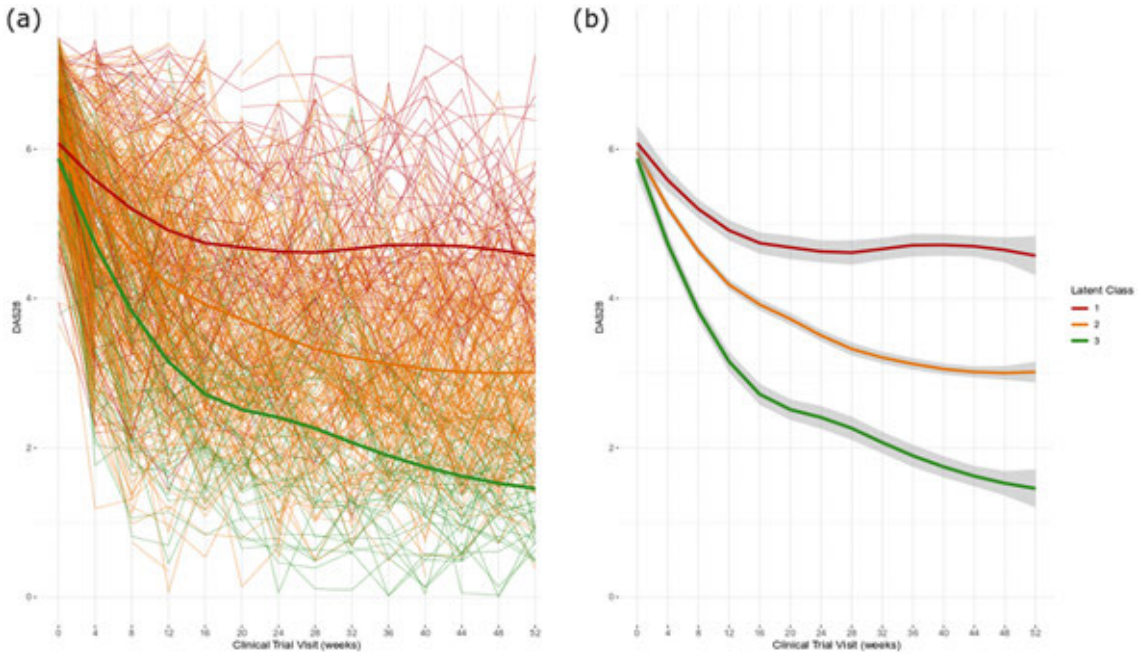
Abstract Number: 1342

Identification of Heterogenous Treatment Response Trajectories to anti-IL6 Receptor Treatment in Rheumatoid Arthritis

Joseph Patrick Michele Blair,[1] Cecilie Bager,[2] Man Hung Eric Tang,[2] Morten Karsdal,[3] Anne Bay-Jensen,[4] and Søren Brunak[5], [1]Univeristy of Copenahgen, Copenhagen, Denmark, [2]Nordic Bioscience ProScion, Copenhagen, Denmark, [3]Nordic Bioscience, Copenhagen, Denmark, [4]Nordic Bioscience, Herlev, Denmark, [5]Novo Nordisk Foundation Center for Protein Research, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark, Copenhagen, Hovedstaden, Denmark

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a complex autoimmune disease with a fluctuating course of disease activity and progression. Although treatments have improved substantially in recent years thanks to the development of novel drugs, response is not guaranteed. Also, response is often monitored in a binary, and not a dynamic way, resulting in loss of information about the level of response. The aim of this study was to identify heterogeneity



All patient trajectories of DAS28 in response to Tocilizumab anti-IL6 treatment, with three identified latent trajectories of DAS28 in response to Tocilizumab over a 52-week clinical trial

in Disease Activity Score 28 (DAS28) in response to tocilizumab in RA patients and investigate molecular and clinical factors which may cause this.

Methods: Longitudinal clinical and biochemical data, as well as baseline demographics for 485 RA patients receiving 4 or 8 mg/kg tocilizumab in combination with MTX, were extracted from the LITHE phase III clinical study (NCT00106535), and post-hoc and exploratory analysis was conducted. Latent class mixed models were used in order to identify distinct trajectories of patients' disease activity using DAS28 after the initiation of treatment. The optimal number of classes was selected using Bayesian Information Criteria (BIC) and Akaike Information Criteria (AIC). Longitudinal and cross-sectional measurements were then analysed using linear mixed effects models in order to characterise patients by serological biomarker levels, and other clinical factors, and identify correlations between drug response and patient characteristics.

Results: Trajectory analysis identified three distinct response subgroups of patients: class 1 (n = 85, 25.9%), class 2 (n=338, 63.9%) and class 3 (n=62, 10.4%). All groups started with a high DAS28 on average (DAS28 > 5.1). Class 1 showed the least reduction in DAS28, with a significantly higher proportion of patients seeking escape therapy ($p < 0.001$). Class 3 showed significantly higher rates of improvement in DAS28 achieving remission status, as well as having the highest rates of patients achieving ACR response levels ($p < 0.001$). Biomarkers associated with inflammation, MMP-3, CRP, C1M, and C3M, were markedly decreased from baseline levels in class 3 in response to treatment compared to the other classes.

Conclusion: Identification of more distinct patient populations of drug response may allow for more targeted therapeutic treatment regimens. Treatment strategies should consider the initial state of disease severity as well as clinical and biochemical disease parameters to achieve optimal response rates.

Estimated marginal means for absolute change in the level of bone and inflammatory biomarkers after initiation of tocilizumab for each latent class

Pop a Pill or Give Myself a Shot? Patient Perspectives of Disease-modifying Anti-rheumatic Drug (DMARD) Choice for Rheumatoid Arthritis (RA)

Jasvinder Singh,[1] Haley Tornberg,[2] and Susan Goodman[3], [1]University of Alabama Medical Center, Birmingham, [2]Hospital for Special Surgery, New York, NY, [3]Hospital For Special Surgery/Weill Cornell Medicine, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Little is known about the patient perspective related to DMARD choice in RA. Our objective was to assess how patients decide whether to add traditional oral DMARDs or injectable biologic DMARDs to methotrexate for the treatment of active RA.

Methods: We conducted 10 nominal groups in patients with RA from rheumatology clinics at two tertiary care centers at Birmingham (n=6; 21 patients) and New York City (n=4; 26 patients). Patients provided responses to the question "What sort of things are important to you when you make a decision between adding pills versus injectable medications to treat rheumatoid arthritis when methotrexate fails to control RA disease activity?" Patients nominated, discussed and voted for the responses.

Results: Forty-seven patients participated in 10 nominal groups, who were predominantly female (85%), 70% white, with a mean (standard deviation) age of 64.5 years and 58% with >10 year RA duration. Present/past DMARDs included methotrexate in 91% and biologics and/or Jak-inhibitors in 68% of participants. The mean MD-HAQ score was 2 on a 0-10 scale and the mean RAPID-3 score on a 0-30 scale was 9.1. The main responses ranked by patients were as follows.

Efficacy/mode of action was among the voted domains in 10/10 nominal groups and got 28% of the votes (78/282 votes; Figure 1). *Side effects/fear of side effects* was among the voted domains in 9/10 nominal groups and got 30% of the votes (84/282 votes). *Cost* was among the voted domains in 9/10 nominal groups and got 19% of the votes (54/282 votes). Out of pocket costs, including co-payments and patient responsibility for the drug cost was the most important aspect of the medication cost that impacted the choice. *Convenience/frequency of use* was among the voted domains in 9/10 nominal groups and got 10% of the votes (27/282 votes). *Doctor's opinion* was among the voted domains in 4/10 nominal groups and got 7% of the votes (20/282 votes). Patients greatly valued their rheumatologist's opinion, which was either a strong factor or a deciding factor for them. *Other drugs/comorbidity/other patient's experience/effects on other people* was among the voted domains in 3/10 nominal groups and got 1% of the votes (3/282 votes). Many patients worried about drug-drug interactions and contra-indications in the presence of other systemic conditions. *Fear of Needles* was among the voted domains in 1/10 nominal groups and got 3% of the votes (8/282 votes). People expressed "Fear of injections" "Anxiety about self-injecting", and "Nauseating concept if you are not a medical person". *The newness of the medication* was among the voted domains in 1/10 nominal groups and got 3% of the votes (8/282 votes).

Conclusion: Our qualitative study identified the patient perspective of DMARD choice between oral versus injectable drugs once methotrexate fails to control disease activity. This knowledge can help in informative shared decision-making in regular clinical care.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk of cardiovascular (CV) diseases. Dyslipidemia is a known adverse reaction to tocilizumab (TCZ). TNFa blockade in RA patients has been associated with weight gain, increase in fat mass and variations in serum adipokines. Adiponectin (Adp) plays a role in the metabolism of glucose and lipids. Numerous studies have confirmed the beneficial role of Adp in insulin sensitivity and CV disease prevention, especially its high molecular weight (HMW) isoform. Increased Adp levels are associated with a reduced risk for coronary heart disease.

Objectives: To analyse the changes in serum adipokines and especially Adp (total and HMW) and body composition during TCZ therapy in RA.

Methods: multicenter open-label study (NCT02843789). All patients enrolled had active RA (DAS28≥ 3.2) with previous inadequate response to a csDMARDs and/or bDMARDs. They all were TCZ naïve and received TCZ IV according to the patient/physician shared decision. Patients were evaluated at baseline, 1, 3, 6, and 12 months. Clinical assessment included body mass index, waist circumference, DAS28 and HAQ scores. Laboratory parameters of inflammation (ESR, CRP, IL-6), lipid parameters (total cholesterol, LDL and HDL cholesterol, triglycerides), metabolic parameters (glycemia, insulin), serum Adp (total and HMW), leptin, resistin, and ghrelin were measured at each time point. Body composition (lean mass, fat mass, % of fat, fat in the android and gynoid regions) was evaluated at baseline, 6, and 12 months (DEXA, Lunar GE). Our primary criteria was the changes in Adp (total and HMW) at 6 months.

Results: 107 patients (78 F; mean age ± SD: 56.6 yr ± 13.5; disease duration: 9.9 yr ± 8.1; previous biological treatment: 64.5%; corticosteroids: 69%; concomitant csDMARD: 72.8% including MTX: 61.6%) were included. 97 were

still on treatment at month 6 and 77 completed the study at 12 months. Most of the patients (95%) received TCZ IV 8 mg/kg. Patients were responding to TCZ with a significant DAS28 decrease between baseline and months 6 and 12. HAQ, ESR, and CRP levels significantly decreased along the study (Table 1). Both total and HMW Adp increased from baseline to month 6 and month 12 (total Adp: baseline vs month 6: p=0.055; HMW Adp: baseline vs month 6: p=0.02, baseline vs month 12: p=0.057).BMI and waist circumference significantly increased at month 6 and 12, as well as lean mass (p=0.0097 at month 6 and p=0.021 at month 12). Fat mas, % of fat and android/abdominal fat did

not change over the study. Lipid parameters (total cholesterol and LDL cholesterol) increased while glycaemia and insulin remained stable. Serum leptin, resistin and ghrelin did not change during the follow-up.

Conclusion: TCZ treatment in RA patients was associated with a significant increase in HMW Adp, increase in total Adp and also a significant gain of lean mass, while fat mass (total fat or abdominal fat) did not change. These variations in Adp during TCZ treatment may have a positive impact on the CV risk of RA patients and may contribute to the protective role of TCZ against the CV burden in RA. In addition, TCZ may have an anabolic impact on lean mass and thus on skeletal muscle.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To compare efficacy and safety of biological disease-modifying antirheumatic drugs (bDMARDs) between elderly-onset rheumatoid arthritis (EORA) and young-onset rheumatoid arthritis (YORA) patients.

Methods: Patients with rheumatoid arthritis (RA) aged ≧18 years enrolled in a Japanese multicenter observational registry between Sep 2009 and December 2017 who had ≧3.2 disease activity score in 28 joints-erythrocyte sedimentation rate (DAS28-ESR) when initiating bDMARDs were included. EORA was defined as RA with onset at 60 or over. Considering selection bias in the estimation of effects of time-varying treatments and clustering effects by individual, a generalized estimating equation model with an inverse probability of treatment weighting was used to assess the relationship between age onset and clinical effectiveness at 48 weeks. Primary outcome was Clinical Disease Activity Index (CDAI) score at 48 weeks. Secondary outcomes included biologic retention at 48 weeks, achievement of CDAI remission, and low disease activity (LDA)/remission. Biologic retention rate was compared using a cox proportional hazards model.

Results: Among a total of 7183 patients in the registry, proportion of patients on bDMARDs was lower in the EORA as compared to the YORA (18.3 % vs 28.0 %, p < 0.001). Of the 989 bDMARDs initiators, 364 (36.8%) were identified as EORA. After adjusting for differences in baseline characteristics between the two age groups, there was no significant difference in CDAI score at 48 weeks (1.01, 95% CI=-0.62-2.64, p=0.22). There was a trend of lower remission in the EORA (OR=0.52, 95%CI=0.24-1.14, p=0.10), but LDA/remission rate was similar (OR=0.86, 95%CI=0.29-2.52,

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Post-traumatic stress disorder (PTSD) is associated with worse outcomes among U.S. Veterans with rheumatoid arthritis (RA) in addition to reduced medication adherence in other chronic disorders. This study examined the association between PTSD and DMARD discontinuation, accounting for comorbidity and other potential confounders that may impact this relationship.

Methods: VA administrative data were used to define unique dispensing episodes of methotrexate (MTX), self-injectable TNF inhibitors (TNFi), other DMARDs, and prednisone for Veterans with a prior diagnostic code for RA. Discontinuation was defined as a lapse in drug refill >90 days. Patient characteristics and diagnosis codes were linked to treatment courses. Patient characteristics were analyzed based on the first dispensing episode of each unique DMARD. Some patients switched TNFi's over time and thus accounted for multiple dispensing episodes. Diagnosis codes (using a "lifetime" lookback) were used to delineate RA patients into 3 mutually exclusive groups: PTSD (with or without depression/anxiety), depression and/or anxiety without PTSD, and none of the aforementioned diagnoses. Multivariate Cox proportional hazards models were used to evaluate associations between psychiatric diagnoses and time to DMARD discontinuation. Covariates included age, sex, race (Black vs. White), calendar year (2005-2009 vs.

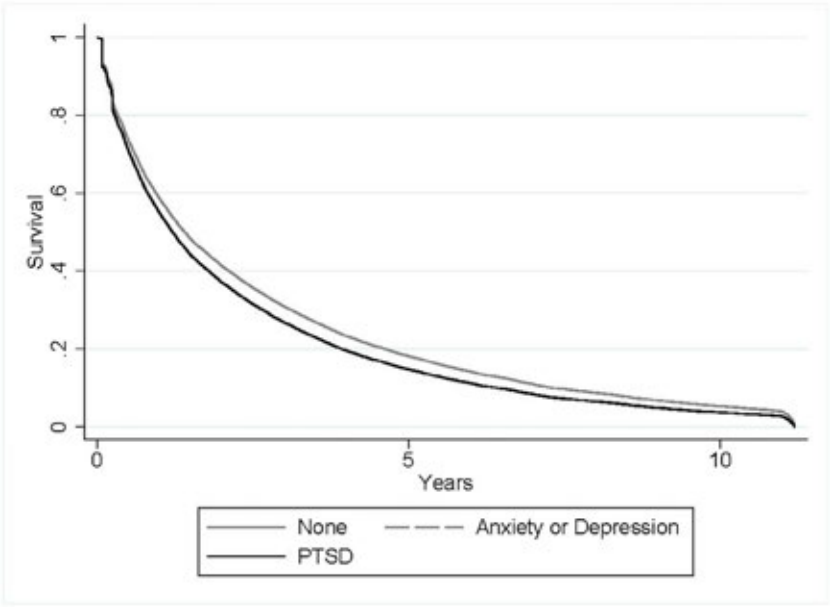

Figure 1. Methotrexate drug survival (Note that PTSD and Anxiety/Depression groups have significant overlap in this figure)

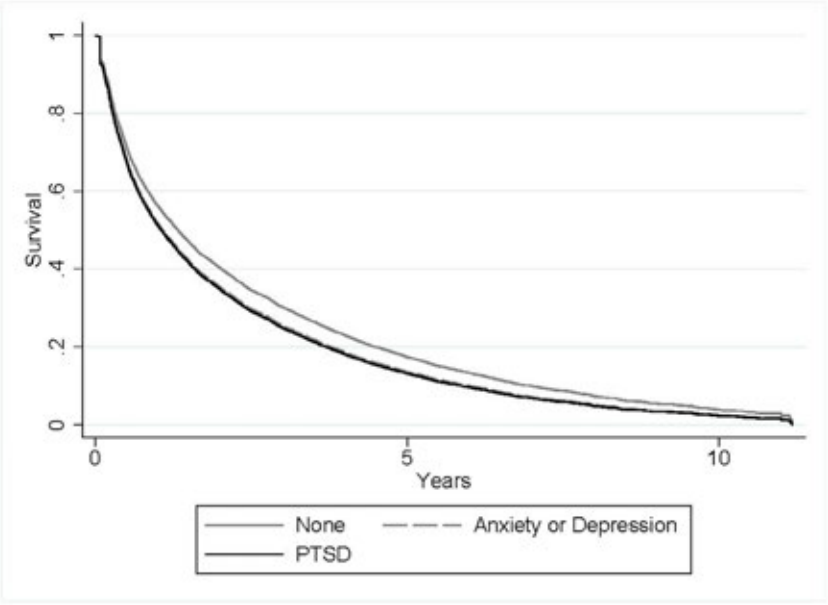

Figure 2. TNF inhibitor drug survival (Note that PTSD and Anxiety/Depression groups have significant overlap in this figure)

2010-2014), BMI, other DMARDs, Rheumatic Disease Comorbidity Index (RDCI), CRP, anti-CCP status, RA duration >5 years, diabetes, hypertension, CHF, history of malignancy, and current smoking status.

Results: There were 15,082 dispensing episodes of MTX in 15,082 unique patients and 8,412 dispensing episodes for TNFi in 7,092 unique RA patients. Patients were predominantly Caucasian (74% MTX, 77% TNFi) and male (88% MTX, 87% TNFi). Median drug survival was 1.30 years (95% CI 1.27-1.35) for MTX and 1.18 years (95% CI 1.13-1.24) for TNFi. Comorbid PTSD was seen in 20% of those initiating MTX and 22% of those initiating TNFi. Depression and/

or anxiety (without PTSD) was seen in 23% of those initiating MTX and 27% of those initiating TNFi. After adjusting for covariates, PTSD was associated with a greater likelihood of discontinuing both MTX [HR 1.12 (1.07,1.18) p< 0.001; Figure 1] and TNFi [HR 1.16 (1.09,1.23) p< 0.001; Figure 2]. Risk of discontinuation in depression/anxiety without PTSD was comparable to that seen in PTSD for both MTX [HR 1.12 (1.07,1.17) p< 0.001] and TNFi [HR 1.14 (1.08,1.21) p< 0.001].

Conclusion: Veterans with RA and a diagnosis of PTSD, depression, or anxiety discontinued DMARDs sooner than those without these diagnoses, even after accounting for a number of other factors. Rates of discontinuation were similar for those with PTSD compared to those with depression and/or anxiety alone and were similar between MTX and TNFi. PTSD, anxiety, and depression may contribute to lower persistence of RA therapy due to non-adherence, apparent lack of response, or a greater incidence of adverse events.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A treat-to-target (TTT) approach results in superior outcomes compared to conventional care in patients with rheumatoid arthritis (RA). However, TTT strategies are still not widely adopted in clinical practice and many patients never reach the target of remission. We compared achievement of remission in two early RA cohorts, examining whether a TTT strategy implemented in a randomized controlled trial (RCT) led to superior outcomes compared to a TTT approach implemented in an observational study.

Methods: Data were provided by two Norwegian multicenter studies, the ARCTIC trial and the NOR-VEAC observational study. Both studies included DMARD-naïve RA-patients in the period 2010-2016 and implemented a TTT strategy. All patients fulfilled the 2010 ACR/EULAR classification criteria for RA. The target in the ARCTIC trial was stringent remission defined as a Disease Activity Score (DAS44) < 1.6 plus no swollen joints, while the target in the NOR-VEAC study was the less stringent DAS28 remission (DAS28< 2.6). In the current study we assessed: 1)

Table 1 Baseline characteristics in the ARCTIC trial and the NOR-VEAC observational study after propensity score weighting

Baseline characteristics*	ARCTIC (n=183)	NOR-VEAC (n=277)	SMD
Age	52.5	53.1	-0.047

achievement of the study specific treatment targets and 2) achievement of a stringent remission defined by the ACR/

Table 2 Achievement of study specific treatment targets during follow-up in the ARCTIC trial and the NOR-VEAC observational study

	ARCTIC (n=183)	NOR-VEAC (n=277)
Study specific targets:	**DAS<1.6 + no swollen joints**	**DAS28<2.6**
3 months, %	37.2	47.4
6 months, %	53.4	56.3
12 months, %	69.4	67.0
24 months, %	66.5	66.1

DAS, Disease Activity Score (44 joint count); DAS28, Disease Activity Score 28 joint count

EULAR Boolean criteria during follow-up over 24 months. We assessed achievement of the study specific targets using descriptive analyses and compared achievement of ACR/EULAR Boolean remission using logistic regression with inverse probability of censoring weights to account for missing data. For the comparative analyses we balanced the two cohorts on baseline covariates using propensity score weights.

Results: We included 183 patients from the ARCTIC trial and 277 patients from the NOR-VEAC study. After baseline balancing with propensity score weights, patients in the two cohorts were similar with regard to age, sex, ACPA positivity and disease activity (**Table 1**). Patients in both cohorts started with methotrexate (MTX) monotherapy. At 12 months, more patients in the NOR-VEAC study than in the ARCTIC trial were still treated with MTX monotherapy (79% vs. 67%), while more patients in ARCTIC had switched to another synthetic DMARD regimen or started a biologic DMARD. At 24 months, 25% of patients in both cohorts had switched to a biologic DMARD, while 17% of patients in the ARCTIC trial and 9% of patients in the NOR-VEAC study had switched to another synthetic DMARD regimen. More than half of patients in each cohort had reached the study specific targets at 6 months, and this increased to more than 2/3 in both cohorts at 12 and 24 months (**Table 2**). The odds of reaching ACR/EULAR Boolean remission during follow-up were higher in the ARCTIC trial compared to the NOR-VEAC study, with statistically significant differences at 3 months (OR 1.73; 95% CI 1.03-2.89), 12 months (OR 1.97, 95% CI 1.21-3.20) and 24 months (OR 1.82; 95% CI 1.05 – 3.16; **Table 3**).

Table 3 Odds of achieving ACR/EULAR Boolean remission in the ARCTIC trial versus the NOR-VEAC observational study during follow-up*

Study visit	OR	95% CI	*p*-value**
3 months	1.73	(1.03 – 2.89)	0.04
6 months	1.44	(0.88 – 2.38)	0.15
12 months	1.97	(1.21 – 3.20)	0.01
24 months	1.82	(1.05 – 3.16)	0.03

*Cohorts were balanced on baseline covariates using inverse probability of treatment weights using the propensity score. Multiple imputation by chained equations was used to impute missing variables at existing visits in the NOR-VEAC study.
**Estimates were obtained using logistic regression with inverse probability of censoring weights.
ACR/EULAR Boolean remission, C-reactive protein ≤1, swollen joint count 28 ≤1, tender joint count 28 ≤1 and patient´s global assessment ≤1; OR, odds ratio; CI, confidence interval

Conclusion: Our results suggest that TTT is feasible and successful in clinical practice, similar to clinical trials. The odds of reaching the stringent ACR/EULAR Boolean remission during follow-up was higher in the ARCTIC trial than in the NOR-VEAC observational study, suggesting that targeting a more stringent remission improves the outcome of a TTT strategy.

Data were pooled from three Phase 3 studies: ORAL Scan (NCT00847613); ORAL Sync (NCT00856544); ORAL Standard (NCT00853385). All patients received background csDMARDs

Analysis is based on observed case data (without imputation) of patients with all 7 components assessed

[a]PBO patients received PBO from Study Day 1 up to either M3 (for non-responders) or M6 (for responders). At M3, PBO non-responders were advanced to tofacitinib 5 or 10 mg BID; therefore, all patients reported under PBO at M6, would have been PBO responders at M3. Patients were considered non-responders if there was <20% improvement in both tender/painful and swollen joint counts at M3

ACR20/50/70, improvement in American College of Rheumatology criteria of 20/50/70%; BID, twice daily; BL, baseline; CGA, Clinician Global Assessment; CRP, C-reactive protein; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; HAQ-DI, Health Assessment Questionnaire-Disability Index; M, month; PBO, placebo; PtGA, Patient Global Assessment; SJC, swollen joint count; TJC, tender joint count

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of RA. In clinical trials, standard criteria for measuring treatment efficacy in patients (pts) with RA include ACR response rates, composite scores that represent ≥ 20/50/70% improvement in seven components of disease activity. This post hoc analysis evaluated the impact of tofacitinib 5 mg BID + csDMARDs, and placebo (PBO) on each ACR score component.

Methods: Efficacy data for tofacitinib 5 mg BID and PBO were pooled from three Phase (P)3 PBO-controlled trials (ORAL Scan, NCT00847613; ORAL Sync, NCT00856544; ORAL Standard, NCT00853385) of tofacitinib + csDMARDs (mostly MTX) in RA pts with inadequate response to ≥ 1 csDMARD. Endpoints summarized descriptively included proportions of pts achieving: ACR20/50/70 responses, and ≥ 20/50/70% improvements from baseline (BL) in individual ACR components (TJC, SJC, CGA, PtGA, Pain, HAQ-DI, and CRP) from Week (W)2 through Month (M)6, and mean percent improvement from BL in all components for ACR20 responders at M3.

Results: Compared with csDMARD-IR pts receiving PBO, greater proportions of csDMARD-IR pts receiving tofacitinib + csDMARDs achieved ≥ 20% improvement from BL in all ACR components by W2, with proportions generally increasing at all subsequent time points to M6 (Table 1a); typically, higher proportions of pts achieved ≥ 20% improvement from BL in individual components vs overall ACR score. Overall, through M6, a higher proportion of pts achieved ≥ 20% improvement for primary components (TJC and SJC) vs the secondary components CGA, PtGA,

Table 2. Mean percent improvement from baseline in ACR score components in patients treated with tofacitinib 5 mg BID + csDMARDs who achieved an ACR20 response at Month 3

ACR score component (N=453)	Mean percent improvement from baseline (SD)
TJC	70.1 (22.8)
SJC	74.3 (22.4)
CGA	58.9 (28.3)
PtGA	49.4 (46.5)
Pain	52.1 (46.3)
HAQ-DI	42.6 (55.6)
CRP[a]	18.6 (314.5)

Data were pooled from three Phase 3 studies: ORAL Scan (NCT00847613); ORAL Sync (NCT00856544); ORAL Standard (NCT00853385). All patients received background csDMARDs

Analysis is based on observed case data (without imputation) of patients with all of 7 components assessed

[a]Median percent improvement for CRP was 76.7%

ACR20, improvement in American College of Rheumatology criteria of 20%; BID, twice daily; CGA, Clinician Global Assessment; CRP, C-reactive protein; csDMARDs, conventional synthetic disease-modifying antirheumatic drugs; HAQ-DI, Health Assessment Questionnaire-Disability Index; PtGA, Patient Global Assessment; SJC, swollen joint count; TJC, tender joint count

Pain, and HAQ-DI; among secondary components, ≥ 20% improvement rates were numerically highest for CGA (excepting CRP at W2 and M1 in pts receiving tofacitinib). In contrast, ≥ 50% and ≥ 70% improvement rates with tofacitinib were numerically higher for PtGA and Pain vs CGA at W2 (Table 1b-c). Among pts achieving an ACR20 response at M3, mean percent improvement from BL was > 70% for primary components, and ranged from 18.6% to 58.9% for secondary components (Table 2).

Conclusion: In this post hoc analysis of pooled P3 data, tofacitinib treatment was associated with rapid and sustained improvements in all ACR components. In tofacitinib- and PBO-treated pts, physician-reported measures (TJC, SJC, and CGA) were found to contribute somewhat more to the achievement of overall ACR20 response, compared with pt-reported outcomes (PROs; PtGA, Pain, and HAQ-DI). This numerical trend may be reflective of the subjective nature of PROs and overall wellbeing of the pt, and thus, their reduced sensitivity to anti-inflammatory treatment. Intriguingly, with more stringent endpoint criteria at earlier time points, some PROs had a somewhat greater contribution to overall ACR response, which may be attributable to rapid symptomatic improvement in these pts. While ACR scores are not generally used in the clinic, individual components may be measured; thus, these data may help guide clinical expectations with new therapies.

Acknowledgments: Study sponsored by Pfizer Inc. Medical writing support was provided by Kirsten Woollcott of CMC Connect and funded by Pfizer Inc.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid (RA) and psoriatic arthritis (PsA) are inflammatory arthritides associated with significant potential functional disability if not well controlled. We reviewed the baseline demographic and disease characteristics over nineteen years in the RAPPORT registry to understand changes in prescribing patterns of biologic disease modifying anti-rheumatic drugs (bDMARDs) over time.

Methods: The **R**heumatoid **A**rthritis **P**harmacovigilance **P**rogram and **O**utcomes **R**esearch in **T**herapeutics (RAPPORT) registry is a large prospective inception cohort for Northern Albertan inflammatory arthritis (IA) patients about to start advanced therapy with at least 4 months of exposure to conventional synthetic DMARDs (csDMARD) including parenteral weekly methotrexate, methotrexate plus a DMARD in combination, and leflunomide. We compared baseline demographic and disease characteristics in two cohorts according to registration year: 2000-2010 (n=1071) and 2011-2019 (n=1632). Specifically, we compared patient demographics including age, sex, education, comorbidities and smoking status; disease characteristics including tender and swollen joint count, HAQ, patient global, CRP, and DAS28, symptom duration; and first bDMARD therapy. Descriptive statistics were use to asses baseline demographics along with univariate analysis for comparison of variables between cohorts.

Results: Of the 2703 RAPPORT patients, IA patients in the later cohort (2011 onwards) were started on biologic therapy an average of 2.61 years earlier from symptom duration ($p< 0.001$) (Table 1). There were differences in the pattern of bDMARD prescriptions within and between classes between the two cohorts; however, there were no significant differences in age, sex or number of comorbidities (Table 1). The prevalence of self-reported depression and osteoarthritis were higher in the later cohort but there was no difference in heart disease or associated cardiovascular risk factors (hypertension, diabetes). Statistically significant but clinically unimportant differences in markers of disease activity including HAQ, swollen joint count, and CRP were found between cohorts (Table 2). Biologic DMARD prescriptions in the latter cohort showed increased TNF inhibitor use and increased use of other classes (Table 3).

Conclusion: Prescribing patterns of bMDARDs changed between the first and second decade of RAPPORT with earlier introduction of bDMARDS in IA patients from time of diagnosis. Possible reasons include the rapid increase in availability of bDMARDs between and across classes and increased uptake and confidence in bDMARD use by prescribing rheumatologists over time. Further work to evaluate the impact of bDMARD prescription patterns on patients and society is planned.

CDAI at Wk 4, Mean (SD)	16.1 (7.5)	35.0 (11.3)	45.2 (10.5)
Change at Wk 4, ΔCDAI (%)	-17.8 (52.6)	-16.3 (31.7)	-7.0 (13.4)
CDAI at Wk 12 , Mean (SD)	12.0 (7.7)	24.6 (9.9)	43.4 (12.2)
Change at Wk 12, ΔCDAI (%)	-21.8 (64.4)	-26.7 (52.0)	-8.8 (17.0)
CDAI at Wk 24, Mean (SD)	11.8 (9.4)	17.3 (8.0)	42.6 (10.6)
Change at Wk24, ΔCDAI (%)	-22.1 (65.3)	-34.0 (66.3)	-9.6 (18.3)

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Baricitinib (BARI), a selective Janus kinase 1 and 2 inhibitor, is approved for the treatment of moderately-to-severely active RA in over 60 countries. In the RA-BEACON[1] phase 3 trial, BARI 2-mg demonstrated clinical efficacy in patients (pts) with RA and an inadequate response to biologic DMARDs. The objectives of this analysis were to assess the response patterns to BARI 2-mg in the RA-BEACON trial and to describe the demographic and clinical characteristics for pts within each response pattern.

Methods: Observed data from all BARI 2-mg treated pts in the RA-BEACON trial (N=174) up to 24 weeks, protocol mandated rescue, treatment discontinuation, or loss to follow-up were included in the analysis. A Growth Mixture Model was used to classify the longitudinal disease patterns based on the time course of Clinical Disease Activity Index (CDAI) improvement from week 0 to week 24. Baseline characteristics and disease measures were described between groups. The trajectories of HAQ-Disability Index (DI), pain, tender joint count (TJC), and swollen joint count (SJC) within each response pattern were also examined.

Results: BARI 2-mg treated pts were classified into 3 groups based on their CDAI trajectory patterns (Figure). Group 1 (n=90, 52%) had lower baseline CDAI (mean=34), achieved 53% improvement in group mean of CDAI at week 4 (change from baseline, ΔCDAI -18), 64% improvement at week 12 (ΔCDAI -22), and maintained similar improvement through 24 weeks. Group 2 (n=29, 17%) had higher baseline CDAI (mean=51), achieved 32% improvement in mean CDAI at week 4 (ΔCDAI -16) with greater improvement at week 12 (52%, ΔCDAI -27) and week 24 (66%, ΔCDAI -34). Group 3 (n=55, 32%) had a baseline CDAI (mean=52) similar to group 2, but had smaller improvement, achieving 18% improvement in CDAI (ΔCDAI -10) at week 24. The distributions of HAQ-DI, pain, TJC, and SJC within each response pattern showed a trajectory similar to the corresponding group CDAI trajectory. Baseline characteristics for these 3

Table. Selected Patient Characteristics at Baseline*

	Group 1 (N=90)	Group 2 (N=29)	Group 3 (N=55)
Age (years)	54.1 (11.6)	59.9 (11.1)	54.2 (9.6)
Male, n (%)	19 (21.1)	6 (20.7)	12 (21.8)
Body Mass Index (kg/m^2)	31.0 (7.6)	31.4 (7.9)	30.2 (8.4)
Rheumatoid Factor positive, n (%)	69 (76.7)	22 (75.9)	37 (67.3)
ACPA positive, n (%)	66 (73.3)	23 (79.3)	35 (63.6)
High-sensitivity C-Reactive Protein (hsCRP) (mg/L)	18.7 (22.3)	18.8 (18.6)	22.3 (24.7)
Erythrocyte Sedimentation Rate (mm/hr)	40.8 (23.2)	43.8 (18.0)	51.4 (25.3)
Duration of RA (years)	13.4 (7.5)	15.8 (8.5)	13.1 (8.6)
≥3 bDMARD use, n (%)	23 (25.6)	7 (24.1)	20 (36.4)
Tender Joint Count 28	12.4 (5.2)	20.8 (3.8)	21.7 (5.5)
Swollen Joint Count 28	8.9 (3.9)	16.3 (4.8)	16.0 (6.2)
Physician's Global Assessment of Disease Severity	62.0 (17.6)	69.9 (13.9)	73.4 (14.9)
Patient's Global Assessment of Disease Severity	62.5 (20.5)	71.8 (14.1)	73.2 (17.7)
Patient's Assessment of Pain	57.2 (22.9)	64.9 (20.5)	69.5 (17.3)
HAQ-DI	1.5 (0.5)	1.7 (0.6)	2.0 (0.5)
DAS28-hsCRP	5.5 (0.7)	6.6 (0.6)	6.6 (0.8)

*Data reported as mean (SD) unless otherwise indicated

groups are presented in Table 1. Compared to groups 1 and 2, group 3 had more pain, worse physical function (HAQ-DI), and a larger proportion of pts who used ≥3 bDMARDs at baseline.

Conclusion: There are three response patterns to BARI 2-mg treatment in the RA-BEACON trial. The majority of BARI 2-mg treated pts achieved good response (groups 1 and 2, 68%) with at least 50% improvement in CDAI by week 12. Response was observed as early as week 4 and was maintained or continued to improve in these groups through week 24. Pts with less response (group 3) tended to be more treatment experienced with more pain and worse physical function at baseline.

Abstract Number: 1351

Mortality of Rheumatoid Arthritis Patients, Treated to Target at Low Disease Activity: 17-years Follow-up of the BeSt Cohort

Johanna M Maassen,[1] YPM Goekoop,[2] JHLM van Groenendael,[3] WF Lems,[4] PJSM Kerstens,[5] Thomas Huizinga,[6] and CF Allaart[1], [1]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, Leiden, Netherlands, [2]Haga Hospital, 's-Gravenhage, Netherlands, [3]Reumazorg Zuid West Nederland, Rozendaal, Netherlands, [4]Amsterdam UMC, Amsterdam, Netherlands, [5]Westfriesgasthuis, Hoorn, Netherlands, [6]Leiden University Medical Center, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis is known to be associated with increased mortality over the years when compared to the general population. In the BeSt study, 508 patients were treated to target (Disease Activity Score ≤2.4) for 10 years between April 2000 and August 2012. At the end of the initial study follow-up observed mortality in

Table 1. BeSt study cohort mortality - stratified for initial treatment strategy

	Sequential monotherapy n=126	Step-up combination therapy n=121	Initial combination therapy with prednisone n=133	Initial combination therapy with infliximab n=128
N (%) †	38 (30)	31 (26)	41 (31)	33 (26)
SMR (95% CI)	1.41 (1.03–1.94)	1.20 (0.84-1.70)	1.53 (1.13-2.09)	1.31 (0.93-1.85)

SMR: standardized mortality ratio (number observed deaths/number expected deaths); CI: confidence interval.

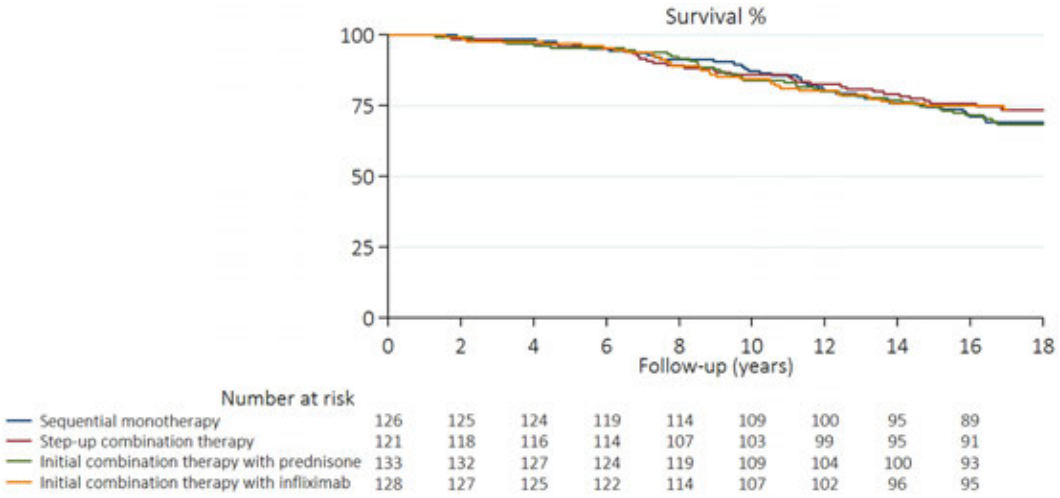

Figure 1. Survival curves per initial treatment strategy

the BeSt cohort was similar to mortality in the general population. In the current study we evaluated the mortality in the BeSt cohort after 17 years follow-up and compared it to the general Dutch population.

Methods: In the BeSt study 508 patients diagnosed with early RA were randomized to four initial treatment strategies: 1. Sequential monotherapy; 2. Step-up combination therapy; 3. Initial combination therapy with prednisone; or 4. Initial combination therapy with infliximab. During the 10-year follow-up period treatment was aimed at low disease activity (DAS ≤2.4) and adjusted every three months if necessary. After 10-years patients were treated and followed-up according to regular care. We explored mortality through the Dutch state registry for mortality (Centrum voor Familiegeschiedenis) and treating rheumatologist. Mortality in the BeSt cohort was compared to the general Dutch population (Statistics Netherlands) matched by gender, age, and calendar year using the standardized mortality ratio (SMR). Kaplan-Meier curves and the log-rank test were used to compare survival among the initial treatment strategies.

Results: The mean duration of follow-up in alive patients was 17 years (range 16-18). In total, 143 patients died (28%) compared to a total of 105 (21%) expected deaths in the reference population. The overall SMR after 17 years was 1.37 (95% CI: 1.16-1.61). Within the study population, no statistically significant difference in survival-curves was observed between the four initial treatment strategies (log-rank p=0.76) (table 1, and figure 1).

Conclusion: After (mean) 17 years of follow-up there was increased mortality in the BeSt study cohort compared to the general Dutch population. We observed no difference in survival among the four treatment strategies.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment with upadacitinib (UPA), a selective Janus kinase-1 (JAK-1) inhibitor, resulted in significant and clinically meaningful improvements in patient-reported outcomes (PROs) at Week 12 in patients with RA with inadequate responses to csDMARDs (csDMARD-IR) or bDMARDs (bDMARD-IR).[1,2] The current analysis evaluated the potential long-term benefits of UPA on PROs in these patients.

Methods: SELECT-NEXT (NCT02675426) and SELECT-BEYOND (NCT02706847) are ongoing Phase 3, randomized controlled trials (RCTs) which randomized patients with active RA on a stable dose of csDMARDs to receive UPA 15 mg or 30 mg once daily (QD) for 24 weeks or placebo for 12 weeks then UPA 15 mg or 30 mg. In this analysis, we report on PROs in patients treated with UPA from the start of study for 24 weeks, including: Patient Global Assessment of Disease Activity (PtGA), pain by visual analog scale (VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F; SELECT-NEXT only), and duration and severity of morning (AM) stiffness. Mean changes from baseline and 95% confidence intervals (CIs) were calculated for each PRO at Week 24. The percentages of patients who continued to report improvements ≥ minimum clinically important differences (MCIDs) at Week 24 were calculated among patients who reported clinically meaningful responses for a given PRO at Week 12.

Results: Overall, 622 and 434 patients completed the double-blind phase of SELECT-NEXT and SELECT-BEYOND, respectively. At Week 24, patients reported improvements from baseline across all PROs: PtGA, pain VAS, HAQ-DI, FACIT-F, duration and severity of AM stiffness in SELECT-NEXT (Table 1) and SELECT-BEYOND (Table 2). In SELECT-NEXT, 85% to 93% of patients treated with UPA 15 mg and 77% to 90% with UPA 30 mg maintained responses ≥ MCIDs from Week 12 to Week 24. Similarly, in SELECT-BEYOND, 66% to 88% of patients treated with UPA 15 mg and 70% to 86% with UPA 30 mg maintained clinically meaningful responses from Week 12 to Week 24.

Conclusion: Substantial and clinically meaningful improvements in disease activity, physical function, pain, fatigue, and AM stiffness were consistently reported over 24 weeks in csDMARD-IR and difficult-to-treat bDMARD-IR patients with active RA who continued to receive UPA 15 mg or 30 mg QD.

Table 1. Mean change in PRO scores and maintenance of MCID responses at Week 24 (SELECT-NEXT)						
PRO	UPA 15 mg QD			UPA 30 mg QD		
	n	Mean Change from BL (95% CI)	Responders, n/N[a,b] (%)	n	Mean Change from BL (95% CI)	Responders, n/N[a,b] (%)

Impact of Smartphone Application Based Management in Rheumatoid Arthritis: SMART- RA Study

Ashit Syngle,[1] Nidhi Garg,[2] Raveena Bhatia,[3] Surbhi Rattan,[4] and Kanchan Chauhan[4], [1]Healing Touch City Clinic/Fortis Multispeciality hospital, Chandigarh, Chandigarh, India, [2]Chitkara College of Pharmacy, Chitkara University, Rajpura, India, [3]Healing Touch City Clinic, Chandigarh, Chandigarh, India, [4]Healing Touch City Clinic, Chandigarh, India

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) treatment has improved considerably over the years. However, patient compliance remains critical to treatment outcomes. Patient compliance still poses challenges in day-to-day care of RA patients and treatment outcomes. In a technology driven era, with more people having access to smart phones, unique opportunities exist for use of phone based technologies to improve patient care in chronic diseases. This study aims to investigate the impact of smart phone application (HealthCius) on inflammatory disease activity and quality of life in RA patients receiving standard treatment.

Methods: 75 consecutive patients fulfilling the 2010 Rheumatoid Arthritis Classification Criteria for RA were recruited in this observational study. Subjects were randomized into 2 groups. First, having access to a smart phone were assigned to the intervention group using the Healthcius application (n=45) and second, the control group not using

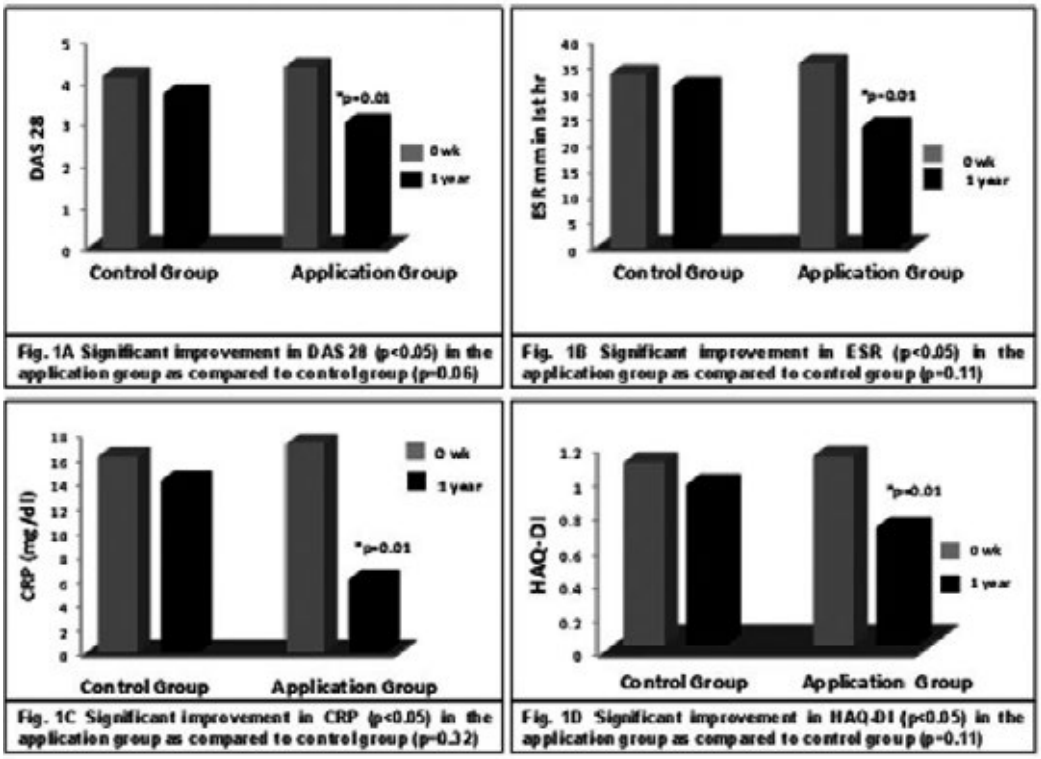

Fig. 1A Significant improvement in DAS 28 ($p<0.05$) in the application group as compared to control group ($p=0.06$)

Fig. 1B Significant improvement in ESR ($p<0.05$) in the application group as compared to control group ($p=0.11$)

Fig. 1C Significant improvement in CRP ($p<0.05$) in the application group as compared to control group ($p=0.32$)

Fig. 1D Significant improvement in HAQ-DI ($p<0.05$) in the application group as compared to control group ($p=0.11$)

Comparison between application group and control group

the application (n=30). The patients in two groups received standard treatment for RA. The application was designed after obtaining feedback from health care providers, patient counselors and RA patients using a questionnaire. To the patients, the app was their individual treatment plan. It helped them comply with the plan by providing an easy to refer checklist, reminders, alerts and a visual dashboard of their progress through the day. The app served as the doctor's virtual assistant inside the patient's smart phone. For the doctor, it was a live dashboard of all patients and their real time compliance levels. The data reported by the patients was available to the doctor in the form of time sliced charts and trend lines. Therefore, this app is designed to leverage technology to shift the patients' focus every day on to their treatment plan thereby driving up compliance and better health outcomes. Outcome measures included erythrocyte sedimentation rate (ESR), C-Reactive protein (CRP), disease activity score (DAS28) and health assessment questionnaire (HAQ-DI) at baseline and after 1 year.

Results: The two groups did not differ significantly for baseline characteristics. There was a significant difference between the control and intervention group for DAS28 ($p < 0.05$), ESR ($p \leq 0.05$), CRP ($p \leq 0.05$) and HAQ-DI ($p \leq 0.5$) after 1 year in favor of smart phone application. Analysis within the groups revealed significant improvement in DAS28 ($p < 0.05$) (Fig.1A), ESR ($p=0.01$) (Fig.1B), CRP ($p=0.001$) (Fig.1C) and HAQ-DI ($p=0.01$) (Fig.1D) in the application group as compared to control group. Impact of DMARDs usage was also evaluated at the end of the study and it was found that the average drug usage of DMARDs was more in control group than the intervention group.

Conclusion: The study suggested that there was greater improvement in inflammatory disease activity and quality of life in smart phone application assisted RA patients suggesting that smart phone technology can be used to leverage health benefits in RA.

Acknowledgement: We acknowledge the development of App used in the present study by HealthCius Services Pvt Ltd. However, App developer did not not have any say in study protocol, abstract or submission. none of the authors have any financial relationship with company.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The HAQ disability index (HAQ-DI) is the most widely used disease-specific measure of physical disability in RA. This study explores the sensitivity to change of 3 scoring methods of the HAQ-DI in relation to disease activity in active RA patients.

Methods: Patient data was extracted from an international RA database, the Measurement of Efficacy of Treatment in the Era of Outcome in Rheumatology (METEOR) database. All adult patients fulfilling the 2010 ACR/EULAR RA classification criteria with complete data with respect to the 20 questions of the HAQ-DI and components of the DAS28 (4 variable) using the ESR (DAS28-ESR(4)) for 2 visits at least 6 – 12 months apart with high disease activity at visit 1, (DAS28-ESR(4) > 5.1) were included in the study. Three scoring methods of the HAQ-DI: 1) the conventional method (HAQ-8), 2) the Tomlin method (HAQ-T) and 3) the 20-item method (HAQ-20) were analysed against the EULAR response criteria dichotomized for good/moderate response group versus the no response group. The proportion of patients achieving the minimally clinical important difference (MCID) of the HAQ-DI was compared in the EULAR responder and non-responder groups. Logistic regression analysis was used to determine independent predictors of achieving a minimally clinical important improvement (MCII) (improvement in HAQ-DI ≥ 0.22) of the HAQ-DI.

Results: Of the 5 539 patients in the METEOR database at the time of data extraction, 421 patients met the inclusion criteria. The mean age (SD) and disease duration (SD) of this cohort of patients were 55.0 (13) years and 10.5 (9.5) years respectively at visit 1. The median DAS28-ESR(4) (IQR) declined from 5.9 (5.4-6.6) to 5.2 (3.7-6.0) over a mean period (SD) of 8.7 (1.9) months and 47 % of patients had a good/moderate EULAR response. Median HAQ-8 (IQR) improved from 1.6 (1.1-2.1) to 1.4 (0.9-1.9); median HAQ-T (IQR) improved from 1.2(0.7-1.6) to 0.7 (0.4-1.4) and median HAQ-20 improved from 1.2 (0.8-1.6) to 0.9 (0.5-1.4) with similar effect sizes. All three scoring methods showed good agreement. The proportion of patients who achieved the MCII of the HAQ-DI was significantly higher in the EULAR good/moderate response group (64%) compared to the EULAR no response group (11%). The strongest independent predictor of achieving a MCII of the HAQ-DI is EULAR response. The odds of achieving a MCII of the HAQ-8 is 7.11 higher if a good/moderate EULAR response is achieved compared to having no response.

Conclusion: The 3 methods performed similarly in assessing sensitivity to change with no particular advantage using alternative methods of scoring compared to the conventional method of scoring the HAQ-DI. By achieving a good or moderate EULAR response over 60% of RA patients with long-standing disease can attain a clinically significant improvement in their physical function.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Despite ACR recommendations to initiate a major therapeutic change (MTC) in rheumatoid arthritis (RA) patients with moderate/severe disease activity, our recent work has shown that MTC is only implemented in about 50% of these patients and that the decision to initiate MTC occurs most often at higher levels than recommended by ACR guidelines – a Youden-MTC threshold (Figure 1). This analysis evaluated the potential for ACR20 response following MTC above and below the Youden-MTC threshold for MTC and compared ACR response potential across different levels of disease activity as reported by three different Disease Activity Measures (DAMs) - DAS28, CDAI, and RAPID3 – Youden-MTC threshold and DAMs defined in Figure 1.

Methods: The clinic visit was the unit of observation for US Veterans enrolled in the VA Rheumatoid Arthritis (VARA) registry between 1/1/2006 and 9/30/2017. Eligible visits had: 1) DAS28, CDAI, and RAPID3 recorded; 2) all DAMs at two visits 18 months prior to and one visit between 60 and 180 days after the eligible visit; 3) 18 months baseline data. MTC definition (measured from 7 days before to 30 days after visit) included: 1) initiation of new biologic or

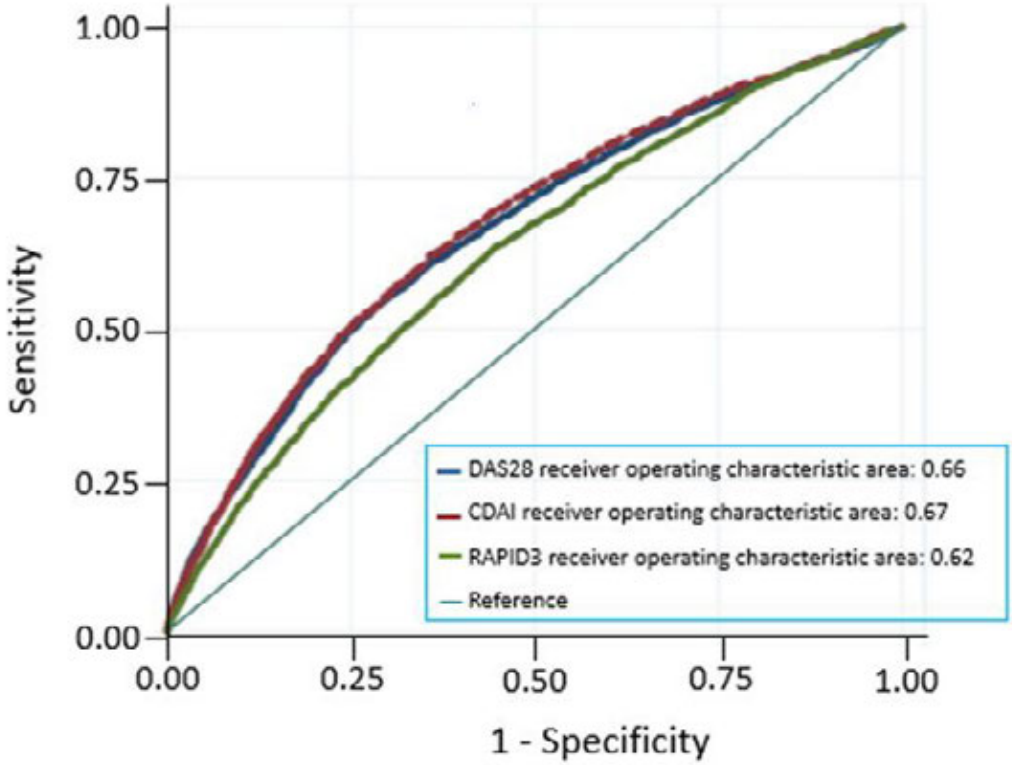
	Empirical Optimal Cut point (95%CI)	Youden Index	Sensitivity Cut point	Specificity Cut point	AUROC Cut point	AUROC Total
DAS28	4.02 (3.7 - 4.36)	0.252	0.55	0.70	0.63	0.66
CDAI	12.9 (10.6 - 15.1)	0.263	0.62	0.64	0.63	0.67
RAPID3	3.81 (3.31 - 4.3)	0.189	0.64	0.55	0.59	0.62



Sauer BC, et al. Thresholds for Disease Activity Measures - DAS28, CDAI, and RAPID3. Do Not Align with Clinical Practice Patterns of Rheumatoid Arthritis (RA) Disease Management Decisions [abstract]. Arthritis Rheumatol. 2018; 70 (suppl 10). #2870

non-biologic disease-modifying antirheumatic drug (DMARD) or prednisone; 2) escalation of DMARD dose by ≥25%; or 3) increase in monthly average prednisone dose by 25%; and/or 4) injection of 2 or more joints with corticosteroids. ACR20 response after each eligible visit was determined at the next follow-up visit between 60 and 180 days after the eligible visit date and stratified by disease activity by the different DAMs and the Youden-MTC threshold. The G-computation with Generalized Estimating Equations (GEE) model was fitted using the exchangeable working covariance structure to account for clustering of visits within patients.

Results: In 1,208 VARA patients, there were 6,138 eligible visits – 1,773 (28.9%) with MTC and 4,365 (71.1%) without MTC. Demographic, clinical, disease stability, and DMARD use are reported in Table 1. Eligible visits with MTC had a higher rate of ACR20 response in comparison to visits without MTC at all levels of disease activity with the percent of patients with ACR response after MTC increasing with higher disease activity level particularly above the Youden threshold (Table 2). While MTC was not common below Youden-MTC threshold, ACR 20 response was still significantly greater for both DAS28 and RAPID3 in the Low Moderate group. ACR20 responses were more common in patients with disease activity above Youden-MTC with DAS28 and CDAI than RAPID3.

Conclusion: Following MTC, the ACR20 response was most likely in patients with disease activity above the Youden-MTC threshold even though the risk ratios were similar across all categories classified as active disease by ACR criteria, including the Low Moderate group. RAPID3 classified more patients at higher disease activity levels which resulted in larger effect estimates (on risk ratio scale) even though the prevalence of ACR20 response was lower. Therefore, DAS28 and CDAI may be preferred DAMs for directing MTC decisions as patients with high disease activity by these DAMs were associated with higher ACR20 response than patients with high disease activity by RAPID3.

Table 1. Demographic and Clinical Characteristics in 1,208 Patients Providing 6,138 Eligible Visits. The median number of visits per patient is 3 and interquartile range is 1-6.

DAS28-CRP Cut-offs for High Disease Activity Assessment Is Lower Than DAS28-ESR in Rheumatoid Arthritis

Jacob Greenmyer,[1] John Stacy,[1] James Beal,[2] and Erdal Diri[1], [1]University of North Dakota, School of Medicine Health Sciences, Minot, ND, [2]University of North Dakota, School of Medicine Health Sciences, Grandforks, ND

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) disease activity and treatment response are usually assessed by using Disease Activity Score 28-joint count (DAS28), which can be calculated using erythrocyte sedimentation rate (ESR) or C reactive protein (CRP). It has been shown that DAS28-CRP values are lower than corresponding DAS28-ESR values, especially when assessing high disease activity. However, existing guidelines do not specify how cut-offs for high disease activity differ between these two calculations. Most existing studies that compare DAS28-CRP and DAS28-ESR are drawn largely on data from clinical trials or registries. Due to potential variation between laboratories and clinical assessment at separate institutions, existing data must be validated by and compared to data from single institutions. The relationship between high disease activity cut-offs for DAS28-ESR and DAS28-CRP must be carefully characterized in order to adequately assess clinical trial data. The purpose of our study was to compare the DAS28-ESR and DAS28-CRP values from a single institution.

Methods: We conducted a chart review for new diagnoses of RA (ICD-9 714) from January 1, 2005 to September 1, 2018 at Trinity Health in Minot, ND. Patients were excluded if they (i) had received previous treatment with a DMARD,

(ii) were currently receiving treatment with steroids upon referral, or (iii) did not contain the data necessary to calculate both ESR and CRP disease activity scores. Disease severity was calculated using the Disease Activity Scores DAS28-ESR and DAS28-CRP; these values were compared with t-test. P-values were two-sided, and p-value < 0.05 was considered significant. The number of patients with high disease activity (> 5.1) was compared using ESR and CRP data to calculate the proportion of discordance. A receiver Operator Curve and Youden's Index was used to calculate the DAS28-CRP high disease activity cut off estimation that corresponds to DAS28-ESR of > 5.1.

Results: A total of 171 newly diagnosed RA patients met inclusion criteria. The mean DAS28-ESR of patients on presentation was 5.061 (SD = 1.15). The mean DAS-28 CRP was 4.134 (SD = .99). The difference between mean DAS28-ESR and DAS28-CRP was statistically significant (p < .001). The prevalence of patients who met high disease activity criteria (> 5.1) for DAS28-ESR was 48.5% and for DAS28-CRP was 14.6%. Discordance between these two parameters was 33.9%. Kappa coefficient was .307, which corresponds to a minimal level of agreement. Receiver Operator Curve and Youden's index analysis suggested that the cut off point for high disease activity of DAS28-CRP > 4.06, which corresponds to DAS28-ESR > 5.1.

Conclusion: There is a significant difference between DAS28-ESR and DAS28-CRP, especially when assessing high disease activity of RA, even if they are performed and calculated at a single institution.

Leptin-adjustment of the Multi-biomarker Disease Activity (MBDA) Score Reduces the Influence of Adiposity

Joshua Baker,[1] Jeffrey Curtis,[2] David Chernoff,[3] and Michael George[4], [1]University of Pennsylvania, Philadelphia, PA, [2]University of Alabama at Birmingham, Birmingham, AL, [3]Myriad Genetics, Inc, Salt Lake City, UT, [4]University of Pennsylvania, Philadelphia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity and excess adiposity influence inflammatory markers and bias assessments of disease activity, most notably among women. A leptin-adjusted multi-biomarker disease activity (MBDA-LA) score has been developed to account for the effects of age, sex and adiposity and improves prediction of radiographic damage progression. We aimed 1) to determine if the adjusted measure demonstrates a reduced association with adiposity, 2) to assess the impact of the leptin-adjustment on the score over the range of adiposity, and 3) to assess relationships between MBDA scores and clinical disease activity.

Methods: Patients with RA, ages 18-75 years, were recruited from clinical practices and completed whole-body DXA to quantify fat mass indices (FMI, kg/m^2). Age-, sex-, and race-specific Z-Scores were calculated based on the distributions in a healthy reference population. Clinical disease activity was assessed with the CDAI and swollen joint count. van der Heijde-Sharpe (vdHS) scores were determined at baseline by a trained radiologist. MBDA assays were performed on stored serum samples. Descriptive statistics described relationships between the FMI Z-Score and the MBDA and the MBDA-LA. Clinical disease activity, swollen joint count (SJC), and radiographic damage were also compared across categories of MBDA scores.

Table 1: Baseline patient characteristics.		
	Men	Women
N	52	52
Age (yrs)	59.1 (11.5)	53.0 (12.8)
Black, N (%)	13 (25%)	19 (36%)
BMI	27.3 (5.4)	30.3 (8.0)
FMI Z-Score	-0.28 (1.3)	0.05 (1.1)
DAS28(CRP)	3.09 (1.13)	3.21 (1.24)
Disease Duration	11.4 (10.9)	11.6 (11.9)
CRP, mg/dL	0.8 (0.5, 1.2)	0.8 (0.5, 1.4)
CCP Positive, N (%)	45 (87%)	40 (78%)
vdHS (N=93)	13 (4, 73)	10.5 (2, 47)
HAQ	0.71 (0.59)	0.83 (0.67)
MBDA	40.0 (13.8)	42.1 (16.6)
$MBDA_{LA}$	43.6 (13.4)	42.1 (15.3)
Leptin, ng/mL	15.1 (21.5)	48.9 (41.5)

Table 1. Baseline patient characteristics.

Results: There were 104 participants (50% female) with mean (SD) age of 56.1 (12.5) and mean BMI of 28.8 (6.9) (Table 1). The unadjusted MBDA score was strongly associated with BMI among women (Women: Rho=0.46 [p< 0.001]; Men: Rho=-0.12), while the MBDA-LA was not associated with BMI in women, and was inversely correlated in men (Women: Rho=0.17; Men: Rho=-0.32 [p=0.02]). The unadjusted MBDA score was also strongly associated with FMI Z-Score among women (Figure) (Women: Rho=0.42 [p=0.002]; Men: Rho=-0.10; p for interaction=0.01). The MBDA-LA was not significantly associated with FMI Z-Score in women or men (Female: Rho= 0.17; Male: Rho=-0.26). Leptin-adjustment reduced the MBDA score in the highest quartile of FMI in women but not men, and increased the MBDA score in the lowest FMI quartiles in both women and men (Figure); these patients in the lowest FMI quartile had the highest median swollen joint counts (p=0.05 for men, p=0.78 for women) (Figure). The MBDA-LA reclassified 4 women (8%) and 9 men (17%) into higher disease activity categories, and reclassified 2 women (4%) and 2 men (4%) into lower categories. CDAI, SJC, and radiographic scores were similar across activity categories for the unadjusted MBDA score and MBDA-LA (Table 2).

Conclusion: Leptin-adjustment of the MBDA score reduces bias related to excess adiposity in women with RA. The adjustment results in lower MBDA scores in women with greater adiposity, and higher MBDA scores in women and men with lesser adiposity. The use of the MBDA-LA may reduce misclassification due to excess adiposity and

Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Patient Activity Scale (PAS)-II is an accepted disease activity measure used in the care of patients with rheumatoid arthritis (RA). A clinically important change in this score has not been defined for patients with RA. We aimed to define the Minimal Clinically Important Improvement (MCII) and Worsening (MCIW) for the PAS-II using anchor- and distribution-based methods.

Methods: Data from *Forward,* The National Databank for Rheumatic Diseases was utilized. Data are collected at 6-month intervals by questionnaires. Data shown in these analyses spans four 6-month data collection periods: (A) January 2017 (n = 3680, (B) July 2017 (n = 3504), (C) January 2018 (n = 3737), and (D) July 2018 (n = 3102). Both anchor-based and distribution-based methods were used to estimate MCII and MCIW. For the anchor-based analyses, the primary anchors used were comparisons of pain and general health to six months ago (e.g., "Compared to 6 months ago, would you say your pain is: much better now, somewhat better now, about the same, somewhat worse, or much worse?"). Mean changes in PAS-II scores and effect sizes were summarized and averaged over the 4 change periods. For the distribution-based calculations, we used 0.5 and 0.35 standard deviations. We further stratified analyses based on PAS-II score (above/below 3.7), hypothesizing that the MCII and MCIW would be dependent on the baseline PAS-II score.

Results: The population (baseline from Period A, n=3680) average age was 64.9 (12.0) years with an average disease duration of 20.8 (12.7) years and an average PAS-II of 3.3 (2.2). The population was 83.1% female, 91.3% white and 43% ever-smokers. For pain and health-related anchor questions, the MCIW was defined as approximately 0.50 to 0.55, respectively (Table 1), representing a small effect size (d=0.23-0.25). The MCII was defined as 0.39 to 0.45 (d=0.18, 0.21), respectively. Stratifying by the PAS-II score affected the results obtained by anchor-based methods. The MCIW for anchor-based methods among participants in low disease activity (< 3.7) was approximately 1.1 [1.09/1.11 (pain/general health)], while the MCII for those in moderate to high disease activity (>3.7) was 1.09 (1.15/1.02) (Table 2). These changes represented a large effect size. Distribution-based methods for 0.5 SD and 0.35 SD were 1.08 and 0.76, respectively. Results were similar in each 6-month data collection periods.

Conclusion: We defined minimal clinically important change for the PAS-II as a change in the score of 0.5 units. Among participants with moderate to high PAS-II, the MCII was estimated to be 1.1 and among participants with in

Table 1. Minimum important change defined by anchor-based methods.

	Somewhat worse		Somewhat better	
Comparison	Δ PAS-II score	Effect size	Δ PAS-II score	Effect size

low disease activity, the MCIW was 1.1. These data suggest that only a more substantial worsening is likely be important to patients that report low activity. Similarly, only a substantial improvement will be important to patients who report high activity. The characterization of clinically meaningful changes in disease activity is important for clinical research studies and clinical settings where this disease assessment is used.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

	Patient 1	Patient 2	Patient 3
Age	65	81	32
Sex	Female	Male	Female
Ethnicity	Caucasian	Caucasian	Asian
Involved joints	Left 4th PIP	Right knee	Left wrist
ESR (mm/hr)	35	88	44
C-RP (mg/L)	1.72	136	2.7
Rheumatoid factor	Negative	Negative	Positive
Anti CCP	Negative	Negative	Positive
X ray findings	Severe joint space narrowing at left 4th PIP joint	Soft tissue swelling with moderate joint effusion	Progressive severe left radio carpal joint space narrowing and mild mid carpal joint space narrowing
MRI findings	Moderate synovitis of 4th PIP joint with adjacent bone marrow edema without obvious erosions	Extensive hypertrophic synovial thickening with a moderate to large joint effusion and medial and lateral meniscus tear	Marked progressive inflammatory arthritic changes of carpal and carpometacarpal joints
Ultrasound findings	Grade 3 synovitis with grade 1 Doppler signal in the left 4th PIP joint with large osteophytes and hyper echoic signal	Grade 3 synovitis with grade 2 power Doppler, and a double contour sign	Grade 3 synovitis with grade 2 doppler signal
Ultrasound guided synovial biopsy findings	Benign dense fibrous tissue, compatible with synovium	Acute on chronic synovitis with hyperplastic synovial lining. The synovium had a dense inflammatory infiltrate of neutrophils, lymphocytes and plasma cells	Benign synovial tissue, with synovial lining cells, and marked chronic lymphoplasmacytic inflammatory changes with scattered acute inflammatory cells compatible with active rheumatoid arthritis
Surgical synovial biopsy findings	Benign fibro connective tissue	Hyperplastic synovium with acute and chronic inflammation	Lymphoplasmacytic synovitis

Table 1 Comparison of Demographic and Clinical Characteristics of Patients who Underwent USGSB and Surgical Biopsies in the Same Joint

Background/Purpose: Synovial biopsy is often performed when other methods of evaluation prove non-diagnostic in the assessment of persistent joint synovitis, whether in the setting of undifferentiated inflammatory arthritis (UIA) or rheumatoid arthritis (RA). The utility of synovial biopsy is well established. Several methods are used to perform synovial biopsies, such as arthroscopic surgery, fluoroscopic-guided and blind needle synovial biopsies. In recent years, ultrasound (US) technology has progressed significantly with improved image resolution and increased feasibility of US-guided synovial needle biopsies (USGSB). In this study, we compare histopathological findings of USGSB to surgical synovial biopsies of the same joint in patients with persistent synovitis.

Methods: Between 2016-2019, 25 patients were referred to a single rheumatology practice at an academic medical center for persistent joint synovitis and underwent USGSB. Chart review was performed to identify those patients who had surgical biopsies performed on the same joint. For each patient, tissue samples were sent to pathology in formalin for standard histologic evaluation, methanol for anhydrous histologic evaluation (to allow crystal visualization), and a sterile container for cultures.

Results: Of 25 patients who underwent USGSB, 3 patients also underwent surgical biopsies in the same joint within 12 months of the original biopsy. The age of the patients ranged from 32-81 years old. The main demographic and clinical characteristics of the patients and biopsy sites are presented in Table 1.

In patient (pt) 1, USGSB of the left 4th proximal interphalangeal (PIP) joint showed benign dense fibrous tissue, compatible with synovium, with similar findings found on a subsequent surgical arthroscopic biopsy, performed for persistent synovitis. Pt 2 was referred for chronic right knee monoarthritis 1 year after surgical arthroscopic synovial biopsy and meniscectomy, which showed hyperplastic synovium with acute and chronic inflammation; USGSB

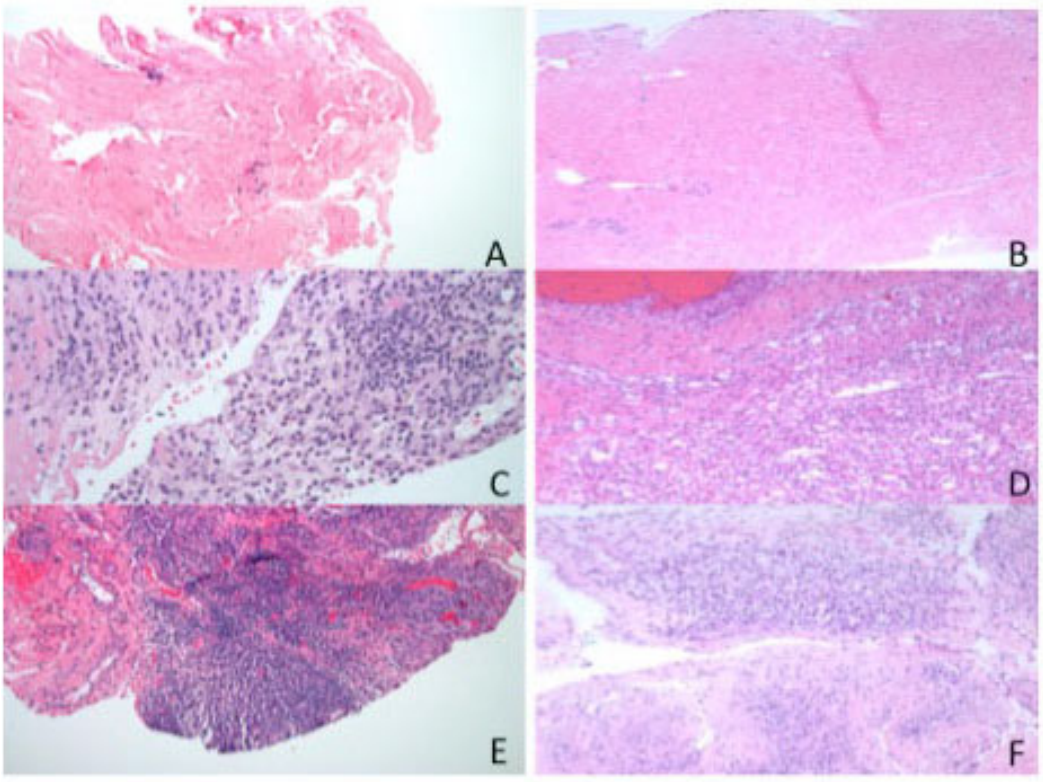

Figure 1. Histologic analysis of synovial sample of A. Left 4th PIP USGSB showing benign dense fibrous tissue B. Arthroscopic synovial biopsy of left 4th PIP joint showing benign dense fibrous tissue C. Right knee USGSB showing acute on chronic synovitis with predominant inflammatory infiltrate of neutrophils D. Right knee surgical synovial biopsy showing acute on chronic inflammation E. Left wrist USGSB showing marked chronic lymphoplasmacytic inflammatory changes F. Surgical biopsy of left wrist synovium showing lymphoplasmacytic synovitis

showed similar findings. Pt 3 had RF +, CCP + rheumatoid arthritis, previously failing multiple biologic and non-biologic DMARDs, and then developed persistent left wrist monoarthritis, suspicious for infection. USGSB showed benign synovial tissue and marked chronic lymphoplasmacytic inflammatory changes with scattered acute inflammatory cells compatible with active rheumatoid arthritis. Subsequent therapeutic left wrist surgical synovectomy identified the same pathology as was found with USGSB.

Conclusion: This study demonstrated that USGSB led to similar pathological results as those obtained by more traditional surgical methods. The three patients underwent synovial biopsies of different joint locations including small, medium and large joints. The surgical biopsies did not produce new or additional information beyond that obtained from the USGSB. All patients tolerated the USGSB well without any complications.

When compared to surgical or fluoroscopic guided biopsies, the USGSB technique has advantages including lower cost, no radiation exposure, and local anesthesia. In addition, we found that USGSB had concordant pathologic findings with surgical biopsies.

Ultrasound Guided Synovial Biopsies Safely Aid in the Assessment of Inflammatory Arthritis

Khin Lim,[1] Ami Ben-artzi,[1] Lindsy Forbess,[1] Swamy Venuturupalli,[2] John Jalas,[3] and Mariko Ishimori[1], [1]Cedars-Sinai Medical Center, Los Angeles, CA, [2]Cedars Sinai Medical Center, Los Angeles, CA, [3]Saint John Health Center, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Synovial biopsies have an important role in the diagnostic evaluation of patients with undifferentiated inflammatory arthritis (UIA) whose clinical examination and blood and synovial fluid testing do not yield a diagnosis. Several methods are used to perform synovial biopsies, including arthroscopic surgery, fluoroscopic guided and blind needle synovial biopsies. In recent years, ultrasound (US) technology has progressed significantly with improved image resolution, musculoskeletal US expertise, and feasibility of US-guided synovial needle biopsies (USGSB). We studied the safety, tolerability, and utility of USGSB in patients with UIA and rheumatoid arthritis (RA).

Methods: Between 2016-2019, we identified all patients referred for USGSB to a single academic medical center. 2 groups of patients underwent this procedure, patients with UIA and those with RA with significant synovitis despite therapy. Chart review was performed to identify clinical characteristics of these patients. For each patient, tissue samples were sent to pathology in formalin for standard histologic evaluation, methanol for anhydrous histologic evaluation, and sterile containers for typical and atypical cultures.

Results: A total of 25 patients were referred for USGSB. There were 18 patients (72%) with UIA and 7 (28%) with RA. All patients presented with inflammatory arthritis > 6 weeks duration. 8 patients had monoarthritis, 4 with oligoarthritis and 13 with polyarthritis. Of the 13 patients with polyarthritis, 7 were previously diagnosed with RA. Demographic and clinical characteristics of patients are shown in Table 1. The results of the biopsies are detailed in Table 2.

Of the 25 USGSB performed, 20 biopsies (80%) retrieved synovial lining cells and thus passed quality control. 5 had no synovial lining cells and therefore were deemed inadequate. Overall, 7 of 25 biopsies showed normal synovium (including 4 RA) and 6 demonstrated chronic lymphocytic inflammation. Among the 6 biopsies with chronic lymphocytic inflammation, 2 were already diagnosed with RA and had been treated with biologic therapy. Among the 4 RA patients with normal synovium on USGSB, one was treated with chronic low dose prednisone and all were on biologic therapy.

The use of USGSB resulted in a definitive diagnosis in 13 out of 14 patients with UIA, while 1 patient remained with the diagnosis of UIA. Among the 13 patients with a definitive diagnosis, 11 of the synovial biopsies helped to achieve a final diagnosis. 2 patients had acute neutrophilic predominant inflammation on USGSB and were treated with empiric antibiotics for presumed infectious arthritis, although cultures were subsequently negative. One patient had septic arthritis. Three patients had CPPD crystals consistent with pseudo gout. One patient had PVNS. The detail of final diagnoses can be seen in Table 3.

All patients tolerated the USGSB procedure well without any complications such as bleeding or infection. Three reported increased stiffness in the biopsied joint, which was resolved over several days.

Conclusion: USGSB is a well-tolerated procedure. Given the minimally invasive nature of the technique, it can be a useful tool to aid in the diagnosis of challenging cases of inflammatory arthritis.

