showed that Ifx concentrations < 6.7 µg/mL at W12 also predict the dropout due to secondary inefficacy (OR: 3.5; 95%CI: 1.2-10.2). The mean survival time was significantly shorter in patients with Ifx levels at W12 < 6.7 µg/mL compared with patients with levels above this cut-off: 5.3 years (95% CI: 4.1-6.5) vs 8 years (95% CI: 6.4-9.7);p=0.03.

Conclusion: Serum Ifx trough levels at W12< 6.7 µg/mL are associated with non-clinical response during the first year of Ifx therapy, more risk to develop secondary inefficacy and a shorter drug survival in patients with axSpA.

Abstract Number: 1487

Impact of TNF-α Inhibitor on Lipid Profile and Atherogenic Index of Plasma in Axial Spondyloarthritis: Two-year Follow-up Data from the Catholic Axial Spondyloarthritis COhort (CASCO)

Hong Ki Min,[1] Seung-Ki Kwok,[2] and Sang-Heon Lee[1], [1]Konkuk university medical center, Seoul, Republic of Korea, [2]Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the influence of TNF-α inhibitor on lipid profile and atherogenic index of plasma (AIP) in axial spondyloarthritis (axSpA) patients with long term use of stable dose TNF-α inhibitor.

Methods: axSpA patients were enrolled in the Catholic Axial Spondyloarthritis COhort (CASCO). We collected their data annually and analyzed their lipid profile and AIP [logarithm of ratio of triglyceride (TG) to high density lipoprotein cholesterol (HDL-C)]. Comparison was conducted between TNF-α inhibitor user group and non-user group. Additionally, lipid profile and AIP of TNF-α inhibitor user group were compared over 2 years.

Results: A total of 238 axSpA patients were enrolled for the present study, including 132 TNF-α inhibitor users and 106 non-users. Changes of total cholesterol (TC), TG, low density lipoprotein cholesterol (LDL-C), and HDL-C over 2 years did not show significant difference between TNF-α inhibitor user group and non-user group. When baseline data and two-year follow-up data were compared within the TNF-α inhibitor user group, there was no significant increase in TG, LDL-C, HDL-C, or AIP. Only TC level was slightly increased in the two-year follow data for the TNF-α inhibitor user group (177.86 ± 28.73 vs. 183.08 ± 29.82, P = 0.019).

Conclusion: Long term use of stable dose TNF-α inhibitor didn't increase atherogenic lipid profile or AIP compared to the control group. Furthermore, atherogenic lipid profile or AIP was not increased significantly in the TNF-α inhibitor user group over two-year follow up. Therefore, using TNF-α inhibitor for a long-term might not affect atherosclerosis of axSpA.

Ixekizumab Demonstrates Improvement Comparable to Adalimumab Across ACR Components in Biologic-Naïve Patients with Psoriatic Arthritis

M. Elaine Husni,[1] Kristin Gowin,[2] Amanda Gellett,[3] Aubrey Trevelin Sprabery,[3] Cameron Helt,[3] Vladimir Geneus,[3] and Maurizio Rossini[4], [1]Department of Rheumatologic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH, [2]Asheville Arthritis & Osteoporosis Center, Asheville, NC, [3]Eli Lilly and Company, Indianapolis, IN, [4]University of Verona, Verona, Italy

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In patients (pts) with active psoriatic arthritis (PsA) and inadequate response or intolerance to conventional synthetic DMARD (csDMARD), use of a biologic DMARD (bDMARD) is often recommended.[1] Multiple bDMARD treatments are available, and head-to-head trials comparing their safety and efficacy provide valuable information to physicians in choosing the best bDMARD for each pt. SPIRIT-H2H is the first completed large head-to-head (H2H) superiority study in active PsA.[2] The study demonstrated superiority at Week 24 of ixekizumab (IXE), an IL-17A antagonist, over adalimumab (ADA), a TNF inhibitor, on a combined endpoint. Improvement in individual American College of Rheumatology (ACR) components is presented.

Methods: Data from the SPIRIT-H2H (NCT03151551) (Phase 3b/4, 52-week, multicenter study) were evaluated. All pts met Classification for Psoriatic Arthritis criteria and are bDMARD-naïve with inadequate response to csDMARD, active PsA (≥3 tender joints [TJ] and ≥3 swollen joints [SJ]), and plaque psoriasis (PsO; body surface area [BSA] ≥3%). Pts were randomized (1:1, stratified by baseline concomitant csDMARD and moderate-to-severe plaque psoriasis) to IXE or ADA on-label PsA or PsO dosing based on the absence/presence of moderate-to-severe plaque psoriasis (de-

fined: BSA ≥10% + Psoriasis Area Severity Index [PASI] ≥12 + static Physician Global Assessment ≥3). All pts could remain on stable dose of csDMARD. A blinded assessor counted TJ (68) and SJ (66). Other ACR components analyzed included C-reactive protein (CRP) and those completed by the unblinded pt and investigator: HAQ-Disability Index (HAQ-DI), joint pain by visual analog scale (VAS), Physician's and Pt's Global Assessments. The primary outcome was the percentage of pts meeting ≥50% or ≥70% improvement in each ACR component at Week 24 and is summarized by treatment groups. Logistic regression analysis was used to detect any treatment group differences at Week 24 on intent-to-treat population. Missing data were imputed using the nonresponder imputation method.

Results: 566 pts were randomized (283 in each arm) with baseline demographics and disease characteristics generally well balanced between groups. IXE and ADA provided comparable efficacy as measured by the percentage of pts achieving ≥50% improvement from baseline at Week 24 for ACR components (Figure 1) other than CRP, where significantly more pts treated with ADA had ≥50% improvement compared with IXE ($p < .05$). No significant differences in the percentage of pts achieving ≥70% improvement from baseline in all ACR components, including CRP, were observed between IXE and ADA groups (Figures 2-3), for both open-label and blinded outcome measures.

Conclusion: In biologic-naïve PsA pts, IXE has comparable efficacy to ADA at Week 24 as determined by the percentage of pts achieving ≥50% or ≥70% improvement in clinical components and in pt-reported outcomes of ACR.

Impact of Apremilast on PsA Impact of Disease Core Components in Patients with a Limited Number of Active Joints: Results from a Real-World Study

Tim Jansen,[1] Eric-Jan Kroot,[2] Arie van Vliet,[3] Jan Pander,[4] and Marijn Vis[5], [1]Viecuri MC, Venlo, Netherlands, [2]Elkerliek, Helmond, Netherlands, [3]Celgene, Utretcht, Netherlands, [4]Celgene, Utrecht, Netherlands, [5]ErasmusMC, Rotterdam, Netherlands

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

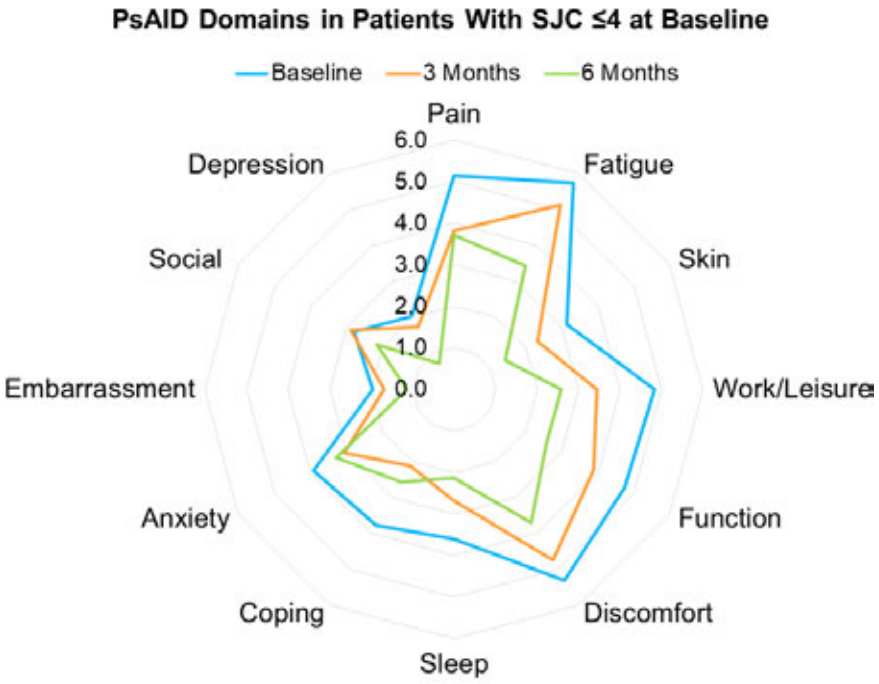
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Recent data suggest that patients with moderately active psoriatic arthritis (PsA) and a limited number of active joints have a high likelihood of achieving treatment goals with apremilast treatment (McInnes I, et al. *Ann Rheum Dis.* 2018;77(Suppl 2). Abstract 0927. Coates LC, et al. *Arthritis Rheumatol.* 2018;70(Suppl 10). Abstract 1607). Real-world evidence on the effect of apremilast on patients' perception of the impact of their disease is limited. Here, we describe the effects of apremilast on the impact of disease in the real-world as measured by the Psoriatic Arthritis Impact of Disease (PsAID) questionnaire in PsA patients with a swollen joint count (SJC) ≤4 at baseline.

Methods: The prospective, multicenter, observational REWARD study (NCT02875184; The Netherlands) is investigating apremilast treatment in real-world patients with PsA. Descriptive statistics were assessed for disease measures, including SJC (0-66) and tender joint count (TJC; 0-68), PsAID (0-10), and Patient's Perception of Pain based on the visual analog scale (VAS; 0-100 mm) among patients with a limited number of swollen joints (SJC ≤4) at baseline. We report the effects of apremilast on these disease measures at treatment initiation and at the first 6 months of treatment with a data cutoff of December 2018.

Results: A total of 48 patients from 9 clinics who were receiving apremilast were included in this interim analysis. Among these patients, 31 (65%) had SJC ≤4 and 17 (35%) had SJC >4 at baseline. Of the patients with SJC ≤4 at baseline, 18 and 8 had at least 3 and 6 months of follow-up, respectively, at the time of data cutoff. Results are reported for patients with available data at each time point. Baseline characteristics for patients with SJC ≤4 included a mean age of 54 years, mean body mass index of 29.1 kg/m^2, and mean years since PsA diagnosis of 7.0 years; 58% of patients were female, 90% had prior cDMARD use, and 29% had prior biologic use. For patients with SJC ≤4, disease measures were reported as follows: The mean SJC at baseline, 3, and 6 months were 1.1, 0.6, and 0.1 and the mean TJC at baseline, 3, and 6 months were 4.5, 3.6, and 1.5, respectively. The mean PsAID scores at baseline, 3, and 6 months were 4.2, 3.4, and 2.6, respectively. Individual PsAID domain scores by time points are shown (Figure). Patients with a limited number of swollen joints showed gradual improvements in all domains of the PsAID. Mean Pain VAS scores at baseline, 2 weeks, 6 weeks, 3 months, and 6 months were 47, 48, 39, 29, and 26, respectively, in these patients.



Data as observed. Of the patients with SJC ≤4 at baseline, 16 and 7 had at least 3 and 6 months of follow-up, respectively, at the time of data cutoff with PsAID values available at each visit.

Conclusion: Results from the real-world, prospective, multicenter, observational REWARD study suggest that PsA patients with a limited number of active swollen joints may benefit from apremilast treatment. Apremilast was associated with improvements in the perceived impact of disease, as observed by reductions in the PsAID and its core components.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

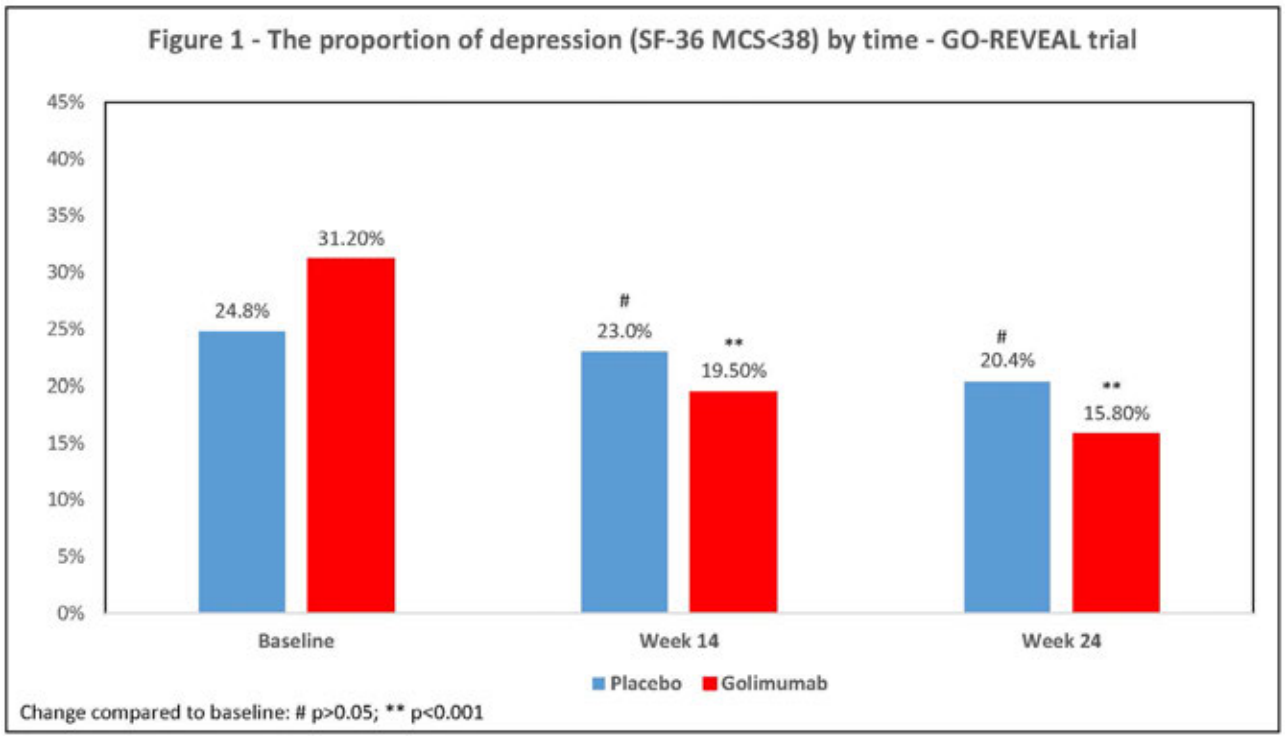
Session Type: Poster Session (Monday)

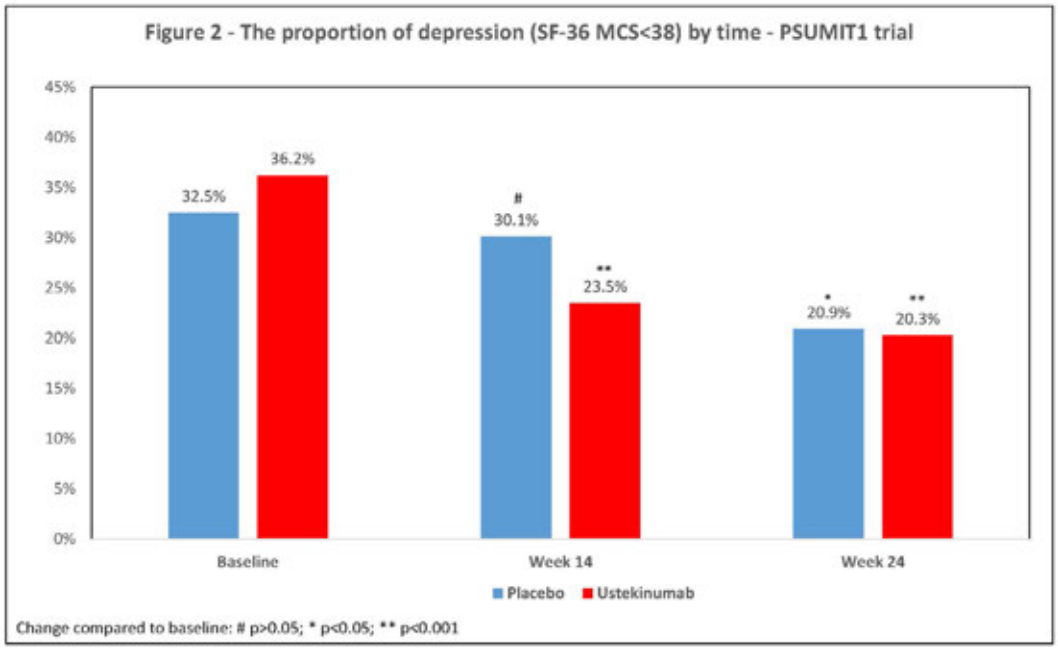
Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of depression is increased in patients with psoriatic arthritis (PsA). Little is known about the impact of effective control of inflammation on depressive mood in patients with PsA and the direct impact of therapies for PsA on depression. The aim of the study was to assess the effect of golimumab (TNFα blocker) and ustekinumab (IL-12/23blocker) on improving depressive symptoms in patients with PsA participating in clinical trials.

Methods: Data from three phase 3, randomized, double blinded placebo-control clinical trials assessing the efficacy of golimumab (GO-REVEAL) and ustekinumab (PSUMIT1 and 2) were analyzed. For each trial the analysis included all patients who were randomized to receive the study drug or placebo. The analysis included information collected during the double-blind portion of the trial (baseline, 14-16 and 24 weeks). The Short-Form Health Survey (SF-36) mental component summary (MCS) score was used to assess the change in depressive symptoms over time in each treatment arm. A threshold of SF-36-MCS < 38 was used to define a state of depression (sensitivity of 87%, sensitivity of 80% and accuracy of 83%)1. The change in proportion of patients classified as being depressed was compared with baseline for each treatment arm using chi square test (Odds Ratio (OR)).

Results: A total of 1,332 patients were enrolled in the three trials (GO-REVEAL 405, PSUMIT1 615, PSUMIT2 312). The mean age was 47 years and the proportion of females ranged from 39.8% and 52.6%. The proportions of patients classified as being in depression at baseline were: 29.4% (GO-REVEAL), 34.9% (PSUMIT-1) and 38.8% (PSUMIT2). Overall, a significant decrease in the proportion of patients with depression was found in the treatment arms of all three studies. In the GO-REVEAL trial the proportion of depression reduced from 31.2% (baseline) to 19.5% (W14: OR 0.54; p=0.001) and 15.8% (W24: OR 0.41;p< 0.001, Figure 1) in the golimumab arm. In the PSUMIT1 trial the proportion of depression decreased from 36.2% (baseline) to 23.5% (W16: OR 0.54;p< 0.001) and 20.3% (W24: 0.45;p< 0.001, Figure 2) in the ustekinumab arm. In the PSUMIT2 trial the proportion of depression decreased from 37.5% (baseline) to 25.5% (W14: OR 0.57;p=0.009) and 21.2% (W24:





OR 0.45;p< 0.001, Figure 3) in the ustekinumab. In general, minimal changes were seen in the proportion of depression in the placebo arm of all three studies.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term data on anti-TNF treatment in patients with early axial spondyloarthritis (SpA) is scarce. The objective of this analysis was to assess the long-term clinical efficacy (up to 10 years of treatment) of a tumor necrosis

factor (TNF) inhibitor etanercept (ETN) in patients with early axial spondyloarthritis, who participated in the long-term (until year 10) extension of the ESTHER (Etanercept vs. Sulfasalazine in Early Axial Spondyloarthritis Trial) trial (1).

Methods: In the previously reported ESTHER trial, patients with early active axial SpA [including both non-radiographic axial SpA (nr-axSpA) and radiographic axial SpA (r-axSpA)/ankylosing spondylitis (AS)] with a symptom duration of < 5 years and a positive MRI of the sacroiliac joints (SIJs) and/or the spine at baseline) were treated with ETN (n= 40) or sulfasalazine (SSZ) (n= 36) during the first year (1). At year 1, all patients who were not in remission continued with - or switched (in case of SSZ therapy) to – ETN for up to 10 years in total (1). Patients in remission discontinued their therapy and were followed-up until end of year 2; in case of remission loss, ETN was (re)-introduced and continued till the end of year 10.

Results: Out of 76 initial patients, 25% (n=19, 12 with r-axSpA and 7 with nr-axSpA) completed year 10 of the study. At baseline, completers were significantly more often male and showed lower values of patient (PGA) and physician global assessments of disease activity (PhGA), ASDAS (Ankylosing Spondylitis Disease Activity Score), BASMI (Bath Ankylosing Spondylitis Metrology Index), and AS-QoL (Ankylosing Spondylitis Quality of Life Questionnaire) as compared to non-completers (Table 1). When analyzing clinical data of the completers, mean BASDAI, BASFI and ASDAS values were constantly < 2 during the follow up with no statistically significant differences between the r-axSpA and nr-axSpA sub-groups (Table 2, Figure 1B). In the entire group, a sustained clinical response was observed over 10 years of follow up (Figure 1A). A total of 39 serious adverse events were documented over the 10 years of the study,

Figure 1: Observed response rates to etanercept (A) and the course of disease related parameters in study completers (n=19) (B).

Table 1: Baseline characteristics of patients with axial spondyloarthritis who completed the study as compared to patients who dropped out.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Upadacitinib, a selective inhibitor of Janus kinase 1 (JAK1), is currently being evaluated for the treatment of several autoimmune disorders, including axial spondyloarthritis (axial SpA). In the SELECT-AXIS I study (NCT03178487), upadacitinib 15 mg once-daily (QD) demonstrated favorable efficacy in ankylosing spondylitis (AS) patients who had an inadequate response to non-steroidal anti-inflammatory drugs and who were naïve to biological disease modifying antirheumatic drugs. The purpose of this analysis was to a) explore the relationship between upadacitinib exposures and several AS efficacy endpoints and safety parameters to support dose selection for future studies and b) compare upadacitinib plasma exposures in subjects with AS to subjects with rheumatoid arthritis to assess disease-related differences in upadacitinib pharmacokinetics (PK).

Methods: The analyses included data from 187 subjects in the SELECT-AXIS I study. Subjects were randomized to receive upadacitinib 15 mg QD (n=93) or matching placebo (n=94). PK samples were taken at pre-defined visits and modeled using a population approach. Within the evaluated dose, exposure-response quartile plots were created to assess the relationship between upadacitinib average plasma concentrations and the probability of achieving Week 14 efficacy endpoints (ASAS 40, ASAS 20, ASAS partial remission [PR]) or experiencing adverse events/relevant changes in laboratory variables (lymphopenia [Grade 3 per CTCAE or higher], infection, decreases in hemoglobin).

Results: Upadacitinib plasma concentrations (Table 1) and PK parameters (drug clearance and volume of distribution) in subjects with AS were similar to those previously observed in subjects with RA in the SELECT-BEYOND and SELECT-NEXT studies.

Subjects in the active treatment arm had statistically significant higher response rates for ASAS 40, ASAS 20, and ASAS PR compared to those in the placebo arm. However, within the single active treatment arm there were no clear exposure-response relationships between increasing upadacitinib average concentrations and the probability of achieving the evaluated efficacy outcomes, suggesting achieving the plateau of response. With increasing upadacitinib exposure, there was an increase in the percentage of subjects experiencing decreases of hemoglobin of ≥ 1 g/dL from baseline; with no subjects having ≥ 2 g/dL decreases of hemoglobin from baseline. There were no upadacitinib exposure-dependent increases in percentage of subjects experiencing lymphopenia or infection. There was a single observed case of Grade 2 neutropenia in a subject receiving active treatment and no observed cases of serious infections.

Conclusion: Upadacitinib pharmacokinetics are similar in subjects with AS and RA. Upadacitinib 15 mg QD dose is predicted to maximize efficacy in subjects with AS. Overall, the results of this analysis support selection of the upadacitinib 15 mg QD dose for further evaluation in future studies in AS/axial SpA.

Indication	Median C_{avg}	5th Percentile	95th Percentile
Ankylosing Spondylitis	15.0 ng/mL	9.60 ng/mL	30.0 ng/mL
Rheumatoid Arthritis (SELECT-BEYOND and SELECT-NEXT)	14.5 ng/mL	9.80 ng/mL	29.2 ng/mL

Table 1. Predicted median average upadacitinib plasma concentrations within a dosing interval (Cavg) in AS and RA subjects receiving upadacitinib 15 mg QD.

Improvement in the Signs and Symptoms of Psoriatic Arthritis with Ixekizumab Compared to Adalimumab in Patient Subgroups Defined by Baseline Disease Characteristics

Joseph Merola,[1] Aubrey Trevelin Sprabery,[2] Amanda Gellett,[2] Chen-Yen Lin,[2] and Dennis McGonagle[3], [1]Harvard Medical School, Brigham and Women's Hospital, Boston, MA, [2]Eli Lilly and Company, Indianapolis, IN, [3]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple biologic DMARD (bDMARD) treatments are available for PsA, but there is limited research that compares the safety and efficacy of these treatments. Head-to-head (H2H) studies may improve the strength of PsA treatment guidelines and provide valuable guidance to physicians in selecting optimal treatment.[1] SPIRIT-H2H, the first completed H2H superiority study in active PsA, showed superiority of ixekizumab (IXE), an IL-17A antagonist, over adalimumab (ADA), a TNF inhibitor, on a combined endpoint at Week 24.[2] Here we report the Week 24 efficacy of IXE and ADA in subgroups defined by baseline disease characteristics.

Methods: SPIRIT-H2H (NCT03151551) is a 52-week, multicenter, open-label, blinded assessor study in bDMARD-naïve patients who were inadequate responders to conventional synthetic DMARD (csDMARD) with active PsA (≥3 tender joint count [TJC] and ≥3 swollen joint count [SJC]) and plaque psoriasis (body surface area [BSA] ≥3%). All patients met Classification Criteria for PsA. Patients were randomized 1:1 to IXE or ADA on-label dosing based on presence/absence of moderate-to-severe psoriasis (BSA ≥10% + Psoriasis Area and Severity Index [PASI] ≥12 + static Physician Global Assessment [sPGA] ≥3). A blinded assessor measured TJC, SJC, enthesitis, dactylitis, PASI, sPGA, BSA, and fingernail psoriasis. This post hoc subgroup analysis assessed efficacy in patients with baseline enthesitis (presence/absence), dactylitis (presence/absence), fingernail psoriasis (presence/absence), BSA (10% cutoff), and CRP (6 mg/L cutoff). Week 24 outcomes were compared between IXE and ADA at ACR20/50/70 responses and minimal disease activity (MDA). Missing data were imputed by nonresponder imputation. While the post hoc analysis was not controlled for multiplicity, all comparisons were analyzed by Fisher's exact test.

Results: The Table summarizes Week 24 efficacy outcomes by subgroup. There were no statistical differences between IXE and ADA at ACR20 and ACR50 response rates across all of the examined subgroups. ACR70 responses were comparable across subgroups, except significantly more IXE-treated patients with baseline fingernail psoriasis achieved ACR70 than ADA-treated patients (p=.02). Significantly more IXE- than ADA-treated patients achieved MDA-6 in subgroups with baseline enthesitis (p=.002), without dactylitis (p=.015), with fingernail psoriasis (p< .001), CRP≤6 mg/L (p=.046), and BSA ≥10% (p=.01). All other subgroups analyzed demonstrated comparable efficacy on IXE and ADA.

A limitation of this analysis is that it was completed post hoc, not controlled for multiplicity, and patients were not stratified by these baseline disease characteristics.

Table: Efficacy Outcomes at Week 24 in patient subgroups defined by baseline disease characteristics (NRI)

Baseline Disease Characteristic	Week 24 Outcome	Treatment Group	ACR20	ACR50	ACR70	MDA-6[a]
Baseline Enthesitis	LEI>0 OR SPARCC>0	ADA (Nx=172)	114 (66.3%)	73 (42.4%)	36 (20.9%)	50 (29.1%)
		IXE (Nx=193)	130 (67.4%)	90 (46.6%)	57 (29.5%)	87 (45.1%)**
	LEI=0 OR SPARCC=0	ADA (Nx=111)	90 (81.1%)	59 (53.2%)	37 (33.3%)	54 (48.6%)
		IXE (Nx=89)	65 (73.0%)	53 (59.6%)	33 (37.1%)	52 (58.4%)
Baseline Dactylitis	LDI-B>0	ADA (Nx=58)	45 (77.6%)	31 (53.4%)	14 (24.1%)	19 (32.8%)
		IXE (Nx=42)	28 (66.7%)	23 (54.8%)	13 (31.0%)	21 (50.0%)
	LDI-B=0	ADA (Nx=225)	159 (70.7%)	101 (44.9%)	59 (26.2%)	85 (37.8%)
		IXE (Nx=240)	167 (69.6%)	120 (50.0%)	77 (32.1%)	118 (49.2%)*
Baseline Fingernail Psoriasis	NAPSI>0	ADA (Nx=177)	129 (72.9%)	82 (46.3%)	39 (22.0%)	57 (32.2%)
		IXE (Nx=191)	136 (71.2%)	101 (52.9%)	63 (33.0%)*	95 (49.7%)***
	NAPSI=0	ADA (Nx=105)	75 (71.4%)	50 (47.6%)	34 (32.4%)	47 (44.8%)
		IXE (Nx=92)	59 (64.1%)	42 (45.7%)	27 (29.3%)	44 (47.8%)
Baseline CRP	CRP ≤6 mg/L	ADA (Nx=167)	124 (74.3%)	74 (44.3%)	41 (24.6%)	61 (36.5%)
		IXE (Nx=167)	110 (65.9%)	81 (48.5%)	48 (28.7%)	80 (47.9%)*
	CRP >6 mg/L	ADA (Nx=109)	76 (69.7%)	55 (50.5%)	30 (27.5%)	42 (38.5%)
		IXE (Nx=109)	82 (75.2%)	60 (55.0%)	40 (36.7%)	55 (50.5%)
Baseline BSA	BSA <10%	ADA (Nx=179)	128 (71.5%)	80 (44.7%)	43 (24.0%)	65 (36.3%)
		IXE	109 (64.1%)	79 (46.5%)	49 (28.8%)	76 (44.7%)

Conclusion: IXE and ADA are associated with comparable efficacy in the signs and symptoms of PsA in patient subgroups defined by baseline enthesitis, dactylitis, fingernail psoriasis, BSA, and CRP.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

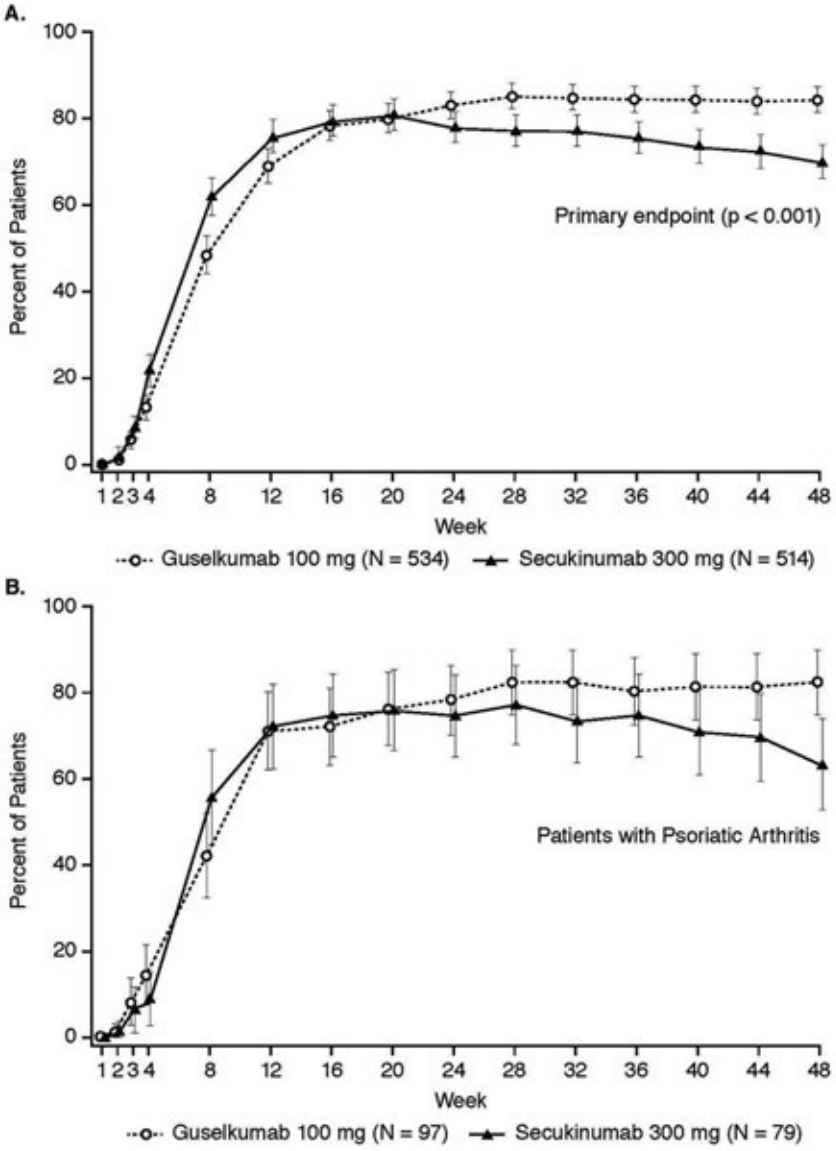
Background/Purpose: Guselkumab (GUS, an antibody against IL-23) and secukinumab (SEC, an antibody against IL-17A) are both approved for the treatment of psoriasis (PsO). Up to 30% of patients with PsO may have psoriatic arthritis (PsA).

The ECLIPSE study compared efficacy and safety of GUS vs SEC in patients with plaque PsO. Post hoc analyses examined outcomes in the subgroup of patients with self-reported psoriatic arthritis (PsA).

Methods: ECLIPSE was a randomized, double-blind trial of adults with moderate-to-severe plaque PsO who received GUS 100 mg at Weeks 0, 4, then every 8 weeks, or SEC 300 mg at Weeks 0, 1, 2, 3, and 4, then every 4 weeks (both being administered according to their labeling), both through Week 44. The primary endpoint was the proportion of patients achieving ≥90% improvement compared to baseline in the Psoriasis Area and Severity Index (PASI) score at Week 48. Cochran-Mantel Haenszel chi-square testing stratified by investigator was used to compare treatment-group responses.

Results: Overall, treatment groups [GUS (n=534), SEC (n=514)] were comparable at baseline: weight 89kg, 24% body surface area PsO, and Investigator Global Assessment (IGA) moderate (76%) or severe (24%). These characteristics were similar to those of subgroups with self-reported PsA [GUS (n=97), SEC (n=79)]. In the overall population, the primary endpoint of PASI 90 response at Week 48 was achieved by 84.5% of GUS vs 70.0% of SEC patients (treatment difference 14.2 [95% CI=9.2%,19.2%], P< 0.001). Among patients with PsA, the primary endpoint of PASI 90 response at Week 48 was achieved by 82.5% of GUS vs 63.3% of SEC patients (treatment difference 19.2% [95% CI=5.0%, 33.4%]). Beyond week 20, in both the overall study population and the PsA subpopulation, GUS-treated patients maintained the PASI 90 response while SEC-treated patients had a reduction in response through week 48 (Figure). In the overall population, results of the first major secondary endpoint (proportion of patients with a PASI 75 response at both Week 12 and 48) showed non-inferiority of GUS vs SEC (GUS-84.6% vs SEC-80.2% of patients, p< 0.001), but superiority was not demonstrated (p=0.062). Adverse events observed in the overall population and PsA subgroup were generally consistent with the established safety profiles for GUS and SEC.

Figure. Proportion of Patients Achieving PASI 90 Response (95% CI)



A. Total ECLIPSE population of patients with moderate to severe plaque psoriasis.
B. Subgroup of patients with Psoriatic Arthritis.
Non-responder imputation was used for missing data.
CI=Confidence interval, PASI 90=90% improvement in the Psoriasis Area and Severity Index (PASI).

Conclusion: In the subset of patients with self-reported PsA in the ECLIPSE study, GUS demonstrated better maintenance of response and higher efficacy at approximately one year compared with SEC in the treatment of moderate to severe plaque PsO. These findings were consistent with those for the overall study population of patients with plaque PsO. AEs observed were generally consistent with the established safety profiles for GUS and SEC.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

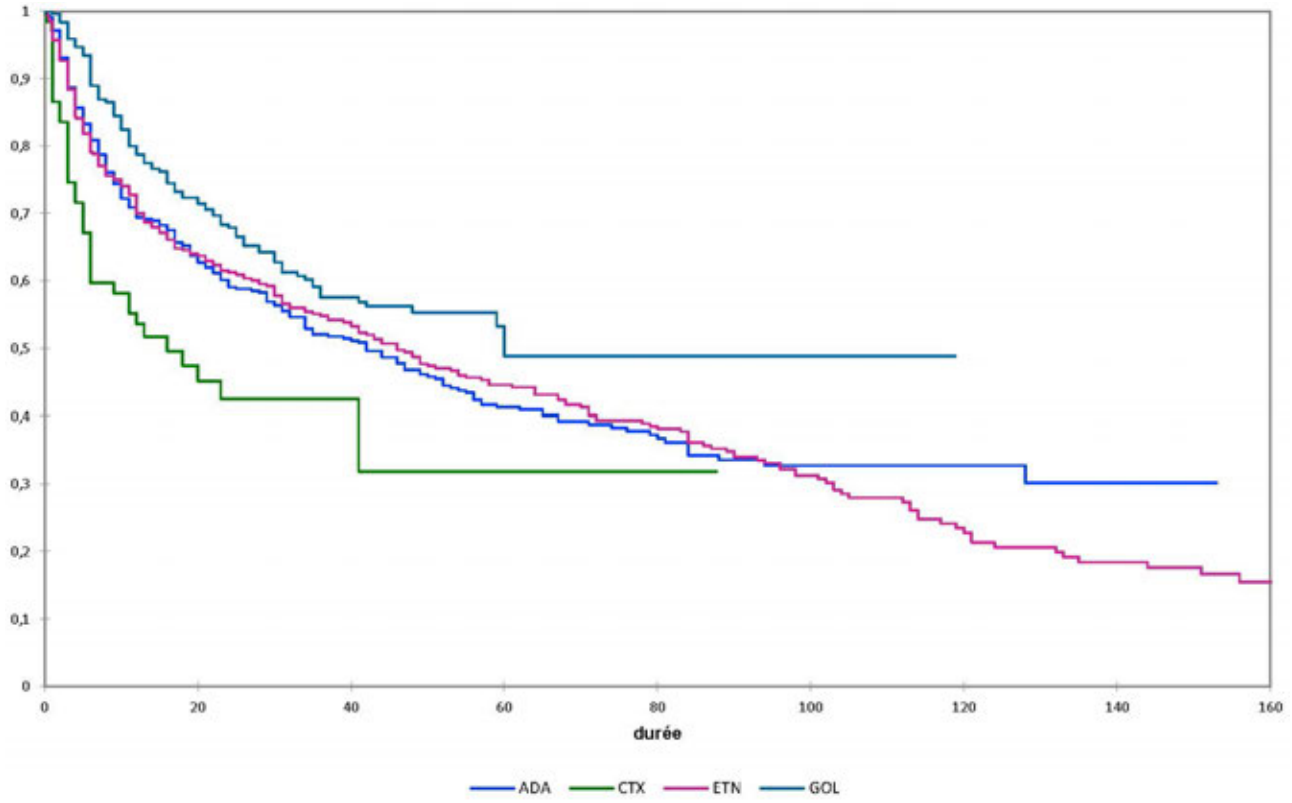
Background/Purpose: Drug survival is used as a tool for treatment effectiveness and safety especially in real-world data. The objective of the study was to evaluate long term survival of subcutaneous TNF inhibitors (TNFi) in spondyloarthritis (SA) patients and to compared drug survival between the different lines.

Methods: Multicentric, retrospective, longitudinal and observational study included all patients with SA under TNFi since 2004, with a record in RIC France. The first part of the study analysed the survival of the fourth anti-TNF : etanercept (ETN), adalimumab (ADA), golimumab (GOL) and certolizumab (CTZ) since their first prescription. The second part of the study included the patients from January 2013 to March 2018, as CTZ has been available in January 2013. Drug survival has been analysed at 6 months, 1, 2, 3 et 5 years for the 1st, 2nd et 3rd course with Kaplan-Meier test compared with log-rank test.

Results: On the total population (n=1170), ADA and ETN has a comparable mean drug survival (MDS) of 42 and 46 months respectively. CTZ has a MDS of 16 weeks and GOL of 60 weeks.

When we analysed the records of the 425 patients treated since January 2013 (836 TNFi treatment) the characteristics were at TNFi initiation : a mean-age of 43.3 years, 45.6% female, mean SA duration of 8.6 years (+/- 12) and the mean BASDAI was 5.43. 824 TNFi have been analysed and 439 were on course

418 first course TNFi with a drug survival at one year at 70 % for adalimumab (ADA), at 58 % for etanercept (ETA), at 85 % for certolizumab (CTZ) and at 83% pour le golimumab (GOL).



In second course of TNFi (n=230), drug survival was at one year of 58 % for ADA, at 62 % ETA, at 57 % for CTZ. and 66 % for GOL.

In third course or more (n=176) drug survival was at one year of 67% for ADA, 76% for ETA, 51% for CTZ and 86% for GOL.

Data for predicting factors of survival are on analysed.

Conclusion: In this retrospective study of real world, golimumab has the best drug survival, in the long-term evaluation as well as the 5 years evaluation and also whatever the line of treatment. Predicting factors of survival might explain this result.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Among the treatment options for PsA, IL-12/23 inhibition with ustekinumab (UST) was the first new biologic mode of action after TNF inhibitors (TNFi). Few data are available from real-world settings comparing the effectiveness of UST to standard TNFi. The objective of this study was to investigate 6-mo treatment responses to UST or TNFi in the 8-country, real-world PsABio study, especially achievement of LDA and remission.

Methods: The PsABio study (NCT02627768) evaluates effectiveness, tolerability and persistence of 1st, 2nd or 3rd-line UST or TNFi in PsA. Proportions of patients (pts) reaching MDA/VLDA and cDAPSA were evaluated. Baseline (BL) and 6-mo data were compared among pts receiving UST or TNFi for full 6 mo (completers), and ITT analysis including pts switching/stopping original treatment during 6-mo observation period, imputed as non-responders. Propensity score (PS) was used to adjust for BL covariates in country, age, gender, BMI, smoking (yes/no), co-morbidities (cardiovascular/metabolic syndrome), PsA type (axial, polyarticular, oligoarticular), psoriasis BSA, disease duration, cDAPSA, PsAID-12, dactylitis, enthesitis, FiRST score, line of biologic (b)DMARD, synthetic DMARD use, and steroid or NSAID use. Factors potentially modifying PS-adjusted treatment effect were investigated.

Results: For N=930 pts, 796 (93.0% and 93.6% of UST- and TNFi-treated, respectively) had evaluable data at BL and 6 mo (Table 1). ITT analysis (n=868) included pts who had stopped/switched before 6 mo (UST: n=28/426 [6.6%], TNFi: n=44/442 [10.0%]). For MDA assessment, 761 (ITT) and 701 (completers) had data for both visits. Both UST and TNFi led to achievement of MDA (up to 35%), VLDA (up to 11%), cDAPSA LDA (up to 57%) and cDAPSA remission (up to 22%) (Table 2). At BL, significant differences between UST and TNFi groups existed in age (higher on UST), line of treatment (UST more frequently 3rd-line), NSAID use (lower in UST), methotrexate use (less concomitant treatment in UST), FiRST score (more chronic widespread pain in UST), and skin involvement (higher in UST). After PS adjustment for BL differences, odds ratios (OR) for reaching MDA, VLDA, cDAPSA LDA or remission at 6 mo, were not statistically different between UST and TNFi (Table 2). In the ITT set, pts with low-grade skin disease (BSA< 3%)

and those with oligoarticular disease had a lower chance of achieving MDA when given UST (OR: 0.45 [0.29, 0.85] and 0.62 [0.39, 0.97] respectively) compared with TNFi, but responses to UST tended to be better in pts with higher grade skin disease (>10% of BSA) and with polyarticular disease at BL (OR: 2.08 [0.88, 4.95] and 1.57 [0.88, 2.82] respectively). Similar results were seen in the analysis obtained with cDAPSA LDA or remission as treatment target.

Table 1: Observed baseline characteristics of the 868 ITT patients and 796 completer patients

	UST ITT	TNFi ITT	UST Completers	TNFi Completers
N	426	442	398	398
Age, years	51.2 (12.5)	48.5 (12.6)	51.1 (12.6)	48.6 (12.7)
Gender (male), %	43.0	45.7	43.2	47.5
Time since initial diagnosis, years	7.54 (8.13)	6.21 (6.63)	7.39 (8.06)	6.12 (6.48)
Cardiovascular/ metabolic syndrome comorbidity, %	41.3	35.5	40.2	35.2
Dactylitis at baseline, %	18.8	20.8	18.1	21.9
Enthesitis at baseline, %	48.9	51.9	49.3	53.3
PsA characteristics: %				
Axial involvement	35.4	37.2	34.9	36.5
Oligoarticular	22.4	28.9	23.0	30.8
Polyarticular	66.7	64.7	65.6	62.5
sDMARD exposure, %				
Previous exposure	88.3	93.0	87.9	93.7
Ongoing exposure at baseline	39.7	55.2	39.9	55.8
Other treatments exposure, %				
NSAIDs	54.5	69.5	54.5	69.8
Steroids	32.4	34.4	31.7	33.7
BMI, kg/m^2	28.6 (6.3)	27.7 (5.0)	28.6 (6.4)	27.7 (5.00)
Psoriasis BSA, %				
<3%	38.4	50.1	37.5	47.4
3–10%	34.9	35.7	34.7	37.9
>10%	26.7	14.1	27.8	14.7
cDAPSA	31.0 (20.3)	29.8 (18.6)	30.8 (20.3)	29.5 (18.4)
Swollen joint count (66)	6.0 (8.12)	5.8 (7.38)	6.0 (8.21)	5.9 (7.51)
Tender joint count (68)	12.5 (12.5)	11.3 (10.8)	12.4 (12.5)	11.0 (10.4)
CRP (mg/dL)	1.33 (2.95)	1.55 (2.86)	1.34 (3.03)	1.49 (2.78)
FiRST total score	3.50 (2.01)	3.12 (1.95)	na	na
FiRST score ≥ 5	39.3%	29.0	na	na
Total PsAID (over past week)	5.71 (2.17)	5.52 (2.08)	5.70 (2.18)	5.48 (2.08)
RF/CCP positive (%)	2.0/3.0	5.6/2.8	na	na

cDAPSA, clinical Disease Activity in Psoriatic Arthritis; FiRST, Fibromyalgia Rapid Screening Tool; ITT, intention to treat; na, not available; PsAID, Psoriatic Arthritis Impact of Disease; sDMARD, synthetic disease-modifying antirheumatic drug.

Table 2: Observed disease outcomes (MDA, VLDA, LDA and remission) at Month 6

Variable	All patients (ITT population)		Completers	
	UST	TNFi	UST	TNFi
MDA, % achieved (observed)	26.4	30.8	28.5	34.8
PS adjusted OR (95% CI), UST compared to TNFi	0.87 (0.61, 1.25)		0.81 (0.56, 1.17)	
VLDA, % achieved(observed)	8.3	9.6	8.9	10.8
PS adjusted OR (95% CI), UST compared to TNFi	0.74 (0.42, 1.30)		0.69 (0.39, 1.22)	
cDAPSA LDA/remission, % achieved (observed)	45.7	50.7	49.4	57.3
PS adjusted OR (95% CI), UST compared to TNFi	0.74 (0.53, 1.04)		0.65 (0.46, 0.93)	
cDAPSA remission, % achieved (observed)	14.9	19.2	16.2	21.7
PS adjusted OR (95% CI), UST compared to TNFi;	0.73 (0.46, 1.15)		0.65 (0.41, 1.04)	

cDAPSA, clinical Disease Activity index for PSoriatic Arthritis; CI, confidence interval; ITT, intention to treat; LDA, low disease activity; MDA, minimal disease activity; OR, odds ratio; PS, propensity score; VLDA, very low disease activity.

Conclusion: UST and TNFi, when used as 1st-, 2nd- or 3rd-line bDMARD in a routine care setting, provide clinically relevant regression of disease signs and symptoms and allow achievement of MDA, LDA or remission in many PsA pts after 6 mo of treatment. After PS adjustment for BL imbalances, clinical results achieved were comparable between UST and TNFi.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC), a selective inhibitor of interleukin 17A, demonstrated rapid, significant, and sustained improvement in the signs and symptoms of PsA, with a favorable safety profile, in the phase 3 FUTURE studies (FUTURE 1–5).[1-5] These studies were conducted in several countries worldwide, including the United States. We evaluated SEC treatment in the US patient (pt) subpopulation in these studies and report pooled efficacy findings for SEC vs placebo (PBO).

Methods: Data from US pts enrolled in FUTURE 2 (NCT01752634), 3 (NCT01989468), 4 (NCT02294227), and 5 (NCT02404350) were pooled and included in this hypothesis-generating analysis. These studies used approved SEC doses, with pts receiving SEC 300 or 150 mg with subcutaneous loading dose (LD), 150 mg without LD, or PBO. FUTURE 1 (NCT01392326) was excluded because pts received an intravenous LD, which is not approved for treating PsA. Assessments included ACR20/50/70 and additional disease activity and quality of life (QOL) outcome measures at week 16. Responses were calculated using nonresponder imputation. No adjustment was made for multiple comparisons.

Results: Of 279 pts included in this pooled analysis, 72 were randomized to SEC 300 mg with LD, 83 to SEC 150 mg with LD, 34 to SEC 150 mg without LD, and 90 to PBO. Baseline characteristics were similar across treatment groups (**Table 1**). Most pts had a BMI of ≥ 30 kg/m^2 and had been previously treated with tumor necrosis factor inhibitors (TNFis). At week 16, ACR20/50/70 response rates were numerically higher with all doses of SEC than with PBO; responses were seen as early as week 4 (**Figure 1**). SEC also improved other disease manifestations, including joint, skin, and nail disease, and various QOL measures; resolution of enthesitis and dactylitis was observed in approximately 50% of pts (**Table 2**). Overall, SEC 300 mg led to higher response rates than SEC 150-mg doses. SEC 150 mg with LD was associated with better response rates than that without LD.

Conclusion: SEC was efficacious in US pts with PsA, leading to rapid improvements in clinical endpoints and QOL. In general, US pts treated with SEC 300 mg achieved the highest response rates, including ACR50/70 response. SEC 150 mg also led to clinical benefits, with an LD regimen associated with higher response rates. Although US pts had high BMIs and a large proportion had been treated with ≥ 2 TNFis, response rates in these pts were similar to those seen in the overall pooled pt population.[6,7] Our findings are consistent with those from previous studies and show that SEC is an effective treatment for pts with PsA.

Table 1. Patient Characteristics at Baseline

Characteristic	SEC 300 mg (n = 72)	SEC 150 mg (n = 83)	SEC 150 mg, no LD (n = 34)	PBO (n = 90)

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory arthritis that often develops in patients (pts) with psoriasis. Secukinumab (SEC) inhibits IL-17A, a key inflammatory cytokine in the pathogenesis of PsA. SEC is approved for treatment of PsA based on the phase 3 FUTURE studies, where SEC proved superior to placebo (PBO) in improving signs and symptoms of PsA. Although pts from several countries were included, US pts were under-represented. We report findings from CHOICE (NCT02798211), a phase 4 study which evaluated SEC vs PBO in US biologic-naive pts with PsA with psoriatic skin lesions.

Methods: CHOICE was a randomized, double-blind, controlled trial conducted in the United States. Biologic-naive pts with active PsA by CASPAR criteria and psoriatic skin lesions (PASI ≥ 1) were enrolled. Pts were randomized 2:2:1 to receive SEC 300 mg, SEC 150 mg, or PBO, respectively, with a weekly loading dose up to Week 4, and every 4 weeks thereafter for 16 weeks. After Week 16, all pts randomized to PBO, and nonresponders from the SEC 150-mg group received SEC 300 mg up to Week 52. The primary objective was to show superiority of SEC 300 mg vs PBO in ACR20 response at Week 16. Secondary and exploratory objectives included the effect of SEC on dactylitis, enthesitis, psoriasis, remission status, RAPID3 score, and safety. Long-term (up to Week 52) efficacy and safety were also assessed.

Results: In total, 258 pts were randomized to SEC 300 mg (n = 103), SEC 150 mg (n = 103), or PBO (n = 52). Pts in all treatment groups had comparable baseline characteristics. In general, pts in CHOICE were older, had a higher mean weight, and higher baseline joint involvement than pts in the FUTURE studies. The study met its primary objective with a greater percentage of pts treated with SEC 300 mg achieving ACR20 response at Week 16 compared with PBO (51.5% vs 23.1%; odds ratio [OR], 3.51 [95% CI: 1.65, 7.45]; *P* = .0011, using logistic regression) (**Figure 1**). ACR20 responses were numerically higher with SEC 150 mg than PBO (36.9%; OR, 1.92 [95% CI: 0.89, 4.15]; *P* = .0961). SEC also led to higher ACR50/70 response rates, higher rates of minimal disease activity, lower RAPID3 scores, and improvements in other variables compared with PBO (**Table 1**). Response rates were generally sustained over time with SEC, with the percentage of responders increasing after uptitration of SEC dose. The most commonly reported adverse events (AEs) with SEC at Week 16 were diarrhea and upper respiratory tract infections (**Table 2**). No inflam-

Musculoskeletal pain	2 (1.9)	1 (1.0)	3 (5.8)
Arthralgia	1 (1.0)	2 (1.9)	4 (7.7)
Pain in extremity	1 (1.0)	3 (2.9)	3 (5.8)
Psoriatic arthropathy	1 (1.0)	4 (3.9)	0
Back pain	1 (1.0)	4 (3.9)	0
Peripheral edema	1 (1.0)	0	2 (3.8)
Psoriasis	1 (1.0)	4 (3.9)	0
Respiratory tract congestion	0	0	2 (3.8)

Conclusion: SEC 300 mg was superior to PBO in leading to rapid and significant improvements in symptoms of PsA in US biologic-naive patients. Benefits were observed with both SEC doses; however, responses were generally higher with SEC 300 mg. Overall, findings in CHOICE were consistent with previous studies and suggest that SEC 300 mg is safe and efficacious as a first-line biologic treatment for pts with PsA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The pivotal GO AFTER study **[1]** and the ongoing observational GO BEYOND study investigate GLM efficacy in rheumatoid arthritis (**RA**) patients who previously received biologics. However, clinical studies of GLM in axial spondyloarthritis (**axSpA**) are lacking. Using data from the GO PRACTICE study, we examined GLM persistence in patients with axSpA.

The primary objective of the study was to estimate GLM persistence at 2 years from initial prescription, as a first line of treatment (in biologic naïve patients: BN) and as a second or further line of treatment (in biologic pretreated patients: **BP**). Secondary outcomes included evaluations of changes over 2 years in 1) clinical disease activity, and 2) patient-reported disease activity, pain, functional ability and quality of life (**QoL**).

Methods: This was an observational, prospective, multicenter French study, that recruited adult patients with RA, psoriatic arthritis or axSpA, who were newly prescribed GLM. Patients were followed-up over 2 years; data were collected at baseline, 1 year and 2 years. This abstract presents findings originating from the axSpA cohort of the GO PRACTICE study. GLM persistence was estimated with the Kaplan-Meier method. Clinical disease activity was assessed with the Ankylosing Spondylitis Disease Activity Score (**ASDAS**) and patient-reported disease activity was evaluated with the Bath Ankylosing Spondylitis Disease Activity Index (**BASDAI**). Pain was evaluated using a visual analogue scale (**VAS**), functional ability with the Health Assessment Questionnaire (**HAQ**) and QoL with the EQ-5D and SF-12 questionnaires.

Results: From January 2015 to March 2016, 478 axSpA patients (constituting 63% of the total cohort) from 134 sites were included in the study. Mean age was 43 years and 55% were female; 61% were BN (n=291) and 39% were

	BN patients		BP patients		
	Baseline	2 years	Baseline	2 years	*p**
ASDAS-CRP, Mean score (SD)	3.2 (0.8)	1.5 (0.9)	3.1 (0.8)	2.0 (1.0)	*p* =.0051
BASDAI, Mean Score (SD)	5.3 (1.7)	2.6 (1.9)	5.7 (1.6)	3.1 (2.0)	*p* <.0001

**p* is from a 2-factor repeated-measures model testing the significance of the effect of prior biologic treatment on score evolution, adjusted to time

Disease activity scores at baseline and 2 years for biologics naïve (BN) and biologics pretreated (BP) axial spondyloarthritis (axSpA) patients who were persisting on golimumab.

	12 months (1 year)	24 months (2 years)
axSpA, BN	71.5%	59.2%
axSpA, BP	66.0%	45.1%
axSpA Total	65.8%	52.6%

BP (n=187). Mean duration of axSpA illness was 5.5 and 10.7 years in BN and BP patients, respectively ($p < .001$). At baseline, most were prescribed 50 mg GLM monthly (97%); DMARDs, corticosteroids and NSAIDs or analgesics were co-prescribed to 34%,17% and 90% of axSpA patients, respectively. GLM persistence over 2 years was significantly higher in BN than BP patients (59.2% vs 45.1%, logrank $p < .01$). For BN and BP patients persisting on GLM at 2 years, disease activity (Table 1) and patient-reported outcomes showed significant improvements, with improvements being more important in BN patients. GLM was well tolerated in axSpA patients (n=478), with 46 (9.6%) discontinuing due to intolerance. In the BN group, 18 patients (6.2%) discontinued GLM due to primary treatment failure, compared to 28 BP patients (15%). GLM was re-prescribed to 213 (88%) of the 241 patients persisting on GLM at 2-years. Post-hoc multivariate analysis showed that being female was a risk factor for GLM discontinuation in axSpA (HR1.9, IC95% 1.4-2.6).

Conclusion: Golimumab is associated with clinical improvements and good persistence in patients with axial spondyloarthritis, especially those who are biologic naïve

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Over the last years, and mostly due to lack of alternatives, it has been common practice to start a second TNF inhibitor (TNFi) in patients with axial spondyloarthritis (axSpA) who discontinue their first TNFi. Evidence informing on the effectiveness of this strategy in clinical practice is limited. Importantly it remains unclear whether the reason for discontinuation of the first TNFi influences the response to the second. We aimed to assess whether the reason of discontinuation of the first TNFi influences the response to the second TNFi.

Methods: Patients with axSpA from the ReumaPt national registry, who discontinued their first TNFi and started a second TNFi were included in this analysis. In addition, patients were required to have complete data on Ankylosing Spondylitis Disease Activity Score (ASDAS) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) at baseline, 3 and 6 months after starting the first TNFi. Afterwards, patients were followed every 6 months up to 12 years. The main outcome was the ASDAS clinically important improvement (ASDAS CII). Secondary outcomes were ASDAS major important improvement (ASDAS MI); ASDAS low disease activity (ASDAS LDA); ASDAS inactive disease (ASDAS ID) and BASDAI 50. The reason for discontinuation of the first TNFi was defined as: i) Primary failure, if

-Secondary failure	**5.3 (1.4;19.5)**	2.3 (0.9;6.0)	**5.3 (1.4;21.4)**	1.1 (0.5;2.3)	1.4 (0.6;3.1)
-Adverse events	3.4 (0.9;12.4)	1.8 (0.7;4.5)	**8.7 (2.4;31.5)**	1.0 (0.5;1.9)	1.1 (0.5;2.4)
-Other	1.5 (0.1;15.6)	1.2 (0.3;4.7)	**7.2 (1.5;34.2)**	1.1 (0.4;2.6)	0.4 (0.1;1.7)

*GEE models with the reason of discontinuation of the first TNFi as predictor (reference category: primary failure); all models adjusted for age and gender. OR in bold are statistically significant (p<0.05).

ASDAS CII was not achieved at 3 or 6 months; ii) Secondary failure if ASDAS CII was achieved at 3 or 6 months but lost in ≥1 visit during follow-up; iii) Adverse events; iv) Other (e.g. pregnancy, surgery). The response to the first TNFi at 3 and 6 months was compared to the response to the second TNFi at the same visits, adjusting for age and gender. The association between the reason of discontinuation of the first TNFi (predictor) and response the second TNFi over time was tested in generalized estimating equations (GEE) models, adjusted for age and gender.

Results: In total, 155 patients (58% male, mean age 41 (SD:11) years) were included, with a median follow-up time on the second TNFi of 1.5 years. Patients had a lower response to the second TNFi compared to the first TNFi according to the main outcome (ASDAS CII) at 3 months (41% vs 51%) and 6 months (35% vs 56%). There was no association between the reason to discontinue the first TNFi and response to the second TNFi as defined by ASDAS CII (Table). This association was present for the most stringent outcomes, namely ASDAS MI and ASDAS ID. Compared to patients who discontinued their first TNFi due to primary failure, patients were more likely to achieve ASDAS ID with the second TNFi when they discontinued their first TNFi due to secondary failure (OR: 5.3 [(95%CI: 1.4; 21.4]), adverse events (OR: 8.7 [2.4; 31.5]), or other reasons (OR: 7.2 [1.5; 34.2]).

Conclusion: In patients with axSpA, response to the second TNFi is worse compared to the first TNFi. The reason to discontinue the first TNFi seems to influence the response to the second TNFi. Patients with a secondary failure to the first TNFi have a better response to the second TNFi compared to those discontinuing the first TNFi due to a primary failure, particularly when response is defined by the most stringent outcomes.

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Week 16 results from COAST-W (NCT02696798) showed that ixekizumab (IXE) was superior to placebo (PBO) in improving the signs and symptoms of active radiographic axial spondyloarthritis (r-axSpA) in patients with prior inadequate response (IR) or intolerance to tumor necrosis factor inhibitors (TNFi).[1] Long-term efficacy and safety of IXE in this population have not been reported. The objective of the study was to assess the efficacy and safety of IXE through 52 weeks of continuous treatment in TNF-IR patients.

Methods: Adults with active r-axSpA (Assessment of SpondyloArthritis international Society [ASAS] criteria) and prior IR/intolerance to 1-2 TNFi were randomized 1:1:1 to PBO or 80 mg IXE every 2 (IXEQ2W) or 4 weeks (IXEQ4W). At Week 16, patients assigned to IXE continued with IXE, and patients assigned to PBO were randomized at 1:1 to IXEQ2W or IXEQ4W through Week 52.

Results: Of 212 patients initially randomized to IXE, 169 (80%) completed Week 52. Both IXE regimens led to sustained improvements in disease activity through 52 weeks (Table). Previously reported[1] improvements in function, objective inflammation, quality of life, health status, and overall function were sustained/further improved through 52 weeks. Patients initially randomized to PBO who switched to IXE rapidly achieved similar levels of improvement in signs and symptoms as patients initially randomized to IXE (Table). The frequency of treatment-emergent adverse events (AEs) through 52 weeks was similar between IXE regimens. In patients who received ≥1 IXE dose (N=305), 16 (5%) reported serious AEs and 23 (7.5%) discontinued due to AEs. Safety through 52 weeks of IXE was consistent with safety through 16 weeks.[1]

Conclusion: These are the first long-term data on the efficacy and safety of IXE in r-axSpA patients with prior IR/intolerance to TNFi. Both IXE regimens provided similar and sustained improvement in signs and symptoms through 52 weeks, with no unexpected safety signals. Patients who switched to IXE after initial PBO treatment rapidly achieved similar levels of improvement in signs and symptoms of r-axSpA as patients originally randomized to IXE. These findings indicate that in r-axSpA patients with prior IR/intolerance to TNFi, treatment with an alternative mode of action can be successful.

Table: Clinical improvement in signs and symptoms at Weeks 16 and 52 in patients treated with IXE for up to 52 weeks and in patients initially treated with PBO and then IXE from Week 16 onwards

Response, n (%) Nonresponder Imputation (Extended Treatment Period Population[a])	PBO/ All IXE (N=93)	IXEQ4W/ IXEQ4W (N=98)	IXEQ2W/ IXEQ2W (N=90)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Current treatments for PsA have proven effective in reducing patient (pt)-reported pain;[1,2] however, residual pain often remains. Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. This descriptive analysis evaluated the effect of tofacitinib, adalimumab and placebo on residual pain in pts with PsA whose inflammation was attenuated after 3 months of therapy.

Methods: Data were included from OPAL Broaden (NCT01877668), a randomized, double-blind, placebo-controlled Phase 3 trial of 12 months' duration in pts with PsA.[3] Pts were randomized to receive tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, adalimumab 40 mg subcutaneous injection every 2 weeks (Q2W), or placebo. This analysis assessed pts with 'residual pain' at Month (M)3. Residual pain was considered as pain in pts with complete attenuation of inflammation at M3, defined by a swollen joint count (SJC) of 0 and CRP levels < 6 mg/L. Pain was measured by a visual analog scale (VAS; 0 ["no pain"] – 100 mm ["most severe pain"]). Changes in pain from baseline to M3 and residual pain (VAS pain reported at M3) were assessed.

Results: Demographics and baseline disease characteristics have previously been reported in the primary study, and were generally similar between treatment groups.[3] At M3, 99/422 (23.5%) pts with PsA had achieved SJC of 0 and CRP < 6 mg/L. At M3, more tofacitinib-treated (tofacitinib 5 mg BID, n=23/107 [21.5%]; tofacitinib 10 mg BID, n=33/104 [31.7%]) and adalimumab-treated pts (n=30/106 [28.3%]) achieved SJC of 0 and CRP < 6 mg/L vs placebo (n=13/105 [12.4%]). Baseline pain appeared numerically higher in the tofacitinib treatment group (tofacitinib 5 mg BID = 54.7 mm; tofacitinib 10 mg BID = 58.4 mm) vs adalimumab (47.7 mm) and placebo (50.4 mm). In pts who achieved SJC of 0 and CRP < 6 mg/L at M3, improvements in pain from baseline to M3 appeared numerically greater in pts receiving tofacitinib vs those receiving placebo (Figure 1a). When considering absolute (residual) pain at M3, mean residual pain was similar across treatment groups (ranging from 22.7–29.2 mm; Figure 1b), despite a higher baseline pain in tofacitinib treatment groups.

Conclusion: Changes from baseline in pain and absolute pain at M3 suggest that in pts with PsA whose inflammation has been completely attenuated, tofacitinib might have an effect on residual pain not obviously attributable to inflammation. However, the sample population was small, and there were large standard deviations. To confirm these results and to understand the mechanisms by which tofacitinib may improve residual pain, a meta-analysis will be performed, using individual participant data from pts with rheumatic disease who have participated in tofacitinib randomized controlled trials.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ixekizumab (IXE) is a high-affinity monoclonal antibody that specifically targets IL-17A. Pooled safety data from IXE studies in moderate-to-severe plaque psoriasis (PsO) and psoriatic arthritis (PsA) have been reported previously.[1, 2] The purpose of this analysis is to report integrated safety results of IXE collected as of March 21, 2019.

Methods: All safety data from controlled and uncontrolled trials were integrated from 14 PsO and 4 PsA studies. The longer-term follow-up was 5 years for PsO trials and 3 years for PsA trials. Safety data were integrated from an all IXE exposure-safety population (defined as all patients receiving ≥1 dose of IXE) by indication. We report exposure-adjusted incidence rates (IRs) per 100 patient-years (PY) at 1-year intervals (over the entirety of exposure) for up to 5 years for adverse events (AEs). Major adverse cerebro-cardiovascular events (MACE) and inflammatory bowel disease (IBD) were adjudicated by an external adjudication committee.

Results: A total of 6091 (17499.3 PY) patients from PsO trials and 1401 (2228.6 PY) patients from PsA trials were analyzed. The Table summarizes safety results for both treatment populations over 1-year intervals. Overall, the IRs for treatment-emergent AEs (TEAEs), serious AEs, and serious infections remained stable with continued IXE exposure, whereas the IRs of patients reporting infections or injection site reactions decreased over time. The most common TEAEs in PsO and PsA were nasopharyngitis, upper respiratory tract infection, and injection-site reaction; most were reported as mild or moderate in severity Opportunistic infections were limited to oral and esophageal candidiasis and localized herpes zoster. Over the entirety of exposure in PsO and PsA studies, respectively, IRs for AEs leading to study drug discontinuation (2.8 and 5.1), serious SAE (5.4 and 6.0) and death (0.2 and 0.3) were reported. The rate of suicide ideation or behavior was 0.1in PsO studies and less than 0.1 in PsA studies. There were no completed suicides in both PsO and PsA studies. In both PsO and PsA studies, IRs for safety topics of special interest in PsO and PsA included, IBD (adjudicated; 0.2 and 0.1), depression (1.2 and 1.7), non-melanoma skin cancer (0.3 and 0.4), other malignancies (0.5 and 0.3) and MACE (0.5 and 0.5), respectively.

Conclusion: The results support a favorable and consistent long-term safety profile of IXE treatment in patients with moderate-to-severe PsO (17499.3 PY) or active PsA (2228.6 PY).

Table: Exposure-adjusted incidence rate of TEAEs over time by 1-year interval of exposure to ixekizumab

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) is a chronic inflammatory condition. Pain, stiffness, and fatigue are reported as the most troubling symptoms by 70–80%, 20–40%, and 50–60% of patients (pts) with AS, respectively.[1-5] Early and sustained relief of these symptoms are essential for effective AS management.[4,6] Secukinumab (SEC) provided sustained relief in pain and fatigue in AS pts over 2 years in the MEASURE 2 study.[7] Here we report the effect of subcutaneous (s.c.) SEC 150mg on key clinical symptoms (pain, morning stiffness, and fatigue) in pts with AS over 208 weeks (wks) in the MEASURE 2 study.

Methods: The MEASURE 2 study design has been reported previously. This post hoc analysis assessed the mean change from baseline at Week (Wk) 208 in total and nocturnal back pain scores (by visual analog scale [0–100]; ASAS outcome component), overall level of spinal pain (neck, back, or hip) from BASDAI score, and morning stiffness (overall level; mean of question 5 and 6 of BASDAI score). Additionally, the SF-36 physical component summary (PCS) score, overall level of fatigue (BASDAI question 1), FACIT-Fatigue score, and pts meeting minimal clinically important difference (MCID) criteria across multiple clinical domains were also assessed. Data are shown for pts originally randomized to SEC 150mg and placebo. Data are reported as observed for overall population and by prior anti-TNF therapy status (naïve vs inadequate response/intolerance [IR]).

Results: Baseline clinical characteristics were generally comparable across the treatment groups SEC 150mg (N=72) and placebo (N=74); total mean back pain score was 67.7±17.79, nocturnal back pain score (0–100 mm scale) was 64.9±19.58, and morning stiffness was 6.5±2.11. SEC 150mg-treated pts reported rapid and early reductions in pain scores by Wk 4, which were sustained through Wk 208 (Table). Improvements with SEC 150mg were also reported in nocturnal back pain, morning stiffness, physical function (SF-36 PCS) and fatigue (overall level of fatigue and FACIT-Fatigue) as early as Wk 4, which were sustained at Wk 208 (Table). A higher proportion of SEC 150mg-treated pts met MCID criteria at Wk 16 vs placebo across multiple clinical domains, which was sustained or further improved through Wk 208. Improvements were observed in both anti-TNF-naïve and -IR pts, with a greater magnitude of improvement in anti-TNF-naïve pts.

Conclusion: SEC 150mg was associated with rapid and clinically meaningful improvement in total back pain and nocturnal back pain, morning stiffness, and fatigue, with improvements sustained over 4 years of treatment.

Table: Summary of results					
Endpoints, mean change ± SD	Treatment group	Wk 4	Wk 16	Wk 104	Wk 208
Pain					
Total back pain	SEC 150 mg	–25.86 ± 26.19	–29.0 ± 25.08	–36.37 ± 28.08	–32.81 ± 29.17
	Placebo	–10.47 ± 22.04	–12.22 ± 25.79	N/A	N/A
Nocturnal back pain	SEC 150 mg	–28.99 ± 26.35	–32.57 ± 27.51	–38.59 ± 28.51	–35.90 ± 28.05
	Placebo	–5.70 ± 26.20	–9.70 ± 26.85	N/A	N/A
Overall level of spinal pain	SEC 150 mg	–2.32 ± 2.39	–2.54 ± 2.55	–3.55 ± 2.43	–3.07 ± 2.52
	Placebo	–1.05 ± 1.89	–1.28 ± 2.36	N/A	N/A
Morning stiffness					
Overall level	SEC 150 mg	–2.24 ± 2.62	–2.46 ± 2.91	–3.57 ± 2.76	–3.32 ± 2.88
	Placebo	–0.96 ± 2.31	–0.86 ± 2.28	N/A	N/A
Physical function					
SF-36 PCS	SEC 150 mg	5.30 ± 6.86	6.93 ± 7.10	8.89 ± 8.0	8.15 ± 8.48
	Placebo	2.56 ± 4.98	2.02 ± 6.04	N/A	N/A
Fatigue					
Overall level	SEC 150 mg	–1.77 ± 2.43	–2.12 ± 2.38	–3.42 ± 2.44	–3.08 ± 2.38
	Placebo	–0.99 ± 1.92	–1.12 ± 2.05	N/A	N/A
FACIT-Fatigue	SEC 150 mg	6.39 ± 8.93	9.35 ± 9.56	11.18 ± 9.96	11.09 ± 10.42
	Placebo	2.02 ± 7.06	3.65 ± 8.30	N/A	N/A

Observed data are presented through Wk 208; SEC 150 mg, N = 72 and placebo, N = 74
n = 71, 67, 59, and 57 pts with a value at both baseline and Wks 4, 16, 104, and 208, respectively, in the SEC 150 mg group; n = 70 and 64 pts with a value at both baseline and Wks 4 and 16, respectively, in the placebo group; N/A, not applicable; N, number of randomized pts; n, number of evaluable pts; SD, standard deviation; SEC, secukinumab; Wk, week

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) and psoriatic arthritis (PsA) treatment includes biologics, prescribed on a long-term basis. As persistence data from real-world practice are limited, the current study analyzes persistence with etanercept treatment for up to 5 years in AS or PsA patients in Germany.

Methods: Patients diagnosed with AS or PsA with a first etanercept bio-original (ETNBo) prescription recorded between 1 January 2008 and 31 December 2012 were retrospectively identified in German Statutory health insurance claims data (ICD-10 code M45 and L40.5, respectively) and followed until 31 December 2015 or until the end of their record. The index date was defined as the first ETNBo prescription after an etanercept-free period of ≥12 months.

Treatment persistence was estimated as days between index date and discontinuation, defined as a gap of ≥90 days after last etanercept prescription. Analyses were also stratified by whether or not the patients were bio-naive, i.e. having no record of initiating a biologic in the 12 months before index. Persistence was evaluated using Kaplan-Meier analysis. Differences between strata were compared using a log-rank test.

Results: We identified 340 patients diagnosed with AS (mean age at index: 44 years [SD 12], 64% male) and 415 with PsA (49 years [SD 12], 51% male). Most patients were considered bio-naïve (AS: 72%; PsA: 73%).

The median etanercept persistence for AS was 14 months (95%CI: 10–17; IQR: 5–40) and for PsA 13 months (95%CI: 11–17; IQR: 4–43). Persistence for AS ranged from 52% (95%CI: 47%–57%) at 1 year to 16% (95%CI: 12%–20%) at 5 years, and for PsA from 51% (95%CI: 46%–55%) at 1 year to 18% (95%CI: 14%–22%) at 5 years.

For AS, the median etanercept persistence was similar between bio-naïve patients (14 months [95%CI: 10–19) and those with biologic use in the 12 months prior to etanercept (13 months [95%CI: 8–18]) (log-rank test, p-value=0.528). For PsA, median persistence in bio-naïve patients was 15 months (95%CI: 11–19) versus those receiving a biologic in the 12 months pre-index (9 months [95%CI: 5–13]) (log-rank test, p-value=0.065).

Conclusion: This is one of the longest analyses on the real-world persistence of a biologic in AS and PsA. Among new etanercept users in AS and PsA, a quarter of patients were persistent with etanercept for more than 40 months. These results are similar to recent reports from analysis of US claims data[1,2]; however future research should explore clinical factors influencing persistence over such long time periods.

Disease cohort	Stratification	Estimates	1-year	2-year	3-year	4-year	5-year	Median

MRI Set. [a] Wk 0 CZP patients only. [b] All CZP-treated patients, including those switching from PBO to CZP treatment at Wks 16/24. [c] Unless stated otherwise. [d] The number of observed VEs FL− at BL recorded as FL+. BL: Baseline; CZP: certolizumab pegol; INFL: inflammatory lesion; MMRM: mixed model repeated measures; PBO: placebo; SE: standard error; VE: vertebral edge; wk: week.

eton erosions, visible on MRI T1 sequences, are post-inflammatory changes that contribute significantly to models predicting new bone formation.[2] It has previously been assumed that resolution of inflammatory lesions (INFLs) in anti-TNF treated axSpA pts may be associated with an increase in FLs.[3,4] RAPID-axSpA was a long-term study in pts with radiographic (r)-axSpA / ankylosing spondylitis or non-radiographic (nr)-axSpA treated with certolizumab pegol (CZP), which rapidly suppressed active inflammation of the spine, with pts showing limited spinal radiographic progression over 4 years.[5] Here, the incidence and association of active inflammation and chronic lesions (FLs, sclerosis, and erosions) in the spine of CZP treated axSpA pts over 4 years is reported.

Methods: RAPID-axSpA (NCT01087762) was double-blind and placebo (PBO)-controlled to Week (Wk) 24, dose-blind to Wk 48, and open-label to Wk 204. Baseline (BL) CZP-randomized pts (200 mg every 2 weeks [Q2W] or 400 mg Q4W) continued their assigned dose throughout; BL PBO-randomized pts received CZP from Wk 16 (non-responders) or Wk 24. Blinded spinal MRI scans at BL, Wk 12, 48, 96, and 204 were assessed by 2 central readers to evaluate the presence/absence of active INFLs (Short Tau Inversion Recovery [STIR] sequence), FLs, sclerosis and erosions (T1 sequence) in vertebral edges (VEs) (present if recorded so by both readers). AxSpA pts with a valid BL and ≥1 post-BL assessment were included. Mean pt level lesion counts were estimated from mixed models with repeated measures (MMRM) fitted on observed data from CZP or PBO pts. Associations between INFLs and FLs at the VE level for all pts were described using cross-tabulations.

Results: Of 325 randomized pts, 136 were eligible for these analyses. In BL CZP pts (n=89), active INFLs were reduced, and FL counts only slightly increased by Wk 12; both were sustained at a low level to Wk 204 (**Table A**). Very few VEs with erosions and sclerosis were observed at BL, and no changes in their frequency were observed to Wk 204 (**Table A**). Over 204 wks, the risk of developing new FLs was greater in VEs with vs without INFLs at BL, regardless of changes to INFLs in these VEs post-BL (**Table B**). At BL the prevalence of FLs was greater in pts with >3 vs ≤3 years' disease duration and more new FLs developed in pts with >3 years disease duration (data not shown).

Conclusion: Long-term CZP treatment in axSpA pts was associated with rapid and sustained reduction in active inflammation, no increase in sclerosis and erosions, and a negligible increase in FLs in VEs over 4 years. More FLs developed in VEs in pts with >3 years disease duration and with INFLs at BL than without, which was not affected by resolution of INFLs, providing evidence of the importance of early treatment in pts with active axSpA.

[a] Due to the large proportion (66%) of PBO pts switching to open-label CZP treatment, both LOCF and OC data are presented for Wk 52; [b] Based only on employed patients at each visit; [c] Does not include work days missed counted in previous question; [d] 0-10 scale, 0=no interference, 10=complete interference. CZP: certolizumab pegol 200 mg Q2W; LOCF: last observed carried forward; OC: observed case; NBBM: non-biologic background medication; PBO: placebo; wk: week; WPS: Work Productivity Survey

Background/Purpose: Patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA) report substantial impairment of productivity and daily activities due to the burden of their disease, similar to pts with ankylosing spondylitis.[1,2] Certolizumab pegol (CZP) treatment has been shown to significantly improve work and household productivity and social participation compared to placebo (PBO) in active nr-axSpA pts up to 24 weeks (wks).[1] Improvements were maintained over 4 years of CZP treatment in RAPID-axSpA.[3] The C-axSpAnd study demonstrated the impact of CZP in combination with non-biologic background medication (NBBM) on signs and symptoms of nr-axSpA compared to PBO + NBBM.[4] Here, we report work and household productivity and social participation from C-axSpAnd.

Methods: C-axSpAnd (NCT02552212) is a 3-year, phase 3, multicenter study including a 52 wk double-blind, PBO-controlled period (completed). Pts had active nr-axSpA, objective signs of inflammation (elevated CRP and/or positive MRI of the sacroiliac joint), and previous inadequate response to ≥2 NSAIDs and were randomized 1:1 to CZP (400 mg at Wks 0, 2, and 4, then 200 mg every 2 wks) + NBBM or PBO + NBBM. The validated arthritis-specific Work Productivity Survey (WPS) assessed the impact of nr-axSpA on work and household productivity and social participation.[5] Missing data were imputed using last observation carried forward (LOCF) post hoc in the Full Analysis Set (FAS, all randomized pts who received ≥1 dose of study medication).

Results: 317 pts were randomized (CZP + NBBM: 159; PBO + NBBM: 158). Mean age at baseline (BL) was 37.3 years and 51.4% of pts were female. At BL, the majority of pts (CZP + NBBM: 124 [77.8%]; PBO + NBBM: 123 [78.0%] pts)

were employed and reported a mean 3.7 (CZP + NBBM) and 3.5 (PBO + NBBM) work days missed per month due to their disease (**Table**). By Wk 12, work absenteeism substantially improved in the CZP + NBBM group compared with the PBO + NBBM group (0.9 vs 2.1 days missed per month, LOCF), with further improvements at Wk 52 (0.3 vs 2.0 days missed per month, LOCF). Between Wk 12 and Wk 52, a majority of PBO pts (104 [65.8%]) switched to open-label CZP, impacting imputed outcomes at Wk 52. Despite this, similar patterns of improvement following CZP + NBBM treatment were seen for absenteeism, work days with impaired productivity, household days with missed/reduced productivity and social participation between imputed and observed case data (**Table**). Improvements were similar between male and female pts (data not shown).

Conclusion: CZP treatment resulted in improvements in work and household productivity and social participation for nr-axSpA pts as early as Wk 12 compared to background medication only, with benefits maintained to Wk 52.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Pain, fatigue, morning stiffness and impaired sleep are some of the main symptoms contributing to reduced quality of life (QoL) in patients (pts) with non-radiographic axial spondyloarthritis (nr-axSpA).[1] Additionally, pts who are poor sleepers have been shown to have higher disease activity, fatigue scores and nocturnal back pain.[2] Certolizumab pegol (CZP) treatment has demonstrated improvements in multiple manifestations of nr-axSpA disease, including pt-reported outcomes (PROs) and QoL.[3,4] We report PROs for nr-axSpA pts treated with CZP or placebo (PBO) from the C-axSpAnd study – the first 52-week (Wk) PBO-controlled study to investigate the efficacy of an anti-TNF agent in a population with active nr-axSpA and objective signs of inflammation (elevated CRP and/or MRI positive).

Table: Clinical PROs in nr-axSpA patients treated with PBO or CZP

Mean (SD)	Baseline		Wk 12		Wk 48			
	PBO	CZP	PBO LOCF	CZP LOCF	PBO LOCF	CZP LOCF	PBO OC	CZP OC
	(n=158)	(n=159)	(n=158)	(n=159)	(n=158)	(n=159)	(n=52)	(n=124)

	(n=158)	(n=159)	(n=158)	(n=159)	(n=158)	(n=159)	(n=51)	(n=121)
Nocturnal spinal pain NRS	6.6 (2.1)	6.6 (2.3)	5.6 (2.6)	3.4** (2.7)	5.4 (2.8)	2.7** (2.7)	3.5 (2.4)	2.0** (2.1)
BASDAI: Fatigue [b]	7.2 (1.4)	7.1 (1.6)	6.1 (2.2)	4.4** (2.4)	5.9 (2.3)	3.7** (2.7)	4.0 (2.0)	3.1* (2.3)
BASDAI: Morning stiffness [c]	6.7 (1.8)	6.9 (1.8)	5.5 (2.4)	3.6** (2.4)	5.2 (2.6)	2.9** (2.4)	3.2 (1.9)	2.3* (2.1)

[a] Final assessments for Sleep Problems Index I and II were conducted at Wk 48 - a higher score indicates improved sleep; [b] BASDAI Q1; [c] Average of BASDAI Q5+Q6. For LOCF, if there were missing data at the time point of interest, the last available double-blind post baseline measurement was carried forward to that time point. BASDAI: Bath Ankylosing Spondylitis Disease Activity Index; CZP: certolizumab pegol; LOCF: last observation carried forward; nr-axSpA: non-radiographic axial spondyloarthritis; NRS: numerical rating scale; MOS: Medical Outcomes Study; OC: observed case; PBO: placebo; PRO: patient-reported outcome; SD: standard deviation; Wk: week. P-values (for CZP vs PBO mean change from baseline at Wk 12 and Wk 52) of <0.05 or <0.001 are denoted by * and **, respectively, and were derived from an ANCOVA model where response (dependent variable) is the change from baseline, with baseline score as a fixed-effect covariate and treatment group, region, and MRI/CRP classification as fixed effect categorical factors (independent variables).

Methods: C-axSpAnd (NCT02552212) is a 3-year, phase 3, multicenter study including a 52-Wk double-blind (DB), PBO-controlled period (completed); patients who had an inadequate response to ≥2 non-steroidal anti-inflammatory drugs were randomized 1:1 to PBO or CZP (400 mg at Wks 0/2/4, then 200 mg every 2 wks).[3] Clinical PROs collected included: Sleep Problems Index scores I (6 items) and II (9 items) from the Medical Outcomes Study Sleep Scale (which assesses sleep disturbance, adequacy, somnolence, quantity, snoring, and awakening short of breath or with a headache),[5] nocturnal spinal pain (numerical rating scale [NRS]), fatigue (BASDAI Q1), and morning stiffness (average of BASDAI Q5 and Q6). Post-hoc analyses of minimal clinically important differences (MCID [≥1-point improvement]) for fatigue and nocturnal spinal pain were conducted.[6] Variables were analyzed using an ANCOVA model including baseline score as a covariate and fixed effects for treatment group, region and MRI/CRP classification. All p-values were nominal. Missing values or data at time points following the discontinuation of the DB study treatment were imputed using last observation carried forward.

Results: 317 pts with nr-axSpA were randomized to CZP (n=159) or PBO (n=158); 54 (34%) and 125 (79%) patients treated with PBO or CZP, respectively, completed Wk 52. Pts treated with CZP showed greater improvements (indicated by higher scores) in Sleep Problems Index II scores vs PBO-treated pts at Wk 12 (mean change from baseline: 4.8 [CZP] vs 2.2 [PBO]; p< 0.001). Improvements were also seen in other clinical PROs (**Table**). By Wk 12, greater proportions of pts treated with CZP vs PBO experienced at least a MCID response in fatigue (85.4% vs 57.6%, respectively) and nocturnal spinal pain (82.8% vs 58.9%, respectively); results were sustained through Wk 52.

Conclusion: Nr-axSpA patients treated with CZP showed substantial improvements in sleep quality and other clinical outcomes important to patients; future analyses of these data will explore associations between sleep quality and other clinical PROs.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS), a chronic inflammatory disease involving the sacroiliac joints and spine, is associated with pain, stiffness, disability, and reduced quality of life.[1,2] Therefore, prompt diagnosis and treatment of patients (pts) is critical. In this post hoc analysis, we assessed the impact of age and disease duration (DD; defined as time since diagnosis) on responses in pts with AS treated with secukinumab (SEC) or placebo (PBO) in the phase 3 MEASURE trials.

Table 1. Baseline Characteristics by Age Group of Patients Included From the Phase 3 MEASURE Studies

	Secukinumab 300 mg, IV LD (n = 76)	Secukinumab 150 mg, IV LD (n = 199)	Secukinumab 150 mg, SC LD (n = 188)	Placebo (n = 389)

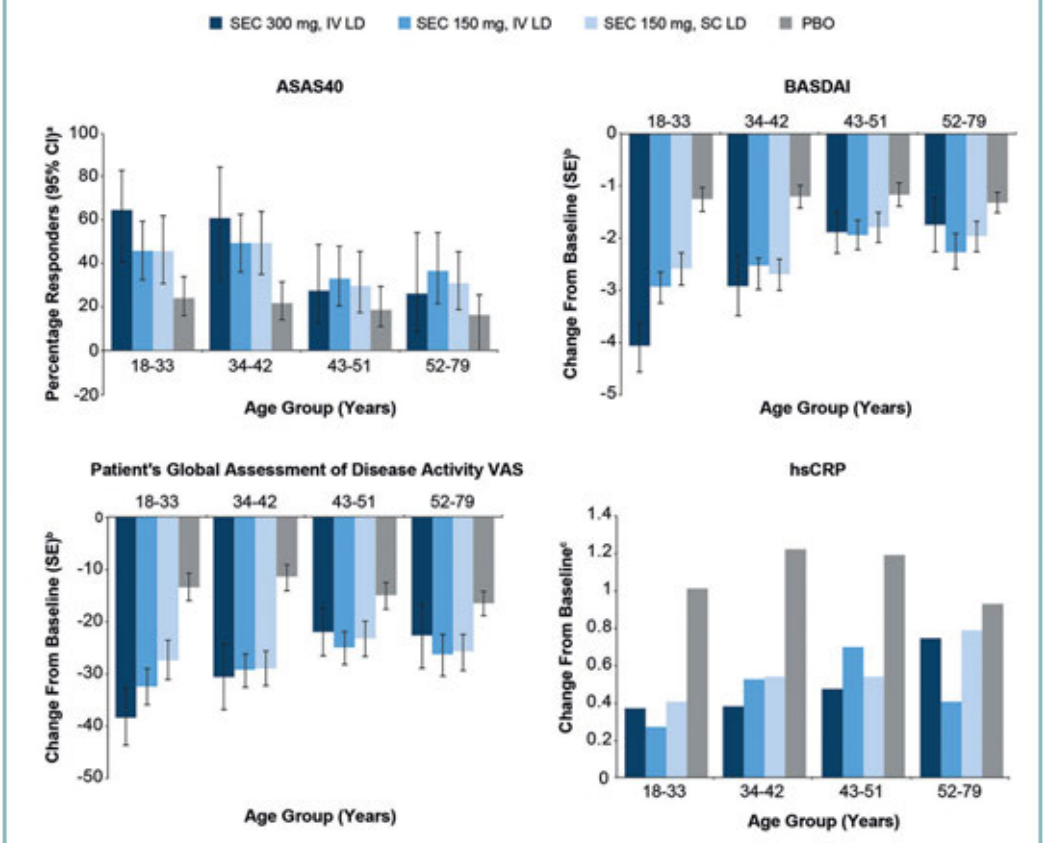
AS, ankylosing spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; hsCRP, high-sensitivity C-reactive protein; IV, intravenous; LD, loading dose; SC, subcutaneous; SD, standard deviation; TNF, tumor necrosis factor.

Figure 1. Response Between Different Age Groups in ASAS40, BASDAI, Patient's Global Assessment of Disease Activity VAS, and hsCRP at Wk 16

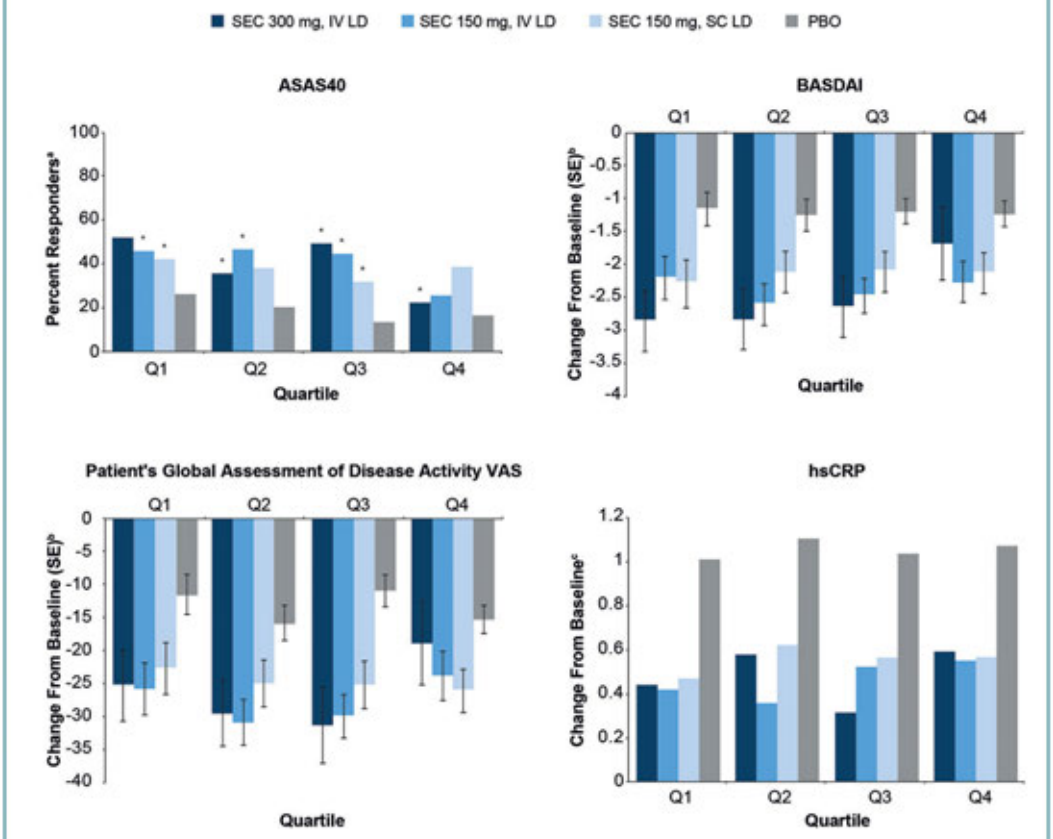


ASAS, Assessment in Ankylosing Spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CI, confidence interval; hsCRP, high-sensitivity C-reactive protein; IV, intravenous; LD, loading dose; LSM, least squares mean; MMRM, mixed-model repeated-measures; PBO, placebo; SC, subcutaneous; SE, standard error; SEC, secukinumab; VAS, visual analogue scale.
[a] Observed data. Full analysis set. [b] MMRM analysis. Within group differences. Full anaysis set. [c] MMRM analysis. Within group differences. Full analysis set. Exponentially transformed LSM, geometric mean ratio of post-baseline/baseline. A value <1 indicates a reduced CRP.

Methods: Pts with active AS from MEASURE 1 (M1; NCT01358175), 2 (M2; NCT01649375), 3 (M3; NCT02008916), and 4 (M4; NCT02159053) randomized controlled trials (RCTs) were included.[3-8] Pts received subcutaneous (SC) SEC 300 or 150 mg with an intravenous (IV) loading dose (M1, M3), SEC 150 mg with an SC loading dose (M2, M4), or PBO (M1-4). Pooled data from different RCTs (IV or SC loading) may be considered heterogeneous and are generalizable to a wider patient population. Data were pooled from M1-4 at the end of the 16-wk treatment period, and responses were analyzed according to 4 age groups: 18-33, 34-42, 43-51, and 52-79 y. Responses were assessed using outcome measures such as ASAS20/40, BASDAI, BASMI, hsCRP, SF-36 (PCS/MCS), and disease activity/back pain instruments. Similar analyses assessed treatment responses by quartiles of time since diagnosis (0-0.97 y [Q1], 0.98-3.47 y [Q2], 3.49-9.79 y [Q3], and 9.88-50.19 y [Q4]). Time since diagnosis was used as a surrogate marker of DD as symptom duration was not collected. No adjustment was made for multiple comparisons.

Results: 852 pts were included in this analysis (SEC, n = 463; PBO, n = 389) (Table 1); 95.5% completed 16 wk of treatment. Baseline demographics were similar across trials (Table 1). Mean time since AS diagnosis differed across age groups: 3.2 y in the 18-33 group and 11.3 y in the 52-79 group. The proportion of TNF inhibitor–naive pts was higher in the 18-33 group vs the 52-79 group (74.4% vs 65.0%). At Wk 16, greater improvements in ASAS20/40, BASDAI, SF-36, hsCRP, and VAS disease activity/back pain scores were reported in younger (18-33 and 34-42) vs older age groups (43-51 and 52-79) treated with SEC (Fig. 1). When stratified by DD, there was a higher proportion of TNF inhibitor–naive pts in Q1 vs Q4 (92.0% vs 61.8%), and pts with a shorter DD (Q1-Q2) had greater improvements in ASAS40; reductions in hsCRP levels were greatest in Q1 pts (Fig. 2).

Figure 2. Differences in Response Between Disease Duration Groups in ASAS40, BASDAI, Patient's Global Assessment of Disease Activity VAS, and hsCRP Scores at Wk 16



ASAS, Assessment in Ankylosing Spondylitis; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; CI, confidence interval; hsCRP, high-sensitivity C-reactive protein; IV, intravenous; LD, loading dose; LSM, least squares mean; MMRM, mixed-model repeated-measures; PBO, placebo; SC, subcutaneous; SE, standard error; SEC, secukinumab; VAS, visual analogue scale.
[a] Nonresponder imputations. Full analysis set. * $P < .05$. [b] MMRM analysis. Within group differences. Full analysis set. [c] MMRM analysis. Within group differences. Full analysis set. Exponentially transformed LSM, geometric mean ration of post-baseline/baseline. A value < 1 indicates a reduced CRP.

Conclusion: SEC treatment led to rapid and sustained improvements in all outcome measures at Wk 16, regardless of age or DD. Older pts reported greater burden of disease. A trend toward higher responses was evident in those with shorter DD. Younger pts had better responses, likely due to shorter DD and a higher proportion being biologic naive. These results emphasize the importance of early AS treatment to delay disease progression and improve pt outcomes.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Axial spondyloarthritis (axSpA) is an inflammatory condition affecting sacroiliac joints and axial skeleton, characterized by fatigue, spinal pain, and sleep disturbances that negatively affect patient health-related quality of life.[1] Ixekizumab (IXE) has demonstrated efficacy in treatment of radiographic axial spondyloarthritis (r-axSpA) in both biologic disease-modifying antirheumatic drug (bDMARD) naïve and tumor necrosis factor inhibitor (TNFi) experienced patients.[2,3] The purpose of this analysis was to evaluate the impact of IXE on fatigue, spinal pain and sleep pattern in patients with r-axSpA over 52 weeks.

Methods: COAST-V and COAST-W were Phase 3 randomized controlled trials (RCTs) conducted to evaluate the efficacy and safety of IXE in bDMARD-naïve and TNFi-experienced patients with r-axSpA, respectively. In both RCTs, patients were randomized to receive IXE 80mg once every two weeks (IXEQ2W), IXE 80 mg once every 4 weeks (IXEQ4W), active reference arm (adalimumab 40 mg [ADAQ2W]) in COAST-V or placebo (PBO) up to Week 16. Patients initially randomized to IXE continued on the same regimen up to Week 52. Patients on PBO were re-randomized to either IXEQ2W or IXEQ4W at Week 16. After a washout period of 6 weeks, patients on ADA were switched to either IXEQ2W or IXEQ4W regimens and received their first IXE dose at Week 20. Fatigue Numeric Rating Scale (NRS) and Jenkins Sleep Evaluation Questionnaire (JSEQ) data were collected at baseline, Weeks 8, 16, 36 and 52. Patient global assessments of disease activity, spinal pain and spinal pain at night were collected at baseline and each post-baseline visit to Week 52. Mean changes from baseline up to Week 16 were analyzed using mixed effects model of repeated measures (MMRM). After Week 16, changes from baseline during extended treatment period were summarized as raw means after imputing the missing data using modified Baseline Observation Carried Forward (mBOCF).

Results: At Week 52, IXEQ2W and IXEQ4W treatments continued to improve fatigue, patient global assessment of disease activity, spinal pain and sleep in bDMARD-naive and TNFi-experienced patients (Table 1). Significant reductions in fatigue and spinal pain at night were reported as early as Week 8 and Week 1 respectively, in patients treated with IXE compared with PBO. Improvements in these parameters at Week 16 with both IXE arms were maintained up to Week 52 (Figure 1).

Conclusion: Fatigue, spinal pain, and sleep improved with IXE treatment over 52 weeks in both biologic-naïve and TNFi-experienced patients with r-axSpA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ustekinumab (UST) is a new biological Disease-modifying AntiRheumatic Drug (bDMARD) available in psoriatic arthritis (PsA), targeting respectively IL12-23. Real-world data are missing for this drug on the contrary to TNF inhibitors. Median drug survival of TNF inhibitors is between 10 and 12 months according to the most recent studies (1).There are only few studies with a low number of patients in UST. Studying drug survival in PsA is important, since new therapies have been launched such IL-17 inhibitors or apremilast.

Methods: This is a retrospective, national, multicentric, non-sponsored by any pharmaceutical company study from patients suffering from PsA (CASPAR criteria or diagnosis confirmed by the rheumatologist) from July 2011 to March 2019. UST has been launched in October 2014. Drug survival was defined as the time from initiation to discontinuation (stop/switch) of bDMARDs. Kaplan-Meier survival curves and Cox-regression analyses [hazard ratios (HR) and 95% confidence intervals (CIs)] were used adjusting for patient demographics, disease characteristics, corticosteroid therapy, co-therapy with methotrexate, previous line of bDMARDs posology of UST and switch to 90 mg every 3 months when patients were at 45 mg every 3 months. Reasons of discontinuation were collected and pooled as primary failure, secondary failure and adverse events. Primary inefficacy was defined as an insufficient response to

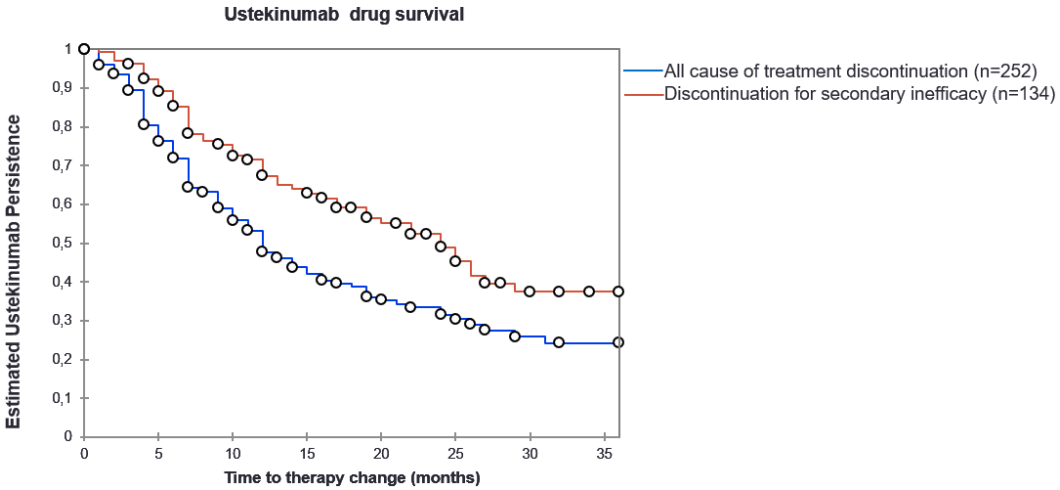

Figure. Drug survival of ustekinumab in psoriatic arthritis

treatment during the six months after the initiation. Secondary inefficacy was defined as a loss of response to treatment after an initial six-month response.

Results: 252 patients were included with a mean follow-up ≥ 6 months: 183 patients satisfy CASPAR. At baseline, the mean age was 49.2 (11.2) years old. 58% of patients were women. 49% of patients were non-smoker. The body mass index was 28.8 (6.3) kg/m². The disease duration was 10.2 (8.9) years. 44% of patients presented axial and peripheral form. 97% of patients presented psoriasis. The mean Charlson Index was 1.3 (1.5). Patients were bDMARDs-naïve in 22%, had a previous bDMARDs in 16% and more than two bDMARDs in 54% and had co-therapy with methotrexate in 39% and 27% of patients received corticosteroid therapy . Patients had a switch to 90 mg every 3 months in 10%. The mean DAS28-CRP was 3.88 (1.3) and the mean CRP was 27.5 (42.7) mg/L. The median drug survival for UST was 12 months (95%CI: 10-15) (Fig1). Baseline high CRP levels and satisfying CASPAR criteria were associated with a favorable drug survival for UST, respectively (HR=1.007, 95%CI 1.002–1.012 and HR=5.56, 95%CI 2.79-11.13), whereas disease duration and nail psoriasis were associated with an unfavorable one, respectively (HR=0.965, 95%CI 0.00–0.99 and HR=0.52, 95%CI 0.00-0.84). 14 patients under UST stopped their treatment due to side effects.

Conclusion: This real-world study for drug survival on PsA is among the studies with the largest number of patients for UST. Drug survival of UST seems similar to the survival of TNF inhibitors (1).

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Enteropathic spondylitis (eSpA) is younger brother of spondyloarthritis, and the retention rate of biological DMARD in eSpA was not yet clear. The objective of this study was to assess anti-TNF response and retention rate in enteropathic spondylitis patients.

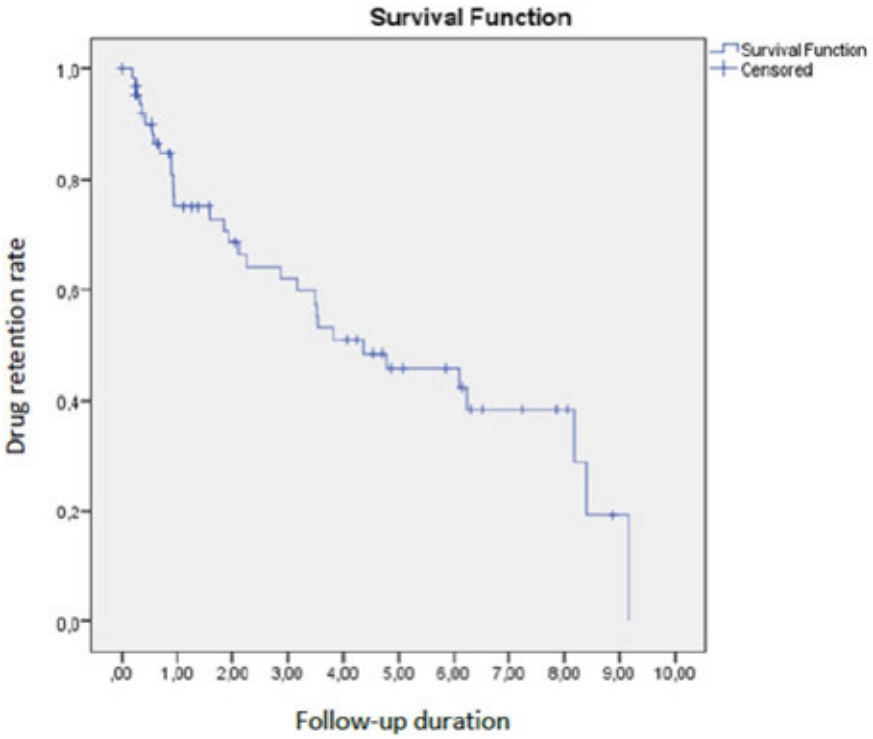
Methods: HUR-BIO (Hacettepe University Rheumatology Biologic Registry) is a prospective, single center database of biological treatments since 2005. Sacroiliitis was defined as modified New York criteria or based on magnetic resonance imaging. Enteropathic spondylitis was defined as inflammatory bowel disease (IBD) and radiological sacroilitis with inflammatory back pain/spine symptoms. Demographic, clinical, laboratory, therapeutic data and imaging features were collected from this database: age, gender, age at disease onset, disease duration, type of IBD. Baseline disease activity before the first biologic DMARD initiation was assessed with BASDAI, BASFI, VAS-patient global assessment, ESR and CRP. Retention rates for first biologic DMARDs were assessed by Kaplan-Meier survival analysis. Anti-TNF response was defined as BASDAI50% improvement, ASAS partial remission, and ASAS 20% improvement.

Results: HUR-BIO SpA registry included 2576 SpA patients, and 90 (3.5%) patients had enteropathic arthritis (EA). Sixty four (71.1%, 47% female) of 90 patients had sacroiliitis and those patients enrolled into analysis. Mean age was 45.0 ± 12.0 years, mean disease duration was 9.2 ± 6.9 years. Of the 64 eSpA, IBD type was ulcerative colitis (UC) in 34 (53%) patients, Crohn's disease (CD) in 30 (47%) patients. Initial bDMARDs were infliximab 26 (40.6%), adalimumab 24 (37.5%), etanercept 9 (14.1%), golimumab 4 (6.3%) and certolizumab 1 (1.6%). Forty one (64.0%) out of 64

Table 1: Anti-TNF response in enteropathic spondylitis

	First Control Visit	Last Control Visit
BASDAI50% response n (%)	23 (48)	20 (40)
ASAS partial remission	18 (38)	18 (36)
ASAS 20% improvement	12 (25.5)	16 (32)
First control visit performed 4.9 ± 3.9 months later, available for 47 patients. Control visit performed 54 ± 39 months later and available for 50 patients.		

Figure 1: Retention rate for first biological DMARD



eSpA patients used concomitant cDMARDs. Baseline disease activity parameters were as follows; BASDAI 5.7 ± 2.1, BASFI 4.3 ± 2.7, patient global assessment-VAS 6 .0 ± 1.9, ESR 38 ± 27 mm/hour, and CRP 3.2 ± 3.6 mg/dl. Patients were followed mean 54 ± 39 months. First control visits were performed 4.9 ± 3.9 months later. Anti-TNF response rate were shown in table 1. The cumulative retention rate of the TNF inhibitors at 12-, 24-, 36-, 48-, and 60-months of follow-up visits were 75.1, 68.6, 62.0, 50.9, and 45.8%, respectively (Figure 1). No differences were identified according to the use of concomitant DMARDs (p = 0.393) or IBD type (p=0.144).

Conclusion: Retention rate for first TNF inhibitor was not different from other SpA subtypes in HUR-BIO registry (1). IBD subtype or concomitant synthetic DMARDs did not have effect on the retention rate of anti-TNF treatments. ASAS partial remission was achieved only one third of eSpA patients during follow-up.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

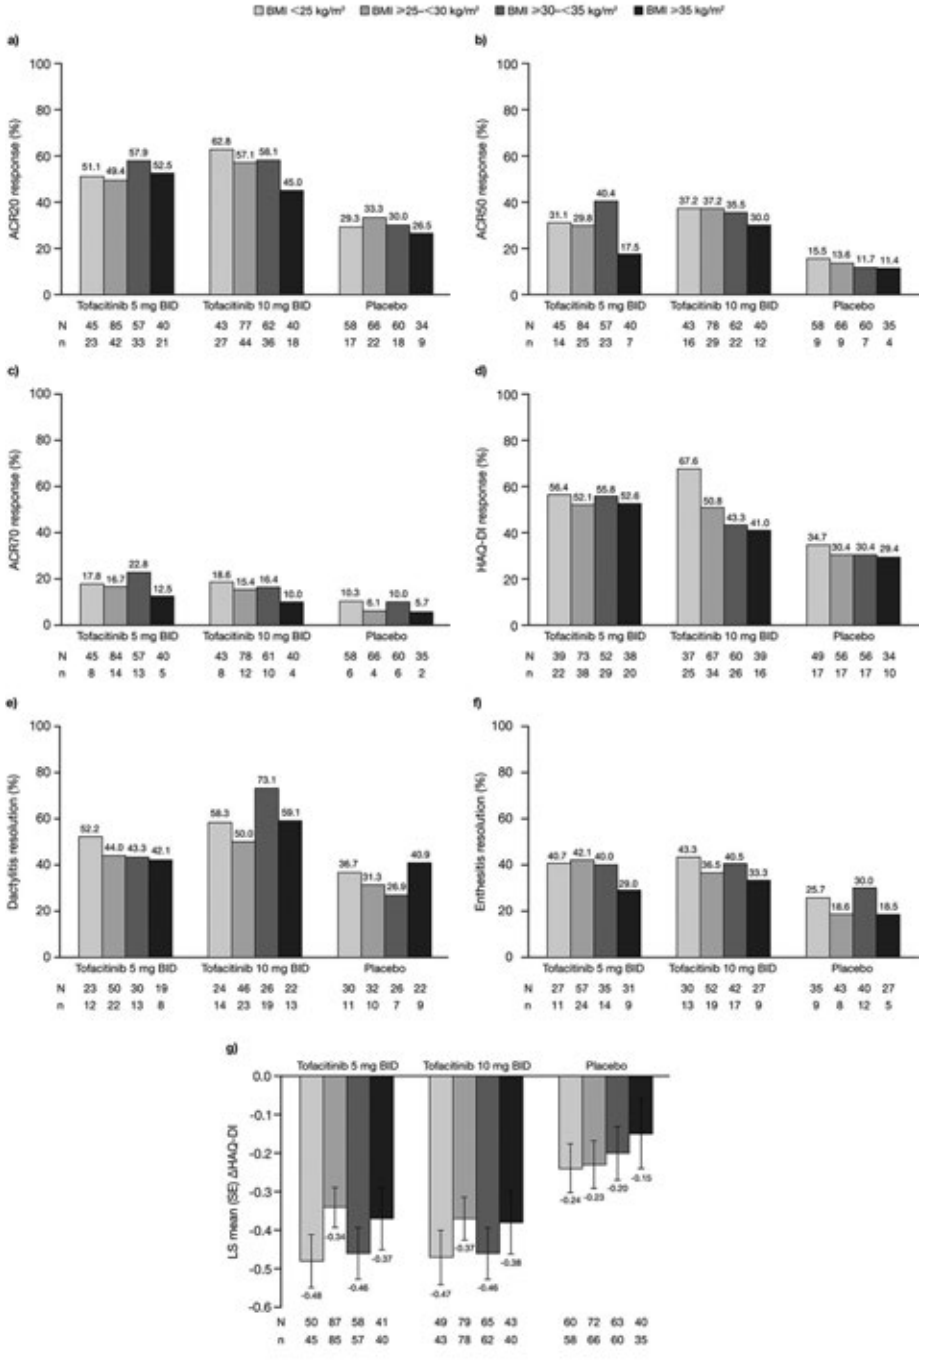
Session Time: 9:00AM–11:00AM

Background/Purpose: Obesity is highly prevalent in PsA (~45%),[1] and has previously been associated with a reduced response to TNF inhibitors.[2] Tofacitinib is an oral Janus kinase inhibitor for the treatment of PsA. This post hoc analysis assessed tofacitinib efficacy and safety in pts with PsA, by baseline (BL) BMI category.

Methods: Data were pooled from two placebo (PBO)-controlled, double-blind, Phase 3 studies in pts with active PsA and an inadequate response to ≥ 1 conventional synthetic DMARD (OPAL Broaden [12 months; NCT1877668]) or to ≥ 1 TNF inhibitor (OPAL Beyond [6 months; NCT01882439]).[3,4] This analysis included pts randomized to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, or PBO, stratified by BL BMI: < 25 kg/m^2, ≥ 25 – < 30 kg/m^2, ≥ 30 – < 35 kg/m^2, or ≥ 35 kg/m^2. Efficacy and safety were reported to Month M3. Efficacy outcomes included ACR20/50/70, HAQ-DI, and Psoriasis Area and Severity Index (PASI)75 responses, dactylitis and enthesitis absence rates, and changes from BL in Short Form-36 Version 2 (SF-36v2) Physical (PCS) and Mental Component Summary (MCS) scores, and Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) scores at M3. Safety outcomes included adverse events (AEs), such as cardiovascular (CV) events, and changes in liver function tests (LFTs) and lipid levels.

Results: This analysis included 710 pts; 43.8% were obese (BMI ≥ 30). At BL, 161 pts had a BMI < 25, 238 had a BMI ≥ 25 – < 30, 186 had a BMI ≥ 30 – < 35 and 125 had a BMI ≥ 35. Most pts were white (92.5–96.8%), middle-aged (44.5–51.2 yrs) and female (49.5–65.6%). Compared with the rest of the world, there were greater proportions of obese pts in Russia/Eastern Europe (35.1%) and US/Canada (31.8%). Higher BL BMI appeared correlated with increased prevalence of metabolic syndrome (4.3% in BMI < 25 to 76.0% in BMI ≥ 35) and CRP levels > 2.87 mg/L (49.1% in BMI < 25 to 84.0% in BMI ≥ 35). Higher proportions of pts (42.5–47.9%) in BL BMI categories < 35 reported no prior biologic DMARD use, vs pts with a BL BMI ≥ 35 (33.6%). At M3, efficacy improvements were generally greater in tofacitinib-treated pts, vs PBO-treated pts (Figure 1). In pts with a BL BMI ≥ 35, there was a trend towards fewer pts responding (Figure 1), and mean changes from baseline in SF-36v2 PCS, MCS and FACIT-F appeared lower (Table 1), vs pts in lower BL BMI categories. Up to M3, the proportions of pts with AEs, lipid levels, and percentage change from BL in LFTs, were generally similar across all BL BMI categories. There were three CV events: non-fatal cerebrovascular accident, transient ischemic attack (both tofacitinib 5 mg BID, BMI ≥ 30 – < 35), and artery revascularization (PBO; BMI ≥ 35).

Figure 1. a) ACR20,[a] b) ACR50,[a] c) ACR70,[a] and d) HAQ-DI[b] responses, e) dactylitis resolution rates,[c] f) enthesitis resolution rates,[c] and g) LS mean change from baseline in HAQ-DI at Month 3 by baseline BMI and treatment group (pooled data from OPAL Broaden and OPAL Beyond)



[a]ACR20/50/70 are calculated as a ≥20/50/70% improvement from baseline in tender and swollen joint counts and ≥20/50/70% improvement from baseline in 3 of the 5 remaining ACR core measures
[b]HAQ-DI response was defined as the number of patients achieving a reduction from baseline ≥0.35 in HAQ DI, considered the minimal clinically important difference
[c]Dactylitis resolution rates, defined as the absence of dactylitis in all of the 20 assessed digits, and enthesitis resolution rates, defined as the absence of enthesitis in all of the 6 assessed sites, were only assessed in patients who reported a baseline value of DSS or LEI >0, respectively
Δ, change from baseline; ACR, American College of Rheumatology; BID, twice daily; BMI, Body Mass Index; HAQ-DI, Health Assessment Questionnaire-Disability Index; LS mean, least squares mean; N, number of patients with a non-missing BMI evaluable at Month 3; n, number of patients in each category; SE, standard error

Conclusion: Regardless of BL BMI, tofacitinib demonstrated greater efficacy than PBO in pts with PsA. Similar to other advanced therapies,[2] reduced efficacy was generally observed in tofacitinib and PBO pts with a BL BMI ≥ 35. Tofacitinib safety appeared consistent across all BL BMI categories.

Abstract Number: 1514

Inadequate Response Within a Year of Biologic and Oral Synthetic DMARD Treatment Initiation Among Psoriatic Arthritis Patients in the USA Real-World Setting

Shannon Grabich,[1] **Anna Sheahan**,[1] Owen Davies,[2] and Robert Suruki[1], [1]UCB Pharma, Raleigh, NC, [2]UCB Pharma, Slough, England, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Real-world biologic persistence in PsA patients is lower compared to persistence in clinical trials. A comprehensive description of patterns of inadequate response (IR) to treatment is lacking. Frequency and timing of IR to biologics in the 1st year of treatment among PsA patients is described in this study.

Methods: This retrospective observational study analyzed USA commercial claims data (IBM® MarketScan®) from 2012–2017. Eligible PsA patients were biologic naïve (no claims for ≥1 year), ≥18 years old, with continuous enroll-

Table: The index biologic (n, %) in the cohort of 7,236 biologic-naïve PsA patients

Index treatment	Number of patients	% of total cohort
Adalimumab	3,015	42
Etanercept	2,100	29
Apremilast	1,165	16
Infliximab	347	5
Ustekinumab	294	4
Golimumab	128	2
Certolizumab pegol	122	2
Secukinumab	62	1
Ixekizumab	3	0

ment in the database in the 12-month baseline and follow-up periods. Diagnoses were based on International Classification of Diseases (ICD) 9/10 codes. Index date was the 1st claim for a biologic or apremilast (small molecule; **Table**). Persistence was defined as treatment with the index biologic with gaps of ≤90 days over 12 months. IR was defined as follows: 110% of the label-recommended dose for ≥30 days (above-label dosing), new biologic initiation within 90 days of discontinuing index biologic (switch), addition of a corticosteroid/immunosuppressant/biologic with ≥30 days of overlap (add-on treatment), and index biologic cessation (>90 days with no treatment) (non-switch discontinuation). Patients were classified according to the first IR event experienced.

Results: A total of 7,236 patients met the inclusion criteria. Persistence at 12 months was 48%, and was higher in males (53%) vs females (44%). Seventy-one percent of patients experienced an IR event in follow-up; the most frequent events were non-switch discontinuation (30%), followed by above-label dosing (16%), biologic switch (14%) and add-on treatment (11%). Median time from treatment initiation to IR event was 4.0 months, and was shortest for add-on treatment (3.1 months) and longest for biologic switch (4.6 months). Among the 1,716 patients with ≥12 months of follow-up after non-switch discontinuation, 53% had no subsequent biologic in the following 12 months, 31% restarted the index biologic, and 16% started a new biologic. IR distribution was similar irrespective of comorbid psoriasis and most recent provider (rheumatologist/dermatologist/other). Females (n=4,036) were more likely to experience an IR event than males (n=3,200) (74% vs 66%). Median time to IR event in females was 3.9 months vs 4.4 months in males.

Conclusion: IR to first biologic treatment, comprised primarily of adalimumab and etanercept, is common in PsA. Female patients are more likely to experience an IR event and to experience an event sooner vs males. Index biologic discontinuation (for >90 days) is common, with half of discontinuers remaining without a biologic exposure for ≥1 year, while the remaining discontinuers appeared to be taking a biologic drug holiday before restarting or initiating a new biologic. These variable treatment patterns suggest a variety of factors (including IR and others) are driving biologic discontinuation. Analysis of patient-level factors, such as clinical response and treatment access, is necessary to better understand the drivers of IR and to improve real-world treatment persistence.

DB = double-blind; IXE = ixekizumab 80 mg; N = number of patients in the analysis population; n = number of patients in the specified category; PBO = placebo; Q4W = every 4 weeks; Q2W = every 2 weeks; Wk = week

[a]The Safety Population was defined as all randomized patients who received at least 1 dose of study treatment.

[b]Analysis for the combined DB and Extended Treatment Periods included only patients in the Safety Population who were initially randomized to IXE Q4W or Q2W.

[c]The Extended Treatment Period Population was defined as all patients who received at least 1 dose of IXE treatment during the Extended Treatment Period.

[d]Opportunistic infections were identified by review of a pre-identified list of potential opportunistic infections using Medical Dictionary for Regulatory Activities preferred terms.

[e]Includes both opportunistic infections and potential opportunistic infections.

biologics may be associated with increased infections, we report on infections in patients with active r-axSpA treated with IXE.

Methods: Eligible patients met ASAS axSpA criteria, had radiographic sacroiliitis according to mNY criteria, and were either biologic-naïve (COAST-V: NCT02696785) or biologic-experienced (COAST-W: NCT02696798). Patients randomized to receive 16 weeks of double-blinded (DB) subcutaneous (SC) IXE 80 mg (once every 4 weeks [Q4W] or 2 weeks [Q2W]), placebo (PBO), or adalimumab (ADA, active reference) 40 mg Q2W (COAST-V only). All patients initially randomized to PBO or ADA (COAST-V) rerandomized to IXE at Weeks 16 through 52. The number and percentage of patients with infections are summarized for DB (Weeks 0 to 16), extended (Weeks 16 to 52), and combined treatment periods (Weeks 0 to 52).

Results: Total patients randomized were 341 in COAST-V (Table 1) and 316 in COAST-W (Table 2).

In COAST-V through Week 16, infections occurred in 19.8% (16/81), 20.5% (17/83), and 15.1% (13/86) of IXE Q4W, IXE Q2W, and PBO patients, respectively, and through Week 52 in 37.0% (30/81) and 43.4% (36/83) of patients initially randomized to IXE Q4W and Q2W, respectively. In COAST-W through Week 16, infections occurred in 29.8% (34/114), 23.5% (23/98), and 9.6% (10/104) of IXE Q4W, IXE Q2W, and PBO patients, respectively, and through Week 52 in 50.9% (58/114) and 43.9% (43/98) of patients initially randomized to IXE Q4W and Q2W, respectively.

In both studies, serious infections were reported in < 2% of IXE patients through Week 16 and in < 3% of patients during extended treatment. Most infections were mild or moderate in severity, and the most common infections were upper respiratory tract infection and nasopharyngitis. Overall, < 3% of patients discontinued due to infection, and no deaths due to infections occurred in either study.

In COAST-V, no IXE patients reported opportunistic infections through Week 16, and < 3% of patients reported opportunistic infections during extended treatment (esophageal candidiasis, fungal esophagitis, herpes simplex, herpes zoster [unidermatomal]). In COAST-W, ≤1% of IXE patients reported opportunistic infections through Week 16 (esophageal and oral candidiasis, herpes zoster), and < 2% of patients reported opportunistic infections during extended treatment (esophageal and oral candidiasis, herpes zoster). Opportunistic infections were mild or moderate in severity and none were serious. No tuberculosis cases were reported in either study and most candida and herpes infections resolved without recurrence.

Conclusion: Infection frequencies in COAST-V and COAST-W over 52 weeks are consistent with those in previous IXE PsA and PsO trials. Infection frequencies were similar between the IXE doses and study periods, with minimal difference between studies; thus, previous exposure to biologics did not affect the incidence of infections. Incidences of serious infections, opportunistic infections, and discontinuations due to infections were low in both studies.

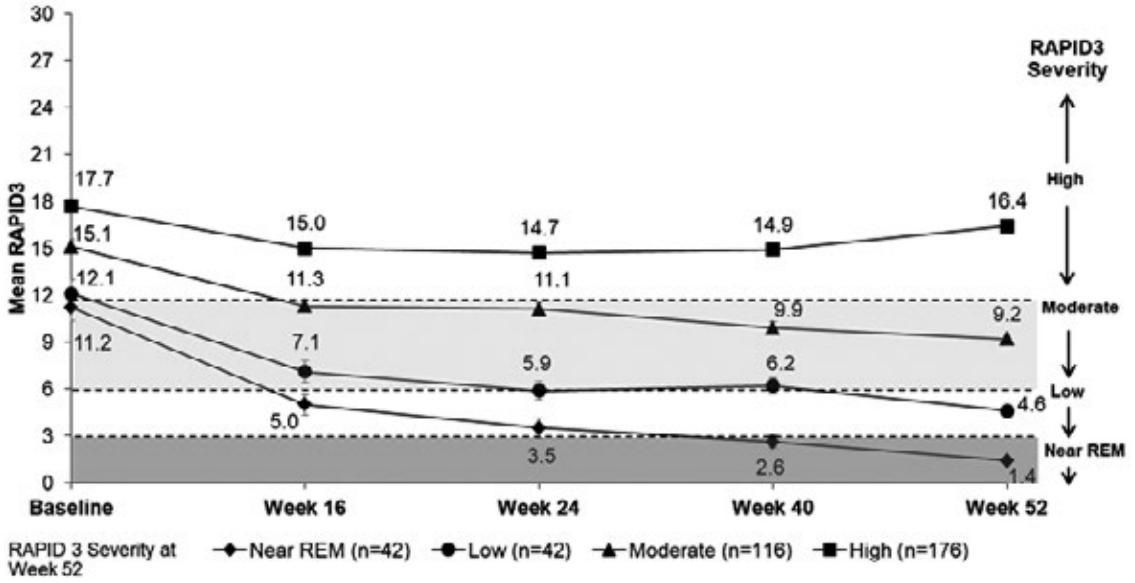
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

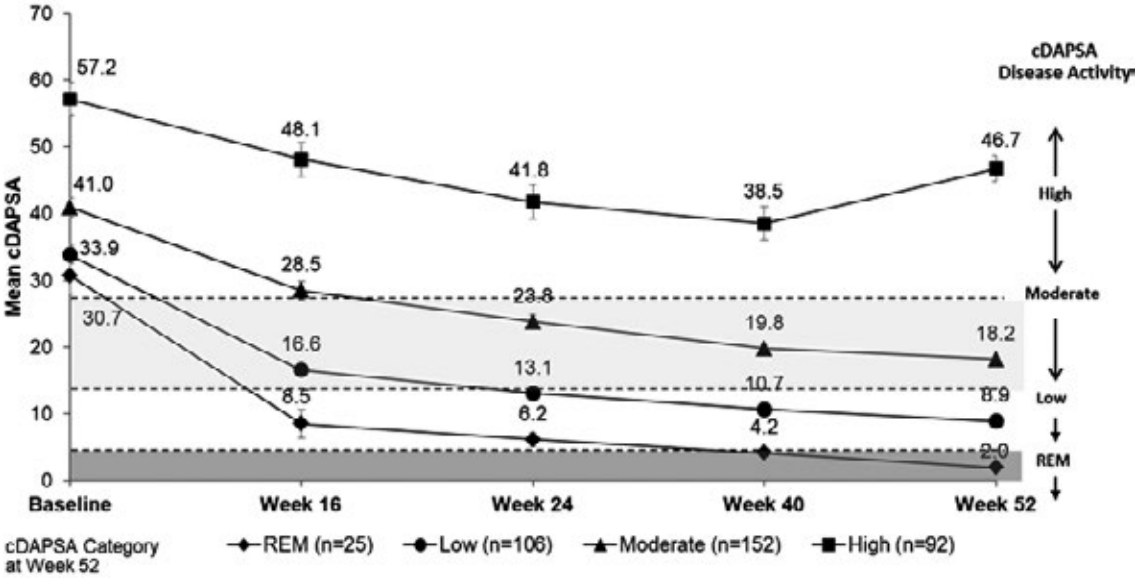
Session Time: 9:00AM–11:00AM

Figure 1. RAPID3 (0-30) Through Week 52 (N=376) by RAPID3 Category at Week 52: Subjects Receiving APR 30 mg BID From Baseline



Includes subjects randomized at baseline who had RAPID3 components available at Week 52; data are as observed. RAPID3 Near remission: ≤3; low severity: >3 to ≤6; moderate severity: >6 to ≤12; and high severity: >12 to 30. REM=remission. Error bars represent standard error of the mean

Figure 2. Disease Activity (cDAPSA [0–154]) Through Week 52 (N=375) by cDAPSA Category at Week 52 in Subjects Receiving APR 30 mg BID From Baseline



Includes subjects assigned to receive APR 30 mg twice daily at baseline who had cDAPSA components available at Week 52. Data are as observed. High disease activity, cDAPSA >27; moderate disease activity, cDAPSA >13 to ≤27; low disease activity, cDAPSA >4 to ≤13; remission (REM), cDAPSA ≤4. Error bars represent standard error of the mean.

Articular and Extra-articular Disease Activity in Subjects Achieving RAPID3 and cDAPSA Treatment Targets at Week 52

	RAPID3 ANALYSIS				cDAPSA ANALYSIS			
	Subjects With Near REM at Week 52		Subjects With Low Severity at Week 52		Subjects With REM at Week 52		Subjects With LDA at Week 52	
Mean	BL	Week 52	BL	Week 52	BL	Week 52	BL	Week 52

Dactylitis count (0-20)[¶]	3.1	0.6	2.6	0.6	2.3	0.0	2.8	0.5
HAQ-DI (0-3)	0.7	0.0	0.9	0.3	0.9	0.1	1.0	0.6

Data are as observed and n values vary by time point based on number of subjects with available data at a given point. *Assessed in subjects with ≥3% psoriasis-involved body surface area at BL. §Assessed in subjects with enthesitis at BL. ¶Assessed in subjects with dactylitis at BL. PhGA=Physician Global Assessment of Disease Activity; PASI=Psoriasis Area and Severity Index; MASES=Maastricht Ankylosing Spondylitis Enthesitis Score.

Background/Purpose: The Routine Assessment of Patient Index Data 3 (RAPID3) is an outcome measure of disease activity entirely derived from patient self-reported measures (Health Assessment Questionnaire-Disability Index [HAQ-DI] or multidimensional HAQ [MDHAQ], Pain visual analog scale [VAS], and Patient's Assessment of Disease Activity [PtGA] VAS). The Clinical Disease Activity in Psoriatic Arthritis (cDAPSA; 0-154) includes objective and subjective physician assessments (i.e., a composite of swollen and tender joints counts [SJC and TJC]), along with Patient's Assessment of Pain (PAP) and PtGA. In subjects receiving apremilast (APR), we examined trajectories for improvement in RAPID3 scores among subjects achieving RAPID3 near remission (REM) or low severity, cDAPSA among subjects achieving cDAPSA REM or low disease activity (LDA), and psoriatic arthritis (PsA) manifestations not measured by either outcome measure by Week 52.

Methods: Pooled analyses of the phase III PALACE 1, 2, and 3 studies were performed for subjects assigned to receive APR 30 mg BID at baseline (BL). Subjects with available scores on RAPID3 and cDAPSA components at Week 52 were included and grouped according to RAPID3 categories at Week 52 (near REM: ≤3; low severity: >3 to ≤6; moderate severity: >6 to ≤12; and high severity: >12 to 30) and cDAPSA categories at Week 52 (REM: ≤4; LDA: >4 to ≤13; moderate disease activity: >13 to ≤27; high disease activity: >27). Mean RAPID3 and cDAPSA scores were assessed from BL through Week 52. Other measures of PsA disease activity were reported longitudinally by RAPID3 and cDAPSA categories at Week 52.

Results: The RAPID3 and cDAPSA analysis included 376 and 375 APR subjects, respectively. Achievement of near REM or low severity (RAPID3) or REM or LDA (cDAPSA) by Week 52 with APR were associated with improvements over time in mean RAPID3 (**Figure 1**) and cDAPSA (**Figure 2**) trajectories. Subjects who achieved cDAPSA treatment targets were associated with no or mild articular and extra-articular manifestations at Week 52. Achieving RAPID3 treatment targets at Week 52 was associated with improvements in articular and extra-articular disease activity, although not all manifestations were controlled at Week 52 (**Table**). In both RAPID3 and cDAPSA analyses, similar improvements in SJC and TJC were observed for patients with REM or low severity (RAPID3) or REM or LDA (cDAPSA) at Week 52. In the RAPID3 analysis, mean TJC was higher than expected at Week 52, and achieving near REM RAPID3 scores was not associated with lower mean Psoriasis Area and Severity Index scores.

Conclusion: Subjects who achieved RAPID3 and cDAPSA targets showed early improvements in disease activity by Week 16 and sustained improvements to Week 52 with continued treatment. Achievement of treatment targets was also associated with improvements in other domains not captured directly by RAPID3 or cDAPSA. Given that some patients may exhibit different disease outcomes from the population, a more comprehensive assessment may help better evaluate treatment targets.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic inflammation may influence cardio-metabolic profiles and increases the risk of CV disorders in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) patients (pts)[1]. Treatment with tumor necrosis factor (TNF) and Janus Kinase inhibitors have reported increased total cholesterol (TC) and triglycerides (TG) despite reduction in inflammation[2,3]. Here, we present the long-term effect of secukinumab (SEC), a fully human monoclonal

Key Cardio-metabolic parameters in AS and PsA pts through Wk 156 (Overall population)						
Parameters	Time points	AS		PsA		
		SEC 150 mg (N=504)	PBO (N=388)	SEC 300 mg (N=461)	SEC 150 mg (N=907)	PBO (N=681)

AS; ankylosing spondylitis; BMI, body mass index; BP, blood pressure; CRP, C-reactive protein; HDL-C, high density lipoprotein cholesterol; N, total number of pts at baseline; PBO, placebo; PsA, psoriatic arthritis; SEC, secukinumab; TG; triglycerides; TC, total cholesterol; Wk, week						

Table: Key Cardio-metabolic parameters in AS and PsA pts through Wk 156 (Overall population)

antibody that directly inhibits interleukin (IL) -17A, on key cardio-metabolic parameters in AS and PsA pts from a pooled analysis of phase 3 clinical trials, through 156 weeks (wks).

Methods: This *post hoc* analysis pooled data from MEASURE 1–4 studies in AS (N=892) and FUTURE 2–5 studies in PsA (N=2049), and included pts treated with SEC 150 mg and SEC 300/150 mg, respectively, or placebo (PBO; Wk 16 data). Serum glucose, body mass index (BMI), TG, TC/high-density lipoprotein cholesterol (TC/HDL-C), systolic/ diastolic blood pressure (BP), C-reactive protein (CRP) levels were assessed at baseline (BL), Wks 16, 104 and 156 in overall population and in sub-groups by prior anti-TNF therapy and concomitant methotrexate (MTX) usage.

Results: BL characteristics were generally comparable across SEC and PBO groups in both disease cohorts. Serum glucose, systolic/diastolic BP, BMI, and lipid (TG, TC/HDL) levels were minimally altered in SEC treated pts with AS and PsA through Wk 156 (**Table**); mean change from BL in AS: TG (mmol/L) = 0.1–0.2, TC/HDL-C = ±0.2, glucose (mmol/L) = 0.08–0.2, BMI (kg/m^2) = 0.08–0.9, BP (mmHg) = ±0.2/±0.9 (systolic/diastolic) and mean change from BL in PsA: TG (mmol/L) = 0.003–0.2, TC/HDL-C = ±0.2, glucose (mmol/L) = ±0.3, BMI (kg/m^2) = 0.1–1.7, BP (mmHg) = ±4.0/±1.0 (systolic/diastolic). CRP reductions were observed through Wk 156 (**Table**). Results were broadly similar in sub-groups by prior anti-TNF therapy and concomitant MTX use through Wk 156.

Conclusion: Secukinumab was associated with minimal changes in cardio-metabolic parameters over 3 years in patients with ankylosing spondylitis and psoriatic arthritis. These findings suggest that anti-IL-17 therapy may be an option in patients with cardio-metabolic risk factors, however, further research is needed.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: A large proportion of psoriatic arthritis (PsA) patients are prescribed a tumour necrosis factor inhibitor (TNFi) in combination with methotrexate (MTX), however the value of combination therapy in PsA remains unresolved. This study aimed to investigate whether TNFi combination therapy with conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs) is more effective or improves TNFi drug survival compared to TNFi monotherapy.

Methods: Five PsA biologics cohorts were investigated between 2000 and 2015; the ATTRA registry (Czech Republic), the Swiss Clinical Quality Management PsA registry, the Hellenic Registry of Biologics Therapies (Greece), the University of Bari PsA biologics database (Italy) and the Bath PsA cohort (UK). Adults (≥18 years) with a clinical diagnosis of PsA who were new (first line) users of TNFi during the study period and registered in their respective database from TNFi initiation were eligible for inclusion. Exposure treatment groups at baseline included TNFi monotherapy, TNFi combination therapy with any csDMARD and a subgroup of TNFi combination therapy with MTX. Drug persistence was analysed using Kaplan-Meier and equality of survival using Log-Rank tests. Comparative effectiveness was investigated using logistic regression with propensity scores. Separate analyses were performed on: (a) the combined Italian and Swiss cohorts for change in rate of DAS-28; and (b) the combined Italian, Swiss and Bath cohorts for change in rate of HAQ.

Results: There were 2294 eligible patients identified from the contributing databases, of which 34% started TNFi in monotherapy and 66% in combination therapy. Patient characteristics and baseline disease activity and severity were generally similar across treatment groups within the databases. The majority of patients (82% monotherapy and 66% combination therapy) did not have changes to their baseline treatment regimen before discontinuing their first TNFi. In the Swiss (p=0.002), Greek (p=0.021) and Bath (p=0.014) databases, patients starting treatment on TNFi in combination with MTX had longer drug survival compared to monotherapy, whilst

in Italy patients starting on monotherapy persisted longer (p=0.030) (Table 1). In all but the Czech database, men persisted significantly longer on their first TNFi than women (Table 1). In the combined Italian/Swiss dataset (n=1066) there was no significant difference in the rate of change of DAS28 between those on TNFi monotherapy versus TNFi combination with any csDMARD (combined Relative Risk (RR_{adj}) 0.98 CI_{95} 0.95-1.03) or when compared to those on TNFi+MTX (RR_{adj} 0.98 CI_{95} 0.95-1.02). Similarly, when also including the Bath cohort (n=1205), there was a comparable rate of change of HAQ in patients on TNFi monotherapy compared with combination with any csDMARD (RR_{adj} 1.01 CI_{95} 0.99-1.04) and when compared to those on TNFi+MTX combination (RR_{adj} 1.02 CI_{95} 0.99-1.05).

Conclusion: Combination therapy of a TNFi with a csDMARD does not appear to affect improvement of disease activity or HAQ. Combination therapy may, however, improve TNFi drug survival. Gender appears to be a major risk factor in determining TNFi survival, with males persisting on treatment for longer.

Abstract Number: 1519

Predicting Response to Biologic Therapy in Patients with Axial Spondyloarthritis (axSpA)

Gareth Jones,[1] Linda Dean,[1] Ejaz Pathan,[2] and Gary Macfarlane[1], [1]University of Aberdeen, Aberdeen, United Kingdom, [2]Toronto Western Hospital, Toronto, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In axial spondyloarthritis (axSpA), the clinical benefits of TNF inhibition (TNFi) are well documented although, by design, most studies report average benefits in groups of patients. Inevitably, a subset of patients will not respond to therapy. Identifying characteristics of these patients is important as it may inform the use of TNFi in clinical practice. The aim of the current study was to identify factors that predict satisfactory treatment response, in a nationwide register of patients commencing TNFi.

Methods: The British Society for Rheumatology Biologics Register for Ankylosing Spondylitis (BSRBR-AS) recruited biologics-naïve patients with axSpA from 83 secondary care rheumatology centres across Great Britain between 2012 and 2017. Clinical data was collected from patients' medical records, and additional data was collected via postal questionnaires. Treatment response was determined at the first eligible follow-up and was defined as moving from high/very high Ankylosing Spondylitis Disease Activity Scale score (ASDAS≥2.1) to

2 High score = worse
3 High score = better

Table. Factors associated with response to TNFi, among patients with axSpA

moderate/inactive disease activity (ASDAS< 2.1). Factors associated with treatment response were assessed using logistic regression. Thereafter, a forward stepwise logistic regression model was used to identify which group of factors best predicted treatment response. Analysis was conducted on the June 2017 BSRBR-AS dataset.

Results: 249 participants were eligible for the current analysis; 69% were male, with median age 47yrs (inter-quartile range: 36-56). 96% met the ASAS imaging criteria, of which 67% had ankylosing spondylitis.

Median follow-up was 14wks, at which point 35% were classified as treatment responders. For every 1 unit increase in disease activity (BASDAI) there was a 29% decrease in the odds of response (odds ratio 0.71; 95%CI 0.60-0.85). A similar effect was seen with increasingly poor function (BASFI: 0.70; 0.61-0.81). Other factors associated with response on univariable analysis were wide-ranging, including clinical, socioeconomic and patient-reported factors, see Table 1.

Only four independent predictors of response were identified. Patients in full-time employment and with high education were more likely to respond, as were those with better mental health scores. Increasing comorbidities was associated with poor response. The final model demonstrated a good level of fit with positive (PPV) and negative predictive values (NPV) of 63% and 77% respectively.

Conclusion: Four variables, none of them disease specific, identified axSpA patients commenced on biologic therapy, who were unlikely to have responded, four months later. Other patients may need additional therapeutic approaches and additional support (e.g. support so that they do not lose their job) to achieve optimal outcomes.

Long-Term Treatment Patterns of Biologics and Apremilast Among Patients with Moderate-to-Severe Plaque Psoriasis by Psoriatic Arthritis Status

Steven Feldman,[1] **Jingchuan Zhang**,[2] Diane Martinez,[3] Lorena Lopez-Gonzalez,[3] Elizabeth Holt Marchlewicz,[3] George Shrady,[3] Alan Mendelsohn,[4] and Yang zhao[5], [1]Wake Forest Baptist Health, Winston-Salem, NC, [2]Sun Pharmaceutical Industries, Princeton, NJ, [3]IBM Watson Health, Washington, DC, [4]Sun Pharmaceutical Industries, Inc., Princeton, NJ, USA, Princeton, NJ, [5]Sun Pharmaceutical Industries, Princeton

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term real-world treatment patterns of psoriasis patients are not well characterized, especially those with comorbid psoriatic arthritis (PsA). This study examined the treatment patterns among psoriasis patients who newly initiated a biologic or apremilast (APR) by PsA status.

Methods: Using a large US claims database, adult patients with psoriasis were classified into 5 mutually exclusive cohorts based on their initial index medication between 01/01/2015 and 08/31/2018: secukinumab (SEC), adalimumab (ADA), ustekinumab (UST), etanercept (ETA), or APR. Eligible patients had no index medication use in the 12-month pre-index period, and had continuous medical and pharmacy benefits in the 12-month pre-index and 24-month post-index periods. Subgroups were created by the presence of a PsA diagnosis over the 12-month pre-index period.

Rates of discontinuation, adherence (proportion of days covered [PDC], adherent if PDC ≥0.8), non-persistence, and switching were compared between patients with and without PsA within each cohort. Treatment gaps were defined as 4 weeks for ETA and APR, 8 weeks for ADA, 10 weeks for SEC, and 18 weeks for UST.

Results: A total of 7,773 psoriasis patients were included: 275, 2,684, 910, 1,063, and 2,841 patients for SEC, ADA, UST, ETA, and APR, respectively, and the proportions of patients with PsA were 35.3%, 35.1%, 22.0%, 45.7%, and 24.8%, respectively. Over the 24-month post-index period, discontinuation rates for patients with and without PsA were: SEC: 54.6% vs. 43.8%; ADA: 48.3% vs. 53.0%; UST: 52.5% vs. 34.4%; ETA: 38.1% vs. 45.4%; and APR: 47.7% vs. 43.4% (all $p< 0.05$ except SEC). Adherence rates were: SEC: 30.9% vs. 34.8%; ADA*: 30% vs. 25.5%; UST: 17.5% vs. 23.9%; ETA*: 26.5% vs. 16.8%; and APR: 22.4% vs. 22.9% (*$p< 0.05$). Non-persistence rates were: SEC: 69.1% vs. 65.7%; ADA: 71% vs. 74.4%; UST*: 68.5% vs. 55.5%; ETA*: 82.1% vs. 90.3%; and APR: 86.6% vs. 84.8% (*$p< 0.05$). Overall switching rates were high for all groups (24.8%–55.1%, all $p< 0.05$ except ETA).

Conclusion: About 22%–46% moderate-to-severe psoriasis patients who initiated biologics or APR had comorbid PsA. Over 24-month post-index period, overall adherence was poor and discontinuation, non-persistence, and switching were high for all groups. Maintaining long-term therapy is still a challenge for psoriasis patients. Treatments that overcome the hurdle of poor adherence to self-administration may be helpful.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

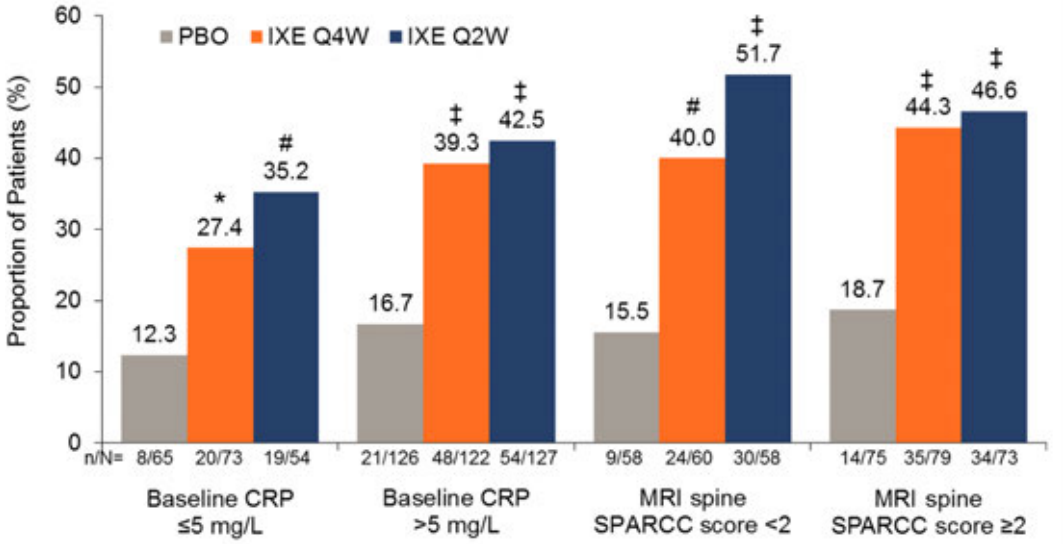
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: IL-17 plays an important role in the pathogenesis of radiographic axial spondyloarthritis (r-axSpA). Elevated CRP levels in serum predict response to TNF inhibitors (TNFi).[1-4] The role of baseline spine MRI as a predictor of response has not been investigated for IL-17 inhibitors. This study evaluates response rates at week (wk) 16 with ixekizumab (IXE), an IL-17A antagonist, in patients with ankylosing spondylitis (AS)/r-axSpA and elevated or normal/low inflammation as measured by CRP or spinal MRI.

Figure 1 **COAST-V/W Integrated Dataset, ITT ASAS40 Response at Week 16, NRI**



*p<.05, #p<.01, ‡p<.001 versus placebo. ASAS40=Assessment in SpondyloArthritis international Society 40% response rate; CRP=C-reactive protein; ITT=intent-to-treat; IXE=ixekizumab; n=number of patients in the specified category; N=number of patients in the analysis population; NRI=nonresponder imputation; PBO=placebo; Q2W=every 2 weeks; Q4W=every 4 weeks; SPARCC=Spondyloarthritis Research Consortium of Canada

Methods: Two Phase 3, randomized, double-blind, placebo (PBO)-controlled trials (COAST-V, NCT02696785; COAST-W, NCT02696798) enrolled biologic-naive or TNFi-experienced patients, respectively, with active disease (BASDI ≥4 and spinal pain ≥4 on a numeric rating scale) and an established diagnosis of r-axSpA and fulfilling Assessment of SpondyloArthritis international Society (ASAS) criteria (sacroiliitis on radiograph by modified New York [mNY] criteria and ≥1 spondyloarthritis feature). All patients fulfilling ASAS criteria also fulfilled mNY criteria for AS. Patients were treated with IXE (80 mg every 2 or 4 wks [Q2W, Q4W]) or PBO; adalimumab (40 mg Q2W) was an active reference arm in COAST-V. We examined ASAS 40% (ASAS40) response rates at wk 16 for the intent-to-treat population by baseline CRP (≤5 or >5 mg/L) and/or MRI spine inflammation (Spondyloarthritis Research Consortium of Canada [SPARCC] spine score < 2 or ≥2). Baseline spine MRI (scored by central readers) was available in 96% of patients in COAST-V and 51% in COAST-W. Higher scores reflect greater baseline disease activity. Missing data for ASAS40 were imputed by nonresponder imputation.

Results: In the COAST-V/W integrated dataset that combined biologic-naive and TNFi-experienced populations, significantly more patients treated with IXE achieved ASAS40 response at wk 16 than with PBO in the baseline CRP elevated (>5 mg/L) group (39.3%, 42.5%, and 16.7% for IXE Q4W, IXE Q2W, and PBO, respectively; p< .001 for IXE Q4W, IXE Q2W vs PBO) and in the baseline CRP normal (≤5 mg/L) group (27.4%, 35.2%, and 12.3% for IXE Q4W, IXE Q2W, and PBO, respectively; p< .05 for IXE Q4W, p< .01 for IXE Q2W vs PBO, Fig 1), and the magnitude of response with IXE between elevated vs normal CRP groups was not statistically significant. Notably, a significantly higher proportion of patients achieved ASAS40 at wk 16 with IXE than with PBO, regardless of whether MRI spine SPARCC scores were < 2 (40%, 51.7%, and 15.5% for IXE Q4W, IXE Q2W, and PBO, respectively; p< .01 for IXE Q4W, p< .001 for IXE Q2W vs PBO) or ≥2 (44.3%, 46.6%, and 18.7% for IXE Q4W, IXE Q2W, and PBO, respectively; p< .001 for IXE Q4W, IXE Q2W vs PBO, Fig 1). Among the patients (n=79) with MRI spine SPARCC score < 2 and CRP ≤5 mg/L, the ASAS40 responses at wk 16 were 13%, 29%, and 48% for PBO, IXE Q4W, and IXE Q2W, respectively, with statistically significantly greater improvement for IXE Q2W vs PBO (p< .05).

Conclusion: IXE demonstrated rapid efficacy in the treatment of AS/r-axSpA at wk 16 irrespective of baseline serum CRP levels or spinal MRI score.

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Radiographic axial spondyloarthritis (r-axSpA) is a chronic inflammatory disease involving the axial skeleton; inflammatory bowel disease (IBD) and acute anterior uveitis (AAU) are common extra-articular manifestations. IBD has been reported in 3–10% of ankylosing spondylitis (AS) patients (pts).[1] Exposure-adjusted incidence rates (EAIRs) of IBD in AS pts treated with TNF inhibitors (TNFi) have been reported as 0.2–2.3 per 100 person years (PY)[3]. The frequency of AAU in AS has been reported as 33%[2] and the EAIR of AAU has been reported as 2.6–3.5 per 100 PY.[4]

Ixekizumab (IXE) is a high-affinity mAb targeting IL-17A with established efficacy and safety in pts with r-axSpA.[5,6] We summarize IBD and AAU cases reported from 2 pivotal studies of IXE in r-axSpA.

Methods: COAST-V (NCT02696785) and COAST-W (NCT02696798) are phase 3, randomized, controlled studies in pts with r-axSpA naïve to biological DMARDs (bDMARDs) or pts who previously failed 1 or 2 TNFi (TNFi-experienced), respectively. Full study designs have been described previously[5,6]. Pts with a history of IBD or AAU were not excluded if these conditions were stable. At each study visit, pts were evaluated for any symptoms of AAU and IBD. AAU events were con-

Table 1. Incidence and exposure-adjusted incidence rates for inflammatory bowel disease and acute anterior uveitis in ixekizumab-treated patients across COAST-V and COAST-W.

	COAST-V and COAST-W
Number of patient who received at least 1 dose of ixekizumab	641
Exposure, total person years[a]	510.1
IBD[b]	
Patients entering study with history of IBD, n (%)[c]	14 (2.1%)
Patients with ≥1 reported event of IBD, n (%)[b]	8 (1.2%)
Patients with history (diagnosis) of IBD, n	3
Patients with no history of IBD, n	5
IBD EAIRs	
Patients with CD, n (%), [EAIR]	4 (0.6%), [0.8]
Patients with UC, n (%), [EAIR]	2 (0.3%), [0.4]
Patients with IBD NOS, n (%), [EAIR]	2 (0.3%), [0.4]
AAU[d]	
Patients entering study with history of AAU,n (%)[c]	145 (22.1%)
Patients with ≥1 reported event of AAU, n (%)[d]	20 (3.1%)
Patients with history (diagnosis) of AAU, n (%)	15
Patients with no history of AAU, n (%)	5
AAU EAIR	3.9

[a]Sum of exposure for any ixekizumab-treated pts in the blinded dosing treatment period and the extended treatment period in both studies. [b]IBD events were identified from the narrow terms and events (MedDRA Version 21.0) that can occur with IBD as specified in the program safety analysis plan and adjudicated following EPIMAD criteria. [c]Pts with previous history of IBD or AAU were calculated based on the total number of randomized patients across both trials (N = 656). [d]AAU was identified using the preferred term "iridocyclitis" (MedDRA Version 21.0); AAU cases were evaluated by ophthalmologists.

firmed by an ophthalmologist. IBD events were adjudicated following Registre Epidemiologique des Maladies de l'Appareil Digestif (EPIMAD) criteria. EAIRs were calculated by the number of patients experiencing these events per 100 PY.

Results: Across both studies, 2.1% of pts had a history of IBD, and there were 4 cases of Crohn's disease (CD), 2 cases of ulcerative colitis (UC), and 2 cases of IBD not otherwise specified (IBD NOS) among patients treated with IXE and 1 case of UC on placebo. Most patients who had events of IBD had a prior diagnosis of IBD or prior gastrointestinal history potentially indicative of IBD. EAIRs for CD, UC, and IBD NOS were 0.8, 0.4, and 0.4 per 100 PY, respectively (Table 1). Four patients permanently discontinued IXE treatment due to IBD.

Across both studies, 20.1% of pts had a history of AAU, and 20 pts reported events of AAU, 15 of those had a prior history of AAU. One case resulted in drug interruption, and 1 case resulted in permanent discontinuation of IXE treatment due to AAU. The EAIR for AAU was 3.9 per 100 PY (Table 1).

Conclusion: In IXE-treated r-axSpA pts, frequencies of IBD and AAU were in the range of those seen in AS pts.[1, 2] EAIRs of IBD were numerically similar to those seen in TNFi-treated AS pts for both studies. More and longer-term data are required to better understand the incidence rates of IBD and AAU in r-axSpA pts treated with IXE.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity, anti–interleukin-23p19 monoclonal antibody approved for the treatment of moderate-to-severe chronic plaque psoriasis. An inverse efficacy–body weight relationship has been reported for multiple fixed-dose systemic agents in patients with psoriasis, who tend to be of greater weight than the general population. We conducted a post hoc analysis of pooled data from 2 randomized, placebo (PBO)-controlled, phase 3 trials (reSURFACE 1 [NCT01722331] and 2 [NCT01729754]) to evaluate the impact of body weight on TIL efficacy in psoriasis.

Methods: In reSURFACE 1 and 2, patients were randomized to PBO or TIL 100 or 200 mg in Part 1 (Week [W] 0–12) and rerandomized in Parts 2 (W12–28) and 3 (W28–64 [reSURFACE 1] or W28–52 [reSURFACE 2]). Treatment was administered at W0, W4, and every 12 weeks thereafter. The median percentage improvement in Psoriasis Area and Severity Index (PASI) is reported for patients randomized to TIL 100 mg at baseline up to W52, or PBO up to W12. Data were stratified by weight decile, calculated separately for Parts 1 and 2 combined, and Part 3. A nonresponder imputation analysis was used.

Results: For Parts 1 and 2 (n=616), median weight (range) for the TIL 100-mg group at baseline was 86.3 kg (40.9–194.7 kg); median PASI was 17.9. For patients who entered Part 3 (n=329), median weight at baseline was 86.0 kg (47.0–194.7 kg); median PASI was 18.0. At W12, a slightly greater median percentage improvement in PASI was observed in the lower weight deciles: 87.4%, 86.6%, 83.6%, 88.9%, 81.5%, 84.3%, 83.1%, 78.0%, 76.7%, and 77.5% (lowest to highest decile). By W28, the difference in improvement between lowest and highest decile had narrowed: 91.6%, 91.9%, 92.6%, 90.4%, 91.1%, 90.6%, 91.2%, 87.7%, 87.0%, and 86.0%. At W52, efficacy was well maintained across all weight deciles: 100%, 96.9%, 96.9%, 96.6%, 96.6%, 97.2%, 95.3%, 93.4%, 93.5%, and 90.8%. For PBO (n=309), median weight at baseline was 85.7 kg (44.0–180.2 kg), and median PASI was 17.7. At W12, there was little improvement, with no distinct pattern, in PASI vs baseline (range: 1.2%–25.3%).

Conclusion: A modest weight-efficacy relationship with TIL 100-mg treatment was observed through W12, with more rapid efficacy in the lower weight deciles. Efficacy improved across deciles through W28, with a decreased difference between the lightest and heaviest deciles due to more rapid improvement in the latter. Efficacy responses in W28 PASI 75 responders were well-maintained, with >90% median PASI improvement across deciles at W52.

Editorial support was provided by Puneet Dang, PhD, of AlphaBioCom, LLC.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity anti–interleukin-23p19 monoclonal antibody approved by the FDA to treat moderate-to-severe plaque psoriasis. A randomized, double-blind, multidose, placebo-controlled, phase 2b study (NCT02980692) is underway to evaluate the efficacy and safety of TIL for the treatment of PsA. In this interim analysis of the phase 2b study, the effect of TIL on Psoriasis Area and Severity Index (PASI) 75/90/100 response rates was evaluated in study patients with PsA and measurable psoriasis (≥3% of the body surface area [BSA] affected at baseline).

Methods: Patients ≥18 years of age with active PsA (Classification of Psoriatic Arthritis criteria)[1] were stratified by prior anti-TNF use (yes/no) and baseline body weight (≤90 kg and ≥90 kg), and randomized 1:1:1:1:1 to receive TIL (200 mg once every 4 weeks [Q4W], 200 mg every 12 weeks [Q12W], 100 mg Q12W, or 20 mg Q12W to week 24) or placebo (PBO Q4W to week 24). PASI75/90/100 were prespecified endpoints and assessments were conducted by an independent assessor. Efficacy was analyzed in the full analysis set, defined as all randomized subjects who received ≥1 dose of study drug. Safety assessments included treatment-emergent adverse event (TEAE) monitoring.

Results: Of 500 patients screened, 391 patients met inclusion criteria with 77–79 per treatment arm (TIL 200 mg Q4W, TIL 200 mg Q12W, TIL 100 mg Q12W, and TIL 20 mg Q12W vs PBO) of which, 234 patients had BSA ≥3% at baseline (41–54 per treatment arm, **Table 1**). Mean age (SD) was 48.8 (12.6), 96.7% white, average body mass index 29.7, and 23.3% were anti–TNF-experienced. At week 24, 61.5%/43.2%/26.0% in combined TIL arms vs 16.7%/7.1%/4.8% in the PBO arm achieved PASI 75/90/100 responses (**Figure 1**). The most frequent TEAEs included nasopharyngitis (pooled TIL arms 5.4% vs PBO 6.3%) and upper respiratory tract infection (pooled TIL arms 3.5% vs PBO 1.3%). No deaths were reported.

Conclusion: By week 24, TIL significantly improved PASI 75/90/100 in patients with PsA and psoriasis vs PBO. Numerically, 200-mg dosing led to higher PASI 75 and 90 responses by week 24 compared with 100-mg dosing in patients with mild to moderate psoriasis and PsA. Further studies that are powered to compare the 100-mg vs 200-mg dose are needed to confirm this observation. Improvements in skin responses were significant vs PBO as early

as week 4 for PASI 75 in the TIL 200 mg Q12W arm. These data provide evidence that TIL significantly improves psoriasis in patients with PsA and is well tolerated in a mixed population of anti–TNF-naïve and -experienced patients.

Editorial and writing support was provided by Marie-Louise Ricketts, PhD, of AlphaBioCom, LLC.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is an anti–interleukin-23p19 monoclonal antibody approved by the FDA for treatment of moderate-to-severe plaque psoriasis[1,2] and is under investigation for treatment of PsA. The objective of this analysis was to evaluate the safety of TIL in patients with active PsA at 24 weeks from the randomized, double-blind, placebo-controlled, multiple-dose, phase 2b TIL trial (NCT02980692).

Methods: Patients ≥18 years old with a diagnosis of PsA (by the Classification of Psoriatic Arthritis criteria[3]) and ≥3 tender and ≥3 swollen joints were randomized 1:1:1:1:1 to 5 treatment arms (administered by subcutaneous injection)—200 mg TIL every 4 weeks (Q4W), 200 mg TIL every 12 weeks (Q12W), 100 mg TIL Q12W, 20 mg TIL Q12W, or placebo to week 24. Treatment-emergent adverse events (TEAEs) were monitored throughout the study; and defined as events that occurred on/after the first dose of TIL but before week 24, or on/before the last dose if the subject discontinued treatment before week 24 (coded by Medical Dictionary of Regulatory Activities v20.1).

Results: In total, 391/500 patients screened met inclusion criteria. Patient demographics and baseline disease characteristics were consistent across the groups (**Table 1**). At 24 weeks, 61 (78.2%) TIL 200 mg Q4W, 64 (81.0%) TIL

Patient Demographics[1]	TIL 200 mg Q4W (N = 78)	TIL 200 mg Q12W (N = 79)	TIL 100 mg Q12W (N = 77)	TIL 20 mg Q12W (N = 78)	PBO (N = 79)

Table 1. Baseline demographics and clinical disease characteristics in tildrakizumab and placebo treatment groups. Data presented as mean ± SD unless otherwise noted. 1Shown for randomized patients who received ≥1 dose of study drug. *For prior anti–TNF-α therapy, total patients analyzed (N) = 79, 78, 80, 78, and 76 for TIL 200 mg Q4W, TIL 200 mg Q12W, TIL 100 mg, TIL 20 mg, and PBO. †For prior baseline PASI, total patients analyzed (N) = 75, 79, 76, 75, and 75 for TIL 200 mg Q4W, TIL 200 mg Q12W, TIL 100 mg, TIL 20 mg, and PBO. BMI, body mass index; BSA, body surface area; GADA, global assessment of disease activity; HAQ, health assessment questionnaire disability index; PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; SD, standard deviation; TIL, tildrakizumab.

200 mg Q12W, 60 (77.9%) TIL 100 mg Q12W, 71 (91.0%) TIL 20 mg Q12W, and 74 (93.7%) placebo patients completed treatment, respectively. Reasons for discontinuation included an adverse event in 1 (1.3%), 2 (2.5%), 1 (1.3%), 2 (2.6%), and 0 patients, respectively, and lack of efficacy in 9 (11.5%), 12 (15.2%), 13 (16.9%), 0, and 0 patients, respectively.

At week 24, 156 (50.0%) TIL-treated and 34 (43.0%) placebo-treated patients had any TEAE, 7 (2.2%) and 2 (2.5%) a serious TEAE, and 35 (11.2%) and 10 (12.7%) a treatment-related TEAE, respectively. The most commonly reported TEAEs were nasopharyngitis (17 [5.4%] TIL-treated vs 5 [6.3%] placebo-treated), headache (15 [4.8%] vs 2 [2.5%]), and hypertension (11 [3.5%] vs 4 [5.1%]), respectively (**Table 2**). The most commonly reported serious TEAE was hypertension (2 [0.6%] in TIL-treated patients, **Table 3**). One patient (0.3%) in the TIL group had a serious infection (chronic tonsillitis). At 24 weeks, there were no reports of candidiasis, inflammatory bowel disease, major adverse cardiac events, significantly increased liver enzymes, or malignancies. In addition, no deaths or discontinuations due to TEAEs were reported. There were no significant elevations in laboratory parameters that led to a serious TEAE designation.

Conclusion: These findings demonstrate that TIL is well tolerated with low rates of TEAEs and serious TEAEs reported during the first 24 weeks of the phase 2b trial.

Editorial support was provided by Puneet Dang, PhD, of AlphaBioCom, LLC.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We assessed residual plaque psoriasis in patients successfully treated with anti–interleukin-23p19 monoclonal antibody tildrakizumab (TIL) who interrupted treatment, relapsed, and were retreated vs continuously treated patients in a post hoc analysis of reSURFACE 1.

Methods: reSURFACE 1 was a 3-part, double-blind, randomized, controlled, 64-week phase 3 study of TIL 100 mg in adults with moderate-to-severe plaque psoriasis (NCT01722331).[1] Patients receiving TIL 100 mg at weeks 0, 4, and 16, and every 12 weeks thereafter who achieved ≥75% relative improvement in Psoriasis Area and Severity Index (PASI) score from baseline at week 28 were rerandomized to receive placebo (N = 113) or continue TIL 100 mg (N = 116). Residual disease (PASI score) and adverse events (AEs) were evaluated every 4 weeks through week 64. Relapse was defined as ≥50% loss of maximum PASI response; successful retreatment as regaining ≥50% of previous maximum PASI response. Patients rerandomized to placebo who relapsed were reassigned to TIL 100 mg; those retreated for ≥12 weeks were included in efficacy analyses. Missing data were imputed using last-observation-carried-forward.

Results: The 61/113 (54.0%) patients rerandomized to placebo who relapsed had median PASI scores at baseline, week 28, and time of relapse of 20.3, 0.8, and 11.0, respectively. Median (interquartile range [IQR]) time to relapse was 238 (167, 294) days. Among 51 patients retreated for ≥12 weeks, median (IQR) time to regain response was 28 (28, 48) days. Median PASI scores were 5.9, 3.2, and 2.7 after 4 (n = 51), 8 (n = 46), and 12 weeks (n = 33) of retreatment, respectively. At week 64 (n = 61), 72.1%/31.2%/13.1% of these patients achieved PASI 75/90/100 responses, respectively.

The 52/113 (46.0%) patients who did not relapse 36 weeks after rerandomization to placebo (week 64) had median PASI scores of 0.8, 2.6, and 4.0 at weeks 28, 52, and 64, respectively. Of patients who continued TIL, 8/116 (6.9%) relapsed after week 28—7 on only 1 visit—and 100% completed the study with median (IQR) PASI score 1.4 (0.0, 3.4). For 108/116 (93.1%) patients who maintained response on TIL 100 mg, median (IQR) PASI at weeks 28, 52, and 64 was 1.0 (0.0, 2.2), 1.0 (0.0, 2.4), and 1.2 (0.0, 3.0).

Two AEs of interest occurred in 2/113 (1.8%) responders rerandomized to placebo after week 28 (cerebellar infarction and basal cell carcinoma). In patients rerandomized to TIL after week 28 (including partial responders), 3/135 (2.2%) reported 4 AEs of interest (basal cell carcinoma, Bowen's disease, carcinoma in situ of the skin, and sinusitis).

Conclusion: In reSURFACE 1, 46.5% of patients treated with TIL 100 mg for 28 weeks and rerandomized to placebo for 36 weeks did not relapse 48 weeks after last TIL dose. In patients who relapsed, residual disease was successfully treated with TIL 100 mg within a median of 28 days. Continuation of TIL was associated with low residual disease; 93.1% of patients responded and all completed the study. Approximately 50% of patients who continued TIL 100 mg to week 52 had residual PASI scores ≤1.0.

Limited Changes in Hematological Parameters During Tildrakizumab Treatment: Post Hoc Analysis of Data from the Tildrakizumab Psoriasis Clinical Program

Holly Glover,[1] Kristine Kucera,[2] **Alan Mendelsohn**,[3] Jeff Parno,[3] Stephen Rozzo,[3] Frank Ferritto,[4] and Renata Block[5], [1]Dermatology and Skin Cancer Surgery Center, McKinney, TX, USA, McKinney, TX, [2]North Texas Dermatology, Richardson, TX, USA, Richardson, TX, [3]Sun Pharmaceutical Industries, Inc., Princeton, NJ, USA, Princeton, NJ, [4]Polley Dermatology, Wilson, NC, USA, Wilson, NC, [5]Pinski Dermatology & Cosmetic Surgery, Chicago, IL, USA, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Tildrakizumab (TIL) is a high-affinity, anti–interleukin-23p19 monoclonal antibody with demonstrated efficacy for the treatment of chronic plaque psoriasis in a phase 2b (P05495 [NCT01225731]) and 2 phase 3 clinical studies (reSURFACE 1 [NCT01722331] and 2 [NCT01729754]).[1,2] We evaluated hematological laboratory findings for evidence of drug-induced changes following TIL treatment using data from 3 randomized, placebo-controlled trials.

Methods: Data were pooled from the P05495 and reSURFACE 1 and 2 trials of patients with moderate to severe chronic plaque psoriasis. Here we report changes at week 52 vs baseline in hematological parameters for patients with continuous exposure to TIL 100 mg or 200 mg administered at week 0 and week 4, and every 12 weeks thereafter up to week 52 (P05495 and reSURFACE 2) or week 64 (reSURFACE 1). An analysis of changes in hematological parameters from baseline to worst values obtained relative to reference ranges is also reported.

Results: Among patients with continuous exposure to TIL 100 mg and 200 mg, limited changes in hematological parameters were observed. Mean (standard deviation) changes at week 52 vs baseline for TIL 100 mg (N = 249 patients with data) were 0.3% (2.4) for hematocrit, 0.1 g/dL (0.7) for hemoglobin, $-4.0 \times 10^3/\mu L$ (37.0×10^3) for platelets, $0.1 \times 10^3/\mu L$ (0.4×10^3) for lymphocytes, $0 \times 10^6/\mu L$ (0.3×10^6) for erythrocytes, and $-0.5 \times 10^3/\mu L$ (1.6×10^3) for neutrophils. Corresponding values for TIL 200 mg (N = 204 patients with data) were 0.3% (2.4) for hematocrit, 0.1 g/dL (0.8) for hemoglobin, $-6.8 \times 10^3/\mu L$ (36.9×10^3) for platelets, $0 \times 10^3/\mu L$ (0.5×10^3) for lymphocytes, $0 \times 10^6/\mu L$ (0.2×10^6) for erythrocytes, and $-0.4 \times 10^3/\mu L$ (1.9×10^3) for neutrophils. Similarly, limited changes were also seen for leukocytes, monocytes, eosinophils, lymphocytes/leukocytes, eosinophils/leukocytes, and basophils/leukocytes. The majority of patients (80.1%–100%) had hematological parameter values within normal ranges at baseline; worst values for most of these patients remained within normal ranges over 52 weeks. No changes correlated with adverse events such as infections or thrombocytopenia.

Conclusion: In this pooled analysis of phase 2b and phase 3 trials, only limited changes in hematological parameters—including white blood cells, erythrocytes, and platelets—were observed in patients treated with TIL over 52 weeks. Based on these data, patients receiving TIL are unlikely to require routine laboratory testing for hematological parameters.

Resolution of Enthesitis and Dactylitis Is Maintained over Two Years of Ixekizumab Treatment in Patients with Psoriatic Arthritis

Arthur Kavanaugh,[1] Lihi Eder,[2] Josef Smolen,[3] Matthew M. Hufford,[4] Chen-Yen Lin,[4] Aubrey Trevelin Sprabery,[4] and Dennis McGonagle[5], [1]University of California, San Diego School of Medicine, La Jolla, CA, [2]Women's College Hospital and the Department of Medicine, University of Toronto, Toronto, Canada, [3]Medical University of Vienna, Vienna, Austria, [4]Eli Lilly and Company, Indianapolis, IN, [5]University of Leeds, Leeds, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Enthesitis and dactylitis are prominent peri-articular domains of involvement in PsA.[1] The activity of enthesitis and dactylitis can vary over time.[1] Some conventional and more biologic DMARDs have demonstrated improvements in enthesitis and dactylitis. Ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets IL-17A, has shown sustained improvement in signs and symptoms of active PsA, including enthesitis and dactylitis.[2] The purpose of this study is to examine patients who had resolution of enthesitis and dactylitis with treatment, to see if efficacy was maintained for up to 2 years of IXE treatment.

Methods: Data was integrated from two Phase 3, double-blind, randomized controlled trials in biologic DMARDs-naïve (SPIRIT-P1) and TNF inhibitor (TNFi; SPIRIT-P2) experienced patients who received subcutaneous: placebo, adalimumab (SPIRIT-P1 only; reference arm) 40 mg every 2 weeks, or IXE 80 mg every 2 weeks (Q2W) or every 4 weeks (Q4W) after a 160-mg starting dose. At Week 24, PBO patients were re-randomized to IXEQ2W or IXEQ4W. All

Table. Baseline demographics of the maintenance primary population

	LEI=0		LDI-B=0	
	IXE Q4W/Q4W (N=80)	IXE Q2W/Q2W (N=65)	IXE Q4W/Q4W (N=76)	IXE Q2W/Q2W (N=51)
Age (years)	48.2 (12.4)	48.7 (13.4)	47.3 (12.1)	47.2 (12.8)
Male, n (%)	39 (48.8%)	31 (47.7%)	41 (53.9%)	26 (51.0%)
Time since PsA onset (years)	10.6 (9.8)	10.9 (7.1)	10.0 (8.1)	9.5 (7.3)
TJC (68 joints)	19.5 (11.7)	20.8 (13.8)	21.6 (12.8)	22.6 (15.4)
SJC (66 joints)	12.6 (9.3)	11.8 (8.4)	14.5 (11.4)	15.2 (10.1)
CRP (mg/L)	17.7 (27.4)	12.5 (21.2)	16.4 (24.3)	19.0 (31.7)
LEI>0	2.5 (1.4)	2.5 (1.5)	2.9 (1.5)	3.1 (1.6)
LDI-B>0	67.3 (97.9)	54.7 (35.4)	59.4 (90.8)	52.2 (42.2)

Unless otherwise indicated, data presented here are mean (SD).

IXE=ixekizumab; IXE80Q2W=IXE 80 mg every 2 weeks; IXE80Q4W=IXE 80 mg every 4 weeks; LDI-B=Leeds dactylitis index-basic; LEI=Leeds enthesitis index; N=total number of analyzed patients in each subgroup; SD=standard deviation; SJC= swollen joint count; TJC=tender joint count.

patients met the Classification Criteria for PsA. Maintenance primary population included patients who were initially randomized to IXE, completed their Week 24 visit, and had resolution of baseline enthesitis or dactylitis at Week 24. Resolution was defined as Leeds enthesitis index (LEI=0) or Leeds dactylitis index-basic (LDI-B=0). Percentage of patients who maintained LEI and LDI-B resolution were presented up to Week 108 by using the observed method.

Results: In this analysis, we evaluated patients that had enthesitis (LEI >0; N=145) and/or dactylitis (LDI-B >0; N=127) present at baseline that had resolved at Week 24 of IXE treatment. Baseline LEI scores were 2.5 for patients who had resolved their enthesitis, and baseline LDI-B scores were 56.7 for patients who had resolved their dactylitis. Patient demographics and disease characteristics in both groups were similar (Table). Resolution of enthesitis and dactylitis was maintained up to 108 weeks of continuous IXE treatment by LEI=0 (>80%) and LDI-B=0 (100%) groups, respectively. Responses were similar for both IXE dosing regimens (Figure).

Conclusion: Resolution of enthesitis or dactylitis can be maintained over 2 years of treatment with IXE in patients with PsA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The first symptoms of ankylosing spondylitis (AS) patients usually begin prior to 45 years, but can occur later in life. The purpose of this study is to evaluate the efficacy and safety of anti-TNFα treatment in late-onset AS (LoAS) patients in comparison to those with adult onset AS (AoAS).

Methods: We studied AS patients in TURKBIO registry between the dates of January 2011 and November 2018. All the patients fulfilled the modified New York criteria for AS and were classified into 2 groups based on their age at symptom onset: AoAS (age >16 but ≤45 years); and LoAS (age >45 years). In both groups, the following data were evaluated and compared: (1) epidemiological variables (2) clinical manifestations, including signs and symptoms at diagnosis; (3) laboratory results (4) disease activity markers and follow-up parameters (BASDAI, ASDAS-CRP and HAQ); (5) previous and current treatments (6) adverse events.

Results: A total of 2551 AS patients (91,1% with AoAS and 8.9% with LoAS) were included in the study. LoAS group had more female patients, older age, shorter disease duration, shorter diagnostic delay, higher initial ESR and less HLA-B27 positivity compared to the AoAS (Table 1). Peripheral arthritis (not statistically significant) and dactylitis was seen more common in the LoAS. The frequency of other involvements was similar between the groups (Table1).The frequency of using drugs was similar between each groups although the use of glucocorticoids and sulphasalazine was more common in the LoAS. Switching from the first anti-TNFa treatment to the second one was more common in the AoAS. However, there was found no significant difference between the two groups in 2 or more switch ratios (Table 1). At the latest visit after the anti-TNFα therapy, the mean improvement in BASDAI was significantly higher in the AoAS (Table 2). A total of 10 (4.4%) serious adverse events were reported in LoAS and 39 (1.7%) in AoAS patients in the follow-up (HR: 2.62; 95% CI: 1.32–5.18). Severe infections were the most commonly seen serious adverse events (1.3% in LoAS and 0.8% in AoAS), followed by rash and allergic reactions (0.9% in LoAS and 0.3% in AoAS).

Table 1. Demographic and clinical characteristics of patients with AoAS and LoAS

	AoAS (≤45 yrs)	LoAS (>45 yrs)	p-value
N	2324	227	
Sex (male), n (%)	1411 (61)	109 (48)	**<0.001**

Anti-TNFα	1467 (63)	134 (59)	0.252
Secukinumab	31 (1)	2 (1)	0.788
Anti-TNFα switch, n (%)			
One switch	359 (15)	22 (10)	**0.026**
Two switch	113 (5)	7 (3)	0.297
Three switch	25 (1)	3 (1)	0.996
Four switch	8 (0.3)	0 (0)	0.792

AoAS: adult-onset ankylosing spondylitis, **LoAS:** late-onset ankylosing spondylitis

***Continuous variables were presented as mean ±SD for both table**

Tuberculosis was observed in 2 patients (0.9%) in LoAS and 9 (0.4%) in AoAS, malignancy in 3 patients (1.3%) in LoAS and 6 (0.3%) in AoAS.