Abstract Number: 1361

Utility of Rheumatoid Arthritis Impact of Disease (RAID) in Routine Care; Identification of Patients Achieving DAS28 Remission or Low Disease Activity, and Burden of Unmet Patient Reported Outcomes

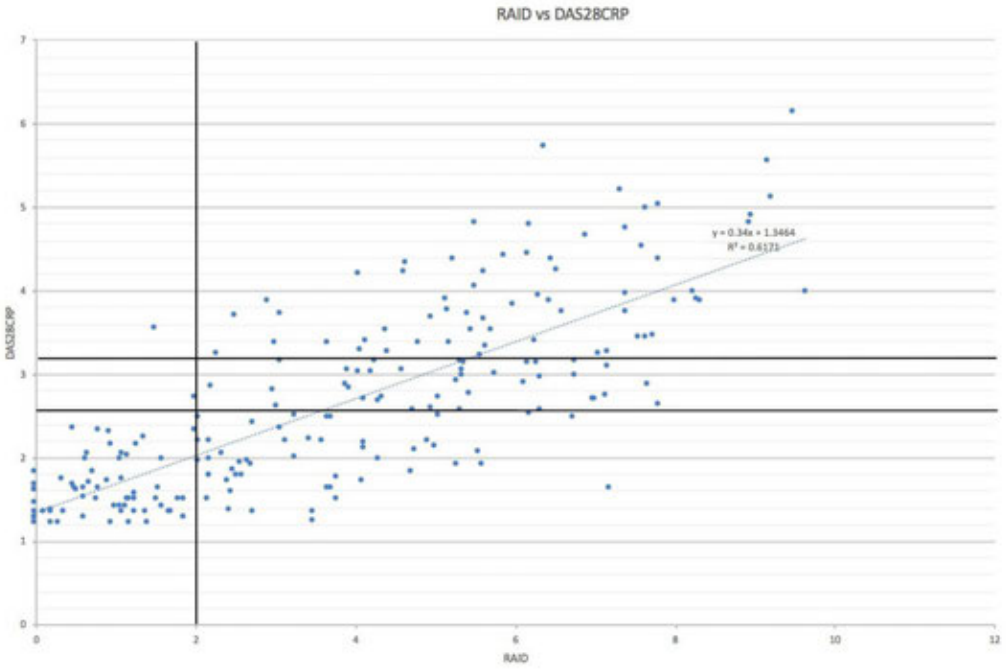
Jatin Mistry,[1] Margaret Sibley,[2] Catherine Smith,[3] Malama Sumbwanyambe,[2] and **Patrick Kiely** [2], [1]St George's University of London, London, United Kingdom, [2]St George's University Hospitals NHS Trust, London, United Kingdom, [3]St Georges University Hospitals NHS Foundation Trust, London, United Kingdom

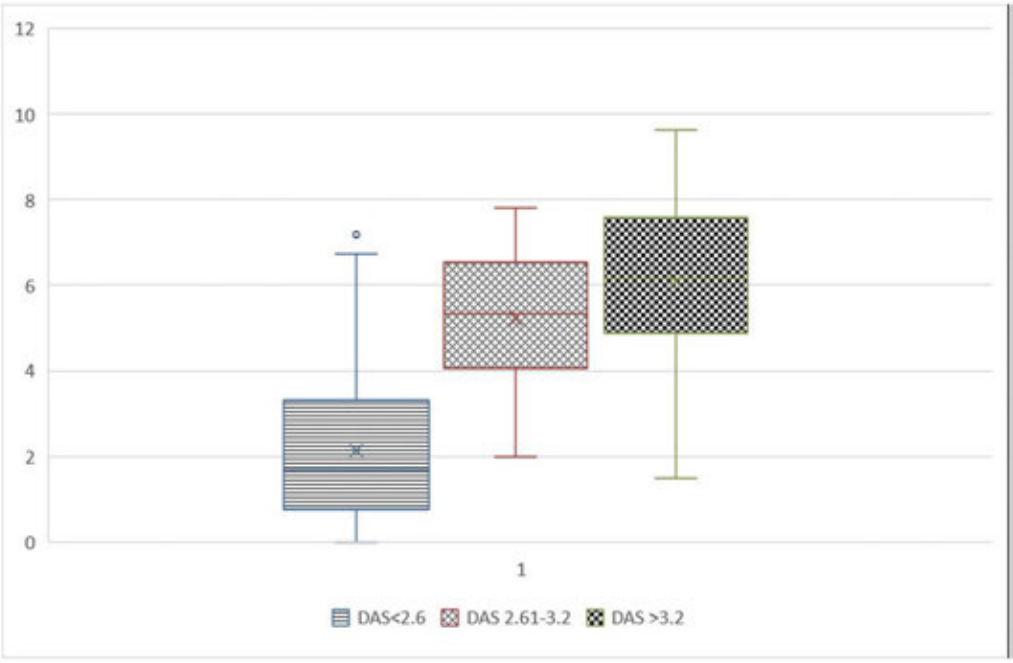
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ACR/EULAR guidelines recommend remission or low DAS28 as the treat to target goal for patients with rheumatoid arthritis (RA). Alternative patient reported outcomes include the rheumatoid arthritis impact of disease (RAID), a self-reported index which assesses seven domains by visual analogue scale: pain, disability, fatigue, sleep, coping, physical and emotional well-being. Responses are weighted differently, producing a final score from 0-10. A score less than 2 is considered a patient-acceptable status. We have assessed the relation of RAID to (i)

DAS28 categories in routine care, (ii) it's utility to identify patients in DAS28 remission (RDAS) or low disease activity (LDAS) and (iii) the burden of unmet patient needs in those achieving RDAS/LDAS.

Methods: RA patients attending for routine review in the outpatient clinic at St George's Hospital were assessed. DAS28 CRP and ESR scores were recorded and RAID questionnaires completed by patients and calculated using the on-line EULAR tool. Summary statistics and Spearman correlation coefficient were analysed on Excel and Mann-Whitney U tests using socscistatistics.com.





Results: 219 patients with established RA were assessed, 81.3% female, mean age 58.8 years, 72.1% RF positive and 79.5% ACPA positive. The number of patients per DAS28 CRP category was RDAS (< 2.6) n=119 (54.6%), LDAS (2.6-3.2) n=34 (15.6%), moderate (MDAS 3.21-5.1) n= 60 (27.5%), high (HDAS >5.1) n= 5 (2.3%). RAID scores correlated strongly with patient global (r=0.69), DAS28 CRP (r=0.62) and DAS28 ESR (r=0.55) but poorly with tender joint count (r=0.30), swollen joint count (r=0.14), ESR (r=0.15) and CRP (r=0.09). The mean RAID score per DAS28 CRP category was RDAS 2.14, LDAS 5.23, M+HDAS 6.09. RAID scores were significantly different (Mann-Witney U) between RDAS versus LDAS (p< 0.00001), RDAS versus M+HDAS (p< 0.00001), LDAS versus M+HDAS (p=0.02). Similar significant differences in RAID scores were found between DAS28 ESR categories. Of 66 patients with RAID < 2, DAS28 CRP was < 2.6 in 64 (97%) and < 3.2 in 65 (98.5%). Of 151 patients with DAS28 CRP < 3.2, RAID was >2 in 86 (57%) with fatigue followed by sleep being the worst scoring domains.

Conclusion: In patients with established RA in routine care, RAID strongly correlates with patient global and DAS28, and scores are significantly lower in patients achieving RDAS versus LDAS and either RDAS or LDAS versus M+HDAS. Virtually all patients with a RAID score < 2 are in DAS28 remission or low disease activity defined by DAS28, and this could be used to minimise unnecessary consultations. However, over half of all patients with DAS28 < 3.2 have unacceptable RAID, and fatigue dominates the unmet needs driving this unacceptable state.

Relationship Between Waking Functions and Disease Activity in Rheumatoid Arthritis Patients Analyzed by Wearable Device

Masahiro Tada,[1] Yutaro Yamada,[2] Koji Mandai,[2] and Noriaki Hidaka[1], [1]Osaka City General Hospital, Osaka, Japan, [2]Osaka City University Graduate School of Medicine, Osaka, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We reported that the prevalence of sarcopenia was 28% and locomotive syndrome was 52% in patients with rheumatoid arthritis (RA)[1]. It is unknown that waking relates with disease activity and body composition in RA patients. Recently, we can quantify number of steps, walking strength, and consumption energy by wearable device. We investigated the relative factors with waking of RA patients, and relationship with disease activity by using wearable device.

Methods: We used the date from prospective observational study (CHIKARA study, UMIN000023744) started form 2016. 85 from 100 RA patients entered and attached with wearable activity meter (HJA-750C; OMRON, Japan) during 7 consecutive days. We calculated the average daily number of steps, walking exercise (EX) (Mets x Time), and calorie consumption. The relationship of disease activity, body composition, muscle function, sarcopenia, locomotive syndrome, and frailty was analyzed by uni- and multivariate analysis. We investigated the correlation of number of steps and locomotive syndrome by ROC curve analysis.

Results: Mean age was 65.2 years (women n=67, men n=18), disease duration was 7.7 years, DAS28-ESR was 3.12, and HAQ was 0.6. Number of steps and walking EX were negatively correlated with matrix metalloproteinase-3, DAS28-ESR, HAQ, locomotive syndrome, and frailty, and positively correlated with leg muscle score, muscle power,

	Univariate		Multivariate	
	R	P	β	P

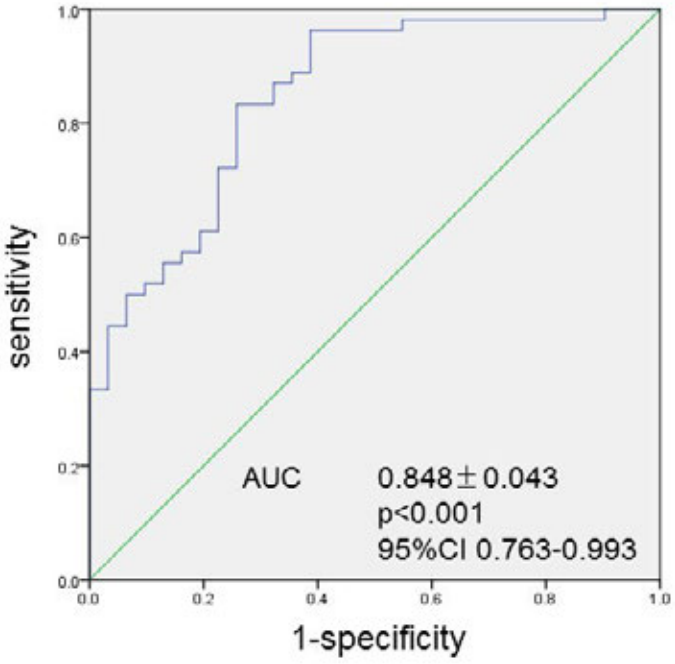
HAQ	-0.431	<0.001		
Locomotive syndrome	-0.581	<0.001	-0.276	0.017
Frailty	-0.565	<0.001		
Leg muscle score	0.342	0.001		
Muscle power	0.622	<0.001	0.414	<0.001
Muscle speed	0.583	<0.001		
Grip strength	0.287	0.008		
Walking speed	0.537	<0.001		

Table 1. Relative factors of number of steps in patients with RA

muscle speed, grip strength, and walking speed by univariate analysis (Table 1). Calorie consumption positively correlated with muscle mass and bone mass in addition to those factors. Locomotive syndrome and muscle power were detected as independently associated with number of steps and walking EX on multivariate analysis (Table 1). About calorie consumption, only muscle power was detected as an independent relative factor. When number of steps were

Figure 1



under 3333 by ROC curve analysis (Figure 1), the odds ratio of locomotive syndrome increased 14.4-hold (95%CI: 5.0-41.6) compared with over 3333 ($p < 0.001$).

Conclusion: Locomotive syndrome and muscle power were independent relative factor of number of steps and walking EX. Over 3333 steps per day was recommended to prevent locomotive syndrome in RA patients.

Longitudinal Work Transitions in Early Inflammatory Arthritis Patients: Are There Targets for Intervention to Improve Employment?

Lily SH Lim,[1] Doris Cheung,[1] Kaviul Mohamed,[2] Diane Lacaille,[3] Eleanor M. Pullenayegum,[4] and Carol Hitchon[1], [1]University of Manitoba, Winnipeg, MB, Canada, [2]University of Toronto, Toronto, ON, Canada, [3]Arthritis Research Canada and University of British Columbia, Vancouver, BC, Canada, [4]Child Health Evaluative Sciences, The Hospital for Sick Children, Dalla Lana School of Public Health, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Historically, increasing proportions of patients with rheumatoid arthritis stop working on long-term follow-up, often due to arthritis. The trajectory of work transitions in early arthritis in the era of targeted treatment is unknown. Since decreasing employment may lead to loss of employment or work disability, we aimed to delineate the longitudinal transition trajectory of early arthritis patients and to identify predictors of decreasing employment.

Methods: This is a single center retrospective inception longitudinal cohort study of early inflammatory arthritis (EIA) patients whose symptom-onset£1 year at diagnosis. Patients were treated to target remission. Disease activity score 28 (DAS28– 3 variables), and patient reported outcomes were collected at each visit. Work status has been recorded annually. The primary outcome was employment states: full-time (FT), part-time (PT), unemployed, homemaker/ student, work disability (WD), retired (RE). We used the Markov multistate model, adjusted for interval censoring, to model the longitudinal transition trajectory of employment. The states in the model are: FT, PT, no income (NI: unemployed, homemaker & students), WD (self-reported) and RE (the only absorbing state). Probabilities of employment were calculated. Candidate predictors, both time-invariant and time-varying, including: sociodemographics, EIA activity, patterns of joint involvement (large upper or lower extremity joints, small upper or lower extremity joints), functional capacity (health assessment questionnaire, HAQ), quality of life (Short Form 36, SF36) and self-reported comorbidities (other chronic diseases, mental illnesses) were tested for association with employment transitions.

Results: 312 patients (76.5% females) diagnosed from 2000-2017, who were not retired at the baseline visit, had a median age at diagnosis was 45.3 years (33.3– 52.7, 25th-75th percentiles P), median duration of follow-up was 4.3 years (1.1– 9.8, 25th-75th P), median baseline DAS28 of 4 (2.9– 5.1, 25th-75th P) and 48% were rheumatoid factor positive. At baseline, 51% were working FT, 14% PT, 7% were students, 13% were homemakers, 8% WD. Baseline median completed school years was 12 yrs (12-15, 25th-75th P). Patients were most likely to stay in the same state of employment they were in at baseline, at 1, 5, 10 yrs (Table 1). Probabilities of transitioning to a FT/PT state from baseline NI increased to 0.33 (5 yrs) and 0.45 (10 yrs) and from baseline WD increased from 0.22 (5yrs) to 0.31 (10 yrs).

Table 1: Transition probabilities of employment states at 1, 5 and 10 years after baseline

State	Full Time	Part Time	No Income	Work Disabled	Retired
			1-year transition probabilities		
Full Time	0.94	0.01	0.01	0.02	0.02
Part Time	0.03	0.90	0.03	0.02	0.01
No Income	0.06	0.03	0.88	0.02	0.02
Work Disabled	0.04	0.02	0.03	0.87	0.04
			5-year transition probabilities		
Full Time	0.76	0.04	0.04	0.06	0.10
Part Time	0.15	0.61	0.11	0.07	0.06
No Income	0.22	0.11	0.53	0.06	0.08
Work Disabled	0.15	0.07	0.09	0.50	0.18
			10-year transition probabilities		
Full Time	0.60	0.07	0.06	0.08	0.19
Part Time	0.24	0.40	0.14	0.10	0.13
No Income	0.31	0.14	0.31	0.08	0.16
Work Disabled	0.22	0.09	0.11	0.27	0.30

Older age was protective of transitioning from PT to NI (hazard ratio, HR 0.87; 95% CI 0.82-0.93). Increased fatigue was associated with increased transitions from PT to NI (HR 1.02, 95%CI 1.00-1.04). Better SF36 was protective of transition from FT to WD (0.92, 95% CI 0.86-0.98). Sex, education, arthritis features, comorbidities & mental health were not associated with employment transitions.

Conclusion: Employment states in EIA patients changed dynamically over time. Even individuals who had NI or were WD at diagnosis had increased probabilities of moving into a working state over time. This work identified potential targets for intervention strategies to help EIA patients gain or regain employment.

Table 2. Degree of agreement between DAS-28 and MBDA (Vectra) disease activity scores

Test	Sample Mean Difference	Test Statistic Value	Degrees of Freedom	P-Value
DAS28	1.19	5.69	74.5	< 0.0001
Unadjusted	5.62	3.27	100.0	0.001
Total Adjusted	2.76	2.04	115.3	0.022
Leptin Adjusted	8.25	5.01	101.7	< 0.001
BMI Adjusted	4.55	3.22	112.9	0.001

Table 3. Welch-approximated two-sample t-test (testing the nullhypothesis that the mean disease activity score in the fibromyalgia group is less than or equal to the mean disease activity scores in the non-fibromyalgia group)

Background/Purpose: The goal for treatment of RA is to obtain low disease activity for better outcomes. In order to achieve low disease activity, it is important to have an accurate way to measure disease activity. Historically, RA disease activity has been measured by scoring systems. The disease activity score in 28 joints (or DAS-28) is one of the most popular measurement tools for disease activity in RA. DAS-28 includes subjective measures of disease activity. Some patients, especially those with co-morbidities such as fibromyalgia, might have higher subjective disease activity than others. Recently, more objective measurements of RA disease activity have been popularized. MBDA (or Vectra DA) is one of these objective measures of disease activity. It uses 12 biomarkers to calculate a disease activity score. Some of the biomarkers included in the MBDA (leptin, CRP and IL-6) can be higher in obese patients. The aim of this study is to study the effects of obesity on MBDA.

Methods: Charts of 244 patients with RA seen by WellStar Medical Group (WMG) rheumatology between January 1, 2014 and April 1, 2019 who had MBDA testing were retrospectively reviewed for this study. MBDA score was compared to DAS-28 score (based on physician notes from the same visit as when Vectra DA lab was drawn) in patients with normal, overweight and obese BMIs.

Results: Adjusted MBDA scores agreed more closely with disease severity (low, moderate or high) by DAS-28 scoring than unadjusted MBDA scores. Still, only 84 of 244 total adjusted MBDA scores agreed with DAS-28 disease activity scores. BMI-adjusted MBDA scores are most closely correlated with DAS-28 scores and this correlation is most apparent in overweight patients (κ = 0.207, 95% CI [0.019,0.394]). However, using a regression equation (DAS28= 1.261 + 0.043 x Leptin-adjusted score - 0.011 x BMI-adjusted score) DAS-28 scores seem to correlate more closely with MBDA scores. MBDA scores tended to show higher levels of disease activity overall than DAS-28 scores (see Table 2). In Fibromyalgia patients, mean disease activity scores were higher than in patients without Fibromyalgia in both DAS-28 and MBDA scoring systems (see Table 3).

Conclusion: MBDA scores may be adversely affected by obesity. A prospective randomized controlled study in a bigger cohort of patients is needed to further investigate this correlation.

Construct Validation of PROMIS Short Form and Profile-29 T-Scores with SF-36 in Rheumatoid Arthritis Patients Treated for 1 Year: Results from a Real World Evidence-Based Study in the United States

Clifton Bingham,[1] Shelly Kafka,[2] Shawn Black,[3] Stephen Xu,[4] and Jeffrey Curtis[5], [1]Johns Hopkins University, Baltimore, MD, [2]Janssen Scientific Affairs, LLC, Horsham, PA, [3]Janssen Scientific Affairs, LLC, Horsham, RI, [4]Janssen Research & Development, LLC, Spring House, PA, [5]University of Alabama at Birmingham, Birmingham, AL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Use of PROs to assess health-related quality of life in clinical practice, research studies, and clinical trials in Rheumatoid Arthritis (RA) remains an ongoing area of research. SF36 is commonly used in RA trials but is not feasible for routine use in clinical practice settings. The PROMIS (Patient Reported Outcomes Measurement Information System) may address this gap but has not been widely assessed in RA patients starting therapy in a real-world comparative effectiveness study, nor examined in that setting in relation to the SF36 and Clinical Disease Activity Index (CDAI). These were evaluated in AWARE (Comparative and Pragmatic Study of Golimumab IV Versus Infliximab in Rheumatoid Arthritis), an ongoing Phase 4 study providing real-world assessment of IV Tumor Necrosis Factor inhibitor (TNFi) medications in RA pts.

Methods: AWARE is a prospective, noninterventional, 3-year study at 88 US sites. RA pts were enrolled when initiating TNFi treatment. Treatment decisions were made by treating rheumatologists. We report baseline PROMIS-29 (7 domains and pain intensity), PROMIS Pain Interference (PI) Short Form (SF) 6b (PI6b) and PROMIS Fatigue (F) Short Form 7a (F7a), domain T-Scores, and SF36 subdomain and Component Scores (CS) in AWARE patients. Here we report baseline data obtained from the final 1-year AWARE dataset. Correlations between PROMIS measures and comparable SF36 component scores were calculated using Pearson Correlations. Data is shown as mean ± standard deviation (SD).

Results: At baseline, mean CDAI of all pts (n=1262) was 32.3±15.6, with 70.4% in High Disease Activity (HDA, CDAI >22), 22.8% in Moderate DA (>10 and ≤22), 6.1% in Low DA (>2.8 and ≤10) and 0.7% in Remission (≤2.8). Mean PROMIS scores were >0.5 SD worse than population means for Physical Function (PF, 38.1±6.84), PI (63.4±7.68), F (58.8±9.95), Sleep Disturbance (55.1±8.68); and Ability to Participate in Social Roles/Activities (PSRA, 43.4±8.58). Baseline Depression and Anxiety were within 0.5 SDs of population T-scores. PI6b, F7a, and P29 domain T-scores correlated with the comparable SF36 subdomain and component scores (r's >0.58), excepting sleep for which no comparable SF36 element was applicable. Examples include: P6b (r=-0.80) and P29-PI (0.81) with SF-36 Bodily Pain; F7a (-0.77) and P29-F (-0.77) with SF36 Vitality; P29-PF with SF36 PF (0.77), Role-Physical (0.69), and Physical CS (0.73); P29 Anxiety with SF36 Mental Health (-0.72), Role- Emotional (-0.56), Mental CS (-0.70); and P29-PRSA with SF36-Social Functioning (0.71). Mean PROMIS-29 T-scores (except Anxiety and Sleep Disturbance) among patients with HDA were significantly different from patients with MDA, LDA or remission ($p < 0.001$ for all). Further, mean PROMIS T-scores of PF, F, PSRA, PI, Pain Intensity, PI6b and P7a among patients with MDA were significantly different from patients with more or less active RA (by CDAI category).

Conclusion: Analysis of baseline results from a large cohort of RA patients indicates high correlations between individual P29 domain T-scores and SF36 component scores, as well as categorical CDAI, providing strong evidence of PROMIS construct validity in a real-world population of RA patients.

Self-joint Counts by People with Rheumatoid Arthritis: Does a Video Increase Accuracy and Does It Matter?

Rebecca Grainger,[1] Simon Stebbings,[2] William Taylor,[1] Andrew Harrison,[1] Celina Capistrano,[1] Niamh Fanning,[3] and Lisa Stamp[4], [1]University of Otago, Wellington, New Zealand, [2]University of Otago, Dunedin, New Zealand, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]University of Otago, Christchurch, New Zealand

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: As a tool for self-monitoring and reporting RA disease activity, a smartphone app was developed to enable people with rheumatoid arthritis (RA) to record their disease activity, including self-reported 28 tender (28TJC) and swollen joint counts (28SJC). Studies suggest self-joint counts by people with RA are relatively similar to those by rheumatologists (28TJC more similar than 28SJC) but little is known about the effects of training on self-joint count accuracy. In collaboration with people with RA we refined techniques for joint self-examination and produced an instructional video. The aims of this study were to determine how patient self-joint counts, and derived disease activity scores, compared to rheumatologist joint counts and whether this was affected by a self-training video.

Methods: Patients (n=100) meeting EULAR/ACR 2010 criteria for RA attending clinics in 3 centres self-reported RA disease activity measures using the app, including a self-examination joint count. Patients were then randomised to either complete the self-report joint count a second time (Pt 2) with no further instruction (n=49) or to complete the self-report after watching the video (n=51). Blinded to patient data, a rheumatologist completed a 28-joint count, which was taken as the “gold standard”.

Results: Most participants were female (77%), had mean age 60.2 years (range 33-83 years), duration of RA 17.0 years (range 0.25-55 years) and 45% were using a biologic DMARD. Video and no-video group participants did not differ on demographic or disease characteristics but the video group had lower smartphone ownership (68% versus 85%, p=0.042). First and second patient-reported joint counts showed high correlation and did not change after watching the video, suggesting that watching the video had no training effect (Pearson R for 28TJC Rheum vs Pt 2 No video 0.568, Video 0.508; 28SJC Rheum vs Pt 2 No video 0.281, Video 0.386). Compared to rheumatologist assessment, people with RA consistently reported higher 28TJC and 28 SJC (28TJC Pt 2 vs rheum mean diff 3.01 (SD 5.76), 28SJC Pt 2 vs rheum mean diff 1.49 (SD 5.49)) but these differences were not statistically significant. Patient-derived DAS28 was never more than one disease activity category higher than rheumatologist-derived DAS28.

Conclusion: People with RA are consistent in reporting of self-joint counts and a training video did not change reporting. Although patients scored their joint counts higher than rheumatologists, the difference was small and not significant and would not invalidate the use of patient-reported scores for clinical purposes.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background: Rheumatoid arthritis (RA) is a long-term, progressive, and disabling autoimmune disease. The disease activity can be quantified by the Disease Activity Score 28-joint count C reactive protein (DAS28-CRP) but the evaluation of disability function (DF) is actually mainly performed only by subjective Patient Reported Outcomes (PROs) like Health Assessment Questionnaire (HAQ). Hence there are no objective and affordable tests to quantify the DF. The Hand Test System (HTS, ETT) is an engineered glove that can evaluate hands motility[1], nowadays applied for neuroscience studies.

Purpose: To quantify by HTS the DF of RA patients (RApts) by the analysis of speed and right execution of fingers opposition movement in both hands, evaluated. To verify the correspondence with the HAQ and DAS28(CRP).

Methods: In this pilot study 14 consecutives RApts (3 males, 11 females, age 61±11,5 years, mean duration of disease 11,21±5,07 years), classified according to 2010 ACR/EULAR criteria[6], and 13 healthy controls (HC – 7 males, 6 females, age 50±15 years) were enrolled. After consent, all participants undergone HTS test; a multiple finger evaluation (MFE) and a single finger evaluation (SFE) were performed analyzing the touches between the finger tips during the opposition movements of the hands in standard sequences of movements. A dedicated software provided the physician these quantitative parameters: Touch Duration (TD), Inter Tapping Interval (ITI) and Movement Rate (MR). RApts compiled the HAQ and a DAS28-CRP was performed. Continue variables were summarized as mean and standard deviation or median and interquartile range, discrete variables were summarized with count and percentage. Variables with skewed distribution was converted to natural logarithm. T-test was used to compare log glove parameters between groups. Pearson's r and p value were used to report the correlation between log-converted glove parameters and HAQ score.

Results: In MFE, glove parameters TD and ITI were found significantly higher in RApts (TD 257.34 ± 123.93 ms, ITI 377.8 ± 211.35 ms) than HC (TD 172.25 ± 59.36 ms, ITI 177.98 ± 78.53 ms) ($p = 0.004$ and $p < 0.001$) and MR was significantly lower in RApts (1.51 ± 0.47 Hz) compared to HC (2.87 ± 0.9 Hz) ($p < 0.001$). There was a trend of increased TD at the increasing of DAS28-CRP (P=0.178). TD of RApts had a significant correlation with the total score of the HAQ (Pearson $r = 0.79$, $p = 0.001$). In SFE not swollen and not tender fingers of RApts performed slightly better than a clinically active finger (AF) but significantly worse than average HC finger (ANOVA, $p < 0.001$).

Conclusion: HTS is a totally safe and promising tool to quantify in an objective manner the DF of the hands in RApts. The significant correlation found with HAQ highlights the loss of motility of the hands as one of the main determinant of DF. The non-significative result with DAS28-CRP is likely due to the low number of subjects enrolled. Further studies are ongoing with larger number of RApts to validate its application to monitor the improving or the worsening of RA in order to optimize pharmacological treatments. The study is now extended to the hands in other Rheumatic and Musculoskeletal Diseases.

One Size Fits All : Replacing ESR by γGT in DAS28 Calculation Permits a Dual Evaluation of Joint Activity Together with Cardiovascular Risk

Hélène Vergneault,[1] Eloïse Vandebeuque,[2] Veronica Codullo,[1] Yannick Allanore,[3] and **Jérôme Avouac** [1], [1]Cochin Hospital, Paris, France, [2]Paris Descartes University, Cochin Hospital, Rheumatology department, Paris, France, [3]Dept. of Rheumatology A, Descartes University, APHP, Cochin Hospital, Paris, France, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) experience premature mortality that is largely due to cardiovascular disease (CVD). Ample evidence suggests that elevated γGT activity is associated with increased risk of CVD. Our aim was to assess the determinants of increased γGT activity in patients with RA, focusing on markers of disease activity and cardiovascular risk factors.

Methods: Cross-sectional study including successive RA patients hospitalized in the Rheumatology department of Cochin Hospital for a 12-month period. Data on liver function, disease activity, hepatotoxic and cardiovascular risk factors were systematically collected and all patients were assessed by Power Doppler Ultrasound (PDUS) performed on 32 joints. DAS28-γGT was calculated by replacing ESR by γGT in the following formula: $0.56^{*}\sqrt{TJ\text{-}28}+0.28^{*}\sqrt{SJ\text{-}28}+2^{*}ln(\gamma GT)+0.014^{*}GH$

Results: We included 124 patients: 85% were women and mean age was 58 years. Thirty-one patients (25%) had isolated γGT increase. γGT correlated with CRP (r=0.30, p=0.002) (Figure 1A). No correlation was observed between γGT and ESR, DAS28 or DAS28-CRP. γGT were significantly increased in patients with alcohol consumption (median (range): 35 (20-144) UI/L *vs*. 22 (7-219) UI/L, p=0.012), type 2 diabetes mellitus (35 (8-215) UI/L *vs*. 21 (7-219) UI/L, p=0.024), blood hypertension (35 (8-215) UI/L *vs*. 21 (7-219) UI/L, p=0.024), dyslipidemia (28 (7-219) UI/L *vs*. 19 (8-215) UI/L, p=0.004) and metabolic syndrome (48 (14-219) UI/L *vs*. 21 (7-144) UI/L). γGT levels gradually increased with the number of cardiovascular risk factors (p< 0.001) (Figure 1B). In multivariate analysis, γGT levels > 35 UI/L was associated with CRP > 10 mg/L (OR : 4,88, 95% CI 1,59-15,03) and the presence of dyslipidemia (OR: 3.13, 5% CI 1.09-8.97). Given that γGT reflected both systemic inflammation and metabolic condition, we constructed a composite index called DAS28- γGT to test the merit of this marker for the global evaluation of RA. DAS28- γGT remains a reliable marker of RA disease activity which correlated with DAS28 (r=0.50, p< 0.001), DAS28-CRP (r=0.70, p< 0.001), ESR (r=0.30, p< 0.001), CRP (r=0.50, p< 0.001), global OMERACT-EULAR synovitis Score on PDUS (r=0.22, p=0.024) and HAQ (r=0.35, p< 0.001). Patients with blood hypertension (median (range) 8.16 (5.41-12.14) *vs* 7.26 (4.80-11.47) p=0.012), dyslipidemia (8.24 (4.80-12.14) *vs*. 7.08 (5.04-11.81), p=0.011) and metabolic syndrome (8.47 (6.23-12.03) *vs.* 6.40 (4.80-12.14)) were more likely to have increased DAS28-γGT. Conversely to the DAS28 and DAS28-CRP, DAS28-γGT steadily increased according to the number of cardiovascular risk factors (Figure 1C), and had a diagnostic value for the presence of at least 2 cardiovascular risk factors characterized by an AUC of 0.70 (p< 0.001) compared to 0.51 for DAS28 and DAS28-CRP (Figure 1D)

Conclusion: Our results support that γGT levels may be considered as markers of systemic inflammation, metabolic syndrome and cardiovascular risk in patients with RA. We propose an original index, the DAS28-γGT, able to evaluate both disease activity and cardiovascular risk. This index would deserve further validation in prospective cohorts.

Angiogenic Factors for Assessing Rheumatoid Arthritis in the Era of Sonographic Diagnosis and Biologic Therapy

Ji-Won Kim,[1] Jin-Sun Kong,[2] Youngjae Park,[3] and Wan-Uk Kim[3], [1]Catholic University of Daegu School of Medicine, Daegu, Republic of Korea, [2]Catholic University of Korea, College of Medicine, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Previously, we demonstrated the direct pro-inflammatory role of the vascular endothelial growth factor (VEGF) and the placenta growth factor (PlGF), and angiogenic factors in rheumatoid arthritis (RA) pathogenesis (Arthritis Rheum 2009, Nat Immunol 2019). Here, we investigated whether these factors can reflect ultrasound (US)-defined synovitis, disease activity, and treatment response in RA patients.

Methods: US was performed to determine synovial hypertrophy (GSUS) and vascularity (PDUS) scores in RA patients (n=54) who underwent arthrocentesis; GSUS ≥2 or PDUS ≥1 was defined as severe synovitis. Serum samples were obtained from 157 RA patients, and among them, RA patients with disease activity score 28 (DAS28) > 3.2 underwent serial serum sampling 6 months after treatment with conventional DMARD (cDMARD, n=53) or biologic DMARD (bDMARD, n=49). Angiogenic proteins primarily produced by synoviocytes, including VEGF, PlGF, soluble flt-1 (sflt-1), and IL6, were measured in the synovial fluid (SF) and sera using an enzyme-linked immunosorbent assay.

Results: SF and serum VEGF, PlGF, sflt-1, and IL6 concentrations were significantly elevated in RA patients compared with osteoarthritis controls. For SF, RA patients with severe synovitis on US examination showed higher concentrations of PlGF, but not VEGF, than those without. In contrast, serum VEGF, but not PlGF, reflected well synovitis severity in the joints, correlating with acute phase reactants and DAS28. In cDMARD users, the serial follow-up of serum VEGF, IL6, ESR, and CRP could all predict the treatment response. However, in biologic drug users (n=49), serial monitoring of VEGF only, but neither IL6 nor CRP, significantly predicted treatment response. Using a multiple logistic regression model, older age, low baseline sharp score, and high VEGF difference were associated with good and moderate treatment response; area under the ROC curve from this model was 0.872.

Conclusion: Angiogenic factors PlGF and VEGF represent well the joint pathology of RA assessed by US. Serum VEGF shows a better value to predict a therapeutic response to anti-rheumatic drugs than CRP and IL6, particularly in patients treated with biologic agents.

Not All Joints Are Equal: Challenge DAS28 System and Identify Factors Leading to a Mismatch Between T2T and HAQ Among RA Patients Through Data Mining from Smart System of Disease Management (SSDM)

Jing Yang,[1] Zhenbiao Wu,[2] Yongfu Wang,[3] Hua Wei,[4] Yu Zhang,[1] Xiaoling Liu,[5] Xiaofeng Rong,[6] Jinmei Zou,[1] Xiaofei Shi,[7] Hongbin Li,[8] Rui Wu,[9] Xiaoli Deng,[10] Huiqiong Zhou,[11] Yuan Jia,[12] Wei Zhao,[13] Shi Chen,[12] Xuewu Zhang,[12] Yingnan Li,[14] Yingkun Nie,[14] Yifang Mei,[15] Jianyu Zhang,[16] Hanyou Mo,[17] li Sun,[18] Yanfei Chen,[19] Haili Shen,[20] Dongsheng Li,[21] Yonggang Zhao,[22] Hui Xiao,[23] Bing Wu,[24] Yuhua Jia,[22] and Fei Xiao[25], [1]Central Hospital of MianYang, Mianyang, Sichuan, China (People's Republic), [2]The First Affiliated Hospital of The Fourth Military Medical University, Xian, Shanxi, China (People's Republic), [3]The First Affiliated Hospital of BaoTou Medical College, Baotou, Nei Mongol, China (People's Republic), [4]Northern Jiangsu People's Hospital, Yangzhou, China (People's Republic), [5]The 1st Affiliated Hospital of Guangzhou University of TCM, Guangzhou, China (People's Republic), [6]The 1st Affiliated hospital of Chongqing medical University, Chongqing, Chongqing, China (People's Republic), [7]First Affiliated Hospital of Henan University of Science and Technology, luoyang, Henan, China (People's Republic), [8]The Affiliated Hospital of Inner Mongolia Medical University, Huhhot, Nei Mongol, China (People's Republic), [9]The First Affiliated Hospital of Nanchang University, Nanchang, Jiangxi, China (People's Republic), [10]Peking University Third Hospital, Beijing, Beijing, China (People's Republic), [11]Fourth Medical Center of PLA Genal Hospital, Beijing, Beijing, China (People's Republic), [12]Peking University People's Hospital, Beijing, Beijing, China (People's Republic), [13]Chinese PLA General Hospital, Beijing, Beijing, China (People's Republic), [14]The 2nd Affiliated Hospital of Harbin Medical University, Harbin, Heilongjiang, China (People's Republic), [15]The First Affiliated Hospital of Harbin Medical University, Harbin, Heilongjiang, China (People's Republic), [16]The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangdong, China (People's Republic), [17]Affiliated Hospital of Guilin Medical University, Guilin, Guangxi, China (People's Republic), [18]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, Zhejiang, China (People's Republic), [19]The First Hospital of Lanzhou University, Lanzhou, Gansu, China (People's Republic), [20]The Second Hospital of Lanzhou University, Lanzhou, Gansu, China (People's Republic), [21]Ganzhou People's Hospital, Ganzhou, Jiangxi, China (People's Republic), [22]Shanghai Gothic Internet Technology Co., Ltd., Shanghai, Shanghai, China (People's Republic), [23]Shanghai Gothic Internet Technology Co., Ltd, shanghai, Shanghai, China (People's Republic), [24]Shanghai Gothic Internet Technology Co., Ltd, Shanghai, China (People's Republic), [25]Shanghai Gothic Internet Technology Co., Ltd., shanghai, China (People's Republic)

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Treat to target (T2T), achieving a DAS28 score lower than 3.2, is the strategy recommended by ACR and EULAR. Health assessment questionnaire (HAQ) is the most widely used in assessment of physical function in RA. However, the T2T may not be always associated with low HAQ score. The purpose of this study is to quantify phenomena of mismatch between T2T and HAQ in RA patients and identify influential factors from real-world data mining in SSDM.

Methods: SSDM are mobile APPs of disease management. The patients were trained by physician to conduct their DAS28 and HAQ self-assessments with SSDM. The data were synchronized with physicians' and uploaded onto cloud for analysis.

Two phases studies were designed. Phase I: from June of 2015 to May of 2018, to identify impact factor for mismatch; phase II: from June 2018 to May 2019, validation.

Results: From June 2015 to May 2019, 54,149 RA patients from 587 hospitals in China used SSDM, of which 41,234 patients made 84,538 times of DAS28 & HAQ self-assessments. Phase I: Total 48,751 assessment from 25,151 pa-

Table 1. The mean scores for each functioning category in HAQ and the top 3 target joints.

	Mean score	Knee	Wrist	Shoulder	Middle finger	Elbow	Index finger	Other fingers
1 Dress yourself including shoelaces and buttons	0.43		0.43	0.34	0.22			0.12
2 Get in and out of bed	0.3	0.3	0.24	0.15				
3 Lift a full glass to your mouth	0.32		0.32	0.26	0.16			
4 Walk outdoors on flat ground	0.38	0.38	0.3	0.19				
5 Wash and dry your body	0.48		0.48	0.38		0.24		
6 Bend down to pick up clothing from the floor *	0.81*	0.81	0.65	0.42				
7 Turn faucets (or corks) on and off	0.47		0.47		0.38		0.24	
8 Get in and out of a car	0.48	0.48	0.38	0.24				
Total scores	3.67	1.97	3.27	1.98	0.76	0.24	0.24	0.12
Mean score	0.46	0.49	0.41	0.28	0.25	0.24	0.24	0.12
impact factors		4	3.4	2.3	2.1	2	2	1

* $P < 0.001$

Table 1. The mean scores for each functioning category in HAQ and the top 3 target joints.

tients included. Among them, 25,738 assessments from 13,110 patients reached T2T. The mean numbers of tender and swollen joints were 1.53 and 1.32, respectively. However, 8,762 assessments (34.04%) of 5,905 patients had abnormal physical function (HAQ > 0), which score for 8 functional tests was 3.67. The "Bend down to pick up cloth from the floor" was the commonest, with a mean score of 0.81, significantly higher than other functional test score, $P< 0.001$. The analysis of correlation between physical dysfunction and the affected joints showed the knees were the major contributor to the mismatch, following by wrists and shoulders. Table 1 showed the mean scores for each functioning category in HAQ and the top target joints. According to the cluster weights for the impacts of affected joints on physical function, the weighted coefficient of impacting factors (IF) on physical function was obtained: knee=4, followed by wrist=3.4, shoulder=2.3, middle finger=2.1, elbow=2, index finger=2, other finger=1. Phase II: total 35,787 assessments from19,941 patients were included. Among them, 18,618 assessments from 10,776 patients achieved T2T, but 5,500 assessments from 3,979 patients (29.54%) had abnormal physical function (HAQ > 0, mean 3.49). After excluding 1,621 assessments without joint involvements, 3,879 left for validation. With standard DAS28 calculator, IFs of knee*4, wrist*3.4, shoulder*2.3, middle finger*2, orther finger*1 were applied for calculation, and 3,373 (86.96%) assessments turn out to be DAS28 >3.2(Mean: 4.19±0.01, Median: 4.08), major mismatches were overcome.

Conclusion: Over 1/4 RA patients suffer from physical dysfunctions though T2T are achieved. Diseased knees, wrists and shoulders are the major contributors to physical dysfunction and to the mismatch between T2T and HAQ. While elbow and finger joints influence on HAQ less. Therefore, not all joints are equal and T2T guided by current DAS28 may mislead. Joints of knees, wrists and middle fingers deserve higher IF (2.1-4) in DAS28. A modified DAS28 should be considered and a special attention should also be paid on these top three joints for rehabilitations.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

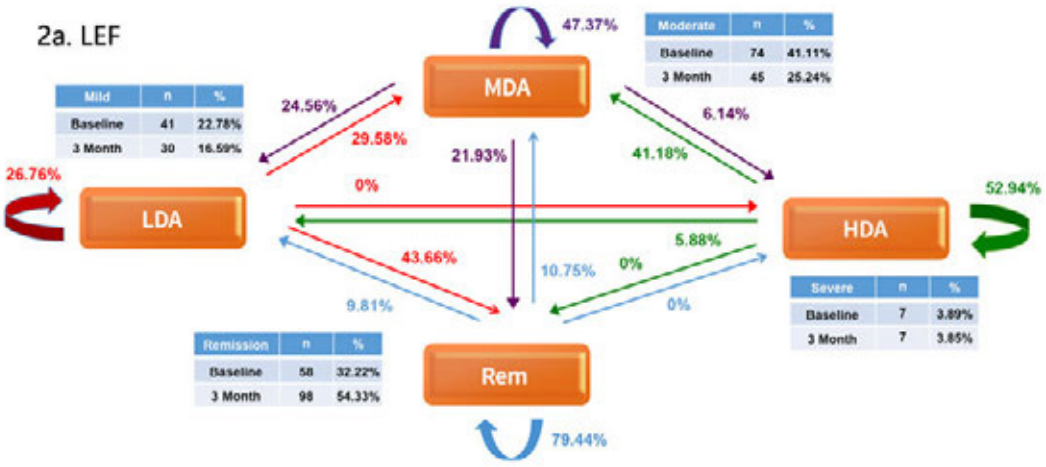
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

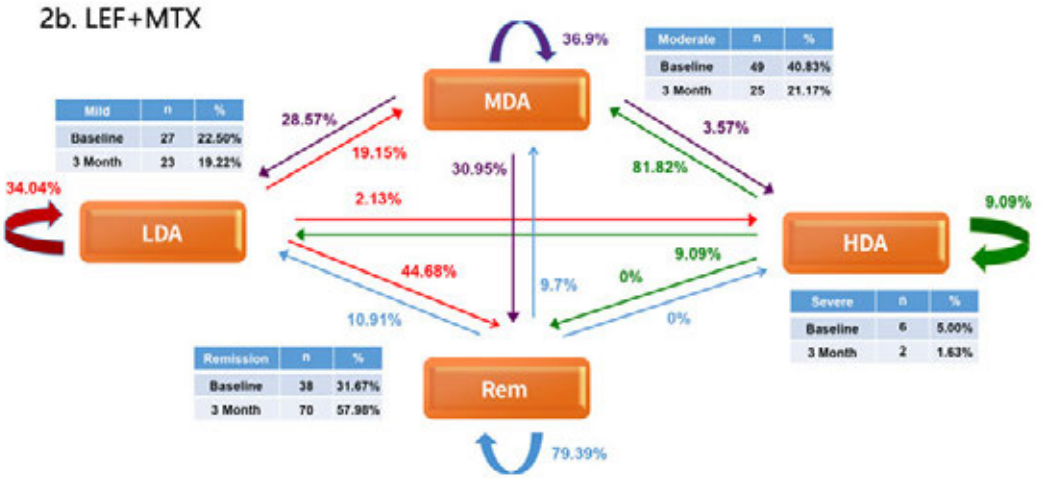
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

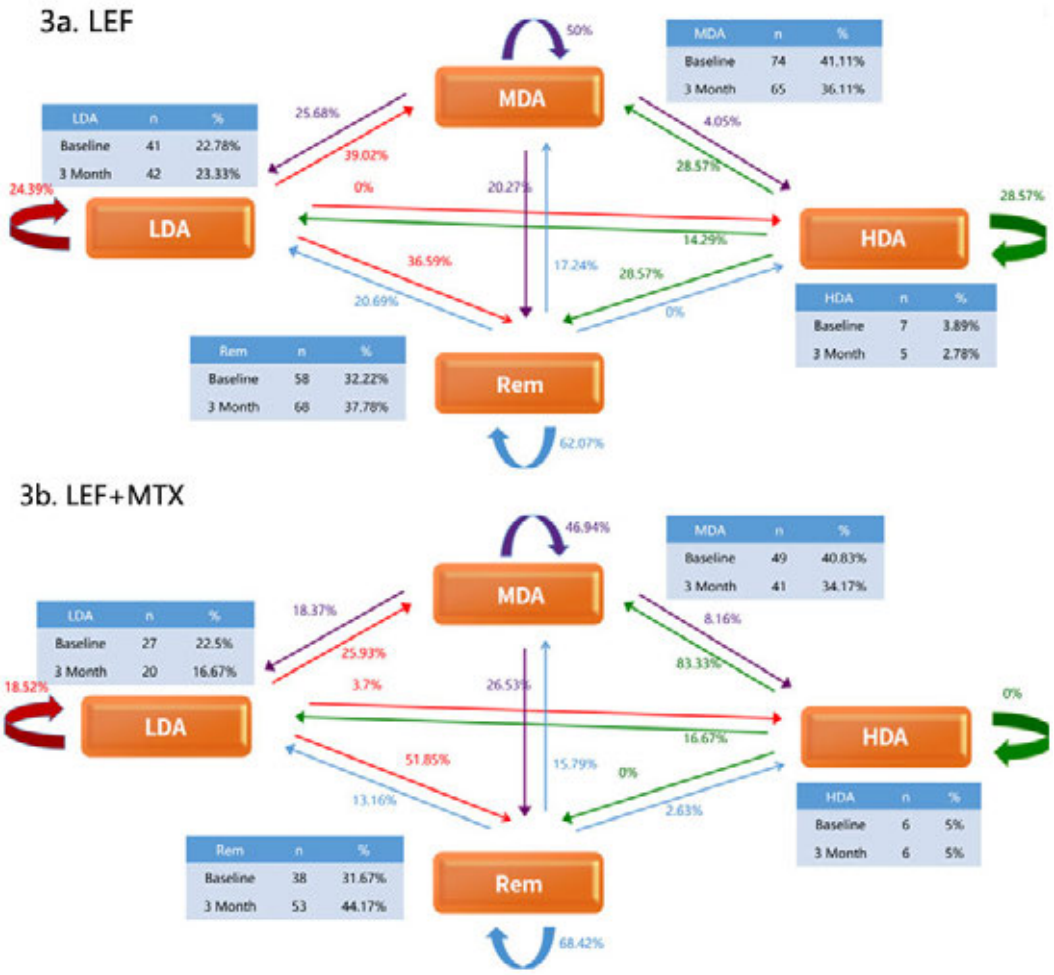
Background/Purpose: Daily health care deals with a wide spectrum of RA patients from statuses of remission (R) to disease activities at low (L), moderate (M) and high (S) based on DAS28. Each patient has 4 potential outcomes of

Graph 2a & 2b. The probability of outcome prediction (P(B)) for patients





Graph 3a and 3b. The true outcomes of DAS28 at month 3 served as evidence



either R, or L, or M, or S at certain time layer. But predicting efficacy and selecting regimens are in trial-and-error style. The objective of this study is to develop an algorithm for efficacy prediction and regimen selection in RA via SSDM.

Methods: SSDM includes 2 APPs for both physicians and patients. The patients input medication and laboratory test results, and perform self-evaluation (DAS28) after training. The data synchronizes to the physician's APP and the advices could be delivered.

In order to develop a prediction model, top 2 regimens, Leflunomide (LEF, 5-10 mg/d) and LEF+MTX (7.5-10mg/w) were selected as samples from SSDM database. Repeat evaluation of DAS28 scores were extracted at 3 months interval.

The study was divided into 2 phases: phase 1. To develop Markov model and generate the probability (P) of prior believe, P(B|A), based on Bayes Theorem, and phase 2. Calculate P of posterior believe, P(A|B), and validate the reliability comparing with true evidence of outcome via Intra-group correlation coefficient (ICC).

Results: From June 2014 to May 2019, 54,149 RA patients from 587 centers registered in SSDM. Among those with 3 months data available, 416 patients with LEF and 307 with LEF+MTX who registered before June 1 of 2018 were enrolled in phase 1, and 180 patients with LEF and 120 with LEF+MTX after June 1 of 2018 were included as phase II. There were no significant difference considering gender, age, race, disease history and DAS28 distribution between

2 phases. Phase I: Four baseline status (P(A)) and 16 outcomes at month 3 (P(B)) for LEF or LEF+MTX are presented in graph 1a and 1b, respectively, based on Markov Chain. The algorithm of probabilistic inference for next month 3 outcome was created as Σ p{Xt+1|Xt (Rt, Lt, Mt, Ht)}=1 0< t< ∞. The beta distribution and P(B|A) were generated. Phase II: The probability of outcome prediction (P(B)) for patients was calculated using the DAS 28 at baseline via the Bayes algorithm: P(A|B)=P(B|A)*P(A)/P(B) and were shown in graph 2a & 2b. The true outcomes of DAS 28 were obtained through repeat self-valuation at month 3 served as evidence (graph 3a & 3b). Comparing the distribution of evidence with those in P(A|B), ICC for LEF was 0.90, and ICC for LEF+MTX was 0.96, which indicated high inter-observer reliability. Based on the algorithm, the inferences of efficacy for both LEF and LEF+MTX were obtained. The advices were that LEF at low dose was good for RA with R and L, but for RA with H, adding MTX was preferred. Both were good for M.

Conclusion: Through patterns extraction, data mining and modeling, a master algorithm of efficacy prediction and decision making for RA were developed. Following data inputting and machine leaning, an artificial intelligent system in assisting clinical practice may be achieved with SSDM.

Adherence to Treatment with Intravenous Biological Agents in Patients with Rheumatoid Arthritis

Gisele Alejandra Luna,[1] Fernando dal Pra,[2] Emilce Schneeberger,[3] Leonela Lysseth Macias Oviedo,[4] and Gustavo Citera[5], [1]Instituto de Rehabilitación Psicofísica, Ciudad Autonoma de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [2]Instituto Rehabilitacion Psicofisica, CABA, Ciudad Autonoma de Buenos Aires, Argentina, [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [4]Instituto de Rehabilitacion Psicofisica, CABA, Ciudad Autonoma de Buenos Aires, Argentina, [5]Instituto de Rehabilitación Psicofísica, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures – ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The adherence to the therapeutic regimen in patients with Rheumatoid Arthritis (RA) varies between 30 and 80%. Classically, it is mentioned that the adherence to intravenous medication (IV) may be better than oral or subcutaneous, however there are few studies that analyzed it. **Objective**: To evaluate the adherence to biological (-b)DMARDs IV in patients with RA in clinical practice and to determine the factors that could have an impact on the adherence.

Methods: Observational study. Patients ≥18 years of age, with a diagnosis of RA according to ACR/EULAR 2010 criteria, who received at least 3 infusions of the b-DMARD IV abatacept (ABA) and/or tocilizumab (TCZ), during the course of their illness. Medical records, were reviewed to collect: sociodemographic data, clinical characteristics of the disease, comorbidities, disease activity, functional capacity by HAQ. Information was obtained on previous and concomitant treatments for b-DMARD, including steroids and conventional (-c) DMARDs, number of infusions of b-DMARD received, date of their initiation and discontinuation and causes of suspension. Adherence was calculated as the number of infusions received during the treatment period, considering a 28 days interval between infusions as

optimal. *Statistical analysis*: descriptive statistics, Chi2 test or Fisher's exact test, Student's T test and Mann Whitney test. Multiple logistic regression model to evaluate predictors of good adherence (≥80%).

Results: 67 patients were included, 94% were women, with a median disease duration of 13.8 years (IQR 8-18,2). 82.1% (55 patients) had medical coverage, 60% corresponded to social work. The median distance to the infusion center was 15 km (IQR 6.5-27). As a concomitant treatment, 72.4% received c-DMARD (without significant differences between ABA and TCZ), 52.7% prednisone and 64.3% NSAIDs. After 3 months of treatment, the baseline DAS28 decreased from 5.46 (IQR 4.77- 5.99) to 3.87 (IQR 2.79-4.68), $p < 0.001$, and the baseline HAQ-A from 2 (IQR 1.5-2) to 1 (IQR 1-2), $p< 0.001$. After a median follow-up time of 2.42 years (IQR 1.2-4.7), 38 patients (56.5%) discontinued definitively the b-DMARD IV. The most frequent causes of suspension were inefficiency in 62.9%, AE in 20% and lack of provision in 14.3%. The median survival was 4 years, without significant differences between ABA and TCZ. The median number of infusions per year was 10.17 (IQR 8.3-10.9), equivalent to an adherence of 78.2%, considering as an optimum of 13 infusions/year. Excluding suspension of b-DMARD IV by AE and/or surgeries, the median number of infusions per year was 10.8 (IQR 9.3-11.6), equivalent to an adherence of 83.1%. The median infusions/year correlated negatively with the distance to the infusion center (Rho: - 0.27, $p = 0.003$) and was significantly lower in patients without health coverage (8.5 ±2.5 vs 10.7 ±1.5, $p < 0.001$). In the multivariate analysis, having health coverage was the only variable that remained associated with better adherence ≥80% (OR: 6.27, 95% CI 1.1- 37.9, $p = 0.04$).

Conclusion: Adherence to treatment with b-DMARD IV was acceptable, however our patients lose, on average of 3 infusions per year. The only independent predictor associated with good adherence was having health coverage.

Performance of CQR5 vs CQR19 in the Evaluation of Adherence to Tofacitinib in Daily Clinical Practice

Tatiana Barbich,[1] Osvaldo Luis Cerda,[2] Emilce Schneeberger,[3] and Gustavo Citera[4], [1]Instituto de Rehabilitación Psicofísica, Ciudad Autonoma de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [2]Instituto de Rehabilitacion Psicofisica, Ciudad Autonoma de Buenos Aires, Ciudad Autonoma de Buenos Aires, Argentina, [3]Instituto de Rehabilitación Psicofísica, Buenos Aires, Argentina, [4]Instituto de Rehabilitación Psicofísica, Ciudad Autónoma de Buenos Aires, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures – ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the adherence to treatment with Tofacitinib in patients with Rheumatoid Arthritis (RA) using both versions of the self-questionnaire Compliance Questionnaire Rheumatology: CQR19 and CQR5. Secondary objectives were to determine the variables associated with adherence to Tofacitinib and to compare the performance of both questionnaires.

Methods: A cross-sectional study was carried out. We included patients ≥18 years old, with a diagnosis of RA according to ACR-EULAR 2010 criteria under treatment with Tofacitinib. Sociodemographic data and clinical disease

characteristics, such as disease duration, Rheumatoid Factor and anti-CCP status, ESR (mm/h), CRP (mg/l) pain and global disease assessment by Numerical Visual Scale (NVA), joint count (28), DAS28, presence and duration of morning stiffness were recorded. Previous treatments (b-DMARD and c-DMARD), concomitant treatments,date of beginning and dose of Tofacitinib (5 mg BID or 11 mg XR), date of discontinuation and its reasons (adverse events (AE) or lack of provision) were consigned. All patients completed self-questionnaires CQR19 and CQR5, CQR19 includes 19 items evaluated by Likert scale of 4 points with a final value of 0 (no adherence) to 100 (perfect compliance). CQR5 is a simplified version, which includes 5 items of the original CQR19, and was previously validated. *Statistical analysis:* Descriptive statistics. T-test or Mann Whitney to compare the continuous variables, Chi^2 test or Fisher's exact test to compare the categorical ones. Kappa concordance index. Multiple logistic regression in order to determine variables associated with adherence.

Results: We included 52 patients, 82.7% women, with a median age *(m*) of 57.7 years, disease duration *m* 16 years. 63.5% had comorbiditiesand 27% were smokers. DAS28 *m* 2.25. 65.4% had received b-DMARD prior to Tofacitinib. 86.5% of the patients treated with Tofacitinib used 5 mg BID and 48% received Tofacitinib as monotherapy. In 52% the concomitant treatment was: Methotrexate 63% and Leflunomide 33.3%. The median time of Tofacitnib treatment was 13 months. 40,4% patients temporarily suspended treatment and in 50% of the cases, it was due to infections: 4 cases of Herpes Zoster, 4 lower urinary tract infections and 2 pneumonias acquired from the community and the rest of the cases for other reasons, such as scheduled surgeries and/or lack of provision. All the events were solved without complications. Only one patient permanently stopped treatment due to lack of provision. Median CQR19 was 89.5. The 84.6% had an adherence ≥ 80%. The variables significantly associated with adherence ≥ 80% were the presence of comorbidities [70.5% vs 29.5% (p = 0.014)] and older age (60 ± 9 years old vs. 45 ± 6 years old, p = 0.033). Using the CQR5, a similar percentage of patients (82.7%) were adherent, however, the concordance with CQR19 was low (ƙ: 0.227).In the multivariate analysis, older age was the only variable independently associated with greater treatment adherence [OR: 1.09 (95% CI 1.06-1.18), p = 0.037].

Conclusion: The treatment adherence of Tofacitinib was very good for both presentations. Older age was associated with higher adherence. The agreement between the questionnaires CQR19 and CQR5 was low.

csDMARD, conventional synthetic DMARD; JAKi, Janus kinase inhibitor; TNFi, TNF-α inhibitor.

estimates of the prevalence and incidence of various infections among patients switching from a first bDMARD to another treatment and estimate healthcare costs associated with them.

Methods: In a US health plan claims database, we selected adult RA (≥2 RA diagnoses) patients who newly initiated a bDMARD (1/1/2012–3/31/2017) and switched to another bDMARD or JAKi (index date; ID). All patients had continuous enrollment 12-months pre- and ≥12-months post-ID. Prevalence (12-month pre-ID) and while-on-treatment incidence per 100 patient-years (P100PY) of serious infections, opportunistic infections, and herpes zoster were evaluated overall and by index treatment. For incidence rates, patients with no prior events were followed from ID until the first event or the end of index treatment. Unadjusted mean annualized all-cause healthcare costs (total, medical, and pharmacy) were assessed during index treatment and compared between patients with and without infections of interest.

Table 2. Duration of Index Treatment and Incidence Rate per 100 Patient-years while on Treatment, by Index Treatment

	Mean treatment duration (months)	Serious infection		Opportunistic infection		Herpes zoster	
		IR	PY	IR	PY	IR	PY
All patients	13.2	12.1	3978	5.4	4526	2.2	4864

Non-TNFi	10.7	13.3	345	3.7	410	1.4	439
JAKi	10.8	12.9	217	8.0	251	5.3*	264
Index combination therapy	16.1	12.3	2612	5.2	2967	2.1	3189
csDMARD + TNFi	15.5	12.8	1739	4.7	1985	1.9	2134
csDMARD + Non-TNFi	17.7	12.6	657	6.0	747	1.9	802
csDMARD + JAKi	16.7	7.0†	215	7.3	235	4.3††	254

csDMARD, conventional synthetic DMARD; IR, incidence rate; JAKi, Janus kinase inhibitor; TNFi, TNF-α inhibitor; PY, patient-years.

† P-value = 0.023 (JAKi vs. bDMARD within combination therapy).

* P-value = 0.002 (JAKi vs. bDMARD within monotherapy).

†† P-value = 0.011 (JAKi vs. bDMARD within combination therapy).

Table 3. Per-patient-per-year (PPPY) Healthcare costs over the Duration of Index Treatment in Patients with and without infection, USD

	With comorbidity		Without comorbidity		p-value
	Mean	SD	Mean	SD	
Serious infection					
Total cost (medical + pharmacy)	$66,588	$53,696	$53,263	$31,103	<0.0001
Total medical cost	$32,671	$49,220	$18,656	$31,533	<0.0001
Total pharmacy cost	$33,917	$27,128	$34,607	$22,421	0.5324
Opportunistic infection					
Total cost (medical + pharmacy)	$59,525	$40,741	$54,369	$33,963	0.0230
Total medical cost	$25,141	$32,467	$19,824	$34,114	0.0180
Total pharmacy cost	$34,384	$33,603	$34,545	$22,223	0.9155
Herpes zoster					
Total cost (medical + pharmacy)	$55,291	$36,686	$54,622	$34,310	0.8421
Total medical cost	$24,523	$37,722	$19,997	$33,954	0.1741
Total pharmacy cost	$30,769	$19,234	$34,625	$23,023	0.0858

Results: 4,656 patients switched from a first bDMARD to another treatment: median age 54 years, 78% female, mean duration of RA 1.8 years. After initial bDMARD, 46% of patients used monotherapy (61% TNF-α inhibitor (TNFi), 24% non-TNFi, 15% JAKi), and 54% used another bDMARD or JAKi in combination with csDMARD (69% TNFi + csDMARD, 23% non-TNFi + csDMARD, 8% JAKi + csDMARD). Pre-index prevalence rates ranged 12–17% for serious infections, 5–7% for opportunistic infections, and 2–3% for herpes zoster and were comparable among treatments (Table 1). While on index treatment, incidence rates ranged 7–13 P100PY for serious infections, 4–8 P100PY for opportunistic infections, and 1–5 P100PY for herpes zoster. Incidence rates varied among different treatments (Table 2). Total unadjusted healthcare costs were significantly higher in patients with serious infections ($66,588 vs $53,263; $p< 0.0001$) or opportunistic infections ($59,525 vs $54,369; $p=0.023$) than without these infections. Cost differences were primarily associated with medical costs (Table 3).

Conclusion: Serious infections, opportunistic infections, and herpes zoster affected RA patients switching from their first bDMARD to another treatment. While on index treatment, incident infections were associated with increased unadjusted costs, posing additional economic burden. Adjusted analyses are needed to estimate the economic burden of these infections accounting for difference in patient cohorts. Clinicians should factor the burden of infections into their clinical decisions.

Patient-Reported Outcomes of Upadacitinib versus Adalimumab Use in Patients with Moderately to Severely Active Rheumatoid Arthritis and an Inadequate Response to Methotrexate: 26-Week Analysis of a Phase 3 Study

Roy Fleischmann,[1] Martin Bergman,[2] Namita Tundia,[3] In-Ho Song,[4] Jessica Suboticki,[4] Yan Song,[5] and Vibeke Strand[6], [1]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, [2]Drexel University College of Medicine, Stockholm, Sweden, [3]AbbVie Inc., North Chicago, IL, [4]AbbVie Inc., North Chicago, IL, USA, North Chicago, IL, [5]Analysis Group, Inc., Boston, MA, [6]Division of Immunology/Rheumatology, Stanford University, Stanford, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In patients with active rheumatoid arthritis (RA), 12-week treatment with upadacitinib (UPA) while on background MTX therapy resulted in significant and clinically meaningful improvements in patient-reported outcomes (PROs) compared with placebo (PBO); these improvements with UPA treatment also met or were superior to adalimumab (ADA) treatment.[1] The current analysis evaluated the potential long-term benefits of UPA versus ADA with background MTX on PROs in patients with active RA.

Methods: SELECT-COMPARE (NCT02629159) is an ongoing Phase 3, randomized, double-blind study where patients with moderately to severely active RA and inadequate responses to MTX received UPA 15 mg once daily (QD), ADA 40 mg every other week (EOW), or PBO while on background MTX therapy. PROs included: Patient Global Assessment of Disease Activity (PtGA), pain by visual analog scale (VAS), HAQ-DI, Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F), and duration and severity of morning (AM) stiffness. The data cutoff for this analysis was July 6, 2018. Mean changes from baseline and 95% confidence intervals (CIs) were calculated for each PRO at Week 26. The percentages of patients who continued to report improvements ≥ minimum clinically important differences (MCID) in PRO scores at Week 26 were calculated based on those with MCID improvements at Week 12.

Results: Patients treated with UPA or ADA reported clinically meaningful changes from baseline in all PtGA, pain VAS, HAQ, FACIT-F, and duration and severity of AM stiffness at Week 26 (Table). Higher proportions of patients receiving UPA (74% to 84% of patients) continued to have clinically meaningful responses from Weeks 12 to 26 than with ADA (66% to 70% of patients; all P values < 0.05 except FACIT-F).

Conclusion: Clinically meaningful improvements in physical function, pain, fatigue, and AM stiffness were reported by patients with inadequate response to methotrexate with active RA at Week 12 which continued over 26 weeks with UPA 15 mg QD or ADA 40 mg EOW, with higher proportions maintaining these responses with UPA 15mg QD than ADA 40 mg EOW.

Table. Mean change in PRO scores and maintenance of MCID[a] responses at Week 26 (SELECT-COMPARE)					
PRO	Mean change from baseline (95% CI)		Patients maintained response from Week 12 to Week 26, n (%)		
	UPA 15 mg QD	ADA 40 mg EOW	UPA 15 mg QD	ADA 40 mg EOW	*P* Value
PtGA	−37.0 (−39.3, −34.7)	−35.0 (−38.3, −31.6)	379 (80.0)	150 (68.5)	0.001
Pain VAS	−38.0 (−40.2, −35.9)	−36.0 (−39.1, −32.8)	383 (79.3)	157 (69.2)	0.003
HAQ	−0.76 (−0.82, −0.71)	−0.69 (−0.75, −0.62)	363 (78.1)	158 (68.4)	0.006
FACIT-F	10.2 (9.4, 11.0)	9.9 (8.7, 11.2)	306 (74.1)	136 (67.3)	0.080
Severity AM stiffness[b]	−4.1 (−4.3, −3.9)	−3.8 (−4.1, −3.6)	421 (80.0)	182 (70.0)	0.002
Duration AM stiffness[c]	−101.4 (−117.7, −85.0)	−106.8 (−127.8, −85.8)	162 (83.5)	61 (65.6)	0.001

[a]MCID was defined as reduction of ≥10 mm for PtGA and for pain VAS, reduction of ≥0.22 units for HAQ-DI, increase of ≥4.0 points for FACIT-F, reduction of ≥10 mm for severity of AM stiffness and reduction proxied at 1/2 standard deviation of mean baseline value for duration of AM stiffness. [b]Assessed on a numeric scale of 1–10, with 10 being the worst level. [c] Duration in minutes. [d]*P* values comparing the proportion of responders between the UPA 15 mg arm and the ADA 40 mg arm were calculated using a Chi-square test.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Diagnosis, Manifestations, & Outcomes Poster II: Treatments, Outcomes, & Measures

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment with upadacitinib (UPA) monotherapy, a selective Janus kinase-1 (JAK-1) inhibitor, resulted in significant and clinically meaningful improvements in patient-reported outcomes (PROs) at Week 12 or 14 in patients with RA with no prior use of MTX (MTX-naïve) and an inadequate response to MTX (MTX-IR).[1,2] The current analysis evaluated the potential long-term benefits of UPA monotherapy on PROs in these patients.

Methods: SELECT-EARLY (NCT02706873) and SELECT-MONOTHERAPY (NCT02706951) are ongoing Phase 3, randomized controlled trials where MTX-naïve or MTX-IR patients (respectively) with active RA received UPA monotherapy (15 mg or 30 mg once daily [QD]) or weekly MTX. Here we report on PROs in SELECT-EARLY and SELECT-MONOTHERAPY patients who continued UPA for 24 or 26 weeks, respectively. PROs included: Patient Global Assessment of Disease Activity (PtGA), pain by visual analog scale (VAS), Health Assessment Questionnaire-Disability Index (HAQ-DI), Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F; SELECT-EARLY only), and duration and severity of morning (AM) stiffness. Mean changes from baseline and 95% confidence intervals (CIs) were calculated for each PRO at Week 24/26. The percentages of patients who continued to report improvements ≥minimum clinically important differences (MCIDs) at Week 24/26 were calculated among those who reported clinically meaningful changes in a given PRO at Week 12/14 (SELECT-EARLY and SELECT-MONOTHERAPY, respectively).

Results: MTX-naïve patients reported improvements from baseline in all PROs at Week 24 (Table 1). Of MTX-naïve patients reporting improvements ≥MCIDs at Week 12, 83% to 90% treated with UPA 15 mg and 84% to 90% with UPA 30 mg maintained clinically meaningful responses ≥MCIDs at Week 24. MTX-IR patients also reported improvements from baseline across all PROs at Week 26 (Table 2). Of MTX-IR patients reporting improvements ≥MCIDs at Week 14, 84% to 90% treated with UPA 15 mg and 85% to 94% with UPA 30 mg maintained clinically meaningful responses ≥MCIDs at Week 26.

Conclusion: A substantial proportion of MTX-naïve and MTX-IR patients with active RA treated with UPA 15 mg or 30 mg QD monotherapy continued to report clinically meaningful improvements in disease activity, physical function, pain, fatigue, and AM stiffness through Week 24/26.

[a]PRO data are from all patients who received at least one dose of tofacitinib monotherapy or tofacitinib + MTX during the double-blind phase. The number of patients who completed each outcome measure (n) may be less than the overall N

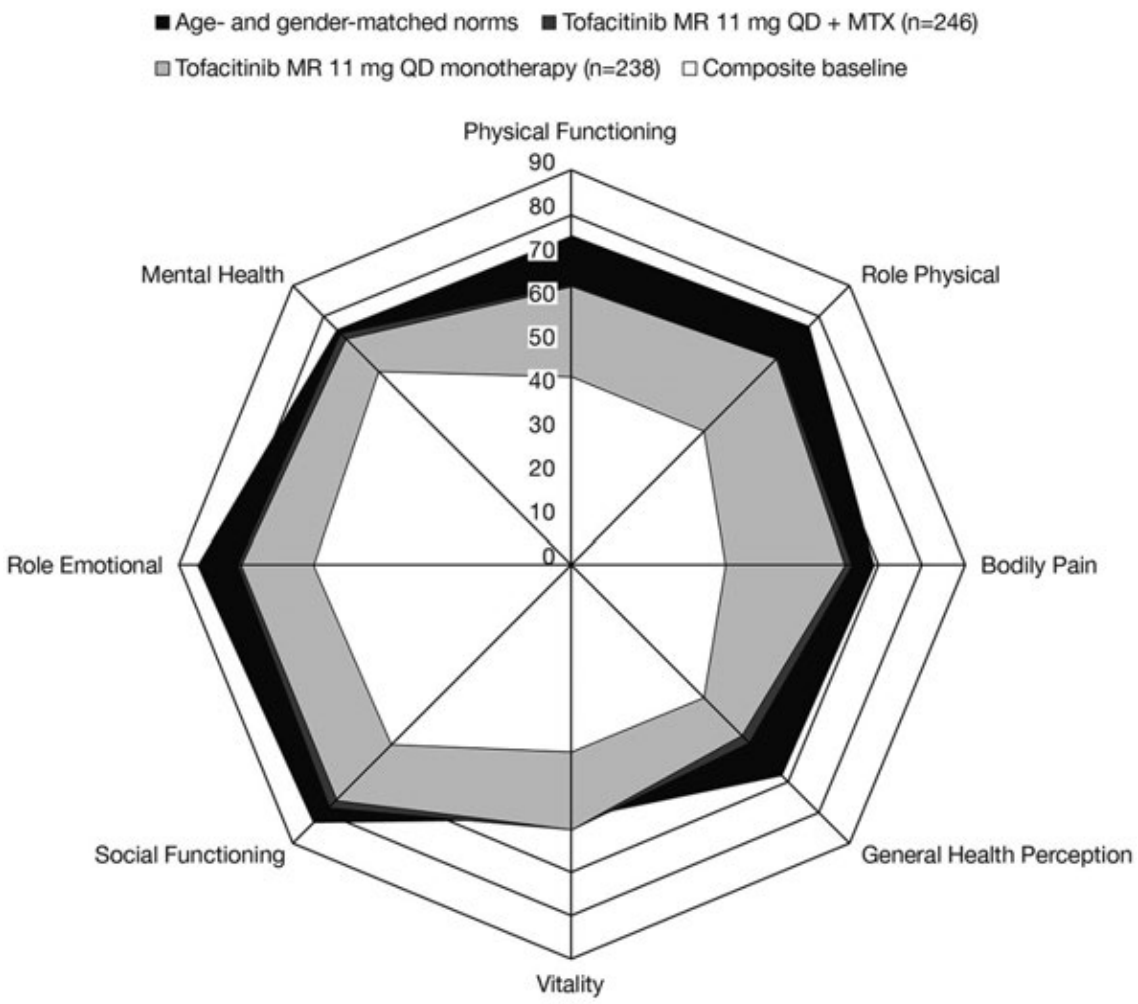
Value at randomization is defined at the last non-missing measurement on or prior to the first dosing date in the double-blind phase

Outcomes were analyzed using linear MMRM: change = treatment + visit + treatment x visit + baseline SF-36 + prior use of bDMARD; unstructured covariance model; denominator degrees of freedom estimated using Kenward-Roger method

bDMARD, biologic disease-modifying antirheumatic drug; CI, confidence interval; LSM, least squares mean; MMRM, mixed model repeat measure; MR, modified-release; MTX, methotrexate; PRO, patient-reported outcome; QD, once daily; SF-36, Short Form-36 Health Survey

Figure 1. Mean SF-36 domains expressed on a 0–100 scale at Week 48 in patients who received treatment in the double-blind phase of ORAL Shift



Age- and gender-matched norms are weighted by the age-gender distribution of patients at the screening visit, for the subset of randomized patients.

MR, modified-release; MTX, methotrexate; QD, once daily; SF-36, Short Form-36 Health Survey

drawal in patients (pts) with RA who achieve low disease activity (LDA) or remission with tofacitinib in combination with MTX is unclear.

Methods: ORAL Shift (NCT02831855) was a global Phase 3b/4 study in pts aged ≥ 18 years with moderate to severe RA and an inadequate response to MTX. Pts received open-label (OL) tofacitinib modified-release (MR) 11 mg once daily (QD) + MTX (tofacitinib + MTX) for 24 weeks. Pts achieving LDA (Clinical Disease Activity Index ≤ 10) at Week (W)24 entered the 24-week double-blind (DB) MTX withdrawal phase and were randomized 1:1 to receive tofacitinib MR 11 mg QD + placebo (tofacitinib monotherapy; ie blinded MTX withdrawal) or continue tofacitinib + MTX. The SF-36 includes Physical and Mental Component Summary (PCS and MCS, respectively) and 8 individual domain scores, and was administered to pts during the OL and DB phases. We report the following SF-36 data (norm-based scores) in pts who achieved LDA and were treated in the DB phase: mean scores at baseline (BL), W12 and W24 (OL phase; post hoc); mean changes from BL to W24 (OL phase; post hoc); least squares mean (LSM) changes from W24 to W36 and W48 (DB phase; pre-defined secondary endpoint); and mean scores at W48 (DB phase; post hoc). SF-36 mean scores at W48 were re-expressed on the 0–100 scale, along with BL values combined in a single group, for comparison with SF-36 values of a 1998 US age and gender matched normative population (A/G norms).

Results: In all, 694 pts received tofacitinib + MTX in the OL phase; 530 achieved LDA at W24 and were treated in the DB phase (tofacitinib monotherapy: n=264; tofacitinib + MTX: n=266). Demographics and pt characteristics at OL phase BL were similar between treatment arms. Mean changes from BL to W24 showed improvements in SF-36 PCS, MCS, and all domain scores (Table 1). LSM changes from W24 to W36 and W48 in SF-36 PCS, MCS, and all domain scores (except Role Physical and Bodily Pain at W36) were similar in both treatment arms (Table 2). By W48, Vitality scores exceeded and Mental Health scores were comparable with A/G norms in both treatment arms (Figure 1).

Conclusion: In the OL phase, pts receiving tofacitinib MR 11 mg QD + MTX reported improvements in health-related quality of life by SF-36 PCS, MCS, and domains. In pts who achieved LDA, MTX withdrawal during the DB phase resulted in similar SF-36 scores, compared with patients continuing combination therapy. These findings are consistent with those from ORAL Shift disease activity measures and PROs (primary and secondary efficacy endpoints; reported elsewhere),[3] and reinforce that pts receiving tofacitinib MR 11 mg QD + MTX who achieve LDA, may withdraw MTX up to W48 without significant worsening of PROs.

High Baseline Serum IL-6 Predicts Increased Sarilumab Treatment Response for Patient Reported Symptoms and Health-Related Quality of Life Among Rheumatoid Arthritis Patients with Inadequate Response to Methotrexate

Vibeke Strand,[1] Jerome Msihid,[2] Toshio Kimura,[3] Anita Boyapati,[3] Gregory St John,[4] and Wenhui Wei[3], [1]Division of Immunology/Rheumatology, Stanford University, Stanford, CA, [2]Sanofi, Chilly-Mazarin, France, [3]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IL-6 is a key cytokine in the pathogenesis of rheumatoid arthritis (RA) and is elevated in serum and synovial fluid of RA patients. However, the impact of baseline IL-6 levels on patient-reported RA symptoms and health-related quality of life (HRQoL) has not been explored in clinical trials evaluating IL-6 blockade. Sarilumab, a human monoclonal antibody targeting IL-6 receptor alpha, plus methotrexate (MTX) significantly improved clinical and patient reported outcomes vs MTX alone among inadequate responders (IR) to MTX in the MOBILITY randomized controlled trial (NCT01061736). This *post-hoc* analysis evaluated if baseline IL-6 levels can predict greater improvements in symptoms and HRQoL with sarilumab + MTX vs MTX.

Methods: 1193 of 1197 patients in the intent-to-treat population with moderate-to-severely active RA receiving MTX or sarilumab (150 mg or 200 mg subcutaneous every 2 weeks) + MTX, with baseline IL-6 values were included. Serum IL-6 was measured by immunoassay (Quantikine IL-6). Patients were grouped into tertiles according to baseline IL-6 levels (high, medium and low, see Table). Patient-reported RA symptoms and HRQoL were measured at baseline and post-treatment (Weeks [W] 24 and 52): pain visual analog scale (VAS), SF-36 physical (PCS) and mental component scores (MCS), FACIT-Fatigue (FACIT-F) and sleep VAS. Linear regression on changes from baseline in symptoms and HRQoL were performed with IL-6 tertile, treatment, prior biologic use, and region as stratification factors, and baseline IL-6 tertile-by-treatment interactions (with placebo and low IL-6 tertile as references) as fixed effects, to assess the predictivity of IL-6 levels. *P*-values of the interaction for each sarilumab group were provided using placebo and low tertile as references. Pairwise comparisons of symptoms and HRQoL improvements between treatment groups were also performed in each tertile; differences in least squares mean vs placebo, and 95% CIs were calculated.

Results: At baseline, patients in the high IL-6 tertile had greater disease activity, more radiographic structural damage, elevated levels of CRP levels, and poorer symptoms and HRQoL (pain VAS, SF36-PCS, and sleep VAS; data not shown) vs those in lower IL-6 levels ($P < 0.05$) and generally reported greater RA symptoms and HRQoL improvements with sarilumab vs placebo (Table). Significant differences (interaction *P*-value < 0.005) between high and low tertiles were evident in pain VAS (W52) and SF-36 PCS (W24 and W52) with 200 mg; SF-36 MCS with both 150 mg and 200 mg (W52) and FACIT-F scores with both 150 mg and 200 mg (W24 and W52). The incidence of treatment emergent adverse events was similar across IL-6 groups.

Conclusion: Among MTX-IR RA patients, high baseline IL-6 levels may predict better improvements in patient-reported RA symptoms and HRQoL with sarilumab treatment vs placebo than those with low levels. This findings support previous analyses, which showed that across clinical and radiographic endpoints, patients with elevated

Table. Impact of IL-6 at baseline on differences in mean patient-reported RA symptoms and HRQoL improvement for sarilumab versus placebo in MTX-IR patients with RA

Estimated difference (95% CI) in least squares mean change from baseline vs placebo		Sarilumab 150 mg			Sarilumab 200 mg

	Week 52	0.5 (-7.0, 7.9)	-5.9 (-14.0, 2.2)	-9.3 (-16.9, -1.6)	-2.1 (-9.5, 5.3)	-3.4 (-11.5, 4.7)	-9.7 (-17.7, -1.8)

Note: Categorization of baseline IL-6 level was based on its tertile distribution (Low: 1.6-9.6 pg/mL ; medium: 9.8-30.7 pg/mL; high (31.2-648.7 pg.mL). * and ** denote significant difference (interaction *P* value < 0.05 and *P* < 0.01, using placebo & low IL6 as references) between high or medium IL6 group and low IL6 group in PRO improvement difference between treatment arm and placebo arm. LS-means differences and 95% confidence intervals are calculated within each IL-6 group.

baseline IL-6 levels had greater responses to sarilumab compared with MTX or adalimumab than those without IL-6 elevations. Prospective validation is warranted to confirm these data.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: EXTEND (NCT01146652) is a long-term, open-label extension (OLE) study of sarilumab for the treatment of RA. This post hoc analysis assessed changes in oral glucocorticoid (OGC) use over time in patients receiving sarilumab 200 mg every 2 weeks (dose reduction to 150 mg every 2 weeks was permitted to manage laboratory abnormalities or per investigator's discretion) in combination with conventional synthetic DMARD (csDMARD) in EXTEND.

Methods: The analysis included patients who had either completed the placebo-controlled Phase 3 studies of sarilumab + csDMARD (NCT01061736 and NCT01709578) or met protocol-defined lack of efficacy after 12 weeks (NCT010709578) and were subsequently treated with sarilumab in the OLE study. Reported total daily oral doses were subsequently converted to prednisone equivalent daily doses (PED) using published conversion tables.[1,2] Patients were categorized into groups by PED dose at enrollment into the OLE: 0–< 5 mg/d, 5–< 10 mg/d and ≥10 mg/d. Patients with a baseline or post-baseline PED < 1 mg/d were imputed to 0 mg/d. PED doses were analyzed over 12-week intervals up to Week 216. Change from baseline for average PED was tested for nominal significance using a Wilcoxon-Pratt-Lehman test for non-parametric data.

Results: In the analysis population, 891/1353 patients (65.9%) had ≥1 record of OGC use. Of the patients with use of OGC, 137 (15.4%) received baseline daily PED of 0–< 5 mg, 515 (57.8%) 5–< 10 mg, and 239 (26.8%) received ≥10 mg. The mean (±SD) PED was 6.3 (±3.1) mg/d at baseline and decreased over the study period (21.3% mean reduction at 4 years; nominal $P < 0.0001$). During the Week 49–60 interval, 660/776 patients (85.1%) had stable PED, 90/776 patients (11.6%) had decreased PED, and 26/776 (3.4%) had increased PED (Figure). This difference increased throughout follow-

up, such that 109/236 patients (46.2%) had decreased PED and 18/236 (7.6%) had increased PED by Week 205–216. When grouped by baseline PED, patients with PED ≥5 mg were more likely than patients with PED < 5 mg to decrease their dose. Baseline characteristics and efficacy by PED reduction will be presented.

Conclusion: Long-term treatment of RA with sarilumab was associated with a substantial frequency of decreased OGC dose and the proportion of patients who reduced their OGC dose increased with time. Reductions were more common among patients with baseline prednisone equivalent doses ≥5 mg/d.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple treatment options are available for patients with RA. ACR guidelines recommend initiating treatment with a conventional synthetic DMARD (csDMARD). If a patient fails to achieve the treat-to-target goal, ACR guidelines recommend adjusting therapy by adding another csDMARD or switching to another mechanism

of action. The aim of this study was to evaluate patient characteristics and treatment patterns and persistency in RA patients who have previously been treated with a biologic DMARD (bDMARD).

Methods: In the Corrona US RA Registry, we identified instances when adult bDMARD-experienced patients initiated another treatment regimen (index date, between 01/2013–11/2018) and had a 6-month follow-up visit. New regimens were categorized as csDMARDs, tumor necrosis factor inhibitors (TNFi), and non-TNFi bDMARDs or Janus kinase inhibitors (JAKi). Fisher's exact test was used for categorical variables and Kruskal-Wallis or Wilcoxon rank-sum tests were used for continuous variables.

Results: Within 5616 bDMARD-experienced patients, 8606 DMARD initiations met study criteria. Most patients were female (81%) and younger than 65 years of age (**Table 1**).

The index treatment regimens were combination therapy (68.8%) or monotherapy (31.2%). Among monotherapies, csDMARDs comprised 14% and TNFi 31%; among combination therapies, csDMARD comprised 27% and TNFi 31%. In monotherapy, the mean RA disease duration was shortest in csDMARD (11.9 years) and longest in non-TNFi or JAKi (13.6 years); similar trends emerged among combination therapies—11.9 years (csDMARD) and 13.0 years (non-TNFi or JAKi; **Table 2**).

The overall 6-month treatment persistency was 74%, similar in both monotherapy and combination therapy. At 12 months, 52% of patients on monotherapy and 54% of those on combination therapy persisted on their index treatment (**Table 3**). Based on unadjusted analyses, persistency varied based on drug class among monotherapies at both 6 months (non-TNFi or JAKi 79%, csDMARDs 70%, TNFi 68%) and 12 months (non-TNFi or JAKi 55%, csDMARD

Persistency through 6-month visit	74%	74%	70%	68%	79%		74%	69%	74%	76%		
Persistency of initiation therapy through 12-month visit[4]	*n=4999*	*n=1540*	*n=205*	*n=501*	*n=834*	*0.02*	*n=3459*	*n=887*	*n=1135*	*n=1437*	*0.44*	*0.12*
Discontinued before 12-month visit	47%	48%	52%	52%	45%		46%	46%	47%	45%		
Persistency through 12-month visit	53%	52%	48%	48%	55%		54%	54%	53%	55%		

Table 3. Treatment Persistency by the Type of Treatment Initiated bDMARD, biologic DMARD; csDMARD, conventional synthetic DMARD; JAK, Janus kinase; JAKi, JAK inhibitors, SD, standard deviation; TNFi, tumor necrosis factor inhibitor. 1) P-value compares the difference among the 3 monotherapies. 2) P-value compares the difference among the 3 combination therapies. 3) P-value compares the difference between all monotherapies and combination therapies. 4) The 6-month visit is defined as a follow up visit occurring ≥3- and ≤9-months following initiation, and the 12-month visit is defined as a follow up visit occurring >9 and ≤15 months following initiation. Based on the cohort inclusion criteria, all patients have a 6-month visit but not all patients have a 12-month visit, which is reflected in the lower sample size for persistency through the 12-month visit. Note 1: p-values were calculated based on Fisher's exact tests for categorical variables; the Kruskal-Wallis tests (3 group comparisons) or Wilcoxon rank sum tests (2 group comparisons) for continuous variables. For ease of interpretation, some tests for categorical variables were calculated based on collapsed groups (eg, Age <55 vs Age ≥55, White vs non-White for race, college/university vs others for education, full-time vs others for work status, and current vs other for smoking). P-values are presented to aid with establishing patterns; care must be taken since we have not formally accounted for the multiple comparisons. Note 2: Note that discontinuation is defined as discontinuation of the index DMARD, no matter whether the patient added another DMARD following initiation of the index DMARD. This is particularly relevant for index csDMARD initiations, because patients may add a bDMARD/JAK while continuing to receive the index csDMARD. In contrast, for index bDMARD initiations, patients will generally need to discontinue the index bDMARD in order to switch to a different bDMARD.

48%, TNFi 48%). Similar results were seen among combination therapies at 6 months (non-TNFi or JAKi 76%, csDMARDs 69%, TNFi 74%) and 12 months (non-TNFi or JAKi 55%, csDMARD 54%, TNFi 53%; **Table 3**).

Conclusion: In bDMARD-experienced patients, demographic and clinical characteristics varied depending on the type of next treatment, most of which were combination therapy. csDMARD patients demonstrated low (48%–54%) 12-month persistence, suggesting a substantial unmet need in this patient population. Persistency differed among the different drug groups both for monotherapy and combination therapy. Clinicians need to closely monitor patients and revise therapy as needed in this patient population.

Abstract Number: 1381

High Serum IgA and High Proportion of Activated Th17 and Activated Treg Cells Are Predictive Biomarkers for Remission Achievement with Abatacept in Patients with Early, Seropositive Rheumatoid Arthritis

Jun Inamo,[1] Yuko Kaneko,[2] Jun Kikuchi,[4] and Tsutomu Takeuchi[4], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Tokyo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku, Tokyo, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [4]Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Abatacept (ABT) is a soluble fusion protein, which links cytotoxic T-lymphocyte-associated protein 4 to the modified Fc portion of IgG1. Seropositivity and a shorter disease duration are well known to be associated with response to ABT in patients with rheumatoid arthritis (RA), however, discrimination of seropositive patients who will respond to ABT is still challenging. The aim of this study is to identify predictive biomarkers for remission achievement with ABT in patients with seropositive RA.

Methods: We enrolled patients with seropositive RA (rheumatoid factor and/or anti-cyclic citrullinated peptide antibody [anti-CCP] positive) who had started ABT from 2010 through 2018 in Keio University Hospital. Early RA was defined as ABT initiation within two years from diagnosis with erosion score less than three in hand X-rays. Laboratory tests and immunophenotyping were conducted before ABT initiation and at 6 months, and compared between patients in remission and non-remission group according to clinical disease activity index (CDAI) at 6 months.

Results: One hundred and three seropositive RA patients who were treated with ABT were enrolled. Among them, 24 and 79 patients were classified into early and established RA, respectively. While in early RA, patients in remission showed higher serum IgA levels, anti-CCP titre and neutrophil count than patients in non-remission (351 mg/dL vs 289 mg/dL, p=0.12; 304 IU/mL vs 156 IU/mL p=0.06 and 6437/uL vs 4751/uL, p=0.10, respectively), no specific laboratory finding was identified in established patients. Receiver operating analysis demonstrated an optimal cut-off value of baseline serum IgA levels, anti-CCP titre, and neutrophil count to predict CDAI remission achievement in early RA as 342 mg/dL with sensitivity of 66.7%, specificity of 86.7%, and area under the curve (AUC) of 0.659, 330 IU/mL with sensitivity of 44.4%, specificity of 86.7%, and AUC of 0.741, 6200/uL with sensitivity of 55.6%, specificity of 86.7% and AUC of 0.704, respectively. In immunophenotyping analysis of peripheral blood of 33 patients (10 early and 23 established patients), primary component analysis demonstrated that the early patients and the established patients in remission made different clusters (Figure 1A-C). The proportion of activated Th17 (aTh17) cells and activated Treg (aTreg) cells were significantly higher in the early patients in remission compared to those in non-remission (aTh17/Th17, 2.86 % vs 1.0 %, p=0.01; aTreg/Treg, 34.3% vs 16.6%, p=0.02), while this difference was not seen in established RA (Figure 1D). Serum IgA at baseline and change in the proportion of effector memory CD4 T cells, and the count of neutrophil at baseline and change in the proportion of effector CD4 T cells were significantly correlated in early RA (Figure 2). Furthermore, the changes were also significantly correlated with changes in CDAI.

Conclusion: We identified serum IgA titer and the count of neutrophil were predictive biomarkers for response to ABT in patients with seropositive and early RA. Immunophenotyping analysis suggested they might reflect upregulation of effector helper T cell subsets, which could be inhibited by ABT.

The Efficacy of Low Dose Prednisone for Remission Induction in Newly Diagnosed Rheumatoid Arthritis Patients

Jacob Greenmyer,[1] John Stacy,[1] James Beal,[2] Abe Sahmoun,[2] and **Erdal Diri** [1], [1]University of North Dakota, School of Medicine Health Sciences, Minot, ND, [2]University of North Dakota, School of Medicine Health Sciences, Grandforks, ND

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Glucocorticoids (GCs) are commonly used in RA patients as remission induction monotherapy or as bridging therapy when starting DMARD/biologic therapy. Despite the ubiquity of GC use in RA treatment, agreed upon standard dosages, particularly for remission induction in newly diagnosed patients, remain elusive. Past studies indicated that the well-known long term adverse effects of GCs are directly related to cumulative dose. Therefore, identification of the lowest GC dose that reproducibly induces remission is imperative. The purpose of our study was to assess the response of newly diagnosed RA patients to low dose prednisone monotherapy (defined as less than or equal to 10 mg/day).

Methods: We conducted a chart review for new diagnoses of RA (ICD-9 714) from January 1, 2005 to September 1, 2018 at Trinity Health Group in Minot, ND. Patients treated with $\leq$ 10 mg prednisone daily for at least six weeks were included. Those previously treated with a DMARD or already started on a GC upon referral were excluded. Disease severity was calculated using the Disease Activity Score (DAS28-ESR). Response to treatment was determined based on the change in the DAS28-ESR score before and after treatment. The European League Against Rheumatism (EULAR) response criteria was used to categorize response to therapy as good, moderate, or no response.

Results: A total of 1386 patients were screened and 201 of them met inclusion and exclusion criteria. The average dose of prednisone was 8 mg daily, ranging between 5 and 10 mg, for an average of 42.2 days. Average age at presentation was 55.1. Majority of them were female (65.7%) and white (91.5%). The average DAS28-ESR score among our entire cohort dropped from 5.1 ± 1.1 at presentation to 2.7 ± 1.3 after 6 weeks of treatment with low dose prednisone ($p < 0.001$). The average DAS28-ESR of our seropositive patients (n=134) dropped from 5.2 ± 1.1 to 2.7 ± 1.3 ($p< 0.001$), and that of our seronegative patients (n=67) dropped from 4.9 ± 1.2 to 2.6 ± 1.1 ($p< 0.001$). As defined by the EULAR response criteria, 69.7% of patients showed a good response to treatment, 20.4% showed a moderate response, and only 10% showed no response. At presentation, 50.2% of the total cohort qualified as having either severe disease according to DAS28-ESR score. After treatment, only 5% qualified for severe disease, and 54.2% had reached remission.

Conclusion: Low dose prednisone monotherapy leads to statistically significant improvement in clinical severity of RA in newly diagnosed patients.

Glucocorticoid Tapering in Monthly 1-mg Decrements Does Not Result in Clinically Manifest Adrenal Insufficiency in Patients with Rheumatoid Arthritis: Learnings from a Phase 3/4 Study

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic glucocorticoids (GCs) are used to treat serious inflammatory diseases but are associated with adverse events. Guidelines recommend tapering GCs to the lowest possible dose and discontinuing them as soon as possible. Physicians have concerns that reductions, even from low doses, may increase disease symptoms or cause adrenal insufficiency, especially in patients receiving GCs long term. The expectation of adrenal insufficiency risk may be inflated by false positives in cortisol testing of patients without relevant symptoms and by a lack of robustly designed GC taper trials. The international, multicenter SEMIRA trial evaluated a taper scheme in rheumatoid arthritis (RA) patients receiving tocilizumab (TCZ) ± conventional synthetic disease-modifying antirheumatic drugs (csDMARDs).[1] The objective of this analysis was to determine whether GC tapering in the SEMIRA trial resulted in any cases of adrenal insufficiency.

Methods: Eligible patients, diagnosed per revised 1987 ACR criteria, had low disease activity or remission for ≥4 weeks and were receiving a stable prednisone regimen (5 mg/day) + TCZ ± csDMARDs for ≥4 weeks. Patients had to have received ≥6 months' total TCZ + GCs (prednisone equivalent 5-15 mg/day). Patients were randomly assigned (1:1) to double-blind continued prednisone 5 mg/day (n = 128) or prednisone taper (n = 131). TCZ ± csDMARDs remained stable during the 24-week study. The prednisone taper consisted of 1-mg decrements every 4 weeks starting at randomization and ending at GC discontinuation (week 16). RA flares were treated with prednisone 5 mg/day for 2 weeks. The primary assessment was maintenance of disease control with GC discontinuation. The protocol provided evidence-based guidance for diagnosis and management of adrenal insufficiency. Confirmatory testing was recommended for patients with suspected adrenal insufficiency, but routine precautionary ACTH stimulation testing was not mandated.

Results: In the taper arm, 65% of patients achieved "treatment success" by meeting all key secondary end point components (maintained low disease activity, experienced no flares, and had no confirmed adrenal insufficiency necessitating replacement therapy) at week 24 versus 77% of continued patients (risk ratio for treatment success, 0.833 [95% CI, 0.714-0.972]; $p = 0.021$). None of the taper patients required ACTH stimulation testing, and no cases of adrenal insufficiency were reported.

Conclusion: SEMIRA demonstrated the usefulness of a new standardized GC dose taper scheme. Two-thirds of patients receiving TCZ underwent successful tapering and could stop GCs entirely, which is higher than the spontaneous 35% discontinuation rate observed in real-world RA patients[2] and underscores the potential to further reduce glucocorticoid burden. Clinical adrenal insufficiency was not observed; thus, routine laboratory testing may be unnecessary in real-world applications of this taper scheme.

Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Synthetic glucocorticoids (steroids) are recommended for and commonly used in rheumatoid arthritis (RA) as initial "bridge therapy", acting to rapidly reduce the inflammatory response and associated symptoms. Current treatment guidelines in several countries recommend short-term use at a low dose, and tapered quickly due to side effect profile. Steroids are given as oral alone and often combined with parenteral (intramuscular and intra-articular) formulations; patients may receive both to control RA inflammation, perhaps with the intent of being able to shorten the duration of exposure to steroids. The objective of this study was to compare duration of oral steroid exposure among those who receive oral monotherapy to those who receive both oral and parenteral formulations.

Methods: Data were from patients with classifiable early RA enrolled in a nationwide real-world early rheumatoid arthritis cohort, with at least 24 months of follow-up. Patients were stratified based on steroid use (oral only vs combination parenteral and oral, regardless of DMARD exposure) within the first 3 months, to account for a potential lag time for the treating rheumatologist to decide steroid initiation was necessary. Persons who already received steroids before study entry were excluded, to avoid prevalent user bias. Parenteral use without an oral steroid was not con-

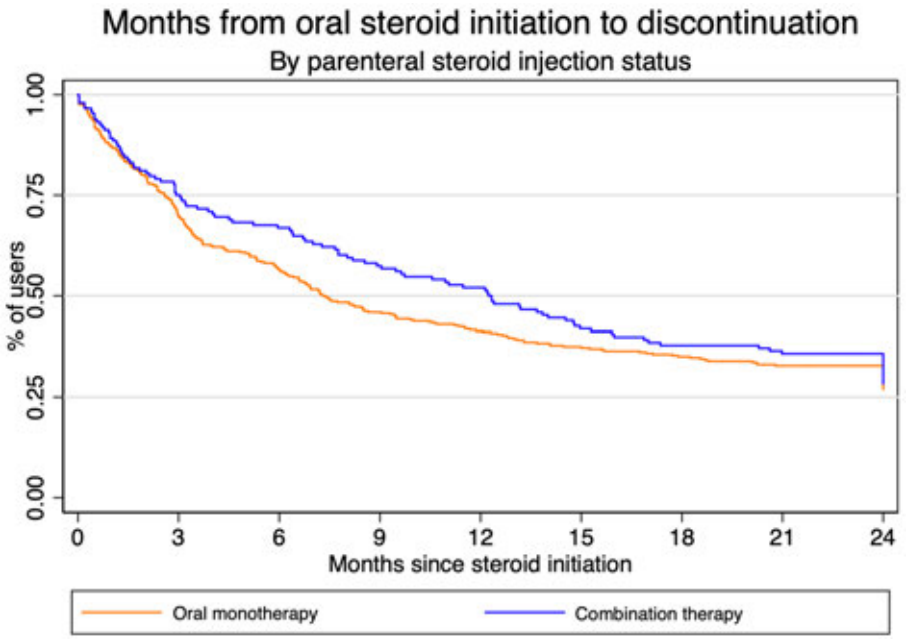

Figure 1. Immunophenotyping analysis before ABT initiation. A, Primary component analysis using immunophenotyping data. B, Top 10 of variables which contributed to make clusters in figure 2A. C, Hierarchical clustering analysis with heatmap using cell subpopulations. D, Comparison of the proportion of activated Th17 (above) and activated Treg (below) between remission and nor-remission group in patients with early RA and established RA. aTh1, activated Th1; aTh2, activated Th2; aTh17, activated Th17; aTreg, activated regulatory T cell; B, B cell; CM, classical monocyte; CMCD4, central memory CD4 T cell; CMCD8, central memory CD8 T cell; ECD4, effector CD4 T cell; ECD8, effector CD8 T cell; EMCD4, effector memory CD4 T cell; EMCD8, effector memory CD8 T cell; GM-CSF, granulocyte macrophage colony-stimulating factor; IL, interleukin; MB; memory B cell; MTreg, memory regulatory T cell; NB, naive B cell; NCD4, naive CD4 T cell; NCD8, naive CD8 T cell; NCM, non-classical monocyte; NONREM, non-remission; REM, remission; Treg, regulatory T cell.

sidered in this analysis, due to an inability to reliably ascertain duration of exposure from an injection. Kaplan-Meier survival curves were constructed to compare steroid persistence time between oral and combination routes of administration, and differences between curves were tested using the log-rank test.

Results: Of 1,573 participants recruited to the overall study between 2007-2017 with at least 24 months of follow-up, 533 (35%) received either oral or combination steroids. Combination steroid users were less likely to be female, to have a higher education and to be currently employed **(Table).** Disease activity at 3 months was highest in the combination steroid groups, as were the physician and patient global assessments of disease. The median duration of oral steroid use did not differ significantly between those receiving oral or combination steroids when parenteral steroid injections were given within the first 3 months of follow-up (7 months oral monotherapy versus 11 months combination, Mann-Whitney U test p-value = 0.20). Throughout follow-up, the discontinuation patterns were similar (**Figure),** and there was no difference in Kaplan-Meier survival curves (p-value = 0.29).

Conclusion: Combination steroids were used in people with more active disease, but combining oral and parenteral steroids did not reduce the duration of oral steroid treatment in this prospective observational cohort compared with those receiving oral steroids alone nor did they reduce disease activity more so than oral steroids. The subset of patients receiving combination steroids may have more persistent disease, and may benefit from closer monitoring and use of more intensive DMARD or other advanced therapeutic strategies.

Table: Characteristics of participants, by steroid route, in first three months of CATCH study follow-up

	Oral Only (n=386)	Combination (n=157)
Age in years	57 (15)	55 (14)
Female	267 (69%)	101 (65%)
Education > high school	220 (57%)	76 (48%)
Currently employed	192 (50%)	71 (45%)
Body mass index, kg/m^2	28.1 (6.0)	29.4 (5.3)
Underweight (<18.5)	3 (1%)	2 (1%)
Normal (18.5-24.9)	76 (20%)	28 (18%)
Overweight (25.0-29.9)	73 (19%)	33 (21%)
Obese (>=30.0)	64 (16%)	42 (27%)
Missing	*170 (44%)*	*52 (33%)*
Current or past smoker	226 (59%)	101 (64%)
Number of comorbidities other than RA		
0	79 (21%)	34 (22%)
1	90 (24%)	32 (21%)
2	86 (22%)	25 (16%)
3 or more	128 (33%)	65 (42%)
Symptom duration at study entry, months	5.4 (3.0)	5.2 (2.8)
Morning stiffness ≥1 hour	242 (63%)	103 (66%)
Seropositive	240 (62%)	109 (69%)
DAS28-ESR score at 3 months, (0-9.4)	3.5 (1.5)	4.1 (1.6)
Remission (< 2.6)	73 (19%)	25 (16%)
Low (2.6 – 3.2)	41 (11%)	12 (8%)
Moderate (> 3.2 – 5.1)	87 (22%)	48 (30%)
High (> 5.1)	185 (48%)	72 (46%)
Physician global assessment, 0-10	3 (2)	3 (3)
Patient global assessment, 0-10	4 (3)	5 (3)
Methotrexate use	337 (87%)	137 (87%)
Among users, dose >=20 mg/week	242 (72%)	

Continuous variables are presented as mean (standard deviation), and categorical variables as number (%).

Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In the treatment of rheumatoid arthritis (RA), glucocorticoid that provide anti-inflammatory effects is an important drug. We recommend discontinuing of glucocorticoid as soon as possible, but many patients have taken oral glucocorticoid for the long term in daily clinical practice. On the other hand, there are several reports on discontinuation of glucocorticoid due to the initiation of biological disease-modifying antirheumatic drugs (bDMARD). The aim of this study is to examine association of methotrexate (MTX) dose with discontinuation of glucocorticoid after 52 weeks since initiation of 1st bDMARDs.

Methods: This study was based on data from a Japanese multicenter registry, Tsurumai Biologics Communication Registry (TBCR), and enrolled 3119 patients who used bDMARDs from 2008 Oct to 2015 Oct. We examined the status of oral glucocorticoid use after 52 weeks since initiation of bDMARDs as 1st bDMARDs. In predictive analyses, discontinuation of glucocorticoid after 52 weeks since initiation of bDMARDs was used as outcome variable. Factor associated with baseline characteristics at the time of initiation of bDMARDs was assessed with univariate and stepwise forward multivariate logistic regression. Propensity score matching (PS) matching was used to align the patients background with selection bias in observational studies. The adjustment variables were age, disease duration, sex, disease activity, seropositivity, and glucocorticoid dose.

Results: 564 patients who used glucocorticoid and MTX when bDMARDs was initiated as 1st bDMARDs were included (Table 1). 164 cases (29.1%) were discontinued glucocorticoid up to 52 weeks after initiation of bDMARDs. In the multivariate analysis, age (odds ratio (OR) 0.98), MTX dose (OR1.11) and glucocorticoid dose (OR0.87) were

Glucocorticoid dose, mg/day*	4.7 ± 1.9	5.0 ± 2.7	n.s.	5.3 ± 2.2	4.9 ± 2.8	n.s.

Data are presented as mean±standard deviation. bDMARDs, biological disease-modifying antirheumatic drugs; MTX, methotrexate; DAS28, disease activity score in 28 joints; CRP, serum c-reactive protein. *Student's t test, **chi-squared test.

rate of glucocorticoid (41.0%) was significantly higher. Regarding the clinical course, DAS28-CRP at baseline was 4.53 in the group of patients taking MTX >8 mg, and 4.51 in the group of patients taking MTX≤8 mg, and there was no obvious significant difference. At 52 weeks, 2.87 in the group of patients taking MTX >8 mg, and 2.59 in the group of patients taking MTX≤8 mg, and there was also no obvious significant difference. Further, there was no obvious significant difference in the rate of change in disease activity.

Conclusion: This cohort study investigated the association with discontinuation of oral glucocorticoid and MTX dose in the patients treated with bDMARDs. In the clinical practice, MTX dose at the time of initiation of bDMARDs was predictive factor of discontinuation of glucocorticoid. A higher dose of MTX associated with discontinuation of glucocorticoid in the patients treated with bDMARDs. Glucocorticoid use suggested that it could be decreased or discontinued in the patients treated with bDMARDs.

Association Between Baseline Anti-citrullinated Protein Antibody Status and Response to Abatacept or Non-TNF Inhibitor Therapy in Patients with RA: Results from a US National Observational Study

Leslie Harrold,[1] Ying Shan,[2] Sabrina Rebello,[2] Lin Guo,[2] Sean Connolly,[3] Joe Zhuo,[3] Sheila Kelly,[3] and Thomas Lehman[3], [1]University of Massachusetts and Corrona, LLC, Waltham, MA, [2]Corrona, LLC, Waltham, MA, [3]Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In a US national observational study conducted in a clinical practice setting, patients who were positive (+) for anti-cyclic citrullinated peptide (CCP) antibodies at baseline showed a greater clinical response to treatment with abatacept (ABA), but not an anti-TNF inhibitor (TNFi), compared with those who were anti-CCP negative (–).[1] This study assessed whether baseline anti-CCP status was associated with response to ABA or non-TNFi in patients with RA.

Table 1. Adjusted mean improvement from baseline in disease and disability outcomes at 6 months, by anti-CCP status, for abatacept or non-TNFi initiators (by time period of drug initiation)

Data are presented as mean (standard error). For continuous variables, significance tests used a mixed model linear regression analysis with site as the random effect (to adjust for potential site differences in treatment patterns)

*Adjusted for baseline covariates that differed by CCP status ($p<0.1$)

Δ=change; ABA=abatacept; anti-CCP+=anti-CCP positive, ≥20 U/mL; anti-CCP–=anti-CCP negative, <20 U/mL; CCP=cyclic citrullinated peptide; mHAQ=modified HAQ; mHAQ=modified HAQ; TNFi=TNF inhibitor

Methods: Patients with RA from the Corrona registry, aged ≥18 years, who initiated ABA, rituximab (RTX), tocilizumab (TCZ) or tofacitinib (TOF) from 12/1/2005–2/28/2019 were included. Eligible patients had to have anti-CCP measures at/prior to index date (ABA or non-TNFi initiation date), must never have used ABA prior to index date and had to have 6 months' follow-up after index date. Patient characteristics at index were compared by anti-CCP status (+, ≥20 U/mL; –, < 20 U/mL). Outcomes included changes in CDAI (primary), modified HAQ and patient global assessment (PGA) from baseline to 6 months, and proportion of patients achieving LDA or remission, minimal clinically important difference in CDAI and modified ACR response at 6 months. Predicted mean differences were estimated using mixed-effects linear regression models adjusting for baseline covariates (if $p < 0.1$) with site as a random effect; odds ratios were estimated using a mixed logistic regression model with the anti-CCP– group as a reference and site as a random effect. Responses for ABA, RTX, TCZ and TOF were estimated separately; comparison of responses to ABA and specific non-TNFi were estimated within a similar time period of initiation (2006, 2010 or 2012).

Table 2. Adjusted odds ratios (with confidence intervals) for the association between anti-CCP status and achieving a clinical response to treatment with abatacept or a non-TNFi at 6 months*

	Abatacept	**Rituximab**
Achievement of LDA†	1.71 (1.17, 2.50)	3.41 (1.06, 11.01)
Achievement of remission†	2.46 (1.35, 4.49)	2.88 (0.55, 15.23)
MCID CDAI§	1.67 (1.22, 2.27)	1.08 (0.54, 2.18)
mACR20¶	1.89 (1.32, 2.71)	2.38 (0.95, 5.95)
mACR50¶	3.13 (1.90, 5.14)	3.39 (0.86, 13.42)
mACR70¶	2.90 (1.49, 5.63)	6.97 (0.79, 61.24)
	Abatacept	**Tocilizumab**
Achievement of LDA†	1.82 (1.19, 2.78)	1.30 (0.69, 2.44)
Achievement of remission‡	2.71 (1.38, 5.33)	0.87 (0.39, 1.94)
MCID CDAI§	1.65 (1.17, 2.33)	0.78 (0.48, 1.26)
mACR20¶	1.88 (1.26, 2.80)	0.92 (0.53, 1.59)
mACR50¶	3.45 (1.95, 6.11)	0.89 (0.44, 1.82)
mACR70¶	3.52 (1.65, 7.52)	0.84 (0.34, 2.06)
	Abatacept	**Tofacitinib**
Achievement of LDA†	1.26 (0.72, 2.19)	1.10 (0.64, 1.88)
Achievement of remission‡	2.16 (0.96, 4.86)	0.95 (0.42, 2.13)
MCID CDAI§	1.40 (0.92, 2.11)	0.98 (0.64, 1.51)
mACR20¶	1.72 (1.03, 2.88)	0.99 (0.61, 1.62)
mACR50¶	2.56 (1.20, 5.43)	1.07 (0.56, 2.04)
mACR70¶	3.62 (1.20, 10.91)	1.22 (0.46, 3.28)

For binary outcomes, odds ratios were estimated using a mixed model logistic regression analysis with site as the random effect (to adjust for potential site differences in treatment patterns)

*Adjusted for baseline covariates that differed by baseline CCP status ($p<0.1$)

†CDAI ≤10 (among those with moderate or higher disease activity)

‡CDAI ≤2.8 (among those with LDA or higher)

§Drop of 2 if LDA, drop of 6 if moderate disease activity, drop of 11 if high disease activity

¶mACR based on 2 out of 4 measures (not using ESR or CRP)

CCP=cyclic citrullinated peptide; mACR20/50/70=20/50/70% improvement in modified ACR criteria; MCID=minimal clinically important difference; TNFi=TNF inhibitor

Results: Overall, 982 ABA, 399 TCZ, 244 RTX and 420 TOF initiators were identified. Across treatments, anti-CCP+ (vs anti-CCP–) patients had longer disease duration and were more likely to have erosive changes on X-ray; additionally, a higher percentage were RF+ and more were in ACR functional class III–IV at index. Association of response at 6 months by anti-CCP status is shown in Tables 1 and 2. During most time periods, adjusted mean changes in CDAI, modified HAQ and PGA were significantly higher for anti-CCP+ vs anti-CCP– patients for ABA (Table 1). For ABA-treated patients, the odds of achieving most secondary outcomes were significantly higher for anti-CCP+ vs anti-CCP– groups (Table 2). Adjusted mean change in CDAI and PGA (Table 1) and odds of achieving LDA were significantly higher (Table 2) in anti-CCP+ vs anti-CCP– groups for RTX-treated patients; differences in other secondary outcomes were observed but were not statistically significant (Tables 1 and 2). No significant differences were seen by anti-CCP status for TCZ- and TOF-treated patients. Limitations included sample size and relatively short length of treatment time.

Conclusion: In patients treated with abatacept and RTX, but not TCZ or TOF, those who were anti-CCP+ had a greater clinical response than anti-CCP– patients at 6 months' follow-up post index.

Abstract Number: 1387

Low Probability of Clinical Worsening Following Switching Biologic DMARD in Patients with RA and Partial Response to Adalimumab

Jeffrey Curtis,[1] Daniel Aletaha,[2] Gerd Burmester,[3] Kerri Ford,[4] Hubert van Hoogstraten,[5] Henry Leher,[6] Karthinathan Thangavelu,[7] and Vivian Bykerk[8], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Medical University of Vienna, Vienna, Austria, [3]Charité—University Medicine Berlin, Berlin, Germany, [4]Sanofi Genzyme, Bridgewater, NJ, [5]Sanofi, Bridgewater, NJ, [6]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [7]Sanofi Genzyme, Boston, MA, [8]Hospital for Special Surgery, New York City, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Guidelines recommend adjusting therapy in patients with RA who fail to reach low disease activity or remission. Partial responders to a TNF inhibitor may decline treatment changes for fear of clinical worsening and losing the response they had so far achieved. Little is known about the likelihood of worsening after switching therapy to a drug with a different mechanism of action, and this limits patients' ability to make informed decisions. We performed a post hoc analysis to assess the effect of switching from adalimumab to sarilumab in patients with RA who partially responded to adalimumab in MONARCH (NCT02332590), a head-to-head study of sarilumab versus

adalimumab monotherapy. At the end of the trial, patients on adalimumab were switched to sarilumab 200 mg q2w for the open-label extension (OLE).

Methods: Thresholds of change in Clinical Disease Activity Index (CDAI) of ±6 and ±12 units were used to define meaningful improvement/worsening, anchored at the OLE baseline (BL). Partial responders to adalimumab or sarilumab were characterized at OLE BL and defined as having had a clinically meaningful change in CDAI (≤–12 if MONARCH BL CDAI >22 or ≤–6 if MONARCH BL CDAI >10 to ≤22) during MONARCH while still having moderate-to-high disease activity (CDAI >10) at OLE BL. Response was assessed by change in CDAI from OLE BL at Week 24. The proportions of partial responders achieving meaningful improvement or worsening were calculated.

Results: There were 369 patients enrolled in MONARCH, of whom 320 (87%) entered OLE—155 switching from adalimumab to sarilumab, 165 continuing sarilumab. Of the patients in OLE, 52% were partial responders at OLE BL: switch, n=91/155 (59%); continuation, n=74/165 (45%). Mean (SE) CDAI at OLE BL was 19.56 (0.86) in switch partial responders and 18.99 (1.02) in continuation partial responders, with mean (SE) change in CDAI from OLE BL at Week 24 of –7.37 (1.10) and –5.52 (0.94), respectively (Table). Based on a CDAI threshold of ±6, improvement in disease activity was observed in 57% (switch) and 43% (continuation), while worsening was observed in 6% and 4% of patients. No change (–6 to +6) was evident in 37% (switch) and 53% (continuation). Based on a CDAI threshold of ±12, improvement in disease activity was observed in 27% (switch) and 17% (continuation), while worsening was observed in 2% and 1%, and no change (–12 to +12) was evident in 71% and 81%, respectively. Other efficacy

Table. Summary of efficacy endpoints among CDAI partial responders*

	Adalimumab→sarilumab*	Sarilumab→sarilumab*
N at OLE baseline	91	74
Week 24 observed cases	83	70
CDAI		
At OLE baseline, mean (SE)	19.56 (0.86)	18.99 (1.02)
Change from OLE baseline to Week 24, mean (SE)	–7.37 (1.10)	–5.52 (0.94)
Improvement in CDAI, n/N (%) of patients		
Change from OLE baseline of –6	47/83 (57)	30/70 (43)
Change from OLE baseline of –12	22/83 (27)	12/70 (17)
Worsening in CDAI, n/N (%) of patients		
Change from OLE baseline of +6	5/83 (6)	3/70 (4)
Change from OLE baseline of +12	2/83 (2)	1/70 (1)
No change in CDAI, n/N (%) of patients		
Change from OLE baseline –6 to +6	31/83 (37)	37/70 (53)
Change from OLE baseline –12 to +12	59/83 (71)	57/70 (81)
Physician Global Assessment		
Change from OLE baseline to Week 24, mean (SE)	–11.28 (1.78)	–5.61 (1.75)
Patient Global Assessment		
Change from OLE baseline to Week 24, mean (SE)	–15.73 (2.28)	–7.47 (1.80)
Swollen joint count (SJC28)		
SJC at OLE baseline, mean (SE)	4.08 (0.34)	4.61 (0.40)
Change from OLE baseline to Week 24, mean (SE)	–1.32 (0.51)	–1.89 (0.33)
Tender joint count (TJC28)		
TJC at OLE baseline, mean (SE)	7.53 (0.56)	7.64 (0.63)
Change from OLE baseline to Week 24, mean (SE)	–3.35 (0.57)	–2.33 (0.67)
DAS28-ESR		
Change from OLE baseline to Week 24, mean (SE)	–1.62 (0.15)†	–0.75 (0.12)

*Partial responders, defined as change in CDAI of −12 (if MONARCH baseline CDAI >22) or −6 (if MONARCH baseline CDAI >10 to ≤22) and CDAI >10 at OLE baseline; †n=84.

measures demonstrated improvements from baseline (Table). No new safety signals emerged during OLE, and the adverse event profile among switch patients was similar to that of continuation patients.

Conclusion: Among adalimumab partial responders who switched to sarilumab, there was a low (6%) likelihood of clinical worsening, and almost all patients (94%) experienced clinical improvement or had no change. These findings can help inform patients' and clinicians' shared decision making when considering changes in RA therapy.

The Association Between Treatment of Abatacept or Other Target Disease-Modifying Anti-rheumatic Drugs and Type 2 Diabetes Mellitus (T2DM)-Related Healthcare Resource Utilization and Costs in Commercially Insured Rheumatoid Arthritis Patients with T2DM

Qian Xia,[1] **Xue Han**,[2] Ying Bao,[1] Vardhaman Patel,[3] Varshini Rajagopalan,[4] and Francis Lobo[2], [1]Bristol-Myers Squibb, Lawrenceville, NJ, [2]Bristol-Myers Squibb Company, Princeton, NJ, [3]Bristol-Myers Squibb, New York City, NY, [4]Mu-Sigma, Bengaluru, India

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Type 2 diabetes mellitus (T2DM)-related complications are costly, and there is lack of information regarding the comparative impact of target disease-modifying anti-rheumatic drugs (tDMARDs) on commercially insured rheumatoid arthritis (RA) patients with T2DM. The objective of this study was to compare T2DM-related healthcare resource utilization (HCRU) and associated costs in TNF-a inhibitors (TNFi)-experienced patients with RA and T2DM receiving abatacept, other non-TNFi, or TNFi.

Methods: A retrospective, observational study was conducted with Truven MarketScan (January 1, 2008- March 31, 2018). The study population included TNFi-experienced adult patients with RA and T2DM initiating abatacept, TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, infliximab) or other non-TNFi (tocilizumab, anakinra, sarilumab, rituximab, tofacitinib) in the study period. The date of the tDMARD initiation was assigned as the index date. Patients were eligible in the analysis if they had 2+ diagnosis of RA separately at least 7 days, 1+ diagnoses of T2DM or were treated with anti-diabetes medications, and had at least 12 months of continuous enrollment prior to the index date. Patients with T1DM or malignancy were excluded. The follow-up period ended at earliest of (1) end of patient insurance enrollment; (2) end of overall study period; (3) end of index treatment date due to discontinuation or switching. Patients demographics and key clinical characteristics were measured in the baseline period. T2DM-related HCRU and associated costs including inpatient stay, outpatient visits, ER visits, and pharmacy costs were measured on a per-patient-per-month (PPPM) basis (2018 USD). Patients treated with abatacept were matched to TNFi and non-TNFi cohorts separately by propensity score (PS) adjusted with confounders such as comorbidities, HCRU and costs.

Results: A total of 4,322 patients initiating abatacept, non-TNFi or TNFi were identified. Overall, most patients were female (75.6%) with an average age of 58 years (Table 1). Unadjusted results showed abatacept is associated with the lowest T2DM-related hospitalization rates per 1,000 patients per month compared to non-TNFi and TNFi (12.2 vs 15.9 vs 12.8). Moreover, T2DM-related complication costs (PPPM) in abatacept group was the lowest than non-TNFi and TNFi ($798 vs $1,130 vs $823) (Table 2). After propensity score matching, a total of 971 pairs of abatecept vs non-TNFi patients, and 1,065 pairs of abatecept vs TNFi paitents were included in the adjusted results. Patients initiating abatacept had $267 lower adjusted T2DM-related complication costs as compared to non-TNFi and $92 lower costs than TNFi cohorts (Table 3).

Conclusion: TNFi-experienced RA patients with T2DM who initiated abatacept had lower rates of T2DM-related hospitalization and lower costs compared to patients who initiated a TNFi or other non-TNFi, which were shown in both unadjusted and adjusted results. The findings suggest that abatacept may be able to reduce the complications of T2DM and hereby lower the T2DM-related costs in RA patients.

Treatment Response to Biologic DMARDs in Patients with RA: A Retrospective Analysis of the RISE Registry

Xue Han,[1] Joshua Bryson,[1] David C Crosby,[1] Michael Evans,[2] and Gabriela Schmajuk[3], [1]Bristol-Myers Squibb, Princeton, [2]University of California San Francisco, San Francisco, [3]UCSF, SFVAMC Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ACR guidelines recommend treatment for patients with RA based on baseline (BL) disease activity. In patients with an inadequate response to conventional synthetic DMARDs, escalation to biologic DMARDs is recommended, although specific algorithms are not specified. The aim of this study was to compare treatment

response, using disease activity scores, to abatacept (ABA), TNF inhibitors (TNFi) or other non-TNFi targeted (t) DMARDs in patients with RA.

Methods: This was a retrospective, observational cohort study using data from the US-based Rheumatology Informatics System for Effectiveness (RISE) registry. The study period included all observations from inception (June 2014) through December 2017. The index date was the date of first prescription of a new tDMARD. Adult patients (≥18 years) with ≥1 International Classification of Diseases code for RA, a prescription for a new tDMARD, documented results for RF and CCP antibody tests and at least one disease activity score < 6 months before and ≥6 months after index date were included. Covariates were assessed during a 6-month BL period preceding the index date. BL disease activity and changes in disease activity (measured by RAPID3 or CDAI scores) ≥6 months after index date were compared across ABA, TNFi (adalimumab, certolizumab, etanercept, golimumab or infliximab) and other non-TNFi

Table 2. Disease Activity at Baseline and Change From Baseline at ≥6 Months

	Abatacept (n=503)	TNFi (n=2894)	Other tDMARDs (n=925)	p value*
Baseline disease activity

NA=not available; RAPID3=Routine Assessment of Patient Index Data 3; tDMARD=targeted DMARD; TNFi=TNF inhibitor

tDMARD (baricitinib, sarilumab, tofacitinib, tocilizumab or rituximab) treatment groups. Disease activity at ≥6 months was compared by treatment and by BL disease activity using validated cut-points (see definitions in footnote below). A one-way ANOVA was used to test patient demographics and the change in RAPID3 and CDAI scores from BL to ≥6 months across treatments.

Results: Of the 4322 patients included, 503, 2894 and 925 patients received ABA, TNFi and other tDMARDs, respectively. The mean (SD) age was 59.6 (13.9) years and the majority were female (Table 1). Mean BL RAPID3 scores were similar between groups and mean BL CDAI scores were highest in the ABA group (Table 2). The improvement in RAPID3 score from BL to ≥6 months was greater with ABA than with TNFi or other tDMARDs (p=0.02). Although not statistically significant, a similar trend was seen for change in CDAI score. After 6 months, the proportion of patients with high disease activity was lower in the ABA vs TNFi or other tDMARD groups, across all BL disease activities: 33% of patients in the ABA group improved improved to lower levels of disease activity at ≥6 months after the index date vs patients in the TNFi (17%) or other tDMARD (24%) groups.

Conclusion: In this retrospective study, abatacept-treated patients were older and had higher BL CDAI scores than comparator groups. Nevertheless, after ≥6 months, abatacept was associated with a trend toward greater improvements in disease activity compared with other treatments, regardless of BL disease activity. More work is needed to understand whether these differences are clinically meaningful.

Prediction of Clinical Response to Abatacept in Rheumatoid Arthritis Patients Through the Determination of Anti-Carbamylated Proteins Antibodies Levels

Silvia Piantoni,[1] Michele Boldini,[1] Rajesh Kumar,[1] Emirena Garrafa,[1] Chiara Bazzani,[2] Micaela Fredi,[3] Ilaria Cavazzana,[1] Angela Tincani,[3] and Franco Franceschini[3], [1]ASST Spedali Civili and University of Brescia, Brescia, Italy, [2]Rheumatology and Clinical Immunology, Spedali Civili, Brescia, Italy, Brescia, Italy, [3]Rheumatology and Clinical Immunology, Spedali Civili and Department of Clinical and Experimental Sciences, University of Brescia, Brescia, Italy, Brescia, Italy

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Carbamylation is a non-enzymatic irreversible post-translational modification of proteins. The presence of anti-carbamylated protein antibodies (anti-CarP) has been observed in rheumatoid arthritis (RA). In particular, it was recently demonstrated that the 16% of anti-citrullinated proteins antibodies (ACPA) negative RA patients had a positivity for anti-CarP, showing a more severe disease course than that of seronegative RA. This study was focused to verify whether anti-CarP antibodies can be used as a predictive factor of clinical response to abatacept (ABA, CTLA4-Ig).

Methods: Sixty rheumatoid arthritis patients (F/M=49/11; media (±standard deviation) of age= 57 (±12.1) years; CRP (C Reactive Protein)-DAS28= 4.59 (±0.99); ACPA positive (n (%))=51 (85); RF positive=35 (58)), treated with ABA were enrolled. A home-made ELISA for anti-CarP immunoglobulin G (IgG) and a commercial anti-CCP3.1 kit (Inova Diagnostic) for ACPA IgG were applied to determine serum levels every six months of therapy. Rheumatoid Factor (RF) IgG (Siemens) was also tested.

Results: At baseline, we found that 30% of our patients were positive for anti-CarP antibodies. Anti-CarP positive patients (n=18) were younger (p=0.01) with a longer disease duration(p=0.05) and with higher levels of CRP ($p< 0.05$), when compared to anti-CarP negative patients (n=42). Considering the entire cohort, a significant reduction of anti-CarP titre after twelve-months of treatment was shown ($p< 0.01$). A significant reduction of CRP-DAS28 in the first six months of therapy was found in the subgroup of anti-CarP positive patients in comparison with the negative ones (p=0.03). No significant results were found by dividing the cohort using the positivity to ACPA and/or RF.

Conclusion: The precocious onset and a longer disease duration in anti-CarP positive patients might suggest them as a specific risk factors for RA in this subgroup of patients. The link between the anti-CarP positivity at baseline and the reduction of disease activity during the first six months of treatment let us to hypothesize that anti-CarP antibodies, but not ACPA and/or RF, could be a predictive factor of a good clinical response to ABA.

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Response to treatments in Rheumatoid Arthritis (RA) is assessed by symptomatic changes, such as ACR-response and DAS28. However, such assessments do not provide information about the effect of the treatment at tissue level. Chronic inflammation is a harmful mechanism, which manifests in upregulated tissue remodeling and release of extracellular matrix (ECM) metabolites into circulation. Released ECM metabolites are biomarkers of tissue remodeling and give insight to treatment effect at tissue level. The purpose of this study was to investigate if tissue remodeling is modulated by tocilizumab (TCZ) and methotrexate (MTX) in the AMBITION study.

Table 1. ANCOVA comparison between treatment groups and measured biomarkers change to week 8.

Treatment group	Mean change at week 8 (%)	Lower 95%-CI	Upper 95%-CI	Treatment comparison	Difference (%)	p<0.05
Inflammation-driven connective tissue metabolite (C1M)						
Placebo	101	85	116	TCZ vs Placebo	-25	0.0319
MTX	100	90	109	MTX vs Placebo	-1	ns
TCZ	76	66	87	TCZ vs MTX	-24	0.004
Inflammation-driven connective tissue metabolite (C3M)						
Placebo	106	97	79	TCZ vs Placebo	-32	<0.0001
MTX	90	84	95	MTX vs Placebo	-16	0.0072
TCZ	74	69	116	TCZ vs MTX	-16	0.0001
Cartilage degradation metabolite (C2M)						
Placebo	104	92	115	TCZ vs Placebo	-6	ns
MTX	104	98	110	MTX vs Placebo	0	ns
TCZ	98	92	105	TCZ vs MTX	-6	ns
Basement membrane remodeling metabolite (C4M)						
Placebo	104	95	113	TCZ vs Placebo	-37	<0.0001
MTX	89	83	94	MTX vs Placebo	-15	0.0161
TCZ	67	61	72	TCZ vs MTX	-22	<0.0001
C-reactive protein metabolite (CRPM)						
Placebo	109	88	130	TCZ vs Placebo	-36	0.011
MTX	100	88	112	MTX vs Placebo	-9	ns
TCZ	73	61	85	TCZ vs MTX	-27	0.0078
C-reactive protein (CRP)						
Placebo	128	9	54	TCZ vs Placebo	-97	0.0001
MTX	101	79	123	MTX vs Placebo	-27	ns
TCZ	31	90	166	TCZ vs MTX	-70	<0.0001

Methods: The AMBITION study is a phase III RCT in which TCZ monotherapy (8 mg/kg every 4 weeks) was compared to MTX monotherapy (starting at 7.5 mg/kg and titrated to 20 mg/kg) over 24 weeks in patients with early RA. Tissue metabolites were measured in baseline and 8-weeks sera from 387 patients by validated ELISA assays. Connective tissue remodeling was measured by C1M and C3M (type I and III collagen degradation), cartilage degradation by C2M (type II collagen degradation), basement membrane remodeling by C4M (type IV collagen degradation), systemic inflammation by C-reactive protein (CRP) and tissue specific inflammation by CRPM (an MMP-derived CRP metabolite). Comparison between treatment and response groups were done by ANCOVA, Spearman's correlation and Logistic regression adjusted for age, gender, BMI and disease duration.

Results: Connective tissue remodeling biomarkers, C1M and C3M, were significantly ($P< 0.05$) inhibited by TCZ and C3M by MTX ($P=0.0072$) compared to placebo (see table 1). The inhibition of C1M and C3M with TCZ was respectively 24% and 16% greater than that of MTX ($P=0.004$ and $P=0.0001$). C4M was likewise inhibited by both TCZ and MTX, but the effect of TCZ was 22% greater than MTX ($P< 0.0001$). In contrast, TCZ and MTX had minimal effect on C2M when compared to placebo or baseline. MTX had no effect on CRP and CRPM compared to placebo or baseline, whereas TCZ reduced the level of CRP and CRPM to 31% and 73% of baseline. In the patients treated with TCZ none of the tested biomarkers correlated to 8 and 16-week changes in DAS28. In the MTX group changes in C4M and CRPM were correlated to 8-week changes in DAS28 (rho=0.21 and 0.19, $P< 0.05$), whereas only C4M correlated to 16-week changes in DAS28 (rho=0.19, $P< 0.05$). Patients with ACR70 response at week 8 had the highest difference between treatments in the inhibition of C1M; 36% for TCZ and 14% for MTX.

Conclusion: This study shows that tissue remodeling in the RA patients can be differently modulated by Tocilizumab and Methotrexate. Both treatments downregulate tissue remodeling and slower the disease progression. Tocilizumab showed a more tissue-protective effect and greater improvement of the disease symptoms than that of Methotrexate.

Abstract Number: 1392

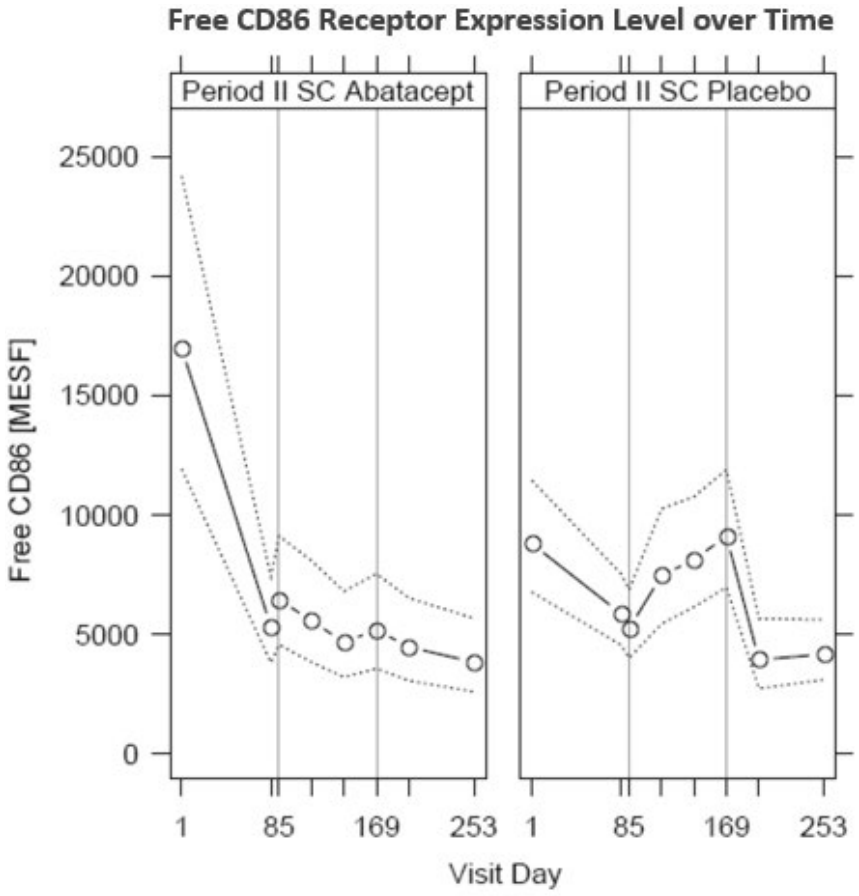
The Relationship Between Abatacept Exposure and CD86 Receptor Occupancy in Rheumatoid Arthritis Patients Following Subcutaneous Administration and Its Association to Patient Outcomes

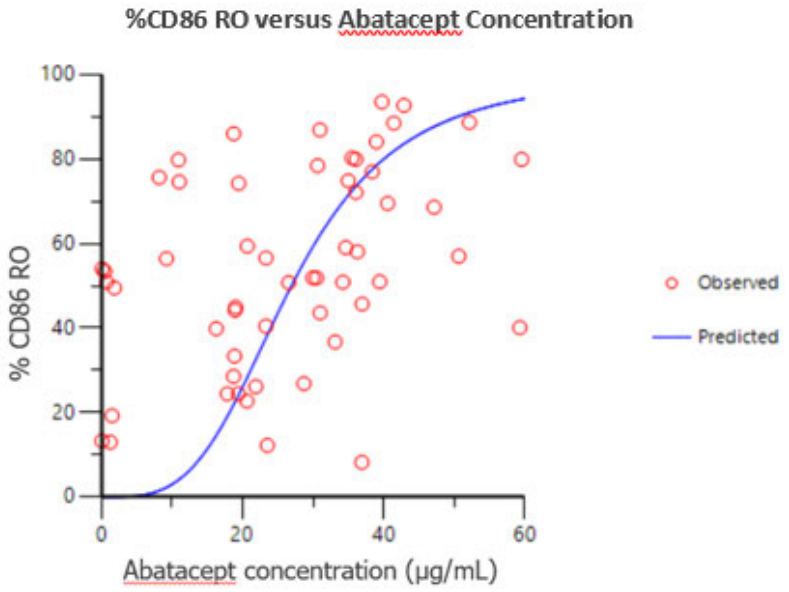
Grigor Abelian,[1] Sheng Gao,[2] Yash Gandhi,[1] Blisse Vakkalagadda,[1] Vidya Perera,[1] and Bindu Murthy[1], [1]Bristol-Myers Squibb, Princeton, [2]Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The purpose of this investigation was to characterize the relationship between systemic exposure of abatacept and measures of target engagement to further support dosing recommendations for abatacept.

Methods: The ALLOW study was a multinational, multicenter, randomized, double-blind, withdrawal study in patients with mild to moderate RA on a stable background of methotrexate to evaluate the immunogenicity and safety of subcutaneous (SC) abatacept. A key exploratory objective in this study was assessing the extent of CD86 receptor saturation in RA subjects following 125 mg weekly SC abatacept during lead-in, withdrawal, and re-introduction pe-





riods. The time course of abatacept concentrations as well as total and free CD86 expression levels on the surface of peripheral blood monocytes were measured upon initiation of abatacept as well as during the withdrawal and re-introduction phases using validated assays and was described by an extended linear model. Percentage of CD86 Receptor Occupancy (RO) was derived from the free CD86 expression levels at baseline and post-treatment. The relationship between abatacept concentrations and percentage of CD86 RO was characterized by a Sigmoidal Emax Model.

Results: Steady-state abatacept trough concentrations were achieved by Day 57 and were consistent from Days 57 to the end of the lead-in period/beginning of the withdrawal period (Day 85). On Day 85, mean free CD86 expression levels were comparable between the patients randomized to the SC abatacept and SC placebo groups for the withdrawal period. Upon withdrawal of abatacept therapy on Day 85, mean abatacept trough concentrations declined and mean free CD86 expression levels increased over time to baseline levels by the end of the withdrawal period on Day 169 (Figure 1, right panel). For patients who continued to receive SC abatacept, mean steady-state trough abatacept concentrations remained consistent while mean free CD86 expression levels incrementally decreased over time (Figure 1, left panel). Binding of abatacept to the CD86 receptor appears to be concentration dependent and was well described by a Sigmoidal Emax model with an EC_{50} (CV%) of 26.9 µg/mL (21.1%) (Figure 2). Administration of the approved SC dosing regimen results in steady state trough concentrations of approximately 25-34 µg/mL[1-4]. Overall, the CD86 binding characteristics are in good agreement with previous exposure-response analyses, where near maximal efficacy (i.e. DAS28 score and ACR20/50/70) is driven by steady state trough concentrations of 10 µg/mL or higher, which is achievable for the approved SC dosing abatacept regimen[5].

Conclusion: Establishing PK/RO relationships associated with patient outcomes enables guidance of dose administration for SC abatacept in RA.

Impact of Sarilumab on Unacceptable Pain and Inflammation Control in Moderately-to-Severely Active Rheumatoid Arthritis (RA) Patients in 3 Phase 3 Studies

Vivian Bykerk,[1] Wenhui Wei,[2] Susan Boklage,[2] Toshio Kimura,[2] Stefano Fiore,[3] and Gregory St John[4], [1]Hospital for Special Surgery, New York City, NY, [2]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [3]Sanofi Genzyme, Bridgewater, NJ, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, a core-set domain and a troubling symptom to patients with RA, may be directly related to inflammation. Unacceptable pain (UP) levels may persist despite treatment-induced inflammation control, i.e. refractory pain (RP). Sarilumab is a subcutaneously-administered interleukin-6 receptor antagonist for treatment of adults with moderately to severely active RA with an inadequate response or intolerance to 1 or more disease-modifying antirheumatic drugs (DMARD-IR). In 3 randomized controlled trials (RCTs) of sarilumab 150 mg or 200 mg every 2 weeks (q2w) vs comparators, we previously observed meaningful improvements in pain. This study assessed UP and RP for sarilumab vs comparators in these trials.

Methods: Data were from RCTs of sarilumab 150 mg and 200 mg q2w vs placebo (+conventional DMARDs for all): MOBILITY [NCT01061736] (24/52 weeks) and TARGET [NCT01709578] (24-weeks); and MONARCH [NCT02332590] sarilumab 200 mg q2w vs adalimumab 40 mg q2w monotherapies. Post-hoc analyses were conducted on the odds ratios (ORs) of pain outcomes: UP (based on patient acceptable symptom state [PASS] on a threshold of visual

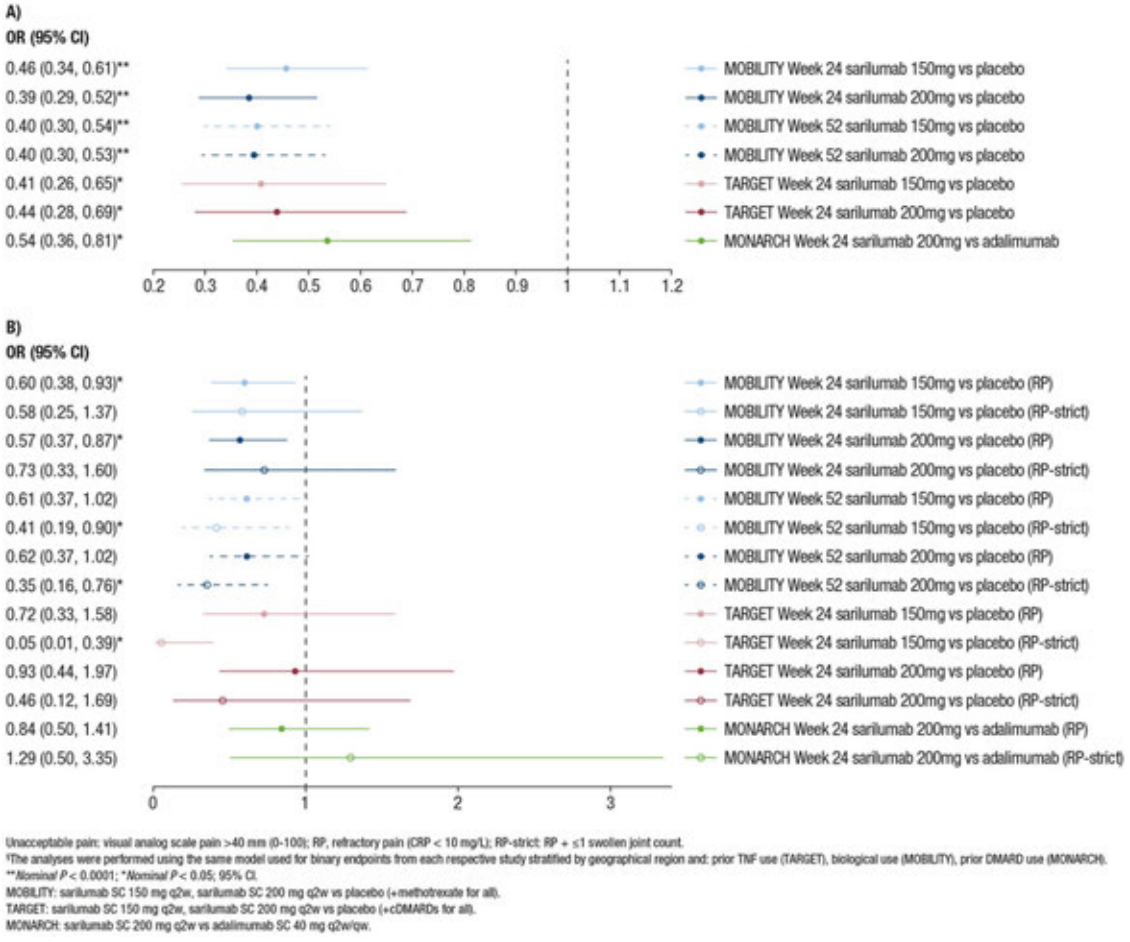
	Adalimumab SC 40 mg q2w/qw (n = 185)		**Sarilumab SC 200 mg q2w (n = 184)**
Age, years, mean ± SD	53.6±11.9		50.9±12.6
Female, n (%)	150 (81.1)		157 (85.3)
Race, White–Caucasian, n (%)	164 (88.6)		171 (92.9)
Duration of RA, years, mean ± SD	6.6 ± 7.8		8.1 ± 8.1
SJC (66 assessed), mean ± SD	17.5 ± 10.3		18.6 ± 10.7

analog scale pain >40 mm [0–100]), RP (UP+C reactive protein < 10 mg/L), and RP-strict (RP+ ≤1 swollen joint count [SJC]), and associations between pain and fatigue (FACIT-Fatigue) and disease activity (Health Assessment Questionnaire [HAQ], SJC and tender joint count [TJC]).

Results: Across all 3 trials (with similar patient baseline characteristics per arm in each trial; **Table**) sarilumab 150 mg and 200 mg had lower odds of UP vs comparators (nominal $P < 0.05$; **Figure**). MOBILITY: both sarilumab doses had lower odds (nominal $P < 0.05$) of RP vs placebo at Week 24 (sarilumab 150 mg: 0.60 [0.38, 0.93]; sarilumab 200 mg: 0.57 [0.37, 0.87]) and Week 52 (sarilumab 150 mg: 0.64 [0.37, 1.02]; sarilumab 200 mg: 0.62 [0.37, 1.02]), and RP-strict at Week 52 (sarilumab 150 mg: 0.41 [0.19, 0.90]; sarilumab 200 mg: 0.35 [0.16, 0.76]); TARGET: sarilumab 150mg had lower odds (nominal $P < 0.05$) of RP-strict at Week 24 (0.05 [0.01; 0.39]) (**Figure**). Higher pain level was associated with worse levels of FACIT-fatigue, HAQ, SJC and TJC (all $P < 0.001$), and UP had mostly moderate agreements with the likelihood of achieving response (minimal clinically important differences) on all these outcomes (*Kappa* coefficient values 0.41–0.60).

Conclusion: In this post hoc analysis of 3 RCTs in DMARD-IR patients, sarilumab was associated with lower odds of unacceptable pain or refractory pain vs comparators. Further research is needed regarding the sources of persistant pain and the potential role of inflammation control in patients with RA.

Figure. ORs[§] for outcomes: A) unacceptable pain, B) refractory pain (RP) or RP-strict



Unacceptable pain: visual analog scale pain >40 mm (0-100); RP, refractory pain (CRP < 10 mg/L); RP-strict: RP + ≤1 swollen joint count.
[§]The analyses were performed using the same model used for binary endpoints from each respective study stratified by geographical region and: prior TNF use (TARGET), biological use (MOBILITY), prior DMARD use (MONARCH).
**Nominal $P < 0.0001$; *Nominal $P < 0.05$; 95% CI.
MOBILITY: sarilumab SC 150 mg q2w, sarilumab SC 200 mg q2w vs placebo (+methotrexate for all).
TARGET: sarilumab SC 150 mg q2w, sarilumab SC 200 mg q2w vs placebo (+cDMARDs for all).
MONARCH: sarilumab SC 200 mg q2w vs adalimumab SC 40 mg q2w/qw.

ANOVA=analysis of variance; mHAQ=modified HAQ; PRO=patient-reported outcome; PtGA=patient global assessment; TNFi=TNF inhibitor; VAS=visual analog scale

baseline (BL) anti-CCP2 concentration and 6-month treatment responses to ABA or any TNF inhibitor (TNFi) in a real-world setting.

Methods: CERTAIN (Comparative Effectiveness Registry to study Therapies for Arthritis and Inflammatory CoNditions) is a prospective cohort study of adult pts with RA,[2] recruited from the Corrona network, who had at least moderate disease activity (CDAI >10) and either started therapy with or switched to a TNFi or non-TNF biologic. Pts were followed for 12 months (mths) or until they switched/discontinued biologic therapy. This analysis included pts from CERTAIN who initiated ABA or any TNFi, were CCP3+ (>20 U/mL), had CDAI >10 at BL and had serum samples at BL and at 6 mths. Eligible pts also had known BL anti-CCP2 concentration and serostatus (–, ≤10 U/mL; +, >10 U/

mL) and prior biologic exposure. TNFi initiators were matched to ABA initiators based on CDAI by line of therapy. BL demographics, pt and disease characteristics were compared within treatment groups using descriptive statistics. Treatment response by BL anti-CCP2 quartile in anti-CCP2+ pts, assessed by change from BL at 6 mths in CDAI and patient-reported outcomes (PROs: modified [m]HAQ, pain, fatigue and patient global assessment [PtGA]), was evaluated separately in the ABA and TNFi groups using a linear regression model adjusted for age, sex, CDAI or PROs at initiation, co-morbidity index and current MTX use.

Results: In total, 151 matched biologic-experienced ABA and TNFi initiators were included (13 and 14 were anti-CCP2– and 138 and 137 were anti CCP2+, respectively). At BL, median age was 57–60 years (yrs), 74–75% were female, median duration of RA was 10–12 yrs and mean BMI was 29.2–29.8. There were significant differences between anti-CCP2 quartiles at BL in mean CDAI, SJC28, CRP, DAS28 (CRP), RF, mHAQ and physician global assessment, and in mean RF, mHAQ and PtGA among TNFi initiators. Among ABA initiators (Table 1), but not TNFi initiators (Table 2), a greater improvement at 6 mths in CDAI and all PROs was observed with increasing CCP2 quartile. In the adjusted analysis, among ABA initiators, there was a numerically greater improvement in CDAI ($p=0.208$) and statistically significantly greater improvements in all PROs ($p< 0.05$) with increasing anti-CCP2 quartile.

Conclusion: In a relatively small sample of abatacept-treated pts, higher anti-CCP2 concentrations at BL were associated with significantly greater improvement in PROs in the adjusted and unadjusted models, a numerically greater improvement in CDAI score in the adjusted model and a significantly greater improvement in CDAI score in the unadjusted model after 6 mths. This association was not observed in a small sample size of TNFi-treated pts.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The most widely used B cell targeted therapies in auto-immune diseases (AID) is Rituximab (RTX), a murine chimeric monoclonal antibody. Among RTX's side effects, immunization and anti-drug antibodies to RTX (RTX-ADA) production have been reportedbut their consequences are poorly described. The immunization rate against RTX in rheumatoid arthritis (RA) is 2.7-9.2% and data is lacking in sAID.

We aimed to evaluate the frequency, consequences and predictive factors of RTX-ADA in RA and sAID, as well as the use of an alternative B-cell targeted therapy, ofatumumab (OFA).

Methods: All patients with RA or sAID treated with RTX from 2012 to 2017 in our tertiary reference centre for RA and sAIDwere retrospectively studied. All patients who were tested for RTX-ADA were identified. Clinical and biological characteristics of RTX immunized patients were compared to those of non-immunized patients. For patients treated with OFA, clinical and biological efficacy was obtained before and after treatment.

Results: 199 patients were treated with RTX (RA: 124, sAID: 75 including 38 primary Sjögren's Syndrome (pSS), 15 systemic lupus erythematous, 7 myositis, 6 overlap syndrome, 5 ANCA-associated vasculitides and 4 other sAID). 62/199 (31.1%) patients were tested for RTX-ADA because of a loss of clinical efficacy or absence of B-cell depletion (43.4%), a long delay between cycles (13.2%), a reaction during the first infusion (7.5%) or at subsequent infusions (35.8%). 14 were positive: 3/35 RA (8.6%) and 11/27 (40.7%) other sAID, (p=0.0025). None of the patients who experienced a reaction to the first RTX infusion were positive for RTX-ADA. Among the whole RTX-treated patients, the frequency of RTX-ADA was 2.4% and 14.7% in RA and in other sAID, respectively (p=0.003). Most of the immunized patients experienced delayed infusion reactions (11/14 [78.5%]). Delayed reactions were observed within the first 15 days after the infusion, and after a median 2 cycles [range; 1-2]. They were mainly rash (72.7%), fever (54.5%) and/or abdominal pain (36.3%). Predictive factors of immunization were a sAID compared to RA (40.7% vs 8.6%, p=0.0025) and African origin (57.1% vs 4.2%, p< 0.001). Neither hypergammaglobulinemia, rheumatoid factor, disease activity, nor associated immunosuppressive therapy were associated with RTX-ADA. Among 23 tested patients with SLE or pSS, anti-SSA antibodies were positive in 9/10 (90%) immunized patients versus in only 8/13 (61.5%) non immunized patients (p=0.18). Three pSS patients immunized against RTX were treated with OFA because of associated cryoglobulinemic vasculitis or MALT lymphoma. All 3 experienced complete remission of their disease without any recurrence of infusions reactions. No other adverse event was reported.

Conclusion: Immunization against RTX is an event leading to loss of efficacy, absence of B-cell depletion and infusion reactions at the 2nd or subsequent infusions. Testing for RTX-ADA must be realized in patients presenting one of these three features, especially if they are of African origin and treated for a sAID. Our results suggest that immunized patients can be treated safely with OFA although OFA should be further evaluated in sAID.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

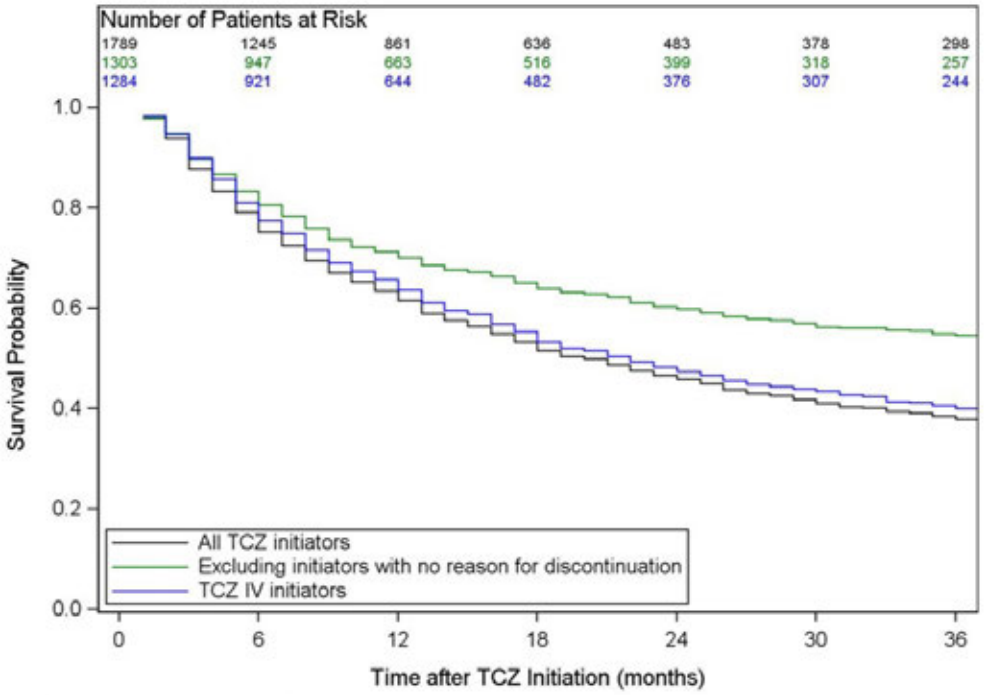
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Understanding persistence of biologic therapies and factors associated with discontinuation can help inform treatment decisions for patients with rheumatoid arthritis (RA). We sought to evaluate the persistence of tocilizumab (TCZ) therapy and identify factors associated with its discontinuation among US patients with RA in routine clinical practice.

Methods: Eligible participants were TCZ-naïve patients enrolled in the Corrona RA registry who initiated TCZ after January 1, 2010 and had ≥ 1 follow-up visit. Persistence of therapy was defined as maintaining continuous TCZ treatment with no interruptions; patients were considered no longer persistent upon the first discontinuation of TCZ.

Figure 1. Kaplan-Meier Plots of Persistence of TCZ Therapy



IV, intravenous; TCZ, tocilizumab.