Conclusion: Our data showed that almost 8.9% of the patients with AS had late-onset of symptoms. The results suggested that LoAS patients might have different demographic, clinical features, disease activity parameters at baseline. The frequency of anti-TNFα use and response rate to the treatment was also similar in LoAS to those in AoAS patients. The patients with LoAS seem to have more common severe adverse events compared to the AOAS patients possibly related to their older age.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Ankylosing spondylitis (AS) can lead to reduced physical functioning and quality of life. Secukinumab has demonstrated clinical benefits in AS patients in clinical trials[1-2]. The purpose of this study was to assess effectiveness of secukinumab in AS in a real-world setting.

Methods: This was a cross-sectional survey of rheumatologists and patients in France, Germany, Italy, Spain, and UK. Data were collected online from June-December 2018 via physician-completed patient record forms. Patients receiving any treatment for AS were included in the survey (n=1392). Patients receiving secukinumab >4 months were included in this analysis. Physicians reported patient overall disease severity (mild/moderate/severe), pain (1-10 scale), global VAS score, and BASDAI score for 2 time points – the initiation of secukinumab, and at the time of data

Table 1: Patient outcomes at initiation of secukinumab and at their current consultation, mean (SD)

	At initiation of secukinumab (n=359)	At current consultation (n=359), length of time received secukinumab		
		4-<6 months (n=54)	6-<12 months (n=171)	12+ months (n=134)
Overall disease severity, n (%)				
Mild	7 (1.9)	32 (59.3)	116 (67.8)	91 (67.6)
Moderate	179 (49.8)	21 (38.9)	48 (28.1)	42 (31.3)
Severe	171 (47.6)	1 (1.9)	7 (4.1)	1 (0.7)
Don't know	2 (0.6)	-	-	-
BASDAI score[a]	6.2 (1.9)	3.1 (1.8)	2.9 (1.7)	2.9 (2.0)
BASDAI score < 4, n (%)[a]	17 (10)	11 (52.4)	56 (66.7)	52 (68.4)
Pain score (1-10)	7.1 (1.4)	3.4 (1.6)	3.3 (1.8)	2.8 (1.7)
Physician global VAS score (1-100)[a]	56.2 (24.2)	25.5 (25.8)	21.9 (19.5)	25.3 (21.1)
Patient global VAS score (1-100)[a]	63.4 (26.4)	22.9 (20.7)	26.2 (20.2)	27.5 (23.5)

[a]Calculated on available data.

collection (current consultation). Outcomes at the current consultation were grouped according to length of time receiving secukinumab (4 - < 6, 6 - < 12, 12+ months). Physicians also reported patient demographic and disease characteristics, current symptoms present, concomitant and previous treatments, time since diagnosis, and physician satisfaction with secukinumab, while patients reported their current satisfaction, quality of life, work, and functioning measures at their current consultation (EQ5D, WPAI, ASAS HI). Data were analysed descriptively.

Results: 359 AS patients were receiving secukinumab >4 months at their current consultation. Patient mean age was 45.4 years, with 25% female, 67% working full time, and a mean BMI of 25.7. On average, patients were diagnosed with AS for 7.1 years, had received secukinumab for 10.6 months, and for 53% of patient secukinumab was their 1st advanced therapy (specifically bDMARDs or tsDMARDs), 30% their 2nd and 17% their 3rd or more. 15% of patients were also receiving a csDMARD concurrently. 9% of patients had enthesitis, and 20% had spinal fusion. Patients reported a mean EQ5D utility score of 0.83, mean WPAI overall work impairment percentage of 27.4%, and mean ASAS HI score of 5.4 at their current consultation. 83% of patients and 92% of physicians reported being satisfied with secukinumab.

Between initiation of treatment and their current consultation, patients achieved a reduction in disease activity scores and disease severity. The proportion of patients achieving a BASDAI score < 4, increased from 10 to 68%. This pattern was seen regardless of length of time receiving secukinumab (Table 1).

Conclusion: Secukinumab provided overall effectiveness and satisfaction in both physicians and patients in a real-world, clinical setting. Significant improvements were seen across all outcomes, regardless of length of time receiving treatment, highlighting an early and sustained response to secukinumab.

ALPN-101, a First-in-Class Dual ICOS/CD28 Antagonist, Suppresses Key Effector Mechanisms Underlying Rheumatoid and Psoriatic Arthritis

Lawrence Evans,[1] Stacey Dillon,[1] Katherine Lewis,[1] Susan Bort,[1] Erika Rickel,[1] Jing Yang,[1] Martin Wolfson,[1] Sherri Mudri,[1] Kayla Susmilch,[1] Steven Levin,[1] Sean MacNeil,[1] Mark Rixon,[1] Jan Hillson,[2] Stanford Peng,[1] and Kristine Swiderek[1], [1]Alpine Immune Sciences, Seattle, WA, [2]Alpine Immune Sciences, Seattle, WI

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: ALPN-101 is an Fc fusion protein of a human inducible T cell costimulator ligand (ICOSL) variant immunoglobulin domain (vIgD™) designed to simultaneously inhibit the CD28 and ICOS costimulatory pathways. CD28 and ICOS each play a role in T cell activation and adaptive immunity which can contribute to autoimmune disease when dysregulated. ALPN-101 has previously been shown to have potent immunosuppressive activity in various *in vitro* and *in vivo* models of disease, including acute graft-versus host disease and multiple sclerosis. We report here *in vitro* analyses using PBMC from rheumatoid arthritis (RA) and psoriatic arthritis (PsA) patients and from healthy donors. ALPN-101 demonstrated superior suppression of human T cell activation and potent reduction of inflammatory mediators known to contribute to the pathogenesis of RA, PsA, and juvenile idiopathic arthritis (JIA). Additionally, the efficacy of ALPN-101 was confirmed *in vivo* in a mouse model of collagen-induced arthritis (CIA).

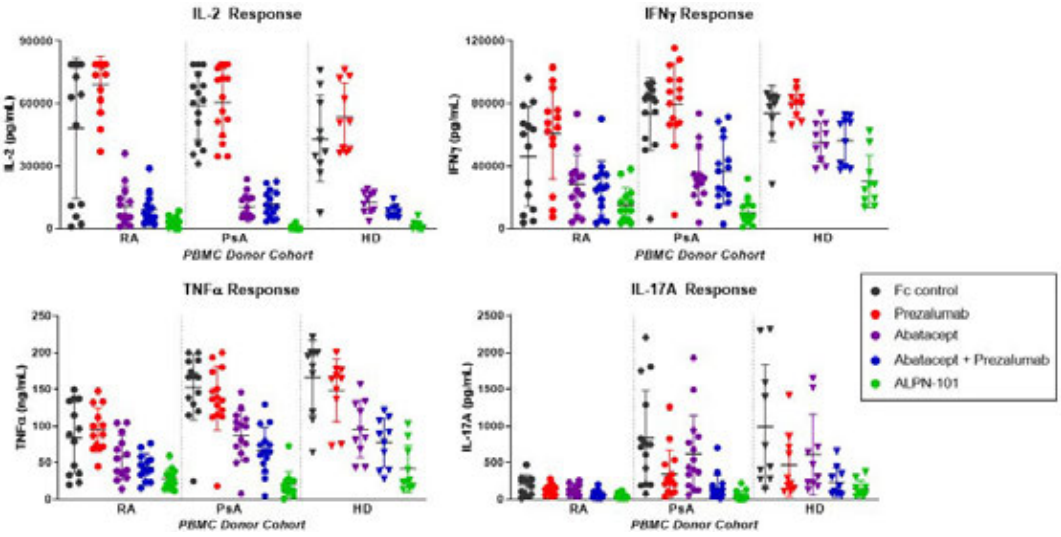

Figure 1: ALPN-101 Potently Inhibits T Cell Activation In Vitro in PBMC from Healthy Donors, Rheumatoid Arthritis, and Psoriatic Arthritis Patients. In vitro stimulation of healthy donor (HD), rheumatoid arthritis (RA), and psoriatic arthritis (PsA) patient PBMC with artificial APC [fixed K562 expressing cell surface OKT3 (anti-CD3)/CD80/CD86/ICOSL)] at a 20:1 ratio. Test articles were added at 100 nM and supernatants were collected and assayed for cytokine concentrations after a 48 hr incubation. ALPN-101 demonstrated statistically significant superiority to prezalumab, abatacept, or a combination of prezalumab+abatacept for the majority of donors and analytes tested.

Methods: Healthy donor, RA, and PsA patient PBMC or Th17-skewed T cell cultures were stimulated with K562 cells expressing CD80, CD86, ICOSL, and anti-CD3 (OKT3) to evaluate the potency of ALPN-101 to suppress pro-inflammatory cytokine production. The activity of dual pathway inhibition by ALPN-101 was compared to the CD28-only inhibitor abatacept (CTLA-4-Fc) and to the ICOS pathway inhibitor prezalumab (AMG-557; anti-ICOSL, Creative Biolabs). ALPN-101 was tested *in vivo* vs. abatacept in a CIA model in which male DBA/1 mice were immunized with bovine collagen in Freund's adjuvant on Days 0 and 18.

Results: Compared to abatacept, prezalumab, or combination abatacept + prezalumab, ALPN-101 demonstrated superior suppression of pro-inflammatory cytokine (i.e. TNF-α, IFN-γ, IL-1β, IL-2, IL-6, IL-17A, GM-CSF, RANKL, etc.) release from stimulated healthy and patient PBMCs (Fig. 1), and suppressed T cell proliferation in Th17-skewed cultures. The administration of ALPN-101 also consistently resulted in significant disease reduction in the mouse CIA model (including decreased paw inflammation, serum cytokines, and anti-collagen antibodies), matching or exceeding the activity of abatacept.

Conclusion: The immunosuppressive efficacy of dual CD28/ICOS antagonist ALPN-101 is superior to CD28 or ICOS costimulatory pathway inhibitors, administered individually or in combination, in human *in vitro* and/or mouse *in vivo* translational studies. The data suggest that ALPN-101 may significantly improve upon the clinical efficacy of currently approved therapeutics like abatacept for treatment of inflammatory diseases, including rheumatoid, psoriatic, and juvenile idiopathic arthritis. A Phase 1 clinical trial with ALPN-101 in healthy volunteers is underway, and trials in inflammatory arthritis and other inflammatory diseases are targeted to begin soon.

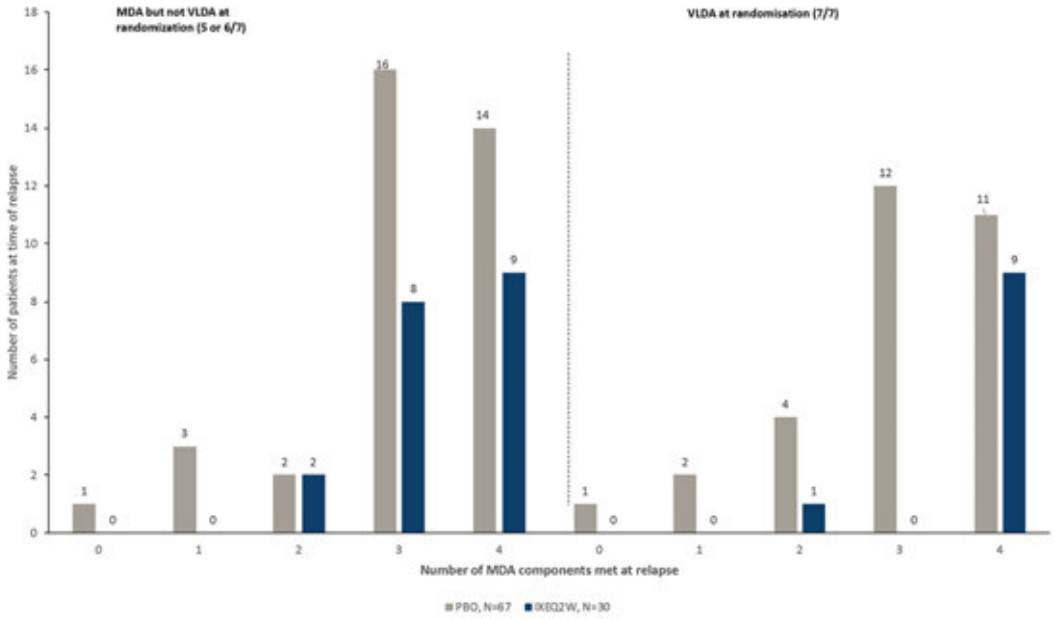
NA=cannot be estimated due to insufficient events in analysis duration

BSA=Body Surface Area; cDMARD=conventional synthetic DMARD; CI=confidence interval; HAQ-DI=Health Assessment Questionnaire Disability Index; IXE=ixekizumab; MDA=minimal disease activity; N=number of patients who met the individual MDA component at time of randomization in each category; n=number of patients with loss of response in each category; PASI=Psoriasis Area and Severity Index; PBO=placebo; RWITT=randomized withdrawal intent-to-treat; SJC=Swollen Joint Count; TJC=Tender Joint count; VAS=Visual Analog Scale

Table. Time to loss of response of individual components of MDA in RW intent-to-treat population

active PsA. SPIRIT-P3 was a randomized withdrawal (RW) phase 3b clinical trial that demonstrated that in patients who achieved sustained minimal disease activity (MDA) after open label (OL) IXE treatment, continued IXE treatment was superior to IXE withdrawal (placebo, PBO) in maintaining MDA. In this pre-specified and post-hoc analysis, we assessed the impact of IXE withdrawal on the individual components of MDA.

Methods: In SPIRIT-P3 (NCT02584855), patients with active PsA who were naïve to biologic DMARDs received OL treatment with IXE 80 mg every two weeks (Q2W) after a 160-mg starting dose for at least 36 weeks. Patients who achieved MDA (at least 5 out of 7 components [see table]) for three consecutive months between Weeks 36 and 64 were flexibly randomized 1:1 to IXE Q2W or placebo (PBO) and evaluated up to Week 104 in a double-blind manner. Patients were considered relapsed if they lost MDA at any point during the RW and received IXEQ2W thereafter. Kaplan-Meier product limit method was used to estimate time to loss of response of individual components in the RW intent-to-treat population. Treatment comparisons were done between groups using adjusted log-rank test stratified



IXE=ixekizumab; MDA=minimal disease activity; N=number of patients in each group; PBO=placebo; VLDA=very low disease activity.

Figure. Patients meeting number of components of MDA met at the time of relapse in PBO and IXE groups in relapse population

by geographic region and conventional synthetic DMARDs (cDMARD) use. A p-value < 0.05 was considered to be significant. Number of components of MDA met at randomization and at time of relapse in both PBO and IXE groups were assessed in the relapse population.

Results: A total of 394 patients entered into the OL treatment period; 158 (40%) of whom met three consecutive months of MDA and randomized to IXE (N=79) or PBO (N=79) in the RW period. At time of randomization, 77 patients (37 assigned to PBO; 40 assigned to IXEQ2W) had achieved very low disease activity (VLDA; i.e., meeting 7 out of 7 components). Overall, significantly more patients randomized to PBO than IXE relapsed during the RW period (data not shown). Among patients who had VLDA at randomization, 30 (81%) of PBO patients and 10 (25%) of IXE patients met relapse criteria. Time to relapse was significantly shorter in patients on PBO than IXE-treated patients for 5 out of 7 individual components (Tender joint count, Swollen joint count, PASI/BSA, patient pain VAS, Patient Global Disease Activity VAS) of MDA ($p < 0.01$, Table). Among patients who relapsed, 18 (60%) from IXEQ2W and 25 (37%) from PBO groups met 4 out of 7 components at time of relapse (figure).

Conclusion: In patients with sustained MDA, IXE withdrawal led to relapse in components of MDA, particularly tender and swollen joints, patient reported joint pain and disease activity, and psoriasis. IXE withdrawal, relative to continued treatment, was associated with relapse in multiple components of MDA within individual patients, even in patients who had achieved VLDA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Composite measures of disease activity are used in psoriatic arthritis (PsA), but their relative performance and contributions of individual components to overall scores are unclear. Primary results were reported* from a phase 3 trial that randomized methotrexate (MTX)- and biologic-naïve patients with active PsA to weekly: MTX 20 mg; etanercept (ETN) 50 mg; or ETN 50 mg + MTX 20 mg. At week 24, the ETN-containing arms were significant-

ly more effective than MTX monotherapy in achieving an American College of Rheumatology 20 response (primary endpoint) and Minimal Disease Activity response (key secondary endpoint). Compared with MTX monotherapy, the ETN-containing arms also had a composite score change from baseline at week 24 that was larger with Psoriatic Arthritis Disease Activity Score (PASDAS) and numerically higher with Activity Index for Psoriatic Arthritis (DAPSA).* Here we further examine the trial composite measures by analyzing contributions of individual components to the change in overall composite scores from baseline at week 24 for: PASDAS, DAPSA, Disease Activity Score (DAS28-CRP), Clinical Disease Activity Index (CDAI), and Simplified Disease Activity Index (SDAI).

Methods: Using the full analysis set of 851 patients, the median and mean (95% CI) contribution of each individual domain change to the composite measure change from baseline at week 24 was calculated. Analyses were repeated for PASDAS in patient subsets with enthesitis or dactylitis at baseline.

Results: The ETN-containing arms had a greater composite score change from baseline at week 24 compared with MTX monotherapy; PASDAS and DAS28-CRP had relatively greater changes compared with DAPSA, CDAI, and SDAI (Table 1). For DAPSA, DAS28-CRP, CDAI, and SDAI, the joint count changes contributed most to score changes, while the global assessment changes contributed less (Table 2). In contrast, the global assessment changes contributed the most to the PASDAS score changes, with less contribution from joint count changes (Table 3). Contribution of enthesitis change to the PASDAS score change in those with enthesitis at baseline was similar to that of the joint counts; in those with dactylitis at baseline, the contribution of dactylitis change was more than that of the joint counts. Except for DAS28-CRP, the composite score changes showed minimal contributions from changes in CRP. Overall, the contributions of changes in the individual components to the composite score changes were similar between treatment arms.

Conclusion: Results show that changes in "joint-focused" composite endpoints (DAPSA, DAS28-CRP, CDAI, and SDAI) are driven most by joint count changes and less by global assessment changes. Change in PASDAS, which captures a wider range of disease domains, was driven most by global assessment changes (and somewhat by physical function) and less by other domain changes depending on the patient population. Changes in CRP consistently contributed less than other components. Results were consistent across treatment arms.

CDAI, Clinical Disease Activity Index; CI, confidence interval; DAPSA, Disease Activity Index for Psoriatic Arthritis; DAS28-CRP, Disease Activity Score (28 joints) using C-reactive protein; ETN, etanercept; MTX, methotrexate; SDAI, Simplified Disease Activity Index.
[a]Contributions to the overall score are calculated by [change from baseline in each of the component scores / change from baseline in the overall score]. Positive values indicate changes in the same direction as the change in overall score. Negative values indicate changes in the opposite direction as the change in overall score.
[b]Represents a 28-joint count except for DAPSA, which had a 68-joint count.
[c]Represents a 28-joint count except for DAPSA, which had a 66-joint count.

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Filgotinib (FIL) is an orally administered, selective Janus Kinase 1 (JAK1) inhibitor in development for psoriatic arthritis (PsA). Efficacy and safety of FIL in patients with active PsA were evaluated in a 16-week phase 2 study (EQUATOR)[1]. After 16 weeks, patients could roll-over to an Open Label Extension (OLE) Study (EQUATOR2) for the purpose of evaluating long-term safety and efficacy. The aim of this analysis was to assess safety and efficacy through 52 weeks of exposure to filgotinib.

Methods: Patients who completed the randomized, double-blind, placebo controlled study were eligible for participation in the OLE, during which all patients received once daily (qd) open-label FIL 200mg. In this interim analysis of OLE, for the safety analysis, all data were included from the screening in the core study up to the data cut of 18 April 2019 in the OLE. For the efficacy analysis, all data until OLE Week 52 visit (for each patient) were included (observed case analysis).

Results: Of the 131 pts randomized and dosed in EQUATOR, 124 (95%) completed the study and 122 (93%) enrolled in EQUATOR2; 50% were female and mean age was 50. At this interim analysis, 106/122 (87%) remained in the OLE (premature discontinuations during OLE due to: 4 for safety, 11 withdrew consent, and 1 for other reasons). Cumulative patient years of exposure (PYE) on FIL were 160, median time on FIL was 66 weeks. Key safety data are summarized in Table 1. Laboratory abnormalities are shown in Table 2. At week 52, 34% of the patients fulfilled criteria for minimal disease activity and 81%, 55%, and 33% of patients, respectively, achieved ACR20/50/70 responses.

Conclusion: FIL 200mg qd was generally well tolerated and the safety profile in PsA was comparable to that observed in the FIL rheumatoid arthritis studies. The data from this interim analysis suggest that further improvement of the patient condition can be expected beyond 16 weeks of treatment.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

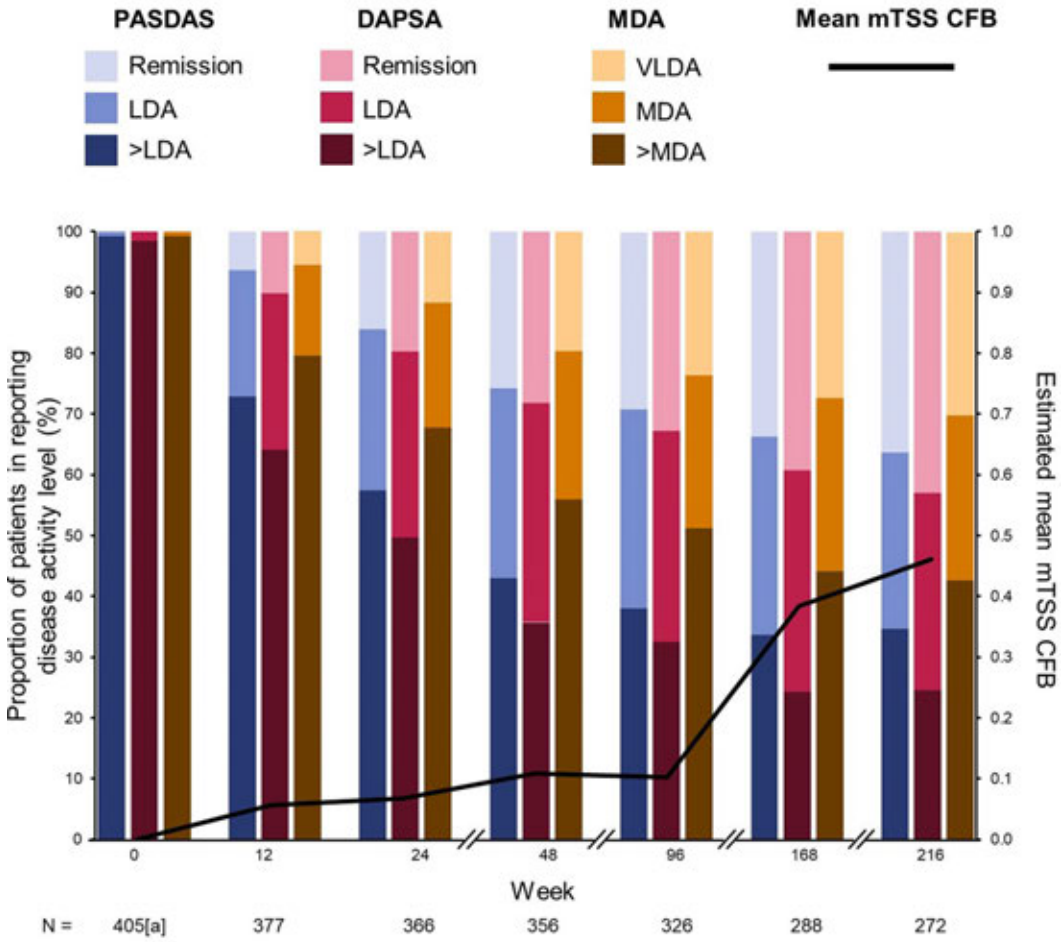
Session Time: 9:00AM–11:00AM

Background/Purpose: Several disease activity measures and thresholds have been recommended as psoriatic arthritis (PsA) treatment targets, although consensus on the most appropriate assessment tool is lacking.[1] Initial reports suggest low disease activity (LDA) and remission may be associated with minimal structural progression in PsA. Here we evaluate the relationship between PsA disease activity and structural progression over 216 weeks' (wks') treatment with certolizumab pegol (CZP), an Fc-free, PEGylated, anti-TNF that has shown long-term efficacy and safety in PsA.[2]

Methods: Patients (pts) enrolled in RAPID-PsA (NCT01087788) with active PsA (≥3 tender joints; ≥3 swollen joints; ESR≥28 mm/hour and/or CRP >upper limit of normal) who had failed treatment with ≥1 conventional synthetic DMARD were randomized 1:1:1 to CZP 200 mg every 2 wks (Q2W), CZP 400 mg every 4 wks (Q4W) (all CZP pts received CZP 400 mg at Wks 0/2/4) or placebo. CZP-randomized pts received the same dose to Wk 216; placebo-pts were re-randomized to CZP 200 mg Q2W or 400 mg Q4W at Wk 16 or 24.[2]

Pts were heterogenous for structural damage and disease duration at baseline. Disease activity was assessed using 3 disease activity measures: minimal disease activity (MDA) criteria (achievement of MDA=5–6/7 MDA criteria; achievement of very LDA [VLDA]=7/7 MDA criteria), Psoriatic Arthritis Disease Activity Score (PASDAS [LDA=score of >1.9–≤3.2; remission=≤1.9]), Disease Activity Index for Psoriatic Arthritis (DAPSA [LDA= >4–≤14; remission=≤4]).

Figure: Observed disease activity levels and estimated mean mTSS change from baseline (mixed effects model) through Wks 0–216 pooled for all randomized patients



[a]Baseline PASDAS data were only available for 398 patients. Data were pooled for all patients randomized to CZP and placebo. Radiographs were taken at Wks 0, 12, 24, 48, 96, 168 and 216. Mean CFB in mTSS was estimated using a hierarchical mixed effects model for repeated measures. The proportion of patients achieving each disease activity level is observed case. PASDAS LDA: >1.9−≤3.2; PASDAS remission: ≤1.9; DAPSA LDA: >4−≤14; DAPSA remission: ≤4; MDA: 5–6/7 MDA criteria; VLDA: 7/7 MDA criteria. CFB: change from baseline; CZP: certolizumab pegol; DAPSA: Disease Activity Index of Psoriatic Arthritis; LDA: low disease activity; MDA: minimal disease activity; mTSS: modified Total Sharp Score; PASDAS: Psoriatic Arthritis Disease Activity Score; VLDA: very low disease activity; wk: week.

Radiographs taken through Wks 0–216 were read in 4 reading campaigns using van der Heijde modified Total Sharp Score (mTSS) for PsA. A subgroup of pts considered at highest risk of structural progression (baseline mTSS >median for all pts) was also assessed. Mean change from baseline (CFB) in mTSS, and associations with disease activity states, were estimated using a hierarchical linear mixed effects model (fixed effects: reading campaign, interactions of concurrent disease activity levels with time; random effects: pt, and reading campaign nested within pt) which allowed the trajectory of mean mTSS, and impact of disease activity levels on this, to be different between each timepoint at which radiographs were taken.

Results: Of 409 randomized pts, 407 were assessed for mTSS at least once. At Wk 0, mean (standard deviation) DAPSA was 44.5 (22.7), PASDAS was 6.0 (1.1). 3/409 (0.7%) pts reported MDA. The proportion of pts achieving remission/VLDA states increased to Wk 216, as did estimated mean mTSS, although overall progression was low (Wk 216 estimated mean mTSS CFB: 0.46; standard error: 0.16) (**Figure**). For all disease activity measures, remission/

Table: Estimated mTSS progression at Wk 216 if a patient had a given disease activity level at all assessments over 216 wks of treatment by MDA, PASDAS and DAPSA categories pooled for all randomized patients (mixed effects model)

		mTSS estimated mean CFB (standard error)	
		All patients (N=407)	Baseline mTSS >median (N=202)
PASDAS	Remission	-0.20 (0.25)	-0.55 (0.49)
	LDA	0.01 (0.23)	-0.07 (0.47)
	>LDA	1.31 (0.22)	2.54 (0.43)
DAPSA	Remission	-0.34 (0.23)	-0.67 (0.46)
	LDA	0.40 (0.22)	0.81 (0.44)
	>LDA	1.37 (0.24)	2.46 (0.48)
MDA	VLDA	-0.40 (0.28)	-0.84 (0.55)
	MDA	0.39 (0.24)	0.55 (0.48)
	>MDA	0.89 (0.20)	1.73 (0.39)

mTSS estimated mean CFB: ≤0; ≤0.5; >0.5. Data were pooled for all patients randomized to CZP and placebo through Wks 0–216. Mean CFB in mTSS was estimated at Wk 216 using a hierarchical mixed effects model for repeated measures. PASDAS LDA: >1.9–≤3.2; PASDAS remission: ≤1.9; DAPSA LDA: >4–≤14; DAPSA remission: ≤4; MDA: 5–6/7 MDA criteria; VLDA: 7/7 MDA criteria. CFB: change from baseline; CZP: certolizumab pegol; DAPSA: Disease Activity Index of Psoriatic Arthritis; LDA: low disease activity; MDA: minimal disease activity; mTSS: modified Total Sharp Score; PASDAS: Psoriatic Arthritis Disease Activity Score; VLDA: very low disease activity; wk: week.

VLDA states were associated with mTSS estimated mean CFB ≤0 in both the overall group of pts and those considered at highest risk of structural progression at baseline (**Table**).

Conclusion: These data indicate that achievement of remission in PsA is important to prevent further structural damage, particularly when pts have pre-existing structural changes. This supports the rationale for strict disease activity targets.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Post-transcriptional control of cytokine and chemokine gene expression is an important checkpoint during inflammation. The MAPKAPK2 (MK2) pathway in particular is critical in regulating the expression of TNF-α and other inflammatory factors by promoting the stability and translation of their transcripts (Kotlyarov 1999 *Nat Cell Biol*; Neininger 2002 *J Biol Chem*). Illustrating the centrality of this pathway, MK2 knockout mice are protected from inflammation in various inflammatory models (Kotlyarov 1999 *Nat Cell Biol*; Hegen 2006 *J Immunol*). We hypothesized that inhibition of MK2 would regulate the production of TNF-α and other inflammatory mediators and would therefore ameliorate diseases in which these cytokines and chemokines play a role, including ankylosing spondylitis (AS).

Methods: A novel inhibitor of MK2 was evaluated in vitro for inhibition of lipopolysaccharide (LPS)-induced inflammatory cytokines from peripheral blood mononuclear cells (PBMCs), and for inhibition of IL-17 production from Th17 polarized cells. In addition, the impact of MK2 inhibition on osteoclast function was assessed using a bone resorption assay. The in vivo effect of the MK2 inhibitor was evaluated in an animal model of joint inflammation. The safety, tolerability, and pharmacokinetics (PK) of single ascending doses of the MK2 inhibitor were evaluated in an ongoing first-in-human (FIH) study. Ex vivo stimulation of PBMCs from participants in the FIH study was conducted to assess the pharmacodynamic properties.

Results: The MK2 inhibitor reduced production of TNF-α and chemokines such as monocyte chemoattractant protein-1 (MCP-1) following in vitro LPS stimulation of PBMCs from healthy donors and patients with AS in a concentration-dependent manner. In addition, decreased IL-17 production was observed in polarized Th17 cells from healthy volunteers. The MK2 inhibitor modulated osteoclastogenesis and reduced osteoclast activity in vitro. In an animal model of spondyloarthropathy, dose-dependent reduction in peripheral joint disease severity was observed. In the FIH study, the MK2 inhibitor was safe and well tolerated when administered orally as single ascending doses to healthy participants. A favorable PK profile was observed across the single dose range tested. In an ex vivo LPS-stimulation assay, PBMCs from study participants secreted reduced levels of TNF-α following administration of the MK2 inhibitor.

Conclusion: We describe an inhibitor of MK2 that reduces expression of inflammatory mediators in vitro and inhibits joint inflammation in an animal model of spondyloarthropathy. Inhibition of TNF-α production was demonstrated in PBMCs from healthy volunteers. Further investigation of this MK2 inhibitor in diseases mediated by MK2-modulated inflammatory factors, such as TNF-α and IL-17, is warranted.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The additional benefit of methotrexate as a concomitant treatment in PsA has not been fully elucidated. Observational data exist for concomitant methotrexate (MTX) use with TNF inhibitors (TNFi) and suggest no additional benefit. No real-world data currently exist for ustekinumab (UST). The objective of this study was to investigate the additive effect of MTX on the ability to reach composite treatment targets beyond monotherapy with UST or TNFi, as well as the ability to improve patient-reported outcomes in a real-world clinical setting in 8 European countries.

Methods: The PsABio study (NCT02627768) evaluates effectiveness, tolerability and persistence of 1st, 2nd or 3rd-line UST or TNFi in patients with PsA. Proportions of patients reaching minimal disease activity (MDA)/very low disease activity (VLDA) and clinical Disease Activity in Psoriatic Arthritis (cDAPSA) low disease activity (LDA) or remission, as well as reaching the 12-item Psoriatic Arthritis Impact of Disease questionnaire (PsAID-12) patient acceptable symptom state (PASS). Baseline (BL) and 6-month data were compared in patients receiving UST or TNFi in an intention to treat (ITT) analysis, including patients who switched/stopped original treatment during the 6-month observation period, who were imputed as non-responders. Logistic regression was used to assess the effect of concomitant conventional synthetic (cs)DMARD use within UST and TNFi cohorts adjusted for baseline PSAID-12, gender, smoking, number of comorbidities, steroid use, NSAID use, dactylitis, biologic (b)DMARD treatment line, BSA, enthesitis, PsA category. Comparison of the UST and TNFi treatment effect and the interaction with csDMARD co-therapy was done using logistic regression analysis that included propensity score (PS) to adjust for BL covariates age, gender, smoking, comorbidities, psoriasis BSA, PsA type, disease duration, cDAPSA, PsAID-12, enthesitis, dactylitis, Fibromyalgia Rapid Screening Tool (FiRST) score, line of bDMARD, csDMARD use, and steroid or NSAID use.

Results: Of 930 patients, data was available for 868 ITT patients (Table 1), including patients who had switched/stopped before 6 months (UST: n=28/426 [6.6%], TNFi: n=44/442 [10.0%]). For MDA assessment, 761 patients had data for both visits. Co-therapy with MTX did not increase the likelihood of achieving any of the outcomes in either the UST or TNFi cohorts (Table 2). After PS adjustment, co-treatment with MTX did not influence treatment effects

Table 1: Baseline characteristics of the 868 ITT patients

	UST	TNFi
N	426	442
Age, years	51.2 (12.5)	48.5 (12.6)

Steroids	32.4	34.4
FiRST total score	3.50 (2.01)	3.12 (1.95)
FiRST ≥5 %	39.3	29.0
Total PsAID-12 (0–10)	5.71 (2.17)	5.52 (2.08)
Rheumatoid factor/cyclic citrullinated peptide positive, %	2.0/3.0	5.6/2.8

Values are mean (standard deviation) unless otherwise indicated.

differently when added to UST compared with TNFi. The concomitant use of any csDMARD or other csDMARDs apart from MTX yielded very similar results (data not shown).

Conclusion: In a real-world setting, concomitant treatment with MTX in addition to UST or TNFi was not associated with enhanced effects across a broad variety of disease outcomes, including disease activity, impact of the disease, and skin involvement within or between treatment cohorts, after PS adjustment for baseline confounders.

Table 2: Effect of MTX co-therapy versus UST- or TNFi_-monotherapy on disease outcomes at Month 6

Percentage achieving outcome	UST + MTX	UST-monotherapy	TNFi + MTX	TNFi-monotherapy

Abstract Number: 1538

The Effects of Apremilast Therapy on Deployability in Active Duty U.S. Army Soldiers with Plaque Psoriasis and Psoriatic Arthritis

Andrew Price,[1] Vanya Wagler,[2] Chase Donaldson,[1] and Patrick Mastin[1], [1]William Beaumont Army Medical Center, El Paso, TX, [2]United Regional Physician Group, Wichita Falls, TX

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Apremilast is a novel oral phosphodiesterase 4 inhibitor that is used for plaque psoriasis (PsO) and psoriatic arthritis (PsA). This medicine is unique in that it is oral and does not require refrigeration or laboratory monitoring. It also does not increase infection risk and has a small side-effect profile in comparison to other agents. These characteristics make apremilast a potentially useful therapy for active duty (AD) military patients who may deploy to austere environments. This retrospective chart review examined the use of apremilast in the Army for PsO and PsA in an effort to describe the effects that it may have on troop deployability.

Methods: Study subjects included AD U.S. Army personnel who were started on apremilast for PsO or PsA between March 31, 2014, and January 1, 2018. A list of candidates was obtained via the defense pharmacy analytics section. In order to be considered for inclusion, prior dermatology or rheumatology documentation needed to be available in the military health record confirming diagnosis of PsO or PsA. Each patient's records were reviewed to assess the efficacy and tolerability of treatment by listing duration of treatment, any discontinuation of therapy, or documented adverse events. Military records were then examined to confirm current deployability. Primary endpoints consisted of deployments while on apremilast and current deployability. Resulting data points were subsequently organized and reported in a descriptive manner for the purpose of analyzing practice patterns in this patient population.

Results: 227 study subjects were included. The patient population was predominantly male (n=209, 92.1%) with an average age of 38. 165 (72.7%) had PsO, and 62 (27.3%) had PsA. As of the date of initial data extraction (April 3, 2019), 63 (27.8%) were still on apremilast, but the remainder had discontinued the medication. The average duration of treatment was 15.2 months for all patients. When available, the most common reason for discontinuation was lack of efficacy (n=58). The most common reported adverse effect was gastrointestinal upset (n=30). 85 patients with both PsO and PsA had deployments during the study timeframe until April 2019. Of the patients with deployments meeting the above criteria, 22 patients with PsO and 5 with PsA were able to deploy while on apremilast. Of the 129 patients who were still AD at initial data extraction, 119 (92.2%) were reported as "Deployable" on military records.

Conclusion: Further research is needed to determine the impact of apremilast on deployability in the U.S. Army. Despite the limitations arising from record heterogeneity and the descriptive nature of this study, this data does provide insight into caring for patients that cannot be given other agents due to career concerns. In our military experience, the medical separation process is almost invariably started when a patient is given an immunosuppressive medication. In examining this data, providers who take care of AD patients should consider apremilast as an alternative therapeutic option in PsO and PsA for maintaining both disease control and deployability while remaining mindful that a lack of efficacy could be a future concern.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Psoriatic arthritis strongly impacts patients' quality of life (QoL). Insights on the effects of biologic treatments on different domains of health-related QoL in a real-world setting are lacking. The objective of this study was to investigate the effect of 6 months of therapy with ustekinumab (UST) or TNF inhibitor (TNFi) on the Psoriatic Arthritis Impact of Disease questionnaire (PsAID-12) and its subdomains.

Methods: The PsABio study (NCT02627768) evaluates effectiveness, tolerability and persistence of 1st, 2nd or 3rd-line UST or TNFi in patients with PsA. Changes from baseline (BL) to 6 months were evaluated in total PsAID-12 and subdomains. Completer analyses were performed on patients staying on UST or TNFi for the full 6 months as well as intent-to-treat (ITT) analyses using non-responder imputation. PsAID-12 was also analyzed as change above the minimal clinical important difference (MCID) of -1.25 points (Holland R, et al. Ann Rheum Dis. 2018;77:343–347), and a patient-acceptable state of PsAID-12 score ≤4. UST and TNFi effectiveness were compared using propensity scores (PS) to adjust for BL confounders.

Results: Of 930 patients, 886 (426 on UST and 442 on TNFi) had evaluable data at BL and 6 months (ITT population, Table 1). This population analysis included patients who had stopped/switched UST (6.6%) or TNFi (10.0%) before 6 months. At BL, significant differences between UST and TNFi groups existed in terms of age (UST patients were older), line of treatment (UST more frequently 3rd-line), NSAID and methotrexate use (less in UST), FiRST score (more chronic widespread pain in UST), and skin involvement (higher in UST). In the ITT analysis, after 6 months, PsAID-12 total score improved by 27.6% for UST (95% confidence interval [CI] 21.6, 33.5) and 32.8% for TNFi (95% CI 28.4, 37.1). MCID improvement was reached by 53.9% (95% CI 48.8, 58.9) of UST and 57.7% (95% CI 52.4, 62.8) of TNFi-treated patients; and 53.1% (95% CI 48.1, 58.1) and 55.4% (95% CI 50.3, 60.4) respectively achieved the patient acceptable state of PsAID (PS-adjusted OR [95% CI] UST vs TNFi: 0.85 [0.61, 1.19]). All PsAID domains also demonstrated improvement (Table 2), with differences between UST and TNFi for the subdomains of impact of pain and skin problems (Table 2).

Table 1: Baseline characteristics of 868 PsA patients starting UST or TNFi

	UST	TNFi
N	426	442
Age, years	51.2 (12.5)	48.5 (12.6)
Gender (male), %	43.0	45.7
Disease duration, years	7.5 (8.1)	6.2 (6.6)
Dactylitis at baseline, %	18.8	20.8
Enthesitis at baseline, %	48.9	51.9
PsA characteristics: %		
Axial involvement	35.4	37.2
Oligoarticular disease	22.4	28.9
Polyarticular disease	66.7	64.7
csDMARD exposure, %		
Previous exposure	88.3	93.0
Ongoing exposure at baseline	39.7	55.2
Other BL treatments, %		
NSAIDs	54.5	69.5
Oral glucocorticoids	32.4	34.4
BMI, kg/m²	28.6 (6.3)	27.7 (5.0)
Swollen joint count (66)	6.0 (8.1)	5.8 (7.4)
Tender joint count (68)	12.5 (12.5)	11.3 (10.8)

<3%	38.4	50.1
3–10%	34.9	35.7
>10%	26.7	14.1
cDAPSA	31.0 (20.3)	29.8 (18.6)
CRP (mg/dL)	1.3 (3.0)	1.6 (2.9)
Total PsAID-12 (0–10)	5.7 (2.2)	5.5 (2.1)
FiRST total score	3.5 (2.0)	3.1 (2.0)
FiRST score ≥5, %	39.3	29.0

Mean (standard deviation) or percentage is presented.
cDAPSA, clinical Disease Activity in Psoriatic Arthritis; csDMARD, conventional synthetic disease-modifying antirheumatic drug. FiRST, Fibromyalgia Rapid Screening Tool

Conclusion: Both UST and TNFi treatment for 6 months are efficacious in reducing impact of PsA and improving patients' QoL, measured by PsAID-12. After PS adjustment for BL imbalances, the improvements seen with UST and TNFi were not significantly different with regard to total PsAID score, though differences were noted for impact of pain (favoring TNFi) and skin problems (favoring UST). This is the first report on the effects of these drugs on QoL in a real-life setting.

Table 2: Change in PsAID-12 and subdomains at month 6 (ITT analyses)

PSAID-12 Total and domains	UST Mean (95% CI) change from baseline	TNFi Mean (95% CI) change from baseline	PS-adjusted UST vs TNFi regression coefficient (95% CI)

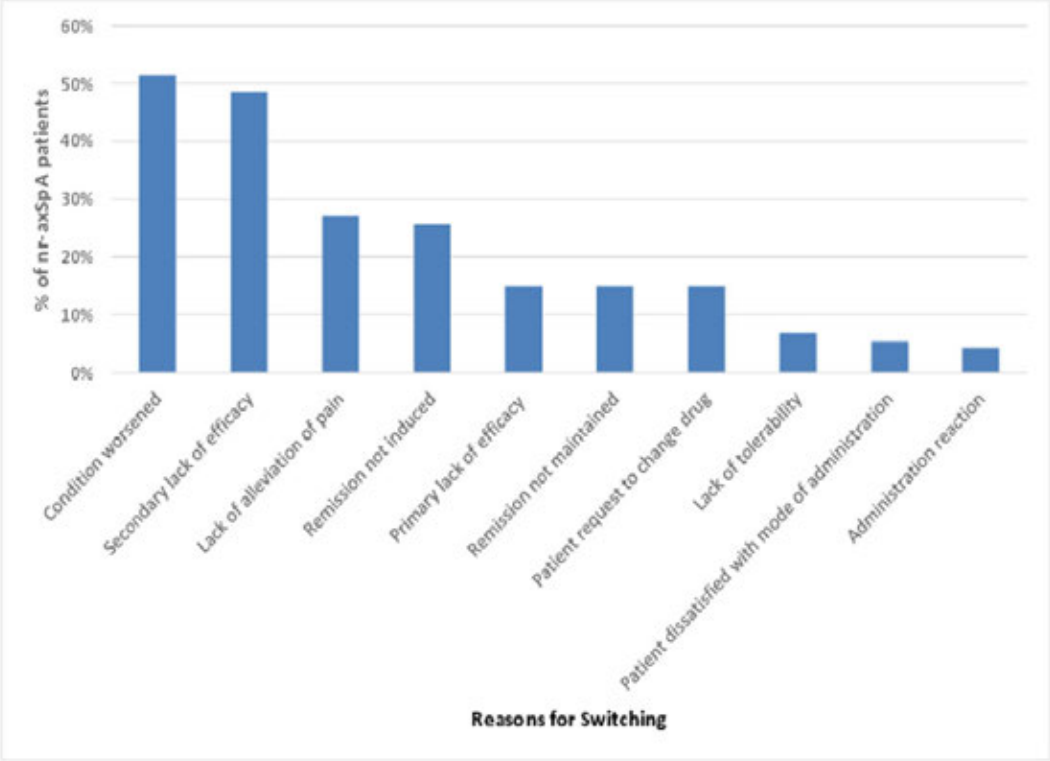
Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Figure 1. Top 10 reasons that US nr-axSpA patients switched to adifferent biologic



Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The FDA approved the first biologic for the treatment of nr-axSpA in the US in March 2019. The objective of our study was to describe biologic use and reasons for switching biologic therapy among patients with non-radiographic axial spondyloarthritis (nr-axSpA).

Methods: Data from a real world, cross-sectional survey of rheumatologists and their consulting nr-axSpA patients in the United States were analyzed descriptively. Data were collected from Jun-Aug 2018 via physician-completed patient record forms and patient self-completed forms. Patients who had physician confirmed diagnosis of nr-axSpA were eligible to participate. Rheumatologists completed record forms for their patients, containing information on current medication use and reasons for switching biologics.

Results: Data from 88 rheumatologists and 495 nr-axSpA patients were included in this analysis. The majority of nr-axSpA patients were male (53.3%), with a mean age of 44.2 years, and 69.8% of patients reported working full-time. Of the 495 nr-axSpA patients, 48.1% were receiving a biologic agent and no csDMARD, 18.4% csDMARD (no biologic), 18.2% NSAIDS/COX-2 (no biologic or csDMARD), 11.5% a biologic and a csDMARD, 2.0% were receiving no therapy, and 1.8% other therapy (no biologic, csDMARD or NSAID/COX-2). Of the 295 patients receiving a biologic, 78.0% were receiving their first, 13.9% their second and 8.1% their third or more biologic. Of the 74 nr-axSpA patients that switched from a previous biologic to their current biologic, physicians reported that 51.4% switched due to condition worsening, 48.6% had a loss of response over time, 27.0% switched due to a lack of pain alleviation, and 25.7% of patients switched because remission was not induced (Figure 1).

Conclusion: This survey suggests that around 60% of nr-axSpA patients were receiving biologic therapy. Switching of biologics is frequent in nr-axSpA patients and is usually due to lack of efficacy, loss or response, and effort to accomplish remission.

Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Clinical studies have shown that a large proportion of psoriatic arthritis (PsA) patients treated with apremilast failed to achieve improved physical function or experienced severe gastrointestinal (GI) symptoms. This study used administrative claims data to evaluate the proportion of biologic treatment-naïve patients experiencing early treatment failure with apremilast, identify characteristics associated with early treatment failure with apremilast, and assess subsequent treatment use after apremilast discontinuation in the real-world setting.

Methods: Adult biologic-naïve patients with PsA and apremilast use during Q1 2013 to Q3 2016 were selected from the IBM MarketScan Research Database (Copyright © 2017 Truven Health Analytics LLC, All Rights Reserved). The index date was defined as the first claim for apremilast after PsA diagnosis. Patients were required to have continuous enrollment during the 6 months before (baseline period) and the 6 months after the index date (study period). Early treatment failure was defined as the occurrence of treatment discontinuation, GI-related healthcare encounters, treatment switching/addition, or dose escalation/reduction within the 6-month study period. Time to treatment failure was described using the Kaplan-Meier method. A logistic regression model was used to assess characteristics associated with early treatment failure with apremilast. Subsequent treatment use was assessed through the end of continuous enrollment among patients who discontinued apremilast within 6 months.

Results: A total of 1,503 biologic-naïve patients with PsA who were treated with apremilast were included, 869 (57.8%) with and 634 (42.2%) without early treatment failure. Median time to apremilast failure was 3.9 months and

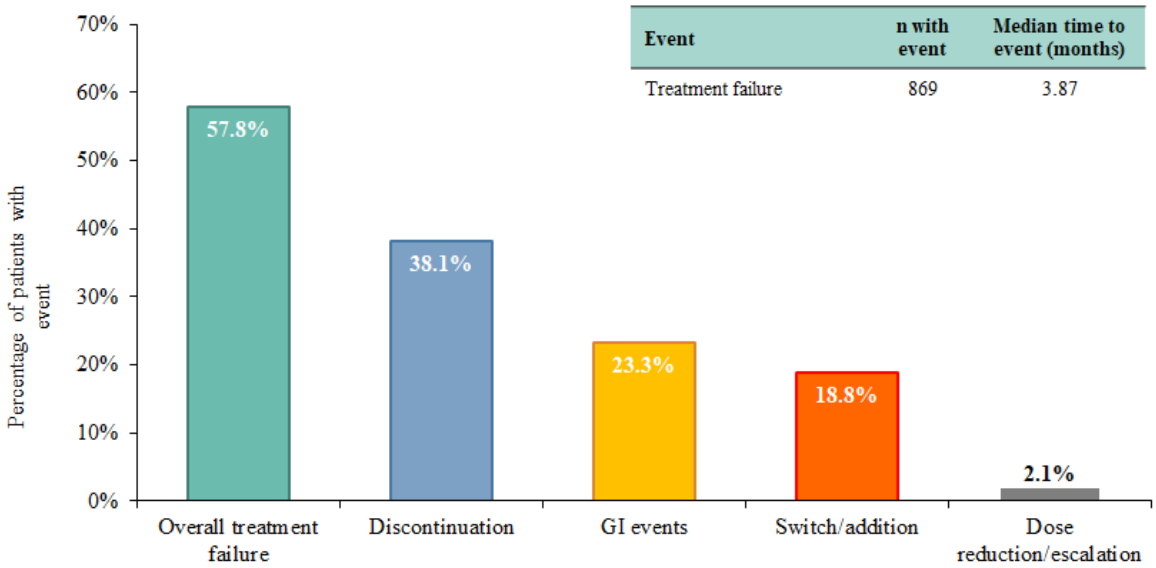

Figure 1. Early treatment failure rates with apremilast

Table 1. Characteristics associated with early treatment failure with apremilast

	Odds ratio [95% CI]	*P*-value	
Female	1.22 [0.99, 1.51]	0.068	
Comorbidities			
CCI ≥1	1.23 [0.99, 1.54]	0.064	
GI-related comorbidities	1.76 [1.32, 2.34]	<0.001	*
Treatment Use			
Orally administered corticosteroids	1.27 [1.01, 1.59]	0.041	*
Opioids	1.29 [1.04, 1.61]	0.022	*

** denotes p-value <0.05; CCI: Charlson Comorbidity Index; CI: confidence interval*

treatment discontinuation was the most common treatment failure event (**Figure 1**). Clinically relevant baseline characteristics that were significantly different between patients with and without early apremilast failure were included in the model (**Table 1**). Presence of GI-related comorbidities (odds ratio [OR]: 1.76, p< 0.001), orally administered corticosteroid use (OR: 1.27, p=0.04), and opioid use (OR: 1.29, p=0.02) were significantly associated with a higher risk of early treatment failure with apremilast. Among the 572 patients (38.1%) who discontinued apremilast within 6 months, 46.5% did not have subsequent treatment use; 20.3% subsequently initiated adalimumab, 15.7% subsequently initiated etanercept, 9.2% subsequently initiated secukinumab, and 9.2% subsequently initiated ustekinumab.

Conclusion: This retrospective claims study showed that approximately 60% of biologic-naïve PsA patients treated with apremilast experienced treatment failure within 6 months. Presence of GI-related comorbidities, use of orally administered corticosteroids, and use of opioids before apremilast initiation were associated with an increased risk of early treatment failure. In addition, approximately 54% of patients initiated a subsequent treatment following apremilast discontinuation. The results of this real-world study are consistent with findings from clinical trials.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term registries are essential to evaluate new therapies in a patient population that differs from clinical trial and usually varies over time. The purpose was to describe the profile of ankylosing spondylitis (AS) patients treated with infliximab (IFX) or golimumab (GLM) treatment in Canadian routine care along with its long-term effectiveness and safety.

Methods: 810 AS patients treated with IFX or GLM were enrolled into the Biologic Treatment Registry Across Canada (BioTRAC) registry between 2005-2015 and 2010-2017, respectively. Study visits occurred at baseline and every 6 months thereafter, as needed per routine care. Effectiveness was assessed with changes in ASDAS, BASDAI, BASFI, MDGA, HAQ-DI, PtGA, back pain and acute phase reactants. Safety was evaluated with the incidence of adverse events (AEs) and drug survival rates.

Results: Of the 389 IFX- and 421 GLM-treated patients, the proportion of males were 62.7% and 59.1%, the mean age were 45.6 and 45.7 years and the mean disease duration were 8.6 and 6.0 years, respectively. Most patients were bio-naive (>82.7%). Interestingly, we observed a significant decrease in disease duration in the IFX cohort from a median of 8.0 to 3.5 and 1.0 years in 2005-2008, 2009-2012 and 2013-2015, respectively ($p< 0.001$). A reduction in baseline BASFI score (6.3 vs. 5.9 vs 5.1; P=0.011) and in the proportion of patient in ASDAS very high disease activity (48.4%, 43.8%, 30.3%; p=0.004) were also observed. As for the GLM cohort, most disease parameters including median disease duration (1.6 years), mean baseline BASFI (5.3) and the proportion of patients in ASDAS very high disease activity (48%) remained similar from 2010-2017.

Treatment with both IFX and GLM significantly improved all disease parameters over time ($P< 0.001$) from baseline up to 120 and 84 months, respectively, with similar efficacy between agents. AEs were reported for 67.9% and 70.5% (136 and 131 events/100 PYs) and SAEs for 15.4% and 8.1% (10.5 and 8.45 events/100 PYs) covering 1251.3 and 674.8 years of exposure for IFX- and GLM-treated patients, respectively. The most frequently occurring AEs (>7% of patient in either group) were upper respiratory tract infection, arthralgia and back pain. Two deaths occurred in IFX-treated patients (myocardial infarct, drowning) and two among GLM-treated patients (oropharyngeal cancer; neutropenia, staphylococcal/pseudomonas infections, septic shock).

The proportion of patients who discontinued treatment were 65.8% over a mean 3.2 years of exposure in the IFX cohort and 56.8% over 1.6 years in the GLM cohort.

Conclusion: Both IFX and GLM treatment significantly reduced disease activity and improved functionality in a similar fashion and were well tolerated in patients with AS. Differences in baseline characteristics over time demonstrate improvement in early diagnosis of AS and earlier access to biologic therapies.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Long-term registries are essential to evaluate new therapies in a patient population that differs from clinical trials and usually varies over time. The purpose of this study was to describe the profile of psoriatic arthritis (PsA) patients selected for treatment with infliximab (IFX), golimumab (GLM) or ustekinumab (UST) treatment in Canadian routine care and to describe the long-term real-world effectiveness and safety of these agents.

Methods: 462 PsA patients treated with IFX, GLM or UST were enrolled into the Biologic Treatment Registry Across Canada (BioTRAC) registry between 2006-2015, 2010-2017 and 2014-2017, respectively. Study visits occurred at baseline and every 6 months thereafter. Effectiveness was assessed with changes in TJC28, SJC28, skin, enthesitis, dactylitis, pain, HAQ, acute phase reactants. Safety was evaluated with the incidence of adverse events (AEs) and drug survival rates.

Results: Of the 111 IFX-, 281 GLM- and 70 UST-treated patients, the proportion of males were 52.3%, 46.3% and 37.1%, the mean age was 48.4, 52.8 and 53.1 years and the mean disease duration was 5.8, 6.1 and 5.7 years, respectively. Most patients were bio-naive (85.6%, 77.9% and 55.7% for IFX, GLM and UST, respectively ($p< 0.001$). A

reduction in mean baseline duration of morning stiffness was observed in the IFX cohort (from 69.8 to 42.6 to 23 min in 2006-2008 to 2009-2012 to 2013-2015; p=0.003). Most other baseline disease parameters remained similar over time in all three cohorts. However, UST-treated patients had lower mean baseline DAS28 CRP (3.4 vs 3.9; p=0.0031), SJC (3.8 vs 5.3; p=0.0046) and higher PASI (4.8 vs 2.2; p=0.0061) compared to patients treated with GLM.

Treatment with IFX, GLM and UST was associated with significant improvements in all disease parameters over time (P< 0.001) from baseline up to 84, 84 and 40 months, respectively with similar efficacy between agents. The only exception was the proportion of patients in minimal disease activity at 12, 24 and 36 months which reached 40.7%, 50.0% and 55% in IFX-patients; 64.7%, 68.8% and 78.9% in GLM-patients and 58.8%, 60.0% and 83.3% in UST-patients (p=0.004 and p< 0.001 vs IFX).

AEs were reported for 74.8%, 69.8% and 52.9% (138, 114 and 115 events/100 PYs) and SAEs for 19.8%, 8.5% and 5.7% (8.8, 7.2 and 8.0 events/100 PYs) covering 325, 567 and 87 years of exposure for IFX-, GLM- and UST-treated patients, respectively. One, one and no death occurred IFX-, GLM- and UST-treated patients, respectively. The proportion of patients who discontinued treatment were 63.1%, 50.9% and 50.0% over a mean exposure of 2.9, 1.9 and 1.2 years to IFX, GLM and UST, respectively.

Conclusion: Differences in baseline characteristics between patients treated with an anti-TNF over an anti-IL12/23 agent suggest that the level of joint to skin involvement might be driving physician choice when the time comes to choose a biologic agent. IFX, GLM and UST treatment significantly reduced disease activity and improved functionality in a similar fashion and were well tolerated in patients with PsA.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The Biologic Treatment Registry Across Canada (BioTRAC) was a prospective, observational registry that enrolled ankylosing spondylitis (AS) (radiographic axial SpA) patients treated with subcutaneous golimumab (GLM) between 2010 and 2017. The registry was closed in June 2018.

Methods: Patient visits occurred at baseline and every 6 months thereafter. Multivariate logistic regression was used to identify independent predictors of achieving specific efficacy and safety endpoints and included the following covariates: age, gender, disease duration, enrollment period, concomitant medication, smoking and employment.

Results: A total of 421 patients were enrolled and followed for a mean duration of 1.6 years. The proportion of male gender was 59.1% and the mean disease duration at baseline was 6.0 years (SD=10.1 years). Most patients were bio-naive (>82%).

ASDAS clinically important improvement was more likely to be achieved with higher baseline ASDAS-CRP score [OR (95%): 2.28 (1.51–3.45); p< 0.001], however less likely in patients with baseline concomitant DMARD use [0.31 (0.12–0.80); p=0.015]. ASDAS major improvement was more likely to be achieved with lower age [OR (95%): 0.94 (0.91–0.97); p< 0.001], higher baseline ASDAS-CRP score [OR (95%): 2.93 (1.80–4.75); p< 0.001], and higher baseline CRP levels [1.04 (1.00–1.07); p=0.025]. ASAS partial remission was more likely to be achieved with lower age [OR (95%): 0.97 (0.94–0.99); p=0.013], male vs. female gender [OR (95%): 2.22 (1.10–4.48); p=0.025], lower baseline ASDAS-CRP [0.67 (0.48–0.94); p=0.020], and higher baseline CRP levels [1.01 (1.00–1.02); p=0.048].

AEs were more likely to occur with older age [1.02 (1.00–1.05); p=0.024] and concomitant DMARD use [3.03 (1.17–7.85); p=0.022], yet less likely in patients who enrolled later [2016–2017 vs. 2010–2012: 0.36 (0.15–0.85); p=0.019]. SAEs were also less likely to occur in patients who enrolled later [2013–2015 vs. 2010–2012: 0.29 (0.10–0.84); p=0.023 and 2016–2017 vs. 2010–2012: 0.15 (0.03–0.64); p=0.010].

Increased treatment retention for AS patients treated with GLM were significantly associated with earlier enrollment period (2010-2012 vs. 2016-2017: HR [95% CI]: 0.51 [0.29–0.89], p=0.017; 2013-2015 vs. 2016-2017: 0.65 [0.44–0.95], p=0.027), and male gender [0.49 (0.35–0.68); p< 0.001].

Conclusion: In this real world, long-term prospective cohort of AS patients treated with GLM, male patients were more likely to achieve a positive treatment response and sustained treatment persistence. Baseline concomitant DMARDs was associated with a lower treatment response, possibly through its association with more complex non-axial disease. Later enrollment period was associated with a lower risk of experiencing an AE but with a higher risk of early treatment discontinuation, possibly driven by the greater availability of alternative therapies.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

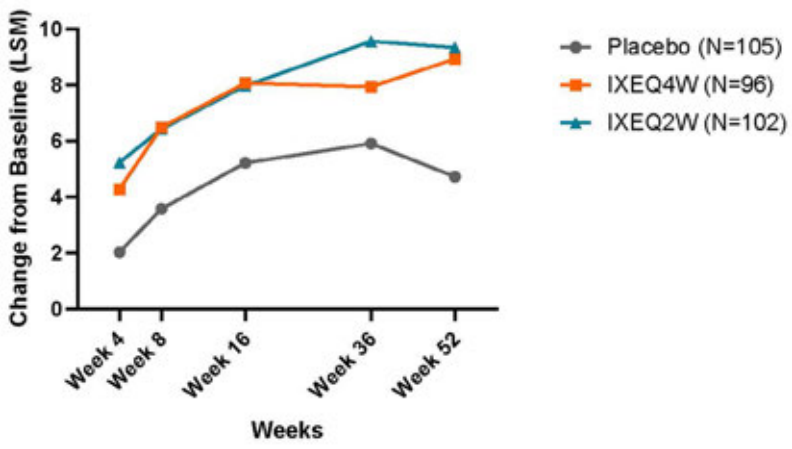
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Previous studies have determined that axial spondyloarthritis (axSpA) significantly impairs patients' health-related quality of life (HRQoL).[1] The patients with nr-axSpA have the same disease burden as patients with r-axSpA.[2] We report the HRQoL results at Weeks 16 and 52 in patients with nonradiographic (nr)-axSpA treated with Ixekizumab (IXE).

Methods: COAST-X (NCT02757352) is a Phase 3, multicenter, randomized, double-blind, placebo (PBO)-controlled, parallel-group, clinical trial. Enrolled patients were adults with active nr-axSpA as per the Assessment of SpondyloArthritis international Society (ASAS) criteria, with a Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and total back pain ≥4, and with no prior treatment with biologic agents. Patients who fulfilled the definition of sacroiliitis

Figure: SF-36 physical component summary LSM changes from baseline



per modified New York (mNY) criteria were excluded. Patients were randomized in a 1:1:1 ratio to subcutaneous PBO, 80 mg IXE every 4 (Q4W) or 2 weeks (Q2W) up to Week 52. For patients who needed rescue and switched to IXE 80 mg Q2W, observations after rescue were considered as missing. Changes from baseline in SF-36 up to Week 52 were analyzed by mixed model for repeated measures without imputation for missing data.

Results: From baseline to Week 16, Physical Component Summary (PCS) significantly differed between PBO and IXE Q4W (p=0.013), and IXE Q2W (p=0.015) groups. Significant improvement over PBO was noted as early as Week 4 (IXE Q4W: p=0.015; IXE Q2W: p< 0.001) and it was maintained until Week 52 (IXE Q4W: p=0.012; IXEQ2W: p=0.006). Since the baseline MCS values were within the normal range across all treatment groups, no significant improve-

#Only domain scores are t-score values

ments were observed from baseline in Mental Component Summary (MCS) at Week 16 or Week 52 compared with the placebo group.

Conclusion: Patients with nr-axSpA treated with IXE demonstrated an improvement over PBO in self-reported HRQoL at Week 16 and throughout Week 52 as measured by SF-36. The improvement was significant for PCS and some domains. Significant improvements were also observed as early as the first time the instrument was applied (Week 4).

Study Sponsor Statement: This study was supported by Eli Lilly and Company. Lilly participated in the study design, data collection, and the analysis and reporting of study results.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Observational data on the use of secukinumab for the treatment of spondyloarthritides are still lacking. The aim of this study is to evaluate the effectiveness and the 3-year retention rate of secukinumab in psoriatic arthritis (PsA) and axial spondyloarthritis (axSpA) patients in a real-life setting.

Methods: Data of all PsA and axSpA patients (diagnosed according to CASPAR and ASAS criteria, respectively) treated with secukinumab were prospectively collected in the Italian multicentric LORHEN registry. Effectiveness was measured as the mean change from baseline of Disease Activity in PSoriatic Arthritis score (DAPSA) in PsA and Ankylosing Spondylitis Disease Activity Score (ASDAS) in axSpA patients. Rates of DAPSA remission and ASDAS inactive disease were also computed. The 3-year retention rate was calculated by the Kaplan-Meier method and compared between PsA and axSpA by a log-rank test. A descriptive analysis of reasons for discontinuation was performed.

Results: The study population included 195 PsA (55.4% females, mean age 50.7 [±11.8] years, mean disease duration 10 [±7.8] years, mean baseline DAPSA 23.12 [±12.3]) and 94 axSpA (61.7% males, mean age 49.1 [±12.7] years, mean disease duration 10.4 [±9.4] years, mean baseline ASDAS 3.41 [±1.1]) patients who received secukinumab as first (26.5 and 33%, respectively) or subsequent biologic agent. Compared with baseline, the 3-, 6- and 12-month mean values of both DAPSA (12.6 [±9], 11.2 [±10.5] and 9.3 [±7.5], respectively) and ASDAS (2.23 [±0.9], 2.15 [±0.9], and 1.84 [±0.9], respectively) were significantly decreased ($p< 0.001$ for all the timepoints). The 3-, 6-, and 12-month rates of remission/inactive disease were 15.5, 25.4, and 30.5% in PsA and 18, 23.7, and 28.6% in axSpA group, respectively. One- and 3-year retention rate (figure 1) were respectively 79.4% and 66.6% in PsA and 72.3% and 70.1% in axSpA patients, with no significant difference between the two groups ($p=0.517$). The most frequent reason for withdrawal was inefficacy in both PsA (n=41) and axSpA (n=20), whereas only 8 PsA and 6 axSpA patients discontinued secukinumab because of adverse events.

Conclusion: Our real-life data confirmed the effectiveness and the favorable safety profile of secukinumab for both PsA and axSpA, resulting in a high 3-year retention rate.

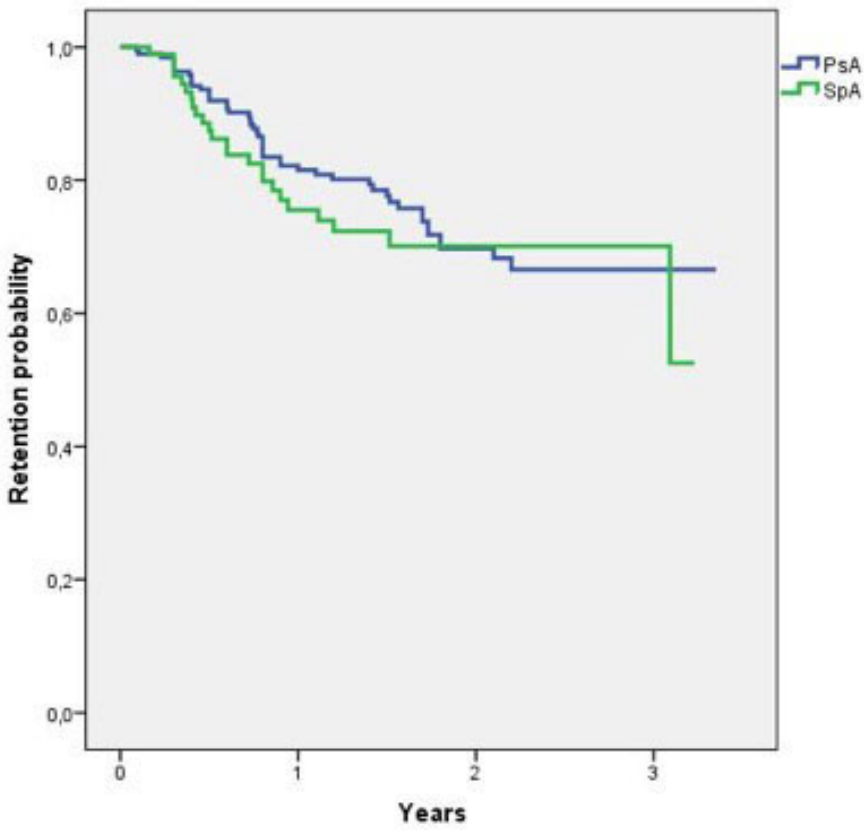

Figure 1: secukinumab retention rate in PsA and axSpA patients.

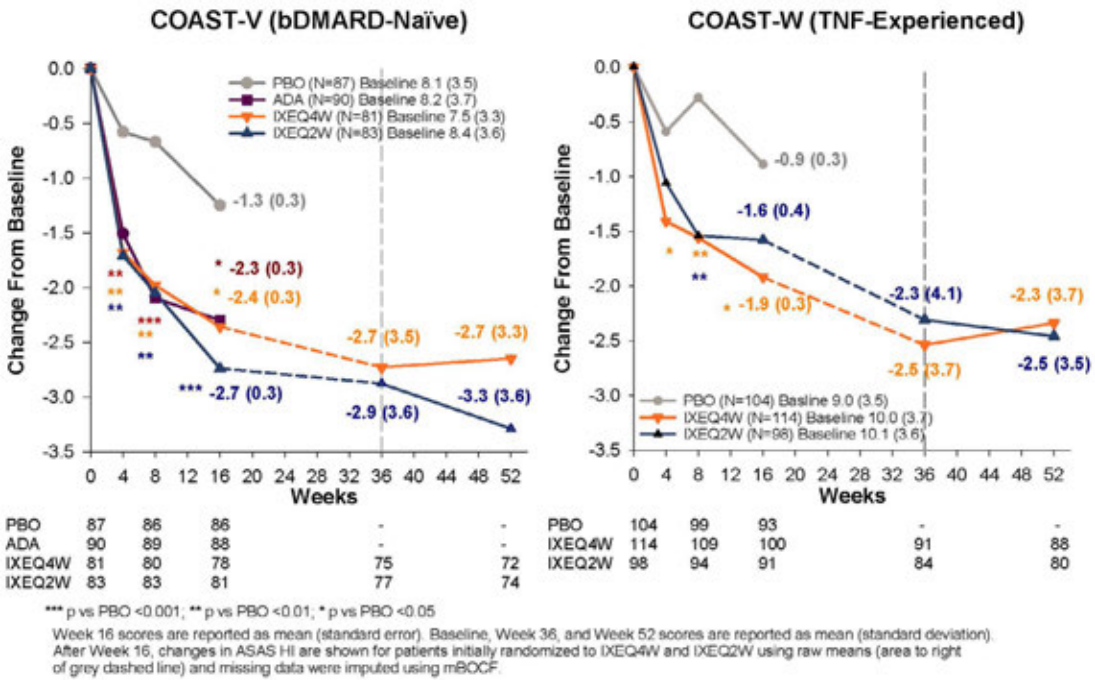
Ixekizumab Improves Self-reported Overall Functioning and Health as Measured by the Assessment of SpondyloArthritis International Society Health Index in Patients with Active Radiographic Axial Spondyloarthritis: 52-Week Results of Two Phase 3 Randomized Trials

Uta Kiltz,[1] Désirée van der Heijde,[2] Annelies Boonen,[3] Lianne Gensler,[4] Theresa Hunter,[5] Fangyi Zhao,[6] Baojin Zhu,[5] Rebecca Bolce,[5] Hilde Carlier,[5] and Jürgen Braun[7], [1]Rheumazentrum Ruhrgebiet/Ruhr University Bochum, Herne, Germany, Herne, Germany, [2]Leiden University Medical Center, Leiden, Netherlands, [3]Maastricht University Medical Center, Maastricht, Netherlands, [4]University San Francisco California, San Francisco, CA, [5]Eli Lilly and Company, Indianapolis, [6]Eli Lilly and Company, Indianapolis, IN, [7]Rheumazentrum Ruhrgebiet/Ruhr University, Herne, Germany

Figure 1. ASAS HI Change From Baseline



*** p vs PBO <0.001; ** p vs PBO <0.01; * p vs PBO <0.05

Week 16 scores are reported as mean (standard error). Baseline, Week 36, and Week 52 scores are reported as mean (standard deviation). After Week 16, changes in ASAS HI are shown for patients initially randomized to IXEQ4W and IXEQ2W using raw means (area to right of grey dashed line) and missing data were imputed using mBOCF.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

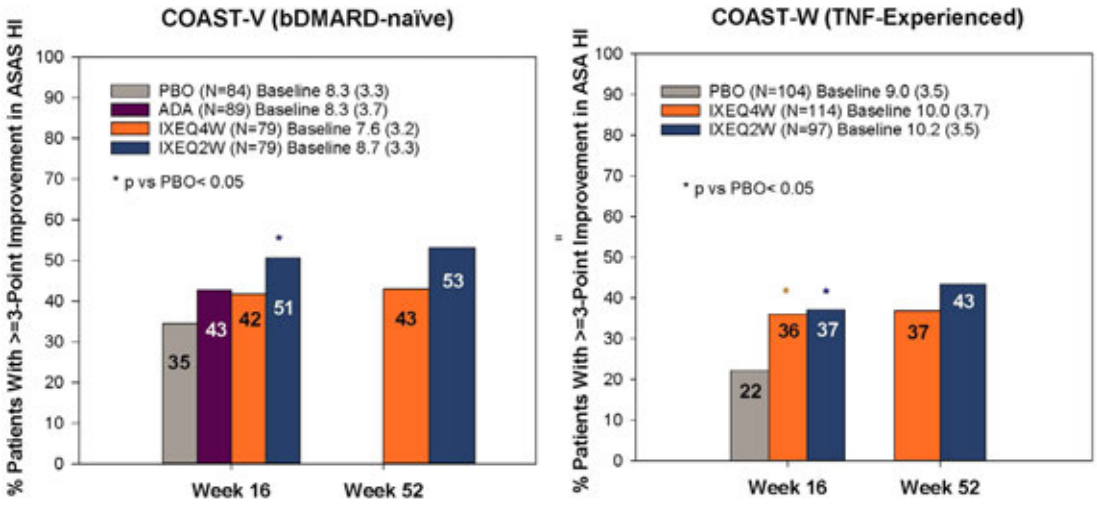
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The Assessment of SpondyloArthritis international Society Health Index (ASAS HI) measures health, disability, and functioning in patients (pts) with spondyloarthritis (SpA)[1,2]. The purpose of this study was to assess the impact of 52 weeks of ixekizumab (IXE) treatment on overall functioning and health in 2 phase 3 trials of pts with ankylosing spondylitis (AS)/radiographic axial SpA (r-axSpA) who were either biologic (b)DMARD-naïve (COAST-V [NCT02696785]) or who previously failed or were intolerant to up to 2 TNF-inhibitors (TNF-experienced) (COAST-W [NCT02696798]).

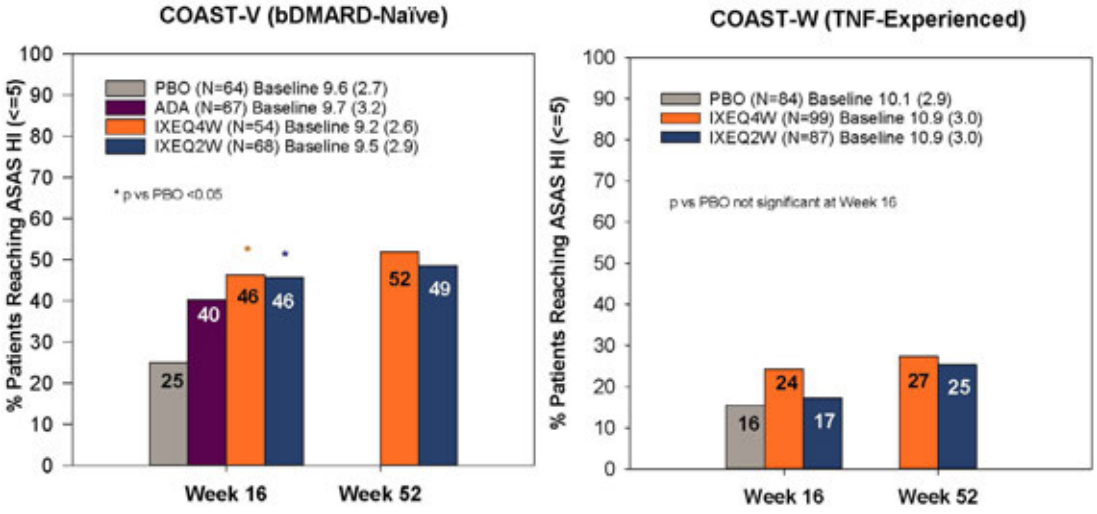
Methods: Pts were originally randomized equally to IXE 80mg every 2 weeks (Q2W), every 4 weeks (Q4W), placebo (PBO) or (in COAST-V only) to adalimumab (ADA) 40mg Q2W. At Week16, original PBO and ADA patients were rerandomized 1:1 to either IXE regimen. All pts were treated for up to 52 weeks. Change from baseline in ASAS HI (score 0-17 with higher score indicating worse health [1,2]) up to Week 16 was analyzed using a mixed-effects model of repeated measures. Changes beyond Week 16 through Week 52 (only for pts originally randomized to IXE) were

Figure 2. Percentages of Patients With >=3 (SDC) Improvement in ASAS HI Scores From Baseline



The analyses were based on patients with baseline ASAS HI score >= 3. Week 52 data are for patients initially randomized to IXEQ4W and IXEQ2W.
Baseline scores are reported as mean (standard deviation).

Figure 3: Percentages of Patients Achieving ASAS HI Good State (<=5)



The analyses were based on patients with baseline ASAS HI score > 5. Week 52 data are shown for patients initially randomized to IXEQ4W and IXEQ2W. Baseline scores are reported as mean (standard deviation).

summarized with missing data imputed using modified baseline observation carried forward (mBOCF) approach. Categorical data were summarized with nonresponder imputation for missing data. For the ASAS HI, the smallest detectable change [SDC] was reported as 3.0 and patients having an ASAS HI total score ≤ 5 were defined as being in a good health state [2].

Results: At baseline, mean (standard deviation) ASAS HI scores were 8.1 (3.6) and 9.7 (3.6) in COAST-V and COAST-W, respectively. At Week 16, IXEQ4W-treated pts had improved ASAS HI scores versus PBO in both trials [3, 4]. Improvement was sustained or further increased through Week 52 (Figure 1). The proportions of pts continuously treated with IXE and having reached SDC (Figure 2) and achieving ASAS HI good state (Figure 3) were maintained at Week 52. Among pts originally randomized to PBO but switched to IXE at Week16, the percentages of pts with improvement above SDC or achieving an ASAS HI good state through 52 weeks were 45% and 36% in bDMARD-naive, and 41% and 31% in TNF-experienced pts, respectively.

Conclusion: Continued treatment with IXE through 52 weeks led to sustained improvement in ASAS HI as measured by change from baseline, and proportions of pts achieving a change above SDC or good ASAS HI state in both in bDMARD-naïve and in TNF-experienced pts.

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab is a newly introduced biologic therapy against IL-17 which has been proved effective in patients with ankylosing spondylitis (AS) in clinical trials and it has been added to the most recent national and international treatment guidelines. However, real-world data of its use is still scarce. This study aims to analyze drug survival of secukinumab for axial spondyloarthritis (AxSpA) in a real world setting and identify response factors.

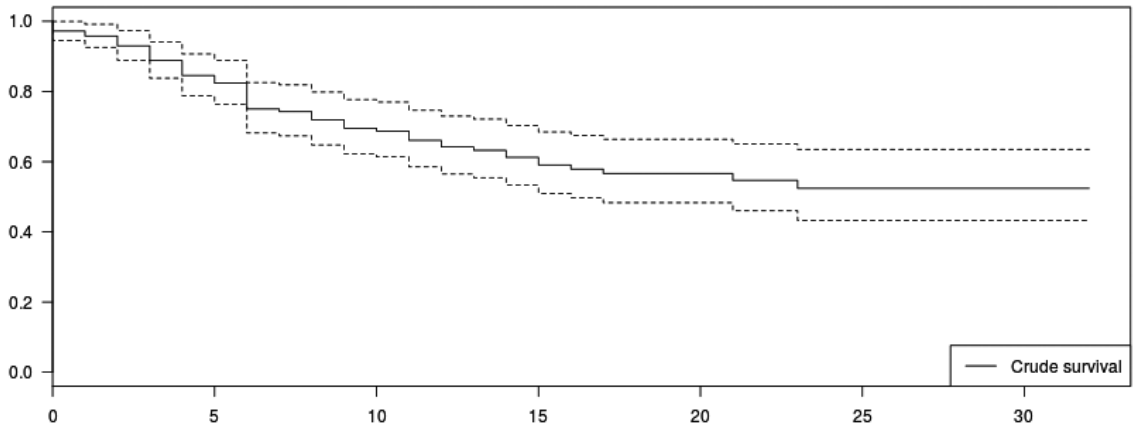

Figure. Time to withdrawal of secukinumab measured in months.

Methods: Multicentric observational, retrospective, longitudinal study conducted in 4 tertiary hospitals of the Madrid region. Patients over 18 y.o. with clinical diagnosis of AxSpa and having received at least one dose of secukinumab between January 2016 and October 2018 were included. Medical records were reviewed to collect demographic and clinical data related to AxSpA, its features and treatment. Statistical analysis was performed including bivariate analisys (considering withdrawal of drug during study period or not) and survival analysis with Kaplan-Meier and Cox regression. Reasons for discontinuating therapy were described. To detect inffluential variables, demographic characteristics, HLA-B27 positivity, radiographic features, previous biologic therapies, comorbidities and extra-articular involvement were analyzed.

Results: Out of 143 patients included, 89 (62%) mantained secukinumab therapy at the end of the observation period (Dec 31, 2018), with an average drug survival time of 17 ± 8,2 months. 54 patients (38%) withdrawn therapy, due to primary ineffectiveness (26) , secundary ineffectiveness (14), adverse events (7) and other reasons (7). Median time to withdrawal was 6 months (0-21). No significative differences were found between groups, but a tendency to higher number of female patients (55% vs 41%, p 0,07), non radiographic AxSpA (35% vs 27%, p 0,053) and lower HLA-B27 positivity (50% vs 65%, p 0,052) was noted in the group withdrawing therapy. Previous exposure to biologic therapy did not differ (75% vs 71%, p 0,37). Number of bDMARDs before Secukinumab therapy was also similar in both groups; the proportion of patients with previous exposure to 2 or more bDMARDs were 17% vs 22% (p 0.373). Neither differences were found in all other variables studied (demographic, hip arthropathy, syndesmophytes, extra-articular involvement -uveitis, psoriasis, inflammatory bowel disease- nor in comorbidities (tobacco exposure, hypertension, diabetes mellitus, dyslipidemia, ischemic heart disease, malignancy).

Conclusion: This study assesing drug survival of secukinumab in real-world setting showed a trend to lower drug survival in comparison to clinical trial data. No differences were found in the treatment withdrawal group. Population in which secukinumab is prescribed in real-world setting differs from clinical trials, with higher previous exposure to bDMARDs and higher comorbidity.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

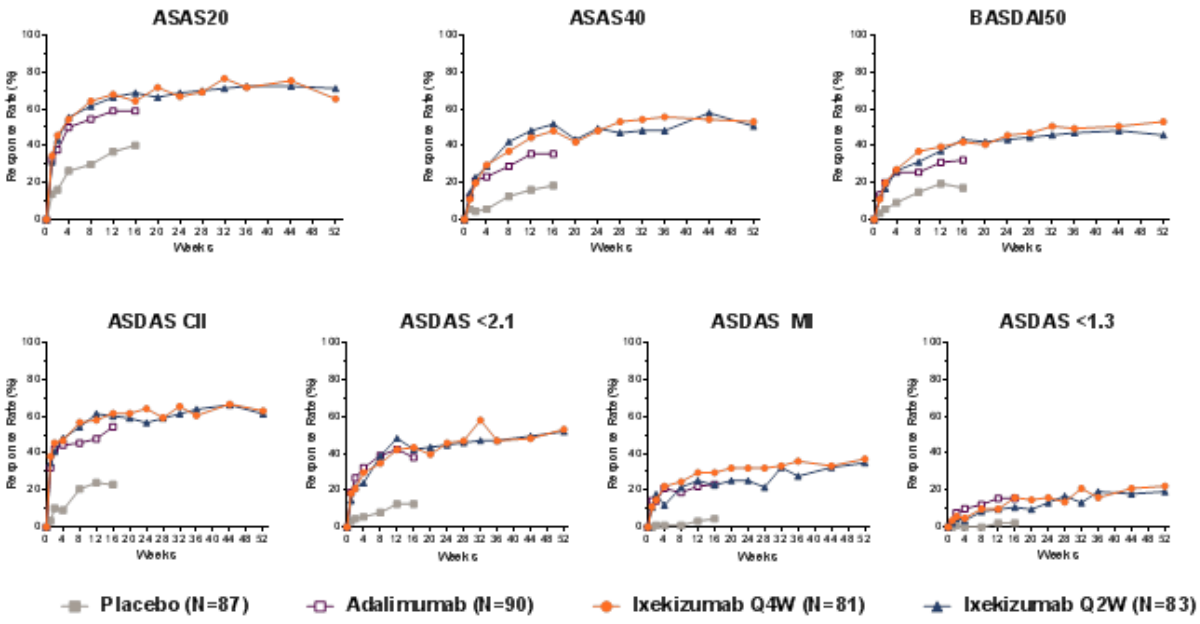
Background/Purpose: During 16 weeks of blinded treatment, ixekizumab (IXE) and an adalimumab (ADA) active reference arm were found superior to placebo (PBO) in improving signs and symptoms of radiographic axial spondyloarthritis (r-axSpA).[1] Here, we assess the safety and efficacy of continuous treatment with IXE through 52 weeks in patients with r-axSpA and describe clinical response at Week 52 for patients who switched to IXE following 16 weeks of treatment with either ADA or PBO.

Efficacy of IXE in bDMARD-naïve patients with active r-axSpA		
Mean (±SD) change from baseline at Week 52 mBOCF (intent-to-treat)	**IXE Q4W (N=81)**	**IXE Q2W (N=83)**
ASDAS-CRP	-1.7 (1.2)	-1.6 (1.0)
BASDAI[a]	-3.3 (2.5)	-3.1 (2.3)
C-Reactive Protein (mg/L)	-9.2 (12.4)	-9.6 (14.5)
BASFI	-2.8 (2.5)	-2.8 (2.4)
SF-36 PCS[b]	8.3 (9.5)	8.1 (7.5)
ASAS Health Index	-2.7 (3.3)	-3.3 (3.6)
SPARCC Spine Score (observed)[c]	-8.8 (17.3)	-8.5 (15.9)

Efficacy in patients rerandomized from adalimumab to ixekizumab			
Response (%) NRI, extended treatment period population[d]	**PBO/All IXE (N=86)**	**ADA/All IXE (N=86)**	**All IXE/All IXE (N=164)**
ASAS40			
Week 16	18.6	36.0	50.0
Week 52	46.5	51.2	51.8

[a]BASDAI items included 1) Fatigue, 2) Spinal pain, 3) Peripheral arthritis, 4) Enthesitis, 5) Intensity, and 6) Duration of morning stiffness. Items were scored on a 0-10 numeric rating scale.
[b]SF-36 analyses based on 2009 US norms
[c]SPARCC Spine: N=72 (IXE Q4W), N=68 (IXE Q2W)
[d]Includes all patients who received ≥1 dose of IXE during Weeks 16-52
ADA=adalimumab; BASFI=Bath Ankylosing Spondylitis Functional Index; IXE=ixekizumab; mBOCF=modified Baseline Observation Carried Forward; NRI=nonresponder imputation; PBO=Placebo; Q2W=every 2 weeks; Q4W=every 4 weeks; SF-36 PCS=Medical Outcomes Study 36-Item Short-Form Health Survey Physical Component Summary; SPARCC=Spondyloarthritis Research Consortium of Canada

Clinical improvements in r-axSpA disease activity in bDMARD-naïve patients with active r-axSpA through Week 52 of treatment with ixekizumab (NRI).



Analyses were conducted on the intent-to-treat population according to initially assigned treatments.
Adalimumab represents an active reference arm. The study was not powered to test equivalence or non-inferiority of the active treatment arms to each other, including ixekizumab versus adalimumab.
ASAS = Assessment of SpondyloArthritis International Society, ASDAS = Ankylosing Spondylitis Disease Activity Scale, BASDAI50 = ≥50% improvement from baseline in the Bath Ankylosing Spondylitis Disease Activity Index, CII = Clinically Important Improvement (ASDAS change from baseline ≥1.1), MI = Major Improvement (ASDAS change from baseline ≥2.0 or reached the minimum ASDAS score), Q2W= every 2 weeks, Q4W= every 4 weeks

Methods: Participants were biologic disease-modifying anti-rheumatic drug (bDMARD)-naïve adult patients with active r-axSpA per Assessment of Spondyloarthritis (SpA) international Society (ASAS) criteria (sacroiliitis centrally defined by modified New York criteria and ≥1 SpA feature) and inadequate response or intolerance to non-steroidal anti-inflammatory drugs. Patients were randomized 1:1:1:1 to receive 80 mg IXE every 2 (Q2W) or 4 weeks (Q4W), 40 mg adalimumab (ADA) Q2W (active reference arm), or PBO. At Week 16, patients assigned to IXE continued their assigned treatment and patients receiving PBO or ADA were re-randomized 1:1 to IXE Q2W or IXE Q4W through Week 52.

Results: Of 164 patients initially randomized to IXE, 146 (89%) completed Week 52. IXE Q4W and IXE Q2W led to persistent improvements in disease activity, function, objective inflammation (MRI and C-reactive protein), quality of life, health status, and overall functioning for up to 52 weeks (Figure and Table). For patients initially assigned to PBO or ADA, ASAS40 response showed a numerical increase upon switching to IXE (Table). Frequencies of treatment-emergent adverse events (AEs) were similar between IXE dosing regimens. Among patients with ≥1 dose of IXE (N=336), serious AEs occurred in 20 (6%) patients. There were no deaths and 11 (3%) patients discontinued due to AEs.

Conclusion: Persistent improvements in the signs and symptoms of r-axSpA were observed through Week 52 in patients who received continuous treatment with IXE. ASAS40 response rates at Week 52 were numerically similar between patients who received continuous treatment with IXE and patients who switched from ADA to IXE. No unexpected safety signals were observed through 52 weeks of treatment.

Ixekizumab Demonstrates Consistent Improvement up to Week 108 in Psoriatic Arthritis Across Individual ACR Components for Patients Naïve to Biologic DMARDs or with Previous Inadequate Response to TNF Inhibitors

Anthony Turkiewicz,[1] Aubrey Trevelin Sprabery,[2] Amanda Gellett,[2] So Young Park,[2] and Arnaud Constantin[3], [1]Rheumatology Associates, Birmingham, AL, [2]Eli Lilly and Company, Indianapolis, IN, [3]Hôpital Pierre-Paul Riquet, Toulouse, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: While the composite ACR core data set is considered a standard for assessing disease severity and improvement in PsA, understanding the response rates of the individual ACR components may be more useful in guiding clinical decisions.[1] Here we present the efficacy response across all ACR components to Week 108 in PsA patients treated with ixekizumab (IXE), a high-affinity monoclonal antibody that specifically targets IL-17A, approved for the treatment of adults with active PsA and moderate-to-severe psoriasis.

Methods: In 2 Phase 3 randomized controlled trials, patients who met Classification Criteria for PsA and were biologic DMARD (bDMARD)-naïve (SPIRIT-P1) or had an inadequate response to 1 or 2 TNFi (SPIRIT-P2) received sub-

Table: Overview of ACR Components at Week 108 of the Intent-to-Treat Population who were randomized to IXE at Week 0 (observed data)

IXE=ixekizumab; IXE Q4W=IXE 80 mg Q4W; IXE Q2W= IXE 80 mg Q2W; N=number of patients in the analysis population; Nx=number of patients with non-missing data; PatGA=Patient's Global Assessment of Disease Activity; PhyGA=Physician Global Assessment; SD=standard deviation; SJC= swollen joint count (66); TJC=tender joint count (68).

cutaneous IXE 80 mg every 2 weeks (Q2W) or every 4 weeks (Q4W), after a 160-mg starting dose. The change from baseline at Week 108 for all components of ACR was assessed: tender joint count (TJC), swollen joint count (SJC), physician global assessment (PhyGA), patient's assessment of pain visual analog scale (VAS), patient's global assessment of disease activity (PatGA), HAQ-Disability Index (HAQ-DI) and CRP. Observed results are reported for the intent-to-treat (ITT) population who were initially randomized to IXE at baseline (Week 0). At Week 16, inadequate responders (< 20% improvement in both TJC and SJC) received rescue therapy and were analyzed as non-responders at Weeks 20 and 24. From Week 32 and at each subsequent visit, patients were discontinued from the study if they failed to achieve ≥20% improvement in both TJC and SJC.

Results: When evaluating group-level changes to 2 years (Week 108), patients treated with the approved PsA dosing of IXE Q4W showed comparable mean change from baseline in clinical components of ACR (TJC, SJC, PhyGA, pain VAS, PatGA, and HAQ-DI) regardless of prior TNFi failure (Table). The median (maximum, minimum) change from baseline in laboratory measure of CRP was comparable between IXE Q4W-treated patients in both populations: SPIRIT-P1, -3.9 (-99.1, 9.2); SPIRIT-P2, -2.3 (-142.0, 8.2).

Conclusion: Irrespective of whether bDMARD-naïve or having prior inadequate response or intolerance to TNFi, IXE Q4W-treated patients with PsA achieved comparable efficacy across all clinical components of ACR as measured by mean change from baseline at Week 108.

SESSION INFORMATION

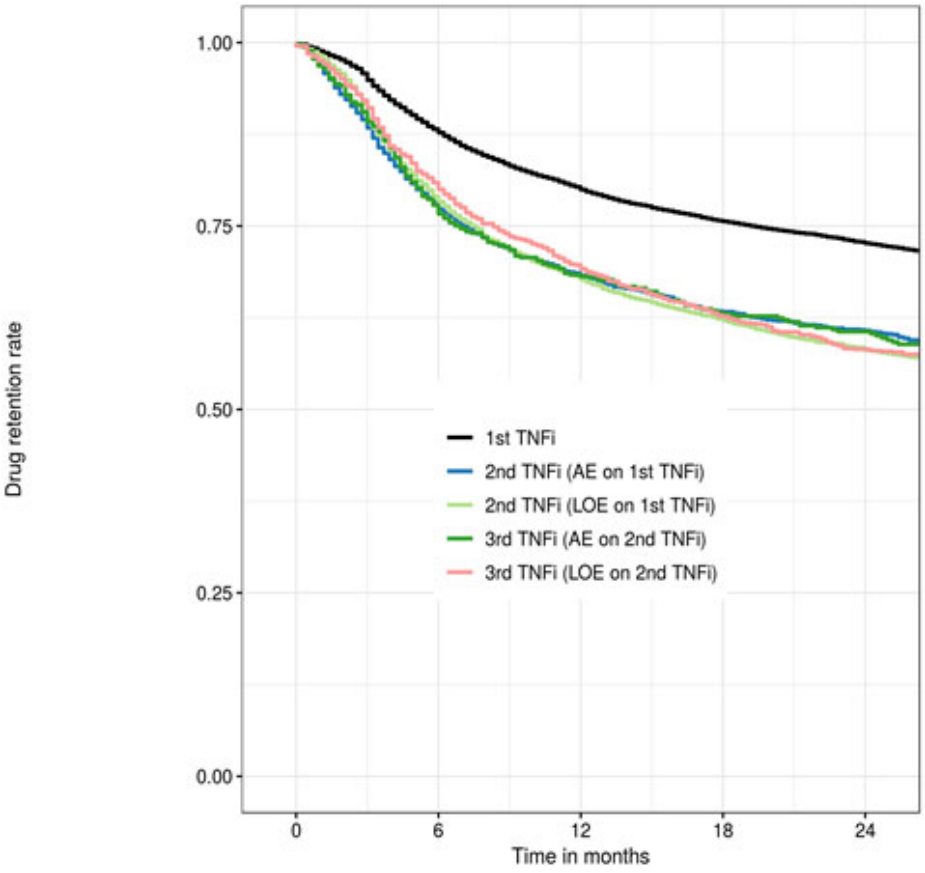
Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumour necrosis factor inhibitors (TNFi) are efficacious in patients with axial spondyloarthritis (axSpA), but still some patients switch to a different TNFi because of adverse effects (AE) or lack of effect (LOE). The EuroSpA Collaboration has previously demonstrated a 1-year retention rate of 79% and 6 months LUNDEX adjusted BASDAI< 4 of 59%[1] in patients initiating the first TNFi treatment. Little is known about the effectiveness of switching to a second and third TNFi in patients with axSpA.



Numbers at risk

	0	6	12	18	24
1st TNFi	23956	19550	16312	13799	11844
2nd TNFi (AE on 1st TNFi)	1829	1317	1050	880	763
2nd TNFi (LOE on 1st TNFi)	4057	2948	2282	1866	1560
3rd TNFi (AE on 2nd TNFi)	541	390	310	260	219
3rd TNFi (LOE on 2nd TNFi)	1521	1128	887	717	597

Time in months

Figure: Kaplan-Meier curves (top) showing drug retention rates up to 24 months for 1st TNFi*, for 2nd (AE or LOE on 1st TNFi) and 3rd TNFi (AE or LOE on 2nd TNFi). The table (bottom) shows the number of patients who were still being treated at the corresponding time points
*previously reported

We aim to investigate retention and response rates at 6, 12 and 24 months in patients with axSpA initiating the 2nd and 3rd TNFi in clinical practice across Europe. Secondly, to investigate whether the outcomes were associated with the reason for withdrawal (AE or LOE) from the previous treatment.

Methods: Prospectively collected data on axSpA patients in routine care from 12 European registries were pooled. Kaplan-Meier estimation was used to investigate TNFi retention rates. LUNDEX adjusted[2] response rates were calculated for BASDAI< 4 and ASDAS inactive disease (ASDAS< 1.3). Group comparisons were performed by Chi-square test.

Results: A total of 7953 patients initiating their 2nd TNFi and 2782 patients initiating 3rd TNFi were included. Baseline characteristics are shown in the Table.

The overall retention rates for both 2nd and 3rd TNFi at 12 months were 72 % (Figure). Corresponding retention rates for the individual registries ranged from 52-90% and 54-89%, respectively. In both patients who stopped 1st TNFi due to AE or LOE, 12-month retention rate for the 2nd TNFi treatment was 68 %. In patients who stopped the 2nd TNFi due to AE or LOE, 12-month retention rates for the 3rd TNFi treatment were 68 % and 69%, respectively.

For the 2nd and 3rd TNFi, 6 months LUNDEX adjusted BASDAI< 4 were 44% and 37% (p< 0.001), respectively, and for ASDAS inactive disease 18% and 13% (p=0.003) (Table).

Conclusion: Data from 12 European countries demonstrated decreasing response rates with increasing number of previous TNFi, although with only minor difference between 2nd and 3rd. Patients who had withdrawn from the previous TNFi due to LOE had retention rates and remission rates similar to those who had withdrawn due to AE.

Acknowledgement: Novartis Pharma AG and IQVIA for supporting the EuroSpA collaboration.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: GO-VIBRANT is a Phase 3 trial of intravenous (IV) golimumab (GLM) in adult patients (pts) with active psoriatic arthritis (PsA). Clinically meaningful improvements in skin and nail psoriasis (PsO) and in Dermatology Life Quality Index (DLQI) that were significantly greater than placebo (PBO) at weeks (wks) 14 & 24 were previously reported.[1]

To evaluate improvement in skin and nail PsO and DLQI with IV GLM through wk52.

Methods: Adult bio-naïve PsA pts with active disease (≥5 swollen & tender joints, CRP ≥0.6mg/dL, active plaque psoriasis or documented history), despite treatment w/csDMARDs &/or NSAIDs, were randomized to IV GLM 2mg/kg at wks 0/4 & every 8 wks thereafter or PBO at wks 0/4/12/20 with crossover to GLM at wk24. Pts with ≥3% body surface area (BSA) psoriasis at baseline (BL) were assessed using Psoriasis Area and Severity Index (PASI, 0-72) of 75/90/100% improvement scale, modified Nail Psoriasis Severity Index (mNAPSI, 0-130) in pts with mNAPSI >0 at BL, and DLQI (0-30) scale.

Results: 394 pts (PBO:n=198; GLM:n=196) had ≥3% BSA psoriasis at BL; 76.5% had mNAPSI >0 at BL (mean 18.6). Pts on IV GLM achieved a greater PASI 75 response rate (RR) vs PBO at wk24 (64.8% vs 13.1%, p< 0.001). At wk52, PASI 75 RR was maintained in pts who continued IV GLM treatment and increased numerically in those who crossed-over from PBO to IV GLM (PBO→IV GLM) at wk24 (71.9% and 60.6%, respectively). At wk24, pts on IV GLM achieved significantly greater PASI 90/100 RR vs PBO. At wk52, PASI 90/100 RR was maintained among those continually on IV GLM and increased numerically in PBO→IV GLM pts (Table). At wk24, significantly greater proportions of pts on IV GLM ± BL methotrexate (MTX) achieved PASI 90/100 vs PBO. By wk52, both ± BL MTX, PASI 90/100 responses were maintained in those continually on IV GLM and increased numerically in PBO→IV GLM pts (Table). The mean decrease (improvement) from BL in the mNAPSI score was also greater with IV GLM vs PBO at wk24, overall and in groups ± BL MTX. At wk52, mNAPSI RR was maintained with continual IV GLM and increased numerically in PBO→IV GLM pts (Table). At wk24, the mean decrease (improvement) from BL in DLQI was greater with IV GLM vs PBO (–8.1 vs –1.9, p< 0.001). At wk52, mean DLQI improvement was maintained in pts continually on IV GLM and increased numerically in PBO→IV GLM pts (-7.8 vs -5.8). Similar patterns were seen in subgroups ± BL MTX. In pts with DLQI improvement >1 at baseline, rate of simultaneous achievement of both PASI 50 response & improvement in DLQI ≥5 was greater at wk24 with IV GLM (59.2%) vs PBO (8.1%, p< 0.001). At wk52, both were achieved by 56.6% continually on IV GLM vs 41.4% of PBO→IV GLM pts. Similar patterns were seen for simultaneous achievement of both improvement in DLQI ≥5 & PASI 75/90/100 at wks 24 and 52.

Table. Change from Baseline in PASI 90/100 and mNAPSI through Week 52				
	Week 24[1]		Week 52	
	PBO	IV-GLM 2 mg/kg	PBO→ IV-GLM 2 mg/kg at Wk 24	IV-GLM 2 mg/kg

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: AS is a chronic, inflammatory disease of the axial skeleton associated with pain, stiffness, disability, and reduced quality of life (QOL).[1] AS is defined by inflammation in spinal joints and radiographic changes at the sacroiliac joints, but patients (pts) frequently also have peripheral involvement, including swollen and tender joints (STJ),[2] a feature associated with worse overall disease activity.[3] Secukinumab is an IL-17 inhibitor approved for AS based on findings from the phase 3 MEASURE studies, in which it showed superiority to placebo in improving symptoms of AS.[4-6] We explored whether peripheral STJ in pts with AS might be prognostic of outcomes following secukinumab treatment.

Methods: Data from MEASURE 1 (NCT01358175), 2 (NCT01649375), 3 (NCT02008916), and 4 (NCT02159053) were pooled from baseline to week 16 and included in this hypothesis-generating analysis. No adjustments for multiple comparisons were made. Pts with active AS received subcutaneous (SC) secukinumab every 4 weeks at doses of 300 mg with intravenous (IV) loading dose (LD), 150 mg with IV LD, 150 mg with SC LD, or placebo. Response to treatment was analyzed in pts with or without peripheral STJ at baseline. Peripheral joint involvement was assessed using a 44-joint STJ count. Response was assessed using multiple outcome measures, including Assessment in AS 20/40 (ASAS20/40), ASAS Partial Remission, BASDAI, BASFI, BASMI, disease activity and back pain assessments, and QOL questionnaires.

Results: Of 852 pts included in this pooled analysis, 814 completed 16 weeks of treatment with secukinumab (n = 450) or placebo (n = 364). On average, pts with no peripheral STJ were younger and more likely to be male; pts with STJ had higher CRP levels, had higher BASDAI and BASFI, had been diagnosed longer, and had more often received prior TNF inhibitors (TNFis) and DMARDs, suggesting more severe disease (**Table 1**). Overall, secukinumab led to significantly higher response rates than placebo in all outcome measures, regardless of the presence of STJ (**Figure 1, Table 2**). However, response rates tended to be numerically higher in pts with no STJ, with higher response rates seen for ASAS20/40 and ASAS partial remission (**Figure 1**). Overall, reductions in disease activity and back pain were also numerically greater in pts with no STJ (**Table 2**). QOL improvements were similar in pts with or without STJ.

Conclusion: Secukinumab led to significant improvements in efficacy outcomes, regardless of peripheral joint involvement. Pts with STJ were more difficult to treat, showing numerically lower responses to treatment.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab (SEC) provided sustained efficacy, inhibition of radiographic progression, and stable safety profile over 52 Weeks (Wks) in patients (pts) with psoriatic arthritis (PsA) in the FUTURE 5 study.[1,2] Here we report the end-of-study (2-year) results of the effect on radiographic progression of SEC in pts with PsA in the FUTURE 5 study.

Methods: Adults (N = 996) with active PsA were randomized to subcutaneous SEC 300 mg load (300 mg), 150 mg load (150 mg), 150 mg no load, or placebo at baseline, Wks 1, 2, 3, and 4, and every 4 wks thereafter. Pts could have the SEC dose escalated from 150 mg to 300 mg starting from Wk 52, based on physicians' judgement. Radiographic progression (mean change in van der Heijde-modified total Sharp score [vdH-mTSS]) was based on hand/wrist/foot radiographs obtained at baseline, Wks 16 (non-responders), 24, 52, and 104, assessed by two blinded readers (plus an adjudicator if required). Radiographic data were analyzed using linear mixed-effects model (random intercept, random slopes) at Wks 24 and 52, and as observed at Wk 104. Data are shown for pts originally randomized to SEC (300 and 150 mg); the 150 mg groups also includes pts who had their dose escalated to 300 mg. Analyses by prior anti-TNF (naïve vs inadequate response/intolerance [IR]; stratification factor) use were also done.

Results: Overall, 85% (300 mg), 82% (150 mg), and 75% (150 mg no load) of pts completed 2 years of treatment. A total of 86 (39%) and 92 (41%) pts had their dose escalated to 300 mg in the 150 mg and 150 mg no load groups, respectively. In overall population, the proportions of pts with no radiographic progression (change from baseline in mTSS ≤0.5) with SEC were 89.5% (300 mg), 82.3% (150 mg), and 81.1% (150 mg no load) at 2 years; the corresponding proportions of pts for change from baseline in mTSS ≤0.0 were: 81.2%, 69.1% and 73.4%, respectively. Radiographic progression was low in SEC-treated pts in the overall population and by prior anti-TNF use over 2 years (Table). Clinical responses were also sustained through 2 years of SEC treatment.

Conclusion: Low radiographic progression was observed over 2 years of treatment with SEC 300 and 150 mg in pts with PsA.

Table. Summary of Radiographic Results through Wk 104 Mean change in vdH-mTSS				
	300 mg	150 mg[1]	150 mg no load[1]	Placebo

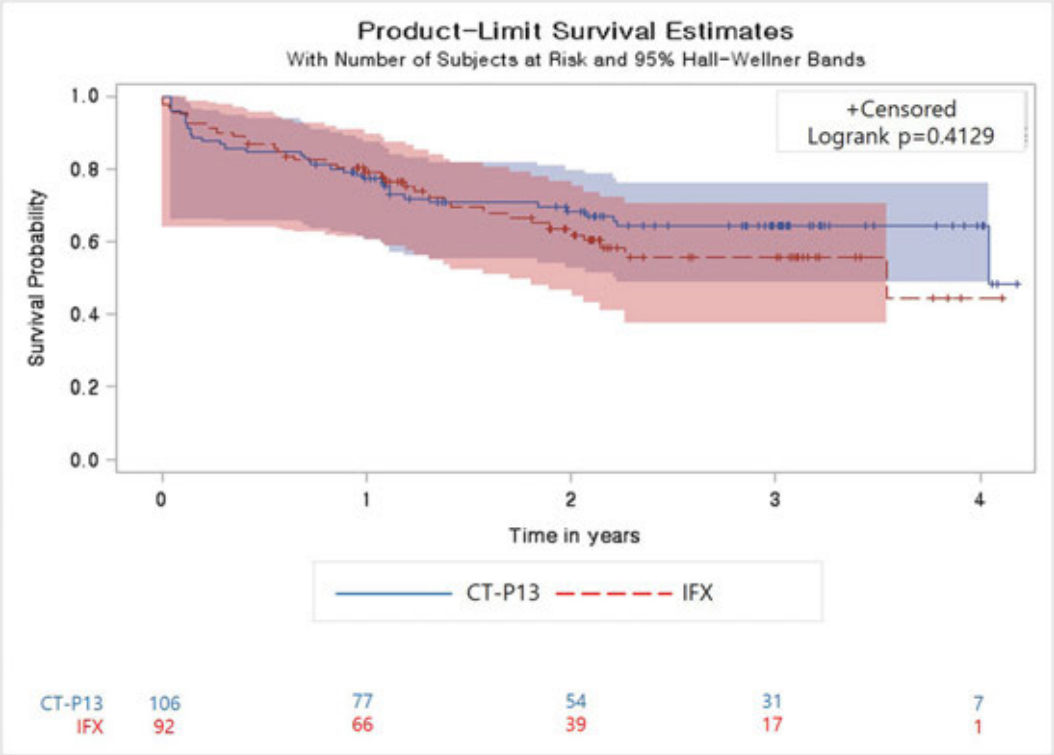
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: CT-P13 is the first biosimilar of the reference infliximab (IFX) prescribed for rheumatoid arthritis, ankylosing spondylitis (AS), Crohn's disease, ulcerative colitis, psoriasis, and psoriatic arthritis. There are few studies showing long-term, real-world data of its drug survival or safety.



Figure

To evaluate drug retention, efficacy and safety of CT-P13 versus IFX in patients with AS enrolled in the Korean College of Rheumatology Biologics (KOBIO) registry.

Methods: Subjects were registered patients with AS who initiated CT-P13 or IFX between Dec 2012 and Dec 2017. Patients in the two groups were matched via propensity score based on age, gender, and baseline Bath Ankylosing Spondylitis Disease Activity Index (BASDAI). In result, 124 patients were selected in each group. Drug retention, efficacy, and adverse events (AEs) in both groups were assessed over the 4-year follow-up period.

Results: The median treatment duration was 2.1 years in CT-P13, and 1.8 years in IFX treated patients (p = 0.1148). Overall, 79% of patients received each agent as first-line therapy. Drug retention of CT-P13 versus IFX was comparable in the total patient population (p = 0.4129, **Figure**), for first-line users (p = 0.1532) and second or more lines of users (p = 0.4452). Changing or discontinuing the agent occurred in 31.5% of patients in the CT-P13 group, and 33.1% in the IFX group. The most common reason for change or discontinuation was lack of efficacy (CT-P13 group: 38.5%; IFX group: 24.4%). CT-P13 and IFX users demonstrated comparable improvements in BASDAI, ASDAS-ESR, ASDAS-CRP and the ASDAS improvement criteria. In total, 13 AEs were reported in the CT-P13 group and 17 in the IFX group that led to treatment change or discontinuation.

Conclusion: In this real-world study, long-term data from Korean patients with AS show that CT-P13 has a drug retention rate comparable to IFX, and also similar efficacy along with an acceptable safety profile.

Exposure–Response Modeling of an Oral, Selective Tyrosine Kinase 2 (TYK2) Inhibitor, BMS-986165, for Pain Visual Analog Scale Score, in Patients with Psoriasis and Musculoskeletal Symptoms

Jun Shen,[1] Anjaneya Chimalakonda,[1] Miroslawa Nowak,[1] John Throup,[1] Subhashis Banerjee,[1] and Ihab Girgis[1], [1]Bristol-Myers Squibb, Princeton, NJ

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

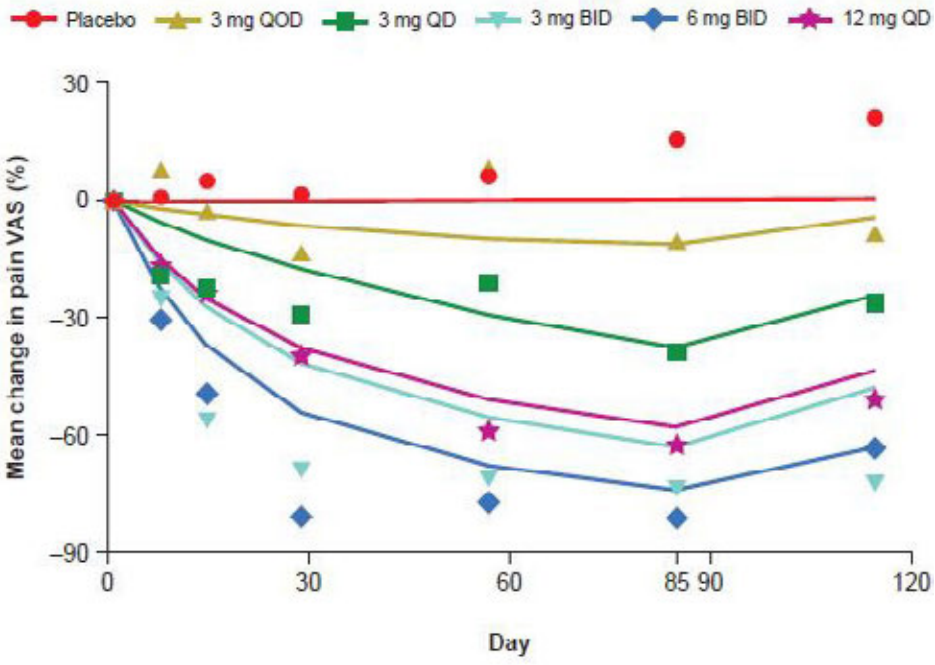
Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: BMS-986165 is an oral, selective inhibitor of TYK2, an enzyme that activates signal transducer and activator of transcription (STAT)-dependent cytokine signaling pathways, including the IL-12/IL-23 signaling pathway. IL-12/IL-23 signaling has a key role in the pathogenesis of skin disease in both psoriasis (PsO) and PsA. In a 12-week Phase 2 study in adults with PsO that included those with musculoskeletal symptoms, BMS-986165 demonstrated a dose-dependent Psoriasis Area and Severity Index (PASI) 75 response and a favorable safety profile.[1] Further analysis was conducted in this study to explore the impact of BMS-986165 on pain scores using exposure–response modeling in those with baseline musculoskeletal symptoms.

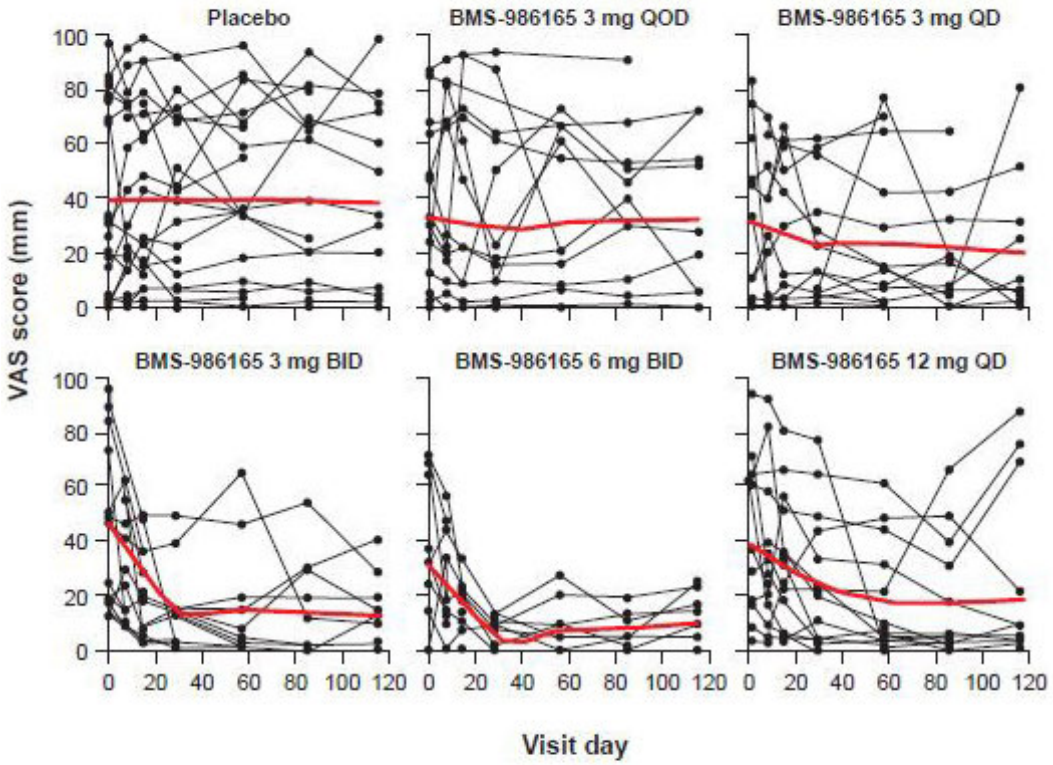
Methods: A longitudinal exposure–pain visual analog scale (VAS) score model was developed to describe the effect of BMS-986165 on pain VAS scores over time in patients with PsO and musculoskeletal symptoms at baseline

Figure 1: Observed and simulated mean percent change from baseline in pain VAS score



Symbols: observed data; lines: simulated data; treatment ended at Day 85.
BID=twice daily; QD=every day; QOD=every other day; VAS=visual analog scale.

Figure 2: Observed pain VAS score by visit



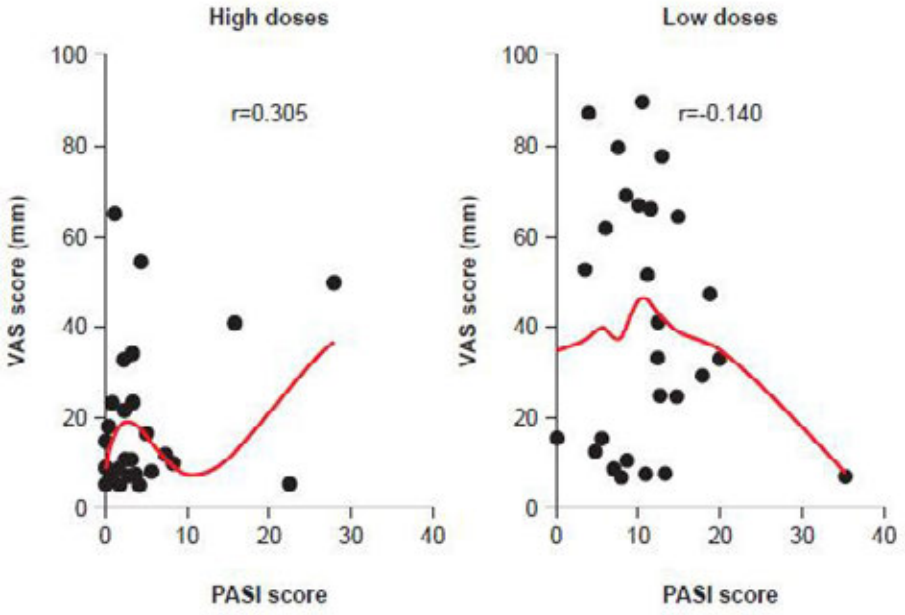
Filled circles: observed data; black solid lines: individual profiles; red lines: LOESS (locally weighted smoothing).
Treatment ended at Day 85.
BID=twice daily; QD=every day; QOD=every other day; VAS=visual analog scale.

in the Phase 2 study (NCT02931838).[1] The exposure data (steady-state minimum plasma drug concentration) were derived from a population pharmacokinetics model and the response data were the pain VAS scores measured on Days 1, 8, 15, 29, 57, 85 (on treatment), and 115 (off-treatment follow-up). The response data from 87 patients were modeled with exposure using a nonlinear mixed effects model. Simulations were performed to compare results for different dosing regimens. Additionally, correlation of median pain VAS and PASI scores were compared across the dose groups.

Results: Median model-simulated percent change from baseline pain VAS score ranged from -62% to -89% across BMS-986165 dosage regimens over 12 weeks; observed and simulated mean percent change are shown in Figure 1. Visual predictive checks of the exposure–response model demonstrated the model-predicted VAS score generally agreed overall with the observed data. BMS-986165 demonstrated a dose-related improvement in pain VAS score, with a sustained effect observed after treatment ended on Day 85 (Figures 1 and 2). A clear relationship between BMS-986165 exposure and pain VAS score reduction can be established. Correlation between median pain VAS and PASI scores was weak overall, suggesting that pain improvements could not be entirely explained by improvements in skin disease (Figure 3).

Conclusion: The relationship between BMS-986165 exposure and pain VAS score, in patients with PsO and baseline musculoskeletal symptoms, was captured using a nonlinear mixed effects exposure–response model. BMS-986165 demonstrated dose-dependent improvements in pain. Pain and PASI scores were weakly correlated. The decreased

Figure 3: Correlation of pain VAS and PASI scores at Day 85



A trend toward a stronger correlation at high versus low dosages of BMS-986165 was observed
High doses: 3 mg BID, 6 mg BID, and 12 mg QD; low doses: placebo and 3 mg QOD.
Red line: LOESS (locally weighted smoothing); treatment ended at Day 85.
BID=twice daily; PASI=Psoriasis Area and Severity Index; QD=every day; r=Pearson correlation coefficient; VAS=visual analog scale.

pain scores with BMS-986165 treatment, which were not well-correlated with improvements in PASI scores, were suggestive of improvements in joint inflammation.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical Poster II: Treatment of Axial Spondyloarthritis & Psoriatic Arthritis

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Secukinumab represents a relatively new approach to treating patients with psoriatic arthritis (PsA) and has shown promising results in RCTs. However, there is a lack of real-life evidence on secukinumab effectiveness. Hence, the aim of this study was to determine the 6- and 12-month secukinumab retention rates as well as the crude and LUNDEX corrected proportions of patients in remission and low disease activity (LDA) at 6 and 12 months after treatment initiation based on observational registries in Europe. This was assessed overall as well as by prior biologic disease-modifying anti-rheumatic drug (bDMARD)/targeted synthetic (ts)DMARD use.

Methods: Data from PsA patients treated with secukinumab in routine care from 11 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were pooled. Time from treatment initiation to data cut was ≥ 12 months regardless of treatment duration and cover start date between May 2015 and April 2018. Crude and LUNDEX[1] adjusted Disease Activity Score with 28 joints and CRP (DAS28CRP) and Disease Activity index for

***Comparisons between b/tsDMARD naïve and non-naïve patients were performed with ANOVA for normally distributed data and with Kruskal-Wallis for skewed data. Drug retention is compared with Kaplan-Meier with log-rank test. **LUNDEX adjusted treatment outcome = (number of patients still treated at the respective timepoints / number of patients starting treatment x (% of patients achieving the respective treatment outcomes). CRP, C-reactive protein; DAPSA28, Disease Activity index for Psoriasis arthritis with 32 joint count; DAS28CRP, 28-joint disease activity score with CRP.**

Table

PSoriatic Arthritis with 28 joints (DAPSA28) [2] remission and LDA rates were calculated. Group comparisons between b/tsDMARD naïve, and 1 or 2 or more prior b/tsDMARD users were performed with ANOVA, Kruskal-Wallis or Chi-square test, or with Kaplan-Meier analyses with log rank test, as appropriate.

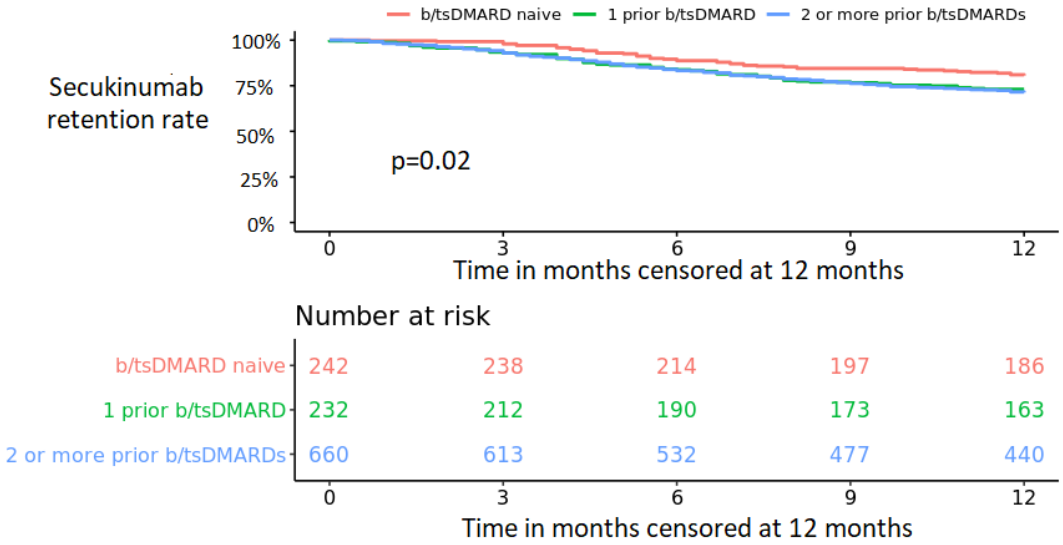

Figure. Pooled 12-month secukinumab retention rates for PsA patients in EuroSpA stratified by b/tsDMARD naive patients, patients treated with 1 prior b/tsDMARD or 2 or more prior b/tsDMARDs (log rank test; p<0.001).

Results: A total of 1134 PsA patients were included, thereof 21 patients who started treatment in year 2015, 375 in 2016, 623 in 2017 and 115 in 2018. Overall 6/12-month secukinumab retention rate was 85%/74% and significantly higher in b/tsDMARD naïve compared with non-naïve patients after 12, but not 6 months (table, figure). Overall 6- and 12-month DAS28< 2.6/DAPSA28≤4 was achieved by 33%/12% and 55%/18% of the patients, respectively and 6- and 12-month DAS28/DAPSA28 LDA by 52%/34% and 73%/49%, respectively. B/tsDMARD naïve patients compared with patients treated with 1 or 2 or more previous b/tsDMARDs had shorter time since diagnosis, higher baseline disease activity, a higher proportion were men and a higher proportion achieved LUNDEX adjusted 6-month remission.

Conclusion: This study of >1100 patients in 11 European countries provided real-world data on the effectiveness of secukinumab in patients with PsA, adding evidence to existing RCTs. A majority of the patients were treated with 2 or more previous b/tsDMARDs, were female and had long disease duration. Overall retention rate was 85%/74% at 6/12 months, respectively, with significantly higher retention rates for b/tsDMARD naïve compared with patients treated with 1 or 2 or more previous b/tsDMARDs after 12, but not 6 months. Overall, a higher proportion of bionaïve than previous b/tsDMARD users achieved remission, regardless of remission criteria.

Should Lupus Podocytopathy Be a Subclass in Class I and Class II Lupus Nephritis?

Whitney Bembry,[1] Dasha Lopez,[2] Christopher Mesa,[3] Nirupa Patel,[3] and Myriam Guevara[4], [1]Tulane University School of Medicine, New Orleans, LA, [2]Baton Rouge General Hospital, Baton Rouge, LA, [3]Louisiana State University School of Medicine, New Orleans, LA, [4]Louisiana State University School of Medicine, New Orleans

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Evidence of podocyte effacement on electron microscopy and significant proteinuria in a systemic lupus erythematosus (SLE) patient with biopsy proven minimal mesangial (MM), mesangial proliferation (MsP) and focal segmental glomerulosclerosis (FSGS) is the defining quality of lupus podocytopathy (LP). Our objective is to recognize the prevalence of LP and significant proteinuria in SLE patients with biopsy proven class I, class II and/or FSGS.

Methods: In this single center retrospective study, two independent reviewers evaluated records from 96 hospitalized patients admitted with ICD-10 codes corresponding to a diagnosis of glomerular disease and/or tubulointerstitial nephropathy in SLE from 2015 to 2018.

Results: The prevalence of LP in our cohort was 8.33% (Table 1). Seventy-five percent of our cohort were females and of African descent. Class II lupus nephritis (LN) was the most common pathological diagnosis (50% of patients); followed by class I LN (37.5%), and one case of FSGS (12.5%). Five patients presented with significant proteinuria (62.5%). Majority of the patients had active disease, presenting with low C3 levels (62.5%). Most patients received corticosteroids (CS), either pulse dose steroids or high dose prednisone being the most common mode (62.5%); four

Table 1. Characteristics of SLE patients with Lupus Podocytopathy in addition to Pre- and Post-treatment Values

Patient	Pathology report	Age	Gender	Ethnicity /race	Progression	PRE Prot/crea	POST prot/crea	BUN/crea	BUN/crea - after	ANA	Anti-dsDNA	C3/C4	Treatment
1	Class I LN; IF with rare mesangial - capillary deposits; EM- podocyte foot processes segmentally effaced.	41 YO	M	AA	CKD II	836	72	21/1.09	26/1.45	Positive	1. 640	33/<8	Prednisone 40mg + MMF
2	Class II LN; EM: less than 20% focal podocyte foot process fusion.	58 YO	F	NH	CKD I	2049	1190	20/1.04	13/1.05	Positive	Negative	173/26	leflunomide
3	Class I LN; additionally, glomeruli with segmental sclerosis and foot process effacement by EM.	30 YO	F	AA	Class III - Deceased (2017)	9899	2270	27/1.53	32/0.67	Positive 1.640	Negative	138/53	solumedrol 500mg IV + MMF
4	Class I LN; IF with minimal mesangial deposits. Podocyte foot process are segmentally irregular	29 YO	F	AA	Stable	574	275	21/1.45	19/1.2	Negative	Negative	153/23	None

patients received a combination of CS and Mycophenolate mofetil (MMF). All of the patients treated with CS and MMF demonstrated greater than 50% improvement in the urine protein/creatinine ratio with mean duration of 27.5 days and persisted in remission. The patient with the FSGS pattern despite having greater than 50% improvement in protein/creatinine ratio relapsed to LN class III within 2 years.

Conclusion: It is important to recognize a subset of patients presenting with clinical signs of nephrotic syndrome despite biopsy demonstrating class I or class II LN. The literature outlines LP as a spectrum, from MM to FSGS, with worse response to treatment in patients with FSGS. [1] As demonstrated in our cohort of predominantly ethnic minorities with Class I and class II LN with LP patterns, majority had a favorable response to CS in combination with MMF; the only patient with the FSGS pattern underwent relapse. A larger cohort with longer duration of study period is needed to suggest recommendations for LP. It may be beneficial to treat LP in Class I and II LN when associated with proteinuria.

Routine Clinical Pathology Measurements Are Predictive of the Risk of Organ Damage Accrual in SLE

Eric Morand,[1] Kevin Zhang,[1] Sarah Boyd,[1] Francois Petitjean,[1] Alberta Hoi,[2] Rachel Koelmeyer,[1] and Hieu Nim[1], [1]Monash University, Melbourne, Victoria, Australia, [2]School of Clinical Sciences, Monash University, Meloburne, Victoria, Australia

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

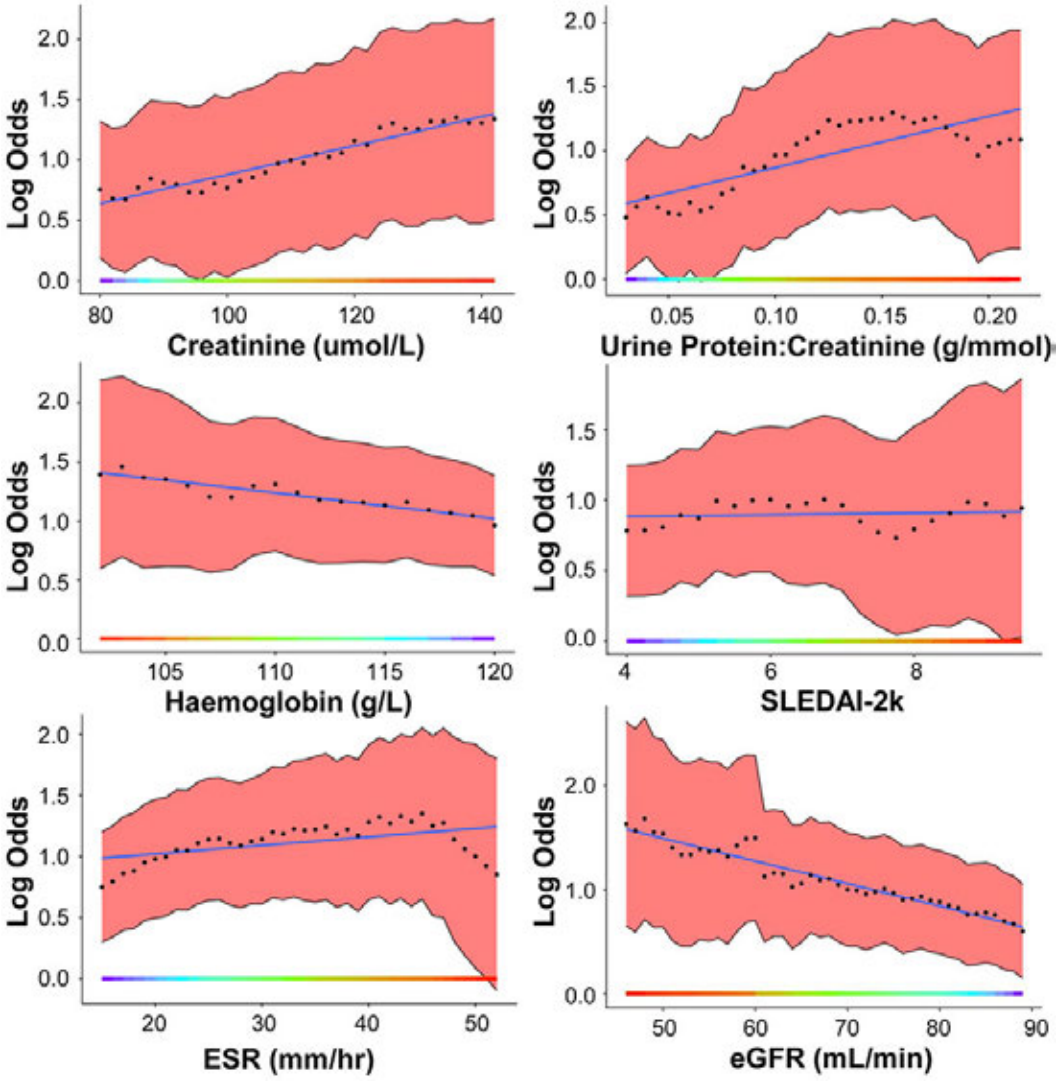

Figure. Ln (natural log) odds ratio for damage transition vs time-adjusted mean of laboratory variables. Red region (95%CI) lying above the y=0 line indicates the risk is statistically significant ($p<0.05$). Regression lines (blue) indicate the risk of damage increase is approximately proportional with the distance from normal pathology measure range.

Background/Purpose: Prevention of permanent organ damage, a major predictor of morbidity and mortality, is a key goal in the treatment of SLE. Physician-measured disease activity scores have only weak predictive value for damage accrual risk, and are in part subjective. Routine pathology laboratory measurements provide objective, continuous biological data, but their association with damage accrual risk in SLE has not been studied.

Methods: Longitudinal data were collected prospectively in a single centre SLE patient cohort between 2007-2017. Variables recorded at each visit included disease activity (SLEDAI-2k), drug treatment and routine pathology measurements. Organ damage (SLICC-SDI) was measured annually. Longitudinal patient data were split into annual periods, and each visit was assigned as being in a "damage transition" or "non-damage transition" period based on whether SDI increased at the subsequent annual measure. Time-adjusted means (TAMs) of laboratory variables were calculated for each period, and multivariable logistic regression analysis of the association with damage accrual (adjusting for age, gender, race, previous organ damage and prednisolone dose) was performed, with Holm-Bonferroni correction.

Results: 893 annual periods, comprising 5082 visits from 245 patients (85.6% female, 50.2% Caucasian), were analysed. Five of 16 routine laboratory variables were significantly associated with risk of damage accrual: estimated glomerular filtration rate (eGFR) ($p< 0.01$), creatinine ($p< 0.01$), urine protein:creatinine ratio ($p< 0.01$), ESR ($p< 0.001$), and haemoglobin ($p< 0.001$). Moreover, the odds of damage increase were proportional to the deviation of each of these variables from its respective normal range (Figure). SLEDAI-2k was also significantly associated with damage accrual ($p< 0.001$), but the association of SLEDAI-2k with damage did not exhibit this proportionality.

Conclusion: Routine pathology measures are proportionally associated with organ damage risk in SLE. These measures have potential as biomarkers for identifying patients at risk of organ damage from SLE.

Imbalance Between Th17 and Regulatory T Cells in Patients with Systemic Lupus Erythematosus Combined EBV/CMV Viremia

Rui Su,[1] Yue Liu,[1] Xinyu Zheng,[1] Xiao-feng Li,[2] and Cai-hong Wang[3], [1]Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan , Shanxi, China, Tai Yuan, China (People's Republic), [2]Department of Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan , Shanxi, China, TaiYuan, China (People's Republic), [3]The Second Hospital of Shanxi Medical University, Tai Yuan, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Infection is common and is one of the leading causes of morbidity and mortality in Systemic Lupus Erythematosus (SLE) patients . Excessive using glucocorticoid and DMARDs lead to decrease immune function, which increasing opportunistic infection, such as EBV or CMV. Recent study show that the imbalance between T help cell 17 (Th17) and regulatory T cell (Treg cell) is a pivotal cause of autoimmune disease. However, the relationship between imbalance of Th17/ Treg and SLE combined EBV or CMV viremia is unknown. We will investigate the

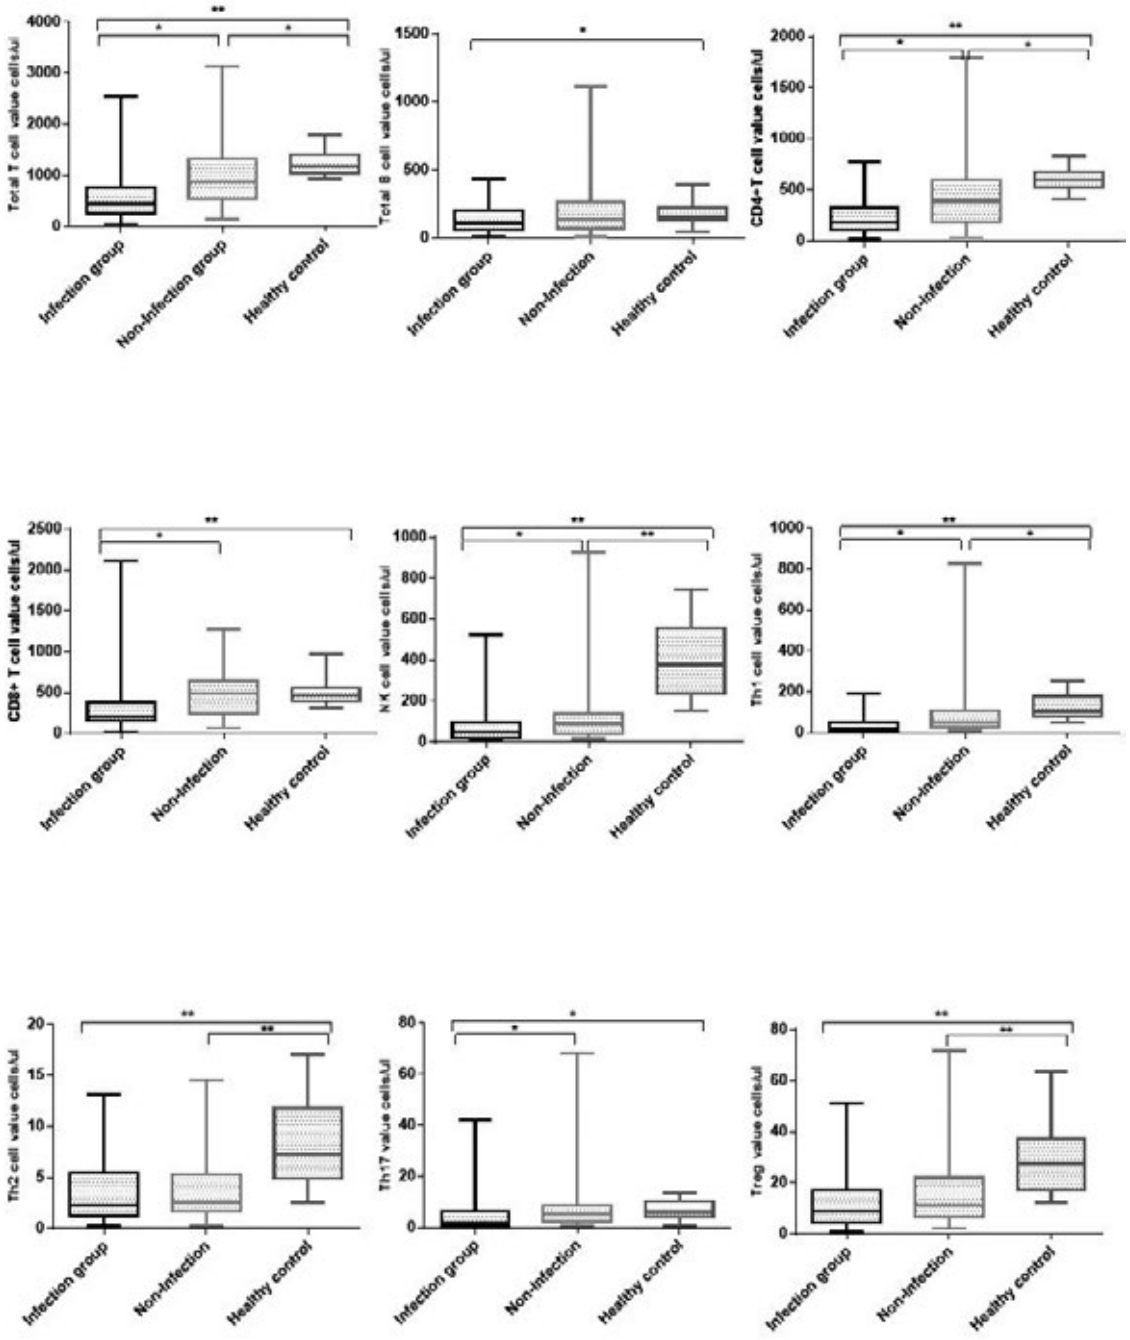

Figure. Comparsion of the absolute value of lymphcytes and CD4+ T cell subsets among SLE patients combined EBV / CMV viremia(n=36),SLE patients without any infection (n=30)and healthy control(n=20).(*P<0.05,**P<0.001).

characteriatic of lymphocytes cell subsets ,especially the CD4+ T subsets in patients with SLE combined EBV / CMV viremia.

Methods: Clinical records of SLE patients combined EBV and CMV viremia (Group infection), 36 SLE patients combines EBV or CMV *Viremia*, hospitalized in ShanXi medical university the second Hospital, were analyzed. As control, we selected 20 health persons (Group health) whose age matched with group infection, 30 SLE patients without any infection. The absolute numbers of Treg cell and effector lymphocytes cell subsets in peripheral blood were examined by flow cytometry.

Results: (1) Compared with SLE patients without infection,36 SLE patients combined EBV or CMV viremia, including 29 patients with EBV, 13 patients with CMV, 6 patients combined EBV and CMV, the absolute number of total T cell (P=0.001), NK cell (P=0.021), CD4+T cell (P=0.000), CD8+T cell (P=0.002), Th1 cell (P=0.002), Th17 (P=0.022) lower than it the non-infection group.The absolute number of and(CD4+CD25+FOXP3+)Treg (P=0.195), Th2 cell (P=0.290) has no obvious difference between them. **(2)** And the absolute value of total T lymph cell (P=0.000), total B lymph cell (P=0.015), NK cell (P=0.000), CD4+T cell (P=0.000), CD8+T cell (P=0.000), Th1 cell (P=0.000), Th2 cell (P=0.000), Th17(P=0.003) and Treg (P=0.000) in infection group significantly lower than healthy control. **(3)**Compared with the healthy control, the absolute number of Total T cell (P=0.011), NK cell (P=0.000), CD4+T cell (P=0.002), Th1 (P=0.005), Th2 cell (P=0.000) and Treg (P=0.000) in non-infection group evidently lower, but there is no siginificant difference in absolute number of Th17 (P=0.325), total B lymph cell (P=0.431), CD8+T cell (P=0.680).

Conclusion: Distortion of the Th17/Treg balance favoring the pro-inflammatory Th17 side is hence believed to contribute to exacerbation of autoimmune disorders.In our study, compared with non-infection group, the absolute count of pro-inflammatory Th17 cells in infection group obviously decreased, this suggests that Th17 might be leading factor of Th17/Treg imbalance in patients with combined SLE EBV or CMVviremia. Appropriate immunodulatory therapy for CD4+ T subsets on the basis of antiviral therapy for SLE patients with EBV or CMV may be beneficial .

Decreased Nocturnal Blood Pressure Dipping in Patients with Systemic Lupus Erythematosus: Association with Markers of Inflammation

Daniel Carranza Leon,[1] Annette Oeser,[1] Qiong Wu,[1] C. Michael Stein,[2] Michelle Ormseth,[1] and Cecilia Chung[2],
[1]Vanderbilt University Medical Center, Nashville, [2]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Blood pressure follows a circadian rhythm; usually systolic blood pressure (SBP) drops by more than 10% during the night. Absence of this phenomenon, known as “non-dipping” is a cardiovascular risk factor independent of hypertension. Patients with systemic lupus erythematosus (SLE) have a high prevalence of hypertension and cardiovascular event risks, but little is known about nocturnal blood pressure dipping in patients with SLE and its association with inflammatory markers.

Methods: Twenty-six patients with SLE and 26 control subjects frequency-matched for age, race and sex were included in this study. All subjects were 18 years of age or older. Patients with SLE met the American College of Rheumatology revised classification criteria for SLE. Control subjects did not have SLE or other autoimmune diseases. We calculated nocturnal blood pressure dipping using data from ambulatory 24-hour blood pressure measurements. Blood pressure measurements were divided into daytime and nighttime periods defined by the patients’ reported hours of sleep. The average systolic blood pressure (mm Hg) was obtained for each period, and the nighttime/daytime systolic blood pressure ratio was calculated. We measured plasma concentrations of 92 inflammation-related markers using a multiplex immunoassay (Inflammation panel; Olink Bioscience, Uppsala, Sweden). Wilcoxon-rank sum tests and Fisher exact test were used to compare blood pressure results between patients with SLE and control

	Rho-coefficient	p-value
CDCP1 (CUB domain-containing protein-1)	-0.61	0.002

Table. Correlation between Nocturnal Blood Pressure Drop and inflammatory biomarkers in SLE patients

subjects. Spearman correlations were used to assess the correlation between blood pressure night dipping (expressed in %) and the inflammatory biomarkers in patients with SLE.

Results: SLE patients have a decreased nocturnal dipping [7% (5 – 13%)], compared to controls [12% (8-20%)] p=0.01. In patients with SLE, lower blood pressure dipping was significantly associated with many inflammatory markers (Table) including CDCP1 (CUB domain-containing protein-1, involved in complement activation), IL15RA (Interleukin-15 receptor subunit-α, which enhances apoptosis), and SLAMF1 (Signaling lymphocytic activation molecule-1, which promotes immunoglobulin production).

Conclusion: Nocturnal blood pressure dipping was less pronounced in patients with SLE compared to control subjects. Lower nocturnal blood pressure dipping was associated with multiple markers of inflammation in patients with SLE.

Weight fluctuation (univariate)	1.497 (0.90-2.48)	0.116
Weight fluctuation (multivariate*)	2.009 (1.16-3.47)	0.012
Baseline weight (univariate)	0.997 (0.98-1.01)	0.587
Baseline weight (multivariate*)	0.989 (0.98-1.00)	0.142

*Multivariate analyses were adjusted for age, sex, race, and baseline Charlson comorbidity index.

Table 2: Association of weight fluctuation and baseline weight with all-cause mortality.

Background/Purpose: Recent studies have suggested that body weight fluctuation in the general population is an independent risk factor for overall mortality. These findings are of particular concern for patients with systemic lupus erythematosus (SLE), who have a significantly elevated risk of mortality compared to the general population. However, little is known about the nature of body weight fluctuation and its association with mortality in SLE patients. We hypothesized that patients with SLE who had greater body weight fluctuation would have increased mortality risk compared to patients with SLE who had lower body weight fluctuation.

Methods: We used a previously validated algorithm (positive predictive value of 94%) to assemble a cohort of SLE patients from a de-identified version of an academic medical center's electronic health record. We extracted outpatient weight measurements and reviewed cases with outlier values to confirm their accuracy. We excluded (1) patients with fewer than three visits or age less than 18 years at the time of the first relevant ICD9 code (710.0 for SLE), (2) weights from 90 days prior to and 270 days after an occurrence of pregnancy, and (3) weights measured during inpatient or emergency department visits. We then conducted a retrospective cohort study in which body weight fluctuation (measured as average successive variability) was analyzed to identify associations with demographic variables, clinical characteristics, and outcomes among SLE patients. We used a Poisson regression and adjusted for age, sex, race, and baseline Charlson comorbidity index in the multivariate analysis. The primary outcome was all-cause mortality.

Results: A total of 690 SLE patients met inclusion criteria. Patients with body weight fluctuation below the median were described as "low body weight fluctuation," while patients with body weight fluctuation above the median were termed "high body weight fluctuation." High body weight fluctuation correlated significantly with several baseline characteristics, including younger age, black race, and higher weight (Table 1). In the multivariate analysis, there was a significant association between body weight fluctuation and mortality (incidence rate ratio [IRR]: 2.009; 95% confidence interval [CI] 1.16-3.47; p = 0.012; Table 2).

Conclusion: In patients with SLE, high fluctuation in body weight, but not baseline BMI nor weight, was associated with increased mortality independent of age, race, sex, and baseline comorbidities. This association may indicate that early recognition by providers of weight fluctuation—even more than BMI or body weight—has the potential to decrease mortality in SLE patients.

Interstitial Lung Disease in Patients with Systemic Lupus Erythematosus: Who Should We Screen?

Muhsen Al-ani,[1] Bobby Kwanghoon Han,[2] and Gregory c Gardner[3], [1]University of Washington, seattle, WA, [2]University of Washington, seattle, [3]University of Wasshington, seattle

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a disease with a variety of clinical manifestations but interestingly interstitial lung disease (ILD) is rare. The literature to date has not identified consistent markers to help with clinical decision making regarding screening for SLE-ILD. Some of these features may depend on specific ethnic variation based on the population studied. We retrospectively identified patients with SLE and ILD at our institution over a twenty-year period to try to identify an SLE-ILD phenotype in our Northwest US SLE population to aid in decisions about screening.

Methods: We conducted a review of our electronic record database at University of Washington Medical center, looking for patients with the diagnosis of SLE who were seen between 1998-2018 in our Rheumatology outpatient clinics. We identified 1335 SLE patients by using the International Classification of Diseases (ICD) 9 and 10 codes. We also identified 29 patients with a diagnosis of SLE-ILD. Diagnosis was confirmed by individual medical record review by a rheumatologist based on history, exam, laboratory, and imaging findings. Clinical and serologic data for each patient was recorded and analyzed and compared to a control group of SLE patient without ILD.

Results: SLE-ILD was found in only 2% of our SLE population. SLE-ILD appears to be more common in Asians (31 vs 14% SLE-ILD vs control population). More than half of the patients who will develop SLE-ILD, will develop it in first

2 years after SLE diagnosis. NSIP is the most common type of SLE-ILD (72.2%) followed by UIP (24%). Common clinical features include the presence of Raynaud's phenomenon (RP) and gastrointestinal esophageal reflux disease (GERD) and both were present in greater than 70% of SLE-ILD patients. Of note, 34% of our SLE-ILD patients had co-existing pulmonary hypertension. Chest x-ray missed ILD changes in almost 30% and required CT scan to make the diagnosis. Common serologic findings included speckled ANA (66%), anti-SM, RNP or SM/RNP antibodies (59%). Seventy-four percent of patients responded (stable or improved) to therapy (most common therapy was MMF). Forced vital capacity measurement (FVC) changed at an average rate of only 1.65 %/year in this population. Those with a UIP pattern on CT tended to do worse (43% worse UIP vs 19% NSIP). Only one death occurred in this population over the study period of unknown cause.

Conclusion: Our retrospective study showed that ILD is a rare manifestation of SLE. Patients with the combination of RP, GERD, and either anti-SM, RNP, or SM/RNP antibodies should be considered high risk for developing SLE-ILD and intermittent screening with pulmonary function tests that include FVC and DLCO measurements. Given that 41% of our patients also had pulmonary hypertension ECHO should also be considered in patients with SLE-ILD especially those with relatively low DLCO. Screening should be considered early in the disease process in patients with this phenotype and Asian patients especially should be watched closely.

Renal Arteriosclerosis Predicts Cardiovascular Disease in Lupus Nephritis

Shivani Garg,[1] Sarah Panzer,[2] Karen Hansen,[3] Callie Plafkin,[4] Maureen Smith,[2] and Christie Bartels[1], [1]University of Wisconsin School of Medicine and Public Health, Madison, WI[2]UW-Madison, Madison[3]UW Madison, Madison[4]UW Health, Madison

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with lupus nephritis (LN) have a 9-fold higher risk of cardiovascular disease (CVD), highlighting the urgent need to target CVD prevention. Studies in IgA nephropathy and transplant report that severe renal arteriosclerosis (ASCL) on biopsies is an early predictor of CVD. We previously reported a high burden of renal ASCL, accelerated by two decades in LN patients compared to healthy peers. We saw 80% positive predictive value of reported ASCL, but 50% of pathology reports overlooked renal ASCL in LN biopsies due to lack of standard systematic reporting of vascular lesions. Therefore, we aimed to examine whether overlooked renal ASCL was partially responsible for the prior negative studies on renal ASCL and CVD in LN. *We hypothesized that renal ASCL would be an early predictor of CVD in LN when over-read pathology and reports were incorporated.*

Methods: We identified all LN patients who underwent a kidney biopsy 1994-2017 at an academic center using a comprehensive native renal biopsy database. Data included socio-demographics and pathology reports from the first renal biopsy. SLE diagnosis was validated using ACR and SLICC 2012 criteria. CVD events were validated using American Heart Association guidelines. At the time of kidney biopsy, chronic kidney disease (CKD) stage and atherosclerotic cardiovascular disease (ASCVD) risk factors were recorded. Pathology reports were reviewed for reported renal ASCL, classified using Banff donor kidney biopsy ASCL grading: none, mild, moderate or severe. A blinded

Table 1. Demographics of LN patients *n=189*

Factor	Category	n, (%)
Age	Age, Median (Range)	25 (2-79) yrs
Gender	Female	148 (78%)
	Male	41 (23%)
Race	White	138 (73%)
	Non White	22 (17%)
ASCVD Risk Factors	>1 risk factors	64 (34%)
Chronic Kidney Disease	Stage ≥ 3	50 (27%)
SLE duration	<2 years	93 (49%)
Reported Renal Arteriosclerosis (ASCL)	Mild	43 (24%)
	Moderate	13 (6%)
	Severe	2 (1%)
Over-read or Reported Renal Arteriosclerosis (ASCL)	Mild	50 (27%)
	Moderate	17 (9%)
	Severe	5 (3%)
CVD events	Over 10 yr-follow-up	22 (12%)

pathologist over-read 25% of biopsies using Banff ASCL grading. When pathology reports lacked any comment on the presence or absence of renal ASCL, we supplemented the over-read renal ASCL grade. Multivariable logistic regression examined relationships with CVD events.

Results: Among 189 incident LN patients with kidney biopsies, 78% were female, 78% white and the median age was 25 (2-79), 27% had ≥ 3 CKD stage and 34% had >1 ASCVD risk factors. Overall, 32% had any and 7% had moderate-severe reported renal ASCL. The prevalence of any and moderate-severe by reported or over-read renal ASCL was 38% and 12% (Table 1). We found 22 CVD events from 1 year before LN through 10 years of follow-up, comparable to published rates in LN *(12% vs 11%, p 0.9)*.

In the group with reported renal ASCL, multivariable analyses showed that ≥ 3 CKD stage increased risk of CVD by 5-fold (*Adjusted OR 5.4, CI 1.8-18, p 0.004*; Table 2) but reported renal ASCL was not a predictor of CVD. However, examining reported or over-read renal ASCL, multivariable analysis showed that severe renal ASCL at LN diagnosis increased risk of CVD by 10-fold compared to those without ASCL (OR 9.6,CI 1.2-99, p 0.038). CKD stage ≥ 3 remained a predictor; >1 ASCVD risk factors and age were not predictors.

Conclusion: Systematic grading and reporting of renal ASCL in at first LN biopsy is critical, because severe renal ASCL can predict CVD in LN patients. In future studies, we recommend over-reading all biopsies to grade renal ASCL and examining CVD associations in diverse LN cohorts.

Table 2. Predictors of CVD in LN reported & over-read renal arteriosclerosis (ASCL)

	Reported Renal ASCL		Reported or Over-read Renal ASCL	
Predictor	Adjusted OR (95% CI)	p	Adjusted OR (95% CI)	p
ASCL - None	ref	ref	ref	ref
ASCL - Mild	0.5 (0.1-2)	0.3	0.7 (0.2-2.3)	0.6
ASCL - Moderate	1.4 (0.2-8.2)	0.7	0.9 (0.1-4.4)	0.9
ASCL - Severe	$1.3 X10^8$ (NA)	0.9	**9.6 (1.2-99)**	**0.038**
Age <30 years	ref	ref	ref	ref

Assessment of the QRISK2, QRISK3, SLE Cardiovascular Risk Equation, Framingham and Modified Framingham Risk Calculators as Predictors of Cardiovascular Disease Events in Systemic Lupus Erythematosus

Jagan Sivakumaran,[1] Paula Harvey,[2] Ahmed Omar,[3] Murray Urowitz,[3] Dafna Gladman,[4] Nicole Anderson,[3] Jiandong Su,[3] and Zahi Touma[3], [1]University of Toronto, Toronto, ON, Canada, [2]Women's College Hospital, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada, [4]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Tool	CVD Status	Low Risk (<10%) (%)	Median Risk (10 – 20%) (%)	High Risk (>20%) (%)
QRISK2	Cases	81	14	4
	Controls	93	5	2
FRS	Cases	78	16	6
	Controls	93	6	1
QRISK3	Cases	53	27	20
	Controls	78	13	9
mFRS	Cases	54	25	21
	Controls	83	10	7
SLECRE	Cases	39	29	32
	Controls	64	23	13

Table 1. Percentage of cases and controls classified as low (<10%), median (10-20%) and high risk of developing CVD according to each CVD risk assessment tool.

Background/Purpose: Systemic lupus erythematosus (SLE) is recognized as an independent risk factor for cardiovascular disease (CVD). This study aimed to determine which cardiovascular risk assessment tool amongst the QRISK2, QRISK3, Framingham (FRS), Modified FRS (mFRS) or SLE Cardiovascular Risk Equation (SLECRE) best predicts CVD in SLE. QRISK3, mFRS and SLECRE are CVD risk assessment tools that consider SLE in risk prognosticating patients.

Methods: Single-centre analyses on prospectively collected data of 1887 SLE patients were performed to compute 10-year CVD risk scores for each tool. Tools' scores were evaluated against CVD development at or within ten years for cases (CVD events) and controls (no CVD events). For cases, the index date for risk score calculation was chosen 10 years, or as close to 10 years as possible prior to the CVD event. Similarly, for controls, risk scores were calculated as close to 10 years as possible prior to the most recent clinic appointment. Proportions of patients classified as low risk (< 10%), median risk (10-20%) and high risk (>20%) of developing CVD according to each tool were determined. Sensitivity, specificity, positive/negative predictive values and c-statistics of these tools were analyzed.

Results: 232 total CVD events were seen in the cohort including myocardial infarction, stroke, transient ischemic attack, heart failure and CVD death. QRISK2 and FRS performances were similar, while the QRISK3 and mFRS performances were similar. The SLECRE classified the highest number of patients as median-high risk (Table 1). The sensitivities and specificities are as follows for each tool: QRISK2 (19%, 93%), FRS (22%, 93%), mFRS (46%, 83%), QRISK3 (47%, 78%), SLECRE (61%, 63%), respectively. The tools were similar in negative predictive value, ranging from 89% (QRISK2) to 92% (SLECRE). The FRS and mFRS had the greatest c-statistics, both equaling 0. 73, demonstrating the greatest predictive accuracy amongst the tools, while the QRISK3 and SLECRE had the lowest (0. 67).

Conclusion: While the mFRS performance was superior to the FRS, the QRISK3 did not outperform the mFRS. Although the SLECRE had the highest sensitivity, it had the lowest specificity, demonstrated by grouping the most

cases and controls in the median-high risk category. Several factors are important to consider when deciding which risk assessment tools to utilize clinically: ease of use, sensitivity/specificity, and laboratory data accessibility. Thus, the mFRS continues to be a practical tool with a simple, intuitive scoring system appropriate for the ambulatory clinic setting based on the initial weighting of the FRS while adjusting for SLE.

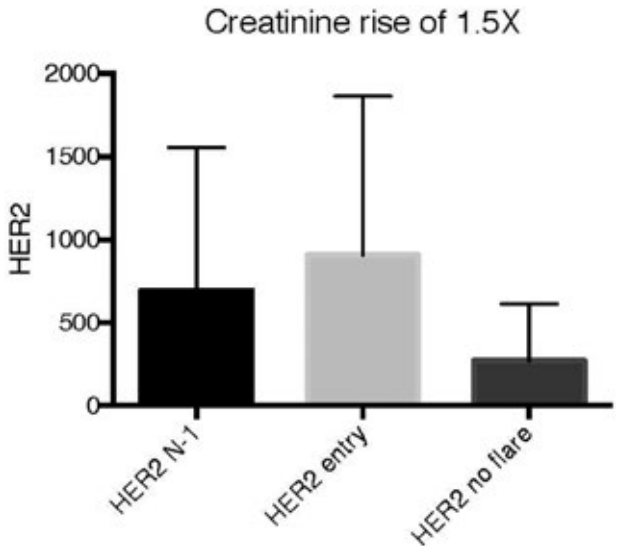
HER2 as a Biomarker of Proliferative Lupus Nephritis in Children

Kathleen Sullivan,[1] Jonathan Burnham,[2] Kathleen O'Neil,[3] Laura Schanberg,[4] Emily von Scheven,[5] Marisa Klein-Gitelman,[6] and Patricia Costa Reis[7], [1]Children's Hospital of Philadelphia, Philadelphia, PA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA, [3]Indiana University, Indianapolis, IN, [4]Duke University Medical Center, Durham, NC, [5]UCSF, San Francisco, CA, [6]Lurie Children's Hospital, Chicago, IL, [7]Hospital de Santa Maria, Lisbon, Portugal

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus nephritis is a common feature of SLE and confers a poor prognosis. 20-50% of patients with lupus nephritis ultimately develop chronic kidney disease and renal failure in spite of efforts to induce remission of nephritis. Chronic kidney disease is epidemiologically associated with more frequent relapses and lack



9 patients with creatinine rise of 1

Figure 1. Urinary HER2 stratified by 1.5X rise in serum creatinine. HER2 N-1 represents the mean HER2 at the time point prior to the rise in serum creatinine. HER2 entry represents the mean of the HER2 at study entry for those who went on to have a rise of 1.5 over entry creatinine. HER2 no flare displays the HER2 levels in patients who never flared. HER2 N-1 and HER2 entry are significantly different than HER2 no flare.

of remission after treatment. Both relapse and lack of remission are difficult to detect on a background of pre-existing renal disease. Proteinuria can represent residual damage. There have been intense efforts in recent years to identify urinary biomarkers, often exploiting known inflammatory features. We identified a urine biomarker that tracks proliferative aspects of lupus nephritis, HER2. This study was designed to test the sensitivity and specificity of HER2 in urine as a biomarker for active lupus nephritis.

Methods: This study design prospectively collects urine every 3 months in 100 pediatric patients with known lupus nephritis. Mean follow up at the time of writing is 3 years. Control groups include RF+ JIA, amplified pain and healthy teen females. HER2, TWEAK and VCAM are measured by ELISA. Clinical data are collected on structured CRFs at each visit. Flares of lupus nephritis are defined by SLEDAI-R (renal SLEDAI) and increased serum creatinine.

Results: Elevated urinary HER2 was observed lupus patients compared to all the control cohorts. The specificity of HER2 in lupus nephritis compared to other kidney disorders was assessed and HER2 was elevated specifically with active lupus nephritis but not vasculitis, IgA nephropathy or acute kidney injury. There was a significant association of urinary HER2 levels with SLEDAI-R by ANOVA ($P < 0.0001$) with a peak association with SLEDAI-R=8. When individual components of SLEDAI-R were assessed, all were associated with an increase in HER2 over non-flare patients. We validated the association of HER2 with SLEDAI-R in a cross-sectional study of adults. In the longitudinal pediatric cohort, we analyzed the subset of patients with a 1.5 fold rise in serum creatinine. HER2 was significantly elevated at the time point preceding the rise in creatinine (HER2 N-1) and at study entry (HER2 entry) for these patients (Figure 1). HER2 outperforms TWEAK and VCAM in these analyses.

Conclusion: We conclude that urinary HER2 is significantly associated with active lupus nephritis and increased levels precede flares detectable by a rise in creatinine.

Abstract Number: 1567

Cachexia in Systemic Lupus Erythematosus

George Stojan,[1] Jessica Li,[2] and Michelle Petri[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cachexia is a syndrome that may accompany a range of diseases, including cancer, chronic heart failure, chronic obstructive pulmonary disease, and rheumatoid arthritis. It is associated with central and systemic increases of pro-inflammatory factors, and with decreased quality of life, poor responses to pharmacological treatment and shortened survival. Despite an abundance of data from other inflammatory diseases, cachexia in systemic lupus erythematosus remains a largely undescribed syndrome. Using the Fearon criteria for defining cachexia

Table 1. Patient characteristics			
	All (n=2452[1])	**Cachexia (n=1067[2])**	**No cachexia (n=825[2])**

(5% stable weight loss in 6 months without starvation relative to the average weight in all prior cohort visits AND/OR weight loss >2% without starvation relative to the average weight in all prior cohort visits and a BMI < 20), we have previously shown that more than half of the Hopkins Lupus Cohort patients met cachexia criteria within the first five years of cohort entry. We decided to revisit this analysis using the Evans criteria for defining cachexia, criteria which are more specific, more extensive, and have been shown to have a better prediction of survival.

Methods: 2406 patients in a prospective SLE cohort had their weight assessed at each visit. Patients were categorized into five predetermined groups based on weight: low (BMI< 20 kg/m2), normal weight (reference, BMI 20-24.9 kg/m2), overweight (25-29.9 kg/m2), obese (BMI 30-34.9 kg/m2), and severely obese (BMI >35 kg/m2). Cachexia was defined based on modified Evans criteria as 5% stable weight loss in 12 months without starvation relative to

Table 2: Risk of cachexia within 5 years of cohort entry		
	Risk of Cachexia within 5 years of cohort entry (95% CI)[1]	P-value for difference by patient characteristics[2]
All	56% (53%, 59%)	
Age at cohort entry		0.7279
<30	58% (53%, 62%)	
30-44	56% (52%, 60%)	
45-59	53% (47%, 58%)	
60+	59% (48%, 69%)	
Ethnicity		0.0029
Black	59% (55%, 63%)	
White	54% (50%, 57%)	
Other	55% (45%, 65%)	
Sex		0.3484
Female	56% (54%, 59%)	
Male	53% (44%, 62%)	
Initial BMI		<0.0001
<20	16% (11%, 23%)	
20-25	59% (55%, 63%)	
25-30	64% (60%, 69%)	
30-35	58% (52%, 63%)	
[1] Based on Kaplan Meier estimates [2] Based on log tank test		

the average weight in all prior cohort visits AND/OR BMI< 20 and 3 out of the following criteria: ESR >20mm/h, hemoglobin < 12g/dL, albumin < 3.2g/dl, and anorexia. Risk of cachexia within 5 years of cohort entry was based on Kaplan Meier estimates.

Results: See Table 1 and Table 2

Conclusion: Within five years of cohort entry, more than half of the Hopkins Lupus cohort patients develop cachexia as defined by Evans criteria. This prevalence of cachexia is higher than the one reported in breast cancer (25%) or

hematological malignancies (40%), and similar to the rates reported for lung cancer (50%). The highest risk of cachexia was seen among African Americans, while those with a BMI< 20 had the lowest risk. Cachexia is an under recognized syndrome in patients with lupus affecting a large proportion of patients regardless of the criteria used for its definition. Further studies are needed to elucidate the implications of cachexia in the response to treatment, long term outcomes, quality of life, as well as its role as a potential cardiovascular risk factor in SLE.

Abstract Number: 1568

High Risk Low Attenuation Non-Calcified Coronary Plaque in Lupus vs. Controls

George Stojan,[1] Jessica Li,[2] and Michelle Petri[2], [1]Johns Hopkins University, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of low attenuation noncalcified plaque (< 30 Haunsfield units) is one of the most characteristic vessel changes in unstable coronary plaques. Low-attenuation noncalcified plaques (< 30 Haunsfield Units) contain necrotic cores that are characterized by endothelial dysfunction, oxidative stress, and inflammation. They have been shown to be a better predictor of future cardiovascular events compared to traditional cardiovascular risk factors in the general population. Accelerated atherosclerosis leading to premature coronary artery disease remains the major cause of late death in SLE. We sought to characterize low attenuation noncalcified plaque in patients with systemic lupus erythematosus versus controls.

Methods: A total of 72 patients who met the ACR or SLICC classification criteria for SLE had CT angiogram studies, 30 of which had follow up CT angiograms. A total of 100 healthy controls who had two CT angiograms were included in the study. Coronary plaque area was measured by manual tracing for the difference between the area within the external elastic membrane and the area of the vessel lumen at the site of maximal luminal narrowing as observed on a cross-sectional coronary CT angiography image. A noncalcified plaque was defined as a low-density mass >1 mm2 in size, located within the vessel wall and clearly distinguishable from the contrast-enhanced coronary lumen and the surrounding pericardial tissue. Each noncalcified plaque detected within the vessel wall was evaluated with the minimum CT density. T-test was used to evaluate baseline characteristics between lupus patients and controls. Paired *t*-test or Wilcoxon signed ranks test were used to compare plaque volume between baseline and follow-up for each cohort. Fisher's exact test was used to evaluate the association between change in low attenuation NCP and demographic and clinical variables including sex, race, age at baseline, ever smoking (from history file), diabetes, hypertension, hyperlipidemia, obesity, lupus anticoagulant, anticardiolipin, anti-beta 2 glycoprotein, hydroxychloroquine and immunosuppressant use, anti- dsDNA, low C3, low C4, antihypertensive, and statin use.

Results: See Table 1 and Table 2

Conclusion: Women with lupus have a significantly higher burden of low attenuation NCP compared to healthy controls in all age subgroups except in those >60 years of age. A similar trend was seen in men but the number of patients was small. While the NCP and low attenuation NCP burden significantly regressed over time in controls, no

Table 1: Mean (SD) of Low Density Non-calcified Plaque at baseline

Sex	Age	Low Density Non-calcified Plaque

Poor Long-term Renal Outcome in Systemic Lupus Erythematosus Without Abnormal Urinalysis: A Possible Link with Silent Lupus Nephritis

Hironari Hanaoka,[1] Jun Kikuchi,[2] Shuntaro Saito,[1] Hiroshi Takei,[3] Kazuoto Hiramoto,[1] Tatsuhiro Oshige,[1] Noriyasu Seki,[4] Hideto Tsujimoto,[4] Yuko Kaneko,[1] and Tsutomu Takeuchi[5], [1]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Keio Universitiy School of Medicine, Tokyo, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, [4]Mitsubishi Tanabe Pharma Corporation Sohyaku, Tokyo, [5]Keio University School of Medicine, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been well investigated that patients with lupus nephritis (LN) have worse prognosis than those without. Recently reported, about 20% of SLE patients without abnormal urinalysis have histopathologically proven lupus nephritis, so-called silent LN. Here, we investigated long-term renal outcome in SLE patients without abnormal urinalysis and additionally determined whether their renal outcomes correlates with abnormal B lymphocyte activity in circulation.

Figure 1

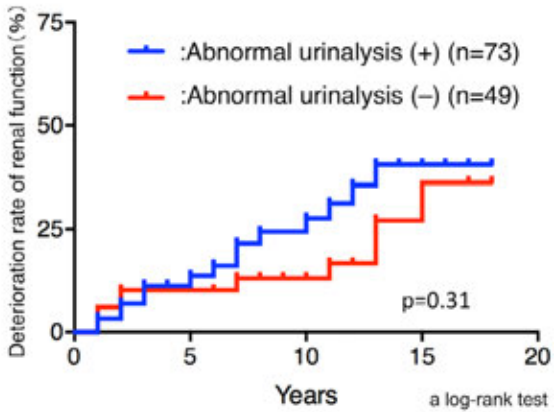

Figure 1. Deterioration rate of renal function. There was no significant difference between patients with and without abnormal urinalysis in SLE.

Figure 2

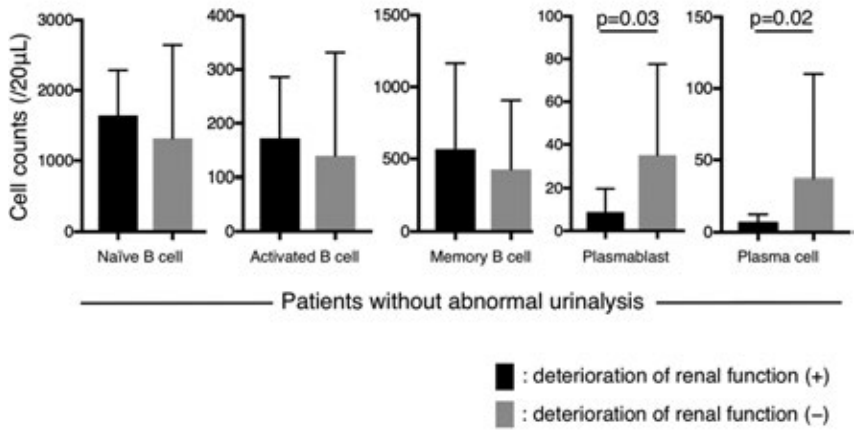

Figure 2. Fluorescence-activated cell sorting analysis of peripheral B cells. A significant lower number of plasmablast and plasma cell was observed in patients without abnormal urinalysis for deterioration of renal function.

Methods: We retrospectively evaluated newly diagnosed SLE patients from 2000 to 2018 in our hospital. All the patients were divided them into 2 groups according to the presence of abnormal urinalysis during the observation. Abnormal urinalysis was defined as a persistent proteinuria (more than 50 mg/dL or 0.5 g/gCr for more than 3 months). Deterioration of renal function (more than 40% eGFR decline from baseline) was compared between them. For the patients without abnormal urinalysis, the distribution of B cell subsets was compared by fluorescence-activated cell sorting analysis using anti-CD19, 20, 27, 38, 138, and IgD antibodies depending on the deterioration of renal function.

Results: Seventy-three patients with abnormal urinalysis and 62 without were evaluated. Among patients with abnormal urinalysis, 62 (84.9%) had biopsy-proven LN. Patients with abnormal urinalysis had a higher titer of anti-dsDNA antibodies ($p< 0.01$), SLEDAI score ($p< 0.01$), maximum dose of prednisolone ($p=0.04$), percentage of IVCY use ($p< 0.01$) and MMF use ($p< 0.01$) than those without. There was no significant difference in observational periods (10.1 vs 11.6 years, $p=0.43$) and cumulative deterioration rate of renal function (19.7 vs 16.1%, $p=0.31$) between them (Figure 1). For patients without abnormal urinalysis, a higher positivity of anti-Sm antibody (70.0% vs 5.0%, $p< 0.01$) and a lower count of plasmablast (CD19+/27+/IgD+/38+/138–) ($p=0.03$) and plasma cell (CD138+) ($p=0.02$) were observed in patients with deteriorated renal function than those without (Figure 2).

Conclusion: Long-term renal outcome was not significantly different between patients with and without abnormal urinalysis for about 10-years observation. Positivity of anti-Sm antibody and decreased number of peripheral plasmablast and plasma cell might be surrogate markers for deterioration of renal function in patients without abnormal urinalysis. Silent LN might contribute to our results and further analysis performing renal biopsy is needed.

Can the Montreal Cognitive Assessment (MoCA) Improve the Automated Neuropsychological Assessment Metrics (ANAM) Performance in Screening for Cognitive Impairment in Lupus Patients?

Oshrat Tayer-Shifman,[1] Robin Green,[2] Dorcas Beaton,[3] Lesley Ruttan,[2] Joan Wither,[4] Maria Tartaglia,[5] Mahta Kakvan,[1] Sabrina Lombardi,[2] Nicole Anderson,[1] Jiandong Su,[1] Dennisse Bonilla,[1] Moe Zandy,[1] May Choi,[6] Marvin Fritzler,[6] and Zahi Touma[7], [1]University Health Network, University of Toronto, Toronto, ON, Canada, [2]University Health Network, Toronto, ON, Canada, [3]St. Michael's Hospital, Toronto, ON, Canada, [4]University Health Network, Krembil Research Institute, Toronto, ON, Canada, [5]University Health Network, University of Toronto, Toronto, ON, Canada, [6]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

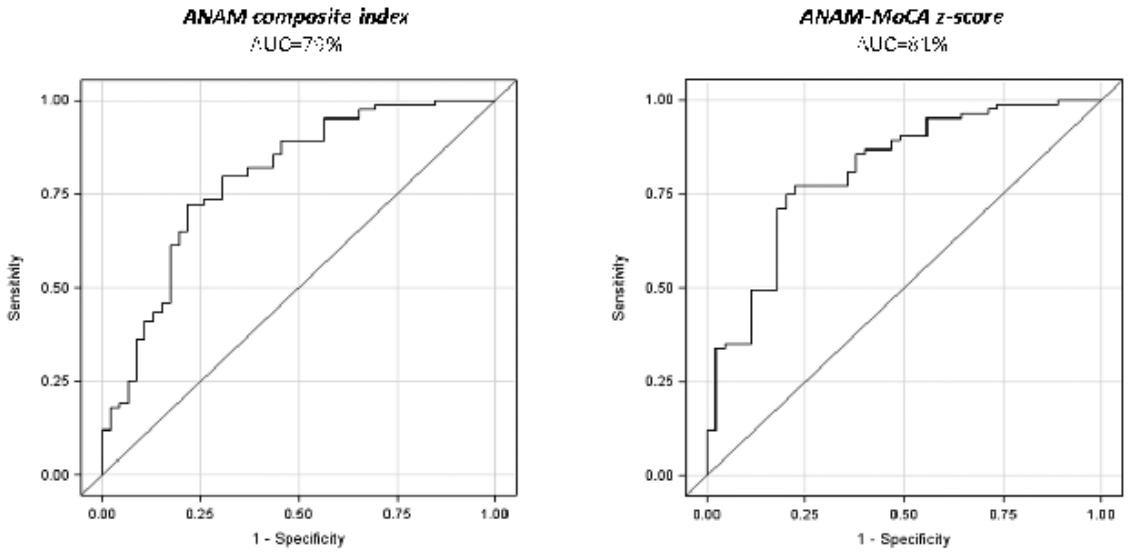
Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: In a related study, we have shown evidence to support the validity of the Automated Neuropsychological Assessment Metrics (ANAM) for the screening of cognitive impairment (CI) in adult systemic lupus

Figure 1: Receiver operating characteristic (ROC) curves for identifying cognitive impairment based on the performances of *ANAM composite index* and of the *ANAM-MoCA z-score*



AUC: Area under the curve

***ANAM composite index* calculated by the following equation: ANAM-index=31.85-0.06*TP/CSL -0.06*PCT/CSD-0.02*TP/SRTR-0.14*PCT/GNG-9.93*CV/SP-0.0008*MS/TPZ+9.74*MR/TL-6.38*CV/TCRT**

[TP: throughput; CSL: code substitution learning; PCT: percentage of correct responses; CSD: code substitution delay; SRTR: simple reaction time repeated; GNG: go/no go; CV: coefficient of variation of reaction time; SP: spatial processing; MS: Mean-Score; TPZ: tower puzzle; MR: mean reaction time; TL: tapping left hand; TCRT: two choice reaction time]

ANAM-MoCA z-score is a combination of the *ANAM composite index* and the MoCA score both standardized to obtain z-score

erythematosus (SLE) using a novel **derived *ANAM composite index***. The Montreal Cognitive Assessment (MoCA) is a brief assessment tool commonly used for screening of CI in the general population and SLE. **The aim of this study was to assess whether the MoCA can improve the performance of the ANAM in screening for CI in SLE compared to the American College of Rheumatology (ACR) Neuropsychological Battery (NB).**

Methods: Between 2016 and 2019, consecutive adult SLE patients were administered the ACR NB, MoCA and ANAM on the same day. Using age- and gender-stratified normative data, patients were classified on the ACR NB as having CI if a z-score of ≤-1.5 was observed in ≥ 2 domains; or non-CI if no domain had a z-score of ≤-1.5 An ANAM composite index was calculated for each patient according to its equation (Figure 1) using selected ANAM subtests and scores and standardized to obtain a z-score. MoCA scores were multiplied by negative 1 to make them compatible with the ANAM composite index (where a higher score corresponds to a higher probability of CI) and standardized to obtain z-scores. The z-scores of the ANAM composite index and of the MoCA were summed to achieve a combined ANAM-*MoCA z-score* with a mean of 0 and standard deviation of 2 and with equal weights from both instruments. The performance of the *ANAM composite index* and the *ANAM-MoCA z-score* to screen for CI against NB were evaluated using Receiver operating characteristic **(**ROC) curve analysis. The Area Under the Curve (AUC) was calculated for both as well as the improvement in CI identification for the combined *ANAM-MoCA z-score* compared to the *ANAM compo*site *index* alone.