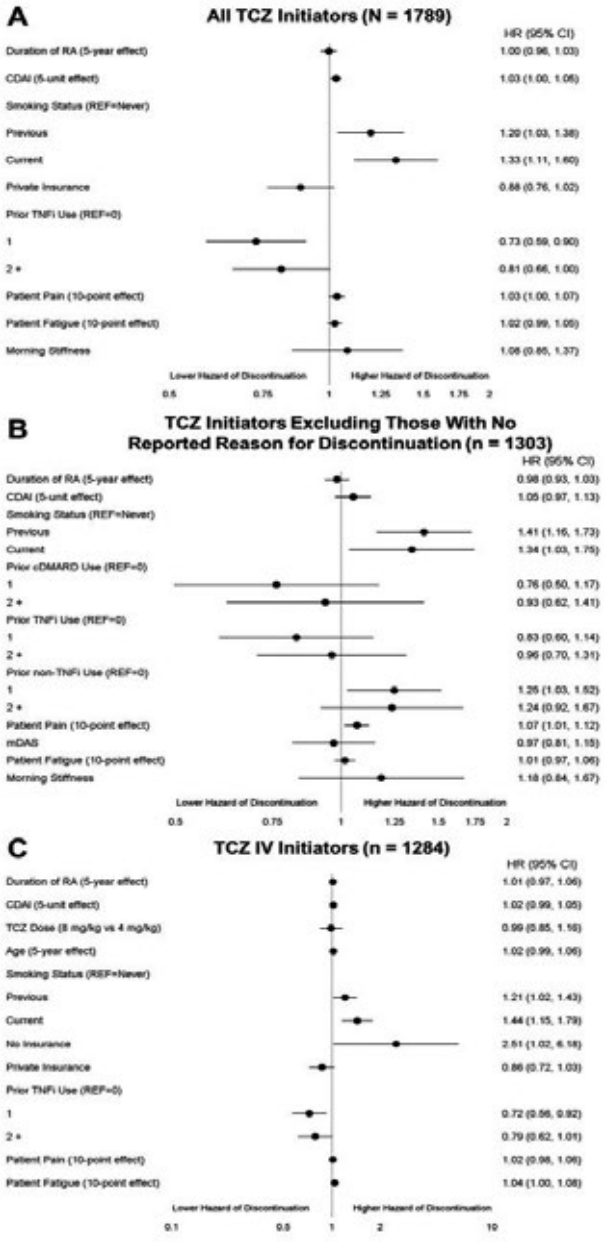
BMI, body mass index; CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; mDAS, modified Disease Activity Score; mHAQ, modified Health Assessment Questionnaire; RA, rheumatoid arthritis; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.

Persistence was calculated using Kaplan-Meier survival analysis for the overall population; secondary analyses evaluated persistence excluding patients who stopped TCZ with no reported reason for discontinuation (patients with non-medical reasons for discontinuation [eg, insurance] were censored) and in only those patients who initiated intravenous (IV) TCZ. Cox proportional hazards modeling was used to identify factors associated with persistence.

Figure 2. Estimated Effects of Covariates on Duration of TCZ Persistence Among (A) All TCZ Initiators, (B) TCZ Initiators Excluding Those With No Reported Reason for Discontinuation and (C) TCZ IV Initiators



CDAI, Clinical Disease Activity Index; csDMARD, conventional synthetic disease-modifying antirheumatic drug; IV, intravenous; mDAS, modified Disease Activity Score; RA, rheumatoid arthritis; REF, reference; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.

Results: A total of 1789 TCZ initiators were included. Patient characteristics at the time of TCZ initiation are summarized in **Table 1**. Most patients (93.4%) had prior biologic use and 67.4% had received ≥ 2 prior biologics (**Table 1**). Overall, 28.8% initiated TCZ as monotherapy (**Table 1**). Among all TCZ initiators, the median (95% CI) duration of persistence was 20 (18 to 22) months (**Figure 1**). Factors associated with an increased hazard of TCZ discontinuation included smoking and higher baseline CDAI, whereas prior tumor necrosis factor inhibitor (TNFi) use was associated with a reduced hazard (**Figure 2A**). After excluding patients with no reported reason for discontinuation (remaining

n = 1303), the median (95% CI) duration of persistence was 46 (38 to 55) months (**Figure 1**); smoking, use of 1 prior non-TNFi and higher baseline patient pain score were associated with an increased hazard of discontinuation (**Figure 2B**). Among the 1284 patients who initiated TCZ IV, median (95% CI) duration of persistence was 22 (19 to 25) months (**Figure 1**); smoking, lack of insurance and higher baseline patient fatigue score were associated with a increased hazard of discontinuation, whereas use of 1 prior TNFi was associated with a decreased hazard (**Figure 2C**).

Conclusion: In this real-world population of US patients with RA, TCZ was most frequently initiated after an inadequate response to ≥ 2 biologics. Overall median duration of persistence was approximately 20 months and was higher (46 months) when patients with no reported reason for TCZ discontinuation were excluded. As expected, factors indicative of higher baseline disease activity were associated with shorter persistence.

Comparative Effectiveness of Tocilizumab in Combination with Methotrexate versus Tumor Necrosis Factor Inhibitors (TNFis) in Combination with Methotrexate in Patients with Rheumatoid Arthritis with Prior Exposure to TNFis

Dimitrios Pappas,[1] Taylor Blachley,[2] Steve Zlotnick,[3] Jennie Best,[3] Kelechi Emeanuru,[2] and Joel Kremer[4], [1]Columbia University, New York, NY, [2]Corrona, LLC, Waltham, MA, [3]Genentech, Inc., South San Francisco, CA, [4]Albany Medical College and The Center for Rheumatology; Corrona, LLC, Albany, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical studies have demonstrated the efficacy of tocilizumab (TCZ) administered with methotrexate (MTX) in improving rheumatoid arthritis (RA) disease activity in patients who have had an inadequate response to tumor necrosis factor inhibitors (TNFis). The objective of this study was to compare the effectiveness of TCZ + MTX with that of TNFis + MTX in patients with RA who had prior exposure to TNFis in routine clinical practice.

Methods: Eligible participants were TCZ-naïve patients from the Corrona RA registry who initiated TCZ + MTX or a TNFi + MTX after January 1, 2010 and had a 6-month follow-up visit. Patients in both groups must have used ≥ 1 TNFi, had a Clinical Disease Activity Index (CDAI) score available at initiation (baseline) and 6 months and had a CDAI score > 10 at baseline. The primary outcome was mean change in CDAI from baseline to 6 months. Secondary outcomes included achievement of low disease activity (LDA; CDAI ≤ 10) and mean change in modified Health Assessment Questionnaire (mHAQ) at 6 months. Patients were grouped by baseline MTX dose (≤ 10 mg; > 10 to ≤ 15 mg; >

Table. Outcomes at 6 months in patients who initiated TCZ + MTX compared with those who initiated TNFi + MTX in the trimmed population.

CDAI, Clinical Disease Activity Index; LDA, low disease activity; mHAQ, modified Health Assessment Questionnaire; MTX, methotrexate; OR, odds ratio; TCZ, tocilizumab; TNFi, tumor necrosis factor inhibitor.
*TCZ + MTX (reference group) compared with TNFi + MTX. Adjusted for potential confounding variables.

15 to ≤ 20 mg; > 20 mg); outcomes were compared between patients initiating TCZ and those initiating a TNFi overall and within each MTX dose group using propensity score (PS)-trimmed populations. As a sensitivity analysis, TCZ and TNFi initiators in each group were PS-matched 1:1 and outcomes were assessed in the matched populations. Linear and logistic regression models were estimated in the trimmed and matched populations, adjusting for covariates not balanced after PS trimming or matching, respectively.

Results: A total of 415 TCZ + MTX initiators and 725 TNFi + MTX initiators met the inclusion criteria prior to PS trimming or matching. The overall trimmed population included 402 TCZ + MTX initiators and 703 TNFi + MTX initiators. In the trimmed population, patient demographics were generally comparable between TCZ + MTX and TNFi + MTX initiators; the mean age was 57.1 years in the TCZ + MTX group and 57.7 years in the TNFi + MTX group, the majority of patients in both groups were female (> 79%) and white (> 82%) and the mean duration of RA was 11.8 and 10.5 years in the TCZ + MTX and TNFi + MTX groups, respectively. Higher proportions of patients initiating TCZ had received ≥ 2 prior biologics (66.0% to 76.3%) compared with those initiating a TNFi (33.2% to 42.2%) across all MTX dose groups. Patients initiating TCZ had higher mean baseline CDAI scores (26.5 to 29.3) than those initiating a TNFi (24.7 to 27.5). Patients in both cohorts had improvement in CDAI scores at 6 months regardless of baseline MTX dose. Improvement in CDAI and mHAQ and the odds of achieving LDA were comparable between TCZ and TNFi initiators across all MTX groups in the trimmed population after adjustment for potential confounding variables (Table). Similar results were observed in the PS-matched cohorts.

Conclusion: In this real-world population of US patients with RA who had prior TNFi exposure, there was no statistically significant or clinically meaningful difference in the effectiveness of therapy in patients who initiated TCZ + MTX compared with TNFi + MTX.

Abstract Number: 1398

Sarilumab and Tocilizumab Receptor Occupancy (RO), and Effects on C-Reactive Protein (CRP) Levels, in Patients with Rheumatoid Arthritis (RA)

Christine Xu,[1] Patrick Nolain,[2] Qiang Lu,[3] Anne Paccaly,[4] Melitza Iglesias-Rodriguez,[5] Gregory St John,[6] Chad Nivens,[4] Rafael Maldonado,[7] Tomonori Ishii,[8] Ernest Choy,[9] and Vanaja Kanamaluru[3], [1]Sanofi, Bridgewater, NJ, [2]Sanofi-Aventis, Montpellier, France, [3]Sanofi, Bridgewater, [4]Regeneron Pharmaceuticals, Inc., Tarrytown, [5]Sanofi Genzyme, Cambridge, MA, [6]Regeneron Pharmaceuticals, Inc., Tarrytown, NY, [7]Pompeu Fabra University, Barcelona, Spain, [8]Tohoku University Hospital, Sendai, Japan, [9]Cardiff University School of Medicine, Cardiff, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The in vitro binding affinity of sarilumab (K_D 61.9 pM) for the human interleukin-6 receptor (IL-6R) is 15–22-fold higher than that of tocilizumab. This study evaluated the relationship between IL-6R receptor occupancy (RO), pharmacodynamic (PD) variables (eg CRP), and the potential clinical relevance of the differences between sarilumab and tocilizumab.

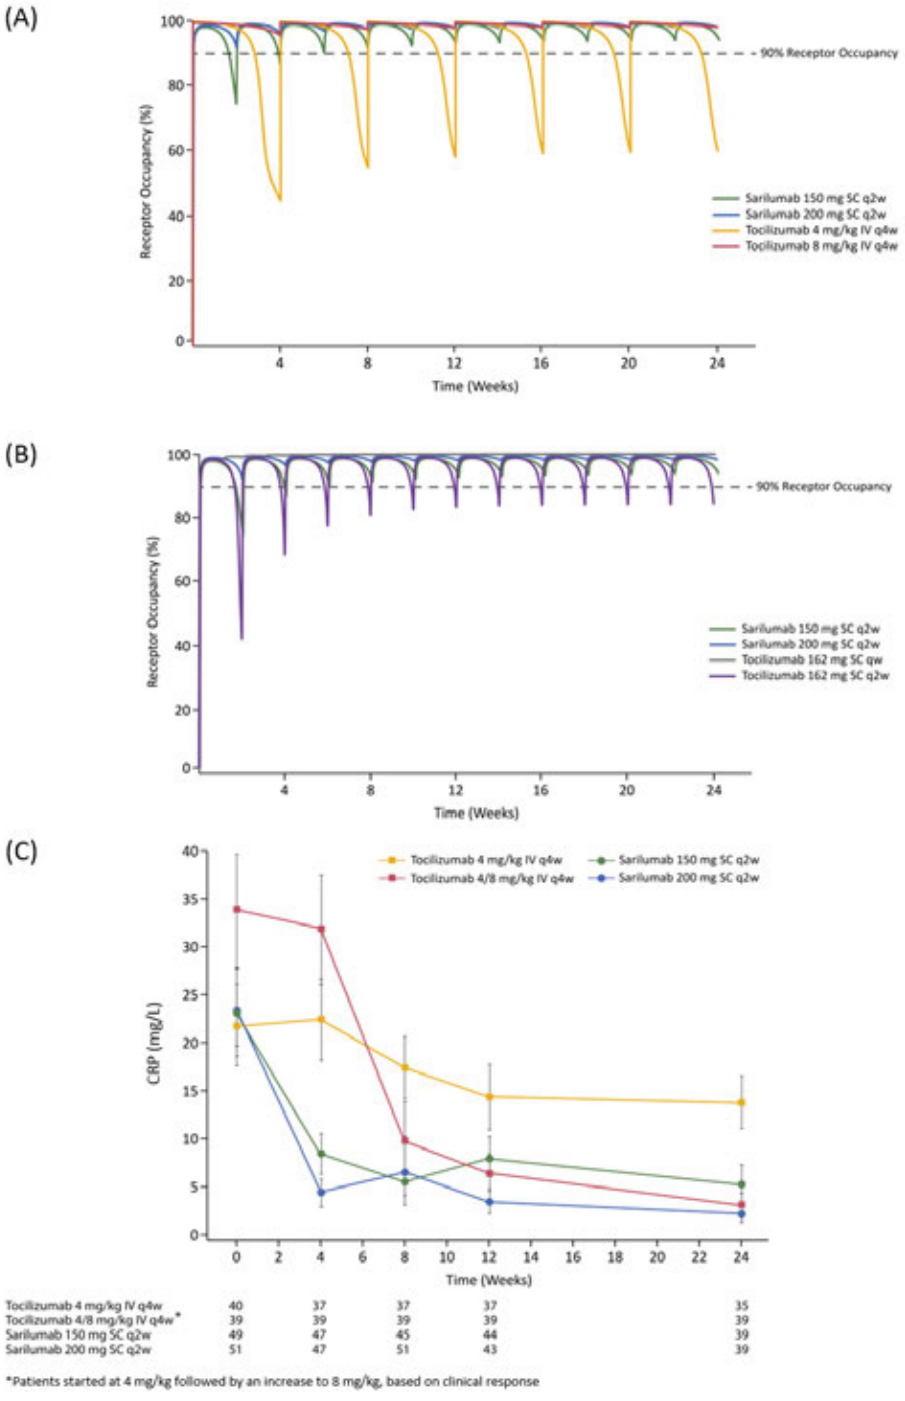
Methods: Binding to soluble IL-6R (sIL-6R) in vivo translates into the quasi-steady-state target-mediated drug disposition pharmacokinetics (PK) and indirect-response PD model with inhibition of elimination of sIL-6R and unbound sIL-6R concentration for both sarilumab and tocilizumab. PK/PD models simulated sIL-6R RO over time for: sarilumab 200 and 150 mg subcutaneously (SC) once every 2 weeks (q2w); tocilizumab 162 mg SC q2w and once every week (qw); and tocilizumab 4 and 8 mg/kg intravenously (IV) once every 4 weeks (q4w). RO profiles were compared with changes in CRP levels following administration of sarilumab SC and tocilizumab IV in patients with RA (ASCERTAIN; NCT01768572); during the study period, 60.8% of patients receiving tocilizumab required a dose increase from 4 to 8 mg/kg IV q4w, based on clinical response.

Results: Sarilumab 200 mg SC q2w achieved >90% RO after the first dose, which was maintained over the dosing interval throughout the 24-week treatment period; at 150 mg SC q2w, RO was >90% from the second dose onwards. Tocilizumab 162 mg SC q2w achieved RO >90% after the first dose but this decreased to < 50% before the second dose. The RO for tocilizumab 4 mg/kg IV q4w was >99% after the first dose at Week 1 but decreased over the dosing interval to < 50% before the second dose. At trough steady state (Week 24), RO was greater with sarilumab 200 mg SC q2w (98%) and 150 mg SC q2w (94%) versus tocilizumab 162 mg SC q2w (84%) and 4 mg/kg IV q4w (60%). At the higher dose (8 mg/kg IV q4w) or dosing frequency (162 mg SC qw), tocilizumab maintained RO ≥99% at steady state, similar to sarilumab 200 mg SC q2w. CRP levels were inversely associated with RO at trough in patients with

RA; the greatest suppression in CRP levels occurred with sarilumab SC (either dose) or with the tocilizumab 8 mg/kg IV q4w (Figure). Proportionally smaller CRP reductions were observed with tocilizumab 4 mg/kg IV q4w, consistent with the lower RO of tocilizumab at this dose.

Conclusion: The higher IL-6R binding affinity of sarilumab translated into higher RO and greater reduction in CRP levels when compared with tocilizumab. Sarilumab 200 mg SC q2w led to a rapid and sustained suppression of CRP over the 24-week treatment course; the higher dose (IV) or increased dosing frequency (SC) of tocilizumab was

Figure. sIL6-R RO for (A) sarilumab SC vs tocilizumab IV and (B) sarilumab SC vs tocilizumab SC, and (C) CRP levels after sarilumab SC and tocilizumab IV



*Patients started at 4 mg/kg followed by an increase to 8 mg/kg, based on clinical response

required to maintain the same degree of RO and CRP suppression. CRP may be a useful tool in clinical practice for patients treated with an IL-6R blocker.

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Limited data from large real-world patient populations exist to describe treatment outcomes of patients who receive tofacitinib for the management of RA in Australia. The objective of this study was to evaluate effectiveness and treatment patterns of tofacitinib in a large real-world cohort of Australian adult patients with RA.

Methods: Routinely collected, de-identified clinical data were sourced from the Optimising Patient outcomes in Australian rheumatology – Quality Use of Medicines Initiative (OPAL-QUMI) dataset. Data from adult patients with a diagnosis of RA, who initiated treatment with tofacitinib or a biologic disease-modifying antirheumatic drug(bDMARD) and had at least 12 months of follow-up between March 2015 and September 2018, were included.Descriptive analyses were performed on overall and propensity score matched populations. Treatment effectiveness was evaluated from baseline to month 18 by DAS28-ESR, simple disease activity index (SDAI) and clinical disease activity index (CDAI) measures. Treatment persistence, in part a surrogate for efficacy, was estimated by Kaplan-Meier methods.

Treatment pattern evaluation included percentage of patients receiving monotherapy or combination therapy at treatment initiation.

Results: 1950 patients were included in the matched population (1300 bDMARD initiators; 650 tofacitinib initiators). Patients were predominantly aged 55 to 74 years (57.8%), and female (81.2%). At baseline, median disease duration was 107 and 120 months, with 16.1% and 17.3% of patients in DAS28-ESR defined disease remission for the bDMARD and tofacitinib groups respectively. After three months of treatment, 49.1% and 49.7% had achieved DAS remission and after 18 months of treatment, 52.4% and 57.8% of patients had achieved DAS remission in the bDMARD and tofacitinib groups respectively. At 18 months the percentage of patients achieving CDAI/SDAI remission was similar with 29.2%/29.0% bDMARD patients and 30.9%/30.5% tofacitinib patients reporting CDAI/SDAI remission respectively. The median persistence of treatment was similar for bDMARD and tofacitinib groups: 33.8 (95% confidence interval (CI) 28.8 to 40.4) and 34.2 (95% CI 32.2 to not reached) months, respectively. In the overall population, more patients were prescribed tofacitinib as monotherapy (43.4%) compared to bDMARD monotherapy (33.4%).

Conclusion: In this analysis of a large real world dataset, tofacitinib demonstrated treatment effectiveness and persistence that was similar to bDMARDs. Overall, there was a trend for more use of tofacitinib as monotherapy than bDMARDs.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (Xeljanz) is an approved treatment for Rheumatoid Arthritis (RA) but data on its use in "real life" are limited. We sought to analyze Tofacitinib drug retention in the Israeli registry and compare it to other mechanism of action agents (Etanercept, Golimumab, Tocilizumab, and Abatacept). Our hypothesis is that Tofacitinib drug retention is mainly influenced by the number of prior therapeutic lines and is similar to other biologic agents.

Methods: This prospective cohort study was based on data from the Israeli registry of RA, status February 2019. We included patients with RA according to the EULAR/ACR criteria. The primary end point was "drug retention". *Episode* was defined 'time on drug' as the period between treatment initiation and treatment discontinuation. We compared drug retention using Kaplan-Meier and Cox models over time with mixed-effects models for longitudinal data.

Results: A total of 864 eligible treatment courses (episodes) were retrieved from January 2010 until February 2019, including 111 Tofacitinib, 242 Etanercept , 99 Golimumab, 297 tocilizumab and 115 Abatacept. In the complete

cohort, the median age at diagnosis and at the time of episode was 47 (range: 0.5-87) and 59 (17-88) years, respectively; median disease duration was 10 (0.5-40) years. [for Tofacitinib only: the median age at the time of episode was 66 (21-88) years; median disease duration was 14 (0.5-50) years.] Tofacitinib was mostly prescribed as third or late line of therapy (64%), similar to Abatacept (63%), (p=0.892). Tofacitinib [HR 1.92, 95% CI:1.33-2.76] as well as all drugs considered had reduced drug survival (Etanercept [HR 1.65, 95% CI:1.26-2.18], Abatacept [HR 1.89, 95% CI:1.35-2.64], Golimumab [HR 1.56, 95% CI:1.08-2.24], Tofacitinib [HR 1.92, 95% CI:1.33-2.76]), in comparison with Tocilizumab which significantly had the best retention rate, at all lines of treatment. Interestingly, Tofacitinib median drug survival (15.8 [95% CI: 8.6-23.1] months) was non-inferior to Etanercept (26.4 [95%CI: 5.9-46.9]; p=0.426), Abatacept (20.3 [95%CI: 9.8-30.9; p=0.157), and Golimumab (15.1 [95%CI: 5.9-24.3]; p=0.698) at first and second line of biologics treatment. In a multivariate analysis, an advanced treatment line was associated with reduced Tofacitinib drug survival (p< 0.05). Age at episode, the duration of disease, body mass index, concomitant use of Methotrexate with Tofacitinib (HR 1.34, 95% CI [0.62-2.90]) and smoking were not found as parameters that influence drug survival.

Conclusion: The line of treatment with Tofacitinib may have influence on its survival. Moreover, there is no statistical difference in drug retention between Tofacitinib and the other compared bDMARDs except for Tocilizumab with demonstrated a longer survival.

Australian Rheumatoid Arthritis (RA) Biologic Treatment Pathways: An Australian Rheumatology Association Database (ARAD) Analysis

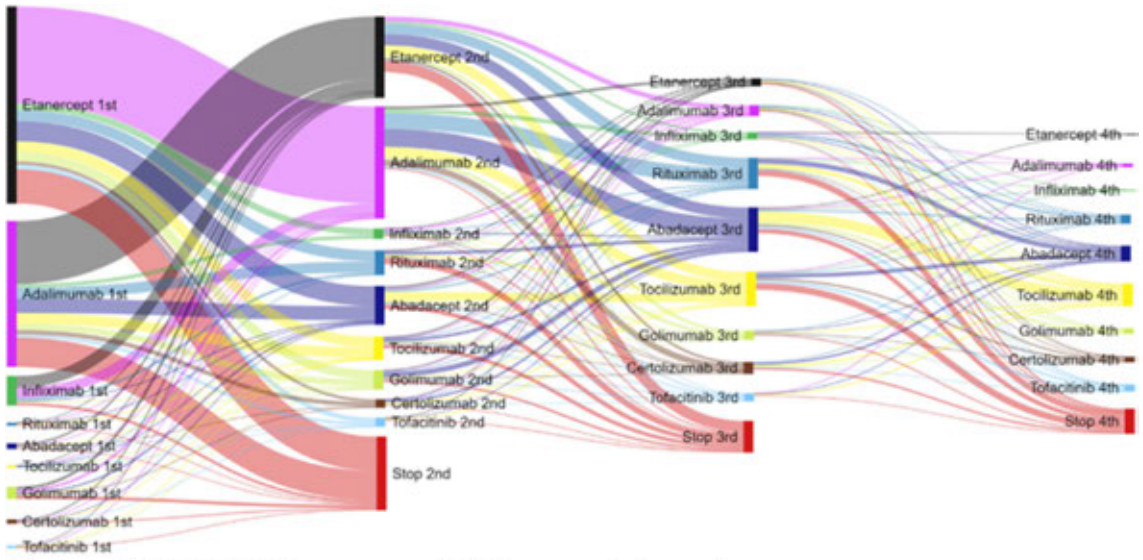
Ashley Fletcher,[1] **Marissa Lassere**,[2] Lyn March,[3] Catherine Hill,[4] Claire Barrett,[5] Graeme Carroll,[6] and Rachelle Buchbinder[1], [1]Cabrini Health/Monash University, Melbourne, Australia, [2]St George Hospital, University of New South Wales, Sydney, Australia, [3]University of Sydney, Sydney, Australia, [4]Royal Adelaide Hospital/The University of Adelaide/The Queen Elizabeth Hospital, Adelaide, Australia, [5]Redcliffe Hospital, University of Queensland, Redcliffe, Australia, [6]Fiona Stanley Hospital, Perth, Australia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

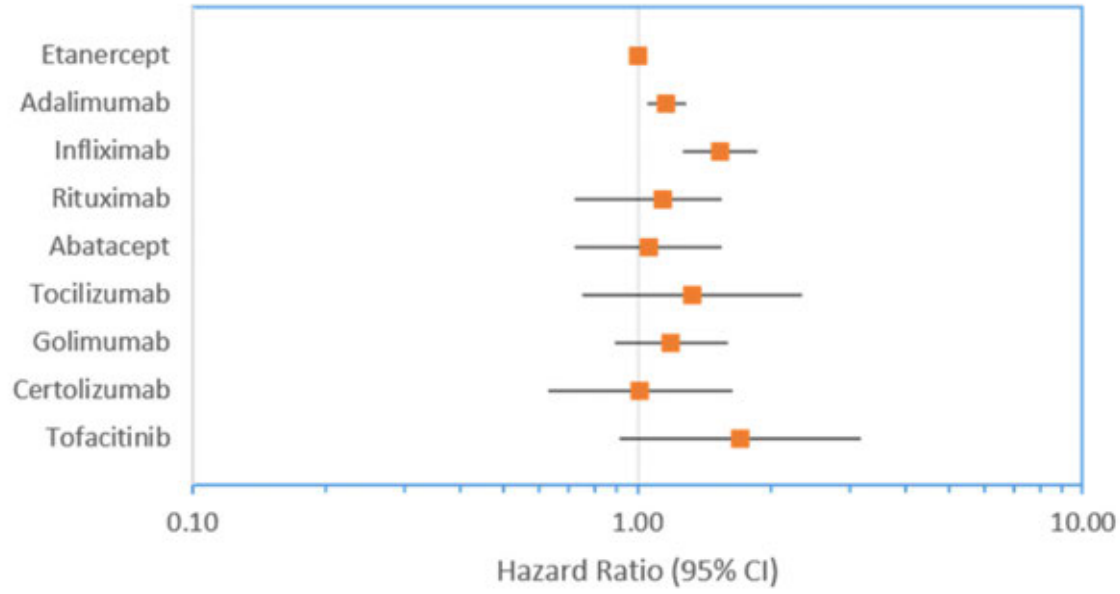
Background/Purpose: To describe current biologic disease-modifying antirheumatic drug (bDMARD) treatment patterns for Australian Rheumatology Association Database (ARAD) participants with Rheumatoid Arthritis (RA) including switching and reasons for switching.

Methods: ARAD, a voluntary longitudinal observational database established in 2001, collects long-term outcome data for people with inflammatory arthritis in Australia. Participants complete semi-annual, then annual questionnaires. Reasons for stopping bDMARD therapy, such as inefficacy or side-effects, were extracted from Sept. 2001 to May 2018 for all RA participants. Logistic regression was used to evaluate the characteristics of participants who switched compared to those who did not at first switch point. Switching patterns determined for each bDMARD and time on first, second and third-line bDMARDs were analysed using Cox regression survival analysis methods.

Results: 3,470 RA participants were included in the analysis. First-line bDMARDS were etanercept (ETA, n=1,414), adalimumab (ADA, n=1,024), infliximab (INX, n=155), golimumab (n=98), abatacept (ABA, n=66), certolizumab (n=38), tocilizumab (TOC, n=21), rituximab (n=24) and tofacitinib (TOF, n=23). 47.7% starting first-line bDMARD therapy switched to another bDMARD, 50.5% switched from second-line therapies and 42.3% switched from third-line therapies. Inefficacy (52.8%) or side effects (20.6%) were the most commonly cited reasons for stopping therapy, irrespective of line of treatment. Factors associated with switching compared to those continuing first-line use were female gender, tertiary education, more recent questionnaire year, higher HAQ score, current prednisolone and current opioid use as shown in the table. Switching due to side effects were more strongly associated with a higher HAQ score and longer duration of disease than with inefficacy.



Flow of bDMARD use - switching and stopping



Cox proportional hazard for stopping first-line bDMARD therapy

Table - Univariate and multivariable - significant factors associated with switching bDMARD compared to continuing use

Figure 1 shows the complex pattern of use of specific bDMARDs. The bars on the left represent the first-line bDMARD, subsequent use is represented as progressing from left to right. The thickness and colour of the lines indicate the number switching to the next line of bDMARD or stopping use.

The median time on first-line bDMARD varied from 258 days for ABA to 98 days for TOF. Compared with first-line ETA, participants were more likely to stop first-line ADA (HR 1.16; 95%CI: 1.04-1.29) and INX (HR 1.52; 95%CI: 1.26-1.85), whereas no differences were seen for other first-line bDMARDs (figure 2). For second-line therapies, compared to ETA, the risk of stopping was higher for INX and lower for TOC and TOF. For third-line, the risk of stopping was lower for all bDMARDs except INX.

Conclusion: Based on ARAD data, the treatment algorithm for bDMARD use in Australia is complex. Overall, around 50% of ARAD participants switch to another bDMARD therapy irrespective of the first, second or third-line bDMARD used. 50% of stoppages were due to inefficacy and 20% were due to side effects.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biologic agents used in patients with rheumatoid arthritis (RA) have increased in recent years. Abatacept (ABT) has been described as relatively safe for elderly patients because of lower risk of infectious events than other biologic agents. Tocilizumab (TCZ) was approved for marketing for use in patients with RA in Japan ahead of other countries in 2008. Randomized controlled trials have been shown the efficacy and safety of ABT and TCZ in RA patients. It is required to compare biologic agents in real clinical practice. Therefore, we investigated the efficacy, safety, and continuation rate of ABT and TCZ in patients with RA.

Methods: One hundred eighty three patients with RA treated with ABT or TCZ retrospectively observed for 12 months in Saitama Medical University Hospital since 2010 to 2018. We compared the baseline characteristics, disease activity, physical disability, drug continuation rate, and adverse events between the patients treated with ABT and TCZ.

Results: In ABT group (n=85) compared with TCZ group (n=98), we found older age at initiation of biologics (ABT vs. TCZ: 64 vs. 58 years, p=0.011), higher HAQ-DI score (1.5 vs. 1.0, p=0.003), higher titer of rheumatoid factor (318.2 vs. 126.5 IU/mL, p=0.001), and fewer MTX-users (44.7 vs. 62.2%, p=0.025). Disease duration, rate of female, naïve rate of biologics, body weight, DAS28-ESR4, CDAI, MMP-3, the positive rate of rheumatoid factor and anti-CCP antibody, dose of MTX and PSL at baseline were similar between the groups. CDAI and HAQ-DI significantly decreased at one year after initiation compared to baseline in both groups. The patients who achieved remission or low disease activity in CDAI at one year after initiation tended to be lower in ABT group than TCZ group (67.3 vs. 82.4%, p=0.061). There was no significant difference in the drug continuation rate (81.2 vs. 80.6%). In the patients who discontinued ABT or TCZ during one year of observational period, the rate of adverse events (10.6 vs.12.2%) and inefficacy rate (7.1 vs. 5.1%) as reasons for discontinuation were not significantly different between the groups. Infection occurred most commonly as adverse events in both groups (4.7 vs. 7.1%). In ABT group, the rate of PSL-users and daily dose of PSL significantly decreased in one year after initiation compared to those at baseline (69% vs. 60%, P=0.031, 6.4 vs. 6.0mg/day, p=0.002). In TCZ group, the rate of PSL-users and daily dose of PSL significantly decreased one year after initiation (60 vs. 35%, p< 0.001, 5.1 vs. 3.6 mg/day, p=0.003).

Conclusion: ABT was tended to be selected for patients, who had disadvantageous conditions such as older age, higher HAQ-DI, fewer MTX users at baseline, and ABT-treated patients achieved lower rates of remission or low disease activity one year after initiation compared to TCZ-treated patients. In spite of these different backgrounds of patients, rate of discontinuation for inefficacy, adherence, and safety were equivalent between the two groups.

CDAI Analysis of Dose Escalation in a Trial of Infliximab for Rheumatoid Arthritis

John Tesser,[1] Shawn Black,[2] Rongshuang Lin,[3] Wayne Langholff,[3] Jonathan Uy,[4] and Shelly Kafka[4], [1]Arizona Arthritis and Rheumatology Associate, Phoenix, AZ, [2]Janssen Scientific Affairs, LLC, Horsham, RI, [3]Janssen Research & Development, LLC, Spring House, PA, [4]Janssen Scientific Affairs, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In the START (Safety Trial for Rheumatoid Arthritis with Remicade Therapy) trial, patients (pts) with active rheumatoid arthritis (RA) received placebo (PBO), or infliximab (IFX) 3 mg/kg or 10 mg/kg, with a primary endpoint of safety at week 22. Pts receiving IFX 3 mg/kg had dose escalation if they met prespecified criteria for lack of response at week 22, which was assessed by combined swollen and tender joint count, S/TJC, (primary nonresponders). They also received dose escalation if they experienced a flare after week 22 (secondary nonresponders, not analyzed here) (1,2). In a post hoc analysis, we examine the effects of IFX dose escalation in the primary nonresponders, using the more relevant tool Clinical Disease Activity Index (CDAI), which includes the 28 S/TJC as well as pt and physician global assessments.

Figure 1. Percentage of Patients by CDAI Category among Primary Nonresponders to Infliximab 3 mg/kg Who Received Dose Escalation

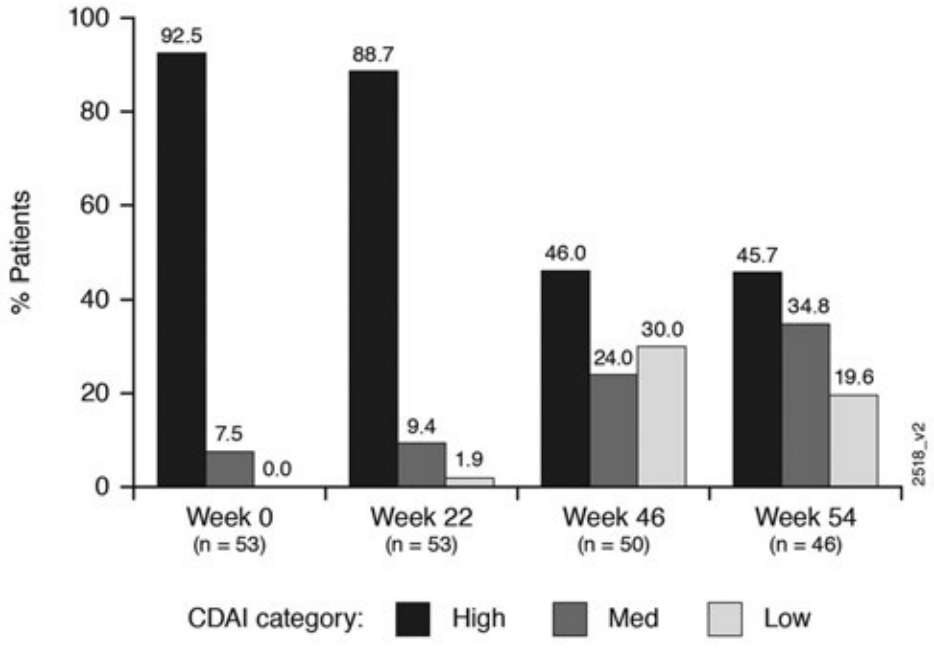

Figure 2. Percentage of Patients by CDAI Category among Primary Nonresponders Receiving Infliximab Doses ≥ 6 mg/kg

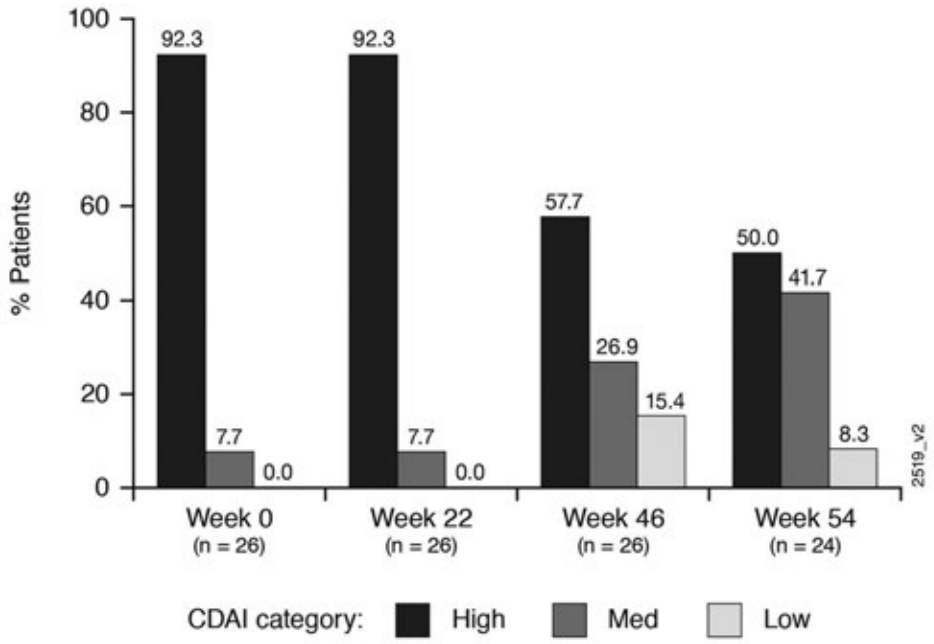

Methods: Adult START pts (N=1082) with 6 swollen and 6 tender joints, despite treatment with methotrexate (MTX), were randomized: PBO (n=363), IFX 3 mg/kg (n=360), or IFX 10 mg/kg (n=361) at weeks 0, 2, 6, and 14. At week 22, PBO pts switched to IFX 3 mg/kg for the remainder of the study, and pts randomized to IFX 3 mg/kg continued dosing every 8 weeks or received dose escalation (in increments of 1.5 mg/kg) every 8 weeks if there was lack of response (< 20% improvement from baseline in S/TJC). The study was terminated after 54 weeks (2).

Results: Among the 360 pts randomized to 3 mg/kg, 220 did not receive dose escalation during the study, 109 pts received dose escalation, and 31 discontinued or were from an excluded site. 53 of those receiving dose escalation were primary non-responders with lack of response at week 22 (2). Baseline characteristics were generally similar among these subgroups (80% female, mean 53 years old, SJC=15, TJC=22, and MTX 15 mg/week). Of the primary non-responders (n=53), IFX doses escalated to an average of 6.3 mg/kg (range 4.5 – 10 mg/kg). CDAI scoring (high, moderate, and low) improved from 89%, 9%, and 2% at week 22 to 46%, 24%, and 30% at week 46, and did not substantially improve further at week 54 (Figure 1). Among the subset of these pts who received doses ≥6 mg/kg (n=26), the average IFX dose was 7.7 mg/kg (range 6 – 10 mg/kg), and the CDAI scores (high, moderate, and low) of 92%, 8%, and 0% at week 22 improved to 58%, 27% and 15% at week 46, and also did not substantially improve further at week 54 (Figure 2).

Conclusion: In this analysis of CDAI in pts who initiated IFX 3 mg/kg and were dose escalated starting at week 22 (average dose 6.3 mg/kg), dose escalation generally improved pts' CDAI category (Figure 1). In a subset of pts who were escalated to doses ≥ 6 mg/kg (average dose 7.65 mg/kg), no further improvements in categorical CDAI were noted (Figure 2). Although START showed no increased risk of serious infections among pts receiving approved doses of INF vs PBO, pts who were treated with 10 mg/kg loading doses and maintenance therapy had more serious infections (relative risk=3.1) (1). These findings may be of clinical significance when considering dose escalation to higher doses of IFX.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Limited data are available on whether patients with rheumatoid arthritis (RA) are treated with conventional disease-modifying anti-rheumatic drugs (cDMARDs) according to the current recommendations before they initiate biologic DMARDs (bDMARDs) or JAK inhibitors (JAKis). We examined the treatment patterns among Korean RA patients who received bDMARDs or JAKis in a real world setting, using the 2002-2016 Korean National Health Insurance Service database that covers the entire Korean population.

Methods: We identified RA patients who initiated bDMARDs (TNF inhibitor, abatacept, rituximab and tocilizumab) or JAKis (tofacitinib). Their treatment patterns during 1 year after RA diagnosis (defined as free of any RA diagnosis or any DMARD use for one year before the diagnosis) and prior to the initiation of index drugs (bDMARDs or JAKis) were examined regarding: initial cDMARD used, dose and parenteral use of methotrexate (MTX), use and time to combination therapy of cDMARDs, and steroid use.

Results: 10,145 RA patients were identified who used index drugs from the database (mean age 57 years, 82% female). Among them, 6,986 patients had identifiable dates for RA diagnosis (mean age 57 years, 79% female). The mean (SD) duration from RA diagnosis to index drug initiation was 1,425 (1,162) days with 1,509 (22%) patients having a duration ≤1 year. At diagnosis, the most common 1st cDMARD used was hydroxychloroquine (63%), followed by MTX (55%) and sulfasalazine (29%) with steroids used in 75%. During the 1 year from the diagnosis, 85% of patients eventually used MTX, 42% ever used MTX ≥ 15mg/week, only 3% used parenteral MTX, and 85% patients used combined cDMARDs with a mean 188 days from the RA diagnosis to combination therapy. Patients whose maximal

Table 2. Treatment patterns before bDMARD initiation

	At RA dx N =6,986	During 1-year post-RA dx N =6,986	During 1-year period prior to bDMARD initiation N =10,145
Dose regimen of MTX			
Mean maximal dose, mg/week	-	14.1 ± 13.1	14.6 ± 15.4
Maximal MTX dose ever used, %			
< 10 mg/week	-	11.1 (13.0)†	8.3 (9.4)‡
10 - <15 mg/week	-	32.5 (38.2)†	34.3 (38.5)‡
15 - <20 mg/week	-	33.7 (39.6)†	37.8 (42.4)‡
≥ 20 mg/week	-	7.9 (9.3)†	8.7 (9.7)‡
Subcutaneous MTX users, %	0.4	2.8	3.9
Any csDMARD combination, %	47.2	85.7	98.9
MTX based csDMARD combination, %	39.2	79.1	82.0
Steroid users, %	75.2	61.9	97.5
Cumulative dose of steroid, mg (prednisolone equivalent dose)	-	2023 ± 1528	1899 ± 1329

† % among 5,953 MTX users
‡ % among 9,028 MTX users

MTX dose reached 20mg/week were rare (9%) and 62% were still on steroid after 1 year. During the 1 year prior to the index drug use (n = 10,145), the most common cDMARD was MTX used in 89% patients with 46% who ever used ≥ 15mg/week and 4% of parenteral users, followed by hydroxychloroquine (55%), leflunomide (52%), sulfasalazine (38%), and tacrolimus (20%). All patients used combination therapy and 98% steroids.

Conclusion: These data indicate that a substantial proportion of RA patient did not try maximal dose or parenteral use of MTX during the 1 year post-diagnosis as recommended by the current treatment guideline. Instead, they often used cDMARDs combination therapy. During the 1 year before initiating bDMARDs or JAKis, they were treated with intensive cDMARD combination therapy rather than escalating their MTX dose

Expression of Uncoupling Protein-1 in Subcutaneous Fat Is Increased by Tocilizumab

Lovisa Lyngfelt,[1] Malin Erlandsson,[2] Karin Andersson,[2] Sofia Silfverswärd,[2] and Maria Bokarewa[2], [1]Department of Rheumatology and Inflammation Research at Institute of Medicine, University of Gothenburg, Gothenburg, Sweden, [2]Department of Rheumatology and Inflammation Research, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden, Gothenburg, Sweden

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Adipose tissue is an important player in cardiovascular (CV) morbidity. Thermogenic brown adipocytes, rich with uncoupling protein 1 (UCP1), increase metabolic and CV health.

The aim of this study was to study the impact of anti-rheumatic treatment on production of UCP1 in subcutaneous fat of RA patients.

Methods: Samples of subcutaneous fat were collected from 125 female RA patients by aspiration from periumbilical region. Expression of UCP1 and a reverse cholesterol transport protein ABCA1 were measured by qPCR and analysied with respect to anti-rheumatic treatment and clinical disease activity. Bt treatment, the patient comprised 4 major groups including tocilizumab (Toci, n=14), anti-TNF (n=29), methotrexate monotherapy (n=47) and methotrexate-sulfasalazine-hyroxychloroquine (tripple therapy, n=15). CV risk was estimated with the Framingham risk algorithm.

Results: Measurable expression of UCP1 was found in 54.6% of the studied fat tissue samples. Patients on Toci had measurable expression of UCP1 in 79%, which was significantly more often than among TNFi-treated (45%, p=0.04) and MTX-treated patients (42%, p=0.02). Patients on triple therapy had also often measurable UCP1 levels compared to other groups (69% vs 43%, p=0.035). Toci patients have more lean body mass than patients treated with TNFi. This was based on lower BMI in Toci and TNFi treated patients compared to triple therapy (24.1 vs 27.1, p=0.041; 23.6 vs 27.1, p=0.017; respectively). Additionally, the estimated mucle mass by creatinin/height ratio was significantly lower in TNFi than in triple therapy (p=0.034) and Toci (p=0.008).Clinically, the treatment groups were similar in age, disease activity DAS28 and disease duration with the except for Toci. Toci patients were older (65 vs 57, p=0.04) and had numerically longer disease duration (17y vs 7y) and lower DAS28 (1.98 vs 3.11).

Notably, Toci patients had significantly higher TC compared to TNFi (p=0.027), and triple therapy (p=0.041). Triple therapy had the lowest TC levels (p=0.017). The differences were due to LDL, here patients on Toci had higher LDL than TNFi (p=0.09) and triple therapy (p=0.015). Serum HDL was similar. These differences in serum lipids were not related to expression of ABCA1 or UCP1. Despite the difference in the serum lipid profile, the estimated CV risk was significantly lower in Toci compared to MTX patients (4.1[0.87-5.75] vs 6.6[3.9-9], p=0.041).

Conclusion: In this study is Toci treatment is associated with persistent UCP1 production by adipose tissue. This was followed by lower estimated CV risk and favourable body composition in female RA patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: U-Act-Early was a 2-year multicentre, double-blind, randomized, placebo-controlled trial in early (DMARD-naïve) RA patients treated to the target of remission. Patients were assigned to step-up treatment strategies starting with tocilizumab (TCZ), methotrexate (MTX) or their combination (TCZ+MTX).[1] If the treatment target was not achieved, MTX and/or TCZ was added. When patients achieved and remained in remission for ≥ 24 weeks, medication was tapered and finally stopped.[1] Patients were followed for 3 years after the trial, during which treatment was at the discretion of the rheumatologist. The current study compares quality-adjusted life years (QALYs) and direct and indirect costs over 5 years between TCZ, MTX or TCZ+MTX initial strategy.

Methods: Costs were based on reported resource use and reference prices.[2] QALYs were calculated based on the EQ5D using Dutch tariff.[2] The economic evaluation considered all 317 randomized patients according to their allocated strategy group, using imputation with chained equations nested in bootstraps (5000 samples) to account for missing data and uncertainty.[3]

Total costs were calculated from the healthcare as well as the societal perspective. Values were discounted using a discount rate of 4% per year for costs, and 1.5% for QALYs according to Dutch guidelines for economic evaluations in healthcare.[2]

Differences in costs and QALYs were calculated for TCZ+MTX vs. MTX and TCZ vs. MTX over a 2 year and 5 year time horizon. Cost-effectiveness acceptability curves were constructed to illustrate the probability of TCZ(+MTX) being cost-effective at different willingness to pay (WTP) thresholds.

Results: Approximately 80% of all patients were employed at baseline, and worked on average 24 hours weekly without differences between strategy groups.

Differences in costs per category (i.e. costs for medication, direct healthcare, indirect non healthcare, and productivity loss) and QALYs are shown in the Table. Differences in QALYs increased between 2 and 5 years, without becoming statistically significant. In most cost categories, no differences were observed either over 2 or 5 years. Medication costs were, as expected, higher in the treatment strategies initiating TCZ. Savings were made in indirect non healthcare costs for TCZ+MTX and TCZ respectively, and productivity loss costs were numerically lower for TCZ. The probability of TCZ(+MTX) being a cost-effective intervention over 5 years, using different WTP thresholds for a QALY, was in general low, and somewhat higher for TCZ compared to TCZ+MTX, see Figure.

Conclusion: Based on current analyses, early initiation of TCZ, with or without MTX, is not cost-effective compared to MTX initiation in a step-up treat-to-target treatment strategy over 2 or 5 years in early RA patients. However, these outcomes are based on limited data.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In Phase 3 trial, RA-BEAM, baricitinib (BARI), a JAK1/JAK2 inhibitor, was associated with significant clinical improvements vs. placebo (PBO) and adalimumab (ADA) in RA patients.[1] Although BARI and ADA had similar improvement in swollen joint count, BARI demonstrated statistically significantly greater pain improvement. While pain is a generic feature of inflammation, not all pain in RA is due to inflammation, and the contribution of different pathways to pain is unclear. In this post hoc analysis, we assessed the relationship between pain improvement and disease activity and evaluated whether BARI provided additional pain improvement vs. PBO and ADA across levels of disease activity.

Methods: 1,305 patients on stable background MTX were randomized 3:2:3 to and treated with PBO, 40 mg subcutaneous ADA every other week, or daily, oral 4 mg BARI. Pain was assessed with a 0-100 mm visual analog scale (VAS); pain improvement from baseline to Week 12 was grouped by ≤30%, >30% to ≤50%, >50% to ≤70%,

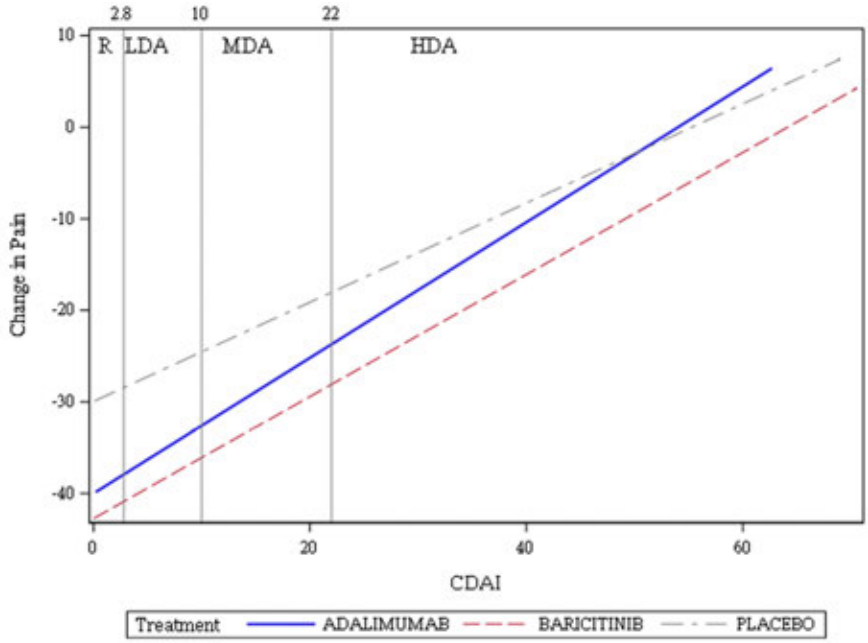

Figure 1. Estimated change in pain VAS by CDAI values at Week 12

	PBO	ADA	BARI	PBO	ADA	BARI	PBO	ADA	BARI
	-32.3	-37.8	-42.9	-28.9	-34.1	-39.1	-18.0	-22.5	-26.9

HDA values are those in excess of the threshold value for MDA and are not presented

Abbreviations: ADA: adalimumab, BARI: baricitinib, CDAI: Clinical Disease Activity Index; CRP: C-reactive protein; DAS28: Disease Activity Score for 28 joints; ESR: erythrocyte sedimentation rate; LDA: low disease activity; MDA: moderate disease activity; PBO: placebo; SDAI: Simplified Disease Activity Index

and >70%[2]. Disease activity was measured with the Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI), Disease Activity Score for 28 joints (DAS28) with C-reactive protein (CRP), and DAS28 with erythrocyte sedimentation rate (ESR). To evaluate change in pain with disease activity, regression was used with continuous change in pain VAS score from baseline to Week 12 as the outcome and continuous CDAI/SDAI/DAS28-CRP/DAS28-ESR values, treatment, and the interaction term between treatment and disease activity as explanatory variables. Last observation carried forward was used to impute missing values. Pain VAS change at Week 12 was estimated from regression for all treatments if patients achieved remission (REM)/low disease activity (LDA)/moderate disease activity (MDA) as defined by the corresponding clinical measure. Analyses were not adjusted for multiplicity. Data visualization with the percentage of pain VAS improvement vs. disease activity was created to examine pain improvement with treatment over time.

Results: With CDAI, 91% of patients had high disease activity and 9% had MDA across all treatments at baseline. At Week 12, the percentage of patients who achieved REM with PBO, ADA, and BARI, respectively, were 2%, 7%, 8%; for LDA: 15%, 27%, 33%; for MDA: 33%, 40%, 38%.[3] At all CDAI values, the estimated change in pain VAS for BARI was greater vs. PBO and ADA (Figure 1); the BARI line is below lines for PBO and ADA across the CDAI range. Similar trends were observed with other disease activity measures (Table). Figure 2 shows the percentage of patients with ≤30%, >30% to ≤50%, >50% to ≤70%, and >70% pain improvement from baseline at Week 12 by disease activity. BARI demonstrated greater pain improvement vs. ADA and PBO in all disease activity categories. With CDAI/SDAI, greater differentiation between BARI and ADA was observed as CDAI/SDAI values increased.

Conclusion: BARI provided additional pain improvement vs. PBO and ADA when disease activity was controlled and across all levels of disease activity, as measured by CDAI, SDAI, DAS28-CRP, or DAS28-ESR at Week 12.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Via a systematic literature review of contemporary efficacy data of pharmacological therapies in RA we sought to inform the 2019 update of the EULAR recommendations for the management of RA.

Methods: A systematic literature review to investigate the efficacy of any DMARD (conventional synthetic (cs) DMARD, bDMARD, tsDMARD) or glucocorticoid (GC) therapy in patients with RA. MEDLINE, Embase and the Cochrane Library were searched for articles published between 2016 and March 8th 2019. Open-label studies were acceptable for strategy trials or trials investigating treatment changes

Results: Of 7876 unique abstracts 234 were selected for detailed review with 136 finally included. Twenty-one studies investigated the efficacy of bDMARDs vs. placebo, with 14 studies meeting their primary efficacy endpoint (PEP). Seven head-to-head (H2H) trials comparing bDMARDs and three H2H trials comparing tsDMARD to bDMARDs were included (Table 1). Twenty placebo-controlled trials demonstrated efficacy of JAK inhibitors across different patient populations. Two studies investigated switching of bDMARD therapy in TNFi primary non-responding patients: one trial evaluated the superiority of switching to non-TNFi bDMARDs and met its PEP, while the second evaluated superiority of switching from adalimumab to certolizumab-pegol (CZP) but did not meet its PEP. Stopping or tapering of bDMARDs and/or csDMARDs/GCs was investigated in 22 studies. Using concomitant csDMARDs when tapering bDMARDs lowered the risk of flaring, while tapering csDMARDs in patients with ongoing bDMARD therapy increased the risk of flaring in most studies. All studies investigating biosimilars (n=17) showed non-inferiority compared to their reference products. Further, switching between bDMARD originators and their respective biosimilars showed non-inferiority across all studies (n=11). An open-label strategy trial compared an MRI-guided treat-to-target (T2T) strategy to a conventional T2T strategy (using DAS28-CRP) and failed to show any benefit regarding clinical outcome or radiographic progression. Another open-label strategy RCT stratified patients naïve to csDMARDs according to poor prognostic factors into different csDMARD/GC combination regimes and reported comparable clinical and radiographic results across groups.

Conclusion: The efficacy of many different bDMARDs as well as tsDMARDs was shown in studies included in this SLR. Switching to TNFi or non-TNFi bDMARDs after TNFi treatment failure seems to be feasible. Tapering of bD-

Table 1. Head-to-head studies investigating biological DMARDs or tsDMARDs versus other biological DMARDs.

Population	Study	Agent	Control	Type	RoB	PEP

Abstract Number: 1409

Comparison of Healthcare Resource Utilization and Costs of Type 2 Diabetes Mellitus (T2DM)-Related Complications in Medicare Beneficiaries with Rheumatoid Arthritis (RA) and T2DM Who Initiated Treatment with Abatacept versus Other Targeted Disease-Modifying Anti-Rheumatic Drugs

Vardhaman Patel,[1] Zulkarnain Pulungan,[2] Anne Shah,[2] Barton Jones,[2] Allison Petrilla,[2] Leticia Ferri,[3] Xue Han,[3] and Kaleb Michaud[4], [1]Bristol-Myers Squibb, New York City, NY, [2]Avalere, washington, DC, [3]Bristol-Myers Squibb Company, Princeton, NJ, [4]University of Nebraska Medical Center, Omaha, NE

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Use of abatacept, a targeted DMARD (tDMARD), in patients with RA has shown to improve whole-body insulin sensitivity and reduce HbA1c levels.[1] Comparative evidence on type 2 diabetes mellitus (T2DM) related outcomes against other tDMARDs is lacking. We measured the healthcare resource utilization (HCRU) and costs associated with T2DM in tDMARD-naïve Medicare beneficiaries with RA and T2DM who initiated treatment with abatacept, tumor necrosis factor inhibitors (TNFi), or other non-TNFi.

Methods: Patients initiating abatacept, a TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, infliximab), or other non-TNFi (anakinra, rituximab, sarilumab, tocilizumab, tofacitinib) from 2010 through 2017 were identified in a retrospective cohort using 100% Medicare fee-for-service (FFS) claims (Parts A/B/D). Elderly patients (≥65 years of age) were included if they had ≥2 diagnoses of RA, ≥1 diagnosis of T2DM or treated with T2DM medications, no recent history of cancer, and were continuously enrolled for 12 months pre-index date or the date of tDMARD initiation. Post-index follow-up was until discontinuation of the index treatment, disenrollment, death, or end of study period, whichever occurred first. Patients who initiated abatacept were propensity score (PS) matched to initiators of TNFi and non-TNFi separately on baseline demographics, comorbidities, medications, T2DM-related healthcare re-

Table. Rates and costs of T2DM-related complications after initiating tDMARDs

Measures	PS-matched cohort 1		PS-matched cohort 2	
	Abatacept (N = 2,664)	TNFi (N = 2,664)	Abatacept (N = 1,507)	Other Non-TNFi (N = 1,507)

T2DM = Type 2 diabetes mellitus, DME = durable medical equipment, PPPM = per-patient per month

source use and costs. T2DM-related complications include neuropathy, nephropathy, cerebrovascular, cardiovascular, retinopathy, peripheral vascular disease and metabolic from the validated Diabetes Severity Complication Index (DCSI).[2] The HCRU of T2DM-related complications was measured using the counts of inpatient stay, ER visits and outpatient visits per 1,000 patients per month whereas costs (2019 USD) were measured as per-patient per month (PPPM).

Results: A total of 2,664 PS-matched pairs of abatacept and TNFi's users, and 1,507 PS-matched pairs of abatacept and other non-TNFi's users were identified. During follow-up, the rate of hospitalizations associated with T2DM-

related complications per 1,000 patients per month was the lowest in abatacept group compared to both TNFi (23.0 vs. 26.0) and other non-TNFi groups (25.5 vs. 32.7). Similar trends were observed for ER visits and outpatient care. The major driver of T2DM-related healthcare costs for each group was hospitalizations. PPPM T2DM-related complication costs decreased following tDMARD initiation in abatacept (˃20%) and TNFi (17%) users and increased in non-TNFi users (1.5%). During follow-up, PPPM T2DM-related costs were $58 and $159 lower for abatacept versus TNFi and non-TNFi initiators, respectively.

Conclusion: In Medicare FFS beneficiaries with RA and T2DM, abatacept initiators had lower T2DM-related HCRU and costs compared to initiators of TNFis and non-TNFis. These findings suggest that use of abatacept as a first line tDMARD could help reduce the clinical and economic burden associated with T2DM in patients with RA.

Cycling of Tumor Necrosis Factor-α (TNF-α) Inhibitors versus Switching to Different Mechanism of Action in Rheumatoid Arthritis Patients with Inadequate Response to TNF-α Inhibitor: A Bayesian Network Meta-analysis

Alberto Migliore,[1] Giuseppe Pompilio,[2] Davide Integlia,[2] Joe Zhuo,[3] and Evo Alemao[4], [1]Unit of Rheumatology Ospedale S. Pietro Fatebenefratelli, Rome, Italy, [2]Isheo Srl, Rome, Italy, [3]Bristol-Myers Squibb, Princeton, NJ, [4]Bristol-Myers Squibb, Princeton

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TNF inhibitors are a common treatment for rheumatoid arthritis (RA), but there is no best practice for when a specific TNF inhibitor stops working[1]. The main options are to 'cycle' patients onto a different TNF inhibitor, or to 'switch' patients onto a drug with a different mechanism of action. Building on a previous developed systematic review of existing RCTs and observational studies, this network meta-analysis (NMA) assess the clinical comparative efficacy of 'cycling' versus 'switching'.

Methods: We conducted a literature search in MEDLINE, Embase and Cochrane Library in June 2018. RCTs and observational studies investigating second-line treatments for rheumatoid arthritis, respectively for TNF inhibitor (adalimumab, infliximab, etanercept, certolizumab, golimumab) and drugs with different mechanism of action (Moa) were considered.

The outcomes included the mean reduction in HAQ score; proportion of patients with a clinically meaningful HAQ reduction (defined as a reduction of at least 0.22); proportion of patients with a 20% (ACR20), 50% (ACR50) or 70% (ACR70) response on the ACR score; proportion of patients achieving a DAS28 score below 2.6 (classified as remission) or between 2.6 and 3.2 (classified as low disease activity); mean change in DAS28 score; rate of serious adverse events (SAEs); and number of withdrawals for any reason or due to adverse events or lack of treatment efficacy.

Risk of bias was assessed both RCTs and observational studies through Cochrane Risk of Bias Tool and Newcastle-Ottawa Scale respectively. We classed interventions as 'cycle', 'switch' or placebo and performed three models of NMA: a fixed effect model, a random-effect model and hierarchical Bayesian network meta-analysis[2,3] for each outcome with appropriate data**.**

Results: We identified 9 RCTs (4 for 'cycling' and 5 for 'switching') and 16 observational studies (8 for 'cycling' and 8 for 'switching') meeting our inclusion criteria, with patient numbers ranging from small studies of 15 patients up to 1683 patients. The proportion of females in the studies were at least 71.1% and the mean age of participants ranged from 45.1 to 59.0 years.

ACR20 – main results – all studies

Statistic	Fixed	LB	UB	Random	LB	UB	Hierarchical	LB	UB
DIC	100			101			111		
OR cycle vs PBO	2.81	2.12	3.89	2.88	1.76	6.07	3.31	1.69	10.46
OR switch vs PBO	3.86	3.11	4.87	3.80	2.50	5.67	3.77	2.12	7.26
OR switch vs cycle	1.38	1.06	1.78	1.33	0.63	2.08	1.14	0.32	2.39

ACR50 – main results – all studies

Statistic	Fixed	LB	UB	Random	LB	UB	Hierarchical	LB	UB
DIC	76			77			98		
OR cycle vs PBO	3.86	2.53	6.20	3.82	1.99	6.55	3.84	1.87	7.39
OR switch vs PBO	5.15	3.68	7.52	5.27	3.31	8.29	5.33	3.26	8.82
OR switch vs cycle	1.35	0.96	1.81	1.38	0.88	2.41	1.39	0.69	2.69

Withdrawals due to lack of efficacy – main results – all studies

Statistic	Fixed	LB	UB	Random	LB	UB	Hierarchical	LB	UB
DIC	94			69			111		
OR cycle vs PBO	0.23	0.1	0.5	0.32	0.02	7.01	0.31	0.02	6.75
OR switch vs PBO	0.08	0.05	0.13	0.1	0.01	0.67	0.09	0.01	0.69
OR switch vs cycle	0.35	0.19	0.62	0.3	0.02	4.17	0.29	0.02	3.78

DIC: Deviance Information Criterion; OR: Odds Ratio; PBO: Placebo; LB: Lower Bound; UP: Upper Bound; Fixed: Fixed Effect Estimate; Random: Random Effect Estimate; Hierarchical: Hierarchical Estimate.

The fixed effects NMA suggested a 0.99 probability that 'switch' was the better strategy for increasinng the odds of a clinically meaningful improvement in ACR20 (OR: 1.38 [95% CI: 1.06-1.78]). 'Switch' was also associated with fewer rates of withdrawals due of lack of efficacy (OR: 0.35 [95% CI: 0.19-0.62]) and withdrawals for any reasons.

Random effects and hierarchical Bayesian models reflected additional uncertainty but gave similar results. (Figure 1)

Conclusion: Results suggest that "switching" to a drug with a different mechanism of action is more effective and with lower rates of withdrawals than "cycling" to a different TNF inhibitor after first-line TNF inhibitor failure. Further trials to directly compare 'cycling' with 'switching' is warranted to better assess the comparative efficacy.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) occasionally overlaps Sjogren's syndrome (SS), and RA patients with secondary SS have a higher disease activity of RA and worse joint damage compared with RA patients without SS.

A previous report indicated that the positivity of anti-Ro/SSA antibody (Ab), which is diagnostic maker for SS, was an independent factor associated with poor response to tumor necrosis factor inhibitors in RA patients. While, abatacept have showed the efficacy of both synovitis and glandular symptoms in RA patients with secondary SS. However, few reports show comparable efficacy of abatacept therapy between anti-Ro/SSA Ab-negative and -positive patients with RA.

To clarify whether the positivity of baseline anti-Ro/SSA Ab influence response to abatacept therapy, we compared clinical profiles between anti-Ro/SSA Ab-negative and -positive patients with RA using a multicenter RA ultrasonography prospective cohort.

Table 1. Baseline participant characteristic by positivity or negativity of anti-Ro/SSA antibody (univariate analysis)

Variables	All patients (n = 51)	Anti-Ro/SSA Ab-negative group (n = 35)	Anti-Ro/SSA Ab-positive group (n = 16)	p-value
Patient characteristics at baseline				
Age (years)	70.0 (66.0 – 77.0, n = 51)	73.0 (67.0 – 79.0, n = 35)	66.5 (57.5 – 72.3, n = 16)	0.04
Disease duration (month)	32.0 (12.0 – 132.0, n = 51)	31.0 (12.0 – 120.0, n = 35)	56.0 (9.8 – 249.0, n = 16)	0.92
Male gender (%)	12/51 (23.5%)	10/35 (28.6%)	2/16 (12.5%)	0.30
Smoking history (%)	9/51 (17.6%)	7/35 (20.0%)	2/16 (12.5%)	0.70
Comorbidity at baseline				
Interstitial pneumonia (%)	13/51 (25.5%)	10/35 (28.6%)	3/16 (18.8%)	0.73
Definite diagnosis of SS (%)	8/51 (15.7%)	1/35 (2.9%)	7/16 (43.8%)	< 0.001
Medication at baseline				
Concomitant prednisolone use (%)	29/51 (56.9%)	22/35 (62.9%)	7/16 (43.8%)	0.24
Doses of concomitant prednisolone (mg/day)	2.0 (0.0 – 5.0, n = 51)	4.0 (0.0 – 5.0, n = 35)	0.0 (0.0 – 6.4, n = 16)	0.36
Concomitant DMARDs use (%)	43/51 (84.3%)	31/35 (88.6%)	12/16 (75.0%)	0.24
Concomitant methotrexate use (%)	25/51 (49.0%)	17/35 (48.6%)	8/16 (50.0%)	1.00
Clinical disease activity at baseline				
Baseline DAS28-ESR	5.2 (4.3 – 5.9, n = 51)	5.3 (3.9 – 5.9, n = 35)	5.0 (4.6 – 6.0, n = 16)	0.90
Baseline DAS28-CRP	4.2 (3.5 – 5.1, n = 51)	4.4 (3.4 – 5.1, n = 35)	4.1 (3.8 – 5.2, n = 16)	0.79
Baseline SDAI	20.5 (14.4 – 30.7, n = 51)	20.5 (14.1 – 30.7, n = 35)	20.4 (17.2 – 30.4, n = 16)	0.75
Baseline CDAI	19.0 (14.0 – 27.0, n = 51)	18.0 (14.0 – 26.5, n = 35)	20.3 (16.9 – 28.5, n = 16)	0.33

Table 1. Baseline participant characteristic by positivity or negativity of anti-Ro/SSA antibody (univariate analysis)

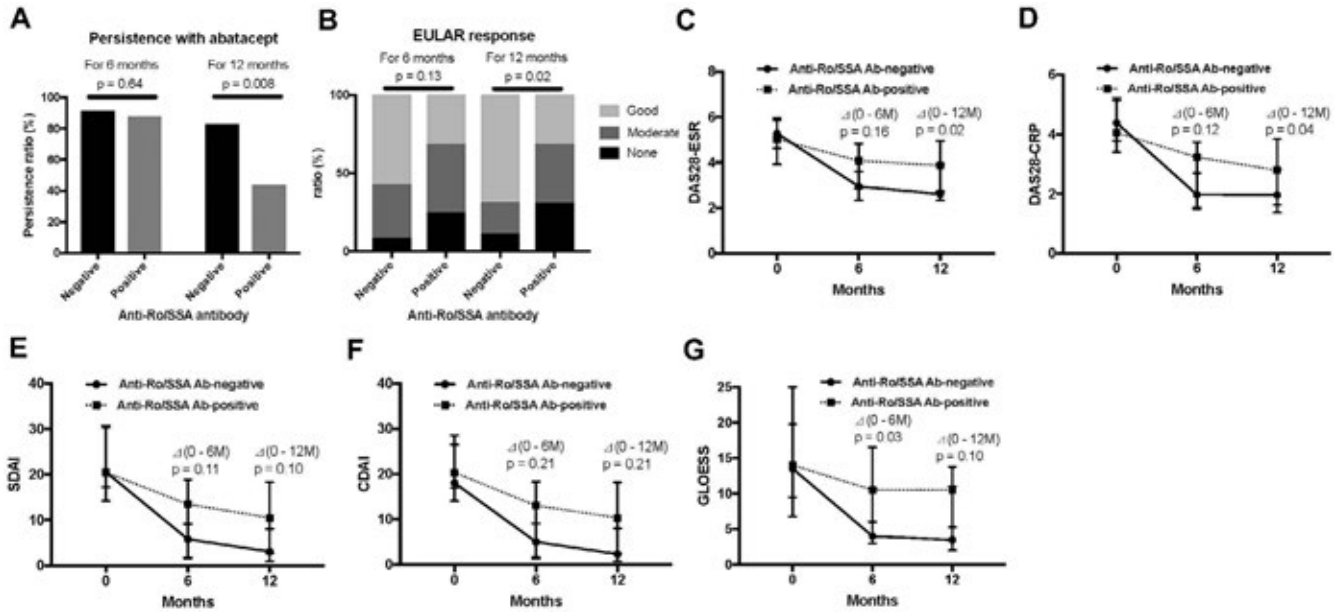

Figure 1. Persistence, response, and each disease activity indicator at 6 or 12 months by positivity or negativity of anti-Ro/SSA antibody

Methods: We initially reviewed Japanese RA patients who newly started abatacept therapy as a first biological DMARDs between June 2013 and April 2018. Subsequently, we excluded patients whose baseline anti-Ro/SSA Ab status were uncleared and patients with baseline low disease activity at the initiation of abatacept therapy. Overall, enrolled total 51 patients were divided into anti-Ro/SSA Ab-negative and -positive groups of 35 and 16, respectively, according to the result of anti-Ro/SSA Ab assay. The Global OMERACT-EULAR Synovitis Score (GLOESS), which is composite PDUS scores of the greyscale (GS) and power Doppler (PD), was calculated at above examined 22 joints as an indicator of comprehensive ultrasonography activity.

Results: The median age at baseline was significantly higher in anti-Ro/SSA Ab-negative group ($p = 0.04$). Anti-Ro/SSA Ab-positive group had significantly higher frequencies of definite SS diagnosis and baseline antinuclear antibody $\geq$ 80 times ($p < 0.001$, $p = 0.02$, respectively). The persistence ratio and the percentage of EULAR good responders at 12 months were significantly higher in anti-Ro/SSA Ab-negative group ($p = 0.008$, $p = 0.02$, respectively). Although there was no significant difference in changes in both SDAI and CDAI scores between anti-Ro/SSA Ab-negative and -positive groups, both DAS28-ESR and DAS28-CRP scores decreased significantly at 12 months in anti-Ro/SSA Ab-negative group ($p = 0.02$, $p = 0.04$, respectively). In addition, GLOESS scores also decreased significantly at 6 months in anti-Ro/SSA Ab-negative group ($p = 0.03$). Univariate and multivariate analyses showed that negativity of anti-Ro/SSA Ab was an independent factor associated with good responders to abatacept therapy.

Conclusion: Our results indicate that the positivity of anti-Ro/SSA Ab confer poor response and persistence to abatacept therapy by comprehensive assessments.

Table 2. Comparison of selected variables associated with good responders to abatacept treatment in multiple logistic regression analysis (continuous variables)

	Variables		p-value	OR (95% CI)
Model 1	Disease duration (month)	1 increase	0.27	1.003 (0.998–1.009)
	Male gender (%)	Presence	0.23	2.980 (0.505–17.564)
	Definite diagnosis of SS (%)	Presence	0.08	0.158 (0.020–1.231)
	Doses of concomitant prednisolone (mg/day)	1 increase	0.10	0.893 (0.780–1.023)
	Baseline antinuclear antibody ≥ 80 times (%)	Presence	0.72	0.788 (0.215–2.891)
Model 2	Disease duration (month)	1 increase	0.40	1.002 (0.997–1.008)
	Male gender (%)	Presence	0.18	3.656 (0.552–24.233)
	Baseline anti-Ro/SSA Ab positive (%)	Presence	0.03	0.198 (0.046–0.854)

Table 2. Comparison of selected variables associated with good responders to abatacept treatment in multiple logistic regression analysis (continuous variables)

Abstract Number: 1412

Efficacy and Safety of Tofacitinib Modified-Release 11 Mg Once Daily + MTX in RA Patients with an Inadequate Response to MTX: Open-Label Phase Results from a Global Phase 3b/4 MTX Withdrawal Study

Stanley Cohen,[1] Janet Pope,[2] Boulos Haraoui,[3] Eduardo Mysler,[4] Annette Diehl,[5] Tatjana Lukic,[6] Shixue Liu,[7] Lori Stockert,[5] Sujatha Menon,[8] and Edward Keystone[9], [1]Metroplex Clinical Research Center, Dallas, TX, [2]Western University, London, ON, Canada, [3]Institut de Rhumatologie de Montréal, Montréal, QC, Canada, [4]Organización Médica de Investigación, Buenos Aires, Argentina, [5]Pfizer Inc, Collegeville, PA, [6]Pfizer Inc, New York, NY, [7]Pfizer Inc, Shanghai, China (People's Republic), [8]Pfizer Inc, Groton, CT, [9]Mount Sinai Hospital and University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA. The tofacitinib modified-release (MR) 11 mg once daily (QD) formulation was first approved in the US in 2016 for the treatment of patients (pts) with moderate to severe RA and an inadequate response or intolerance to MTX. ORAL Shift is the first global study of tofacitinib MR 11 mg QD + MTX. Efficacy and pt-reported outcomes (PROs), and safety, from the open-label (OL) phase of ORAL Shift are reported here.

Methods: ORAL Shift (NCT02831855) was a global Phase 3b/4 study in pts aged ≥ 18 years with moderate to severe RA and an inadequate response to MTX. Pts received OL tofacitinib MR 11 mg QD + MTX (tofacitinib + MTX) for 24 weeks; those achieving low disease activity (LDA; Clinical Disease Activity Index [CDAI] ≤ 10) at Week (W)24 entered the 24-week double-blind (DB) MTX withdrawal phase, where the primary endpoint was assessed (data reported elsewhere).[1] Outcomes from the OL phase, reported descriptively here, include: mean change from baseline (BL) to W12 and W24 in disease activity measures, and PROs; rates of ACR and HAQ-Disability Index (DI) response, and LDA and remission, at W12 and W24 (see Table 1); and safety (see Table 2).

Results: In the OL phase, 694 pts received tofacitinib + MTX. Most pts were female (76.7%), white (85.6%), with a mean age of 56.8 years and mean RA duration of 8.8 years. At W24 (end of the OL phase), 526 (75.8%) pts achieved CDAI-defined LDA (Table 1). In the OL phase, Disease Activity Score in 28 joints, ESR (DAS28-4[ESR]) improved with

Table 1. Efficacy and patient-reported outcomes during the open-label phase

Opportunistic infections[c]	0
GI perforation[c]	0
PE	0

[a]Safety data are from the safety analysis set (all patients who received at least one dose of tofacitinib + MTX during the open-label phase). Events are counted up to 28 days beyond the last dose. [b]All herpes zoster events reported involved one or two adjacent dermatomes and were non-serious; [c]Reviewed by an independent adjudication committee
AE, adverse event; ALT, alanine aminotransferase; GI, gastrointestinal; MACE, major adverse cardiovascular event; MedDRA, Medical Dictionary for Regulatory Activities; MR, modified-release; MTX, methotrexate; n, number of patients with an event; NMSC, non-melanoma skin cancer; PE, pulmonary embolism; PT, preferred term; QD, once daily; SAE, serious adverse event

mean (standard deviation) changes from BL of -1.96 (1.19) and -2.67 (1.25) at W12 and W24, respectively (Table 1). Mean changes from BL at W12 and W24 showed improvements in all other efficacy outcomes and PROs (Table 1). ACR20/50/70 and HAQ-DI response rates, and LDA and remission rates, improved from W12 to W24 (Table 1). Adverse events (AEs), serious AEs, and discontinuations due to AEs were reported by 52.2%, 2.9%, and 5.9% of pts, respectively; no deaths were reported (Table 2). The most common AEs were nasopharyngitis and upper respiratory tract infections. AEs of special interest each occurred in ≤ 1% of pts (Table 2).

Conclusion: Tofacitinib MR 11 mg QD + MTX improved disease activity and PROs in pts with moderate to severe RA and an inadequate response to MTX. No new safety risks were observed. Efficacy and safety in this OL phase appeared consistent with that of tofacitinib immediate-release 5 mg twice daily[2], with the DB phase of ORAL Shift.[1]

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of RA. Greater improvements in efficacy outcomes have been reported with tofacitinib 5 mg BID ± conventional synthetic DMARDs in patients (pts) with early vs established RA.[1,2] This post hoc analysis of ORAL Strategy data evaluated the efficacy and safety of tofacitinib monotherapy, tofacitinib + methotrexate (MTX), and adalimumab (ADA) + MTX, stratified by baseline (BL) RA duration.

Methods: ORAL Strategy (NCT02187055) was a P3b/4, 1-yr, double-blind, triple-dummy, active comparator-controlled study. MTX inadequate-responders were randomized 1:1:1 to receive tofacitinib 5 mg BID (tofa mono), tofacitinib 5 mg BID + MTX (tofa+MTX), or ADA SC 40 mg Q2W + MTX (ADA+MTX); MTX was dosed at 15–25 mg/wk except in cases of intolerance/toxicity. In this analysis, pts were stratified by BL RA duration as having early (≤ 2 yrs) or established (> 2 yrs) RA. Efficacy outcomes (Months [M]3, 6 and 12): ACR20/50/70; change from BL (Δ) in DAS28-4(ESR), Simplified Disease Activity Index (SDAI) and Clinical Disease Activity Index (CDAI); and rates of DAS28-4(ESR)-, SDAI- and CDAI-defined low disease activity (≤ 3.2, ≤ 11, and ≤ 10, respectively) and remission (< 2.6, ≤ 3.3, and ≤ 2.8, respectively). Nominal p values for treatment comparisons were calculated without multiplicity

Table 1. Demographics and disease characteristics at baseline, and safety up to Month 12

	Early RA (≤2 years) N=241			Established RA (>2 years) N=905		
	Tofacitinib monotherapy N=80	Tofacitinib + MTX N=83	Adalimumab + MTX N=78	Tofacitinib monotherapy N=304	Tofacitinib + MTX N=293	Adalimumab + MTX N=308
Baseline demographics and disease characteristics[a]						
Age (years), mean (SD)	47.1 (12.9)	46.2 (13.8)	49.2 (13.5)	50.4 (12.0)	51.0 (13.1)	51.0 (13.3)

Safety, n (%)						
AEs	52 (65.0)	47 (56.6)	53 (67.9)	174 (57.2)	184 (62.8)	200 (64.9)
SAEs	10 (12.5)	2 (2.4)	8 (10.3)	25 (8.2)	24 (8.2)	16 (5.2)

[a]N for each assessment may differ from N for each treatment group; [b]Average dose immediately prior to randomization
AE, adverse event; Anti-CCP, anti-cyclic citrullinated peptide antibody; CDAI, Clinical Disease Activity Index; DAS28-4(ESR), Disease Activity Score in 28 joints based on erythrocyte sedimentation rate; GC, glucocorticoid; HAQ-DI, Health Assessment Questionnaire-Disability Index; MTX, methotrexate; RA, rheumatoid arthritis; RF, rheumatoid factor; SAE, serious adverse event; SDAI, Simplified Disease Activity Index; SD, standard deviation; TNFi, tumor necrosis factor inhibitor; wk, week

adjustment; $p < 0.05$ was considered significant. Treatment-emergent AEs and serious AEs (SAEs) were assessed throughout the study.

Results: In total, 241 pts had early RA (tofa mono: N=80; tofa+MTX: N=83; ADA+MTX: N=78; mean RA duration: 1.0–1.1 yrs); 905 pts had established RA (tofa mono: N=304; tofa+MTX: N=293; ADA+MTX: N=308; mean RA duration: 9.4–10.4 yrs). BL demographics and disease characteristics were generally comparable for early vs established RA pts, with some expected differences (the latter were slightly older, and a greater proportion had received prior biologic DMARDs); RF+ and anti-CCP+ rates were higher for established RA pts (Table 1). ACR50 and ΔDAS28-4(ESR) were generally similar for tofa mono and tofa+MTX up to M12 in early RA but significantly greater with tofa+MTX in established RA ($p < 0.05$); generally, ADA+MTX was not statistically different vs tofa+MTX in early RA (Figure 1). Trends were similar for all outcomes. AE rates were generally similar in early vs established RA. Trends for SAEs were less clear; rates were lowest for tofa+MTX in early RA and higher for both tofacitinib arms vs ADA+MTX in established RA (Table 1).

Conclusion: Efficacy was similar for tofa mono and tofa+MTX in early RA, and significantly higher with tofa+MTX in established RA. ADA+MTX was numerically but not always significantly more effective than tofacitinib in early RA. AE rates were generally similar regardless of BL RA duration. These findings, especially in established RA, are consistent with the conclusion of the primary analysis.[3] Limitations to this post hoc analysis include low numbers of early RA pts.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In rheumatoid arthritis (RA), the proinflammatory cytokine IL-6 is associated with mental disorders such as depression and anxiety.[1] Furthermore, depression and anxiety are comorbidities associated with a lower response to RA therapy.[2]

In this interim analysis (data cut-off 1 Feb 2019) of the non-interventional study ARATA, we analyzed the possible influence of depressiveness and anxiety on the effectiveness of tocilizumab (RoActemra®) therapy for the first time

Methods: The ARATA study (NCT02251860) examined the effectiveness and tolerability of subcutaneous tocilizumab therapy in patients with RA in routine practice for up to 104 weeks. Patients were divided into subgroups according to Beck Depression Inventory (BDI)-II or State-Trait Inventory (STAI-X2) category at baseline.

Results: The safety and effectiveness sets were comprised of 627 and 574 patients, respectively. Patients in all depressive symptom and anxiety categories benefitted from tocilizumab therapy (tables 1 and 2), regardless of baseline characteristics. Patients had an overall reduction in depressiveness, and a slight reduction of fear and anxiety in all depressiveness categories. During tocilizumab treatment, patients with positive answers to the question about su-

icidal ideation benefitted the most in regards to disease activity outcomes (DAS28-ESR, CDAI), while patients with severe depressive symptoms benefitted the least. The more severe anxiety categories had greater proportions of patients with a HAQ-DI improvement of at least 0.5 at week 104.

Results in patients-reported outcomes mirrored the results in effectiveness outcomes. Patients without, with mild or with moderate depressive symptoms and patients with positive answers to the question about suicidal ideation had

			Depressive symptoms (BDI-II)

¥Safety/effectiveness set
CRP and ESR were analyzed in the safety set.
BDI-II, STAI-X1 and STAI-X2, DAS 28-ESR, CDAI, HAQ-DI, fatigue, insomnia and pain were analyzed in the effectiveness set. At week 104, 184/1198 patients had completed the BDI-II, 250/1198 patients had completed the STAI-X1 and 248/1198 patients had completed the STAI-X2. Baseline data was not available for all patients.
*Patients with data at the visit
Abbreviations: BL=baseline, CRP=C-reactive protein, ESR=erythrocyte sedimentation rate, BDI-II=Beck Depression Inventory (no depressive symptoms: BDI-II score 0-13; mild depressive symptoms: BDI-II score 14-19; moderate depressive symptoms: BDI-II Score 20-28; severe depressive symptoms: BDI-II Score 29-63; Suicidal ideation= answer on BDI-II question "9. Suicidal ideation" ≥ 1), SD=standard deviation, STAI=State-Trait Anxiety Inventory (mild fear or anxiety: X1 or X2 score 20-≤30; moderate fear or anxiety: X1 or X2 score 31-≤50; severe fear or anxiety: X1 or X2 score > 50), DAS-28=Disease Activity Score, CDAI=Clinical Disease Activity Index, HAQ-DI=Health Assessment Questionnaire-Disability Index, VAS=Visual Analog Scale

reductions in fatigue, insomnia and pain. In contrast to insomnia, patients with severe depressive symptoms had slight increases in fatigue and pain.

Fatigue, insomnia, and pain were reduced in all three anxiety categories – the more severe the anxiety category, the greater the reductions were in insomnia and pain.

Adverse events were documented more often for patients with depressive symptoms and anxiety. However, there was no difference in serious adverse events. Discontinuation due to adverse events increased with more severe depressive symptoms and anxiety.

Conclusion: For the first time, the influence of depressiveness and anxiety on TCZ effectiveness was investigated in a German collective of RA patients in routine practice. The interim analysis of the non-interventional ARATA study underlines not only the clinical effectiveness and safety, but also a positive influence of the therapy on depressiveness, anxiety, fear, fatigue, insomnia and pain. Patients with severe depression did not benefit from fatigue and pain despite improved disease activity.

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatoid arthritis (RA) have an increased risk for cardiovascular diseases. Recent studies found that RA patients present dysfunctional high density lipoproteins (HDL) with low activity of paraoxonase 1 (PON1), which might contribute to the increased cardiovascular risk. Tofacitinib has been associated with an increase in total cholesterol (TC) and low density lipoproteins (LDL-c). The objective of this study was to compare functional markers of HDL at baseline and 3 months after tofacitinib in patients with RA.

Methods: Patients diagnosed with RA (ACR / EULAR 2010 criteria) who started tofacitinib were included from January 2016. Patients with personal history of cardiovascular disease, renal, hepatic or thyroid alterations were excluded.

Table 1. Baseline characteristics of patients with Rheumatoid Arthritis.

	Biologic DMARD naive (n =16)	With previous biologic DMARD (n= 18)	P value	Total (n =34)
Age at diagnosed, years, mean (SD)	54.3 (15.9)	42.4 (18.6)	0.06	47.7 (17.9)
Female, n (%, CI 95%)	13 (81.2, 53.0-94.3)	18 (100)	**0.05**	31 (91.17)
Duration of disease, months, median (IQR)	102 (53-132)	150 (108-192)	**0.04**	120 (78-180)
Positive FR, n (%, CI 95%)	11 (68.7, 41.5-87.2)	13 (72.2, 46.3-88.7)	0.82	24 (70.6,52.4-83.9)
Anti CCP, n (%, CI 95%)	12 (75.0, 47.1-90.9)	16 (88.9, 62.5-97.5)	0.29	28 (82.3, 64.8-92.2)
Baseline DAS 28, mean (SD)	4.9 (1.19)	5.2 (0.96)	0.40	5.1 (1.1)
Baseline HAQ, mean (SD)	1.25 (0.69)	1.24 (0.62)	0.99	1.25 (0.64)
Use of statins, n (%, CI 95%)	3 (18.7, 5.7-46.9)	0	**0.05**	3 (8.8, 2.7-25.2)
Current use of corticosteroids, n (%, CI 95%)	9 (56.3, 30.8-78.7)	14 (77.8, 51.6-91.9)	0.18	23 (67.6, 49.5-81.7)
Baseline total cholesterol(mg/dl), mean (SD)	205 (34)	187 (35.6)	0.1425	196 (35.5)
Baseline HDL (mg/dl), mean (SD)	55 (12.6)	57 (13.4)	0.7211	55.8 (13)
Baseline LDL (mg/dl), mean (SD)	124 (33)	105 (34)	0.1021	114 (34)
Baseline Triglycerides (mg/dl), mean (SD)	137 (43)	109 (31)	**0.0341**	122 (39)
Baseline PON (nmol/ml.min), mean (SD)	130 (47)	166 (78)	0.1129	149 (67)
Baseline ARE (umol/ml.min), mean (SD)	103 (32)	114 (24)	0.2870	109 (29)
Baseline CETP (%/ml.h), mean (SD)	149 (29)	144 (36)	0.6931	146 (32)

Table 2. Baseline and at 3 months values of functional parameters of HDL.

	Biologic DMARD naive (n =16)	P valor	With previous biologic DMARD (n= 18)	P valor	Total group	p
Baseline PON, mean (SD)	130 (47)	0.0299	166.6 (78)	0.3328	149 (67)	Mean difference 4.4 P 0.32
PON 3 months, mean (SD)	145.6 (66)		161 (74)		153.9 (69.5)	
Baseline ARE, mean (SD)	103.6 (32.5)	**0.0164**	114 (24)	0.3225	109 (29)	Mean difference 3.1 P 0.29
ARE 3 months, mean (SD)	114 (29)		111 (25)		112.3 (26.4)	
Baseline CETP, mean (SD)	149 (29)	0.084	144 (36)	0.8804	146.3 (32.2)	Mean difference 5.4 P 0.36
CETP 3 months, mean (SD)	161 (40)		143 (24)		151.6 (33.6)	

DAS-28, lipid profile and ultrasensitive C-reactive protein (usPCR) values were analyzed by standardized methods at baseline and 3 months after tofacitinib. The activity of PON1 was evaluated on two substrates, paraoxon (PON activity) and phenylacetate (ARE activity). Differences in quantitative variables were analyzed through paired Wilcoxon test and McNemar test was used for qualitative variables. Correlations were analyzed with Spearman test.

Results: Patients baseline characteristics are shown in Table 1. Patients were positive for rheumatoid factor in 70.6% (95% CI 52.4-83.9) and anti-CCP in 82.3% (95% CI 64.8-92.2). Eighteen patients (52.95%) were biologic DMARDs failures and the remaining ones received tofacitinib after conventional DMARDs failure. At three months of follow up, DAS28 decreased significantly (-24%, $p < 0.001$), and TC, C-LDL, HDL-C and C-non-HDL levels increased significantly (TC: + 8%, $p = 0.046$, LDL-C: 8%, $p = 0.046$; HDL-C: + 8%, $p = 0.027$ and C-non-HDL: + 13%, $p = 0.031$). No changes were observed in PON or ARE activity associated with tofacitinib use in the whole cohort. Sub analysis on patients not previously treated with biologic DMARDs showed a significant increase in the activity of ARE and PON (Table 2). None of the groups showed significant changes in the cholesteryl ester transfer protein (CETP).

Conclusion: On biologic DMARD naïve patients, treatment with tofacitinib improved the antioxidant activity of HDL (paroxonase activity), in spite of an increase in the overall lipoprotein levels. This might provide additional protection to the accelerated atherosclerotic process.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatoid arthritis (RA) is a chronic, inflammatory and heterogeneous autoimmune disorder of unknown etiology characterized by progressive joint damage. Although TNF inhibitors (TNFi) have contributed to change the natural history of RA, approximately 30-50% of patients do not respond to this therapy and only a maximum of 47% achieved clinical remission. The aim of this study was to investigate whether the blood immunological profile at baseline of patients with RA could contribute to predict clinical remission to TNFi.

Methods: This is a prospective bi-center pilot study including 98 patients with RA that initiated a TNFi therapy. Clinical activity was assessed at baseline and after 6 months of treatment by disease activity score 28 (DAS28), considering optimal response if patients reached remission (DAS28≤2,6). We obtained PBMC before treatment and different leukocyte subsets were evaluated by flow cytometry in a FACSCantoII instrument. Baseline characteristics of the patients included in the study were collected. All the analyses were adjusted by sex, anti-citrullinated peptide antibodies (ACPA), rheumatoid factor (RF), baseline-c reactive protein (CRP) and baseline-DAS28 through univariable and multivariate logistic regression models (odds ratio; 95% CI; p value).

Results: At 6 months of follow-up, 39% of patients reached remission by DAS28 (REM patients). Univariable analyses were performed to investigate the association between clinical remission and baseline variables: a significant association was found for positivity of RF, presence of ACPA, lower CRP and lower baseline DAS28. In the multivariate analysis, only lower baseline DAS28 (OR: 0.32; 95% CI: 0.18-0.56; p< 0.0001) remained independently associated with REM after 6m of treatment. Basal leukocyte profile clearly differentiated between REM versus no-REM patients. REM patients showed higher percentage of B cells (OR=1.19; 95%; CI:1.05-1.35; p=0.007) and naive B cells (Bn; OR=1,32; 95%; CI:1.08-1.61; p=0.007) than no-REM patients at baseline (Figure 1). The other PBMC subsets (monocytes, NK cells, CD4+ and CD8+ T cells subtypes) did not show statistical differences.

Conclusion: Our results suggest that B cell profile would be the group of determinant cells to organize the response to TNFi in patients with RA. Further studies are necessary for a better understanding of the biological meaning of the increase in the naive B cells in REM patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term registries are essential to evaluate new therapies in a patient population that differs from clinical trials and usually varies over time. The purpose was to describe the profile of rheumatoid arthritis (RA) patients treated with infliximab (IFX), golimumab subcutaneous (GLM) or intravenous (GLM-IV) in Canadian routine care, along with its effectiveness and safety.

Methods: A total of 1577 RA patients treated with IFX, GLM or GLM-IV were enrolled into the Biologic Treatment Registry Across Canada (BioTRAC) between 2006-2015, 2010-2017 and 2014-2017, respectively. Study visits occurred at baseline and every 6 months thereafter. Effectiveness was assessed with changes in TJC28, SJC28, MDGA, PtGA, pain, HAQ, and acute phase reactants. Safety was evaluated with the incidence of adverse events (AEs) and drug survival.

Results: Of the 890 IFX-, 530 GLM- and 157 GLM-IV-treated patients, the proportion of females were 75.7%- 77.1%, the mean age were 55.8-57.7 and the mean disease duration were 6.5-8.6 years. Most patients were bio-naive (> 80%).

A significant decrease in disease duration and disease activity scores (DAS, TJC, SJC, HAQ, AM stiffness, MDGA, PtGA, CRP, ESR) were observed in the IFX cohort over time ($p< 0.001$). Interestingly, baseline disease duration and disease activity scores for the GLM cohort (DAS, TJC, SJC, PtGA, Pain, CRP, ESR) were higher than in the IFX cohort from 2010-2012 when GLM was first introduced while the mean MDGA remained the same between the two groups.

Treatment with IFX, GLM and GLM-IV significantly improved all disease parameters over time ($P< 0.001$) from baseline to 6 months and up to 120, 78 and 42 months, respectively. The proportion of patients in SDAI remission at 12, 24 and 36 months reached 16.2%, 20.8% and 22.8% in IFX-patients; 34.7%, 47.5% and 52.7% in GLM-patients and 33.8%, 47.5% and 61.9% in GLM-IV-patients ($p=0.1978$ and $p=0.0081$ vs IFX).

AEs were reported for 61.5%, 67.4% and 59.2% (105, 113 and 82.6 events/100 PYs) and SAEs for 21.2%, 15.5% and 3.8% (11.7, 11.2 and 4.68 events/100 PYs) covering 2714, 1077 and 257 years of exposure for IFX, GLM and GLM-IV-treated patients, respectively. The most frequently occurring AEs were arthralgia and upper respiratory tract infection (>5%). Eighteen, 7 and 1 deaths occurred among IFX-, GLM- and GLM-IV-treated patients, respectively. The proportion of patients who discontinued treatment were 74.0% over a mean 3.0 years of exposure to IFX-, 52.8% over 2.0 years of exposure to GLM and 45.2% over 1.6 year of exposure to GLM-IV.

Conclusion: In this real-world study of Canadian patients with RA, differences in baseline characteristics between patients treated with an anti-TNF over time and between agents shows potential selection biases when selecting a given therapy and may impact the proportion of patients achieving a target-specific outcome. Treatment significantly reduced disease activity and improved functionality in a similar fashion and were also safe and well tolerated.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Biologic Treatment Registry Across Canada (BioTRAC) was a prospective, observational registry that enrolled rheumatoid arthritis (RA) patients treated with either subcutaneous golimumab (GLM-SC) or intravenous golimumab (GLM-IV) between 2010 and 2017. The registry was closed in June 2018.

Methods: Patient visits occurred at baseline and every 6 months thereafter. Multivariate logistic regression was used to identify independent predictors of achieving specific efficacy and safety endpoints and included the following covariates: age, gender, disease duration, enrolment period, concomitant medication, smoking and employment.

Results: A total of 687 Golimumab treated patients (530 GLM-SC and 157 GLM-IV) were enrolled and followed for a mean of 2.0 and 1.6 years, respectively. Most patients were bio-naive (> 80%).

DAS28-CRP low disease activity was more likely to be achieved with lower baseline DAS28-CRP [OR (95% CI): 0.73 (0.57–0.92); p=0.009], among those with concomitant DMARD use [2.86 (1.35–6.08); p=0.006], and in patients who were employed [2.26 (1.18–4.33); p=0.014]. However, it was less likely among those with baseline concomitant corticosteroid (CS) use [0.55 (0.30–0.99); p=0.047]. DAS28-CRP remission was more likely to be achieved in males [OR (95% CI): 2.06 (1.10–3.86); p=0.023], later enrolment [2013–2015 vs. 2010–2012: 1.91 (1.02–3.59); p=0.045], and among those with concomitant DMARD use [3.15 (1.53–6.51); p=0.002] and less likely in patients with baseline concomitant CS use [0.37 (0.22–0.62); p< 0.001]. A HAQ-DI < 0.5 was more likely to be achieved with lower age [OR (95% CI): 0.98 (0.96–1.00); p=0.023), in males [2.00 (1.10–3.67); p=0.024], lower baseline HAQ-DI scores [0.13 (0.08–0.20); p< 0.001], higher baseline CRP levels [1.01 (1.00–1.02); p=0.009], in patients who were employed [2.0 (1.09–3.53); p=0.026], and among those with GLM-SC vs. GLM-IV treatment [2.19 (1.12–4.31); p=0.023].

AEs were more likely to occur with lower baseline CDAI [OR (95% CI): 0.98 (0.97–1.00); p=0.023], and in patients with baseline concomitant CS [1.62 (1.04–2.52); p=0.032] or NSAID use [1.79 (1.19–2.70); p=0.005], whereas SAEs were less likely to occur in patients enrolled later [2013–2015 vs. 2010–2012: 0.42 (0.23–0.79); p=0.007 and 2016–2017 vs. 2010–2012: 0.18 (0.08–0.44); p< 0.001], and in those with baseline DMARD use [0.37 (0.18–0.79); p=0.009].

Early treatment period (2013–2015 vs. 2016–2017: 0.58 [0.39–0.87], p=0.008) and concomitant DMARD use [0.58 (0.37–0.90); p=0.016] increased the likelihood of treatment continuation.

Conclusion: In this real-world, long-term prospective cohort of RA patients treated with golimumab, concomitant DMARD use at baseline appears to be a positive predictor of achieving treatment targets, avoiding SAEs and treatment retention. Patients with concomitant CS at baseline, however, were less likely to meet efficacy endpoints and at higher risk of AEs. Finally, patients enrolled later had a lower likelihood of experiencing an SAE but a higher likelihood of discontinuation, possibly driven by the larger availability of treatment options and/or more rigorous adherence to treat to target guidelines.

Cost-per-Responder Analysis of Sarilumab for the Treatment of Moderately-to-Severely Active Rheumatoid Arthritis (RA)

Marie Fournier,[1] Susan Boklage,[2] Florence Joly,[1] **Kerri Ford**,[3] Zsofia Kiss,[4] Peter Gal,[4] and Jeannie Choi[5], [1]Sanofi, Chilly-Mazarin, France, [2]Regeneron Pharmaceuticals, Inc, Tarrytown, NY, [3]Sanofi Genzyme, Bridgewater, NJ, [4]Evidera, London, United Kingdom, [5]Formerly of Sanofi, Bridgewater, NJ

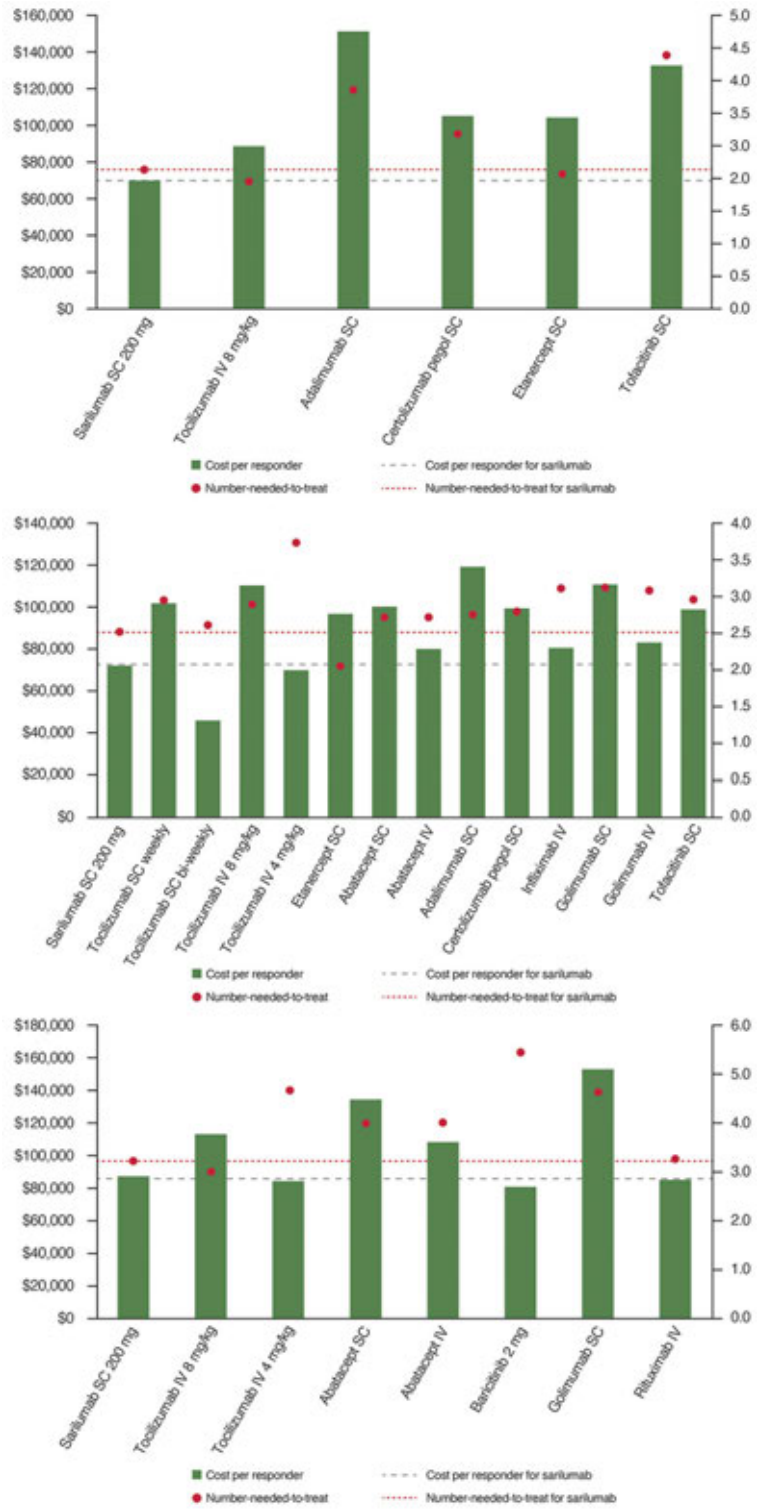
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Network meta-analyses (NMA) have been conducted to compare the efficacy and safety of sarilumab, a fully human monoclonal antibody against the interleukin 6 receptor α, vs other monotherapies for patients with RA who were inadequate responders to, inappropriate candidates for, or intolerant of conventional synthetic disease-modifying antirheumatic drugs (csDMARD-IR)[1] and vs other combination treatments with methotrexate in patients with inadequate response to csDMARDs[1] or anti-tumor necrosis factor therapy[2] (csDMARD-IR and TNF-IR, respectively). Using this comparative efficacy data, the present study evaluated 1-year costs associated with obtaining treatment response with sarilumab 200 mg subcutaneous (SC) vs other currently used therapies in these patient populations.

Methods: Cost-per-responder (CPR) analyses were conducted on 2018 US wholesale acquisition costs of drugs and administration. The number-needed-to-treat (NNT) to obtain one responder per American College of Rheumatology (ACR)50 was derived from the NMAs of sarilumab.[1,2] Responders were assumed to receive treatment for 12 months; non-responders were assumed to stop treatment after 6 months without subsequent treatments. Scenario analyses were conducted on ACR20 and ACR70 criteria.

Results: For monotherapies in csDMARD-IR (**Figure A**), the NNT for sarilumab (2.4) was lower vs all comparators except etanercept (2.3) and tocilizumab intravenous (IV) 8 mg/kg (2.2). Sarilumab had the lowest CPR ($69,440) vs all treatments (ranging from $150,348 for adalimumab SC to $88,291 for tocilizumab IV 8 mg/kg). For combinations in csDMARD-IR (**Figure B**), the NNT for sarilumab (2.5) was lower vs all comparators except etanercept (2.1). Sarilumab CPR ($72,438) was lower vs all comparators ($119,559 for adalimumab SC to $80,409 for abatacept IV) except lower

dose intensities of tocilizumab (IV and SC). In TNF-IR (**Figure C**), the NNT for sarilumab (3.2) was lower vs all combinations except vs tocilizumab IV 8 mg/kg (3.0). Sarilumab CPR ($87,047) was lower vs all comparators ($152,551 for golimumab SC to $107,761 for abatacept IV) except tocilizumab IV 4 mg/kg, baricitinib 2 mg and rituximab IV. Scenario analysis results were similar except per ACR70 lower CPRs for certolizumab and etanercept monotherapies, and a higher CPR for tocilizumab IV 4 mg/kg in combination (csDMARD-IR and TNF-IR populations).



Conclusion: Due to the lower NNT for sarilumab vs most comparators and reasonable cost, sarilumab achieved better CPR outcomes vs all monotherapies, vs all combinations except lower dose intensities of tocilizumab in csDMARD-IR and except baricitinib and rituximab in the TNF-IR population.

*Reimbursement starting in June 2019

1: There are no national recommendation but in the label it is recommended together with methotrexate if possible

2: Reimbursement since 2014 in non-bionaive patients and since 2016 in bionaïve patients

3: The decision to reimburse by the National Health System may take a long time. Patients with other health systems (e.g. private insurance) can have access to the medication as soon as EMA approves it.

Table 2 Information on market introduction, reimbursement and national recommendation about JAKi

Background/Purpose: In many countries, JAK-inhibitors (JAKi) have been recently accepted for the treatment of patients with rheumatoid arthritis (RA). However, prescription patterns may differ notably between countries, which may influence effectiveness and safety analyses. The purpose of this study was to evaluate how and to whom JAKi are prescribed as a first investigation of an international collaboration of registers aiming at analysing the effectiveness and safety of JAKi.

Methods: Patients with diagnosis of RA, treated with either tofacitinib or baricitinib, and included in one of the registers participating in the JAK-pot collaboration registers (17 registers) were investigated. We used standard descriptive statistics to evaluate patient-, disease-, and treatment characteristics, as well as year of treatment initiation. Information on marketing and reimbursement date and national recommendations/guidelines were also retrieved using a questionnaire sent to a register representative in each country of the collaboration.

Results: A total of 3,804 patients initiating JAKi were included, with 4 countries having access only to tofacitinib (Table 1). Patients were on average >50 years old, with disease duration >10 years and mostly female. Patients generally had moderate to high disease activity (DAS28 > 3.2) at JAKi initiation, high levels of inflammatory markers and mild to moderate disability (Table 1). Seropositivity status (ACPA or RF) varied from 49.7 to 92.5% as could be expected since none of the countries had recommendations related to antibodies (Table 2). Treatment characteristics varied widely between countries: between 6.1 and 61.3% of patients had not received a previous bDMARDs (but only in one country JAKi was recommended only after failure of bDMARDs, Table 2); between 0.9 to 60.2% patients were prescribed JAKi as monotherapy; between 14.2 to 99.1% received concomitant glucocorticoids. Indeed, national recommendations on the use of concomitant csDMARD treatment varied by country (Table 2) but in every country, JAKi was prescribed after at least one csDMARDS failure. The first years of JAKi initiation in the registers ranged from 2012 to 2016 depending on the availability of this class of treatment (Tables 1 and 2). In some countries, compassionate use was possible before market availability.

Conclusion: JAKi were prescribed to a population that was similar in terms of age, gender, disease duration, disease activity and functional disability between countries, but differed greatly in terms of seropositivity, number of previous bDMARDs and use of csDMARD co-medication, which was not attributable to differences in national treatment recommendations. These differences must be taken into account when analyzing the real-life effectiveness and safety of JAKi across different countries and in collaborative studies.

Baseline ARE (umol/ml.min), mean (SD)	73.8 (22)	

Table 2. Baseline and 3 months after the start of treatment values of characteristics of HDL and LDL.

Background/Purpose: In patients with Rheumatoid Arthritis (RA), qualitative alterations of low and high density lipoproteins (LDL and HDL, respectively) might partially explain their increased cardiovascular risk. Tocilizumab has been associated with increase in lipids, including triglycerides (TG) and cholesterol levels, in all its lipoprotein fractions. The aim of this study was to compare, in patients with RA, the effect of tocilizumab on HDL and LDL characteristics at baseline and 3 months after the start of treatment.

Methods: patients diagnosed with RA (ACR/EULAR 2010 criteria) who received tocilizumab were included from November 2016. Patients with personal history of cardiovascular disease, renal, hepatic or thyroid alterations were excluded. Clinical assessment (Health assessment questionnaire -HAQ-, DAS28) lipid profile, and ultrasensitive C reactive protein (usCRP) by standardized methods were collected in all patients at baseline and after three months of follow up. Lipoproteins characteristics were measured with the activity of paraoxonase (PON1) evaluated through the activity of arylesterase (ARE), and by the ability to promote the efflux of cholesterol from foam cells generated in vitro, and by levels of oxidized LDL (LDLox). Changes were evaluated by paired means difference tests and correlations between lipoproteins characteristics and acute phase reactants were analyzed by Spearman tests.

Results: baseline characteristics of the 34 patients included are shown in Table 1. Most of the patients were seropositive (table 1). Twenty-five patients (74%) had been previously treated with other biologics disease-modifying antirheumatic drugs (DMARDs) while 9 (26%) received tocilizumab after conventional DMARDs failure. 59% of patients used monotherapy tocilizumab and 41% used concomitant conventional DMARD (methotrexate: 71.4%). At three months, DAS28 (-51%, $p < 0.001$), HAQ (-23.57%, $p = 0.0045$) and usCRP decreased significantly. Total cholesterol and LDL-C levels increased significantly after 3 months of treatment (CT: 9.2%, $p = 0.03$ and LDL-C: 11.29%, $p = 0.0072$). A decrease in LDLox was observed after 3 months of treatment (11.29%, $p = 0.0156$). No changes were observed in arylesterase activity or HDL capacity to promote cholesterol efflux ($p > 0.05$) in the whole group (Table 2). Changes in HDL efflux correlated positively with ARE activity ($r = 0.58$, $p = 0.03$), and with CRP levels reduction ($r = -0.77$, $p = 0.021$).

Conclusion: treatment with tocilizumab decreased LDLox levels, (a classic risk factor for cardiovascular disease) in spite an increase in total cholesterol and LDL-C levels. Decreases in usCRP levels significantly correlated with an improvement of HDL anti atherogenic capacities.

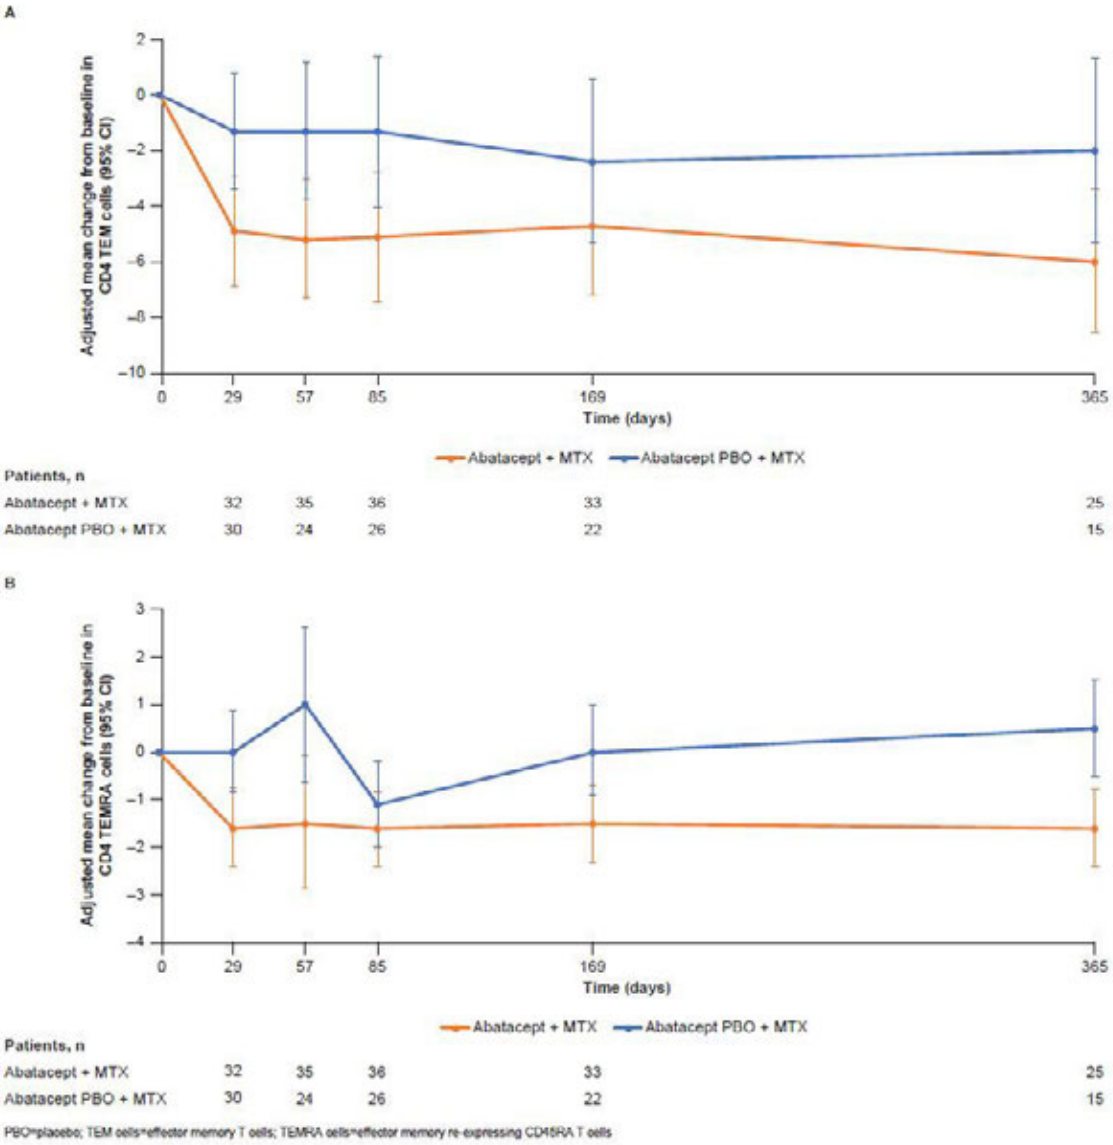
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: T-cell profiles are heterogeneous between individuals and consist of naïve T cells, memory T cells (including effector memory T cells [TEM] and central memory T cells [TCM]) and short-lived or terminally differentiated effector cells (effector memory re-expressing CD45RA [TEMRA] cells).[1] CD4 TEMRA cells (CD4+CD8–CD45RA+CD197–) vary in frequency and function, including distinct cytotoxic properties, between healthy individuals.[2] However, their role in RA is unknown. The ongoing Phase IIIb Assessing Very Early Rheumatoid arthritis Treatment (AVERT)-2 trial (NCT02504268) aims to assess the efficacy and safety of abatacept (ABA) + MTX, vs ABA placebo (PBO) + MTX, in achieving clinical remission in DMARD-naïve adults with early RA, using stringent SDAI ≤3.3 criteria.[3] We assessed the pharmacodynamic modulation of CD4 T-cell phenotypes and its association with ABA treatment (tx) response in AVERT-2.

Methods: AVERT-2 is a 132-week (wk), randomized, double-blinded study of ACPA+ and DMARD-naïve adults with RA diagnosis ≤6 months (ACR/EULAR 2010 criteria). Patients (pts) were randomized (3:2) to wkly SC ABA 125 mg + MTX vs ABA PBO + MTX for 56 wks (induction period [IP]) and then entered a 48-wk de-escalation period. Immune cell phenotyping via flow cytometry was performed on samples from a subset of pts in cohort 1 (all pts randomized who received ≥1 dose in the IP) through Wk 52. Data were analyzed using FlowJo® software. Estimates of adjusted mean change from baseline (BL) over time in CD4 T cells were from a repeated measures mixed model that included BL CD4 cell count, tx group, time and time-by-BL and time-by-tx group interaction. Changes over time were analyzed by whether pts achieved DAS28 (CRP) < 2.6 at Wk 52.

Results: Overall 58 pts who received ABA + MTX and 43 pts who received ABA PBO + MTX were included. BL demographics and disease characteristics at BL and Wk 52, between immune-cell–phenotyped and non-immune-cell–phenotyped cohorts, were comparable. BL DAS28 (CRP) scores were similar across these two cohorts for the ABA + MTX (5.80 vs 5.53, respectively) and ABA PBO + MTX (5.84 vs 5.58, respectively) tx arms. At the earliest time sampled (Month 1), a reduction in CD4 TEM and CD4 TEMRA cells was seen with ABA + MTX (Figure), which was sustained through Wk 52. Adjusted mean changes (95% CI) at Wk 52 with ABA + MTX vs ABA PBO + MTX were –6.0 (–8.6, –3.4) vs –2.0 (–5.3, 1.3) for TEM, and –1.6 (–2.4, –0.8) vs 0.5 (–0.5, 1.5) for TEMRA cells. Responders with DAS28 (CRP) < 2.6 at Wk 52 had greater reduction in these cell types with ABA + MTX vs ABA PBO + MTX (CD4 TEM: –6.5 [–10.2, –2.9] vs 4.2 [–2.8, 11.2]; CD4 TEMRA: (–2.9 [–4.0, –1.9] vs 1.2 [–0.4, 2.7]). This difference was not seen in non-responders. No association was observed with CD4 TCM cells between responders and non-responders.

Figure. Adjusted Mean Change From Baseline in (A) CD4 TEM Cells and (B) CD4 TEMRA Cells



PBO=placebo; TEM cells=effector memory T cells; TEMRA cells=effector memory re-expressing CD45RA T cells

Conclusion: Changes in CD4 TEM and CD4 TEMRA cells, probably suggestive of reduced proinflammatory immune response, were associated with abatacept response of DAS28 (CRP) < 2.6 in pts with seropositive RA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Early biologic use can improve long-term control of RA, and early use of abatacept (ABA) + MTX has demonstrated sustained improvements in selected patient-reported outcomes (PROs).[1,2] AVERT-2 (NCT02504268) is an ongoing, large, Phase IIIb, randomized, double-blinded study evaluating efficacy and safety of SC ABA + MTX vs ABA placebo (PBO) + MTX in ACPA positive (+) patients (pts) with early RA (disease duration ≤6 months) for 56 weeks, followed by a 48-week de-escalation.[3] Results of a *post hoc* analysis of PROs at 24 and 52 weeks in the AVERT-2 study are presented.

Methods: For the induction period, pts were randomized to SC ABA (125 mg weekly) + MTX or ABA PBO + MTX for 56 weeks. Key inclusion criteria: age ≥18 years; RA diagnosis ≤6 months (ACR/EULAR 2010 criteria); ACPA+; CRP >3 mg/L (upper limit of normal/ESR ≥28 mm/h); TJC ≥3 and SJC ≥3; DMARD naïve. PROs included pain (visual analog scale [VAS], 0–10 cm), pt assessment of disease activity (PtDA; VAS, 0–10 cm), physical function (HAQ-DI; 0–3), fatigue (Functional Assessment of Chronic Illness Therapy-Fatigue), Work Productivity and Activity Impairment (WPAI) questionnaire and pt overall quality of life (Short-Form 36 [SF-36] physical component summary [PCS]/mental component summary version 2.0). Adjusted mean change from baseline (adMCFB) and the proportion of pts attaining a minimal clinically important difference (MCID; values defined in Table 2)[4] at 24 and 52 weeks were calculated

Table 1. AdMCFB in PROs at Weeks 24 and 52; ITT Analysis

	Baseline*	Week 24				Week 52			
	Mean (SD)	n	Mean (SD)	adMCFB	Adjusted mean difference in CFB between treatments (p value)	n	Mean (SD)	adMCFB	Adjusted mean difference in CFB between treatments (p value)
Pain VAS

ABA PBO + MTX	16.19 (26.24)	126	5.52 (16.14)	−10.87		115	2.22 (6.49)	−14.09	

Estimates of adjusted mean change are from a repeated measures mixed model that includes baseline value, treatment group, time, time-by-baseline and time-by-treatment group interaction

Decreases in score indicate an improvement for all PROs, except SF-36 PCS and MCS, where increases in score indicate an improvement

*n numbers at baseline for each outcome match those presented for Week 24

ABA=abatacept; adMCFB=adjusted mean change from baseline; CFB=change from baseline; FACIT=Functional Assessment of Chronic Illness Therapy; ITT=intent-to-treat; MCS=mental component summary; PBO=placebo; PCS=physical component summary; PRO=patient-reported outcome; SF-36=Short Form-36; VAS=visual analog scale; WPAI=work productivity and activity impairment

for each PRO in the intention-to-treat population. AdMCFB was estimated using a mixed effect model with repeated measures.

Results: Of the 752 randomized pts, 451 were treated with ABA + MTX and 301 with ABA PBO + MTX. Baseline characteristics were similar across treatment arms.3 The adMCFB showed improvements in all PROs at both time-points for both treatment arms (Table 1), with ABA + MTX vs ABA PBO + MTX showing greater magnitude of improvement in pain PtDA, HAQ-DI and SF-36 PCS at both Weeks 24 and 52 ($p \leq 0.0001$). For all PROs except WPAI, more than half of pts achieved the MCID (Table 2). Compared with ABA PBO + MTX, a significantly greater proportion of ABA + MTX–treated pts attained the MCID in pain, PtDA and HAQ-DI at Weeks 24 and 52 ($p < 0.05$). Although there was no difference at Week 24, by Week 52 a greater proportion of pts attained the MCID in SF-36 PCS with ABA + MTX than with PBO + MTX.

Table 2. Percentage of Patients Attaining MCID in PROs at Weeks 24 and 52; ITT Analysis

	Week 24			Week 52		
	ABA + MTX (n=451)	ABA PBO + MTX (n=301)	p value	ABA + MTX (n=451)	ABA PBO + MTX (n=301)	p value
Pain VAS	80.9	69.4	0.0003	75.4	65.1	0.0023
Patient global disease activity VAS	77.8	67.4	0.0015	75.4	63.1	0.0003
HAQ-DI	82.5	75.7	0.0242	77.2	69.4	0.0178
SF-36 PCS	80.0	75.4	0.1320	78.9	66.1	0.0001
SF-36 MCS	51.2	52.2	0.8005	51.4	51.2	0.9403
FACIT-Fatigue	64.3	65.1	0.8189	63.4	58.5	0.1724
WPAI presenteeism	29.0	29.2	0.9554	30.6	27.2	0.3216
WPAI absenteeism	14.0	15.9	0.4537	14.4	14.3	0.9613

MCID: patient global assessment of pain and patient global assessment of disease activity (decrease >10 mm), HAQ-DI (decrease ≥0.22 units), SF-36 PCS and MCS (increase ≥2.5), FACIT-Fatigue (decrease ≥4.0), WPAI presenteeism and absenteeism (decrease ≥7)[4]

Missing values at Week 24 and Week 52 are imputed as not attaining MCID

p values are assessed by chi-square test if n≥5 and Fisher's exact test otherwise

ABA=abatacept; FACIT=Functional Assessment of Chronic Illness Therapy; ITT=intent-to-treat; MCID=minimal clinically important difference; MCS=mental component summary; PBO=placebo; PCS=physical component summary; PRO=patient-reported outcome; SF-36=Short Form-36; VAS=visual analog scale; WPAI=work productivity and activity impairment

Conclusion: In pts with early RA, treatment with abatacept + MTX and abatacept PBO + MTX were both associated with substantial improvements in PROs and quality of life by 24 weeks that were sustained over 1 year. Compared with abatacept PBO + MTX, a significantly greater proportion of abatacept + MTX–treated pts reported clinically meaningful improvements in pain, PtDA and function (HAQ-DI) by 24 weeks; this difference was sustained at 52 weeks. Further long-term follow-up analysis including impact of de-escalation of therapy is warranted.

Abstract Number: 1424

The Effect of HLA-DRB1 Risk Alleles (Shared Epitope) on Changes in Immune Cell Subsets and Disease Activity Following Treatment with Abatacept versus Adalimumab in Seropositive Biologic-Naïve Patients with Early, Moderate-to-Severe RA: Data from a Head-to-Head Single-Blinded Trial

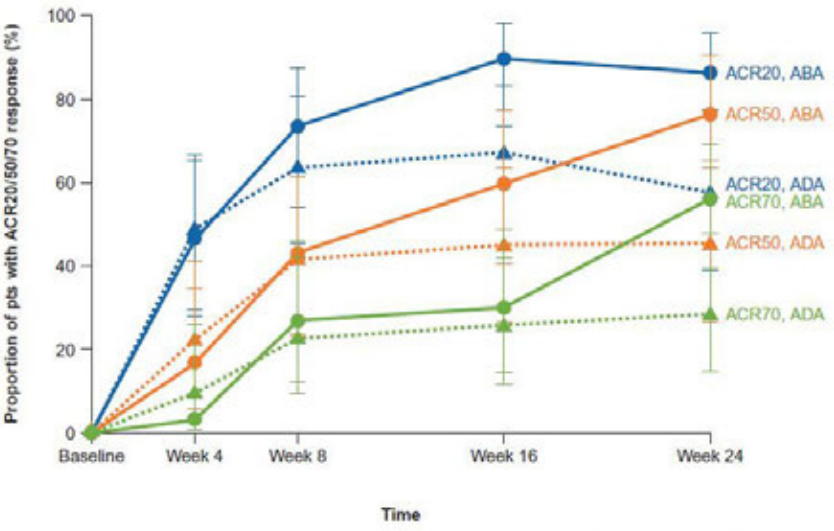
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mechanistic differences between biologic DMARDs are poorly understood. Exploring these mechanisms includes assessing the role of *HLA-DRB1* alleles containing the shared epitope (SE), which are present in 85% of anti-CCP2+ patients (pts) with RA,[1] and changes in immune cell subsets relevant in RA. In a head-to-head (H2H) study, abatacept (ABA) markedly altered immune cell subsets in pts with RA.[2] In the present study, numerically higher efficacy responses with ABA versus adalimumab (ADA) were reported after 24 weeks (wks) in the overall population, specifically in SE+ pts.[3] In the analysis reported here, we explored the relationship between *HLA-DRB1* SE genotype and the effects of ABA or ADA on immune cell subsets and disease activity.

Methods: This H2H, single-blinded trial (NCT02557100) in biologic-naïve pts with active RA enrolled anti-CCP+ (>3x upper limit of normal), RF+ adults with early (≤12 months of symptoms), moderate-to-severe RA (ACR/EULAR 2010 criteria). Pts were randomized 1:1 to SC ABA 125 mg wkly or SC ADA 40 mg every 2 wks (both with stable MTX) for 24 wks. Pts were grouped by *HLA-DRB1* SE genotype (–, no SE allele; +, ≥1 SE allele). Efficacy was assessed to Wk 24 by proportions of ACR20/50/70 responders in ABA versus ADA arms by SE status. Changes in immune cell subsets with ABA versus ADA were measured by flow cytometry to Wk 24 in the overall population and by SE status. Benjamini–Hochberg procedure with a 10% false positive discovery rate was used to select significant immune cell subsets in the overall population.

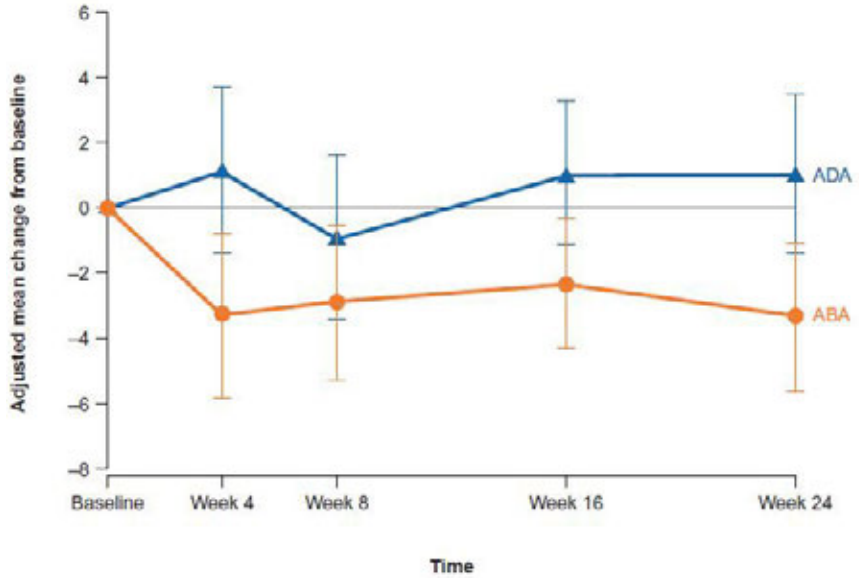
Results: 80 pts were treated: 40 ABA (9 SE–, 30 SE+, 1 SE unknown) and 40 ADA (9 SE–, 31 SE+). Baseline characteristics were similar between treatment (tx) arms. Mean (SD) age, disease duration and DAS28 (CRP) were 46.0 (14.4) years, 5.5 (2.6) months and 5.2 (1.1), respectively; 75% were female. SE+ pts versus SE– pts had greater (mean [SD]) CRP (16.1 [27.8] vs 4.8 [3.5] mg/L), anti-CCP2 (1216.6 [1525.1] vs 368.1 [433.6] U/mL) and RF levels (148.5 [130.1] vs 78.2 [44.2] kU/L); other characteristics were similar. SE+ pts had similar or numerically higher ACR20/50/70 responses with ABA versus ADA as early as Wk 8 and sustained to Wk 24 (Figure 1). At Wk 24, ABA significantly changed the proportions of key immune cell subsets versus ADA (tx difference [95% CI]): naïve CD4+ T cells (8.7 [5.6, 11.7]; p< 0.0001), naïve CD8+ T cells (6.3 [1.9, 10.7]; p=0.0059), CD8+ CD28– T cell (–4.3 [–7.7, –0.9]; p=0.0136; Figure 2), CD4+ effector memory T cells (–4.4 [–7.6, –1.2]; p=0.0086) and regulatory T cells (–1.6 [–2.2, –0.9]; p< 0.0001) in the overall population. The differential reduction in CD8+ CD28– T cells by tx group in the overall population was driven by the SE+ pts (Figure 3).

Figure 1. Proportion of SE+ Patients With ACR Responses Over Time



Error bars show 95% CIs. At all time points: ABA n=30, ADA n=31. Missing values are imputed as non-responders. Estimates of difference (95% CI) for ABA vs ADA at Week 24 were 28.6 (4.6, 51.7), 31.5 (6.8, 54.5), 27.6 (1.4, 50.5), for ACR20/50/70, respectively
ABA=abatacept; ACR20/50/70=20/50/70% improvement in ACR criteria; ADA=adalimumab; pts=patients; SE=shared epitope

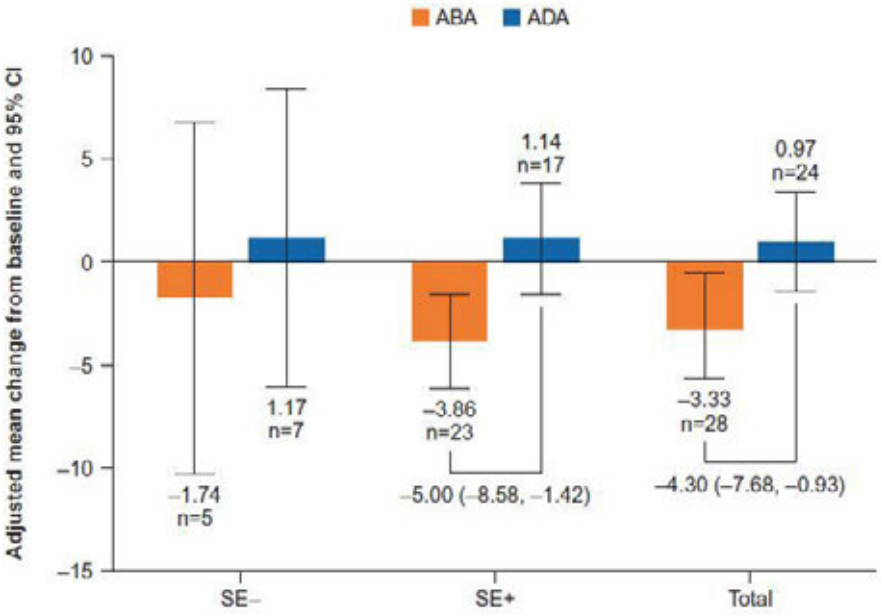
Figure 2. Adjusted Mean Change From Baseline in CD8+ CD28− T cells Over Time During the Single-Blind Treatment Period



ABA, n	34	31	34	33	28
ADA, n	31	30	30	27	24

Error bars represent 95% CI
ABA=abatacept; ADA=adalimumab

Figure 3. Adjusted Mean Change From Baseline in Percentage of CD8+ CD28− T Cells at Week 24 by Shared Epitope Status



Error bars represent 95% CI
ABA=abatacept; ADA=adalimumab; SE=shared epitope

Conclusion: In this anti-CCP2+ early RA population, abatacept was effective in SE+ pts and had a significant effect on key immune cell subsets involved in adaptive immune response, relevant in RA, versus adalimumab.

Abstract Number: 1425

Effect of ACPA IgM Serostatus on Efficacy Outcomes Following Treatment with Abatacept or Adalimumab: A *Post Hoc* Analysis of a Phase III Head-to-Head Trial

Thomas Huizinga,[1] René Toes,[1] Michael Weinblatt,[2] Michael Schiff,[3] Roy Fleischmann,[4] Yedid Elbez,[5] Sean Connolly,[6] Michael Maldonado,[6] and Sheng Gao[6], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Brigham and Women's Hospital, Boston, MA, USA, Boston, MA, [3]University of Colorado, Denver, CO, [4]Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, [5]Excelya, Boulogne-Billancourt, France, [6]Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

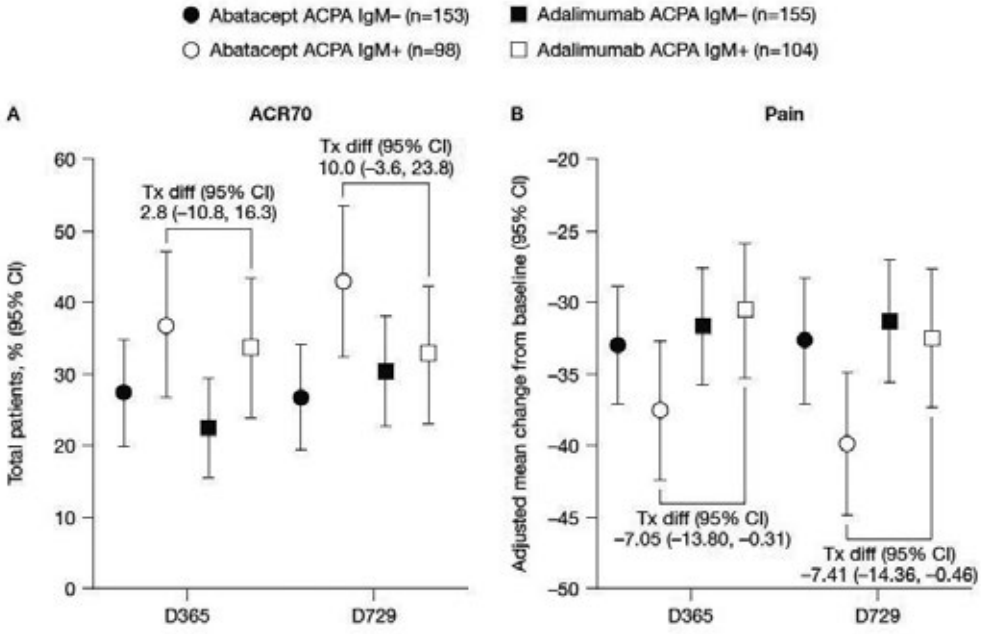
Background/Purpose: Anti-citrullinated protein antibody (ACPA) is a marker for early, erosive RA.[1] In the Abatacept (ABA) versus adaliMumab (ADA) comParison in bioLogic-naïvE RA subjects with background MTX (AMPLE; NCT00929864) trial, higher versus lower baseline (BL) ACPA IgG levels were associated with improved clinical outcomes, and in patients (pts) with high ACPA IgG levels, ABA was associated with improved outcomes compared with ADA.[2] The persistent presence of IgM is more indicative of continuous immune activation than IgG.[1] In the Assessing Very Early Rheumatoid arthritis Treatment (AVERT) trial, ABA + MTX had greater clinical efficacy in pts who were ACPA IgM positive (+) compared with ACPA IgM negative (–) at BL, and in seroconverters versus non-seroconverters.[3] This *post hoc* analysis of the AMPLE trial compared the treatment differences between ABA and ADA over 2 years, in pts who were ACPA IgM+ at BL by Day (D) 365 seroconversion status.

Table 1. Proportion of Patients With Seroconversion to from ACPA IgM+ to ACPA IgM– Status by Treatment Over Time

ACPA IgM seroconversion, n/N (%)	Converter	
	Abatacept	Adalimumab
Day 85	16/84 (19)	9/88 (10)
Day 365	22/87 (25)	20/81 (25)
Day 729	13/52 (25)	16/59 (27)

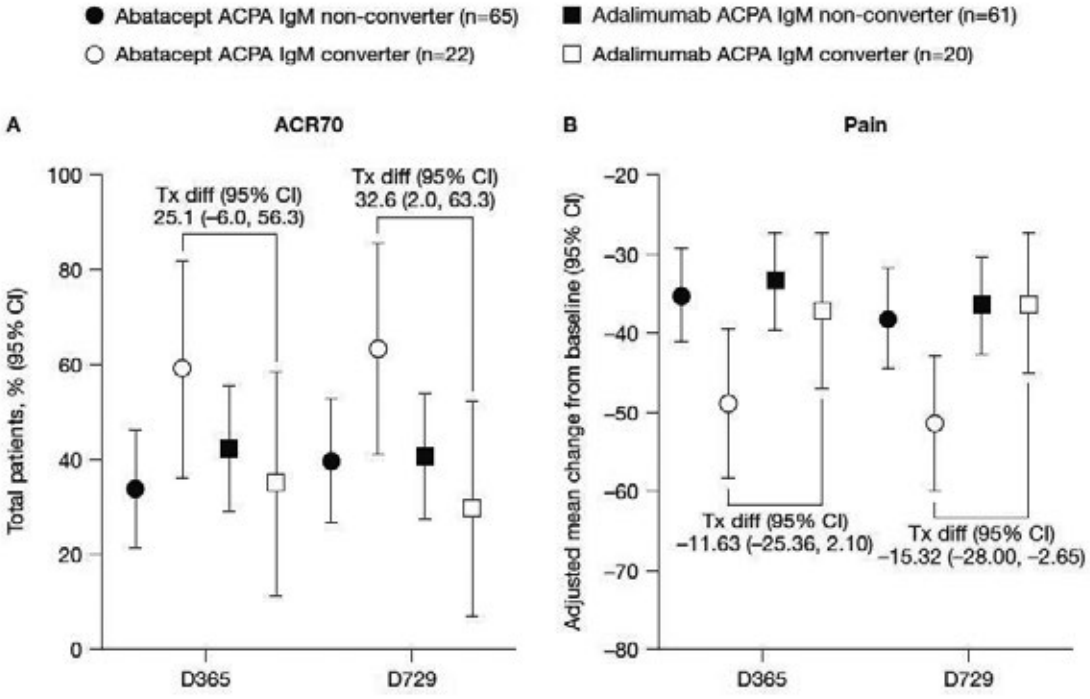
Subgroup analysis based on seroconversion status was done for Day 365 only, where there were n≥20 per subgroup
n=number of patients who seroconverted; N=total number of patients with baseline ACPA IgM+ status
ACPA=anti-citrullinated protein antibody

Figure 1. Clinical Outcomes by Baseline ACPA IgM Seroreactivity: (A) Proportion of Patients With ACR70 Response and (B) Adjusted Mean Change From Baseline in Pain



ACPA=anti-citrullinated protein antibody; D=Day; Tx diff=treatment difference

Figure 2. Clinical Outcomes by ACPA IgM Seroconversion: (A) Proportion of Patients With ACR70 Response and (B) Adjusted Mean Change From Baseline in Pain



ACPA=anti-citrullinated protein antibody; D=Day; Tx diff=treatment difference

Methods: The AMPLE trial (NCT00929864) has been published.[4] Samples, including those from ACPA+ pts were analyzed by ELISA to determine ACPA IgM serostatus. Outcomes over 2 years of treatment were analyzed by treatment group, based on BL ACPA IgM serostatus, and seroconversion to ACPA IgM– status, at D365. Analysis of covariance models were used to assess the adjusted mean changes, with treatment as factor and BL values and screening DAS28 (CRP) randomization stratification as covariates.

Results: Of 646 pts with RA (1987 ACR criteria[5]) in the AMPLE study, BL ACPA IgM status was available for 510 pts: 308 ACPA IgM– and 202 ACPA IgM+. BL characteristics were comparable between ACPA IgM+ and ACPA IgM– groups, and among all ACPA IgM+ pts across treatment arms between seroconverters at D365 versus non-converters. In pts who were ACPA IgM+ at BL, ABA was associated with a numerically higher ACR70 response rate (Figure 1A) and greater reduction in pain (Figure 1B) than ADA at D365 and D729. The trend in treatment difference for ACR70 and pain was consistent over time (data not shown). By D365, a similar proportion of pts from each treatment group seroconverted from ACPA IgM+ to ACPA IgM– status (Table 1). In pts who seroconverted from ACPA IgM+ at BL to ACPA IgM– at D365, ABA was associated with a greater numerical improvement in ACR70 response (Figure 2A) and reduction in pain (Figure 2B) than ADA at D365 and D729.

Conclusion: ACPA IgM seropositive status at BL predicted numerically better clinical outcomes after 365 and 729 days of treatment in abatacept-treated pts compared with ADA-treated pts. Among the subset of pts who seroconverted to ACPA IgM– status, abatacept treatment was associated with numerically better clinical responses. ACPA IgM+ status may help identify a subset of pts with active RA who respond better to abatacept treatment.

Impact of TNF Inhibitor Cycling with Adalimumab and Etanercept vs Switching to Tofacitinib

James Harnett,[1] Timothy Smith,[1] John Woolcott,[2] David Gruben,[3] and Christopher Murray[2], [1]Pfizer Inc, New York, NY, [2]Pfizer Inc, Collegeville, PA, [3]Pfizer Inc, Groton, CT

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib is an oral JAK inhibitor for the treatment of RA. It was approved for RA by the US FDA in Nov 2012. TNFi cycling in non-responder patients (pts) with RA may be reinforced by payers limiting access to similarly indicated advanced therapies with different mechanisms of action, such as tofacitinib. In a retrospective analysis, adalimumab (ADA) and etanercept (ETN) were the most common prior bDMARDs for pts with RA initiating ETN and ADA, respectively, with no other advanced therapy history.[1] We assessed the impact of TNFi cycling with ADA and ETN vs switching to tofacitinib.

Methods: This retrospective cohort study used the US-based IBM® MarketScan® Commercial and Medicare Supplemental insurance claims databases to identify pts with RA who newly started index medication with tofacitinib or select TNFi (ADA or ETN) between Jan 2014 and Sep 2016. Eligible pts had continuous enrolment for ≥ 12 months pre-/post-index and their only pre-index advanced therapy (bDMARD or JAK inhibitor) claim was for non-index ADA or ETN. Pts were analyzed by treatment switch: ADA to tofacitinib; ADA to ETN; ETN to tofacitinib; ETN to ADA. Outcomes assessed over 12 months post-index were: persistence without a ≥ 60-day gap in index therapy or switch;

Table. Demographics, baseline clinical characteristics, adherence, persistence, effectiveness (proxy), and costs in patients with RA switching from ADA to tofacitinib or ETN, and ETN to tofacitinib or ADA: data from the US-based IBM® MarketScan® Commercial and Medicare Supplemental insurance claims databases[a]

	ADA to tofacitinib (N=287)	ADA to ETN (N=79)	P value	ETN to tofacitinib (N=262)	ETN to ADA (N=112)	P value
Female, n (%)	243 (84.7)	62 (78.5)	0.1913	219 (83.6)	85 (75.9)	0.0806
Age, mean (SD)	55.2 (11.1)	50.5 (11.6)	0.0013	54.5 (12.3)	53.4 (12.1)	0.4068
Medicare Supplemental, n (%)	54 (18.8)	5 (6.3)	0.0075	46 (17.6)	13 (11.6)	0.1482
Quan-Charlson Comorbidity Index Score, mean (SD)	1.8 (1.2)	1.7 (1.3)	0.7460	1.9 (1.4)	1.6 (1.2)	0.1039
Baseline RA-related costs, mean $ (SD)	27,391 (20,611)	16,359 (15,754)	<0.0001	22,780 (16,635)	18,432 (15,755)	0.0192
Persistence[b,c], n (%)	145 (50.5)	29 (36.7)	0.0295	120 (45.8)	43 (38.4)	0.1857
Duration of therapy (days)[b,c], mean (SD)	239.0 (134.5)	203.7 (133.2)	0.0387	234.3 (131.1)	219.8 (126.1)	0.3194
Effectiveness proxy (patients meeting criteria)[b], n (%)						
Met all criteria below	85 (29.6)	11 (13.9)	0.0050	59 (22.5)	17 (15.2)	0.1061

<2 days intra-articular injections	237 (82.6)	59 (74.7)	0.1141	200 (76.3)	93 (83.0)	0.1497
Change in RA-related costs, mean $ (SD)						
Total	10,048 (27,257)	17,681 (21,412)	0.0220	14,188 (19,538)	21,595 (20,979)	0.0011
Prescription	9,260 (19,001)	15,566 (17,959)	0.0086	12,140 (14,603)	19,712 (15,916)	<0.0001

[a]Categorical variables were compared using chi-square tests and continuous variables were compared using t-tests. There was no correction for multiple comparisons
[b]12-month follow-up
[c]<60-day gap and no advanced therapy switches
[d]≤30 days of oral glucocorticoid between Months 3-12 post-index in patients with no glucocorticoid prescriptions for 6 months pre-index
[e]No increase in oral glucocorticoid dose ≥20% during Months 6-12 post-index (for those with 6 months of pre-index glucocorticoid use)
ADA, adalimumab; csDMARD, conventional synthetic disease-modifying antirheumatic drug; ETN, etanercept; PDC, proportion of days covered; RA, rheumatoid arthritis; SD, standard deviation

duration of therapy; effectiveness, estimated based on a validated claims-based algorithm. Changes in 12-month post-index RA-related (medical and pharmacy) costs were assessed.

Results: Of 740 pts: 549 switched from ADA or ETN to tofacitinib; 191 cycled between ADA and ETN (Table). Pts switching to tofacitinib had significantly ($p < 0.05$) higher baseline (BL) RA-related costs vs pts who cycled between ADA and ETN. Pts who switched from ADA to tofacitinib were older and a greater % were Medicare Supplemental beneficiaries, vs pts who cycled from ADA to ETN. In pts who switched from ADA to tofacitinib vs those who cycled from ADA to ETN: persistence and duration of therapy were significantly higher and longer, respectively; and the % effectively treated was significantly higher, driven by better adherence, and no new csDMARDs or advanced therapy switch. A significantly lower % of pts who switched from ETN to tofacitinib had an advanced therapy switch or dose escalation thereafter vs pts who cycled from ETN to ADA. A numerically, but not significantly, higher % of pts switching from ETN to tofacitinib were persistent and effectively treated vs pts cycling from ETN to ADA. RA-related cost increases were significantly lower in pts who switched to tofacitinib vs pts who cycled between ADA and ETN, driven by significantly smaller increases in prescription costs.

Conclusion: Pts who switched from ADA or ETN to tofacitinib had higher persistence, effectiveness, and significantly lower change in RA-related costs vs pts cycling between ADA and ETN. Further adjusted analyses are planned to understand potential delays in tofacitinib use due to access barriers promoting 1st-line TNFi use. Larger sample sizes may be needed to further evaluate statistical differences for pts switching from ETN to tofacitinib vs ADA.

Abstract Number: 1427

Comparison of Real-World Persistence of Subcutaneously Administered Biologic Disease-Modifying Antirheumatic Drug Therapies Among Patients with Rheumatoid Arthritis Switching from Another Biologic

Jennie Best,[1] Lenore Tominna,[1] and Ibrahim Abbass[1], [1]Genentech, Inc., South San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The EULAR and ACR clinical guidelines recommend switching to a different disease-modifying antirheumatic drug (DMARD) when biologic-treated patients experience treatment failure or toxicity. Lack of efficacy and adverse events are among the most commonly reported reasons for switching biologic therapies. Limited information is available regarding biologic therapy persistence across subcutaneously administered (SC) biologic

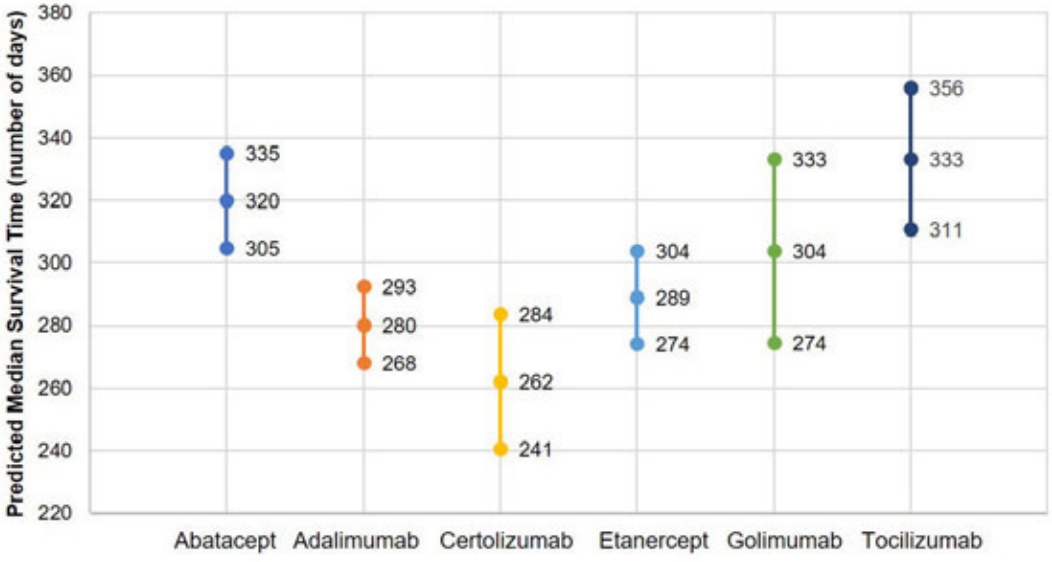
agents in the real-world setting, as well as comparative information on biologic persistence for SC biologics among patients with rheumatoid arthritis (RA) who are not naïve to biologic treatment. This study compared the persistence of SC biologic DMARDs (bDMARDs) in patients with RA as subsequent-line therapy following a failure of first-line bDMARDs.

Methods: US administrative claims data were used to create a longitudinal cohort of adult patients with RA initiating SC biologic between 1/1/2012 and 6/30/2017 (initiation date = index). Patients were required to have failed 1st bDMARD to enter study (but could later switch therapy) and to have 6 and at least 3 months of continuous enrollment pre- and post-index (date of prescription for bDMARD). Those with other autoimmune conditions were excluded from the study. Outcomes were biologic persistence, defined as number of days between initiation date and last supplied day of last fill. Parametric survival models with exponential distribution with robust variance estimator were used to compare outcomes for tocilizumab versus other biologics, adjusting for differences in baseline characteristics, accounting for correlation among different bDMARD episodes.

Results: There were 10,301 patients with 12,704 bDMARD episodes: abatacept (n = 2,988), adalimumab (n = 3,599), certolizumab (n = 982), etanercept (n = 2,760), golimumab (n = 745), or tocilizumab (n = 1,630). Mean age ranged from 51.0 to 53.3 years. Mean [SD] Elixhauser comorbidity scores were significantly higher ($P < 0.001$) for tocilizumab (2.8 [2.3]) compared with abatacept (2.5 [2.2]), adalimumab (2.5 [2.1]), certolizumab (2.4 [2.0]), etanercept (2.4 [2.0]) or golimumab (2.4 [2.2]). Adjusted median days (95% CI) of persistence were: abatacept 320 (305, 335); adalimumab 280 (268, 293); certolizumab 262 (241, 284); etanercept 289 (274, 304); golimumab 304 (274, 333); and tocilizumab 333 (311, 356). Tocilizumab had significantly ($P < 0.05$) higher persistence compared with adalimumab, certolizumab and etanercept (**Figure 1**). Of patients who were observed for 12 months, 45% of patients initiated tocilizumab biweekly and 55% initiated weekly. Of the 347 patients initiating biweekly tocilizumab, 33% switched to weekly over 12-month follow up; the mean time to switch was 177 days. After 12 months of follow-up, approximately 68% of patients finished on weekly dosing and 32% on biweekly dosing.

Conclusion: Among patients with RA who previously used ≥ 1 other biologic, tocilizumab-treated patients had similar or statistically significantly better biologic persistence compared with other biologics.

Figure 1. Adjusted Persistence (with 95% CI) of Biologic DMARDs Among Patients with RA



DMARD, disease-modifying antirheumatic drug.

Abstract Number: 1428

Time to Discontinuation of Tofacitinib in Rheumatoid Arthritis Patients with and Without Methotrexate: Results from a Rheumatoid Arthritis Cohort

Mohammad Movahedi,[1] Angela Cesta,[2] Xiuying Li,[2] Edward Keystone,[1] Claire Bombardier,[2] and And Other OBRI Investigators[2], [1]Division of Rheumatology, Mount Sinai Hospital, Toronto, ON, Canada, [2]Toronto General Hospital Research Institute, University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib (TOFA) is an oral, small molecule drug which can be used as an alternative to biologic disease modifying antirheumatic drugs (bDMARDs) for rheumatoid arthritis (RA) treatment and is prescribed alone or with methotrexate (MTX). We aimed to evaluate the discontinuation rate of this drug, with and without concurrent MTX, and with and without prior biologic use, in patients with RA in the Ontario Best Practices Research Initiative (OBRI).

Methods: RA patients enrolled in the OBRI initiating their TOFA within 30 days prior to or any time after enrolment between 1st June 2014 (TOFA approval date in Canada) and 31st Dec 2017 were included. Patients were excluded if they had ≤ 2 visits and ≤ 6 months' follow-up. Time to discontinuation due to (1) any reason, (2) lack/loss of response, and 3) adverse events (AEs) were assessed using Kaplan-Meier survival to compare patients 1) with and without MTX use; 2) with or without prior biologic use at initiation of TOFA was assessed using Kaplan-Meier survival analysis. Cox proportional hazards regression model was also used to assess TOFA discontinuation adjusting for propensity score to balance the two treatment groups.

Results: Among the 131 patients, 70 (53.4%) received TOFA without MTX and 61 (46.6%) TOFA with MTX. Mean (SD) age and disease duration were 60.2 (9.8) years and 13.7 (9.3) years, respectively. The majority were females (89.3%) and most had prior biologic use history (74.0%). Discontinuation was reported in 44 (33.6%) of all TOFA patients with a median survival of 31.3 months. Overall retention of TOFA at 6, 12 and 24 months was 80.5%, 63.1% and 53.5% respectively. These findings are very similar to the results reported from the RHUMADATA registry at ACR 2018.[1] Fifteen (34.0%) patients stopped their TOFA due to non-response/loss of response, 22 (50.0%) due to adverse events, and 7 (16%) due to other reasons. Discontinuation due to any reason was borderline significantly lower in the "TOFA with MTX" group compared with "TOFA without MTX" group. There was no significant difference in TOFA discontinuation between the two groups of patients with and without prior biologic use (Logrank p=0.77).

Conclusion: We found that half of the RA patients remained on TOFA 31 months after initiation. TOFA retention is similar between patients with and without MTX group specifically for lack/loss of response or adverse events reasons. However, the interpretation of results is limited because of small sample size. Merging data with other RA registries in Canada is proposed to increase study power and to provide more robust results.