Results: 211 patients were enrolled. Mean age and SLE disease duration at study visit were 42 ± 12 years and 15 ± 10 years, respectively. CI was diagnosed by the ACR NB in 45.5% (n=96) of patients and no CI in 24.6% (n=52). The *ANAM composite index* showed good ability to identify CI operationalised on NB with AUC of 79% (95% confidence interval): 0.71, 0.88). Adding the MoCA score to create the *ANAM-MoCA z-score* demonstrated AUC of 81% (95% confidence interval: 0.73, 0.89), an improvement of 2.5% (**Figure 1**).

Conclusion: ANAM is a promising tool for screening of CI in SLE patients. The addition of the MoCA to the ANAM score, improves the performance of the ANAM only to a small extent but sufficient to move AUC from good to excellent category. Further research is required to enhance ANAM screening ability and usefulness.

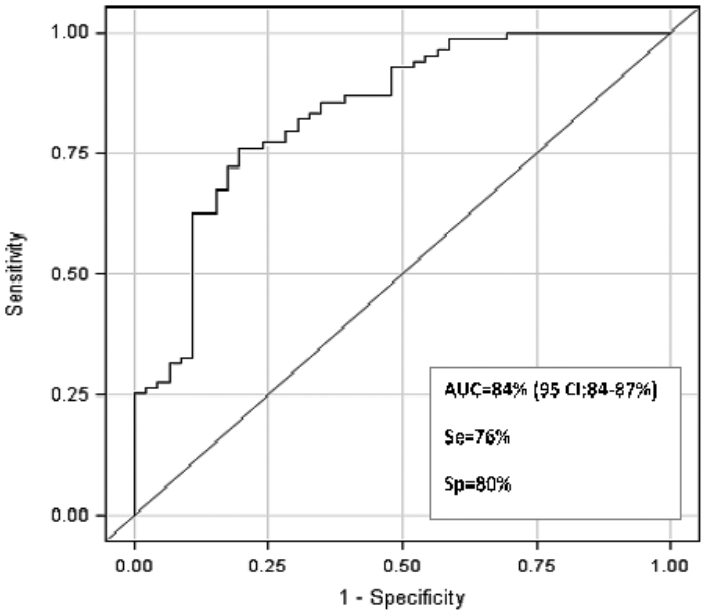
Formula of ANAM-index=31.85-0.06*TP/CSL -0.06*PCT/CSD-0.02*TP/SRTR-0.14 *PCT/GNG-9.93*CV/SP-0.0008*MS/TPZ+9.74*MR/TL-6.38*CV/TCRT

ANAM= Automated Neuropsychological Assessment Metrics; PCT=percentage of correct responses; CV=coefficient of variation of reaction time; MR=mean reaction time; TP=throughput; MS=Mean-Score; CSL=code substitution learning; CSD=code substitution delay; SRTR=simple reaction time repeated; GNG=go/no go; SP=spatial processing; TPZ=tower puzzle; TL=tapping left hand; TCRT=two choice reaction time

Background/Purpose: Cognitive impairment (CI) is highly prevalent in Systemic Lupus Erythematosus (SLE). Screening for CI in SLE may be delayed, if relying on the American College of Rheumatology (ACR) neuropsychological battery (NB), which is time- and resource- intensive. The **Automated Neuropsychological Assessment Metrics (**ANAM) is a quick and low-cost computer-based screening tool for CI**. The overarching aim of this study was to assess the performance of the ANAM as a screening tool for CI in SLE patients employing the ACR NB as the gold standard**. The specific objective were to: (a) determine the ability of the ANAM to differentiate between SLE patients with and without CI, (b) assess the ability of selected ANAM subtests to accurately identify CI, and (c) derive an ANAM composite index and cut-off to facilitate its use.

Methods: Between 2016 and 2019, 211 consecutive adult SLE patients were administered the ACR NB and the ANAM on the same day. Using age- and gender-stratified normative data, patients were classified on the ACR NB as having CI if a z-score of ≤-1.5 was observed in ≥ 2 domains; or non-CI if no domain had a z-score of ≤-1.5. **First**, ***discriminative validity*** of the ANAM was assessed by its ability to differentiate between CI and non-CI patients com-

Figure 1: Receiver operating characteristic (ROC) curve for identifying cognitive impairment based on the performance of ANAM best model using subtests selected by step-down multivariate analysis



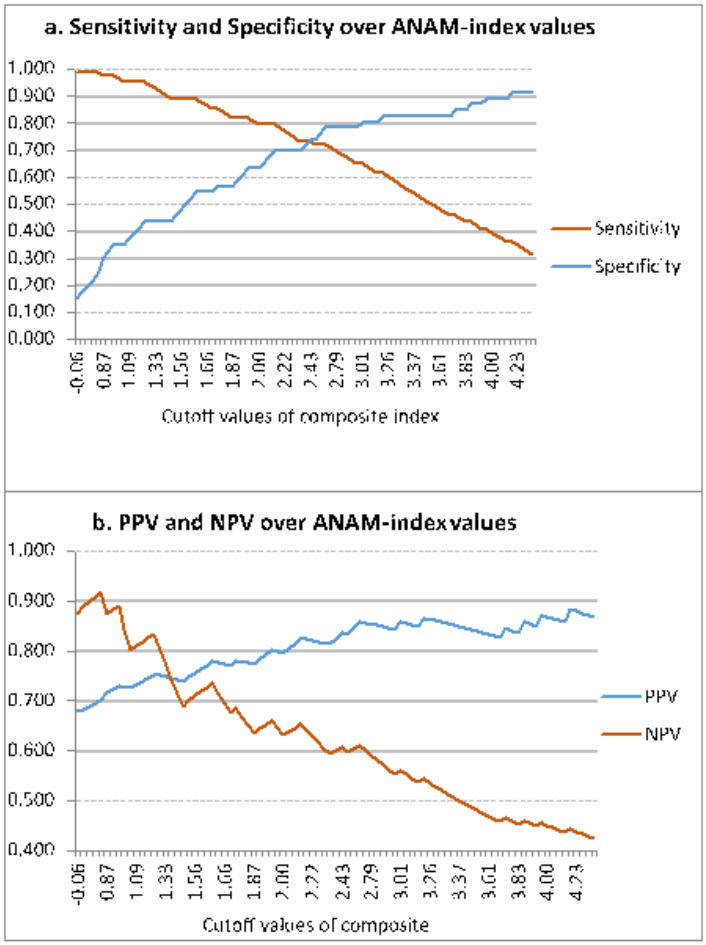
ANAM= Automated Neuropsychological Assessment Metrics; AUC: area under the curve; Se: sensitivity; Sp: specificity

pared to the ACR NB. All 15 ANAM subtests and their scores (percentage of correct responses [PCT], mean reaction time [MR], throughput [TP], and coefficient of variation [CV]) were studied. **Second,** we developed 6 ANAM models and the most discriminatory subtests and scores within each model were selected using logistic regression analyses. The area under the receiver operating characteristics curve (AUC) was calculated to establish ANAM models construct validity against the ACR NB. **Third**, an ***ANAM composite index and cut-off*** were derived for the best selected model using the sum of the subtests' scores multiplied by their parameter estimate from the logistic regression. The sensitivity (Se), specificity (Sp), positive predictive value (PPV), and negative predictive value (PPV) of the ANAM *composite index* and cut-off, to differentiate CI from non-CI were evaluated.

Results: Patients with non-CI performed better on the majority of ANAM subtests in PCT, MR and TP scores compared to those with CI, providing support for ANAM ***discriminative validity***. CI was accurately identified by the best ANAM model (Table 1) with an excellent AUC of 84% [95% confidence interval: 0.84, 0.87] (Figure 1), providing support for the ***construct validity of the ANAM model*** using 8 selected ANAM subtests and corresponding scores. The derived ***composite index*** (equation provided in Table 1) demonstrated good performance with AUC of 79%. The proposed ***cut-off*** yielded Se, Sp, PPV and NPV of 80%, 70%, 83% and 65%, respectively. Figure 2 demonstrates the performance of the composite index over different cut-off values.

Conclusion: This study provides support for the validity of the ANAM along with 8 selected subtests for the screening of CI in adult SLE in the selected model. We derived an ***ANAM composite index*** and a ***cut-off*** to serve as a summary measure of cognitive performance of SLE patients. This will enhance the applicability and interpretation of the ANAM in clinical practice.

Figure 2: Performance of the candidate ANAM composite index for identifying cognitive impairment over different cut-off values



ANAM= Automated Neuropsychological Assessment Metrics; NPV: negative predictive value; PPV: positive predictive value

Cut-off 2.17 provides a Se of 80% and Sp of 70% with PPV 83% and NPV 65%

Cut-off 1.61 provides a Se of 88% and Sp of 54% with PPV 78% and NPV 74%

All variables measured at baseline unless stated otherwise

SLE: systemic lupus erythematosus; ACR: American College of Rheumatology; SDI: Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index, excluding cognition component; SLEDAI-2K: SLE Disease Activity Index 2000; BDI-II: BECK Depression Inventory-II, cut-off score of ≥18 was used to define depression; BAI: BECK Anxiety Inventory, cut-off score of ≥ 22 was used to define anxiety; CVE: Cardiovascular event including stroke, transient ischemic attack, myocardial infarction or atherosclerotic congestive heart failure; aPL: antiphospholipid antibodies; ASA: acetylsalicylic acid.

Hypertension defined as blood pressure of >140/90 or antihypertensive treatment; Dyslipidemia defined as abnormal total cholesterol or on specific treatment

[§]According to SLEDAI-2K

[¶]Transformed score from bodily pain domain of 36-Item Short Form Survey (SF-36), low score corresponds to higher pain reported

Background/Purpose: Cognitive impairment (CI) is a common manifestation of systemic lupus erythematosus (SLE) and its course may change over time. The objective was to determine the prevalence of persistent CI in SLE patients over 1 year time and investigate the associated factors.

Methods: Consecutive SLE patients, aged 18-65 years, who attended a single centre (2016- 2019) were included. Patients were administered the Neuropsychological Battery (NB) at baseline (T0), 6 months (T1) and 12 months (T2). Patients' scores were compared to normative data to obtain z-scores. CI was operationalized on the NB as a z-score of ≤-1.5 on ≥2 domains. Three groups were identified: Persistent CI group - CI present in all 3 assessments; stable non-CI group - CI not present in all 3 assessments; or fluctuating CI group - CI was on 1-2 assessments. At each visit, data on sociodemographic, clinical and laboratory/medications were collected. Fatigue was measured by the Fatigue Severity Score (FSS), pain by the transformed scale of the Bodily Pain domain of SF-36 and anxiety by BECK Anxiety Inventory (BAI). Patients with persistent CI were compared to stable non-CI patients. Multivariable polynomial logistic regression was performed on all 3 groups to study the likelihood of a patient classified to adjunct worse group.

Results: The prevalence of CI was 40%, 26% and 38% at T0, T1 and T2 respectively among 111 patients who completed all 3 assessments. Sixteen patients (14%) experienced persistent CI, 46 (41%) fluctuating CI and 49 (44%) stable non-CI. Patients with persistent CI had higher proportion of **male**, **Black**, and **widowed/divorced/separated** patients compared to stable non-CI group (**Table 1**). A higher level of **fatigue**, **pain** and **anxiety** were identified in persistent CI group (**Table 2**). The persistent CI group showed higher proportions of **cardiovascular events (CVEs)** and abnormal brain imaging. Glucocorticoid use was higher while antimalarial use was lower in the persistent CI group with no difference in immunosuppressives, aspirin, pain or psychotropic medications. There were no differences in SLE manifestations, other comorbidities (e.g. fibromyalgia and antiphospholipid syndrome), SDI, SLEDAI-2K and immunological profile.

The Multivariate analysis on all 3 groups showed that **Black** [odds ratio (OR) of 2.9 (95% confidence interval: 1.1-7.7, p 0.03)] and **Fatigue** [OR 1.3 (1.04-1.7; p 0.02)] **were associated with a higher likelihood of being classified in the adjunct worse group.**

Conclusion: Persistent CI was found in 14% of the patients in all 3 assessments over 1 year. Higher proportion of male, Black, CVE, fatigue and anxiety were observed among patients with persistent CI. Black patients and fatigue were also associated with a higher likelihood of being classified in the adjunct worse group. Our results advocate for further research into the associated factors with CI persistence in SLE patients. This demonstrates the complexity of the underlying factors associated with persistence CI – genetic/epigenetic, disease severity, sociodemographic, comorbidities (fatigue, anxiety, etc.), which requires further research.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The prevalence of atherosclerotic vascular events (AVE) in published literature of an inception cohort with SLE is 10%. We aimed to investigate the accrual and the associated factors of AVE in a multinational multiethnic inception cohort of patients with SLE.

Methods: A large 33-centre multinational inception cohort of SLE patients was followed yearly according to a standardized protocol between 1999-2017. Patients (≥4 ACR criteria) entered the cohort within 15 months of SLE diagnosis. Patients with at least one follow-up visit after enrolment were identified. AVEs were collected and attributed on a specialized form. Diagnosis of AVE was confirmed using standard clinical criteria, relevant laboratory data and imaging. Attribution to atherosclerosis (AS) was made on the basis of SLE being inactive at the time of the event, and/or the presence of typical AS changes on imaging or pathology and/or evidence of AS elsewhere. Analysis included descriptive statistics, prevalence, rate of AVE's per 1000 patient-years of follow-up and univariable / multivariable time-dependent survival regressions.

Table 1. The distribution of first AVE (N = 61) in 1710 patients	
Follow-up	**AVE**
Sudden Death	2 (3.28%)
Angina	20 (32.79 %)
Chronic Heart Failure	9 (14.75)
Insertion of Pacemaker	2 (3.28%)
Intermittent Claudication	6 (9.84%)
Myocardial Infarction	12 (19.67%)
Stroke	6 (9.84%)
Transient Ischemic Attack	4 (6.56%)

Results: Of the 1848 patients enrolled in the cohort, 1710 who had at least one follow up visit and comprised the study sample. 88.6% were female, 49.4% Caucasian, 16.4% Black, 15.0% Asian, 15.5% Hispanic and 3.7% other. At enrolment mean (SD) disease duration was 5.7 ± 4.2 months, age rolment was 35.2 ± 13.4 years and SLEDAI-2K was 5.4 ± 5.4. The prevalence of AVEs was 3.6% and the rate per 1000-patient years was 4.6. Sixty-one patients had atherosclerotic events after enrolment (Table 1). Univariate time-dependent Cox regression revealed the predictive factors for AVE were female sex, average steroid dose and antimalarial treatment. Multivariable analyses confirmed female gender had an independent protective effect [hazard ratio and 95% confidence interval [HR (95%CI)] [0.531 (0.288, 0.992)], as did antimalarial treatment [0.517 (0.306, 0.874)] (Table 2). Since only 1305 patients had been tested for antiphospholipid antibodies (APLA) this analysis was repeated in those patients with APLA results. In these patients in the multivariable analysis female sex and antimalarial therapy were protective and APLA, SLEDAI-2K and BMI were predictive (results not shown).

Conclusion: The prevalence of AVE in this study is much lower than previously published data. Female sex and antimalarials were protective for AVE. In patients with APLA similar factors were protective but the APLA, SLEDAI-2K and BMI were predictive for AVE. In clinical practice all classic risk factors should be monitored and treated as they are in the general population.

Table1: Baseline Characteristics and Investigation in Early death group and SLE control patients

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Mortality in Systemic lupus erythematosus (SLE) has reduced over the years but it is still two to three folds as compared to general population. The major causes of death in SLE are infections and cardiovascular disease. In India due to increased burden of infection and limited access to health care, the causes may be different thus, we studied the causes of death in SLE and its predictors at a tertiary care center in India.

Methods: All patients with SLE (fulfilling ACR 1997 criteria) admitted during 2000-2018 were screened. The records of patients who died in hospital were retrieved and data on disease variables and cause of death were collected. Active disease was defined as patients having SLEDAI2k ≥5. Infections were either bacteriologically proven or based on radiological or serological evidence. Predictor's for death during first admission at the time of diagnosis of SLE were analyzed by comparing them with two SLE controls (having registration number before and after the index case) who survived. Statistical analysis was done using SPSSv23.0

Results: Among 920 patients admitted during this period,74 died. The mean age at death was 39.2±16.5 years. Thirty-three patients died of infection, 17 of disease activity and 23 patients had features of both infection and flare. Lower respiratory tract was the most common site of infection followed by gastrointestinal and urinary tract. Nine patients died of tuberculosis (TB), of which one patient had multidrug resistance pulmonary TB and 5 had disseminated TB. Two patients died of drug toxicity (methotrexate induced cytopenia,anticoagulant induced intracranial bleed).

Among 35 patients who died when diagnosis of SLE was made,12 had active disease ,6 had infection and 18 had features of both. In contrast in patients on follow up (n=39) 27(69.2%) died of infection alone. Comparing these 35 patients who died during the first admission,to 70 control SLE patients, they had older age at onset, low platelet count and albumin, higher serum creatinine, CRP and SLEDAI .(Table1)

Conclusion: Infections are the most common cause of in-hospital mortality in our cohort of SLE patients. TB is still a major concern in India. High disease activity is associated with risk for early mortality.

Lymphocyturia Is a Good and Cheap Biomarker for Active Lupus Nephritis and Is Sensitive to Change

Sarit Sekhar Pattanaik,[1] Ankita Singh,[2] Shilpa Venkataraman,[3] Ramnath Misra,[4] Vinita Agrawal,[2] and Amita Aggarwal[5], [1]Sanjay Gandhi post graduate institute of medical sciences, Lucknow, Uttar Pradesh, India, [2]Sanjay Gandhi Post Graduate institute of medical science, Lucknow, India, Lucknow, Uttar Pradesh, India, [3]Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India, [4]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, Lucknow, Uttar Pradesh, India, [5]Sanjay Gandhi Postgraduate Institute of Medical Sciences, Lucknow, India, Lucknow, Uttar Pradesh, India

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Multiple urinary biomarkers have been described for lupus nephritis, however none has reached the clinic due to either complex methodology or low discriminatory power. Recently, urinary CD4 and CD8 T cells have shown high specificity for active lupus nephritis (LN). Thus we studied whether urinary lymphocyte count by simple staining of sediment or T cell count by flowcytometry can serve as a simple and cheap biomarker.

Methods: Patients with active LN (ALN) defined as renal SLEDAI (rSLEDAI) >4, active lupus without nephritis (ANR) defined as SLEDAI >4, inactive nephritis (IN) defined as rSLEDAI ≤4 and SLEDAI < 4, and age matched healthy controls(HC)were included. Renal biopsy was done if not contraindicated. Lymphocytes in the urine were stained using Kovak stain and reported as number of cells/high power field. CD3 T cells were counted by FACS using anti-CD3

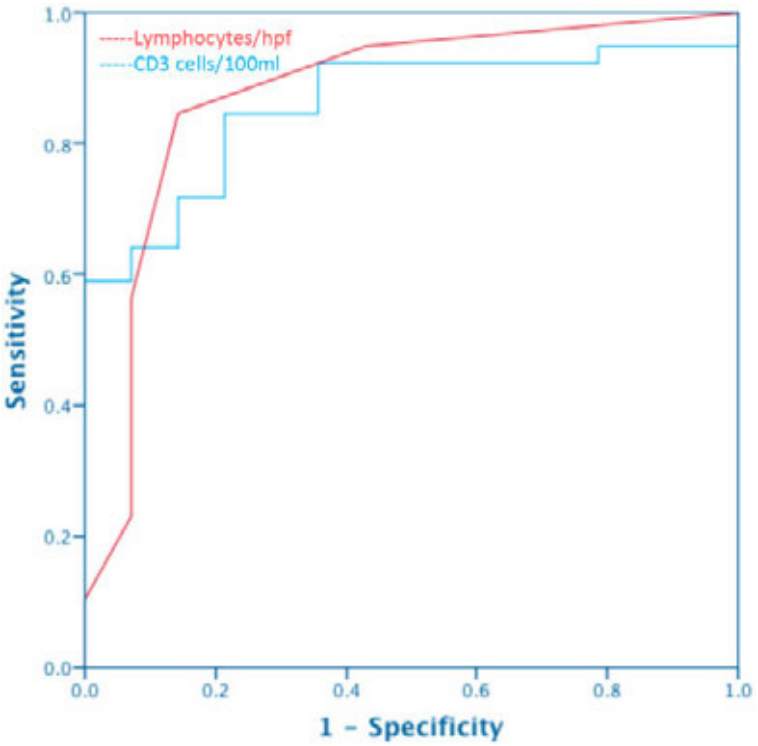

Figure 1: ROC curve of lymphocyturia and urinary CD3 cells to differentiate ALN from IN

antibody and DAPI for live gate. Immunohistochemistry was done on formalin fixed paraffin blocks of renal biopsy for CD3 and the distribution and number of cells was counted. Statistical analysis was done using SPSSv23.0

Results: Among 74 patients, 44 had ALN (40 females, mean age 30 years and mean SLEDAI:12.9±6.5), 10 had ANR disease (9 females, mean age: 27 years, mean SLEDAI:8.3±3.74)and 20 patients had IN (19 females, mean age: 33 years, mean SLEDAI:0.35±0.74). 10 healthy controls (all females, mean age:26 years) The median(IQR)Lymphocyte count in the urine was 4(7) in ALN as compared to ANR [2(3.5),p=0.1], IN (0, p< 0.001) and HC(0,p< 0.001). The median CD3 count by FACS was 2793(8982) in ALN as compared to ANR [209(539.2), p=0.001],IN [86(303),p< 0.001] and HC [115(195),p< 0.001).There was moderate correlation between lymphocyturia and urinary CD3 count (r=0.59, p< 0.001).

Lymphocyturia had moderate correlation with SLEDAI (r=0.59, p< 0.001), rSLEDAI(r=0.58, p< 0.001). Similarly, urinary CD3 cell count had moderate correlation with SLEDAI (r=0.47,p< 0.001), rSLEDAI (r=0.54, p< 0.001).The ROC curve for lymphocyturia to differentiate ALN from IN (AUC: 0.87) and for CD3 (AUC: 0.874)[Fig 1].

In 15 patients of ALN on follow up, there was a excellent correlation between change in SLEDAI and change in lymphocyte count (r=0.845,p< 0.001).In 31 patients with renal biopsy, there was a moderate correlation between the CD3 cells by IHC in tubulointerstitial compartment and urinary CD3 cells(r=0.55,p=0.001) however there was no relation with glomerular CD3 count

Conclusion: Lymphocyturia measured by simple staining of urinary sediment can be a cheap and effective marker of active LN and can be used to follow up patients with active nephritis in resource poor countries.

Prevalence and Outcome of Thrombocytopenia in Systemic Lupus Erythematosus – Single Centre Cohort Analysis

Tatiana Costa Pires,[1] Raquel Caparrós-Ruiz,[2] and David A Isenberg[3], [1]Serviço de Medicina 1, Centro Hospitalar de Leiria, Leiria, Portugal, [2]UGC de Reumatologia, Instituto de Investigación Biomédica de Málaga, Hospital Universitario de Málaga, Universidad de Málaga, Málaga, Spain, [3]Centre for Rheumatology, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To characterize the frequency of thrombocytopenia in SLE and determine its time of onset during the course of the disease, severity and impact on mortality.

Methods: This was a single centre cohort analysis of 708 patients with SLE (fulfilling the revised ACR criteria) followed for a period of 5 to 40 years (January 1979 – December 2018). We reviewed the patients' clinical notes identifying the presence of thrombocytopenia, and ascertained other clinical and serological features of the disease. Thrombocytopenia was classified as mild (100-149x10^9/L), moderate (31-99x10^9/L) or severe (≤30x10^9/L platelets). It

was also classified as asymptomatic (no relation to any bleeding event), with minor bleeding or with major bleeding. Statistical analysis was performed using Statistical Package for the Social Sciences (SPSS) software.

Results: A total of 163 patients (23.0%) were identified as having developed thrombocytopenia sometime during the course of SLE. Mean age at diagnosis of SLE was 28.37 (SD=13.33 years), ranging from 7 to 77 years; 149 (91.4%) patients were female and 14 (8.6%) male. Twenty two patients (13.5%) had isolated ITP before the diagnosis of SLE. Median follow-up time was 19 years (IQR=13). The median time from diagnosis of SLE to development of thrombocytopenia was 8 years (IQR=14). Most patients (N=65, 39.9%) had mild thrombocytopenia, 38 (23.3%) moderate and 31 (19.9%) severe thrombocytopenia. More than half the patients (N=90, 55.2%) developed asymptomatic thrombocytopenia, while 27 (16.6%) presented with minor bleeding but only 5 patients (3.1%) had major bleeding events in the context of thrombocytopenia. The development of severe thrombocytopenia anytime during the course of SLE was associated with an increased risk of death (HR=3.57, p=.025). When considering the survival rates after the development of thrombocytopenia it was found that there is an increased risk of death for male patients (HR=3.41, p=.036) and for those who present with concomitant haemolytic anaemia (HR=3.07, p=.027). There was no statistical correlation found between the presence of bleeding events and mortality.

Conclusion: The presence of severe thrombocytopenia (platelets $\leq 30x10^9$) in patients with SLE is associated with an increased risk of death, regardless of bleeding events. Male patients with SLE and thrombocytopenia (any degree) have an increased mortality risk, as have those who develop concomitant thrombocytopenia and haemolytic anaemia.

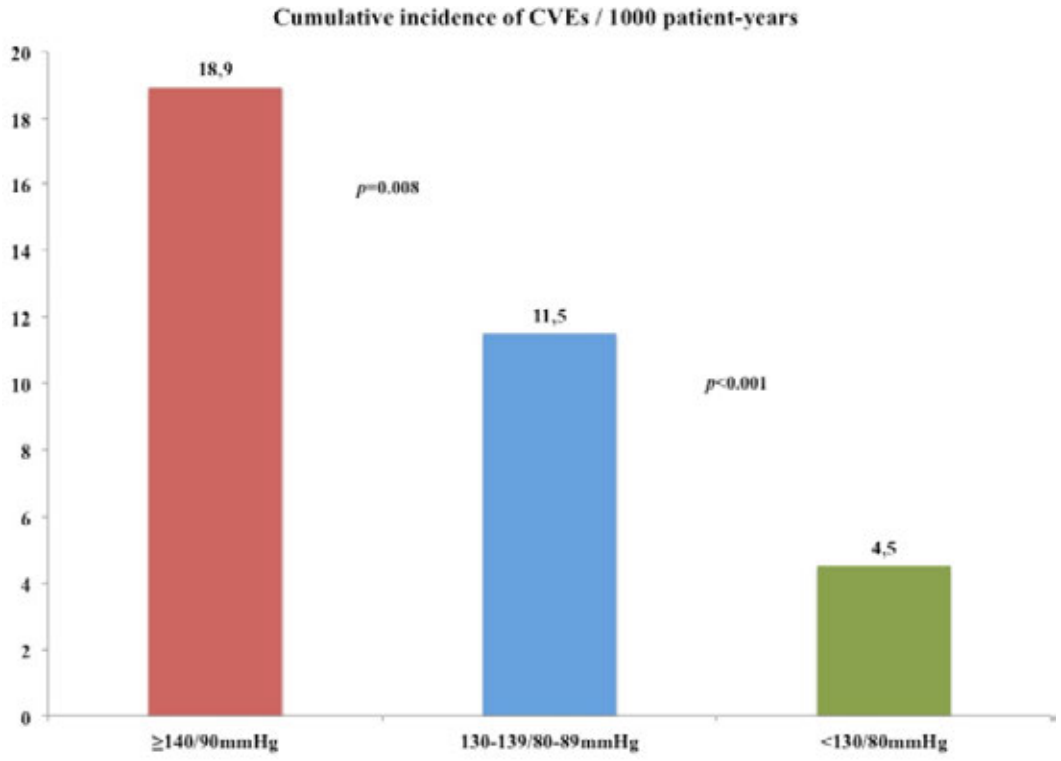
The Impact of the New American College of Cardiology/American Heart Association Definition of Hypertension on Cardiovascular Events in Systemic Lupus Erythematosus

Konstantinos Tselios,[1] Dafna Gladman,[2] Jiandong Su,[3] and Murray Urowitz[4], [1]University Health Network, University of Toronto, Toronto, [2]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada, [4]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2017 guidelines by the American College of Cardiology/American Heart Association (ACC/AHA) define hypertension at a threshold of ≥130/80mmHg for the systolic and diastolic blood pressure (SBP, DBP) respectively instead of ≥140/90mmHg. Studies in patients with systemic autoimmune diseases, where BP is fluctuating over time due to various reasons, were not considered. The aim of the present study was to assess the impact of the new definitions on the prevalence and incidence of atherosclerotic cardiovascular events (CVEs) in systemic lupus erythematosus (SLE).

Methods: Patients from the Lupus Clinic with at least two years of follow-up and no previous atherosclerotic CVEs were included. Since the blood pressure (BP) in lupus patients varies particularly in the early phases, we calculated the adjusted mean BP over the first two years and divided the patients into three groups (≥140/90mmHg,



130-139/80-89mmHg and < 130/80mmHg). Patients were followed until the first occurrence of a CVE (new onset of: angina, myocardial infarction, congestive heart failure, coronary angioplasty or by-pass graft, transient ischemic attack, stroke and cardiovascular death) or the last visit. Prevalence and incidence rates of CVEs were calculated separately for each group. SAS 9.4 was used for statistics (time-to-event analysis); p< 0.05 was considered significant.

Results: 1532 patients satisfied the inclusion criteria (88.1% females, mean age at baseline 36.2±14.3 years, mean disease duration 6.1±6.3 years). The prevalence of hypertension by the previous definition was 10.1% (155/1532) and with the current definition 30.7% (471/1532); the rest 1061 (69.3%) were normotensives. After a mean follow-up of 10.8 years, there were 124 CVEs (104 non-fatal and 20 fatal) among all patients. The total prevalence of CVEs in the three groups was 32/155 (20.6%) in the ≥140/90mmHg, 41/316 (13%) in the 130-139/80-89mmHg and 51/1061 (4.8%) in the normotensive group, respectively. The cumulative incidence per 1000 patient-years is shown in Figure 1. Similar trends (gradually increasing incidence rates from the normotensives to the 130-139/80-89mmHg and the ≥140/90mmHg groups) were found individually for the coronary artery disease (CAD) events, cerebrovascular events and cardiovascular deaths.

Conclusion: SLE patients with an adjusted mean BP of 130-139/80-89mmHg over two years developed approximately 2.5fold more CVEs compared to normotensive patients. The new definition of hypertension highlights a group of patients with a high incidence of CVEs who should be targeted for more intensive therapy in order to improve cardiovascular outcomes.

Factors Implicated in the Development of Early Osteonecrosis in Systemic Lupus Erythematosus

Konstantinos Tselios,[1] Dafna Gladman,[2] Jiandong Su,[3] and Murray Urowitz[3], [1]University Health Network, University of Toronto, Toronto, [2]Toronto Western Hospital, Toronto, Canada, Toronto, ON, Canada, [3]University Health Network, University of Toronto, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Osteonecrosis (ON) complicates approximately 15-20% of patients with systemic lupus erythematosus (SLE) on an average of six years after diagnosis. However, a small subgroup of patients will develop ON early, sometimes in a few weeks after treatment initiation. It is possible that these patients display an increased "end-organ sensitivity" and, in turn, an increased responsiveness to the administered treatment (particularly glucocorticosteroids). The aim of this study was to evaluate if patients who develop early ON will achieve better control of their disease over time compared to individuals with late ON.

Methods: Inception patients (enrolled in the Lupus Clinic within 18 months of diagnosis) who developed symptomatic ON were retrieved from the electronic database and divided into four quartiles based on the time to ON development. Patients in the first quartile were compared to individuals of the remaining three quartiles as per the demographic, clinical, immunological and therapeutic characteristics. Outcomes also included the adjusted mean SLE Disease Activity Index-2000 (SLEDAI-2K) from diagnosis until the development of ON and the severity of ON (affected joints/patient at ON diagnosis, at 12 months after ON and at the last visit). Descriptive statistics were used.

Results: Ninety-seven inception patients developed ON (time range 0.1-19.9 years from diagnosis). Twenty-three patients developed ON within 1.3 years after diagnosis (1st quartile, mean 1.2±0.6 years) whereas 74 developed ON later (2nd-4th quartiles, mean 7.4±5.2 years). There were no significant differences regarding age, sex distribution and race/ethnicity between the two groups. Initial SLEDAI-2K was higher in the patients with late ON (12.9±10.2 vs. 9.6±7, $p< 0.001$) as well as the initial prednisone dose (39.2±25.6 vs. 26.9±17.2, $p< 0.001$). For the first 12 months since diagnosis (approximately the time of early ON development), the average daily prednisone dose was similar between groups (21.6±12.1 vs. 21.3±10.7mg/day) as well as the cumulative prednisone dose (10.5±7.1 vs. 9.4±5.5grams). The evolution of the mean clinical SLEDAI-2K for seven years from diagnosis (approximately the time of late ON development) in the two groups is shown in the figure.

Concerning ON severity, this was comparable between groups both at ON diagnosis (1.46 vs. 1.43 affected joints/patient), at 12 months after ON (1.78 vs. 1.91 affected joints/patient) and at the last visit (3.3 vs. 2.87 affected joints/patient).

Conclusion: The early ON group had a lower disease activity score, lower initial steroid dose and a similar cumulative dose at one year, but developed ON within 1.3 years of diagnosis. Thus, other factors, such as genetic predisposition and organ responsiveness may be implicated in early development of ON.

Presence of Antiphospholipid Antibodies in Patients with SLE and Venous Thromboembolic Events of African American and Caucasian Race

Elena Gkrouzman,[1] Julia Davis-Porada,[1] Mary Peng,[2] and Kyriakos Kirou[2], [1]Hospital for Special Surgery, New York, [2]Hospital for Special Surgery, New York, NY

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Risk of thrombosis is elevated in patients with systemic lupus erythematosus (SLE) compared to healthy individuals, especially during the first year after diagnosis. The increased risk for events may be related to co-occurrence of antiphospholipid syndrome (APS) but can also be seen in patients with SLE without APS. Higher SLE disease activity has been hypothesized to contribute to increased risk for thrombotic events. In this study we aim to explore differences in antiphospholipid antibody (aPL) positivity in patients with SLE and venous thrombo-

Table: Patient and Clinical Characteristics of Caucasian and African American patients with SLE and Venous Thromboembolic Events
SD: Standard Deviation, IR: Interquartile Range, SLE: Systemic Lupus Erythematosus, aPL: Antiphospholipid Antibody

	Total (n=97)	Caucasian (n=59)	African American (n=38)	p-value
Female sex	85 (88%)	48 (81%)	37 (97%)	*0.019*
Current age (mean, ±SD, in years)	48 (±14)	48 (±15)	50 (±14)	0.400
Age at SLE diagnosis (median, IR, in years)	28 (19-39)	29 (19-39)	28 (19-39)	0.981
Hispanic ethnicity	16 (16%)	16 (27%)	0	*<0.001*
BMI (median, IR, in years)	28 (24-32)	28 (24-33)	29 (23-32)	0.950
Smoking (former or current)	24 (25%)	20 (34%)	4 (11%)	*0.009*
Severe SLE	55 (57%)	31 (53%)	24 (63%)	0.303
Lupus Nephritis	36 (37%)	18 (31%)	18 (47%)	0.132
Significant aPL profile	35 (36%)	27 (46%)	8 (21%)	*0.013*

embolic (VTE) events between Caucasian and AA race. Based on our clinical experience we hypothesize that AA with SLE and VTE events are less likely to have a significant aPL profile compared to Caucasians.

Methods: Patients with diagnosis of SLE and VTE events of Caucasian and AA race were retrieved from the electronic medical record of a large Rheumatology practice based at an academic hospital. All patients had to fulfill ACR and/or SLICC criteria for SLE. Relevant clinical and laboratory characteristics were recorded. Significant aPL profile was defined as presence of moderate-to-high aPL titers (anti-cardiolipin IgG/IgM ≥40 units and/or anti-β_2 glycoprotein I IgG/IgM ≥40 units), and/or positive lupus anticoagulant >1.3. Definition of severe SLE included but was not limited to history of lupus nephritis, central nervous system lupus, severe cytopenias, vasculitis, pulmonary hemorrhage, myocarditis, lupus pneumonitis, severe myositis and lupus enteritis. T-test, Wilcoxon rank-sum test, chi-square and Fisher's exact test were used to compare patient characteristics. Logistic regression was used to explore predictors of a significant aPL profile.

Results: Ninety-seven patients were identified that fulfilled ACR and/or SLICC criteria for SLE, had history of VTE and available aPL tests (Table). Of those, 59 were Caucasian and 38 AA. Twenty-seven (46%) out of 59 Caucasians had a significant aPL profile compared to 8 out of 38 (21%) AA (p=0.013). Recorded VTE events included deep venous thrombosis of extremities, pulmonary embolism, thrombosis of renal, portal, retinal, splenic, mesenteric and sinus vein, and microthrombotic events. Using logistic regression, AA with SLE and VTE events were 66% less likely (95% CI 0.12-0.96, p=0.041) to have a significant aPL profile compared to Caucasians after controlling for age, gender, Hispanic ethnicity, smoking status and SLE severity.

Conclusion: From this study of 97 patients of AA and Caucasian race with history of SLE and VTE events, AA were less likely to have a significant aPL profile compared to Caucasians. These results suggest that a negative aPL profile in AA patients with SLE does not confer a decreased risk for thrombotic events. Further analysis will explore differences in disease activity at time of VTE events between AA and Caucasians.

Development of Comorbidity in Danish Nationwide Cohort of Newly Diagnosed Patients with *Systemic Lupus Erythematosus*

Renata Hansen,[1] Titilola Falasinnu,[2] Julia Simard,[3] Mikkel Faurschou,[4] and Søren Jacobsen[5], [1]Copenhagen Lupus and Vasculitis Clinic, Denmark, Stanford, CA, [2]Department of Health Research and Policy, Stanford School of Medicine, Palo Alto, CA, [3]Stanford University School of Medicine, Palo Alto, CA, [4]Copenhagen Lupus and Vasculitis Clinic, Denmark, Copenhagen, Hovedstaden, Denmark, [5]Copenhagen Lupus and Vasculitis Clinic, Denmark, Copenhagen, Denmark

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Development of comorbidity over time in patients with systemic lupus erythematosus (SLE) is not well characterized. To provide a detailed and comprehensive picture hereof, we estimated the incidence of frequent Charlson, Elixhauser and SLICC-ACR damage index (SDI) comorbidities following diagnosis in a large inception cohort of patients with SLE compared with matched population controls.

Methods: All patients aged 18 + years at first time registration with SLE International Classification of Diseases (ICD) codes in the Danish National Patient Register (DNPR) from January 1, 1996 to July 31, 2018 and no SLE ICD codes prior to 1996 were included (incident cases, n=3178). The date of first SLE registration was set as index date and baseline for follow-up. For each SLE case, 19 general population comparators were matched by gender and age at index date using the Danish Civil Registration System (n=60090). ICD-coded diagnoses during outpatient and inpatient care were retrieved from the DNPR and DNPR-Psychiatry (for psychosis and depression). For osteoporosis, hypertension and diabetes, we used first date of ICD codes in the DNPR or date of first filled prescription of medication for these conditions (National Register of Medicinal Product Statistics).

We identified prevalent comorbidities at baseline and excluded these individuals from analyses of incident events. For comorbidities and mortality, incidence rates (IRs) per 1000 person-years and adjusted incidence rate ratios (IRRs) with corresponding 95% confidence intervals (95% CI) were estimated during time intervals (0-1, 1-2, 2-5, 5-10 years) after index date. Poisson regression estimated IRR adjusted for age at index date and gender.

Results: 84% of patients with SLE and general population comparators were female; mean age at baseline was 47 years. Most comorbidities studied occurred more frequently during follow up in SLE patients compared with general population controls (Figure); nearly every 95% CI for these IRRs excluded the null. For most comorbidities and mortality, adjusted IRRs were highest in the first year of follow-up and decreased over time. The highest first-year IRRs (range: 15-56) were seen for typical features of SLE, including coagulopathy, renal disease, polyneuropathy and pulmonary circulation disease. Osteoporosis also occurred frequently during the first years of SLE. The IRRs for depression were consistently increased to about 2.0 during the whole follow-up. The highest IRRs during 5-10 years of follow-up were seen for renal disease, coagulopathy and osteoporosis.

Conclusion: This study provides a unique and comprehensive overview of the occurrence and timing of comorbidity in a nationwide, incident cohort of adult Danish SLE patients. We saw the highest comorbidity rates during the first year of follow-up, which may be due to features of SLE disease presentation as well as increased surveillance. However, compared to the general population the patients also demonstrated consistently increased rates of a broad

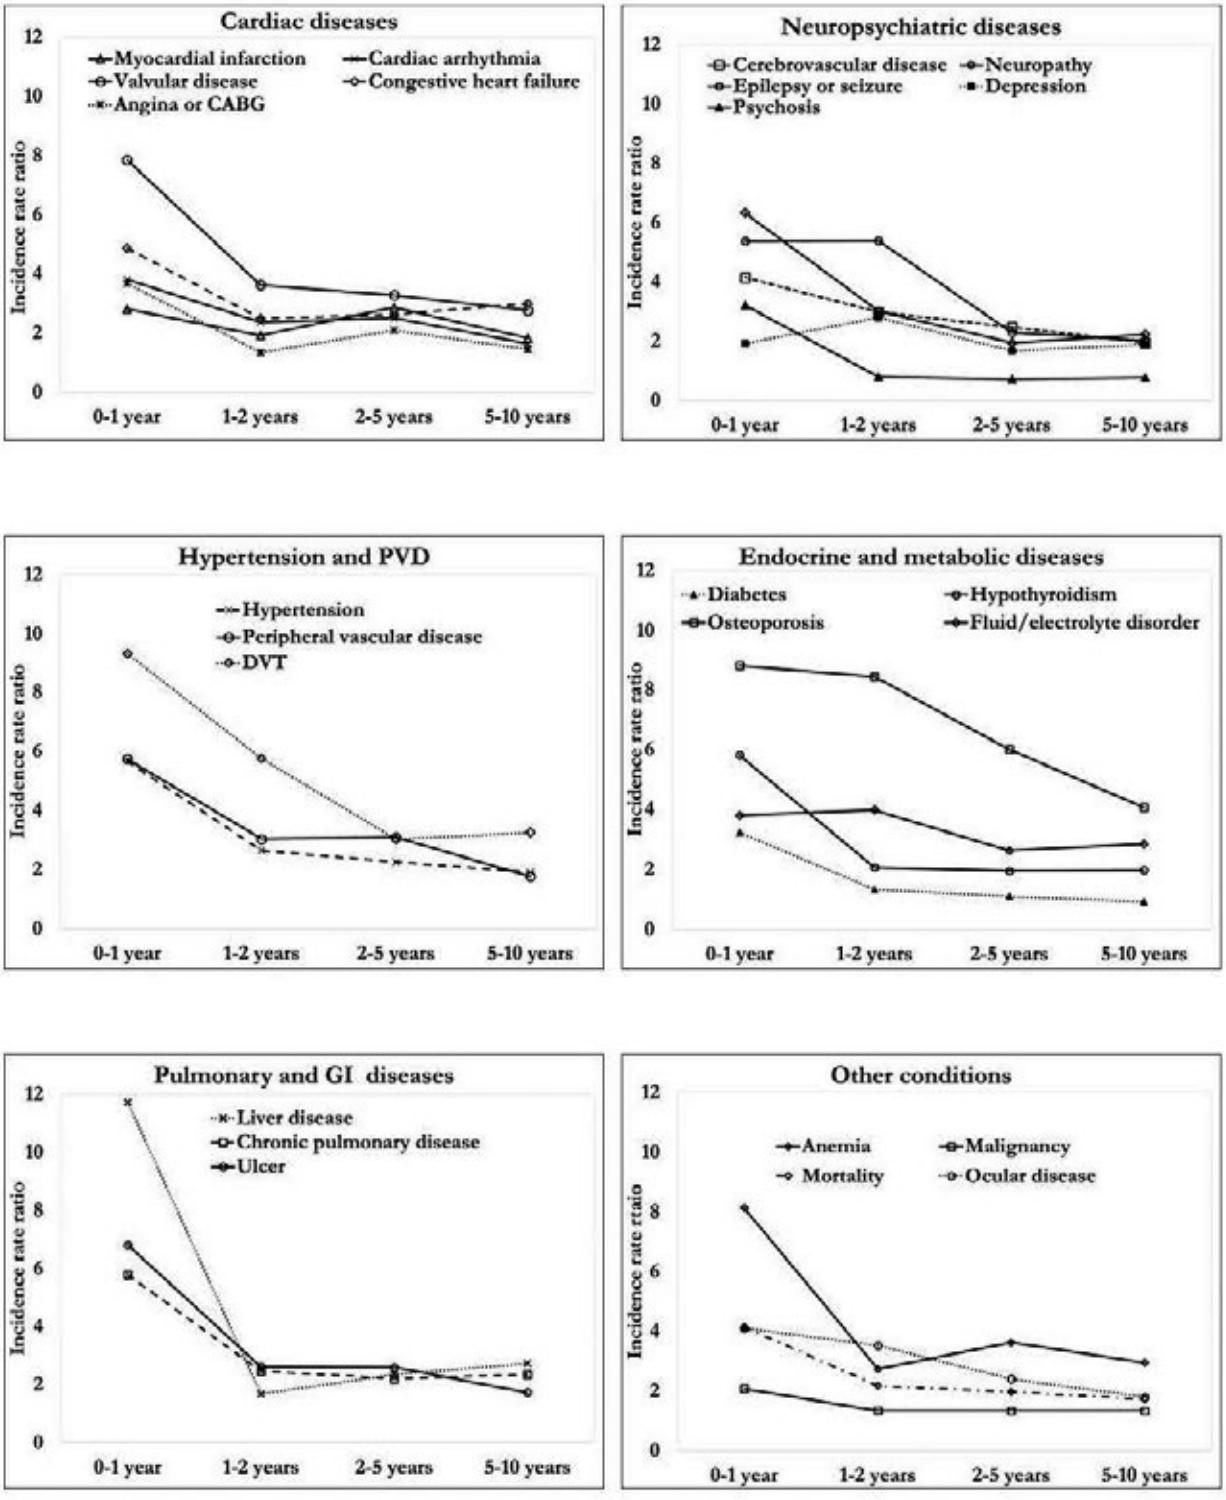

Figure. Incidence rate ratios adjusted for gender and age at baseline of frequent Charlson, Elixhauser and SLICC-ACR damage index comorbidities (per 1000 person-years) during 0-1, 1-2, 2-5 and 5-10 years post index date.

range of comorbidities featured by the SDI, Charlson and Elixhauser indices. These data may prove valuable for upcoming works on evaluating comorbidity and damage accrual in patients with SLE.

Impact of Diabetes on Risk of End Stage Renal Disease in Danish Nationwide Cohort of Newly Diagnosed Patients with *Systemic Lupus Erythematosus*

Renata Hansen,[1] Julia Simard,[2] Mikkel Faurschou,[3] Søren Jacobsen,[4] and Titilola Falasinnu[5], [1]Copenhagen Lupus and Vasculitis Clinic, Denmark, Stanford, CA, [2]Stanford University School of Medicine, Palo Alto, CA, [3]Copenhagen Lupus and Vasculitis Clinic, Denmark, Copenhagen, Hovedstaden, Denmark, [4]Copenhagen Lupus and Vasculitis Clinic, Denmark, Copenhagen, Denmark, [5]Department of Health Research and Policy, Stanford School of Medicine, Palo Alto, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Risk of end stage renal disease (ESRD) is increased in patients with systemic lupus erythematosus (SLE). Due to lifestyle –related risk factors, inflammation, and medications such as steroids, SLE patients are also more likely to have diabetes mellitus (DM), the leading cause of ESRD in the world. We estimated the impact of DM on ESRD incidence in a large inception cohort of patients with SLE.

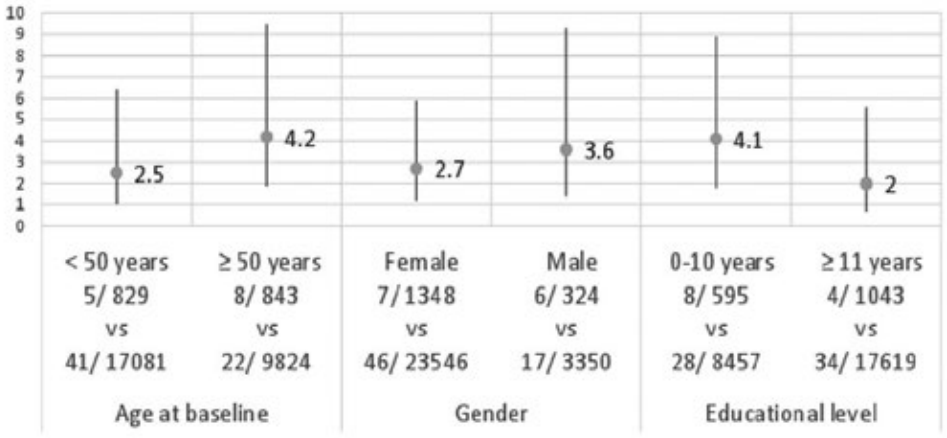
Methods: All adult patients registered with SLE International Classification of Diseases (ICD) codes in the Danish National Patient Register (DNPR) from January 1, 1996 to July 31, 2018 were identified. Individuals had no SLE ICD codes prior to 1996 (incident cases, n=3178). The date of this first SLE registration was set as SLE diagnosis date (baseline). DM was defined as the date of first DM ICD code or the date of first filled DM prescription (National Register of Medicinal Product Statistics). ESRD was defined as first registration of dialysis, renal transplant or terminal

Table 1. Characteristics of SLE inception cohort stratified by diabetes mellitus (DM).

	DM	non-DM
n	290	2859
Female (n, %)	224 (77.2 %)	2441 (85.4 %)
Age at SLE diagnosis (mean, SD)	53.4 (14.8)	46.2 (16.4)
Age at DM diagnosis (mean, SD)	54.3 (15.8)	
Mean duration from SLE to DM date, years (mean, SD)	6.4 (5.8)	
Prevalent DM	119 (41 %)	
Incident DM	171 (59 %)	
Educational level (n, %)		
Unknown	13 (4.5 %)	105 (3.7 %)
Primary and lower secondary education (0-10 years)	114 (39.3 %)	844 (29.5 %)
Upper secondary education (11-15 years)	110 (37.9 %)	1237 (43.3 %)
Higher education (>15 years)	53 (18.3 %)	673 (23.5 %)
Hypertension at baseline (n, %)	104 (35.9 %)	578 (20.2 %)

SLE: systemic lupus erythematosus

Figure 1. Incidence rate ratios (with 95% CI) of ESRD in SLE patients with diabetes compared with SLE patients with no diabetes; stratified by gender, age group at baseline and educational level at baseline (also showing number of ESRD/ person years in DM group vs non-DM group).



ESRD: end stage renal disease, SLE: systemic lupus erythematosus

(stage 5) kidney insufficiency using ICD codes. Patients with prevalent ESRD at baseline were excluded from the analyses (n=29). ESRD incidence was compared in those with DM vs those without DM (non-DM). Incidence rates per 1000 person years (IRs) and incidence rate ratios (IRRs) with corresponding 95% confidence intervals (95% CI) were estimated, stratified by gender, age at baseline (< 50 years vs >= 50 years) and educational level at baseline. Poisson regression estimated IRR.

Results: The DM group included 290 patients of whom 77% were female compared to 85% of the 2859 in the non-DM group. Those with DM were older at baseline (53 vs 46 years) (Table 1). Of those with DM at any time, DM was prevalent at baseline in 119 (41%) and incident in 171 (59%) of the patients. Mean duration from SLE to DM date for patients with incident DM was 6.4 years. Hypertension was more prevalent at baseline in those with DM compared with the non-DM group (35 % vs 20 %). Patients with DM had nearly 3 times higher incidence rate of ESRD compared with non-DM patients, adjusted for gender, age, and educational level (2.6 (1.4-4.9)). The rates were higher in females, patients aged ≥50 years, and those with lower educational level (Figure1). However, due to overlapping CIs these differences might not be significantly different from one another.

Conclusion: We found that DM greatly increased the risk of ESRD in SLE patients. Timely diagnosis and treatment of comorbidities like DM are essential to prevent long term complications and damage accrual in SLE patients.

The Association of Lupus Nephritis Histopathologic Classification with Venous Thromboembolism Is Modified by Age at Biopsy

Ian Cooley,[1] Vimal Derebail,[1] Keisha Gibson,[1] Carolina Alvarez,[2] Caroline Poulton,[1] Lauren Blazek,[1] Andrew Love,[1] Susan Hogan,[1] Ronald Falk,[1] and Saira Sheikh[3], [1]University of North Carolina at Chapel Hill, Chapel Hill, [2]University of North Carolina at Chapel Hill Thurston Arthritis Research Center, Chapel Hill, NC, [3]University of North Carolina, Chapel Hill, NC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease that is associated with an increased incidence of venous thromboembolism (VTE). Lupus nephritis (LN) has been shown to be an independent risk factor for VTE. To our knowledge the risk of VTE has not been studied by International Society of Nephrology/Renal Pathology Society (ISN/RPS) LN class.

Methods: A cross-sectional analysis was performed using data from the Glomerular Disease Collaborative Network (GDCN). Patients with class V LN were compared to those with class III or IV (but not associated class V) LN. Classes I, II and VI were excluded from analysis due to their low prevalence. The outcome of interest was image-confirmed VTE. Logistic regression was used to calculate odds ratios and 95% confidence intervals, adjusted for age, sex, race, hormonal contraception use, serum albumin and use of hydroxychloroquine. Effect modification was assessed between the main effect and other covariates and considered if $p < 0.05$.

Results: Our cohort consisted of 533 patients; 311 (58.3%) with class III/IV and 222 (41.7%) with class V LN. Mean±SD age was 30.9±15.0 years (range 6-79 years), with an overall incidence of image-confirmed VTE of 54/533 (10.1%). In adjusted analyses, the odds of VTE were not significantly different for those with class III/IV compared to class V LN (OR, 95% CI: 1.00, 0.54-1.84). There was, however, evidence of effect modification of LN class on VTE by age at biopsy, as displayed in table 1.

Conclusion: VTE was common in LN patients in the GDCN, occurring in ~10%, and its incidence was similar among patients with class III/IV LN and those with class V LN. These findings suggest that the association between LN and VTE is not limited to class V-related nephrotic syndrome. Interestingly, however, age-specific analysis demonstrated increased odds of VTE with class III/IV LN diagnosed at a younger age and decreased odds ratio for VTE with class III/

Age, continuous	Effect	OR (95% CI)
Estimated at age 15 (-1SD)	Class III/IV vs V	5.38 (1.42-20.34)
Estimated at age 30 (mean)	Class III/IV vs V	1.19 (0.59-2.42)
Estimated at age 45 (+1SD)	Class III/IV vs V	0.26 (0.09-0.78)

Table 1

IV LN diagnosed at an older age. This may suggest the presence of an age-sensitive modulation of LN class-specific VTE risk.

Prognostic Value of Urinary Biomarkers for the Developing of End Stage Renal Disease in Patients with Systemic Lupus Erythematosus

Jose A Gómez-Puerta,[1] Tomás Urrego,[2] Blanca Ortiz Reyes,[3] Adriana Vanegas-García,[4] Carlos H Muñoz-Vahos,[4] Luis A González,[4] and Gloria Vasquez[5], [1]Rheumatology Department, Hospital Clinic de Barcelona, Barcelona, Catalonia, Spain, [2]Grupo de Inmunología Celular e Inmunogenética, Universidad de Antioquia, Medellín, Antioquia, Colombia, [3]Grupo de Inmunología Celular e Inmunogenética, Facultad de Medicina, Universidad de Antioquia, Medellín, Antioquia, Colombia, [4]Grupo de Reumatología, Universidad de Antioquia, Medellín, Antioquia, Colombia, [5]University of Antioquia, Medellin, Antioquia, Colombia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There is an increasing knowledge about the utility of urinary biomarkers for the diagnosis of lupus nephritis (LN) in patients with systemic lupus erythematosus (SLE). However, information as prognostic factors is more limited. Our aim was to evaluate a wide panel of urinary biomarkers in patients with SLE in order to assess their capability for prediction of progression to end stage renal disease (ESRD) in LN patients.

Methods: We conducted a prospective single center study including patients with SLE. Only those with LN criteria according ACR were included. A wide panel of urinary biomarkers were measured at the moment of study inclusion, then, a prospective follow up was made according daily clinical practice. We measured urinary levels of 6 different biomarkers including: monocyte chemoattractant protein 1 (MCP-1), neutrophil gelatinase-associated lipocalin (NGAL), TWEAK, Ceruloplasmin (CP), Transferrin (TF) and vascular cell adhesion molecule-1 (VCAM-1) using a commercial ELISA kits (R&D system and Assaypro, USA). In addition, serum anti C1q antibodies were measured by ELISA (Inova, USA).

Continuous data were summarized as means ± SDs and compared by an independent T test or Mann–Whitney test. Categorical data were expressed as number of patients and percentages and compared by Fisher's exact test. Receiver operating characteristic (ROC) curve analysis was used to explore discrimination between those with ESRD and determine the optimal cutoff point for different biomarkers. Survival curves were drawn using the Kaplan–Meier method. Statistical analyses were performed using IBM SPSS Statistics version 23.0.

SLEDAI at inclusion (SD)	11.2 ± 9.31

Table. General Characteristics of LN patients

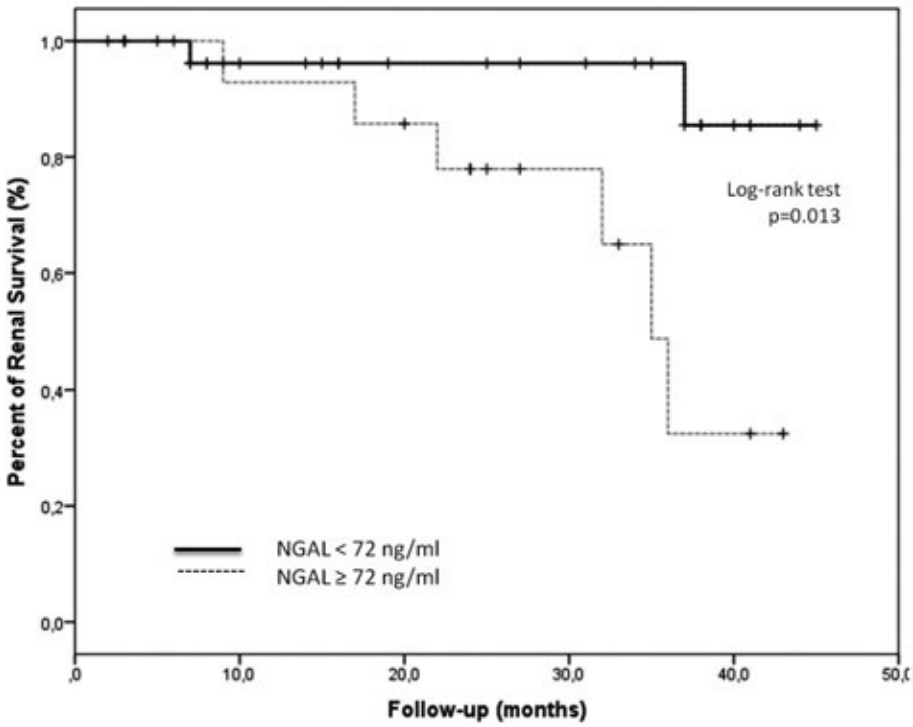

Figure. Kaplan–Meier survival curve for renal survival among SLE patients with LN according NGAL levels, Log rank test was used for analysis. p-value <0.05 were considered significant.

Results: From 120 patients with SLE, 76 (63%) had LN. The median age of patients at time of inclusion was 29.3 ± 9.4 years and the average follow-up period was 23.0 ± 13.1 months. Main clinical and serological characteristics are summarised in Table. During the follow-up 4 patients had LN progression (From class II to Class IV or V). Two patients had chronic renal disease at baseline. Eight out of 76 (10.5 %) progressed to ESRD, and 2 patients deceased. Urinary levels of NGAL (434.5 ± 193.0 vs 73.7 ± 21.5 ng/ml) and TF (8528.5 ± 234.2 vs 6780 ± 539 ng/ml) were significantly higher in those patients who progressed to ESRD. No differences were found with other urinary biomarkers or serum Anti C1q levels and risk of ESRD. The combination of these NGAL and TF compared to any of the urine

markers individually improved the prediction of future ESRD. AUC values were 0.71 and 0.63, respectively. Comparisons of renal survival grouped by the level of urinary NGAL at baseline were predictors for ESRD in LN patients (Figure).

Conclusion: In this cohort of patients with LN, around 10% of patients progressed to ESRD. High levels of Urinary NGAL levels at baseline were related with a higher risk of progression to ESRD.

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with Systemic Lupus Erythematosus (SLE) are at risk of accumulating damage, having an impaired quality of life and experiencing a premature death. The different domains and items of the SLICC/ACR Damage Index (SDI) and the predictors of their development and progression in patients from a large multiethnic, multinational Latin American Lupus Cohort were studied.

Methods: 1,385 SLE patients, with a recent SLE diagnosis (< 24 months and >6 months to comply with SDI definition), were studied and followed-up for a mean of 47.0 (SD 25.1) months. Socio-demographic and clinical variables were assessed. The 41 items and 12 domains of SDI were evaluated annually. Kaplan-Meier (Log-rank test) and Cox frailty models as multivariate analysis were performed.

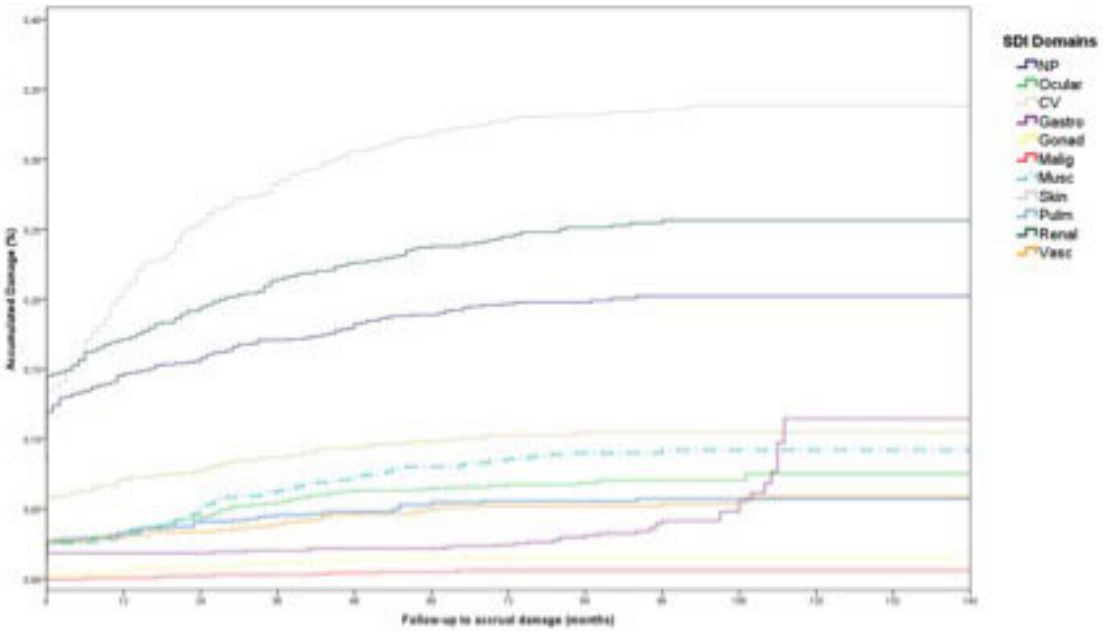

Figure 1: Accumulative damage curves in the 12 domains of the SDI during follow-up

Results: At cohort entry 565 patients (40.8%) had damage score ≥1, with a mean baseline SDI 0.66 (SD 1.01). During follow-up 658 patients (47.5%) accrued new damage ≥1, with a meantime between cohort entry and new damage of 33.2 months (SD 26.2). 11.3% accrued severe new damage (SDI ≥3 points).At last follow-up: 952 patients (68.7%) had a total damage score ≥1, with a mean final SDI of 1.57 (SD 1.67). 76 patients (5.5%) died during follow-up, at a mean time of 50.0 (SD 23.5) months from cohort entry; 56.6% of they had damage at baseline, with a mean SDI of 1,12 (SD 1.4). The highest proportion of new damage occurrence was in the skin domain, followed by renal and neuropsychiatric domains, and the lowest proportion were for gonadal and malignancy domains, as shown in Figure 1 of damage accrual for the 12 SDI domains. Multivariate analysis (including gender, age, medical coverture, country of origin, race, rural or urban residency, socioeconomic status, education years, SLE duration, and diagnosis delay), to investigate predictors of different damage domains, showed that higher baseline SLEDAI scores associated with a significant Hazard Risk for new damage in the neuropsychiatric, ocular, cardiovascular, skin, pulmonary and renal domains. There were differences according to country of origin, with more new damage occurring in patients from Perú and Argentina, and with less damage accrual occurring in those from Guatemala, Cuba and Brazil. No other differences were observed. At last follow-up: alopecia was the most frequent SDI item (30.4% SLE) followed by proteinuria >3.5g/d (11.2%), estimated glomerular filtration range < 50% (9.0%), and seizures requiring therapy for >6 months (7.5%). The other 37 SDI items were present in < 5% of the members of the cohort.

Conclusion: In this cohort, skin (mostly alopecia) was the most prevalent domain in damage accrual. SLEDAI predicts damage accrual in several domains, including major organs, reinforcing the need for early treatment intervention to minimize the inflammatory process and consequent damage. Relevant differences according to country of origin were identified.

AI: augmentation index; CI: confidence interval; DM: diabetes mellitus; MRI: magnetic resonance imaging; FMD: flow-mediated dilatation; MD: Mean difference; MFR: myocardial flow reserve; NMD: nitroglycerin-mediated dilatation; PAT: peripheral arterial tonometry; PWV: pulse wave velocity; SD: standard deviation.

dothelial dysfunction (ED) and peripheral arterial stiffness (AS), which have been evaluated in SLE patients. The aim of this study was to systematically review and meta-analyze existing reports of CV disease (CVD) in SLE patients, as measured by ED and AS.

Methods: We performed a systematic review and meta-regression of studies evaluating the impact of SLE on the risk of ED and AS. Studies analyzing the relationship of SLE with ED (flow-mediated dilatation [FMD], nitroglycerin-mediated dilatation [NMD] and peripheral arterial tonometry [PAT]) and AS (augmentation index [AI], pulse wave velocity [PWV]) were systematically searched for in PubMed, EMBASE, Web of Science databases. Inclusion criteria included peer-reviewed publication, and report of original data in English. Mean differences (MD) and 95% confidence intervals (CIs) between SLE patients and controls were estimated using the random effect model.

The study was registered with PROSPERO, number CRD42019121068

Results: For the analysis of ED 21 studies were included. Compared with controls (n=644), SLE patients (n=943) showed a significantly lower mean FMD (MD= -4.30 %; 95% CI: -6.13%, -2.47%; $p < 0.001$). However, NMD did not significantly differ between SLE patients (n=404) and controls (n=265) (MD= – 2.68%; 95% CI -6.00, 0.62; p= 0.11). For the AS analysis 25 studies were included. A significantly-increased AS between SLE patients (n=1234) and controls (n=678) according to overall PWV (MD= 1.12 m/s; 95% CI 0.72-1.52; $p < 0.001$), central PWV (MD= 1.12 m/s; 95% CI 0.64, 1.59; $p < 0.001$), and peripheral PWV (MD= 1.52 m/s; 95% CI 0.82- 2.22; $p < 0.001$) was found, but not for the brachial-ankle PWV. AI (reported in 12 studies) was also increased in SLE patients (n=740) compared with healthy controls (n=411) (MD= 4.55%; 95% CI 1.48-7.63; $p = 0.003$).

Conclusion: SLE patients showed impaired FMD, an independent predictor of CV events. We also found a higher degree of AS in SLE patients compared with controls. The presence of ED and AS in SLE should be taken into account to plan adequate prevention strategies and therapeutic approaches.

Table 2: Top 10 primary diagnoses among SLE hospitalizations who DIED (3405), N (%)

Abbreviations: ARF (acute respiratory failure), ILD (interstitial lung disease), PPH (primary pulmonary hypertension), PUD (peptic ulcer disease), IBD (inflammatory bowel disease), UGIB (upper gastro-intestinal bleeding)

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic multisystem autoimmune disorder with variable presentation. While several studies have outlined the risk factors for hospitalization and mortality in SLE, the frequency of these causes have varied among studies and over the years. We aimed to assess leading nationwide causes of SLE hospitalizations and mortality in the US in a recent year, 2016 using a large inpatient database.

Methods: We used the National Inpatient Sample (NIS) database from the year 2016 to identify hospitalizations with SLE using the previously validated International Classification of Disease (ICD-10) code M32. NIS is a part of the Healthcare Cost and Utilization Project (HCUP). It contains 20 % stratified sample of US hospital discharges (~ 7 million/year), the weighted estimate of which corresponds to about ~ 35 million/year. Hospitalizations with SLE in primary and secondary positions were identified. Among SLE as the secondary diagnosis, ICD-10 codes used to look for primary diagnoses associated with hospitalizations and mortality.

Results: We identified 174,235 SLE hospitalizations in 2016 among which 89% were females. The mean age of hospitalization for SLE was 52 years and mean length of stay was 5.6 days. SLE was the primary diagnosis in 10,195 (5.85%) patients, among which lupus nephropathy was the most common (32.42%). Among SLE as the secondary diagnosis, infection was the commonest primary diagnosis (16.33 %) followed by acute kidney injury (2.36%) and gastrointestinal manifestations (2.15%). Cardiac manifestations including acute heart failure (2.09%), acute coronary syndrome (1.96%) and conduction disturbances (1.58%) were other important causes of hospitalization **(Table 1)**. In-hospital mortality of SLE was 1.95% and infection was the leading cause of in-hospital mortality (38%) **(Table 2)**.

Conclusion: In our study using a large national database, we noted that SLE was the primary cause for hospitalization in 5.85 %, which is fewer than previously reported. Infection was the leading primary diagnosis associated with SLE hospitalization, which is in accordance with other recent studies globally. On 2016, the inpatient mortality for SLE was 1.95 %, which was fewer than the 3.15% reported by Krishnan et al. using the same NIS database (1998 – 2002), which suggests possible improvement in mortality in SLE hospitalizations in the recent years. In conclusion, infection was the leading reason for hospitalization and in-hospital mortality in SLE. Renal and cardiac involvements were other important causes of hospitalization.

Oxidized Human Serum Albumin Is Increased in Systemic Lupus Erythematosus, but Not in Rheumatoid Arthritis

Hideto Takada,[1] Keiko Yasukawa,[2] Suguru Honda,[1] Masako Majima,[1] Naoko Konda,[1] Yasuhiro Katsumata,[1] Michi Tsutsumino,[1] Yutaka Yatomi,[3] and Masayoshi Harigai[1], [1]Department of Rheumatology, Tokyo Women's Medical University School of Medicine, Shinjuku-ku, Tokyo, Japan, [2]Department of Clinical Laboratory, The University of Tokyo Hospital, Bunkyo-ku, Tokyo, Japan, [3]Department of Clinical Laboratory Medicine, Graduate School of Medicine, The University of Tokyo, Bunkyo-ku, Tokyo, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) and rheumatoid arthritis (RA) are at high risk of atherosclerosis and have high mortality due to cardiovascular disease. Oxidative stress is involved in the progression of atherosclerosis, with the percentage of human non-mercaptoalbumin (HNA%), the oxidized form of human serum albumin, attracting considerable attention as a potential biomarker of oxidative stress. Although previous studies have shown increased HNA% in the elderly people and in patients with either chronic kidney disease, diabetes mellitus, or liver cirrhosis, there are no reports on HNA% in patients with rheumatic diseases. The aim of this study was to evaluate HNA% in patients with SLE or RA and to identify factors associated with this biomarker.

Methods: We measured HNA% in patients with SLE, RA, and healthy controls by using high-performance liquid chromatography. Analysis of covariance was used to compare HNA% between SLE and healthy controls, or RA and healthy controls. Factors associated with HNA% in SLE and RA patients were assessed by using multiple linear regression analysis.

Results: HNA% was measured in 89 SLE patients [age (mean ± SD), 44 ± 11 years; female, 97%], 51 RA patients [age (mean ± SD), 62 ± 13 years; female, 94%], and 65 healthy controls [age (mean ± SD), 55 ± 14 years; female, 58%)]. All participants were Japanese. Mean HNA% (SD) of SLE, RA, and healthy controls were 23.0% (5.0%), 23.7% (4.7%), and 21.8% (3.7%), respectively. The correlation between HNA% and age was significant in RA patients and healthy controls, but not in SLE patients (Figure 1). The age-adjusted mean difference in HNA% between the SLE patients and the healthy controls was 2.9% (95% CI, 0.96 to 4.9%; Bonferroni corrected p value = 0.001), and between the RA patients and the healthy controls, 0.84% (95% CI, –3.0 to 1.3%; Bonferroni corrected p value=1.0), respectively. In SLE patients, SLICC/ACR damage index (β=0.48, p< 0.001) and serum creatinine level (β=0.24, p=0.01) were significantly associated with HNA%. In RA patients, serum creatinine level (β=0.42, p< 0.001), age (β=0.37, p=0.002), and daily prednisolone dosage (β=0.29, p=0.006) were significantly associated with HNA%.

Conclusion: SLE patients have increased HNA% compared to the healthy controls, especially in association with the SLICC/ACR damage index. Patients with RA do not show this association. In SLE patients, increased HNA% might reflect excessive oxidative stress and possibly be associated with an increased risk of atherosclerosis.

Disease Activity and Dysregulated Iron Metabolism: A Potentially Overlooked Mechanism for Anaemia in Patients with Systemic Lupus Erythematosus?

Chris Wincup,[1] Thomas McDonnell,[1] George Robinson,[1] Filipa Farinha,[1] Anna Radziszewska,[1] and Anisur Rahman[1], [1]University College London, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Haematological manifestations of SLE are common with anaemia reported in approximately 50% of cases, yet the role of altered iron metabolism is poorly understood. Key regulators of iron homeostasis include; 1. Hepcidin, which prevents iron release from stores (under the influence of IL6 and IL1β); 2, Ferritin, an iron carrier protein also implicated as a functional potent pro-inflammatory mediator; 3. Erythropoietin (EPO); 4. Lipocalin-2 (LCN2), released on innate immune activation that induces iron sequestration; 5. Transferrin, binds circulating iron and regulates transport to stores in the liver, spleen and bone marrow; 6. Soluble transferrin receptor (sTfR), a cleaved extracellular receptor; 7. Haptoglobin (Hp), binds free haemoglobin (Hb); 8. Natural resistance-associated macrophage protein 2 (NRAMP2), a metal ion transporter that facilitates transfer of iron into enterocytes.

In this study, we aimed to evaluate the changes in these regulators in patients with SLE and assess for the influence of disease activity for the first time.

	Healthy Control N=17	Low Lupus Disease Activity (SLEDAI ≤4) N=17	Active Lupus (SLEDAI >4) N=22	p-value
Hepcidin (ng/ml ± SD)	7.63 ± 5.0	14.56 ± 12.2	75.02 ± 103.7	<0.0001†
Interleukin-6 (pg/ml ± SD)	0.71 ± 0.4	1.60 ± 1.6	9.00 ± 8.8	<0.0001†
Interleukin-1β (pg/ml ± SD)	0.01± 0.02	0.19 ± 0.3	0.53 ± 0.8	<0.0001*
Ferritin (ng/ml ± SD)	40.3 ± 23.3	92.5 ± 95.9	345.2 ± 299.4	<0.0001†
Transferrin (ng/ml ± SD)	648.3 ± 204.0	729.7 ± 262.7	563.1 ± 203.8	0.08
Soluble transferrin receptor (µg/ml ± SD)	8.24 ± 2.3	15.02 ± 12.5	11.64 ± 6.3	0.04†

Figure 1: Correlations between SLEDAI-2K, haemoglobin and regulators of iron metabolism. Results expressed as r values (*p<0.05; **p<0.01)

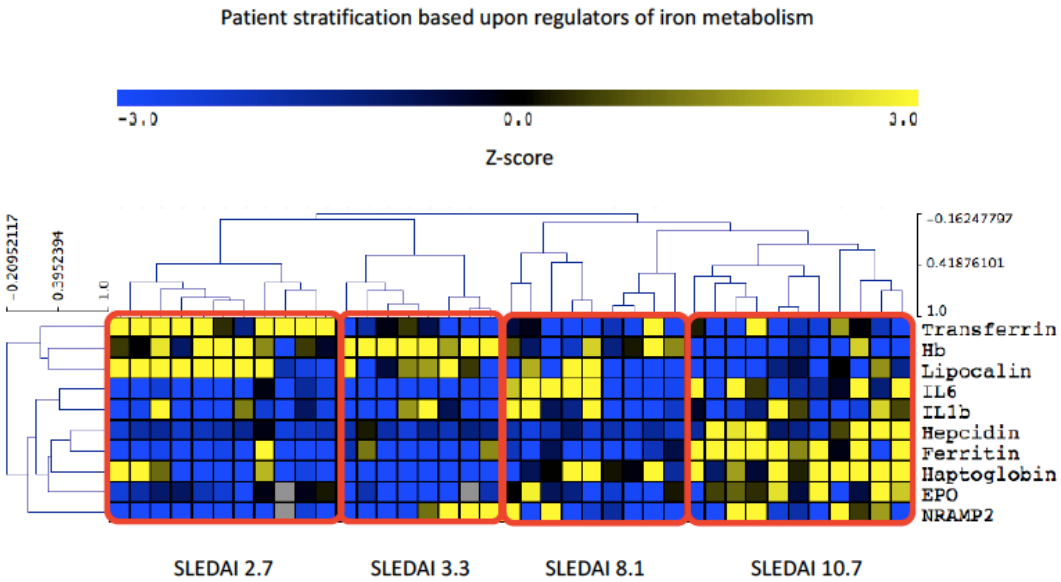

Figure 2: Heatmap representation of cluster analysis of key iron mediators in SLE. Normalised data is presented as Z-score with 3.0 being elevated and -3.0 reduced in comparison to the mean (0.0). Results presented as correlative clusters with mean SLEDAI expressed beneath each group.

Methods: Serum samples were collected from patients with SLE (n=39) attending University College London Hospital, UK, in addition to 17 healthy controls (HC). Patients with haemolytic anaemia were excluded. Clinical measures including Hb, dsDNA, complement C3 and SLEDAI-2K (where >4 was considered active disease; ≤4 classified in-

active / low disease activity) were recorded. Levels of IL6, IL1β, Hepcidin, Ferritin, LCN2, Transferrin, sTfR, EPO, Hp and NRAMP2 were measured by ELISA. Differences between groups were calculated by One-way ANOVA / Kruskal-Wallis and correlations by Spearman's / Pearson's. Following normalisation of significant variables, Z-scores were used in hierarchical correlate clustering performed using MeV software to present as a heatmap.

Results: Of the 39 patients recruited 90% were female (35/39) with a mean age of 27.8 (± 11.7) years. Results comparing HC, inactive / low disease activity SLE and active SLE are summarised in Table 1. Interestingly LCN2 levels were lower in active SLE, which is surprising given that elevated levels are commonly observed in systemic inflammation. SLEDAI-2K showed a strong positive correlation with hepcidin, ferritin, IL6 and Hp, whilst negatively correlating with both LCN2 and Transferrin. In SLE, ferritin and LCN2 correlated significantly regardless of disease activity ($p< 0.001$, $r=0.40$). Figure 1 summarises all correlations in SLE. Figure 2 demonstrates the results of hierarchical clustering. The cluster containing patients with a combination of reduced LCN2 and Hb with elevated Hp, Ferritin, Hepcidin and EPO showed the highest mean SLEDAI-2K (10.7) whilst higher Hb, LCN2 and Transferrin was observed in the group with the lowest mean SLEDAI-2K (2.7).

Conclusion: We have detailed the dysregulation of key mediators in iron homeostasis in SLE for the first time. Key findings include a paradoxical reduction in LCN2, which inversely correlates with ferritin. Further, reduced Transferrin with elevated EPO and Hepcidin in active disease suggests a state of functional iron deficiency with iron being held in stores and therefore not available for use in erythropoiesis thus representing a novel mechanism for anaemia.

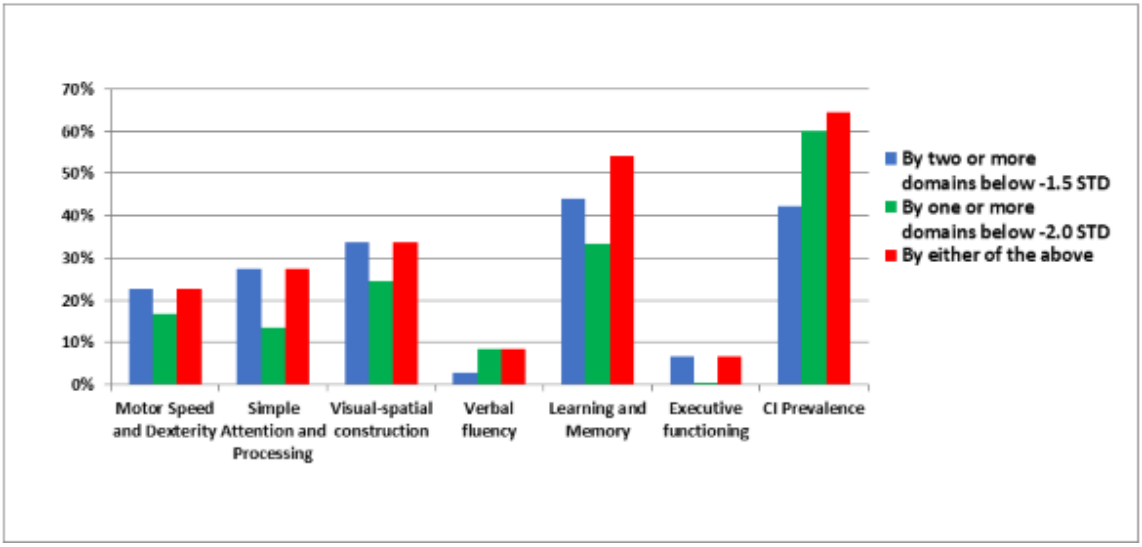
Prevalence of Cognitive Impairment in an Inception Lupus Cohort as Assessed by a Comprehensive Neuropsychological Battery

Bahar Moghaddam,[1] Dorcas Beaton,[2] Robin Green,[3] Maria Tartaglia,[4] Lesley Ruttan,[3] Mahta Kakvan,[5] Marvin Fritzler,[6] May Choi,[6] Moe Zandy,[5] Jiandong Su,[5] Michelle Vitti,[7] Dennisse Bonilla,[5] Joan Wither,[8] Sabrina Lombardi,[3] and Zahi Touma[5], [1]University of Toronto, Toronto, ON, Canada, [2]St. Michael's Hospital, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]University Health Network, University of Toronto, Toronto, ON, Canada, [5]University Health Network, University of Toronto, Toronto, ON, Canada, [6]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]University Health Network/University of Toronto, Toronto, NU, Canada, [8]University Health Network, Krembil Research Institute, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) can lead to a number of neuropsychiatric manifestations including cognitive impairment (CI). Previous meta-analyses have reported the prevalence of CI at 38% (95% confidence interval: 33-43%), with a range of 15-79%. We aim to report the prevalence of CI in a lupus cohort as assessed by a comprehensive neuropsychological battery (NB) of tests. Additionally, we were interested in exploring differences in demographic, clinical and serological characteristics of SLE patients in an inception cohort, with and without CI.

Figure 1. Prevalence of patients with domain z-scores of ≤ - 1.5 and ≤ - 2.0 (n=279)



Methods: Consecutive consenting patients aged 18-65 years, who attended a single center were enrolled (Jul 2016 – Mar 2019). Each patient completed a comprehensive NB evaluating six cognitive domains including: manual motor speed and dexterity, simple attention and processing, visual spatial construction, verbal fluency, learning and memory (verbal and visuospatial) and executive function. Using age- and gender-stratified normative data, patients were classified on the ACR NB as having CI if a z-score of ≤-1.5 was observed in ≥ 2 domains or z-score of ≤ -2.0 on ≥1 domain; otherwise non-CI. Further, patients with CI (z-score of ≤ -1.5 on ≥2 domains) were compared to non-CI patients.

Results: 279 patients were included in this study, 89.6% comprised of females. The average age and SLE duration at enrolment were 41.2 ± 12.2 and 14.1 ± 10.1 years, respectively. The prevalence of CI was 42.3% (z-score of ≤ -1.5 on ≥2 domains) and 60.2% (z-score of ≤ -2.0 on ≥1 domain).

The most affected domains were learning and memory, and visual spatial construction – prevalence of 44.1% (n=147/279,) and 33.3% (n=94/279,) respectively. Prevalence of impairment in visual spatial construction was 33.8% (n=94, z-score of ≤ -1.5 on ≥2 domains) and 24.5% (n=68, z-score of ≤ -2.0 on ≥1 domains). The least affected domains were verbal fluency, and executive function. Prevalence of impairment in verbal fluency was 2.9-8.6% (z-score of ≤ -1.5 on ≥2 domains, z-score of ≤ -2.0 on ≥1 domains). Prevalence of executive function impairment varied between 0.4-6.8% (z-score of ≤ -2.0 on ≥1 domains, z-score of ≤ -1.5 on ≥2 domains).

There were no differences in demographics, medication use, disease duration and activity, and serologic markers between those with and without CI [using the definition of CI as z-score of ≤ -1.5 on ≥2 domains].

Conclusion: The pooled prevalence of CI in this cohort varied with different definitions of CI (44.3%-60.2 % [z-score of ≤ -1.5 on ≥2 domains, z-score of ≤ -2.0 on ≥1 domains]). There is an unmet need to standardize the metrics and the definitions for CI. CI is identified across all cognitive domains with particularly high prevalence in learning and memory.

Clinical and Sociodemographic Associates of Depression and Anxiety in Systemic Lupus Erythematosus

David Eldeiry,[1] Moe Zandy,[2] Oshrat Tayer-Shifman,[2] Andrew Kwan,[3] Sherief Marzouk,[2] Jiandong Su,[2] Kathleen Bingham,[2] and Zahi Touma[2], [1]Royal College of Surgeons in Ireland, Dublin, Ireland, [2]University Health Network, University of Toronto, Toronto, ON, Canada, [3]Queens University, Kingston, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In our recent systematic review, we have shown a high prevalence for depression (35%) and anxiety (25.8%) in Systemic Lupus Erythematosus (SLE)[1]. A better understanding of the SLE phenotypic manifestations associated with depression and anxiety may lead to enhanced early diagnosis and treatment strategies.

Objectives: To determine the overall prevalence of anxiety and depression in a cohort of SLE patients, stratified by SLE-implicated organ systems and to study their associations.

Methods: Patients attending the Toronto Lupus Clinic from August 2017 to January 2019 were studied. Depression and Anxiety were diagnosed with Center for Epidemiological Studies-Depression Scale (cut-off26), BECK Depres-

[a]Encompasses seizure, psychosis, organ brain syndrome, cranial nerve involvement, visual disturbance, lupus headache, cardiovascular accident, and vasculitis. [b]Encompasses leukopenia and thrombocytopenia. [c]Encompasses low complements and positive anti-dsDNA antibodies. [d]Encompasses fever. *Statistically significant at $p < 0.05$ by Chi-square test or Cochran-Armitage trend test (reference group = patients with neither anxiety or depression).

sion Inventory-II (cut-off18), and the BECK Anxiety Inventory (cut-off19). Disease activity was measured with the SLE Disease Activity Index 2000 (SLEDAI-2K). The SLE phenotypic manifestations were stratified based on the organ systems of cumulative 10-year SLEDAI-2K – skin, musculoskeletal (MSK), ocular, neuropsychiatric, and internal organ manifestations (renal, pulmonary, immunologic, and haematologic). Separate multivariate logistic regression analyses (for depression [D], anxiety [A], and comorbid anxiety and depression [AD]) were performed to study the factors associated factors, including age at enrollment, sex, ethnicity, disease duration, inception status (enrolled in the clinic within 1 year of SLE diagnosis), fibromyalgia, and SLE phenotypic manifestations, comparing their significance to the group with neither A or D.

Results: 341 patients (89.7% female), with mean age 45.917.8 years were studied. The prevalence of A and D in the cohort was 34% and 27% respectively, while 21% of the total cohort was found to have AD. Among the 3 outcome groups, MSK system involvement has a significantly higher prevalence when compared to the group with neither A or D (p-values< 0.05). Skin system involvement was also significantly more prevalent among A, D, and AD groups, in comparison to the normal group. Patients with A had significantly higher odds of skin system involvement compared to the normal group (OR=1.8; 95% CI: 1.1, 3.0). Patients with D had higher odds of MSK (OR=1.9; 95% CI: 1.1, 3.5) and skin system involvement (OR=1.8; 95% CI: 1.04, 3.2) compared to the group with neither A or D. Additionally, the odds of skin system involvement was significantly higher among patients with AD, compared to the group with neither (OR=2.0, 95% CI: 1.2, 3.9). In all three models, employment and fibromyalgia were also significant. Age at enrolment was significant in the D and AD models, while inception patient status was significant in the D model exclusively.

Conclusion: SLE phenotypic manifestation, specifically those involving patients' skin or MSK systems, along with fibromyalgia, socio-demographic factors, and inception status were associated with anxiety or depression. Routine patient screening and evaluation, especially among patients with shorter disease duration, for these associated factors may facilitate the diagnosis of these mental health disorders, and allow for more timely diagnosis and intervention strategies.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Treatment of systemic lupus erythematosus (SLE) with cyclophosphamide is associated with premature menopause, especially those at an older age of treatment and those receiving a higher cumulative dose. We hypothesized that reduced ovarian reserve caused by ovarian autoimmunity would be associated with premature ovarian failure among SLE patients treated with cyclophosphamide. We undertook this study to test this hypothesis. Treatment of systemic lupus erythematosus (SLE) with cyclophosphamide is associated with premature menopause, especially those at an older age of treatment and those receiving a higher cumulative dose. We hypothesized that reduced ovarian reserve caused by ovarian autoimmunity would be associated with premature ovarian failure among SLE patients treated with cyclophosphamide. We undertook this study to test this hypothesis.

Methods: All SLE women with a history of cyclophosphamide therapy were identified in the Lupus Registry and Repository (LFRR). The subjects met the revised ACR classification criteria. Spontaneous lack of menstrual periods prior to age 45 was defined as premature menopause. Anti-ovarian antibodies were measured by ELISA (Anti-Ovarian Ab ELISA, IBL, Minneapolis, catalog # IB9184). We used Student's T test and chi square testing for data analyses. Approval was obtained from local Institutional Review Boards.

Results: Among ~3000 SLE women enrolled in the LFRR, 258 had received cyclophosphamide. Of these 169 had menopause before age 45, while 73 underwent menopause after age 45. 16 patients were over age 45 and still having menstrual periods at the time of evaluation. Thus, there were a total of 89 SLE women who did not have premature menopause. Among the 169 with premature ovarian failure the mean anti-ovarian antibody level was 16.2 units (SD=20.3), while the mean among those without premature menopause was 17.4 units (SD=21.7). These values were not statistically different. Considering categorical results, 11 of 169 (6.5%) SLE women with premature menopause had a positive result while 8 of 89 (8.9%) without premature menopause were positive (X^2=0.53, p=0.46, OR=1.02 (95% CI 0.95-1.1)).

Conclusion: A small percentage of SLE patients treated with cyclophosphamide had anti-ovarian antibodies in their serum. Nonetheless, the presence of these antibodies was not related to premature menopause.

Abstract Number: 1592

Defining the SLE-Associated Pulmonary Arterial Hypertension Phenotype

Marisa Mizus,[1] Jessica Li,[1] Daniel Goldman,[2] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary arterial hypertension (PAH) is a leading cause of death in SLE patients. Hypocomplementemia, antiphospholipid antibodies, and elevated antibodies to RNP and Ro are correlated with SLE-associated PAH. In this study, we sought to define the SLE phenotype associated with PAH.

Methods: 207 (8%) SLE patients with pulmonary hypertension (PH), defined as a right ventricular systolic pressure greater than 40 mmHg on transthoracic echocardiogram or as pulmonary artery dilatation noted on CT of the chest, were identified from a longitudinal SLE cohort (94% female, 56.5% African American, 39% Caucasian, mean age 45.6 years). All patients with SLE met either the revised ACR or SLICC classification criteria.

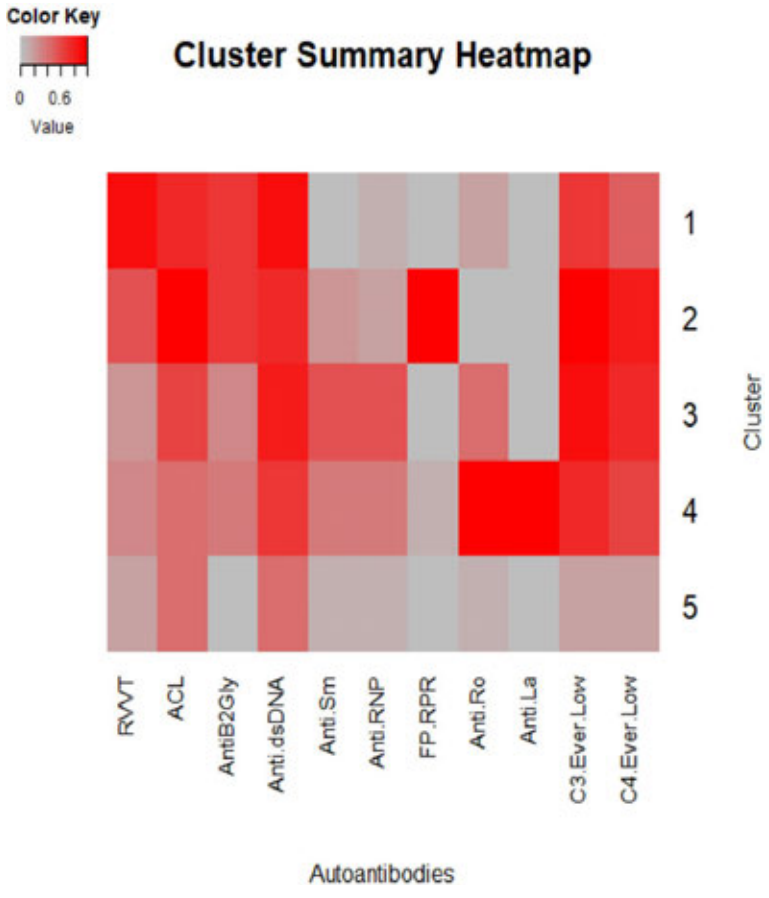

Figure. Clustering of Pulmonary Arterial Hypertension Patients by Autoantibodies

136 patients with SLE and PAH were eligible for the cluster analysis, as they had information available for all 11 selected autoantibodies (lupus anticoagulant, anticardiolipin, anti-beta2 glycoprotein 1, anti-dsDNA, anti-Sm, anti-RNP, false positive(FP)-RPR, anti-Ro, anti-La, and hypocomplementemia (C3 ever low or C4 ever low)). Agglomerative hierarchical clustering algorithm with Ward's method was used to cluster the patients who had PAH, based on their history of autoantibodies. All analyses were performed in JMP version 13.0 and R version 3.5.1 using package cluster and gplots.

Results: Five clusters were identified, representing five different phenotypes. Clusters 1 and 2 had high frequencies of hypocomplementemia, antiphospholipid antibodies, and anti-dsDNA. Cluster 2 additionally had a high frequency of FP-RPR. Cluster 3 had high frequencies of hypocomplementemia, anticardiolipin, anti-Sm, anti-RNP, and anti-dsDNA, but only moderate frequencies of anti-Ro. Cluster 4 had high frequencies of hypocomplementemia, anti-Ro, anti-La, and anti-dsDNA. Cluster 5 had only moderate frequencies of anti-dsDNA and anticardiolipin.

Conclusion: Our data indicate an important association in several, but not all, clusters between antiphospholipid and PAH in SLE. Elevated anti-dsDNA and hypocomplementemia in some clusters may represent an association with active SLE in these subsets. Two clusters were antiphospholipid antibody predominant and two clusters were extractable nuclear antigen predominant, which may represent different pathophysiology and associate with divergent responses to immunosuppressive therapy.

Heart Rate Visit-to-Visit Variability in Patients with Systemic Lupus Erythematosus Is Associated with Increased Mortality

Tyler Reese,[1] Alyson Dickson,[1] Jocelyn Gandelman,[1] Sarah Bayefsky,[1] April Barnado,[1] Katherine Barker,[1] C. Michael Stein,[1] Vivian Kawai,[1] and Cecilia Chung[1], [1]Vanderbilt University Medical Center, Nashville, TN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with systemic lupus erythematosus (SLE) have increased mortality compared to the general population. Heart rate visit-to-visit variability (HRVVV) has emerged as an adverse risk factor for long-term outcomes, particularly in patients with cardiovascular disease. SLE patients represent a high-risk population for cardiovascular disease; however, the relationship between HRVVV and all-cause mortality in patients with SLE has not been examined. We studied the association between increased HR visit-to-visit variability and all-cause mortality in patients with SLE.

Methods: We identified a cohort of patients with SLE using a previously validated algorithm (PPV 94%) from a de-identified version of an academic medical center's electronic health record that contains more than 2.8 million patients. Demographic variables (age, race, and sex), ICD9 codes, laboratory results, and HR measures were extracted. We excluded HR measures from inpatient admissions or emergency department visits, measures for individuals under 18, measures < 40 or >140 beats per minute, and individuals with fewer than three outpatient measures. HR variability was defined as the intraindividual standard deviation of all qualifying measures. The primary outcome was all-cause mortality with incident rate ratios (IRR) calculated using Poisson regression.

Results: A total of 687 patients with SLE met our inclusion criteria with 16,981 heart rate measures. The median intraindividual standard deviation was 12.1 (mean 12.51 ± 4.05). HRVVV correlated significantly with age and creati-

Table 1: Factors associated with heart rate visit-to-visit variability in SLE

Variable	Spearman coefficient	p-value
Age	-0.23	<0.001
Creatinine	-0.13	<0.001
C-reactive protein	-0.002	0.97
Charlson score	-0.03	0.34
C3	0.02	0.55
C4	0.005	0.91
Body mass index	-0.04	0.35

Table 2: Heart rate visit-to-visit variability and mortality in SLE

Variable	Incidence Rate Ratio (95% CI)	p-value
Unadjusted	1.10 (1.06-1.15)	<0.001
Adjusted for age, sex, race, and Charlson baseline score	1.14 (1.09-1.19)	<0.001

nine, but not with C-reactive protein, C3, C4, nor body mass index (Table 1). Over a median follow-up of 5.7 years, 66 patients died. One SD of HRVVV was associated with a higher risk of mortality (IRR: 1.10 95% CI: 1.06-1.15, p< 0.001). After adjustment for age, sex, race, and baseline Charlson comorbidity score, the association between HR variability and increased mortality remained significant (IRR: 1.14, 95% C.I.: 1.09-1.19, Table 2).

Conclusion: In patients with SLE, higher heart rate visit-to-visit variability was associated with increased mortality independent of age, sex, race, and baseline comorbidities.

High Expression of CD38 on CD8 T Cells Predicts Increased Burden of Infections in Patients with SLE

Lama Mulki,[1] Abel Suarez-Fueyo,[2] Eri Katsuyama,[2] Vasileios Kyttaris,[2] and George Tsokos[2], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We have previously reported that CD38 gene expression in the peripheral blood T cell from patients with SLE is increased. $CD8^{+}CD38^{+}$ T cells have impaired cytotoxicity leading to increased risk of infections.

The purpose of the current study was to further investigate whether the expansion of $CD8^+CD38^+$ T cells in patients with SLE predicts increased load of infectious episodes.

Methods: CD38 surface expression was measured by flow cytometry in fresh T cells from patients with SLE (n=43) over a period of time ranging from 6 to 24 months. The expression of CD38 on the surface of T cells was estimated my flow cytometry. Clinical parameters (SLEDAI, flare rate and medications) as well as rate and type of infections were recorded from patients with SLE for further analysis.

Results: CD38 surface expression was higher in CD8+ T cells from patients with SLE (30%±3, n=37) compared to normal controls (18.7% 1, n=18, p< 0.001). Within group of patients with SLE we identified two groups of patients: those with high (> 28.9%; mean +2 standard deviations of normal values) and those with low (< 28.9%) expression levels of CD38. We followed these patients longitudinally and recorded number of infections over the study period. 43 subjects were found to had two or more visits. Interestingly, 23 out of the 30 SLE patients with lower percentage of CD8+CD38+ T cells did not report any infections at the initial visit compared with 4 out of the 14 SLE with higher CD8+CD38+ percentages who reported at least one infectious episode (p< 0.01 using Chi-squared test). Even more, patients with SLE who had a higher percentage of CD8+CD38+ T cells (n=32) at their initial visit were more prone to developing subsequent infections (1.1 infections/year) compared to those with low percentage of CD8+CD38+ cells (n=14, 0.7 infection/year, p=0.05). Early analyses did not reveal an association with disease activity and treatment.

Conclusion: Our data indicate that increased percentage of $CD8^+CD38^+$ T cells in the peripheral blood of patients with SLE predicts increased numbers of infections. Identification of this subset of patients should alert care-takers to expect, identify and treat promptly in order to limit morbidity and mortality.

Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that predominantly afflicts women. One of the most debilitating symptoms experienced by SLE patients is persistent fatigue. We previously found that fatigue, as measured by the Fatigue Severity Scale (FSS), is independent of SLE disease activity, as measured by the Safety of Estrogen in Lupus Erythematosus National Assessment Group-Systemic Lupus Erythe-

matosus Disease Activity Index (SELENA-SLEDAI) scores. The purpose of this study is to characterize the response and adaptation to an aerobic exercise program in SLE patients with significant fatigue and minimal disease activity.

Methods: A cohort of 20 SLE patients with minimal to no disease activity (SELENA-SLEDAI < 4) and a FSS score of > 3 are being enrolled in a supervised, aerobic exercise training program that consists of vigorous walking on a treadmill for 30 minutes, three times a week for 12 weeks. The primary outcome measure is the time it takes the subjects to reach anaerobic threshold during a cardiopulmonary exercise test (CPET), which is performed pre and post exercise training. Vascular endothelial dysfunction and arterial stiffness are measured by non-invasive vascular studies. Secondary outcome measures such as the FSS, SELENA-SLEDAI scores and the Patient-Reported Outcomes Measurement Information System (PROMIS) survey assesses changes in disease activity and fatigue.

Table-3- Patient-Reported Outcomes Measurement Information System (PROMIS) pre and post Exercise Study			
PROMIS Domains	Pre-exercise Median (Q1--Q3)	Post-exercise Median (Q1--Q3)	*p-value*
Physical Function	4.5(4--4.8)	4.8(4.5--4.9)	0.0781
Anxiety	2(1.1--2.8)	1.5(1--2.4)	**0.0156**
Depression	1.6(1.3--1.9)	1(1--1.8)	0.0938
Fatigue	2.3(1.8--2.4)	1.8(1.3--2)	**0.0195**
Sleep Disturbance	2.6(2.4--2.8)	2.3(1.6--2.5)	0.0898
Satisfaction with Social Roles	1.3(1.1--1.8)	1.4(1--2.3)	0.7188
Pain Interference	2(1.1--2)	1(1--1.1)	0.1563
Pain Intensity	2(2--4)	1(1--2)	0.1211
P-Value (*) were obtained using Wilcoxon signed-rank test. Median; Q1, first quartiles; Q3, third quartile			

Results: So far, 13 SLE patients have been screened and enrolled into the protocol. Of the 13 patients enrolled, the average age is 42 years with the mean disease duration of 9.5 years. In the 9 patients that have completed the study so far, baseline average SLEDAI score was 1.4 and remained unchanged at the end of the study. All patients attended ≥ 80% of the exercise sessions, with no serious adverse events. The FSS average baseline scores was 4.8 and significantly decreased to 2.2 following the exercise program (p=0.0039). At the end of the study, the PROMIS survey also demonstrated an overall improvement most significantly in anxiety and fatigue.

Conclusion: Supervised aerobic exercise training improves patient-reported fatigue in SLE, without exacerbation of disease activity. These patients with SLE were able to tolerate vigorous exercise training, suggesting physical exercise may be a valuable intervention to consider for SLE patients with significant fatigue and minimal disease activity.

Abstract Number: 1596

Assessing the Validity of QRISK3 at Predicting Cardiovascular Events in Systemic Lupus Erythematosus Patients

Lisa Zhu,[1] Manpreet Singh,[1] Sonia Lele,[1] Mei Liang,[2] Lori Sahakian,[1] Jennifer Grossman,[1] and Maureen McMahon[1], [1]UCLA David Geffen School of Medicine, Los Angeles, CA, [2]Williams College, Williamstown, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: It has been well established that patients with systemic lupus erythematosus (SLE) have an increased risk of developing cardiovascular disease (CVD). Traditional CVD risk calculators such as the Framingham risk score (FRS) have been shown to underestimate risk in this patient population. QRISK3 is unique in including SLE and corticosteroid use as risk factors and has been shown to enhance CVD risk detection in a cohort of SLE patients in the UK. The purpose of this study was to assess the validity of QRISK3 compared to other cardiovascular risk models (FRS, modified FRS and PREDICTS) in predicting CVD risk in a cohort of SLE patients in the United States.

Table 1: Comparison of Sensitivity and Specificity between Risk Calculators

	Sensitivity (%, 95% CI)	Specificity (%, 95% CI)	PPV (%, 95% CI)	NPV (%, 95% CI)
QRISK3 >10%	46.0 (33.4-59.1)	80.9 (75.4-85.6)	38.2 (29.9-42.2)	85.4 (82.2-88.1)
FRS >10%	11.1 (4.6-21.6)	93.9 (90.1-96.6)	31.8 (16.6-52.3)	80.5 (79.0-81.9)
Modified FRS >10%	41.3 (29.0-54.4)	72.0 (66.0-77.5)	27.4 (20.9-35.0)	82.7 (79.3-85.7)
High PREDICTS	66.7 (53.7-78.1)	63.8 (57.5-69.8)	32.1 (27.1-37.5)	88.2 (83.9-91.5)

Table 2: Comparison of Area under ROC between Risk Calculators

	Area under ROC	Std Error	Asymptomatic Sig.	95% CI
QRISK3 >10%	0.635	0.042	0.001	0.553-0.716
FRS >10%	0.525	0.042	0.539	0.443-0.607
Modified FRS >10%	0.566	0.041	0.105	0.485-0.647
High PREDICTS	0.652	0.039	0.000	0.557-0.728

Methods: We studied a prospective cohort of 309 patients with SLE without prior history of any cardiovascular event, defined as coronary artery disease (CAD), myocardial infarction (MI), ischemic stroke, transient ischemia attack (TIA) or peripheral artery disease (PAD). Patients received care at an academic medical center and were followed over a 10-year period. Baseline data on demographic factors, diagnosis and clinical values were obtained via chart review and used to calculate QRISK3, FRS, modified FRS (FRS multiplied by 2, as described by Urowitz et al., 2016) and PREDICTS (Predictors of Risk for Elevated Flares, Damage Progression, and Increased Cardiovascular Disease in Patients with SLE) scores. Chi-squared test was used for dichotomous variables and Student's t-test for continuous variables. Receiver operator characteristic (ROC) curves were created using SPSS software to evaluate the diagnostic performance of QRISK3, FRS, modified FRS and PREDICTS using a threshold of risk greater than 10% for the first 3 calculators and "high-risk" categorization for PREDICTS.

Results: The cohort was composed of 98% females, and the mean age of all patients was 42.3 years. Sixty-three of the 309 patients (20.2%) experienced a cardiovascular event during the 10-year follow-up period. Forty-six percent of patients who had a cardiovascular event had a QRISK3 risk score greater than 10%, whereas 19.1% of patients who did not have an event had a QRISK3 score greater than 10% ($p< 0.001$). In comparison, 11% of patients who had a cardiovascular event had a FRS greater than 10%, whereas 6.2% who did not have an event had an FRS greater than 10% ($p=0.17$). The corresponding numbers for modified FRS and PREDICTS were 41.3% and 28.0% ($p=0.04$), and 67% and 36% ($p< 0.001$), respectively. A QRISK3 score greater than 10% had sensitivity of 46.0% and specificity of 80.9%, with comparison to other calculators shown in Table 1. The area under the ROC using QRISK3 greater than 10% was larger than that using FRS or modified FRS greater than 10%, though it was slightly smaller than that using high PREDICTS score (Table 2).

Conclusion: Both QRISK3 and PREDICTS demonstrated better performance at predicting risk of CVD in this cohort of SLE patients compared to FRS and modified FRS. These results indicate that QRISK3 may be a more useful risk assessment tool in this population compared to traditional calculators.

Abstract Number: 1597

Assessing Long-term Poor Outcomes in Systemic Lupus Erythematosus Patients with Acute Coronary Syndromes

Paramjit Singh [1], [1]Kaiser Permanente Fontana, Fontana

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a significant risk factor for coronary atherosclerosis, independent of the classic risk factors. Previous studies have found poor acute outcomes in regard to in-hospital mortality and prolonged hospitalizations in SLE patients with acute myocardial infarction. This study aims to examine long term adverse events in lupus patients who have a first time acute coronary syndrome (ACS). We hypothesize that SLE patients with ACS are more likely than age and gender-matched controls to have worse outcomes.

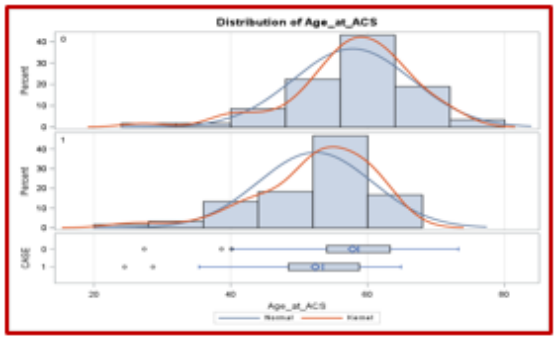
Methods: This is a retrospective study conducted within time frame of 2007-2019 that involved adults above the age of 18. The study comprised of two groups including SLE and non SLE group with 60 patients in each. SLE group consisted of patients diagnosed with SLE who experienced a first time ACS. A second group (non SLE) comprised of randomly selected age, ethnicity, and gender-matched patients with ACS who have no history of SLE. A multivariate analyses was performed to adjust for the confounders. Primary outcome included major adverse clinical events (MACE), including 30-day readmit, 30-day CV readmit, CVA, CHF admission, ACS readmit, and CV death. Secondary outcomes evaluated included LV dysfunction, STEMI, and multivessel CAD.

Results: Our results indicated that on average, the SLE patients develop ACS 5.5 years earlier than non SLE patients. There is evidence of more single vessel and more nonobstructive disease in the SLE patients (77% vs 47%, p=0.0003). SLE patients have more STEMI (35% vs 11%, p = 0.002) and less unstable angina (11% vs 42%, p =

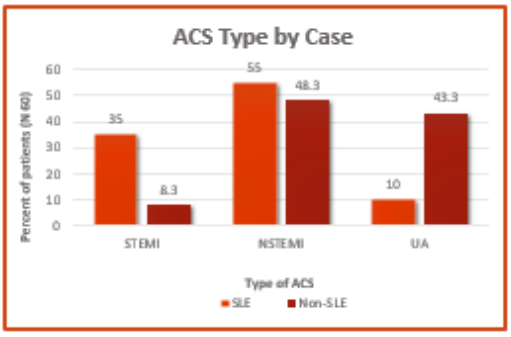
	SLE		Non-SLE		
Variable	N	%	N	%	p-value
HLD	43	72%	40	67%	0.5532
HTN	45	75%	49	82%	0.3754
DM2	13	22%	37	62%	<0.0001
CKD	19	32%	7	12%	0.0078
FHx	16	27%	23	38%	0.1725
Smoking	23	38%	29	49%	0.2342
Alcoholic	3	5%	5	8%	0.4492
Addict	2	3%	1	2%	0.5686

Table 1: Study population covariable characteristics

Demographic characteristic and traditional risk factor profile

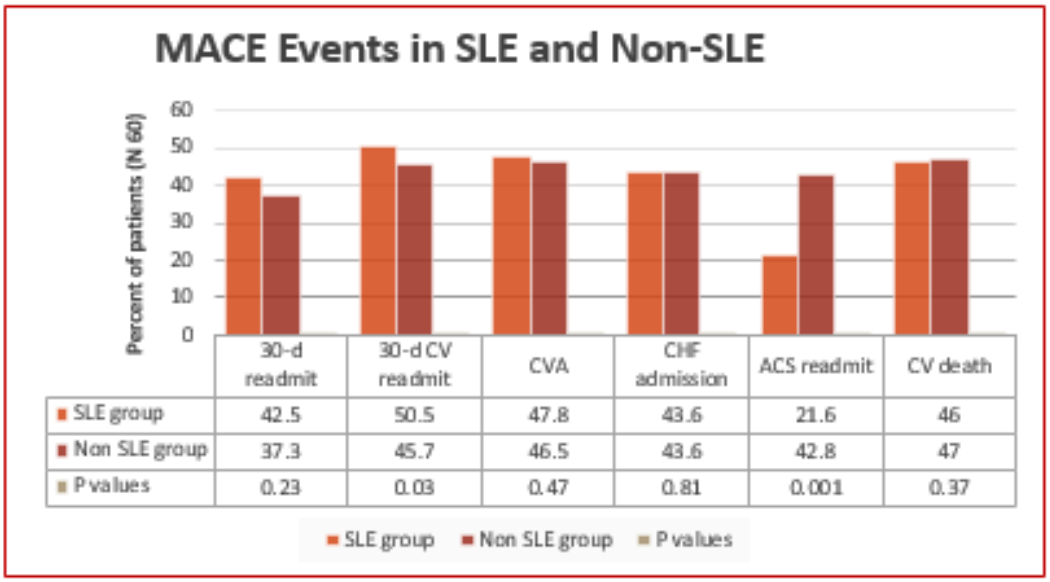


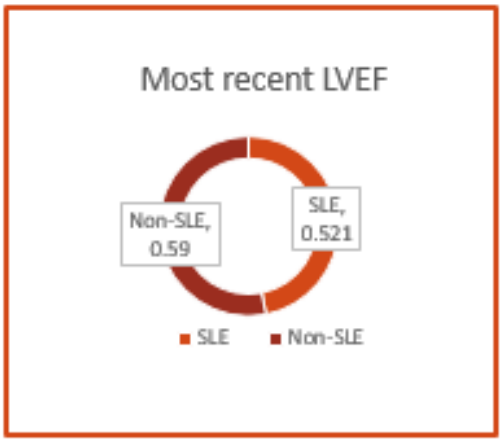
On average, the SLE patients develop ACS 5.5 years earlier than non SLE patients.



ACS type: SLE patients have more STEMI (35% vs 8%, p 0.002) & less unstable angina (10% vs 43%, p = 0.0001)

Distribution of age at ACS event and ACS type





MACE events and Left ventricular ejection fraction (LVEF) in SLE and Non SLE group

0.0001). For MACE, 30-day readmission, 30-day CV readmission, and CV death was more frequent although not statistically significant in patients with SLE. These findings may be statistically significant with bigger sample size that would increase the power of the study or an increased time frame of the study as MACE events of stroke or cardio-

vascular death may take longer to manifest. Based on propensity score balanced weights, SLE patients have worse LV systolic function and they have less rebound in LVEF during follow up (p value < 0.001).

Conclusion: Based on the results of our study, we conclude that SLE patients develop ACS much earlier than their age, gender, and ethnicity matched non SLE cohort. SLE group has less severe CAD lesions (shown by 1 vessel disease) but more acute events, manifested by STEMI. Inflammatory mediators likely contribute to plaque instability that lead to rupture, thrombosis, and vessel occlusion. Identification of risk factors in SLE patients may enable early and aggressive intervention and risk factor modification. The results of this study show that SLE as an atherogenic risk factor results in worse long-term outcomes for patients with ACS as compared to non-SLE patients including early onset of disease, worse LV function as well as worse 30 day CV readmit. Further directions of this study can implore into whether tighter control of inflammation will reduce the risks of acute ACS events in patients with SLE.

Disclosure: P. Singh, None.

Disability Among Subtypes of SLE

Jennifer Rogers,[1] Raeann Whitney,[1] Megan Clowse,[1] Lisa Criscione-Schreiber,[1] Jayanth Doss,[1] David Pisetsky,[2] Rebecca Sadun,[1] Kai Sun,[1] and Amanda Eudy[1], [1]Duke University, Durham, [2]Duke University, Durham VAMC, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The rate of medical disability among patient with systemic lupus erythematosus (SLE) ranges from 20-40% and is associated with a number of socioeconomic, disease-related and clinical factors. Our group has developed a conceptual model of SLE symptoms reflecting the patients' experience: Type 1 SLE activity includes classic inflammatory manifestations of SLE such as arthritis and serositis, whereas Type 2 SLE activity includes fatigue, depression, widespread pain, sleep dysfunction and perceived cognitive dysfunction. We examined the socioeconomic status of patients within these SLE subtypes and factors associated with disability.

Methods: This was a cross-sectional study of SLE patients (SLICC classification criteria) at a university lupus clinic (September 2018 to March 2019). All patients completed Patient Health Quesionnaire-9 (PHQ-9), 2016 ACR fibromyalgia criteria and socioeconomic surveys. Patients were divided into 4 groups: active Type 1 SLE (SLEDAI ≥ 6, clinical SLEDAI ≥ 4, active lupus nephritis, or PGA ≥ 1.5); active Type 2 SLE (fibromyalgia severity score (FSS) ≥ 10); Mixed

Table 2 Clinical and socioeconomic differences between disabled and non-disabled groups

SLE (both Type 1 and 2); Minimal SLE (neither Type 1 nor 2). Differences were analyzed by Fisher's exact test. A step-wise regression analysis examined predictors for disability.

Results: 164 patients completed the surveys (93% female, mean age 43.5 years, 58% Black, 39% Caucasian, 2% Asian, average length of disease 15 years). The demographics of the SLE subtypes were similar, except that more patients with active Type 1 SLE were Black and more with active Type 2 SLE were unable to work (Table 1).

Disabled patients were older, less educated, had less social support, longer disease duration, less historical nephritis, and were more likely to be uninsured or be on Medicare/Medicaid insurance. Furthermore, disabled patients had greater Type 2 symptoms including a higher fibromyalgia severity score (FSS) (10.8 vs 7.2, p = 0.0007), symptom severity score (5.7 vs 4.2, p = 0.005) , more frequent sleep dysfunction (55% vs 31%, p =0.005), and more areas of pain (5.1 vs 2.8, p = 0.005).

There were no differences in current Type 1 SLE activity between patients with and without disability; these two groups had similar SLEDAI and physician's global assessment, as well as similar features of arthritis, cardiopulmonary, hematologic, or cutaneous SLE.

In multivariate analysis, patients on disability were older (OR 1.07 for every 1 year in age, 95% CI:1.03, 1.12), less educated (OR 2.72, 95% CI: 1.15, 6.45), had a lower income (OR 3.78, 95% CI 1.26, 11.40), and had a higher FSS (OR 1.08 for every 1 point in FSS, 95% CI: 1.00, 1.16).

Conclusion: The overall rate of disability mirrors that of other SLE cohorts, but this study provides evidence that Type 2 not Type 1 SLE that drives SLE patients' limitations in the workforce. As such, this study suggest that addressing pain, fatigue, and sleep dysfunction could improve health-related quality of life and the care of SLE patients. Incorporating the Type 1 and Type 2 categorization system into clinical practices encourages the provider to focus on all aspects of SLE, including the Type 2 symptoms, which contribute significantly to the high societal cost of SLE.

The Impact of Body Mass Index Variability in Systemic Lupus Erythematosus

Xuan Gao,[1] Tejal Vashi,[1] and S Sam Lim[2], [1]Emory University School of Medicine, Atlanta, GA, [2]Emory University, Atlanta, GA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: SLE is a chronic illness that carries both a physical and psychosocial burden, where the cumulative impact can lead to worse global outcomes. One outcome of interest is BMI especially with recent public health efforts highlighting the risk of BMI elevation to obesity and its affiliated metabolic risk factors. We examined the associated features and impact of BMI variability amongst SLE patients.

Methods: The Georgians Organized Against Lupus (GOAL) is a population-based research cohort of SLE patients in Atlanta derived from the Centers for Disease Control and Prevention supported by Georgia Lupus Registry who consent to and complete annual surveys encompassing multiple domains. The 2017 results included calculated BMI and the Patient-Reported Outcomes Measurement Information System (PROMIS) questionnaire for depression with T-score conversion, disease activity (Systemic Lupus Activity Questionnaire, SLAQ), perceived stress (Perceived Stress Scale), discrimination (Everyday Discrimination Scale), and self-assessment of continuity of care with a regular

provider. Logistic regression evaluated the potential relationship between BMI and aforementioned factors. BMI was categorized as either non-elevated (BMI< 25) or elevated (BMI≥25).

Results: The 2017 GOAL survey comprised of 795 patients, of whom 265 (33.3%) had non-elevated BMI and 530 (66.6%) had elevated BMI. African Americans (AA) made up 81.4% of this cohort. The average disease duration was

16.11 ± 10.38 years. Univariate logistic regression analyses demonstrated that older age was linked to elevated BMI (p = 0.016, Table 1). Additionally, greater years of higher education was linked to non-elevated BMI, p=0.0042; whereas being below the federal poverty level and/or being AA carried greater association with elevated BMI (p< 0.001 and p=0.0491, respectively). While disease duration carried no impact on BMI, diagnosis at a later age was linked to higher incidence of elevated BMI, p=0.0116. Patients with elevated BMI had greater disease activity and damage and experienced more discrimination.

Conclusion: The variability of BMI amongst SLE can be associated with different clinical and behavioral impact. Patients with greater disease activity had elevated BMI. They were also likelier to experience more discrimination, but this may be affected by the greater proportion of AA's (81.4%) in the cohort. Poverty was associated with elevated BMI. Further research into understanding the prolonged impact of BMI variability in SLE needs to be investigated and can prove to be instrumental in the overall care of SLE patients.

Background/Purpose: Frailty is a clinical phenotype that increases with age. However, frailty can occur in younger patients with chronic disease, including SLE. Based on few studies, frailty has been found in up to 27.5% of patients with SLE and is associated with increased mortality [1-2]. The prevalence of frailty in other cohorts of patients with SLE and its association with sarcopenia, an important related domain, or patient-centered domains, is unclear.

Methods: Adult women < 70 years old who fulfilled ACR criteria for SLE were recruited from a single center. Exclusions included pregnancy, dialysis, active malignancy, overlap autoimmune syndromes, or severe SLE disease activity. Frailty and pre-frailty were measured according to Fried frailty criteria [3] (Table 1). Patient-reported outcomes were measured using a) global Patient-Reported Outcomes Measurement Information System (PROMIS) computerized adaptive tests and b) the disease-specific LupusQOL. Disease activity was measured with the SELENA-SLEDAI, and damage with the SLICC/ACR index. DXA was used to compute sarcopenia [4] (Table 2). Differences between frail, pre-frail, and non-frail participants were evaluated using chi-square tests and Kruskal-Wallis tests as appropriate.

Results: 50 women enrolled from 8/2018-3/2019. Although median age was only 51 years, 74% and 18% were pre-frail and frail, respectively (Table 1). Frail women had increased disease activity and damage as compared to pre-frail and non-frail women; however, this did not differ significantly across the three groups (Table 2). Age and comorbidities, including fibromyalgia, were similar between non-frail, pre-frail, and frail women. Educational attainment differed significantly across pre-frail, frail and non-frail patients (p=.03), with a larger proportion of lower educational attainment among frail women. Significant differences in PROMIS mobility (p=0.004), physical function (p=0.014), pain interference (p=0.030), and fatigue (p=0.004) and LupusQOL physical health (p=0.008) and pain (p=0.008) were observed across frailty groups, with frail women reporting clinically meaningfully worse scores in all measures. While not statistically significantly different across the frailty groups, frail women were 6x more likely to be sarcopenic (Table 2).

Conclusion: The prevalence of frailty and pre-frailty is high in this cohort of mid-aged women with SLE. Frailty did not appear to be a proxy for comorbidity or fibromyalgia. Compared to pre-frail and non-frail women, frail women had poorer health-related quality of life and a higher proportion of sarcopenia. Data collection is ongoing to clarify the relationship between frailly and potential confounders. If frailty is associated with worse health outcomes, it could be a potential therapeutic target.

Prevalence of Peripheral Neuropathy and Its Electrophysiological Types in Patients with Systemic Lupus Erythematosus

Cynthia Matilda Wendo,[1] George Oyoo,[1] Thomas Otieno Kwasa,[1] Marybeth Maritim,[1] Sybil Nakitare,[2] and Judith Kwasa[1], [1]University of Nairobi, Nairobi, Kenya, [2]Kenyatta National Hospital, Nairobi, Kenya

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

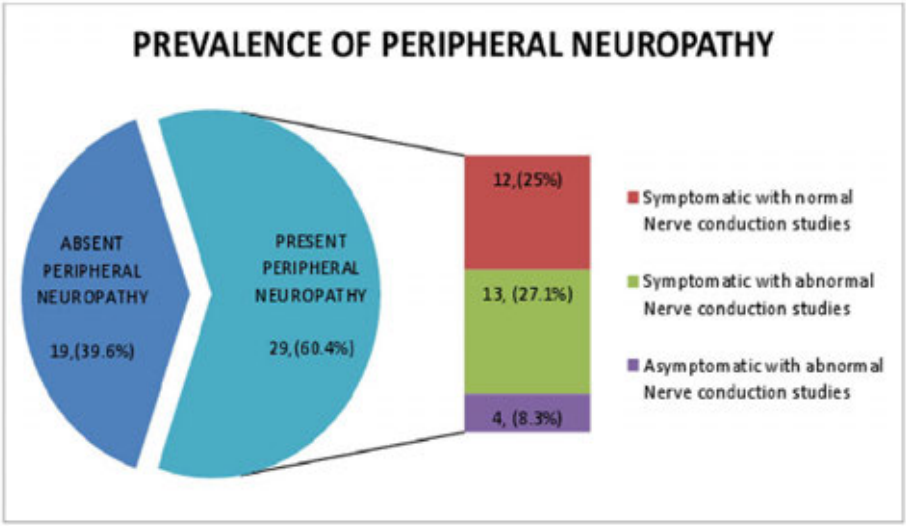

Figure 1: Prevalence of Peripheral Neuropathy and its presentation in the study participants (Sample population N=48)

Background/Purpose: Peripheral neuropathy (PN), one of the neuropsychiatric syndromes of SLE, occurs in 2% to 36% of patients. It has been associated with high disease activity indices and poor quality of life scores. The aim of this study was to determine the prevalence of peripheral neuropathy using clinical evaluation and Nerve Conduction Studies (NCS), to describe its electrophysiological types using NCS; and to correlate quality of life with presence of peripheral neuropathy among SLE patients

Methods: This was a crossectional study of SLE patients attending Rheumatology outpatient clinic. Fourty eight patients with a diagnosis of SLE as per the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria who were 18 years and above were consecutively selected for the study. Patients were excluded if they were Amputees, had history of traumatic involvement affecting the nerves, had foot ulcerations, those with other known causes of peripheral neuropathy such as mixed connective tissues disease, diabetes mellitus, and history of heavy alcohol consumption, chronic renal failure and pernicious anemia. Socio-demographic data and clinical information were obtained from the patient's medical records. Structured history and clinical examination was performed on all patients. All patients had NCS carried out and at least 5 nerves were tested: the median, the ulnar, the peroneal, the sural and the Tibial. Lupus quality of life questionnaire was administered to all patients.

Results: Prevalence of PN was suggestive in 29 out of 48 patients (60.4%). Of these 27.1% were symptomatic for peripheral neuropathy and had abnormal nerve conduction studies while 25 % were symptomatic for peripheral neuropathy and had normal nerve conduction studies. The other 8.3 % had abnormal nerve conduction studies despite being asymptomatic (figure 1). Numbness was the most common symptom complaint in 41.7% of patients. The most common nerve conduction abnormality was demyelination 9(52.94%). However excluding 5 patients found to have carpal tunnel syndrome, then demyelination was 4(23.52%), While axonopathy was found in 5(29.41%) of the patients. Motor neuropathy was the most prevalent nerve conduction syndromes in 9(52.94%) patients. There was a significant correlation between the presence of peripheral neuropathy with lower quality of life scores involving the domains of physical health ($p =< 0.001$), pain ($p=0.012$), planning ($p=0.003$), and fatigue ($p=0.005$).

Conclusion: There is a high prevalence of peripheral neuropathy among SLE patients, with variable clinical and electrophysiologic presentation. Quality of life is scores are lower in affected patients

Persistency in Platelet C4d and Thrombosis Risk Score Associate with Thrombosis in Systemic Lupus Erythematosus

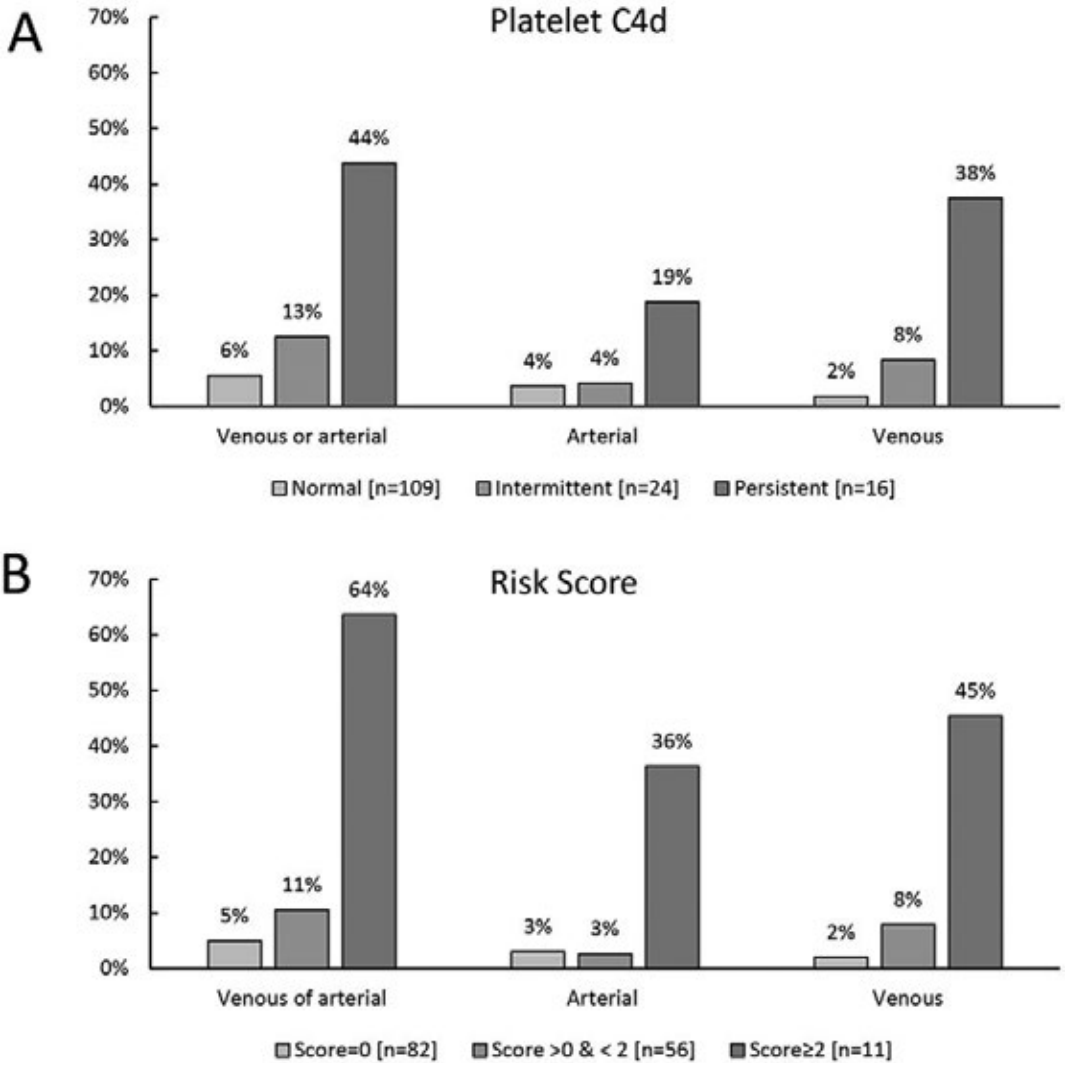
Michelle Petri,[1] John Conklin,[2] Tyler O'Malley,[3] Jo-Anne Ligayon,[2] Leilani Wolover,[2] and Thierry Dervieux[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Exagen, Vista, CA, [3]Exagen, Oceanside, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: A thrombosis risk score containing abnormal Platelet-bound C4d (PC4d), low complement C3 and abnormal anti-phosphatidyl serine prothrombin (PS/PT) IgG antibody has been shown to associate with thrombosis in Systemic Lupus Erythematosus (SLE). Our objective was to evaluate the relationships between persistency in PC4d, risk score and thrombosis during follow-up (FU). A secondary objective evaluated the impact of whole blood Hydroxychloroquine (HCQ) levels in associating with thrombosis.

Methods: This was a longitudinal study of 149 SLE patients (mean age: 47±1 years, 86% female), with (n=16, 11%) or without (n=132, 89%) a history of thrombosis (venous or arterial) in the past 5 years. PC4d was measured using flow cytometry. Percent FU visits with abnormal PC4d status (>20 mean fluorescence intensity [MFI]) was calculated. Persistency in PC4d was defined as abnormal PC4d (>20 net MFI) status at baseline and all FU visits, intermittent PC4d was defined as abnormal PC4d status during at least one visit. Complement C3 (< 81 mg/dl) and anti-PS/PT IgG (>30 Units) were measured using immunoassays. Mean thrombosis risk score for each patient was calculated. Whole blood HCQ levels were measured using liquid chromatography and mean HCQ per patient was calculated. Statistical analysis consisted of Wilcoxon, Fisher's Exact and logistic regression. Odds Ratio (OR) with confidence intervals (CI) were calculated.

Results: 424 FU visits were collected (average 3 visits per patient). Persistent and intermittent PC4d status were observed in 16 (11%) and 24 patients (16%), respectively. Logistic regression analysis revealed that the percentage FU visits with abnormal PC4d status significantly associated with any thrombosis (OR range 11.7 CI 95%: 3.23-42.44) (p< 0.001), venous thrombosis (OR range= 33.4 CI95: 5.8-193.5) (p< 0.001) and approached significance with arterial thrombosis (OR=4.7 CI 95%: 0.9-25.4) (p=0.08) (Figure 1, panel A). During FU, the mean risk score per patient was 0.57±0.76 (n=149). Risk score at FU associated with any thrombosis (OR= 3.8 CI 95%: 2.0-7.2 per unit change, OR range = 53.9 CI 95%: 7.8-372.4) (p< 0.001), venous thrombosis (OR= 3.9 CI 95%: 1.9-8.2 per unit change, OR range = 60.3 CI95%: 6.5-560.8) and arterial thrombosis (OR= 3.0 CI95%: 1.4-6.4 per unit change, OR range = 26.5 CI95%: 2.7-259.4) (Figure 1, panel B). Among 133 patients treated with HCQ, median HCQ levels were 696 ng/ml (Interquartile range [IQR]: 537-989 ng/ml, n=15), 794 ng/ml (IQR: 628-1121 ng/ml, n=22), and 976 ng/ml (IQR: 675-1300 ng/ml, n=96) in the group of patients presenting with persistent, intermittent and normal PC4d status, respectively. Levels were significantly lower in the group of patients with persistent or intermittent PC4d status when compared to normal PC4d (p=0.028). Risk score did not associate with HCQ levels. Lower HCQ levels tended to associate with venous



thrombosis (median=916 ng/ml [IQR: 675-1300], n=10 vs 648 ng/ml [IQR: 382-929], n=123) (p=0.061) but not with arterial thrombosis (p >0.20).

Conclusion: Our data suggest that persistency in PC4d and the thrombosis risk score both associate with thrombosis. Lower HCQ levels may associate with venous thrombosis.

ACR 2019-Stroke Clusters in SLE by Lupus Autoantibodies-Table2
Cluster Analysis of Stroke Patients with Anti-beta2 GP1Cluster Analysis of Stroke Patients without Anti-beta2 GP1

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Stroke is the most common arterial thrombotic event in SLE. It is known to be associated with antiphospholipid antibodies, but clinicians have additional concern about the contribution of SLE. We performed the first cluster analysis of stroke in a longitudinal SLE cohort.

Methods: There were 245 strokes in SLE patients confirmed by brain CT or MRI. Patients were 93.5% female, 50.5% Caucasian, and 45.3% African-American. Age at time of stroke was 41.5 ± 15.0 years (mean ± SD). Autoantibodies included lupus anticoagulant (dRVVT with confirmatory testing), anticardiolipin, anti-dsDNA, low C3, low C4, anti-Sm, anti-RNP, anti-Ro and anti-La. Analyses were done both without (Table 1, 214 patients) and with (Table 2, 145 patients) anti-beta2 glycoprotein 1, due to more missing data on anti-beta2 glycoprotein 1. Clustering was performed using Ward's Hierarchical Clustering method (JMP v 13.0.0, SAS Institute Inc).

Results: Five clusters were identified. Cluster 5 (Table 1) and cluster 4 (Table 2) are an antiphospholipid cluster without strong serologic activity. Cluster 4 (Table 1) and Cluster 5 (Table 2) are clusters without antiphospholipid and without serologic activity. Clusters 1, 2 and 3 (Table 1) and clusters 2, 3 and to some extent cluster 1 (Table 2) are

clusters with serologic activity. Clusters 2 and 3 (Table 1) and cluster 2 (Table 2) have strong anti-Sm and anti-RNP markers, and are associated with more African-American ethnicity compared to the other clusters combined (63.3% vs 42.3%, p=0.0136).

Conclusion: Stroke clustering identified 4 major serologic backgrounds for stroke in SLE: antiphospholipid alone, serologic markers alone, both antiphospholipid and serologic, and a group with neither. Some clusters represent stroke in predominantly African-American patients. These clusters may be helpful in formulating risk scores for stroke in SLE, in risk prevention, and eventually might be useful in treatment.

The Systemic Lupus Erythematosus Cardiovascular Risk Equation

Michelle Petri,[1] Erik Barr,[2] and Laurence Magder[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]University of Maryland School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Accelerated atherosclerosis remains the major cause of late death (after 5 years) in systemic lupus erythematosus (SLE). Yet, the "traditional" cardiovascular risk equations (such as Framingham) consistently underestimate the risk. We revised our data-driven formula for cardiovascular risk in SLE, to base it on data collected during just the first year of follow up in a longitudinal cohort, versus two years.

Methods: We included 1,721 patients from a longitudinal cohort. They were assessed for cardiovascular adverse events (stroke, myocardial infarction [MI], angina or coronary procedures, claudication, or congestive heart failure), for traditional cardiovascular risk factors (age, sex, ethnicity, systolic blood pressure, total cholesterol, smoking, and diabetes mellitus) and for SLE-related risk factors (low C3 and C4, anti-dsDNA, proteinuria, SELENA SLEDAI score, and history of lupus anticoagulant and anticardiolipin) during the first year of follow up. Using Cox proportional hazards modeling, SLE formulas to calculate the 10-year risk of a subsequent cardiovascular event were derived and compared to the Framingham (for all outcomes) and to the American Heart Association/American College of Cardiology (AHA/ACC) formula (for MI and stroke).

	Hazard Ratio (95% CI)	P-value
Age (per decade)	1.41 (1.24, 1.60)	<0.0001
Male (vs. female)	1.56 (1.00, 2.45)	0.052
Systolic Blood Pressure (per 10 mmHg)	1.25 (1.12, 1.39)	<0.0001
Current or Past Smoking	1.74 (1.28, 2.38)	0.0004
Total Serum Cholesterol≥140 mg/dl	2.38 (1.16, 4.87)	0.018
Diabetes Mellitus	2.34 (1.61, 3.40)	<0.0001
SLEDAI (per unit increase)	1.10 (1.04, 1.17)	0.0024
History of Lupus Anticoagulant	1.67 (1.21, 2.31)	0.0021
Low Mean C3 (< 79)	1.89 (1.29, 2.76)	0.0011

ACR 2019-Development of SLE CV Risk Equation-Abstract-Table2
Estimated 10-year risk of a cardiovascular event based on the formulas from the Hopkins Lupus Cohort and the Framingham cohort, given various risk factors

Results: Of the 1,721 patients, 168 had a cardiovascular event after the first year of cohort participation, and during cohort participation. Of these 168 events there were 70 strokes, 27 myocardial infarctions, 27 patients with angina or requiring coronary procedures, 14 patients with heart failure, 13 with peripheral artery disease, 11 with claudication, and 6 with more than one type of event. Table 1 shows the hazard ratios for rates of a cardiovascular event. Using the hazard ratios from Table 1, we compared the estimated 10-year risk based on our formula with the calculated risk using the Framingham formula (Table 2). We also derived a formula for a more restricted definition of cardiovascular event (cardiovascular death, MI and stroke) using hazard ratios from a separate Cox proportional hazards model and derived a formula that was compared with the AHA/ACC formula (Table 3). Using our formulas, which includes SLE-related risk factors, the risk was substantially higher than the estimated risk based on the formulas for the general population.

Conclusion: The excess cardiovascular risk among SLE patients varies substantially depending on the SLE-related risk factors, age, and traditional risk factors. Cardiovascular risk formulas based on individual data from SLE patients from the first year of their rheumatology followup may better estimate 10-year cardiovascular risk among SLE patients than the Framingham or AHA/ACC equations.

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Homocysteinemia is present 8-15% of patients with SLE and is associated with increased risk of atherosclerosis, arterial thrombosis and stroke in SLE patients. Recently, it was found to be an independent predictor of new damage accrual in Mestizo SLE patients. The aim of this study was to determine the association between homocysteinemia and episodes of renal insufficiency.

ACR 2019-homocysteine-Table1
Table-1 Prevalence of Homocysteinemia by time-invariant patient characteristics

Methods: A total of 1,688 SLE patients, diagnosed according to the SLICC or ACR classification criteria, had at least one homocysteine measurement. Among these, 341 had two visits with homocysteine measurement, 572 had three or more. Patients were followed quarterly per protocol. First, patients were classified as having homocysteinemia if their average homocysteine level was above 15 umol/L. and demographic and clinical subgroups were compared

with respect to prevalence of homocysteinemia. Second, we used a longitudinal regression model to explore whether homocysteine levels were associated with serum creatinine levels longitudinally. Third, to assess whether a history of homocysteine was associated with episodes of renal insufficiency, we assessed whether there was a relationship between past measures of homocysteine and episodes of renal insufficiency (defined as serum creatinine exceeding 1.5 mg/dl). For each visit, we calculated the mean homocysteine level based on previous homocysteine levels and those with a mean level over 15 mg/dl were considered as a visit with previous homocysteinemia. We used a multivariable GEE model to assess the association between previous homocysteinemia and later renal insufficiency.

Results: 295 of the patients (17.7%) had homocysteinemia. Patients who were male, African-American, had a smoking history, proteinuria, and neurological manifestations were more likely to have homocysteinemia (Table 1). In the longitudinal analysis, we observed that those patients with generally higher levels of homocysteine tended to have higher levels of serum creatinine and that changes in homocysteine coincided with changes in serum creatinine. Specifically, a 1 umol /L increase in mean homocysteine levels was associated with a 0.04 mg/dl increase in serum creatinine (CI: 0.03, 0.04) ($p< 0.0001$). To assess the relationship between homocysteine and episodes of renal insufficiency, 10779 visits were identified after homocysteinemia, while 43651visits occurred following normal homocysteine levels. The proportion of visits with renal insufficiency was significantly higher in visits following a history of homocysteinemia (21% vs 3%). This association remained significant after adjusting for age, gender, ethnicity, hydroxychloroquine use, previous low C3, and previous proteinuria (CI: 2.7, 6.3) ($p< .0001$).

Conclusion: Homocysteinemia is a strong predictor of renal insufficiency even after adjusting for potential confounders. Homocysteine is a modifiable risk factor, as combination B-vitamins (B6, B12, and folic acid) can reduce it. Although treatment of homocysteinemia fell out of favor for prevention of cardiovascular outcomes, it should be reconsidered for the prevention of renal insufficiency. Longitudinal studies are needed.

Abstract Number: 1606

Association of African- American Ethnicity and Smoking Status and Total and Individual Damage Index in Systemic Lupus Erythematosus

Romy Kallas,[1] Jessica Li,[1] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Smoking and African- American ethnicity are risk factors for systemic lupus erythematosus (SLE). Smoking has been associated with increased prevalence of SLE, increased disease activity and decreased effectiveness of hydroxychloroquine in cutaneous lupus. The objective of the study was to determine the association between smoking status and total damage, as well as individual damage items, in SLE by ethnicity.

Methods: We analyzed data from a longitudinal Lupus Cohort. Damage was recorded using the Systemic Lupus Erythematosus International Collaborating Clinics/ American College of Rheumatology (SLICC/ACR) Damage Index. Poisson regression was used to model the total damage score against ever smoking. Cox regression was used to assess the relationship between time to damage items and ever smoking, stratified by ethnicity. Adjusted hazard ra-

Abstract- ACR 2019-RomyKallas-Table1
Table 1 - Adjusted Associations Between Damage Index Items and Smoking Status

tios (HR) and 95% confidence intervals were reported. For each damage item, patients who had a damage diagnosis prior to or at the date of SLE diagnosis were excluded in the analysis.

Results: The study included 2629 patients. The prevalence of ever smokers was 35.8%. There was no significant difference in total damage score between eve smokers and never smokers after adjustment. Table 1 summarizes the Damage Index findings.

Ever smokers had more atherosclerotic cardiovascular (angina, coronary bypass, myocardial infarction and claudication) damage and skin damage compared to non-smokers. Caucasian SLE patients who ever smoked were more likely to have muscle atrophy. African- American patients who ever smoked were more likely to have any skin damage.

Conclusion: Smoking is a modifiable factor for organ damage in SLE. Our analysis proved the major effect was on cardiovascular damage (angina, coronary bypass, myocardial infarction and claudication). Surprisingly, these cardiovascular damage items have higher hazard ratios in Caucasian smokers. Smoking also increased some skin damage items. These skin damage items hazard ratios were higher in African-Americans.

Abstract Number: 1607

Risk Factors for Avascular Necrosis in SLE: A Multivariate Model

Romy Kallas,[1] Jessica Li,[1] and Michelle Petri[1], [1]Johns Hopkins University School of Medicine, Baltimore, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus patients, particularly those who received corticosteroids are at high risk of avascular necrosis (AVN). A past meta-analysis identified other risk factors including African-American ethnicity, active disease, Raynaud's, arthritis, cyclophosphamide use, and IgM anticardiolipin antibodies. In this analysis, we determined the predictors of AVN in a longitudinal lupus cohort in which Caucasian and African-American ethnicities were well represented.

Methods: We analyzed data from 1986 until April 2019. AVN was recorded using the Systemic Lupus Erythematosus International Collaborating Clinics/ American College of Rheumatology (SLICC/ACR) Damage Index. Cox regression was used to identify variables that were associated with time to AVN. First, we assessed the univariate relationship between each variable and time to AVN. Those variables with significant association with time to AVN were then entered into the multivariable model; the ones that remained significant were retained in the final model. Variables that were highly colinear with highest prednisone were not included in the same model. Hazard ratios (HR) and 95% confidence intervals were reported.

	HR (95% CI)	p-value
Highest dose of prednisone with duration		
None	Ref	
1-40 mg/day for <1 months	2.24 (0.5 ,10)	0.2911
1-40 mg/day for >=1 months	3.04 (0.9 ,10.3)	0.0736
40-60 mg/day for <1 months	2.02 (0.45 ,9.06)	0.3577
40-60 mg/day for >=1 months	5.61 (1.68 ,18.79)	0.0052
60+ mg/day for <1 months	10.17 (3.16 ,32.74)	0.0001
60+mg/day for >=1 months	9.79 (3.09 ,30.96)	0.0001
Ethnicity		
Caucasian	Ref	
African American	1.99 (1.48 ,2.68)	<.0001
Other	2.01 (1.15 ,3.51)	0.0138
Gender: male	1.66 (1.07 ,2.57)	0.0236
Year of SLE diagnosis (per 5 year difference)	0.90 (0.84, 0.96)	0.0008
History of vasculitis	1.57 (1.15 ,2.16)	0.0049
History of obesity	1.47 (1.1 ,1.97)	0.0102
Other variables not significantly predictive of AVN included education level, hypertension, low complement, anti-RNP, anti-Sm, history of lupus anticoagulant, ESRD, and cytotoxic drugs.		

ACR Abstract-AVN and SLE_MP_Table1
Predictors of Avascular Necrosis

Results: This analysis included 2477 patients who were 92.2% female, 39.1% African American, and 52.8% Caucasian. Non- Caucasian patients, male gender, obesity and history of vasculitis conferred a higher risk of AVN. Patients who received prednisone doses more than 60 mg had 10 times the risk of having an AVN, regardless of the duration of treatment, compared to patient who did not receive any prednisone. Patient who were on prednisone 40 mg daily had 6 times the risk of having AVN if the duration of treatment was more than 1 month compared to those who did not receive any prednisone (Table 1). The association between AVN and antiphospholipid antibodies (lupus anticoagulant) was only significant in the univariate analysis.

Conclusion: Prednisone dose remains the most important predictor of AVN. At doses below 60 mg, AVN occurrence is dependent on the duration of highest prednisone dose. However, for doses above 60 mg, the risk is independent of the duration. The major reduction in AVN incidence in later decades likely reflects lower use of such high prednisone doses. Particular attention should be paid to avoidance of prednisone at 60 mg doses in African-Americans, given the doubling of risk of AVN as compared to Caucasians.

Effect of the Metabolic Syndrome on Renal Function Decline in Four Rheumatic Diseases: An 8-year Longitudinal Analysis

Chiu Sum Chu,[1] **Chi Chiu Mok**,[2] Ling Yin Ho,[1] and Chi Hung To[1], [1]Tuen Mun Hospital, Hong Kong, Hong Kong, [2]Department of Medicine, Tuen Mun Hospital, Hong Kong, China (People's Republic)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the effect of the metabolic syndrome (MetS) on renal function decline in four rheumatic diseases.

Methods: Consecutive patients who fulfilled the ACR/SLICC criteria for systemic lupus erythematosus (SLE), EULAR/ACR criteria for rheumatoid arthritis (RA), ASAS criteria for spondyloarthritis (SpA) and the CASPAR criteria for psoriatic arthritis (PSA) were recruited in 2009/2010. At entry, patients recruited had measurement of body weight, height, waist circumference and blood pressure. MetS was defined by the updated joint consensus criteria, using the Asian criteria for central obesity, when ≥3 of the following were present: (1) waist ≥90cm in men or ≥80cm in women; (2) blood pressure ≥130/85mmHg or requiring therapy; (3) serum triglyceride level ≥1.7mmol/L; (4) serum HDL-chol ≤1.0mmol/L in men and 1.3mmol/L in women; and (5) fasting glucose ≥5.6mmol/L. Renal function of the participants was assessed by the 4-variable MDRD formula (eGFR). Patients were followed longitudinally for eGFR change. Change in eGFR was compared between those with and without the MetS at baseline. Regression analysis was performed for the effect of MetS on eGFR decline adjusted for other confounding factors.

Results: 1497 patients were studied (693 RA, 577 SLE, 121 SpA and 106 PSA). The age at entry was highest in RA (53.4±12.0 years) and lowest in SpA (39.0±11.9 years). Disease duration was longest in SLE (9.3±7.2 years) and shortest in PSA (3.6±3.2 years). MetS was present in 137 RA (20%), 85 SLE (15%), 13 SpA (11%) and 39 PSA (37%) patients. Patients were followed for 91.1±12.1 months. The mean decline of eGFR (ml/min/1.73m2) at last observation from baseline was 5.00±13.5 in RA, 4.16±11.6 in SpA, 3.95±12.3 in PSA and 8.93±16.4 in

SLE (p=0.03; one-way ANOVA). The proportion of patients with eGFR decline by ≥10% was also greatest in SLE (41%) compared with RA (29%), SpA (24%) and PSA (25%) patients (p< 0.001). Among patients with SLE, a significantly more profound drop in eGFR over 8 years was observed in patients with the MetS at baseline (-17.8±26%) than those without (-7.6±18%; p=0.002). The difference in last eGFR between patients with and without the MetS was significant after adjustment for baseline eGFR, age and sex (65.5±32.2 vs 88.4±24.4 ml/min/1.73m2; p< 0.001). In a linear regression model, eGFR at last follow-up was significantly associated with the baseline eGFR (slope 0.72 SE 0.03; Beta 0.77; p< 0.001), renal involvement (slope -4.36 SE 1.30; Beta -0.08; p=0.001) and the MetS (slope -6.88 SE 1.86; Beta -0.09; p< 0.001). In patients with RA/SpA/PSA, eGFR also showed a greater trend of decline over time in those with MetS than without, but the difference did not reach statistical significance.

Conclusion: Among patients with common rheumatic diseases, SLE showed the greatest decline in renal function over time. presence of MetS in SLE significantly accelerated renal function decline over time independent of the presence of renal disease. The MetS also unfavorably affected eGFR in patients with inflammatory arthritis. A more detailed analysis on the causes of eGFR decline in individual diseases and a longer period of follow-up of the renal function is needed.

Organ Damage Free Survival in Southern Chinese Patients with Active Lupus Nephritis

Chi Chiu Mok,[1] Chi Shan Sin,[2] Kai Ching Hau,[2] and Tse Hoi Kwan[2], [1]Department of Medicine, Tuen Mun Hospital, Hong Kong, China (People's Republic), [2]Tuen Mun Hospital, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To study the organ damage free survival and its predictive factors in patients with active LN.

Methods: Consecutive patients who fulfilled ≥4 ACR/SLICC criteria for SLE and with biopsy proven active LN between 2003 and 2018 were retrospectivey analyzed. Those with organ damage before LN onset were excluded. Data on renal parameters and treatment regimens were collected. Complete renal response (CR) was defined as normalization of serum creatinine (SCr), urine P/Cr (uPCR) < 0.5 and inactive urinary sediments. Partial renal response (PR) was defined as ≥50% reduction in uPCR and < 25% increase in SCr. Organ damage of SLE was assessed by the ACR/SLICC damage index (SDI). The cumulative risk of having any organ damage or mortality since LN was studied by Kaplan-Meier's analysis. Factors associated with a poor outcome were studied by a forward stepwise Cox regression model, with entry of covariates with p< 0.05 and removal with p >0.10.

Results: 273 LN patients were identified but 64 were excluded (organ damage before LN onset). 211 LN patients were studied (92% women; age at SLE 30.4±13.5 years; SLE duration at LN 1.9±3.1years). 47 (22%) patients had nephrotic syndrome and 60 (29%) were hypertensive. Histological LN classes was: III/IV±V (75.1%), I/II (7.8%) and pure V (17.1%) (histologic activity and chronicity score 7.0±4.2 and 1.8±1.5, respectively). Induction regimens were: prednisolone (33.1±17.5mg/day) in combination with intravenous cyclophosphamide (CYC) (21.4%; 1.0±0.2g per

pulse), oral CYC (8.6%; 96.4±37.8mg/day), azathioprine (AZA) (14.3%; 78.6±25.2mg/day), mycophenolate mofetil (MMF) (22.8%; 1.9±0.43g/day) and tacrolimus (TAC) (17.1%; 4.3±1.1mg/day). After a follow-up of 8.6±5.4 years, 94(45%) patient developed organ damage (SDI≥1) and 21(10%) patients died. The commonest organ damage was renal (36.3%) and musculoskeletal (17.9%), and the causes of death were: infection (38.1%), malignancy (19.0%), cardiovascular events (9.5%) and ESRF complications (9.5%). At last visit, 114 (55%) patients survived without any organ damage. The cumulative organ damage free survival at 5, 10 and 15 years after renal biopsy was 73.5%, 59.6% and 48.3%, respectively. The 5, 10 and 15-year renal survival rate were 95.2%, 92.0% and 84.1% respectively. In a Cox regression model, nephritic relapse (HR 3.72[1.78-7.77]), proteinuric relapse (HR 2.30[1.07-4.95]) and older age (HR 1.89[1.05-3.37]) were associated with either organ damage or mortality, whereas CR (HR 0.25[0.12-0.50]) at month 12 were associated with organ damage free survival. Baseline SCr, uPCR and histological LN classes were not significantly associated with a poor outcome. Among patients with class III/IV LN, the long-term organ damage free survival were not significantly different in users of MMF (reference) from CYC (IV/oral) (HR 1.45[0.76- 2.75]) or TAC (HR 1.03[0.26-1.62]) as induction therapy.

Conclusion: Organ damage free survival is achieved in 55% of patients with active LN upon 9 years of follow-up. CYC/MMF/TAC based induction regimens did not differ for the long-term outcome of LN. Targeting complete renal response and preventing renal relapses remain important goals of LN treatment.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: We previously constructed a frailty index (FI) as a measure of susceptibility to adverse outcomes among patients with systemic lupus erythematosus (SLE). In this work, higher baseline FI values were associated with increased mortality risk during follow-up. However, the association with other clinically important health outcomes has not been described. Therefore, the objective of the current study was to estimate the association of baseline FI values with the risk of subsequent organ damage accrual in a large, prospective, international, inception cohort of SLE patients.

Methods: Patients fulfilling ≥ 4 ACR classification criteria for SLE were recruited within 15 months of diagnosis and were assessed annually for medication use, comorbidities, disease activity (SLEDAI-2K), organ damage [SLICC/ACR Damage Index (SDI)], health-related quality of life [Short-Form 36 (SF-36)], and other measures.

For our analysis, the baseline visit was defined as the first at which both SDI and SF-36 data were available as both instruments, in addition to other variables, were used to generate the baseline FI scores. We determined organ damage accrual during follow-up by subtracting the baseline SDI score from the SDI score at the final study visit. Any change in SDI ≥ 1 defined damage accrual.

Multivariable negative binomial regression was used to estimate the association between baseline FI values and the rate of change in SDI scores per patient-year of follow-up, adjusting for relevant demographic and clinical characteristics. Model fit was evaluated using likelihood ratio (LR) tests and Akaike information criterion (AIC) values.

Results: The 1,549 SLE patients (84.8% of the cohort) eligible for this analysis were mostly female (88.7%) with mean (SD) age 35.7 (13.3) years and median (IQR) disease duration 1.2 (0.9-1.5) years at baseline. Mean (SD) baseline FI score was 0.17 (0.08) with a range from 0 to 0.51.

Over a mean (SD) follow-up of 7.2 (3.7) years, 653 patients (42.2%) had an increase in SDI score. Higher baseline FI values (per 0.05 increment) were associated with higher rates of change in SDI scores during follow-up (Incidence Rate Ratio [IRR] 1.19; 95% CI 1.13-1.25), after adjusting for age, sex, ethnicity/region, post-secondary education, baseline SLEDAI-2K, baseline SDI, and baseline use of corticosteroids, antimalarials, and immunosuppressives.

The addition of the baseline FI to the multivariable model was associated with significant improvement in model fit (LR test statistic 40.49 [p< 0.001]) and relative predictive quality (change in AIC = 3563.60 - 3602.09 = -38.49). Furthermore, the association between the baseline FI and subsequent damage accrual persisted when overlapping damage items were omitted from the FI (IRR 1.12; 95% CI 1.08-1.16) and when the analysis was restricted to the subgroup of patients without organ damage (SDI=0) at the baseline visit (IRR 1.21; 95% CI 1.14-1.30).

Conclusion: Frailty, measured using an FI, predicts organ damage accrual among SLE patients and provides added prognostic value when considered in addition to existing SLE measures. This further supports the FI as a valid and robust health measure in SLE.

Systemic Lupus Erythematosus Registries: Are the Measures Captured in the Real World Similar to Those in Clinical Trials?

Jennifer Lofland,[1] Eric Wan,[2] Pamela Berry,[3] and Chetan Karyekar[4], [1]Janssen Scientific Affairs, LLC, Spring House, PA, [2]Johns Hopkins Bloomberg School of Public Health, Spring House, PA, [3]Janssen Scientific Affairs, LLC, Horsham, PA, [4]Janssen Global Services, LLC, Horsham, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic, autoimmune disease that causes connective tissue inflammation and can result in multiple organ damage. Registries may be a valuable source of real-world data that complements randomized clinical trial data.

To 1) identify SLE registries, 2) determine what measures are collected within the registries, and 3) determine which registries capture metric(s) and/or endpoints which have been collected within a SLE clinical trial.

Methods: Utilizing the Preferred Reporting Items for Systematic reviews and Meta-Analysis (PRISM) guidelines, we conducted a systematic review of the literature search using PubMed, EMBASE, and Scopus databases between 2012 to the present and a gray literature search to identify SLE registries. We reviewed each registry for the following criteria: 1) population diagnosed with SLE, who were 16 years or older; 2) published in English language; and 3) contained content on any of the following measures or endpoints; Short-Form(SF)-36, SRI (SLE responder index),

Characteristic	Registries
Collect SLEDAI, PGA	Monash Lupus Clinic Hopkins Lupus Cohort Childhood Arthritis and Rheumatology Research Alliance (CARRA) International registry-unknown name Swiss Systemic lupus erythematosus Cohort Study (SSCS) Plaquenil LUpus Systemic: PLUS Study
Collect SLEDAI, BILAG	UK BIOGEAS Jiangsu Rheumatology Associates British Isles Lupus Assessment Group Biologics Registry UK Juvenile SLE Cohort Study
Collect SLEDAI, SF36	Asia Pacific Lupus Collaboration 1000 Canadian Faces of Lupus Lupus Outcomes Study
Collect PGA, SF-36	Lupus in Minorities; Nature vs. nurture (LUMINA)
Collect biobank data	UK Juvenile SLE Cohort Study Asia Pacific Lupus Collaboration SPOCS
Collect SF-36	Asia Pacific Lupus Collaboration Lupus Outcomes Study LuLa Study LUMINA 1000 Canadian Faces of Lupus

Table 1: Overview of SLE Registries

SLEDAI (SLE Disease Activity Index), PGA (physician global assessment), BILAG (British Isles Lupus Activity Group), Systemic Lupus Collaborating Clinics (SLICC) damage index, Lupus Quality of Life (LupusQoL), Functional Assessment of Chronic Illness Therapy (FACIT)-fatigue, healthcare utilization, clinical outcomes (e.g. flares) or biobank information.

Results: A total of 41 SLE registries were identified. No registry captures all the components of the SRI-4, the SLEDAI, BILAG, and PGA. Ten registries collect 2 components of the SRI-4 (Table 1). Four SLE registries capture the SF-36 and 3 registries collect biobank data (Table 1). There is at least 1 SLE registry in each of the 4 main regions of the world; North America, Europe, Asia Pacific, and Latin America.

Conclusion: There is variability among the measures collected by SLE registries. Many of the SLE registries capture a subset of measures common to those collected by SLE clinical trials. It appears that measures collected by SLE clinical trials are not necessarily the same as those captured in real world settings. Additional research is needed to develop validated measures which may be captured within clinical trials as well as within real world settings such as registries.

Abstract Number: 1612

Disease Activity and Cognitive Function in Systemic Lupus Erythematosus

Session Title: SLE – Clinical Poster II: Comorbidities

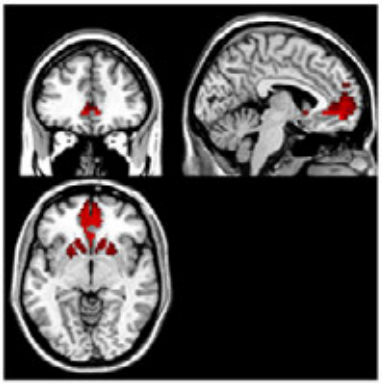
Session Type: Poster Session (Monday)

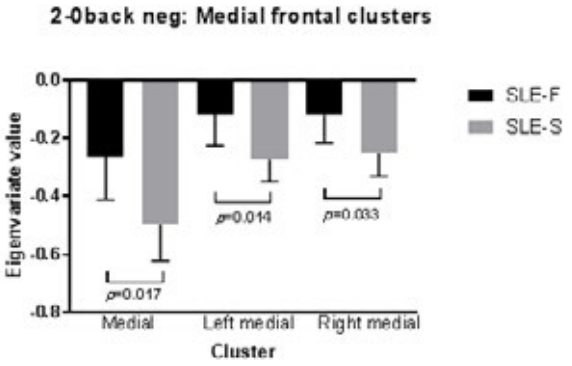
Session Time: 9:00AM–11:00AM

Background/Purpose: Cognitive dysfunction (CD) is a common symptom in systemic lupus erythematosus (SLE), that significantly affects quality of life but there are limited treatment options available. There are many factors causative of CD which are shared with other chronic diseases. However, CD is more prevalent in SLE than in other conditions, such as rheumatoid arthritis. This suggests a direct link between SLE and CD but the effect of disease activity on CD in SLE is still unclear. The aim of this study was to investigate the effects of active disease in SLE on CD. We compared cognitive measures in SLE patients with stable disease activity (SLE-S) to those with active disease (SLE-F).

Table 1: Baseline characteristics, SLE-S vs SLE-F

	Variable	SLE-F (n=24)	SLE-S (n=34)	p-value
		Mean (S.D.), Median (LQ, UQ) or n (%)		
Demographic and clinical	Age (years)	36 (12)	39 (11)	0.330
	Disease duration (years from diagnosis)	10 (8)	12 (7)	0.470
	BILAG global score	12 (9, 16)	1 (0, 2)	**<0.001**
	Oral corticosteroids (y/n)	15 (63)	12 (35)	0.061
	Current immunosuppressant use	18 (75)	14 (41)	**0.016**
	Current antimalarial use	18 (75)	19 (58)	0.261
	Biologic medication	4 (17)	3 (9)	0.432
Depression & anxiety	MADRS	8 (4, 12)	4 (1, 8)	**0.003**
	HADS – A	6 (5, 10)	6 (3, 10)	0.713
CANTAB® task scores (Higher is better except where indicated with *)	Visual memory* *(Total errors adjusted)*	28 (17, 75)	28 (19, 63)	0.897
	Verbal memory *(Maximum = 18)*	9 (2)	10 (3)	0.135
	Attention *(Maximum = 27)*	18 (15, 22)	13 (12, 20)	0.063
	Emotion processing *(Percentage correct)*	62 (10)	62 (9)	0.727
	Executive function* *(Mean choices to correct)*	1.3 (1.3, 1.6)	1.4 (1.3, 1.7)	0.981
	Spatial working memory* *(Between errors)*	107 (56)	112 (57)	0.793





The medial frontal cluster includes the medial frontal cortex, superior frontal cortex-medial segment, anterior cingulate gyrus and frontal pole.

The left and right frontal clusters include the putamen, accumbens, caudate and subcallosal area.

Figure 1 Differences in BOLD response between the SLE-S and SLE-F groups during the n-back (working memory task), 2-0back condition, negative main effect.

Table 2: Significant correlations for change in SLE-F results between v1 and v2 (v2 minus v1)

Variable	n-back task condition	Cluster	r_s	*p*-value
MADRS	2-0back positive main effect	Left angular gyrus	-0.670	0.004
		Right angular gyrus	-0.604	0.013
		Right middle temporal gyrus	-0.594	0.015
		Parietal	-0.656	0.006
BG-VRS		Parietal	0.567	0.022
IL-6		Frontal	-0.618	0.011
FSMC-Cog	2-0back negative main effect	Cingulate gyrus	0.509	0.044
VCAM-1		Cingulate gyrus	-0.541	0.030

MADRS: Montgomery Asberg Depression Rating Scale, BG-VRS: Basal Ganglia Virchow-Robin spaces, IL-6: Interleukin-6, FSMC-Cog: The Fatigue Scale for Motor and Cognitive Functions, VCAM-1: Vascular Cell Adhesion Molecule-1

Methods: 34 SLE-S and 24 SLE-F were recruited, all meeting 1997 ACR or SLICC criteria. Active disease was defined as BILAG A or B with a change in treatment. Stable disease was defined as SLEDAI-2K ≤4. 17/24 SLE-F patients were assessed again at a 2nd visit (v1 vs v2), approximately 4 months later. CD was measured using a computerized battery of tests (CANTAB®). fMRI was used to examine neuronal responses to a working memory and attention task (n-back) and a facial emotional processing task (FERT). Analyses compared the SLE-S to the SLE-F group and SLE-Fv1 to SLE-Fv2 for "responders" only. Responders were defined as having a decreased BILAG score at their second visit. Exploratory correlations were also undertaken, for all of the SLE-F group who had 2 visits, using delta scores. fMRI data were analysed using SPM12. All other data were analysed using SPSS 22.

Results: There were no differences between the SLE-S and SLE-F groups or between v1 and v2 on demographic and clinical measures except disease activity. The SLE-F group scored higher than the SLE-S group on the MADRS depression scale (p=0.003) but no other significant differences in psychiatric symptoms were observed. There were no significant differences on CANTAB® performance for either comparison (table 1). The fMRI showed a SLE-S vs

SLE-F difference in n-back related response in the medial prefrontal cortex (p=0.012; figure 1) but no differences on the FERT. There were no differences in the n-back or FERT for the SLE-F v1 vs v2 comparison. However, the exploratory correlations showed changes in BOLD signal response were associated with changes in the MADRS (depression score), BG-VRS (basal ganglia Virchow-Robin spaces), IL-6, vascular cell adhesion molecule-1 (VCAM-1) and FSMC-cognition (cognitive fatigue measure) (table 2).

Conclusion: Flares in SLE are associated with both increased inflammatory markers and depression scores. Compensatory brain mechanisms to maintain cognitive function may negatively affect mood during flares and this adversely affects overall cognitive function independent of the active phase response. Reduction in inflammation over time also influences cognitive function and so consideration of mood and disease activity is needed when treating flares.

LDL-cholesterol as a Risk Factor of Progression to ESRD in Patients with Lupus Nephritis

Ji-Hyoun Kang,[1] Seong-Eun Choi,[1] Haimuzi Xu,[1] Dong-Jin Park,[1] and Shin-Seok Lee[2], [1]Chonnam National University Medical School & Hospital, Gwangju, Republic of Korea, [2]Department of Rheumatology, Chonnam National University Medical School and Hospital, Gwangju, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: There are few data on the effect of dyslipidemia in patients with lupus nephritis (LN). Thus, we investigated the effect of low-density lipoprotein-cholesterol (LDL-C) on the progression to end-stage renal disease (ESRD) in patients with biopsy-proven LN.

Methods: We followed 121 LN patients who underwent kidney biopsy and were subsequently treated with immunosuppressive drugs. Sociodemographic, clinical, laboratory (including lipid profile), and treatment-related data at the time of kidney biopsy and during follow-up were obtained by a review of patients' charts. Patients were divided into two groups related to the mean LDL-C level: < 100 mg/dL and ≥100 mg/dL. Cox's proportional regression analysis was performed to identify the independent predictors of progression to ESRD in LN patients.

Results: Seventy-one of 121 biopsy-proven LN patients (58.7%) showed more than 100 mg/dL of LDL-C at the time of LN diagnosis. The higher LDL-C group excreted more 24-hour urine protein (p=0.003), and showed a higher proportion of proliferative LN (p=0.013) and an activity score >12 (p=0.023). During a mean follow-up of 83.0 (range, 12–171) months, ESRD was more frequent in the higher LDL-C group than in the lower group (15.5% vs.

2.0%; *p*=0.012). In the multivariate Cox's proportional regression analysis, LDL-C ≥100 mg/dL (hazard ratio [HR], 171.340; *p*=0.012), estimated glomerular filtration rate during the renal biopsy (HR, 0.977; *p*=0.005), statin exposure during follow-up (HR, 0.163; *p*=0.031), relapse (HR, 9.752; *p*=0.036), and complete remission at 1-year of treatment (HR, 0.034; *p*=0.003) were significant predictors of progression to ESRD in LN patients.

Conclusion: Our findings suggest that dyslipidemia at the onset of LN is an independent risk factor for predicting the development of ESRD in LN patients. Therefore, lipid profile should be monitored carefully and managed aggressively to avoid the deterioration of kidney function in patients with LN.

Age (years)	1.054	1.007-1.103	0.23
Time between SLE diagnosis and the PNP* (months)	1.007	1-1.013	0.04

*PNP: peripheral neuropathies

Background/Purpose: The prevalence of peripheral neurological manifestations in Systemic Lupus Erythematosus (SLE) ranges between 1.5% and 27% and are a major cause of morbidity.

To determine associated factors with the different neurophysiological patterns in peripheral neuropathies in patients with systemic lupus erythematosus.

Methods: A retrospective study was performed. We included patients with SLE (ACR 1997 and SLICC 2012 criteria), who presented a PNP associated with SLE according to ACR 1999 nomenclature, from January 2014 to December 2018. Patients were classified according to the neurophysiologic pattern by the Neuromuscular Clinic Disorders at our Institute in 3 groups: 1. Sensory or sensory-motor axonal neuropathy (ANP). 2. Multiplex Mononeuropathy (MNP), and 3. Demyelinating neuropathy (DNP). Clinical information including demographics and SLE characteristics were gathered from the clinical chart and reviewed by an expert rheumatologist in three different moments: Previous visit (3 months before to PNP presentation); at the time of PNP presentation, and one year after. Demographic characteristics: gender, age, Body Mass Index (BMI), and comorbidities. Lupus characteristics: ACR criteria, the time between SLE diagnosis and PNP presentation, ACR / 2012 criteria, disease activity (SLEDAI-2K), cumulative damage (ACR/SLICC-DI), and treatment were compared. One year after, disease activity, cumulative damage, and treatment were reviewed. Statistical analysis: Mann-Whitney U, Chi-squared test and Fisher exact test were used as appropriate. Multiple comparisons and logistic regression analysis was made.

Results: Ninety one PNP were included, 45 (49.5%) ANP, 17 (18.9%) MNP, and 20 (21.9%) DNP. Demographics and comorbidities were similar between groups. At previous visit, the (SLICC/SDI) was higher in APN group compared with MNP and DNP (table 1). Patients with DNP presented more frequently cutaneous manifestations (alopecia) compared with MNP and ANP (table1). Patients with MNP had more nephropathy compared with ANP and DNP, and patients with APN had more hemolytic anemia compared with other groups (table 1).

At the time of PNP presentation, patients with ANP were older and had a long time between SLE diagnosis and the PNP presentation, compared with MNP and with DNP (table 1). Patients with MNP had higher disease activity compared with ANP and DNP groups (table 1). Pulses of methylprednisolone, cyclophosphamide, and higher doses of prednisone were used in the MNP compared with DNP and ANP group ($p < 0.05$). One year after, disease activity and cumulative damage were similar between groups. In the logistic regression analyses, older age, the time between SLE diagnosis and PNP presentation, and cumulative damage in the previous visit were factors independently associated with APN compared with MNP and DNP (table 2).

Conclusion: ANP was the most frequent PNP. Patients with MNP have more disease activity than the other groups. MNP and DNP considered more severe and received more aggressive treatment than APN. Factors independently associated with APN were older age, have a longer time between SLE diagnosis and the PNP presentation and have more damage 3 months previous the PNP presentation.

Session Time: 9:00AM–11:00AM

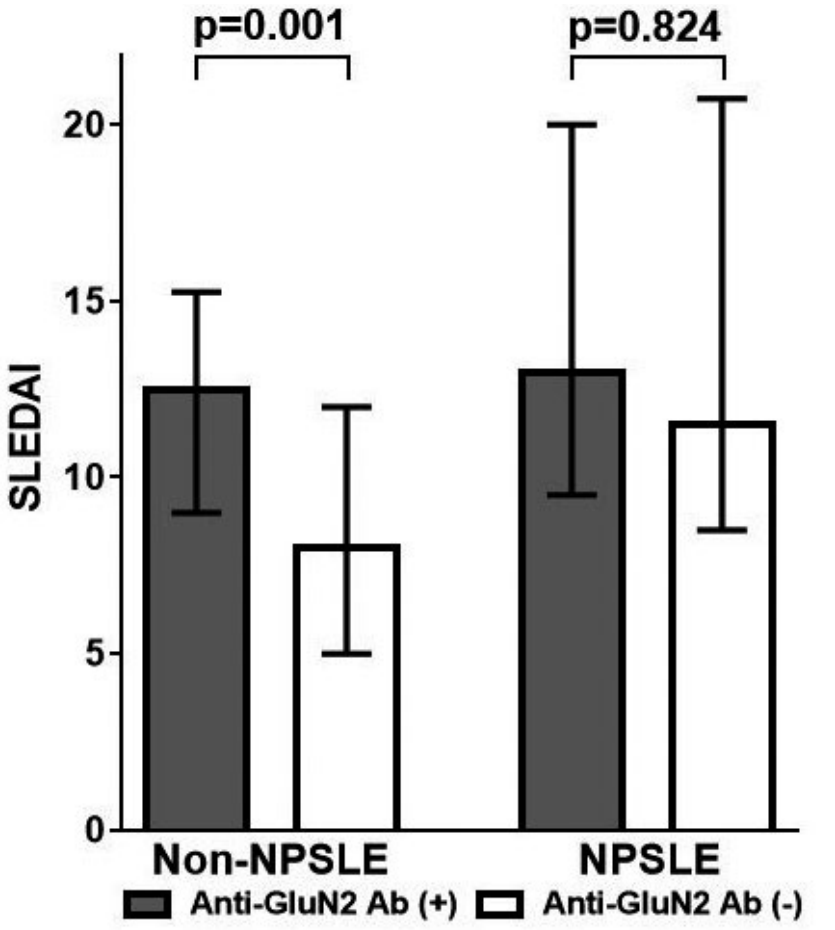

Fig.1 SLEDAI by anti-GluN2 Ab presence

Background/Purpose: Autoantibodies against N-methyl-D-aspartate receptor subunit GluN2 (anti-GluN2) in the cerebrospinal fluid are known to be related with the development of diffuse psychiatric/neuropsychological manifestations in NPSLE. However, relation with serum anti-GluN2 antibody (Ab) is unknown. The aim of this study is to clarify the association of damages due to SLE disease activity and serum anti-GluN2 Ab.

Methods: Sera were collected from SLE patients with active disease (N=132), anti-GluN2 Ab were measured in ELISA and clinical information was collected from the past medical history retrospectively.

Results: Patients were subdivided into those complicated with NPSLE (n=37) and those without NPSLE (non-NPSLE) (n=95). Among the NPSLE patients, anti-GluN2 Ab positivity and negativity made no difference in SLEDAI. Whereas, SLEDAI was significantly higher in patients with positive anti-GluN2 Ab (p=0.001) than those with negative within non-NPSLE patients (Fig. 1). In addition, there was significant positive correlation between SLEDAI and anti-GluN2 titers only in non-NPSLE patients (p< 0.001). In univariate analysis using components of SLEDAI, the positivity for anti-GluN2 Ab was a significant risk for complicating pleuritis, arthritis, fever, leukocytopenia, the positivity for anti-dsDNA Abs or hypocomplementemia. Multivariate analysis resulted with high odds ratio (OR) for fever (OR 9.19, 95% confidence interval (CI) 2.42-46.70, p=0.003) and hypocomplementemia (OR 12.74, 95%CI 2.37-103.28, p=0.007) in non-NPSLE patients with positive anti-GluN2 Ab.

Conclusion: Anti-GluN2 existing in serum can be pathogenic autoantibodies, causing damages related to lupus activity even in SLE patients without complicating NPSLE.

Table 2 ACR

Background/Purpose: Antiphospholipid antibodies (aPL) have been associated with organ damage and certain features in SLE patients. Our aim is to investigate the association between the different aPL and SLE manifestations as well as to elucidate the influence of the load of antibodies.

Methods: Patients from the RELESSER-T registry were included. RELESSER-T is a multicenter, hospital-based registry, with retrospective cross-sectional collection of data from a large representative sample of adult non-selected patients with SLE attending Spanish rheumatology services from the public national health system.

Results: Out of a total of 3651 SLE patients, 1368 were aPL positive (24.8 % were positive for IgG anticardiolipin (aCL) antibodies, 20.1% for IgM aCL, 13.5% showed positivity for IgG antib2glycoprotein I (aB2GPI) and 13.8% for IgM aB2GPI. Lupus anticoagulant (LA) was positive in 24% of patients). Regarding the load of antibodies, 20.6%, 12.1% and 4.8% were positive for one, two and three antibodies respectively. The association between the different aPL, the number of positive antibodies and antiphospholipid syndrome related manifestations is showed in Table 1. Overall, all types of aPL were associated with classic APS manifestations, although LA, IgG isotypes, and patients with more than one aPL display a higher risk to develop clinical APS. Regarding specific lupus manifestations, all aPL types showed a negative association with cutaneous manifestations. LA and aCL were associated with an increased risk of haematological, ophthalmological and neuropsychiatric manifestations ($p< 0.001$). Furthermore, LA was also associated with an increased risk of renal disease ($p< 0.001$). IgG isotypes were associated with a higher risk of specific lupus manifestations compared with IgM. IgG aCL were associated with an increased risk of cardiac and respiratory manifestations. When evaluating the influence of the load of antibodies, we found that the risk of neuropsychiatric manifestations significantly increased with a higher number of positive antibodies (OR for one antibody was 1.19 and 1.7 for 2 and 3 antibodies). Inversely, the risk of cutaneous symptoms decreased while the number of positive antibodies increased (OR=0.9 for one antibody, OR=0.8 for double positivity and OR=0.7 for triple positivity).

Conclusion: There is a hierarchy for aPL and the risk of APS and SLE manifestations. aCL, and especially LA, confer a higher risk for major organ involvement in SLE patients. IgG isotypes seem to have a more important role. The load of aPL confer a higher risk for APS and certain SLE manifestations

Platelet Bound Complement Split Product (PC4d) May Be a Marker of Platelet Activation and Cardiovascular Events in Systemic Lupus Erythematosus

Yevgeniya Gartshteyn,[1] Adam Mor,[2] Laura Geraldino,[2] Teja Kapoor,[2] Tommy Chen,[2] Thierry Dervieux,[3] and Anca Askanase[4], [1]Columbia University School of Medicine, Glen Rock, NJ, [2]Columbia University School of Medicine, New York, NY, [3]Exagen, Vista, CA, [4]Columbia University, New York

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cell-bound complement activation products (CB-CAPs), including platelet bound C4d (PC4d), are sensitive markers for diagnosis and evaluation of lupus activity. Presence of PC4d is associated with antiphospholipid antibodies and thrombotic events in SLE, but its role in cardiovascular (CV) disease is not fully understood. The current study investigates if PC4d is a biomarker for CV disease in SLE.

Methods: In a cohort of 96 SLE patients, we evaluated the association between PC4d and clinical and subclinical cardiovascular (CV) disease, defined by CV events and/or presence of coronary artery calcium (CAC), respectively. Blood was collected and PC4d levels, measured by flow cytometry, were reported as positive or negative, defined by a cutoff of 20 mean fluorescence intensity (MFI). CV events were defined as any medical record documentation or self-report of a myocardial infarction or ischemic cerebrovascular accident. Non-contrast CT chest, performed when required for routine clinical care, was used for calculating CAC scores. Demographics, disease characteristics, and cardiovascular comorbidities were ascertained. Disease activity was assessed using SLE Disease Activity Index 2000 (SLEDAI-2K).

Results: 96 SLE patients were included (41±13 years old, 91% female, 35% Caucasian, 31% Hispanic, 19% African American, disease duration 12±7 years). SLE patients met on average 6±2 ACR-SLE classification criteria. All were ANA+, 64% were dsDNA+, 31% antiphospholipid (aPL) antibodies positive. Average SLE disease activity was 6±5, 39% had lupus nephritis. CV comorbidities included: 19% had a history of smoking, 26% had hypertension, 7% were diabetic and 8% had hyperlipidemia. Average total cholesterol level was 173±53 mg/dL. A positive PC4d level was detected in 16% (n=15). 13% (n=12) had a history of a CV event while CAC >0 was detected in 37% of the 38 patients with available scores. There was no association between history of CV event and presence of CAC >0 (p=0.62). PC4d was associated with history of a CV event (OR 5.3 95% CI 1.4-19.9 p=0.008) but not with the presence of CAC >0 (35% vs 50%, p=0.62). Additionally, positive PC4d was associated with low complement levels (60% vs 21%, p=0.001), history of thrombocytopenia by ACR criteria (47% vs 15%, p=0.004), a lower platelet count (253±81 vs. 148±58 x cells/μL, p=0.0001) and a larger platelet volume (11±1.1 vs 12±1.4fL p=0.003) at the time of PC4d measurement. In a multivariable model, the association between CV events and PC4d, as well as between platelet count/volume and PC4d, remained significant and independent of aPL status or low complement.

Conclusion: In this pilot study, the presence PC4d was associated with history of CV events, lower platelet counts, and larger mean platelet volumes, suggesting that PC4d may be a marker for complement-mediated platelet activation and morphological change, as well as arterial thrombotic events in SLE. No association was found between

Session Title: SLE – Clinical Poster II: Comorbidities

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Accrual of irreversible organ damage is a major risk factor for death in SLE. While unmodifiable factors, such as age at disease onset and ethnicity, are associated with increased damage accrual in SLE, disease activity and medications, in particular glucocorticoids, are also associated. Understanding the independent contribution of glucocorticoid use to organ damage in SLE is confounded by the fact that glucocorticoid use is associated with active disease. We determined factors contributing to the risk of damage accrual in SLE independent of disease activity by studying patients who had no measurable disease activity.

Methods: SLE patients were prospectively recruited from 13 centres in 8 countries and followed longitudinally between 2013-2016. Disease activity (SLEDAI-2K) and treatment details were recorded at each visit, and organ damage measured annually (SDI). Cox-proportional hazards analyses were used to examine time-dependent associations of variables with damage accrual. The absence of disease activity was defined as time-adjusted mean (TAM)-SLEDAI-2K=0.

Results: 1707 patients were studied. Patient characteristics are shown in Table 1. 157 patients (9%) had no clinical or serological disease activity for the entire study period (TAM-SLEDAI-2K=0). Prednisolone exposure was 66% (103/157) in this group, with a median TAM-prednisolone dose of 2.0mg/day (0.0-5.9). Forty-one per cent (65/157) of patients had irreversible organ damage at baseline. Despite SLEDAI-2K=0 throughout, accrual of irreversible organ damage occurred in 13% of this subset, with 21 events captured over a median (IQR) 1.9 (1.0-2.3) years follow-up. In univariable analysis of time-adjusted mean variables, prednisolone exposure was associated with damage accrual (HR 1.1, 95% CI 1.0-1.3, p=0.05), as was physician global assessment (PGA) (HR 1.15, 95% CI 1.0-1.3, p=0.01). Baseline SDI organ damage, gender and ethnicity were not associated with damage accrual in this subset (Table 2). In multivariable analysis, damage accrual was independently associated with prednisolone exposure (HR 1.14, 95% CI 1.03-1.25, p=0.01), physician global assessment (PGA) (HR 1.13, 95% CI 1.03-1.23, p=0.01) and age at enrolment (HR 1.04, 95% CI 1.01-1.07, p< 0.02) (Table 3).

Baseline SDI damage	1.2	(0.54,2.67)	0.66

Table 2 Univariable associations of damage accrual in patients with no clinical or serological disease activity as measured by SLEDAI-2K throughout the study period (N=157)

Conclusion: Irreversible damage accrual occurs in SLE patients with no clinical or serological disease activity as captured by SLEDAI-2K. Glucocorticoid use contributes to the risk of organ damage in these patients. These findings confirm an independent contribution of glucocorticoid use to organ damage accrual in SLE.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erithematosus (SLE) is associated with increased cardiovascular (CV) risk compared with general population; an accelerated atherosclerosis is considered the main underlying mechanism. Arterial Stiffness (AS) is considered a reliable surrogate marker of arterial wall dysfunction and an independent predictor of cardiovascular events in the general population. Several studies showed that AS in SLE patients is abnormally in-

CV risk factor	N patients (%)
Smoking habit	20 (30.7%)
Diabetes	1 (1,6%)
Hypertension	21 (32.8%)
Dyslipidemia	17 (26.6%)
Antiphospholipids Syndrome	13 (20%)
Overweight (BMI≥25)	19 (29.2%)
Obesity (BMI≥30)	7 (10.8%)

Table 1 CV risk factors

creased with respect to healthy controls; however, the prognostic value of AS has not been fully evaluated in patients with SLE. The aim of the study was to evaluate the predictive value of AS for major cardiovascular events, mortality and poor renal outcome in SLE patients.

Methods: Consecutive SLE patients classified according to the 1997 ACR criteria were enrolled for this study. At baseline, demographics, clinical history, menopause status, cumulative dose of glucocorticoid (GC), traditional CV risk factors, disease activity and organ damage (according to SELENA-SLEDAI and SLICC/DI respectively) were recorded; AS was assessed by measuring carotid-femoral pulse wave velocity (PWV). The patients were prospectively followed, and the following outcomes were evaluated at last observation: major events (including IMA, PTCA, mortality due to CV events, overall mortality, stroke, TIA); poor renal outcome (end-stage renal disease, dialysis or renal transplantation).

Results: A total of 65 patients were included (63 Caucasian, %, 63 females, %). At baseline, median age was 41.5 ± 11.9 years, median disease duration was 14 years (IQR 9-24). As for cumulative organ involvement, the most prevalent was cutaneous involvement (n= 48, 75%), followed by renal (n=31, 48.4%), serositis (n=10, 15.6%) and neuropsychiatric (n=10, 15.6%). Cumulative median dose of GC was 16.75 g (IQR 10.25-30.00). Fifteen patients (23.1%) presented active disease (SLEDAI >4) at the time of enrolment, 19 (29.2%) had at least one organ damage (SLICC >0); in those patients the median SLICC-DI resulted 2 (IQR 1-3). The prevalence of traditional CV risk factors is reported in table 1. Overall, at baseline PWV resulted 7 (IQR 6.35-8.45) and vascular age 48 (IQR 39.3-60.0). During the observational period (mean duration of follow-up 4.5 ± 2.4 years), 7 major events occurred in seven patients (10.8%), namely: 5 patients suffered from IMA, 1 from stroke; one death also occurred, for non-CV cause (sepsis). Only one patient developed a poor renal outcome, requiring dialytic treatment and then renal transplant. CV events occurred at median age of 43.8±9.8 years. At univariate cox-regression analysis, baseline age (OR= 1.078) , PWV (OR= 1.71) and vascular age (OR= 1.08) all resulted predictors of future major events ($p< 0.01$; $p< 0.01$; $p< 0.02$ respectively); baseline SLICC was also predictive of major events ($p< 0.01$).

Conclusion: These data suggest that arterial stiffness could be considered a reliable marker of early vascular aging in patients with SLE and its predictive value for cardiovascular events was confirmed in this population. Thus, these data support the utility of the vascular ageing assessment to set-up preventive strategies tailored on the single patient.

T-cell Exhaustion in Prolonged Remission SLE Patients

Francisco Treviño-Tello,[1] Guadalupe Lima,[1] Juan Jakez-Ocampo,[2] Luis Llorente,[1] Yemil Atisha-Fregoso,[1] and Hilda Fragoso-Loyo[3], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Distrito Federal, Mexico, [3]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Cellular exhaustion is a cellular dysfunction characterized by the progressive loss of the effector function, and an increased expression of multiple inhibitory receptors. Exhaustion develops after repetitive stimulation and a high antigenic load. Remission in SLE can be defined as the lack of clinical and serological activity for a specific period, and it has been associated with less accrual damage, and number and severity of flares. Cellular exhaustion has been associated with a better outcome in autoimmune diseases, such as SLE and antibody associated vasculitis.

To identify exhausted CD8+ T-cells populations in prolonged remission SLE patients, active SLE patients, and in healthy subjects.

Methods: We performed a transversal exploratory study. We included patients classified with SLE according to the revised SLE ACR 1997 and SLICC 2012 criteria. Three groups were studied: 1. Prolonged remission SLE (PR SLE): patients with SLE in clinical remission of the disease, defined as a SLEDAI-2K of 0 (excluding hypocomplementemia and high anti-DNA titers), and absence of corticosteroid or immunosuppressant treatment for at least 10 continuous years. 2. Active SLE: patients with SLE with clinical activity measured with SLEDAI-2K. 3. Healthy controls: paired by gender and age ± 5 years with PR SLE group. Flow cytometry was performed to measure the expression of surface and intracellular markers associated to exhausted T CD8+ lymphocytes (Table 1). Percentage of T cells was determined using FlowJo software v10. Leukocyte counts and percent lymphocytes were used to determine the absolute lymphocytes subset counts (cells/μL) of the different subpopulations. Descriptive statistics and multiple comparisons were performed between groups.

Results: We included 15 patients in each group, with an age of 49 years (48 – 60) in the PR SLE patients, 33 (30 – 46) in active SLE, and 47 (44 – 48) in healthy controls. No difference was found between age of PR SLE and healthy controls. In PR SLE patients, disease duration of SLE was 308 (230 – 425) months, and in active SLE 111 (69 – 161) months. Duration of remission state in PR SLE was 203 (146 – 248) months. The exhausted CD8+ lymphocytes analysis between groups is shown in table 2. Comparing PR SLE patients with active SLE patients with Mann Whitney U test, differences were found in CD8+2B4+ % ($p = 0.049$), CD8+2B4+ a ($p = 0.014$), CD8+2B4+PD-1+ a ($p = 0.012$), CD8+PD-1+ a ($p = 0.040$), CD8+Tim-3+PD-1+ a ($p = 0.023$), CD8+T-bet+ % (PR SLE 65.4 [33.3 – 71.7] vs Active SLE 28.1 [10.7 – 59.2], $p = 0.010$), CD8+EOMES+ % (PR SLE 42.9 [21.1 – 68.5] vs Active SLE 13.9 [10.5 – 37.2], $p = 0.029$), CD8+EOMES+ a (PR SLE 111.6 [58.3 – 321.4] vs Active SLE 46.2 [22.3 – 133.7], $p = 0.024$), CD8+T-bet+EOMES+ % (PR SLE 25.0 [18.9 – 47.6] vs Active SLE 9.86 [4.44 – 20.7], $p = 0.010$), and CD8+T-bet+EOMES+ a (PR SLE 93.4 [48.1 – 161.7] vs Active SLE 24.3 [8.1 – 92.3], $p = 0.014$).

ns = not statistically significant.
The lymphocytes populations are shown in Median and IQR, for both the percentage of CD8+ T cells (%) and in absolute lymphocytes counts (a). Kruskal – Wallis test was performed to compare between the three groups, a p value < 0.05 was considered statistically significant.

Conclusion: SLE patients in prolonged remission express more exhausted CD8+ T cells than patients with active SLE. These findings support that cellular exhaustion is inherent to a better clinical outcome.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Attribution of cognitive dysfunction (CD) to SLE is compromised by potential confounders. Studies reveal conflicting results on the relationship between CD and disease activity, likely due to testing differences, subject demographics, comorbidities (NPSLE in particular), and small sample sizes. We assessed cognition in a large cohort of SLE subjects compared to healthy controls (HC) to determine the impact of disease activity.

Methods: Seventy-four adult SLE subjects that met ACR criteria, had no history of NPSLE or other CNS deficits, and 74 age, gender and racially matched HC underwent cognitive testing and assessments for depression, pain, fatigue, sleepiness, anxiety and anger. SLE subjects were assessed for disease activity and medication use. Exclusion criteria included alcohol or illicit drug dependence/abuse, infection, and current narcotic/psychiatric medication use.

Table 2

Cognitive and Behavioral Test Performance	SLE (N = 74)	HC (N = 74)	*p*	Flare (N=23)	Stable Active (N=29)	Inactive (N=22)	*p*
Automated Neuropsychological Assessment Metric (ANAM)							
Simple Reaction Time (SRT) *visuomotor processing speed, simple motor speed, attention*	363.8 +/- 88.0	321.1 +/- 65.4	p=0.001	366.6 +/- 94.4	347.7 +/- 76.8	382.0 +/- 95.0	p=0.407

Spatial Memory Test (SM) *spatial memory*	3.6 +/- 1.1	4.3 +/- 1.6	p=0.008	3.6 +/- 1.2	3.7 +/- 1.0	3.7 +/- 1.2	p=0.818
Behavioral tests							
Beck Depression Index (BDI) score, range: 0 – 63 Median +/- IQR (range)	9.0 +/- 12.3 (0 – 44)	1.5 +/- 3.0 (0 – 34)	p=0.000	10.0 +/- 12.0 (0 – 28)	10.0 +/- 13.5 (0 – 30)	2.5 +/- 8.0 (0 – 44)	p=0.002[a]
# BDI scores > 13 (%) (clinically significant scores)	19 (25.7%)	1 (1.4%)	p=0.000	9 (39.1%)	8 (27.6%)	2 (9.1%)	p=0.067
Pain Numerical Rating, range: 0 - 10 Median +/- IQR (range)	1.5 +/- 4.0 (0 – 8)	0.0 +/- 0.0 (0 – 7)	p=0.000	3.0 +/- 5.0 (0 – 8)	1.0 +/- 4.5 (0 – 8)	0.0 +/- 2.0 (0 – 8)	p=0.015[b]

SLE disease activity status was categorized as “Flare” (met SELENA SLEDAI Flare Index criteria), “Stable active” [clinical SLEDAI (all descriptors other than serology) > 0 or PGA > 0.5 or prednisone > 10 mg and lack of flare], and “Inactive” (clinical SLEDAI = 0 and PGA ≤ 0.5 and prednisone ≤ 10 mg and lack of flare). Differences in group characteristics and test performance were assessed between SLE and HC (t-test and/or Mann Whitney), and among the SLE disease activity groups (ANOVA with post-hoc Tukey’s). The impact of variables on individual test performance was determined by multivariable modeling for SLE versus HC and SLE only grouped by disease activity; variables on univariate screen ($p < 0.1$) were included.

Results: There were no demographic differences among SLE and HC groups (Table 1). Compared to HC, SLE scored worse on most tests and this poor performance was driven by increased reaction time rather than poor accuracy for most tests (Table 2). Among SLE subjects, disease activity did not impact test performance; unexpectedly, inactive SLE performed the worst compared to HC (Table 2). Multivariable models demonstrate significant impacts of 1) SLE, age (as expected), Black race, depression, anger, computer experience and history of psychiatric illness in SLE ver-

Table 3: Final results of multivariable models to determine predictors of test performance

Variables Significantly Impacting Test Performance	Individual Cognitive Tests*						
SLE versus HC	**SRT**	**MG**	**MTS**	**CPT**	**SP**	**NSM**	**SM**
Inactive SLE (versus HC)	X	X	X				
SLE (versus HC)				X			
Black race (versus Other)	X	X			X	X	X
Age	X	X	X	X	X	X	X
History of psychiatric illness requiring medication	X			X			
Depression score		X			X		
Anger score				X		X	X
Decreased computer experience (versus extensive)						X	X
SLE Only grouped by disease activity							
Age		X	X				X
History of psychiatric illness requiring medication	X		X			X	
History of thrombosis		X	X				
Decreased computer experience (versus extensive)						X	X
Increased platelet count	X	X			X		

*All of the test scores were significantly lower in SLE compared to HC except for the Spatial Processing test (SP)

sus HC and 2) age, increased platelets, history of psychiatric illness, computer experience and history of thrombosis in SLE only (Table 3).

Conclusion: Multivariable analyses suggest that poor cognitive performance is related to having SLE after controlling for other factors. Surprisingly, disease activity did not associate with performance, and unpredicted variables such as Black race, increased platelets, history of thrombosis and psychiatric illness did. Black race may be a surrogate for socioeconomic status. The potential of platelets as contributors to other neurodegenerative disease(1) supports further investigation in SLE. The paucity of associations between SLE cognitive performance and disease measures demonstrated in this study highlights the importance of continued study of biologic neurotoxic mechanisms for CD.

Cognitive Impairments in SLE Negatively Related to Participation and Quality of Life: A Systematic Review

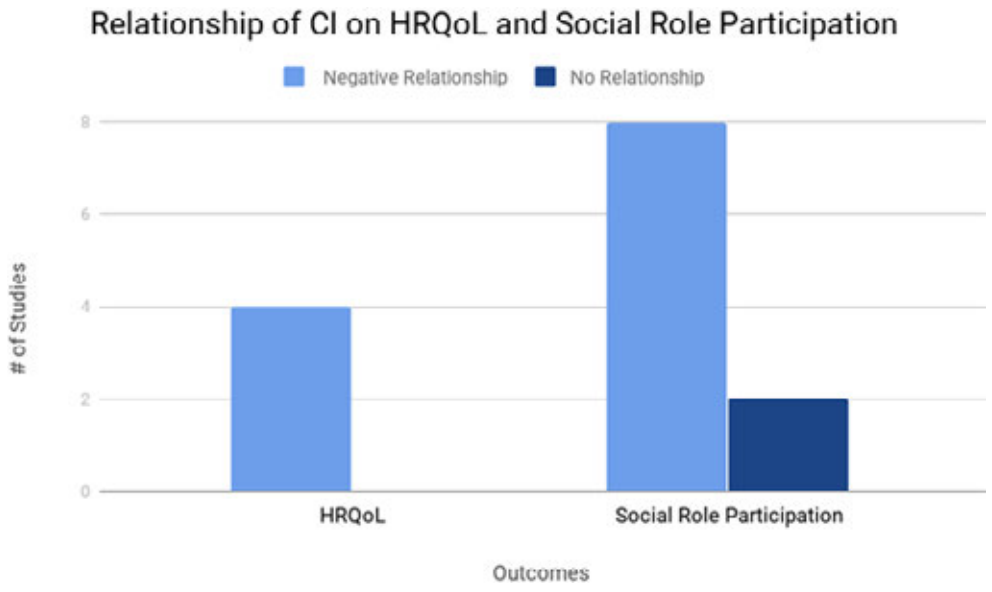
Sofia Alfred,[1] Lina Khoja,[1] Melanie Anderson,[2] Zahi Touma,[3] and Lisa Engel[4], [1]University of Toronto, Toronto, Canada, [2]University Health Network, Toronto, Canada, [3]University Health Network, University of Toronto, Toronto, Canada, [4]University of Manitoba, Winnipeg, MB, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) is a chronic autoimmune disease affecting multiple organ systems. Approximately 33 to 43% of individuals with SLE experience cognitive impairments (CI) such as declines in attention/concentration, verbal fluency, visuo-spatial constructions, memory, processing speed and/or executive functions. Patients report significant effects of CI on Health Related Quality of Life (HRQoL), health status, and social participation roles. However, the quantitative data regarding the relationship of CI on these outcomes has not been synthesized. The objective of this review is to critically appraise and synthesize literature on the relationship of CI on HRQoL, health status, and social participation roles in individuals with SLE.

Methods: Six electronic databases were searched using a wide search strategy and the support of a librarian. Two reviewers (SA, LK) independently completed all phases of the review (title/abstract screening, full-article selection, quality rating, extraction), and a third reviewer resolved disagreement (LE). Forward and backward citation searches of included articles were completed to ensure relevant articles were identified. Fourteen articles were selected for this review.

Results: Five thousand six hundred fifty- two titles were identified and screened. Fourteen articles were included in the data extraction process. Twelve of the fourteen articles found the presence of CI negatively correlated with individuals' HRQoL and social participation roles such as employment status, academic performance and valued life ac-



tivities (**Figure 1**). The most common cognitive domains assessed in these studies were memory, attention, language and executive function. The two articles that did not find a relationship had a small sample size and unclear methodology. There was heterogeneity of measures used between studies: eight articles used different cognitive batteries, two articles used a self- report cognitive measure, and the remaining four articles used a brief cognitive screening measure to assess cognition. Three different HRQoL measures were used in the four articles examining HRQoL; all articles examining social role participation used different measures to assess social role participation. Studies were unable to be pooled for meta-analysis secondary to the heterogeneity across measures used.

Conclusion: Cognitive impairments are negatively related to HRQoL and social role participation in SLE patients. Healthcare professionals need to be aware of this relationship so that they are addressed in clinical practice. Further research is needed across different SLE patients using standardized metrics to enable pooling of data. Also, research examining a broader set of social participation roles, such as leisure, family and community roles, would provide more understanding of the effects of CI in SLE patients. Future research focusing on creating evidence-based treatment plans targeting CI, life roles participation, and/or HRQoL is needed.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To determine mortality and identify risk factors for mortality at 10 years in a mexican-mestizo SLE inception cohort at a tertiary care center in Mexico City.

Methods: In October 1999, an inception cohort of patients aged >16years, who were within 12 months of accrual ≥4 ACR classification criteria for SLE was assembled. At entry, patients had a standardized medical evaluation, and laboratory test. Every 3-6 months, patients were seen at the lupus clinic for medical care. Every year, information was updated, including irreversible damage index, any comorbidity and blood sample was drawn. For this purpose, we assessed disease characteristics, comorbidities, autoantibodies profile, medication, clinical and laboratory variables present at baseline and follow up (FU). Univariate and multivariate analysis were performed.

Results: Two hundred and twenty three patients were included (89.7% females, mean age 27.2±9.2 years), with a mean disease duration of 5.2 months at time of enrolment. Seventeen patients (7.62%) lost FU at our center before 10 years, so were excluded from the analysis. During FU, 34 (16.5%) have died at 10 years and 21 (61.73%) died in the first 5 years. Main causes of death were infection (35%), diffuse pulmonary hemorrhage (8.8%) and chronic renal failure (8.8%). Twenty five deaths were considered SLE related (SLE activity or morbidity). Among patients who died during first 10 years, hypertension (56% vs 39%, p=0.001), hematologic activity (97 vs 73%, p=0.002) and peripheral neuropathy (3% vs 0, p=0.02) were more prevalent. At baseline, lower serum albumin (2.8 ± 0.7 vs 3.1 ± 0.8, p=0.03),

higher proteinuria (2.6 ± 3.5gr vs 1.6 ± 2.6gr, p=0.05), C-reactive protein (4.5 ± 4.0 vs 2.8 ± 3, p=0.02) and cumulative dose of prednisone (6.3 ± 4.3gr vs 3.7 ± 3.4gr, p=0.0003) were observed in patients who died. Antimalarial use at inclusion (53% vs 26%, p=0.005) or during FU (77% vs 47%, p < 0.001) were more frequent in survivors. Male gender was not associated with an increased risk of death (10 vs 15%, p=0.41). SLICC damage index score ≥1 was more frequent in patients who died within first 10 years (8 vs 21%, p=0.03). In multivariate analysis, hematologic activity (HR 10.26, 95%CI 1.40-75.21, p=0.022) and cumulative prednisone dose at baseline (HR 1.14, 95%CI 1.06-1.23, p< 0.001) were associated with risk of death at 10 yrs. Antimalarial use or length of usage does not persist as independently associated with a protective effect for death however, only 50% of patients in the whole cohort were on antimalarials at baseline.

Conclusion: We identified baseline factors associated with 10 years mortality in a mexican-mestizo SLE inception cohort. Ten-year survival was 83.2% in the entire cohort. Almost two-thirds of deaths occurred during the first 5 years of FU. Hematologic activity and cumulative prednisone at baseline were the only factors associated with increased risk of dead at 10 years.

Progression and Factors Associated with Damage Accrual in a SLE Inception Cohort of Hispanic Patients

Maria del Carmen Zamora Medina,[1] Jessica Roldan Ortega,[2] Mario Cesar Ocampo Torres,[3] Pilar Lara Reyes,[1] Alba Cicero Casarrubias,[1] Ivon Bautista Mejia,[1] and Juanita Romero-Diaz[4], [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, MEXICO CITY, Mexico, [2]Monterrey Institute of Technology and Higher Education, MEXICO CITY, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, MEXICO CITY, [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador, Zubiran Vasco de Quiroga, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The aims of our study were to determine the cumulative prevalence of damage at baseline, 5 years and 10 years of follow-up, to identify factors associated with damage accrual and incident damage in a mexican-mestizo SLE inception cohort.

Methods: Patients fulfilling the ACR classification criteria for SLE were enrolled at inception and followed-up to 10 years at a tertiary care center in Mexico City. SLICC damage index (SDI) was measured annually. Damage was defined as an SDI score ≥1 and progression or incident damage as an increase of ≥1 in SDI score compared to baseline. We assessed disease characteristics, comorbidities, medication, autoantibodies profile, clinical and laboratory variables at baseline and follow up (FU). Univariate and multivariate analysis were performed.

Results: Two hundred and twenty three patients were included (89.7% females, mean age 27.2±9.2 years), with a mean disease duration of 5.2 months at time of enrolment. At baseline, no damage was present in 200 patients (89.7%). During FU, 34 (15%) died and 48 (21%) were lost before 10 year assessment, so 141 were included for the analysis for incident damage. Eighty four (48.3%) and 88 patients (62.4%) accrued damage at 5 and 10 years,

respectively. Among patients without damage at baseline, 75 (58.6%) developed damage and 53 (41.1%) remained damage free at 10 yrs. Patients with damage at enrolment were more likely to accrue damage at 5 and 10 years FU (p< 0.001 and p< 0.003). Lupus nephritis at baseline (p=0.014 and p=0.01), lower C3 (p=0.004 and p< 0.008), lower serum albumin levels (p< 0.001 both), cyclophosphamide use (p=0.03) and a higher cumulative prednisone dose at 1 year (p=0.002 both) were more frequent in patients with damage at 5 and 10 years compared to patients with no damage. Patients with damage at 10 years showed at baseline higher SLEDAI-2K score (p=0.03), higher systolic blood pressure (p=0.006), lymphopenia (p=0.03) and lower antimalarial length usage (p=0.03), compared to patient with no damage. Patients with incident damage had higher systemic blood pressure (p=0.005), lymphopenia (p=0.03), low C3 levels (p< 0.002), higher baseline SLEDAI-2K score (p=0.03), renal activity (p=0.04) and higher prednisone cumulative dose at 1 year FU (p=0.0003). A higher prevalence of any anti-cardiolipin antibody positivity (< 0.001), low dose aspirin use (p=0.03), photosensitivity (p=0.03) and longer antimalarial use (p=0.03) were observed in patients free of damage at 10 years. In multivariate analysis, only photosenstivity (HR 0.52, 95% CI 0.3-0.90, p=0.02) and a higher GFR at baseline (HR 0.99, 95% CI 0.98-0.99) were inversely associated with incident damage at 10 years. Antimalarial usage was associated with a protective effect for damage accrual at 5 years (HR 0.99, 95% CI 0.98-0.99, p=0.01) but this effect did not persist at 10 years (HR 0.99, 95% CI 0.99-1.00, p=0.081) and for incident damage (HR 1.32, 95% CI 0.70-2.48, p=0.39).

Conclusion: Damage accrual was present in 10% of SLE patients at baseline, at 5 years of FU it progress to 48.3% and 62.4% at 10 years. Incident damage was observed in 58.6%. Photosensitivity and higher GFR at baseline were protective for incident damage in our cohort.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Lupus is a systemic autoimmune disease whose mechanism of development is largely unknown. Prior infection is a suspected sentinel event that may trigger disease in susceptible people and have an impact on disease development. In this exploratory study, we investigated if severe infections prior to SLE diagnosis were associated with specific SLE attributes and comorbidities.

Methods: We identified 469 patients with known SLE in a physician validated registry, the Chicago Lupus Database, with medical records in the Northwestern Medicine Enterprise Data Warehouse (NMEDW). Each patient was assessed for the Systemic Lupus International Collaborating Clinics classification (SLICC) criteria, via chart review, to determine the presence or absence of each criteria. We excluded ANA from the analysis because 15% patients had missing ANA values (likely due to tests being performed at an outside institutions). Prior severe infections (viral, bacterial, fungal and mycobacterial) and comorbidities (heart failure, stroke, sepsis, end stage renal disease and

	Heart Failure	Stroke	ESRD	Sepsis	Osteoporosis

P-value	0.10	0.59	0.89	**0.009**	0.30

Table 2: Association Between Prior Infections and SLE Comorbidities

osteoporosis) were identified based on ICD9/10 codes in the NMEDW. The association between prior infections and SLE criteria and comorbidities were evaluated using multivariate logistic regression. Models were adjusted for age of SLE onset, sex and race/ethnicity. Severe viral and bacterial infections were also analyzed separately in relation to criteria and comorbidities to assess associations.

Results: Among 469 patients, 26% had severe infections prior to SLE diagnosis, including 71 with viral infections and 49 with bacterial infections. The average age of SLE diagnosis in our population is 30.1 years; 50% are white, 29% African American, 21% identified in other racial/ethnic categories; 92% are female. For SLE comorbidities, 14% developed heart failure, 15% had a stroke, 9% developed ESRD, and 58% developed osteoporosis. Association coefficients and p-values between infection prior to diagnosis of SLE and classification criteria are shown in Tables 1a and 1b and the relation between infections and comorbidities are shown in Table 2. Among classification criteria, prior infection is significantly associated with leukopenia (p=0.03). Among comorbidities, prior infection is significantly associated with heart failure and sepsis. When analyzing prior infections by viral and bacterial subgroups, bacterial infections had significant association with stroke (p=0.02) and sepsis (p= 0.004). Viral infections were significantly associated with oral ulcers (p=0.02) and sepsis (p= 0.009). Association between prior bacterial infection and alopecia (p= 0.07), serositis (0.06), as well as association between prior viral infection and leukopenia (p = 0.08) had borderline significance.

Conclusion: Our exploratory study shows severe infections prior to SLE diagnosis are associated with leukopenia, oral ulcers and an increased risk of heart failure, stroke and sepsis. These results suggest that prior infection could increase the likelihood of long term cardiovascular comorbidities, and that supportive care should be considered to minimize infections and cardiovascular complications for persons with SLE.

Baseline Serum Osteopontin (OPN) Level Is Associated with Early Coronary Artery-calcification and Its Progression in Patients with Systemic Lupus Erythematosus

Mario Cesar Ocampo Torres,[1] Elizabeth Olivares-Martinez,[2] and **Juanita Romero-Diaz** [3], [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, MEXICO CITY, [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Distrito Federal, Mexico, [3]Instituto Nacional de Ciencias Medicas y Nutricion Salvador, Zubiran Vasco de Quiroga, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Background/purpose Premature atherosclerosis has been recognized as a major cause of morbidity and mortality in SLE patients. We aimed to determine 1) the incidence and progression of Coronary-Artery calcification (CAC) and 2) if OPN serum levels are associated with progression of CAC in SLE patients

Methods: Design: Inception Cohort. Since enrollment into the cohort, all patients had a standardized medical history, physical examination, and laboratory tests, including lipid profile, apoB, homocystein, high-sensitivity C-reactive

protein (hs-CRP), serum complement (C3 and C4), and autoantibodies. Every 3-6 months, patients have been seen at the lupus clinic for medical care, and assessments of disease activity using the SLE disease activity scores, and medications usage. Every year, information has been updated, including irreversible damage accrual, any co-morbidities, traditional cardiovascular risk-factors, and a blood sample has been drawn. In 2008, 104 lupus patients from the cohort (93% females) were screened for coronary-artery calcifications using Multidetector Computed Tomography, after first 5 years of follow-up. In 2018 a follow-up screening for CAC was carried-up. Progression of CAC was considered as positive if i) patients without CAC in 2008 were found with CAC+ in the second screening or ii) patients with CAC positive in 2008 were found with any increase of their Calcium Score. OPN plasma levels were measured by ELISA. Correlates for calcifications were analyzed. Cumulative incidence of CAC was calculated and risk factors for CAC progression were identified by multivariate analysis.

Results: At-enrollment, lupus patients were 27.2+9.1 years of age and disease duration 5.4+3.8 months.. On 2008 during the first screening, CAC were detected in 7. 2% patients, since age 23 years, and from three years of disease duration. At follow-up screening, progression of CAC was identified in 16. 3% (IC95% 10. 4-24. 6). Cumulative incidence of CAC was observed in 9%. Mean value of OPN level at baseline was 102.7 ng/mL (95% CI = 89.3-116.1 ng/mL). Earlier Risk factors associated with CAC were disease activity (p=0. 03) and disease duration (p=0. 03) while risk factors for progression of CAC were postmenopausal status (p=0. 01), apoB levels (p=0. 01) and OPN levels (p=0.009). There was a positive correlation for progression of CAC and adjusted mean SLEDAI at first 5 years of follow-up and baseline OPN levels (p=0.006).

Conclusion: Our findings suggest that in patients with SLE, early CAC is associated with disease severity while in the progression of CAC, traditional risk factors atherosclerosis and OPN level were adding

Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical Poster II: Comorbidities
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate the pathogens from bronchoalveolar lavage fluid (BALF) and risk factors of mortality in SLE patients with pneumonia and respiratory failure.

Methods: Twenty-four SLE patients were enrolled. Clinical characteristics, laboratory profiles at admission, and microbiology from BALF were presented. We also performed univariable analyses for mortality risk.

Results: Among the 24 patients (21 women, median age: 46.5 years; duration of SLE: 11 years), 8 of them had septic shock, and 9 of them died within 30 days. All of them were supported with mechanical ventilations with a medial duration of 11 days (Table 1). Pathogens identified from BALF were *Pneumocystis jiroveci* pneumonia (PJP) in 12

Table 1 Characteristics of SLE patients with bilateral pneumonia and respiratory failure under mechanical ventilation

Parameter	All (N=24)
Age at admission, years	46.5 (31.53 – 53.19)
Female gender	21 (87.5)
Duration of SLE, years	11 (4.0 – 18.3)
Lupus nephritis	17 (70.8)
Background medication	
Prednisolone equivalent dose, mg/day	15 (10.0 – 20.0)
Azathioprine	5 (20.8)
Mycophenolate	7 (29.2)
Calcineurin inhibitors	8 (33.3)
Pulse MP within 1 months	2 (8.3)
Cyclophosphamide within 3 months	1 (4.2)
Rituximab within 6 months	7 (29.2)
Clinical status at ICU admission	
Septic shock at endotracheal intubation	8 (33.3)
APACHE II score	25 (20.0 – 28.8)
SOFA score	10 (8.0 – 10.8)
ECMO support	2 (8.3)
MV to BAL duration, days	3 (2.0 – 5.0)
Duration of MV, days	11 (7.3 – 15.0)
Laboratory finding	
WBC count, $10^3/\mu l$	9.65 (6.63 – 13.9)
Lymphocyte count, $10^3/\mu l$	0.58 (0.23 – 0.89)
Platelet count, $10^9/l$	156 (80 – 243)
Serum albumin, g/dl	2.6 (2.10 – 3.10)
Serum total bilirubin, mg/dl	0.6 (0.35 – 0.61)
Serum creatinine, mg/dl	1.5 (1.13 – 4.70)
Serum CRP, mg/dl	3.9 (0.95 – 13.10)
Serum procalcitonin > 0.5 ng/ml	11 (45.8)
Serum C3, mg/dl	64 (47.0 – 85.4)
Serum C4, mg/dl	17 (10.1 – 24.6)
Serum IgG, mg/dl	710 (431 – 1070)
30-day mortality	9 (37.5)
Hospitalization mortality	11 (45.8)

Values are presented as median (interquartile range) or number (percentage)

APACHE: Acute Physiology and Chronic Health Evaluation; BALF: bronchoalveolar

patients (50%), Cytomegalovirus in 7 patients (29.2%), bacteria in 11 patients (45.8%). Thirteen patients (54.2%) had blood stream infections, the leading causes were cytomegalovirus in 8 patients (33.3%) and *E. coli* in 5 patients (20.8%). Univariable analysis indicated that the presence of thrombocytopenia (odd ratio [OR]: 8.0, 95% confidence interval [CI]: 1.23–52.25), bacteremia before or after one month of endotracheal intubation (OR: 8.0, 95% CI: 1.23–52.5), and PJP (OR: 7.0, 95% CI: 1.04–46.95) were risk factors for 30-day mortality (Table 2). Kaplan-Meier analysis also confirmed the risk of 30-mortality in patients with thrombocytopenia and bacteremia (Figure 1).

Table 2 Risk factor analysis for 30-day mortality in SLE patients with pneumonia under mechanical ventilation

Variable	OR	95% CI	p value
Age	1.0	0.93 – 1.04	0.555
Lupus nephritis	0.3	0.05 – 1.94	0.212
Prednisolone > 10 mg/day	4.0	0.62 – 25.96	0.146
Mycophenolate	1.4	0.23 – 8.30	0.728
Calcineurin inhibitors	2.2	0.39 – 12.58	0.375
Rituximab within 6 months	1.4	0.23 – 8.30	0.728
APACHE II score ≧ 20	0.5	0.06 – 4.69	0.575
Septic shock at intubation	0.4	0.07 – 2.81	0.377
Platelet < 100 x 10^9/L	8.0	1.23 – 52.25	0.030
Serum CRP > 6 mg/dL	1.9	0.35 – 9.98	0.461
Serum PCT > 0.5 ng/ml	2.3	0.19 – 28.19	0.519
Low C3 or C4	5.3	0.52 – 54.34	0.158
Serum IgG < 751 mg/dL	8.0	0.71 – 90.00	0.092
Bacteremia[a]	8.0	1.23 – 52.25	0.030
Pathogen in BALF			
Pneumocystic jiroveci	7.0	1.04 – 46.95	0.045
Cytomegalovirus	3.2	0.52 – 19.84	0.212
Bacteria	1.9	0.35 – 9.98	0.461

APACHE, Acute Physiology and Chronic Health Evaluation; BALF, bronchoalveolar lavage fluid; CMV, Cytomegalovirus; Ig, immunoglobulin; OR, odds ratio; SOFA, Sequential Organ Failure Assessment; WBC, white blood cell

[a]within one month before or after endotracheal intubation.

SLE pneumonia BAL table 2

Table 2

Conclusion: The prevalence of cytomegalovirus and *Pneumocystis jiroveci* was high in BALF from SLE patients encountered pneumonia and respiratory failure. BALF analysis facilitated a pathogen-specific treatment, which may lower the overall mortality rate in such vulnerable patients. Thrombocytopenia, bacteremia, and PJP may indicate an increased 30-day mortality rate.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

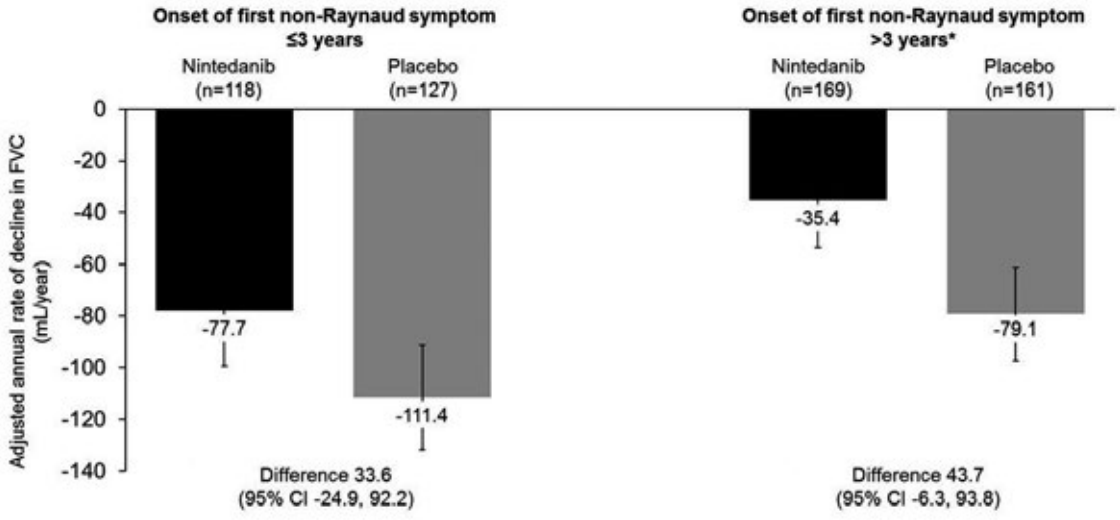
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is a common and usually early manifestation of systemic sclerosis (SSc). Decline in lung function in patients with SSc-ILD is generally believed to be most rapid early in the course of the disease. In the SENSCIS trial, nintedanib reduced the annual rate of decline in forced vital capacity (FVC) vs

Figure. Annual rate of decline in FVC (mL/yr) over 52 weeks in the SENSCIS trial in subgroups by time since onset of first non-Raynaud symptom.



Treatment-by-time-by-subgroup interaction p=0.80

*Inclusion criterion was onset of first non-Raynaud symptom <7 years before screening. Actual maximum was 7.2 years.

placebo in patients with SSc-ILD. We analyzed outcomes in the SENSCIS trial in subgroups based on time since onset of first non-Raynaud symptom.

Methods: Subjects with SSc-ILD with onset of first non-Raynaud symptom < 7 years before screening, ≥10% fibrosis of the lungs on high-resolution computed tomography (HRCT) and FVC ≥40% predicted were randomized to receive nintedanib 150 mg bid or placebo. We analyzed outcomes in subgroups based on time (at randomization) since onset of the first non-Raynaud symptom (≤3 vs >3 years).

Results: Among 576 patients who received ≥1 dose of trial drug, the time since onset of first non-Raynaud symptom was ≤3 years in 118 (40.9%) and 127 (44.1%) of patients in the nintedanib and placebo groups, respectively. At baseline, in patients with onset of first non-Raynaud symptom ≤3 years and >3 years, respectively, 41% and 60% had diffuse cutaneous SSc, 59% and 62% were positive for anti-topoisomerase I antibody, mean (SD) modified Rodnan skin score (mRSS) was 9.8 (8.8) and 12.1 (9.0), C-reactive protein level (mg/dL) was 7.1 (20.1) and 5.8 (10.7), extent of fibrosis on HRCT (%) was 34.8 (21.0) and 36.9 (21.4), FVC (mL) was 2549 (819) and 2463 (744), and FVC % predicted was 73.1 (16.1) and 72.1 (17.1). In both the nintedanib and placebo groups, the rate of decline in FVC (mL/year) was numerically greater in patients with onset of first non-Raynaud symptom ≤3 than >3 years (Figure). Nintedanib reduced the rate of decline in FVC compared with placebo both in patients with onset of first non-Raynaud symptom ≤3 and >3 years, with a similar effect between subgroups (Figure). In the nintedanib and placebo groups, respectively, absolute declines in FVC >5% predicted were seen in 21.2% and 33.1% of patients with onset of first non-Raynaud symptom ≤3 years (OR 0.55 [95% CI 0.31, 0.98) and 20.1% and 24.8% with onset >3 years (OR 0.76 [0.45, 1.28]) (treatment-by-subgroup interaction p=0.41). The adverse event profile of nintedanib was consistent between the subgroups by time since onset of first non-Raynaud symptom.

Conclusion: In patients with SSc-ILD in the SENSCIS trial, the rate of FVC decline over 52 weeks was numerically greater in patients whose onset of first non-Raynaud symptom was ≤3 years than >3 years before randomization. The effect of nintedanib on reducing decline in FVC was consistent between subgroups of patients by time since first non-Raynaud symptom.

Significance of Abnormal Nailfold Videocapillarscopy Among Patients with Raynaud's Phenomenon And/or Suspected Connective Tissue Disease: A Cross-Sectional Single-Center US Experience

Yasser Radwan,[1] Tina Gunderson,[2] Cynthia Crowson,[3] Alicia Hinze,[1] Kevin Moder,[4] Floranne Ernste,[4] Shreyasee Amin,[4] Uma Thanarajasingam,[2] Thomas Osborn,[1] Kenneth Warrington,[4] Paul Wennberg,[4] and Ashima Makol[1], [1]Mayo Clinic Minnesota, rochester, MN, [2]Mayo Clinic, Rochester, MN, [3]Mayo Clinic Rochester, Rochester, [4]Mayo Clinic Rochester, rochester, MN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Nailfold videocapillaroscopy (NVC) is a simple, non-invasive & highly sensitive tool to evaluate structural abnormalities of the microcirculation in vivo and considered a key clinical finding to help differentiate primary from secondary Raynaud's phenomenon (RP). It is available at limited centers across the US. We examined the significance of NVC patterns in an unselected cohort of patients with RP and/or suspected connective tissue disease (CTD) referred to a recently instituted NVC Clinic at our institution.

Characteristic	PRP (34) n (%)	SSc (35) n (%)	UCTD (42) n (%)	MCTD (15) n (%)	SLE (4) n (%)	Sjögren's (9) n (%)	DM (2) n (%)	APLS (2) n (%)
NVC Pattern								
Normal	34 (100)	2 (6)	22 (52)	5 (33)	2 (50)	7 (78)	1 (50)	1 (50)

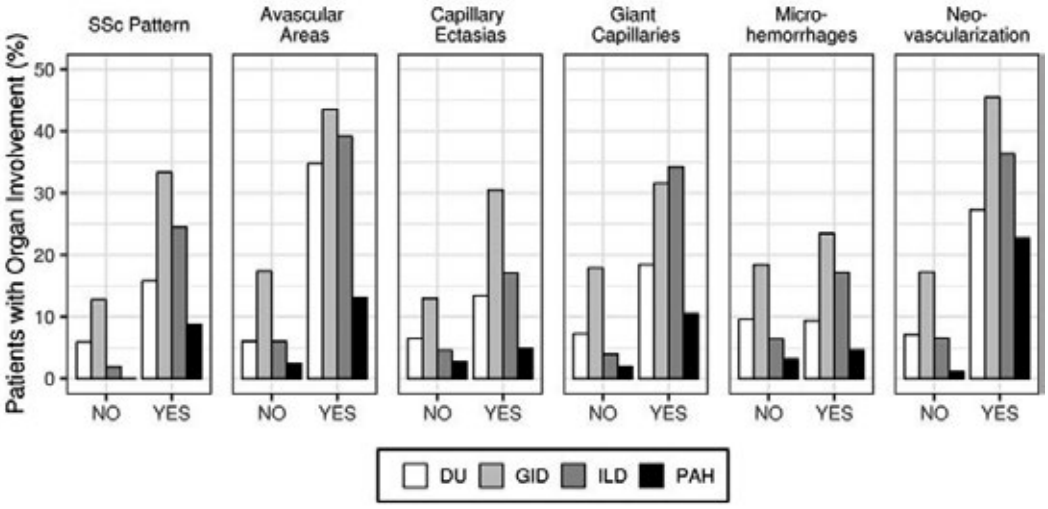
ILD=interstitial lung disease; PAH=pulmonary arterial hypertension; GID=gastrointestinal dysmotility; DU=digital ulcers; ANA=Antinuclear Antibody

Table 2. Organ involvement, autoantibodies and nailfold videocapillaroscopy patterns among 190 patients with Raynaud's phenomenon and/or suspected connective tissue disease



DU=Digital ulcers; GID=gastrointestinal dysmotility; ILD=interstitial lung disease; PAH= pulmonary arterial hypertension

Figure. Association of "SSc pattern" and other nailfold videocapillaroscopy findings with organ involvement

Methods: Medical records of all patients referred to our NVC Clinic between 1/1/2017 to 3/31/2019 were retrospectively reviewed. Demographics, clinical diagnosis, major organ involvement that can been seen in systemic sclerosis (SSc) or CTDs (interstitial lung disease (ILD), pulmonary arterial hypertension (PAH), digital ulcers (DU) and gastrointestinal dysmotility (GID)) and autoantibodies were abstracted. NVC results (Optilia, 200x; 2nd-5th Digits examined bilaterally) were classified as normal or abnormal (described as non-specific or SSc specific pattern- early, active, late). Fulfilment of ACR/EULAR 2013 SSc classification criteria and Very Early Diagnosis of SSc (VEDOSS) criteria was ascertained.

Results: 190 patients (mean age 46 ± 15 yrs, 81 % females, 93% white) underwent NVC during the study period. Indications for referral were RP (92%), positive autoantibodies (56%) and/or suspicion for underlying CTD (21%).

A normal NVC was noted in 102 (54%) patients, of whom 34 patients were considered to have Primary RP. Abnormal NVC was noted in 88 (46%) patients of which 57 (65%) had SSc pattern (39% early, 46% active, and 16% late). Among those with SSc NVC pattern, 26 (46%) met classification criteria for SSc, 48 (84%) fulfilled VEDOSS criteria

and 28 (49%) were diagnosed as other CTDs. Among patients met ACR/EULAR 2013 SSc diagnosis, NVC abnormalities were noted in 33 (94%). NVC abnormalities were also notable in patients with other CTDs (Table 1).

Organ involvement was observed more frequently with SSc NVC pattern (Table 2). Among the 13 patients with SSc NVC pattern (6 early, 7 active) that did not meet criteria for SSc or other CTDs, 3 had ILD, 1 DU and 2 had GID.

Among patients with SSc NVC pattern, 74% had a positive ANA, 37% had SSc specific autoantibodies (anti-centromere 14%, anti-Scl70 12% and anti RNA polymerase-III 14%), and 39% had a positive ENA (16% anti-Ro/SSA, 2% anti-La/SSB, 7% anti-Sm, 16% anti-RNP).

In absence of RP (n=13), SSc pattern was observed in 4 (31%) patients: 3 met VEDOSS, 2 met ACR/EULAR SSc criteria and 1 had Sjogren's syndrome; 2 had anti-RNA polymerase-III and 1 had anti-Scl70 antibody.

The association of NVC abnormalities (giant capillaries, dilatations, microhemorrhages and avascularity) with organ dysfunction is shown in the figure.

Conclusion: Our study underscores the importance of performing NVC for early diagnosis of SSc. This study supports the role of NVC as a valuable screening tool for evaluation of CTDs where abnormal NVC, particularly SSc pattern, may be associated with a high prevalence of disease-specific autoantibodies and internal organ involvement (particularly ILD and PAH), even in the absence of RP and may signal an evolving CTD.

Department of Medicine and Clinical Science, Yamaguchi University Graduate School of Medicine, Yamaguchi, Japan, Tokyo, Japan, [2]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Tokyo, Japan, [3]Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo, Japan, Bunkyo-ku, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is the leading causes in patients with systemic sclerosis (SSc). Forced vital capacity (FVC) is routinely used for assessment of severity of SSc-ILD. Since FVC decline is shown to predict poor survival, serial FVC change is used as an outcome measure in clinical practice as well as in clinical trials. In general, FVC is decreased in the presence of restrictive lung diseases such as ILD, but also by neurologic and

muscle disorders that affect respiratory muscles[1]. Here, we have investigated whether chest wall muscle atrophy influences on FVC change in patients with SSc-ILD.

Methods: This is a retrospective study involving 36 patients with SSc-ILD, who were selected from our SSc database, based on fulfillment of 2013 ACR/EULAR classification criteria, disease duration from non-Raynaud's symptoms < 10 years, availability of at least 2 simultaneous measurements of pulmonary function test (PFT; FVC, FEV1, DLco) and chest high-resolution computed tomography (HRCT) at an interval of 1-3 years. Two independent examiners measured the extent of ILD according to Goh et al [2] and chest wall muscle volume at the level of 9th thoracic spine on HRCT by manual tracing in a setting of blinded patient identity, and the mean values were used for analysis. Serial changes of FVC, ILD extent, and chest wall muscle volume between two measurements (ΔFVC, ΔILD, and Δmuscle) were statistically assessed using Wilcoxon signed-rank test. Correlation coefficient was calculated by Spearman's rank sum test. Multiple regression analysis was used to evaluate independent roles of ΔILD, Δmuscle in contributing to ΔFVC, by incorporating various co-variables.

Results: Baseline characteristics of the patients included: 72% female, age of 54.9 ± 13.5 years, disease duration of 2.8 ± 3.0 years (range: 0-10 years), 53% dcSSc, 53% anti-topoisomerase I-positive, FVC of 2.37 ± 0.56 L (%predicted FVC of 86 ± 19%), %predicted DLco of 69 ± 21%, and ILD extent of 20.5 ± 16.1%. An interval between the first and second PFT/HRCT evaluations was 20.8 ± 6.9 months. Inter-examiner correlation coefficient was 0.79 for chest wall muscle volume and 0.61 for ILD extent. Sixteen patients (44%) were treated with cyclophosphamide, mycophenolate mofetil, tocilizumab, and/or nintedanib, while 19 (53%) received corticosteroids. There was no change in FVC ($P = 0.30$) or ILD extent ($P = 0.078$), whereas chest wall muscle volume reduced significantly with time (5232 ± 1416 to 4895 ± 1259 mm^2: $P = 0.0008$). ΔFVC was correlated negatively with ΔILD ($r = -0.48$, $P = 0.003$) and positively with Δmuscle ($r = 0.53$, $P = 0.01$), but ΔILD and Δmuscle were not correlated with each other ($r = -0.073$, $P = 0.67$). A variety of multivariate models consistently demonstrated that ΔILD and Δmuscle were independent contributors to ΔFVC (adjusted R-squared 0.50-0.59).

Conclusion: In patients with SSc-ILD, FVC decline might reflect not only ILD progression but also chest wall muscle atrophy, which potentially attribute to skeletal muscle involvement of SSc. Our finding may call our attention upon interpretation of serial FVC changes in SSc-ILD patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: There have been a number of recent negative clinical trials of SSc utilising the modified Rodnan Skin Score. High Frequency Ultrasound (HFUS) allows objective quantitative and qualitative assessment of dermal pathology and could be a useful surrogate measure of skin involvement in Systemic sclerosis (SSc). No previous studies have examined the convergent validity between HFUS features and dermal collagen in SSc. The repeatability of HFUS warrants further assessment before this method can be accepted in clinical practice. This study aims to assess the repeatability and convergent validity of HFUS parameters with dermal collagen deposition in SSc.

Methods: Fifty-three patients with SSc meeting ACR/EULAR 2013 criteria and 15 healthy controls (HC) underwent HFUS assessment of skin thickness (ST), echogenicity (as a reflection of cutaneous oedema) and Shear Wave Elastography (demonstrating skin stiffness, SWE) at the middle finger, hand, distal forearm and abdomen. Ten SSc patients and 10 HC underwent skin biopsies taken from the distal forearm. Dermal collagen was determined using Masson's Trichrome stain.

Results: Strong positive correlations were found between dermal collagen quantification and both ST (Spearman's rank correlation coefficient, ρ = +0.697, p=0.025) and SWE (ρ = +0.709, p=0.022) at the forearm in SSc, but not with echogenicity. Multiple linear regression analysis confirmed ST and SWE as significant predictors of localised skin collagen deposition in SSc (R^2 = 0.876). ST and SWE were highly reproducible across all 4

Intra-observer variability in HFUS parameters			
Anatomical region of interest	**Intra-class Correlation Coefficient (95% CI)**		
	Skin thickness (mm)	**Echogenicity (mean, Gray scale)**	**SWE (mean, kPa)**
Proximal Middle Finger	0.946 (0.913-0.967)	0.782 (0.642-0.866)	0.954 (0.926-0.972)
Dorsal Hand	0.970 (0.952-0.982)	0.744 (0.586-0.842)	0.953 (0.923-0.971)
Distal Forearm	0.978 (0.965-0.987)	0.648 (0.432-0.783	0.964 (0.941-0.978)
Abdomen	0.963 (0.940-0.977)	0.865 (0.781-0.917)	0.973 (0.955-0.983)

Table 1. Intra-Class Correlation coefficient demonstrating excellent reproducibility (intra-observer variability) for skin thickness and Shear Wave Elastography. Reproducibility for echogenicity was good, but marginally less so than the other HFUS parameters.

regions of interest for the combined cohort (SSc and HC combined) with Intra-class Correlation Coefficients (ICC) of 0.946-0.978 and 0.953-0.973 respectively (Table 1). Echogenicity reproducibility was good, but weaker than ST and SWE (ICC 0.648-0.865).

Conclusion: We have demonstrated for the first time that ST and SWE on HFUS reflect collagen deposition in affected SSc skin. However, whilst low echogenicity is felt to reflect cutaneous oedema, increasing echogenicity does not accurately reflect fibrosis. HFUS parameters were highly reproducible although notably more so for ST and SWE than echogenicity. Our findings strongly support the use of ST and SWE in particular as a surrogate marker for skin fibrosis in clinical trials.

Evidence-based Consensus Statements for the Identification and Management of Interstitial Lung Disease in Systemic Sclerosis

Anna-Maria Hoffmann-Vold,[1] Toby M. Maher,[2] Edward E. Philpot,[3] Ali Ashrafzadeh,[4] and Oliver Distler[5], [1]Dept. of Rheumatology, Oslo University Hospital, Oslo, Norway, Oslo, Norway, [2]National Heart and Lung Institute, Imperial College London; Interstitial Lung Disease Unit, Royal Brompton Hospital, London, UK, London, United Kingdom, [3]Respiratory Center of Excellence, IQVIA, Durham, NC, USA, Durham, NC, [4]Rheumatology Center of Excellence, IQVIA, San Diego, CA, USA, San Diego, CA, [5]Dept. of Rheumatology, University Hospital Zürich, Zürich, Switzerland, Zürich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Guidelines are needed to aid early recognition and treatment of interstitial lung disease in systemic sclerosis (SSc-ILD). This study was conducted to develop expert consensus statements for the identification and management of SSc-ILD.

Methods: Evidence-based consensus statements were established using a modified Delphi process based on a systematic literature analysis. An expert panel of 27 European-based pulmonologists, rheumatologists and internists participated in three rounds of online surveys, a face-to-face discussion and a WebEx meeting, to establish statements and define an SSc-ILD management algorithm.

Results: The final evidence-based consensus included detailed statements on screening and risk stratification, diagnosis, assessment of severity, treatment options, monitoring, assessment of progression and treatment escalation. The consensus management algorithm is presented here in an abbreviated form for clinical use (figure).

Conclusion: These evidence-based expert consensus statements, developed using a modified Delphi process, provide important guidance for the identification and management of SSc-ILD in clinical practice**.**

Relationship Between YKL-40, VEGF, and IL-5 in Borderline mPAP and Pulmonary Hypertension in Systemic Sclerosis

Tetsuya Furukawa,[1] Yuichi Yokoyama,[2] Teppei Hashimoto,[3] Naoto Azuma,[4] and Kiyoshi Matsui[4], [1]Hyogo College of Medicine, Nishinomiya, Japan, [2]Hyogo College of Medicine, Kyoto, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Kobe, Hyogo, Japan, [4]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic sclerosis (SSc) is an intractable connective tissue disease that causes skin and organ fibrosis, and its prognosis is affected by pulmonary hypertension (PH). Attention has been paid to borderline mPAP that does not lead to PH diagnosis at 21 ≤ mean pulmonary arterial pressure < 25 mmHg with a right heart catheter (RHC). In recent years, a mouse model of PH has been established by administering IL-33, which leads to pulmonary artery narrowing. In this model, PH was prevented by suppressing IL-5. Previous reports have demonstrated elevated serum YKL-40 levels in SSc and SSc-PH in Japanese patients with progressive pulmonary capillary lesions. The chitinase-like protein, YKL-40, has been implicated in inflammation, tissue remodeling, and angiogenesis in malignant tumors. We examined the relationship among YKL-40, VEGF, and IL-5 levels, which play an important role in SSc patients with borderline mPAP and PH.

Methods: We conducted a retrospective analysis of 64 SSc patients who were referred to our institution for treatment between August 2014 and April 2017. Group 1 included 47 patients without PH, group 2 included 6 patients with borderline mPAP, and group 3 included 11 patients with PH. Exclusion criteria were arthritis, infection, and malignant tumor complications. We measured serum YKL-40, VEGF, and IL-5 levels using ELISA and examined the correlation between YKL-40 age percentile, which was age-corrected for serum YKL-40 levels. The diagnosis of PH was made using an RHC.

Results: Age, sex (male:female), disease duration, and disease type (diffuse cutaneous SSc: limited cutaneous SSc) were as follows: group 1, 63.5 ± 12.8 years, 7: 40, 10. 2 ± 10.0 years, and 7: 40; in group 2, 66.0 ± 8.5 years, 1: 5, 13.7 ± 12.5 years, and 1:5; and in group 3; 60.7 ± 9.2 years, 1:10, 11.9 ± 11.2 years, 4: 7, respectively. The YKL-40 age percentile, VEGF (pg/mL), and IL-5 (pg/mL) results were as follows: in group 1, 44.2 ± 26.8, 307.8 ± 167.4, and 1.2 ± 0.3; in group 2, 93.3 ± 7.2, 401.0 ± 128.4, and 1.8 ± 0.6; and in group 3, 90.2 ± 11.2, 584.1 ± 387.3, and 1.3 ± 0.4, respectively. YKL-40 level was significantly elevated in groups 2 and 3, VEGF level was higher in group 3 that in group 1, and IL-5 level was higher in group 2 than in group 1. Moreover, a positive correlation was found between YKL-40 and IL-5 levels, with a correlation coefficient of r = 0.3.

Conclusion: YKL-40, a biomarker that reflects vascular lesions of SSc at an early stage, may be a useful biomarker for the early diagnosis of borderline mPAP as it was significantly elevated in groups 2 and 3. We found that IL-5 level was elevated in the borderline mPAP complex, indicating that it may be involved in the progression at an early stage of pulmonary artery injury. As VEGF was elevated in the PH complex, it may also contribute to the progression of the vascular injury. From these results, early therapeutic intervention may improve the survival prognosis.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Pulmonary hypertension (PH) is an important cause of morbidity and mortality in patients with systemic sclerosis (SSc). Different screening algorithms have been proposed for identifying patients who have a high probability of PH and require right heart catheterization (RHC), which is the gold standard for diagnosing PH. The aim of this study was to compare the performance of PH screening algorithms in patients with SSc.

Methods: Forty-eight consecutive pts fulfilling ACR/EULAR 2013 SSc criteria have been screened for PH until now, using the 2015 ESC/ERS, DETECT and ASIG algorithms. Pulmonary function tests (PFT), diffusing capacity of the lung for carbon monoxide (DLCO), trans-thoracic echocardiography, serum NT-proBNP, serum uric acid assay and

Table 1. Demographic and Clinical Features of Patients									
	All Patients n=33	ESC/ESR screen positive, n=8 (25%)	ESC/ESR screen negative, n=24 (7%5)	DETECT screen positive, n=9 (27%)	DETECT screen negative, n= 24 (63%)	ASIG screen positive, n=13(41%)	ASIG screen negative, n=19 (59%)	Any of the algorithms, n=14 (41%)	Any of the algorithms, n=20 (59%)

Table 2. Performance of the PAH screening algorithms

	Performance for 25-mmHg cut-off			Performance for 20-mmHg cut-off		
	ESC/ESR	ASIG	DETECT	ESC/ESR	ASIG	DETECT
Sensitivity, %	100	100	100	75	100	50
Specificity, %	54	9	40	67	17	0
PPV, %	37.5	23	33	75	61	44
NPV,%	100	100	100	67	0	0

high-resolution computed tomography (HRCT) were performed as needed. Pts with known PH, severe interstitial lung disease and severe left ventricular dysfunction (LVD) were not included. RHC was performed in all patients with positive screening according to any one of the screening algorithms. Pts with PH were classified according to the updated PH classification criteria. Sensitivity and specificity of the 3 screening algorithms were evaluated according to the estab-

lished cut-off value of 25 mmHg for mean systolic pulmonary artery pressure and for the recently proposed cut-off value of 20 mmHg.

Results: Among the 48 SSc pts, 15 were excluded due to already diagnosed PH (n=4), LVD (n=4), no measurable tricuspid regurgitation velocity (TRV) (n=5) and coexisting lung cancer (n=2). Among the remaining 33 patients, 14 required RHC according to at least one of the screening algorithms. Demographic and clinical features were summarized in Table 1. Number of patients who had suspected PH and required RHC according to ESC/ERS 2015, DETECT and ASIG algorithms were 8 (%25), 9 (%27), and 13 (%41) respectively (Figure 1). Among the 14 who had RHC, PH was present in 3 pts according to the 25-mmHg cut-off (Group1 in 1, Group 2 in 1, Group 3 in 1) and in 8 pts according to the 20-mmHg cut-off (Group 1 in 5, Group 2 in 2, Group 3 in 1). The sensitivity,specificity, positive and negative predictive values of each algorithm are presented in Table 2. Sensitivity was similar at 100% for the 3 algorithms, but the ESC/ERS algorithm had better specificity, when PH was diagnosed with the 25-mmHg cut-off. For the 20-mmHg cut-off, sensitivity was better with ASIG and the specificity was better with the ESC/ERS algorithm. For both cut-offs ESC/ERS had the best positive predictive value, and the best negative predictive value for the 20-mmHg cut-off. The negative predictive values were similar for the 3 algorithms.

Conclusion: The ESC/ERS algorithm seems to perform better in detecting PH in patients with SSc. However our numbers are still small for a firm conclusion. Another limitation of this study was that RHC was not performed in patients who did not fulfill criteria according to any of the screening algorithms. The sensitivities may be lower than what we propose, if there are patients with PH who are asymptomatic and not captured with any of the algorithms.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate any correlation between the Raynaud's Condition Score (RCS) and the morphological and functional methods available to evaluate microvascular damage in systemic sclerosis (SSc) patients (1-4).

Methods: Sixty-six SSc patients with Raynaud's phenomenon (RP) were enrolled during routine clinical assessment after informed written consent (60 women and 6 men, mean age 61±17 years, mean RP duration 11±9 years, mean disease duration 7±5 years). RCS, frequency and duration of Raynaud's attacks were assessed together. All patients had been on a stable drug regimen for at least two months, all vasodilator drugs had been suspended at least four week before evaluation (cyclic prostanoids, endothelin-1 receptor antagonists, ACE-inhibitors, calcium channel blockers). Patients were allowed to continue other treatments: hydroxychloroquine (5 patients), methotrexate (3 patients), cyclosporine A (10 patients), mycophenolate (6 patients), proton-pomp inhibitors (21 patients).

Nailfold videocapillaroscopy (NVC) was performed in each patient to assess any morphological microvascular damage and the microangiopathy evolution score (MES) was calculated (2). Blood perfusion (BP) was measured by Laser Speckle Contrast Analysis (LASCA) (3) at the level of fingertips, periungual areas, dorsum and palm of the hands. Statistical analysis was carried out by non-parametric tests.

Results: A positive correlation was observed between RCS and BP at the level of the fingertips, periungual areas and palms of the hand ($p< 0.01$, $r=0.85$, for all areas). There was no statistically significant correlation between RCS and BP at the dorsum hand level, whilst there was a positive correlation between RCS and MES ($p=0.03$, $r=0.79$).

RCS for RP activity (possible range 0-10) was 5±2, frequency (number of event during the day) was 2±1 and duration (in minutes) was 14±6 of Raynaud's attacks.

BP at the level of fingertips was 67±17 PU, periungual areas 60±16, palm of hands 59±18 and dorsum of hand 49±22. The MES average value was 3±2.

Conclusion: Our findings demonstrate a significant correlation between the RCS and the morphological and functional methods used to evaluate microvascular damage in SSc patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

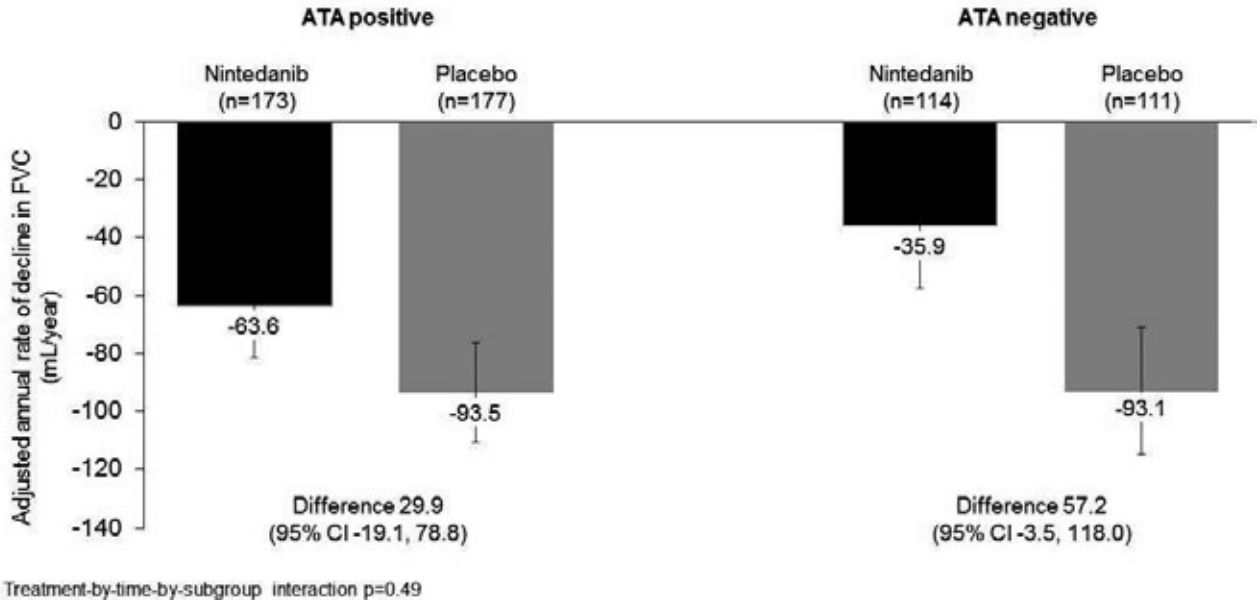
Session Time: 9:00AM–11:00AM

Background/Purpose: The presence of anti-topoisomerase I antibody (ATA) in patients with systemic sclerosis (SSc) has been associated with a greater risk of developing interstitial lung disease (ILD) and a greater rate of lung function decline in patients with early SSc. In the SENSCIS trial, nintedanib reduced the annual rate of decline in forced vital capacity (FVC) versus placebo in patients with SSc-ILD. We analyzed data from the SENSCIS trial in subgroups based on ATA status at baseline.

Methods: Patients with SSc according to the 2013 ACR/EULAR classification criteria, with ≥10% fibrosis of the lungs on a high-resolution computed tomography (HRCT) scan and with onset of the first non-Raynaud symptom < 7 years before screening were randomized to receive nintedanib 150 mg bid or placebo, stratified by the presence of ATA (based on historical information or, if not available, analysis at a central laboratory). We analyzed outcomes and adverse events over 52 weeks in subgroups of patients who were ATA positive or negative at baseline.

Results: Of 576 patients treated in the SENSCIS trial, 173 (60.1%) and 177 (61.5%) patients in the nintedanib and placebo groups, respectively, were ATA positive. In the subgroups that were ATA positive and negative, respectively, mean (SD) FVC (mL) was 2459 (773) and 2563 (781), and mean FVC % predicted was 71.4 (15.9) and 74.3 (17.7). Nintedanib reduced the rate of FVC decline compared with placebo both in patients who were ATA positive and negative. The treatment effect of nintedanib on reducing the rate of FVC decline was numerically greater in patients who were ATA negative than positive (Figure) (-63.6 vs -35.9 ml/year), but the treatment-by-time-by-subgroup interaction did not indicate heterogeneous treatment effects between the subgroups (p=0.49). In the nintedanib and placebo groups, respectively, absolute declines in FVC >5% predicted were seen in 23.1% and 30.5% of patients who were ATA positive (OR 0.69 [95% CI 0.43, 1.10]) and 16.7% and 25.2% who were ATA negative (OR 0.59 [0.31, 1.14]) (treatment-by-subgroup interaction p=0.73). Adjusted mean absolute changes from baseline in modified Rodnan skin score at week 52 in the nintedanib and placebo

Figure. Annual rate of decline in FVC (mL/yr) over 52 weeks in the SENSCIS trial in subgroups by ATA status at baseline.



groups were -1.5 and -1.7 in patients who were ATA positive (difference 0.2 [95% CI -0.7, 1.2]) and -3.2 and -2.4 in patients who were ATA negative (difference -0.8 [-2.0, 0.4]; treatment-by-visit-by-subgroup interaction p=0.18). The adverse event profile of nintedanib was consistent between patients who were ATA positive and negative.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, the rate of FVC decline over 52 weeks in placebo-treated patients was similar between patients who were ATA positive and ATA negative. Nintedanib reduced the rate of FVC decline compared with placebo both in patients who were ATA positive and negative, with a numerically greater treatment effect in patients who were ATA negative.

The Clinical Features of Anti-RNA Polymerase III Antibodypositive Systemic Sclerosis with and Without Malignancy

Masanari Kodera,[1] Yoshihito Tanaka,[2] Yumi Ito,[2] Miho Sugata,[2] Satoko Hisada,[2] Naohisa Ichiki,[2] and Toshiaki Tanabe[2], [1]Japan Community Health care Organization Chukyo Hospital, Department of Dermatology and Rheumatology, Aichi, Japan, [2]Japan Community Health care Organization Chukyo hospital, Nagoya, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Sclerosis (SSc) patients with anti-RNA polymerase III (RNAP) antibody have been reported to have an increased risk of malignancy as compared with those with other disease-specific autoantibodies in Caucasian populations. The aim of this study was to investigate the relationship between disease-specific autoantibodies and malignancy, to examine the expression of RNAP in tumor tissues and to examine of the clinical features of cases with and without malignancy.

Methods: The study involved 208 Japanese patients with SSc consisting of 47 male and 161 female patients with a mean age of 63.1 ± 14.0 years. Of 208 patients, 52patients had diffuse cutaneous systemic sclerosis (dcSSc) and 156 had limited cutaneous systemic sclerosis (lcSSc). Fourteen patients (6.7%)had anti-RNAP antibody, 36 (17.3%) patients had anti-topoisomerase I (Topo I) antibody and 112 patients (53.8%) had anticentromere antibody (ACA), 19 patients had the other antibodies, and 27 patients had unknown antibodies. Malignant tumor tissues were stained using an anti-POLR3A antibody (Atlas antibodies, Sweden), which provided instructions for making the subunit A of RNA polymerase III.Statistical analysis: Statistical analysis was performed using the Mann-Whitney U test for determining the level of significance of differences between sample means. A p value less than 0.05 was considered statistically significant.

Results: The prevalence of malignancy was significantly higher in patients with RNAP antibody (8/14, 57.1%) than in those with Topo I antibody (2/36, 5.5%) and in those with ACA (5/112, 4.4%). Importantly, among 8 patients with RNAP antibody and malignancy, 5 patients (62.5%) developed malignancy from 2 years before to 1 years after SSc onset. Tumor tissues obtained from SSc patients with RNAP antibody complicated with

malignancy were stained using POLR3A antibody. Expression of POLR3A protein was observed in the tumor tissue.Regarding other clinical correlation, RNAP poisitive SSc patients with malignancy exhibited increased male/all ratio relative to those without malignancy (75% vs 33% p< 0.05). The mean age of RNAP SSc patients with maligncay was significantly higher than without malignancy (66.9 vs 52.8 years old p< 0.05). RNAP SSc patients with malignancy had average modified Rodnan skin score (MRSS) less than those without malignancy (7.38 vs 21.5 p< 0.05).

Conclusion: Japanese SSc patients with RNAP have an increased risk of malignancy as compared with those with other disease-specific autoantibodies. This result was similar to previous reports in Caucasian populations. In SSc patients with RNAP antibody complicated with malignancy, it was shown that POLR3A protein was expressed frequently in tumor tissues. SSc patients with RNAP could be considered to share the same pathological process among different ethnic groups. Furthermore, among SSc patients with anti-RNAP antibody, it was considered that male, relatively old, and patients with low MRSS should pay attention especially to the complication of malignancy.

HAP: Human Activity Profile–adjusted activity score: 0(worst)-94(best)	50.0±3.0	81.5±1.3	p<0.0001
HAQ: Health Assessment Questionnaire: 0(best)-3(worst)	0.9±0.1	0.1±0.0	p<0.0001

Background/Purpose: Systemic sclerosis (SSc) is a chronic, multisystem, connective tissue disorder characterized by fibrosis of the skin and internal organ involvement, which can influence all aspects of life including sexual life. The aim of this study was to assess sexual functioning in female SSc patients compared to age-/sex-matched healthy controls (HC) and to determine the association between sexual health impairment and disease activity, treatment, physical and psychological aspects of the disease.

Methods: In total, 60 women (45 currently have a partner) with SSc (mean age: 49.5, disease duration: 6.2 years, lcSSc/dcSSc: 38/22, mRSS: 11.0, ESSG activity index: 2.4), who fulfilled the ACR/EULAR 2013 criteria, and 60 healthy controls (54 currently have a partner, mean age: 49.5) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function (FSFI, SFQ28, BISFW, PISQ-12), quality of sexual life (SQoL-F), pelvic floor function (PFIQ-7), fatigue (FIS, MAF), physical activity (HAP), severity of functional impairment (SHAQ – only in SSc patients) and depression (BDI-II). A standard laboratory testing was performed. Data are presented as mean ± SEM.

Results: Patients with SSc had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W, SFQ28, PISQ-12 – in all subscales as well as total scores) and worse sexual quality of life (SQoL-F) compared to HC (table). Worse scores in SSc patients were associated with increased inflammation [CRP: FSFI (r=-0.260, p=0.0499), BISF-W (r=-0.273, p=0.0398), SFQ28 Pain Domain (r=-0.362, p=0,0056], disease activity [ESSG activity score: FSFI Pain Domain (r=-0.297, p=0.0210), FSFI Satisfaction Domain (r=-0.263, p=0.0423), PISQ-12 (r=0.403, p=0.0024)], more severe functional impairment [SHAQ: FSFI (r=-0.526, p< 0.0001), BISF-W (r=-0.477, p< 0.0001], greater fatigue [FIS: FSFI (r=-0.490, p< 0.0001), BISF-W (r=-0.458, p=0.0002), MAF: FSFI (r=-0.358, p=0.0011), BISF-W (r=-0.378, p=0.0030)], more severe depression [BDI-II: FSFI (r=-0.411, p< 0.0001), BISF-W (r=-0.419, p=0.0008)], deteriorated quality of life [HAQ: FSFI (r=-0.342, p=0.0073)], and worse ability to perform physical activities [HAP: FSFI (r=0.509, p< 0.0001), BISF-W (r=0.474, p=0.0002)]. No associations were found with disease duration, current prednisone equivalent dose or skin score.

Conclusion: Women with SSc reported significantly impaired sexual function and sexual quality of life and pelvic floor function than healthy controls with identical age. Worse scores in SSc were associated with disease activity, increased inflammation, more severe functional impairment, physical inactivity, fatigue, depression and decreased quality of life.

Gastritis and esophagitis	0.80	0.15 – 4.25	0.7933

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastro-intestinal (GI) involvement is universal in systemic sclerosis (SSc) and may affect the entire length of the bowel, most commonly the esophagus (1). The pathogenesis is unknown but it is proposed that vasculopathy, immune-mediated abnormalities, fibrosis and atrophy, all contribute to disruption of GI function in SSc. Esophageal involvement has been associated with more severe scleroderma-related interstitial lung disease (SSc-ILD), which is a major cause of morbidity and mortality (2,3,4). Pulmonary function tests (PFT) and high resolution chest CT scan (HRCT) are commonly used to evaluate for SSc-ILD. Common HRCT findings may include potentially reversible changes such as ground glass opacities (GGO), and irreversible findings such as fibrosis, traction bronchiectasis and honeycombing (5). We sought to study the association of abnormal endoscopic and HRCT findings in our SSc cohort with ILD.

Methods: We examined the records of 140 SSc outpatients, all of whom met the 2013 ACR criteria for SSc (6). SSc-ILD was confirmed by HRCT associated with restrictive pattern on PFT. Descriptive HRCT findings included outcomes of honeycombing, bronchiectasis, and GGO. Pearson chi-square tests and student's t-tests were used to assess differences in distributions of clinical and sociodemographic variable across outcomes, respectively. Odds ratios of presence of honeycombing, bronchiectasis and GGO were estimated using logistic regression.

Results: A total of 140 SSc patients were enrolled, of whom 71 had endoscopies performed. Among those who were scoped, 68 (96%) had abnormalities detected, of which the majority were gastritis (n=40, 59%) and esophagitis (n=26, 38%). SSc patients with GGO on HRCT were less likely to have esophagitis than those without GGO (53% vs 25%, p=0.02; table 1). Patients with gastritis had 3.2 times higher odds of having GGO than patients with esophagitis (95% Confidence interval=0.76-13.41; table 2). We observed no significant differences in demographics, disease duration or serologic status between SSc patients with and without ILD who had abnormal endoscopies.

Conclusion: Abnormal endoscopies are common in SSc. Patients with SSc-ILD had a higher prevalence of gastritis relative to esophagitis, and those with gastritis had a higher likelihood of having GGO on HRCT. Larger prospective studies are needed to elucidate any causal relationship and to better understand the complex relationship between the upper GI tract and pulmonary findings in patients with SSc-ILD.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic graft-versus-host disease (cGVHD) is a major cause of morbidity and mortality after allogeneic hematopoietic stem cell transplantation (HCT). Clinically, cGVHD is a multiorgan syndrome involving

tissue inflammation and fibrosis that often result in permanent organ dysfunction with important repercussions at the systemic, cutaneous and musculoskeletal levels.

Objectives: To describe the musculoskeletal and connective tissue manifestations, in the first visit, of the patients with cGVHD treated in a multidisciplinary consultation (Hematology /Dermatology/Rheumatology).

Methods: Observational and prospective study to describe the clinical characteristics of patients with cutaneous and musculoskeletal cGVHD collected in the database. We describe the clinical characteristics of 58 patients with sclerodermiform GVHD well cutaneous, fascial and / or tendinous detected in the first visit. The usual variables, the transplant reason disease, the type of transplant, and the assessment of clinical manifestations according to NIH diagnostic and follow-up criteria: for skin involvement, ROM (range of motion) and P-ROM (scale of photographic range of motion) to objectify the degree of limitation of joint mobility. The descriptive and frequency statistical analysis is done through Microsoft Office Excel 2007.

Results: Sixty-three (67%) of the patients seen in the clinic had some type of non-lichenoid and / or musculoskeletal skin reaction. Five (7%) patients did not meet diagnostic or distinctive criteria of cGVHD (1 muscle cramps, 2 arthralgias and 2 polymyalgia). The cohort with sclerotic involvement (58 patients): 23 (40%) were women and 35 (60%) males, with a mean age of 52 years (r 7-78 years). The most frequent diseases that cause the transplant were acute myeloid leukemia (32%) and non-Hodgkin lymphoma (31%), and thirteen (22%) patients did not receive immunosuppressive treatment at the time of the visit. Ten (30%) patients were diagnosed by skin biopsy. The mean time from transplant to the initial visit was 3 years (r 8 months to 9 years). Seven (12%) had musculoskeletal sclerotic involvement (fascial / tendinous) detected by ROM without objective cutaneous involvement and the cutaneous involvement was severe in most cases (Tables attached)

Table 1: Skin and joint/fascia scoring

	SCORE 0	SCORE 1	SCORE 2	SCORE 3
ECOG*	43 (74%)	12 (20%)	2 (3%)	1 (1,7%)
ROM^	43 (74%)	11 (19%)	3 (5%)	1 (1,7%)
Skin"	7 (12%)	0 (0%)	11 (19%)	40 (69%)

* ECOG Eastern Cooperative Oncology Group Perfomance status " ROM Range of mobility

Table 2: Clinical forms

	n= 58
Sclerodermiform	41 (70%)
Superficial Scl	11 (19%)
Deep Scl	21(36%)
Lipodermatosclerosis type	3 (5%)
Mixed (lichenoid + Scl)	6 (10%)
Eosinophilic fasciitis	10 (17%)
Soft tissue sclerosis without skin involvement	7 (12%)

Conclusion: Sclerodermiform affectation is very common in our cohort, with fascial and tendon affectation, mainly of the flexor tendons of the carpus, the most frequent and, sometimes, without cutaneous involvement, making it difficult to detect them, being necessary the use of scales of joint assessment systematically. Physiotherapy is a fundamental part of the treatment.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Calcinosis cutis is a debilitating complication of systemic sclerosis (SSc) affecting one quarter of patients, most frequently involving the hands. We previously developed and published a radiographic scoring system to assess severity of calcinosis affecting the hands in patients with SSc that is feasible with excellent inter- and intra-rater reliability. We sought to further validate our radiographic scoring system to assess for change over 1 year and to identify factors associated with improvement or progression.

Methods: Baseline and 1-year antero-posterior hand radiographs were obtained in 39 SSc patients with calcinosis who were prospectively enrolled at 6 centers within the US, Canada, Mexico and Australia. Two blinded readers scored all radiographs using the calcinosis scoring system. We defined progressive calcinosis as >10% increase in score from baseline at 1 year, stable calcinosis as change in score between -10% to 10%, and improvement of calcinosis as decrease in score by >10% (Figure 1).

Results: Our cohort was 85% female, 69% Caucasian, 28% Hispanic, and 3% Asian. 72% had limited cutaneous disease. Mean disease duration from first non-Raynaud phenomenon (RP) symptom was 16.9±11.4 years. Inter-rater reliability was high with intra-class correlation coefficient of 0.93 (0.89-0.95). The median percentage of change from

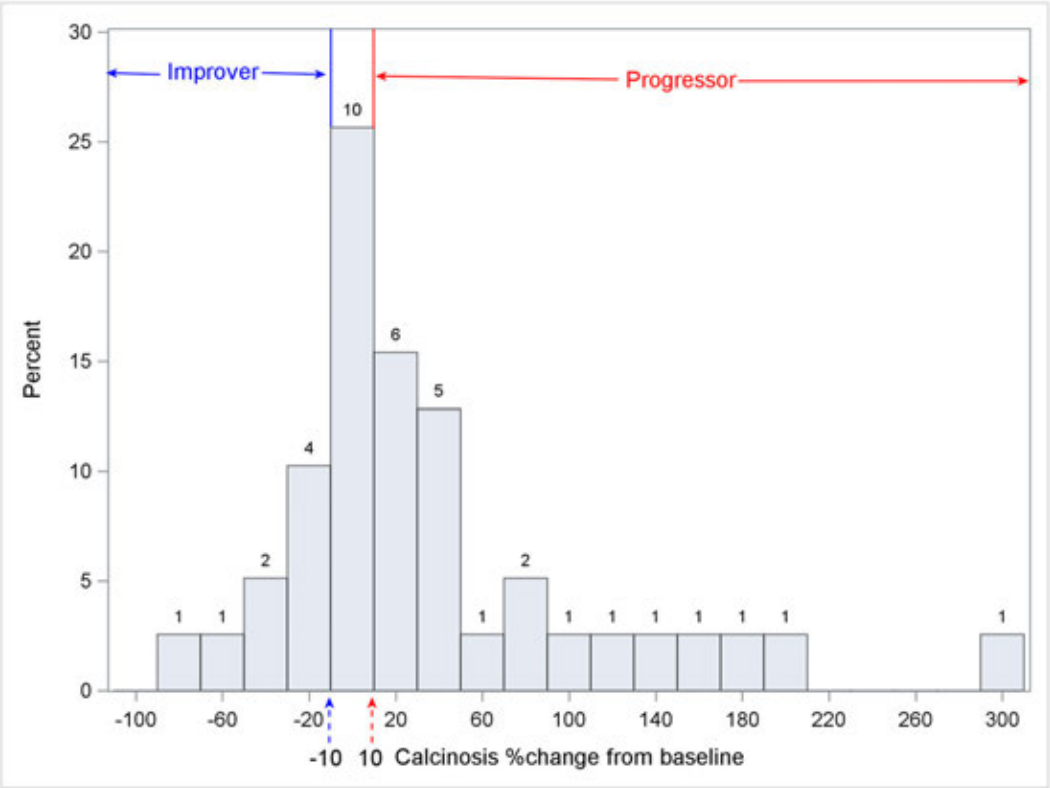

Figure 1. Distribution of change in calcinosis score over 1 year

baseline to 1 year was 12.8% (range -89.3-290.2%). Twenty-one patients (54%) experienced progression of calcinosis over 1 year with a range of 12.7-290.2% worsening from baseline; 10 (26%) remained stable; and 8 (20%) had improvement (range -89.3-7.4%)(Figure 1). Patients with progressive calcinosis had lower mean modified Rodnan skin score (mRSS) (3.81 vs. 6.5, p=0.0446) and lower prevalence of pulmonary artery hypertension (PAH) by right heart catheterization than patients who did not progress (0 % vs 23%, p= 0.022)(Table 1). They also exhibited a trend toward having more digital pitting scars (76% vs. 50%, p= 0.0892), and arthritis (52% vs. 34%, p= 0.0694). Patients whose calcinosis improved had higher mean mRSS (7.13 vs. 4.52, p=0.061), less arthritis (0 vs. 50%, p=0.0154) and greater prevalence of antibodies against PM-Scl (43 vs. 3%, p=0.018) than patients whose calcinosis did not improve. They also exhibited a trend toward having less gastrointestinal disease (50 vs. 84%, p=0.0651). In multivariable analysis, a trend for anti-PM-Scl antibodies to be a predictor of calcinosis improvement persisted (OR 13.5 (0.99 - 183.14), p=0.051)(Table 2).

Conclusion: We confirmed the excellent inter-rater reliability of our radiographic calcinosis scoring system and quantified changes in calcinosis severity over 1 year in a longitudinal cohort of SSc patients. More than half of patients experienced >10% progression of calcinosis over one year; however, 20% of patients improved and these patients were more likely to be positive for the PM-Scl antibody.

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Nailfold videocapillaroscopy (NVC) allows assessment of possible microvascular markers of severity and progression in systemic sclerosis (SSc), such as reduced capillary number, which has been associated with a high risk of developing disease complications (1-2). An automated capillary counting system (AUTOCAPI) has recently been validated in SSc patients (3). The aim of this study was to evaluate the performance of this automated software for absolute nailfold capillary number counting, in SSc patients with different NVC patterns of microangiopathy (Early, Active, and Late).

Methods: 183 SSc patients were random collected and enrolled at both Genova and Ghent Divisions of Rheumatology (LeRoy 2001 or ACR 2013 criteria, mean age 55±13 year, mean disease duration 5.5±6.8 years) and classified by NVC in one the following patterns: 28 "not specific", 37 "Early", 89 "Active", 29 "Late") (4). Eight fingers for each patient were analysed, counting the number of nailfold capillaries manually and by the AUTOCAPI software (DS Medica, Italy) along a millimetre in each finger image (3). The mean capillary number value from the eight finger images was calculated. The software reliability was assessed through calculation of the intraclass correlation coefficient (ICC) between automatic and manual counting.

Results: The mean number of capillaries assessed by manual vs automatic counting was as follows: 5.23±1.7 vs 5.47±1.3 in the total group of SSc patients, 5.91±1.2 vs 6.87±1.2 in the "not specific", 7.23±1.4 vs 5.67±1.1 in the "early", 4.67±1.1 vs 5.16±1.2 in the "active" and 3.72±1.5 vs 4.85±1.1 in the "Late" pattern of microangiopathy.The higher standard deviation observed for automatic counting was 1.23 in the "not specific" group. The following ICC's were obtained respectively for total patients, "not specific", "Early", "Active", and "Late" NVC patterns: 0.53, 0.51, 0.48, 0.50 and 0.66. The mean values for the manual versus automatic capillary counting assessed by the two centres in all SSc patients were respectively: 5.92±1.8 and 5.02±1.1 for Genova centre, and 4.71±1.5 and 5.83±1.4 for Ghent centre. The automatic counting confirmed that capillary number progressively reduces from "Early" to "Active" to "Late" NVC pattern of microangiopathy in SSc.

Conclusion: This study demonstrates the good reliability of AUTOCAPI software in nailfold capillary number counting in SSc patients with different patterns of microangiopathy. The use of automated counting software allows to standardize nailfold capillary assessment among different Rheumatologic centres.

SESSION INFORMATION

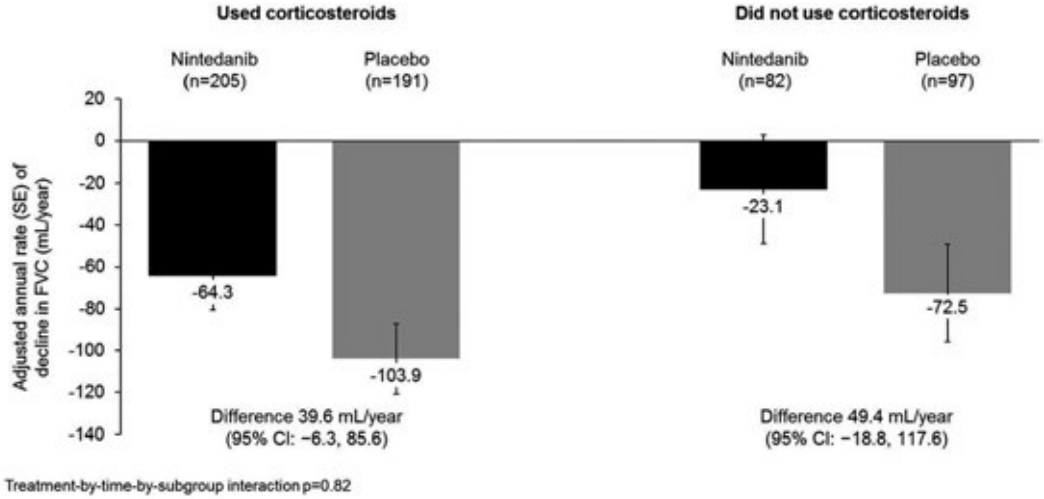
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In the SENSCIS trial in patients with systemic sclerosis-associated interstitial lung disease (SSc-ILD), nintedanib reduced the rate of decline in forced vital capacity (FVC) over 52 weeks compared with placebo (–52.4 versus –93.3 mL/year; difference 41.0 mL/year [95% CI 2.9, 79.0]; p=0.04), with adverse events that were manageable for most patients. Corticosteroids are commonly used in patients with SSc-ILD, despite a lack of evidence to support their efficacy. We assessed the efficacy and safety of nintedanib in patients who did and did not use corticosteroids in the SENSCIS trial.

Methods: Patients with SSc-ILD with ≥10% fibrosis of the lungs on HRCT were randomized to receive nintedanib 150 mg bid or placebo. Patients taking prednisone ≤10 mg/day or equivalent were allowed to participate. Lung function outcomes and adverse events (irrespective of causality) were analyzed in subgroups of patients who did and did not use corticosteroids. Corticosteroid use included use at baseline, during treatment with trial drug, and following discontinuation of trial drug (up to week 52).

Results: Of 576 patients who received trial drug, 206 (71.5%) and 191 (66.3%) patients in the nintedanib and placebo groups, respectively, used corticosteroids. Mean (SD) FVC (mL) at baseline was 2499 (814) in patients who used corticosteroids and 2501 (691) in patients who did not, and FVC % predicted was 71.9 (17.0) and 73.8 (15.9) in these

Figure. Annual rate of decline in FVC (mL/year) over 52 weeks in the SENSCIS trial in subgroups by use of corticosteroids



groups respectively. In patients who received placebo, the mean (SE) rate of decline in FVC over 52 weeks was numerically greater in patients who used corticosteroids than in those who did not [-103.9 (16.7) versus -72.5 (23.3) mL/year]. Nintedanib reduced the annual rate of decline in FVC (mL/year) versus placebo both in patients who did and did not use corticosteroids, with no difference in the treatment effect between subgroups detected (treatment-by-time-by-subgroup interaction p=0.82) (Figure). In the nintedanib and placebo groups, respectively, absolute declines in FVC >5% predicted were seen in 22.4% and 27.2% of patients who used corticosteroids (OR 0.78 [95% CI: 0.49, 1.23]) and 15.9% and 30.9% of patients who did not use corticosteroids (OR 0.42 [95% CI: 0.20, 0.87]) (treatment-by-subgroup interaction p=0.16). The adverse event profile of nintedanib was similar between the subgroups by corticosteroid use, but the proportions of patients with nausea or vomiting adverse events were lower, and the proportion with upper respiratory tract infection was higher, in those who used corticosteroids (Table). The proportion of patients treated with nintedanib who had adverse events leading to discontinuation of study drug was similar in patients who did and did not use corticosteroids. A limitation of these analyses is that they have not been adjusted for differences between the subgroups of patients taking and not taking corticosteroids at baseline.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, over two-thirds of patients used corticosteroids. Nintedanib reduced the annual rate of decline in FVC irrespective of use of corticosteroids. The adverse event profile of nintedanib was similar in patients who did and did not use corticosteroids.

SESSION INFORMATION

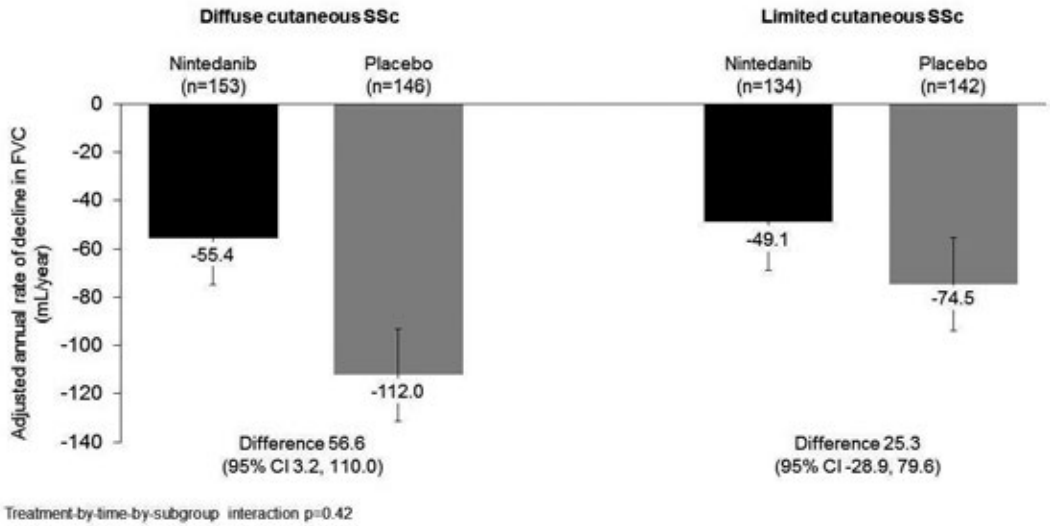
Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Figure. Annual rate of decline in FVC (mL/yr) over 52 weeks in the SENSCIS trial in subgroups with diffuse cutaneous SSc or limited cutaneous SSc.



Background/Purpose: Patients with diffuse cutaneous systemic sclerosis (dcSSc) are at greater risk of developing interstitial lung disease (ILD) than patients with limited cutaneous systemic sclerosis (lcSSc). In the SENSCIS trial in patients with SSc-ILD, nintedanib reduced the rate of decline in forced vital capacity (FVC) vs placebo over 52 weeks, with no difference between groups in the change from baseline in modified Rodnan skin score (mRSS). We analyzed data from the SENSCIS trial in subgroups of patients with lcSSc or dcSSc.

Methods: Patients with SSc-ILD with onset of first non-Raynaud symptom < 7 years before screening and ≥10% fibrosis of the lungs on a high-resolution computed tomography (HRCT) scan were randomized to receive nintedanib 150 mg bid or placebo. We analyzed outcomes and adverse events over 52 weeks in subgroups of patients with lcSSc or dcSSc at baseline.

Results: Of 288 patients treated in each group, 153 (53.1%) and 146 (50.7%) in the nintedanib and placebo groups, respectively, had dcSSc. At baseline, in patients with dcSSc and lcSSc, respectively, mean (SD) FVC (mL) was 2461 (797) and 2542 (755), FVC % predicted was 70.5 (16.3) and 74.8 (16.8), and modified Rodnan skin score (mRSS) was 16.7 (8.8) and 5.2 (4.1). In the placebo group, the annual rate of FVC decline was numerically greater in patients with dcSSc than lcSSc (-112.0 vs -74.5 mL/year). Nintedanib reduced the rate of FVC decline both in patients with lcSSc and dcSSc. The treatment effect of nintedanib on FVC decline was numerically greater in patients with dcSSc than lcSSc, but no difference in the treatment effect between subgroups was detected (treatment-by-time-by-subgroup interaction p=0.42) (Figure). In the nintedanib and placebo groups, respectively, absolute declines in FVC >5% predicted at week 52 were seen in 22.2% and 28.8% of patients with dcSSc (OR 0.71 [95% CI 0.42, 1.20]) and 18.7% and 28.2% with lcSSc (OR 0.59 [0.33, 1.04]) (treatment-by-subgroup interaction p >0.05). Adjusted mean absolute changes from baseline in mRSS at week 52 in the nintedanib and placebo groups were -1.6 and -1.5 in patients with dcSSc (difference -0.2 [95% CI -1.2, 0.8]) and -2.7 and -2.5 in patients with lcSSc (difference -0.3 [-1.3, 0.8]; treatment-by-subgroup interaction p >0.05). The adverse event profile of nintedanib was similar between patients with dcSSc and lcSSc.

Conclusion: In the SENSCIS trial in patients with SSc-ILD, the rate of decline in FVC in patients who received placebo was greater in patients with dcSSc than lcSSc. Nintedanib reduced the rate of FVC decline both in patients with dcSSc and lcSSc. The treatment effect of nintedanib was numerically greater in patients with dcSSc than lcSSc,

but statistical testing did not indicate heterogeneity in the treatment effect between the subgroups. No effect of nintedanib was demonstrated on skin fibrosis assessed using the mRSS.

Comparison of Automated Capture and Analysis System of Sublingual Microvessels and Nailfold Videocapillarscopy for Microvascular Assessment in Systemic Sclerosis

Mislav Radic,[1] Julie Thomas,[2] and Tracy Frech[3], [1]University Hospital Split, Split, Croatia, [2]University of Utah, Division of Rheumatology, Salt Lake City, UT, [3]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT

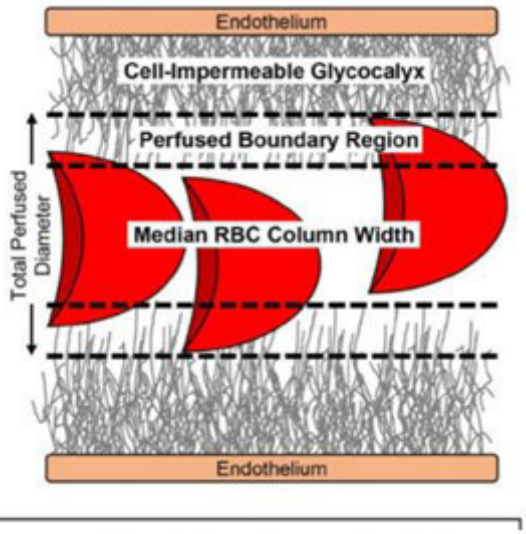

Figure. Sublingual intravital microscopy parameters

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Similar to nailfold videocapillaroscopy (NVC), automated capture and analysis of sublingual microvessel segments (intravital microscopy) can define vasculopathy, and distinguish systemic sclerosis (SSc) patients from healthy controls. The aim of this study is to compare automated capture and analysis of sublingual microcirculation parameters with NVC derived scores for assessment of SSc-related vasculopathy.

Methods: Consecutive, consented SSc registry patients that met ACR/EULAR classification criteria had intravital microscopy of the sublingual microcirculation and NVC at the time of routine care. The following intravital microscopy parameters were captured: total microvascular density, median RBC width (RBCfract) and perfused boundary region (PBR) (Figure 1). The following NVC parameters were obtained: (1) capillaroscopy patterns (early, active and late); (2) degree of enlarged capillaries, giant capillaries, capillary hemorrhages, capillary density, disorganization of vascular array and capillary ramification assessed by a semi-quantitative method; and (3) microangiopathy evolution score (sum of capillary density, disorganization of vascular array and capillary ramification). Non-parametric tests were used for statistical evaluation.

Results: Thirty-nine SSc patients were enrolled (37 women and 2 men, mean age 59±21 years, mean SSc duration years 9.5±8.9, 30 limited cutaneous SSc and 9 diffuse cutaneous SSc). There was a statistically significant negative correlation between sublingual total microvascular density and microangiopathy evolution score (r=-0.532, p=0.0006). Furthermore, there was a highly significant inverse association between the total microvascular density and number of capillaries measured by NVC (r=-0.569, p=0.0002). There was significant, negative correlation between the total microvascular density and disorganization of vascular array and capillary ramification (r=-0.461, p=0.003) and degree of giant capillaries (r=-0.387, p=0.01). There was no correlation between RBCfract and PBR with NVC parameters.

Conclusion: This study confirmed a significant correlation between intravital microscopy of the sublingual microcirculation and NVC in terms of sublingual total microvascular density and microangiopathy evolution score. The two methods

did not correlate in all captured parameters. Consequently, in order to define progressive vasculopathy in SSc, intravital microscopy of the sublingual microcirculation could be a valuable tool in addition to NVC for longitudinal analysis.

Severe	0 (0)	0.04 (0.00, 0.13)

Valvular heart disease (VHD) in SSc has not been well studied. In this referral-based single-institution cohort, we evaluate the incidence rate (IR) and prevalence of VHD in SSc.

Methods: In this retrospective cohort study, medical records of 506 cases with SSc seen between 1/1/2000 and 11/10/2018, with at least two echocardiograms in the health care system, were manually reviewed. All cases included fulfilled ACR/EULAR 2013 classification criteria for SSc or 3/5 CREST criteria, and had a baseline echocardiogram within five years of diagnosis. Mild, moderate, and severe VHD was clinically defined at time of echocardiogram. IR of VHD, per 100 person-years, and prevalence of VHD were determined. Cox models were used to examine associations between incident VHD and SSc characteristics as well as cardiovascular disease (CVD) risk factors, adjusting for age and sex.

Results: Demographics, SSc characteristics, and baseline CVD risk factors are reported in table 1. Mitral regurgitation (MR) was most common, with 20% of cases having at least mild MR on baseline echocardiogram (table 2). The prevalence of at least mild aortic regurgitation (AR) or aortic stenosis (AS) was 7% and 1%, respectively (table 2). The highest IR (IR) (per 100 person-years) was 6.36 (95% CI 5.24 - 7.59) for mild MR, followed by 1.80 (95% CI 1.31 - 2.36) for mild AR and 1.25 (95% CI 0.87 - 1.70) for mild AS (table 2). Development of severe VHD was only observed for AS, with an IR of 0.28 (95% CI 0.12 - 0.51). On age- and sex-adjusted hazard models examining baseline SSc and CVD risk factors for incident VHD, age remained a significant risk factor for all VHD types (table 3). Coronary artery disease (CAD) was associated with incidence of at least mild MR (HR 2.20, 95% CI 1.04 - 4.65) (table 3). Anti-Scl70 antibody was associated with at least mild incident MR (HR 1.81, 95% CI 1.11 - 2.97) and was negatively associated with at least mild incident aortic stenosis (HR 0.18, 95% CI 0.04 – 0.87) (table 3). Anti-centromere antibody trended towards significance for at least mild incident AS (HR 2.02, 95% CI 0.92 - 4.47) (table 3).

Conclusion: MR was the most common VHD found at baseline echocardiogram in this retrospective cohort of patients with SSc, and was also the most common valve abnormality to develop, typically mild in severity. Development of any severe valve disease was less common, with severe aortic stenosis having the highest IR. Follow-up time was

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The Collaborative National Quality and Efficacy Registry (CONQUER) for Scleroderma is a multicenter US-based longitudinal study of patients with systemic sclerosis (SSc) within 5 years of first non-Raynaud's symptom. Supported by the Scleroderma Research Foundation, CONQUER is designed to provide linked bio-specimen and clinical outcomes data on a longitudinal cohort of SSc patients for validation of hypothesis driven research and to provide a platform for studying patient reported outcomes. The purpose of this analysis was to assess the effectiveness of guideline-based registry practices on database quality at 6 months.

Methods: The CONQUER registry was developed using the guidelines of the International Society for Biological Repositories. It was an iterative process between 13 physicians with an expertise in SSc, patient stakeholders, and information technology experts to ensure there is minimal missing data in 775 fields of data elements.

Results: During the first 6 months of the CONQUER Scleroderma study, 151 SSc patients with less than 5 years of disease duration (from first non-Raynaud's symptom) were recruited. The mean age is 51 ± 14 years, 83% are female and 60% of patients have diffuse disease. Data completion is shown in Table 1. Survey completion rates are above 88% for all patient reported outcome surveys. Bio-specimen collection rates are over 97% and disease severity score completion rates are over 98%.

Conclusion: As demonstrated by data completion, the CONQUER study demonstrates the value of guideline-based registries that are designed by physicians, patients, and information technology experts. CONQUER is a unique and growing resource for studying SSc in a longitudinal, US-based population.

Systemic Sclerosis Auto-antibody Profiles Predict Interstitial Lung Disease Onset but Not Progression

Boyang Zheng,[1] Mianbo Wang,[2] Marvin Fritzler,[3] May Choi,[3] Murray Baron,[4] and Marie Hudson[5], [1]Jewish General Hospital, McGill University, Montreal, QC, Canada, [2]Lady Davis Institute, Jewish General Hospital, Montreal, QC, Canada, [3]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [4]Jewish General Hospital, McGill University, Montreal, Canada, [5]Jewish General Hospital, Lady Davis Institute for Medical Research, and Department of Medicine, McGill University, Montreal, QC, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Figure 1: Kaplan-Meier curves to compare the time to ILD onset between auto-antibody subsets

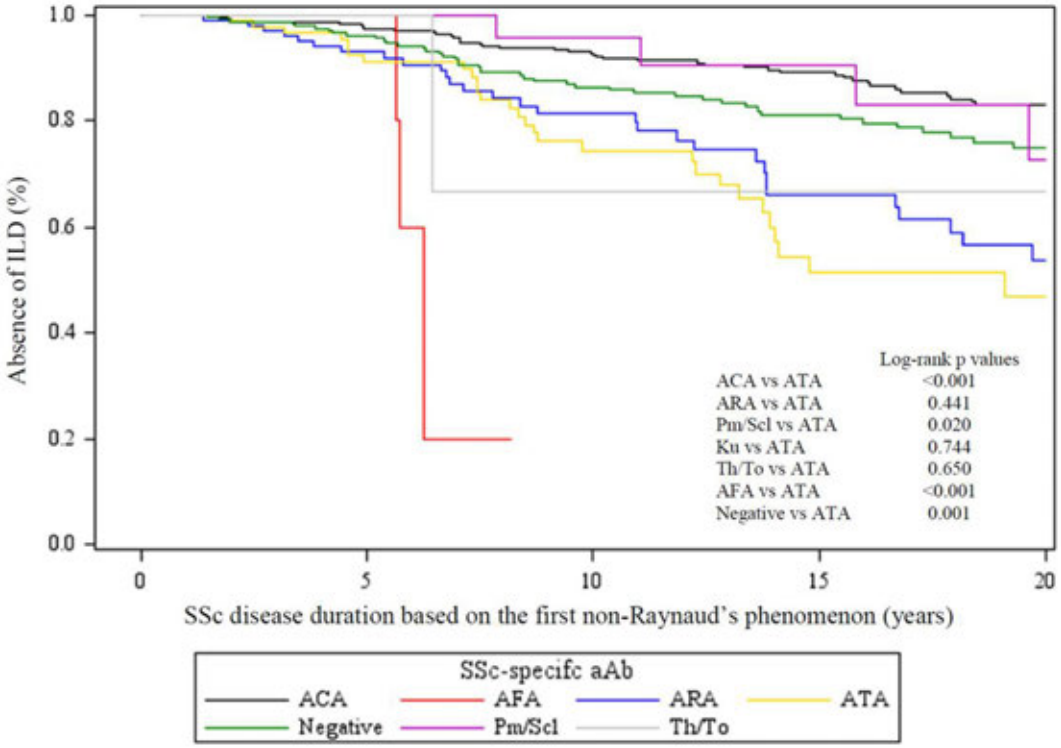

Figure 2: Kaplan-Meier curves to compare the time to clinically meaningful ILD progression between auto-antibody subsets after ILD diagnosis

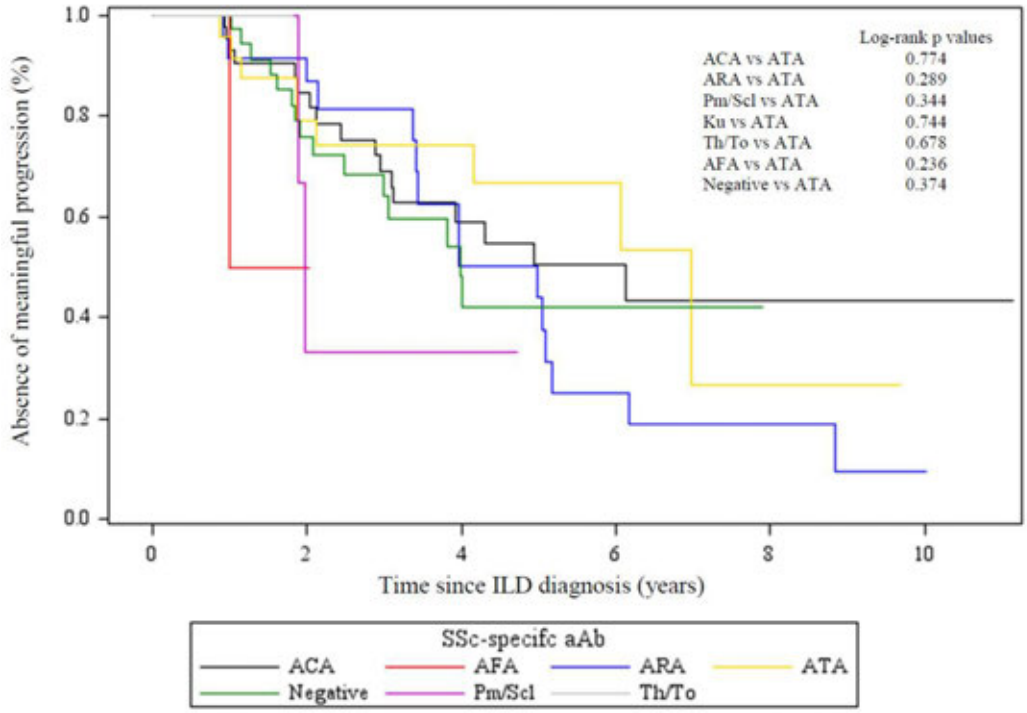

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Interstitial lung disease (ILD) is frequent manifestation and a leading cause of mortality in systemic sclerosis (SSc). Some SSc-related autoantibodies (aAbs), especially anti-topoisomerase I (ATA), are associated with an increased prevalence of ILD. In contrast, anti-centromere (ACA) may be protective. The association with other aAbs is unclear and it is unknown whether aAb profiles can predict the rate of ILD progression. Our goal was to examine the incidence of SSc-ILD and its subsequent progression between different aAb profiles. We hypothesized that while aAbs predict ILD development, all SSc-ILD progress similarly.

Methods: SSc subjects without pre-existing ILD in a large multi-center longitudinal cohort from 2004-2018 were included. ILD was defined by the presence of high-resolution computed tomography (HRCT) findings, or if no HRCT was available, then either a chest x-ray showing interstitial fibrosis, and/or the presence of "velcro like crackles" on exam. Clinically meaningful progression of ILD was defined using OMERACT criteria(1) of ≥10% relative decline in FVC, or ≥5% to < 10% relative decline in FVC and ≥15% relative decline in DLCO. Subjects were grouped based on single specificity aAbs: ATA, ACA, anti-RNA polymerase III (ARA), anti-PM/Scl, anti-Ku, anti-Th/To (hPOP1), anti-fibrillarin (AFA), or negative aAbs. The time to ILD onset was compared between groups using Kaplan Meier and multivariate Cox analyses adjusted for age, gender, diffuse (vs. limited) subset, physician global assessment of severity, immunosuppression exposure at or prior to baseline and presence of anti-Ro52/TRIM21 antibodies. In those with incident ILD, the time to clinically meaningful progression and mortality after ILD onset were examined. ATA served as the reference for all comparisons.

Results: Of 931 patients, 190 (20%) developed ILD: 60/429 (14%) ACA, 31/94 (33%) ATA, 32/114 (28%) ARA, 6/24 (25%) anti-Pm/Scl, 0/2 anti-Ku, 2/5 (40%) anti-Th/To, 4/5 (80%) AFA, and 55/258 (21%) negative aAb. Subjects with ATA developed ILD earlier than ACA, anti-PM/Scl and negative aAb groups (log rank $p < 0.01$, $p = 0.02$ and $p < 0.01$, respectively), although AFA group had the most rapid onset ($p < 0.01$) (Figure 1). In multivariate analyses, ACA and negative aAb groups were less likely (HR (95% CI) 0.36 (0.22, 0.57) and 0.53 (0.34, 0.84) respectively), whereas AFA was more likely (HR (95% CI) 4.12 (1.22, 13.86)) to develop ILD compared to ATA. On the other hand, no differences in the time to clinically meaningful ILD progression (Figure 2) or survival after ILD onset were found between groups.

Conclusion: Compared to patients with ATA, AFA conferred a higher risk of developing ILD, whereas ACA, anti-PM/Scl and the absence of SSc specific aAbs were associated with a lower risk. Nevertheless, ILD developed in all aAb sub-groups and, once present, the aAb profile was not associated with ILD progression or subsequent mortality.

Session Time: 9:00AM–11:00AM

Table 1. Changes in patient reported outcomes, as well as the proportion of participants meeting the minimum clinically important difference (MCID) for each patient reported outcome for SLS II participants randomized to mycophenolate (MMF) versus cyclophosphamide (CYC).

	Change from baseline to 24 months in CYC arm	Change from baseline to 24 months in MMF arm	Treatment group differences (P-value)	% Patients meeting MCID in CYC arm at 24 months	% Patients meeting MCID in MMF arm at 24 months
SF-36 PCS[a]	N=53 Mean change: 2.34 P=0.08	N=53 Mean change: 2.04 P=0.13	0.87	17%	17%
SF-36 MCS[a]	N=53 Mean change: 2.10 P=0.11	N=53 Mean change: 3.41 P=0.02	0.67	20%	21%
Total GIT 2.0[b]	N=53 Mean change: -0.04 P=0.39	N=52 Mean change: 0.05 P=0.33	0.19	13%	10%
HAQ-DI[c]	N=53 Mean change: -0.04 P=0.43	N=53 Mean change: 0.02 P=0.79	0.51	17%	14%
TDI[d]	N=39 Mean change: 2.09 P=0.0003	N=53 Mean change: 1.86 P=0.005	0.80	29%	24%
LCQ[e]	N=52 Mean change: 0.62 P=0.24	N=52 Mean change: 0.74 P=0.12	0.87	16%	10%
SGRQ[f]	N=53 Mean change: -5.53 P=0.029	N=52 Mean change: -3.36 P=0.43	0.34	28%	25%

[a] Postive change for the SF-36 Physical Component Summary (PCS) and Medical Component Summary (MCS) indicates improvement. The MCID for the SF-36 PCS and MCS domains is >= 5.
[b] Negative change for GIT 2.0 indicates improvement. The MCID for the total GIT 2.0 score is <= -0.21.
[c] Negative change for HAQ-DI indicates improvement. The MCID for the HAQ-DI score is <= -0.22.
[d] Postive change for the TDI indicates improvement. The MCID for the TDI score is >= 1.
[e] Positive change for LCQ indicates improvement. The MCID for the LCQ is >= 1.5.
[f] Negative change for SGRQ indicates improvement. The MCID for the SGRQ is <= -4.

Background/Purpose: Interstitial lung disease (ILD) is the leading cause of morbidity and mortality in systemic sclerosis (SSc). The majority of studies investigating novel therapies for SSc-ILD use the forced vital capacity (FVC) as the primary outcome. However, changes in the FVC may not consistently translate into clinically meaningful improvements from a patient's perspective. This study evaluated whether treatment with cyclophosphamide (CYC) and mycophenolate (MMF) improves health-related quality of life (HRQOL) among SSc patients with active ILD.

Methods: This study examined outcomes in patients (N=142) who participated in Scleroderma Lung Study (SLS) II (Tashkin et al. Lancet Resp Med 2016), a randomized controlled trial comparing mycophenolate (MMF) for 2 years versus oral CYC for 1 year followed by 1 year of placebo in patients with relatively early SSc-ILD. The following HRQOL outcomes were examined: Short Form 36 (SF-36), Health Assessment Questionnaire (HAQ) disability index (DI), Baseline and Transitional Dyspnea Index (BDI, TDI), the Leicester Cough Questionnaire (LCQ), St. George's Respiratory Questionnaire (SGRQ), and the Scleroderma Clinical Trials Consortium Gastrointestinal Tract (GIT) 2.0. The differences in HRQOL scores from baseline to 24 months were measured in each treatment arm. The proportion of subjects in each treatment group whose scores improved at >= the minimum clinically important difference (MCID) in HRQOL measures was assessed. Correlations between changes in HRQOL and those in FVC%-predicted were also examined using Pearson correlation coefficient.

Results: Treatment with CYC and MMF led to improvements in HRQOL outcomes, with no appreciable between treatment arm differences (Table 1). The TDI improved significantly in both treatment arms (CYC: P=0.0003; MMF: P=0.005), and 29% and 24% of CYC and MMF patients, respectively, met or exceeded MCID estimates. For the HAQ-DI, 17% and 14% of CYC and MMF patients, respectively, met or exceeded the MCID estimates. For Total SGRQ scores 28% and 25% of CYC and MMF patients, respectively, met or exceeded MCID estimates. At baseline, the FVC%-predicted did not correlate with any of the HRQOL outcomes (coefficients with HRQOL ranged from 0.01 to 0.11; data not shown) The 24-month change in the FVC-% predicted correlated weakly with only a few of the changes in HRQOL scores (HAQ-DI r=-0.30; TDI r=-0.40; SF-36 Physical Component Summary r=0.30).

Conclusion: Treatment with CYC and MMF improved overall HRQOL in patients with SSc-ILD, including a large proportion who improved in dyspnea and respiratory HRQOL by >= MCID estimates. The relationship between HRQOL measures and changes in the FVC was relatively weak, suggesting that changes in the PROs provide additional information about treatment efficacy not captured by changes in the FVC alone in this patient population. The overall improvement in FVC%, along with HRQOL in the SLS-II, supports the treatment of SSc-ILD with immunosuppressive therapies. Future SSc-ILD trials should include PROs as they directly measure how a patient feels and functions.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Three randomized controlled trials in systemic sclerosis (SSc) demonstrated that autologous hematopoietic stem cell transplantation (aHSCT) is superior to standard cyclophosphamide therapy. This EBMT trial was a multi-center, prospective non-interventional study (NISCC1), designed to further decipher aHSCT efficacy and safety in real-life practice and to search for prognostic factors.

Methods: All consecutive adult patients, fulfilling the 2013 ACR/EULAR classification criteria for SSc, and undergoing a first aHSCT between December 2012 and February 2016 were included in the study. Primary endpoint was progression free survival (PFS) after two years. Secondary endpoints were overall survival (OS), non-relapse mortality (NRM) and response (RESP) to treatment, defined as >25% improvement in modified Rodnan skin score (mRSS) and/or ≥10% improvement in lung function test for Forced vital capacity (FVC) or diffusion capacity for carbon monoxide (DLCO) and with no need for further immunosuppression.

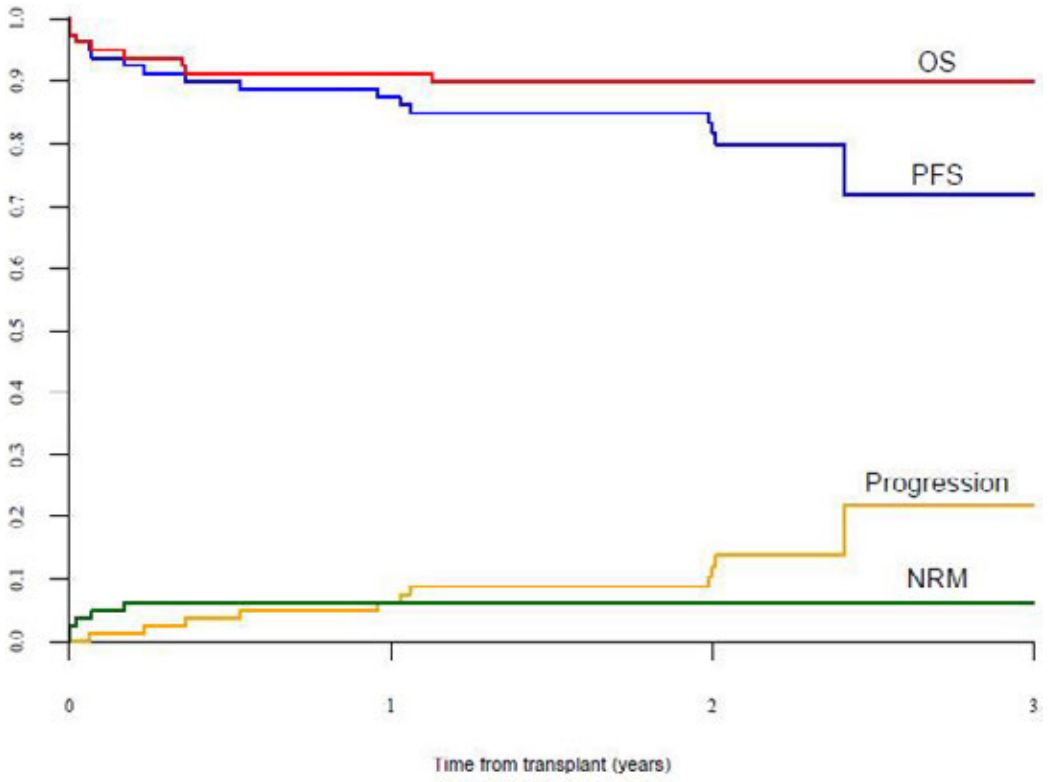

Figure. Kaplan-Mayer curves showing data for overall survival (OS), progression free survival (PFS), progression and non-relapse (treatment) related mortality (NRM) over time

Results: Eighty SSc patients were included. Median follow-up was 24 (6-57) months after aHSCT using cyclophosphamide plus antithymocyte globulin conditioning for all, with CD34+ selection in 35 (44%) patients. Following aHSCT, G-CSF was administered to 34 (43%) patients for a median duration of five (1-13) days. Median time following aHSCT to neutrophil engraftment was 11 (8-24) days and nine (1-25) days to platelet engraftment. There was an inverse correlation between the number of CD34+ cells infused and the time to engraftment (Spearman: r2= -0.31; p< .01), while the number of infused CD34+ cells or addition of G-CSF until aplasia recovery were not associated with a reduced number of infectious complications (p=0.32). At two years, PFS was 81.8%, OS was 90% and RESP was 88.7%. The 100 day NRM was 6.25% (n=5) with four deaths from cardiac events. Mean mRSS decreased from 23.9 at baseline to 14.2 at month 12 and 12.6 at month 24 (n=55, p< 0.001). Regarding lung function, mean FVC increased from 73.6% at baseline to 79.5% at month 12, and 80.6% at month 24 (n=37, p< 0.001); mean DLCO was 60.2% at baseline, 59.7% at month 12 and 60.4% at month 24 (n=35). By multivariate analysis, baseline mRSS >24 and older age at transplant were associated with lower PFS. CD34+-selection was associated with better RESP.

Conclusion: The NISCC1 study is the largest prospective cohort today demonstrating the efficacy and safety of aHSCT in eighty severe SSc patients in a real-life setting. NISCC1 showed superior response in patients with CD34+ graft selection with regard to response to treatment no increase in the rate of infectious complications.

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The soluble guanylate cyclase stimulator riociguat (RIO) is a vasodilator with efficacy in patients with pulmonary arterial hypertension associated with connective tissue disease. Our objective was to evaluate the efficacy and safety of RIO in patients with systemic sclerosis-associated digital ulcers (SSc-DU) (NCT02915835).

Methods: Eligible subjects (with active or painful indeterminate DUs) were randomized in a 1:1 ratio to either placebo (PLA, n = 8) or RIO (n = 9) in individualized doses (maximum of 2.5 mg three times daily) during an 8-week titration period, followed by an 8-week stable dosing period.PDE5 inhibitors were not allowed. This was followed by an optional

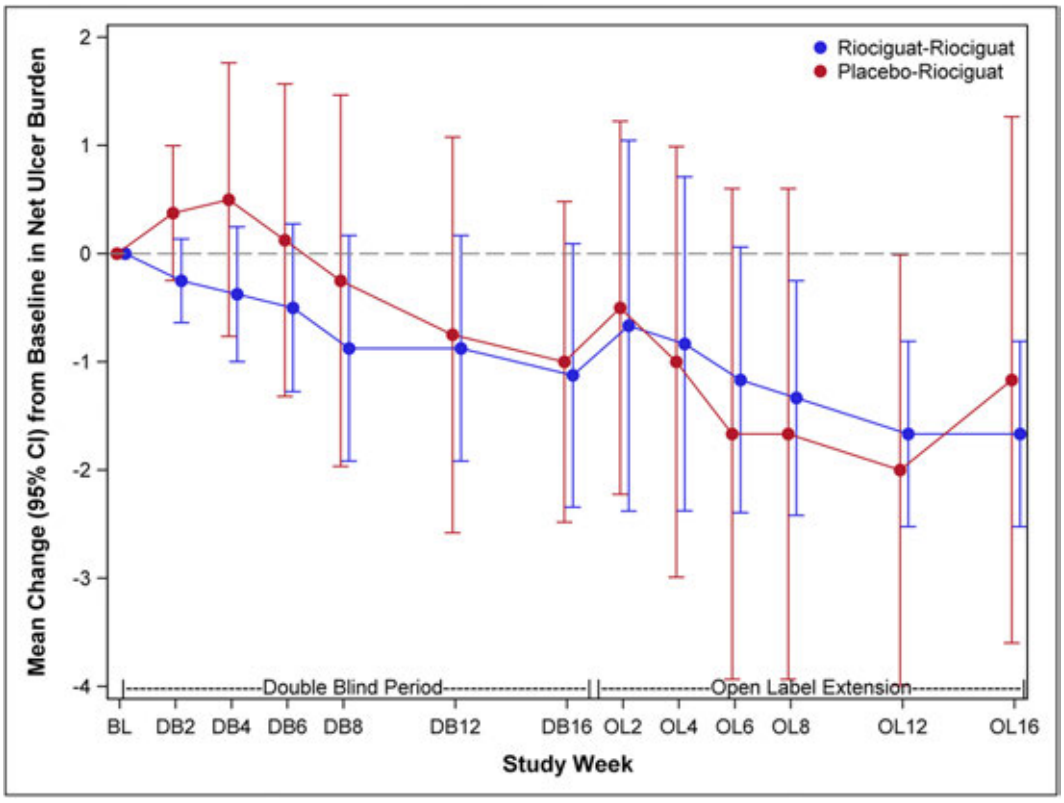

Figure 1: Mean Trend Over Time: Change in Net Ulcer Burden

	Placebo (N=8)	Riociguat (N=7)	Treatment Difference (95% CI)	p-value
Net Ulcer Burden, LS mean †*	-0.98	-1.22	-0.24 (-1.46 to 0.99)	0.706
Patient global assessment for overall disease, LS mean †	-1.19	0.31	1.50 (-1.30 to 4.30)	0.27
Patient assessment, LS mean †				
Severity of RP	-1.41	-3.47	-2.06 (-4.63 to 0.51)	0.11
Severity of DU	-4.00	-4.63	-0.63 (-3.68 to 2.41)	0.66
Pain during RP attack (0-100)	-7.01	-0.30	6.71 (-14.01 to 27.43)	0.49
Numbness during RP attack (0-100)	-15.44	-19.73	-4.28 (-33.44 to 24.87)	0.75
Tingling during RP attack (0-100)	-7.49	1.18	8.67 (-13.75 to 31.09)	0.41

Table 1: Changes from baseline to week 16 in primary and secondary efficacy endpoints

16-week open-label extension phase for participants with active DUs / reoccurrence of DUs within 1 month of the end of the main treatment phase. The primary endpoint was the change from baseline to week 16 in net ulcer burden (NUB), analyzed using ANCOVA. Other endpoints included plasma biomarkers and the proportion of participants with treatment-emergent adverse events (AEs).

Results: We randomized 17 participants with SSc-DUs at 5 US centers between January 2017 and March 2018. Six participants in each group progressed transitioned to the open-label extension phase. Baseline characteristics were comparable between treatment groups, except participants randomized to PLA were older (mean 61 vs. 43 yrs) with longer disease duration (mean 17.5 vs. 7.1 yrs). At baseline, the mean (SD) NUB was 2.5 (2.0) in the PLA and 2.4 (1.4) in the RIO. No significant difference was observed between RIO and PLA in change from baseline to 16 weeks in NUB [treatment difference -0.24 favoring RIO, p=0.70; Figure 1]. In the open-label extension, participants in the RIO-RIO arm had complete healing of their DUs.There were no statistically significant treatment differences in secondary efficacy endpoints, except for the eating component of HAQ-DI (Table 1). All 17 participants reported ≥1 adverse event, with the vast majority being mild or moderate. Four participants experienced 5 serious AE (4 in RIO and 1 in PLA); none was considered related to study medication. Statistically significant elevations of cGMP were observed at 16 weeks [treatment difference 157.3 nM, p=0.05, Figure 2]; no other biomarkers showed statistically significant changes.

Conclusion: In participants with SSc-DU, treatment with RIO did not reduce the number of DU net burden compared with PLA. Open-label extension suggests that a longer duration is needed to promote DU healing, which needs to be confirmed within a new trial.

The negative results may reflect a small number of patients, low number of NUB at baseline, moderate-to-severe vasculopathy with long term disease, and the difficulty to recruit patients in the era of widespread use of PDE5 inhibitors.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Although some studies suggest a possible association between clinical characteristics and isotypes of anticentromere antibodies (ACA) in patients with systemic sclerosis (SSc), characteristics of ACA response have not been described thoroughly. Therefore, we evaluated whether ACA isotype expression and levels: 1.

Baseline characteristics and ACA isotype expression and levels in patients with very early SSc and SSc

	Very early SSc (n=90)	SSc without organ involvement (n=211)	SSc with organ involvement (n=144)
Female, n(%)	82 (94)	199 (94)	126 (87)
Age, mean (SD)	52 (15)	60 (11)	**62 (12)***
Since RP, median(IQR) in years	6 (3-13)	11 (6-18)	**12 (6-25)***
Since non RP, median(IQR) in years	NA	5 (2-11)	6 (3-13)
mRSS, median (IQR)	0 (0-0)	2 (0-4)	3 (1-6)
Digital ulcers, n(%)	0 (0)	0 (0)	73 (51)
ILD on HRCT, n(%)	0 (0)	0 (0)	64 (45)
PAH, n(%)	0 (0)	0 (0)	39 (27)
Renal crisis, n(%)	0 (0)	0 (0)	2 (1)
ACA characteristics			
IgA positivity, n(%)	53 (72)	145 (76)	105 (77)
IgA level [aU/mL], median (IQR)	78 (33-160)	75 (38-173)	**88 (44-181)***
IgM positivity, n(%)	57 (76)	**168 (87)***	**122 (89)***
IgM level [aU/mL], median (IQR)	105 (17-551)	142 (43-593)	**217 (69-1193)***
IgG level [aU/mL], median (IQR)	283 (92-658)	**455 (205-940)***	**678 (302-1146)***

Table 1. Baseline characteristics of the three groups, SSc=systemic sclerosis, RP=Raynaud phenomenon, mRSS= modified Rodnan Skin Score, ILD= interstitial lung disease, HRCT= high resolution computed tomography, PAH= pulmonary arterial hypertension.

* Significant difference compared to very early SSc group p< 0.05. Both groups were separately compared with very early SSc group. No significant differences were found between the SSc group without and the SSc group with organ involvement.

Table 2:Multivariate logistic regression: higher IgG levels independently associate with disease severity in SSc

	Very early SSc patients (n=90) vs. SSc patients (n=355)	SSc patients with organ involvement (n=144) vs. SSc patients without organ involvement (n=211.)
	OR (95% CI)	OR (95% CI)
High IgG level	**0.29 (0.15-0.58)***	**2.55 (1.48-4.40)***
High IgM level	1.22 (0.61-2.46)	0.80 (0.46-1.41)
High IgA level	1.79 (0.87-3.28)	0.96 (0.57-1.60)
IgM positivity	0.48 (0.21-1.08)	1.34 (0.63-2.84)

Table 2. All analyses were adjusted for age and disease duration since first Raynaud symptom.
* Significant p < 0.05

associate with disease severity, 2. differ between patients with very early SSc and SSc, and 3. can identify very early SSc patients that will progress to SSc.

Methods: All ACA IgG+ patients fulfilling the American College of Rheumatology (ACR) 2013 criteria for SSc and ACA+ IgG patients with very early SSc (based on ACA, Raynaud and puffy fingers or abnormal nailfold capillaroscopy but not fulfilling ACR 2013 criteria), from the prospective SSc cohorts from the Leiden University Medical Centre (LUMC), the University Hospital Zurich, and the Oslo University Hospital were included. Presence and levels of ACA IgM and IgA were determined by J.B. at the LUMC. Patients were categorized in three groups according to disease severity: very early SSc, SSc without organ involvement, and SSc with organ involvement. Organ involvement was defined as any of: digital ulcers, interstitial lung disease, pulmonary arterial hypertension, renal crisis and myocardial involvement. Associations between isotype presence and levels and disease severity were evaluated with logistic re-

gression, with adjustment for age and disease duration. ACA response characteristics were compared between very early SSc patients that progressed to ACR 2013 criteria and those who did not.

Results: ACA characteristics were measured in 445 ACA IgG + patients. Ninety patients (20%) had very early SSc and 355 (80%) fulfilled the ACR criteria, in which 41% (n=144) were classified as SSc with organ involvement (Table 1). At baseline, 86% of patients were ACA IgM+, and 75% were ACA IgA+. Very early SSc patients show lowest titers of IgM and IgG. In contrast, SSc patients with organ involvement most often express ACA IgM and show highest titers of all isotypes, indicating a more active, specific B cell responses (Table 1). With adjustment for disease duration and age, ACA IgG levels were significantly higher in SSc patients vs. very early SSc, and in SSc patients with organ involvement vs. SSc without organ involvement (Table 2). Of all very early SSc patients with follow-up (n=70; median FU 2.1 year) 30% progressed to SSc, mostly due to skin progression (88%), and 23% developed lung involvement, after a median period of 4.3 year. As age and follow-up duration were significantly higher in the progressors we were underpowered to analyse isotype characteristics by means of regression. However, again, we observed a trend for higher ACA IgG levels in the very early SSc patients progressing to SSc fulfilling ACR 2013 criteria.

Conclusion: Here we show in a large multicentre SSc cohort that ACA IgG levels increase with increasing disease severity, from very early SSc, to SSc without organ involvement and SSc with organ involvement. Our data indicate that ACA+ SSc specific B cell responses are potentially involved in disease-relevant pathogenic processes. In addition, ACA response characteristics might also be useful for risk stratification in clinical practice.

Background/Purpose: Systemic sclerosis (SSc) is a progressive, multi-organ disease with limited treatment options. Interleukin-4 (IL-4) and IL-13 have been implicated in the general fibrotic pathway and pathogenesis of SSc and are promising targets. Romilkimab (RKB) is an engineered humanized bispecific immunoglobulin-G4 antibody that binds and neutralizes both IL-4/IL-13. We report a Phase IIa randomized, double-blind, placebo-controlled trial (NCT02921971, Sanofi funded) employing RKB in SSc.

Methods: Patients with dcSSc (disease duration ≤36 months, mRSS 10-35) with or without immunosuppressive background therapy were randomized (1:1) to subcutaneous RKB 200mg or placebo (PBO) for 24 weeks and stratified based upon history of SSc-ILD. The primary endpoint was mean change in mRSS from baseline to Week 24 and FVC/DLco and HAQ-DI served as secondary endpoints. All analyses employed a 1-sided p-value < 0.05 as reaching statistical significance.

Results: Ninety-seven patients with similar baseline characteristics between arms (Table 1), including the use of background therapy (PBO 59.2% vs. RKB 52.1%) were randomized. Six (12.2%) and 4 (8.3%) patients discontinued study treatment early in the PBO and RKB arms, respectively. The primary endpoint showed an absolute change in mRSS of -2.45 (0.85) and -4.76 (0.86) for the PBO and RKB groups, respectively with a difference of -2.31 (1.21) favoring RKB (p-value = 0.029) (Table 2). Subgroup analysis based upon stratification criteria did not yield a significant difference (interaction p-value=0.731). Subgroup analysis based on background therapy showed a similar treatment

effect with a placebo subtracted difference in mRSS of -2.69 (1.83) and -2.38 (1.59) (Table 2), suggesting an additive effect between background therapy and RKB. Secondary endpoints did not show a statistically significant difference between RKB vs. PBO arms, although there was numerically less decline in FVC with RKB (Table 2). Exploratory endpoints suggested possible effect of RKB on overall pain, Raynaud's, digital ulcers, and EQ-5D-5L (Table 2). Adverse events (AE) were balanced between the two groups (PBO 83.7% and RKB 83.3%). There were 5 and 4 patients with serious AEs in the PBO and RKB arms, respectively. One death occurred in each arm (PBO – cardiomyopathy, RKB – scleroderma renal crisis).

Conclusion: Patients with dcSSc who were treated with RKB showed a statistically significant reduction in mRSS compared to those receiving placebo. None of the secondary outcomes were met, although RKB was associated with a smaller decline in FVC than placebo. Romilkimab was well tolerated with no major safety concerns.

Radiographic ILD, present	100 (73%)	40 (78%)	60 (69%)	0.23
FVC % predicted	78 (17)	78.6 (16.5)	77.3 (16.9)	0.67
DLCO % predicted	61 (19)	59.1 (21.4)	60.4 (19.8)	0.73
Digital ulcers, present	52 (38%)	14 (28%)	38 (44%)	0.06
Widest esophageal diameter, mm	17.6 (8.2)	18.2 (8.5)	17.2 (8.0)	0.53

Legend. *SSc disease duration defined as the interval between first non-Raynaud SSc symptom and baseline HRCT date. WED=widest esophageal diameter; HRCT=high-resolution computed tomography of the chest; SSc=systemic sclerosis; ILD=interstitial lung disease; PAH=pulmonary arterial hypertension; RHC=right heart catheterization; FVC=forced vital capacity; DLCO=diffusing capacity of the lungs for carbon monoxide (adjusted for hemoglobin).

Background/Purpose: Prior work has shown that Scl-70 positive autoantibody status and baseline c-reactive protein (CRP) are associated with more rapid pulmonary function decline in patients with systemic sclerosis (SSc). We previously found that patients with esophageal dilation on chest high-resolution computer tomography (HRCT) scan had lower % predicted forced vital capacity (FVC) and diffusing capacity for carbon monoxide (DLCO) at baseline.

Table 2. Change over time in % predicted forced vital capacity (N=138) and diffusing capacity for carbon monoxide (N=99) in patients with systemic sclerosis, by Scl-70 and widest esophageal diameter, adjusted models* (95% CI)

	Positive Scl-70 autoantibody status (N=50)		Negative Scl-70 autoantibody status (N=86)		Widest esophageal diameter ≥19mm (N=64)		Widest esophageal diameter <19mm (N=74)	
PFT	FVC	DLCO	FVC	DLCO	FVC	DLCO	FVC	DLCO
Baseline	63 (52, 74)	46 (30, 61)	72 (60, 83)	52 (36, 68)	61 (50, 72)	45 (28, 61)	71 (60, 82)	50 (33, 67)
Modeled 5-year change	-6.3 (-9.9, -2.8)	-4.2 (-10.3, 2.0)	1.8 (-0.6, 4.2)	-3.4 (-6.6, -0.25)	-2.4 (-5.4, 0.5)	-6.1 (-10.4, -1.8)	0.7 (-2.0, 3.4)	-1.7 (-5.4, 2.0)

Legend. Scl-70= anti-topoisomerase 1; FVC = forced vital capacity; DLCO = diffusing capacity for carbon monoxide (adjusted for hemoglobin); PFT = pulmonary function test. PFT results shown as % predicted. *Scl-70 PFT means adjusted for sex, proton pump inhibitor use, prednisone use, SSc disease subtype, duration since first non-Raynaud (years), smoking history (current or former), widest esophageal diameter, and presence of digital ulcers. WED PFT means adjusted for sex, proton pump inhibitor use, prednisone use, SSc disease subtype, duration since first non-Raynaud (years), smoking history (current or former), Scl-70 autoantibody status, and presence of digital ulcers.

The purpose of this study is to identify clinical factors, including HRCT esophageal dilation, that are associated with pulmonary function decline in SSc.

Methods: Included participants were enrolled in the Northwestern Scleroderma Registry, fulfilled 2013 SSc criteria, and had ≥1 HRCT and ≥2 pulmonary function tests (PFT) obtained as standard of care. The widest esophageal diameter (WED) and radiographic interstitial lung disease (ILD) were assessed using published methods. The WED was dichotomized as dilated (≥19 mm) vs. not dilated (< 19mm) based upon published data. Clinically meaningful PFT change was defined as % predicted FVC ≥5-point difference and % predicted DLCO ≥15-point difference based upon published data. Clinical characteristics at the time of baseline HRCT scan were collected. Pulmonary arterial hypertension (PAH) was present if mean pulmonary arterial pressure was ≥25 mmHg on right heart catheterization. Linear mixed effect models were used to model PFT change.

Results: 138 SSc patients met study criteria. Radiographic ILD was present in 100 of 138 (73%) participants (Table 1). 51 of 138 (40%) patients demonstrated clinically meaningful FVC decline (median follow-up 2.8 years). In adjusted models, patients with (vs. without) esophageal dilation had statistically significant 5-year % predicted DLCO decline (-6.1; 95% CI -10.4, -1.8), however this change did not meet the 15-percentage point threshold for clinical significance (Table 2, Figure 1). There was no difference in the presence of PAH at baseline between those with vs. without DLCO decline (14% vs. 13%, p=0.51). Patients with positive (vs. negative) Scl-70 autoantibody status had statistically significant 5-year % predicted FVC decline (-6.3; 95% CI -9.9, -2.8) (Table 2, Figure 1). Esophageal diameter did not distinguish between those with vs. without significant FVC decline. There was no difference in baseline SSc disease duration, modified Rodnan skin score, smoking status, gender, age, baseline CRP, or race between those with vs. without clinically meaningful FVC change.

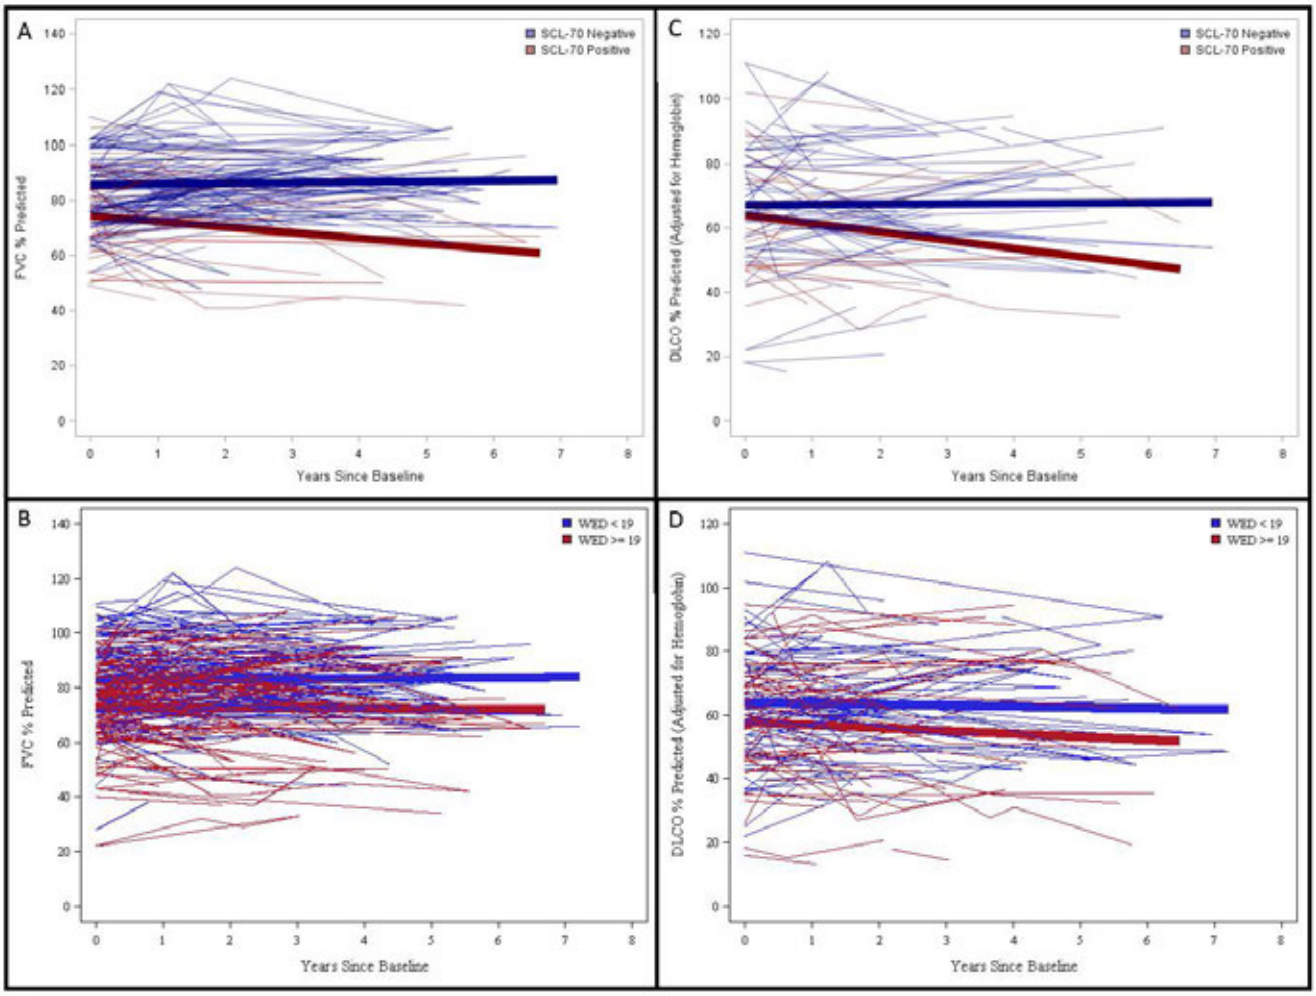

Figure 1. Change in pulmonary function by Scl70 and Widest Esophageal Diameter (WED) status. Change in forced vital capacity (FVC) % predicted (N=138) by Scl70 autoantibody status (A) and WED (B); and change in carbon monoxide diffusing capacity (DLCO) % predicted, corrected for hemoglobin (N=99) by Scl70 autoantibody status (C) and WED (D), unadjusted. Thin lines represent individual patient data. Thick lines represent estimated % predicted DLCO from statistical model using data from all patients.

Conclusion: Scl-70 positivity, but not elevated baseline CRP, is a risk factor for % predicted FVC decline. Esophageal dilation on HRCT was associated with a minimal, non-clinically significant 5-year decline in DLCO and no change in FVC during follow-up. These results have important prognostic implications for SSc-ILD patients with esophageal dilation.

Histologic Features Correlate with the Modified Rodnan Skin Score, Serum Inflammatory Markers, and Patient Reported Outcomes in Patients with Early, Diffuse Cutaneous Systemic Sclerosis

Kimberly Showalter,[1] Cynthia Magro,[2] Dana Orange,[3] Yaxia Zhang,[4] Phaedra Agius,[5] Jackie Finik,[6] Robert Spiera,[1] and Jessica Gordon[1], [1]Hospital for Special Surgery, New York, NY, [2]Weill Cornell Medicine, New York, [3]Rockefeller University, New York, [4]Hospital for Special Surgery, New York, [5]New York Genome Center, New York City, [6]Hospital for Special Surgery, New York, NY, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The association between systemic sclerosis (SSc) skin histology and clinical findings is not fully characterized. In two SSc trials, we developed a scoring system to evaluate histologic change. The purpose of this study is to determine (1) the reliability of our histology scores and (2) if histologic features correlate with clinical findings.

Methods: Skin biopsies were assessed from patients enrolled in Nilotinib (n=7) and Belimumab (n=18) trials. Our skin histology scoring approach, developed with dermatopatholgist (CM) consultation, includes skin thickness (epidermis to subcutis), follicle count, and semi-quantitative (0-3) assessment of infiltrate, collagen density, alpha-smooth muscle actin (aSMA) and CD34 staining intensity, and global histologic severity. Blinded to prior scores, a dermatopathogist (CM) and second pathologist (YZ), oriented to our approach, analyzed a sub-sample of biopsies. Intraclass correlation coefficients (ICC) were calculated for inter- and intra-rater reliability. Spearman correlations were used to correlate histology scores (baseline, 52-weeks post-treatment, and overall) and clinical variables (local and total modified Rodnan skin score (MRSS), erythrocyte sedimentation rate (ESR), c-reactive protein (CRP), 36-item Short Form Health Survey (SF-36), and physician global assessment (PGA)).

Results: 56 biopsies were analyzed from 26 diffuse SSc patients (median (IQR) disease duration 0.8 (0.54) years). Most were female (77%), Caucasian (73%), and RNA polymerase III positive (58%). Median (IQR) baseline MRSS was 25 (9). Reliability was excellent (ICC≥0.90) for follicle count and intra-rater CD34; good (0.75< ICC >0.90) for thickness, inter-rater CD34, intra-rater collagen density, and intra-rater global score; and moderate (0.5< ICC >0.75) for infiltrate, intra-rater collagen density, aSMA, and inter-rater global score.

Histologic scores correlated moderately with MRSS, ESR, CRP, and SF-36 (Table 1). Post-treatment local MRSS correlated with thickness (r=0.674, p< 0.001), collagen density (r=0.497, p=0.04), global histologic severity (r=0.467, p=0.02), follicle count (r=-0.550, p=0.01), and CD34 stain intensity (r=-0.653, p=0.001). However, local MRSS did not correlate with infiltrate score or PGA and weakly correlated with aSMA stain intensity (r=0.337, p=0.01). In strat-

Table 1. Correlation between clinical variables and histologic features in diffuse systemic sclerosis

Clinical Feature	Significant* Spearman's Correlation Coefficients (r_s) for Histologic Features	p-value
Local modified Rodnan skin score	Collagen density (0.470)	<0.001
	CD34 staining intensity (-0.518)	<0.001
	Post-treatment thickness (0.674)	<0.001
	Post-treatment collagen density (0.497)	0.04
	Post-treatment global histologic severity (0.467)	0.02

Legend: If no time point specified, reported data are from combined baseline and post-treatment samples.
*$p \leq 0.05$ and $r_s \geq 0.4$.

ified analysis, collagen density correlated with local MRSS in patients with low (< 1) but not high (≥1) infiltrate score (r=0.578, p< 0.001 vs. r=0.253, p=0.256). Total MRSS correlated with collagen density (r=0.425, p=0.001) and CD34 stain intensity (r=-0.460, p< 0.001). Total MRSS and thickness correlated positively in patients with low infiltrate (r=0.326, p=0.05) but negatively in patients with high infiltrate (r=-0.456, p=0.03).

Conclusion: Our scores demonstrate moderate to excellent reliability, thus have potential to be used across centers. Histologic features correlate with MRSS, inflammatory markers, and patient reported outcomes. However, infiltrate does not correlate with MRSS and confounds the correlation of MRSS with collagen density and thickness. This supports further study of skin histology as an SSc outcome measure.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: SSc-ILD is a major cause of morbidity and mortality in patients with systemic sclerosis. A subset of patients with SSc-ILD show a decline in lung function and increasing symptoms that interfere with daily activities and ultimately impair patients' health-related quality of life (HRQoL). The aim of this analysis was to evaluate the impact of lung function changes on HRQoL as measured by patient-reported outcomes (PRO) within the Phase III SENSCIS® trial.

Methods: In the SENSCIS® trial (NCT02597933), patients with SSc-ILD were randomized to nintedanib 150 mg twice daily or placebo. Patients in the nintedanib arm experienced a significantly lower adjusted annual rate of decline in forced vital capacity (FVC) (–52.4mL vs –93.3mL: difference 41.0 [95% CI 2.9–79.0]; P=0.04). PRO assessments were conducted at baseline, week 24, week 52 and study completion, with no differences between arms in changes from baseline to week 52 in the St. George's Respiratory Questionnaire (SGRQ). In this analysis, PRO scores and changes from baseline were assessed according to baseline lung function parameters, independent of treatment arm. PRO assessments included Functional Assessment of Chronic Illness Therapy (FACIT)-Dyspnea, Health Assessment Questionnaire Disability Index (HAQ-DI) and Scleroderma Health Assessment Questionnaire (SHAQ) visual analog scale (VAS).

Results: A total of 576 patients were randomized. In patients categorized by baseline FVC percent predicted (FVC %pred), those with FVC ≥70% pred had a mean SGRQ total score of 33.8 at week 52, whereas mean score for those with FVC < 70% pred was 45.1 (P< 0.0001) (higher scores indicate a worse quality of life). This pattern was also reflected for the subdomains of the SGRQ score, including activities, impacts and symptoms. Similarly, FACIT-Dyspnea, FACIT-Dyspnea functional limitations, HAQ-DI and SHAQ VAS breathing problems scores were lower in patients with FVC ≥70% pred than those with FVC < 70% pred (Table 1). When PRO assessments were compared in patients categorized by supplemental oxygen use at baseline, those using oxygen had a mean SGRQ total score of 51.2, compared with 39.0 in those not requiring oxygen (P=0.0005). Again, these differences were also evident for the

	FVC %pred groups				Mean difference (SD)	P-value
	FVC ≥70% pred		FVC <70% pred			
	N	Mean (SD)	N	Mean (SD)		
SGRQ total	257	33.8 (20.5)	242	45.1 (20.2)	−11.3 (20.4)	<.0001
FACIT-Dyspnea						
Dyspnea	249	44.6 (10.3)	240	48.7 (9.5)	−4.2 (9.9)	<.0001
Dyspnea-related functional limitation	251	45.0 (10.1)	242	48.8 (9.7)	−3.8 (9.9)	<.0001
HAQ-DI	255	0.5 (0.7)	245	0.7 (0.7)	−0.2 (0.7)	0.0043
SHAQ VAS breathing problems	252	2.5 (2.7)	240	3.6 (2.7)	−1.1 (2.7)	<.0001

Table 1. Week 52 HRQoL scores stratified by FVC %pred at baseline

	Supplemental oxygen use				Mean difference (SD)	P-value
	Yes		No			
	N	Mean (SD)	N	Mean (SD)		
SGRQ total	37	51.2 (18.0)	612	39.0 (20.7)	12.2 (20.6)	0.0005
FACIT-Dyspnea						
Dyspnea	38	52.1 (10.0)	608	45.9 (9.8)	6.2 (9.8)	0.0002
Dyspnea-related functional limitation	38	52.0 (10.2)	612	46.0 (9.5)	6.0 (9.5)	0.0002
HAQ-DI	37	0.7 (0.6)	610	0.6 (0.7)	0.1 (0.7)	0.2286
SHAQ VAS breathing problems	38	4.5 (3.3)	577	2.9 (2.7)	1.6 (2.8)	0.0006

Table 2. Week 52 HRQoL scores stratified by supplemental oxygen use at baseline

subdomains of the SGRQ score. FACIT-Dyspnea, HAQ-DI and SHAQ VAS breathing problems scores were also all higher in patients with oxygen use (Table 2). In patients with a moderate (5–10%) or large (>10%) improvement in FVC %pred from baseline to week 52, changes in SGRQ scores indicated improved HRQoL (–3.4 and –3.8, respectively). A moderate or large deterioration in FVC %pred was associated with worsening HRQoL (+1.4 and +5.5, respectively). Other PRO assessments showed a largely similar pattern (Table 3).

Conclusion: In the SENSCIS® trial, while there was no significant difference between arms in the change from baseline in SGRQ, patients with FVC < 70% pred or requiring supplemental oxygen had consistently worse PRO scores, independent of treatment arm. Improvements in lung function between baseline and week 52 were reflected in improving PRO scores, potentially indicating an association between lung function and HRQoL in patients with SSc-ILD.

HRQoL score	FVC changes from baseline to week 52							
	Large deterioration (decline >10% pred)		Moderate deterioration (decline 5–10% pred)		Moderate improvement (increase 5–10% pred)		Large improvement (increase >10% pred)	
	N	Mean (SD)	N	Mean (SD)	N	Mean (SD)	N	Mean (SD)
SGRQ								
Total	37	+5.5 (17.9)	81	+1.4 (13.8)	33	−3.4 (11.1)	9	−3.8 (6.9)
FACIT-Dyspnea								
Dyspnea	36	+3.1 (7.6)	82	+0.9 (6.3)	32	−1.2 (6.3)	8	+0.4 (6.2)
Dyspnea-related functional limitation	36	+2.9 (6.2)	82	+1.0 (6.2)	33	−0.5 (6.3)	8	+2.2 (5.0)
HAQ-DI	37	+0.2 (0.4)	79	+0.1 (0.4)	34	0.0 (0.4)	9	−0.1 (0.5)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal tract involvement in systemic sclerosis (SSc) occurs in almost all patients varying in severity and affecting motility, digestion, absorption and excretion. These abnormalities can cause malnutrition and significant changes in body composition, perhaps the most important is the progressive and gradual loss

of the mass, function and strength of the skeletal muscle known as sarcopenia, which increases the risk of physical disability, worsening of the quality of life and risk of falls.

Methods: An observational, prospective, cross-sectional study was conducted in adult patients who met the ACR/EULAR 2013 classification criteria, evaluated by the rheumatology outpatient service of the British Hospital of Buenos Aires. Body composition was assessed by dual energy X-ray absorptiometry (DXA), grip strength using a Jamar dynamometer following the standardized Mathiowetz standards and performance by 4-meter gait speed. According to European Working Group on Sarcopenia in Older People (EWGSOP), skeletal muscle mass index (SMMI) was calculated as the sum of arms and legs fat and bone-free mass, in kilogram, and height squared meter. The cutoff values for sarcopenia were ≤5.5 kg/m2 in women and ≤7.26 kg/m2 in men, grip strength for women < 20 kg and men < 30 kg and for walking speed < 0.8 m/s in both genders.

Results: A total of 27 patients were included, 20 (74%) were females. The mean inclusion age was 52.5 (± 14.1) years and mean diagnosis age was 44.6 (± 12.8) years, with a mean time of disease evolution of 93.62 (± 83.68) months. LcSSc were reported in 16 (59.2%) patients. We found a mean Rodnan score of 7.2 (± 6.8), Medsger score of 2.3 (± 1.2), EUSTAR activity score of 0.5 (± 0.2), SHAQ of 1.2 (± 0.4) and EVA of 17 (± 14.5). The mean weight was 68.8 (± 12.5) kg, size 162.5 (± 7.9) cm and BMI was 26.1 (± 4.5) kg/m2. Mean lean appendicular mass was 17.92 (± 4.3) kg with an SMMI of 6.74 (± 1.16) kg/m2, grip strength in dominant hand of 22.8 (± 7.9) kg and non-dominant hand of 21.4 (± 9) kg, speed of 0.65 (± 0.57) m/s. Sarcopenia was found in 9 (33.3%) patients (lcSSc in 6/16 (37.5%) and dcSSc in 3/11 (27.2%) patients), among whom was found presarcopenia in 4 (14.81%) patients, mild sarcopenia in 4 (14.81%) patients and severe sarcopenia in 1 (3.7%) patient, with an average of physical activity of 2094 (± 2063) METS and risk of malnutrition with a median of 0.58 (range: 0-4).

Conclusion: Sarcopenia frequency was found in 33.3% of patients. The recognition of this condition has important therapeutic implications, due to the impact on the quality of life, morbidity and mortality. Strategies should include a focus on the nutritional aspects, improving the protein-rich diet intake with physical training program that aims to increase muscle mass and improve strength and performance, maintaining an adequate control of the disease and associated comorbidities.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The 2013 ACR/EULAR classification criteria for systemic sclerosis (SSc) allowed the inclusion of a subset of patients without skin involvement, not considered by the 1980 criteria. As the severity and the prognosis of these patients are still controversial, a pragmatic approach to characterize them according to the severity of visceral involvement is useful in the current daily practice.

Methods: Consecutive patients classified as SSc according to 2013 ACR/EULAR criteria attended in a single scleroderma outpatient clinic between 2010 and 2018 were included. Overlap syndromes were excluded. Patients with SSc skin involvement were classified as diffuse (dSSc) and limited (lSSc) according to LeRoy criteria. Patients without skin thickness were divided in two distinct groups: visceral sine-scleroderma (vsSSc) and non-visceral sine scleroderma (nvsSSc). VsSSc was considered in the presence of: a) Interstitial lung disease (ILD) [ground-glass > 10% in chest high resolution computed tomography (HRCT) or forced vital capacity < 70%]; b) Pulmonary arterial hypertension (PAH) confirmed by right heart catheterization; c) Heart (symptomatic arrhythmia, pericarditis or congestive heart failure); d) Kidney (scleroderma renal crisis). Clinical and laboratory data were obtained from an electronic register database. Proper statistics tests were applied and considered significant when $p< 0.05$. Log-Rank test was used to compare the survival curves.

Results: The cohort comprised 638 patients, 27.3% dSSc, 50.5% lSSc13.3% vsSSc, and 8.9% nvsSSc. Patients with skin involvement had longer disease duration and time of follow-up when compared to vsSS and nvsSSc ($p< 0.001$). As expected, patients with vsSSc presented a predominant clinical picture of ILD (85.9% of any ground-glass and 42.4% of >10% ground-glass in chest HRCT) or PAH (29.4%). Remarkably, the frequency of ILD in vsSSc was similar to dSSc($p=0.95$), and PAH was more common in vsSSc than in any other subset ($p< 0.01$). Although cardiac (23.5%) and renal (2.4%) involvement were observed, they were never referred as a SSc initial symptom in the vsSSc subgroup. In the other hand, nvsSSc also presented a lower frequency (36.8%, $p< 0.001$) of ILD (all with < 10% of ground-glass in chest HRCT). These nvsSSc patients were predominantly women with higher frequencies of SD pattern at the nailfold capillaroscopy (98.1%,$p=0.03$) and anticentromere antibody(70.9%,$p< 0.001$), presenting a similar frequency of peripheral vascular manifestations as the other subsets($p >0.05$) (table 1). At the end of follow-up, deaths represented 20.1% of dSSc 18.1% of vsSSc and 15.8% of limited SSc, with no death in nvsSSc ($p< 0.01$). The survival rate in vsSSc was similar to dSSc, but significantly higher than lSSc and nvsSSc (figure 1).

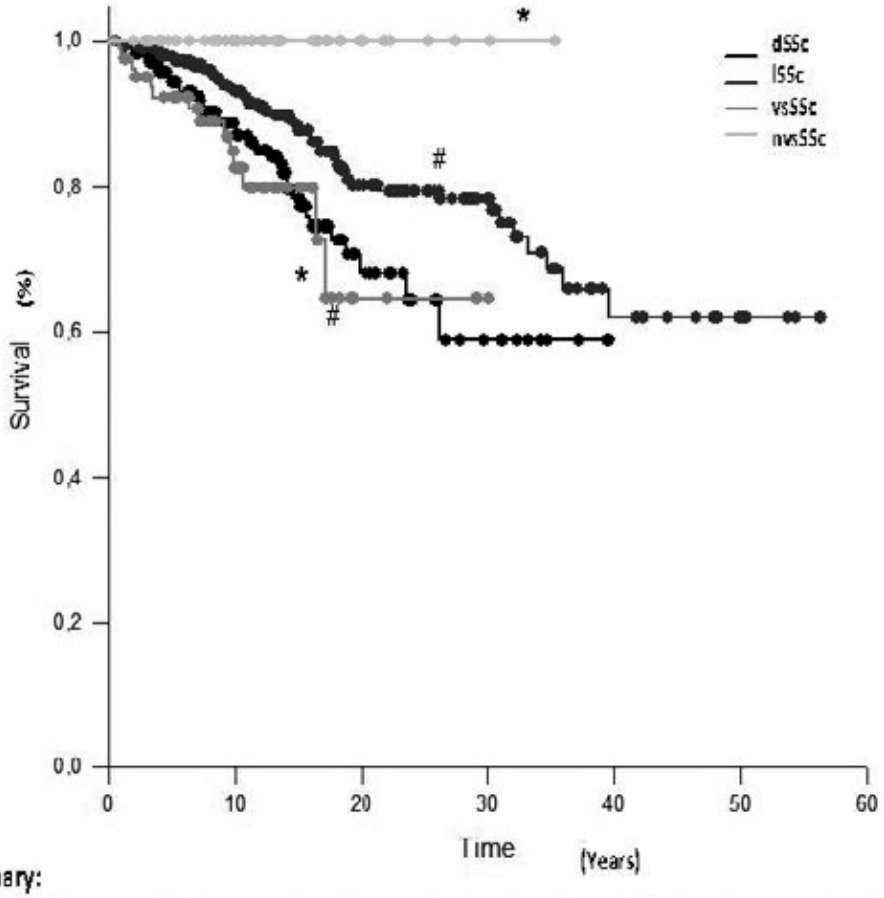
e = lSSc *vs* nvsSSc
f = vsSSc *vs* nvsSSc
**p<0.05; - p≥0.05

Conclusion: The analysis of the visceral involvement permitted the characterization of two distinct subgroups without skin thickening (vsSSc and nvsSSc) with significant differences in survival. One subset is characterized by predominant visceral involvement (ILD or PAH), and worse prognosis (vsSSc), while the other had a significantly milder disease and higher frequency of anticentromere antibody (nvsSSc).

Figure 1. SSc Subsets Survival Analysis (since first non-Raynaud SSc symptoms)



Data Summary:

Group	Total	Missing	Events	Censored	Percent Censored	Survival time (years) mean (SD)
dSSc	174	0	35	139	80	29(1.6)
lSSc	322	0	51	271	84	41(2.2)
vsSSc	85	0	15	70	82	15.5(0.8)
nvsSSc	57	0	0	57	100	-
Overall	638	0	101	534	84	

Log-Rank Test: p <0.001, significant for the following comparisons: vsSSc vs. lSSc (# p=0.0003); vsSSc vs. nvsSSc (* p=0.0057)

Abstract Number: 1659

Linaclotide for the Treatment of Gastrointestinal Symptoms in Systemic Sclerosis

Eric Dein,[1] John Clarke,[2] Frederick Wigley,[3] and Zsuzsanna McMahan*,[3], [1]Johns Hopkins, Baltimore, MD, [2]Stanford, Pao Alto, [3]Johns Hopkins University, Division of Rheumatology, Baltimore

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal (GI) involvement is the most common internal organ affected in systemic sclerosis (SSc). Constipation is a common GI complication in SSc that affects over 50% of patients. It can be severe and impacts quality of life. We sought to examine the safety, tolerability, and efficacy of linaclotide, a selective agonist of guanylate cyclase C (GC-C) as an intervention for SSc patients with refractory constipation.

Methods: We performed a retrospective analysis of all patients seen at Johns Hopkins Scleroderma Center between August 2012 and January 2019 who were prescribed linaclotide as an outpatient for refractory constipation. All patients had data prospectively collected in our longitudinal database if they met criteria for systemic sclerosis. Patients were defined as linaclotide responders if they were to medication for at least 12 months and had documentation of clinical effectiveness documented by the treating physician. We examined the prescribed dose and frequency of the drug, rates of symptom improvement, duration of treatment, treatment response, and side effect profiles among linaclotide-treated patients.

Results: Thirty-one patients with SSc were treated for refractory constipation with linaclotide. We found that the majority of patients (90.3%; 28/31) had a favorable response to treatment and tolerated it well, while only three patients (9.7%) reported ineffectiveness or had intolerable side effects. Low-dose linaclotide achieved adequate symptom control in approximately 2/3 patients (58.1%; 18/31), though high-dose linaclotide (equivalent to at least 145 mcg daily dosage) was required in a subset (41.9%; 13/31). The most common side effects were diarrhea, cramping, or bloating, which was present in 8 patients (8/31, 25.8%). Ineffectiveness, cost, and abdominal pain were the complaints cited among those who discontinued therapy. We then evaluated the subset of linaclotide-treated SSc patients with objectively measured colonic transit times by whole gut scintigraphy. We found that 11/14 (78.6%) had delayed colonic transit and 3/14 (21.4%) had normal colonic transit. This demonstrated that while severely delayed colonic transit was present among a subset of patients treated with linaclotide, not all significant constipation in SSc is associated with delayed colonic . The presence of responders to linaclotide in both groups (8/11, 72.7%, with delayed transit; 3/3100%, with normal transit) suggests that SSc patients with refractory may respond favorably to linaclotide, independent of colonic transit abnormalities.

Conclusion: Linaclotide is a well-tolerated and efficacious prosecretory agent that can be used to manage refractory constipation in who have failed management with over the counter laxatives and/or stool softeners. We find that low-dose treatments with linaclotide are an effective option with a lower side effect profile than high-dose treatment regimens, though high doses are required for optimal symptom control in some patients.

Serial Sublingual Videomicroscopy in Systemic Sclerosis Clinic: Are the Microcirculation Measurements Correlated with Gastrointestinal Symptoms?

Tracy Frech,[1] Guo Wei,[2] and Maureen Murtaugh[3], [1]Division of Rheumatology, University of Utah and Salt Lake VAMC, Salt Lake City, UT, [2]University of Utah, Salt Lake City, UT, [3]University of Utah and Salt Lake VAMC, Salt Lake City

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Systemic Sclerosis & Related Disorders – Clinical Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Intravital microscopy of the sublingual microcirculation provides estimates of perfused barrier region (PBR) and red blood cell fraction (RBCfract), which quantifies vasculopathy and, similar to nailfold capillaroscopy, may be valuable in serial assessment of systemic sclerosis (SSc) disease progression. In this report, we examine the longitudinal correlates of sublingual videomicroscopy with gastrointestinal symptoms of SSc.

Association of change in GIT 2.0 measures with change in RBC fraction		
GIT 2.0 Component	Beta coefficient for 1 point change PBR	p-value
Total score	-2.98 (-6.09, 0.13) *	0.06
Reflux	-3.52 (-5.83, -1.20)	0.003
Distention	-1.11 (-2.91, 0.68)	0.222
Fecal Soilage	-1.31 (-3.53, 0.90)	0.243
Diarrhea	-0.64 (-2.83, 1.55)	0.562
Social Function	-2.65 (-5.96, 0.67)	0.116
Wellbeing	-1.31 (-3.79, 1.17)	0.298
Constipation	-3.58 (-6.46, -0.70)	0.015
Association of change in GIT 2.0 measures with change in PBR		
GIT 2.0 Component	Beta coefficient for 1 point change	p-value
Total score	0.17 (0.03, 0.32)	0.02
Reflux	0.21 (0.10, 0.31)	<0.001
Distention	0.05 (-0.03, 0.14)	0.209
Fecal Soilage	0.08 (-0.03, 0.18)	0.141
Diarrhea	0.06 (-0.04, 0.17)	0.231
Social function	0.12 (-0.04, 0.28)	0.129
Wellbeing	0.08 (-0.04, 0.20)	0.188
Constipation	0.18 (0.04, 0.32)	0.01

Methods: Patients enrolled in a single center SSc (2013 ACR/EULAR Classification Criteria) registry, who completed the Scleroderma Clinical Trials Consortium Gastrointestinal Tract (GIT 2.0) questionnaire and had sublingual videomicroscopy are in this analysis. The GIT 2.0 includes 34 questions (assessing reflux, bloating/distention, diarrhea, soilage, emotional well-being, social function, and constipation), and provides a total score of GIT severity. Automated capture and analysis of sublingual microvessel segments provides detailed, objective microvascular structural (RBCfract) and functional data (PBR). To find the association between the GIT 2.0 and vascular outcomes (PBR and RBC fract), we ran 2 different models for a) Baseline vascular outcome vs baseline GIT score (total score and 7 individual scales + severity) and b) Delta vascular outcome vs delta GIT scores (Stable / improved GIT score vs worse GIT score; total score and 7 individual scales + severity). All models are adjusted by SSc disease duration, reflux medication, vasodilator, and immunosuppression use.