Results at 6 Months of Abatacept vs TNF-α Blockers in Patients with Severe, Long-standing, DMARDs Resistant Rheumatoid Arthritis

Omar Valenzuela,[1] **Sebastian Ibanez**,[2] Maria Paz Poblete,[3] Claudia Mardones,[2] Francisco Silva,[2] Maria Jose Villar,[2] and Katherine Mogollones[1], [1]Facultad de Medicina Clinica Alemana -UDD, Santiago, Region Metropolitana, Chile, [2]Facultad de Medicina Clinica Alemana - UDD, Santiago, Region Metropolitana, Chile, [3]Rheumatology dpt., Facultad de Medicina Clinica Alemana - UDD, Santiago, Region Metropolitana, Chile

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Since January 2016, Chilean patients with rheumatoid arthritis (RA), with severe activity despite the use of 3 DMARDs for at least 6 months, have guaranteed access to biologics. In the first year the only first-line option was abatacept, in the second year etanercept and adalimumab were added. Our objetive was to evaluate the efficacy at 6 months of abatacept vs TNF-α blockers as first-line biologic.

Methods: Real life, prospective-cohort, single-center study. Only RA patients with a DAS28 ESR greater than 5.1 or with ≥ 6 painful joints, ≥3 swollen joints, ESR ≥30 mm/h, and morning stiffness ≥45 minutes on 2 evaluations, separated between 30-120 days, were allowed to postulate for biologic treatment. Included patients during 2016 received abatacept as first-line biologic, and since 2017 the first-line biologic was selected by randomizing patients in order of attention to abatacept, etanercept or adalimumab, unless there was a particular condition that made it preferable one over another (latent tuberculosis, intersticial lung disease). Tapering of other DMARDs and prednisone was done depending on the clinician's judgment. The patients were followed for 6 months, DAS28 ESR change was evaluated and the EULAR response criteria was calculated. HAQ, other medications use changes, and adverse events were evaluated. Comparisons were made between abatacept and TNF-α blockers (etanercept/adalimumab). Multivariate analysis was performed taking into account age, sex, years with symptoms, comorbidities, smoking, BMI, CCP status, DMARDs, corticoids, NSAIDs and tramadol use, and baseline DAS28.

Results: 123 patients were enrolled (table 1 for baseline characteristics). Users of TNF-α blockers had a significantly greater decrease in DAS28 ESR, higher rate of remission, higher rate of good EULAR response, and a lower rate of failure according to the physician (Table 2). These differences maintained statistical significance ($p < 0.05$) after multivariate analysis. A higher BMI was significantly related, after multivariate analysis, to a lower reduction of DAS28 ESR and lower rate of remission after 6 months. For HAQ there was no difference in the reduction and the result after 6 months of biologic treatment (from 1.9 to 1.5). The median number of DMARDs and the median prednisone dose was reduced without differences between groups. The rate of tramadol use saw a 10.9% reduction in the abatacept group and 2.5% in the TNF-α blocker group (table 3). After multivariate analysis more years with symptoms was related to higher rate of tramadol use after 6 months of biologics. The rate of adverse events (AE) was higher in the TNF-α blocker group (39.1 vs 27.7%) but the rate of serious events was higher in the abatacept group (30.4 vs 22.2% of all AE), although no significant differences were found.

Conclusion: At 6 months, in this real life study, more than 80% of the patients with severe, long standing, DMARDs resistant, RA had at least a moderate response to biologic treatment. This improvement was significantly higher in the

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Etanercept (ETN) plus methotrexate (MTX) was shown to be superior to MTX plus another conventional disease-modifying anti-rheumatic drug (DMARD) in an open-label, randomized study of Latin American patients with rheumatoid arthritis (RA). Determining possible predictors of response would allow a more personalized approach to the treatment of RA in this heterogeneous population. The aim of this post hoc analysis was to identify potential predictors of response to 24- and 128-week treatment ETN+MTX in Latin American patients with RA.

Table 1: Baseline demographic and disease characteristics of responders and non-responders (observed cases)

	Week 24			Week 128

Table 2: Odds ratios for predictors of response at Week 24 and Week 128

Baseline Characteristic	OR (95% CI)	P-value
	Week 24	
Age (≤49 years vs >49 years)	3.33 (1.61, 6.90)	0.001
BMI (>28.5 kg/m^2 vs ≤28.5 kg/m^2)	3.40 (1.57, 7.36)	0.002
Disease duration (>4.1 years vs ≤4.1 years)	2.69 (1.30, 5.53)	0.007
ESR (≤42 mm/h vs >42 mm/h)	2.67 (1.20, 5.95)	0.016
Physician Global Assessment score (≤6.0 vs >6.0)	2.87 (1.43, 5.75)	0.003
Total HAQ score (≤1.63 vs >1.63)	4.22 (1.99, 9.01)	<0.001
	Week 128	
ESR (≤35 mm/h vs >35 mm/h)	14.29 (3.13, 66.67)	0.001

BMI, body mass index; ESR, erythrocyte sedimentation rate; HAQ, health assessment questionnaire.

Methods: During Phase 1 (24 weeks) of this study (NCT00848354), patients from Latin America with MTX-resistant, moderate to severe RA were randomized 2:1 to receive open-label ETN 50 mg/week plus MTX (ETN+MTX, n=281) or an additional conventional DMARD (hydroxychloroquine or sulfasalazine) plus MTX (DMARD+MTX; n=142). Phase 2 (104 weeks) was an optional extension period allowing the continuation with Phase 1 treatment or the addition, discontinuation or titration of the other DMARD therapy. In this analysis, response was defined as Disease Activity Score-28 for Rheumatoid Arthritis with erythrocyte sedimentation rate (DAS28-ESR) score < 2.6 (DAS28-ESR remission). Baseline variables between responders and non-responders were compared using chi-square test (discrete) or one-way ANOVA (continuous). Odds of attaining response in the ETN+MTX group at Weeks 24 and 128 (observed cases) were estimated using a stepwise logistic regression model.

Results: At 24 and 128 weeks, 26% (70/269) and 35% (n=19/54) of patients in the ETN+MTX group achieved DAS28-ESR remission, respectively. On average, Week 24 and Week 128 responders had lower baseline scores of ESR and PGA, and were more likely to be men than non-responders (Table 1). In addition, Week 24 responders were on average younger and had lower baseline total HAQ and VAS pain scores, compared to non-responders. Significantly higher odds of attaining remission at Week 24 were associated with baseline age ≤49 years, BMI >28.5 kg/m^2, disease duration >4.1 years, ESR ≤42 mm/h, PGA ≤6, and Total HAQ score ≤1.63; ESR ≤35 mm/h was a predictor of response at Week 128 (Table 2). Fewer predictors of response at Week 128 compared to Week 24 may be due to lower predictability of long-term events or due to a loss of statistical power, based on the smaller sample size for Week 128.

Conclusion: Factors that predicted response to therapy were younger age, higher body mass index, longer disease duration, and an overall lower disease activity. Limitations of this post hoc analysis include the small sample size for Week 128. Further studies are needed to confirm these predictors of response.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The GO PRACTICE study was initiated following a demand by the French Health Authorities for long-term data on the real-life use of golimumab (**GLM**) in patients with rheumatoid arthritis (**RA**), psoriatic arthritis (**PsA**) or axial spondyloarthritis (**axSpA**). The primary objective was to assess the persistence of GLM over 2 years after initiation. Secondary objectives included evaluations of 1) clinical disease activity from baseline to 2 years, 2) changes in patient-reported disease activity, functional abilityand quality of life (**QoL**), and 3) GLM clinical safety.

Methods: Observational, prospective, multicenter French study. Patients ≥18 years with RA, PsA and axSpA were included consecutively following GLM initiation, and followed-up for 2 years. Data were collected at baseline, year 1 and

	12 months (1 year)	24 months (2 years)
RA	65.4%	56.5%
PsA	66.0%	45.1%
axSpA	65.8%	52.6%
Total	*65.7%*	*52.4%*

Kaplan-Meier curves showing the cumulative persistence probability of GLM over 24 months for RA, PsA and axSpA patients

year 2. GLM persistence was estimated with the Kaplan-Meier method. Clinical disease activity was measured using the Disease Activity Score 28 (**DAS28**) for RA and PsA, and the Ankylosing Spondylitis Disease Activity Score (**ASDAS**) for axSpA. Patient-reported disease activity was measured with the Routine Assessment of Patient Index Data 3 (**RAPID3**) for RA and PsA, and the Bath Ankylosing Spondylitis Disease Activity Index (**BASDAI**) for axSpA. Functional ability was assessed with the Health Assessement Questionnaire (**HAQ**) and QoL was assessed with the EQ-5D and SF-12 surveys.

Results: From January 2015 to March 2016, 770 patients were selected at 134 sites, of which 754 were included in the analysis. Mean age was 46 years and 61% were female. Most had axSpA (63%), then RA (23%) and PsA (14%). Mean duration of rheumatic disease was 7.6 years; 37% had previously received biologics; the proportion of patients who received 1, 2, 3 and ≥4 biologics were 18%, 11%, 6% and 2%, respectively. Most patients were prescribed 50 mg GLM monthly (97%). Concomitant treatments included DMARDs (38%), corticosteroids (19%) and NSAIDs/analgesics (71%). GLM persistence at 2 years was 52.4% (56.5%, 45.1% and 52.6% in RA, PsA and axSpA, respectively). Disease activity showed clinically significant improvements from baseline to 2 years in patients persisting on GLM: for RA, mean DAS28-CRP from 4.3±1.1 to 2.3±0.8 ($p < .0001$), mean RAPID3 from 4.5±1.8 to 1.8±1.7 ($p < .0001$); for PsA, mean DAS28-CRP from 3.9±1.0 to 2.0±0.8 ($p < .0001$), mean RAPID3 from 5.3±1.4 to 2.8±2.2 ($p < .0001$); for axSpA, mean ASDAS-CRP from 3.2±0.8 to 1.7±1.0 ($p < .0001$), mean BASDAI from 5.5±1.6 to 2.8±1.9, ($p < .0001$). HAQ, EQ-5D and SF-12 scores also improved significantly over 2 years. GLM was discontinued by 67 (8.9%) patients due to intolerance or adverse event (**AE**); reported AEs were consistent with GLM's known safety profile. Post-hoc multivariate analyses with patients' sociodemographic and medical history variables showed that for GLM discontinuation over the 2 years, gastrointestinal disease was a risk factor in RA [HR 3.9, CI95% (2.0-7.6)] and being female was a risk factor in axSpA [HR 1.9, CI95% (1.4-2.6)]. GLM was re-prescribed to 338 (93.4%) of 362 patients who persisted on GLM at 2 years.

Conclusion: Real-life GLM persistence is satisfactory at 2 years and is accompanied by clinical improvements in RA, PsA and axSpA patients.

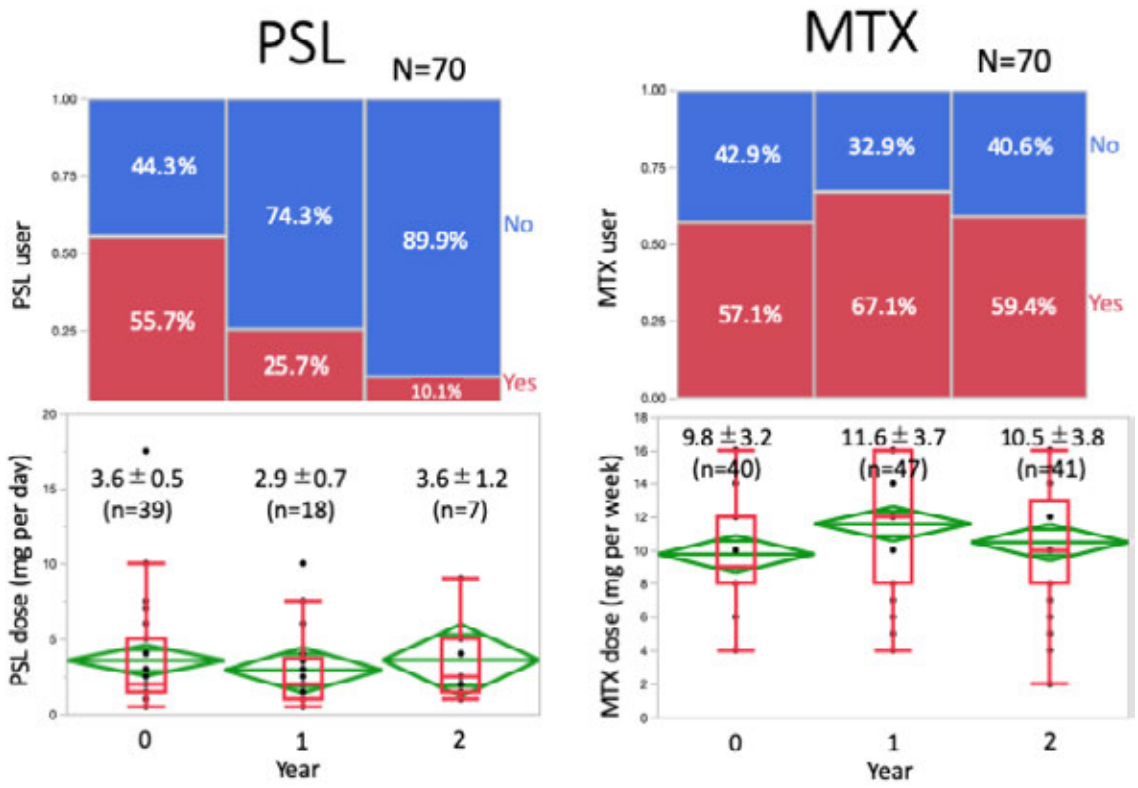
SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM



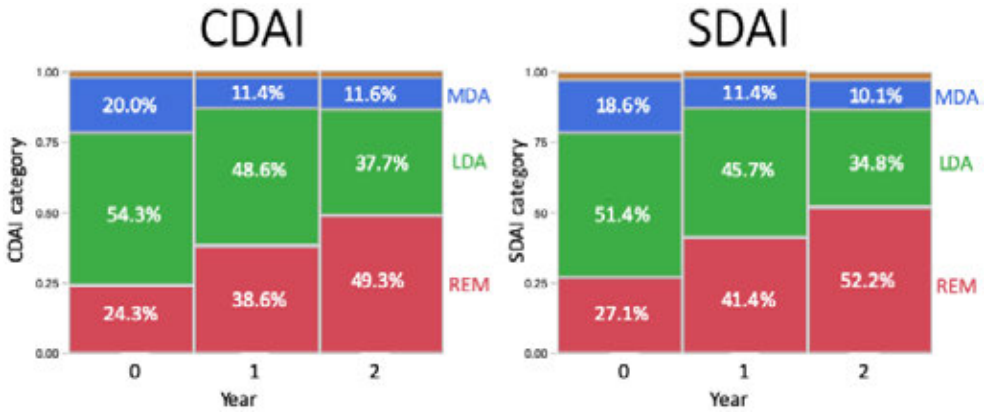
Proportion and dosage of PSL and MTX at BL, year-1, and year-2.

Background/Purpose: To determine whether prednisolone (PSL) could be tapered or discontinued without deterioration of disease control through optimizing methotrexate (MTX) for 2-yrs in patients with rheumatoid arthritis (RA) under stable treatment.

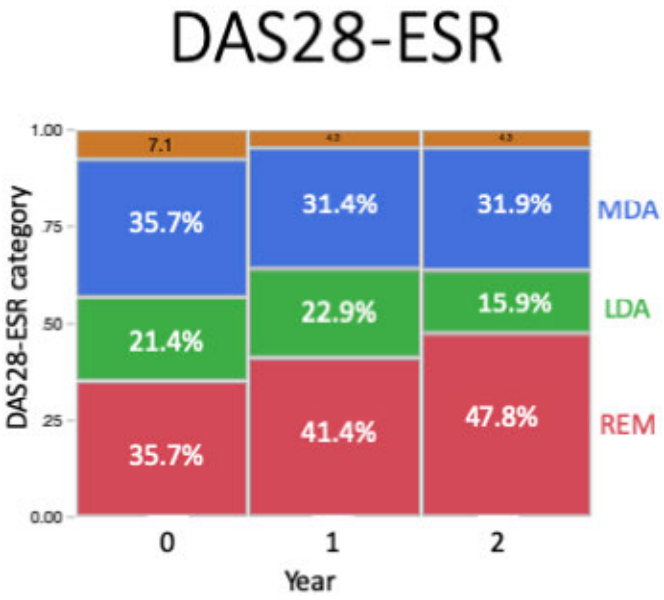
Methods: Patients with RA who fulfilled ARA 1987 criteria and/or ACR/EULAR 2010 criteria and had regularly visited our clinic for ≥1year under stable treatment were consecutively registered during Sep-Oct 2016. Clinical demographics as well as disease status and medication at baseline (BL), year-1- and -2 were collected. The basic therapeutic strategy was to increase MTX while reducing PSL as much as possible, based on patient's consent agreement. Initiation of biological DMARDs (bDMARDs) or JAK inhibitors (JAKi) was allowed if required.

Results: 70 patients were enrolled to the study. Age (median [IQR]) 62 [51, 68] years; female 69%; disease duration 6.8 [3.4, 13.7] years. Proportion of the patients using MTX at BL, 1 and 2 years were 57, 67 and 59%, respectively, while doses (mean ± SD) of MTX were 9.8 ± 3.2, 11.6 ± 3.7 and 10.5 ± 3.8 mg per week, respectively. Percentage of the patients using PSL were 56, 26 and 10%, respectively, while doses of PSL were 3.6 ± 3.4, 2.9 ± 2.6 and 3.6 ± 2.8mg per day, respectively. bDMARDs/JAKi users were 16, 18 and 26, newly initiated in 2 and 8 during BL-1-2years. CDAI / SDAI / DAS28(ESR) -remission ratio at BL, 1-year and 2-years were; 24/ 39/ 49%, 27/ 41/ 52%, and 35/ 41/ 48%, respectively. These results were consistent in patients without bDMARDs/JAKi. Severe adverse events were found in two patients (peritoneal cancer in one, myelodysplastic syndromes in one).

Conclusion: PSL was successfully discontinued in 90% of the patients by optimizing MTX with or without bDMARDs/JAKi with improved disease control in patients with RA under stable treatment. However, tapering PSL to withdrawal required more than 6 months in the majority of the patients that might delay clinical decision-making of starting bDMARDs or JAKi.



Proportion of disease activity categories in CDAI and SDAI at BL, year-1, and year-2.



Proportion of disease activity categories in DAS28-ESR at BL, year-1, and year-2.

Association Between Seropositivity and Discontinuation of Tumor Necrosis Factor Inhibitors Due to Insufficient Response in Rheumatoid Arthritis

Yoshikazu Ogawa,[1] Nobunori Takahashi,[2] Toshihisa Kojima,[2] and Naoki Ishiguro[2], [1]Nakatsugawa Municipal General Hospital, Nakatsugawa, Japan, [2]Department of Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Discontinuation of biologic therapy in rheumatoid arthritis is attributable to various reasons, with the most important cause being insufficient response. In this study, we investigated the association between rheumatoid factor (RF) and anti–citrullinated protein autoantibody (ACPA) status and the discontinuation of tumor necrosis factor inhibitors (TNFi) therapy due to ineffectiveness in bio-naïve rheumatoid arthritis (RA) patients.

Methods: This study included patients enrolled in the Tsurumai Biologic Communication Registry in Japan. The crude comparison of TNFi discontinuation due to insufficient response between seropositive and seronegative patients was analyzed using the cumulative incidence function of competing events and Gray test. We assessed the associations between baseline characteristics and discontinuation of TNFi treatment due to insufficient response using Fine-Gray proportional hazard regression. Fine-Gray proportional hazard analysis considered competing events of interest, including insufficient response, adverse event, palliation, and personal reasons.

Results: Of 1237 patients evaluated, 79.3% were positive for RF and 85.4% for ACPA; 72.6% were double positive and 11.1% were double negative. TNFi therapy had been discontinued because of insufficient response at 200 weeks in 19.8% RF-positive, 16.7% RF-negative, 23.0% ACPA-positive, and 13.8% ACPA-negative patients. There was a significantly higher discontinuation rate due to insufficient response in ACPA positive patients than in ACPA negative patients using Gray test, with a similar trend as that for RF status. RF positivity was significantly predictive of the discontinuation of TNFi treatment due to insufficient response using Fine-Gray proportional hazard regression analysis after adjusting for baseline characteristics, including age, sex, stage, class, disease activity at baseline, methotrexate use, and prednisolone use (hazard ratio 1.73 [95% confidence interval 1.07–2.80]).

Conclusion: Using Fine-Gray proportional hazard regression, we demonstrated that RF positivity was related to a higher discontinuation rate of TNFi treatment due to insufficient response in bio-naïve RA patients.

Abstract Number: 1434

Improvement in Matrix metalloproteinase-3 Levels at 12 Weeks Independently Predicts Achievement of Low Disease Activity at 52 Weeks in Bio-switch Patients with Rheumatoid Arthritis Treated with Abatacept

Nobunori Takahashi,[1] Toshihisa Kojima,[1] Kenya Terabe,[1] Shuji Asai,[1] and Naoki Ishiguro[1], [1]Department of Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Japanese post-marketing surveillance (PMS) data demonstrated that effectiveness of abatacept in rheumatoid arthritis (RA) patients with previous biologics treatment (bio-switch) was significantly lower than that in bio-naïve patients. Useful predictive factors for good clinical response of abatacept is necessary especially in the bio-switch patients. Serum matrix metalloproteinase-3 (MMP-3) is an enzyme produced by synoviocytes which can be used to predict clinical effectiveness and joint destruction in RA patients. However, little is known about the relationship between MMP-3 and effectiveness of abatacept. This study aimed to study whether serum MMP-3 levels can predict good clinical effectiveness of abatacept in the bio-switch RA patients using data from a multicenter cohort.

Methods: Participants were consecutive 423 RA patients treated with abatacept, observed for longer than 52 weeks, and registered in the TBCR, a Japanese multicenter registry system for RA patients treated with biologics. Multivariate logistic regression analysis was used to study predictive factors for achievement of low disease activity at 52 weeks separately in bio-naïve and bio-switch group.

Results: A total of 189 bio-switch and 234 bio-naïve patients were included in this study. ROC analysis revealed that MMP-3 improvement rate at 12 weeks, compared to 4 and 24 weeks, had highest AUC and the best cut-off value was 20.0% at 12 weeks for predicting achievement of low disease activity (LDA) at 52 weeks in the bio-switch group (Figure 1, right panel). We performed multivariate logistic regression analysis to study independent predictive factors for LDA at 52 weeks using patients‘ background factors as well as 20% improvement of MMP-3 at 12 weeks. In the bio-naïve group, DAS28-CRP score at baseline was the only predictive factor, while the achievement of 20% improvement of MMP-3 at 12 weeks was an independent predictive factor (adjusted OR: 3.550, p=0.005) in addition to DAS28-CRP in the bio-switch group (Table). In the bio-switch group, patients that achieved 20% improvement of MMP-3 at 12 weeks demonstrated significantly higher achievement rate of LDA at 52 weeks compared to those that did not achieved 20% improvement (60.0 vs 33.3%, p=0.001) (Figure 2).

	AUC	std. Err.	95% CI
at 4 weeks	0.595	0.043	0.512-0.679
at 12 weeks	0.586	0.042	0.504-0.669

	AUC	std. Err.	95% CI
at 4 weeks	0.538	0.050	0.439-0.636
at 12 weeks	0.644	0.048	0.550-0.737

	Bio-naive		Bio-switch	
variables	adjusted OR (95% CI)	p-value	adjusted OR (95% CI)	p-value
Age	0.998 (0.962-1.035)	0.926	0.990 (0.951-1.030)	0.627
Male (vs female)	0.672 (0.289-1.566)	0.357	0.954 (0.266-3.418)	0.943
RF positive	2.117 (0.912-4.913)	0.081	0.427 (0.127-1.430)	0.167
with concomitant MTX	1.628 (0.764-3.468)	0.207	1.310 (0.522-3.289)	0.565
with concomitant PSL	0.680 (0.320-1.442)	0.314	0.580 (0.230-1.465)	0.249
DAS28-CRP @baseline	0.590 (0.413-0.844)	***0.004***	0.646 (0.449-0.930)	***0.019***
mHAQ score @baseline	0.672 (0.363-1.246)	0.207	0.588 (0.267-1.291)	0.186
20% improvement of MMP-3	1.884 (0.885-4.010)	0.100	4.277 (1.658-11.028)	***0.003***

Conclusion: In the bio-switch patients, we sometimes have difficulty to obtain good clinical response of abatacept and it would be even more important to judge whether to continue abatacept or whether to add other anti-rheumatic drugs as early as possible.

Our results suggest that improvement in MMP-3 levels at 12 weeks is key to predicting the clinical efficacy of abatacept at 1 year. It will be important to pay closer attention not only to major clinical indices such as DAS28, but also to changes in MMP-3 levels, in order to optimize clinical outcomes when treating Bio-switch patients with abatacept.

Acute Effects of IL-6 Blockade, TNFα Inhibitor or Glucocorticoids on Bone Turnover Markers and Wnt Inhibitors in Early Rheumatoid Arthritis

Angelo Fassio,[1] GIovanni Adami,[1] Ombretta Viapiana,[1] Luca Idolazzi,[1] Giovanni Orsolini,[1] Alessandro Giollo,[1] Davide Gatti,[2] and Maurizio Rossini[1], [1]University of Verona, Verona, Italy, [2]Univerisity of Verona, Verona, Italy

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

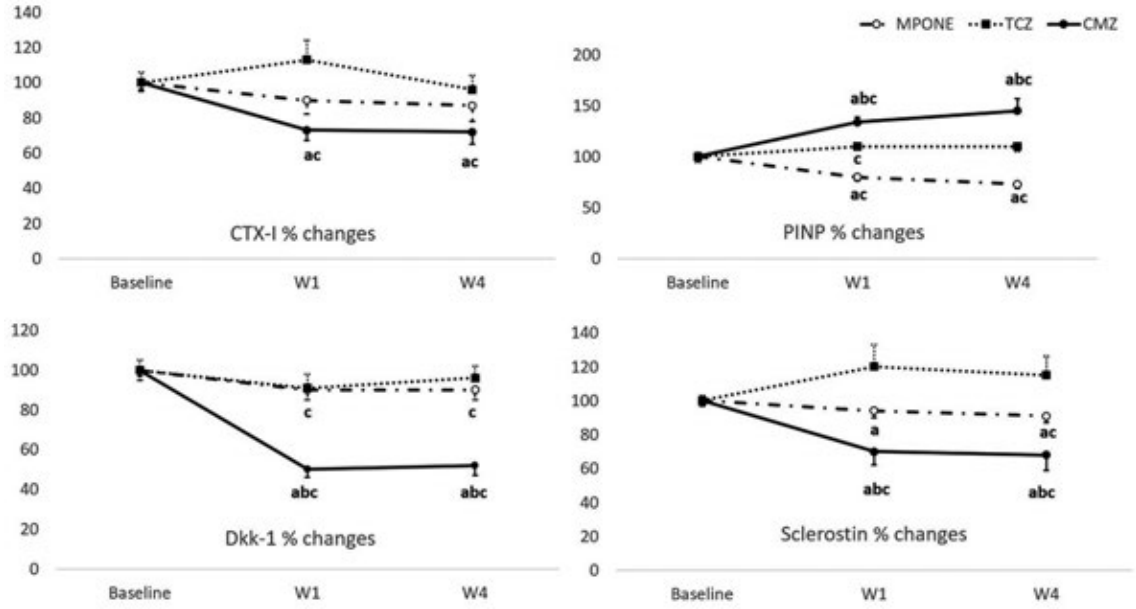

Figure 1. Bone turnover markers and Wnt inhibitors changes after 1 and 4 weeks of treatment with methyl-prednisolone (MPONE), tocilizumab (TCZ) and certolizumab pegol (CMZ)

Background/Purpose: Wnt signaling is an important regulator of bone remodeling and it is involved in the pathogenesis of focal and systemic bone loss in Rheumatoid Arthritis (RA) patients. The aim of the present study is to investigate the short-term effects of three different anti-inflammatory therapies on Wnt inhibitors and bone turnover markers (BTMs) in patients with early RA.

Methods: We performed a retrospective analysis of prospectively collected data. We enrolled women affected by early RA (< 12 months) according to 2010 ACR/EULAR criteria who started treatment with certolizumab pegol (200 mg SC weekly), tocilizumab (162 mg SC weekly) or methyl-predinsolone (8 mg daily). Women enrolled in the study were required to have positive RF and/or positive ACPA and active disease (DAS28 ≥2.6) despite stable treatment with subcutaneous methotrexate (10-15 mg/week) for at least 6 months. Clinical parameters and blood samples were collected at baseline, week 1 and week 4.

Results: Data were obtained for 14 patients treated with certolizumab pegol, 14 patients treated with tocilizumab and 20 patients treated with methyl-prednisolone. Mean DAS28 at baseline was 4.0 ± 0.7 No difference in any of the tested parameters was found at baseline. The percent changes of the serum levels of bone turnover markers, Dkk-1 and sclerostin are reported in **Figure 1**. CTX-I, Dkk-1 and sclerostin decreased abruptly after 1 week of treatment with certolizumab pegol (-27% ± 21.5%, -50% ± 13.2% and -30% ± 30.4% respectively), and similar results were found after 4 weeks. Methyl-prednisolone induced comparable changes, albeit less evident, on CTX-I and Wnt inhibitors. We found an increase in PINP serum levels after treatment with anti-TNFα, while we observed a decrease with methyl-prednisolone. Tocilizumab did not significantly affect BTMs or Wnt inhibitors.

Conclusion: TNFα inhibition seems to have a strong and quick effect on BTMs and Wnt inhibitors, which was not observed with IL-6 blockade, at least in the short-term. Glucocorticoid treatment exerts similar, though less prominent, changes, potentially linked to the suppression of inflammation, nonetheless it still show some undesired effects on bone metabolism (ie, suppression of bone formation).

Analysis of Adverse Events of Methotrexate (MTX), bDMARDs and Tofacitinib (TOFA) Reported to Pharmaceuticals and Medical Devices Agency (PMDA), Japan

Naonori Tsuda,[1] Shigeko Inokuma,[2] Kenichi Hiraga,[3] Yoshinori Masui,[3] and Toshikazu Kano[3], [1]Kohondai Hospital, National Center for Global health and Medicine, Ichikawa, Chiba, Japan, [2]Chiba Central Medical Center, Ichikawa, Chiba, Japan, [3]Kohnodai Hospital, National Center for Global health and Medicine, Ichikawa, Chiba, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Among DMARDs (disease modifying anti-rheumatic drugs), methotrexate (MTX), bDMARDs (biologic DMARDs) and JAK (Janus kinase) inhibitors are the major. Many adverse events of these are reported to Pharmaceuticals and Medical Devices Agency (PMDA) from all over Japan and listed in the Japanese Adverse Event Report database (JADER). There have been few studies adopting on that database concerning DMARDs.

Methods: The total numbers and numbers of each adverse event related to MTX, bDMARDs, and TOFA were searched in JADER of PMDA homepage, year by year. Biologic DMARDs included those covered by Japanese Health Insurance System for Rheumatoid Arthritis: Infliximab (IFX), Etanercept (ETN), Tocilizumab (TCZ), Adalimumab (ADA), Abatacept (ABT), Golimumab (GOL), Certolizumab pegol (CZP). Conventional synthetic DMARDs other than MTX were out of search this time.

Categories of adverse events were only partially reclassified to suit the clinical entities. Adverse events searched included infectious diseases, cytopenia, pulmonary diseases, lymphoproliferative diseases, and other tumors. The

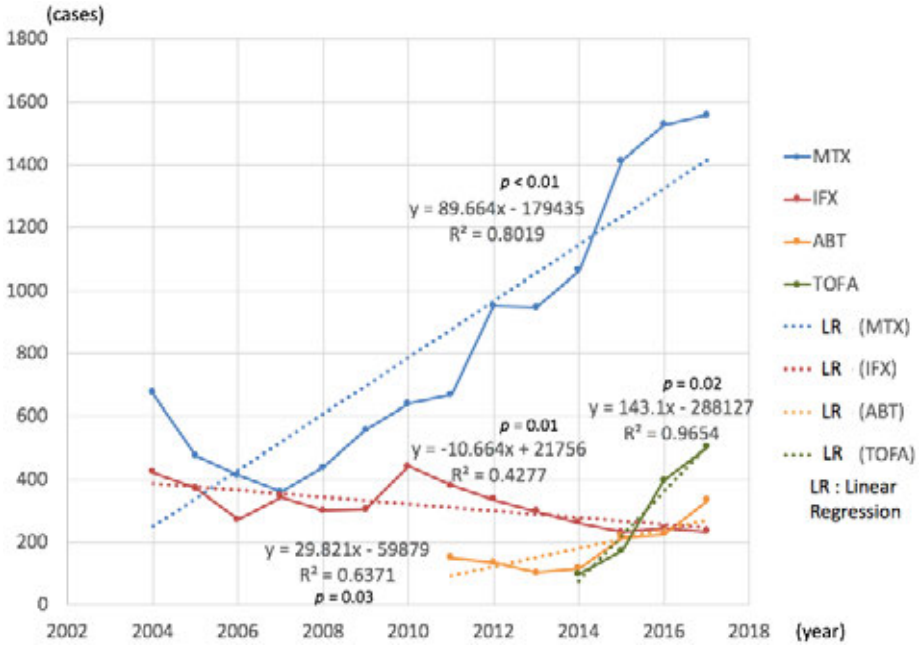

Figure 1. Total number of adverse events of DMARDs - with significant change -

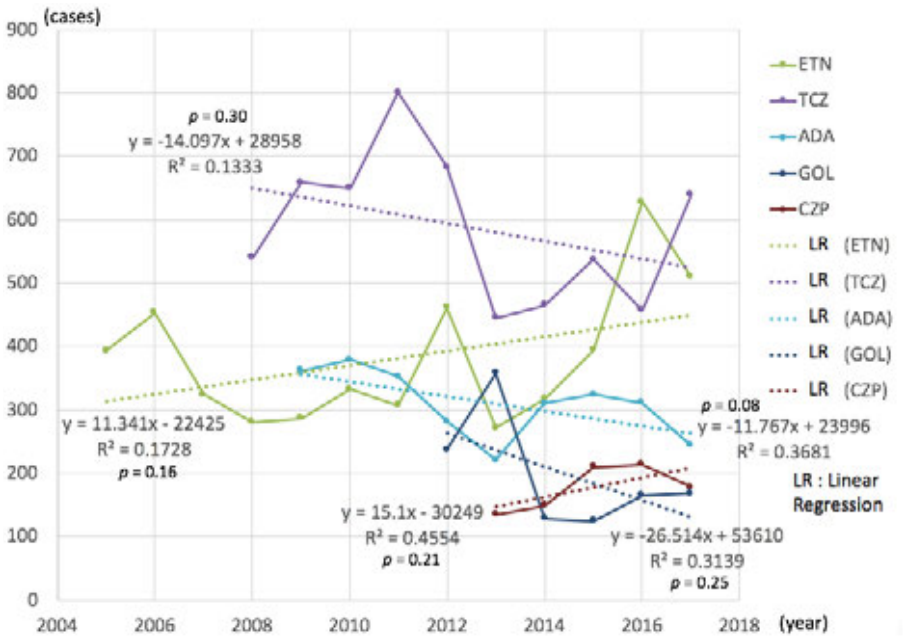

Figure 2. Total number of adverse events of bDMARDs - with no significant change -

data of the first year of introduction of the drugs were not included because of that total prescription number might have differed from that in the years afterward. Linear regression analysis was adopted, and the statistical significance was by $p < 0.05$.

Results: The total number of adverse events related to MTX has increased significantly year by year (average 90 cases per year, correlation coefficient (CC) = 0.80, $p < 0.01$) (Figure 1). As for either ABT (average 30 / year, CC = 0.64, $p = 0.03$) or TOFA (average 143 / year, CC = 0.97, $p = 0.02$), the numbers were also increased. But the numbers decreased as for IFX (average -11 / year, CC = 0.43, $p = 0.01$) by each year, whereas other DMARDs showed no significant increase or decrease (Figure 2).

For MTX, LPD (lymphoproliferative disorders) contributed most to the increase among the detailed adverse events (average 41/ year, CC = 0.85). Secondary, infections other than those specified (average 8.0 / year, CC = 0.66) and solid tumor (average 6.6 / year, CC = 0.88) contributed (Table 1).

As for ABT, solid tumor (average 4.7 / year, CC = 0.59), pneumonia (average 4.0 / year, CC = 0.59) and other infections (average 3.6 / year, CC = 0.50) were top 3. As for TOFA, other infections (average 19 / year, CC = 0.99), pneumonia (average 16 / year, CC = 0.91) and herpes zoster (average 16 / year, CC = 0.91) contributed.

IFX related adverse events were decreased, including other infections (average -4.0 / year, CC = 0.62), pneumonia (average -3.8 / year, CC = 0.81) and gastrointestinal disorder (average -2.0 / year, CC = 0.46).

Conclusion: The adverse events related to MTX, ABT, TOFA have been increasingly reported to PMDA. Among them, LPD under MTX has more and more.

	slope (cases per year)	R-squared	*p* value

Comparison of the Efficacy and Safety of Abatacept in Rheumatoid Arthritis Patients with and Without Interstitial Lung Disease

Sho Sasaki,[1] Akira Ishii,[2] Mai Sugiyama,[2] Yuto Izumi,[2] Yoko Nakagome,[2] Kazuki Hirano,[3] Takayoshi Kurabayashi,[1] Noriko Sasaki,[2] Chiho Yamada,[2] and Shinji Sato[4], [1]Tokai Universitiy School of Medicine, Isehara, Japan, [2]Tokai University School of Medicine, Isehara, Japan, [3]Tokai University School of Medicine, Isehara, [4]Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Yokohama, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is one of complication in patients with rheumatoid arthritis (RA) and its presence often has an effect on the management of RA. As the presence of ILD is thought to be one of risk factors of pulmonary infection, careful attention should be needed when biological products are used for the treatment of RA with ILD. Although the usefulness of biologics in RA patients without ILD has been already shown, the utility of biologics in patients with RA complicated with ILD remains unclear. Therefore, the aim of this study is to examine differences in the efficacy and safety of biologics for RA with ILD and without ILD.

Methods: Patients with RA who fulfilled the ACR 1987 or 2010 ACR/EULAR classcication criteria and were treated with Abatacept (ABT) at Tokai University Hospital between 2009 and 2018 were enrolled. We retrospectively collected clinical information from medical records and stored computerized database. We compared the efficacy and safety between RA patients with ILD and without ILD. Both disease activities and safety were evaluated using DAS28-CRP, CDAI, SDAI, occurrence of adverse events and continuation rate of ABT at 52 weeks. Statistical analyses were performed using paired T-test, Man-Whitney test, and the log-rank test.

Results: Twenty-eight patients with RA were enrolled. Among these patients, 2 patients were excluded because of lack of data. Of these 26 patients, 15 (58%) were complicated with ILD. There were no significant differences in age, gender, disease duration, positivity of rheumatoid factor or anti-citrullinated peptide antibodies, DAS28-CRP, CDAI and SDAI score at baseline of each group. However, RA with ILD group had significantly higher rate of combination use and the dosage of PSL than RA without ILD group at baseline. DAS28-CRP, CDAI and SDAI were significantly improved after treatment at 52 weeks in both group (RA with ILD group: 3.8 vs. 2.6, $P< 0.05$; 16.4 vs. 4.4, $P< 0.001$; 15.7 vs. 4.2, $P< 0.001$, RA without ILD group: 3.6 vs. 2.1, $P=0.004$; 18.1 vs. 6.5, $P< 0.05$; 16.6 vs. 6.2, $P< 0.05$, respectively). There were no significant differences in mean % change of DAS28-CRP, CDAI and SDAI at 52 weeks between both groups (-1.5 vs. -1.9, $P=0.8$, -12.0 vs. -11.6, $P=0.8$, -11.5 vs. -10.3, $P=0.7$, respectively). There was no significant difference in the continuation rate of ABT between two groups (93.3% vs. 100%, $P=0.4$).

Conclusion: These results suggested that ABT demonstrated the same efficacy and safety in patients with RA complicated with ILD as well as RA without ILD.

Discontinuation of Concomitant Methotrexate in Japanese Patients with Rheumatoid Arthritis Treated with Tocilizumab: An Interventional Study

Toshihisa Kojima,[1] Shuji Asai,[1] Masahiro Hanabayashi,[2] Masatoshi Hayashi,[3] Nobunori Takahashi,[1] Yachiyo Kuwatsuka,[4] Masahiko Ando,[4] and Naoki Ishiguro[1], [1]Department of Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Ichinomiya Municipal Hospital, Ichinomiya, Japan, [3]Hayashi Orthopedic Clinic, Nagano, Japan, [4]Nagoya University Hospital, Nagoya, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Biological DMARD (bDMARD) concomitant with methotrexate (MTX) has made great progress in the treatment of rheumatoid arthritis (RA) in these decades. There are various issues relating to safety, efficacy and economics in clinical practice during long-term therapy. Some patients discontinue MTX due to toxicity including gastrointestinal (GI) disorders. Thus, de-escalation of MTX during treatment with bDMARD while maintaining a favourable disease activity state may be beneficial treatment option from the perspective of reducing adverse events. The efficacy of tocilizumab (TCZ) has been demonstrated in monotherapy as well as with concomitant MTX, opening up the possibility of MTX discontinuation in these patients if disease control can be maintained.

This study aimed to evaluate the efficacy and safety of MTX discontinuation in RA patients with sustained low disease activity undergoing combination therapy with TCZ plus MTX.

Methods: This multicentre, open-label, uncontrolled, prospective 64-week study included RA patients maintaining low disease activity (Clinical Disease Activity Index [CDAI] ≤10) for ≥12 weeks with TCZ plus MTX. MTX was discontinued following 12 weeks of biweekly administration while continuing TCZ therapy. The rescue treatments were performed if the CDAI score was >10 and at the discretion of the investigator and/or upon patient request. The primary endpoint was the proportion of patients maintaining low disease activity with no flare at week 36 (24 weeks after MTX discontinuation). Disease flare was defined as a CDAI score >10 or intervention with the rescue treatments for any reasons. Assuming that 80% of patients would maintain low disease activity at week 36, 43 patients were calculated as necessary to prove the clinical feasibility of discontinuing MTX at a power of ≥80% with a threshold response rate of 60%. Secondary endpoints were GI symptoms (Frequency Scale for Symptoms of Gastro-oesophageal reflux disease score), physical function (HAQ-DI), and quality of life(EQ-5D).

Results: A total of 49 patients completed 36 weeks of therapy. Table 1 shows the baseline (week 0) characteristics of patients included in the efficacy analyses. The proportions (95% CI) of patients who maintained low disease activity without a flare at weeks 12, 24, and 36 were 87.8% (75.2 – 95.4%), 81.6% (68.0 – 91.2%), and 75.5% (61.1 – 86.7%), respectively (Fig. 1). The lower limit of the 95% CI at week 36 exceeded the assumed threshold response rate of 60%, demonstrating the clinical feasibility of MTX discontinuation. The prevalence of gastro-oesophageal reflux disease, defined as a Frequency Scale for Symptoms of Gastro-oesophageal reflux disease score ≥8, significantly decreased from week 0 to 12 (27.1% to 18.4%; $P = 0.025$) (Fig. 2). No significant impairment were observed in the HAQ-DI and EQ-5D from week 0 to 36 (Fig. 3).

Patient characteristics at baseline

	Total, n = 49		
Age, years	62	±	10
Female, %	84		
Weight, kg	55	±	11
Disease duration, years	11	±	8
Route of TCZ, intravenous/subcutaneous, %	65/35		
Rheumatoid factor positive, %	79		
Anticyclic citrullinated peptide positive, %	90		
MTX dose, mg/week	8.2	±	2.3
Use of glucocorticoids, %	29		
CDAI	2.7	±	2.5
CDAI ≤2.8, %	67		
CRP, mg/dl	0.04	±	0.06
HAQ-DI	0.472	±	0.613
EQ-5D	0.822	±	0.17

Data are shown as mean ± SD or percentage.

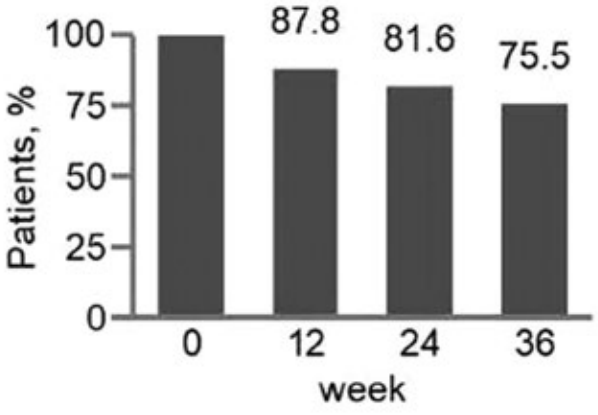

Figure 1. Proportion of patients maintaining low disease activity without a flare.

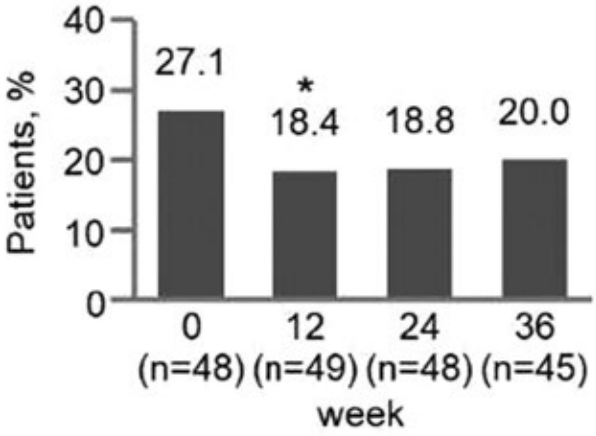

Figure 2. Prevalence of gastro-oesophageal reflux disease defined as a FSSG score ≥8. *$P < 0.05$ vs. week 0 by McNemar's test.

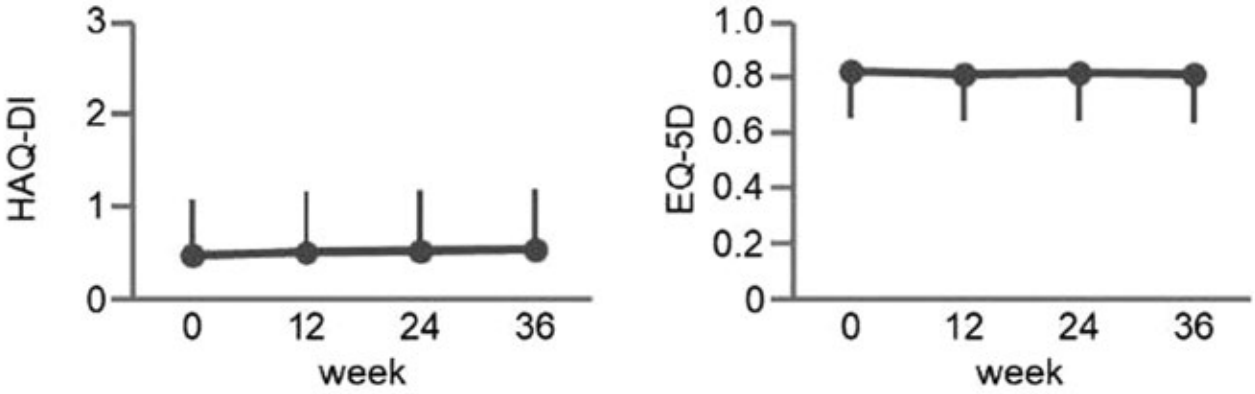

Figure 3. Changes in Health Assessment Questionnaire Disability Index (HAQ-DI) and EuroQol-5 dimension (EQ-5D) from week 0 to 36. Values represent mean (standard deviation).

Conclusion: Discontinuation of concomitant MTX is clinically feasible for maintaining low disease activity without impairment of physical function and QOL, and may be beneficial from the perspective of reducing GI symptoms in RA patients treated with TCZ.

Effect of Baricitinib on Functional Impairment in RA Patients with Moderate Disease Activity and an Inadequate Response to Conventional DMARDs

Bruce Kirkham,[1] Elena Nikiphorou,[2] Pedro López-Romero,[3] Ilias Kouris,[3] Thorsten Holzkaemper,[3] Liliana Zaremba-Pechmann,[4] Inmaculada de la Torre,[3] and Peter Taylor[5], [1]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom, [2]King's College London, London, United Kingdom, [3]Eli Lilly and Company, Indianapolis, IN, [4]HaaPACS GmbH, Schriesheim, Germany, [5]University of Oxford, Oxford, United Kingdom

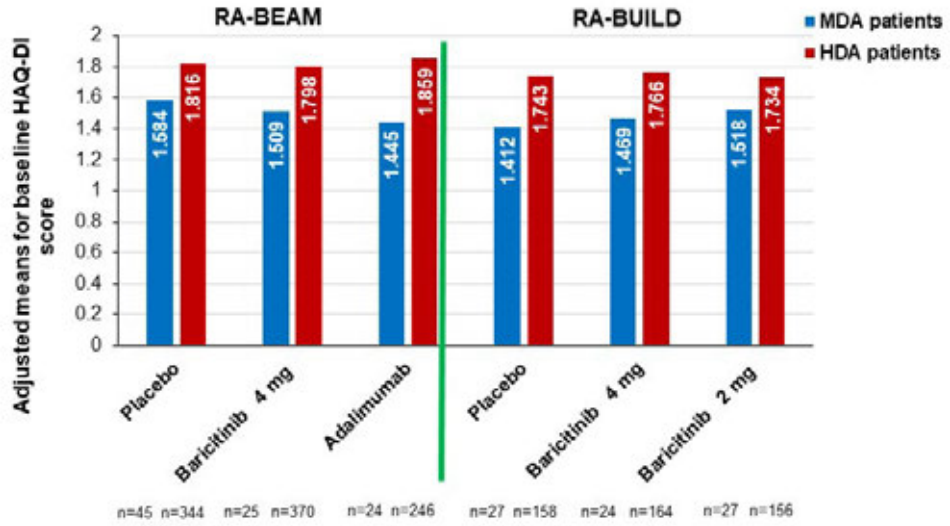
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In RA, disease activity correlates with physical function[1] and there is a link between joint damage and functional disability[2]. In many countries, RA patients (pts) with inadequate response (IR) to MTX or other conventional DMARDs (cDMARDs) are not eligible for potentially more effective treatments, such as biologic or targeted synthetic DMARDs (tsDMARDs), unless they have high disease activity (HDA). Thus, managing RA pts with persistent moderate disease activity (MDA) despite cDMARD treatment poses a problem. Baricitinib (BARI) is a tsDMARD approved for the treatment of moderate to severe RA in adults. This post-hoc analysis assessed if RA pts with MDA benefit from improved physical function with BARI treatment to the same extent as pts with HDA

Methods: Pts analysed were from the modified intention-to-treat populations in the two BARI phase 3 studies RA-BEAM[3] (MTX-IR) and RA-BUILD[4] (cDMARD-IR) with moderate to severe disability (HAQ-Disability Index [HAQ-DI] score ≥1), MDA (Simplified Disease Activity Index [SDAI] score 11.1–26.0) or HDA (SDAI score >26.0) and non-missing SDAI data at baseline. All pts fulfilled ACR criteria for RA. Pts from RA-BEAM received BARI 4 mg + MTX once daily (n=396), adalimumab 40 mg every 2 weeks + MTX (n=270) or placebo (PBO) + MTX (n=390); pts from RA-BUILD received BARI 4 mg (n=189) or 2 mg (n=186) or PBO (n=185). Multivariable linear regression (MLR) models were used to estimate mean HAQ-DI scores at baseline and week (wk) 24 for the treatment arms stratified by baseline disease activity (MDA or HDA SDAI). Age, RA duration, BMI, high sensitivity CRP, baseline SDAI disease activity (MDA or HDA), treatment and treatment-by-baseline SDAI interaction were included as covariates. The MLR model for HAQ-DI at wk 24 was further adjusted by baseline HAQ-DI

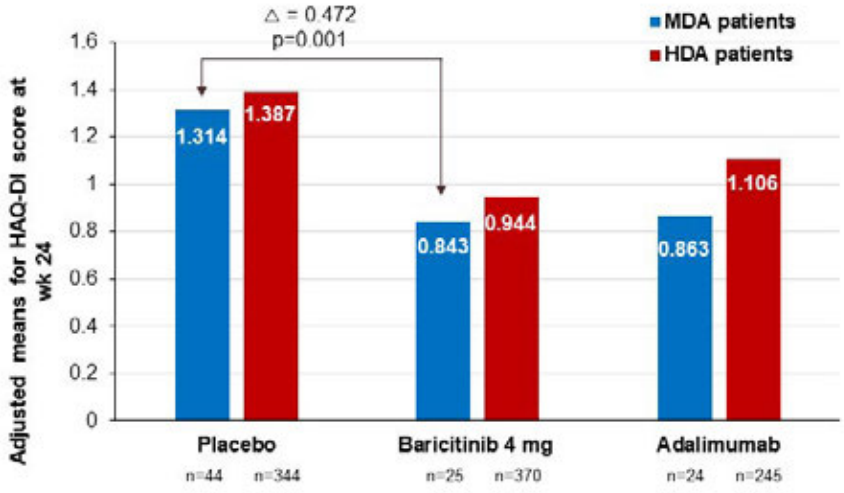
Results: Mean adjusted HAQ-DI scores at baseline were greater in pts with HDA than in those with MDA (Fig. 1). In pts from RA-BEAM with MDA at baseline, the mean adjusted HAQ-DI score at wk 24 was 0.472 points greater in PBO

Figure 1. Baseline mean adjusted HAQ-DI scores in pts from RA-BEAM and RA-BUILD with MDA or HDA



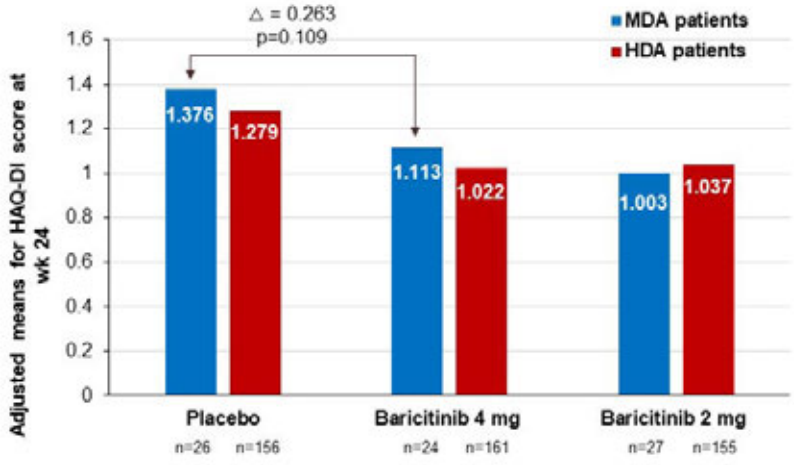
Data presented for patients with HAQ-DI ≥1 and non-missing data after MLR. Patient numbers do not match those presented in the text due to some missing data for the baseline covariates used in the MLR.
HAQ-DI, Health Assessment Questionnaire-Disability Index; HDA, high disease activity; MDA, moderate disease activity; MLR, multivariable linear regression; pts, patients.

Figure 2. Mean adjusted HAQ-DI scores at wk 24 in pts from RA-BEAM with MDA or HDA at baseline



Data presented for patients with HAQ-DI ≥1 and non-missing data after MLR. Patient numbers do not match those presented in the text due to some missing data for the baseline covariates used in the MLR.
HAQ-DI, Health Assessment Questionnaire-Disability Index; HDA, high disease activity; MDA, moderate disease activity; MLR, multivariable linear regression; pts, patients; wk, week; △, difference in HAQ-DI score.

Figure 3. Mean adjusted HAQ-DI scores at wk 24 in pts from RA-BUILD with MDA or HDA at baseline



Data presented for patients with HAQ-DI ≥1 and non-missing data after MLR. Patient numbers do not match those presented in the text due to some missing data for the baseline covariates used in the MLR. HAQ-DI, Health Assessment Questionnaire-Disability Index; HDA, high disease activity; MDA, moderate disease activity; MLR, multivariable linear regression; pts, patients; wk, week; △, difference in HAQ-DI score.

than in BARI 4 mg pts (Fig. 2; p=0.001). A similar pattern of improved physical function with BARI was seen in RA-BUILD, but the adjusted mean difference in HAQ-DI score between PBO and BARI 4 mg (0.263) was not statistically significant (Fig. 3; p=0.109). In pts with HDA at baseline, the mean adjusted HAQ-DI score at wk 24 was 0.443 points greater (p< 0.001) with PBO than with BARI 4 mg in RA-BEAM, and 0.257 points greater (p< 0.001) in RA-BUILD

Conclusion: MTX-IR and/or cDMARD-IR RA pts with MDA and moderate to severe disability at baseline treated with BARI show a similar pattern of improvement in physical function vs. PBO-treated pts to that seen in pts with HDA, supporting early use of BARI in MDA pts. As for those with HDA, pts with persistent MDA despite MTX and/or other cDMARD treatment could benefit from access to biologic and tsDMARDs to prevent disability progression.

Relationship Between Adalimumab Concentrations, Plasma Cytokines, Anti-drug Antibodies and Disease Activity in Rheumatoid Arthritis

Lisa Stamp,[1] Paula Keating,[2] Christopher Frampton,[3] Murray Barclay,[3] Niamh Fanning,[3] Melanie Millier,[4] Paul Hessian,[4] and John O'Donnell[5], [1]University of Otago, Christchurch, Christchurch, Canterbury, New Zealand, [2]Canterbury Health Laboratories, Christchurch, New Zealand, [3]University of Otago, Christchurch, Christchurch, New Zealand, [4]University of Otago, Dunedin, New Zealand, [5]Christchurch Hospital, Christchurch, New Zealand

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Therapeutic drug monitoring (TDM) would be important if there was evidence to support the utility of measured drug concentrations in making changes to dose in order to improve drug efficacy and/or reduce toxicity. To determine the influence from variables, including patient characteristics and disease activity, on adalimumab concentrations and to assess the relationships between adalimumab concentrations, the presence of anti-drug antibodies (ADAs) and disease activity in RA.

Methods: 156 people with RA, receiving adalimumab for at least 4 months were recruited. Disease activity assessed by DAS28 with responders defined as DAS28≤3.2. Serum and plasma obtained for measurement of adalimumab concentrations and ADAs, and a panel of cytokines in a sub-group.

Results: Univariate analysis revealed a negative correlation between weight, DAS28, SJC28, TJC28, CRP, pain VAS, fatigue VAS, physicians global, duration of morning stiffness, and adalimumab concentrations. NZ Europeans, those on methotrexate, those without ADAs, and those with DAS28≤3.2 had higher adalimumab concentrations. Multivariate analysis, which included the presence of ADAs, revealed CRP ($p< 0.001$), weight ($p< 0.004$) and ethnicity ($p< 0.001$) were all independently negatively associated with adalimumab concentrations. There was a negative correlation between IL-6 and adalimumab concentrations ($r=-0.038$; $p< 0.01$). There was a negative correlation between adalimumab concentration and DAS28 ($r=-0.37$; $p< 0.0001$). Adalimumab concentrations were higher in those with DAS28 ≤3.2 compared to those with DAS28 >3.2 (median (IQR) 10.8 (6.4-20.8) mg/l vs.7.1 (1.5-12.6) mg/l; $p < 0.001$). Anti-drug antibodies were measured in the 45 participants with an adalimumab concentration < 5mg/l. 23/45 (51%) had HMSA titer >2 indicating the presence of anti-drug antibodies and of these 8/23 (34.8%) had an anti-drug antibody/adalimumab ratio ≥8AU, consistent with these being neutralizing antibodies. Adalimumab concentrations were lower in those with anti-drug antibody ratios ≥8AU compared to those with anti-drug antibody ratios < 8AU (mean (95%CI) 0.43 (0.00-1.06) vs. 1.84 (1.39-2.37) p=0.001). Adalimumab concentrations were lower in those 23 with HMSA titer >2 compared to those without ADA (mean (95%CI) 1.01 (0.00-1.56) vs. 2.47 (1.75-3.38) p=0.002).

Conclusion: Adalimumab concentration correlates negatively with markers of inflammatory disease activity in RA. Adalimumab concentration in the range 5 to 7 mg/l detected in serum are associated with better inflammatory disease control. Very low drug concentrations (< 5mg/l) are associated with the detection of anti-drug antibodies. These associations are consistent with the hypothesis that achieving an adequate serum adalimumab concentration is important for disease control and that the presence of ADA may be one mechanisms important in drug resistance.

Is Background Methotrexate Still Advantageous in Extending TNF Drug Survival in the Elderly: An Analysis of the British Society for Rheumatology Biologics Register – Rheumatoid Arthritis

Katie Bechman,[1] Anuoluwapo Oke,[2] Mark Yates,[3] Sam Norton,[3] Elaine Denderson,[4] Andrew Cope,[5] and James Galloway[2], [1]Kings College London, London, England, United Kingdom, [2]Kings College London, London, United Kingdom, [3]Kings College London, London, [4]MRC Lifecourse Epidemiology Unit, University of Southampton, Southampton, [5]Academic Rheumatology, King's College London, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term observational data from national registries in rheumatoid arthritis allow the examination of TNF drug survival rates. Despite a good initial response to a TNF inhibitor, efficacy can wane over time. Secondary failure may result from the formation of antidrug antibodies (ADA). Concomitant immunosuppression with methotrexate increases TNF inhibitor concentrations via the suppression of ADAs, prolonging TNF drug survival [1]. It is plausible that the production of ADA is less robust in elderly adults, as the aging immune system undergoes a gradual process of decline, termed immunosenescence. This may eliminate the need for concomitant immunosuppression with methotrexate. The objective of this study was to evaluate drug survival with TNF monotherapy compared to combination therapy with methotrexate in rheumatoid arthritis older adults (≥75 years).

Methods: Patients from the British Society for Rheumatology Biologics Register (BSRBR-RA), a prospective observational cohort study, who were biologic naïve and commencing their first TNF inhibitors were included in the analysis. The cohort was stratified according to age at registration: < 75 and ≥75 years. Cox proportional hazards were generated to compare the risk of TNF discontinuation between patients prescribed TNF monotherapy compared to TNF-methotrexate combination. Three models were developed evaluating treatment discontinuation; 1) any cause 2) inefficacy and 3) adverse events. Propensity score models were used to address confounding by indication.

Results: The analysis included 15,700 patients, of which 14, 932 (95%) were < 75 years old. Comorbidity burden and RA disease activity were higher in the ≥75 cohort. Fifty two percent of patients discontinued TNF therapy during the follow up period. Persistence with therapy was higher in the < 75 cohort. Patients receiving TNF monotherapy were more likely to discontinue compared to patients receiving concomitant methotrexate [hazard rate (HR) 1.12 (1.06-1.18) p=< 0.001]. This finding only held true in patients in the < 75 cohort. Examining TNF discontinuation by cause revealed patients ≥75 receiving TNF monotherapy were less likely to discontinue TNF due to inefficacy [HR 0.66 (0.43-0.99) p=0.04] and more likely to discontinue therapy from adverse events [HR 1.21 (1.11-1.32) p< 0.001] (figure 1). These results were supported by the propensity score analyses.

Conclusion: TNF monotherapy is associated with an increase in treatment failure. In the older adults the disadvantage of TNF monotherapy on drug survival is no longer seen. Patients over 75 have fewer discontinuations due to inefficacy compared to younger patients. We speculate that this may reflect a decline in immunogenicity associated with immunosenescence.

Abstract Number: 1442

Comparison of Sustained Clinical Remission And/or Low Disease Activity Rate Between Rapidly and Gradually De-escalation of Abatacept in Rheumatoid Arthritis

Masaomi Yamasaki[1], [1]Shin-Yokohama Arthritis and Rheumatology Clinic, Yokohama, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: However biological DMARDs (bDMARDs) and treatment strategies have improved the outcomes of rheumatoid arthritis (RA), it is unknown who can taper or stop bDMARDs and strategies for de-escalation.

We analyze predictors of tapering of withdrawal failure in rheumatoid arthritis (RA) patients treated with abatacept. This study will assess and compare (1) characteristic of patients who achieve remission (REM) or low disease activity

(LDA) as who can taper abatacept and (2) two de-escalation methods, rapidly and gradually de-escalation in patients who respond first-line therapy.

Methods: Cases were recruited to SHin-yokohama Arthritis REgister (SHARE) between 2015 and 2019 (n=3,674). Patients were diagnosed according to ACR/EULAR 2010 classification criteria, and treated with DMARDs which included abatacept (n=248). In 248 (Male24, Female224 cases, RA duration 11.3+/-8.0 years, CDAI 24.5+/-14.7) cases, Clinical Disease Activity Index (CDAI) , Health Assessment Questionnarie-Disability Index (HAQ-DI), anti-CCP2 and patients clinical parameters were analyzed. Two de-escalation methods were compared in this study. In rapidly de-escalation methods, abatacept were decreased to half dose in patients with stable REM/LDA over 12 weeks. In gradually de-escalation methods, abatacept were decreased to 75%, 50%, 33%, 25%, 20%, 17%, 14%, 12.5% in order with stable REM/LDA over 12 weeks.

Results: Of 248 patients, 161 patients (73.2%) were achieved to REM and/or LDA within 6 months after using abatacept.

(1) Multivariate logistic regression examined the predictors to detect who can taper abatacept. Higher anti-CCP2 titer patients were correlate with patients who achieve remission (REM) or low disease activity (LDA) in patients treated with abatacept (OR 0.99, 95%CI 0.994-0.999, p=0.0016). ROC analysis of anti-CCP2 showed cut-off value of 84.5 U/ml with the area under the curve was 0.7633. (2) Comparison of sustained REM and/or LDA rate between rapidly and gradually de-escalation methods of abatacept in rheumatoid arthritis. 11 cases were tapered abatacept with rapidly de-escalation method and 88 patients were with gradually de-escalation method. Gradually de-escalation method showed less relapse rate tapered abatacept after 6 months (6.8% vs. 63.6%, p< 0.0001) and showed less swollen joints (0.1+/10.6 joints vs. 0.4+/-0.7 joints, p=0.004) compared with rapidly de-escalation method. (3) Sustained REM and/or LDA rate after tapered abatacept using gradually de-escalation method were 63.4% in 12 months and 82.7% in 24 months.

Conclusion: A combination of high anti-CCP2 titer and tapering abatacept using gradually de-escalation method may help to predict successful abatacept deduction in RA patients with sustained clinical REM and/or LDA.

Real World Switching Patterns of Etanercept Original and Biosilmilar in Germany

Rieke Alten,[1] Miriam Tarallo,[2] Christen Gray,[3] and Cristiana Miglio[3], [1]Schlosspark-Klinik University Medicine, Berlin, Germany, [2]Pfizer Inc., Rome, Italy, [3]IQVIA, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously evaluated switching dynamics between etanercept biologic original (EtnBO) and etanercept biosimilars (EtnBS) over approximately 18 months following the first EtnBS launch in Germany (February 2016). As new data has become available, analysis was repeated over longer time-periods.

Methods: Patients receiving their first EtnBS prescription in February 2016-October 2018 were retrospectively identified in the German Longitudinal Prescriptions database (IQVIA® LRx, January 2008-October 2018). The proportion, mean age and gender of patients previously treated with EtnBO was determined using a 12-month lookback period. For these patients, the proportions of those switching to other biologics and of those switching back to EtnBO were evaluated, along with mean age, gender and median time to switch-back. The analysis was performed separately for patients initiating EtnBS in three consecutive 11-month time-periods from EtnBS launch: February 2016-December 2016 (period 1), January 2017-November 2017 (period 2), and December 2017-October 2018 (period 3).

Results: Of 16,543 identified patients (56 years, 34% males) initiating EtnBS, 4,471 (27%) had prior EtnBO (56 year, 38% males): 1,311 in period 1, 1,683 in period 2 and 1,653 in period 3. After initiation, the proportion of patients who switched from EtnBS to other biologics in period 1, 2 and 3 respectively was 186 (14%), 187 (11%) and 71 (4%) and of those who switched back to EtnBO was 278 (21%), 381 (23%) and 278 (17%). The median time to switch-back was similar across the 3 periods (3-4 months), as was the age and gender distribution across the different patient groups.

Conclusion: This study confirms previous findings on switching dynamics between EtnBO and its biosimilars and shows that approximately a fifth of patients in the entire study period switch back to EtnBO after 3-4 months from EtnBS initiation. Future research should explore factors influencing switching dynamics.

Session Title: RA – Treatments Poster II: Established Treatments

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Depression and anxiety are common in patients (pts) with RA[1] and can lead to reduced quality of life, functional capacity, and RA treatment response.[2-4] Elevated IL-6 levels have been associated with depressive symptoms in pts with RA.[5] The 36-Item Short Form Health Survey (SF-36) Mental Component Summary score (MCS) ≤ 38 has been used as an identifier of probable major depressive disorder (pMDD) and/or probable generalized anxiety disorder (pGAD) in pts with RA.[6] Tofacitinib is an oral JAK inhibitor for the treatment of RA. We assessed the prevalence of pMDD and/or pGAD by SF-36 MCS ≤ 38 status in tofacitinib clinical trials for RA, and tofacitinib efficacy by baseline (BL) pMDD and/or pGAD status.

Methods: In this post hoc analysis, data were pooled from 5 Phase (P)3 trials and 1 P3b/4 trial. Pts receiving tofacitinib 5 or 10 mg BID, adalimumab 40 mg every other week (ADA), or placebo (PBO), with a non-missing BL SF-36 MCS, were included. Demographics and BL disease characteristics were reported by BL pMDD and/or pGAD status (SF-36 MCS ≤ 38 [presence] or > 38 [absence]). At Months (M)3/6/9/12: SF-36 MCS change from BL (Δ) was estimated by modeling of pooled data, and the % of pts with pMDD and/or pGAD was reported. Efficacy endpoints were estimated at M3/6/12 by linear models, comparing tofacitinib-treated pts by BL pMDD and/or pGAD status.

Results: BL pMDD and/or pGAD were reported in 44.5%, 39.8%, 45.4%, and 39.1% of pts receiving tofacitinib 5 mg BID, tofacitinib 10 mg BID, ADA, and PBO, respectively. At BL, higher CRP levels and worse disability, fatigue, pain, and sleep were reported in pts with pMDD and/or pGAD vs those without (Table 1). A numerically, and sometimes significantly ($p < 0.05$), greater increase in SF-36 MCS was reported in pts receiving tofacitinib vs PBO or ADA (Figure 1a). The % of pts with BL pMDD and/or pGAD who continued to have pMDD and/or pGAD reduced over time,

*p<0.05; **p<0.01

Data were pooled from 5 Phase 3 trials and 1 Phase 3b/4 trial of tofacitinib in RA

[a]Baseline pMDD and/or pGAD was defined by SF-36 MCS ≤38

[b]Logistic regression models were fit by month. The models included fixed effects of treatment (including placebo and adalimumab), baseline 'pMDD and/or pGAD' status (MCS ≤ or >38), treatment-by-baseline-status interaction, study (ORAL Scan, Solo, Sync, Standard, Step, Strategy), geographic region (US, EU/Canada, Latin America, other), and anti-depressant/anti-anxiety medication use on Day 1 (yes or no). Missing responses were imputed as failures. For patients randomized to a placebo sequence in a study where they may have advanced to tofacitinib post Month 3, only placebo observations were included in the model

[c]A mixed-effects linear model was fit applying the same effects as in the logistic regression models, except: the model was longitudinal and included the effect of month (3, 6, 9, and 12) as a main effect, and two- and three-way interactions involving month, treatment, and baseline status, along with baseline value of the dependent variable. Patients were included as a random effect and compound symmetry was used to model covariance. Missing data due to 'missing at random' were implicitly imputed by this modeling approach

Δ, change from baseline; ACR, American College of Rheumatology; BID, twice daily; CI, confidence intervals; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; LS, least squares; MCS, Mental Component Summary score; OR, odds ratio; pGAD, probable generalized anxiety disorder; pMDD, probable major depressive disorder; Q2W, every other week; RA, rheumatoid arthritis; SF-36, Short Form-36 health survey

pts, the % with SF-36 MCS ≤ 38 (ie identified as having pMDD and/or pGAD) reduced by around 60% at M12. Tofacitinib efficacy was similar in those with and without BL pMDD and/or pGAD (identified using SF-36 MCS). Limitations include using SF-36 MCS to identify probable rather than confirmed MDD or GAD. Future research is required to replicate the findings of this study using a gold-standard psychiatric interview against which to validate the use of SF-36 MCS ≤ 38.

Abstract Number: 1445

Pre-Biologic Use of Janus Kinase Inhibitors for the Treatment of Rheumatoid Arthritis in the United States

Lynn Price,[1] Phil Pouliot,[1] and Lauren Schmitt[1], [1]Spherix Global Insights, Exton, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Treatments Poster II: Established Treatments
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tofacitinib was the first Janus kinase (JAK) inhibitor FDA approved for the treatment of RA in November 2012, five- and one-half years later, baricitinib, also received approval. The oral delivery of JAKs make them particularly appealing treatment options for patients with moderate to severe disease, however, many patients still receive a TNF-α-inhibitor in the first-line biologic/JAK treatment setting. With two JAKs available and several JAK entities in clinical development, it is important to understand how US rheumatologists are prescribing these agents in relation to biologics, why patients typically discontinue first-line JAK treatment, and how likely rheumatologists are to prescribe consecutive JAK inhibitors to their RA patients.

Methods: An independent market analytics firm collaborated with US rheumatologists (n=101) to conduct analysis of the RA Market. Data were collected via an online survey fielded in May 2019 and included physician demographics and attitudinal survey responses.

Results: US Rheumatologists estimate that half of their biologic/JAK-treated RA patients are on a first-line agent. Despite increased advanced treatment options available, TNF-α-inhibitors continue to dominate first-line advanced systemic therapy, with rheumatologists reporting 79% are prescribed a TNF-α-inhibitor prior to JAKs or other biologics. Just 8% are treated with a JAK-inhibitor prior to biologic therapy, though use does significantly increase with each consecutive line of therapy, and 18% and 26% of all second- and third-line biologic/JAK-treated RA patients, respectively, are prescribed either tofacitinib or baricitinib. The most common reasons for pre-biologic JAK discontinuation include primary efficacy failure/lack of initial response (41%) and secondary efficacy failure/waning efficacy over time (29%). Aspects such as tolerability, safety concerns, and patient adherence also play a role, albeit to a much lesser degree than those related to efficacy. When first-line JAK patients discontinue due to primary efficacy

failure they are the most likely to be prescribed a TNF-α-inhibitor in the second-line setting. Of note, one-quarter of first-line JAK patients who have discontinued due to primary efficacy failure will bypass TNF inhibitor treatment and move from a JAK to the IL-6 inhibitor, tocilizumab. Only 6% report that when a lack of initial response is at play, they will prescribe a consecutive JAK-inhibitor; however, if a patient discontinues due to waning response, respondents are more likely to cycle JAKs, with 11% of all secondary JAK failures prescribed another JAK. When JAK cycling occurs, it is most often attributed to patient preference for oral treatments.

Conclusion: With two JAK inhibitors currently available in the US RA armamentarium, and several late stage JAKs in development, the relationship and typical treatment protocol for JAK use is important to understand. Current pre-biologic use of JAKs is limited at just 8% of all first-line patients, though use of the class does increase in later lines of therapy. Currently, rheumatologists' propensity to cycle consecutive JAK therapies for the treatment of RA is minimal, and when it does occur, is most commonly patient-driven.

BASDAI [SD]	2.1 ±1.8*	2.9 ± 2.4*	2.9 ± 2.0*

*p<.0001 vs BL

Background/Purpose: The aim of this post hoc analysis is to assess effectiveness of GLM used as first, second, or at least third biologic agent in RA, PsA and AS in a real-life setting.

Methods: Post hoc analysis of the non-interventional, GO-NICE study with RA, PsA and AS patients starting GLM 50mg SC in a real practice setting in Germany, details were shown earlier (1,2). Endpoint measures DAS28, PsARC, and BASDAI are shown as observed.

Results: In 1458 patients with RA, PsA or AS, GLM was administered as first (n=305, 286, 292, respectively), second (n=104, 136, 130), or at least third biologic agent (n=64, 79, 58). In total, 43.0, 30.8, 39.1% of patients with RA, 53.1, 38.2, 34.2% with PsA, and 53.8, 49.2, 41.4% with AS completed the study until month 24. **RA pts.** (n=473): Baseline DAS28 scores were 5.0, 4.9, 5.1 in 1st, 2nd, and at least 3rd line use of GLM, respectively, and dropped significantly over time in all groups. Remission rates increased to 27.5%, 19.5%, and 14.5% (month 3) to 45.3%, 50.0% and 33.3% after 24 months of treatment, respectively. **PsA pts**. (n=501): PsARC response was achieved in 76.4%, 51.0% and 50.0% respectively in patients with GLM use as 1st, 2nd, at least 3rd line at 24 months. **AS pts.** (n=483): Patients with at least 2 previous bDMARDs had higher BASDAI at BL than patients with GLM use in first or second line: 5.7 vs. 5.0, and 4.9. After 24 months of treatment, the mean BASDAI scores decreased significantly ($p< 0.001$ vs. BL) to 2.1, 2.9, 2.9 in 1st, 2nd, and at least 3rd line use of GLM, respectively.

Conclusion: In this post-hoc analysis of the non-interventional study, Golimumab as first, second or at least third biologic agent were an effective treatment and showed remarkable improvements in clinical parameters DAS28, PsARC, and BASDAI in patients with RA, PsA, and AS.

Significant improvements of DAS28 and BADSAI was arrived after 3 months vs. BL and maintained over 24 months.

Abstract Number: 1447

Comparison of Ultra High-resolution Ultrasound (UHFUS) of Labial Salivary Glands and Conventional Salivary Gland Ultrasonography in Primary Sjögren's Syndrome Assessment

Chiara Baldini,[1] Francesco Ferro,[1] Nicoletta Luciano,[1] Saverio Vitali,[2] Rossana Izzetti,[3] Silvia Fonzetti,[4] Veronica Iodice,[2] Marta Mosca,[5] Valentina Donati,[6] and Davide Caramella[2], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy, [2]Department of Diagnostic and Interventional Radiology, University of Pisa, Pisa, Italy, [3]Department of Translational Research and of New Surgical and Medical Technologies, University of Pisa,, Pisa, Italy, [4]University of Pisa, Pisa, Italy, [5]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [6]University of Pisa, Pisa

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Labial salivary gland (LSG) biopsy remains a key tool for the diagnosis of primary Sjögren's syndrome (pSS). Nowadays, however, interest is growing in non-invasive methods able to supplement more invasive diagnostic procedures. Last-generation ultra high-resolution ultrasound (UHFUS) transducers, which can produce frequencies up to 70 MHz and achieve tissue resolution up to 30 μm, have recently opened up new possibilities for the study of a variety of superficial targets. In this work, we investigated the diagnostic accuracy of UHFUS in detecting LSGs involvement in patients with suspected SS and compared UHFUS findings with both LSG histopathology and conventional SGUS.