Results: There were a total of 116 participants with complete vascular outcomes, treatment data, and GIT scores at baseline visit and 55 participants with a second complete measurement set. These SSc patients were mostly female (n=100), white (n=110) with a SSc mean disease duration of 9.7 years (SD 8.3) and ANA/SSc-specific antibody positive (n=92). At baseline, GIT 2.0 total severity score significantly associated with PBR (p=0.01) and RBCfract (p=0.015); and the subdomains of reflux (p=0.02) and distention (p=< .001) were significantly associated with PBR. The association of vascular outcomes with change in GIT 2.0 components are shown in Table 1.

Conclusion: Gastrointestinal complaints are common in SSc and may be due to progressive vasculopathy. Intravital microscopy provides a bedside monitoring approach that can be correlated easily to clinical features and warrants further study.

Circulating Cell Free DNA Released from Eosinophils Is a Practical Biomarker in Patients with Eosinophilic Granulomatosis with Polyangiitis

Teppei Hashimoto,[1] Yuichi Yokoyama,[2] Tetsuya Furukawa,[3] Takahiro Yoshikawa,[3] Naoto Azuma,[2] Kohsuke Yoshida,[4] Akira Hashiramoto,[4] and Kiyoshi Matsui[3], [1]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Kobe, Hyogo, Japan, [2]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Japan, [3]Division of Rheumatology, Department of Internal Medicine, Hyogo College of Medicine, Nishinomiya, Hyogo, Japan, [4]Kobe University Graduate School of Health Sciences, Kobe, Hyogo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Fragmented cell-free DNA (cfDNA) is released into blood circulation as results of damage or death of peripheral blood cells as well as organ tissues, and it is significantly increased in those of cancer patients to be used in monitoring disease activities. CfDNA was also reported as a potential biomarker in autoimmune diseases, such as rheumatoid arthritis and systemic lupus erythematosus.

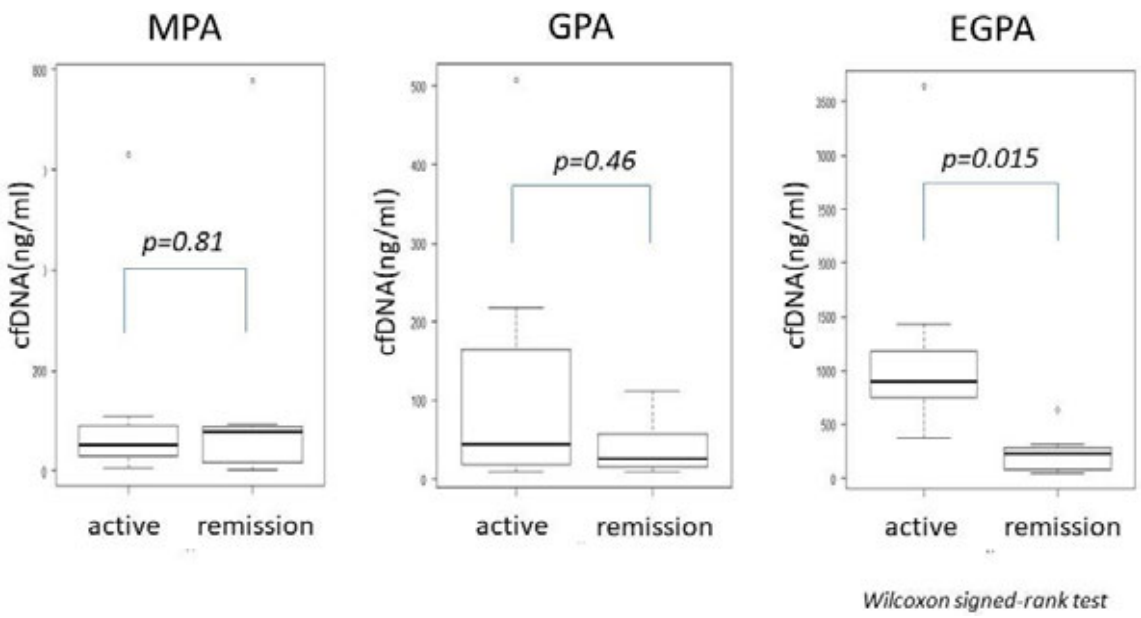

Figure 1. The concentration of cfDNA in patients with AAV before immunosuppresssive therapy and remission period

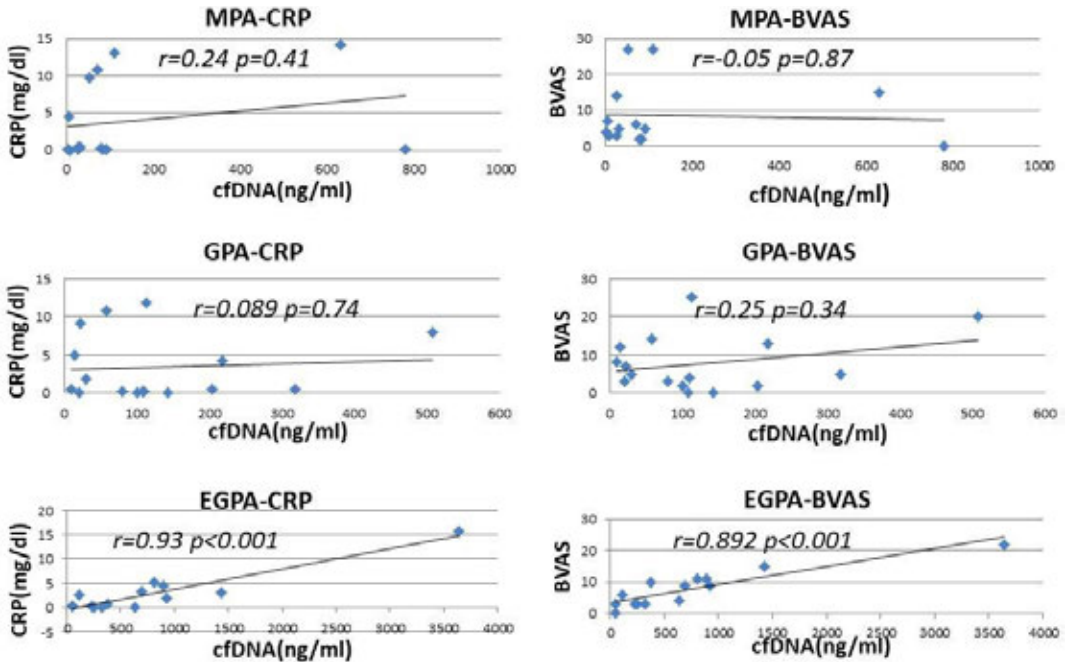

Figure 2. Correlation between cfDNA and disease activity in patients with AAV

The cfDNA sequence is identical to that of genomic DNA, since the DNA of each cell type possesses specific methylation patterns. In eosinophils, methylation levels of the loci, *interleukin 5 receptor alpha unit (IL5RA)* and *interleukin 4 (IL4)*, were reported to be lower as compared to other blood cells.

The purpose of this study is to evaluate the correlation between serum cfDNA and clinical disease activities in patients with Eosinophilic granulomatosis with polyangiitis (EGPA), and to examine tissue specific methylation patterns of cfDNA.

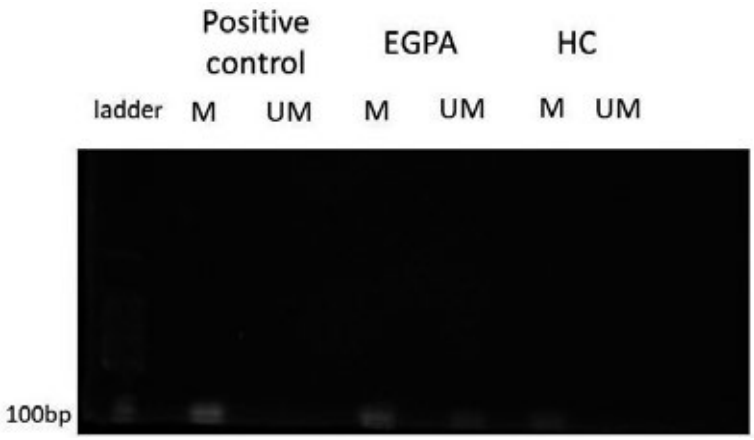

Figure 3. Representative analysis of MSP products amplified by IL5RA methylated specific primer (M) and unmethylated spesific primer (UM) positive control: Methylated HeLa gDNA

Methods: The study group included 24 patients with ANCA associated vasculitis (AAV), 8 patients with EGPA, 7 with microscopic polyangiitis (MPA) and 9 with granulomatosis with polyangiitis (GPA). CfDNA was extracted from serum using Qiamp MinElute cfDNA kit (QIAGEN). By quantitative real-time PCR, the concentration of cfDNA was measured twice retrospectively; before immunosuppressive therapy and remission period. CfDNA from 10 healthy controls (HC) was also measured. Then, we evaluated the correlation between cfDNA and the clinical disease activity, using Birmingham vasculitis score (BVAS) and C reactive protein (CRP).

Next, cfDNA from patients with EGPA and HC was treated with bisulfite to convert unmethylated cytosines to uracils. Methylation specific PCR was performed to evaluate two loci, *IL5RA* and *IL4*.

Results: The concentration of cfDNA in AAV was higher than HC ($p< 0.001$) before treatment, and cfDNA in EGPA was significantly higher than the other AAV ($p< 0.001$). After introduced immunosuppressive therapy, cfDNA was significantly decreased in EGPA ($p=0.015$), but not changed in MPA ($p=0.81$) and GPA ($p=0.46$) (fig.1). In patients with EGPA, cfDNA was strongly correlated with BVAS (EGPA; $r=0.89$, $p< 0.001$, MPA; $r=-005$, $p=0.87$ and GPA; $r=0.25$, $p=0.34$, respectively). CfDNA also strongly correlated with CRP in EGPA (EGPA; $r=0.92$, $p< 0.001$, MPA; $r=0.24$, $p=0.4$ and GPA; $r=0.09$, $p=0.74$, respectively) (fig.2). Methylated DNA of IL5RA and IL4 was detected in both EGPA and HC, while those of un-methylated DNA was detected in EPGA (fig.3).

Conclusion: CfDNA is expected to be a useful biomarker for EGPA, representing the lower methylation of *IL5RA* and *IL4* loci in eosinophils from patients with EPGA .

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) (Churg–Strauss) is a small-vessel necrotizing vasculitis characterized by blood and tissue eosinophilia and asthma. Only a third of EGPA patients are ANCA+, mainly directed against myeloperoxidase (MPO). ANCA+ patients have more neurological and renal involvements, while ANCA– patients have more cardiac manifestations. ANCA directed against proteinase (PR3) are rarely found in EGPA, and their interpretation remains unclear. We aimed to examine the significance of PR3-ANCA in EGPA.

Methods: We set up a multicenter, European, EGPA cohort including 845 patients who satisfied the American College of Rheumatology criteria, 2012 Chapel Hill Consensus Conference definitions and/or MIRRA trial criteria. Baseline characteristics and outcomes were analyzed and compared according to ANCA status.

Results: ANCA status and specificity were available for 734 patients: 508 (69.2%) ANCA–, 209 (28.5%) MPO-ANCA+ and 17 (2.3%) PR3-ANCA+. At diagnosis, PR3-ANCA+ patients, compared to those MPO-ANCA+ or ANCA–, respectively, had: less frequent asthma (71% vs 91% or 93%, P=0.004), especially steroid-dependent asthma (21% vs. 34% or 46%, P=007); more skin manifestations (65% vs. 38% or 34%, P=0.03); less frequent pulmonary infiltrates (41% vs. 40% or 58%, P=0.03) but more frequent nodules (25% vs. 10% or 8%, P=0.046); less frequent peripheral

neuropathy (29% vs. 72% and 47%, P< 0.0001); and lower median [IQR] eosinophil count/mm3(2015 [IQR 802–5826] vs. 5718 [2330–10444] or 3224 [1332–7570], P< 0.0001). Renal involvement did not differ between PR3-ANCA+ and MPO-ANCA+ patients.Median follow-up was74 [37–116] months for the whole cohort. PR3-ANCA+ vs. MPO-ANCA+ or ANCA– patients, respectively, experienced vasculitis relapses more frequently (47% vs. 34% or 24%; P=0.004). Moreover, vasculitis relapse-free survival was much shorter for PR3-ANCA+ [hazard ratio (HR) 7.32, 95% CI 2.02–26.5; P=0.002] and MPO-ANCA+ patients (HR 1.71, 95% CI 1.23–2.37; P=0.002) compared to those ANCA–. Also, median prednisone doses at 24 and 60 months, respectively, were significantly higher for PR3-ANCA+ than MPO-ANCA+ or ANCA– patients (P=0.02 and P=0.007). Finally, at 24 months of follow-up, PR3-ANCA+ vs. MPO-ANCA+ or ANCA– patients, respectively, had less frequent chronic asthma (38% vs. 51% or 60%, P=0.04) but more frequent renal damage (20% vs. 10% or 1%, P< 0.0001).

Conclusion: PR3-ANCA+ EGPA patients' characteristics differ from those MPO-ANCA+ or ANCA–, especially asthma and eosinophil counts, which are the cardinal features of EGPA. Since eosinophilia can be mild-to-moderate in granulomatosis with polyangiitis (GPA, Wegener's), we wonder if PR3-ANCA+ EGPA is not a third phenotype of EGPA but rather a particular form of GPA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is characterized by asthma and other manifestations of vasculitis, some of which can be life-threatening, cause major organ damage, or become chronic. Data on health-related quality of life (HRQoL) and patient-reported outcomes (PRO) in EGPA are limited. This study aimed to describe HRQoL in patients with EGPA enrolled in a large cohort.

Table 1: Demographic and disease-associated factors at baseline and end of follow-up for patients with eosinophilic granulomatosis with polyangiitis

	Baseline	End of follow-up
Age, years (SD)	53.1 (13.8)	57.0 (14.1)
Disease duration, years, median (IQR)	3.11 (0.35-3.62)	6.1 (2.5-9.7)
Relapse after diagnosis (%)		63%
Duration of glucocorticoids, months, median (IQR)		12 (3-13)
Ever used cyclophosphamide (%)		41%
PROMIS Fatigue score (SD)	55.6 (9.6)	51.1 (11.1)
PROMIS Physical functioning score (SD)	43.5 (8.3)	46.3 (9.2)
SF36 PCS (SD)	40.7 (11.5)	42.6 (11.0)
SF36 MCS (SD)	48.2 (11.5)	50.0 (11.0)

SD = standard deviation; IQR = inter-quartile range; VDI=Vasculitis Damage Index; SF36=Short form 36; PCS =physical component summary; MCS=mental component summary

Table 2. Association of demographic and disease-associated factors with fatigue, physical functioning, and HRQoL in patients with eosinophilic granulomatosis with polyangiitis

	PROMIS Fatigue	PROMIS Physical functioning	SF36 PCS	SF36 MCS
Age, years	-0.07 (0.24)	-0.17 (0.001)	-0.16 (<0.001)	0.07(0.14)
Female	4.64 (0.01)	-2.42(0.11)	-0.38 (0.78)	-2.01(0.13)
Disease duration, years,	0.06 (0.68)	-0.09 (0.42)	0.07 (0.50)	0.04 (0.68)
ANCA-positive	-2.44 (0.21)	1.41 (0.37)	0.82 (0.57)	2.08 (0.15)
Duration of glucocorticoid use, months	0.08 (0.25)	-0.05 (0.41)	-0.02 (0.42)	-0.01 (0.87)
Ever flared after diagnosis	2.19 (0.24)	-0.80 (0.61)	-1.61 (0.24)	-0.31 (0.82)
Ever used cyclophosphamide	-2.96 (0.10)	0.18 (0.90)	0.87 (0.52)	1.94 (0.15)

Results are expressed as increased in PROMIS/SF36 measures per one unit increase in predictor variables with p-values within parenthesis. SD = standard deviation; IQR = inter-quartile range; VDI=Vasculitis Damage Index; SF36=Short form 36;
PCS =physical component summary; MCS=mental component summary

Methods: Retrospective analysis of HRQoL in patients with EGPA participating in a multicenter longitudinal study from 2003-2019. Demographic and disease-associated factors at baseline include age, sex, ANCA status, use of cyclophosphamide or not, and cumulative duration of glucocorticoid (GC) use. Fatigue and physical functioning were

assessed using the Patient-Reported Outcomes Measurement Information System (PROMIS) instruments administered through computer adaptive testing (CAT). PROMIS instruments are calibrated so that scores are normally distributed with a mean of 50 and a standard deviation of 10 in the US population. Higher scores signify better physical functioning and increased fatigue. HRQoL was assessed with the SF36 with physical component summary (PCS) and mental component summary (MCS) scores calculated. SF36 summary scores are calibrated so that scores are normally distributed with a mean of 50 and a standard deviation of 10 in the US population. Continuous and categorical variables are presented as a percentage and continuous variable presented as means with standard deviations or medians with inter-quartile range (IQR). The association of demographic and disease-related factors with PROMIS and SF-36 measures were assessed at the end of follow-up using general linear models. Results are presented as an increase in measures per one unit increase in the predictor variables.

Results: Data from 276 patients with EGPA were included; 57% were female, with a mean age of 53.1 years (SD ±13.8) years. The median duration of follow-up was 3.1 (IQR 0.9-6.2) years. Table 1 shows demographic and disease-associated factors. At baseline, fatigue and physical functioning was assessed among 66 study patients and 151 patients at the end of follow-up. SF36 was assessed among all patients at baseline and at the end of follow-up. At baseline, patients had substantially increased fatigue scores 55.6 (SD 9.6) and reduced physical functioning scores 43.5 (SD 8.3) compared to the general population. The mean SF36 PCS scores were quite low 42.6 (11.0) but the mean SF36 MCS scores were the same as the population norm, 50.0 (11.0). At the end of follow-up, scores were closer to the population norms (Table 1). At the end of follow-up, female sex was associated with a 4.6 point higher fatigue score ($p=0.01$) and age was associated with reduced physical functioning and PCS and with reduction of 0.17 ($p=0.001$) and 0.16 ($p < 0.001$) for one-year increase in age, respectively (Table 2).

Conclusion: Compared to the general population, patients with EGPA have an increase in fatigue, reduced physical functioning, and substantially reduced HRQoL.

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) superiority over azathioprine to maintain ANCA-associated vasculitis (AAV) remission was demonstrated.The MAINRITSAN2 trial was designed to compare an individually tailored RTX-infusion schedule to 5 RTX infusions at a predefined schedule. The tailored-regimen group received a 500-mg RTX infusion at randomization (day (D) 0), with reinfusion only when CD19 lymphocytes or ANCA had reappeared, or ANCA titer rose markedly, based on testing every 3 months until month (M) 18. The fixed-schedule group received RTX (500 mg) on D0 and D14, then at M6, M12 and M18. AAV relapse rates did not differ significantly between the 2 groups at M28. The objective of this post hoc analysis was to evaluate the effect of omitting the D14 500-mg RTX infusion on early AAV-relapse rates.

Methods: MAINRITSAN2-trial data were subjected to post-hoc analyses of M3, M6, M9 and M12 relapse-free survival rates in each arm as primary endpoints. Relapses were defined as reappearance or worsening of AAV symptoms, i.e., BVAS >0. Exploratory sub-group analyses were run according to cyclophosphamide or rituximab induction and newly-diagnosed or relapsing AAV. Other endpoints were ANCA status and titer, and CD19+ B-cell–count evolutions.

Results: At M3, M6, M9 and M12, respectively, among the 161 patients included, 79/80 (98.8%), 76/80 (95%), 74/80 (92.5%) and 73/80 (91.3%) from D0, and 80/81 (98.8%), 78/81 (96.3%), 76/81 (93.8%) and 76/81 (93.8%) from D0+D14 groups were alive and relapse-free. No between-group differences were observed. Results were not affected by cyclophosphamide or rituximab induction, or newly-diagnosed or relapsing AAV. On D0, a higher percentage of D0-infusion patients were ANCA-positive and that difference remained stable at M12. Median (IQR) circulating CD19+ B-cell counts/mm^3 on D0, and at M3, M6, M9 and M12, respectively, were: 14 (1–44), 0 (0–0), 0 (0–1), 0 (0-4) and 0 (0–2) for the D0-infusion group; and 9 (0–35), 0 (0–0), 0 (0–2), 0 (0–1) and 0 (0–2) for the D0+D14-infusion group. Those results remained unchanged in the sub-group analyses

Conclusion: Eliminating the D14 rituximab remission-maintenance dose did not seem to impact the relapse-free survival rate at M12.

Glucocorticoids in Incident ANCA-Associated Vasculitis (AAV) Patients - A Study of Routine Clinical Practice in the EU Demonstrates Prolonged Use and Temporal Relationship to Adverse Events and Infections

Dieter Goette,[1] and Peter Rutherford[1], [1]Vifor Pharma, Zurich, Zurich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: AAV is a severe systemic vasculitis and rapid induction of remission is essential and high dose glucocorticoids (GC) are part of standard of care. Achieving control of AAV is critical but patients are also at risk from GC-related adverse events leading to long term organ damage as well as acute morbidity and mortality. This retrospective study aimed to examine GC prescribing patterns, AAV response and adverse events (AEs) in incident AAV patients managed in routine clinical practice in Europe.

Methods: 929 incident AAV patients (54% of patients had granulomatosis with polyangiitis, and 46% had microscopic polyangiitis; mean age was 56.82 years (SD 14.2) with 53.7% male) from 4 European countries (399 physicians) were diagnosed between 2014-17. Routine clinical data collected at baseline, 1, 3, 6 and 12 months following commencement of induction therapy were collected and analysed.

Results: Severity of vasculitis varied - 12% patients were mild/localized, 54% moderate systemic and 34% had severe, life threatening vasculitis. Overall 83% of patients received GCs initially – 49% IV followed by oral, 17% oral only and 17% IV only. 43% used a combination of cyclophosphamide and GC, 13% rituximab and GC, 10% only GC with the remainder using other regimes. As BVAS was not used routinely, full clinical response was assessed as no vasculitis activity and GC taper on track. Most patients remained on GCs over 12 months, AAV response was incomplete and AEs were common especially in first 3 months when GC dose highest. GC dose changes were performed

	1 month	3 months	6 months	12 months
Full response %	22	43	61	68
Still receiving GC %	82	79	67	61
Decrease/stop GC at visit %	38/1	45/4	38/5	26/8
At least one AE/infection %	64/46	42/28	35/23	30/20

variably and varied geographically - for instance more UK patients had GC reductions at 3 (55%) and 6 months (46%) compared to other countries. At 12 months, of the 61% patients still needing GCs, 34% were receiving < 5mg, 56% 5-10mg, 9% 10-20mg and 2% > 20mg. 67% had no vasculitis activity, 17% local disease only, 11% mild to moderate systemic disease and 6% moderate to severe systemic disease

Conclusion: Most incident AAV patients receive high dose GCs as part of remission induction therapy, commonly IV initially, and the majority remain on GCs over 12 months. AEs and infections are common especially in the first months when GC dose is high. Clinical response is variable and only a minority of patients at 12 months have full remission of AAV without the clinical need for steroids. New targeted therapeutic approaches are needed to address this unmet medical need in AAV.

Abstract Number: 1666

Maintenance Treatment in ANCA Associated Vasculitis in Real World Clinical Practice – Burden of Disease, Use of Glucocorticoids and Impact on Patient Functional Status Remain Major Problems

Dieter Goette,[1] and Peter Rutherford[1], [1]Vifor Pharma, Zurich, Zurich, Switzerland

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: After successful remission induction AAV is a relapsing remitting long term condition and patients are at risk of organ damage from both active AAV and therapy in particular from glucocorticoids (GC). The remission maintenance phase of AAV is critical for good long term outcomes. This retrospective study aimed to examine the definition of maintenance, therapies used and outcomes in AAV patients managed in routine clinical practice

Methods: AAV patients from 4 European countries (310 physicians) who completed induction therapy for organ or life threatening AAV and initiated maintenance therapy between 2014-16 were studied. Data were collected at the time maintenance was determined to begin by the physician and then at following 6, 12, 18 and 36 months

Results: 929 patients were studied - 51% of patients had granulomatosis with polyangiitis,; mean age 54 years with 54% male. 49% were studied from incident AAV and 51% from a relapse. Physicians defined the start of maintenance with mean of 5.6 months from induction start on basis of fixed time point 38%, starting of new drug for maintenance 27%, reaching full remission 26% and no specific criteria 9%. At this time 45% were in full AAV remission vs 49% in partial and 6% refractory. Over 36 months from when maintenance was defined, 84% were in remission but 10% had major relapse requiring re-induction therapy and left follow up, 6% died (in 2/3 of cases at time of relapse). There is variation in the drugs used for maintenance therapy in real world practice. At 36 months, 9% of AAV patients were receiving renal replacement therapy and CKD was reported in 17% of patients vs 7% at start of remission induction therapy and osteoporosis also increased 15% vs 7%. 55% of patients had no AAV activity, 28% positive ANCA serology but no clinical disease, 8% local AAV, 6% mild to moderate systemic disease and 3% moderate to severe systemic disease. Active AAV was see most commonly in kidney (29%), lung (13%) and sinuses (8%). There was

	Maintenance start	6 months	12 months	18 months	36 months
Remission n	929	817	789	777	742
Total relapse %/major %		12/46	10/53	6/51	7/66
GC/Azathioprine/Rituximab/ MMF %	62/37/19/18	59/37/20/19	49/31/17/18	40/28/15/16	33/23/13/12
GC dose > 7.5mg %		59	41	30	29
At least one infection %		43	34	28	26

negative impact on patient functional status after 36 months with 13% having reduced working hours, 13% restricted social life, 6% had to leave employment, 5% were registered as disabled and 2% had to leave full time education

Conclusion: Maintenance therapy in AAV has variable definitions but typically begins after 6 months of remission induction therapy. Relapse of varying degree is still a clinical problem and many patients require ongoing GC therapy to maintain remission. Infectious complications are a problem and there is significant negative impact on patient functional status over time. There is an ongoing need for new targeted therapies in AAV to improve clinical and patient functional status

Long Term Outcome of Hydralazine-Associated Vasculitis

Saja Almaaitah,[1] Kinanah Yaseen,[2] Yuxuan Jin,[3] and Rula Hajj-ali[4], [1]Internal Medicine Residency/Cleveland Clinic, University Heights, OH, [2]Cleveland Clinic, Cleveland, OH, [3]Quantitative Health Science, Cleveland Clinic, Cleveland, OH, [4]Rheumatologic and Immunologic Disease/Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydralazine associated vasculitis (HAV) is rare but with potentially detrimental complications, affecting different organ systems. Most case series described short term disease course. Hence, data is sparse regarding long term management and outcome of HAV. The aim of this study is to determine long term outcome and whether variable duration of therapy has any impact on outcome.

Methods: We identified cases of HAV by searching electronic medical records for ICD codes of vasculitis and association of hydralazine intake from July of 2001 to July of 2017. Patients who received hydralazine after vasculitis onset were excluded. 23 patients were identified with diagnosis of HAV as deemed by the treating clinician. Data collected included demographics, hydralazine dose/duration, comorbid conditions, clinical presentation, laboratory, radiologic and pathological data, treatment strategies and outcomes. Continuous variables were summarized using means or medians, and categorical variables were summarized using frequencies and percentages. Outcomes were defined by full renal recovery, chronic kidney damage or relapse. Lung involvement was also registered.

Results: 23 patients (age 65.8±10.5 years, 65% males) with HAV were identified. Median duration of hydralazine use at onset of vasculitis was 34 months (5,170), with median total daily dose of 150 mg. Table 1 represents organ involvement, serological findings and treatment. The most commonly involved organs were the kidneys (100%) and lungs (48%). Majority of patients had positive serology (ANCA 100%, ANA 91%, anti-histone 71%, ds-DNA 63%).

Table 1: Organ involvement, serological findings and treatment

Factor	Total (N=23) Statistics
Organ involvement	
Constitutional	3(13)

Induction	19 (83)
Induction and short-term maintenance	12 (52)
Induction and ongoing maintenance	4 (18)
No treatment	2 (8)
Relapse	0

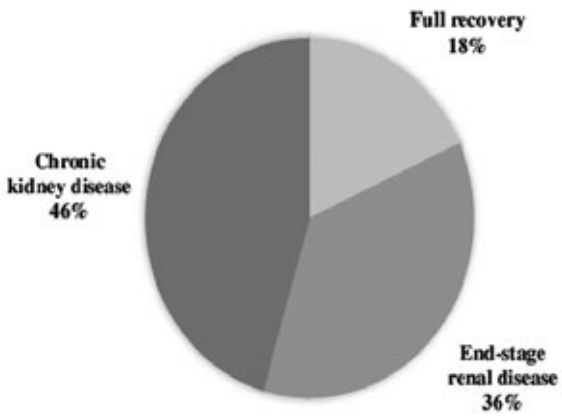
Statistics presented as Mean ± SD, Median (min, max) or N (column %)

Median follow up duration: 34 months (5,170)

Median duration of follow-up was 30 months. One patient was lost to follow up, 4 patients (18%) had complete renal recovery and 18 patients (82%) had chronic kidney damage (Figure 1). Higher serum Creatinine and need for dialysis at onset of the disease were associated with worse outcome (p=0.002, p=0, 0046 respectively). Overall death in the cohort was 6 (26%) patients, 3 of whom died within the first year of diagnosis due to complications related to vasculitis. 7 patients (30%) had diffuse alveolar hemorrhage, while 4 (17%) had nodular opacities, with resolution of both entities on follow up testing.

Most commonly used treatments were systemic steroids (83%), cyclophosphamide (34%) and rituximab (26%). 19 patients (83%) received induction therapy. 12 patients (52%) received induction and short-term maintenance therapy, with a median duration of 6 months. 4 patients (18%) received induction and are still on maintenance therapy to date. 2 patients (8%) did not receive any treatment. No relapse or progression of kidney disease was noted in the whole cohort despite variable treatment regimens, including patients who did not receive any treatment.

Figure 1: Long-term outcome of renal involvement



Conclusion: HAV mainly involves the kidneys and the lungs. Renal outcome is poor regardless of induction or maintenance therapy regimens. No relapse occurred in our series, which represents the longest follow up to date. Maintenance therapy may not be needed in these patients. Cohorts with longer follow up duration are needed to validate this observation.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The long-term features of granulomatosis with polyangiitis (GPA), a systemic small-vessel ANCA-associated necrotizing vasculitis, have been mainly reported in small patient series. The aim of this study was to describe the main characteristics and long-term outcomes of patients entered in the nationwide French Vasculitis Study Group (FVSG) database.

Methods: Clinical and laboratory characteristics of patients with GPA, satisfying 1990 ACR criteria and/or revised Chapel Hill Nomenclature, enrolled in the FVSG cohort were collected. All patients had ANCA detection by immunofluorescence and/or ELISA determination of ANCA specificity at diagnosis or during follow-up. Estimated patients' overall and relapse-free survival rates were analyzed by Kaplan–Meier curves and Cox regression analysis.

Results: Between May 1983 and April 2018, 795 GPA patients were entered in the Registry: 181 (23%) before 2000, 419 (53%) 2000–2010 and 195 (24%) after 2010. They were followed for a mean ± SD of 4.6 ± 3.9 years. At diagnosis, mean ± SD age was 53 ± 16 years, with 52 (7%) >75 years old; their main clinical manifestations were: fever >38°C (43%); weight loss (45%); arthralgias/arthritis (52%); ENT involvement (80%), including rhinitis (54%), sinusitis (42%) and/or otitis (23%); lung involvement (68%), including nodules (41%) and alveolar hemorrhage (18%); neurologic (29%) involvement, including peripheral (21%) and central (10%) manifestations; and renal (56%) involvement. Median creatinine at diagnosis was 93 µmol/L, when 177/609 (29%) patients' had levels >150 µmol/L; between baseline and diagnosis those levels had already risen >30% for 193 (24%) patients. At diagnosis, 13 (2%) patients had subglottic stenosis; 55 (7%) had GPA limited to ENT and/or lungs (localized). Among the 728 available ELISA results, 546 (75.0%) patients were anti-PR3+ and 120 (16.5%) anti-MPO. Mean BVAS was 17.4 ± 8.8. To induce remission, glucocorticoids (GCs) were prescribed for 772 (97%) patients (median dose 60 [IQR 50–70] mg/day), combined with intravenous (76%) or oral (7%) cyclophosphamide, rituximab (6%) or methotrexate (4.5%). Among 729 (92%) patients achieving remission, 394 (54%) relapsed a mean of 2.7 ± 2.2 years after diagnosis. Kaplan–Meier estimated 5- and 10-year relapse-free survival rates, respectively, were 37% and 17% for the entire cohort, 35% and 14% for PR3+ patients, and 46% and 25% for those MPO+ (P=0.11). Univariable analysis identified PR3 positivity (HR 1.30; P=0.04) as the only factor associated with relapse, while oral cyclophosphamide use lowered relapse probability (HR 0.60; P=0.05). Multivariable analysis retained PR3 positivity (HR 1.29; P=0.05) as the only factor independently associated with relapse. Five- and 10-year overall survival rates were 90% and 85%, respectively. Among the 90 main severe side effects were 34 (4%) cancers, 32 (4%) opportunistic infections and 20 (3%) cardiovascular events.

Conclusion: Findings based on this large series showed good survival of GPA patients, with a low rate of side effects, and confirmed the higher probability of relapse among those PR3-ANCA+ at diagnosis.

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mizoribine (MZR) is an immunosuppressant working as an inhibitor of purine synthesis, which mechanism of action is similar to mycophenolate mofetil. MZR is approved as the treatment of rheumatoid arthritis and lupus nephritis in Japan, and is reported to have effect in ANCA-associated renal vasculitis. But the data about the effect in remission maintenance and glucocorticoid dose reduction in patients with ANCA-associated vasculitis (AAV) are limited.

Table1. Baseline Characteristics and outcomes in patients treated with MZR and AZA

	Overall (n=31)	MZR (n=21)	AZA (n=10)	p value
Age	69 [58, 75]	70 [63, 74]	59 [54, 77]	0.281

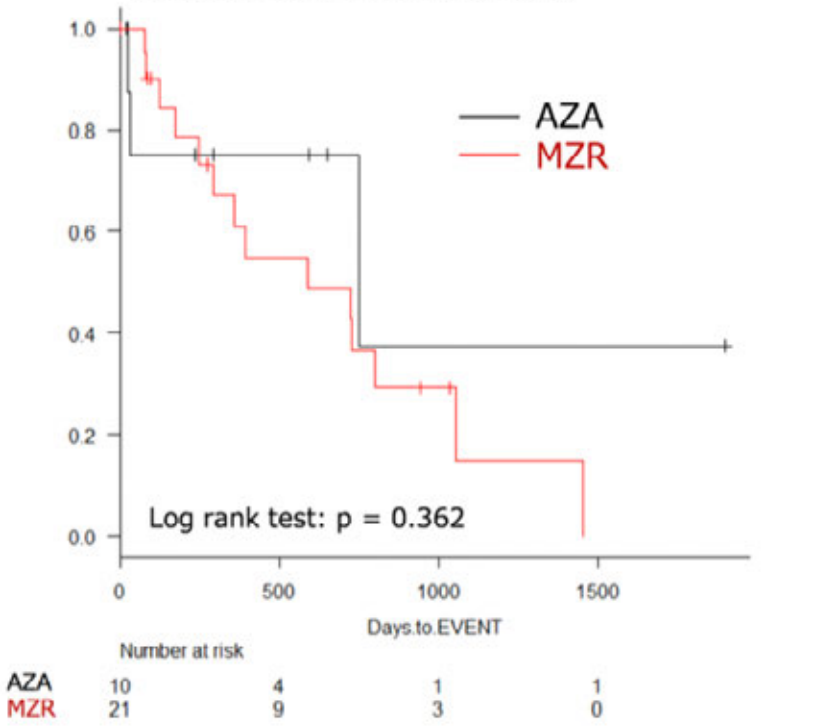
Figure1. Flare-free survival curves in AAV patients treated with MZR and AZA



Methods: We retrospectively reviewed charts of patients with AAV who used MZR or azathioprine(AZA) at St. Luke's International Hospital, Tokyo, Japan from January 2004 to December 2018. We investigated basic demographics, types of AAV, results of blood tests, and medications used in the treatment of AAV including glucocorticoid and other immunosuppressants(IS). We defined flare of AAV as a new onset AAV-related symptom that required increase or initiation of glucocorticoids or IS. We calculated and flare-free rate and compare between MZR treatment group and AZA treatment group with Kaplan Meier curve by using log rank test. We also check the dose reduction effect in glucocorticoids before and after MZR treatment by using Wilcoxon signed-rank test.

Results: We identified 31 patients in total, and there were 21 and 10 patients who were primarily treated with MZR and AZA. Baseline characteristics are shown in Table1. 8 Patents (38.1%) in MZR-treatment group used concurrent IS (5: methotrexate, 1: azathioprine, 1: abatacept and 1: tacrolimus). Flare-up of AAV was seen in 14 (66.7%) in MZR and 3 (30.0%) in AZA-treated group, but there was no significant differences in the flare free rate (Figure 1). Dose of glucocorticoids significantly decreased after using MZR and steroid dose at flare is low (median 40mg [20, 50] vs 5 mg [3, 10]; $p < 0.01$, Wilcoxon signed-rank test). Mild liver dysfunction is common in MZR group, but just 3 (14.3%) patients discontinued MZR for adverse events(AE) (2: allergy, 1: infection) and major reason for discontinuation was insufficient effect, although 40% of patients treated with AZA had to discontinue due to bone marrow suppression and severe liver dysfunctions.

Conclusion: MZR seemed to have significant steroid-sparing effect in patients with AAV although rate of flare-up is high. Given the safe profile of MZR, MZR may be a useful agent can be used as alternative in patients who cannot continue AZA or other IS for AE, or in addition to regular IS for AAV.

Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is the most prevalent adult vasculitis and is associated with significant inflammatory burden; chest computed tomography (CT) is frequently obtained as part of the diagnostic work up and prognosis. Coronary calcium score (CCS) is a non-invasive modality used to evaluate the presence of coronary arterial calcium (CAC). Visual assessment of

* Plus–minus values are means ± standard deviation

CAC – coronary artery calcification; GPA – granulomatosis polyangiitis; MPA – microscopic polyangiitis; EGPA – eosinophilic granulomatosis polyangiitis

[a] – adjusted for age, sex, race, body mass index, smoking, family history of coronary artery disease, and hypertension

CAC via previously validated ordinal scoring in routine non-gated chest CT accurately predicts CCS (in Agatston units) from electrocardiogram-gated CT. Studies have demonstrated increased CCS/CAC burden in rheumatoid arthritis and systemic lupus erythematosus, but none have studied vasculitides, specifically AAVs: granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), and microscopic polyangiitis (MPA). We evaluated the cardiovascular burden in AAVs through visual assessment of CAC, compared to matched controls.

Methods: In a single tertiary care center we performed a retrospective chart review (2006-2018) of all adults with GPA, MPA, and EGPA (identified by ICD-9 and ICD-10 code) who had routine non-gated chest CT within 1 year before, or any time after diagnosis, and cholesterol profile within 5 years of diagnosis. Exclusion criteria included a history of coronary artery disease (CAD), peripheral arterial disease, or stroke. Abstracted data included: demographics, AAVs characteristics including the Birmingham vasculitis activity score (BVAS), and CAD risk factors. One thoracic radiologist blindly reviewed the chest CTs of AAVs and control patients matched by age (within 5 years), sex, race, body mass index (BMI, within 3 units), and same year of chest CT. CAC was scored ordinally: 0 = none, 1 = mild, 2 = moderate, and 3 = severe, in each of the main four coronary arteries; total scores ranged 0-12. All chest CTs were done without intravenous contrast.

Results: We identified 61 AAV patients and 61 controls (Table 1). For the AAV group: disease duration (mean ± SD) until CT scan was 37.2 ± 25.8 months, subjects were mostly white (88.5 %), and female (60.7%); BVAS was able to be calculated within 6 months of CT scan in 53 (87%) of subjects with a mean score of 6. Creatinine was significantly

Variable	Disease Duration (0-12 months)		Disease Duration (13-36 months)		Disease Duration (≥ 37 months)	
	GPA, MPA, EGPA	Controls	GPA, MPA, EGPA	Controls	GPA, MPA, EGPA	Controls
Number of subjects	27	27	14	14	20	20
CAC Score*	2.48 ± 2.58	1.52 ± 1.99	1.29 ± 1.77	1.36 ± 1.82	2.40 ± 2.66	1.45 ± 1.61
CAC Score Severity						
0	9 (33%)	13 (48%)	0 (0%)	0 (0%)	8 (40%)	8 (40%)
Mild (1-4)	9 (33%)	8 (30%)	7 (50%)	7 (50%)	6 (30%)	10 (50%)
Moderate (5-8)	5 (19%)	5 (19%)	4 (29%)	5 (36%)	2 (10%)	2 (10%)
Severe (9-12)	4 (15%)	1 (4%)	3 (21%)	2 (14%)	4 (20%)	0 (0%)
CAC Prevalence	18 (67%)	14 (52%)	7 (50%)	7 (50%)	12 (60%)	12 (60%)

Table 3. CAC score and prevalence based on GPA/MPA/EGPA disease duration and matched control group comparison.
Data was not shown to be statistically significant ($p < 0.05$) in all groups
* Plus–minus values are means ± standard deviation
GPA – granulomatosis polyangiitis; MPA – microscopic polyangiitis; EGPA – eosinophilic granulomatosis polyangiitis; CAC – coronary arterial calcium

higher in the AAV group (*P* = 0.028). The mean CAC scores (AAV: 2.18 ± 2.46; control: 1.46 ± 1.80; *P* = 0.089) and prevalence of CAC (AAV: 60.7%, control: 54.1%; *P* = 0.464) in AAVs were not significantly different compared to controls (Table 2). The prevalence of CAC in AAVs, even when adjusted for CAD risks, was not significantly different compared to controls. 34 of the AAV patients (64%) had a BVAS > 0, but the CAC score was comparable to controls (*P* = 0.26). Longer disease duration was not associated with higher CAC score or prevalence (Table 3).

Conclusion: CAC interpreted through ordinal scoring is similar in patients with GPA, MPA, or EGPA, compared to control group. Though CAC score and prevalence were higher in the vasculitis group, they did not reach statistical significance (likely due to small sample size and retrospective nature of our study). Controlled prospective studies are needed to best analyze the cardiovascular risk and utility of CAC assessment in AAV.

Abstract Number: 1671

Hospital Admissions and Mortality in Patients with ANCA-associated Vasculitis

Jon Golenbiewski,[1] Amanda Eudy,[2] Megan Clowse,[2] and Nancy Allen[2], [1]Duke University, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) has a high rate of complications, both from disease itself and treatments. Hospital mortality rates for AAV range between 10-20%. There is a lack of information regarding reasons for hospitalization and outcomes of these hospitalizations. It is important to characterize the current state of treatment and outcomes in AAV in order to improve patient care.

Methods: A retrospective chart review was performed at a large academic medical center in which all hospitalizations were reviewed in adults with a diagnosis of granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) from 10/1/2015 - 12/31/2018. The electronic medical record (EMR) was queried for in-patient visits with an ICD-10 code of M30.1, M31.30, M31.31, and M31.7. The diagnosis of vasculitis was made by the treating rheumatologist or nephrologist. Patients with eosinophilic granulomatosis with polyangiitis (EGPA), without AAV or an unclear diagnosis, and absent ANCA titers were excluded. Differences in outcomes between GPA and MPA patients were measured by Fisher's exact test and t-tests.

Results: There were 127 total hospitalizations amongst 54 patients (33 GPA, 21 MPA). Forty-one hospitalizations (35 patients) were for active disease: 25 had a new vasculitis diagnosis and 16 for recurrence or flare. Patients with new disease were most commonly admitted with simultaneous lung (n=15) and renal involvement (n=16); 8 of these patients had diffuse alveolar hemorrhage (DAH). Patients with recurrent disease were most commonly admitted for respiratory disease, 6 with lower respiratory and 5 with upper airway disease (1 required emergent tracheotomy).

Of the 86 hospitalizations in patients with inactive disease (n=31 patients), infection caused almost half of admissions (41%, n=36) with pneumonia and skin/soft tissue infections being most common. There were 24 admissions for cardiovascular related causes; 9 for blood loss (most commonly GI bleed (n=6)); 4 for a deep vein thrombosis; 4 for osteoporotic fractures, and only 1 patient had a new diagnosis of cancer (urothelial carcinoma with remote history of prior Cytoxan).

There were 27 ICU admissions among 21 patients (39% of all patients) attributed to respiratory failure in 56%, renal failure in 33%, and infection in 26% of cases. More than half (56%) were for active disease and 10 of these had new disease. Mechanical ventilation and vasopressors were required in nearly half of ICU admissions.

Overall mortality was 7% for hospitalized patients and 19% for those admitted to the ICU (3 GPA, 1 MPA). All 4 hospital deaths occurred in the setting of infection. An additional 5 patients died within 28 days of discharge, for a total mortality rate of 17% (n=9).

Conclusion: Patients with GPA and MPA can have frequent hospitalizations, many that are not related to active disease. Those hospitalized with new disease were more likely to have both pulmonary and renal involvement. Although outcomes have improved considerably, mortality rates for hospitalized patients with disease remain high.

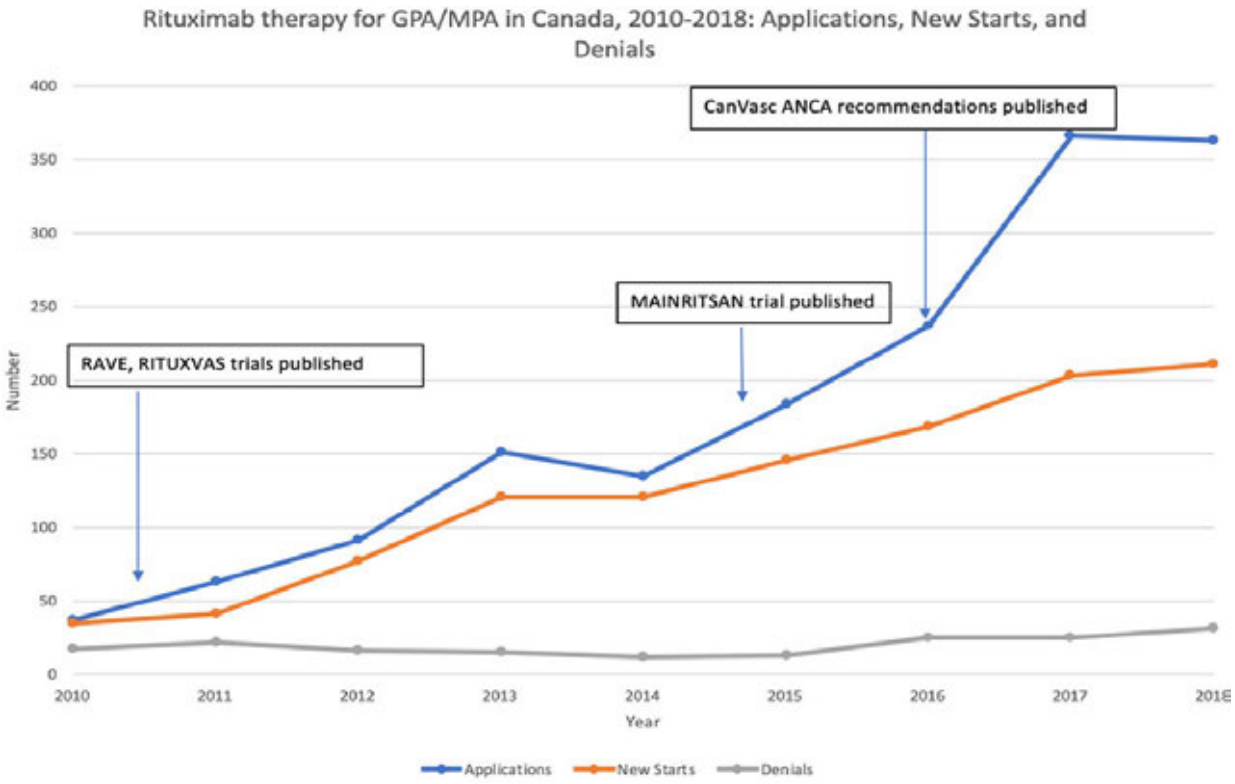
Use of Rituximab for the Treatment of ANCA-Associated Vasculitis in Canada, 2010-2018

Arielle Mendel,[1] Simon Carette,[2] and Christian Pagnoux[2], [1]Mount Sinai Hospital, Toronto, ON, Canada, [2]Mount Sinai Hospital and University Health Network, Toronto, ON, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Rituximab (RTX) is an effective therapy for ANCA-Associated Vasculitis (AAV). The Canadian Vasculitis Research Network (CanVasc) recommends RTX for induction among patients with unacceptable risk of infertility or other contraindication to cyclophosphamide, and among those who have not responded or have relapsed after conventional induction therapy. RTX is also recommended for maintenance, where available. Our objectives were to (1) describe real-world use of RTX in AAV since the publication of the Rituximab in ANCA-associated vasculitis (RAVE) trial in 2010, and (2) compare current RTX use for AAV across regions, sexes, and age groups.

Methods: Anonymized, aggregate-level data on RTX use in AAV (Granulomatosis with Polyangiitis and Microscopic Polyangiitis) from January 2010-December 2018 were obtained from the national pharmaceutical-funded patient support program database, covering approximately 85% of RTX prescriptions for vasculitis in Canada and exclud-



RTX in Canada 2010-2018
Rituximab use in Canada, 2010-2018

ing inpatient infusions. RTX use was compared across sexes, age groups, geographic regions, and coverage type (private, public, or combination). The number of unique applications and denials (all funding sources), and new drug starts were assessed over time. Data on RTX indication (induction, relapse, or maintenance) were not available.

Results: From 2010, 1124 patients started RTX therapy for AAV (including new diagnosis, relapsing disease, or maintenance). New RTX starts increased 6-fold, from 35 in 2010 to 211 in 2018, while the number of application denials (from public and/or private funders) remained relatively stable (from 18 in 2010 to 32 in 2018). Applications for treatment of AAV represented only 11% of the total RTX applications for other disease indications. Among current RTX users (n=556), 306 (55%) patients were female and 115 (21%) were of reproductive age (18-39 years). Patients received public coverage more often in Quebec (51% [95% CI, 42-60]) and Western provinces (46% [38-53]) compared to Ontario/Atlantic provinces (26%[22-32]).

Conclusion: The use of RTX for AAV in Canada has increased substantially since clinical trials established its efficacy. Between provinces, there are significant differences in the proportion of patients covered publicly, although this could reflect practice variations in the use of RTX for maintenance (not currently covered publicly). Only 21 % of RTX users were in the reproductive age group, suggesting that RTX is used broadly for AAV treatment and is not being limited to those with fertility concerns.

Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Overall mortality in ANCA-associated vasculitides (AAVs) over the last two decades has been reported to be decreasing with the use of immunosuppressive therapies. However, despite treatment, mortality rates remain high, particularly in the first year after diagnosis. In this study, we aimed to determine the prevalence of mortality in AAV patients and to investigate the factors that may be associated with first-year and overall mortality.

Table 1. Demographic and clinical characteristics of ANCA-associated vasculitis patients

Methods: AAV patients who were categorized according to the 2012 Chapel Hill consensus nomenclature, were included in this study from two university centers. Diagnostic subgroups were; granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA), eosinophilic granulomatosis with polyangiitis (EGPA) and renal-limited vasculitis (RLV). Patients with only clinical renal involvement and diagnosed by renal biopsy were classified as RLV. The clinical and demographic characteristics of the patients were collected retrospectively. Factors predictive of mortality were evaluated by Kaplan-Meier method and the Cox proportional hazard model.

	Univariate analysis results for overall mortality			Univariate analysis results for first-year mortality		
	B	CI 95 %	p	B	CI 95%	p
Age at diagnosis[1]	1.07	1.04-1.10	<0.001	1.064	1.02-1.10	<0.001

Table 2. The results of Kaplan-Meier survival analysis: Factors associated with overall and first-year mortality

Results: In total 232 (123 [53%] male and mean age at diagnosis51.4±15.75 years) AAV patients (137 [59%] GPA; 40 [17%] MPA; 30 [13%] RLV and 25 [11%] EGPA) were included in the analysis. ANCA positivity was detected in 82%

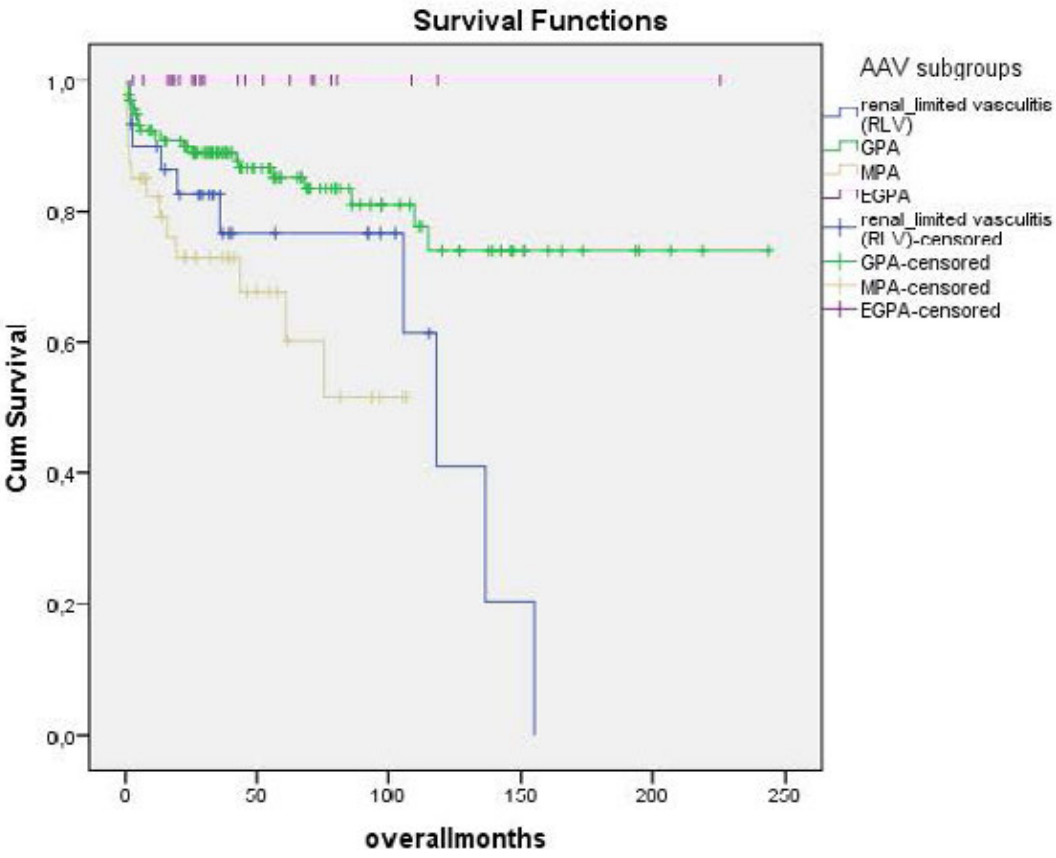

Figure. The results of the Kaplan-Meier analysis: Overall mortality was significantly different in ANCA-associated vasculitis subgroups

(180/220) patients with IIF and/or ELISA. 167 patients (73%) had renal involvement and among them, one in third patients (52/167) had developed end-stage renal disease (ESRD). Other clinical features are shown in table 1. Overall 44 patients (19%) died during a median 40 months (0-244) of follow-up. First-year and five-year mortality rates were 10% and 30% respectively. Overall mortality was significantly different in AAV subgroups ($p< 0.001$, Figure). Factors associated with overall and first-year mortalities that were detected with univariate analysis, including disease activity scores (Five Factor Score [FFS] and Birmingham Vasculitis Activity Score [BVAS]), are summarized in table 2. In the multivariate analysis age at diagnosis (Hazard ratio [HR] 1.05, 95 % Confidence interval [CI] 1.01-1.08, p=0.002) and cardiac involvement (HR 6.79, 95 % CI 1.97-23.32, p=0.002) were found to be the independent predictive factors of overall mortality. The same factors were also predictors of the first-year mortality (Age at diagnosis [HR 1.06, 95 % CI 1.02-1.10, p=0.001] and cardiac involvement [HR 5.45, 95 % CI 1.81-16.40, p=0.003]).

Conclusion: Our findings suggest that there could be some survival differences between AAV subgroups and, disease activity scores (both FFS and BVAS at diagnosis) are helpful to predict mortality. However, the age at diagnosis and cardiac involvement seems to be the only significant predictors of first-year and overall mortality in AAV patients.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To identify demographic and clinical risk factors for mortality in patients with ANCA-associated vasculitis (AAV) who were followed-up in a Latin-American Tertiary Referral Hospital.

Methods: Medical records of patients with AAV according to the 1990 ACR criteria, Chapel Hill 2012 consensus, EMEA criteria, or diagnosed by an experienced rheumatologist, and covering the period between January 1990 and December 2018, were reviewed. Granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA) were included. Renal limited vasculitis (RLV) was considered separate from MPA. Features analyzed as potential predictors of mortality were demographic factors (age at diagnosis, gender), disease duration, clinical manifestations (per organ involvement), creatinine level at diagnosis (mg/dl), ANCA status [by method (ELISA or IIF)], diagnosis, and EULAR disease categorization (limited, early systemic, generalized

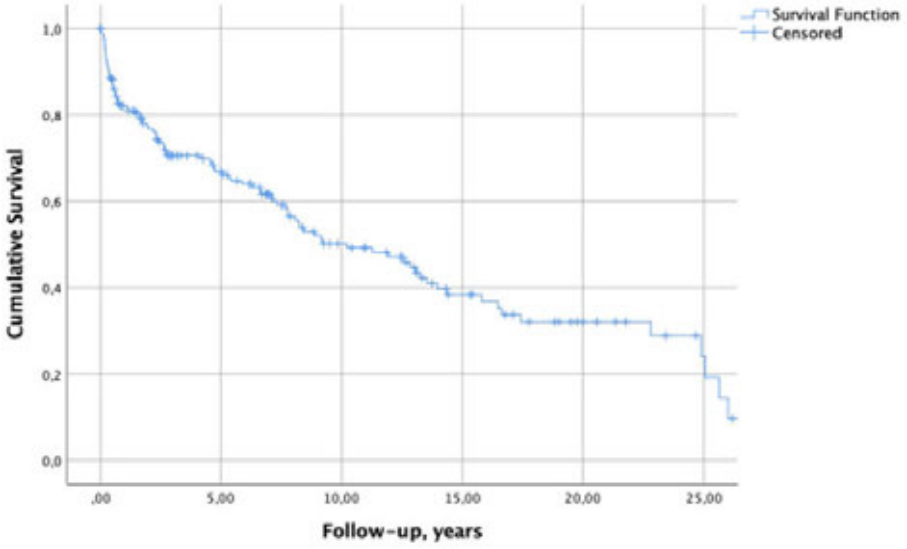

Figure 1. Kaplan-Meier survival analysis.

AAV: ANCA-associated vasculitis. ENT: Ear, nose and throat. GPA: Granulomatosis with polyangiitis. MPA: Microscopic polyangiitis. EGPA: Eosinophilic granulomatosis with polyangiitis RLV: Renal limited vasculitis.

Table 1. Variables predictive of mortality in AAV. Univariable and multivariable analysis

and severe renal). Categorical variables were summarized as frequencies and percentages while continuous variables were presented as medians and their interquartile ranges (IQR). Cox regression models were used to determine the risk factors for mortality. Univariable and multivariable analyses using a backward selection method with α-level to stay in the model set at 0.05 were performed. Statistical analyses were performed using SPSS v26.0.

Results: One hundred eighty-nine patients were included with a female/male ratio of 2:1 [127 (67.2%)/62 (32.8%)]. Their median (IQR) age at diagnosis and disease duration were 60.0 (51.5-68.5) and 4.7 (1.0-11.1) years, respectively. One hundred forty-six (77.2%) patients had MPA, 32 (16.9%) GPA, 5 (2.6%) EGPA and 6 (3.2%) RLV. One hundred seventy-eight patients had ANCA-IIF results [p-ANCA: 119 (66.9%), c-ANCA: 38 (21.3%), negative-ANCA: 21 (11.8%)] and 172 patients had ANCA-ELISA results [MPO: 117 (68.0%), PR3: 31 (18.0%), negative-ANCA: 24 (14.0%)]. According to EULAR categorization, 5 (2.6%) were limited, 67 (35.5%) were early systemic, 88 (46.6%) were generalized and 29 (15.3%) were severe renal. The last two categories had a median (IQR) creatinine level of 1.4 (0.9-2.7) and 8.0 (6.7-10.1). Until April 2019, 96 (50.8%) patients had died. The corresponding Kaplan-Meier survival curve is depicted in Figure 1; five-year survival was 66.9%, ten-year survival was 50.1% and twenty-year survival was 32.0%. Ocular involvement was protective [HR 0.39 (CI95% 0.19-0.81), p=0.012] while renal involvement [HR 2.24 (CI 95% 1.42-3.52), p=0.001], lung involvement [HR 1.60 (CI95% 1.02-2.48), p=0.039] and age at diagnosis [HR 1.02 (CI95% 1.00-1.04), p=0.031] were predictive factors of mortality (Table 1).

Conclusion: Ocular involvement was protective while age at diagnosis and renal and lung involvements were predictive factors of mortality in Latin-American AAV patients. At ten years of follow-up, the survival rate was 50%.

A Retrospective Cohort Study Using Clinical Notes and Latent Topic Modeling to Characterize the Natural History of ANCA-Associated Vasculitis

Liqin Wang,[1] Eli Miloslavsky,[2] John Stone,[3] Hyon K. Choi,[4] Li Zhou,[5] and Zachary Wallace[2], [1]Brigham and Women's Hospital, Boston, [2]Massachusetts General Hospital, Boston, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA, [4]Massachusetts General Hospital, Boston, MA, [5]Brigham and Women's Hospital, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is associated with end-organ damage, complications of treatment, and excess death. Retrospective studies on the clinical course of AAV, including the evolution of clinical manifestations, comorbidities, and complications before and after the diagnosis are limited to analyses of claims data and case series relying on chart review or coded fields in electronic health records. No study has used automated methods to evaluate the clinical notes documented in the patients' EHR as a data source to characterize AAV's natural history.

Characteristic[a]	Study cohort N=660 (%)
Age, mean (SD), years[b]	56.9 (18.1)

Table. Characteristics of the Study Cohort

Methods: The Partners AAV (PAAV) cohort is a consecutive inception cohort established at Partners HealthCare System (PHS), a large hospital system in New England, that has been previously described. All cases are PR3- or MPO-ANCA+. The clinical notes of this study cohort were obtained from PHS Research Patient Data Registry between the inception of the database and 08/23/2018. We then conducted automatic topic modeling to capture the trends of various themes mentioned in care provider notes three years prior to and five years after the initiation of AAV treatment. Each topic was manually labeled independently by two vasculitis experts; differences were resolved through consensus.

Results: This cohort analysis included 660 patients with AAV, with mean (SD) age of 56.9 (18.1) years and 392 (59.4%) female (**Table 1**). We generated 89 stable topics from a total of 70,519 notes. We studied the progression of the disease using topics that included AAV and treatment, cutaneous symptoms, psychiatric disorders, joint symptoms, and topics related to AAV complications of the kidneys and lungs like end-stage renal disease, renal transplantation, and bronchiectasis. Examples of topics are shown in **Table 2**. The temporal trends of selected topics are shown in **Figure 1**. Generally, AAV follows a prolonged clinical course with treatment mentioned for years following initiation (**Figure 1a**). Joint issues, skin lesions, and foot ulcers were frequently mentioned in the years preceding AAV, while these conditions appeared to be less commonly discussed following diagnosis and treatment of AAV (**Figure 1c**). Symptoms, including anxiety and stress, were often mentioned in the year prior to the disease diagnosis but then become less frequent (**Figure 1d**). Topics related to pulmonary and renal disease were common during the disease course but followed distinct patterns (**Figures 1e and 1f**). While pulmonary symptoms were common before and after diagnosis, renal disease (e.g., glomerulonephritis) was particularly common at the time of and following diagnosis.

Conclusion: Using the clinical notes of a large AAV cohort, we identified several topics relevant to the diagnosis, treatment, comorbidities, and complications of AAV. The patterns and trends of these topics support the notion that diagnostic delay is common and that some symptoms (e.g., cutaneous) may respond better to treatment than others

Abstract Number: 1676

Does Pneumocystis Jiroveci Pneumonia (PJP) Prophylaxis Prevent Hospitalizations for Other Infections in Vasculitis Patients?

Veena Patel,[1] and Kim Trotter[1], [1]University of Chicago, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Patients with rheumatic diseases are often at risk for opportunistic infections given the combination of disease manifestations and immunosuppressive treatment regimens, but the rates of *Pneumocystis jiroveci* pneumonia (PJP) are fairly low in this population. Prophylaxis against *Pneumocystis jiroveci* is often recommend for immunosuppressed transplant, leukemia and HIV patients, but there are no guidelines for patients with rheumatic diseases. The purpose of this study is to review the number of PJP cases at our institution in vasculitis patients and compare the rates of hospitalizations for other infections for patients receiving PJP prophylaxis to those who are not.

Methods: Using Epic's Slicer Dicer tool, we selected microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) patients over the past ten years who received care at our institution. Patients under 18 years-old, and patients without documented MPA or GPA were excluded. We then reviewed the electronic charts for these patients and recorded demographic information, PJP prophylaxis, hospitalizations at our institution for infections, disease and

MPA		PJP Prophylaxis (n=10)	No PJP Prophylaxis (n=13)
	Age (Average)	62 years old	58 years old
	Sex		
	Female	7 (70%)	8 (62%)
	Male	3 (30%)	5 (38%)
	Cases of PCP	0	0
	Infection requiring hospitalization	5 (50%)	2 (15%)
	Lung involvement	7 (70%)	5 (38%)
GPA		PJP Prophylaxis (n=55)	No PJP Prophylaxis (n=76)
	Age (Average)	55 years old	61 years old
	Sex		
	Female	27 (49%)	43 (57%)
	Male	28 (51%)	33 (43%)
	Cases of PJP	1	0
	Infection requiring hospitalization	5 (9%)	5 (7%)

Figure 1 compares MPA and GPA patients with and without Pneumocystis jiroveci pneumonia (PJP) prophylaxis. Only one case of PJP was found in the GPA group with prophylaxis. The p-value for GPA patients for infection hospitalizations between prophylaxis and non-prophylaxis groups was 0.7415. For MPA patients, the p-value was 0.1688.

treatment information. Fisher's exact test was used to compare rates of hospitalizations for infections for the PJP prophylaxis group vs. the non-prophylaxis group for MPA and GPA.

Results: Initially, 287 charts were reviewed and 154 met our inclusion criteria. Of all MPA and GPA charts reviewed, there was only one reported case of PJP listed in the past medical history of a GPA patient's chart happened to be on PJP prophylaxis. This case was complicated by a history of renal transplant and it was unclear when PJP was contracted in relation to PJP prophylaxis timing. The PJP prophylaxis group for MPA and GPA together had more cases of hospitalizations due to infections. The majority of these infections were viral (influenza, CMV) and skin-related (abscesses and cellulitis). The p-value for GPA patients for infection hospitalizations between prophylaxis and non-prophylaxis groups was 0.7415 and was 0.1688 for MPA patients, neither of which were statistically significant.

Conclusion: The rate of PJP in our vasculitis population is low, as suggested by prior literature. Our results do not indicate that PJP prophylaxis decreases hospitalizations for infections in MPA or GPA patients, although our results likely underestimate the number of hospitalizations, since we were unable to include hospitalizations at other institutions. The next steps of this study will be to evaluate other diseases including EGPA, PM/DM, SLE, CTD-ILD for rates of PJP and hospitalizations for other infections.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Induction therapy for severe ANCA-associated vasculitides (AAVs) is based on the combination of glucocorticoids and cyclophosphamide (CYC) or rituximab (RTX). For patients with severe acute renal impairment, use of RTX alone has not been evaluated in randomized–controlled trials and CYC is usually given in this situation. The additional benefit of plasma exchanges (PEs) is controversial. We compared the efficacies of glucocorticoid and RTX or CYC induction therapy for severe renal AAV flares and evaluated the potential benefit of PE adjunction to manage those flares.

Methods: This retrospective, multicenter study included patients with severe renal flares of granulomatosis with polyangiitis, microscopic polyangiitis or pauci-immune renal-limited vasculitis. The severity of renal impairment was defined as serum creatinine ≥350 μmol/L and/or an estimated glomerular filtration rate ≤15 mL/min/1.73 m^2. The primary endpoint was AAV remission at month (M) 3 and M6, and being dialysis-free at M3, M6 and M12. A propensity score and a double robust adjustment were used to compare groups.

Results: Between 2005 and 2017, 173 AAV renal flares occurred in the 161 patients included: 65 (40%) women and 96 (60%) men; mean (±SD) age at the time of the flare was 63 ± 13.1 years. Twenty-nine (17%) flares were treated with RTX and 144 (83%) with CYC. Remission rates did not differ between RTX- and CYC-treated groups, respectively, at M3 (93% vs 94%) and M6 (100% vs 92%). Although more RTX- than CYC-treated patients were dialysis-free at M12 (respectively: 91% vs 69%; odds ratio (OR) 4.59 [95% CI 1.02–20.6]), the difference was not significant after adjustment. At M12, 10 patients—all treated with CYC—had died.Because of too few RTX-treated flares, PE efficacy was evaluated only for CYC-treated patients. Among 144 CYC-treated flares, 81 (56%) also had PEs. M3 and M6 remission rates were comparable for the weighted CYC groups treated with or without PEs, respectively, at M3 (94% vs 95%) and M6 (92% vs 91%).The dialysis-free survival rates were significantly higher for CYC- and PE-treated patients vs no PE, respectively, in weighted groups (74% vs 65%; OR 2.91 [95% CI 1.11–7.62] at M6 and 73.2% vs 62.3%; OR 3.05 [95% CI 1.13–8.21] at M12). Significance was confirmed after double robust adjustment at M6 (OR 6.91 [95% CI 1.24–38.6]) but not at M12 (OR 5.37 [95% CI 0.90–32.1]).

Conclusion: According to the results of this retrospective study, RTX was apparently equivalent to CYC as induction therapy for patients with severe AAV renal flares. PE adjunction to CYC was associated with higher dialysis-free rates at M6. Despite the use of a propensity score, we were not able to overcome all the biases and these results need to be confirmed by prospective controlled trials. Subgroup analyses may be required to better identify the place of each treatment for AAV patients with severe renal involvement.

Interstitial Lung Disease in ANCA Associated Vasculitis: A Single Center Retrospective Analysis

Haidy Adel Youssef,[1] and Mehrnaz Hojjati[2], [1]Riverside Community Hospital/ UCR School of Medicine Internal Medicine Residency Program, Corona, CA, [2]Department of Rheumatology, Loma Linda University, Loma Linda, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA associated vasculitis patients have a wide spectrum of pulmonary involvement in the form nodular disease (especially peri-bronchial nodules), cavitating lesions, diffuse alveolar hemorrhage and less commonly interstitial lung disease (ILD) either usual interstitial pneumonitis (UIP) or nonspecific interstitial pneumonia

Characteristic	Subcategory of AAV with ILD manifestations	GPA (N=1)	EGPA (N=2)	MPA (N=4)
Demographic characteristics	M:F ratio	0:1	2:0	1:3
	Mean BMI	36.1	29.8	23.4
	Mean age at diagnosis of ILD	26	59	57.5
	Hispanic or Latino ethnicity	1 (100%)	1 (50%)	1 (25%)
	White/Caucasian ethnicity	0	1 (50%)	1 (25%)
Associated symptoms	Presence of Cough	1 (100%)	2 (100%)	4 (100%)
	Cutaneous vasculitis	0	2 (100%)	3 (75%)
Other pulmonary disease associations	Pulmonary hypertension	1 (100%)	1 (50%)	1(25%)
	Chronic sinus disease	1 (100%)	1 (50%)	1(25%)
	Tracheobronchial disease	1 (100%)	0	1(25%)
	Asthma	0	2 (100%)	0
Other major organ involvement	Eye	0	1 (50%)	3 (75%)
	Kidneys (mainly decreased GFR)	1 (100%)	0	1 (25%)
	Nervous System (mainly peripheral neuropathy)	1 (100%)	1 (50%)	0
CT scan chest findings	NSIP	1 (100%)	1 (50%)	1 (25%)
	UIP	0	0	0
	Granulomatous disease on CT chest	0	1 (50%)	2 (50%)
PFTs findings	Restrictive Lung disease pattern	1 (100%)	1 (50%)	2 (50%)
Labs values and serology	RF (rheumatoid factor)	0	1 (50%)	1 (25%)
	c-ANCA/PR-3	0	0	0
	p-ANCA/MPO	0	0	4 (100%)
	hematuria	1 (100%)	0 (0%)	3 (75%)
	ESR/CRP	1 (100%)	1 (50%)	3 (75%)

Table 1. Comparison between ILD in GPA, EGPA and MPA patients' demographic characteristics, clinical symptoms, other major organ involvement, CT chest findings, pulmonary function tests findings and relevant serological values.

Characteristic	GPA (N=1)	EGPA (N=2)	MPA (N=4)
Smoking history	0	0	0
TB exposure	0	0	1 (25%)
Chemotherapy exposure	1 (100%)	1 (50%)	4 (100%)
Silica Exposure	0	1 (50%)	0
Asbestos Exposure	0	1 (50%)	0

Table 2. Comparison between ILD in GPA, EGPA and MPA patients in terms of environmental/ hazardous exposures.

(NSIP). ILD seems to be a rare manifestation mostly associated with MPA (Microscopic Polyangiitis). However, the disease characteristics, serologic findings, demographics and associated risk factors is not well described to date in this subset of patients.

Methods: We performed a single center analysis of patients diagnosed with ANCA associated vasculitis (diagnosed based on biopsy findings and/or appropriate lab criteria with typical clinical characteristics) followed in the vasculitis clinic at Loma Linda University Health from 2017 to current. A retrospective chart analysis was performed on patients with diagnosis of AAV and ILD. Epidemiologic, demographic, clinical, imaging and serological data for these patients were collected. ILD was diagnosed by typical findings on CT scan, lung biopsy or restrictive pattern on PFTs in the absence of other potential causes of restrictive lung disease.

Results: Thirty patients with AAV (M:F= 8:22, mean age at diagnosis 51.3) were enrolled. 15 patients (50%) had Granulomatosis with Polyangiitis (GPA), 11 patients (36.6%) had Microscopic Polyangiitis (MPA) and 4 patients (13.3%) had Eosinophilic Granulomatosis with Polyangiitis (EGPA). ILD was diagnosed in 1 out of 15 GPA patients (6.6%), 2 out of 4 EGPA patients (50%) and 4 out of 11 MPA patients (36.3%). Mean time of diagnosis of ILD from the time of AAV diagnosis was 7 years in GPA, 9 months in EGPA and 10 years in MPA. 42.8% were of Hispanic/Latino ethnicity and 28.5% patients were of White/Caucasian ethnicity. Mean age of ILD diagnosis for GPA was noted to be 26 years as compared to EGPA and MPA which was 58.2 years. NSIP was the most frequent CT pattern found in all AAV patients with ILD in our cohort. None of the patients had any smoking history. TB exposure was reported in 1 patient and occupational asbestos and silica exposures were reported in 1 patient. All 7 patients had some degree of chronic prednisone use. 6 out of 7 patients received treatment with Rituximab and 1 patient was treated with Cytoxan for their AAV. Of note the 2 patients that had associated kidney disease were found to have pauci-immune crescentic GN on kidney biopsy.

Conclusion: Our study revealed ILD is most seen in MPA and least common in GPA. It is strongly associated with MPO Abs. ILD tends to present earlier through the course of the disease in EGPA patients as compared to MPA and GPA patients. Chronic sinusitis and pulmonary hypertension were the most frequent concurrent pulmonary manifestations while cutaneous vasculitis and eye involvement seems to be the most common extra-pulmonary manifestations. None of the patients with AAV-ILD had a smoking history. Although hematuria was a common manifestation

observed in most AAV-ILD patients, decreased GFR was only observed in 2 patients. Further prospective studies in larger cohorts are required to clarify the clinical characteristics and prognosis of ILD in patients with AAV.

Adaptive Study Design of a Randomized, Multicenter, 2-Part Phase 2 Trial of Replacement of Glucocorticoids by IFX-1, a C5a Inhibitor, in Active Granulomatosis with Polyangiitis and Microscopic Polyangiitis

Peter Merkel,[1] Bernhard Hellmich,[2] David Jayne,[3] Simon Rückinger,[4] Zsuzsanna Tamas,[5] Claus Thielert,[5] and Othmar Zenker[6], [1]University of Pennsylvania, Philadelphia, PA, [2]Department of Internal Medicine, Rheumatology and Immunology, Vasculitis-Center Tübingen-Kirchheim, Medius Klinik Kirchheim, University of Tübingen, Kirchheim-Teck, Germany, Kirchheim, Germany, [3]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, University of Cambridge, UK, Cambridge, United Kingdom, [4]Metronomia Clinical Research GmbH, Munich, Germany, [5]InflaRx GmbH, Planegg, Germany, [6]InflaRx GmbH, Jena, Germany

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are life-threatening rare autoimmune diseases are both forms of anti-neutrophil cytoplasmic antibody-associated vasculitis (AAV). Standard of care treatment includes high-dose glucocorticoids (GC) in combination with cyclophosphamide (CYC) or rituximab (RTX). There is a high unmet medical need to reduce or eliminate high-dose GC to prevent patients from experiencing severe side effects. Complement component 5a (C5a) is known to prime and activate neutrophils, which is a major contributor to the pathogenesis of AAV. IFX-1, a monoclonal antibody, specifically binds to C5a inhibiting C5a-induced biological effects.

Methods: This clinical trial uses an adaptive, stepwise approach to evaluate if GC can be replaced by IFX-1 in AAV.

Results: This is a randomized, double-dummy, double-blind, multicenter trial evaluating the efficacy and safety of IFX-1 in subjects with moderate to severe GPA or MPA (ClinicalTrials.gov NCT03895801). The trial consists of two parts (**Figure 1**). All subjects in both parts are treated with RTX or CYC. In Study Part 1, subjects are randomized to receive either IFX-1 plus a reduced-dose of GC (Group A) or placebo-IFX-1 plus high-dose GC (Group B). Following global clinical evaluation, the trial proceeds to Part 2 in which either additional subjects are randomized to Group B (as above) or subjects are randomized to Group C: IFX-1 and placebo-GC. Patients in Group B are used as the comparison group in both Parts. In total, about 80 subjects will be randomized at approximately 90 sites in Europe and Russia.

Major eligibility criteria are a diagnosis of new or relapsing GPA or MPA requiring treatment with CYC or RTX plus GCs, known positive test for ANCA, ≥ 1 major item or ≥ 3 minor items or ≥ 2 renal items on the Birmingham Vasculitis Assessment Score version 3 (BVASv3).

Intravenous IFX-1 or corresponding placebo is given on days 1, 4, 8, 15 and then every other week until Week 16. GC or corresponding placebo is given according to a standardized tapering scheme. The primary endpoint is the propor-

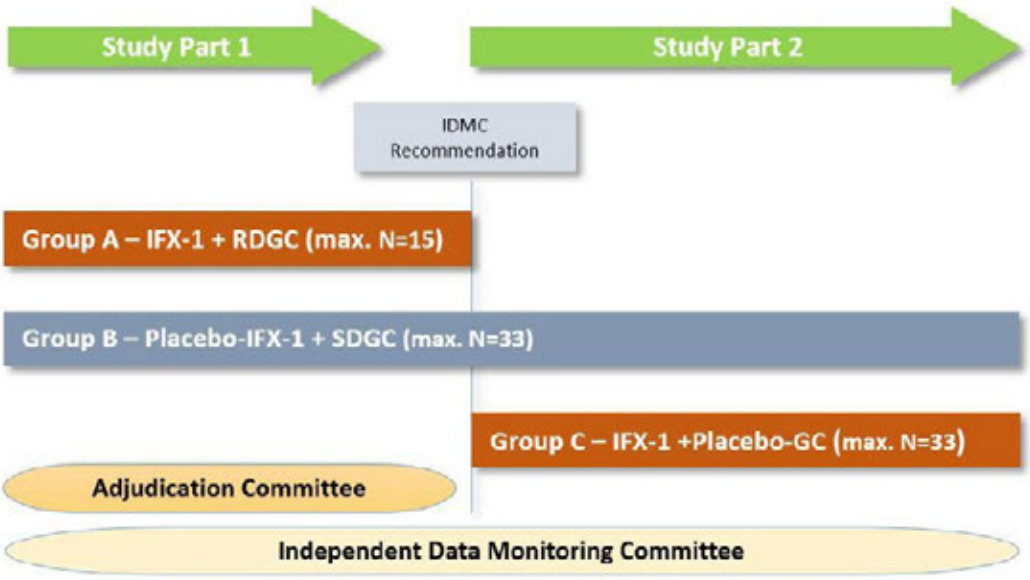

Figure 1. Adaptive, Two-Stage Study Design
IDMC: independent data monitoring committee;
RDCG: reduced-dose glucocorticoids;
SDGC: standard-dose glucocorticoids.

tion of subjects achieving clinical response, defined as ≥ 50% reduction in BVASv3 at Week 16 compared to baseline and no worsening in any body system. Key secondary endpoints include the clinical response at other time points, proportion of subjects with a clinical remission (BVASv3 = 0) at Week 16, adverse events, and pharmacokinetic and pharmacodynamics parameters.

An Adjudication Committee (AC) evaluates the treatment response of each subject after each study visit under blinded conditions. An unblinded Independent Data Monitoring Committee is responsible for continuous review of subject safety data and of reports from the AC to make a recommendation to continue with Study Part 2. Study enrollment started in April 2019.

Conclusion: This ongoing trial is designed to address the substantial unmet need for new therapies that allow for reducing the burden of GCs in the treatment of AAV. This adaptive design provides an innovative approach to investigating new agents in AAV that allows for testing smaller sample sizes in this rare disease while maintaining a strong focus on patient safety.

Design of a Phase 2, Multicenter, Randomized, Double-Blind, Placebo-Controlled Trial of 2 Different Dose Regimens of IFX-1, a C5a Inhibitor, as an Add-On Therapy for Granulomatosis with Polyangiitis or Microscopic Polyangiitis

Peter Merkel,[1] Bernhard Hellmich,[2] David Jayne,[3] Simon Rückinger,[4] Zsuzsanna Tamas,[5] Claus Thielert,[5] and Othmar Zenker[6], [1]University of Pennsylvania, Philadelphia, PA, [2]Department of Internal Medicine, Rheumatology and Immunology, Vasculitis-Center Tübingen-Kirchheim, Medius Klinik Kirchheim, University of Tübingen, Kirchheim-Teck, Germany, Kirchheim, Germany, [3]Vasculitis and Lupus Clinic, Addenbrooke's Hospital, University of Cambridge, UK, Cambridge, United Kingdom, [4]Metronomia Clinical Research GmbH, Munich, Germany, [5]InflaRx GmbH, Planegg, Germany, [6]InflaRx GmbH, Jena, Germany

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – ANCA-Associated Poster II

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) are life-threatening rare autoimmune diseases to anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Standard of care (SOC) treatment includes glucocorticoids (GCs) in combination with cyclophosphamide (CYC) or rituximab (RTX). SOC is still associated with incomplete treatment response, disease relapses, and long-term side effects. Complement component 5a (C5a) is known to prime and activate neutrophils, which is a major contributor to the pathogenesis of AAV. IFX-1, a monoclonal antibody, specifically binds to C5a inhibiting C5a-induced biological effects. Observations in previous clinical studies of sepsis, hidradenitis suppurativa, and cardiac surgery indicate that IFX-1 is safe and well-tolerated. These data suggest that IFX-1 might be a safe, tolerable, and efficacious agent for the treatment of AAV.

Methods: We describe the design of an ongoing clinical trial evaluating the safety of two different doses of IFX-1 or placebo as add-on therapy to SOC in subjects with moderate to severe GPA or MPA.

Results: This randomized, placebo-controlled, multicenter trial is evaluating the safety of two different doses of IFX-1 in combination with SOC, including a standard tapering schedule for GCs (ClinicalTrials.gov NCT03712345). The trial will be performed in about 40 sites in the USA and Canada and will include a total of 36 subjects, 12 per arm. A pharmacokinetic (PK) substudy is planned to enroll 15 subjects. Participation could last for up to 26 weeks, including a 16-week treatment and an 8-week follow-up period.

Major eligibility criteria are a diagnosis of new or relapsing GPA or MPA that requires treatment with CYC or RTX plus GCs, positive test for ANCA, and ≥ 1 major item or ≥ 3 minor items or ≥ 2 renal items on the Birmingham Vasculitis Assessment Score version 3 (BVASv3). Intravenous IFX-1 or placebo will be given on days 1, 4, 8, 15 and then every other week until Week 16. Primary outcome is the number and percentage of subjects who experience at least one treatment-emergent adverse event (TEAE) per treatment group. Key secondary endpoints are IFX-1-related serious AEs and TEAEs, AEs of special interest, proportion of subjects achieving clinical response (reduction in BVAS of ≥50% at Week 16 and no worsening in any body system), proportion of subjects with clinical remission (BVAS = 0) at Week 16, and PK and pharmacodynamic (PD) parameters. The safety of subjects will be monitored continuously by an unblinded Independent Data Monitoring Committee.

Study enrollment in this trial began in October 2018.

Conclusion: This prospective Phase 2 trial of subjects with AAV is intended to demonstrate the safety, tolerability, and efficacy of IFX-1, a C5a blocking therapy, in two different dose regimens in comparison with placebo.

Abstract Number: 1681

The Association of Reduced Low-Density Lipoprotein (LDL) Cholesterol Levels with ANCA-Associated Vasculitis (AAV)

Zachary Wallace,[1] Xiaoqing Fu,[1] Yuqing Zhang,[2] John Stone,[3] and Hyon K. Choi[2], [1]Massachusetts General Hospital, Boston, [2]Massachusetts General Hospital, Boston, MA, [3]Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: ANCA-associated vasculitis (AAV) is a small vessel vasculitis associated with an intense inflammatory state. AAV patients are at a 2-fold higher risk of cardiovascular disease (CVD) compared to the general population and CVD is the leading cause of death in this population. As such, CVD risk stratification, often with lipid levels, is recommended in AAV. However, the effect of inflammation on lipid levels in AAV is poorly understood and may impact the interpretation of risk stratification. We sought to evaluate the association between AAV and lipid levels.

Methods: The Partners AAV (PAAV) cohort is a consecutive inception cohort established in the Partners HealthCare System (PHS), a large hospital system in New England. The PAAV cohort has been previously described. All cases are PR3- or MPO-ANCA+. Each AAV case was matched to up to five controls from the PHS Research Patient Data Registry by age, sex, race, and index date (date of AAV treatment initiation). We identified matched cases and controls who had lipid levels (total cholesterol [TC], high-density lipoprotein cholesterol [HDL-C], and low-density lipoprotein cholesterol [LDL-C]) measured as part of routine care following the index date. The primary outcome of interest was the difference in lipid levels between cases and controls using the first available lipid level within one year of the index date. We also evaluated the difference in lipid levels between AAV cases and controls in the second and third years of follow-up after the index date. We compared lipid levels between cases and controls using linear regression after adjusting for relevant covariates.

Results: We included 217 cases and 538 matched controls with lipid levels measured in the first year following the index date. The mean age (65 vs 67) and proportion of males (57% vs 53%) and White persons (84% vs 82%) was similar in cases and controls. The majority of AAV cases were MPO-ANCA+ (155, 71%). Compared with controls,

	AAV Cases	Controls	P-Value
N	217	538	
Age (mean, SD)	65 (15)	67 (13)	0.06
Male (N, %)	123 (57)	287 (53)	0.4
Race (N, %)			0.07
White	183 (84)	443 (82)	
Black	6 (3)	27 (5)	
Asian	4 (2)	11 (2)	
Other/Unknown	24 (11)	57 (10)	
Statin Use (when 1st lipid measured) (N, %)	133 (61)	275 (51)	0.01
AAV Characteristics			
MPO-ANCA+ (N, %)	155 (71)	--	
PR3-ANCA+ (N, %)	62 (29)	--	
BVAS/WG (Median, IQR)	4 (4-6)	--	
Any Renal Involvement (N, %)	161 (74)	--	
BMI (kg/m^2, mean, SD)	28.4 (6)	28.7 (7)	0.8
SBP (mmHg, mean, SD)	133 (20)	128 (16)	0.02
DBP (mmHg, mean, SD)	73 (13)	76 (9)	0.08
A1C (%, mean, SD)	6.1 (1)	6.5 (1)	0.01

Table 1. Baseline Characteristics of PAAV Cases and Controls

	TC (mg/dL)	HDL (mg/dL)	LDL (mg/dL)
Unadjusted Difference (AAV vs Control)	-2.3	+3.6	-11.0*
Age- & Sex-Adjusted Difference (AAV vs Control)	-4.2	+3.0	-12.5*
Age-, Sex-, & Race-Adjusted (AAV vs Control)	-4.1	+3.2	-12.7*
Age-, Sex-, Race, & Statin-Adjusted (AAV vs Control)	-3.9	+3.8	-12.2*

*P<0.05

Table 2. Differences in First Lipid Measurement After Index Date Among AAV Cases vs Controls

AAV cases were more frequently prescribed a statin prior to the lipid measurement (61% vs 51%). In unadjusted analyses, TC (187 mg/dL vs 189 mg/dL, P= 0.62) and HDL-C (57 mg/dL vs 52 mg/dL, P= 0.08) were similar between cases and controls. In contrast, LDL-C was significantly lower in cases compared with controls (98 mg/dL vs 109 mg/dL, P=0.006). In analyses adjusted for age, sex, race, and statin use, AAV cases had a significantly lower LDL-C compared with controls (β= - 12.2 mg/dL (95% CI: -20.0 to -4.4), P= 0.002). During follow-up, the difference in LDL-C between cases and controls were no longer significant (Year 2: β= -8.9 mg/dL (95% CI: -19.0 to +1.3), P=0.09; Year 3: β= -5.2 mg/dL (95% CI: -16.4 to +6.1), P=0.4).

Conclusion: We found that LDL-C levels are significantly lower in AAV cases compared to controls in the first year following treatment initiation and these differences appear to dissipate subsequently. We hypothesize that this reflects improvements in the inflammatory state among AAV cases. When screening for dyslipidemia in AAV and assessing CVD risk, one should consider the effect of inflammation on lipid levels. Future studies are necessary to understand if lipid levels, especially as part of risk stratification tools, accurately predict CVD events in this population.

Inpatient Epidemiology of Granulomatosis with Polyangiitis in the United States

Patompong Ungprasert,[1] Matthew Koster,[2] Wisit Cheungpasitporn,[3] Karn Wijarnpreecha,[4] Charat Thongprayoon,[2] and Paul Kroner[5], [1]Cleveland Clinic, Cleveland, OH, Bangkok, Thailand, [2]Mayo Clinic Rochester, Rochester, MN, [3]University of Mississippi Medical Center, Jackson, MS, [4]Mayo Clinic Florida, Jacksonville, FL, [5]Mayo Clinic Florida, Jacksonville

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA, formerly known and Wegener's granulomatosis) is a major subtype of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis characterized by granulomatous inflammation of small- and medium- size vessels. Data on inpatient epidemiology, resource utilization, and healthcare expenditures of GPA are not well described. The aim of this study was to explore those characteristics using a large national inpatient database.

Methods: This retrospective cohort study used the data from the National Inpatient Sample (NIS), the largest public inpatient database in the US, in the year 2005-2014. Data for more than seven million individual hospitalization across all-payers from over 4,000 non-federal acute care hospitals across 40 states are recorded annually in the NIS data-

Table 1 – Adjusted odds ratios, means and additional adjusted means in patients with GPA compared to patients admitted with other medical conditions

Variable	Odds Ratio	95% Confidence Interval	p-value
Mortality	1.50	1.41 – 1.61	<0.01
Shock	1.65	1.53 – 1.78	<0.01
ICU	1.80	1.70 – 1.90	<0.01
AKI	2.55	2.45 – 2.66	<0.01
Multi-organ failure	2.38	2.30 – 2.48	<0.01
Arteriography	0.88	0.80 – 0.95	0.01
CT Scan	1.31	1.07 – 1.61	0.01
MRI	1.18	0.87 – 1.60	0.29
Mean Costs/Charges/LOS			
Costs ($USD)	$18,358		
Charges ($USD)	$61,317		
Length of Stay (days)	7.1		
Variable			
Additional Adjusted Costs	$5,125	4719-5531	<0.01
Additional Adjusted Charges	$16,841	15280-18403	<0.01
Additional Adjusted LOS (days)	1.8	1.6 – 1.9	<0.01

base. All patients with ICD9-CM diagnostic codes for GPA were included. None were excluded. The primary outcome was determining the inpatient prevalence of GPA. Secondary outcomes included determining inpatient mortality, morbidity, resource utilization, hospital length of stay (LOS), and inflation-adjusted total hospital costs and charges. Multivariate regression analyses were used to adjust for age, gender, Charlson Comorbidity Index, income in patient zip code, hospital region, location, size and teaching status.

Results: A total of 124,682 admissions of patients with a diagnosis of GPA occurred in the study period. The mean age was 60.2 years and 52.3% were female. For the primary outcome, the inpatient prevalence of GPA was 32.6 cases per 100,000 discharges. The most common reasons for hospitalization were GPA itself (38.3%) followed by pneumonia (13.7%), sepsis (8.4%), acute kidney injury (8.3%), and acute respiratory failure (4.8%). Patients with GPA displayed significantly higher odds of inpatient all-cause mortality compared to patients admitted for all other causes. Patients with GPA displayed significantly higher morbidity odds of shock, ICU stay, AKI, and multiorgan failure when compared to patients admitted for all other reasons. Patients with GPA were also found to have increased odds of utilizing special investigations, including CT, MRI, and arteriography. Patients with associated diagnosis of GPA displayed higher hospital costs, charges and LOS compared to patients with no GPA (Table 1).

Conclusion: The inpatient prevalence of GPA was higher than what would be expected from the overall incidence. Hospitalizations of these patients were associated with high morbidity and mortality. The mean total hospital costs, charges, and LOS for patients admitted with GPA were higher than patients without GPA.

Abstract Number: 1683

Cardiac Involvement of Eosinophilic Granulomatosis with Polyangiitis (Churg–Strauss): Initial Manifestations and Outcomes Based on Data from a Monocenter Patient Cohort

Silvia Sartorelli,[1] Pascal Cohen,[2] Bertrand Dunogue,[2] Alexis Régent,[2] Xavier Puéchal for the French Vasculitis Study Group,[2] Luc Mouthon,[2] Loic Guillevin,[2] and **Benjamin Terrier** [2], [1]Vita-Salute San Raffaele University, IRCCS San Raffaele Hospital, Milan, Italy, [2]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Eosinophilic granulomatosis with polyangiitis (EGPA) is a systemic necrotizing vasculitis characterized by blood and tissue eosinophilia, and asthma. Its cardiac involvement is a major concern that was previously described as the most important predictor of death; however, definitions of that involvement differ according to study. We aimed to describe the first EGPA cardiac manifestations and outcomes in recent decades.

Methods: This retrospective, monocenter study included all EGPA patients followed in our vasculitis center. Patients' and disease characteristics were recorded at diagnosis and throughout follow-up, especially cardiac assessments. Cardiac involvement was defined as clinical or extra-clinical signs of patent cardiopathy, with no other potential caus-

es identified.EGPA relapses, major cardiac-related events (i.e. acute and chronic heart failure, atrial fibrillation and/or ventricular tachycardia, ischemic cardiopathy) and causes of death were recorded.

Results: The 150 EGPA patients (78 men; mean±SD age 47.8±15.9 years) included were characterized by asthma (99%), eosinophilia (95%), sinonasal abnormalities (84%), pulmonary infiltrates (51%), peripheral neuropathy (57%) and eosinophil-rich infiltrates (19%); 39% were ANCA+. Median baseline BVAS was 17.5 [IQR 13–22].Sixty-five (43%) patients had cardiac involvement, 55 (85%) diagnosed at EGPA diagnosis and 10 (15%) during follow-up. The main clinical cardiac manifestations included chest pain (16%), peripheral edema (8%), palpitations (4%), cardiogenic shock (3%) and arrhythmia (1%). Patients with cardiac involvement, compared to those without, respectively, were less frequently ANCA+ (27% vs. 48%, P=0.02), had less frequent peripheral neuropathy (46% vs. 66%, P=0.02), and had higher eosinophil count (9748±7639 vs. 6346±5291/mm^3, P=0.004).Patients with cardiac involvement had abnormal ECG (70%), abnormal echocardiography [(68%; mainly pericardial effusion (42%) and left ventricular dysfunction (31%)] and cardiac MRI abnormalities [(98%; with left ventricular dysfunction (43%), myocardial edema (24%) and late gadolinium enhancement (74%)]. However, ECG, echocardiography and cardiac MRI, respectively, were also abnormal for 32%, 40% and 61% of the patients without patent cardiopathy.After mean follow-up of 121±97.2 months, 65 (43%) patients experienced EGPA relapses, with no between-group differences (37 vs 48%, P=0.19). However, 46% of patients with cardiac involvement had cardiac relapses. Major heart-related events occurred in 17/150 (11%) patients, most often those with known cardiac involvement (18% vs. 6%, P=0.02). Finally, 4 patients died but none from cardiac causes.

Conclusion: Cardiac involvement is frequent in EGPA in a tertiary referral center, especially in patients without ANCA, with higher eosinophil counts and no peripheral neuropathy. Long-term outcome was better than previously reported. However, in the absence of a consensual definition of cardiac involvement, comparisons among studies remains difficult.

Remission and Low Disease Activity State in Patients with Granulomatosis with Polyangiitis and Microscopic Polyangiitis: Prevalence and Impact on Damage Accrual

Paolo Delvino,[1] Federica Sardanelli,[2] Pascal Cohen,[3] Xavier Puéchal for the French Vasculitis Study Group,[3] Luc Mouthon,[3] Loic Guillevin,[3] and **Benjamin Terrier** [3], [1]Rheumatology Department, IRCCS Policlinico S. Matteo Foundation, University of Pavia, Vercelli, Italy, [2]Department of Internal Medicine , Clinical Immunology Unit of Genoa and Policlinico San Martino, Genova, Italy, [3]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – ANCA-Associated Poster II
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) require glucocorticoids (GCs) and immunosuppressants (IS) to induce and maintain remission. At the era of highly active drugs

and treat-to-target strategies, defining the goal to achieve in terms of remission could be beneficial for the long-term management. We aimed to assess the impact of prolonged remission or low disease activity state (LDAS) in GPA and MPA patients and its relationship with damage accrual.

Methods: Patients diagnosed with GPA and MPA, according to ACR criteria and/or Chapel Hill definitions, seen in our vasculitis center and followed-up for ≥5 years were included. Disease activity was assessed by BVAS , and damage accrual by the VDI. Three levels of remission were defined: complete remission (CR): BVAS=0 and negative ANCA in GCs-free and IS-free patients; clinical remission off therapy: no disease activity and positive ANCA in GCs-free and IS-free patients; clinical remission on therapy: no disease activity in patients with low dose GCs (≤5 mg/d) and/or IS. LDAS was defined as 0< BVAS≤3 without major organ activity, no new disease activity, low-dose GCs (≤7.5 mg/day) and well-tolerated IS. We defined remission or LDAS as prolonged when lasting ≥2 consecutive years. The effect of prolonged remission and LDAS on damage accrual was evaluated.

Results: 126 patients were included: 94 (75%) GPA, mean age 51.6±16.9 years. At 5-years, mean VDI was 2.6±1.9, mainly because of AAV-related items (2.0±1.7) rather than treatment-related items (0.6±0.9). During the 5-year follow-up, 8 (6.3%) patients achieved prolonged CR, 6 (4.8%) prolonged clinical remission off therapy, 62 (49.2%) prolonged clinical remission on therapy, 37 (29.3%) prolonged LDAS and 13 (10.3%) never achieved LDAS. Damage accrual at 5-years in patients with prolonged CR, clinical remission off therapy, clinical remission on therapy, LDAS or those never achieved LDAS was 1.8±1.3, 1.8±1.7, 2.2±1.7, 3.3±1.6and 3.8±2.7, respectively (P< 0.003). Damage was comparable between patients in prolonged remission off therapy and those in remission on therapy (P=0.44). In contrast, patients in prolonged LDAS or those never in LDAS had significantly more damage accrual (P=0.002 and P=0.048, respectively) than those in prolonged remission off therapy. The inability to achieve prolonged remission was associated with a VDI ≥3 at 5-years (OR 3.86, 95% CI 1.77-7.84, P=0.0005), and considering only prolonged CR or clinical remission off therapy did not had any benefit on damage accrual. In contrast, achieving prolonged LDAS had no benefit compared to spending no time in LDAS (P >0.99). Compared to patients achieving prolonged remission, those not able to achieve prolonged remission were younger (46±16 vs. 55±16, P=0.004), had more frequent GPA (P=0.0003) and ENT involvement (P=0.01).

Conclusion: Sixty percent of GPA and MPA patients achieved prolonged remission, which was associated with a better outcome in terms of damage accrual. In contrast, prolonged LDAS was associated with increased damage and was not a sufficient target to achieve in GPA and MPA.

Inpatient Burden, Expenditures and Comorbidities of Polyarteritis Nodosa: National Inpatient Sample 2014

Patompong Ungprasert,[1] Matthew Koster,[2] Wisit Cheungpasitporn,[3] Karn Wijarnpreecha,[4] Charat Thongprayoon,[2] and Paul Kroner[5], [1]Cleveland Clinic, Cleveland, OH, Bangkok, Thailand, [2]Mayo Clinic Rochester, Rochester, MN, [3]University of Mississippi Medical Center, Jackson, MS, [4]Mayo Clinic Florida, Jacksonville, FL, [5]Mayo Clinic Florida, Jacksonville

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Due to the rarity of polyarteritis nodosa (PAN), no study has ever investigated inpatient characteristics, healthcare utilization and frequency of comorbidities of patients with PAN. The current study was conducted with the aim to better describe those information using data from a large national database.

Methods: Patients with PAN were identified from the Nationwide Inpatient Sample (NIS) database for the year 2014 using ICD-9 diagnostic codes. The primary outcome was determining the inpatient prevalence of PAN in hospitalized patients in the US. Secondary outcomes included determining inpatient mortality, morbidity, comorbidities, hospital length of stay (LOS) and expenditures. Expenditures were sub-divided into total hospitalization charges and hospital costs. Total hospital charges represent the amount of money that each hospital billed the payers for the service provided during each admission, while hospital costs represent the amount of money the hospital invested to provide care during each admission. A cohort of patients without PAN was also identified from the same database to serve as comparators for analysis of comorbidities. Multivariate regression analysis was used to adjust for age, sex, ethnicity and hospital characteristics.

Results: A total of 4,110 patients with PAN were included in the study. The mean age was 59.5 years and 61% were female. The inpatient prevalence of PAN was 11.6 cases per 100,000 admissions. The most common reasons for admission among patients with PAN in this database were as follows; PAN itself (17.6%), sepsis (6.9%), acute kidney injury (4.9%), acute respiratory failure (2.1%) and pneumonia (2.0%). During hospitalization, a significantly higher

Table 1: Adjusted odds ratios comparing the prevalence of comorbidities between patients with polyarteritis nodosa versus patients without polyarteritis nodosa

	Adjusted odds ratio	95% CI	*p*-value
Deep venous thrombosis	1.97	1.47 – 2.63	<0.01
Pulmonary embolism	1.93	1.41 – 2.65	<0.01
Acute myocardial infarction	1.13	0.64 – 2.00	0.66
Congestive heart failure	0.96	0.78 – 1.18	0.68
Arrhythmia	1.09	0.86 – 1.37	0.48
Acute kidney injury	3.73	3.15 – 4.42	<0.01
Chronic kidney disease	8.40	6.50 – 10.87	<0.01
End-stage renal disease	4.79	3.76 – 6.10	<0.01
Hepatitis B virus infection	5.85	3.17 – 10.80	<0.01
Hepatitis C virus infection	1.97	1.32 – 2.93	<0.01
Sepsis	1.87	1.51 – 2.32	<0.01

morbidity among patients with PAN was observed as indicated by a significantly higher risk of shock (adjusted OR 1.75; 95% CI, 1.23 – 2.50), admission to ICU (adjusted OR 1.88; 95% CI, 1.44 – 2.45) and multi-organ failure (adjusted OR 3.12; 95% CI, 2.64 – 3.69) although the odds of mortality was not significantly elevated (adjusted OR 1.35; 95% CI, 0.91 – 2.00). Patients with PAN also displayed significantly higher hospital costs (additional adjusted mean [aAM]: $9,693, p< 0.01), hospitalization charges (aAM: $34,273, p< 0.01) and LOS (aAM: 4.1 days, p< 0.01) compared to patients without PAN. Analysis of comorbidities found a significant association between PAN and several comorbidities as shown in table 1.

Conclusion: The inpatient prevalence of PAN is higher than what would be expected from the overall general prevalence. Hospitalizations of patients with PAN are associated with significantly higher rates of morbidity and expenditures.

Abstract Number: 1686

Risk of Vasculitis Associated with Inflammatory Bowel Diseases: Evidence for a Role of TNF-α Blockers

Benjamin Terrier,[1] Laurent Beaugerie,[2] Philippe Seksik,[2] Harry Sokol,[2] and Julien Kirchgesner[2], [1]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France, [2]Saint-Antoine Hospital, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An increased risk of side effects, especially infections, has been reported among patients receiving tumor necrosis factor (TNF)-α blockers. Some leukocytoclastic cutaneous vasculitides reportedly occurred under TNF-α blockers used to treat various inflammatory diseases, but the risk of vasculitis with TNF-α blockers remains uncertain, especially in comparison with other immunosuppressive agents.We aimed to assess the risk of vasculitis associated with thiopurines and TNF-α blockers prescribed to manage inflammatory bowel diseases (IBD).

Methods: This nationwide population-based study included patients (≥18 years old) affiliated with the French National Health Insurance (FNHI), with an IBD diagnosis based on long-term diseases listed and/or hospital-discharge diagnoses in the FNHI database from January 2010 through 2011, and followed until 31 December 2014. The risks of vasculitis associated with exposure to thiopurines or TNF-α blockers were compared using a Cox regression model adjusted for baseline sociodemographic characteristics and comorbidities. The primary outcome was incident vasculitis.

Results: Among the 193,663 IBD patients included in our analysis, 173 developed vasculitis, mainly IgA vasculitis (n=41), hypersensitivity vasculitis (n=41) and large-vessel vasculitis (n=39). Incidences per 100,000 person-years were 4.9 for IgA vasculitis, 4.9 for hypersensitivity vasculitis, 4.6 for large vessel vasculitis, 2.1 for ANCA-associated vasculitis and 1.2 for medium-sized–vessel vasculitis.

Compared with patients not exposed to TNF-α blockers or thiopurines during the study period, TNF-α blockers (hazard ratio [HR], 2.39; 95% confidence interval [95% CI], 1.49–3.84) were associated with a higher risk of vasculitis

but not thiopurines (HR, 0.72; 95% CI, 0.40–1.31). The magnitude of TNF-α-blocker–associated risk was higher for patients with ulcerative colitis (HR, 4.07; 95% CI, 1.96–8.47) than those with Crohn's disease (HR, 1.75; 95% CI, 0.95–3.22). The risk of vasculitis with TNF-α–blocker exposure was independently associated with older age (per 1-year increment, HR, 1.09; 95% CI 1.04–1.15), female sex (HR, 1.47; 95% CI, 1.08–2.00), cardiovascular disease (HR, 2.01; 95% CI, 1.33–3.04) and diabetes mellitus (HR, 1.77; 95% CI, 1.12–2.79).Finally, exploratory analyses showed that exposure to TNF-α blockers was not associated with a specific subtype of vasculitis: IgA vasculitis (HR, 3.11; 95% CI, 1.36–7.09), hypersensitivity vasculitis (HR, 3.48; 95% CI, 1.52–1.7.95), large-vessel vasculitis (HR, 2.56; 95% CI, 0.87–7.57) or ANCA-associated vasculitides (HR, 7.68; 95% CI, 1.99–29.7).

Conclusion: Based on a nationwide cohort study of IBD patients in France, TNF-α blockers were associated with an increased risk of vasculitis, unlike thiopurines. Cardiovascular disease and diabetes mellitus were also associated with the risk of vasculitis, suggesting relationships among atherosclerosis, chronic hyperglycemic state andinflammation.

Abstract Number: 1687

Dramatic but Suspensive Effect of interleukin-1 Inhibitors on Persistent Urticarial Vasculitis

Thomas Bettuzzi,[1] Alban Deroux,[2] Marie Jachiet,[3] Meryem-Maud Farhat,[4] Julien Wipff,[1] Marc Fabre,[5] Laurence Bouillet,[2] Nora Kramkimel,[1] Selim Aractingi,[1] Nicolas Dupin,[1] and **Benjamin Terrier** [6], [1]Cochin Hospital, Paris, France, [2]CHU, Grenoble, France, [3]Saint Louis Hospital, Paris, France, [4]CHRU, Lille, France, [5]CH, Bourgoin-Jailleu, France, [6]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Urticarial vasculitis (UV) is a rare disease characterized by dermal capillary inflammation responsible for long-lasting urticarial lesions. UV can be separated into 2 different entities according to complement fraction levels: hypocomplementemic urticarial vasculitis (HUV), associated with low C1q levels and inconstant anti-C1q antibodies, and normocomplementemic urticarial vasculitis (NUV).UV is characterized by frequent relapses or glucocorticoid (GC)-dependence. We report the efficacy of IL-1β inhibitors against relapsing and GC-dependent UVs.

Methods: This retrospective multicenter study included patients with relapsing and/or GC-dependent UVs treated with IL-1β inhibitors. Patients had to have biopsy-proven UV with long-lasting urticarial lesions and leukocytoclastic vasculitis in a skin biopsy, associated or not with systemic involvement. Relapsing and GC-dependent disease was defined as cutaneous lesions despite GCs at a dose >10 mg/day. For each patient, retrospectively collected data included clinical and biological characteristics, previous and concomitant treatments and theirevolutions, details on IL-1β inhibitors, and disease under IL-1β–inhibitor therapy at discontinuation. Clinical complete response (CR) was defined as total disappearance of cutaneous lesions and other systemic manifestations. Clinical partial response (PR) was defined as attenuation of disease activity without achieving CR. The primary endpoint was the CR rate.

Results: Six patients were included [3 men and 3 women, median age 41 (range 23–62) years], 4 with HUV and 2 with NUV. Median time from diagnosis to starting IL-1β inhibitors was 5.5 (range 1–16) years. All patients had cutaneous and joint involvement, and 2 had gastrointestinal manifestations. All patients received anakinra (100 mg/day); 5 had concomitant treatments, mostly GCs. Under IL-1β inhibitors, 5 (83%) patients achieved CR, within 7 days after starting treatment for 4 (80%) of them, and 1 had a PR. GC use was discontinued for 4 (80%).In the HUV subgroup, no normalization of complement-fraction levels was obtained. Progressive discontinuation of IL-1β inhibitors was attempted for 4 patients but was constantly associated with relapses within a few days. Safety was good, but 2 patients experienced reactions at the injection site, leading to an anakinra-to-canakinumab switch for 1, with CR persistence. No death, infection or neutropenia occurred.

Conclusion: IL-1β inhibitors had a dramatic—but only suspensive—effect on persistent UV and could be considered alternative agents to treat relapsing and GC-dependent UV.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: A previous retrospective study suggested superiority of glucocorticoids (GCs) plus rituximab (RTX) compared to GCs alone to induce complete clinical response in non-infectious cryoglobulinemia vasculitis (CryoVas). However, GCs plus RTX regimen was associated with severe infections, whereas death rates did not differ between therapeutic regimens. The ESBAM trial (NCT02556866) aimed to evaluate the efficacy and safety of RTX in combination with GCs for the treatment of non-infectious active mixed CryoVas.

Methods: We conducted a multicenter, randomized, double-blind, superiority trial of RTX as compared with placebo for remission induction in non-infectious active mixed CryoVas. To be included, patients had to have an active CryoVas defined by positive serum cryoglobulin and an active vasculitis, and to be treatment-naive or relapsing patients. Patients were randomized to receive prednisone plus RTX administered by intravenous infusion at 375 mg/m^2 at day (D) 1, D8, D15 and D22, or prednisone plus placebo administered following the same schedule.GCs were tapered off.

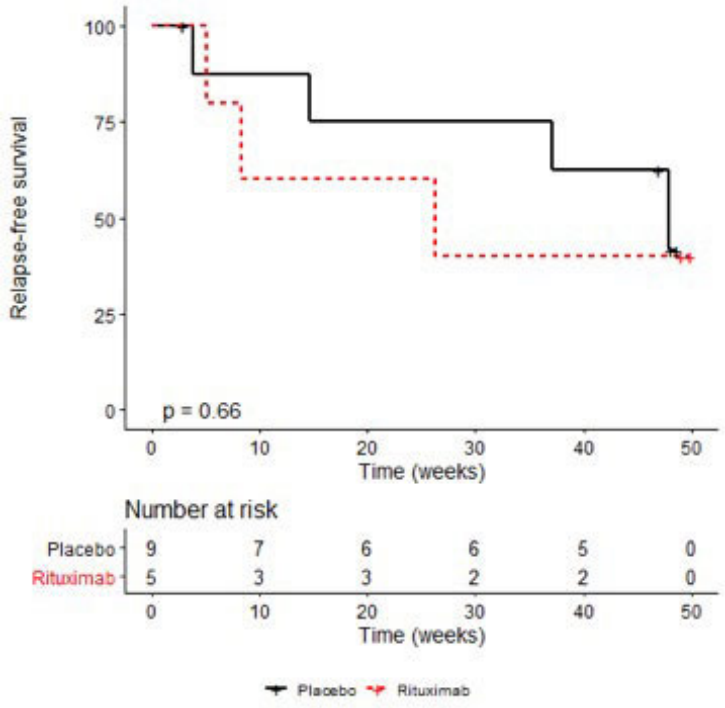

Figure. Relapse-free survival between the two groups of treatment

The primary endpoint was the remission of mixed CryoVas without the use of prednisone at week (W) 24. This study was initially planned to include 79 patients per group.

Results: Between July 2015 and July 2017, 15 patients were enrolled in the ESBAM trial and 14 were randomized (one patient died before randomization): 5 to receive RTX and 9 to the placebo-group. Their median age was 62 [45;71] years, 73% were women, and 73% relapsing-patients. Main CryoVas manifestations included: purpura (71%), neuropathy (43%), arthralgias (36%) and glomerulonephritis (29%). Patients' characteristics were comparable between groups.

At W24, 4/5 (80%) had an inactive vasculitis in the RTX-group compared to 6/8 (75%) in the placebo-group. A remission with no prednisone was achieved in 1/5 (20%) patient the RTX-group vs. 0/8 in the placebo-group. Cumulative doses of GCs at W24 and W48 were comparable in the two groups.

During the 48-week follow-up, 7 vasculitis relapses occurred, i.e. 3 in the RTX-group vs. 4 in the placebo-group. Relapse-free survival rates at W48 were 40.0% [13.7–100%] in the RTX-group vs. 41.7% [15.9–100%] in the placebo-group (**Figure**). The SF-36 physical health summary significantly improved in the RTX-group compared to placebo-group, especially at W36 and W48 (P=0.02 and P=0.04). Cryoglobulinemia remained positive in both groups for the majority of patients, and evolution of serum C4 fraction was comparable between groups during the 48 weeks. Twenty severe adverse events were recorded, 6 in the RTX-group and 20 in the placebo-group, including 1 patient in the RTX-group and 2 in the placebo-grouphaving severe infections. No patient died after randomization.

Conclusion: Combination of glucocorticoids plus rituximab and glucocorticoids plus placebo seemed to induce similar rates of remission at week 24 in non-infectious active mixed cryoglobulinemia vasculitis.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Polyarteritis nodosa (PAN) is a rare systemic necrotizing vasculitis of medium- and small-sized arteries, not associated with antineutrophil cytoplasmic antibodies (ANCA). Conventional treatments include glucocorticoids (GCs) for non-severe disease, and combined GCs and immunosuppressants for severe disease. Nevertheless, some patients have refractory and/or relapsing disease. We examined off-label biotherapy use for relapsing/refractory PAN.

Methods: This retrospective European collaborative study included patients with PAN meeting ACR criteria and/or Chapel Hill Consensus Conference 2012 definitions. Treatment efficacy and safety were recorded. Remission was defined as the absence of vasculitis manifestations (BVAS = 0) with ≤5 mg/day of prednisone. Partial response was defined as BVAS = 0, with 6–10 mg/day of prednisone.

Results: Fifty-two patients (24 men and 28 women; median age 51 years) were included. Nineteen (37%) patients received TNF-α blockers, 16 (31%) rituximab (RTX), 9 (17%) tocilizumab (TCZ), and 8 (15%) other biologics (i.e. alemtuzumab for 3, anakinra for 2, interferon-α for 2 and abatacept for 1). Previous treatments were: GCs for all, including methylprednisolone infusions (73%), cyclophosphamide (62%), azathioprine (54%), mycophenolate mofetil (48%) or methotrexate (46%). At inclusion, median BVAS was 5 (range 0-18), including 5 (2-12) for the TNF-α blocker group, 5 (2-12) for the RTX recipients and 4 (0-6) for those given TCZ.

At month (M) 6 and M12, respectively, median BVAS fell to 3 and 0 for TNF-α blockers group, to 3.5 and 0 for those given RTX, and to 0 and 0 for the TCZ group. Median GCs dose declined from baseline 17.5 mg/day to 10 at 6 months and 5 at 12 months for the TNF-α blocker recipient, from 15 to 10 and 5 mg/day for those given RTX, respectively, and from 15 to 7 and 5 mg/day for the TCZ group.

Nine (47%) patients stopped TNF-α blockers: for adverse events in 2 and/or refractory disease in 8. Refractory disease led 6 (38%) to stop RTX. Finally, 4 (44%) stopped TCZ: 2 for adverse events (testicular abscess and worsening renal failure), and 2 for refractory disease. Two additional patients had to decrease the dose because of cytopenias.

After median follow-up of 34.4 [IQR 21.5–59.5] months, remissions, partial responses, treatment failure and stop for adverse event, respectively, occurred in 43%, 5%, 47% and 5% for TNF-α blockers recipients, 31%, 13%, 56% and 0% for RTX recipients, and 56%, 0%, 22% and 22% for TCZ recipients. No remission was noted in patients treated with anakinra, alemtuzumab, interferon-α and abatacept.

Conclusion: These results suggest that TNF-α blockers and TCZ could achieve higher remission and GC-sparing rates for relapsing and/or refractory PAN than other biologics. Our findings warrant further study to confirm or refute them.

The Long-term Outcome of Patients with Arthritis of Behçet's Disease

Hirotoshi Kikuchi,[1] Takafumi Tomizuka,[1] Kurumi Asako,[1] Hajime Kono,[1] and Shunsei Hirohata[2], [1]Teikyo University School of Medicine, Tokyo, Japan, [2]Nobuharra Hospital & Institute of Biomechanics, Tokyo, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is characterized by recurrent aphthous stomatitis, eye lesions, skin lesions, and genital ulcer. In addition to these symptoms, Behçet's disease is frequently complicated by joint symptoms, usually affecting large joints. Although glucocorticoid and NSAIDs are effective in subsiding each arthritis attack, they are unable to prevent recurrence of attacks. In 2018 EULAR recommendations, colchicine as well as other drugs, such as TNF inhibitors, IFN-alpha and azathioprine are recommended to control arthritis in BD. However, long-term outcome of patients with arthritis has not been determined. In fact, bone deformity and bone destruction are considered rare in BD in contrast with rheumatoid arthritis. In this study, we investigated the long-term outcome of joint symptoms in patients with BD.

Methods: Retrospective analysis of the clinical charts of 107 patients with BD was carried out, who visited the clinic of our hospital between 2017 and 2018. All the patients met the International Study Group for BD criteria. The pres-

ence and clinical course of joint symptoms were surveyed in these patients. The status of activity of daily living was evaluated using Steinbrocker's functional grade (Class I–IV) at the most recent visit.

Results: Of the 107 patients, 36 (15 men and 21 women) were treated for joint symptoms associated with BD. Arthritis attacks in most patients were successfully treated with glucocorticoid and/or NSAIDs. After the initial attacks, colchicine, methotrexate and infliximab were given to 18 patients, 10 patients and 2 patients, respectively, to prevent the relapse of arthritis attacks. The mean (± SD) duration from the onset of joint symptoms to the most recent check-up was 21.2±14.6 years (mean ± SD). The functional stages at the time of the most recent check-up were Class I in 30 patients and Class II in 6 patients, whereas there were no patients in Class III or IV. The functional stages at the evaluation were not significantly correlated with the duration of the disease or treatment with colchicine, methotrexate or infliximab. Thus, no major impairment in active daily living was noted throughout the long-term course in all the patients. Consistently, no patients showed bone erosion or destructive arthritis on radiography.

Conclusion: The results in the present study have disclosed that the long-term outcome of arthritis in BD is much better that that of RA, resulting in no patients with serious disability over Class III even after a long time of disease duration of 21.2 years in average. Although the final functional stages were not correlated with their use, further studies with a larger number of patients are needed to confirm whether colchicine, methotrexate and infliximab might have beneficial effects for arthritis in BD.

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Vascular involvement is one of the major causes of morbidity and mortality in Behcet's Disease (BD) patients. Immunosuppressive (IS) agents are the mainstay of vascular BD (VBD) treatment, however up to one third of patients relapse under conventional ISs. In this case series, we present the results of tumor necrosis factor-alpha (TNFα) inhibitor use for the treatment of VBD patients who were refractory to conventional ISs and corticosteroids.

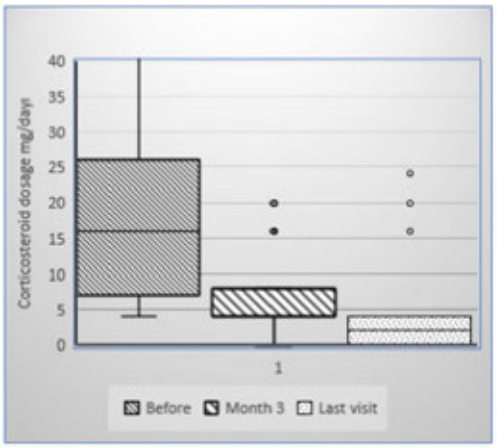

Figure 1: Corticosteroids sparing effects of TNF α inhibitors

Figure 1 Corticosteroids sparing effects of TNF α inhibitors (The median daily dose at baseline was 16 (4-64) mg vs 4 (0-20) mg at 3 months (p=0.000) and 2 (0-20) mg at last visit (p=0.000), respectively)

Methods: This retrospective multicenter study included 27 refractory VBD patients treated with TNFα inhibitor agents. All data were acquired from patient charts.Activity was assessed by the treating clinician according to clinical manifestations, imaging findings and acute-phase reactant results. Complete remission was defined as no new signs and symptoms of vascular disease assessed by physician and corticosteroid dose under 10 mg/day at the third month of treatment. Partial response was defined as an improvement of clinical and laboratory parameters and at least 50% reduction of initial corticosteroid dose at the third month.

Results: Infliximab was the first choice of TNFα inhibitor in 24 and adalimumab in 3 patients. Complete clinical remission was achieved in 22 (80%) patients within 3 months of the initiation of TNFα inhibitors. The median daily dose of corticosteroids significantly decreased at 3 months. (Figure 1) and stopped in 7 patients during follow-up without any relapse. Also, 89% of patients discontinued or maintained 4 mg or lower daily of methylprednisolone dosage at the last visit. Fifteen patients received concomitant immunosuppressive (all was azathioprine) together with a TNFα inhibitor. A trend towards a higher rate of complete remission was observed with concomitant IS use compared to monotherapy of TNFa inhibitors (93% vs 67%, p=0.09). Also, duration of first TNFα inhibitor drug survival was also 12.5 (1-43) months and 24 (4-67) months for monotherapy and concomitant IS user groups, respectively (p >0.05) (Figure 2) Three patient had vascular relapses under the treatment of TNFα inhibitors (2 Infliximab, 1 Adalimumab). Serious side effects were observed in 2 patients (1 pneumonia and 1 tuberculosis). TNFα inhibitors were stopped with sustained remission in 2 patients (after 24 and 37 months of treatment). One of the patients relapsed 6 months after cessation of TNFα inhibitor. After median 14 (3-67) months of follow-up period under TNFα inhibitors, 23 patients were still under TNFα inhibitors and all were in remission.

Conclusion: TNFα inhibitors seem a highly effective option for remission-induction of refractory VBD with an acceptable safety data. Concomitant IS use may achieve higher complete remission rates as compared to TNFα inhibitor monotherapy. Comparative efficacy and safety of biological agents for VBD require further prospective, randomized controlled studies with a longer duration of follow-up.

Table 1: Characteristics of patients

Patient	Drug initiation Age	Sex	Indication of TNF α inhibitors	Previous treatment
1	28	M	PAA, cardiac thrombi	CS, CYC, IFN

Abbreviations: AC= anterior chamber; BCVA= best corrected visual acuity; n= number of available eyes; OCT= optical coherence tomography.

Background/Purpose: Ocular involvement in Behçet's disease (BD) is a potential severe and disabling complication. Anti-TNF-α agents have shown an improvement of visual outcome in BD-related uveitis refractory to conventional immunosuppressive (IS) drugs. However, these drugs do not achieve control of intraocular inflammation in all patients or are not well tolerated. Tocilizumab (TCZ) has shown efficacy in different refractory ocular inflammatory diseases. To assess the efficacy of long-term therapy with TCZ in refractory uveitis associated to extraocular manifestations due to BD.

Methods: Multicenter study of patients with BD refractory to standard systemic treatment.

Results: We followed up 14 patients (9 men/5 women) (26 affected eyes); mean age 40.8±19.5 years. Pattern of ocular involvement: panuveitis (10; 4 with retinal vasculitis), anterior (3) and posterior (1) uveitis; 8 recurrent and 6 chronic; 9 with cystoid macular edema. At TCZ onset the following extraocular manifestations were present: oral and/or genital ulcers (10), arthritis (6), folliculitis/pseudofolliculitis (6), erythema nodosum (3), livedo reticularis (1), intestinal affection (1) and neurological involvement (3).

Before TCZ, they had received corticosteroids (13 intraocular, 12 oral and 12 iv), conventional IS drugs and biologic agents: methotrexate (11), cyclosporine (8), azathioprine (10), colchicine (1), cyclophosphamide (2), mycophenolate mofetil (1), adalimumab (10), infliximab (6), golimumab (3), canakinumab (1), or etanercept (1). TCZ was used in monotherapy (7) or combined with conventional IS drugs (7) at 8 mg/kg/iv/4 w (11) or 162 mg/sc/w (3).

After a mean follow-up of 21.7±14.5 months using TCZ, all patients experienced ocular improvement, with complete remission in 10. However, TCZ was only effective in 5 of the patients with extraocular manifestations. TABLE shows the evolution of ocular parameters.

TCZ had to be withdrawn temporally in 1 case, due to an episode of cellulitis with sepsis, and definitely in 4 cases, due to a severe infusion reaction, arthritis impairment, persistence of oral ulcers or a new episode of uveitis (1 each). Prednisone dose was significantly reduced until suspension in all patients.

Conclusion: TCZ seams a useful and secure therapy in highly refractory BD-related uveitis.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's disease (BD) is a variable vessel vasculitis and typically presents with mucocutaneous involvement. However, any organ can be affected, being the neurological affectation (neurobehçet, NB) one of the most serious manifestations.

Our aim was to assess the efficacy and safety of biological therapy as treatment of NB.

Methods: We set up a multicenter observational study of 31 patients with NB on treatment with biological therapy (BT). NB diagnosis was made by neuroimaging, CSF analysis and/or suggestive clinical signs of central and/or peripheral nervous system involvement, excluding infectious causes or more prevalent pathology. Results are expressed as mean±SD or as median and interquartile range (IQR) as appropriate.

Results: 31 patients (16♂ / 15♀) with an average age of 39.7 ± 10.5 years. HLA-B51 was positive in 51.6% of the patients. **Table** shows the non-neurological manifestations. Regarding the neurological manifestations, 23 patients (74.2%) had parenchymal involvement (hemiparesis (n=6), brainstem involvement (n=1), encephalopathy (n = 4), optic neuropathy (n=3), dysphasia (n=1), polyneuropathy (n=6), cognitive impairment (n=4), and non-steroidal psychosis (n=1), while the remaining 8 patients (25.8%) presented aseptic meningitis as a non-parenchymal affectation (**Table**).

Prior to BT, patients had received the following treatment: oral prednisone (n=29), methylprednisolone bolus (n=9), CsA (n=10), AZA (n=17), MTX (n=16) and mycophenolate (n=2).

Demographical parameter	
- Patients, n	31
- Sex, n (%)	$16_{♀}/15_{♂}$ (51.6/48.4)
- Age, year (mean±SD)	39.7±10.5
- HLA-B51 +	16 (51.6)
Non Neurological manifestation	
- Oral ulcers	30 (96.8)
- Genital ulcers	25 (80.6)
- Uveitis	18 (58.1)
- Skin lesions	22 (70.1)
- Arthritis	7 (22.6)
- Arthralgia	21 (67.7)
- Venous/arterial thrombosis	7 (22.6)/3 (9.7)
Neurological manifestation	
Parenchymal Disease, n (%)	23 (74.2)
- Hemiparesis	6 (19.4)
- brainstem syndrome	1 (3.2)
- encephalopathy	4 (12.9)
- optic neuropathy	2 (6.5)
- dysphasia	1 (3.2)
- polyneuropathy	6 (19.4)
- cognitive dysfunction	4 (12.9)
- psychosis	1 (3.2)
Non-parenchymal Disease (aseptic meningitis), n (%)	8 (25.8)
Time from diagnosis to BT onset, months (median[IQR])	34 [10-72]
Previous immunosuppressants	
- Oral corticoids	29 (93.5)
- Bolus MTP	9 (29.0)
- Azathioprine	17 (54.8)
- Methotrexate	16 (51.6)
- Cyclosporine	10 (32.2)
- Mycophenolate	2 (6.5)
First Biological therapy	
- Infliximab	19 (61.3)
- Adalimumab	7 (22.6)
- Tocilizumab	2 (6.5)
- Golimumab	2 (6.5)
- Etanercept	1 (3.2)
Follow-up, months (median[IQR])	22 [18.5-74]
- 1st/2nd Switch, n (%)	9 (29.0) / 2 (6.5)
- Discontinued (inefficacy)	3 (9.7)
- Severe adverse events	0 (0)

After a median of 34 [10-72] months since the beginning of the neurological symptoms, the following BT was initiated: infliximab (IFX)(n=19), adalimumab (ADA)(n=7), tocilizumab (TCZ) (n=2), golimumab (GOL) (n=2) and Etanercept (ETN) (n=1). A first switch to ADA was necessary in 9 patients with IFX due to primary failure. In addition, 2 of them needed a second switch to TCZ, getting a partial response. The BT was discontinued in 5 patients, 2 of them for obtaining clinical remission and the remaining 3 for inefficacy.

After a median follow-up of 5.4±4.6 years, complete response was obtained in 15 patients, partial response in 11 and no response in the remaining 3. We observed an anaphylactic reaction and psoriasis induced by IFX, without other serious adverse events (**Table**).

Conclusion: BT, especially anti-TNF, seems effective and safe for treatment in NB.

Pharmacogenetics and Pharmacodynamics of Response to Apremilast in a Phase 3 Clinical Study in Subjects with Active Behçet's Disease

Joseph Maranville,[1] Irina Medvedeva,[1] Robert Yang,[1] Mindy Chen,[2] Lorraine Ruoying Fang,[2] Sandra Collazo,[3] Shannon McCue,[3] Marla Hochfeld,[3] and Peter Schafer[3], [1]Celgene Corporation, Cambridge, MA, [2]Celgene Corporation, Berkeley Heights, NJ, [3]Celgene Corporation, Summit, NJ

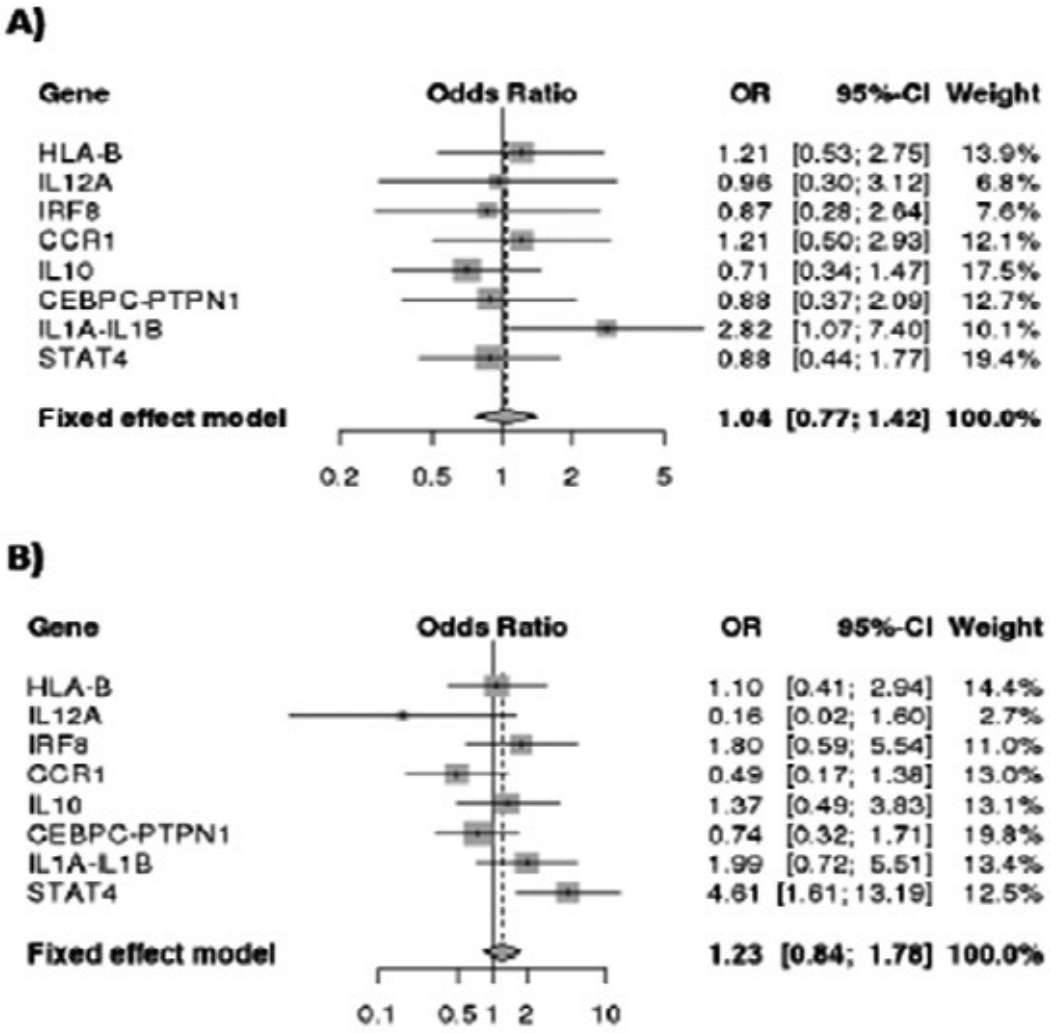
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: This was an exploratory analysis of genetic polymorphisms, plasma biomarkers, and blood leukocytes with clinical response in the phase 3 clinical study CC-10004-BCT-002 (NCT02307513).

Methods: Subjects with active Behçet's disease (BD) were randomized (1:1) to apremilast (APR) 30 mg BID or placebo (PBO). The primary clinical efficacy endpoint was the oral ulcer area under the curve from Week 0 to 12 (AUC_{Wk0-12}). Among 207 subjects enrolled, 140 provided consent for DNA genotyping, 116 for plasma biomarker testing, and 96 for leukocyte subset testing. Genotyping was performed on the Illumina Omni2.5 BeadChip (Covance Genomics Laboratory). TNF-α, IL-6, IFN-γ, and IL-17A levels were measured using Simoa Single Molecule Array; IL-8 and IL-23 were measured using the Human DiscoveryMAP multiplex panel (Myriad RBM). Th17, Treg, and CD3 T cells were counted using bisulfite-specific RT-PCR (Epiontis Gmbh). A rank ANCOVA model focused on between-treatment differences (APR vs. PBO) in % change from baseline for each biomarker/leukocyte subtype over the 12 weeks of treatment. Within each treatment group, the correlation of % change from baseline at Week 12 in biomarker/leukocyte subtype with the primary efficacy endpoint AUC_{Wk0-12} was examined using a univariate regression model. A separate regression model was used to assess the interaction between treatment and the biomarker/leukocyte subtype clinical response.

Results: Pharmacogenetic analysis of BD risk variants in HLA-B, IL-10, TLR2, ACE, TNF, GIMAP, PDGFRL, and UBAC2 + 55 genes associated with PDE4 biology yielded no candidate variants that were significantly associated with response to APR or PBO at a Bonferroni-corrected *P* value of 2×10^{-6}. Clinical response to APR with respect to

Figure 1. Forest Plots Showing Association With Response for Each Lead Polymorphism at a Behçet's Disease Genome-Wide Association Study Locus, and Results of a Fixed Effects Meta-analysis



Results for A) APR and B) PBO are plotted separately.

HLA-B51 yielded an OR of 1.21 (95% CI, 0.53-2.75), indicating no significant relationship (Figure 1). Pharmacodynamic changes for IL-6, IL-3, IL-17A, IL-23, and TNF-α were not statistically significant. APR treatment was associated with a significant change in IFN-γ (mean: +107.4%; median: –19.2%) vs. PBO (mean: +78.8%; median: +7.9%) (*P*=0.0077) (Table 1). Using a univariate regression model, TNF-α showed strong positive correlation with AUC_{Wk0-12} in the APR group (*r*=0.90; *P*=0.0140); IL-8 had weak positive correlation with AUC_{Wk0-12} in the APR group (*r*=0.04; *P*=0.0333). A significant negative correlation was observed between the % change from baseline in number of Th17 cells and AUC_{Wk0-12} in the APR group (*r*=–0.79; *P*=0.0392) and a significant positive correlation was observed with the % change from baseline in number of Treg cells and efficacy in the PBO group (*r*=0.94; *P*=0.0182). Of all the biomarkers and leukocyte subtypes examined in a regression model using treatment as a factor, only Treg had a statistically significant treatment interaction (*P*=0.0069) (Table 2).

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Oral and/or genital aphthous ulcers are the most common symptoms of Behçet´s disease (BD), and are often refractory to conventional treatment. The inhibitor of phosphodiesterase-4 apremilast (APR) has demonstrated efficacy in the treatment of this manifestations. Our aim was to compare the efficacy and safety of APR in monotherapy or combined with disease-modifying anti-rheumatic drugs (DMARDs) in BD patients with oral and/or genital ulcers refractory to conventional treatment.

Methods: National multicenter open-label study on 51 BD patients treated with APR at maintained standard dose of 30 mg twice daily. The main outcome was achievement of oral and/or genital ulcers remission.

Results: We included 51 patients (35 women/16 men), mean age of 47.7±13.2 years. Before APR, all patients had received several systemic conventional drugs. The main clinical symptoms for starting APR were oral (n=19) and genital (n=2) aphthous ulcers or both (n=30). Other manifestations present at APR onset were: arthralgia/arthritis (n=16),

	Combined group (N=20)	Monotherapy group (N=31)	p

TABLE 1. Main baseline features and follow-up of a series of 31 patients with refractory oral and/or genital ulcers due to Behçet's disease undergoing apremilast (APR) in combination or monotherapy.

folliculitis/pseudofolliculitis (n=14), asthenia (n=7), erythema nodosum (n=3), furunculosis (n=2), paradoxical psoriasis by TNFi (n=2), ileitis (n=2), deep venous thrombosis (n=2), erythematosus and scaly skin lesions (n=1), fever (n=1), eating disorder (n=1), fibromyalgia (n=1), unilateral anterior uveitis (n=1) and neurobehçet (n=1).

Excluding corticosteroids, colchicine or NSAIDs, APR was given in monotherapy in 31 cases or combined with conventional or biologic DMARDs in 20. There were not found statistically significant differences in baseline characteristics or sides effects, neither in previous treatment, except for tocilizumab that was more frequent in the combined group. The main demographic and clinical features are shown in TABLE 1.

C= combined; M= monotherapy; n= available data.

TABLE 2. Evolution of main symptoms with apremilast in combination vs monotherapy.

After a mean follow-up of 8.45±6.9 months, most of the patients experienced clinical improvement in both groups, without statistically significant differences. TABLE shows the evolution of the mucocutaneus manifestations in each group, combined vs monotherapy. In this period of time, 33 patients developed any side-effect (TABLE 1), 11 (55%) patients in the combined group and 22 (70%) patients in the monotherapy group), most of them mild and during the first 3 months of treatment.

Apremilast was discontinued in 11 patients due to: not obtaining the expected improvement (5), intense gastrointestinal adverse effects (n=4), desire of pregnancy (n=1) and development of neurological involvement (n=1).

Conclusion: Apremilast leads to a rapid and maintained improvement in many patients with highly refractory mucocutaneous ulcers of BD. This therapy seems as effective and safe in monotherapy as in combination with DMARDs.

Is the Risk of Tuberculosis Increased in Behçet's Disease Compared to Other Rheumatological Disorders After Anti-TNF-α Treatment?

Ummugulsum Gazel,[1] Derya Kocakaya,[2] Irem Topcu,[3] Hakan Karatas,[4] Murat Karabacak,[5] Pamir Atagunduz,[6] Nevsun Inanc,[7] Fatma Alibaz-Oner,[5] and **Haner Direskeneli** [8], [1]Marmara University, Faculty of Medicine, Department of Rheumatology, Istanbul, Turkey, Istanbul, Turkey, [2]Marmara University Faculty of Medicine Department of Chest Diseases, Istanbul, Turkey, Istanbul, Istanbul, Turkey, [3]Marmara University, School of Medicine, Istanbul,Turkey, ıstanvul, Turkey, [4]Marmara University ,School of Medicine, Istanbul,Turkey, Istanbul, Turkey, [5]Marmara University Faculty of Medicine,Department of Rheumatology,Istanbul,Turkey, Istanbul, Turkey, [6]Marmara University Faculty of Medicine,Department of Rheumatology, Istanbul, Turkey, Istanbul, Turkey, [7]Marmara University, Faculty of Medicine, Division of Rheumatology, Istanbul, Turkey, ISTANBUL, Turkey, [8]Marmara University, School of Medicine, Division of Rheumatology, Istanbul, Turkey

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Tumor necrosis factor (TNF)-α inhibitors are extensively utilized in the treatment of inflammatory rheumatic diseases. These agents increase the risk of tuberculosis (TB), especially in countries with a high incidence, such as Turkey. This study aims to evaluate the incidence of tuberculosis after anti-TNF-α treatment for Behcet's disease (BD) and to report the risk in comparison to other disorders in our center.

Methods: The data of 1302 patients who received anti-TNF-α treatment for more than six months between 2005 and 2018 were assessed retrospectively. Demographic features, type of aTNF-α treatment used, treatment duration, tuberculin skin test (TST) and Quantiferon results, use of isoniazid prophylaxis and the development of tuberculosis were recorded. We compared the disease characteristics of patients with and without tuberculosis after aTNF-α treatment.

Results: Among the 1302 patients (F/M: 698/604, mean age: 48.8±13.2 years), aTNF-α agents were most commonly used in ankylosing spondylitis (AS) patients (n=659, 50.9%). Median aTNF-α treatment duration in all patients was 32.5 months (Q1-Q3: 12-61). During the follow-up period, 13 patients developed tuberculosis. Seven (54%) of the TB patients had pulmonary and six (46%) had extrapulmonary TB. Median time from the initiation of aTNFα therapy to the diagnosis of TB was 40 months (Q1-Q3: 22-56). The characteristics of all patients receiving aTNFα therapy and developed TB were displayed in Table 1. The TNFα antagonists patients receiving were Etanercept in 4, Adalimumab in 5, Infliximab in 2 and Certolizumab in 2 patients.

TB was detected in 3 (7.5%) of 40 BD patients and 10 (0.8%) of 1256 non-Behçet's patients. There was a statistically significant increase in TB risk, in Behcet's patients after aTNF-α treatment when compared to the rest of the group (p=0.006). When we combined our patients with a large, multicenter cohort from Turkey, among 8320 patients who received aTNF-α treatment(1), TB developed in 8 (4.9%) patients among 161 BD and 75 (0.9%) patients in 8159 non-Behçet's patients (p=0.0002).

Conclusion: Comparable to the previous literature from Turkey, our results verified an increased risk of tuberculosis after aTNF-α treatment in patients with Behçet's Disease compared to other rheumatological disorders. Pro-inflammatory nature of BD with a higher risk for infections or concomitant therapies such as corticosteroids might

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's syndrome is a chronic, multi-system, variable vessel vasculitis characterized by painful, recurrent oral ulcers (OU) that can be disabling and may impair quality of life. Apremilast (APR), an oral phosphodiesterase 4 inhibitor, demonstrated efficacy in the treatment of OU of Behçet's syndrome in a phase III, multinational, randomized, double-blind, placebo (PBO)-controlled study (RELIEF). Here, we report efficacy and safety of APR assessed over 64 weeks in the subgroup of Japanese patients in RELIEF.

Methods: Patients were randomized (1:1) to APR 30 mg BID or PBO BID for a 12-week PBO-controlled phase, followed by a 52-week active treatment extension. Patients were stratified by region (Japan/other). Eligible patients were ≥18 years of age, had active Behçet's syndrome, with ≥3 OU at randomization or ≥2 OU at screening and randomization and without active major organ involvement. The primary efficacy endpoint was area under the curve for the number of OU over 12 weeks (AUC_{Wk0-12}). Clinical improvement in OU was evaluated by assessments of OU number and pain (100 mm visual analog scale), disease activity (Behçet's Disease Current Activity Form [BDCAF], composed of the Behçet's Disease Current Activity Index [BDCAI] and Patient's and Clinician's Perception of Disease Activity, and Behçet's Syndrome Activity Score [BSAS]) over 64 weeks. An ANCOVA model was used to analyze the primary endpoint. In the Japanese subgroup, Week 12 variables were prespecified without multiplicity adjustment. Nominal *P* values are given. Data at Week 64 are as observed.

Results: Of the 207 randomized patients, 39 were Japanese (APR: n=19; PBO: n=20); 26 Japanese patients completed the active treatment phase (12 initially randomized to APR and 14 initially randomized to PBO). Consistent with the findings of the overall study population, the primary endpoint of AUC_{Wk0-12} was significantly lower for APR vs PBO (115.9 vs 253.3; nominal *P*=0.0168). At Week 12, significantly more Japanese patients had OU complete response with APR (57.9%) vs PBO (25.0%) (nominal *P*=0.0426); numerically greater reductions in OU pain were observed with APR vs PBO (–17.0 [95% CI: –39.1, 5.1]; nominal *P*=0.1273). Improvements in mean number of OU (**Figure 1**), OU pain (**Figure 2**), complete and partial response rates, as well as disease activity assessments (BDCAF and BSAS) were observed at Week 12 and generally maintained in Japanese patients continuing APR 30 mg BID treatment for up to 64 weeks and emerged in those who switched from PBO to APR. At 4 weeks after APR treatment discontinuation, worsening in measures of oral ulcer disease was observed in both treatment groups. Adverse event (AE) rates were similar in the 2 groups during the PBO-controlled period (APR: 73.7%; PBO: 75.0%). Common AEs were diarrhea, upper respiratory tract infection, nausea, and headache. No new safety concerns were identified up to 64 weeks.

Conclusion: APR demonstrated efficacy in the treatment of OU in a subset of Japanese patients with Behçet's syndrome from RELIEF. Benefits were sustained up to 64 weeks with continued APR treatment. Safety findings were consistent with the known AE profile of APR.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Ocular involvement in Behçet's Disease (BD) is associated with chronic damage and high morbidity; however, limited evidence is available on risk factors to recognize the subset of BD patients at jeopardy to develop vision-threatening disease (VTD). There is a clear need for identification of those patients early in order to reduce morbidity. Machine learning (ML), including Artificial Neural Networks (ANNs), have been used to forecast

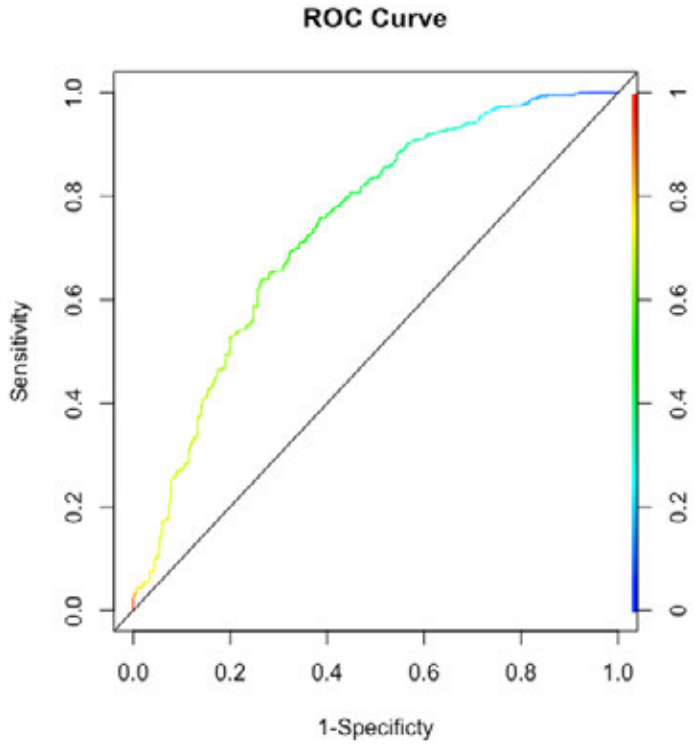

Figure 1. The ROC graph of the Logistic regression analysis for predicting vision-threatening outcomes in BD patients.

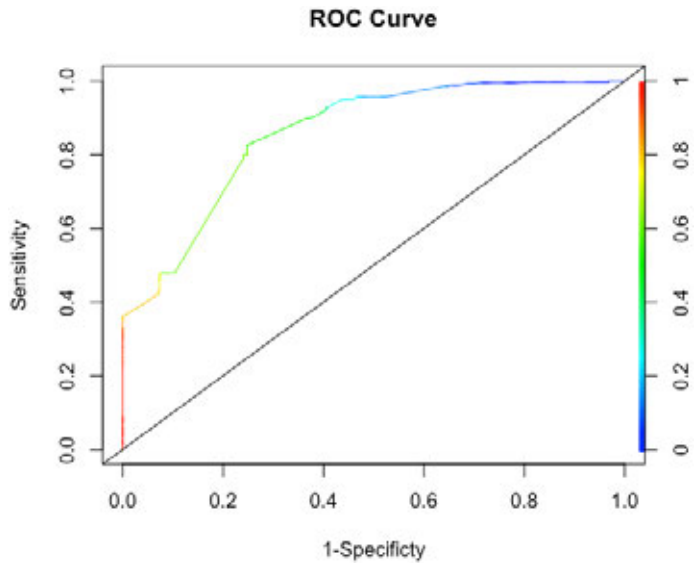

Figure 2. The ROC graph of the selected artificial neural networks for predicting vision-threatening outcomes in BD patients.

complex disease outcomes in the medical setting including rheumatology. Using the Egyptian College of Rheumatology (ECR) cohort data available, we aimed to develop a data-driven ECR-BD accurate model to predict the risk of VTD using ML techniques, with a combination of demographic, clinical, and biochemical information.

Methods: Out of an ECR-BD, a large multicentric cohort, 1094 patients fulfilling the 2014 International Study Group diagnostic criteria for BD were included. VTD was determined by the presence of retinal disease and/or optic nerve affection and/or occurrence of blindness. Twenty-seven variables including patient demographics, clinical manifesta-

tions, comorbidities, medications and laboratory data for each patient were used as predictors (inputs) for building-up and testing the ANNs. Prior to the training of the ANNs, the dataset was randomly split into training (80%), and testing (20%) data. The testing set was used to evaluate the final performance of the networks. Inputs were normalized before being entered in networks. Several networks with different properties were trained, and the performance of each network was evaluated. In order to evaluate and select the most accurate network, we used a confusion matrix (sensitivity, specificity, and accuracy), the receiver operating characteristic (ROC) curve and the area under the ROC curve(AUC) of each network and compared them to the logistic regression (LR) model results. R studio v. 3.5.0 software was used to design the neural networks and LR.

Results: A total of 1094 BD patients [71.5% were men, mean ± SD age; 36.1 ± 10 years; and median disease duration 72 months] had complete ocular manifestations data. The mean BD current activity form was 4.7±3.7. About 75% of the ECR-BD cohort had at least one form of ocular involvements, 49.8% of them had VTD. By applying ANNs, we obtained a model (2 hidden layer and 4 neurons) characterized by a sensitivity of 90%, a specificity of 64%, an accuracy of 77%, and AUC value of 0.86, able to predict VTD. These measures for the LR were 73%, 65%, 76.8%, and AUC value of 0.74 respectively. The ANNs results suggest that C-reactive protein is the most important positive predictor of VTD, followed by disease duration, oral ulcers, and presence of diabetes mellitus.

Conclusion: These findings suggest that the artificial neural network could be an accurate technique for prediction of vision-threatening BD. Therefore, building accurate ML models allowed to identify patients at risk to develop VTD in a large BD cohort. The application of this model on longitudinal data in future work is required.

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Behçet's syndrome (BS) shows a heterogeneous phenotype involving many organ systems and is diagnosed by recognizing the coexisting manifestations. Patients may have major organ manifestations before they fulfill the International Study Group (ISG) criteria and failure to recognize BS and treat promptly may lead to permanent damage in such patients. We aimed to determine the magnitude of this problem by identifying the presentation patterns and the outcome of patients who did not fulfill ISG criteria when they presented to our clinic but were followed and treated for manifestations strongly suggesting BS.

Methods: We conducted a retrospective chart review of all BS patients who were registered between 2003 and 2008. Among the 2385 patients, there were 199 (8%) patients who did not fulfill ISG criteria at their initial visit but had manifestations strongly suggesting BS. A standard form was used for recording data on demographic features, BS manifestations, and treatment at the initial visit and during follow-up. An attempt was also made to invite them to our dedicated clinic to assess the outcome.

Of these 199 patients, 6 died (massive hemoptysis due to pulmonary artery aneurysm in 1, pancreatic cancer in 1, lung adenocarcinoma in 1 and unknown reasons in 3), 32 including 3/6 patients who died due to unknown reasons had only 1 visit, 54 including 3/6 who died could not be reached but there were enough data in the charts for the purposes of this study, 71 were contacted by telephone and 42 were evaluated in the clinic. Overall, 167 patients who had at least one more visit with a median follow-up of 11 years (IQR: 7-12) were analyzed.

Results: Among the 167 patients (M/W: 77/90, mean age: 33.4 ± 11.4 years), 62 (37%) had major organ involvement (eye disease in 32, venous thrombosis in 22, arterial aneurysms in 8, nervous system disease and gastrointestinal disease in 1 patient each) at the initial visit. Eighteen (11%) did not have recurrent oral ulcers but had major organ involvement at the initial visit. Thirty-two patients (19%) had a family history of BS.

49/113 patients we could contact and 13/54 patients we could not reach but were being followed in our clinic had fulfilled ISG criteria. Thus, a total of 62 (37%) patients fulfilled ISG criteria after a median follow-up of 1.5 years (IQR: 1-4.5). Sixty of these 62 patients fulfilled ISG criteria with added skin-mucosa findings and 2 with added eye involvement.

Among the remaining 102 patients who did not fulfill ISG criteria during the follow-up, 19 (19%) patients had developed at least one non-criteria BS manifestation (arthritis in 14 and vascular involvement in 5) after a median follow-up of 4 years (IQR: 1-6). 12 (12%) had developed at least one mucocutaneous manifestations. Three patients had another rheumatologic diagnosis (Figure).

Conclusion: In this 10-year follow-up study among at least 167 BS patients not fulfilling ISG criteria at presentation, 62 of 167 (37%) patients had fulfilled ISG criteria after a median duration of 1.5 years. In 60/62 (97%) of these patients, this was additional skin-mucosa disease.

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet´s disease (BD) is a systemic autoimmune disease that affects multiple organ systems with recurrent oral ulcers, genital ulcers and skin lesions, which might be accompanied by psychological abnormalities such as anxiety or depression. Behcet´s Disease Current Activity Form (BDCAF) and Electronic Medical Record-based Activity Index (EMRAI) are commonly used internationally to evaluate the disease activity of BD; Hospital Anxiety & Depression Scale (HADS) is commonly used to evaluate patients' mental health.

This study aimed to analyze the clinical characteristics, the level of disease activity, and the incidence of anxiety and depression for Chinese BD patients. Patients can perform self-management of disease with Smart System of Disease Management (SSDM).

Methods: SSDM is a series of doctor-patient interactive applications for self-management of patients with chronic diseases. Patients can perform BDCAF, EMRAI and HADS self-assessment with SSDM and upload the self-assessment data to their authorized doctors. The SSDM patients' application system integrates the BDCAF and EMRAI into one scoring system. Patients could obtain scores of BDCAF and EMRAI by responding to one questionnaire through SSDM. Patients with a score ≥4, will be diagnosed as BD. HADS is divided into two sub-tables of HADS-Anxiety (HADS-A) and HADS- Depression (HADS-D). A patient's HADS score >10, will be diagnosed with anxiety or depression.

Results: From April 2017 to May 2019, 1,072 BD patients from 225 hospitals used SSDM, with a mean age of 38.78±12.23 (14~78) years old, and median disease duration of 21.77 months. 513 patients performed BDCAF and

Table 1. Clinical Characteristics of different systems in Chinese BD patients.

Presence of clinical features	Total	Males	Females	P value
Oral ulcer	76.29% (666)	80.27% (240)	74.22% (426)	0.046*
Genital ulcer	40.21% (351)	32.11% (96)	44.43% (255)	<0.001**
Epididymitis	4.70% (41)	10.03% (30)	0 (0)	<0.001**
Erythema	24.40% (213)	26.09% (78)	23.52% (135)	0.402
Skin lesions	24.28% (212)	28.09% (84)	22.30% (128)	0.058
Superficial thrombophlebitis	29.21% (255)	21.74% (65)	33.10% (190)	<0.001**
Headache	29.21% (255)	21.74% (65)	33.10% (190)	<0.001**
Joint pain	43.87% (383)	46.82% (140)	42.33% (243)	0.205
Arthritis	10.54% (92)	11.71% (35)	9.93% (57)	0.418
Gastrointestinal involvement	21.76% (190)	21.40% (64)	21.95% (126)	0.853
Nausea or vomiting or abdominal pain	16.95% (148)	17.39% (52)	16.72% (96)	0.803
Diarrhea with altered or frank blood	9.28% (81)	9.70% (29)	9.06% (52)	0.757
Ocular symptoms	48.11% (420)	61.87% (185)	40.94% (235)	0.316
Red eye	22.34% (195)	29.77% (89)	18.47% (106)	<0.001**
Painful eye	18.56% (162)	18.39% (55)	18.64% (107)	0.929
Blurred vision	31.73% (277)	36.45% (109)	29.27% (168)	0.03*
Reduced vision	29.90% (261)	25.75% (77)	32.06% (184)	0.054
Nervous involvement	21.42% (187)	22.74% (68)	20.73% (119)	0.492
Blackout	2.86% (25)	4.35% (13)	2.09% (12)	0.058
Difficulty with speech or hearing	6.76% (59)	7.69% (23)	6.27% (36)	0.428
Double vision	4.93% (43)	6.35% (19)	4.18% (24)	0.159
Weakness or loss of feeling in the face, arm or leg	4.93% (43)	6.69% (20)	4.01% (23)	0.082
Memory loss	9.74% (85)	10.03% (30)	9.58% (55)	0.831
Loss of balance	4.93% (43)	5.35% (16)	4.70% (27)	0.675
Vascular involvement	14.20% (124)	16.72% (50)	12.89% (74)	0.124
Chest pain	2.86% (25)	4.35% (13)	2.09% (12)	0.058
Breathless	6.76% (59)	7.69% (23)	6.27% (36)	0.428
Coughed up blood	4.93% (43)	6.35% (19)	4.18% (24)	0.159
Pain, swelling or discoloration of either the face, arm or leg	4.93% (43)	6.69% (20)	4.01% (23)	0.082

P values are for the comparison between the males and females.

EMRAI self-assessment 873 times, 130 patients repeat assessments for 360 times. The mean score of BDCAF and EMRAI are 3.69±2.25 and 3.60±2.03, respectively. The matching degree of the two score was 0.8818.

The most common clinical characteristics were oral ulcers (76.9%), joint pain (43.87%) and genital ulcer (40.21%). The comparative study between males and females revealed significant difference in the aspects of epididymitis (10.03% vs 0, $p< 0.001$), genital ulcer (32.11% vs 44.43%, $p< 0.001$), headache (21.74% vs 33.10%, $p< 0.001$), superficial thrombophlebitis (21.74% vs 33.10%, $p< 0.001$) and red eye (29.77% vs 18.47%, $p< 0.001$). Please see details in Table 1.

The incidence of anxiety and depression was 15% and 16%, among 134 patients assessed for HADS.

Conclusion: Chinese BD patients can effectively perform BDCAF and EMRAI self-assessment with SSDM. The results of the assessment conducted by the two scoring systems are similar. The clinical characteristics of Chinese BD were different depending on gender.

Amyloidosis in Behcet's Disease: Experience of a Vasculitis Centre at Silk Road

Ertugrul Cagri Bolek,[1] Enes Erul,[1] Gozde Kubra Yardımcı,[1] Levent Kilic,[2] Ali Akdoğan,[1] and **Omer Karadag** [3], [1]Hacettepe University Vasculitis Centre, Ankara, Turkey, ankara, Turkey, [2]Hacettepe University, Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey, [3]Hacettepe University Vasculitis Centre, Ankara, Turkey / Vasculitis and Lupus Clinic, Addenbrooke's Hospital, University of Cambridge, UK, Ankara, Turkey

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Bechet's disease (BD) is a vasculitis characterized by oral aphtae, genital ulcers, skin lesions, uveitis and with less frequent involvement of the neurological, vascular and gastrointestinal tract. Amyloidosis is an uncommon but highly morbid complication of BD. This study is aimed to investigate frequency, clinicodemographic features and disease course of amyloidosis in Behcet's Disease.

Methods: Patients with vasculitis diagnosis have been recording at Hacettepe University Vasculitis Center (HUVAC) database since October 2014. Enrolled 451 Adult BD patients were searched in terms of clinically and histopathologically amyloidosis. Demographics, clinical features and treatment characteristics of patients were re-evaluated.

Results: Two hundred thirty seven (52.5%) patients were male and 211 (46.8%) of all patients had only mucocutaneous disease. Mean age at BD diagnosis was 30.9 ±8.2 years. Five patients (1.1%) had biopsy-proven AA-type amyloidosis diagnosis (Table). All BD-amyloidosis patients were male and presented with nephrotic-range proteinuria. Diarrhea was observed in two patients. There was no clinical evidence about familial mediterranean fever (FMF) and other rheumatic or infectious etiology for development of amyloidosis in any patient. All of five patients had genital ulceration. During follow-up time after amyloidosis diagnosis (median 51 month), end-stage kidney disease (ESKD) were developed in two patients (No: 4 and 5) and no death was observed. Interferon alpha and Tocilizumab were emerging drugs used in these patients. Proteinuria almost completely regressed in two patients (No: 2 and 3).

Conclusion: BD is one of the rare causes of the AA amyloidosis. Furthermore amyloidosis in BD is an important but it is relatively rare. Therefore other possible etiologies (e.g. FMF) should be excluded. Amyloidosis could result in life-threatening disease course. Amyloidosis-related symptoms and findings (e.g. proteinuria) may be treatable according to data from our cohort and literature. Definite predictors for development of ESRD are unknown in amyloidosis of

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Polyarteritis nodosa (PAN) is a rare type of the systemic vasculitides with heterogeneous presentations.There is a paucity of information on the current phenotypes, ethnic and geographic differences of PAN. A global PAN study group has been working for clinical subphenotypes and GWAS studies.

Methods: A retrospective survey of databases from centres was done for PAN patients fulfilling the EMEA Vasculitis Classification algorithm. Patients with typical angiographic and/or histopathologic findings consistent with PAN were enrolled. In addition to baseline clinical characteristics, treatment and outcome data was recorded.

Factor analysis was used to analyze target organ associations of these 229 patients. Four factors were identified by factor analysis of variables sex, ethnicity, disease onset age, pediatric-onset, monogenic disease relationship, HBV relationship, any cutaneous features, any musculoskeletal symptoms, any constitutional symptoms, any other

	Factors			
	Factor 1	**Factor 2**	**Factor 3**	**Factor 4**
Any of gastrointestinal findings	0,723			
Renal involvement	0,681			
Cutaneous involvement	-0,585			
Testicular involvement	0,541			
Any of musculoskeletal findings		0,822		
Any positive constitutional symptoms		0,647		
Any of neurologic findings			0,770	
Ear nose throat involvement			0,699	
Any monogenic relationship FMF or ADA				0,877

Note: Only loadings above 0.5 are displayed

Table Target organ associations in Polyarteritis Nodosa (PAN)

involved areas (abdominal, renal, testicular, neurologic, ear nose and throat (ENT), cardiac, pulmonary), positive angiographic findings and relapses.

Results: PAN Cohorts from 5 different countries were investigated in this study. (Japan: n=39, Mexico: n=29, Slovenia: n=14, TUR: n=100, UK: n=47). Totally 229 (M/F: 130/99 and Caucasian 70.3%, Asian 17.0%, and Hispanic 12.7%) patients were included in the study. Four were HBV-related, and 21 of TR patients had a monogenic form of disease (Familial Mediterranean Fever association in 14, deficiency of adenosine deaminase 2-DADA2- in 7).

20.5% of patients were cutaneous-only PAN patients. 45.4% of patients had radiologic, and 69.4% had biopsy-proven PAN. Median age at disease onset was 38.5 (IQR 24.0-57.0) years. During a median 60 (16-130) months follow-up, 23 patients died.

Factor analysis revealed 4 factors that explained 60% of the original information on the matrix as follows: Factor 1,represented the association between any of gastrointestinal findings, renal involvement, and testicular involvement which are negatively associated with any of cutaneous involvement; **Factor 2,**the association between any of musculoskeletal findings, and any positive constitutional symptoms; **Factor 3,**any neurologic involvement was associated with ENT involvement, **Factor 4,**any monogenic relationship FMF or ADA itself. The eigenvalues of the 4 factors were 1.853, 1.297, 1.164, and 1.085, in decreasing order, i.e., the highest contribution to the overall variance in the matrix came from the togetherness of the 3 clinical manifestations that made up Factor 1. Factors, their relative contributions to the total variance and the communalities for each of the variables are shown in Table.

Conclusion: The target organ associations found in this study could support the hypothesis of subphenotypes in PAN. Factor 1-more organ involvement with less cutaneous features seems to be the most severe form. Patients with any monogenic genetic background (FMF or DADA2) have distinct target organ associations. Even though ENT involvement was rare, its association with neurologic involvement might define a different subphenotype- looks like a ANCA negative medium vessel vasculitis.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Behcet's disease(BD) is a multisystem inflammatory disorder of unknown etiology.Improved understandings indicate the Th17/Treg immune imbalance may play a critical role in BD's pathogenesis, which was accompanied by an increased levels of IL-17 and IL-23.The aim of this study was to examine associations between levels of a broad selection of cytokines and Th17/Treg immune balance in patients with BD.

Methods: The study included 67 BD patients and 66 healthy controls. The circulating levels of lymphocyte subpopulations were detected by flow cytometry for all participants.Serum levels of the following 6 cytokines were determined in the same samples using a cytometric beads array: IL-2, IL-4,IL-6,IL-10,INF-γ and TNF-α for all BD patients.

Results: A significant increase in the Th1 cells and Th17 cells and the ratio of Th1/Th2 and Th17/Treg were observed. When patients with BD were divided into active (patient index score $\geq$ 2 in the BDCAF) and inactive groups, the absolute counts of Th17 cells and the ratio of Th17/Treg tended to be higher in patients with active BD, and this observation was statistically insignificant. A significantly positive correlation was found between the investigated cytokines and Th17/Treg:i.e.,IL-2(r=0.261,P=0.033) and IL-4(r=0.292,P=0.016)(P$\geq$0.2 for all other cytokines),and Th17 cells(r=0.246,P=0.045vs r=0.291,P=0.017).

Conclusion: The T cell homeostasis perturbation,especially Th1 and Th17 expansion and Th17/Treg immune imbalance,may serve as the cornerstone of BD pathogenesis.Immune responses associated with increased levels of IL-2 and IL-4 may promote Th17/Treg immune imbalance.

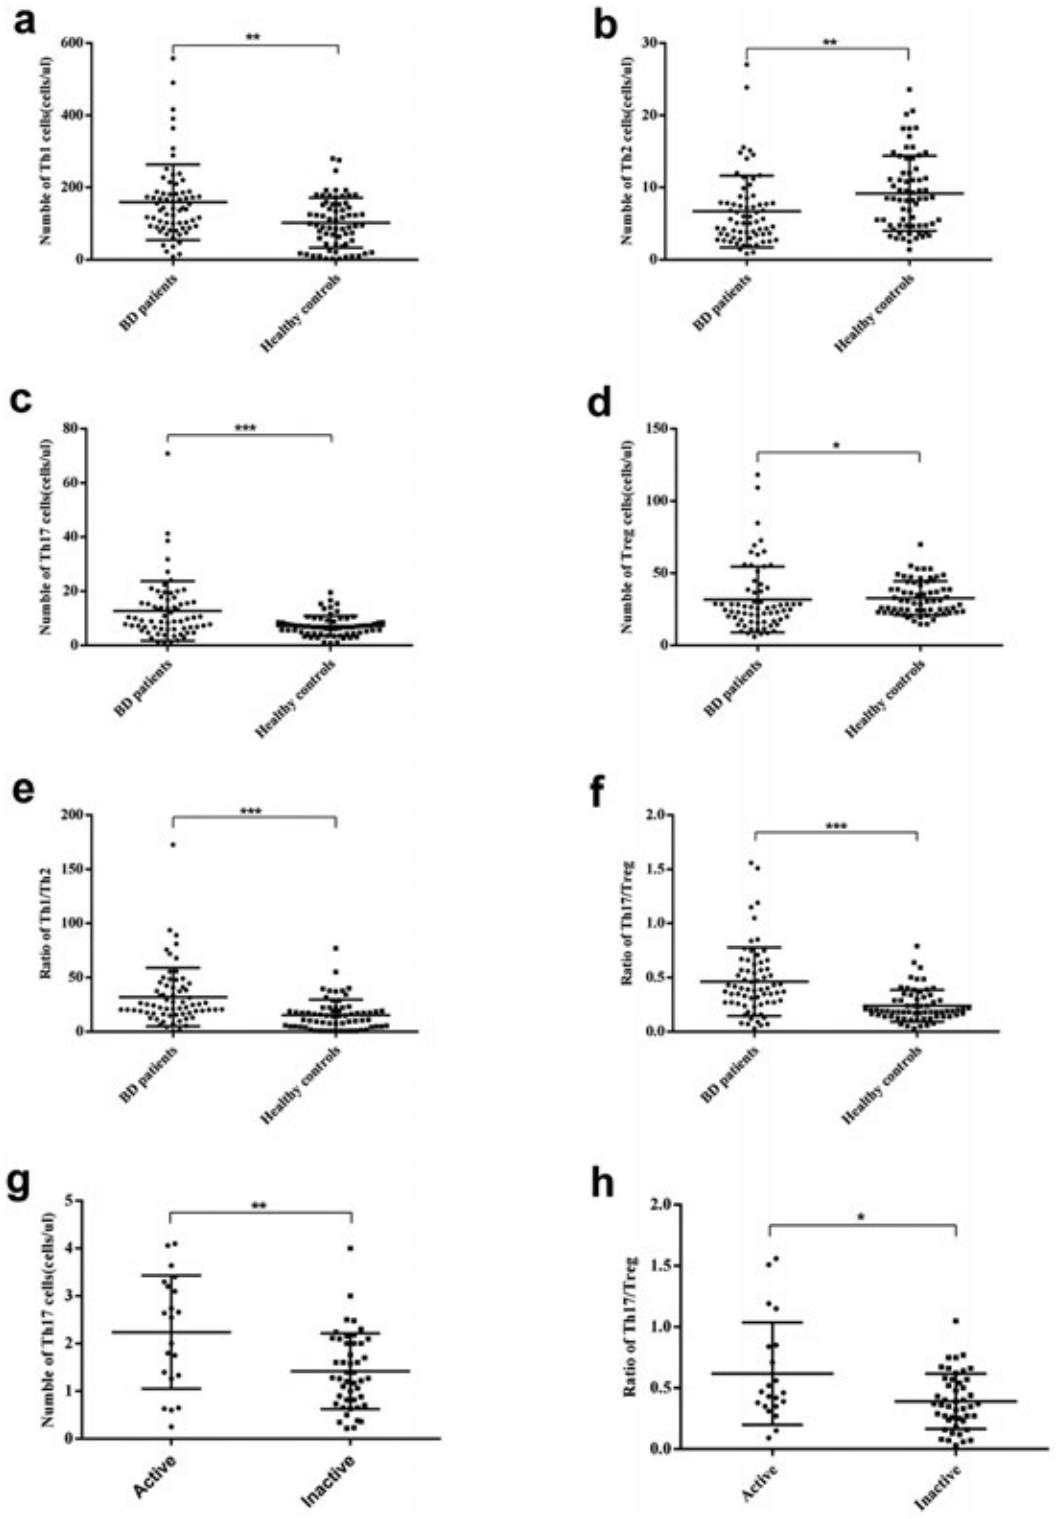

Figure 1 Characteristics of the absolute numbers proportions of CD4+ T cells in the PB of patients with BD. Lymphocytes in the PB of the healthy control (n=66) and BD group (n=67) were assessed by flow cytometry. (a and c) The absolute number Th1 cells and Th17 cells were significantly increased. (b and d) Reduction of Th 2cells and Treg cells were observed. (e and f)The ratio of Th1/Th2 and Th17/Treg were evidently increased.(g and h)The absolute counts of Th17 cells and the ratio of Th17/Treg in active BD patients were higher than inactive.*P<0.05; **P<0.01; ***P<0.001 vs healthy control group.

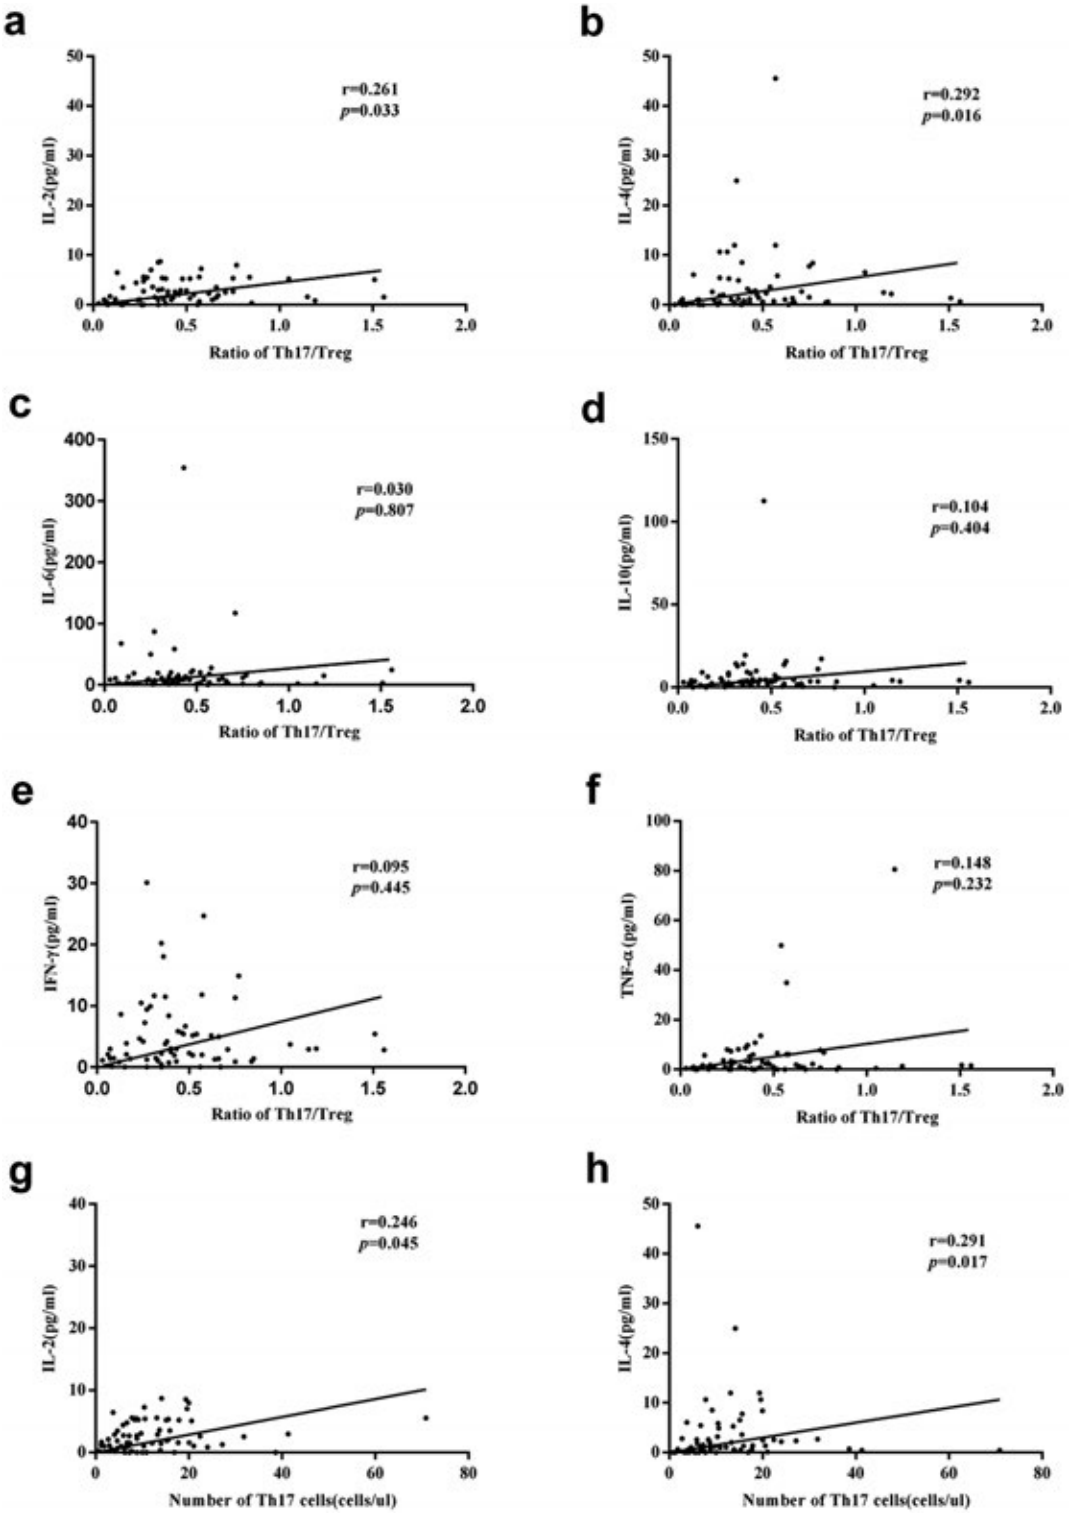

Figure 2 Correlation between the level of cytokines and the ratio of Th17/Treg,the absolute of Th17 cells in patients with Behcet's disease,which were calculated by Sperman's rank correlation.(a and b) Two cytokines were positively correlated with Th17/Treg:i.e.,IL-2(r=0.261,P=0.033) and IL-4(r=0.292,P=0.016)(P≥0.2 for all other cytokines).Th17/Treg was not correlated with IL-6,IL-10,IFN-γ and TNF-α.(g and h)The levels of IL-2 and IL-4 are positively associated with the absolute counts of Th17 cells(r=0.246,P=0.045vs r=0.291,P=0.017).

Others*	21 (23%)

Data are n (%) of patients unless otherwise indicated.

*n= 4, hydroxychloroquine; n=4, intravenous immunoglobulin; n=3, plasma exchange; n=3, etanercept; n=2, tocilizumab; n=3, sulfasalazine; n=1, cyclosporine; and n=1, eculizumab (in a pediatric patient with severe refractory GPA).

Background/Purpose: Only a few small case series, case reports, and one small clinical trial suggested some benefit of leflunomide (LEF) in ANCA-associated vasculitis and other vasculitides. We analyzed the clinical efficacy and tolerability of LEF in a large cohort of patients with various vasculitides.

Methods: This was a retrospective analysis of patients who received LEF for treatment of their vasculitis enrolled in the Vasculitis Clinical Research Consortium (VCRC) Longitudinal Study and in 3 additional centers from the Canadian vasculitis research network (CanVasc). Efficacy was defined as a response to LEF at 6 months after its initiation, as per the treating physician, with the ability to taper glucocorticoids (GC), if applicable, the relief of symptoms for which LEF was started, or the maintenance of remission without the need to add or substitute another agent. Efficacy was further analyzed at 12 and 24 months. The validation of efficacy also required the absence of active disease, corresponding to a Birmingham Vasculitis Activity Score of 0.

Results: Data for 93 patients were analyzed. As shown in Table 1, 45 patients had granulomatosis with polyangiitis (GPA), 8 microscopic polyangiitis (MPA), 12 eosinophilic granulomatosis with polyangiitis (EGPA), 14 giant-cell arteritis (GCA), 9 Takayasu's arteritis (TAK) and 5 polyarteritis nodosa (PAN). The main reason for initiation of LEF was active disease (89%). The mean duration of treatment with LEF was 2.3±2.3 years; it was used with GC (mostly low-dose prednisone), at least initially, for 79% of patients; as monotherapy without GC for 18%; and in addition to another non-GC immunosuppressive sparing agent for 27%. As shown in Table 2, LEF was efficacious for remission induction or maintenance at 6 months for 62 (67%) patients (64% with GCA, 89% with TAK, 80% with PAN, 69% with GPA, 33% with EGPA); 20% discontinued LEF before achieving remission because of persistent disease activity. Five (5.4%) patients experienced nausea, vomiting, or diarrhea. Neuropathy was reported in 4, which resolved after cessation of LEF in 1 (3 had symptoms of minor sensory neuropathy and stopped LEF). Infections were reported in 4 patients (1 with GCA, also on GC, died from sepsis before month 6 of LEF) and mild transient elevation of transaminase levels in 3 patients. High blood pressure was reported in 1 patient after 12 months of use. Overall, 22 adverse

Table 2. Response to treatment with leflunomide among patients with vasculitis

	All patients	Type of vasculitis					
		GPA	MPA	EGPA	GCA	TAK	PAN
No. of patients (%)	93	45 (48.4%)	8 (8.6%)	12 12.9%)	14 15.1%)	9 (28.1%)	5 (5.4%)
Efficacy at 6 months	62 (67%)	31 (69%)	6 (75%)	4 (33%)	9 (64%)	8 (89%)	4 (80%)
Reason for treatment inefficacy							
Active disease	19 (20%)	7 (16%)	-	6 (50%)	4 (29%)	1 (1%)	1 (20%)
Adverse events	12 (13%)	7 (16%)	2 (25%)	2 (17%)	1 (7%)	0	0
Sustained remission at 12 months	54 (58%)	27 (63%)	6 (75%)	4 (33%)	7 (54%)	8 (89%)	3 (60%)
Sustained remission at 24 months	46 (50%)	23 (58%)	5 (71%)	4 (33%)	7 (54%)	7 (88%)	2 (40%)

Given percentages are for the proportion of patients in each type of vasculitis with available data, which was incomplete at 12 and/or 24 months for 7 individuals (2 lost to follow-up after 12 months [MPA and TAK]; 4 had not yet reached 12 and/or 24 months with LEF (3 GPA and 1 GCA); one with GPA died of natural causes before 24 months of LEF).

EGPA, eosinophilic granulomatosis with polyangiitis; GCA, giant cell arteritis; GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; PAN, polyarteritis nodosa; TAK, Takayasu's arteritis.

events led to drug discontinuation in 18 (19%) patients, of which 6 stopped LEF before month 12 and before showing any benefit in 8/12 of these patients.

Conclusion: LEF can be an effective therapeutic option for various vasculitides, especially for non-severe refractory or relapsing ANCA-associated vasculitis or large-vessel vasculitis, and for maintenance in GPA or MPA. No new safety signals for LEF were identified in this population.

Abstract Number: 1705

Cyclophosphamide Therapy for the Neurologic Involvement of Behçet's Disease – Is It Superior to Azathioprine in Preventing Relapses?

Priscila Dias Cardoso Ribeiro,[1] Eduarda Bonelli Zarur,[1] Flávia Maria Matos Melo Campos Peixoto,[1] Pedro Matos,[1] Pedro Paulo de Alcantara Pedro,[1] Rywka Tenenbaum Medeiros Golebiovsk,[1] Livia Dutra,[2] and **Alexandre Wagner de Souza** [3], [1]UNIFESP-EPM, Sao Paulo, Sao Paulo, Brazil, [2]Escola Paulista de Medicina (EPM), Brazil, São Paulo, Brazil, [3]UNIFESP-EPM, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Neurologic involvement is one of the most serious cause of long-term morbidity and mortality in Behçet's disease (BD). To date, no controlled trials have assessed therapy for Neuro-BD and therapy is guided by expert opinion. It is usually recommended to treat active parenchymal Neuro-BD with 5-10 intravenous pulses of methylprednisolone and a course of high-dose glucocorticoids followed by azathioprine. Biologic agents such as interferon (IFN)α or TNF antagonists are used in refractory cases. However, Brazilian rheumatologists usually prescribe intravenous pulse therapy with cyclophosphamide to treat and prevent relapses of neuro-BD. Thus, the objective of this study is to compare the use of monthly intravenous pulse therapy with cyclophosphamide to azathioprine in preventing relapses of Neuro-BD.

Methods: An observational, retrospective cohort study was performed. Inclusion criteria were BD diagnosis according to the criteria of the International Study Group (ISG) or the International Criteria for Behcet's Disease (ICBD), neurologic involvement of BD and written informed consent. Neuro-BD was treated with high-dose glucocorticoids and at physician's discretion patients were treated either by a monthly course of intravenous cyclophosphamide pulse

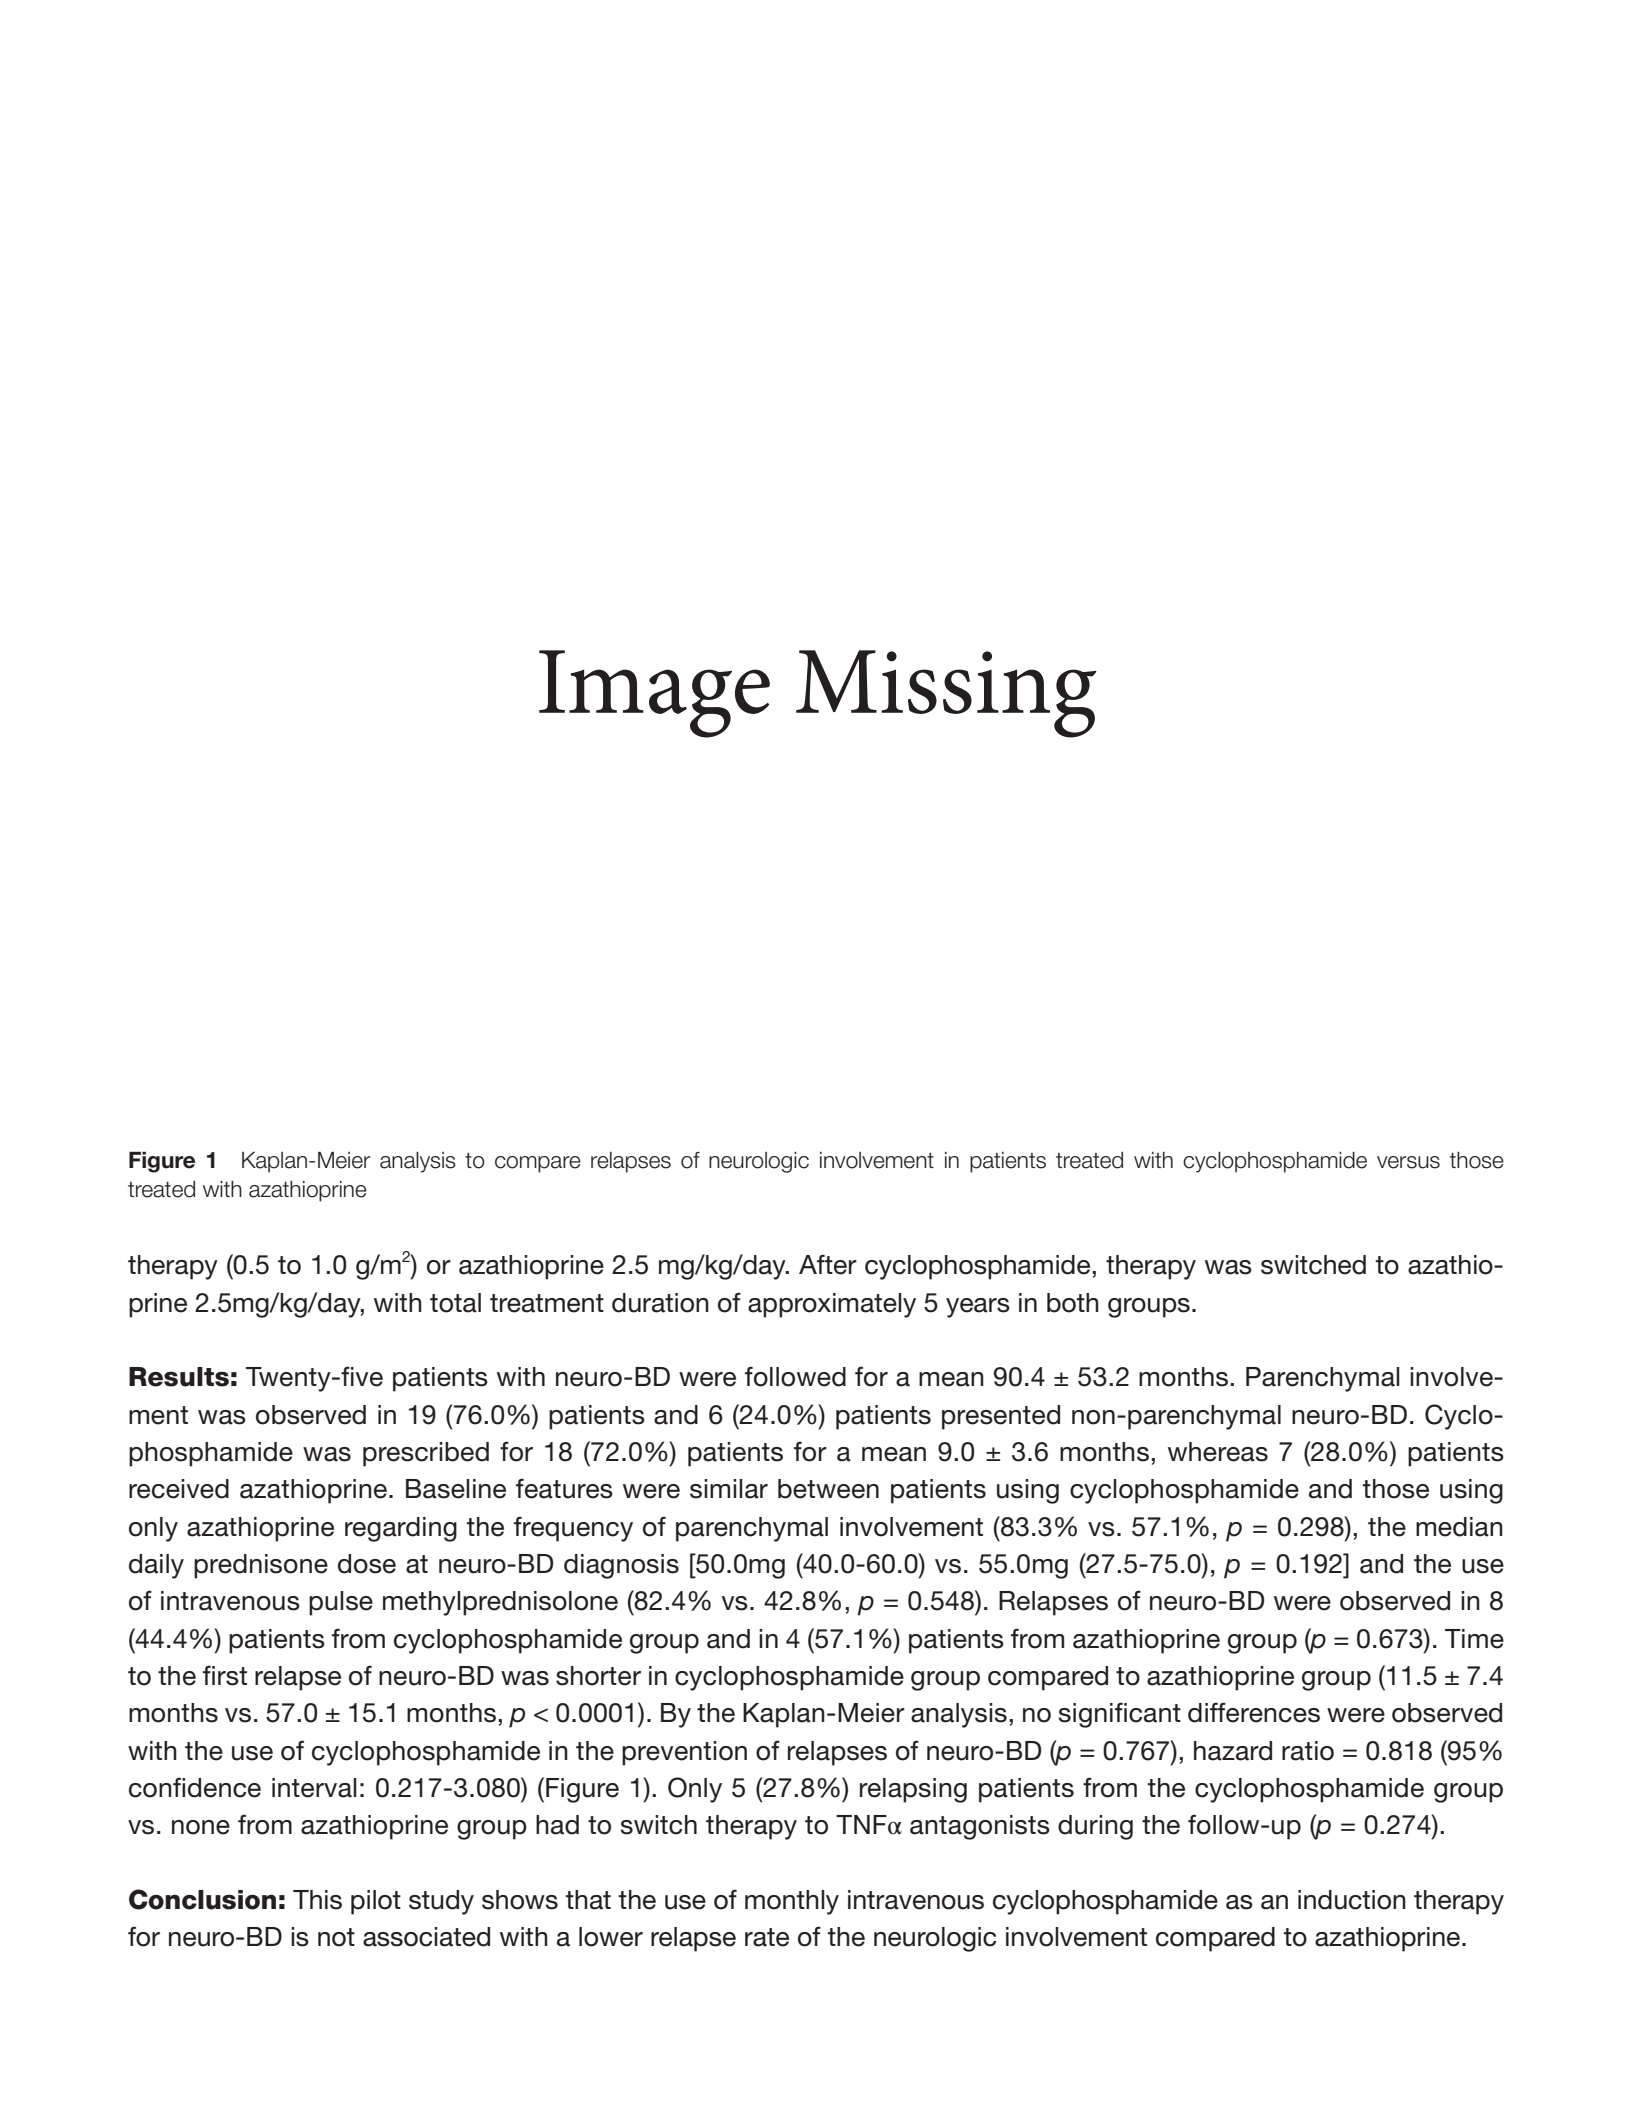

Figure 1 Kaplan-Meier analysis to compare relapses of neurologic involvement in patients treated with cyclophosphamide versus those treated with azathioprine

therapy (0.5 to 1.0 g/m^2) or azathioprine 2.5 mg/kg/day. After cyclophosphamide, therapy was switched to azathioprine 2.5mg/kg/day, with total treatment duration of approximately 5 years in both groups.

Results: Twenty-five patients with neuro-BD were followed for a mean 90.4 ± 53.2 months. Parenchymal involvement was observed in 19 (76.0%) patients and 6 (24.0%) patients presented non-parenchymal neuro-BD. Cyclophosphamide was prescribed for 18 (72.0%) patients for a mean 9.0 ± 3.6 months, whereas 7 (28.0%) patients received azathioprine. Baseline features were similar between patients using cyclophosphamide and those using only azathioprine regarding the frequency of parenchymal involvement (83.3% vs. 57.1%, p = 0.298), the median daily prednisone dose at neuro-BD diagnosis [50.0mg (40.0-60.0) vs. 55.0mg (27.5-75.0), p = 0.192] and the use of intravenous pulse methylprednisolone (82.4% vs. 42.8%, p = 0.548). Relapses of neuro-BD were observed in 8 (44.4%) patients from cyclophosphamide group and in 4 (57.1%) patients from azathioprine group (p = 0.673). Time to the first relapse of neuro-BD was shorter in cyclophosphamide group compared to azathioprine group (11.5 ± 7.4 months vs. 57.0 ± 15.1 months, $p < 0.0001$). By the Kaplan-Meier analysis, no significant differences were observed with the use of cyclophosphamide in the prevention of relapses of neuro-BD (p = 0.767), hazard ratio = 0.818 (95% confidence interval: 0.217-3.080) (Figure 1). Only 5 (27.8%) relapsing patients from the cyclophosphamide group vs. none from azathioprine group had to switch therapy to TNFα antagonists during the follow-up (p = 0.274).

Conclusion: This pilot study shows that the use of monthly intravenous cyclophosphamide as an induction therapy for neuro-BD is not associated with a lower relapse rate of the neurologic involvement compared to azathioprine.

*HLA-B*51* and Its Subtypes in Brazilian Patients with Behçet's Disease

Joice Belem,[1] Ana Maria Fraga,[2] Luís Eduardo Coelho Andrade,[1] and **Alexandre Wagner de Souza** [1], [1]UNIFESP-EPM, São Paulo, Sao Paulo, Brazil, [2]Fleury Group, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: *HLA-B*51* is considered the genetic marker mostly associated with Behçet's disease (BD), mainly in countries of the silk route, where its prevalence ranges from 40-80% in individuals with BD. To date, the frequency of *HLA-B*51* and its subtypes in Brazilian patients with BD and their associations with clinical manifestations of the disease are not known. The aims of this study are to evaluate the prevalence of *HLA-B*51, B*51:01* and *HLA-B*51:08* in Brazilian patients with BD and in healthy controls, to evaluate associations between *HLA-B*51* and its subtypes and a higher risk for BD in the Brazilian population and to evaluate associations with specific clinical manifestations BD.

Methods: We carried out a cross-sectional study with BD patients and healthy controls. The presence of *HLA-B*51* was investigated by sequence-specific polymerase chain reaction (PCR-SSP) and *HLA-B*51* positive samples were submitted to genetic sequencing by the Sanger method to evaluate their alleles at medium resolution.

Results: Eighty-three BD patients and 258 healthy controls were evaluated. The prevalence of *HLA-B*51* was 30.1% in DB patients and 15.5% in control subjects (p = 0.003). The most frequent alleles among DB patients were *HLA-*51:01* (18.1%), *HLA-B*51:08* (6.0%), *HLA-B*51:22* (2.4%), *HLA-B*51:29* (2.4%) and *HLA-B*51:02* (2.1%), while *HLA-B*51:01* (12.0%) and *HLA-B*51:55* (1.2%) were the most frequent subtypes in the control group. Each of the other *HLA-B*51* subtypes were observed in less than 1% of the control group. As for clinical manifestations, *HLA-B*51* was less frequent in BD patients with neurological involvement (8.0% vs. 29.3%; p = 0.034) while *HLA-B*51:01* was more frequently observed in BD patients with ocular involvement (93.3% vs. 60.3%; p = 0.014) and no BD patient with neurological involvement or vascular involvement had *HLA-B*51:01*. *HLA-B*51:08* was more frequent in patients with vascular involvement (60.0% vs. 15.4%; p = 0.012). In the multivariate analysis, the presence of *HLA-B*51* was an independent risk factor for BD (OR = 2.410; 95%CI: 1.332-4.361; p = 0.004) and *HLA-B*51:08* had an independent association with the development of vascular manifestations of BD (OR = 14.843; 95%CI: 1.550 - 142.115; p = 0.019). No independent associations were observed between *HLA-B*51* or with *HLA-B*51:01* and disease manifestations of BD.

Conclusion: *HLA-B*51* is more frequent in Brazilian BD patients compared to healthy controls and it is an independent risk factor for BD. The *HLA-B*51:08* subtype was independently associated with vascular manifestations of BD.

IL-6 Promotes IgG4-related Disease by Inducing Fibroblast-dependent Tfh Cell and B Cell Differentiation Factors

Zongfei Ji,[1] Rongyi Chen,[2] Xiaomeng Cui,[2] Lili Ma,[2] Xiufang Kong,[3] Lingying Ma,[2] Ying Sun,[2] Xiaomin Dai,[2] Zhuojun Zhang,[2] Huiyong Chen,[2] and Lindi Jiang[2], [1]Department of Rheumatology, Zhongshan hospital, Fudan University, Shanghai, China (People's Republic), [2]Zhongshan hospital, Fudan University, Shanghai, China (People's Republic), [3]University of Michigan & Fudan University, Ann Arbor, MI

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Considering the unsatisfied effect of conventional therapy, to investigate the pathogenesis of IgG4-related disease (IgG4-RD) is crucial to explore novel treatment strategies. This study aims to clarify the pathogenesis of interleukin 6 (IL-6) in IgG4-RD through the induction of fibroblast-dependent Tfh cell and B cell differentiation factors and find the new therapeutic target.

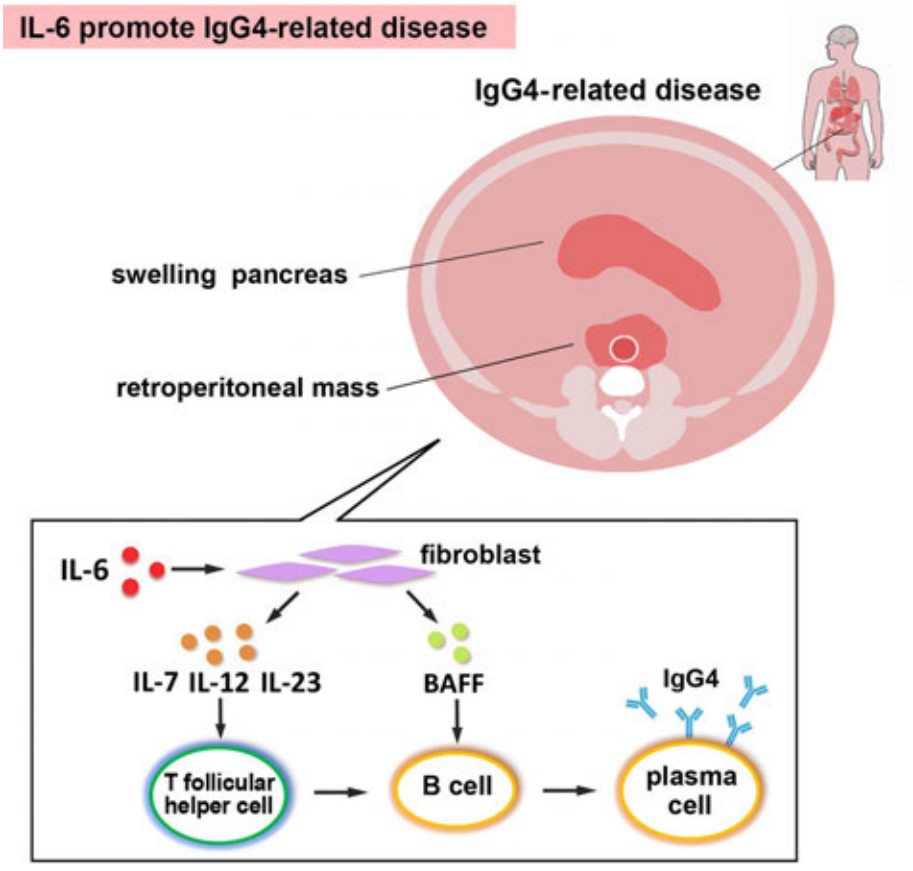

Figure. IL-6 promotes IgG4-related disease by promoting the production of B cell differentiation cytokine (BAFF), and Tfh cell differentiation cytokines (IL-7, IL-12, and IL-23) in fibroblast.

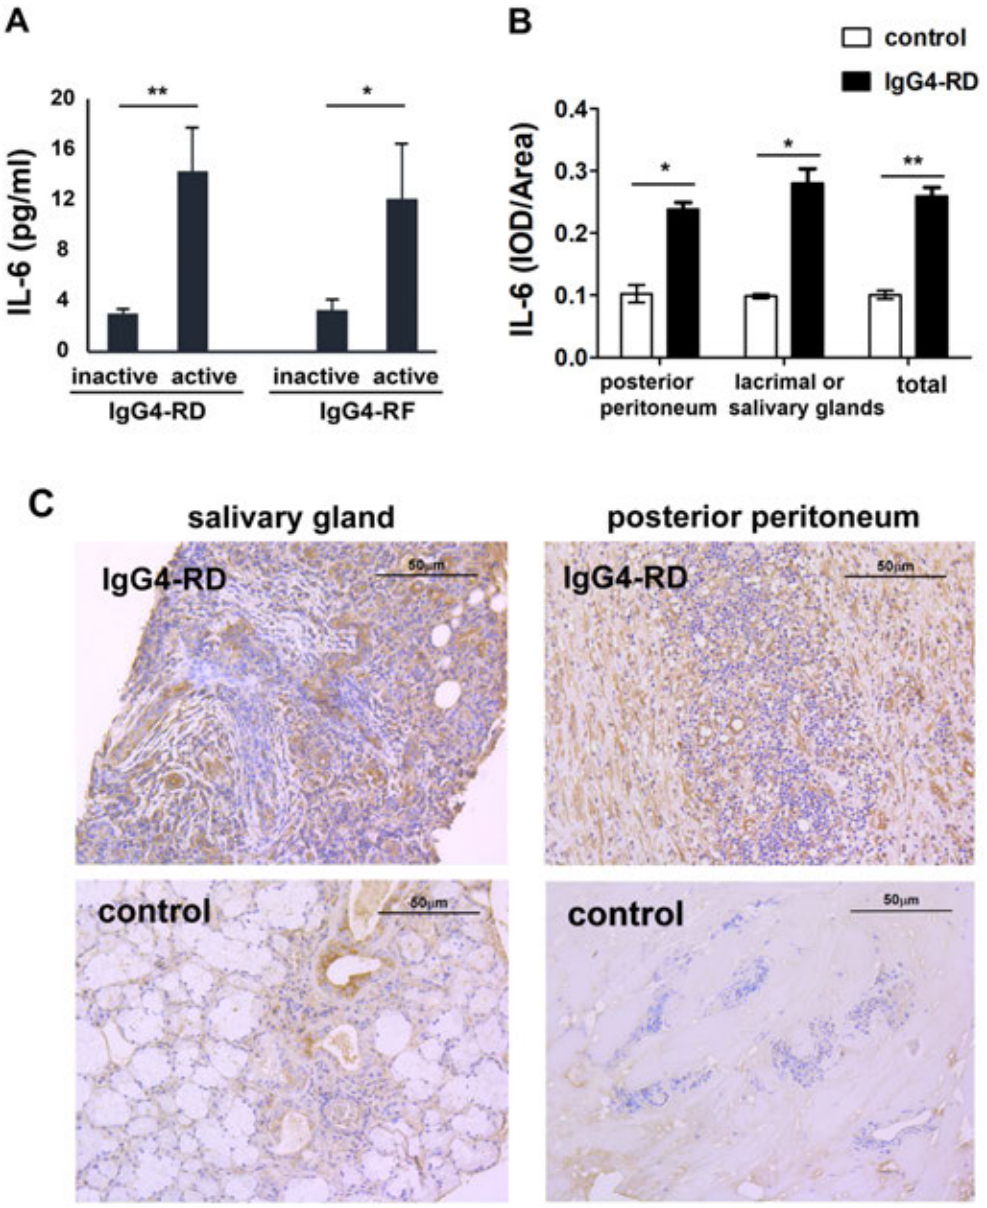

Figure. The level of serum IL-6 was elevated in active IgG4-RD patients. The expression of IL-6 in the tissue of IgG4-RD patients was also significantly higher than that in the normal tissue. *$p < 0.05$; **$p < 0.01$

Methods: The IL-6 expression in the serum and tissues of patients with IgG4-RD and healthy controls were detected by ELISA, immunohistochemistry, and immunofluorescence, respectively. Human aorta adventitial fibroblasts (AAFs) were cultured and stimulated with IL-6/IL-6 receptor (IL-6R). The effect of IL-6/IL-6R on AAFs was determined by CCK-8 and Luminex assays.

Results: The level of serum IL-6 was elevated in active IgG4-RD patients and was positively correlated with IgG4-RD reactive index (RI).The expression of IL-6 in the tissue of IgG4-RD patients was also significantly higher than that in the normal tissue. IL-6-producing fibroblasts were found to co-localize with $IgG4^+$ plasma cells in the tissue of IgG4-related retroperitoneal fibrosis (IgG4-RF). Co-localization of α-SMA and B cell differentiation cytokines (i.e., B cell activating factor (BAFF)), α-SMA and T follicular helper (Tfh) cell differentiation cytokines (e.g., IL-7, IL-12, and IL-23) were present in the local lesions. IL-6/IL-6R significantly promoted the production of BAFF, IL-7, IL-12, and IL-23 in AAFs in a dose-dependent manner. This effect was blocked by JAK1, JAK2, STAT3, and Akt inhibitors, respectively.

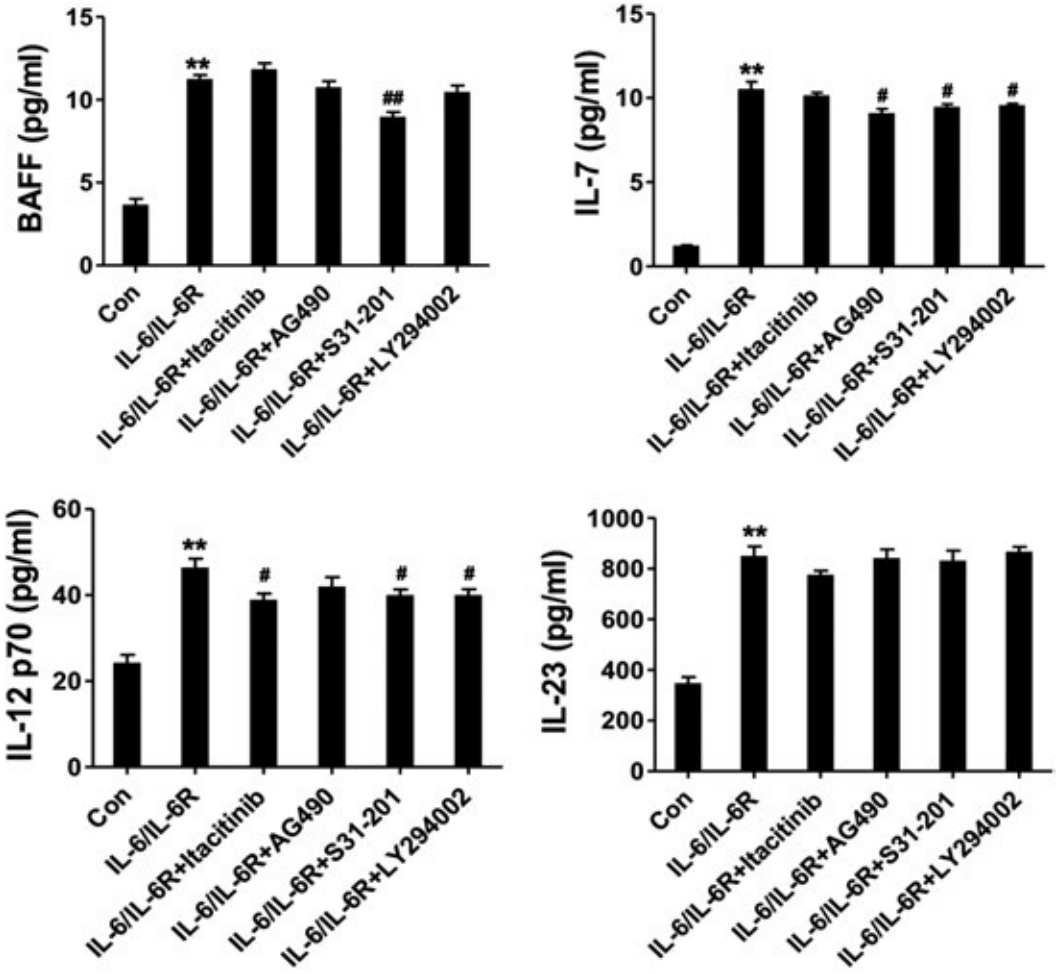

Figure. The secretion of cytokines (IL-7, BAFF, IL-12 p70, and IL-23) in the supernatant following stimulation with IL-6/IL-6R (50 ng/mL) with or without different inhibitors. **p < 0.01 versus control group; #p < 0.05 versus IL-6/IL-6R group.

Conclusion: IL-6 promotes IgG4-RD by inducing fibroblast-dependent Tfh and B cell differentiation factors via the JAK2/STAT3, JAK1/STAT3, and JAK2/Akt pathways. Thus, IL-6 and JAK1/2 inhibitors may be therapeutic targets for IgG4-RD.

Esophagus disease	1 (1.9)
Lung disease	1 (1.9)

**two patients had periaortit and aortic aneurysm and one patient had periaortit and pericardiyal effusion together

Methods: Patients diagnosed as having Ig-G4-related disease by their typical histopathological findings and imaging features and/or increased serum IgG4 concentrations (> 135 mg / dl) from two university hospital in Izmir were included in the study.

Results: There were 53 patients with a mean age of 51.49 yrs (69.8% male). The most common involvement was retroperitoneal fibrosis (54.7%), followed by the cardiovascular system (CVS) involvement (45.3%) (Table 1). While 22 patients had at least two organ involvement, the most common association was retroperitoneal fibrosis and CVS involvement (15 patients). Serum IgG4 levels were studied in 36 patients (67.9%) and found to be higher levels in 20 patients. (55.5%) (Table 2). In 44 patients (83%), acute phase reactants (APRs) were increased at the time of the diagnosis. There was no correlation between the extent of the disease and serum IgG4 levels and initial erythrocyte sedimentation rate (ESR) or C-reactive protein (CRP) values. 28 patients (52.8%) were diagnosed by imaging, 9 (17%) by imaging and IgG4 elevation, 5 (9.4%) by imaging and histopathology, 10 (18.9%) by imaging, histopathology and IgG4 elevation and 1 patient (1.9%) by only histopathology. The most commonly (58.5%) used imaging method for diagnosis was computed tomography (CT). All the patients used initial glucocorticoid treatment.4 patients (7.5%)

recieved only glucocorticoid,others were underwent the following treatments combined with glucocorticoid: azathioprine (AZA) (60.4%); methotrexate (mtx) (11.3%), rituximab (RTX) + AZA (9.4%), mtx + AZA (5.7%), RTX (3.8%) and infliximab (1.9%). In the follow-up, a significant decrease in acute phase reactants was found in 62% of the patients at their last visits. While 27.3% of the patients had complete remission, 36.4% had partial remission, 20.5% had stable course, 13.6% had progression in the disease and 2.3% had recurrence. In 18 patients (64.3%) out of 28 patients who were in partial or complete remission, remission was achieved by using glucocorticoid and AZA combination treatment.

Conclusion: In conclusion, we have described a considerably large serie of patients with IgG4-related disease from Turkey. The results of the study suggested that AZA and glucocorticoid combination treatment was commonly used in Turkish patients with IgG4-related disease and it might be a good treatment option to achieve remission.

Juvenile-Onset IgG4-Related Disease: A Systematic Review

Eduardo Martin-Nares,[1] Talia Díaz-Prieto,[2] Enrique Faugier-Fuentes,[2] Luis A. Aparicio Vera,[2] and Gabriela Hernandez-Molina[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Department of Rheumatology, Hospital Infantil de México Federico Gómez, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related disease (IgG4-RD) presenting in the pediatric age is rare. Natural history and outcomes are not well defined. The aim of this study was to describe the clinical characteristics and outcomes of juvenile-onset IgG4-RD.

Methods: We included patients with juvenile-onset IgG4-RD reported in the English literature that fulfilled de Comprehensive Diagnostic Criteria (CDC) for IgG4-RD and patients followed at two referral centers in Mexico City. Juvenile-onset IgG4-RD was defined as first manifestation of the disease < 18 years. We searched relevant articles on Medline and Pubmed. We extracted variables such as: demographics (sex, age), clinical (number and type of organs involved, clinical phenotype), serological and histopathological data, treatment and outcomes. The juvenile-onset cohort was compared with a published multi-ethnic cohort of adult-onset IgG4-RD patients.

Results: We found 53 articles describing 57 patients with juvenile-onset IgG4-RD. After screening, 49 cases in 46 articles fulfilled the CDC for IgG4-RD. Five new cases from our centers were included. A total of 54 patients with juvenile-onset IgG4-RD were analyzed. Thirty (55.6%) were female. Mean age at presentation was 11.62 ± 4.1 years. Single organ involvement was found in 33 (61.1%). Most frequently involved organs were: orbit (29.3%), lacrimal glands (14.8%), lymph nodes (14.8%), salivary glands (11.1%) and lung (11.1%) (Figure 1). Most frequent clinical phenotype was "head and neck-limited" in 31 (57.4%) patients, followed by "pancreato-hepatobiliary" in 11 (20.4%), "retroperitoneum and aorta" in 5 (9.3%) and "Mikulicz and Systemic" in 2 (3.7%) (Figure 2). Serum IgG4 level were elevated in 33 out of 37 (86.5%) patients tested; the median IgG4 level was 420 mg/dl (range: 4-1650). Forty two

Table 1.	Juvenile-onset IgG4-RD (N=54)	Adult-onset IgG4-RD (N=493)	P

*Unclassified phenotype: solitary lung involvement.			

Table 1 Clinical characteristics of Juvenile-onset VS Adult-onset IgG4-RD.

(77.8%) were biopsy proven. Forty six (85.2%) patients received glucocorticoids, 9 (16.6%) azathioprine, and 8 each (14.8%) mycophenolate mofetil and Rituximab. Nineteen (35.2%) patients had a surgical procedure. Thirty five (64.8%) achieved total and 12 (22.2%) partial remission. When we compare juvenile-onset VS adult-onset patients, the former were more frequently female, had single-organ involvement, orbital involvement and belonged to the "head and neck-limited" and less commonly to the "Mikulicz and Systemic" phenotype (Table 1).

Conclusion: Juvenile-onset IgG4-RD differs in demographics and clinical presentation compare to the adult counterpart. Juvenile-onset IgG4-RD patients are more frequently female and have a "head and neck-limited" phenotype.

Chemokine and Cytokine Tear Profile of Patients with IgG4-Related Disease

Eduardo Martin-Nares,[1] Luis Llorente,[1] Guadalupe Lima,[1] Diego Hernández-Ramírez,[1] Isela Chan-Campos,[1] Vanessa Saavedra-González,[1] and Gabriela Hernandez-Molina[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The lacrimal gland is frequently involved in both IgG4-related disease (IgG4-RD) and Sjögren's syndrome (SS) and presents with swelling and/or dry eye symptoms. Although a distinct chemokine and cytokine tear profile might distinguish SS from idiopathic dry eye, as of today no study has assessed this issue in IgG4-RD. Our aim was to evaluate and compare a set of chemokine/cytokine in the tears of patients with IgG4-RD and primary SS.

Methods: We included 11 patients with IgG4-RD according to the Comprehensive Diagnostic Criteria for IgG4-RD and 17 with primary SS according the AECG criteria, who attended a tertiary referral center in Mexico City. Schirmer-I test were performed using two standardized sterile tear strips, and then immediately frozen at -86°C until assayed. Once defrosted, the tears were extracted from the strips using a buffer containing 0.5 M NaCl and 0.5% Tween-20. Then, the amount (pg/mL) of the following selected chemokines and cytokines were measured by Luminometry: CCL11, G-CSF, IFN-γ, IL-12p40, IL-12p70, IL-13, IL-17A, IL-1α, IL-1β, IL-4, IL-7, CXCL10, CCL2, CCL3, CCL4 and TNF-α.

Results: Patients with IgG4-RD were younger (51.3±14.7 vs. 55.7±10.6) and more frequently men (45.5% vs. 5.9%) than SS patients. Regarding the IgG4-RD group, 7 (63.6%) had lacrimal gland involvement, 5 (45.5%) dry eye symptoms and 6 (54.5%) positive Schirmer-I test. We observed multi-organic involvement in 9 patients (81.8%), median number of involved organs of 5, 9 (81.8%) patients had active disease, median IgG4-RD responder index of 6 points, 8 (72.7%) patients had high IgG4 serum levels, and 9 (81.8%) biopsy proven diagnosis. We found higher levels of IL-7 and CCL2, and a trend for G-CSF in the IgG4-RD group. Conversely, primary SS patients had higher levels of IL-12p40, IL-1α, IL-1β, CCL3 and CCL4. At the logistic regression analysis, the variables that remained associated with IgG4-RD were IL-7 (OR 1.43 95% CI 1.06-1.93, p=0.01) and IL12p40 (OR 0.92, 95% CI 0.84-0.99, p=0.01).

In a sensitivity analysis, including only 7 IgG4-RD patients with dacryoadenitis, we also observed higher levels of IL-7 and G-CSF in the IgG4-RD group vs primary SS.

Conclusion: The chemokine and cytokine profile of tears of patients with IgG4-RD is characterized by a mixed immune response (Th1/Th2/Th17) compare with a predominantly Th1 response in primary SS. Our results also suggest a possible role of IL-7 in the pathogenesis of IgG4-RD.

Table 1.			
Chemokine/cytokine pg/mL, median(range)	IgG4-RD n=11	pSS n=17	*p*
CCL11	11.9 (3.7-34.4)	15.4 (3.7-33.0)	0.06
G-CSF	118.7 (14.5-325.9)	88.5 (14.5-226.5)	0.08
IFN-γ	1.3 (0.3-2.1)	1.7 (0.01-7.2)	0.19
IL-12p40	8.7 (1.3-35.5)	24.1 (1.3-69.3)	0.02

Distinctive Imaging Features Between IgG4-Related Ophthalmic Disease and Graves' Orbitopathy: A Comparative Study

Eduardo Martin-Nares,[1] Oziel Amaya-Piña,[2] Rosa Delia Delgado Hernández,[2] and Gabriela Hernandez-Molina[1], [1]Department of Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico, [2]Department of Radiology and Molecular Medicine, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: IgG4-related ophthalmic disease (IgG4-ROD) may present as a cause of orbital myositis leading to proptosis and diplopia. This clinical scenario can be mistakenly diagnosed as Graves' orbitopathy (GO), preventing a timely and adequately treatment. Our aim was to elucidate if there are specific radiological features that might differentiate between IgG4-ROD and GO by imaging.

Methods: We included 19 patients with diagnosis of IgG4-related disease (IgG4-RD) according to the Comprehensive Diagnostic Criteria for IgG4-RD. All had ophthalmic involvement and available computed tomography (CT) and/or magnetic resonance imaging (MRI) of the orbits. We also included 32 patients with GO with available CT and/or MRI of the orbits. Imaging studies were evaluated by a blinded head and neck radiologist for the following features: exophthalmos, extraocular muscles (EOM) size and morphology, lacrimal gland enlargement, orbital fat involvement, stretching of the optic nerve (ON), ON sheath thickening and orbital bone changes.

Results: Groups were similar in age (49.1±15.8 vs. 51.6±14.7, p=0.58) and gender (men 58.9% vs. 40.6%, p=0.23). In addition to ophthalmic involvement, 18 (94.7%) IgG4-RD patients had extra-ophthalmic involvement with a median number of organs involved of 7 (1-12). Three patients were misdiagnosed as GO before IgG4-RD diagnosis. Graves' disease was the underlying thyroid disorder in 28 (87.5%) GO patients, Hashimoto's thyroiditis in 2 (6.3%), papillary thyroid carcinoma in one (3.1%) and one patient was euthyroid with positive thyroid stimulating immunoglobulin. The prevalence of exophaltmos (78.9% vs. 93.8%), bilateral involvement (78.9% vs. 87.8%) and overall EOM involvement (47.4% vs. 68.8%) was similar between IgG4-ROD and GO groups. However, IgG4-ROD patients had a higher frequency of lacrimal gland involvement (73.7% vs. 10.7%, p=0.001) and a tendency for the lateral rectus to be the most frequently involved EOM (22.2% vs. 0%, p=0.07); conversely they had a lower prevalence for the inferior rectus to be the most frequently involved EOM, (33.3% vs. 72.7%, p=0.04), orbital fat involvement (47.4% vs. 81.3%, p=0.01), ON stretching (57.9% vs. 87.5%, p=0.02) and orbital bone changes (0% vs. 25%, p=0.02). EOM bellies were involved in all the IgG4-ROD and GO cases, whereas EOM tendon involvement was present in 9% of GO and in none of the IgG4-ROD group. Patients with IgG4-ROD had more frequently the combination of lacrimal gland and lateral rectus (31.6% vs. 3.1%, p=0.008) and less frequently the combination EOM and orbital fat involvement (21.2% vs. 59.4%, p=0.008).

At the logistic regression analysis we found an association of lacrimal gland involvement (OR 64.4.0, 95% CI 6.8-609.5, p=0.001) with IgG4-ROD. In a second model including combined variables, the combination of lacrimal gland and lateral rectus involvement was associated with IgG4-ROD (OR 62.5, 95% CI 3.31-1000), P=0.006), whereas the presence of EOM and orbital fat involvement was protective (OR 0.05, 95% CI 0.006-0.48, p=0.009).

Conclusion: Imaging features may reliably differentiate between IgG4-ROD and GO. The presence of both lacrimal gland and lateral rectus enlargement must alert clinicians to consider IgG4-ROD diagnosis.

Head and Neck Involvement of IgA Vasculitis: A Case-Control Study

Michel Villatoro-Villar,[1] David Wetter,[1] Cynthia Crowson,[2] Kenneth Warrington,[1] and Matthew Koster[1], [1]Mayo Clinic Rochester, Rochester, MN, [2]Mayo Clinic Rochester, Rochester

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IgA vasculitis (IgAV) is an immune-complex mediated, small-vessel vasculitis which predominantly involves the skin on the lower extremities. Head and neck involvement is rarely reported. The purpose of this study was to describe the presentation and outcome of a series of patients with head and/or neck involvement in comparison to patients with cutaneous findings isolated to the lower extremities.

Methods: Patients with biopsy-proven IgAV from January 1, 1997 through December 31, 2016 were retrospectively identified through direct medical chart review. IgAV was diagnosed in accordance with the American College of Rheumatology (ACR) and the European League Against Rheumatism/ Paediatric Rheumatology European Society/ Paediatric Rheumatology International Trials Organisation (EULAR/PRINTO/PRES) criteria. Among this cohort, patients with documented clinical, photographic, or histologic descriptions of vasculitic skin lesions affecting the head or neck were compiled. Each patient with head/neck (H/N) involvement of IgAV (case) was matched to two age- and sex-matched control patients with IgAV for which the cutaneous features were isolated to the waistline or distal. Baseline characteristics, laboratory parameters, treatments and outcome were collected by a physician abstractor.

Results: Thirteen patients with H/N-IgAV involvement were identified. Baseline characteristics of the cases and controls are demonstrated in Table 1. H/N involvement included facial (cheeks, forehead) [n=6], perioral/oral/lip [n=6], auricular [n=2], nasal [n=2], and neck [n=1]. All patients in both groups had evidence of purpuric skin lesions. Patients with H/N-IgAV involvement more frequently had evidence of skin ulcerations (23% vs. 0%; p=0.01) [Figure 1]. Overall baseline renal involvement and microscopic hematuria were less commonly observed in patients with H/N-IgAV. Among H/N-IgAV cases, at last follow-up all had resolution of H/N lesions but 3 of 13 had persistent skin lesions on the lower extremities despite ongoing treatment. Long-term outcome between cases and controls did not identify any significant differences in the development of end-stage renal disease, time to resolution of hematuria or proteinuria, time to complete IgAV response, or time to first IgAV relapse.

Conclusion: This study reports the largest series of patients with head/neck involvement of IgA, a rarely reported entity. In this cohort, patients with H/N-IgAV had less frequent renal involvement compared to IgAV patients with lower extremity only skin lesions. Clinicians should be aware of atypical locations of IgAV involvement. Additional research is needed to further understand this clinical subset.

Drug-induced IgA Vasculitis: Data from the French Pharmacovigilance Network and the WHO VigiBase

Camille Rasmussen,[1] Mylene Tisseyre,[2] Julie Garon-Czmil,[2] Marina Atzenhoffer,[3] Loïc Guillevin,[4] Laurent Chouchana,[2] and Benjamin Terrier[4], [1]Cochin Hospital, National Referral Center for Rare Systemic Autoimmune Diseases, PARIS, PARIS, France, [2]Pharmacovigilance, Cochin Hospital, Paris, Paris, France, [3]Pharmacovigilance Center Lyon, France, Lyon, France, [4]National Referral Center for Rare Systemic Autoimmune Diseases Paris Cochin, Paris, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: IgA vasculitis (IgAV) is an immune complex small-vessel vasculitis, with IgA1-dominant immune deposits. Drug-induced IgAV were rarely reported in the literature, but no systematic analysis was done so far. We used a novel approach combining the analysis of two pharmacovigilance (PV) databases to identify the main drugs associated with drug-induced IgA.

Methods: We used VigiBase, the WHO global individual case safety reports database, and the FPVD (French PV Database), to extract drug-induced IgAV using MedDRA terms compatible with the diagnosis of IgAV, between database inception and Jan 2019. Detailed narratives of cases from BNPV were analyzed by two investigators and then categorized into possible or definitive IgAV based on predefined criteria. Demographic and clinical data on IgAV, drugs class and chronological relationship with IgAV were described. Using VigiBase data, we evaluated the association between IgAV and drugs by conducting disproportionality analyses (case-noncase method) calculating reporting odds ratios (RORs). Significance was reached if RORs were >1.

Results: From the 466 cases extracted from the FPVD database, we finally included 113 definitive or possible IgAV cases (for which 177 drugs were suspected as potential triggers); and among 18,518,924 individual case safety reports from VigiBase, we included 1242 cases (associated with 40 drugs with significant RORs).

FPVD population was mainly male (58%), with a median age of 28 years. Main IgAV clinical characteristics were purpura in 100%, joint involvement in 55%, gastrointestinal involvement in 36% and renal involvement in 33%. No vasculitis-specific treatment was required in 67%, whereas 32% of patients received glucocorticoids, 3% colchicine, and 1% cyclophosphamide. Outcome was favorable in 60% of patients, but 16% had sequelae, most frequently mild to moderate (only 2 patients had chronic renal failure). No death was reported during follow up.

The drugs associated with the highest number of drug-induced IgAV were vaccines (23% of all treatments), antibiotics and others antimicrobial drugs (21%), and tumor necrosis factor (TNF)-α blockers (8%). Median interval between initiation of vaccines, antibiotics/antimicrobial drugs and TNF-α blockers and IgAV onset were 11 days, 10 days and 26.5 months, respectively.

Frequencies of drugs identified within the FPVD and their associated RORs calculated within VigiBase are summarized in the Table.

Conclusion: Our study enables the identification of the main drugs associated with drug-induced IgAV using a combined approach of the detailed narratives from the FPVD and the large international Vigibase. Main suspected drugs

Table 1 : Drugs frequencies in BNPV and associated RORs in Vigibase	FPVD %	n =	Vigibase RORs

Can We Predict Early Relapses in Adult IgA Vasculitis?

Jaka Ostrovrsnik,[1] Ziga Rotar,[1] Matija Tomsic,[1] and Alojzija Hocevar[1], [1]Department of Rheumatology, University Medical Center Ljubljana, Slovenia, Ljubljana, Slovenia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: In adults, IgA vasculitis (IgAV) frequently takes a severe course in the acute phase of the disease. Data on long term outcomes is limited. It has been observed that a proportion of patients relapse. Our aim was to define potential predictors of relapsing IgAV in a cohort of unselected adult IgAV cases.

Methods: We analysed medical records of histologically proven IgAV cases diagnosed between January 2010 and September 2018, and prospectively followed until May 2019. The relapse was defined as a new development of skin purpura, joint or gastrointestinal tract (GIT) symptoms or laboratory signs of renal disease at follow-up visit after clinical/laboratory remission, after exclusion of other causes. We explored the differences in the baseline characteristics between the relapsing and non-relapsing IgAV cases. A multivariate logistic regression model included predictors that significantly differed between the groups.

Table 1. Baseline characteristic of IgAV

Characteristics*	Relapsing IgAV (30)	Non-relapsing IgAV (183)	p-value*

BVAS-3$	6 (2-12)	8 (3-15)	0.049

Legend: # - number (%) of patients; $ median (IQR); & - purpura above the waistline, GIT - gastrointestinal tract; BVAS-3 - Birmingham vasculitis activity score. *Fisher's exact test or Mann-Whitney U test

Results: During the 105-month observation period we identified 250 new IgAV cases. During the acute disease 4 patients died. 33 patients were lost to follow-up. Of the remaining 213 patients who were followed for a median 12.5 (IQR 6.8–24.2) months, 30 (14.1%) patients relapsed. 21 (70%), 5 (16.7%), and 4 (13.3%) patients relapsed once, twice, and three or more times, respectively. The relapse was limited to the skin in 24 (80%) patients, involved skin, joints, GIT and kidneys in 4 (13.3%), and was limited to the kidneys in 2 (6.7%) patients. The comparison of baseline characteristics between relapsing and non-relapsing IgAV subgroup is shown in Table 1. In a multivariate logistic regression model, the relapsing IgAV was associated with younger patient age (OR 0.98 (95% CI 0.96-0.99; p=0.024) and non-smoking status (OR 4.41 (95%CI 1.6-12.1), p=0.004).

Conclusion: Younger IgAV patients, who never smoked, tend to have a higher risk for early relapse and should be followed closely.

Predictors of Gastrointestinal and Renal Involvement in Adult IgA Vasculitis

Alojzija Hocevar[1] Ziga Rotar,[2] and Matija Tomšič[3], [1]Department of Rheumatology, University Medical Center Ljubljana, Slovenia, LJUBLJANA, Slovenia, [2]UMC LJUBLJANA, DPT. OF RHEUMATOLOGY, LJUBLJANA, Slovenia, [3]Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia, LJUBLJANA, Slovenia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: IgA vasculitis (IgAV) is a common vasculitis of adult population, yet the disease in adults is still poorly defined. The aim of our study was to determine the predictors of gastrointestinal (GI) or renal involvement in adult IgAV.

Methods: Medical records of histologically proven adult IgAV cases diagnosed between January 2013 and April 2019 at our secondary/tertiary rheumatology center were analyzed. The impact of 7 variables (age, gender, smoking, history of preceding infection, use of new medication prior IgAV, the extent of skin purpura (generalized above the waist vs. localized), and the presence of elevated serum immunoglobulin A (IgA) level) on the development of GI and renal involvement was evaluated using logistic regression models.

Results: During the 76-month observation period we identified 203 new adult IgAV cases (58.1% males, median (interquartile range) age 64 (47-76) years, 91 (44.8%) ever smokers). GI tract and renal involvement developed in 55 (27.1%) and 78 (38.4%) cases, respectively. Clinical characteristics of IgAV patients are presented in Table 1. In a multivariate logistic regression model generalized purpura increased (OR 5.45 (95%CI 2.56 - 11.59), p< 0.001) and elevated serum IgA level decreased (OR 0.45 (95%CI 0.21 - 0.95), p=0.037) GI tract involvement. Current smoking (OR 3.04 (1.34-6.89), p=0.008), generalized purpura (OR 1.97 (95%CI 1.06-3.65), p=0.032), elevated serum IgA (OR 1.96 (95%CI 1.02-3.74), p=0.041), and marginally also age (OR 1.02 (95%CI 1.01-1.04), p=0.012,) were associated

Clinical characteristics	*IgAV cases (203)*	*Clinical characteristics*	*IgAV cases (203)*
Male gender (%)	58.1	Necrotic purpura (%)	45.8
Age (years)*	58 (38-74)	Generalized purpura[&] (%)	51.2
Prior infection (%)	33.0	Joint involvement (%)	35.5
New medication (%)	24.6	Arthritis (%)	12.8
Current smoking (%)	19.7	GI tract involv. (%)	27.1
Past smoking (%)	25.1	Renal involv. (%)	38.4
Elevated serum IgA (%)	46.3	BVAS-3	6 (2-13)

Legend: * median (IQR); [&] purpura above the waistline; GI gastrointestinal; BVAS-3 Birmingham vasculitis activity score;

with an increased risk of renal involvement in our cohort. Gender and potential triggers of IgAV (i.e. prior infections, and the use of new medication) did not significantly influence the clinical presentation of adult IgAV.

Conclusion: Generalized purpura predicted both renal and GI involvement in adult IgAV, active smoking renal involvement, while the serum IgA level had a divergent effect on renal and GI involvement.

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Gastrointestinal (GI) involvement was described as a poor-prognosis factor of systemic necrotizing vasculitides. However, the prognostic impact of GI involvement may vary according to clinical manifestation and vasculitis subtype. We aimed to describe initial symptoms and outcomes of GI involvement of vasculitides and identify factors predictive of poor outcomes among systemic vasculitides.

Methods: Patients with systemic vasculitides as defined by the 2012 Chapel Hill Consensus Conference and with initial GI involvement were retrospectively included. Baseline characteristics, treatments received and outcomeswere recorded. The primary endpoint was a composite of intensive care unit (ICU) admission, emergency surgical procedure, GI-related sepsis or death.

Results: Among the 191 patients diagnosed between 2006 and 2019 included (67% men, mean±SD age 50±19 years), vasculitides were distributed as follows: 75 IgA vasculitis, 50 ANCA-associated vasculitis, 35 polyarteritis nodosa (PAN), 9 large-vessel vasculitis and 22 other vasculitides (including Behçet's disease). Seventy-four (39%) patients reached the composite primary endpoint after a median [IQR] of 10 [0–32] days.Sixty (31%) patients were admitted to the ICU, 34 (18%) required emergency surgery, 30 (16%) had GI-related sepsis. Twelve (6%) patients died of a GI cause after a median of 41 [24–68] days. Vasculitis subtype was associated with the primary endpoint: PAN diagnosis was associated with a poor outcome (hazards ratio [HR] 2.21 (95% CI 1.36–3.62); P< 0.001), while IgA vasculitis had a better outcome (HR 0.32 (95% CI 0.18–0.58); P< 0.001).

Baseline characteristics associated with the primary endpoint [HR (95% CI)] included: age [1.02 (1.0–1.03); P=0.007], fever [2.52 (1.56–4.08); P< 0.001], abdominal pain requiring morphine [3.05 (1.74–5.34); P< 0.001], abdominal guarding [2.76 (1.53–4.98); P=0.001], ileus [3.1 (1.79–5.36); P=0.001], melena [2.30 (1.33–3.98); P=0.003]and intestinal ischemia [3.95 (2.14–7.28); P< 0.001]. High serum C-reactive protein level, WBC count, lactate dehydrogenase levels, performance status, in-hospital admission SOFA score, low oxygen saturation, and hemoglobin and bicarbonate levels were associated with poor outcomes. Endoscopy-identified mucosal abnormalities were not associated with the primary outcome.

To identify patients requiring ICU admission, emergency surgery, GI-related sepsis or death, a score predictive of poor outcome is being developed.

Conclusion: Vasculitides with initial GI involvement, mainly PAN, had poor outcomes for >30% of the patients. We identified a set of clinical and biological factors present at diagnosis associated with this poor outcome. We are devising a predictive score based on these variables to identify patients requiring early supportive care.

Identifying Patterns of Histopathologic Presentation in CNS Vasculitis

Chan Mi Lee,[1] Richard Prayson,[2] Marcia Leon Rabanal,[3] Leonard Calabrese,[3] and Rula Hajj-ali[3], [1]Cleveland Clinic Lerner College of Medicine of Case Western Reserve University/Cleveland Clinic, Cleveland, OH, [2]Anatomic Pathology/Cleveland Clinic, Cleveland, OH, [3]Rheumatologic and Immunologic Disease/Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Primary central nervous system vasculitis (CNS-V) is vasculitis confined to the brain, spinal cord and meninges. It is a rare condition with unknown pathogenesis. Brain biopsy is the gold standard for the diagnosis of CNS-V, which histologically is marked by transmural inflammation of small and medium-sized leptomeningeal and parenchymal arterial vessels. This study aimed to analyze in depth other histopathologic features that may better distinguish CNS-V from other non-CNS-V conditions.

Methods: We identified patients who had brain biopsy and who were enrolled in the prospective CNS Vasculopathy Bioregistry at the Cleveland Clinic between 2012 and 2019. Registry participants are enrolled in both outpatient and inpatient settings based on differential diagnosis of CNS-V or a mimic of its symptoms. Out of 33 patients included, 19 were diagnosed with CNS-V according to (Calabrese and Mallek, 1988). Fourteen patients had uncertain diagnosis or diagnosis not consistent with CNS-V. Pathology reports were analyzed looking for documented inflammatory cell types (T cells, B cells, macrophages, reactive astrocytes, plasma cells, and giant cells) and other histological features (granuloma/epithelioid histiocytes, necrotizing vasculitis, infection, neuronal loss, myelin loss, and amyloid deposits), each categorized by the presence ('yes/no') of cell type or histological feature, abundance ('scant' or 'abundant'), confirmation by staining ('yes/no'), and localization ('transmural' or 'perivascular').

Results: Our cohort consisted of mostly white (~90%), male (≥50%) and middle-aged (48.6±15.8 years; age at biopsy) individuals who had undergone 1.15±0.44 biopsies. Both CNS-V and non-CNS-V cases had the right side (53% and 64%) and frontal lobe (35% and 29%) as the most affected sites. Patients with diagnosis of CNS-V were more likely to have vascular wall infiltration by T cells (33% vs 10%), B cells (20% vs 10%), macrophages (18% vs 0%), and reactive astrocytes (22% vs 0%), and more prevalence of necrotizing vasculitis (11.8% vs 0%). Perivascular distribution was conversely lower in CNS-V than non-CNS-V, noted in 42% vs 70% for T cells, 40% vs 60% for B cells, and 18% vs 20% for macrophages.

Conclusion: In this retrospective study, we took a broad approach of comparing brain biopsies of patients with or without CNS-V to identify histopathological features that may be unique or more predictive of CNS-V. Intramural infiltration of inflammatory cells was more specific to the diagnosis of CNS-V than findings of perivascular inflammatory process. The presence of perivascular inflammation is nonspecific and is more common in non-CNS-V specimens.

Abstract Number: 1718

Geographic Disparities in Mortality Rates of Vasculitis in the United States: 1999 to 2017

Alicia Rodriguez-Pla[1], [1]University of Arizona/Banner Health Medical Center, Tucson, AZ

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Earlier diagnosis and less toxic immunosuppressive therapies have improved the survival of patients with vasculitis. Current data on mortality rates of vasculitis are limited. We aimed to estimate the mortality rates of primary vasculitis using the most recent publicly available mortality data in the United States.

Methods: We used the CDC Wonder Underlying Cause of Death database and its query system to obtain mortality rates of vasculitis as the underlying cause of death from 1999 to 2017. We used the following ICD-10 codes: D69.0 (Allergic purpura) for Henoch-Schoenlein purpura, D89.1 (Cryoglobulinaemia) for cryoglobulinemia, M30.0 (Polyarteritis nodosa) for polyarteritis nodosa (PAN), M30.1 (Polyarteritis with lung involvement [Churg-Strauss]) for eosinophilic granulomatosis with polyangiitis (EGPA), M30.2 (Juvenile polyarteritis) for juvenile polyarteritis, M30.3 (Mucocutaneous lymph node syndrome [Kawasaki]) for Kawasaki's disease, M30.8 (Other conditions related to PAN), M31.0 (Hypersensitivity angiitis) for Goodpasture's syndrome, M31.3 (Wegener's granulomatosis) for granulomatosis with polyangiitis (GPA), M31.4 (Aortic arch syndrome [Takayasu]) for Takayasu's arteritis (TAK), M31.5 (Giant cell arteritis

Figure 1. Age-adjusted mortality rate for vasculitis as underlying cause of death by year.

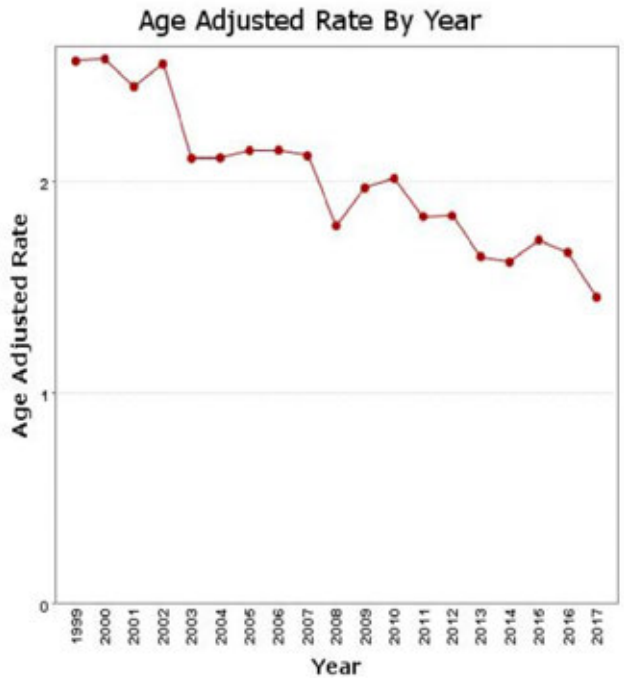

Table 1. Age-adjusted mortality rate per million for vasculitis as underlying cause of death, by race and gender.

Race	Gender	Deaths	Population	Age-Adjusted Rate (95% CI)	% of Total Deaths
White	Female	6,125	2,326,457,753	2.067 (2.015 - 2.120)	50.771%
	Male	4,906	2,275,993,219	2.159 (2.098 - 2.220)	40.666%
	Total	**11,031**	**4,602,450,972**	**2.122 (2.082 - 2.162)**	**91.437%**
American Indian or Alaska Native	Female	62	36,894,044	2.473 (1.863 - 3.219)	0.514%
	Male	35	37,044,572	1.624 (1.070 - 2.362)	0.290%
	Total	**97**	**73,938,616**	**2.087 (1.658 - 2.594)**	**0.804%**
Black or African American	Female	369	406,808,112	1.025 (0.919 - 1.131)	3.059%
	Male	319	372,183,341	1.142 (1.007 - 1.277)	2.644%
	Total	**688**	**778,991,453**	**1.063 (0.981 - 1.145)**	**5.703%**
Asian or Pacific Islander	Female	137	158,995,020	1.012 (0.839 - 1.185)	1.136%
	Male	111	147,089,506	0.993 (0.797 - 1.189)	0.920%
	Total	**248**	**306,084,526**	**1.003 (0.873 - 1.132)**	**2.056%**

CI: Confidence interval.

[GCA] with polymyalgia rheumatica [PMR]) for GCA with PMR, and M31.6 (Other GCA) for GCA, M31.7 (Microscopic polyangiitis [MPA]), and M35.2 (Behcet's disease). Mortality rates were obtained by year, gender, race, state and separately for the specific ICD codes. To obtain age-adjusted mortality rates we used year 2000 U.S. standard population. Mortality rates are given as number of deaths per million. A linear regression model was applied to evaluate trends over time.

Results: During the 19-year period, vasculitis was the underlying cause of death of 12,064 patients. Age-adjusted mortality rate was 1.99 per million (95% CI: 1.95-2.02). Since 1999, there has been a significant trend to the decrease ($p< 0.0001$) (Figure 1). The age-adjusted mortality rate was higher in males than in males (2.05 vs. 1.94 per million). Age-adjusted mortality rate was higher in Whites (2.12, 2.08-2.16) than in Blacks (1.06, 0.98-1.14) (Table 1). GPA accounted for 50.93% of all vasculitis deaths. Interestingly, there was only one death for GCA with PMR and only one for juvenile polyarteritis. There was geographic distribution in the mortality rates of vasculitis by estates. The estates with the highest age-adjusted mortality rates were Oregon, Maine, Vermont, Wyoming and Alaska (Table 2). The estates with the lowest rates were New York, North Dakota, Hawaii, New Jersey and Rhode Island. and.

Conclusion: Mortality by vasculitis remains very low, probably due to the low incidence of these disorders. There is a progressive decrease of the mortality rates. Age-adjusted mortality rate was higher in males and in Whites, which can

Table 2. The 12 states with the highest mortality due to vasculitis as underlying cause of death with age-adjusted rates and 95% confidence interval.

	Deaths	Population	Age-Adjusted Rate per 1,000,000 (95% CI)
Oregon	264	71,265,198	3.274 (2.876 - 3.671)
Maine	97	25,013,975	3.166 (2.562 - 3.870)
Vermont	42	11,801,177	3.085 (2.214 - 4.185)
Wyoming	32	10,296,319	3.077 (2.091 - 4.368)
Alaska	29	13,100,743	2.976 (1.907 - 4.428)
Montana	61	18,443,327	2.884 (2.201 - 3.712)
Idaho	76	28,525,825	2.751 (2.164 - 3.449)
New Mexico	107	37,679,448	2.735 (2.214 - 3.257)
Tennessee	327	117,660,805	2.609 (2.323 - 2.894)
Iowa	179	57,386,432	2.562 (2.181 - 2.942)
Kansas	147	53,312,917	2.552 (2.137 - 2.968)
Minnesota	270	99,446,183	2.535 (2.231 - 2.840)

CI: Confidence Interval.

be explained by the fact that GPA, which is more frequent in males and Whites, is responsible for half of the overall number of deaths. Investigation of the reasons for the geographic disparities is warranted. Our findings should be taken with caution until quality studies to determine the reliability of the data about these rare diseases available in national databases are performed.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Relapsing polychondritis (RP) is a systemic inflammatory disease that can be fatal. The main clinical feature that typically leads to diagnosis is ear inflammation, however the disease is very heterogeneous and can involve multiple organs. Failure to recognize RP can lead to diagnostic delay and further complications. The study objective was to identify specific phenotypes in a prospective cohort of patients with RP.

Methods: Patients 18 years and older were selected from a prospective, observational cohort. All patients met McAdams or Damiani's diagnostic criteria for RP. Six clinical variables were used to identify clusters of patients using latent class analysis. Model selection was based on the akaike information criterion. Cases were assigned to a cluster based on probability of membership. The variables included in the model were saddle nose deformity, subglottic stenosis (SGS), tracheomalacia (TM), bronchomalacia (BM), ear inflammation and tenosynovitis/synovitis. SGS was defined as pathological narrowing of the subglottis visualized by laryngoscopy. TM was defined as antero-posterior and/or lateral flattening of the tracheal wall during expiration on dynamic CT of ≥50%. BM was defined as collapse of the bronchi during dynamic CT scan. Ear involvement was defined as physician-observed tender swelling of the pinna with associated redness. Differences were assessed by chi square or Kruskal-Wallis test. Median values are presented.

Results: A total of 73 patients were included. Three clusters were identified: Cluster 1 "Typical" (n=10, 14%); Cluster 2 "Airway Predominant" (n=21, 29%); and Cluster 3 "Mild' (n=42, 57%) (Table 1). Typical RP was characterized by saddle nose deformity (86%), SGS (78%), TM (98%) and ear involvement (98%). Compared to the other clusters, these patients were defined by the shortest time to diagnosis (median = 1 year) and the greatest frequency of weight loss, stridor, air trapping, tracheal wall thickening, decreased FEF 25-75% and FEV1/FVC, ICU admissions, and tracheostomy. Airway Predominant RP was defined by TM (98%) and BM (56%) without saddle nose deformity or SGS and with infrequent ear involvement (41%). Patients in this cluster had the longest delay to diagnosis (median = 10 years) and the greatest percentage of genital ulcers, a previous diagnosis of asthma, and disability. Mild RP was defined by ear involvement (55%) and inflammatory arthritis (41%) without saddle nose deformity, SGS, TM, or BM. These patients had the highest prevalence of skin disease (33%). There were no significant differences in sex, ethnicity, hearing loss, use of DMARDs or biologics between the three clusters. Comparisons between the three clusters are summarized in Table 2.

Table 1. Three subgroups of patients with relapsing polychondritis identified using unbiased, clustering algorithm.

	Mild n=42	Airway Predominant n=21	Typical n=10	p value
Variables Included in Latent Class Analysis				
Saddle nose n (%)	0	0	8 (86)	<0.001
SGS n (%)	0	0	7 (78)	<0.001
TM n (%)	0	21 (98)	9 (98)	<0.001

Sex (Female n (%))	36 (86%)	17 (81%)	9 (90%)	0.78
Age, symptom onset (yrs, IQR)	35 (26-43)	37 (31-46)	37 (22-40)	0.36
Age at diagnosis (yrs, IQR)	42 (31-50)	48 (43-56)	39 (23-49)	0.08
Diagnostic Delay (yrs, IQR)	4.5 (2-8.5)	10(3.5-20)	1 (0.6-5)	0.007
Clinical Symptoms				
Fever n (%)	9 (21)	7 (33)	2 (20)	0.55
Weight loss n (%)	4 (9)	0(0)	4 (40)	0.02
Oral ulcers n (%)	10 (24)	10 (48)	2 (20)	0.12
Genital ulcers n (%)	5 (12)	7 (33)	0 (0)	0.02
Audiovestibular n (%)	34 (80)	16 (76)	7 (70)	0.73
Eye inflammation n (%)	11 (26)	4 (19)	4 (40)	0.47
Sinonasal disease n (%)	40 (95)	19 (95)	9 (90)	0.82
Costochondritis n (%)	37 (88)	17 (80)	9 (90)	0.70
Dry cough n (%)	32(76)	20 (95)	10 (100)	0.09
Skin symptoms n (%)	14 (33)	5 (24)	0 (0)	0.02
Sicca symptoms n (%)	17 (40)	8 (28)	5 (50)	0.82
Wheezing n (%)	12 (28)	13 (62)	5 (50)	0.03
Stridor n (%)	3 (7)	0 0	7 (70)	<0.0001
Other Diagnosis prior to RP Diagnosis				
Asthma n (%)	12 (28)	13 (62)	5 (50)	0.009
Ear infections n (%)	6 (15)	1 (5)	2 (20)	0.36
Sinusitis n (%)	10 (24)	4 (19)	4 (40)	0.46

Conclusion: We identified three phenotypic clusters of patients with RP that differ in time to diagnosis, clinical and radiological characteristics, and complications. Recognizing a broader spectrum of clinical patterns of disease in RP, beyond cartilaginous involvement of the ear and upper airway, may reduce diagnostic delay and facilitate development of targeted management approaches.

Pentoxifylline Gel for Oral Ulcers in Patients with Behçet's Syndrome

Gulen Hatemi,[1] Berna Yurttas,[2] Zekayi Kutlubay,[3] Tim Cote,[4] Semsi Burak Derkunt,[4] Yusuf Yazici,[5] and Hasan Yazici[6], [1]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul University-Cerrahpasa, Behcet's Disease Research Center, Istanbul, Turkey, Istanbul, Turkey, [2]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Internal Medicine, Division of Rheumatology, Istanbul University- Cerrahpasa, Behçet's Disease Research Center, Istanbul, Turkey, Istanbul, [3]Istanbul University-Cerrahpasa, Cerrahpasa Medical Faculty, Department of Dermatology, Istanbul University – Cerrahpasa, Behçet's Disease Research Center, Istanbul, Turkey, Istanbul, Turkey, [4]Silk Road Therapeutics, Washington, DC, USA, Washington, WA, [5]New York University School of Medicine, New York, NY, USA, New York, NY, [6]Academic Hospital, Istanbul, Turkey, Istanbul, Turkey

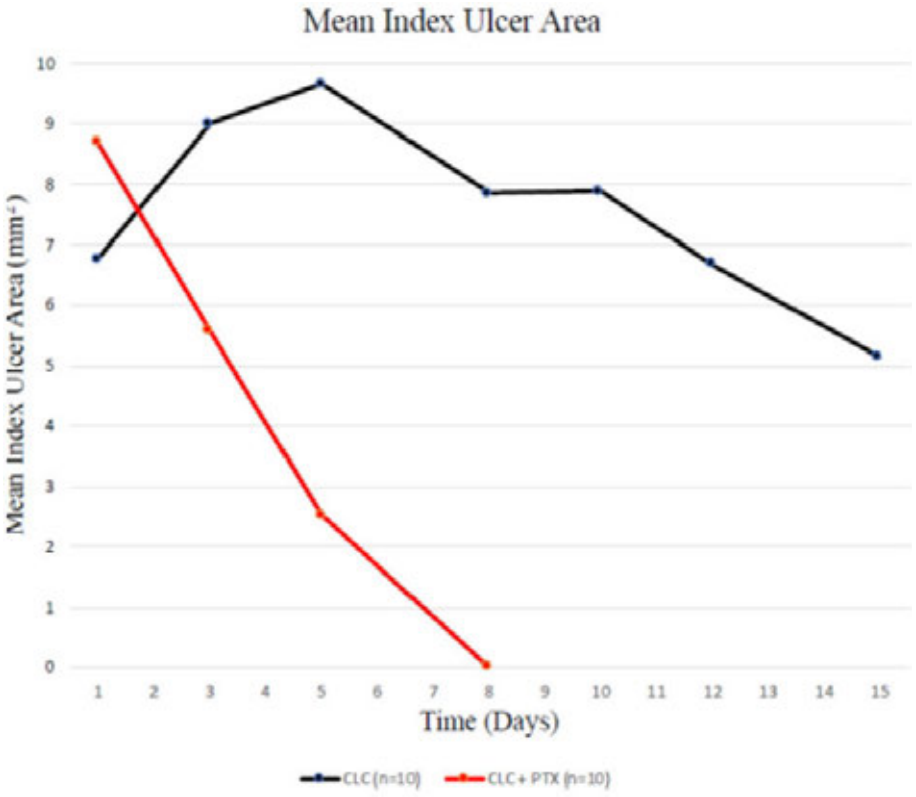
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Oral ulcers, the hallmark lesion of Behçet's syndrome (BS) can be disabling and impair eating, drinking and speaking. Despite recent advances in systemic medications for the treatment of oral ulcers, some patients do not achieve complete remission. Topical agents may help such patients by decreasing the pain and duration of oral ulcers. Pentoxifylline (PTX) is a methylxanthine derivative that inhibits phosphodiesterase and is thought to have immunomodulatory effects in addition to improving blood flow which is its main reason for use in peripheral vascular disorders. The aim of this study is to assess the efficacy and safety of PTX gel for oral ulcers in patients with BS. We also aimed to explore the best tools for the assessment of treatment response to topical agents in randomized controlled trials (Clinicaltrial.gov ID: NCT 03888846).

Methods: This was an open-label, randomized, parallel group study comparing PTX gel in addition to colchicine (PTX-COL) with colchicine alone (COL). Patients with BS who were treated with colchicine and not using any other systemic medications for BS, having at least one oral ulcer that appeared during the last 48 hours were included. PTX 5% gel with a dose of 1000 mg/day was applied in 4 divided doses per day for 14 days. Patients were contacted daily for 14 consecutive days. Photographs were taken every 24 - 48 hours and graphical processing software was used to calculate the area of the index ulcer. Duration of the index ulcer, time to start of index ulcer shrinkage, time to 50% reduction in oral ulcer pain on a 10 mm visual analog scale (VAS), change from baseline in the area of the index ulcer over time, total number of oral ulcers and adverse events were evaluated. A total of 60 patients are planned to be recruited. We present here results of the interim analysis of the first 21 patients.

Results: A total of 21 patients (ratio M:F 1:1.1, mean age:39.9 years), 11 in the PTX-COL group and 10 in the COL group have completed the study at the time of this analysis. One patient in the PTX-COL group withdrew from the study after day 1 and was not included in the current analysis. Mean duration of index ulcer, time to start of index ulcer shrinkage, time to 50% reduction in oral ulcer pain, and total number of oral ulcers during 14 days in each group were lower in the PTX-COL group as presented in the Table. Change from baseline in the area of index ulcer over time

	PTX-COL (n=10)	COL (n=10)	Difference of means (95% CI)	Effect size (Cohen's *d*)
Mean duration of index ulcer (days)	3.4 ± 2.01	7.5 ± 3.89	4.1 ± 9 (1.2 to 7)	1.32
Mean time to start of index ulcer shrinkage	1.2 ± 0.6	4.3 ± 3.5	3.1 ± 2.36 (0.74 to 5.46)	1.23
Mean time to 50% reduction in pain VAS (days)	2.8 ± 1.03	5.9 ± 3	3.1 ± 2.11 (0.99 to 5.21)	1.38
Mean total number of oral ulcers during 15 days	0.8 ± 0.48	1.97 ± 1.64	1.17 ± 1.14 (0.03 to 2.31)	0.97



is shown in the Figure. There were no serious adverse events. Seven patients in the PTX-COL group reported transient discomfort and nausea while they kept the gel in their mouth, 1 patient withdrew from the study for this reason.

Conclusion: The preliminary analysis of the first 21 patients of this open label, randomized trial showed that PTX gel may be a promising agent for decreasing the duration and pain of oral ulcers in patients with BS: However, caution is required when interpreting these results in a yet small number of patients. Duration of oral ulcers, time to start of ulcer shrinkage and 50% reduction in pain score seem to be relevant outcomes for studying topical agents in RCTs for oral ulcerations of BS.

Adult Primary Central Nervous System Vasculitis Treatment and Course: A Long-term Follow-up Study

Carlo Salvarani,[1] Robert D Brown,[2] Teresa JH Christianson,[2] John HustonIII,[2] Caterina Giannini,[2] and Gene G Hunder[2],
[1]Division of Rheumatology, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy, [2]Mayo Clinic, Rochester

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: To evaluate long-term treatment and outcomes of a large cohort of patients with primary central nervous system vasculitis (PCNSV)

Methods: The study cohort consisted of 191 consecutive patients seen at Mayo Clinic (Rochester, MN) over 35-years (1983 to 2017). The follow-up and treatment of all PCNSV patients were updated until June 2018. The diagnosis of PCNSV was based on findings of brain or spinal cord biopsy, cerebral angiography, or both. Biopsy specimens were reviewed by a neuropathologist, and neurological imaging by a neuroradiologist. We used the treating physician's global opinion to assess response to therapy. Disability was defined using the modified Rankin scale. Outcomes, relapses, treatment response and ability to suspend treatment at last follow-up were analyzed (mean follow-up length: 54.2+73.6 months).

Results: Treatment at diagnosis in 186/191 patients were as follows: 72 prednisone (PDN) alone, 90 PDN and cyclophosphamide (CYC), 2 CYC alone, 13 mycophenolate mofetil (MMF) and PDN, 6 azathioprine (AZA) and PDN, 1 chlorambucil and PDN, 1 rituximab (RTX) and PDN and 1 infliximab and PDN. A favorable response was observed in 83.1% of patients treated with PDN alone, in 81.2% of patients treated with CYC and PDN, and in 94.7% of patients treated with MMF or AZA and PDN. Relapses were observed in 30.4% of patients (13.1% had at least 2 flares), and 34.6% of patients discontinued therapy by the time of the last followup visit. Patients with prominent gadoliniun-enhanced cerebral or meningeal lesions had more frequently relapses (OR 1.76), while no significant differences in relapse rates were observed comparing patients treated with only PDN versus those associating PDN and CYC. High disability scores (Rankin score of 4-6) were equally frequent at last followup in patients with relapsing disease (34.5%) and in those without relapses (30.1%). Large vessel involvement (OR 2.80) and cerebral infarction on imaging at diagnosis (OR 3.92) were associated with a poor treatment response. Cerebral infarction at diagnosis (OR 1.76) were also associated with continued treatment at last followup. Higher disability scores at last followup visit were associated with increasing age at diagnosis (OR 1.48) and cerebral infarctions on imaging (OR 2.09). No differences in mortality or in high disability scores at last follow-up (Rankin score 4-6) were observed comparing patients initially treated with PDN plus CYC (HR 0.740, OR 1.450) and PDN plus AZA or MMF (HR 0.538, OR 0.486) to those treated with PDN alone. 26 patients treated with MMF at the beginning or during followup had less frequent high disability scores (Rankin score of 4-6) at last followup than those treated with other drugs initially (15.3% vs 34.5%, $p = 0.06$), while patients given MMF had more relapses (53.8% vs 27.5%, $p = 0.01$). Three patients were treated with RTX for a disease flare and one as initial treatment. In 3 patients RTX was associated with a marked reduction in the number of flares (from 9 before starting RTX to 2 after).

Conclusion: The majority of patients with PCNSV responded to treatment. Cerebral infarctions at diagnosis were associated with poor response to treatment and worst outcomes. MMF and RTX appears to be effective therapy for PCNSV.

Mixed Cryoglobulin Immune Complex Proteomics: Analysis by Mass Spectroscopy

Peter Gorevic,[1] Frank Eng,[2] Andrea Branch,[3] Ahmed Elshamy,[4] Erin Doyle,[2] and Thomas Schiano[2], [1]Mount Sinai Hospital, New York, [2]Mount Sinai Medical Center, New York, [3]Mount Sinai Medical School, New York, [4]California Northstate University, Sacramento

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Mixed Cryoglobulins (MCs) are cold precipitable Rheumatoid Factors (RFs) that provide a biomarker for immune complex formation, particularly associated with chronic Hepatitis C Virus (HCV) and Cryoglobulinemic Vasculitis (CryoVas) syndromes. Both the IgM and IgG components of MCs may span a spectrum of clonality, in type 2 >95% being IgMk and bearing Cross-reactive Idiotypes (CRIs) that can be revealed antigenically or by assessing specific heavy and/or light chain V-gene usage. Older studies indicated that C1q may be an integral part of MCs and that up to a third of the protein content is nonimmunoglobulin.

Objectives: We aimed to define the Immune Complexome of MCs by Mass Spectroscopy and protein sequence analysis (MALDI TOF) compared to existing data bases

Methods: MCs were isolated from the sera of patients with (a) HCV/CroVas before and after clearance of virus by Direct Acting Antivirals (DAAs), (b) persistent disease (purpura, nephritis) 2-15 years after HCV cure; (c) HIV-HCV coinfection, and (d) sjogrens or lupus patients with MCs consistently negative for HCV RNA . Isolated MCs were characterized by immunofixation and gel electrophoresis (SDS-PAGE) before being processed for MALDI-TOF. Specific gel bands identified by SDS-PAGE, including the IgM heavy chain, were excised and sequenced. In addition, serum obtained before cryoprecipitation was analyzed for the three pathways of complement activation and k/l by free and heavy-light chain immunoassays.

Results: In a prospective clinical trial (NTC0282512) the prevalence of complement abnormalities and an expansion of k light chains was demonstrated and the short-term effects of DAA, as well as SVR 24 were analyzed to assess biomarkers concomitant with viral clearance from blood and cryoprecipitates. Depression of C4/C1q was particularly apparent among the patients with persistent cryoglobulinemia, along with IgMk clonality. The validity of MALDI-TOF was reflected in the abundance of Ig heavy and light chain sequences, IgG subclasses, k/l ratios, V-region subgroups, and MC/monoclonal RF VH1-69, VH3-30, VK3D-15 and VK3D-20 MC CRI protein sequences In addition, complement (notably C1q) co-associated with the MC Igs, as well as other proteins relevant to known phlogistic activities of MCs, binding of IgM and the aggregation of proteins in the cold.

Conclusion: Our studies provide a platform for the analysis of MC immune complex proteomics as a laboratory biomarker relevant to CryoVas clinical syndromes

---

Abstract Number: 1723

Mixed Cryoglobulinaemia Since the Advent of New Direct-acting Antivirals for Hepatitis C Infection: Clinical Characteristics, Etiologies and Biological Features in 679 Patients

Gonçalo Boleto,[1] Pascale Ghillani-Dalbin,[2] Lucile Musset,[2] Patrice Cacoub,[1] and David Saadoun[1], [1]AP-HP, Groupe Hospitalier Pitié-Salpêtrière, Department of Internal Medicine and Clinical Immunology, F-75013, Paris, France, Paris, France, [2]Department of Immunology, UF d'Immunochimie et d'autoimmunité, APHP, Groupe Hospitalier Pitié-Salpétrière, Paris, France, Paris, France

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Vasculitis – Non-ANCA-Associated & Related Disorders Poster III: Behçet's Disease & Other Vasculitides

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Previously chronic hepatitis C virus (HCV) infection was accountable for 80-90% of cases of mixed cryoglobulinemia (MC). The advent of direct-acting antivirals (DAA) has dramatically changed the management of chronic HCV infection. However, since their approval in 2011, data are very scarce on the prevalence of HCV-related MC. We aimed to study the main etiologies, clinical manifestations and immunological parameters of MC in the era of DAA agents.

Methods: Observational longitudinal cohort study that included 679 patients with MC at the Pitié-Salpêtrière Universitary Hospital, Paris, France, between 2011 and 2018. Demographic information (age at diagnosis, gender, year of diagnosis, etiology of MC) and laboratory data were recorded. Patients included were divided into two categories: HCV-related MC and non-HCV-related MC.

Results: The mean age of the patients was 55.5 (15.8) years, 54.5% were female, and 20.5% had vasculitis. Presence of vasculitis was not statistically different between HCV-related and non-HCV-related MC cases. Main clinical manifestations included skin involvement in 54.7%, neurological involvement in 49.6%, renal involvement in 21.6% and arthritis in 10.1% of patients. HCV-related MC cases had higher cryoglobulin levels (378 vs 369 mg/L, $p< 0.001$) and lower serum levels of complement C4 (0.16 vs 0.18, $p< 0.001$), whereas RF activity was higher in non-HCV-related cases (280 vs 261 UI/Lm $p< 0.001$).

Over the period of 2011 and 2018 chronic HCV infection accounted for 56% of cases of MC. The remaining causes of MC were autoimmune diseases (23%), hematological and neoplastic conditions (6%), infectious diseases other than chronic HCV infection (5%), whereas 10% of MC cases were identified as essential. In 2016-2017, HCV-related cases dropped with non-HCV-related cases representing the leading cause of MC. Indeed, in 2018, non-HCV-related represented 66.7% of MC.

Conclusion: DAA have changed the landscape of MC with HCV no longer being its leading cause in our cohort. Due to the safety profile and cure rates of DAA regimens, with HCV elimination being high on the world health agenda, we speculate that the incidence of HCV-related MC will dramatically decrease in the upcoming years.

Disease Manifestations and Impact on Quality of Life in Subjects with Pre-Pubertal Onset Systemic Lupus Erythematosus

Brandi Stevens,[1] Martha Rodriquez,[1] Amy Rakestraw,[2] and Kathleen O'Neil[1], [1]Indiana University, Indianapolis, IN, [2]Indiana University Health, Indianapolis, IN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic Lupus Erythematosus (SLE) can be a severe disease, especially when diagnosed in childhood. Onset prior to puberty (Tanner stage II) is rare, and less is known about the impact SLE has on this pediatric subpopulation. We assessed clinical and quality of life (QOL) measures in a pre-pubertal SLE onset cohort to better globally understand the burden of this disease in this group.

Methods: In a prospective, multicenter (10 Childhood Arthritis and Rheumatology Research Alliance sites), observational study, subjects with pre-pubertal onset of SLE were enrolled. Subjects either were still in Tanner I or no later than Tanner stage II at enrollment. QOL measures were collected in addition to comprehensive medical history, physical examination findings, laboratory assessments, SLEDAI-2K scores, and SLICC/ACR Damage Index. QOL measures were obtained by PedsQL™ 4.0 Core and PedsQL™ 3.0 Rheumatology Module surveys completed by the child at the enrollment visit. QOL data was available for 42 subjects (31 females, 11 males) and longitudinal QOL data was available for 25 subjects. QOL means were compared with disease manifestations by t tests.

Manifestations of Disease Activity	Number	Percent
Psychosis	1	2%
Organic Brain Syndrome	1	2%
Lupus Headache	1	2%
Vasculitis	3	7%
Arthritis	5	12%
Rash	10	24%
Alopecia	5	12%
Pleurisy	2	5%
Pericarditis	1	2%
Thrombocytopenia	1	2%
Hematuria	5	12%
Pyuria	9	21%
Urinary Casts	1	2%
Increased DNA Binding	25	60%
Low Complement	18	43%
Proteinuria	12	29%
No individuals affected by the following disease activity indices at baseline: seizure, visual disturbance, cranial nerve disorder, cerebrovascular accident, myositis, mucosal ulcers, fever, or leukopenia		

Table 1. Frequency of Manifestations of Disease Activity at Enrollment

Table 3. Child and Parent Quality of Life Responses Compared between Enrollment and Follow Up 12 Months Later

Results: At enrollment, the mean age of diagnosis was 9.9 years, with a mean disease duration of 1.2 years. Duration between enrollment and follow up QOL was a median of 12.3 months (IQR 11.7-13). Males were older at diagnosis than females (10.9 vs 9.5 years, p=0.023) with no difference in enrollment disease duration. The mean SLEDAI-2K score was 7 (range 0-18) with diverse manifestations of activity (Table 1). Disease activity and individual SLE manifestations did not vary by gender. Laboratory markers of activity were present more frequently on the SLEDAI-2K than clinical exam findings, of which rash (24%), alopecia (12%) and arthritis (12%) were the most common. Seven subjects had disease damage reported on the SLICC/ACR DI.

School functioning domain had the worst QOL measure with the greatest number of children impacted (Table 2). Active arthritis was associated with lower mean scores in Physical Health (p=0.007), PedsQL Core total (p=0.048), Pain and Hurt (p=0.002), Daily Activities (p=0.003), Treatment (p=0.002), Worry (p=0.036), and PedsQL Rheumatology total (p=0.001). There was no association with QOL measures for rash, alopecia, or laboratory markers. Disease damage on SLICC/ACR DI was associated with greater impact on the Worry domain (mean 64.3 vs 88.1, p=0.23). On examination of follow up QOL, change in quality of life was trending towards improvement while physician global assessment was stable (Table 3).

Conclusion: Children with pre-pubertal SLE onset report significant impacts on QOL regarding school. The disease manifestation affecting the most QOL domains was arthritis, whereas skin manifestations, while common, did not demonstrate an impact on QOL. This is the first study to specifically address quality of life for children who develop SLE prior to pubertal development.

Disease Activity in Childhood-Onset Systemic Lupus Erythematosus: Initial Analysis of the Childhood Arthritis and Rheumatology Research Alliance Registry

Emily Smitherman,[1] Mary Beth Son,[2] Andrea Knight,[3] Timothy Beukelman,[4] Jeffrey Curtis,[1] and Aimee Hersh[5], [1]University of Alabama at Birmingham, Birmingham, AL, [2]Boston Children's Hospital, Boston, MA, [3]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Toronto, ON, Canada, [4]University of Alabama Birmingham, Birmingham, AL, [5]University of Utah, Salt Lake City, UT

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Substantial risk of early morbidity and mortality exists for patients with childhood-onset systemic lupus erythematosus (cSLE) despite widespread use of immunosuppressive therapy. There are limited studies describing predictors of longitudinal disease activity in cSLE. Our objective was to determine patient-level demographic and clinical predictors for high disease activity scores.

Methods: We performed a retrospective analysis of prospectively collected data from the Childhood Arthritis and Rheumatic Disease Research Alliance (CARRA) Registry. Eligible patients had symptom onset before 18 years, new diagnosis of cSLE or established cSLE with new onset lupus nephritis within 24 months of enrollment, and were less than 21 years at enrollment. Data was collected every 6 months, and patients were included if at least one follow-up visit was recorded in the Registry. The primary outcome was Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K) at most recent visit, dichotomized into ≤ 4 (low disease activity) or > 4 (high disease activity). Predictor variables included sex, race, age at diagnosis, number of ACR classification criteria at diagnosis, presence of lupus nephritis, number of follow-up visits, time since enrollment in months, and SLEDAI-2K at enrollment. Descriptive statistics were calculated across the study population. Univariate analyses were performed using two-sample Student t test or Mann-Whitney U test for continuous variables and Chi-square for categorical variables.

Table 1. Demographic and Clinical Baseline Predictors of High vs Low Disease Activity at Follow-up for Patients with cSLE in the CARRA Registry

	Total Cohort (n = 268)	SLEDAI ≤ 4 (n = 188)	SLEDAI > 4 (n = 80)	*p* value
Female, n (%)	227 (85%)	162 (86%)	65 (81%)	0.4
Race, n (%)				
Black	84 (31%)	59 (31%)	25 (31%)	0.8
White	64 (24%)	42 (22%)	22 (28%)	
Hispanic	61 (23%)	41 (22%)	20 (25%)	
Asian	42 (16%)	32 (17%)	10 (13%)	
Other	17 (6%)	14 (7%)	3 (4%)	
Age at diagnosis, mean (SD)	13.7 (3)	13.6 (3)	13.9 (3.2)	0.5
Number of ACR classification criteria, median (range)	5 (1-10)	5 (4-6)	6 (5-7)	< 0.001
Lupus nephritis, n (%)	131 (49%)	92 (49%)	39 (49%)	1
Number of follow-up visits, median (range)	2 (1-4)	2 (1-4)	1 (1-4)	0.6
Time since enrollment, mean (SD) months	10.8 (5.2)	10.8 (4.9)	10.8 (5.9)	0.99
SLEDAI-2K at enrollment, median (range) score	3 (0-37)	2 (0-30)	6 (0-37)	< 0.001
SLEDAI-2K at most recent visit, median (range) score	2 (0-23)	1 (0-4)	8 (5-23)	

Results: We identified 268 cSLE patients enrolled in the CARRA Registry with a mean duration of 10.8 months and median of 2 follow-up visits (Table 1). This multiracial North American cohort was 85% female with a mean age at diagnosis of 13.7 years. Lupus nephritis was present in 49%. The median (range) SLEDAI-2K score at enrollment was 3 (0-37) and at most recent visit was 2 (0-23). At the most recent visit, 30% of patients had high disease activity. Statistically significant differences between the high and low disease activity groups were noted in the number of ACR classification criteria and the SLEDAI-2K at enrollment, with higher number of criteria ($p < 0.001$) and higher SLEDAI-2K at enrollment ($p < 0.001$) in the high disease activity group. Interestingly, in the high disease activity group, the median SLEDAI-2K was 2 points higher at the most recent visit compared to enrollment, which may indicate more disease activity flare in this subgroup.

Conclusion: This study provides an initial analysis of predictors of disease activity scores in cSLE patients enrolled in the longitudinal CARRA Registry. While the majority of patients had a low disease activity score at their most recent visit, there was still a substantial proportion of patients with high disease activity. The number of ACR classification criteria and SLEDAI-2K at enrollment were significant predictors of subsequent disease activity scores, highlighting the importance of including these factors in future longitudinal analyses. Additional investigation is needed to better understand modifiers of disease activity, such as early diagnosis and treatment, in order to identify targets for intervention and improved outcomes.

Background/Purpose: Individuals with childhood-onset systemic lupus erythematosus (cSLE) must transfer from pediatric to adult health care as they enter adulthood. Previous analyses of the Pediatric Lupus Outcomes Study demonstrated significantly lower rates of medication usage and more frequent gaps in rheumatology care in a post-transfer cohort compared to a pre-transfer group, in spite of similar levels of disease activity. This study aims to further explore these findings by comparing transition readiness, illness perceptions, comorbid conditions, pregnancy, and insurance barriers to obtaining medication.

Methods: Data derived from the baseline interview of the Pediatric Lupus Outcomes Study, an annual telephone survey of 91 English- and Spanish-speaking participants age 18-30 with confirmed cSLE. Subjects were recruited from rheumatology clinics. To define a cohort undergoing transition from pediatric to adult care, we included respondents who received care from a pediatric rheumatologist currently or in the past (N=85). Transition readiness and illness perception were assessed using Transition Readiness Questionnaire (TRAQ) and Brief Illness Perception Questionnaire (IPQ-B). Patients answered questions related to medication compliance, insurance barriers, comorbidities, and

Scores for each section range from 1-5, correlating to the following answers: 1. No, I do not know how; 2. No, but I want to learn; 3. No, but I am learning to do this; 4. Yes, I have started doing this; 5. Yes, I always do this when I need to
Scores reflect median values

reproductive health. Bivariate analyses were used to compare individuals currently cared for by pediatric vs adult rheumatologists.

Results: Mean age was 21 years; mean age at diagnosis was 13 years. 38 respondents (45%) had transferred to adult care. Post-transfer patients were more likely to report 100% medication compliance than the pre-transfer group (66 vs 47%), which neared significance. Pre-transfer patients were more likely to forget to take medications (26 vs 6%). Post transfer patients had significantly higher incidence of hyperlipidemia (11 vs 0%) and a trend towards higher incidence of osteoporosis (13 vs 2%). The rate of pregnancy was higher in the post-transfer (39%) vs pre-transfer (0%) patients. The post-transfer group scored lower on General Health (47 vs 58) and Social Functioning (75 vs 100) metrics of the Short-form 36 health survey. The post transfer group had significantly higher overall TRAQ scores (4.8 vs 4.4), with higher scores in the appointment keeping (5 vs 3.9) and medication management (4.8 vs 4.3) subcategories.

Conclusion: Both post- and pre-transfer groups demonstrated similar disease perceptions and quality of life, while the post-transfer group reported higher transition readiness. While previous findings showed that decreased immunosuppressant use in the post-transfer group could not be explained by differences in disease activity, this difference in medication utilization could be explained by higher pregnancy rates and medication side-effects/comorbidities. Despite lower rates of medication usage the post-transfer group reported better medication compliance, which may reflect both different prescribing practices between pediatric and adult providers and expected developmental changes during adulthood. Future studies will use longitudinal data to assess changes in disease activity and healthcare utilization as pre-transfer patients move to adult rheumatology care.

Abstract Number: 1727

Worsening Disease Activity and Inability to Taper Corticosteroids in an Ethnically Diverse Cohort of Pediatric-Onset Lupus Patients After Transition to Adult Care

Marla Guzman,[1] B. Anne Eberhard,[1] and Joyce Hui-Yuen[1], [1]Cohen Children's Medical Center, New Hyde Park, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Transition of pediatric lupus (pSLE) patients from pediatric to adult rheumatology care is historically difficult and challenging. Although our division routinely assesses for transition readiness, we do not administer a formal transition readiness questionnaire to evaluate ways in which transition preparedness can improve. We aim to investigate disease activity and medication use in pediatric lupus patients before and after transition to adult care.

Methods: A retrospective chart review was conducted of all patients who were seen in our pediatric rheumatology clinic between the years 2003-2019 who fulfilled 1997 ACR classification criteria, were diagnosed with pSLE, and transitioned to our institution's adult rheumatology division. Descriptive statistics and paired t-tests were used.

Results: Thirty three patients with pSLE had documentation of transition from pediatric rheumatology to adult rheumatology within our institution. Twenty-six patients were female. Twelve patients were Black (36%), 7 patients were White (21%), and 5 patients were Asian (15%). 6 patients reported race as unknown or other. Four patients (12%) reported Hispanic ethnicity. The mean age at diagnosis was 12.7 +/- 2.9 years. The mean age at the first adult visit was 20.8 +/- 1.6 (range 18-24) years. The average time between last pediatric visit and first adult visit was 6.7 (median 3.0) +/-7.9 months. The mean SLEDAI score at final pediatric visit was 3.44 (median 3.0) +/- 3.7, and the mean SLEDAI score at approximately 12 (range 4-24) months after first adult visit was 6.59 (median 6.0) +/- 5.7 (p= 0.0008). The mean daily dose of prednisone at final pediatric visit was 10.6 (range 0-60, median 2.5) +/- 16.2 mg, and the mean daily dose of prednisone approximately 12 (range 4-24) months after first adult visit was 9.2 (range 0-50, median 2.5) +/- 14.2 mg (p=0.5898). Nineteen patients were on at least one steroid sparing medication at final pediatric visit, and 4 additional patients were started on a steroid sparing medication approximately 1 year (range 4 months-2 years) after first adult visit. Fourteen patients had been diagnosed with nephritis and underwent induction treatment while under pediatric care, and 2 additional patients developed nephritis post-transition.

Conclusion: Disease activity in pSLE increases as early as within the first 4 months after transition to adult rheumatology in our primarily Black cohort of pSLE patients. Daily prednisone dosing in patients on prednisone during pediatric care did not significantly decrease post-transition, suggesting continued active disease. Similarly, 4 patients who were not on treatment with immunosuppressive medications were started on at least 1 immunosuppressive post-transition. Analyses are currently underway to determine whether demographic and socioeconomic factors affect disease activity and medication use after transition in this population. Use of a formal assessment of transition readiness to assist with areas of weakness prior to transition may be beneficial.

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Avascular necrosis (AVN) is a serious comorbidity of juvenile systemic lupus erythematosus (jSLE) associated with disability, impaired quality of life, and increased cost of care. Many factors have been been reported to be associated with AVN risk, with most studies focused on adult SLE. A recent meta-analysis found high maximum and cumulative glucocorticoids (GC) dosage, lupus nephritis (LN), central nervous system disorder, and Cushingoid body habitus to be associated with AVN (Nevskaya et al 2017; Clin Exp Rheumatol; 35:700). The aims of this study were to identify factors associated with AVN risk in jSLE.

Methods: We conducted a single center retrospective cohort study of jSLE patients seen between 2009-2010. Eligible patients had to fulfill 1997 American College of Rheumatology (ACR) classification criteria for SLE and/or have LN, and been treated with GC. Data was collected from disease onset to AVN development for AVN patients, and

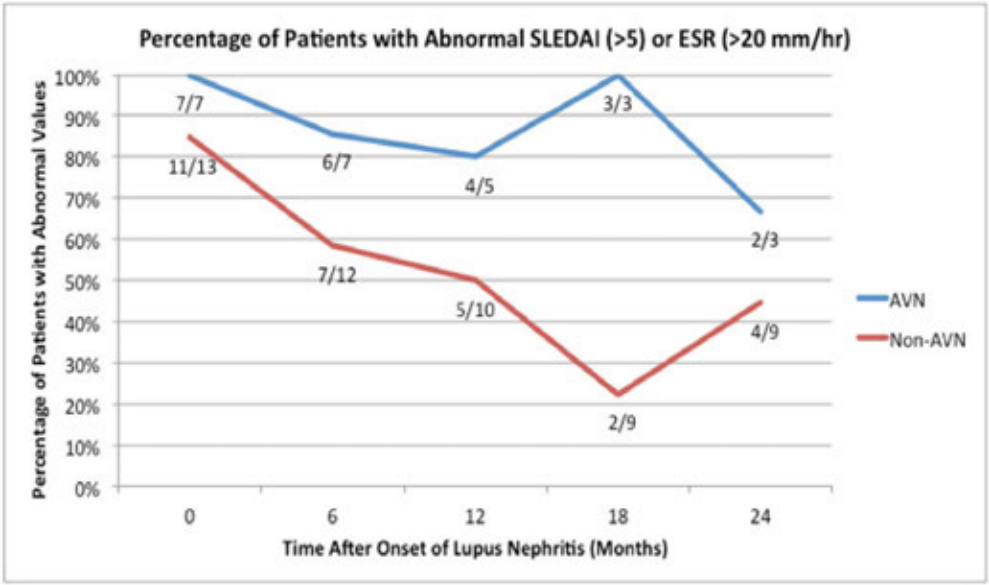

Figure Active disease following onset of lupus nephritis. Patients were censored after developing AVN (AVN patients), or at the end of the study period (non-AVN patients). At each timepoint, the number of patients with active disease (numerator), and total number of patients evaluated (denominator) are shown. Data was missing for 1 non-AVN patient at 18 months.

to 12/31/10 for non-AVN patients. Onset of LN was considered to be time of renal biopsy. For the subanalysis, the minimum age of disease onset for the comparator group was the youngest age of onset in the AVN group (11 years old). We calculated Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) scores for each 6-month timepoint following renal biopsy based upon reported clinical features and laboratory values within 2 months of timepoint. Active disease was considered to be SLEDAI score >5 and/or erythrocyte sedimentation rate (ESR) score >20. Univariate statistics, two-tailed Fisher's exact tests, and independent samples t-tests were performed. P values < 0.05 were considered to be significant.

Results: Of the 101 jSLE patients identified, 49 fulfilled study criteria, 7 (14.0%) of whom developed AVN. AVN patients had an older age of SLE onset, higher prevalence of LN class III, higher prevalence of neurologic or CNS disorder, and higher mean daily oral GC dose than non-AVN patients (Table). No significant differences were found for gender, race, ethnicity, mucocutaneous involvement, cytopenia, autoantibody pattern, Cushingoid habitus, cumulative GC dose, methylprednisolone pulse treatment, or other treatment (Table). To evaluate for additional factors associated with AVN risk, we did a sub-analysis of patients that had adolescent age of SLE onset and LN (adolescent LN)(Figure). Patients were censored after developing AVN (AVN patients), or at the end of the study period (non-AVN patients). Compared to adolescent LN who did not develop AVN, the AVN group were more likely to have persistently elevated SLEDAI scores and/or ESR values for up to 2 years following onset of LN.

Conclusion: We found older age of SLE onset, LN class III, neurologic/CNS disorder, and higher mean daily GC dose were associated with AVN risk. Patients with AVN were more likely to have persistently active disease following onset of LN than LN patients who did not develop AVN. This suggests that higher disease activity at certain times may also contribute to AVN risk in jSLE. Prospective studies are needed to assess these potential risk factors for AVN development and improve our ability to identify and manage at-risk patients.

Abstract Number: 1729

Infections and Mortality in 230 Childhood Lupus Patients: A Single Center Experience from North India

Sumidha Mittal,[1] Manjari Agarwal,[1] and **Sujata Sawhney**[1], [1]Department of pediatric rheumatology, Sir Ganga Ram Hospital, New Delhi, India, New Delhi, India

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Children with systemic lupus erythematosus(cSLE) have more severe disease as compared to adults. Additionally, Asians in their geographic area have high burden of infections as well. There is paucity of data on infections & mortality in cSLE from India. We are a pediatric rheumatology referral center & have studied infections and mortality in cSLE at our unit.

Purpose
1 To study spectrum of infections in cSLE.
2 To study mortality in cSLE.
3 To compare infections & mortality with other centers.

Methods: Records of cSLE patients(onset < 18) from Jan09-Mar19 were reviewed. Data on infections & death collated. Patients who did not attend clinic for ≥1 year were considered lost to follow up & contacted via telephone. Serious infections:leading to hospitalization/ death/ required iv. therapy. Chi square test was applied as needed.

Results: 230 cSLE seen over 10 yrs. Thirty(13 %) infections: 25 girls, 5 boys. Median time to infections from diagnosis: 1.91 yrs. Median SLEDAI-2K at the time of infection:6. Eighty three percent of children with serious infection had SLEDAI >4 whereas 16.7% had SLEDAI < 4 (p=0.009). Patient details-table 1 Medications at the time of infection: 78% on steroids(low dose).Therapy details Table 2. INFECTIONS: Thirty(13%) children had 34 infectious episodes with 39 infections.Twelve (40%) had serious infection in 15 episodes. Ten improved & 2(16.6%) died-one with septicemia, second, invasive aspergillosis(pulmonary).Twenty patients had non-serious infections, commonest herpes zoster(30%).Details in Table 3. MORTALITY: Of 230 cSLE patients,156 were on regular follow up & 74 lost to follow up. Ten(4.3%) deaths in this cohort. Three of 156 patients(2%) who were on regular follow up died: mean follow up 1.91 yrs (0.5-4.25 yrs). Cause of death infections in 2, non infectious in one: Patient 1. Invasive aspergillosis(pulmonary),Patient 2. Adenoviremia with refractory septic shock(defaulted treatment 9 mths). Patient 3. Probable thrombotic thrombocytopenic purpura. Seven(9.4%) of 74 patients who were lost to follow up died: cause not known. Infectious complications(13%) & mortality(4.3%) in this cohort are far superior than those reported from other centers in the subcontinent(infections25%,mortality5-20%)(1,2). Mortality rates at this centre are comparable to other cohorts across the world(1.4-30%)(3-8).

7. Pattaragarn A.et al. J Med Assoc Thai. 2005
8. Ramírez Gómez LA et al. Lupus 2008

Conclusion: Infections in cSLE occurred in 13%, 40% serious infections,6.6 % mortality. Of non serious infections, herpes zoster was most common. Infections occurred predominantly in patients with active disease (SLEDAI >4). Overall mortality was 4.3%. In addition to infections, irregular follow up was major contributor to death. Patients on regular follow up had a lower mortality(2%) when compared to those that were lost to follow up(9.4%). Mortality at this centre is comparable to the west and infection rate is lower than other centers in the region(1).

Table 1. Comparison of demographic, clinical and laboratory characteristics of 130 incident patients with childhood-onset systemic lupus erythematosus from January 1, 2000 and June 30, 2016 by baseline autoimmune cytopenia status

lower prevalence of lupus nephritis (LN) and are a unique disease sub-population. The reason for this association is unclear. Also, it has not been well studied in cSLE which has a higher risk of LN. LN often occurs within 2 years of

cSLE diagnosis. Since autoimmune cytopenias are more common in cSLE and often occur early in this disease, assessing their impact on cSLE phenotype is important. In addition, the effect of treatment for idiopathic autoimmune cytopenias on subsequent cSLE has not previously been explored. Therefore, the objectives of our study were to assess whether in cSLE, autoimmune cytopenias decrease the 2-year risk and severity of LN; to assess associated serologic differences in those with and without autoimmune cytopenias at cSLE diagnosis; the effect of prior immune therapy for autoimmune cytopenias on 2-year risk of LN; and to perform descriptive analyses of these pediatric patients without LN at cSLE diagnosis.

Methods: We conducted a retrospective cohort study of incident cSLE cases at our institution from January 1, 2000 to June 30, 2016. We included patients aged less than 17 years who met American College of Rheumatology and/or Systemic Lupus International Collaborating Clinics classification criteria for systemic lupus erythematosus. We excluded patients diagnosed outside our institution and those with LN at cSLE diagnosis. Our follow-up period was 2 years. We defined autoimmune cytopenias as either autoimmune hemolytic anemia, Coombs positive anemia without hemolysis, immune thrombocytopenia or Evan's syndrome before or at cSLE diagnosis.

Results: We had 130 incident cSLE patients who met our inclusion and exclusion criteria. Of these, 43 (33%) had autoimmune cytopenias (Figure1). At cSLE diagnosis, there was no serologic difference between those with and without autoimmune cytopenias. Those with autoimmune cytopenias had significantly more neuropsychiatric symptoms and higher mean ESR versus those without autoimmune cytopenias. However, they had less arthritis, malar rash and myositis (Table1). 2-year incidence of LN was 12% in our cohort. Patients with autoimmune cytopenias had lower 2-year risk of LN compared to other cSLE patients (7% vs 15%). Of the 16 patients that developed LN, those with autoimmune cytopenias had mostly class V (2 of 3 patients) versus mostly class III and IV in those without autoimmune cytopenias (6 of 12 patients). None of the 13 patients pre-treated for autoimmune cytopenias prior to cSLE diagnosis developed LN.

Conclusion: Patients with autoimmune cytopenias before or at cSLE diagnoses have statistically significant and clinically relevant differences in their presentation from other cSLE patients. Our findings call for further studies on the immunologic and genetic basis of these differences.

Validation of the 2017 Weighted Criteria in Pediatric Systemic Lupus Erythematosus (SLE)

Meiqian Ma,[1] **Joyce Hui-Yuen**,[2] Jane Cerise,[3] Sabah Iqbal,[4] and B. Anne Eberhard[5], [1]Cohen Children's Medical Center Northwell Health, Lake Success, NY, [2]Cohen Children's Medical Center, Northwell Health, New Hyde Park, NY, [3]Feinstein Institute for Medical Research, Manhasset, [4]Hofstra Northwell School of Medicine, Hempstead, [5]Cohen Children's Medical Center Northwell Health, Lake Success

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Different classification criteria for systemic lupus erythematosus (SLE) have been proposed over many years. The most widely used and accepted criteria have been the 1997 ACR criteria. In 2012, the SLICC criteria were published in an attempt to improve clinical relevance of SLE criteria and address concerns with the 1997 ACR criteria. In 2017, a weighted criteria were proposed at the ACR meeting. Our aim was to validate the 2017 weighted criteria for pediatric-onset SLE.

Methods: Retrospective chart review of patients with a clinical diagnosis of SLE diagnosed before the age of 19 years at our tertiary care center between 2003 and 2018. The 2017 weighted, 2012 SLICC, and 1997 ACR classification criteria were applied to these patients, and compared against a gold standard of physician diagnosis. Autoimmune controls were defined as patients who were referred for serologies positive for ANA only but who did not fulfill criteria for diagnosis of SLE at the initial visit, or were diagnosed with another autoimmune disease.

Results: There were 156 patients (82.7% female) who were diagnosed with SLE over the past 15 years. The mean age at diagnosis was 13.1±2.8 years, with 21.8% Asian, 27.6% Black, 26.9% Caucasian, 22.4% Other, and 1.3% Unknown; 23.1% also identified as Hispanic. pSLE patients had a median of 6 of 11 (range 2-9) positive domains and a median of 21 (range 6-41) points by 2017 weighted criteria. The most commonly met domains were antibodies and complement, and the most frequently met clinical criteria were hematologic and synovitis. The sensitivity for the 2017 weighted criteria was 97.4 (CI: 0.94-0.99) and specificity was 98.4 (CI: 0.97-0.99). The median score was 21. The sensitivity for the 2012 SLICC criteria was 97.4 (CI: 0.94-0.99) and specificity was 99.7 (CI: 0.99-1.00). The sensitivity for the 1997 ACR criteria was 87.2 (CI: 0.81-0.92) and specificity was 100 (CI: 0.99-1.00).

Conclusion: The 2017 weighted criteria and the 2012 SLICC were more sensitive, and similarly specific to the 1997 ACR criteria. There were no significant difference in sensitivity and specificity between the 2017 weighted and 2012 SLICC criteria. The sensitivity findings are comparable with the observed sensitivities in the adult population. Analyses are underway to further evaluate the performances of these criteria in a larger cohort of patients.

Evaluating the New 2018 ACR/EULAR SLE Classification in Pediatric Patients

Catherine Strahle,[1] Angela Merritt,[2] Xiaoling Niu,[3] Arjun Mathur,[4] Allen Watts,[2] and Hermine Brunner[5], [1]Univeristy of Cincinnati Medical Center, Cincinnati, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Fudan University, Shanghai, Shanghai, China (People's Republic), [4]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [5]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: The traditional 1997 ACR SLE classification criteria classify a patient as having SLE if 4 of the 11 criteria have been met over time. In comparison, the 2018 ACR/EULAR SLE classification criteria uses a point system (2018-SLE-Score) for 22 clinical and immunologic domains (range:0-51; threshold score for SLE presence:10 points including an antinuclear antibody (ANA) titer of at least 1:80 on HEp-2 cells or an equivalent positive test). We

Table 2: Current cSLE patients that were diagnosed earlier using the 2018 criteria

	Patients that received treatment (n=6)	Patients not receiving treatment (n=3)
Average number of days between 2018 vs 1997 classification criteria	510.33	108.17

investigated the difference of classifying patients with childhood-onset SLE (cSLE) when using the 2018 vs. 1997 SLE criteria. Further, we explored the association between the 2018 Criteria and disease activity in cSLE.

Methods: We reviewed the electronic medical record of ALL patients treated at a tertiary referral center carrying a diagnosis of cSLE, undifferentiated (UCTD) or mixed connective tissue disease (MCTD) from 2008 – 2018, as per the assessment of the treating pediatric rheumatologist. Patient data were reviewed starting from the initial encounter at the medical center, with external data reviewed if available. Disease activity as measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) score was recorded within 1 month of diagnosis, and the most recent SLICC damage index (SDI) score was collected. SLEDAI and SDI scores were compared with the 2018-SLE-Score at initial diagnosis, and the sensitivity of 1997 ACR criteria and 2018 ACR criteria was compared to the current diagnosis of the patient's pediatric rheumatologist.

Table 3: Sensitivity of the 1997 vs 2018 ACR criteria

	Current Diagnosis cSLE	Current Diagnosis Not cSLE
1997 ACR criteria +	93	0
1997 ACR criteria -	18	8

	Current Diagnosis cSLE	Current Diagnosis Not cSLE
2018 ACR criteria +	98	5
2018 ACR criteria -	13	3

Results: Our study consisted of 119 patients diagnosed with cSLE, UCTD, or MCTD: 87 (73.1%) were female with an average age at diagnosis of 14.56 years. These patients were predominantly white 68 (57.1%), black 36 (30.3%), and non-Hispanic 115 (96.6%; see Table 1). Of this cohort, the number of cSLE patients that were classified earlier using the 2018 criteria as compared to the 1997 SLE criteria was 9 out of 109 (8.3%) (See Table 2). The number of UCTD patients that were reclassified as SLE according to the 2018 criteria was 11 out of 33 (33.33%), and the number of MCTD that were reclassified was 4 out of 5 (80%). Our study found that there was neutral correlation between the SDI score and the 2018 SLE Score with a correlation coefficient= 0.28 and a median score of 22 that is associated with a patient SDI score > 1. The median 2018-SLE-Score that was associated with SLEDAI scores ≥ 6 during the first month post diagnosis was 16.5. 2018-SLE-Score and SLEDAI scores were moderately associated (r = 0.631; p= .000946). The sensitivity of the 1997 ACR criteria for our cohort was 83.78% and the 2018 ACR criteria was 88.29%. The 2018 ACR criteria were more sensitive but also produced more false positives (type I error; see Table 3). The median 2018-SLE-score of the 5 false positives was 10.8, close to the lower threshold for SLE presence.

Conclusion: Patients were found to be diagnosed earlier with cSLE using the 2018 ACR criteria among those carrying a current diagnosis of UCTD or MCTD . The 2018 ACR disease criteria proved to be more sensitive in detecting cSLE in our patient population than the 1997 ACR disease criteria. In addition, our study revealed that the 2018 criteria score did not correlate with patient disease damage as indicated by the recent SDI score.

Long-term Renal Survival of Pediatric Onset Lupus Patients in a Population-Based Cohort

Catherine Park,[1] Janet Figueroa,[1] Cristina Drenkard,[1] Laura Plantinga,[1] Larry Greenbaum,[2] and **S Sam Lim** [1], [1]Emory University, Atlanta, GA, [2]Emory University and Children's Healthcare of Atlanta, Atlanta, GA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Compared to adult-onset disease, pediatric-onset SLE (p-SLE) has more severe renal involvement. There are no population-based, long-term follow-up studies of pediatric lupus nephritis (LN) in the United States. This study characterized the long-term risk of end-stage renal disease (ESRD) in p-SLE.

Methods: The Georgia Lupus Registry is a population-based registry supported by the Centers for Disease Control and Prevention of validated SLE patients in 2 counties of Atlanta, Georgia. Trained abstractors reviewed medical

Lupus Nephritis defined as meeting ACR renal criterion and/or kidney biopsy consistent with lupus nephritis

Table 2. End Stage Renal Disease Characteristics of Incident Cases Stratified by Presence or Absence of Baseline Lupus Nephritis				
	Overall	Baseline Lupus Nephritis	No Baseline Lupus Nephritis	P-value
Dialysis, n(%)	6 (100)	3 (50)	3 (50)	1.00
Age at Dialysis in Years, median (25^{th} – 75^{th} percentile)	19.6 (18.0-23.0)	23.0 (17.9-25.0)	19.5 (19.4-19.6)	0.66
Time from SLE Diagnosis to First Dialysis in Months, median (25^{th} – 75^{th} percentile)	50 (33-89)	89 (35-138)	33 (23-65)	0.19
P-value: Wilcoxon Rank-sum test for continuous variables or Chi-squared (Fisher's exact if cell count <5) for categorical variables. Baseline Lupus Nephritis defined as meeting ACR renal criterion and/or kidney biopsy consistent with lupus nephritis in 2002-04				

records to validate incident SLE cases in 2002-2004 (baseline), including p-SLE (diagnosed < 18 years of age) using the following criteria: ≥ 4 ACR classification criteria for SLE or 3 criteria with a final diagnosis of SLE made by a board-certified rheumatologist. Patients were matched to the United States Renal Data System through 2015. ESRD cases were defined as being on dialysis or having received a renal transplant. Wilcoxon rank-sum tests were used to analyze continuous variables and Chi-squared (or Fisher's exact) tests for categorical variables using SAS.

Results: The median age at diagnosis was 14 years (12.1–15.8), 82% were females, and 82% were black. Out of 25 incident cases, 6 (24%) developed ESRD through 2015. There were 14 (56%) who had LN at baseline, from which 3 (21.4%) developed ESRD. The other 3 ESRD cases had no record of renal involvement at baseline. There were no significant differences in baseline ACR criterion between those with and without eventual ESRD, including renal and immunologic parameters. Biopsy findings were not associated with ESRD (Table 1). The median age at first dialysis was 19.6 years, and the median time from SLE diagnosis to dialysis initiation was 50 months. Median age of dialysis initiation was 19.6 years. Those with baseline nephritis were slightly older (23.0 vs. 19.5 years, median) and had much longer time from SLE diagnosis to first dialysis (89 vs. 33 months, median) (Table 2).

Conclusion: This is the first population-based, long-term follow-up of validated p-SLE patients and their renal survival in an incident cohort. More than half had LN at baseline, with most maintaining renal survival during follow-up. However, after 12-14 years of follow-up, nearly a quarter of all p-SLE patients developed ESRD, and there were no associations between baseline clinical or immunologic characteristics and eventual ESRD. Various factors associated with p-SLE and the transition to adult care must be explored to improve long-term outcomes.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: An estimated 10-20% of all patients with systemic lupus erythematosus (SLE) develop clinical disease before the age of 18 years and are therefore classified as juvenile-onset SLE (JSLE). JSLE patients have a higher prevalence of lupus nephritis (LN) compared to adult-onset SLE and decreased long-term survival compared to JSLE patients without LN. We aimed to identify clinical and laboratory predictors of LN in JSLE patients by comparing the baseline characteristics of JSLE patients with and without LN.

Table 1: Baseline characteristics

	Lupus nephritis	Without Lupus nephritis	P value

Belimumab, months	0	0	0.310
Numbers are medians (interquartile ranges) unless otherwise stated. MMF= mycophenolate mofetil. *p< 0.05 is significant			

Methods: This is a single-center retrospective study that included JSLE patients reviewed in our young adult and adolescent clinics after transitioning from paediatric services. All data was analysed descriptively. Mann-Whitney U or Chi-square test were performed to compare the characteristics between patients with and without LN. In addition, we performed uni and multivariate analysis to investigate potential predictor biomarkers for LN.

Results: We identified 134 JSLE patients, 45 (34%) of which had LN. The baseline characteristics are detailed in **table 1.** As expected, the highest dsDNA levels ever were observed in patients with LN (p= 0.022).Patients with LN also had longer disease duration (p= 0.012). The overall clinical manifestations and complications did not differ between JSLE patients with or without LN, except for the prevalence of low bone mineral density (**Table 2**). Factors associated with low bone mineral density in a univariate logistic regression analysis were: the use of mycophenolate mofetil (p= 0.021) and the presence of LN (p= 0.007), while LN also associated with low bone density (p= 0.008) in a multivariate analysis. Skin involvement was the most common clinical manifestation in both JSLE patient groups. Treatment was more aggressive in patients with LN, including the use of cyclophosphamide, mycophenolate and rituximab, but there was no difference regarding the length of the steroid treatment (**Table 3)**. The majority of patients (67%) had one flare of nephritis. For the remaining patients, the number of flares ranged from 2 (13%) to 12 (2.2%). The class of nephritis was reported in 34 out of 45 patients, and focal lupus nephritis (class III) was the most common type (44%) reported. There were no statistically significant differences in the baseline characteristics or treatments among the different classes of LN.

Conclusion: Low bone mineral density in patients with JSLE is well described. However, this is the first study highlighting the association of low bone density with LN independent of total duration of steroid treatment or other clinical manifestations.

Clinical Variables Influencing Prednisone Dosing Towards the Development of Corticosteroid Treatment Algorithms in Pediatric Proliferative Lupus Nephritis

Nathalie Chalhoub,[1] Tingting Qiu,[2] Jianghong Deng,[3] Angela Merritt,[2] Bin Huang,[4] and Hermine Brunner[4], [1]The University of Cincinnati College of Medicine, Cincinnati, OH, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Beijing Children's Hospital, Beijing, China (People's Republic), [4]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

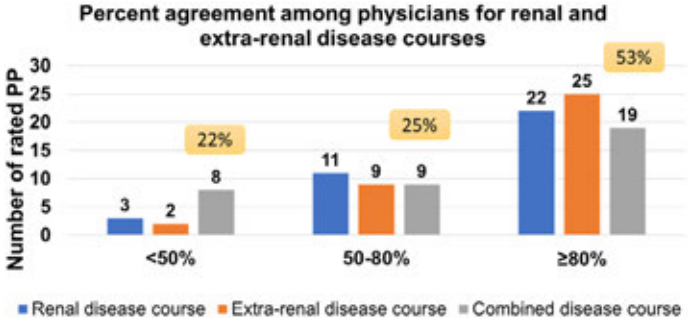
Session Type: Poster Session (Monday)

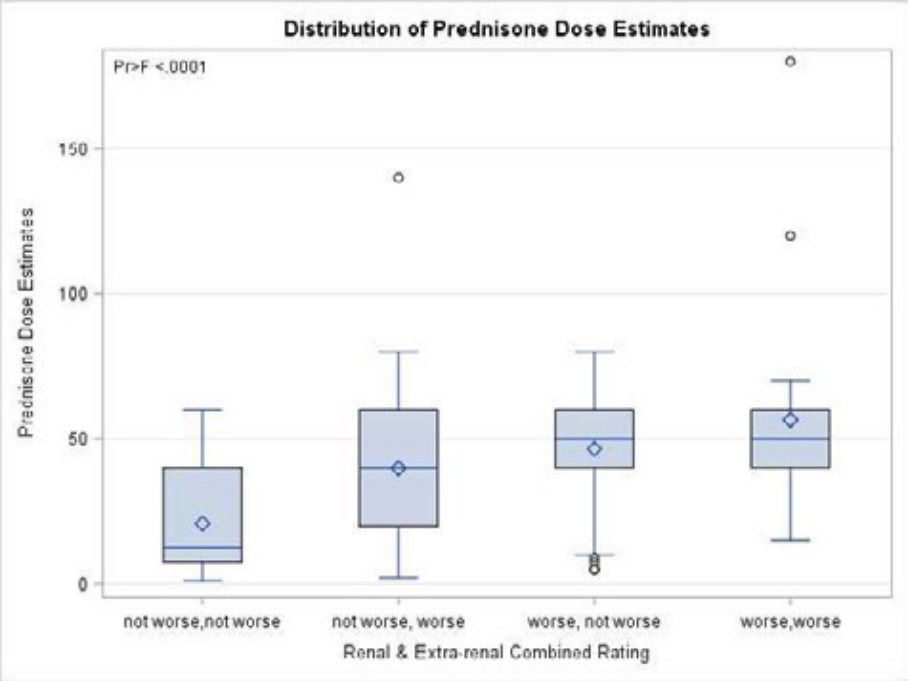
Session Time: 9:00AM–11:00AM

Background/Purpose: Corticosteroids (CS) are the mainstay of childhood-onset systemic lupus erythematosus (cSLE) and proliferative lupus nephritis (LN) therapy. However, there are no widely accepted CS dosing regimens for the treatment of LN. As a first step to establish CS dosing standards for cSLE and proliferative LN, we aimed to identify clinical variables influencing CS dosing with focus on oral prednisone dosing in children with newly diagnosed proliferative LN.

Methods: Consensus formation techniques were used. Patient profiles (PP) were generated using data from the medical records of children with proliferative LN at Cincinnati Children's Hospital Medical Center (CCHMC). Using the extracted data, an online survey was sent to rheumatologists (PP raters) at CCHMC and the University of Cincinnati Medical Center (UCMC) to adjudicate on renal and extra-renal clinical disease courses and estimate prednisone dosing for a given PP. Pearson correlation coefficients were computed to identify clinical variables that correlate with the estimated prednisone doses by PP raters. Mixed model analysis was performed to determine multivariable predictors of the estimated prednisone dose.

Results: Overall, the survey completion rate was 87% with a total of 291 completed PP. Each PP provides information about 2 subsequent visits (V1 and V2). PP survey responses showed a high level of agreement among raters for renal and extra-renal clinical disease courses when categorized into worsening vs non-worsening disease (Figure 1). The estimated prednisone dose by PP raters is found to be most strongly correlated with the pre-visit prednisone dose (r=0.70), and C3 level at V2 (r= -0.56). Proteinuria and SLEDAI-2K scores at V2 show moderate correlations with the estimated prednisone dose (r=0.49, and r=0.48 respectively). Using one-way ANOVA, the highest mean prednisone dose estimates are noted for worsening of the combined renal and extra-renal disease courses (57 ± 34 mg)





Prednisone dose estimate= β0 + β1 * (pre-visit prednisone dose) + β2 * (renal SLEDAI at V2) + β3 * (renal SLEDAI at V2-renal SLEDAI at V1) + β4 * (extrarenal SLEDAI at V2) + β5 * (extrarenal SLEDAI at V2- extrarenal SLEDAI at V1)

Renal and extra-renal clinical disease courses	β0	β1	β2	β3	β4	B5
Worse, Worse	44.87	0.14	0.35	0.77	-0.45	2.71
Not worse, Worse	3.28	0.95	0.35	0.77	-0.45	2.71
Worse, Not worse	17.53	0.70	0.35	0.77	-0.45	2.71
Not worse, Not worse	1.62	0.78	0.35	0.77	-0.45	2.71

and the lowest when the combined disease courses are not worse (21 ± 18 mg) (Figure 2). The pre-visit prednisone dose and the PP ratings of renal, extra-renal and combined renal and extra-renal clinical disease courses are found to be the best predictors of prednisone dose estimates using mixed model analysis (Table 1).

Conclusion: Prednisone dosing regimens in children with newly diagnosed proliferative LN depend on physicians' opinions of renal, extra-renal and the combined clinical disease courses as well as the pre-visit prednisone dose. The identification of clinical variables that correlate with and predict prednisone dosing regimens is key to the future development of CS treatment algorithms in children with proliferative LN.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Systemic lupus erythematosus (SLE) is a chronic inflammatory disease characterized by the presence of various autoantibodies. Unnoticed and progressive cognitive impairment may develop in the course of disease even without overt neuropsychiatric (NP) features. Some authors attributed this mild impairment to the immune-mediated myelinopathy. Evidence exists that myelin oligodendrocyte glycoprotein (MOG) might act as a mediator of interactions between myelin and the immune system. We sought to detect the role of MOG-Ab in neurologic manifestations of childhood-onset SLE (cSLE) and to better delineate the actual grade of cognitive dysfunction by neurocognitive tests in patients without overt NP features (non-NPSLE). Moreover, we aimed to identify the localization of pathology at molecular level by analyzing the presence of any correlation between various metabolite peaks in MR spectroscopy (MRS) and the severity of cognitive dysfunction in non-NPSLE children.

Methods: MOG-Ab levels were studied in all healthy subjects (n=28) and in all patients with (NPSLE =9) and without (non-NPSLE=36) overt neuropsychiatric manifestations. All of the non-NPSLE group and healthy group underwent brain MR and MRS examination. However, only 20 subjects in each group met the MRS imaging standards for evaluation. In the non-NPSLE group, 29 cSLE patients were further evaluated by neurocognitive tests. Sixteen children with non-NPSLE were assessed by both MRS and neurocognitive tests.

Results: The mean age of the SLE patients at study time was 16.22±3.22 years. MOG-Ab was detected positive neither in cSLE nor in healthy group.

In children with non-NPSLE, verbal IQ ranged from 40 to 108 (mean: 79.06±17.66), performance IQ ranged from 42 to 111 (mean: 92.03±16.28), and full-scale IQ ranged from 40 to 106 (mean: 84.31±16.39). There were 15 patients (51%) in non-NPSLE group with a full-scale IQ under 85. There was no significant difference between the non-NPSLE group and healthy subjects in terms of choline, N-aspartic acid (NAA), creatine, NAA/creatine and choline/creatine.

A negative correlation was observed between the NAA/Creatine level of the left frontal white matter in MRS and the stroop test time (measures the ability to shift a perceptual set with changing demands which is a function of the frontal lobes) (p=0.015; r=0.596).

Conclusion: More than a half of our patients in non-NPSLE group were found to have a full-scale IQ under 85. Cognitive impairment may develop insidiously in cSLE children even without any overt symptom or sign. There was no association of MOG-Ab with cSLE, whether neuropsychiatric manifestations present or not. A causal relationship between immune-mediated myelinopathy and neuropsychiatric involvement/cognitive impairment could not be suggested, since there has been no patient with positive MOG-Ab and there has been no difference in choline, cholin/creatine between cSLE patients and healthy subjects. Decrease in the NAA/Creatine level of the left frontal white matter in MRS, which is a finding of neuronal loss, may be used as a first sign of cognitive impairment in patients with cSLE.

Abstract Number: 1737

Systemic Vascular Involvement in Kawasaki Disease: A Single Center Cohort

Monica Bray,[1] Andrea Ramirez,[1] Eyal Muscal,[1] and Marietta De Guzman[2], [1]Baylor College of Medicine, Houston, TX, [2]Baylor College of Medicine/Texas Children's Hospital, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Kawasaki disease is classically thought to be a monophasic disease that primarily targets the coronary arteries. The American Heart Association Kawasaki guidelines note that patient with severe coronary involvement may have peripheral aneurysms but does not specify which patients to image and how to follow peripheral involvement over time. Hoshino et al followed a cohort of twenty patients with peripheral aneurysms and concluded a diameter greater than 10 millimeters was associated with increased risk of development of stenotic lesions. The risks of additional radiation and sedation to image pediatric patients' peripheral vessels must be weighed against the benefit of detection peripheral lesions that may cause hemodynamically significant lesions as the patients grow. In this case series, we discuss the presentation and outcome of seven patients found to have peripheral artery aneurysms at a single institution.

Methods: With approval from the Baylor College of Medicine institutional review board, a retrospective review of the medical records of KD patients identified to have peripheral vessel disease was performed. Data including ethnicity, sex, age at diagnosis, total days of fever, day of illness first intravenous immunoglobulin (IVIG) received, coronary aneurysms, peripheral aneurysm characteristics and medications received were abstracted by chart review.

Results: The median age was 9 months, with range of 2 months to 7 years. Most patients described are Hispanic in ethnicity, with one Asian and one African American. Four of the patients described were male and three were female. The median days of fever was 13 days with range of 6 to 34 days. The median day of illness that first IVIG was

received was day 10 with range from day 4 to day 34. Six of seven patients had giant coronary aneurysms at some point in the disease course. The peripheral arteries involved were axillary, subclavian, aorta, iliac and femoral. All of the patients received intravenous methylprednisolone in addition to the first IVIG. Three of the seven received a second IVIG, five received infliximab, three received anakinra, and three received cyclophosphamide. Median duration

Patient	Age at diagnosis	Sex	Ethnicity	Day of illness at first IVIG	Initial fever duration	Other Treatment	Coronary disease second echo	Coronary disease at 6-week echo	Day of illness of peripheral imaging	Peripheral vascular disease	Duration of follow-up	Coronary outcome at last follow-up
1	2 m	Female	Hispanic	34	34	IVMP	Normal LMCA, LAD and RCA with giant aneurysms	left coronary aneurysm 4.7 mm, smaller RCA aneurysm of 3.7 mm	49	Irregular contours to the lateral portions of the axillary arteries, right femoral artery is more conspicuous than the iliac artery, similar finding to a lesser degree for left femoral artery	1 y + 6 m	No coronary aneurysm
2	3 m	Male	Asian	10	9	IVMP, infliximab	Small aneurysm in LMCA, medium in LAD and RCA	No coronary aneurysm	14	Mild aneurysmal dilation of distal abdominal aorta with significant dilation of bilateral proximal iliac arteries with abrupt transition in caliber to distal common iliacs	2 m	No coronary aneurysm
3	9 m	Male	Hispanic	15	15	IVMP, infliximab, cyclophosphamide	Small aneurysm in LMCA, giant in LAD and RCA	Giant aneurysm of LAD	21	Bilateral aneurysms of internal iliac with bulbous dilation at the common iliac bifurcation	1 y + 5 m	No coronary aneurysm
4	9 m	Male	African-American	11	11	Second IVIG, IVMP	Normal at outside hospital	Fusiform aneurysm of RCA, diffuse dilation of left coronary arteries	39	Focal large aneuryms of the bilateral subclavian and axillary arteries, at least 3 on each side with areas of stenosis in between	8 y + 4 m	No coronary aneurysm
5	1 y + 2 m	Male	Hispanic	6	16	Second IVIG, IVMP, infliximab, anakinra, cyclophosphamide	Dilation only in all 3 vessels	Severe dilation of LMCA and LAD, giant saccular aneurysm of RCA	18	Fusiform aneurysmal dilations in bilateral internal iliac arteries	1 y + 10 m	Giant fusiform aneurysm of the LAD, moderate to large aneurysm in RCA

KD peripheral aneursym table
Individual characterisitics of patients

of follow-up was 18 months with range from 2 months to 8 years. Notably, the youngest four of the seven had no coronary aneurysms observed on echo at last follow-up.

Conclusion: Patients described in this cohort had severe disease and often required aggressive multi-modal immunomodulation due to persistent systemic inflammation and extra-coronary involvement. It is reasonable to obtain peripheral imaging in patients that have severe coronary involvement at the second echo or 6-week echo. It is the practice of our center to obtain such imaging when the patients are undergoing cardiac computed tomography. More research is required to understand the frequency of clinically relevant peripheral changes in patients with Kawasaki disease. From this small case series, young patients under 18 months appear to be at increased risk. It is also important to gather information about the normal size of peripheral vessels for very small body sizes. It is possible that this is an under recognized aspect of the disease.

Abstract Number: 1738

Tracking Whole-Brain Volumetric Trends in Childhood-onset Systemic Lupus Erythematosus Patients in the Clinical Setting by Magnetic Resonance Imaging

Hermine Brunner,[1] Arjun Mathur,[2] William O'Brien,[3] and Mark DiFrancesco[3], [1]Pediatric Rheumatology Collaborative Study Group (PRCSG), Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [2]Division of Rheumatology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: The course of childhood-onset Systemic Lupus Erythematosus (cSLE) commonly includes neurocognitive dysfunction, a manifestation with poor prognosis. It has been challenging to diagnose and categorize CNS involvement in cSLE due to its heterogeneity, especially in early stages. As part of development of a comprehensive patient-centered care approach, we are collecting clinical MRI in cSLE patients, including specialized protocols for CNS lupus assessment. Here, we focus on whole-brain volumetric measures from our protocol. We have previously identified multiple areas of gray matter (GM) loss on structural MRI in cSLE patients with neurocognitive deficits. This work is part of our overall aim to identify clinical neuroimaging signatures for patient-specific categorization of CNS involvement and to allow tracking of disease course and treatment response.

Methods: The first 12 cSLE patients referred for a specialized clinical lupus MRI evaluation were analyzed. Appended to a routine clinical brain MRI protocol were sequences for diffusion-weighted imaging, resting-state functional MRI, and so-called synthetic MRI (synMRI). Using multiple weightings, synMRI provides quantitative mapping of tissue magnetic relaxation properties permitting segmentation of gray matter (GM), white matter (WM), cerebrospinal fluid, and myelin tissue classes. Our initial analyses focused on whole-brain volumes, specifically tissue class volumes as percentage of total intracranial volume (%ICV). We assessed the association of GM, WM, myelin, and parenchyma (GM+WM) as %ICV with SLE severity (SLEDAI) and neurocognitive performance via the Pediatric Automated Neuropsychological Assessment Metrics (PedANAM), principle component (PCA) and Multiscore summary scores.

Results: The 12 cSLE patients included 10 females and 4 African Americans, with mean age 16.6 ± 3.1 years. Mean SLEDAI score at the time of the MRI was 4.8 ± 3.2 (range 0 to 12). On the PedANAM, mean PCA was -2.3 ± 3.8 (range -11.7 to 1.4), and mean Multiscore was 7.3 ± 5.3 (range 1.6 to 21.4). One patient lacked SLEDAI data and another lacked PedANAM indices, resulting in 11 available for correlative analyses. Regression results are summarized in Table 1. Total parenchymal volume as %ICV was found to significantly decrease as the Multiscore index increased (Figure 1). This relationship was driven by decreases in GM (Figure 2) rather than myelin (WM). Lack of correlation between parenchymal volume and PCA or SLEDAI could be at least partly explained by counterbalanced dependencies on GM and myelin volumes. WM and myelin volumes were highly correlated (R^2=0.79) and gave similar outcomes. Age, gender, and race covariates were tested individually and found to not contribute significantly.

Table 1: Correlation of Brain Volumes to Patient Assessment

Brain Tissue Volume[a]	Patient Assessment[c]	coefficient	R^2	p-value
GM	SLEDAI*	0.526	0.297	0.083
	PCA*	0.437	0.290	0.087
	Multiscore**	-0.387	0.428	0.029
Myelin[b]	SLEDAI*	-0.138	0.333	0.063
	PCA**	0.140	0.442	0.026
	Multiscore	0.030	0.039	0.562
Parenchyma	SLEDAI	0.125	0.016	0.712
	PCA	0.090	0.015	0.719
	Multiscore**	-0.350	0.424	0.030

a. expressed as % intracranial volume (ICV), b. Myelin content highly correlated with WM volume, c. PCA and Multiscore are PedANAM indices.
* trending $p < 0.1$, ** $p < 0.05$.

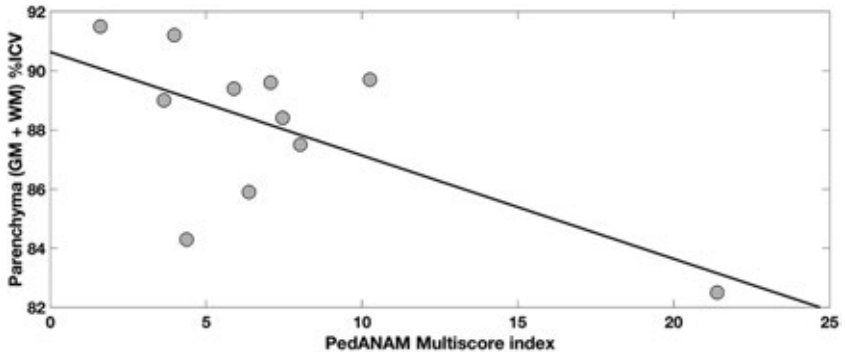

Figure 1 Regression of Total Parenchyma %ICV against PedANAM Multiscore index

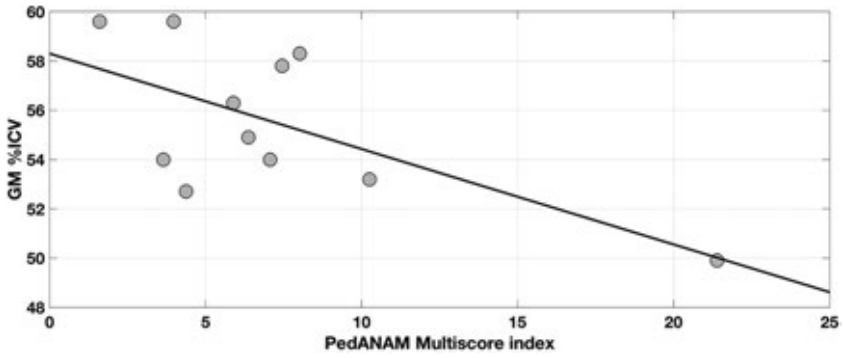

Figure 2 Regression of Total GM %ICV against PedANAM Multiscore

Conclusion: We present the results of whole-brain volumetric analysis in an initial group of cSLE patients referred for clinical brain MRI showing a significant association between neurocognitive measures and brain tissue class volumes. These outcomes motivate continued collection of clinical MRI data using our specialized protocol extensions with the aim of developing specific neuroimaging signatures for SLE for application to patient-centered care.

Kawasaki Disease Shock Syndrome - More Common Than We Think: Our Experience at Chandigarh, North India

Rakesh Kumar,[1] Himanshi Chaudhary,[1] Manphool Singhal,[2] and Surjit Singh[1], [1]Allergy Immunology Unit, Department pf Pediatrics, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India, [2]Department of Radiodiagnosis and Imaging, PGIMER, Chandigarh, India

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Approximately 5% patients with Kawasaki disease (KD) can present with cardiovascular collapse-the KD Shock Syndrome (KDSS). This is an unusual presentation of KD and is often confused with septic shock. As a result, the diagnosis can be easily missed. We report the profile of patients with KDSS from a cohort of 810 KD patients at Pediatric Rheumatology Clinic, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, North-West India.

Methods: 810 children were diagnosed to have KD during the period January 1994-December 2018. Case files of patients with KDSS were retrieved and clinical details recorded.

Results: Of the 810 cases, 28 (15 boys; 13 girls) had hemodynamic instability. Median age at diagnosis was 7 years (range 6 months-14.5 years). All patients required inotropic support. Infection triggered KD was seen in 6 patients and most common organism was *Staphylococcus aureus*. Initial diagnosis of toxic shock syndrome (TSS) had been given in 15 (53.6%) patients. Thrombocytopenia was seen in 12 (42.9%). We were able to perform NT-proBNP in 11 patients and median value was 921.5 (225-9450) pg/mL. First line treatment was intravenous immunoglobulin (IVIg) therapy. Second line therapy was required in 9 patients - infliximab in 3; second dose IVIg in 2 and glucocorticoids in 4. Coronary artery abnormalities (CAAs) were seen in 5 (17.8%) - of these, one had giant aneurysms in left anterior descending coronary artery and right coronary artery. Six had severe myocardial dysfunction secondary to myocarditis. We recorded one death amongst the patients with KDSS.

Conclusion: Both KDSS and TSS can present to the Emergency Room with fever, rash, and shock. Clinical differentiation between the two entities is crucial as management protocols for the 2 conditions are completely different. Delays in recognition of KDSS are not uncommon and may result in avoidable morbidity and occasional mortality. Patients with KDSS are at an increased risk of developing CAAs.

Orange Brown Chromonychia in Kawasaki Disease: A Clinical Sign That Merits Greater Attention

Rakesh Kumar,[1] Ankur Kumar Jindal,[2] Himanshi Chaudhary,[1] and Surjit Singh[1], [1]Allergy Immunology Unit, Department pf Pediatrics, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigarh, India, [2]Allergy Immunology Unit, Department pf Pediatrics, Advanced Pediatrics Centre, Postgraduate Institute of Medical Education and Research, Chandigaarh, India

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Figure 1 A, B: Shows orange brown transverse lines (chromonychia) on all nails in patient 1 C: Chromonychia in patient 2 D: Chromonychia in patient 3 E, F: Orange brown chromonychia in convalescent phase patient 4 G: Peripheral gangrene in patient 5 F: BCG reactivation in patient 1

Background/Purpose: Peripheral signs in Kawasaki disease (KD) include erythematous swelling of hands and feet during acute phase, periungual desquamation and Beau's lines on nails in convalescent phase. Orange–brown discoloration of nails has, however, not been frequently described in KD.

Methods: Although chromonychia was described by Pal et al way back in 2010, we had not been looking prospectively for this sign until very recently. We report 20 patients with KD and orange-brown chromonychia that were seen during the period May 2017 - February 2019.

Results: Median age at diagnosis in these patients was 1.4 years (range:3 months-4 years). Seven patients were below 1 year. Eleven patients developed chromonychia in acute phase of KD, while in 9 this finding was identified in convalescent phase. Associated atypical features that were seen in these patients included BCG reactivation in 2; macrophage activation syndrome in 2; uveitis in 1; peripheral gangrene in 1; bilateral parotidomegaly in 1; HIN1 pneumonia in 1. Ten (50%) children required second line therapy - infliximab in 6; second dose of IVIg in 1; methylprednisolone in 3. Coronary artery abnormalities were seen in 5 patients and 2 had giant aneurysms - one in left main coronary artery; another in left main, left anterior descending and left circumflex coronary arteries.

Conclusion: Transverse orange brown chromonychia is a useful clinical sign in KD and may be seen in both acute and convalescent phases of the disease. This sign can be easily missed if not looked for carefully. It appears to be more common in infants and young children and may be a marker of more severe disease. Presence of this sign may help pediatricians in arriving at a diagnosis of KD, especially in situations where the presentation is incomplete.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Depression and anxiety disorders are common in patients with childhood-onset systemic lupus erythematosus (cSLE). It is unclear if they are due to central nervous system involvement, secondary to a chronic illness or to treatment. We aimed to determine the prevalence and risk factors for clinically elevated depression and anxiety symptoms in a cohort of children with SLE.

Methods: Eligible participants for this cross-sectional study were all patients ≥8 years old who were seen in the cSLE clinic at The Hospital for Sick Children between July 2017 and January 2019, with cSLE or incipient SLE (iSLE) per ACR or SLICC classification criteria. Non-English speakers were excluded. Participants completed demographic questionnaires, the Center for Epidemiologic Studies Childhood Depression Scale (CES-DC), the Screen for Childhood Anxiety Related Disorders (SCARED), and Quality of My Life (QoML) scales. Medical history, SLE features, and medications were collected via chart review and clinic database. Clinically significant depression and anxiety symptoms were indicated by scores of >15 for CES-DC and >25 for SCARED, respectively, and prevalence was compared to general North American population data from the National Comorbidity Survey Study– Adolescent Supplement[1]. Anxiety subtypes were tabulated. CES-DC and SCARED scores were analyzed with Spearman correlation for association with SLEDAI-2K score, disease duration, global and health related QoML score.

Results: There were 51 patients recruited (48 cSLE and 3 iSLE; mean age 14.9 years, SD 2.1), 84.3% females (Table 1). Mean disease duration was 4.6 years (SD 0.4), history of anti-phospholipid antibodies was present in 41.1% (21/51), lupus nephritis 39.2% (20/51), CNS lupus in 21.6% (11/51), and SLEDAI-2K median was 1, IQR (0,2). Mean CES-DC score was 13.5 (SD 9.8), child-reported SCARED score 20.2 (SD 9.9) and parent-reported SCARED score was 13.6 (SD 8.2) (Table 2). Compared with NCS-A population data, cSLE patients had a higher prevalence of clinically significant depression on the CES-DC (29.5% vs 11%; x2=15.2, 95% CI 7.1-22.1, p =0.0001), and anxiety (36.4% vs 12%; x2= 24.5, 95% CI 11.8-39.2; p< 0.0001) by child report. Past history of depression or anxiety was reported in 9.8% (5/43); past or current psychological treatment in 3.9% (2/43), and mood or anxiety disorder in a first degree relative in 35.3% (18/43). CES-DC scores correlated with global QoML score (r=-0.55, p< 0.001), health related QoML

Table 1 Baseline Characteristics and Demographics in a Cohort of Patients with Childhood-Onset Lupus

	Patient-reported	Parent-reported
CES-DC score, mean (SD)	13.5 (9.8)	-
Positive screen for depression on CES-DC, N (%)	13 (29.5)	-
SCARED score, mean (SD)	20.2 (9.9)	13.6 (8.2)
Positive for screen for anxiety on SCARED, N (%)	16 (36.4)	3 (7.8)
Positive for screen anxiety subcategories on SCARED, N (%)		
Panic Somatic	6 (13.6)	1 (2.6)
Generalized Anxiety	17 (38.6)	2 (5.1)
Separation Anxiety	6 (13.6)	1 (2.6)
Social Anxiety	11 (25.0)	5 (12.8)
School Avoidance	4 (9.1)	2 (5.1)

Table 2 Prevalence of Depression and Anxiety Symptoms in a Cohort of Patients with Childhood-Onset Lupus

(-0.35, p=0.03), and both child (0.36, p=0.02) and parent-reported SCARED scores (0.47, p< 0.01). CES-DC and SCARED scores were not correlated with SLEDAI-2K or disease duration (Table 3).

Conclusion: Clinically significant depression and anxiety symptoms are prevalent in our cSLE group (with low rates of prior psychological treatment), and are not associated with current disease severity or treatment duration. Increased depression in cSLE patients is associated with decreased quality of life. Study of the longitudinal relationship between mood disorders and cSLE disease course, and optimal strategies for mental health intervention is warranted.

Silverman,[5] and Linda Hiraki[6], [1]Division of Rheumatology, The Hospital for Sick Children, Toronto, Canada, [2]Fetal Cardiac Program, The Hospital for Sick Children, Toronto, Canada, [3]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Toronto, ON, Canada, [4]Mount Sinai Hospital, University of Toronto, Toronto, Canada, [5]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Translational Medicine, Research Institute, The Hospital for Sick Children, Toronto, Canada, [6]Division of Rheumatology, The Hospital for Sick Children, Department of Paediatrics, University of Toronto, Child Health Evaluative Sciences, Research Institute, The Hospital for Sick Children, Toronto, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Neonatal Lupus Erythematosus (NLE) is an acquired autoimmune disorder of newborns secondary to the transplacental passage of maternal anti-Ro/La antibodies. Prior studies have suggested that children of non-European ancestry have a higher risk of cardiac disease compared to European ancestry children; however, this finding has not been consistently replicated. The risk of non-cardiac NLE manifestations by ethnicity is unknown. We aimed to evaluate the association between ethnicity and NLE risk and NLE manifestations in a large multi-ethnic population.

Methods: We conducted a cohort study of the children seen at the NLE clinic at SickKids. Children born to anti-Ro/La antibody positive mothers in the Greater Toronto Area were referred to the NLE clinic. All data was prospectively entered into a dedicated database. Beginning in 2011, families routinely reported ethnicity (Canada census categories). The cohort consisted of children ≤ 1 year of age seen between January 2011 and April 2019. The NLE patient cohort was divided into European and non-European groups according to the child's ethnicity. Outcomes were NLE and specific NLE manifestations (cardiac, dermatologic, cytopenias, transaminitis and macrocephaly). The frequency of NLE and specific manifestations were compared among ethnic groups with Fisher's exact test. Using separate logistic regression models, we tested the association between ethnicity and 1) NLE risk and 2) specific NLE manifes-

*Effect of Child Non-European Ethnicity (vs. European Ethnicity) tested in multivariate models including covariates: Sex – Male (vs. female), maternal hydroxychloroquine use in pregnancy (taken or not taken), maternal rheumatic disease status (present or absent). Excluded for the analysis without information about pregnancy maternal hydroxychloroquine (n=2). NLE: Neonatal Lupus Erythematosus; OR: Odd Ratio; 95% CI: 95% confidence interval

tations, including covariates for child sex, maternal rheumatic disease status in pregnancy (present or absent) and maternal use of hydroxychloroquine during pregnancy, Bonferroni-corrected p-value < 0.002.

Results: Our study included 326 children born to anti-Ro/La antibody positive mothers. Median follow-up period was 12 months (IQR: 2,24months). We censored 51 children with mixed ethnicity (European and Non-European). The non-European group (59%) was comprised of East Asian (30%), South Asian (25%), African (20%), Latin American (6%) and Mixed non-European ancestry (18%). In comparing European and non-European children, there was no difference in the proportion of NLE in children of European (50%) vs. non-European (54%) ancestry (p 0.46). There was no significant association between Non-European ethnicity and NLE risk and frequency of specific NLE manifestations, in univariate of multi-variable adjusted models (Table 1).

Conclusion: In our large multi-ethnic cohort, there was no statistically significant association between the child's ethnicity and NLE risk, nor specific NLE manifestations. Future analysis will incorporate additional maternal medications during pregnancy and genetic analysis of NLE risk and specific NLE manifestations.

Abstract Number: 1743

Kawasaki Disease: Is Intravenous Immunoglobulin Alone Adequate for the Child with Kawasaki Disease and Coronary Artery Lesions? A Retrospective Study of 65 Children with Kawasaki Disease from a Single North Indian Centre

Manjari Agarwal,[1] Sumidha Mittal,[1] Anju Singh,[1] Neeraj Agarwal,[2] and **Sujata Sawhney** [1], [1]Department of pediatric rheumatology, Sir Ganga Ram Hospital, New Delhi, India, New Delhi, India, [2]Sir Gangaram Hospital, New delhi, India

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Steroid use in Kawasaki disease (KD)is controversial and has swung from contraindicated, to maybe & now perhaps "should be given to all."(1) Currently, standard practice is to use IVIg for *all* children with KD and add upfront steroids to IVIg only for those children who are at risk of non- response to IVIg , if such children can be identified. (2) There is data to support the use of steroids at 2mg/kg/day as an add on to IVIg for the child who is at high risk of non response to the 1st IVIg (3) At our center, over the last 18 years we have observed1. significant no. of children present with CALs & 2. These children often do not respond to 1st dose of IVIG. Thus, from 2017 we changed our practice & added steroids to IVIG as an upfront therapy to children presenting with CALs. We audited our practice & present the data on 65 children with KD.

Purpose
1 To study demographic & clinical profile of children with KD.
2 To study response rate of IVIg
3 To study the difference in response rate (if any) for the child with KD & CALs who was given only IVIg (pre 2017) or IVIg & steroids (post 2017) at first presentation

Methods: All children diagnosed with KD from Jan13 to Apr19 were included. Clinical & demographic details were recorded on predesigned proformas. CALs were defined by z score (Boston) of more than 2 in any coronary artery. Response to IVIG was defined as no fever 36 hours post IVIG completion. Patients given IVIG alone got high dose aspirin, with steroids only low dose was given.SPSS 17.0 was used for analysis.

Results: 65 KD patients reviewed. Clinical & demographic details in Table 1. CALs were present in 31(47.6%) children at diagnosis. Boys had more CALs at onset than girls(p=0.059) IVIg was given to all. Steroids as first line were given to 13(20%): All had CALs. A second dose of IVIG was required by 13(20%). Therapy detailed in Table 2. IVIg alone had a poor response in those presenting with CALs. Addition of steroids to IVIG upfront was associated with significant increase in response in those with CALs(p=0.001) Details in table 3. No factors predicted the response to IVIG alone(age, day of diagnosis, C reactive protein). A higher z score predicted poor response to IVIG alone(p< 0.005), thus reiterating the fact that steroids are helpful in KD patients with CALs Kawasaki shock syndrome was seen in 2(3%) and macrophage activation syndrome in 1(1.5%),requiring high dose methylprednisolone(10-30mg/kg/day). At median follow up of 14 months(IQR 8-15), CALs normalized in 27(86%),5 persisted to have abnormal CALs. (All had giant aneurysms at presentation, Z scores >10). There was no mortality in this cohort.

Table 1: Clinical and demographic characteristics

Characteristics	
Male: females	45:20
Median age at diagnosis(years)	2.77 years (IQR 1.28-5.24)
Median time to diagnosis(days)	9 days (IQR 7-13)
Complete KD	31(48%)
Incomplete KD	31 (48%)
Atypical KD *Seizures* *Jaundice* *Severe hemolytic anemia*	3 (4%) 1 1 1
Clinical features at presentation Oral cavity changes Non purulent bulbar conjunctivitis Rash Extremity changes(acute and subacute) Cervical lymphadenopathy Arthritis Irritability Urethritis BCG scar reactivation	 48 (74%) 48 (74%) 45 (69%) 42 (65%) 29 (45%) 19 (29%) 13 (20%) 3 (5%) 2 (3%)
Complications Kawasaki shock syndrome Macrophage activation syndrome Sensori neural hearing loss	 2(3%) 1(1.5%) 2 (3%)
Median C reactive protein	60.5mg/l(IQR 6-344)
Echocardiographic findings No CAL CAL at time of diagnosis	 33 (51%) 32 (49%)
Z scores(Boston criterion) <2 2-2.4 2.5-5 5.1-10 >10	 33 (51%) 4 (6%) 13 (20%) 9 (14%) 6 (9%)

References

1. Corticosteroids for the treatment of KD in children. Cochrane Review 2017.
2. Diagnosis, Treatment, and Long-Term Management of KD. 2017.
3. Efficacy of IVIG plus prednisolone for prevention of CALs in severe Kawasaki disease (RAISE study): Lancet 2012

Conclusion

1. 47% KD patients presented with CALs.
2. KD with CALs have poor response to IVIG alone vs IVIG with upfront steroids (p=0.001)
3. In addition to the well described scoring systems that predict a poor response to IVIG in the Japanese population, the presence of CALs and risk of non response to IVIG needs further study and replication in cohorts across the world.

Table 2: Details of therapy given per the echocardiographic finding

Patient profile	Upfront therapy with IVIG alone	Upfront therapy with IVIG and IV steroid	No of patients given second IVIG only	No of patients given rescue with steroids AND second dose of IVIG	No of patients given only steroid after 1st IVIG failure and no 2nd dose of IVIG	No of patients given additional anti inflammatory therapy ie Infliximab Azathioprine Cyclosporin Others	No of patients given additional antithrombotic therapy: Clopidegrol Low molecular weight heparin
KD with no CAL N=33	32	1* steroid for MAS	1	2	0	Infliximab 1** (for intolerance to IVIg)	0
KD with any CAL N=32	21	11	4	6	1	Infliximab 2 Azathioprine 1	LMW heparin 6 Clopidogrel 6
KD with CAL z 2-2.4 N=4	4	0	0	1	0	0	0

Serum Sickness Following Rituximab Treatment of Childhood-Onset SLE: A Single Center Experience

Ugo Awa,[1] Marietta De Guzman,[2] and Eyal Muscal[3], [1]Baylor College of Medicine/Texas Children's Hospital, Houston, [2]Baylor College of Medicine/Texas Children's Hospital, Houston, TX, [3]Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset SLE (cSLE) is an autoimmune disease characterized by multiorgan involvement often necessitating a variety of immunolytic and immunomodulatory therapies to achieve adequate disease control and remission. One of these agents, in which effectiveness and safety has been well defined, is Rituximab, a chimeric monoclonal antibody that binds to CD20 expressed on B lymphocytes initiating B cell lysis and subsequent depletion of antibody burden. An uncommon adverse reaction is serum sickness (SS), an immune complex-mediated ("type III") hypersensitivity characterized as a triad of rash, fever and polyarthritis/arthralgias. Though not commonly documented, rituximab-induced SS has been noted in patients with underlying autoimmune diseases, and reported disorders including Sjogren's syndrome, chronic ITP, and rheumatoid arthritis.

Methods: With a local IRB approval, a retrospective review of the electronic health records of patients with cSLE from July 2011 to May 2019 was performed. Patients who developed SS following Rituximab treatment were included. Descriptive analyses were done to ascertain similarities amongst the patients, possible risk factors for the development of SS, response to treatment and use of other anti-CD20 medication use.

Results: At the time of this study, there were 210 cSLE patients being actively followed, 20 patients had received Rituximab as part of treatment. 6 patients developed SS after Rituximab treatment, 1 was excluded due to incomplete record. Of the 5 patients, 4 were female. The mean age of patients was 16.6 years old. All 5 were Hispanic. Mean disease duration was 3.8 years (Range: 2 to 6 years). Mean SLEDAI score at time of Rituximab treatment was 6.6 (Range: 4 to 11); 2 patients had polyclonal hypergammaglobulinemia and cSLE treatment included steroids (4/5), MMF (2/5), hydroxychloroquine (5/5). 3 patients had history of prior rituximab treatment with a mean dose of 858 mg/dose (575mg/dose to 1000 mg/dose) and mean interval from previous to most recent dose of 17.3 months. Mean time for drug exposure to SS manifestation was 9.8 days (Range: 7-13 days). Manifestations of SS included fever (4/5), acute polyarthritis (4/5), and rash (5/5). Anti-rituximab antibody was not determined at time of SS diagnosis. All patients required increased dose of glucocorticoids. 2 required hospitalization. 2 patients received and tolerated alternative B-cell depletion (ofatumumab).

Conclusion: We described a small cohort of cSLE who developed SS following rituximab treatment. It is important to recognize this adverse reaction as SS manifestations mimic that of active SLE features.

Exercise Improves Arterial Inflammation in Childhood-onset Takayasu Arteritis: A Randomized Controlled Trial

Camilla Astley,[1] Gleice Clemente,[2] Maria Teresa Terreri,[3] Camila Carneiro,[4] Marcos lima,[4] Carlos Buchpiguel,[4] Hilton Leão Filho,[4] Fernanda Lima,[1] Ana Lúcia Sá-Pinto,[1] Clovis Silva,[5] Nadia Aikawa,[6] Saulo Gil,[1] Hamilton Roschel,[1] Rosa Pereira,[7] and Bruno Gualano[1], [1]Division of Rheumatology, Hospital das Clinicas da Faculdade de Medicina da Universidade de São Paulo, sao paulo, Sao Paulo, Brazil, [2]ivision of Paediatric Rheumatology, Departament of Paediatrics, Universidade Federal de São Paulo, sao paulo, Sao Paulo, Brazil, [3]Pediatric Rheumatology Unit, Universidade Federal de São Paulo, São Paulo, Brazil, [4]Nuclear Medicine Institute, Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, sao paulo, Sao Paulo, Brazil, [5]Pediatric Rheumatology Unit, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Brazil., Sao Paulo, Brazil, [6]Rheumatology Division, Hospital das Clinicas, Faculdade de Medicina da Universidade de Sao Paulo (HCFMUSP), Sao Paulo, Brazil., Sao Paulo, Brazil, [7]Faculdade de Medicina da Universidade de Sao Paulo, São Paulo, Sao Paulo, Brazil

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Childhood-onset Takayasu Arteritis (c-TA) is a rare primary systemic vasculitis that affects aorta and its major branches. This condition is associated with reduced wall thickness, stenosis, hypertension and high cardiovascular risk. In addition, these patients may display exacerbated inflammation and poor physical fitness. Evidence-based treatment in c-TA is limited by the absence of randomized controlled trials. Exercise training is a non-pharmacological strategy able to counteract several adverse effects related to c-TA, such as increased inflammation. We investigated the effects of an exercise-training program on arterial inflammation and pro- and anti- inflammatory cytokines in patients with c-TA.

Methods: This was a 3-center, prospective, randomized controlled trial (clinical.trials.gov: NCT03494062). Patients diagnosed with c-TA Takayasu Arteritis were randomly assigned (2:1) into the exercise training group (ET) or the non-exercised control group (CTRL). ET underwent a 12-week, 3-times-a-week, home-based exercises for the major muscle groups (squats, push-ups, sit-ups, lunges and front planks), with the support of an illustrated booklet and

video, whereas CTRL received standard of care. A member of the research team (C.A.) monitored the compliance and adequacy to the exercises every two weeks. The exercise protocol comprised 3-4 sets of 8-12 repetitions maximum (RM), with a 60 to 90-second rest interval between sets and exercises. Adherence, adverse events, or signs and symptoms were self-reported. Before (PRE) and after 12 weeks of intervention (POST), the arterial inflammation (standard uptake value [SUV_{max}], as assessed by [^{18}F] fluoro-deoxy-D-glucose positron emission tomography/magnetic resonance imaging [FDG-PET/MRI]), inflammatory cytokines (as assessed by CRP, ESR, IFN-γ, IL-10, IL-12p70, IL-1ra, IL-1β, IL-6 and TNF-α) and clinical scores were evaluated. A complete-case analysis was conducted using delta scores (POST - PRE) and between-group differences were tested using unpaired T-tests.

Results: Twelve patients were assigned into ET and 5 into CTRL. Three individuals from ET dropped out for personal reasons. Adherence to exercise training was 93 ± 0.06%. It was not reported any adverse events. Baseline characteristics were similar between groups ($p > 0.05$, table 1). Importantly, ET showed higher decreases in SUV_{max} values in the ascending aorta (-1.37 ± 0.38 *vs* -0.9 ± 0.42, $p = 0.08$), aortic arch (-1.13 ± 0.21 *vs* -0.63 ± 0.19, $p < 0.01$), ab-

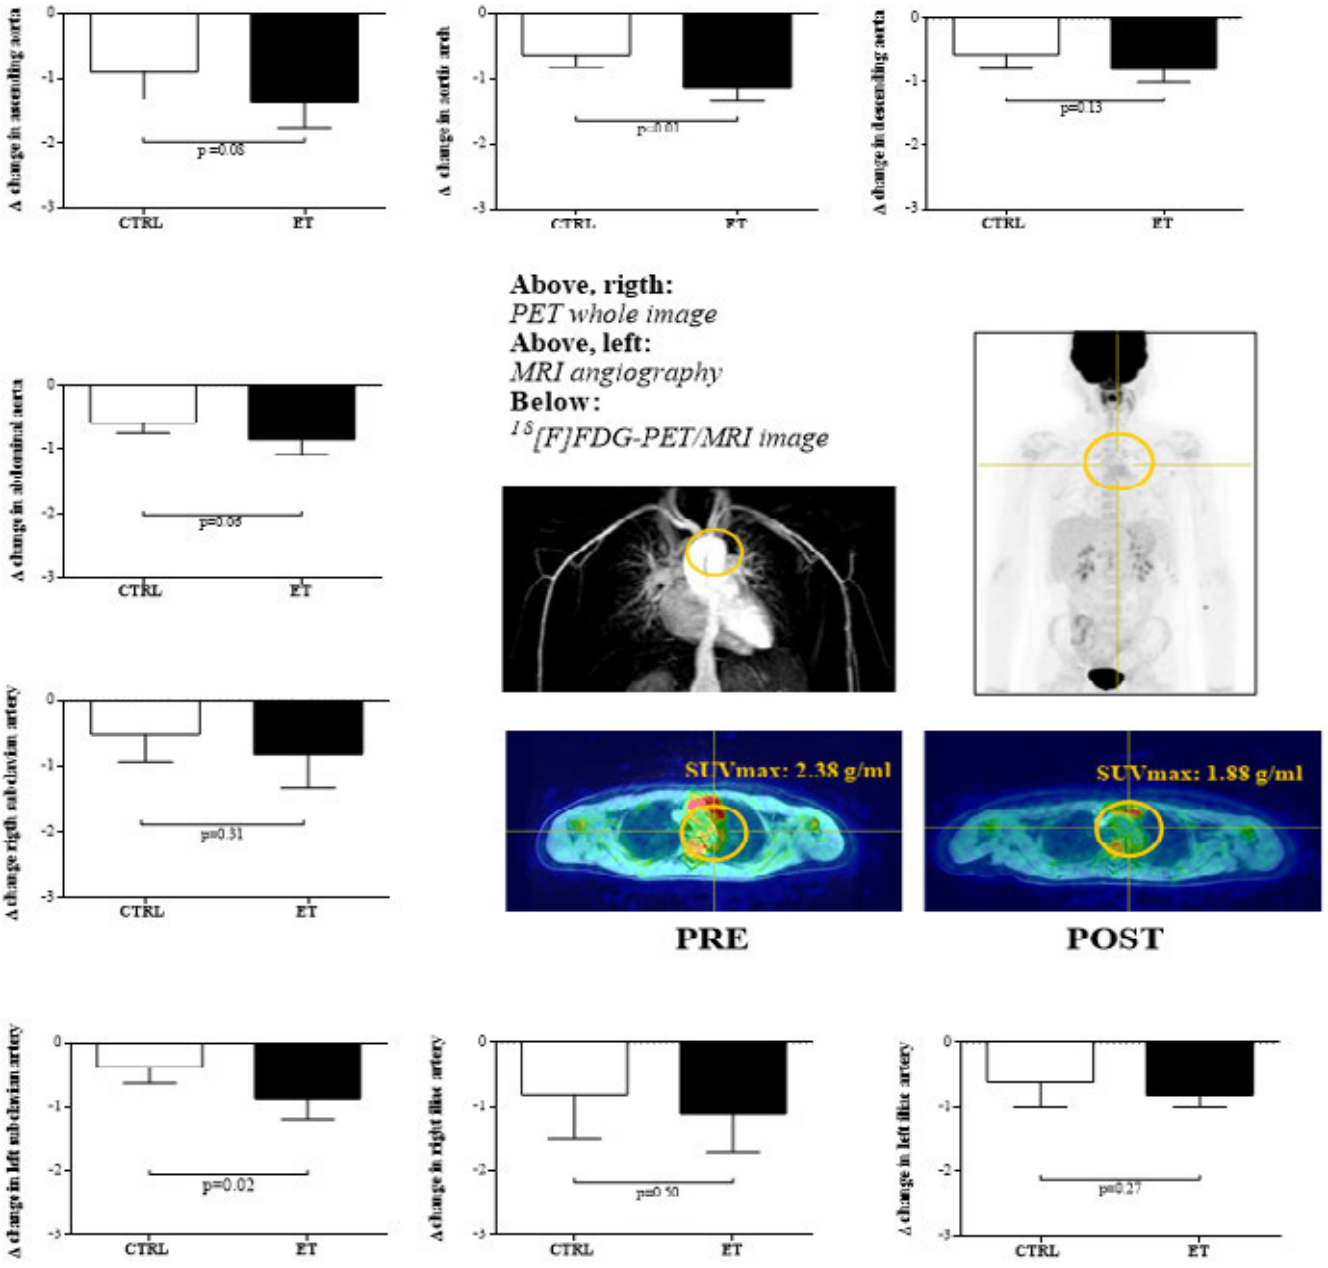

Figure 1. Changes in arterial inflammation (SUVmax), as assessed by [18F] fluoro-deoxy-D-glucose positron emission tomography/magnetic resonance imaging (FDG-PET/MRI), following 12 weeks of a home-based, exercise training program. A 12-year-old child SUVmax in the aortic arch pre (2.38 g/ml) and post exercise intervention (1.88 g/ml) (below).

dominal aorta (-0.85 ± 0.23 *vs* -0.59 ± 0.16, p = 0.06) and, left subclavian artery (-0.85 ± 0.33 *vs* -0.37 ± 0.24, p = 0.02) (Figure 1) *vs* CTRL. Inflammatory cytokines and clinical parameters did not change between groups (all p > 0.05).

Conclusion: In this first randomized controlled trial involving c-TA patients, a 12-week, home-based exercise training program was effective in reducing arterial inflammation in this disease. These findings provide evidence that exercise could be incorporated into the treatment routine of c-TA patients in order to mitigate their cardiovascular risk.