Methods: We enrolled consecutive patients undergoing a complete diagnostic work-up for suspected pSS, including conventional SGUS and LSG biopsy. The same expert pathologist assessed LSG focus score (FS) also reporting number of foci, presence of ectopic germinal centers (GCs) and percentage of total area infiltrated. UHFUS of LSG was performed by specialized radiologists scanning first the central compartment of the inferior lip, and then both peripheral compartments. The following parameters were evaluated: distribution of the glands, parenchymal inhomogeneity (score 0-3, from normal to evident), fibrosis and eco color-Doppler vascular pattern and grade of vascular intensity.

Results: We included 75 patients with suspected pSS. At the end of the work-up, pSS diagnosis was confirmed in 42/75 (56%) cases. With respect to no-SS sicca controls, pSS patients presented higher UHFUS inhomogeneity scores in both central (p=0.001) and peripheral labial compartments (p=0.001) as well as higher degree of central (p=0.003) and peripheral fibrosis (p=0.002). Considering a score ≥2 in parenchymal inhomogeneity as suggestive for pSS, UHFUS appeared less specific than conventional SGUS (UHFUS Sp=72% vs SGUS Sp=93%) but more sensitive (UHFUS Se=79% vs SGUS Se = 53%). Moreover, in comparison with conventional SGUS, the correlation coefficients between UHFUS inhomogeneity and LSG FS (UHFUS r=0.503** *vs* SGUS r=0.290*), number of foci (UHFUS r=0.493** *vs* SGUS r=0.307*), number of ectopic GCs (UHFUS r=0.315** *vs* SGUS r=0.173), and percentage of total area infiltrated (UHFUS r=0.506** *vs* SGUS r=0.332) were significantly higher.

Conclusion: The use of UHFUS of LSG in pSS appeared feasible and sensitive potentially offering unique advantages over the conventional imaging modalities in pSS assessment.

Abstract Number: 1448

Ultrasonography of Major Salivary Glands in Primary Sjögren's Syndrome: Identification of Distinct Evolving Patterns in the Long-Term Follow-up

Francesco Ferro,[1] Nicoletta Luciano,[1] Gianmaria Governato,[1] Elena Elefante,[2] Marta Mosca,[2] Valentina Donati,[3] and Chiara Baldini[1], [1]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy, [2]Rheumatology Unit, Department of clinical and experimental medicine, University of Pisa, Pisa, Italy, [3]University of Pisa, Pisa

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: to evaluate the longitudinal changes of major salivary glands ultrasonography (SGUS) in primary Sjögren's Syndrome (pSS) and to investigate its relationship with patients' imaging pattern of presentation.

Methods: Patients with pSS underwent a complete SGUS examination at baseline and subsequently during follow-up. The echostructure of each gland on B-mode images was graded on a 5-point scale (0–4), and a SGUS score ≥2 was defined as pathological. Hypo-anechoic areas in the glands were defined as isolated (< 25% of the surface), localized (25-50%) and diffuse-scattered (>50%). Number of intra-parotid lymph nodes, presence of hyperechoic bands in more than 50% of the parenchyma and gland size were also recorded.

Results: We included 133 pSS patients (2M:131F, mean age 51±14 yrs) followed for a median follow-up of 24 months (IQR, 12-36 months). At baseline, 48/133 (36.1%) patients had a normal SGUS pattern, 14/133 (10.5%) presented a SGUS pattern characterized by mild inhomogeneity in the glands with no hypo-anechoic areas and 71/133 (53.4%) had a SGUS score ≥2 with a number of hypo-anechoic areas varying greatly among subjects. Patients with a normal SGUS pattern presented less frequently hypergammaglobulinemia, Rheumatoid Factor, anti-Ro/SSA and anti-LA-SSB positivity, whereas patients with a SGUS score ≥2 were significantly younger, had more frequently a history of chronic recurrent parotitis and presented a higher focus score in their labial glands, and a lower unstimulated salivary flow (p< 0.01). At the end of the follow-up, we did not observe any significant change in the number of hypo-anechoic areas; by contrast, 36/133 (27%) patients presented a variation in the number of intra-parotid lymph nodes and 50/133 (37.6%) presented an increase in salivary gland fibrosis and/or a decrease in glandular size. Considering patients' imaging pattern of presentation, pSS subjects with normal SGUS pattern at the baseline had significantly lower rates of new damage (p=0.001) when compared with the other two imaging patterns.

Conclusion: SGUS pattern of presentation may predict damage accrual in pSS, allowing to personalized medical treatments in clinical practice.

Clinical Phenotyping of Patients with Primary Sjögren's Syndrome Using Salivary Gland Ultrasonograhpy

Esther Mossel,[1] Jolien van Nimwegen,[1] Robin Wijnsma,[1] Alja Stel,[1] Konstantina Delli,[1] Greetje van Zuiden,[1] Lisette Olie,[1] Leonie Los,[1] Arjan Vissink,[1] Frans Kroese,[1] Suzanne Arends,[2] and Hendrika Bootsma[3], [1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]Dept. of Rheumatology and Clinical Immunology - University Medical Center Groningen (UMCG), University of Groningen, Groningen, Netherlands, [3]University of Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Salivary gland ultrasonography (SGUS) is a promising tool in primary Sjögren's syndrome (pSS). The objective of this study was to investigate SGUS abnormalities in relation to patient characteristics, disease activity and disease damage in patients with pSS in daily clinical practice.

Methods: The REgistry of Sjögren Syndrome LongiTudinal (RESULT) cohort is an ongoing observational prospective cohort study at the University Medical Center Groningen. For the present analysis, we used data from the baseline visit of patients with pSS, fulfilling the ACR-EULAR criteria, who were included between January 2016 and December 2018 (n=186). At baseline, clinical, patient-reported, functional, imaging, histopathological and serological parameters were obtained according to a fixed protocol. Patients underwent ultrasonographic examination according to the Hocevar scoring system (range 0-48)[1]. SGUS score was considered positive if the Hocevar score was ≥15[2]. Patient characteristics, disease activity and disease damage were compared between SGUS positive and SGUS negative pSS patients.

Results: In total, 172 out of 186 patients were included, with a mean age of 53 years (SD 13.9) and median disease duration of 8 years (IQR 4.0-13.0). 136 patients (79%) were SGUS positive. SGUS positive patients had significant longer disease duration (8.5 vs. 5.0 years; p=0.003), higher EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI) (4.0 vs. 2.0; p=0.028) and higher Sjögren's Syndrome Disease Damage Index (SSDDI) (2.0 vs. 1.5; p=0.018) compared to SGUS negative patients. Furthermore, SGUS positive patients more often had a positive parotid gland biopsy (i.e. focus score≥1) (90.1% vs. 50.0%; p< 0.001), unstimulated whole saliva flow rate (UWS) ≤0.1ml/min (74.8% vs. 45.7%; p=0.001) and ocular staining score (OSS) ≥5 (41.0% vs. 8.3%; p< 0.001). With respect to serological parameters, SGUS positive patients more frequently had anti-SSA/SSB antibodies (94.1% vs. 75.0% and 61.5% vs. 25.0%), higher levels of IgG (16.9 vs. 11.2; p< 0.001) and rheumatoid factor (21.0 vs. 2.1; p< 0.001), and showed lower levels of leucocytes (5.2 vs. 6.3; p=0.002) and complement C3 and C4 (1.10 vs. 1.20; p=0.012 and 0.18 vs. 0.20; p=0.015). Regarding patient-reported outcome measurements, SGUS positive patients experienced significantly less fatigue (7.0 vs. 8.0; p=0.024) and pain (4.5 vs. 7.0; p< 0.001), as measured by EULAR Sjögren Syndrome Patient Reported Index (ESSPRI), and more often rated their symptoms as acceptable (75.6% vs. 58.3%; p=0.042). SGUS total score showed highest correlation with OSS (ρ=0.532) and UWS (ρ=-0.551).

Conclusion: SGUS positive patients had longer disease duration, higher disease activity and more disease damage compared to SGUS negative patients, whereas SGUS negative patients experienced more fatigue and pain. Therefore, SGUS could assist in the stratification of pSS patients and herewith provide another step towards personalized medicine.

Salivary Gland Hypofunction in a Mouse Model for Sjögren's Syndrome Is Strongly Associated with Hyperglycemia

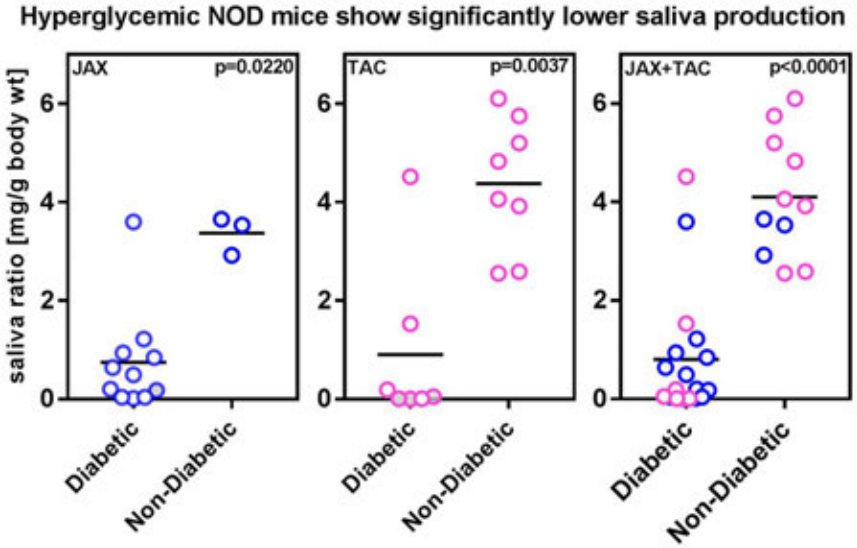
Bujana Allushi,[1] Joanna Papinska,[1] Harini Bagavant,[1] and **Umesh Deshmukh** [1], [1]Oklahoma Medical Research Foundation, Oklahoma City, OK

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been demonstrated that the non-obese diabetes (NOD) mice from the Jackson Laboratory (JAX) have a distinct gut microbiome and higher incidence of type I diabetes than NOD mice from the Taconic Biosciences. Since the female NOD mice recapitulate several features of Sjögren's syndrome, this study was undertaken to test the hypothesis that the incidence and severity of Sjögren's syndrome-like disease will be distinct in NOD mice from JAX and Taconic.

Methods: Seven week old female NOD mice were purchased from JAX (n=15) and Taconic (n=15). Mice were monitored at different time points for hyperglycemia (non-fasting blood sugar >250mg/dL), pilocarpine-induced salivation, serum IgG levels, ANA, and circulating cytokines. Mice were euthanized at 22wk of age, and submandibular glands were evaluated for the presence of inflammatory foci and antibody deposition.

Results: At 20 wks of age, 80% of JAX mice were hyperglycemic, in comparison with only 46% from Taconic. The JAX mice had significantly higher total serum IgG (p=0.0007), IL-2 (p=0.0009), IL-6 (p=0.0287), TNFα (p=0.0447) and IP-10 (p=0.013) levels than the Taconic mice. The incidence of ANA was similar between the two groups. Although the severity of sialoadenitis was significantly higher in Taconic mice (p=0.0289), the loss of saliva production was more prominent in JAX mice. Surprisingly, a trend of higher saliva production was seen in mice with higher salivary



Hyperglycemia is associated with salivary gland hypofunction. Pilocarpine induced saliva was measured in female NOD mice at 20wks of age. A blood sugar of >250mg/dl was considered diabetic. Statistical analysis done by using the Mann-Whitney test and a $p<0.05$ considered significant.

gland inflammation. In both groups, the hyperglycemic mice had significantly lower ($p< 0.0001$) pilocarpine-induced salivation than mice with normal blood sugar levels. Furthermore, hyperglycemia was significantly associated with higher circulating IL-1β ($p=0.0174$), IL-16 ($p=0.007$) and lower IL-10 ($p=0.0227$) levels.

Conclusion: Our data demonstrate that in the NOD mouse model for Sjögren's syndrome, salivary gland dysfunction is strongly associated with hyperglycemia, rather than the ANA response and the level of salivary gland inflammation. Our data suggest that metabolic syndrome should be evaluated in SS patients and efforts made to reduce hyperglycemia.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The xerostomia and/or xerophtalmia (SICCA syndrome: items I and II of 2002 AECG criteria) are conspicuous characteristics of primary Sjögren´s syndrome (pSS). pSS diagnostic criteria include anti-SSA and anti-SSB antibodies, keratoconjunctivitis SICCA and characteristic findings in minor salivary gland biopsy (MSGB). Up to 40% of the cases with negative autoantibodies have been cataloged as pSS based on MSGB results.

Objective: The aim of this study was to compare the clinical and serological characteristics associated with inflammatory or non-inflammatory findings in the MSGB.

Methods: It is a cohort study of cases of SICCA syndrome attending the Rheumatology Department. At the time of patient inclusion an interview was conducted and clinical charts reviewed, obtaining the follow information; sex, age, evolution time of symptoms, history of mumps, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor (RF), antinuclear antibodies (ANA), Schirmer´s test and histopathological (Chilshom and Mason) study of MSGB.

Results: One hundred fifty-one females and one male patients were included. Mean age was 51.9±9.2 years. Patients were classified into inflammatory subgroup (n=110) when they presented MSGB focus score ≥1, or non-inflammatory subgroup (n=42) when displayed a MSGB focus score < 1. According with AECG 2002 inside of the inflammatory subgroup 57 patients (52%) fulfilled criteria for pSS and only 5 (12%) in the non-inflammatory subgroup ($p=0.0001$), additionally it was found that 11 patients (10%) had parotitis in the inflammatory subgroup while no patients in the non-inflammatory subgroup ($p=0.03$).

No differences were found in both groups for the following variables: age (years) 52±9.7 vs 51.6±8.1 (p=0.8), time of evolution (months) 71.6±55.4 vs 70.3±8.6 (p=0.99), arthralgia 98 patients (89%) vs 36 (86%) (p=0.58), Schirmer´s positive test 66 (70%) vs 32 (91%) (p=0.01), ESR > 20 in 67 (63%) vs 25 (59%) (p=0.85); positive CRP 30 (29%) vs 15 (36%) (p=0.43), positive RF 33 (31%) vs 20 (48%) (p=0.058), positive ANA in 41 (42%) vs 21 (49%) (p=0.46), fibrosis in MSGB 13 patients (12%) vs 6 (14%) (p=0.78).

Conclusion: In patients with SICCA, MSGB is essential to confirm the diagnosis, majorly in those who lack evidence for systemic autoimmunity, such as the relevant autoantibodies or concomitant autoimmune diseases. It should also be performed for this purpose when the sole evidence for systemic autommunity by the performance of anti-La/SSB or anti-Ro/SSA antibodies is not available. In these clinical settings, the test has particular utility if the results would influence the choice of therapies for non SICCA manifestations, such as fatigue, arthritis, or another systemic symptom.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's syndrome (pSS) is a female predominant autoimmune disease and very few studies have been conducted to investigate the phenotypic differences of the disease between the two genders. The purpose of this study is to investigate whether gender in pSS interferes with clinical manifestations, serology, disease course and lymphoma development, in a multi-center analysis from three centers specializing in Sjögren's Syndrome [Udine, Piza, Athens-(UPA)].

Methods: The combined cohorts of the 3 Mediterranean centers were harmonized and 82 male pSS patients, who fulfill the 2016 ACR/EULAR criteria for Sjögren's, were recruited from a pool of 1605pSS patients (n=254from Udine, n=753from Piza, n=598fromAthens). Each male was matched to a female patient in a 1:2 ratio, according to age and

disease duration from SS onset. Glandular (dry mouth, dry eyes, parotid gland enlargement) and extra-glandular manifestations (Raynaud's phenomenon, lymphadenopathy, arthralgias/arthritis, palpable purpura, liver involvement, kidney involvement, lymphoma) as well as serology (anti Ro/SSA, anti La/SSB, rheumatoid factor, cryoglobulinemia, low C4 complement levels) and histologic features (focus score, presence of germinal centers) were recorded and compared. Statistical analysis for categorical data was performed by Fisher exact test or χ^2square test accordingly and numerical data with Man-Whitney test.

Results: The median age of disease onset was 50 years (range: 15-77 years) for the male group and 50 years (range: 15-78 years) for the females. The median disease duration was 7,73 years (range: 0-26 years) and 8,38 years (range: 0-26 years) for males and females respectively. The male to female ratio in the total harmonized population was approximately 1:20. Interestingly, males with pSS had statistically significant higher frequency of lymphoma compared to females [15/82 (18.2%) vs 9/163 (5.5%) respectively, p=0.003]. Anti-La/SSB antibodies were more frequently detected in males compared to females [41/81 (50,6%) vs 54/162 (33.3%), respectively, p=0.015]. Finally, the prevalence of sicca manifestations including both dry mouth and dry eyes was higher among females compared to males [97,5% vs 91,2%, p=0.046, for dry mouth and 96,3% vs 87,8% for dry eyes, p=0.022, respectively].

Conclusion: To our knowledge this is the largest study comparing males with females pSS patients after applying the 2016 ACR/EULAR classification criteria. The higher frequency of lymphoma among males without classical risk factors may suggest distinct lymphomagenesis mechanisms between the two genders, implying that gender could be an independent risk factor for lymphoma development among pSS patients. Furthermore, the difference in the prevalence of anti-La/SSB antibodies and sicca symptoms indicates a potential role of gender and hormones in the production of autoantibodies and the clinical phenotype of pSS.

Baseline EULAR Sjögren's Syndrome Patient-Reported Index Has a Significant Impact on the Longitudinal Course of Sjögren's Syndrome

Eun Hye Park,[1] You-Jung Ha,[1] Eun Ha Kang,[1] Yeong-Wook Song,[2] and Yun Jong Lee[3], [1]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea, [2]Seoul National University Hospital, Seoul, Republic of Korea, [3]Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea, Seongnam, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The EULAR Sjögren's syndrome (SS) disease activity index (ESSDAI) and EULAR SS Patient-Reported Index (ESSPRI) have been validated as disease activity and outcome measures for primary SS. However, there has been few studies on longitudinal ESSPRI and ESSDAI changes. We therefore aimed to prospectively investigate their temporal changes and to analyze the clinical features associated with a favorable course of ESSPRI in pSS patients.

Methods: A total of 115 pSS patients were evaluated using the ESSPRI, ESSDAI, EQ5-D, Fatigue Severity Score (FSS), Beck Depression Inventory (BDI), EULAR Sicca Score (ESS), Xerostomia Inventory (XI), patient's global assessment (PGA) for pSS, and visual analog scale (VAS) scores for symptoms. After a median 3 (range 3.0-3.2) years, 100 patients repeatedly completed the questionnaires. The favorable course was defined as an improvement in ESSPRI (from baseline ESSPRI≥5 to follow-up ESSPRI< 5) or maintenance of ESSPRI< 5, and the unfavorable course as worsening of ESSPRI (from baseline ESSPRI< 5 to follow-up ESSPRI≥5) or maintenance of an unsatisfactory symptom status (ESSPRI≥5). The minimal clinically important improvement (MCII) was defined as decreased at least one point or 15% of ESSPRI in patients with ESSPRI≥5.

Results: The ESSPRI remained stable over 3 years although VAS scores for arthralgia, myalgia, anxiety, and PGA were significantly reduced (all P< 0.001). Serum IgG levels (P< 0.01) and ESSDAI scores (P< 0.05) were significantly reduced but clinical ESSDAI scores were unchanged during the follow-up. Fourteen (28.0%) showed the worsening of ESSPRI among patients with baseline ESSPRI< 5 (n=50) and 16 (36.0%) showed the improvement of ESSPRI among those with baseline ESSPRI≥5 (n=50). Only 8 (16.0%) achieved MCII in ESSPRI in patients with unsatisfactory symptom status at the baseline and 52 (52.0%) had a favorable course in total patients. Patients with MCII had higher total and clinical ESSDAI scores (all P< 0.001) and more lacrimal flow (P< 0.05) at the diagnosis than those without MCII. Patients with favorable course had lower scores of ESS, FSS, BDI, and XI and VAS levels for oral or eye dryness, myalgia, anxiety, and PGA. On the contrary, they showed higher ESSDAI scores than those with unfavorable course. Unexpectedly, the use of bupropion increased in patients with favorable course (19.2% vs 8.3%) and in patients with an improvement of unsatisfactory ESSPRI (50.0% vs 11.8%, p=0.01), when compared to those without, respectively. Multivariate analysis revealed that the favorable course was significantly associated with low levels of anxiety (OR 5.6), low ESS scores (OR 8.0), moderate-to-high ESSDAI (OR 7.1), bupropion use (OR 7.9), and baseline ESSPR< 5 (OR 5.8).

Table 1. Multivariate analysis by logistic regression of factors associated with favorable ESSPRI outcome

Parameters	Beta	SE	P-value	OR	(95% CI)
Favorable ESSPRI outcome as a dependent variable (1st model)[a]					
Baseline ESSPRI	-0.644	0.143	<0.001	0.525	(0.397-0.695)
Bupropion usage	2.038	0.759	0.007	7.678	(1.733-34.008)
Favorable ESSPRI outcome as a dependent variable (2nd model)[b]					
Baseline ESSPRI<5	1.755	0.626	0.005	5.787	(1.696-19.734)
Lowest quartile of ESS	2.077	0.748	0.005	7.984	(1.842-34.607)
Lowest quartile of Anxiety VAS	1.715	0.616	0.005	5.559	(1.662-18.586)
Moderate to high disease activity (ESSDAI≥5)	1.963	0.760	0.010	7.119	(1.604-31.594)
Bupropion usage	2.069	0.826	0.012	7.921	(1.569-39.976)

[a]The first model included age, bupropion usage, EQ-5D VAS, ESS, ESSPRI, FSS, BDI-II, XI, overall oral dryness VAS, nocturnal oral dryness VAS, overall eye dryness VAS, eyeball pain VAS, OSDI score, Myalgia VAS, Anxiety VAS, PGA VAS, and ESSDAI.

[b]For the second model, we converted some of continuous variables into categorical variables, including EQ-5D index scores or VAS levels in the highest quartile; XI scores, OSDI scores, myalgia VAS levels, anxiety VAS levels, or PGA VAS levels in the lowest quartile; FSS≥4; BDI-II≥14; ESSDAI≥5; ESSPRI<5.

Conclusion: This study suggests that baseline ESSPRI provides a prognostic value for its longitudinal change, and the presence of extra-glandular features and more residual exocrine function could be associated with a favorable outcome in pSS. Additionally, bupropion may have beneficial effect on temporal changes in ESSPRI.

Abstract Number: 1454

Sjögren's Syndrome Foundation National Survey: The Impact and Burden of Oral Symptoms

Sara McCoy,[1] Christie Bartels,[2] Esen Akpek,[3] Ian Saldanha,[4] Vatinee Bunya,[5] Matthew Makara,[6] and Alan Baer[7], [1]University of Wisconsin School of Medicine and Public Health, Madison, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI, [3]Johns Hopkins University, Baltimore, [4]Brown University School of Public Health, Providence, RI, [5]University of Pennsylvania, Philadelphia, PA, [6]Sjogren's Syndrome Foundation, Reston, VA, [7]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren's syndrome (SS) is the second most common systemic autoimmune disease, typically characterized by ocular and oral sicca. SS is associated with reduced quality of life and increased costs, but the contribution of oral symptoms to morbidity is unclear. The Sjögren's Syndrome Foundation conducted a national survey of 2,962 adults with SS. We hypothesized that oral symptoms of SS predict reduced quality of life and financial burden in SS.

Methods: This survey included adults with self-reported SS. Oral symptoms/signs were assessed by frequency (never to daily) of eight categories: parotid swelling, dry mouth, oral ulcers, oral candidiasis, dysphasia ("trouble speaking"), dysphagia, sialolithiasis/gland infection, and caries. We calculated the prevalence of oral symptoms/signs (classified as present if symptoms occurred ≥ monthly) and current/ever use of oral treatments. We performed multivariable logistic regression to evaluate the association between oral symptoms (predictor) and quality of life and financial burden (outcome variables), adjusted for age, sex, race, and employment. Binary (present = "a lot of negative impact" or "a great deal of negative impact"; absent = no or "some negative impact") quality of life/financial burden outcomes included: 1) challenge of living with SS, 2) financial burden, 3) activities of daily living (ADLs), and 4) ability to work.

Table 1. Medication Use Among Adult Patients with SS (n=2962)

	Ever Use	Prevalence	Current Use	Prevalence
Saliva Substitutes	1812	0.61	1033	0.89
Oral Comfort Agents	2475	0.84	1876	0.63
Fluoride	1996	0.67	1462	0.49
Chorhexadine Rinse/Non-Fluoride Remineralizing	1173	0.40	556	0.19
Secretagogues	1785	0.60	1059	0.36

Table 2. Impact of Oral Symptoms on Quality of Life and Financial Burdens (n=2962)

Quality Outcome Measure	Oral Symptoms	Frequency of Symptoms	OR	95%CI
Daily Challenge Living With SS				
	Oral Ulcers	Never (ref)		
	n=1150 (40%)	Once/Few Times Yearly	1.88	1.42-2.48
		Monthly/Almost Monthly	3.12	2.18-4.46
		Weekly/Almost Weekly	6.44	3.44-12.06
		Daily/Almost Daily	4.70	2.26-9.78
	Dysphasia	Never (ref)		
	n=1354 (47%)	Once/Few Times Yearly	1.51	1.09-2.08
		Monthly/Almost Monthly	2.11	1.41-3.15
		Weekly/Almost Weekly	2.78	1.92-4.05
		Daily/Almost Daily	7.05	3.96-12.56
	Dysphagia	Never (ref)		
	n=1646 (56%)	Once/Few Times Yearly	1.43	1.05-1.94
		Monthly/Almost Monthly	1.62	1.16-2.27
		Weekly/Almost Weekly	3.10	2.14-4.49
		Daily/Almost Daily	5.08	3.14-8.19
Activities of Daily Life				
	Dysphasia	Never (ref)		
	n=1354 (47%)	Once/Few Times Yearly	1.48	1.14-1.92
		Monthly/Almost Monthly	1.87	1.42-2.47
		Weekly/Almost Weekly	2.57	2.02-3.27
		Daily/Almost Daily	2.77	2.15-3.57
	Dysphagia	Never (ref)		
	n=1646 (56%)	Once/Few Times Yearly	1.18	0.89-1.56
		Monthly/Almost Monthly	1.87	1.42-2.46
		Weekly/Almost Weekly	2.69	2.08-3.47
		Daily/Almost Daily	3.03	2.32-3.96
Ability to Work				
	Oral Ulcers	Never (ref)		
	n=1150 (40%)	Once/Few Times Yearly	1.18	0.95-1.48
		Monthly/Almost Monthly	1.67	1.3-2.14
		Weekly/Almost Weekly	1.72	1.26-2.35
		Daily/Almost Daily	2.47	1.6-3.82
	Dysphasia	Never (ref)		
	n=1354 (47%)	Once/Few Times Yearly	1.21	0.94-1.57
		Monthly/Almost Monthly	1.64	1.22-2.21
		Weekly/Almost Weekly	1.79	1.38-2.31
		Daily/Almost Daily	2.02	1.53-2.67

Results: The 2,962 survey participants were 92.6% white, 95.6% female, and averaged 65.1 years of age. Most respondents had dry mouth (96.5%) followed by dysphagia (57.5%), dysphasia (47.0%), oral ulcers (40.0%), caries (22.4%), parotid swelling (17.7%), oral candidiasis (8.8%), and sialolithiasis/gland infection (3.8%). Eighty-four percent of respondents used oral comfort agents, 67% used fluoride, and 60% used secretagogues previously, but less than half currently use fluoride and secretagogue treatment (Table 1). Significant dose dependent relationships between frequency of oral symptoms quality of life/financial burden measures were observed. Dysphasia impacted all four quality/financial measures including daily living challenges (OR 7.05 [95% CI 3.96-12.56), ADLs (OR 2.77 [95%CI 2.15-3.57), work ability (OR 2.02 [95% CI 1.53-2.67]), and financial burden (OR 3.08 [95% CI 2.34-4.06]) (Table 2). Oral ulcers and dysphagia impacted three of four quality/financial measures (Table 2).

Conclusion: Oral symptoms occurred in the majority of SS respondents, yet less than half of respondents remain on secretagogue or fluoride therapies. This lack of persistence might reflect reduced perceived symptomatic benefits or cost burdens of SS. Dysphasia impacted all four outcome categories in a dose dependent manner by symptom frequency with up to a seven fold odds increase in the challenges with daily living. Dysphasia, oral ulcers, and dysphagia most strongly impacted multiple quality of life measures compared to other oral aspects, potentially identifying dysphasia, oral ulcers, and dysphagia as important but underutilized patient reported outcome measures. Furthermore, these findings highlight the potential importance of targeted treatment toward dysphasia and dysphagia.

B and T Cell Immunologic Features Associated with Higher Disease Activity Score and Focus Score in Primary Sjögren Syndrome

Alice Mai,[1] Yuriy Baglaenko,[2] Dario Ferri,[3] Kieran Manion,[4] Dennisse Bonilla,[5] Arthur Bookman,[6] and Joan Wither[7], [1]University of British Columbia Department of Rheumatology, Vancouver, Canada, [2]Brigham Woman's Hospital, Boston, [3]University Health Network, Toronto, ON, Canada, [4]Krembil Research Institute, Toronto, ON, Canada, [5]University Health Network, University of Toronto, Toronto, ON, Canada, [6]University Health Network, Toronto, Canada, [7]University Health Network, Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease with an incompletely understood pathogenesis and heterogenous disease manifestations. Identifying cellular immune changes that may predict disease severity could lead to identification of biomarkers and potential targets for therapy. We examined a cohort of pSS patients to identify the cellular immunologic features significantly associated with disease activity, as measured by the EULAR Sjögren's syndrome disease activity index (ESSDAI) and the focus score on minor salivary gland (MSG) biopsy.

Methods: 35 participants who met the ACR 2016 classification criteria for pSS were recruited. Peripheral blood cellular immunological changes were assessed by flow cytometry and transcript levels of BAFF, interferon (IFN)-induced and plasma cell-expressed genes were quantified by NanoString. Normalized Log_2 transformed expression levels of 5 IFN-induced genes were summed to generate the IFN5 score. Associations between the ESSDAI, focus score, and cellular immunological changes were evaluated using Spearman's correlation coefficient.

Results: The ESSDAI was significantly correlated with the focus score ($r=0.64$, $p< 0.01$). The majority of T and B cell populations, including the proportions of naïve, class-switched memory, un-switched memory, and $CD27^-$ memory B cells and their activation, as well as IFN-γ-, IL-17-, or IL-21-producing T cells, did not correlate with either measure of disease activity. However, the proportion of transitional B cells ($CD27^-IgD^+CD24^{hi}CD38^{hi}$; $r=0.40$, $p=0.03$) and proportion of activated memory T follicular helper cells ($CXCR5^+PD1^{hi}$) in the $CD4^+$ T cell compartment ($r=0.39$, $p=0.05$) and $CD3^+$ T cell compartment ($r=0.42$, $p=0.04$) were significantly associated with the focus score. In addition, the frequency of T regulatory cells ($CD4^+FOXP3^+HELIOS^+$) was positively correlated with the ESSDAI ($r=0.61$, $p=0.04$). Type

I IFN-induced gene expression, as measured by the IFN5 score, was significantly associated with both focus score (r=0.37, p=0.05) and ESSDAI (r=0.37, p=0.04).

Conclusion: The findings suggest that elevated levels of IFN-induced gene expression and increased proportions of T follicular helper cells are potential biomarkers of increased disease activity and may constitute good targets for disease treatment.

The Increased Ratio of Blood CD56^{bright} to CD56^{dim} NK Cells Is a Distinguishing Feature of Primary Sjögren's Syndrome

Bingxia Ming,[1] Tong Wu,[1] and Lingli Dong[2], [1]Department of Rheumatology and Immunology, Tongji hospital, Huazhong university of science and technology, Wuhan, China (People's Republic), [2]Department of Rheumatology and Immunology, Tongji hospital, Huazhong university of science and technology, Wuhan, Hubei, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To investigate the characteristic and clinical significance of peripheral blood CD56 NK cell subsets in patients with primary Sjögren's syndrome (pSS).

Methods: From November 2017 to November 2018, 52 patients fulfilled the 2002 AECG criteria or 2012 ACR criteria of pSS and 20 healthy volunteers were enrolled in this study. The proportion and absolute number of NK cells and CD56 NK cell subsets in peripheral blood samples were detected by flow cytometry. Disease activity was determined by score of EULAR Sjogren's syndrome disease activity index (ESSDAI). Other laboratory parameters such as anti-nuclear antibody (ANA), anti-SSA/SSB, C-reactive protein (CRP) and the treatment regimen were extracted from the clinical system. The ROC curve was used to assess the diagnostic value of the ratio of CD56bright NK to CD56dim NK.

Results: The proportion and absolute number of peripheral blood NK cells were reduced in pSS patients compared to healthy controls. The proportion of CD56^{bright} NK cell subset was increased and its absolute number was decreased. The proportion and absolute number of CD56^{dim} NK cell subset were decreased. Moreover, the ratio of CD56^{bright}NK to CD56^{dim}NK was significantly elevated in pSS patients than that in healthy controls. ROC curve analysis indicated that the area under the curve (AUC) of the peripheral blood CD56^{bright}NK/CD56^{dim}NK was 0.838, and the best diagnostic cut-off point was 0.0487 for pSS patients. Furthermore, the decreased blood CD56^{dim}NK cell count was increased again after treatment in pSS patients consistent with the decreased ESSDAI and serum IgG level.

Conclusion: The ratio of blood CD56^{bright}NK to CD56^{dim}NK may be a valuable biomarker for the diagnosis of pSS. The absolute counts of CD56^{dim} NK cell subsets is sensitive to the treatment response in pSS patients.

Neurological Involvement in a Cohort of Primary Sjogren's Syndrome Patients: Results of a Multicenter Italian Study

Elena Bartoloni,[1] Chiara Baldini,[2] Luca Quartuccio,[3] Roberta Priori,[4] Francesco Carubbi,[5] Francesco Ferro,[2] Saviana Gandolfo,[3] Angelica Gattamelata,[6] Alessia Alunno,[7] Stefano Bombardieri,[8] Salvatore De Vita,[3] Roberto Giacomelli,[5] Vittorio Bini,[7] and Roberto Gerli[1], [1]Rheumatology Unit, Department of Medicine, University of Perugia, Perugia, Italy, Perugia, Italy, [2]Rheumatology Unit, Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy, Pisa, Italy, [3]Rheumatology Clinic, Udine University Hospital, Department of Medical Area, University of Udine, Udine, Italy, Udine, Italy, [4]Rheumatology Unit, Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy, Roma, Italy, [5]Rheumatology Unit, Department of Biotechnological and Applied Clinical Science, School of Medicine, University of L'Aquila, L'Aquila, Italy, L'Aquila, Italy, [6]University of Roma Sapienza, Rome, Italy, [7]University of Perugia, Perugia, Italy, [8]Rheumatology Unit, University of Pisa, Pisa, Italy, Pisa, Italy

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The course of primary Sjögren's syndrome (pSS) may be characterized by extra-glandular and potentially life-threatening manifestations. Among these, neurological involvement represents a clinical challenge due to its heterogeneous clinical presentation and diagnostic complexity. Indeed, reported prevalence of central (C) and peripheral (P) nervous system (NS) involvement is high variable due to lack of unified definition and diagnostic tools. Moreover, the association between disease clinical and serological manifestations and SN involvement remains unclear. Aim of this study was to evaluate the prevalence of neurological involvement in a pSS cohort and to investigate factors associated with this risk.

Methods: Data of a cohort of pSS patients fulfilling the 2002 AEGC criteria and enrolled in an Italian multicenter database (the Italian Group of SS Study-GRISS) were retrospectively analyzed. Disease clinical and serologic data were sistematically collected with specific analysis of CNS and PNS involvement. Clinical and serologic features associated with SN involvement were investigated. The Shapiro–Wilk test was used to assess the normal distribution of variables. The chi-squared test and the Mann–Whitney *U*-test were used for comparisons of categorical variables and non-normally distributed continuous variables, respectively. Separate multivariate logistic regression analysis was performed.

Results: The cohort comprised 1.707 patients (1.629 F, 78 M). Mean age at diagnosis was 52±14 and mean disease duration 6±7 years. Prevalence of NS involvement was 4.5% (78/1.707). PNS manifestations were recorded in 61 (3,6%), including 29 sensorimotor neuropathy, 17 pure sensory neuropathy, 8 sensory or sensorimotor polyneuropathy, 6 small-fiber neuropathy and 1 mononeuritis multiplex. CNS manifestations were recorded in 13 (0,8%), including 4 cerebral vasculitis, 3 trasverse myelitis, 2 otpic neuritis, 2 cranial nerve involvement and 1 multiple sclerosis-like syndrome. No diagnosis was available in 4 patients. Male sex was associated with higher risk of NS involvement (10% M vs 4% F, p= 0.025). Patients with NS involvement showed significant higher frequency of articular involvement (76% vs 62%), purpura (24% vs 7%), other organ involvement (96% vs 38%) lymphoma (9% vs 4%), low complement (42% vs 19%), leukopenia (39% vs 24%) and cryoglobulins (20% vs 4%). Median salivary gland focus score was higher in patients without NS involvement (p=0.001). At multivariate analysis, male sex (OR=2,7; 95% CI 1,1, 6), other organ involvement (OR=15; 4,5, 50,6), low complement (OR=2; 1,2, 3,5) and cryoglobulins (OR=3; 1,4,

6,3) were independently associated with NS involvement risk. Higher focus score was associated with lower risk (OR=0.7; 0,5, 0,9).

Conclusion: Results of this multicenter study highlight that, although not frequent, NS involvement in pSS is protean and mainly characterizing male sex. The association with specific clinical and serologic disease features suggests that vasculitis may exert a prominent role in its pathogenesis. Awareness of these factors may help in predict neurological complications in different subgroups of patients and provide insight into better therapeutic approach.

Dual Analysis with Nerve Ultrasound and Skin Biopsy in Painful Neuropathy Associated with Sjögren's Syndrome

Takeshi Yoshida,[1] Hiroyuki Nodera,[2] Yoshitaka Kumon,[3] and Hiroki Mizukami[4], [1]Chikamori Hospital, Kochi, Japan, [2]Kanazawa Medical University, Kanazawa, Japan, [3]Chikamori Hospital, Kochi, [4]Hirosaki University, Hirosaki, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: 6% of primary Sjögren's syndrome (pSS) patients manifests as various forms of neuropathies including painful sensory neuropathy (PSN), which can be treatable with immunomodulatory drugs such as steroid and immunoglobulin. Our objective is to evaluate usefulness of ultrasound (US) in detecting abnormality of peripheral nerves, and to elucidate the relationship between US findings, histopathological findings and treatment response to immunomodulatory drugs. Recently, nerve US and skin biopsy with analysis of intraepidermal nerve fiber density (IENFD) have increasingly been used for the assessment of various forms of neuropathies. In PSN, skin biopsy is reported to be the most sensitive test for the diagnosis. There is an emerging evidence to suggest association of peripheral nerve swelling on US in patients with PSN. However, there has been no reports assessing the efficacy of peripheral nerve US in pSS associated neuropathy.

Methods: We conducted retrospective chart review from 2017 to 2019. Included patients were pSS fulfilling 2016 ACR-EULAR criteria, and were diagnosed as having neuropathic pain by Neurology specialist. We obtained clinical, serological, and electrophysiological features. On US analysis, we used LOGIQ S8 and LOGIQ ePremium devices. In each of patients, we obtained axial images to measure cross sectional area (CSA) of right median, ulnar, tibial, and sural nerve. Measurement of CSA was preformed by manually tracing the area along the nerve's hyperechoic rim. Additionally, intraneural vascular flow was assessed by using power doppler technique. Skin biopsy was performed on right lateral thigh and lower leg. IENFD was measured by counting number of nerve fibers entering epidermis. Information about pharmacological treatment was also obtained, and treatment response to immunomodulatory drugs were assessed.

Results: We included 12 patients who underwent US and skin biopsy, and seven of them already completed measurement of IENFD. Majority of these patients were advanced age, and female gender dominated. Duration of neuro-

pathic pain was chronic, ranging from one to five years except one patient with very chronic course over 18 years. Pain was described as burning or tingling sensation, distributed on bilateral arms and legs, although two patients showed truncal involvement. Three patients also showed various degree of sensory ataxia. Only two patients showed decreased pain sensation on neurological exam. Five patients were anti-SSA antibody positive. On nerve US, increased CSA of sural nerve was observed in four patients. And three of them also showed decreased IENFD. Majority of patients showed decreased IENFD of lower leg. Only one patient showed increased intraneural vascular flow.

Case	Age	Gender	Duration	Neuropathic pain	Sensory ataxia	Sensory loss	DTRs	Diagnostic tests for SS	Extraglandular Sx	ESSDAI

Ultrasonographic, electrophysiological, and histopathological Findings.

Case	Non-immunomodulatory drugs		Immunomodulatory drugs	
1	Gabapentin Enacarbil	Not effective	Predonisolone 30mg/day	Not effective
2	Pregabalin	Effective	Predonisolone 20mg/day	Not effective
3	Tramadol/acetaminophen, duloxetine	Not effective	Predonisolone 30mg/day	**Effective**
4	Tramadol/acetaminophen	Effective	Predonisolone 30mg/day	**Effective**
5	Pregabalin	Effective	None	
6	Pregabalin	Effective	mPSL 500mg x3 days and PSL 15mg/day	**Effective**
7	None		None	

Choice of treatment and the response.

Five patients were treated with moderate dose of predonisolone. Three of them showed significant improvement, as judged from description of treating physician.

Conclusion: Our patients with pSS-associated PSN showed heterogenous clinical, US, and histological findings. Nerve swelling and decreased IENFD were observed in many of them. Steroid therapy was effective in three out of five patients. These changes might reflect inflammatory environment within nerve fibers and resultant axonal loss.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

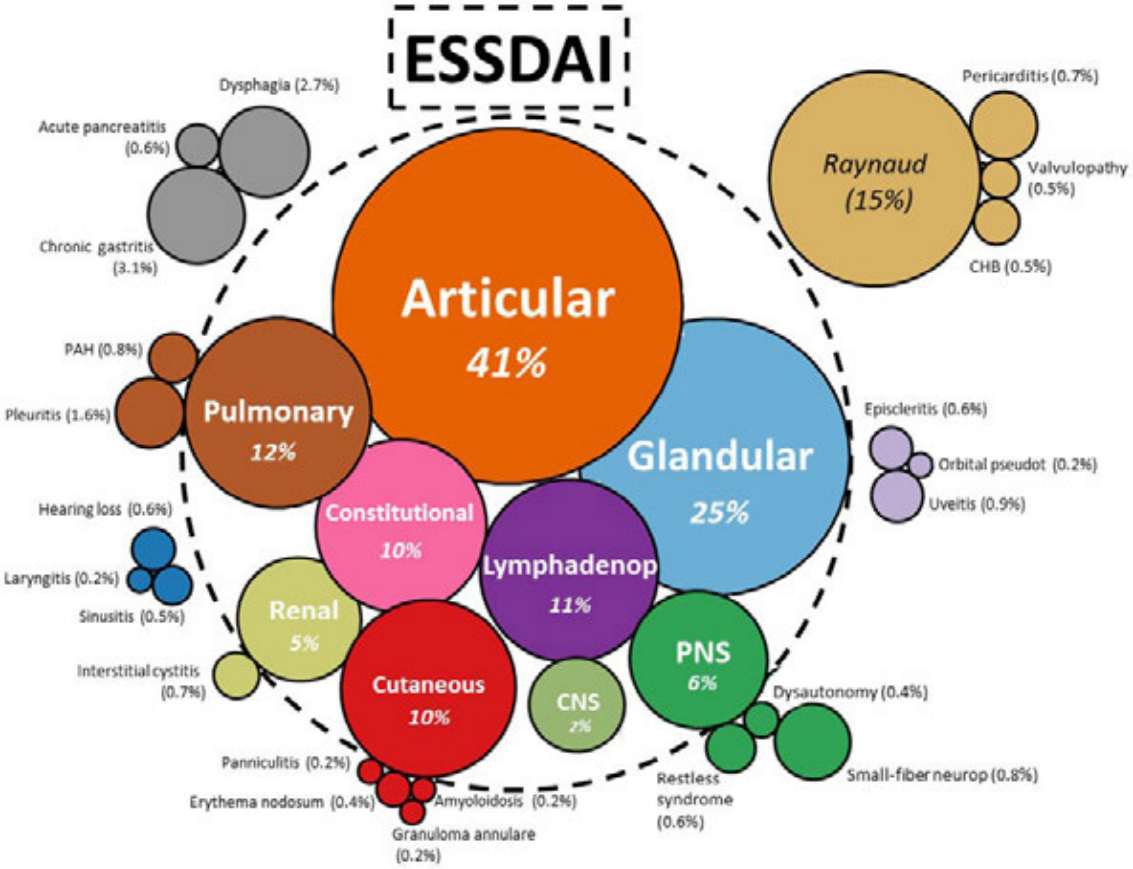
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To analyse the frequency and characterize the systemic presentation of primary Sjögren syndrome (SjS) out of the ESSDAI classification in a large international, multi-ethnic cohort of patients.

Methods: The Big Data Sjögren Project Consortium is an international, multicentre registry based on worldwide data-sharing and cooperative merging of pre-existing clinical SjS databases from leading centres in clinical research in SjS from the five continents. A list of 26 organ-by-organ systemic features not currently included in the ESSDAI classification was defined according to previous studies; these features were retrospectively recorded.

Results: Information about non-ESSDAI features was available in 6331 patients (5,917 female, mean age at diagnosis 52 years, mainly White (86.3%). A total of 1641 (26%) of 6331 patients presented at least one of the out of ESSDAI systemic features listed in Annex 1; among them, there were 359 (22%) patients who presented two or more of these features. The most frequent organs involved included cardiovascular in 1079 (17%) patients, digestive in 390 (6.2%), pulmonary in 145 (2.3%), neurological in 110 (1.7%), ocular in 97 (1.5%), ENT in 80 (1.3%), cutaneous in 55 (0.9%) and urological features in 43 (0.7%) patients (Figure). Cardiovascular manifestations were the most frequent organ-specific group of non-ESSDAI features reported in our patients (17% of the total cohort), with Raynaud phenomenon being reported in 15%. Patients with systemic disease due to non-ESSDAI features had a lower frequency of dry mouth (90.7% vs 94.1%, $p< 0.001$) and positive minor salivary gland biopsy (86.7% vs 89%, $p=0.033$), a higher



frequency of anti-Ro/SSA (74.7% vs 68.7%, p< 0.001), anti-La/SSB antibodies (44.5% vs 40.4%, p=0.004), ANA (82.7% vs 79.5%, p=0.006), low C3 levels (17.4% vs 9.7%, p< 0.001), low C4 levels (14.4% vs 9.6%, p< 0.001), and positive serum cryoglobulins (8.6% vs 5.5%, p=0.001). Systemic activity measured by the ESSDAI, clinESSDAI and DAS was higher in patients with systemic disease out of the ESSDAI in comparison with those without these features (p< 0.001 for all comparisons).

Conclusion: More than a quarter of patients with primary SjS may have systemic manifestations not currently included in the ESSDAI classification, with a wide variety of cardiovascular, digestive, pulmonary, neurological, ocular, ENT, cutaneous and urological features that increase the scope of the systemic phenotype of the disease. However, the individual frequency of each of these non-ESSDAI features was very low, except for Raynaud phenomenon. The results of this study, together with the already-published evidence supporting a pivotal role of systemic disease in primary SjS, are pointing out the need of a future re-evaluation about how we are defining, classifying and diagnosing primary SjS.

Minor Salivary Gland Biopsy and Dry Ocular Tests to Detect Occult Sjögren Syndrome in Patients with Interstitial Pneumonia with Autoimmune Features

Maria Garbarino,[1] Santiago Auteri,[2] Maria Blanco,[3] Laura Alberti,[4] Francisco Paulin,[5] Martin Fernandez,[4] Gabriel Carballo,[6] Mercedes Raya,[4] Gabriela Guman,[4] and Fabian Caro[5], [1]Hospital Argerich, Buenos Aires, Argentina, [2]Hospital Ferrer, Rosario, Argentina, [3]Hospital Lagleyze, Buenos Aires, Argentina, [4]Hospital Ferrer, Buenos Aires, Argentina, [5]HOSPITAL MARIA FERRER, Buenos Aires, Argentina, [6]Hospital Durand, Buenos Aires, Argentina

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) are a heterogeneous group of diseases that could be either idiopathic or secondary to environmental exposure, drugs or connective tissue disease (CTD). ILD related to CTD has different treatment options and different survival depending on the underlying CTD disease. Interstitial pneumonia with autoimmune features (IPAF) is the term used to describe patients with interstitial lung disease that have clinical or serological markers that suggest an underlying autoimmune process, but do not meet stablished criteria of a CTD. This diagnosis is made based on three domains: clinical, serologic and intrathoracic morphologic features. It is not known if Sjögren's Syndrome (SS) is underdiagnosed among patients with IPAF. The aim of the study is to define the utility of performing a Minor Salivary Gland Biopsy (MSGB) and dry eye tests (DET) in patients with IPAF to detect occult SS.

Methods: Prospective study. Interstitial Lung Disease patients without defined Connective Tissue Disease and at least one criteria of one or more IPAF classification domains were included. A MSGB, Schirmer's test (ST) and Ocular Staining Score (OSS) were performed in a blinded manner by experienced specialists. MSGB was considered positive when at least 1 focus of lymphocytes was detected, while DET were positive if OSS $\geq$ 5 and/or ST $\leq$5 secs. SS diagnosis was according to the 2016 ACR EULAR criteria.

Results: 534 patients on first consult were screened. 67 patients had at least one IPAF criteria, of which 53 (79.1%) were female with a mean age (SD) of 64.18 years (10.81). Positive ST in 36 (53.73%), positive OSS in 29 (43.28%) and positive MSGB in 36 (53.73%) were found. 27 (40.29%) met SS diagnostic criteria. Of these, 2 (7.41%) and 8 (29.6%) did not report dry eyes or dry mouth respectively, 16 (59.25%) had negative anti RO, 22 (81.48%) negative anti LA, 7 (25.92%) negative ANA, and 10 of 17 (58.8%) negative RF. Comparing patients with and without SS we found a significant higher proportion of patients with ANA (+), positive DET and positive MSGB in the SS population.

Conclusion: We found a significant proportion of patients with occult SS in our study population. Most of these patients with IPAF met Sjogren criteria despite having negative anti Ro, anti LA or RF. In addition to physical examination and immunological profile, the MSGB and dry eye tests should be considered in the evaluation of patients with IPAF.

Pulmonary Cysts: Very Common Finding on Computed Tomography of the Chest of Asymptomatic Patients with Primary Sjögren's Syndrome

Alisson Pugliesi,[1] Pamella Bellini,[2] Rachel Zerbini Mariano,[2] Manoel Bertolo,[2] and Zoraida Sachetto[1], [1]University of Campinas, Campinas, Sao Paulo, Brazil, [2]University of Campinas, Campinas, Brazil

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of pulmonary cysts is a relatively unusual radiological finding, but frequently described in patients with primary Sjögren's syndrome (pSS). Its true meaning, however, remains unclear, and may be associated with other forms of interstitial lung disease, lymphoma, or even a benign finding. Previous data on the subject are retrospective and also involve secondary forms of the disease, besides contemplating mainly symptomatic patients. Our main objective is to evaluate the prevalence of pulmonary cysts in asymptomatic respiratory patients with pSS, as well as possible clinical-laboratory association factors.

Methods: From September 2017 to April 2019, patients with pSS and without any form of respiratory symptomatology were selected for high-resolution computed tomography (HRCT). Patients older than 18 years and classified as having Sjögren's syndrome (SS) were included according to the American-European Consensus of 2002 (68.5% of the individuals met the 2016 ACR criteria). Only patients with the primary form of the disease were recruited. A single, experienced radiologist evaluated the images. A cyst was defined by the presence of a clearly demarcated airspace surrounded by thin (< 2 mm) walls. Numbers, size, and lung distribution of cysts were analyzed. Epidemiological, clinical, and laboratory data were extracted from medical records. Data from pSS patients with and without pulmonary cysts were compared, and Fisher's exact test was used to evaluate statistical association.

Results: Thirty-five pSS patients (median age 52.3±17; 100% female) and respiratory asymptomatic patients underwent CT of the thorax. Of these, 11 (31%) presented evidence of pulmonary cysts, mainly in the lower lobe (75%) and with a size varying from 0.3 to 6.6 cm. No extraglandular (renal, neurological, cutaneous, articular or hematologic), autoantibody (anti-Ro, anti-La, RF, ANA) or laboratorial manifestations (complement dosage, cryoglobulins, protein electrophoresis) were statistically associated with pulmonary cysts found on chest CT.

Conclusion: The high prevalence of pulmonary cysts in asymptomatic respiratory patients with pSS reinforces their probable benign nature, as well as the important association of this unusual pulmonary finding with this form of connective tissue disease. No clinical-laboratory element related to pSS was associated with this pulmonary manifestation. Prospective evaluation of this and other studies is necessary for a better understanding of the evolutionary nature of pulmonary cysts.

Pathogenesis of Vaginal Dryness in Primary Sjögren's Syndrome: A Histopathological Case-control Study

Jolien van **Nimwegen**,[1] Karin van der Tuuk,[1] Sylvia Liefers,[1] Gwenny Verstappen,[1] Robin Wijnsma,[1] Harry Hollema,[1] Marian Mourits,[1] Hendrika Bootsma,[2] and Frans Kroese[1], [1]University Medical Center Groningen, University of Groningen, Groningen, Netherlands, [2]University of Groningen, Groningen, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Women with primary Sjögren's syndrome (pSS) often experience vaginal dryness, but the pathogenesis of this symptom is unknown. Previously, we reported impaired vaginal health and presence of a subepithelial infiltrate in the vagina of women with pSS[1]. In the current analysis, we quantitatively studied changes in lymphocyte subsets, endothelial cells and soluble immune markers in the vagina and endocervix of women with pSS, compared to age-matched controls, which may explain vaginal dryness.

Methods: Gynaecological examinations were performed in 10 premenopausal women with pSS, fulfilling the ACR-EULAR criteria, with symptoms of vaginal dryness, and 10 premenopausal non-pSS controls scheduled for laparoscopic procedures. Participants with inflammatory or infectious gynaecological morbidity were excluded. Endocervical swab and cervicovaginal lavage samples were collected, in which levels of pro-inflammatory chemokines and cytokines were analyzed using a multiplex bead based immunoassay. Mid-vaginal biopsies and endocervical biopsies were collected and stained for leucocyte markers, caldesmon for smooth muscle cells, ERG for endothelial cells and anti-podoplanin (clone D2-40) for lymphatic endothelium. The number of positive pixels/μm^2 was calculated digitally using Aperio ImageScope v 12.1.

Results: One pSS patient was excluded due to chlamydia, and 2 controls due to discovery of endometriosis during their laparoscopy. In the remaining 9 patients and 8 controls, median age was 36 years (IQR 33-46) and 41 years (36-44), respectively (p=0.61). A higher level of CXCL10 was measured in endocervical swabs of pSS patients (median 37.1 pg/ml, IQR 19.4-66.1) compared to controls (median 12.6 pg/ml, IQR 5.9-31.1, p= 0.046). No differences were found in levels of APRIL, BAFF, RANKL, TNF-α, CCL2, CXCL11, CXCL13, IL6, IL7 or IL8. One vaginal biopsy from a control was excluded from analysis as it was too superficial, consisting for 98% of epithelium. Three pSS and two control cervix biopsies which did not show representative endocervical tissue were excluded from analysis. The number of CD45+ and CD3+ cells (expressed as number of positive pixels/μm^2) in vaginal biopsies was significantly higher in pSS patients (p=0.012 for CD45, p=0.008 for CD3). Lymphocytic infiltration was mainly located in the subepithelial layer, with aggregates in dermal papillae. Endocervical CD45+ leucocytic infiltrates were seen in patients as well as controls, but CD20+ positive pixels/μm2 were significantly higher in pSS patients (p=0.041). Importantly, there was a significantly lower number of vascular smooth muscle cells (caldesmon+ pixels/μm2) in the vagina of pSS (p=0.031). In the endocervix, no significant differences were seen in endothelial or smooth muscle cells.

Conclusion: Our findings indicate that in addition to chronic inflammation, vascular disturbances in the vaginal mucosa are likely to contribute to vaginal dryness in women with pSS.

Positive Rate of Small Intestinal Bacterial Overgrowth Test (SIBO) Was Significant Correlations to Disease Activity of Primary Sjogren's Syndrome (pSS)

xiaodong li,[1] Xiao feng li,[2] Sha Dong,[3] Sheng-xiao Zhang,[4] Junwei Chen,[5] and guangying liu[3], [1]Second Affiliated Hospital of Shanxi Medical University, tai yuan, China (People's Republic), [2]The Second hospital of Shanxi Medical University, Taiyuan, China (People's Republic), [3]Second Affiliated Hospital of Shanxi Medical University, taiyuan, China (People's Republic), [4]The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China (People's Republic), [5]the Second Hospital of Shanxi Medical University, Taiyuan, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

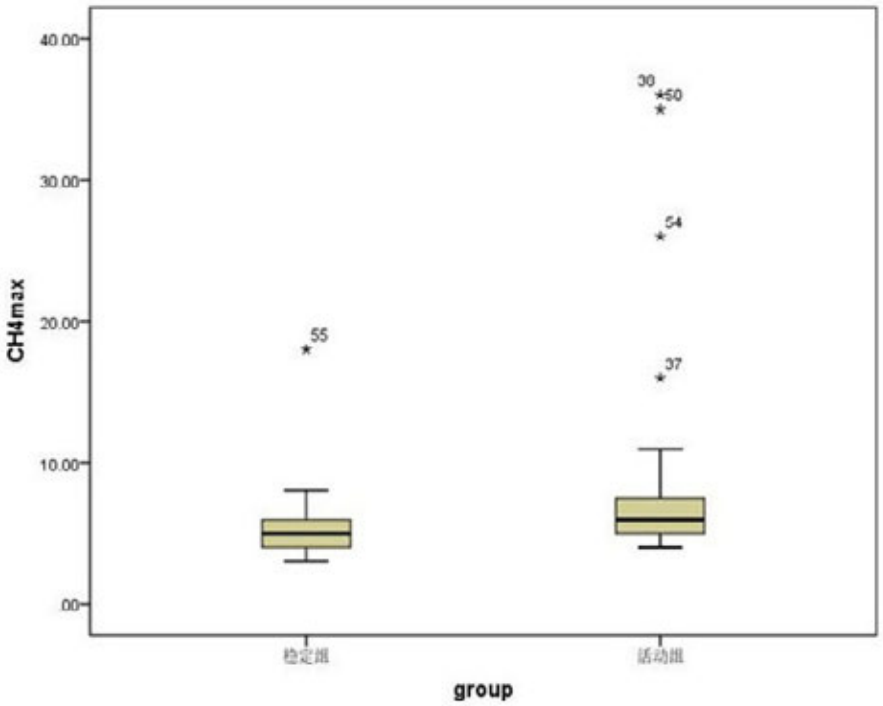
Background/Purpose: Primary Sjogren's syndrome (pSS) is a chronic inflammatory autoimmune disease that primarily affects the exocrine glands, which is involved in gastrointestinal unavoidably. Once intestinal flora imbalance, it will have a major impact on health. The Small intestinal bacterial overgrowth test (SIBO) is an important method for detecting bacterial growth in the small intestine.

To investigate the difference in the positive rate of SIBO between disease active and stable patients with pSS, and to retrospectively analyze the correlation between disease activity and SIBO.

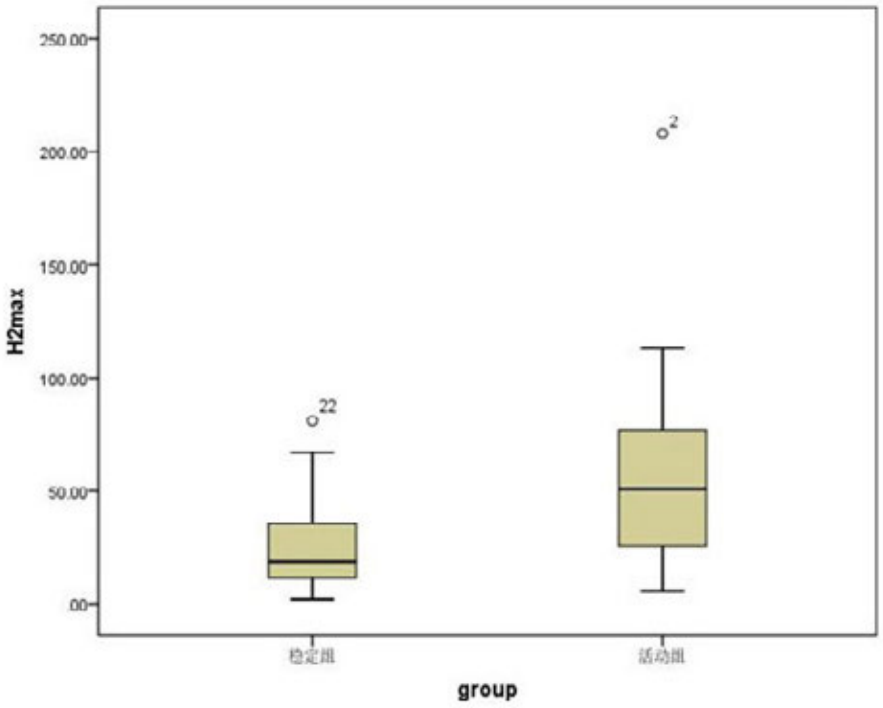
Methods: Total 60 patients with pSS diagnosed and treated in our hospital were selected as subjects of this study from October 2018 to March 2019, according to the PSS Disease Activity Rating System (SSDAI) scores. They were divided into Group A: active period (point≥5 points), 30 cases and group B: stable period (point< 5 points), 30cases. Two sets of clinical data were collected, including SSDAI scores and SIBO. The difference between the percentage of active and stable SIBO positive patients was compared. The maximum sum of hydrogen and methane in the two groups was tested by rank sum test, and the correlation between pSS disease activity and SIBO positive rate was analyzed.

Table 1 Comparison of SIBO positive rate between active period and stable period [n (%)]

	SIBO positive	SIBO negative	total
active period	28 (93.33%)	2 (6.67%)	30 (100%)
stable period	17 (56.67%)	13 (43.33%)	30 (100%)
Total	45 (75.00%)	15 (25.00%)	60 (100%)



Mann-Whitney U test of two sets of CH4MaX independent samples



Mann-Whitney U test of two sets of H2MaX independent samples

Results: The positive rate of SIBO in patients with active pSS was significantly higher than that in stable phase, and the difference was statistically significant (P< 0.05), as shown in Table 1. The two groups were compared with H2MaX or CH4MaX, and the Mann-Whitney U test results were statistically significant (P=0.001, P=0.003), as shown in image1 and image2.

Conclusion: SIBO positive rate was significant correlations to pSS disease activity. So, correcting intestinal flora imbalance combined with conventional treatment may bring greater benefits to patients with Sjogren's syndrome.

The Oral Microbiome as a Risk Factor for Benign or Pathologic Autoimmunity Associated with Anti-SSA/Ro Positivity and Mimicry for Von Willebrand Factor Type a Domain Protein (vWFA) of *L. Mirabilis*

Robert Clancy,[1] Miranda Marion,[2] Peter Izmirly,[1] Hannah Ainsworth,[3] Timothy Howard,[3] Mala Masson,[1] Jill Buyon,[1] and Carl Langefeld[3], [1]NYU School of Medicine, New York, [2]Wake Forest School of Medicine, Winston-Salem, NC, [3]Wake Forest School of Medicine, Winston-Salem

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Autoantibody production precedes SLE or SS by years, including anti-Ro. Anti-Ro$^+$ mothers of children with congenital heart block (CHB) are a unique population at risk for pathologic autoimmunity, as many are asymptomatic (Asym/UAS) and become aware of autoantibodies due to fetal disease and yet have a 10-year progression rate to SS/SLE of 20%-30%. We hypothesized that variation in the oral microbiome correlates with transition to SLE or SS and pathogenicity involves sequence homology between Ro60 and bacterial von Willebrand factor type A domain protein (vWFA).

Methods: The oral microbiome of 25 anti-Ro$^+$ mothers of CHB children (Asym/UAS, N=9; SS/SLE, N=16) and 7 healthy controls (HC) were processed using 16S ribosomal RNA sequencing. Analysis of variance methods compared the centered log ratio transformed relative abundances for 1) HC vs. anti-Ro$^+$ mothers, and 2) assuming an ordering of severity from HC < Asym/UAS < SS/SLE. To adjust for multiple comparisons, a taxonomic stepdown method coupled with false discovery rate (FDR) was used. The Basic Local Alignment Search Tool evaluated homology of Ro60 at aa 371-381 and peptides of vWFA.

Results: Sequencing 16S rRNA identified microorganisms from 2 kingdoms, 16 phyla, 25 classes, 41 orders, 70 families, 164 genera, and 166 species. The Shannon Index (H) revealed that for each taxonomic level except species, there were significant reductions in diversity in the anti-Ro$^+$ mothers relative to HC ($P \leq 0.05$). There were global differences in the microbiota of these mothers relative to HC (perMANOVA P=0.00049). The phylum *Actinobacteria* was more abundant in the anti-Ro$^+$ mothers vs HC (P_{FDR}=0.0231). Within *Actinobacteria*, the class *Coriobacteriia* and subsequent lower taxonomic levels down to *Atopobium parvulum*, all exhibited increases in relative abundance in the anti-Ro$^+$ mothers compared to HC. There was a significant reduction in the relative abundance as clinical severity increased within one of the most frequent phyla, *Proteobacteria* (P_{FDR}=0.030; mean±SD; HC 0.24±0.07; Asym/UAS 0.19±0.12; SS/SLE 0.11±0.08). The difference in the relative abundances between Asym/UAS and SS/SLE within *Proteobacteria* was significant (P=0.042). Within *Proteobacteria*, the common class *Betaproteobacteria* also showed reduced relative abundance with increasing clinical severity (P_{FDR}=0.0037; HC 0.11±0.04; Asym/UAS 0.072±0.07; SS/SLE 0.031±0.04). These ordered differences were maintained down the taxonomic hierarchy to the genus (*Lautropia*, P_{FDR}=0.0072) and species within this genus (*L. mirabilis*, P_{FDR}=0.012). Next, sequences of vWFA secreted by these taxa were evaluated. For a comparison of Ro60 T cell epitope, FLLAVDVSASMNQ, the vWFA, VLVVFDNSSSMTA

AA Sequence	Protein
FLLAVDVSASMNQ	Ro60
LLLLLDVSGSMAG (WP_005674879.1)	vWFA *Lautropia mirabilis*
VLVVFDNSSSMTA (WP_012809344.1)	vWFA *Atopobium parvulum*

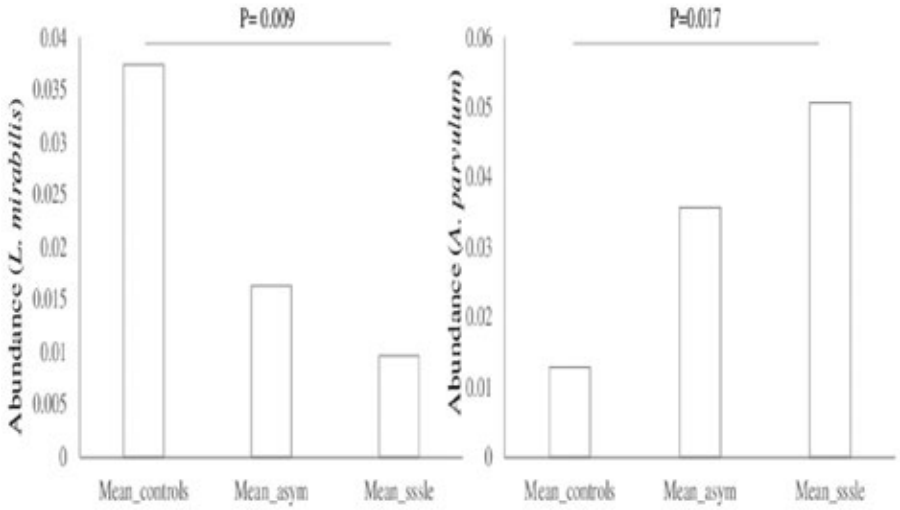

Figure 1. Sequence homology of human Ro60 and peptides found in bacterial vWFA (upper panel) and associations of targeted taxa and anti-Ro+ mothers vs controls (lower panel). For the former, note that Ro60 shares seven of its first 11 aa with L. mirabilis vWFA, while it shares only five with A. parvulum vWFA (sharing denoted by yellow and disharmony by red). For the latter, note the depletion of L mirabilis, possibly occurring secondary to a pathologic role of anti-Ro along with an expansion of A. parvulum, an opportunistic taxon.

vWFA of *A. parvulum* was not a fit due to the aromatic and polar aa at positions 5 and 9, respectively. In contrast, the vWFA of *L. mirabilis*, LLLLLDVSGSMAG, was identical at 7 of the first 11 aa.

Conclusion: These data provide evidence that the microbiome differs along a clinical spectrum of autoimmunity. In part, the data reflect a path involving depletion of *L. mirabilis*, which is secondary to a pathologic role of anti-Ro along with an expansion of *A. parvulum*, an opportunistic taxon.

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Sjogren's syndrome (SS) is characterized by lymphocyte infiltration of exocrine gland, resulting in decreased exocrine function and dry symptoms, affecting the quality of life of patients. Studies have found that intestinal microbial imbalance is associated with sjogren's syndrome. This study aims to detecte the differences

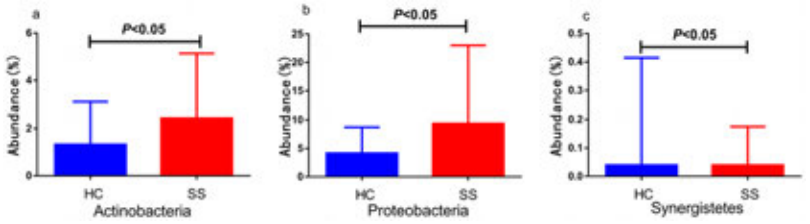

Figure1 The phylum level profile for SS patients and healthy control.

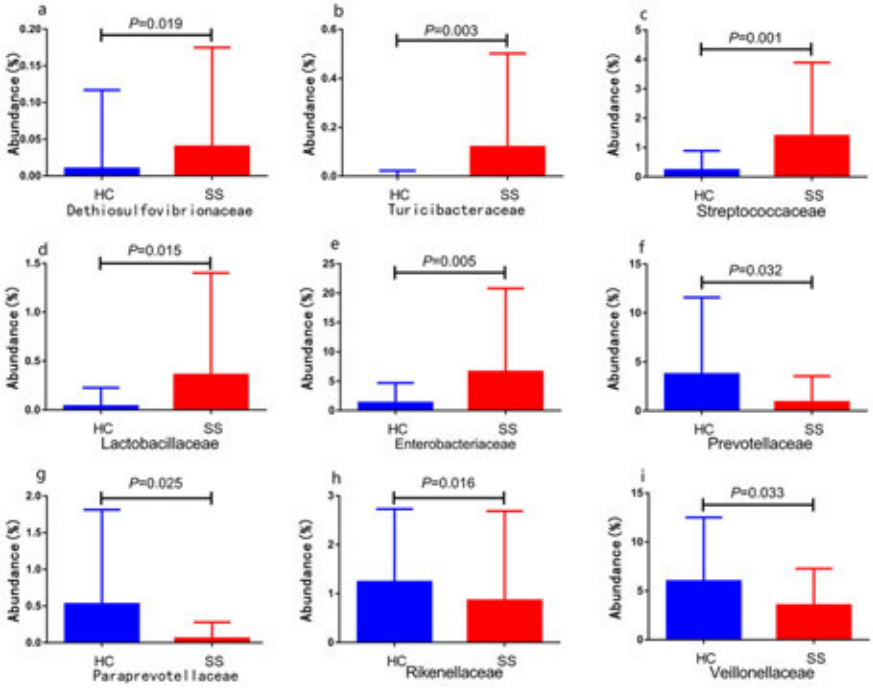

Figure2 The division level profile for SS patients and healthy control

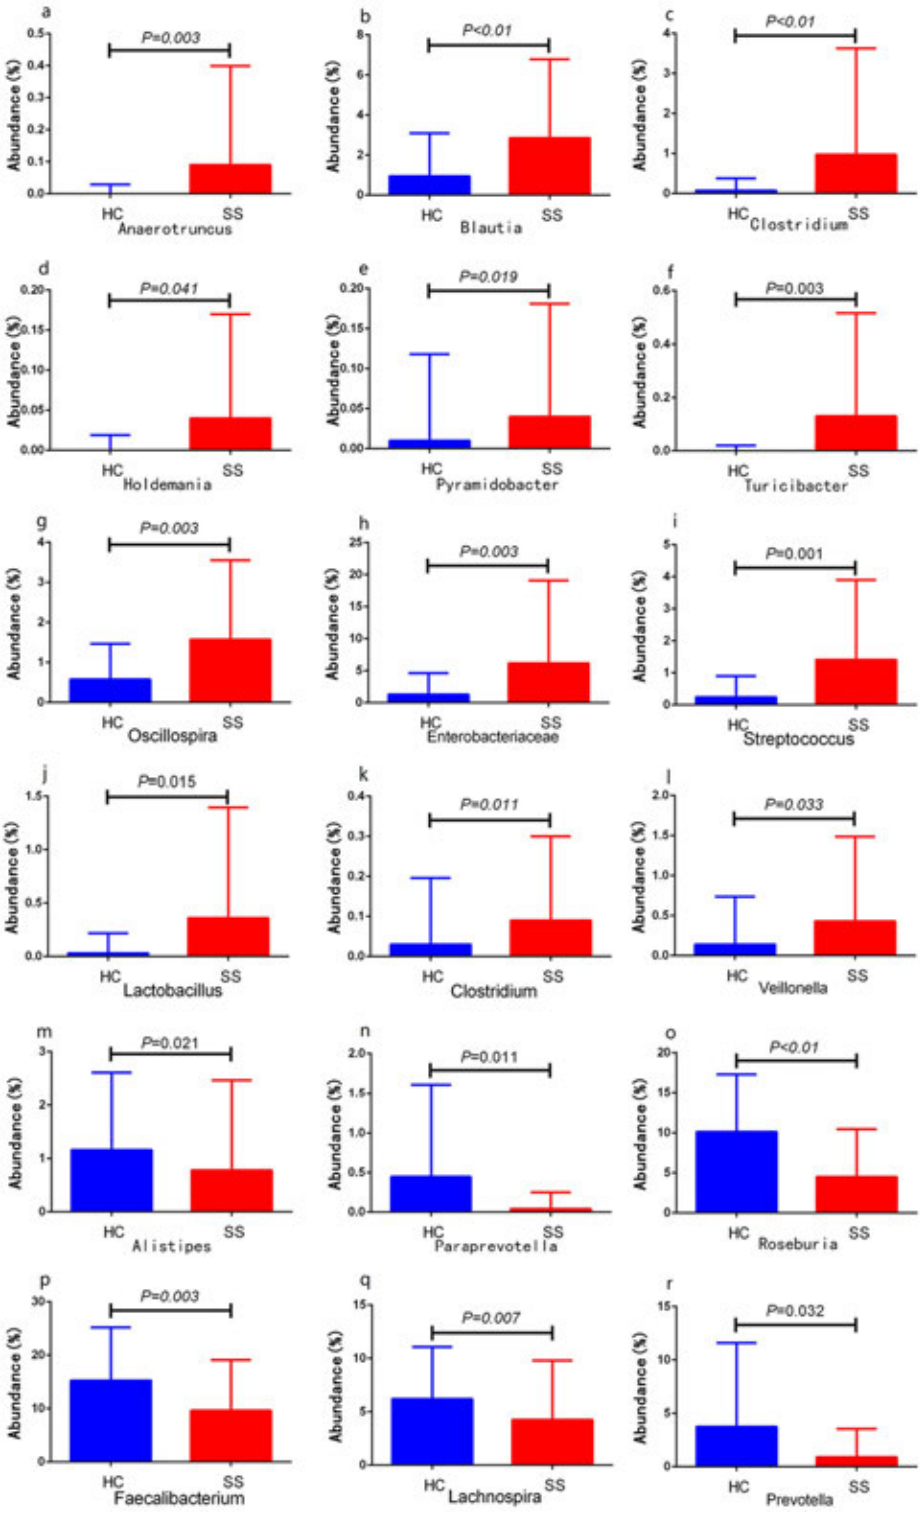

Figure3 The genus level profile for SS patients and healthy control

of microbial population distribution in stool samples of healthy individuals and patients with sjogren's syndrome (SS), and explore the changes of intestinal flora in SS patients.

Methods: The 16s rRNA V3 region in the stool samples of 29 SS patients was qualitatively analyzed by using 16s high-through put sequencing platform, and compared with that of 126 healthy controls (HC).

Results: Patients with SS had an increased feces bacterial flora of bacteria species OTU information (P< 0.01) and the diversity index (Shannon) increased (P< 0.05), though only a slightly difference of Evenness index compared with that of HC (P >0.05). As for intestinal flora abundance patients had more Actinobacteria, Proteobacteria, Synergistetes at phylum level (P< 0.05) and also had a large amounts of Dethiosulfovibrionaceae, Turicibacteraceae, Streptococcaceae, Lactobacillaceae, Enterobacteriaceae at division level (P< 0.05) but a lower proportion of Prevotellaceae, Paraprevotellaceae, Rikenellaceae, Veillonellaceae (P< 0.05). When considered genus level, there were also more percentages in Anaerotruncus, Blautia, Clostridium, Holdemania, Pyramidobacter, Turicibacter, Oscillospira, Enterobacteriaceae, Streptococcus, Lactobacillus, Clostridium, Veillonella (P< 0.05), but smaller proportion of Alistipes, Paraprevotella, Roseburia, Faecalibacterium, Lachnospira, Prevotella (P< 0.05) in SS patients when compared with those of HC.

Conclusion: The diversity and equilibrium of bacterial community in intestinal microecology of SS patients were significantly different from that of normal population.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In addition to xerostomia symptoms, patients with Sjögren's syndrome (SS) experience pain and discomfort in the oral cavity, and difficulties in speaking and eating, due to refractory stomatitis, oral ulcer, glossitis, atrophy in the oral mucosa and tongue, and increased carious teeth. These dry mouth symptoms cause not only intraoral problems but also psychological and social problems; therefore, oral health-related quality of life (OHRQoL) is broadly deteriorated in SS patients. However, no previous reports have documented changes in OHRQoL evaluated over time in SS patients. In this study, we evaluated OHRQoL in SS patients and identified their specific troubles. Furthermore, we monitored OHRQoL over time in the same SS patients, and revealed changes in the troubles and the relationship with their clinical conditions.

Methods: Thirty-five SS patients (22 with primary SS and 13 with secondary SS; 32 women and 3 men; mean age, 56.2 ± 13.2 years; mean disease duration, 5.8 ± 3.7 years) and 23 non-SS (control) individuals (18 women and 5 men; mean age, 56.1 ± 17.4 years) participated in this study. All SS patients met the 2012 American College of Rheumatology classification criteria for SS. Individuals with factors affecting intraoral lesion formation, saliva secretion, or OHRQoL were excluded. OHRQoL was quantitatively evaluated with the Japanese version of shortened Oral Health Impact Profile (OHIP-14), which is a self-administered questionnaire (maximum possible score, 56 points). Saliva

secretion was measured by the chewing gum test method. Twenty-two SS patients and 14 non-SS individuals completed 3-year follow-up, and underwent the OHIP-14 survey and saliva secretion measurement again three years after the first evaluation.