Identifying Additional Risk Factors for Arterial and Venous Thrombosis Among Pediatric Antiphospholipid Antibodies Carriers

Elizabeth Sloan,[1] Tracey Wright,[1] and Yu Zuo[2], [1]University of Texas Southwestern, Texas Scottish Rite Hospital for Children, Children's Health, Dallas, TX, [2]University of Texas Southwestern, Dallas, TX

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Antiphospholipid antibodies (aPL) have been extensively reported in children; however, research on thrombotic risks associated with aPL among pediatric patients is scarce. Positive aPL are not uncommon in pediatric connective tissue diseases, but identification and management of these patients is challenging due to lack of validated criteria and a paucity of data. Misconceptions surrounding clinically significant aPL profiles may lead to missed diagnoses or incorrect diagnoses of APS, and many asymptomatic patients are managed with prophylactic ASA without a clear understanding of risk factors for thrombosis. Our aim is to identify additional risk factors for thrombosis in a unique cohort of pediatric aPL positive carriers.

Methods: Retrospective chart review was performed on 491 pediatric patients with connective tissue diseases seen in our institution from 2001 to 2019. Patients without persistently moderate to high titer aPL at least 12 weeks apart

Characteristics	aPL+ Patients with Thrombosis (n=14)	Percent	aPL+ Asymptomatic Patients (n=57)	Percent
Female	11	78.6%	51	89.5%
Ethnicity/Race				
Hispanic	9	64.3%	31	54.4%
African American	3	21.4%	17	29.8%
Caucasian	1	7.1%	6	10.5%
Asian	1	7.1%	2	3.5%
Native American	0	0%	1	1.8%
Age in years (mean ± SD)				
At diagnosis of CTD	12.7 ± 3.3		12.7 ± 2.5	
At first + aPL test	13.3 ± 2.6		13.3 ± 2.5	
At last follow-up visit	16.1 ± 2.5		17.2 ± 1.7	
Average duration of follow-up (years)	3.5 ± 2.2		4.5 ± 2.6	
Arterial Thrombosis	4	28.6%		
Venous Thrombosis	11	78.6%		
Recurrent Thrombosis	2	14.3%		
aCL IgG/IgM/IgA	8	57.1%	25	43.9%
aβ2GPI IgG/IgM/IgA	8	57.1%	41	71.9%
Lupus Anticoagulant	12	85.7%	35	61.4%
Triple positive	4	28.6%	14	24.6%

CTD: connective tissue diseases. aPL: antiphospholipid antibodies. aCL: Anti-cardiolipin. aβ2GPI: Anti-β2 Glycoprotein-I. Triple positive: positive aCL, aβ2GPI, and Lupus anticoagulant.

Table 1. Demographic summary of 71 aPL positive pediatric patients

were excluded. Univariate analysis was performed to evaluate the relationship between different risk factors and arterial/venous thrombosis.

Results: Seventy-one aPL positive children with underlying connective tissue diseases are included in this cohort (*Table 1*). The majority (87%) are female and of Hispanic ethnicity (56%). Mean age of the cohort at the diagnosis of connective tissue disease is 12.7 (SD 2.6) years, and mean age of first positive aPL is 13.3 (SD 2.5) years. Average length of follow-up is 4.3 (SD 2.5) years. Four (5.6%) patients had arterial thrombosis, and 11 (15.5%) had venous thrombosis. Fifty-seven (80.3%) patients did not have any thromboembolic events. Among traditional risk factors and signs of endothelial injury, only Raynaud's phenomena demonstrated significant association with arterial thrombosis (OR=8.4, 95%CI 1.13 – 111, P=0.039), and hypertension or antihypertensive use demonstrated significant association with venous thrombosis (OR=8.387, 95%CI 1.2 – 94, P=0.02) (*Figure 1*). Of the asymptomatic patients, forty-six (81%) were placed on long-term low dose ASA for primary thrombosis prophylaxis. Our investigation also identified several real-world clinical challenges, including variations in reference ranges for aPL studies over time and between reporting laboratories, inconsistencies in interpretation of aPL profiles by providers, over-identification of positive aPL, and subsequent over-utilization of prophylactic ASA without sufficient supporting evidence.

Conclusion: Data from our cohort suggests that Raynaud's phenomenon is a potential predictor of arterial thrombosis and the presence of hypertension or anti-hypertensive medication use is a potential predictor of venous thrombosis in aPL positive pediatric carriers. Due to lack of validated criteria and standardized clinical guidelines specifically for pediatric patients, identification and subsequent management of aPL positivity in this population remains problematic for clinicians. Further studies investigating pediatric aPL profiles and risk factors for development of thrombosis are needed to help guide clinicians in caring for these challenging patients.

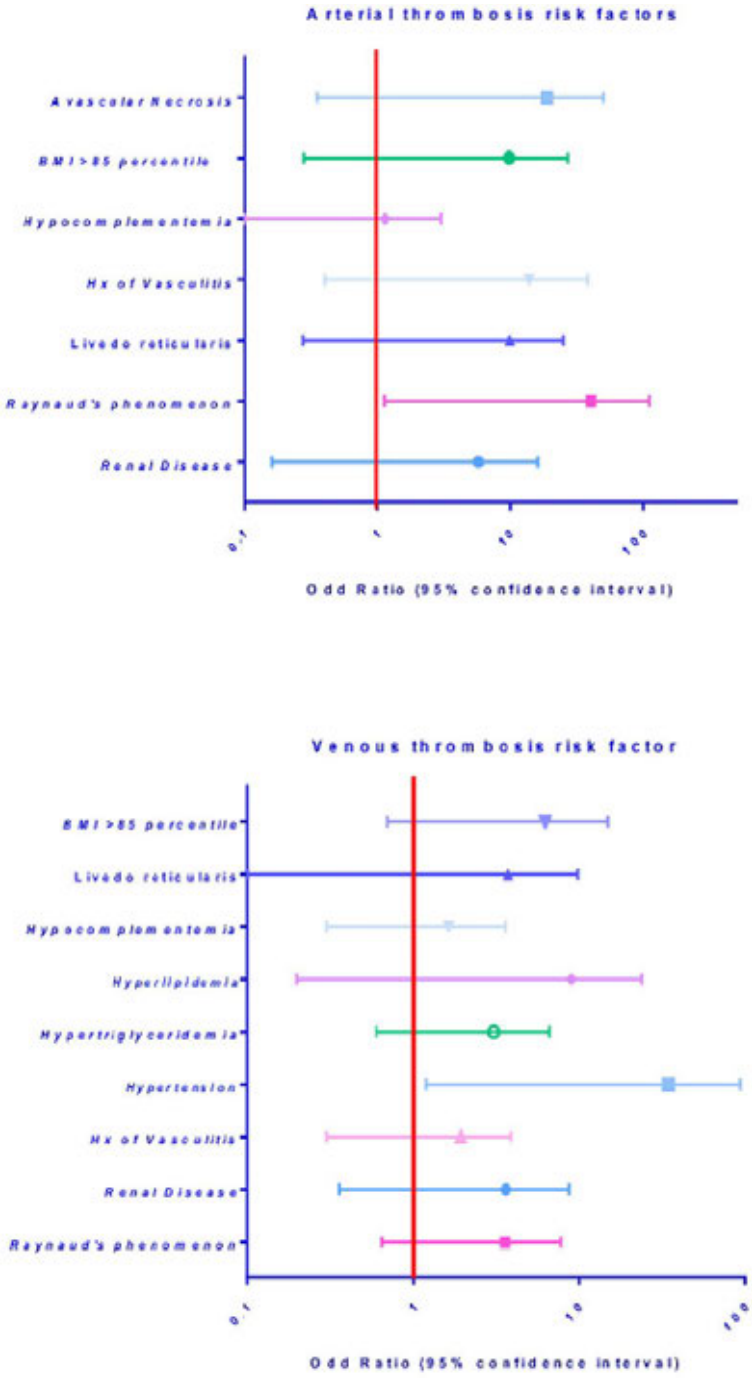

Figure 1. Logistic regression analyses for arterial thrombosis and venous thrombosis risk. Forest plots showing the results of univariate analysis for "second hit" arterial thrombosis risk (a) and venous thrombosis risk (b).

Practice Variations in Treatment of Pediatric Anti-neutrophil Cytoplasmic Antibody (ANCA)-associated Vasculitis (AAV) with Renal Disease

Audrea Chen,[1] Cherry Mammen,[1] Jaime Guzman,[2] David Cabral,[2] and Kimberly Morishita[1], [1]BC Children's Hospital, Vancouver, BC, Canada, [2]University of British Columbia, Vancouver, BC, Canada

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Renal disease is common in ANCA-associated vasculitis (AAV) and one of the goals of early treatment is to maximize renal function recovery. Corticosteroids are a cornerstone of induction treatment. However, the optimal dosing and weaning schedule is not known. The objectives of this study are to: 1) Describe practice variation in corticosteroid use in treatment of pediatric AAV with renal disease; 2) Assess for associations between baseline patient characteristics and corticosteroid dose at the time of diagnosis; and 3) Explore whether any variation in corticosteroid use at diagnosis is associated with outcomes at 12 months.

Methods: Patient data was obtained from an international pediatric vasculitis registry – PedVas. Patients followed for at least 12 months with AAV and biopsy confirmed pauci-immune glomerulonephritis were included. Patients' baseline characteristics such as dialysis requirement, glomerular filtration rate (GFR) and pediatric vasculitis activity score (PVAS) were examined for associations with the oral corticosteroid dose initiated at diagnosis. Outcomes ana-

Variables	Total	HiCS (>1.5mg/kg/day)	ModCS (0.5-1.5 mg/kg/day)	P-value

Table 1 Baseline characteristics and association with corticosteroid dosing at diagnosis

Variables	HiCS (>1.5mg/kg/day)	ModCS (0.5-1.5 mg/kg/day)	P-value
GFR (12 months)			0.882
- *>60*	25 (66%)	37 (66%)	
- *15-59*	8 (21%)	10 (18%)	
- *<15*	5 (13%)	9 (16%)	
Oral corticosteroid dose at 12 months			0.435
- *< 0.2mg/kg/day*	28 (68%)	43 (75%)	

Table 2 12 month outcomes and association with corticosteroid dosing at diagnosis

lyzed for association with oral corticosteroid dose at diagnosis included GFR at 12 months, and the ability to wean to < 0.2mg/kg/day of oral corticosteroid. Statistical analysis was conducted using the Chi-squared test for proportions and the Mann-Whitney U Test.

Results: 106 patients were included in total. 83 (78%) patients were diagnosed with GPA, and 24 (21%) had MPA. 28 (26%) patients required dialysis at diagnosis, and 36 (34%) received plasmapheresis as part of induction treatment. 41 (38.7%) received >1.5mg/kg/day of oral corticosteroid (Hi-CS) and 57 (53.8%) received 0.5-1.5mg/kg/day of oral corticosteroid (Mod-CS) at diagnosis. No significant difference was found between oral CS dosing groups with regards to baseline patient characteristics (Table 1). Additionally, no associations were found between oral corticosteroid dose at diagnosis and 12 month outcomes such as renal function (Table 2).

Conclusion: Corticosteroid use in pediatric AAV with renal disease is highly variable, and with no associations between baseline patient characteristics and oral corticosteroid dose, it is unclear what guides physicians' use of corticosteroid at diagnosis. Furthermore, the results suggest that patient outcomes at 12 months were not improved for those treated with higher oral corticosteroid doses at diagnosis. This study highlights the need for prospective studies to further explore optimal corticosteroid dosing strategies in pediatric AAV.

Incidence of Retinopathy in Individuals Who Initiated Hydroxychloroquine Therapy During Childhood

Sara Patrizi,[1] Douglas Stram,[2] Miranda Weintraub,[3] and Alexandra Aminoff[1], [1]Kaiser Permanente, Department of Pediatrics, Oakland, [2]Kaiser Permanente Northern California, Division of Research, Oakland, [3]Kaiser Permanente, Department of Graduate Medical Education, Oakland

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ), a medication used to treat Systemic Lupus Erythematosus (SLE), Discoid Lupus Erythematosus (DLE) and Sjogren's Syndrome (SS), reduces disease flare-ups, organ damage, and increases rates of remission[1,2]. While HCQ is relatively safe, recent research among adults has shown its long-term use to be associated with an increased risk of developing retinopathy[2]. The link between HCQ exposure during

childhood and the incidence of retinopathy has not been established. This study describes a contemporary cohort of pediatric patients who initiated treatment with HCQ for SLE, DLE or SS prior to their 18th birthday and assesses the incidence of retinopathy.

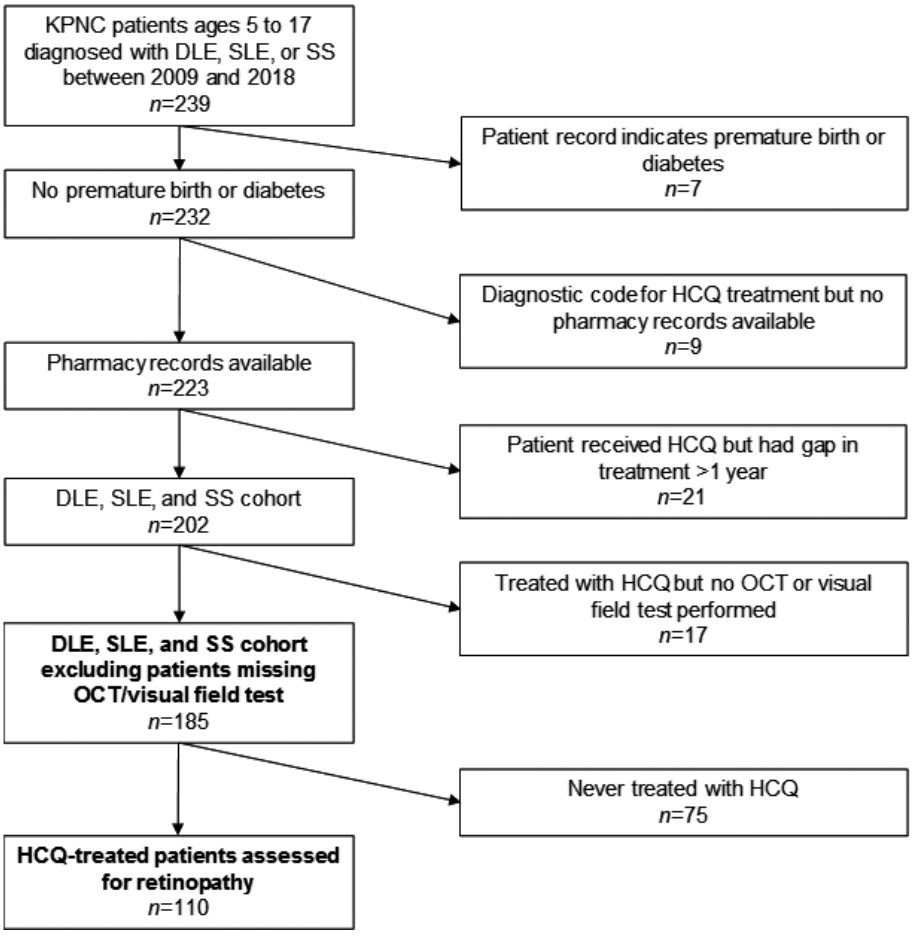

Figure 1 Flow chart of study identification, inclusion and exclusion criteria.

†Retinopathy only assessed by OCT/VFT in patients who received HCQ treatment

Table 1 Demographic and clinical characteristics by HCQ treatment duration.

Methods: This is a retrospective descriptive analysis of patients receiving treatment within Kaiser Permanente Northern California (KPNC), who were diagnosed with SLE, DLE or SS between the ages of 5-17 years, and did not have evidence of premature birth or diabetes. Demographic information, as well as the age at diagnosis, were obtained from the electronic health record. The pharmacy database was queried for HCQ use. Chart review was performed to ensure patients met the American College of Rheumatology criteria for SLE and DLE, and the proposed criteria for juvenile SS. Further chart review was performed to determine evidence of retinopathy, defined by vision loss on the Humphrey Visual Field testing (HVF) and/or retinal thinning on the Spectral-domain optical coherence test (SD-OCT). Of the 232 patients who met the initial criteria, we further excluded those with no pharmacy record (n=9), those with treatment gaps greater than one year (n=21) and those with no evidence of a completed HVF or SD-OCT (n=17), resulting in a final study cohort of 185 patients and 110 patients with continuous HCQ exposure (Figure 1).

Results: The 185 individuals who met the initial study criteria had a mean age at diagnosis of 13.8 years (standard deviation: 3.01) and 80.0% were female. Of this cohort, 14.1% identified as non-Hispanic white, 18.9% black, 34.6% Hispanic non-black, 22.7% Asian/Pacific Islander and for 9.7%, the race/ethnicity was unknown. There were 75 patients who were never treated with HCQ, 63 who received less than three years of treatment, and 47 who were treated for three or more years (Table 1). HCQ treatment duration ranged from 0.1 to 9.6 years, with a median of 2.5 years and an interquartile range between 1.5 and 5.5 years. There were no demographic variations according to HCQ treatment duration. No patients developed retinopathy.

Conclusion: To the best of our knowledge, this is the first study to evaluate the incidence of retinopathy in a pediatric population exposed to HCQ for the treatment of SLE, DLE and SS. None of the patients developed retinopathy. Establishing a low risk of retinopathy for children taking HCQ is clinically relevant for treatment discussions in pediatric rheumatology, between providers, patients, and families. Further studies are needed to investigate risk in longer-term use.

Abstract Number: 1749

Improving Eye Screening Among Pediatric Rheumatology Patients Receiving Hydroxychloroquine: Experience of a Quaternary Care Center

Ohoud AlAhmed,[1] Amanda Way,[2] Shoghik akoghlanian,[2] Fatima Barbar-Smiley,[2] Stephanie Lemle,[2] Darby MacDonald,[2] Kelly Wise,[2] Stacy Ardoin,[2] and Vidya Sivaraman[3], [1]Nationwide Children's Hospital, Columbu, OH, [2]Nationwide Children's Hospital, Columbus, OH, [3]Nationwide Children's Hospital and The Ohio State University, Columbus, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Hydroxychloroquine (HCQ) is commonly used in the treatment of autoimmune diseases. However, its use is associated with progressive irreversible retinal damage and vision loss with an estimated overall prevalence of 7.5%. In 2016, the American Academy of Ophthalmology (AAO) published revised recommendations on eye screening for patients receiving HCQ. Only 65% of rheumatology patients receiving HCQ at Nationwide Children's Hospital (NCH) were screened in concordance with these recommendations. We developed a quality improve-

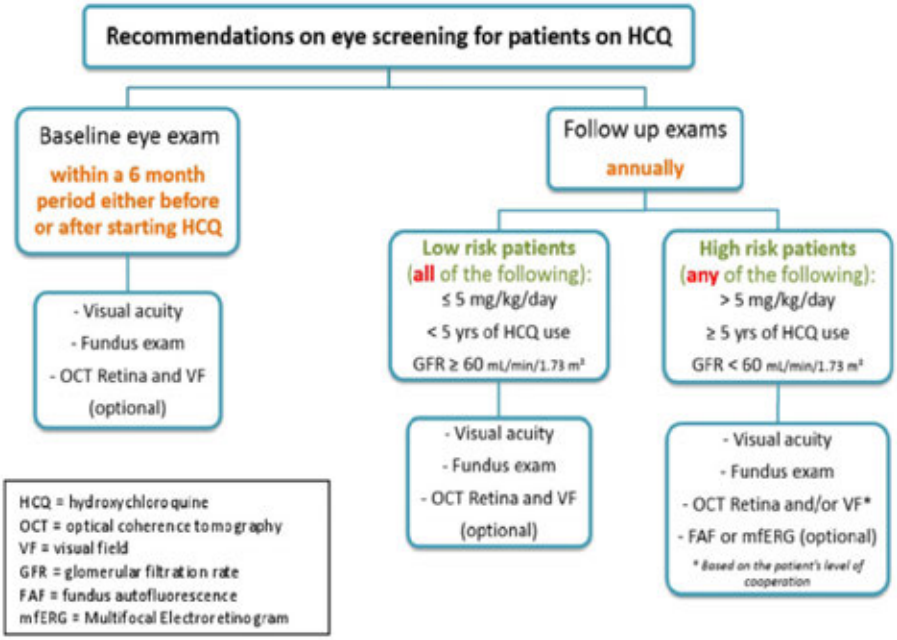

Figure 1 Consensus guidelines and risk-level-based algorithm based on the 2016 revision of the American Academy of Ophthalmology eye screening recommendations for patients receiving hydroxychloroquine

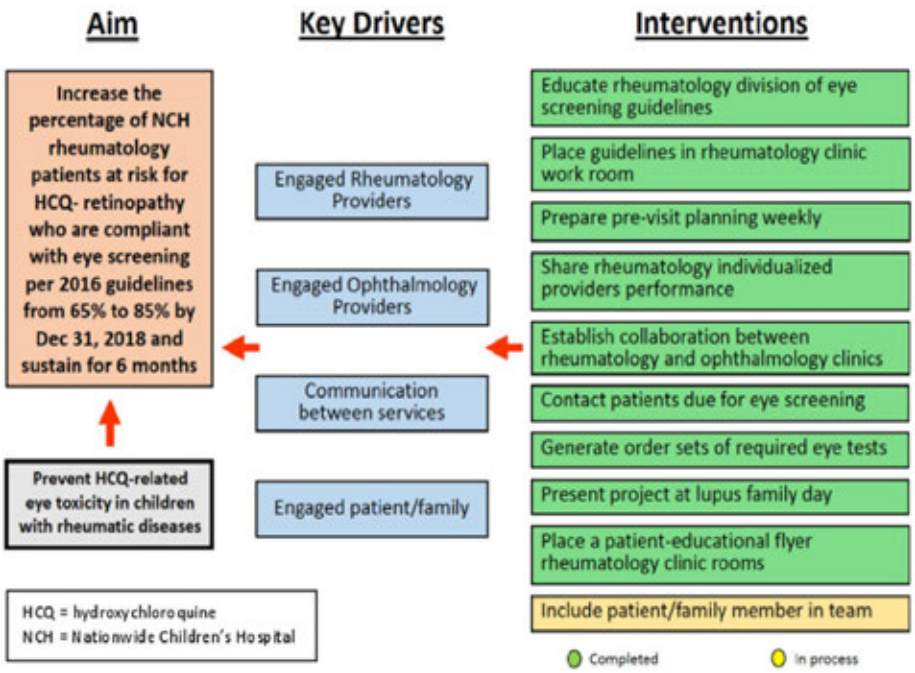

Figure 2 Key Driver Diagram showing the aim, key drivers and interventions to improve compliance with eye screening recommendations for rheumatology patients receiving hydroxychloroquine.

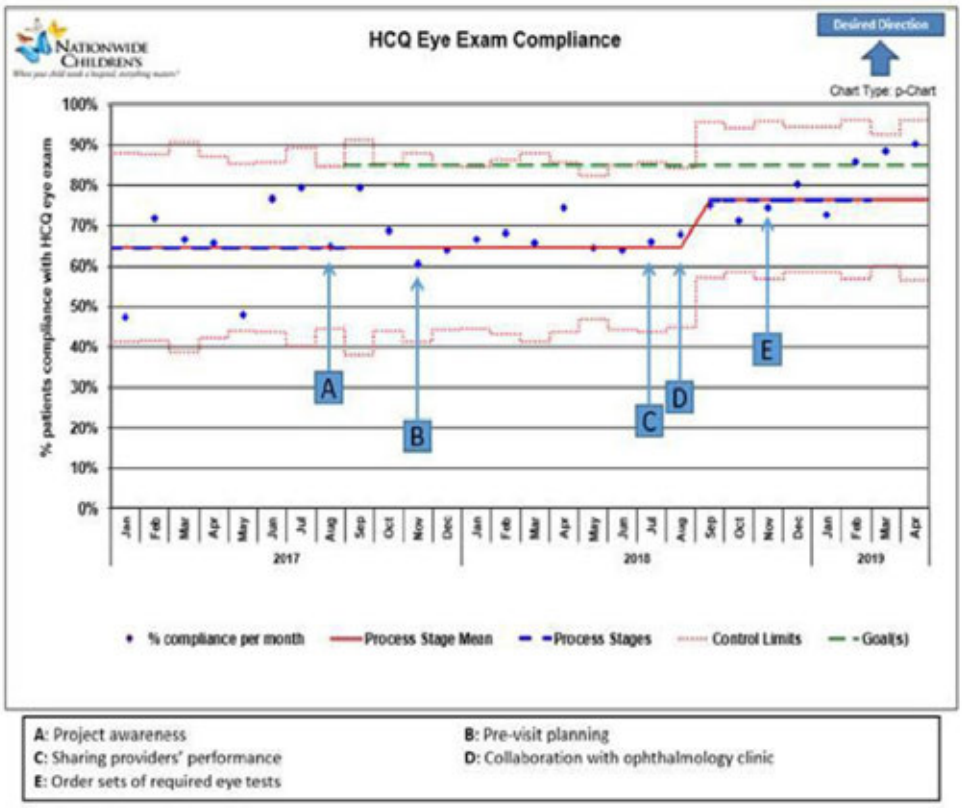

Figure 3 P-chart showing compliance with eye screening recommendations for rheumatology patients receiving hydroxychloroquine (HCQ) before and after the introduction of this quality improvement project.

ment (QI) initiative aiming to increase eye screening compliance in rheumatology clinic patients receiving HCQ from 65% to 85% by December 31, 2018 and to sustain the improvement for 6 months.

Methods: Our baseline analysis included patients receiving HCQ and were followed at NCH rheumatology clinic from 1/01/2017 to 8/31/2017. We formed a multidisciplinary team of rheumatologists, ophthalmologists, a clinical pharmacist, clinic nurses, a quality data technician and administrative staff. We developed consensus eye screening guidelines with risk-level stratification based on the AAO recommendations (Figure 1). A key driver diagram was utilized to identify barriers to compliance and determine possible interventions (Figure 2).

Results: Baseline performance data included 328 patients. Monthly performance assessment included an average of 41 patients on HCQ (range 30-51) (Figure 3). We reached our target of 85% compliance in February 2019 with a shift noticed in September 2018. We identified the following barriers to compliance: 1) Lack of knowledge among providers and patients, 2) Poor accuracy of data reports to reflect the population of interest, and 3) System barriers for interventions that involve another specialty with different locations and EHR systems. Major interventions included: 1) Educating providers and patients, 2) Preparing weekly pre-visit planning (PVP) to identify at-risk patients and provide screening recommendations, 3) Collaborating with ophthalmology clinic to facilitate same day eye screening, 4) Transparent sharing of provider-level data on a monthly basis showing individual performance, and 5) Implementing order-sets of specific eye tests in the EHR system.

Conclusion: This study is the first reported QI initiative to address the compliance with the 2016 eye screening recommendations for patients on HCQ. Our QI project highlights the following conclusions: 1) The usefulness of KDD in identifying root causes and planning interventions, 2) The importance of multidisciplinary team for large QI projects

that involve more than one department, 3) The role of PVP in QI projects in a busy clinic setting managing multisystem diseases, and 4) The advantage of implementing interventions such as order sets in the EHR system. Next steps will be directed at maintaining providers buy-in and recruit patient/family member in the QI team.

Abstract Number: 1750

Pediatric Sjögren Syndrome: A Single-Center Experience

Rachel Randell,[1] and Heather Van Mater[1], [1]Duke University, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Sjögren syndrome (SS) is a chronic autoimmune disease of exocrine gland dysfunction that affects up to 4 million adults in the United States. Children are much less commonly affected, but have been reported to present with distinct, sometimes severe, manifestations. Little is known about clinical features, treatment and outcomes of SS in children.

Methods: An institutional web-based clinical research tool was used to identify patients with Sjögren or sicca syndrome diagnosis codes from year 2000-current in any child (< 18 years old at time of diagnosis). Query revealed 237 charts which were manually reviewed and narrowed to 25 cases of SS diagnosed by a pediatric rheumatologist, for whom in-depth chart review was performed.

Results: Of all 25 cases, 19 (76%) had primary SS and 6 (24%) had SS in the context of another autoimmune disease. Of those with primary SS, 10 (53%) had recurrent parotitis and 6 (32%) had sicca syndrome as predominant presenting symptom; 2 (10%) developed severe, persistent central nervous system symptoms. Of those with other autoimmune disease, 3 (50%) had a diagnosis of autoimmune disease prior to onset of SS, and 3 (50%) were initially diagnosed with SS and subsequently developed other autoimmune disease (undifferentiated connective tissue disease or systemic lupus erythematosus). Frequently reported symptoms included arthralgia, headache and fatigue. Nearly all (96%) had high ANA and SSA/Ro antibody titers. Shirmer test and salivary gland biopsy were less commonly used (44% and 36%, respectively). The most frequently prescribed systemic treatments were hydroxychloroquine, methotrexate, prednisone and methylprednisolone. Long-term outcome data were not available for the majority of cases, however there were no reports of malignancy or death, and only one case where the disease was not controllable with systemic medications.

Conclusion: In this single center study of 25 cases of SS in children, clinical presentation was variable and included recurrent parotitis, sicca syndrome and severe neurologic symptoms, both with and without other autoimmune disease. Although follow up data were not available for the majority of cases, it seemed that disease was controlled in nearly all cases using systemic therapies during treatment course. Long-term studies are needed to better understand the natural history and outcomes of SS in children.

A Systematic Literature Review of Efficacy and Safety of Biologic Agents for the Treatment of Juvenile Dermatomyositis

edoardo marrani,[1] Sarah Abu Rumeileh,[1] Francesca Tirelli,[2] Ilaria Maccora,[3] and Gabriele Simonini[4], [1]Post graduate School of pediatrics, University of Florence, Firenze, Italy, [2]Post Graduate School of Pediatrics, University of Florence, Florence, Italy, Firenze, Italy, [3]Post Graduate School of Pediatrics, University of Florence, Florence, Italy, Florence, Toscana, Italy, [4]Anna Meyer Children's Hospital, Flotence, Italy

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma

Session Type: Poster Session (Monday)

Session Time: 9:00AM–11:00AM

Background/Purpose: Juvenile dermatomyositis (JDM) is a rare, chronic autoimmune illness characterized by symmetric, proximal muscle damages and involvement of the skin. While first line treatment is based on a combination of DMARDs (Methotrexate or cyclosporin) and glucocorticoids, there is limited evidence on treatment strategies for patients unresponsive to first-line treatment. We assessed the efficacy/effectiveness and safety of biologic agents in JDM.

Methods: A systematic literature review was conducted using Embase®, MEDLINE®, MEDLINE®-In Process and Cochrane library to identify studies on biologics agents in JDM published in English language as full-text articles (1975 to May 2019) or conference abstracts (2000 to May 2019).

Databases were searched with the key words "(juvenile dermatomyositis) crossed with "biologic agents OR tocilizumab OR rituximab OR adalimumab or INFLIXIMAB or anti TNF or baricitinib OR etanercept OR JAK inhibitors". Of note, we did not include children, age, or age limits in the search as medical subject headings terms because we may have been able to extract a sub cohort of children from studies including both children and adults

Results: Of the 1584 retrieved publications, 20 articles were identified for a total of 167 patients. 7 patients presented with a**nti**-signal recognition particle polymyositis. Only one RCT was identified for Rituximab; however, in the Rituximab in Myositis (RIM) trial no pediatric data could be extracted since they were reported as aggregate. In real-world studies, complete (CR) or partial response (PR) was often assessed, and their definitions and follow-ups (FUP) varied (table 1). JDM pts were most often treated with anti-TNF (90 pts); 11 pts received etanercept (ETA), 12 pts Infliximab (IFX), 1 pt adalimumab (ADA). Data regarding specific anti-TNFa agents were not available for the other 66 pts, as were not extractable. Rituxumab (RTX) was used in 76 pts. Single case reports reported the use of tocilizumab (TCZ), abatacept (ABA) e baricitinib (Table 1). Complete response was reported for 72% of pts treated with at least one anti-TNF and 64% for RTX, without statistical difference in head-to-head drug comparison. Anti-TNF were generally well-tolerated but 9 pts experience severe reactions (8 infusion-related adverse reaction; 1 infection). In the RTX group 6 patients experience severe events (3 infections; 1 infusion-related adverse reaction; 1 gastrointestinal perforation).

Table 1 . Main outcome measures and other data entered for each of the eligible studies.

Abstract Number: 1752

Is Early Standardized Rituximab Therapy Sufficient for Toddlers with NMDAR Encephalitis?

Hitha Amin ,[1] Mered Parnes,[1] Christian Niedzwecki,[2] Sarah Risen,[1] and Eyal Muscal[3], [1]BCM, child neurology, houston, TX, [2]BCM, Physical medicine and rehabilitation, houston, TX, [3]Baylor College of Medicine, Houston, TX

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Anti-NMDAR encephalitis may be more prevalent than some forms of viral encephalitis in children. Pediatric rheumatologists are called upon to assist in the diagnosis and immuno-modulation of children with autoimmune encephalitides (AE). With prompt identification and early B cell depletion clinical outcomes may be robust in these disorders. Yet, children younger than 5 years of age with anti-NMDAR encephalitis may present differently than older patients and pose a diagnostic challenge. We present the presentation and outcomes of a cohort of young NMDAR encephalitis patients treated at a single center using a standardized step-up approach.

Methods:

- After obtaining approval from a local IRB we reviewed the charts of children diagnosed with Anti-NMDAR encephalitis between Jan 2012-April 2019 at a pediatric tertiary hospital. Diagnosis was based on clinical findings, and serum and CSF-Anti-NMDAR IgG antibodies. We reviewed all treatment modalities, adverse events of immunosuppression, and assessed disability at hospital discharge and last follow up using the Modified Rankin Scale (mRS) for children.

Results: Nine (20%) of children diagnosed with NMDAR encephalitis were ≤ 5 years of age at presentation (Median age 3 years, range 1.5-5 yr; 67% F). Presentations in younger children included gait disturbances, encephalopathy, reduction in speech, acute regression and severe movement disorders. Unlike older patients, seizures occurred in only one child. Median time to AE diagnosis was 5 days (range 4-99 days). Treatment followed a standardized institution protocol of: methylprednisolone, IVIG, and rituximab (2 doses at 500 mg/m2). Rituximab was administered 5-7 days after IVIG if a child did not show significant improvement. Children received rituximab at a median of 33 d, (range 16-128 d) from symptom onset. All children tolerated rituximab without infections or adverse events. All children with > 6 month follow-up re-populated their B cells, and none flared.

Prolonged hospitalizations were prevalent (median LOS 30 d, range 7-100 d) Five (55%) children required inpatient rehabilitation after initial hospital discharge. Modified Rankin Scale (mRS) scores improved from 4-5 (moderately severe-severe) at presentation to a mRS of 1 (mild symptoms) in one child (11%), a 2 (slight disability) in 5 children (56%), and a 3 in three children (33%) at their last visit (median f/u time 310 days, range 34-1219 d). Disability scores for younger children were higher than those of older patients (whose scores were predominantly 0-1). Deficits at time of last follow up related to language skills, and behavioral concerns.

Conclusion: Younger children with NMDAR encephalitis present differently than the "classic" phenotype of older children. Early B cell depletion practices were well tolerated in younger children. With rehabilitation, there were gradual and sustained gains in function in all children. It is unclear if greater disability of younger children was related to a shorter follow-up period or is a reflection of the vulnerability of toddlers to acquired CNS insults. There is a need for pediatric centers to share AE data so to answer questions regarding appropriate therapy and functional outcomes.

Are Patterns of Early Disease Severity Predictive of Grade 12 Academic Achievement in Patients with Childhood-onset Chronic Rheumatic Diseases?

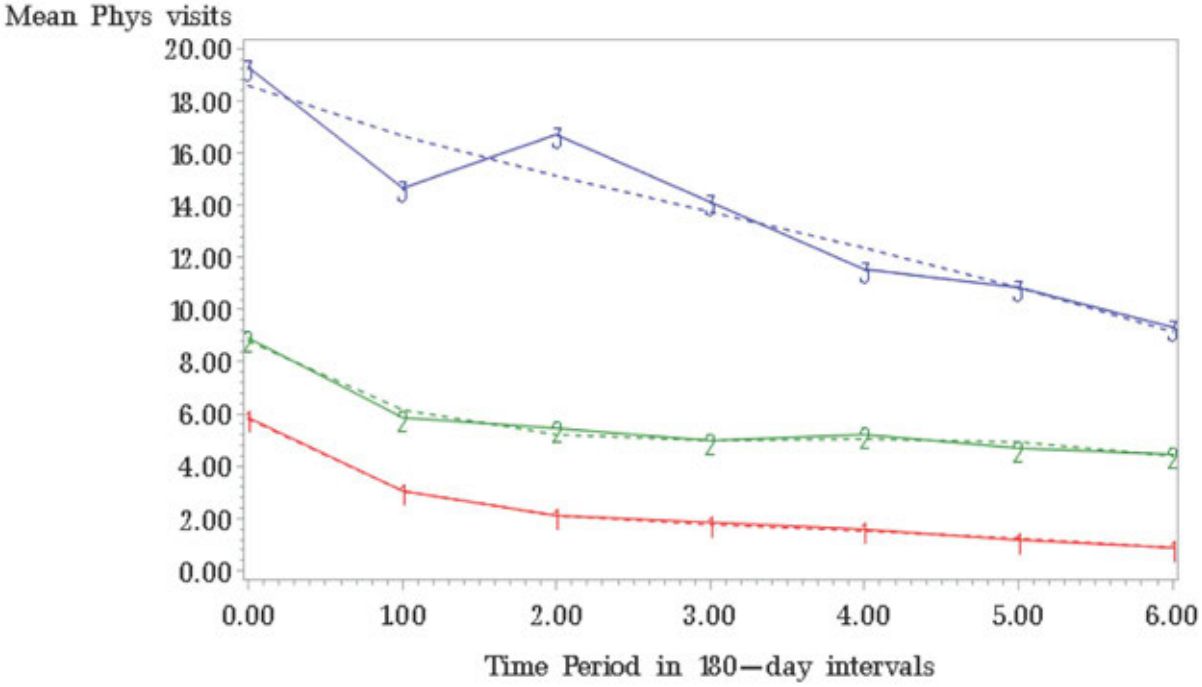
Lily SH Lim ,[1] Okechukwu Ekuma,[2] Ruth Ann Marrie,[1] Marni Brownell,[2] Christine Peschken,[1] Carol Hitchon,[1] Kerstin Gerhold,[1] and Lisa Lix[3], [1]University of Manitoba, Winnipeg, MB, Canada, [2]Manitoba Center for Health Policy, Winnipeg, MB, Canada, [3]University of Manitoba, Winnipeg, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Youths with childhood-onset chronic rheumatic diseases (ChildCRD), including juvenile arthritis (JA) and systemic autoimmune rheumatic diseases (SARD), have worse grade 12 standards tests results compared to their peers. SARD includes systemic lupus erythematous, dermatomyositis, Sjogren's syndrome and systemic sclerosis. We aimed to test if ChildCRD disease severity predicted the performance of ChildCRD patients on grade 12 standards tests.

Methods: Population-based longitudinal cohort study from one Canadian province. All ChildCRD patients had been captured in a registry since 1984. Data from ChildCRD patients born 1979-1998 (grade 12, 1996-2015) were linked to the administrative health (hospitalizations, physician billings, medications), education (grade 12 standards tests

Figure 1: Latent Trajectories of Physician Visits as an *Universal Disease Severity Indicator* in Childhood-onset Chronic Rheumatic Diseases



and enrollment) and social data (income assistance, child welfare involvement) housed in the provincial population data repository. *Outcomes:* Validated language and arts achievement index (LAI) and Maths achievement index (MAI) derived from grade 12 standards tests results and enrollment data. *Key predictor and covariates* : We constructed a universal disease severity indicator using latent class trajectory analysis (including disease groups: SARD, oligo- and non-oligoarticular JA, as membership covariate) of all physician visit within the first 3.5 years after diagnosis (early disease). Model covariates included an area-based socioeconomic factor index (SEFI2), maternal age at first child-birth, family ever on income assistance or involved with child welfare services, psychiatric morbidities pre-diagnosis and in the 12-months preceding tests. *Model***:** Effects of the severity indicator and covariates were tested in linear regressions for LAI and MAI; standardized coefficients (b) with standard errors (SE) and scaled deviance (DEV) were reported.

Results: 541 participants (474 JA, 44 SARD), of whom 70% were females were studied. The best fitting latent class model of disease severity, showed 3 latent trajectories: high (9%), moderate (54%) and low numbers of visit (37%) corresponding to severe, moderate and mild disease severities (Figure 1). The membership probabilities for the groups were 0.98 (severe), 0.97 (moderate) and 0.96 (mild). The severe group predicted LAI (b= –0.44, SE=0.17, p< 0.01) and MAI (b= –0.54, SE= 0.17, p< 0.01) in univariable models. After covariate adjustments, the severe disease group did not predict LAI, (b= –0.29, SE= 0.16, p=0.06, DEV=1.03) but predicted MAI (b= –0.41, SE=0.15, p< 0.01, DEV=1.03).

Conclusion: Longitudinal patterns of disease severity in early disease predicted grade 12 Maths standards tests results of ChildCRD patients, after covariate adjustment. Recognizing severe disease in early disease, in association

with sociodemographic and psychiatric histories can help identify ChildCRD patients who are at risk of reduced academic achievement and who may benefit from increased education support.

Comorbidities and Treatments in United States Youth with Chronic Musculoskeletal Pain

Matthew Taylor,[1] Sabrina Gmuca,[2] Lakshmi Moorthy,[3] Alexis Boneparth ,[4] and **Daniel Horton** [3], [1]Sidney Kimmel Medical College, Thomas Jefferson University, Philadelphia, PA, [2]Children's Hospital of Philadelphia, Philadelphia, PA, [3]Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, [4]Columbia University Medical Center, New York, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Chronic musculoskeletal (MSK) pain has been associated with chronic illnesses, including mental disorders, and with high rates of pain medication use, often in referral centers, European populations, or studies focused on single drug classes. We aimed to characterize broad patterns of comorbidities and treatments associated with chronic MSK pain in a nationally representative sample of US youth.

Methods: We used the National Ambulatory Medical Care Survey (2002-2015) and outpatient National Hospital Ambulatory Medical Care Survey (2002-2011), which contain national cross-sectional data on demographics, reasons for visit (RFV), diagnoses, and drugs ordered in visits to US office-based physicians. The study included all visits for youth age 8-24, excluding those for MSK pain of unknown duration or with diagnoses of malignancy or sickle cell disease. We identified visits for chronic (≥3mo) or acute (< 3mo) MSK pain based on the main RFV. We compared comorbidities and drugs ordered in visits for chronic MSK pain with (1) visits for any reason besides MSK pain (primary) and (2) visits for acute MSK pain (secondary), using chi-square tests and logistic regression, adjusting for age, sex, race, ethnicity, insurance, and setting of care.

Results: Chronic and acute MSK pain accounted for 1.3% and 4.1% of all visits, respectively. Chronic diseases besides mental disorders were more common among visits for chronic MSK pain (32.0%) in comparison to both visits for acute MSK pain (17.9%) and visits for other reasons (18.8%) (Table). Mental disorders and psychotropic drugs were more common in visits for chronic MSK pain than for acute MSK pain but not compared to visits for other reasons (Table). Nonsteroidal anti-inflammatories were more commonly ordered in visits for chronic MSK pain (23.9%) than in non-pain visits (4.7%) but not compared to acute MSK pain visits (31.3%) (Table). Opioids were also more common in visits for chronic MSK pain (13.5%) than non-pain visits (2.1%) and, to a lesser extent, acute MSK pain visits (8.4%) (Table). Orders for gabapentinoids and complementary and alternative medicine (CAM) were markedly higher in visits for chronic MSK pain (Table). Orders for opioids, muscle relaxants, and psychotropic drugs increased over time in visits for chronic MSK pain; similar trends were seen in other groups for psychotropic drugs but not pain medicines (Figure).

Table. Factors associated with chronic musculoskeletal (MSK) pain in multivariable models. 1 Odds ratios (ORs) from multivariable logistic regression models, adjusted for sex, race/ethnicity, year, region, insurance type, and survey setting (NAMCS vs. NHAMCS). 2 Non-steroidal anti-inflammatory agents. - denotes cell counts < 30, which may yield unreliable estimates. * P < 0.05; ** P <0.01; *** P < 0.001.

	Chronic MSK Pain vs. Other Visits [N = 116,913]		Chronic MSK Pain vs. Acute MSK Pain [N = 5,570]	
	OR[1]	95% CI	OR	95% CI

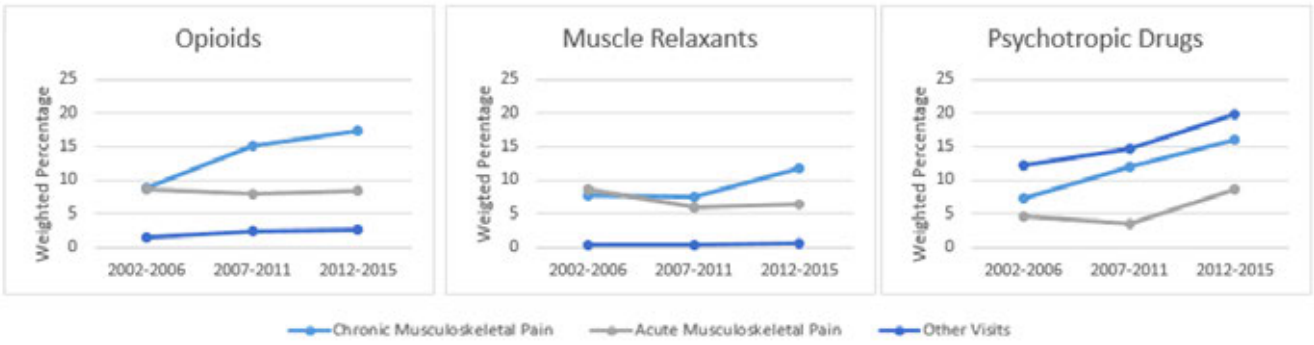
Treatment				
NSAIDs[2]	6.9***	5.1-9.3	0.6***	0.5-0.8
Acetaminophen	0.3***	0.2-0.5	0.6	0.3-1.05
Opioids	4.2***	2.9-5.9	1.3	0.94-1.9
Acid-Blocking Agents	1.4	0.8-2.6	3.0**	1.3-6.7
Psychotropic Drugs	0.5**	0.4-0.8	1.4	0.9-2.3
Gabapentinoids	11.2***	5.6-22.4	-	-
Alternative Medicine	21.3***	9.5-48.1	-	-

Figure 1. Trends in opioid, muscle relaxant, and psychotropic drug orders in youth with and without chronic MSK pain (2002-2015)



Conclusion: Compared to youth without pain,youthwith chronicMSK weremore likely to have chronic non-psychiatric medical conditions but not mental disordersin a large ambulatory US population. Orders for gabapentanoids (unapproved for children with chronic MSK pain) and CAM were particularly common for those with chronic MSK pain, and orders for opioids and muscle relaxants rose over time in this group. Further research must clarify the effectiveness and safety of treatments commonly used to treat youth with chronic MSK pain.

Abstract Number: 1755

Improving Adolescent Health Care Transition: Piloting the Transition Readiness Assessment Questionnaire

Meghan Foster ,[1] Matthew Hollander,[2] Amanda Kennedy,[3] Laura Lewis,[4] Olivia Thompson,[3] Bradley Tompkins,[3] and Constance Van Eeghen[4], [1]UVMMC, Jericho, VT, [2]UVMMC, Burlington, VT, [3]UVMMC, Burlington, [4]UVM, Burlington

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Successful adolescent health care transition (HCT) is a vital process in providing developmentally appropriate care and minimizing negative outcomes, especially in adolescents with special health care needs. The purpose of this mixed-methods quality improvement project was to pilot the Transition Readiness Assessment Questionnaire (TRAQ) tool in a pediatric rheumatology clinic and assess its utility as a transition tool as well as to inquire about specific patient and family-based transition needs.

Methods: The TRAQ tool and follow-up survey were administered in dyads to all established pediatric rheumatology patients between the ages of 12-18, and one caregiver, who presented to the clinic during the two-month intervention period. A post-intervention interview with the treating team was also conducted to assess provider experience.

Results: 29/30 paired TRAQ and surveys returned with overall acceptance of the tool across adolescents, caregivers and providers. 84% of adolescents and 91.3% of caregivers agreed that they were seeking greater independence for themselves or their child and the skills listed on TRAQ would help them take care of themselves. Caregivers found the TRAQ easier to fill out, understand and more helpful as a transition tool than the adolescents. The treatment team reported the TRAQ was useful in starting a conversation about transition and highlighted the need for a structured transition process.

Conclusion: The TRAQ is an accepted and valuable HCT tool for adolescents, caregivers and providers. Future projects could be aimed at piloting the TRAQ or other readiness assessment tools in other sub-specialty clinics, building a transition framework to support utilization of transitional tools and addressing the transition themes identified by adolescents and their caregivers.

Health-related Social Media Use by Parents of Children with Rheumatic Diseases

Jonathan Hausmann ,[1] Vincent Del Gaizo,[2] Kara Magane,[3] Alexandra Marin,[4] Shannon Malloy,[5] Sanjay Mishra,[6] Tory Aquino,[7] Marc Natter,[8] Laura Schanberg,[9] and Elissa Weitzman[8], [1]Boston Children's Hospital / Beth Israel Deaconess Medical Center, Boston, MA, [2]Childhood Arthritis and Rheumatology Research Alliance, Whitehouse Station, NJ, [3]Boston Children's Hospital, Boston, MA, [4]Boston Children's Hospital, Boston, MA, [5]Cure JM Foundation, Seattle, WA, [6]Seattle Public Schools, Seattle, WA, [7]Hearing Life, Patterson Heights, PA, [8]Boston Children's Hospital / Harvard Medical School, Boston, MA, [9]Duke University Medical Center, Durham, NC

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Disease and treatment burdens are high for children living with rheumatic diseases. Pediatric patients and their families lack a mature evidence base to guide treatment decisions and often need greater levels of psychosocial support than may be available in traditional healthcare settings. In this context, engaging with others facing similar challenges and health problems via social media may be helpful and impactful for healthcare decision-making.

Table 1. Demographics of participants in the study. Disease activity is represented as the proportion of patients within each disease group in the following categories: remission (off medications) in green, stable (on medications) in yellow, and active disease (flare) in red.

Disease	N (%)	Age at diagnosis (SD)	Current age (SD)	Disease activity
Juvenile idiopathic arthritis	341 (32.5)	7.1 (4.2)	12.6 (5.4)	
Juvenile dermatomyositis	260 (24.8)	8.2 (4.2)	13.8 (6.3)	
Autoinflammatory disease	202 (19.2)	6.1 (4.2)	9.6 (5.1)	
Autoimmune encephalitis	79 (7.5)	10.2 (5.3)	14.1 (5.6)	
Systemic lupus erythematosus	71 (6.8)	14.5 (4.9)	18.5 (5.7)	
Vasculitis	26 (2.5)	14.9 (3.2)	19.0 (3.3)	Scleroderma	25 (2.4)	9.8 (3.5)	12.0 (3.4)	
CRMO	20 (1.9)	9.4 (3.1)	12.1 (2.7)	
Sjogren's	14 (1.3)	11.5 (2.8)	14.4 (3.1)	
Other	12 (1.1)	9.2 (4.2)	12.7 (4.3)	Total	1050 (100)	8.3 (4.9)	13 (5.9)	

In this study, we sought to understand attitudes, beliefs, and behaviors concerning social media use among parents of children with rheumatic diseases, and how such engagement might affect decision-making about their child's health care.

Methods: We worked with PARTNERS, a patient-powered research network, to disseminate an online survey through 9 different patient support organizations. The survey was distributed through email, website links, and on these groups' social media accounts.

Surveys were completed anonymously under implied consent. The survey was active between January 22 - April 2, 2019. The study was deemed exempt by the Boston Children's Hospital IRB.

Results: The survey was accessed 1,360 times and 1,050 surveys had non-missing data available for analysis. Participant characteristics are shown in Table 1. The mean age of children was 13; their mean age at diagnosis was 8.3 years. Only 11.1% of children were in remission and off medications, the rest had stable (44.5%) or active (44.3%) disease. Juvenile arthritis was the most common condition represented (32.5%).

Most parents (94.9%) used social media; of these, 97.8% had viewed content about other families with a child with a similar rheumatic condition on these platforms, and 92.9% had posted, shared, or commented on social media about their own child's rheumatic condition. Reading about other families was most helpful to learn how these families were living their lives in the setting of their child's disease. Other reasons for reading this content are shown in Figure 1. Social media use affected the child's medical care mainly by helping the parent manage their child's symptoms (67.7%) and medication side effects (64.3%). Other ways in which social media affected the child's medical care are shown in Figure 2.

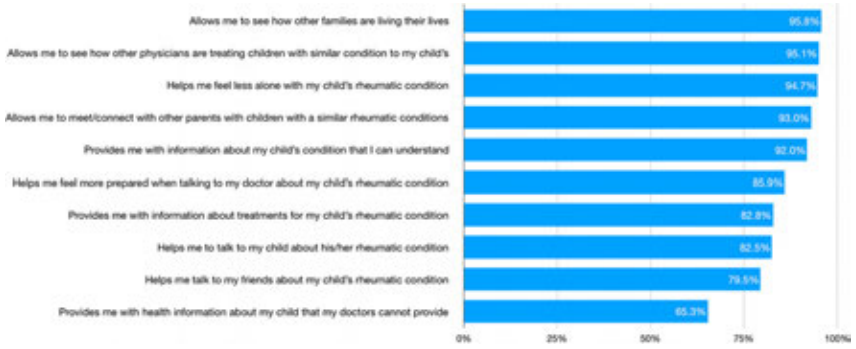

Figure 1. Proportion of parents who "agree" or "strongly agree" to the question: "Reading about other families who have a child with a rheumatic condition similar to your child's…" Denominators ranged from n=929 to n=933 across individual items.

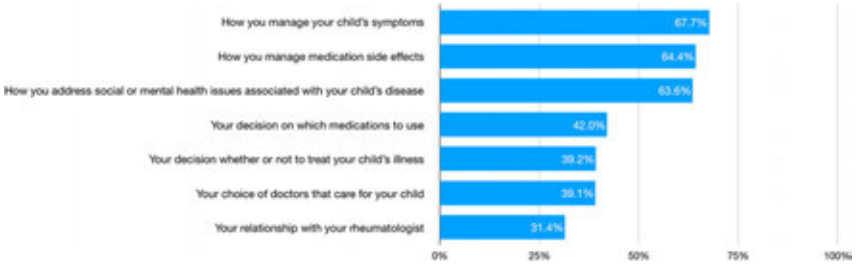

Figure 2. Proportion of parents who responded "somewhat" or "a great deal" to the question: "To what extent has what you learned about your child's rheumatic condition from social media affected…" Denominators ranged from n=862 to n=864 across individual items.

Conclusion: Health-related social media use by parents of children with rheumatic diseases was widespread in this large cohort of parents recruited online through patient support organizations. The greatest benefit from online interactions resulted from decreasing feelings of isolation of the parent and normalizing the diagnosis of a rheumatic illness in a child. While for most parents these online interactions did not have significant effects in the choices of medications used or the choice of doctors selected to treat their child's medical condition, they seemed to provide some utility in helping parents better manage their child's symptoms, medication side effects, and the mental and social challenges related to their diagnosis.

A better understanding of parental needs may allow us to create interventions that could help provide greater support for families and improve health outcomes for children with rheumatic diseases.

Abstract Number: 1757

Review of Effectiveness of an Intensive Rehabilitation Programme in Managing Strength, Pain and Function in 123 Young People with Rheumatological Conditions

Susan Maillard ,[1] Kim Noar,[2] and Lauren Stone[2], [1]Great Ormond Street Hospital NHS Foundation Trust, Maidenhead, United Kingdom, [2]Great Ormond Street Hospital NHS Foundation Trust, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – ePoster II: SLE, Juvenile Dermatomyositis, & Scleroderma – ARP
Session Type: Poster Session (Monday)
Session Time: 9:00AM–11:00AM

Background/Purpose: Young people with Rheumatological conditions often experience ongoing pain, muscle weakness and reduced function despite modern medication. The unit at Great Ormond Street Hospital provides an intensive rehabilitation programme which focuses upon managing these symptoms. This review examines the immediate response and longer term follow up to the treatment.

Methods: A retrospective review of the notes was completed upon 123 children admitted for the intensive exercise therapy. Outcomes of specific muscle strength in the form of the Kendall scale grouped into the Manual Muscle Strength of 3 groups – gluteus maximus, gluteus medius and vastus medialis (MMT3) and the more extensive MMT8 are used, as well as a measure of pain and function (CHAQ). The outcomes were assessed at the admission and discharge of the rehabilitation programme and at the first follow up at 3 months.The treatment consists of focusing on a progressive resisted exercise programme completed 2x daily (2.5hrs per day) for 2 weeks (16 sessions in total) and primarily focuses upon correcting the biomechanics of the body as well as increasing aerobic fitness and education into managing pain and fatigue and learning to function despite pain. All the young people increased their exercises to 30 repetitions with the use of weights (max 3kg) focusing initially on specific muscle strengthening.

Results: The notes of 123 children were reviewed consecutively. 71/123 were female and the average age was 11.7 years (Range 4 – 17.5yrs). 44/123 had non-inflammatory pain, 10/123 has CRPS and the others had an inflammatory condition with 36/123 diagnosed with JIA. On admission the average pain score was 5.6/10 VAS and this reduced

Table 1. Muscle Strength Change Before and After Rehabilitation

	Initial assessment	D/C Assessment	Follow-up
Hip Abductor	6	9	9
Hip Extensor	6	9	8
Inner Range Quads	5	9	9
Plantar Flexors	1 rep	7 reps	6 reps
MMT 3	17/30	26/30	26/30
MMT 8	60/80	75/80	74/80

to 3.8/10 at follow up. The CHAQ reduced from 1.25/0.825. School attendance improved for most after the rehabilitation.

Conclusion: An intensive rehabilitation programme is effective in improving muscle strength and function as well as reducing pain and this is maintained for many months after discharge from the programme.

Development of Ultrasound Detectable Arthritis Among ACPA Positive Subjects with Musculoskeletal Symptoms: The Risk RA Prospective Study

Aase Hensvold ,[1] Yogan Kisten,[2] Alexandra Circiumaru,[1] Monika Hansson,[3] Meng Sun,[1] Guozhong Fei,[4] Nancy Vivar,[2] Erik af Klint,[2] Hamed Rezaei,[2] Lars Klareskog,[3] Aleksandra Antovic,[5] and Anca Catrina[3], [1]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, [2]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden, [3]Rheumatology unit Karolinska University Hospital and Karolinska Institutet, Stockholm, Sweden, Stockholm, Sweden, [4]Center for Rheumatology, Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden, Stockholm, Sweden, [5]Center for Rheumatology, Academic Specialist Center, Stockholm Health Services, Stockholm, Sweden, Stockholm, Stockholms Lan, Sweden

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: Studies have shown that anti-citrullinated protein antibodies (ACPA) are a risk factor for the development of arthritis. We aimed to nvestigate in a prospective setting whether ACPA and other biomarkers could predict the development of ultrasound detected arthritis

Methods: Subjects with positive ACPA-test referred from primary-care to the Rheumatology clinic, that lacked arthritis in the hands, feet and any other symptomatic joints by clinical and ultrasound examination (according to EULAR-OMERACT definition), were recruited into the Risk-RA research program during 2015-2016, and were followed-up to the end of January 2019. at inclusion, a detailed clinical examination was performed and blood samples were analyzed for 13 specific ACPA reactivities (using custom made peptide microarray) as well as 92 inflammation-associated protein biomarkers (using a multiplex immunoassay with Olink proximity extension technology). Presence of HLA-SE was analyzed using DR low-resolution kit. Univariate and multivariate analysis were used to investigate the association between clinical and laboratory parameters and development of ultrasound detected arthritis adjusting for the follow-up time.

Results: 46% (30 out of 65) of the Risk RA subjects developed ultrasound detectable arthritis during a median follow-up time of 11 months. The remaining 54% (35 out of 55) were followed for a median of 27 months (range 17-39) without any signs of ultrasound detectable arthritis. Those subjects that developed arthritis had a higher prevalence of HLA-SE (83% vs 55%) as well as an increased incidence of ultrasound detected tenosynovitis (40% vs 5%) as compared to those that did-not develop arthritis. ACPA reactivities to citrullinated vimentim peptides (cit vim 2-17: 20% vs 6%; and cit vim 60-75: 67% vs 44%) and citrullinated histone peptides (cit H4 31-50: 87% vs 47%; and cit H3 21-44: 47% vs 22%) were a more common occurrence in subjects developing ultrasound detectable arthritis.

Backward selection in Cox regression model showed that ultrasound detectable arthritis could be predicted in a model including HLA-SE, tenosynovitis and ACPA reactivity to cit H4 31-50. Hazard ratio (HR) for arthritis development were 2.2 (95% CI 0.8-6, p=0.13) for HLA-SE carriers and 2.9 (95% CI 1.3-6.5, p=0.01) for tenosynovitis, and 3.4 (95% CI 1.2-10, p=0.02) for Anti-citrullinated H4 31-50 positivity. Only modest differences were observed for few of the tested inflammatory markers in those developing as compared to those not developing ultrasound detectable arthritis: Interleukin- 6 (3.9 vs 3.3 AU/ML), Programmed death-ligand 1 (4.9 vs 5.2 AU/ML) and Chemokine (C-X-C motif) ligand 6 (9.2 vs 9.5 AU/ML).

Conclusion: Certain ACPA fine specificities, HLA-SE and tenosynovitis predicts the development of ultrasound detectable arthritis in seropositive individuals with musculoskeletal symptoms who are at risk for RA.

Abstract Number: 1759

Methotrexate in Patients with Hand Erosive Osteoarthritis Refractory to Usual Treatments: A Randomized, Double-blind, Placebo-controlled Trial

stéphanie Ferrero,[1] Ruth Wittoek,[2] Edem Allado,[3] Coralie Cruzel,[4] Véronique Breuil,[1] Liana Euller Ziegler,[5] Damien louille,[6] **Christian Roux** ,[7] and Joel Kremer[8], [1]University of Nice, nice, France, [2]Ghent University Hospital, Gent University, Gent, Belgium, [3]Centre Hospitalier Universitaire de Nancy, Nancy, France, [4]Université Cote d'Azur, nice, France, [5]PUPH CHU NICE, nice, France, [6]Université Cote d'Azur, Nancy, France, [7]Université Cote d'Azur, Nice, [8]Albany Medical College, Albany, NY

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: No studies have assessed the effect of methotrexate (MTX) in osteoarthritis of the hand (HOA). The purpose of our study was to examine the effect of MTX on pain and structural progression in symptomatic erosive HOA (EHOA).

Methods: This 1-year prospective, monocentric, randomized, double-blind, placebo-controlled study (NCT1968405) followed patients with symptomatic EHOA. Patients were randomized into two groups: 10 mg MTX per week or placebo. The primary endpoint was pain assessment at 3 months, and secondary endpoints were clinical features (pain

on visual analog scale (VAS)), radiographic features (Verbruggen anatomical radiographic score and Gent University Score System), and magnetic resonance imaging (MRI) at 12 months.

Results: Sixty-four EHOA patients were randomized to either the placebo or MTX group. At 3 months, there was no significant difference in the mean decrease in VAS pain score (mm) (MTX: 17.5 (28.4) vs placebo: 8.4 (25.2); p=0.2). Erosive joints progressed significantly more to a remodeling phase in the MTX group than in the placebo group (27% vs 15%) (p=0.03). Joints with joint space loss appeared to be less eroding in the MTX group than in the placebo group (8% vs 29%; p=0.2). Interleukin-6 level (p< 0.0001) and synovitis findings on MRI (p=0.02) at baseline were found to be predictive factors for erosive structural evolution of non-erosive joints.

Conclusion: Our study shows that MTX did not demonstrate superior efficacy over placebo on pain and function evolution at 3 and 12 months in subjects with EHOA.. However, MTX significantly reduced the progression of joint damage compared to placebo and seems to facilitate bone remodeling. The presence of systemic and local inflammations at baseline were predictors of erosive progression.

Six-week Treatment with Low-dose Prednisolone in Patients with Painful Hand Osteoarthritis (HOPE): Results from a Randomised Double-blind Placebo-controlled Trial

Féline Kroon ,[1] Marion Kortekaas,[1] Annelies Boonen,[2] Stephan Böhringer,[3] Monique Reijnierse,[1] Frits R Rosendaal,[3] Naghmeh Riyazi,[4] Mirian Starmans,[5] Franktien Turkstra,[6] Jende van Zeben,[7] CF Allaart,[8] and Margreet Kloppenburg[3], [1]Leiden University Medical Center, Leiden, Netherlands, [2]Maastricht University Medical Center, Maastricht, Netherlands, [3]Leiden University Medical Center, Leiden, Zuid-Holland, Netherlands, [4]Haga Hospital, The Hague, Netherlands, [5]Zuyderland Medical Center, Heerlen, Netherlands, [6]Amsterdam Rheumatology and immunology Center | Reade, Amsterdam, Netherlands, [7]Sint Franciscus Vlietland Groep, Rotterdam, Netherlands, [8]Department of Rheumatology, Leiden University Medical Center, Leiden, The Netherlands, Leiden, Netherlands

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: Hand osteoarthritis (OA) is a prevalent joint disease with high disease-burden in need for effective therapeutic options. Studies have shown that synovial inflammation is often present in hand OA and a main determinant of pain and radiographic disease progression. Our aim was to investigate the efficacy and safety of short-term low-dose prednisolone in patients with painful hand OA.

Methods: This randomised, double-blind, placebo-controlled trial enrolled patients with painful hand OA, fulfilling American College of Rheumatology criteria, and signs of synovial inflammation. Patients with ≥4 interphalangeal joints (IPJ) with osteoarthritic nodes, ≥1 IPJ with soft swelling or erythema and ≥1 IPJ with positive power Doppler signal (PDS) or synovitis grade ≥2 on ultrasound, were eligible. Key exclusion criteria were chronic inflammatory rheumatic diseases, psoriasis, using immune modulating drugs within 90 days before baseline, and predominant thumb base pain. Eligible patients with visual analogue scale (VAS) finger pain ≥30 mm, flaring ≥20 mm upon non-steroidal

Table. Baseline characteristics and results of secondary endpoints at week 6 of HOPE study.

*Adjusted for baseline value and study center. †Norm-based scores with a standardized mean of 50 and SD of 10 using age- and sex-specific Dutch population-based norms. AUSCAN=Australian/Canadian Hand Osteoarthritis Index. FIHOA=Functional Index for Hand Osteoarthritis. SF-36=Short Form-36. VAS=visual analogue scale.

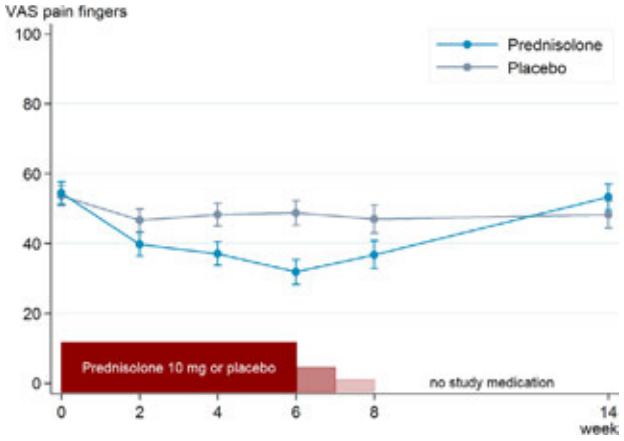

Figure. Results from primary endpoint (VAS pain) at week 6 of HOPE study.

anti-inflammatory drug washout, were randomised to receive prednisolone 10 mg daily for 6 weeks or placebo, followed by a two-week tapering scheme and 6 weeks without study medication. Outcomes were assessed at 2, 4, 6, 8 and 14 weeks. Primary endpoint was VAS finger pain at week 6 in intention-to-treat analysis. Secondary clinical endpoints included fulfilment of OMERACT-OARSI responder criteria, Australian/Canadian Hand OA Index (AUSCAN) pain/function, Functional Index for Hand OA (FIHOA), VAS patient global assessment, Short-Form 36 and grip strength. Imaging endpoints included ultrasound synovitis and PDS.

Results: Of 92 patients (mean (SD) age 63.9 (8.8), 79% women) randomised to prednisolone (n=46) or placebo (n=46), 42 patients in each group completed the study. Baseline characteristics were well-balanced between the groups. The mean (SD) change from baseline to week 6 in VAS finger pain was -21.5 (21.7) in the prednisolone and -5.2 (24.3) in the placebo group, with a mean between-group difference of -16.5 (95% confidence interval (CI) -26.1 to -6.9; figure). At week 6, 33 (72%) patients in the prednisolone versus 15 (33%) in the placebo group fulfilled OARSI responder criteria (odds ratio 5.3, 95% CI 2.0 to 13.6, p=0.001). In analogy with the primary endpoint, prednisolone was superior to placebo in most other secondary clinical endpoints (table). Ultrasound synovitis significantly improved at week 6 in the prednisolone compared to the placebo group, while no difference was observed in PDS (table). After tapering, between-group differences disappeared. Adverse events were mostly mild and comparable between groups.

Conclusion: Six-week treatment with low-dose oral prednisolone led to a substantial improvement of symptoms in patients with painful hand OA and signs of inflammation. This trial provides evidence that local inflammation is a suitable target for drug-treatment in hand OA.

The Prospective Open Label Preventive Approach to Congenital Heart Block with Hydroxychloroquine (PATCH) Study Demonstrates a Reduction in the Recurrence Rate of Advanced Block

Peter Izmirly ,[1] Mimi Kim,[2] Nathalie Costedoat-Chalumeau,[3] Deborah Friedman,[4] Amit Saxena,[5] Joshua Copel,[6] Rebecca Cohen,[1] Mala Masson,[1] Tishaun Middleton,[1] Kimberly Robins,[1] Robert Clancy,[1] and Jill Buyon[1], [1]NYU School of Medicine, New York, [2]Albert Einstein College of Medicine, Bronx, NY, [3]Cochin University Hospital, Paris, France, [4]New York Medical College, Valhalla, [5]New York University School of Medicine, New York, NY, [6]Yale School of Medicine, New Haven

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: Based on encouraging bench to bedside results including experimental evidence supporting Toll-like receptor signaling in the pathogenesis of CHB, a case control study demonstrating CHB risk reduction in hydroxychoroquine (HCQ) exposed fetuses of anti-Ro positive SLE women, and a historical cohort study supporting a reduction in recurrence rate, an open label single arm Phase 2 clinical trial was initiated to evaluate whether HCQ reduces the CHB recurrence rate (π) below the historical recurrence rate of 18%.

Methods: A two-stage trial design (N=19 first stage; N=54 second stage) using Simon's optimal approach was employed to allow for early stopping due to absence of treatment efficacy. The null hypothesis, H_0:$\pi \geq 18\%$, would be rejected and HCQ considered efficacious at the end of the trial if ≤ 5 of 54 mothers with anti-Ro and a previous CHB child had a subsequent child with 2nd or 3rd degree block (primary outcome). The protocol required HCQ initiation or maintenance at 400mg by 10 wks gestation. Mothers underwent serial echocardiograms, with bloods drawn each trimester and delivery for cord blood to measure antibody and HCQ levels.

Results: Sixty five mothers (all with previous CHB child and anti-Ro52 or Ro60 > 1,000 EU; 47.9% with anti-La; 71.4% White; 47.6% SLE and/or SS; 42.9% started HCQ solely for CHB prevention; 41% prior CHB child died, 3.2% had > 1 CHB child) signed consent. Ten were considered screen failures (2 miscarriages < 12 wks, 7 wherein dating of conception placed HCQ initiation at > 10 wks, 1 given dexamethasone (dex) 1mg at 10 wks) and 1 was lost to follow up before delivery leaving 54 pregnancies evaluable with serial fetal echos and birth or one yr EKG or echo results known. In Stage I, 2/19 fetuses had CHB, and the study proceeded to Stage II. By intention to treat analysis, 4/54 pregnancies resulted in CHB (7.4%; p = 0.02 for H_0), all at 19-20 wks. Three presented with 2nd degree block, one reverted to NSR at birth following dex and two progressed to 3rd degree despite dex and IVIG (one electively terminated). One presenting with 1st degree was treated with dex prophylactically (eliminating this case from evaluating HCQ exposure alone), progressed to 2nd but reverted to NSR at birth. At 2 yrs, the 2 in NSR had intermittent 2nd degree on Holter monitor. In 8 mothers potentially confounding medications, IVIG and/or dex, were prescribed after enrollment for lupus flare, cardiac concerns apart from advanced block (APCs, echo brightness, 1st degree block), and/or phy-

sician decision to consider additional prophylaxis. To evaluate HCQ alone, 9 additional mothers were enrolled, one whose fetus developed 3rd degree block at 19 wks. Including only pregnancies exposed to HCQ alone prior to confirmed 2nd or 3rd degree block, 4/54 developed CHB (7.4%; p = 0.02). In total 5/63 pregnancies (7.9%) resulted in advanced block. HCQ levels in the second trimester confirmed a 98% adherence rate. Anti-Ro levels remained > 1,000 EU (considered vulnerable for CHB) throughout pregnancy. No CHB developed in any of the 7 mothers screened out because of low dose or delayed start of HCQ.

Conclusion: These prospective data from a single-arm clinical trial support that HCQ significantly reduces the recurrence of CHB below the historical rate.

UV Light Induces Acute Type I Interferon Production in the Skin and Blood Which Is cGAS Dependent

Sladjana Skopelja-Gardner ,[1] Jie An,[2] Xizhang Sun,[2] Lena Tanaka,[2] Joyce Tai,[2] Payton Hermanson,[2] Masaoki Kawasumi,[2] and Keith Elkon[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: Interferon response genes (ISG) are strongly expressed in the skin of many patients with systemic lupus erythematosus (SLE). Since plasmacytoid dendritic cells (pDC) are also found in the skin of SLE patients with rashes, it is assumed that type I Interferon (IFN-I) activation in the skin is caused by immune complex activation of pDC. We previously showed that UV responses were blunted in mice deficient in the DNA sensing adapter protein STING. Since cyclic cGAS acting upstream of STING is implicated in Aicardi Goutieres Syndrome patients with skin manifestations, and a proportion of SLE patients have elevated cGAMP in their blood, we examined the role of cGAS in UVB light mediated skin injury.

Methods: Mice (B6 female (f) and male (m), B6.*cGAS*-/- f, and B6.*Ifnar*-/- f, 3-4mo) were exposed to a single dose of UVBL (500mJ/cm2). Blood draws and skin biopsies were performed prior to and at different times after UVB light injury. For experiments looking at non-lesional ISG expression, mice were irradiated along one half of the back (UVB) while the other half was shielded from exposure (non-UVB). Biopsies in the non-UVB region were performed ~0.5 cm away from the UVB area. ISG (*Mx1, Isg15, Isg20, Ifit1, Ifit3, Irf7, Ifi44)* and inflammatory genes (*TNFα, Il6, Il1β)* transcripts were quantified by QPCR and normalized to 18s.

Results: A single high dose of UVB light triggered rapid (6hr) and sustained (48hr) cutaneous ISG expression in B6 mice (~10 fold increase), with significantly greater early ISG upregulation in female mice compared to their age-matched male counterparts. Local cutaneous IFN-I response was accompanied by early (6hr) increase in circulating IFNβ protein levels and upregulation in ISG expression in the peripheral blood cells. Female mice deficient in cGAS

showed no ISG expression in the skin 6hr after UVB light exposure, while ISG expression at 24hr, though present, was significantly lower than in the B6 controls (45.7% - 84.1% less). ISG expression in peripheral blood cells was also significantly reduced in the absence of cGAS. In contrast to ISG, rapid gene expression of inflammatory cytokines TNFα, IL6, and IL1β (6hr) in the skin following acute UVB light exposure was not impacted by the loss of cGAS. Of note, ISG expression in non-lesional skin covered during irradiation was detected at 6 and 24hr after injury. The ISG expression in non-lesional skin was cGAS-dependent at 6hr and partially at 24hr after UVB light injury.

Conclusion: Acute skin exposure to UVB light triggers rapid and sustained ISG expression in both skin and blood. The early cutaneous response is higher in the females and is cGAS dependent, while blood ISG expression is partially dependent on cGAS. The requirement for cGAS in UVB light-mediated IFN-I response in the skin is temporally regulated: i) cGAS is required for early (6hr after UV) ISG expression and ii) cGAS contributes to, but is not the sole player in late (24hr after UV) ISG induction. Presence of IFN-I signature in both the non-lesional skin as well as in peripheral blood cells, together with increased circulating IFNβ levels, provide a model by which skin exposure to UVB light drives systemic activation of the IFN-I response.

A Phase 3 Randomized Controlled Trial of Anifrolumab in Patients with Moderate to Severe Systemic Lupus Erythematosus

Richard Furie ,[1] Eric Morand,[2] Ian Bruce,[3] Susan Manzi,[4] Kenneth Kalunian,[5] Edward Vital,[6] Theresa Lawrence-Ford,[7] Ramesh Gupta,[8] Falk Hiepe,[9] Mittermayer Santiago,[10] Philip Brohawn,[11] Anna Berglind,[12] and Raj Tummala[13], [1]Zucker School of Medicine at Hofstra/Northwell, New York, NY, [2]Monash University, Melbourne, Victoria, Australia, [3]University of Manchester, Manchester, United Kingdom, Manchester, England, United Kingdom, [4]Allegheny Health Network, Pittsburg, PA, [5]Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, CA, [6]University of Leeds, Leeds, United Kingdom, [7]North Georgia Rheumatology, Lawrenceville, GA, [8]Baptist Memorial Hospital-Memphis, Memphis, TN, [9]Charité University Hospital Berlin, Berlin, Germany, [10]Bahiana School of Medicine and Public Health, Bahia, Brazil, [11]AstraZeneca, Gaithersburg, MD, [12]AstraZeneca, Gothenburg, Sweden, [13]AstraZeneca, Gaithersburg, MD, USA, Gaithersburg, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Plenary II
Session Type: Plenary Session II
Session Time: 11:00AM–12:30PM

Background/Purpose: In a phase 2 study in SLE patients (pts), substantial efficacy was observed with anifrolumab, a human monoclonal antibody that binds the type I IFN receptor subunit 1. TULIP-1, a phase 3 randomized, double-blind, placebo-controlled trial (NCT02446912), evaluated efficacy and safety of anifrolumab in pts with moderate to severe SLE.

Methods: SLE pts meeting ACR criteria with SLEDAI-2K ≥6 and BILAG ≥1 A or ≥2 B were randomized 2:1:2 to receive IV anifrolumab 300 or 150 mg or placebo (PBO) Q4W and background standard-of-care (SOC) therapy. Stable SOC was required throughout the study except for mandatory attempts at oral corticosteroid (OCS) tapering for pts receiving ≥10 mg/d prednisone or equivalent at entry. The primary endpoint was the difference between Week (W) 52 SRI(4) rates for anifrolumab 300 mg and PBO. Key secondary endpoints included OCS dosage reduction (baseline ≥10 mg/d to ≤7.5 mg/d), W12 CLASI response, and annualized flare rates. BICLA, joint counts, IFN gene signature

Table. Baseline Demographics and Disease Characteristics

Patient characteristic	Anifrolumab 300 mg (n=180)	Anifrolumab 150 mg (n=93)	PBO (n=184)
Age, years, mean (SD)	42.0 (11.99)	40.8 (12.05)	41.0 (12.30)
Female, n (%)	165 (91.7)	86 (92.5)	171 (92.9)
Time from SLE diagnosis to randomization, months, median (min, max)	88.0 (0, 450)	87.0 (6, 458)	79.5 (4, 503)
SLEDAI-2K global score, mean (SD)	11.3 (4.04)	11.0 (3.50)	11.5 (3.50)
BILAG-2004 ≥1 A, n (%)	93 (51.7)	40 (43.0)	84 (45.7)
BILAG-2004 no A and ≥2 B, n (%)	79 (43.9)	48 (51.6)	84 (45.7)
PGA score, mean (SD)	1.87 (0.399)	1.84 (0.446)	1.84 (0.383)
CLASI activity score, mean (SD)	8.5 (7.26)	7.7 (6.71)	8.1 (6.66)
SDI global score, mean (SD)	0.7 (1.16)	0.5 (0.96)	0.6 (0.98)
Swollen joint count, mean (SD)	7.4 (5.79)	7.4 (6.20)	7.0 (4.80)
Tender joint count, mean (SD)	11.7 (7.50)	11.3 (8.03)	10.6 (7.17)
High type I IFNGS, n (%)	148 (82.2)	76 (81.7)	151 (82.1)
Elevated anti-dsDNA antibodies, n (%)	81 (45.0)	44 (47.3)	82 (44.6)
Abnormal complement concentration, n (%)			
C3	58 (32.2)	34 (36.6)	65 (35.3)
C4	35 (19.4)	21 (22.6)	39 (21.2)
Key baseline SLE treatments			
OCS (prednisone or equivalent), n (%)	150 (83.3)	78 (83.9)	153 (83.2)
OCS dosage ≥10 mg/d, n (%)	103 (57.2)	48 (51.6)	102 (55.4)
Immunosuppressants, n (%)	85 (47.2)	38 (40.9)	91 (49.5)
Antimalarials, n (%)	124 (68.9)	76 (81.7)	134 (72.8)

Abbreviations: anti-dsDNA = anti–double-stranded DNA; BILAG = British Isles Lupus Assessment Group; CLASI = Cutaneous Lupus Erythematosus Disease Area and Severity; IFNGS = interferon gene signature; OCS = oral corticosteroid; PBO = placebo; PGA = Physician's Global Assessment; SD = standard deviation; SDI = Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index; SLE = systemic lupus erythematosus; SLEDAI = SLE Disease Activity Index.

(IFNGS), and safety were assessed. Post hoc analyses used modified restricted medication rules that were revised after unblinding to be more clinically appropriate.

Results: All 457 randomized pts received ≥1 dose of study drug and were included in the analyses (anifrolumab 300 mg, n=180; anifrolumab 150 mg, n=93; PBO, n=184). Baseline characteristics (**Table**) and treatment completion rates (~80%) were similar across groups. No difference in W52 SRI(4) response rates was observed for anifrolumab 300 mg (36.2% [65/180]) vs PBO (40.4% [74/184]); SRI(4) rates in the IFNGS test–high subgroup were 35.9% (53/148) and 39.3% (59/151), respectively. In prespecified analyses, any increase in NSAID dose or new NSAID use inadvertently resulted in nonresponse classification. Post hoc analyses, therefore, used modified restricted medication rules. In these post hoc analyses, W52 SRI(4) rates were 46.9% (84/180) for anifrolumab 300 mg vs 43.0% (79/184) for PBO; SRI(4) rates in the IFNGS test–high subgroup were 48.2% (71/148) vs 41.8% (63/151), respectively. Differences favored anifrolumab 300 mg over PBO for BICLA in all pts (46.1% [83/180] vs 29.6% [54 /184], diff: 16.4%; 95% CI: 6.7, 26.2) and in the IFNGS test–high subgroup (45.9% [68/148] vs 27.5% [41/151], diff: 18.4%; 7.7, 29.1). Differences favoring anifrolumab 300 mg vs PBO also occurred for OCS dosage reduction (48.8% [50/103] vs 32.1% [33/102], diff: 16.7%; 95% CI: 3.5, 29.8) and CLASI (43.6% [25/58] vs 24.9% [14/54], diff: 18.7%; 1.4, 36.0) as well as joint activity and flare reduction. IFNGS was suppressed with anifrolumab 300 mg but not PBO. Serologic changes showed trends toward normalization for anifrolumab 300 mg. Serious AEs occurred in 13.9% and 10.8% of pts with anifrolumab 300 and 150 mg vs 16.3% with PBO. Herpes zoster was more common in the anifrolumab groups vs PBO (5.6% and 5.4% vs 1.6%).

Conclusion: Although the primary endpoint, SRI(4), was not achieved in TULIP-1, numeric improvements achieving thresholds associated with clinical benefit were observed for BICLA, OCS, and other organ-specific endpoints. Anifrolumab 300 mg suppressed IFNGS and was generally well tolerated.

CCL25, a Novel Fibroblast and Macrophage Chemoattractant That Potentiates RA Bone Erosion

Sadiq Umar ,[1] Katrien Raemdonck,[1] Karol Palasiewicz,[1] Michael Volin,[2] Shiva Arami,[1] Suncica Volkov,[1] Nadera Sweiss,[1] M Amin,[3] and Shiva shahrara[1], [1]University of Illinois at chicago, Chicago, IL, [2]Department of Microbiology & Immunology, Midwestern University, Downer Grove, IL, [3]University of Michigan, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: CCL25 and its receptor CCR9 have been detected in the inflamed joint; however their role is undefined in rheumatoid arthritis (RA). Hence studies were conducted to characterize the expression and functional significance of CCL25 and CCR9 in the inflammatory & erosive phases of RA.

Methods: For this purpose, expression pattern of CCR9 was determined in RA, osteoarthritis (OA) and normal (NL) synovial tissues (STs) as well as in RA ST fibroblasts (FLS) & *in vitro* differentiated macrophages (Mφ). Protein levels of CCL25 were quantified in synovial fluid (SF) and plasma from RA, OA and/or NL donors. Next role of CCL25 was evaluated in RA FLS and Mφ trafficking & inflammatory response in addition to identifying the signaling pathways linked to these functions. Last CCL25 potency was examined in the remodeling of RA naïve cells into mature osteoclasts.

Results: We show that CCR9 is highly expressed on RA ST lining, sublining and endothelial cells compared to OA and NL STs. While CCL25 expression is markedly elevated in RA & OA ST lining, sublining and endothelial cells relative to NL ST counterparts. Consistent with this notion, we found that CCR9 was expressed on unstimulated RA FLS (35%) and activation with IL-1β, TNF, IL-6 and RA SF can further accentuate its cell surface expression by 4-5 fold. In contrast, these inflammatory mediators did not impact CCR9 cell surface expression on RA Mφs. Nevertheless, we demonstrate that CCR9 cell surface expression is enhanced by 10 fold when RA monocytes (4%) are differentiated into Mφs (48%). Corroborating the histological findings, we reveal that CCL25 protein levels are comparable in RA and OA SF; which was significantly higher than those detected in RA and NL plasma. Interestingly, we showed that CCL25 present in RA SF can dose responsively attract RA FLS and monocytes into the joint and this process was suppressed by ERK and p38 inhibitors. On the contrary, stimulation with CCL25 did not instigate phagocytosis in fully differentiated RA Mφ. Next impact of CCL25 was examined on RA FLS and RA Mφ inflammatory response. We demonstrated that unlike RA FLS that were unaffected by CCL25 activation; stimulation of RA Mφ with CCL25

enhanced IL-8 production by 2 fold which was dependent on p38 and ERK signaling. However addition of RA FLS to RA Mφs in culture did not amplify CCL25's inflammatory response detected in myeloid cells. We also established that in later stages of disease, CCL25 was capable of remodeling RA myeloid progenitor cells into mature osteoclasts potentially by IL-8 induction.

Conclusion: We have uncovered that elevated levels of CCL25 in RA SF trigger infiltration of CCR9+ RA fibroblast and monocyte into the joint and accelerates transformation of myeloid cells into bone eroding osteoclasts. Our results suggest that CCL25 and CCR9 play an important role in the early and the later phases of RA pathology.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: It is known that rheumatoid arthritis (RA) should be treated early and a delay in treatment increases the rate of treatment non-response, joint damage, and disability. This is often explained by a diversity of molecular processes in the early and established phases of RA. The purpose of this study was to assess cytokine-dependent change in DNA methylation in CD4+ T cells of patients with early and established RA.

Methods: A cross-sectional RA cohort was analysed by comparing patients with the disease duration < 3y (mean 1.7y, n=23), 3-10y (mean 5.6y, n=94) and >10y (mean 19y, n=68). Serum levels of cytokines were measured by ELISA. Genome-wide DNA methylation was performed in sorted and activated CD4+ T cells of early (mean 1.3y, n=10) and established (mean 12.6y, n=14) RA patients using Infinium MethylationEPIC BeadChip (Illumina). Chromatin was immunoprecipitated with survivin (BIRC5) of CD4+T cells and coupled with high throughput sequencing (Hiseq2000, Illumina). False discovery rate was calculated using the Benjamini method.

Results: The groups differed with respect to the serum levels of IFNg, IL9, and IL6. The patients with RA< 3y had low cytokine levels and high serum survivin, while the patients with RA >10y had high IFN, IL9, and BIRC5 mRNA, suggesting IFNg and IL9 to be important for maintaining disease activity in patients with the established RA. The differential DNA methylation in CD4+ T cells of early and established RA (p< 10-5) identified IFNg- and IL9-dependent change in CpG rich areas. In dominating majority of CpG areas, an increase of cytokines was associated with a reduction of DNA methylation, which is known to precede the initiation of gene transcription. Since patients with established RA frequently combined high cytokines with high BIRC, we analyzed if this affects DNA methylation. Comparing CD4 with high and low BIRC5, we found that 85% of IFNg-dependent and 67% of IL9-dependent DNA

methylation changes occurred in presence of high BIRC5. To study if BIRC5 is found attached to chromatin, we performed chromatin immunoprecipitation in CD4+T cells. Analysis of the BIRC5-bound chromatin revealed enrichment for IRF-specific sequences where IRF1- and IRF8-binding sequences, but not IRF3 and IRF2 were predominantly found. We also found enrichment with complex sequences specific for binding bZIP-IRF (and not IRF-bZIP) and IRF-BATF sequences.

Conclusion: IFNg and IL9 are important for maintaining disease activity in patients with the established RA. In collaboration with intracellular survivin (BIRC5), these cytokines change the DNA methylation and gene transcription in CD4+ cells.

GM-CSF Is a Pro-Inflammatory Cytokine in Experimental Vasculitis of Medium and Large Arteries

Ryu Watanabe,[1] Hui Zhang,[2] Toshihisa Maeda,[3] Mitsuhiro Akiyama,[2] Rohan Gandhi,[4] John Paolini,[5] Gerald Berry,[1] and **Cornelia Weyand** [2], [1]Stanford University, Stanford, [2]Stanford University, Stanford, CA, [3]Matsubara Mayflower Hospital, Kobe, Japan, [4]Kiniska Pharmaceuticals, San Diego, [5]Kiniska Pharmaceuticals, Lexington, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Giant Cell Arteritis (GCA) is a granulomatous vasculitis with tissue tropism for medium and large arteries. Macrophages are a key cellular component of the granulomatous infiltrates and contribute to the disease process through the production of cytokines, growth factors and tissue-injurious proteases. Lesional macrophages can fuse to form the typical giant cells, the namesakes of the disease. To which extent the number of macrophages in the vasculitis lesions affects the intensity of inflammation is unknown. We have tested whether granulocyte-macrophage colony-stimulating factor (GM-CSF), a soluble cytokine involved in the generation the survival and the activation of macrophages has a role in exacerbating vascular inflammation. In a preclinical animal model of vasculitis, we have injected recombinant GM-CSF (rGM-CSF) or blocked GM-CSF activity by treating with Mavrilimumab (KPL-301), a monoclonal antibody, which inhibits the GM-CSF receptor-α.

Methods: Vasculitis was induced in human artery mouse chimeras by engrafting medium-sized human arteries and adoptively transferring peripheral blood mononuclear cells from patients with GCA. One group of mice received 50 ug of recombinant GM-CSF. Another group of mice was treated with control IgG or anti-GM-CSF. Another group of mice was treated with control IgG or anti-GM-CSFRα antibody intraperitoneally over one week. Arteries were harvested and examined by Hematoxylin and eosin staining and tissues transcripts.

Results: Compared to treatment controls, recombinant GM-CSF intensified and KPL-301 reduced tissue inflammation in the arteries. The numbers of tissue-residing T cells doubled after rGM-CSF injection and was reduced by about 50% after treating with the blocking antibody. Changes in the density of inflammatory cells were accompanied by parallel changes in he tissue gene expression of IL-1β, IL-6 and IFN-γ. the tissue expressions of IL-17 and TNF-α transcripts were unaffected by either intervention.

Conclusion: We conclude that GM-CSF has a role as an inflammatory cytokine in medium vessel vasculitis. The density of inflammatory cells in the lesions appears to be GM-CSF dependent. the effect of GM-CSF seems selective, with IL-17 and TNF-α being independent of GM-CSF signaling in this model.

Biomarker Profiling Reveals Novel Mechanistic Insights into Ustekinumab Therapeutic Responses in Systemic Lupus Erythematosus

Matteo Cesaroni ,[1] Loqmane Seridi,[1] Jarrat Jordan,[1] Kristen Sweet,[1] Keying Ma,[1] Carol Franks,[1] Jessica Schreiter,[1] Peter Lipsky,[2] Ronald van Vollenhoven,[3] Bevra Hahn,[4] Shawn Rose,[1] Frédéric Baribaud,[1] Matthew Loza,[1] Kim Campbell,[1] and George Tsokos[5], [1]Janssen Research & Development, LLC, Spring House, PA, [2]AMPEL BioSolutions, LLC, Charlottesville, VA, [3]Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, [4]University of California, Los Angeles, CA, [5]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Systemic lupus erythematosus (SLE) is a heterogenous autoimmune disease that causes progressive organ damage. The cytokines type I interferon (IFN-I), IL-12 and IL-23 have all been shown to contribute to SLE pathogenesis. We previously reported that treatment with ustekinumab (UST), an anti-IL-12/23 p40 neutralizing monoclonal antibody, improved global and organ-specific measures of disease activity in a randomized, placebo (PBO)-controlled study of patients with active SLE (NCT02349061)[1]. Here, we utilized biomarker data from this clinical study to elucidate the mechanism of action of UST in SLE.

We aimed to determine whether modulation of IL-12, IL-23, or both cytokines was associated with clinical efficacy, and to ascertain whether UST treatment could modulate IFN-I or improve disease activity in patients exhibiting an elevated IFN-I signature at baseline.

Methods: A Phase 2, placebo (PBO)-controlled study enrolled 102 patients with seropositive SLE and active disease despite standard-of-care therapy[1]. Patients were randomized 3:2 to receive UST IV ~6 mg/kg or PBO at week 0, then subcutaneous injections of 90mg UST q8w or PBO. Whole blood RNA from PAXgene tubes and serum were collected over 24 weeks. Age and sex-matched healthy controls were also studied. Serum IFN-g, and IL-17A, IL-17F and IL-22 levels were quantified by ELISA as indicative of the IL-12 and IL-23 pathways, respectively and an IFN-a ELISA was utilized to quantify the IFN-I pathway. Whole blood RNA was assessed for gene expression by microarray. Two Th17[2,3], an IFN-g[4] gene signature and 21-gene IFN-I signature (IGS)[5] were analyzed. SLE Responder Index (SRI)-4 at week 24 was used to define UST response (UST-R) and non-response (UST-NR).

Results: Serum IL-17A, IL-17F and IL-22 levels and Th17 gene signature levels in blood remained largely stable over the course of 24 weeks in all treatment groups. In contrast, UST-R was associated with a durable reduction in IFN-g protein and IFN-g gene signature levels relative to baseline, which was not observed in UST-NR or PBO patients. IGS levels were elevated in 67% of patients at baseline versus healthy controls. Serum IFN-a levels and IGS levels in blood were not modulated by UST treatment through week 24. Baseline IFN-I signature status did not associate

with response to UST, as the treatment effect size (UST vs PBO) was similar in IGS low (Δ=27%) and high (Δ=28%) patients.

Conclusion: Response to UST was associated with reductions in IFN-g levels, whereas IL-17A, IL-17F, IL-22 and IFN-I remained largely unchanged. While these findings require confirmation in an ongoing Phase 3 study, these data implicate the involvement of the IL-12 pathway and suggest a novel mechanism of action for UST-R in SLE.

A First-in-class Selective and Potent IRAK4 Degrader Demonstrates Robust *in Vitro* and *in Vivo* Inhibition of TLR/IL-1R Activation and Inflammation

Veronica Campbell ,[1] Joseph Kelleher,[1] Jesse Chen,[1] Jared Gollob,[2] Nan Ji,[2] Christine Klaus,[2] Christine Loh,[2] Michelle mayo,[2] Alice McDonald,[2] Haojing Rong,[2] Scott Rusin,[2] Kirti Sharma,[2] Matt Weiss,[2] Karen Yuan,[2] Duncan Walker,[2] Xiaozhang Zheng,[2] Anthony Slavin,[2] and Nello Mainolfi[2], [1]Kymera Therapeutics, cambridge, MA, [2]Kymera Therapeutics, Cambridge

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: IL-1R/TLR activation plays a central role in the pathophysiology of multiple autoimmune and inflammatory diseases driven by the IL-1 family of cytokines and by TLR ligands. Full signaling from IL-1Rs and TLRs through the Myddosome is dependent on both the kinase and scaffolding functions of Interleukin-1 receptor associated kinase 4 (IRAK4) (De Nardo et al. JBC 2018, De et al. JBC 2018). Therefore, hetero-bifunctional molecules that selectively target IRAK4 for degradation and elimination by the ubiquitin proteasome pathway have greatest po-

tential to abrogate IL-1R/TLR signaling and shut down both the production of and response to TLR and IL-1 family cytokines.

Methods: Heterobifunctional degraders were designed to selectively target IRAK4 protein. Degradation selectivity was assessed in relevant human PBMC population by unbiased tandem mass tag proteomics. *In vitro,* PBMC flow cytometry and cytokine release assays were established to determine degradation potency (DC_{50}) and inhibition of R848, LPS and IL-1β induced pro-inflammatory cytokines. IRAK4 degrader was dosed orally in the mouse monosodium urate (MSU) air pouch model of gouty arthritis. *In vivo,* degradation was measured in mouse spleen tissues by targeted mass spectrometry.

Results: Unbiased proteomics with a depth >10,000 proteins showed exclusive degradation of IRAK4 in human PBMCs. *In vitro*, selective IRAK4 degraders led to potent and greater than 90% degradation in both lymphocytes (DC_{50}= 1.5nM) and monocytes (DC_{50}=0.4nM). Pre-treatment with IRAK4 degraders achieved potent single digit nanomolar inhibition of R848, LPS and IL-1β induced pro-inflammatory cytokines (TNF-α, IL-6) and chemokines (CCL3). Importantly, IRAK4 degradation led to more effective inhibition of cytokine and chemokine induction compared to a selective IRAK4 kinase inhibitor. Oral administration of an IRAK4 degrader in the mouse MSU air pouch model led to dose-dependent IRAK4 degradation in spleen tissue and a marked decrease in neutrophil infiltration (p=0.002 unpaired t test, two-tailed).

Conclusion: Selective and potent targeted IRAK4 degradation led to marked inhibition of both TLR- and IL-1R-mediated pro-inflammatory cytokine and chemokine production. By removal of both scaffolding and kinase functions, IRAK4 degradation demonstrated greater activity compared to kinase inhibition alone across multiple TLR/IL-1R stimuli. Promising *in vivo* mouse data showed that oral administration of an IRAK4 degrader can be achieved and have an effect on TLR/IL-1β-driven inflammation in a gouty arthritis model. Together, these data show the potential for IRAK4 degraders to treat TLR/IL-1R-driven inflammatory and autoimmune diseases.

Myosin Regulation of TNF Receptor 2 Signaling May Contribute to Anti-TNF Therapy Response

Unnikrishnan M Chandrasekharan ,[1] Jennifer Harvey,[2] Mackenzie Dunlap,[2] Marcia Leon Rabanal,[2] Vandana Rai,[2] and M. Elaine Husni[3], [1]Cleveland clinic foundation, Cleveland, OH, [2]Cleveland clinic, Cleveland, [3]Department of Rheumatologic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Cytokines & Cell Trafficking
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Anti-TNF agents have revolutionized the clinical outcomes of patients with rheumatoid and psoriatic diseases. However, up to 40% of patients do not respond or partially respond, or lose efficacy of therapeutic response over time. There are no clinical tests available to predict responsiveness to anti-TNF therapy ahead of time. Small studies have supported that patients carrying TNFR2-M196R, (approx. 20% prevalence in general population) demonstrate a higher risk of being an inadequate responders to anti-TNF drugs, however, the underlying mechanisms are unclear. We have shown previously that non-muscle myosin (myosin) functions as a negative regulator of TNFR2 activation. Here, we test the hypothesis that a defect in myosin binding to TNFR2-M196R causes a TNF-independent proinflammatory activity and that leads to reduced responsiveness to anti-TNF agents.

Methods: We expressed equal levels of recombinant TNFR2-M196R or TNFR2 in primary endothelial cells and Jurkat T cells using lentiviral approach. To test whether myosin binds with TNFR2-M196R, we immunoprecipitated the recombinant TNFR2-M196R from the cells and probed for myosin by immunoblot. Proinflammatory gene induction in response to TNF in cells expressing TNFR2-M196R was measured at mRNA and Protein level by Q-PCR and ELISA, respectively. ROCK1 activity, which cause the release of myosin from TNFR2 were measured using Immunoprecipitated ROCK1 followed by MYPT1 phosphorylation.

Results: Our co-immunoprecipitation studies demonstrate that TNFR2-M196R variant does not bind to myosin as opposed to TNFR2. We also found TNFR2-M196R expressing cells show TNF-independent, ROCK1 activity and proinflammatory gene induction (e.g. ICAM1, CXCL10) in endothelial cells and Jurkat T- cells. Importantly, a TNF-neutralizing antibody failed to inhibit this constitutive gene induction in TNFR2-M196R expressing cells. ROCK1 inhibition blocks this TNF-independent activity. Furthermore, elevated proinflammatory gene induction upon TNF is sustained for longer time period in TNFR2-M196R expressing cells is (8 -10 hour) compared to TNFR2 expressing cells (4-6 hour). Mechanistically, TNFR2-M196R drives cells to a constitutive proinflammatory statepotentially due to a defect in myosin binding. Since this constitutive activity is TNF-independent, and given that ~20% of the general population carry TNFR2-M196R polymorphic variant, our findings may potentially explain in part, why a significant percentage of patients do not adequately respond to anti-TNF therapy.

Conclusions: Our mechanism-based approach implicating TNFR2-M196R could be tested in patients that are candidates for anti TNF therapy. Our approach not only may help to predict anti-TNF responsiveness but may also reveal novel pathways that can be targeted to treat inadequate responders of anti-TNF therapy in a subset of patients with rheumatoid and psoriatic diseases.

Experimental Rheumatoid Joint Ameliorated by CRISPR Interference Targeting Long Non-coding RNA H19 Through Wnt Signaling Inactivation

Chrong-Reen Wang ,[1] Shih-Yao Chen,[1] Yu-Chi Chou,[2] Chao-Liang Wu,[3] Yu-Ting Lo,[1] and Ai-Li Shiau[4], [1]National Cheng Kung University Hospital, Tainan, Taiwan (Republic of China), [2]Genomics Research Center, Academia Sinica, Taipei, Taiwan (Republic of China), [3]National Cheng Kung University Medical College, Tainan, Taiwan (Republic of China), [4]National Cheng Kung University Medical College, Tainan, Taiwan (Republic of China)

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Long non-coding RNAs (lncRNAs) participate in the rheumatoid arthritis (RA) pathogenesis. The aim of this study was to examine the lncRNA H19 and HOTAIR expression in RA patients, and whether delivery of CRISPR interference (CRISPRi) with catalytically dead Cas9 (dCas9) targeting H19 can ameliorate the experimental rheumatoid joint.

Methods: Synovial tissue (ST) and venous blood samples were obtained from RA and osteoarthritis (OA) patients. Synovial fibroblasts (SFs) were purified from ST, and normal SFs were acquired commercially. To generate CRISPRi-H19 and CRISPRi-HOTAIR, guide RNA spacer sequences targeting H19 or HOTAIR were cloned into the CRISPRi vector containing the dCas9/Krüppel-associated box repressor domain with an efficient transcription repression ability. SFs and 293T cells were transduced with CRISPRi-H19 and CRISPRi-HOTAIR, respectively, to create stable transfectants. Therapeutic effects of intra-articular CRISPRi-H19 injection were assessed in a rat model of collagen-induced arthritis. LncRNAs expression were examined by quantitative real-time PCR. Cell invasion was assayed by Transwells with membrane coated with Matrigel.

Results: Increased synovial and peripheral H19 levels were found in RA patients with decreased H19 expression in venous mononuclear cells (MNCs) after a TNF blockade (adalimumab) therapy as compared with OA counterparts. There were higher HOTAIR levels in MNCs from RA patients, but no differences after the anti-TNF therapy. H19 levels in SFs were enhanced by the TNF stimulation. Reduced H19, pGSK-3β (Wnt signaling), EZH2 and Snail expression, cell invasion and IL-6 production with increased Nkd1 (Wnt inhibitor) expression were identified in H19-silenced SF transfectants. Decreased Tri-Methyl-H_3K_{27} expression were found in HOTAIR-silenced 293T transfectants. Lower arthritis indexes and histological scores with less erosion on cartilage/bone were demonstrated in the CRISPRi-H19-injected joints with enhanced NKd1 and decreased H19, pGSK-3β, EZH2, Snail and IL-6 expression, suggesting silencing H19 to ameliorate experimental rheumatoid joint through inactivating the Wnt signaling.

Conclusion: Our results demonstrate that intra-articular delivery of CRISPRi targeting lncRNA can alleviate the experimental rheumatoid joint. Such findings might contribute to the development of lncRNAs-related therapeutics in RA patients.

MyD88 S209R Enhances Inflammation in Mouse Models of Arthritis

Sufia Bakshi ,[1] Anders Lindstedt,[2] Malika Waschmann,[3] Wanxia Tsai,[1] Robert Colbert,[4] and Keith Sikora[1], [1]National Institutes of Health, Bethesda, MD, [2]NIH, Bethesda, MD, [3]Oregon Health and Science University, Portland, OR, [4]Pediatric Clinical Trials Unit, Pediatric Translational Research Branch, NIAMS, NIH, Bethesda, MD

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: MyD88 is a critical adaptor protein that connects Toll-like and IL-1 receptor signaling to activation of NF-kB. We previously reported a heterozygous *de novo* gain-of-function mutation in *MYD88* (S222R) in a patient with a progressively deforming arthritis characterized by marked bony overgrowth in arthritic lesions. To further investigate the contribution of MyD88 to arthritis pathogenesis, we created a novel *Myd88* gene-edited (S209R) mouse using CRISPR/Cas.

Methods: We induced arthritis with collagen (CIA) in wild-type (WT), *Myd88*$^{S209R/WT}$, and *Myd88*$^{S209R/S209R}$ C57BL/6 mice to assess differences in incidence, duration, and severity of arthritic phenotype. Arthritis was assessed via clinical scoring, caliper measurements of limb swelling, and H&E and safranin-O staining of limb sections. Since CIA elicits a directly-pathogenic adaptive immune response, anti-collagen antibodies were quantified from serum samples. To bypass the role of MyD88 in collagen-antibody production, we induced arthritis with anti-collagen antibodies (CAIA) in WT, *Myd88*$^{S209R/WT}$, and *Myd88*$^{S209R/S209R}$ mice and assessed arthritis severity as above. *In vitro* assays were conducted to determine the effect of the mutation on T cells, including supernatant cytokine quantification, and measurement of proliferation rates by dye dilution.

Results: Mice harboring the *Myd88*-S209R mutation did not develop a spontaneous arthritic phenotype. CIA was achievable in 75% of *Myd88*$^{S209R/S209R}$ mice, 56% of *Myd88*$^{S209R/WT}$, and 38% of WT mice. *Myd88*$^{S209R/S209R}$ mice produced significantly higher amounts of anti-collagen antibodies than WT mice. Histological scoring revealed significantly more bone overgrowth in *Myd88*$^{S209R/S209R}$ and *Myd88*$^{S209R/WT}$ mice compared to WT. All mice that received exogenous anti-collagen antibodies developed arthritis, however arthritis in *Myd88*$^{S209R/S209R}$ and *Myd88*$^{S209R/WT}$ persisted longer than WT mice. Data from these experiments indicate enhancement of both the lymphocyte-dependent production of antibodies and their downstream pathogenic effects. *In vitro* analysis showed that *Myd88*$^{S209R/WT}$ T cells secreted more GM-CSF, IL-1b and CCL4 in response to stimulation. Additionally, naive T cells from *Myd88*$^{S209R/S209R}$ and *Myd88*$^{S209R/WT}$ mice showed increased rates of proliferation.

Conclusion: The *Myd88*-S209R mutation impacts CIA and CAIA models by increasing the incidence and duration of the arthritic phenotype, as well as changes suggestive of new bone formation. This is the first description of a mouse model harboring the *Myd88*-S209R mutation, which will allow for further investigation of the mechanism(s) by which innate and adaptive immune activation through MyD88 contributes to the complex phenotype of arthritis.

Chronotherapy Using Baricitinib Attenuates Collagen-induced Arthritis in Mice

Arisa Yaekura ,[1] Kanta Morii,[2] Yuto Oketani,[3] Ikumi Okumura,[2] Kenta Kaneshiro,[4] Kohsuke Yoshida,[2] Yoshiko Kawasaki,[5] Nao Shibanuma,[5] Yoshitada Sakai,[6] and Akira Hashiramoto[2], [1]Kobe University Graduate School of Health Sciences, Kawanishi, Hyogo, Japan, [2]Kobe University Graduate School of Health Sciences, Kobe, Hyogo, Japan, [3]Kobe University Graduate School of Health Sciences, Himeji, Hyogo, Japan, [4]Kobe University Graduate School of Health Sciences, Osaka, Osaka, Japan, [5]Kobe Kaisei Hospital, Kobe, Hyogo, Japan, [6]Kobe University Graduate School of Medicine, Kobe, Hyogo, Japan

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: RA – Animal Models

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

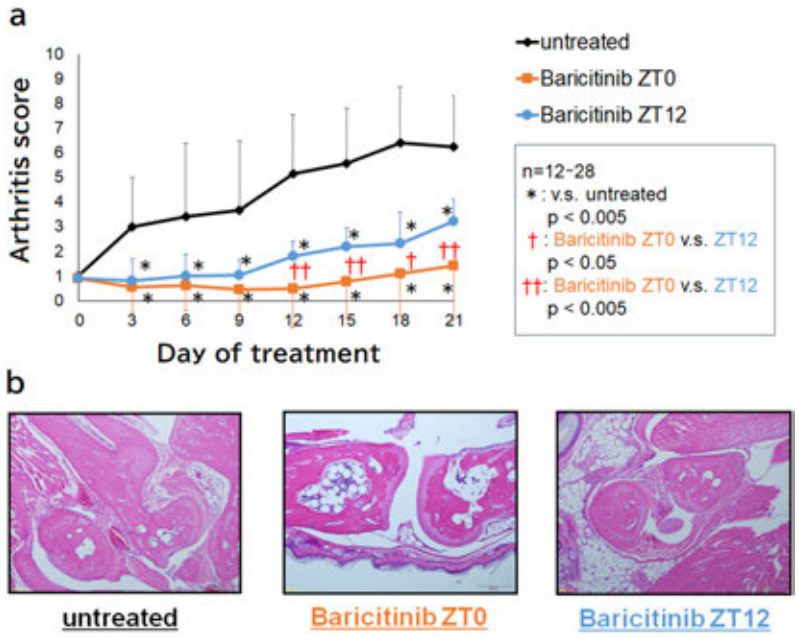

Figure 1. Arthritis score of ZT0/12 group decreased from day3 as compared to the untreated group, and those of ZT12 group rose significantly higher than those of ZT0 group from day12 (a). Joint destructions with synovial hyperplasia were observed in untreated group and ZT12 treated group, while those were suppressed in ZT0 group (b).

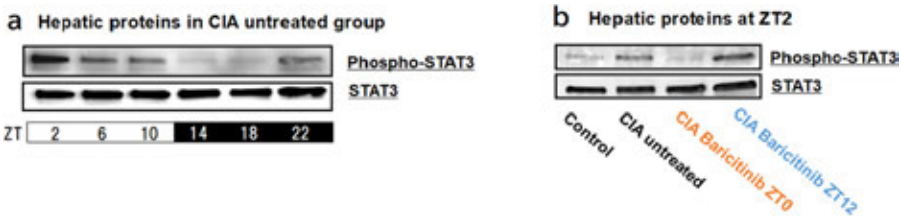

Figure 2. In CIA mice, STAT3 was highly phosphorylated from ZT22 to ZT10 (a). Phosphorylation of STAT3 was suppressed in ZT0 group at ZT2 (b).

Background/Purpose: Diurnal variations are observed in symptoms of rheumatoid arthritis (RA). Among them, “morning stiffness of joints” is closely reflects the daily medical condition of RA patients. The diurnal variation is also present in the production of inflammatory cytokines that interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-α) or interferon-gamma (IFN-γ) show peak concentrations in sera of RA patients during mid night, and similarly, those of collagen-induced arthritis (CIA) mice are reported to increase from morning to evening. A Janus kinase (JAK) inhibitor Baricitinib, orally administrated once a day, competitively inhibits phosphorylation of JAK1/2 bound of type 1/2 cytokine receptors, and suppresses productions of wide range of inflammatory cytokines derived from JAK/ signal transducers and activator of transcription (STAT) pathway. As reference to a recent report that chronotherapy using modified-release prednisone effectively suppresses “morning stiffness” of RA patients, in this study, differences in efficacy according to oral administration time of Baricitinib, targeting peaks of cytokine secretion, were examined in CIA mice.

Methods: CIA mice were administered a dose of 3 mg/kg of Baricitinib once a day at zeitgeber time (ZT) 0 or ZT12 for 21 days. Mice paws and ankles were scored on a scale from 0-4, as the cumulative value for all paws with a maximum possible score of 16, every third day. On day21, Hind limbs were examined by hematoxylin eosin staining.

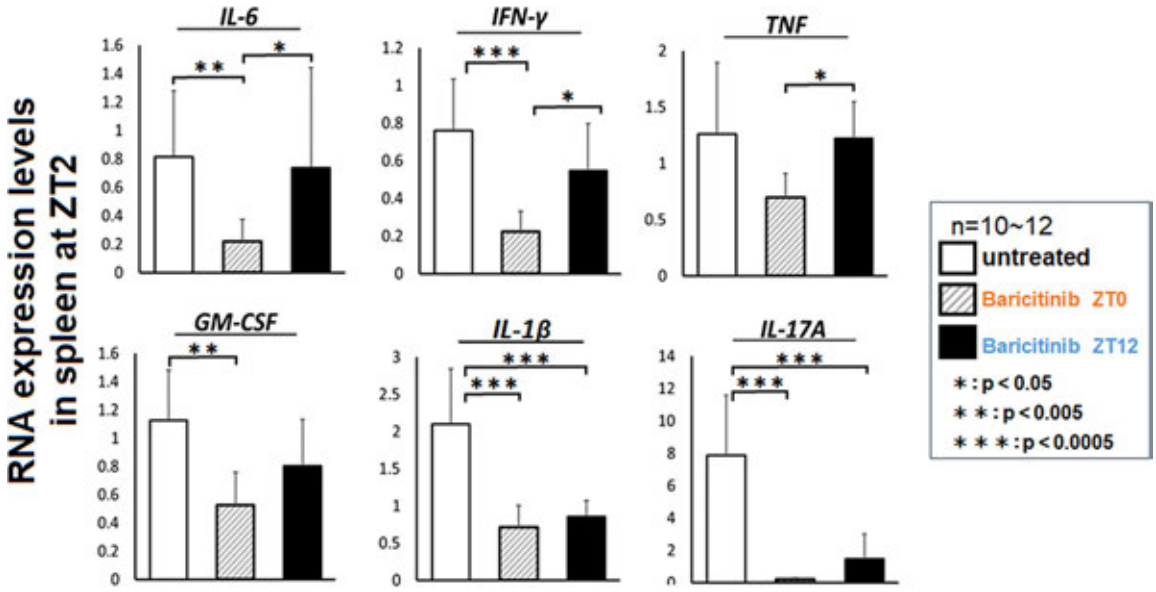

Figure 3. RNA expression levels in spleen at ZT2.

Hepatic proteins at ZT2, 6, 10, 14, 18 and 22 were analyzed for phosphorylation of STAT3 by western blotting. Splenic lymphocytes were isolated at ZT2, 6, 10, 14, 18 and 22 to measure expressions of *IL-1β*, *IL-6*, *IL-17A*, *TNF*, *IFN-γ* and *Granulocyte Macrophage Colony-Stimulating Factor* (*GM-CSF)* by Real-time PCR.

Results: Arthritis score of ZT0/12 group decreased from day3 as compared to the untreated group, and those of ZT12 group rose significantly higher than those of ZT0 group from day12 (Fig. 1a). Joint destructions with synovial hyperplasia were observed in untreated group and ZT12 treated group, while those were suppressed in ZT0 group (Fig. 1b). In CIA mice, STAT3 was highly phosphorylated from ZT22 to ZT10 (Fig. 2a), and it was suppressed in ZT0 group (ZT2) (Fig. 2b). The expressions of *IL-1β*, *IL-6*, *TNF*, and *GM-CSF* reached maximum levels at ZT2 in untreated group, and that of *IFN-γ* reached maximum level at ZT22. At ZT2, the expressions of *IL-6*, *IFN-γ*, *TNF* and *GM-CSF* in ZT0 treated group were significantly decreased as compared to untreated mice, whereas those of ZT12 group were not. The expressions of *IL-1β*, *IL-17A* in lymphocytes were significantly decreased by Baricitinib treatment as compared to untreated group (Fig. 3).

Conclusion: Administration of Baricitinib at ZT0 significantly attenuated the progression of arthritis in CIA mice. Results show that chronotherapy targeting cytokine secretions is far more effective than previously considered, and clinical application of chronotherapy using Baricitinib can be expected to enhance the drug efficacy by appropriate administration.

Abstract Number: 1773

The Card9-Neutrophil Signaling Axis Is Critical to Induction of Th17-Mediated Arthritis in SKG Mice

Ruth Napier ,[1] Ellen Lee,[1] Emily Vance,[1] Beatitude Steffen,[2] Shimon Sakaguchi,[3] and Holly Rosenzweig[4], [1]Oregon Health & Science University and Portland VA Hospital, Portland, OR, [2]Oregon Health & Science University and Portland VA Hospital, Portland, [3]Osaka University, Osaka, Japan, [4]Oregon Health & Science University and Portland VA Hospital, Oregon

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Caspase recruitment domain-containing protein 9 (CARD9) is an adaptor protein downstream of C-type lectin receptor signaling within myeloid cells. CARD9 is critical for anti-fungal immunity; yet also linked to inflammatory diseases including ankolysing spondylitis and Crohn's Disease. Here, we investigated the role of Card9 in autoimmunity as modeled in SKG mice, which develop T cell-mediated arthritis in response to microbial triggers.

Methods: SKG and Card9$^{-/-}$SKG mice,were injected with zymosan (1.5 mg), clinically monitored for arthritis, and histologically analyzed for joint pathology. At 8 wk post-zymosan, CD4^{+} T cells from draining lymph nodes were stimulated *in vitro* with PMA/ionomycin and Th effector subsets were quantified by intracellular cytokine staining and flow cytometry. For adoptive T cell transfers, splenic CD4^{+} T cells purified from naïve mice by immunomagnetic selection were intravenously injected (4x10^{6}) into nude (*nu*/*nu*) recipients who were injected 24h later with zymosan. For lavage studies, peritoneal fluid collected 4h post-zymosan was analyzed for cellular (ie. neutrophils) and non-cellular (ie. chemokine/cytokine) content by flow cytometry and ELISA. Neutrophils were depleted in SKG mice with anti-Ly6G (1A8) or isotype control (2A3) beginning 24h prior to zymosan and every 2d for 11d. For all studies, three independent experiments were performed (n=5-6 mice/genotype), and data analyzed using non-parametric statistics.

Results: After zymosan injection, SKG mice developed chronic arthritis while Card9$^{-/-}$SKG mice developed no detectable arthritis. Card9$^{-/-}$SKG mice had reduced numbers of T cells in pLN including reduced CD4^{+} T effector cells (Th17, Th1, Th22), and decreased IL-17A in synovial fluid. The mechanism by which Card9 suppresses arthritis is T cell-extrinsic since Card9-deficient and –sufficient T cells had similar abilities to induce arthritis. Given the known anti-fungal role for Card9 within myeloid cells we examined acute myeloid cell responses to zymosan. Within 4h of zymosan injection Card9$^{-/-}$SKG mice had dramatically reduced proportions of peritoneal neutrophils, whereas the dendritic cells and macrophage responses were comparable in Card9$^{-/-}$SKG vs. SKG mice. Neutrophil chemoattractants (CXLC1, CXCL2) or inflammatory cytokines (IL-1b, IL-6, IL-23) levels in the peritoneum were not altered by Card9-deficiency. However, Card9-deficient neutrophils had significant reduction in activation status (CD62L) and in their ability to undergo degranulation as determined by mobilization of secondary (CD66b) and primary granules (CD63). Neutrophil depletion during the priming stage delayed arthritis onset.

Conclusion: These data reveal a previously unconsidered role for Card9-signaling within neutrophils in response to environmental triggers in conferring susceptibility to arthritis in SKG mice.

Potential Involvement of OX40 Expressing Tfh Cells on Regulation of Autoantibody Sialylation in Experimental and Rheumatoid Arthritis

Izumi Kurata ,[1] Isao Matsumoto,[1] Natsuko Mikami,[1] Ayako Ohyama,[1] Atsumu Osada,[1] Yuya Kondo,[1] Hiroto Tsuboi,[1] and Takayuki Sumida[1], [1]Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Recently, IL-23-Th17 cells axis and hyposialylation of antibodies were proved to be linked to experimental and rheumatoid arthritis. However it remains uncertain how Tfh, including IL-17 producing Tfh (Tfh17) cells, behaves as regulator of antibody hyposialylation. The aim of this study is to explore the molecular mechanisms of Tfh17 cells-associated autoantibody hyposialylation using glucose-6-phosphate isomerase (GPI) induced arthritis (GIA) model and peripheral blood of RA patients.

Methods:

1) Fluctuation of Tfh cells and their cytokine production in draining lymph nodes were analyzed in GIA. Cell surface molecule expression of Tfh cells was examined.

2) Expression of *st6gal1*, the responsible enzyme for sialylation, in plasmablasts (PBs) was followed during arthritis course. Sialic acid in purified anti-GPI antibodies obtained at the arthritis onset (day 7) and resolving phase (day 28) was quantified by mass spectrometry. Dendritic cells (DCs) were stimulated with anti-GPI antibodies from both phases. Artificial sialic acid removal/supplement was performed *in vitro* and *vivo*.

3) Expression of *st6gal1* in co-cultured PBs with Tfh cells was measured. OX40-OX40 ligand (OX40L) pathway was blocked with mAbs both *in vivo* and *vitro*.

4) Correlation between circulating Tfh17 cells, ACPA titers and *st6gal1* expression in PBs were analyzed in treatment-naïve patients with RA. OX40 expression of Tfh17 cells was analyzed.

Results:

1) Tfh cells, especially IL-17 producing Tfh17 cells were increased at day 7 in GIA. They highly expressed OX40.
2) *St6gal1* expression in PBs was significantly decreased at day 7 and 14 (arthritis peak) and gradually recovered. Mass spectrometric analysis revealed significant hyposialylation of day 7 antibodies. DCs produced more TNFα and CXCL1 when stimulated with day 7 antibodies than with those of day 28. Sialic acid-removed antibodies became stronger stimulants for DCs and GIA was ameliorated when sialic acid was supplied to mice.
3) Decreased expression of *st6gal1* was observed in PBs co-cultured with Tfh cells. OX40-OX40L pathway blockade rescued this decrease *in vitro*. By the blockade, GIA was ameliorated accompanied by sialylated anti-GPI antibodies and diminished Tfh17 cells *in vivo*.
4) Proportion of circulating Tfh17 cells had positive correlation with ACPA tiers in RA patients. Moreover, they negatively correlated with the *st6gal1* expression in RA patients (R^2= -0.596). OX40 was highly expressed in their Tfh17 cells.

Conclusion: Our findings suggested Tfh, including Tfh17 cells could have a crucial role in the development of arthritis via regulation of autoantibody sialylation through OX40-OX40L axis in experimental and rheumatoid arthritis.

Abstract Number: 1775

Cholesterol Sequestering in Macrophages Contributes to the Lipid Paradox in Chronic Arthritis

Sandra Pérez-Baos ,[1] Junko Arakawa,[2] Raquel Largo,[1] Katsunori Ikewaki,[2] and Gabriel Herrero-Beaumont[1], [1]IIS-Fundación Jiménez Díaz, Madrid, Madrid, Spain, [2]National Defense Medical College, Tokorozawa, Saitama, Japan

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: RA – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Patients with active rheumatoid arthritis (RA) have increased cardiovascular mortality, paradoxically associated with reduced circulating lipid levels. Several disease-modifying antirheumatic drugs (DMARDs), such as the JAK inhibitor tofacitinib, ameliorate disease activity along with an increase in serum lipids. We previously demonstrated *in vitro* that tofacitinib favored cholesterol efflux from macrophages through an ABCA1-dependent mechanism. Furthermore, tofacitinib-treated chronic arthritic rabbits showed increased circulating lipids and decreased lipid accumulation within the synovium. Our aim was to explore *in vivo* whether inflammation impedes cholesterol efflux from macrophages, and whether tofacitinib restores macrophage cholesterol release during chronic arthritis. For that purpose, we assessed the ability of intraperitoneally-injected ^{3}H-cholesterol labelled macrophages to efflux cholesterol to circulating lipoproteins in collagen-induced arthritis (CIA) mice treated with tofacitinib or placebo, as compared to healthy controls.

Methods: DBA/1J mice were randomly assigned to healthy controls (Control, n = 9), CIA (CIA, n = 6) and CIA mice receiving 50 mg/kg/day tofacitinib, orally, for three consecutive days, starting on day 39 after CIA induction and coinciding with disease peak (CIA+TOFA, n = 6). The day after, ^{3}H-cholesterol labeled RAW264.7 macrophages were intraperitoneally injected into mice and tracer appearance was monitored in plasma lipoprotein subfractions, synovium, liver, bile and feces.

Results: The CIA group showed higher C-Reactive protein levels (CRP, *μg/ml*; Control: 10.90±0.49, CIA: 13.86±1.05, p=0.03 *vs.* Control) and lower circulating ^{3}H-cholesterol levels (*% of injected disintegrations per minute (dpm)/ml;* Control: 1.29±0.11, CIA: 0.92±0.11, p=0.04 *vs.* Control). Both serum CRP and ^{3}H-cholesterol –particularly the HDL fraction– were restored to baseline after the treatment with the JAK inhibitor (CIA+TOFA: 10.97±0.67 *μg/ml* and 1.37±0.20 *% of injected dpm/ml*, respectively, p=0.05 *vs.* CIA). Concomitantly, we observed an upward trend in ^{3}H-cholesterol accumulation within the synovium of CIA animals as compared to controls, which tended to normalize with the treatment.

Conclusion: Systemic inflammation induces cholesterol sequestering within macrophages *in vivo* by acting on cholesterol efflux transporters. Tofacitinib favors cholesterol release to plasma lipoproteins, hence increasing circulating cholesterol. This is not only due to a decrease in inflammation –an effect very likely shared with some other biologic DMARDs–, but also to a direct mechanism on ABCA1 transporters that favors cholesterol efflux. To our knowledge, this is the first report suggesting that cholesterol dynamics in the macrophage may contribute to the overall circulating cholesterol levels, especially considering that this phenomenon may occur in other cell types, such as adipocytes.

Abstract Number: 1776

Causal Effect of TNF-α, IL-12p70, IL-17 Levels on the Risk of Psoriatic Arthritis: A Mendelian Randomization Study

Dongze WU ,[1] Priscilla Wong,[1] Steven H.M. Lam,[1] Isaac T. Cheng,[1] Edmund K. Li,[1] Ling Qin,[1] and Lai-Shan Tam[1], [1]The Chinese University of Hong Kong, Hong Kong, Hong Kong

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Biologic agents targeting cytokines including TNF-α, IL-12p70 and IL-17 have been proven to be very effective in treating psoriatic arthritis (PsA). Nonetheless, whether these cytokines are causally associated with PsA is uncertain. The study aims to compare causal associations between genetically predicted cytokine level and risk of psoriatic arthritis via a two-sample Mendelian Randomization approach.

Methods: We used the publicly available summary-level findings from genome-wide association studies (GWAS) for identification of loci influencing concentrations of circulating cytokines (PMID: 27989323, n=8 293) as exposure and a GWAS for non-cancer illness code self-reported: PsA from the individuals included in the UK Biobank (total n = 462 933; case = 900, control = 462 033) as the outcome. A two-sample Mendelian randomization (MR) analysis was performed using the inverse-variance weighted (IVW), weighted median, and MR-Egger regression methods. Sensitivity analysis and MR-Egger regression analysis were performed to evaluate the heterogeneity and pleiotropic effects of each variant.

Table 1. MR estimates from each method of assessing the causal effect of three cytokines on the risk of PsA

Exposure	MR method	No. of SNPs	Beta	SE	Association p-value	Cochran Q statistic	df	Heterogeneity p-value	Horizontal pleiotropy
Tumor necrosis factor alpha levels (SD units increase)	MR Egger	6	0.000	0.001	0.959	0.9251	4	0.9209	
Tumor necrosis factor alpha levels (SD units increase)	Weighted median	6	0.000	0.000	0.647				0.67
Tumor necrosis factor alpha levels (SD units increase)	Inverse variance weighted	6	0.000	0.000	0.306	1.135	5	0.9509	
Tumor necrosis factor alpha levels (SD units decrease)	MR Egger	3	0.000	0.001	0.762	0.81	1	0.3681	
Tumor necrosis factor alpha levels (SD units decrease)	Weighted median	3	0.000	0.000	0.593				0.981
Tumor necrosis factor alpha levels (SD units decrease)	Inverse variance weighted	3	0.000	0.000	0.571	0.8109	2	0.6667	
Interleukin-17 levels (SD units increase)	MR Egger	7	-0.002	0.001	**0.087**	5.414	5	0.3674	
Interleukin-17 levels (SD units increase)	Weighted median	7	-0.001	0.001	**0.014**				0.513

Interleukin-17 levels (SD units decrease)	MR Egger	5	0.001	0.001	0.651	1.127	3	0.7706	
Interleukin-17 levels (SD units decrease)	Weighted median	5	0.000	0.001	0.487				0.721
Interleukin-17 levels (SD units decrease)	Inverse variance weighted	5	0.000	0.000	0.685	1.28	4	0.8647	
Interleukin-12p70 levels (SD units increase)	MR Egger	9	-0.002	0.002	0.400	9.047	7	0.2493	
Interleukin-12p70 levels (SD units increase)	Weighted median	9	-0.001	0.001	0.162				0.558
Interleukin-12p70 levels (SD units increase)	Inverse variance weighted	9	-0.001	0.000	0.242	9.536	8	0.2991	
Interleukin-12p70 levels (SD units decrease)	MR Egger	5	-0.001	0.001	0.631	5.021	3	0.1703	
Interleukin-12p70 levels (SD units decrease)	Weighted median	5	0.000	0.001	0.692				0.821
Interleukin-12p70 levels (SD units decrease)	Inverse variance weighted	5	0.000	0.001	0.516	5.122	4	0.275	

Results: Single-nucleotide polymorphisms (SNPs) at genome-wide significance from GWASs on TNF-α (6 and 3 SNPs for increased and decreased TNF-α levels respectively), IL-12p70 (9 and 5 SNPs for increased and decreased in IL-12p70 levels respectively), IL-17 (7 and 5 SNPs for increased and decreased IL-17 levels respectively) were identified as the instrumental variables (IVs). Our results provided evidence to support a causal association between elevated level of Il-17 (IVs: rs117556572, rs141312283, rs149738638, rs17282552, rs187475560, rs57920188, rs62191444) and PsA (MR Egger, p = 0.087; Weighted median: p=0.014; Inverse variance weighted: p= 0.002). All three methods did not show any causal association between PsA and increased and decreased TNF-α and IL-12p70, and decreased IL-17 level (Table 1). Cochran's Q test and the funnel plot indicated no evidence of heterogeneity and asymmetry, indicating no directional pleiotropy.

Conclusion: Our findings provided strong evidence on the causal association of genetically elevated circulating IL-17 levels with the risk of developing psoriatic arthritis. IL-17 blockade might prevent the transition from psoriasis to psoriatic arthritis that warrants testing in suitably powered randomized trials.

Abstract Number: 1777

The Deubiquitinase TRABID Is a Potential Therapeutic Target in Spondyloarthritis

Daniele Mauro ,[1] Federica Macaluso,[2] Alessandra Nerviani,[3] Marie-Astrid Boutet,[3] Aroldo Rizzo,[4] Riccardo Alessandro,[2] Giuliana Guggino,[2] Costantino Pitzalis,[3] and Francesco Ciccia[5], [1]Centre for Experimental Medicine & Rheumatology, Queen Mary University of London, London, England, United Kingdom, [2]University of Palermo, Italy, Palermo, Italy, [3]Centre for Experimental Medicine & Rheumatology, Queen Mary University of London, London, United Kingdom, [4]Pathology Unit, Azienda Ospedaliera Ospedali Riuniti Villa Sofia Cervello, Palermo, Italy., Palermo, Italy, [5]University of Campania L. Vanvitelli, Naples, Italy

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Interleukin 12 (IL-12) and 23 (IL-23) may play a pivotal role in the pathogenesis of inflammatory diseases, including Spondyloarthritis (SpA). In mice, the deubiquitinase Trabid, encoded by Zranb1, participates to the epigenetic regulation of *IL-12* and *IL-23* genes via the stabilization of the histone demethylase JMJD2D. TRABID also regulates the methyltransferase EZH2, involved in the epigenetic control of the inflammatory response in human.

This study aims to assess the expression and the functional relevance of TRABID in controlling the inflammation and activation of IL-12/IL-23 axis in SpA.

Methods: TRABID expression was assessed in synovial tissue (ST) (n=10), Peripheral blood (PBMCs) (n=10), Bone Marrow (BM) (n=5) and Gut (n=20) of SpA patients with active disease and matched healthy by immunohistochemistry (IHC) and quantitative PCR.

Gene expression of *ZRANB1*, *JMJD2D*, *EZH2*, *IL-23*, *IL-12a*, *IL-17a* in ST was further investigated in the Pathobiology of Early Arthritis Cohort (PEAC) in DMARDs naïve RA (n= 91) and SpA (n=14) patients via RNA sequencing.

Ultrasound-guided synovial biopsies of clinically active joints from twenty-five patients (11 males) with active (DAS: mean 4.3; SD 1.1) SpA, were also studied. The degree of synovitis was histologically assessed by hematoxylin and eosin staining. Immunohistochemistry (IHC), followed by semi-quantitative scoring, was also performed to determine the degree of $CD20^+$ B cells, $CD3^+$ T cell, $CD68^+$ macrophage and $CD138^+$ plasma cell infiltration.

Accordingly, STs were categorized STs into fibroid, myeloid and lymphoid-myeloid pathotypes and TRABID, IL-23p19 and IL-23R expression were assessed by IHC.

Results: The expression of ZRANB1 was increased in SpA PBMCs and ileal samples ($p< 0.001$). In particular, the highest expression of *ZRANB1* was observed in chronic inflamed gut samples of SpA patients, being its expression directly correlated with IL-23p19 ($r=0.49$, $p< 0.05$) and IL-23R ($r=0.67$, $p< 0.001$). Within the early arthritis cohort the expression of *ZRANB1* in STs was higher in PsA versus Rheumatoid arthritis (RA) ($p< 0.05$) and expression of the TRABID target *EZH2* correlated with the levels of *IL12A* ($r= 0.46$; padj < 10-5), *IL23A* ($r= 0.45$; padj< 10^{-5}) and *IL-17A* ($r= 0.23$; padj< 0.05). The number of $TRABID^+$ cells was significantly increased in SpA ST ($p< 0.001$), gut ($p< 0.001$) especially among infiltrating inflammatory mononuclear cells, and BM ($p< 0.001$). In ST the number of $TRABID^+$ cells was particularly increased in the lymphoid and myeloid pathothypes compared to the pauci-immune fibroid ($p< 0.01$) and correlated with the synovitis score ($r= 0.48$; $p< 0.05$), CD68 in the sub-lining ($r= 0.69$; $p< 0.001$), CD3 ($r= 0.57$; $p< 0.01$), and CD20 ($r= 0.64$; $p< 0.01$). Finally, $TRABID^+$ cells were enriched in the STs rich in IL-23p19 versus the low expressing IL-23p19 STs ($p< 0.05$) and correlated with the number of IL-23R expressing cells ($r= 0.58$; $p< 0.05$).

Conclusion: ZRANB1/TRABID levels are increased in the synovial tissue, bone marrow and gut of SpA patients and correlated with specific histologic pathothypes, the degree of synovitis and the levels of IL-23 and IL-23R. In conclusion, this study may pave the way for future TRABID therapeutic inhibition in the treatment of SpA.

Entheseal CD90+ SOX9+ Cartilage-like Cells Initiate Spinal Ankylosis in Ankylosing Spondylitis

Sungsin Jo ,[1] Young Lim Lee,[1] Tae-Han Lee,[1] Ye-Soo Park,[2] and Tae-Hwan Kim[1], [1]Hanyang University Hospital for Rheumatic Diseases, Seoul, Republic of Korea, [2]Department of Orthopedic Surgery, Hanyang University Medical Center, Guri Hospital,, Guri, Republic of Korea

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Enthesitis is characterized by inflammation at the interface where tendon or ligament attaches to the bone and is a representative symptom of ankylosing spondylitis(AS). The enthesitis is primarily responsible for the initiation and progression of AS. However, it is not known which cellular and molecular characterizations

of enthesitis contribute to cartilage fusion and enchondral ossification causing ankylosis. Here, we hypothesized that inflammatory stimuli to cartilage-like cells in spinal ligaments cells are a pivotal driver of ankylosis.

Methods: The bone and ligament tissues of the facet joint of 5 patients with AS and 7 disease control obtained from spinal surgery were assessed by histology and immunofluorescence. Primary bone and ligament cells were isolated by outgrowth and collagenase type I&II-digested method, respectively. Isolated bone or ligament cells of both AS and control were analyzed by FACS for CD90 and SOX9 and used for further experiments. Both bone and ligament cells stimulated by TNF and/or IL-17A as inflammatory stimuli were assessed by qPCR, immunoblotting, immunostaining, human MMP antibody array, and ELISA. We also examined the differences in the response to osteogenic activity and differentiation status under identical conditions. Furthermore, distinct expressions in AS patients were confirmed by immunostaining at spinal ligaments in Curdlan-injected SKG mice.

Results: Histological results show that granulation tissues and blood vessels were frequently eroded in subchondral bone area of AS facet joints, as previously reported. Additionally, there is strong CD34 expression of the blood vessels in subchondral bone of AS joint. Ectopic cartilage-like cells were seen in granulation tissues eroding the subchondral bone. Intriguingly, SOX9+ cartilage-like cells were co-localized in the granulation tissues expressing MMP13 of AS. SOX9 level by FACS analysis was statistically higher in primary AS bone cells. When we analyzed cell surface markers of primary ligament cells by FACS, expression of CD90+ was determined as a ligament marker. In particular, high frequency of SOX9+ and CD90+ were found to be expressed in AS ligaments, but not in controls. Furthermore, expressions of MMP1, 3, and 13 were obviously increased and secreted more in AS ligament cells with co-stimulation of TNF and IL-17A than that in controls. The co-stimuli condition under osteoblast differentiation boosted calcium deposit and hydroxyapatite formation in AS ligament cells. Consistent with the above data, co-expression of MMP13 and SOX9 were markedly increased at spinal ligament in curdlan-treated SKG mice compared to controls.

Conclusion: Collectively, our findings reveal that entheseal CD90+ SOX9 cartilage-like cells contribute to the progression of spinal ankylosis.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Interleukin-23 (IL-23) and its cognate receptor interleukin-23R (IL-23R):IL-12Rβ1 plays a critical role in the pathogenesis of autoimmune diseases including psoriasis and psoriatic arthritis. Although significance of IL-23 signaling in adaptive immunity has been well-studied, the role of IL-23 in myeloid cell activation remains unknown.

Methods: To investigate role of CLEC5A/MDL-1 in psoriatic arthritis-like pathology, we performed *in vivo* gene transfer of IL-23 in WT, IL-23R^{GFP} reporter, and *Mdl-1*$^{-/-}$ mice. qRT-PCR, RNAseq, Western blot, flow cytometry, ELISA, H&E stain, and immunofluorescence staining methods were used to analyze the phenotype of WT and transgenic mice.

Results: Herein, we show in the IL-23R^{GFP} reporter mice, that IL-23 induces the expansion of myeloid cell populations including an epidermal myeloid DNAX activation protein 12 (DAP12)-associating lectin-1 (MDL-1)$^{+}$CD11b^{+}Ly6G^{+}IL-23R^{+} cell population associated with epidermal hyperplasia and an MDL-1^{+}CD11b^{+}Ly6C^{high}IL-23R^{+} associated with bone destruction. Mechanistically, genetic ablation of MDL-1 prevented IL-23-gene transfer elicited myelopoiesis and showed a marked reduction of skin inflammation markers (*K16*, *S100a7, S100a8, S100a9*, *Cxcl-1*, *Cxcl-2*) and bone destruction markers (*Acp5*, *Ctsk*, *Mmp9*) compared to wildtype mice. Moreover, we found that *Mdl-1*$^{-/-}$ mice had significantly higher bone mass and impaired osteoclast differentiation *in vitro* and *in vivo* as well as reduced joint inflammation in IL-23 gene transfer induced arthritis. Mechanistic data through of flow cytometry, Western blotting and co-immunoprecipitation experiments revealed that a trimeric complex of IL-23R/DAP12/MDL-1 elicited the associated pathologies in our murine model. Furthermore, we performed RNAseq analysis of murine skin following IL-23 gene transfer and revealed 297 differentially expressed genes (DEGs) affected by MDL-1 deletion. Specifically, these DEGs are associated with myelopoiesis, neutrophil proteases, DAP12, cell survival and apoptosis. We correlated our findings with RNAseq meta-analyses derived from human psoriatic skin (135 patients vs 133 controls), which showed elevation of *MDL-1* in psoriatic patients and positive correlation for *IL-23* versus *MDL-1* and *IL-23R* versus *MDL-1.*

Conclusion: Collectively, our data demonstrate that MDL-1 is a critical component of IL-23 signaling that dictates synovial and skin inflammation *in vivo*, and could be targeted for the treatment of PsA.

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

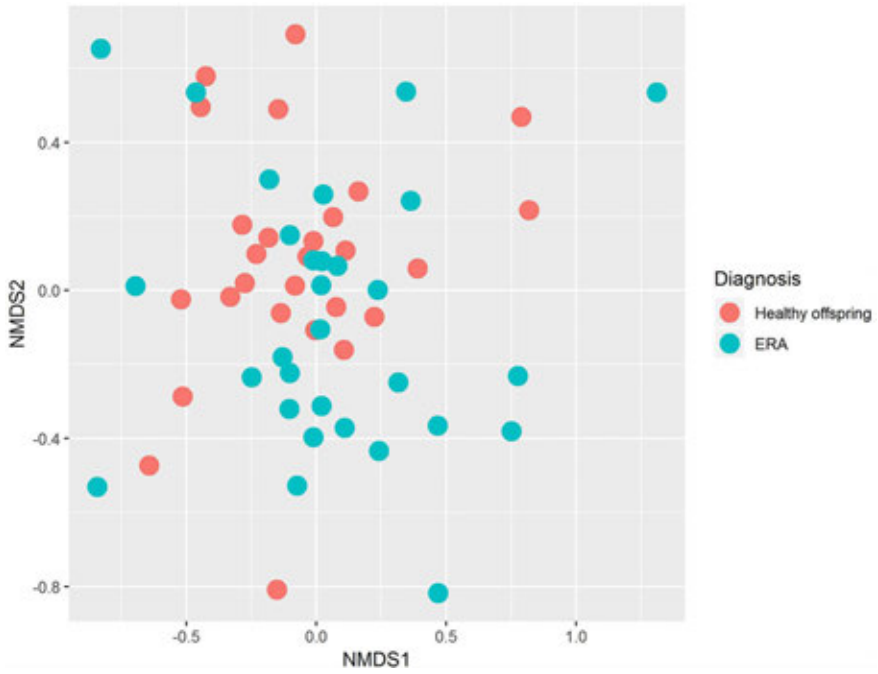

Figure 1. Visualization of the microbiota of healthy offspring (red) compared to ERA patients (blue). NMDS = nonmetric multidimensional scaling, an ordination method similar to principal coordinates analysis.

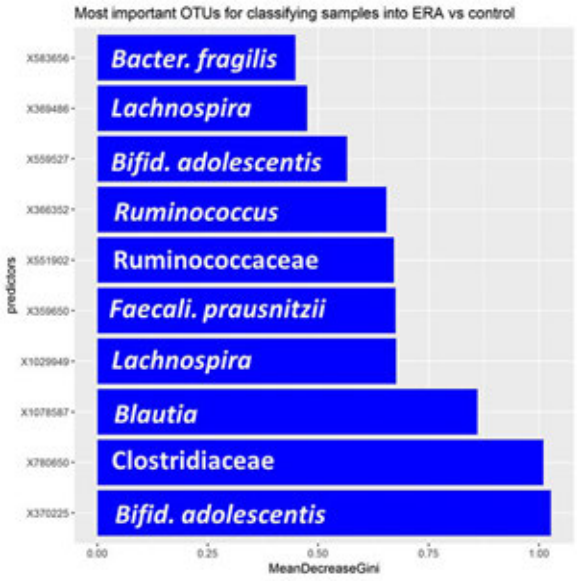

Figure 2. Results of Random Forests analysis evaluating the microbiota as a Predictor of arthritis. The top 10 most important OTUs (as reflected by the MeanDecreaseGini are shown.) The higher the MeanDecreaseGini, the more important the variable (in this case, OTU) is for classification of the sample. Two of the organisms were each represented by two different OTUs.

Background/Purpose: Spondyloarthritis (SpA) results from the interplay between genetic and environmental factors. An emerging factor is the human intestinal microbiota, which multiple studies in children and adults have shown to be abnormal in SpA patients, including enthesitis-related arthritis (ERA) and Ankylosing Spondylitis (AS). Considering the microbiota pathogenic, we may have the opportunity to both identify an at-risk population and consider ways to modify their microbiota. The purpose of this study was to analyze the microbiota of healthy children at risk for SpA, stratified by HLA-B27, and to compare these healthy children to HLA-B27+ ERA patients.

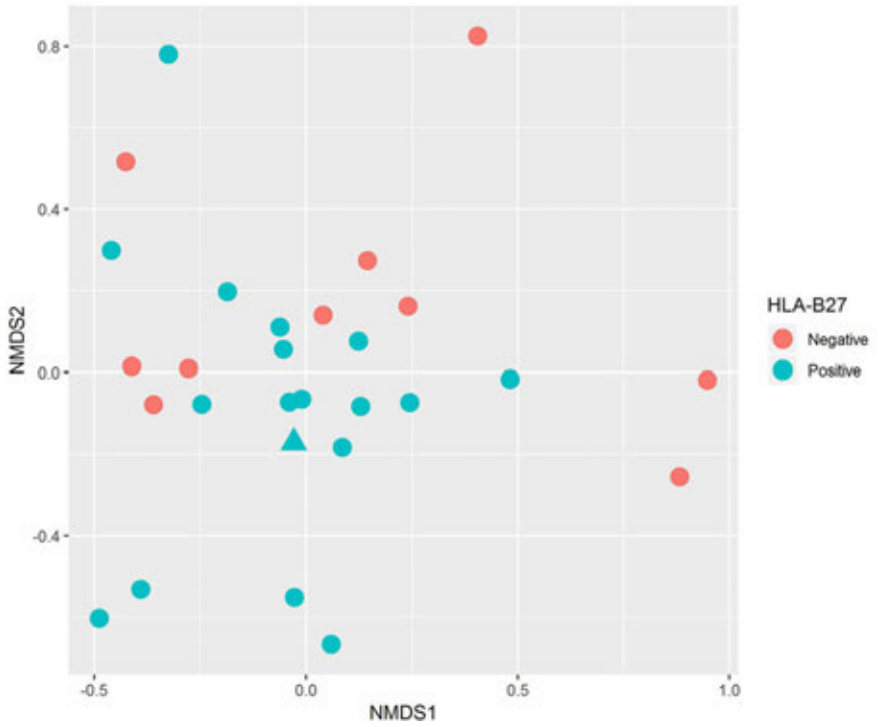

Figure 3. Visualization of the microbiota of HLA-B27- offspring (red) compared to HLA-B27+ offspring (blue) using NMDS. The microbiota of the child diagnosed with SpA is depicted as a triangle.

Methods: Children age 5 – 18 years (along with their AS parent) were examined by a rheumatologist for evidence of SpA. Human DNA as well as fecal specimens were collected from both parent and children. Microbiota specimens were subject to amplification of the V4 region of the ribosomal RNA gene, which was sequenced on the Illumina MiSeq device. Host SNP genotyping was performed with the Illumina Global Screening Array, a single nucleotide polymorphism (SNP) microarray with 760,000 markers, from which HLA types were imputed using SNP2HLA. The Quantitative Insight into Microbial Ecology was used for quality control as well as clustering into operational taxonomic units (OTUs) using uclust. The OTU table was imported as a phyloseq object for further processing, visualization, and diversity analysis. DeSeq2 was used for FDR-corrected comparisons of abundances of the major taxa, and the Random Forest algorithm was used to predict the development of arthritis based upon the microbiota contents.

Results: Fecal specimens were obtained on 28 offspring of AS patients, of whom 18 were HLA-B27+; one had a SpA diagnosis at study enrollment. Healthy offspring were compared to 29 additional children with HLA-B27+ ERA (ILAR criteria) recruited from 6 sites. Among ERA patients, clustering by diagnosis was present (Figure 1; $p = 0.004$, adonis). Following transformations and adjustment for multiple comparisons, 20 OTUs were significantly associated with diagnosis state, of which four (*Bifidobacterium adolescentis*, Ruminococcaceae, and Clostridiaceae higher in controls; *Bacteroides fragilis* higher in ERA) were identified among the top 10 most associated with the diagnosis in the Random Forest model (Figure 2). Comparison of the HLA-B27+ to negative offspring revealed clustering by genotype (Figure 3; $p = 0.05$) and demonstrated that several of the OTUs that distinguished healthy offspring from patients (e.g. *Ruminococcus gnavus*, higher in ERA vs offspring and HLA-B27+ vs HLA-B27- offspring) were also significantly associated with genotype.

Conclusion: Our data identified several bacteria associated with HLA-B27 in healthy at-risk children and ERA patients, and thus may identify a high-risk population that could be the target of future preventative efforts.

Cytokine Dependence of Enthesis-resident Lymphocytes in Murine Spondyloarthritis

Mederbek Matmusaev,[1] **Emma Haley** ,[1] Imtiyaz Hossain,[1] and Joerg Ermann[1], [1]Brigham and Women's Hospital, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Basic Science
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Enthesis-resident CD4-CD8- double-negative (DN) T cells have been implicated in the pathogenesis of spondyloarthritis. Overexpression of IL-23 in adult mice activates these cells to produce IL-17A and other pathogenic cytokines leading to spondyloarthritis-like disease. Many innate lymphocytes require IL-1 for IL-23-induced production of IL-17A in vitro. We therefore investigated the role of IL-1 receptor signals on CD4-CD8- DN T cell homeostasis and induction of murine spondyloarthritis.

Methods: Lymphocytes were isolated from the spleen and Achilles enthesis of wildtype, Il23r-/-, Il1r1-/- and Il23r-gfp reporter mice (C57BL/6 background) and analyzed in vitro. Disease was induced by hydrodynamic injection of IL-23 minicircles (System Biosciences) in B10.RIII mice. To block IL-1 signals, animals were injected ip. with a cocktail of three monoclonal antibodies against IL-1α, IL-1β and IL-1R1. Animals were monitored every other day for arthritis development. Animals were euthanized two weeks after disease induction for tissue harvest and analysis.

Results: Enthesial CD4-CD8- DN T cells comprise $\gamma\delta$ T cells and DN $\alpha\beta$ T cells. Both $\gamma\delta$ T cells and DN $\alpha\beta$ T cells secreted IL-17A upon in vitro stimulation with IL-23 + IL-1β but not IL-23 alone. Cell frequencies were not substantially different in Il23r-/- or Il1r1-/- mice compared with wildtype mice. Disease induction in Il1r1-/- mice could not be tested as C57BL/6 wildtype mice do not develop arthritis upon IL-23 minicircle injection. Antibody blockade of IL-1 signals in susceptible B10.RIII mice had no impact on disease incidence but ameliorated arthritis severity.

Conclusion: IL-23 and IL-1 receptor signals control the function but not the development of enthesial $\gamma\delta$ T cells and DN $\alpha\beta$ T cells. Antibody-mediated blockade of IL-1 in susceptible B10.RIII mice reduced arthritis severity but not disease incidence suggesting that mediators other than IL-1 may provide a second signal for IL-23-induced IL-17A production in vivo. The lack of arthritis development in C57BL/6 mice injected with IL-23 minicircles diminishes the utility of this model for studies of spondyloarthritis pathogenesis.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: We previously identify a p.Arg90His (p.R90H) substitution encoded in phagocyte neutrophil cytosolic factor (*NCF1*) as a novel risk variant for SLE, with decreased and increased*NCF1*copy numbers predisposing to and protecting against SLE, respectively. Our data highlights the pathogenic role of reduced reactive oxygen species (ROS) production in SLE. To study how reduced ROS promotes lupus, we established a C57BL/6 (B6) mouse model with a knock-in (KI) 90H mutation in *Ncf1*locus by CRISPR/Cas9 genome editing.

Methods: We compared 90H KI and wild-type (WT) R90 littermates for R90H genotypic effects on ROS production, type I interferon (IFN-I) signature and immune cell subsets in splenocytes, autoantibody production by ELISA and slide-based antigen array, renal IgG and C3 deposition and pathology. Pristane was injected intraperitoneally twice as an environmental trigger (0.1ml at 8wks and 0.5ml at 10wks), and lupus-like features were assessed at 30-36 wks.

Results: Compared with R90 WT littermates,untreated 5-week-old 90H KI mice exhibited reduced phorbol myristate acetate-induced extracellular ROS in splenocytes (n=5, p=0.03), splenomegaly (n=5, p=0.02),elevated IFN-I scores (p=0.047), as well as increased numbers of $CD4^{+}CXCR5^{++}PD\text{-}1^{++}$follicular helper T cells (Tfh, p=0.045) and $CD19^{+}CD23^{high}CD21^{int}$follicular B cells (p=0.005). Because KI mice had no spontaneous kidney disease at one-year old, we used pristane injection to induce lupus. Compared with pristane-treated female WT mice (n=10), 30-36-week-old female KI littermates (n=8) developed lupus-like manifestations including splenomegaly (p=0.02), increased IgG anti-RNP (p=0.02) and total IgG (p=0.004) levels, glomerulonephritis with increased glomerular score (p=0.046), elevated renal deposition of IgG (p=0.005) and C3 (p=0.04). IgG autoantibody profiles confirmed elevated IgG anti-Sm, dsDNA and RNP in those female KI mice. Increased numbers of $B220^{+}IgD^{low}CD95^{high}GL7^{high}$germinal center B cells (p=0.03) and $CD4^{+}CXCR5^{++}PD\text{-}1^{++}$(p=0.04) or $CD4^{+}Bcl\text{-}6^{+}$(p=0.02) Tfh were found in 30-36-week-old pristane-treated KI mice.

Conclusion: A single nucleotide polymorphism p.Arg90His (p.R90H) in the *Ncf1*gene resulted in reduced oxidative burst, elevated IFN-I scores, splenomegaly, and increased cell numbers of Tfh and follicular B cells in 5-week-old 90H KI C57BL/6 mice. Pristane treatment caused increased IgG autoantibodies and kidney disease development in 30-36-week-old female 90H KI C57BL/6 mice. The disease development might be attributed to increased cell numbers of Tfh, facilitating germinal center formation and autoantibody production.

Reversible Dysregulation of Renal Circadian Rhythm in Lupus Nephritis

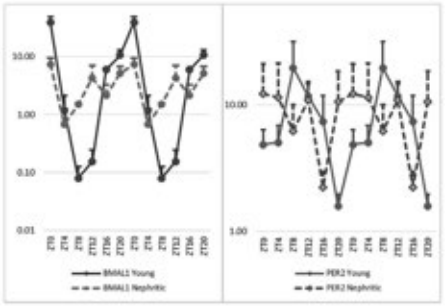
Rakesh Mishra,[1] Ramalingam Bethunaickan,[1] Celine Berthier,[2] Zhengzi Yi,[3] Joshua Strohl,[1] Patricio Huerta,[1] Weijia Zhang,[4] and **Anne Davidson** [5], [1]Feinstein Institute for Medical Research, manhasset, NY, [2]University of Michigan, Ann Arbor, MI, [3]Mount Sinai School of Medicine, New York, [4]Mount Sinai School of Medicine, New York, NY, [5]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Circadian rhythm is a universal phenomenon that governs homeostasis of overall organism functioning as well as of individual organs. Circadian regulation of homeostatic functions in the kidneys regulates multiple renal functions including GFR, electrolyte excretion and blood pressure control. The effect of renal pathologic processes such as glomerulonephritis on circadian rhythms is not well described. In the course of genomic profiling of lupus kidneys from several mouse models of lupus nephritis we found abnormal expression of several master transcriptional regulators of circadian rhythm. Our goal was to determine how renal circadian rhythm is disrupted in lupus nephritis and the consequences of this disruption.

Methods: Perfused kidneys were obtained for molecular profiling at 4 hrly intervals over a 24hr period from groups of 5-9 young and nephritic NZB/W F1 mice. Genes with a circadian pattern of expression were identified using RAIN test. The enriched biological functions of the genes with circadian rhythm pattern at different time intervals were determined using REVIGO program. Dysregulated expression of transcriptional regulators Bmal1 and Per2 was confirmed by ELISA of renal lysates. Renal sodium and potassium excretion, urine pH and glucose, serum and urine aldosterone and blood pressure were measured at 4 hrly intervals. The effect of remission induction on gene expression and renal function was evaluated using the same assays.

Results: We found a major effect of circadian dysregulation on renal metabolic functions in nephritic mice that was not simply due to age or altered sleep-wake cycles including a change in diurnal regulation of fatty acid metabolism, a switch in carbohydrate metabolism from gluconeogenesis to the pentose phosphate pathway, loss of diurnal variation of multiple tubular transporters, altered diurnal sodium excretion, acquisition of a high aldosterone state, increased expression of genes that mediate diurnal control of vascular constriction and reverse blood pressure dipping. This circadian dysregulation was partially reversed by remission induction therapy with correction of the abnormalities in



PCR confirmation of dysregulated expression of master circadian transcriptional regulators Bmal1 and Per2 in kidneys of young and nephritis NZB/W F1 mice.

fatty acid and carbohydrate metabolism and of abnormal blood pressure dipping phenotype but significantly less effect on the dysregulation of tubular transporters.

Conclusion: There is a profound alteration of renal circadian rhythms in mice with lupus nephritis leading to multiple adverse effects on renal homeostasis and metabolism as well as blood pressure dipper status that are only appreciated upon multiple sampling of kidneys at sequential intervals. Our study indicates the role of inflammation in causing renal circadian disruption and suggests a potential role for circadian agonists in the treatment of lupus nephritis.

Abstract Number: 1784

Single Cell Analysis of Renal Myeloid Cells from NZB/WF1 Mice with Lupus Nephritis Reveals Multiple Subsets with Altered Functions

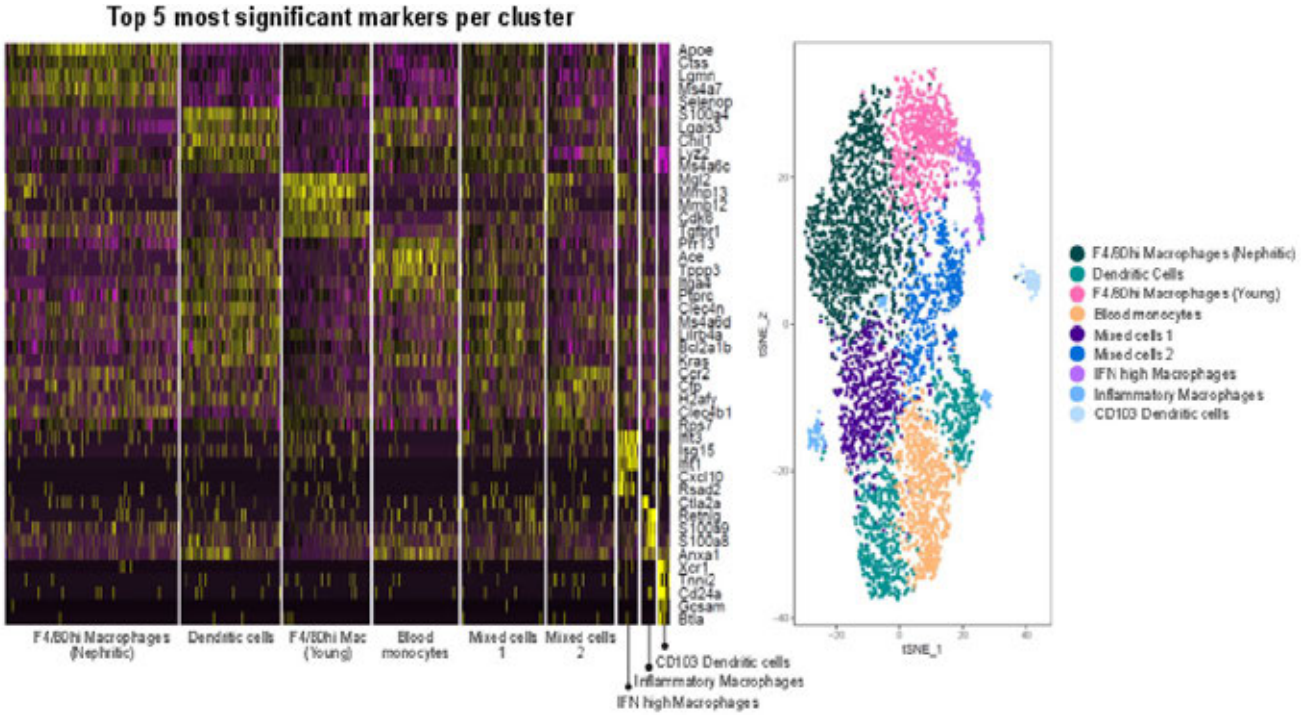
Rakesh Mishra,[1] Celine Berthier,[2] Heather Geiger,[3] Weijia Zhang,[4] and **Anne Davidson** [5], [1]Feinstein Institute for Medical Research, manhasset, NY, [2]University of Michigan, Ann Arbor, MI, [3]New York Genome Center, New York, NY, [4]Mount Sinai School of Medicine, New York, NY, [5]Feinstein Institutes for Medical Research, Manhasset

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Renal infiltration with macrophages and dendritic cells is associated with poor prognosis in humans with lupus nephritis (LN). However, the precise pathogenic and/or protective functions of these cells in the LN context are still unknown.

Methods: To characterize the myeloid subsets infiltrating the LN kidney we performed RNASeq of 4 subsets of isolated renal macrophages and dendritic cells from kidneys of nephritic (classical DCs, CD103 DCs, F480hi macrophages, F4/80lo monocytes) and prenephritic (F4/80hi macrophages only) NZB/W mice and Ly6Clo peripheral monocytes of nephritic mice. Single cell RNASeq was performed on renal CD11b+/CD11c+ cells from 2 nephritic and 3 young NZB/W mice and peripheral blood monocytes from nephritic mice using 10X genomics technology and labeling with hashtag olionucleotides to allow subsequent deconvolution of samples. Doublets and cells with >1 hashtag, < 500 expressed genes and/or >15% mitochondrial content were excluded.

Results: Different cell subpopulations clustered separately by PCA analysis, confirming differences in gene expression between each subset and between young and nephritic mice. Functional analysis of gene expression using GO analysis showed a molecular profile of infiltrating myeloid DCs in nephritic mice that supports lymphoid neogenesis and lymphocyte activation suggesting that these cells help to organize and regulate the inflammatory infiltrates. The profile of F4/80hi macrophages reflects cell metabolism and repair; nevertheless macrophages from nephritic mice had a more inflammatory profile than those from young mice. Single cell analyses were performed on 2096 renal and 1091 blood cells from nephritic and 1449 renal cells from young NZB/W mice. Cluster analysis revealed 9 clusters of myeloid cells of which 7 could be identified as myeloid and CD103 DCs, F4/80hi macrophages (young and nephritic clustered separately), inflammatory macrophages, blood monocytes and a small subset of macrophages with a high IFN signature. The other two subsets comprising < 25% of the cells appeared to contain a mixture of subpopula-



Cluster analysis of all myeloid cells from NZB/W F1 kidneys

tions including CD209a expressing DCs. Subclustering of the larger clusters revealed that the blood cells and young F4/80hi macrophages were quite homogeneous, whereas F4/80hi macrophages from nephritic mice could be separated into 3 subclusters. Myeloid dendritic cells could be split into 3 subclusters and the two unknown subsets could also each be split into 3 further subclusters. Importantly a significantly higher percentage of IFN high macrophages expressed inflammatory chemokines than the other subsets.

Conclusion: We found several subsets of renal macrophages in nephritic mice whereas those in young mice were more homogeneous. An interferon high macrophage subset may contribute disproportionately to renal inflammation. Dendritic cells appear to play an important role in lymphoid neogenesis but also displayed considerable heterogeneity. An understanding of the heterogeneity of infiltrating myeloid cell types in LN may allow more precise targeting of those cells that are most likely to be causing renal damage while preserving the protective function of resident cells.

Abstract Number: 1785

The Pathogenic Potential of Choroid Plexus T Cells in Neuropsychiatric Lupus

Erica Moore ,[1] Michelle Huang,[1] Cara Reynolds,[1] and Chaim Putterman[2], [1]Albert Einstein College of Medicine, Bronx, NY, [2]Albert Einstein College of Medicine, New York, NY

SESSION INFORMATION

Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

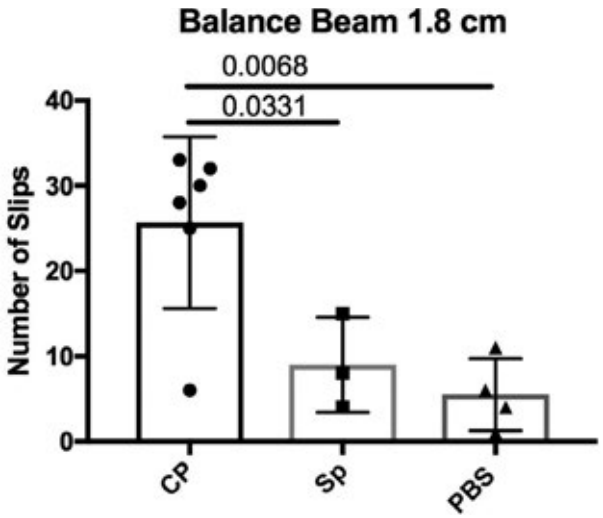

Figure 1A. Motor coordination assessment counting number of slips while crossing a balance beam, CP = choroid plexus, Sp = splenic T cell group, PBS = PBS group.

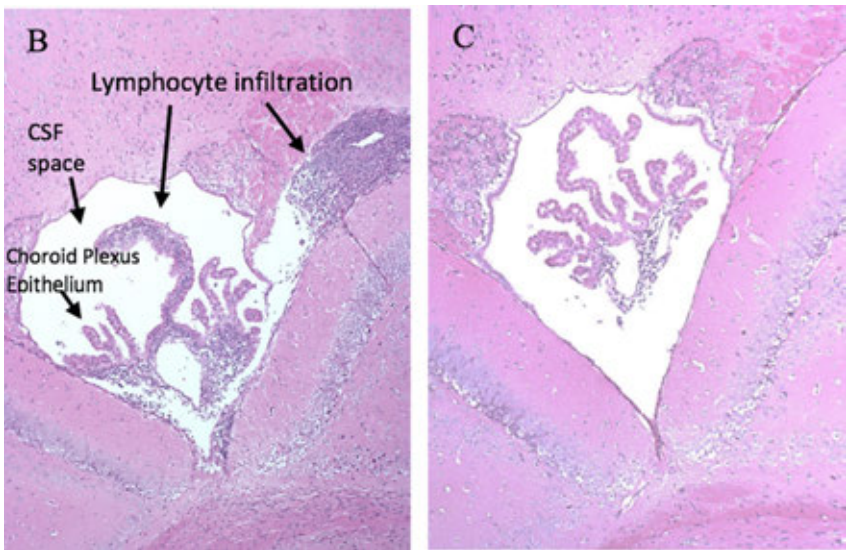

Figure 1B. H&E image of the third ventricle choroid plexus in MRL/lpr CP T cell recipient mouse; Figure 1C: H&E image of the third ventricle choroid plexus in MRL/lpr PBS recipient mouse.

Background/Purpose: The pathogenesis of neuropsychiatric Systemic Lupus Erythematosus (NPSLE) is incompletely understood, but is considered to be complex and multifactorial. Additionally, there is a wide range of possible NPSLE manifestations, including cognitive abnormalities, mood disorders, confusion, psychosis, and seizures. We have recently proposed that the blood-cerebrospinal fluid barrier at the brain choroid plexus (CP), rather than the blood-brain barrier, is the entry site for lymphocytes and other neuroinflammatory mediators into the brain. Indeed, the choroid plexus in the spontaneous MRL/lpr lupus mouse model is heavily infiltrated with predominantly T follicular helper CD4+ T cells and B cells, while preliminary imaging studies in human NPSLE have similarly revealed inflammation in the region of the CP. However, the function of CP-infiltrating T cells has not been studied as a potential contributor to the pathogenesis of NPSLE.

Methods: Six week old female MRL/lpr mice were intracerebroventricularly (ICV) injected with either MRL/lpr choroid plexus CD3+ T cells (n=6), MRL/lpr splenic CD3+ T cells (n=5), or PBS (n=4). The T cells were pooled from the choroid plexus of 16 week old MRL/lpr mice (n=7) and from the spleen of 6 week old MRL/lpr mice (n=2). The cells were stimulated and expanded with anti-CD3/CD28 antibodies (1 ug/mL) and mIL-2 (10 U/mL) for 4 days. About ~200,000

cells were injected into the lateral ventricle from the bregma at AP -0.34 mm, ML -1.0 mm, and depth -2.0 mm. Mice were sacrificed 4 weeks post-injection, with behavioral assessments and histology performed to assess features of NPSLE.

Results: In this pilot study, we found that CP T cell recipient mice had increased cognitive and depressive deficits compared to PBS controls and the MRL/lpr splenic T cell recipient mice. Additionally, the CP T cell recipient mice had a significantly compromised motor function, as assessed by the number of slips while crossing a balance beam ($p = 0.0068$), when compared to the splenocyte injected groups and the PBS controls (Figure 1A). Histological assessment and immunohistochemical staining revealed an increase in lymphocytic infiltration, the number of proliferating cells (Figure 1B-C), as well as in IgG and complement deposition, in the choroid plexus of CP T recipient mice compared to the PBS group.

Conclusion: Our result indicate that T cells can migrate to and proliferate in the CP following ICV injection, and that brain infiltrating MRL/lpr T cells may be a key contributor to the pathogenesis of NPSLE.

Surrogate Pathways of Complement Activation in Novel Polygenic SLE-like Models of Kidney Injury

Sladjana Skopelja-Gardner ,[1] Xizhang Sun,[2] Yufeng Peng,[2] Lucrezia Colonna,[2] Payton Hermanson,[2] Lena Tanaka,[2] Joyce Tai,[2] David Salant,[3] and Keith Elkon[2], [1]University of Washington, Seattle, WA, [2]University of Washington, Seattle, [3]Boston University, Boston

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Lupus nephritis (LN) is a major contributor to morbidity and mortality in systemic lupus erythematosus (SLE). Defective clearance of apoptotic cells (AC), autoantibodies, and low complement levels are three hallmarks of SLE pathogenesis that have not yet been captured in a single disease model. We posit that such a model will allow us to elucidate the clinically relevant mechanisms of kidney injury in SLE and shed light on the multifaceted role of complement in this disease.

Methods: To investigate mechanisms of kidney injury in a disease model that mimics the polygenic nature of human SLE, we generated C57BL/6 mice that produced anti-chromatin antibodies (*Sle1*), had defective clearance of AC (*Mfge8*-/-) and were deficient in either C1q [C1q Triple mutant (C1qTM)] or C3 (C3TM). Kidney injury was evaluated by urine albumin/creatinine ratio (UACR), PAS staining, immunofluorescence (IF) staining and electron microscopy (EM). The effect of thrombin inhibition with argatroban on kidney injury in *Mfge8*-/-*C3*-/- (C3 double mutant, DM) mice was studied in the nephrotoxic-nephritis (NTN) model of kidney injury.

Results: C1qTM and C3TM mice, but not any double mutant controls, developed spontaneous membranoproliferative glomerulonephritis (MPGN) with PAS positive deposits, glomerular hypercellularity and variable mesangial and endocapillary proliferation at ~10 months of age. EM revealed features reminiscent of human LN: “wire loop”

and glomerular mesangial immune deposits in fibrillary organized structures. MPGN in C1qTM and C3TM mice was accompanied by increased glomerular deposition of IgG and AC. At 5 months of age, C1qTM and C3TM mice spontaneously developed high anti-dsDNA and anti-chromatin IgG titers as well as marked antigen spreading, including antigens previously implicated in LN pathogenesis.

Remarkably, IF staining revealed membrane attack complex (MAC) deposition in both TM strains. In C1qTM mice MAC deposition was associated with glomerular deposition of C3/C3d. Terminal complement activation in C3TM kidneys was accompanied by increased glomerular deposition of the thrombin substrate, fibrin. We also observed increased thrombin enzymatic activity in the plasma of C3TM mice, relative to C1qTM controls. Using the NTN model of kidney injury in *Mfge8-/-C3-/-* mice, the thrombin inhibitor, argatroban, significantly reduced glomerular MAC deposition and UACR, compared to vehicle treated controls.

Conclusion: In the context of reduced clearance of AC (*Mfge8-/-)* and non-pathogenic autoantibodies (*Sle1)*, early complement component deficiencies (C1q or C3) have two distinct effects: i) their absence leads to B cell activation and epitope spreading and ii) surrogate pathways allow terminal complement MAC activation. In C1qTM mice, increased glomerular C3/C3d deposition suggests activation of the lectin or alternative complement pathways, in the absence of C1q. Increased fibrin deposition in C3TM and rescue of proteinuria in NTN C3DM mice by a thrombin inhibitor, suggest that thrombin acts as a C5 convertase in low C3 states. These data encourage surrogate pathway evaluation in SLE patients with low complement states and offer new potential targets for therapy.

The Glucocorticoid-Induced Protein GILZ Represent a Checkpoint in the IFN Program in SLE

Eric Morand ,[1] Champa Nataraja,[1] Melissa Northcott,[1] Wendy Dankers,[1] Jacqueline Flynn,[1] Wendy Zhu,[1] Taylah Bennett,[1] Mehnaz Pervin,[1] Brendan Russ,[1] James Harris,[1] and Sarah Jones[1], [1]Monash University, Melbourne, Victoria, Australia

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Animal Models
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Given the primacy of Type I interferon (IFN) pathways in SLE pathogenesis, and the near-ubiquity of glucocorticoid (GC) use in SLE treatment, clarifying the intersection between these two domains is required. IFN activation in SLE appears largely GC-resistant, suggesting a permissive defect in GC-mediated regulatory events in SLE. GC-induced leucine zipper (GILZ) (*TSC22D3*) is one of the most exquisitely GC-sensitive genes in the genome, has endogenous effects which limit activation of T cells, B cells, macrophages and dendritic cells, but is underexpressed in SLE. We investigated the effect of GILZ on the IFN program in SLE.

Methods: Wildtype and GILZ deficient mice, and isolated cells, were stimulated using TLR ligands, and the effects of GILZ deficiency measured by qPCR, ELISA, Luminex, bioassay, and FACS. IFN effects on GILZ expression were studied in human PBMC and in public gene expression datasets. Mechanisms of regulation examined by ChIP.

Results: GILZ overexpression in human cells suppressed IFNα-induced gene expression. Conversely, loss of GILZ permitted unregulated expression of IFNs and other pro-inflammatory cytokines, including in vivo, in response to TLR ligands. GILZ directly suppressed TLR-stimulated expression of IRF7, the transcription factor that drives production of IFNα, by binding at the IRF7 locus. In parallel, IFNα suppressed GC induction of GILZ in PBMC, through direct binding of STAT1 at the GILZ promoter. Correspondingly, GILZ expression was significantly lower in IFN-positive SLE patients. Murine lupus and IFN activation were exacerbated when GILZ was deleted.

Conclusion: This work establishes GILZ as a key regulator of the IFN program that is in turn suppressed by IFN, a finding which may provide the explanation for GC resistance in high-IFN SLE. Restoring GILZ expression and activity represents a potential therapeutic opportunity to interrupt the IFN program in SLE, without the use of GC.

Anti-neutrophil Extracellular Trap (NET) Autoantibodies in Primary Antiphospholipid Syndrome

Yu Zuo ,[1] Srilakshmi Yalavarthi,[2] Kelsey Gockman,[2] David Karp,[3] Quan-Zhen Li,[4] and Jason Knight[5], [1]University of Texas Southwestern, Dallas, TX, [2]University of Michigan, Ann Arbor, MI, [3]UTSouthwestern Medical Center, Dallas, TX, [4]Department of Immunology & Internal Medicine/University of Texas Southwestern Medical Center, Charleston, [5]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Neutrophil extracellular traps (NETs) are prothrombotic tangles of chromatin and microbicidal proteins ejected from neutrophils in response to a variety of stimuli. In antiphospholipid syndrome (APS), recent work has demonstrated high levels of NETs in the blood of APS patients; that antiphospholipid antibodies can engage neutrophils to trigger NET release; and that APS serum degrades NETs poorly. Here, we hypothesized that APS might be perpetuated by crosstalk between NETs and anti-NET autoantibodies.

Methods: Purified, partially-digested NETs were used to coat ELISA plates. Levels of anti-NET IgG and IgM (OD at 450 nm) were determined. A positive cut-off was established as mean OD+2 SD of healthy-control samples. For a subset of patients, we also measured autoantibody formation with a microarray platform that included 120 potential autoantigens (48 NET-associated antigens and 72 other autoantigens). Univariate logistic regression was performed to determine clinical associations. Non-parametric Mann-Whitney U-test was used to compare levels of anti-NET autoantibodies and plasma NET remnants (myeloperoxidase-DNA complexes) between groups.

Results: As compared with controls (n=46), primary APS (n=78) was characterized by marked elevations in IgG (0.51 ± 0.36 vs. 0.29 ± 0.09; p< 0.0001) and IgM (0.76 ± 0.50 vs. 0.26 ± 0.23; p< 0.0001) anti-NET autoantibodies. Importantly, levels of anti-NET antibodies did not correlate with levels of anti-β2GPI (R2 < 0.01). By univariate logistic regression, positive anti-NET IgG/IgM was significantly associated with arterial thrombosis (P< 0.0001 for IgG / P<

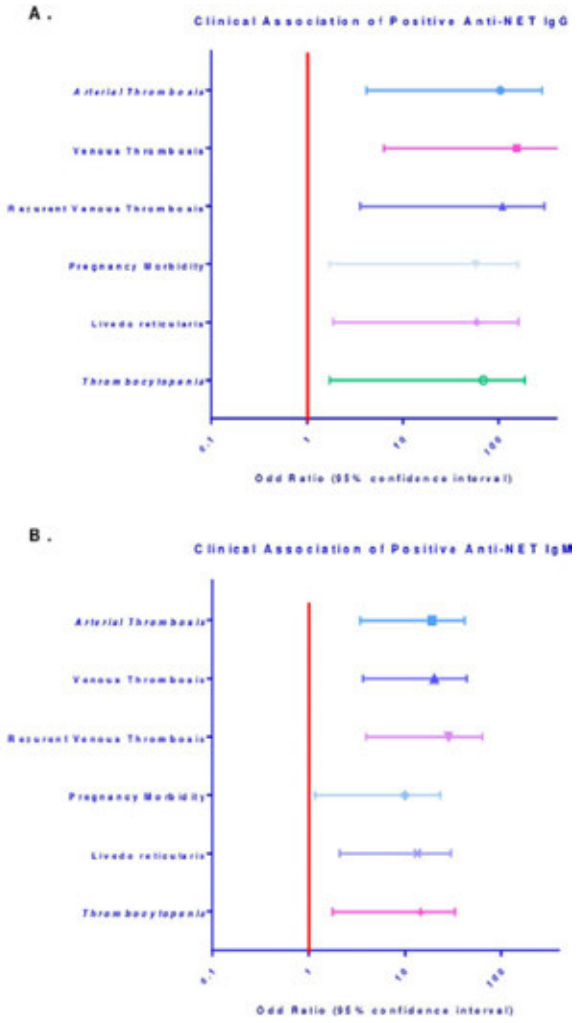

Figure 1. *Clinical association of anti-NET IgG (A) and IgM (B).*

Fig 1

0.0001 for IgM), venous thrombosis (P< 0.0001 for IgG / P< 0.0001 for IgM), and pregnancy morbidity (P=0.02 for IgG / P=0.03 for IgM). Intriguingly, positive anti-NET IgG/IgM was also associated with non-criteria features such as thrombocytopenia and livedo reticularis (Figure 1). Higher circulating NET remnants were observed in primary APS patients with venous thrombosis (P=0.0007) and recurrent venous thrombosis (P=0.0003) as compared with healthy controls (Figure 2). In pursuit of the antigen specificity of anti-NET autoantibodies, 20 of the primary APS samples were analysed by autoantibody microarray and compared with 20 matched controls. IgG/IgM autoantibodies against the following NET-relevant antigens were significantly elevated in primary APS: anti-citrullinated-histone H3, anti-chromatin, anti-nucleosome, and anti-bactericidal/permeability-increasing protein (BPI).

Conclusion: Patients with primary APS have high levels of anti-NET autoantibodies. Anti-NET IgG/IgM is associate with both criteria and some non-criteria APS clinical features. Autoantigen microarray reveals a marked enrichment of various specific citrullinated /non-citrullinated anti-NET autoantibodies in patients with primary APS. Anti-NET activity may associate with specific antigens present in NETs such as citrullinated-histone H3 and BPI. Interestingly, anti-NET autoantibodies do not correlate with anti-β_2GPI, suggesting their potential as a novel, independent, and clinically-relevant biomarker.

Abstract Number: 1789

Defibrotide Inhibits Antiphospholipid Antibody-Mediated NET Release and Endothelial Cell Activation

Ramadan Ali ,[1] Hui Shi,[1] Srilakshmi Yalavarthi,[1] and Jason Knight[2], [1]University of Michigan, Ann Arbor, MI, [2]Division of Rheumatology, Department of Internal Medicine, Michigan Medicine, Ann Arbor, MI

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Defibrotide is a mixture of phosphodiester oligonucleotides derived from porcine intestinal mucosa, currently approved for treatment of hepatic sinusoidal obstruction syndrome. Defibrotide has been considered a “multi-target compound,” and may have a particular role in limiting endothelial cell activation. Having said that, older literature also demonstrates anti-leukocyte and anti-neutrophil properties, with all of that work done prior to the first descriptions of neutrophil extracellular traps (NETs) in 2004. Our group and others have recently revealed a role for neutrophils and particularly NETs in the thrombotic complications of antiphospholipid syndrome (APS). Although defibrotide has been suggested as a possible treatment for APS, especially the microangiopathic variant known as catastrophic APS (CAPS), this possibility has not been investigated in the laboratory. Here, we hypothesized that defibrotide may act at the thromboinflammatory neutrophil-endothelium interface to neutralize APS-relevant NET release and endothelial cell activation.

Methods: Human neutrophils were prepared from healthy volunteers and stimulated with total IgG isolated and pooled from three CAPS patients (CAPS IgG). Stimulation was in the presence or absence of different concentrations of defibrotide, and NET release was quantified via the enzymatic activity of NET-associated myeloperoxidase.

In parallel, primary human umbilical vein cells (HUVECs) were isolated from human umbilical cord, and stimulated with 10% plasma pooled from three CAPS patients (CAPS plasma) in the presence or absence of defibrotide. Gene expression of ICAM-1, VCAM-1, and E-selectin were measured by real-time PCR. At this early stage of the study, statistical corrections were not made for multiple comparisons. P-values are therefore nominal, speaking to the scientific meaningfulness of the results, rather than statistical significance.

Results: We first assessed the effect of defibrotide on CAPS IgG-mediated NET release. As compared with control IgG, CAPS IgG triggered a significant increase in NET release from control neutrophils (~3-fold; $p< 0.05$). At doses ranging from 1 to 10 μg/ml, defibrotide significantly suppressed CAPS IgG-mediated NET release (40-50% suppression; $p< 0.05$). Interestingly, defibrotide also inhibited NET release induced by the canonical protein kinase C activator, phorbol 12-myristate 13-acetate (PMA). Regarding HUVEC activation, CAPS plasma significantly increased gene expression of ICAM-1 (~3-fold), VCAM-1 (2-fold), and E-selectin (2.5-fold), as compared with control plasma ($p< 0.05$ for each). Importantly, treatment with defibrotide returned the expression of all three genes essentially to baseline/control levels.

Conclusion: We demonstrate for the first time that defibrotide attenuates NET release and endothelial cell activation in the context of IgG and plasma derived from CAPS patients. Studies are underway to fully characterize defibrotide's mechanism of action and to assess its therapeutic potential in preclinical models of APS.

The Epidemiology of the Antiphospholipid Syndrome in the UK, 1990 – 2016

Mia Rodziewicz ,[1] David D'Cruz,[2] Martin Gulliford,[3] and Nisha Hazra[3], [1]The Louise Coote Lupus Unit, Guy's and St Thomas' Hospital NHS Foundation Trust, London, United Kingdom, [2]The Louise Coote Lupus Unit, Guy's Hospital, London, England, United Kingdom, [3]School of Population Health and Environmental Sciences, King's College London, London, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Antiphospholipid syndrome (APS) is a systemic autoimmune disorder characterised by recurrent vascular thrombosis and/or pregnancy morbidity in the presence of persistently positive antiphospholipid autoantibodies. It is estimated to account for 6% of all pregnancy morbidity, 13.5% of stroke, 11% of myocardial infarction and 9.5% of all deep vein thromboses. One small population-based study of APS has been reported and included only 33 individuals. This study aimed to estimate the incidence of APS and its complications in a large UK population.

Methods: A cohort study was conducted using the UK Clinical Practice Research Datalink. This is a database of primary care records kept by general practitioners in the National Health Service. It is deemed to be generally representative and contains active records for around 7% of the UK population. Data for all recorded cases of APS were included in this study. The incidence and prevalence of APS in the general population and the occurrence of venous thromboembolism (VTE), coronary heart disease (CHD), stroke and miscarriage in APS patients were estimated. The standardised mortality ratio was calculated to compare the mortality of APS patients to that of the UK general population.

Figure 1 - Age-specific incidence rates of APS for men and women

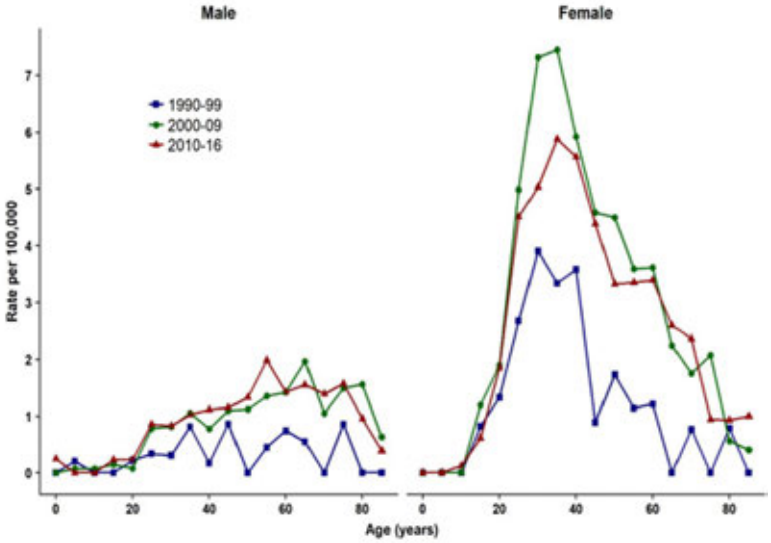

Figure 1. Age-specific incidence rates of APS for men and women

Table 1 - The incidence of complications in APS patients before and after diagnosis

	Before diagnosis		After diagnosis*	
	N	Incidence per 1,000 per year (95% CI)	N	Incidence per 1,000 per year (95% CI)
Miscarriage				
Women	247	19.0 (16.8 - 21.5)	84	10.4 (8.4 - 12.9)
Venous Thromboembolism				
Men	121	27.2 (22.7 - 32.5)	35	21.1 (15.2 - 29.4)
Women	213	15.6 (13.6 - 17.8)	10	13.4 (11.1 - 16.2)
			7	
Coronary Heart Disease				
Men	33	7.0 (5.0 - 9.9)	21	12.3 (8.0 - 18.8)
Women	41	2.8 (2.0 - 3.8)	41	4.9 (3.6 - 6.6)
Stroke				
Men	41	8.5 (6.2 - 11.5)	15	8.5 (5.1 - 14.1)
Women	76	5.2 (4.1 - 6.5)	31	3.7 (2.6 - 5.2)

*recurrent events were included after diagnosis if they were more than one year after last recorded event

Results: Data were analysed for 2,606 participants recorded with APS. In women, a peak incidence of 7.5 (95% confidence interval (CI) 6.2 to 8.9) APS cases per 100,000 person-years was observed at 35-39 years; in men, incidence reached a maximum of 2.2 (95% CI 1.2 - 3.5) per 100,000 at 55 to 59 years. Prevalence peaked at 50 (95% CI 49 - 55) in females in 2011 and 9.8 (95% CI 8.6 - 11.1) per 100,000 in males in 2012. Overall female to male ratio was 4:1. Before diagnosis, APS patients showed elevated incidence of miscarriage (19.0); VTE (men 27.2; women 15.6); CHD (men 7.0; women 2.8); and stroke (men 8.5; women 5.2) per 1,000 per year. The rate of miscarriage was lower after APS diagnosis (10.4 per 1,000 per year, 95% CI 8.4 – 12.9). There was no significant change in the rate of thrombotic complications after APS diagnosis. SLE was found in 20% of APS cases (SLE-APS). Female to male ratio was higher in this group compared to APS patients without SLE (10:1 and 4:1, respectively) and there was no significant difference in the rate of miscarriage or thrombotic manifestations. The overall standardised mortality ratio was 1.49 and 1.33 in females and males respectively.

Conclusion: This is the largest cohort of APS patients published to date. The overall estimated incidence is 1.8 and point prevalence of 43 per 100,000 persons in 2015. APS patients have elevated rates of thromboses, miscarriage and death compared to the general population.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: APS ACTION "Registry" was created to study long-term outcomes in persistently antiphospholipid antibody (aPL)-positive patients with and without other systemic autoimmune diseases. Our primary objective was to determine whether clinically significant aPL profiles at baseline remain stable over time.

Methods: A web-based data capture system is used to store patient demographics and aPL-related medical history. Inclusion criteria are positive aPL, based on the Updated Sapporo APS Classification Criteria, tested at least twice within one year prior to enrollment. Patients are followed every 12±3 months with clinical data and blood collection. For this prospective analysis of available follow-up (f/u) aPL tests, *clinically significant aPL profile* was defined as

Table: Baseline Clinical and Laboratory Characteristics of 420 Patients with Stable or Unstable aPL Profile at Follow-Up Included in APS ACTION Clinical Database and Repository ("Registry")

	Total (n=420)	Clinically Significant aPL Profile		p-value
		Stable (n=366)	Unstable (n=54)	
Female	305 (73%)	267 (73%)	38 (70%)	0.74
Age Median (IR)	48.9 [48.1, 50.4]	48.6 [47.9, 49.4]	48.6 [48, 50]	0.09

IR: Interquartile Range, **aPL:** Antiphospholipid Antibody, **APS:** Antiphospholipid Syndrome, **SAIDx:** Systemic Autoimmune Diseases, **TIA:** Transient Ischemic Attack, **aCL:** Anticardiolipin Antibody, **aβ_2GPI:** Anti-β_2-Glycoprotein-I Antibody

positive lupus anticoagulant (LA) test and/or aCL/aβ_2GPI IgG/M ≥40U. *Stable aPL profile* was defined as a clinically significant aPL profile in at least two-thirds of f/u measurements. Univariate and multivariable generalized linear mixed models with logit link were used to assess the effect of time and other variables of interest on odds of clinically significant aPL profile. Wilcoxon rank-sum and Fisher's exact tests were employed to compare clinical characteristics of patients with stable versus unstable aPL profiles.

Results: As of January 2019, 796 patients were enrolled from 26 centers worldwide, 482 had f/u visits with aPL results, and 472 patients had a clinically significant aPL profile at baseline. Based on aPL profiles at f/u visits (median follow up: 5.1 years [interquartile range [IR]: 4.3, 5.8]; median number of f/u visits with aPL profiles: 2 [interquartile range: 1, 3]), 366/472 (78%) patients had stable aPL profiles over time (54 [11%] unstable; 52 [11%] inconclusive). Time did not affect odds of maintaining a clinically significant aPL profile at f/u (p=0.906). In multivariable analysis, time, age, concomitant systemic autoimmune disease (mainly lupus), smoking history, and hydroxychloroquine use did not affect odds of maintaining a clinically significant aPL profile at f/u. Based on crude unadjusted comparisons, patients with stable aPL profiles, compared to those with unstable profiles, were more likely to have baseline positive LA test, aCL IgM ≥ 40U (positive trend for IgG), aβ_2GPI IgG ≥ 40U (positive trend for IgM), two or more positive aPL tests, and history of arterial events and aspirin use (Table).

Conclusion: In approximately 80% of patients with a baseline clinically significant aPL profile (LA test and/or aCL/aβ_2GPI IgG/M ≥40U), aPL profiles remain consistently significant (stable) during five years of follow-up. Further mul-

tivariate analysis will investigate predictors of aPL profile stability over time, and guide future validation studies of stored samples through APS ACTION core laboratories.

Cognitive Dysfunction (CD) and Serum Levels of Brain-Derived Neurotrophic Factor (BDNF) in Primary Antiphospholipid Syndrome (PAPS)

Renata Rosa ,[1] Michelle Remião Ugolini-Lopes,[2] Ana Paula Gandara,[2] Kenia Campanholo,[2] Livia Dutra,[3] and Danieli Andrade[4], [1]Faculdade de Medicina da Universidade de São Paulo (USP), Brazil., São Paulo, Sao Paulo, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo (USP), Brazil., São Paulo, Brazil, [3]Escola Paulista de Medicina (EPM), Brazil, São Paulo, Brazil, [4]Hospital das Clinicas, Faculdade de Medicina, Universidade de São Paulo, Sao Paulo, Brazil

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Cognition dysfunction (CD) is a poorly understood non-stroke central neurologic manifestation of antiphospholipid syndrome, whose diagnosis involves a specific neuropsychological (NP) evaluation. Brain-derived neurotrophic factor (BDNF) is a protein that plays an important role in neural plasticity, and could potentially be a biomarker of CD in primary antiphospholipid syndrome (PAPS). Our aim was to assess CD in PAPS patients and to evaluate its association with clinical data, antiphospholipid antibodies and serum BDNF levels.

Methods: This is a cross-sectional study that compared 44 PAPS patients (according to Sydney´s criteria) and 20 healthy controls matched for age, gender and education. PAPS patients and controls underwent a standardized cognitive examination. The demographic, clinical, and laboratorial characteristics of patients were recorded. Serum BDNF was measured by sandwich ELISA.

Results: Fourteen of the 44 (31,8%) PAPS patients had cognitive impairment compared with only 1 (5%) healthy control (p=0.019). The most common cognitive domains involved were verbal memory, executive function and attention. PAPS patients presented lower serum levels of BDNF compared to controls (p=0.007) and it was associated

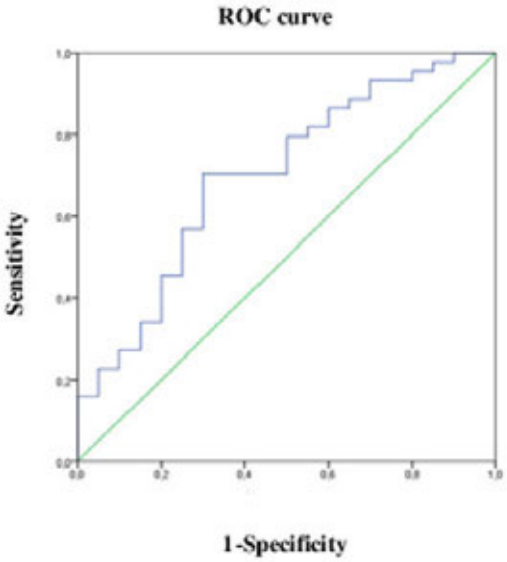

Figure 1: Receiver-operation characteristic (ROC) curve for determination of the cut-off for serum BDNF between PAPS and Control groups (Area under the curve = 0.700 ± 0.071; p=0.011; cutoff=736.5 ng/mL, sensitivity:70.5%, specificity: 70.0%).

with CD (p=0.032). The calculated cut-off value of serum BDNF was 736.5 ng/mL with sensitivity of 70.5% (CI95% 0,54-0,83), specificity of 70.0% (CI95% 0,45-0,88) and accuracy of 70.3% (CI95% 0,57-0,81)(Figure 1)**.** In a multivariate logistic regression stroke (OR 137.06; 95%CI, 4.73-3974.32; p=0.004), seizure/ epilepsy (OR 15.25; 95%CI, 0.65-356.37;p=0.090) and serum BDNF (OR 0.66; 95%CI, 0.41- 1.07;p=0.091) were independently associated with CD in PAPS.

Conclusion: Cognitive dysfunction is frequently diagnosed late in PAPS patients. The association of CD and low serum BDNF levels suggests that this neurotrophin can be a potential biomarker for predicting early cognitive dysfunction.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Antiphospholipid Syndrome
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Antiphospholipid antibody (aPL) nephropathy is a distinct entity that can be challenging to recognize and treat; it remains unknown if uniform pathologic criteria are used to characterize this diagnosis world-wide. The primary aim of this project was to evaluate how aPL nephropathy lesions as described in renal biopsy reports of APS ACTION registry patients with "biopsy-proven aPL nephropathy".

Methods: APS ACTION "Registry" was created to study long-term outcomes in persistently aPL-positive patients with and without other systemic autoimmune diseases. The registry includes adults aged 18 to 60 years with positive aPL, based on the Updated Sapporo APS Classification Criteria, tested on two occasions at least twelve weeks apart within one year prior to enrollment. We descriptively reviewed the results and conclusion sections of the renal biopsy reports of APS ACTION registry patients with biopsy proven aPL nephropathy. For biopsies not reported in English, translation was provided by specific APS ACTION centers. We categorized patients based on whether the biopsy report conclusion specifically stated "acute" versus "chronic" aPL nephropathy. We compared the terminology used

Description of aPL-Nephropathy Biopsy Reports of Patients in APS ACTION Registry (2000-2019)

	"Acute" aPL-Nephropathy n: 3	"Chronic" aPL-nephropathy n: 8	"aPL" Nephropathy* n: 14	
Sapporo aPL Nephropathy Terminology				*Alternative Definitions Representative of Sapporo Terminology*
Thrombotic Microangiopathy	3	3 **	5 ***	
Fibrous Intimal Hyperplasia	1	7	8	*Intimal sclerosis, intimal fibrosis with/without mucoid intimal edema, and, fibro-intimal thickening (14 of 16 biopsies)*
Recanalization	0	3	0	-
Organized Microthrombi	1	2	0	*Chronic thrombi (1 of 3 biopsies)*
Fibrous/Fibrocellular Occlusions	0	1	0	*Arteriole with obliteration of lumen by intimal expansion (1 of 1 biopsy)*
Focal Cortical Atrophy	2	8	12	*Scarring, tubular atrophy, interstitial fibrosis, and ischemic glomeruli (19 of 22 biopsies)*
Thyroidization	0	2	0	-
Other Terminology				
Fibrin Thrombi	3	0	4	-
Focal Segmental Glomerulosclerosis	0	6	1	--
Membranous Glomerulonephritis	0	1	5	-

*Acute vs chronic status not reported (4 did not use the term "aPL nephropathy"); **reported as "chronic TMA" (n: 1); ***: reported as "chronic TMA" (n: 2).

in the biopsy reports to the aPL-nephropathy definitions from the 2006 APS Sapporo Classification Criteria (thrombotic microangiopathy [TMA] involving both arterioles and glomerular capillaries, fibrous intimal hyperplasia involving organized thrombi with/without recanalization, fibrous/fibrocellular occlusions of arteries and arterioles, focal cortical atrophy, and tubular thyroidization). Under the guidance of a team of experts in aPL-nephropathy (MT, MT, SS), we used our clinical judgement in the interpretation of "alternative" biopsy report terms representative of the Sapporo criteria terms. Based on our literature review of terminology used to define aPL nephropathy, we also included "other" biopsy findings that may be associated with aPL.

Results: Of 804 patients included in the registry as of Jan 2019, 23 patients (3%) had "biopsy-proven aPL nephropathy". Twelve (52%) patients had primary APS, and 11 (48%) fulfilled the ACR lupus classification criteria. Two patients had kidney biopsies twice; thus 25 biopsy reports, performed between 1997 and 2018 were reviewed. Majority of biopsies (14/25) did not specify "acute" versus "chronic" aPL nephropathy. The number of biopsy reports with aPL-nephropathy related terms (Sapporo, alternative, and other) is shown in Table; four out of 7 Sapporo terms were also represented by alternative terminology . While "TMA" was reported in 11/25 (44%) of the biopsies: a) 9/11 (82%) used the term in the conclusion; b) 3/11 (27%) used the term "chronic TMA"; and c) 2/11 biopsies did not report the type of TMA (glomerular: 6; arterial/arteriolar: 2; both: 1; and unspecified: 2).

Conclusion: The use of aPL-nephropathy related terms varies among pathologists while reporting the biopsy findings of kidney involvement in aPL-positive patients. An international effort/consensus is needed to update and harmonize the terminology used to describe aPL-nephropathy.

*p<0.05

^Adjusted for all variables listed in table with p-value <0.05 in bivariate analysis

whole, there have not been any national studies of burnout among rheumatology trainees. The objective of this study is to evaluate levels of burnout among U.S. rheumatology fellows.

Table 3. Thematic Analysis of Open-ended Responses on Factors that Improve and Worsen Burnout.	
Factors Leading to Increased Burnout	Factors Leading to Reduced Burnout
Pager	Exercise
Documentation	Family/friends
Long hours	Sleep
Demands of patient care	Hobbies
Presentations and expectations	Support from colleagues and superiors

Methods: This is a cross-sectional study of U.S. rheumatology fellows conducted anonymously via an electronic survey tool from January to February 2019. The survey was disseminated to fellows at ACGME-accredited adult and pediatric rheumatology programs via the ACR program directors' listserv and ACR Fellows-In-Training Google group. Participants were given an incentive for participation in form of raffle of an Amazon gift card. Survey instruments included the Maslach Burnout Inventory (MBI) and the Patient Health Questionnaire 2 (PHQ2) to measure depression. We also measured burnout using the single-item measures for emotional exhaustion and depersonalization adapted from the full MBI. Measures of fatigue, quality of life, demographics (age, gender, ethnicity, marital status), and training year were also collected. We included open-ended questions about perceived factors to promote resiliency and reduce burnout and factors that worsen or lead to increased levels of burnout. Bivariate and multivariate regression analyses were used to examine correlates of burnout using STATA statistical software (STATA Corp. 2017). Open-ended responses were analyzed using thematic analysis.

Results: Response rate was 18.5% (105/567 total pediatric and adult rheumatology fellows) based on most recent data of trainees from 2017-2018. Survey responders were 64.8% female, 69.5% between 31-35 years, 59% white, and 61.9% married. When utilizing the MBI, 28.2% of PGY4 and 10.6% of PGY5/6 rheumatology fellows were found to have at least one symptom of burnout (p = 0.021). 12.8% of respondents in PGY4 year met criteria for depression compared with 2.4% in PGY5/6. In addition, PGY4 fellows reported worse fatigue and poorer quality of life compared with PGY5/6 (table 1). In multivariable models that controlled for training year and gender, higher age was associated with decreased odds of burnout (table 2). Additionally, PGY5/6 training year was associated with reduced odds of burnout in unadjusted models, but this effect was attenuated in adjusted models.

In thematic analysis of open-ended survey responses, participants identified factors to promote resilience and reduce burnout including: exercise, family/friends, sleep, support at work, and hobbies. Factors that contribute to burnout included pager, documentation, presentations/expectations, long hours, and demands of patient care.

Conclusion: This national survey of U.S. rheumatology fellows reveals that early trainee level and younger age are associated with worsened levels of fatigue, quality of life, and burnout. While awareness of and strategies to reduce burnout are needed for all fellows, targeted interventions for younger fellows and those in their first year of training may be of highest yield.

Abstract Number: 1795

Education of Rheumatology Faculty: Evaluation of an Interactive Team Based Approach versus Traditional Didactic Teaching

Alysia Kwiatkowski,[1] Najia Shakoor,[1] Andrew Ruthberg,[1] Joel A. Block,[1] and Sonali Khandelwal[1], [1]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Education
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Medical schools have been moving from traditional teaching to interactive approaches. Team-based learning (TBL) is a conceptual model that focuses on learner engagement, and the current literature focuses on the use of TBL in health profession learners. The impact of interactive small group sessions on attending physicians has not been well elucidated (Reimschisel et al, Medical Teacher, 2017), nor has the application of TBL in rheumatology topics been well studied. The major aim of this study was to determine if TBL can be used effectively to increase topic specific competency and comfort with management among a group of faculty learners when compared to didactic lecture.

Methods: Informed consent was obtained from all participants, the majority of whom were clinical faculty rheumatologists. There were 2 sessions on various aspects of osteoporosis: A 1-hour lecture and a TBL session. Knowledge based multiple choice questions were administered pre and post each session. For TBL, a pre-reading assignment was given and participants completed individual readiness assurance tests and group application exercises. Pre and post surveys assessing learning preferences and comfort with diagnosing and treating osteoporosis were completed. Comfort was measured on a 5-point Likert scale (1: not comfortable and 5: very comfortable). Paired and independent samples t-tests were used for analyses.

Results: There were 17 participants in each group. For the lecture group, there were significant improvements in pre and post session test scores (0.2±0.4 vs 1.4±0.6, p = p < 0.001), comfort with diagnosis (3.3±1.3 vs 3.9±0.8, p = 0.045) and treatment (2.9±1.3 vs 3.8±0.9, p = 0.006), moving from neutral to comfortable ranges. The lecture was helpful for 88% and liked by 82%. For the TBL group, there were no significant changes in pre and post test scores (1.4±1.1 vs 1.5±0.07, p = 0.525), comfort with diagnosis (3.2±1.1 vs 3.5±1.1, p = 0.160) or treatment (3.0±0.8 vs 3.5±1.1, p = 0.128), though comfort moved from neutral to comfortable ranges. TBL was helpful for 82%, liked by 88% and 82% completed the pre-reading. When comparing groups, the lecture group had greater improvement in test scores (p = 0.016), but there were no differences in comfort with diagnosis (p = 0.459) or treatment (p = 0.326). Preferences for combined learning methods increased from 53% to 88% after TBL completion.

Conclusion: In an era emphasizing interactive learning, this study shows that traditional lecture formats remain effective in increasing topic specific knowledge, as well as comfort with diagnosis and treatment. Both sessions were well liked, leading to a considerable change in learning preferences for the TBL group. High rates of pre-reading completion possibly contributed to baseline differences between the groups and lack of change in test scores. Comfort did increase within the TBL group. The addition of an interactive session to a lecture-based curriculum may further refine knowledge and augment comfort levels. Additional research is needed regarding potential differences in knowledge retention between the groups.

Normal serology or CRP/HsCRP (9)		
Serology or CRP/HsCRP not checked (12)		
Question regarding abnormal laboratory tests	25	23.6%
Abnormal serologies such as ANA/RF (20)		
Elevated CPK/Aldolase (5)		
Question on management of established rheumatic disease	12	11.3%
Confirmation of a diagnosis based on stated clinical characteristics (i.e. Relapsing Polychondritis,? Gout, ? autoimmune disease)	11	7.5%
Question on rash or biopsy	7	6.6%
Question on imaging	3	2.8%

Table 3. Rheumatology eConsultant teaching themes, n= number of identified themes

	n= 119	
Education on specific rheumatic disease	39	32.8%
PMR (9)		
Crystalline arthropathy (8)		
Myositis (7)		
Sjogren's syndrome (4)		
Spondyloarthropathy (3)		
Scleroderma (3)		
Relapsing Polychondritis (1)		
Fibromyalgia (2)		
Sweet's syndrome (1)		
Retroperitoneal fibrosis (1)		
Laboratory test interpretation	34	28.6%
Autoantibodies in rheumatic disease (24)		
HsCRP vs CRP value (10)		
Education on differential diagnoses of rheumatic diseases	27	22.7%
Non-inflammatory versus inflammatory arthropathy (18)		
Rheumatic causes of skin rash (6)		
Membranous nephropathy causes (1)		
Migratory arthritis (1)		
Elevated CPK/Aldolase (1)		
Management of specific rheumatic disease	16	13.4%
Radiographic/Imaging findings in rheumatic disease	3	2.5%

subspecialty visits, and satisfaction of PCPs. Studies have also investigated common eConsult diagnoses along with which types of questions were associated with recommendations for subsequent Rheumatology outpatient consultations.

eConsults also provide a forum of education by providing immediate feedback and by developing educational content based on common themes stemming from PCP questions. The objective of our study was to identify these themes and knowledge gaps in PCP's understanding of rheumatic diseases which may be used to improve patient care.

Methods: We performed a qualitative analysis of eConsult encounters from 2018-2019. Conventional content analysis was used to explore themes in eConsult communication from 1) questions posed by the PCP and 2) the recommendations provided by the Rheumatologist eConsultant. Each eConsult question and response could contain multiple themes. We also investigated if the Rheumatologist eConsultant recommended a visit following the eConsult.

Results: We reviewed 102 eConsult communications, 18% provided recommendations without a need for a face-to-face rheumatology appointment. The most common question types by the PCP were: further work up required to understand a patient's constellation of symptoms (43%), treatment recommendations for patient's symptoms (19%), and diagnosis confirmation based on patient's clinical history (15%). Within these question types, the following themes in question content were the most prevalent: joint pain/arthralgias (45%), abnormal autoantibody or inflammatory markers (24%), and management of an established rheumatic disease (11%). Table 2.

The most common educational recommendations provided by the Rheumatology eConsultant included: education on specific rheumatic diseases (33%, PMR most common), laboratory test interpretation (29%, autoantibody analysis most common), and differential diagnoses of rheumatic diseases (23%, features of non-inflammatory vs. inflammatory arthritis most common). Table 3.

The following knowledge gaps were identified: overdiagnoses of PMR, use of CRP and HsCRP interchangeably, and differentiation between inflammatory and non-inflammatory arthritis prior to lab testing.

Conclusion: This analysis of eConsult communication revealed common themes in both PCP questions and Rheumatologist recommendations. This knowledge may lead to focused educational opportunities, with greater understanding of rheumatic diseases and reduction in unnecessary lab testing. A larger proportion of eConsult questions required an outpatient visit than previously reported at other institutions. This highlights the importance of a detailed physical exam and subtle history in rheumatic disease diagnosis which often requires face to face visits with patients rather than relying solely on lab testing. This was a common teaching theme seen in our eConsults.

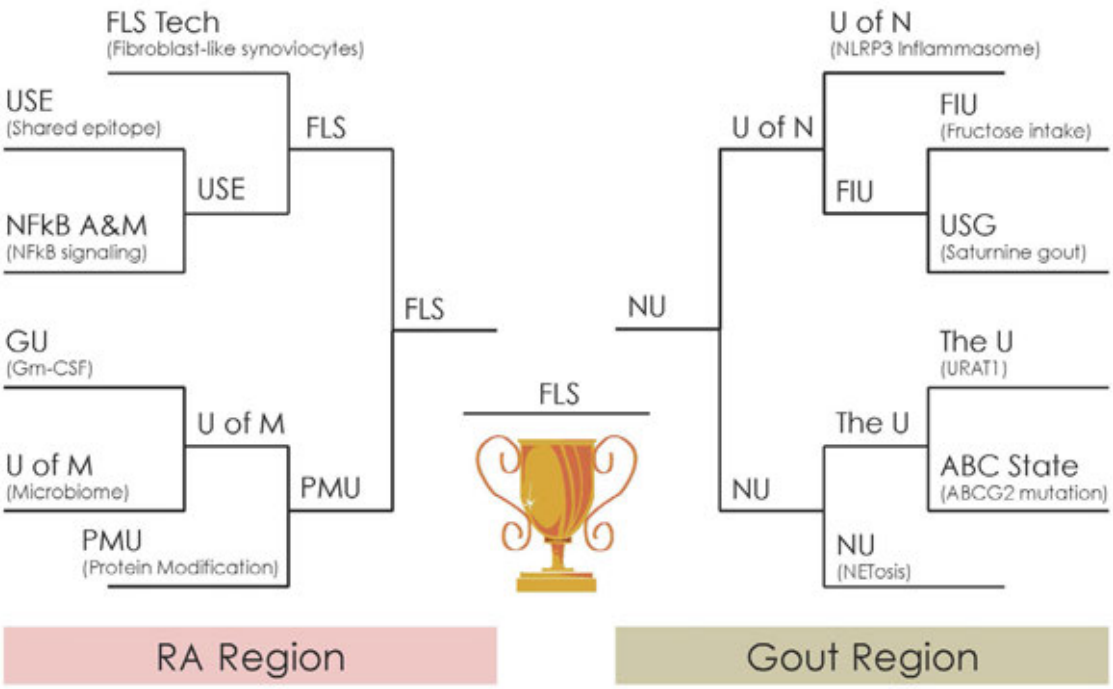
Rheumatology Mechanism Madness: A Pilot Collaborative Learning Activity for Rheumatology Trainees

David Leverenz ,[1] and Lisa Criscione-Schreiber[2], [1]Duke University, Durham, NC, [2]Duke University, Durham

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Education
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Figure 1: Rheumatology Mechanism Madness Bracket
(including winners of each matchup)



Background/Purpose: The Community of Inquiry (CoI) is a framework to understand how a group of individuals learns together and includes concepts of social, teaching, and cognitive presences. Inspired by the popular Neph-Madness online educational tournament that mimics the NCAA "March Madness" basketball tournament, we piloted Rheumatology Mechanism Madness (RMM) at our institution. Our primary goals were to test feasibility and assess the activity's educational impact using the CoI framework.

Methods: In two core curriculum sessions, fellows together identified and chose key disease mechanisms in RA and gout to include as individual "teams" in the RMM bracket. Fellows then wrote half page "scouting reports" reviewing each mechanism and presented topic overviews at one divisional grand rounds. The Division was invited to complete brackets and attendees voted for the winner of each matchup during grand rounds. We reviewed metrics on tournament engagement and distributed a modified validated CoI survey to the fellows who participated in RMM. In the CoI survey, cognitive presence describes learners' progression through four stages of cognitive processing: triggering, exploration, integration, and resolution; teaching presence describes the oversight of the learning activity. Our modified CoI survey included questions relating to the cognitive and teaching presences but omitted social presence as our fellows had already developed a social community. Each question was rated on a 5-point Likert scale (1 = strongly disagree, 2 = disagree, 3 = neutral, 4 = agree, 5 = strongly agree). Data was analyzed using descriptive statistics.

Results: Fellows created a bracket with 12 mechanisms related to RA and gout (Figure 1). Out of 32 possible participants in our division, 19 (59%) submitted a bracket. The winning pathogenic mechanism was fibroblast-like synoviocytes in RA, and one participant correctly predicted every matchup outcome. All 6 fellows who participated in RMM responded to the post-survey. The average Likert score for questions relating to the cognitive presence was 4.1; subdomain scores were: triggering 4.6, exploration 3.9, integration 4.2, and resolution 4.1 (Table 1). The average Likert score for questions relating to the teaching presence was 4.5; subdomain scores were: design and organization

Overall Direct Instruction	0	2	4	6	6	3.9
Total Teaching Presence	0	2	6	18	52	4.5

4.8, facilitation 4.7, and direct instruction 3.9 (Table 2). Every respondent agreed or strongly agreed that they enjoyed RMM (average score 4.7) and would be interested in participating in a future version that included fellows from other institutions (4.7).

Conclusion: The pilot RMM activity was feasible and enjoyable for fellow participants. CoI survey results provided evidence of effective cognitive and teaching presences within the activity. In the cognitive domain, this activity was most effective to trigger interest, and least effective in knowledge applicability. Next steps include adapting the initiative to include trainees at other institutions, adding steps to enhance applicability and further evaluating the CoI framework as a tool for studying this initiative, including the social presence.

Time to Bridge the Gap in Rheumatology Education: Interactive Team Based Learning Is Most Effective in Increasing Internal Medicine Residents' Knowledge

Alysia Kwiatkowski ,[1] Najia Shakoor,[1] Augustine Manadan,[1] Michael Grant,[1] Joel A. Block,[1] and Sonali Khandelwal[1], [1]Rush University Medical Center, Chicago, IL

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Education
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Medical education curricula have evolved to more interactive approaches. Fully interactive, team-based learning (TBL) is a flipped classroom model that has been well studied at the pre-graduate level. The impact of TBL in post graduate populations, especially on Rheumatology specific topics, has not been well explored (Reimschisel et al, Medical Teacher, 2017). How TBL compares to a more moderately interactive session is also not clear. The major aim of this study was to evaluate the efficacy of TBL versus a moderately interactive teaching approach and traditional lecture in increasing rheumatology specific topic competency in medical trainees.

Methods: Three 1-hour sessions on various rheumatology topics: a didactic, a moderately interactive lecture and a TBL session were performed. Three knowledge based multiple choice questions were administered pre and post each session. For the moderately interactive session, the group was asked open ended questions at regular intervals. For TBL, a pre-reading assignment was given and participants completed individual readiness assurance tests and group application exercises. Pre and post rotation surveys assessing learning preferences and to what degree the sessions enhanced comfort with diagnosis and treatment were completed. Comfort was measured on a 5-point Likert scale (1: not comfortable and 5: very comfortable). Paired and independent samples t-tests were used for analyses.

Results: There were 29 participants in the lecture, 27 in the moderately interactive and 46 in the TBL group. The majority were medical residents PGY 1-3. For the lecture, there were *decreases* in post test scores (1.7±0.6 vs 0.8±0.8, $p < 0.001$), though comfort with diagnosis (3.2±0.8 vs 4.0±0.7, $p < 0.001$) and treatment (2.5±0.7 vs 3.5±0.8, $p < 0.001$) improved. For the moderately interactive, there were improvements in test scores (0.8±0.8 vs 1.32±0.8, $p = 0.049$), comfort with diagnosis (2.9±0.7 vs 3.9 ±0.9, $p < 0.001$) and treatment (2.5±1.0 vs 3.5±1.0, $p = 0.011$). For TBL, there were improvements in test scores (1.0±0.6 vs 2.1±0.8, $p < 0.001$), comfort with diagnosis (2.7±1.0 vs 3.3±1.0, $p = 0.001$) and treatment (2.3±0.9 vs 3.2±1.1, $p < 0.001$). When comparing changes in test scores between groups, there were significant differences between TBL and lecture ($p < 0.001$), TBL and moderately interactive ($p = 0.019$) and between moderately interactive and lecture ($p < 0.001$). All increases in comfort went from uncomfortable or neutral to comfortable ranges and there were no significant differences in change in comfort between groups. The majority of residents preferred mixed learning formats.

Conclusion: Though residents prefer mixed learning models and all formats subjectively increased comfort with diagnosis and treatment, this study shows that TBL yields a significantly greater increment in rheumatology specific knowledge than moderately interactive and non-interactive sessions. Interestingly, knowledge scores after traditional lecture-based teaching actually decreased. Post graduate curricula should reflect the trends seen in pre-graduate education, by utilizing interactive small group formats.

Wellness and Resiliency Among Recent Rheumatology Fellowship Graduates: A Qualitative Study

Priyanka Iyer ,[1] and Bharat Kumar[2], [1]University of Iowa Hospitals and Clinics, Iowa City, IA, [2]University of Iowa Hospital and Clinics, Iowa City, IA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Education
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The recent ACR workforce projections suggest that there will be a significant shortage of rheumatologists by 2030. Retirement of senior physicians, an increase in part-time providers and increased demand for rheumatologic care are cited as major reasons for this shortage. This has implications for recent rheumatology fellowship graduates, who are entering this challenging environment with an eye towards building preserving well-being and bolstering resiliency. Indeed, studies demonstrate that young physicians as a whole have the lowest career satisfaction, highest frequency of personal conflicts and highest rates of depersonalization. In this qualitative study, the investigators explore the characteristics of wellness and resiliency among newly board-certified rheumatologists.

Methods: We performed a qualitative study using semi-structured phone interviews of rheumatologists who completed fellowship in 2017. Participants were recruited through purposive sampling. Eight questions were devised by the investigators, covering wellness, resiliency, and burnout and probing their perceived challenges, motivations, and opportunities for improvement.

Interviews were recorded and transcribed independently and verified for consistency. Discrepancies were resolved through mutual consensus. The two investigators used grounded theory to sequentially code the transcripts line-by-line. These codes were then compiled and organized into larger themes and subthemes. We continued to analyze these data until reaching theoretical sufficiency.

Results: 24 rheumatologists were interviewed, of which 12 were in private practice and 12 were in academic practice. Five themes were identified: (1) work-family balance as a dynamic equilibrium changing over time, (2) inadequacy of formal training in addressing self-doubt over independence and autonomy, (3) uncertainty over career development and progression, and (4) excessive burden of documentation and billing, and (5) protective nature of longitudinal patient-physician relationships. These themes overlapped in both groups, although subthemes were unique (e.g. concerns over extramural funding in academics vs. developing a patient panel in private practice).

Conclusion: New rheumatologists face a series of challenges as they enter the workforce. This qualitative study empowers participatory research to understand the needs of this unique and vulnerable population. Investments into their well-being can help reduce the risk of burnout and enlarge our community. Our results highlight priorities as identified by recent fellowship graduates and provide suggestions to training program leaders to enable successful transitions to independent practice.

Safety and Humoral Immunogenicity to Herpes Zoster Vaccine in Patients with Rheumatoid Arthritis (interim Analysis)

Ori Elkayam ,[1] Itzhak Rosner,[2] Devy Zisman,[3] Merav Lidar,[4] Reuven Mader,[5] Amir Bieber,[5] Alexandra Balbir-Gurman,[6] Mirit Amit,[7] Smadar Gertel,[8] and Victoria Furer[9], [1]Rheumatology Department, Tel Aviv Medical Center, and Sackler Faculty of Medicine, Tel Aviv University, Israel., Tel Aviv, Israel, [2]Bnei Tzion, Haifa, Israel, [3]Carmel Hospital and Ruth and Bruce Rappaport Faculty of Medicine, Technion, Israel, Haifa, Israel, [4]Sheba Medical Center, Ramat Gan, Israel, [5]Ha emek medical center, Afula, Israel, [6]Rambam Medical Center, Haifa, Israel, [7]Shamir medical center, Zerifin, Israel, [8]Tel Aviv medical center, Tel Aviv, Israel, [9]Sourasky Medical Center, Tel-Aviv, Israel

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Infection-Related Rheumatic Disease

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: To evaluate the safety and humoral immunogenicity of a live attenuated herpes zoster (HZ) vaccine in patients with rheumatoid arthritis (RA) compared with healthy controls (HC).

Methods: This is a prospective multicenter study of a live attenuated HZ vaccine in 132 patients with RA receiving conventional disease-modifying anti rheumatic drugs (cDMARD) and/or low-dose glucocorticoids (GC), candidates to receive biologics or tofacitinib. The control groups was composed of 35 HC. All the subjects, above the age of 50 years. Clinical and laboratory assessments were performed at baseline and after 6 weeks. Each assessment included RA disease activity score (DAS-28) for RA patients, recording of side effects and blood samples for the evaluation of immunogenicity for each subject. At week 2 and 4 after vaccination, patients were contacted by phone and asked for adverse events. The immunogenicity was assessed using varicella zoster virus (VZV)-specific ELISA (Serion)

Results: 132 RA patients (median age 66, range 50-89, 81% women) and 35 HC (median age 67, range 51-100, 69 % women) were vaccinated with the Zostavax (MSD) vaccine. Safety: 67 (52%) of the RA patients and 12 (32%) of the HC developed vaccine related side effects. In the HC, all were local reactions to the vaccine which resolved after a few days. In the RA group, the adverse events included: 56 local reactions, 11 systemic reactions such as fever, 2 mild rash, and 1 event of herpes zoster. Seven RA patients reported worsening of the RA Effect on disease activity :No change in disease activity was observed . DAS28-ESR at baseline was (median [min, max], n (out of 132)) (4 [2,8], n=126/132) and (4, [1,9], n=121/132) after 6 weeks. Immunogenicity: The number of patients with non-protective titer at baseline was 1 (RA=0, and controls=1). The titer increased from (median [min, max], n) (877 [101, 3153], n=129/132) to (1327 [99, 4836], n=126) for RA and from (962 [54, 1650], n=35) to (1533 [222, 3564]) in the control group. The increase in each group was statistically significant (pv< 0.0001 for both groups, Wilcoxon signed-rank test, n.RA=124, n.Control=35). The degree of humoral response was similar in the 2 groups (p=0.238, Mann-Whitney Test, n.RA=124, n.Control=35)

Conclusion: In RA patients treated with cDMARDs, vaccination with a live attenuated vaccine against herpes zoster was safe and induced an adequate booster response

Abstract Number: 1801

Comparison of Infection-Related Hospitalization Risk and Cost in TNFi-Experienced Medicare Beneficiaries with Rheumatoid Arthritis Treated with Abatacept or Other Targeted Disease-Modifying Anti-Rheumatic Drugs

Vardhaman Patel ,[1] Zulkarnain Pulungan,[2] Anne Shah,[2] Mahesh Kambhampati,[2] Francis Lobo,[3] and Allison Petrilla[2], [1]Bristol-Myers Squibb, New York City, NY, [2]Avalere, washington, DC, [3]Bristol-Myers Squibb Company, Princeton, NJ

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Infection-Related Rheumatic Disease
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The risk and cost of infection-related hospitalizations in tumor necrosis factor inhibitors (TNFi)-experienced patients with rheumatoid arthritis (RA) receiving subsequent targeted disease-modifying antirheumatic drug (tDMARD) is unknown in the Medicare population. This study compared the risk and cost of infection-related hospitalization costs between TNFi-experienced patients receiving abatacept, TNFi and other non-TNFi.

Methods: A retrospective cohort study using 100% Medicare fee-for-service (FFS) claims (Parts A/B/D) was designed to identify TNFi-experienced patients with RA who initiated a subsequent treatment with abatacept, TNFi (adalimumab, certolizumab pegol, etanercept, golimumab, and infliximab) or other non-TNFi (anakinra, sarilumab, rituximab, tocilizumab, tofacitinib) between January 2010-December 2017. The date of the new tDMARD therapy

Table. Baseline characteristics and unadjusted infection-related hospitalization costs

Variable	Abatacept (N = 6,343)	TNFi (N = 5,054)	p-Value Abatacept - TNFi	Other Non-TNFi (N = 5,250)	p-Value Abatacept – Non-TNFi
Mean Age, Years	73.0	73.1	0.25	72.7	0.02
Mean CCI Score	4.9	4.8	0.01	5.0	0.14
Mean Duration of Follow-up, Days	441.9	402.8	<0.0001	460.0	0.05
Follow-up Infection-related Hospitalization Costs, PPPM	$77.3	$107.7	0.11	$141.4	0.01
Genitourinary*	$41.8	$54.6	0.45	$59.9	0.03
Pneumonia*	$37.5	$54.7	0.12	$74.0	0.06
Sepsis*	$34.3	$49.1	0.44	$69.0	0.19
Skin & Soft Tissue*	$8.7	$20.6	0.37	$23.2	0.05
Joint*	$4.3	$11.4	0.32	$10.5	0.18
Bacterial Respiratory*	$4.2	$3.8	0.73	$9.5	0.96

CCI = Charlson comorbidity index, PPPM = per-patient per month

*Type of infections were not mutually exclusive

initiation was the index date. Patients were included if age 65+, ≥2 claims with a diagnosis code for RA, continuous enrollment 12-months pre- and post-index date, and no evidence of cancer and other auto-immune conditions. Follow-up ended at the date of disenrollment, death, end of study period, or end of index treatment, whichever occurred first. Infections included pneumonia, bacterial respiratory, sepsis, skin and soft tissue, joint or genitourinary. A two-part generalized linear model controlling for baseline demographics, comorbidities, infections, healthcare resource use and costs was used to examine differences in per-patient per month (PPPM) Medicare payments (2019 USD). A Cox regression model was used to compare the risk of infections.

Results: Of the study population, 6,343 patients were treated with abatacept, 5,054 with TNFi, and 5,250 with non-TNFi. At baseline, abatacept group had the highest proportion of patients with infection-related hospitalization (9.8% vs. 7.1% vs. 9.7%, P< 0.05). However, the risk of infection-related hospitalizations during follow-up was lower in patients treated with abatacept compared with TNFi (7.5% vs. 8.1%, P=0.21) and other non-TNFis. (7.5% vs. 10.7%, P< 0.0001). After adjusting for differences in patient characteristics, Cox regression analysis showed that the risk for an infection-related hospitalization was significantly higher for RA patients treated with TNFi's (HR: 1.48; 95% CI: 1.26-1.75, P< 0.0001) and other non-TNFi's (HR: 1.46; CI: 1.28-1.66, P< 0.0001) than in those treated with abatacept. During follow-up, after controlling for potential confounding variables, infection-related hospitalization PPPM cost was significantly higher in patients treated with a TNFi's (difference: $93; 95% CI: $51-$134) and other non-TNFi's (difference: $84; 95% CI: $52-$116) than in those treated with abatacept.

Conclusion: Medicare FFS beneficiaries with RA who initiated abatacept following the exposure of TNFi, had lower infection-related hospitalization costs compared to patients who switched to a different TNFi or other non-TNFi.

Abstract Number: 1802

Utility of Repeat Latent Tuberculosis Testing in Patients Taking Biologics

Urmi Khanna ,[1] Ariana Ellis,[2] AbdulAziz Galadari,[3] Jeffery Hu,[4] Josh Gallop,[5] M. Elaine Husni,[6] and Anthony Fernandez[7], [1]Department of Dermatology , Cleveland Clinic, Cleveland, OH, [2]Northeast Ohio Medical University, Cleveland, OH, [3]Cleveland Clinic, Abu Dhabi, Cleveland, [4]Case Western Reserve University, Cleveland, [5]Cleveland Clinic Lerner College of Medicine, Cleveland, OH, [6]Department of Rheumatologic and Immunologic Diseases, Cleveland Clinic, Cleveland, OH, [7]Department of Dermatology and Pathology, Cleveland Clinic, Cleveland, OH

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Infection-Related Rheumatic Disease
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Guidelines for repeat Latent Tuberculosis Infection (LTBI) testing while on biologics are not clearly defined. The American College of Rheumatology recommends repeat LTBI screening only in persons with risk factors for tuberculosis(TB) whereas the National Psoriasis Foundation recommends repeat annual LTBI screening in all patients on biologics. Furthermore, recommendations for annual LTBI screening for patients on biologics have been incorporated into the Medicare Merit-Based Incentive Payment Systems and will impact physician reimburse-

Table 1: Patient Characteristics of entire study cohort

Characteristics	Value
Total cases	5212
Age (years), mean	40.9
Most common medical diagnoses, N (%)*	5925 (100)
• Inflammatory bowel disease	1868 (31.52)
• Rheumatoid Arthritis	1722 (29.06)
• Psoriasis	1505 (25.40)
Average number of biologics per patient	1.80
Duration(months)of biologic therapy, mean	63.76
Most common biologics administered, N (%)*	9412 (100)
• Adalimumab	3107 (33.01)
• Etanercept	1630 (17.31)
• Infliximab	1561 (16.58)
No of QFT tests, mean	3.17

**The Medical diagnoses and biologics are more than total cases since some patients had more than one medical diagnoses and some received more than one biologic*

Table 2: Comparative characteristics of patients with indeterminate and positive QFTs

Characteristic	Indeterminate QFTs group	Positive QFTs group	P value
Number of patients	479	172	
Age(years), mean (SD)	40.99 (18.23)	44 (17.27)	0.0601
Most common medical diagnoses, N (%)*	575 (100)	196 (100)	
o Inflammatory bowel disease	235 (40.86)	65 (33.16)	
o Rheumatoid Arthritis	163 (28.34)	65 (33.16)	
o Psoriasis	85 (14.78)	34 (17.34)	
No of QFT tests, mean(SD)	3.68 (2.77)	3.46 (1.63)	0.0667
Latent TB treatment, N (%)	4(0.83)	83(48.25)	<0.00001
Biologic discontinued, N (%)	92(19.20)	12(6.97)	0.000173
Duration(months)of biologic therapy, mean(SD)	20.99(21.29)	75.08(52.15)	0.0001
Risk Factors for TB present, N (%)	61(12.73)	73(42.44)	<0.00001

**The Medical diagnoses are more than total cases since some patients had more than one medical diagnoses*

ment. However, little evidence supports that this practice of repeat annual screening is clinically valuable and/or cost-effective in patients on biologics.

Objective: To determine the value and cost-effectiveness of serial LTBI screening in patients taking biologics and to identify risk factors in patients who convert from negative to positive QuantiFERON TB test (QFT) results while on biologics.

Methods: We retrospectively reviewed LTBI screening results in patients treated with biologics for chronic inflammatory/autoimmune conditions at a single, tertiary care center between August 2007 and March 2019. For each patient, we collected demographic information, primary underlying diagnosis, biologics used, length of biologic therapy, number of QFTs and QFT results. Patients without repeat QFT results following biologic initiation and/or all QFTs outside the treatment period with biologics were eliminated from the study.

Results: Of 10,914 patients treated with biologics and with QFT results, 5212 had ≥1 repeat QFT result after starting biologic therapy (mean 3.2 per patient) and were included in our study (Table 1). The most common medical diagnosis in the study cohort were Inflammatory Bowel Disease (31%), Rheumatoid Arthritis (29%) and Psoriasis +/- Psoriatic Arthritis (25%). Majority patients had all negative QFTs (87.5%, n=4561), 9.2 % patients (n=479) had ≥1 indeterminate QFT and 3.3% patients (n=172) had ≥1 positive QFT (Table 2). Amongst patients with positive QFTs, only 61 patients converted from a negative to a positive QFT after initiation of biologic therapy. Importantly, only one case of active TB was found in the entire study cohort and this patient had a significant risk factor in the form of recent travel to a TB endemic area.

Conclusion: This represents the largest single institution study evaluating rates of QFT test positivity/conversion in patients taking biologics. Repeat LTBI testing in patients taking biologics revealed a low rate of conversion (1.17%), suggesting low clinical value and an undesirable cost-benefit ratio. Additionally, a high percentage of positive QFT converters had risk factors for TB exposure. Our results suggest clinical utility and cost-effectiveness of repeat LTBI screening in patients on biologics may be more valuable if not performed routinely, but driven by a focused review of TB exposure risk factors in each patient.

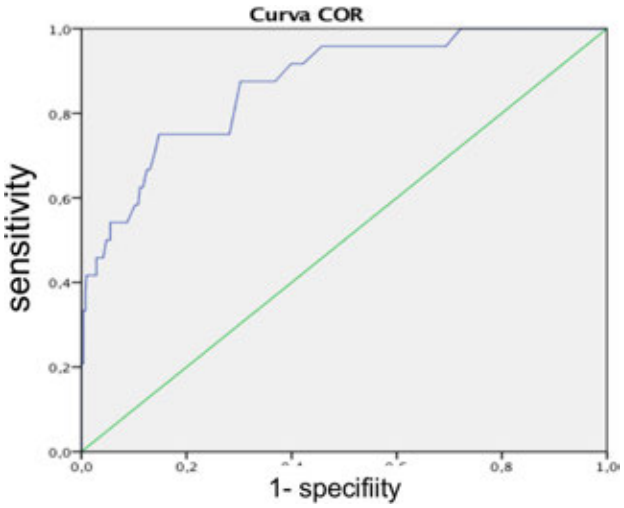
SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Infection-Related Rheumatic Disease
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: The biologics therapies in rheumatoid arthritis (RA) implies a well-known risk of infection. It is of utterly importance to count with predictive models to define risk factors for infection. Objectives: Validate the RABBIT risk score for serious infections in a cohort of RA patients followed for 12 months. Evaluate which variables of our population could be of relevance to optimize the score.

Methods: Patients ≥18 years old fulfilling 2010 ACR/EULAR criteria for RA were included and followed for 12 months. Basal sociodemographic data, comorbidities, RA characteristics and vaccination was consigned . Basal RABBIT score was calculed. Serious infections were consigned, describing site and time since enrollment. Statistical analysis: Categorical variables were compared using x2 test and continual variables using Student´s t test or Mann Whitney. Cumulative survival of infection was assessed using Kaplan Meier curves. Variables associated serious infections were evaluated using Cox proportional regression model.

Results: 605 patients were included. 83.5% female, mean age 52.8±12.8 years, 96.2% urban residence, 83% GRAFFAR III/IV (middle, middle-low class), median years of formal studies 10 (IQR 7-13) years. 70% had health insurance. Median time of RA evolution 84 (36-168) months, 90% RF+, 80% ACPA+, median DAS-28 3.5 (2.4-4.8), median CDAI 10 (3-19) and median HAQ 0.87 (0.37-1.50). Comorbidities: 7% Previous infection, 10% lung disease, 1% chronic kidney disease, 6% diabetes. Vaccination status: 67% antiinfluenza, 66.5% antipneumococcal, 47% antiHBV. Treatment: 75% patients were on MTX. 60% were on csDMARDs alone and 40% on bDMARDs (60% TNFi, 20% Tocilizumab, 13% Abatacept, 7% Tofacitinib). 15.6% had a prior history of bDMARDs use. Mean dose of prednisone was 3.6 mg/day and 75% of patients received under 7.5 mg/day. Incidence of serious infection was 5% (CI95% 3-7). Most frequent sites were respiratory and urinary (90%). Mean time to serious infection was 3.5 mont. Variables associated with serious infection: High disease activity by CDAI 4.1 (1.8-9.5) and DAS-28 3.2 (1.3-7.3), previous serious infection 19.3 (8-47), pulmonary disease 5.2 (2.1-13), diabetes 6.4 (2.3-17.6), prednisone >20mg/day 14.3 (4.8-42.5), Tocilizumab treatment 12.4 (3-53) and current use of DMARDs 0.24 (0.1-0.6). Cox regresión model (serious infection): Previous serious infection (expB:10.6 p:0.00001), diabetes (expB:4.8 p:0.02), Tocilizumab treatment (expB: 11.4 p:0.012), high dose of corticoids (expB: 9.3 p:0.008) and current use of DMARDs (expB: 0.3 p:0.04) were



independently associated. Performance of RABBIT score: Patients with no infection during follow up had a median score of 1.2 (IQR 0.8-2.1) and patients with infection a median score of 5.1 (IQR 2.15-12.6)(p=0.00001). ROC curve analysis: AUC 0.86 (CI95% 0.8-0.94), best cut-off 2.85 (sensibility 75%, specificity 85%).

Conclusion: The RABBIT score performed excellently in our patients. Serious infections was 5% during the 12 months, mean time to serious infection was 3.5 months and it was independently associated with previous serious infection, diabetes, use of Tocilizumab, prednisone dose >20 mg/day and negatively with current use of DMARDs.

Safety of the Zoster Vaccine Recombinant, Adjuvanted in Rheumatoid Arthritis and Other Systemic Rheumatic Disease Patients: A Single Center's Experience with 400 Patients

Emma Stevens ,[1] Michael Weinblatt,[1] Elena Massarotti,[2] Frances Griffin,[1] Srinivas Emani,[1] and Sonali Desai[3], [1]Brigham and Women's Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, [3]Brigham and Women's Hospital Assistant Professor of Medicine, Harvard Medical S, Boston, MA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Infection-Related Rheumatic Disease
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Patients with rheumatoid arthritis (RA) and other systemic diseases (SD) are at an increased risk of developing Herpes Zoster (HZ) due to either the nature of the diseases or the medications used to treat them. Zoster Recombinant Adjuvanted (ZRA) is a novel vaccine that can be used in immunosuppressed populations and was approved by the FDA in 2018. ZRA provides >90% efficacy in non-immunosuppressed patients older than 50. However, concern has been raised that ZRA may trigger disease flares and cause more side effects in immunocompromised patients. We investigated the impact of the new ZRA vaccine in RA and other SD patients, and measured the incidence of flares and side effects.

Methods: We performed a retrospective chart review of patients with RA and SD seen at BWH who received the ZRA vaccine between 2/1/2018 and 2/1/2019. Co-variates of interest were collected. A flare was defined as occurring within 12 weeks of vaccine administration by either: 1) documentation of RA flare in the rheumatologist office notes, telephone encounter or patient portal communication, or 2) new prednisone prescription, or an increase in dose of existing prednisone prescription. Vaccine side effects were defined as muscle soreness or rash at the injection site, redness, mild swelling, fatigue, fevers, myalgias, headaches, nausea, and abdominal pain. All potential flares were independently reviewed, adjudicated, and confirmed by three rheumatologists (EM, MEW, and SD).

Results: 402 (236 RA and 166 SD) patients who received the new ZRA vaccine between 2/1/2018 and 2/1/2019 were identified. Mean follow up was 13.2 weeks ranging from 1-50 weeks following administration. Patient characteristics are identified in **Table 1**. We identified 6.7% (n=27) patients who experienced a flare, lower than the observed background six-month flare rate of 30% in RA patients at our center (Bykerk VP et al., 2014). Of these patients 5.7%

Table 1: Characteristics of Subjects to Study the Safety of the Zoster Vaccine Recombinant

Total N	402
Mean Age (STD)	67 (10.9)
Females (%)	304 (75.6)
White (%)	344 (85.6)
Received 2nd Vaccine (%)	149 (37.1)
RA (%)	236 (58.7)
Other*	166 (41.3)
Medications	
MTX (mean dose=17.1mg/week)	134 (33.3)
Prednisone (mean dose=4.7 mg/day)	106 (26.4)
Tofacitinib (%)	50 (12.4)
TNF inhibitors (%) -Adalimumab, Certolizumab pegol, Etanercept, Golimumab, Infliximab	106 (26.4)
Other biologic therapy (%) -Abatacept, Tocilizumab, Rituximab, Sarilumab	50 (12.4)
Other immunosuppressants (%) -Azathioprine, Cyclophosphamide, Mycophenolic acid, Leflunomide	45 (11.2)

*Psoriatic Arthritis(28), SLE(16), Spondylitis(12), Sjogren's(12), GCA(10), and other(88)

(n=23) of flares occurred following the first dose and 3.4% (n=5) occurred following the second dose. One patient flared after both doses. All flares were mild, self-limited, responded to treatment with low dose glucocorticoids, and did not warrant a change in immunosuppressive therapy. 13.4% (n=54) patients experienced side effects. Of the patients who experienced side effects, 11.4% (n=46) occurred after the first dose and 8.7% (n=13) occurred following the second dose. Five patients experienced side effects after both doses. All side effects were regarded as mild. No cases of HZ were reported.

Conclusion: In 402 patients who received the new ZRA vaccine, the incidence of disease flares was ≤7% and side effects were 13.4%, which is lower than that observed in the general population. Both flares and side effects were mild, self-limited, and did not require a change in DMARD therapy. No cases of HZ were reported. Formal studies of patients exposed to the vaccine are required to confirm this conclusion. Immunosuppressive therapies may reduce the effectiveness of vaccines. Studies are needed to determine the immune response to the vaccine, and its efficacy in rheumatology patients. We encourage the use of the ZRA vaccine in RA and other SD patients.

Perioperative Anti-rheumatic Medications Are Not Associated with 30-day Odds of Infection in Rheumatoid Arthritis Patients Undergoing Surgery: A Retrospective Cohort Study

Marianne Kerski ,[1] Peter Boersma,[2] Eric Miller,[3] Ashley Brenner,[4] Genevieve Melton,[5] and Anna Shmagel[6], [1]University of Minnesota Medical School, Minneapolis, MN, [2]University of Minnesota School of Public Health, Minneapolis, [3]University of Minnesota, Woodbury, MN, [4]University of Minnesota Best Practices Integrated Informatics Core [BPIC], Minneapolis, MN, [5]University of Minnesota Department of Surgery, Minneapolis, MN, [6]University of Minnesota, Minneapolis, MN

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Infection-Related Rheumatic Disease

Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Perioperative management of anti-rheumatic drugs in rheumatoid arthritis (RA) patients undergoing surgery remains controversial. Previous studies produced conflicting results, and data on non-orthopedic surgeries in RA patients are limited. The objective of the current study was to measure the impact of perioperative anti-rheumatic medication management on the 30-day odds of infection among RA patients undergoing surgery.

Methods: We conducted a retrospective cohort study of seropositive RA patients who underwent musculoskeletal or major organ surgery within the Fairview Health System in Minnesota between January 1, 2010 and December 31, 2017. Each surgical event was identified through the electronic medical record and manually reviewed by two trained clinicians for demographic variables, perioperative medication management, and outcomes. Surgeries were classified into three groups according to anti-rheumatic medication use during surgery: 1. neither DMARD nor biologic (either not prescribed or held for a pre-specified period of time, based on each medication's dosing schedule and mode of action); 2. DMARD with no biologic; 3. biologic with or without DMARD. The perioperative use of corticosteroids and antibiotics was also recorded. The primary outcome, post-operative infection, included surgical site infections, urinary tract infections, pneumonia, and blood stream infections occurring within 30 days of surgery as defined by CDC criteria. ANOVA, Chi-square tests and logistic regression were used for analyses.

Results: 154 seropositive RA patients underwent 244 surgeries (165 musculoskeletal and 79 major organ). Patients were predominantly female (78%), white (94%), overweight or obese (73%) with a mean age of 62 years, and a mean Charlson comorbidity index of 2.3. Of the 244 surgeries, 116 (47.8%) were performed on no anti-rheumatic medications, 95 (39.1%) on a DMARD with no biologic, and 32 (13.2%) on a biologic with or without a DMARD. The groups were well-balanced on age, sex, race, baseline BMI, Charlson comorbidity index, surgery type, perioperative steroid use, antibiotic use and expected duration of surgery ($p \geq 0.1$ for all comparisons). In total, 28 surgeries (11.5%) among 23 patients were complicated by a post-operative infection within 30 days: 14 (12%) in the no-medication group, 10 (11%) in the DMARD group, and 4 (13%) in the biologic group ($p = 0.9$). Of the other examined predictors, higher Charlson comorbidity index and longer expected duration of surgery were associated with infection ($p < 0.05$). After adjustment for these two predictors, overall and for musculoskeletal and major organ surgeries separately, perioperative use of anti-rheumatic drugs was not associated with increased odds of post-operative infection (table 1).

Conclusion: Perioperative use of anti-rheumatic medications was not associated with 30-day odds of post-operative infection in RA patients undergoing musculoskeletal or major organ surgery. Rather, higher Charlson comorbidity index and longer expected duration of surgery predicted postoperative infections in this RA population.

Inflammatory Arthritis Induced by Immune Checkpoint Inhibitor Therapy: A Distinct Clinical Entity and Immunologic Phenotype

Uma Thanarajasingam ,[1] Xingxing Zhu,[1] Xian Zhou,[1] Jane Jaquith,[1] Yanfeng Li,[1] and Hu Zeng[1], [1]Mayo Clinic, Rochester, MN

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are being used in the treatment of a variety of malignancies. ICIs target cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4), programmed cell-death protein 1 (PD-1) and its ligand PD-L1, which negatively regulate T-cell activation. ICIs can induce widespread manifestations of autoimmunity, which are called immune-related adverse events (irAEs). Rheumatic irAEs have been increasingly reported, with inflammatory arthritis (IA-irAE) being the most common. IA-irAE symptoms can be severe and persistent, even after discontinuation of ICI. We sought to clinically and immunologically characterize a cohort of patients with IA-irAE.

Methods: From patients on ICI therapy for any malignancy, we recruited 15 cases of *de novo* IA-irAE. IA-irAE had physician-confirmed inflammatory arthritis supplemented by laboratory or imaging studies. As controls, 8 patients with seronegative rheumatoid arthritis (**Rh-control**), 4 ICI-treated cancer patients without any irAE (**ICI control**), and age and sex-matched healthy controls (**HC**) were included. Biospecimens including serum and peripheral blood mononuclear cells (PBMCs) were collected. Fifteen-parameter flow cytometry panels were used to profile T cell exhaustion and senescence phenotypes in PBMCs and serum cytokine levels were measured using Luminex technology.

Results: The majority of IA-irAE patients were treated with pembrolizumab (86.6%). The average onset of inflammatory arthritis was 4.36 months after ICI initiation. The predominant pattern of inflammatory arthritis was polyarticular/symmetric, as well as large joint involvement (66.6%), although patterns seen in spondyloarthopathies were observed as well. Four patients (27%) had positive serologies after the onset of symptoms, without having pre-existing symptoms of arthritis. IA-irAE patients had significantly reduced PD-1 expression on CD8 and CD4 T cells compared to ICI-controls ($p = 0.02$) and HC ($p < 0.0001$). In IA-irAE, the senescent T cell population was significantly increased in frequency compared to HC ($p = 0.01$) and tended to be increased compared Rh-control ($p = 0.05$). Finally, IA-irAE had elevated levels of pro-inflammatory cytokines IL-6, MIG and IP-10 compared to controls ($p = 0.02$, 0.001 and 0.007, respectively) and a similar trend was observed in comparison to Rh-controls.

Conclusion: Our preliminary findings suggest that IA-irAE is a distinct clinical entity with a heterogeneous clinical presentation and distinct immune phenotype. The latter suggests that ICI therapy may lead to over-activation of T cells, and sustained inflammation. Further, there is a tendency for these patients to have increased pro-inflammatory cytokines compared to Rh-controls. Increased sample sizes are needed to more definitively conclude whether these alternations can distinguish Rh-irAE from Rh-control, and these studies are ongoing. To our knowledge, this is one of the first studies addressing the immunological basis of IA-irAE, and the connection between IA-irAE and rheumatoid arthritis.

Teprotumumab, a Novel Biologic for Active Thyroid Eye Disease

George J. Kahaly,[1] Saba Sile,[2] Elizabeth H.Z. Thompson,[2] Thomas Vescio,[3] Renee Perdok,[3] **Jeffrey W. Sherman** ,[3] Terry J. Smith,[4] and Raymond S. Douglas[5], [1]Johannes Gutenberg University Medical Center, Mainz, Germany, [2]Horizon Therapeutics plc, Brisbane, CA, [3]Horizon Therapeutics plc, Lake Forest, IL, [4]University of Michigan Kellogg Eye Center, Ann Arbor, MI, [5]Cedars Sinai Medical Center, Los Angeles, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Thyroid eye disease (TED) is a debilitating autoimmune disorder characterized by inflammation and exophthalmia along with significantly altered appearance and vision changes. TED is predominately associated with Graves' disease, that can coexist with other autoimmune disease commonly managed by rheumatologists such as RA and SLE. Herein, we report results from the pooled 24-week randomized, double-masked, placebo-controlled, parallel-group, multicenter, Phase 2 (NCT01868997) and Phase 3 (NCT03298867) studies of teprotumumab, an insulin-like growth factor 1 receptor (IGF-1R) monoclonal antibody, in adults with active, moderate-to-severe TED.

Methods: Patients (Pts) with recent onset of TED (< 9 months) were treated with a teprotumumab or placebo infusion every 3 weeks for a total of 8 infusions. Primary and secondary endpoint data were pooled between the two studies and included: the % of patients with a reduction in proptosis of ≥2 mm at week 24 in the study eye without similar fellow-eye worsening, overall responder rate (% of patients with ≥2 mm proptosis reduction AND ≥2-point clinical activity score [CAS] reduction in a 7-point scale) at week 24, CAS responder rate (% of patients with a CAS value of 0 or 1) at week 24, % of patients with an improved diplopia score at week 24, average proptosis and GO-QoL (TED specific quality of life questionnaire) score change from baseline through week 24, as compared with placebo.

Results: 171 pts were included in the intent-to-treat analyses (84 teprotumumab, 87 placebo). The demographics were as follows: mean age of 51.5 years (teprotumumab) vs 51.4 (placebo), 69% female (teprotumumab) vs 77% (placebo) and 76% non-smokers (teprotumumab) vs 70% (placebo). Significantly more teprotumumab pts had reductions in proptosis of ≥2 mm (65/84 [77.4%] vs 13/87 [14.9%], p< 0.001) and an overall response (% of pts meeting proptosis AND CAS outcome) (62/84 [73.8%] vs 12/87 [13.8%], p< 0.001) at week 24. The reduction in average change from baseline through week 24 in proptosis, was significantly greater in pts who received teprotumumab (-2.63 mm) than in those who received placebo (-0.31 mm, p< 0.001). The % of pts with absent TED activity (CAS of 0 or 1) was greater with teprotumumab at week 24 (52/84 [61.9%] vs 19/87 [21.8%], p< 0.001). The diplopia responder rate (% pts improved 1 or more grades) was significantly higher with teprotumumab (69.7%) vs placebo (30.5%; p< 0.001) in those with baseline diplopia (66 and 59 pts, respectively). Improvements in average change from baseline through week 24 in GO-QoL in overall score and subscales were significantly greater in the teprotumumab group (overall 15.55 vs 5.92, p< 0.001; visual functioning 16.81 vs 6.10, p< 0.001; appearance 13.51 vs 5.78, p=0.002).

Conclusion: In the largest placebo-controlled evaluation of active TED thus far conducted, teprotumumab reduced inflammation, proptosis, and diplopia resulting in clinical and quality of life improvements as compared with placebo over 24 weeks. Teprotumumab is a promising infused biologic option for TED, with implications for rheumatologists involved in managing patients with TED.

Immune Checkpoint Inhibitor-Induced Inflammatory Arthritis Persists After Immunotherapy Cessation

Tawnie Braaten ,[1] Julie Brahmer,[1] Patrick Forde,[1] Dung Le,[1] Evan Lipson,[1] Jarushka Naidoo,[1] Megan Schollenberger,[1] Lei Zheng,[1] Michelle Jones,[1] Ami Shah,[2] Clifton Bingham,[3] and Laura Cappelli[3], [1]Johns Hopkins, Baltimore, MD, [2]Johns Hopkins Hospital, Baltimore, MD, [3]Johns Hopkins University, Baltimore, MD

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: The use of immune checkpoint inhibitor (ICI) therapy for malignancy is growing. Various autoimmune and inflammatory syndromes, known as immune-related adverse events (irAEs) have been reported, including inflammatory arthritis (IA). Despite its growing incidence, the clinical features and optimal treatments of IA are not well defined, and long-term outcomes are unknown. This study aims to investigate long-term outcomes of patients (pts) who develop IA due to ICIs and to evaluate those with symptom persistence after ICI cessation, the need for immunosuppressants, and the impact of these medications on underlying malignancy.

Methods: This is a prospective observational study of pts referred to the Johns Hopkins Arthritis Center for IA due to ICIs recruited from 6/2015 to 12/2018 with data available after ICI cessation. ICIs were discontinued for cancer progression, treatment completion, or severe irAEs. Baseline demographics, cancer type, specific ICI treatment, tumor response, personal and family history of autoimmunity, other irAEs, labs, and clinical exam were obtained. Follow up occurred at varying intervals for up to 24 months (mo) from ICI cessation to assess the clinical status of IA and malignancy. Active IA was defined as active joint disease or the need for continued immunosuppression. Kaplan-Meier curves were developed to evaluate pts with persistent IA. A Cox proportional hazards model was used to assess the influence of various factors on IA persistence.

Results: A total of 60pts (53.3% female) were monitored with a median follow up after ICI cessation of 9 mo (1-24 mo). Pts had a wide range of cancers and 50% had other irAEs. Combination ICI therapy was used in 30% of patients. There were low rates of seropositivity (RF 1.8%, CCP 5.5%, ANA 14.3%) and 7pts had a family history of autoimmune disease. Immunosuppressive treatment was required in 75%. Forty-eight pts (80%) were treated with systemic/intraarticular steroids. csDMARDs were used in 19 pts and bDMARDS in 11. A majority (53.1%) had active IA at most recent follow up. Three-month follow up data after ICI cessation was available in 51pts, with 6mo data for 41. At 3mo, 70.6% had active disease; 48.8% had active disease at 6 mo. Among the 20 pts with persistent arthritis at 6 mo, 14 continued to have active disease at last follow up. IA was less likely to improve in those with longer duration of ICI use (hazard ratio 0.93, 95% CI 0.87 to 0.99; p=0.02), in those receiving combination therapy (hazard ratio 0.29, 95% CI 0.12 to 0.72; p=0.008) and in pts with other irAEs (hazard ratio 0.61, 95% CI 0.39 to 0.95, p=0.03). Although not significant, a better tumor response was associated with persistent IA. Tumor response did not appear to be impacted by immunosuppression.

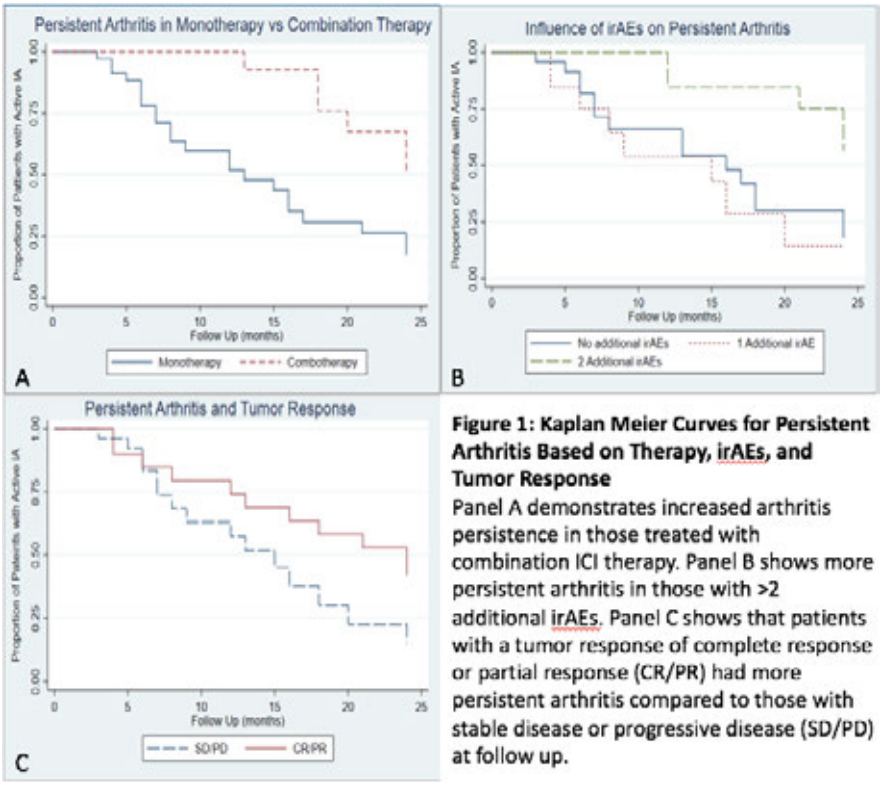

Figure 1: Kaplan Meier Curves for Persistent Arthritis Based on Therapy, irAEs, and Tumor Response
Panel A demonstrates increased arthritis persistence in those treated with combination ICI therapy. Panel B shows more persistent arthritis in those with >2 additional irAEs. Panel C shows that patients with a tumor response of complete response or partial response (CR/PR) had more persistent arthritis compared to those with stable disease or progressive disease (SD/PD) at follow up.

Conclusion: This study demonstrates that a significant number of pts developing ICI-induced IA have persistent arthritis at 3 and 6mo. Specific factors such as longer ICI exposure, combination ICI therapy, and other irAEs increase the risk of persistence. Immunomodulatory treatments were efficacious for symptomatic control while having no apparent effect on tumor response at follow up and persistent arthritis may associate with better tumor response.

SESSION INFORMATION
Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Immune checkpoint inhibitors (ICIs) are increasingly becoming the mainstay of management of advanced malignancies, but can result in immune related adverse events (irAEs) affecting nearly every organ system. The purpose of this retrospective study is to determine the incidence and nature of irAEs in patients treated with ICIs at our single center university hospital. The primary objective was to assess risk factors for development of irAEs. Secondary objectives included determining 1) incidence of rheumatic and non-rheumatic irAEs; 2) time to onset of irAEs; 3) proportion required to discontinue ICIs due to irAEs; 4) comparative risk of specific ICIs causing irAEs.

Methods: Patients over age 18 were identified by electronic chart review with oncologist-diagnosed cancer who were prescribed ICIs between March 31, 2011 to December 31, 2018. ICIs included cytotoxic T-lymphocyte-associated protein 4 inhibitors (CTLA-4), programmed death-1/programmed death-ligand 1 inhibitors (PD-1/PD L-1) or combination therapy. We performed a detailed chart review to collect patient demographics, type of cancer, ICI(s) utilized, time to onset of irAEs, type of irAEs, treatment, and outcome. Cases were defined as patients who either developed new irAEs or experienced a flare of their pre-existing autoimmune disease after initiation of ICI. Controls were defined as those without any irAEs. The Fisher test and the Kruskal-Wallis test were used to compare categorical and continuous variables, respectively.

Table 1. Comparison of patients with (cases) and without (controls) immune-related adverse events (irAEs) after treatment with immune checkpoint inhibitors (ICIs). The "other" category under ICIs denotes the remaining FDA-approved ICIs (durvalumab, avelumab and atezolizumab). Fischer tests were completed for categorical variables and Kruskal-Wallis tests were completed for continuous variables.

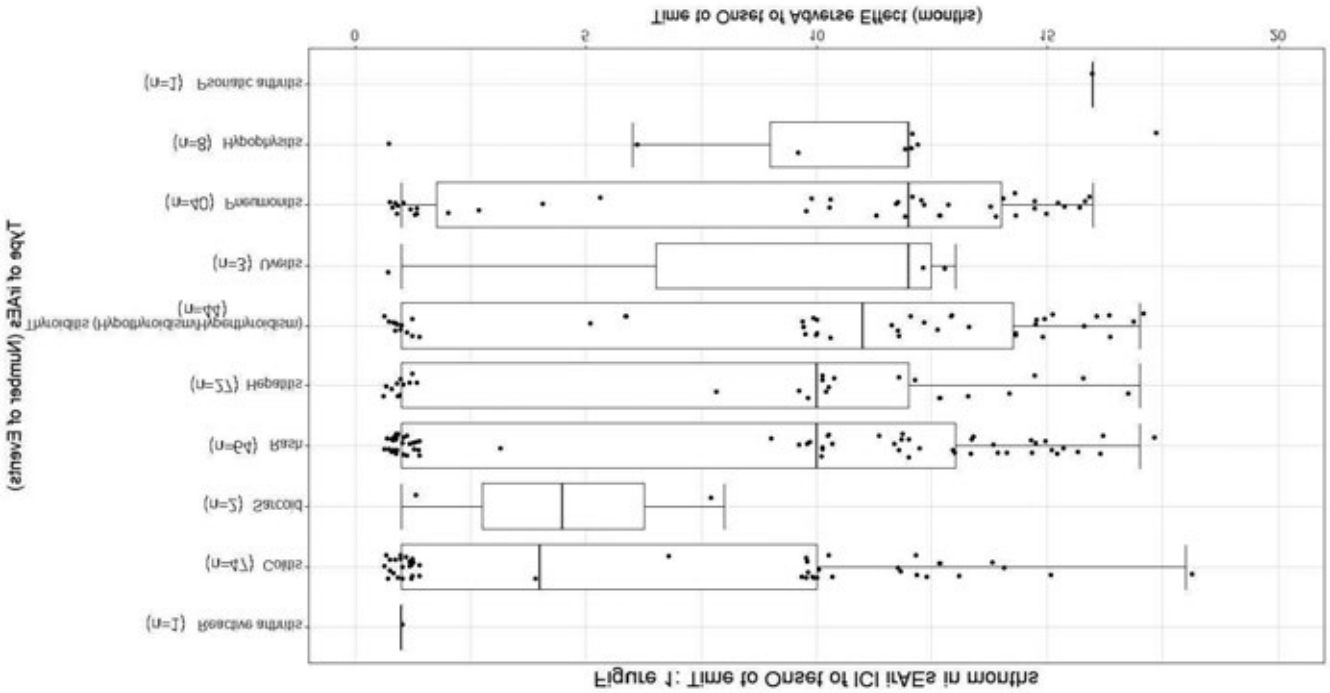

Figure 1. Time to diagnosis of immune-related adverse events (irAEs) since onset of immune checkpoint inhibitor therapy. The X-axis shows time in months and the Y axis shows the type and number of irAEs. Each dot represents an event. Each box shows the range of values within the 25th to 75th percentile while the vertical line in the box denotes the median.

Results: A total of 827 patients were prescribed ICIs, of which 209 (25%) developed 264 independent irAEs. A comparison of those who developed irAEs and those who did not is shown in Table 1. Sixteen patients (6%) developed rheumatic irAEs. Seven patients developed inflammatory arthritis. Less common rheumatic irAEs included uveitis, myositis, psoriatic arthritis, reactive arthritis and sarcoidosis. The majority were treated with oral prednisone. Time to onset of select irAEs since initiation of ICIs is shown in Figure 1. Of the 209 with irAEs, 145 (69.4%) required temporary/permanent discontinuation of ICIs due to irAEs. The odds of developing irAEs were 3.6 times higher with CTLA-4 compared to PD-1/PD-L1 agents. Odds for developing irAEs were also 1.5 times higher with combination therapy than CTLA-4 monotherapy, and 5.2 times higher than PD-1/PD-L1 alone.

Conclusion: We found that a quarter of patients treated with ICIs developed irAEs, and that non-rheumatic irAEs were much more common than rheumatic irAEs. Type of malignancy, type of ICI agent and nature of previous cancer therapies factored into the development of irAEs. The odds of developing irAEs were higher with usage of combination ICI compared to the single agents. However, in our study no rheumatic irAEs were attributed to CTLA-4 use alone. This could be explained by sample size. Data continues to remain scarce on treatment and long-term follow up of rheumatic irAEs. Partnering with oncologists, expediting patient referral to a dedicated ICI-rheumatology clinic and establishing multicenter registries will provide more robust data on these heterogenic irAEs.

Session Date: Monday, November 11, 2019
Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Monoclonal antibodies targeting co-inhibitory immune checkpoints (PD-1/PDL1 axis or CTLA-4) showed unprecedented clinical activity in several types of cancer by restoring antitumor immune responses. We recently described that vasculitis (giant cell arteritis) was a rheumatic immune-related adverse event (irAE) but the description of other rheumatic adverse events remains sparse.

Methods: Using WHO's global database of individual case safety reports, we compared rheumatic adverse events reporting in immune checkpoint inhibitors (ICI) exposed patients with the reporting in the full database. All rheumatic irAEs (except vasculitis) were included (according to the Medical Dictionary for Regulatory Activities). The association between ICI and rheumatic adverse events was analyzed using the reporting odds ratio (ROR) and the information component (IC: an indicator value for disproportionate reporting observed vs expected values). A positive IC_{025} (the lower end of the IC 95% credibility interval) is considered to be significant.

Results: We identified 54,416 adverse events reported in patients treated with ICI (14,988,450 adverse events reported in patients treated with any drugs, full database since 2008). Compared to the full database, ICI treatment was associated with higher reporting of arthritis (121,811 reports for the full database vs 606 for ICI, ROR 1.4 [1.3-1.5]; IC_{025} 0.34), myositis (26,722 vs 465, ROR 4.9 [4.5-5.4]; IC_{025} 2.12), sarcoidosis (2,772 vs 94, ROR 9.6 [7.9-11.9]; IC_{025} 2.85), polymyalgia rheumatica (1,504 vs 76, ROR 14.6 [11.6-18.4]; IC_{025} 3.34), Sjogren's syndrome (2,000 vs 49, ROR 6.9 [5.2-9.2]; IC_{025} 2.24) and scleroderma (2,385 vs 17, ROR 2.0 [1.2-3.2]; IC_{025} 0.17). Myositis patients were more frequently male (70.4%; $p< 0.0001$ vs 56% in other rheumatological irAE patients) and treated with anti-PD1/L1 (ROR 2.8 [1.9-4.0] vs anti-CTLA4) or with ICIs combination (ROR 2.0 [1.6-2.6] vs monotherapy). Myositis occurred earlier compared to other rheumatic irAEs (time to onset: 31 IQR [19.5-58.5] days) and were associated with the highest mortality rate (30.3%, $p< 0.0001$). Arthritis and Sjogren's syndrome had similar time to onset (78.5 [25-166.5] and 88 [47.8-145.8] days, respectively), and were associated with a mortality of 6.9 and 0%. Arthritis and Sjogren's syndrome occurred more frequently in patients with anti-PD1/L1 (vs anti-CTLA4; ROR 2.1 [1.6-2.8] or 4.4 [1.0-18.1]) with

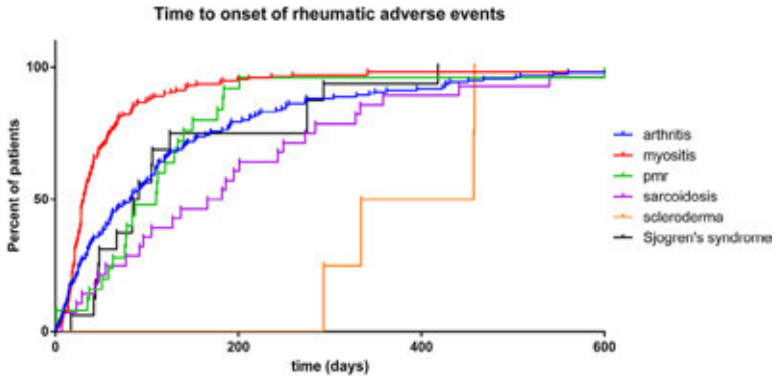

Figure 1. Delay between the first immune checkpoint inhibitor infusion and the onset of the rheumatic adverse events.

ICI combination (vs monotherapy; ROR 1.6 [1.3-2.0] and 2.9 [1.5-5.6]) whereas polymyalgia rheumatica was more frequently reported in patients with anti-PD1/L1 monotherapy (ROR 5.6 [1.8-17.7]). Sarcoidosis occurred in younger patients (57 [48-65.3] years) and with a longer time to onset (174 [71.5-275.8] days; p< 0.001). Scleroderma had the longest time to onset (395.5 [323.8-457.2] days; p< 0.001).

Conclusion: Among rheumatic disorders in addition to vasculitis: arthritis, myositis, sarcoidosis, polymyalgia rheumatica, Sjogren's syndrome and scleroderma have a higher reporting. Patients characteristics, type of ICI, time to onset, and patient outcome depend on the type of rheumatic irAEs. Myositis is the most severe.

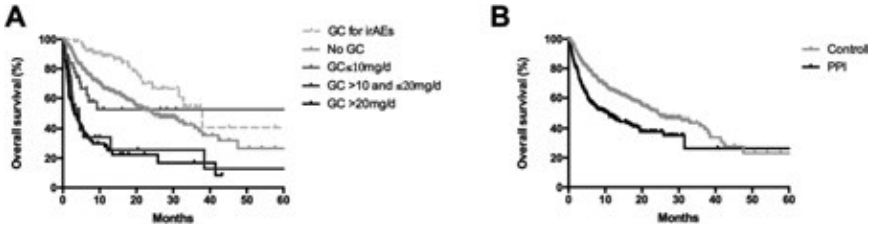
SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Miscellaneous Rheumatic & Inflammatory Disease II: Checkpoint Inhibitors-Induced & Other Rheumatic Conditions

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM



Background/Purpose: Immune checkpoint inhibitors (ICIs) are revolutionizing the treatment of some advanced cancers. Gut microbiota has emerged as an important component of anti-tumoral response and can also be related to the occurrence of immune-related adverse events (irAEs). It has recently been shown that antibiotic treatment given at the initiation of ICI therapy had a dramatic impact on microbiota that compromised the anti-tumoral effect of ICIs.

The objective of this study is to evaluate whether co-medications known to have a potential impact on gut microbiota may alter ICI efficacy and/or irAE occurrence when given at ICI onset.

Methods: This was a retrospective cohort study including all cancer patients who received ICIs at our institution from May 2015 to September 2017. Co-medications given to the patients within one month before or one month after the first administration of ICI were extracted from medical records on the basis of a predefined list of medications known to impact gut microbiota. The tumour response, occurrence of irAEs and patient outcomes were assessed on a regular basis. Overall survival (OS) has been considered from the start of ICI therapy.

Results: 635 patients (70% male, mean age 64.5 years) were included, of whom 293 had melanoma, 150 had advanced non-small cell lung cancer and 83 had renal carcinoma. A previous autoimmune disorder was present in 8% of patients, mainly rheumatic and endocrine diseases. Psychotropic drugs (41.1%), proton pump inhibitors (PPIs) (37.3%), angiotensin-converting enzyme (ACE) inhibitors and/or angiotensin II receptor blockers (ARBs) (32%), glucocorticoids (GC) (24.2%), antibiotics (21.4%), statins (20.8%) and morphine (20.6%) were the most co-prescribed medications. Baseline GC use, when ≥ 10mg of prednisone equivalent, was associated with significant decreased OS (median 4.5 months versus 24.3 months; p< 0.0001) and a less frequent tumour response (55% versus 73% ; p=0.0001). When given after ICI onset for the management of irAEs, GC did not influence ICI efficacy (Figure A). Baseline PPI use also altered both OS (median 10.9 versus 24.3 months; p< 0.0001) and tumour response (62% versus 71%; p=0.02) (Figure B). We confirmed the detrimental impact of antibiotics when given at ICI onset, and also found worse outcomes for patients receiving baseline psychotropic drugs (median OS 9.3 versus 19.4 months; p=0.0001). No significant difference was observed with baseline use of NSAIDs, aspirin, statins and ARBs/ACE. Furthermore, co-medication with antibiotics, GC, PPIs, morphine, NSAIDs, aspirin and psychotropic drugs was associated with decreased occurrence of irAE.

Conclusion: As many of these treatments are used by rheumatologists, one should be aware of their potential detrimental effect when used at ICI initiation, that sometimes could have been avoided.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – Clinical II: JIA
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Most biologic trials in juvenile idiopathic arthritis (JIA) treat all participants with the biologic under study for 12 to 16 weeks before randomizing responders into a withdrawal phase. This implies that patients are expected to respond quickly to biologics. If treatment response can be predicted from early response patterns (< 12-16 weeks), this information may be applied to identify likely responders from likely non-responders early during clinical care, allowing earlier termination of ineffective treatment. We aimed to delineate the early treatment response trajectory of JIA patients to biologics.

Methods: Longitudinal data from early treatment phase (12-16 weeks) from 3 JIA trials: 1) Tocilizumab (Roche), 2) Etanercept (Amgen) and 3) the Trial of Early Aggressive Therapy TREAT (Etanercept), were obtained and combined. Primary outcome is the ACR response states: ACR50, 70, 90. Clinically significant minimal improvement was defined as attaining at least an ACR50 state. Secondary outcome was the clinical juvenile arthritis disease activity score (cJADAS): inactive, low, moderate and high disease states. Longitudinal responses (ACR states and cJADAS) were modelled using the Markov multistate model, corrected for interval censoring and allowing heterogeneous transition rates.

Results: 342 patients (188 Tocilizumab, 69 Etanercept, 85 TREAT) with polyarticular course JIA were studied. 27% (92/341) were males, median age at baseline (25 th -75 th percentile P) was 10.0 (5.7- 15.0) years and median (25 th – 75 th P) duration of disease was 3.6 (1.0- 8.7) years. Baseline median (25 th -75 th P) active joint counts was 15 (7-24). Pateints were on methotrexate (46%) and corticosteroids (34%) at baseline. 87% patients were on biologics (Tocilizumab 188, Etanercept 111). At week 4, the probabilities of transitioning from active disease to ACR50, 70 and 90, was 0.29, 0.13, 0.03. Probabilities of transition continued to increase from week 4 to 16, without plateau. At week 16, the probabilities of transition to ACR50, 70, 90 were: 0.19, 0.32, 0.25. By week 16, the mean durations of time spent in ACR50, 70, 90 were 0.91, 0.76 and 0.43 months. Even if no clinically significant minimal improvement was achieved by week 4, the probabilities of attaining this was substantial by weeks 12 (0.55) and 16 (0.67). At week 4, the probabilities of transition from a high cJADAS state to a moderate state was 0.20, to low state was 0.01, and to inactive disease < 0.01. At week 16, the probabilities for a moderate cJADAS state was 0.36, for low state was 0.10 and for inactive disease was 0.11. By week 16, the mean durations of time spent in low and inactive disease states were 0.15 and 2.37 months.

Conclusion: Patients treated with biologics continued to improve over the first 12-16 weeks, without plateau. Lack of early (4 weeks) clinically significant minimal response did not preclude attaining such response by 16 weeks. Our work suggests that response to biologics (Tocilizumab, Etanercept) continues to improve over the first 16 weeks of treatment. Therefore, patients should not be switched out of biologics before 16 weeks for a lack of effectiveness.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – Clinical II: JIA

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Existing legislation in the United States (US) promotes the study of new medications in children. Biologic disease-modifying-drugs (bDMARDs) and small molecules proven effective and safe in adults with rheumatoid arthritis and other forms of inflammatory arthritis require testing in children with juvenile idiopathic arthritis (JIA) to establish proper dosing, effectiveness, and safety. Several bDMARDs have been approved for the treatment of JIA in the US, but not all children with JIA have a complete clinical response to the available medications and are treated with medications off-label (i.e., anakinra, golimumab, infliximab, rituximab, secukinumab, tofacitinib, ustekinumab). The *purpose* of this research was to document the continuing medical need for new approved medications for the treatment of JIA.

Methods: The electronic medical record of JIA patients (n= 1599) treated at Cincinnati Children's Hospital Medical Center (CCHMC) since 2008 were reviewed for medication use and disease activity over time. JIA patients enrolled in the Childhood Arthritis & Rheumatology Research Alliance (CARRA) Registry (n=7,379) were assessed for medication use and disease activity at the most recent Registry visit. Medication need was defined as active JIA despite sequential use of ≥2 bDMARDs. Active JIA was defined as either a) physician-global assessment of JIA activity (MD-global; 0-10; 0 = inactive) ≥3 OR b) number of active joints (AJC) ≥3 OR c) patient-global assessment of well-being (Pt-global; 0-10; 0=very well) ≥3. Medication failure was only assessed for patients with complete data (a-c).

Results: At CCHMC, polyarticular-course JIA (40%), systemic JIA (9%) and juvenile psoriatic arthritis/enthesitis-related arthritis (JPSA/ERA; 17%) were common, and only 16% had persistent-oligoarticular JIA. Overall, use of bDMARDs (n=829; 53%) was common. Systemic JIA (85%) and jPSA/ERA patients (79%) were most commonly treated with bDMARDs. At least 5% (25/1599) of patients had failed ≥5 bDMARDs. Of 829 biologic users in the CCHMC cohort, 304 (37%) children were exposed to non-approved bDMARDs. Among 278 CCHMC patients

*** with complete data Row %; column %**

with jPSA /ERA 27 (9.7%) had failed ≥2 bDMARDs. In the CARRA Registry, 46% of JIA patients had polyarticular disease course, 8% systemic JIA, and 18% jPSA/ERA; 4766 (65%) children had received a bDMARD with 1122 (24%) of these children receiving bDMARDs off label. Among 1351 jPSA/ERA patients in the CARRA Registry, about 10% failed ≥2 bDMARDs with active disease at their most recent visit. **Table 1** summarizes medication failures in both cohorts.

Conclusion: Data from a population-based cohort and a large national registry demonstrate a profound medical need for additional therapies to control JIA signs and symptoms, despite the availability of several approved biologic DMARDs. Given FDA approval ensures bDMARD access, the testing of new medications in JIA as they become available to treat adults is critical to further improve JIA outcomes.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – Clinical II: JIA
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: After nearly two decades from the start of the Biologic era, systematic analyses of patients with juvenile idiopathic arthritis (JIA) have shown a high frequency of attainment of inactive disease (ID) and satisfactory levels of physical function and quality of life. However, whether and to what extent the disease prognosis has improved in comparison with the methotrexate (MTX) era is still uncertain.

Purpose of the present study was to compare the long-term disease state, in terms of activity and damage, of children with JIA who had their disease onset in MTX or Biologic eras.

Methods: Patients were included in MTX or Biologic era cohort depending on whether their disease presentation occurred before or after January 2000. Patients in the MTX era cohort and part of the patients in the Biologic era cohort were taken from a previous cross-sectional study published by our group,[1] which enrolled 310 patients with disease onset between December 1986 and December 2002. An additional sample of patients with onset in the Biologic era was enrolled in a subsequent prospective cross-sectional study, which included all consecutive patients meeting the ILAR criteria for JIA, who were seen consecutively at the Istituto Gaslini of Genoa, Italy, between January 2015 and June 2017. All patients had disease duration ≥ 5 years and underwent a prospective cross-sectional assessment, which included measurement of disease activity and damage. ID and low disease activity (LDA) states were defined according to Wallace, JADAS10 and cJADAS10 criteria. Articular and extra-articular damage was assessed with the Juvenile Arthritis Damage Index (JADI).

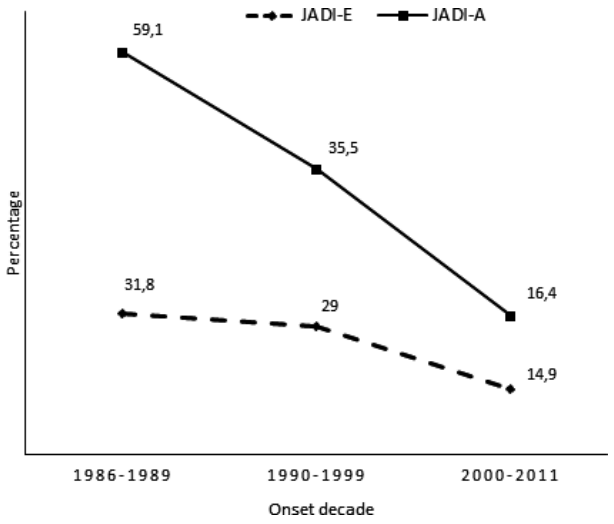

Figure 1. Trend in disease damage (JADI-A and JADI-E) over time. JADI-A: articular Juvenile Arthritis Damage Index; JADI-E: extra-articular Juvenile Arthritis Damage Index.

Results: MTX and Biologic era cohorts included 239 and 269 patients, respectively. Patients were divided in the "functional phenotypes" of oligoarthritis and polyarthritis. At cross-sectional visit, patients in the Biologic era cohort with either oligoarthritis or polyarthritis had consistently higher frequencies of ID and LDA than patients in the MTX era cohort. The measurement of disease damage at cross-sectional visit revealed that the frequency of impairment of > 1 JADI-Articular items was higher in MTX than in Biologic era cohort (17.6% versus 11% in oligoarthritis and 52.6% versus 21.8% in polyarthritis). Likewise, frequency of involvement of > 1 JADI-Extraarticular item was higher in MTX than in Biologic era cohort (26.5% versus 16.2% in oligoarthritis and 31.4% versus 13.5% in polyarthritis). The sole JADI items that were detected in more than 5% of patients in the Biologic era cohort were temporomandibular damage in oligoarthritis and polyarthritis, ankle damage in polyarthritis and leg-length inequality in oligoarthritis. The analysis of the temporal trend of damage development over the 25 years of our analysis (1986-2011) highlighted the marked decrease in damage over time and the more pronounced decline in the Biologic era (Figure 1).

Conclusion: Our study provides evidence of the remarkable prognostic improvement obtained with the recent therapeutic advance in JIA.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – Clinical II: JIA

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: In EU, abatacept (ABA) with MTX is approved in patients (pts) with polyarticular-course JIA (pJIA), as young as 2 years (SC) and 6 years (IV), intolerant or with an inadequate response to prior DMARDs, and can be used as monotherapy if MTX use is inappropriate.[1] In US, ABA can be used in combination with MTX or as monotherapy.[2] Here we report ABA efficacy and safety in pts without concomitant MTX or in pts with prior biologic use treated in an open-label, Phase III study of SC ABA (NCT01844518) and in a double-blind, Phase III study of IV ABA (NCT00095173).

Methods: Study design and eligibility criteria for both studies were reported previously.[3,4] In SC study, pts with pJIA and prior DMARD failure/intolerance were stratified by age cohort (2–5 and 6–17 years) to receive weight-tiered SC

ABA=abatacept; SAE=serious AE

ABA (10 to < 25 kg [50 mg], 25 to < 50 kg [87.5 mg], ≥50 kg [125 mg]) weekly for 4 months (primary endpoint). JIA-ACR30 criteria responders at Month 4 could receive SC ABA for another 20 months.[3] In IV study, pts with pJIA and prior DMARD failure/intolerance received open-label IV ABA (10 mg/kg body weight) for 4 months (Period A); JIA-ACR30 criteria responders at Month 4 were randomized 1:1 to receive IV ABA (10 mg/kg body weight) or placebo every 4 weeks for 6 months or until flare (Period B). Pts could receive open-label ABA in a 5-year follow-up (Period C).[4] In this analysis, data were evaluated descriptively.

Results: Baseline characteristics were mostly balanced between the arms in both studies (Table 1). No additional numerical benefit in JIA-ACR responses was seen with ABA+MTX versus ABA monotherapy in either study at Month 4 (JIA-ACR90: SC ABA+MTX, 34.7% [60/173] vs SC ABA, 34.8% [16/46]; IV ABA+MTX, 12.3% [17/138] vs IV ABA, 13.5% [7/52]). Flare rates (95% CI) were comparable with ABA+MTX and ABA monotherapy in Period B of the IV study: 18.8% (7.7, 29.8) and 25.0% (0.5, 49.5), respectively. Efficacy responses of ABA+MTX and ABA monotherapy-treated JIA-ACR responders with prior MTX intolerance/lack of efficacy at Month 4 were similar in both studies (Table 2). As expected, ABA-treated biologic-naïve pts had a numerically greater clinical response than those with prior biologic use at Month 4 in both trials (Table 3); effect was independent of concomitant MTX use (data not shown). Rates of reported AEs were comparable for ABA+MTX- versus ABA-treated pts and for biologic-naïve versus those with prior biologic use across studies over 4 months (Tables 2, 3). No anti-drug antibodies (ADAs) were reported with ABA monotherapy in SC study; few pts receiving ABA monotherapy in IV study developed ADAs, with no impact on ABA efficacy seen (data not shown).

Conclusion: Abatacept (SC and IV) monotherapy was effective and well tolerated in pts with pJIA intolerant to MTX or when prior MTX was not effective. In addition, abatacept monotherapy can be considered for use in those with prior biologic therapy if MTX use is inappropriate.

Psoriasis Associated with Anti-Tumor Necrosis Factor-Alpha Therapies in Children with Inflammatory Bowel Disease, Juvenile Idiopathic Arthritis, and Chronic Noninfectious Osteomyelitis

Lisa Buckley ,[1] Rui Xiao,[1] Marissa Perman,[2] Andrew Grossman,[2] and Pamela F. Weiss[2], [1]Children's Hospital of Philadelphia, Philadelphia, [2]Children's Hospital of Philadelphia, Philadelphia, PA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Pediatric Rheumatology – Clinical II: JIA
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: TNF-alpha inhibiting therapies (TNFi) are a cornerstone of treatment for inflammatory conditions such as IBD, JIA, and chronic noninfectious osteomyelitis (CNO) but have been increasingly implicated in the development of psoriasis. The objective of this study was to compare the rate of psoriasis in children with IBD, JIA, and CNO with TNFi exposure to those without TNFi exposure and to the general pediatric population.

Methods: This was a single-center retrospective cohort study of electronic health record data from 2008 to 2018. Inclusion criteria were at least 2 ICD-9 or ICD-10 codes for JIA, IBD, or CNO, age at diagnosis of under 19 years, and at least 2 visits with a study center rheumatologist or gastroenterologist due to the frequent nature of one-time second opinion visits. Subjects with a listed past medical history or diagnosis code of psoriasis prior to the diagnosis of JIA, IBD, or CNO were excluded. TNFi exposure was defined as at least 1 prescription for either adalimumab, etanercept, or infliximab, and subjects were dichotomized as "ever" or "never" having TNFi exposure. The primary outcome was incident psoriasis which was defined as the first ICD-9 or ICD-10 code for psoriasis during a visit with a study center rheumatologist, gastroenterologist, or dermatologist. Subjects who had not developed psoriasis by their final recorded visit were considered censored. Incidence rates (IRs) were calculated as well as standardized incidence ratios (SIRs) comparing the observed to expected number of psoriasis cases in the general pediatric population according to previously published data. Univariate and multivariate Cox proportional hazards models determined by stepwise model selection were used to estimate the strength of association between TNFi exposure and incident psoriasis and to evaluate risk factors associated with psoriasis development.

Results: Between January 2008 and October 2018, 4403 children met inclusion criteria. Of these children, 1738 (39%) had TNFi exposure and 2665 (61%) did not with 5245 and 7365 person-years of follow-up, respectively. The IRs and SIRs for the entire cohort and for each condition are presented in **Table 1**. There were 64 (IR 1.2 per 100

	Person-years			Events			IR (per 100 person-years)			SIR[a] (95% CI)		
	All	TNFi unexposed	TNFi exposed	All	TNFi unexposed	TNFi exposed	All	TNFi unexposed	TNFi exposed	All	TNFi unexposed	TNFi exposed
All	12610.6	7365.3	5245.3	90	26	64	0.7	0.4	1.2	17.5 (14.2, 21.5)	8.7 (5.9, 12.7)	29.9 (23.4, 38.2)
IBD	8460.6	5052.9	3407.7	50	13	37	0.6	0.3	1.1	14.5 (11.0, 19.1)	6.3 (3.7, 10.9)	26.6 (19.3, 36.7)
JIA	3954.3	2206.3	1748.0	33	9	24	0.8	0.4	1.4	20.5 (14.5, 28.8)	10.0 (5.2, 19.2)	33.7 (22.6, 50.2)
CNO	195.7	106.1	89.6	7	4	3	3.6	3.8	3.3	87.7 (41.8, 183.9)	92.4 (34.7, 246.3)	82.1 (26.5, 254.5)

IR: incidence rate; SIR: standardized incidence ratio; CI: confidence interval; IBD: inflammatory bowel disease; JIA: juvenile idiopathic arthritis; CNO: chronic noninfectious osteomyelitis; TNFi: tumor necrosis factor inhibitor aSIRs were calculated as the ratio of observed psoriasis cases to expected psoriasis cases as estimated by the incidence in the general pediatrics population (40.8 per 100,000) (Tollefson, et al. Incidence of psoriasis in children: a population-based study. J Am Acad Dermatol. 2010; 62(6): 979-87). A SIR >1 indicates that more cases were observed than expected.

JIA: juvenile idiopathic arthritis; TNFi: tumor necrosis factor inhibitor; BMI: body mass index; HR: hazard ratio; CI: confidence interval aReference is white; bReference is IBD; cCNO removed from both models due to small sample size and low event rate.

person-years) and 26 (IR 0.4 per 100 person-years) cases of psoriasis in children with and without TNFi exposure, respectively. The SIR was 17.5 (95% CI 14.2, 21.5) for the entire cohort, 29.9 (95% CI 23.4, 38.2) for the TNFi exposed group, and 8.7 (95% CI 5.9, 12.7) for the TNFi unexposed group. When holding all other covariates constant, the hazard ratio for psoriasis comparing TNFi exposure to no TNFi exposure was 4.23 (95% CI 2.56, 7.01, p< 0.001) (**Table 2**). In children with TNFi exposure, family history of psoriasis was independently associated with an increased hazard of psoriasis (HR 3.09, 95% CI 1.83, 5.22, p< 0.001) (**Table 2**).

Conclusion: Children with IBD, JIA, and CNO had an increased rate of psoriasis compared to the general pediatric population, with the highest rate in those with TNFi exposure. TNFi treatment in children with IBD and JIA was associated with an increased hazard of developing psoriasis compared to those not treated with TNFi.

Arthropathy of Down Syndrome: An Under-diagnosed Inflammatory Joint Disease That Warrants a Name Change

Charlene Foley ,[1] Derek Deely,[2] Emma Jane MacDermott,[2] and Orla Killeen[2], [1]Great Ormond Street Hospital, London, Ireland, [2]National Centre for Paediatric Rheumatology (NCPR), Our Lady's Children's Hospital Crumlin (OLCHC), Dublin, Ireland

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Pediatric Rheumatology – Clinical II: JIA

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Incidence and prevalence of arthropathy of Down syndrome (A-DS) is increased. It is rarely recognised at onset and remains under-diagnosed. Children with A-DS are therefore presenting with significant joint damage and disability at diagnosis.

The aim of this study was to identify undiagnosed cases of A-DS, document time to diagnosis, and describe clinical, laboratory and radiological features of A-DS at diagnosis.

Methods: Children with DS (0–21 years) were invited to attend a local, regional musculoskeletal screening clinic (figure 1). At this appointment a paediatric rheumatology clinical fellow performed a detailed musculoskeletal examination. A second physician at a further clinic confirmed suspected cases of A-DS. Investigations and treatment were instigated as per normal clinical practice for JIA. Data on a convenience sample of 21 newly diagnosed children with JIA was collected to create a comparison group.

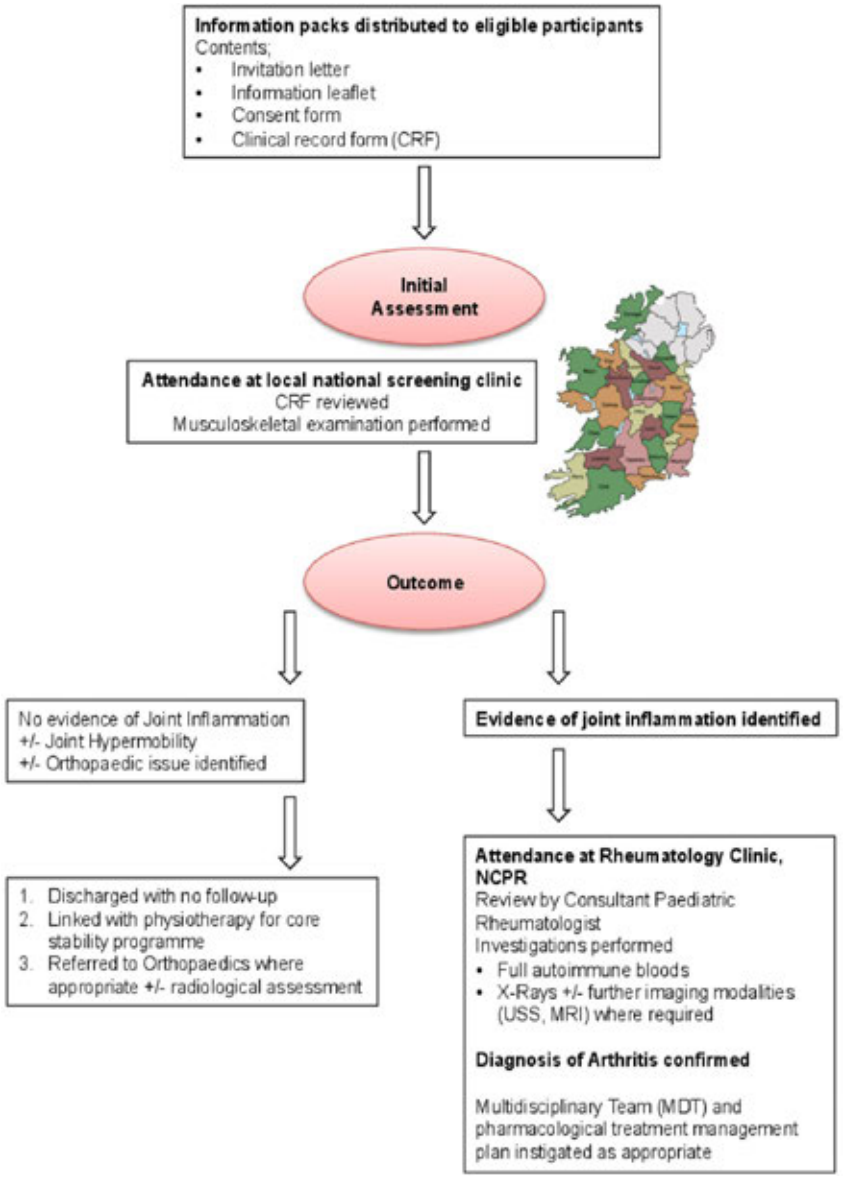

Figure 1. Flow diagram summarising the musculoskeletal screening process and follow-up provided to all children with Down syndrome that participated in the study.

Table 1. Demographic, clinical and laboratory features at diagnosis of A-DS (n=33) and JIA (n=21). Where data are presented as median and range, statistical significance was determined using the Mann-Whitney U-test. For data presented as a proportion of the total population, statistical significance was calculated using the Chi-square test or Fisher exact test. AJC = Active joint count; RJC = Restricted joint count, ESR = Erythrocyte sedimentation rate, CRP = C-Reactive Protein, ANA = Anti-nuclear antibody, RF = Rheumatoid factor. ϖSmall joint involvement is defined as evidence of active inflammation in the metacarpophalangeal (MCP), proximal (PIP) and/or distal (DIP) interphalangeal joints of the hands; ♯DA cohort of n = 25; ★DA cohort of n = 29 (n numbers less than total cohort as results missing)

Characteristic	A-DS n = 33	JIA n = 21	p value
Age, median in years (range)	11.4 (0.3 – 19.2)	6.3 (1.1 – 16)	p < 0.001
Gender, n male (% male)	18 (55)	11 (52)	ns
AJC, n (range)	3 (0 – 18)	4 (1 – 13)	ns
RJC, n (range)	4 (0 – 12)	1 (0 – 10)	p < 0.05
ϖSmall joint involvement, n (%)	28 (85)	9 (43)	p < 0.01
Raised ESR at diagnosis, n (%)	8♯ (32)	15 (71)	p < 0.01
Raised CRP at diagnosis, n (%)	3★ (10)	6 (29)	ns
ANA positive, n (%)	0 (0)	5 (24)	p < 0.01
RF positive, n (%)	0 (0)	1 (5)	ns

Results: Over an 18 month period, 503 children with DS were screened for arthritis and 18 new cases diagnosed. In total, 33 children were identified with A-DS (combining cases attending predating commencement of the study and those referred to our Centre during the study period) (Table 1). This suggests prevalence of A-DS is 20/1000. A significant delay in diagnosis of A-DS was observed. The majority of children presented with polyarticular RF negative arthritis, with predominance in the small joints of the hands and wrists. No children with A-DS were ANA positive. In the majority of cases, ESR and CRP were unhelpful in aiding diagnosis of A-DS. Erosive changes were reported on X-ray in a significantly ($p< 0.05$) greater proportion (42%) of children with A-DS than JIA (14%).

Conclusion: Studies of A-DS are limited. We describe a cohort of 33 children with A-DS. Comparable to previous reports, our results confirm an increased risk of arthritis in children with DS. However, we suggest that prevalence is at least 2–3 times greater than previously reported. We also observed a significant delay in diagnosis of A-DS, the reasons for this being multifactorial (figure 2). Children with A-DS most frequently present with a polyarticular RF negative arthritis, predominantly affecting the small joints of the hands and wrists. The arthritis is erosive in nature; a finding we do not believe is solely related to the observed delay in diagnosis.

Figure 5. corrected
Schematic highlighting challenges which may impede correct and timely diagnosis of A-DS (from top, clockwise). The first is lack of awareness about the increased risk of arthritis in children with DS among both the general public and healthcare professionals; Gradual functional loss over time rather than an acute presentation may go undetected by the child's carer. Frequently, delay in motor development is falsely attributed to intellectual disability, and changes in activities of daily living to behavioural problems associated with DS, rather than a possible diagnosis of arthritis. Hypermobility, a feature of DS may make musculoskeletal examination more challenging, as it may be difficult to appreciate loss of range of movement secondary to an inflammatory arthritis. Many children may be uncooperative when it comes to examination. This combined with poor verbal skills can make eliciting a clear history and thorough musculoskeletal examination challenging. Apparent differences in pain expression have been reported in children with DS. Children with DS often adapt to pain with reported observations such as slowing mobility, reluctance to hold a parental hand or behavioural change. Therefore, these are key features to try and elicit when taking a history from a child with a suspected diagnosis of A-DS.

This study highlights the importance of raising awareness about the increased risk of arthritis in children with DS to aid recognition and more timely diagnosis of A-DS. The addition of an annual musculoskeletal examination to the well recognised health surveillance guidelines for all children with DS would be an initiative of great benefit to this cohort. We propose a more appropriate clinical term that better reflects the inflammatory, erosive nature of the disease would be DS-associated arthritis (DA). In order to facilitate more cohesive clinical practice and future collaborative research, we would hope that this could become a universally accepted term among healthcare professionals and the general public. Future research to accurately define disease pathogenesis, identify a biomarker of disease and establish best practice in terms of treatment of A-DS would be of benefit.

Continuing versus Withdrawing Ixekizumab in Patients with Psoriatic Arthritis Who Achieved Sustained Minimal Disease Activity: Results from the SPIRIT-P3 Study

Laura Coates ,[1] Sreekumar Pillai,[2] Lu Zhang,[2] David Adams,[2] Lisa Kerr,[2] Maja Hojnik,[2] Gaia Gallo,[2] Ivo Valter,[3] Hasan Tahir,[4] Vinod Chandran,[5] Philip Mease,[6] and Arthur Kavanaugh[7], [1]Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, [2]Eli Lilly and Company, Indianapolis, IN, [3]Center for Clinical and Basic Research, Tallinn, Estonia, [4]Department of Rheumatology, Whipps Cross University Hospital, London, United Kingdom, [5]Division of Rheumatology, University of Toronto, Krembil Research Institute, University Health Network, Toronto, ON, Canada, [6]Swedish Medical Center/Providence St. Joseph Health and University of Washington, Seattle, WA, [7]University of California, San Diego School of Medicine, La Jolla, CA

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Miscellaneous

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Psoriatic arthritis (PsA) is a chronic inflammatory disease that may lead to serious disability if not appropriately treated. Data on the effect of treatment discontinuation and retreatment in the case of flare are scant. Ixekizumab (IXE), a high-affinity IL-17A antagonist, has demonstrated consistent efficacy in PsA for up to 3 years.[1] This study evaluated efficacy and safety of continuing vs. withdrawing IXE in PsA patients (pts) who achieved sustained minimal disease activity (MDA) on IXE and re-treating with IXE if required.

Methods: SPIRIT-P3 (NCT02584855) was a multicenter phase 3b study enrolling biologic-naïve pts with active PsA (diagnosis for ≥6 months, meeting Classification Criteria for Psoriatic Arthritis, ≥3/68 tender joints, ≥3/66 swollen joints) and previous inadequate response to conventional synthetic DMARDs (csDMARDs). Pts entered a 36-week, open-label (OL) treatment period with IXE every 2 weeks. Between Weeks 36–64, pts were randomized 1:1 to IXE or placebo (PBO) at the visit for which randomization criteria were met (sustained MDA for at least 4 visits over 3 consecutive months) and evaluated up to Week 104. Pts not meeting randomization criteria by Week 64 continued on IXE up to Week 104. Maintenance of treatment response was measured by the time to loss of sustained MDA (relapse) during the randomized withdrawal (RW) period. The proportion of pts who relapsed during the first 40 weeks of the RW period and time to regain MDA after re-treatment with IXE in relapsed pts were assessed. The Kaplan-Meier product limit method was used to estimate survival curves for time-to variables. Treatment comparisons were performed using a log-rank test adjusting for geographic region and csDMARD use as factors. Cumulative proportion of relapse was analyzed using a logistic regression model with treatment, geographic region, and csDMARD use as factors. Safety data were summarized for the entire study period for pts who received ≥1 dose of IXE.

Results: A total of 394 pts entered into the OL treatment period; 158 (40%) achieved sustained MDA criteria and were randomized to IXE (N=79) or PBO (N=79). Baseline characteristics were similar between groups (Table 1). The time to relapse for pts on PBO was significantly shorter than for pts on IXE ($p < 0.001$) during the RW period, with

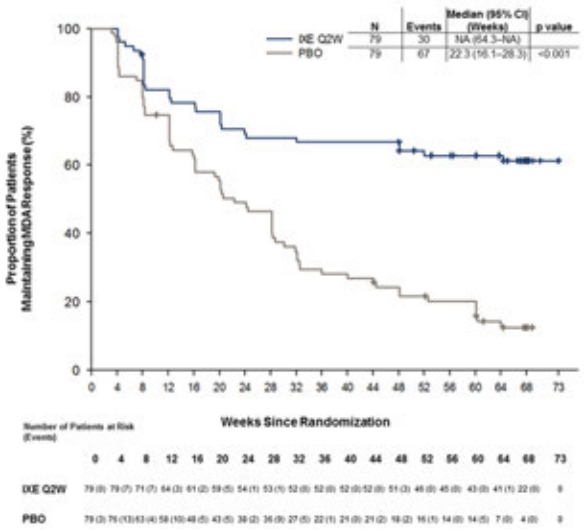
[a]Week 0 to randomization or Week 64. [b]Randomization to relapse or Week 104. [c]Current csDMARD use reported at time of randomization. [d]In patients with baseline PASI >0. [e]In patients with baseline BSA >0.

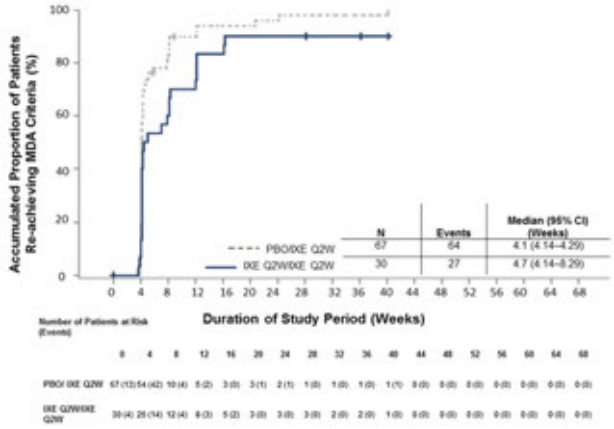
BMI=body mass index; BSA=body surface area; csDMARD=conventional synthetic disease-modifying anti-rheumatic drug; IXE Q2W=ixekizumab 80-mg every 2 weeks; HAQ-DI=Health Assessment Questionnaire-Disability Index; LEI: Leeds Enthesitis Index; N=number of patients in analysis population; PASI=Psoriasis Area and Severity Index; PatGA=Patient's Global Assessment of Disease Activity; PBO=placebo; RW=randomized withdrawal; SJC=swollen joint count; TJC=tender joint count; VAS=Visual Analog Scale.

Figure 1. Time to relapse (loss of MDA).



CI=confidence interval; MDA=minimal disease activity; IXE Q2W=ixekizumab 80 mg every 2 weeks; PBO=placebo. Time to relapse in weeks = (date of relapse – date of first injection of randomized dose of study treatment in the randomized double-blind withdrawal period +1)/7. Patients completing the withdrawal period without meeting relapse criteria were censored at the date of completion (the date of the last scheduled visit in the withdrawal period). Patients without a date of completion or discontinuation were censored at the latest non-missing date from the following dates: date of last injection of study treatment in the withdrawal period and date of last attended visit in the withdrawal period.

Figure 2. Time to re-achieving MDA following relapse.



CI=confidence interval; IXE Q2W=ixekizumab 80 mg every 2 weeks; PBO=placebo; RW=randomized withdrawal. The relapse population is defined as randomized patients who relapsed (no longer met criteria for MDA) after randomization and who received at least 1 dose of IXE after relapse.

a median time to relapse of 22.3 weeks in the PBO group (Figure 1). The cumulative relapse rate during the first 40 weeks of the RW period was 73% for PBO vs. 34% for IXE ($p < 0.001$). Of the patients who relapsed on PBO, 96% regained MDA following re-treatment with IXE. The median time to regain MDA was 4.1 weeks (95% CI 4.14–4.29) for PBO and 4.7 weeks (95% CI 4.14–8.29) for IXE (Figure 2). Safety data were consistent with previous IXE PsA studies with no unexpected safety signals.1

Conclusion: Continued IXE therapy was superior to PBO in maintaining MDA in biologic-naïve PsA pts who achieved sustained MDA on initial IXE treatment. A vast majority of pts who lost MDA after IXE withdrawal regained MDA with IXE re-treatment. Continuous IXE treatment is optimal for maintaining MDA; however, patients can regain MDA after re-treatment with IXE in case of treatment interruption.

The Ankylosing Spondylitis Disease Activity Score Reflects and Predicts Response to Biologic Treatment in Axial Spondyloarthritis Patients with Coexistent Fibromyalgia Compared to the Bath Ankylosing Spondylitis Disease Activity Index

Sarah Sacks ,[1] Kathryn Rigler,[2] and Antoni Chan[2], [1]Royal Berkshire Hospital, Maidenhead, United Kingdom, [2]Royal Berkshire Hospital, Reading, United Kingdom

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Miscellaneous
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Currently the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Spinal pain are used to assess whether a patient with Axial Spondyloarthritis (AxSpA) requires biologic therapy and their response to biologic therapy. However, the BASDAI does not just reflect inflammatory disease activity as it includes questions relating to fatigue (question 1) and musculoskeletal areas of tenderness (question 4) and therefore escalating treatment to biologic therapy, and/or stopping or switching biologic treatment based on a BASDAI may not improve symptoms or quality of life. We assessed the sensitivity of individual questions of the BASDAI, ASDAS and CRP against the response to biologics.

Methods: Data from 85 AxSpA patients were collected, including demographic characteristics, extraarticular manifestations and outcome measures. Patients were then analysed according to the following groupings: responder or non-responder to biologics. In each group, mean scores for individual questions of BASDAI, BASFI, ASDAS and CRP were calculated. Subjects were further analysed according to groups: Group 1 (BASDAI ≥4, ASDAS ≥2.1), Group 2 (BASDAI < 4, ASDAS ≥2.1) and Group 3 (BASDAI < 4, ASDAS < 2.1).

Results: There were n=65 male and n=20 female subjects. Mean (SD) age was 44.7 (13.3) years and AxSpA disease duration 9.5 (9.9) years. The mean BASDAI scores at baseline in patients receiving biologics were similar in respond-

Figure 1. Mean scores for Q1 and 4 of BASDAI

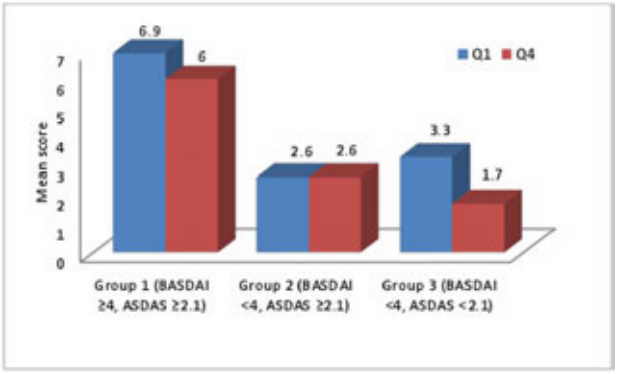

Figure 2. Mean BASFI score

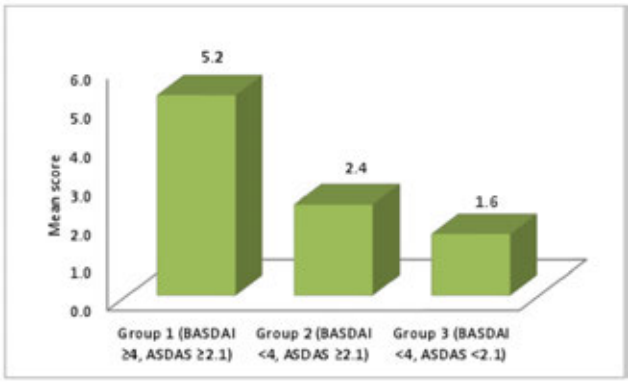

ers 6.1 (1.8) and non-responders 6.2 (1.4). Post treatment with biologics, clinical non-responders had a higher mean score for Q1 and Q4 of the BASDAI (7.7 and 6.5) compared to responders (3.8 and 2.2). A similar trend was seen for BASFI (mean 5.9 in non-responders compared to 2.2 in responders). Further analysis using ASDAS, showed that patients in Group 1 had higher scores for Q1 and Q4 of the BASDAI (mean 6.9 and 6.0 respectively) and coexistent fibromyalgia compared to Groups 2 (mean 2.6 and 2.6) and 3 (mean 3.3 and 1.7), see Figure 1. This correlated with a high BASFI (mean of 5.2 in Group 1) compared to Group 2 (2.4) and 3 (1.6), see Figure 2. Patients in Group 2 had a higher CRP (mean 11.4) than the other groups (3.5 in Group 1 and 3.1 in Group 3), reflecting higher inflammatory burden. There was a lower proportion of females (16%) in Group 3 compared to the other groups (32% in Group 1 and 30% in Group 2). Furthermore, Group 3 had the highest percentage of patients with extra-articular manifestations (73%, compared to 51% and 58% respectively for Groups 1 and 2).

Conclusion: These findings support the hypothesis that fatigue and pain, as reflected by high scores for Q1 and Q4 of the BASDAI and coexistent fibromyalgia, are possible drivers of high perceived disease activity and non-response to biologics. This is correlated with a high BASFI. The elevated CRP seen in Group 2 suggests a higher burden of inflammation, in spite of low BASDAI scores, suggesting a need for more intensive therapy in this group. There was a trend for biologic responders to be males and with more extra-articular manifestions. ASDAS provides a means of incorporating more objective measures of disease activity, such as CRP, into clinical assessment, and therefore provides a useful adjunct to traditional Bath scores in assessing response to biologics.

SESSION INFORMATION

Session Date: Monday, November 11, 2019

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Miscellaneous

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Background/Purpose: Physical function in axial spondyloarthritis (axSpA) usually assessed by the BASFI questionnaire is an established core domain of that disease. There is evidence that self- reported physical function is not equivalent with the actual performance of patients. Physical performance can be assessed as a single task such as grip strength or single stance, or as a generic compound measure such as the short physical performance battery test (SPPB). SPPB comprises a chair rising test, a balance test and gait speed. The aim of the study is to investigate which performance tests are most frequently impaired in patients with axSpA.

Methods: Consecutive axSpA patients presenting to our tertiary hospital underwent a standardized assessment including patient and disease characteristics, patient-reported outcomes (ASDAS, BASFI, BASMI, ASAS Health Index (ASAS HI), PHQ-9) and performance tests (SPPB, grip strength and single stance). Structural damage was assessed by mSASSS. Validated cut-offs were used for SPPB, chair rise test, grip strength and gait speed. Impairment of performance tests as well as discrimination between subgroups was analysed.

Results: A total of 200 patients (r-axSpA 65.5%, nr-axSpA 34.5%) were included: 69% males, 44.3±12.5 years of age, mean symptom duration 17.9±12.6 years, mean ASDAS 2.5±1.1, BASFI 4.0±2.7, BASMI 3.5±1.8, ASAS HI 7.0±4.1, PHQ-9 8.8±6.2, mSASSS (n=157) 10.2± 18.8. A total of 132 patients were treated with bDMARDs (66.5%). The two most impaired performance tests were repeated chair rising and single stance (Figure 1). An impairment

Measure (n=200)	Patients with impairments	Mean (SD)	95% CI	Min-Max	Median	25-p75 percentile
SPPB (range 0-12), threshold ≤ 8	22 (11,0 %)	10,3 (1,8)	10,0-10,5	2-12	11	9-12
Repeated chair stand test, threshold > 15 s*	75 (37,5 %)	14,3 (5,9)	13,4-15,1	6,8-42,9	12,8	10,5-17,0
Gait speed, threshold ≤ 0,8 m/s	18 (9,0 %)	1,1 (0,3)	1,08-1,16	0,4-2,4	1,1	1,0-1,3
Grip strength male, threshold < 27 kg, n =138	11 (8,0 %)	42,2 (9,7)	40,5-43,8	15,0-66,0	43,0	36,4-48,0
Grip strength female, threshold < 16kg, n =62	6 (9,7 %)	24,0 (5,4)	22,6-25,3	12,0-38,0	24,0	21,8-27,0
Single stance, threshold ≤ 10 s, n =169**	25 (14,8 %)	66,6 (45,8)	59,5-73,6	2,2-120,0	60,2	19,9-120,0

*14 patients were not able to perform the test
** 4 patients were not able to do a single stance

Performance tests in patients with axSpA

in≥ 1 performance test was seen in 87 patients (43.5%). Patients with impairments, in comparison to those without, were older (48.9 vs. 40.8 years), more often obese (28.7 vs. 26.1%), more often depressed (PHQ 12.1 vs. 6.3%), had lower BASFI values (5.7 vs. 2.8), a decreased ASAS HI (9.6 vs. 5.0), and higher disease activity (ASDAS 3.0 vs. 2.1), all p< 0.01. The documented impairment in performance was irrespective of medication and structural damage on the group and the individual patient level. The correlation between BASFI and the performance test was moderate for SPPB (0.6), gait speed (0.5), chair rise (0.5) and single stance (0.4), while the correlation between BASFI and grip strength (0.2) and mSASSS (0.2) was rather limited.

Conclusion: n this consecutively recruited relatively young axSpA patients with limitations in physical function and health as assessed by established measures, we found a high prevalence of patients who didn't perform well in tests originally developed for older people. Importantly, a lot of impairment was seen when patients were asked to perform complex tasks requiring coordination and muscle strength. Impairment was present even though most patients received bDMARDs. Since such impairment is potentially influenced by physiotherapeutic interventions, we propose to perform studies to address these deficits. Our data strongly suggest to not only collect questionnaires but also do performance tests to better assess the 'real' physical capacity of patients.

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Miscellaneous
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Tildrakizumab (TIL), a high-affinity anti–interleukin-23p19 monoclonal antibody, is approved to treat moderate-to-severe plaque psoriasis. A randomized, double-blind, multidose, placebo (PBO)-controlled, phase 2b study (NCT02980692) is evaluating the efficacy and safety of TIL for PsA. This analysis evaluated the efficacy of TIL on 66 swollen and 68 tender joint counts (SJC and TJC) and pain in patients with active PsA at week 24.

Table 1. Patient demographics and baseline disease characteristics. *For prior anti–TNF-α therapy, total patients analyzed (N) = 79, 78, 80, 78, and 76 for TIL 200 mg Q4W, TIL 200 mg Q12W, TIL 100 mg, TIL 20 mg, and PBO, respectively. BMI, body mass index; PBO, placebo; Q4W, every 4 weeks; Q12W, every 12 weeks; SD, standard deviation; TIL, tildrakizumab.

	TIL 200 mg Q4W (N = 78)	TIL 200 mg Q12W (N = 79)	TIL 100 mg Q12W (N = 77)	TIL 20 mg Q12W (N = 78)	PBO (N = 79)
Age, years, mean ± SD	50.1 ± 13.3	49.3 ± 11.2	49.2 ± 11.9	47.2 ± 13.4	48.1 ± 13.3
Female, n (%)	46 (59.0)	37 (46.8)	47 (61.0)	41 (52.6)	44 (55.7)
Race, n (%)					
White	76 (97.4)	78 (98.7)	75 (97.4)	75 (96.2)	74 (93.7)
Black or African American	0	0	1 (1.3)	1 (1.3)	3 (3.8)
Other	2 (2.6)	1 (1.3)	1 (1.3)	2 (2.6)	2 (2.5)
Weight, kg, mean ± SD	85.1 ± 19.7	87.1 ± 19.5	83.6 ± 18.9	85.1 ± 18.1	85.3 ± 20.2
BMI, kg/m², mean ± SD	30.1 ± 6.5	30.2 ± 6.5	29.5 ± 6.8	29.4 ± 5.2	29.5 ± 6.0
Duration of PsA, years, mean ± SD	6.9 ± 7.3	6.8 ± 6.3	6.3 ± 7.2	6.6 ± 6.7	7.3 ± 8.0
Prior anti–TNF-α therapy, n (%)*	18 (22.8)	17 (21.8)	19 (23.8)	19 (24.4)	18 (23.7)
Swollen joint count, mean ± SD	10.4 ± 7.4	10.0 ± 8.0	11.0 ± 8.2	9.4 ± 6.4	11.8 ± 9.8
Tender joint count, mean ± SD	16.6 ± 11.9	19.5 ± 13.9	21.3 ± 14.8	19.0 ± 13.0	19.7 ± 14.7
Pain, mean ± SD	55.4 ± 19.1	59.6 ± 23.5	59.2 ± 22.1	60.9 ± 19.7	64.2 ± 20.4

Methods: Patients with active PsA (Classification of Psoriatic Arthritis criteria),[1] stratified by prior anti-TNF use and baseline body weight (≤90 kg and ≥90 kg), were randomized 1:1:1:1:1 to receive TIL (200 mg once every 4 weeks [Q4W], 200 mg every 12 weeks [Q12W], 100 mg Q12W, 20 mg Q12W to week 24) or PBO Q4W to week 24. SJC and TJC were performed by an independent blinded assessor at baseline and Q4W through week 24. Patients rated pain using a visual analog scale (0–100 mm). Safety was assessed by monitoring treatment-emergent adverse events.

Results: Of 500 patients screened, 391 met the inclusion criteria with 77–79/treatment arm. Mean (SD) age was 48.8 (12.6) years, disease duration 6.8 (7.1) years, body mass index 29.7 (6.2), and 91 were TNF-α experienced (**Table 1**). At week 24, the least squares (LS) mean (standard error [SE]) reduction from baseline in SJC was 8.3 (0.5)/7.7 (0.5)/8.2 (0.5)/7.6 (0.5) in TIL arms vs 6.5 (0.5) in the PBO arm and statistically significant in TIL 100 mg Q12W and 200 mg Q4W vs PBO (P = 0.0189 and 0.0111, respectively, **Figure 1**). LS mean (SE) reduction in TJC was 11.9 (1.0)/12.6 (1.0)/13.0 (1.0)/12.0 (1.0) in TIL arms vs 9.4 (1.0) in the PBO arm; statistically significant for TIL 100 and 200 mg Q12W vs PBO (P = 0.0140 and 0.0234). LS mean (SE) reduction in patient pain was 35.2 (2.7)/31.7 (2.6)/32.2 (2.6)/28.9 (2.7) in TIL arms vs 21.5 (2.6) in the PBO arm; statistically significant for TIL 100, 200 mg Q12W, and 200 mg Q4W vs PBO (P = 0.0039, 0.0056, and 0.0003). Percent change from baseline for SJC (73.0%–79.8% TIL vs 59.3% PBO), TJC (62.1%–67.5% TIL vs 48.7% PBO), and pain (47.5%–63.5% TIL vs 33.5% PBO) at week 24 are shown in **Figure 2**. No malignancies, major adverse cardiac events, or deaths were reported.

Conclusion: At week 24, TIL 100 mg Q12W and 200 mg Q4W significantly reduced SJC vs PBO; TIL 100 and 200 mg Q12W significantly reduced TJC vs PBO. All TIL treatment arms had significant improvement in pain vs PBO in patients with PsA who were anti–TNF-naïve or experienced.

Editorial and writing support was provided by Marie-Louise Ricketts, PhD, of AlphaBioCom, LLC.

*Comparisons between b/tsDMARD naïve and non-naïve patients are performed with ANOVA for normally distributed data and with Kruskal-Wallis for skewed data. Drug retention is compared with Kaplan-Meier with log-rank test. **LUNDEX adjusted treatment outcome = (number of patients still treated at the respective timepoints / number of patients starting treatment) x (% of patients achieving the respective treatment outcomes)

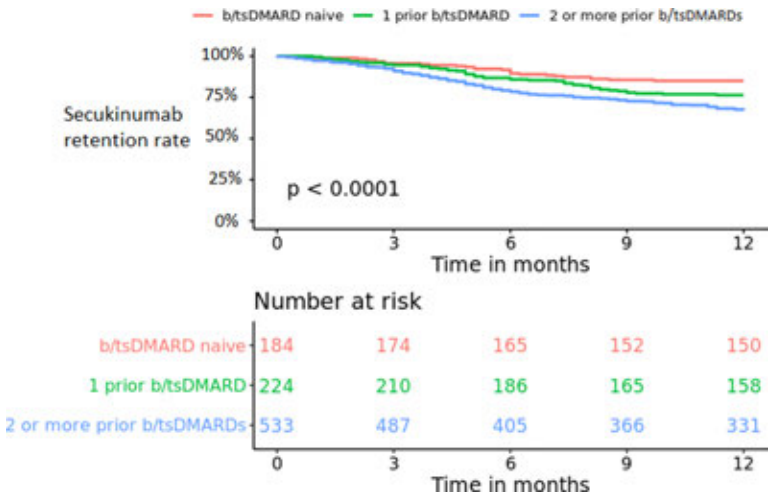

Figure. Pooled 12-month secukinumab retention rates for axSpA patients in EuroSpA stratified by previous b/tsDMARD treatment (log rank test; p<0.001).

Background/Purpose: Secukinumab is a fully human IgG1 monoclonal antibody targeting interleukin-17A. There is a lack of real-life evidence on secukinumab retention rates and treatment outcomes in axial spondyloarthritis (axSpA) patients. Hence, the aim of this study was to determine the 6- and 12-month secukinumab retention rates as well as the crude and LUNDEX corrected proportions of patients in remission after 6 and 12 months of treatment in Europe. This was assessed overall as well as stratified by prior biologic disease-modifying anti-rheumatic drug (bDMARD)/ targeted synthetic (ts)DMARD use.

Methods: Data from axSpA patients treated with secukinumab in routine care from 12 countries in the European Spondyloarthritis (EuroSpA) Research Collaboration Network were pooled. Time from treatment initiation to data cut was ≥ 12 months regardless of treatment durations and cover start date between May 2015 and April 2018. The following outcomes were calculated: Proportions of patients achieving Bath Ankylosing Spondylitis Disease Activity Score (BASDAI) < 2 / BASDAI < 4 and Ankylosing Spondylitis Disease Activity Score (ASDAS) < 1.3/ ASDAS < 2.1 at 6 and 12 months, including with LUNDEX1 adjustments. Group comparisons between b/tsDMARD naïve and 1 or ≥2 prior b/tsDMARD users were performed with ANOVA, Kruskal-Wallis or Chi-square test or with Kaplan-Meier analyses with log rank test, as appropriate.

Results: A total of 941 axSpA patients were included, thereof 6 who started treatment in 2015, 215 in 2016, 573 in 2017 and 147 in 2018. Overall 6/12-month secukinumab retention rate was 82%/73% and higher in b/tsDMARD naïve compared to non-naïve patients (table, figure). After 6/12 months treatment BASDAI < 4 was achieved by 51%/62%, BASDAI < 2 by 24%/34%, ASDAS < 2.1 by 23/33% and ASDAS < 1.3 by 8%/14% of the patients. b/tsDMARD naïve patients compared with patients treated with 1 prior or 2 or more prior b/tsDMARDs had shorter time since diagnosis, higher baseline disease activity and a higher proportion were men. Overall, LUNDEX adjusted 6 and 12 months' responses were achieved more often in b/tsDMARD naive patients than in patients who had received 1 or 2 or more previous b/tsDMARDs (table).

Conclusion: This study of >900 patients in 12 European countries provided real-world data on the effectiveness of secukinumab in patients with axSpA, adding evidence to existing RCTs. A majority of the patients were treated with 2 or more previous b/tsDMARDs and had long disease duration. Overall retention rate was 82%/73% at 6/12 months, respectively, with higher retention rates for b/tsDMARD naïve compared with patients treated with 1 or 2 or more previous b/tsDMARDs. Overall, a higher proportion of bionaïve than previous b/tsDMARD users achieved remission regardless of remission criteria.

Session Title: Spondyloarthritis Including Psoriatic Arthritis – Clinical III: Miscellaneous

Session Type: ACR Abstract Session

Session Time: 2:30PM–4:00PM

Table 1. Baseline Patient Demographics Divided by Presence of Sacroiliitis

Table 1: Baseline Patient Demographics Divided by SI				
	Total (n=258)	No SI (n=213)	SI (n=45)	p-value
Age at MRE (years, median, IQR)	30.71 (25.24, 42.75)	30.24 (24.92, 41.16)	34.21 (26.86, 48.53)	0.232
Female	46.5% (120/258)	43.7% (93/213)	60% (27/45)	**0.046**
White	79.7% (204/258)	79.20% (168/212)	81.80% (36/44)	0.649
Back pain at the time of MRE	7.8% (20/258)	6.10% (13/213)	15.60% (7/45)	**0.031**
Seen by rheumatologist	13.6% (35/258)	9.90% (21/212)	31.10% (14/45)	**<0.001**
Personal history of Rheumatologic Disease	39.92% (103/258)	38.00% (81/213)	48.90% (22/45)	0.176
FHx of Rheumatologic disease	10.9% (28/258)	10.30% (22/213)	13.30% (6/45)	0.556
FHx of IBD	31.8% (82/258)	32.40% (69/213)	28.90% (13/45)	0.646
SI= sacroiliitis; MRE=Magnetic Resonance enterography; FHx=Family History				

Background/Purpose: Prevalence of sacroiliitis (SI) in Crohn's disease (CD) varies widely (range 4% -39%), depending on criteria utilized to define the disease (e.g. inflammatory back pain, plain radiographs or MRI). Sacroiliitis may remain underdiagnosed in CD patients given lack of association with clinical symptoms of back pain and CD activity. However, patients with CD often undergo magnetic resonance enterography (MRE) to assess extent, severity of small bowel CD and radiographic healing, affording clinicians the opportunity to evaluate for the presence of active and/or chronic SI. We sought to identify the prevalence of sacroiliitis in CD patients utilizing MRE and determine its relationship with CD activity, especially with concurrent biologic therapy.

Methods: All CD subjects undergoing MRE between years 2014-2018 at a large IBD referral center were identified. A musculoskeletal radiologist, blinded to clinical data, reviewed all MRE exams for the presence of acute bone marrow edema (BME) lesions and chronic lesions suggestive of acute and chronic SI, respectively. A second radiologist, also blinded, assessed MRE for mucosal CD activity using validated measures. Charts were reviewed for demographics, IBD characteristics, presence of back pain, clinical and endoscopic activity of CD, and Crohn's therapies within 3 months of MRE. Comparisons were made between CD subjects with and without SI using chi-square test. Univariate and multivariate logistic regression were used to determine risk factors of SI.

Results: 258 subjects with CD underwent MRE during the study period with a mean age of 35 years old, 53% (n=138) were male, and mean duration of CD at the time of MRE was 9 years. Few reported back pain (8%) and 14% had previously seen a rheumatologist. Overall, 17% (n=45) of patients had MR evidence of sacroiliitis (Table 1). Female gender, presence of back pain, and later age of CD diagnosis were associated with signs of sacroiliitis (p=0.05, p< 0.001, p=0.04 respectively; Table 2). Stricturing phenotype was associated with a lower rate of SI (7% vs. 24%; p=0.018), but inflammatory or penetrating phenotypes were not. CD location, activity as noted by clinical scores, endoscopic disease activity, or radiographic disease activity on MRE, were not associated with sacroiliitis (Table 2). On multivariable analysis, back pain was associated with the presence of sacroiliitis on MRE (OR 3.0, 95% CI 1.1- 5.6; p=0.04). Concurrent CD therapy with biologics did not lower the risk of sacroiliitis.

Conclusion: Although often underdiagnosed, SI is a common comorbid condition in CD. While recent history of back pain was associated with the presence of sacroiliitis visualized on MRE, no correlations were found with other clinical and endoscopic markers of CD activity. Moreover, concurrent CD therapy, especially biologics, was not associated with a lower risk of sacroiliitis on MRE. With limited clinical clues and CD characteristics to suggest sacroiliitis, gastroenterologists can utilize MRE as a screening tool to detect SI and refer CD patients to rheumatologists. Presence of SI on MRE in CD patients with back pain may help identify a subset of individuals likely to benefit from switching to therapies with proven efficacy in axial SpA.

Table 2. Crohn's Disease History and Activity Divided by Presence of Sacroiliitis

Table 2: Crohn's Disease History and Activity Divided by SI			
	No SI (n=213)	SI (n=45)	p-value
Age at Diagnosis, (years, median, IQR)	21.86 (15.52; 29.66)	27.82 (19.12; 36.39)	**0.04**

Perceived Stress Independently Associates with Worse Type 2 Symptoms in Systemic Lupus Erythematosus

Sarah Patterson ,[1] Laura Trupin,[1] Cristina Lanata,[1] Louise Murphy,[2] Wendy Hartogenesis,[1] Maria Dall'Era,[1] Jinoos Yazdany,[3] and Patricia Katz[1], [1]University of California, San Francisco, San Francisco, CA, [2]Centers for Disease Control and Prevention, Division of Population Health, Atlanta, [3]UCSF Division of Rheumatology, San Francisco, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: A new posited framework for categorizing patients with systemic lupus erythematosus (SLE) is the division of symptomatology into two groups: type 1 manifestations represent classic signs and symptoms of lupus, link to immune-mediated inflammatory pathways, and respond to immunosuppressive therapy; type 2 manifestations represent symptoms such as fatigue, widespread pain, cognitive dysfunction, and self-reported disease activity that do not respond to the same treatments and are an area of major unmet need[1]. The pathogenesis and risk factors for type 2 symptoms remain poorly defined, and prior studies suggest a possible link between stress and disease severity in SLE. We examined whether high levels of psychological stress were associated with worse disease status in SLE and whether the association differed for type 1 and type 2 symptoms.

1. Pisetsky et al. A Novel System to Categorize the Symptoms of SLE. Arthritis Care Res 2018.

Table. Adjusted Means for Type 1 and Type 2 Lupus Symptoms by Perceived Stress

	Adjusted Mean* (95% CI)		
Disease Outcomes	High Perceived Stress**	Low/Moderate Stress***	P-value
Type I Symptoms			
Physician-assessed disease activity (SLEDAI) ‡	3.2 (2.5, 3.9)	2.9 (2.5, 3.3)	0.511
Type 2 Symptoms			
Self-report disease activity (SLAQ) ‡	13.2 (11.9, 14.6)	7.2 (6.5, 7.9)	<0.001
Cognitive function (PROMIS) †	44.6 (42.9, 46.3)	50.3 (49.4, 51.3)	<0.001
Pain (SF-36 Pain) †	42.2 (40.2, 44.3)	48.5 (47.4, 49.6)	<0.001
Fatigue (SF-36 Vitality) †	38.7 (36.5, 41.0)	50.7 (49.4, 51.9)	<0.001

*Adjusted means calculated based on multivariable linear regression adjusted for age, sex, race, education, income, smoking, disease duration, and disease damage (Brief Index of Lupus Damage score).
**Patients with scores in the top quartile of the 4-item Perceived Stress Scale (PSS) (range 8-16).
***Patients with scores in the three lower quartiles of the PSS (range 0-7).
‡ Higher score reflect worse status (more physician-assessed/self-reported disease activity)
†Higher scores reflect better status (better cognitive function, less pain/fatigue)
SLEDAI – Systemic Lupus Erythematosus Disease Activity Index
SLAQ – Systemic Lupus Activity Questionnaire
PROMIS – Patient Reported Outcomes Measurement Information System
SF-36 – Short Form 36 Health Survey

Methods: Participants in this sample, drawn from the California Lupus Epidemiology Study (CLUES), were at least 18 years old and met ACR criteria for SLE. In this cross-sectional study, stress was measured using the 4-item Perceived Stress Scale (PSS, range 0-16). No cut-points have been defined for the PSS and therefore participants with scores in the top quartile were identified as those with higher stress. Type 1 symptoms were represented by the physician assessed SLE disease activity index (SLEDAI) and type 2 symptoms by self-report disease activity (SLE Activity Questionnaire, SLAQ), cognitive function (PROMIS cognitive ability scale), pain (SF-36 Bodily Pain subscale), and fatigue (SF-36 Vitality subscale). We used multivariable linear regression to evaluate the associations of stress with SLEDAI and type 2 symptoms while controlling for potential confounders (age, sex, race, education, income, smoking, disease duration, and disease damage). We then calculated adjusted means for each outcome based on the multivariable regression.

Results: The sample (n=431) was 90% female, 30% white, 34% Asian, 22% Hispanic, and 11% African American; mean age 47 (± 14) years; 19% with poverty-level income; 73% with education beyond high school; mean disease duration 18 (± 11) years; and 38% on glucocorticoid therapy with ≥ 7.5 mg/day prednisone equivalent. The mean PSS score in the high stress group was 9.6 (± 1.9), compared with 3.5 (± 2.2) among the rest of the cohort. In the multivariate regression model, high stress was not associated with the Type 1 symptoms (worse scores for physician-assessed disease activity). However, high stress was associated with worse scores for each type 2 symptom: greater self-reported disease activity, lower cognitive function, more pain, and more fatigue (Table).

Conclusion: In a racially diverse sample of patients with SLE, high psychological stress was independently associated with worse type 2 symptoms including self-reported disease activity, cognitive dysfunction, pain, and fatigue. Evidence-based non-pharmacologic interventions to bolster stress resiliency, such as cognitive behavioral therapy, mindfulness-based stress reduction, and modified physical activity programs may be a strategy for improving outcomes in this patient population.

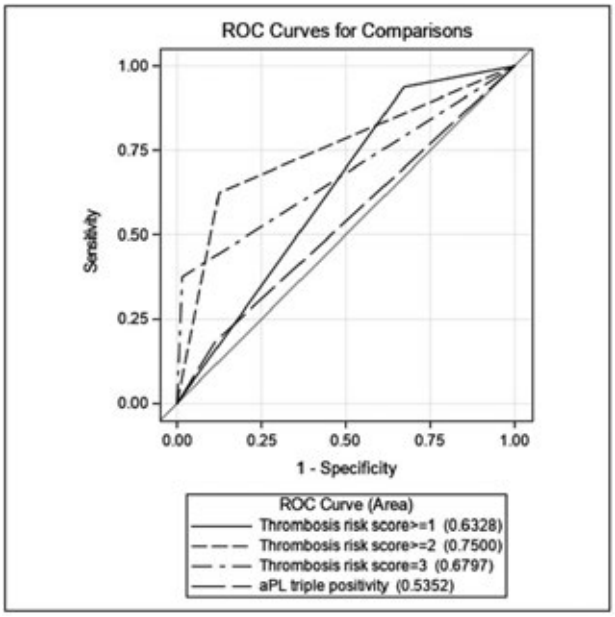
Abstract Number: 1825

Comparison of the Thrombosis Risk Score with Triple Positivity in SLE Thrombosis

Michelle Petri ,[1] Jessica Li,[1] John Conklin,[2] Tyler O'Malley,[3] Jo-Anne Ligayon,[2] Leilani Wolover,[2] and Thierry Dervieux[2], [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Exagen, Vista, CA, [3]Exagen, Oceanside, CA

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: We previously developed a Thrombosis Risk Score, a sum of three factors: lupus anticoagulant (by RVVT confirm); low C3; and C4d bound to platelets. We now compare the Thrombosis Risk Score to a widely used risk score for APS thrombosis, "triple positivity", which is the presence of lupus anticoagulant, anticardiolipin, and anti-beta2 glycoprotein 1.



Discrimination performance according to area under the ROC curve

ROC Model	Area (95% CI)	p-value
Thrombosis risk score>=1	0.63 (0.56 ,0.71)	0.1041
Thrombosis risk score>=2	0.75 (0.62 ,0.88)	0.0207
Thrombosis risk score>=3	0.68 (0.56 ,0.8)	0.1276
APL triple positivity	0.54 (0.43 ,0.64)	Reference

Performance of different models

Methods: The study contained 149 SLE patients (85.9% female, 34.2% African American, 55.7% Caucasian). To evaluate the discriminatory performance of the fitted logistic models, the c-statistics, known as the area under the curve of the receiver operating characteristics (ROC curve), was calculated and 95% confidence intervals reported. The c-statistic is the proportion of predictions agreeing with the outcome (ability of the test to correctly classify those with and without thrombosis within the past 5 years).

Results: The area under the curves ranged from 0.54 (95% CI: 0.43-0.64) for the triple positivity model to 0.75 (95% CI: 0.62-0.88) for the model with thrombosis risk score >=2 (Figure 1, Table 1). The model with a thrombosis risk score of at least 2 points demonstrated better discrimination (AUC=0.75) while the model with triple positivity had the poorest performance (AUC=0.54). When comparing the thrombosis risk scores to triple positivity, the area of the thrombosis risk score >=2 ROC curve was significantly better.

Conclusion: The thrombosis risk score is superior to “triple positivity” in its association with any thrombosis (over the last 5 years) in SLE. The thrombosis risk score includes 2 pathways – low complement and platelets – not included in triple positivity.

Abstract Number: 1826

Describing Intra-Individual Cognitive Function Course over Time in Lupus Patients: Persistent and Fluctuating Cognitive Impairment, Affected Cognitive Domains, and Severity

Oshrat Tayer-Shifman ,[1] Dorcas Beaton,[2] Robin Green,[3] Lesley Ruttan,[3] Joan Wither,[4] Maria Tartaglia,[5] Mahta Kakvan,[1] Sabrina Lombardi,[3] Nicole Anderson,[1] Jiandong Su,[1] Dennisse Bonilla,[1] Moe Zandy,[1] May Choi,[6] Marvin Fritzler,[6] and Zahi Touma[7], [1]University Health Network, University of Toronto, Toronto, ON, Canada, [2]St. Michael's Hospital, Toronto, ON, Canada, [3]University Health Network, Toronto, ON, Canada, [4]University Health Network, Krembil Research Institute, Toronto, ON, Canada, [5]University Health Network, University of Toronto, Toronto, ON, Canada, [6]Cumming School of Medicine, University of Calgary, Calgary, AB, Canada, [7]University Health Network, University of Toronto, Toronto, Canada

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Cognitive impairment (CI) is a common manifestation of systemic lupus erythematosus (SLE). The course of CI in SLE patients has been described as persistent in some patients and fluctuating in others. **The objective was to describe the intra-individual course of CI over time, determine the severity of CI and the affected domains, over a 1-year period.**

Methods: One-hundred and eleven consecutive SLE patients, aged 18-65 years, from a single centre (July 2016-March 2019) were included. Patients were administered the American College of Rheumatology (ACR) Neuropsychological Battery (NB) at baseline (T0), 6 months (T1) and 12 months (T2). Patients' scores were compared to a normative data to obtain z-scores. CI was operationalized on the NB as a z-score of ≤-1.5 on ≥2 domains. Six domains were studied: *simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory, executive functioning* and *manual motor speed and dexterity.* Patients were defined as ***persistent CI*** if they had CI over 3 time-points (T0, T1 and T2), as ***stable non-CI*** if they did not have CI in any time-point, or as ***fluctuating CI*** if they had CI on 1-2 assessments. The severity of impairment of CI was determined based on the mean z-score of all 6 domains.

Fig 1: Mean z-scores of the six domains for each patient over time by the 3 groups: stable non-CI (green), fluctuating (orange) and persistent CI (red)

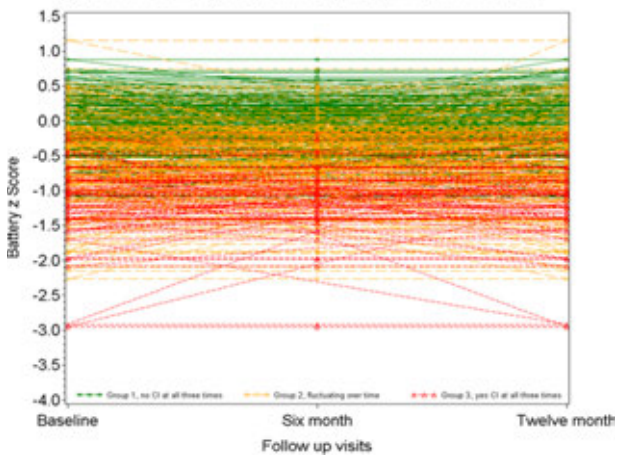

Figure 2: Percentage of impairment in each domain over 3 time points in the persistent CI group (a), fluctuating group (b) and stable non-CI group (c)

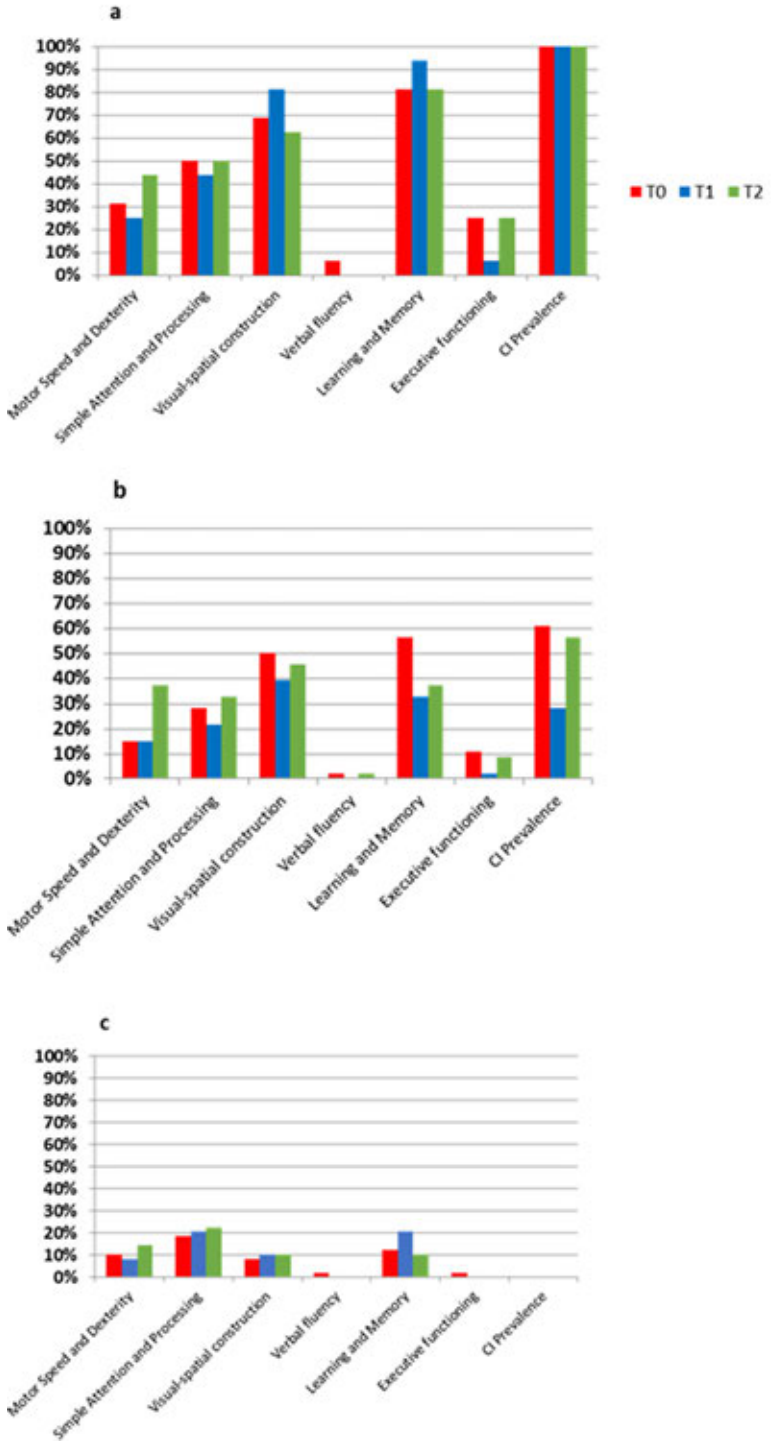

Results: One-hundred and eleven patients (90% female) completed 3 assessments at T0, T1 and T2. The mean age was 43.6 ± 12 years and SLE duration at enrolment was 15.2 ± 11 years. Fifty-six percent (62/111) experienced CI at some point over one year. The prevalence of CI was 39.6%, 26.1% and 37.8% at T0, T1 and T2 respectively. Sixteen patients (14.4%) experienced ***persistent CI***, 46 (41.4%) ***fluctuating CI*** and 49 patients (44.1%) were ***stable non-CI***. Mean z-score of all 6 domains for each patient at each time point by the 3 groups (**Fig. 1**) showed almost complete separation of the groups, with the persistent CI patients displaying lower mean z-score than the fluctuating CI pa-

tients – implying more severe CI. Percentage of impairment of the 6 different domains in the 3 groups (**Fig. 2**) revealed the most affected domain over time was *learning and memory* followed by *visual-spatial construction, simple attention and processing and motor speed and dexterity. Verbal fluency and executive functioning* were not significantly affected. ***There was no marked change over time*** in the domains involvement of the persistent CI group. The most affected domains in the fluctuating CI group were similar and there was more variation in the degree of impairment of the involved domains over time.

Conclusion: Fifty-six percent (62/111) of patients experienced CI at some point over a one-year period. While CI fluctuated in 74% (46/62) of patients, 26% (16/62) experience persistent CI across all time points. Although the same domains were affected in fluctuating and persistent CI groups, fluctuating patients displayed less severe CI with more variation in the affected domains compared to persistent CI patients. Our results support the close monitoring of cognition in patients with SLE and further research into the causes and nature of CI in SLE patients.

Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: Neutrophil activation, including formation of neutrophil extracellular traps (NETs), is essential in host defense. However, NET formation has also been linked to inflammation and autoimmunity, such as systemic lupus erythematosus (SLE). We recently described that SLE-derived immune complexes (ICs) induced NET formation, with NETosis promoting lupus-like disease, including nephritis, in mice. However, whether these mechanisms would occur in human SLE, and the clinical implications of elevated levels of NETs in SLE has not been carefully addressed.

Methods: Levels of NETs (MPO-DNA complexes) were analyzed in plasma in four cross-sectional well-characterized SLE cohorts (n=44-142), and healthy individuals (n=100) using ELISA. Levels of immune complexes and calprotectin were determined by ELISA. Type I interferon (IFN) activity was analyzed using a cell reporter system. Endothelial-derived microparticles (EMPs) were measured by flow cytometry. To determine the capacity of NETs to predict disease flare, patients (n=47) were recruited at time-point of low disease activity and followed over three months, with 14 patients remaining in remission, and 33 patients developing worsening of disease. Statistical analyses were done using Mann-Whitney U test and logistic regression analysis.

Results: SLE patients had elevated levels of NETs in circulation as compared to healthy controls ($p< 0.01$). Consistent with prior in vitro studies, levels of NETs were associated with heightened type I IFN activity ($p< 0.05$) and levels

of immune complexes (r=0.40, p< 0.0001). In contrast to the neutrophil activation marker calprotectin (p< 0.01), levels of NETs (a marker of neutrophil cell death) were not associated with current disease activity (p=0.20), nor individual SLEDAI items. However, of note, levels of NETs predicted future increase in disease activity. Thus, patients with elevated levels of NETs at time-point of clinical remission, were likely to develop disease flare within a few months (OR=13.8, p=0.002). These results are consistent with NET formation occurring early in the disease development, prior to clinical manifest disease. As such, NET formation may be a promising therapeutic target. Further, elevated levels of NETs identified patients with a severe disease phenotype involving nephritis, independent on presence of anti-dsDNA antibodies (OR=1.25 per 1 U/mL NETs, p=0.03). Finally, we made the intriguing observation that levels of NETs were elevated in patients with arterial thrombosis, including myocardial infarction (OR=9.55, p=0.01), and associated with endothelial damage and EMPs (p< 0.0001).

Conclusion: NET levels are elevated in SLE patients, and associated with immune complex-driven disease involving nephritis and arterial thrombosis. NET levels provide significant clinical value in identifying patients at risk of flare and/or severe disease, which may allow for early preventive treatment interventions, reducing overall disease morbidity and mortality.

Avascular Necrosis Is Associated with APOL1 Variants in African Americans with Systemic Lupus Erythematosus

Kevin Yip ,[1] Elizaveta Efuni,[2] Yingzhi Qian,[1] Robert Clancy,[3] Jill Buyon,[2] and Ashira Blazer[1], [1]New York University School of Medicine, New York City, [2]New York University School of Medicine, New York, NY, [3]New York University School of Medicine, New York

SESSION INFORMATION
Session Date: Monday, November 11, 2019
Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: African Americans (AA) with systemic lupus erythematous (SLE) are at higher risk for both renal disease and avascular necrosis (AVN). The two Apolipoprotein L1 (APOL1) risk variants (RV), G1 and G2, have been associated with chronic kidney disease and atherosclerosis in AAs and are responsible for excess renal risk in this population. We therefore investigated the association between carriers of the risk variants and prevalence of AVN in AA SLE patients.

Methods: Our retrospective cohort study of 113 AA SLE patients addressed the hypothesis that APOL1 variants increase the risk of avascular necrosis. Subjects were recruited from three high volume urban SLE clinical sites. This IRB-approved study included patients over 18 years of age, of self-reported AA ancestry, meeting at least four of the American College of Rheumatology (ACR) revised criteria for SLE. PCR/sequencing was used to stratify subjects by APOL1 genotype. Medical charts including clinical notes and imaging reports were reviewed for documentation of avascular necrosis. Subjects were stratified into groups with zero, one or two risk alleles. Association between presence of AVN and APOL1 risk allele, basic demographic characteristics and duration of SLE disease were evaluated using logistic regression analysis via R statistical software.

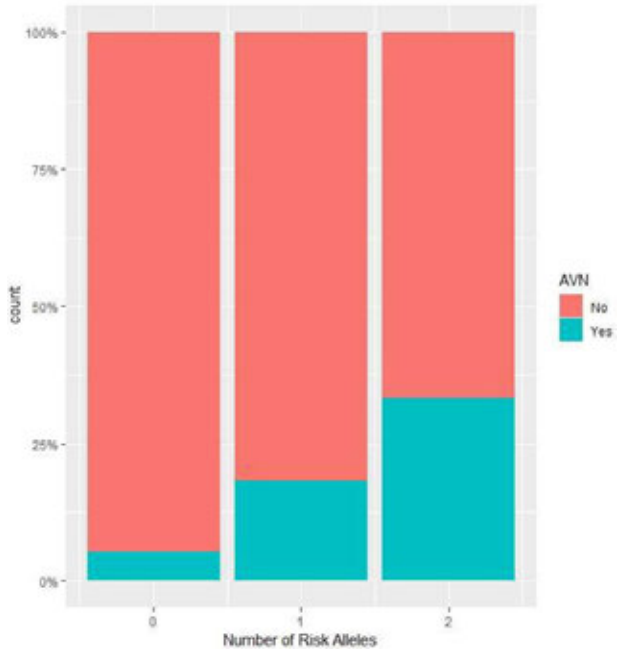

Figure 1. APOL1 risk alleles were associated with AVN with homozygotes variant carriers having the highest prevalence (OR 31.4 95% CI 3.25-303.63, p=0.003).

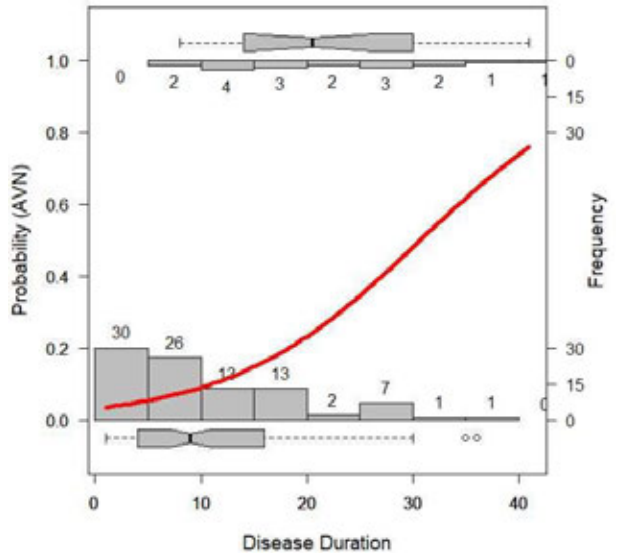

Figure 2. Longer disease duration was associated with increased risk of AVN (p<0.001).

Results: The frequencies of the G0, G1, and G2 alleles were 0.6, 0.22, and 0.18 respectively. Of the 113 patients 18 (16%) had documented AVN. Higher proportion of patients with documented AVN n = 16 (89%) had at least one risk APOL1 allele present vs those without AVN n = 59 (62%). There were no significant differences for age and gender between patients with and without AVN. Presence of one APOL1 allele trended towards increased risk of AVN (p=0.081), having two APOL1 risk alleles (p=0.016) and longer disease duration (p< 0.001) were associated with increased risk of AVN. Having one APOL1 risk allele (p=0.011) or two risk APOL1 risk alleles (p=0.003) and disease duration (p< 0.001) were significant when adjusted for age in multivariable logistic model. APOL1 variant alleles were associated with AVN in a dose dependent relationship with homozygotes variant carriers having the highest prevalence (OR 31.4 95% CI 3.25-303.63, p=0.003). BMI, average disease activity, corticosteroid use, presence of nephritis and ESRD were not associated with presence of AVN.

Conclusion: Our analysis suggests higher risk of avascular necrosis among African American SLE patients who are carriers of APOL1 risk allele. Given the high allelic frequencies of these variants in African Americans, this relationship may underpin the observed association of AVN with Black race. Further work is necessary to uncover the mechanism of this association.

Session Title: SLE – Clinical II: Flares & Morbidity of SLE
Session Type: ACR Abstract Session
Session Time: 2:30PM–4:00PM

Background/Purpose: SLE is marked by altered immune regulation linked to waxing and waning clinical disease activity. This study seeks to verify the alteration of inflammatory and regulatory mediators prior to clinical disease flare in a confirmatory cohort of SLE patients, seeking the best mediators to inform our Lupus Flare Prediction Index (LFPI).

Methods: Immune mediators were evaluated by xMAP assay in pre-flare (n=90) and "self" pre-nonflare (SNF) plasma samples (n=90) from the same female patients (49 European-, 41 African-American) with classified SLE (≥4 ACR criteria), as well as 48 race/age matched healthy controls (HC). Hybrid SLEDAI (hSLEDAI) scores, clinical features, medication usage, and the presence of SLE-associated autoantibody (AutoAb) specificities, including dsDNA, chromatin, Ro/SSA, La/SSB, Sm, SmRNP, and RNP, were also compared at pre-flare (100 ± 40 days prior to flare) vs. pre-SNF

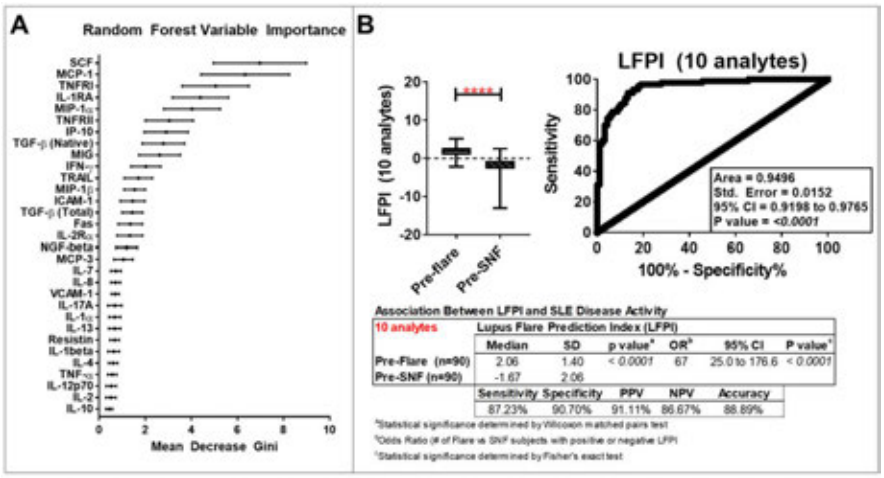
[c]Odds Ratio (# of Pre-Flare vs Pre-SNF SLE patients with positive or negative LFPI component value)

[d]Fisher's exact test; Bonferonni corrected significant *p=0.0035* in **bold**



Determination of the top soluble mediators (A) to inform the Lupus Flare Prediction Index (LFPI) and its ability to differentiate SLE patients with imminent clinical disease flare (Pre-Flare) from the same patients during a comparable "self" non-flare (Pre-SNF) period of clinical disease activity (B).

(96 ± 40 days prior to SNF) time points. A subset of 31, log-transformed, immune mediators were further evaluated using applied machine learning modeling approaches (random forest and XG Boost) to determine an optimal subset of mediators to inform the LFPI. The LFPI is the sum of log-transformed, standardized immune mediators, weighted by the Spearman r correlation coefficient of pre-flare/SNF immune mediator levels vs. hSLEDAI scores at disease flare/SNF.