Results: The SS group had a significantly higher OHIP-14 score (i.e., lower OHRQoL) than the non-SS group (11.3 ± 9.4 vs 7.1 ± 7.6; p=0.027). The high-score SS group was significantly more advanced in age (61.5 ± 10.4 vs 52.7 ± 14.0; p=0.026) and had a significantly smaller amount of saliva secretion (6.9 ± 4.2 vs 9.3 ± 4.4 ml/ 10min; p=0.047) compared to the low-score SS group. Among individual items in OHIP-14, scores for "Trouble pronouncing words," "Uncomfortable to eat," "Self-conscious," and "Diet unsatisfactory" were significantly higher in the SS group than in the non-SS group. In the SS group, the OHIP-14 score significantly increased over 3 years (10.2 ± 8.8 vs 12.6 ± 9.2; p=0.040), while the score remained unchanged in the non-SS group. A negative correlation was found between the change rate of saliva secretion amount and the OHIP-14 score change over 3 years in the SS group (r_s=–0.418, p=0.027). Among individual OHIP-14 items, scores for "Irritable with others," "Difficulty doing jobs," "Life unsatisfying," and "Unable to function" significantly increased in 3 years, and scores for other items remained comparable with baseline scores.

Conclusion: In SS patients, a decrease in OHRQoL occurred over 3 years and was associated with a decrease in saliva secretion. Moreover, SS patients' troubles in social life and mental aspect were found to intensify over time.

Background/Purpose: Although there is little information, the debut of primary Sjögren's syndrome in adult patients aged less than or equal to 35 years, would be expressed with less pronounced Sicca manifestations and with a high degree of systemic commitment. For this reason, we decided to compare the behavior of the disease in the Argentine population with a diagnosis of primary Sjögren's syndrome at age less than or equal to 35 years versus those older than 35 years.

Methods: Cross-sectional observational analytical study. We analyzed the data of patients older than 18 years, with diagnosis of primary Sjögren's syndrome (American-European criteria 2002 / ACR EULAR 2016), included in the GESSAR database (Sjögren Syndrome Study Group of the Argentine Society of Rheumatology), with minus one control in the last 12 months. The presence of systemic manifestations assessed from the domains of the ESSDAI and the glandular manifestations, and as possible confounders were considered: sex, diabetes, hypothyroidism, treatments and time of follow-up in years of each group. The continuous variables were described as mean and standard deviation or median and interquartile range (RIQ), according to distribution and sample size. The categorical variables were expressed in percentages. For the bivariate analysis, for the continuous variables, the Student or Mann Whitney test was used according to distribution and sample size. The categorical variables were analyzed using Chi square or Fisher's exact test, according to the expected frequency distribution table. A $p < 0.05$ was considered statistically significant.

Results: 665 patients were included. One hundred of them with an age at diagnosis ≤ 35 years and with a mean age at diagnosis of 29 ± 4 years, 92% of them women. The average age at diagnosis of the group > 35 years was 54 ± 11 years. Within the glandular manifestations, statistically significant differences were found between ≤ 35 years vs >35 years, in xerophthalmia (90.72% vs 95.64%, *p*: 0.04) and xeroderma (42.35% vs 57.36%, *p*: 0.03). No significant differences were found in xerostomia (87.37% vs 90.33%, *p*: 0.38), nor xerovagina (30.86% vs 39.18%, *p*: 0.15). Statistically significant differences were found between ≤35 years vs >35 years in the following domains of ESSDAI: peripheral nervous system (4.05 vs 11.32, *p*: 0.03), respiratory (6% vs 15.40%, *p*: 0.01) and renal (6% vs. 1.59%, *p*: 0.02). In a subanalysis of ESSDAI domains, significant differences were found in arthritis (37.37% vs 27.16%, *p*: 0.04) and persistent dry cough (4.04% vs 11.47%, *p*: 0.03).

Conclusion: A significantly lower frequency of xerophthalmia and xeroderma was observed in the group ≤35 years old compared to those >35 years old. Regarding systemic activity, less involvement of the peripheral nervous system and pulmonary domain and higher in the renal domain, with statistically significant differences. These results suggest a lower glandular compromise in patients diagnosed at a younger age, without a characteristic differential pattern in terms of systemic involvement.

Effects of Resistive Exercise on Fatigue and Disease Activity in Women with Primary Sjogren's Syndrome

Luciana Paula Dardin,[1] Fernanda Gazoni,[1] Ana Beatriz Garcia,[1] Paulo Alexandre Minali,[2] and **Virginia Fernandes Moça Trevisani**[3], [1]Sao Paulo Federal University - Brazil, Sao Paulo, Sao Paulo, Brazil, [2]Sao Paulo Federal University - Brazil, Sao Paulo, Brazil, [3]Department of Evidence-Based Medicine, Brazilian Cochrane Centre, Federal University of São Paulo, Sao Paulo, Brazil, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fatigue is a frequent symptom of pSS, considered debilitating and the most important cause of dysfunction in these patients. The present study aimed to assess the effectiveness of resistive exercise as a non-pharmacological intervention for reducing fatigue in primary Sjögren's Syndrome patients (pSS).

Methods: This is a single-blinded randomized clinical trial performed at the Ophthalmology outpatient clinic and at the Center for Psychobiology Studies at the Federal University of São Paulo, Brazil. Participants were randomized into a resistive exercise program and a control group and evaluated by a blinded evaluator. We used ESSDAI to evaluate disease activity; ESSPRI to evaluate fatigue, pain and dryness; PROFAD, VAS–fatigue and FACIT-fatigue for fatigue; and VAS-pain for pain. (Table 1) Participants from the exercise group performed a resistive program of 16 weeks with a one-hour duration, 2 times a week.

Results: We evaluated 73 female patients diagnosed with pSS according to the European-American Consensus Group Criteria and with complaints of fatigue. A total of 59 participants were included and randomized for exercise group (n=29) and control group (n=30). Participants in the exercise group had mean age of 62.1 years (SD=12.9) and a mean time of disease symptoms of 19 years (SD=10.4). The mean age in the control group was 58.1 years old (SD=10.2) and mean symptom time was 13.8 years (SD=9.3), with no difference between groups ($p< 0.001$). According to ESSDAI, there was no significant difference in disease activity between the two groups over the study time. All scales related to fatigue and pain presented better scores in the exercise group when comparing to control group. (See Table 2 for detailed results) ESSPRI- fatigue exercise group had a mean score of 6.5 before and of 2.23 after intervention and control group a mean score of 5.52 versus 6.03; ESSPRI- pain exercise group mean score of

Table 1 - Questionnaires

Questionnaire	Definition
ESSDAI	EULAR Sjögren's Syndrome Disease Activity Index: to evaluate disease activity;
ESSPRI	EULAR Sjögren's Syndrome Patient Reported Index: to evaluate fatigue, pain and dryness;
PROFAD	Profile of Fatigue and Discomfort: to evaluate fatigue in different domains (somatic, mental, arthralgia, vascular)
VAS-fatigue	Visual Analog Scale: to evaluate fatigue
FACIT-fatigue	Functional Assessment of Chronic Illness Therapy – fatigue: to evaluate fatigue
VAS-pain	Visual Analog Scale: to evaluate pain

Table 2 - Questionnaires scores before and after intervention

	Control				Exercise				p-intergroup
	INITIAL		FINAL		INITIAL		FINAL		
	Mean	SD	Mean	SD	Mean	SD	Mean	SD	FINAL
VAS PAIN	5.8	2.7	6	2.8	6	2.9	3.1	2.5	< 0.01
VAS FATIGUE	6.1	3	6.4	2.6	6.7	2.2	2.4	1.9	< 0.001
ESSDAI	3.3	3.4	3.1	3.2	2.5	3.5	1.9	3.2	0.223
PROFAD									
Somatic	3.52	2.03	3.14	1.96	2.98	1.72	1.14	1.21	< 0.001
Mental	3.6	2.21	3.98	2.23	3.57	2.03	3.03	2.03	0.322
Arthralgia	3.38	2.04	3.26	1.68	2.55	1.82	1.45	1.55	< 0.001
Vascular	1.31	2.39	1.07	1.93	1.38	2.24	1.28	1.94	0.776
FACIT	30.5	12.8	30.4	12	34	10.1	42.4	10.3	< 0.001
ESSPRI									
Dryness	6.07	2.78	6.86	2.39	7.73	1.76	7.73	8.44	0.17
Fatigue	5.52	3.05	6.03	2.87	6.5	2.37	2.23	2.13	< 0.001
Pain	5.55	2.97	5.28	2.85	5.57	3.13	2.8	2.82	< 0.001

5.57 before and of 2.8 after intervention and control group mean score of 5.55 before versus 5.28 after intervention. The exercise group had an initial mean in VAS-fatigue of 6.7 dropping significantly to 2.4 at the end of the training while the control group had no difference from the beginning to the final time. Also, VAS-pain in exercise group was 6 and dropped to 3.1 while in the control group had no difference. In the PROFAD questionnaire, the mean physical fatigue score in the exercise group was initially 2.98 dropping to 1.14 at the end and in the control group, the results did not present significant variation; in PROFAD- arthralgia, initial and final means scores in exercise group were 2.55 and 1.45 respectively, while in the control group there was no significant variation between the initial and final scores. Regarding FACIT, there was a significant improvement in the score for fatigue in the exercise group at the end of the exercise program (initial mean of 34 and final mean score of 42.4) while in the control group there was no significant difference.

Conclusion: The present study states that after a resistive 16-week exercise program, patients with primary Sjogren's Syndrome improved the parameters related to fatigue and pain with no effect in reducing or increasing disease activity.

New 2019 SLE EULAR/ACR Classification Criteria for SLE Are Valuable for Distinguishing Patients with SLE from Patients with pSS in Daily Practice

Florence Assan,[1] Raphaele Seror,[2] Gaetane Nocturne,[3] and Xavier Mariette[4], [1]Université Paris Sud, Hôpitaux Universitaires Paris-Sud, AP-HP, INSERM UMR 1184, Le Kremlin-Bicêtre, France, [2]Hopitaux universitaires Paris Sud, Kremlin-Bicetre, France, [3]Center for Immunology of Viral Infections and Autoimmune Diseases, Assistance Publique – Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, Université Paris Sud, INSERM, Paris, France., Paris, France, [4]Center for Immunology of Viral Infections and Autoimmune Diseases, Assistance Publique – Hôpitaux de Paris, Hôpitaux Universitaires Paris-Sud, Le Kremlin-Bicêtre, Université Paris Sud, INSERM, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The new 2019 SLE EULAR/ACR Classification Criteria for Systemic lupus erythematosus (SLE) have been developed to find a better equilibrium between specificity and sensitivity compared to SLE ACR-1997 and SLE SLICC. Given the biological and clinical similarities and the frequent overlap between SLE and primary Sjögren's Syndrome (pSS), these criteria could be useful in clinical practice for differentiating SLE from pSS.

The aim of this study was to explore the utility of the 2019 SLE EULAR/ACR criteria compared to SLE ACR-1997 and SLE SLICC criteria for differentiating in clinical practice SLE from pSS and overlap between both.

Methods: This retrospective study included 3 different groups of patients followed in Department of Rheumatology, Hopitaux Universitaires Paris Sud: (i) 49 SLE patients (diagnosis made by the clinician with exclusion of patients with another connective tissue disease associated). (ii) 49 pSS patients randomly chosen from the Paris Sud database, fulfilling the pSS ACR/EULAR 2016 criteria, with exclusion of patients with association of another connective tissue disease (iii) 26 SLE/Sjögren's Syndrome (SS) overlap patients based on clinical diagnosis, made of 13 patients diagnosed as SLE and presenting objective signs of associated SS (minor salivary glands biopsy Focus Score ≥ 1, and/or objective sicca syndrome) and 13 patients diagnosed as SS with anti-DNA antibodies.

The biological, immunological, and clinical data were collected at diagnosis, or at the first visit at the centre. SLE ACR-1997, SLE SLICC and 2019 SLE EULAR/ACR criteria were tested in each group. Categorical variables were compared using a Chi^2 or Fischer's exact test as appropriate. Quantitative variables were compared with Kruskal-Wallis test.

Results: As shown in Table, the 2019 SLE EULAR/ACR criteria were met in 97.9% of the SLE patients vs 4.2% of the pSS patients ($p< 0.001$). Interestingly, patients from the overlap group fulfilled both criteria for SLE and SS confirming the capacity of the criteria to detect the overlap. Lymphopenia and biological inflammation were significantly associated with SLE (respectively 33% vs 14%, $p=0.004$ and 28% vs 14%, $p< 0.001$), whereas initial rheumatoid factor detection was significantly associated with pSS (3.5% vs 35%, $p=0.001$). Systematic assessment of sicca syndrome could help to differentiate SLE from pSS. Overlap syndrome patients had a more systemic disease than pSS patients as assessed by the EULAR Sjögren's syndrome Disease Activity Index (ESSDAI): respectively 5.6 vs 9.7 ($p=0.001$).

Conclusion: In conclusion this study shows that the new 2019 SLE EULAR/ACR criteria for SLE can be useful in clinical practice helping to differentiate between SLE and pSS and detecting overlap presentations.

Characteristics		SLE pants	pSS patients	Overlap patients	p-value

Health-Related Quality of Life in Primary Sjogren's Syndrome: Insights from Using PROMIS and Comparison to ESSPRI

Dana DiRenzo,[1] Susan Robinson,[2] Clifton Bingham,[1] and Thomas Grader-Beck[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University, Baltimore

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Table 1. Baseline demographic and clinical characteristics of patients who met 2016 ACR/EULAR Classification Criteria for Sjogren's Syndrome.

Demographic/Clinical Characteristic	Primary Sjogren's Syndrome (n=99)
Age, median (IQR)	57 (43, 66)
Gender, (n, % female)	89 (90%)
Race (n, % white)	80 (81%)
ESSPRI, median (IQR)	
Total	5.3 (3.7, 6.8)
Pain (0-10)	4.5 (2, 7)
Dryness (0-10)	6 (5, 8)
Fatigue (0-10)	6 (4, 7)
Hydroxychloroquine (n, %)	63 (64%)
Rituximab (n, %)	7 (7%)
Methotrexate (n, %)	11 (11%)
Leflunomide (n, %)	3 (3%)
Azathioprine (n, %)	3 (3%)
PROMIS Global Profile Mean T-Score (SD)	
Pain Interference	56.6 (11.5)
Physical Function	44.5 (10.0)
Fatigue	56.9 (11.0)
Social Participation	48.0 (11.1)
Sleep Disturbance	52.9 (8.7)
Anxiety	55.2 (9.6)
Depression	50.8 (8.9)

ESSPRI= EULAR's Sjogren's Syndrome Patient Reported Index.

Background/Purpose: Sjogren's Syndrome (SS) is a chronic, autoimmune disease affecting the exocrine glands that may negatively affect health-related quality of life (HRQL). The importance of measuring symptoms and impacts has increasingly been recognized in patient care and clinical trials. Patient Reported Outcome Measurement Information System (PROMIS) provides universal HRQL instruments, but has not been previously implemented in SS. Currently, EULAR Sjogren's Syndrome Patient Reported Index (ESSPRI) is widely utilized in SS but is limited in measuring HRQL domains. We sought to evaluate how selected PROMIS domains in SS would compare to US normative values and how scores may correlate with the ESSPRI.

Methods: This was a cross-sectional evaluation of adult patients with SS who completed PROMIS short-forms (SF) (depression 4a, anxiety 4a, fatigue 8a, physical function 10a, pain interference 8a, sleep disturbance 4a, participation in social roles and activities 8a) and had a clinical assessment between May 2018-March 2019. PROMIS T-scores are normalized to a score of 50 with a standard deviation of 10 in the US population; higher scores indicate more of the concept being measured; and a clinically meaningful difference is generally considered ½ SD, or 5 T-score units for some domains. Descriptive statistics, including means and proportions, were calculated for disease-related and sociodemographic variables. Pearson correlation was used to evaluate the relationship between subdomains of the ESSPRI and PROMIS.

Results: Ninety-nine individuals met the 2016 ACR criteria for SS and completed PROMIS SF and clinical measures. Individuals with SS had a median age (IQR) of 57 (43, 66) and were mostly female (90%) and white (81%) (Table 1). Median (IQR) ESSPRI scores were 5.33 (3.66, 7), indicating moderate patient-reported disease activity; median (IQR) ESSRPI subdomain scores were 5 (2, 7) for pain, 6 (5, 8) for dryness, and 6 (4, 7) for fatigue. PROMIS scores for pain interference, fatigue, physical function, and anxiety were at least ½ SD worse than US population normative values. PROMIS pain interference (r=0.78) and fatigue (r=0.79) highly correlated with ESSPRI pain and fatigue sub-domains, respectively. PROMIS fatigue was highly correlated with pain interference (r=0.78) and negatively correlated with social participation (r=-0.71); pain interference was negatively correlated with social participation (r=-0.78) and physical

Table 2. Correlation between ESSPRI domains and PROMIS domains in patients with primary Sjogren's Syndrome.

	ESSPRI Pain (n=96)	ESSPRI Fatigue (n=96)	ESSPRI Dryness (n=96)	PROMIS Pain Interference (n=99)	PROMIS Physical Function (n=98)	PROMIS Fatigue (n=98)	PROMIS Social Participation (n=99)	PROMIS Sleep Disturbance (n=97)	PROMIS Anxiety (n=96)	PROMIS Depression (n=97)
ESSPRI Pain	1.00									
ESSPRI Fatigue	0.67	1.00								
ESSPRI Dryness	0.40	0.33	1.00							
PROMIS Pain Interference	0.78	0.60	0.30	1.00						
PROMIS Physical Function	-0.68	-0.60	-0.45	-0.73	1.00					
PROMIS Fatigue	0.52	0.79	0.20	0.71	-0.66	1.00				
PROMIS Social Participation	-0.61	-0.71	-0.31	-0.78	0.81	-0.84	1.00			
PROMIS Sleep Disturbance	0.50	0.53	0.23	0.55	-0.53	0.62	-0.55	1.00		
PROMIS Anxiety	0.24	0.33	0.07	0.48	-0.35	0.52	-0.49	0.49	1.00	
PROMIS Depression	0.30	0.33	0.05	0.47	-0.33	0.49	-0.47	0.52	0.80	1.00

function (r=-0.73) (Table 2). PROMIS anxiety and depression were highly correlated (r=0.80) with each other but not with other ESSPRI or PROMIS domains.

Conclusion: In our SS cohort, PROMIS pain interference and fatigue scores highly correlated with respective ESSPRI domains. Levels of PROMIS pain interference, fatigue, physical function, and anxiety were at least ½ SD worse than US population normative values. Pain interference and fatigue were not highly correlated with anxiety or depression. PROMIS instruments should be considered for use in SS research and clinical care. Future work will require validation in a larger cohort of SS patients and across broader demographics.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Polyautoimmunity has been described to be associated with primary Sjögren´s syndrome (SjS) and the most frequent observed associated autoimmune diseases (AID) are autoimmune thyroid disease, autoimmune hepatitis and primary biliary cirrhosis, which are common organ-specific AID. In the same track, renal and lung involvement has increasingly been documented in SjS further highlighting its systemic nature. Objective: To describe and classify prevalence of polyautoimmunity and major organ involvement in a primary SjS-cohort.

Methods: This cross-sectional study included 179 patients [160 (89%) females and 19 (11%) males] diagnosed with primary SjS and fulfilling the ACR classification criteria that had been admitted to our outpatient clinic between December 2008 and December 2018. Demographic and disease-specific characteristics were recorded in all patients.

Results: In our cohort the median age at diagnosis was 57 years (range: 20-85). Thyroid AID was found in 55/179 (30%) patients, with the following distribution: Hashimoto thyroiditis without (n=21) and with hypothyroidism (n=22), Graves's disease without (n=4) and with thyroidectomy (n=8). Liver AID was detected in 8/179 patients (4%), 3 patients with autoimmune hepatitis and 5 patients with primary biliary cirrhosis. Regarding major organ involvement, 20/179 (11%) patients had renal manifestations: renal insufficiency (n=12), glomerulonephritis (n= 3), interstitial ne-

phritis (n=2) and IgA nephritis (n=3). Eight/179 (4%) patients had lung manifestations: interstitial fibrosis (n=6), emphysema (n=1) and chronic obstructive pulmonary disease (n=1).

Conclusion: Our results add evidence for the presence of polyautoimmnunity and major organ involvement in SjS. We found a slightly lower prevalence of polyautoimmunity and major organ involvement compared to recently reported data. Nonetheless, extra-glandular organ involvement should be assessed in order to elucidate cumulative damage and how it might impact outcome, prognosis and therapeutic approaches in SjS.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary Sjögren's Syndrome (pSS) is a chronic autoimmune disease characterized by lymphocytic infiltration of the exocrine glands. Is the connective tissue disease that is most frequently associated with other autoimmune disorders and approximately 30% of these patients have another associated autoimmune condition. To date, no studies have evaluated the frequency of another autoimmune connective tissue disease development in patients with initial diagnosis of pSS.

OBJECTIVES: To determine the frequency of patients who, following the diagnosis of pSS, developed another autoimmune rheumatic disease during their follow-up using the GESSAR database (Sjögren Syndrome Study Group of the Argentine Society of Rheumatology). To detail the connective tissue diseases that occurred most frequently in these patients. To describe the clinical, serological and salivary gland histology characteristics of these patients.

Methods: Descriptive, observational, cross-sectional study. We analyzed the data of patients diagnosed with pSS (American-European criteria 2002 / ACR-EULAR 2016), included in the GESSAR database. It was considered the

development of another connective tissue autoimmune disease in those cases in which the diagnosis was added during follow-up.

Results: 681 patients were included, mean of following in years was 4.7 años (SD 4.94), 94.8% were women, mean age of 54 (+/- 14) and mean age at diagnosis of 50 (+/- 13) years. Of the total of patients, 30 (4.41%) developed another autoimmune rheumatic disease, according to the classification criteria for each disease, in its evolution. The median time to development was 4 (ICR 2-9). They were: Rheumatoid Arthritis (RA) 14 patients, scleroderma 9 patients, lupus (SLE) 5 patients, dermatomyositis 1 patient and RA plus SLE 1 patient. The mean age of this subgroup was 53 (+/- 14), with a mean age at diagnosis of pSS 48 (+/- 13), 91 % were women. Regarding the SICCA symptoms: 96% reported xerophthalmia, and 86.2% xerostomia to the diagnosis of pSS. With respect to the objective tests: 92% had positive Schirmer test, 88.24% Bengal Rose test or Lisamine Green or positive staining score, 81.2% positive sialometry, Ro + 82.1% and La + 33.33% of patients. Of the 30 patients, 14 had a minor salivary gland biopsy, 12 of them with positive results. Prior to the diagnosis of RA, 78% of the patients presented with arthralgia and arthritis, 12 had RF + and in 2 of the 14 patients the dose of ACPA was recorded and the result was positive. Prior to the diagnosis of scleroderma, 44% of the patients who developed this disease had raynaud's phenomenon and 22.22% ANA with centromeric pattern, 1 patient with PHT and 3 patients with esophagitis due to reflux. 20% of patients who added SLE also presented raynaud's phenomenon. 1 patient had anticardiolipin +, 100% reported arthralgia and 80% had arthritis.

Conclusion: Of all the patients analyzed, 4.4% developed another connective tissue disease during their follow-up. We consider the importance of recognizing this possibility in order to arrive at an early diagnosis. The presence of certain clinical and serological manifestations could be considered as suggestive of the subsequent development of another autoimmune rheumatic disease.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

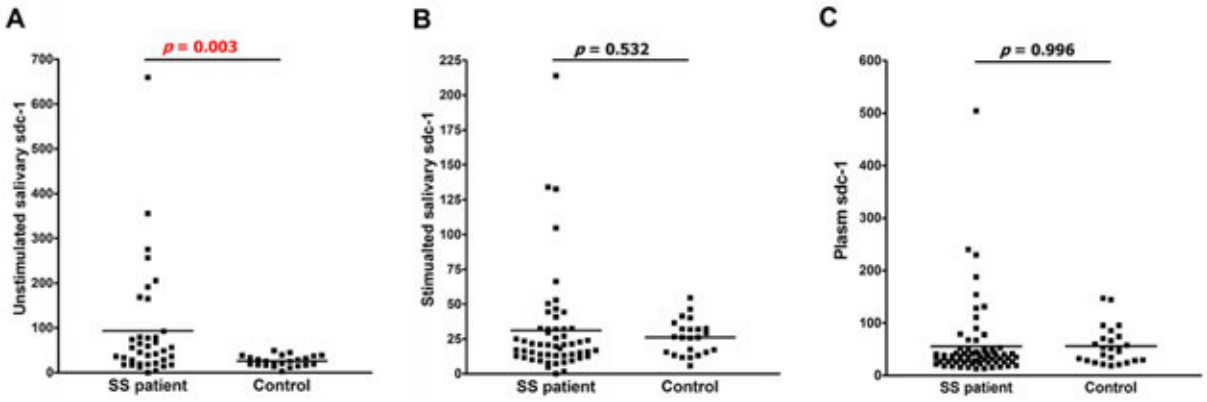

Figure. The levels of syndecan-1 in plasma and unstimulated and stimulated saliva from patients with Sjogren's syndrome and normal controls.

Background/Purpose: Sjögren's syndrome (SS) is known as autoimmune epithelitis, because epithelial cells in the glands are the primary target of disease and play a major role in pathogenesis of SS by mediating the development, maintenance and progression of the local autoimmune inflammatory response. Syndecan-1 (sdc-1), a transmembrane heparin sulfate proteoglycan, is predominantly expressed on epithelial cells and functions as coreceptors through binding to variant ligands. Furthermore, sdc-1 functions as soluble HSPG that can function as paracrine or autocrine effectors, or competitive inhibitors by ectodomain shedding. However, the expression and clinical significance of sdc-1 in patients with SS remain unclear. In this study, we investigated the expression of sdc-1 in minor salivary glands and association of syndecan-1 levels in plasma and saliva with disease activity and glandular functional parameters in SS patients.

Methods: We measured the levels of sdc-1 in plasma and unstimulated and stimulated saliva by ELISA and assessed the salivary flow rates in 70 SS patients and 26 normal controls. We also performed disease activity indexes, salivary gland scan, serologic markers and minor salivary gland biopsies in SS patients.

Results: Salivary gland tissue sections obtained from patients and normal controls were stained with monoclonal anit-sdc-1 antibody. Sdc-1 was up-regulated in ductal epithelial cells from patients and showed a more intense staining in severe inflamed glandular tissue. In specimen from patients, sdc-1 stain was also detected in infiltrating plasma cells as well as glandular epithelial cells. The mean unstimulated and stimulated salivary flow rates were significantly lower in patients than controls ($p< 0.001$). The levels of unstimulated salivary sdc-1 from patients were significantly higher than those from controls ($p=0.003$) and reversely correlated with unstimulated salivary flow rates ($r=-0.358$, $p=0.032$) and ejection fraction of parotid ($r=-0.363$, $p=0.027$) and submandibular glands ($r=-0.485$, $p=0.002$) on salivary gland scan. The levels of plasma sdc-1 were not different between patients with controls but showed a significant correlation with EULAR's Sjögren's Syndrome Disease Activity Index ($r=0.507$, $p< 0.001$) and EULAR's Sjögren's Syndrome Patient Reported Index ($r=0.267$, $p=0.033$). Minor salivary gland specimens included 68.3% with focus scores of ≥1 per 4mm2. Focus scores of ≥ 2 were significantly associated with higher levels of unstimulated salivary sdc-1, serum anti-Ro positivity and ocular stained scores and lower parotid gland functions on salivary gland scan. Those with higher levels of unstimulated salivary sdc-1 were 12.5 times (95% CI 1.76–88.74) more likely to have a focus score ≥2.

Conclusion: The levels of unstimulated salivary sdc-1 reflected the glandular function and degree of minor salivary gland inflammation. The levels of plasma sdc-1 showed a significant correlation with disease activity indexes in SS patients. These results suggested that the levels of unstimulated salivary and plasma sdc-1 are potential biomarkers for salivary glandular function and disease activity, respectively, in SS patients.

Factors Influencing the ESSPRI Index in Primary Sjögren's Syndrome

Maria Graciela Sandoval-Flores,[1] Isela Chan-Campos,[2] and Gabriela Hernandez-Molina[2], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Ciudad de México, Distrito Federal, Mexico, [2]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Sjögren's Syndrome – Basic & Clinical Science Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The ESSPRI is a validated index for measuring symptoms (pain, fatigue and dryness) in primary Sjögren's syndrome (pSS). Herein we evaluated its association with disease and non-disease related variables, and its variation though the follow-up.

Methods: We included consecutive patients with pSS according to the ACR/EULAR classification criteria who attended a referral tertiary center during 2016-2018. We excluded patients with another connective disease. A single rheumatologist interviewed the patients and registered the following variables: demographics, scholarship, smoking, menopause, body mass index, disease duration, comorbidities such as diabetes mellitus, hypothyroidism, depression, and fibromyalgia as well as the Charlson comorbidity index. We also asked about the current use of hormonal replacement, diuretics, anticholinergics antihistamines, prednisone and immunosuppressors. We evaluated the non-stimulated whole salivary flow (NSWSF), Schirmer-I test, and scored the ESSDAI and the ESSPRI. In addition, in a subset of patients, we scored a second ESSPRI during a follow-up time within 6-36 months. We used descriptive statistics, X2 test, T student test, Mann–Whitney U test and Wilcoxon signed-rank test as appropriated. We used logistic regression analysis reporting OR and 95% CI. A two-tailed $P< 0.05$ was considered statistically significant. All analyses were performed using the SPSS.

Results: We included 130 patients, most of them were women (98.4%), mean age 57 years±13.4 and median disease duration of 9.3 years. Ocular and oral symptoms were present in 93.8% and 88.4%, respectively. The median ESSPRI score was 6, being the median score 6 for fatigue, 4 for pain and 8 for dryness. Eighty patients (61.5%) had an ESSPRI score >5 points. When we compared this group vs. the group with an ESSPRI ≤5 (n=50), the first group had a higher frequency of fibromyalgia (12.5% vs. 2%, p=0.05) and depression (30% vs. 10%, p=0.008) as well as a lower NSWSF (0.2 ml/15 min vs. 1.1 ml/15 min, p=0.05). We did not observe differences among the rest of the variables. At the logistic regression analysis, the variables that remained associated were depression (OR 3.7, 95% CI 1.23-11.3, p=0.02) and NSWSF (OR 0.59, 95% CI 0.36-0.97, p=0.03).

In 62 patients, we performed a second ESSPRI assessment after a median time of 25 months (6-41). Now, the median ESSPRI score was 5.1, being the median score 5 for fatigue, 4 for pain and 6 for dryness. When we compared the basal and the follow up ESSPRI results, we found a statistically difference between the overall ESSPRI score (p=0.01), the fatigue (p=0.02) and dryness (p=0.004) domains, but not for pain. Among the patients with a second ESSPRI score, 44 (70%) patients increased their ESSPRI in ≥1 points. None of the studied variables were associated with this change in the ESSPRI.

Conclusion: We observed that the ESSPRI was associated with low NSWSF, but also with non-disease related variables such as depression. Most of the patients experienced a variation of this score though the follow- up, nevertheless the variables that might influence its change remains to be elucidated.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

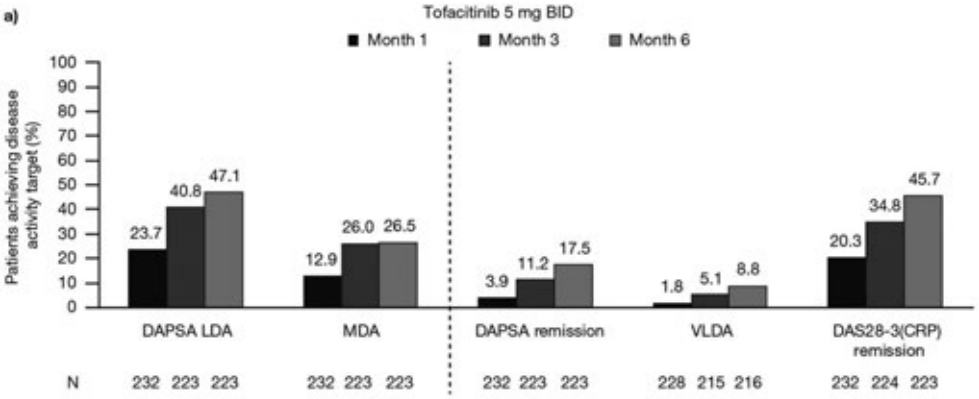
Session Time: 9:00AM–11:00AM

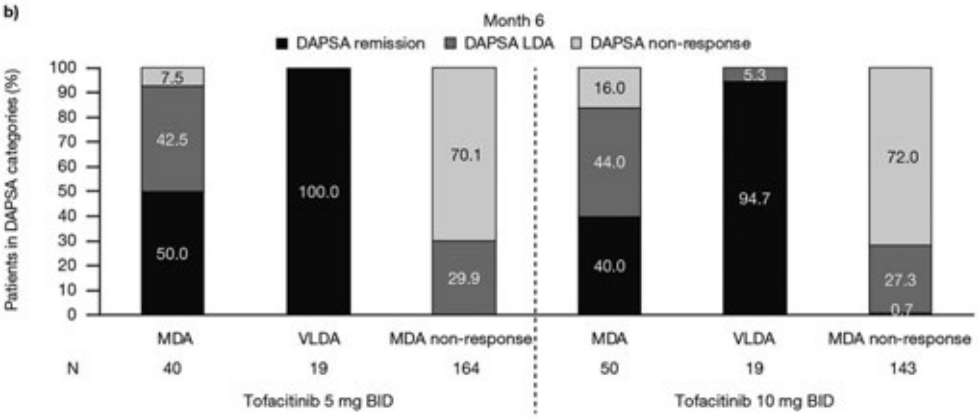
Background/Purpose: An international task force has agreed that remission or low disease activity (LDA) are key treatment targets for patients (pts) with PsA, and recommends the Disease Activity Index in Psoriatic Arthritis (DAPSA) or minimal disease activity (MDA) to assess respective disease activity states.[1] Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. In this post hoc analysis, we compared DAPSA LDA with MDA, and DAPSA remission with very low disease activity (VLDA) and DAS28-3(CRP) remission, in pts with PsA receiving tofacitinib.

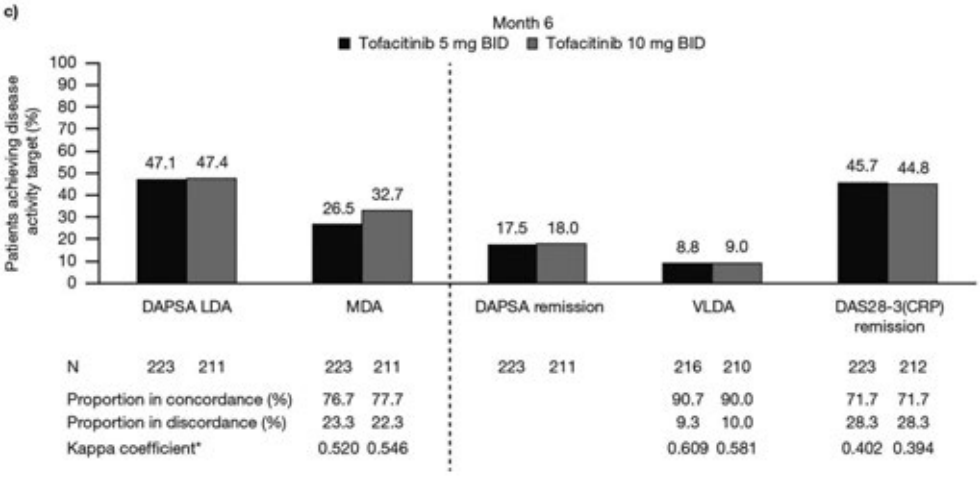
Methods: Data were pooled from 2 Phase 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]) for pts receiving tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO). DAPSA was determined by summing: swollen joint count (SJC66); tender joint count (TJC68); Patient's Global Assessment of Arthritis (PtGA; visual analog scale [VAS]); pain (VAS); and CRP. Pts were classified as achieving MDA or VLDA when meeting ≥ 5 (MDA) or 7 (VLDA) of the following criteria: TJC68 ≤ 1; SJC66 ≤ 1; Psoriasis Activity and Severity Index ≤ 1 or body surface area ≤ 3%; pain (VAS) ≤ 15; PtGA (VAS) ≤ 20; HAQ-DI ≤ 0.5; tender entheseal points (using Leeds Enthesitis Index) ≤ 1. A logistic regression model was used to assess demographic and baseline characteristics as predictors of a trend in DAPSA scores at Month (M)3. DAPSA LDA (≤ 14), MDA, DAPSA remission (DAPSA ≤ 4), VLDA, and DAS28-3(CRP) remission (DAS28-3[CRP] < 2.6) rates were compared at M1, M3, and M6 for pts receiving tofacitinib 5 mg BID, and at M6 for pts receiving tofacitinib 5 or 10 mg BID. Agreement between disease activity indices at M6 was evaluated using a kappa test. The percentage of tofacitinib-treated pts who achieved MDA, VLDA, and non-response was reported at M6 stratified by achievement of DAPSA LDA, remission, or non-response.

Results: This analysis included 709 pts: tofacitinib 5 mg BID, n=237; tofacitinib 10 mg BID, n=236; PBO, n=236. Older pts treated with tofacitinib, and pts with higher baseline PsA activity and HAQ-DI treated with tofacitinib or PBO were significantly ($p < 0.05$) more likely to have a worse DAPSA response at M3; Hispanic/Latino pts treated with tofacitinib or PBO were significantly more likely to have a better DAPSA response at M3 than pts of other ethnicities (Table 1). DAPSA LDA, MDA, remission (DAPSA and DAS28-3[CRP]), and VLDA rates generally increased from M1

Figure 1. Percentage of patients receiving a) tofacitinib 5 mg BID achieving DAPSA LDA, MDA, DAPSA remission, VLDA, or DAS28-3(CRP) remission at Month 1, 3, or 6; b) tofacitinib 5 or 10 mg BID achieving MDA or VLDA, by DAPSA categories at Month 6; c) tofacitinib 5 or 10 mg BID achieving DAPSA LDA, MDA, DAPSA remission, VLDA, or DAS28-3(CRP) remission at Month 6







*Kappa test of agreement between: DAPSA LDA and MDA; DAPSA remission and VLDA or DAS28-3(CRP) remission
BID, twice daily; DAPSA; Disease Activity Index for Psoriatic Arthritis; DAS28-3(CRP), Disease Activity Score in 28 joints, CRP; LDA, low disease activity; MDA, minimal disease activity; N, number of evaluable patients; VLDA, very low disease activity

Table 1. Demographics and baseline disease characteristics as predictors of a trend in DAPSA scores at Month 3, in patients treated with tofacitinib or PBO

		Remission (DAPSA ≤4)	Low disease activity (4< DAPSA ≤14)	Moderate disease activity (14< DAPSA ≤28)	High disease activity (DAPSA >28)	p value[a]

Pain (VAS), mean (SD)	All tofacitinib	52.5 (24.5)	51.9 (24.0)	56.4 (22.5)	63.1 (20.5)	0.0004
	PBO	40.1 (24.9)	41.5 (23.6)	52.8 (23.7)	60.4 (22.6)	0.0001

[a]p value for trend in baseline parameter across Month 3 DAPSA categories, from an ordered logistic regression model of Month 3 DAPSA categories with baseline parameter as predictor
BMI, body mass index; DAPSA, Disease Activity Index for Psoriatic Arthritis; HAQ-DI, HAQ-Disability Index; LEI, Leeds Enthesitis Index; N, number of patients in DAPSA category; n, number of patients; PBO, placebo; PtGA, Patient's Global Assessment of Arthritis; SD, standard deviation; SJC, swollen joint count; TJC, tender joint count; VAS, visual analog scale

to M6 (Figure 1a). At M6, most tofacitinib-treated pts who achieved MDA, and all who achieved VLDA, were also in DAPSA remission or LDA (Figure 1b). Moderate agreement (defined by kappa values 0.41–0.60) was observed between DAPSA LDA and MDA, and between DAPSA remission and VLDA (Figure 1c).

Conclusion: Remission and LDA rates generally increased over time in pts with PsA receiving tofacitinib. DAPSA LDA showed moderate agreement with MDA, and DAPSA remission showed moderate agreement with VLDA, confirming that DAPSA is a useful measurement tool to assess disease activity in pts with PsA treated with tofacitinib.

Abstract Number: 1476

Impact of Alternate Mechanism of Action Biologics and Tofacitinib on TNF-α Inhibitor Prescribing in Psoriatic Arthritis: Results from Annual National Patient Chart Audits

Lynn Price,[1] Phil Pouliot,[1] and Lauren Schmitt[1], [1]Spherix Global Insights, Exton, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: TNF-α inhibitor therapy has long been the standard of care for adult patients diagnosed with moderate to severe psoriatic arthritis (PsA), though several new biologics and small molecules have recently received FDA approval for the treatment of PsA. This research sought to understand the extent to which biologics and small molecules with a different mechanism of action (MOA) have been adopted for the treatment of PsA and their impact on the use of well-established TNFs.

Methods: An independent market analytics firm collaborated with US rheumatologists (n=192) to conduct a retrospective chart review of patients diagnosed with psoriatic arthritis (PsA) (n=994), who had switched from one biologic therapy or apremilast to another in the prior twelve weeks. Rheumatologists were able to submit up to seven PsA patient charts. Data were collected in March 2019 and included clinical and non-clinical patient demographics, as well as physician demographics and attitudinal survey responses. This study was a non-longitudinal trending analysis to 2016, 2017, and 2018 audits following the same methodology.

Results: 83% of rheumatologists reported recent changes to the management of their PsA patients and the two most commonly recalled treatment shifts were: more aggressive/earlier use of biologics in general and increased use of non-TNF agents for the treatment of PsA. Despite increased PsA treatment options, annual reported rates of PsA patient switching have remained stable since 2016, with rheumatologists reporting approximately one-quarter of biologic/apremilast-treated patients switch brands within a given year. Audited switches between TNF agents have significantly and consecutively decreased year-over-year: in 2016, consecutive TNF cycling accounted for 52% of audited patients, a figure that has declined with each audit and is presently just 35%. Conversely, switches from a TNF to an alternative MOA agent have significantly increased during the same period from 13% to 30%, respectively. The growth in the switching share of alternative MOAs is driven primarily by increased use of the IL-17 inhibitors, secukinumab and ixekizumab, as well as the oral JAK inhibitor, tofacitinib.

Conclusion: Increased biologic and small molecule options for the treatment of PsA has resulted in US rheumatologists switching fewer patients to a TNF in second- or later-lines of therapy, and a notable and significant decline in the practice of TNF cycling. Though TNF inhibitors remain the predominant MOA for the treatment of PsA, the introduction of secukinumab, ixekizumab, and tofacitinib have had a direct impact on the PsA switching environment, and in particular, use of the TNF class.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rheumatic diseases are associated with pain, loss of functionality, fatigue, hospitalization, sick leave, and work disability. This results in high economic burden for patients and society.Golimumab (GLM) is an effective but costly treatment option for patients with moderate to severe, active rheumatic diseases.

The aim of this analysis of the GO-NICE study was to investigate the direct and indirect costs of healthcare utilization and sick leave after starting a treatment with GLM.

Methods: Data from outpatients collected in the non-observational study GO-NICE in 1,483 patients with RA (n = 474), PsA (n=501), and AS (n=483) in 158 sites (2010-2015) in Germany were analysed. Details on the study design, patient characteristics, clinical and patient-reported outcomes, and safety data have been reported earlier [1,2].

Table: Costs per patient and year (Subgroup patients with RA)

	RA biologic-naïve (n=265)			RA with biologics as pre-treatment (n=208)		
	Baseline	Month 24	Changes	Baseline	Month 24	Changes
Consultation fees / €	354	168	- 186	369	178	- 191
Physiotherapy, massages etc. / €	162	59	- 103	144	91	- 53
Hospitalisation / €	939	99	- 840	1,163	423	- 740
Rehabilitation measures / € (in- and outpatients)	163	55	- 109	148	0	- 148
Direct med. costs / € (excl. medication)	1,618	381	- 1,237	1,823	692	- 1,131
Comedication / €	498	417	- 81	417	414	- 3
Biologicals / €	0	19,082	+ 19,082	21,673	19,082	- 2,591
Medication / €	498	19,498	+ 19,000	22,091	19,496	- 2,595
Absenteeism / €	2,991	892	- 2,099	3,028	464	- 2,564
Total / €	5,107	20,771	+ 15,664	26,942	20,653	- 6,289

Direct medical and indirect costs per patient and year were calculated for consultations, physiotherapy, massages, hospitalisations and inpatient rehabilitation, medication (DMARDs, Glucocorticoids, NSAIDs, and biologics) as well as sick leave days. Findings were shown for RA-, PsA- and AS-patients and categorised by biologic-naïve patients and patients previously treated with a biologic argent. The 6-month periods prior baseline (BL) / start of a GLM therapy vs. month 24 (M24) were compared.

For this calculation standardized evaluation rates were used (Bock et al. (2015), AG MEG of the DGSMP (2005). Costs for prescribed and documented medication were calculated by the mean cost per defined daily dose (based 2010-2015). Indirect costs were estimated through the human capital approach (HCA).

Results: Data from 758 biologic-naïve patients (n = 265 RA, 247 PsA and 246 AS) and 694 patients with biologics as pre-therapy (n = 208 RA, 252 PsA and 234 AS) were included in the analysis.

Direct medical costs (excluding medication) decreased in all 6 groups, min. 765€ (PsA pre-treatment group) and max. 2,426€ (AS pre-treatment) as well as the costs due to work disability / absenteeism, min. 855€ (PsA pre-treatment) and max. 2.564€ (RA pre-treatment, table).

Total costs in biological-naïve patients increased due to the additional expense of the biologic agent.

Absolute changes in costs totalled 15,665€ (RA-, table), 15,799€ (PsA-) and 14,764€ (AS-patients) per patient and year when comparing the BL vs. M24 periods.

Total savings of 6,289€ (RA-, table), 2,617€ (PsA-), and 5,555€ (AS-patients) per patient and year were observed in the group of biologic-pre-treated patients.

Conclusion: Costs of healthcare utilization, as well as work disability, decreased after starting GLM within an observation period of 24 months, for patients with RA, PsA, and AS.

Due to the high costs of TNFi therapy, drug costs in the group of biologic-naive patients rose markedly. Savings were observed in the group of patients previously treated with a biologic argent.

Systematic Literature Review and Network Meta-Analysis Comparing Incidence of Uveitis and IBD in Axial Spondyloarthritis Patients Treated with Anti-TNF versus Anti-IL17A in Placebo Controlled Randomized Trials

Damien Roche,[1] Martin Badard,[1] Laurent Boyer,[2] Pierre Lafforgue,[1] and Thao Pham[1], [1]Aix-Marseille University, CHU Marseille, department of Rheumatology, 13,000 Marseille, France, Marseille, France, [2]Aix-Marseille University, EA 3279 Research Unit, 13,000 Marseille, France, Marseille, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Inflammatory bowel diseases (IBD) and anterior uveitis (AU) are frequent extra-articular features of axial spondyloarthritis (axSpA). Although effect of anti-TNF on IBD and AU are well known, data are lacking for anti-IL17A. Our objective was to assess and compare the incidence of IBD and AU in axSpA patients treated with anti-TNF and anti-IL17A.

Methods: A systematic literature review was performed by 2 independent reviewers in 3 databases (PubMed, EMBase and Cochrane) until 2019/04/04 and completed with 2016-18 ACR and EULAR abstracts. We included randomized controlled trials (RCT) assessing anti-TNF (monoclonal antibodies (Mab): adalimumab, certolizumab, golimumab, infliximab, and soluble receptor fusion protein: etanercept (ETN)) or anti-IL17A (ixekizumab, secukinumab) versus placebo or another biologic in axSpA according to ASAS criteria and reporting safety data on IBD or UA. History of IBD or AU was not an exclusion criterion in these RCTs, although recent onset or active IBD/AU was. The risk of bias in included RCTs was evaluated according to the Cochrane risk of bias tool. Data from these studies was used to perform a network meta-analysis to assess incidence of IBD and UA under each treatment, using the Mantel-Haenszel method relevant for rare events (netmeta R Package).

Results: Out of initially 725 studies, 31 were included for analysis, provided a total of 3888 treated patients (anti-TNF MAb: 2011, ETN: 699, anti-IL17A: 1178) and 2207 placebo-receiving axSpA patients. The mean study duration was 20.8 weeks ± 17.4 (SD), median: 16 weeks. Incidence of AU was 1.09%, 2.14%, 3.53%, 3.26% per year in anti-TNF MAb, ETN, anti-IL17A and placebo groups, respectively. Incidence of IBD was 0.22%, 1.28%, 2.17%, 0.48% per year in anti-TNF MAb, ETN, anti-IL17A and placebo groups, respectively.

Incidence of UA was reduced with anti-TNF MAb compared to anti-IL17A (OR = 7.59; IC95% 1.37-42.09) and placebo (OR = 2.32; IC95% 1.01-5.36) (Figure 1). There was no statistical difference between anti-TNF MAb and ETN. There was no statistical difference in IBD incidence between anti-TNF MAb, ETN, anti-IL17A and placebo (Figure 2). No evidence of inconsistency was found in this network model.

Conclusion: In RCT assessing anti-TNF and anti-IL17A in axSpA, incident AU or IBD are rare events. However, this network meta-analysis demonstrate that anti-IL17A are associated with a higher incidence of AU compared to placebo and anti-TNF, while there was no statistical difference between treatments concerning IBD incidence.

Multi-Symptom Impact on the EQ5D Index in Bio-naïve Active Psoriatic Arthritis Patients: An Analysis Through Week 24 of the GO-VIBRANT Study

Alexis Ogdie,[1] Nan Li,[2] Steve Peterson,[2] Chetan Karyekar,[2] Soumya Chakravarty,[3] Shelly Kafka,[4] and Jessica Walsh[5], [1]Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA, [2]Janssen Global Services, LLC, Horsham, PA, [3]Janssen Scientific Affairs, LLC; Drexel University College of Medicine, Horsham; Philadelphia, PA, [4]Janssen Scientific Affairs, LLC, Horsham, PA, [5]Division of Rheumatology, University of Utah, Salt Lake City, UT

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease characterized by peripheral arthritis, axial inflammation, dactylitis, enthesitis and skin and nail psoriasis. The impact of skin and joint components of the disease on patient health-related quality of life (HRQoL) has been described in previous research but the impact of other major clinical manifestations has not been similarly characterized. This analysis quantified the impact of the major clinical manifestations of PsA on patient reported HRQoL, as estimated by disease state preference (utility) derived from the EQ-5D index in a randomized clinical trial.

Methods: This analysis used data from a multicenter, randomized, double-blind, placebo-controlled trial of intravenous (IV) Golimumab in biologic naïve patients with active PsA (GO-VIBRANT study). Patient baseline characteristics of the GO-VIBRANT study population have been previously described (1). Core outcome measures recommended by OMERACT (Outcome Measures in Rheumatology Clinical Trials) and guideline on utility mapping by ISPOR (International Society for Pharmacoeconomics and Outcome Research) were used to guide initial attribute selection. Utility was derived from patient responses to the EQ-5D index, which assesses mobility, self-care, usual activities, pain/discomfort, and anxiety/depression, and was completed at weeks 0, 8, 14, and 24 in the trial (placebo-controlled period). EQ5D index is used as a measure of overall health and is an outcome commonly used in health economic analyses. Multivariate analysis was performed using a Mixed-Effect Repeated Measures model based on observed data until week 24 in pooled patient population.

Results: Based on univariate analyses and evaluation of collinearity between variables, the following attributes were included in the multivariate models: age, gender, region, PsA disease duration, PASI score, enthesitis, dactylitis, tender joint count (TJC), swollen joint count (SJC), C-reactive protein (CRP mg/L) and Health Assessment Questionnaire-Disability Index (HAQ-DI). In the final model, PASI score (β=-0.00126, p=0.0006), enthesitis (β=-0.01237, p=0.03), TJC (β=-0.00112, p< 0.0001), CRP (β=-0.00079, p< 0.0001) and HAQ-DI (β=-0.1664, p< 0.0001) were all statistically significantly associated with the EQ-5D index. A sensitivity analysis among a subgroup of patients who had spondylitis with peripheral joint arthritis as their primary arthritic presentation of PsA showed that spinal pain (β=0.0101, p< 0.0001), as measured by question #2 of the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), was also statistically significantly associated with the EQ-5D index in the multivariate model.

Conclusion: Multiple PsA clinical manifestations including psoriasis, enthesitis, TJC, spinal pain, CRP, and physical function were statistically significantly associated with utility among PsA patients as derived from the EQ-5D index. These findings indicate that consideration of multiple clinical manifestations of PsA is warranted when evaluating the impact of PsA on patients.

Clinical Characteristics and Treatment Profiles of Patients with Ankylosing Spondylitis Who Initiated Secukinumab and Other Biologics: Results from the Corrona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) Registry

Alexis Ogdie,[1] Mei Liu,[2] Sabrina Rebello,[2] Meghan Glynn,[3] Blessing Dube,[2] Robert McLean,[3] Esther Yi,[4] Yujin Park,[5] and Philip Mease[6], [1]Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, [2]Corrona, LLC, Waltham, MA, [3]Corrona, LLC, Waltham, [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ, [5]Novartis Pharmaceuticals Corporation, East Hanover, [6]Swedish Medical Center/Providence St Joseph Health, and University of Washington, Seattle, WA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab is the only non–tumor necrosis factor inhibitor biologic therapy approved for the treatment of ankylosing spondylitis (AS) in the United States. Patients with AS in clinical trials who receive biologics, including secukinumab, may not be representative of those treated in real-world clinical practice due to differences in patient characteristics, practice patterns, physician experience, and insurance coverage (ie, access). Few real-world studies have characterized patients with AS who initiate secukinumab. The Corrona PsA/SpA Registry collects data on a robust list of outcome measures, many of which overlap with those used in clinical trials. We aim to describe the characteristics of patients who initiated secukinumab and other biologics for the treatment of AS in the Corrona PsA/SpA Registry.

Methods: This study included patients aged ≥ 18 years with AS (and without concurrent PsA diagnosis) enrolled in the Corrona PsA/SpA Registry who initiated secukinumab or other biologics (adalimumab, etanercept, certolizumab pegol, infliximab, and golimumab) between April 2017 and December 2018. Patient demographics, clinical characteristics, treatment profiles, disease activity, quality of life, and work productivity were assessed at the time of biologic initiation (baseline) and compared between patients who initiated secukinumab and other biologics using *t* tests or Wilcoxon rank-sum tests for continuous variables and χ^2 or Fisher exact tests for categorical variables.

Results: Of the 106 patients with AS who initiated a biologic, 26 (24.5%) initiated secukinumab and 80 (75.5%) initiated other biologics. Secukinumab initiators were similar to patients who initiated other biologics in terms of demographics and clinical characteristics except that a higher proportion of secukinumab initiators had a history of prior biologic use

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Apremilast (APR), an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in adult patients with active PsA despite prior use of csDMARDs and/or biologics in phase III studies of PsA (Kavanaugh. *Ann Rheum Dis*. 2014; Cutolo. *J Rheumatol*. 2016; Edwards. *Ann Rheum Dis*. 2016). Although APR has been studied in combination with csDMARDs, APR in combination with biologic therapies has not been studied. The objective of this analysis was to understand the characteristics at treatment initiation of US patients with PsA in the real-world setting who are prescribed APR + biologic therapy and to compare them with patients treated with biologic monotherapy and patients treated with biologic therapy + csDMARDs.

Methods: Adult patients diagnosed with PsA and enrolled in the Corrona PsA/Spondyloarthritis Registry who received APR + biologic therapy, biologic monotherapy, or biologic therapy + csDMARDs for PsA from March 2013 to March 2019 were included. For biologic monotherapy, the index date was defined as the date of the treatment initiation visit. For combination therapy, the index date was defined as the date of the treatment initiation visit for the second/add-on drug. Patient demographics, clinical/treatment characteristics, disease activity, and physician- and patient-reported outcomes at the index date were summarized using descriptive statistics for continuous (mean [SD], median [interquartile range]) and categorical (n [%]) variables.

Results: In all, 961 patients were included in the analysis (APR + biologic: n=93; biologic monotherapy: n=405; biologic therapy + csDMARDs: n=463). Mean age was generally comparable across groups (**Table 1**). A greater proportion of females were treated with APR + biologic vs biologic monotherapy and biologic + csDMARDs (**Table 1**). Comorbidity history was generally similar among the groups, but the proportion of patients with depression and diabetes was numer-

Table 1. Patient Demographics and Comorbidity Profile at the Index Date

Characteristic	APR + Biologic Therapy Total n=93	Biologic Monotherapy Total n=405	Biologic Therapy + csDMARD Total n=463

High	18 (20.7)	75 (19.6)	83 (19.4)

The n represents the total sample; number of patients with data available may vary.

cDAPSA=Clinical Disease Activity in Psoriatic Arthritis; DAS28=28-item Disease Activity Score; HAQ-DI=Health Assessment Questionnaire-Disability Index; MDA=minimal disease activity; SJC=swollen joint count; SPARCC=Spondyloarthritis Research Consortium Canada; TJC=tender joint count; VAS=visual analog scale.

ically greater in the APR + biologic group and the proportion of patients with hypertension was numerically greater in the biologic + csDMARD group vs the other groups. The proportion of patients with comorbid psoriasis and nail psoriasis was highest in the biologic monotherapy group (**Table 1**). Mean duration of PsA was comparable across groups (**Table 2**). The majority (90.3%) of the APR + biologic group had received prior biologic therapy (**Table 2**). Disease activity was generally similar among groups based on mean cDAPSA score, proportion of patients in DAS28 remission, mean SJC (0-66) and TJC (0-68), presence of enthesitis and dactylitis, SPARCC enthesitis score, and mean dactylitis count, although fewer patients in the APR + biologic group had minimal disease activity (MDA) vs the other groups (**Table 2**). Mean PhGA and PtGA, as well as HAQ-DI, and pain VAS scores were similar among groups.

Conclusion: The majority of US patients who received APR + biologic were previously exposed to biologics. Patients initiating APR + biologic had similar characteristics vs those initiating biologic monotherapy and biologic + csDMARDs; however, fewer were in MDA at the time of initiation of the second/add-on drug. This suggests a greater use of APR + biologic combination in patients who previously were unable to achieve MDA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis can be a debilitating spondyloarthritis (SpA) manifestation and the cause of pain, reduced quality of life and impaired physical function.[1,2] Herein, we evaluated the effect of secukinumab on axial and peripheral enthesitis in ankylosing spondylitis (AS) patients with baseline enthesitis (BLE) across all Maastricht AS EnthesiS (MASES) sites (N=13), axial sites [N=11; 13 MASES minus Achilles tendons (AT); AxS] and peripheral sites (N=6; AT + lateral condyles of humerus/femur; PS) and the AT (N=2) at Weeks 16 and 52.

Methods: This post hoc analysis pooled data across 4 secukinumab studies in AS (MEASURE 1-4) from patients originally randomized to secukinumab 150mg (approved dose in AS), 300mg (MEASURE 3 only), or placebo (PBO) with BLE (MASES >0). Study designs have been reported previously.[3-5] Evaluations include mean change from BL in MASES, complete resolution (CR; MASES=0) and improvement from BL in MASES score of ≥5 counts. Mixed-effect model repeat measurement (MMRM) analysis was done on change from BL in MASES score and non-responder imputation for resolution of enthesitis at Week 16; data are reported as observed at Week 52.

Table. Summary of results

	Secukinumab 150mg N=355		Secukinumab 300mg N=58		PBO N=280
	Week 16	Week 52[o]	Week 16	Week 52[o]	Week 16
LS mean change from BL in MASES score*					
Overall MASES[a]	-2.4‡	-3.5	-2.9§	-3.9	-1.9
AxS[b]	-2.3‡	-3.2	-2.9§	-3.6	-1.8
PS[c]	-1.3	-1.9	-1.6	-2.1	-1.2
AT[d]	-1.0	-1.2	-1.0	-1.3	-0.8
Complete resolution of enthesitis (MASES=0)#, %					
Overall MASES[a]	40.8§	56.4	36.2	52.9	28.9
AxS[b]	42.7§	58.6	42.1	60.0	30.1
PS[c]	46.3	65.5	52.5	69.7	38.3
AT[d]	57.0	78.4	55.0	77.8	48.0
Improvement from BL in MASES score (≥5 counts)#, %					
Overall MASES[a]	23.7	34.1	27.6	43.1	16.1
AxS[b]	20.1	28.0	22.8	32.0	15.4

§P <0.01; ‡P <0.05 vs PBO. *P-values from repeated MMRM until Week 16. #P-values from logistic regression model. Secukinumab 150mg (n=[a]355, [b]344, [c]229, [d]128); 300mg (n=[a]58, [b]57, [c]40, [d]20) and PBO (n=[a]280, [b]272, [c]188, [d]98). [o]Observed data. N, number of patients analysed; n, number of patients with measurement; AT, Achilles tendon site; AxS, axial entheseal site; BL, baseline; LS, least squares; MASES, Maastricht Ankylosing Spondylitis Enthesis; PS, peripheral site; PBO, placebo

Results: A total of 355 (70.4%), 58 (76.3%), and 280 (72%) patients had BLE in 150mg, 300mg and PBO groups, respectively. BL characteristics were generally comparable across groups. At Week 16, mean change from BL for overall MASES and AxS was greater for secukinumab 150mg (-2.4 and -2.3; both $p< 0.05$) and 300mg (-2.9 and -2.9; both $p< 0.01$) vs PBO (-1.9 and -1.8). At Week 16, patients treated with secukinumab 150mg (40.8% and 42.7%) and 300mg (36.2% and 42.1%) vs PBO (28.9% and 30.1%) achieved CR of enthesitis based on overall MASES and at AxS, respectively. A higher proportion of patients treated with secukinumab 150/300mg vs PBO achieved a higher threshold of improvement (≥5 counts) in overall MASES at Week 16. Further improvements were observed for all endpoints at Week 52 (Table).

Conclusion: Secukinumab 150mg and 300mg were associated with higher mean change in MASES and complete resolution of enthesitis at overall MASES and axial sites compared to placebo in AS patients at Week 16, which further increased through Week 52.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is associated with obesity and increased cardiometabolic risk. Weight loss has been noted in association with the phosphodiesterase 4 (PDE4) inhibitor apremilast. Studies also suggest a potential role for PDE4 in glucose metabolism. We aimed to investigate the effects of PDE4 inhibition with apremilast on metabolic and vascular status in PsA.

Methods: The Immune Metabolic Associations in Psoriatic Arthritis (IMAPA) study was a prospective, open label study of adults receiving apremilast as part of routine care for PsA and/or psoriasis. Cardiometabolic, anthropometric, and disease activity assessments were performed at baseline, months 1, 3, and 6 of apremilast treatment in 60 patients. A subgroup underwent endothelial function assessment by Endo-PAT (n=38) and MRI of abdominal fat distribution (n=25) at baseline and 3 months of apremilast treatment. The primary endpoints were change in body weight and glucose homeostasis parameters after 3 months of PDE4 inhibition with apremilast. Secondary outcomes included change in lipid profile, blood pressure, endothelial function, visceral, subcutaneous, and liver fat percentage on MRI. Repeated measures mixed models were used to compare mean changes in outcomes.

Results: 60 participants were recruited; median age (IQR) 55 (43, 62) years, 63% female, median disease duration (IQR) 8.0 (2.0, 12.2) years. To date, outcome data available for n=59 at baseline, n=54 month 1, n=49 month 3, and n=43 month 6. Results are summarised in table 1. Mean weight loss after 3 and 6 months apremilast treatment was -1.4kg (95% CI -2.1, -0.6, p=0.001) and -2.2kg (95% CI -3.1, -1.4, p< 0.001), respectively. >5% weight loss was achieved in 6.1% (3/49) and 21.4% (9/42) after 3 and 6 months treatment, respectively. There was no statistically significant change in HbA1c, fasting, 1 hour and 2 hour glucose and insulin concentrations, Homeostatic Model Assessment for Insulin Resistance (HOMA-IR), and area under the OGTT curve for glucose or insulin after 3 months treatment. Small reductions in total cholesterol, HDL-C, and LDL-C were seen at 3 months. Mean systolic BP decreased by 4.7mmHg after 6 months, however this was no longer statistically significant after excluding antihypertensive use. There was no statistically significant change in Reactive Hyperemia Index (RHI). Median liver fat fraction was 8.12% (IQR 4.00-13.89) at baseline. There was a modest reduction in abdominal subcutaneous adipose tissue (ASAT), with no change in visceral adipose tissue or liver fat fraction after 3 months treatment. Statistically significant improvements in 66/68 joint count, DAS28-ESR, PtGA, PGA, pain-VAS, LEI, and PASI were seen at month 6. These were independent of weight changes.

Conclusion: Apremilast was associated with modest weight loss and reduced disease activity over 6 months. There was no statistically significant change in glucose parameters or endothelial function, although there was minimal gly-

caemic and vascular dysfunction at baseline. Apremilast was associated with reduced total cholesterol, LDL-C, and HDL-C and modest reductions in ASAT at 3 months. Improvements in disease activity with apremilast appear largely independent of weight change in this cohort.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

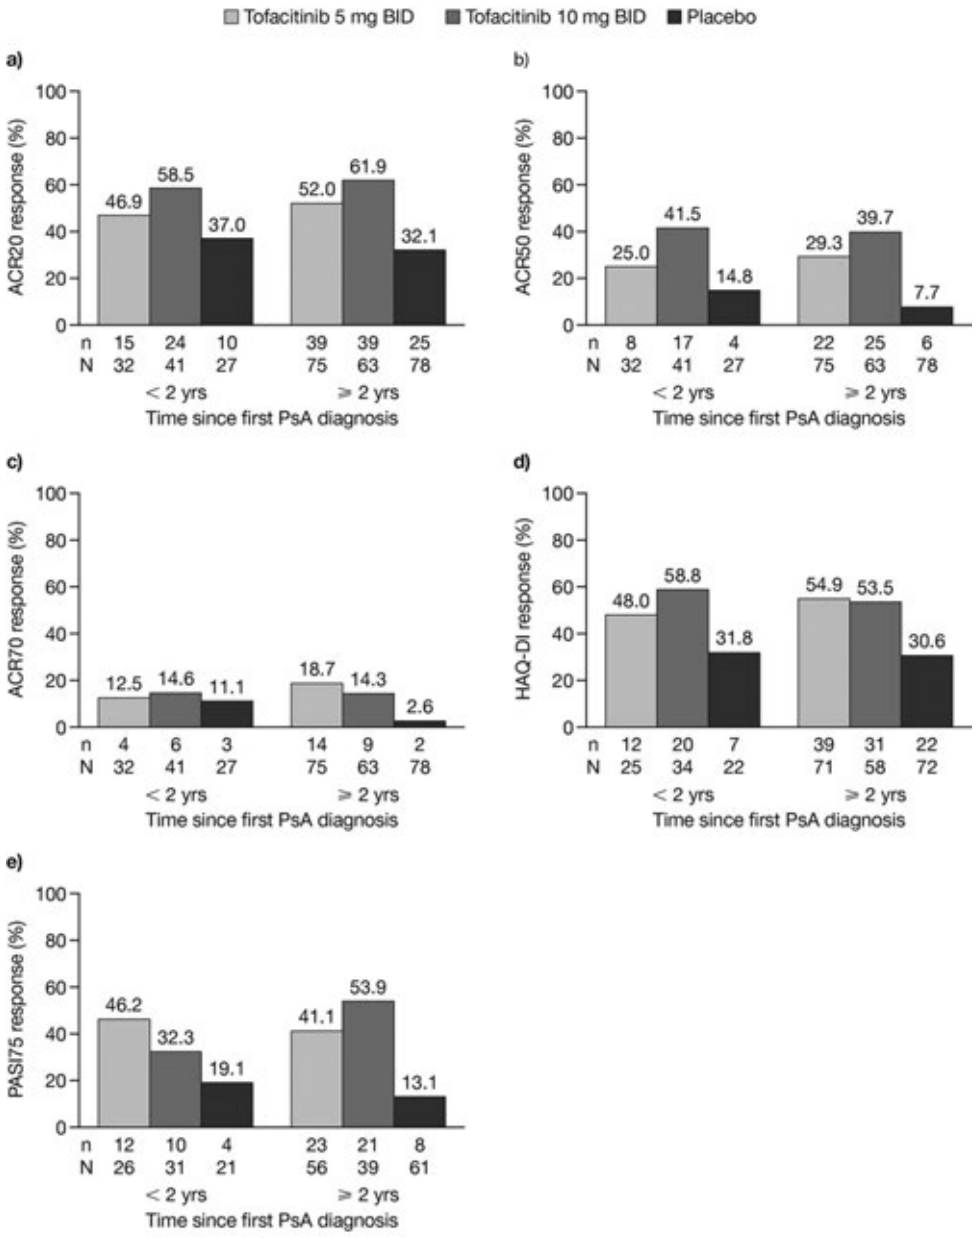
Background/Purpose: Early identification, diagnosis, and treatment of psoriatic arthritis (PsA) is important in preventing long-term joint damage and disability, and the associated socioeconomic consequences.[1] Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. Here, we assessed the efficacy and safety of tofacitinib in patients (pts) with PsA, stratified by time since first PsA diagnosis.

Methods: In this 12-month, randomized, placebo (PBO)-controlled, Phase 3 study (OPAL Broaden [NCT01877668]),[2] pts received tofacitinib 5 or 10 mg twice daily or PBO. Pts had active PsA and an inadequate response to ≥ 1 conventional synthetic DMARD. Pts were stratified by time since first PsA diagnosis: < 2 yrs and ≥ 2 yrs. Efficacy outcomes included response rates at Month (M)3 for ACR20/50/70, HAQ-DI, and Psoriasis Area and Severity Index (PASI)75. Safety outcomes up to M3 were also assessed.

Results: This analysis included 316 pts; 100 pts in the < 2 yrs group, and 216 in the ≥ 2 yrs group. Baseline demographics and characteristics were generally similar between treatment groups and across stratification groups; however, pts in the ≥ 2 yrs group were older (mean age: 49.6 yrs vs 44.6 yrs in the < 2 yrs group). Mean disease duration was 1.0 yrs (min–max: 0.3–1.8 yrs) for the < 2 yrs group, and 8.8 yrs (min–max: 2.0–39.0 yrs) for the ≥ 2 yrs group. At M3, the response rates for ACR20/50/70, HAQ-DI, and PASI75 were greater in tofacitinib-treated pts, compared with PBO-treated pts for both the < 2 yrs and the ≥ 2 yrs group (Figure 1). Across the efficacy outcomes, the response rates for tofacitinib-treated pts in the < 2 yrs group were similar to the ≥ 2 yrs group; however, for pts treated with tofacitinib 10 mg, PASI75 response was lower in the < 2 yrs group. Response rates were higher with PBO in the < 2 yrs group vs the ≥ 2 yrs group. The difference in ACR20 response rates for tofacitinib 5 mg and 10 mg vs PBO was 9.8% and 21.5%, respectively, in the < 2 yrs group; and 20.0% and 29.9%, respectively, in the ≥ 2 yrs group. Adverse events (AEs), serious AEs, discontinuations due to AEs, deaths, and most common AEs are reported in Table 1. There was one case of herpes zoster (tofacitinib 5 mg, < 2 yrs group).

Conclusion: For pts with active PsA, the efficacy of tofacitinib was greater than PBO, irrespective of disease duration; however, PBO response was generally greater in the < 2 yrs group vs ≥ 2 yrs group. Due to the low numbers in the < 2 yrs group and the post hoc nature of this analysis, these results should be interpreted with caution. Safety outcomes were consistent with those previously reported for tofacitinib in pts with PsA.[3]

Figure 1. Percentage of patients with a) ACR20, b) ACR50, c) ACR70, d) HAQ-DI, and e) PASI75 response at Month 3, stratified by time since first PsA diagnosis (< 2 yrs and ⩾ 2 yrs)



ACR20/50/70 are calculated as a ⩾ 20/50/70% improvement from baseline in tender and swollen joint counts, and a ⩾ 20/50/70% improvement from baseline in 3 of the 5 remaining ACR core measures

HAQ-DI response was defined as the number of patients achieving a reduction from baseline ⩾ 0.35 in HAQ-DI in patients with a baseline HAQ-DI ⩾ 0.35

PASI was only performed if ⩾ 3% of subject's BSA is affected at baseline. PASI75 response was defined as a ⩾ 75% reduction from baseline in PASI

ACR, American College of Rheumatology; BID, twice daily; HAQ-DI, Health Assessment Questionnaire-Disability Index; N, number of patients with a non-missing disease duration; n, number of patients in each category; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis

Table 1. Summary of AEs up to Month 3, stratified by time since first PsA diagnosis (< 2 yrs and ≥ 2 yrs)

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Nail psoriasis (PsO) is present in up to 80% in psoriatic arthritis (PsA) patients (pts) and associated with significant pain, psychosocial disability, decreased physical function and quality of life (QoL).[1] Nail PsO is considered as one of the six core PsA domains by GRAPPA[2] and is a predictor of severe disease with joint involvement and structural damage. Secukinumab (SEC) has demonstrated efficacy for pts with nail PsO in the TRANSFIGURE study[3] and improvement in signs and symptoms and low radiographic progression in pts with PsA

*P<0.0001; †P<0.001; §P<0.01; ‡P<0.05 vs. PBO. NRI data for binary and MMRM data for continuous variables presented at Wk 16. Observed data presented at Wk 52.

[1]Mean change from baseline;

[2]% responders (n); [3]Data from pts with BL psoriasis ≥3% BSA: N=75 [300 mg]; 87 [150 mg], 84 [150 mg no LD] and 118 [PBO]; [4]Data from pts with enthesitis/dactylitis at BL: N=98/58 [300 mg]; 88/57 [150 mg], 89/76 [150 mg no LD] and 140/102 [PBO]

ACR 20/50, American College of Rheumatology (ACR) criteria scores of 20 and 50; BL, baseline; LD, load; HAQ-DI, Health assessment questionnaire disability index; mTSS, modified total sharp score; N, number of pts with nail PsO in each group; n, number of evaluable pts; PASI, psoriasis area and severity index; PCS, Physical Component Score; PsAQoL, Psoriatic Arthritis Quality of Life; pts, patients; SF-36, Short Form Health Survey,

in FUTURE 5 (NCT02404350) study[4].Here, we report the efficacy of SEC on nail PsO, and other facets of disease, including radiographic progression, in the nail subset through 52 weeks (wks) from the FUTURE 5 study.

Methods: Pts (N=996) with active PsA, were randomized to subcutaneous SEC 300 mg loading dosage (LD; 300 mg), 150 mg LD (150 mg), 150 mg no LD or placebo (PBO). All groups received SEC or PBO at baseline (BL), Wks 1, 2, 3, and 4, and then every 4 wks. Efficacy assessments through Wk 52 included mNAPSI, radiographic progression (mTSS), ACR, PASI, HAQ-DI, SF-36 PCS, PsAQoL and resolution of dactylitis and enthesitis. Analyses through Wk 16 used non-

responder imputation (NRI) for binary and mixed-effect model repeated measure (MMRM) for continuous variables. Observed data are presented for radiographic progression at Wks 24 and 52, and for all efficacy endpoints at Wk 52.

Results: A total of 663/996 (66.6%) PsA pts had concomitant nail PsO at BL. Demographics and BL disease characteristics were balanced between treatment groups in the nail subset, which were comparable with overall population. The total mean Nail Psoriasis Severity Index (mNAPSI) score at BL was 16.4. SEC 300 and 150 mg doses improved nail PsO vs. placebo (PBO) at Wk 8, 12 and 16 ($P < 0.0001$), with further improvements through Wk 52 (Figure). Mean change from baseline in mTSS score at Wks 24 and 52 are shown in the Table. Proportions of pts with no radiographic progression (change from BL in mTSS ≤0.5) with SEC at 52 Wks were 94.0% (300 mg LD), 83.5% (150 mg LD), and 88.4% (150 mg No LD). ACR20/50 and PASI 90 responses, resolution of dactylitis and enthesitis, physical function and QoL were also improved with SEC vs. PBO at Wk 16 with sustained improvements through 52 wks (Table).

Conclusion: Secukinumab provided sustained improvements in nail disease, signs and symptoms of PsA, physical function and QoL along with low radiographic progression through 52 wks in PsA pts with moderate to severe nail PsO.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Infliximab (Ifx) has proven to be efficacious for improving symptoms in patients with axial SpA(axSpA). Several factors may influence the pharmacokinetic-pharmacodynamic of Ifx and its relation with clinical response such as: disease activity, anti-drug antibodies and the use of concomitant conventional synthetic DMARDs. The prediction of early response through Ifx concentrations could be a feasible tool to optimize the early detection of non-responders to Ifx therapy.

The main objective is to identify if serum Ifx trough levels at early stages of treatment could predict the non-response in patients with axSpA. The secondary objective was to analyze if early drug levels could also predict the development of secondary inefficacy.

Methods: Observational study including 75 patients with axSpA recruited from the axSpA-Paz cohort treated with Ifx and monitored during 52 weeks (W).. Serum Ifx levels and ADA were measured by capture and bridging ELISA respectively at baseline, W2, W6, W12 and W24. Disease activity was assessed at baseline, W24 and W52 by the Ankylosing Spondylitis Disease Activity Score (ASDAS) and clinical response was defined by ΔASDAS≥1.1. The association between serum Ifx trough levels at early stages and clinical response at W52 was evaluated. After that, receiver operating characteristic (ROC) curves for the outcome of clinical response after 52W of treatment were employed to determine the best cut-off values for serum Ifx trough levels. The association between the best cut-off Ifx levels at early stages and clinical outcomes was evaluated by a logistic regression analysis. Ifx survival was evaluated through Kaplan-Meier curves.

Results: Out of the 75 patients studied, 37(49%) were non-responders and 38 (51%) were responders. During the treatment with Ifx, 35(47%) patients discontinued Ifx, most of them due to secondary inefficacy 27/35(77%). Patients with good response after 52W tended to have higher Ifx concentrations compared with non- responder patients at W12: 6.9(4.7-10.7) vs 3.1(0.7-8.5); p=0.006. In addition, patients with concomitant MTX had higher serum Ifx trough levels (median and IQR) than patients without MTX at different time points: at W6: 25.9(16-40) vs 16(11.3-26.6); p=0.008; at W12: 8.6(5.2-12) vs 3.8(1.7-7.7); p=0.005 and at W22: 4.7(2.1-8.3) vs 3.1(0.6-5.1); p=0.007; respectively). ROC curve for serum Ifx concentrations at W12 showed an area under the curve of 0.687 (95% confidence interval (CI): 0.558-0.815), p< 0.01). A cut-off of 6.7 µg/mL showed a sensitivity of 52% and specificity of 71%.Values < 6.7 µg/mL were found to be associated with lower ΔASDAS at W52 (OR: 2.7; 95%CI: 1.0-7.1). The regression analysis
